   (b) $|f(x_1, u) - f(x_2, u)| \leq L_f |x_1 - x_2|$,
   (c) $\min_{w \in \overline{\text{co}} f(x, \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}})} DV(x; w) \leq -2c$;
2. $f(\cdot, u)$ is continuous and bounded in norm by $\widetilde{M}$ on $\mathcal{V}(\ell_2 + \varepsilon_2) + \varepsilon_3 \overline{\mathcal{B}}_n$ for all $u \in \mathcal{U} \cap \sigma(|\cdot|_{\mathcal{A}} + \varepsilon_4)\overline{\mathcal{B}}_{\mathcal{U}}$.

Note again that, with appropriate values for the constants, these assumptions are all satisfied by the control-Lyapunov function of Theorem 3.2.

4.2. Control design. For the control system

$$\dot{x} = f(x, u) + d, \quad u \in \mathcal{U} \cap \sigma(|x|_{\mathcal{A}} + \varepsilon_4)\overline{\mathcal{B}}_{\mathcal{U}}, \tag{4.1}$$

we define a (discontinuous) control law as follows.

1. Let $r \in (0, \min\{\frac{\varepsilon_2}{L_V}, \varepsilon_3, \varepsilon_4, \frac{c}{L_f L_V}\}]$.
2. For each $x \in \mathcal{V}(\ell_1, \ell_2 + \varepsilon_2)$,
   (a) let $s \in \overline{\mathcal{B}}_n(x, r)$ be such that $V(s) \leq V(\xi)$ for all $\xi \in \overline{\mathcal{B}}_n(x, r)$;
   (b) let $\alpha \in \mathcal{U} \cap \sigma(|x|_{\mathcal{A}} + r)\overline{\mathcal{B}}_{\mathcal{U}}$ be such that $\langle x - s, f(x, \alpha)\rangle \leq -\frac{c}{L_V}|x - s|$.
3. For any $x \notin \mathcal{V}(\ell_1, \ell_2 + \varepsilon_2)$ let $\alpha \in \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}}$ be arbitrary.
4. Take $u = \alpha(x)$.

4.3. Closed-loop results. We let $T_1 > 0$ be such that $\frac{cT_1}{16L_V} \leq r - \sqrt{r^2 - \frac{rcT_1}{4L_V}}$. Such a value exists since the derivative with respect to T_1 of the function on the right-hand side evaluated at $T_1 = 0$ is equal to $\frac{c}{8L_V}$. We define $M := \widetilde{M} + \frac{c}{2L_V}$, $a_1 := M^2 L_f$, $a_2 := M(M + rL_f)$, $a_3 := \frac{cr}{4L_V}$, and

$$T^* := \min\left\{T_1, \ \frac{\ell_2 - \ell_1}{L_V M}, \ \frac{\varepsilon_3}{M}, \frac{\sqrt{a_2^2 + 4a_1 a_3} - a_2}{2a_1}\right\}.$$

We note that $T^* > 0$ and $T^* \to 0$ as $r \to 0$. This is evident from the last term that defines T^*.

THEOREM 4.1. *Suppose $u = \alpha(x)$ is implemented by sampling and holding with holding period $T \in (0, T^*]$. Then for every $x_0 \in \mathcal{V}(\ell_2)$, for all $d(\cdot)$ such that $||d||_\infty \leq \frac{c}{2L_V}$, and for all $t \geq 0$, the resulting solutions satisfy*

$$V(x(t)) \leq \max\left\{V(x_0) - \frac{c^2 \max\{t - T, 0\}}{8L_V M}, \ell_1 + L_V M T\right\} + L_V r.$$

An outline of the proof of this theorem may be found in [15] with full details to be found in [13].

4.4. Robustness to measurement noise. In this section we will demonstrate that our control design is robust with respect to small measurement errors. That is, if we implement our control using a corrupted measurement $x + n$ rather than with the true state x, the trajectory of the controlled system will still approach the set $\mathcal{A}$. Similar results are established by Sontag [28] and Clarke et al. [5]. The important observation here is that, while the measurement noise may be persistent, nondifferentiable, and unknown, since we implement the control via a sample-and-hold procedure, it is only the noise values at the sampling instants that are important.

Consider the system

$$\dot{x} = f(x, \alpha(x_i + n_i)),$$

where n_i represents samples of a bounded noise function $n : \mathbb{R}_{\geq 0} \to \mathbb{R}^n$. We construct a fake noise function $n_L(\cdot)$ that is globally Lipschitz and matches $n(\cdot)$ at sampling instances. If N is a bound for $|n(\cdot)|$ and T is the sampling period, then $n_L(\cdot)$ can be constructed so that it is bounded by N and its Lipschitz constant is $2N/T$. Note that such an approximation always exists. For instance, taking a linear interpolation between each noise sample yields such a function. Also note that, in what follows, precise knowledge of this signal is unnecessary. That is, we have not assumed that we know this function, only that it is bounded and we know its Lipschitz constant. We perform a coordinate change, $z = x + n_L$, in order to write

$$\dot{z} = f(z - n_L, \alpha(z_i)) + \dot{n}_L \ .$$

We rewrite the system as

$$\dot{z} = f(z - n_L, \alpha(z_i)) + f(z, \alpha(z_i)) - f(z, \alpha(z_i)) + \dot{n}_L = f(z, \alpha(z_i)) + d \ ,$$

where we have defined $d := f(z - n_L, \alpha(z_i)) - f(z, \alpha(z_i)) + \dot{n}_L$. Utilizing the Lipschitz constant for $f(\cdot, u)$ and the bound on $|\dot{n}_L|$ we have that $|d| \leq N(L_f + 2/T)$. Therefore the result of Theorem 4.1 applies if we insist that $N \leq \frac{Tc}{2L_V(2+L_fT)}$. That is, selecting the noise bound N appropriately yields $|d| \leq c/2L_V$, which allows us to appeal to the result of the theorem.

Remark 5. It is well known that fast sampling is advantageous for stability properties. Specifically, fast sampling is needed for large states to guarantee stability and is desirable for small states to decrease the size of the "practical stability" region. However, as shown by the bound required on the noise, as the sampling time T becomes small, the allowable noise also becomes small. Therefore, one wants to sample fast but not too fast. This observation was also made by Sontag [28, Theorem 1]. However, the observation is worth repeating as the result is made transparent via the above coordinate change. □

5. Proof of weak converse result. We turn now to the proof of Theorem 2.1. We prove the result without the assumption that $F(\cdot)$ is locally Lipschitz, uniform in distance to the set $\mathcal{A}$. It is easy to see that the Lyapunov function then inherits this property.

5.1. Technical preliminaries. In what follows we will appeal to the following lemma to demonstrate the local Lipschitz property of our Lyapunov function by demonstrating an appropriate bound on the Dini subderivate (see [9, Corollary 3.7]).

LEMMA 5.1. *Let the function $V : \mathcal{O} \to (-\infty, \infty]$ be lower semicontinuous. Let $\mathcal{U} \subset \mathcal{O}$ be open and convex. The function $V(\cdot)$ is Lipschitz with Lipschitz constant M on $\mathcal{U}$ if and only if $DV(x; v) \leq M|v|$, for all $x \in \mathcal{U}$, and all $v \in \mathbb{R}^n$.*

The following lemma is [26, Corollary 10].

LEMMA 5.2. *For each $\omega_0 \in \mathcal{K}_\infty$ there exist $\omega_1, \omega_2 \in \mathcal{K}_\infty$ such that $\omega_0(rs) \leq \omega_1(r)\omega_2(s)$ for all $r, s \geq 0$.*

Next, we state some lemmas that are proved in section 6. We start with a slight refinement of Sontag's lemma on $\mathcal{KL}$-estimates wherein we specify the required regularity property of one of the $\mathcal{K}_\infty$ functions [26, Proposition 7].

LEMMA 5.3. *For each $\beta \in \mathcal{KL}$ and $\lambda > 0$, there exist $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that $\alpha_1(\cdot)$ is Lipschitz on its domain, continuously differentiable (C^1) on $(0, \infty)$, $\alpha_1(s) \leq s\alpha_1'(s)$ for all $s > 0$, and $\alpha_1(\beta(s, t)) \leq \alpha_2(s)e^{-\lambda t}$ for all $(s, t) \in \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$.*

The next lemma comes from [19, Lemmas 11 and 12].

LEMMA 5.4. *For each continuous, positive definite function $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ there exists $\rho \in \mathcal{K}_\infty$ such that $\rho(\cdot)$ is locally Lipschitz on its domain, continuously differentiable on $(0, \infty)$, and $\rho(s) \leq \alpha(s)\rho'(s)$ for all $s > 0$.*

LEMMA 5.5. *For each $\omega_2 \in \mathcal{K}_\infty$ there exist a locally Lipschitz, strictly increasing, unbounded function $\kappa : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 1}$ and a continuous, nonincreasing function $\vartheta : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0}$ such that, with $s_0 := \omega_2^{-1}(0.5)$,*

$$\kappa(0) = 1, \tag{5.1}$$

$$\kappa(t)\kappa(T) \geq \kappa(t + T) \qquad \forall t, T \geq 0\ , \tag{5.2}$$

$$\frac{\kappa(t)}{\kappa(T)} \leq e^{2(t-T)} \qquad \forall t \geq T \geq 0\ , \tag{5.3}$$

$$\kappa(t) \leq \min\left\{e^t, \frac{1}{\omega_2(s_0 e^{-t})}\right\}\ \forall t \geq 0, \tag{5.4}$$

$$\max_{s\in[0,T]} \frac{\kappa(s)}{\kappa(s + t)} \leq 1 - \vartheta(T)t \quad \forall t \in [0, 1]\ . \tag{5.5}$$

The next fact follows [18, Lemma 4.3].

LEMMA 5.6. *Let $\mathcal{A} \subset \mathbb{R}^n$ be a closed set. Suppose $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, continuous on $\mathbb{R}^n$, $V(x) = 0$ for all $x \in \mathcal{A}$, and $V(x) > 0$ for all $x \in \mathbb{R}^n \backslash \mathcal{A}$. Then there exists a function $\rho \in \mathcal{K}_\infty$ that is C^1 on $(0, \infty)$, satisfies $\rho(s) \leq s\rho'(s)$ for all $s > 0$, and is such that $V_L := \rho \circ V$ is locally Lipschitz on $\mathbb{R}^n$ and $DV_L(x; v) = 0$ for all $x \in \mathcal{A}$ and all $v \in \mathbb{R}^n$.*

The next lemma is used twice in the proof of our main result.

LEMMA 5.7. *Suppose we are given the following:*

1. *A function $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ defined as*

$$V(x) := \inf_{\phi\in\mathcal{S}[0,\infty)(x)} \sup_{t\geq 0} g(\phi(t, x))\kappa(t),$$

where $g(\cdot)$ is locally Lipschitz on $\mathbb{R}^n$ and $\kappa : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 1}$ is locally Lipschitz, strictly increasing, unbounded, $\kappa(t)\kappa(T) \geq \kappa(t + T)$ for all $t, T \geq 0$, and $\kappa(0) = 1$.

2. *$\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that $\alpha_1(|x|_\mathcal{A}) \leq g(x)$, $V(x) \leq \alpha_2(|x|_\mathcal{A})$.*

3. *A sequence $\{\ell_j\}_{j=1}^\infty$, where $\ell_j \to 0$ as $j \to \infty$ such that $|x|_\mathcal{A} = \ell_j$, implies $V(x) = g(x)$. Then V is continuous on $\mathbb{R}^n$, locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, and there exists a function $T : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ that is continuous on $\mathbb{R}_{>0}$ and, for each $x \in \mathbb{R}^n$,*

there exists $\phi^* \in \mathcal{S}[0,\infty)(x)$ *such that*

$$V(x) \;=\; \sup_{t\geq 0} g(\phi^*(t,x))\kappa(t) \;=\; \max_{t\in[0,T(|x|_{\mathcal{A}})]} g(\phi^*(t,x))\kappa(t)\ .$$

5.2. Construction and Lipschitz property of $V(x)$. The following proposition is the key to constructing our Lyapunov function and is proved in section 5.5.

PROPOSITION 5.8. *Under the assumptions of Theorem* 2.1*, there exists a family of locally Lipschitz functions* $W_i : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$*,* $i \in \mathbb{Z}_{>0}$*, that have the following properties.*

1. *There exist* $\tilde{\alpha}_1, \alpha \in \mathcal{K}_\infty$ *such that, for each* $x \in \mathbb{R}^n$*,* $i \in \mathbb{Z}_{>0}$*,*

$$\tilde{\alpha}_1(|x|_{\mathcal{A}}) \leq W_i(x) \leq \alpha(|x|_{\mathcal{A}}). \tag{5.6}$$

2. *There exists* $\tilde{\alpha}_2 \in \mathcal{K}_\infty$ *such that, for every* $x \in \mathbb{R}^n$*, there exists* $\hat{\phi} \in \mathcal{S}[0,\infty)(x)$ *such that, for all* $i \in \mathbb{Z}_{>0}$*,*

$$W_i(\hat{\phi}(t,x)) \leq \tilde{\alpha}_2(|x|_{\mathcal{A}})e^{-2t}\ \forall t \geq 0. \tag{5.7}$$

3. *For every* $i \in \mathbb{Z}_{>0}$ *and* $|x|_{\mathcal{A}} \geq \frac{1}{i}$*, there exists* $\phi_i \in \mathcal{S}[0,\infty)(x)$ *such that the set* $\left\{t : |\phi_i(t,x)|_{\mathcal{A}} = \frac{1}{i}\right\}$ *is nonempty and, with* $T := \inf\left\{t : |\phi_i(t,x)|_{\mathcal{A}} = \frac{1}{i}\right\}$*,*

$$W_i(\phi_i(t,x)) \leq W_i(x)e^{-2t} \quad \forall t \in [0,T]\ . \tag{5.8}$$

Remark 6. Note that the functions $W_i(\cdot)$ are locally Lipschitz weak Lyapunov functions on sets defined by $|x|_{\mathcal{A}} \geq \frac{1}{i}$. This follows from items 1 and 3 above. ∎

Let $\tilde{\alpha}_1, \tilde{\alpha}_2 \in \mathcal{K}_\infty$ come from Proposition 5.8, and let $\omega_1, \omega_2 \in \mathcal{K}_\infty$ come from Lemma 5.2 satisfying

$$\tilde{\alpha}_2 \circ \tilde{\alpha}_1^{-1}(rs) \leq \omega_1(r)\omega_2(s) \quad \forall r,s \geq 0\ . \tag{5.9}$$

Define $s_0 := \omega_2^{-1}(0.5)$, and let $\kappa(\cdot)$ and $\vartheta(\cdot)$ come from Lemma 5.5 satisfying (5.1)–(5.5). Let $\widetilde{\omega} \in \mathcal{K}_\infty$ satisfy

$$\widetilde{\omega}(s) \leq s \qquad \forall s \geq 0 \text{ and} \tag{5.10}$$

$$\widetilde{\omega}(s) \leq s_0^2 \frac{\left(\omega_1^{-1}(s)\right)^2}{s} \quad \forall s \in (0,1]\ . \tag{5.11}$$

Let $\alpha \in \mathcal{K}_\infty$ also come from Proposition 5.8, and define

$$\alpha_f := \tilde{\alpha}_2^{-1} \circ \widetilde{\omega} \circ \tilde{\alpha}_1 \circ \alpha^{-1} \circ \tilde{\alpha}_1\ . \tag{5.12}$$

The function $\alpha_f(\cdot)$ belongs to class-$\mathcal{K}_\infty$. Also

$$\alpha_f(s) \leq s \qquad \forall s \geq 0 \tag{5.13}$$

since, from (5.6), $\alpha^{-1} \circ \tilde{\alpha}_1(s) \leq s$, and from (5.6), (5.7) with $t = 0$, and (5.10), $\tilde{\alpha}_2^{-1} \circ \widetilde{\omega} \circ \tilde{\alpha}_1(s) \leq s$. Now choose a function $q : \mathbb{Z}_{\geq 0} \to \mathbb{Z}_{>0}$ satisfying

$$q(0) = 1\ , \quad q(j+1) \geq \frac{1}{\alpha_f(\frac{1}{q(j)+1})}\ ,\ j \in \mathbb{Z}_{\geq 0}\ . \tag{5.14}$$

It follows from (5.13) that $\frac{1}{q(j)+1} \geq \frac{1}{q(j+1)}$; i.e., $q(j)+1 \leq q(j+1)$. Therefore, the sequence of integers $q(j)$ is strictly increasing with j. Let the locally Lipschitz functions $\lambda_i : \mathbb{R}^n \to [0,1]$ $(i \in \mathbb{Z}_{>0})$ be such that

$$\frac{1}{q(j+1)} \leq |x|_{\mathcal{A}} \leq \frac{1}{q(j)+1} \Longrightarrow \lambda_{q(j+1)}(x) = 1 \ , \tag{5.15}$$

and for each $x \in \mathbb{R}^n$ there exists a finite index set $\mathcal{I}_x$ such that $\sum_i \lambda_i(x) = \sum_{i \in \mathcal{I}_x} \lambda_i(x) = 1$. Let the functions $W_i(\cdot)$ come from Proposition 5.8, and define

$$f(x) = \sum_i \lambda_i(x) W_i(x) \ . \tag{5.16}$$

Note that, on the strips defined by (5.15), this corresponds to $f(x) = W_{q(j+1)}(x)$ and a convex combination of the $W_i(\cdot)$ functions between these strips. It follows from the properties of $W_i(\cdot)$, given in Proposition 5.8, and $\lambda_i(\cdot)$ that $f(\cdot)$ is locally Lipschitz,

$$\tilde{\alpha}_1(|x|_{\mathcal{A}}) \leq f(x) \leq \alpha(|x|_{\mathcal{A}}) \quad \forall x \in \mathbb{R}^n, \tag{5.17}$$

and, for each $x \in \mathbb{R}^n$, there exists $\hat{\phi} \in \mathcal{S}[0,\infty)(x)$ such that

$$f(\hat{\phi}(t,x)) \leq \tilde{\alpha}_2(|x|_{\mathcal{A}}) e^{-2t} \quad \forall t \geq 0 \ . \tag{5.18}$$

Next define

$$V_1(x) := \inf_{\phi \in \mathcal{S}[0,\infty)(x)} \sup_{t \geq 0} f(\phi(t,x)) \kappa(t) \tag{5.19}$$

and note that, using (5.1) and (5.17), we have

$$V_1(x) \geq f(x)\kappa(0) \geq \tilde{\alpha}_1(|x|_{\mathcal{A}}) \tag{5.20}$$

and, using (5.4) and (5.18), we have

$$V_1(x) \leq \sup_{t \geq 0} f(\hat{\phi}(t,x))\kappa(t) \leq \tilde{\alpha}_2(|x|_{\mathcal{A}}) \ . \tag{5.21}$$

The following claim is proved at the end of this section.

Claim 1. There exists a decreasing sequence $\{\ell_j\}_{j=1}^{\infty}$ such that $\ell_j \to 0$ as $j \to \infty$ and $|x|_{\mathcal{A}} = \ell_j$ implies $V_1(x) = f(x)$.

Since (5.1) and (5.2) hold, we can apply Lemma 5.7 with $V(x) := V_1(x)$, $g(x) := f(x)$, $\alpha_1(s) := \tilde{\alpha}_1(s)$, $\alpha_2(s) := \tilde{\alpha}_2(s)$, and the sequence $\{\ell_j\}_{j=1}^{\infty}$ constructed in Claim 1. So $V_1(\cdot)$ is continuous on $\mathbb{R}^n$, locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, and there exists a function $T : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ that is continuous on $\mathbb{R}_{>0}$ and for each $x \in \mathbb{R}^n$ there exists $\phi^* \in \mathcal{S}[0,\infty)(x)$ such that

$$V_1(x) = \max_{t \in [0, T(|x|_{\mathcal{A}})]} f(\phi^*(t,x))\kappa(t) \ . \tag{5.22}$$

We define $\alpha_3 : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ by $\alpha_3(0) = 0$ and

$$\alpha_3(s) := \min_{r \in [\tilde{\alpha}_2^{-1}(s), \tilde{\alpha}_1^{-1}(s)]} \vartheta(T(r)+1)s \ . \tag{5.23}$$

Since $\vartheta(\cdot)$ is continuous and positive, $T(\cdot)$ is continuous, and $\tilde{\alpha}_1^{-1}(\cdot)$ and $\tilde{\alpha}_2^{-1}(\cdot)$ are continuous, $\alpha_3(\cdot)$ is continuous. It is also positive definite. We apply Lemma 5.4 with $\alpha_3(\cdot)$ to get $\rho_1 \in \mathcal{K}_\infty$, locally Lipschitz on its domain, and C^1 on $(0,\infty)$ such that $\rho_1(s) \leq \alpha_3(s)\rho_1'(s)$ for all $s > 0$. We define $V_2 := \rho_1 \circ V_1$, and we note that $V_2(\cdot)$ is continuous on $\mathbb{R}^n$, locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, and from (5.20) and (5.21) we have

$$\rho_1 \circ \tilde{\alpha}_1(|x|_{\mathcal{A}}) \leq V_2(x) \leq \rho_1 \circ \tilde{\alpha}_2(|x|_{\mathcal{A}}) \ . \tag{5.24}$$

It follows that we can apply Lemma 5.6 with $V_2(\cdot)$ to get $\rho_2 \in \mathcal{K}_\infty$ that is C^1 on $(0,\infty)$ such that $\rho(s) \leq s\rho'(s)$ for all $s > 0$ and $V := \rho_2 \circ V_2$ is locally Lipschitz on $\mathbb{R}^n$ and satisfies $DV(x;v) = 0$ for all $x \in \mathcal{A}$ and all $v \in \mathbb{R}^n$. Moreover, it follows from (5.24) that (2.1) holds with the class-$\mathcal{K}_\infty$ functions $\alpha_1 := \rho_2 \circ \rho_1 \circ \tilde{\alpha}_1$ and $\alpha_2 := \rho_2 \circ \rho_1 \circ \tilde{\alpha}_2$.

5.3. Infinitesimal decrease. The infinitesimal decrease condition holds for each $x \in \mathcal{A}$ since $DV(x;v) = 0 = -V(x)$, for any $x \in \mathcal{A}$, and $v \in \mathbb{R}^n$. Let $x \in \mathbb{R}^n \backslash \mathcal{A}$, and let $\phi^* \in \mathcal{S}[0,\infty)(x)$ satisfy (5.22). Define $T := T(|x|_{\mathcal{A}})$, and let $t^* \in (0,1]$ be such that $T(|\phi^*(t,x)|_{\mathcal{A}}) \leq T+1$ for all $t \in [0,t^*]$. With (5.22), for each $t \in [0,t^*]$ let $\psi^* \in \mathcal{S}[0,\infty)(\phi^*(t,x))$ satisfy

$$V_1(\phi^*(t,x)) = \max_{s \in [0, T(|\phi^*(t,x)|_{\mathcal{A}})]} f(\psi^*(s,\phi^*(t,x)))\kappa(s) \ .$$

Then, for each $t \in [0,t^*]$, we have

$$\begin{aligned} V_1(\phi^*(t,x)) &= \max_{s \in [0, T(|\phi^*(t,x)|_{\mathcal{A}})]} f(\psi^*(s,\phi^*(t,x)))\kappa(s) \leq \max_{s \in [0,T+1]} f(\phi^*(s+t,x))\kappa(s) \\ &= \max_{s \in [0,T+1]} f(\phi^*(s+t,x))\kappa(s+t)\frac{\kappa(s)}{\kappa(s+t)} \\ &\leq \sup_{\tau \geq 0} f(\phi^*(\tau,x))\kappa(\tau)\,[1-\vartheta(T+1)t] = V_1(x)\,[1-\vartheta(T+1)t]\,. \end{aligned} \tag{5.25}$$

For almost all s, let $g(s)$ be the unique closest point in $F(x)$ to $\dot{\phi^*(s,x)}$. Such a unique closest point exists since $F(x)$ is convex (see [11, section 5, Lemma 2]). Since $F(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, $x \in \mathbb{R}^n \backslash \mathcal{A}$, $\phi^*(\cdot,x)$ is (absolutely) continuous, $\dot{\phi^*(s,x)} \in F(\phi^*(s,x))$ for almost all s, and $F(\cdot)$ is locally bounded, there exist $\bar{s}, M, L > 0$ such that, for almost all $s \in [0,\bar{s}]$,

$$|g(s) - \dot{\phi^*(s,x)}| \leq L|x - \phi^*(s,x)| \leq LMs \ . \tag{5.26}$$

We can also write

$$\frac{\phi^*(t,x)-x}{t} = t^{-1}\int_0^t \dot{\phi^*(s,x)}ds = t^{-1}\int_0^t g(s)ds + t^{-1}\int_0^t [\dot{\phi^*(s,x)} - g(s)]ds \ . \tag{5.27}$$

Then note that the first term on the right-hand side belongs to $F(x)$ for all t since $F(x)$ is convex (see [11, section 5, Lemma 12]) and the second term on the right-hand side converges to zero as t converges to zero (using (5.26)).

Call the first term on the last line of (5.27) $v(t)$ and the sum $w(t)$. Since $F(x)$ is compact, there exists an accumulation point $v \in F(x)$ for $v(t)$, i.e., a sequence of

times t_j converging to zero so that $v(t_j) \to v$. So, we can write $\phi^*(t_j, x) = x + t_j w(t_j)$, where $w(t_j) \to v$ as $t_j \to 0$. Then, using (5.23) and (5.25),

$$\begin{aligned} DV_1(x;v) &\leq \liminf_{j\to\infty} [V_1(x + t_j w(t_j)) - V_1(x)]/t_j = \liminf_{j\to\infty} [V_1(\phi^*(t_j, x)) - V_1(x)]/t_j \\ &\leq -V_1(x)\vartheta(T(|x|_{\mathcal{A}}) + 1) \leq -\alpha_3(V_1(x)). \end{aligned}$$

Since $V_2 = \rho_1 \circ V_1$ and $\rho_1(s) \leq \alpha_3(s)\rho_1'(s)$ for all $s > 0$, we have, for all $x \in \mathbb{R}^n \backslash \mathcal{A}$,

$$\min_{w\in F(x)} DV_2(x;w) \leq -\rho_1'(V_1(x))\alpha_3(V_1(x)) \leq -\rho_1(V_1(x)) = -V_2(x).$$

Similarly, since $V = \rho_2 \circ V_2$ and $\rho_2(s) \leq s\rho_2'(s)$ for all $s > 0$, we have, for all $x \in \mathbb{R}^n \backslash \mathcal{A}$,

$$\min_{w\in F(x)} DV(x;w) \leq -\rho_2'(V_2(x))V_2(x) \leq -\rho_2(V_2(x)) = -V(x).$$

5.4. Proof of Claim 1. For each $j \in \mathbb{Z}_{\geq 0}$ define

$$\ell_j := \tilde{\alpha}_1^{-1} \circ \widetilde{\omega}^{-1} \circ \tilde{\alpha}_2 \left(\frac{1}{q(j+1)} \right) . \tag{5.28}$$

Since $q(j)$ is strictly increasing and unbounded, it follows that ℓ_j decreases monotonically to zero. We now restrict our attention to integers j sufficiently large so that $\alpha(\ell_j) \leq 1$. We consider $x \in \mathbb{R}^n \backslash \mathcal{A}$ such that $|x|_{\mathcal{A}} = \ell_j$, and we will show that $V_1(x) = f(x)$. Clearly, $V_1(x) \geq f(x)$. It remains to show that $V_1(x) \leq f(x)$. First, it follows from (5.17) that $0 < f(x) \leq 1$. Second, it follows from (5.17), (5.18) with $t = 0$, and (5.28) that

$$|z|_{\mathcal{A}} = \frac{1}{q(j+1)} \quad \Longrightarrow \quad f(z) \leq \widetilde{\omega}(f(x)) . \tag{5.29}$$

Third, it follows from (5.11) and $0 < f(x) \leq 1$ that

$$\widetilde{\omega}(f(x)) \leq s_0^2 \frac{\omega_1^{-1}(f(x))^2}{f(x)} . \tag{5.30}$$

Fourth, since $\tilde{\alpha}_1^{-1} \circ \widetilde{\omega}^{-1} \circ \tilde{\alpha}_2(s) \geq s$ for all $s \geq 0$, it follows from (5.28) that $|x|_{\mathcal{A}} \geq \frac{1}{q(j+1)}$. From property 3 of Proposition 5.8, there exists a trajectory $\phi_{q(j+1)} \in \mathcal{S}[0,\infty)(x)$ such that the set $\{t : |\phi_{q(j+1)}(t,x)|_{\mathcal{A}} = \frac{1}{q(j+1)}\}$ is nonempty and for all $t \in [0,T]$, where $T := \inf\{t : |\phi_{q(j+1)}(t,x)|_{\mathcal{A}} = \frac{1}{q(j+1)}\}$, we have

$$W_{q(j+1)}(\phi_{q(j+1)}(t,x)) \leq W_{q(j+1)}(x)e^{-2t}. \tag{5.31}$$

It follows from the definition of T that, for all $t \in [0,T]$,

$$|\phi_{q(j+1)}(t,x))|_{\mathcal{A}} \geq \frac{1}{q(j+1)} . \tag{5.32}$$

With (5.6), $|x|_{\mathcal{A}} = \ell_j$, (5.28), (5.12), and (5.14), one can show that (5.31) implies that, for all $t \in [0,T]$, $|\phi_{q(j+1)}(t,x)|_{\mathcal{A}} \leq \frac{1}{q(j)+1}$. Combining this with (5.32), (5.31), (5.15), and (5.16), we have

$$f(\phi_{q(j+1)}(t,x)) \leq f(x)e^{-2t} \quad \forall t \in [0,T] \tag{5.33}$$

and thus, using (5.4), we have for all $t \in [0,T]$,

$$f(\phi_{q(j+1)}(t,x))\kappa(t) \le f(x)e^{-2t}\kappa(t) \le f(x)\ . \tag{5.34}$$

Now define $z := \phi_{q(j+1)}(T,x)$ and note that

$$|z|_{\mathcal{A}} = \frac{1}{q(j+1)}\ . \tag{5.35}$$

Let $\tilde{\phi} \in \mathcal{S}[0,\infty)(z)$ satisfy (see (5.18))

$$f(\tilde{\phi}(t,z)) \le \tilde{\alpha}_2(|z|_{\mathcal{A}})e^{-2t} \qquad \forall t \ge 0\ . \tag{5.36}$$

Define $\tilde{\psi} \in \mathcal{S}[0,\infty)(x)$ as

$$\tilde{\psi}(t,x) := \begin{cases} \phi_{q(j+1)}(t,x), & t \in [0,T], \\ \tilde{\phi}(t-T,z), & t \ge T. \end{cases}$$

Now, using (5.36), (5.3), (5.17), (5.33), (5.9), (5.4), (5.35), (5.29), and (5.30) one may show that, for $t \ge T$, $f(\tilde{\phi}(t-T,z))\kappa(t) \le f(x)$. Combining this with (5.34), we have $f(\tilde{\psi}(t,x))\kappa(t) \le f(x)$ for all $t \ge 0$, which implies $V_1(x) \le f(x)$. ∎

5.5. Proof of Proposition 5.8. Given $\dot{x} \in F(x)$, where $F(\cdot)$ satisfies the basic conditions and is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, let M_1 come from Assumption 1. We define a modified inclusion

$$\dot{x} \in F_i(x) := F(x) + \gamma_i(|x|_{\mathcal{A}})\,[M_1+1]\,\overline{\mathcal{B}}_n, \tag{5.37}$$

where $\gamma_i : [0,\infty) \to [0,1]$ is locally Lipschitz and $\gamma(s) = 0$ for $s \ge \frac{1}{i}$ and $\gamma(s) = 1$ for $s \le \frac{1}{i+1}$. It follows from the properties of $F(\cdot)$ and $\gamma_i(\cdot)$ that $F_i(\cdot)$ satisfies the basic conditions on $\mathbb{R}^n$ and is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$.

Note that $F(x) \subseteq F_i(x)$ for all $x \in \mathbb{R}^n$ by taking the origin in $\overline{\mathcal{B}}_n$. Furthermore, note that for all

$$|x|_{\mathcal{A}} \le \frac{1}{i+1} \quad \Longrightarrow \quad \overline{\mathcal{B}}_n \subseteq F_i(x). \tag{5.38}$$

To see this, let $x_1 \in \overline{\mathcal{B}}_n$ and $x_2 \in F(x)$, where $|x|_{\mathcal{A}} \le \frac{1}{i+1}$. Therefore, $-x_2 + x_1 \in \left[\max_{z\in F(x)} |z| + 1\right]\overline{\mathcal{B}}_n \subseteq [M_1+1]\,\overline{\mathcal{B}}_n$, which implies that $x_1 = x_2 + (-x_2 + x_1) \in F(x) + [M_1+1]\,\overline{\mathcal{B}}_n = F_i(x)$. We will denote the set of maximal solutions of (5.37) starting at the point x as $\mathcal{S}_i(x)$.

Since $F(x) \subseteq F_i(x)$, the assumption of weak-UGAS of $\mathcal{A}$ for $\dot{x} \in F(x)$ gives $\hat{\phi} \in \mathcal{S}_i[0,\infty)(x)$ such that

$$|\hat{\phi}(t,x)|_{\mathcal{A}} \le \beta(|x|_{\mathcal{A}}, t)\ \forall t \ge 0\ . \tag{5.39}$$

Let $\lambda = 4$, and then let $\widehat{\alpha}_1 \in \mathcal{K}_\infty$ and $\widehat{\alpha} \in \mathcal{K}_\infty$ come from Lemma 5.3 so that $\widehat{\alpha}_1(\cdot)$ is Lipschitz on its domain, C^1 on $(0,\infty)$, $\widehat{\alpha}_1(s) \le s\widehat{\alpha}_1'(s)$ for all $s \in (0,\infty)$, and

$$\widehat{\alpha}_1(\beta(s,t)) \le \widehat{\alpha}(s)e^{-4t} \quad \forall s \ge 0,\ t \ge 0\ . \tag{5.40}$$

We make the following definitions:

- $\widetilde{W}_i(x) := \inf_{\phi \in \mathcal{S}_i[0,\infty)(x)} \sup_{t\geq 0} \widehat{\alpha}_1(|\phi(t,x)|_{\mathcal{A}})e^{2t}$;
- $\beta_2(s,t) := \widehat{\alpha} \circ \widehat{\alpha}_1^{-1}\left(\widehat{\alpha}(s)e^{-4t}\right)$ (note that $\beta_2 \in \mathcal{KL}$);
- applying Lemma 5.3 with $\beta_2 \in \mathcal{KL}$ and $\lambda = 2$, we get $\alpha_m \in \mathcal{K}_\infty$ and $\tilde{\alpha}_2 \in \mathcal{K}_\infty$ such that $\alpha_m(\cdot)$ is Lipschitz on its domain, C^1 on $(0,\infty)$, $\alpha_m(s) \leq s\alpha_m'(s)$ for all $s \in (0,\infty)$, and

$$\alpha_m(\beta_2(s,t)) \leq \tilde{\alpha}_2(s)e^{-2t} \quad \forall s \geq 0,\ t \geq 0; \tag{5.41}$$

- $W_i := \alpha_m \circ \widetilde{W}_i$, $\alpha := \alpha_m \circ \widehat{\alpha}$, $\tilde{\alpha}_1 := \alpha_m \circ \widehat{\alpha}_1$.

5.5.1. Proof of (5.6). Given the bound for $\hat{\phi} \in \mathcal{S}_i[0,\infty)(x)$ in (5.39) and the $\mathcal{KL}$-estimate given by (5.40), we have

$$W_i(x) \leq \alpha_m\left(\sup_{t\geq 0} \widehat{\alpha}_1(\beta(|x|_{\mathcal{A}},t))e^{2t}\right) \leq \alpha_m\left(\sup_{t\geq 0} \widehat{\alpha}(|x|_{\mathcal{A}})e^{-2t}\right) \leq \alpha(|x|_{\mathcal{A}}), \tag{5.42}$$

while the lower bound follows from

$$W_i(x) \geq \alpha_m\left(\inf_{\phi\in\mathcal{S}_i[0,\infty)(x)} \widehat{\alpha}_1(|\phi(t,x)|_{\mathcal{A}})e^{2t}\Big|_{t=0}\right) = \alpha_m(\widehat{\alpha}_1(|x|_{\mathcal{A}})) = \tilde{\alpha}_1(|x|_{\mathcal{A}}). \tag{5.43}$$

5.5.2. Proof of (5.7). From the upper bound on $W_i(x)$, the $\mathcal{KL}$-bound in (5.39), and the $\mathcal{KL}$-estimates in (5.40) and (5.41) we can write, for all $x \in \mathbb{R}^n$ and all $t \geq 0$,

$$\begin{aligned} W_i(\hat{\phi}(t,x)) &\leq \alpha(|\hat{\phi}(t,x)|_{\mathcal{A}}) = \alpha_m \circ \widehat{\alpha}(|\hat{\phi}(t,x)|_{\mathcal{A}}) \leq \alpha_m \circ \widehat{\alpha}(\beta(|x|_{\mathcal{A}},t)) \\ &\leq \alpha_m \circ \widehat{\alpha} \circ \widehat{\alpha}_1^{-1}\left(\widehat{\alpha}(|x|_{\mathcal{A}})e^{-4t}\right) = \alpha_m\left(\beta_2(|x|_{\mathcal{A}},t)\right) \leq \tilde{\alpha}_2(|x|_{\mathcal{A}})e^{-2t}\ . \end{aligned}$$

5.5.3. Proof of (5.8). We make the following claim and defer its proof to the end of this section.

Claim 2. For $|x|_{\mathcal{A}} \leq \frac{1}{i+1}$, we have $\widetilde{W}_i(x) = \widehat{\alpha}_1(|x|_{\mathcal{A}})$.

Construct any decreasing sequence $\{\ell_j\}_{j=1}^\infty$ such that $\ell_j \to 0$ as $j \to \infty$ and $\ell_1 = \frac{1}{i+1}$. Apply Lemma 5.7 with $V(x) := \widetilde{W}_i(x)$, $\alpha_1(s) := \widehat{\alpha}_1(s)$, $\alpha_2(s) := \widehat{\alpha}(s)$, $\kappa(t) = e^{2t}$, and the sequence $\{\ell_j\}_{j=1}^\infty$ constructed above. Therefore, for each $x \in \mathbb{R}^n$, there exists $\tilde{\phi}_i \in \mathcal{S}_i[0,\infty)(x)$ such that $\widetilde{W}_i(x) = \sup_{t\geq 0} \widehat{\alpha}_1(|\tilde{\phi}_i(t,x)|_{\mathcal{A}})e^{2t}$. Then

$$\begin{aligned} \widetilde{W}_i(x)e^{-2t} &= \sup_{\tau\geq 0} \widehat{\alpha}_1(|\tilde{\phi}_i(\tau,x)|_{\mathcal{A}})e^{2\tau}e^{-2t} \geq \sup_{\tau\geq t} \widehat{\alpha}_1(|\tilde{\phi}_i(\tau,x)|_{\mathcal{A}})e^{2(\tau-t)} \\ &= \sup_{s\geq 0} \widehat{\alpha}_1(|\tilde{\phi}_i(s+t,x)|_{\mathcal{A}})e^{2s} \geq \inf_{\phi\in\mathcal{S}_i[0,\infty)(\tilde{\phi}_i(t,x))} \sup_{s\geq 0} \widehat{\alpha}_1(|\phi(s,\tilde{\phi}_i(t,x))|_{\mathcal{A}})e^{2s} \\ &= \widetilde{W}_i(\tilde{\phi}_i(t,x)). \end{aligned} \tag{5.44}$$

If we define $U(t) := \alpha_m(\widetilde{W}_i(x)e^{-2t})$, then $U(\cdot)$ is C^1 on $(0,\infty)$ since $\alpha_m(\cdot)$ is C^1 on $(0,\infty)$, and we can write $\dot{U}(t) = (-2\widetilde{W}_i(x)e^{-2t})\alpha_m'(\widetilde{W}_i(x)e^{-2t}) \leq -2U(t)$, where the inequality follows from the property $\alpha_m(s) \leq s\alpha_m'(s)$ for all $s \in (0,\infty)$. By a standard comparison lemma we obtain $U(t) \leq U(0)e^{-2t}$; i.e., $\alpha_m(\widetilde{W}_i(x)e^{-2t}) \leq \alpha_m(\widetilde{W}_i(x))e^{-2t}$. Combining this result with (5.44) we get

$$\begin{aligned} W_i(\tilde{\phi}_i(t,x)) &= \alpha_m(\widetilde{W}_i(\tilde{\phi}_i(t,x))) \leq \alpha_m\left(\widetilde{W}_i(x)e^{-2t}\right) \leq \alpha_m\left(\widetilde{W}_i(x)\right)e^{-2t} \\ &= W_i(x)e^{-2t}. \end{aligned} \tag{5.45}$$

Fix $i \in \mathbb{Z}_{>0}$, and let $|x|_{\mathcal{A}} \geq \frac{1}{i}$. It follows from (5.45) with (5.6) that the set $\{t : |\tilde{\phi}_i(t,x)|_{\mathcal{A}} = \frac{1}{i}\}$ is nonempty. Moreover, since $F_i(x) = F(x)$ on the set $|x|_{\mathcal{A}} \geq \frac{1}{i}$, it follows, with $T := \inf\{t : |\tilde{\phi}_i(t,x)|_{\mathcal{A}} = \frac{1}{i}\}$, that $\tilde{\phi} \in \mathcal{S}[0,T](x)$. Let $\psi \in \mathcal{S}[0,\infty)(\tilde{\phi}_i(T,x))$ be arbitrary. Define

$$\phi_i(t,x) := \begin{cases} \tilde{\phi}_i(t,x), & t \in [0,T], \\ \psi(t-T, \tilde{\phi}_i(T,x)), & t \geq T\ . \end{cases}$$

Therefore, $\phi_i \in \mathcal{S}[0,\infty)(x)$. Furthermore, for all $t \in [0,T]$, $W_i(\phi_i(t,x)) \leq W_i(x)e^{-2t}$.

5.5.4. Local Lipschitz property of $W_i(x)$. From Lemma 5.7 we know that $\widetilde{W}_i(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$. Consequently, since $\alpha_m(\cdot)$ is locally Lipschitz, $W_i(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$. This, coupled with Claim 2 and the local Lipschitz property of $\widehat{\alpha}_1(\cdot)$ and $\alpha_m(\cdot)$, implies that $W_i(\cdot)$ is locally Lipschitz on $\mathbb{R}^n$.

5.5.5. Proof of Claim 2. Via the same argument as in (5.43), we observe that $\widetilde{W}_i(x) \geq \widehat{\alpha}_1(|x|_{\mathcal{A}})$. So, we just need to show that $\widetilde{W}_i(x) \leq \widehat{\alpha}_1(|x|_{\mathcal{A}})$ for all $|x|_{\mathcal{A}} \leq \frac{1}{i+1}$.

Let $|x|_{\mathcal{A}} \leq \frac{1}{i+1}$, $a \in \mathcal{A}$, be a closest point to x, and define

$$\psi(t,x) := \begin{cases} x + \frac{a-x}{|a-x|}t & \forall t \in [0, |a-x|], \\ a & \forall t \geq |a-x|\ . \end{cases} \tag{5.46}$$

We see that $\psi(\cdot,x)$ is absolutely continuous and

$$\left|\frac{d}{dt}\psi(t,x)\right| = \begin{cases} \left|\frac{a-x}{|a-x|}\right| = 1 \in \overline{\mathcal{B}}_n & \forall t \in (0,|a-x|), \\ 0 \in \overline{\mathcal{B}}_n & \forall t > |a-x|, \end{cases}$$

which, with (5.38), implies that (5.46) is a solution to (5.37); i.e., $\psi \in \mathcal{S}_i[0,\infty)(x)$. For $t \in [0,|a-x|]$ we can write

$$\begin{aligned} |x - \psi(t,x)| &= \left|\tfrac{a-x}{|a-x|}t\right| = t \ \text{ and} \\ |\psi(t,x) - a| &= \left|(x-a)\left(1 - \tfrac{1}{|a-x|}t\right)\right| = |x-a| - t \end{aligned} \tag{5.47}$$

so that $|a-x| = |x-\psi(t,x)| + |\psi(t,x)-a|$. Furthermore, $|x-a| = |x|_{\mathcal{A}}$, and $|x|_{\mathcal{A}} \leq \frac{1}{i+1}$. These facts, together with (5.47), imply that $|\psi(t,x)|_{\mathcal{A}} \leq \frac{1}{i+1}$ for all $t \geq 0$.

Now, for some $t \in (0,|a-x|]$, assume there exists $b \in \mathcal{A}$ such that $|b-\psi(t,x)| < |a-\psi(t,x)|$; i.e., b is closer than a to $\psi(t,x)$. The triangle inequality yields

$$|x-b| \leq |x-\psi(t,x)| + |b-\psi(t,x)| < |x-\psi(t,x)| + |a-\psi(t,x)| = |x-a|\ ,$$

which contradicts that $a \in \mathcal{A}$ is a closest point to x. Therefore, $a \in \mathcal{A}$ is also a closest point to $\psi(t,x)$ for $t \in [0,|a-x|]$. More explicitly, $|\psi(t,x)|_{\mathcal{A}} = |\psi(t,x)-a|$. Combining this with (5.47) yields, for almost all $t \in [0,|a-x|]$,

$$\frac{d}{dt}|\psi(t,x)|_{\mathcal{A}} = \frac{d}{dt}\left(|x-a| - t\right) = -1\ . \tag{5.48}$$

Using (5.47) and (5.48), and since $\widehat{\alpha}_1(\cdot)$ is C^1 on $(0,\infty)$ and $\widehat{\alpha}_1(s) \leq s\widehat{\alpha}_1'(s)$, we can write, for almost all $t \in [0, |a-x|]$,

$$\frac{d}{dt}\left(\widehat{\alpha}_1(|\psi(t,x)|_{\mathcal{A}})e^{2t}\right) = \left(2\widehat{\alpha}_1(|\psi(t,x)|_{\mathcal{A}}) + \widehat{\alpha}_1'(|\psi(t,x)|_{\mathcal{A}})(\dot{\overbrace{|\psi(t,x)|_{\mathcal{A}}}})\right)e^{2t}$$
$$\leq \widehat{\alpha}_1'(|\psi(t,x)|_{\mathcal{A}})\left(2(|x|_{\mathcal{A}} - t) - 1\right)e^{2t} \quad \leq \quad 0,$$

where the final step follows from $|x|_{\mathcal{A}} \leq \frac{1}{i+1} \leq \frac{1}{2}$. Furthermore, for $t > |a-x|$ we have

$$\frac{d}{dt}\left(\widehat{\alpha}_1(|\psi(t,x)|_{\mathcal{A}})e^{2t}\right) = \frac{d}{dt}\left(\widehat{\alpha}_1(0)e^{2t}\right) = 0\ .$$

This gives $\frac{d}{dt}\left(\widehat{\alpha}_1(|\psi(t,x)|_{\mathcal{A}})e^{2t}\right) \leq 0$ for almost all $t \geq 0$. It follows by integrating that $\sup_{t\geq 0}\widehat{\alpha}_1(|\psi(t,x)|_{\mathcal{A}})e^{2t} = \widehat{\alpha}_1(|x|_{\mathcal{A}})$. So $\widetilde{W}_i(x) \leq \widehat{\alpha}_1(|x|_{\mathcal{A}})$ for all $|x|_{\mathcal{A}} \leq \frac{1}{i+1}$. □

6. Proofs of Lemmas 5.3–5.7. Collected in this section are the proofs of lemmas utilized in proving Theorem 2.1.

6.1. Proof of Lemma 5.3. The proof relies on the proof of [30, Lemma 3]. First we pick $\rho \in \mathcal{K}_\infty$ and a function $\theta : \mathbb{R}_{\geq 0} \to \mathbb{R}_{>0}$ continuous and strictly decreasing with $\lim_{t\to\infty}\theta(t) = 0$ such that, for all $t \geq 0$, $\beta(\rho(t), t) \leq \theta(t)$. (The proof that such functions exist can be found at the beginning of [30, Lemma 3].) Next, let $\theta^{-1}(\cdot)$ be the inverse of $\theta(\cdot)$, which is defined and continuous on $(0, \theta(0)]$. It is also strictly decreasing with $\lim_{s\to 0}\theta^{-1}(s) = +\infty$. It follows that the function $e^{-2\lambda\theta^{-1}(s)}$ is well defined, continuous, positive and strictly increasing on $(0, \theta(0)]$. Then we define a continuous, positive definite, nondecreasing function $\pi(\cdot)$ as

$$\pi(s) := \begin{cases} 0, & s = 0, \\ \frac{1}{\theta(0)}e^{-2\lambda\theta^{-1}(s)}, & s \in (0, \theta(0)], \\ \frac{1}{\theta(0)}, & s \geq \theta(0). \end{cases}$$

We then define $\alpha_1(s) := \int_0^s \pi(\tau)d\tau$. It follows that $\alpha_1(\cdot)$ is Lipschitz on its domain (with global Lipschitz constant $\frac{1}{\theta(0)}$), continuously differentiable on $(0,\infty)$, and of class-$\mathcal{K}_\infty$. From the definition of $\alpha_1(\cdot)$, $\alpha_1(s) \leq s\pi(s) = s\alpha_1'(s)$, for all $s > 0$, and $\alpha_1(\cdot)$ satisfies, for any $s \in (0, \theta(0)]$,

$$\alpha_1(s) \leq s\pi(s) \leq \theta(0)\pi(s) \leq e^{-2\lambda\theta^{-1}(s)}\ . \tag{6.1}$$

One may now follow [30, Lemma 3].

6.2. Proof of Lemma 5.4. We follow the proofs of [19, Lemmas 11 and 12]. Without loss of generality, we assume that $\alpha(\cdot)$ is C^1 at the origin, $\alpha(s) \leq s$, and $\alpha'(0) = 0$. Now define $\rho(0) = 0$ and

$$\rho(s) := \exp\left(2\int_1^s \frac{1}{\alpha(\tau)}d\tau\right) \qquad \forall s > 0\ . \tag{6.2}$$

Since $\alpha(s) \leq s$, for $s \geq 1$ we have $\rho(s) \geq \exp\left(2\int_1^s \frac{d\tau}{\tau}\right) = s^2$ and for $s \leq 1$ we have $\rho(s) \leq \exp(-2\int_s^1 \frac{d\tau}{\tau}) = s^2$. It follows with the fact that $\rho(\cdot)$ is C^1 on $(0,\infty)$ that $\rho \in \mathcal{K}_\infty$. By differentiating (6.2), we have, for all $s > 0$, $\rho'(s) = \frac{2\rho(s)}{\alpha(s)}$ so that $\rho(s) = \frac{1}{2}\alpha(s)\rho'(s) \leq \alpha(s)\rho'(s)$. The Lipschitz property for $\rho(\cdot)$ on its domain, demonstrated by showing the boundedness of $\rho'(s)$ for small s, follows from the proof of [19, Lemma 12].

6.3. Proof of Lemma 5.5. Pick $\kappa(t) = 1 + \int_0^t q(s)ds$, where $q : \mathbb{R}_{\geq 0} \to (0, 1]$ is piecewise continuous, nonintegrable (so that $\kappa(\cdot)$ is unbounded), nonincreasing, and such that

$$1 + \int_0^t q(s)ds \leq \frac{1}{\omega_2(s_0 e^{-t})}. \tag{6.3}$$

We can always pick a nonintegrable, nonincreasing, piecewise continuous function $q(\cdot)$ taking values in $(0, 1]$ satisfying (6.3) as follows: We take $q(\cdot)$ to be piecewise constant with $q(s) = q_j$ for $s \in [j-1, j)$, where $\{q_j\}_{j=1}^{\infty}$ is a sequence of nonincreasing strictly positive numbers chosen inductively as follows: Define $q_0 = 1$. Let $\kappa_i = \sum_{j=0}^{i} q_j$. Note that $1 = \kappa_0 \leq 1/\omega_2(s_0 e^{-0}) = 2$. Define

$$m_i := \frac{1}{\omega_2(s_0 e^{-i})} - \kappa_i \tag{6.4}$$

and pick $q_{i+1} = \min\{m_i, q_i\}$. It follows that q_i is nonincreasing. It also follows that

$$\kappa_{i+1} = \kappa_i + q_{i+1} \leq \frac{1}{\omega_2(s_0 e^{-i})} < \frac{1}{\omega_2(s_0 e^{-(i+1)})},$$

from which it follows that $m_i > 0$ and so $q_i > 0$. Let $t \geq 0$, and let i be such that $t \in [i, i+1)$. Then

$$\kappa_i \leq 1 + \int_0^t q(s)ds \leq \kappa_{i+1} \leq \frac{1}{\omega_2(s_0 e^{-i})} \leq \frac{1}{\omega_2(s_0 e^{-t})}. \tag{6.5}$$

Now, suppose that $q(\cdot)$ is integrable. Since the function $\frac{1}{\omega_2(s_0 e^{-t})}$ is unbounded, (6.4) and (6.5) imply that $\lim_{i\to\infty} m_i = \infty$, which implies that there exists $j > 0$ such that $q_k = q_j > 0$ for all $k \geq j$. This contradicts $q(\cdot)$ being integrable.

That $\kappa(\cdot)$ is strictly increasing and (5.1) holds (i.e., $\kappa(0) = 0$) is obvious from the definition. We observe that

$$\frac{\kappa(t)}{\kappa(T)} = \frac{\kappa(T) + \int_T^t q(s)ds}{\kappa(T)} \leq 1 + \frac{t-T}{\kappa(T)} \leq 1 + (t-T) \leq e^{t-T}; \tag{6.6}$$

that is, (5.3) holds. Furthermore, by considering $T = 0$ in (6.6) and the constraint (6.3) we see that (5.4) holds.

Since $q(s) > 0$ for all $s \in \mathbb{R}_{\geq 0}$ and $q(\cdot)$ is nonincreasing, we have

$$\begin{aligned}\kappa(t)\kappa(T) &\geq 1 + \int_0^t q(s)ds + \int_0^T q(s)ds \geq 1 + \int_0^t q(s)ds + \int_t^{t+T} q(s)ds \\ &= 1 + \int_0^{t+T} q(s)ds = \kappa(t+T);\end{aligned}$$

that is, (5.2) holds.

To see that we can simultaneously satisfy (5.5), let $q_s : \mathbb{R}_{\geq 0} \to (0, 1]$ be continuous, nonincreasing, and such that $q_s(t) \leq q(t)$. Then, using the mean value theorem for locally Lipschitz functions, we have that for all $t \in [0, 1]$,

$$\max_{s\in[0,T]} \frac{\kappa(s)}{\kappa(s+t)} = \max_{s\in[0,T]} 1 - \frac{\kappa(s+t) - \kappa(s)}{\kappa(s+t)} \leq 1 - \frac{q_s(T+1)}{\kappa(T+1)} t =: 1 - \vartheta(T)t.$$

Clearly, $\vartheta(\cdot)$ is continuous, nonincreasing, and takes values in $\mathbb{R}_{>0}$. ∎

6.4. Proof of Lemma 5.6. We require some preliminary definitions. Let $\Omega \subset \mathbb{R}^n \backslash \mathcal{A}$ denote the set (of measure zero) where the gradient of $V(\cdot)$ is not defined in $\mathbb{R}^n \backslash \mathcal{A}$. For $(c,d) \in \mathbb{R}_{\geq 0} \times (0,1]$ define

$$\eta(c,d) := \sup_{\{|x| \leq c, V(x) \in [d,1], x \notin \Omega\}} |\nabla V(x)| \ .$$

For each $(c,d) \in \mathbb{R}_{\geq 0} \times (0,1]$, $\eta(c,d)$ is finite since for these (c,d) the set

$$\{x \in \mathbb{R}^n : |x| \leq c, \ V(x) \in [d,1]\}$$

is a compact subset of $\mathbb{R}^n \backslash \mathcal{A}$, the latter being a set on which $V(\cdot)$ is locally Lipschitz. Also $\eta(\cdot,d)$ is nondecreasing and $\eta(c,\cdot)$ is nonincreasing so that $\sigma : \mathbb{R}_{>0} \to \mathbb{R}_{\geq 0}$ defined as

$$\sigma(s) := \begin{cases} \eta\left(\frac{1}{s}, s\right) & \forall s \in (0,1), \\ \eta(1,1) & \forall s \geq 1 \end{cases}$$

is nonincreasing. We claim that

$$x \in \left\{\xi \in (\mathbb{R}^n \backslash \mathcal{A}) \backslash \Omega : \max\{1, |\xi|\} \leq \frac{1}{V(\xi)}\right\} \quad \Longrightarrow \quad |\nabla V(x)| \leq \sigma(V(x)) \tag{6.7}$$

since, in the indicated set, $V(x) \in (0,1]$, $|x| \leq \frac{1}{V(x)}$ so that $\sigma(V(x)) \geq \eta(|x|, V(x)) \geq |\nabla V(x)|$.

Let $\varphi : \mathbb{R}_{\geq 0} \to [0,1]$ be continuous, zero at zero, positive definite, nondecreasing, and let $\pi : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ be continuous, positive definite, nondecreasing and such that

$$\pi(s)\sigma(s) \leq \varphi(s) \leq 1 \qquad \forall s > 0 \ . \tag{6.8}$$

Define $\rho(r) := \int_0^r \pi(s) ds$. Since $\pi(\cdot)$ is continuous, positive definite, and nondecreasing, we have that $\rho \in \mathcal{K}_\infty$ and $\rho(r) \leq r\pi(r) = r\rho'(r)$ for all $r > 0$.

We now demonstrate the local Lipschitz property for $V_L := \rho \circ V$ on $\mathbb{R}^n$. Since both $\rho(\cdot)$ and $V(\cdot)$ are continuous on $\mathbb{R}^n$, $V_L := \rho \circ V$ is continuous on $\mathbb{R}^n$. Since $\rho(\cdot)$ is locally Lipschitz and $V(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$ and on the interior of $\mathcal{A}$, $V_L(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$ and on the interior of $\mathcal{A}$. To show that $V_L(\cdot)$ is locally Lipschitz on $\mathbb{R}^n$ it is sufficient to establish that, for each $x \in \text{bdry}\mathcal{A}$ (the boundary of $\mathcal{A}$), there exists $M > 0$ and an open, convex neighborhood $\mathcal{U}$ of x such that $DV_L(\xi; v) \leq M|v|$ for all $\xi \in \mathcal{U}, v \in \mathbb{R}^n$, and then use Lemma 5.1. Using $\text{int}(\mathcal{A})$ for the interior of $\mathcal{A}$,

$$\xi \in \text{int}(\mathcal{A}) \quad \Longrightarrow \quad DV_L(\xi; v) = 0 \ \forall v \in \mathbb{R}^n \ . \tag{6.9}$$

Also, it follows from (6.7), (6.8), and $\rho'(s) = \pi(s)$ that

$$\xi \in \left\{\zeta \in (\mathbb{R}^n \backslash \mathcal{A}) \backslash \Omega \ , \ \max\{1, |\zeta|\} \leq \frac{1}{V(\zeta)}\right\} \quad \Longrightarrow \quad |\nabla V_L(\xi)| \leq \varphi(V(\xi)) \leq 1.$$

That $DV_L(\xi; v) \leq \limsup_{y \to \xi} \{\langle \nabla V_L(y), v\rangle : y \notin \Omega\}$ is a combination of [8, Corollary 2.8.2] and [8, Exercise 3.4.1]. Consequently, we have

$$\xi \in \left\{\zeta \in \mathbb{R}^n \backslash \mathcal{A} : \max\{1, 2|\zeta|\} \leq \frac{1}{V(\zeta)}\right\} \quad \Longrightarrow \quad DV_L(\xi; v) \leq |v| \ \forall v \in \mathbb{R}^n. \tag{6.10}$$

With (6.9) and (6.10), we will be done if we can show that

$$x \in \text{bdry}\mathcal{A} \quad \Longrightarrow \quad DV_L(x;v) = 0 \ \forall v \in \mathbb{R}^n \ . \tag{6.11}$$

Since $V(x) = 0$ and $V(\xi) \geq 0$ for all $\xi \in \mathbb{R}^n$, we just need to show $DV_L(x;v) \leq 0$. Let $x \in \text{bdry}\mathcal{A}$. Since $\varphi \circ V(\cdot)$ is continuous and $\varphi(V(x)) = 0$, for each $\varepsilon > 0$ there exists a convex neighborhood $\mathcal{U}$ of x such that

$$\xi \in (\mathbb{R}^n \backslash \mathcal{A}) \cap \mathcal{U} \quad \Longrightarrow \quad \begin{cases} \max\{1, |\xi|\} \leq \frac{1}{V(\xi)} \ , \\ \varphi(V(\xi)) \leq \varepsilon. \end{cases}$$

It follows from (6.7), (6.8), and $\rho'(s) = \pi(s)$ that

$$\xi \in ((\mathbb{R}^n \backslash \mathcal{A}) \backslash \Omega) \cap \mathcal{U} \quad \Longrightarrow \quad |\nabla V_L(\xi)| \leq \varepsilon \ . \tag{6.12}$$

It follows from continuity of $V_L(\cdot)$ that for each $\xi \in (\mathbb{R}^n \backslash \mathcal{A}) \bigcap \mathcal{U}$ there exists $s^*(\xi) \in (0,1)$ such that

$$\begin{aligned} V_L(x + s(\xi - x)) &\geq \frac{V_L(\xi)}{2} \quad \forall s \in [s^*(\xi), 1] \ , \\ V_L(x + s^*(\xi)(\xi - x)) &= \frac{V_L(\xi))}{2} \ . \end{aligned}$$

It follows from the convexity of $\mathcal{U}$ that $\xi \in (\mathbb{R}^n \backslash \mathcal{A}) \cap \mathcal{U}$, and $s \in [s^*(\xi), 1]$ imply $x + s(\xi - x) \in (\mathbb{R}^n \backslash \mathcal{A}) \cap \mathcal{U}$. So, with (6.12) and the mean value theorem for locally Lipschitz functions (see [8, Theorem 2.2.4]) together with [8, Theorem 2.8.1], for all $\xi \in (\mathbb{R}^n \backslash \mathcal{A}) \bigcap \mathcal{U}$,

$$\begin{aligned} 0 \leq V_L(\xi) - V_L(x) &= 2\left(V_L(\xi) - V_L(x + s^*(\xi)(\xi - x))\right) \\ &\leq 2\varepsilon(1 - s^*(\xi))|\xi - x| \leq 2\varepsilon|\xi - x|. \end{aligned}$$

Since, for every $\xi \in \mathcal{A} \bigcap \mathcal{U}$, we have $V_L(\xi) - V_L(x) = 0$, it follows that, for all $\xi \in \mathcal{U}$, we have $0 \leq V_L(\xi) - V_L(x) \leq 2\varepsilon|\xi - x|$. Since $\varepsilon > 0$ can be taken arbitrarily small, (6.11) holds. □

6.5. Proof of Lemma 5.7. For $\dot{x} \in F(x)$ we denote by $\mathcal{R}_{\leq T}(\mathcal{C})$ the set of points reachable from a compact set $\mathcal{C} \subset \mathbb{R}^n$ in time $T > 0$; i.e., $\mathcal{R}_{\leq T}(\mathcal{C}) := \{\xi \in \mathbb{R}^n : \xi = \phi(t,x), t \in [0,T], x \in \mathcal{C}, \phi \in \mathcal{S}(x)\}$.

DEFINITION 8. *The differential inclusion is said to be forward complete if, for every $x \in \mathbb{R}^n$, all $\phi \in \mathcal{S}(x)$ are defined on $[0,\infty)$.*

We require several preliminary lemmas prior to proving Lemma 5.7. The first is also [11, section 7, Theorem 3].

LEMMA 6.1. *Let $F(\cdot)$ satisfy the basic conditions on $\mathbb{R}^n$, and suppose $\dot{x} \in F(x)$ is forward complete. For each compact set $\mathcal{C} \subset \mathbb{R}^n$ and $T \in \mathbb{R}_{>0}$, $\mathcal{R}_{\leq T}(\mathcal{C})$ is a compact subset of $\mathbb{R}^n$ and $\mathcal{S}[0,T](\mathcal{C})$ is a compact set in the metric of uniform convergence.*

An easy corollary of the above appeared as [30, Lemma 5].

LEMMA 6.2. *Let $F(\cdot)$ satisfy the basic conditions on $\mathbb{R}^n$, and let $\dot{x} \in F(x)$ be forward complete. Then each sequence $\{\phi_n\}_{n=1}^{\infty}$ of solutions satisfying $\phi_n \in \mathcal{S}[0,\infty)(x_n)$, where $x_n \to x$, has a subsequence converging to a function $\phi \in \mathcal{S}[0,\infty)(x)$, and the convergence is uniform on each compact time interval.*

The following appeared as [30, Lemma 10] (which derives from [10, Lemma 8.3] and [8, Theorem 4.3.11]) and describes how solutions to locally Lipschitz inclusions depend on initial conditions in a locally Lipschitz manner.

LEMMA 6.3. *Let $F(\cdot)$ satisfy the basic conditions on $\mathbb{R}^n$ and be locally Lipschitz on the open set $\mathcal{O} \subseteq \mathbb{R}^n$. For each $T > 0$ and each compact set $\mathcal{C} \subset \mathcal{O}$, there exist L and $\delta > 0$ such that, for each $\xi \in \mathcal{C}$, each $\phi \in \mathcal{S}(\xi)$, and each $\bar{v}$ satisfying $|\bar{v}| \leq \delta$, there exists $\psi \in \mathcal{S}(\xi + \bar{v})$ with the property $|\phi(t,\xi) - \psi(t,\xi+\bar{v})| \leq L|\bar{v}|$ for all $t \in [0, T_\phi]$, where $T_\phi \in [0,T]$ is such that $\phi(t,\xi) \in \mathcal{C}$ for all $t \in [0,T_\phi]$.*

6.5.1. Preliminaries. We define, for all $(s,\mu) \in \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$,

$$\gamma(s,\mu) := \begin{cases} 1 & \text{if} \quad s \leq 2+\mu, \\ 3+\mu-s & \text{if} \quad s \in [2+\mu, 3+\mu], \\ 0 & \text{if} \quad s \geq 3+\mu. \end{cases}$$

It follows from this definition that $\gamma(\cdot,\mu)$ is Lipschitz of rank one (i.e., Lipschitz with a Lipschitz constant of one). We define the set-valued map

$$F_\mu(x) := \gamma\left(|x|_{\mathcal{A}}, \mu\right) F(x) \ .$$

We note that, for each μ, $F_\mu(\cdot)$ satisfies the basic conditions and is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$. Also, using Assumption 1 and the definition of $F_\mu(x)$, we have $\max_{w \in F_\mu(x)} |w| \leq M_{3+\mu}$ for all $x \in \mathbb{R}^n$. Therefore, for each $\mu \geq 0$, the inclusion $\dot{x} \in F_\mu(x)$ is forward complete. We define $\mathcal{S}_\mu(x)$ to be the set of maximal solutions for $\dot{x} \in F_\mu(x)$. We let $\mathcal{Q}_\mu(x)$ be the subset of $\mathcal{S}_\mu(x)$ whose elements $\phi(\cdot,x)$ satisfy

$$|\phi(t,x)|_{\mathcal{A}} \leq \alpha_1^{-1}\left(\alpha_1(1+\mu)/\kappa(t)\right) \leq 1+\mu \quad \forall t \geq 0 \ . \tag{6.13}$$

Notice that $\mathcal{Q}_\mu(x)$ may be empty. It follows from the definitions of $\gamma(\cdot,\mu)$ and $F_\mu(\cdot)$ and (6.13) that when $\mathcal{Q}_\mu(x)$ is nonempty we have $\mathcal{Q}_\mu(x) \subseteq \mathcal{S}[0,\infty)(x)$.

6.5.2. An optimal trajectory. We require the following claim.

Claim 3. There exists $\phi^* \in \mathcal{S}[0,\infty)(x)$ such that $V(x) = \sup_{t \geq 0} g(\phi^*(t,x))\kappa(t)$ and, for every $\mu \geq \alpha_1^{-1} \circ \alpha_2(|x|_{\mathcal{A}})$, $\phi^* \in \mathcal{Q}_\mu(x)$.

Proof. Let $\mu \geq \alpha_1^{-1} \circ \alpha_2(|x|_{\mathcal{A}})$, which, since $\alpha_1 \in \mathcal{K}_\infty$, implies $\alpha_1(1+\mu) - \alpha_2(|x|_{\mathcal{A}}) > 0$, and let $\varepsilon > 0$ be such that $\varepsilon \leq \alpha_1(1+\mu) - \alpha_2(|x|_{\mathcal{A}})$. Let $\{\phi_k\}_{k=1}^\infty$ be a sequence within $\mathcal{S}[0,\infty)(x)$, and let $\{\varepsilon_k\}_{k=1}^\infty$ be a sequence of positive real numbers satisfying $\varepsilon_k \leq \varepsilon$ and monotonically decreasing to zero such that

$$\sup_{t \geq 0} g(\phi_k(t,x))\kappa(t) \leq V(x) + \varepsilon_k \ . \tag{6.14}$$

Since $V(x) + \varepsilon_k \leq \alpha_2(|x|_{\mathcal{A}}) + \varepsilon \leq \alpha_1(1+\mu)$ and $g(x) \geq \alpha_1(|x|_{\mathcal{A}})$, it follows that $|\phi_k(t,x)|_{\mathcal{A}} \leq \alpha_1^{-1}(\alpha_1(1+\mu)/\kappa(t)) \leq 1+\mu$ for all $t \geq 0$; i.e., $\phi_k \in \mathcal{Q}_\mu(x) \subseteq \mathcal{S}_\mu(x)$. Since $\dot{x} \in F_\mu(x)$ is forward complete and $F_\mu(\cdot)$ satisfies the basic conditions, it follows from Lemma 6.2 that the sequence ϕ_k has a converging subsequence converging to an element $\phi^* \in \mathcal{S}_\mu(x)$ and that the convergence is uniform on each compact time interval. (We now use ϕ_k to refer to this converging subsequence and ε_k to refer to the corresponding values in (6.14).)

We claim that $\phi^* \in \mathcal{Q}_\mu(x)$. If not, then there exist $\widetilde{t} \geq 0$ and $\widetilde{\rho} > 0$ such that

$$|\phi^*(\widetilde{t},x)|_{\mathcal{A}} \geq \alpha_1^{-1}\left(\alpha_1(1+\mu)/\kappa(t)\right) + \widetilde{\rho} \ . \tag{6.15}$$

From the uniform convergence of ϕ_k to ϕ^* on the interval $[0,\widetilde{t}]$ and since $|\cdot|_{\mathcal{A}}$ is Lipschitz of rank one, there exists $\widetilde{k}$ such that

$$|\phi_{\widetilde{k}}(\widetilde{t},x)|_{\mathcal{A}} \geq |\phi^*(\widetilde{t},x)|_{\mathcal{A}} - \frac{\widetilde{\rho}}{2}\ . \tag{6.16}$$

Combining (6.15) and (6.16), we get that $\phi_{\widetilde{k}} \notin \mathcal{Q}_\mu(x)$, which is a contradiction.

Next we claim that

$$V(x) = V^*(x) := \sup_{t\geq 0} g(\phi^*(t,x))\kappa(t)\ . \tag{6.17}$$

Since $\mathcal{Q}_\mu(x) \subseteq \mathcal{S}[0,\infty)(x)$, we have that $V(x) \leq V^*(x)$. So if (6.17) does not hold, then there exists $\rho > 0$ and $\bar{t} \geq 0$ such that

$$\sup_{t\in[0,\bar{t}]} g(\phi^*(t,x))\kappa(t) \geq V(x) + \rho. \tag{6.18}$$

Now, from the uniform convergence of ϕ_k to ϕ^* on the interval $[0,\bar{t}]$, the compactness of $\mathcal{R}^{\mu}_{\leq\bar{t}}(\{x\})$ (the set of points reachable from x in time $\bar{t}$ for the modified inclusion $\dot{x} \in \overline{F}_\mu(x)$) from Lemma 6.1, and the continuity of $g(\cdot)$, there exists k such that $\varepsilon_k < \rho/2$ and

$$\sup_{t\in[0,\bar{t}]} g(\phi_k(t,x))\kappa(t) \geq \sup_{t\in[0,\bar{t}]} g(\phi^*(t,x))\kappa(t) - \frac{\rho}{2}\ . \tag{6.19}$$

Combining (6.19) with (6.18) and $\varepsilon_k < \rho/2$ we get

$$\sup_{t\in[0,\bar{t}]} g(\phi_k(t,x))\kappa(t) \geq V(x) + \frac{\rho}{2} > V(x) + \varepsilon_k,$$

which contradicts (6.14). This establishes (6.17). □

6.5.3. The local Lipschitz property. We make the following claim.

Claim 4. $V(\cdot)$ is lower semicontinuous on $\mathbb{R}^n$; i.e., for each $x \in \mathbb{R}^n$ and any sequence $x_k \to x$, $\liminf_{k\to\infty} V(x_k) \geq V(x)$.

Proof. Fix $x \in \mathbb{R}^n$, and let $\mu \geq \alpha_1^{-1} \circ \alpha_2\left(|x|_{\mathcal{A}} + 1\right)$. Let x_k be a sequence converging to x and, without loss of generality, assume that $|x_k - x| \leq 1$ for all k so that $\mu \geq \alpha_1^{-1} \circ \alpha_2\left(|x_k|_{\mathcal{A}}\right)$ for all k. Define $\underline{V}(x) := \liminf_{k\to\infty} V(x_k)$. By extracting a suitable subsequence from x_k (and using x_k to denote the subsequence), we can construct a sequence ε_k monotonically decreasing to zero so that

$$V(x_k) \leq \underline{V}(x) + \varepsilon_k\ . \tag{6.20}$$

Let $\phi_k^* \in \mathcal{S}[0,\infty)(x_k)$ come from Claim 3 so that $\phi_k^* \in \mathcal{Q}_\mu(x_k)$. With Lemma 6.2 this sequence has a converging subsequence converging to an element $\psi \in \mathcal{S}_\mu(x)$, and the convergence is uniform on each compact time interval. (We now use ϕ_k and x_k to refer to this convergent subsequence and ε_k to refer to the corresponding values in (6.20).) We can use the same argument as in the proof of Claim 3 to establish that $\psi \in \mathcal{Q}_\mu(x)$. We claim

$$\underline{V}(x) \geq \sup_{t\geq 0} g(\psi(t,x))\kappa(t)\ . \tag{6.21}$$

If this is not the case, then there exist $\rho > 0$ and $\bar{t} \geq 0$ such that

$$\sup_{t\in[0,\bar{t}]} g(\psi(t,x))\kappa(t) \geq \underline{V}(x) + \rho \ . \tag{6.22}$$

Now, from the uniform convergence of $\phi_k^*(\cdot, x_k)$ to $\psi(\cdot, x)$ on the interval $[0, \bar{t}]$, the compactness of $\mathcal{R}^{\mu}_{\leq \bar{t}}(\{x\} + \overline{\mathcal{B}}_n)$ from Lemma 6.1, and the continuity of $g(\cdot)$, there exists k such that $\varepsilon_k < \rho/2$ and

$$\sup_{t\in[0,\bar{t}]} g(\phi_k^*(t,x_k))\kappa(t) \geq \sup_{t\in[0,\bar{t}]} g(\psi(t,x))\kappa(t) - \frac{\rho}{2} \ . \tag{6.23}$$

Combining (6.23) with (6.22) and $\varepsilon_k < \rho/2$ we get

$$V(x_k) \geq \sup_{t\in[0,\bar{t}]} g(\phi_k^*(t,x_k))\kappa(t) \geq \underline{V}(x) + \frac{\rho}{2} > \underline{V}(x) + \varepsilon_k,$$

which contradicts (6.20); i.e., (6.21) holds. Using (6.21) and $\psi \in \mathcal{Q}_\mu(x) \subseteq \mathcal{S}[0,\infty)(x)$, it follows that $\underline{V}(x) \geq V(x)$. □

We now proceed to set ourselves up to apply Lemma 5.1 in order to prove that $V(\cdot)$ is locally Lipschitz. Without loss of generality, we can assume that the sequence ℓ_j is strictly decreasing. For notational convenience, we set $\ell_0 = +\infty$. For $s > 0$, define $\underline{j}(s) := \inf\{j : s \geq \ell_j\}$ and then let $\Upsilon : \mathbb{R}_{>0} \to \mathbb{R}_{>0}$ be a continuous, nondecreasing function satisfying $\Upsilon(s) \leq \ell_{\underline{j}(s)+3}$. To see that such a function exists, we note that $\underline{j}(s)$ is nonincreasing and $\underline{j}(s) \to \infty$ as $s \to 0$. Consequently, $\ell_{\underline{j}(s)+3}$ is nondecreasing and $\ell_{\underline{j}(s)+3} \to 0$ as $s \to 0$.

We note that $s \geq \ell_{\underline{j}(s)} \geq \ell_{\underline{j}(s)+3} \geq \Upsilon(s)$. With the fact that $s \leq \alpha_1^{-1} \circ \alpha_2(s)$ for all $s \geq 0$ and that $\kappa(\cdot)$ has a continuous inverse on $[1, \infty)$, this allows us to define $T : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ by $T(0) = 0$ and

$$T(s) := \kappa^{-1}\left(\frac{\alpha_1(1 + \alpha_1^{-1} \circ \alpha_2(s+2))}{\alpha_1(\Upsilon(s))}\right) \quad \forall s > 0 \ .$$

It follows that $T(\cdot)$ is continuous on $\mathbb{R}_{>0}$.

Let $\zeta \in \mathbb{R}^n \backslash \mathcal{A}$, $j := \underline{j}(|\zeta|_{\mathcal{A}})$, $\mu := \alpha_1^{-1} \circ \alpha_2(|\zeta|_{\mathcal{A}} + 1)$ and

$$\mathcal{U} := \{\zeta\} + \frac{1}{2}\min\{1, (\ell_{j-2} - \ell_{j-1}), (\ell_j - \ell_{j+1})\}\,\mathcal{B}_n.$$

Notice that $\mathcal{U}$ is open and convex and that $\ell_j \leq |\zeta|_{\mathcal{A}} < \ell_{j-1}$. Since $\mu > \ell_j > \ell_{j+2}$, we can define $\overline{T} := \kappa^{-1}(\frac{\alpha_1(1+\mu)}{\alpha_1(\ell_{j+2})})$. It follows from the definition of $\mathcal{U}$ and since $|\cdot|_{\mathcal{A}}$ is globally Lipschitz of rank one that, for all $\xi \in \overline{\mathcal{U}}$,

$$|\zeta|_{\mathcal{A}} - \frac{1}{2}\min\{1, (\ell_j - \ell_{j+1})\} \leq |\xi|_{\mathcal{A}} \leq |\zeta|_{\mathcal{A}} + \frac{1}{2}\min\{1, \ell_{j-2} - \ell_{j-1}\} \ . \tag{6.24}$$

Therefore for all $\xi \in \overline{\mathcal{U}}$ we have that

$$\mu \geq \alpha_1^{-1} \circ \alpha_2(|\xi|_{\mathcal{A}}) \ , \tag{6.25}$$

$$|\xi|_{\mathcal{A}} + 2 \geq |\zeta|_{\mathcal{A}} + 1 \ , \text{ and} \tag{6.26}$$

$$|\xi|_{\mathcal{A}} \geq \ell_{j+1} \ . \tag{6.27}$$

Finally, using the upper bound on $|\xi|_{\mathcal{A}}$ and $|\zeta|_{\mathcal{A}} < \ell_{j-1}$ one may show that $|\xi|_{\mathcal{A}} \leq \ell_{j-2}$. We note that from the definition of $\underline{j}$ we have that $\underline{j}(s) \geq i+1$ if $s < \ell_i$. Consequently, $\underline{j}(|\xi|_{\mathcal{A}}) \geq j-1$, which implies

$$\Upsilon(|\xi|_{\mathcal{A}}) \leq \ell_{\underline{j}(|\xi|_{\mathcal{A}})+3} \leq \ell_{j+2} \ . \tag{6.28}$$

Inequalities (6.28) and (6.26) imply that $\overline{T} \leq \min_{\xi \in \overline{\mathcal{U}}} T(|\xi|_{\mathcal{A}})$.

Define $\mathcal{C} := \mathcal{R}^{\mu}_{\leq \overline{T}}(\overline{\mathcal{U}}) \bigcap \{z : |z|_{\mathcal{A}} \geq \ell_{j+2}\}$. It follows that $\mathcal{C}$ is a compact subset of $\mathbb{R}^n \backslash \mathcal{A}$, the latter being an open set where $F_\mu(\cdot)$ is locally Lipschitz. We apply Lemma 6.3 to generate $L > 0$ and $\delta > 0$.

Let $\xi \in \mathcal{U}$. Using (6.25), let $\phi^* \in \mathcal{Q}_\mu(\xi)$ come from Claim 3 so that

$$V(\xi) = \sup_{t \geq 0} g(\phi^*(t,\xi))\kappa(t) \text{ and} \tag{6.29}$$

$$|\phi^*(t,\xi)|_{\mathcal{A}} \leq \alpha_1^{-1}\left(\alpha_1(1+\mu)/\kappa(t)\right) \ \forall t \geq 0 \ . \tag{6.30}$$

It follows from combining (6.30) and (6.27) that the set $\{t : |\phi^*(t,\xi)|_{\mathcal{A}} = \ell_{j+2}\}$ is nonempty and $T_\xi := \inf\{t : |\phi^*(t,\xi)|_{\mathcal{A}} = \ell_{j+2}\}$ is well defined. Since $\phi^*(\cdot,\xi)$ is continuous, we see that

$$\ell_{j+2} = |\phi^*(T_\xi,\xi)|_{\mathcal{A}} \leq \alpha_1^{-1}\left(\alpha_1(1+\mu)/\kappa(T_\xi)\right), \tag{6.31}$$

which leads to $\kappa(T_\xi) \leq \alpha_1(1+\mu)/\alpha_1(\ell_{j+2}) = \kappa(\overline{T})$, which, since $\kappa(\cdot)$ is strictly increasing, implies that $T_\xi \leq \overline{T}$.

Again since $\phi^*(\cdot,\xi)$ is continuous, it follows that $|\phi^*(t,\xi)|_{\mathcal{A}} \geq \ell_{j+2}$ for all $t \in [0,T_\xi]$; i.e., $\phi^*(t,\xi) \in \mathcal{C}$ for all $t \in [0,T_\xi]$. According to the result of Lemma 6.3, for all $\bar{v} \in \mathbb{R}^n$ such that $|\bar{v}| \leq \delta$, there exists $\psi \in \mathcal{S}_\mu(\xi+\bar{v})$ such that

$$|\phi^*(t,\xi) - \psi(t,\xi+\bar{v})| \leq L|\bar{v}| \ \forall t \in [0,T_\xi] \ . \tag{6.32}$$

We define $\delta_1 := \min\left\{\delta, \frac{1}{L}, \frac{1}{L}\left(\ell_{j+1}-\ell_{j+2}\right), \frac{1}{2}\left(\ell_j - \ell_{j+1}\right)\right\}$. Henceforth we assume $|\bar{v}| \leq \delta_1$. It follows with (6.24) that

$$|\xi+\bar{v}|_{\mathcal{A}} \geq |\xi|_{\mathcal{A}} - \frac{1}{2}\left(\ell_j - \ell_{j+1}\right) \geq |\zeta|_{\mathcal{A}} - \left(\ell_j - \ell_{j+1}\right) \geq \ell_{j+1} \tag{6.33}$$

and with (6.32) that

$$|\phi^*(t,\xi) - \psi(t,\xi+\bar{v})| \leq L|\bar{v}| \leq \min\left\{1, (\ell_{j+1}-\ell_{j+2})\right\} \quad \forall t \in [0,T_\xi]. \tag{6.34}$$

The relations (6.34), (6.30), and (6.31) imply that

$$|\psi(t,\xi+\bar{v})|_{\mathcal{A}} \leq |\phi^*(t,\xi)|_{\mathcal{A}} + 1 \leq 2+\mu \ \ \forall t \in [0,T_\xi] \text{ and} \tag{6.35}$$

$$|\psi(T_\xi,\xi+\bar{v})|_{\mathcal{A}} \leq |\phi^*(T_\xi,\xi)|_{\mathcal{A}} + \ell_{j+1} - \ell_{j+2} = \ell_{j+1} \ . \tag{6.36}$$

It follows from (6.35) and the definition of $F_\mu(x)$ that

$$\psi \in \mathcal{S}[0,T_\xi](\xi+\bar{v}) \ . \tag{6.37}$$

The inequalities (6.33) and (6.36) imply that the set $\{t : |\psi(t,\xi+\bar{v})|_{\mathcal{A}} = \ell_{j+1}\}$ is nonempty and we can define $T_{\psi,\bar{v}} := \inf\{t : |\psi(t,\xi+\bar{v})|_{\mathcal{A}} = \ell_{j+1}\}$. We see that $T_{\psi,\bar{v}} \leq T_\xi \leq \overline{T}$, and, since $\psi(\cdot,\xi+\bar{v})$ is continuous, $|\psi(T_{\psi,\bar{v}},\xi+\bar{v})|_{\mathcal{A}} = \ell_{j+1}$. For clarity, define

$z := \psi(T_{\psi,\bar{v}}, \xi + \bar{v})$. From the third assumption of the lemma $g(z) = V(z)$; so, with (6.37) and $\kappa(\tau)\kappa(T_{\psi,\bar{v}}) \geq \kappa(\tau + T_{\psi,\bar{v}})$ for all $\tau \geq 0$, $T_{\psi,\bar{v}} \geq 0$, we have

$$\begin{aligned}\max_{t\in[0,T_{\psi,\bar{v}}]} g(\psi(t,\xi+\bar{v}))\kappa(t) &= \max\left\{\max_{t\in[0,T_{\psi,\bar{v}}]} g(\psi(t,\xi+\bar{v}))\kappa(t), V(z)\kappa(T_{\psi,\bar{v}})\right\}\\ &= \max\left\{\max_{t\in[0,T_{\psi,\bar{v}}]} g(\psi(t,\xi+\bar{v}))\kappa(t), \inf_{\phi\in\mathcal{S}[0,\infty)(z)} \sup_{\tau\geq 0} g(\phi(\tau,z))\kappa(\tau)\kappa(T_{\psi,\bar{v}})\right\}\\ &\geq \inf_{\phi\in\mathcal{S}[0,\infty)(\xi+\bar{v})} \sup_{t\geq 0} g(\phi(t,\xi+\bar{v}))\kappa(t) \;=\; V(\xi+\bar{v}). \qquad (6.38)\end{aligned}$$

One consequence of this calculation, which comes by taking $\bar{v} = 0$ and $\psi = \phi^*$ so that (6.32) is satisfied, is that for each $\xi \in \mathcal{U}$,

$$V(\xi) \geq \max_{t\in[0,T(|\xi|_{\mathcal{A}})]} g(\phi^*(t,\xi))\kappa(t) \geq \max_{t\in[0,T_{\phi^*,0}]} g(\phi^*(t,\xi))\kappa(t) \geq V(\xi)\ ;$$

i.e., $\max_{t\in[0,T(|\xi|_{\mathcal{A}})]} g(\phi^*(t,\xi))\kappa(t) = V(\xi)$. Let $L_{\mathcal{C}} > 0$ be such that $|g(x_1) - g(x_2)| \leq L_{\mathcal{C}}|x_1 - x_2|$ for all $x_1, x_2 \in \mathcal{C} + \overline{\mathcal{B}}_n$. From (6.29), (6.32), and (6.38) it follows that

$$\begin{aligned}V(\xi) &\geq \max_{t\in[0,T_{\psi,\bar{v}}]} g(\phi^*(t,\xi))\kappa(t) \geq \max_{t\in[0,T_{\psi,\bar{v}}]} g(\psi(t,\xi+\bar{v}))\kappa(t) - LL_{\mathcal{C}}|\bar{v}|\kappa(\overline{T})\\ &\geq V(\xi+\bar{v}) - LL_{\mathcal{C}}|\bar{v}|\kappa(\overline{T})\ .\end{aligned}$$

Therefore, with the definition $M := LL_{\mathcal{C}}\kappa(\overline{T})$ for all $\xi \in \mathcal{U}$ and all $v \in \mathbb{R}^n$, we have

$$DV(\xi;v) = \liminf_{w\to v,\varepsilon\to 0^+} \frac{V(\xi+\varepsilon w) - V(\xi)}{\varepsilon} \leq \liminf_{w\to v,\varepsilon\to 0^+} LL_{\mathcal{C}}|w|\kappa(\overline{T}) = M|v|\ .$$

Having already shown that $V(\cdot)$ is lower semicontinuous on $\mathbb{R}^n$ (Claim 4), it follows from Lemma 5.1 that $V(\cdot)$ is locally Lipschitz on the open, convex set $\mathcal{U}$ with Lipschitz constant M. Since $\zeta \in \mathbb{R}^n\backslash\mathcal{A}$ was arbitrary, $V(\cdot)$ is locally Lipschitz on $\mathbb{R}^n\backslash\mathcal{A}$. With this Lipschitz property and the relation $0 \leq V(x) \leq \alpha_2(|x|_{\mathcal{A}})$, it follows that $V(\cdot)$ is continuous on $\mathbb{R}^n$. □

FAST CONSTRUCTION OF ROBUSTNESS DEGRADATION FUNCTION*

XINJIA CHEN†, KEMIN ZHOU†, AND JORGE L. ARAVENA†

Abstract. We develop a fast algorithm to construct the robustness degradation function, which describes quantitatively the relationship between the proportion of systems guaranteeing the robustness requirement and the radius of the uncertainty set. This function can be applied to predict whether a controller design based on an inexact mathematical model will perform satisfactorily when implemented on the true system.

Key words. robustness, uncertainty, sample reuse algorithm

1. Introduction.

In recent years, there has been growing interest in the development of probabilistic methods for robustness analysis and design problems aimed at overcoming the computational complexity and the conservatism issue of the deterministic worst-case framework [16, 17, 14, 12, 19, 2, 5, 4, 18, 8, 9, 6, 7, 21, 22, 15, 3]. In the deterministic worst-case framework, one is interested in knowing if the robustness requirement is guaranteed for every value of the uncertainty. However, it should be borne in mind that the uncertainty set may include worst cases which never happen in reality. Instead of seeking the worst-case guarantee, it is sometimes "acceptable" that the robustness requirement is satisfied for most of the cases. It has been demonstrated that the proportion of systems guaranteeing the robustness requirement can be close to 1 even if the radii of the uncertainty set are much larger than the worst-case deterministic robustness margin [2, 13, 4, 8, 18]. Therefore, it is of practical importance to construct a function which describes quantitatively the relationship between the proportion of systems guaranteeing the robustness requirement and the radius of the uncertainty set. Such a function can serve as a guide for control engineers in evaluating the robustness of a control system once a controller design is completed. Such a function, referred to as a *robustness degradation function*, has been proposed by a number of researchers [2, 8]. For example, Barmish, Lagoa, and Tempo [2] have constructed a curve of the robustness margin amplification versus risk in a probabilistic setting. In a similar spirit, Calafiore, Dabbene, and Tempo [8, 9] have constructed a probability degradation function in the context of real and complex parametric uncertainty.

In this paper, allowing the robustness analysis to be performed in a distribution-free manner, we introduce the concept of *proportion* and adopt the assumption from the classical robust control framework that uncertainty is deterministic and bounded. It follows naturally that the robustness of a system can be reasonably measured by the ratio of the volume (Lebesgue measure) of the set of uncertainty guaranteeing the robustness requirement to the overall set of uncertainty [19]. Evaluation of such a measure of robustness requires generating samples with uniform distribution over un-

certainty sets such as a spectral normal ball or an l_p ball. The difficulty of generating such samples has been successfully resolved in [8, 9].

The conventional method for constructing the robustness function is to perform, independently, a certain number of simulations for each value of the uncertainty radius and then plot the function. Although such a curve can be applied to evaluate the robustness of the control system, it may be computationally expensive. This is especially true when many cycles of controller synthesis and robustness analysis are needed in the development of a high performance control system. Motivated by this situation, we focus on the machinery that can make the construction of such a function efficient. We have developed a sample reuse algorithm that allows the simulations to be conducted in an iterative manner. The idea is to start simulation from the larger uncertainty set and save appropriate evaluations of the robust requirement for the use of later simulations on the smaller uncertainty set. In this way the total number of simulations can be reduced significantly as compared to the conventional method.

In addition to deriving our sample reuse algorithm from the worst-case deterministic framework, we show that the technique is also applicable when considering the random nature of the uncertainty. In such cases, the worst-case properties of uniform distribution given in the pioneering work [5, 2, 1] allow our algorithm to be applied to efficiently solve a wide variety of robustness analysis problems. In particular, the radial truncation theory [2] can be applied to robustness analysis problems with uncertainty bounding sets defined as spectral norm balls and l_p balls.

The organization of the paper is as follows. Section 2 gives the problem formulation. Section 3 presents our sample reuse algorithm. Section 4 is the performance analysis of the algorithm. Section 5 applies the algorithm to examples. Section 6 shows the justification of the algorithm for the case of random uncertainties. Section 7 is the conclusion. The proofs of the theorems are included as an appendix.

2. Problem formulation. We adopt the assumption, from the classical robust control framework, that the uncertainty is deterministic and bounded. We formulate a general robustness analysis problem as follows.

Let $\mathbf{P}$ denote a robustness requirement. The definition of $\mathbf{P}$ can be a fairly complicated combination of the following:

- stability or $\mathcal{D}$-stability;
- H_∞ norm of the closed-loop transfer function;
- time specifications such as overshoot, rise time, settling time, and steady state error.

Let $\mathcal{B}(r)$ denote the set of uncertainties with size smaller than r. In applications, we are usually dealing with uncertainty sets such as the following:

- l_p ball $\mathcal{B}_p(r) := \{\Delta \in \mathbf{R}^n : \ ||\Delta||_p \le r\}$, where $||.|_p$ denotes the l_p norm and $p = 1, 2, \ldots, \infty$. In particular, $\mathcal{B}_\infty(r)$ denotes a box.
- Spectral norm ball $\mathcal{B}_\sigma(r) := \{\Delta \in \mathbf{\Delta} : \bar{\sigma}(\Delta) \le r\}$, where $\bar{\sigma}(\Delta)$ denotes the largest singular value of Δ. The class of allowable perturbations is

  $$\mathbf{\Delta} := \{\text{blockdiag}[q_1 I_{r_1}, \ldots, q_s I_{r_s}, \Delta_1, \ldots, \Delta_c]\}, \tag{2.1}$$

  where $q_i \in \mathbb{F}$, $i = 1, \ldots, s$ are scalar parameters with multiplicity $r_1, \ldots, r_s$ and $\Delta_i \in \mathbb{F}^{n_i \times m_i}$, $i = 1, \ldots, c$ are possibly repeated full blocks. Here $\mathbb{F}$ is either the complex field $\mathbf{C}$ or the real field $\mathbf{R}$.
- Homogeneous star-shaped bounding set $\mathcal{B}_H(r) := \{r(\Delta - \Delta_0) + \Delta_0 : \Delta \in Q\}$, where $Q \subset \mathbf{R}^n$ and $\Delta_0 \in Q$ (see [2] for a detailed illustration).

Throughout this paper, $\mathcal{B}(r)$ refers to any type of uncertainty set described above.

Define a function $\ell(.)$ such that, for any X,

$$\ell(X) := \min\{r : X \in \mathcal{B}(r)\},$$

i.e., $\mathcal{B}(\ell(X))$ includes X exactly in the boundary. By such definition,

$$\ell(X) = \min\left\{r : \frac{X - \Delta_0}{r} + \Delta_0 \in Q\right\},$$

$$\ell(X) = \bar{\sigma}(X),$$

and

$$\ell(X) = ||X||_p$$

in the context of a homogeneous star-shaped bounding set, spectral norm ball, and l_p ball, respectively.

To allow the robustness analysis to be performed in a distribution-free manner, we introduce the notion of *proportion* as follows. For any $\Delta \in \mathcal{B}(r)$ there is an associated system $G(\Delta)$. We define *proportion* as follows:

$$\mathbb{P}(r) := \frac{\text{vol}(\{\Delta \in \mathcal{B}(r) : \text{The associated system } G(\Delta) \text{ guarantees } \mathbf{P}\})}{\text{vol}(\mathcal{B}(r))}$$

with

$$\text{vol}(S) := \int_{q \in S} dq,$$

where the notion of dq is illustrated as follows:

- (I): If $q = [x_{rs}]_{n\times m}$ is a real matrix in $\mathbf{R}^{n\times m}$, then $dq = \prod_{r=1}^{n}\prod_{s=1}^{m} dx_{rs}$.
- (II): If $q = [x_{rs} + jy_{rs}]_{n\times m}$ is a complex matrix in $\mathbf{C}^{n\times m}$, then $dq = \prod_{r=1}^{n}\prod_{s=1}^{m}(dx_{rs}dy_{rs})$.
- (III): If $q \in \mathbf{\Delta}$, i.e., q possesses a block structure defined by (2.1), then $dq = (\prod_{i=1}^{s} dq_i)(\prod_{i=1}^{c} d\Delta_i)$, where the notion of dq_i and $d\Delta_i$ is defined by (I) and (II).

It follows that $\mathbb{P}(r)$ is a reasonable measure of the robustness of the system [8, 20]. In the worst-case deterministic framework, we are interested only in knowing if $\mathbf{P}$ is guaranteed for every Δ. However, one should bear in mind that the uncertainty set in our model may include worst cases which never happen in reality. Thus, it would be "acceptable" in many applications if the robustness requirement $\mathbf{P}$ is satisfied for most of the cases. Hence, due to the inaccuracy of the model, we should also obtain the value of $\mathbb{P}(r)$ for uncertainty radius r which exceeds the deterministic robustness margin.

Clearly, $\mathbb{P}(r)$ is deterministic in nature. However, we can resort to a probabilistic approach to evaluate $\mathbb{P}(r)$. To see this, one needs to observe that a random variable with *uniform distribution* over $\mathcal{B}(r)$, denoted by $\mathbf{\Delta}^u$, guarantees that

$$\Pr\{\mathbf{\Delta}^u \in S\} = \frac{\text{vol}(S \bigcap \mathcal{B}(r))}{\text{vol}(\mathcal{B}(r))}$$

for any S, and thus

$$\mathbb{P}(r) = \Pr\{\text{The associated system } G(\mathbf{\Delta}^u) \text{ guarantees } \mathbf{P}\}.$$

It follows that a Monte Carlo method can be employed to estimate $\mathbb{P}(r)$ based on independently and identically distributed (i.i.d.) observations of $\mathbf{\Delta}^u$.

It is interesting to know how the function $\mathbb{P}(r)$ degrades with respect to r when r increases from a to b, where $b > a \geq 0$. In a similar spirit, such a function has been proposed as a *confidence degradation function* in [2] and as a *probability degradation*

function in [8, 9]. In this paper, we refer to the function $\mathbb{P}(.)$ as a *robustness degradation function* for the following reasons. First, we introduce the confidence interval for assessing the accuracy of the estimate of $\mathbb{P}(r)$. To be useful, every numerical method should be associated with an assessment for the accuracy of the estimate. Monte Carlo simulation is no exception. To avoid confusion, we reserve the notion of "confidence" for the purpose of interval estimation. Second, we introduce the concept of *proportion* for measuring robustness, which has no probabilistic content. Third, $\mathbb{P}(r)$ is a robustness measure and is usually decreasing with respect to r when $\mathbb{P}(r)$ is close to 1.

To construct such a function of practical importance, the conventional way is to grid the interval $[a, b]$ as $a = \rho_1 < \rho_2 < \cdots < \rho_l = b$ and estimate $\mathbb{P}(\rho_i)$ by conducting N i.i.d. sampling experiments for each ρ_i. In total, we need Nl samples. In the next section we show that the number of experiments can be significantly reduced.

3. Sample reuse algorithm. To improve efficiency, we shall make use of the following simple yet important observation.

Let q^* be an observation of a random variable with uniform distribution over $\mathcal{B}(r^*) \supseteq \mathcal{B}(r)$ such that $q^* \in \mathcal{B}(r)$. Then q^* can also be viewed as an observation of a random variable with uniform distribution over $\mathcal{B}(r)$.

In our algorithm, we flip the order of ρ_i by defining

$$r_i = \rho_{l+1-i}$$

for $i = 1, 2, \ldots, l$. Thus, the direction of simulation is backward. Our algorithm is described as follows.

Sample Reuse Algorithm

- Input: Sample size N, confidence parameter $\delta \in (0, 1)$ and uncertainty radii r_i, $i = 1, 2, \ldots, l$.
- Output: Proportion estimate $\widehat{\mathbb{P}}_i$ and the related confidence interval for $i = 1, \ldots, l$. In the following, m_{i1} denotes the number of sampling experiments conducted at r_i, and m_{i2} denotes the number of observations guaranteeing $\mathbf{P}$ during the m_{i1} sampling experiments.
- *Step* 1 (initialization). Let $M = [m_{ij}]_{l\times 2}$ be a zero matrix.
- *Step* 2 (backward iteration). For $i = 1$ to $i = l$ do the following:
  - Let $r \leftarrow r_i$.
  - While $m_{i1} < N$ do the following:
    - Generate uniform sample q from $\mathcal{B}(r)$. Evaluate the robustness requirement $\mathbf{P}$ for q.
    - Let $m_{s1} \leftarrow m_{s1} + 1$ for any s such that $r \geq r_s \geq \ell(q)$.
    - If robustness requirement $\mathbf{P}$ is satisfied for q, then let $m_{s2} \leftarrow m_{s2}+1$ for any s such that $r \geq r_s \geq \ell(q)$.
  - Let $\widehat{\mathbb{P}}_i \leftarrow \frac{m_{i2}}{N}$ and construct the confidence interval of confidence level $100(1-\delta)\%$.

It follows that q can be viewed as an observation of a random variable with uniform distribution over $\mathcal{B}(r_j)$ if and only if $r \geq r_j \geq \ell(q)$. Hence, if the robustness requirement $\mathbf{P}$ has been evaluated for $\mathcal{B}(r_i)$ at sample q, the result can be accepted without repeated evaluation of $\mathbf{P}$ for all $\mathcal{B}(r_j)$ such that $r \geq r_j \geq \ell(q)$. *Thus, sample reuse allows us to save both the sample generation and the evaluation of $\mathbf{P}$ for the sample. It is also interesting to point out that the samples collected for each r_i are i.i.d. and thus the confidence interval can be rigorously constructed based on the evaluation of $\mathbf{P}$ for the samples.*

4. Sample reuse factor. Let $\mathbf{n}_i$ be the number of simulations required at r_i. Define *sample reuse factor* as follows:

$$\mathcal{F}_{reuse} := \frac{Nl}{\mathcal{E}[\sum_{i=1}^{l} \mathbf{n}_i]},$$

where $\mathcal{E}(X)$ denotes the expectation of random variable X. Obviously, $\mathcal{F}_{reuse}$ measures the improvement of efficiency upon the conventional method. We demonstrate that the improvement can be significant in most applications.

THEOREM 1. *The sample reuse factor* $\mathcal{F}_{reuse} = l/l - \sum_{i=2}^{l} \left(\frac{r_i}{r_{i-1}}\right)^d$, *where* $d = n$ *for* l_p *ball* $\mathcal{B}_p(r)$ *and homogeneous star-shaped bounding set* $\mathcal{B}_H(r)$*; and*

$$d = \sum_{i=1}^{s} \kappa(q_i) + \sum_{j=1}^{c} \kappa(\Delta_j)$$

for spectral norm ball $\mathcal{B}_\sigma(r)$ *with* $\kappa(.)$ *defined as*

$$\kappa(X) := \begin{cases} 2mn & \text{if } X \text{ is a variable in } \mathbf{C}^{n\times m} \\ mn & \text{if } X \text{ is a variable in } \mathbf{R}^{n\times m}. \end{cases}$$

See the appendix for proof. For illustration purposes, we choose $r_i = b - \frac{(b-a)(i-1)}{l-1}$ for $i = 1, 2, \ldots, l$. By Theorem 1, $\mathcal{F}_{reuse} = l/l - \sum_{i=2}^{l} \left(1 - \frac{1}{\frac{l-1}{1-\frac{a}{b}} - i + 2}\right)^d$. Figures 1 and 2 show that the improvement over the conventional approach is significant when d is not large. These figures also reveal that the sample reuse factor does not scale well with the uncertainty dimension. For example, when $d > 160$, the efficiency gained from sample reuse techniques may not be attractive.

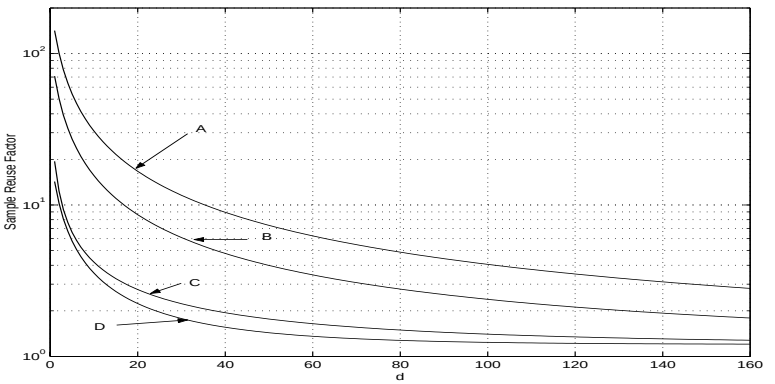

FIG. 1. *Performance improvement (*A : $l = 200,\ b = 2a$; B : $l = 100,\ b = 2a$; C : $l = 100,\ a = 0$; D : $l = 20,\ b = 2a$*).*

5. Illustrative examples. In this section we demonstrate through examples the power of the sample reuse algorithm in solving a wide variety of complicated robustness analysis problems which are intractable in the classical deterministic framework.

First, we consider an example which has been studied in [11] by a deterministic approach. The system is as shown in Figure 3.

The compensator is $C(s) = \frac{s+2}{s+10}$ and the plant is $P(s) = \frac{800(1+0.1\delta_1)}{s(s+4+0.2\delta_2)(s+6+0.3\delta_3)}$ with parametric uncertainty $\Delta = [\delta_1, \delta_2, \delta_3]^{\mathrm{T}}$. The nominal system is stable. The closed-loop roots of the nominal system are

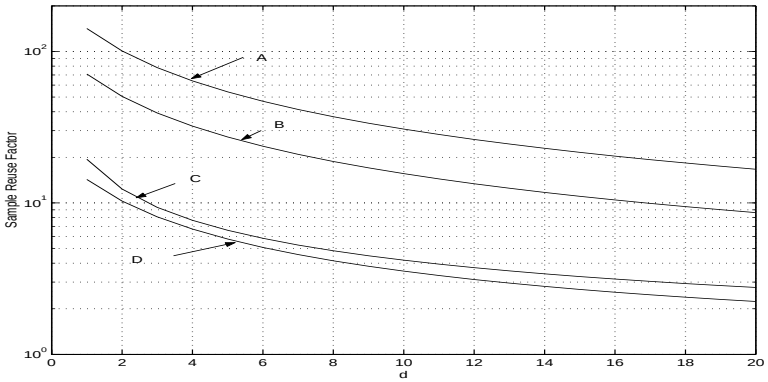

FIG. 2. *Performance improvement (*A : $l = 200,\ b = 2a$; B : $l = 100,\ b = 2a$; C : $l = 100,\ a = 0$; D : $l = 20,\ b = 2a$*).*

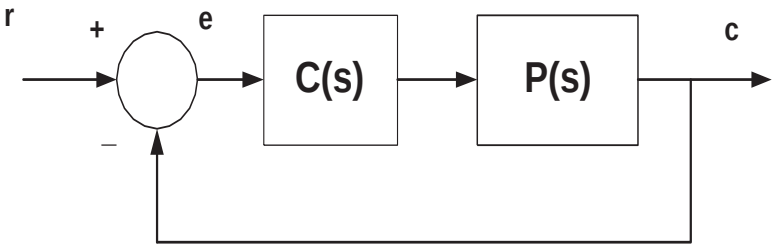

FIG. 3. *Uncertain system.*

$$z_1 = -15.9178,\ \ z_2 = -1.8309,\ \ z_3 = -1.1256 + 7.3234i,\ \ z_4 = -1.1256 - 7.3234i.$$

The H_∞ norm of the nominal closed-loop transfer function is $||T^0||_\infty = 2.78$. The peak value, rise time, and settling time of step response of the nominal system are, respectively, $P^0_{peak} = 1.47$, $t^0_r = 0.185$, and $t^0_s = 3.175$. In all of the following examples, we take $l = 100$. To guarantee that the absolute error of the estimate for the proportion is less than 0.01 with confidence level 99%, we choose $N = 26,492$ based on the well-known Chernoff bound (see [12, 19] for "sharper" bounds). Since the Chernoff bound is conservative, we also performed a post-experimental evaluation of the estimates by constructing confidence intervals with confidence level 99% based on Clopper–Pearson's method [10].

Figure 4 is the robustness degradation curve for robust stability over uncertainty set $\mathcal{B}_\infty(r) := \{\Delta :\ ||\Delta||_\infty \le r\}$. It demonstrates that a significant enhancement of the robustness margin can be achieved at the price of a small risk.

Figure 5 is the robustness degradation curve, with the robustness requirement $\mathbf{P}$ defined as stability and H_∞ norm $< 170\%\ ||T^0||_\infty$, and the uncertainty set defined as the ellipsoid $\mathcal{B}_2(r) := \{\Delta :\ ||\Delta||_2 \le r\}$.

Figure 6 is the robustness degradation curve with the robustness requirement $\mathbf{P}$ defined as $\mathcal{D}$-stability with the domain of poles defined as: real part < -1.5, or it falls within one of the two disks centered at z_3 and z_4 with radius 0.3. The uncertainty set is defined as the polytope

$$\mathcal{B}_H(r) := \left\{ r\Delta + (1-r)\,\frac{\sum_{i=1}^4 \Delta^i}{4} : \Delta \in \mathrm{conv}\{\Delta^1, \Delta^2, \Delta^3, \Delta^4\} \right\},$$

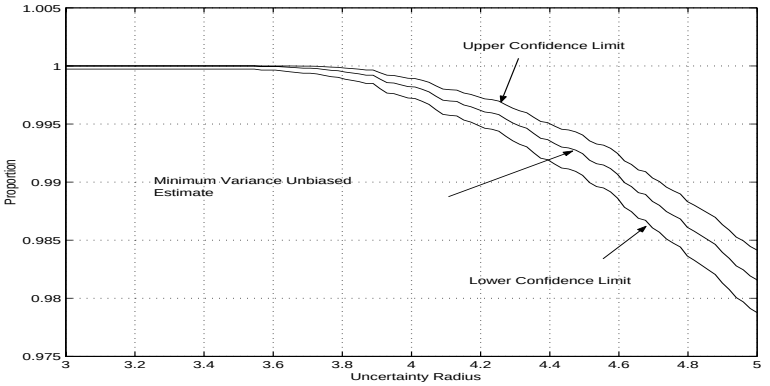

FIG. 4. *Robustness degradation curve (reuse factor = 41).*

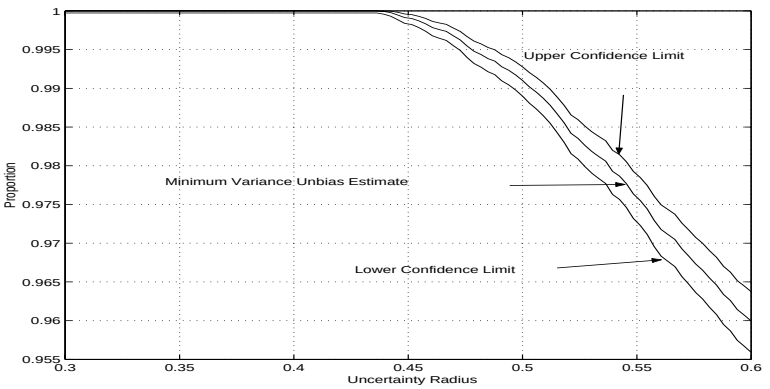

FIG. 5. *Robustness degradation curve (reuse factor = 43).*

where "conv" denotes the convex hull of $\Delta^i = [\frac{1}{2}\sin(\frac{2i-1}{3}\pi),\ \frac{1}{2}\cos(\frac{2i-1}{3}\pi),\ -\frac{\sqrt{3}}{2}]^{\mathrm{T}}$ for $i = 1, 2, 3$ and $\Delta^4 = [0,\ 0,\ 1]^{\mathrm{T}}$.

Figure 7 is the robustness degradation curve for the case where the uncertainty set is $\mathcal{B}_\infty(r) := \{\Delta :\ ||\Delta||_\infty \le r\}$, the robustness requirement $\mathbf{P}$ is: stability, and rise time $t_r < 135\%\ t_r^0 = 0.25$, settling time $t_s < 110\%\ t_s^0 = 3.5$, and overshoot $P_{peak} < 116\%\ P_{peak}^0 = 1.7$.

Finally, we consider the same example in [8] where the class of uncertainty is defined as

$$\mathbf{\Delta} := \{\text{blockdiag}[q_1 I_5,\ q_2 I_5,\ \Delta_1]\},$$

where $\Delta_1 \in \mathbf{C}^{4\times 4}$, and I_5 denotes the identity matrix of 5×5. By Theorem 1, we have $d = 34$. Figure 8 shows the robustness degradation curve. An improvement (of efficiency) about fivefold is achieved by our algorithm.

6. A probabilistic perspective. In sections 2 and 3, we have derived our sample reuse algorithm from the worst-case deterministic framework. In this section, we show that the proposed algorithm is also applicable from the perspective of the random nature of uncertainty. In situations where we need to take into account the random nature of uncertainty, the pioneering work of Barmish, Lagoa, Tempo, Bai, and Fu [2, 1] allows our sample reuse algorithm to be applied to solve efficiently a

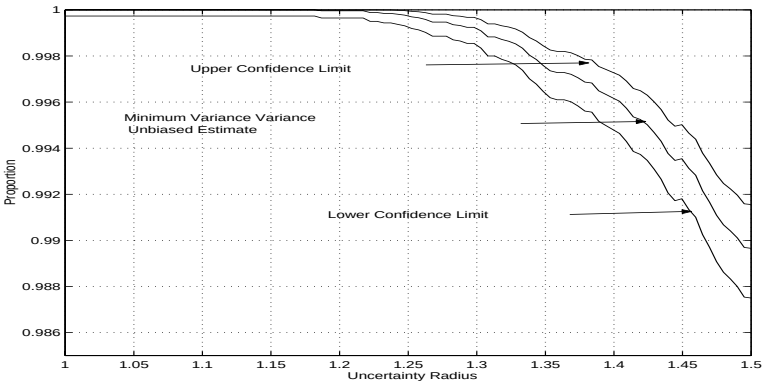

FIG. 6. *Robustness degradation curve (reuse factor = 49).*

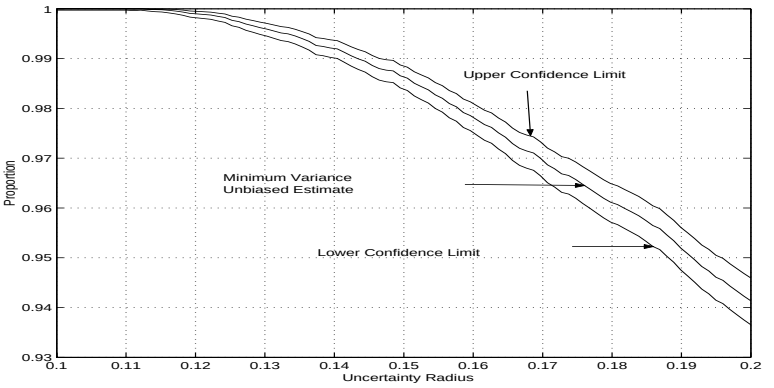

FIG. 7. *Robustness degradation curve (reuse factor = 38).*

wide variety of robustness problems. The following theorem plays an important role.

THEOREM 2 (see [2]). *Suppose that uncertainty* $\mathbf{\Delta}$ *is a random variable with a density function* $f(\Delta)$ *which depends only on* $\ell(\Delta)$ *and is nonincreasing with respect to* $\ell(\Delta)$. *Then*

$$\Pr\{\text{The associated system } G(\mathbf{\Delta}) \text{ guarantees } \mathbf{P} \mid \mathbf{\Delta} \in \mathcal{B}(r)\} \geq \inf_{0 \leq \rho \leq r} \mathbb{P}(\rho).$$

Remark 1. A remarkable fact of Theorem 2 is that no assumption needs to be imposed on the robustness requirement $\mathbf{P}$. The assumption in Theorem 2 is roughly interpreted to mean that the probability measure of the uncertainty is radially symmetrical with respect to the nominal value. In many applications, small perturbations are more likely than large perturbations, and the uncertainty is sufficiently unstructured so as to be treated equally likely in the surface of $\mathcal{B}(r)$ [2].

Remark 2. It should be noted that Theorem 2 applies to a homogeneous star-shaped bounding set, l_p ball, and spectral norm ball. We introduce in Theorem 2 a conditional probability based on the following reason: It does not seem logical to treat the uncertainty as different bounded random variables. For example, if the uncertainty possesses a certain distribution over $\mathcal{B}(r_1)$, it would be a contradiction that the uncertainty possesses another distribution over $\mathcal{B}(r_2)$ for $r_2 > r_1$. In fact, if the uncertainty is of random nature, then the associated distribution is unique.

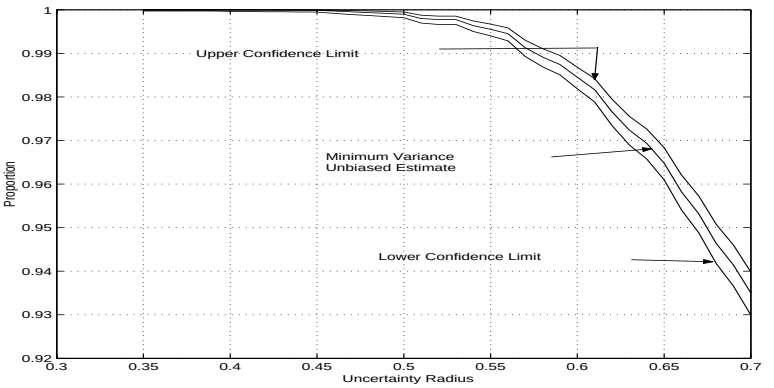

FIG. 8. *Robustness degradation curve (reuse factor = 5).*

Based on Theorem 2, we can apply the sample reuse algorithm to estimate $\mathbb{P}(r)$ for $r \in [0, b]$, from which we can construct the lower bounds for $\Pr\{G(\mathbf{\Delta})$ guarantees $\mathbf{P} \mid \mathbf{\Delta} \in \mathcal{B}(r)\}$.

7. Conclusion. We develop a fast algorithm for computing the robustness degradation function which overcomes the computational complexity and conservatism issue of the deterministic worst-case methods. We also demonstrate that our algorithm can provide efficient solutions for a wide variety of robustness analysis problems which are intractable by the deterministic worst-case methods. We derive our algorithm from the worst-case deterministic framework and also show that the algorithm is applicable from a probabilistic perspective.

Appendix. Proof of Theorem 1.

The following lemma follows essentially from the definition of volume function vol(.).

LEMMA 3. *Let* $X = \{\Delta \in \mathbf{C}^{n\times m} : \bar{\sigma}(\Delta) \le r\}$ *and* $Y = \{\Delta \in \mathbf{C}^{m\times n} : \bar{\sigma}(\Delta) \le r\}$. *Let* $Z = \{\Delta \in \mathbf{R}^{n\times m} : \bar{\sigma}(\Delta) \le r\}$ *and* $W = \{\Delta \in \mathbf{R}^{m\times n} : \bar{\sigma}(\Delta) \le r\}$. *Then* $\mathrm{vol}(X) = \mathrm{vol}(Y)$ *and* $\mathrm{vol}(Z) = \mathrm{vol}(W)$.

LEMMA 4. *Let* $m \ge n$. *Define spectral norm ball* $\mathcal{B}_\sigma^C(r) = \{\Delta \in \mathbf{C}^{n\times m} : \bar{\sigma}(\Delta) \le r\}$ *and spectral norm ball* $\mathcal{B}_\sigma^R(r) = \{\Delta \in \mathbf{R}^{n\times m} : \bar{\sigma}(\Delta) \le r\}$. *Then* $\mathrm{vol}(\mathcal{B}_\sigma^C(r)) = \mathrm{vol}(\mathcal{B}_\sigma^C(1))r^d$ *with* $d = 2mn$ *and* $\mathrm{vol}(\mathcal{B}_\sigma^R(r)) = \mathrm{vol}(\mathcal{B}_\sigma^R(1))r^d$ *with* $d = mn$.

Proof. By Theorem 1 of [8], we have

$$\frac{\Upsilon_C}{\mathrm{vol}(\mathcal{B}_\sigma^C(r))} \int_{r\ge\sigma_1>\sigma_2>\cdots>\sigma_n>0} \prod_{i=1}^{n} \sigma_i^{2(m-n)+1} \times \prod_{1\le i<k\le n} (\sigma_i^2 - \sigma_k^2)^2 \, d\sigma_1 d\sigma_2 \cdots d\sigma_n = 1$$

with $\Upsilon_C = \frac{2^n \pi^{mn}}{\prod_{k=1}^{n}(n-k)!(m-k)!}$. Performing a change of variables with $x_i = \frac{\sigma_i}{r}$ for $i = 1, \ldots, n$, we have

$$\frac{r^{2mn}\Upsilon_C}{\mathrm{vol}(\mathcal{B}_\sigma^C(r))} \int_{1\ge x_1>x_2>\cdots>x_n>0} \prod_{i=1}^{n} x_i^{2(m-n)+1} \times \prod_{1\le i<k\le n} (x_i^2 - x_k^2)^2 \, dx_1 dx_2 \cdots dx_n = 1.$$

Thus

$$\mathrm{vol}(\mathcal{B}_\sigma^C(1)) = \Upsilon_C \int_{1\geq x_1>x_2>\cdots>x_n>0} \prod_{i=1}^{n} x_i^{2(m-n)+1} \times \prod_{1\leq i<k\leq n} (x_i^2 - x_k^2)^2 \, dx_1 dx_2 \cdots dx_n,$$

and

$$\mathrm{vol}(\mathcal{B}_\sigma^C(r)) = \mathrm{vol}(\mathcal{B}(1))\, r^{2mn}.$$

Similarly, by Theorem 2 of [8], we can show that $\mathrm{vol}(\mathcal{B}_\sigma^R(r)) = \mathrm{vol}(\mathcal{B}_\sigma^R(1))r^d$ with $d = mn$. □

LEMMA 5. *$\mathrm{vol}(\mathcal{B}(r)) = \mathrm{vol}(\mathcal{B}(1))r^d$ where $d = n$ for l_p ball $\mathcal{B}_p(r)$ and homogeneous star-shaped bounding set $\mathcal{B}_H(r)$; and $d = \sum_{i=1}^{s} \kappa(q_i) + \sum_{j=1}^{c} \kappa(\Delta_j)$ for spectral norm ball $\mathcal{B}_\sigma(r)$.*

Proof. The truth is obvious for cases of an l_p ball and homogeneous star-shaped bounding set. To prove the lemma for the case of a spectral norm ball, we need to apply Lemmas 3 and 4. □

LEMMA 6. *For $i = 1, \ldots, l-1$,*

$$\mathcal{E}\left[\mathbf{n}_{i+1}\right] = N - \sum_{j=1}^{i} \left(\frac{r_{i+1}}{r_j}\right)^d \mathcal{E}\left[\mathbf{n}_i\right].$$

Proof. Let $q^1, q^2, \ldots, q^{\mathbf{n}_j}$ be the samples generated on r_j. For $l = 1, \ldots, \mathbf{n}_j$, define binomial random variable $X_{j,i+1}^l$ such that

$$X_{j,i+1}^l := \begin{cases} 1 & \text{if } q^l \text{ fall in } \mathcal{B}(r_{i+1}), \\ 0 & \text{otherwise.} \end{cases}$$

By the rule of the sample reuse algorithm,

$$N = \mathbf{n}_{i+1} + \sum_{j=1}^{i} \sum_{l=1}^{\mathbf{n}_j} X_{j,i+1}^l.$$

Thus for $i = 1, \ldots, l-1$,

$$\begin{aligned} \mathcal{E}\left[\mathbf{n}_{i+1}\right] &= N - \sum_{j=1}^{i} \mathcal{E}\left[\sum_{l=1}^{\mathbf{n}_j} X_{j,i+1}^l\right] \\ &= N - \sum_{j=1}^{i} \sum_{n\in\Omega_{\mathbf{n}_j}} \sum_{l=1}^{n} \mathcal{E}\left[X_{j,i+1}^l \mid \mathbf{n}_j = n\right] \Pr\{\mathbf{n}_j = n\}, \end{aligned}$$

where $\Omega_{\mathbf{n}_j}$ denotes the sample space of $\mathbf{n}_j$. Since q^l is a random variable with uniform distribution over $\mathcal{B}(r_i)$, it follows from Lemma 5 that

$$\mathcal{E}[X_{j,i+1}^l \mid \mathbf{n}_j = n] = \frac{\mathrm{vol}(\mathcal{B}(r_{i+1}))}{\mathrm{vol}(\mathcal{B}(r_j))} = \left(\frac{r_{i+1}}{r_j}\right)^d.$$

Therefore,

$$\begin{aligned} \mathcal{E}\left[\mathbf{n}_{i+1}\right] &= N - \sum_{j=1}^{i} \sum_{n\in\Omega_{\mathbf{n}_j}} n \left(\frac{r_{i+1}}{r_j}\right)^d \Pr\{\mathbf{n}_j = n\} \\ &= N - \sum_{j=1}^{i} \left(\frac{r_{i+1}}{r_j}\right)^d \sum_{n\in\Omega_{\mathbf{n}_j}} n \Pr\{\mathbf{n}_j = n\} \end{aligned}$$

$$= N - \sum_{j=1}^{i} \left(\frac{r_{i+1}}{r_j}\right)^d \mathcal{E}[\mathbf{n}_i]. \qquad \square$$

LEMMA 7. *For* $i = 2, \cdots, l$,

$$\mathcal{E}[\mathbf{n}_i] = N - N\left(\frac{r_i}{r_{i-1}}\right)^d.$$

Proof. We use induction. Obviously,

$$\mathcal{E}[\mathbf{n}_1] = N.$$

By Lemma 6, we get

$$\mathcal{E}[\mathbf{n}_2] = N - N\left(\frac{r_2}{r_1}\right)^d.$$

Suppose it is true that

$$\mathcal{E}[\mathbf{n}_i] = N - N\left(\frac{r_i}{r_{i-1}}\right)^d.$$

Then

$$\begin{aligned}
\sum_{j=1}^{i} \left(\frac{r_{i+1}}{r_j}\right)^d \mathcal{E}[\mathbf{n}_j] &= \sum_{j=1}^{i} \left(\frac{r_{i+1}}{r_j}\right)^d \left[N - N\left(\frac{r_j}{r_{j-1}}\right)^d\right] \\
&= \sum_{j=1}^{i} \left[N\left(\frac{r_{i+1}}{r_j}\right)^d - N\left(\frac{r_{i+1}}{r_{j-1}}\right)^d\right] \\
&= N\left(\frac{r_{i+1}}{r_i}\right)^d.
\end{aligned}$$

It follows from Lemma 6 that

$$\begin{aligned}
\mathcal{E}[\mathbf{n}_{i+1}] &= N - \sum_{j=1}^{i} \left(\frac{r_{i+1}}{r_j}\right)^d \mathcal{E}[\mathbf{n}_j] \\
&= N - N\left(\frac{r_{i+1}}{r_i}\right)^d.
\end{aligned}$$

The proof of Lemma 7 is thus completed by induction. $\square$

Now we are in the position to prove Theorem 1. By Lemmas 6 and 7, we have

$$\mathcal{E}\left[\sum_{i=1}^{l} \mathbf{n}_i\right] = N + \sum_{i=2}^{l} \left[N - N\left(\frac{r_i}{r_{i-1}}\right)^d\right] = Nl - N \sum_{i=2}^{l} \left[1 - \left(\frac{r_i}{r_{i-1}}\right)^d\right].$$

Therefore,

$$\begin{aligned}
\mathcal{F}_{reuse} &= \frac{Nl}{\mathcal{E}[\sum_{i=1}^{l} \mathbf{n}_i]} \\
&= \frac{l}{l - \sum_{i=2}^{l} \left(\frac{r_i}{r_{i-1}}\right)^d}
\end{aligned}$$

and thus the proof of Theorem 1 is completed. $\square$

STOCHASTIC FOREST STAND VALUE AND OPTIMAL TIMBER HARVESTING*

LUIS H. R. ALVAREZ†

Abstract. We consider a Faustmann timber harvesting problem arising in the literature on rational forest management by modeling the value of the harvested resource as a time homogeneous, regular, and linear diffusion. We state a set of easily verifiable general conditions under which the existence and uniqueness of an optimal cutting value and, consequently, an optimal impulse control, are guaranteed. We also present a set of conditions under which increased volatility increases both the value and the optimal harvesting threshold at which the irreversible harvesting strategy is exercised.

Key words. optimal rotation, impulse control, recursive optimal stopping, diffusions, minimal r-excessive mappings

AMS subject classifications. 93E20, 60G40, 60J65, 49J40, 35R35

DOI. 10.1137/S0363012901393456

1. Introduction. Assume that a forest stand value is subject to a given potentially state-dependent and random growth rate (i.e., the growth dynamics are stochastic). Assume also that the discount rate (i.e., the rate of intertemporal preference) is a known exogenously determined constant. Given these assumptions, consider now the following problem: When should the forest stand be optimally harvested? Put somewhat differently, what is the optimal rotation period of the forest stand? This problem, which is known as the optimal rotation problem or the so-called *Faustmann problem* (or the *ongoing rotation problem*; cf. [27]) is probably the best known impulse control problem in natural resource economics (see, for example, [9], [14], [15], [17], [19], [23], [26], [27], [31], [32], [33], [34], and [36]). The Faustmannian tradition relies on the net present value (NPV) of all future harvests from the present up to a potentially infinite future, the relevance of which has been postulated on the seminal study [28], where the economic foundations of different approaches to the optimal rotation problem were also discussed.

While attempts to both characterize and solve this general stochastic rotation problem have been made (cf. [15], [27], [32], [34], and [35]), nobody has yet established easily verifiable sufficient conditions under which the general optimal rotation problem is solvable. This is somewhat surprising especially in light of the vast literature on the classical theory of linear diffusions and its representation theorems of r-excessive mappings and Markovian functionals in general (see, for example, [10], [18], and [20]). Moreover, given the recent studies emphasizing the mean reverting nature of commodity prices (cf. [16], [17], [30], and [34]) it is clear that a general analysis valid for a broad class of stochastic models of the value of a forest stand could provide us with valuable information on the general properties of the optimal rotation policy and its value.

Motivated by these arguments, we plan to consider in this study the general

†Department of Economics, Quantitative Methods in Management, Turku School of Economics and Business Administration, FIN-20500 Turku, Finland (luis.alvarez@tukkk.fi).

stochastic optimal ongoing rotation problem when the value of the forest stand is assumed to evolve according to a general time homogeneous, regular, and linear diffusion. By relying on a combination of the classical theory of diffusions, stochastic calculus, and ordinary nonlinear programming, *we first state, in terms of the growth rate of the value of the forest stand, the reforestation costs, and the discount rate, a set of easily verifiable conditions under which the considered stochastic impulse control problem is solvable* (see [1], [2], [4], and [5] for a similar approach to singular control and [7] and [8] for a similar approach to optimal stopping). In economic terms, our condition essentially requires that the appreciation rate of the NPV of the forest stand has to be declining and negative for sufficiently high values of the forest stand. Since this condition is satisfied by all mean reverting diffusion models for the value of a forest stand, we find that our conditions imply that the ongoing rotation problem is always solvable in such a case. *We then present an algebraic equation from which the unique optimal cutting value can be determined.* Interestingly, and in line with previous studies of optimal stopping and singular stochastic control, a direct implication of this equation is that the smooth-fit principle can be viewed as an ordinary first order necessary condition for an optimum (cf. [1], [2], [5], [8], and [11]). Given the optimal cutting value, we then derive the expected cumulative present value of the future harvests from the present up to an arbitrarily distant future in terms of the increasing minimal r-excessive mapping for the controlled diffusion. In this way, we generalize previous results obtained in studies relying on explicit diffusion models for the value growth of the forest stand (cf. [15], [27], [32], [34], and [35]). Given our general results, we are able to present *a representation for the Faustmann formula in terms of the underlying diffusion process characterizing the value growth of the forest stand.* In line with previous studies of the optimal rotation problem (see, for example, [9], [32], and [34]), we also establish a close connection between the optimal ongoing rotation problem and an associated optimal stopping problem, which is also known as the *Wicksellian rotation problem* (i.e., the *single rotation problem* where the cutting decision is viewed as a once-and-for-all strategy; cf. [27]). In line with the results obtained in explicit models, we are able to prove that *the optimal cutting value in the single rotation case dominates the optimal cutting value in the infinite rotation case.* Consequently, we are able to confirm that *the required exercise premium is typically higher in the single rotation model than in the ongoing rotation model.* Moreover, we also consider the impact of increased volatility on the value of the optimal rotation problem and show that typically *increased volatility increases the expected cumulative present value of the future harvests and expands the set where harvesting is suboptimal and thus is postponed into the future.* Consequently, we are able to confirm that increased volatility increases the required exercise premium of a rational harvester and therefore postpones the optimal exercise of the irreversible policy.

It is at this point worth mentioning that there are many different approaches to the optimal rotation problem in the presence of uncertainty (for a survey of deterministic models, see [28]; see also [14] and [19]). In the studies [9] and [31], the stumpage price process is assumed to be stochastically fluctuating but differentiable with respect to time. Consequently, the nondifferentiability of diffusion processes is avoided and both the optimal policy and its value are derived by relying on standard optimization techniques. One of the major advantages of that approach is that it can be applied to establishing that the relationship between increased uncertainty and the optimal rotation period is positive (by relying on arguments first derived by Sandmo in [29]). However, it also simultaneously limits the class of stochastic processes which

can actually be applied for such a modeling effort, since one is left with the problem of finding a stochastic model satisfying the required differentiability properties. The analysis of the above studies was later extended to the diffusion case in, among others, [33] and [36]. However, in those studies the rotation problem is considered by relying on a discrete approximation of the original continuous time diffusion model (the authors rely on the Cox–Ross–Rubinstein-type binomial approximation of a diffusion). In this way the optimal policy and its value can be derived numerically by relying on standard recursive dynamic programming techniques. Another approach to the rotation problem relies on option valuation techniques and models the value of the optimal policy as a European forward contract written on a dividend paying asset and with known maturity (the rotation length). For studies relying on this approach and its variants, see, for example, [15], [17], [26], and [27]. Finally, the authors of [35] consider the optimal rotation problem under the assumption that both the timber volume and the timber price evolve according to two potentially correlated geometric Brownian motions. They consider the rotation strategies under different criteria and present a comparison of the various policies.

The contents of this study are as follows. In section 2 we present the considered optimal rotation problem and prove a set of useful results needed for the verification of optimality and the analysis of the comparative static properties of the value. In section 3 we then solve the considered optimal impulse control problem and present an associated optimal stopping problem when the increasing minimal r-excessive mapping for the controlled diffusion is convex. Section 4 extends our results to the case where the increasing minimal r-excessive mapping for the controlled diffusion is not necessarily globally convex. Our results are then explicitly illustrated in section 5 in a model based on logistic growth subject to a stochastic intrinsic growth rate. Finally, some concluding comments are presented in section 6.

2. The optimal rotation problem. Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, \mathbb{P})$ be a filtered probability space, and assume that the dynamics of the controlled diffusion process (i.e., the *stochastic forest stand value growth*) are described up to extinction by the generalized Itô equation (cf. [34])

$$X_t^\nu = x + \int_0^t \mu(X_s^\nu)ds + \int_0^t \sigma(X_s^\nu)dW_s - \sum_{\tau_k \leq t} \zeta_k, \quad 0 \leq t \leq \tau^\nu(0), \tag{2.1}$$

where $\tau^\nu(0) = \inf\{t \geq 0 : X_t^\nu \leq 0\} \leq \infty$ denotes the possibly finite first exit time from the state-space $(0, \infty)$ (i.e., *the extinction date*) and $\mu : \mathbb{R}_+ \mapsto \mathbb{R}$ and $\sigma : \mathbb{R}_+ \mapsto \mathbb{R}_+$ are known sufficiently smooth (at least continuous) mappings for guaranteeing the existence of a solution for (2.1). In order to avoid interior singularities, we also assume that $\sigma(x) > 0$ for all $x \in (0, \infty)$. As in [34], a *cutting strategy* for the system (2.1) is a possibly finite sequence

$$\nu = (\tau_1, \tau_2, \ldots, \tau_k, \ldots; \zeta_1, \zeta_2, \ldots, \zeta_k, \ldots)_{k\leq N} \quad (N \leq \infty),$$

where $\{\tau_k\}_{k\leq N}$ is an increasing sequence of $\mathcal{F}_t$-stopping times (known as the *cutting times*) for which $\tau_1 \geq 0$, and $\{\zeta_k\}_{k\leq N}$ denote a sequence of nonnegative impulses (i.e., $\zeta_k \geq 0$ for all $k \leq N$, which can be interpreted as the *cutting values*) exerted at the corresponding intervention times $\{\tau_k\}_{k\leq N}$, respectively. In line with previous studies of the optimal rotation problem, we assume that whenever the cutting decision is made, the system is instantaneously driven to a known state $x_0 \in \mathbb{R}_+$. More precisely, if the forest stand is cut when the system is in the state $y \in \mathbb{R}_+$, it is instantaneously

driven to the new lower state $y-(y-x_0)=x_0$ (i.e., $y-x_0$ is the size of the impulse). Consequently, *given the optimal threshold value $y^*_{x_0}$ at which the irreversible cutting decision is made, the subsequent value of the implemented impulse control is always a known constant.* That is, if the initial state of the system is above the optimal cutting value $y^*_{x_0}$, then the value of the first impulse is $(x-x_0)^+$. The size of the subsequent impulses is then always a constant $y^*_{x_0}-x_0$ (i.e., $\zeta_k=y^*_{x_0}-x_0$ for $k\geq 2$). We denote as $\mathcal{V}$ the class of *admissible impulse controls* $\nu=(\tau_1,\tau_2,\ldots,\ldots;\zeta_1,\zeta_2,\ldots)_{k\leq N}$ and assume that $\tau_k\to\tau^\nu(0)$ almost surely for all $\nu\in\mathcal{V}$ and $x\in\mathbb{R}_+$. In accordance with the economic and biologic literature considering impulse control models, we assume that the upper boundary ∞ is *natural for the controlled diffusion in the absence of regulation.* Since the unregulated diffusion dominates the controlled diffusion almost surely, we find that the controlled diffusion is never expected to become arbitrarily great in finite time. If the lower boundary is regular for the unregulated diffusion, we assume that it is killing (in line with the concept of *extinction*). As usual, we denote as

$$\mathcal{A}=\frac{1}{2}\sigma^2(x)\frac{d^2}{dx^2}+\mu(x)\frac{d}{dx}$$

the differential operator representing the infinitesimal generator of the controlled diffusion. Given the stochastic forest stand value growth described in (2.1) and our assumptions, define *the expected cumulative NPV of all future harvests from the present up to a potentially infinite future* as

$$J^\nu(x)=\mathbf{E}_x\left[\sum_{k=1}^{N}e^{-r\tau_k}(X^\nu_{\tau_k}-c)\right], \tag{2.2}$$

where $c>0$ denotes the reforestation cost of the forest stand. Given the definition of $J^\nu(x)$, we consider the optimal rotation problem

$$V(x)=\sup_{\nu\in\mathcal{V}}J^\nu(x),\quad x\in\mathbb{R}_+, \tag{2.3}$$

and to determine an admissible cutting policy $\nu^*\in\mathcal{V}$ for which

$$J^{\nu^*}(x)=V(x),\quad x\in\mathbb{R}_+.$$

That is, we plan to consider and determine the rotation policy maximizing the expected cumulative NPV of the future harvests from the present up to a potentially arbitrarily distant future.

Denote now as X_t the controlled diffusion in the absence of interventions. For the sake of boundedness, we will assume throughout this study that

$$\mathbf{E}_x[e^{-rt}(X_t-c);t<\tau(0)]<\infty$$

for all $(t,x)\in\mathbb{R}^2_+$. Given our assumptions above, we now define the value of the associated single rotation (Wicksellian) problem as

$$\bar{V}(x)=\sup_{\tau}\mathbf{E}_x\left[e^{-r\tau}(X_\tau-c)\right], \tag{2.4}$$

where τ is an arbitrary $\mathcal{F}_t$-stopping time.

In line with the standard literature on diffusion processes and their resolvent operators, we denote as $\mathcal{L}^1(\mathbb{R}_+)$ the class of measurable mappings $f : \mathbb{R}_+ \mapsto \mathbb{R}$ satisfying the uniform integrability condition

$$\mathbf{E}_x \int_0^{\tau(0)} e^{-rs} |f(X_s)| ds < \infty,$$

where $\tau(0) = \inf\{t \geq 0 : X_t \leq 0\}$. Given the class $\mathcal{L}^1(\mathbb{R}_+)$, we define for $f \in \mathcal{L}^1(\mathbb{R}_+)$ the (resolvent) functional $(R_r f) : \mathbb{R}_+ \mapsto \mathbb{R}$ as

$$(R_r f)(x) = \mathbf{E}_x \int_0^{\tau(0)} e^{-rs} f(X_s) ds.$$

As is well known from the literature on linear diffusions, if $f \in \mathcal{L}^1(\mathbb{R}_+)$, then

$$(R_r f)(x) = B^{-1}\varphi(x) \int_0^x \psi(y) f(y) m'(y) dy + B^{-1}\psi(x) \int_x^\infty \varphi(y) f(y) m'(y) dy,$$

where $\psi(x)$ denotes the increasing and $\varphi(x)$ the decreasing fundamental solution of the ordinary second order differential equation $(\mathcal{A}u)(x) = ru(x)$ (defined on the domain of the operator of the diffusion $\{X_t; t \in [0, \tau(0))\}$; see [10, pp. 18–20] for a thorough characterization of the fundamental solutions and the Green function of a linear diffusion), $B = \frac{\psi'(x)}{S'(x)}\varphi(x) - \frac{\varphi'(x)}{S'(x)}\psi(x) > 0$ denotes the constant (with respect to the scale) Wronskian determinant,

$$S'(x) = \exp\left(-\int^x \frac{2\mu(y)}{\sigma^2(y)} dy\right)$$

denotes the density of the scale function S of X, and

$$m'(x) = \frac{2}{\sigma^2(x) S'(x)}$$

denotes the density of the speed measure m of X. It is worth pointing out that since ∞ was assumed to be natural, we know that $\lim_{x\to\infty} \psi(x) = \infty$, $\lim_{x\to\infty} \psi'(x)/S'(x) = \infty$, $\lim_{x\to\infty} \varphi(x) = 0$, and $\lim_{x\to\infty} \varphi'(x)/S'(x) = 0$. It is also worth pointing out that the fundamental solutions $\psi(x)$ and $\varphi(x)$ constitute the minimal r-excessive mappings for the underlying diffusion $\{X_t; t \in [0, \tau(0))\}$ in the sense that any nontrivial r-excessive mapping for $\{X_t; t \in [0, \tau(0))\}$ can be expressed in terms of these mappings (an integral representation of r-excessive mappings; cf. [10, p. 32]). Before proceeding any further in our analysis, we first prove the following.

LEMMA 2.1. *Assume that $\theta \in \mathcal{L}^1(\mathbb{R}_+)$, where $\theta : \mathbb{R}_+ \mapsto \mathbb{R}$ is defined as $\theta(x) = \mu(x) - rx$ (the net value appreciation rate of X). Then, for all $x \in \mathbb{R}_+$ we have that*

$$\psi''(x) = \frac{2S'(x)}{\sigma^2(x)} \left[r \int_0^x \psi(y)\theta(y) m'(y) dy - \theta(x) \frac{\psi'(x)}{S'(x)} \right]. \tag{2.5}$$

In particular, if 0 is unattainable for X, then

$$\psi''(x) = \frac{2rS'(x)}{\sigma^2(x)} \int_0^x \psi(y)(\theta(y) - \theta(x)) m'(y) dy. \tag{2.6}$$

Proof. As in [3] and [6], we find by applying Dynkin's theorem to the identity mapping $x \mapsto x$ that for all $x \in (a,b) \subseteq (0,\infty)$ we have that

$$\mathbf{E}_x\left[e^{-r\tau^*}X_{\tau^*}\right] = x + \mathbf{E}_x\int_0^{\tau^*} e^{-rs}\theta(X_s)ds, \tag{2.7}$$

where $\tau^* = \inf\{t \geq 0 : X_t \notin (a,b)\}$ denotes the first exit time of the diffusion X from the set (a,b). It is well known from the classical theory of diffusions that (2.7) can be rewritten as

$$a\frac{\hat{\varphi}(x;b)}{\hat{\varphi}(a;b)} + b\frac{\hat{\psi}(x;a)}{\hat{\psi}(b;a)} = x + \int_a^b \tilde{G}(x,y)\theta(y)m'(y)dy, \tag{2.8}$$

where

$$\tilde{G}(x,y) = \begin{cases} \tilde{B}^{-1}\hat{\varphi}(x;b)\hat{\psi}(y;a), & x \geq y, \\ \tilde{B}^{-1}\hat{\varphi}(y;b)\hat{\psi}(x;a), & x \leq y, \end{cases}$$

denotes the Green function of the diffusion X killed at a and b,

$$\hat{\psi}(x;a) = \psi(x) - \frac{\psi(a)}{\varphi(a)}\varphi(x),$$

$$\hat{\varphi}(x;b) = \varphi(x) + \frac{\varphi(b)}{\psi(b)}\psi(x),$$

and $\tilde{B} = B\varphi(a)/\hat{\varphi}(a;b) = B\psi(b)/\hat{\psi}(b;a)$ denotes the Wronskian of the fundamental solutions $\hat{\psi}(x;a)$ and $\hat{\varphi}(x;b)$. Standard differentiation of (2.8) now yields that

$$\begin{aligned} a\frac{\hat{\varphi}'(x;b)}{\hat{\varphi}(a,;b)} + b\frac{\hat{\psi}'(x;a)}{\hat{\psi}(b;a)} &= 1 + \tilde{B}^{-1}\hat{\varphi}'(x;b)\int_a^x \hat{\psi}(y;a)\theta(y)m'(y)dy \\ &\quad + \tilde{B}^{-1}\hat{\psi}'(x;a)\int_x^b \hat{\varphi}(y;b)\theta(y)m'(y)dy. \end{aligned}$$

Dividing this equation first with the term $\hat{\psi}'(x;a)$ and reordering terms then yield

$$\begin{aligned} \frac{1}{\hat{\psi}'(x;a)} &= \frac{a\hat{\varphi}'(x;b)}{\hat{\psi}'(x;a)\hat{\varphi}(a;b)} + \frac{b}{\hat{\psi}(b;a)} - \tilde{B}^{-1}\frac{\hat{\varphi}'(x;b)}{\hat{\psi}'(x;a)}\int_a^x \hat{\psi}(y;a)\theta(y)m'(y)dy \\ &\quad - \tilde{B}^{-1}\int_x^b \hat{\varphi}(y;b)\theta(y)m'(y)dy. \end{aligned}$$

Differentiating this equation with respect to x and observing that

$$\frac{d}{dx}\left[\frac{\hat{\varphi}'(x;b)}{\hat{\psi}'(x;a)}\right] = \frac{2r\tilde{B}S'(x)}{\sigma^2(x)\hat{\psi}'^2(x;a)}$$

then yield

$$\frac{\hat{\psi}''(x;a)}{\hat{\psi}'^2(x;a)} = \frac{2S'(x)}{\sigma^2(x)\hat{\psi}'^2(x;a)}\left[r\int_a^x \hat{\psi}(y;a)\theta(y)m'(y)dy - \theta(x)\frac{\hat{\psi}'(x;a)}{S'(x)} - \frac{arB}{\varphi(a)}\right]. \tag{2.9}$$

Equation (2.5) then follows from (2.9) after we notice that $\lim_{a\downarrow 0}\hat{\psi}(x;a) = \psi(x)$, $\lim_{a\downarrow 0}\hat{\psi}''(x;a) = \psi''(x)$, and $\lim_{a\downarrow 0} a/\varphi(a) = 0$ and invoke the assumption $\theta \in \mathcal{L}^1(\mathbb{R}_+)$. Equation (2.6) then follows from (2.5) after we notice that

$$\frac{\psi'(x)}{S'(x)} = r\int_0^x \psi(y)m'(y)dy$$

whenever 0 is unattainable for X. □

Lemma 2.1 presents an integral representation of the second derivative of the increasing fundamental solution $\psi(x)$. Two key consequences of this representation are now summarized in the following corollary.

COROLLARY 2.2. (A) *Assume that* 0 *is unattainable (i.e., either natural or entrance) for* X, *that* $\theta \in \mathcal{L}^1(\mathbb{R}_+)$, *and that there is a threshold* $\tilde{x} \in [0,\infty]$ *such that* $\mu(x) \le 0$ *for* $x \ge \tilde{x}$ *and* $\theta(x)$ *is nonincreasing on* $(0,\tilde{x})$. *Then* $\psi(x)$ *is strictly convex on* $\mathbb{R}_+$.

(B) *Assume that* 0 *is attainable (i.e., either regular or exit) for* X, *that* $\theta \in \mathcal{L}^1(\mathbb{R}_+)$, *that* $\lim_{x\downarrow 0}\mu(x) \le 0$, *and that there is a threshold* $\tilde{x} \in [0,\infty]$ *such that* $\mu(x) \le 0$ *for* $x \ge \tilde{x}$ *and* $\theta(x)$ *is nonincreasing on* $(0,\tilde{x})$. *Then* $\psi(x)$ *is strictly convex on* $\mathbb{R}_+$.

Proof. (A) Assume now that 0 is unattainable for X and that there is a threshold $\tilde{x} \in [0,\infty]$ such that $\mu(x) \le 0$ for $x \ge \tilde{x}$ and $\theta(x)$ is nonincreasing on $(0,\tilde{x})$. It is clear that the r-harmonicity of $\psi(x)$ implies that for all $x \in [\tilde{x},\infty)$ we have

$$\frac{1}{2}\sigma^2(x)\psi''(x) = r\psi(x) - \mu(x)\psi'(x) > 0,$$

since $\psi(x) > 0$, $\psi'(x) > 0$, and $\mu(x) \le 0$ on $[\tilde{x},\infty)$. On the other hand, the assumed monotonicity of $\theta(x)$ and (2.6) implies that $\psi''(x) > 0$ on $\mathbb{R}_+$, that is, that $\psi(x)$ is strictly convex on $\mathbb{R}_+$.

(B) As in the case of part (A), $\psi(x)$ is strictly convex on $[\tilde{x},\infty)$. Define the functional $I : \mathbb{R}_+ \mapsto \mathbb{R}$ as

$$I(x) = r\int_0^x \psi(y)\theta(y)m'(y)dy - \theta(x)\frac{\psi'(x)}{S'(x)}.$$

It is clear that

$$\lim_{x\downarrow 0} I(x) = -\lim_{x\downarrow 0}\mu(x)\frac{\psi'(x)}{S'(x)} \ge 0,$$

since $\psi'(x)/S'(x) > 0$ and $\lim_{x\downarrow 0}\mu(x) \le 0$. Assume now that $0 < x_1 < x_2 < \tilde{x}$. Then

$$\begin{aligned} I(x_2) - I(x_1) &= r\int_{x_1}^{x_2} \psi(y)\theta(y)m'(y)dy + \theta(x_1)\frac{\psi'(x_1)}{S'(x_1)} - \theta(x_2)\frac{\psi'(x_2)}{S'(x_2)} \\ &\ge r\theta(x_2)\int_{x_1}^{x_2} \psi(y)m'(y)dy + \theta(x_1)\frac{\psi'(x_1)}{S'(x_1)} - \theta(x_2)\frac{\psi'(x_2)}{S'(x_2)} \\ &= (\theta(x_1) - \theta(x_2))\frac{\psi'(x_1)}{S'(x_1)} \ge 0, \end{aligned}$$

proving that $I(x)$ is nondecreasing on the set where $\theta(x)$ is nonincreasing. Consequently, we find that $\psi''(x) > 0$ on $\mathbb{R}_+$, that is, that $\psi(x)$ is strictly convex on $\mathbb{R}_+$. □

Corollary 2.2 states a set of conditions under which the increasing minimal r-excessive mapping for the controlled diffusion $\{X_t; t \in [0, \tau(0))\}$ is strictly convex on $\mathbb{R}_+$. As we will later observe, the strict convexity of the increasing fundamental solution is useful when proving the existence and uniqueness of the optimal cutting policy and its value. Another auxiliary result which is helpful in proving the existence of an optimal exercise threshold in both the single rotation (Wicksellian) and the ongoing rotation (Faustmannian) case is now summarized in the following (extending the results obtained in Proposition 1 in [8]).

LEMMA 2.3. *Assume that there is a threshold* $\check{x} \in \mathbb{R}_+$ *such that* $\theta(x) + rc \gtreqless 0$ *when* $x \lesseqgtr \check{x}$. *Then there is a threshold* $\bar{y} = \operatorname{argmax}\{\frac{(x-c)}{\psi(x)}\} > \max(\check{x}, c)$ *satisfying the ordinary first order condition*

$$\psi(\bar{y}) = \psi'(\bar{y})(\bar{y} - c). \tag{2.10}$$

Moreover,

$$\frac{d}{dx}\left[\frac{x-c}{\psi(x)}\right] \gtreqless 0, \quad x \lesseqgtr \bar{y}.$$

In particular, $\bar{\tau} = \inf\{t \geq 0 : X_t \notin (0, \bar{y})\}$ *is the optimal stopping time and*

$$\bar{V}(x) = \psi(x) \sup_{y \geq x}\left[\frac{y-c}{\psi(y)}\right] = \begin{cases} x - c, & x \geq \bar{y}, \\ \frac{\psi(x)}{\psi'(\bar{y})}, & x < \bar{y}. \end{cases} \tag{2.11}$$

Proof. Since the mapping $x - c$ is bounded on any bounded and open interval $(0, y) \subset \mathbb{R}_+$, Dynkin's theorem implies that for all $x \in \mathbb{R}_+$ we have that

$$\mathbf{E}_x\left[e^{-r\tau(0,y)}(X_{\tau(0,y)} - c)\right] = x - c + \mathbf{E}_x \int_0^{\tau(0,y)} e^{-rs}(\theta(X_s) + rc)ds, \tag{2.12}$$

where $\tau(0, y) = \inf\{t \geq 0 : X_t \notin (0, y)\}$ and $y \in (0, \infty)$. It is well known from the classical theory of diffusions that for $x \in (0, y)$ (2.12) can be rewritten as

$$\begin{aligned}(y-c)\frac{\psi(x)}{\psi(y)} - c\frac{\bar{\varphi}(x)}{\bar{\varphi}(0)} &= x - c + B^{-1}\bar{\varphi}(x)\int_0^x \psi(t)(rc + \theta(t))m'(t)dt \\ &\quad + B^{-1}\psi(x)\int_x^y \bar{\varphi}(t)(rc + \theta(t))m'(t)dt,\end{aligned} \tag{2.13}$$

where $\bar{\varphi}(x) = \varphi(x) - \varphi(y)\psi(x)/\psi(y)$. Dividing (2.13) now with $\psi(x)$ and differentiating then yield

$$\frac{d}{dx}\left[\frac{x-c}{\psi(x)}\right] = \frac{S'(x)}{\psi^2(x)}\left[\frac{cB}{\bar{\varphi}(0)} + \int_0^x \psi(y)(rc + \theta(y))m'(y)dy\right].$$

Letting y tend to infinity in $\bar{\varphi}(x)$ and simplifying then yield

$$\psi(x) - \psi'(x)(x-c) = S'(x)\left[\frac{cB}{\varphi(0)} + \int_0^x \psi(y)(rc + \theta(y))m'(y)dy\right].$$

Since $S'(x) > 0$, it is sufficient to consider the behavior of the functional

$$I(x) = \frac{cB}{\varphi(0)} + \int_0^x \psi(y)(rc + \theta(y))m'(y)dy.$$

It is clear that $I(x) > 0$ as long as $x \leq \check{x}$. If $x > K > \check{x}$, then the mean value theorem implies that

$$I(x) = I(K) + \int_K^x \psi(y)(rc + \theta(y))m'(y)dy = I(K) + \frac{rc + \theta(\xi)}{r}\left[\frac{\psi'(x)}{S'(x)} - \frac{\psi'(K)}{S'(K)}\right],$$

where $\xi \in (K, x)$. Since $rc + \theta(\xi) < 0$ and $\lim_{x\to\infty} \psi'(x)/S'(x) = \infty$, we find that $\lim_{x\to\infty} I(x) = -\infty$. Since $I(x)$ is continuous on $\mathbb{R}_+$ and monotonically decreasing on $(\check{x}, \infty)$, we find that there is a unique threshold $\bar{y}$ for which $I(\bar{y}) = 0$ and, consequently, for which $\psi(\bar{y}) = \psi'(\bar{y})(\bar{y} - c)$.

Denote now the proposed value function as $\bar{V}_p(x)$. Since $\bar{V}_p(x) = \mathbf{E}_x[e^{-r\bar{\tau}}(X(\bar{\tau}) - c)]$ and the stopping time in (2.4) is arbitrary, we immediately find that $\bar{V}(x) \geq \bar{V}_p(x)$. In order to prove the opposite inequality, we first observe that the proposed value function is continuously differentiable on $\mathbb{R}_+$ and twice continuously differentiable on $\mathbb{R}_+\backslash\{\bar{y}\}$ and dominates the exercise payoff $(x - c)$ for all $x \in \mathbb{R}_+$. Moreover, since $(\mathcal{A}\bar{V}_p)(x) = r\bar{V}_p(x)$ on $(0, \bar{y})$ and

$$(\mathcal{A}\bar{V}_p)(x) - r\bar{V}_p(x) = \theta(x) + rc < 0$$

on $(\bar{y}, \infty)$, we find that $\bar{V}_p(x)$ is an r-excessive majorant of the exercise payoff $x - c$. However, since $V(x)$ is the least of such majorants, we find that $\bar{V}(x) \leq \bar{V}_p(x)$, completing the proof of our theorem. □

Lemma 2.3 states a set of weak conditions under which the single rotation problem (2.4) is solvable and under which the mapping $\psi(x) - \psi'(x)(x - c)$ has a unique root on $(0, \infty)$. In economic terms, Lemma 2.3 essentially states that if there is a threshold above which the expected present value of the NPV of the project is decreasing (that is, if there is a threshold above which the futures price effect dominates the option effect; cf. [22]), then there is a unique threshold at which the harvesting opportunity should be irreversibly exercised. As we will later observe, this finding plays an important role in the determination of the optimal threshold in the ongoing rotation case as well.

3. The nonlinear programming approach. Having presented the considered optimal rotation problem and a set of auxiliary results, it is our purpose to now solve the stochastic impulse control problem (2.3) explicitly. It is now clear that if there is a state $y \in \mathbb{R}_+$ at which the diffusion is instantaneously driven to the lower state $x_0 \in (0, y)$ (a *suboptimal impulse control*), then for all $x < y$ we have that the value of such a cutting strategy reads as

$$\begin{aligned} F_y(x) &= \mathbf{E}_x\left[e^{-r\tau(0,y)}\left(X_{\tau(0,y)} - c + F_y(x_0)\right)\right] \\ &= (y - c + F_y(x_0))\,\frac{\psi(x)}{\psi(y)}, \end{aligned} \tag{3.1}$$

where $\tau(0, y) = \inf\{t \geq 0 : X_t \geq y\}$ and $\psi : \mathbb{R}_+ \mapsto \mathbb{R}_+$ denotes the increasing fundamental solution of the ordinary second order differential equation $(\mathcal{A}u)(x) = ru(x)$ subject to the boundary condition $\psi(0) = 0$ whenever 0 is a regular boundary for X_t. It is now clear from (3.1) that letting x tend to y yields the *value-matching condition*

$$F_y(y) = y - c + F_y(x_0). \tag{3.2}$$

Similarly, letting $x \downarrow x_0$ in (3.1) then yields that

$$F_y(x_0) = (y - c + F_y(x_0))\,\frac{\psi(x_0)}{\psi(y)},$$

implying that

$$F_y(x_0) = \frac{\psi(x_0)(y-c)}{\psi(y)-\psi(x_0)}. \tag{3.3}$$

Plugging (3.3) into (3.1) then yields that for all $x \in (0,y)$ we have that

$$F_y(x) = \frac{\psi(x)(y-c)}{\psi(y)-\psi(x_0)}, \tag{3.4}$$

which can be rewritten as

$$F_y(x) = \frac{\mathbf{E}_x[e^{-r\tau(y)}(X_{\tau(y)}-c)]}{1-\mathbf{E}_{x_0}[e^{-r\tau(y)}]},$$

where $\tau(y) = \inf\{t \geq 0 : X_t = y\}$. Consequently, we find that for all potentially suboptimal rotation policies described in the beginning of this section the expected cumulative present value of the future harvests from the present up to a potentially infinite future reads as

$$F_y(x) = \begin{cases} x - c + \psi(x_0)g(y), & x \geq y, \\ \psi(x)g(y), & x < y, \end{cases} \tag{3.5}$$

where

$$g(y) = \frac{(y-c)}{\psi(y)-\psi(x_0)}.$$

Standard differentiation now yields that

$$g'(y) = \frac{[\psi(y)-\psi(x_0)-\psi'(y)(y-c)]}{(\psi(y)-\psi(x_0))^2}. \tag{3.6}$$

Therefore, if a threshold $y^*_{x_0}$ maximizing the mapping $g(y)$ on the set (x_0,∞) exists, it has to satisfy the ordinary first order condition

$$\psi(y^*_{x_0}) = \psi(x_0) + \psi'(y^*_{x_0})(y^*_{x_0}-c). \tag{3.7}$$

Since

$$g''(y^*_{x_0}) = -\frac{\psi''(y^*_{x_0})}{\psi'(y^*_{x_0})(\psi(y^*_{x_0})-\psi(x_0))},$$

we find that $y^*_{x_0}$ can be a maximum of $g(y)$ on the set (x_0,∞) provided that the condition $\psi''(y^*_{x_0}) > 0$ is satisfied (i.e., the increasing fundamental solution has to be locally convex at the optimal threshold). Moreover, if a threshold $y^*_{x_0} \in (x_0,\infty)$ satisfying the necessary condition (3.7) exists, then $g(y^*_{x_0}) = 1/\psi'(y^*_{x_0})$ and, therefore,

$$F_{y^*_{x_0}}(x) = \begin{cases} x - c + \frac{\psi(x_0)}{\psi'(y^*_{x_0})}, & x \geq y^*_{x_0}, \\ \frac{\psi(x)}{\psi'(y^*_{x_0})}, & x < y^*_{x_0}. \end{cases} \tag{3.8}$$

It is at this point worth observing that dividing the necessary condition (3.7) with the term $\psi(y^*_{x_0})$ and reordering terms then yield

$$1 - \frac{\psi(x_0)}{\psi(y^*_{x_0})} = \frac{\psi'(y^*_{x_0})}{\psi(y^*_{x_0})}(y^*_{x_0}-c).$$

Since $x_0 < y^*_{x_0}$ and, consequently, $\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}] = \psi(x_0)/\psi(y^*_{x_0})$, we observe that the equation above can be rewritten as

$$1 - \mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}] = \frac{\psi'(y^*_{x_0})}{\psi(x_0)}\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}(X_{\tau(y^*_{x_0})} - c)].$$

A simple algebraic manipulation of this equation then yields that

$$\frac{\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}]}{\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}(X_{\tau(y^*_{x_0})} - c)]}\frac{r\psi(y^*_{x_0})}{\psi'(y^*_{x_0})} = \frac{r}{1 - \mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}]}. \tag{3.9}$$

Invoking now the r-harmonicity of the fundamental solution $\psi(x)$ then yields that $r\psi(y^*_{x_0}) = \mu(y^*_{x_0})\psi'(y^*_{x_0}) + \frac{1}{2}\sigma^2(y^*_{x_0})\psi''(y^*_{x_0})$ and, therefore, that (3.9) can be rewritten as

$$\frac{\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}B(X_{\tau(y^*_{x_0})})]}{\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}(X_{\tau(y^*_{x_0})} - c)]} = \frac{r}{1 - \mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}]}, \tag{3.10}$$

where $B(x) = \mu(x) + \frac{1}{2}\sigma^2(x)\psi''(x)/\psi'(x) = \mu(x) + \frac{1}{2}\sigma^2(x)\frac{d}{dx}\ln\psi'(x)$. *Equation* (3.10) *is the stochastic version of the well-known Faustmann formula for the optimal rotation period* (cf. [34]). As is clear from (3.10), the major difference between the stochastic and the deterministic version of the Faustmann formula is the term $\frac{1}{2}\sigma^2(x)\frac{\psi''(x)}{\psi'(x)}$ measuring the *required risk premium of the decision maker*. It is also clear that the deterministic Faustmann formula for the optimal rotation period can be obtained from (3.10) simply by letting $\sigma(x) \downarrow 0$. Given the results of Corollary 2.2, we can now prove the following.

COROLLARY 3.1. *Assume that the conditions of Corollary* 2.2 *are met. Then*

$$\frac{\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}\mu(X_{\tau(y^*_{x_0})})]}{\mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}(X_{\tau(y^*_{x_0})} - c)]} \leq \frac{r}{1 - \mathbf{E}_{x_0}[e^{-r\tau(y^*_{x_0})}]}. \tag{3.11}$$

Proof. Given the conditions of Corollary 2.2, $\psi(x)$ is strictly convex and, therefore, $B(x) \geq \mu(x)$ for all $x \in \mathbb{R}_+$. □

Although our analysis above demonstrates what an optimal policy has to satisfy whenever it exists, it is not clear whether an *optimal exercise threshold* (i.e., *the optimal cutting value*) exists. Fortunately, we can now prove the following.

LEMMA 3.2. *Assume that $x_0 < c$ and that the conditions of Corollary* 2.2 *and Lemma* 2.3 *are met. Then there is a unique threshold $y^*_{x_0} \in (c, \bar{y})$ satisfying* (3.7).

Proof. Consider now the mapping $f : \mathbb{R}_+ \mapsto \mathbb{R}$ defined as

$$f(y) = \psi(y) - \psi(x_0) - \psi'(y)(y - c).$$

Since $f'(y) = -\psi''(y)(y-c)$ and $\psi(x)$ is strictly convex given the conditions of Corollary 2.2, we find that $f'(y) \gtreqless 0$ when $y \lesseqgtr c$, implying that $c = \text{argmax}\{f(y)\}$, that is, that the mapping $f(y)$ attains its global maximum at c. Since $\psi(x)$ is increasing, we find that $f(c) = \psi(c) - \psi(x_0) > 0$. However, since

$$f(\bar{y}) = \psi(\bar{y}) - \psi(x_0) - \psi'(\bar{y})(\bar{y} - c) = -\psi(x_0) < 0$$

and $\psi(y) < \psi'(y)(y - c)$ for all $y > \bar{y}$ by Lemma 2.3, we find that the mapping $f(y)$ has a unique root $y^*_{x_0} \in (c, \bar{y})$. Combining this finding with (3.6) then implies that $y^*_{x_0} = \text{argmax}\{g(y)\}$. □

Lemma 3.2 essentially establishes that if the increasing fundamental solution is strictly convex, the conditions of Lemma 2.3 are met, and $x_0 < c$, then a unique threshold $y^*_{x_0}$ maximizing $g(y)$ always exists. It is worth noticing that if $x_0 > c$, then $f(c) = \psi(c) - \psi(x_0) < 0$ and, therefore, in that case the necessary condition (3.7) can never be satisfied. If $c = x_0$, then the equation $f(y) = 0$ has a unique root at c (as was noted in [34]). However, since $f(y)$ does not change sign in that case, we find that c constitutes an inflection point for $g(y)$ and, therefore, that no interior root maximizing $g(y)$ exists. It is worth pointing out that the results of Lemma 3.2 extend the results obtained in [34], since they show not only that an optimal threshold $y^*_{x_0}$ exists but that the threshold $y^*_{x_0}$ also maximizes the representation $F_y(x)$ on the *continuation set* $x \in (0, y)$ (i.e., in the *do-nothing region*). As we will observe in the subsequent analysis, the findings of Lemma 3.2 play a key role in the verification of the existence and uniqueness of an optimal cutting strategy. Before stating the main result of our study, we assume from now on that $x_0 < c$. Given this assumption, consider the *recursive optimal stopping problem*

$$H(x) = \sup_{\tau < \tau(0)} \mathbf{E}_x \left[e^{-r\tau} (X_\tau - c + H(x_0)) \right], \tag{3.12}$$

where τ is an arbitrary $\mathcal{F}_t$-stopping time satisfying the constraint $\tau < \tau(0)$. Since $H(x) \geq x - c + H(x_0)$ for all $x \in \mathbb{R}_+$, we find by letting $x \to x_0$ that especially $H(x_0) \geq x_0 - c + H(x_0)$, that is, that $x_0 \leq c$. Consequently, we find that the assumption $x_0 < c$ is actually a *consistency condition needed for the existence of a solution for the recursive stopping problem* (3.12). We can now prove the following.

LEMMA 3.3. *Assume that $x_0 < c$ and that the mapping $M : \mathbb{R}_+ \mapsto \mathbb{R}_+$ is r-excessive for the diffusion $\{X_t; t \in [0, \tau(0))\}$ and satisfies the recursive condition $M(x) \geq x - c + M(x_0)$ for all $x \in \mathbb{R}_+$. Then*

$$M(x) \geq \sup_{\tau < \tau(0)} \mathbf{E}_x \left[e^{-r\tau} (X_\tau - c + M(x_0)) \right]$$

for all $x \in \mathbb{R}_+$.

Proof. Our assumptions imply that for all $x \in \mathbb{R}_+$ we have that

$$M(x) \geq \mathbf{E}_x \left[e^{-r\tau_n} M(X_{\tau_n}) \right] \geq \mathbf{E}_x \left[e^{-r\tau_n} (X_{\tau_n} - c + M(x_0)) \right],$$

where $\tau_n = n \wedge \inf\{t \geq 0 : X_t \notin (n^{-1}, n)\} \wedge \tau$ is an almost surely finite $\mathcal{F}_t$-stopping time. Letting $n \to \infty$ and invoking Fatou's lemma then yield

$$M(x) \geq \mathbf{E}_x \left[e^{-r(\tau(0) \wedge \tau)} (X_{\tau(0) \wedge \tau} - c + M(x_0)) \right].$$

Since this inequality is valid for an arbitrary stopping time, it must be valid for the optimal one as well and, therefore,

$$M(x) \geq \sup_{\tau < \tau(0)} \mathbf{E}_x \left[e^{-r\tau} (X_\tau - c + M(x_0)) \right]$$

for all $x \in \mathbb{R}_+$. □

Having stated the auxiliary Lemma 3.3, we are now in a position to state our main results on the optimal cutting strategy and its value. These results are now summarized in the following.

THEOREM 3.4. *Assume that $x_0 < c$ and that the conditions of Lemma 3.2 are met. Then the optimal stopping time is $\tau(0, y^*_{x_0}) = \inf\{t \geq 0 : X_t \geq y^*_{x_0}\}$ and the value of*

the optimal stopping problem (3.12) *reads as* $H(x) = F_{y^*_{x_0}}(x)$, *where* $F_{y^*_{x_0}}(x)$ *is defined as in* (3.8) *and* $y^*_{x_0}$ *is the optimal exercise threshold satisfying* (3.7) *and defined as in Lemma* 3.2. *Moreover, the optimal cutting value is* $y^*_{x_0}$ *and* $V(x) = H(x) = F_{y^*_{x_0}}(x)$ *for all* $x \in \mathbb{R}_+$.

Proof. It is now clear that since the stopping time in (3.12) is arbitrary and the threshold $y^*_{x_0}$ exists and is unique under the conditions of our theorem, we have that $H(x) \geq F_{y^*_{x_0}}(x)$. To prove the opposite inequality, we first observe that the proposed value function $F_{y^*_{x_0}}(x)$ is nonnegative, that $F_{y^*_{x_0}} \in C^1(\mathbb{R}_+) \cap C^2(\mathbb{R}_+ \setminus \{y^*_{x_0}\})$, and that $\infty > \lim_{x \uparrow y^*_{x_0}} F''_{y^*_{x_0}}(x) = \frac{\psi''(y^*_{x_0})}{\psi'(y^*_{x_0})} \geq 0 = \lim_{x \downarrow y^*_{x_0}} F''_{y^*_{x_0}}(x)$ (i.e., $F_{y^*_{x_0}}(x)$ is stochastically of class $C^2(\mathbb{R}_+)$; cf. [12], [13], and [24, pp. 215–216]). Since $F_{y^*_{x_0}}(x)$ satisfies the ordinary second order linear differential equation $(\mathcal{A}F_{y^*_{x_0}})(x) = rF_{y^*_{x_0}}(x)$ on $(0, y^*_{x_0})$, it is sufficient to consider the sign of the mapping $D(x) = (\mathcal{A}F_{y^*_{x_0}})(x) - rF_{y^*_{x_0}}(x)$ on $(y^*_{x_0}, \infty)$. The convexity of the increasing fundamental solution implies that $r\psi(x) > \mu(x)\psi'(x)$ for all $x \in \mathbb{R}_+$. Thus we find that for all $x \in (y^*_{x_0}, \infty)$

$$\begin{aligned} D(x) &= \frac{1}{\psi'(x)} \left[\mu(x)\psi'(x) - r\psi'(x)(x-c) - r\frac{\psi(x_0)}{\psi'(y^*_{x_0})}\psi'(x) \right] \\ &\leq r \left[\frac{\psi(x)}{\psi'(x)} - (x-c) - \frac{\psi(x_0)}{\psi'(y^*_{x_0})} \right]. \end{aligned} \tag{3.13}$$

However, since $\psi(x) - \psi'(x)(x-c) < \psi(x_0)$ for all $x \in (y^*_{x_0}, \infty)$, we find that

$$D(x) \leq \frac{\psi(x_0)}{\psi'(x)} - \frac{\psi(x_0)}{\psi'(y^*_{x_0})} = \frac{\psi(x_0)(\psi'(y^*_{x_0}) - \psi'(x))}{\psi'(x)\psi'(y^*_{x_0})} \leq 0,$$

proving that $F_{y^*_{x_0}}(x)$ is r-superharmonic for the diffusion X (cf. [25, Chapter 10]). Since the class of nonnegative r-superharmonic mappings coincides with the class of r-excessive mappings, we find that $F_{y^*_{x_0}}(x)$ is r-excessive for the diffusion X. Consider now the difference

$$F_{y^*_{x_0}}(x) - (x - c + F_{y^*_{x_0}}(x_0)) = \begin{cases} 0, & x \geq y^*_{x_0}, \\ \frac{\psi(x) - \psi(x_0) - \psi'(y^*_{x_0})(x-c)}{\psi'(y^*_{x_0})}, & x < y^*_{x_0}, \end{cases}$$

and define the twice continuously differentiable mapping $\tilde{M} : \mathbb{R}_+ \mapsto \mathbb{R}$ as

$$\tilde{M}(x) = \frac{\psi(x) - \psi(x_0) - \psi'(y^*_{x_0})(x-c)}{\psi'(y^*_{x_0})}.$$

It is now clear that $\tilde{M}'(x) = (\psi'(x) - \psi'(y^*_{x_0}))/\psi'(y^*_{x_0})$ and that $\tilde{M}''(x) = \psi''(x)/\psi'(y^*_{x_0}) > 0$. Consequently, $y^*_{x_0}$ is a global minimum of the mapping $\tilde{M}(x)$. Since $\tilde{M}(y^*_{x_0}) = 0$, we find that $\tilde{M}(x) > 0$ for all $x \in \mathbb{R}_+$. Consequently, we find that $F_{y^*_{x_0}}(x)$ satisfies the conditions of Lemma 3.3 and, therefore, that

$$F_{y^*_{x_0}}(x) \geq \sup_{\tau < \tau(0)} \mathbf{E}_x \left[e^{-r\tau}(X_\tau - c + F_{y^*_{x_0}}(x_0)) \right].$$

However, since $F_{y^*_{x_0}}(x)$ satisfies the recursive relation

$$F_{y^*_{x_0}}(x) = \mathbf{E}_x \left[e^{-r\tau(0, y^*_{x_0})}(X_{\tau(0, y^*_{x_0})} - c + F_{y^*_{x_0}}(x_0)) \right],$$

we find that $\tau(0, y^*_{x_0})$ is optimal and that $F_{y^*_{x_0}}(x) \geq H(x)$, finally proving that $F_{y^*_{x_0}}(x) = H(x)$. It remains to prove that $F_{y^*_{x_0}}(x) = V(x)$. Since $X^\nu_t \in (0, y^*_{x_0})$ for all $t > 0$ under the proposed cutting policy, we find that

$$\lim_{k\to\infty} \mathbf{E}_x[e^{-r\tau_k} F_{y^*_{x_0}}(X^\nu_{\tau_k})] = 0.$$

Combining this finding with our previous results then proves that $F_{y^*_{x_0}}(x)$ satisfies the conditions of part (b) of Theorem 2.1 in [25] and, therefore, that $F_{y^*_{x_0}}(x) = V(x)$ as well. □

Theorem 3.4 states a set of conditions under which the stochastic impulse control problem (2.3) is solvable. In line with previous studies relying on explicit parametric models, we find that the optimal cutting strategy is such that there is a critical threshold $y^*_{x_0}$ at which the irreversible cutting decision should be exercised and at which the controlled diffusion is instantaneously driven to the lower state x_0. The results of Theorem 3.4 are general, since they show that an optimal cutting policy may exist even in the presence of extinction risk, i.e., in cases where the lower boundary may be attainable for the controlled diffusion X_t (this can be also interpreted as liquidation or default risk). This observation is of interest since *it demonstrates the surprising robustness of the modified Faustmann formula* (3.10). It is also worth pointing out that the proof of Theorem 3.4 also shows that $F_y(x)$ as defined in (3.5) is r-excessive for $\{X_t; t \in [0, \tau(0))\}$ and satisfies the inequality $F_y(x) \geq x - c + F_y(x_0)$ only when $y = y^*_{x_0}$. Consequently, we find that $F_{y^*_{x_0}}(x)$ is the unique r-excessive mapping for $\{X_t; t \in [0, \tau(0))\}$ satisfying the recursive condition (3.1) and the inequality $F_y(x) \geq x - c + F_y(x_0)$. An important consequence of the findings of Theorem 3.4 is now summarized in the following.

COROLLARY 3.5. *Assume that the conditions of Theorem* 3.4 *are met. Then the value of the ongoing rotation problem dominates the value of the single rotation problem; that is, then* $V(x) \geq \bar{V}(x)$.

Proof. As was demonstrated in the proof of Theorem 3.4, $V(x)$ is r-excessive for the diffusion $\{X_t; t \in [0, \tau(0))\}$ and satisfies the condition $V(x) \geq x - c + V(x_0)$ for all $x \in \mathbb{R}_+$. Consequently,

$$V(x) \geq \mathbf{E}_x\left[e^{-r\tau_n} V(X_{\tau_n})\right] \geq \mathbf{E}_x\left[e^{-r\tau_n}(X_{\tau_n} - c + V(x_0))\right] \geq \mathbf{E}_x\left[e^{-r\tau_n}(X_{\tau_n} - c)\right],$$

where $\tau_n = n \wedge \inf\{t \geq 0 : X_t \notin (n^{-1}, n)\} \wedge \tau$ is an almost surely finite $\mathcal{F}_t$-stopping time and τ is an arbitrary stopping time. Letting $n \to \infty$ and invoking Fatou's lemma then prove the alleged result. □

Corollary 3.5 shows the intuitively clear result that the value of the ongoing rotation (*Faustmann's tree cutting problem*) impulse control problem dominates the value of the associated single rotation (*Wicksell's tree cutting problem*) optimal stopping problem. The reason for this finding is clear in light of the recursive stopping problem (3.12). Interestingly, we find that the impulse control problem (2.3) is actually very closely related to the optimal stopping problem presented in Corollary 3.5. Our main result on this relationship is summarized in the following.

THEOREM 3.6. *Assume that the conditions of Theorem* 3.4 *are met and that the lower boundary* 0 *is exit, killing, or natural for* $\{X_t; t \in [0, \tau(0))\}$. *Then the following hold.*

(A) $\lim_{x_0 \downarrow 0} y^*_{x_0} = \bar{y} = \operatorname{argmax}\left\{\frac{x-c}{\psi(x)}\right\}$ *and* $\lim_{x_0\downarrow 0} V(x) = \bar{V}(x)$, *where* $\bar{V}(x)$ *is defined as in* (2.11).

(B) *The single rotation (Wicksellian) boundary* $\bar{y}$ *dominates the ongoing rotation (Faustmannian) boundary* $y^*_{x_0}$; *that is,* $\bar{y} > y^*_{x_0}$.

Proof. (A) If 0 is exit, killing, or natural for $\{X_t; t \in [0, \tau(0))\}$, then $\lim_{x_0 \downarrow 0} \psi(x_0) = 0$, implying the alleged results. The rest is a direct consequence of Proposition 1 in [8]. Part (B) then follows directly from Theorem 3.4. □

Theorem 3.6 shows that the associated optimal stopping problem (3.12) is solvable under the conditions of our Theorem 3.4 and under a set of suitable boundary conditions at 0. As one can also immediately observe from Theorem 3.6, the exercise threshold of the single rotation stopping problem dominates the threshold of the considered optimal rotation problem. Consequently, our results establish the intuitively clear result that the required exercise premium is higher in the single rotation problem than in the optimal rotation problem (2.3). *It is also worth observing that in line with the modified Faustmann rule* (3.10)*, the single rotation rule* (2.10) *can be rewritten as*

$$\frac{\mathbf{E}_x[e^{-r\tau(\bar{y})}B(X_{\tau(\bar{y})})]}{\mathbf{E}_x[e^{-r\tau(\bar{y})}(X_{\tau(\bar{y})} - c)]} = r, \tag{3.14}$$

implying that

$$\frac{\mathbf{E}_x[e^{-r\tau(\bar{y})}B(X_{\tau(\bar{y})})]}{\mathbf{E}_x[e^{-r\tau(\bar{y})}(X_{\tau(\bar{y})} - c)]} \leq \frac{r}{1 - \mathbf{E}_x[e^{-r\tau(\bar{y})}]}$$

and that given the conditions of Corollary 2.2 we have that

$$\frac{\mathbf{E}_x[e^{-r\tau(\bar{y})}\mu(X_{\tau(\bar{y})})]}{\mathbf{E}_x[e^{-r\tau(\bar{y})}(X_{\tau(\bar{y})} - c)]} \leq r \leq \frac{r}{1 - \mathbf{E}_x[e^{-r\tau(\bar{y})}]}. \tag{3.15}$$

Having considered the existence and uniqueness of a solution for the optimal rotation problem (2.3), it is our purpose to now consider the risk sensitivity of the optimal policy and its value. To accomplish this task, define the process

$$\tilde{X}_t^\nu = x + \int_0^t \mu(\tilde{X}_s^\nu)ds + \int_0^t \tilde{\sigma}(\tilde{X}_s^\nu)dW_s - \sum_{\tau_k \leq t} \zeta_k, \quad 0 \leq t \leq \tilde{\tau}^\nu(0), \tag{3.16}$$

where $\tilde{\tau}^\nu(0) = \inf\{t \geq 0 : \tilde{X}_t^\nu \leq 0\} \leq \infty$ and $\tilde{\sigma} : \mathbb{R}_+ \mapsto \mathbb{R}_+$ is a continuous mapping satisfying the inequality $\tilde{\sigma}(x) \leq \sigma(x)$ for all $x \in \mathbb{R}_+$. In accordance with our previous notation, we denote as

$$\tilde{\mathcal{A}} = \frac{1}{2}\tilde{\sigma}^2(x)\frac{d^2}{dx^2} + \mu(x)\frac{d}{dx}$$

the differential operator representing the infinitesimal generator of $\{\tilde{X}_t; t \in [0, \tilde{\tau}(0))\}$ and as $\tilde{V}(x)$ the value of the impulse control problem (2.3) in the presence of the less volatile process $\tilde{X}_t$. Our main results on the risk sensitivity of the optimal policy and its value are now summarized in the following.

THEOREM 3.7. *Assume that the conditions of Theorem* 3.4 *are met. Then,* $\tilde{V}(x) \leq V(x)$ *for all* $x \in \mathbb{R}_+$*. That is, increased volatility increases the value of the optimal rotation problem* (2.3).

Proof. Theorem 3.4 shows that $V(x)$ is convex and r-excessive for $\{X_t; t \in [0, \tau(0))\}$. Moreover, for all $x \in \mathbb{R}_+ \backslash \{y_{x_0}^*\}$ we have that

$$(\tilde{\mathcal{A}}V)(x) - rV(x) = ((\tilde{\mathcal{A}} - \mathcal{A} + \mathcal{A})V)(x) - rV(x) \leq \frac{1}{2}(\tilde{\sigma}^2(x) - \sigma^2(x))V''(x) \leq 0.$$

Consequently, we find that $V(x)$ is r-excessive for $\{\tilde{X}_t; t \in [0, \tilde{\tau}(0))\}$ as well (cf. [3]). Since $V(x) \geq x - c + V(x_0)$ and $\lim_{k\to\infty} \mathbf{E}_x[e^{-r\tau_k} V(X^{\nu}_{\tau_k})] = 0$, we find that $V(x)$ satisfies the conditions of part (a) of Theorem 2.1 in [25] and, therefore, that $V(x) \geq \tilde{V}(x)$ for all $x \in \mathbb{R}_+$. □

Theorem 3.7 shows that given the conditions of Theorem 3.4, increased volatility increases the value of the optimal rotation problem (2.3). In other words, Theorem 3.7 demonstrates that increased volatility increases the expected NPV of the future harvests from the present up to an arbitrarily distant future. The impact of increased volatility on the optimal exercise threshold and rotation length is summarized in the following.

THEOREM 3.8. *Assume that the conditions of Theorem* 3.4 *are met. Then, increased volatility increases the optimal exercise threshold and, therefore, decelerates rational harvesting. More precisely,* $\tilde{y}_{x_0} \leq y^*_{x_0}$, *where* $\tilde{y}_{x_0}$ *denotes the optimal harvesting threshold in the presence of the less volatile value dynamics* $\tilde{X}^{\nu}_t$.

Proof. Define the continuous mappings $u : \mathbb{R}_+ \mapsto \mathbb{R}_+$ and $\tilde{u} : \mathbb{R}_+ \mapsto \mathbb{R}_+$ for all $y \in (x_0, x)$ as

$$u(y) = \frac{\psi(y)}{\psi(x)} - \frac{\psi(y) - \psi(x_0)}{\psi(x) - \psi(x_0)} \quad \text{and} \quad \tilde{u}(y) = \frac{\tilde{\psi}(y)}{\tilde{\psi}(x)} - \frac{\tilde{\psi}(y) - \tilde{\psi}(x_0)}{\tilde{\psi}(x) - \tilde{\psi}(x_0)},$$

where $\tilde{\psi}(x)$ denotes the increasing fundamental solution of the ordinary second order differential equation $(\tilde{\mathcal{A}}v)(x) = rv(x)$. Since $\lim_{y\uparrow x} u(y) = \lim_{y\uparrow x} \tilde{u}(y) = 0$, the mappings $\tilde{u}(y)$ and $u(y)$ are continuous, and $\psi(y)/\psi(x) \geq \tilde{\psi}(y)/\tilde{\psi}(x)$ for all $y \leq x$ and we find that for all $\varepsilon > 0$ there is an open neighborhood $(x - \delta, x)$ of x such that for all $y \in (x - \delta, x)$ we have that

$$\frac{\psi(y) - \psi(x_0)}{\psi(x) - \psi(x_0)} > \frac{\psi(y)}{\psi(x)} - \varepsilon > \frac{\tilde{\psi}(y)}{\tilde{\psi}(x)} - \varepsilon > \frac{\tilde{\psi}(y) - \tilde{\psi}(x_0)}{\tilde{\psi}(x) - \tilde{\psi}(x_0)} - \varepsilon.$$

However, since $\varepsilon > 0$ is arbitrary and $\lim_{y\uparrow x}(\psi(y) - \psi(x_0))/(\psi(x) - \psi(x_0)) = \lim_{y\uparrow x}(\tilde{\psi}(y) - \tilde{\psi}(x_0))/(\tilde{\psi}(x) - \tilde{\psi}(x_0)) = 1$, we find that

$$\frac{\psi'(x)}{\psi(x) - \psi(x_0)} \leq \frac{\tilde{\psi}'(x)}{\tilde{\psi}(x) - \tilde{\psi}(x_0)}$$

for all $x \in (x_0, \infty)$. Denote now as $\tilde{y}_{x_0}$ the optimal harvesting threshold in the presence of the less volatile value dynamics $\tilde{X}^{\nu}_t$. Then

$$\begin{aligned} f(\tilde{y}_{x_0}) &= (\psi(\tilde{y}_{x_0}) - \psi(x_0)) \left(1 - \frac{\psi'(\tilde{y}_{x_0})}{\psi(\tilde{y}_{x_0}) - \psi(x_0)}(\tilde{y}_{x_0} - c)\right) \\ &\geq (\psi(\tilde{y}_{x_0}) - \psi(x_0)) \left(1 - \frac{\tilde{\psi}'(\tilde{y}_{x_0})}{\tilde{\psi}(\tilde{y}_{x_0}) - \tilde{\psi}(x_0)}(\tilde{y}_{x_0} - c)\right) = 0, \end{aligned}$$

implying that $\tilde{y}_{x_0} \leq y^*_{x_0}$ and completing the proof of our theorem. □

Thus we find, in line with studies considering irreversible investment decisions, that increased volatility increases both the value and the optimal exercise threshold of the optimal rotation problem. Consequently, we observe that increased volatility increases the required exercise premium of a rational harvester and, therefore, postpones the irreversible harvesting decision.

4. Extensions. Although the results of our previous section are general, they rely heavily on the strict convexity of the increasing fundamental solution $\psi(x)$. Unfortunately, this condition is not always satisfied in models subject to *mean reversion or pure compensation* (for example, for the logistic model $\mu(x) = \mu x(1 - \gamma x)$ the auxiliary mapping $\theta(x)$ is decreasing only when $\mu \leq r$, that is, only when *the intrinsic growth rate at low densities is smaller than the discount rate* r). An important implication of Lemma 2.1 dealing with these cases is now summarized in the following (cf. [3] and [5]).

COROLLARY 4.1. *Assume that* $\lim_{x\downarrow 0}\theta(x) \geq 0 \geq \lim_{x\to\infty}\theta(x)$ *and that there is a threshold* $\bar{x} \in (0,\infty)$ *such that* $\theta(x)$ *is increasing on* $(0,\bar{x})$ *and decreasing on* $(\bar{x},\infty)$ *(i.e.,* $\bar{x} = \operatorname{argmax}\{\theta(x)\}$*). Then there is a unique threshold* $x^* \in (\bar{x}, \theta^{-1}(0))$ *for which* $\psi''(x^*) = 0$ *and* $\psi''(x) \lessgtr 0$, *when* $x \lessgtr x^*$. *Moreover,* $\lim_{x\downarrow 0}\psi'(x)x = 0$.

Proof. As was shown in the proof of Corollary 2.2, the mapping $I(x)$ is increasing on the set where $\theta(x)$ is decreasing. Proving then that $I(x)$ is decreasing on the set where $\theta(x)$ is increasing is completely analogous. Since $\lim_{x\downarrow 0}\psi'(x)/S'(x) \geq 0$, we find that

$$\lim_{x\downarrow 0} I(x) = -\lim_{x\downarrow 0}\theta(x)\frac{\psi'(x)}{S'(x)} \leq 0.$$

Consequently, $I(x)$ is negative on the set $(0,\bar{x})$. However, since $\theta(x)$ is decreasing on $(\bar{x},\infty)$ and satisfies the condition $\lim_{x\to\infty}\theta(x) \leq 0$, we find that $\theta(x)$ has a unique root $\theta^{-1}(0)$ on $(\bar{x},\infty)$. Since

$$I(\theta^{-1}(0)) = r\int_0^{\theta^{-1}(0)} \psi(y)\theta(y)m'(y)dy > 0$$

and $I(x)$ is monotonically increasing and continuous on $(\bar{x},\infty)$, we find that the equation $I(x) = 0$ has a unique root on $(\bar{x},\theta^{-1}(0))$, thus completing the proof of the first part of our corollary. To prove that $\lim_{x\downarrow 0}\psi'(x)x = 0$ we observe that the concavity of $\psi(x)$ on $(0,x^*)$ implies that $\psi(0) \leq \psi(x) - \psi'(x)x$ for all $x \in (0,x^*)$. Consequently, we find that $0 \leq \psi'(x)x \leq \psi(x) - \psi(0)$. Letting $x \downarrow 0$ then completes the proof of our corollary. □

Corollary 4.1 states a set of conditions under which the increasing fundamental solution $\psi(x)$ is strictly convex above a threshold x^* and concave below it (that is, $\psi'(x)$ has a unique global minimum on $\mathbb{R}_+$). An important consequence of this finding is now summarized in the following.

LEMMA 4.2. *Assume that* $x_0 < c$ *and that the conditions of Corollary* 4.1 *and Lemma* 2.3 *are met. Then there is a unique threshold* $y^*_{x_0} \in (\max(x^*,c),\bar{y})$ *satisfying* (3.7).

Proof. First, we observe that, given the conditions of Lemma 2.3, the mapping $(x-c)/\psi(x)$ attains its maximum on the set where $\psi(x)$ is convex, that is, on (x^*,∞). Assume first that $x^* < c$. Then we find that $f(y)$ is decreasing on $(0,x^*)\cup(c,\infty)$ and increasing on (x^*,c), thus implying that c constitutes an interior local maximum of $f(y)$. The concavity of $\psi(x)$ on $(0,x^*)$ and Taylor's theorem imply that

$$\psi(x_0) \leq \psi(x^*) + \psi'(x^*)(x_0 - x^*)$$

and, therefore, that

$$f(x^*) \geq \psi'(x^*)(c - x_0) > 0.$$

Since $f(c) = \psi(c) - \psi(x_0) > 0$ and $f'(y) = -\psi''(y)(y-c) < 0$ on (x^*, ∞) by the strict convexity of $\psi(y)$ on (x^*, ∞), the alleged result follows from the proof Lemma 3.2. The proof in the case $x^* > c$ is completely analogous (with the only exception being that in that case x^* constitutes an interior local maximum of $f(y)$). If $x^* = c$, then $f(y)$ is decreasing on $\mathbb{R}_+$. However, since $f(c) = \psi(c) - \psi(x_0) > 0$ and $f'(y) = -\psi''(y)(y-c) < 0$ on (x^*, ∞) by the strict convexity of $\psi(y)$ on (x^*, ∞), the alleged result follows again from the proof Lemma 3.2. □

Lemma 4.2 shows that given the conditions of Corollary 4.1 and Lemma 2.3 the necessary condition (3.7) also has a unique root on $(\max(x^*, c), \bar{y})$ at which the representation (3.4) is maximized on (x_0, ∞) since $g'(y) \gtreqless 0$ whenever $y \lesseqgtr y^*_{x_0}$. Consequently, we observe that the global convexity of the increased fundamental solution $\psi(x)$ is not necessarily required for the existence and uniqueness of an optimal cutting value $y^*_{x_0}$. Our main result is now summarized in the following.

THEOREM 4.3. *Assume that $x_0 < c$, that the conditions of Lemma* 4.2 *are met, and that $\psi'(y^*_{x_0})c > \psi(x_0)$ (that is, that $\psi'(y^*_{x_0})y^*_{x_0} > \psi(y^*_{x_0})$). Then, the optimal stopping time is $\tau(0, y^*_{x_0}) = \inf\{t \geq 0 : X_t \geq y^*_{x_0}\}$, and the value of the optimal stopping problem* (3.12) *reads as $H_c(x) = F_{y^*_{x_0}}(x)$, where $F_{y^*_{x_0}}(x)$ is defined as in* (3.8) *and $y^*_{x_0}$ is the optimal exercise threshold satisfying* (3.7) *and defined as in Lemma* 4.2. *Moreover, the optimal cutting value is $y^*_{x_0}$ and $V(x) = H(x) = F_{y^*_{x_0}}(x)$ for all $x \in \mathbb{R}_+$.*

Proof. Proving the r-excessivity of the mapping $F_{y^*_{x_0}}(x)$ for the diffusion $\{X_t; t \in [0, \tau(0)\}$ is analogous to the proof in Theorem 3.4. To prove that $F_{y^*_{x_0}}(x) \geq (x - c + F_{y^*_{x_0}}(x_0))$ for all $x \in \mathbb{R}_+$ we again observe that $\tilde{M}'(x) = (\psi'(x) - \psi'(y^*_{x_0}))/\psi'(y^*_{x_0})$ and that $\tilde{M}''(x) = \psi''(x)/\psi'(y^*_{x_0})$. Consequently, $y^*_{x_0}$ constitutes a local minimum of the mapping $\tilde{M}(x)$. Since $x^* = \operatorname{argmin}\{\psi'(x)\}$, we find that $\tilde{M}(x)$ is decreasing on $(x^*, y^*_{x_0})$. The concavity of $\psi(x)$ on $(0, x^*)$ then implies that $\tilde{M}(x) > 0$ on $(0, y^*_{x_0})$ provided that $\tilde{M}(0) > 0$, that is, provided that the condition $\psi'(y^*_{x_0})c > \psi(x_0)$ is met. Consequently, the proposed value function satisfies the conditions of the verification lemma and, therefore, $H(x) = F_{y^*_{x_0}}(x)$. The rest of the proof is analogous to the proof of Theorem 3.4. □

Theorem 4.3 extends the results of Theorem 3.4 to the case where the increasing fundamental solution $\psi(x)$ is not globally convex. As one can observe from Theorem 4.3, in order to guarantee the existence of an optimal cutting value, we have to make the extra assumption (in comparison with Theorem 3.4) $\psi'(y^*_{x_0})c > \psi(x_0)$ needed for the verification of the condition $V(x) > x - c + V(x_0)$. If this assumption is not satisfied, then the optimal rotation problem does not have a solution. It is also worth pointing out that the results of Corollary 3.5 and Theorem 3.6 are also satisfied in the case of this section, since the condition $\psi'(y^*_{x_0})c > \psi(x_0)$ is trivially satisfied when 0 is exit, killing, or natural for X_t and $x_0 \downarrow 0$. Unfortunately, the local concavity of the increasing fundamental solution makes it difficult to extend the results of Theorem 3.7 to the case of this section. In any case, it is a straightforward implication of the proof of Theorem 3.7 that increased volatility increases the value of the optimal policy at least locally on the set where the value is convex (cf. [9]). Moreover, since the increasing fundamental solution $\psi(x)$ is locally convex on a neighborhood of the optimal threshold $y^*_{x_0}$, we conjecture that the conclusion of Theorem 3.8 holds locally in the present case too. That is, we conjecture that increased volatility decelerates rational harvesting by increasing the optimal threshold $y^*_{x_0}$ in the case of this section as well.

5. Explicit example. In order to illustrate our results, we now plan to consider the optimal rotation problem when the underlying forest stand value process evolves according to the mean reverting diffusion (corresponding to logistic growth subject to a random intrinsic growth rate) considered in, among others, [4] and [21]. More precisely, we now assume that the stochastic forest stand value growth evolves according to the dynamics described by the stochastic differential equation

$$X_t^\nu = x + \int_0^t \mu X_s^\nu (1 - \gamma X_s^\nu) ds + \int_0^t \sigma X_s^\nu (1 - \gamma X_s^\nu) dW_s - \sum_{\tau_k \leq t} \zeta_k, \quad 0 \leq t \leq \tau^\nu(0),$$

where $\gamma, \mu, \sigma \in \mathbb{R}_+$ are known exogenously determined constants. It is now clear that in the present example $\theta(x) = \mu x(1 - \gamma x) - rx$ and consequently that the conditions of Lemma 3.2 or Corollary 4.1 are satisfied depending on whether $r \geq \mu$ or $r < \mu$, respectively. As was established in [4], the increasing fundamental solution of the ordinary second order differential equation

$$\frac{1}{2}\sigma^2 x^2 (1 - \gamma x)^2 u''(x) + \mu x(1 - \gamma x) u'(x) - ru(x) = 0$$

reads as

$$\psi(x) = \left(\frac{\gamma x}{1 - \gamma x}\right)^\alpha F\left(a, b, d; -\frac{\gamma x}{1 - \gamma x}\right),$$

where F is the standard hypergeometric function,

$$a = 1 + \sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}} + \sqrt{\left(\frac{1}{2} + \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}},$$

$$b = 1 + \sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}} - \sqrt{\left(\frac{1}{2} + \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}},$$

$$d = 1 + 2\sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}},$$

and

$$\alpha = \frac{1}{2} - \frac{\mu}{\sigma^2} + \sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}} > 0.$$

Although it is impossible to solve the threshold $y_{x_0}^*$ explicitly from the ordinary first order condition $\psi(y_{x_0}^*) - \psi(x_0) = (y_{x_0}^* - c)\psi'(y_{x_0}^*)$ it can usually be solved numerically when the values of the exogenous parameters are given. We illustrate graphically the optimal cutting values $y_{x_0}^*$ and $\bar{y}$ as functions of the underlying volatility coefficient σ under the assumption that $x_0 = 1, c = 2, \mu = 4.8\%, \gamma = 0.01$, and $r = 3\%$. In line with the findings of Lemma 3.2, Corollary 3.5, and Lemma 4.2, Figures 1 and 2 demonstrate that the value of the ongoing rotation problem dominates the value of the associated single rotation problem and that the exercise threshold is higher for the single rotation problem than for the ongoing rotation problem. Moreover, Figure 1 also shows that increased volatility increases the required exercise premium and prolongs the rotation period by increasing the optimal value at which the irreversible harvesting decision should be made.

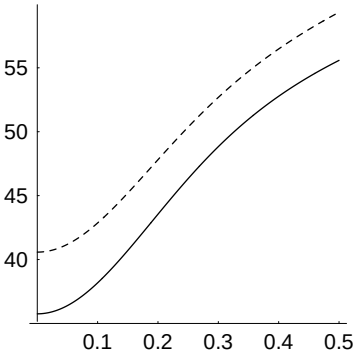

FIG. 1. *The optimal cutting values* $y^*_{x_0}(\sigma)$ *(uniform) and* $\bar{y}(\sigma)$ *(dashed).*

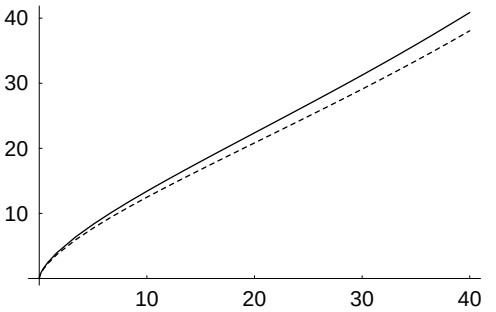

FIG. 2. *The values* $V(x)$ *(uniform) and* $\bar{V}(x)$ *(dashed) when* $\sigma = 0.1$.

6. Concluding comments. We considered the determination of the ongoing rotation policy maximizing the expected NPV of the future harvests from the present up to a potentially infinite future when the underlying stochastic forest stand value growth is modeled as a linear diffusion. By relying on a combination of stochastic calculus, the classical theory of diffusions, and ordinary nonlinear programming techniques, we presented a set of typically satisfied general sufficient conditions under which the optimal Faustmannian rotation problem is solvable and under which the optimal harvesting threshold can be determined from an algebraic equation. In accordance with previous studies considering single rotation problems and the optimal timing of irreversible investments, we found that at the optimum the project value has to be equal to its full costs and that the value of the optimal policy satisfies the familiar smooth-fit condition at the optimal harvesting threshold. We also considered the impact of increased volatility on the optimal rotation policy and stated a set of conditions under which increased volatility unambiguously increases the value of the optimal rotation policy and prolongs the rotation period by increasing the required exercise premium of the irreversible harvesting opportunity. Put somewhat differently, while increased volatility increases the (lost) option value of a single harvesting opportunity, it simultaneously increases the value of all future harvesting opportunities (i.e., the future harvesting potential). Since the latter effect dominates the former, we find that the impact of increased volatility on harvesting is unambiguously negative. This result is of interest since it illustrates the robustness of the qualitative findings obtained in studies relying on geometric Brownian motion.

Even though we considered a broad class of harvesting models, our analysis is subject to two significant constraints limiting at least to some extent the general applicability of our findings. First, by assuming that only timber revenues affect the optimal rotation policy, we overlooked the valuation of amenities which especially affect the rotation policies of preserved old forests. Second, while rotation periods are typically very long (especially in Nordic countries, where forestry plays an important role) we relied on a constant discount rate. Thus our analysis overlooked the potentially significant role of the intertemporal variability of the opportunity cost of investment. Unfortunately, an analysis of a model incorporating these important factors is out of the scope of this study and, therefore, is left for future research.

SURROGATE PROGRAMMING AND MULTIPLIERS IN QUASI-CONVEX PROGRAMMING*

JEAN-PAUL PENOT† AND MICHEL VOLLE‡

Abstract. A result due to Luenberger on the existence of multipliers in a quasi-convex programming problem is extended to the case of constraints given by an arbitrary convex cone under a constraint qualification condition more general than Slater's condition. The existence of solutions is not assumed. We point out links with even convexity in the sense of Fenchel and quasi subdifferentiability in the sense of Greenberg–Pierskalla, and we observe that the couples of primal-dual optimal solutions reduce to saddle-points of a suitable Lagrangian function.

Key words. even convexity, Lagrangian, multipliers, qualification conditions, quasi-convex functions, surrogate programming

1. Introduction. We consider the following mathematical programming problem:

$$(\mathcal{P}) \quad \text{minimize } f(x) \quad \text{subject to} \quad x \in B,\ g(x) \in C,$$

where B (resp., C) is a convex subset (resp., closed convex cone) of a Banach space X (resp., Z), $g : B \to Z$ is convex with respect to $-C$ (i.e., epi $g := \{(x, z) \in X \times Z : x \in B,\ z \in g(x) - C\}$ is a convex subset of $X \times Z$), and $f : B \to \mathbb{R}$ is quasi-convex on B (i.e., for each $r \in \mathbb{R}$, $\{x \in B : f(x) < r\}$ is convex). We denote by Y the topological dual of Z. Here the constraint $x \in B$ is considered as a basic constraint which is easy to deal with (for instance, $B = X$ or a box or an orthant).

Relaxing Slater's condition imposed in [20], we prove the existence of $\bar{y}$ in the negative polar cone $Y_+ := C^\circ = \{y \in Y : z \in C \Longrightarrow \langle y, z\rangle \le 0\}$ of C such that

$$(M) \qquad \inf\{f(x) : x \in B\ ,\ g(x) \in C\} = \inf\{f(x) : x \in B\ ,\ \langle \bar{y}, g(x)\rangle \le 0\}.$$

An element $\bar{y} \in Y_+$ such that (M) holds will be called a *surrogate multiplier* by analogy with the classical notion of Lagrange multiplier which satisfies the relation

$$(L) \qquad \inf\{f(x) : x \in B\ ,\ g(x) \in C\} = \inf\{f(x) + \langle \bar{y}, g(x)\rangle : x \in B\}.$$

The terminology made popular by [14] is justified as follows: when Lagrange multipliers do not exist, despite the fact that it is not possible to substitute $f + \langle \bar{y}, g(\cdot)\rangle$ for f in order to eliminate the constraint $g(x) \in C$ without changing the value of $(\mathcal{P})$, a surrogate multiplier enables one to replace problem $(\mathcal{P})$ by a simpler problem in which the constraint is a scalar one. In particular, when $B = X$ and g is linear, one is led to the minimization of f on a half-plane.

It is easy to see that relation (L) entails (M) while the converse is not true. Simple examples show that one cannot expect existence of usual Lagrange multipliers when f is just quasi-convex, even in the case when the Slater condition is satisfied.

Example 1.1. Let $X = B = \mathbb{R}$, $Z = \mathbb{R}$, $C = -\mathbb{R}_+$, $g(x) = -x$, $f(x) = x^3$. Then for any $y \in Y$ one has $\inf\{f(x) + y \cdot g(x) : x \in X\} = -\infty$, while for $\bar{y} = 1$ one has $\inf\{f(x) : x \in X, \bar{y} \cdot g(x) \leq 0\} = 0 = \inf\{f(x) : x \in g^{-1}(C)\}$.

Such a fact compels one to substitute the study of the set M_S of surrogate multipliers to the study of the set of Lagrange multipliers.

A different approach is adopted in [22], [28]. There one considers the set $M_<$ of $y \in Y_+$ such that

$$\inf\{f(x) : x \in B \cap g^{-1}(C)\} = \inf\{f(x) + \langle y, g(x)\rangle_+ : x \in B\},$$

where $\langle y, g(x)\rangle_+ = \max\{\langle y, g(x)\rangle, 0\}$. Since $f(x) + \langle y, g(x)\rangle_+ = f(x)$ for $x \in A_y := \{x \in B : \langle y, g(x)\rangle \leq 0\}$, we have

$$\inf\{f(x) + \langle y, g(x)\rangle_+ : x \in X\} \leq \inf\{f(x) : x \in A_y\};$$

hence any element of $M_<$ belongs to M_S. Again, the elements of M_S are surrogate to the elements of $M_<$ and lead to a problem with just one scalar convex inequality constraint. Such a problem is more tractable than the primal problem (see [34, Theorem 3.4], for example). The set M_S of surrogate multipliers can be interpreted as the set S_D of optimal solutions to the dual problem

$$(\mathcal{D}_S) \qquad \text{maximize} \quad d_S(y) := \inf\{f(x) : x \in B\ ,\ \langle y, g(x)\rangle \leq 0\} \quad \textit{over} \ \ Y_+ = C^\circ$$

when the values of $(\mathcal{P})$ and $(\mathcal{D}_S)$ are equal. We also provide a Lagrangian whose saddle-points give the optimal solution of $(\mathcal{P})$ and $(\mathcal{D}_S)$. Finally, we study some properties of the performance function p associated with $(\mathcal{P})$ in terms of even convexity and observe that the optimal solutions of $(\mathcal{D}_S)$ are linked with the quasi subdifferential of p at zero.

The constraint qualification condition we use can be considered as a classical condition ([1], [2], [3], [4], [13], [17], [26]); it is a general assumption as it does not suppose that the negative cone C of Z (ordered by $z_1 \leq z_2$ iff $z_1 - z_2 \in C$) has a nonempty interior, in contrast with Slater's condition, a concern common in [3], [4], [13], [17], [26]. It is well known that for many usual linear spaces of functional analysis the ordering cone has an empty interior. Moreover, in the existence result we present we do not assume that the primal problem $(\mathcal{P})$ has solutions. In the convex case it is known that this assumption is superfluous (see [8], [32], for instance). It appears that, in our quasi-convex case, we can face a similar situation: the dual problem has solutions whereas the primal has no solution. These duality questions are considered in Corollary 3.1 below; for a more systematic treatment we refer to [6], [14], [15], [23], [28], [35].

An abstract study of surrogate duality is conducted in [35], [36], [37, p. 28]. Surrogate duality methods are of particular importance for discrete optimization. Numerous studies and algorithms have been devised for such purposes; see [9], [11], [12], [14], [15], [18], [19] among many articles and monographs.

2. The main result. Our assumptions are as follows (we use the familiar convention $\sup \emptyset = -\infty$, and we write u.s.c. instead of upper semicontinuous).

(F) $\qquad f : B \to \mathbb{R}$ is quasi-convex and directionally u.s.c.:

$$\text{for any} \quad x \in B\ ,\ v \in X\backslash\{0\} : \quad \limsup_{\substack{(t,u) \to (0_+, v) \\ x+tu \in B}} f(x+tu) \le f(x).$$

This assumption is satisfied when f is quasi-convex and u.s.c. on B; on the other hand, it implies the upper semicontinuity of f along lines, which is the corresponding assertion of [20]. When X is finite dimensional (as in [20]), directional upper semicontinuity is equivalent to upper semicontinuity, as a compactness argument shows.

Our assumption on g is slightly reinforced (the closedness of the epigraph of g is not required in [20]):

$$(G) \qquad g \quad \text{has a closed convex epigraph} \quad \text{epi } g.$$

The qualification condition we choose among known ones has become classical (see [1], [2], [4], [13], [17]). It is as follows:

$$(H) \qquad W := \mathbb{R}_+(g(B) - C) \quad \text{is a closed vector subspace of} \quad Z.$$

This condition is obviously satisfied when the following assumption of [3], [26], [38], [40] holds:

$$(H_0) \qquad Z = \mathbb{R}_+(g(B) - C).$$

In turn, as $g(B)-C$ is convex (being the projection on Z of epi g), the latter condition is equivalent to

$$0 \in \text{ core } (g(B) - C),$$

i.e., $g(B) - C$ is absorbent. In fact, as the proof of the theorem below shows, under condition (H_0), the set $g(B)-C$ has a nonempty interior, so that (H_0) can be rewritten

$$(H_0') \qquad 0 \in \text{ int } (g(B) - C).$$

However, condition (H_0) is easier to check than (H_0') since it is just the algebraic condition: given $z \in Z$ there exist $r \in \mathbb{R}_+$, $b \in B$, $c \in C$ such that $z = r(g(b) - c)$. Both conditions are obviously satisfied when the following Slater condition holds:

$$(S) \qquad \text{there exists} \quad x_1 \in B \quad \text{such that} \quad g(x_1) \in \text{ int } C.$$

A discussion about the qualification conditions (H) and (S) is contained in [1], [3], [4], [13], [17], [26]. Let us make brief observations about these relationships. The fact that (H) is more general than (S) is clear.

Example 2.1. Taking for C a closed convex cone with empty interior in $Z = X = B$, g being the identity map I_X, we see that (H_0) is satisfied but (S) does not hold.

Condition (H) is called the generalized qualification condition in [13]; it amounts to $0 \in \text{sqri}(g(B) - C)$, where, for a convex subset D of Z, sqri (D) is the set of $z \in D$ such that $\mathbb{R}_+(D - z)$ is a closed vector subspace. Condition (H) is stronger than the purely algebraic condition

$$(H') \qquad W := \mathbb{R}_+(g(B) - C) \ \text{ is a vector subspace of } Z.$$

Observe that conditions $(F), (G), (H')$ do not entail relation (M), as shown by the following example.

Example 2.2. Let X be a normed vector space (n.v.s.) containing two closed vector subspaces B, C such that $B \cap C = \{0\}$ and $B + C$ is dense in X. As in [30, p. 77] and [13, Example 3.3], one can take $X = l_2$,

$$B = \{x \in l_2 : x_{2n-1} + x_{2n} = 0\ ,\ n = 1, 2, \dots\},$$
$$C = \{x \in l_2 : x_{2n-1} - x_{2n} = 0\ ,\ n = 1, 2, \dots\}.$$

Let $g = I_X$, and let $f(x) = x_1^3$ for $x = (x_1, x_2, \dots)$. Then, for any $y \in Y_+ = \{y \in Y : y|C = 0\}$ one has $\inf\,(f + y \circ g)(B) = -\infty$, but since $B \cap C = \{0\}$, we have $\inf\,\{f(x) : x \in B \cap g^{-1}(C)\} = 0$. Note that $(F), (G)$, and (H') are satisfied.

THEOREM 2.3. *Under assumptions* (F), (G), (H) *there exists a surrogate multiplier* $\bar{y} \in Y_+$*:*

$$\inf\{f(x) : x \in B\ ,\ g(x) \in C\} = \inf\{f(x) : x \in B,\ \langle \bar{y}, g(x)\rangle \le 0\}.$$

Moreover, if $\bar{x} \in B$ *is a solution to* $(\mathcal{P})$*, then it is a solution to*

$$(\mathcal{Q}_{\bar{y}}) \qquad \textit{minimize } f(x) \quad \textit{subject to} \quad x \in B, \langle \bar{y}, g(x)\rangle \le 0.$$

Conversely, if $\bar{x} \in B \cap g^{-1}(C)$ *is a solution to* $(\mathcal{Q}_{\bar{y}})$*, then it is a solution to* $(\mathcal{P})$*.*

Let us observe that for the proof we may assume (H_0) holds instead of (H): since $C \subset W$ and since g takes its values in W, we may replace Z by W and then extend $\bar{y} \in W_+^*$ to some element in $Z^* = Y$ which is still nonpositive on C.

The proof depends on the following result (which holds for spaces more general than Banach spaces, so that the preceding theorem is valid for such spaces; see [33], for instance).

LEMMA 2.4. (see [31], [38]). *Let* $G : X \to 2^Z$ *be a relation with closed convex graph such that* $Z = \mathbb{R}_+ G(X)$*. Then for any* $v \in G^{-1}(0)$*,* G *is open at* $(v, 0)$*; for each neighborhood* V *of* v*,* $G(V)$ *is a neighborhood of* 0 *in* Z*.*

Proof of Theorem 2.3. Let $G : X \to 2^Z$ be the relation given by $G(x) = g(x) - C$ if $x \in B$, and $G(x) = \emptyset$ if $x \in X \backslash B$. The graph of G is nothing but epi g and hence is closed and convex. Moreover, $Z = \mathbb{R}_+ G(X)$. Let $v_0 \in G^{-1}(0)$ i.e., $v_0 \in B$, and $g(v_0) \in C$ (such a v_0 exists by (H) and a well-known argument [1]) and let $x_0 \in S_m$, where

$$S_m = \{x \in B : f(x) < m\}\ ,$$

m being the value of $(\mathcal{P})$, $m = \inf\ f(B \cap g^{-1}(C))$. If such an x_0 does not exist then any $\bar{y} \in Y_+$ can be chosen since in that case $B \cap g^{-1}(C) \subset B \cap (\bar{y} \circ g)^{-1}(\mathbb{R}_-) \subset B$ and $f(x) \ge m$ for each $x \in B$. Now one has $f(x_0) < m \le f(v_0)$. Thus one has $v_0 - x_0 \ne 0$. As f is directionally u.s.c., there exist $t \in]0, 1[$ and a neighborhood V of v_0 in X such that for each $v \in V \cap B$, one has $f(x_0 + t(v - x_0)) < m$, i.e., $(1-t)x_0 + t(V \cap B) \subset S_m$.

Then, by the convexity of g,

$$(1-t)g(x_0) + tg(V \cap B) \subset g((1-t)x_0 + t(V \cap B)) - C \subset g(S_m) - C.$$

It follows that

$$(1-t)g(x_0) + t(g(V \cap B) - C) \subset g(S_m) - C,$$

i.e.,

$$(1-t)g(x_0) + tG(V) \subset g(S_m) - C,$$

so that by Lemma 2.4 $g(S_m) - C$ contains the neighborhood $(1-t)g(x_0) + tG(V)$ of $(1-t)g(x_0)$. By definition of m and S_m, the convex set $g(S_m) - C$ does not contain 0. As it has a nonempty interior, we can find $\bar{y} \in Y \backslash \{0\}$ such that

$$(*) \qquad \langle \bar{y}, z \rangle \geq 0 \quad \text{for each} \quad z \in g(S_m) - C.$$

It follows that $\langle \bar{y}, z \rangle \leq 0$ for each $z \in C : \bar{y} \in C^\circ$. Let us show that $\langle \bar{y}, z \rangle = 0$ for some $z \in g(S_m) - C$ is impossible. Otherwise, we can choose $x_0 \in S_m$, t, and V as above with, in addition, $g(x_0) - z \in C$. Then the linear functional $\bar{y}$ is nonnegative on the neighborhood $(1-t)g(x_0) + tG(V)$ of $(1-t)g(x_0)$ (and even on $g(S_m) - C$) and $\langle \bar{y}, (1-t)g(x_0)) = (1-t)\langle \bar{y}, g(x_0) - z \rangle \leq 0$. As a nonzero linear functional has no local minimum, we get a contradiction. Therefore, $\langle \bar{y}, z \rangle > 0$ for each $z \in g(S_m) - C$, and we have, for each $x \in B$,

$$\langle \bar{y}, g(x) \rangle \leq 0 \Longrightarrow g(x) \notin g(S_m) - C \Longrightarrow f(x) \geq m$$

so that

$$\inf\{f(x) : x \in B, \langle \bar{y}, g(x) \rangle \leq 0\} \geq m.$$

In fact, equality holds as $\{x \in B : \langle \bar{y}, g(x) \rangle \leq 0\}$ contains $B \cap g^{-1}(C)$. The two last assertions are obvious. □

The following result is a counterpart to [20, Theorem 2]. Here we do not assume that C has a nonempty interior, but f is supposed to be *semistrictly quasi-convex* in the following sense: for any $x_0, x_1 \in X$ with $f(x_0) < f(x_1)$ and for any $t \in [0,1[$ one has $f((1-t)x_0 + tx_1) < f(x_1)$. This assumption is satisfied when f is convex or strictly quasi-convex.

THEOREM 2.5. *Suppose with $(F), (G), (H)$ that f is semistrictly quasi-convex. Then, for any solution $\bar{x}$ to $(\mathcal{P})$ one can find $\bar{y} \in M_S$ such that $\langle \bar{y}, g(\bar{x}) \rangle = 0$.*

Proof. As observed in the proof of Theorem 2.3, when S_m is empty one has $M_S = Y_+$, so that we can take $\bar{y} = 0$. Let us suppose S_m is nonempty. For any $x_0 \in S_m$ and any $t \in [0,1[$ we have $x_t := (1-t)x_0 + t\bar{x} \in S_m$ since B is convex and f is semistrictly quasi-convex. It follows from relation $(*)$ that $\langle \bar{y}, g(x_t) \rangle \geq 0$, where $\bar{y}$ is as in the proof of Theorem 2.3. Since $t \longmapsto \langle \bar{y}, g(x_t) \rangle$ is convex, we have $\langle \bar{y}, g(\bar{x}) \rangle \geq 0$. Since $g(\bar{x}) \in C$ and $\bar{y} \in Y_+$, we get $\langle \bar{y}, g(\bar{x}) \rangle = 0$. □

3. Duality results. Theorem 2.3 can be interpreted in terms of dual problems. Here we set $r \vee s = \max(r, s)$.

COROLLARY 3.1. *Under assumptions $(F), (G), (H)$ the dual problems*

$$(\mathcal{D}_S) \qquad \textit{maximize } d_S(y) := \inf\{f(x) : x \in B \ , \ \langle y, g(x) \rangle \leq 0\} \textit{ over } Y_+ = C^\circ,$$

$$(\mathcal{D}'_S) \qquad \textit{maximize } d'_S(y) := \inf\{f(x) \vee (m + \langle y, g(x) \rangle) : x \in B\} \textit{ over } Y_+ = C^\circ$$

have solutions and their values are equal to the value of $(\mathcal{P})$.

Proof. This follows from the fact that $d_S(y) \leq m$, $d'_S(y) \leq m$ for each $y \in Y_+$ and $d_S(\bar{y}) = m$, and $d'_S(\bar{y}) = m$ for any surrogate multiplier $\bar{y}$. □

We now extend the Lagrangian introduced in [20, p. 1092] by setting

$$L_S(x,y) = \begin{cases} -\infty & \text{if } (x,y) \in X \times (Y \backslash Y_+), \\ f(x) & \text{if } (x,y) \in B \times Y_+ \text{ and } \langle y, g(x) \rangle \leq 0, \\ +\infty & \text{if } (x,y) \in B \times Y_+ \text{ and } \langle y, g(x) \rangle > 0 \text{ or } (x,y) \in (X \backslash B) \times Y_+. \end{cases}$$

We also extend the function d_S introduced above by setting

$$d_S(y) := \inf \{f(x) : x \in B,\ \langle y, g(x)\rangle \leq 0\} \ \text{ for } y \in Y_+ \ , \ d_S(y) = -\infty \text{ for } y \in Y\backslash Y_+.$$

It follows that

$$d_S(y) = \inf_{x\in X} L_S(x,y) \quad \text{for any } \ y \in Y,$$

and hence $\sup(\mathcal{D}_S) = \sup_{y\in Y} \ \inf_{x\in X} \ L_S(x,y)$.

LEMMA 3.2. *The function L_S is a Lagrangian for $(\mathcal{P})$: if i_A is the indicator function of the admissible set $A := B \cap g^{-1}(C)$ given by $i_A(x) = 0$ if $x \in A$, $i_A(x) = +\infty$ else, and if $f_A = f + i_A$, one has*

$$f_A(x) = \sup_{y\in Y} L_S(x,y) \quad \textit{for each } x \in X.$$

Proof. For $x \in A$, we have $\langle y, g(x)\rangle \leq 0$ for any $y \in Y_+$; hence $L_S(x,y) = f_A(x)$ and $\sup_{y\in Y} L_S(x,y) = f_A(x)$. For $x \in X\backslash A$, either $x \notin B$ or we have $g(x) \notin C$, and the bipolar theorem yields some $y \in Y_+$ such that $\langle y, g(x)\rangle > 0$. In both cases we get $L_S(x,y) = +\infty = f_A(x)$. □

It follows that

$$\inf(\mathcal{P}) = \inf_{x\in X} \sup_{y\in Y} L_S(x,\bar{y}).$$

Recall that $(\bar{x},\bar{y}) \in X \times Y$ is a saddle point of a function $L : X \times Y \to \mathbb{R}\cup\{-\infty,+\infty\}$ if $L(\bar{x},\bar{y})$ is finite and if for any $(x,y) \in X \times Y$ one has

$$L(\bar{x},y) \leq L(\bar{x},\bar{y}) \leq L(x,\bar{y}).$$

Since L_S is a Lagrangian for $(\mathcal{P})$, we can apply a general characterization of its saddle points; see, for instance, [28] in which L is the quasi-convex Lagrangian given by

$$L_<(x,y) = \begin{cases} f(x) + \langle y, g(x)\rangle_+ & \text{for} \quad (x,y) \in X \times Y_+, \\ -\infty & \text{for} \quad (x,y) \in X \times (Y\backslash Y_+). \end{cases}$$

Note that one has $L_< \leq L_S$ and $d_<(y) := \inf_{x\in X} L_<(x,y) \leq d_s(y)$ for each $y \in Y$. Moreover, L_S is quasi-convex in its first variable and quasi-concave (and even quasi-affine) in its second variable.

PROPOSITION 3.3. *Let $(\bar{x},\bar{y}) \in X \times Y$ be such that $L_S(\bar{x},\bar{y})$ is finite. Then the following assertions are equivalent:*

(a) *$(\bar{x},\bar{y})$ is a saddle point of L_S.*

(b) *$\bar{x}$ is a solution to $(\mathcal{P})$, $\bar{y}$ is a solution to $(\mathcal{D}_S)$, and $f(\bar{x}) = d_S(\bar{y})$ is finite.*

(c) *$\bar{x} \in A := B \cap g^{-1}(C)$ and $f(\bar{x}) = d_S(\bar{y})$ is finite.*

In view of this characterization and the analogous one for $L_<$, we get that any saddle point for $L_<$ is a saddle-point for L_S. Thus the search of saddle-points of L_S represents an easier task than the search of saddle-points of $L_<$.

Let us now consider the performance function p associated with the natural perturbation of $(\mathcal{P})$ given by

$$p(w) = \inf \{f(x) : x \in B, g(x) + w \in C\}$$

for $w \in Z$, with the usual convention $\inf \emptyset = +\infty$. As shown in [20, Lemma 3], the extended real-valued function p is quasi-convex and its domain is the convex set

$$\operatorname{dom} p := \{z \in Z : p(z) < +\infty\} = C - g(B).$$

Another important property of p is homotonicity (or isotonicity or monotonicity): for any $w, z \in Z$ with $w - z \in C$, one has $p(w) \leq p(z)$. While in [28] the set of multipliers $M_<$ associated with $L_<$ is related to the lower subdifferential of p at 0, here we relate the set M_S of surrogate multipliers of p to the quasi subdifferential $\partial^* p(0)$ of p at 0 in the sense of Greenberg and Pierskalla [15], where, given $\bar{z} \in p^{-1}(\mathbb{R})$,

$$\partial^* p(\bar{z}) = \{\bar{y} \in Y : \langle \bar{y}, z - \bar{z}\rangle < 0 \quad \forall z \in p^{-1}((-\infty, p(\bar{z})))\}\ .$$

COROLLARY 3.4. *Let $\hat{z} \in Z$. Under assumptions (F), (G), (H), for any $\hat{z} \in$ core $(C - g(B))$ there exists $\hat{y} \in Y_+$ such that*

$$p(\hat{z}) = \inf\{f(x) : x \in B\ ,\ \langle \hat{y}, g(x)\rangle \leq -\langle \hat{y}, \hat{z}\rangle\} \tag{1}$$

or, equivalently,

$$\text{for each} \quad z \in Z\ ,\ \langle \hat{y}, z\rangle \geq \langle \hat{y}, \hat{z}\rangle \Longrightarrow p(z) \geq p(\hat{z}). \tag{2}$$

When $p(\hat{z}) \in \mathbb{R}$, condition (2) amounts to saying that $\hat{y} \in \partial^* p(\hat{z})$.

Proof. Let us first show that the following condition is satisfied for any $\hat{z} \in$ core $(C - g(B))$:

$$\mathbb{R}_+(g(B) - C + \hat{z}) = W. \tag{$H_{\hat{z}}$}$$

Since $-\hat{z} \in$ core $(g(B) - C)$, we can find $s > 0$ such that $-\hat{z} = s(1+s)^{-1}\big(g(\hat{b}) - \hat{c}\big)$ for some $\hat{b} \in B$, $\hat{c} \in C$. Now, given $z \in W$ we can find $r \geq 0$, $b \in B$, $c \in C$ such that $z = r(g(b) - c)$; hence $z = r((1+s)\hat{z} + sg(\hat{b}) + g(b) - c - s\hat{c})$. Since g is convex, there is $c_1 \in C$ such that $sg(\hat{b}) + g(b) = (1+s)g((1+s)^{-1}(s\hat{b} + b)) - c_1$. Then

$$z = r(1+s)\left(\hat{z} + g\left(\frac{s\hat{b} + b}{1+s}\right) - \frac{c_1 + c + s\hat{c}}{1+s}\right) \in \mathbb{R}_+(\hat{z} + g(B) - C).$$

To prove (1) it suffices to replace the mapping $g : x \longmapsto g(x)$ by the mapping $\hat{g} : x \longmapsto g(x) + \hat{z}$ in the proof of the theorem. Then $(H_{\hat{z}})$ is the required assumption for the relation $\hat{G}$ given by $\hat{G}(x) = g(x) + \hat{z} - C$ if $x \in B$ and by $\hat{G}(x) = \emptyset$ if $x \in X \backslash B$ to be open at each point of $\hat{G}^{-1}(0)$. The existence of some multiplier $\hat{y}$ satisfying (1) follows. It remains to prove the equivalence between (1) and (2). Let us suppose that (1) holds. As $\hat{y} \in Y_+$, for each $z \in Z$ the definition of p ensures that

$$p(z) \geq \inf\{f(x) : x \in B\ ,\ \langle \hat{y}, g(x)\rangle \leq -\langle \hat{y}, z\rangle\}. \tag{3}$$

It follows that for each $z \in Z$ such that $\langle \hat{y}, z\rangle \geq \langle \hat{y}, \hat{z}\rangle$ we have

$$p(z) \geq \inf\{f(x) : x \in B\ ,\ \langle \hat{y}, g(x)\rangle \leq -\langle \hat{y}, \hat{z}\rangle\} = p(\hat{z}).$$

Conversely, suppose that (2) holds. Then for every $x \in B$ such that $\langle \hat{y}, g(x)\rangle \leq -\langle \hat{y}, \hat{z}\rangle$ we have $p(\hat{z}) \leq p(-g(x)) \leq f(x)$; this leads to the inequality

$$p(\hat{z}) \leq \inf\{f(x) : x \in B\ ,\ \langle \hat{y}, g(x)\rangle \leq -\langle \hat{y}, \hat{z}\rangle\}.$$

The opposite inequality is obtained by putting $z = \hat{z}$ in (3). □

COROLLARY 3.5. *Suppose $p(0)$ is finite and assumptions (F), (G), and (H) hold. Then the set M_S of surrogate multipliers is nonempty and coincides with the set of solutions to $(\mathcal{D}_S)$, and*

$$M_S = \partial^* p(0) \cap Y_+.$$

Moreover, if $\inf\ f(B) < p(0)$, *one has* $M_S = \partial^* p(0)$.

Proof. If $\inf f(A) = \inf\ f(B)$, then 0 is a global minimizer of p, so that $\partial^* p(0) = Y$ and then $M_S = Y_+$. If $\inf f(A) > \inf\ f(B)$, there exists some $x_0 \in B$ with $p(-g(x_0)) \leq f(x_0) < p(0)$. Let $z_0 = -g(x_0)$. For any $z \in C$ we have $p(z_0 + z) \leq p(z_0) < p(0)$; hence for any $\bar{y} \in \partial^* p(0)$ we get $\langle \bar{y}, z_0 + z\rangle \leq 0$, and since C is a cone, $\langle \bar{y}, z\rangle \leq 0$. Thus $\bar{y} \in Y_+$. Then we can apply Corollary 3.4. □

In the case when g is affine, one gets a simple multiplier rule.

COROLLARY 3.6. *Suppose B is closed and g is affine: $g(x) = \ell(x) - c$ with $c \in Z$ and ℓ linear and continuous. Under assumptions (F), (G), and (H), if $\bar{x}$ is a solution to $(\mathcal{P})$, then there exists $\bar{y} \in Y_+$ such that*

$$0 \in \partial^* f(\bar{x}) + \bar{y} \circ \ell(\bar{x}).$$

Proof. Let $\bar{y} \in Y_+$ be as in the statement of the theorem. For any $x \in X$ with $\bar{y} \circ \ell(x) \leq \bar{y} \circ \ell(\bar{x}) \leq \langle \bar{y}, c\rangle$ we have $\langle \bar{y}, g(x)\rangle \leq 0$; hence $f(x) \geq f(\bar{x})$. This shows that $-\bar{y} \circ \ell$ belongs to $\partial^* f(\bar{x})$. □

In the following result we show that the performance function p has some regularity property. This property is weaker than semicontinuity. Lower semicontinuity is a strong property which has been looked for by many researchers. Here we just get even quasi convexity; recall that p is *evenly quasi-convex* if for each $r \in \mathbb{R}$ the strict inferior level set $\{z \in Z : p(z) < r\}$ is an intersection of open half-spaces or the whole space. This property has been studied or used in various works [7], [10], [21], [25], [29].

COROLLARY 3.7. *Suppose that B is closed and conditions $(F), (G), (H_{\hat{z}})$ hold for each $\hat{z} \in C - g(B)$. Then the performance function is evenly quasi-convex.*

Proof. Given $r \in \mathbb{R}$, let $Z_r := \{z \in Z : p(z) < r\}$, and let $\hat{z} \in Z \backslash Z_r : p(\hat{z}) \geq r$. If $p(\hat{z}) = +\infty$, $\hat{z}$ does not belong to $D := C - g(B) = \operatorname{dom} p$. As D is the image by G (defined in the proof of Theorem 2.3) of the closed convex subset B, D is ideally convex [16]. Since (H_0) holds, $\operatorname{int} D = \operatorname{core} D$ is nonempty by [16] or [17, Proposition 3.2.] Since $\hat{z} \notin D$, there exists $y \in Y \backslash \{0\}$ (in fact $y \in Y_+ \backslash \{0\}$) such that

$$z \in Z_r \subset D = C - g(B) \Longrightarrow \langle y, z\rangle < \langle y, \hat{z}\rangle.$$

If $p(\hat{z}) < +\infty$, then $\hat{z} \in C - g(B)$. By hypothesis, $(H_{\hat{z}})$ is fulfilled; hence there exists $\hat{y} \in Y_+$ such that (2) holds. Then we have for each $z \in Z$

$$z \in Z_r \Longrightarrow p(z) < p(\hat{z}) \Longrightarrow \langle \hat{z}, z\rangle < \langle \hat{y}, \hat{z}\rangle.$$

In both cases there exists an open half space which includes Z_r and does not contain $\hat{z}$. □

Remark 3.8. If $C - g(B)$ is open, then $(H_{\hat{z}})$ holds for each $\hat{z} \in C - g(B)$.

FIRST ORDER CONDITIONS FOR NONSMOOTH DISCRETIZED CONSTRAINED OPTIMAL CONTROL PROBLEMS*

XIAOJUN CHEN†

Abstract. This paper studies first order conditions (Karush–Kuhn–Tucker conditions) for discretized optimal control problems with nonsmooth constraints. We present a simple condition which can be used to verify that a local optimal point satisfies the first order conditions and that a point satisfying the first order conditions is a global or local optimal solution of the optimal control problem.

Key words. optimal control, first order condition, nonsmooth, discretization

1. Introduction.

We consider the distributed optimal control problem

$$\begin{aligned} &\text{minimize} \quad \frac{1}{2}\int_\Omega (y-y_d)^2 d\omega + \frac{\alpha}{2}\int_\Omega (u-u_d)^2 d\omega \\ &\text{subject to} \quad -\triangle y + \lambda \max(0,y) = u \quad \text{in} \quad \Omega, \quad y = g \quad \text{on}\,\Gamma, \\ &\qquad u \in U, \end{aligned} \tag{1.1}$$

where $y_d, u_d \in L^2(\Omega)$, $g \in C(\Gamma)$, $\alpha > 0$, and $\lambda > 0$ are constants, Ω is an open bounded convex subset of $R^N, N \le 3$, with smooth boundary Γ, and

$$U = \{u \in L^2(\Omega) \,|\, u(x) \le q(x) \text{ a.e in } \Omega\},$$

$q \in L^\infty(\Omega)$.

This problem is a special case of semilinear elliptic control problems whose constraints involve a semilinear elliptic equation [3]

$$\begin{aligned} \triangle y &= f(x,y,u) \quad \text{in} \quad \Omega, \\ y &= g \quad \text{on} \quad \Gamma, \end{aligned}$$

where $f : \Omega \times R^2 \to R$ is a continuous function. Optimality conditions for semilinear elliptic control problems have been studied extensively. However, most of papers assume that f is continuously differentiable with respect to the second and third variables [3]. These results are not applicable to (1.1) because the elliptic equation in (1.1) has a nonsmooth term $\lambda \max(0,y)$. Such nonsmooth equations can be found in equilibrium analysis of confined magnetohydrodynamics (MHD) plasmas [4, 5, 11], thin stretched membranes partially covered with water [9], or reaction-diffusion problems [1].

In this paper, we study first order conditions for the discretized nonsmooth constrained optimal control problems derived from a finite difference approximation or a finite element approximation of (1.1), which has the form

$$\text{minimize } \frac{1}{2}(y-y_d)^T H(y-y_d) + \frac{\alpha}{2}(u-u_d)^T M(u-u_d)$$

†Department of Mathematical System Science, Hirosaki University, Hirosaki, Japan (chen@cc.hirosaki-u.ac.jp).

$$\begin{aligned} &\text{subject to } Ay + \lambda D \max(0, y) = Nu, \\ &\qquad\qquad u \le b. \end{aligned} \tag{1.2}$$

Here $y_d \in R^n$, $u_d, b \in R^m$, $H \in R^{n\times n}$, $M \in R^{m\times m}$, $A \in R^{n\times n}$,$D \in R^{n\times n}$, $N \in R^{n\times m}$, and $\max(\cdot)$ is understood coordinatewise. Moreover, H, M, A, D are symmetric positive definite matrices. We assume that D is a diagonal matrix. This assumption holds for finite difference discretization and finite element discretization with mass lumping.

For every $u \in R^m$, there is a unique vector y satisfying the equality constraints in (1.2), since $Ay + \lambda D \max(0, y)$ is strongly monotone. Therefore, (1.2) is equivalent to

$$\begin{aligned} &\text{minimize } \frac{1}{2}(y(u) - y_d)^T H(y(u) - y_d) + \frac{\alpha}{2}(u - u_d)^T M(u - u_d) \\ &\text{subject to} \qquad u \le b, \end{aligned} \tag{1.3}$$

where $y(u)$ is the solution function defined by the equations in the constraints of (1.2). We show that $y(\cdot)$ is a piecewise linear function in the next section.

Let $E(y)$ be an $n \times n$ diagonal matrix whose diagonal elements satisfy

$$E_{ii}(y) = \begin{cases} 1 & \text{if } y_i > 0, \\ 0 & \text{otherwise.} \end{cases}$$

It is easy to verify that $E(y)$ is the Jacobian of the function $\max(0, \cdot)$ at y if y has no zero component.

Since A is a symmetric positive definite matrix and $\lambda DE(y)$ is a nonnegative diagonal matrix, the matrix $A + \lambda DE(y)$ is nonsingular and its inverse is symmetric positive definite.

We say (y, u) satisfies first order conditions for (1.2) or (y, u) is a Karush–Kuhn–Tucker (KKT) point of (1.2) if it together with some $(s, t) \in R^n \times R^m$ satisfies

$$\begin{pmatrix} H(y - y_d) + As + \lambda DE(y)s \\ \alpha M(u - u_d) - N^T s + t \\ Ay + \lambda D \max(0, y) - Nu \\ \min(t, b - u) \end{pmatrix} = 0. \tag{1.4}$$

The vectors $s \in R^n$ and $t \in R^m$ are referred to as Lagrange multipliers.

We say u satisfies first order conditions for (1.3) or u is a KKT point of (1.3) if it together with some $t \in R^m$ satisfies

$$\begin{pmatrix} ((A + \lambda DE(y(u)))^{-1}N)^T H(y(u) - y_d) + \alpha M(u - u_d) + t \\ \min(t, b - u) \end{pmatrix} = 0. \tag{1.5}$$

For $\lambda = 0$, the constraints in (1.1) involve only linear Dirichlet problems. In this case, problem (1.2) is a convex programming problem with linear constraints, and the function $y(\cdot)$ in problem (1.3) can be expressed explicitly as $y(u) = A^{-1}Nu$. Moreover, (1.4) and (1.5) are equivalent in the sense that if (y, u) is a KKT point of (1.2), then u is a KKT point of (1.3); conversely, if u is a KKT point of (1.3), then $(A^{-1}Nu, u)$ is a KKT point of (1.2). Furthermore, the convexity implies that (y, u) is a KKT point of (1.2) if and only if (y, u) is a global solution of (1.2). Therefore, problems (1.2), (1.3), (1.4), and (1.5) are equivalent in the case $\lambda = 0$. Many algorithms for solving

(1.1) based on the equivalent relation have been developed; we refer the reader to a comprehensive paper written by Bergounioux, Ito, and Kunisch [2].

For $\lambda > 0$, the constraints in (1.1) involve nonsmooth partial differential equations. In this case, problem (1.2) is a nonconvex programming problem with nondifferentiable constraints. It fails to satisfy the constraint qualification in mathematical programming [7] in the sense that the set of feasible directions and the set of feasible directions for the linearized constraint set are not same at points where the constraint is not differentiable. There are examples in [7] which show that a KKT point is not necessarily a minimizer for a nonconvex programming problem, and a minimizer is not necessarily a KKT point if the constraint qualification fails.

Recently many numerical methods for solving nonsmooth equations have been developed [4, 5, 8, 12]. We can find a solution of nonsmooth equation (1.4) or (1.5) by a fast (superlinearly convergent) algorithm. However, we do not know if the solution of (1.4) or (1.5) is a minimizer of (1.2) or (1.3). There are open questions in the relations between the four problems:

$$\begin{array}{ccc|ccc} (1.2) & \Leftrightarrow & (1.3) & & (1.2) & \Leftrightarrow & (1.3) \\ \Updownarrow & & \Updownarrow & | & ? & & ? \\ (1.4) & \Leftrightarrow & (1.5) & | & (1.4) & ? & (1.5) \\ & & & | & & & \\ \multicolumn{3}{c|}{\lambda = 0} & & \multicolumn{3}{c}{\lambda > 0} \end{array}$$

In this paper, we provide a necessary and sufficient condition for the solution function $y(\cdot)$ to be differentiable at a point u. By using the differentiability results, we show that problems (1.4) and (1.5) are equivalent. Moreover, we present a simple condition which can be used to verify that a local optimal solution of (1.3) is a solution of (1.5) and that a solution of (1.4) is a global or local optimal solution of (1.2).

We introduce our notation. For any matrix $B \in R^{m\times n}$, let $B_{\mathcal{K}\mathcal{J}}$ be the submatrix of B whose entries lie in the rows of B indexed by $\mathcal{K}$ and the columns indexed by $\mathcal{J}$. If $\mathcal{J} = \{1, 2, \ldots, n\}$, we simply denote $B_{\mathcal{K}\mathcal{J}}$ by $B_{\mathcal{K}}$. Let $e_i \in R^n$ be the ith column of the identity matrix $I \in R^{n\times n}$.

2. Differentibility. In this section, we study the function

$$F(y, u) = Ay + \lambda D \max(0, y) - Nu$$

and the solution function $y(u)$ defined by

$$F(y, u) = 0.$$

For a given $y \in R^n$, we define the index sets

$$\begin{aligned} \mathcal{J}(y) &:= \{\, i \,|\, y_i > 0\}, \\ \mathcal{K}(y) &:= \{\, i \,|\, y_i = 0\}, \\ \mathcal{L}(y) &:= \{\, i \,|\, y_i < 0\}. \end{aligned}$$

Note that $\mathcal{J}(y)$, $\mathcal{K}(y)$, and $\mathcal{L}(y)$ are mutually disjoint, and $\mathcal{J}(y) \cup \mathcal{K}(y) \cup \mathcal{L}(y) = \{1, 2, \ldots, n\}$. Using the function E, we can write the functions F and $y(\cdot)$ as follows:

$$F(y, u) = (A + \lambda DE(y))y - Nu$$

and

$$y(u) = (A + \lambda DE(y(u)))^{-1} Nu.$$

Moreover, for any $u, v \in R^m$, we have

$$\max(0, y(u)) - \max(0, y(v)) = V(y(u) - y(v)),$$

where V is an $n \times n$ diagonal matrix whose diagonal elements are defined by

$$V_{ii} = \begin{cases} 1, & y_i(u) > 0, \quad y_i(v) > 0, \\ \frac{y_i(u)}{y_i(u) - y_i(v)}, & y_i(u) > 0, \quad y_i(v) \le 0, \\ \frac{-y_i(v)}{y_i(u) - y_i(v)}, & y_i(u) \le 0, \quad y_i(v) > 0, \\ 0, & y_i(u) \le 0, \quad y_i(v) \le 0. \end{cases}$$

Since $V_{ii} \in [0, 1]$, $A + \lambda DV$ is symmetric positive definite and it holds that

$$\begin{aligned} \|y(u) - y(v)\|_2 &= \|(A + \lambda DV)^{-1} N(u - v)\|_2 \\ &\le \|A^{-1}\|_2 \|N\|_2 \|u - v\|_2. \end{aligned}$$

Hence y is a Lipschitz continuous function.

THEOREM 2.1. (i) *The function $F : R^n \times R^m \to R^n$ is differentiable at (y, u) if and only if $\mathcal{K}(y) = \emptyset$; in this case the derivative of F at (y, u) is given by*

$$F'(y, u) = (A + \lambda DE(y), -N).$$

(ii) *The function $y(\cdot) : R^m \to R^n$ is differentiable at u if and only if either $\mathcal{K}(y(u)) = \emptyset$ or*

$$((A + \lambda DE(y(u)))^{-1} N)_{\mathcal{K}(y(u))} = 0; \tag{2.1}$$

in this case the derivative of $y(\cdot)$ at u is given by

$$y'(u) = (A + \lambda DE(y(u)))^{-1} N.$$

Proof. (i) If $\mathcal{K}(y) = \emptyset$, then there is an open neighborhood $\mathcal{N}_y$ of y such that for all $z \in \mathcal{N}_y$, $\mathcal{J}(z) = \mathcal{J}(y), \mathcal{L}(z) = \mathcal{L}(y)$, and

$$F(z, u) \equiv (A + \lambda DE(y))z - Nu.$$

Hence F is differentiable at (y, u) and $F'(y, u) = (A + \lambda DE(y), -N)$.

Suppose that there is an $i \in \mathcal{K}(y)$. Then for any $\epsilon > 0$, we have

$$E(y + \epsilon e_i)(y + \epsilon e_i) = E(y)y + \epsilon e_i$$

and

$$E(y - \epsilon e_i)(y - \epsilon e_i) = E(y)y.$$

It follows that

$$\begin{aligned} &F(y + \epsilon e_i, u) - F(y, u) \\ &= \epsilon A e_i + \lambda D(E(y + \epsilon e_i)(y + \epsilon e_i) - E(y)y) \\ &= (A + \lambda D)(\epsilon e_i) \end{aligned}$$

and

$$\begin{aligned} &F(y - \epsilon e_i, u) - F(y, u) \\ &= -\epsilon A e_i + \lambda D(E(y - \epsilon e_i)(y - \epsilon e_i) - E(y)y) \\ &= -\epsilon A e_i. \end{aligned}$$

This shows that

$$\lim_{\epsilon\downarrow 0}\frac{F(y+\epsilon e_i,u)-F(y,u)}{\epsilon}\neq -\lim_{\epsilon\downarrow 0}\frac{F(y-\epsilon e_i,u)-F(y,u)}{\epsilon}.$$

Hence F is not differentiable with respect to y at (y,u). Consequently, if F is differentiable at (y,u), then $\mathcal{K}(y)=\emptyset$.

(ii) If $\mathcal{K}(y(u))=\emptyset$, the differentiability of $y(\cdot)$ follows directly from the first part of this theorem and the implicit function theorem, Theorem 5.2.4 in [10].

Now we consider the case that $\mathcal{K}(y(u))\neq\emptyset$ and (2.1) holds.

In order to simplify the notation, for a given $\bar{u}\in R^n$, we denote the unique vector $y(\bar{u})\in R^n$ by $\bar{y}$ and the associated index sets by

$$\mathcal{J}=\mathcal{J}(\bar{y}),\ \mathcal{K}=\mathcal{K}(\bar{y}),\ \mathcal{L}=\mathcal{L}(\bar{y}).$$

By the continuity of $y(\cdot)$, there is a neighborhood $\mathcal{N}$ of $\bar{u}$ such that for all $w\in\mathcal{N}$ we have

$$y_{\mathcal{J}}(w)>0\quad\text{and}\quad y_{\mathcal{L}}(w)<0,$$

which implies that $\mathcal{J}\subseteq\mathcal{J}(w)$ and $\mathcal{L}\subseteq\mathcal{L}(w)$. Assume that for a vector $w\in\mathcal{N}$ there is a nonempty subset $\mathcal{K}_1$ of $\mathcal{K}$ such that $\mathcal{J}\cup\mathcal{K}_1=\mathcal{J}(y(w))$. From (2.1) and the equality

$$N(w-\bar{u})=(A+\lambda DE(\bar{y}))(y(w)-\bar{y})+\lambda D(E(y(w))-E(\bar{y}))y(w),$$

we obtain

$$\begin{aligned}0&=((A+\lambda DE(\bar{y}))^{-1}N(w-\bar{u}))_{\mathcal{K}_1}\\&=(y(w)-\bar{y}+\lambda(A+\lambda DE(\bar{y}))^{-1}D(E(y(w))-E(\bar{y}))y(w))_{\mathcal{K}_1}\\&=(I_{\mathcal{K}_1\mathcal{K}_1}+\lambda(A+\lambda DE(\bar{y}))^{-1}_{\mathcal{K}_1\mathcal{K}_1}(DE(y(w)))_{\mathcal{K}_1\mathcal{K}_1})y(w)_{\mathcal{K}_1},\end{aligned}$$

where the last equality uses that $E_{ii}(\bar{y})=0$ for $i\in\mathcal{K}_1$ and

$$E_{ii}(y(w))-E_{ii}(\bar{y})=0\quad\text{for}\quad i\notin\mathcal{K}_1.$$

This implies that $y(w)_{\mathcal{K}_1}=0$, since $\lambda(A+\lambda DE(\bar{y}))^{-1}_{\mathcal{K}_1\mathcal{K}_1}$ and $(DE(y(w)))_{\mathcal{K}_1\mathcal{K}_1}$ are symmetric positive definite. This is a contradiction to $\mathcal{K}_1\subset\mathcal{J}(y(w))$. Hence we have $\mathcal{J}(y(w))=\mathcal{J}$, which gives $E(y(w))=E(\bar{y})$. The results ensure that the solution function $y(\cdot)$ in the neighborhood $\mathcal{N}$ can be expressed by

$$y(w)=(A+\lambda DE(\bar{y}))^{-1}Nw.$$

Hence $y(\cdot)$ is differentiable at $\bar{u}$ and

$$y'(\bar{u})=(A+\lambda DE(\bar{y}))^{-1}N.$$

Conversely, we assume that $y(\cdot)$ is differentiable at $\bar{u}$. According to the positive definite property of $A+\lambda DE(\bar{y})$, for any $h\in R^m$ the system

$$(A+\lambda DE(\bar{y}))z+\phi(z)=Nh \tag{2.2}$$

has a unique solution where

$$\phi_i(z)=\begin{cases}0, & i\in\mathcal{J}\cup\mathcal{L},\\ \lambda D_{ii}\max(0,z_i), & i\in\mathcal{K}.\end{cases}$$

Letting $t > 0$ be sufficiently small, we can therefore be assured that

$$(A + \lambda DE(\bar{y}))y(\bar{u} + th) + \phi(y(\bar{u} + th)) = N(\bar{u} + th).$$

Moreover, from $\bar{y}_{\mathcal{K}} = 0$, we have

$$\phi(y(\bar{u} + th)) - \phi(\bar{y}) = \phi(y(\bar{u} + th)) = \phi(y(\bar{u} + th) - \bar{y}).$$

Hence we find

$$(A + \lambda DE(\bar{y}))(y(\bar{u} + th) - \bar{y}) + \phi(y(\bar{u} + th) - \bar{y}) = N(\bar{u} + th) - N\bar{u} = tNh.$$

Note that $(A + \lambda DE(\bar{y}))(tz) + \phi(tz) = tNh$ for $t > 0$. This establishes that the unique solution of system (2.2) is the directional derivative $y'(\bar{y}; h)$ of $y(\cdot)$ along a direction $h \in R^m$ at $\bar{u}$, since

$$y(\bar{u} + th) - y(\bar{u}) = ty'(\bar{u}; h)$$

for sufficiently small $t > 0$, which gives

$$\lim_{t \downarrow 0} \frac{y(\bar{u} + th) - y(\bar{u})}{t} = y'(\bar{u}; h).$$

Moreover, the differentiability of $y(\cdot)$ at $\bar{u}$ implies

$$y'(\bar{u})h = y'(\bar{u}; h) = -y'(\bar{u}; -h),$$

from which we obtain that

$$(A + \lambda DE(\bar{y}))y'(\bar{u}; h) + \phi(y'(\bar{u}; h)) = Nh$$

and

$$-(A + \lambda DE(\bar{y}))y'(\bar{u}; h) + \phi(-y'(\bar{u}; h)) = -Nh.$$

It follows that

$$\phi(y'(\bar{u}; h)) + \phi(-y'(\bar{u}; h)) = 0.$$

Since ϕ is nonnegative, we have $\phi(y'(\bar{u}; h)) = 0$. Consequently, we obtain

$$y'(\bar{u}; h) = (A + \lambda DE(\bar{y}))^{-1}Nh = y'(\bar{u})h \quad \text{for all } h \in R^m,$$

which implies

$$y'(\bar{u}) = (A + \lambda DE(\bar{y}))^{-1}N.$$

Now we show $(y'(\bar{u}))_{\mathcal{K}} = 0$.

We have found that in a neighborhood $\mathcal{N}$ of $\bar{u}$, the function $y(\cdot)$ is linear and can be expressed by

$$y(w) = \bar{y} + (A + \lambda DE(\bar{y}))^{-1}N(w - \bar{u}) \quad \text{for all} \quad w \in \mathcal{N}. \tag{2.3}$$

From (2.3) and the equalities

$$N(w - \bar{u}) = (A + \lambda DE(\bar{y}))(y(w) - \bar{y}) + \lambda D(E(y(w)) - E(\bar{y}))y(w)$$

we obtain

$$\lambda(A+\lambda DE(\bar{y}))^{-1}D(E(y(w))-E(\bar{y}))y(w)=0.$$

Since $\lambda(A+\lambda DE(\bar{y}))^{-1}D$ is nonsingular, this implies that $(E(y(w))-E(\bar{y}))y(w)=0$, that is, $y_i(w)\le 0$ for all $i\in\mathcal{K}$.

If there is an $i\in\mathcal{K}$ such that $y_i(w)<0$, we can choose $t>0$ sufficiently small such that

$$\tilde{w}=\bar{u}-t(w-\bar{u})\in\mathcal{N}.$$

Then from the linearity of $y(\cdot)$ in the neighborhood $\mathcal{N}$, we get

$$y(\tilde{w})=\bar{y}-t(y(w)-\bar{y})$$

and

$$\lambda(A+\lambda DE(\bar{y}))^{-1}D(E(y(\tilde{w}))-E(\bar{y}))y(\tilde{w})=0.$$

However, $((E(y(\tilde{w}))-E(\bar{y}))y(\tilde{w}))_i=y_i(\tilde{w})>0$. This is a contradiction. Therefore, we have that $y_{\mathcal{K}}(\cdot)\equiv 0$ in the neighborhood $\mathcal{N}$, and thus $(y'(\bar{u}))_{\mathcal{K}}=0$.

Since $\bar{u}$ is arbitrarily chosen, we obtain the deserved result. □

A function $f:R^m\to R^n$ is called *piecewise linear* if there exists a finite number of linear functions $f^{(i)}:R^m\to R^n$, $i\in\{1,\dots,\ell\}$, such that the active index set $\{i|f(u)=f^{(i)}(u)\}$ is nonempty for every $u\in R^m$.

Theorem 2.1 states that there exists a finite number of linear functions

$$y^{(1)}u=A^{-1}Nu,\quad y^{(i)}u=\left(A+\lambda D\sum_{j\in\mathcal{I}_i}e_je_j^T\right)^{-1}Nu,$$

$\mathcal{I}_i\subseteq\{1,2,\dots,n\}$, such that the index set $\{i\mid y(u)=y^{(i)}(u)\}$ is nonempty for every $u\in R^m$. Hence $y(\cdot)$ is a piecewise linear function and the number of pieces is not more than 2^n.

The following example illustrates the differentiability of $y(\cdot)$ in the two cases of Theorem 2.1.

Example 2.1. Let $n=2,m=1,\lambda=1,b=1,D=I$,

$$A=\begin{pmatrix}2&-1\\-1&2\end{pmatrix},\qquad\text{and}\qquad N=\begin{pmatrix}3\\-1\end{pmatrix}.$$

The solution function $y(\cdot)$ can be given explicitly as

$$y(u)=\begin{cases}\begin{pmatrix}u\\0\end{pmatrix}, & u\ge 0,\\ \begin{pmatrix}5u/3\\u/3\end{pmatrix}, & u<0.\end{cases}$$

The solution function $y(\cdot)$ is differentiable at every point in R except $u=0$. Moreover, $2\in\mathcal{K}(y(u))$ for $u>0$. Let

$$y^{(1)}(u)=A^{-1}Nu=\begin{pmatrix}5/3\\1/3\end{pmatrix}u,\quad y^{(2)}(u)=(A+e_1e_1^T)^{-1}Nu=\begin{pmatrix}1\\0\end{pmatrix}u,$$

$$y^{(3)}(u) = (A + e_2 e_2^T)^{-1} N u = \begin{pmatrix} 8/5 \\ 1/5 \end{pmatrix} u, \quad y^{(4)}(u) = (A + I)^{-1} N u = \begin{pmatrix} 1 \\ 0 \end{pmatrix} u.$$

We have

$$\begin{array}{ll} y(u) = y^{(2)}(u) = y^{(4)}(u), & u > 0, \\ y(u) = y^{(1)}(u), & u < 0, \\ y(u) = y^{(1)}(u) = y^{(2)}(u) = y^{(3)}(u) = y^{(4)}(u), & u = 0. \end{array}$$

Hence y is a piecewise linear function and the number of pieces is less than 2^n. It is interesting to notice that $(A+I)^{-1}N = (A+E(y(u)))^{-1}N$ for $u > 0$. We can explain it theoretically.

The generalized Jacobian [6] of the function $\max(0, \cdot)$ at a point y is the convex hull of the set defined by a finite number of matrices:

$$\partial \max(0, y) = \operatorname{co} \left\{ \{E(y)\} \cup \left\{ E(y) + \sum_{i \in \mathcal{I}} e_i e_i^T \quad | \quad \mathcal{I} \subseteq \mathcal{K}(y) \right\} \right\}.$$

LEMMA 2.2. *If $\mathcal{K}(y) \neq \emptyset$ and $((A + \lambda DE(y))^{-1}N)_{\mathcal{K}(y)} = 0$, then for any $W \in \partial \max(0, y)$, we have*

$$(A + \lambda DW)^{-1} N = (A + \lambda DE(y))^{-1} N.$$

Proof. For a fixed point $y \in R^n$ which has r zero components, any element $W \in \partial \max(0, y)$ can be expressed by

$$W = E(y) + \sum_{j=1}^{r} \alpha_j \sum_{i \in \mathcal{I}_j} e_i e_i^T,$$

where $1 \geq \alpha_j \geq 0$ and $\mathcal{I}_j$ are subsets of $\mathcal{K}(y)$. Let

$$V = (A + \lambda DE(y))^{-1} N \quad \text{and} \quad U = (A + \lambda DW)^{-1} N. \tag{2.4}$$

We set $B = A + \lambda DE(y)$, $C = \lambda D(W - E(y))$, $\mathcal{K} = \mathcal{K}(y)$, $\mathcal{M} = \mathcal{J}(y) \cup \mathcal{L}(y)$. From (2.4), we get

$$\begin{pmatrix} B_{\mathcal{M}\mathcal{M}} & B_{\mathcal{M}\mathcal{K}} \\ B_{\mathcal{K}\mathcal{M}} & B_{\mathcal{K}\mathcal{K}} \end{pmatrix} \begin{pmatrix} V_{\mathcal{M}} \\ V_{\mathcal{K}} \end{pmatrix} = \begin{pmatrix} B_{\mathcal{M}\mathcal{M}} & B_{\mathcal{M}\mathcal{K}} \\ B_{\mathcal{K}\mathcal{M}} & (B + C)_{\mathcal{K}\mathcal{K}} \end{pmatrix} \begin{pmatrix} U_{\mathcal{M}} \\ U_{\mathcal{K}} \end{pmatrix}.$$

From $V_{\mathcal{K}} = 0$, we have

$$B_{\mathcal{M}\mathcal{M}}(V_{\mathcal{M}} - U_{\mathcal{M}}) - B_{\mathcal{M}\mathcal{K}} U_{\mathcal{K}} = 0 \tag{2.5}$$

and

$$B_{\mathcal{K}\mathcal{M}}(V_{\mathcal{M}} - U_{\mathcal{M}}) - (B + C)_{\mathcal{K}\mathcal{K}} U_{\mathcal{K}} = 0. \tag{2.6}$$

Since B is symmetric positive definite, $B_{\mathcal{M}\mathcal{M}}$ is nonsingular. Thus (2.5) and (2.6) yield

$$(B_{\mathcal{K}\mathcal{M}} B_{\mathcal{M}\mathcal{M}}^{-1} B_{\mathcal{M}\mathcal{K}} - (B + C)_{\mathcal{K}\mathcal{K}}) U_{\mathcal{K}} = 0. \tag{2.7}$$

The submatrix $B_{\mathcal{K}\mathcal{M}}B_{\mathcal{M}\mathcal{M}}^{-1}B_{\mathcal{M}\mathcal{K}} - (B+C)_{\mathcal{K}\mathcal{K}}$ is the Schur complement of the nonsingular matrix

$$\begin{pmatrix} B_{\mathcal{M}\mathcal{M}} & B_{\mathcal{M}\mathcal{K}} \\ B_{\mathcal{K}\mathcal{M}} & (B+C)_{\mathcal{K}\mathcal{K}} \end{pmatrix},$$

and thus it is nonsingular. It follows from (2.7) that $U_{\mathcal{K}} = 0$. Moreover, (2.5) and $U_{\mathcal{K}} = 0$ imply $V_{\mathcal{M}} = U_{\mathcal{M}}$. We complete the proof. □

LEMMA 2.3. *For any $W \in \partial \max(0, y)$, the following two systems are equivalent:*

$$\begin{pmatrix} H(y - y_d) + As + \lambda DWs \\ \alpha M(u - u_d) - N^T s + t \\ Ay + \lambda D \max(0, y) - Nu \\ \min(t, b - u) \end{pmatrix} = 0 \tag{2.8}$$

and

$$\begin{pmatrix} ((A + \lambda DW)^{-1}N)^T H(y(u) - y_d) + \alpha M(u - u_d) + t \\ \min(t, b - u) \end{pmatrix} = 0. \tag{2.9}$$

Proof. Note that $e_i^T \bar{y} = 0$ for $i \in \mathcal{K}(\bar{y})$, and any element $W \in \partial \max(0, \bar{y})$ can be expressed by

$$W = E(\bar{y}) + \sum_{j=1}^{r} \alpha_j \sum_{i \in \mathcal{I}_j} e_i e_i^T,$$

where $1 \le r \le n, 0 \le \alpha_j \le 1, \mathcal{I}_j \subseteq \mathcal{K}(\bar{y})$. Hence we have

$$\max(0, \bar{y}) = E(\bar{y})\bar{y} = W\bar{y} \quad \text{for any} W \in \partial \max(0, \bar{y}). \tag{2.10}$$

Suppose that $(\bar{y}, \bar{u}, s, t)$ satisfies (2.8). Then we have $y(\bar{u}) = \bar{y}$ and

$$\begin{aligned} &((A + \lambda DW)^{-1}N)^T H(y(\bar{u}) - y_d) + \alpha M(\bar{u} - u_d) + t \\ &= -((A + \lambda DW)^{-1}N)^T (A + \lambda DW)s + \alpha M(\bar{u} - u_d) + t \\ &= -N^T s + \alpha M(\bar{u} - u_d) + t \\ &= 0. \end{aligned}$$

Suppose that $(\bar{u}, t)$ satisfies (2.9). By the definition of $y(\cdot)$ and (2.10), we have $A\bar{y} + \lambda D \max(0, \bar{y}) - N\bar{u} = 0$ with $\bar{y} = y(\bar{u})$. Let $s = -(A + \lambda DW)^{-1}H(\bar{y} - y_d)$. We get

$$H(\bar{y} - y_d) + (A + \lambda DW)s = 0$$

and

$$\begin{aligned} \alpha M(\bar{u} - u_d) - N^T s + t = \alpha M(\bar{u} - u_d) + t \\ + N^T (A + \lambda DW)^{-1} H(\bar{y} - y_d) = 0. \end{aligned}$$

□

3. First order conditions. In this section we show the relations between (1.2), (1.3), (1.4), and (1.5). To simplify the notation, we denote, respectively, the objective functions of (1.2) and (1.3) by

$$f(y,u) = \frac{1}{2}(y-y_d)^T H(y-y_d) + \frac{\alpha}{2}(u-u_d)^T M(u-u_d)$$

and

$$\theta(u) = \frac{1}{2}(y(u)-y_d)^T H(y(u)-y_d) + \frac{\alpha}{2}(u-u_d)^T M(u-u_d).$$

From Lemma 2.3 and $E(y) \in \partial \max(0,y)$, we can see that (1.4) and (1.5) are equivalent.

THEOREM 3.1. *If $(\bar{y},\bar{u},\bar{s},\bar{t})$ is a solution of* (1.4)*, then $(\bar{u},\bar{t})$ is a solution of* (1.5)*. Conversely, if $(\bar{u},\bar{t})$ is a solution of* (1.5)*, then $(y(\bar{u}),\bar{u},-(A+\lambda DE(y(\bar{u})))^{-1}H(y(\bar{u})-y_d),\bar{t})$ is a solution of* (1.4)*.*

Now we show that (1.4) implies (1.2) and that (1.3) implies (1.5) under certain conditions.

THEOREM 3.2. *If (y^*,u^*,s^*,t^*) is a solution of* (1.4)*, then all feasible points (y,u) of* (1.2) *satisfy*

$$f(y,u) \geq f(y^*,u^*) + \lambda(D(E(y)-E(y^*))y)^T s^*.$$

Moreover, if either $\mathcal{K}(y^*) = \emptyset$ or $((A+\lambda DE(y^*))^{-1}N)_{\mathcal{K}(y^*)} = 0$, then (y^*,u^*) is a strict local optimal solution of (1.2)*.*

Proof. The objective function in (1.2) is quadratic. If (y^*,u^*,s^*,t^*) is a solution of (1.4), then we have

$$\begin{aligned}
&f(y,u) - f(y^*,u^*)\\
&= (y-y^*)^T H(y^*-y_d) + \alpha(u-u^*)^T M(u^*-u_d)\\
&\qquad + \frac{1}{2}(y-y^*)^T H(y-y^*) + \frac{\alpha}{2}(u-u^*)^T M(u-u^*)\\
&\geq (y-y^*)^T H(y^*-y_d) + \alpha(u-u^*)^T M(u^*-u_d)\\
&\geq (y-y^*)^T H(y^*-y_d) + \alpha(u-u^*)^T M(u^*-u_d) + (u-b)^T t^*\\
&= -(y-y^*)^T(A+\lambda DE(y^*))s^* + (u-u^*)^T(N^T s^* - t^*) + (u-u^*+u^*-b)^T t^*\\
&= -(y-y^*)^T(A+\lambda DE(y^*))s^* + (u-u^*)^T N^T s^*\\
&= -((A+\lambda DE(y^*))(y-y^*) - N(u-u^*))^T s^*\\
&= \lambda(D(E(y)-E(y^*))y)^T s^*,
\end{aligned}$$

where the second inequality uses $u \leq b$ and $t^* \geq 0$, the third equality uses $(u^*-b)^T t^* = 0$, and the fifth equality uses $(A+\lambda DE(y))y = Nu$.

If $\mathcal{K}(y^*) = \emptyset$ or $((A+\lambda DE(y^*))^{-1}N)_{\mathcal{K}(y^*)} = 0$, by Theorem 2.1, there is a neighborhood $\mathcal{N}_y$ of y^* such that for all *feasible* points $y \in \mathcal{N}_y$, we have $y = (A+\lambda DE(y^*))^{-1}Nu$ and

$$(E(y)-E(y^*))y = (E(y)-E(y^*))(A+\lambda DE(y^*))^{-1}Nu = 0.$$

Hence (y^*,u^*) is a local optimal solution of (1.2). Moreover, the first inequality above is strict if $y \neq y^*$, which implies that (y^*,u^*) is a strict local optimal solution. ∎

THEOREM 3.3. *Suppose that u^* is a local optimal solution of* (1.3). *If either $\mathcal{K}(y(u^*)) = \emptyset$ or $((A + \lambda DE(y(u^*)))^{-1}N)_{\mathcal{K}(y(u^*))} = 0$, then there is t^* such that (u^*, t^*) is a solution of* (1.5).

Proof. By Theorem 2.1, the function $y(\cdot)$ is differentiable at u^* and can be expressed by

$$y(u) = (A + \lambda DE(y^*))^{-1}Nu$$

in a neighborhood $\mathcal{N}_u$ of u^*. The gradient of θ at u^* is

$$\theta'(u^*) = ((A + \lambda DE(y^*))^{-1}N)^T H(y(u^*) - y_d) + \alpha M(u^* - u_d).$$

Let $W = (A + \lambda DE(y^*))^{-1}N$. For all $u \in \mathcal{N}_u$ we have

$$\theta(u) = \theta(u^*) + \theta'(u^*)^T(u - u^*) + (u - u^*)(W^T HW + \alpha M)(u - u^*) \geq \theta(u^*),$$

which implies that there is a sufficiently small $\epsilon > 0$ such that if $\|u - u^*\| \leq \epsilon$, then

$$\theta'(u^*)^T(u - u^*) \geq 0. \tag{3.1}$$

By choosing m feasible points

$$u_j^{(i)} = \begin{cases} u_i^* - \epsilon, & j = i, \\ u_j^*, & j \neq i, \end{cases}$$

for $i = 1, 2, \ldots m$, we find $\theta'(u^*) \leq 0$. From $u^* \leq b$, this gives

$$\theta'(u^*)^T(b - u^*) \leq 0.$$

If $\theta'(u^*)^T(b - u^*) < 0$, then there is an $i (1 \leq i \leq m)$ such that $\theta_i'(u^*) < 0$ and $b_i - u_i^* > 0$. We define a feasible point $\tilde{u}$ by

$$\tilde{u}_i = u_i^* + \min(\epsilon, b_i - u_i^*), \quad \tilde{u}_j = u_j^* \ (j \neq i).$$

Then we have

$$\theta'(u^*)^T(\tilde{u} - u^*) < 0.$$

This contradicts (3.1). Hence we obtain $\theta'(u^*)^T(b - u^*) = 0$. Let $t^* = -\theta'(u^*)$. Then (u^*, t^*) is a solution of (1.5). We complete the proof. ∎

COROLLARY 3.4.

1. *Let (y^*, u^*, s^*, t^*) be a solution of* (1.4). *If $y^* = y_d$, then (y^*, u^*) is a global optimal solution of* (1.2).
2. *Let u^* be a local optimal solution of* (1.3). *If $y(u^*) = y_d$, then $(u^*, -\alpha M(u^* - u_d))$ is a solution of* (1.5). *Moreover, u^* is a global optimal solution of* (1.3).

Proof. 1. From the first equality of (1.4), we find that $s^* = 0$. Then the result is derived from Theorem 3.2.

2. By the relation between (1.2) and (1.3), (y_d, u^*) is a local optimal solution of (1.2) and

$$f'(y_d, u^*)^T(u - u^*) = \alpha(u - u^*)^T M(u^* - u_d) \geq 0$$

for u being sufficiently close to u^*. Let $t^* = \alpha M(u^* - u_d)$. We can show that $\max(t^*, b - u^*) = 0$ by using the same technique in the proof for Theorem 3.3. Moreover, by Theorem 3.1 and part 1 of this corollary, u^* is a global optimal solution of (1.3). ∎

4. Final remarks. This paper presents new theoretical results on the first order conditions for the discretization problem arising from nonsmooth constrained optimal control problems. The results generalize existing results for smooth discretized constrained optimal control problems and answer some open questions on first order conditions for two kinds of discretization problems. Theorem 3.1 states that the first order conditions for problem (1.2) are equivalent to the first order conditions for problem (1.3). Theorems 3.2 and 3.3 show that the condition $\mathcal{K}(y) = \emptyset$ and $((A + \lambda DE(y))^{-1}N)_{\mathcal{K}(y)} = 0$ can be used to verify a local optimal point satisfies the first order conditions and that a point satisfying the first order conditions is a local optimal solution. Notice that $((A + \lambda DE(y))^{-1}N)_{\mathcal{K}(y)} = 0$ does not imply that $F(y, u) = Ay + \lambda D \max(0, y) - Nu$ is differentiable at (y, u).

A CONVEX APPROACH TO ROBUST STABILITY FOR LINEAR SYSTEMS WITH UNCERTAIN SCALAR PARAMETERS*

PIERRE-ALEXANDRE BLIMAN†

Abstract. In this paper, robust stability for linear systems with several uncertain (complex and/or real) scalar parameters is studied. A countable family of conditions sufficient for robust stability is given, in terms of solvability of some simple linear matrix inequalities (LMIs). These conditions are of increasing precision, and it is shown conversely that robust stability implies solvability of these LMIs from a certain rank and beyond. This result constitutes an extension of the characterization by solvability of Lyapunov inequality of the asymptotic stability for usual linear systems. It is based on the search of parameter-dependent quadratic Lyapunov functions, polynomial of increasing degree in the parameters.

Key words. robust stability, real and complex parametric uncertainty, polytopic uncertainty, parameter-dependent Lyapunov functions, linear matrix inequalities, μ-analysis, structured singular values, Kalman–Yakubovich–Popov lemma

DOI. 10.1137/S0363012901398691

1. Introduction.

In this paper we study the robust asymptotic stability of finite-dimensional linear systems subject to several scalar parametric uncertainties, namely

$$\dot{x} = A(z)x, \quad z \stackrel{\text{def}}{=} (z_1, \ldots, z_m), \quad A(z) \stackrel{\text{def}}{=} A_0 + z_1 A_1 + \cdots + z_m A_m, \tag{1}$$

where the fixed matrices $A_0, A_1, \ldots, A_m$ are elements of $\mathbb{C}^{n\times n}$. Here, the uncertain scalar parameters z_i may be complex or real numbers. In the latter case, for the sake of clarity, we shall rather write r_i.

It is a well-known fact that asymptotic stability of system (1) without uncertainty ($z_1 = \cdots = z_m = 0$) is equivalent to the existence of a hermitian matrix $P \in \mathbb{C}^{n\times n}$ such that

$$P > 0_n, \ A_0^H P + P A_0 < 0_n.$$

This is the well-known Lyapunov inequality. This approach is related to the search for a Lyapunov function of the form $x(t)^H P x(t)$, positive definite and decreasing along the trajectories of $\dot{x} = A_0 x$.

This approach has been extended in different ways in order to consider uncertain systems (1). In the various existing variants, one usually considers a set of constant systems, typically compact and convex: the task is to establish whether all the systems in this set are asymptotically stable or not. Various types of parameter sets are in consequence associated to (1), usually elliptic or polytopic. In the present paper, we mainly face the case of constant noncorrelated parameters, with values in closed unit balls of $\mathbb{R}$ or $\mathbb{C}$. In other words, we wish to test the existence of a hermitian matrix $P(z)$ such that

$$P(z) > 0_n, \ A(z)^H P(z) + P(z) A(z) < 0_n \tag{2}$$

for any $z \in \mathbb{C}^m$ with $|z_i| \leq 1$, $z_i \in \mathbb{R}$, or $\mathbb{C}$, $i = 1, \ldots, m$. This problem appears as a *parameter-dependent linear matrix inequality* (LMI).

This problem is decidable but NP-hard. Indeed, it amounts to evaluating some particular structured singular values [15, 46]. Generally speaking, computing and approximating μ is a hard task [9, 39, 18], and the gap with its usual upper bound is infinite [40, 37]. The more specific problem studied here may be seen equivalently [10] as checking delay-independent stability [27, 28, 23] of a delay system, which has been proved to be NP-hard too [38].

A first method to cope with uncertainty consists of looking for a simultaneous Lyapunov function, i.e., for a constant hermitian positive definite P such that $x(t)^H P x(t)$ decreases along the trajectories of (1), for any value of z in the convenient set; see the bibliography on quadratic stability in [8, pp. 72–73]. Subsequent developments have led to consider *parameter-dependent Lyapunov functions*: sufficient conditions for existence of affine parameter-dependent functions $P(z)$ in (2) are provided in [21, 17, 12, 33] and in [41, 42] for functions quadratic in the parameters. Methods involving piecewise quadratic Lyapunov functions [43, 35] and LMIs with augmented numbers of variables [22, 32] may also be found.

Another approach is based on the use of *scaling* or *multiplier* in an input/output stability framework. The use of diagonal scaling (D-scaling) [15] permits us to obtain upper bound for μ, whereas DG-scaling [16] plays an analog role for real parametric uncertainty. Contributions based on the larger class of LFT-scaling [1] and on multiplier technique [19] have provided less conservative results. Some results are based on mixed methods [13, 20].

The contributions presented previously provide sufficient conditions for *robust stability* of (1), that is, for asymptotic stability for any value of the parameters in the adequate set. However, they are far from being necessary and, due to their conservatism, may fail to detect robust stability. On the other hand, they may be checked easily. Indeed, most of them reduce to testing the solvability of LMI problems, a standard convex optimization problem [8], achievable in polynomial-time. Efficient interior-point methods have been developed and are available as toolboxes in widely spread control-oriented scientific softwares, such as MATLAB or SCILAB.

From a theoretical point of view, the connection between the two methods has been enlightened by Iwasaki [24] and Iwasaki and Hara [26]. Both may be interpreted as special cases of the *quadratic separator*, separating in an appropriate space a graph associated to the "system" from a graph associated to the "perturbation," here the parameters. Roughly speaking, the previous results are obtained when looking for such a separator with prespecified "simple" dependency, with respect to either the frequency (frequency-dependent scaling matrix in μ-analysis) or to parameters (parameter-dependent Lyapunov functions). Clearly, taking small separator classes yields gain in computational simplicity. On the other hand, increasing the separator class size reduces the conservatism of the obtained criterion.

The existing exact methods of resolution of the problem are based on the use of upper and lower bounds on (smaller and smaller) subdomains of the parameter space; see [11, 3, 45]. Due to the computational complexity of the task, they lead to prohibitive growth in computation cost with the problem size, at least in the worst case. The main problem is to find an acceptable trade-off between precision and computational burden.

The results in the present paper provide a systematic way for the use of parameter-dependent Lyapunov functions and their related LMI criteria. The general principle

for their derivation may be explained as follows.

First, the solution $P(z)$ of the Lyapunov equation $A(z)^H P(z) + P(z)A(z) = -I_n$ is *analytic* with respect to the vector of parameters z and its conjugate $\bar{z}$ (this fact may be checked from the explicit form $P(z) = \int_0^{+\infty} e^{A(z)^H t} e^{A(z)t}\, dt$). This suggests that for systems which are robustly stable, there always exists a parameter-dependent Lyapunov function $x(t)^H P(z)x(t)$ with P fulfilling (2) which is *polynomial with respect to* $z, \bar{z}$. Basically, this comes from the fact that one may truncate the latter expansion, due to convergence uniform in z. One hence takes as new unknowns of the problem a positive integer k such that $k-1$ represents the maximal power in the variables $z, \bar{z}$ of the polynomial $P(z)$, plus the k^m coefficients themselves, which are hermitian matrices of size $n \times n$. Second, it turns out that the conditions that must be verified by the previous coefficients (including the global condition of positivity of $P(z)$ for all z) may be transformed into a set of LMIs in a total of $m+1$ unknown hermitian matrices. The main tool for this operation is the application, repeated m times, of the discrete-time Kalman–Yakubovich–Popov lemma.

This two-step procedure motivates the form of the results presented in the core of the paper, which we now summarize. A *family of LMIs* is exhibited, indexed by the positive integer k (roughly speaking, the degree in the $z, \bar{z}$ of a solution of (2)), and whose solvability implies robust stability of system (2). Also, it is shown that solvability for rank k implies solvability for $k' \geq k$, so these sufficient conditions are more and more precise (less and less conservative) as the degree of the polynomial solution increases. A key issue is that a *necessity* property also holds in the precise sense that if robust stability holds, then the corresponding LMIs are fulfilled *from a certain rank k and beyond*. Thus, the conservatism vanishes asymptotically. Robust stability of system (1) is hence *characterized* by solvability of LMI problems. The originality of the proposed method is to associate to a sequence of increasing classes of candidate parameter-dependent Lyapunov functions, whose existence for a precise problem may be checked by solving a LMI, a *completeness* result, ensuring that robust stability implies existence of a Lyapunov function in at least one of the classes. A related idea for generation of parameter-dependent Lyapunov functions based on nonminimal state is used in [25] without, however, insight into the necessity part.

The paper is organized as follows. In section 2 some notation is given necessary for the statement of the results. In section 3 a class of parameter-dependent Lyapunov functions is presented which plays a central role in the paper. In section 4 the two results corresponding to m complex parameters (Theorem 4.1) and m real parameters (Theorem 4.3) are stated. The mixed case may be written down easily and is not extensively developed here. In what follows, we provide as a straightforward consequence a result on robust stability of systems with polytopic uncertainties (Corollary 4.4). A numerical example is presented further on in section 5. Comments on the status of the results are given in section 6. Complete proofs of Theorems 4.1 and 4.3 are given in section 7. Last, concluding remarks are made in section 8.

2. Notation. The matrices I_n, 0_n, $0_{n\times p}$ are the $n \times n$ identity matrix and the $n \times n$ and $n \times p$ zero matrices, respectively. The symbol $\otimes$ denotes Kronecker product, the power of Kronecker products being used with the natural meaning $M^{0\otimes} = 1$, $M^{p\otimes} \stackrel{\text{def}}{=} M^{(p-1)\otimes} \otimes M$. Recall the important property that $(A \otimes B)(C \otimes D) = (AC \otimes BD)$ for any matrices with compatible size. The spectrum of a square matrix M is written $\sigma(M)$, and, applying the operation Re to this set, one denotes by $\mathrm{Re}\,\sigma(M)$ the set $\{\mathrm{Re}\, s \ : \ s \in \sigma(M)\}$. For example, $\mathrm{Re}\,\sigma(M) < 0$ means that M is Hurwitz. The spectral radius of a square matrix M is written $\rho(M)$. The conjugate

and transconjugate of M are denoted M^T and M^H. $\mathbb{N}$ is the set of positive integers. $\overline{\mathbb{D}}$ is denoted the closed unit ball in $\mathbb{C}$. The unit circle is denoted as the boundary $\partial\mathbb{D}$. $\overline{\mathbb{C}^+}$ is the closed set of complex numbers with nonnegative real part. Last, the set of complex hermitian matrices of size $n \times n$ is denoted by $\mathcal{H}^n$.

Let $\hat{J}_k, \check{J}_k \in \mathbb{R}^{k\times(k+1)}$ be defined by

$$\hat{J}_k \stackrel{\text{def}}{=} \begin{pmatrix} I_k & 0_{k\times 1} \end{pmatrix}, \ \check{J}_k \stackrel{\text{def}}{=} \begin{pmatrix} 0_{k\times 1} & I_k \end{pmatrix}.$$

These matrices will prove essential for polynomial manipulation. In particular, a key property is that, for $u^{[k]} \in \mathbb{C}^k$ defined, for $u \in \mathbb{C}$, by

$$u^{[k]} \stackrel{\text{def}}{=} \begin{pmatrix} 1 \\ u \\ \vdots \\ u^{k-1} \end{pmatrix}, \tag{3}$$

one has

$$\hat{J}_k u^{[k+1]} = u^{[k]}, \ \check{J}_k u^{[k+1]} = u u^{[k]}. \tag{4}$$

Also, we will use the fact that, for any $k \in \mathbb{N}$,

$$\hat{J}_k \check{J}_{k+1} = \check{J}_k \hat{J}_{k+1} = \begin{pmatrix} 0_{k\times 1} & I_k & 0_{k\times 1} \end{pmatrix}. \tag{5}$$

Finally, one shows directly that, for any matrix $M \in \mathbb{C}^{p\times q}$, for any $u \in \mathbb{C}$,

$$(u^{[k]} \otimes I_p)M = (I_k \otimes M)(u^{[k]} \otimes I_q). \tag{6}$$

3. Polynomially parameter-dependent quadratic functions and their evolution. In the study of system (1), a crucial role will be played here by the search for parameter-dependent Lyapunov functions chosen within the following class.

DEFINITION 3.1. *We call a* polynomially parameter-dependent quadratic function *(PPDQ function for short) any quadratic function $x^H P(z)x$ on $\mathbb{C}^n$ such that*

$$P(z) \stackrel{\text{def}}{=} (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H P_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n) \tag{7}$$

for a certain $P_k \in \mathcal{H}^{k^m n}$. The integer $k-1$ is called the degree of the PPDQ function P.

Notice that the expression $(z_m^{[k]} \otimes \cdots \otimes z_1^{[k]})$ gathers in a column all the monomials with degree at most $k-1$ in each of the components of z.

The following auxiliary result provides the derivative of a PPDQ function along the trajectories of (1).

PROPOSITION 3.2. *The derivative of the PPDQ function* (7) *of degree $k-1$ along the trajectories of the system $\dot{x} = A(z)x$ is a PPDQ function $R(z)$ of degree k given by*

$$R(z) \stackrel{\text{def}}{=} (z_m^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n)^H R_k (z_m^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n), \tag{8}$$

where $R_k \in \mathcal{H}^{(k+1)^m n}$ *is defined as*

(9)

$$R_k \stackrel{\text{def}}{=} \left(\left(\hat{J}_k^{m\otimes}\otimes A_0\right)+\sum_{i=1}^{m}\left(\hat{J}_k^{(m-i)\otimes}\otimes \check{J}_k\otimes \hat{J}_k^{(i-1)\otimes}\otimes A_i\right)\right)^H P_k\left(\hat{J}_k^{m\otimes}\otimes I_n\right)$$
$$+\left(\hat{J}_k^{m\otimes}\otimes I_n\right)^T P_k\left(\left(\hat{J}_k^{m\otimes}\otimes A_0\right)+\sum_{i=1}^{m}\left(\hat{J}_k^{(m-i)\otimes}\otimes \check{J}_k\otimes \hat{J}_k^{(i-1)\otimes}\otimes A_i\right)\right)$$

and depends linearly upon $P_k \in \mathcal{H}^{k^m n}$.

Proof of Proposition 3.2. Clearly, $R(z) = A(z)^H P(z) + P(z)A(z)$. As an example, let us evaluate $P(z)A(z)$. One has

$$\begin{aligned}
P(z)A(z) &= (z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H P_k (z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)A(z)\\
&= (z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H P_k (I_{k^m}\otimes A(z))(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)\\
&\qquad \text{(due to (6))}\\
&= (z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H P_k \Big[(I_{k^m}\otimes A_0)(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)\\
&\quad +(I_{k^m}\otimes A_1)(z_m^{[k]}\otimes\cdots\otimes z_1 z_1^{[k]}\otimes I_n)\\
&\quad +\cdots+(I_{k^m}\otimes A_m)(z_m z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)\Big],
\end{aligned}$$

and the second term in (9) is obtained by repeated use of the two formulas in (4). □

To study systems with real parameters $\dot{x} = A(r)x$, we use the change of variables $r = \frac{z+\bar{z}}{2}$, which maps $\overline{\mathbb{D}}^m$ onto $[-1;+1]^m$. It turns out that the formulas are of smaller size when one is directly looking for a Lyapunov function parametrized by z and not by r. The analogue of Proposition 3.2 for this case is given below, and its proof, using the same techniques, is left to the reader.

Proposition 3.3. *The derivative of the PPDQ function* (7) *of degree* $k-1$ *along the trajectories of the system* $\dot{x} = A(\frac{z+\bar{z}}{2})x$ *is a PPDQ function* $R(z)$ *of degree* k *given as* (8)*, where* $R_k \in \mathcal{H}^{(k+1)^m n}$ *is now defined by*

(10)

$$\begin{aligned}
R_k \stackrel{\text{def}}{=}\ & \frac{1}{2}\left(\left(\hat{J}_k^{m\otimes}\otimes A_0\right)+\sum_{i=1}^{m}\left(\hat{J}_k^{(m-i)\otimes}\otimes \check{J}_k\otimes \hat{J}_k^{(i-1)\otimes}\otimes A_i\right)\right)^H P_k\left(\hat{J}_k^{m\otimes}\otimes I_n\right)\\
+\ & \frac{1}{2}\left(\left(\hat{J}_k^{m\otimes}\otimes A_0\right)^H P_k\left(\hat{J}_k^{m\otimes}\otimes I_n\right)+\sum_{i=1}^{m}\left(\hat{J}_k^{m\otimes}\otimes A_i\right)^H P_k\left(\hat{J}_k^{(m-i)\otimes}\otimes \check{J}_k\otimes \hat{J}_k^{(i-1)\otimes}\otimes I_n\right)\right)\\
+\ & \frac{1}{2}\left(\hat{J}_k^{m\otimes}\otimes I_n\right)^T P_k\left(\left(\hat{J}_k^{m\otimes}\otimes A_0\right)+\sum_{i=1}^{m}\left(\hat{J}_k^{(m-i)\otimes}\otimes \check{J}_k\otimes \hat{J}_k^{(i-1)\otimes}\otimes A_i\right)\right)\\
+\ & \frac{1}{2}\left(\left(\hat{J}_k^{m\otimes}\otimes I_n\right)^T P_k\left(\hat{J}_k^{m\otimes}\otimes A_0\right)+\sum_{i=1}^{m}\left(\hat{J}_k^{(m-i)\otimes}\otimes \check{J}_k\otimes \hat{J}_k^{(i-1)\otimes}\otimes I_n\right)^T P_k\left(\hat{J}_k^{m\otimes}\otimes A_i\right)\right)
\end{aligned}$$

and depends linearly upon $P_k \in \mathcal{H}^{k^m n}$.

4. Main results. We are now in a position to state the main results of the paper.

Theorem 4.1 (robust stability of systems with complex parameters). *The following three properties are* equivalent.

(i) *The matrix* $A(z)$ *in* (1) *is Hurwitz for any* $z \in \overline{\mathbb{D}}^m$.

(ii) *There exists a PPDQ Lyapunov function* $x^H P(z)x$ *for the class of systems* $\dot{x} = A(z)x$ *with* $A(z)$ *defined by* (1), *i.e., such that*

$$\forall z \in \overline{\mathbb{D}}^m,\ P(z) > 0,\ R(z) < 0,$$

where $R(z)$ *is defined by* (8), (9).

(iii) *There exist a positive integer* k *and* $(m+1)$ *matrices*

$$P_k \in \mathcal{H}^{k^m n} \text{ and } Q_{k,i} \in \mathcal{H}^{k^{m-i+1}(k+1)^{i-1}n},\ i = 1, \dots, m,$$

which solve the following LMI:

(LMI_k)

$$\begin{cases} P_k > 0_{k^m n}, \\ R_k + \displaystyle\sum_{i=1}^{m} \left(\hat{J}_k^{(m-i+1)\otimes} \otimes I_{(k+1)^{i-1}n}\right)^T Q_{k,i} \left(\hat{J}_k^{(m-i+1)\otimes} \otimes I_{(k+1)^{i-1}n}\right) \\ - \displaystyle\sum_{i=1}^{m} \left(\hat{J}_k^{(m-i)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{i-1}n}\right)^T Q_{k,i} \left(\hat{J}_k^{(m-i)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{i-1}n}\right) < 0_{(k+1)^m n}, \end{cases}$$

with $R_k = R_k(P_k)$ *defined in* (9).

Moreover, if (LMI_k) *with* (9) *is solvable for the index* k, *then it is also solvable for all indices* $k' \geq k$. *Finally, if the matrices* A_i, $0 \leq i \leq m$, *are real, then the statement holds with real, symmetric, matrices* $P_k, Q_{k,i}$, $1 \leq i \leq m$.

The proof of Theorem 4.1 is given in section 7.1.

From Theorem 4.1, one deduces in particular that, for any positive integer k,

$$\begin{aligned} &(\mathrm{LMI}_k) \text{ is solvable} \Rightarrow (\mathrm{LMI}_{k'}) \text{ is solvable for } k' \geq k \\ &\qquad\qquad \Rightarrow \text{system (1) is robustly stable against any } z \in \overline{\mathbb{D}}^m. \end{aligned} \tag{11}$$

In other words, any of the conditions (LMI_k) is sufficient for robust stability, and they are more and more precise. Necessity of the condition is obtained asymptotically for large enough k.

The sufficiency result (11) is central and turns out to be the "easy" part of the proof. Before commenting further on Theorem 4.1, we provide indications on its demonstration, leaving the details for the complete proof in section 7.1.

Sketch of proof for (11). Left- and right-multiplication of the second inequality in (LMI_k) by $(z_m^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n)$ and its transconjugate yields $R(z) + \sum_{i=1}^m (1 - |z_i|^2)(z_m^{[k]} \otimes \cdots \otimes z_i^{[k]} \otimes z_{i-1}^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n)^H Q_{k,i} (z_m^{[k]} \otimes \cdots \otimes z_i^{[k]} \otimes z_{i-1}^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n) < 0_n$. Indeed, this is a direct consequence of (4). Thus, $R(z) < 0_n$ if $|z_1| = \cdots = |z_m| = 1$, so the matrix $A(z)$ is Hurwitz for all $z \in (\partial\mathbb{D})^m$, and this may be extended to the whole $\overline{\mathbb{D}}^m$; see the details in section 7.1.1. This proves that solvability of (LMI_k) is sufficient for robust stability.

To prove that solvability of (LMI_k) implies solvability of (LMI_{k+1}), one constructs

directly a new solution $P_{k+1}, Q_{k+1,1}, \dots, Q_{k+1,m}$, by taking

$$P_{k+1} \stackrel{\text{def}}{=} \sum_{M_i \in \{\hat{J}_k, \check{J}_k\},\ i=1,\dots,m} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T P_k (M_m \otimes \cdots \otimes M_1 \otimes I_n),$$

$$Q_{k+1,i} \stackrel{\text{def}}{=} \sum_{\substack{M_l \in \{\hat{J}_{k+1}, \check{J}_{k+1}\},\ l=1,\dots,i-1,\\ M_l \in \{\hat{J}_k, \check{J}_k\},\ l=i,\dots,m}} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T Q_{k,i} (M_m \otimes \cdots \otimes M_1 \otimes I_n),$$

for $i = 1, \dots, m$. One then shows that the matrix R_{k+1} obtained from P_{k+1} by formula (9) verifies

$$R_{k+1} \stackrel{\text{def}}{=} \sum_{M_i \in \{\hat{J}_{k+1}, \check{J}_{k+1}\},\ i=1,\dots,m} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T R_k (M_m \otimes \cdots \otimes M_1 \otimes I_n).$$

As a matter of fact, one may show that this amounts to multiplying $P(z)$ and $R(z)$ by $(1+|z_1|^2)\dots(1+|z_m|^2)$ in (ii). Based on properties (5), (6), the two inequalities of (LMI_{k+1}) are then deduced from the inequalities of (LMI_k); see details in section 7.1.3 below. □

Remark 4.2. Paradoxically, the positive definite PPDQ function $x^H P(z) x$ of degree $k-1$ formed from a solution of (LMI_k) is not ensured to decrease along the trajectories of the system. The argument developed above consisted of showing that $R(z) < 0_n$ for $z \in (\partial\mathbb{D})^m$. As said before, this yields Hurwitzness of $A(z)$ for $z \in (\partial\mathbb{D})^m$, which implies the same property in $\overline{\mathbb{D}}^m$, basically by an analyticity result; see section 7.1.1. However, in general $R(z) \not< 0_n$ for $z \in \overline{\mathbb{D}}^m$, unless $Q_{k,i} > 0_{k^{m-i+1}(k+1)^{i-1}n}$ for all $i = 1, \dots, m$. In the case of a *unique* scalar uncertainty ($m = 1$), there is no loss of generality to add this positivity condition on $Q_{k,1}$ in the LMI; see [5]. We conjecture that the same remains true for $m > 1$.

In the case $m = 0$, the problem (LMI_k) simply states that $\exists P \in \mathcal{H}^n$, $P > 0_n$, $A_0^H P + P A_0 < 0_n$. For $m = 1$, one gets the following family of LMIs indexed by $k \in \mathbb{N}$: $\exists P_k \in \mathcal{H}^{kn}$, $P_k > 0_{kn}$, $\exists Q_k \in \mathcal{H}^{kn}$,

$$\begin{aligned}(\hat{J}_k \otimes A_0)^H P_k (\hat{J}_k \otimes I_n) + (\check{J}_k \otimes A_1)^H P_k (\hat{J}_k \otimes I_n)\\ + (\hat{J}_k \otimes I_n)^T P_k (\hat{J}_k \otimes A_0) + (\hat{J}_k \otimes I_n)^T P_k (\check{J}_k \otimes A_1)\\ + (\hat{J}_k \otimes I_n)^T Q_k (\hat{J}_k \otimes I_n) - (\check{J}_k \otimes I_n)^T Q_k (\check{J}_k \otimes I_n) < 0_{(k+1)n};\end{aligned}$$

that is,

(12)
$$\begin{pmatrix} \hat{J}_k \otimes I_n \\ \check{J}_k \otimes I_n \end{pmatrix}^T \begin{pmatrix} (I_k \otimes A_0)^H P_k + P_k (I_k \otimes A_0) + Q_k & P_k (I_k \otimes A_1) \\ (I_k \otimes A_1)^H P_k & -Q_k \end{pmatrix} \begin{pmatrix} \hat{J}_k \otimes I_n \\ \check{J}_k \otimes I_n \end{pmatrix} < 0_{(k+1)n}.$$

For two parameters ($m = 2$), one obtains $\exists P_k \in \mathcal{H}^{k^2 n}, P_k > 0_{k^2 n}$, $\exists Q_{k,1} \in \mathcal{H}^{k^2 n}$, $\exists Q_{k,2} \in \mathcal{H}^{k(k+1)n}$,

$$\begin{aligned}(\hat{J}_k^{2\otimes} \otimes A_0)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\hat{J}_k^{2\otimes} \otimes A_0)\\ + (\hat{J}_k \otimes \check{J}_k \otimes A_1)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\hat{J}_k \otimes \check{J}_k \otimes A_1)\\ + (\check{J}_k \otimes \hat{J}_k \otimes A_2)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\check{J}_k \otimes \hat{J}_k \otimes A_2)\\ + (\hat{J}_k^{2\otimes} \otimes I_n)^T Q_{k,1} (\hat{J}_k^{2\otimes} \otimes I_n) - (\hat{J}_k \otimes \check{J}_k \otimes I_n)^T Q_{k,1} (\hat{J}_k \otimes \check{J}_k \otimes I_n)\\ + (\hat{J}_k \otimes I_{(k+1)n})^T Q_{k,2} (\hat{J}_k \otimes I_{(k+1)n}) - (\check{J}_k \otimes I_{(k+1)n})^T Q_{k,2} (\check{J}_k \otimes I_{(k+1)n})\\ < 0_{(k+1)^2 n},\end{aligned}$$

or again

(13)
$$\begin{pmatrix} \hat{J}_k \otimes \hat{J}_k \otimes I_n \\ \hat{J}_k \otimes \check{J}_k \otimes I_n \\ \check{J}_k \otimes \hat{J}_k \otimes I_n \end{pmatrix}^T \begin{pmatrix} (I_{k^2} \otimes A_0)^H P_k + P_k (I_{k^2} \otimes A_0) + Q_{k,1} & P_k (I_{k^2} \otimes A_1) & P_k (I_{k^2} \otimes A_2) \\ (I_{k^2} \otimes A_1)^H P_k & -Q_{k,1} & 0_{k^2 n} \\ (I_{k^2} \otimes A_2)^H P_k & 0_{k^2 n} & 0_{k^2 n} \end{pmatrix}$$
$$\times \begin{pmatrix} \hat{J}_k \otimes \hat{J}_k \otimes I_n \\ \hat{J}_k \otimes \check{J}_k \otimes I_n \\ \check{J}_k \otimes \hat{J}_k \otimes I_n \end{pmatrix} + \begin{pmatrix} \hat{J}_k \otimes I_{(k+1)n} \\ \check{J}_k \otimes I_{(k+1)n} \end{pmatrix}^T \begin{pmatrix} Q_{k,2} & 0_{k(k+1)n} \\ 0_{k(k+1)n} & -Q_{k,2} \end{pmatrix} \begin{pmatrix} \hat{J}_k \otimes I_{(k+1)n} \\ \check{J}_k \otimes I_{(k+1)n} \end{pmatrix} < 0_{(k+1)^2 n}.$$

An interesting comparison may be made, concerning the simplest criterion, obtained for $k = 1$. In the case $m = 1$ (see (12)), (LMI_1) writes

$$P_1 = P_1^H > 0,\ Q_{1,1} = Q_{1,1}^H,\ \begin{pmatrix} A_0^H P_1 + P_1 A_0 + Q_{1,1} & P_1 A_1 \\ A_1^H P_1 & -Q_{1,1} \end{pmatrix} < 0,$$

which matches the conditions for quadratic stability with D-scalings. For the case $m = 2$ of two parameters (see (13)), the inequalities are

$$P_1 = P_1^H > 0,\ Q_{1,1} = Q_{1,1}^H,\ Q_{1,2} = Q_{1,2}^H,$$
$$\begin{pmatrix} A_0^H P_1 + P_1 A_0 + Q_{1,1} & P_1 A_1 & P_1 A_2 & 0_n \\ A_1^H P_1 & -Q_{1,1} & 0_n & 0_n \\ A_2^H P_1 & 0_n & 0_n & 0_n \\ 0_n & 0_n & 0_n & 0_n \end{pmatrix} + \begin{pmatrix} Q_{1,2} & 0_{2n} \\ 0_{2n} & -Q_{1,2} \end{pmatrix} < 0,$$

where here the size of $Q_{1,2}$ is twice that of $Q_{1,1}$. This is clearly less restrictive than the conditions obtained with D-scalings, namely,

$$P_1 = P_1^H > 0,\ Q_{1,1} = Q_{1,1}^H,\ Q_{1,2} = Q_{1,2}^H,$$
$$\begin{pmatrix} A_0^H P_1 + P_1 A_0 + Q_{1,1} + Q_{1,2} & P_1 A_1 & P_1 A_2 \\ A_1^H P_1 & -Q_{1,1} & 0_n \\ A_2^H P_1 & 0_n & -Q_{1,2} \end{pmatrix} < 0.$$

For larger values of m, (LMI_1) is obtained by introduction of the remaining multipliers $Q_{1,i}$, along the same principles. The obtained conditions are related to, but less conservative than, the ones obtained with D-scalings.

The result for systems with real parameters is analogous to Theorem 4.1.

THEOREM 4.3 (robust stability of systems with real parameters). *The following three properties are* equivalent.

(i) *The matrix $A(r)$ in* (1) *is Hurwitz for any $r \in [-1;+1]^m$.*

(ii) *There exists a PPDQ Lyapunov function $x^H P(r) x$ for the class of systems $\dot{x} = A(r)x$ with $A(r)$ defined by* (1)*, i.e., such that*

$$\forall r \in [-1;+1]^m,\ P(r) > 0,\ R(r) < 0,$$

where $R(r)$ is defined as in (8)*, with R_k given by* (10).

(iii) *There exist a positive integer k and $(m+1)$ matrices*

$$P_k \in \mathcal{H}^{k^m n} \text{ and } Q_{k,i} \in \mathcal{H}^{k^{m-i+1}(k+1)^{i-1} n}, \quad i = 1, \ldots, m,$$

which solve the (LMI_k) *with $R_k = R_k(P_k)$ defined in* (10).

Moreover, if (LMI$_k$) *with* (10) *is solvable for the index* k*, then it is also solvable for all indices* $k' \geq k$*. Finally, if the matrices* A_i*,* $0 \leq i \leq m$*, are real, then the statement holds with real, symmetric, matrices* $P_k, Q_{k,i}$*,* $1 \leq i \leq m$*.*

The proof of Theorem 4.3 is given in section 7.2.

For $m = 1$ and $m = 2$, respectively, the two following families of LMIs are obtained: $\exists P_k \in \mathcal{H}^{kn}$, $P_k > 0_{kn}$, $\exists Q_k \in \mathcal{H}^{kn}$,

$$(\hat{J}_k \otimes A_0)^H P_k (\hat{J}_k \otimes I_n) + \tfrac{1}{2}\left((\hat{J}_k \otimes A_1)^H P_k (\check{J}_k \otimes I_n) + (\check{J}_k \otimes A_1)^H P_k (\hat{J}_k \otimes I_n)\right)$$
$$+ (\hat{J}_k \otimes I_n)^T P_k (\hat{J}_k \otimes A_0) + \tfrac{1}{2}\left((\check{J}_k \otimes I_n)^T P_k (\hat{J}_k \otimes A_1) + (\hat{J}_k \otimes I_n)^T P_k (\check{J}_k \otimes A_1)\right)$$
$$+ (\hat{J}_k \otimes I_n)^T Q_k (\hat{J}_k \otimes I_n) - (\check{J}_k \otimes I_n)^T Q_k (\check{J}_k \otimes I_n) < 0_{(k+1)^n}$$

and $\exists P_k \in \mathcal{H}^{k^2 n}, P_k > 0_{k^2 n}$, $\exists Q_{k,1} \in \mathcal{H}^{k^2 n}$, $\exists Q_{k,2} \in \mathcal{H}^{k(k+1)n}$,

$$(\hat{J}_k^{2\otimes} \otimes A_0)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\hat{J}_k^{2\otimes} \otimes A_0)$$
$$+ \tfrac{1}{2}\left((\hat{J}_k^{2\otimes} \otimes A_1)^H P_k (\hat{J}_k \otimes \check{J}_k \otimes I_n) + (\hat{J}_k \otimes \check{J}_k \otimes A_1)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n)\right)$$
$$+ \tfrac{1}{2}\left((\hat{J}_k^{2\otimes} \otimes A_2)^H P_k (\check{J}_k \otimes \hat{J}_k \otimes I_n) + (\check{J}_k \otimes \hat{J}_k \otimes A_2)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n)\right)$$
$$+ \tfrac{1}{2}\left((\hat{J}_k \otimes \check{J}_k \otimes I_n)^T P_k (\hat{J}_k^{2\otimes} \otimes A_1) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\hat{J}_k \otimes \check{J}_k \otimes A_1)\right)$$
$$+ \tfrac{1}{2}\left((\check{J}_k \otimes \hat{J}_k \otimes I_n)^T P_k (\hat{J}_k^{2\otimes} \otimes A_2) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\check{J}_k \otimes \hat{J}_k \otimes A_2)\right)$$
$$+ (\hat{J}_k^{2\otimes} \otimes I_n)^T Q_{k,1} (\hat{J}_k^{2\otimes} \otimes I_n) - (\hat{J}_k \otimes \check{J}_k \otimes I_n)^T Q_{k,1} (\hat{J}_k \otimes \check{J}_k \otimes I_n)$$
$$+ (\hat{J}_k \otimes I_{(k+1)n})^T Q_{k,2} (\hat{J}_k \otimes I_{(k+1)n}) - (\check{J}_k \otimes I_{(k+1)n})^T Q_{k,2} (\check{J}_k \otimes I_{(k+1)n}) < 0_{(k+1)^2 n}.$$

Forms similar to (12) and (13) may be obtained. For $k = 1$, $m = 1$, one gets for the LMI defined in Theorem 4.3

$$P_1 = P_1^H > 0,\ Q_{1,1} = Q_{1,1}^H,\ \begin{pmatrix} A_0^H P_1 + P_1 A_0 + Q_{1,1} & \frac{1}{2}(A_1^H P_1 + P_1 A_1) \\ \frac{1}{2}(A_1^H P_1 + P_1 A_1) & -Q_{1,1} \end{pmatrix} < 0,$$

to be compared to the condition obtained by *DG*-scaling:

$$P_1 = P_1^H > 0,\ D = D^H,\ G + G^H = 0,\ \begin{pmatrix} A_0^H P_1 + P_1 A_0 + D & P_1 A_1 + G \\ A_1^H P_1 + G^H & -D \end{pmatrix} < 0.$$

One may verify that there is no loss of generality to take $G = \frac{1}{2}(A_1^H P_1 - P_1 A_1)$ in the latter inequality, so the two criteria are equivalent. The formulas for larger m are obtained similarly to the complex case; they provide also tighter sufficient conditions than the ones based on *DG*-scaling.

Theorems 4.1 and 4.3 are easily adapted to treat the mixed complex/real case. The result is not stated completely here for the sake of space. As an example, for stability analysis of $A_0 + zA_1 + rA_2$, for a complex parameter z and a real parameter

r, both of norm less than or equal to 1, the criterion is based on the following family of LMIs: $\exists P_k \in \mathcal{H}^{k^2 n}$, $P_k > 0_{k^2 n}$, $\exists Q_{k,1} \in \mathcal{H}^{k^2 n}$, $\exists Q_{k,2} \in \mathcal{H}^{k(k+1)n}$,

$$
\begin{aligned}
&(\hat{J}_k^{2\otimes} \otimes A_0)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) + (\hat{J}_k \otimes \check{J}_k \otimes A_1)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) \\
&\quad + \tfrac{1}{2}\left((\hat{J}_k^{2\otimes} \otimes A_2)^H P_k (\check{J}_k \otimes \hat{J}_k \otimes I_n) + (\check{J}_k \otimes \hat{J}_k \otimes A_2)^H P_k (\hat{J}_k^{2\otimes} \otimes I_n) \right) \\
&\quad + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\hat{J}_k^{2\otimes} \otimes A_0) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\hat{J}_k \otimes \check{J}_k \otimes A_1) \\
&\quad + \tfrac{1}{2}\left((\check{J}_k \otimes \hat{J}_k \otimes I_n)^T P_k (\hat{J}_k^{2\otimes} \otimes A_2) + (\hat{J}_k^{2\otimes} \otimes I_n)^T P_k (\check{J}_k \otimes \hat{J}_k \otimes A_2) \right) \\
&\quad + (\hat{J}_k^{2\otimes} \otimes I_n)^T Q_{k,1} (\hat{J}_k^{2\otimes} \otimes I_n) - (\hat{J}_k \otimes \check{J}_k \otimes I_n)^T Q_{k,1} (\hat{J}_k \otimes \check{J}_k \otimes I_n) \\
&+ (\hat{J}_k \otimes I_{(k+1)n})^T Q_{k,2} (\hat{J}_k \otimes I_{(k+1)n}) - (\check{J}_k \otimes I_{(k+1)n})^T Q_{k,2} (\check{J}_k \otimes I_{(k+1)n}) < 0_{(k+1)^2 n}.
\end{aligned}
$$

The robust stability of a polytope of matrices is now addressed by reduction to the problems solved in Theorem 4.3. Consider, for $m+1$ fixed matrices $B_1, \ldots, B_{m+1} \in \mathbb{C}^{n\times n}$, the class of systems

$$
\dot{x} = B(\beta)x, \quad \beta \stackrel{\text{def}}{=} (\beta_0, \beta_1, \ldots, \beta_m), \quad B(\beta) \stackrel{\text{def}}{=} \beta_0 B_0 + \beta_1 B_1 + \cdots + \beta_m B_m. \tag{14}
$$

Define the polytope $\mathbb{P}^{m+1} \stackrel{\text{def}}{=} \{\beta \in \mathbb{R}^{m+1} \ : \ \beta_i \geq 0, \ \beta_0 + \cdots + \beta_m = 1\}$.

COROLLARY 4.4 (robust stability of real convex polytopic systems). *The following three properties are* equivalent.

(i) *The matrix $B(\beta)$ in* (14) *is Hurwitz for any $\beta \in \mathbb{P}^{m+1}$.*

(ii) *There exists $m+1$ PPDQ functions $x^H P_i(\beta) x$, $i = 0, \ldots, m$ such that*

$$
\forall \beta \in \mathbb{P}^{m+1}, \ \begin{array}{l} P_i(\beta) > 0, i = 0, \ldots, m, \\ B(\beta)^H P_{\arg\max \beta_i}(\beta) + P_{\arg\max \beta_i}(\beta) B(\beta) < 0. \end{array}
$$

(iii) *For each value of $i = 0, \ldots, m$, there exists a positive integer k for which* (LMI$_k$) *with R_k defined in* (10) *is solvable, with*

$$
A_0 \stackrel{\text{def}}{=} B_i + \frac{1}{2} \sum_{j=0, j\neq i}^{m} B_j, \quad \{A_1, \ldots, A_m\} = \left\{ \frac{1}{2} B_j \ : \ j \neq i \right\}. \tag{15}
$$

Proof of Corollary 4.4. Let, for example, $\max_{0\leq i\leq m} \beta_i = \beta_0 > 0$, and write

$$
B(\beta) = \beta_0 \left(B_0 + \frac{1}{2} \sum_{i=1}^{m} B_i + \frac{1}{2} \sum_{i=1}^{m} \left(2\frac{\beta_i}{\beta_0} - 1 \right) B_i \right).
$$

Remark that the map $[0; +1] \to [-1; +1]$, $u \mapsto 2u - 1$ is one-to-one. For any fixed value of $i = \arg\max \beta_j$ (take any value if the maximum is attained for more than one index), property (i) is thus equivalent to robust stability of $\dot{x} = A(r)x$ with the definition of $A_0, A_1, \ldots, A_m$ given in (15), and it is possible to apply Theorem 4.3. For any fixed $i = \arg\max \beta_j$, a PPDQ Lyapunov function is found as a function of $r_j \stackrel{\text{def}}{=} -1 + 2\beta_j / \max \beta_i$, $j \neq i$, and may be expressed with respect to β_j after adequate change of the coefficients. ∎

Application of Theorem 4.3 thus provides for this problem too a family of sufficient conditions for robust stability, whose conservatism vanishes asymptotically: $m+1$ families of LMIs are found such that robust stability of (14) is equivalent to the solvability of at least one LMI in each family. Clearly, this approach amounts to the search for a piecewise PPDQ Lyapunov function, chosen, in $m+1$ quadrants of the parameter space, according to the value of $\max \beta_i$.

5. Numerical example. Consider the following example. Let $n = 3$,

$$A_0 = \begin{pmatrix} -12 & -7 & 7 \\ -11 & -13 & -5 \\ -2 & 9 & -8 \end{pmatrix},\ A_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 2 \\ 0 & 3 & 0 \end{pmatrix},\ A_2 = \begin{pmatrix} 1 & 2 & 0 \\ -3 & -1 & 0 \\ -1 & 0 & 0 \end{pmatrix}.$$

We evaluate the following robustness margins:

$$\begin{aligned}
\alpha_{zz} &\stackrel{\text{def}}{=} \sup_{(z_1,z_2)\in\overline{\mathbb{D}}^2} \operatorname{Re}\sigma(A_0 + z_1A_1 + z_2A_2),\\
\alpha_{zr} &\stackrel{\text{def}}{=} \sup_{(z,r)\in\overline{\mathbb{D}}\times[-1;+1]} \operatorname{Re}\sigma(A_0 + zA_1 + rA_2),\\
\alpha_{rz} &\stackrel{\text{def}}{=} \sup_{(r,z)\in[-1;+1]\times\overline{\mathbb{D}}} \operatorname{Re}\sigma(A_0 + rA_1 + zA_2),\\
\alpha_{z} &\stackrel{\text{def}}{=} \sup_{z\in\overline{\mathbb{D}}} \operatorname{Re}\sigma(A_0 + z(A_1 + A_2)),\\
\alpha_{rr} &\stackrel{\text{def}}{=} \sup_{(r_1,r_2)\in[-1;+1]^2} \operatorname{Re}\sigma(A_0 + r_1A_1 + r_2A_2),\\
\alpha_{r} &\stackrel{\text{def}}{=} \sup_{r\in[-1;+1]} \operatorname{Re}\sigma(A_0 + r(A_1 + A_2)).
\end{aligned}$$

Clearly, the latter quantities are linked by the inequalities:

$$\alpha_{zz} \geq \alpha_{zr}, \quad \alpha_{rz} \geq \alpha_{rr} \geq \alpha_r, \quad \text{and } \alpha_{zz} \geq \alpha_z \geq \alpha_r. \tag{16}$$

We use the previously presented LMIs to find, for each uncertainty structure, the least real number α such that $A(z) - \alpha I_n$ is robustly stable. For each integer k and for each value of α, a convex problem is solved, but the problem is not jointly convex in the four unknowns $P_k, Q_{k,1}, Q_{k,2}$, and α, so a bisection process is achieved.

The computations presented here have been performed using the package `lmitool` of the free software Scilab. The successive (upper) estimates of the robustness margins, according to the value of k, are given in Table 1. Between parentheses is given the CPU time necessary for the solution of the LMIs (for the corresponding values of α and k), measured on a computer equipped with a Pentium III 800MHz.

The values are compared to those obtained by checking directly the robust stability by means of gridding of the parameter space, which are presented in Table 2. Due to the small size of the problem, small computation times are required.

One verifies that, for each margin, the successive estimates are nonincreasing functions of k and that the inequalities corresponding to (16) are fulfilled for any value of k. In the present case, the tests achieved for $k = 2$ provide these true values up to three digits, except for α_r ($k = 3$).

In principle, the previous numbers may also be determined using the fact that

$$\alpha_{zz} = \inf\left\{\alpha \in \mathbb{R} \ :\ \forall \omega \in \mathbb{R}, \forall \alpha' \in (\alpha; +\infty),\ \mu_\Delta(G(j\omega + \alpha')) < 1\right\},$$

TABLE 1
Successive estimates of the margins and corresponding CPU times.

10×10	-4.15 (0.01s)	-5.24 (0.01s)	-5.42 (0.01s)
100×100	-4.15 (0.02s)	-5.24 (0.84s)	-5.42 (0.01s)

where $G(s) \stackrel{\text{def}}{=} \binom{I_n}{I_n} \left(sI_n - A_0\right)^{-1} \begin{pmatrix} A_1 & A_2 \end{pmatrix}$, and for the uncertainty structure $\Delta = \{\text{diag}\{z_1 I_n; z_2 I_n\} : z_i \in \mathbb{C}\}$. Similar formulas hold for the other margins. Define the constants

$$\overline{\alpha} \stackrel{\text{def}}{=} \inf\left\{\alpha \in \mathbb{R} \ : \ \forall \omega \in \mathbb{R}, \forall \alpha' \in (\alpha; +\infty), \ \overline{\sigma}(G(j\omega + \alpha')) < 1\right\},$$

$$\overline{\alpha}_{zz} \stackrel{\text{def}}{=} \inf\left\{\alpha \in \mathbb{R} \ : \ \forall \omega \in \mathbb{R}, \forall \alpha' \in (\alpha; +\infty), \ \nu_\Delta(G(j\omega + \alpha')) < 1\right\},$$

where Δ is the same set as above, and $\overline{\sigma}$ and ν_Δ denote, respectively, the largest singular value and the usual upper bound of μ_Δ [16]. Based on the properties of ν_Δ [16], one has $\alpha_{zz} \leq \overline{\alpha}_{zz} \leq \overline{\alpha}$. The results of the estimation of the previous constants, based on the underlying LMI problems, are summarized in Table 3. As before, the CPU time necessary to check that, for a fixed value of α, $\overline{\sigma}(G(j\omega+\alpha)) < 1$ (respectively, $\nu_\Delta(G(j\omega+\alpha)) < 1$) for a discretized sample of frequencies ω on the real axis is indicated between parentheses. Tighter discretization, not reproduced here, shows that the values obtained for 1000 gridding points are the true values of the extrema $\overline{\alpha}$ and $\overline{\alpha}_{zz}$.

Recall that the estimate α_{zz} obtained by use of Theorem 4.1 for $k = 2$ is exact (up to the precision considered), while $\overline{\alpha}$ and $\overline{\alpha}_{zz}$ provide conservative robust stability margins. For this simple example, the gain in precision is clear for comparable computation time.

6. Comments on the results. The results stated in section 4 permit a systematic approach to the study of parameter-dependent quadratic Lyapunov functions for robust stability: a class of candidate Lyapunov functions is exhibited (given in Definition 3.1), rich enough to *characterize* robust stability but structured enough to permit the use of LMI tests. In our opinion, this offers a useful insight into the powerfulness of quadratic Lyapunov functions for stability analysis. Similarly, it provides information on the kind of problems solvable by LMIs: the issue of robust stability analysis is located "on the boundary" of these problems, as it may be relaxed with

TABLE 3
Successive estimates of the margins by upper bounds and corresponding CPU times.

Number of nodes in frequency domain	$\overline{\alpha}$	$\overline{\alpha}_{zz}$
100	-0.241 (0.43s)	-1.30 (0.84s)
1000	-0.151 (5.22s)	-1.21 (7.96s)

arbitrary precision into a standard LMI, obtained explicitly. In this sense, the results given here constitute an attempt to investigate in more detail the abilities of the LMIs, which have become, in the last decade, a unifying framework for expressing and solving many problems in control theory.

We believe that, beyond their theoretical interest, the proposed results may offer attractive numerical alternatives for robust stability analysis, at least for problems of low order. The construction of the LMIs involved is reasonably simple, using only elementary algebraic operations. For a given value of k, their complexity is polynomial with respect to the dimension n of the matrices and exponential with respect to the number m of scalar parameters. More precisely, the total number of scalar elements of the unknowns $P_k, Q_{k,1}, \ldots, Q_{k,m}$ in (LMI_k) is $\frac{1}{2}[k^m n(k^m+1) + \sum_{1\leq i\leq m} k^{m-i+1}(k+1)^{i-1}(k^{m-i+1}(k+1)^{i-1}+1)]$, which is equivalent to $\frac{m+1}{2}k^{2m}n^2$ when $k \to +\infty$, while the number of rows of the inequalities involved is $[k^m + (k+1)^m]n$, which is of the order of $2k^m n$ when $k \to +\infty$.

A quantitative evaluation of the relationship between the size of k and the precision of the criteria should be considered as a natural next step in forthcoming research. In the general case, however, when no special matrix structure exists for the system under study, the growth of the value of k needed to check robust stability of a system cannot be polynomial in the worst case. The effective use of large values of k hinges upon the possibility of intensive computation and use of large memory.

The method for robust stability analysis proposed here may be compared to the one consisting of checking stability in every node of a grid of the parameter space. Both methods are able to provide less and less conservative criteria—when the discretization step goes to zero or when the degree, with respect to the parameters, of the underlying parameter-dependent Lyapunov function goes to infinity. Both methods are exact, in the sense that they provide asymptotically arbitrarily precise estimates of the true stability margins. The gridding method, however, offers successive (less and less) optimistic estimates, whereas the other one provides (less and less) pessimistic indications, usually more useful in practice.

Also, both methods are, in the present state of knowledge, computationally *undecidable*: no information is known on the size of the least k, if any, for which the LMIs are solvable (in other words, of the largest k which is necessary to test numerically to decide whether the system is robustly stable or not). This is an important question, both from theoretical and practical points of view. Some numerical experiments (see section 5) indicate that small values of k often yield correct answers.

Finally, recall that ensuring robust stability analysis is equivalent to checking that a certain structured singular value is less than 1. In consequence, the results presented above may also be seen as providing a family of more and more precise *upper bounds* for these special-structured singular values. In a future work, the extension of this to the general case of structured singular values with repeated scalar blocks will be investigated. Indeed, it may be reasonable to employ these new upper bounds in a

branch and bound algorithm [3] in place of the usual ones.

Alternatively, in the case of real parameters, a possible way to consider problems of larger size rests in the combination of decomposition of the parameter domain and resolution on each subdomain by use of a low-order test. This should permit us to find a compromise between the number of independent LMIs to be solved (equal to the number of subdivisions) and the computational complexity (due to the high degree of the underlying parameter-dependent Lyapunov functions). When coupled with decomposition in the parameter space, one may expect a better fit of the proposed method than the direct use of Theorems 4.1 and 4.3, at least for problems of medium size.

7. Proofs. The following decomposition of the matrix $\hat{J}_k$ defined in section 2 will be used:

$$\hat{J}_k = \begin{pmatrix} I_k & 0_{k\times 1} \end{pmatrix} = \begin{pmatrix} f_k & F_k \end{pmatrix},$$

where

$$f_k \stackrel{\text{def}}{=} \begin{pmatrix} 1 \\ 0_{(k-1)\times 1} \end{pmatrix}, \quad F_k \stackrel{\text{def}}{=} \begin{pmatrix} 0_{1\times(k-1)} & 0 \\ I_{k-1} & 0_{(k-1)\times 1} \end{pmatrix}. \tag{17}$$

The size of the previous matrices is $f_k : k \times 1$, $F_k : k \times k$, and the spectrum of F_k is $\{0\}$. Simple computation shows that, for any $z \in \mathbb{C}$, $(I_k - zF_k)z^{[k]} = f_k$, that is,

$$(I_k - zF_k)^{-1} f_k = z^{[k]}. \tag{18}$$

Another useful property is the fact that, for any $i \in \mathbb{N}$, $0 \le i \le k-1$,

$$F_k^{iT} z^{[k]} = \begin{pmatrix} 0_{(k-i)\times i} & I_{k-i} \\ 0_i & 0_{i\times(k-i)} \end{pmatrix} \begin{pmatrix} z^{[i]} \\ z^i z^{[k-i]} \end{pmatrix} = z^i \begin{pmatrix} z^{[k-i]} \\ 0_{i\times 1} \end{pmatrix}. \tag{19}$$

7.1. Proof of Theorem 4.1. We now prove Theorem 4.1. The proof of the equivalence between the properties (i), (ii), and (iii) consists of three main stages that we now present and which are detailed below in sections 7.1.1–7.1.3.

1*st stage.* We detail here the ideas given in the sketch of the proof of formula (11). We show that the computations proposed there permit us to establish that solvability of (LMI_k) implies solvability of (2) for all $z \in (\partial\mathbb{D})^m$. It remains to show that this implies, however, Hurwitzness of $A(z)$ for any z *in the whole set* $\overline{\mathbb{D}}^m$. This gives the implication (iii) $\Rightarrow$ (i).

2*nd stage.* The second step establishes that the robust stability property (i) implies that the parameter-dependent Lyapunov inequality (2) admits a solution $P(z)$ of the form (7), for a certain $k \in \mathbb{N}$, with P_k *positive definite*. For this, one shows essentially that the associated Lyapunov *equation* $A(z)^H P(z) + P(z)A(z) = -I_n$ admits as a solution an infinite sum of powers of $z, \bar{z}$, converging uniformly in $\overline{\mathbb{D}}^m$. It then suffices to truncate this expansion to obtain a polynomial solution (of unknown degree) to *inequality* (2). The corresponding coefficient matrix P_k is positive *semidefinite* by construction, and some more work is necessary to obtain an expression with a *positive* definite matrix. This gap is filled in Lemma 7.1. As a by-product, the implication (i) $\Rightarrow$ (ii) is obtained here.

3*rd stage.* At this point, (i) has been shown to imply existence, for large enough k, of a certain $P_k > 0$ such that $R(z)$ given by (8), (9) is negative definite for any $z \in \overline{\mathbb{D}}^m$. The next step (Lemma 7.2) is the key part of the necessity proof. It consists

of showing that $R(z) < 0$ for all $z \in (\partial\mathbb{D})^m$ *if and only if* the second inequality in (LMI_k) holds. This is done by applying recursively D-scaling with respect to each of the parameters z_i. At each step, a new matrix, depending upon the remaining parameters $z_{i+1}, \ldots, z_m$, is introduced. The latter may be assumed polynomial in the previous parameters and their conjugates (this is deduced from a general result on existence of polynomial solutions to parameter-dependent LMIs, Theorem 7.3), with coefficients defined by a constant matrix, which is precisely the variable $Q_{k,i}$ of (LMI_k). The transformation carried out by this procedure is not restrictive, as the scaling technique (the Kalman–Yakubovich–Popov lemma, recalled in Appendix A) is lossless for one complex parameter. This yields the implication (ii) $\Rightarrow$ (iii). Incidentally, we prove at this stage that the solvability of (LMI_k) implies the same property for largest indices.

When the coefficients are real, then the polynomial solutions exhibited above are easily proved to be real too, basically due to the remark on realness given after the version of the Kalman–Yakubovich–Popov lemma recalled in Appendix A.

7.1.1. First stage. Suppose (LMI_k) holds. As suggested in the sketch of the proof of formula (11), left- and right-multiplication of its second inequality by $(z_m^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n)$ and its transconjugate yields $R(z) + \sum_{i=1}^m (1-|z_i|^2)(z_m^{[k]} \otimes \cdots \otimes z_i^{[k]} \otimes z_{i-1}^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n)^H Q_{k,i} (z_m^{[k]} \otimes \cdots \otimes z_i^{[k]} \otimes z_{i-1}^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n) < 0_n$. Indeed, this comes directly from the fact that, due to (4), for any $i = 1, \ldots, m$,

$$\left(\hat{J}_k^{(m-i+1)\otimes} \otimes I_{(k+1)^{i-1}n}\right)(z_m^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n) = (z_m^{[k]} \otimes \cdots \otimes z_i^{[k]} \otimes z_{i-1}^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n),$$

$$\left(\hat{J}_k^{(m-i)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{i-1}n}\right)(z_m^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n) = z_i (z_m^{[k]} \otimes \cdots \otimes z_i^{[k]} \otimes z_{i-1}^{[k+1]} \otimes \cdots \otimes z_1^{[k+1]} \otimes I_n).$$

Thus, $R(z) < 0_n$ if $|z_1| = \cdots = |z_m| = 1$, so the matrix $A(z)$ is Hurwitz for all $z \in (\partial\mathbb{D})^m$.

The remaining argument is based on a subharmonicity and continuity argument. Using the fact that the map $\overline{\mathbb{C}^+} \cup \{\infty\} \to \overline{\mathbb{D}}, s_z \mapsto (1-s_z)/(1+s_z)$ is one-to-one, one proves [7] that

$$\begin{aligned}\max_{z\in\overline{\mathbb{D}}^m} \rho(e^{A(z)}) &= \sup_{s\in\overline{\mathbb{C}^+}^m} \rho(e^{A_0+(1-s_1)/(1+s_1)A_1+\cdots+(1-s_m)/(1+s_m)A_m}) \\ &= \sup_{s\in(j\mathbb{R})^m} \rho(e^{A_0+(1-s_1)/(1+s_1)A_1+\cdots+(1-s_m)/(1+s_m)A_m}) \\ &= \max_{z\in(\partial\mathbb{D})^m} \rho(e^{A(z)}).\end{aligned}$$

As a consequence, if all the matrices $A(z)$ are Hurwitz for $z \in (\partial\mathbb{D})^m$, then the previous expression is less than 1, and the same property holds on the whole $\overline{\mathbb{D}}^m$. This shows that (iii) implies (i).

7.1.2. Second stage. Property (i) implies solvability of (2) for each $z \in \overline{\mathbb{D}}^m$, which, as is well known, is equivalent [29] to the solvability of the (Lyapunov) *equation*

$$P(z) > 0_n, \ A(z)^H P(z) + P(z)A(z) = -I_n. \tag{20}$$

Now, when (i) holds, the latter has a solution *analytic in* z, $\bar{z}$ *in* $\overline{\mathbb{D}}^m$. Indeed, when $A(z)$ is Hurwitz, the explicit form of the solution of (20) is given by

$$P(z) = \int_0^{+\infty} e^{A(z)^H t} e^{A(z)t}\, dt.$$

When $A(z)$ is Hurwitz for any z in the compact set $\overline{\mathbb{D}}^m$, the convergence of this integral in $t = +\infty$ is uniform with respect to z, so there exists $T > 0$ independent of z such that $P(z)$ defined now by

$$P(z) = \int_0^{T} e^{A(z)^H t} e^{A(z)t}\, dt \tag{21}$$

is positive definite and solves inequality (2) in $\overline{\mathbb{D}}^m$.

Expanding the integrand in powers of the $z_i, \bar{z}_i$, $1 \le i \le m$, and interverting the sum and the integral, one exhibits an expansion of $P(z)$ in powers of $z, \bar{z}$, converging uniformly for $(z,t) \in \overline{\mathbb{D}}^m \times [0;T]$. More precisely, let $M_k : [0;T] \to \mathbb{C}^{n \times k^m n}$ be such that $M_k(t)(z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)$ represents the terms of degree less than k in each of the z_i in the expansion of $e^{A(z)t}$. Then

$$\int_0^{T} e^{A(z)^H t} e^{A(z)t}\, dt = \lim_{k \to +\infty} (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H \tilde{P}_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n) \tag{22}$$

with uniform convergence in $\overline{\mathbb{D}}^m$, where $\tilde{P}_k \in \mathcal{H}^{k^m n}$ is defined by

$$\tilde{P}_k \stackrel{\text{def}}{=} \int_0^{T} M_k(t)^H M_k(t)\, dt \ge 0. \tag{23}$$

Now this implies that, for large enough k, $(z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H \tilde{P}_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)$ solves inequality (2) in $\overline{\mathbb{D}}^m$. This provides a PPDQ Lyapunov function for (1), but not the desired one, as the matrices $\tilde{P}_k$ are only positive *semidefinite* (except $\tilde{P}_1 = P(0)$, which is positive definite).

Let instead, for the matrix F_k defined in (17),

$$P_k \stackrel{\text{def}}{=} \sum_{i_1,\ldots,i_m=0}^{k-1} (F_k^{i_m} \otimes \cdots \otimes F_k^{i_1} \otimes I_n) \tilde{P}_k (F_k^{i_m} \otimes \cdots \otimes F_k^{i_1} \otimes I_n)^T. \tag{24}$$

LEMMA 7.1. *The matrix* $P_k \in \mathcal{H}^{k^m n}$ *defined in* (24) *is positive definite and, for large enough* $k \in \mathbb{N}$, $(z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H P_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)$ *solves* (2) *in* $\overline{\mathbb{D}}^m$.

Proof. We begin with the positivity property. Note first that $P_k \ge 0$, because $\tilde{P}_k \ge 0$. Let $u \in \mathbb{C}^{k^m n}$ such that $u^H P_k u = 0$, and let us establish that this implies $u = 0$. In view of (24), and thanks to the fact that $\tilde{P}_k \ge 0$, this implies that for all $0 \le i_1, \ldots, i_m \le k-1$,

$$u^H (F_k^{i_m} \otimes \cdots \otimes F_k^{i_1} \otimes I_n) \tilde{P}_k (F_k^{i_m} \otimes \cdots \otimes F_k^{i_1} \otimes I_n)^T u = 0. \tag{25}$$

First, notice that for any integer i, k, $i \le k$, all the terms of degree less than $k-i$ in $e^{A(z)t}$, whose total sum is $M_{k-i}(t)(z_m^{[k-i]} \otimes \cdots \otimes z_1^{[k-i]} \otimes I_n)$ by definition, are also

present in $M_k(t)(z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)$. At the level of the matrices $\tilde{P}_k$, this property reads as

(26)
$$\tilde{P}_{k-i} = \left(\begin{pmatrix} I_{k-i} \\ 0_{i\times(k-i)} \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} I_{k-i} \\ 0_{i\times(k-i)} \end{pmatrix} \otimes I_n\right)^T \tilde{P}_k \left(\begin{pmatrix} I_{k-i} \\ 0_{i\times(k-i)} \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} I_{k-i} \\ 0_{i\times(k-i)} \end{pmatrix} \otimes I_n\right).$$

Indeed, for $z \in \mathbb{C}$, $\begin{pmatrix} I_{k-i} \\ 0_{i\times(k-i)} \end{pmatrix} z^{[k-i]}$ is equal to $z^{[k]}$, except for the terms of degree larger than $k-i-1$, which are replaced by zero. Remark also that, for $i' \leq i \leq k$,

$$F_k^{iT} = \begin{pmatrix} 0_{(k-i)\times i} & I_{k-i} \\ 0_i & 0_{i\times(k-i)} \end{pmatrix} = \begin{pmatrix} I_{k-i'} \\ 0_{i'\times(k-i')} \end{pmatrix} \begin{pmatrix} 0_{(k-i)\times i} & I_{k-i} \\ 0_{(i-i')\times i} & 0_{(i-i')\times(k-i)} \end{pmatrix}. \tag{27}$$

Putting now $i_1 = \cdots = i_m = k-1$ in (25) and using identity (27) with $i = i' = k-1$ and (26), one deduces first that

$$\left\| \tilde{P}_1^{1/2} \left(\begin{pmatrix} 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes I_n \right) u \right\|^2 = 0;$$

i.e., as $\tilde{P}_1 > 0$,

$$\left(\begin{pmatrix} 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes I_n \right) u = 0. \tag{28}$$

Taking then $i_1 = k-2, i_2 = \cdots = i_m = k-1$ in (25), using (27) with $i = i' = k-2$ and $i' = k-2$, $i = k-1$, and then using (26), yields

$$\left\| \tilde{P}_2^{1/2} \left(\begin{pmatrix} 0_{2\times(k-2)} & I_2 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes I_n \right) u \right\|^2 = 0.$$

Now

$$\begin{aligned}
&\tilde{P}_2^{1/2} \left(\begin{pmatrix} 0_{2\times(k-2)} & I_2 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes I_n \right) u \\
&= \tilde{P}_2^{1/2} \left(\begin{pmatrix} 0_{1\times(k-2)} & 1 & 0 \\ 0_{1\times(k-2)} & 0 & 0 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes I_n \right) u \\
&\quad + \tilde{P}_2^{1/2} \left(\begin{pmatrix} 0_{1\times(k-1)} & 0 \\ 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes I_n \right) u \\
&\qquad \text{(by linearity)} \\
&= \tilde{P}_2^{1/2} \left(\begin{pmatrix} 0_{1\times(k-2)} & 1 & 0 \\ 0_{1\times(k-2)} & 0 & 0 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes I_n \right) u \\
&\qquad \text{(due to (28))},
\end{aligned}$$

and, thanks to (26),

$$\begin{aligned}
&\left\| \tilde{P}_2^{1/2} \left(\begin{pmatrix} 0_{1\times(k-2)} & 1 & 0 \\ 0_{1\times(k-2)} & 0 & 0 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \\ 0_{1\times(k-1)} & 0 \end{pmatrix} \otimes I_n \right) u \right\| \\
&\quad = \left\| \tilde{P}_1^{1/2} \left(\begin{pmatrix} 0_{1\times(k-2)} & 1 & 0 \end{pmatrix} \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes \cdots \otimes \begin{pmatrix} 0_{1\times(k-1)} & 1 \end{pmatrix} \otimes I_n \right) u \right\|.
\end{aligned}$$

The last term is thus null, due as before to the definiteness of $\tilde{P}_1$, so one concludes that

$$\left(\begin{pmatrix}0_{1\times(k-2)} & 1 & 0\end{pmatrix}\otimes\begin{pmatrix}0_{1\times(k-1)} & 1\end{pmatrix}\otimes\cdots\otimes\begin{pmatrix}0_{1\times(k-1)} & 1\end{pmatrix}\otimes I_n\right)u=0.$$

Carrying on in this way, one shows that all the components of u, taken n by n, are null. Thus, $u^H P_k u = 0$ implies $u = 0$, so $P_k > 0$ for any $k \in \mathbb{N}$.

We now show that, for large enough values of k, P_k defined in (24) generates a PPDQ function fulfilling the requirement of (ii). For this, let us first establish that

$$\lim_{k\to+\infty}\frac{1}{\|z_1^{[k]}\|^2\dots\|z_m^{[k]}\|^2}(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H P_k(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n) = \lim_{k\to+\infty}(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H\tilde{P}_k(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n), \tag{29}$$

where both limits are uniform in $\overline{\mathbb{D}}^m$. The second limit is already known to exist and to be equal to $P(z)$ in (21).

From identity (24) one deduces, thanks to (19), that

$$\begin{aligned}&(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H P_k(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)\\ &\quad=\sum_{i_1,\dots,i_m=0}^{k-1}|z_1|^{2i_1}\dots|z_m|^{2i_m}\left(\begin{pmatrix}z_m^{[k-i_m]}\\0_{i_1\times1}\end{pmatrix}\otimes\cdots\otimes\begin{pmatrix}z_1^{[k-i_1]}\\0_{i_m\times1}\end{pmatrix}\otimes I_n\right)^H\\ &\qquad\times\tilde{P}_k\left(\begin{pmatrix}z_m^{[k-i_m]}\\0_{i_m\times1}\end{pmatrix}\otimes\cdots\otimes\begin{pmatrix}z_1^{[k-i_1]}\\0_{i_1\times1}\end{pmatrix}\otimes I_n\right).\end{aligned}$$

As

$$\sum_{i_1,\dots,i_m=0}^{k-1}|z_1|^{2i_1}\dots|z_m|^{2i_m}=\|z_1^{[k]}\|^2\dots\|z_m^{[k]}\|^2,$$

we get

$$\begin{aligned}&\|z_1^{[k]}\|^2\dots\|z_m^{[k]}\|^2P(z)-(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H P_k(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)\\ &=\sum_{i_1,\dots,i_m=0}^{k-1}|z_1|^{2i_1}\dots|z_m|^{2i_m}\left[P(z)\right.\\ &\quad\left.-\left(\begin{pmatrix}z_m^{[k-i_m]}\\0_{i_m\times1}\end{pmatrix}\otimes\cdots\otimes\begin{pmatrix}z_1^{[k-i_1]}\\0_{i_1\times1}\end{pmatrix}\otimes I_n\right)^H\tilde{P}_k\left(\begin{pmatrix}z_m^{[k-i_m]}\\0_{i_m\times1}\end{pmatrix}\otimes\cdots\otimes\begin{pmatrix}z_1^{[k-i_1]}\\0_{i_1\times1}\end{pmatrix}\otimes I_n\right)\right].\end{aligned} \tag{30}$$

Now, uniform convergence of the right-hand side of (29) yields the following: for any $\varepsilon > 0$, there exists k_ε such that, for any $k > k_\varepsilon$, for any $z \in \overline{\mathbb{D}}^m$,

$$\|P(z)-(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)^H\tilde{P}_k(z_m^{[k]}\otimes\cdots\otimes z_1^{[k]}\otimes I_n)\|<\varepsilon.$$

Distinguishing between the terms for which $\max\{i_1,\dots,i_m\} < k-k_\varepsilon$ and $\max\{i_1,\dots,i_m\} \geq k-k_\varepsilon$ allows us to show that the norm of the left-hand side of (30) is bounded

from above by

$$\varepsilon\ \|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2 + 2c \sum_{\substack{i_1,\dots,i_m=0 \\ \max\{i_1,\dots,i_m\} \geq k-k_\varepsilon}}^{k-1} |z_1|^{2i_1} \dots |z_m|^{2i_m}.$$

In the previous expression, c is defined as

$$c \stackrel{\text{def}}{=} \max \left\{ \left\| \left(\begin{pmatrix} z_m^{[k-i_m]} \\ 0_{i_m \times 1} \end{pmatrix} \otimes \dots \otimes \begin{pmatrix} z_1^{[k-i_1]} \\ 0_{i_1 \times 1} \end{pmatrix} \otimes I_n \right)^H \right.$$
$$\left. \times \tilde{P}_k \left(\begin{pmatrix} z_m^{[k-i_m]} \\ 0_{i_m \times 1} \end{pmatrix} \otimes \dots \otimes \begin{pmatrix} z_1^{[k-i_1]} \\ 0_{i_1 \times 1} \end{pmatrix} \otimes I_n \right) \right\| :$$
$$\left. z \in \overline{\mathbb{D}}^m, i_1, \dots, i_m \leq k, k \in \mathbb{N} \right\}.$$

The constant c is finite, because, when $i_j \to +\infty$, $1 \leq j \leq m$, the expression inside the norm converges uniformly in $\overline{\mathbb{D}}^m$ towards $P(z)$, which, being continuous, is itself bounded. On the other hand, for any $z \in \mathbb{C}^m$,

$$\sum_{\substack{i_1,\dots,i_m=0 \\ \max\{i_1,\dots,i_m\} \geq k-k_\varepsilon}}^{k-1} |z_1|^{2i_1} \dots |z_m|^{2i_m}$$
$$= \sum_{i_1,\dots,i_m=0}^{k-1} |z_1|^{2i_1} \dots |z_m|^{2i_m} - \sum_{i_1,\dots,i_m=0}^{k-k_\varepsilon-1} |z_1|^{2i_1} \dots |z_m|^{2i_m}$$
$$= \|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2 - \|z_1^{[k-k_\varepsilon]}\|^2 \dots \|z_m^{[k-k_\varepsilon]}\|^2$$
$$= \left(\|z_1^{[k]}\|^2 - \|z_1^{[k-k_\varepsilon]}\|^2 \right) \|z_2^{[k]}\|^2 \dots \|z_m^{[k]}\|^2$$
$$+ \dots + \|z_1^{[k-k_\varepsilon]}\|^2 \dots \|z_{m-1}^{[k-k_\varepsilon]}\|^2 \left(\|z_m^{[k]}\|^2 - \|z_m^{[k-k_\varepsilon]}\|^2 \right)$$
$$\leq m \|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2 \max_{i=1,\dots,m} \frac{\|z_i^{[k]}\|^2 - \|z_i^{[k-k_\varepsilon]}\|^2}{\|z_i^{[k]}\|^2}$$
$$= m \|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2 \max_{i=1,\dots,m} |z_i|^{2(k-k_\varepsilon)} \frac{1 + |z_i|^2 + \dots + |z_i|^{2(k_\varepsilon-1)}}{1 + |z_i|^2 + \dots + |z_i|^{2(k-1)}}.$$

It turns out that, uniformly in $\overline{\mathbb{D}}^m$, the following estimate holds:

$$\left\| P(z) - \frac{1}{\|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2} (z_m^{[k]} \otimes \dots \otimes z_1^{[k]} \otimes I_n)^H P_k (z_m^{[k]} \otimes \dots \otimes z_1^{[k]} \otimes I_n) \right\|$$
$$\leq \varepsilon + 2mc \sup_{r \in [0;1)} r^{k-k_\varepsilon} \frac{1 - r^{k_\varepsilon}}{1 - r^k},$$

provided that $k > k_\varepsilon$. Notice that, for any fixed k_ε, the quantity

$$\sup_{r \in [0;1)} r^{k-k_\varepsilon} \frac{1 - r^{k_\varepsilon}}{1 - r^k}$$

vanishes when k goes to infinity. Thus, for large enough k, it is smaller than $\varepsilon/2mc$ and then, for any $z \in \overline{\mathbb{D}}^m$,

$$\left\| P(z) - \frac{1}{\|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2} (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H P_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n) \right\| < 2\varepsilon.$$

This achieves the proof of the announced convergence property (29).

As a consequence of (29), the truncated expression $\frac{1}{\|z_1^{[k]}\|^2 \dots \|z_m^{[k]}\|^2} (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H P_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)$ solves (2) for large enough k, and $x^H (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n)^H P_k (z_m^{[k]} \otimes \cdots \otimes z_1^{[k]} \otimes I_n) x$ with $P_k > 0$ is also a PPDQ Lyapunov function for (1). This achieves the proof of Lemma 7.1. ∎

As a conclusion of this second stage of the proof of Theorem 4.1, we have shown until now that property (i) is equivalent to (ii), in which, moreover, the hermitian P_k defining $P(z)$ may be supposed *positive definite* without loss of generality.

7.1.3. Third stage. This part is achieved by induction. Consider for any $i = 0, \dots, m$ the following property.

Property $(\mathcal{P}_i)$: $\exists k \in \mathbb{N}$, $\exists P_k \in \mathcal{H}^{k^m n}$, $P_k > 0$, $\exists Q_{k,j} \in \mathcal{H}^{k^{m-j+1}(k+1)^{j-1} n}$, $j = 1, \dots, i$, for all $(z_{i+1}, \dots, z_m) \in (\partial\mathbb{D})^{m-i}$,

$$\begin{aligned} &\left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+1}^{[k+1]} \otimes I_{(k+1)^i n}\right)^H \\ &\quad \left[R_k + \sum_{j=1}^{i} \left(\hat{J}_k^{(m-j+1)\otimes} \otimes I_{(k+1)^{j-1} n}\right)^T Q_{k,j} \left(\hat{J}_k^{(m-j+1)\otimes} \otimes I_{(k+1)^{j-1} n}\right) \right. \\ &\quad \left. - \sum_{j=1}^{i} \left(\hat{J}_k^{(m-j)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{j-1} n}\right)^T Q_{k,j} \left(\hat{J}_k^{(m-j)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{j-1} n}\right) \right] \\ &\qquad \left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+1}^{[k+1]} \otimes I_{(k+1)^i n}\right) < 0_{(k+1)^i n}. \end{aligned}$$

In the previous expression, the matrix $R_k = R_k(P_k)$ is defined in (9). One verifies easily that $(\mathcal{P}_0)$ may also be expressed as follows: there exists $P(z)$ as in (7) such that $P_k > 0$ and $R(z)$ defined in (8), (9) is negative definite for all $z \in (\partial\mathbb{D})^m$. Property $(\mathcal{P}_0)$ is thus a consequence of (ii) (see section 7.1.2), while in parallel $(\mathcal{P}_m)$ writes simply the following: there exists $k \in \mathbb{N}$ such that (LMI_k) holds, that is, (iii).

In order to prove that $(\mathcal{P}_0)$ implies $(\mathcal{P}_m)$, we establish the slightly stronger following result.

LEMMA 7.2. *For all $i = 0, \dots, m-1$, $(\mathcal{P}_i) \Leftrightarrow (\mathcal{P}_{i+1})$.*

Proof of Lemma 7.2. First, remark that

$$\begin{aligned} &\left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+1}^{[k+1]} \otimes I_{(k+1)^i n}\right) \\ &= \left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^{i+1} n}\right) \left(z_{i+1}^{[k+1]} \otimes I_{(k+1)^i n}\right) \\ &= \left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^{i+1} n}\right) \\ &\quad \times \begin{pmatrix} I_{(k+1)^i n} \\ z_{i+1} \left(I_{k(k+1)^i n} - z_{i+1}(F_k \otimes I_{(k+1)^i n})\right)^{-1} (f_k \otimes I_{(k+1)^i n}) \end{pmatrix}, \end{aligned}$$

the last identity being obtained after writing $z_{i+1}^{[k+1]} = \begin{pmatrix} 1 \\ z_{i+1} z_{i+1}^{[k]} \end{pmatrix}$ and using (18).

Applying the Kalman–Yakubovich–Popov lemma as recalled in Appendix A, with $p = k(k+1)^i n$, $q = (k+1)^i n$, $A = F_k \otimes I_{(k+1)^i n}$, $B = f_k \otimes I_{(k+1)^i n}$, and remarking that the following identities hold:

$$\begin{pmatrix} B & A \end{pmatrix} = \hat{J}_k \otimes I_{(k+1)^i n}, \ \begin{pmatrix} 0_{p \times q} & I_p \end{pmatrix} = \check{J}_k \otimes I_{(k+1)^i n},$$

property $(\mathcal{P}_i)$ is proved to be equivalent to $\exists k \in \mathbb{N}$, $\exists P_k \in \mathcal{H}^{k^m n}$, $P_k > 0$, $\exists Q_{k,j} \in \mathcal{H}^{k^{m-j+1}(k+1)^{j-1} n}$, $j = 1, \ldots, i$, for all $(z_{i+2}, \ldots, z_m) \in (\partial \mathbb{D})^{m-i-1}$, $\exists \tilde{Q}_{k,i+1}(z_{i+2}, \ldots, z_m) \in \mathcal{H}^{k(k+1)^i n}$,

$$\begin{aligned}
&\left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^i n} \right)^H \\
&\quad \left[R_k + \sum_{j=1}^{i} \left(\hat{J}_k^{(m-j+1)\otimes} \otimes I_{(k+1)^{j-1} n} \right)^T Q_{k,j} \left(\hat{J}_k^{(m-j+1)\otimes} \otimes I_{(k+1)^{j-1} n} \right) \right. \\
&\quad \left. - \sum_{j=1}^{i} \left(\hat{J}_k^{(m-j)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{j-1} n} \right)^T Q_{k,j} \left(\hat{J}_k^{(m-j)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{j-1} n} \right) \right] \\
&\qquad \left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^i n} \right) \\
&+ \left(\hat{J}_k \otimes I_{(k+1)^i n} \right)^T \tilde{Q}_{k,i+1} \left(\hat{J}_k \otimes I_{(k+1)^i n} \right) - \left(\check{J}_k \otimes I_{(k+1)^i n} \right)^T \tilde{Q}_{k,i+1} \left(\check{J}_k \otimes I_{(k+1)^i n} \right) \\
&< 0_{(k+1)^{i+1} n}.
\end{aligned}$$

The next step consists of assigning polynomial form to $\tilde{Q}_{k,i+1}$. This is done with the help of the following general result, proved in Appendix B, and which, up to our knowledge, is original.

THEOREM 7.3. *Suppose $G_0, G_1, \ldots, G_p$ are continuous mappings defined in a* compact *subset K of $\mathbb{R}^m$ and taking values in the set of symmetric matrices of $\mathbb{R}^{n \times n}$. If, for any $\delta \in K$, there exists a solution $x(\delta) \in \mathbb{R}^p$ to the parameter-dependent LMI*

$$\exists x \in \mathbb{R}^p, \ G(x, \delta) \stackrel{\text{def}}{=} G_0(\delta) + x_1 G_1(\delta) + \cdots + x_p G_p(\delta) > 0_n, \tag{31}$$

then there exists a polynomial *function $x^* : K \to \mathbb{R}^p$ such that, for any $\delta \in K$, $G(x^*(\delta), \delta) > 0_n$.*

Remark 7.4. Incidentally, one may wonder why Theorem 7.3 was not used in section 7.1.2 in order to get a polynomial expansion of $P(z)$; see formula (22) above. The reason is that semidefiniteness of the matrices $\tilde{P}_k$ as given by (23), which cannot be obtained by Theorem 7.3, was a crucial point to carry on the second stage.

Notice that any LMI depending upon a finite number of scalar parameters may be put under the form (31).

By use of the previous result, $\tilde{Q}_{k,i+1}(z_{i+2}, \ldots, z_m)$, being the solution of a LMI continuous with respect to the parameters $(z_{i+2}, \ldots, z_m)$ in $(\partial \mathbb{D})^{m-i-1}$ (seen as a compact set in $\mathbb{R}^{2(m-i-1)}$), may be chosen polynomial in the real and imaginary parts of the z_i, or also in the $z_i, \bar{z}_i$; that is,

$$\tilde{Q}_{k,i+1} = \left(z_m^{[\tilde{k}]} \otimes \cdots \otimes z_{i+2}^{[\tilde{k}]} \otimes I_{k(k+1)^i n} \right)^H Q_{\tilde{k},i+1} \left(z_m^{[\tilde{k}]} \otimes \cdots \otimes z_{i+2}^{[\tilde{k}]} \otimes I_{k(k+1)^i n} \right) \tag{32}$$

for certain degree $\tilde{k}-1$ and coefficient matrix $Q_{\tilde{k},i+1} \in \mathcal{H}^{k\tilde{k}^{m-i-1}(k+1)^i n}$.

A priori, the integers k and $\tilde{k}$ are different. If $\tilde{k} < k$, one may also suppose that $\tilde{k} = k$, enlarging the coefficient matrix $Q_{\tilde{k},i+1}$ by addition of zeros. If $\tilde{k} > k$, one shows now that k may also be replaced by $k+1$. For this, define

$$P_{k+1} \stackrel{\text{def}}{=} \sum_{M_i \in \{\hat{J}_k, \check{J}_k\},\ i=1,\dots,m} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T P_k (M_m \otimes \cdots \otimes M_1 \otimes I_n),$$

and, for $j = 1, \dots, i$,

$$Q_{k+1,j} \stackrel{\text{def}}{=} \sum_{\substack{M_l \in \{\hat{J}_{k+1}, \check{J}_{k+1}\},\ l=1,\dots,j-1, \\ M_l \in \{\hat{J}_k, \check{J}_k\},\ l=j,\dots,m}} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T Q_{k,j} (M_m \otimes \cdots \otimes M_1 \otimes I_n),$$

$$\tilde{Q}_{k+1,i+1} \stackrel{\text{def}}{=} \sum_{\substack{M_j \in \{\hat{J}_{k+1}, \check{J}_{k+1}\},\ j=1,\dots,i, \\ M_j \in \{\hat{J}_k, \check{J}_k\},\ j=i+1,\dots,m}} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T \tilde{Q}_{k,i+1} (M_m \otimes \cdots \otimes M_1 \otimes I_n).$$

One first shows that the positivity of P_k implies positivity of P_{k+1}: for any $u \in \mathbb{C}^{(k+1)^m n}$ such that $u^H P_{k+1} u = 0$, one has $P_k^{1/2}(M_m \otimes \cdots \otimes M_1 \otimes I_n)u = 0$ for any $M_i \in \{\hat{J}_k, \check{J}_k\}, i = 1, \dots, m$, and this implies that $u = 0$, whence the positivity of P_{k+1}. One then shows that the matrix R_{k+1} obtained from P_{k+1} by formula (9) verifies

$$R_{k+1} \stackrel{\text{def}}{=} \sum_{M_i \in \{\hat{J}_{k+1}, \check{J}_{k+1}\},\ i=1,\dots,m} (M_m \otimes \cdots \otimes M_1 \otimes I_n)^T R_k (M_m \otimes \cdots \otimes M_1 \otimes I_n).$$

This requires cumbersome but straightforward calculations, using property (5). A new set of matrices verifying property $(\mathcal{P}_i)$ has thus been generated, with index $k+1$ instead of k. Remark that otherwise the degree $\tilde{k}-1$ in the unknowns $z_{i+2}, \dots, z_m$ of the new matrix $\tilde{Q}_{k+1,i+1}$ is the same as for $\tilde{Q}_{k,i+1}$. It thus suffices to repeat this operation to obtain a solution with $k = \tilde{k}$. Finally, *up to a possible increase of* k, one may always suppose that $k = \tilde{k}$ in the decomposition (32) of $\tilde{Q}_{k,i+1}$.

Remark 7.5. Applying the previous argument to $(\mathcal{P}_m)$ proves that solvability of (LMI_k) implies the same property for the larger values of the index, as announced in the sketch of the proof of formula (11).

It now remains to achieve some matrix manipulations. Using the following formula, obtained by use of (6),

$$\begin{aligned}
&\left(z_m^{[k]} \otimes \cdots \otimes z_{i+2}^{[k]} \otimes I_{k(k+1)^i n}\right)\left(\hat{J}_k \otimes I_{(k+1)^i n}\right) \\
&= \left(I_{k^{m-i-1}} \otimes \hat{J}_k \otimes I_{(k+1)^i n}\right)\left(z_m^{[k]} \otimes \cdots \otimes z_{i+2}^{[k]} \otimes I_{(k+1)^{i+1} n}\right) \\
&= \left(\hat{J}_k^{(m-i)\otimes} \otimes I_{(k+1)^i n}\right)\left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^{i+1} n}\right),
\end{aligned}$$

and similarly

$$\begin{aligned}
&\left(z_m^{[k]} \otimes \cdots \otimes z_{i+2}^{[k]} \otimes I_{k(k+1)^i n}\right)\left(\check{J}_k \otimes I_{(k+1)^i n}\right) \\
&\qquad = \left(\hat{J}_k^{(m-i-1)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^i n}\right)\left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^{i+1} n}\right),
\end{aligned}$$

one finally proves that $(\mathcal{P}_i)$ is equivalent to

$\exists k \in \mathbb{N}, \exists P_k \in \mathcal{H}^{k^m n}, P_k > 0, \exists Q_{k,j} \in \mathcal{H}^{k^{m-j+1}(k+1)^{j-1}n}$, $j = 1, \ldots, i+1$, $\forall (z_{i+2}, \ldots, z_m) \in (\partial\mathbb{D})^{m-i-1}$,

$$\left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^{i+1}n}\right)^H \left[R_k + \sum_{j=1}^{i+1} \left(\hat{J}_k^{(m-j+1)\otimes} \otimes I_{(k+1)^{j-1}}\right)^T Q_{k,j} \left(\hat{J}_k^{(m-j+1)\otimes} \otimes I_{(k+1)^{j-1}}\right) - \sum_{j=1}^{i+1} \left(\hat{J}_k^{(m-j)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{j-1}}\right)^T Q_{k,j} \left(\hat{J}_k^{(m-j)\otimes} \otimes \check{J}_k \otimes I_{(k+1)^{j-1}}\right)\right] \left(z_m^{[k+1]} \otimes \cdots \otimes z_{i+2}^{[k+1]} \otimes I_{(k+1)^{i+1}n}\right) < 0_{(k+1)^{i+1}n}.$$

One recognizes property $(\mathcal{P}_{i+1})$. Hence, $(\mathcal{P}_i) \Leftrightarrow (\mathcal{P}_{i+1})$, and Lemma 7.2 is proved. □

The equivalence between $(\mathcal{P}_0)$ and $(\mathcal{P}_m)$ shows in particular that (ii) implies (iii). This achieves the proof of Theorem 4.1.

7.2. Proof of Theorem 4.3. The proof proceeds by using the change of variables $r = (z + \bar{z})/2$, $z \in \overline{\mathbb{D}}^m$, already introduced to get Proposition 3.3, and by achieving the slight necessary adaptations of the proof of Theorem 4.1, using R_k defined in (10) and not in (9). The argument used in the first stage is here trivial, as the sets $\{A((z+\bar{z})/2) : z \in \overline{\mathbb{D}}^m\}$ and $\{A((z+\bar{z})/2) : z \in (\partial\mathbb{D})^m\}$ are identical.

Remark 7.6. Notice that the change of variables which is used leads to D-scaling as in the complex parameter case, and not DG-scaling, although the parameters involved here are real.

8. Conclusion. Robust stability of linear systems with several scalar (complex or real) parameters has been studied. For each problem, a family of LMIs, indexed by a positive integer k, is provided. Their solvability is sufficient for robust stability, and the corresponding conditions are becoming less conservative with increasing k. Conversely, if robust stability holds, then the corresponding LMI problems are solvable from a certain k and beyond. The method involves the search for a quadratic Lyapunov function depending polynomially on the parameters and their conjugates.

The LMIs are obtained in a constructive and systematic way, resulting from a limited set of elementary algebraic matrix operations. In consequence, the derived algorithms are immediately implementable in a MATLAB/SCILAB-like environment. In practice, the accuracy of the approximation is only limited by computation time and available memory size.

Further research includes the following aspects.

1. Determination of the degree of accuracy needed to test the robust stability of any specific system, that is, of an a priori (upper) estimate on the least k, if any, for which the LMIs are solvable. More generally, the complexity and numerical aspects have to be analyzed.

2. Extension of the results to robust input/output performance evaluation for systems with scalar parameters and to systems with polynomial and LFT dependency (see the first results in [6] and [5, 4], respectively). Application to μ-analysis.

Appendix A. Discrete-time version of the Kalman–Yakubovich–Popov lemma.

Initially appearing in [44], the result has been first published under its discrete-time form by Szegö and Kalman [36]. We use the statement as expressed, e.g., in [34]. A proof of the result in the complex case (and for the continuous-time case) may be found in [30, Theorem 1.11.1 and Remark 1.11.1].

Let $A \in \mathbb{C}^{p\times p}, B \in \mathbb{C}^{p\times q}, M \in \mathcal{H}^{p+q}$.

LEMMA A.1. *If* $\det(I_n - zA) \neq 0$ *for any* $z \in \partial\mathbb{D}$, *then the following two statements are equivalent.*

(i) *There exists* $Q \in \mathcal{H}^p$ *such that*

$$0_{p+q} > \begin{pmatrix} B & A \end{pmatrix}^H Q \begin{pmatrix} B & A \end{pmatrix} - \begin{pmatrix} 0_{p\times q} & I_p \end{pmatrix}^H Q \begin{pmatrix} 0_{p\times q} & I_p \end{pmatrix} + M.$$

(ii) *For any* $z \in \partial\mathbb{D}$,

$$\begin{pmatrix} I_p \\ z(I_p - zA)^{-1}B \end{pmatrix}^H M \begin{pmatrix} I_p \\ z(I_p - zA)^{-1}B \end{pmatrix} < 0_p.$$

When in the statements the matrices A, B, M are real, then Q is real symmetric.

Appendix B. Proof of Theorem 7.3.

Under the hypothesis of solvability of (31) for any $\delta \in K$, there exists, by continuity and compactness, a real number $\alpha > 0$ such that

$$\forall \delta \in K,\ \{x \in \mathbb{R}^p\ :\ G_0(\delta) + x_1 G_1(\delta) + \cdots + x_p G_p(\delta) \geq 2\alpha I_n\} \neq \emptyset.$$

Define

$$\begin{aligned} F\ :\ & K \to 2^{\mathbb{R}^p}, \\ & \delta \mapsto F(\delta) = \{x \in \mathbb{R}^p\ :\ G_0(\delta) + x_1 G_1(\delta) + \cdots + x_p G_p(\delta) \geq \alpha I_n\}. \end{aligned} \tag{33}$$

The set-valued map F maps K into the nonvoid closed convex subsets of $\mathbb{R}^p$.

Let us first establish that F fulfils the following property of *lower semicontinuity*; see, e.g., [2].

DEFINITION B.1. *Let* X *be a topological space and* Y *a metric space. A set-valued map* F *from* X *to* Y *is said to be* lower semicontinuous *at* $x^0 \in X$ *if for any* $y^0 \in F(x^0)$ *and any neighborhood* $N(y^0)$ *of* y^0 *there exists a neighborhood* $N(x^0)$ *such that*

$$\forall x \in N(x^0),\ F(x) \cap N(y^0) \neq \emptyset.$$

F *is said to be* lower semicontinuous *if it is lower semicontinuous at every point* $x^0 \in X$.

Let $\delta^0 \in K$, $x^0 \in F(\delta^0)$, $\varepsilon > 0$. To prove lower semicontinuity of F at δ^0, we exhibit $\eta > 0$ such that for any $\delta \in K$ with $\|\delta - \delta^0\|_m < \eta$, there exists $x \in F(\delta)$, $\|x - x^0\|_p < \varepsilon$.

Indeed, by assumption, there exists $x^{\delta^0} \in \mathbb{R}^p$ such that $G(x^{\delta^0}, \delta^0) \geq 2\alpha I_n$. For $\lambda \in (0, 1]$ to be defined afterwards, let $x \stackrel{\text{def}}{=} (1-\lambda)x^0 + \lambda x^{\delta^0}$. Then the fact that G is

affine with respect to x implies for any $\eta > 0$, any $\delta \in K$ such that $\|\delta - \delta^0\|_m < \eta$:

$$\begin{aligned} G(x,\delta) &= (1-\lambda)G(x^0,\delta) + \lambda G(x^{\delta^0},\delta) \\ &= (1-\lambda)G(x^0,\delta^0) + \lambda G(x^{\delta^0},\delta^0) \\ &\quad +(1-\lambda)\left(G(x^0,\delta) - G(x^0,\delta^0)\right) + \lambda\left(G(x^{\delta^0},\delta) - G(x^{\delta^0},\delta^0)\right) \\ &\geq \alpha(1+\lambda)I_n \\ &\quad -\left(\sup_{\|\delta-\delta^0\|_m<\eta} \|G(x^0,\delta) - G(x^0,\delta^0)\|_n + \sup_{\|\delta-\delta^0\|_m<\eta} \|G(x^{\delta^0},\delta) - G(x^{\delta^0},\delta^0)\|_n\right) I_n. \end{aligned}$$

On the other hand,

$$\|x - x^0\|_p = \lambda \|x^{\delta^0} - x^0\|_p.$$

So take $\lambda \in (0,1]$ such that

$$\lambda \leq \frac{\varepsilon}{2\|x^{\delta^0} - x^0\|_p},$$

and choose $\eta > 0$ such that

$$\sup_{\|\delta-\delta^0\|_m<\eta} \|G(x^0,\delta) - G(x^0,\delta^0)\|_n + \sup_{\|\delta-\delta^0\|_m<\eta} \|G(x^{\delta^0},\delta) - G(x^{\delta^0},\delta^0)\|_n \leq \alpha\lambda.$$

With these choices, one has $\|x - x^0\|_p \leq \varepsilon/2 < \varepsilon$, and $G(x,\delta) \geq \alpha(1+\lambda)I_n - \alpha\lambda I_n = \alpha I_n$, so $x \in F(\delta)$, provided that $\delta \in K$ and $\|\delta - \delta^0\|_m < \eta$. One concludes that F is lower continuous at δ^0. This achieves the proof of lower semicontinuity of F.

We now apply to F defined in (33) Michael's selection theorem [31]; see also [2].

THEOREM B.2 (Michael's selection theorem). *Let X be a metric space and Y a Banach space. Let F from X into the closed convex subsets of Y be lower semicontinuous. Then there exists $f : X \to Y$, a continuous selection from F.*

This yields existence of a continuous selection $f : K \to \mathbb{R}^p$ from F defined in (33). This function is such that

$$\forall \delta \in K,\ G(f(\delta),\delta) \geq \alpha I_n.$$

It remains to apply to each of the p coefficients of f the following result; see, e.g., [14].

THEOREM B.3 (Weierstrass approximation theorem). *Every continuous real-valued function defined on a compact subset K of $\mathbb{R}^m$ is the limit of a sequence of polynomials, which converges uniformly in K.*

Thus, the selection f previously exhibited is the uniform limit in K of a sequence of (matrix-valued) polynomials in x. In particular, there exists a polynomial function $x^* : K \to \mathbb{R}^p$ such that

$$\forall \delta \in K,\ G(x^*(\delta),\delta) \geq \frac{\alpha}{2} I_n > 0_n.$$

One concludes that there exists a polynomial solution to the parameter-dependent LMI (31), and this achieves the proof of Theorem 7.3.

Acknowledgments. The revised form of this paper has benefited from many comments and encouragements during seminaries given in 2002 in St. Petersburg, Russia. The author wishes to express his indebtedness to his colleagues of this community, especially to Prof. V. A. Yakubovich and to Prof. A. L. Fradkov. He also wishes to thank Prof. P. Tsiotras for his attentive reading and anonymous reviewers whose constructive criticism allowed precious improvements of the manuscript.

NECESSARY OPTIMALITY CONDITIONS IN MULTIOBJECTIVE DYNAMIC OPTIMIZATION*

SAÏD BELLAASSALI† AND ABDERRAHIM JOURANI†

Abstract. We consider a nonsmooth multiobjective optimal control problem related to a general preference. Both differential inclusion and endpoint constraints are involved. Necessary conditions and Hamiltonian necessary conditions expressed in terms of the limiting Fréchet subdifferential are developed. Examples of useful preferences are given.

Key words. multiobjective optimal control, necessary conditions, Hamiltonian necessary conditions, preference, utility function, differential inclusions

AMS subject classifications. 49K24, 90C29

DOI. 10.1137/S0363012902406576

1. Introduction. This paper is mainly concerned with the following multiobjective dynamic optimization problem with the dynamic governed by a differential inclusion:

$$\text{(P)} \qquad \begin{aligned} &\min f(x(a), x(b)), \\ &(x(a), x(b)) \in S, \\ &\dot{x}(t) \in F(t, x(t)) \quad \text{a.e.} \quad t \in [a, b], \end{aligned}$$

where $f\colon \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R}^m$ is a mapping, $S \subset \mathbb{R}^n \times \mathbb{R}^n$ is a closed nonempty set, and $F\colon [a, b] \times \mathbb{R}^n \mapsto \mathbb{R}^n$ is a closed-valued multivalued mapping which is measurable in $t \in [a, b]$.

These problems naturally arise, for example, in economics (economic growth models) (see [16] and references therein), in chemical engineering (polymerization processes) (see [3], [4], and references therein), and in multiobjective control design (see [45], [9], and references therein). Problems considered in this paper use preferences determined by cones (Pareto and weak Pareto optimum), use preferences determined by utility function, or use the concept of Nash equilibrium.

Our aim in this paper is to use a general preference including the previous ones in order to state necessary and Hamiltonian necessary conditions for multiobjective optimal control problems (P).

The concept of preference appeared in the value theory in economics. Many authors in the early studies often defined the preference by a utility function, i.e., given a preference whether it is always possible to find a utility function that can determine the preference.

In [17] the author proved that a preference $\prec$ can be determined by a continuous utility function if and only if for any x the sets

$$\text{(1)} \qquad \{y : x \prec y\} \quad \text{and} \quad \{y : y \prec x\} \quad \text{are closed.}$$

This theorem is not general and besides this it is an existence theorem (i.e., does provide methods for determing a utility function), and there are some useful preferences

that do not satisfy (1) (like the preference determined by lexicographical order). There are different approaches and various results on necessary conditions for (P). Several researches have been devoted to the weak Pareto solution and its generalization (see [5], [11], [15], [32], [42], [46], [47], and references therein). Other research gets refinements of necessary optimality conditions for real-valued objective optimal control problems (see [23], [29], [30], [31], [44], [43], and [26]) or Hamiltonian necessary conditions (see [37], [19], [20], [13], [35], [36], [39], [48], and [49]).

These results are expressed in terms of various generalized derivatives including Clarke's generalized subgradient [11], a limiting subgradient which is also known under other names: limiting subgradient set in [12], approximate subdifferential in Ioffe [22], subdifferential in Mordukhovich [36], and subgradient set in the general sense in Rockafellar [40]. Most of these results are obtained for Lipschitz, integrably sub-Lipschitz, bounded, or unbounded differential inclusions.

In [23], Ioffe used results of [40] and [24] to obtain general necessary optimality conditions and Hamiltonian optimality conditions for single-objective optimal control problems.

In [49], Zhu used recent progress in nonsmooth analysis, in particular calculus for smooth subdifferentials of lower semicontinuous (l.s.c.) functions (see [6], [7], [14], [24]), the methods for proving the extremal principle (see [27], [28], [33], [38]), and techniques in handling the Hamiltonian for a differential inclusion, to prove Hamiltonian necessary conditions that extend the classical Hamiltonian necessary conditions for optimal control problems that had previously been derived for uniformly Lipschitz, bounded, and convex-valued differential inclusions related to a general preference. The obtained conditions are expressed in terms of Clarke's generalized gradient which is larger than the limiting Fréchet subdifferential. The regularity conditions $(A3)$ imposed in [49], which use the usual limiting normal cone, are too strong to include the preference defined by a utility function (see Example 3).

In this paper we propose a different approach. We introduce a definition of regularity modified from that introduced in [49]. To solve the problem of regularity of preference determined by a utility function, we define a larger limiting normal cone to replace the usual one in [49]. Under our regularity condition of the general preference and a sub-Lipschitz property of multivalued mappings, introduced by Loewen and Rockafellar in [29], we obtain Euler–Lagrange necessary optimality conditions for multiobjective optimal control problems with nonconvex differential inclusion constraints in terms of the limiting Fréchet subdifferential. Necessary optimality conditions for the weak Pareto solution and its generalization can be derived and refined by using our necessary conditions.

Our main result extends the necessary optimality condition of Ioffe (see Theorem 1 in [23]) from a single objective optimal control of differential inclusion problem to a multiobjective one. This is also an extension of the Hamiltonian necessary optimality conditions for convex differential inclusions obtained in [49].

The paper is organized as follows. Section 2 contains the key definitions, normals, subgradients, and coderivatives used in what follows. In section 3 we state our main result and establish necessary optimality conditions for multiobjective control problems with some examples and discussions. Then we derive necessary conditions for these examples of preferences. In section 4 we give a technical proof of the main result.

2. Background. Now we state basic tools of generalized differentiation that are more appropriate for our main purpose. Details may be found in [33].

Let C be a closed subset of $\mathbb{R}^n$ containing some point c. The ε-normal cone to C at c is the set

$$\hat{N}_\varepsilon(C,c) := \left\{ \zeta \in \mathbb{R}^n \ : \ \liminf_{x \in C \to c} \frac{\langle -\zeta, x-c\rangle}{\|x-c\|} \geq -\varepsilon \right\}.$$

The normal cone to C at c is the set

$$N(C;c) := \limsup_{\substack{x \in C \to c \\ \varepsilon \to 0^+}} \hat{N}_\varepsilon(C,c).$$

Now let $f : \mathbb{R}^n \longrightarrow \mathbb{R} \cup \{\infty\}$ be an l.s.c. function, and let $c \in \mathbb{R}^n$ such that $f(c) < \infty$. The limiting Fréchet subdifferential of f at c is the set

$$\partial f(c) = \{\zeta \in \mathbb{R}^n \ : \ (\zeta, -1) \in N(epi\, f; (c, f(c)))\},$$

where *epi* f denotes the epigraph of f. We have the following analytic characterization of $\partial f(c)$:

$$\partial f(c) = \limsup_{\substack{x \to c \\ f(x) \to f(c) \\ \varepsilon \to 0^+}} \partial_\varepsilon f(x),$$

where

$$\partial_\varepsilon f(x) = \left\{ x^* \in X^* \ : \ \liminf_{h \to 0} \frac{f(x+h) - f(x) - \langle x^*, h\rangle}{\|h\|} \geq -\varepsilon \right\}.$$

The singular subdifferential of f at c is the set

$$\partial^\infty f(c) = \{\zeta \in \mathbb{R}^n \ : \ (\zeta, 0) \in N(epi\, f; (c, f(c)))\}.$$

Next we consider a multivalued mapping F from $\mathbb{R}^n$ to $\mathbb{R}^m$ of the closed graph

$$\mathrm{Gr}F := \{(x,y) : \ y \in F(x)\}.$$

The multivalued mapping $D^*F(x,y) : \mathbb{R}^m \mapsto \mathbb{R}^n$ defined by

$$D^*F(x,y)(y^*) := \{x^* \in \mathbb{R}^n : \ (x^*, -y^*) \in N(\mathrm{Gr}F; (x,y))\}$$

is called the coderivative of F at the point $(x,y) \in \mathrm{Gr}F$.

The domain over which our study occurs is typically one of the functions $W^{1,1}([a,b], \mathbb{R}^n)$ (abbreviated $W^{1,1}$) consisting of all absolutely continuous functions $x\colon [a,b] \mapsto \mathbb{R}^n$ for which $|\dot{x}|$ is integrable on $[a,b]$ ($\dot{x}$ denotes the derivative (a.e.) of x). An *arc* is a function in $W^{1,1}$. The space $W^{1,1}$ is endowed with the norm

$$\|x\| = |x(a)| + \int_a^b |\dot{x}(t)| dt,$$

where $|\cdot|$ denotes the Euclidean norm of $\mathbb{R}^n$. Here $\mathbb{B}$ stands for the closed unit ball in $\mathbb{R}^n$ and

$$B(z,r) = \{x \in W^{1,1} \colon \ \|x - z\| \leq r\}.$$

The distance function on $W^{1,1}$, $\mathbb{R}^n$ or $\mathbb{R}^n \times \mathbb{R}^n$ will be denoted by $d(\cdot\,,\cdot)$. The convex hull and the closed convex hull are denoted by co and $\bar{\mathrm{co}}$, respectively.

The following lemma is needed.

LEMMA 2.1. *Let G be pseudo-Lipschitzian* [1], [41] *around $(x_0, y_0) \in \mathrm{Gr}G$ with modulus K; i.e., there exists $r > 0$ such that for all $x, u \in x_0 + r\mathbb{B}$*

$$G(x) \cap (y_0 + r\mathbb{B}) \subset G(u) + K|x - u|\mathbb{B}.$$

Then for all $y^* \in \mathbb{R}^n$, with $D^*G(x_0, y_0)(y^*) \neq \emptyset$, one has

$$\sup\{|x^*| : \quad x^* \in D^*G(x_0, y_0)(y^*)\} \leq K|y^*|.$$

If in addition G is closed-valued, then for all $(x, y) \in (x_0 + \frac{r}{12}\mathbb{B}) \times (y_0 + \frac{r}{12}\mathbb{B})$, with $(x, y) \notin \mathrm{Gr}G$, and all $(x^*, y^*) \in \partial d(\cdot\,; G(\cdot))(x, y)$ we have

$$|y^*| = 1 \text{ and } |x^*| \leq K|y^*|.$$

Proof. It suffices to establish the second part; the first one follows from the definition of limiting Fréchet subdifferential. Let $(x, y) \in (x_0 + \frac{r}{12}\mathbb{B}) \times (y_0 + \frac{r}{12}\mathbb{B})$, with $(x, y) \notin \mathrm{Gr}G$, and let $(x^*, y^*) \in \partial d(\cdot; G(\cdot))(x, y)$. Then there are sequences $x_k \to x$, $y_k \to y$, $x_k^* \to x^*$, $y_k^* \to y^*$, $\varepsilon_k \to 0^+$, and $r_k \to 0^+$ such that

$$d(v; G(u)) - d(y_k; G(x_k)) - \langle x_k^*, u - x_k\rangle - \langle y_k^*, v - y_k\rangle + \varepsilon_k[|u - x_k| + |v - y_k|] \geq 0$$

for all $u \in x_k + r_k\mathbb{B}$ and $v \in y_k + r_k\mathbb{B}$. For each integer k, there exists $v_k \in G(x_k)$ such that

$$d(y_k; G(x_k)) = |y_k - v_k|.$$

So

$$|y' - v| - |y_k - v_k| - \langle x_k^*, u - x_k\rangle - \langle y_k^*, v - y_k\rangle + \varepsilon_k[|u - x_k| + |v - y_k|] \geq 0$$

for all $u \in x_k + r_k\mathbb{B}$, $v \in y_k + r_k\mathbb{B}$, and $y' \in G(u)$.

Consider the function g defined by

$$g(u, y', v) = |y' - v| - \langle x_k^*, u - x_k\rangle - \langle y_k^*, v - y_k\rangle + \varepsilon_k[|u - x_k| + |v - y_k|].$$

Then [34]

$$(0, 0, 0) \in \partial g(x_k, v_k, y_k) + N(\mathrm{Gr}G; (x_k, v_k)) \times \{0\}.$$

As for k large enough $y_k \neq v_k$, then

$$\partial g(x_k, v_k, y_k) \subset \{(0, v^*, -v^*) \colon |v^*| = 1\} + (-x_k^*, 0, -y_k^*) + \varepsilon_k\mathbb{B} \times \{0\} \times \varepsilon_k\mathbb{B},$$

and hence we obtain $(u_k^*, v_k^*) \in N(\mathrm{Gr}G; (x_k, v_k))$, with $|v_k^*| = 1$, such that

$$|x_k^* - u_k^*| \leq \varepsilon_k \text{ and } |y_k^* - v_k^*| \leq \varepsilon_k.$$

Now since $d(y_k; G(x_k))) = |y_k - v_k|$, we get for k sufficiently large

$$|y_k - v_k| \leq \frac{r}{2},$$

and hence

$$|x_0 - x_k| + |y_0 - v_k| \leq \frac{5r}{6}.$$

Thus for all $u, u' \in x_k + \frac{r}{6}\mathbb{B}$

$$G(u) \cap \left(v_k + \frac{r}{6}\mathbb{B}\right) \subset G(u') + K|u - u'|\mathbb{B}.$$

So the first part of the lemma ensures that

$$|u_k^*| \leq K|v_k^*|,$$

and since $u_k^* \to x^*$ and $v_k^* \to y^*$ we get $|x^*| \leq K|y^*|$, and the proof is complete.

LEMMA 2.2. *Let $G\colon V \mapsto \mathbb{R}^m$ be a multivalued mapping, where V is a nonempty set in $\mathbb{R}^n$. Suppose that*

(i) GrG *is closed and*

(ii) *there exists a compact set K in $\mathbb{R}^m$ such that*

$$G(x) \subset K \quad \forall x \in V.$$

Then G is upper semicontinuous (u.s.c.) on V; that is, for all $u \in V$ and all $\varepsilon > 0$ there exists a neighborhood U of u in V such that

$$G(x) \subset G(u) + \varepsilon\mathbb{B} \quad \forall x \in U.$$

With the help of the last lemma, we can prove the following one.

LEMMA 2.3. *Suppose that the mapping $f\colon (x_0, y_0) + r\mathbb{B} \mapsto \mathbb{R}$ is Lipschitzian with constant K. Define the multivalued mapping $\Gamma\colon (x_0, y_0) + r\mathbb{B} \times \mathbb{R}^n \times \mathbb{R} \mapsto \mathbb{R}^n$ by*

$$\Gamma(x, y, p, s) = co\{q\colon (q, p) \in \partial f(x, y) + s\mathbb{B}\}.$$

Then for all $\lambda \in]0, 1[$, all $(x, y, s) \in (x_0, y_0, 0) + \lambda r\mathbb{B}$, and all $p \in \mathbb{R}^n$, with $\Gamma(x, y, p, s) \neq \emptyset$, Γ is u.s.c. at (x, y, p, s) in the sense of Lemma 2.2.

Proof. Note that (ii) of Lemma 2.2 is satisfied. It is not difficult to show that Γ is of closed graph and to apply Lemma 2.2.

LEMMA 2.4 (see [11]). *Let $\varepsilon > 0$ and $\Gamma : [a, b] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \mapsto \mathbb{R}^n$ be a multivalued mapping such that for almost all $t \in [a, b]$, $\Gamma(t, \cdot)$ has nonempty, compact, and convex values around $(z(t), \dot{z}(t), p, s)$, with $s \in [0, \varepsilon]$ and $\Gamma(t, z(t), \dot{z}(t), p, s) \neq \emptyset$. For sequences (z_k) and (p_k) in $W^{1,1}$, (ϕ_k) in $L^1([a, b],]0, +\infty[)$, (α_k) and (s_k) in $\mathbb{R}_+$ with $z_k \to z$ in $W^{1,1}$, $\phi_k \to \phi$ in $L^1([a, b],]0, +\infty[)$ for some integrable function ϕ, $\alpha_k \to 0$, and $s_k \to 0$ we suppose the following:*

(i) *For every (x, y, p, s) in the interior of the set*

$$\{(x', y', p', s') : t \in [a, b],\ x' \in z(t) + \varepsilon\mathbb{B},\ y' \in \dot{z}(t) + \varepsilon\mathbb{B},\ s' \in [0, \varepsilon],\ \Gamma(t, x', y', p', s') \neq \emptyset\}$$

the multivalued mapping $t' \mapsto \Gamma(t', x, y, p, s)$ is measurable.

(ii) *For all k, $|\dot{p}_k(t)| \leq \phi_k(t)$ for almost all $t \in [a, b]$.*

(iii) *For all k, $\dot{p}_k(t) \in \Gamma(t, z_k(t), \dot{z}_k(t), p_k(t), s_k) + \alpha_k\mathbb{B}$ a.e. $t \in [a, b]$.*

(iv) *For almost all $t \in [a, b]$ for every $p \in \mathbb{R}^n$ with $\Gamma(t, z(t), \dot{z}(t), p, 0) \neq \emptyset$, the multivalued mapping $(x', y', p', s') \mapsto \Gamma(t, x', y', p', s')$ is u.s.c. at $(z(t), \dot{z}(t), p, 0)$.*

(v) *The sequence $(p_k(a))$ is bounded.*

(vi) *There exists an integrable function ψ such that*

$$\sup_{\{(p', s') : s' \in [0, \varepsilon],\ \Gamma(t, z(t), \dot{z}(t), p', s') \neq \emptyset\}} \max_{y \in \Gamma(t, z(t), \dot{z}(t), p', s')} |y| \leq \psi(t) \text{ a.e.}$$

Then there is a subsequence of (p_k) *which converges uniformly to an arc* p *satisfying*

$$\dot{p}(t) \in \Gamma(t, z(t), \dot{z}(t), p(t), 0) \quad \text{a.e. } t \in [a, b].$$

We conclude this section by recalling necessary optimality conditions for the following generalized problem of Bolza:

$$(\mathrm{P_B}) \qquad \min \left\{ \ell(x(a), x(b)) + \int_a^b L(t, x(t), \dot{x}(t))\, dt \right\},$$

where the functions $L : [a, b] \times \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R} \cup \{+\infty\}$ and $\ell : \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R} \cup \{+\infty\}$ are such that for each $t \in [a, b]$, the functions $L(t, \cdot, \cdot)$ and ℓ are l.s.c. on $\mathbb{R}^n \times \mathbb{R}^n$.

The function L is *epi-Lipschitz* [10] at an arc z if there exist an integrable function $k : [a, b] \mapsto \mathbb{R}$ and a positive ε satisfying the following conditions: for almost all $t \in [a, b]$, given two points z_1 and z_2 within ε of $z(t)$ and $u_1 \in \mathbb{R}^n$ such that $L(t, z_1, u_1)$ is finite, there exist a point $u_2 \in \mathbb{R}^n$ and $\delta \geq 0$ such that $L(t, z_2, u_2)$ is finite and

$$|u_1 - u_2| + |L(t, z_1, u_1) - L(t, z_2, u_2) - \delta| \leq k(t)|z_1 - z_2|.$$

This is equivalent to saying that the multivalued mapping

$$E(t, s) = \{(u, r) \in \mathbb{R}^n \times \mathbb{R} : L(t, s, u) \leq r\}$$

is Lipschitzian in s on $z(t) + \varepsilon\mathbb{B}$ with constant $k(t)$ (i.e., for all $s, s' \in z(t) + \varepsilon\mathbb{B}$ we have $E(t, s') \subset E(t, s) + k(t) \mid s' - s \mid \mathbb{B}$).

L is said to be epimeasurable (in t) [10] if for each $s \in \mathbb{R}^n$ the multivalued mapping $E(t, s)$ is Lebesgue measurable in t.

The notation ∂L will denote the limiting Fréchet subdifferential of the function $L(t, \cdot, \cdot)$.

Now we may state a variant of the necessary conditions for the generalized Bolza problem established in Jourani [26].

THEOREM 2.1. *Let* z *solve locally the generalized problem of Bolza* $(\mathrm{P_B})$ *(in* $W^{1,1}$*). Suppose that* $L(t, z, u)$ *is epimeasurable in* t*, and* $L(t, \cdot, \cdot)$ *is epi-Lipschitzian at* z*, and* ℓ *is locally Lipschitzian around* $(z(a), z(b))$*. Then there exists an arc* p *such that one has*

$$\dot{p}(t) \in co\{q : \quad (q, p(t)) \in \partial L(t, z(t), \dot{z}(t))\} \quad \text{a.e. } t \in [a, b],$$

$$(p(a), -p(b)) \in \partial \ell(z(a), z(b)),$$

$$\langle p(t), \dot{z}(t) \rangle - L(t, z(t), \dot{z}(t)) = \max\{\langle p(t), v \rangle - L(t, z(t), v) : v \in \mathbb{R}^n\}.$$

3. The main result.

DEFINITION 3.1. *F is said to be sub-Lipschitzian in the sense of Loewen and Rockafellar* [29] *at z if there exist $\beta > 0$, $\varepsilon > 0$, and a summable function $k : [a, b] \mapsto \mathbb{R}$ such that for almost all $t \in [a, b]$, for all $N > 0$, for all $x, x' \in z(t) + \varepsilon\mathbb{B}$, and $y \in \dot{z}(t) + N\mathbb{B}$ one has*

$$d(y, F(t, x)) - d(y, F(t, x')) \leq (k(t) + \beta N)|x - x'|.$$

Let $\prec$ be a (nonreflexive) preference for vectors in $\mathbb{R}^m$. We consider the following multiobjective optimization problem:

$$\text{(P)} \qquad \begin{gathered} \min f(x(a), x(b)), \\ (x(a), x(b)) \in S, \\ \dot{x}(t) \in F(t, x(t)) \quad \text{a.e.} \quad t \in [a, b], \end{gathered}$$

where $f\colon \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R}^m$ is a mapping, $S \subset \mathbb{R}^n \times \mathbb{R}^n$ is a closed nonempty set, and $F\colon [a, b] \times \mathbb{R}^n \mapsto \mathbb{R}^n$ is a closed-valued multivalued mapping which is measurable in $t \in [a, b]$.

We say that an arc $x \in W^{1,1}$ is a feasible trajectory for problem (P) if x satisfies $(x(a), x(b)) \in S$ and $\dot{x}(t) \in F(t, x(t))$ a.e. $t \in [a, b]$.

z is a solution to (P), provided that it is feasible and there does not exist any feasible trajectory x of (P) such that $f(x(a), x(b)) \prec f(z(a), z(b))$. For all $r \in \mathbb{R}^m$, we denote

$$\mathcal{L}(r) := \{s \in \mathbb{R}^m \,:\, s \prec r\}.$$

We will need the following regularity assumptions on the preference modified from [49].

Definition 3.2. *We say that a preference $\prec$ is regular at $r \in \mathbb{R}^m$, provided that*
(A_1) for any $s \in \mathbb{R}^m$, $s \in \mathrm{cl}\mathcal{L}(s)$;
(A_2) for any $r \prec s$, $t \in \mathrm{cl}\mathcal{L}(r)$ implies that $t \prec s$.

Remark 3.1. The preference determined by the lexicographical order $\prec$ is defined by $r \prec s$ if there exists an integer $q \in \{0, 1, \dots, m-1\}$ such that $r_i = s_i,\ i = 1, \dots, q$, and $r_{q+1} < s_{q+1}$. This preference is not regular. Indeed we consider in $\mathbb{R}^3$ the vectors $r = (1, 1, 3)$, $s = (1, 1, 5)$, and $t = (1, 1, 6)$. We have $r \prec s$ and $t \in \mathrm{cl}\mathcal{L}(r)$, but $s \prec t$; then (A_2) does not hold so that $\prec$ is not regular at r.

Note that a preference determined by the lexicographical order does not correspond to any real utility function [16].

Remark 3.2. Our definition of regularity is different from that given by Zhu in [49], where the following third condition is in force: for any sequences $r_k, \theta_k \mapsto r$ in $\mathbb{R}^m$

$$\limsup_{k \to +\infty} N(\mathrm{cl}\mathcal{L}(r_k); \theta_k) \subset N(\mathrm{cl}\mathcal{L}(r); r).$$

But with this condition, preferences defined by a utility function (e.g., u) are not regular at any $r \in \mathbb{R}^m$ even if

$$\lim_{s \to r} d(0, \partial u(s)) > 0.$$

For more details, see Example 3.

We consider the following enlargement cone of the limiting Fréchet normal cone:

$$\tilde{N}(\mathrm{cl}\mathcal{L}(x), x) = \limsup_{y, x' \to x} N(\mathrm{cl}\mathcal{L}(y); x').$$

Before stating our main result we recall that the Hamiltonian associated with F is defined by

$$H(t, x, y) = \sup_{v \in F(t,x)} \langle y, v \rangle.$$

THEOREM 3.1. *Let z be a local solution to the multiobjective optimal control problem* (P). *Suppose that F is sub-Lipschitzian at z and that the preference $\prec$ is regular at $f(z(a), z(b))$. Then there exist $p \in W^{1,1}$, $\lambda \geq 0$, and $w \in \tilde{N}(\mathrm{cl}\mathcal{L}(f(z(a), z(b))), f(z(a), z(b)))$, with $|\omega| = 1$ such that $(\lambda, p) \neq 0$ and*

$$\dot{p}(t) \in coD^*F(t, z(t), \dot{z}(t))(-p(t)) \ \text{a.e. } t \in [a, b]; \tag{2}$$

$$(p(a), -p(b)) \in \lambda\partial(\langle\omega, f(\cdot,\cdot)\rangle)(z(a), z(b)) + N(S; (z(a), z(b))); \tag{3}$$

$$\langle p(t), \dot{z}(t)\rangle = H(t, z(t), p(t)) \ \text{a.e. } t \in [a, b]. \tag{4}$$

If in addition F is convex-valued, then (2) *may be replaced by the following one:*

$$\dot{p}(t) \in co\ \{q :\ (-q, \dot{z}(t)) \in \partial H(t, (z(t), p(t)))\} \quad \text{a.e. } t \in [a, b]. \tag{5}$$

The aim of Theorem 3.1 is to extend the necessary optimality conditions of Ioffe (Theorem 1 in [23]) from a single objective optimal control of differential inclusion problem to a multiobjective one. By using the large class of sub-Lipschitz differential inclusion, Theorem 3.1 also extends the Hamiltonian necessary optimality conditions for convex-valued differential inclusions obtained in [49].

In the remainder of this section we now examine a few examples. The proof of Theorem 3.1 is postponed to the next section.

Example 1 (a generalized Pareto optimal). Let K be a pointed convex cone ($K \cap (-K) = \{0\}$). We define the preference $\prec$ by $r \prec s$ if and only if $r - s \in K$ and $r \neq s$. A multiobjective optimal control problem with this preference is called a generalized Pareto optimal control problem. Notice that if $K = \mathbb{R}^m_-$ (resp., $K = \operatorname{int}\mathbb{R}^m_-$, where $\mathbb{R}^m_- = \{(x_1, x_2, \dots, x_m) \in \mathbb{R}^m : x_i \leq 0 \text{ for all } i = 1, \dots, m\}$) we get Pareto (resp., weak Pareto) optimal control problems. This preference is regular at any $r \in \mathbb{R}^m$. Moreover, for any $r \in \mathbb{R}^m$ we have $\tilde{N}(\mathrm{cl}\mathcal{L}(r), r) = K^0$ with $K^0 = \{s \in \mathbb{R}^m : \langle s, q\rangle \leq 0 \ \text{ for all } \ q \in K\}$.

COROLLARY 3.1. *Let z be a local solution to the generalized Pareto multiobjective optimal control problem* (P). *Then there exist $p \in W^{1,1}$, $\lambda \geq 0$, and $\omega \in K^0$ with $|\ \omega\ | = 1$ such that $(\lambda, p) \neq 0$ and*

$$\dot{p}(t) \in coD^*F(t, z(t), \dot{z}(t))(-p(t)) \ \text{a.e. } t \in [a, b]; \tag{6}$$

$$(p(a), -p(b)) \in \lambda\partial(\langle\omega, f(\cdot,\cdot)\rangle)(z(a), z(b)) + N(S; (z(a), z(b))); \tag{7}$$

$$\langle p(t), \dot{z}(t)\rangle = H(t, z(t), p(t)) \ \text{a.e. } t \in [a, b]. \tag{8}$$

Example 2 (a preference determined by a utility function). Let u be a continuous function; we define the preference $\prec$ determined by utility function u by $r \prec s$ if and only if $u(r) < u(s)$.

LEMMA 3.1. *Let u be a continuous utility function determining the preference $\prec$. Suppose that*

$$\liminf_{s \to r} d(0, \partial u(s)) > 0. \tag{9}$$

Then the preference $\prec$ is regular at r and

$$\tilde{N}(\mathrm{cl}\mathcal{L}(r), r) = \limsup_{r' \to r} N(\mathrm{cl}\mathcal{L}(r'); r') = \partial^{\infty} u(r) \bigcup \Big(\bigcup_{a>0} a \partial u(r) \Big).$$

Proof. The proof of Lemma 3.1 is similar to that given in [49]. From (9), $\mathcal{L}(r)$ is nonempty, and from the continuity of u it follows that $\prec$ satisfies (A_1) and (A_2) in Definition 3.2, and thus $\prec$ is regular. Now for $r^{'}$ sufficiently close to r, $\mathrm{cl}\mathcal{L}(r^{'}) = \{s \in \mathbb{R}^m : u(s) - u(r^{'}) \leq 0\}$. Then

$$\partial_{\varepsilon} u(r^{'}) \subset \hat{N}_{\varepsilon}(\mathrm{cl}\mathcal{L}(r^{'}), r^{'}).$$

By passing to the limits we have

$$\partial^{\infty} u(r) \bigcup \Big(\bigcup_{a>0} a \partial u(r) \Big) \subset \limsup_{r' \to r} N(\mathrm{cl}\mathcal{L}(r'); r') \subset \tilde{N}(\mathrm{cl}\mathcal{L}(r), r).$$

Conversely, let $\zeta \in \tilde{N}(\mathrm{cl}\mathcal{L}(r), r)$ such that $\zeta \neq 0$. Then there are sequences $\zeta_k \to \zeta$, $r_k, r_k^{'} \to r$ such that $\zeta_k \in N(\mathrm{cl}\mathcal{L}(r_k); r_k^{'})$. By the definition of limiting Fréchet normal cone, we may assume that $\zeta_k \in \hat{N}_{\varepsilon_k}(\mathrm{cl}\mathcal{L}(r_k), r_k^{'})$. We must have $u(r_k) = u(r_k^{'})$. Indeed, $\hat{N}_{\varepsilon_k}(\mathrm{cl}\mathcal{L}(r_k), r_k^{'}) = \{0\}$ when $u(r_k^{'}) < u(r_k)$ and is empty when $u(r_k^{'}) > u(r_k)$. Then $\hat{N}_{\varepsilon_k}(\mathrm{cl}\mathcal{L}(r_k), r_k^{'}) = \hat{N}_{\varepsilon_k}(\mathrm{cl}\mathcal{L}(r_k), r_k)$. From $\hat{N}_{\varepsilon_k}(\mathrm{cl}\mathcal{L}(r_k), r_k) = \hat{N}_{\varepsilon_k}(\{s : u(s) - u(r_k) \leq 0\}, r_k)$ and [8], there exist $a_k > 0$ and $\theta_k \in \partial_{\varepsilon_k} u(r)$ such that $\mid a_k \theta_k - \zeta_k \mid < \frac{1}{k}$ so that

$$\lim_{k \to \infty} a_k \theta_k = \zeta.$$

We claim that (a_k) is bounded. Indeed, suppose the contrary. Then (a_k) has a subsequence going to infinity. But in this case (θ_k) must have a subsequence converging to zero, and this contradicts (9). So (a_k) is bounded, and we can assume that $a_k \to a$. If $a \neq 0$, then $\zeta \in a \partial u(r)$. If $a = 0$, then $\zeta \in \partial^{\infty} u(r)$, and the proof is complete.

From Lemma 3.1 and Theorem 3.1 we have the following corollary.

COROLLARY 3.2. *Let $\prec$ be a preference determined by a utility function u and z be a local solution to the multiobjective optimal control problem* (P). *Suppose that*

$$\liminf_{s \to f(z(a), z(b))} d(0, \partial u(s)) > 0.$$

Then there exist $p \in W^{1,1}$, $\lambda \geq 0$, and

$$\omega \in \partial^{\infty} u(f(z(a), z(b))) \bigcup \Big(\bigcup_{a>0} a \partial u(f(z(a), z(b))) \Big)$$

with $\mid \omega \mid = 1$ such that $(\lambda, p) \neq 0$, and

$$\dot{p}(t) \in co D^* F(t, z(t), \dot{z}(t))(-p(t)) \ \ a.e.\ t \in [a, b]; \tag{10}$$

$$(p(a), -p(b)) \in \lambda \partial(\langle \omega, f(\cdot, \cdot) \rangle)(z(a), z(b)) + N(S; (z(a), z(b))); \tag{11}$$

$$\langle p(t), \dot{z}(t) \rangle = H(t, z(t), p(t)) \ \ a.e.\ t \in [a, b]. \tag{12}$$

In [49], the author showed that, for a preference $\prec$ defined by a continuous utility function u, $N(\mathrm{cl}\mathcal{L}(r);r) = \partial^\infty u(r) \bigcup \big(\bigcup_{a>0} a\partial u(r)\big)$, provided that $\lim_{s\to r} d(0,\partial u(s)) > 0$. This could give him the regularity and the explicit shape of $N(\mathrm{cl}\mathcal{L}(r);r)$. But there is a gap in the proof. The following example shows that Zhu's regularity does not hold.

Example 3. Consider the function $u : \mathbb{R}^2 \to \mathbb{R}$ defined by

$$u(x,y) = \mid x \mid - \mid y \mid .$$

Then u is Lipschitz continuous and satisfies $\partial u(0,0) = [-1,1] \times \{-1,1\}$, so that $(0,0) \notin \partial u(0,0)$, $\partial^\infty u(0,0) = \{(0,0)\}$, and

$$N(\mathrm{cl}\mathcal{L}(0,0);(0,0)) = \{(x,y) \in \mathbb{R}^2 : |y| = |x|\}.$$

Then it is clear that

$$N(\mathrm{cl}\mathcal{L}(0,0);(0,0)) \neq \partial^\infty u(0,0) \bigcup \Big(\bigcup_{a>0} a\partial u(0,0) \Big).$$

4. Proof of Theorem 3.1. Since F is sub-Lipschitzian at z there exist $\beta > 0$, $\varepsilon > 0$, and a summable function $k : [a,b] \mapsto \mathbb{R}$ such that for almost all $t \in [a,b]$, for all $N > 0$, for all $x, x' \in z(t) + \varepsilon\mathbb{B}$, and $y \in \dot{z}(t) + N\mathbb{B}$ one has

$$d(y, F(t,x)) - d(y, F(t,x')) \leq (k(t) + \beta N)|x - x'|.$$

Let G be the solution set of the system

$$\dot{x}(t) \in F(t,x(t)) \, a.e., \ (x(a),x(b)) \in S. \tag{13}$$

Let ε be as above. We say that the system (13) is seminormal [25] at z if there exist $\alpha > 0$ and $r > 0$ such that for all $x \in B(z,r)$

$$d(x, G \cap B(z,\varepsilon)) \leq \alpha \left\{ d((x(a),x(b));S) + \int_a^b d(\dot{x}(t); F(t,x(t)))dt \right\}. \tag{14}$$

Set $G_\varepsilon = G \cap B(z,\varepsilon)$.

We divide the proof into two parts and each part is divided into two steps.

Part 1 (when system (13) is not seminormal at z). The proof of this part is similar to that given in [23].

Step 1 (*application of Ekeland's variational principle* [18] *and Theorem* 2.1). Consider the function h defined by

$$h(x) = d((x(a),x(b));S) + \int_a^b d(\dot{x}(t); F(t,x(t)))dt.$$

Since F is sub-Lipschitzian at z, then h is l.s.c. on the set $B(z,\varepsilon)$ and G_ε is closed (see the appendix). If system (13) is not seminormal at z, then there is a sequence $x_k \to z$ in $W^{1,1}$ such that for k large enough

$$d(x_k, G_\varepsilon) > kh(x_k).$$

Set $\varepsilon_k = \sqrt{h(x_k)} > 0$, $\lambda_k = \min(\varepsilon_k, k\varepsilon_k^2)$, and $s_k = \frac{\varepsilon_k^2}{\lambda_k}$. Then $\varepsilon_k \to 0^+$ and $s_k \to 0^+$. Therefore one has

$$h(x_k) \leq \inf_{x \in B(z,\varepsilon)} h(x) + \varepsilon_k^2.$$

By Ekeland variational principle we get $z_k \in B(z,\varepsilon)$ satisfying

$$\|z_k - x_k\| < \lambda_k, \tag{15}$$

$$h(z_k) \le h(x) + s_k\|x - z_k\| \quad \forall x \in B(z,\varepsilon). \tag{16}$$

Observe that for k sufficiently large $\| z_k - z \| \le \frac{\varepsilon}{2}$. By the closedness of G_ε and relation (15) $z_k \notin G$, and by (16) z_k is a local solution to the following Bolza problem:

$$\min\left\{\ell_k(x(a),x(b)) + \int_a^b L_k(t,x(t),\dot{x}(t))dt\right\},$$

where

$$\ell_k(u,v) = d((u,v);S) + s_k|u - z_k(a)|$$

and

$$L_k(t,x,y) = \begin{cases} d(y;F(t,x)) + s_k|y - \dot{z}_k(t)| & \text{if } (x,y) \in A(t), \\ +\infty & \text{otherwise,} \end{cases}$$

where $A(t) = (z(t) + \varepsilon\mathbb{B}) \times (\dot{z}(t) + (N + |\dot{z}(t) - \dot{z}_k(t)|)\mathbb{B})$ and $N > 0$ is an arbitrary integer.

Since $L_k(t,\cdot,\cdot)$ is l.s.c, epi-Lipschitzian at z_k (see the appendix) and epimeasurable in t and since ℓ_k is locally Lipschitzian around $(z_k(a), z_k(b))$, then Theorem 2.1 yields the existence of an arc p_k in $W^{1,1}$ satisfying

$$\dot{p}_k(t) \in \operatorname{co}\{q : \quad (q, p_k(t)) \in \partial L_k(t, z_k(t), \dot{z}_k(t))\} \quad a.e. \quad t \in [a,b] \tag{17}$$

$$(p_k(a), -p_k(b)) \in \partial\ell_k(z_k(a), z_k(b)), \tag{18}$$

$$\langle p_k(t), \dot{z}_k(t)\rangle - L_k(t, z_k(t), \dot{z}_k(t)) = \max_{v\in\mathbb{R}^n}\{\langle p_k(t), v\rangle - L_k(t, z_k(t), v)\}. \tag{19}$$

From (17), (18), and (19) we have

$$(p_k(a), -p_k(b)) \in \partial d((z_k(a), z_k(b)); S) + s_k\mathbb{B} \times \{0\}, \tag{20}$$

$$\dot{p}_k(t) \in \text{ co } \{q : (q, p_k(t)) \in \partial d(\cdot; F(t,\cdot))(z_k(t), \dot{z}_k(t)) + \{0\} \times s_k\mathbb{B}\} \text{ a.e.}, \tag{21}$$

$$\begin{aligned} &\langle p_k(t), \dot{z}_k(t)\rangle - d(\dot{z}_k(t); F(t, z_k(t))) \\ &\quad = \max_{v\in\dot{z}(t)+(N+|\dot{z}(t)-\dot{z}_k(t)|)\mathbb{B}} \{\langle p_k(t), v\rangle - d(v; F(t, z_k(t))) - s_k|v - \dot{z}_k(t)|\} \text{ a.e.} \end{aligned}$$

Step 2 (*application of Lemmas* 2.1–2.4). By (20) there exists $\zeta_k \in \partial d((z_k(a), z_k(b)); S)$ such that

$$(p_k(a), -p_k(b)) - \zeta_k \in s_k\mathbb{B} \times \{0\}. \tag{22}$$

Since $z_k \notin G$, we have either

$$|\zeta_k| = 1 \text{ if } (z_k(a), z_k(b)) \notin S \tag{23}$$

or (because of Lemma 2.1 and (21)) on a set of positive measure on which $\dot{z}_k(t) \notin F(t, z_k(t))$ we have

$$1 - s_k \leq |p_k(t)| \leq 1 + s_k. \tag{24}$$

It follows from (22)–(24) that

$$\frac{1}{\sqrt{2}} - s_k \leq \max_{t\in[a,b]} |p_k(t)| \leq 1 + s_k. \tag{25}$$

Now let $\Gamma : [a, b] \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}_+ \mapsto \mathbb{R}^n$ be the multivalued mapping defined by

$$\Gamma(t, x, y, w, s) = \text{ co } \{q : (q, w) \in \partial d(\cdot; F(t, \cdot))(x, y) + \{0\} \times s\mathbb{B}\}.$$

Then

$$(p_k(a), -p_k(b)) - \zeta_k \in s_k\mathbb{B} \times \{0\}, \tag{26}$$

$$\dot{p}_k(t) \in \Gamma(t, z_k(t), \dot{z}_k(t), p_k(t), s_k) \quad \text{a.e.}, \tag{27}$$

$$\begin{aligned} &\langle p_k(t), \dot{z}_k(t)\rangle - d(\dot{z}_k(t); F(t, z_k(t))) \\ &= \max_{v\in\dot{z}(t)+(N+|\dot{z}(t)-\dot{z}_k(t)|)\mathbb{B}} \{\langle p_k(t), v\rangle - d(v; F(t, z_k(t))) - s_k|v - \dot{z}_k(t)|\} \quad \text{a.e.} \end{aligned} \tag{28}$$

Extracting a subsequence if necessary we may suppose that $\zeta_k \to \zeta$ for some ζ in $\partial d((z(a), z(b)); S)$ with

$$|\zeta| = 1 \text{ if } (z_k(a), z_k(b)) \notin S \text{ for infinite number of } k.$$

On the other hand, by Lemma 2.2, the multivalued mapping $\Gamma(t, \cdot)$ is u.s.c. with compact convex values and by the definition of the limiting Fréchet subdifferential and the sub-Lipschitz condition we have (via Lemma 2.1 and (21)) for all k

$$|\dot{p}_k(t)| \leq 1 + k(t) + \beta(1 + |\dot{z}(t) - \dot{z}_k(t)|) \quad \text{a.e.}$$

Note that $\Gamma(t, x, y, w, s)$ is measurable in t (see the appendix). By Lemma 2.4 there exists a subsequence of (p_k) converging uniformly to an arc p satisfying

$$\dot{p}(t) \in \Gamma(t, z(t), \dot{z}(t), p(t), 0) \quad \text{a.e.}, \tag{29}$$

and hence we obtain, by passing to the limit in (26) and (28),

$$(p(a), -p(b)) \in \partial d((z(a), z(b)); S), \tag{30}$$

$$\langle p(t), \dot{z}(t)\rangle = \max_{v\in F(t,z(t))\cap(\dot{z}(t)+N\mathbb{B})} \langle p(t), v\rangle \text{ a.e.} \tag{31}$$

Now because of (25) the pair (ζ, p) must be nonzero. In fact we have

$$\frac{1}{\sqrt{2}} \leq \max_{t\in[a,b]} |p(t)| \leq 1. \tag{32}$$

As p depends on N, we obtain a sequence (p_N) satisfying (29)–(32) and

$$|\dot{p}_N(t)| \leq 1 + k(t) + \beta \quad \text{a.e.}$$

Again Lemma 2.4 produces a subsequence of (p_N) converging uniformly to some p which satisfies the following:

$$\dot{p}(t) \in \Gamma(t, z(t), \dot{z}(t), p(t), 0) \quad \text{a.e.},$$

$$(p(a), -p(b)) \in \partial d((z(a), z(b)); S),$$

$$\langle p(t), \dot{z}(t)\rangle = \max_{v \in F(t,z(t))} \langle p(t), v\rangle,$$

$$\frac{1}{\sqrt{2}} \leq \max_{t\in[a,b]} |p(t)| \leq 1.$$

Finally we have

$$\dot{p}(t) \in \mathrm{co}D^*F(t, z(t), \dot{z}(t))(-p(t)) \ \ a.e.\ \ t \in [a, b],$$

$$(p(a), -p(b)) \in N(S; (z(a), z(b))),$$

$$\langle p(t), \dot{z}(t)\rangle = H(t, z(t), p(t)) \ \ a.e.\ \ t \in [a, b].$$

Part 2 (when system (13) is seminormal).

Step 1 (*application of Ekeland's variational principle*). Let k be a positive integer, choose $\theta_k \prec f(z(a), z(b))$ such that $|\theta_k - f(z(a), z(b))| < \frac{1}{k^2}$, and define $\Theta := \mathrm{cl}\mathcal{L}(\theta_k)$. Define the function

$$h(x, \theta) = \begin{cases} |f(x(a), x(b)) - \theta| & \text{if } x \in B(z, s_1), \\ +\infty & \text{otherwise,} \end{cases}$$

where s_1 is such that f is Lipschitzian on $(z(a), z(b)) + s_1\mathbb{B}$ with constant k_f. From (A_1) we have $(z, \theta_k) \in G_\varepsilon \times \Theta$, and hence

$$h(z, \theta_k) \leq \inf_{(x,\theta)\in G_\varepsilon\times\Theta} h(x, \theta) + \frac{1}{k^2}.$$

Note that G_ε and Θ are closed in $W^{1,1}$ and $\mathbb{R}^m$, respectively, and that h is l.s.c. on $G_\varepsilon \times \Theta$. Then by Ekeland variational principle there exists $(z_k, \gamma_k) \in G_\varepsilon \times \Theta$ such that

$$\|z_k - z\| + |\gamma_k - \theta_k| \leq \frac{1}{k} \tag{33}$$

and

$$h(z_k, \gamma_k) \leq h(x, \theta) + \frac{1}{k}\left[\|z_k - x\| + |\gamma_k - \theta|\right] \forall (x, \theta) \in G_\varepsilon \times \Theta. \tag{34}$$

From (34) one gets

$$h(z_k, \gamma_k) \leq h(x, \gamma_k) + \frac{1}{k}\|z_k - x\| \forall x \in G_\varepsilon \tag{35}$$

and

$$h(z_k,\gamma_k) \le h(z_k,\theta) + \frac{1}{k}|\gamma_k - \theta| \,\forall \theta \in \Theta. \tag{36}$$

Since z is an optimal local solution to problem (P), then, by (A_2) and the choice of θ_k, one has $\gamma_k \neq f(z_k(a), z_k(b))$. Set $w_k = \frac{f(z_k(a),z_k(b))-\gamma_k}{|f(z_k(a),z_k(b))-\gamma_k|}$. Extracting a subsequence we may assume that (w_k) converges to some w, with $|w| = 1$ so that by (36) one has

$$w \in \limsup_{k\to+\infty} N(\mathrm{cl}\mathcal{L}(\theta_k);\gamma_k)$$

and then

$$\omega \in \tilde{N}(\mathrm{cl}\mathcal{L}(f(z(a),z(b))), f(z(a),z(b))).$$

Now from (35) and the seminormality of (13) there exist $\alpha > 0$ and $\min(s_1, r, \varepsilon) > s > 0$ (both not depending on k) such that

$$h(z_k,\gamma_k) \le h(x,\gamma_k) + \frac{1}{k}\|z_k - x\| + \alpha(k_f+1)\left[d((x(a),x(b));S) + \int_a^b d(\dot{x}(t), F(t,x(t))dt\right]$$

for all $x \in B(z,s)$, where r and α are as in (14).

Define the functions

$$\ell_k(u,v) = |f(u,v) - \gamma_k| + \frac{1}{k}|u - z_k(a)| + \alpha(k_f+1)d((u,v);S)$$

and

$$L_k(t,x,y) = \begin{cases} \alpha(k_f+1)d(y;F(t,x)) + \frac{1}{k}|y - \dot{z}_k(t)| & \text{if } (x,y) \in A(t), \\ +\infty & \text{otherwise,} \end{cases}$$

where $A(t) = (z(t) + s\mathbb{B}) \times (\dot{z}(t) + (N + |\dot{z}(t) - \dot{z}_k(t)|)\mathbb{B})$ so that z_k is a local solution to the Bolza problem

$$\min\left\{\ell_k(x(a),x(b)) + \int_a^b L_k(t,x(t),\dot{x}(t))dt\right\}.$$

Step 2 (*application of Theorem* 2.1 *and Lemmas* 2.1–2.4). It is easy to check that ℓ_k is l.s.c and locally Lipschitzian around $(z_k(a), z_k(b))$, $L_k(t,\cdot,\cdot)$ is l.s.c, and L_k is epimeasurable in t and epi-Lipschitzian at z_k (see the appendix). Then by Theorem 2.1 there exists an arc p_k in $W^{1,1}$ satisfying

$$\dot{p}_k(t) \in \mathrm{co}\{q : \quad (q, p_k(t)) \in \partial L_k(t, z_k(t), \dot{z}_k(t))\} \quad a.e.\ t \in [a,b], \tag{37}$$

$$(p_k(a), -p_k(b)) \in \partial \ell_k(z_k(a), z_k(b)), \tag{38}$$

$$\langle p_k(t), \dot{z}_k(t)\rangle - L_k(t, z_k(t), \dot{z}_k(t)) = \max_{v\in\mathbb{R}^n}\{\langle p_k(t), v\rangle - L_k(t, z_k(t), v)\}. \tag{39}$$

Consider the multivalued mapping defined by

$$\Gamma(t,x,y,w,s) = \text{ co } \{q : (q,w) \in \alpha(k_f+1)\partial d(\cdot; F(t,\cdot))(x,y) + \{0\} \times s\mathbb{B}\}.$$

From (37)–(39) we have

$$(40)\quad (p_k(a), -p_k(b)) \in \partial(|f(\cdot) - \gamma_k|)(z_k(a), z_k(b)) + N(S; (z_k(a), z_k(b))) + \frac{1}{k}\mathbb{B} \times \{0\},$$

$$(41)\qquad \dot{p}_k(t) \in \Gamma\left(t, z_k(t), \dot{z}_k(t), p_k(t), \frac{1}{k}\right) \quad \text{a.e.},$$

$$(42)\quad \langle p_k(t), \dot{z}_k(t)\rangle - \alpha(k_f+1)d(\dot{z}_k(t); F(t, z_k(t))) = \max_{v \in z_k(t) + (N + |\dot{z}(t) - z_k(t)|)\mathbb{B}} \{\langle p_k(t), v\rangle - \alpha(k_f+1)d(v; F(t, z_k(t))) - s_k|v - \dot{z}_k(t)|\} \text{ a.e.}$$

By Lemma 2.2, the multivalued mapping $\Gamma(t,\cdot)$ is u.s.c. with compact convex values, and by the definition of the limiting Fréchet subdifferential and the sub-Lipschitz condition we have (via Lemma 2.1 and (41)) for all k

$$|\dot{p}_k(t)| \le \alpha(k_f+1)(1 + k(t) + \beta(1 + |\dot{z}(t) - \dot{z}_k(t)|)) \quad \text{a.e.}$$

By Lemma 2.4 there exists a subsequence of (p_k) converging uniformly to an arc p satisfying

$$(43)\qquad \dot{p}(t) \in \Gamma(t, z(t), \dot{z}(t), p(t), 0) \quad \text{a.e.}$$

Note that

$$\partial(|f(\cdot,\cdot) - \gamma_k|)(z_k(a), z_k(b)) \subset \partial(\langle w_k, f(\cdot,\cdot)\rangle)(z_k(a), z_k(b)),$$

and hence, by passing to the limit in (40) and (42) and using the same argument as in Part 1, Step 2, we have

$$(p(a), -p(b)) \in \partial(\langle \omega, f(\cdot,\cdot)\rangle)(z(a), z(b)) + N(S; (z(a), z(b))),$$

$$\langle p(t), \dot{z}(t)\rangle = H(t, z(t), p(t)) \text{ a.e.}$$

Now if we assume that F is convex-valued, then, by (29) and/or (43) and Rockafeller result [40], we obtain

$$\dot{p}(t) \in \text{co}\,\{q : (-q, \dot{z}(t)) \in \partial H(t, z(t), p(t))\} \quad \text{a.e.} \quad t \in [a,b],$$

which completes the proof.

5. Appendix.

- $h(x) = d((x(a), x(b)); S) + \int_a^b d(\dot{x}(t); F(t, x(t)))dt$ is l.s.c. on $B(z, \varepsilon)$.
Since F is sub-Lipschitzian at z, then there exist $\beta > 0$, $\varepsilon > 0$, and a summable function $k : [a, b] \mapsto \mathbb{R}$ such that for almost all $t \in [a, b]$, for all $N > 0$, for all $x, x' \in z(t) + \varepsilon\mathbb{B}$, and $y \in \dot{z}(t) + N\mathbb{B}$ one has

$$d(y, F(t, x)) - d(y, F(t, x')) \leq (k(t) + \beta N)|x - x'|.$$

Let $x \in B(z, \varepsilon)$ and $\varepsilon' > 0$, and set $\delta < \frac{\varepsilon'}{1+\int_a^b k(t)\,dt+\beta(\varepsilon+b-a)}$.
Let $x' \in B(z, \varepsilon)$ such that $\| x - x' \| < \delta$, and set $N = | \dot{x'}(t) - \dot{z}(t) | +1$. We have

$$\begin{aligned}\int_a^b d(\dot{x}(t), F(t, x(t)))\,dt - \int_a^b d(\dot{x'}(t), F(t, x'(t)))\,dt \,| &\leq | \dot{x}(t) - \dot{x'}(t) \,| \\ &+ \int_a^b d(\dot{x'}(t), F(t, x(t)))\,dt - \int_a^b d(\dot{x'}(t), F(t, x'(t)))\,dt \\ &\leq \delta + \int_a^b (k(t) + \beta N) \mid x(t) - x'(t) \mid dt \\ &\leq \delta + \delta \left(\int_a^b k(t)\,dt + \beta(\varepsilon + b - a) \right) \leq \varepsilon'.\end{aligned}$$

Thus h is l.s.c on $B(z, \varepsilon)$.

- G_ε is closed.
Let (x_n) be a subsequence in G_ε such that $x_n \longrightarrow x$ in $W^{1,1}$. Since S is closed $(x(a), x(b)) \in S$. Set $N' = | \dot{x}(t) - \dot{z}(t) | +1$; since F is sub-Lipschitzian at z we have

$$d(\dot{x}(t), F(t, x(t))) \leq (k(t) + \beta N) \mid x(t) - x_n(t) \mid + d(\dot{x}(t), F(t, x_n(t)))$$

so that

$$\begin{aligned}\int_a^b d(\dot{x}(t), F(t, x(t)))\,dt \leq &\| x - x_n \| \int_a^b (k(t) + \beta N)\,dt \\ &+ \int_a^b d(\dot{x}(t), F(t, x_n(t)))\,dt \\ \leq &\| x - x_n \| \left(\beta \| x - z \| + \beta(b - a) + \int_a^b k(t)\,dt \right) \\ &+ \| x - x_n \| .\end{aligned}$$

Then $d(\dot{x}(t), F(t, x(t))) = 0$ a.e., and since F is closed-valued $x \in G_\varepsilon$.

- $L_k(t, \cdot, \cdot)$ is epi-Lipschitzian at z_k.
We have

$$L_k(t, x, y) = \begin{cases} \alpha(k_f + 1)d(y; F(t, x)) + \frac{1}{k}|y - \dot{z}_k(t)| & \text{if } (x, y) \in A(t), \\ +\infty & \text{otherwise,} \end{cases}$$

where $A(t) = (z(t) + s\mathbb{B}) \times (\dot{z}(t) + (N + |\dot{z}(t) - \dot{z}_k(t)|)\mathbb{B})$.
For k large enough we can suppose that $| z_k(t) - z(t) | < \frac{s}{2}$. Let $x_1, x_2 \in B(z_k(t), \frac{s}{2})$ and $y \in \mathbb{R}^n$ such that $L_k(t, x_1, y)$ is finite. Then

$$| x_1 - z(t) | \leq s \text{ and } | y - \dot{z}(t) | \leq N + |\dot{z}(t) - \dot{z}_k(t)|.$$

Since $\mid x_2 - z(t) \mid < s$, $L_k(t, x_2, y)$ is finite, and using the fact that F is sub-Lipschitzian at z we get

$$L_k(t, x_2, y) - L_k(t, x_1, y) = \alpha(k_f + 1)[d(y; F(t, x_2)) - d(y; F(t, x_1))]$$

$$\leq \alpha(k_f + 1)(k(t) + \beta(N + |\dot{z}(t) - \dot{z}_k(t)|)) \mid x_1 - x_2 \mid .$$

Then $L_k(t, \cdot, \cdot)$ is epi-Lipschitzian at z_k.

- $\Gamma(t, x, y, w, s)$ is measurable in t.
  The measurability of the multivalued mapping $\Gamma(t, x, y, w, s)$ in t follows from the two following lemmas.
  LEMMA 5.1. *Let $G : [a, b] \to \mathbb{R}^n$ be a measurable multivalued mapping, and let K be a compact set in $\mathbb{R}^n$. Then the multivalued mapping $G(\cdot) + K$ is also measurable.*
  Proof. It suffices to see that for any set A in $\mathbb{R}^n$ we have

$$(G(\cdot) + K)^{-1}(A) = G^{-1}(A - K),$$

  where $G^{-1}(A) = \{t : G(t) \cap A \neq \emptyset\}$.
  LEMMA 5.2. *Let $f : [a, b] \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ be a l.s.c. function in (x, y) and measurable in (t, x, y). Consider the multivalued mapping*

$$R(t, x, y, p) = \{q : (q, -p) \in \partial f(t, x, y) + \{0\} \times s\mathbb{B}\} .$$

  Then R and $\bar{co}\, R$ are measurable in t.
  Proof. It follows from Lemma 2 in [21] that the graph of the multivalued mapping $t \to \partial f(t, x, y)$ is measurable. As this multivalued mapping is closed-valued, Theorem 8.1.4 in [2] implies that it is measurable in t. Now Lemma 5.1 asserts that the multivalued mapping

$$t \longrightarrow \partial f(t, x, y) + \{0\} \times s\mathbb{B}$$

  is measurable in t. The measurability of $t \to R(t, x, y, p)$ follows from the formula

$$(\partial f(\cdot, x, y) + \{0\} \times s\mathbb{B})^{-1}(A \times \{-p\}) = R^{-1}(\cdot, x, y, p)(A).$$

  The measurability of $\bar{co}R$ follows from Theorem 8.2.2 in [2].

Acknowledgment. We wish to thank the anonymous referees for their careful reading of the manuscript. Their helpful comments are greatly appreciated.

ON LINEAR-QUADRATIC OPTIMAL CONTROL PROBLEMS FOR TIME-VARYING DESCRIPTOR SYSTEMS*

GALINA A. KURINA† AND ROSWITHA MÄRZ‡

Abstract. We deal with linear-quadratic optimal control problems for time-varying descriptor systems in a Hilbert space setting. A sufficient solvability condition is given by means of an appropriately stated linear boundary value problem (BVP) and by discussing the special structure of the regular differential system inherent in this BVP.

Key words. linear-quadratic control problem, abstract implicit differential equation, variable coefficient descriptor system

1. Introduction.

This paper aims at minimizing quadratic cost functionals over solutions of singular linear differential equations or differential-algebraic equations (DAEs) of the form

$$(A(t)x(t))' = C(t)x(t) + B(t)u(t), \quad t \in [0,T],$$

with fixed $T > 0$ and continuous coefficients A, C, and B. Especially in the case of constant coefficients, with singular A, the equation

$$Ax'(t) = Cx(t) + Bu(t), \quad t \in [0,T],$$

is often called a descriptor system. We keep this name for more general cases, too. There is an extensive literature (see [4], and [1], [2], [10] for an overview) on optimal control problems for time-invariant descriptor systems, and there are some papers investigating the case of smooth time-varying coefficients [9] and that of C and B being variable while A remains constant, respectively, [5], [6].

In [5], [6] the linear quadratic optimization problem—given in a Hilbert space setting—is traced back to the solution of a linear boundary value problem (BVP), where the appropriate formulation of the adjoint system as well as the invertibility properties of a specially structured linear operator play an essential role. Let us remark that this approach is fundamentally different from that in [1], [4], [10], for instance, where the matrix pencil $\lambda A - C$ is assumed to be regular, the descriptor system is subject to a reduction, and, finally, an approach based on solving a Riccati equation, which, however, may not be solvable in [1], [10] (cf. [12]), is studied.

The new insights concerning the structure of linear DAEs and their adjoint systems obtained in [7] allow for further generalizations of the results from [5], [6], in particular in the case of time-varying coefficients A. The main results of the present paper are the given sufficient solvability condition by means of an appropriate linear

BVP in section 2 as well as solvability statements for the BVP and, hence, for the optimal control problem in section 5. We do not need any assumptions on the regularity and index of the descriptor system itself. Properties of a special operator

$$F = \begin{pmatrix} F_1 & 0 & F_2 \\ F_3 & -F_1^* & F_4 \\ -F_4^* & F_2^* & -F_5 \end{pmatrix}, \tag{1.1}$$

whose invertibility turns out to be equivalent to the index-1 property of the DAE contained in the BVP, are essential here. The necessary characteristics of the operator F itself are provided in section 4.

A special aspect of the linear BVP under consideration is the question regarding the structure of the inherent regular differential equation. This question is answered in Theorem 5.1. It turns out that this structure is not nonnegative Hamiltonian in each case but only if the image of $A(t)$ does not vary with t.

In section 6 we discuss two transparent simple examples. The first one is characterized by a time-varying image of $A(t)$; in the second example the descriptor system is time-invariant but infinite-dimensional. In both examples, the optimization problems and the BVPs, respectively, are uniquely solvable, whereas, for a given control, the system state is not uniquely determined by the respective descriptor system to be controlled.

2. Sufficient conditions of control optimality. First of all, let us collect some notation and well-known facts on linear operators in real Hilbert spaces, which we want to use in the following.

For given Hilbert spaces X, Y we denote by $L(X,Y)$ the Banach space of linear bounded mappings of X with values in Y. The kernel $\mathrm{Ker}A$ of an operator $A \in L(X,Y)$ is a closed linear manifold in X, i.e., a subspace. We speak of a nullspace then. A subspace of a Hilbert space equipped with the same scalar product is a Hilbert space again. Note that $A \in L(X,Y)$ leads to $A^* \in L(Y,X)$ for the adjoint operator A^* to A. Recall that a mapping $A \in L(X,Y)$ with closed image $\mathrm{Im}A \subset Y$ is said to be normally solvable [8].

For a normally solvable operator $A \in L(X,Y)$ we can make use of orthogonal decompositions

$$X = \mathrm{Ker}A \oplus \mathrm{Im}A^*, \quad Y = \mathrm{Ker}A^* \oplus \mathrm{Im}A.$$

In particular, there are uniquely determined orthogonal projectors $P \in L(X,X) =: L(X), Q \in L(Y)$, such that $\mathrm{Im}P = \mathrm{Ker}A, \mathrm{Im}Q = \mathrm{Ker}A^* = (\mathrm{Im}A)^\perp$. The Moore inverse A^+ of a normally solvable operator $A \in L(X,Y)$ is again a bounded map, i.e., $A^+ \in L(Y,X), AA^+A = A, A^+AA^+ = A^+, AA^+ = I - Q, A^+A = I - P$ hold true (cf. [8]).

By I we mean the identity operator in the given spaces. For scalar products we shall use the uniform notation $\langle .,. \rangle$, even if we have different spaces.

We say that an operator $A \in L(X)$ is positive definite (semidefinite) if $\langle Ax, x\rangle > 0$ (≥ 0) for all nonzero $x \in X$.

Now we turn to our main topic, the problem of minimizing the quadratic cost functional

$$\begin{aligned} J(u,x) = \frac{1}{2}\langle x(T), Vx(T)\rangle + \frac{1}{2}\int_0^T (\langle x(t), W(t)x(t)\rangle \\ + 2\langle x(t), S(t)u(t)\rangle + \langle u(t), R(t)u(t)\rangle)dt \end{aligned} \tag{2.1}$$

on trajectories of the linear system

$$(A(t)x(t))' = C(t)x(t) + B(t)u(t), \quad t \in [0,T], \tag{2.2}$$

$$A(0)x(0) = y_0. \tag{2.3}$$

Here $T > 0$ is fixed, $x(t) \in X, u(t) \in U, y_0 \in Y$. X, Y, U are real Hilbert spaces, $V, W(t) \in L(X), S(t) \in L(U,X)$, $R(t) \in L(U), A(t), C(t) \in L(X,Y)$, $B(t) \in L(U,Y)$, $W(t) = W^*(t)$, $R(t) = R^*(t)$ for all $t \in [0,T], V = V^*$, the operators $W(t), S(t), R(t)$, $A(t), C(t), B(t)$ are continuous with respect to t. $A(t)$ is assumed to be normally solvable for all $t \in [0,T]$.

Admissible controls are continuous functions with values in U for which there is a solution of the problem (2.2), (2.3). A solution of (2.2) is a continuous function $x : [0,T] \to X$ that has a continuously differentiable product $A(t)x(t)$ and satisfies (2.2) pointwise.

Since the operator $A(t)$ is normally solvable for all $t \in [0,T]$, the spaces X and Y are decomposed into the orthogonal sums $X = \mathrm{Ker}A(t) \oplus \mathrm{Im}A^*(t), Y = \mathrm{Ker}A^*(t) \oplus \mathrm{Im}A(t)$. Denote by $P(t)$ the orthogonal projector of the space X onto $\mathrm{Ker}A(t)$ and by $Q(t)$ the orthogonal projector of the space Y onto $\mathrm{Ker}A^*(t)$.

Remark 2.1. From the relation (2.3) it follows that $y_0 \in \mathrm{Im}A(0)$; that is, for some $\tilde{x}_0 \in X$ the equality $y_0 = A(0)\tilde{x}_0$ should hold. Later on we will assume that $y_0 \in \mathrm{Im}A(0)$. Note that differential-algebraic systems (2.2) and initial value problems (2.2), (2.3) are considered, e.g., in [7].

The following conditions shall be used as basic assumptions throughout this paper:

I. The operator V is positive semidefinite.

II. For all $t \in [0,T]$ the operator $\begin{pmatrix} W(t) & S(t) \\ S^*(t) & R(t) \end{pmatrix}$ is positive semidefinite.

III. The projector $P(t)$ is continuous in t, and the projector $Q(t)$ depends continuously differentiably on t.

LEMMA 2.2. *Let conditions* I, II, *and* III *be given. If the triple of continuous functions* $(x_*, \psi_*, u_*) : [0,T] \to X \times Y \times U$ *has continuously differentiable parts* $Ax_* : [0,T] \to Y$, $(I-Q)\psi_* : [0,T] \to Y$ *and satisfies the system*

$$(Ax)'(t) = C(t)x(t) + B(t)u(t), \quad A(0)x(0) = y_0, \tag{2.4}$$

$$\begin{gathered} A^*(t)((I-Q)\psi)'(t) = W(t)x(t) - (C^*(t) + A^*(t)Q'(t))\psi(t) + S(t)u(t), \\ A^*(T)\psi(T) = -Vx(T), \end{gathered} \tag{2.5}$$

$$0 = -S^*(t)x(t) + B^*(t)\psi(t) - R(t)u(t), \tag{2.6}$$

then $u_*(t)$ *is an optimal control for the problem* (2.1)–(2.3).

Proof. Let $x_*(t), u_*(t), \psi_*(t)$ be a solution of the system (2.4)–(2.6), $u(t)$ be an arbitrary admissible control, and $x(t)$ be a corresponding solution of the problem (2.2), (2.3).

Taking into account the relations (2.1)–(2.6), straightforward computations yield the equality

$$\begin{aligned} J(u,x) - J(u_*,x_*) = \mathfrak{A} &+ \frac{1}{2}\langle x(T) - x_*(T), V(x(T) - x_*(T))\rangle \\ &+ \frac{1}{2}\int_0^T \left\langle \begin{pmatrix} x(t) - x_*(t) \\ u(t) - u_*(t) \end{pmatrix}, \begin{pmatrix} W(t) & S(t) \\ S^*(t) & R(t) \end{pmatrix} \begin{pmatrix} x(t) - x_*(t) \\ u(t) - u_*(t) \end{pmatrix} \right\rangle dt \end{aligned}$$

with $\mathfrak{A} = \langle x(T) - x_*(T), Vx_*(T)\rangle + \int_0^T \{\langle x(t) - x_*(t), W(t)x_*(t) + S(t)u_*(t)\rangle + \langle u(t) - u_*(t), S^*(t)x_*(t) + R(t)u_*(t)\rangle\}dt$. The term $\mathfrak{A}$ will be shown to vanish. Then conditions I and II yield the inequality

$$J(u, x) - J(u_* x_*) \geq 0;$$

hence, u_* is an optimal control. Now we show $\mathfrak{A} = 0$ to be true in fact. We have

$$\begin{aligned}
\mathfrak{A} &= \langle x(T) - x_*(T), Vx_*(T)\rangle \\
&\quad + \int_0^T \{\langle x(t) - x_*(t), A^*(t)((I-Q)\psi_*)'(t) + C^*(t)\psi_*(t) + A^*(t)Q'(t)\psi_*(t)\rangle \\
&\quad + \langle u(t) - u_*(t), B^*(t)\psi_*(t)\rangle\}dt \\
&= \langle x(T) - x_*(T), Vx_*(T)\rangle + \int_0^T \{\langle A(t)(x(t) - x_*(t)), ((I-Q)\psi_*)'(t)\rangle \\
&\quad + \langle C(t)(x(t) - x_*(t)) + B(t)(u(t) - u_*(t)) + Q'(t)A(t)(x(t) - x_*(t)), \psi_*(t)\rangle\}dt \\
&= \langle x(T) - x_*(T), Vx_*(T)\rangle + \int_0^T \{\langle A(t)(x(t) - x_*(t)), ((I-Q)\psi_*)'(t)\rangle \\
&\quad + \langle (A(x - x_*))'(t) + Q'(t)A(t)(x(t) - x_*(t)), \psi_*(t)\rangle\}dt.
\end{aligned}$$

Taking into account that $A = (I-Q)A$, $Q' = -(I-Q)'$, and therefore $(A(x-x_*))' + Q'A(x-x_*) = ((I-Q)A(x-x_*))' - (I-Q)'A(x-x_*) = (I-Q)(A(x-x_*))'$, we derive

$$\begin{aligned}
\mathfrak{A} &= \langle x(T) - x_*(T), Vx_*(T)\rangle + \int_0^T \{\langle A(t)(x(t) - x_*(t)), ((I-Q)\psi_*)'(t)\rangle \\
&\quad + \langle (I - Q(t))(A(x - x_*))'(t), \psi_*(t)\rangle\}dt \\
&= \langle x(T) - x_*(T), Vx_*(T)\rangle + \int_0^T \{\langle A(t)(x(t) - x_*(t)), ((I-Q)\psi_*)'(t)\rangle \\
&\quad + \langle (A(x - x_*))'(t), (I - Q(t))\psi_*(t)\rangle\}dt \\
&= \langle x(T) - x_*(T), Vx_*(T)\rangle + \int_0^T \frac{d}{dt}\langle A(t)(x(t) - x_*(t)), (I - Q(t))\psi_*(t)\rangle dt \\
&= \langle x(T) - x_*(T), Vx_*(T)\rangle + \langle x(T) - x_*(T), A^*(T)\psi(T)\rangle = 0. \qquad \square
\end{aligned}$$

Remark 2.3. The boundary condition $A^*(T)\psi(T) = -Vx(T)$ can be rewritten in two parts as

$$(I - Q(T))\psi(T) = -A^{*+}(T)Vx(T),\ P(T)Vx(T) = 0. \tag{2.7}$$

If the inclusion

$$\operatorname{Im} V \subseteq \operatorname{Im} A^*(T) \tag{2.8}$$

is valid, then it holds that $P(T)V = 0$ and $V = V(I - P(T)) = VA^+(T)A(T)$. In the consequence, the boundary condition (2.7) simplifies to

$$(I - Q(T))\psi(T) = -A^{+*}(T)VA^+(T)A(T)x(T) \tag{2.9}$$

such that the boundary conditions in the BVP (2.4)–(2.6) are exclusively directed to the smooth components Ax and $(I-Q)\psi$. We will exploit this fact in section 5 in order to derive the solvability of (2.4)–(2.6) from the solvability of BVPs in inherent Hamiltonian systems. Condition (2.8) is a helpful means for formulating sufficient solvability conditions of control problems. If it is not satisfied, the BVP (2.4)–(2.6) may be solvable nevertheless, or it is unsolvable (cf. Remark 6.1 below). Let us stress here once more that we are concerned with sufficient solvability conditions but not with necessary conditions.

Let us mention that in the standard reference [4], assumption (2.8) is built in the problem at the very beginning by using a cost functional with $A^*\tilde{V}A$ instead of V.

3. Equations in subspaces. For each $t \in [0,T]$ the operators

$$\begin{aligned} A(t) &= (I-Q(t))A(t)(I-P(t)) &&: \text{Im } A^*(t) \to \text{Im } A(t), \\ A^*(t) &= (I-P(t))A^*(t)(I-Q(t)) &&: \text{Im } A(t) \to \text{Im } A^*(t) \end{aligned}$$

have the Moore inverses $A^+(t) = (I-P(t))A^+(t)(I-Q(t))$ and $A^{*+}(t) = (I-Q(t))A^{+*}(t)(I-P(t)) = A^{+*}(t)$.

Using the projectors P, Q, and the identities $Q(t)(Ax)'(t) = -Q(t)Q'(t)(Ax)(t)$, $Q(t)((I-Q)\psi)'(t) = -Q(t)Q'(t)((I-Q)\psi)(t)$, $((I-P)x)(t) = (A^+Ax)(t)$, $Q'(t)(I-Q(t)) = Q(t)Q'(t)$ we obtain the following two relations from the system (2.4)–(2.6):

$$0 = L \begin{pmatrix} Ax \\ (I-Q)\psi \end{pmatrix} + G \begin{pmatrix} Px \\ Q\psi \\ u \end{pmatrix}, \tag{3.1}$$

$$\begin{pmatrix} Ax \\ (I-Q)\psi \end{pmatrix}' = M \begin{pmatrix} Ax \\ (I-Q)\psi \end{pmatrix} + K \begin{pmatrix} Px \\ Q\psi \\ u \end{pmatrix}, \tag{3.2}$$

where

$$L = \begin{pmatrix} QQ'(I-Q) + QCA^+ & 0 \\ PWA^+ & -PC^*(I-Q) \\ -S^*A^+ & B^*(I-Q) \end{pmatrix},$$

$$G = \begin{pmatrix} QCP & 0 & QB \\ PWP & -PC^*Q & PS \\ -S^*P & B^*Q & -R \end{pmatrix}, \tag{3.3}$$

$$\hat{M} = \begin{pmatrix} (I-Q)CA^+ & 0 \\ A^{*+}WA^+ & -A^{*+}C^*(I-Q) \end{pmatrix},$$

$$M = \hat{M} - \begin{pmatrix} QQ'(I-Q) & 0 \\ 0 & QQ'(I-Q) \end{pmatrix},$$

$$K = \begin{pmatrix} (I-Q)CP & 0 & (I-Q)B \\ A^{*+}WP & -A^{*+}C^*Q - (I-Q)Q'Q & A^{*+}S \end{pmatrix}.$$

For brevity we often omit the argument t. With

$$J = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix} \tag{3.4}$$

and

$$\hat{J} = \mathrm{diag}(J, I)$$

it holds that

$$K = JL^*\hat{J}.$$

By construction it holds that

$$\mathrm{Ker}G(t) \supseteq \mathrm{Ker}P(t) \times \mathrm{Ker}Q(t) \times 0 = \mathrm{Im}A^*(t) \times \mathrm{Im}A(t) \times 0,$$
$$\mathrm{Im}G(t) \subseteq \mathrm{Im}Q(t) \times \mathrm{Im}P(t) \times U = \mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U.$$

Following the lines of [7], [11] one may easily check that (2.4)–(2.6) represents an index-1-tractable DAE if and only if the mapping $G(t)$ acts bijectively from $\mathrm{Ker}A(t) \times \mathrm{Ker}A^*(t) \times U$ onto $\mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U$. Consequently, the respective properties of the operator $G(t)$ are of great interest. It is evident that the operator G has a matrix representation of the form (1.1), which shall be studied in the next section.

If $G(t) : \mathrm{Ker}A(t) \times \mathrm{Ker}A^*(t) \times U \to \mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U$ is actually a bijection and $G(t)^{-1}$ denotes its inverse, then (3.1) yields

$$\begin{pmatrix} Px \\ Q\psi \\ u \end{pmatrix} = -G^{-1}L \begin{pmatrix} Ax \\ (I-Q)\psi) \end{pmatrix}, \tag{3.5}$$

and (3.2) leads to a regular differential equation concerning the components Ax, $(I-Q)\psi$. This implies the solutions x, ψ, u of the optimality BVP (2.4)–(2.6) a priori to be continuous functions having continuously differentiable components Ax, $(I-Q)\psi$. More regularity, e.g., a fully continuously differentiable ψ, can be obtained via (3.5) by assuming the corresponding entries of the operator $G^{-1}L$ to be continuously differentiable.

4. Properties of the operator (1). We begin with the statement of sufficient conditions for the invertibility of operators $F : X_1 \times X_2 \times X_3 \to X_2 \times X_1 \times X_3$ having a matrix representation of the form (1.1), namely,

$$F = \begin{pmatrix} F_1 & 0 & F_2 \\ F_3 & -F_1^* & F_4 \\ -F_4^* & F_2^* & -F_5 \end{pmatrix},$$

where $X_i,\ i = 1, 2, 3$, are real Hilbert spaces, $F_i,\ i = 1, \ldots, 5$, denote bounded linear operators acting in the corresponding spaces and, additionally, F_3, F_5 are symmetric. Thereby, our special interest is directed to the particular case where, for fixed $t \in [0, T]$, $X_1 = \mathrm{Ker}A(t) = \mathrm{Im}P(t)$, $X_2 = \mathrm{Ker}A^*(t) = \mathrm{Im}Q(t)$, $X_3 = U$, $F_1 = (Q(t)C(t)P(t))^r$, $F_2 = (Q(t)B(t))^r$, $F_3 = (P(t)W(t)P(t))^r$, $F_4 = (P(t)S(t))^r$, $F_5 = R(t)$, where $(.)^r$ indicates the restriction of the operators inside the brackets to the

corresponding spaces, i.e., $F_1 = (Q(t)C(t)P(t))^r \in L(X_1, X_2)$ and so on. Clearly, if the operator $G(t)$ given by (3.3) acts bijectively on $\mathrm{Ker}A(t) \times \mathrm{Ker}A^*(t) \times U$ onto $\mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U$, then the corresponding F is invertible and vice versa.

LEMMA 4.1. *If the operator*

$$\begin{pmatrix} F_3 & F_4 \\ F_4^* & F_5 \end{pmatrix} \tag{4.1}$$

is positive definite and has a bounded inverse, and if the operator $(F_1F_2)^*$ is injective and normally solvable, then F has a bounded inverse.

Proof. First we show that there is no sequence $\{x_n\}$ such that $x_n \in X_1 \times X_2 \times X_3$, $\|x_n\| = 1$ for all $n \in N$ and $Fx_n \to 0$. We assume the contrary, namely,

$$\begin{aligned} F_1x_n^1 \quad &+ \quad F_2x_n^3 \quad &&\to \quad 0, \\ F_3x_n^1 \quad &- \quad F_1^*x_n^2 \quad + \quad F_4x_n^3 \quad &&\to \quad 0, \\ -F_4^*x_n^1 \quad &+ \quad F_2^*x_n^2 \quad - \quad F_5x_n^3 \quad &&\to \quad 0, \end{aligned}$$

where

$$x_n = \begin{pmatrix} x_n^1 \\ x_n^2 \\ x_n^3 \end{pmatrix}, \quad x_n^i \in X_i, i = \overline{1,3}, \ \|x_n\| = 1 \text{ for all } n \in N.$$

We scalarly multiply the left-hand side of the first relation of this system by x_n^2, the second relation by x_n^1, and the third one by $(-x_n^3)$. Adding the results we obtain the relation

$$\left\langle \begin{pmatrix} x_n^1 \\ x_n^3 \end{pmatrix}, \begin{pmatrix} F_3 & F_4 \\ F_4^* & F_5 \end{pmatrix} \begin{pmatrix} x_n^1 \\ x_n^3 \end{pmatrix} \right\rangle \to 0.$$

By virtue of the assumptions we have $x_n^1 \to 0, x_n^3 \to 0$. Then the relation $(F_1\ F_2)^* x_n^2 \to 0$ follows from the last system. Hence, we obtain $x_n^2 \to 0$. This contradicts the equality $\|x_n\| = 1$. Therefore, there is a constant $k > 0$ such that the inequality $\|Fx\| \geq k$ is valid for all $x \in X_1 \times X_2 \times X_3$ with $\|x\| = 1$. Consequently, the inequality

$$\|Fx\| \geq k\|x\| \tag{4.2}$$

is valid for all $x \in X_1 \times X_2 \times X_3$.

Next we prove that $\mathrm{Ker}F^* = 0$ is valid. The operator F^* has the matrix representation

$$F^* = \begin{pmatrix} F_1^* & F_3 & -F_4 \\ 0 & -F_1 & F_2 \\ F_2^* & F_4^* & -F_5 \end{pmatrix}.$$

Assume that there is an $x \in X_2 \times X_1 \times X_3$ such that $F^*x = 0$. This means in detail

$$\begin{aligned} F_1^*x_2 \quad &+ \quad F_3x_1 \quad - \quad F_4x_3 \quad = \quad 0, \\ -F_1x_1 \quad &+ \quad F_2x_3 \quad = \quad 0, \\ F_2^*x_2 \quad &+ \quad F_4^*x_1 \quad - \quad F_5x_3 \quad = \quad 0, \end{aligned}$$

where

$$x = \begin{pmatrix} x_2 \\ x_1 \\ x_3 \end{pmatrix}, \quad x_i \in X_i,\ i = \overline{1,3}.$$

We scalarly multiply the first equation of this system by x_1, the second equation by x_2, and the third equation by $(-x_3)$. Adding the results yields the equality

$$\left\langle \begin{pmatrix} -x_1 \\ x_3 \end{pmatrix}, \begin{pmatrix} F_3 & F_4 \\ F_4^* & F_5 \end{pmatrix} \begin{pmatrix} -x_1 \\ x_3 \end{pmatrix} \right\rangle = 0.$$

By virtue of the assumption on (4.1) we have $x_1 = 0, x_3 = 0$. Hence, the equality $(F_1\ F_2)^* x_2 = 0$ follows. We obtain $x_2 = 0$; therefore $\mathrm{Ker} F^* = 0$.

It remains to prove that the range of the operator F is a closed set. We take a sequence $\{y_n\}$, where $y_n = Fx_n, x_n \in X_1 \times X_2 \times X_3, y_n \to y_0$. The sequence $\{Fx_n\}$ is fundamental. From (4.2) it follows that the sequence $\{x_n\}$ is also fundamental. It tends to an element $x_0 \in X_1 \times X_2 \times X_3$ due to the completeness of X_i. As F is a bounded operator, $Fx_n \to Fx_0$. Hence, $y_0 \in \mathrm{Im}\ F$, i.e., $\mathrm{Im}\ F$ is a closed set.

Therefore, the following decomposition is realized: $X_2 \times X_1 \times X_3 = \mathrm{Im} F \oplus \mathrm{Ker} F^* = \mathrm{Im} F$, since $\mathrm{Ker} F^* = 0$. Using the inequality (4.2) we are done (see, e.g., Theorem (2) in [3, p. 204]). □

Remark 4.2. In the finite-dimensional case, if $X = Y$ is valid and A, C, B, W, S, R are constant matrices, the conditions of Lemma 4.1 for the operator G coincide with Assumption 2 in [4].

LEMMA 4.3. *If the operator* (4.1) *is positive semidefinite and the operators*

$$(F_1\ F_2)^* \quad \textit{and} \quad \begin{pmatrix} F_1 & F_2 \\ F_3 & F_4 \\ F_4^* & F_5 \end{pmatrix}$$

are injective and normally solvable, then F has a bounded inverse operator.

The proof of Lemma 4.3 is similar to the proof of Lemma 4.1.

Remark 4.4. The conditions of Lemma 4.1 and Lemma 4.3 are not necessary for the invertibility of an operator F of the form (1.1). For example, the specific operator

$$F = \begin{pmatrix} 1 & 0 & 0 \\ -1 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

is invertible, but neither the conditions of Lemma 4.1 nor those of Lemma 4.3 are satisfied. For the operator

$$F = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

(corresponding to the example in [4, p. 677]) the conditions of Lemma 4.1 (Assumption 2 from [4]) fail to be valid, but Lemma 4.3 applies.

From section 3 recall the operator

$$\hat{J} = \mathrm{diag}(J, I) = \begin{pmatrix} 0 & I & 0 \\ -I & 0 & 0 \\ 0 & 0 & I \end{pmatrix}.$$

LEMMA 4.5. *If the operator F is invertible, then the operator $\hat{J}F^{-1}$ is symmetric.*

Proof. The identity $F = -\hat{J}\tilde{F}$, where

$$\tilde{F} = \begin{pmatrix} F_3 & -F_1^* & F_4 \\ -F_1 & 0 & -F_2 \\ F_4^* & -F_2^* & F_5 \end{pmatrix},$$

is easily checked. $\tilde{F}$ is obviously symmetric and invertible. Thus, $\hat{J}F^{-1} = -\hat{J}\tilde{F}^{-1}\hat{J}^{-1}$ is a symmetric operator, as $\tilde{F}^{-1}$ is symmetric and $\hat{J}$ is unitary. ∎

COROLLARY 4.6. *If the operator F is invertible, then the inverse operator F^{-1} has a matrix representation of the form*

$$F^{-1} = \begin{pmatrix} D_1 & D_2 & D_3 \\ D_4 & -D_1^* & D_5 \\ D_5^* & -D_3^* & D_6 \end{pmatrix}, \tag{4.3}$$

where D_2, D_4, D_6 are symmetric operators.

The proof of this corollary follows from Lemma 4.5 *and the matrix representation of the operator $\hat{J}^{-1}$.*

LEMMA 4.7. *If the operator F is invertible and the operator* (4.1) *is positive semidefinite, then the operators $\begin{pmatrix} D_2 & D_3 \\ D_3^* & -D_6 \end{pmatrix}$ and D_4 in the representation* (4.3) *are positive semidefinite.*

Proof. The proof follows the lines of [5], where the special case of $F_4 = 0$ is considered. Introduce the operator $\tilde{J}$ having the matrix representation

$$\begin{pmatrix} 0 & I & 0 \\ I & 0 & 0 \\ 0 & 0 & -I \end{pmatrix}.$$

For every

$$z = \begin{pmatrix} z_2 \\ z_1 \\ z_3 \end{pmatrix} \in X_2 \times X_1 \times X_3$$

the identity

$$\langle \tilde{J}F^{-1}z, z\rangle = \langle D_4 z_2, z_2\rangle + \left\langle \begin{pmatrix} D_2 & D_3 \\ D_3^* & -D_6 \end{pmatrix} \begin{pmatrix} z_1 \\ z_3 \end{pmatrix}, \begin{pmatrix} z_1 \\ z_3 \end{pmatrix} \right\rangle \tag{4.4}$$

is valid. With

$$v = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix} = F^{-1}z$$

we also have

$$\langle \tilde{J}F^{-1}z, z\rangle = \langle \tilde{J}v, Fv\rangle = \left\langle \begin{pmatrix} F_3 & F_4 \\ F_4^* & F_5 \end{pmatrix} \begin{pmatrix} v_1 \\ v_3 \end{pmatrix}, \begin{pmatrix} v_1 \\ v_3 \end{pmatrix} \right\rangle. \tag{4.5}$$

Here z, v are represented in a form that corresponds to the matrix representation of the operator F. Since the operator (4.1) is positive semidefinite, (4.5) yields $\langle \tilde{J}F^{-1}z, z\rangle \geq 0$ for all z. Hence, the expression on the right-hand side of formula (4.4) is nonnegative. Setting in (4.4) at first $z_2 = 0$ and second $z_1 = 0$, $z_3 = 0$ we obtain the statement. ∎

5. Solvability of the problem. Now we turn back to the system (3.1), (3.2) and to the BVP (2.4)–(2.6), respectively.

The operator $G(t)$ defined by (3.3) maps $X \times Y \times U$ into $Y \times X \times U$. By construction, it holds that $\mathrm{Im}G(t) \subseteq \mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U = \mathrm{Im}Q(t) \times \mathrm{Im}P(t) \times U$, $\mathrm{Ker}G(t) \supseteq \mathrm{Ker}P(t) \times \mathrm{Ker}Q(t) \times 0$. It is natural to consider the restriction $(G(t))^r : \mathrm{Im}P(t) \times \mathrm{Im}Q(t) \times U \to \mathrm{Im}Q(t) \times \mathrm{Im}P(t) \times U$. Below we also use the shorter denotation $G(t)$ for $(G(t))^r$.

THEOREM 5.1. *Let conditions* I, II, *and* III *be satisfied. If, for every* $t \in [0, T]$, *the operator* $G(t) : \mathrm{Ker}\ A(t) \times \mathrm{Ker}\ A^*(t) \times U \to \mathrm{Ker}\ A^*(t) \times \mathrm{Ker}\ A(t) \times U$ *is bijective, then the system* (3.1), (3.2) *provides an explicit differential equation for the pair* $(Ax, (I-Q)\psi)$, *which is of the form*

$$\begin{pmatrix} Ax \\ (I-Q)\psi \end{pmatrix}' = E \begin{pmatrix} Ax \\ (I-Q)\psi \end{pmatrix} - \begin{pmatrix} QQ'(I-Q) & 0 \\ 0 & QQ'(I-Q) \end{pmatrix} \begin{pmatrix} Ax \\ (I-Q)\psi \end{pmatrix}, \tag{5.1}$$

where

$$E = \begin{pmatrix} E_1 & E_2 \\ E_3 & -E_1^* \end{pmatrix}, \quad E_2 = E_2^*,\ E_3 = E_3^*, \tag{5.2}$$

and the operators E_2 *and* E_3 *are positive semidefinite.*

Proof. Since $G(t)$ is invertible, (3.1), (3.2) immediately imply, in view of the relation for K, that (5.1) holds true with $E = \hat{M} - JL^*\hat{J}G^{-1}L$. The term $\hat{J}G^{-1}$ is symmetric (cf. Lemma 4.5); thus $L^*\hat{J}G^{-1}L$ is also symmetric. Due to the structure of $\hat{M}$, we arrive at (5.2).

It remains to show that the operators E_2 and E_3 in (5.2) are positive semidefinite. Expressions for the operators $E_2,\ E_3$ are

$$\begin{aligned} E_2 &= ((I-Q)CPD_2 - (I-Q)BD_3^*)PC^*(I-Q) - ((I-Q)CPD_3 \\ &\quad + (I-Q)BD_6)B^*(I-Q), \\ E_3 &= A^{*+}WA^+ + ((I-Q)Q'Q + A^{*+}C^*Q)(D_4(QQ'(I-Q) + QCA^+) \\ &\quad - D_1^*PWA^+ - D_5S^*A^+) + A^{*+}WP(-D_1(QQ'(I-Q) + QCA^+) \\ &\quad - D_2PWA^+ + D_3S^*A^+) - A^{*+}S(D_5^*(QQ'(I-Q) + QCA^+) \\ &\quad - D_3^*PWA^+ - D_6S^*A^+). \end{aligned}$$

Here the operators $D_i,\ i = \overline{1,6}$, belong to the matrix representation (4.3) of G^{-1} by Corollary 4.6.

For any $y \in Y$ we compute

$$\langle E_2(I-Q)y, (I-Q)y\rangle = \left\langle \begin{pmatrix} D_2 & D_3 \\ D_3^* & -D_6 \end{pmatrix} \begin{pmatrix} PC^*(I-Q)y \\ -B^*(I-Q)y \end{pmatrix}, \begin{pmatrix} PC^*(I-Q)y \\ -B^*(I-Q)y \end{pmatrix} \right\rangle.$$

Due to Lemma 4.7, E_2 is positive semidefinite.

Next we turn to the operator E_3.

Taking into account the symmetry of the operators $D_2,\ D_4,\ D_6$ (see Corollary

4.6) it is not difficult to verify the identities

$$\begin{aligned}
&\langle E_3(I-Q)y,(I-Q)y\rangle = \langle WA^+(I-Q)y, A^+(I-Q)y\rangle - \langle D_2z_1,z_1\rangle\\
&+\langle D_4z_2,z_2\rangle + \langle D_6z_3,z_3\rangle - 2\langle D_1^*z_1 + D_5z_3,z_2\rangle + 2\langle D_3z_3,z_1\rangle\\
&= \left\langle \begin{pmatrix} W & S\\ S^* & R\end{pmatrix}\begin{pmatrix} z_4\\ z_5\end{pmatrix}, \begin{pmatrix} z_4\\ z_5\end{pmatrix}\right\rangle\\
&+\langle (D_2 - D_2PWPD_2 + D_2PSD_3^* + D_3S^*PD_2 - D_3RD_3^*)z_1,z_1\rangle\\
&+\langle (D_4 - D_1^*PWPD_1 - D_1^*PSD_5^* - D_5S^*PD_1 - D_5RD_5^*)z_2,z_2\rangle\\
&+\langle (-D_6 - D_3^*PWPD_3 - D_3^*PSD_6 - D_6S^*PD_3 - D_6RD_6)z_3,z_3\rangle\\
&+2\langle (-D_1^*PWPD_2 + D_1^*PSD_3^* - D_5S^*PD_2 + D_5RD_3^*)z_1,z_2\rangle\\
&+2\langle (-D_3^* + D_3^*PWPD_2 - D_3^*PSD_3^* + D_6S^*PD_2 - D_6RD_3^*)z_1,z_3\rangle\\
&+2\langle (D_3^*PWPD_1 + D_3^*PSD_5^* + D_6S^*PD_1 + D_6RD_5^*)z_2,z_3\rangle,
\end{aligned}$$

where $z_1 = PWA^+(I-Q)y,\ z_3 = (QQ'(I-Q)+QCA^+)(I-Q)y,\ z_3 = S^*A^+(I-Q)y,$ $z_4 = A^+(I-Q)y + P(-D_2z_1 - D_1z_2 + D_3z_3),\ z_5 = D_3^*z_1 - D_5^*z_2 + D_6z_3.$

Due to Corollary 4.6 and the identities

$$\begin{aligned}
&QCPD_1 + QBD_5^* = I,\ QCPD_2 - QBD_3^* = 0,\ QCPD_3 + QBD_5 = 0,\\
&PWPD_1 - (QCP)^*D_4 + PSD_5^* = 0,\ PWPD_2 + (QCP)^*D_1^* - PSD_3^* = I,\\
&PWPD_3 - (QCP)^*D_5 + PSD_6 = 0,\\
&-S^*PD_1 + B^*QD_4 - RD_5^* = 0,\ -S^*PD_2 - B^*QD_1^* + RD_3^* = 0,\\
&-S^*PD_3 + B^*QD_5 - RD_6 = I,
\end{aligned}$$

all of which follow from the representation (4.3) of the operator G^{-1}, we obtain that all scalar products in the expression for $\langle E_3(I-Q)y,(I-Q)y\rangle$, except for the first one, vanish identically. For example, we have $D_2 - D_2PWPD_2 + D_2PSD_3^* + D_3S^*PD_2 - D_3RD_3^* = D_2 - D_2(I-(QCP)^*D_1^*) + D_3(-B^*QD_1^*) = (D_2(QCP)^* - D_3B^*Q)D_1^* = 0.$ □

Remark 5.2. If the continuously differentiable functions $y:[0,T]\to Y, z:[0,T]\to Y$ satisfy the explicit differential equation (cf. (5.1))

$$\begin{pmatrix} y\\ z\end{pmatrix}' = E\begin{pmatrix} y\\ z\end{pmatrix} - \begin{pmatrix} QQ'(I-Q) & 0\\ 0 & QQ'(I-Q)\end{pmatrix}\begin{pmatrix} y\\ z\end{pmatrix}, \tag{5.3}$$

then, multiplying (5.3) by diag (Q,Q) and taking into account that diag $(Q,Q)E = 0,\ Q'(I-Q) = QQ'$, we find that

$$\begin{pmatrix} Qy\\ Qz\end{pmatrix}' = \begin{pmatrix} (I-Q)Q'Q & 0\\ 0 & (I-Q)Q'Q\end{pmatrix}\begin{pmatrix} Qy\\ Qz\end{pmatrix} \tag{5.4}$$

holds true. Consequently, if $Q(t_0)y(t_0) = 0,\ Q(t_0)z(t_0) = 0$ for a certain $t_0\in[0,T]$, then $Q(t)y(t), Q(t)z(t)$ vanish identically, i.e., Im $A(t)\times$ Im $A(t)\subseteq Y\times Y$ becomes a time-varying invariant subspace of the differential equation (5.3). Since (5.4) decouples into $(Qy)' = (I-Q)Q'Q(Qy), (Qz)' = (I-Q)Q'Q(Qz),\ y(0)\in \mathrm{Im}A(0), z(T)\in \mathrm{Im}A(T)$ also imply $y(t)\in \mathrm{Im}A(t),\ z(t)\in \mathrm{Im}A(t),\ t\in[0,T]$, and vice versa.

If this invariant subspace does not vary with t, i.e., if $\mathrm{Im}A(t) = \mathrm{Im}A(0)$ for all $t\in[0,T]$ and, hence, if the projector $Q(t)$ is constant, things become easier. Then

(5.3) simplifies to the nonnegative Hamiltonian system

$$\begin{pmatrix} y \\ z \end{pmatrix}' = E \begin{pmatrix} y \\ z \end{pmatrix}$$

with the constant invariant subspace $\mathrm{Im}A(0) \times \mathrm{Im}A(0)$.

THEOREM 5.3. *Under the conditions of Theorem* 5.1*, if* Im $A(t)$ *is time-invariant, the system* (3.1), (3.2) *provides an explicit nonnegative Hamiltonian system.*

Remark 5.4. For operators $A(t),\ R(t)$ that have bounded inverses $A^{-1}(t),\ R^{-1}(t)$ on $Y,\ U$, respectively, and if $S(t) = 0,\ t \in [0,T]$, then (5.1) is of the special form

$$\begin{pmatrix} Ax \\ \psi \end{pmatrix}' = \begin{pmatrix} CA^{-1} & BR^{-1}B^* \\ A^{*-1}WA^{-1} & -A^{*-1}C^* \end{pmatrix} \begin{pmatrix} Ax \\ \psi \end{pmatrix}. \tag{5.5}$$

Obviously, this is a nonnegative Hamiltonian system. If, additionally, $A(t)$ depends continuously differentiably on t, we can turn to an explicit differential equation with respect to the unknowns x, ψ, but the resulting system

$$\begin{pmatrix} x \\ \psi \end{pmatrix}' = \begin{pmatrix} A^{-1}C - A^{-1}A' & A^{-1}BR^{-1}B^* \\ A^{*-1}W & -A^{*-1}C^* \end{pmatrix} \begin{pmatrix} x \\ \psi \end{pmatrix}$$

is no longer Hamiltonian in general. This is why we should prefer the form (5.5) also in this case. It should be mentioned that if we consider the new variable $y = A^*\psi$, then the latter system provides again a nonnegative Hamiltonian system with respect to the unknowns x, y.

If V satisfies the inclusion (2.8), the boundary conditions in the BVP (2.4)–(2.6) apply to the components $Ax = y$ and $(I - Q)\psi = z$ only (cf. (2.9)). Then Theorem 5.3 allows us to apply results concerning the unique solvability of two-point boundary values problems, which are known for nonnegative Hamiltonian systems, to systems of the form (2.4)–(2.6). In particular, we have the theorem stated below.

THEOREM 5.5. *Let conditions* I, II, *and* III *be satisfied. Let the inclusion* (2.8) *be valid. If, for every* $t \in [0,T]$*, the operator* $G(t)$ *is invertible on the space* $\mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U$*, and* $\mathrm{Im}A(t)$ *does not depend on* t*, then the problem* (2.1)–(2.3) *is solvable.*

Now we take a closer look at the BVP for (5.3) with the boundary conditions

$$y(0) = y_0,\ z(T) = -A^{+*}(T)VA^+(T)y(T). \tag{5.6}$$

THEOREM 5.6. *If the space* Y *is finite-dimensional, then the BVP* (5.3), (5.6) *is uniquely solvable.*

Proof. It is enough to prove that the problem

$$\begin{aligned} x_1' &= E_1x_1 + E_2x_2 - QQ'(I-Q)x_1, \\ x_2' &= E_3x_1 - E_1^*x_2 - QQ'(I-Q)x_2, \\ x_1(0) &= 0, \\ x_2(T) &= -\tilde{V}x_1(T), \end{aligned} \tag{5.7}$$

where $\tilde{V} = A^{*+}(T)VA^+(T)$, has only the zero solution.

We scalarly multiply the first equation of (5.7) by x_2 and the second equation by x_1. Adding the results and taking into account Remark 5.2 we obtain the relation $\langle x_1, x_2\rangle' = \langle E_2x_2, x_2\rangle + \langle E_3x_1, x_1\rangle$.

Integrating the last equation on the interval $[0,T]$ due to the boundary conditions we have $\langle x_1(T), \tilde{V}x_1(T)\rangle + \int_0^T (\langle E_2x_2, x_2\rangle + \langle E_3x_1, x_1\rangle)dt = 0$.

Since the self-adjoint operators $\tilde{V}, E_2,\ E_3$ are positive semidefinite (see Theorem 5.1) and the operators $E_2,\ E_3$ are continuous with respect to t, it follows from the previous relation that $E_2x_2 \equiv 0,\ E_3x_1 \equiv 0$. By this, system (5.7) implies $x_1 \equiv 0$, $x_2 \equiv 0$. □

Lemma 2.2 and Theorems 5.1 and 5.6 provide the next statement, which applies to the case of time-varying Im $A(t)$.

THEOREM 5.7. *Let conditions* I, II, *and* III *be satisfied. Let the inclusion* (2.8) *be valid. If the space Y is finite-dimensional and if, for every $t \in [0,T]$, the operator $G(t)$ is invertible on the space* $\mathrm{Ker}A^*(t) \times \mathrm{Ker}A(t) \times U$, *then the problem* (2.1)–(2.3) *is solvable.*

Remark 5.8. For $A(t)$ being time-invariant, results of the present paper are given in [5] ($S = 0$) and in [6] ($S \neq 0$).

Comparing with [4], [10], where $X = Y$ are finite-dimensional spaces and the time-invariant problem is considered, we stress that we do not use conditions on the regularity of the pencil $\lambda A - C$. Further, we do not diagonalize or transform A and factorize the coefficients in the cost functional. In particular, Assumption 2 in [4] turns out to be no longer mandatory.

6. Small but illustrative examples.

Example 1. Let us consider the problem of minimizing the functional (2.1) on trajectories of the system (2.2), (2.3) with

$$V = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix},\ W(t) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix},\ S(t) = \begin{pmatrix} 0 \\ 0 \end{pmatrix},\ R(t) = 1,\ A(t) = \begin{pmatrix} 0 & t \\ 0 & 1 \end{pmatrix},$$

$$C(t) = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},\ B(t) = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Here $Q(t) = \frac{1}{1+t^2}\begin{pmatrix} 1 & -t \\ -t & t^2 \end{pmatrix}, P = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. The system (2.4)–(2.6) is specified to

$$\left(\begin{pmatrix} 0 & t \\ 0 & 1 \end{pmatrix} x(t)\right)' = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} x(t) + \begin{pmatrix} 1 \\ 0 \end{pmatrix} u(t),$$

$$\begin{pmatrix} 0 & 0 \\ t & 1 \end{pmatrix} ((I - Q(t))\psi(t))' = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} x(t) - \left(\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ t & 1 \end{pmatrix} Q'(t)\right)\psi(t),$$

$$0 = (1\ \ 0)\psi(t) - u(t),$$

with the boundary conditions

$$\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} x(0) = y_0 := \begin{pmatrix} 0 \\ y_{02} \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ T & 1 \end{pmatrix} \psi(T) = 0,\ y_{02} \neq 0.$$

Theorem 5.1 provides the special explicit differential system (5.1)

$$(Ax)' = \frac{1}{1+t^2} \begin{pmatrix} t & 1 \\ 0 & 0 \end{pmatrix} Ax, \tag{6.1}$$

$$((I - Q)\psi)' = -\frac{1}{(1+t^2)^2} \begin{pmatrix} t^3 - t & t^2 - 1 \\ 2t^2 & 2t \end{pmatrix} (I - Q)\psi. \tag{6.2}$$

In particular, (6.1) immediately leads to $x_2'(t) = 0$. Taking into account the initial condition, we obtain $x_2(t) \equiv y_{0_2}$. Due to the boundary condition $(I - Q(T))\psi(T) = 0$, the function $(I - Q(t))\psi(t)$ vanishes identically, i.e., $\psi(t) = Q(t)\psi(t)$, $A^*(t)\psi(t) = 0$; hence, $t\psi_1(t) + \psi_2(t) = 0$.

Next we derive from (2.5) that

$$\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} x(t) = 0,$$

i.e., $x_1(t) \equiv 0$, and from (2.4), (2.6) that $u(t) \equiv 0$, $\psi_1(t) \equiv 0$; hence, $\psi(t) \equiv 0$.

Consequently, the BVP (2.4)–(2.6) has the unique solution

$$x_*(t) \equiv y_0, \quad \psi_*(t) \equiv 0, \quad u_*(t) \equiv 0,$$

and, by Lemma 2.2, $u_*(\cdot)$ is the optimal control for (2.1)–(2.3).

This confirms the result that we could have in this special case by much simpler considerations. Namely, by looking at the problem in detail,

$$J(u, x) = \frac{1}{2} \int_0^T \{x_1(t)^2 + u(t)^2\} dt,$$

$(tx_2(t))' = x_2(t) + u(t)$, $(x_2(t))' = 0, t \in [0, T], x_2(0) \neq 0$ given, we find immediately that

$$x_{*2}(t) \equiv x_2(0), \quad u_*(t) \equiv 0.$$

For obtaining a minimum we obviously have to put $x_{*1}(t) \equiv 0$. Let us stress once more that this special DAE (2.2) has even a singular pencil $\lambda A(t) - C(t)$, but the resulting DAE in (2.4)–(2.6) is index-1 tractable. In this case, Lemmas 4.1 and 4.7, and further Theorems 5.1 and 5.6 apply. However, since $\mathrm{Im} A(t) = \mathrm{Im}(I - Q(t))$ varies with time, the resulting system of explicit differential equations (6.1), (6.2) is obviously no longer a Hamiltonian one.

Remark 6.1. If the matrix $V = 0$ in Example 1 is replaced by

$$V = \alpha \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}, \ \alpha > 0,$$

then the functional

$$J(u, x) = \frac{\alpha}{2}(x_1(T) + x_2(T))^2 + \frac{1}{2} \int_0^T \{x_1(t)^2 + u(t)^2\} dt$$

is to be minimized on the trajectories as above. The resulting BVP (2.4)–(2.6) differs from that in Example 1 only by the condition

$$\begin{pmatrix} 0 & 0 \\ T & 1 \end{pmatrix} \psi(T) = -\alpha \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} x(T)$$

(which replaces the condition $\left(\begin{smallmatrix} 0 & 0 \\ T & 1 \end{smallmatrix}\right)\psi(T) = 0$). Now, because of $\alpha > 0$, the inclusion (2.8) fails to be true, whereas it is valid in Example 1. In particular, the relation

$$x_1(T) + x_2(T) = 0$$

has to be taken into account. On the other hand, as in Example 1, we have $x_2(t) \equiv x_2(0),\ x_1(t) \equiv 0$; thus $x_1(T) + x_2(T) = x_2(0) \neq 0$. Because of the resulting contradiction this BVP (2.4)–(2.6) is no longer solvable.

Considering the control problem itself, say for $x_2(0) = 1,\ T = 1$, we realize immediately that we have to put $x_2(t) \equiv 1, u(t) \equiv 0$ and then minimize $\tilde{J}(x_1) := \frac{\alpha}{2}(x_1(1)+1)^2 + \frac{1}{2}\int_0^1 x_1(t)^2 dt$ on the continuous functions $x_1(.)$. However, $\tilde{J}$ has the zero infimum, but there is no minimal element in this setting.

Another situation arises if we choose $V = \alpha I, \alpha > 0$, instead. Condition (2.8) fails again, but the boundary condition

$$\begin{pmatrix} 0 & 0 \\ T & 1 \end{pmatrix} \psi(T) = -\alpha x(T),$$

and, in particular, condition $x_1(T) = 0$ do not contradict (2.5). The resulting BVP (2.4)–(2.6) is solvable. The corresponding control problem with

$$J(u,x) = \frac{\alpha}{2}\{(x_1(T)^2 + x_2(T)^2\} + \frac{1}{2}\int_0^T \{x_1(t)^2 + u(t)^2\} dt$$

obviously has the solution $u_*(t) \equiv 0,\ x_{*1}(t) \equiv 0,\ x_{*2}(t) \equiv x_2(0)$.

Example 2. The functional $J(u,x) = \frac{1}{2}\int_0^T (x_1(t)^2 + u(t)^2) dt$ is to be minimized subject to the infinite-dimensional system

$$\begin{aligned} x_2'(t) &= x_1(t) + u(t), \\ x_i'(t) &= 0 \quad \text{for } i \geq 3, \end{aligned}$$

and the initial condition $x_i(0) = \frac{1}{i}$ for $i \geq 2$. Obviously, the minimum is obtained by

$$u_*(t) \equiv 0, \quad x_{*1}(t) \equiv 0, \quad x_{*i}(t) \equiv \frac{1}{i} \quad \text{for } i \geq 2.$$

Choosing $X = Y = l^2, U = \mathbb{R}$, as well as

$$A = \begin{pmatrix} 0\,1\,0\,\cdots \\ 0\,0\,1\,\cdots \\ \cdots \end{pmatrix},\ C = \begin{pmatrix} 1\,0\,\cdots \\ 0\,0\,\cdots \\ \cdots \end{pmatrix},\ B = \begin{pmatrix} 1 \\ 0 \\ \cdots \end{pmatrix},\ W = \begin{pmatrix} 1\,0\cdots \\ 0\,0\cdots \\ \cdots \end{pmatrix},\ y_0 = \begin{pmatrix} \frac{1}{2} \\ \frac{1}{3} \\ \cdots \end{pmatrix},$$

$R = 1,\ S = 0,\ V = 0$, we put this problem into the form (2.1)–(2.3) with infinite-dimensional Hilbert spaces. Next we compute

$$P = \begin{pmatrix} 1\,0\,\cdots \\ 0\,0\,\cdots \\ \cdots \end{pmatrix} \quad \text{and} \quad Q = 0.$$

The resulting BVP (2.4), (2.5), (2.6) is

$$\begin{aligned} x_2'(t) &= x_1(t) + u(t), \\ x_i'(t) &= 0 \quad \text{for } i \geq 3,\ x_i(0) = \tfrac{1}{i} \ \text{ for } i \geq 2, \\ 0 &= x_1(t) - \psi_1(t), \\ \psi_i'(t) &= 0 \quad \text{for } i \geq 1,\ \psi_i(T) = 0 \ \text{ for } i \geq 1, \\ 0 &= \psi_1(t) - u(t). \end{aligned} \tag{6.3}$$

The explicit differential system (5.1) is also an infinite-dimensional one, namely,

$$(Ax(t))' = \begin{pmatrix} 2 & 0 & \dots \\ 0 & 0 & \dots \\ & \dots & \end{pmatrix} \psi(t), \quad \psi'(t) = 0, \tag{6.4}$$

or, equivalently, $x_2'(t) = 2\psi_1(t)$, $x_i'(t) = 0$ for $i \geq 3$, $\psi_i'(t) = 0$ for $i \geq 1$. This is a nonnegative Hamiltonian system. Due to the boundary conditions we obtain

$$x_{*i}(t) \equiv \frac{1}{i} \text{ for } i \geq 2, \quad \psi_{*i}(t) \equiv 0 \text{ for } i \geq 1,$$

as solutions of (6.4). Finally, (6.3) gives $u_*(t) \equiv \psi_{*1}(t) \equiv 0$ and $x_{*1}(t) \equiv \psi_{*1}(t) \equiv 0$.

7. Concluding remarks. Our paper refers to descriptor systems with coefficients $A(t), C(t)$, and $B(t)$ that are bounded linear operators for all t and depend continuously on t in the norm sense. In the meantime, certain ideas about abstract DAEs with unbounded coefficients $C(t)$ have evolved; they take into consideration, among other things, the case of so-called partial differential-algebraic systems (cf. [11]). A corresponding generalization of this case does not seem to be impossible; however, it will require further elaborate investigations.

Acknowledgments. The idea to write this paper arose during the visit of the first author to Humboldt University; therefore she is grateful to all persons that supported this visit. Our thanks are due to the unknown referees for their valuable comments which helped to improve our paper.

POLE PLACEMENT AND MATRIX EXTENSION PROBLEMS: A COMMON POINT OF VIEW*

MEEYOUNG KIM†, JOACHIM ROSENTHAL‡, AND XIAOCHANG ALEX WANG§

Dedicated to the memory of Meeyoung Kim, 1966–2001

Abstract. This paper studies a general inverse eigenvalue problem which generalizes many well-studied pole placement and matrix extension problems. It is shown that the problem corresponds geometrically to a so-called central projection from some projective variety. The degree of this variety represents the number of solutions the inverse problem has in the critical dimension. We are able to compute this degree in many instances, and we provide upper bounds in the general situation.

Key words. pole placement and inverse eigenvalue problems, matrix completion problems, Grassmann varieties, degree of a projective variety

DOI. 10.1137/S0363012999354429

1. Introduction and motivational examples. Let $\mathbb{K}$ be an arbitrary field and consider matrices A of size $n \times n$ and matrices G, H of size $n \times m$. Let $Mat_{m\times n}$ be the vector space of all $m \times n$ matrices over $\mathbb{K}$, and let $\mathcal{L} \subset Mat_{m\times n}$ be a linear subspace of dimension d. This paper will be devoted to the following question.

Problem 1.1. Given an arbitrary monic polynomial $\varphi(s) \in \mathbb{K}[s]$ of degree n, is there a $F \in \mathcal{L}$ such that

$$\det[s(I + HF) - (A + GF)] = \varphi(s)? \tag{1.1}$$

We can think of the triple (A, G, H) representing a dynamical system in various ways, and we will say more about it in a moment. The set of monic polynomials of degree n can be identified with the vector space $\mathbb{K}^n$. If Problem 1.1 has a positive answer for all monic polynomials $\varphi(s) \in \mathbb{K}^n$ of degree n, then we will say that the system (A, G, H) is arbitrarily pole assignable in the class of feedback compensators $\mathcal{L}$. If for a generic set of monic polynomials $\varphi(s) \in \mathbb{K}^n$ of degree n Problem 1.1 has a positive answer, then we will say that system (A, G, H) is generically pole assignable in the class of feedback compensators $\mathcal{L}$.

Problem 1.1 covers a large set of "constrained" state and output pole placement problems. It also covers some important matrix extension problems. The following three examples will illustrate this.

Example 1.2 (constrained state feedback pole placement problem). Consider a linear system having the following form:

$$\dot{x} = Ax + Bu + H\dot{u}, \quad x \in \mathbb{C}^n,\ u \in \mathbb{C}^m. \tag{1.2}$$

If a state feedback law of the form $u = -Fx$ is applied, then the closed loop characteristic polynomial has the form $\det[s(I + HF) - (A - BF)]$ which is exactly the form of (1.1). Assume that not every feedback law of the form $u = -Fx$ can be applied, and that a valid feedback matrix must satisfy some linear constraints of its parameters, i.e., $F \in \mathcal{L}$ for some linear subspace $\mathcal{L} \subset Mat_{m\times n}$. Such constraints occur, e.g., if the ith input channel has to be kept zero all the time. Problem 1.1 covers such situations.

Of course if $H = 0$ and the feedback laws are unconstrained, then we simply deal with the classical state feedback problem, and it is well known that this problem always has a positive solution as soon as rank $\left[B, AB, \ \ldots \ A^{n-1}B\right] = n$.

Example 1.3 (constrained output feedback pole placement problem). Consider the linear system

$$\dot{x} = Ax + Bu, \ y = Cx, \quad x \in \mathbb{C}^n, \ u \in \mathbb{C}^m, \text{ and } y \in \mathbb{C}^p. \tag{1.3}$$

The problem asks for a static feedback law $u = Ky$ such that the closed loop system has some desired closed loop characteristic polynomial. Once more assume that the feedback laws have to satisfy some linear constraints. For this we assume that $\mathcal{U} \subset Mat_{m\times p}$ is some linear subspace, and we do require that $K \in \mathcal{U}$. One immediately verifies that Problem 1.1 covers this situation if one chooses $H := 0$, $G := B$, and $\mathcal{L} := \{KC \mid K \in \mathcal{U}\}$.

For the unconstrained problem ($\mathcal{U} = Mat_{m\times p}$) the main result in this area of research was given by Brockett and Byrnes [2]. It states the following.

THEOREM 1.4. *If $\mathcal{U} = Mat_{m\times p}$ and if $n \leq mp = \dim\mathcal{U}$, then for a generic set of matrices A, B, C, the system* (1.3) *is arbitrarily pole assignable. Moreover, if $n = mp$, then when counted with multiplicities there are exactly as many solutions as the degree of the complex Grassmann variety* $\mathrm{Grass}(m, \mathbb{C}^{m+p})$ *once embedded via the Plücker embedding.*

The importance of the matrix H becomes apparent if we deal with general proper systems of the form:

$$\dot{x} = Ax + Bu, \ y = Cx + Du, \quad x \in \mathbb{C}^n, \ u \in \mathbb{C}^m, \text{ and } y \in \mathbb{C}^p.$$

Assume C has rank p, and let C^+ be a right inverse of C, i.e., an $n \times p$ matrix such that $CC^+ = I_p$. Assume again that the feedback laws are constrained to some subspace $\mathcal{U} \subset Mat_{m\times p}$. If we apply the feedback law $u = Ky$, $K \in \mathcal{U}$, then we obtain the closed loop system:

$$\dot{x} = Ax + BKy, \ y = Cx + DKy, \quad x \in \mathbb{C}^n, \text{ and } y \in \mathbb{C}^p.$$

The closed loop characteristic polynomial is therefore computed as

$$\begin{aligned}
&\det \begin{bmatrix} sI_n - A & -BK \\ -C & I_p - DK \end{bmatrix} \\
&= \det(sI_n - A) \det\left(I_p - DK - C(sI_n - A)^{-1}BK\right) \\
&= \det(sI_n - A) \det\left(I_n - C^+DKC - (sI_n - A)^{-1}BKC\right) \\
&= \det\left((sI_n - A)(I_n - C^+DKC) - BKC\right) \\
&= \det\left(s(I_n - C^+DKC) - (A + (B - AC^+D)KC\right).
\end{aligned}$$

If one defines $H := -C^+D$, $G := (B - AC^+D)$, and $\mathcal{L} := \{KC \mid K \in \mathcal{U}\}$ one immediately verifies that the output feedback pole placement problem involving proper transfer functions is also covered by Problem 1.1 and that in this case it is of importance to have the matrix H in the formulation of Problem 1.1.

Example 1.5 (matrix extension problems). Let $m = n$, $H = 0$, and $G = I_n$. In this case Problem 1.1 asks for conditions which guarantee that the characteristic map

$$\chi_A : \mathcal{L} \longrightarrow \mathbb{K}^n, \quad F \longmapsto \det(sI + A + F), \tag{1.4}$$

is surjective or at least "generically" surjective. This general matrix extension problem itself contains many of the matrix completion problems as they were studied in [1, 4, 5, 7].

The main result in the situation of Example 1.5 has been derived in [11]. It states the following.

THEOREM 1.6. *If the base field $\mathbb{K}$ is algebraically closed, then for a generic set of matrices $A \in Mat_{n\times n}$ the characteristic map* (1.4) *is dominant (generically surjective) if and only if*

1. $\dim \mathcal{L} \geq n$;
2. *there must be at least one element $L \in \mathcal{L}$ whose trace $tr(L) \neq 0$, i.e., $\mathcal{L} \not\subset sl_n$.*

The main results of this paper will show that if $\mathbb{K}$ is algebraically closed, then for a generic set of matrices (A, G, H) Problem 1.1 is solvable in a projective closure of $\mathcal{L}$ for every $\varphi(s)$ if and only if $\dim \mathcal{L} \geq n$ (Theorem 2.7), and if $\dim \mathcal{L} = n$, then there are at most $\min(m, n)^n$ solutions for each $\varphi(s)$ for each subspace $\mathcal{L}$ (Theorems 2.8, 4.3, and 4.8).

The paper is structured as follows: In section 2 we will introduce a natural compactification of the linear space $\mathcal{L}$ which we will denote by $\bar{\mathcal{L}}$. In order to prove the main theorems we will show that one has a characteristic map χ defined on a Zariski open set of the variety $\bar{\mathcal{L}}$. Geometrically χ describes a central projection from the variety $\bar{\mathcal{L}}$ to the projective space $\mathbb{P}^n$. As a consequence the number of solutions in the critical dimension, i.e., in the situation where $\dim \mathcal{L} = n$, is equal to $\deg \bar{\mathcal{L}}$ when counted with multiplicities and when some possible "infinite solutions" are taken into account. The results in section 2 generalize mathematical ideas which have been developed for the static pole placement problem by Brockett and Byrnes [2] and for the dynamic pole placement problem by Ravi, Rosenthal, and Wang [14], Rosenthal [15], and Rosenthal and Wang [16].

The degree of the variety $\bar{\mathcal{L}}$ is of crucial importance for the understanding of the characteristic map χ. In section 3 we compute the degree of $\bar{\mathcal{L}}$ in many special cases. As a corollary we will rediscover several matrix completion results as they were derived earlier in [3, 4, 5, 7].

In section 4 we will be concerned with the value of the "generic degree"; this is the largest possible degree a variety $\bar{\mathcal{L}}$ of a fixed dimension can have. We determine an upper bound for the generic degree in the case when $d = n$ and prove that this bound is reached when $m = n < 5$.

2. Compactification of the problem. The inverse eigenvalue problem formulated in Problem 1.1 describes an intersection problem in the linear variety $\mathcal{L}$. In order to invoke results from intersection theory [6] it is important to understand the intersection at the "boundary" of $\mathcal{L}$. What is needed is a good compactification of $\mathcal{L}$. It turns out that Problem 1.1 induces in a natural way a compactification, and we will explain this in what follows.

Recall [8, 9] that the Grassmannian $\mathrm{Grass}(m, \mathbb{K}^q)$, $m \leq q$, is the set of all m-dimensional subspaces in $\mathbb{K}^q$. For each $X \in \mathrm{Grass}(m, \mathbb{K}^q)$, let $X = \mathrm{span}\,\{\alpha_1, \ldots, \alpha_m\}$; then

$$\alpha_1 \wedge \alpha_2 \wedge \cdots \wedge \alpha_m$$

is a vector in the exterior product $\wedge^m \mathbb{K}^q \cong \mathbb{K}^{\binom{q}{m}}$, and

$$\mathrm{span}\,\{\alpha_1, \ldots, \alpha_m\} = \mathrm{span}\,\{\beta_1, \ldots, \beta_m\}$$

if and only if

$$\alpha_1 \wedge \cdots \wedge \alpha_m = k(\beta_1 \wedge \cdots \wedge \beta_m)$$

for some $k \neq 0$ in $\mathbb{K}$. Therefore, by considering the components of $\alpha_1 \wedge \cdots \wedge \alpha_m$ as homogeneous coordinates of a point in $\mathbb{P}^{\binom{q}{m}-1}$, we have an embedding

$$\mathrm{Grass}(m, \mathbb{K}^q) \subset \mathbb{P}\left(\wedge^m \mathbb{K}^q\right) = \mathbb{P}^{\binom{q}{m}-1},$$

which is called Plücker embedding, and $\alpha_1 \wedge \cdots \wedge \alpha_m$ are called Plücker coordinates of $X \in \mathrm{Grass}(m, \mathbb{K}^q)$. If $\{\alpha_i\}$ are row vectors, then the Plücker coordinates of $\mathrm{span}\,\{\alpha_1, \ldots, \alpha_m\}$ are given by all the full size minors of the $m \times q$ matrix

$$\begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_m \end{bmatrix}.$$

The closed loop characteristic polynomial can be written as

$$\det\left[s(I + HF) - (A + GF)\right] = \det \begin{bmatrix} I_m & F \\ -sH + G & sI - A \end{bmatrix}. \tag{2.1}$$

Following an idea introduced by Brockett and Byrnes [2] for the static output pole placement problem we will identify $\mathrm{rowsp}\,[I_m\ F]$ with an element of $\mathrm{Grass}(m, \mathbb{K}^{m+n})$. In this way we have natural embeddings

$$\mathcal{L} \subset \mathrm{Grass}(m, \mathbb{K}^{m+n}) \subset \mathbb{P}\left(\wedge^m \mathbb{K}^{m+n}\right) = \mathbb{P}^N, \quad N = \binom{m+n}{m} - 1.$$

Definition 2.1. *Let $\bar{\mathcal{L}}$ be the projective closure of $\mathcal{L}$.*

By definition $\bar{\mathcal{L}}$ is a projective variety of dimension $\dim \bar{\mathcal{L}} = \dim \mathcal{L} = d$. The remainder of the paper will be devoted to a large extent to the study of this variety. In order to have a general idea of how the projective closure of $\mathcal{L}$ is defined, we start with an illustrative example.

Example 2.2. Let $m = n = d = 3$, and let $\mathcal{L} \subset Mat_{3\times 3}$ be defined by

$$\mathcal{L} = \left\{ \begin{bmatrix} a & b & 0 \\ c & a & b \\ 0 & c & a \end{bmatrix} \right\}, \tag{2.2}$$

where $a,\ b,\ c \in \mathbb{K}$ are arbitrary elements. Then for fixed a, b, c

$$\mathrm{rowsp} \begin{bmatrix} 1 & 0 & 0 & a & b & 0 \\ 0 & 1 & 0 & c & a & b \\ 0 & 0 & 1 & 0 & c & a \end{bmatrix} \tag{2.3}$$

is a point in $\mathrm{Grass}(3,\mathbb{K}^6)$. Let z_{ijk} be the full size minor of (2.3) consisting of the ith, jth, kth columns. Then $\{z_{ijk}\}$ are the Plücker coordinates of $\mathrm{Grass}(3,\mathbb{K}^6)$ in $\mathbb{P}^{\binom{6}{3}-1}=\mathbb{P}^{19}$. $\mathcal{L}$ is defined by 6 linear equations of its entries. In terms of the Plücker coordinates, they become

$$\begin{aligned} &z_{234}=-z_{135}, \quad z_{234}=z_{126}, \quad z_{235}=-z_{136},\\ &z_{125}=-z_{134}, \quad z_{124}=0, \qquad z_{236}=0. \end{aligned} \tag{2.4}$$

$\mathcal{L}$ has 9 minors of size 2×2, but there are only 6 monomials of degree 2 of a,b,c:

$$a^2, b^2, c^2, ab, ac, bc.$$

So there are 3 linear relations among the 2×2 minors. In terms of the Plücker coordinates, they are

$$z_{146}=-z_{245}, \quad z_{345}=z_{156}, \quad z_{346}=-z_{256}. \tag{2.5}$$

The monomials $a^2, b^2, c^2, ab, ac, bc$ are not algebraically independent; they satisfy the relation

$$\operatorname{rank}\begin{bmatrix} a^2 & ab & ac\\ ab & b^2 & bc\\ ac & bc & c^2 \end{bmatrix} = \operatorname{rank}\begin{bmatrix} a\\ b\\ c \end{bmatrix}\begin{bmatrix} a & b & c \end{bmatrix} \le 1; \tag{2.6}$$

i.e., all the 2×2 minors of (2.6) are zero, which induce 6 quadratic relations among the 2×2 minors of $\mathcal{L}$:

$$\begin{aligned} &z_{346}^2+z_{246}z_{356}=0, && z_{146}^2+z_{246}z_{145}=0,\\ &(z_{246}+z_{345})^2-z_{356}z_{145}=0, && z_{246}(z_{246}+z_{345})-z_{346}z_{146}=0,\\ &z_{346}(z_{246}+z_{345})+z_{356}z_{146}=0, && z_{146}(z_{246}+z_{345})+z_{145}z_{346}=0. \end{aligned} \tag{2.7}$$

Every point in $\mathrm{Grass}(3,\mathbb{K}^6)$ defined by $z_{123}=0$ and (2.4), (2.5), (2.7) is indeed a limit point of (2.3); therefore $\bar{\mathcal{L}}$ is defined by (2.4), (2.5), and (2.7) in $\mathrm{Grass}(3,\mathbb{K}^6)\subset\mathbb{P}^{19}$.

Note that every element in $\bar{\mathcal{L}}$ can be simply represented by a subspace of the form $\operatorname{rowsp}[F_1\ F_2]$, where the $m\times m$ matrix F_1 is not necessarily invertible. Row span $[F_1\ F_2]$ describes an element of $\mathcal{L}$ if and only if F_1 is invertible. Note that a characteristic equation is even defined if F_1 is singular unless the polynomial in (2.1) is the zero polynomial.

Let $f_i,\ i=0,\dots,N$, be the Plücker coordinates of $\operatorname{rowsp}[F_1\ F_2]$. In terms of the Plücker coordinates the characteristic equation can then be written as

$$\det\begin{bmatrix} F_1 & F_2\\ -sH+G & sI-A \end{bmatrix} = \sum_{i=0}^{N} f_i p_i(s), \tag{2.8}$$

where the $p_i(s)$ is the cofactor of f_i in the determinant (2.8).

Let $\mathcal{Z}\subset\mathbb{P}^N$ be the linear subspace defined by

$$\mathcal{Z}=\left\{ z\in\mathbb{P}^N \,|\, \sum_{i=0}^{N} p_i(s) z_i = 0 \right\}. \tag{2.9}$$

Following [14, 15, 18] we identify a closed loop characteristic polynomial $\varphi(s)$ with a point in $\mathbb{P}^n$. In analogy to the situation of the static pole placement problem considered in [2, 18] (compare also with [15, section 5]) one has a well-defined characteristic map

$$\begin{array}{rccc} \chi: & \bar{\mathcal{L}} - \mathcal{Z} & \longrightarrow & \mathbb{P}^n, \\ & \operatorname{rowsp}[F_1 \ F_2] & \longmapsto & \displaystyle\sum_{i=0}^{N} f_i p_i(s). \end{array} \tag{2.10}$$

It will turn out that surjectiveness of the map χ will imply the generic pole assignability of system (A, G, H) in the class of compensators $\mathcal{L}$.

Recall the notion of degree of a variety [10, Chapter I, section 7] and the notion of a central projection (see [17, Chapter I, section 4]). The geometric properties of the map χ are as follows.

THEOREM 2.3. *The map χ defines a central projection. In particular, if $\mathcal{Z} \cap \bar{\mathcal{L}} = \emptyset$ and $\dim \mathcal{L} = n$, then χ is surjective, and there are $\deg \bar{\mathcal{L}}$ many preimages (counted with multiplicity) for each point in $\mathbb{P}^n$, where $\deg \bar{\mathcal{L}}$ is the degree of the projective variety $\bar{\mathcal{L}}$ in $\mathbb{P}^N$.*

The proof for this theorem is identical to the one given in [14, 18]. In the algebraic geometry literature (see, e.g., [9, 13, 17]) χ is sometimes referred to as a *projection of $\mathcal{L}$ from the center $\mathcal{Z}$ to $\mathbb{P}^n$*, and $\mathcal{Z} \cap \bar{\mathcal{L}}$ is sometimes referred to as the *base locus*. Of course the interesting part of the theorem occurs when $\mathcal{Z} \cap \bar{\mathcal{L}} = \emptyset$ since in this situation very specific information on the number of solutions is provided. If $\mathcal{Z} \cap \bar{\mathcal{L}} = \emptyset$ and $\dim \mathcal{L} = n$, then one says that χ describes a *finite morphism* from the projective variety $\bar{\mathcal{L}}$ onto the projective space $\mathbb{P}^n$.

In analogy to the situation of the static pole placement problem [2, 18] and the dynamic pole placement problem [15] we introduce a definition for this important situation.

DEFINITION 2.4. *A particular system (A, G, H) is called* $\mathcal{L}$-nondegenerate *if $\mathcal{Z} \cap \bar{\mathcal{L}} = \emptyset$. A system which is not $\mathcal{L}$-nondegenerate will be called $\mathcal{L}$-degenerate.*

In general it will always happen that certain systems A, G, H are $\mathcal{L}$-degenerate. We first make a definition.

DEFINITION 2.5. *Let X be an arbitrary (affine or projective) variety. A subset $S \subset X$ is called a* generic set *of X if it contains a nonempty Zariski open set of X.*

The next theorem shows that if the dimension of $\mathcal{L}$ is not too large, then the set of systems A, G, H which are $\mathcal{L}$-degenerate are contained in a proper algebraic subset when viewed as a subset in the vector space $\mathbb{K}^{(n^2+2mn)}$.

LEMMA 2.6. *Assume the base field $\mathbb{K}$ is algebraically closed. If $\dim \mathcal{L} > n$, then every system A, G, H is $\mathcal{L}$-degenerate. If $\dim \mathcal{L} \leq n$, then a generic set of systems A, G, H is $\mathcal{L}$-nondegenerate.*

Proof. If $\dim \mathcal{L} > n$, then $\mathcal{Z} \cap \bar{\mathcal{L}}$ is nonempty by the (projective) dimension theorem (see, e.g., [10, Chapter I, Theorem 7.2]) and the fact that $\dim \mathcal{Z} \geq N - n - 1$.

Assume now that $\dim \mathcal{L} \leq n$. Consider

$$\det \begin{bmatrix} I_m & F \\ -sH+G & sE-A \end{bmatrix}, \tag{2.11}$$

and identify the set of matrices E, A, G, H with the vector space $\mathbb{K}^{2n(m+n)}$. In analogy to the proof of [15, Lemma 5.3] we compute the dimension of the coincidence set

$$\mathcal{S} := \left\{ (F_1, F_2;\ E, A, G, H) \in \bar{\mathcal{L}} \times \mathbb{K}^{2n(m+n)} \mid \det \begin{bmatrix} F_1 & F_2 \\ -sH+G & sE-A \end{bmatrix} = 0 \right\}.$$

Using the same arguments as in [15] one computes

$$\dim \mathcal{S} = \dim \bar{\mathcal{L}} + 2n(m+n) - n - 1.$$

Since $\bar{\mathcal{L}}$ is projective the projection onto the second factor (namely, $\mathbb{K}^{2n(m+n)}$) is an algebraic set by the main theorem of elimination theory (see, e.g., [13]). This projection can result in an algebraic set of dimension at most $\dim \mathcal{S} < 2n(m+n)$. So for generic matrices E, A, G, H, we have $\det E \neq 0$ and

$$\det \begin{bmatrix} F_1 & F_2 \\ -sH+G & sE-A \end{bmatrix} \neq 0$$

for all $[F_1 \quad F_2]$ in $\bar{\mathcal{L}}$. For such matrices $\{E, A, G, H\}$, the systems $\hat{A} = E^{-1}A, \hat{G} = E^{-1}G, \hat{H} = E^{-1}H$ are $\mathcal{L}$-nondegenerate, and the claim therefore follows. □

We are now in a position to state one of the main theorems of this paper.

THEOREM 2.7. *Assume the base field $\mathbb{K}$ is algebraically closed. Let $\mathcal{L} \subset Mat_{m\times n}$ be a fixed subspace. Then the map χ introduced in* (2.10) *is surjective for a generic set of matrices A, G, H if and only if $\dim \mathcal{L} \geq n$. If $\dim \mathcal{L} = n$, then for a generic set of matrices A, G, H the intersection $\mathcal{Z} \cap \bar{\mathcal{L}} = \emptyset$ and there are $\deg \bar{\mathcal{L}}$ many preimages (counted with multiplicity) for each point in $\mathbb{P}^n$.*

Proof. If $\dim \mathcal{L} < n$, then a simple dimension argument shows that χ cannot be surjective. The result for $\dim \mathcal{L} = n$ follows from Lemma 2.6 and Theorem 2.3. If $\dim \mathcal{L} > n$, we can always choose a subspace of $\mathcal{L}$ of dimension n. It follows that χ is surjective as soon as $\dim \mathcal{L} \geq n$. □

Theorem 2.7 gives a partial answer to Problem 1.1. The following result makes this clear.

THEOREM 2.8. *Let $\mathcal{L} \subset Mat_{m\times n}$ be a fixed subspace, and assume that $\mathbb{K}$ is algebraically closed. If $\dim \mathcal{L} < n$, then for almost all monic polynomials $\varphi(s) \in \mathbb{K}[s]$ of degree n there does not exist a $F \in \mathcal{L}$ such that* (1.1) *holds true.*

If $\dim \mathcal{L} \geq n$, then for a generic set of matrices A, G, H and a generic set of monic polynomials $\varphi(s)$ of degree n Problem 1.1 *has a solution.*

Finally, if $\dim \mathcal{L} = n$, then for a generic set of matrices A, G, H and a generic set of polynomials the number of solutions is always finite, and when counted with multiplicities there are exactly $\deg \bar{\mathcal{L}}$ solutions.

Proof. The only statement which does not immediately follow from Theorem 2.7 is the claim about the number of solutions in the critical dimension. We therefore assume that $\dim \mathcal{L} = n$. Consider the characteristic map χ introduced in (2.10). According to Theorem 2.7, χ is a finite morphism of degree $\bar{\mathcal{L}}$. For a generic set of polynomials $\varphi(s) \in \mathbb{K}^n \subset \mathbb{P}^n$ the inverse image $\chi^{-1}(\varphi(s))$ contains $\deg\left(\bar{\mathcal{L}}\right)$ different solutions, and all these solutions are contained in $\mathcal{L} \subset \bar{\mathcal{L}}$. □

Theorems 2.7 and 2.8 assume that the field is algebraically closed. For general fields it is often possible to deduce some results by considering the corresponding question over the algebraic closure. The following result is of this sort.

COROLLARY 2.9. *If the degree of the variety $\bar{\mathcal{L}}$ defined over the complex numbers $\mathbb{C}$ is odd and if $\dim \mathcal{L} \geq n$, then χ is also surjective over the real numbers $\mathbb{R}$ for a generic set of real matrices A, G, H.*

Proof. We will view a triple of complex matrices A, G, H as a point in $\mathbb{C}^{n(2m+n)}$. If $d := \dim \mathcal{L} = n$, then χ represents a finite morphism for a generic set of complex matrices A, G, H by Theorem 2.7. Since the subset of real matrices inside $\mathbb{C}^{n(2m+n)}$ is not contained in any algebraic set, χ is even a finite morphism for a generic set of real matrices A, G, H. Over the complex numbers the inverse image $\chi^{-1}(y) \subset \bar{\mathcal{L}}$

represents a finite set of complex conjugate points for every real point $y \in \mathbb{P}^n$; in particular, $\chi^{-1}(y)$ contains a real point for a generic set of real matrices A, G, H.

If $d < n$ we follow the reasoning in the proof of [14, Theorem 2.14]: for a generic set of real matrices A, G, H one has

$$\dim \mathcal{Z} \cap \bar{\mathcal{L}} = \dim \mathcal{L} - n - 1 = d - n - 1.$$

If this dimension formula holds choose a subspace $H \subset \mathbb{P}^N$ having codimension $d-n$ inside $\mathbb{P}^N$ and having the property that

$$\bar{\mathcal{L}} \cap \mathcal{Z} \cap H = \emptyset. \tag{2.12}$$

Such a subspace H exists by [13, Corollary (2.29)]. Let $\pi_1 : \bar{\mathcal{L}} \to \mathbb{P}^d$ be the central projection with center $\mathcal{Z} \cap H$, and let $\pi_2 : \mathbb{P}^d - \pi_1(\mathcal{Z}) \to \mathbb{P}^n$ be the central projection with center $\pi_1(\mathcal{Z})$. Then π_1 is a finite morphism which is surjective over $\mathbb{C}$. π_2 is a linear map, it is surjective as well, and

$$\chi = \pi_2 \circ \pi_1.$$

If the degree of $\bar{\mathcal{L}}$ is odd, then π_1 is surjective over the reals, and the claim follows. □

3. The degree of $\bar{\mathcal{L}}$ in some special situations. From Theorems 2.7 and 2.8 it became clear that $\deg \bar{\mathcal{L}}$ is equal to the number of solutions for Problem 1.1 in the critical dimension, at least generically. In this and in the next section we will compute $\deg \bar{\mathcal{L}}$ in many situations.

For the rest of the paper we will assume that $\mathbb{K}$ is an algebraically closed field of characteristic zero. We will show in a moment that the compactification $\bar{\mathcal{L}}$ is, in many cases, isomorphic to the product of some Schubert varieties. This will allow us to compute the degree of $\bar{\mathcal{L}} \subset \mathbb{P}^N$ in these cases.

For the convenience of the reader we summarize the basic notions. More details can be found in [12, 16] and [6, Chapter 14].

Consider a flag of linear subspaces

$$\mathcal{F} : \ \{0\} \subset V_1 \subset V_2 \subset \cdots \subset V_{m+n} = \mathbb{K}^{m+n},$$

where we assume that $\dim V_q = q$ for $q = 1, \ldots, m+n$. Let $\nu = (\nu_1, \ldots, \nu_m)$ be an ordered index set satisfying

$$1 \le \nu_1 < \cdots < \nu_m \le m+n.$$

With respect to the flag $\mathcal{F}$ one defines the Schubert variety

$$S(\nu_1, \ldots, \nu_m) := \{W \in \mathrm{Grass}(m, \mathbb{K}^{m+n}) \mid \dim(W \bigcap V_{\nu_k}) \ge k \ \text{ for } k = 1, \ldots, m\} \tag{3.1}$$

and the Schubert cell

$$C(\nu_1, \ldots, \nu_m) := \{W \in S(\nu_1, \ldots, \nu_m) \mid \dim(W \bigcap V_{\nu_k - 1}) = k - 1 \text{ for } k = 1, \ldots, m\}. \tag{3.2}$$

The closure of the Schubert cell $C(\nu_1, \ldots, \nu_m)$ inside the variety $\mathrm{Grass}(m, \mathbb{K}^{m+n}) \subset \mathbb{P}^N$ is equal to the Schubert variety $S(\nu_1, \ldots, \nu_m)$. By definition, $S(\nu_1, \ldots, \nu_m)$ is

a projective variety. There is a well-known formula for the degree of a Schubert variety [12, Chapter XIV, section 6, equation (7)]:

$$\deg S(\nu_1,\ldots,\nu_k) = \left(\sum_i(\nu_i - i)\right)!\frac{\prod_{j>i}(\nu_j-\nu_i)}{\prod_i(\nu_i-1)!}.$$

Let $\mathcal{B} := \{v_1,\ldots,v_{m+n}\} \subset \mathbb{K}^{m+n}$ be a basis which is compatible with the flag $\mathcal{F}$. In other words this basis has the property that $V_i = \operatorname{span}(v_1,\ldots,v_i)$. With respect to the basis $\mathcal{B}$ one can represent the Schubert cell $C(\nu_1,\ldots,\nu_m)$ as the set of all m-dimensional subspaces in $\mathbb{K}^{m+n}$ which are the rowspaces of a matrix of the form

$$\begin{bmatrix} * & \cdots & * & 1 & 0 & \cdots & 0 & 0 & \cdots & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ * & \cdots & * & 0 & * & \cdots & * & 1 & \cdots & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \vdots & & \vdots & \vdots & \vdots & & \vdots & \vdots & & \vdots & & \vdots & \vdots & \vdots & & \vdots \\ * & \cdots & * & 0 & * & \cdots & * & 0 & \cdots & * & \cdots & * & 1 & 0 & \cdots & 0 \end{bmatrix}, \tag{3.3}$$

where the 1's are in the columns $\nu_1,\ldots,\nu_m$.

The cell $C(\nu_1,\ldots,\nu_m)$ is isomorphic to $\mathbb{K}^d$, where $d = \sum_{i=0}^m(\nu_i - i)$. In particular, the cell $C(\nu_1,\ldots,\nu_m)$ is isomorphic to every subspace $\mathcal{L} \subset Mat_{m\times n}$ having dimension $\dim\mathcal{L} = d$. In general it is not true that the closures $S(\nu_1,\ldots,\nu_m) \subset \mathbb{P}^N$ and $\bar{\mathcal{L}} \subset \mathbb{P}^N$ are isomorphic. This happens, however, in the following situation.

Let $E_{i,j}$ be the $m \times n$ matrix whose i,j-entry is 1 and all the other entries are 0. Let $\mu = (\mu_1,\ldots,\mu_m)$ be an ordered index set satisfying

$$0 \le \mu_1 \le \cdots \le \mu_m \le n.$$

Definition 3.1. *$\mathcal{L} \subset Mat_{m\times n}$ is called a* lower left filled linear space *of type μ if $\mathcal{L}$ is spanned by the matrices*

$$E_{i,j} \quad \textit{for} \quad j \le \mu_i,\ i = 1,\ldots,m.$$

Lemma 3.2. *If $\mathcal{L} \subset Mat_{m\times n}$ is a lower left filled linear space of type μ, then $\bar{\mathcal{L}}$ is isomorphic to the Schubert variety $S(\mu_1+1,\mu_2+2,\ldots,\mu_m+m)$.*

Proof. Let $\nu_i := \mu_i + 1$, $i = 1,\ldots,m$. There is a fixed $(m+n)\times(m+n)$ permutation matrix P such that the set

$$\{[I_m \;\; F]\,P \mid F \in \mathcal{L}\} \subset Mat_{m\times(m+n)}$$

is equal to the cell $C(\nu_1,\ldots,\nu_m)$ described in (3.3). The linear transformation $P \in Gl_{m+n}$ extends to a linear transformation in $\mathbb{P}(\wedge^m\mathbb{K}^{m+n}) = \mathbb{P}^N$, and this linear transformation maps $\bar{\mathcal{L}}$ isomorphically onto $S(\nu_1,\ldots,\nu_m)$. ∎

The proof of the lemma shows in particular that permutations of the columns inside $Mat_{m\times n}$ result in isomorphic compactifications. The following lemma shows that a broader range of transformations do not change the topological properties of the compactification.

Lemma 3.3. *Assume there are subspaces $\mathcal{L}_1,\mathcal{L}_2 \subset Mat_{m\times n}$. If there are linear transformations $S \in Gl_m$ and $T \in Gl_n$ such that $\mathcal{L}_2 = S\mathcal{L}_1T^{-1}$, then there exists an automorphism of $\mathbb{P}^N$ which maps the compactification $\overline{\mathcal{L}_1}$ isomorphically onto the compactification $\overline{\mathcal{L}_2}$.*

Proof.

$$\begin{bmatrix} I_m & S\mathcal{L}_1T^{-1} \end{bmatrix} = S\begin{bmatrix} I_m & \mathcal{L}_1 \end{bmatrix}\begin{bmatrix} S^{-1} & 0 \\ 0 & T^{-1} \end{bmatrix}.$$

The matrix to the right, an element of GL_{m+n}, induces a linear transformation on the projective space $\mathbb{P}(\wedge^m \mathbb{K}^{m+n}) = \mathbb{P}^N$ which maps $\overline{\mathcal{L}_1}$ onto $\overline{\mathcal{L}_2}$. □

THEOREM 3.4. *Assume there are linear transformations $S \in Gl_m$ and $T \in Gl_n$ such that*

$$S\mathcal{L}T^{-1} = \begin{pmatrix} \mathcal{L}_1 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \mathcal{L}_k \end{pmatrix},$$

where each $\mathcal{L}_l, l = 1, \ldots, k$, is the space of $m_l \times n_l$ lower left filled matrices of type μ^l:

$$0 \le \mu_1^l \le \cdots \le \mu_{m_l}^l \le n_l.$$

Then $\bar{\mathcal{L}}$ is isomorphic to the product of Schubert varieties

$$S(\mu_1^1 + 1, \mu_2^1 + 2, \ldots, \mu_{m_1}^1 + m_1) \times \cdots \times S(\mu_1^k + 1, \mu_2^k + 2, \ldots, \mu_{m_k}^k + m_k)$$

and

$$\deg \bar{\mathcal{L}} = \left(\sum_{i,l} \mu_i^l \right)! \frac{\prod_{i,l_r > l_s} \left(\mu_i^{l_r} + l_r - \mu_i^{l_s} - l_s \right)}{\prod_{i,l} (\mu_i^l + l - 1)!}.$$

Proof. The closure of $[I_{m_l} \;\; \mathcal{L}_l]$ in the Grassmann variety $\mathrm{Grass}(m_l, \mathbb{K}^{m_l+n_l})$ is the Schubert variety $S(\mu_1^l + 1, \ldots, \mu_{m_l}^l + m_l)$, and $\bar{\mathcal{L}}$ is a product of Schubert varieties.

The degree formula of a product of projective varieties under the Segre embedding [19, Proposition 2.1] is given by

$$\deg Z_1 \times \cdots \times Z_k = \frac{(\sum_i \dim Z_i)!}{\prod_i (\dim Z_i)!} \prod_i \deg Z_i.$$

Combining these formulas gives the result. □

COROLLARY 3.5. *When $\mu_1^1 = \cdots = \mu_{m_1}^1 = n_1$ and $\mu_i^l = 0$ for $l > 1$, then the compactification $\bar{\mathcal{L}} = \mathrm{Grass}(m_1, \mathbb{K}^{m_1+n_1})$ and its degree is*

$$\frac{(m_1 n_1)! 1! 2! \cdots (m_1 - 1)!}{n_1! (n_1 + 1)! \cdots (n_1 + m_1 - 1)!}.$$

Using Lemma 3.3 and Corollary 3.5 we can deduce Theorem 1.4, the result of Brockett and Byrnes. For this assume that $H = 0$, $G = I$, and $\mathcal{L} = \{BFC \mid F \in Mat_{m\times p}\}$. Without loss of generality we can assume that B, C have full rank, $\operatorname{rank} B = m$, and $\operatorname{rank} C = p$. (Theorem 1.4 assumes genericity!) There are invertible matrices S, T such that $SB = \left[\begin{smallmatrix} I_m \\ 0 \end{smallmatrix}\right]$ and $CT^{-1} = \left[\begin{smallmatrix} I_p \\ 0 \end{smallmatrix}\right]$. It follows that

$$S\mathcal{L}T^{-1} = \left\{ \begin{bmatrix} F & 0 \\ 0 & 0 \end{bmatrix} \in Mat_{n\times n} \mid F \in Mat_{m\times p} \right\}.$$

According to Lemma 3.3 and Corollary 3.5 the compactification is isomorphic to the Grassmannian $\mathrm{Grass}(m, \mathbb{K}^{m+p})$ as predicted by Theorem 1.4. In order to fully prove

Theorem 1.4 it remains to be shown that for a generic set of matrices $A \in Mat_{n\times n}$ the system is $\mathcal{L}$-nondegenerate as soon as $n = mp$.

COROLLARY 3.6. *When $m_l = n_l = 1$ and $\mu_1^l = 1$ for all l, then $\bar{\mathcal{L}} = \prod_{i=1}^n \mathbb{P}^1 = \mathbb{P}^1 \times \cdots \times \mathbb{P}^1$ and its degree is*

$$n!.$$

Corollary 3.6 covers a result first studied by Friedland [4, 5]. Indeed the subspaces $\mathcal{L} \subset Mat_{n\times n}$ correspond in this case exactly to the set of diagonal matrices. By Theorem 2.7 we know that for a generic set of matrices A, G, H the characteristic map χ is a finite morphism of mapping degree $n!$. Friedland [4, 5] and Byrnes and Wang [3] did show that the set of all matrices of the form $A, I_n, 0$ belongs to this generic set. We therefore have the following result.

THEOREM 3.7 (see [3, 4, 5]). *Let $\mathcal{L} \subset Mat_{n\times n}$ be the set of all diagonal matrices defined over an algebraically closed field $\mathbb{K}$. If $A \in Mat_{n\times n}$ is an arbitrary matrix and $\varphi \in \mathbb{K}[s]$ is an arbitrary monic polynomial of degree n, then there are exactly $n!$ diagonal matrices $F \in \mathcal{L}$ (when counted with multiplicity) such that the matrix $A + F$ has characteristic polynomial $\varphi(s)$.*

4. The degree of $\bar{\mathcal{L}}$ in the generic situation. In the previous section we computed the degree of the variety $\bar{\mathcal{L}}$ in many special cases. The set of all subspaces $\mathcal{L} \subset Mat_{m\times n}$ having the property that $\dim \mathcal{L} = d$ can be identified with the Grassmannian variety $\mathrm{Grass}(d, \mathbb{K}^{mn})$. The degree in our concern attains its maximal value on a Zariski open subset of $\mathrm{Grass}(d, \mathbb{K}^{mn})$. This largest possible degree is sometimes referred to as the *generic degree*. In other words, the generic degree is obtained by algebraic perturbation of the subvariety $\mathcal{L}$ in the ambient space, $\mathbb{K}^{mn}$. In this section we determine an upper bound of the generic degree in the case when $d = n$ and prove that this upper is reached when $m = n < 5$. Let $\mathbb{K}$ be an algebraically closed field.

LEMMA 4.1. *Let $H_1, \ldots, H_k$, $k \le n$, be hypersurfaces in $\mathbb{P}^n$ of degrees $d_1, \ldots, d_k$, respectively, and let $Z_1, \ldots, Z_m$ be the irreducible components of $\bigcap_{i=1}^k H_i$ (not necessarily the same dimensions). Then*

$$\sum_{j=1}^m \deg Z_j \le \prod_{i=1}^k d_i.$$

Proof. It is sufficient to prove that for any l-dimensional projective variety Z of degree d, $l > 0$, and for any hypersurface H of degree q, the sum of the degrees of the irreducible components of $Z \cap H$ is at most dq.

If $Z \subset H$, then $Z \cap H = Z$ and $\deg Z = d \le dq$. On the other hand, if $Z \not\subset H$, then each irreducible component of $Z \cap H$ has dimension $l - 1$ (see the proof of [10, Chapter 1, Proposition 7.1]), and by Bézout's theorem [9, Theorem 18.4, p. 228], the sum of the degrees of the irreducible components of $Z \cap H$ is dq counted with multiplicity. ∎

LEMMA 4.2. *Let $p_i(x) \in \mathbb{K}[x_1, \ldots, x_n]$ be polynomials of degree d_i, $i = 1, \ldots, k$, $k \le n$. Then the number of irreducible components of*

$$\{x \in \mathbb{K}^n \mid p_i(x) = 0, i = 1, \ldots, k\}$$

is at most $\prod_{i=1}^k d_i$.

Proof. Let $\hat{p}_i(z)$ be the homogenization of $p(x)$, i.e.,

$$\hat{p}_i(z) = z_0^{d_i} p(z_1/z_0, \ldots, z_n/z_0).$$

Then $\hat{p}_i(z)$ defines a hypersurface of degree d_i in $\mathbb{P}^n$. Lemma 4.1 implies that the number of irreducible components of

$$\{z \in \mathbb{P}^n | \hat{p}_i(z) = 0, i = 1, \ldots, k\}$$

is at most $\prod_{i=1}^{k} d_i$. So is the number of irreducible components of

$$\{x \in \mathbb{K}^n \mid p_i(x) = 0, i = 1, \ldots, k\}. \qquad \square$$

THEOREM 4.3. *Let $\mathbb{K}$ be an algebraically closed field. The generic degree of $\bar{\mathcal{L}} \subset \mathbb{P}(\wedge^m \mathbb{K}^{m+n}) = \mathbb{P}^N$ is at most $\min(m,n)^n$. When $m = n$ the sharper bound $n(n-1)^{n-1}$ even holds.*

Proof. For a generic $(N-n)$-dimensional projective subspace $H \subset \mathbb{P}^N$, the intersection $H \cap \bar{\mathcal{L}}$ contains exactly $\deg \bar{\mathcal{L}}$ many points, and all of them are in $\mathcal{L}$. Let

$$\sum_{\nu} z_\nu (e_{\nu_1} \wedge \cdots \wedge e_{\nu_n}) \tag{4.1}$$

be the homogeneous coordinates of the points in $\wedge^m \mathbb{K}^{m+n}$, where $\{e_i\}$ is the standard basis of $\mathbb{K}^{m+n}$. Then each $(N-n)$-dimensional projective subspace H is defined by n linear equations in $\{z_\nu\}$. Let $\mathcal{L} = \text{span}\,\{F_1, \ldots, F_n\}$, and define

$$F(x) = x_1 F_1 + \cdots + x_n F_n. \tag{4.2}$$

Consider the Plücker coordinates z_ν for the row space of $[I_m,\ F(x)]$. There are now two cases. When $m \le n$, then the coordinates z_ν have degree at most m when viewed as polynomials of $\mathbb{K}[x_1, \ldots, x_n]$. Intersecting with the subspace H results in n polynomial equations in n variables having degree at most m. By the previous lemma the number of solutions is at most m^n.

When $m \ge n$, then the z_ν have degree at most n, and we get the upper bound n^n. When $m = n$ we get the sharpened upper bound as follows: In order to describe the generic plane H we can always choose a set of equations such that at most one of them contains the last Plücker coordinate $z_{(n+1,\ldots,2n)}$ which is equal to $\det F(x)$, a polynomial of degree n at most. All other polynomials z_ν have degree $n-1$ at most. Therefore $\deg \bar{\mathcal{L}}$ equals the number of solutions of one polynomial equation of degree at most n and $n-1$ of polynomial equations of degrees at most $n-1$. By Lemma 4.2, if the number of solutions is finite, then it is at most $n(n-1)^{n-1}$, and hence $\deg \bar{\mathcal{L}}$ is at most $n(n-1)^{n-1}$ when $m = n$. $\square$

The reader may wonder how good the bound of the degree in Theorem 4.3 is. It is readily shown that the bound is sharp when $\min(m,n) = 1$. In the following two pages we show that the degree is $n(n-1)^{n-1}$ for $m = n < 5$.

Note that the Plücker coordinate $z_\nu = z_{(\nu_1,\ldots,\nu_n)}$ defined by (4.1) is the full size minor consisting of the $\nu_1, \ldots, \nu_n$ columns of $[F_1,\ F_2] \in \text{Grass}(n, 2n)$. Define

$$|\nu| = \sum_{i=1}^{n} (\nu_i - i)$$

and partial order $\nu \le \mu$ if $\nu_i \le \mu_i$ for all i. Under the standard flag (i.e., the flag spanned by the ordered standard basis), the Schubert variety (3.1) is defined by

$$S(\nu) := S(\nu_1, \ldots, \nu_i) = \{z \in \text{Grass}(n, \mathbb{K}^{2n}) \mid z_\mu = 0 \text{ for } \mu \not\le \nu\},$$

and the Schubert cell (3.2) is defined by

$$C(\nu) := C(\nu_1, \ldots, \nu_i) = \{z \in \mathrm{Grass}(n, \mathbb{K}^{2n}) \mid z_\mu = 0 \text{ for } \mu \not\leq \nu \text{ and } z_\nu \neq 0\},$$

and $\dim S(\nu) = \dim C(\nu) = |\nu|$.

LEMMA 4.4. *Let*

$$f_k(z) = \sum_{|\nu|=k} z_\nu,$$

and let Z_k be the algebraic subset of $\mathrm{Grass}(n, \mathbb{K}^{2n})$ *defined by $f_{k+1}(z) = 0, f_{k+2}(z) = 0, \ldots, f_{n^2}(z) = 0$. Then*

$$Z_k = \bigcup_{|\nu|=k} S(\nu).$$

Proof. Clearly $\bigcup_{|\nu|=k} S(\nu) \subset Z_k$. Let $z \in Z_k$. If $z \notin \bigcup_{|\nu|=k} S(\nu)$, then z must be in a Schubert cell $C(\mu)$ for some μ with $|\mu| > k$. Then it implies that $z_\nu = 0$ for all ν such that $|\nu| = |\mu|$ and $\nu \neq \mu$. From one of the defining equations, $f_{|\mu|}(z) = 0$, we derive a contradiction: $z_\mu = 0$. Therefore $z \in \bigcup_{|\nu|=k} S(\nu)$ and $Z_k = \bigcup_{|\nu|=k} S(\nu)$. ∎

We call a coordinate z_ν type i if exactly i of the indices $\{\nu_1, \ldots, \nu_n\}$ are in the set $\{n+1, \ldots, 2n\}$. For example, $z_{(n+1,\ldots,2n)}$ is type n, and $z_{(1,3,\ldots,n,n+1)}$ is type 1. Let

$$\widehat{Mat_{n\times n}} = \{[I_n,\ F] \mid F \in Mat_{n\times n}\}.$$

Then $\widehat{Mat_{n\times n}}$ is an open set of $\mathrm{Grass}(n, \mathbb{K}^{2n})$ which is isomorphic to $Mat_{n\times n}$. In $\widehat{Mat_{n\times n}}$, a type k coordinate is a homogeneous polynomial of degree k of the entries of F.

LEMMA 4.5. *Let $k > 0$ and Z be a k-dimensional subvariety of* $\mathrm{Grass}(n, \mathbb{K}^{2n})$ *such that it is not completely contained in the hypersurface*

$$H_0 := \{z \in \mathrm{Grass}(n, \mathbb{K}^{2n}) | z_{(1,2,\ldots,n)} = 0\}.$$

Then each irreducible component of $Z \cap H$ has dimension $k-1$ for generic hypersurfaces H defined by linear equations of type 1 *coordinates.*

Proof. For any H, either $Z \subset H$ or each irreducible component of $Z \cap H$ has dimension $k-1$ (see the proof of [10, Chapter 1, Proposition 7.1]). Therefore we need only to show that $Z \not\subset H$ for generic H's. Since the set of all such H's form a Zariski open set, we need only to show that it is nonempty. Since $\dim Z > 0$ and $Z \not\subset H_0$, we can always find a point $[I_n,\ F] \in Z$ with $F \neq 0$. Let z_ν be the type 1 Plücker coordinate corresponding to a nonzero entry of F. Then Z is not contained in the hypersurface defined by $z_\nu = 0$. ∎

LEMMA 4.6 (see [5]). *Let $p_1(x), \ldots, p_n(x)$ be polynomials on $\mathbb{K}^n$ of degrees $d_1, \ldots, d_n$, respectively, and let $p_i^h(x)$ be the homogeneous part of $p_i(x)$ of the highest degree (degree d_i). If $p_1^h(x) = 0, \ldots, p_n^h(x) = 0$ have only zero solutions, then the system of polynomial equations*

$$\begin{aligned} p_1(x) &= b_1, \\ &\vdots \\ p_n(x) &= b_n \end{aligned}$$

has $\prod_{i=1}^n d_i$ solutions counted with multiplicity for any $(b_1, \ldots, b_n) \in \mathbb{K}^n$.

Proof. Let $(1, x_1, \ldots, x_n) = (1, z_1/z_0, \ldots, z_n/z_0)$. Then $\mathbb{K}^n$ can be considered as an open subset of $\mathbb{P}^n$ defined by $z_0 \neq 0$. Let $h_i(z)$ be the homogenization of $p_i(x) - b_i$; i.e., $h_i(z) = z_0^{d_i}(p_i(z_1/z_0, \ldots, z_n/z_0) - b_i)$. $h_i(z)$ defines a hypersurface H_i of degree d_i in $\mathbb{P}^n$. Let H_0 be the hyperplane in $\mathbb{P}^n$ defined by $z_0 = 0$. The condition implies that the system of equations $z_0 = 0$ and $h_i(z) = 0$, for $i = 1, \ldots, n$, has only zero solution $z_i = 0$, $i = 0, \ldots, n$; i.e., in $\mathbb{P}^n$, $\cap_{i=0}^n H_i = \emptyset$. By the projective dimension theorem, $\dim \cap_{i=1}^n H_i = 0$, and by Bézout's theorem, $\cap_{i=1}^n H_i$ contains exactly $\prod_{i=1}^n d_i$ points counted with multiplicity and again by the given condition, all of them are in $\mathbb{K}^n$. ∎

THEOREM 4.7. *The generic degree of $\bar{\mathcal{L}}$ is $n(n-1)^{n-1}$ for $m = n < 5$.*

Proof. By Theorem 4.3, we need only to find one $\mathcal{L}$ such that $\deg \bar{\mathcal{L}} = n(n-1)^{n-1}$. From Lemma 4.4 we know that

$$\{z \in \mathrm{Grass}(n, \mathbb{K}^{2n}) \mid f_{n^2}(z) = 0, f_{n^2-1}(z) = 0, \ldots, f_{n^2-n+1}(z) = 0\} = \bigcup_{|\nu|=n^2-n} S(\nu).$$

By repeatedly using Lemma 4.5 we can find $n^2 - n$ linear equations

$$l_1(z) = 0, \ldots, l_{n^2-n}(z) = 0$$

of type 1 coordinates such that each irreducible component of

$$Z := \left\{ z \in \bigcup_{|\nu|=n^2-n} S(\nu) \mid l_1(z) = 0, \ldots, l_{n^2-n}(z) = 0 \right\}$$

either is contained completely in H_0 or has dimension 0.

Note that for $n < 5$, $f_{n^2-1}(z) = 0, \ldots, f_{n^2-n+1}(z) = 0$ are linear equations of type $n-1$ coordinates, and in $\widehat{Mat_{n\times n}} = \{[I_n,\ F]\}$ they are homogeneous equations of degree $n-1$ of the entries of F. Therefore if $[I_n,\ F]$ is in Z, then $[I_n,\ tF]$ are also in Z for all t. Since $\dim Z \cap \widehat{Mat_{n\times n}} = 0$, we must have

$$\dim Z \cap \widehat{Mat_{n\times n}} = \{[I_n,\ 0]\}. \tag{4.3}$$

On $\widehat{Mat_{n\times n}}$, $l_1(z) = 0, \ldots, l_{n^2-n}(z) = 0$ are linear equations of the entries of matrices $F \in Mat_{n\times n}$. Let $\mathcal{L}$ be the n-dimensional linear subspace of $Mat_{n\times n}$ defined by these linear equations, and let $F(x)$ be defined as in (4.2). Then in terms of x, the equation $0 = f_{n^2}(z) = \det F(x)$ is a homogeneous equation of degree n, and the equations $f_{n^2-1}(z) = 0, \ldots, f_{n^2-n+1}(z) = 0$ are homogeneous equations of degree $n-1$, and (4.3) implies that the system of these equations has only zero solution. Therefore, by Lemma 4.6, the system $f_{n^2}(z) = b_1, \ldots, f_{n^2-n+1}(z) = b_n$ has $n(n-1)^{n-1}$ solutions counted with multiplicity in $\mathcal{L}$, which means that the linear system of the Plücker coordinates

$$\begin{aligned} f_{n^2}(z) &= b_1 z_{(1,2,\ldots,n)}, \\ &\vdots \\ f_{n^2-n+1}(z) &= b_n z_{(1,2,\ldots,n)} \end{aligned}$$

has $n(n-1)^{n-1}$ solutions in $\bar{\mathcal{L}}$ counted with multiplicity, i.e., $\deg \bar{\mathcal{L}} = n(n-1)^{n-1}$. ∎

Theorem 2.8 showed the existence of solutions over an algebraically closed field when $d \geq n$. In the critical dimension ($d = n$) we already know that the number of

solutions is finite generically. Theorem 4.3 gives the following upper bound for the number of solutions in Problem 1.1.

THEOREM 4.8. *Let $\mathbb{K}$ be an arbitrary field. Let $\mathcal{L} \subset Mat_{m\times n}$ be a subspace of dimension n, let A, G, H be a "generic set of matrices," and let $\varphi(s) \in \mathbb{K}^n$ be an arbitrary monic polynomial $\varphi(s) \in \mathbb{K}[s]$ of degree n. Then there exist at most $\min(m,n)^n$ different feedback laws $F \in \mathcal{L}$ such that (1.1) holds. If, in addition, $m = n$, then the number of solutions is bounded by $n(n-1)^{n-1}$.*

Proof. Consider the problem over the algebraic closure $\bar{\mathbb{K}}$ of $\mathbb{K}$. By Theorem 2.7 there are for every monic polynomial $\varphi(s)$ of degree n exactly $\deg \bar{\mathcal{L}}$ many feedback laws $[F_1\ F_2] \in \bar{\mathcal{L}}$ (when counted with multiplicity) such that

$$\det \begin{bmatrix} F_1 & F_2 \\ -sH+G & sI-A \end{bmatrix} = \varphi(s).$$

Therefore, there are at most $\deg \bar{\mathcal{L}}$ many feedback laws $F \in \mathcal{L}$ whose coefficients are in the base field $\mathbb{K}$. $\deg \bar{\mathcal{L}}$ is always less than the generic degree. By Theorem 4.3 the generic degree is at most $\min(m,n)^n$ (respectively, $n(n-1)^{n-1}$ when $m = n$). ∎

Acknowledgment. We started to work on this project in 1998. Meeyoung was very enthusiastic about this research since it brought together nontrivial ideas from algebraic geometry and systems theory. She hoped that it would be the start of a longer research project. In June 2001, Meeyoung died in a tragic drowning accident in the Mediterranean Sea at the young age of 35. Her passing leaves everybody who knew her saddened, and we feel a deep sense of loss.

CONVERGENCE PROPERTIES OF POLICY ITERATION*

MANUEL S. SANTOS† AND JOHN RUST‡

Abstract. This paper analyzes asymptotic convergence properties of policy iteration in a class of stationary, infinite-horizon Markovian decision problems that arise in optimal growth theory. These problems have continuous state and control variables and must therefore be discretized in order to compute an approximate solution. The discretization may render inapplicable known convergence results for policy iteration such as those of Puterman and Brumelle [*Math. Oper. Res.*, 4 (1979), pp. 60–69]. Under certain regularity conditions, we prove that for piecewise linear interpolation, policy iteration converges quadratically. Also, under more general conditions we establish that convergence is superlinear. We show how the constants involved in these convergence orders depend on the grid size of the discretization. These theoretical results are illustrated with numerical experiments that compare the performance of policy iteration and the method of successive approximations.

Key words. policy iteration, method of successive approximations, quadratic and superlinear convergence, complexity, computational cost

1. Introduction.

The goal of this paper is to provide new insights into the convergence properties of *policy iteration,* an algorithm developed by Bellman (1955, 1957) and Howard (1960) for solving stationary, infinite-horizon Markovian dynamic programming (MDP) problems. Policy iteration has some rough similarities to the simplex algorithm of linear programming (LP). Just as the simplex algorithm generates a sequence of improving trial solutions to the LP problem (along with their associated costs), policy iteration generates an improving sequence of decision rules to the MDP problem (along with their associated value functions). Also, similarly to the simplex algorithm, policy iteration has been found to converge to the optimal solution in a remarkably small number of iterations. Typically fewer than 10 to 20 policy iterations are required to find the optimal solution. But analogously to LP, where the number of possible vertices increases exponentially fast as the number of variables M and constraints N increases, the number of possible decision rules of an MDP problem with M states and N actions in each state is N^M, which also grows exponentially fast in M. Klee and Minty (1972) have constructed worst-case families of LP problems where the simplex algorithm visits a large and exponentially increasing number of vertices before converging to the optimal solution. Are there also "worst-case" families of MDP problems where policy iteration visits an exponentially increasing number of trial decision rules before converging to the optimal solution?

Although we do not answer this question in the present paper, we consider an example due to Tsitsiklis (2000) of a family of finite state MDP problems with M states and two actions in each state where roughly M policy iteration steps are required to find the optimal solution. While this example may not represent the "worst case," it is a fairly pessimistic result that suggests that policy iteration will not be an

efficient method for solving all types of MDP problems. The reason is that each policy iteration step is expensive: it involves (among other computations) a solution of a linear system with M equations in M unknowns at a total cost of $O(M^3)$ arithmetic operations using standard linear equation solvers.

This paper was motivated by a desire to characterize those families of MDP problems for which only a small number of policy iteration steps are required to find the solution. Puterman and Brumelle (1979) were among the first to analyze the convergence properties of policy iteration for MDP problems with continuous state and action spaces. They showed that policy iteration is mathematically equivalent to *Newton's method*, and so under certain regularity conditions the policy iteration algorithm displays a quadratic order of convergence. The shortcoming of Puterman and Brumelle's abstract infinite-dimensional space analysis is that the generalized version of policy iteration that they describe is not actually computationally feasible in problems where there are an infinite number of states and actions. Their analysis assumed that the exact value functions are computed at each policy evaluation step, and this requires solving an infinite-dimensional system of linear equations. Furthermore, they impose a Lipschitz order condition which is not easily verifiable in their framework.

We analyze a computationally feasible version of policy iteration for a class of optimal growth problems with a continuum of states and decisions. We establish sufficient conditions under which the policy iteration solution for discretized versions of this problem exhibits a quadratic rate of convergence and a global operative estimate with a convergence rate equal to 1.5. We study how the constants involved in the convergence orders depend on the grid size of the discretization. Also, under more general conditions we show that convergence is superlinear. Thus, desirable convergence properties that Puterman and Brumelle demonstrated for an abstract, idealized version of policy iteration also hold for a practical, computationally feasible version that can be applied to solve actual problems in economics and finance. To the best of our knowledge, this is the first numerical algorithm with such convergence properties.

Despite the scant theoretical work and evaluations of the performance of policy iteration in economic models, computational economists (e.g., see Chapter 12 of Judd (1998)) have been well aware of this numerical procedure. Rust (1987) applies policy iteration to solve a durable good replacement problem. A recent paper by Benitez-Silva et al. (2001) offers an extensive numerical evaluation of policy iteration in general economic models. Unfortunately, there is little guidance about the conditions under which one should use policy iteration as opposed to a variety of alternative algorithms including the *method of successive approximations.* This latter method can be shown to be globally convergent since the value function to an MDP problem is the fixed point to a contraction mapping. Section 6 contains a computational illustration that compares successive approximations and our computationally feasible version of policy iteration for an optimal growth problem whose solution can also be computed analytically.

The paper is structured as follows. In section 2 we present some background on the policy iteration algorithm, reviewing known results in the finite and infinite state cases, respectively. In section 3, we focus our analysis on a class of multidimensional optimal growth problems. Then, in section 4 we describe our computationally feasible version of the policy iteration algorithm using bilinear interpolation. In section 5 we state and prove the main results on the convergence properties of our algorithm. Section 6 provides a comparison of the performance of both policy iteration and the method of successive approximations in the case of an optimal growth problem that

admits an analytic solution. This enables us to evaluate the uniform approximation errors of the two algorithms as well as compare their relative computational speed. The computational results are consistent with theoretical predictions. We conclude in section 7 with a discussion of our main findings.

2. Background. As noted in the introduction, policy iteration is a commonly used algorithm for solving stationary, infinite-horizon MDP problems. The MDP problem is mathematically equivalent to computing the fixed point V^* to *Bellman's equation*

$$V^* = \Gamma(V^*), \tag{2.1}$$

where Γ is the *Bellman operator* given by

$$\Gamma(V)(s) \equiv \max_{a \in A(s)} \left[u(s,a) + \beta \int V(s') p(ds'|s,a) \right], \tag{2.2}$$

and $\beta \in (0,1)$ is the discount factor, $u(s,a)$ represents the utility or payoff earned in state s when action a is taken, and $p(ds'|s,a)$ is a conditional probability distribution for next period's state s' given the current state s and action a. As is well known (see, e.g., Blackwell (1965)), under mild regularity conditions the Bellman operator is a contraction mapping, and hence its fixed point V^*, the *value function,* is unique. The solution to Bellman's equation is of considerable interest because it has been shown that from V^* we can compute the corresponding *optimal decision rule or policy function* α^* given by

$$\alpha^*(s) \equiv \arg\max_{a \in A(s)} \left[u(s,a) + \beta \int V^*(s') p(ds'|s,a) \right]. \tag{2.3}$$

The policy iteration algorithm computes V^* via a sequence of trial value functions $\{V_n\}$ and decision rules $\{\alpha_n\}$ under an alternating sequence of *policy improvement* and *policy evaluation* steps. The policy improvement step computes an improved policy α_n implied by the previous value function V_n:

$$\alpha_n(s) = \arg\max_{a \in A(s)} \left[u(s,a) + \beta \int V_n(s') p(ds'|s,a) \right] \quad \text{(policy improvement)}. \tag{2.4}$$

The policy evaluation step computes a new value function V_{n+1} implied by policy α_n:

$$V_{n+1}(s) = \left[u(s,\alpha_n(s)) + \beta \int V_{n+1}(s') p(ds'|s,\alpha_n(s)) \right] \quad \text{(policy evaluation)}. \tag{2.5}$$

Policy iteration continues until $V_{n+1} = V_n$, $\alpha_{n+1} = \alpha_n$, or the difference between two successive value functions or decision rules is less than a prescribed solution tolerance. Under fairly general conditions, policy iteration can be shown to generate a monotonically improving sequence of trial value functions, $V_{n+1} \geq V_n$. In the case of MDP problems where both the state space S and action sets $A(s)$ are finite, there is only a finite number of possible policies bounded by N^M, where M is the number of states and N is the maximum number of possible actions in the constraint sets $A(s)$. This, together with the fact that policy iteration is monotonic (and thus cannot cycle) implies that the policy iteration algorithm will converge to the true fixed point in a finite number of steps (assuming all arithmetic operations are carried

out exactly, without any rounding error). Although the number of potential policies is vast (for example a stopping problem with two choices and 1000 states has 2^{1000} or about 1.07×10^{301} possible policies), it has been observed in most computational examples that policy iteration converges in a remarkably small number of iterations, typically less than 20. Furthermore, the number of policy iteration steps appears to be independent of the number of states and decisions.

The most commonly used alternative to policy iteration is the method of successive approximations

$$V_{n+1} = \Gamma(V_n). \tag{2.6}$$

As is well known, this algorithm is globally convergent (an implication of the fact that Γ is a contraction mapping), but it converges at a geometric rate. The error after $\widehat{T}$ successive approximations steps is $O(\beta^{\widehat{T}}/(1-\beta))$. Since each successive approximation step requires $O(M^2N)$ arithmetic operations (and thus each iteration is an order faster than policy iteration), as the discount factor $\beta \to 1$, the number of successive approximation steps required to obtain acceptable accuracy rises rapidly, calling for a huge number of computations. Hence, when β is close to 1 (as in the calibration of models with quarterly data or smaller time intervals), the total computational burden of doing a small number of more expensive policy iteration steps may be less than the total amount of work involved in doing a large number of less expensive successive approximation steps.

Of course, this advice will not hold if the number of policy iteration steps increases sufficiently rapidly with M. Unfortunately, the following counterexample (Tsitsiklis (2000)) shows that in general the number of policy iteration steps cannot be bounded by a constant that is independent of M. Consider an MDP problem with $M+1$ states $s \in \{0, 1, \ldots, M\}$. In each state there are two possible actions, $a \in \{-1, +1\}$, with the interpretation that $a = -1$ corresponds to "moving one state to the left" and $a = +1$ corresponds to "moving one state to the right." This can be mapped into a transition probability given by $p(ds'|s, a)$ that puts probability mass 1 on state $s' = s-1$ if $a = -1$ and probability mass 1 on state $s' = s+1$ if $a = +1$. States $s = 0$ and $s = M$ are zero–cost-absorbing states regardless of the action taken, so that we have

$$u(s, a) = 0 \quad \text{if } s = 0 \text{ or } s = M. \tag{2.7}$$

For states $s = 1, 2, \ldots, M-2$, the payoff equals -1 for moving left and -2 for moving right:

$$u(s, a) = \begin{cases} -1 & \text{if } a = -1, \\ -2 & \text{if } a = +1. \end{cases} \tag{2.8}$$

Finally, for state $s = M-1$ there is a reward of $2M$ for moving right and a reward of -1 for moving left:

$$u(s, a) = \begin{cases} -1 & \text{if } a = -1, \\ 2M & \text{if } a = +1. \end{cases} \tag{2.9}$$

Consider policy iteration starting from the initial value function $V_0(s) = 0$ for all s. Then it is easy to see that the optimal policy α_0 implied by this value function is

$\alpha_0(s) = -1$ for states $s = 1, \ldots, M-2$ and $\alpha_0(M-1) = +1$ (observe that the choice of policy is irrelevant at the absorbing states $s = 0$ and $s = M$). It is not difficult to check that when $\beta = 1$, the value V_1 associated with this policy α_0 is given by

$$V_1(s) = \begin{cases} 0 & \text{if } s = 0, M, \\ -s & \text{if } s \in \{1, 2, \ldots, M-2\}, \\ 2M & \text{if } s = M-1. \end{cases} \tag{2.10}$$

This is the value function generated by the first policy iteration step. For the second step, notice that optimal policy α_1 implied by V_1 is to go left at states $s = 1, 2, \ldots, M-3$, but to go right at states $s = M-2$ and $s = M-1$. This new policy α_1 differs from the initial policy α_0 in only one state, $s = M-2$, where it is now optimal to go right because the updated value V_1 assigns a higher value $V_1(M-1) = 2M$ to the penultimate state $s = M-1$. Moreover, after each succeeding policy iteration $n = 2, \ldots, M-1$, the updated decision rule α_n differs from the previous policy α_{n-1} in state $s = M-n-1$, flipping the optimal action from left to right. This process continues for $M-1$ policy iteration steps until the optimal policy $\alpha^*(s) = +1$ for all s; i.e., it is optimal to always move to the right. The optimal value function $V^*(s)$ for this policy is then given by

$$V^*(s) = \begin{cases} 0 & \text{if } s = 0, M, \\ 2(s+1) & \text{if } s \in \{1, 2, \ldots, M-1\}. \end{cases} \tag{2.11}$$

It should be stressed that the same type of result occurs for discounted problems with $\beta \in (0, 1)$ as long as β is sufficiently close to 1.

In summary, this counterexample provides a family of MDP problems with $M+1$ states in which a total of $M-1$ policy iteration steps are required to converge to the optimal solution starting from an initial guess $V_0 = 0$. Therefore, it will not be possible to provide a bound on the number of steps that is independent of the number of states M. But an alternative analysis of the convergence of policy iteration, initiated by Puterman and Brumelle (1979), does suggest that under additional conditions only a small number of policy iterations should be required to solve the MDP problem and this number should be essentially independent of the number of states M. Puterman and Brumelle were among the first to notice that policy iteration is mathematically equivalent to Newton's method for solving nonlinear functional equations. Then, building on some generalized results on the quadratic convergence of the Newton iteration with supports replacing derivatives, Puterman and Brumelle showed that for some constant L the iteration (2.4)–(2.5) satisfies the quadratic convergence bound

$$\|V_{n+1} - V^*\| \leq \frac{\beta L}{(1-\beta)} \|V_n - V^*\|^2, \tag{2.12}$$

where $\|V\|$ is a norm in the space of functions V. There are, however, two limitations to this result. For the case of finite state, finite action MDP problems, the quadratic convergence bound is not effective. First, (2.12) may hold only in a neighborhood of the fixed-point solution V^*. Consequently, the errors $\|V_n - V^*\|$ tend to be either very large until V_n is in a "domain of attraction" of V^*, in which case the error immediately falls to 0 after one further policy iteration step. In more technical terms, following the analysis below one can show that for the case of finite state, finite action MDP problems, constant L is equal to zero if there is no policy switch after a small

perturbation in the value function, but L becomes undefined (i.e., $L = \infty$) at points with multiple maxima in which a small perturbation in the value function leads to a sudden switch in the optimal action. Therefore, for MDP problems with a finite number of states and actions the Puterman and Brumelle results cannot be applied. The second limitation was noted in the introduction; namely, the abstract infinite-dimensional version of policy iteration in (2.4)–(2.5) is not computationally feasible for problems where there are infinite numbers of states. In these problems some sort of discretization procedure must be employed. And it seems crucial to understand how constant L will depend on the discretization procedure.

3. A reduced form model of economic growth. For expositional convenience and for our later computational purposes, we now consider a reduced-form version of our MDP problem (2.1)–(2.2) that encompasses most standard models of economic growth (cf. Stokey, Lucas with Prescott (1989)). As in most of the economics literature, we distinguish between endogenous and exogenous growth variables. This is commonly assumed in macroeconomic applications, where Bellman's equation is usually expressed in the following form:

$$V^*(k_0, z_0) = \max_{k_1} v(k_0, k_1, z_0) + \beta \int_Z V^*(k_1, z') Q(dz', z_0) \tag{3.1}$$
$$\text{subject to (s.t.) } (k_0, k_1, z_0) \in \Omega,$$
$$(k_0, z_0) \text{ fixed, } 0 < \beta < 1.$$

Here, k is a vector of endogenous state variables in a set K, which may include several types of capital stocks and measures of wealth. Also, z is a vector made up of stochastic exogenous variables such as some indices of productivity or market prices. This latter random vector lies in a set Z, and is governed by a probability law Q which is assumed to be weakly continuous. As is typical in economic growth theory (cf. Stokey, Lucas with Prescott (1989)), this formulation is written in reduced-form in the sense that the action or control variables are not explicitly laid out. It should be understood that for every (k_0, k_1, z_0) an optimal control has been selected from which the one-time payoff $v(k_0, k_1, z_0)$ can be defined.

The technological constraints of this economy are represented by a given feasible set $\Omega \subset K \times K \times Z$, which is the graph of a continuous correspondence $\Gamma : K \times Z \to K$. The intertemporal objective is characterized by a return function v and a given discount factor $0 < \beta < 1$. Then, $s = (k, z)$ is the vector of state variables lying in the set $S = K \times Z$. Let $(S, \mathbb{S})$ denote a measurable space.

As discussed in Stokey, Lucas with Prescott (1989) (see p. 240), the optimization problem of the preceding section is clearly more general. That is, with an appropriate choice of the action space and laws of motion for the state variables, our MDP problem (3.1) can be embedded in the framework of functional equations (2.1)–(2.2). The converse is not true. Our main interest, however, is to apply policy iteration to a standard macroeconomic setting. This optimization problem will become handy for our numerical experiments in section 6 of a neoclassical growth model with leisure. Moreover, it becomes transparent from our arguments below that our results can be extended to related MDP problems since the analysis centers on the following specific assumptions.

Assumption 1. The set $S = K \times Z \subset \mathbb{R}^\ell \times \mathbb{R}^m$ is compact, and $\mathbb{S}$ is the Borel σ-field. For each fixed z the set $\Omega_z = \{(k, k') \mid (k, k', z) \in \Omega\}$ is convex.

Assumption 2. The mapping $v : \Omega \longrightarrow \mathbb{R}$ is continuous. Also, there exists $\eta > 0$ such that for every z function $v(k, k', z) + \frac{\eta}{2}\|k'\|^2$ is concave in (k, k').

These assumptions are fairly standard. In Assumption 2, $\|\cdot\|$ denotes the Euclidean norm. The asserted uniform concavity of v will be needed only for some stronger versions of our results. Under these conditions the value function $V^*(k_0, z_0)$, given in (3.1), is well defined and jointly continuous in $K \times Z$. Moreover, for each fixed z_0 the mapping $V^*(\cdot, z_0)$ is concave. The optimal value $V^*(k_0, z_0)$ is attained at a unique point k_1 given by the policy function $k_1 = g(k_0, z_0)$ characterizing the set of optimal solutions.

4. Policy iteration in a space of piecewise linear interpolations. In what follows we shall be concerned with a policy iteration algorithm in a space of piecewise bilinear interpolations. Most of our results below apply to other interpolation schemes provided that (a) the operator is monotone, and (b) the operator has a fixed point. These two conditions may be quite restrictive for some approximation schemes such as polynomial and spline interpolations, but they hold true for several forms of piecewise linear interpolation.

We would like to remark that piecewise linear interpolation has certain computational advantages over the usual discretization procedure in which the domain and functional values are restricted to a fixed grid of prespecified points. Indeed, discretizations based on functional evaluations over a discrete set of points are not computationally efficient for smooth problems. Most calculations may become awkward under a discrete state space, and hence the corresponding algorithms are usually rather slow. For instance, the most powerful maximization procedures make use of the information provided by the values of the functional derivatives. These powerful techniques may still be applied under piecewise linear interpolation (cf. Santos (1999)). Therefore, piecewise linear interpolation preserves the aforementioned properties of monotonicity and existence of a fixed point for the operator, and at the same time allows for the use of efficient searching procedures over a continuous state space.

4.1. Formulation of the numerical algorithm. Let us assume that both K and Z are convex polyhedra. This does not entail much loss of generality in most economic applications. Let $\{S^j\}$ be a finite family of *simplices*[1] in K such that $\cup_j S^j = K$ and $\text{int}(S^i) \cap \text{int}(S^j) = \varnothing$ for every pair S^i, S^j. Also, let $\{D^i\}$ be a finite family of simplices in Z such that $\cup_i D^i = Z$ and $\text{int}(D^i) \cap \text{int}(D^j) = \varnothing$ for every pair D^i, D^j. Define the *grid size* or *mesh level* as

$$h = \max_{j,i} diam\left\{S^j, D^i\right\}.$$

Let (k^j, z^i) be a generic vertex of the triangulation. Then, every k and z can be represented as a convex combination of $\{k^j\}$ and $\{z^i\}$. More precisely, for $k \in S^j$ and $z \in D^i$ there is a unique set of nonnegative weights $\lambda_j(k)$ and $\varphi_i(z)$, with $\sum_j \lambda_j(k) = 1$ and $\sum_i \varphi_i(z) = 1$, such that

$$k = \sum_j \lambda_j(k) k^j \quad \text{and} \quad z = \sum_i \varphi_i(z) z^i \quad \text{for all } k^j \in S^j \text{ and } z^i \in D^i. \tag{4.1}$$

We next define a finite-dimensional space of numerical functions compatible with the simplex structure $\{S^j, D^i\}$. Each element V^h is determined by its nodal values

[1] A simplex S^j in $\mathbb{R}^\ell$ is the set of all convex combinations of $\ell + 1$ given points (cf. Rockafellar (1970)). Thus, a simplex in $\mathbb{R}^1$ is an interval, a simplex in $\mathbb{R}^2$ would be a triangle, and a simplex in $\mathbb{R}^3$ would be a tetrahedron.

$\{V^h(k^j, z^i)\}$ and is extended over the whole domain by the bilinear interpolation

$$V^h(k,z) = \sum_j \lambda_j(k)\left[\sum_i \varphi_i(z) V^h(k^j, z^i)\right].$$

Note that the interpolation is first effected in space Z and then in space K. This interpolation ordering is appropriate for carrying out the numerical integrations and maximizations outlined below. Let the function space

$$\mathcal{V}^h = \left\{ V^h : K \times Z \longrightarrow \mathbb{R} \;\middle|\; \begin{array}{l} V^h(k,z) = \sum_j \lambda_j(k)\left[\sum_i \varphi_i(z) V^h(k^j, z^i)\right] \\ \text{for } \lambda_j \text{ and } \varphi_i \text{ satisfying (4.1)} \end{array} \right\}. \tag{4.2}$$

It follows that $\mathcal{V}^h$ is a Banach space when equipped with the norm

$$\|V^h\| = \max_{(k^j, z^i) \in K \times Z} |V^h(k^j, z^i)| \quad \text{for } V^h \in \mathcal{V}^h. \tag{4.3}$$

We now consider the following algorithm for policy iteration in space $\mathcal{V}^h$.

(i) *Initial step*: Select an accuracy level ε and an initial guess V_0^h.

(ii) *Policy improvement step*: Find $k_1 = g_n^h(k_0^j, z_0^i)$ that solves

$$B^h(V_n^h)(k_0^j, z_0^i) \equiv -V_n^h(k_0^j, z_0^i) + \max_{k_1} v(k_0^j, k_1, z_0^i) + \beta \int_Z V_n^h(k_1, z') Q(dz', z_0^i) \tag{4.4}$$

for each vertex point (k_0^j, z_0^i).

(iii) *Policy evaluation step*: Find $V_{n+1}^h(k_0^j, z_0^i)$ that solves

$$V_{n+1}^h(k_0^j, z_0^i) = v(k_0^j, g_n^h(k_0^j, z_0^i), z_0^i) + \beta \int_Z V_{n+1}^h(g_n^h(k_0^j, z_0^i), z') Q(dz', z_0^i) \tag{4.5}$$

for each vertex point (k_0^j, z_0^i).

(iv) *End of iteration*: If $\|V_{n+1}^h - V_n^h\| \le \varepsilon$, stop; else, increment n by 1 and return to step (ii).

Observe that in step (ii) for a given V_n^h we first carry out the integration operation and then find the optimal policy g_n^h. And in step (iii) for a given g_n^h we search for a fixed-point solution V_{n+1}^h. Technically, a natural approach for solving (4.5) is to use numerical integration and then limit the search for the fixed point to a finite system of linear equations (cf. Dahlquist and Bjorck (1974) (pp. 396–397)). Regarding step (iv), the iteration process will stop once the term $\|V_{n+1}^h - V_n^h\|$ falls within a prespecified accuracy level, ε.

The solution to (4.5) can be written as

$$v_{g_n^h} = [I - \beta P_{g_n^h}] V_{n+1}^h, \tag{4.6}$$

where $v_{g_n^h}$ represents the utility implied by policy function g_n^h, that is, $v_{g_n^h}(k_0^j, z_0^i) = v(k_0^j, g_n^h(k_0^j, z_0^i), z_0^i)$ for each vertex point (k_0^j, z_0^i), and $P_{g_n^h}$ is the Markov (conditional expectation) operator defined by

$$\begin{aligned} P_{g_n^h}(V(k_0^j, z_0^i)) &= \int_Z V(g_n^h(k_0^j, z_0^i), z') Q(dz', z_0^i) \\ &= \sum_{j'} \lambda_{j'}(g_n^h(k_0^j, z_0^i)) \left[\int_Z \sum_{i'} \varphi_{i'}(z') V(k_0^{j'}, z_0^{i'}) Q(dz', z_0^i) \right]. \end{aligned} \tag{4.7}$$

It should be understood that in this latter expression $g_n^h(k_0^j, z_0^i)$ belongs to some simplex $S^{j'}$, and z' is integrated out over simplices of the form $D^{i'}$.

Observe that $P_{g_n^h}$ defines a linear operator in the space $\mathcal{V}^h$ of functions V^h that can be represented by its nodal values $\{V^h(k_0^j, z_0^i)\}$. Since this operator is positive and bounded and $\beta \in (0,1)$, it can be shown that the inverse operator $[I - \beta P_{g_n^h}]^{-1}$ exists and has the following series representation:

$$[I - \beta P_{g_n^h}]^{-1} = \sum_{t=0}^{\infty} \beta^t P_{g_n^h}^t. \tag{4.8}$$

The distance between two operators P_g and $P_{\widehat{g}}$ will be defined by

$$\|P_g - P_{\widehat{g}}\| = \max_{\{(k_0^j, z_0^i)\}} \left\{ \sum_{S^{j'}} \left[\sum_{j'} |\lambda_{j'}(g(k_0^j, z_0^i)) - \lambda_{j'}(\widehat{g}(k_0^j, z_0^i))| \right] \right\}. \tag{4.9}$$

The summation of these absolute differences goes over all weights $\lambda_{j'}$ and over all simplices $S^{j'}$, under the convention that $\lambda_{j'}(g(k_0^j, z_0^i)) = 0$ if $g(k_0^j, z_0^i)$ does not belong to $S^{j'}$.

If $\{V_n^h\}_{n \geq 1}$ is a sequence of functions generated by (4.4)–(4.5), one can readily check from these equations that such a sequence satisfies

$$V_{n+1}^h = V_n^h + [I - \beta P_{g_n^h}]^{-1} B^h(V_n^h). \tag{4.10}$$

Moreover, if in the policy improvement step the set of maximizers g_n^h is unique, then $-[I - \beta P_{g_n^h}]$ is the derivative of B^h at V_n^h when $P_{g_n^h}$ is considered as a linear operator in the finite-dimensional space $\mathcal{V}^h$. Hence, (4.10) implies that policy iteration is equivalent to Newton's method applied to operator B^h defined in (4.4). As is well known (e.g., Traub and Woźniakowski (1979)), Newton's method exhibits locally a quadratic rate of convergence provided that the functional derivative satisfies a certain regular Lipschitz condition. But the uniqueness of the set of maximizers seems fairly stringent for operator B^h. Indeed, function V_{n+1}^h is not necessarily concave, since it is obtained as the solution to (4.5). Therefore, there is no guarantee that the maximizer in (4.4) is unique, and consequently that B^h has a well-defined derivative. To circumvent these technicalities, Puterman and Brumelle (1979) apply an extension of Newton's method to policy iteration following a familiar procedure with supports replacing derivatives. Even though operator B^h may not have a well-defined derivative, the following general property follows from the above maximization step: If g_n^h is a selection of the correspondence of maximizers in (4.4), then it must be the case that $-[I - \beta P_{g_n^h}]$ is the support of operator B^h at V_n^h. More precisely, (4.4) implies that for any other function V^h in $\mathcal{V}^h$ the following condition must hold:

$$B^h(V^h) - B^h(V_n^h) \geq -[I - \beta P_{g_n^h}][V^h - V_n^h]. \tag{4.11}$$

Of course, one readily sees from (4.11) that if there is a unique set of maximizers g_n^h, then $-[I - \beta P_{g_n^h}]$ is the derivative of B^h at V_n^h.

4.2. Existence of a fixed point and monotonicity. For our later analysis, we need to establish the existence of a unique fixed point for our algorithm and the monotone convergence to such a solution. We begin with the following discretized

version of Bellman's equation.

$$V^h(k_0^j, z_0^i) = \max_{k_1} v(k_0^j, k_1, z_0^i) + \beta \int_Z V^h(k_1, z') Q(dz', z_0^i) \quad \text{s.t. } (k_0^j, k_1, z_0^i) \in \Omega \quad \text{for each vertex point } (k_0^j, z_0^i). \tag{4.12}$$

Note that this equation needs to be satisfied only at each vertex point (k_0^j, z_0^i).

LEMMA 4.1. *Equation* (4.12) *has a unique solution* V^h *in* $\mathcal{V}^h$.

Proof. The proof is standard. One just defines the discretized dynamic programming operator $V_{n+1}^h = T^h(V_n^h)$ given by

$$V_{n+1}^h(k_0^j, z_0^i) = \max_{k_1} v(k_0^j, k_1, z_0^i) + \beta \int_Z V_n^h(k_1, z') Q(dz', z_0^i) \quad \text{s.t. } (k_0^j, k_1, z_0^i) \in \Omega \quad \text{for each vertex point } (k_0^j, z_0^i). \tag{4.13}$$

One immediately sees that T^h is a contraction mapping in $\mathcal{V}^h$ with modulus $0 < \beta < 1$. By a well-known fixed-point theorem, T^h has a unique fixed point V^h in $\mathcal{V}^h$.

Notice that $V^h = T^h(V^h)$ implies that $B^h(V^h) = 0$. Therefore, the method of successive approximations as defined by (4.13) allows us to prove the existence of a fixed point for our algorithm as defined by (4.4)–(4.5). We next verify the monotone convergence of the algorithm to the fixed-point solution. □

LEMMA 4.2. *Assume that* $\{V_n^h\}_{n\geq 0}$ *is a sequence satisfying* (4.4)–(4.5). *Then* $V_{n+1}^h \geq V_n^h$ *for all* $n \geq 1$.

Proof. From (4.5), consider the following equation:

$$V_n^h = v_{g_{n-1}^h} + \beta P_{g_{n-1}^h} V_n^h. \tag{4.14}$$

That is, V_n^h is the value function under policy g_{n-1}^h. Now, call g_n^h the corresponding set of maximizers over the right-hand side of (4.4) under function V_n^h. Then,

$$v_{g_n^h} + \beta P_{g_n^h} V_n^h \geq V_n^h. \tag{4.15}$$

Moreover, a further application of this procedure for function V_n^h on the left-hand side of (4.15) yields

$$v_{g_n^h} + \beta P_{g_n^h} v_{g_n^h} + \beta^2 [P_{g_n^h}]^2 V_n^h \geq V_n^h.$$

Hence, after t iterations, we obtain

$$\sum_{s=0}^{t} \beta^s [P_{g_n^h}]^s v_{g_n^h} + \beta^{t+1} [P_{g_n^h}]^{t+1} V_n^h \geq V_n^h. \tag{4.16}$$

Now, letting $t \to \infty$, it follows from (4.6)–(4.8) that the left-hand side of (4.16) converges to V_{n+1}^h. Therefore, $V_{n+1}^h \geq V_n^h$. □

Remark 4.3. Assume that $\{V_n^h\}_{n\geq 1}$ is a sequence satisfying (4.4)–(4.5). Let T^h be the discretized dynamic programming operator as defined by (4.13). Then, from the previous method of proof one can readily establish that $V_{n+1}^h \geq T^h(V_n^h) \geq V_n^h$. In this sense, the policy iteration algorithm converges faster to the fixed-point solution than the method of successive approximations generated by operator T^h.

5. Convergence properties of the numerical algorithm. We now establish some convergence properties of our policy iteration algorithm. We begin with a global result for concave interpolations in which the convergence order is equal to 1.5 and the constant involved in the convergence order is relatively easy to estimate. Among other applications, this result may be useful in placing an upper bound on the number of policy iteration steps over a well-defined convergence region to reach a tolerance level ε. Then, the same strategy of proof used for this global convergence result will be applied to address further local convergence properties. Thus for concave interpolations we prove quadratic convergence of the algorithm, and for a more general setting of continuous functions we prove that convergence is superlinear. The constants involved in these convergence orders are shown to depend on the mesh level of the discretization.

5.1. Global convergence in a space of concave functions. For present purposes, we shall assume that either the fixed point $V^h(k,z)$ is a concave function in k or the sequence $\{V_n^h(k,z)\}_{n\geq 1}$ generated by policy iteration is a sequence of concave functions in k.

In what follows, for a real-valued function the norm $\|V_n^h\|$ is as defined in (4.3), and the distance between operators $\|P_g - P_{\widehat{g}}\|$ is as defined in (4.9). Also, for an ℓ-dimensional function $g = (g_1, \ldots, g_r, \ldots, g_\ell)$ let

$$\|g\| = \max_{0\leq r\leq \ell} \left| \max_{(k_0^j, z_0^i)} g_r(k_0^j, z_0^i) \right|. \tag{5.1}$$

The following simple result will be very useful.

LEMMA 5.1. *Let h be the grid size of triangulation $\{S^j, D^i\}$. Then, there exists a constant κ that depends on the grid configuration and the dimension ℓ such that $\|P_g - P_{\widehat{g}}\| \leq \frac{\kappa}{h}\|g - \widehat{g}\|$.*

As presently shown, constant κ depends on the uniformity of the grid; also, $\frac{\kappa}{h}$ converges to ∞ as h goes to 0. Therefore, the constants involved in our convergence results below will depend on the uniformity of the grid and on the mesh level, h, of the discretization. These constants get unbounded as h goes to zero.

Proof of Lemma 5.1. The proof becomes more transparent for the case $\ell = 1$. In this simple case, we can show that

$$\kappa = \frac{2h}{h_0}, \tag{5.2}$$

where $h_0 = \min_r\{k^{r+1} - k^r\}$ is the minimum distance over all pairs of adjacent grid points. Thus, for a uniform grid we obtain $\kappa = 2$.

To verify (5.2), consider two points $k_1 = g(k_0^j, z_0^i)$ and $\widehat{k}_1 = \widehat{g}(k_0^j, z_0^i)$. If k_1 and $\widehat{k}_1$ are contained in the same grid interval $[k^r, k^{r+1}]$, then $k = \lambda(k)k^r + (1-\lambda(k))k^{r+1}$ for $k = k_1, \widehat{k}_1$. Hence,

$$\begin{aligned} &|\lambda(k_1) - \lambda(\widehat{k}_1)| + |(1-\lambda(k_1)) - (1-\lambda(\widehat{k}_1))| \\ &\qquad = 2|\lambda(k_1) - \lambda(\widehat{k}_1)| \leq \frac{2|k_1 - \widehat{k}_1|}{k^{r+1} - k^r} \leq \frac{2|k_1 - \widehat{k}_1|}{h_0}. \end{aligned} \tag{5.3}$$

If $k_1 < \widehat{k}_1$ belong to different grid intervals, then $k^r < k_1 < k^{r+1} < \cdots < k^{r+n} < \widehat{k}_1 < k^{r+n+1}$ for some integers r and n. Notice that for $n > 1$ we get from (4.9) that

$\|P_g - P_{\widehat{g}}\| = 2$. Thus, for this case the result is trivially satisfied for κ in (5.2). If $n = 1$, then (4.9) amounts to

$$|\lambda(k_1)| + |(1 - \lambda(k_1)) - \lambda(\widehat{k}_1)| + |1 - \lambda(\widehat{k}_1)|. \tag{5.4}$$

By continuity, for $\widehat{k}_1 = k^{r+1}$ the bound in (5.3) is also valid for (5.4). From $\widehat{k}_1 = k^{r+1}$ this bound can be extended for all $\widehat{k}_1$ in the interval $[k^{r+1}, k^{r+2}]$, since $\lambda(\widehat{k}_1)$ has Lipschitz constant bounded by $1/h_0$. Consequently,

$$|\lambda(k_1)| + |(1 - \lambda(k_1)) - \lambda(\widehat{k}_1)| + |1 - \lambda(\widehat{k}_1)| \leq \frac{2|k_1 - \widehat{k}_1|}{h_0}.$$

Therefore, in all cases the stated result holds true for (k_0^j, z_0^i), and (k_0^j, z_0^i) is an arbitrarily chosen vertex point.

The proof in the multidimensional case is very similar. Let us assume that the domain K is subdivided into a family of simplices $\{S^j\}$ such that $\bigcup_j S^j = K$ and $\text{int}(S^i) \cap \text{int}(S^j) = \varnothing$ for every pair S^i, S^j. Then, every point k in S^j has a unique representation as a convex combination of the vertex points, $k = \sum_{j=1}^{\ell+1} \lambda_j k_0^j$. Moreover, every λ_j is a Lipschitz function on K, and we can find a uniform Lipschitz constant that applies for all λ_j. Therefore, given any pair of points $k_1 = g(k_0^j, z_0^i)$ and $\widehat{k}_1 = \widehat{g}(k_0^j, z_0^i)$, the proof proceeds in the same way as above. □

PROPOSITION 5.2. *Let $\{V_n^h(k,z)\}_{n\geq 1}$ be a sequence of functions generated by* (4.4)–(4.5)*, and assume that every function V_n^h is concave in k. Let $\{g_n^h\}_{n\geq 1}$ be the corresponding sequence of policy functions. Then, under Assumptions* 1 *and* 2 *there exists a constant L such that for any pair of functions V_n^h, V_{n+1}^h, it must hold that $\|P_{g_n^h} - P_{g_{n+1}^h}\| \leq L\|V_n^h - V_{n+1}^h\|^{1/2}$.*

Proof. First, the contraction property of operator T^h implies that

$$\left\|v_{g_n^h} + \beta P_{g_n^h} V_n^h - v_{g_{n+1}^h} - \beta P_{g_{n+1}^h} V_{n+1}^h\right\| \leq \beta \left\|V_n^h - V_{n+1}^h\right\|.$$

Moreover, by (4.3) and (4.7), we have $\|\beta P_{g_{n+1}^h} V_n^h - \beta P_{g_{n+1}^h} V_{n+1}^h\| \leq \beta\|V_n^h - V_{n+1}^h\|$. Hence, an application of the triangle inequality yields

$$\left\|v_{g_n^h} + \beta P_{g_n^h} V_n^h - v_{g_{n+1}^h} - \beta P_{g_{n+1}^h} V_n^h\right\| \leq 2\beta \left\|V_n^h - V_{n+1}^h\right\|. \tag{5.5}$$

Now, as is well known (e.g., see Lemma 3.2 of Santos (2000)) by the concavity of V_n^h in k, the convexity of Ω, and the postulated concavity of v in Assumption 2, we can assert from (5.5) that

$$\left\|g_n^h - g_{n+1}^h\right\| \leq 2\left(\frac{\beta}{\eta}\right)^{1/2} \left\|V_n^h - V_{n+1}^h\right\|^{1/2}. \tag{5.6}$$

Therefore, a straightforward application of Lemma 5.1 proves the result for $L = 2\frac{\kappa}{h}(\frac{\beta}{\eta})^{1/2}$. □

It should be stressed that in the preceding proof only one value function V_n^h needs to be concave. Hence, the following result is an easy consequence of the previous arguments.

COROLLARY 5.3. *Let V^h be the fixed point of the discretized Bellman equation* (4.12)*, and assume that $V^h(k,z)$ is a concave function in k. Let $\{V_n^h\}_{n\geq 1}$ be a sequence of (not necessarily concave) functions generated by* (4.4)–(4.5)*. Then, under*

Assumptions 1 *and* 2, *there exists a constant* L *such that*

$$\left\|P_{g^h} - P_{g_n^h}\right\| \leq L \left\|V^h - V_n^h\right\|^{1/2} \quad \textit{for all } n.$$

Remark 5.4. Observe that for $\ell = 1$ the fixed-point solution $V^h(k,z)$ is in fact a concave function in k. Indeed, for $\ell = 1$ the concavity of $V^h(k,z)$ can be established by the method of successive approximations.

Remark 5.5. Note that in Corollary 5.3 operator $P_{g_n^h}$ is not necessarily unique, since there may not be a unique set of maximizers g_n^h. But the result holds true for any $P_{g_n^h}$, and the distance between two optimal policies must be arbitrarily small for a large enough n.

All the basic ingredients are now in place to demonstrate that the algorithm displays a convergence rate equal to 1.5 (cf. Puterman and Brumelle (1979)).

THEOREM 5.6. *Assume that the conditions of Proposition* 5.2 *are satisfied. Then*

$$\left\|V_{n+1}^h - V_n^h\right\| \leq \frac{\beta L}{1-\beta} \left\|V_n^h - V_{n-1}^h\right\|^{1.5} \quad \textit{for all } n.$$

Proof. First, for any two functions V_n^h and V_{n-1}^h we must have (see (4.11))

$$B^h(V_{n-1}^h) - B^h(V_n^h) \geq -[I - \beta P_{g_n^h}][V_{n-1}^h - V_n^h]. \tag{5.7}$$

Moreover, a further application of (5.7) yields

$$\begin{aligned} B^h(V_n^h) - [I - \beta P_{g_n^h}][V_{n-1}^h - V_n^h] &\leq B^h(V_{n-1}^h) \\ &\leq B^h(V_n^h) - [I - \beta P_{g_{n-1}^h}][V_{n-1}^h - V_n^h]. \end{aligned}$$

Now, subtracting $B^h(V_n^h) - [I - \beta P_{g_n^h}][V_{n-1}^h - V_n^h]$ from each of the three terms, we obtain

$$\begin{aligned} 0 &\leq B^h(V_{n-1}^h) - B^h(V_n^h) + [I - \beta P_{g_n^h}][V_{n-1}^h - V_n^h] \\ &\leq ([I - \beta P_{g_n^h}] - [I - \beta P_{g_{n-1}^h}])[V_{n-1}^h - V_n^h]. \end{aligned} \tag{5.8}$$

Then, for any V_{n+1}^h and V_n^h satisfying (4.4)–(4.5) we must have

$$\begin{aligned} \left\|V_{n+1}^h - V_n^h\right\| &= \left\|[I - \beta P_{g_n^h}]^{-1} B^h(V_n^h)\right\| \\ &\leq \left\|[I - \beta P_{g_n^h}]^{-1}\right\| \left\|B^h(V_n^h)\right\| \\ &= \left\|[I - \beta P_{g_n^h}]^{-1}\right\| \left\|B^h(V_n^h) - B^h(V_{n-1}^h) + [I - \beta P_{g_{n-1}^h}][V_n^h - V_{n-1}^h]\right\| \\ &\leq \left\|[I - \beta P_{g_n^h}]^{-1}\right\| \left\|([I - \beta P_{g_n^h}] - [I - \beta P_{g_{n-1}^h}])[V_n^h - V_{n-1}^h]\right\|. \end{aligned} \tag{5.9}$$

Here, both equalities come from (4.10). Also, the first inequality follows from the definition of the norm, and the last inequality is a consequence of (5.8).

Therefore, from (5.9) we obtain

$$\left\|V_{n+1}^h - V_n^h\right\| \leq \left\|[I - \beta P_{g_n^h}]^{-1}\right\| \left\|[I - \beta P_{g_n^h}] - [I - \beta P_{g_{n-1}^h}]\right\| \left\|V_n^h - V_{n-1}^h\right\|. \tag{5.10}$$

Finally, Proposition 5.2 together with (5.10) implies that

$$\left\|V_{n+1}^h - V_n^h\right\| \leq \frac{\beta L}{1-\beta} \left\|V_n^h - V_{n-1}^h\right\|^{1.5}. \qquad \square$$

THEOREM 5.7. *Assume that the conditions of Corollary* 5.3 *are satisfied. Then,*

$$\left\|V^h - V^h_{n+1}\right\| \leq \frac{\beta L}{1-\beta}\left\|V^h - V^h_n\right\|^{1.5} \quad \textit{for all } n.$$

Proof. From the monotonicity of policy iteration we have $0 \leq V^h - V^h_{n+1}$. Then,

$$\begin{aligned} 0 \leq V^h - V^h_{n+1} &= V^h - V^h_n - [I - \beta P_{g^h_n}]^{-1} B^h(V^h_n) \\ &\leq [I - \beta P_{g^h_n}]^{-1}[I - \beta P_{g^h_n}][V^h - V^h_n] - [I - \beta P_{g^h_n}]^{-1}[I - \beta P_{g^h}][V^h - V^h_n] \\ &= [I - \beta P_{g^h_n}]^{-1}([I - \beta P_{g^h_n}] - [I - \beta P_{g^h}])[V^h - V^h_n]. \end{aligned}$$

Here, the first equality comes from (4.10); the inequality is a consequence of the maximization involved in operator B^h (cf. (4.11)) and the fact that $B^h(V^h) = 0$; and after a simple factorization we get the last equality.

Now, taking norms and applying Proposition 5.2 it follows that

$$\begin{aligned} \left\|V^h - V^h_{n+1}\right\| &\leq \left\|[I - \beta P_{g^h_n}]^{-1}\right\| \left\|[I - \beta P_{g^h_n}] - [I - \beta P_{g^h}]\right\| \left\|V^h - V^h_n\right\| \\ &\leq \frac{\beta L}{1-\beta}\left\|V^h - V^h_n\right\|^{1.5}. \qquad \square \end{aligned}$$

5.2. Local convergence properties. Suitable variations of the preceding arguments will now allow us to establish further convergence properties near the fixed-point solution V^h.

5.2.1. Quadratic convergence. To guarantee the quadratic convergence of policy iteration we need the following strengthening of Corollary 5.3.

PROPOSITION 5.8. *Let V^h be the fixed point of the discretized Bellman equation* (4.12). *Assume that $V^h(k,z)$ is a concave function in k. For each vertex point (k^j_0, z^i_0), assume that $g^h(k^j_0, z^i_0)$ is not a grid point in the family of simplices $\{S^j\}$. Let $\{V^h_n\}_{n\geq 1}$ be a sequence of functions generated by* (4.4)–(4.5). *Then, under Assumptions* 1 *and* 2, *there are constants $\widehat{L}$ and $\widehat{N}$ such that*

$$\left\|P_{g^h} - P_{g^h_n}\right\| \leq \widehat{L}\left\|V^h - V^h_n\right\| \quad \textit{for all } n \geq \widehat{N}.$$

After some obvious adjustments in the power estimates of the proof of Theorem 5.7, we now get the convergence result in Theorem 5.9.

THEOREM 5.9. *Assume that the conditions of Proposition* 5.8 *are satisfied. Then,*

$$\left\|V^h - V^h_{n+1}\right\| \leq \frac{\beta\widehat{L}}{1-\beta}\left\|V^h - V^h_n\right\|^2 \quad \textit{for all } n \geq \widehat{N}.$$

Remark 5.10. One may argue that Theorem 5.9 is a stronger result than Theorem 5.7. But Theorem 5.7 may be of interest for numerical applications[2] as constant L is easier to estimate. Also, note that constant $L = 2\frac{\kappa}{h}(\frac{\beta}{\eta})^{1/2}$ is $O(\frac{1}{h})$, whereas the proof of Proposition 5.8 below reflects that constant $\widehat{L}$ is $O(\frac{1}{h^2})$. Finally, the arguments

[2]For instance, we can define the region of convergence $R_\alpha = \{V \in \mathcal{V}^h | \frac{\beta L}{1-\beta}\|V - V^h\|^{0.5} \leq 1-\alpha\}$, where V^h is the fixed-point solution and $\alpha > 0$. Then, for all V in R_α we can find an upper bound on the number of policy iteration steps that are necessary to reach a certain tolerance level ε.

leading to the proof of Theorem 5.9 are heavily dependent on certain properties of piecewise linear approximations and the assumed interiority of the solution. In contrast, the arguments involved in the proof of Theorem 5.7 seem to be less specific.

Proof of Proposition 5.8. Let every function V^h in $\mathcal{V}^h$ be represented by a finite-dimensional vector u^h that lists all nodal values $\{V^h(k_0^j, z_0^i)\}$. Then, we may rewrite optimization problem (4.12) as follows:

$$\max_{k_1} \ \psi(k_0^j, z_0^i, k_1, u^h) = \max_{k_1} \ v(k_0^j, k_1, z_0^i) + \beta \int_Z V^h(k_1, z') Q(dz', z_0^i) \quad \text{s.t. } (k_0^j, k_1, z_0^i) \in \Omega. \tag{5.11}$$

In what follows, there is no restriction of generality to focus on a single vertex point (k_0^j, z_0^i). The mapping $\psi(k_0^j, z_0^i, \cdot, \cdot)$ has the following properties:

(i) The mapping $\psi(k_0^j, z_0^i, \cdot, \cdot)$ is continuous in (k_1, u).

(ii) For (k_0^j, z_0^i, u^h) function $\psi(k_0^j, z_0^i, k_1, u^h) + \frac{\eta}{2}\|k_1\|^2$ is concave in k_1.

(iii) Let $D_3\psi(k_0^j, z_0^i, k_1, u; v)$ be the directional derivative of function ψ at (k_0^j, z_0^i, k_1, u) with respect to k_1 in the direction v. Let $B_\delta(u^h) = \{u \mid \|u - u^h\| < \delta\}$. Then, for some small $\delta > 0$, and for all $\|v\| = 1$ and all k_1 sufficiently close to $k_1^h = g^h(k_0^j, z_0^i)$, there is a constant $H > 0$ such that $|D_3\psi(k_0^j, z_0^i, k_1, u; v) - D_3\psi(k_0^j, z_0^i, k_1, u^h; v)| \leq H\|u - u^h\|$ for every u in $B_\delta(u^h)$.

The continuity of $\psi(k_0^j, z_0^i, \cdot, \cdot)$ follows from standard arguments. In (ii) the curvature parameter η of Assumption 2 still applies as the fixed-point solution $V^h(k_1, z')$ is assumed to be concave in k_1. The Lipschitz property in (iii) comes from the fact that small changes in the nodal values lead to bounded variations in the slopes or directional derivatives of a piecewise linear function. In fact, for a given choice of norm $\|u - u^h\|$ constant H will depend on the form of the triangulation $\{S^j\}$, especially on $1/h_0$ (where h_0 is the minimum distance between two grid points).

Now, the proof of this proposition will result from some simple extensions of standard arguments[3] (e.g., Fleming and Rishel (1975) (p. 170) and Montrucchio (1987) (p. 263)). For fixed (k_0^j, z_0^i) let k_1^h be the unique maximum point in (5.11) and let $\widehat{k}_1$ be a maximum solution under $\psi(k_0^j, z_0^i, k_1, \widehat{u})$ for $\widehat{u}$ in $B_\delta(u^h)$.

By Assumption 2 and the presupposed concavity of $V^h(k_1, z')$ in k_1, we have

$$\psi(k_0^j, z_0^i, k_1^h, u^h) - \psi(k_0^j, z_0^i, \widehat{k}_1, u^h) \geq -D_3\psi(k_0^j, z_0^i, k_1^h, u^h; \widehat{k}_1 - k_1^h) + \frac{\eta}{2}\|\widehat{k}_1 - k_1^h\|^2. \tag{5.12}$$

Since the objective reaches the maximum value at k_1^h, the directional derivative in (5.12) is nonpositive. Moreover, concave and piecewise linear functions in $\mathbb{R}^\ell$ are absolutely continuous. Hence, we can apply the integral form of the mean-value theorem to the left-hand side of (5.12) so as to obtain

$$-\int_0^1 D_3\psi(\Phi_1(\lambda))d\lambda \geq \frac{\eta}{2}\|\widehat{k}_1 - k_1^h\|^2 \tag{5.13}$$

for $\Phi_1(\lambda) = (k_0^j, z_0^i, k_1^h + \lambda(\widehat{k}_1 - k_1^h), u^h; \widehat{k}_1 - k_1^h)$.

[3]The added difficulty in the proof is that concavity in k_1 is assumed only at point $u = u^h$; i.e., see property (ii) above.

Also, by definition, $\psi(k_0^j, z_0^i, \widehat{k}_1, \widehat{u}) - \psi(k_0^j, z_0^i, k_1^h, \widehat{u}) \geq 0$. Hence,

$$\int_0^1 D_3\psi(\Phi_2(\lambda))d\lambda \geq 0 \tag{5.14}$$

for $\Phi_2(\lambda) = (k_0^j, z_0^i, k_1^h + \lambda(\widehat{k}_1 - k_1^h), \widehat{u}; \widehat{k}_1 - k_1^h)$. Adding up inequalities (5.13)–(5.14), we get

$$-\int_0^1 [D_3\psi(\Phi_1(\lambda)) - D_3\psi(\Phi_2(\lambda))]d\lambda \geq \frac{\eta}{2}\|\widehat{k}_1 - k_1^h\|^2. \tag{5.15}$$

By (iii) above,

$$\int_0^1 |D_3\psi(\Phi_1(\lambda)) - D_3\psi(\Phi_2(\lambda))|d\lambda \leq H\|\widehat{u} - u^h\|\|\widehat{k}_1 - k_1^h\|. \tag{5.16}$$

Therefore, (5.15)–(5.16) implies

$$\|\widehat{k}_1 - k_1^h\| \leq \frac{2H}{\eta}\|\widehat{u} - u^h\|. \tag{5.17}$$

Finally, a straightforward application of Lemma 5.1 establishes Proposition 5.8 for $\widehat{L} = \frac{\kappa}{h}\frac{2H}{\eta}$. □

5.2.2. Superlinear convergence. In this part we lift the convexity and concavity conditions. Hence, we just assume that Ω is the graph of a continuous correspondence $\Gamma : K \times Z \to K$ defined on compact set $K \times Z$ and the reward function v is a continuous mapping on Ω.

Even though we are not able to guarantee quadratic convergence for the iteration scheme, we shall establish the intermediate property of superlinear convergence. This is a faster rate of convergence than that of the method of successive approximations, where by the contraction property of the dynamic programming operator one easily shows that

$$\|V^h - V_{n+1}^h\| \leq \beta\|V^h - V_n^h\| \tag{5.18}$$

for all $n \geq 1$, for every sequence $\{V_n^h\}_{n\geq 1}$ generated by (4.13).

PROPOSITION 5.11. *Let $\{V_n^h\}_{n\geq 1}$ be a sequence of functions generated by* (4.4)–(4.5) *that converge to the fixed point V^h. Then, for every $\epsilon > 0$ there is $\widehat{n}$ such that for each $P_{g_n^h}$ with $n \geq \widehat{n}$ there exists some P_{g^h} with the property that $\|P_{g_n^h} - P_{g^h}\| \leq \epsilon$.*

What this result states is that the correspondence of maximizers is upper-semicontinuous. Hence, for every $P_{g_n^h}$ one can find an arbitrarily close P_{g^h}, provided that n is sufficiently large. With Proposition 5.11 at hand, from the proof of Theorem 5.7 one can easily obtain the following result.

THEOREM 5.12. *Assume that the conditions of Proposition* 5.11 *are satisfied. Then,*

$$\limsup_{n\to\infty} \frac{\|V^h - V_{n+1}^h\|}{\|V^h - V_n^h\|} = 0. \tag{5.19}$$

6. Numerical experiments. In this section we report some simple numerical experiments which are intended to evaluate the performance of policy iteration and the method of successive approximations. The analysis centers on a one-sector deterministic growth model with leisure, and the main purpose is to evaluate the computing cost and approximation errors of the value and policy functions under each computational method.

Formally, our one-sector growth model is described by the following optimization problem:

$$
\begin{aligned}
V(k_0) = \max_{\{c_t, l_t, i_t\}} & \sum_{t=0}^{\infty} \beta^t [\lambda \log c_t + (1-\lambda)\log l_t] \\
\text{s.t. } & c_t + i_t = A k_t^{\alpha} (1-l_t)^{1-\alpha}, \\
& k_{t+1} = i_t + (1-\delta) k_t, \\
& k_t, c_t \geq 0,\ 0 \leq l_t \leq 1,\ k_0 \text{ given},\ t = 0, 1, 2, \ldots, \\
& 0 < \beta < 1,\ 0 < \lambda < 1,\ A > 0, \\
& 0 < \alpha < 1,\ 0 < \delta \leq 1.
\end{aligned} \tag{6.1}
$$

This is a familiar optimization problem in which c represents consumption, k represents the stock of physical capital, and l the fraction of time devoted to leisure activities. It is well known that for $\delta = 1$ the value function $V(k_0)$ takes the simple form $V(k_0) = B + C \log k_0$, where B is a certain constant and $C = \frac{\lambda\alpha}{(1-\alpha\beta)}$. Also, the policy function $k_{t+1} = \alpha\beta A k_t^{\alpha}(1-l_t)^{1-\alpha}$ with $l_t = \frac{(1-\lambda)(1-\alpha\beta)}{\lambda(1-\alpha)+(1-\lambda)(1-\alpha\beta)}$. Under these simple functional forms, there is a unique steady state $k^* = g(k^*)$, which is globally stable.

The existence of one state variable, k, and two controls, l and c, suggests that all numerical maximizations may be efficiently carried out with a unique decision variable. Let us then write the model in a more suitable form for our computations. Note that at time $t = 0$ the first-order conditions for our two control variables c and l are given by

$$
\frac{\lambda}{c_0} = \mu \qquad \text{and} \qquad \frac{(1-\lambda)(1-l_0)^{\alpha}}{l_0 A k_0^{\alpha}(1-\alpha)} = \mu,
$$

where μ is a Lagrange multiplier. After some simple rearrangements, we obtain

$$
c_0 = \frac{\lambda l_0 A k_0^{\alpha}(1-\alpha)}{(1-\lambda)(1-l_0)^{\alpha}}.
$$

Hence,

$$
k_1 = A k_0^{\alpha}(1-l_0)^{-\alpha}\left[(1-l_0) - \frac{\lambda l_0(1-\alpha)}{1-\lambda}\right].
$$

The iterative process $V_{n+1}^h = T^h(V_n^h)$ in (4.13) is then effected as follows:

$$
\begin{aligned}
V_{n+1}^h(k_0) = \max_{l_0} & \lambda \log\left(\frac{\lambda A k_0^{\alpha} l_0(1-\alpha)}{(1-\lambda)(1-l_0)^{\alpha}}\right) + (1-\lambda)\log l_0 \\
& + \beta V_n^h\left(A k_0^{\alpha}(1-l_0)^{-\alpha}\left[(1-l_0) - \frac{\lambda l_0(1-\alpha)}{1-\lambda}\right]\right).
\end{aligned} \tag{6.2}
$$

Although expression (6.2) may appear rather cumbersome, this form will prove appropriate for our computations as it involves maximization only in one single variable.

Our numerical exercises will focus on the following parameterization:

$$\beta = 0.95, \qquad \lambda = \frac{1}{3}, \qquad A = 10, \qquad \alpha = 0.34, \qquad \delta = 1.$$

For such values the stationary state is $k^* = 1.9696$.

We consider a uniform grid of points k^j with step size h. For the purposes of this exercise, the domain of possible capitals is restricted to the interval $[h, 10]$. We should remark that in this simple univariate case our interpolations will yield concave value functions $\{V_n^h\}_{n\geq 1}$ for the method of successive approximations, but the sequence of functions $\{V_n^h\}_{n\geq 1}$ may not be concave under policy iteration, since each V_n^h must solve the equation system (4.5) for a given g_{n-1}^h.

Our numerical computations were coded in standard C and run on a Silicon Graphics Octane 2 (with a dual processor, each component rated at 600 MHz), which in a double precision floating-point arithmetic allows for a 16-digit accuracy. All required numerical maximizations were effected by Brent's algorithm (cf. Press et al. (1992)) with an accuracy of 10^{-12}. Such a high precision should allow us to trace out the errors derived from other discretizations embedded in our algorithms. Also, for both policy iteration and the method of successive approximations the iteration process will stop once two consecutive value functions V_n^h and V_{n+1}^h satisfy the tolerance bound

$$\left\|V_n^h - V_{n+1}^h\right\| \leq \frac{1}{5}h^2. \tag{6.3}$$

The adequacy of this stopping rule for the method of successive approximations is discussed in Santos (1999). Roughly, constant $\frac{1}{5}h^2$ is selected so as to balance the approximation error from the use of a finite grid of points and the truncation error from stopping the iteration process in finite time.

For the method of successive approximations as specified in (6.2), we start each numerical exercise with a given grid size h and initial condition $V_0 \equiv 0$. The program then stops once condition (6.3) is satisfied. For each h, Table 6.1 reports the number of iterations, computing time, and the maximum observed errors in the last iteration for the value and policy functions.[4] For policy iteration, we follow the procedure specified in (4.4)–(4.5); for each h the iteration process starts with an initial condition $V_0 \equiv 0$, and it stops once condition (6.3) is satisfied. These findings are displayed in Table 6.2.

From the calculations reflected in Tables 6.1 and 6.2, we now discuss the computational cost and speed of convergence of these two algorithms.

(a) *Complexity.* As one can determine from Table 6.1, for $h = 10^{-1}$ the average time cost per iteration is roughly 0.017 seconds, and for $h = 10^{-2}$ the average time cost per iteration is roughly 0.17 seconds. Hence, for the method of successive approximations the average time cost per iteration grows linearly with the number of grid points. (This regular pattern is also observed for pairwise comparisons of other grid sizes.) To a certain extent, this result is to be expected since the major computational cost in each iteration is the number of maximizations, which grows linearly with the number of grid points. (Incidentally, this exercise shows that the cost of each maximization remains roughly invariant to the grid size.) In contrast, for policy iteration

[4]These values are defined, respectively, by $\|V - V_n^h\|$ and $\|g - g_n^h\|$, where V and g are the closed-form solutions for (6.1), and V_n^h and g_n^h are the computed value and policy functions corresponding to the last iteration, n, under a grid size h.

TABLE 6.2
Computational method: Policy iteration with linear interpolation.[b]

No. of vertex points	Mesh size h	Iterations	CPU time	Constant $\widehat{\mathcal{L}}^h$	Max. error in V	Max. error in g
100	1.00×10^{-1}	4	0.11	27.35	4.36×10^{-2}	6.136×10^{-2}
300	3.33×10^{-2}	5	2.54	1629.63	8.47×10^{-4}	2.264×10^{-2}
1000	1.00×10^{-2}	7	215.93	19816.63	8.51×10^{-6}	7.160×10^{-3}
3000	3.33×10^{-3}	10	16868.33	78308.85	1.35×10^{-6}	2.400×10^{-3}

[b]Parameter values: $\beta = 0.95$, $\lambda = \frac{1}{3}$, $A = 10$, $\alpha = 0.34$, and $\delta = 1$.

we can see from Table 6.2 that for $h = 10^{-1}$ the average time cost per iteration is roughly 0.03 seconds, whereas for $h = 10^{-2}$ the average time cost per iteration goes up to about 31 seconds. Hence, for policy iteration an increase in the number of grid points by a factor of 10 leads to an increase in the average time cost by over a factor of 10^3. Again, this result is to be expected since the most complicated step in policy iteration is (4.5), which involves a matrix inversion. This simple complexity analysis illustrates that policy iteration is faster for small grids, but it becomes relatively more costly for fine grids, unless further operational procedures are introduced for the matrix inversion required in (4.5). Under our present methods, it is extremely costly to go beyond grids of 3000 points for policy iteration, whereas we can carry out the method of successive approximations over grids of about 50000 points.

(b) *Convergence.* It is well known that the dynamic programming algorithm approaches the fixed-point solution at a linear rate, and this has been observed in many applications. In order to evaluate the quadratic convergence of policy iteration, we have computed the corresponding constant

$$\widehat{\mathcal{L}}_n^h = \frac{\left\|V_{\widehat{n}}^h - V_{n+1}^h\right\|}{\left\|V_{\widehat{n}}^h - V_n^h\right\|^2},$$

where $V_{\widehat{n}}^h$ is the value function of an arbitrarily high iteration, $\widehat{n}$, so that $V_{\widehat{n}}^h$ is a good approximation of the fixed point V^h (cf. Theorem 5.9). For each h, in Table 6.2 we report the max value, $\widehat{\mathcal{L}}^h = \max_n \widehat{\mathcal{L}}_n^h$. This constant takes on relatively high values, and it seems to grow as predicted by our analysis. Indeed, from the previous section (cf. Remark 5.10) we may conclude that our worst-case theoretical bounding constant $\widehat{\mathcal{L}} = \frac{\beta\widehat{L}}{1-\beta}$ is at least $O(\frac{1}{h^2})$, which appears to be in line with the observed estimates. The quadratic convergence near the fixed-point solution was further confirmed by a

TABLE 6.3

detailed analysis of the evolution of the errors $\|V_{\widehat{n}}^h - V_n^h\|$. For the sake of brevity, these results are not reported here.

It may seem paradoxical that the number of required iterations in Table 6.2 does not vary greatly with the grid size. But one could argue that stopping rule (6.3) is suitable for the method of successive approximations, which features a linear rate of convergence, but such a stopping rule is not so sensitive for algorithms displaying faster rates of convergence. The insensitivity on the number of policy steps was also observed as we varied the discount factor. Variations in β were reflected in changes in the above constant $\widehat{\mathcal{L}}^h$, but the number of required policy iterations was always below 20. For the method of successive approximations, however, the required number of iterations changes substantially with variations in the discount factor. For instance, in Table 6.3 the discount factor is increased from $\beta = 0.95$ to $\beta = 0.99$. Then, as compared to Table 6.1, the number of required iterations and the corresponding computational cost go up by a factor of 5.

As one can see, the bounding constant $\widehat{\mathcal{L}} = \frac{\beta \widehat{L}}{1-\beta}$ of Theorem 5.9 varies inversely with the discount factor β. A related type of dependence under (6.3) can be established for the bounding constant in the method of successive approximations (see (5.18)). But convergence is linear for the method of successive approximations, and hence changes in the bounding constant should necessarily be reflected in changes of the same magnitude in the number of iteration. Policy iteration, however, displays a faster convergence rate. Thus, for changes in the discount factor and corresponding bounding constant, the extra required iteration steps should be of a smaller order of magnitude. Therefore, quadratic convergence seems to be driving the insensitivity of the required number of policy iteration steps under this algorithm for changes in the grid size of the discretization and the discount factor. This does not mean that it is possible to bound the required number of policy iteration steps regardless of the discount factor or the mesh level of the discretization. Indeed, this paper shows that the theoretical constants involved in the orders of convergence get unbounded as the grid size of the discretization converges to zero.

7. Concluding remarks. This paper provides new convergence results on the policy iteration algorithm. Our work is motivated by the fact that this algorithm usually converges in a small number of steps (typically fewer than 20) even though the number of feasible policies that the policy iteration algorithm could evaluate is huge and increases exponentially fast with the number of states and possible actions. Unfortunately, in section 2 we presented an example of an MDP problem in which the number of iteration steps grows equally with the number of states, thus dispelling

the hope of proving a general result that only a small number of policy iteration steps will be necessary to solve an MDP problem.

We then focused on the observation that policy iteration is equivalent to Newton's method and thus ought to have quadratic rates of convergence. This equivalence holds even for MDP problems where the state and action spaces are no longer finite sets. This very rapid rate of convergence suggests that policy iteration could dominate the method of successive approximations, at least for discount factors β close to 1. A standard sufficient condition used to establish quadratic convergence is that the derivative of the nonlinear operator defining the system of equations to be solved by Newton's method (which in the case of policy iteration equals the identity minus the derivative of the Bellman operator) satisfies a Lipschitz condition. In the original work of Puterman and Brumelle (1979) this Lipschitz condition was assumed to hold globally, but they did not provide easily verifiable primitive conditions under which this Lipschitz bound could be satisfied. As a result, an open question remains: Under what conditions and for which classes of MDP problems might we obtain quadratic convergence rates for policy iteration?

This paper attempts to address this question by considering a relatively narrow class of dynamic models arising in economic growth theory. This class involves continuous state and control variables, and thus some sort of discretization procedure must be used to implement policy iteration in practical situations. The key Lipschitz condition that guarantees quadratic convergence is shown to hold for piecewise linear interpolation under a concavity assumption at the optimal interior solution, and it may be extended to other approximation schemes. But we also demonstrate that a weaker general bound does hold that involves the *square root* of the maximum absolute difference in the value function from the fixed-point solution. To establish that this weaker bound holds globally, we have imposed a concavity condition on both the return function and the fixed-point solution which are defined on a convex domain of state and control variables. Under this concavity assumption, we were able to prove a global result for the policy iteration algorithm of superlinear convergence with an exponent equal to 1.5. Furthermore, the best bounding constant on the errors of our algorithm is inversely proportional to the grid size h of the discretization of the state space. These results suggest the following two pessimistic conclusions about policy iteration: (1) As h goes to zero, not only will the number of states in the approximate MDP problem tend to infinity, but the theoretical convergence bounds (and possibly the number of policy iteration steps) will also tend to infinity as well. (2) Policy iteration will not converge globally at a rapid quadratic rate; quadratic convergence was validated under the concavity assumption and piecewise interpolation, but the general rate of convergence is expected to be superlinear.

Section 6 reported the results of some numerical experiments in which these theoretical results were verified. We corroborated the quadratic convergence of the algorithm, and that the bounding constants evolved as predicted by our analysis. As a result of the computational cost involved in finding the solution in each policy iteration step, our numerical experiments illustrated that for very fine grids policy iteration is substantially slower than simple successive approximations. Thus, our results provide a rather pessimistic perspective on the usefulness of policy iteration for solving large-scale MDP problems. Fine discretizations with large numbers of states are required to approximate the solutions accurately in most applications in economics and engineering. Other studies (see Benitez-Silva et al. (2001)) have suggested that an alternative type of policy iteration known as *parametric policy iteration* can be more effective for solving such large continuous-state MDP problems. Relatively little is

known, however, about the convergence properties of this latter algorithm. In fact, the results of this paper suggest that there is still much to be learned about the convergence properties of the standard policy iteration algorithm.

POLE ASSIGNMENT FOR A VIBRATING SYSTEM WITH AERODYNAMIC EFFECT*

J. N. WANG†, S. H. CHOU‡, Y. C. CHEN§, AND W. W. LIN§

Abstract. This paper deals with a pole assignment problem by single-input state feedback control arising from a one-dimensional vibrating system with aerodynamic effect. On the practical side, we derive explicit formulae for the required controlling force terms, which can reassign part of the spectrum to the desired values while leaving the remaining spectrum unchanged. On the mathematical side, unlike the classical Sturm–Liouville problem, our eigenvalue problem is associated with a cubic pencil with unbounded operators as coefficients and has many interesting new features, one of which is that a new controllability condition appears. This condition together with the known controllability condition in the quadratic case are necessary and sufficient. This sheds light on the adjustment of the model parameters. We also analyze the spectrum of the associated noncompact operator and in particular show that the discrete spectrums of controlled and uncontrolled systems lie outside a closed interval on the negative real axis.

Key words. vibrating system, aerodynamic effect, state feedback control, pole assignment

AMS subject classifications. 93B55, 93B52

DOI. 10.1137/S0363012902411568

1. Introduction.

Consider a vibrating system whose displacement $u = u(x,t)$ is governed by the initial boundary value problem

$$\begin{aligned} &\partial_x[p_1(x)\partial_x u + p_2(x)\mathcal{W}(\partial_x u)] - q(x)\partial_t^2 u = 0, \qquad 0 < x < L,\ t > 0, \\ &u(0,t) = u(L,t) = 0 \end{aligned} \tag{1.1}$$

with proper initial conditions, where $p_1(x)$, $p_2(x)$, and $q(x)$ are real-valued positive functions, and $\mathcal{W}$ is an integral operator defined by

$$\mathcal{W}v(x,t) = \rho v + \rho \int_0^t e^{\omega(t-s)} v(x,s)ds \tag{1.2}$$

for any complex-valued function $v : [0,L] \times [0,\infty) \to \mathbb{C}$, where $\rho \neq 0$ and $\omega \neq 0$ are real constants. The function $\mathcal{W}(\partial_x u)$ is called the Wagner lift-growth buildup function accounting for some dynamic effect. If $\mathcal{W}$ is zero, we recover the familiar lateral vibrating string or longitudinal vibrating rod case, depending on the boundary conditions. The more general nonzero case, i.e., the vibrating system with aerodynamic effect incorporated, has its origin in a dynamic loads analysis system (DYLOFLEX) [1].

Applying (1.2) to (1.1) with $v = \partial_x u$, multiplying (1.1) by $e^{-\omega t}$, and then differentiating with respect to t, we obtain the third order differential system

$$\begin{aligned} &\partial_x(\alpha(x)\partial_x u) + \partial_x(\beta(x)\partial_x\partial_t u) + \omega q(x)\partial_t^2 u - q(x)\partial_t^3 u = 0, \\ &u(0,t) = u(L,t) = 0, \end{aligned} \tag{1.3}$$

where

$$\begin{aligned} \alpha(x) &= (1-\omega)\rho p_2(x) - \omega p_1(x), \\ \beta(x) &= p_1(x) + \rho p_2(x). \end{aligned} \tag{1.4}$$

To look for vibration modes, we substitute the form $u(x,t) = \phi(x)e^{\lambda t}, \lambda \in \mathbb{C}$, into (1.3) and obtain the eigenvalue problem

$$\begin{aligned} &\mathcal{L}(x, D, \lambda)\phi := (\alpha(x)\phi')' + \lambda(\beta(x)\phi')' + \lambda^2\omega q(x)\phi - \lambda^3 q(x)\phi = 0, \\ &\phi(0) = \phi(L) = 0, \end{aligned} \tag{1.5}$$

where $D = ' = \frac{d}{dx}$. Unlike the classical Sturm–Liouville eigenvalue problem, this problem is cubic in λ. To the best of our knowledge we have not seen such a formulation before. The main purpose of this paper is to study the pole assignment associated with this problem, using the state feedback control function $b(x)$. Namely, we look at the controlled system

$$\begin{aligned} &\partial_x[p_1(x)\partial_x v + p_2(x)\mathcal{W}(\partial_x v)] - q(x)\partial_t^2 v = b(x)w(t), \qquad 0 < x < L,\ t > 0, \\ &v(0,t) = v(L,t) = 0, \end{aligned} \tag{1.6}$$

where the feedback control force $w(t)$ has the form

$$w(t) = \int_0^L [f_1(x)\partial_t v(x,t) + f_2(x)v(x,t) + g_1(x)\tilde{\mathcal{W}}(\partial_x v)(x,t) + g_2(x)\tilde{\mathcal{W}}(v)(x,t)]dx$$

with

$$\tilde{\mathcal{W}}(v)(x,t) = \rho \int_0^t e^{\omega(t-s)} v(x,s)ds. \tag{1.7}$$

Note that here the first term ρv in the definition (1.2) has been absorbed into the first two terms on the right side of (1.7). Now substitution of $v(x,t) = \psi(x)e^{\lambda t}$ as done previously yields the eigenvalue problem associated with the controlled problem:

$$\begin{aligned} \mathcal{L}_c(x, D, \lambda)\psi &:= (\alpha(x)\psi')' + \lambda(\beta(x)\psi')' + \lambda^2\omega q(x)\psi - \lambda^3 q(x)\psi \\ &\quad - b\int_0^L \lambda(\lambda f_1 + f_2)\psi - \omega(\lambda f_1 + f_2)\psi + \rho g_1\psi' + \rho g_2\psi dx = 0, \\ \psi(0,t) &= \psi(L,t) = 0. \end{aligned} \tag{1.8}$$

From now on, we write $\mathcal{L}$ or $\mathcal{L}(\lambda)$ for $\mathcal{L}(x, D, \lambda)$ when no confusion can arise. Similar notation is also used for $\mathcal{L}_c(x, D, \lambda)$. Before investigating the pole assignment problem for (1.1), we first analyze its spectrum structure. Let the function $\alpha(x)$ in (1.4) be continuously differentiable and $\alpha(x) \neq 0$ for all x in the interval $[0, L]$. For definiteness, we assume that α is positive throughout the whole interval. The function $\beta = \beta(x) > 0$ is continuously differentiable. Then it is shown using the analytic Fredholm theorem [13] (cf. Theorem 3.3 and Remark 3.1) that the operator pencil $\mathcal{L}$ has only discrete spectrum in $\mathbb{C} \setminus E := E^c$, where

$$E := \left[-\max_{0\le x\le L} \frac{\alpha(x)}{\beta(x)}, -\min_{0\le x\le L} \frac{\alpha(x)}{\beta(x)} \right]. \tag{1.9}$$

Since the interval E lies in the negative real axis, we are mainly concerned with relocating discrete spectrum or poles of (1.5) in $E^c \setminus (-\infty, 0)$. More precisely, let the discrete spectrum of $\mathcal{L}$ in E^c be $\{\lambda_1, \dots, \lambda_\ell, \lambda_{\ell+1}, \dots\}$ and the first ℓ poles $\{\lambda_1, \dots, \lambda_\ell\}$ be distinct, closed under complex conjugation, and furthermore $\{\lambda_1, \dots, \lambda_\ell\} \cap \{\lambda_{\ell+1}, \dots\} = \emptyset$. Our goal is to replace $\{\lambda_1, \dots, \lambda_\ell\}$ by $\{\mu_1, \dots, \mu_\ell\}$, which is a conjugate set of distinct complex values in E^c, with $\{\mu_1, \dots, \mu_\ell\} \cap \{\lambda_1, \lambda_2, \dots\} = \emptyset$. It turns out under suitable *controllability conditions* that we can find explicitly the functions f_1, f_2, g_1, and g_2 so that $\{\lambda_1, \dots, \lambda_\ell\}$ are replaced by $\{\mu_1, \dots, \mu_\ell\}$ and other poles $\{\lambda_{\ell+1}, \lambda_{\ell+2}, \dots\}$ remain unchanged. In Theorem 4.1, the reader can find the following formulae for the above functions with ϕ_j being the eigenfunction:

$$f_1(x) = q \sum_{j=1}^{\ell} \xi_j \phi_j,$$

$$f_2(x) = q \sum_{j=1}^{\ell} \xi_j \lambda_j \phi_j,$$

$$g_1(x) = \left(\frac{\beta}{\rho}\right) \sum_{j=1}^{\ell} \xi_j \phi_j',$$

$$g_2(x) = \left(\frac{q}{\rho}\right) \sum_{j=1}^{\ell} \xi_j \lambda_j^2 \phi_j,$$

where

$$\xi_j = \frac{\lambda_j - \mu_j}{\int_0^L b\phi_j dx} \prod_{r=1,\, r\neq j}^{\ell} \frac{\lambda_j - \mu_r}{\lambda_j - \lambda_r}$$

and

$$\int_0^L b\phi_j \neq 0 \tag{1.10}$$

for $j = 1, 2, \dots, \ell$. Note that (1.10) can be seen as a continuous version of the usual controllability condition in the matrix (discrete) case (see, for example, [3]). However, unlike the matrix case, (1.10) alone does not guarantee that λ_j is a controllable mode. As a matter of fact, for the continuous case, we need to define an additional controllability condition

$$(3\lambda_j^2 - 2\omega\lambda_j) \int_0^L q(x)\phi_j(x)\phi_j(x)dx + \int_0^L \beta(x)\phi_j'(x)\phi_j'(x)dx \neq 0 \tag{1.11}$$

for any $1 \leq j \leq \ell$. With the help of the two controllability conditions (1.10) and (1.11), we show in Theorem 4.2 that outside E no extra discrete spectrum of $\mathcal{L}_c$ are generated except those poled. That is, the discrete spectrum of $\mathcal{L}_c$ in E^c is precisely described by $\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\}$. To further refine the answer to the pole assignment problem for (1.1), we also prove that the essential spectrum of $\mathcal{L}_c$ is identical to that of $\mathcal{L}$, i.e., the essential spectrum of $\mathcal{L}$ does not change in the course of state feedback control. This property is, roughly, due to the fact that $\mathcal{L}_c$ is a compact perturbation of $\mathcal{L}$. Finally, in order for the controlled system to be realizable, the functions f_1, f_2, g_1, and g_2 need to be real, which is shown in Theorem 4.4.

The pole assignment problem, which is concerned with assigning all eigenvalues to desired locations, is a well known and important problem in control theory. It has been extensively studied for the linear system with state or output feedback control. We refer to [16] for the detailed description of this problem and to [2] for the state-of-the-art numerical methods. Our problem here is a variant of the pole assignment problem called the *partial* pole assignment problem, which is concerned with assigning some eigenvalues to desired positions and keeping all other eigenvalues unchanged. The partial pole assignment is more practical than the pole assignment problem, especially for distributed parameter models where we encounter infinitely many eigenvalues. The most studied distributed parameter model in this respect is the vibrating system (see, for example, [10]). The partial pole assignment problem with state feedback control for the usual vibrating distributed parameter system has been considered in [5], [6], [7], [12]. It should be noted that systems in the matrix formulation can be treated as approximations of distributed parameter systems by finite-difference or finite-element methods. In this setting, the problem becomes finite-dimensional.

This paper is partly motivated by the article [12], which considered the partial pole assignment for the vibrating rod without aerodynamic effect ($\mathcal{W} = 0$ in (1.1)). The resulting equation is a standard Sturm–Liouville type. Therefore, the spectrum consists of only the discrete spectrum (i.e., eigenvalues). In [12], an explicit solution to the partial pole assignment problem with suitable state feedback was constructed and the conditions under which this solution is unique were determined. Before [12], by the similar state feedback law, Russell [15] considered the (full) pole assignment for a class of hyperbolic distributed parameter control systems. Another motivation of this paper is the partial pole assignment problem for a discrete version of (1.1) [11]. In [11], we dealt with a cubic matrix pencil rather than an operator pencil. The similar pole assignment problem for the quadratic matrix pencil was studied in [3], [4].

In the presence of aerodynamic effect, the equation in (1.1) is a Volterra integro-differential type. This type of equation also arises in modelling phenomena involving viscoelasticity. Our pole assignment method can be used to stabilize the vibrating system with aerodynamic effect by suitable state feedback control. From the perspective of the stabilization by state feedback control, some related results for Volterra integrodifferential equations were obtained in [8], where the authors considered exponential stabilization of an abstract linear Volterra integrodifferential equation in a Hilbert space

$$u'' = -E_1 A u(t) + E_2 \int_0^t k(t-s) A u(s) ds + f(t)$$

by a state feedback control given as

$$f(t) = -C_0 u(t) - C_1 u'(t),$$

where A is a positive semidefinite self-adjoint unbounded operator, E_1, E_2 are positive constants, and C_0, C_1 are bounded linear operators of finite rank. Here k is a nonnegative, convex, and exponentially decreasing function with finite value at 0. Besides considering a simpler system and having different viewpoints from ours, [8] used techniques from semigroup theory. The similar problem was also considered in [9] with a slightly different system.

2. Elementary properties of the eigensystem. In this section, we will derive some general properties of the eigenstructure of (1.5). In mathematical formalism,

the cubic eigenvalue problem is to find a complex number λ and a complex function ϕ such that

$$\mathcal{L}(\lambda)\phi = 0, \tag{2.1}$$

$$\phi(0) = \phi(L) = 0. \tag{2.2}$$

Assume for the time being that the eigenpairs (2.1) and (2.2) exist and that the eigenmodes are C^1 functions.

THEOREM 2.1 (dimension of eigenspace). *Let λ be an eigenvalue of* (1.5). *Then the dimension of the eigenspace corresponding to λ is one, provided* $(\alpha(x)+\lambda\beta(x)) \neq 0$ *identically.*

Proof. Let $\{\lambda, \phi\}$ and $\{\lambda, \psi\}$ be eigenpairs of the eigenvalue problem (1.5), where ϕ and ψ are smooth. Then we have

$$\mathcal{L}\phi = (\alpha(x)\phi')' + \lambda(\beta(x)\phi')' + \lambda^2\omega q(x)\phi - \lambda^3 q(x)\phi = 0, \tag{2.3}$$

$$\mathcal{L}\psi = (\alpha(x)\psi')' + \lambda(\beta(x)\psi')' + \lambda^2\omega q(x)\psi - \lambda^3 q(x)\psi = 0. \tag{2.4}$$

Subtracting $\phi\mathcal{L}\psi$ from $\psi\mathcal{L}\phi$, we get

$$(\alpha(x)\phi')'\psi + \lambda(\beta(x)\phi')'\psi - (\alpha(x)\psi')'\phi - \lambda(\beta(x)\psi')'\phi = 0,$$

which implies

$$\frac{d}{dx}((\alpha(x) + \lambda\beta(x))(\phi'\psi - \phi\psi')) = 0.$$

Using the boundary conditions, we have

$$(\alpha(x) + \lambda\beta(x))(\phi'\psi - \phi\psi') = 0, \qquad 0 < x < L.$$

Noting that $(\alpha(x) + \lambda\beta(x)) \neq 0$ and ϕ, and that ψ are continuously differentiable, we conclude that the Wronskian

$$\phi'\psi - \phi\psi' = 0,$$

and hence the functions ϕ and ψ are dependent. This implies that the dimension of the eigenspace corresponding to λ is one. ∎

THEOREM 2.2 (orthogonality relation). *Given two complex functions f and g, we define*

$$\langle f, g\rangle := \int_0^L f(x)g(x)dx. \tag{2.5}$$

Let $\{\lambda_m, \phi_m\}$ and $\{\lambda_n, \phi_n\}$ be two distinct eigenpairs, i.e., $\lambda_m \neq \lambda_n$. Then we have the following relation:

$$((\lambda_m^2 + \lambda_m\lambda_n + \lambda_n^2) - \omega(\lambda_m + \lambda_n))\langle q\phi_m, \phi_n\rangle + \langle \beta\phi_m', \phi_n{}'\rangle = 0. \tag{2.6}$$

Proof. Note that

$$\begin{aligned}
\mathcal{L}(\lambda_m)\phi_m &= (\alpha(x)\phi_m')' + \lambda_m(\beta(x)\phi_m')' + \lambda_m^2\omega q(x)\phi_m - \lambda_m^3 q(x)\phi_m = 0,\\
\mathcal{L}(\lambda_n)\phi_n &= (\alpha(x)\phi_n')' + \lambda_n(\beta(x)\phi_n')' + \lambda_n^2\omega q(x)\phi_n - \lambda_n^3 q(x)\phi_n = 0,\\
\phi_m(0) &= \phi_n(0) = \phi_m(L) = \phi_n(L) = 0.
\end{aligned}$$

Then from the fact that

$$\phi_n \mathcal{L}(\lambda_m)\phi_m - \phi_m \mathcal{L}(\lambda_n)\phi_n = 0,$$

we can deduce

$$\begin{aligned}(\alpha(x)\phi_m')'\phi_n + \lambda_m(\beta(x)\phi_m')'\phi_n - (\alpha(x)\phi_n')'\phi_m - \lambda_n(\beta(x)\phi_n')'\phi_m \\ +(\lambda_m^2 - \lambda_n^2)\omega q(x)\phi_m\phi_n - (\lambda_m^3 - \lambda_n^3)q(x)\phi_m\phi_n = 0,\end{aligned} \tag{2.7}$$

or equivalently

$$\begin{aligned}\frac{d}{dx}(\alpha(x)(\phi_m'\phi_n - \phi_n'\phi_m)) + \frac{d}{dx}(\beta(x)(\lambda_m\phi_m'\phi_n - \lambda_n\phi_n'\phi_m)) \\ -(\lambda_m - \lambda_n)\beta(x)\phi_m'\phi_n' + (\lambda_m^2 - \lambda_n^2)\omega q(x)\phi_m\phi_n \\ -(\lambda_m^3 - \lambda_n^3)q(x)\phi_m\phi_n = 0.\end{aligned} \tag{2.8}$$

Now integrating over the interval $[0, L]$ leads to

$$\begin{aligned}\int_0^L \frac{d}{dx}(\alpha(x)(\phi_m'\phi_n - \phi_n'\phi_m))dx + \int_0^L \frac{d}{dx}(\beta(x)(\lambda_m\phi_m'\phi_n - \lambda_n\phi_n'\phi_m))dx \\ - \int_0^L (\lambda_m - \lambda_n)\beta(x)\phi_m'\phi_n'dx + \int_0^L (\lambda_m^2 - \lambda_n^2)\omega q(x)\phi_m\phi_n dx \\ - \int_0^L (\lambda_m^3 - \lambda_n^3)q(x)\phi_m\phi_n dx = 0,\end{aligned} \tag{2.9}$$

which, upon using the boundary conditions and cancelling the nonzero common factor $\lambda_m - \lambda_n$, gives

$$((\lambda_m^2 + \lambda_m\lambda_n + \lambda_n^2) - \omega(\lambda_m + \lambda_n)) \int_0^L q(x)\phi_n\phi_m dx + \int_0^L \beta(x)\phi_m'\phi_n' dx = 0. \qquad \square$$

Note that the product in (2.5) is not really an inner product. Nevertheless we can think of (2.6) as an orthogonality relation for the eigenvalue system (1.5). From the proof we can view it as a generalization of Green's identity in the Sturm–Liouville eigenvalue problem to the present cubic eigenvalue problem.

3. Analysis of the spectrum of $\mathcal{L}$. Let us write down the operator pencil associated with (1.5):

$$\mathcal{L}(x, D, \lambda) = P_0(x, D) + \lambda P_1(x, D) + \lambda^2 P_2(x, D) + \lambda^3 P_3(x, D),$$

where

$$\begin{aligned}P_0(x, D)\phi &= (\alpha(x)\phi')', \\ P_1(x, D)\phi &= (\beta(x)\phi')', \\ P_2(x, D)\phi &= \omega q(x)\phi, \\ P_3(x, D)\phi &= -q(x)\phi.\end{aligned}$$

Recall that $\alpha(x)$ and $\beta(x)$ are positive C^1 functions on the closure of $\Omega := (0, L)$. In this section we want to analyze the spectrum structure of $\mathcal{L}$ as an unbounded operator in $L^2(\Omega)$ with domain $\mathrm{Dom}(\mathcal{L}) := H^2(\Omega) \cap H_0^1(\Omega) \subset L^2(\Omega)$ and range $L^2(\Omega)$. We need a few definitions first.

DEFINITION 3.1. *We say that $\lambda \in r(\mathcal{L})$, the resolvent set of $\mathcal{L}$, if $\mathcal{L}^{-1}(\lambda)$ exists and is bounded on $L^2(\Omega)$.*

DEFINITION 3.2. *The set $\sigma(\mathcal{L}) = \mathbb{C} \setminus r(\mathcal{L})$ is called the spectrum of $\mathcal{L}$. To further classify the spectrum of $\mathcal{L}$, we define $\lambda_0 \in \sigma_{disc}(\mathcal{L})$, the discrete spectrum (eigenvalues) of $\mathcal{L}$, if λ_0 is an isolated point of $\sigma(\mathcal{L})$ and the Laurent expansion of $\mathcal{L}^{-1}$ near λ_0 can be written as*

$$\mathcal{L}^{-1}(\lambda) = \sum_{j=-k}^{\infty} A_j(\lambda - \lambda_0)^j, \tag{3.1}$$

where $0 \le k < \infty$ and the coefficients $A_{-k}, \ldots, A_{-1}$ are all finite rank operators. The essential spectrum of $\mathcal{L}$, denoted by $\sigma_{ess}(\mathcal{L})$, is defined by $\sigma_{ess}(\mathcal{L}) = \sigma(\mathcal{L}) \setminus \sigma_{disc}(\mathcal{L})$. In other words, $\mathcal{L}^{-1}$ is a meromorphic function in $\mathbb{C} \setminus \sigma_{ess}(\mathcal{L})$ and the coefficients of the negative terms in the Laurent expansion of $\mathcal{L}^{-1}$ at the point in $\sigma_{disc}(\mathcal{L})$ are finite rank operators.

Remark 3.1. If we consider the operator pencil $B = Q - \lambda$, where Q is a closed operator, then the definitions of $\sigma_{\rm disc}(B)$ and $\sigma_{\rm ess}(B)$ in Definition 3.2 agree with the usual ones defined, for example, in [14, p. 13, p. 108]. Moreover, any isolated point of $\sigma(B)$ is in the discrete spectrum. We can also see that if $\lambda_0 \in \sigma_{\rm disc}(\mathcal{L})$ then the kernel of $\mathcal{L}(\lambda_0)$ is nontrivial. In fact, with the help of Theorem 2.1, the kernel of $\mathcal{L}(\lambda_0)$ is one-dimensional whenever $\lambda_0 \in E^c$, where E is as in (1.9).

To understand the structure of $\sigma(\mathcal{L})$, let us examine $\sigma(\mathcal{A})$, where

$$\mathcal{A} = P_0 + \lambda P_1.$$

Intuitively, $\sigma(\mathcal{L})$ and $\sigma(\mathcal{A})$ have similar structures except discrete points, since $\mathcal{L}$, in some sense, can be treated as $\mathcal{A}$ plus compact perturbations. Note that $P_1^{-1} : L^2(\Omega) \to H^2(\Omega)$ is bounded. Since P_0 is self-adjoint, we have that $P_0P_1^{-1} : L^2(\Omega) \to L^2(\Omega)$ is a closed operator. Also, it is readily seen that $\sigma_{ess}(\mathcal{A}) = \sigma_{ess}(P_0P_1^{-1}+\lambda)$ and $\sigma_{disc}(\mathcal{A}) = \sigma_{disc}(P_0P_1^{-1} + \lambda)$. For consistency, here we have used the unconventional notation $\sigma_{ess}(P_0P_1^{-1}+\lambda)$ and $\sigma_{disc}(P_0P_1^{-1}+\lambda)$ to represent, respectively, the essential and discrete spectrum of $P_0P_1^{-1}$. In view of the assumptions on $\alpha(x)$ and $\beta(x)$ and the standard elliptic regularity theorem, we can see that $\sigma(\mathcal{A}) \subseteq E$, where E is as in (1.5). Clearly, E is an interval in the negative real axis. We are now ready to give a description of $\sigma(\mathcal{L})$.

THEOREM 3.3. *Let $\alpha(x), \beta(x)$ satisfy the assumptions as stated and $q(x) \in L^\infty(\Omega)$. Then the operator pencil $\mathcal{L}$ has only discrete spectrum in $\mathbb{C} \setminus \sigma(\mathcal{A})$.*

Proof. If $\lambda \notin \sigma(\mathcal{A})$, then $\mathcal{L}^{-1}$ exists if and only if $(I + (\lambda^2P_2 + \lambda^3P_3)\mathcal{A}^{-1})^{-1}$ exists. Observe that

$$(\lambda^2P_2 + \lambda^3P_3)\mathcal{A}^{-1} = (\lambda^2P_2 + \lambda^3P_3)P_1^{-1}(P_0P_1^{-1} + \lambda)^{-1}$$

is compact for all $\lambda \notin \sigma(\mathcal{A})$ and is an analytic operator-valued function of λ in $\mathbb{C}\setminus\sigma(\mathcal{A})$. In addition, we can check that $(I + (\lambda^2P_2 + \lambda^3P_3)\mathcal{A}^{-1})^{-1}$ exists at $0 \in \mathbb{C} \setminus \sigma(\mathcal{A})$. Now by the analytic Fredholm theorem [13, p. 201], we conclude that there exists a set of discrete points S in $\mathbb{C} \setminus \sigma(\mathcal{A})$ such that $(I + (\lambda^2P_2 + \lambda^3P_3)\mathcal{A}^{-1})^{-1}$ exists in $\mathbb{C} \setminus (\sigma(\mathcal{A}) \cup S)$. Moreover, $(I + (\lambda^2P_2 + \lambda^3P_3)\mathcal{A}^{-1})^{-1}$ is a meromorphic of λ in $\mathbb{C} \setminus \sigma(\mathcal{A})$ and the coefficients of the negative terms in the Laurent expansion of $(I + (\lambda^2P_2 + \lambda^3P_3)\mathcal{A}^{-1})^{-1}$ at $\lambda_0 \in S$ are finite rank operators. In other words, points in S belong to $\sigma_{disc}(\mathcal{L})$. ∎

Remark 3.2. It follows from Theorem 3.3 that $\mathcal{L}$ has only discrete spectrum in E^c.

Next, we want to discuss the essential spectrum of $\mathcal{L}$. It turns out that $\sigma_{ess}(\mathcal{L})$ and $\sigma_{ess}(\mathcal{A})$ are equal.

THEOREM 3.4.

$$\sigma_{ess}(\mathcal{L}) = \sigma_{ess}(\mathcal{A}).$$

Proof. Notice that the operator

$$\Phi(\lambda) := (\mathcal{L} - \mathcal{A})\ \mathcal{A}^{-1} = (\lambda^2 P_2 + \lambda^3 P_3) P_1^{-1} (P_0 P_1^{-1} + \lambda)^{-1}$$

is compact and analytic in $\mathbb{C} \setminus \sigma(\mathcal{A})$. Now if $\lambda \in \mathbb{C} \setminus \sigma(\mathcal{A})$, we can see that $\mathcal{L}^{-1}$ exists if and only if $(I + \Phi(\lambda))^{-1}$ exists. Obviously, $0 \in \mathbb{C} \setminus \sigma_{ess}(\mathcal{A})$ and $(I + \Phi(0))^{-1} = I$ exists. Recall that $(P_0 P_1^{-1} + \lambda)^{-1}$ is a meromorphic function in $\mathbb{C} \setminus \sigma_{ess}(\mathcal{A})$ with finite rank residues at points in $\sigma_{disc}(\mathcal{A})$. Hence, the operator $\Phi(\lambda)$ is compact for all $\lambda \in \mathbb{C} \setminus \sigma_{\rm ess}(\mathcal{A})$ and meromorphic in $\mathbb{C} \setminus \sigma_{ess}(\mathcal{A})$ with finite rank residues at points in $\sigma_{disc}(\mathcal{A})$. Now, by the meromorphic Fredholm theorem [14, p. 107], there exists a set of discrete points S' such that $(I + \Phi(\lambda))^{-1}$ is meromorphic in $\mathbb{C} \setminus \sigma_{ess}(\mathcal{A})$ with finite rank residues at points in S'. In other words, $\mathcal{L}$ has only discrete spectrum in $\mathbb{C} \setminus \sigma_{ess}(\mathcal{A})$. Therefore, we conclude that $\sigma_{ess}(\mathcal{L}) \subseteq \sigma_{ess}(\mathcal{A})$. Conversely, by exchanging the roles of $\mathcal{L}$ and $\mathcal{A}$ and going over the same argument, we can show that $\sigma_{ess}(\mathcal{A}) \subseteq \sigma_{ess}(\mathcal{L})$. ∎

4. Pole assignment. In this section we focus mainly on the method for replacing some particular poles of $\mathcal{L}$ in E^c with the prescribed poles while keeping the others in E^c unchanged. In other words, the whole concept is to determine a control force required to do such a job. We have shown that $\mathcal{L}$ has only discrete spectrum in E^c and the kernel of $\mathcal{L}$ at this discrete spectrum is one-dimensional. Therefore, we will call (λ, ϕ) an eigenpair of $\mathcal{L}$ whenever $\mathcal{L}(\lambda)\phi = 0$ for $\lambda \in E^c$. Suppose that $b(x)$ is a real control function, and $w(t)$ is a control force being applied to (1.1). Let $v(x,t)$ be the response of the controlled system. For our study, we take the control force $w(t)$ of the form

$$w(t) = \int_0^L [f_1(x)\partial_t v(x,t) + f_2(x)v(x,t) + g_1(x)\tilde{W}(\partial_x v)(x,t) + g_2(x)\tilde{W}(v)(x,t)]dx,$$

where

$$\tilde{W}(v)(x,t) = \rho \int_0^t e^{\omega(t-s)} v(x,s)ds. \tag{4.1}$$

(We use $\tilde{W}$, since the first term ρ in the function W has been absorbed into other terms.) Thus, the controlled system is expressed as

$$\begin{aligned} &\partial_x[p_1(x)\partial_x v + p_2(x)W(\partial_x v)] - q(x)\partial_t^2 v \\ &\qquad = b(x) \int_0^L [f_1(x)v + f_2(x)\partial_t v + g_1(x)\tilde{W}(\partial_x v) + g_2(x)\tilde{W}(v)]dx, \\ &v(0,t) = v(L,t) = 0. \end{aligned} \tag{4.2}$$

Simplifying (4.2) as done previously for the free system and letting $v(x,t) = \psi(x)e^{\lambda t}$ yields

$$\begin{aligned}\mathcal{L}_c(\lambda)\psi := {} & (\alpha(x)\psi')' + \lambda(\beta(x)\psi')' + \lambda^2\omega q(x)\psi - \lambda^3 q(x)\psi \\ & -b\int_0^L [\lambda(\lambda f_1 + f_2)\psi - \omega(\lambda f_1 + f_2)\psi + \rho g_1\psi' + \rho g_2\psi]dx = 0, \\ (4.3)\quad & \psi(0,t) = \psi(L,t) = 0.\end{aligned}$$

Here we restate that $\alpha(x)$ and $\beta(x)$ belong to $C^1(\bar{\Omega})$, and $q(x)$ is in $L^\infty(\Omega)$.

Before we begin, we would like to do some simple adjustments and arrangements. Let $\{\lambda_1, \lambda_2, \dots\} = \sigma_{disc}(\mathcal{L}) \setminus E$ with associated eigenvectors $\{\phi_1, \phi_2, \dots\}$ and let the first ℓ discrete spectrum $\{\lambda_1, \dots, \lambda_\ell\}$ satisfy $\{\lambda_1, \dots, \lambda_\ell\} \cap \{\lambda_{\ell+1}, \lambda_{\ell+2}, \dots\} = \emptyset$. Now we will show how to obtain the control force $w(t)$, which assigns poles $\{\lambda_1, \dots, \lambda_\ell\}$ of $\mathcal{L}$ to prescribed values (still lying in E^c) while leaving the other poles in E^c unchanged. More precisely, let $\{\mu_1, \dots, \mu_\ell\}$ be in E^c with $\{\mu_1, \dots, \mu_\ell\} \cap \{\lambda_1, \lambda_2, \dots\} = \emptyset$. Then we wish to find $f_1(x)$, $f_2(x)$, $g_1(x)$ and $g_2(x)$ in (4.3) such that $\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\} = \sigma_{disc}(\mathcal{L}_c) \setminus E$.

THEOREM 4.1. *Let $b(x) \in L^2(\Omega)$ satisfy*

$$(4.4)\qquad \int_0^L b\phi_j dx = \langle b, \phi_j \rangle \neq 0 \qquad \text{for } j = 1, 2, \dots, \ell.$$

Assume that $\{\lambda_1, \dots, \lambda_\ell\}$ has distinct elements and so does $\{\mu_1, \dots, \mu_\ell\}$. Let the following functions be defined:

$$\begin{aligned} f_1(x) &:= q\sum_{j=1}^{\ell} \xi_j \phi_j, \\ f_2(x) &:= q\sum_{j=1}^{\ell} \xi_j \lambda_j \phi_j, \\ g_1(x) &:= \left(\frac{\beta}{\rho}\right)\sum_{j=1}^{\ell} \xi_j \phi_j', \\ (4.5)\qquad g_2(x) &:= \left(\frac{q}{\rho}\right)\sum_{j=1}^{\ell} \xi_j \lambda_j^2 \phi_j, \end{aligned}$$

where

$$(4.6)\qquad \xi_j = \frac{\lambda_j - \mu_j}{\langle b, \phi_j \rangle} \prod_{r=1,\, r\neq j}^{\ell} \frac{\lambda_j - \mu_r}{\lambda_j - \lambda_r}, \qquad j = 1, 2, \dots, \ell.$$

Then we have that

(i) *$\sigma_{ess}(\mathcal{L}_c) = \sigma_{ess}(\mathcal{L})$ and $\mathcal{L}_c$ has only discrete spectrum in E^c,*
(ii) *$\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\} \subset \sigma_{disc}(\mathcal{L}_c) \setminus E$.*

Proof. (i) Since $\alpha(x), \beta(x) \in C^1(\bar{\Omega})$ and $q(x) \in L^\infty(\Omega)$, we get from the elliptic regularity theorem that $\phi_j \in H^2(\Omega) \cap H_0^1(\Omega)$. Using the integration by parts in the

integral term $\int_0^L \rho g_1 \psi' dx$ of (4.3), we obtain that

$$\begin{aligned} & b\int_0^L [\lambda(\lambda f_1 + f_2)\psi - \omega(\lambda f_1 + f_2)\psi + \rho g_1 \psi' + \rho g_2 \psi] dx \\ &= b\int_0^L \{\lambda(\lambda f_1 + f_2) - \omega(\lambda f_1 + f_2)\psi - \rho g_1' + \rho g_2\}\psi dx \\ &:= G(\lambda)\psi(x). \end{aligned}$$

It is clear that $G(\lambda)$ is an integral operator depending on λ analytically. In view of (4.5) and the fact that $b \in L^2(\Omega)$, we have that $G(\lambda)$ is a Hilbert–Schmidt operator on $L^2(\Omega)$ and hence compact. Going over the proofs of Theorems 3.3 and 3.4 once again, we immediately conclude that $\mathcal{L}_c$ has only discrete spectrum in E^c and $\sigma_{ess}(\mathcal{L}_c) = \sigma_{ess}(\mathcal{A}) = \sigma_{ess}(\mathcal{L})$.

(ii) We first show that with (4.5), for each $k \geq \ell + 1$, the eigenpair $\{\lambda_k, \phi_k\}$ of $\mathcal{L}$ satisfies $\mathcal{L}_c(\lambda_k)\phi_k = 0$. The idea is simply to show that the control term in (4.3) is zero when λ is replaced by any $\lambda_k, k \geq \ell + 1$. Clearly,

$$\begin{aligned} & (\alpha\phi_k')' + \lambda_k(\beta\phi_k')' + \lambda_k^2\omega q\phi_k - \lambda_k^3 q\phi_k \\ &\qquad -b\int_0^L \lambda_k(\lambda_k f_1 + f_2)\phi_k - \omega(\lambda_k f_1 + f_2)\phi_k + \rho g_1 \phi_k' + \rho g_2 \phi_k \, dx \\ &= -b\int_0^L \lambda_k(\lambda_k f_1 + f_2)\phi_k - \omega(\lambda_k f_1 + f_2)\phi_k + \rho g_1 \phi_k' + \rho g_2 \phi_k \, dx \\ &= -b\sum_{i=1}^{\ell} \xi_i \{((\lambda_k^2 + \lambda_k\lambda_i + \lambda_i^2) - \omega(\lambda_k + \lambda_i))\langle q\phi_k, \phi_i\rangle + \langle \beta\phi_k', \phi_i{}'\rangle\}. \end{aligned}$$

By the orthogonality relation (2.6) we then conclude that $\mathcal{L}_c(\lambda_k)\phi_k = 0$, i.e., $\lambda_k \in \sigma_{disc}(\mathcal{L}_c)$.

Now suppose that $\{\mu_k, \chi_k\}$ is the solution of the system

$$\begin{aligned} & (\alpha\chi_k')' + \mu_k(\beta\chi_k')' + \mu_k^2\omega q\chi_k - \mu_k^3 q\chi_k = b, \\ & \chi_k(0) = \chi_k(L) \end{aligned} \tag{4.7}$$

for $1 \leq k \leq \ell$. The existence of the solution is guaranteed by the fact that $\mu_k \in r(\mathcal{L})$ for all k and $b \in L^2(\Omega)$. We will now show that $\mathcal{L}_c(\mu_k)\chi_k = 0$ for all $1 \leq k \leq \ell$. First we consider the following:

$$\begin{cases} (\alpha\chi_k')' + \mu_k(\beta\chi_k')' + \mu_k^2\omega q\chi_k - \mu_k^3 q\chi_k = b, \\ \chi_k(0) = \chi_k(L) = 0, \qquad 1 \leq k \leq \ell, \end{cases} \tag{4.8}$$

and

$$\begin{cases} (\alpha\phi_j')' + \lambda_j(\beta\phi_j')' + \lambda_j^2\omega q\phi_j - \lambda_j^3 q\phi_j = 0, \\ \phi_j(0) = \phi_j(L) = 0, \qquad 1 \leq j \leq \ell. \end{cases} \tag{4.9}$$

Multiplying (4.8) by ϕ_j and subtracting from it the quantity (4.9) times χ_k, we get, on the one hand,

$$\begin{aligned} & (\lambda_j - \mu_k)\langle \beta\chi_k', \phi_j{}'\rangle + (\mu_k^2 - \lambda_j^2)\omega\langle q\chi_k, \phi_j\rangle \\ & \qquad -(\mu_k^3 - \lambda_j^3)\langle q\chi_k, \phi_j\rangle = \langle b, \phi_j\rangle. \end{aligned} \tag{4.10}$$

On the other hand, let $\mu \in \mathbb{C}$ and $\psi : [0, L] \to \mathbb{C}$, and define

$$\begin{aligned} F(\mu, \psi) &:= \int_0^L \mu(\mu f_1 + f_2)\psi - \omega(\mu f_1 + f_2)\psi + \rho g_1 \psi' + \rho g_2 \psi dx \\ &= \sum_{j=1}^{\ell} \xi_j [\langle \beta\psi', \phi_j{}' \rangle - (\mu + \lambda_j)\omega\langle q\psi, \phi_j\rangle \\ &\qquad +(\lambda_j^2 + \mu\lambda_j + \mu^2)\langle q\psi, \phi_j\rangle]. \end{aligned} \tag{4.11}$$

Here in the notation we suppress the dependence of F on ϕ_j's.

By writing

$$\begin{aligned} \xi_j &= \left(\frac{\lambda_j - \mu_j}{\langle b, \phi_j\rangle} \prod_{r=1,\, r\neq j}^{\ell} \frac{\lambda_j - \mu_r}{\lambda_j - \lambda_r} \right) \\ &= (\lambda_j - \mu_k) \left(\frac{\prod_{r=1, r\neq k}^{\ell} (\lambda_j - \mu_r)}{\prod_{r=1, r\neq j}^{\ell} (\lambda_j - \lambda_r)} \right) \left(\frac{1}{\langle b, \phi_j\rangle} \right), \end{aligned} \tag{4.12}$$

we obtain

$$\begin{aligned} F(\mu_k, \psi) = \sum_{j=1}^{\ell} &\left(\frac{\prod_{r=1, r\neq k}^{\ell} (\lambda_j - \mu_r)}{\prod_{r=1, r\neq j}^{\ell} (\lambda_j - \lambda_r)} \right) \left(\frac{1}{\langle b, \phi_j\rangle} \right) \\ &\times [(\lambda_j - \mu_k)\langle \beta\psi', \phi_j{}'\rangle + (\mu_k^2 - \lambda_j^2)\omega\langle q\psi, \phi_j\rangle \\ &-(\lambda_j^3 - \mu_k^3)\langle q\psi, \phi_j\rangle]. \end{aligned} \tag{4.13}$$

Let us check the validity of the equation

$$(\alpha\chi_k')' + \mu_k(\beta\chi_k')' + \mu_k^2\omega q\chi_k - \mu_k^3 q\chi_k - bF(\mu_k, \chi_k) = 0. \tag{4.14}$$

Using (4.8), (4.10), and (4.12), we see that the left-hand side of (4.14) is

$$b - b\left\{ \sum_{j=1}^{\ell} \frac{\prod_{r=1, r\neq k}^{\ell} (\lambda_j - \mu_r)}{\prod_{r=1, r\neq j}^{\ell} (\lambda_j - \lambda_r)} \right\} = 0, \quad 1 \le k \le \ell,$$

where we used an identity from [3]: for any $1 \le k \le \ell$,

$$\sum_{j=1}^{\ell} \frac{\prod_{r=1, r\neq k}^{\ell} (\lambda_j - \mu_r)}{\prod_{r=1, r\neq j}^{\ell} (\lambda_j - \lambda_r)} = 1.$$

This completes the proof of (ii). □

Next we want to show that the discrete spectrum of $\mathcal{L}_c$ in E^c is precisely given by $\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\}$. That is, no new extra discrete spectrum occurs in E^c except those prescribed.

THEOREM 4.2. *Let f_1, f_2, g_1, and g_2 be defined as in* (4.5) *and* (4.6), *and the assumptions of Theorem* 4.1 *hold. Moreover, assume that (λ_k, ϕ_k) satisfies*

$$(3\lambda_k^2 - 2\omega\lambda_k)\langle q\phi_k, \phi_k\rangle + \langle \beta\phi_k', \phi_k'\rangle \neq 0 \tag{4.15}$$

for $1 \le k \le \ell$. *Then the discrete spectrum of* $\mathcal{L}_c$ *in* E^c *is precisely given by* $\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\}$, *i.e.,*

$$\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\} = \sigma_{disc}(\mathcal{L}_c) \setminus E.$$

Proof. The previous theorem shows that

$$\{\mu_1, \dots, \mu_\ell, \lambda_{\ell+1}, \dots\} \subset \sigma_{disc}(\mathcal{L}_c) \setminus E.$$

Here, we only need to prove the opposite inclusion.

We first claim that $\{\lambda_1, \dots, \lambda_\ell\} \notin \sigma_{disc}(\mathcal{L}_c) \setminus E$. Equivalently, those poled will not show up again. To begin, we show that $\mathcal{L}_c(\lambda_k)\phi_k \neq 0$ for $1 \le k \le \ell$. In fact, since $\{\lambda_k, \phi_k\}$ is an eigenpair of $\mathcal{L}$, we have that

$$\begin{aligned}\mathcal{L}_c(\lambda_k)\phi_k &= \mathcal{L}(\lambda_k)\phi_k - b(x)F(\lambda_k, \phi_k)\\ &= -b(x)F(\lambda_k, \phi_k).\end{aligned}$$

By virtue of (4.11) and the orthogonality relation, we can see that

$$F(\lambda_k, \phi_k) = \xi_k\{(3\lambda_k^2 - 2\omega\lambda_k)\langle q\phi_k, \phi_k\rangle + \langle \beta\phi_k', \phi_k'\rangle\}.$$

It is clear that $\xi_k \neq 0$ and, therefore, $F(\lambda_k, \phi_k) \neq 0$ by the condition (4.15).

Next, we claim $\mathcal{L}_c(\lambda_k)\psi \neq 0$ for $1 \le k \le \ell$ if ψ and ϕ_k are linearly independent. In fact, since the dimension of the eigenspace of $\mathcal{L}$ is one, we have $\mathcal{L}(\lambda_k)\psi \neq 0$. Suppose, on the contrary, $0 = \mathcal{L}_c(\lambda_k)\psi = \mathcal{L}(\lambda_k)\psi - b(x)F(\lambda_k, \psi)$. On the one hand,

$$\begin{aligned}0 &= \langle \psi, \mathcal{L}(\lambda_k)\phi_k\rangle = \langle \mathcal{L}(\lambda_k)\psi, \phi_k\rangle\\ &= \langle bF(\lambda_k, \psi), \phi\rangle = F(\lambda_k, \psi)\langle b, \phi_k\rangle.\end{aligned}$$

But in view of (4.4), this leads to $F(\lambda_k, \psi) = 0$, and hence $0 = \mathcal{L}(\lambda_k)\psi$, a contradiction.

Finally we show that if $\mu \notin \{\lambda_1, \lambda_2, \dots\} \cup \{\mu_1, \dots, \mu_k\}$ and $\mu \notin E$, then $\mu \notin \sigma_{disc}(\mathcal{L}_c) \setminus E$. We will use a contradiction. Suppose that $\{\mu, \phi\}$ is an eigenpair of $\mathcal{L}_c$. Thus

$$\begin{aligned}0 &= \mathcal{L}_c(\mu)\phi\\ &= \mathcal{L}(\mu)\phi - b(x)C,\end{aligned}$$

where the constant $C = F(\mu, \phi)$. Note that $C \neq 0$; otherwise $\mu \in \sigma_{disc}(\mathcal{L}) \setminus E$. By normalization, we can find $\{\mu, \psi\}$, where $\psi = \frac{1}{C}\phi$, so that

$$\mathcal{L}(\mu)\psi = b.$$

Now we can compute $F(\mu, \psi)$ as we did for $F(\mu_k, \psi)$ going from (4.8) to (4.13), and hence

$$\begin{aligned}0 &= \mathcal{L}_c(\mu)\psi\\ &= \mathcal{L}(\mu)\psi - b(x)F(\mu, \psi)\\ &= b - bF(\mu, \psi)\\ &= b\left[1 - \sum_{j=1}^{\ell} \frac{1}{\lambda_j - \mu} \frac{\Pi_{r=1}^{\ell}(\lambda_j - \mu_r)}{\Pi_{r=1, r\neq j}^{\ell}(\lambda_j - \lambda_r)}\right]\\ &\neq 0,\end{aligned}$$

which is a contradiction since the bracketed term can be transformed into a polynomial of degree ℓ in μ and $\mu_1, \ldots, \mu_\ell$ have been used up as the ℓ roots. This completes the proof. ∎

In view of the above, conditions (4.4) and (4.15) can be legitimately called the controllability conditions. We now show that if either one of (4.4) and (4.15) is violated, then the mode λ_j cannot be relocated by our designed control force, where $1 \le j \le \ell$.

THEOREM 4.3. *For any $1 \le j \le \ell$, let (λ_j, ϕ_j) satisfy either $\langle b, \phi_j \rangle = 0$ or $(3\lambda_j^2 - 2\omega\lambda_j)\langle q\phi_j, \phi_j \rangle + \langle \beta\phi_j', \phi_j' \rangle = 0$. Then $\lambda_j \in \sigma_{disc}(\mathcal{L}_c)$, with f_1, f_2, g_1, and g_2 of $\mathcal{L}_c$ being given in* (4.5) *and* (4.6).

Proof. From the proof of Theorem 4.2, we immediately see that $\mathcal{L}_c(\lambda_j)\phi_j = 0$ if $(3\lambda_j^2 - 2\omega\lambda_j)\langle q\phi_j, \phi_j \rangle + \langle \beta\phi_j', \phi_j' \rangle = 0$. Now we assume that $\langle b, \phi_j \rangle = 0$. In view of the form of $\mathcal{L}_c$, we have $\langle \mathcal{L}_c(\lambda_j)\psi, \phi_j \rangle = 0$ for any $\psi \in H^2(\Omega) \cap H_0^1(\Omega)$, which implies that $\mathcal{L}_c(\lambda_j)$ is not invertible. For, if $\mathcal{L}_c(\lambda_j)^{-1}$ exists, then we can find a $\psi_j \in H^2(\Omega) \cap H_0^1(\Omega)$ such that $\mathcal{L}_c(\lambda_j)\psi_j = \bar{\phi}_j$ and therefore $\langle \mathcal{L}_c(\lambda_j)\psi, \phi_j \rangle \neq 0$. Since $\mathcal{L}_c$ has only discrete spectrum in E^c, λ_j must be in $\sigma_{disc}(\mathcal{L}_c)$. ∎

Finally, in order for the control to be realizable, we need to show that f_1, f_2, g_1, and g_2 are real functions.

THEOREM 4.4. *Assume that both sets $\{\lambda_1, \ldots, \lambda_\ell\}$ and $\{\mu_1, \ldots, \mu_\ell\}$ are closed under complex conjugation. Then the functions f_1, f_2, g_1, and g_2 are real functions.*

Proof. Rewriting ξ_j yields

$$\begin{aligned}\xi_j &= \frac{\lambda_j - \mu_j}{\langle b, \phi_j \rangle} \prod_{r=1,\, r\neq j}^{\ell} \frac{\lambda_j - \mu_r}{\lambda_j - \lambda_r} \\ &= \frac{\prod_{r=1}^{\ell}(\lambda_j - \mu_r)}{\langle b, \phi_j \rangle \prod_{r=1,\, r\neq j}^{\ell}(\lambda_j - \lambda_r)}.\end{aligned}$$

Therefore, if λ_j is real and its associated eigenfunction ϕ_j is also real, then $\bar{\xi}_j = \xi_j$, i.e., ξ_j is real. Now assume that λ_j and λ_{j+1} are a conjugate pair and their eigenfunctions satisfy $\phi_j = \bar{\phi}_j$. Then we can see that

$$\begin{aligned}\xi_{j+1} &= \frac{\prod_{r=1}^{\ell}(\lambda_{j+1} - \mu_r)}{\langle b, \phi_{j+1} \rangle \prod_{r=1,\, r\neq j+1}^{\ell}(\lambda_{j+1} - \lambda_r)} \\ &= \frac{\prod_{r=1}^{\ell}(\bar{\lambda}_j - \mu_r)}{\langle b, \bar{\phi}_j \rangle \prod_{r=1,\, r\neq j+1}^{\ell}(\bar{\lambda}_j - \lambda_r)} \\ &= \frac{\prod_{r=1}^{\ell}(\bar{\lambda}_j - \mu_r)}{\langle b, \bar{\phi}_j \rangle \prod_{r=1,\, r\neq j}^{\ell}(\bar{\lambda}_j - \bar{\lambda}_r)} \\ &= \bar{\xi}_j.\end{aligned}$$

Thus, for f_1, we have that

$$\bar{f} = q \sum_{j=1}^{\ell} \bar{\xi}_j \bar{\phi}_j = q \sum_{j=1}^{\ell} \xi_j \phi_j = f_1,$$

i.e., f_1 is real. Similarly, we can prove that f_2, g_1, and g_2 are real. ∎

WIENER–HOPF FACTORIZATION INDICES AND INFINITE STRUCTURE OF RATIONAL MATRICES*

A. AMPARAN†, S. MARCAIDA†, AND I. ZABALLA†

Abstract. The relationship between the infinite structure and the Wiener–Hopf factorization indices of polynomial matrix representations of controllable systems is investigated. On the way, local Wiener–Hopf factorization indices must be defined. In addition, the finite and infinite structure of a rational matrix is characterized given its Wiener–Hopf factorization indices.

Key words. matrix polynomial, rational matrix, Wiener–Hopf factorization indices, finite invariant factors, infinite structure, majorization

1. Introduction.

Given a linear time invariant system of the form

$$\dot{x}(t) = Ax(t) + Bu(t), \quad A,\ n \times n, \quad B,\ n \times m \tag{1.1}$$

we can associate with it a nonsingular polynomial matrix as follows: Define a nonsingular $m \times m$ polynomial matrix $D(s)$ to be a polynomial matrix representation of system (1.1) if $D(s)$ is the denominator of any right coprime factorization of the transfer function $(sI_n - A)^{-1}B$; i.e., $(sI_n - A)^{-1}B = N(s)D(s)^{-1}$ for some $n \times m$ polynomial matrix such that $D(s), N(s)$ are relatively right coprime. Then it was proven in [16] that given two matrix pairs (A_1, B_1) and (A_2, B_2) with polynomial matrix representations $D_1(s)$ and $D_2(s)$, respectively, there is an invertible matrix T such that $(T^{-1}A_1T, T^{-1}B_1) = (A_2, B_2)$ if and only if there is a unimodular matrix $U(s)$ such that $D_1(s)U(s) = D_2(s)$ (notice that no mention is made of the corresponding numerators). In other words, there is a one-to-one correspondence between the set of orbits of matrix pairs under similarity and the set of orbits of nonsingular polynomial matrices under right equivalence. This fact has some important consequences. Let us mention just three of them:

(i) Since the Hermite normal form of any nonsingular polynomial matrix is a canonical representative of each orbit for the right equivalence, we can associate each class of system similar matrix pairs to an upper right proper polynomial matrix with the identity as leading coefficient: the Hermite normal form of any polynomial matrix representation of the system.

(ii) As any nonsingular polynomial matrix is right equivalent to a column proper matrix (see [15]), and the column degrees of this matrix are uniquely determined, these degrees are invariant under system similarity (these degrees are the controllability indices of the system). This is a well-known fact that can be derived, of course, from other approaches (see, for example, [9, 11]).

(iii) All polynomial matrix representations of system similar matrix pairs have the same invariant factors, and these are (apart from invariant factors equal to 1)

the invariant factors of the state matrix in any pair in the similarity class (see, for example, [9]).

Feedback equivalence of matrix pairs is also related to an equivalence relationship between the corresponding polynomial matrix representations. In order to expose it, we need to introduce some notation and terminology. First, since we are going to deal only with algebraic properties of systems, we will assume that the underlying field, $\mathbb{F}$, is arbitrary. Let $\mathbb{F}[s]$ and $\mathbb{F}(s)$ be the ring of polynomials and the field of rational functions with coefficients in $\mathbb{F}$. Let $\mathbb{F}_{pr}(s)$ denote the subset of rational functions of $\mathbb{F}(s)$ whose denominators have a degree higher than or equal to that of the numerators. This is a Euclidean ring called the ring of proper rational functions. As usual, a polynomial matrix $U(s) \in \mathbb{F}[s]^{m\times m}$ is said to be unimodular if it is invertible in $\mathbb{F}[s]^{m\times m}$; i.e., its determinant is a constant nonzero polynomial. The unities in $\mathbb{F}_{pr}(s)^{m\times m}$ are called biproper or bicausal matrices; their determinants are biproper rational functions, i.e., rational functions whose denominators and numerators have equal degrees.

Two rational matrices $T_1(s), T_2(s) \in \mathbb{F}(s)^{m\times n}$ are said to be (left) Wiener–Hopf equivalent if there exist matrices $U(s) \in \mathbb{F}[s]^{n\times n}$, unimodular, and $B(s) \in \mathbb{F}_{pr}(s)^{m\times m}$, biproper, such that $T_2(s) = B(s)T_1(s)U(s)$. The right Wiener–Hopf equivalence is defined similarly by exchanging the roles of $B(s)$ and $U(s)$. It is well known (see, for example, [1, 4, 5]) that any $m \times n$ rational matrix $T(s)$ is (left) Wiener–Hopf equivalent to a diagonal matrix

$$\Delta = \begin{bmatrix} \operatorname{diag}(s^{k_1}, s^{k_2}, \ldots, s^{k_r}) & 0 \\ 0 & 0 \end{bmatrix},$$

where the integers $k_1 \geq \cdots \geq k_r$ are uniquely determined by $T(s)$ and are called the (left) Wiener–Hopf factorization indices of $T(s)$. In other words $T_1(s)$ and $T_2(s)$ are Wiener–Hopf equivalent if and only if they have the same Wiener–Hopf factorization indices. In particular, for a nonsingular polynomial matrix $P(s) \in \mathbb{F}[s]^{m\times m}$ its (left) Wiener–Hopf factorization indices are nonnegative integers. These indices are the column degrees of any column proper matrix right equivalent to $P(s)$ (see [4]).

As shown in [4, 16], given two controllable systems (A_1, B_1) and (A_2, B_2), if $D_1(s)$ and $D_2(s)$ are their respective polynomial matrix representations, then (A_1, B_1) and (A_2, B_2) are feedback equivalent if and only if $D_1(s)$ and $D_2(s)$ are left Wiener–Hopf equivalent. In other words, there are invertible matrices T and Q and a matrix R such that $(A_2, B_2) = (T^{-1}(A_1 + B_1R)T, T^{-1}B_1Q)$ if and only if there are matrices $U(s)$, unimodular, and $B(s)$, biproper, such that $D_2(s) = B(s)D_1(s)U(s)$. This is actually a result that follows from the fact that a proper precompensator, $C(s)$, can be implemented as a state feedback on a system with transfer function $T(s) = N(s)D(s)^{-1}$ if and only if $C(s)$ is biproper and $C(s)^{-1}D(s)$ is polynomial (see [7]).

As a conclusion we have that the controllability indices of (A, B) are the Wiener–Hopf factorization indices of any of its polynomial matrix representations.

We recall now that given a controllable system, (A, B), the famous Rosenbrock's theorem on pole placement [12] calls for the existence of a feedback gain F such that the state matrix of the closed-loop system, $A+BF$, lies in a prescribed similarity class. We can easily translate this theorem into a result about polynomial matrices. In fact, let (A, B) be a controllable pair and assume that there is a matrix F such that $A+BF$ lies in a prescribed similarity class. Then any polynomial matrix representation of $(A + BF, B)$ has Wiener–Hopf factorization indices of (A, B), and invariant factors of $A + BF$ (apart from invariant factors equal to 1). This implies the existence of a

polynomial matrix with prescribed Wiener–Hopf factorization indices and invariant factors. Conversely, if there is a nonsingular polynomial matrix, $D(s) \in \mathbb{F}[s]^{m\times m}$, with $k_1 \geq \cdots \geq k_m$ as Wiener–Hopf indices and $\alpha_1(s) \mid \cdots \mid \alpha_m(s)$ as invariant factors and $(A, B) \in \mathbb{F}^{n\times n} \times \mathbb{F}^{n\times m}$ is a controllable pair with $k_1 \geq \cdots \geq k_m$ as controllability indices, then there is a matrix $F \in \mathbb{F}^{m\times n}$ such that $A + BF$ has $\alpha_1(s), \ldots, \alpha_m(s)$ and $n - m$ polynomials equal to 1 as invariant factors. For if $\tilde{D}(s)$ is a polynomial matrix representation of (A, B) and (A_1, B_1) is a controllable pair such that $D(s)$ is a polynomial matrix representation of this pair (such a pair always exists), then $D(s)$ and $\tilde{D}(s)$ are Wiener–Hopf equivalent and so (A, B) and (A_1, B_1) are feedback equivalent. Since A_1 and $D(s)$ have the same nontrivial invariant factors, there is a matrix F such that $A + BF = TA_1T^{-1}$ has the desired invariant factors.

Thus Rosenbrock's theorem can be stated as follows.

THEOREM 1.1. *Let $k_1 \geq k_2 \geq \cdots \geq k_m$ and $\alpha_1(s) \mid \alpha_2(s) \mid \cdots \mid \alpha_m(s)$ be nonnegative integers and monic polynomials, respectively. Then there exists a nonsingular matrix $D(s) \in \mathbb{F}[s]^{m\times m}$ with $\alpha_1(s), \alpha_2(s), \ldots, \alpha_m(s)$ as invariant factors and $k_1, k_2, \ldots, k_m$ as Wiener–Hopf factorization indices if and only if the following relations hold:*

$$\sum_{i=1}^{j} k_i \leq \sum_{i=1}^{j} d(\alpha_{m-i+1}(s)), \quad j = 1, 2, \ldots, m-1, \tag{1.2}$$

$$\sum_{i=1}^{m} k_i = \sum_{i=1}^{m} d(\alpha_i(s)), \tag{1.3}$$

where $d(\cdot)$ stands for "degree of."

Rosenbrock's result relates the invariant factors (Smith structure) of a nonsingular polynomial matrix and its Wiener–Hopf factorization indices. In this paper we generalize Rosenbrock's result by studying the relationship between the finite and infinite Smith–McMillan structure of a nonsingular rational matrix and its Wiener–Hopf factorization indices (see [2] for a control interpretation of the infinite structure of a rational matrix). A partial result on the problem of the relationship between the Wiener–Hopf factorization indices and the Smith–McMillan structure at infinity of nonsingular polynomial matrices can be found in [5].

It should be noted that these problems admit different but equivalent formulations. In fact, we aim to completely characterize, for a given nonsingular rational matrix $T(s) \in \mathbb{F}(s)^{m\times m}$, the possible finite Smith–McMillan structure of matrices in the set

$$\{B(s)T(s) : B(s) \text{ biproper}\}$$

and the infinite Smith–McMillan structure of

$$\{T(s)U(s) : U(s) \text{ unimodular}\}.$$

The infinite structure of rational matrices has shown to be of interest in control theory (see, for example, [14]). A test for the solution of the well-known model matching problem is based on the equality of the infinite structure of several matrices; this structure appears significantly in the solution of the decoupling problem (see, for example, [8, 10]).

First, we recall the finite and infinite Smith–McMillan forms of a rational matrix: Two rational matrices $T_1(s), T_2(s) \in \mathbb{F}(s)^{p\times m}$ are said to be equivalent if there are unimodular matrices $U(s) \in \mathbb{F}[s]^{p\times p}$ and $V(s) \in \mathbb{F}[s]^{m\times m}$ such that $T_1(s) = U(s)T_2(s)V(s)$. And they are said to be equivalent at infinity if there exist biproper rational matrices $B_1(s) \in \mathbb{F}_{pr}(s)^{p\times p}$ and $B_2(s) \in \mathbb{F}_{pr}(s)^{m\times m}$ such that $T_1(s) = B_1(s)T_2(s)B_2(s)$.

Any rational matrix $T(s) \in \mathbb{F}(s)^{p\times m}$ is equivalent to a diagonal matrix

$$S(s) = \begin{bmatrix} \operatorname{diag}\left(\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_r(s)}{\psi_r(s)}\right) & 0 \\ 0 & 0 \end{bmatrix},$$

where $r = \operatorname{rank} T(s)$, $\epsilon_i(s), \psi_i(s) \in \mathbb{F}[s]$ are monic and coprime such that $\epsilon_1(s) \mid \epsilon_2(s) \mid \cdots \mid \epsilon_r(s)$ and $\psi_r(s) \mid \psi_{r-1}(s) \mid \cdots \mid \psi_1(s)$. The rational functions, $\frac{\epsilon_i(s)}{\psi_i(s)}$, $1 \le i \le r$, are said to form the finite structure of $T(s)$. The zeros of $T(s)$ are the roots, with their respective multiplicites, of $\epsilon_i(s)$, $1 \le i \le r$, and the poles of $T(s)$ are the roots of $\psi_i(s)$, $1 \le i \le r$, with their respective multiplicites. The matrix $S(s)$ is the Smith–McMillan form of $T(s)$ (see, for example, [12, 13]). The rational functions $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_r(s)}{\psi_r(s)}$ will be called invariant rational functions of $T(s)$. (Recall that they are uniquely determined by $T(s)$.)

Similarly, any rational matrix is equivalent at infinity to a diagonal matrix [2, 13]

$$D(s) = \begin{bmatrix} \operatorname{diag}\left(s^{q_1}, s^{q_2}, \ldots, s^{q_r}\right) & 0 \\ 0 & 0 \end{bmatrix},$$

where $r = \operatorname{rank} T(s)$ and $q_1 \ge q_2 \ge \cdots \ge q_r$, $q_i \in \mathbb{Z}$. The rational functions $s^{q_1}, s^{q_2}, \ldots, s^{q_r}$ are called the invariant factors at infinity of $T(s)$. In particular, a nonsingular polynomial matrix $P(s) \in \mathbb{F}[s]^{m\times m}$ is equivalent at infinity to a diagonal matrix $D(s) = \operatorname{diag}(s^{q_1}, s^{q_2}, \ldots, s^{q_m})$, where $q_1 \ge q_2 \ge \cdots \ge q_m$ are (possibly negative) integers.

The paper is organized as follows: In section 2 we extend Rosenbrock's result to rational matrices with prescribed finite structure. In order to deal with the problem related to the infinite structure of rational matrices we work first with matrix polynomials. We will need the concept of *local Wiener–Hopf factorization indices*. This is not a new concept (see [5]) but since we want to work over an arbitrary field the definition in [5] cannot be applied. So we will adopt a different and more general approach. This is done in section 3. In section 4 we give some auxiliary results that will provide a necessary and sufficient condition for the existence of a nonsingular rational matrix with both Wiener–Hopf and infinite invariant factors prescribed. In the last section we deal with the problem of the existence of a rational matrix with the three types of invariants prescribed: Wiener–Hopf factorization indices and finite and infinite structures.

Remark. We finish this section with two remarks:

1. If $P(s) \in \mathbb{F}[s]^{m\times m}$, we can see from [13] that $\sum_{i=1}^{j} q_i$ is the greatest degree among the degrees of all minors of $P(s)$ of order j, $j \in \{1, 2, \ldots, m\}$. In particular, $q_1 = d(P(s))$; i.e., q_1 is the degree of the element of $P(s)$ of highest degree.

2. Conditions (1.2) and (1.3) will play an important role along the way. They are usually summarized as

$$(k_1, \ldots, k_m) \prec (d(\alpha_m(s)), \ldots d(\alpha_1(s)))$$

by using the majorization symbol, $\prec$, in the sense of Hardy, Littlewood, and Polya (see [6]).

2. Wiener–Hopf factorization indices and finite structure of rational matrices. Many problems about the structure of rational matrices can be deduced from the corresponding problems about polynomial matrices. This is the case when extending the Rosenbrock's polynomial version given in Theorem 1.1 to rational matrices. The idea is as follows: Let $T(s) \in \mathbb{F}(s)^{m\times m}$ be a rational matrix and let $d(s)$ be the monic least common denominator of all the elements $t_{ij}(s) = \frac{n_{ij}(s)}{d_{ij}(s)}$ of $T(s)$. Then $T(s)$ can be written as

$$T(s) = \frac{1}{d(s)} N(s), \tag{2.1}$$

where $N(s) \in \mathbb{F}[s]^{m\times m}$.

The following three lemmas examine the relationship between the finite and infinite Smith–McMillan form of a rational matrix $T(s)$ and the finite and infinite Smith–McMillan form of the corresponding polynomial matrix $N(s)$, as well as the relationship between the Wiener–Hopf factorization indices of $T(s)$ and $N(s)$. The proofs of the three lemmas are straightforward.

LEMMA 2.1. *Let $T(s) \in \mathbb{F}(s)^{m\times m}$ be a nonsingular rational matrix, $d(s)$ the least common multiple of its denominators, and $d(s)T(s) = N(s) \in \mathbb{F}[s]^{m\times m}$. Let $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ be irreducible rational functions, where $\epsilon_i(s), \psi_i(s) \in \mathbb{F}[s]$ are monic and coprime such that $\epsilon_i(s) \mid \epsilon_{i+1}(s)$, $i = 1, 2, \ldots, m-1$, while $\psi_{i+1}(s) \mid \psi_i(s)$, $i = 1, 2, \ldots, m-1$. Let $\sigma_i(s) = \frac{d(s)}{\psi_i(s)}$, $i = 1, \ldots, m$. Then $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ are the invariant functions of $T(s)$ if and only if $\epsilon_1(s)\sigma_1(s), \ldots, \epsilon_m(s)\sigma_m(s)$ are the invariant factors of $N(s)$.*

Notice that since $\psi_{i+1}(s) \mid \psi_i(s)$, we have that $\sigma_i(s) \mid \sigma_{i+1}(s)$, $i = 1, \ldots, m$; and then $\epsilon_1(s)\sigma_1(s) \mid \cdots \mid \epsilon_m(s)\sigma_m(s)$.

LEMMA 2.2. *With $T(s)$, $d(s)$, and $N(s)$ as in Lemma 2.1, let $d = d(d(s))$ and $q_1 \geq q_2 \geq \cdots \geq q_m$ integers. Then $s^{q_1}, s^{q_2}, \ldots, s^{q_m}$ are the invariant factors at infinity of $T(s)$ if and only if $s^{q_1+d}, s^{q_2+d}, \ldots, s^{q_m+d}$ are the invariant factors at infinity of $N(s)$.*

LEMMA 2.3. *With $T(s)$, $d(s)$, $N(s)$, and d as in Lemma 2.2, let $k_1 \geq k_2 \geq \cdots \geq k_m$ be integers. Then $k_1, k_2, \ldots, k_m$ are the Wiener–Hopf factorization indices of $T(s)$ if and only if $k_1 + d, k_2 + d, \ldots, k_m + d$ are the Wiener–Hopf factorization indices of $N(s)$.*

Remark. As we already said, the Wiener–Hopf factorization indices of polynomial matrices are nonnegative integers. In the case of rational matrices, these are not always positive. In particular, the following is true for nonsingular proper rational matrices:

1. If $T(s) \in \mathbb{F}(s)^{m\times m}_{pr}$, then $k_i \leq 0$, $i = 1, 2, \ldots, m$. In particular, if $T(s)$ is strictly proper, then $k_i < 0$, $i = 1, 2, \ldots, m$.

2. If $T(s) \in \mathbb{F}(s)^{m\times m}_{pr}$, then $q_i \leq 0$, $i = 1, 2, \ldots, m$ (see [13]). In particular, if $T(s)$ is strictly proper, then $q_i < 0$, $i = 1, 2, \ldots, m$.

With the help of Lemmas 2.1 and 2.3, we can give a necessary and sufficient condition for the existence of a nonsingular rational matrix with prescribed Wiener–Hopf factorization indices and finite structure.

THEOREM 2.4. *Let $k_1 \geq \cdots \geq k_m$ be integers and $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ irreducible rational functions, where $\epsilon_i(s), \psi_i(s) \in \mathbb{F}[s]$ are monic and coprime such that $\epsilon_i(s) \mid \epsilon_{i+1}(s)$, $i = 1, 2, \ldots, m-1$, and $\psi_{i+1}(s) \mid \psi_i(s)$, $i = 1, 2, \ldots, m-1$. Then there exists a nonsingular matrix $T(s) \in \mathbb{F}(s)^{m\times m}$ with $k_1, \ldots, k_m$ as Wiener–Hopf factorization*

indices and $\frac{\epsilon_1(s)}{\psi_1(s)}, \dots, \frac{\epsilon_m(s)}{\psi_m(s)}$ *as invariant rational functions if and only if*

$$(k_1, \dots, k_m) \prec (d(\epsilon_m(s)) - d(\psi_m(s)), \dots, d(\epsilon_1(s)) - d(\psi_1(s))). \tag{2.2}$$

Proof. Let $T(s)$, $d(s)$, $N(s)$, and d be as in Lemma 2.2. By using Lemmas 2.1 and 2.3 we know that if $\sigma_i(s) = \frac{d(s)}{\psi_i(s)}$, $i = 1, \dots, m$, then $\epsilon_1(s)\sigma_1(s) \mid \cdots \mid \epsilon_m(s)\sigma_m(s)$ are the invariant factors of $N(s)$ and $k_1 + d, \dots, k_m + d$ are its Wiener–Hopf factorization indices. Thus, by Theorem 1.1 we have that

$$(k_1 + d, \dots, k_m + d) \prec (d(\epsilon_m(s)\sigma_m(s)), \dots, d(\epsilon_1(s)\sigma_1(s))).$$

But $d(\sigma_i(s)) = d - d(\psi_i(s))$, $i = 1, \dots, m$. Thus,

$$(k_1 + d, \dots, k_m + d) \prec (d(\epsilon_m(s)) - d(\psi_m(s)) + d, \dots, d(\epsilon_1(s)) - d(\psi_1(s)) + d),$$

and condition (2.2) follows.

Conversely, as by definition of majorization $k_m \geq d(\epsilon_1(s)) - d(\psi_1(s))$, we have that $k_m + d(\psi_1(s)) \geq d(\epsilon_1(s)) \geq 0$. Thus, $k_1 + d(\psi_1(s)) \geq \cdots \geq k_m + d(\psi_1(s)) \geq 0$.

On the other hand, as $\psi_i(s)$ divides $\psi_1(s)$, $i = 1, \dots, m$, we have that $\frac{\epsilon_1(s)}{\psi_i(s)}\psi_1(s)$ are polynomials satisfying $\frac{\epsilon_1(s)}{\psi_1(s)}\psi_1(s) \mid \cdots \mid \frac{\epsilon_m(s)}{\psi_m(s)}\psi_1(s)$.

Now, from (2.2),

$$\begin{aligned}&(k_1 + d(\psi_1(s)), \dots, k_m + d(\psi_1(s)))\\ &\prec (d(\epsilon_m(s)) - d(\psi_m(s)) + d(\psi_1(s)), \dots, d(\epsilon_1(s)) - d(\psi_1(s)) + d(\psi_1(s))).\end{aligned} \tag{2.3}$$

Hence

$$(k_1 + d(\psi_1(s)), \dots, k_m + d(\psi_1(s))) \prec \left(d\left(\frac{\epsilon_m(s)}{\psi_m(s)}\psi_1(s)\right), \dots, d\left(\frac{\epsilon_1(s)}{\psi_1(s)}\psi_1(s)\right)\right). \tag{2.4}$$

By Theorem 1.1 there exists $N(s) \in \mathbb{F}[s]^{m\times m}$ with $k_1 + d(\psi_1(s)), \dots, k_m + d(\psi_1(s))$ as Wiener–Hopf factorization indices and $\frac{\epsilon_1(s)}{\psi_1(s)}\psi_1(s) \mid \cdots \mid \frac{\epsilon_m(s)}{\psi_m(s)}\psi_1(s)$ as invariant factors. By Lemmas 2.1 and 2.3, $T(s) = \frac{1}{\psi_1(s)}N(s)$ is the desired matrix. ∎

In the following two sections we study the existence of polynomial matrices with prescribed infinite structure and Wiener–Hopf factorization indices. Then we will extend the obtained results to rational matrices with the help of Lemmas 2.2 and 2.3.

3. Local Wiener–Hopf factorization indices of a polynomial matrix. We are led by the following idea to relate the infinite structure and the Wiener–Hopf factorization indices of a polynomial matrix: By a conformal transformation we can bring the point at infinity to any desired finite point, and then use the known properties (Rosenbrock's theorem) for the finite structure of the corresponding polynomial matrix in order to obtain information about those properties at infinity by reversing the transformation. Locally the invariant factors reduce to the elementary divisors, but we still need the concept of local Wiener–Hopf factorization indices. As we said in the introduction, this is a well-known concept when $\mathbb{F} = \mathbb{C}$, the field of the complex numbers (see, for example, [5]), but since we are working on an arbitrary field we will use a different approach.

We need some preliminary results.

PROPOSITION 3.1. *Let* $P(s) \in \mathbb{F}[s]^{m\times m}$ *be a nonsingular polynomial matrix and* $\pi(s) \in \mathbb{F}[s]$ *a monic irreducible polynomial. Then there exist matrices* $A(s) \in \mathbb{F}[s]^{m\times m}$ *and* $B(s) \in \mathbb{F}[s]^{m\times m}$ *such that*

(i) $P(s) = A(s)B(s)$,
(ii) *the invariant factors of* $A(s)$ *are powers of the polynomial* $\pi(s)$,
(iii) *the invariant factors of* $B(s)$ *are relatively prime with* $\pi(s)$.

Proof. Let $S(s) = \operatorname{diag}(\alpha_1(s), \dots, \alpha_m(s))$ be the Smith canonical form of $P(s)$, $\alpha_1(s) \mid \cdots \mid \alpha_m(s)$ being its invariant factors. So there exist unimodular matrices $U(s), V(s) \in \mathbb{F}[s]^{m\times m}$ such that

$$P(s) = U(s)\operatorname{diag}(\alpha_1(s), \dots, \alpha_m(s))V(s). \tag{3.1}$$

If $\pi(s)$ is not a divisor of $\det P(s)$, then $A(s) = I_m$ and $B(s) = P(s)$ satisfy the requirements. If $\pi(s) \mid \det P(s)$, then $\alpha_i(s) = \pi(s)^{d_i}\beta_i(s)$ with $d_m \geq \cdots \geq d_1 \geq 0$ and $\gcd(\beta_i(s), \pi(s)) = 1$, $i \in \{1, 2, \dots, m\}$. Thus,

$$P(s) = A(s)B(s) \tag{3.2}$$

with

$$A(s) = U(s)\operatorname{diag}(\pi(s)^{d_1}, \dots, \pi(s)^{d_m}),$$
$$B(s) = \operatorname{diag}(\beta_1(s), \dots, \beta_m(s))V(s),$$

and the proposition follows. ∎

PROPOSITION 3.2. *Let* $P(s) \in \mathbb{F}[s]^{m\times m}$ *be a nonsingular polynomial matrix and* $\pi(s) \in \mathbb{F}[s]$ *a monic irreducible polynomial. If there exist polynomial matrices* $A_1(s), B_1(s) \in \mathbb{F}[s]^{m\times m}$ *and* $A_2(s), B_2(s) \in \mathbb{F}[s]^{m\times m}$ *such that*
(i) $P(s) = A_1(s)B_1(s) = A_2(s)B_2(s)$,
(ii) *the invariant factors of* $A_1(s)$ *and* $A_2(s)$ *are powers of* $\pi(s)$,
(iii) *the invariant factors of* $B_1(s)$ *and* $B_2(s)$ *are relatively prime with* $\pi(s)$,
then $A_1(s)$ *and* $A_2(s)$ *are right equivalent.*

Proof. By using conditions (i), (ii), and (iii), we can see that $A_1(s)$ and $A_2(s)$ as well as $B_1(s)$ and $B_2(s)$ have, respectively, the same invariant factors: the first being powers of $\pi(s)$ and the second relatively prime with $\pi(s)$.

By using (i) we have that

$$A_1(s) = A_2(s)B_2(s)B_1(s)^{-1}. \tag{3.3}$$

Let $G(s) = B_2(s)B_1(s)^{-1}$. As $B_1(s)^{-1} = \frac{1}{\det B_1(s)}Adj(B_1(s))$, it follows that the matrix $(\det B_1(s))G(s)$ is polynomial. Let $D(s) \in \mathbb{F}[s]^{m\times m}$ be the Smith canonical form of $(\det B_1(s))G(s)$. So there exist unimodular matrices $U(s)$, $V(s) \in \mathbb{F}[s]^{m\times m}$ such that

$$D(s) = U(s)(\det B_1(s))G(s)V(s).$$

Therefore

$$U(s)G(s)V(s) = \frac{1}{\det B_1(s)}D(s).$$

On the other hand, if we divide $D(s)$ by $\det B_1(s)$ and cancel out common factors, we obtain the Smith–McMillan form of $G(s)$ (see [13]):

$$S_G(s) = U(s)G(s)V(s) = \frac{1}{\det B_1(s)}D(s) = \operatorname{diag}\left(\frac{\epsilon_1(s)}{\psi_1(s)}, \dots, \frac{\epsilon_m(s)}{\psi_m(s)}\right),$$

where $\epsilon_i(s), \psi_i(s)$ are monic and coprime polynomials such that $\epsilon_i(s)|\epsilon_{i+1}(s)$, while

$\psi_{i+1}(s)|\psi_i(s)$, $i = 1, 2, \ldots, m-1$. Furthermore, as $\psi_k(s)$ is a divisor of $\det B_1(s)$ for all k, we conclude that the polynomials $\psi_k(s)$ are relatively prime with the invariant factors of $A_2(s)$.

Note that since $\det(B_2(s)B_1(s)^{-1})$ is a constant, $\det(S_G(s)) = 1$. We claim that, in fact, $S_G(s) = I_m$. If this were not true, there would exist a k such that $\psi_k(s) \neq 1$ (because otherwise, since $\det(S_G(s)) = 1$, we would have that $\epsilon_i(s) = 1$ for all i and then $S_G(s) = I_m$).

Let $a_{ik}(s)\frac{\epsilon_k(s)}{\psi_k(s)}$ be an arbitrary element of the kth column of $A_2(s)U(s)^{-1}S_G(s)$, where $a_{ik}(s)$ is the element in the (i,k) position of $A_2(s)U(s)^{-1}$. As $A_1(s)V(s) = A_2(s)U(s)^{-1}S_G(s)$ is a polynomial matrix, $a_{ik}(s)\frac{\epsilon_k(s)}{\psi_k(s)}$ is a polynomial. But since $\gcd(\epsilon_k(s), \psi_k(s)) = 1$ we conclude that necessarily $\psi_k(s) \mid a_{ik}(s)$ for all i; i.e., $\psi_k(s)$ is a divisor of every entry in the kth column of $A_2(s)U(s)^{-1}$ and thus a divisor of $\det(A_2(s)U(s)^{-1})$. This would be a contradiction unless $\psi_k(s) = 1$ because this polynomial is a divisor of $\det B_1(s)$ and this one is relatively prime to $\det A_1(s)$, which is equal (up to the product by a constant) to $\det(A_2(s)U(s)^{-1})$. So $S_G(s) = I_m$ as claimed and $A_1(s) = A_2(s)U(s)^{-1}V(s)^{-1}$ as desired. □

As said in the introduction, the Wiener–Hopf factorization indices of a polynomial matrix $P(s)$ are the column degrees of any of its right equivalent column reduced matrices. In fact, there may be more than one column reduced matrix right equivalent to $P(s)$ but all of them have the same column degrees. Thus, by Propositions 3.1 and 3.2, the following definition makes sense.

DEFINITION 3.3. *Let $P(s) \in \mathbb{F}[s]^{m\times m}$ be a nonsingular polynomial matrix, and $\pi(s) \in \mathbb{F}[s]$ a monic irreducible polynomial. Let $A(s), B(s) \in \mathbb{F}[s]^{m\times m}$ be polynomial matrices such that*

(i) *$P(s) = A(s)B(s)$,*
(ii) *the invariant factors of $A(s)$ are powers of the polynomial $\pi(s)$,*
(iii) *the invariant factors of $B(s)$ are relatively prime with $\pi(s)$.*

Then the Wiener–Hopf factorization indices of $A(s)$ will be called local Wiener–Hopf factorization indices of $P(s)$ with respect to $\pi(s)$.

4. Wiener–Hopf factorization indices and infinite structure. In this section we first give the relationship between the Wiener–Hopf factorization indices of a nonsingular polynomial matrix and its invariant factors at infinity. We need some technical lemmas. The proof of the first one is straightforward.

LEMMA 4.1.

(a) *Let $P(s) \in \mathbb{F}[s]^{m\times m}$ and $q = d(P(s))$. Then $s^qP(1/s)$ is a polynomial matrix.*

(b) *Let $U(s) \in \mathbb{F}[s]^{m\times m}$ be a unimodular matrix. Then $\det(U(1/s)) = c \in \mathbb{F}, c \neq 0$ and $U(1/s)$ is a biproper matrix.*

(c) *Let $L(s) \in \mathbb{F}_{pr}(s)^{m\times m}$ be a biproper matrix and $m(s)$ the least common denominator of the elements of $L(1/s)$. Then $m(s)L(1/s)$ is a polynomial matrix, $\gcd(m(s), s) = 1$, and $\gcd(\det(m(s)L(1/s)), s) = 1$.*

(d) *If $P(s)$ is a column reduced matrix with column degrees $p_1, \ldots, p_m$ and $D(s) = \operatorname{diag}(s^{p_1}, \ldots, s^{p_m})$, then $P(1/s)D(1/s)^{-1}$ is a polynomial matrix.*

LEMMA 4.2. *Let $P(s) \in \mathbb{F}[s]^{m\times m}$ be a nonsingular polynomial matrix with $q = d(P(s))$ and let $k_1 \geq k_2 \geq \cdots \geq k_m$ be its Wiener–Hopf factorization indices. Then there exist both a nonnegative integer d and a polynomial, relatively prime with s, $m(s)$ such that $d + q - k_m, \ldots, d + q - k_1$ are the local Wiener–Hopf factorization indices of $m(s)s^{d+q}P(1/s)^T \in \mathbb{F}[s]^{m\times m}$ with respect to the polynomial s.*

Proof. As $k_1, k_2, \dots, k_m$ are the Wiener–Hopf factorization indices of $P(s)$, there exist matrices $U(s) \in \mathbb{F}[s]^{m\times m}$, unimodular, and $L(s) \in \mathbb{F}_{pr}(s)^{m\times m}$, biproper, such that

$$P(s) = L(s)\,\mathrm{diag}(s^{k_m}, \dots, s^{k_1})U(s). \tag{4.1}$$

Let $m(s)$ be the least common denominator of the elements of $L(1/s)$ and $d = d(U(s))$. Then, replacing s by $1/s$ and multiplying by $m(s)s^{d+q}$ in (4.1), we get

$$m(s)s^{d+q}P(1/s) = m(s)L(1/s)\,\mathrm{diag}(s^{d+q-k_m}, \dots, s^{d+q-k_1})U(1/s),$$

and transposing

$$m(s)s^{d+q}P(1/s)^T = U(1/s)^T\,\mathrm{diag}(s^{d+q-k_m}, \dots, s^{d+q-k_1})m(s)L(1/s)^T.$$

Now, let $B(s) = m(s)L(1/s)^T$ and $A(s) = U(1/s)^T\,\mathrm{diag}(s^{d+q-k_m}, \dots, s^{d+q-k_1})$. Then, using Lemma 4.1, the following hold.

(i) $m(s)s^{d+q}P(1/s)^T = A(s)B(s)$ is a polynomial matrix. $A(s)$ is also polynomial. In fact, on the one hand, $s^dU(1/s)^T$ is polynomial, and on the other hand, one can easily deduce from [15] that $q - k_i \geq 0$ for all $i = 1, \dots, m$.

(ii) The invariant factors of $A(s)$ are powers of s.

(iii) The invariant factors of $B(s)$ are relatively prime with s.

(iv) The Wiener–Hopf factorization indices of $A(s)$ are $d+q-k_m, \dots, d+q-k_1$, since $U(1/s)$ is a biproper matrix.

We conclude then, from Definition 3.3, that the local Wiener–Hopf factorization indices of $m(s)s^{d+q}P(1/s)^T$ are $d+q-k_m, \dots, d+q-k_1$ as desired. ∎

Recall now, from the first remark in this paper, that if $s^{q_1}, \dots, s^{q_m}$ are the invariant factors at infinity of $P(s)$, then $q_1 = d(P(s))$. So $s^{q_1}P(1/s)$ is a polynomial matrix (Lemma 4.1).

LEMMA 4.3. *Let $P(s) \in \mathbb{F}[s]^{m\times m}$ be a nonsingular polynomial matrix and $s^{q_1}, \dots, s^{q_m}$, with $q_1 \geq q_2 \geq \cdots \geq q_m$ its invariant factors at infinity. Then for any nonnegative integer d and any polynomial relatively prime with s, $m(s)$, the polynomials $s^{d+q_1-q_1} \mid \cdots \mid s^{d+q_1-q_m}$ are the finite elementary divisors of the polynomial matrix $m(s)s^{d+q_1}P(1/s)^T \in \mathbb{F}[s]^{m\times m}$ associated to s.*

Proof. Let $\alpha_1(s) \mid \cdots \mid \alpha_m(s)$ be the finite invariant factors of $s^{q_1}P(1/s)$. Then there exist unimodular matrices $U(s), V(s) \in \mathbb{F}[s]^{m\times m}$ such that

$$U(s)s^{q_1}P(1/s)V(s) = \mathrm{diag}(\alpha_1(s), \dots, \alpha_m(s)). \tag{4.2}$$

If we write $\alpha_i(s) = s^{a_i}\beta_i(s)$ with $\gcd(\beta_i(s), s) = 1$, $i = 1, \dots, m$, then $0 \leq a_1 \leq \cdots \leq a_m$. By changing s by $1/s$ in (4.2) we have

$$U(1/s)\frac{1}{s^{q_1}}P(s)V(1/s) = \mathrm{diag}\left(\frac{1}{s^{a_1}}\beta_1(1/s), \dots, \frac{1}{s^{a_m}}\beta_m(1/s)\right). \tag{4.3}$$

Notice that $\beta_i(1/s)$ is a biproper rational function because $\gcd(\beta_i(s), s)) = 1$. Thus, by multiplying (4.3) on the right by the biproper matrix

$$B(s) = \mathrm{diag}\left(\frac{1}{\beta_1(1/s)}, \dots, \frac{1}{\beta_m(1/s)}\right)$$

and setting $B_1(s) = U(1/s)$ and $B_2(s) = V(1/s)B(s)$, we have that

$$B_1(s)P(s)B_2(s) = \mathrm{diag}(s^{q_1-a_1}, \dots, s^{q_1-a_m}),$$

with $B_1(s)$ and $B_2(s)$ biproper matrices and $q_1 - a_1 \geq \cdots \geq q_1 - a_m$. This means that $s^{q_1-a_1}, s^{q_1-a_2}, \ldots, s^{q_1-a_m}$ are the invariant factors at infinity of $P(s)$. But, by hypothesis, these are $s^{q_1}, \ldots, s^{q_m}$. Therefore $a_i = q_1 - q_i$, $i = 1, \ldots, m$.

Now, let d be any nonnegative integer and $m(s)$ any polynomial relatively prime with s. By multiplying (4.2) by $m(s)s^d$ and transposing, we get

$$\begin{aligned} &V(s)^T(m(s)s^{d+q_1}P(1/s)^T)U(s)^T \\ &= \operatorname{diag}(s^{d+q_1-q_1}m(s)\beta_1(s), \ldots, s^{d+q_1-q_m}m(s)\beta_m(s)), \end{aligned}$$

where $\gcd(m(s)\beta_i(s), s) = 1$ for all $i = 1, \ldots, m$. This means that

$$s^{d+q_1-q_1}m(s)\beta_1(s), \ldots, s^{d+q_1-q_m}m(s)\beta_m(s)$$

are the invariant factors of $m(s)s^{d+q_1}P(1/s)^T$ and so $s^{d+q_1-q_1} \mid \cdots \mid s^{d+q_1-q_m}$ are its elementary divisors associated to the irreducible polynomial s. ∎

LEMMA 4.4. *Let $k_1 \geq \cdots \geq k_m$, $t_m \geq \cdots \geq t_1$ be nonnegative integers. Let $\pi(s) \in \mathbb{F}[s]$ be a monic irreducible polynomial. Then there exists a nonsingular matrix $P(s) \in \mathbb{F}[s]^{m\times m}$ with $k_1, \ldots, k_m$ as its local Wiener–Hopf factorization indices with respect to $\pi(s)$ and $\pi(s)^{t_1} \mid \cdots \mid \pi(s)^{t_m}$ as its finite elementary divisors associated to $\pi(s)$ if and only if*

$$(k_1, \ldots, k_m) \prec (t_m d(\pi(s)), \ldots, t_1 d(\pi(s))). \tag{4.4}$$

Proof. Assume that there is a nonsingular matrix $P(s) \in \mathbb{F}[s]^{m\times m}$ such that $\alpha_1(s) \mid \cdots \mid \alpha_m(s)$ are its invariant factors. We can write $\alpha_i(s) = \pi(s)^{t_i}\beta_i(s)$ with $\gcd(\beta_i(s), \pi(s)) = 1$, $i = 1, \ldots, m$. The Smith canonical form of $P(s)$ is $\operatorname{diag}(\alpha_1(s), \ldots, \alpha_m(s))$ and there exist unimodular matrices $U(s), V(s) \in \mathbb{F}[s]^{m\times m}$ such that $P(s) = A(s)B(s)$ with

$$A(s) = U(s)\operatorname{diag}(\pi(s)^{t_1}, \ldots, \pi(s)^{t_m})$$

and

$$B(s) = \operatorname{diag}(\beta_1(s), \ldots, \beta_m(s))V(s).$$

By Definition 3.3 the local Wiener–Hopf factorization indices of $P(s)$ with respect to $\pi(s)$, i.e., $k_1, \ldots, k_m$, are the Wiener–Hopf factorization indices of $A(s)$. Since $\pi(s)^{t_1} \mid \cdots \mid \pi(s)^{t_m}$ are the invariant factors of $A(s)$, condition (4.4) follows from Rosenbrock's theorem (Theorem 1.1).

Conversely, by Rosenbrock's theorem there exists a nonsingular matrix $A(s) \in \mathbb{F}[s]^{m\times m}$ with Wiener–Hopf factorization indices $k_1, \ldots, k_m$ and $\pi(s)^{t_1} \mid \cdots \mid \pi(s)^{t_m}$ as invariant factors. So it is sufficient to take $P(s) = A(s)$. ∎

Now we can give our main result.

THEOREM 4.5. *Let $k_1 \geq \cdots \geq k_m \geq 0$ and $q_1 \geq \cdots \geq q_m$ be integers. Then there exists a nonsingular matrix $P(s) \in \mathbb{F}[s]^{m\times m}$ with $k_1, \ldots, k_m$ as Wiener–Hopf factorization indices and $s^{q_1}, \ldots, s^{q_m}$ as invariant factors at infinity if and only if*

$$(k_1, \ldots, k_m) \prec (q_1, \ldots, q_m). \tag{4.5}$$

Proof. First, we are going to prove the necessity. We know that $q_1 = d(P(s))$. By using Lemma 4.2, there exist both a polynomial $m(s)$ such that $\gcd(m(s), s) = 1$ and

a nonnegative integer d such that $d+q_1-k_m,\dots,d+q_1-k_1$ are the local Wiener–Hopf factorization indices of $m(s)s^{d+q_1}P(1/s)^T \in \mathbb{F}[s]^{m\times m}$ with respect to s, and by Lemma 4.3, $s^{d+q_1-q_1} \mid \cdots \mid s^{d+q_1-q_m}$ are its finite elementary divisors associated to the irreducible polynomial s. Then, by Lemma 4.4 applied to the polynomial matrix $m(s)s^{d+q_1}P(1/s)^T$, we have that

$$(d+q_1-k_m,\dots,d+q_1-k_1) \prec (d+q_1-q_m,\dots,d+q_1-q_1).$$

From the definition of majorization we conclude that condition (4.5) holds.

Conversely, if condition (4.5) holds and bearing in mind that $q_1 \geq k_1 \geq k_i$, $i=1,\dots,m$, we have that

$$(q_1-k_m,\dots,q_1-k_1) \prec (q_1-q_m,\dots,q_1-q_1).$$

By Rosenbrock's theorem, there is a nonsingular matrix $A(s) \in \mathbb{F}[s]^{m\times m}$ with $q_1-k_m,\dots,q_1-k_1$ as Wiener–Hopf factorization indices and $s^{q_1-q_1} \mid \cdots \mid s^{q_1-q_m}$ as invariant factors. As postmultiplication by unimodular matrices does not change either the Wiener–Hopf factorization indices or the invariant factors, we can assume that $A(s)$ is column-reduced and the degree of its ith column is q_1-k_{m-i+1}. Thus we can write

$$A(s) = L(s)\,\mathrm{diag}(s^{q_1-k_m},\dots,s^{q_1-k_1}) \tag{4.6}$$

with $L(s)$ a biproper matrix. Furthermore, since $q_1-k_m \geq \cdots \geq q_1-k_1$, it follows that $d(A(s)) = q_1-k_m$.

By replacing s by $1/s$ and multiplying equation (4.6) by s^{q_1} we have that

$$s^{q_1}A(1/s) = L(1/s)\,\mathrm{diag}(s^{k_m},\dots,s^{k_1}),$$

where $s^{q_1}A(1/s)$ is a polynomial matrix (Lemma 4.1). Then

$$s^{q_1}A(1/s)^T = \mathrm{diag}(s^{k_m},\dots,s^{k_1})L(1/s)^T.$$

Recall now that, by Lemma 4.1, if $D(s) = \mathrm{diag}(s^{q_1-k_m},\dots,s^{q_1-k_1})$, then matrix $L(1/s) = A(1/s)D(1/s)^{-1}$ is polynomial. But since $L(s)$ is biproper, $\det L(1/s)$ is both a biproper rational function and a polynomial. Thus $\det L(1/s) = c \in \mathbb{F}, c \neq 0$ and $L(1/s)$ is unimodular. Hence the Wiener–Hopf factorization indices of $s^{q_1}A(1/s)^T$ are $k_1,\dots,k_m$.

On the other hand, as $s^{q_1-q_1} \mid \cdots \mid s^{q_1-q_m}$ are the invariant factors of $A(s)$, there exist unimodular matrices $U(s), V(s) \in \mathbb{F}[s]^{m\times m}$ such that

$$U(s)A(s)V(s) = \mathrm{diag}(s^{q_1-q_1},\dots,s^{q_1-q_m}). \tag{4.7}$$

Then, replacing s by $1/s$ and multiplying by s^{q_1}, we have that

$$U(1/s)s^{q_1}A(1/s)V(1/s) = \mathrm{diag}(s^{q_1},\dots,s^{q_m})$$

and

$$V(1/s)^T s^{q_1}A(1/s)^T U(1/s)^T = \mathrm{diag}(s^{q_1},\dots,s^{q_m}),$$

where $U(1/s)^T$ and $V(1/s)^T$ are biproper matrices (Lemma 4.1). Hence $s^{q_1},\dots,s^{q_m}$ are the invariant factors at infinity of $s^{q_1}A(1/s)^T$. Therefore if we write $P(s) = s^{q_1}A(1/s)^T$ the theorem follows. ∎

We finish this section by extending the previous result to nonsingular rational matrices.

THEOREM 4.6. *Let $k_1 \geq \cdots \geq k_m$ and $q_1 \geq \cdots \geq q_m$ be integers. Then there exists a nonsingular matrix $T(s) \in \mathbb{F}(s)^{m\times m}$ with $k_1, \ldots, k_m$ as Wiener–Hopf factorization indices and $s^{q_1}, \ldots, s^{q_m}$ as invariant factors at infinity if and only if*

$$(k_1, \ldots, k_m) \prec (q_1, \ldots, q_m). \tag{4.8}$$

Proof. Recall that if $d(s)$ is the monic least common denominator of all the elements of $T(s)$ and $d = d(d(s))$, then

$$T(s) = \frac{1}{d(s)} N(s),$$

where $N(s) \in \mathbb{F}[s]^{m\times m}$. By using Lemmas 2.2 and 2.3 we know that $k_1+d, \ldots, k_m+d$ are the Wiener–Hopf factorization indices of $N(s)$ and $s^{q_1+d}, \ldots, s^{q_m+d}$ are its invariant factors at infinity. Now, by Theorem 4.5 applied to the nonsingular polynomial matrix $N(s)$, we have that

$$(k_1 + d, \ldots, k_m + d) \prec (q_1 + d, \ldots, q_m + d),$$

and (4.8) follows.

Conversely, let d be any integer such that $d \geq |k_m|$. Then $k_1 + d, \ldots, k_m + d$ are nonnegative integers and $q_1 + d, \ldots, q_m + d$ are integers. From (4.8)

$$(k_1 + d, \ldots, k_m + d) \prec (q_1 + d, \ldots, q_m + d).$$

Thus, by Theorem 4.5 there exists $N(s) \in \mathbb{F}[s]^{m\times m}$ with $k_1+d, \ldots, k_m+d$ as Wiener–Hopf factorization indices and $s^{q_1+d}, \ldots, s^{q_m+d}$ as invariant factors at infinity.

Let $T(s) = \frac{1}{d(s)} N(s)$, where $d(s)$ is any polynomial of degree d. By applying Lemmas 2.2 and 2.3, we have that $T(s)$ is the desired matrix. □

As a consequence we get the following relationship between the Wiener–Hopf factorization indices and invariant factors at infinity of proper rational function matrices.

COROLLARY 4.7. *Let $k_1 \geq \cdots \geq k_m$ and $q_1 \geq \cdots \geq q_m$ be nonpositive integers. Then there exist a nonsingular matrix $T(s) \in \mathbb{F}(s)_{pr}^{m\times m}$ with $k_1, \ldots, k_m$ as Wiener–Hopf factorization indices and $s^{q_1}, \ldots, s^{q_m}$ as invariant factors at infinity if and only if*

$$(k_1, \ldots, k_m) \prec (q_1, \ldots, q_m).$$

5. Wiener–Hopf factorization indices and finite and infinite structures of rational matrices. Although prescribing three types of invariants usually results in a more difficult problem, this is not the case for the one that we are studying. The reason is that, for a given rational matrix $T(s) \in \mathbb{F}(s)^{m\times m}$, the Wiener–Hopf factorization indices of all matrices in the sets

$$\{B(s)T(s) : B(s) \text{ biproper}\} \text{ and } \{T(s)U(s) : U(s) \text{ unimodular}\}$$

are the same. The following theorem characterizes the finite and infinite structure of nonsingular rational matrices when their Wiener–Hopf factorization indices are prescribed.

THEOREM 5.1. *Let $k_1 \geq \cdots \geq k_m$, $q_1 \geq \cdots \geq q_m$ be integers and $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ irreducible rational functions, where $\epsilon_i(s), \psi_i(s) \in \mathbb{F}[s]$ are monic and coprime such that $\epsilon_i(s) \mid \epsilon_{i+1}(s)$, $i = 1, 2, \ldots, m-1$, and $\psi_{i+1}(s) \mid \psi_i(s)$, $i = 1, 2, \ldots, m-1$. Then there exists a nonsingular rational matrix $T(s) \in \mathbb{F}(s)^{m\times m}$ with $k_1, \ldots, k_m$ as Wiener–Hopf factorization indices, $s^{q_1}, \ldots, s^{q_m}$ as invariant factors at infinity, and $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ as invariant rational functions if and only if*

$$(k_1, \ldots, k_m) \prec (d(\epsilon_m(s)) - d(\psi_m(s)), \ldots, d(\epsilon_1(s)) - d(\psi_1(s))), \tag{5.1}$$

$$(k_1, \ldots, k_m) \prec (q_1, \ldots, q_m). \tag{5.2}$$

Proof. The necessity of (5.1) and (5.2) follows from Theorems 2.4 and 4.6. Conversely, by Theorem 2.4 there exists a rational matrix $T_1(s)$ whose Wiener–Hopf factorization indices are $k_1, \ldots, k_m$ and whose invariant rational functions are $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$. And by Theorem 4.6 there exists a rational matrix $T_2(s)$ whose Wiener–Hopf factorization indices are $k_1, \ldots, k_m$ and whose invariant factors at infinity are $s^{q_1}, \ldots, s^{q_m}$. As $T_1(s)$ and $T_2(s)$ have the same Wiener–Hopf factorization indices, they are Wiener–Hopf equivalent. So there exist both a biproper matrix $B(s) \in \mathbb{F}_{pr}(s)^{m\times m}$ and a unimodular matrix $U(s) \in \mathbb{F}[s]^{m\times m}$ such that $T_1(s) = B(s)T_2(s)U(s)$. Thus $T(s) = B(s)T_2(s) = T_1(s)U(s)^{-1}$ has the same infinite structure as $T_2(s)$, the same finite structure as $T_1(s)$ and the Wiener–Hopf factorization indices of both $T_1(s)$ and $T_2(s)$. That is to say, $T(s)$ is the desired matrix. ∎

Remark. All throughout the paper we have been working with left Wiener–Hopf factorization indices. The left Wiener–Hopf factorization indices of a nonsingular polynomial matrix $P(s) \in \mathbb{F}[s]^{m\times m}$ are the column degrees of any column proper polynomial matrix right equivalent to $P(s)$. And these are, in turn, the controllability indices of any controllable pair (A, B) with $P(s)$ as polynomial matrix representation.

As said in the introduction, we also have right Wiener–Hopf indices and right Wiener–Hopf equivalence of rational matrices. This is the same as the left Wiener–Hopf equivalence but exchanging the roles of matrices $B(s)$ and $U(s)$. That is to say, $T_1(s), T_2(s)$ are right Wiener–Hopf equivalent if there are matrices $U(s)$, unimodular, and $B(s)$, biproper, such that $T_1(s) = U(s)T_2(s)B(s)$. In other words, $T_1(s)$ and $T_2(s)$ are left Wiener–Hopf equivalent if and only if $T_1(s)^T$ and $T_2(s)^T$ are right Wiener–Hopf equivalent. For a polynomial matrix, P(s), the right Wiener–Hopf factorization indices are the row degrees of any row proper polynomial matrix *left* equivalent to $P(s)$. And these are, again, the observability indices of any pair (B^T, A^T) such that $P(s)^T$ is a polynomial matrix representation of (A, B).

Since matrix transposition of a rational matrix does not change its finite or infinite structure, all results in this manuscript can be translated straightforwardly into results about the right Wiener–Hopf factorization indices of rational matrices just by transposition.

We finish with two results that relate the left and right Wiener–Hopf factorization indices. A partial result on this problem can be found in [3]. Actually, in that paper the relationship between several types of factorization indices was studied. In particular, a necessary and sufficient condition for two integer vectors to be the left and right Wiener–Hopf factorization indices of a rational matrix function is provided. This result is a consequence of our Theorem 5.3 and is presented as Corollary 5.4.

We consider again the sets

$$\{U(s)T(s) : U(s) \text{ unimodular}\} \text{ and } \{T(s)U(s) : U(s) \text{ unimodular}\}.$$

All matrices in these sets have the same finite structure and all the matrices in the sets

$$\{B(s)T(s) : B(s) \text{ biproper}\} \text{ and } \{T(s)B(s) : B(s) \text{ biproper}\}$$

have the same infinite structure. Ideas similar to those of Theorem 5.1 enable us to prove the following.

THEOREM 5.2. *Let $k_1 \geq \cdots \geq k_m$, $l_1 \geq \cdots \geq l_m$ be integers and $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ m irreducible rational functions, where $\epsilon_i(s), \psi_i(s) \in \mathbb{F}[s]$ are monic and coprime such that $\epsilon_i(s) \mid \epsilon_{i+1}(s)$, $i = 1, 2, \ldots, m-1$, and $\psi_{i+1}(s) \mid \psi_i(s)$, $i = 1, 2, \ldots, m-1$. Then there exists a nonsingular rational matrix $T(s) \in \mathbb{F}(s)^{m\times m}$ with $k_1, \ldots, k_m$ as left Wiener–Hopf factorization indices, $l_1, \ldots, l_m$ as right Wiener–Hopf factorization indices, and $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ as invariant rational functions if and only if*

$$(k_1, \ldots, k_m) \prec (d(\epsilon_m(s)) - d(\psi_m(s)), \ldots, d(\epsilon_1(s)) - d(\psi_1(s))), \tag{5.3}$$

$$(l_1, \ldots, l_m) \prec (d(\epsilon_m(s)) - d(\psi_m(s)), \ldots, d(\epsilon_1(s)) - d(\psi_1(s))). \tag{5.4}$$

Proof. The necessity of (5.3) follows from Theorem 2.4. As $T(s)^T$ has $l_1, \ldots, l_m$ as left Wiener–Hopf factorization indices and $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$ as invariant rational functions, (5.4) holds by applying Theorem 2.4 to $T(s)^T$. Conversely, by Theorem 2.4 there exists a rational matrix $T_1(s)$ whose left Wiener–Hopf factorization indices are $k_1, \ldots, k_m$ and whose invariant rational funtions are $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$, and there exists another rational matrix $T_2(s)$ whose left Wiener–Hopf factorization indices are $l_1, \ldots, l_m$ and whose invariant rational funtions are $\frac{\epsilon_1(s)}{\psi_1(s)}, \ldots, \frac{\epsilon_m(s)}{\psi_m(s)}$. As $T_1(s)$ and $T_2(s)^T$ have the same finite structure, there are unimodular matrices $U_1(s), U_2(s) \in \mathbb{F}[s]^{m\times m}$ such that $T_1(s) = U_1(s)T_2(s)^T U_2(s)$. Thus the desired matrix is $T(s) = U_1(s)T_2(s)^T = T_1(s)U_2(s)^{-1}$. ∎

Similarly we can prove the following.

THEOREM 5.3. *Let $k_1 \geq \cdots \geq k_m$, $l_1 \geq \cdots \geq l_m$ and $q_1 \geq \cdots \geq q_m$ be integers. Then there exists a nonsingular rational matrix $T(s) \in \mathbb{F}(s)^{m\times m}$ with $k_1, \ldots, k_m$ as left Wiener–Hopf factorization indices, $l_1, \ldots, l_m$ as right Wiener–Hopf factorization indices, and $s^{q_1}, \ldots, s^{q_m}$ as invariant factors at infinity if and only if*

$$(k_1, \ldots, k_m) \prec (q_1, \ldots, q_m), \tag{5.5}$$

$$(l_1, \ldots, l_m) \prec (q_1, \ldots, q_m). \tag{5.6}$$

COROLLARY 5.4. *Let $k_1 \geq \cdots \geq k_m$ and $l_1 \geq \cdots \geq l_m$ be integers. Then there exists a nonsingular rational matrix $T(s) \in \mathbb{F}(s)^{m\times m}$ with $k_1, \ldots, k_m$ as left Wiener–Hopf factorization indices and $l_1, \ldots, l_m$ as right Wiener–Hopf factorization indices if and only if*

$$\sum_{i=1}^{m} k_i = \sum_{i=1}^{m} l_i. \tag{5.7}$$

Proof. The necessity of (5.7) is evident. Let us prove the sufficiency. We use the notation $q^+ = \max(q, 0)$ and choose integers $q_1 \geq \cdots \geq q_m$ in the following way:

$$q_1 = \max\left(\sum_{i=1}^{m} {k_i}^+, \sum_{i=1}^{m} {l_i}^+\right), \quad q_2 = \cdots = q_{m-1} = 0, \quad q_m = \sum_{i=1}^{m} k_i - q_1. \tag{5.8}$$

We have that

$$(k_1, \dots, k_m) \prec (q_1, \dots, q_m), \tag{5.9}$$

$$(l_1, \dots, l_m) \prec (q_1, \dots, q_m). \tag{5.10}$$

The existence of $T(s)$ follows from Theorem 5.3. ∎

6. Conclusions. In this paper the relationship between the Wiener–Hopf factorization indices of nonsingular polynomial matrices and their finite and infinite structures has been investigated. The main result states that they must satisfy a Rosenbrock-like theorem. In order to get this result the concept of local Wiener–Hopf factorization indices with respect to any irreducible polynomial has been introduced. The main results were generalized for rational matrices and the existence of matrices with all kind of invariants (left and right Wiener–Hopf indices, and finite and infinite structure) has been studied.

ASYMPTOTIC CONTROL OF PAIRS OF OSCILLATORS COUPLED BY A REPULSION, WITH NONISOLATED EQUILIBRIA II: THE SINGULAR CASE*

MARC-OLIVIER CZARNECKI†

Abstract. Let $\phi : H \to \mathbb{R}$ be a $\mathcal{C}^1$ function on a real Hilbert space H, and let $\gamma > 0$ be a positive damping parameter. For any (singular) repulsive potential $V : H \setminus \{0\} \to \mathbb{R}_+$, i.e., such that $\lim_{z\to 0} V(z) = +\infty$, and any control function $\varepsilon : \mathbb{R}_+ \to \mathbb{R}_+ \setminus \{0\}$ which tends to zero as $t \to +\infty$, we study the asymptotic behavior of the trajectories of the coupled dissipative system of nonlinear oscillators

$$(\mathrm{HBFC}^2_{sing}) \qquad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V(x-y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V(x-y) = 0. \end{cases}$$

This system is the singular version of the regular (HBFC^2_{reg}) system studied in [A. Cabot and M.-O. Czarnecki, *SIAM J. Control Optim.*, 41 (2002), pp. 1254–1280], where the potential V is defined on the whole space H. The purpose of this paper is to obtain whenever possible the same existence and convergence results in the singular case as in the regular case considered by A. Cabot and M.-O. Czarnecki. This study is mainly motivated by a better convergence behavior of (HBFC^2_{sing}) with the same sharp condition on the control ε exhibited in [H. Attouch and M.-O. Czarnecki, *J. Differential Equations*, 179 (2002), pp. 278–310] and by A. Cabot and M.-O. Czarnecki. Precisely, when $H = \mathbb{R}$, and if ε is a "slow" control, i.e., $\int_0^{+\infty} \varepsilon(t)dt = +\infty$, then the trajectories x and y converge to extremal points of the set $S = \{\lambda \in \mathbb{R}, \nabla\phi(\lambda) = 0\}$ of the equilibria of ϕ. The awkward case in A. Cabot and M.-O. Czarnecki, where the trajectories may have the same limit, disappears. Of importance, from a physical point of view, we thus can consider actual, for example electromagnetic, repulsive potentials.

Key words. nonlinear oscillator, coupled system, slow control, heavy ball with friction, global optimization, singular potential

1. Introduction.

Let H be a real Hilbert space, with scalar product and corresponding norm, respectively, denoted by $\langle ., . \rangle$ and $|\ .\ |$. Let $\phi : H \to \mathbb{R}$ be a given $\mathcal{C}^1$ real-valued function, called the potential function. An important problem is the search of the equilibria of the function ϕ (i.e., the solutions of the equation $\nabla\phi(x) = 0$, where $\nabla\phi$ is the gradient of ϕ), among which the minima (global or local) play a particular role in optimization, physics, economics, etc. To obtain equilibria or minima of the function ϕ, a powerful method is to follow the trajectories of an associated dissipative gradient-like dynamical system, possibly discretized for numerical applications. In many practical problems (for example, when minimizing a convex function which is not strictly convex), the function ϕ has nonisolated equilibria and one wants to choose a particular equilibrium or minimum, or also one may desire a full and global description of the set of equilibria or minima of ϕ.

As motivated in [6], a fruitful direction is to consider coupled dynamical systems, exchanging information, and thus having more ability of globally exploring the

†Institut de Mathématiques et de Modélisation de Montpellier, CNRS UMR 5149, case courrier 051, Université Montpellier 2, Place Eugène Bataillon, 34095 Montpellier Cedex 5, France (marco@math.univ-montp2.fr).

function ϕ than a single noncoupled system. In order to obtain a global dynamical approach of the set of the equilibria of ϕ, [6] studies the asymptotic behavior of the regular (HBFC^2_{reg}) system

$$(\mathrm{HBFC}^2_{reg}) \qquad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V_{reg}(x-y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V_{reg}(x-y) = 0, \end{cases}$$

where $\gamma > 0$ is a positive damping parameter, $\varepsilon : \mathbb{R}_+ \to \mathbb{R}_+ \setminus \{0\}$ is a control function such that $\lim_{t\to+\infty} \varepsilon(t) = 0$, and $V_{reg} : H \to \mathbb{R}_+$ is a (regular) coupling potential function.

We refer the reader to [6] for the detailed reasons that lead us to consider the regular (HBFC^2_{reg}) system and also for more references on the subject. Let us simply mention that to obtain more exploration properties than a first order in time dynamical system, one considers second order in time dynamical systems, among which the heavy ball with friction system

$$(\mathrm{HBF}) \qquad \ddot{x}(t) + \gamma\dot{x}(t) + \nabla\phi(x(t)) = 0$$

enjoys most of the nice properties of the steepest descent method (see the recent papers of Alvarez [1], Attouch, Goudou, and Redont [4], Goudou [7], Haraux and Jendoubi [8], and Jendoubi [9]). By adding a Tikhonov-like asymptotic control term $\varepsilon(t)x(t)$, Attouch and Czarnecki [3] show that the system

$$(\mathrm{HBFC}) \qquad \ddot{x}(t) + \gamma\dot{x}(t) + \nabla\phi(x(t)) + \varepsilon(t)x(t) = 0$$

will select a specific equilibrium when ϕ is convex and $\varepsilon : \mathbb{R}_+ \to \mathbb{R}_+$ is a $\mathcal{C}^1$ control function which tends to zero slowly, i.e., such that $\int_0^{+\infty} \varepsilon(t)dt = +\infty$.

It was then natural to examine if the selection property of the control in (HBFC) could be adapted to a repulsive coupling of two systems, a case which is considered in [6]. Precisely, when $H = \mathbb{R}$ and if ε is a "slow" control, i.e., $\int_0^{+\infty} \varepsilon(t)dt = +\infty$, then the trajectories x and y of (HBFC^2_{reg}) converge to extremal points of the set $S = \{\lambda \in \mathbb{R}, \nabla\phi(\lambda) = 0\}$ of the equilibria of ϕ or have the same limit. However, in this last case, one does not obtain more information than with the not coupled (HBF) system. This is due to the lack of strength of the (regular) repulsive potential at the origin, which allows the two trajectories to asymptotically collapse.

In order to forbid the solutions to collapse, we consider in this paper the case of a singular potential, defined on $H \setminus \{0\}$, which, moreover, tends to $+\infty$ at 0. Since we want the potential to always be "active," it is essential to impose $\varepsilon(t) > 0$ for every t. Note that the (HBFC^2_{sing}) system has a similar mechanical interpretation as the (HBF) system with an extra repulsion force—deriving from the potential V—between the two "balls." Also, because of this natural physical aspect of the coupled system, it is important to consider singular interaction potentials that are the ground of the gravitational and electromagnetic theories. For example, in the case where $V(z) = 1/|z|^2$, it corresponds to the electric potential between two particles having a varying load $\varepsilon(t)$ of same sign.

We obtain the same types of properties for the (HBFC^2_{sing}) system as for the (HBFC^2_{reg}) system, mainly showing that the trajectories x and y of (HBFC^2_{sing}) satisfy

$$\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0,$$

$$\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0.$$

But the proofs in the singular case cannot be derived from the regular case and are much more involved. In the one-dimensional case, we show that the (HBFC^2_{sing}) system enjoys nicer properties than the (HBFC^2_{reg}) system, precisely the awkward case in [6], where the trajectories may have the same limit disappears.

One may wonder whether the singular case can be seen as an asymptotic limit of regular cases. This question is of importance for numerical applications, since a singular potential is likely to be numerically approximated by a regular potential. A first look seems to indicate a positive answer (section 7.2).

Obviously one wants to obtain more results in higher, possibly infinite, dimension. As in the regular case, the techniques that we use for the one-dimensional convergence results are specific to the dimension one. These convergence results do not immediately apply in higher dimension (Remark 2.7), at least with the same precision. But a numerical study (section 7.1) seems to indicate that the (HBFC^2_{sing}) system still enjoys good global exploration properties in higher dimension and opens perspective of generalizations to higher dimension.

The paper is organized as follows. In section 2.1, we precisely state the global existence results and general asymptotic properties (Proposition 2.1 and Theorem 2.2). In section 2.2, we precisely state the asymptotic convergence results in dimension one (Theorems 2.4 and 2.6, Corollaries 2.7 and 2.8). In section 3, we provide remarks on and counterexamples of our results. The results are proved in section 4 (global existence), section 5 (asymptotic properties), and section 6 (asymptotic convergence in dimension one). Finally, in section 7, we give numerical experiments in higher dimension and address the question of the singular case as a limit of regular cases.

2. Main results. We assume the following (rather standard) set of assumptions.

Hypothesis 1. Let H be a real Hilbert space and $\phi : H \to \mathbb{R}$ be a map of class $\mathcal{C}^1$ such that

$$(\mathcal{H}_\phi) \quad \begin{cases} \text{(i)} & \text{the map } \phi \text{ is bounded from below on } H; \\ \text{(ii)} & \text{the map } \nabla\phi \text{ is Lipschitz continuous on the bounded subsets of } H. \end{cases}$$

Let $V : H \setminus \{0\} \to \mathbb{R}_+$ be a map of class $\mathcal{C}^1$ such that

$$(\mathcal{H}_V) \quad \begin{cases} \text{(i)} & \text{the map } \nabla V \text{ is locally Lipschitz continuous on } H \setminus \{0\}; \\ \text{(ii)} & \lim_{z\to 0} V(z) = +\infty \quad \textit{(singularity assumption).} \end{cases}$$

Let $\varepsilon : [0, +\infty) \to \mathbb{R}_+ \setminus \{0\}$ be a function of class $\mathcal{C}^1$ such that

$$(\mathcal{H}_\varepsilon) \quad \begin{cases} \text{(i)} & \text{the function } \varepsilon \text{ is nonincreasing, i.e., } \dot\varepsilon(t) \le 0 \quad \forall t \in \mathbb{R}_+; \\ \text{(ii)} & \lim_{t\to+\infty} \varepsilon(t) = 0. \end{cases}$$

Let $\gamma > 0$, set $\Gamma = \{(x, y) \in H^2, \quad x - y \neq 0\}$, and $\Big((x_0, y_0), (\dot x_0, \dot y_0)\Big) \in \Gamma \times H^2$, the ($HBFC^2_{sing}$) system is defined as follows:

$$(\mathrm{HBFC}^2_{sing}) \quad \begin{cases} \ddot x + \gamma\dot x + \nabla\phi(x) + \varepsilon(t)\nabla V(x - y) = 0, \\ \ddot y + \gamma\dot y + \nabla\phi(y) - \varepsilon(t)\nabla V(x - y) = 0 \\ \Big(x(0), y(0), \dot x(0), \dot y(0)\Big) = \Big(x_0, y_0, \dot x_0, \dot y_0\Big). \end{cases}$$

Remark 2.1. For the sake of readability, we take 0 as initial time. All the results of the paper clearly hold by taking any other initial time $t_0 \in \mathbb{R}$ and making the corresponding adaptations in the statements.

2.1. Global properties. The following proposition ensures the global existence of the solutions of the (HBFC^2_{sing}) system.

PROPOSITION 2.1 (global existence). *Assume Hypothesis* 1. *Then*

(i) *there exists a unique maximal solution* $(x, y) : [0, +\infty) \to \Gamma$ *of* (HBFC^2_{sing}) *which is of class* $\mathcal{C}^2$*;*

(ii) $(\dot{x}, \dot{y}) \in L^\infty([0, +\infty); H \times H) \cap L^2([0, +\infty); H \times H)$, $(\phi(x), \phi(y)) \in L^\infty([0, +\infty); \mathbb{R} \times \mathbb{R})$, *and* $\varepsilon V(x - y) \in L^\infty([0, +\infty); \mathbb{R})$*;*

(iii) *the energy function* E, *defined by* $E(t) = \frac{1}{2}|\dot{x}(t)|^2 + \frac{1}{2}|\dot{y}(t)|^2 + \phi(x(t)) + \phi(y(t)) + \varepsilon(t)V(x(t) - y(t))$, *is nonincreasing.*

Proposition 2.1 is proved in section 4 and commented on in section 3.1.

The next result shows first global (and essential for the following results) convergence properties of the solutions of the (HBFC^2_{sing}) system. The conclusions hold as in the regular case [6, Theorem 2.1], with a stronger assumption on the potential V for the convergence of $\dot{x}$ and $\dot{y}$, but the proofs heavily differ because of the singularity assumption. Most of the difficulties specific to the singular case are concentrated in the proof of Theorem 2.2 given in section 5.

We shall consider two additional assumptions in the statement of Theorem 2.2. The first assumption is a limit condition on the potential ϕ, which covers a wide set of cases.

Hypothesis 2 (limit condition (LIM)). For every sequence $(z_n) \subset H$ such that $\lim_{n\to+\infty} |z_n| = +\infty$, there exists a subsequence $(z_{\varphi(n)})$ such that $\lim_{n\to+\infty} \phi(z_{\varphi(n)}) = +\infty$ or $\lim_{n\to+\infty} \nabla\phi(z_{\varphi(n)}) = 0$.

The limit condition (LIM) is discussed in detail in [6, section 3.3]. Let us just mention that it is equivalent to the following assertion:

$$\forall \alpha > 0, \quad \forall A \in \mathbb{R}, \text{ the set } \{z \in H, \phi(z) \leq A \text{ and } |\nabla\phi(z)| \geq \alpha\} \text{ is bounded,}$$

and it is clearly satisfied in the two following more simple cases: (c) the map ϕ is coercive, i.e., $\lim_{|z|\to+\infty} \phi(z) = +\infty$, and (d) $\lim_{|z|\to+\infty} \nabla\phi(z) = 0$.

The second assumption is a double assumption on the potential V, repulsion and radial symmetry (with an additional error term).

Hypothesis 3 (radial symmetry and repulsion ($\mathcal{H}_V$)(iii)). There exist a decreasing function $W : \mathbb{R}_+ \setminus \{0\} \to \mathbb{R}_+$ of class $\mathcal{C}^1$ and a bounded "error" function $e : H \setminus \{0\} \to \mathbb{R}_+$ of class $\mathcal{C}^1$ such that, for every $z \in H \setminus \{0\}$,

$$V(z) = W(|z|) + e(z)$$

and such that, on a neighborhood of 0, ∇e is bounded and $\langle \nabla e(z), z \rangle \leq 0$.

Note that the typical electric potential $V(z) = 1/|z|^2$ satisfies Hypothesis 3. The error term is important, for instance to allow computations errors in numerical applications.

THEOREM 2.2 (asymptotic properties). *Part* 1. *Assume Hypothesis* 1*, and that, for every* $r > 0$ *the map* ∇V *is bounded on the bounded subsets of* $H \setminus B(0, r)$*. Assume, moreover, Hypothesis* 2*, i.e., the map* ϕ *satisfies the limit condition* (LIM)*, or that the trajectory* (x, y) *is bounded. Then*

$$\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0.$$

Hence if x_∞*(resp.,* y_∞*) is a cluster point of* x *(resp.,* y*), then,* x_∞ *(resp.,* y_∞*)* $\in S$*, with* $S = \{z \in H, \nabla\phi(z) = 0\}$.

Part 2. *Additionally assume Hypothesis* 3; *i.e., the potential* V *is a radial repulsion. Then*

$$\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0.$$

Theorem 2.2 is proved in section 5 and commented on in section 3.2.

The following result specifies the behavior in the convex case.

COROLLARY 2.3. *Under the assumptions of Theorem* 2.2, *additionally assume that the map* ϕ *is convex. Then*

(v) *if the trajectory* x *(resp.,* y*) is bounded, then* $\lim_{t\to+\infty} \phi(x(t)) = \inf \phi$ *(resp.,* $\lim_{t\to+\infty} \phi(y(t)) = \inf \phi$*);*

(vi) *if an element* x_∞*(resp.,* y_∞*) is a weak cluster point of* x*(resp.,* y*), then* x_∞*(resp.,* y_∞*)* $\in S$.

We refer the reader to [6] for the classical proof of Corollary 2.3.

2.2. Convergence in the one-dimensional case. In this section, we explore the convergence and minimizing properties of the solutions of the (HBFC$^2_{sing}$) system, under the additional assumption that the space H is one-dimensional (i.e., $H = \mathbb{R}$). The singularity assumption implies in particular that the trajectories x and y may never cross. We show that this property "passes to the limit" with a slow control and thus improves the (slow control) results of [6], when the potential V is a repulsion, i.e., satisfies

$$(\mathcal{H}_V)(\text{iv}) \qquad \forall z \in \mathbb{R} \setminus \{0\}, \quad zV'(z) \le 0.$$

Precisely, the awkward case in [6], where the two trajectories x and y have the same limit, does not appear in the forthcoming slow control results (section 2.2.2). Finally, since $H = \mathbb{R}$, note that the limit condition (LIM) is satisfied if ϕ is convex and bounded from below.

2.2.1. Convergence of the trajectory. The next result shows the convergence of the solutions of the (HBFC$^2_{sing}$) system. Recall that S denotes the set of the equilibria of ϕ: $S = \{z \in \mathbb{R}, \phi'(z) = 0\}$. In order to give a unified presentation of our results, we let

$$\widehat{S} = \{\overline{z} \in \overline{\mathbb{R}}, \lim_{z\to\overline{z}} \phi'(z) = 0\}.$$

THEOREM 2.4 (convergence of the solutions). *Assume Hypothesis* 1, *with* $H = \mathbb{R}$.

Part 1. *Assume that the solution* (x, y) *of the* (HBFC$^2_{sing}$) *system is bounded. Then it converges:*

(i) *There exists* $(x_\infty, y_\infty) \in \widehat{S} \times \widehat{S}$ *such that* $\lim_{t\to+\infty} \Big(x(t), y(t)\Big) = \Big(x_\infty, y_\infty\Big)$.

If $y_0 < x_0$ *(resp.,* $x_0 < y_0$*), then* $y_\infty \le x_\infty$ *(resp.,* $x_\infty \le y_\infty$*). Moreover, if* $x_\infty \ne y_\infty$, *then*

$$\text{(ii)} \quad \lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0.$$

Part 2. *Assume Hypothesis* 2, *i.e., the map* ϕ *satisfies the limit condition* (LIM) *(for example, if* ϕ *is convex), or that the trajectory* (x, y) *is bounded,*[1] *together with*

$$(\mathcal{H}_V)(\text{iv}) \qquad \forall z \in \mathbb{R} \setminus \{0\}, \quad zV'(z) \le 0.$$

Then the conclusions (i) *and* (ii) *of Part* 1 *hold.*

[1]This last case, mentioned again only for the convergence of $\dot{x}$ and $\dot{y}$ when $x_\infty = y_\infty$, could be deduced from the previous one—the (LIM) assumption—by changing the map ϕ.

Theorem 2.4, Part 2 is similar to its regular version [6, Theorem 2.2]. Part 1 can be also stated in the regular case and thus improves [6, Theorem 2.2]. This is precisely done in section 7.3. Theorem 2.4 is commented on in section 3.3 and proved in sections 6.1 and 6.2. As in the regular case, when the map ϕ is convex, the trajectory minimizes ϕ. The following corollary states this precisely.

COROLLARY 2.5. *Under the assumptions of Theorem* 2.4*, Part* 2*, additionally assume that the map ϕ is convex. Then* $\lim_{t\to+\infty}(\phi(x(t))\,,\,\phi(y(t))) = (\inf\phi\,,\,\inf\phi)$.

Remark 2.2. Corollary 2.5 may not hold if the map ϕ is not assumed to be convex, even if it is quasi-convex. Adapt the counterexample in [6].

Proof of Corollary 2.5. Consider the different cases: (i) $x_\infty \in \mathbb{R}$ (hence x is bounded), (ii) $x_\infty = -\infty$ (hence $\phi' \geq 0$), (iii) $x_\infty = +\infty$ (hence $\phi' \leq 0$). □

2.2.2. Slow control. By contrast with a "fast" control ε, i.e., such that $\int_0^{+\infty}\varepsilon(t)\,dt < +\infty$, which merely acts as a perturbation (see [3] and [6]), a "slow" control ε, i.e., such that $\int_0^{+\infty}\varepsilon(t)\,dt = +\infty$, has a more actual effect. The results in this section show the convergence of the solution map (x, y) toward specific points of $\widehat{S}$ with a "slow" control ε. They are the exact singular counterpoint of the regular versions given in [6, section 2.2.2]. The difference between the singular and regular results is more obvious for Corollary 2.8 and [6, Corollary 2.4] and their consequences (Corollary 2.9 and [6, Corollary 2.5]). An awkward case appears in the regular version, namely [6, Corollary 2.4(iii)] $\lim_{t\to+\infty} x(t) = \lim_{t\to+\infty} y(t)$, and it is the existence of this case that originally motivated the study of the singular case. The other convergence results are more general, but the differences with their regular version are less spectacular. For every $\lambda \in \overline{\mathbb{R}}$, we denote by $P^+(\lambda)$ (resp., $P^-(\lambda)$) the following proposition:

$$\text{For every neighborhood } V(\lambda) \text{ of } \lambda \quad \exists \mu \in V(\lambda)\cap\mathbb{R}, \quad \phi'(\mu) > 0 \quad (\text{resp., } \phi'(\mu) < 0).$$

THEOREM 2.6 (slow parametrization).[2] *Under the assumptions of Theorem* 2.4*, Part* 2*, additionally assume that*

$$(\mathcal{H}_\varepsilon)(\text{iii}) \qquad \int_0^{+\infty}\varepsilon(t)\,dt = +\infty,$$

$$(\mathcal{H}_V)(\text{v}) \qquad \forall M > 0, \quad \inf_{0<|z|\leq M}|V'(z)| > 0.$$

Let $(x_\infty, y_\infty) \in \widehat{S}\times\widehat{S}$ *be the limits of the trajectories. Assume* $y_0 < x_0$ *Then the solution* (x, y) *of the* (HBFC^2_{sing}) *system satisfies the following properties:*

- *if* $y_\infty > -\infty$ *and* $x_\infty < +\infty$, *then we have* $P^-(y_\infty)$ *and* $P^+(x_\infty)$.
- *if* $y_\infty = -\infty$ *and* $x_\infty < +\infty$, *then we have* $P^+(y_\infty)$ *or* $P^+(x_\infty)$.
- *if* $y_\infty > -\infty$ *and* $x_\infty = +\infty$, *then we have* $P^-(y_\infty)$ *or* $P^-(x_\infty)$.

If $x_0 < y_0$*, then the corresponding assertions hold (by exchanging the letters* x *and* y*).*

Theorem 2.6 is proved in section 6.3.

Remark 2.3. Assumption $(\mathcal{H}_V)$(v) means that the potential V always remains active near the origin, never being locally constant. This assumption is clearly satisfied if the potential V is strictly convex on $\mathbb{R}_+$ and on $\mathbb{R}_-$.

[2] Theorem 2.6 applies for every initial condition, contrary to its regular version [6, Theorem 2.3], which assumes that the trajectories do not have the same limit. The same holds for Corollary 2.7.

In fact, Theorem 2.6 specifies the points of $\widehat{S}$, where the trajectories x and y converge, as precisely stated in the next result.

COROLLARY 2.7 (slow parametrization). *Under the assumptions of Theorem* 2.6*, let $I(\lambda)$ be the connected component of λ in $\widehat{S}$. If $y_0 < x_0$ and if one of the following conditions is satisfied:*

$$\begin{array}{ll} \text{(a)} & -\infty < y_\infty, \\ \text{(b)} & y_\infty = -\infty \text{ and } \exists \lambda \in \mathbb{R},\ \phi'((-\infty, \lambda]) \leq 0, \end{array}$$

then the trajectory x converges to an extremal point of $I(x_\infty)$, precisely

$$x_\infty \in \{\inf I(x_\infty), \sup I(x_\infty)\}.$$

If $x_0 < y_0$, then the corresponding assertions hold (by exchanging the letters x and y).

Corollary 2.7 is proved in section 6.4.

Remark 2.4. The conclusion of Corollary 2.7 may not be more precise in general. Precisely, one cannot replace the conclusion $x_\infty \in \{\inf I(x_\infty), \sup I(x_\infty)\}$ by $x_\infty = \sup I(x_\infty)$. Adapt the counterexample in [6].

Remark 2.5. The conclusion of Corollary 2.7 does not hold if $y_\infty = -\infty$ and there exists no $\lambda \in \mathbb{R}$ such that $\phi'((-\infty, \lambda]) \leq 0$. Adapt the counterexample in [6].

When the set of equilibria is an interval, the behavior of the trajectories is more precise.

COROLLARY 2.8 (slow parametrization with a connected set of equilibria). *Under the assumptions of Theorem* 2.6*, additionally assume that the set $\widehat{S}$ is an interval (in $\overline{\mathbb{R}}$) (for example, if ϕ is convex). Then the solution (x,y) of the* (HBFC$^2_{sing}$) *system satisfies one of the following cases:*

$$\begin{array}{lll} \text{(i)} & \lim_{t\to+\infty} \Big(x(t)\,,\, y(t) \Big) = \Big(\sup \widehat{S}\,,\, \inf \widehat{S} \Big) & \text{if } y_0 < x_0; \\ \text{(ii)} & \lim_{t\to+\infty} \Big(x(t)\,,\, y(t) \Big) = \Big(\inf \widehat{S}\,,\, \sup \widehat{S} \Big) & \text{if } x_0 < y_0. \end{array}$$

Corollary 2.8 is proved in section 6.5. As a (clear) consequence of Corollary 2.8, the limit of the difference of the trajectories maximizes the (possibly) infinite diameter of the set S.

COROLLARY 2.9. *Under the assumptions of Theorem* 2.6*, additionally assume that S is a nonempty interval and that $\widehat{S} = \mathrm{cl}_{\overline{\mathbb{R}}}(S)$. Then the solution (x, y) of the* (HBFC$^2_{sing}$) *system satisfies*

$$\lim_{t\to+\infty} |x(t) - y(t)| = \mathrm{diam}\,(S).$$

The proof of Corollary 2.9 is immediate.

Remark 2.6. Corollary 2.9 may not hold if we do not assume $\widehat{S} = \mathrm{cl}_{\overline{\mathbb{R}}}(S)$, even if S is a nonempty interval. Adapt the counterexample in [6].

Remark 2.7. The formulation of Theorem 2.6 is specific to the dimension one. This is not the case of Corollary 2.9, but Corollary 2.9 may not remain true in higher dimension. Adapt the counterexample in [6].

3. Remarks and counterexamples.

3.1. On Proposition 2.1.

Remark 3.1. Proposition 2.1 easily generalizes by replacing the domain $H \setminus \{0\}$ by any open set $\Omega \subset H$, replacing $(\mathcal{H}_V)$(ii) by the following: for all $\bar{z} \in$

$\mathrm{bd}\,\Omega, \lim_{z\in\Omega,\, z\to\bar{z}} V(z) = +\infty$, and letting $\Gamma = \{(x,y) \in H^2, \quad x - y \in \Omega\}$. We let the reader check that the proof in section 4 still holds. This may be of interest, on one side, if one wants to avoid points other than 0 and, on the other side, since it then covers and thus generalizes the regular case (by taking $\Omega = H$).

Remark 3.2. In Proposition 2.1, we consider only the case where $\varepsilon(t) > 0$ for every t, i.e., the case where the control is effective. The case where $\varepsilon(T) = 0$ for some T can be easily proved. But, first, since the function ε is assumed to be nonincreasing, $\varepsilon(t) = 0$ for every $t \geq T$, and there is no control on the system for $t \geq T$. Second, one cannot ensure that the difference of the trajectories $x - y$ remains in the domain $H \setminus \{0\}$. For our purpose of controlling the system, the case where $\varepsilon(t) > 0$ for every t is the only interesting one.

3.2. On Theorem 2.2.

Remark 3.3. Theorem 2.2, Part 1 may not hold if the trajectory (x, y) is not bounded and if the map ϕ does not satisfy the limit condition (LIM). Adapt the counterexample in [6].

Remark 3.4. If the trajectory (x, y) is bounded, then $\lim_{t\to+\infty} \nabla\phi(x(t)) + \nabla\phi(y(t)) = 0$ without assuming that ∇V is bounded on the bounded subsets of $H \setminus B(0, r)$ (see Lemma 5.2 below).

Remark 3.5. Theorem 2.2, Part 1 may not hold if one replaces the set $H \setminus \{0\}$ by any open set $\Omega \subset H$ and makes the corresponding adjustment for $(\mathcal{H}_V)$(ii). Let $H = \mathbb{R}$, $\Omega = \mathbb{R} \setminus [-2, 2]$, $\phi(x) = \frac{x^2}{2}$, and $V(z) = \frac{1}{|z-2|}$ for $z \notin [-2, 2]$. Then $x(t) = 1 + \frac{1}{\sqrt{t}}$, $y(t) = -x(t)$, are solutions to the corresponding (HBFC^2_{sing}) system with $\varepsilon(t) = 4t^{-1} - 2t^{-5/2} + 3t^{-7/2}$ and $\nabla\phi(x(t)) \to 1$ when $t \to +\infty$. In some sense, defining the singular potential V on more general open subsets Ω may create too many constraints since the trajectory (x, y) must stay in the corresponding set Γ.

Remark 3.6. Theorem 2.2, Part 2 holds under the following more general assumptions on the potential V:

(i) $\lim_{n\to+\infty} V(z_n) = +\infty \Rightarrow \lim_{n\to+\infty} z_n = 0$ for every sequence (z_n) in H. In view of the singularity assumption $(\mathcal{H}_V)$(ii), the previous implication would be an equivalence.

(ii) The potential V is repulsive near 0, precisely $\langle \nabla V(z), z\rangle \leq 0$ for every $z \in B(0, r) \setminus \{0\}$ for some $r > 0$.

(iii) For some function $\lambda : H \to (-\infty, 0)$, the function $z \mapsto \nabla V(z) - \lambda(z)z$ is bounded.

These assumptions are clearly technical and are mentioned for the record.

Remark 3.7. Under the assumptions of Theorem 2.2, it is easy to find examples of nonconvergent (nonbounded) trajectories of the (HBFC^2_{sing}) system. In the regular case [6, section 3.8], one immediately deduces examples of bounded and nonconvergent trajectories of the (HBFC^2_{reg}) system by taking $\varepsilon(t) = 0$ for every t, in which case (HBFC^2_{reg}) becomes a noncontrolled (HBF) system, with examples of bounded and nonconvergent trajectories of (HBF); see Redont [11] (also in [4]) and Jendoubi and Poláčik [10]. This cannot be done in the singular case, since we impose the condition $\varepsilon(t) > 0$ for every t. But our concern being the exploration of the equilibria of ϕ by the (HBFC^2_{sing}) system, the extensive study of the converging properties of (HBFC^2_{sing}), of high interest for itself, is beyond the scope of this paper.

3.3. On Theorem 2.4.

Remark 3.8. Theorem 2.4, Part 1, (i) may not be true if the trajectory (x, y) is not assumed to be bounded. It is possible to build an example such that $\lim_{t\to+\infty} x(t) =$

$+\infty$, $\liminf_{t\to+\infty} y(t) = -1$, $\limsup_{t\to+\infty} y(t) = 1$. Take

$$x(t) = 3\log(t) - \cos(\log(t)), \qquad y(t) = \cos(\log(t)),$$

and $\varepsilon(t) = 1/\sqrt{t}$. Then the maps $t \mapsto x(t)$ and $t \mapsto x(t) - y(t)$ are strictly increasing, hence invertible, and their reciprocal functions are locally Lipschitz continuous. Define $\phi : \mathbb{R} \to \mathbb{R}$ of class $\mathcal{C}^1$, with a Lipschitz continuous derivate, by $\phi|_{[-1,1]} = 0$ and $\ddot{x}(t) + \ddot{y}(t) + \dot{x}(t) + \dot{y}(t) + \phi'(x(t)) = 0$ (for $t \geq e$), i.e., $\phi'(3\log(t) - \cos(\log(t))) = -3/t + 3/t^2$. Then $\phi'(z) \sim -3\alpha(z)e^{-z/3}$ with $\alpha(z) \in [e^{-1/3}, e^{1/3}]$ when $z \to +\infty$; hence ϕ is bounded from below. Define $V : (0, +\infty) \to \mathbb{R}$ of class $\mathcal{C}^1$, with a Lipschitz continuous derivate, by $\ddot{y}(t) + \dot{y}(t) - \varepsilon(t)V'(x(t) - y(t)) = 0$ (for $t \geq e$), i.e., $V'(3\log(t) - 2\cos(\log(t))) = -(1/\sqrt{t})\sin(\log(t)) + (1/t\sqrt{t})(\sin(\log(t)) - \cos(\log(t)))$. Then $|V'(z)| \leq e^{-z/6+1/3} + o(e^{-z/6})$; hence V can be chosen positive. The map (x, y) is by construction a solution of the corresponding (HBFC^2_{sing}) system with $\gamma = 1$, and the assumptions of Theorem 2.4, Part 1 are satisfied except for the bound on the trajectory x.

Remark 3.9. Theorem 2.4, Part 1, (ii) may not be true if $x_\infty = y_\infty$. In $\mathbb{R}$, take $\phi(x) = 0$, and consider a function $f : \mathbb{R} \to \mathbb{R}_+$ of class $\mathcal{C}^1$ such that $\operatorname{supp} f = [-1, 1]$, $\int_{\mathbb{R}} f = 1$, $f'|_{[-1,0]} \geq 0$, $f'|_{[0,1]} \leq 0$, and $f(0) = 1$. Define x by $\dot{x}(t) = -e^{-t} - \sum_{n\in\mathbb{N}} \sqrt{1 + 1/n}\, f(2^n(t - n))$ and $\lim_{n\to+\infty} x(t) = 0$, i.e.,

$$x(t) = e^{-t} + \sum_{n\in\mathbb{N}} \sqrt{1 + \frac{1}{n}} \int_{u\geq t} f\left(2^n(u - n)\right) du.$$

Then $\dot{x}(t) < 0$; hence $t \mapsto x(t)$ is monotone, it strictly decreases to 0, and the reciprocal map $z \mapsto t(z)$ is defined on $(0, x(0)]$ and is locally Lipschitz continuous (since $\dot{x}$ is bounded from above by some negative real number on every compact set).[3] Assume that for every n, there is a unique solution of $2^n f'(2^n(t - n)) + f(2^n(t - n)) = 0$ on the interval $(n - 1/2^n, n - 1/2^n)$, which we denote $n + \alpha_n$, such that $\lim_{n\to+\infty} n^2 2^n \alpha_n = 0$. This is the case if we take $f(x) = (1 - x^2)^2$, and in this case $\alpha_n = 1/2^{2n+1} + o(1/2^{2n})$. Let us choose a nonincreasing control $\varepsilon : [0, +\infty) \to (0, +\infty)$ of class $\mathcal{C}^\infty$ such that

$$\varepsilon(t) = \frac{1}{n} \text{ for every } t \in [n + \alpha_n + \beta_n,\ n + 1 + \alpha_{n+1} - \beta_{n+1}]$$

for some decreasing sequence $(\beta_n)_{n\in\mathbb{N}}$ of small enough positive real numbers. Define $V : (0, +\infty) \to \mathbb{R}$ by

$$V'(2x(t)) = -(\ddot{x}(t) + \dot{x}(t))/\varepsilon(t).$$

Then V' is locally Lipschitz continuous. Let us verify that $\lim_{z\to 0} V(z) = +\infty$. We have $dV(2x(t))/dt = 2V'(2x(t))\dot{x}(t) = -2\dot{x}(t)(\ddot{x}(t) + \dot{x}(t))/\varepsilon(t)$. The map $\dot{x}$ is negative, and for every n and every $t \in [n - 1 + 1/2^{n-1}, n + 1 - 1/2^{n+1}]$,

$$\ddot{x}(t) + \dot{x}(t) = -\sqrt{1 + \frac{1}{n}} \left(2^n f'\left(2^n\left(t - n\right)\right) + f\left(2^n\left(t - n\right)\right)\right).$$

[3]This immediate statement is of importance in order to obtain a locally Lipschitz continuous map V'. Without this constraint, one could forget the term e^{-t} in the definition of x and $\dot{x}$ and obtain a $\mathcal{C}^1$ coupling potential V, but nonunique solutions appear.

Then $\ddot{x}(t)+\dot{x}(t)=0$ if $t\in[n+1/2^n, n+1-1/2^{n+1}]$, $\ddot{x}(t)+\dot{x}(t)>0$ if $t\in(n+\alpha_n, n+1/2^n)$, and $\ddot{x}(t)+\dot{x}(t)<0$ if $t\in(n+1-1/2^{n+1}, n+1+\alpha_{n+1})$. Hence $t\mapsto V(2x(t))$ increases on the interval $[n+\alpha_n, n+1/2^n]$, is constant on $[n+1/2^n, n+1-1/2^{n+1}]$, and decreases on $[n+1-1/2^{n+1}, n+1+\alpha_{n+1}]$. It is then sufficient to estimate $V(2x(n+1+\alpha_{n+1}))-V(2x(n+\alpha_n))$.

$$\begin{aligned}
V(2x(n+1+\alpha_{n+1}))-V(2x(n+\alpha_n)) &= \int_{n+\alpha_n}^{n+1+\alpha_{n+1}} -2\frac{\dot{x}(t)\ddot{x}(t)+\dot{x}(t)^2}{\varepsilon(t)}dt\\
&= \int_{n+\alpha_n}^{n+1+\alpha_{n+1}} -2\frac{\dot{x}(t)\ddot{x}(t)+\dot{x}(t)^2}{1/n}dt + o\left(\frac{1}{n}\right)^4\\
&= -2n\int_{n+\alpha_n}^{n+1/2^n} \dot{x}(t)\ddot{x}(t)+\dot{x}(t)^2dt - 2n\int_{n+1-1/2^{n+1}}^{n+1+\alpha_{n+1}} \dot{x}(t)\ddot{x}(t)\\
&\quad +\dot{x}(t)^2dt + o\left(\frac{1}{n}\right)\\
&= n\left(\dot{x}(n+\alpha_n)^2-\dot{x}(n+1+\alpha_{n+1})^2\right)+o\left(\frac{1}{n}\right)^5\\
&= n\left(1+\frac{1}{n}-1-\frac{1}{n+1}\right)+o\left(\frac{1}{n}\right)^6\\
&= \frac{1}{n+1}+o\left(\frac{1}{n}\right).
\end{aligned}$$

Hence $\lim_{z\to 0}V(z)=+\infty$, and by choosing $V(2x(0))$ large enough, V is positive. Defining V symmetrically on $\mathbb{R}_-\setminus\{0\}$, all the assumptions of Theorem 2.4, Part 1 are satisfied. The map $(x,-x)$ is by construction a solution of the corresponding (HBFC^2_{sing}) system with $\gamma=1$, $x_\infty=y_\infty=0$, and, clearly, the map $\dot{x}$ does not converge to 0.

Remark 3.10. The radial symmetry and repulsion assumption $(\mathcal{H}_V)$(iii), with $e=0$, implies assumption $(\mathcal{H}_V)$(iv), but the converse is not true. However, since $H=\mathbb{R}$, and since $x-y$ keeps a constant sign, assumption $(\mathcal{H}_V)$(iv) is sufficient to obtain Theorem 2.2, Part 2, i.e., $\lim_{t\to+\infty}\dot{x}(t)=\lim_{t\to+\infty}\dot{y}(t)=0$.

4. Global existence: Proof of Proposition 2.1. The proof, which we briefly recall, is quite standard and differs from the regular case only when showing that the trajectories are defined on the whole set $[0,+\infty)$. We let

$$\begin{aligned}
&X=(x,y)\in H^2, \quad \Phi(X)=\phi(x)+\phi(y), \quad U(X)=V(x-y),\\
&X_0=(x_0,y_0), \quad \dot{X}_0=(\dot{x}_0,\dot{y}_0).
\end{aligned}$$

The system (HBFC^2_{sing}) then reduces to

$$(\mathrm{HBFC}) \quad \ddot{X}+\gamma\dot{X}+\nabla\Phi(X)+\varepsilon(t)\nabla U(X)=0, \quad X(0)=X_0, \quad \dot{X}(0)=\dot{X}_0.$$

Proof of (i). The second order system (HBFC) can be written as a first order system in $\Gamma\times H^2$, $\dot{Y}=F(t,Y)$ with $Y(t)=(X(t),\dot{X}(t))$, and $F(t,u,v)=(v,-\gamma v-$

[4]The equality holds true by choosing β_n and β_{n+1} small enough.

[5]The equality holds true since $\dot{x}(n+1/2^n)=-e^{n+1/2^n}=o(1/n^2)$ and $\dot{x}(n+1+1/2^{n+1})=o(1/n^2)$.

[6]The function f attains its maximum at 0, $f'(0)=0$, and $\dot{x}(n+\alpha_n)=-e^{n+\alpha_n}-\sqrt{1+\frac{1}{n}}f(2^n\alpha_n)=o(1/n^2)-\sqrt{1+\frac{1}{n}}(1+o(2^n\alpha_n))=-\sqrt{1+\frac{1}{n}}+o(1/n^2)$.

$\nabla\Phi(u) - \varepsilon(t)\nabla U(u))$. For $Y_0 = (X_0, \dot{X}_0)$ given in $\Gamma \times H^2$, the Cauchy–Lipschitz theorem and Hypothesis 1 ensure the existence of a unique local solution to the problem $\dot{Y} = F(t, Y)$, $Y(0) = Y_0$. Let X denote the maximal solution defined on the interval $[0, T_{max})$ with $0 < T_{max} \leq +\infty$. Observe that equation (HBFC) and the regularity assumptions on $\phi, V,$ and ε automatically imply that the map X is $\mathcal{C}^2$ on the interval $[0, T_{max})$. We first show that the map $\dot{X}$ is bounded.

We can define along every trajectory of (HBFC) the energy function by

$$E(t) = \frac{1}{2}|\dot{X}(t)|^2 + \Phi(X(t)) + \varepsilon(t)U(X(t)).$$

By differentiation of $E(t)$, and in view of (HBFC), we obtain for every $t \in [0, T_{max})$

$$\begin{aligned} \dot{E}(t) &= \left\langle \dot{X}(t), \ddot{X}(t) + \nabla\Phi(X(t)) + \varepsilon(t)\nabla U(X(t)) \right\rangle + \dot{\varepsilon}(t)U(X(t)) \\ &= -\gamma|\dot{X}(t)|^2 + \dot{\varepsilon}(t)U(X(t)). \end{aligned} \tag{4.1}$$

Since $\dot{\varepsilon}(t) \leq 0$ (assumption $(\mathcal{H}_\varepsilon)$(i)) and $U \geq 0$, we have $\dot{E}(t) \leq 0$. Hence the function E is nonincreasing, which proves (iii), and for all $t \in [0, T_{max})$ $E(t) \leq E(0)$. Equivalently,

$$\frac{1}{2}|\dot{X}(t)|^2 + \Phi(X(t)) + \varepsilon(t)U(X(t)) \leq E(0). \tag{4.2}$$

Since Φ is bounded from below, $U(X(t)) \geq 0$, and $\varepsilon(t) \geq 0$, we obtain that

$$\sup_{t\in[0,T_{max})} |\dot{X}(t)| < +\infty \quad \text{and} \quad \sup_{t\in[0,T_{max})} \varepsilon(t)U(X(t)) < +\infty.$$

We now prove $T_{max} = +\infty$, noting that assumption $(\mathcal{H}_V)$(ii) is crucial in the singular case. Indeed, assume that $T_{max} < +\infty$. We have $|X(t) - X(t')| \leq ||\dot{X}||_\infty |t - t'|$, and since $T_{max} < +\infty$, then $\lim_{t\to T_{max}} X(t) := X_\infty$ exists and belongs to $\mathrm{cl}\,\Gamma$. Hence, X and $\dot{X}$ are bounded on $[0, T_{max})$. From assumption $(\mathcal{H}_\phi)$(ii)

$$\nabla\Phi(X) \quad \text{is bounded on } [0, T_{max}). \tag{4.3}$$

From (4.2), we obtain for every $t \in [0, T_{max})$, $\varepsilon(t)U(X(t)) \leq E(0) - \inf\Phi$. Hence, since the function ε is nonincreasing

$$\forall t \in [0, T_{max}), \qquad U(X(t)) \leq \frac{E(0) - \inf\Phi}{\varepsilon(T_{max})}.$$

Assume $X_\infty \notin \Gamma$. Then $X_\infty \in \mathrm{bd}\,\Gamma$ and assumption $(\mathcal{H}_V)$(ii) implies

$$\lim_{t\to T_{max}} U(X(t)) = +\infty,$$

which contradicts the previous inequality. Hence $X_\infty \in \Gamma$. Then the set $\{\nabla U(X(t)), t \in [0, T_{max})\} \cup \{\nabla U(X_\infty)\}$ is compact and, in particular,

$$\nabla U(X) \quad \text{is bounded on } [0, T_{max}). \tag{4.4}$$

From (HBFC), (4.3), and (4.4) the map $\ddot{X}$ is also bounded on the interval $[0, T_{max})$. Hence $\lim_{t\to T_{max}} \dot{X}(t) = \dot{X}_\infty$ exists. Applying again the local existence theorem with

initial data $(X_\infty, \dot{X}_\infty) \in \Gamma \times H^2$, we extend the maximal solution to a strictly larger interval, a contradiction. Hence $T_{max} = +\infty$, which completes the proof of (i). ∎

Proof of (ii). From (4.1), since $\dot{\varepsilon} \leq 0$ and $U \geq 0$, we derive, for every t,

$$\int_0^t |\dot{X}(s)|^2 ds \leq \frac{1}{\gamma}(E(0) - E(t)).$$

Since the function E is nonincreasing, for every t, $E(0) \geq E(t) \geq \Phi(X(t))$; hence the map Φ is bounded from above, hence bounded, and the function E is bounded from below. Hence $\lim_{t\to+\infty} E(t) = E_\infty$ for some $E_\infty \in \mathbb{R}$. Hence $\dot{X} \in L^2([0,+\infty); H^2)$. We proved above that $\dot{X} \in L^\infty([0,+\infty); H^2)$ and $\varepsilon U(X) \in L^\infty([0,+\infty); \mathbb{R})$. ∎

5. Asymptotic properties: Proof of Theorem 2.2. The proof of Theorem 2.2 goes in three steps. In section 5.1, we prove preliminary results. In section 5.2, we prove Part 1. Finally, we prove Part 2 in section 5.3.

5.1. Preliminary results. In this section, we first obtain results by adding the two equations of (HBFC$^2_{sing}$), with no influence from the interaction potential V.

LEMMA 5.1. *Under the assumptions of Theorem* 2.2*,*

(i) *the maps* $\nabla\phi(x)$ *and* $\nabla\phi(y)$ *are bounded;*

(ii) $\lim_{t\to+\infty} \dot{x}(t) + \dot{y}(t) = 0$*, and the map* $\ddot{x} + \ddot{y}$ *is bounded.*

Proof of Lemma 5.1. *Proof of* (i). If the trajectory (x, y) is bounded (case (a)), it is an immediate consequence of assumption $(\mathcal{H}_\phi)$(ii). Let us now consider case (b). From Proposition 2.1(ii), the map $\phi(x)$ is bounded. The limit condition (LIM) implies that the set

$$C = \{z \in H, \phi(z) \leq \|\phi(x)\|_\infty \text{ and } |\nabla\phi(z)| \geq 1\}$$

is bounded. Since the map $\nabla\phi$ is bounded on the bounded sets, it is bounded on C. If $x(t) \notin C$, since $\phi(x(t)) \leq \|\phi(x)\|_\infty$, we deduce $|\nabla\phi(x(t))| < 1$. Hence the map $\nabla\phi(x)$ is bounded, and so is the map $\nabla\phi(y)$.

Proof of (ii). By adding the two equations of (HBFC$^2_{sing}$), we obtain

$$\ddot{x}(t) + \ddot{y}(t) + \gamma(\dot{x}(t) + \dot{y}(t)) + \nabla\phi(x(t)) + \nabla\phi(y(t)) = 0. \tag{5.1}$$

Since, by (i), $\nabla\phi(x)$ and $\nabla\phi(y)$ are bounded and since by Proposition 2.1(ii), $\dot{x}$ and $\dot{y}$ are bounded, then from (5.1) the map $\ddot{x} + \ddot{y}$ is bounded. From Proposition 2.1(ii), the map $\dot{x} + \dot{y}$ belongs to $L^2([0,+\infty), H)$, and we deduce by a classical argument

$$\lim_{t\to+\infty} \dot{x}(t) + \dot{y}(t) = 0. \qquad ∎$$

LEMMA 5.2. *Under the assumptions of Theorem* 2.2*, let* $(t_n) \subset \mathbb{R}_+$ *be a sequence such that* $\lim_{n\to+\infty} t_n = +\infty$ *and* $(x(t_n), y(t_n))$ *is bounded. Then*

$$\lim_{n\to+\infty} \nabla\phi(x(t_n)) + \nabla\phi(y(t_n)) = 0.$$

Proof of Lemma 5.2. In view of Lemma 5.1(ii) and (5.1), it is equivalent to prove that $\lim_{n\to+\infty} \ddot{x}(t_n) + \ddot{y}(t_n) = 0$. Take a real number $\tau > 0$. Since the maps $\dot{x}$ and $\dot{y}$ are bounded, and since the sequence $(x(t_n), y(t_n))$ is bounded, the sets $\bigcup_{n\geq0} x([t_n - \tau, t_n + \tau])$ and $\bigcup_{n\geq0} y([t_n - \tau, t_n + \tau])$ are also bounded. Hence the map $\nabla\phi$ is K-Lipschitz continuous on the bounded set

$$\bigcup_{n\geq0} x([t_n - \tau, t_n + \tau]) \cup \bigcup_{n\geq0} y([t_n - \tau, t_n + \tau])$$

for some $K > 0$. Let $z = x + y$; then $\dot{z}$ and $\ddot{z}$ are also Lipschitz continuous on the bounded set $\bigcup_{n\geq 0} x([t_n-\tau, t_n+\tau]) \cup \bigcup_{n\geq 0} y([t_n-\tau, t_n+\tau])$. The proof now consists in a.e. differentiating (5.1). We obtain, for almost every t,

$$\dddot{z}(t) + \gamma\ddot{z}(t)(t) + \frac{d}{dt}\nabla\phi(x(.))(t) + \frac{d}{dt}\nabla\phi(y(.))(t) = 0.$$

But $|\frac{d}{dt}\nabla\phi(x(.))(t) + \frac{d}{dt}\nabla\phi(y(.))(t)| \leq K(|\dot{x}(t)| + |\dot{y}(t)|)$. From the above equation,

$$\text{for a.e. } t,\ \dddot{z}(t) + \gamma\ddot{z}(t)(t) \leq K\left(|\dot{x}(t)| + |\dot{y}(t)|\right). \tag{5.2}$$

Assuming without loss of generality that $t_n - \tau \geq 0$, we multiply (5.2) by $e^{\gamma t}$ and integrate between $t_n - \tau$ and t_n.

$$\ddot{z}(t_n) \leq \ddot{z}(t_n - \tau)e^{-\gamma\tau} + e^{-\gamma t_n}\int_{t_n-\tau}^{t_n} e^{\gamma s}K\left(|\dot{x}(s)| + |\dot{y}(s)|\right)\, ds.$$

By Cauchy–Schwarz inequality

$$\begin{aligned}|\ddot{z}(t_n)| &\leq |\ddot{z}(t_n - \tau)|e^{-\gamma\tau} + e^{-\gamma t_n}\left(\int_{t_n-\tau}^{t_n} e^{2\gamma s}\, ds\right)^{\frac{1}{2}}\left(\int_{t_n-\tau}^{t_n} K^2\left(|\dot{x}(s)| + |\dot{y}(s)|\right)^2\, ds\right)^{\frac{1}{2}}\\ &\leq |\ddot{z}(t_n - \tau)|e^{-\gamma\tau} + \frac{1}{\sqrt{2\gamma}}\left(\int_{t_n-\tau}^{t_n} K^2\left(|\dot{x}(s)| + |\dot{y}(s)|\right)^2\, ds\right)^{\frac{1}{2}}.\end{aligned}$$

Recalling that $\dot{x}$ and $\dot{y}$ belong to $L^2([0,+\infty); H)$, let us take the upper limit of each member when $n \to +\infty$:

$$\limsup_{n\to+\infty} |\ddot{x}(t_n) + \ddot{y}(t_n)(t_n)| \leq \|\ddot{x} + \ddot{y}\|_\infty e^{-\gamma\tau}.$$

At the limit when $\tau \to +\infty$, we obtain $\lim_{t\to+\infty} \ddot{x}(t_n) + \ddot{y}(t_n) = 0$. □

5.2. Proof of Theorem 2.2, Part 1. We distinguish the two cases (a) and (b).

5.2.1. Proof in case (a). The trajectory (x, y) is bounded, and the fact that $\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0$ is an immediate consequence of the following lemma. □

LEMMA 5.3. *Under the assumptions of Theorem* 2.2*, let* $(t_n) \subset \mathbb{R}_+$ *be a sequence such that* $\lim_{n\to+\infty} t_n = +\infty$ *and* $(x(t_n), y(t_n))$ *is bounded. Then*

$$\lim_{n\to+\infty} \nabla\phi(x(t_n)) = \lim_{n\to+\infty} \nabla\phi(y(t_n)) = 0.$$

Contrary to its regular version [6, Lemma 4.1], the proof of Lemma 5.3 uses the coupled structure of the system. An important step is the proof that the map $t \mapsto \nabla V(x(t) - y(t))$ is bounded on a convenient set.

Proof of Lemma 5.3. Assume that it is not true. Then there exists $\alpha > 0$ and a subsequence of (t_n), still denoted by (t_n), such that $\lim_{n\to\infty} t_n = +\infty$ and $|\nabla\phi(x(t_n))| \geq 2\alpha$ or $|\nabla\phi(y(t_n))| \geq 2\alpha$ for every n. Without loss of generality, we may assume that, for every $n \geq 0$,

$$|\nabla\phi(x(t_n))| \geq 2\alpha. \tag{5.3}$$

By assumption, the map $\nabla\phi$ is K-Lipschitz continuous on the bounded set

$$C = \{z \in H, \quad \exists n \in \mathbb{N}, \quad |z - x(t_n)| \leq 1 \text{ or } |z - y(t_n)| \leq 1\}$$

for some $K > 0$. Let $\tau = \frac{\alpha}{K \max\{\|\dot{x}\|_\infty, \|\dot{y}\|_\infty\}}$ (assuming, without loss of generality, that $\max\{\|\dot{x}\|_\infty, \|\dot{y}\|_\infty\} \neq 0$) and let $t \in [t_n, t_n + \tau]$. Then

$$|x(t) - x(t_n)| \leq \|\dot{x}\|_\infty \tau \leq \frac{\alpha}{K} \quad \text{and} \quad |y(t) - y(t_n)| \leq \|\dot{y}\|_\infty \tau \leq \frac{\alpha}{K}.$$

Assuming without loss of generality that $\frac{\alpha}{K} \leq 1$, then from above $x(t) \in C$ and $y(t) \in C$. Consequently,

$$|\nabla\phi(x(t)) - \nabla\phi(x(t_n))| \leq K|x(t) - x(t_n)| \leq K\frac{\alpha}{K} = \alpha, \tag{5.4}$$

$$|\nabla\phi(y(t)) - \nabla\phi(y(t_n))| \leq K|y(t) - y(t_n)| \leq K\frac{\alpha}{K} = \alpha. \tag{5.5}$$

For every $t \in [t_n, t_n + \tau]$, let us now multiply the first equation of (HBFC^2_{sing}) by $e^{\gamma s}$ and integrate on the interval $[t_n, t]$

$$e^{\gamma t}\dot{x}(t) - e^{\gamma t_n}\dot{x}(t_n) + \int_{t_n}^{t} e^{\gamma s}\,\nabla\phi(x(s))\,ds + \int_{t_n}^{t} e^{\gamma s}\,\varepsilon(s)\nabla V(x(s) - y(s))\,ds = 0. \tag{5.6}$$

In view of (5.4), we have

$$\left|\int_{t_n}^{t} e^{\gamma s}\,\nabla\phi(x(s))\,ds - \int_{t_n}^{t} e^{\gamma s}\,\nabla\phi(x(t_n))\,ds\right| \leq \int_{t_n}^{t} e^{\gamma s}\alpha\,ds = \alpha\,\frac{e^{\gamma t} - e^{\gamma t_n}}{\gamma}.$$

On the other hand,

$$\left|\int_{t_n}^{t} e^{\gamma s}\,\nabla\phi(x(t_n))\,ds\right| = \frac{e^{\gamma t} - e^{\gamma t_n}}{\gamma}|\nabla\phi(x(t_n))| \geq 2\alpha\,\frac{e^{\gamma t} - e^{\gamma t_n}}{\gamma}.$$

Then, noticing, moreover, that $\nabla\phi$ is bounded by some $M > 0$ on the bounded set C,

$$\alpha\,\frac{e^{\gamma t} - e^{\gamma t_n}}{\gamma} \leq \left|\int_{t_n}^{t} e^{\gamma s}\,\nabla\phi(x(s))\,ds\right| \leq M\,\frac{e^{\gamma t} - e^{\gamma t_n}}{\gamma}. \tag{5.7}$$

Let us now prove that the map $t \mapsto \nabla V(x(t) - y(t))$ is bounded on the set $\bigcup_{n\in\mathbb{N}}[t_n, t_n + \tau]$. From Lemma 5.2, $\lim_{n\to+\infty} \nabla\phi(x(t_n)) + \nabla\phi(y(t_n)) = 0$; hence there exists $N \in \mathbb{N}$ such that, for every $n \geq N$,

$$|\nabla\phi(x(t_n)) + \nabla\phi(y(t_n))| \leq \alpha. \tag{5.8}$$

Writing

$$\begin{aligned} 2\,\nabla\phi(x(t_n)) = \quad & \nabla\phi(x(t)) - \nabla\phi(y(t)) \quad + \quad \nabla\phi(x(t_n)) - \nabla\phi(x(t)) \\ & + \nabla\phi(y(t)) - \nabla\phi(y(t_n)) \quad + \quad \nabla\phi(x(t_n)) + \nabla\phi(y(t_n)) \end{aligned}$$

and taking into account (5.3), (5.4), (5.5), and (5.8), we find $4\,\alpha \leq |\nabla\phi(x(t)) - \nabla\phi(y(t))| + 3\,\alpha$, i.e.,

$$|\nabla\phi(x(t)) - \nabla\phi(y(t))| \geq \alpha.$$

Since $\nabla\phi$ is K-Lipschitz continuous on the bounded set C, we have $|\nabla\phi(x(t)) - \nabla\phi(y(t))| \le K\,|x(t)-y(t)|$, which combined with the previous inequality yields

$$|x(t)-y(t)| \ge \frac{\alpha}{K}.$$

Since $(x(t_n), y(t_n))$ is bounded, and since the maps $\dot{x}$ and $\dot{y}$ are bounded, the above equation implies that the set

$$\left\{ x(t)-y(t), t \in \bigcup_{n\ge N} [t_n, t_n+\tau] \right\}$$

is a bounded subset of $H \setminus B(0, \frac{\alpha}{K})$, and the map ∇V is bounded on this set. Equivalently, the map $t \mapsto \nabla V(x(t)-y(t))$ is bounded on the set $\bigcup_{n\ge N}[t_n, t_n+\tau]$, hence on the set $\bigcup_{n\in\mathbb{N}}[t_n, t_n+\tau]$. Since $\lim_{t\to+\infty}\varepsilon(t)=0$, for n large enough and for every $t \in [t_n, t_n+\tau]$,

$$\left| \int_{t_n}^{t} e^{\gamma s}\,\varepsilon(s)\nabla V(x(s)-y(s))\,ds \right| \le \frac{\alpha}{2}\,\frac{e^{\gamma t}-e^{\gamma t_n}}{\gamma}. \tag{5.9}$$

In view of (5.6), (5.7), and (5.9), for every $t \in [t_n, t_n+\tau]$,

$$\frac{\alpha}{2}\,\frac{e^{\gamma t}-e^{\gamma t_n}}{\gamma} \le \left| e^{\gamma t}\dot{x}(t) - e^{\gamma t_n}\dot{x}(t_n)\right| \le \left(M+\frac{\alpha}{2}\right)\,\frac{e^{\gamma t}-e^{\gamma t_n}}{\gamma},$$

which can be rewritten as

$$\frac{\alpha}{2}\,\frac{e^{\gamma(t-t_n)}-1}{\gamma} \le |e^{\gamma(t-t_n)}\dot{x}(t) - \dot{x}(t_n)| \le \left(M+\frac{\alpha}{2}\right)\,\frac{e^{\gamma(t-t_n)}-1}{\gamma}.$$

Taking the following claim into account, we obtain, for some $\beta>0$ and n large enough, $\int_{t_n}^{t_n+\tau} e^{\gamma(t-t_n)}\,|\dot{x}(t)|\,dt \ge \beta$. We then deduce from Cauchy–Schwarz inequality

$$\frac{e^{2\gamma\tau}-1}{2\gamma}\int_{t_n}^{t_n+\tau} |\dot{x}(t)|^2\,dt \;\ge\; \beta^2,$$

and, finally, $\int_{t_n}^{t_n+\tau}|\dot{x}(t)|^2\,dt \;\ge\; 2\gamma\,\beta^2\,e^{-2\gamma\tau}$, which contradicts $\dot{x} \in L^2([0,+\infty), H)$. Hence $\lim_{n\to+\infty}\nabla\phi(x(t_n)) = \lim_{n\to+\infty}\nabla\phi(y(t_n)) = 0$. □

Claim 5.1. Let $g \in \mathcal{C}^0([0,\tau],\mathbb{R}_+)$ and $h \in \mathcal{C}^0([0,\tau],\mathbb{R}_+)$ such that $\int_0^\tau g(t)\,dt > 0$, $h(0)=0$. There exists $\beta>0$ such that, for every $f \in \mathcal{C}^0([0,\tau],H)$ which satisfies $g(t) \le |f(t)-f(0)| \le h(t)$ for every $t\in[0,\tau]$,

$$\int_0^\tau |f(t)|dt \ge \beta.$$

Proof of Claim 5.1. Since $h(0)=0$, we clearly have $\lim_{t\to0}\frac{\int_0^t h(s)\,ds}{t}=0$. Let $\theta \in]0,\tau[$ such that $\int_0^\theta h(s)\,ds \le \frac{\int_0^\tau g(t)dt}{4\tau}\theta$. Let $\beta = \min\{\frac{\int_0^\tau g(t)\,dt}{2}, \frac{\int_0^\tau g(t)dt}{4\tau}\theta\}$. First assume $|f(0)| \le \frac{\int_0^\tau g(t)dt}{2\tau}$. Then $|f(t)| \ge g(t) - |f(0)|$ implies $\int_0^\tau |f(t)|dt \ge \frac{\int_0^\tau g(t)\,dt}{2}$. Now assume $|f(0)| \ge \frac{\int_0^\tau g(t)dt}{2\tau}$. Then $|f(t)| \ge |f(0)| - h(t)$ implies $\int_0^\tau |f(t)|dt \ge \int_0^\theta |f(t)|dt \ge \frac{\int_0^\tau g(t)dt}{2\tau}\theta - \frac{\int_0^\tau g(t)dt}{4\tau}\theta = \frac{\int_0^\tau g(t)dt}{4\tau}\theta$. □

5.2.2. Proof in case (b). Let us argue by contradiction and assume that it is not true; i.e., there exists $\alpha > 0$ and a sequence $(t_n) \subset \mathbb{R}_+$ such that $\lim_{n\to+\infty} t_n = +\infty$ and $|\nabla\phi(x(t_n))| \geq \alpha$ or $|\nabla\phi(y(t_n))| \geq \alpha$. Without loss of generality, we may assume that $|\nabla\phi(x(t_n))| \geq \alpha$. Since the map $\phi(x)$ is bounded (Proposition 2.1(ii)) and since the map ϕ satisfies the limit condition (LIM), the sequence $(x(t_n))$ is bounded. The following lemma from [6] shows that the sequence $(y(t_n))$ is also bounded. From Lemma 5.3, $\lim_{n\to+\infty} \nabla\phi(x(t_n)) = 0$, a contradiction. Hence $\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0$. □

LEMMA 5.4 (see [6, Lemma 4.2]). *Assume Hypothesis* 1 *and Hypothesis* 2*; i.e., the map ϕ satisfies the limit condition* (LIM). *Let $\alpha > 0$ and $(t_n) \subset \mathbb{R}_+$ be a sequence such that $\lim_{n\to+\infty} t_n = +\infty$, $(x(t_n))$ is bounded, and $|\nabla\phi(x(t_n))| \geq \alpha$. Then the sequence $(y(t_n))$ is also bounded.*

The proof of Lemma 5.4 is independent from the singularity assumption on V, and the proof given in [6] remains valid in the present case.

5.3. Proof of Theorem 2.2, Part 2. The proof of Part 2 heavily relies on the direct study of the map $x - y$. By taking the difference of the two equations of (HBFC^2_{sing}), we obtain

(5.10)
$$\ddot{x}(t) - \ddot{y}(t) + \gamma(\dot{x}(t) - \dot{y}(t)) + \nabla\phi(x(t)) - \nabla\phi(y(t)) + 2\varepsilon(t)\nabla V(x(t) - y(t)) = 0.$$

We then deduce that the function $h(t) := \frac{1}{2}|x(t) - y(t)|^2$ satisfies the following equation:

$$\begin{aligned}\ddot{h}(t) + \gamma\dot{h}(t) =& |\dot{x}(t) - \dot{y}(t)|^2 - \langle \nabla\phi(x(t)) - \nabla\phi(y(t)), x(t) - y(t)\rangle \\ &-2\varepsilon(t)\langle \nabla V(x(t) - y(t)), x(t) - y(t)\rangle.\end{aligned} \tag{5.11}$$

Recalling that $\lim_{t\to+\infty} \dot{x}(t) + \dot{y}(t) = 0$ (Lemma 5.1), it is sufficient to prove that $\lim_{t\to+\infty} \dot{x}(t) - \dot{y}(t) = 0$. Assume that it is not true. Then there is $\alpha > 0$ and a sequence $(t_n) \subset \mathbb{R}_+$ such that $\lim_{n\to+\infty} t_n = +\infty$ and

$$\lim_{t\to+\infty} |\dot{x}(t_n) - \dot{y}(t_n)|^2 = \alpha.$$

Since $|\dot{x}-\dot{y}|^2 \in L^1([0,+\infty);\mathbb{R}_+)$ (Proposition 2.1), then $\liminf_{t\to+\infty} |\dot{x}(t)-\dot{y}(t)|^2 = 0$. Hence there exists two sequences (a_n) and (b_n) in $\mathbb{R}_+$ such that

$$|\dot{x}(t) - \dot{y}(t)|^2 \geq \frac{\alpha}{2} \text{ for every } t \in [t_n - a_n, t_n + b_n], \tag{5.12}$$

$$|\dot{x}(t_n - a_n) - \dot{y}(t_n - a_n)|^2 = |\dot{x}(t_n + b_n) - \dot{y}(t_n + b_n)|^2 = \frac{\alpha}{2}. \tag{5.13}$$

Without loss of generality, we assume $|\dot{x}(t_n)-\dot{y}(t_n)|^2 = \alpha$ for every n. Since $|\dot{x}-\dot{y}|^2 \in L^1([0,+\infty);\mathbb{R}_+)$, we have $\lim_{n\to+\infty} a_n = \lim_{n\to+\infty} b_n = 0$. From Rolle's theorem, there are $t^a_n \in (t_n - a_n, t_n)$ and $t^b_n \in (t_n + b_n, t_n)$ such that

$$2\,\langle \ddot{x}(t^a_n) - \ddot{y}(t^a_n), \dot{x}(t^a_n) - \dot{y}(t^a_n)\rangle = \frac{d}{dt}|\dot{x} - \dot{y}|^2(t^a_n) = \frac{\alpha}{2a_n}, \tag{5.14}$$

$$2\,\big\langle \ddot{x}(t^b_n) - \ddot{y}(t^b_n), \dot{x}(t^b_n) - \dot{y}(t^b_n)\big\rangle = \frac{d}{dt}|\dot{x} - \dot{y}|^2(t^b_n) = -\frac{\alpha}{2b_n}. \tag{5.15}$$

Taking the scalar product of (5.10) with $\dot{x}(t) - \dot{y}(t)$, we deduce

$$\begin{aligned}&\langle \ddot{x}(t) - \ddot{y}(t), \dot{x}(t) - \dot{y}(t)\rangle + \gamma|\dot{x}(t) - \dot{y}(t)|^2 + \langle \nabla\phi(x(t)) - \nabla\phi(y(t)), \dot{x}(t) - \dot{y}(t)\rangle \\ &\qquad +2\varepsilon(t)\langle \nabla V(x(t) - y(t)), \dot{x}(t) - \dot{y}(t)\rangle = 0.\end{aligned} \tag{5.16}$$

Since the map $t \mapsto \gamma|\dot{x}(t)-\dot{y}(t)|^2+\langle\nabla\phi(x(t))-\nabla\phi(y(t)),\dot{x}(t)-\dot{y}(t)\rangle$ is bounded, and in view of (5.14) and (5.15), for n large enough, we have

$$\langle\nabla V(x(t_n^a)-y(t_n^a)),\dot{x}(t_n^a)-\dot{y}(t_n^a)\rangle \le -\frac{\alpha}{5a_n},$$
$$\big\langle\nabla V(x(t_n^b)-y(t_n^b)),\dot{x}(t_n^b)-\dot{y}(t_n^b)\big\rangle \ge \frac{\alpha}{5a_n}.$$

At this point, let us first assume for simplicity that the error function e is equal to zero. Note that in this case, the assumption that the function W is of class $\mathcal{C}^1$ is automatically satisfied since we assumed that the potential V is of class $\mathcal{C}^1$. From $(\mathcal{H}_V)$(iii), $\nabla V(z)=W'(|z|)\frac{z}{|z|}$. Hence $\langle\nabla V(x-y),\dot{x}-\dot{y}\rangle=\frac{W'(|x-y|)}{|x-y|}\langle x-y,\dot{x}-\dot{y}\rangle=\frac{W'(|x-y|)}{|x-y|}\dot{h}$, and we deduce

$$\dot{h}(t_n^a)>0 \quad\text{and}\quad \dot{h}(t_n^b)<0.$$

Let us now multiply (5.11) by $e^{\gamma t}$ and integrate between t_n^a and t_n^b:

$$\frac{1}{\gamma}\left(e^{\gamma t_n^b}\,\dot{h}(t_n^b)-e^{\gamma t_n^a}\,\dot{h}(t_n^a)\right)=\int_{t_n^a}^{t_n^b}|\dot{x}(t)-\dot{y}(t)|^2-\langle\nabla\phi(x(t))-\nabla\phi(y(t)),x(t)-y(t)\rangle$$
$$-2\varepsilon(t)\langle\nabla V(x(t)-y(t)),x(t)-y(t)\rangle dt.$$

From $(\mathcal{H}_V)$(iii), $\langle\nabla V(z),z\rangle=W'(|z|)|z|$; hence $\langle\nabla V(x(t)-y(t)),x(t)-y(t)\rangle\le 0$. In view of (5.12), we deduce

$$\frac{\alpha}{2}(t_n^b-t_n^a)\le\sup_{t\in[t_n^a,t_n^b]}|x(t)-y(t)|\sup_{t\in[t_n^a,t_n^b]}|\nabla\phi(x(t))-\nabla\phi(y(t))|(t_n^b-t_n^a).$$

From the following lemma, the sequence $(\sup_{t\in[t_n^a,t_n^b]}|x(t)-y(t)|)_{n\in\mathbb{N}}$ is bounded (remark that this is clear when the trajectories x and y are bounded). From Theorem 2.2, Part 1, we have $\lim_{t\to+\infty}\nabla\phi(x(t))=\lim_{t\to+\infty}\nabla\phi(y(t))=0$, and we obtain a contradiction in the previous equation, for n large enough. Hence $\lim_{t\to+\infty}\dot{x}(t)-\dot{y}(t)=0$, which implies $\lim_{t\to+\infty}\dot{x}(t)=\lim_{t\to+\infty}\dot{y}(t)=0$. □

LEMMA 5.5.

$$\lim_{n\to+\infty}\sup_{t\in[t_n^a,t_n^b]}|x(t)-y(t)|=0.$$

Proof of Lemma 5.5. It is a consequence on a direct estimation on the energy function $E(t)=\frac{1}{2}|\dot{x}(t)|^2+\frac{1}{2}|\dot{y}(t)|^2+\phi(x(t))+\phi(y(t))+\varepsilon(t)V(x(t)-y(t))$. Recall that it is decreasing (Proposition 2.1(iii)); hence $E(t_n-a_n)\ge E(t_n)$. Since $|\dot{x}|^2+|\dot{y}|^2=\frac{1}{2}|\dot{x}-\dot{y}|^2+\frac{1}{2}|\dot{x}+\dot{y}|^2$, and since $\lim_{t\to+\infty}\dot{x}(t)+\dot{y}(t)=0$ (Lemma 5.1), for n large enough

$$\frac{1}{2}\,|\dot{x}(t_n-a_n)|^2+\frac{1}{2}\,|\dot{y}(t_n-a_n)|^2\le\frac{\alpha}{3},$$
$$\frac{1}{2}\,|\dot{x}(t_n)|^2+\frac{1}{2}\,|\dot{y}(t_n)|^2\ge\frac{\alpha}{2}.$$

Thus the inequality $E(t_n-a_n)\ge E(t_n)$ implies

$$\varepsilon(t_n-a_n)V(x(t_n-a_n)-y(t_n-a_n))\ge\frac{\alpha}{6}+\phi(x(t_n))+\phi(y(t_n))-\phi(x(t_n-a_n))$$
$$-\phi(y(t_n-a_n))+\varepsilon(t_n)V(x(t_n)-y(t_n)).$$

But $\frac{d}{dt}\phi(x(t)) + \frac{d}{dt}\phi(y(t)) = \langle \nabla\phi(x(t)), \dot{x}(t)\rangle + \langle \nabla\phi(y(t)), \dot{y}(t)\rangle$, the maps $\dot{x}$ and $\dot{y}$ are bounded, $\lim_{t\to+\infty} \nabla\phi(x(t)) = \lim_{t\to+\infty} \nabla\phi(y(t)) = 0$, and $\lim_{n\to+\infty} a_n = 0$; hence for n large enough

$$\varepsilon(t_n - a_n)V(x(t_n - a_n) - y(t_n - a_n)) \geq \frac{\alpha}{7}.$$

Since $\lim_{t\to+\infty} \varepsilon(t) = 0$, we have $\lim_{t\to+\infty} V(x(t_n - a_n) - y(t_n - a_n)) = +\infty$. Assumption $(\mathcal{H}_V)$(iii) clearly implies that the potential V is bounded on $H \setminus B(0, r)$, for every $r > 0$, and we deduce that $\lim_{n\to+\infty} |x(t_n - a_n) - y(t_n - a_n)| = 0$. Since $\lim_{n\to+\infty} a_n = \lim_{n\to+\infty} b_n = 0$, since the map $\dot{x} - \dot{y}$ is bounded, we deduce that $\lim_{n\to+\infty} \sup_{t\in[t_n-a_n,t_n+b_n]} |x(t) - y(t)| = 0$. Since $[t_n^a, t_n^b] \subset [t_n - a_n, t_n + b_n]$, this ends the proof of Lemma 5.5. □

We now proceed to the proof of Theorem 2.2, Part 2 in the general case. First notice that Lemma 5.5 remains valid. From $(\mathcal{H}_V)$(iii), $\nabla V(z) = W'(|z|)\frac{z}{|z|} + \nabla e(z)$. Hence $\langle \nabla V(x-y), \dot{x}-\dot{y}\rangle = \frac{W'(|x-y|)}{|x-y|}\langle x-y, \dot{x}-\dot{y}\rangle + \langle \nabla e(x-y), \dot{x}-\dot{y}\rangle = \frac{W'(|x-y|)}{|x-y|}\dot{h} + \langle \nabla e(x-y), \dot{x}-\dot{y}\rangle$. Since the gradient ∇e is bounded near 0, in view of Lemma 5.5, and since the map $\dot{x} - \dot{y}$ is bounded, we deduce that the term $\langle \nabla e(x-y), \dot{x}-\dot{y}\rangle$ is bounded on the interval $[t_n^a, t_n^b]$. We thus deduce again $\dot{h}(t_n^a) > 0$ and $\dot{h}(t_n^b) < 0$. Since $\langle \nabla V(z), z\rangle = W'(|z|)|z| + \langle \nabla e(z), z\rangle$, which is negative near 0, the remainder of the proof holds. □

5.3.1. Toward an alternate proof of Part 2. In this section, we show how a more classical proof can lead to the same result without the strong repulsion assumption on the potential V but, of course, with an additional assumption, namely, that the two trajectories do not collapse.

PROPOSITION 5.6. *Under the assumptions of Theorem* 2.2, *Part* 1, *for every* $\mu > \lambda > 0$,[7]

$$\lim_{t\to+\infty, |x(t)-y(t)|\in[\lambda,\mu]} \dot{x}(t) = \lim_{t\to+\infty, |x(t)-y(t)|\in[\lambda,\mu]} \dot{y}(t) = 0. \tag{5.17}$$

Assume, moreover, that (x, y) *is bounded, that the maps* $\phi \circ x$ *and* $\phi \circ y$ *converge,*[8] *and that* $x - y \not\to 0$. *Then*

$$\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0.$$

Proof of Proposition 5.6. Assume that (5.17) is not true. Then there exist $\alpha > 0$ and a sequence $(t_n) \subset \mathbb{R}_+$ such that $\lim_{n\to+\infty} t_n = +\infty$ and $|\dot{x}(t_n)| \geq \alpha$, $|x(t_n) - y(t_n)| \in [\lambda, \mu]$. Let $\tau \in (0, \frac{\lambda}{2(\|\dot{x}\|_\infty + \|\dot{y}\|_\infty)}]$. Then for every $t \in [t_n, t_n + \tau]$, $|x(t) - y(t)| \in [\lambda/2, \mu + \lambda/2]$. Hence the map $t \mapsto \nabla V(x(t) - y(t))$ is bounded on the set $\bigcup_{n\in\mathbb{N}}[t_n, t_n + \tau]$. Hence the map $\ddot{x}$ is bounded on the set $\bigcup_{n\in\mathbb{N}}[t_n, t_n + \tau]$. By a classical argument, we obtain a contradiction with $\dot{x} \in L^2([0, +\infty))$.

Let us now prove the second part. Since $x-y \not\to 0$ there exist $\alpha > 0$ and a sequence $(t_n) \subset \mathbb{R}_+$ such that $\lim_{n\to+\infty} t_n = +\infty$ and $|x(t_n) - y(t_n)| \in [\alpha, \max|x - y|]$. From part (a), $\dot{x}(t_n) \to 0$ and $\dot{y}(t_n) \to 0$. Since $U(x(t_n), y(t_n)) = V(x(t_n) - y(t_n))$ is bounded, $E(t_n) \to \lim_{t\to+\infty} \phi(x(t)) + \phi(y(t))$. Since $\frac{1}{2}|\dot{x}(t)|^2 + \frac{1}{2}|\dot{y}(t)|^2 \leq E(t) - \phi(x(t)) - \phi(y(t))$, we deduce the result. □

[7] Of course we assume that the limits have a meaning, i.e., $\{t \geq T| \quad |x(t) - y(t)| \in [\lambda, \mu]\} \neq \emptyset$ for every T.

[8] This is here the case if ϕ is convex.

6. Proof of the one-dimensional convergence results. In this section, we consider the one-dimensional and singular case, i.e., $H = \mathbb{R}$. Note that V' is clearly bounded on the bounded subsets of $\mathbb{R} \setminus \{0\}$; hence Theorem 2.2, Part 1 applies. In particular, it implies

(6.1)
$$\phi'(\lambda) = 0 \text{ for every } \lambda \in \left[\liminf_{t\to+\infty} x(t), \limsup_{t\to+\infty} x(t)\right] \cup \left[\liminf_{t\to+\infty} y(t), \limsup_{t\to+\infty} y(t)\right]$$

such that $\lambda \in \mathbb{R}$. For the sake of readability, we prove the second part of Theorem 2.4 before the first part.

6.1. Proof of Theorem 2.4, Part 2. Without loss of generality, we assume $y_0 < x_0$. From Proposition 2.1(i), the trajectory (x, y) satisfies $y(t) \neq x(t)$ for every t; hence, since x and y are continuous,

$$y(t) < x(t).$$

Hence $V'(x(t) - y(t)) \leq 0$ from the repulsion assumption $(\mathcal{H}_V)$(iv). From the two equations of (HBFC^2_{sing}), we deduce

$$\ddot{x} + \gamma\dot{x} + \phi'(x) \geq 0 \quad \text{and} \quad \ddot{y} + \gamma\dot{y} + \phi'(y) \leq 0. \tag{6.2}$$

6.1.1. Proof of (ii). The proof in the general case remains valid in dimension one, noticing that $x - y$ has a constant sign. But we give here a short and (much) simpler proof. Since the maps $\dot{x}$ and $\dot{y}$ are bounded (Proposition 2.1(ii)) and the maps $\phi'(x)$ and $\phi'(y)$ are bounded, we deduce from (6.2) that the map $\ddot{x}$ (resp., $\ddot{y}$), is bounded from below (resp., above). Since $\dot{x} \in L^2([0, +\infty))$ and $\dot{y} \in L^2([0, +\infty))$, we deduce by a classical argument

$$\lim_{t\to+\infty} \dot{x}(t) = 0 \quad \text{and} \quad \lim_{t\to+\infty} \dot{y}(t) = 0. \qquad \square$$

6.1.2. Proof of (i). In view of (6.2) and (6.1), the proof of the convergence is identical to the proof of [6, Lemma 5.2] in the regular case. We now briefly recall the argument of [6]. Assume that the map x does not converge, i.e., $\liminf_{t\to+\infty} x(t) < \limsup_{t\to+\infty} x(t)$. There exist two sequences (t_n) and (t'_n) in $\mathbb{R}_+$ such that $t_n \leq t'_n$, $\lim_{n\to+\infty} t_n = \lim_{n\to+\infty} t'_n = +\infty$, and

$$\begin{aligned} x([t_n, t'_n]) &\subset \left[\liminf_{t\to+\infty} x(t), \limsup_{t\to+\infty} x(t)\right], \\ \lim_{n\to+\infty} x(t_n) &= \limsup_{t\to+\infty} x(t), \\ \lim_{n\to+\infty} x(t'_n) &= \liminf_{t\to+\infty} x(t). \end{aligned}$$

Indeed, take a sequence (τ_n) such that $\lim_{n\to+\infty} \tau_n = +\infty$ $\lim_{n\to+\infty} x(\tau_n) = \limsup_{t\to+\infty} x(t)$, and, for n large enough, let

$$t'_n = \sup\left\{u \geq \tau_n,\ x([\tau_n, u]) \geq \liminf_{t\to+\infty} x(t) + \frac{1}{n}\right\}, \tag{6.3}$$

$$t_n = \inf\left\{u \in [\tau_n, t'_n],\ x([u, T_n]) \leq \limsup_{t\to+\infty} x(t)\right\}. \tag{6.4}$$

Then, for every $u \in [t_n, t_n']$, $\phi'(x(u)) = 0$; hence, in view of (6.2), $\ddot{x}(u) + \gamma\dot{x}(u) \geq 0$. We integrate the previous inequality on $[t_n, t_n']$ to find

$$x(t_n') \geq x(t_n) - \frac{1}{\gamma}(\dot{x}(t_n') - \dot{x}(t_n)).$$

Since $\lim_{t\to+\infty} \dot{x}(t) = 0$ (assertion (ii) above) and passing to the limit when $n \to +\infty$, we obtain $\liminf_{t\to+\infty} x(t) \geq \limsup_{t\to+\infty} x(t)$, a contradiction. Hence there exists $(x_\infty, y_\infty) \in \overline{\mathbb{R}} \times \overline{\mathbb{R}}$ such that $\lim_{t\to+\infty} x(t) = x_\infty$ and $\lim_{t\to+\infty} y(t) = y_\infty$. Since $\lim_{t\to+\infty}(\phi'(x(t)), \phi'(y(t))) = (0,0)$ (Theorem 2.2, Part 1), then $(x_\infty, y_\infty) \in \widehat{S} \times \widehat{S}$, which ends the proof of Theorem 2.4, Part 2. □

6.2. Proof of Theorem 2.4, Part 1. The trajectory (x, y) is now assumed to be bounded. We distinguish the two cases, $x - y \not\to 0$ and $x - y \to 0$, and again assume $y_0 < x_0$.

6.2.1. Proof in the case $x - y \not\to 0$. In view of (6.1), the map ϕ is constant on each of the intervals $[\liminf_{t\to+\infty} x(t), \limsup_{t\to+\infty} x(t)]$ and $[\liminf_{t\to+\infty} y(t), \limsup_{t\to+\infty} y(t)]$. By continuity of the trajectory and ϕ, the maps $\phi \circ x$ and $\phi \circ y$ converge. Recalling that (x, y) is bounded, we obtain from Proposition 5.6

$$\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0, \tag{6.5}$$

which proves (ii). We now prove the convergence of the map $x - y$.

LEMMA 6.1. *The map $x - y$ converges.*

Proof of Lemma 6.1. Assume that the map $x - y$ does not converge, i.e., $\liminf_{t\to+\infty} x(t) - y(t) < \limsup_{t\to+\infty} x(t) - y(t)$. Since the map V' is continuous, there exists some $z \in \big(\liminf_{t\to+\infty} x(t) - y(t), \limsup_{t\to+\infty} x(t) - y(t)\big)$ such that V' keeps a constant sign on a neighborhood of z (write $[a, b] = V'^{-1}(\{0\}) \cup V'^{-1}((0, +\infty)) \cup V'^{-1}((-\infty, 0))$). Without loss of generality, we assume that it is nonpositive. Consider $\alpha > 0$ such that

$$[z - 4\alpha, z + 4\alpha] \subset \left[\liminf_{t\to+\infty} x(t) - y(t), \limsup_{t\to+\infty} x(t) - y(t)\right], \tag{6.6}$$

$$V'(z') \leq 0 \text{ for every } z' \in [z - 4\alpha, z + 4\alpha]. \tag{6.7}$$

Consider $T \geq 0$ such that, for every $t \geq T$,

$$x(t) \in \left[\liminf_{s\to+\infty} x(s) - \alpha, \limsup_{s\to+\infty} x(s) + \alpha\right], \tag{6.8}$$

$$y(t) \in \left[\liminf_{s\to+\infty} y(s) - \alpha, \limsup_{s\to+\infty} y(s) + \alpha\right],$$

$$|\dot{x}(t)| \leq \gamma\alpha, \tag{6.9}$$

$$|\dot{y}(t)| \leq \gamma\alpha.$$

Consider $t' \geq t \geq T$ such that

$$(x - y)\,([t, t']) \subset [z - 4\alpha, z + 4\alpha], \tag{6.10}$$

$$x(t) - y(t) = z + 4\alpha, \tag{6.11}$$

$$x(t') - y(t') = z - 4\alpha. \tag{6.12}$$

Let us now show that

$$x(t') \geq x(t) - 3\alpha. \tag{6.13}$$

In view of (6.6), (6.7), and (6.10), for every $u \in [t, t']$, we have $V'(x(u) - y(u)) \leq 0$; hence $\ddot{x}(u) + \gamma\dot{x}(u) + \phi'(x(u)) \geq 0$.

First assume that $x([t, t']) \subset \left[\liminf_{s\to+\infty} x(s), \limsup_{s\to+\infty} x(s)\right]$. Then, for every $u \in [t, t']$, $\phi'(x(u)) = 0$; hence $\ddot{x}(u) + \gamma\dot{x}(u) \geq 0$. Integrating on $[t, t']$, we deduce $x(t') \geq x(t) + \frac{1}{\gamma}(\dot{x}(t) - \dot{x}(t'))$. In view of (6.9), $x(t') \geq x(t) - 2\alpha$.

Now assume that $x(u) > \limsup_{s\to+\infty} x(s)$ for some $u \in [t, t']$. If we have $x(t') \geq \limsup_{s\to+\infty} x(s)$, then $x(t') \geq x(t) - \alpha$ from (6.8). On the other hand, if $x(t') < \limsup_{s\to+\infty} x(s)$, then there exists $\tau \in [t, t']$ such that $x(\tau) = \limsup_{s\to+\infty} x(s)$ and $x([\tau, t']) \subset \left[\liminf_{s\to+\infty} x(s), \limsup_{s\to+\infty} x(s)\right]$, assuming without loss of generality that $2\alpha < \limsup_{s\to+\infty} x(s) - \liminf_{s\to+\infty} x(s)$, hence that $x([t, t'])$ cannot meet both $\limsup_{s\to+\infty} x(s)$ and $\liminf_{s\to+\infty} x(s)$. Then again $x(t') \geq x(\tau) - 2\alpha = \limsup_{s\to+\infty} x(s) - 2\alpha \geq x(t) - 3\alpha$ in view of (6.8).

Finally, assume that $x(u) < \liminf_{s\to+\infty} x(s)$ for some $u \in [t, t']$. If $x(t) \leq \liminf_{s\to+\infty} x(s)$, then $x(t') \geq x(t) - \alpha$ from (6.8). If $x(t) > \liminf_{s\to+\infty} x(s)$, then $x([t, \tau]) \subset \left[\liminf_{s\to+\infty} x(s), \limsup_{s\to+\infty} x(s)\right]$ and $x(\tau) = \liminf_{s\to+\infty} x(s)$ for some $\tau \in [t, t']$. Again $x(\tau) \geq x(t) - 2\alpha$, and, in view of (6.8), $x(t') \geq \liminf_{s\to+\infty} x(s) - \alpha = x(\tau) - \alpha \geq x(t) - 3\alpha$.

In the same way

$$y(t') \leq y(t) + 3\alpha.$$

In view of (6.13), $x(t') - y(t') \geq x(t) - y(t) - 6\alpha$. From (6.11) and (6.12), we deduce $z - 4\alpha \geq z + 4\alpha - 6\alpha$, a contradiction with $\alpha > 0$. Hence the map $x - y$ converges and its limit z_∞ is finite since (x, y) is bounded. □

Let us now prove that the map x converges. Assume that it is not true, i.e., $\liminf_{t\to+\infty} x(t) < \limsup_{t\to+\infty} x(t)$. The remainder of the proof is an adaptation of the proof of Theorem 2.4, Part 2, (i). Note that $\liminf_{t\to+\infty} y(t) = \liminf_{t\to+\infty} x(t) - z_\infty$ and $\limsup_{t\to+\infty} y(t) = \limsup_{t\to+\infty} x(t) - z_\infty$. Replacing x by $\min\{x, y + z_\infty\}$ (resp., $\max\{x, y + z_\infty\}$ in (6.3) (resp., (6.4)), we obtain two sequences (t_n) and (t'_n) in $\mathbb{R}_+$ such that $t_n \leq t'_n$, $\lim_{n\to+\infty} t_n = \lim_{n\to+\infty} t'_n = +\infty$, and

$$\begin{aligned}
x([t_n, t'_n]) &\subset \left[\liminf_{t\to+\infty} x(t), \limsup_{t\to+\infty} x(t)\right], \\
y([t_n, t'_n]) &\subset \left[\liminf_{t\to+\infty} y(t), \limsup_{t\to+\infty} y(t)\right], \\
\lim_{n\to+\infty} x(t_n) &= \lim_{n\to+\infty} y(t_n) + z_\infty = \limsup_{t\to+\infty} x(t), \\
\lim_{n\to+\infty} x(t'_n) &= \lim_{n\to+\infty} y(t'_n) + z_\infty = \liminf_{t\to+\infty} x(t).
\end{aligned}$$

Then, in view of Theorem 2.2, Part 1, $\phi'(x(u)) = \phi'(y(u)) = 0$ for every $u \in [t_n, t'_n]$. Recall (5.1):

$$\ddot{x}(u) + \ddot{y}(u) + \gamma(\dot{x}(u) + \dot{y}(u)) + \phi'(x(u)) + \phi'(y(u)) = 0;$$

hence

$$\ddot{x}(u) + \ddot{y}(u) + \gamma(\dot{x}(u) + \dot{y}(u)) = 0.$$

Integrating the previous equation on $[t_n, t'_n]$, we obtain

$$x(t'_n) + y(t'_n) + \gamma(\dot{x}(t'_n) + \dot{y}(t'_n)) = x(t_n) + y(t_n) + \gamma(\dot{x}(t_n) + \dot{y}(t_n)).$$

We have $\lim_{n\to+\infty} \dot{x}(t'_n) + \dot{y}(t'_n) = \lim_{n\to+\infty} \dot{x}(t_n) + \dot{y}(t_n) = 0$, from above or from Lemma 5.1. Taking the limit in the above equation when $n \to +\infty$, we deduce $\liminf_{t\to+\infty} x(t) = \limsup_{t\to+\infty} x(t)$, a contradiction. Hence the map x converges, and the very final argument in section 6.1.2 permits us to end the proof. □

6.2.2. Proof in the case $x - y \to 0$. In that case, we prove only the convergence of the trajectory. We may not have $\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0$, but, in view of Lemma 5.1, $\lim_{t\to+\infty} \dot{x}(t) + \dot{y}(t) = 0$. Then the above proof remains valid, with $z_\infty = 0$. □

6.3. Proof of Theorem 2.6. The proofs of Theorem 2.6 and Corollary 2.7 are almost identical to their regular version. This is not surprising if we recall the assumption $\lim_{t\to+\infty} x(t) \neq \lim_{t\to+\infty} y(t)$ in the regular case, which thus makes the regular case analogous to a singular case (see section 7.2). Without loss of generality, we assume $y_0 < x_0$; hence $y(t) < x(t)$ for every t. Let us first consider the case where $y_\infty > -\infty$ and $x_\infty < +\infty$. Without loss of generality, we prove only the assertion $P^+(x_\infty)$. Let us argue by contradiction and assume that there exists a neighborhood $V(x_\infty)$ of x_∞ such that $\phi'_{|V(x_\infty)} \leq 0$. There exists $t_0 \geq 0$ such that, for all $t \geq t_0$, $x(t) \in V(x_\infty)$; hence

$$\forall t \geq t_0, \quad \phi'(x(t)) \leq 0. \tag{6.14}$$

Since, by assumption, $y_\infty > -\infty$ and $x_\infty < +\infty$, there exists $M > 0$ such that, for all $t \geq t_0$, $0 < x(t) - y(t) \leq M$. From $(\mathcal{H}_V)$(iv) and $(\mathcal{H}_V)$(v), there exists $\eta > 0$ such that

$$\forall t \geq t_0, \quad V'(x(t) - y(t)) \leq -\inf_{0<|z|\leq M} |V'(z)| = -\eta. \tag{6.15}$$

By using the first equation of (HBFC^2_{sing}), (6.14), and (6.15), we find

$$\forall t \geq t_0, \ \ddot{x}(t) + \gamma\dot{x}(t) \geq \eta\varepsilon(t).$$

Integrating the above differential inequality between t_0 and t, we find $\dot{x}(t) - \dot{x}(t_0) + \gamma(x(t) - x(t_0)) \geq \eta \int_{t_0}^{t} \varepsilon(u)du$. But the trajectory x is convergent, hence bounded, and $\int_{t_0}^{+\infty} \varepsilon(u)du = +\infty$. Hence $\lim_{t\to+\infty} \dot{x}(t) = +\infty$, a contradiction.

Let us now assume that $y_\infty = -\infty$ and $x_\infty < +\infty$. Let us argue by contradiction and assume that we have neither $P^+(y_\infty)$ nor $P^+(x_\infty)$. Then there exists a neighborhood $V(x_\infty)$ (resp., $V(y_\infty)$) of x_∞ (resp., y_∞) such that $\phi'_{|V(x_\infty)} \leq 0$ (resp., $\phi'_{|V(y_\infty)} \leq 0$). Consequently, there exists $t_0 \geq 0$ such that, for all $t \geq t_0$,

$$\phi'(x(t)) \leq 0 \quad \text{and} \quad \phi'(y(t)) \leq 0.$$

By adding the two equations of (HBFC^2_{sing}), we deduce

$$\forall t \geq t_0, \ \ddot{x}(t) + \ddot{y}(t) + \gamma(\dot{x}(t) + \dot{y}(t)) \geq 0.$$

A direct computation shows that $x + y$ is bounded from below, a contradiction with $y_\infty = -\infty$. The proof of the last case $y_\infty > -\infty$ and $x_\infty = +\infty$ goes along the same lines. □

6.4. Proof of Corollary 2.7. Let $I(x_\infty)$ be the connected component of x_∞ in the set $\widehat{S}$. Let us argue by contradiction and assume that $x_\infty \notin \{\inf I(x_\infty), \sup I(x_\infty)\}$. In particular, we have $x_\infty < +\infty$. If condition (a) is satisfied, we obtain, by Theorem 2.6, the assertions $P^-(y_\infty)$ and $P^+(x_\infty)$. If condition (b) is satisfied, the assertion $P^+(y_\infty)$ is false and then, by Theorem 2.6, we obtain the assertion $P^+(x_\infty)$. In both cases, we have $P^+(x_\infty)$, a contradiction with $x_\infty \in \operatorname{int} I(x_\infty)$. □

6.5. Proof of Corollary 2.8. Since $\widehat{S}$ is connected, $I(x_\infty) = I(y_\infty) = \widehat{S}$. From Corollary 2.7, $x_\infty \in \{\inf \widehat{S}, \sup \widehat{S}\}$ and $y_\infty \in \{\inf \widehat{S}, \sup \widehat{S}\}$. If the set $\widehat{S}$ is reduced to a singleton, there is nothing more to prove. So let us assume that $\inf \widehat{S} < \sup \widehat{S}$. Let us argue by contradiction and assume that $(x_\infty, y_\infty) = (\inf \widehat{S}, \inf \widehat{S})$ (resp., $(x_\infty, y_\infty) = (\sup \widehat{S}, \sup \widehat{S})$). From Theorem 2.6 we deduce that the assertion $P^+(\inf \widehat{S})$ (resp., $P^-(\sup \widehat{S})$) holds. On the other hand, it is immediate to verify that $\phi' \le 0$ (resp., $\phi' \ge 0$) in a neighborhood of $\inf \widehat{S}$ (resp., $\sup \widehat{S}$), which contradicts $P^+(\inf \widehat{S})$ (resp., $P^-(\sup \widehat{S})$). Hence, we have $(x_\infty, y_\infty) = (\inf \widehat{S}, \sup \widehat{S})$ or $(x_\infty, y_\infty) = (\sup \widehat{S}, \inf \widehat{S})$. □

7. Singular versus regular: Higher dimension and dimension one. From a physical point of view, it is clearly necessary to consider singular interaction potentials that naturally appear in various models as the classical gravitation and electromagnetism and also in molecular models. Even if models in dimension one do exist and are of interest in physics, this motivation is sufficient to examine at least the dimension three. In optimization, the advantage of a singular potential is a priori less obvious. In the next section, we indicate what we conjecture on the behavior of our coupled oscillators in higher dimension in both regular and singular cases. In the following section, we show that in dimension one the singular system can be seen as the limit case of regular systems.

7.1. Properties in higher dimension. We consider the coupled system

$$(\mathrm{HBFC}^p) \qquad \begin{cases} \ddot{x_1} + & \gamma \dot{x_1} + & \nabla\phi(x_1) + & \varepsilon(t)\frac{\partial U}{\partial x_1}(x_1, \dots, x_p) = & 0 \\ \dots & \dots & \dots & \dots & \dots \\ \ddot{x_p} + & \gamma \dot{x_p} + & \nabla\phi(x_p) + & \varepsilon(t)\frac{\partial U}{\partial x_n}(x_1, \dots, x_p) = & 0 \end{cases}$$

with initial conditions ϕ and ε as in Hypothesis 1, Ω an open subset of H^p, $U : \Omega \to \mathbb{R}_+$ a potential such that $\operatorname{div} U = 0$, $\lim_{x \to \operatorname{bd}\Omega} U(x) = +\infty$. The existence part corresponding to Proposition 2.1 clearly holds.

For $p = 2$ and $\dim H = 1$, Corollary 2.9 shows that the corresponding system will (asymptotically) maximize the diameter $\operatorname{diam}(S)$. We know (Remark 2.7) that the statement of Corollary 2.9 does not remain true in dimension greater than 2, but we conjecture that under suitable assumptions on ϕ and V, say, for example, ϕ convex, the trajectory $(x_1, \dots, x_p)$, the solution of (HBFC^p), will converge to some $(x_{1,\infty}, \dots, x_{p,\infty})$ in Ω that shall minimize (at least locally) the interaction potential U on the solution set. The whole difference between the singular and regular version will reside in Ω, equal to the whole space H^p in the regular case. Assuming that the limit $(x_{1,\infty}, \dots, x_{p,\infty})$ will belong to Ω helps to avoid a priori uninteresting limits (as $x_{1,\infty} = \dots = x_{p,\infty}$).

7.1.1. Numerical experiments. Figure 1 illustrates our conjecture for $N = \dim H = 2$, $p = 4$, $\phi(a, b) = \max\{5(\sqrt{a^2/4 + b^2} - 1)^2, 0\}$, $\varepsilon(t) = 1/\log(t + 2)$, $\gamma = 2$. Other tests for different potentials ϕ, V, different controls ε, and mainly different

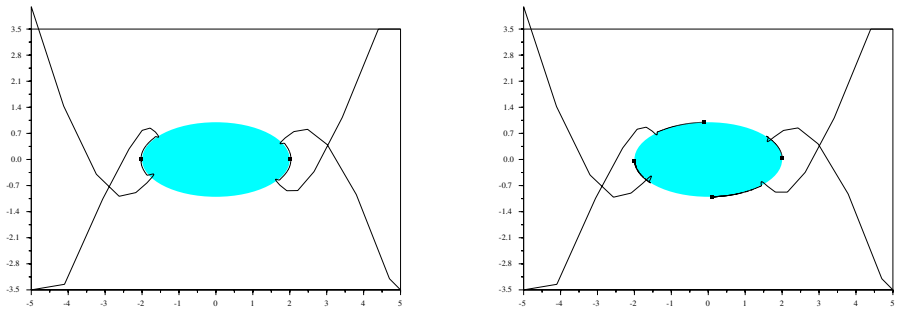

FIG. 1.

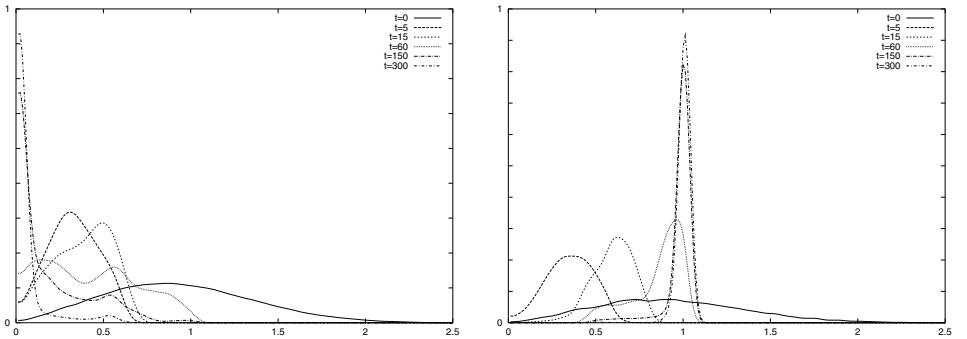

FIG. 2.

numbers of *systems* ($p = 3, 4, 5$ up to now) and different dimensions ($N = 2, 3$ up to now) show the same behavior. We give below the trajectories of the corresponding (HBFC^4_{reg}) system, with $V(z) = \exp(-|z|^2/50)$ and $U(x_1, \ldots, x_4) = \sum_{i<j} V(x_i - x_j)$, on the left, and of the corresponding (HBFC^4_{sing}) system, with $V(z) = 1/|z|^2$ and $U(x_1, \ldots, x_4) = \sum_{i<j} V(x_i - x_j)$, on the right.[9]

The numerical experiment that we now describe highlights the nice asymptotic properties of the (HBFC^p_{sing}) system. Taking the previous systems, Figure 2 illustrates the convergence of the area $\mathcal{A}rea(\mathrm{co}\{x_1(t), \ldots, x_4(t)\})$, up to a normalization factor[10] both in the regular case (on the left) and in the singular case (on the right). It precisely consists of evaluating the distribution of the function $\mathcal{A}rea(\mathrm{co}\{x_1(t), \ldots, x_4(t)\})$. For initial data $(x_1(0), \ldots, x_4(0), \dot{x}_1(0), \ldots, \dot{0}_4(t))$ in the set $([-5, 5] \times [-5, 5])^4 \times \{(0, 0)\}^4$ and for different times t, we compute the function $\mathcal{A}rea(\mathrm{co}\{x_1(t), \ldots, x_4(t)\})$ and, for a given number $n > 0$, the proportion of points which belong to an interval $[\frac{k}{n}, \frac{k+1}{n})$ for $n \in \mathbf{Z}$. The experiments are computed on a grid of $11^8 = 214\,358\,881$ points, and we limit the representation at $t = 300$ for a matter of readability. They indicate the likeliness of our conjecture and of the good asymptotic behavior of the (HBFC^p_{sing}) system.

[9] In both figures, the initial conditions are $x_1(0) = (5, -3.5)$, $\dot{x}_1(0) = (-1, 1)$, $x_2(0) = (-5, 3.5)$, $\dot{x}_2(0) = (0, 2)$, $x_3(0) = (-5, -3.5)$, $\dot{x}_3(0) = (3, 0.5)$, $x_4(0) = (5, 3.5)$, $\dot{x}_4(0) = (-2, 0)$.

[10] Precisely, the normalization factor is the area of the largest polygon included in S with (at most) four extremal points.

7.2. The singular case as a limit of regular cases in dimension one. When the potential V is defined on the whole line $\mathbb{R}$ (regular case), the convergence results are not as precise as in the singular case. Namely, the two trajectories x and y may have the same limit. Precisely, we recall the following result from [6].

THEOREM 7.1 (slow parametrization in the regular case [6]). *Under the assumptions of Corollary* 2.8, *let* $V : \mathbb{R} \to \mathbb{R}$ *be a (regular) repulsion potential, i.e., a map of class* $\mathcal{C}^1$ *such that*

$$(\mathcal{H}_{V_{reg}}) \qquad \begin{cases} \text{the map } \nabla V \text{ is locally Lipschitz continuous on } \mathbb{R} \\ \forall z \in \mathbb{R} \setminus \{0\}, \quad zV'(z) < 0. \end{cases}$$

Then there is a unique maximal solution $(x, y) : [0, +\infty) \to \mathbb{R} \times \mathbb{R}$ *of the* (HBFC^2_{reg}) *system*

$$(7.1) \qquad (\mathrm{HBFC}^2_{reg}) \qquad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V(x-y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V(x-y) = 0, \\ \Big(x(0), y(0), \dot{x}(0), \dot{y}(0)\Big) = \Big(x_0, y_0, \dot{x}_0, \dot{y}_0\Big). \end{cases}$$

Moreover, the solution (x, y) *satisfies one of the following cases:*

(i) $\lim_{t\to+\infty} \Big(x(t)\,,\, y(t) \Big) = \Big(\sup \widehat{S}\,,\, \inf \widehat{S} \Big)$;

(ii) $\lim_{t\to+\infty} \Big(x(t)\,,\, y(t) \Big) = \Big(\inf \widehat{S}\,,\, \sup \widehat{S} \Big)$;

(iii) *there exists* $x_\infty \in \widehat{S}$ *such that* $\lim_{t\to+\infty} x(t) = \lim_{t\to+\infty} y(t) = x_\infty$.

It is then a natural question to know if the singular case can be seen as a limit of regular cases or if it corresponds to a singularity. If the (singular) repulsion potential $V : \mathbb{R} \setminus \{0\} \to \mathbb{R}$ is a limit of (regular) potentials $V_n : \mathbb{R} \to \mathbb{R}$, how does the solution (x_n, y_n) of the corresponding $(\mathrm{HBFC}^2_{reg}(n))$ systems behave when $n \to +\infty$? More than a theoretical interest, the importance of this problem for numerical applications comes from an obvious remark: in numerical applications, a singular potential would be approximated by regular potentials. The general study of these questions is beyond the scope of this paper, but we give an indication of a positive answer with the following result, where the potential V_n corresponds to a truncated V.

PROPOSITION 7.2. *Under the assumptions of Corollary* 2.8, *let* (V_n) *be a sequence of regular repulsion potentials, i.e., for every* n, $V_n : \mathbb{R} \to \mathbb{R}_+$ *is a map of class* $\mathcal{C}^1$ *satisfying* $(\mathcal{H}_{V_{reg}})$, *and let* (α_n) *be a sequence in* $\mathbb{R}_+ \setminus \{0\}$ *such that* $\lim_{n\to+\infty} \alpha_n = 0$. *Assume that, for every* n,

$$V_n(x) = V(x) \text{ for every } x \notin (-\alpha_n, \alpha_n).$$

Assume that $\widehat{S}$ *is not reduced to a singleton. Then, for every initial condition* $(x_0, y_0, \dot{x}_0, \dot{y}_0) \in \mathbb{R}^4$, *such that* $x_0 \neq y_0$, *there is an integer* N *such that, for every* $n \geq N$, *the solution* (x_n, y_n) *of*

$$(7.2) \qquad (\mathrm{HBFC}^2_{reg}(n)) \qquad \begin{cases} \ddot{x} + \gamma\dot{x} + \nabla\phi(x) + \varepsilon(t)\nabla V_n(x-y) = 0, \\ \ddot{y} + \gamma\dot{y} + \nabla\phi(y) - \varepsilon(t)\nabla V_n(x-y) = 0, \\ \Big(x(0), y(0), \dot{x}(0), \dot{y}(0)\Big) = \Big(x_0, y_0, \dot{x}_0, \dot{y}_0\Big) \end{cases}$$

satisfies

$$(x_n, y_n) = (x, y),$$

where (x, y) *is the solution of the* (HBFC$^2_{sing}$) *system corresponding to* V*, with initial condition* $(x_0, y_0, \dot{x}_0, \dot{y}_0)$*. Hence*

$$\lim_{t\to+\infty} \Big(x_n(t)\,,\, y_n(t) \Big) = \Big(\sup \widehat{S}\,,\, \inf \widehat{S} \Big) \quad \text{if} \quad y_0 < x_0;$$

$$\lim_{t\to+\infty} \Big(x_n(t)\,,\, y_n(t) \Big) = \Big(\inf \widehat{S}\,,\, \sup \widehat{S} \Big) \quad \text{if} \quad x_0 < y_0.$$

Proof of Proposition 7.2. Let (x, y) be the solution of the (HBFC$^2_{sing}$) system corresponding to V, with initial condition $(x_0, y_0, \dot{x}_0, \dot{y}_0)$. Without loss of generality, assume that $x_0 > y_0$. From Corollary 2.8, $\lim_{t\to+\infty}(\, x(t)\,,\, y(t)\,) = (\, \sup \widehat{S}\,,\, \inf \widehat{S}\,)$. Since $x(t) > y(t)$ for every t, we obtain that $\inf_{t\geq 0}(x(t) - y(t)) > 0$. Let $N \in \mathbb{N}$ such that, for every $n \geq N$, $\alpha_n < \inf_{t\geq 0}(x(t) - y(t))$. Then (x, y) is a solution of the (HBFC$^2_{reg}(n)$) system, with initial condition $(x_0, y_0, \dot{x}_0, \dot{y}_0)$; hence $(x_n, y_n) = (x, y)$. □

7.3. Remark on the convergence in the one-dimensional and regular case. As we mentioned after stating Theorem 2.4, we can improve the one-dimensional and regular convergence result [6, Theorem 2.2] when the trajectory is assumed to be bounded. The following theorem states this precisely.

THEOREM 7.3 (convergence of the solutions, regular case). *Assume that* ϕ *and* V *are maps from* $\mathbb{R}$ *to* $\mathbb{R}$ *of class* $\mathcal{C}^1$ *and that their gradients are locally Lipschitz continuous. Assume that the solution* (x, y) *of the* (HBFC$^2_{reg}$) *system is bounded. Then it converges; precisely,*

(i) *there exists* $(\, x_\infty, y_\infty\,) \in \widehat{S} \times \widehat{S}$ *such that* $\lim_{t\to+\infty} \Big(x(t)\,,\, y(t) \Big) = \Big(x_\infty\,,\, y_\infty \Big)$.

We let the reader check that the proof in the singular case can be easily adapted (with a simplification since one already has $\lim_{t\to+\infty} \dot{x}(t) = \lim_{t\to+\infty} \dot{y}(t) = 0$ in the regular case).

Acknowledgments. Many thanks to Alexandre Cabot for his great help on the numerical experiments and valuable discussions. I'm grateful to an anonymous referee who raised the question of the possible nonconvergence of the trajectories of (HBFC$^2_{sing}$) and, consequently, pushed me to improve the one-dimensional convergence results (Theorem 2.4, Part 1, Remarks 3.8 and 3.9) in the nonrepulsive case.

ROBUST POINT STABILIZATION OF UNDERACTUATED MECHANICAL SYSTEMS VIA THE EXTENDED CHAINED FORM*

DAVID A. LIZÁRRAGA†, NNAEDOZIE P. I. ANEKE‡, AND HENK NIJMEIJER§

Abstract. This paper addresses point stabilization for the extended chained form (ECF), a control system that may be used to model a number of mechanical underactuated systems. A control law is proposed, based on well-known hybrid open-loop/feedback techniques, which exponentially stabilizes the origin of a dynamic extension of the ECF and ensures a degree of robustness to additive disturbance terms that may represent, for instance, model uncertainties. Numerical simulations are included to illustrate the performance of the presented stabilizers.

Key words. extended chained form, second-order chained form, point stabilization, hybrid feedback, underactuated manipulator, surface vessel

1. Introduction.

The study of mechanical control systems with fewer actuators than degrees of freedom constitutes a stimulating and active subject of research. Examples of such systems include underactuated manipulators [21], underactuated (surface and underwater) maritime vehicles [30, 5], underactuated spacecraft [18], and mechanical systems with internal degrees of freedom subject to virtual holonomic constraints [15, 24]. Besides the study of properties such as accessibility and controllability, the research efforts have focused mainly on problems such as open-loop steering from one configuration to another, trajectory tracking, and stabilization to an equilibrium point (or configuration). For underactuated mechanical systems, the latter problem is especially challenging since such systems typically do not meet Brockett's necessary condition for stabilization to a point by continuous, pure-state feedback [3]. As a consequence, solutions usually involve elaborate control techniques, such as time-varying feedback or hybrid control. In this paper we are particularly interested in stabilization to a point.

A valuable tool when addressing control problems is the possibility of transforming the system dynamics, via coordinate change and feedback, into a "canonical" control system with a simpler, more tractable structure. Among such canonical representations, the *extended chained form* (ECF)

$$\begin{aligned} \ddot{x}_1 &= u_1, \\ \ddot{x}_2 &= u_2, \\ \ddot{x}_3 &= u_1 x_2 \end{aligned} \tag{1}$$

plays, for some underactuated mechanical systems, a role similar to the one played by the *chained form* for driftless nonholonomic systems (cf. [19, 26]). By slight abuse of nomenclature we are calling the particular system (1), with six state variables and two inputs, the ECF, although more general extensions to the chained form can be envisaged and have been considered. System (1) has also been termed *second-order chained form*. However, no definitive unifying notation seems to exist as yet for the family of "chained systems." In [11], for instance, a two-input control system is introduced which is referred to as an *n-dimensional, high-order generalized chained system*. On the other hand, chained systems having more than two inputs have also been studied under the denomination *multi-input chained systems*, e.g., in [29]. Finally, the reader should be aware that in some references—but not in the present paper—the term *extended chained form* refers to a driftless chained system, as introduced in [19], with integrators added in cascade to each of its inputs, cf., e.g., [31].

The ECF made its appearance in the context of underactuated mechanical systems in [4], where it was shown that the dynamic model of a simplified underwater vehicle is feedback-equivalent to two interconnected ECFs. In [8], the model of a planar PP$\overline{\text{R}}$ manipulator was directly transformed into the ECF (PP$\overline{\text{R}}$ denotes a manipulator with two *prismatic* joints and one *revolute* joint at its most distal end; the bar above "R" designates an *unactuated* or *passive* joint). Among the two-input, three-DOF systems that are feedback-equivalent to the ECF one finds the planar, vertical take-off and landing (VTOL) system in the absence of gravity [25], a simplified underwater vehicle [22], the planar, serial-drive RR$\overline{\text{R}}$ manipulator [32], and the planar, parallel-drive RRR manipulators with any two joints actuated. Two additional examples are multibody systems possessing an unactuated, internal DOF which is required, by design, to satisfy a virtual holonomic constraint, namely the rigid body with internal DOF in [15] and the dynamics of the spring-coupled, third link of a planar PPR manipulator in [24]. It is worth noting that the transformations involved in these examples allow one to map generic equilibrium configurations of the mechanical system to *the origin* of the ECF, thereby reducing stabilization of any such configuration to stabilization of the latter point.

In view of these results, considerable emphasis has been given to the design of controllers for the ECF and some of its generalizations. For instance, a time-varying controller, updated in terms of the state only at isolated time-instants, was developed in [4] to achieve a "discrete-time" version of $\mathcal{K}$-exponential stability for the origin of two interconnected ECFs. Tracking controllers were proposed in [8] which, associated with carefully selected state trajectories (cf. also [32]), exponentially drive the state of the ECF towards the origin. In [11], discontinuous controllers were introduced to *almost-exponentially* stabilize the origin of two-input, generalized, n-dimensional chained form systems, including the ECF. More recently, the authors of [6] pointed out conditions for two-input systems with drift to be feedback-linearizable by non-smooth (and eventually discontinuous) state and input transformations. Once such a transformation is applied, linear controllers can be used to drive the system state exponentially to the origin, provided the initial conditions belong to a set where the new coordinates are well defined. In [1] a time-varying, continuous, homogeneous control-law was introduced which, to date and to the extent of our knowledge, is the only one capable of ensuring Lyapunov-stability as well as exponential convergence (indeed $\mathcal{K}$-exponential stability) for the origin of the ECF.

In this paper we propose controllers that are both *stabilizing* and *robust*—in appropriately defined senses—based on a well-known *hybrid open-loop/feedback* approach (also known as *iterative state steering*). Essentially, this goes along the lines

of *discrete-time* control of *continuous-time* systems: at a given sample instant t_k the state $x(t_k)$ is sensed, and an input function $t \mapsto u_k(t)$ is computed and used to drive the system until the next sample instant t_{k+1}. Within the interval (t_k, t_{k+1}) the input may change with t, but it is *independent* of the instantaneous value of the state $x(t)$. The input u_k is designed so that, at the end of the interval, the state $x(t_{k+1})$ is "closer" to the origin than it was at the beginning. This control algorithm is iterated indefinitely and, under appropriate assumptions, it leads to a robustly stable equilibrium point. Let us remark that the use of iterated control is not new and that important results have been reported in the literature. One example is [4], mentioned above, where iterated controls were developed, but where no robustness study was carried out. A hybrid control combining sampled-time control with continuous-time, linear feedback was proposed in [20] to stabilize chained form systems, with applications to wheeled mobile robots. Among the earliest references addressing the *robustness* of time-varying, iterative control in the framework of nonholonomic systems one finds [2], where control laws are developed for the three- and four-dimensional chained forms. These feedback laws render the origin exponentially stable (in the discrete-time sense) and this stability property is preserved in the presence of additive disturbance vector fields. The authors of [14] consider a large class of systems, possibly with drift, under iterative state steering control. Although no algorithm is presented to construct any such controller—it is assumed that one is known beforehand—conditions are pointed out for discrete-time stability of the origin and robustness to the presence of additive disturbance vector fields. A drawback of the reported conditions for robustness is that some of them are stated in terms of *the flow* of the disturbance vector field(s), thus limiting the class of disturbances for which robustness can be assessed in practice. For driftless systems, a powerful approach was presented in [17], where a constructive algorithm is given to design stabilizers for *any* driftless, analytic, controllable system. The controllers thus obtained guarantee local exponential stability of the origin for a *dynamic extension* of the original system, and the stability is robust to additive disturbance vector fields. Our controller design and methodology share similarities with [4] and [14], although the stability and robustness analysis is inspired by [17]. The presence of a drift term, however, makes the analysis—and the eventual generalization of the present approach to a larger class of systems—more difficult. As a consequence, our result is merely applicable to a class of systems which can be represented as a (perturbed) ECF.

This paper is organized as follows. Section 2 contains definitions of stability and robustness, as used in the present context, as well as a statement of the robust stabilization problem. In section 3, a feedback law is introduced and then shown to be a robust stabilizer in the specific sense considered here. Section 4 contains two simulation examples. Some concluding remarks are given in section 5. Finally, in the appendix, notational conventions are fixed and some technical lemmas are stated or proved.

2. Preliminaries and definition of the problem. Prior to stating the problem, let us precisely define the notions of stability and robustness used in this context. To this end consider the ECF, regarded as the *nominal system*, rewritten in the form

$$\dot{x} = b_0(x) + u_1 b_1(x) + u_2 b_2(x),$$

with

$$b_0(x) = x_2 \frac{\partial}{\partial x_1} + x_4 \frac{\partial}{\partial x_3} + x_6 \frac{\partial}{\partial x_5}, \quad b_1(x) = \frac{\partial}{\partial x_2} + x_3 \frac{\partial}{\partial x_6}, \quad b_2(x) = \frac{\partial}{\partial x_4}. \tag{2}$$

As a result of model errors, such as parameter uncertainties, disturbance vector fields may be present in the system to be actually controlled, and one way to model this is by considering the *perturbed system*

$$\dot{x} = b_0(x) + h_0(x,\varepsilon) + \sum_{i=1}^{2} u_i(b_i(x) + h_i(x,\varepsilon)), \tag{3}$$

where $\boldsymbol{h} = (h_0, h_1, h_2)$ is a 3-tuple of real-analytic mappings $h_i : U \times E \to \mathbb{R}^6$, and $E \subset \mathbb{R}$ is an interval containing 0. $\boldsymbol{h}$, referred to in what follows as a *disturbance*, is assumed to satisfy $h_0(0,\varepsilon) = 0$ for every $\varepsilon \in E$, so that $(x,u) = (0,0)$ is an equilibrium point for the perturbed system. The interpretation of ε is that of an additional parameter quantifying the "magnitude" of the perturbation. For ease of reference we denote by $\mathcal{D}^3$ the set of all disturbances $\boldsymbol{h} = (h_0, h_1, h_2)$, each defined on a set $U \times E$ (E may thus depend on the choice of $\boldsymbol{h}$). In what follows we also write $h_i^\varepsilon(x) = h_i(x,\varepsilon)$.

Essentially, these disturbances are intended to represent two kinds of error terms, namely, those that do not depend on ε, which may typically encompass "high-order" terms neglected when the model is derived, and those that result from inaccuracies—quantified by ε—in the knowledge of the physical dimensions involved in the model (cf. also Remark 2(i) after Proposition 3.1). Obviously, however, not all disturbances may be modeled by additive vector fields as in (3). Phenomena such as neglected modes, nonsmooth effects (e.g., friction) or measurement noise would require different representations. Therefore, the notion of robustness one can aim at by considering such disturbances bears some limitations.

Before we proceed, let us recall the notion of exponential stability for continuous-time systems. Let $0 \in U \subset \mathbb{R}^n$, with U open, and consider the system

$$\dot{z} = f(z,t), \quad f(0,\,\cdot\,) = 0, \quad f : U \times \mathbb{R} \to \mathbb{R}^n. \tag{4}$$

The mapping $(z,t) \mapsto f(z,t)$ is assumed to be continuous in z and piecewise continuous in t. The origin $z = 0$ is *locally exponentially stable* for (4) if there exist $K > 0$, $\gamma > 0$ and a neighborhood $V \subset U$ of 0 such that, for every $(z_0, t_0) \in V \times \mathbb{R}$, a solution $z(\cdot)$ satisfying $z(t_0) = z_0$ is defined on $[t_0, \infty)$ and also satisfies

$$\|z(t)\| \le K\|z_0\|e^{-\gamma(t-t_0)} \tag{5}$$

for all $t \ge t_0$.

Now suppose that a continuous, time-varying (T-periodic) feedback law $\alpha : U \times \mathbb{R} \to \mathbb{R}^2$ is given. As mentioned in the introduction, one intends to act on the perturbed system (3) by periodically iterating this control law in the hope that such process stabilizes the system exponentially to a point (the origin, say, without loss of generality). Nevertheless, according to the definition of (local) exponential stability, the iteration of such a control law cannot, in general, achieve that goal since the origin may even fail to be an equilibrium. Indeed, the state of the system may reach the origin at some time $t_0 \in (kT, (k+1)T)$, which need not coincide with any of the sampling instants. Since the control operates in "open-loop" between samples, it may continue acting on the system, thus causing the state to leave the origin again. In such a case, inequality (5)—which is required to hold for every choice of "initial data" $(z_0, t_0) \in V \times \mathbb{R}$—would not hold for $(0, t_0)$ and any selection of $K > 0, \gamma > 0$. One way to remedy this issue is to consider stability in the *discrete-time*

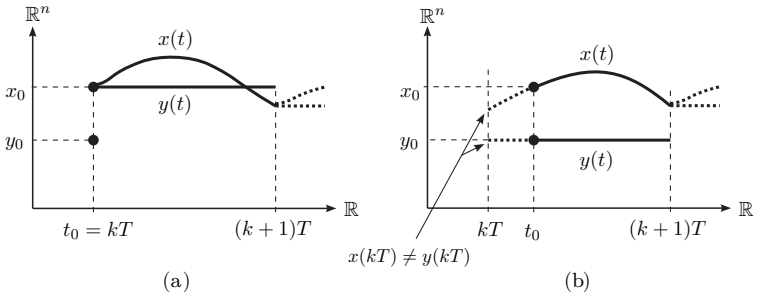

FIG. 1. *Initial conditions for system* (6): (a) *If* $t_0 \mod T = 0$, *both* $x(\cdot)$ *and* $y(\cdot)$ *are initialized to* x_0*;* (b) *If* $t_0 \mod T \neq 0$, $x(\cdot)$ *and* $y(\cdot)$ *are initialized to* x_0 *and* y_0, *respectively. Note that in the latter case the solutions are in general* not reversible in time, *since extending* $x(t)$ *and* $y(t)$ *for* $t \in [kT, t_0)$, *using the dynamics* (6), *may lead to the condition* $x(kT) \neq y(kT)$.

sense and concentrate only on the sequence of state values at the sampling instants, $(z(kT))_{k\in\mathbb{N}}$. However, since one is dealing with a continuous-time system (3), we adopt the alternative approach proposed in [17], where local exponential stability is considered *for a dynamic extension* of the perturbed system (3). More precisely, in order to cope with the case when $t_0 \mod T \neq 0$ (so t_0 does not equal any sampling instant) we adjoin a signal $t \mapsto y(t)$, which coincides with the state $x(kT)$ at the update instants indexed by $k \in \{\lfloor t_0/T \rfloor + 1, \lfloor t_0/T \rfloor + 2, \dots\}$, and then consider the *dynamically extended perturbed system*

$$\left\{ \begin{array}{rcl} \dot{x} & = & b_0(x) + h_0(x,\varepsilon) + \sum_{i=1}^{2} \alpha_i(y,t)(b_i(x) + h_i(x,\varepsilon)), \\ \dot{y} & = & \sum_{k=\lfloor t_0/T \rfloor + 1}^{\infty} \delta(t - kT)x(t), \end{array} \right. \tag{6}$$

under the proviso that its "initial condition" be defined, given any $(x_0, y_0) \in \mathbb{R}^6 \times \mathbb{R}^6$, by setting $(x(t_0), y(t_0))$ equal to (x_0, x_0) if $t_0 \mod T = 0$, or equal to (x_0, y_0) otherwise. (The symbol $\delta(t - kT)$ in (6) represents Dirac's delta "function" and satisfies $\int_{-\infty}^{\infty} \delta(t - kT) f(t) dt = f(kT)$ for any mapping $f : \mathbb{R} \to \mathbb{R}^n$.)

The meaning of the initial conditions for system (6) is illustrated in Figure 1. Clearly, the *first* sample instant *after* the initial time t_0 occurs at $t = (\lfloor t_0/T \rfloor + 1)T$ or, using the notation in the figure, at $t = (k+1)T$. This explains the initial value for the index k in the second summation of (6). Note also that the trajectories initialized in this way are defined for forward time ($t \geq t_0$), but they may fail to be reversible in time. In other words, when $t_0 \mod T \neq 0$, the solution $(x(\cdot), y(\cdot))$ may be prolonged to the interval $[kT, t_0)$ by using the dynamics (6); however, $x(kT)$ may differ from $y(kT)$.

Remark 1. It is worth pointing out that the dynamic extension in (6) is a technical artifice merely used to establish the proofs in a precise setting. In particular, the extension does not have to be "implemented," nor does it restrain the way the control signals are actually applied to system (1), or the set of allowable initial conditions for the latter.

The problem of robust stabilization may now be formulated as follows.

Problem 1 (robust stabilization of the extended chained form). Design a control law $\alpha : U \times \mathbb{R} \to \mathbb{R}^2$ which ensures that, for every disturbance $\boldsymbol{h}$ in a given set $\mathcal{A} \subset \mathcal{D}^3$, there is a constant $\varepsilon_0 > 0$ such that the origin $(x, y) = (0, 0)$ of system (6) is locally

exponentially stable whenever $\varepsilon \in E$ and $|\varepsilon| \leq \varepsilon_0$.

3. Robust stabilizers for the extended chained form. In this section we derive a solution to Problem 1 for the ECF system (1). The solution is obtained in two main steps: first the feedback law α is *designed* to have certain properties; then, in the slightly more involved second step, a stability/robustness *analysis* is carried out to guarantee that α indeed solves the problem. For more details on the notation used in this and the ensuing sections, the reader may consult section 6.1 in the appendix.

3.1. Design of the feedback law. Fix $T > 0$ and set $\omega = 2\pi/T$. Our goal is to design a feedback law $\alpha \in C^0(\mathbb{R}^6 \times \mathbb{R}; \mathbb{R}^2)$, T-periodic in its second argument, such that the solution $x(\cdot)$ to the controlled ECF

$$\dot{x} = b_0(x) + \sum_{i=1}^{2} \alpha_i(x_0, t) b_i(x), \quad x(0) = x_0 \in \mathbb{R}^6, \tag{7}$$

with b_0, b_1, b_2 given in (2), satisfies

$$x(T) = Ax_0 + \mathrm{o}(\|x_0\|), \tag{8}$$

where $A \in \mathbb{R}^{6\times 6}$ a *discrete–time-stable* matrix, i.e., a matrix whose spectrum is contained in $\{z \in \mathbb{C} : |z| < 1\}$. We propose the following controller structure:

$$\alpha_1(x,t) = a_1 x_1 + a_2 x_2 + G\rho(x)\cos(\omega t), \tag{9}$$

$$\alpha_2(x,t) = a_3 x_3 + a_4 x_4 - \frac{2\omega^2}{G}\frac{1}{\rho(x)}(a_5 x_5 + a_6 x_6)\cos(\omega t), \tag{10}$$

where the vector of control gains $a \in \mathbb{R}^6$ is determined below, $G > 0$, and ρ is given[1] by $\rho(x) = (\sum_{i=1}^{6} |x_i|^{\frac{2}{r_i}})^{\frac{1}{2}}$, with $r = (1,1,1,1,2,2)$. We set $\alpha(0,\cdot) = 0$. By virtue of the definition of ρ, one easily shows that $\alpha(x,t) \to 0$ whenever $x \to 0$, uniformly for $t \in \mathbb{R}$, so that α *is continuous on* $\mathbb{R}^6 \times \mathbb{R}$.

Now, the closed-loop system can be explicitly integrated thanks to the simple structure of the ECF and the fact that $u(t) = \alpha(x_0, t)$ is independent of $x(t)$ on the interval $(0, T)$. After some calculations, one verifies the solution $x(\cdot)$ is of the form

$$x(T) = Ax_0 + w(x_0), \tag{11}$$

where A is a block-diagonal matrix $A = \mathrm{diag}(A_1, A_2, A_3)$ with blocks defined by

$$A_i = \begin{pmatrix} 1 + \frac{1}{2}T^2 a_{2i-1} & T + \frac{1}{2}T^2 a_{2i} \\ T a_{2i-1} & 1 + T a_{2i} \end{pmatrix}, \quad i = 1,2,3. \tag{12}$$

The spectrum of A is the union of the spectra of the A_i, each of which can be made equal to $\{k_{i1}, k_{i2}\} \subset \{z \in \mathbb{C} : |z| < 1\}$—thus making A a discrete–time-stable matrix—by setting

$$a_{2i-1} = \frac{k_{i1} + k_{i2} - k_{i1}k_{i2} - 1}{T^2} \quad \text{and} \quad a_{2i} = \frac{k_{i1} + k_{i2} + k_{i1}k_{i2} - 3}{2T}, \quad i = 1,2,3. \tag{13}$$

[1] In the language of homogeneity, ρ is a homogeneous norm with respect to a dilation of weight r. In this paper, however, no further use is made of this terminology or the associated results, and the interested reader is referred to, e.g., [7, 9] for more detailed discussions on that subject.

Of course, a_{2i-1} and a_{2i} must be real, for which it suffices to choose k_{i1}, k_{i2} to be complex conjugate. On the other hand, it is readily checked that the function $w = (w_1, \dots, w_6) : \mathbb{R}^6 \to \mathbb{R}^6$ in (11) is given by $w_1 = \cdots = w_4 = 0$ and

$$(w_5, w_6)(x_0) = \rho(x_0)L(x_0) + (\rho(x_0))^{-1}P(x_0) + Q(x_0),$$

where $L : \mathbb{R}^6 \to \mathbb{R}^2$ is linear and $P, Q : \mathbb{R}^6 \to \mathbb{R}^2$ are quadratic. Since $\rho(x_0) = \mathrm{O}(\|x_0\|^{\frac{1}{2}})$, it follows that $w(x_0) = \mathrm{O}(\|x_0\|^{\frac{3}{2}})$ and hence $w(x_0) = \mathrm{o}(\|x_0\|)$, so the solution $x(T)$ has the form (8). Since A is discrete–time-stable, there exists a symmetric, positive-definite matrix $P \in \mathbb{R}^{6\times 6}$ and a real number $\tau \in [0, 1)$ such that $\|Ax_0\|_P \leq \tau\|x_0\|_P$ for every $x_0 \in \mathbb{R}^6$, with $\|x\|_P = x^T Px$ denoting the norm of x induced by P. This means that, locally around the origin, the mapping which assigns $x(T)$ to x_0 is a contraction in the norm $\|\cdot\|_P$.

3.2. Some links between the proposed controller and other approaches. The remarkably simple structure of the control law (9)–(10) shares common traits with the one in [1]. In particular, both involve terms that are linear in the state components governed by second-order chains of integrators, namely, $x_1, \dots, x_4$ in the notation of the present paper. In addition, both of them use normalization by ρ—multiplication of some terms by $1/\rho$—in order to adjust the "degree of homogeneity" of the control law α (see [1] for further details and definitions). The important difference, however, lies in the way the control signals are calculated and applied, to wit, iterative state steering vs. feedback. As a matter of fact, this difference is instrumental in establishing robustness.

Interestingly, the *frequency* ω of the time-varying terms in the control law (9)–(10) does not have to be large. In fact, that frequency may be taken arbitrarily small (i.e., the period between samples may be arbitrarily long) without qualitatively altering the nature of the result. This is in opposition with the control laws in [1] or, more generally, with previous results based on averaging of "highly oscillatory" systems, e.g., [28, 16].

Furthermore, in contrast with the control laws in [8], which provide tracking controllers that steer the state asymptotically towards the origin by following an appropriately designed trajectory, the computation of (9)–(10) does not require the use of any such trajectory.

It is also interesting to note that, while our approach and that of [4] exhibit similarities (e.g., both are intended to be implemented as hybrid open-loop/feedback) the control expressions (9)–(10) are less involved than the ones in [4], which make use of time-varying gains determined by the solutions of an exogenous system. Moreover, even though robustness is not explicitly addressed in [4], it seems difficult to assess whether those control laws ensure robustness in the sense considered in this paper or not. In particular, the result in [13], which allows us to ascertain nonrobustness of [1], does not apply in that case.

On the other hand, the work reported in [14], where stability is considered in the discrete-time sense, may be used to ascertain robustness of our controllers with respect to disturbances of a particularly simple nature. It is not clear, however, how a larger class of disturbances (such as the one considered in our main result; cf. Proposition 3.1 below) can be encompassed by the same methodology. In fact, the strongest result in [14] holds when disturbances are simple enough that adding them to the closed-loop system results in a vector field whose flow can be explicitly computed. Since our stability/robustness analysis uses a Chen–Fliess series expansion to scrutinize the

terms that add up to the flow, in a very loose sense it may be regarded as a refinement, for the special case of system (1) controlled by (9)–(10), of the results in [14].

To close this paragraph, let us add that our approach yields control laws that are globally defined on $\mathbb{R}^6 \times \mathbb{R}$; hence they are nonsingular on the whole domain of validity of the coordinate chart containing the point to be stabilized. A slightly different situation occurs for the control laws of [11] and [6], where singularities may appear near the target point due to the nature of the control laws and to the nature of the coordinate transformations, respectively.

3.3. Stability and robustness analysis. In this section we present our main result, Proposition 3.1, which characterizes the stability and robustness properties of the feedback law (9)–(10) applied to the ECF.

PROPOSITION 3.1. *The control law α defined in* (9)–(10) *is a local exponential stabilizer for the origin of system* (6)*, robust to disturbances in* $\mathcal{A} = \{(h_0^\varepsilon, h_1^\varepsilon, h_2^\varepsilon) \in \mathcal{D}^3 : \mathrm{Ord}(h_0^\varepsilon) \geq 1, \mathrm{Ord}(h_0^0) \geq 2 \text{ and } \mathrm{Ord}(h_i^0) \geq 1, i = 1, 2\}$.

Remark 2. (i) In view of the definition of $\mathcal{A}$, for $\boldsymbol{h} \in \mathcal{A}$ one can write $h_i(x, \varepsilon) = w_i^\varepsilon(x) + h_i^0(x)$, with $w_i^0(\,\cdot\,) = 0$, $h_0^\varepsilon(x) = \mathrm{O}(\|x\|^2)$, and $h_j^0(x) = \mathrm{O}(\|x\|^1)$, $(i = 1, 2, 3,$ $j = 1, 2)$. Hence each disturbance vector field can be thought of as consisting of two parts, one containing only "high-order" terms in x and the other one vanishing identically when $\varepsilon = 0$. The terms corresponding to these two parts may have different origins. For instance, $w_i^\varepsilon(x)$ may arise from uncertainty in the knowledge of the physical parameters; if ε is a quantitative measure of the uncertainty, then these terms should vanish when ε equals zero. On the other hand, $h_i^0(x)$ may include high-order terms truncated from a series expansion of the system's nominal model, and these terms do not necessarily vanish when $\varepsilon = 0$.

(ii) A measure of the extent to which robustness is ensured by a feedback law α lies in the nature of the set $\mathcal{A}$. Roughly stated, the larger this set is, the more sources of disturbances α can tolerate. In this respect, the control law in [1] is *not* robust to disturbances taken from $\mathcal{A}$; thus the origin may be destabilized by the addition of disturbances in $\mathcal{A}$ regardless of how small their magnitude is (i.e., for arbitrarily small $|\varepsilon| > 0$). This lack of robustness, which can be checked by using the results in [13], is illustrated through numerical simulation in the examples in section 4.

The proof of Proposition 3.1 shares the same basic structure as that of Theorem 1 in [17], and some other technical facts are easy modifications of proofs in [27] and [10]. For the sake of conciseness, we prove only those claims particular to our solution and explicitly refer the reader to the appropriate references when necessary.

Proof of Proposition 3.1. Let us fix a disturbance $\boldsymbol{h} \in \mathcal{A}$ defined on an open set $U \times E \subset \mathbb{R}^n \times \mathbb{R}$. It must be shown that there is $\varepsilon_0 > 0$ such that the origin of (6) is locally exponentially stable when $\varepsilon \in [-\varepsilon_0, \varepsilon_0] \cap E$. The proof is divided into two main steps corresponding to the following two claims.

Claim 1. For every compact interval $E' \subset E$ there is a compact neighborhood $U' \subset U$ of 0 such that if $x_0 \in U'$ and $\varepsilon \in E'$, the solution $t \mapsto x(t) = \pi(t, 0, x_0, \varepsilon)$ to

$$\dot{x} = b_0(x) + h_0^\varepsilon(x) + \sum_{i=1}^{2} \alpha_i(x_0, t)(b_i(x) + h_i^\varepsilon(x)), \quad x(0) = x_0, \tag{14}$$

satisfies

$$x(T) = Ax_0 + \lambda(\varepsilon, x_0) + \mu(\varepsilon, x_0) + \mathrm{o}(\|x_0\|),$$

where the mappings λ, μ (which need not be uniquely defined) are such that

$$\frac{\|\lambda(\varepsilon, x_0)\|}{\|x_0\|} \to 0 \quad \text{as} \quad \varepsilon \to 0, \quad \text{uniformly for } x_0 \in U' \setminus \{0\}, \tag{15}$$

$$\frac{\|\mu(\varepsilon, x_0)\|}{\|x_0\|} \to 0 \quad \text{as} \quad x_0 \to 0, \quad \text{uniformly for } \varepsilon \in E'. \tag{16}$$

Claim 2. [17, Theorem 1]. There exists a nonempty interval $E_0 \subset E$ containing 0 such that, for every $\varepsilon \in E_0$, the origin of system (6) is locally exponentially stable. The proof that Claim 1 implies Claim 2 can be found in [17, Theorem 1]; here we proceed with the proof of Claim 1. The first step consists in showing that the system's solution at time T can be represented by means of a Chen–Fliess series expansion and, to this end, the following lemma is instrumental.[2]

LEMMA 3.2. *Let M be a real-analytic manifold and let $\overline{x} \in M$. Assume that the following hold:* (1) *$f_0, \dots, f_m$ are real-analytic vector fields on M, with $f_0(\overline{x}) = 0$;* (2) *$\phi : M \to \mathbb{R}$ is real-analytic; and* (3) *$\alpha \in C^0(M \times \mathbb{R}; \mathbb{R}^m)$ is such that $\alpha(\overline{x}, \cdot\,) = 0$ and $\alpha(x, \cdot\,)$ is bounded for every $x \in M$. Then, given $T > 0$, there is a neighborhood $\in K$ of $\overline{x}$ such that, for $x_0 \in K$ and $t_0 \in \mathbb{R}$, the solution $t \mapsto \pi(t, t_0, x_0)$ to $\dot{x} = f_0(x) + \sum_{i=1}^m \alpha_i(x_0, t) f_i(x)$, $x(t_0) = x_0$ is defined for $t \in [t_0, t_0 + T]$, and the Chen–Fliess series $\mathrm{Ser}_{\phi, \boldsymbol{f}, \alpha}(t, t_0, x_0) = \sum_I f_I \phi(x_0) \int_{t_0}^t \alpha_I(x_0)$ converges to $\phi(\pi(t, t_0, x_0))$, absolutely and uniformly for $(x_0, t_0) \in K \times \mathbb{R}$ and $\in t[t_0, t_0 + T]$.*

Proof. The proof of Lemma 3.2 is given in the appendix. □

Let $E' \subset E$ be any compact interval containing 0. Define real-analytic vector fields g_0, g_1, g_2 on $U \times E$ and a feedback law $\overline{\alpha} \in C^0(U \times E \times \mathbb{R}; \mathbb{R}^m)$ by setting $g_i(x, \varepsilon) = b_i(x) + h_i^\varepsilon(x)$ and $\overline{\alpha}_i(x, \varepsilon, t) = \alpha_i(x, t)$. It is clear that $g_0(0, \varepsilon) = 0$ for $\varepsilon \in E$, and that $\boldsymbol{g} = (g_0, g_1, g_2)$ and $\overline{\alpha}$ satisfy the assumptions of Lemma 3.2. Hence, for every $\varepsilon \in E'$ there is an open neighborhood V_ε of $(0, \varepsilon) \in U \times E$ for which the conclusion of that lemma holds. But $(V_\varepsilon)_{\varepsilon \in E'}$ is an open cover for the compact set $\{0\} \times E'$; thus one can extract from it a finite, open subcover. This implies the existence of a neighborhood $U' \subset U$ of the origin with the property that, for any $\varepsilon \in E'$, the solution $t \mapsto x(t) = \pi(t, 0, x_0, \varepsilon)$ to system (14), issued from any point $x_0 \in U'$ at $t = 0$, is defined on $[0, T]$, and the corresponding Chen–Fliess series

$$S(x_0, \varepsilon, t) = \mathrm{Ser}_{\mathrm{id}, \boldsymbol{b} + \boldsymbol{h}^\varepsilon, \alpha}(t, 0, x_0) = \sum_I (b + h^\varepsilon)_I \mathrm{id}(x_0, \varepsilon) \int_0^t \alpha_I(x_0) \tag{17}$$

converges to $\pi(t, 0, x_0, \varepsilon)$ absolutely, uniformly for $(x_0, \varepsilon, t) \in U' \times E' \times [0, T]$. (Here we use the notation $(b + h^\varepsilon)_I \mathrm{id}(x_0) = (b_{i_1} + h_{i_1}^\varepsilon) \cdots (b_{i_r} + h_{i_r}^\varepsilon) \mathrm{id}(x_0)$, given a multi-index $I = (i_1, \dots, i_r)$.) Note that the terms $(x_0, \varepsilon) \mapsto (b + h^\varepsilon)_I \mathrm{id}(x_0)$ involved in the series (17) represent real-analytic, first-order differential operators iterated on the function id; hence these terms are real-analytic as well. We may therefore use (17) to express the solution at $t = T$ in order to prove that it satisfies Claim 1.

[2] In [27, Lemma 4.2], conditions are given for the Chen–Fliess series to converge for every t in a *sufficiently short* interval $[0, \tau]$. In the present case, however, one requires the value of the solution at the end of the interval $[0, T]$, with T fixed beforehand. When the system is driftless, the interval $[0, \tau]$ of validity of the series expansion can be made arbitrarily long by imposing small enough bounds on the control inputs $\|u(\cdot)\|$ (cf. [17, Prop. 1] and the remarks that follow it). Nevertheless, the system here contains a drift term, so the convergence results in [27] cannot be applied without modification. This motivates the role of Lemma 3.2, which states conditions for convergence of the series for arbitrarily large times and initial conditions near an equilibrium point.

Set $w_i^\varepsilon(x) = h_i^\varepsilon(x) - h_i^0(x)$ so that $h_i^\varepsilon = w_i^\varepsilon + h_i^0$, $i = 0, 1, 2$. Obviously, each $(x, \varepsilon) \mapsto w_i^\varepsilon(x)$ is real-analytic and vanishes when $\varepsilon = 0$. For convenience define the sets of vector fields $\mathcal{B} = \{b_0, b_1, b_2\}$, $\mathcal{W} = \{w_0^\varepsilon, w_1^\varepsilon, w_2^\varepsilon\}$, and $\mathcal{H} = \{h_0^0, h_1^0, h_2^0\}$. Considering that each of the iterated differential operators $(b + h^\varepsilon)_I$ in (17) can be written as $(b+w^\varepsilon+h^0)_I$, it is easy to check that, since $S(x_0, \varepsilon, T)$ converges absolutely, the series can be rearranged as $S(x_0, \varepsilon, T) = \sum_{i=1}^5 S_i(x_0, \varepsilon, T)$, where $S_1, \ldots, S_5$ are absolutely convergent series defined by

$$\begin{aligned}
S_1(x_0, \varepsilon, T) &= x_0 + \sum_{1 \le |I|} b_I \mathrm{id}(x_0) \textstyle\int_0^T \alpha_I(x_0), \\
S_2(x_0, \varepsilon, T) &= \sum_{1 \le |I|} X_I \mathrm{id}(x_0, \varepsilon) \textstyle\int_0^T \alpha_I(x_0), \\
S_3(x_0, \varepsilon, T) &= \sum_{1 \le |I| \le 2} Y_I \mathrm{id}(x_0, \varepsilon) \textstyle\int_0^T \alpha_I(x_0), \\
S_4(x_0, \varepsilon, T) &= \sum_{3 \le |I|} Y_I \mathrm{id}(x_0, \varepsilon) \textstyle\int_0^T \alpha_I(x_0), \\
S_5(x_0, \varepsilon, T) &= \sum_{1 \le |I|} Z_I \mathrm{id}(x_0, \varepsilon) \textstyle\int_0^T \alpha_I(x_0),
\end{aligned}$$

and, for $I = (i_1, \ldots, i_r)$, the iterated differential operators X_I, Y_I, Z_I satisfy the following:

1. For $j = 1, \ldots, r$, X_{i_j} and Y_{i_j} belong to $\mathcal{B} \cup \mathcal{W} \cup \mathcal{H}$, whereas Z_{i_j} belongs to $\mathcal{B} \cup \mathcal{H}$.
2. *At least one* of the X_{i_j} and *at least one* of the Y_{i_j} are contained in $\mathcal{W}$.
3. *None* of the X_{i_j} belongs to $\{b_0, w_0^\varepsilon, h_0^0\}$.
4. *At least one* of the Y_{i_j} belongs to $\{b_0, w_0^\varepsilon, h_0^0\}$.
5. *At least one* of the Z_{i_j} is contained in $\mathcal{H}$.

It follows from the first property that all of the Z_I are independent of ε and, from the second, that $X_I \mathrm{id}(x_0, 0) = Y_I \mathrm{id}(x_0, 0) = 0$ for every $x_0 \in U$. In what follows, S_1 through S_5 are analyzed separately in order to show that their sum has the form announced in Claim 1. Let us first present Lemma 3.3, which gathers some simple facts to be used below.

LEMMA 3.3. *Under the assumptions of Proposition* 3.1 *the following hold:*

(i) *For every compact neighborhood $U' \subset U$ of the origin there exists $K > 0$ such that $\|\alpha(x_0, t)\| \le K \|x_0\|^{\frac{1}{2}}$ for $(x_0, t) \in U' \times \mathbb{R}$.*

(ii) *Let $r \in \{1, 2\}$. For any* nonzero *multi-index $I \in \{0, 1, 2\}^r$, the iterated integral $\int_0^T \alpha_I$ satisfies $\int_0^T \alpha_I(x_0) = \mathrm{O}(\|x_0\|)$, and for any multi-index $I \in \{1, 2\}^r$ it satisfies $\int_0^T \alpha_I(x_0) = \mathrm{O}(\|x_0\|^2)$.*

(iii) *Say that $k_0 = 0$ and $k_1 = k_2 = 1/2$. Then for any multi-index $I = (i_1, \ldots, i_r) \in \{0, 1, 2\}^r$, $r > 0$, one has $\mathrm{Ord}(\int_0^T \alpha_I) \ge \sum_{j=1}^r k_{i_j}$.*

(iv) *For every multi-index I, $x_0 \mapsto \int_0^T \alpha_I(x_0)$ is continuous.*

(v) *For $i = 1, 2$ the following hold:*
   (i) $\mathrm{Ord}(b_0) = 0$, $\mathrm{Ord}(b_i) = -1$,
   (ii) $\mathrm{Ord}(h_0^\varepsilon) = \mathrm{Ord}(w_0^\varepsilon) \ge 1$, $\mathrm{Ord}(h_i^\varepsilon) = \mathrm{Ord}(w_i^\varepsilon) \ge -1$,
   (iii) $\mathrm{Ord}(h_0^0) \ge 2$, $\mathrm{Ord}(h_i^0) \ge 1$.

(vi) *If $\phi \in C^\infty(U; \mathbb{R})$ and $k \ge 1$, then $\mathrm{Ord}(b_0^k \phi) \ge k$. (Here $b_0^0 \phi = \phi$ and $b_0^j \phi = b_0(b_0^{j-1} \phi)$, $j \ge 1$.)*

Proof. Given in the appendix. ∎

The first sum S_1 converges to the solution of the nominal system (7) controlled by $u = \alpha(x_0, t)$; thus

$$S_1(x_0, \varepsilon, T) = x_0 + \sum_{1 \le |I|} b_I \mathrm{id}(x_0) \int_0^T \alpha_I(x_0) = Ax_0 + \mathrm{o}(\|x_0\|). \tag{18}$$

Let us now prove that S_2–S_4 can be written in terms of functions satisfying properties analogous to (15)–(16), while S_5 converges to an $\mathrm{o}(\|x\|)$ function. The following lemma is crucial to attaining this goal.

LEMMA 3.4. *Let $U \times E \subset \mathbb{R}^n \times \mathbb{R}$ be an open neighborhood of $(0,0)$ and assume that, for every I in a countable set $\mathcal{I}$, $a_I : U \times E \to \mathbb{R}^n$ is real-analytic and vanishes at $U \times \{0\}$ and $b_I : U \to \mathbb{R}$ is continuous. Assume further that $\sum_{I \in \mathcal{I}} a_I(x, \varepsilon) b_I(x)$ converges to $f(x, \varepsilon)$, absolutely and uniformly for $(x, \varepsilon) \in U \times E$. Then there is a compact neighborhood $U' \subset U$ of 0 such that*

(1) *f satisfies (15) (with $\lambda = f$) if $\mathcal{I}$ is finite and any of the following conditions holds:*
   (i) *$a_I(x, \varepsilon) = \mathrm{O}(\|x\|)$ for every $I \in \mathcal{I}$,*
   (ii) *$b_I(x) = \mathrm{O}(\|x\|)$ for every $I \in \mathcal{I}$.*

(2) *f satisfies (16) (with $\mu = f$) if any of the following conditions holds:*
   (i) *$a_I(x, \varepsilon) = \mathrm{o}(\|x\|)$ for every $I \in \mathcal{I}$,*
   (ii) *there is $c > 0$ such that $b_I(x) = \mathrm{O}(\|x\|^{1+c})$ for every $I \in \mathcal{I}$,*
   (iii) *$a_I(x, \varepsilon) = \mathrm{O}(\|x\|)$ and there is $d > 0$ such that $b_I(x, \varepsilon) = \mathrm{O}(\|x\|^d)$ for every $I \in \mathcal{I}$.*

Proof. The proof of Lemma 3.4 is given in the appendix. ∎

Consider the sum S_2. If $1 \le |I| \le 2$, Lemma 3.3(ii) yields $\mathrm{Ord}(\int_0^T \alpha_I) \ge 1$. On the other hand, since the X_I's do not involve any drift term (i.e., none of the indices in I equals zero), for the terms such that $|I| \ge 3$ one invokes Lemma 3.3(iii) to conclude that $\int_0^T \alpha_I(x_0) = \mathrm{O}(\|x_0\|^{1+c})$ with $c = 1/2$. Thus, by setting $S_2(x_0, \varepsilon, T) = \lambda_2(x_0, \varepsilon) + \mu_2(x_0, \varepsilon)$,

$$\lambda_2(x_0, \varepsilon) = \sum_{1 \le |I| \le 2} X_I \mathrm{id}(x_0, \varepsilon) \int_0^T \alpha_I(x_0) \quad \text{and}$$

$$\mu_2(x_0, \varepsilon) = \sum_{|I| \ge 3} X_I \mathrm{id}(x_0, \varepsilon) \int_0^T \alpha_I(x_0);$$

the first is a sum of finitely many terms, and the second is the limit of an absolutely convergent series. By virtue of Lemma 3.4(1)(ii) and Lemma 3.4(2)(ii), λ_2 and μ_2 satisfy properties analogous to (15) and (16), respectively.

Let us turn to S_3. If $I \in \{(0), (0,0)\}$, then, since $\mathrm{Ord}(b_0) = 0$, $\mathrm{Ord}(w_0^\varepsilon) \ge 1$, and $\mathrm{Ord}(h_0^0) \ge 2$, one has $\mathrm{Ord}(Y_I \mathrm{id}) \ge 1$ by virtue of Lemma 6.1(v). If $I \notin \{(0), (0,0)\}$, then Lemma 3.3(ii) implies $\mathrm{Ord}(\int_0^T \alpha_I) = 2$. The number of multi-indices I with $1 \le |I| \le 2$ being finite, one concludes by successive application of points (1)(i) and (1)(ii) of Lemma 3.4 that λ_3 defined by

$$S_3(x_0, \varepsilon, T) = \sum_{1 \le |I| \le 2} Y_I \mathrm{id}(x_0, \varepsilon) \int_0^T \alpha_I(x_0) = \lambda_3(x_0, \varepsilon) \tag{19}$$

satisfies (15) with $\lambda = \lambda_3$.

Now let us turn to S_4 and consider two cases according to the values of the multi-indices I.

Case (i) ($|I| \geq 3$ and I involves three or more *nonzero* indices). Lemma 3.3(iii) implies that $\int_0^T \alpha_I(x_0) = \mathrm{O}(\|x\|^{1+c})$ with $c = 1/2$. Thus the sum of the terms for which the multi-index I involves three or more nonzero indices converges to a function $(x_0, \varepsilon) \mapsto \mu_{4i}(x_0, \varepsilon)$ which, by virtue of Lemma 3.4(2)(ii), satisfies (16) with $\mu = \mu_{4i}$.

Case (ii) ($|I| \geq 3$ and I involves two or less *nonzero* indices). Consider the following four subcases:

- *Subcase* (a) ($|I| \geq 3$ and $I = (0, \dots, 0)$). By the definition of Y_I, w_0^ε appears at least once in Y_I; it follows that $\mathrm{Ord}(Y_I \mathrm{id}) \geq 2$ as a consequence of Lemma 3.3(v) and Lemma 6.1(v). Thus in this subcase $Y_I \mathrm{id}(x, \varepsilon) = \mathrm{o}(\|x\|)$, so the sum of these terms converges to a function $(x, \varepsilon) \mapsto \mu_{4a}(x, \varepsilon)$ which, by Lemma 3.4(2)(i), satisfies (16) with $\mu = \mu_{4a}$.
- *Subcase* (b) ($r = |I| \geq 3$, $I = (0, i_2, \dots, i_r)$ and one or two indices are *nonzero*). Using again Lemma 3.3(v) and Lemma 6.1(v), one deduces that $\mathrm{Ord}(Y_I \mathrm{id}) \geq 1$. Also, by virtue of Lemma 3.3(iii), $\mathrm{Ord}(\int_0^T \alpha_I) \geq \frac{1}{2}$. Thus the sum of terms in this subcase converges to a function $(x, \varepsilon) \mapsto \mu_{4b}(x, \varepsilon)$ which, in view of Lemma 3.4(2)(iii), satisfies (16) with $\mu = \mu_{4b}$.
- *Subcase* (c) ($|I| \geq 3$, $I = (i_1, 0, \dots, 0)$, $i_1 \neq 0$). It is clear that $\mathrm{Ord}(\int_0^T \alpha_I) = \frac{1}{2}$ as a consequence of Lemma 3.3(iii). Also, if neither w_0^ε nor h_0^0 is involved in Y_I, then Lemma 3.3(vi) implies $\mathrm{Ord}(Y_I \mathrm{id}) \geq -1 + 2 = 1$. If, on the contrary, any of w_0^ε or h_0^0 is involved at least once in Y_I, then $\mathrm{Ord}(Y_I \mathrm{id}) \geq -1 + \sum_{j=2}^r \mathrm{Ord}(Y_{i_j}) + \mathrm{Ord}(\mathrm{id}) \geq 1$ since, under that condition, one has $\sum_{j=2}^r \mathrm{Ord}(Y_{i_j}) \geq 1$ in view of Lemma 3.3(v) and Lemma 6.1. Therefore the sum of these terms converges to a function $(x, \varepsilon) \mapsto \mu_{4c}(x, \varepsilon)$ which, by Lemma 3.4(2)(iii), satisfies (16) with $\mu = \mu_{4c}$.
- *Subcase* (d) ($r = |I| \geq 3$, $I = (i_1, \dots, i_r)$, $i_1 \neq 0$ and *exactly one* of $i_2, \dots, i_r$ is *nonzero*). Let $\mathcal{I}$ denote the set of multi-indices corresponding to this subcase. One has $\mathrm{Ord}(\int_0^T \alpha_I) \geq 1$, since exactly two indices in I are nonzero. Assume that the nonzero indices are i_1 and i_j, $2 \leq j \leq r$, so both $\mathrm{Ord}(Y_{i_1})$ and $\mathrm{Ord}(Y_{i_j})$ are ≥ -1. Setting $\omega_1 = \sum_{k=2}^{j-1} \mathrm{Ord}(Y_{i_k})$ and $\omega_2 = \sum_{k=j+1}^{r} \mathrm{Ord}(Y_{i_k})$, one gets $\omega_1 \geq 0$ and $\omega_2 \geq 0$. For those terms with $|I| \leq 7$, Lemma 6.1(v) implies that $\mathrm{Ord}(Y_I \mathrm{id}) \geq 0$. For the terms with $|I| \geq 8$, on the other hand, either b_0 appears three times consecutively in Y_I, or it does not. In the former case, if the iterated differential operator $Y_{i_2} \cdots Y_{i_{j-1}}$ involves the three successive b_0's, then Lemma 3.3(vi) yields $\mathrm{Ord}(Y_I \mathrm{id}) \geq -1 + \max\{1, 3\} = 2$. If the three successive b_0's are involved in $Y_{i_{j+1}} \cdots Y_{i_r}$, the same lemma yields $\mathrm{Ord}(Y_{i_j} \cdots Y_{i_r} \mathrm{id}) \geq -1 + \max\{1, 3\} = 2$. Thus $\mathrm{Ord}(Y_{i_2} \cdots Y_{i_r} \mathrm{id}) \geq \omega_1 + 2$ and $\mathrm{Ord}(Y_I \mathrm{id}) \geq -1 + \max\{1, 2\} = 1$.

Consider now the case when Y_I does not involve three consecutive b_0's. In this case,

$$\begin{aligned} \mathrm{Ord}(Y_{i_j} \cdots Y_{i_r} \mathrm{id}) &\geq -1 + \max\{1, \omega_2 + 1\} = \omega_2, \\ \mathrm{Ord}(Y_{i_2} \cdots Y_{i_r} \mathrm{id}) &\geq \omega_1 + \max\{1, \omega_2\}; \end{aligned}$$

thus

$$\begin{aligned} \mathrm{Ord}(Y_{i_1} \cdots Y_{i_r} \mathrm{id}) &\geq -1 + \max\{1, \omega_1 + \max\{1, \omega_2\}\} \\ &= \max\{0, \max\{\omega_1, \omega_1 + \omega_2 - 1\}\}. \end{aligned}$$

But since $|I| \geq 8$, at least two vector fields from $\{w_0^\varepsilon, h_0^0\}$ appear in Y_I, so $\omega_1 + \omega_2 \geq 2$,

$\max\{\omega_1, \omega_1 + \omega_2 - 1\} \geq 1$, and, consequently, $\mathrm{Ord}(Y_I\mathrm{id}) \geq 1$. Therefore, by setting

$$\lambda_4(x_0, \varepsilon) = \sum_{I \in \mathcal{I}, |I| \leq 7} Y_I\mathrm{id}(x_0, \varepsilon) \int_0^T \alpha_I(x_0) \quad \text{and}$$

$$\mu_{4d}(x_0, \varepsilon) = \sum_{I \in \mathcal{I}, |I| \geq 8} Y_I\mathrm{id}(x_0, \varepsilon) \int_0^T \alpha_I(x_0),$$

one sees that these mappings are well defined, the first being the sum of finitely many terms and the second being the limit of an absolutely convergent sequence. But then, with the help of points (1)(ii) and (2)(iii) of Lemma 3.4, one concludes that λ_4 and μ_{4d} satisfy (15) and (16) with $\lambda = \lambda_4$ and $\mu = \mu_{4d}$, respectively. Summarizing the results from Cases (i) and (ii) for S_4, one obtains

$$S_4(x_0, \varepsilon, T) = \sum_{3 \leq |I|} Y_I\mathrm{id}(x_0, \varepsilon) \int_0^T \alpha_I(x_0) = \lambda_4(x_0, \varepsilon) + \mu_{4i}(x_0, \varepsilon) + \mu_{4ii}(x_0, \varepsilon) \tag{20}$$

with $\mu_{4ii} = \mu_{4a} + \mu_{4b} + \mu_{4c} + \mu_{4d}$.

Finally, let us show that S_5 converges to a function f_5 such that $f_5(x) = \mathrm{o}(\|x\|)$. Consider three cases according to the value of I.

Case (i) (I involves three or more *nonzero* indices). From Lemma 3.3(iii), we see that $\mathrm{Ord}(\int_0^T \alpha) \geq 3/2$.

Case (ii) (I involves one or two *nonzero* indices). If $r = |I| \in \{1, 2\}$, then $I \in \{1, 2\}^r$ is nonzero, so Lemma 3.3(ii) implies that $\mathrm{Ord}(\int_0^T \alpha) = 2$, whereas $\mathrm{Ord}(Z_I\mathrm{id}) \geq 0$. Now suppose that $r = |I| \geq 3$. From Lemma 3.3(iii), $\mathrm{Ord}(\int_0^T \alpha_I) \geq 1/2$. If $i_1 = 0$, then $\mathrm{Ord}(Z_I\mathrm{id}) \geq 0 + \mathrm{Ord}(Z_{i_2} \cdots Z_{i_r}\mathrm{id}) \geq 0 + \max\{1, 0\} = 1$. Now let us consider the case where $i_1 \neq 0$. If $I = (i_1, 0, \ldots, 0)$, then, by definition of Z_I, either $Z_{i_1} \in \mathcal{H}$, in which case $\mathrm{Ord}(Z_{\mathrm{id}}) \geq \mathrm{Ord}(Z_{i_1}) + \max\{1, 2\} \geq 3$, or $Z_{i_j} \in \mathcal{H}$ for some $j \in \{2, \ldots, r\}$, in which case $\mathrm{Ord}(Z_{i_2} \cdots Z_{i_r}\mathrm{id}) \geq \sum_{j=2}^r \mathrm{Ord}(Z_{i_j}) + 1 \geq 2$, and so, $\mathrm{Ord}(Z_I\mathrm{id}) \geq -1 + \max\{1, 2\} = 1$. If $i_1 \neq 0$ and $i_j \neq 0$ for some $j \in \{2, \ldots, r\}$, then $\mathrm{Ord}(\int_0^T \alpha_I) \geq 1$. Moreover, either $Z_{i_1} \in \mathcal{H}$, in which case $\mathrm{Ord}(Z_I\mathrm{id}) \geq 1 + \max\{1, 0\} = 2$, or $Z_{i_1} \notin \mathcal{H}$. Suppose the latter is true and set $\omega_1 = \sum_{k=2}^{j-1} \mathrm{Ord}(Z_{i_k})$ and $\omega_2 = \sum_{k=j+1}^r \mathrm{Ord}(Z_{i_k})$, so that $\omega_1 \geq 0, \omega_2 \geq 0$ and

$$\mathrm{Ord}(Z_{i_j} \cdots Z_{i_r}\mathrm{id}) \geq \mathrm{Ord}(Z_{i_j}) + \max\{1, \omega_2 + 1\} = \mathrm{Ord}(Z_{i_j}) + \omega_2 + 1,$$
$$\mathrm{Ord}(Z_{i_2} \cdots Z_{i_r}\mathrm{id}) \geq \omega_1 + \max\{1, \mathrm{Ord}(Z_{i_j}) + \omega_2 + 1\}.$$

If $Z_{i_j} \in \mathcal{H}$, then $\mathrm{Ord}(Z_{i_j}) \geq 1$ and hence $\mathrm{Ord}(Z_I\mathrm{id}) \geq -1 + \max\{1, 2 + \omega_2\} \geq 1$. If $Z_{i_j} \notin \mathcal{H}$, then $Z_{i_k} = h_0^0$ for some $k \in \{2, \ldots, r\} \setminus \{j\}$. In that case $\omega_1 + \omega_2 \geq 2 = \mathrm{Ord}(h_0^0)$ and $\mathrm{Ord}(Z_{i_j}) \geq -1$; thus $\mathrm{Ord}(Z_I\mathrm{id}) \geq -1 + \omega_1 + \max\{1, \omega_2\} \geq 1$. Summarizing, every term pertaining to Case (ii) satisfies $\mathrm{Ord}(Z_I\mathrm{id} \cdot \int_0^T \alpha_I) \geq 3/2$.

Case (iii) ($I = (0, \ldots, 0)$, $|I| = r$). Since (a) $\mathrm{Ord}(Z_{i_j}) \geq 0$ for $j = 1, \ldots, r$; (b) at least one of the Z_{i_j} is equal to h_0^0; and (c) $\mathrm{Ord}(h_0^0) \geq 2$, one has $\mathrm{Ord}(Z_I\mathrm{id}) = \sum_{j=1}^r \mathrm{Ord}(Z_{i_j}) + 1 \geq 3$.

All terms corresponding to Cases (i)–(iii) satisfy $\mathrm{Ord}(Z_I\mathrm{id} \cdot \int_0^T \alpha_I) \geq 3/2$; that is, $Z_I\mathrm{id}(x_0) \int_0^T \alpha_I(x_0) = \mathrm{o}(\|x\|)$. Thus their sum converges to a function f_5 with the required property. Clearly, the sum of finitely many functions $f_1, \ldots, f_N$ satisfying (15) on compact sets $U_1, \ldots, U_N$ (resp., (16)) also satisfies (15) on $U' = \bigcap_{i=1}^N U_i$

(resp., (16)). Therefore $x(T)$ is as in Claim 1, and the proof of Proposition 3.1 is complete. □

In Proposition 3.1, the condition that the disturbances belong to $\mathcal{A}$ is *sufficient* but not necessary for stability and robustness. In particular, disturbances in $\mathcal{A}$ satisfy $h_0(x,\varepsilon) = \mathrm{O}(\|x\|)$ or, stated otherwise, each component of the drift disturbance satisfies $h_{0,i} = \mathrm{O}(\|x\|^2)$. This is somewhat conservative since in some cases the latter condition is not satisfied and yet the conclusion of the previous proposition seems to hold in simulations. Indeed, a refinement of that result *seems plausible*, although the proof would require surmounting some technical obstacles. We are thus led to formulate the following conjecture which, as we shall see in the examples in section 4, might be of interest when addressing the stabilization of systems whose models can be written as an ECF with additional terms. By viewing these terms as disturbances, one might successfully use the control laws (9)–(10), *without modification*, to stabilize some of those systems to a point. A drawback of the stated condition, however, is that testing it may be difficult in practice.

CONJECTURE 1. *Let $\mathcal{A}'$ be the subset of $\mathcal{D}^3$ defined by stipulating that $(h_0^\varepsilon, h_1^\varepsilon, h_2^\varepsilon)$ belongs to $\mathcal{A}'$ if and only if* (1) $\mathrm{Ord}(h_0^\varepsilon) \geq 0$, $\mathrm{Ord}(h_0^0) \geq 2$, $\mathrm{Ord}(h_i^0) \geq 1$, $i = 1, 2$, *and* (2) *for every $k \geq 2$, every $X \in \{b_1, b_2, h_1^\varepsilon, h_2^\varepsilon\}$, and every k-tuple $(Y_1, \ldots, Y_k) \in \{b_0, h_0^\varepsilon\}^k$ having at least one of the Y_i equal to h_0^ε, one has $\mathrm{Ord}(XY_1 \cdots Y_k \mathrm{id}) \geq 1$. Then the control law α defined in* (9)–(10) *is a local exponential stabilizer for* (6)*, robust to disturbances in $\mathcal{A}'$.*

Remark 3. If this conjecture holds true, its proof should essentially coincide with that of Proposition 3.1. The only differences would arise in arguments that explicitly appeal to the assumption $\mathrm{Ord}(h_0^\varepsilon) \geq 1$ (i.e., $\mathrm{Ord}(w_0^\varepsilon) \geq 1$), namely, Subcases (a), (c), and (d) of Case (ii) in the sum S_4. One should show that, by dropping that assumption, the terms pertaining to those subcases satisfy the required properties. For Subcase (c) one has $\mathrm{Ord}(\int_0^T \alpha_I) \geq 1/2$ and, since in this subcase every multi-index I is of the form $I = (i_1, 0, \ldots, 0)$ with $i_1 \neq 0$, the corresponding terms are of the form $Y_I \mathrm{id} = XZ_1 \cdots Z_k \mathrm{id}$ with $X \in \{b_i, h_i^0, w_i^\varepsilon : i = 1, 2\}$ and $(Z_1, \ldots, Z_k) \in \{b_0, h_0^0, w_0^\varepsilon\}^k$. By a simple induction argument one sees that the definition of $\mathcal{A}'$, in particular condition (2) in Conjecture 1, implies that all such terms satisfy $\mathrm{Ord}(Y_I \mathrm{id}) \geq 1$, so by virtue of Lemma 3.4(2)(iii) these terms have the required properties. On the other hand, each term of the series involved in Subcase (a) satisfies $\mathrm{Ord}(Y_I \mathrm{id}) \geq 1$ and $\mathrm{Ord}(\int_0^T \alpha_I) = 0$ since $\int_0^T \alpha_I(x_0) = \frac{T^{|I|}}{|I|!}$, whereas the terms of the series in Subcase (d) satisfy $\mathrm{Ord}(Y_I \mathrm{id}) \geq 0$ and $\mathrm{Ord}(\int_0^T \alpha_I) \geq 1$. To prove the conjecture, then, it would suffice to show that the (infinite) series in these two subcases converge to functions λ_{4a} and λ_{4d} satisfying (15).

4. Examples.

4.1. Underactuated manipulator. Consider the example of a $\mathrm{PP}\overline{\mathrm{R}}$ manipulator, depicted in Figure 2, with unactuated third joint, constrained to move on a horizontal plane. Considering the links and joints as rigid bodies and neglecting gravitational and frictional forces, this system can be modeled by

$$\begin{aligned} M_1\ddot{q}_1 - m_3 l \sin(q_3)\ddot{q}_3 - m_3 l \cos(q_3)\dot{q}_3^2 &= \tau_1, \\ M_2\ddot{q}_2 + m_3 l \cos(q_3)\ddot{q}_3 - m_3 l \sin(q_3)\dot{q}_3^2 &= \tau_2, \\ -M_3 l \sin(q_3)\ddot{q}_1 + M_3 l \cos(q_3)\ddot{q}_2 + J\ddot{q}_3 &= 0, \end{aligned} \tag{21}$$

where m_i, $i = 1, 2, 3$, is the mass of the ith link, $M_i = \sum_{j=i}^3 m_j$, J is the moment of inertia of the third link with respect to the axis of the third joint, and l is the

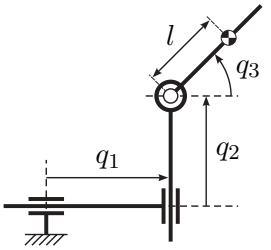

FIG. 2. *Schematic representation of the $PP\overline{R}$ manipulator.*

distance from the same axis to the center of mass of the third link. The input vector $\tau = (\tau_1, \tau_2)$ represents the forces applied in the q_1 and q_2 directions, respectively. The configuration manifold is $Q = \mathbb{R}^2 \times SS^1$, for which $q : Q \to \mathbb{R}^2 \times (-\pi, \pi)$ is a local coordinate system.

Given a target configuration $\overline{q} \in Q$, the dynamics can be transformed into the ECF, locally around $\overline{q}$, by using the coordinates of the third link's "center of percussion." A detailed description of the corresponding transformation can be found in [8]; for simplicity, however, in what follows we assume without loss of generality that the target configuration—the one that should be stabilized—is given by $q(\overline{q}) = (0, 0, 0) \in U$. After simple computations one verifies that, by setting $K = J/M_3/l$, the dynamic model (21) can be transformed into the ECF $\dot{x} = b_0(x) + u_1 b_1(x) + u_2 b_2(x)$ by means of the feedback transformation $x = \varphi(q, \dot{q})$, $u = A(q, \dot{q}) + B(q)[\tau_1 \;\; \tau_2]^T$, where

$$\varphi(q, \dot{q}) = \begin{pmatrix} q_1 + K(\cos(q_3) - 1) \\ \dot{q}_1 - K \sin(q_3)\dot{q}_3 \\ \tan(q_2) \\ (1 + \tan^2(q_3))\dot{q}_2 \\ q_2 + K \sin(q_3) \\ \dot{q}_2 + K \cos(q_3)\dot{q}_3 \end{pmatrix},$$

and

$$A(q, \dot{q}) = \frac{1}{\Delta(q)} \begin{pmatrix} \frac{(JK^2M_2 - J^2 - K^4M_1M_2 + JK^2M_1)\cos(q_3)\dot{q}_3^2}{K} \\ \frac{(2K^2M_1M_2 - 3JM_1\cos^2(q_3) - 2JM_2 + 3JM_2\cos^2(q_3))\sin(q_3)\dot{q}_3^2}{\cos^3(q_3)} \end{pmatrix},$$

$$B(q) = \frac{1}{\Delta(q)} \begin{pmatrix} (K^2M_2 - J)\cos^2(q_3) & (K^2M_1 - J)\cos(q_3)\sin(q_3) \\ \frac{KM_2\sin(q_3)}{\cos^2(q_3)} & -\frac{KM_1}{\cos(q_3)} \end{pmatrix},$$

$$\Delta(q) = K^2M_1M_2 - JM_1\cos^2(q_3) - JM_2\sin^2(q_3).$$

The control laws developed above can be iterated, after the system has been transformed into the ECF, in order to stabilize the origin $x = 0$. To this end, at each sample time $t_k = kT$ one uses the measurements of the state variables to calculate $x(t_k) = \varphi(q(t_k), \dot{q}(t_k))$, then the prescribed control law $u(t) = \alpha(x(t_k), t)$ is computed from (9)–(10). The actual force used to drive the system is obtained by using the inverse transformation $\tau(t) = [B(q)]^{-1}(u(t) - A(q, \dot{q}))$.

When the system parameters are not accurately known, which is most often the case, the functions φ, A, and B typically include additional terms. For the sake of illustration let us suppose that uncertainties are present in the values of the (cumulated) masses M_i, the position of the third link's center of mass l, and its inertia

moment J. This entails that only the erroneous values $\widetilde{M}_i = M_i + \nu_i$, $\widetilde{l} = l + \nu_4$, and $\widetilde{J} = J + \nu_5$, where $\nu = (\nu_1, \ldots, \nu_5) \in \mathbb{R}^5$ represents the parameter errors, are available to the controller. Note that, if one sets $\varepsilon = \|\nu\|^2$, the norm of the error tends to zero as $\varepsilon \to 0$. Ultimately, the effect of the inaccuracies results in disturbance vector fields $h = (h_0^\varepsilon, h_1^\varepsilon, h_2^\varepsilon)$ being added to the nominal ECF system, yielding a perturbed system in the form of (3). Using a computer algebra package, one readily verifies that for $i = 1, 2, 3$, the mappings $(x, \varepsilon) \mapsto h_i^\varepsilon(x)$ are analytic and have the following structures:

$$h_0^\varepsilon(x) = x_4^2(a_{2,0}^\varepsilon + \mathrm{O}(|x_3|^2))\frac{\partial}{\partial x_2} + x_4^2(a_{4,3}^\varepsilon x_3^3 + \mathrm{O}(|x_3|^5))\frac{\partial}{\partial x_4} + x_4^2(a_{6,1}^\varepsilon x_3 + \mathrm{O}(|x_3|^2))\frac{\partial}{\partial x_6},$$

$$h_1^\varepsilon(x) = (b_{2,0}^\varepsilon + \mathrm{O}(|x_3|^2))\frac{\partial}{\partial x_2} + (b_{4,1}^\varepsilon x_3 + \mathrm{O}(|x_3|^3))\frac{\partial}{\partial x_4} + (b_{6,1}^\varepsilon x_3 + \mathrm{O}(|x_3|^3))\frac{\partial}{\partial x_6},$$

$$h_2^\varepsilon(x) = (c_{2,1}^\varepsilon x_3 + \mathrm{O}(|x_3|^3))\frac{\partial}{\partial x_2} + (c_{4,0}^\varepsilon + \mathrm{O}(|x_3|^2))\frac{\partial}{\partial x_4} + (c_{6,0}^\varepsilon + \mathrm{O}(|x_3|^2))\frac{\partial}{\partial x_6},$$

where the symbols $a_{i,j}^\varepsilon$, $b_{i,j}^\varepsilon$, and $c_{i,j}^\varepsilon$ represent real numbers which vanish when $\varepsilon = 0$ but are nonzero for generic parameter and error values. This implies that $\mathrm{Ord}(h_0^\varepsilon) = 1$ and $\mathrm{Ord}(h_1^\varepsilon) = \mathrm{Ord}(h_2^\varepsilon) = -1$, so the assumptions in Proposition 3.1 are verified. As a result, the iterated application of the control laws (9)–(10) will ensure that the origin of the dynamically extended system (6) is locally exponentially stable, provided ε *is small enough*.

Now consider a PP$\overline{\mathrm{R}}$ manipulator whose *nominal*, physical dimensions are as follows. The three masses are equal: $m_1 = m_2 = m_3 = 10$ kg. The third link is a homogeneous parallelepiped of length $\ell = 1.5$ m and width $w = 0.15$ m; its center of mass is located at a distance $l = \ell/2 = 0.75$ m from the joint axis and its inertia moment is $J = (\ell^2/3 + w^2/12)m_3 = 7.51875\ \mathrm{kg\,m^2}$. The goal is to stabilize the system to the equilibrium configuration $(q, \dot{q}) = (0, 0)$ starting at rest ($\dot{q}_0 = 0$) from the initial configuration $q_0 = (-50\ \mathrm{cm}, 75\ \mathrm{cm}, \pi/4)$. A convenient DOF, useful for fine-tuning the transient response, is encompassed by the choice of the controller settings (T, G, and the a_i's), which can be made with the aid of some intuitively deduced "rules of thumb." T controls the length of the periods during which the system operates in open-loop; smaller values of T lead to more frequent updates of the feedback terms. G moderates the control effort exerted on the system due to the oscillatory, time-varying terms; large values of G lead to shorter settling time (to within a given tolerance) but may require larger control efforts. The values of a_i set the position of the poles $\{k_{i1}, k_{i2}\}$, within the unit circle in $\mathbb{C}$, for each of the submatrices A_i in (12). As can be expected, the closer the poles are to the origin, the shorter the settling time is, but also the larger the control effort becomes. In these simulations the settings are $\omega = 1$ rad/s, so $T = 2\pi \approx 6.28$ s; $G = 0.1$ and $k_{i,j} = 0.25$ ($i = 1, 2, 3$, $j = 1, 2$); the gain values $a_1 = a_3 = a_5 \simeq -0.01425$ and $a_2 = a_4 = a_6 \simeq -0.194$ were determined from (13). In order to perform the numerical simulation in the perturbed case, it is assumed that $\widetilde{m}_3 = 1.1m_3$ and $\widetilde{l} = 0.95l$; that is, errors of 10% and -5%, respectively, are present in the knowledge of these two parameters. The latter induce an error of -0.7% in the moment of inertia, so that $\widetilde{J} = 0.993J$. The response of the perturbed system controlled by (9)–(10) appears in Figure 3, which shows the time history of $\log(\|(q(t), \dot{q}(t))\|)$, the configuration variables $q(t)$, and velocities $\dot{q}(t)$, as well as the input forces $\tau(t)$. The differences between the transient responses in the perturbed and nominal cases are barely perceptible, so no simulation for the latter case is included. In order to assess the improved performance of the control law (9)–(10) in the presence of disturbances, let us end this example with a qualitative

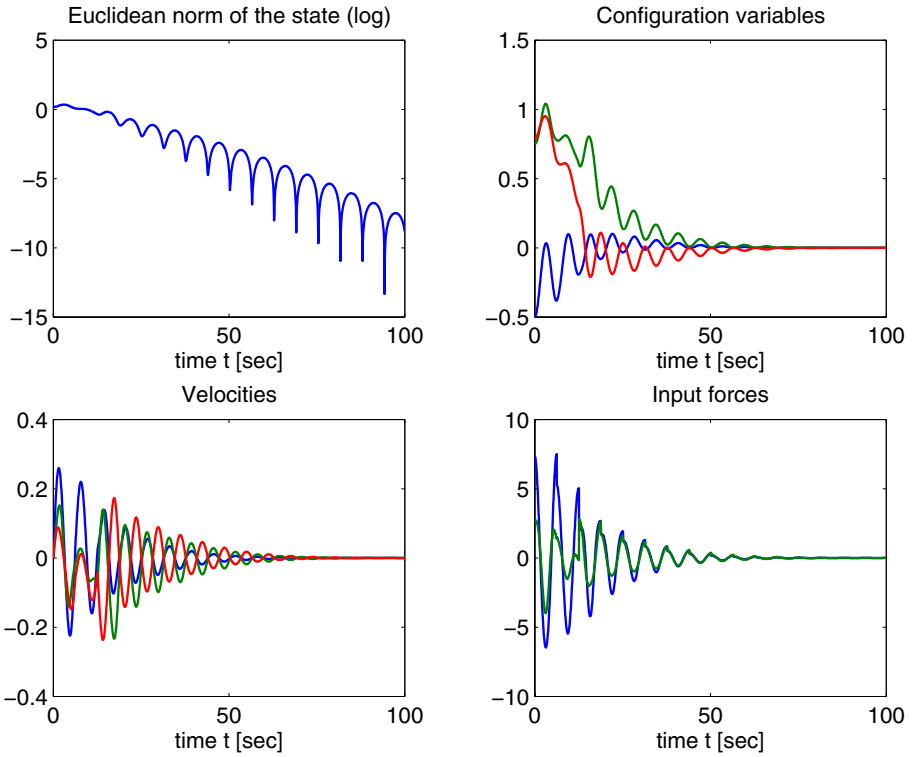

FIG. 3. *Transient response of the* perturbed $PP\overline{R}$ *manipulator using the hybrid control law* (9)–(10).

comparison with another control approach. Recall that in [1], a homogeneous, time-varying feedback law was introduced which ρ-exponentially stabilizes the ECF to the origin. Nevertheless, by virtue of the main result in [13], these control laws are not robust to disturbances in $\mathcal{D}^3$ and, in fact, as illustrated in Figure 4, the disturbances considered in this example make the system's solution tend towards what seems to be a limit cycle (in particular the origin is not Lyapunov-stable).

4.2. Simplified surface vessel. Consider a simplified surface vessel with configuration variables (x, y, θ), as depicted in Figure 5. Research studies concerning this system are reported in several references, including [23], where more details on the modeling assumptions can be found. In particular, it is shown in that reference that the corresponding dynamic model can be written in the form

$$\begin{aligned} \ddot{x} &= u_1, \\ \ddot{\theta} &= u_2, \\ \ddot{y} &= u_1 \tan(\theta) + \frac{c_y}{m}(-\dot{y} + \tan(\theta)\dot{x}). \end{aligned} \tag{22}$$

Clearly this can be viewed as a perturbed ECF system. More precisely, by setting $\varepsilon = c_y/m$ and relabeling the state variables $(x_1, \ldots, x_6) = (x, \dot{x}, \theta, \dot{\theta}, y, \dot{y})$ one can also write system (22) as

$$\dot{x} = b_0(x) + h_0^{\varepsilon}(x) + \sum_{i=1}^{2} u_i(b_i(x) + h_i^{\varepsilon}(x)), \tag{23}$$

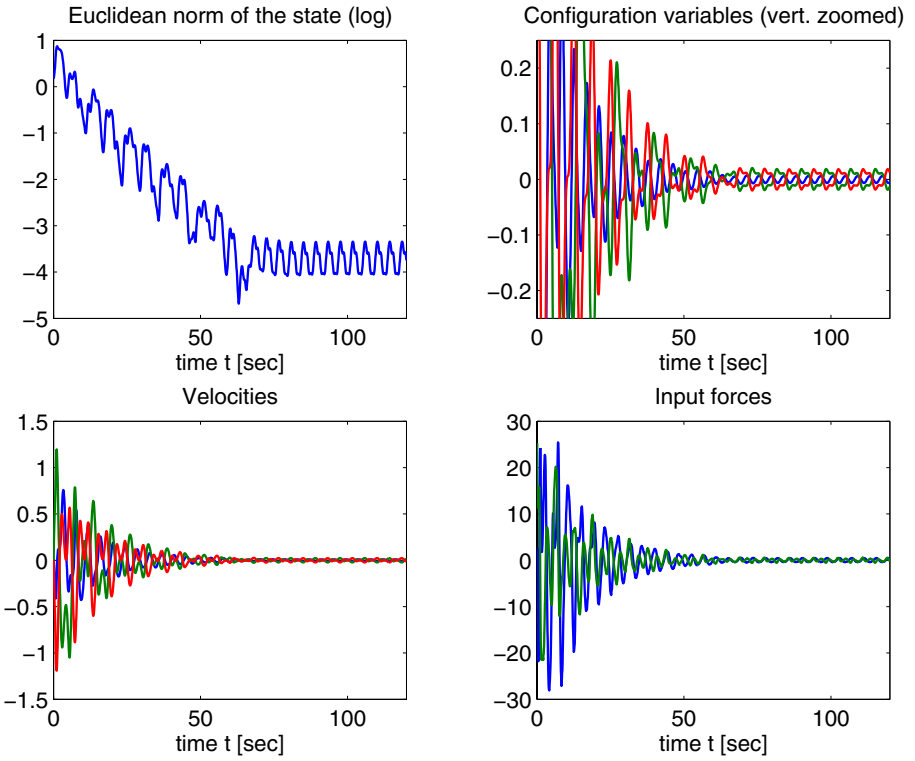

FIG. 4. *Transient response of the* perturbed $PP\overline{R}$ *manipulator using the continuous, homogeneous, time-varying feedback from* [1]. *The time histories of the configuration variables are plotted with a different scale to illustrate their ultimately oscillatory nature.*

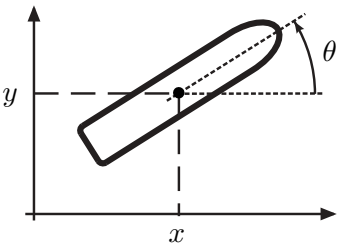

FIG. 5. *Configuration variables for the simplified surface vessel model.*

with b_0, b_1, b_2 given by (2), and the disturbance vector fields defined by

$$h_0^\varepsilon(x) = \varepsilon(-x_6 + x_2\tan(x_3))\frac{\partial}{\partial x_6}, \quad h_1^\varepsilon(x) = (\tan(x_3) - x_3)\frac{\partial}{\partial x_6}, \quad h_2^\varepsilon(x) = 0. \tag{24}$$

Obviously, the family $\boldsymbol{h} = (h_0^\varepsilon, h_1^\varepsilon, h_2^\varepsilon)$ is a disturbance in $\mathcal{D}^3$, but it is not contained in the set $\mathcal{A}$ defined in Proposition 3.1 since $\mathrm{Ord}(h_{0,6}^\varepsilon) = 1$, i.e., $\mathrm{Ord}(h_0^\varepsilon) = 0$. Let us show, however, that $\boldsymbol{h}$ belongs to $\mathcal{A}'$ and hence that it satisfies the assumptions of Conjecture 1. To this end, let $g(x) = \varepsilon(-x_6 + x_2\tan(x_3))$, so that $h_0^\varepsilon(x) = g(x)\partial/\partial x_6$. Note that $\mathrm{Ord}(h_1^\varepsilon) = 2$ and $\mathrm{Ord}(h_2^\varepsilon) = +\infty$; hence we need only certify that all terms

$XY_1 \cdots Y_k\mathrm{id}$, with $X \in \{b_1, b_2\}$, $k \geq 2$ and $Y_1, \ldots, Y_k \in \{b_0, h_0^\varepsilon\}$, satisfy

$$\mathrm{Ord}(XY_1 \cdots Y_k\mathrm{id}) \geq 1. \tag{25}$$

Since $b_1\phi(x) = \partial\phi/\partial x_2 + x_3\partial\phi/\partial x_6$ and $b_2\phi(x) = \partial\phi/\partial x_4$ for any smooth function ϕ, a necessary condition to have $\mathrm{Ord}(b_1\phi) \geq 1$ and $\mathrm{Ord}(b_2\phi) \geq 1$ is that $\mathrm{Ord}(\partial\phi/\partial x_2) \geq 1$ and $\mathrm{Ord}(\partial\phi/\partial x_4) \geq 1$. Naturally, this necessary condition holds whenever $\phi = Y_1 \cdots Y_k\mathrm{id}$ and $\mathrm{Ord}(\phi) \geq 2$. In what follows we shall show that it holds even when the latter is not the case. One has

$$b_0\mathrm{id}_i(x) = \begin{cases} x_{i+1}, & i = 1, 3, 5, \\ 0, & i = 2, 4, 6, \end{cases} \quad \text{and} \quad h_0^\varepsilon\mathrm{id}_i(x) = \begin{cases} 0, & i = 1, \ldots, 5, \\ g(x), & i = 6, \end{cases}$$

from which it follows that $b_0b_0\mathrm{id} = 0$, $h_0^\varepsilon b_0\mathrm{id}_i = 0$ for $i \neq 5$, and $b_0h_0^\varepsilon\mathrm{id}_i = h_0^\varepsilon h_0^\varepsilon\mathrm{id}_i = 0$ for $i \neq 6$. Furthermore,

$$h_0^\varepsilon b_0\mathrm{id}_5(x) = g(x), \quad b_0h_0^\varepsilon\mathrm{id}_6(x) = x_4\frac{\partial g}{\partial x_3}(x) \quad \text{and}$$
$$h_0^\varepsilon h_0^\varepsilon\mathrm{id}_6(x) = g(x)\frac{\partial g}{\partial x_6}(x) = -\varepsilon g(x).$$

By direct calculation one obtains that

$$\frac{\partial g}{\partial x_2}(x) = -\varepsilon\tan(x_3), \quad \frac{\partial g}{\partial x_4}(x) = 0, \tag{26}$$

$$\frac{\partial}{\partial x_2}\left(x_4\frac{\partial g}{\partial x_3}(x)\right) = x_4\frac{\partial^2 g}{\partial x_2\partial x_3}(x), \tag{27}$$
$$\frac{\partial}{\partial x_4}\left(x_4\frac{\partial g}{\partial x_3}(x)\right) = \frac{\partial g}{\partial x_3}(x) = \varepsilon x_2(1 + \tan^2(x_3)).$$

The orders $\mathrm{Ord}(\cdot)$ of all of these functions being ≥ 1, the required condition (25) is satisfied for $k = 2$. Now consider the case $k \geq 3$ and note that, since $\mathrm{Ord}(b_0b_0\mathrm{id}) = +\infty$ and $\mathrm{Ord}(b_0h_0^\varepsilon\mathrm{id}) = 2$, all terms $XY_1 \ldots Y_k\mathrm{id}$ which end with $b_0b_0\mathrm{id}$ or with $b_0h_0^\varepsilon\mathrm{id}$ satisfy (25) for $k \geq 3$. Moreover, $b_0h_0^\varepsilon b_0\mathrm{id}_5 = b_0h_0^\varepsilon\mathrm{id}_6$ and $b_0h_0^\varepsilon h_0^\varepsilon\mathrm{id}_5 = -\varepsilon b_0h_0^\varepsilon\mathrm{id}_6$, so those terms that end with $b_0h_0^\varepsilon h_0^\varepsilon\mathrm{id}$ and $b_0h_0^\varepsilon h_0^\varepsilon\mathrm{id}$ also satisfy (25) for $k \geq 3$. It remains only to consider terms ending with $h_0^\varepsilon h_0^\varepsilon b_0\mathrm{id}$ and $h_0^\varepsilon h_0^\varepsilon h_0^\varepsilon\mathrm{id}$. But $h_0^\varepsilon h_0^\varepsilon b_0\mathrm{id}_5 = h_0^\varepsilon h_0^\varepsilon\mathrm{id}_6$; thus one needs only to analyze terms of the form $X(h_0^\varepsilon)^\ell\mathrm{id}_6$ and $Xb_0(h_0^\varepsilon)^\ell\mathrm{id}_6$. A routine calculation yields, for $\ell \geq 1$,

$$(h_0^\varepsilon)^\ell\mathrm{id}_6(x) = (-\varepsilon)^{\ell-1}g(x) \quad \text{and} \quad b_0(h_0^\varepsilon)^\ell\mathrm{id}_6(x) = (-\varepsilon)^{\ell-1}x_4\frac{\partial g}{\partial x_3}(x). \tag{28}$$

Hence, in view of (26)–(28), those terms also satisfy (25) for every $k \geq 3$. Consequently $\boldsymbol{h} \in \mathcal{A}'$. A numerical simulation of system (23) with the controller (9)–(10) is shown in Figure 6. For this simulation the size of the error is taken to be $\varepsilon = c_y/m = 0.1$, the initial condition is $x = (1, 0, \pi/4, 0, -1, 0)$, and the controller settings are $\omega = 2\pi/T = 1.5$ rad/s, $G = 1$, and $k_{i,j} = 0.1$, $i = 1, 2, 3$, $j = 1, 2$. The gain values $a_1 = a_3 = a_5 \simeq -0.0462$ and $a_2 = a_4 = a_6 \simeq -0.333$ were determined using (13). As depicted in the time-plots, the simulation appears to validate Conjecture 1.

5. Conclusions. A controller scheme, based on well-known hybrid open-loop/feedback techniques, has been introduced for the ECF. This controller exponentially

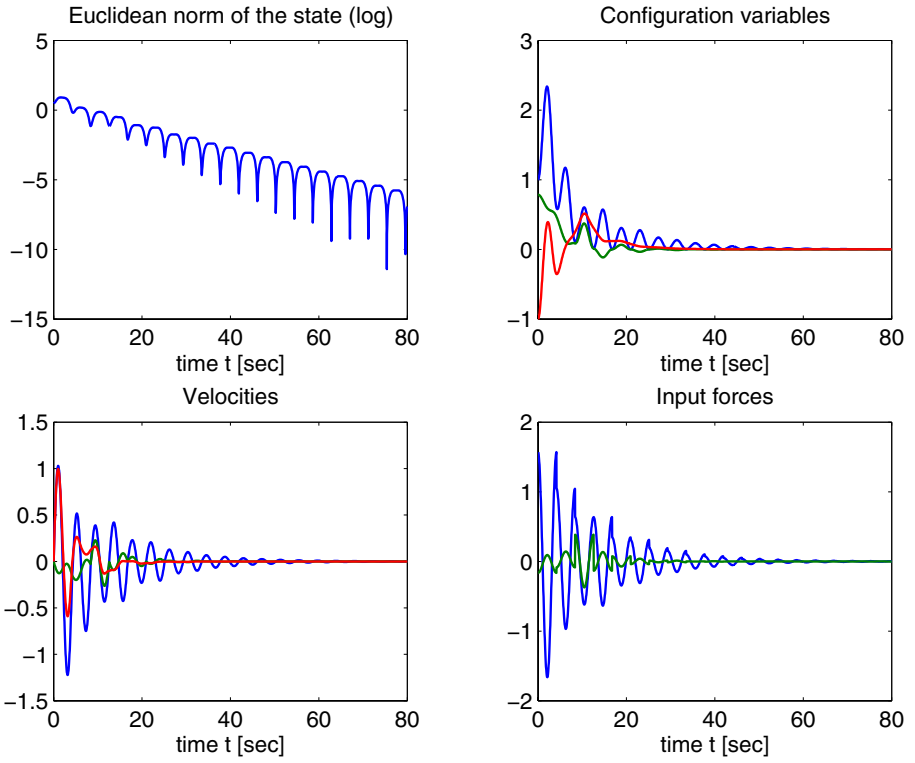

FIG. 6. *Transient response of the system* (23)*—equivalent to the simplified surface vessel model—controlled by* (9)–(10).

stabilizes the origin of a dynamic extension of the ECF, with robustness to a class of additive disturbance vector fields. The class of disturbances includes analytic vector fields added to the control vector fields as well as "high-order" drift perturbations. One positive feature of these results is that, for a class of underactuated systems—whose models need not be feedback-equivalent to the ECF—the problem of local point stabilization with exponential convergence can be effectively tackled by using the same control scheme as for the ECF. The typical performance of the proposed control laws seems qualitatively acceptable, as illustrated by the numerical simulations. On the other hand, these controllers clearly have some limitations regarding their robustness, and instability may be induced by disturbances not contained in the class $\mathcal{A}$ of Proposition 3.1 or by disturbances of a different nature, such as errors in the update time of the control.

A problem that remains open is the extension of the approach in this paper to systems with more inputs and less structure than the ECF. Such an extension would typically involve a design and an analysis stage, the former yielding control laws that stabilize the origin of a dynamically extended, *nominal* system—analogous to (6), but with $h_i^e = 0$, $i = 1, \ldots, m$. The design stage, of an essentially algebraic nature, might be based on techniques related to the design of oscillatory open-loop controls, such as the ones developed in [12]. By contrast, the analysis can be expected to be significantly involved, all the more so as it would be desirable to guarantee robustness to a large class of admissible disturbances.

6. Appendix.

6.1. Notational conventions.

6.1.1. Local order of mappings. Let us recall some definitions and properties about *local order* of mappings, a notion that simplifies the proofs. In this paragraph, n and m represent positive integers, ℓ represents a nonnegative integer, and $\|\cdot\|$ represents Euclidean norm. Given open sets $U \subset \mathbb{R}^n$ and $V \subset \mathbb{R}^m$, the symbols $PC(U;V)$, $C^0(U;V)$, $C^\infty(U;V)$, and $C^\omega(U;V)$ denote the sets of *piecewise-continuous*, *continuous*, *smooth*, and *(real-)analytic* mappings from U to V, respectively. Consider a neighborhood U of the origin in $\mathbb{R}^n$. We deal with mappings defined on $U \times \Lambda$, where $\Lambda \subset \mathbb{R}^\ell$, and view the elements of Λ as parameters (e.g., "time" or other parameters). Given a mapping $f : U \times \Lambda \to \mathbb{R}^m$, we write $f(x,\lambda) = \mathrm{o}(\|x\|^k)$ if, for every $\lambda \in \Lambda$,

$$\lim_{x\to 0} \frac{\|f(x,\lambda)\|}{\|x\|^k} = 0. \tag{29}$$

We write $f(x,\lambda) = \mathrm{O}(\|x\|^k)$ if for every $\lambda \in \Lambda$ there is a constant $K > 0$ and a neighborhood $U' \subset U$ of the origin such that, for every $x \in U'\backslash\{0\}$,

$$\frac{\|f(x,\lambda)\|}{\|x\|^k} \le K. \tag{30}$$

Consider a mapping $X = (X_1, \dots, X_n) : U \times \Lambda \to \mathbb{R}^n$ representing a family of *vector fields* $X(\cdot,\lambda) : U \to \mathbb{R}^n$. We write $X(x,\lambda) = \mathrm{o}(\|x\|^k)$ (resp., $X(x,\lambda) = \mathrm{O}(\|x\|^k)$) if $X_i(x,\lambda) = \mathrm{o}(\|x\|^{k+1})$ (resp., $X_i(x,\lambda) = \mathrm{O}(\|x\|^{k+1})$) for $i = 1, \dots, n$. We shall also use the function $\mathrm{Ord} : f \mapsto \mathrm{Ord}(f) \in \mathbb{R} \cup \{+\infty\}$ defined by $\mathrm{Ord}(f) = \sup\{k \in \mathbb{R} : f(x,\lambda) = \mathrm{O}(\|x\|^k)\}$. Every vector field $X(\cdot,\lambda)$ is a *differential operator* acting on $C^\infty(U;\mathbb{R})$; thus, for $\phi \in C^\infty(U;\mathbb{R})$ one has $X\phi(\cdot,\lambda) \in C^\infty(U;\mathbb{R})$, where $X\phi(x,\lambda) = L_X\phi(x,\lambda) = \sum_{i=1}^n \frac{\partial\phi}{\partial x_i}(x,\lambda)$ denotes the Lie derivative of ϕ in the direction of X evaluated at (x,λ). We extend this notation to the case when $\phi \in C^\infty(U;\mathbb{R}^m)$ and use $X\phi(\cdot,\lambda)$ to denote the m-tuple $(X\phi_i)_{i=1,\dots,m}$ of functions $X\phi_i(\cdot,\lambda) \in C^\infty(U;\mathbb{R})$. The following properties are easily established:

LEMMA 6.1. *Assume that, for every $\lambda \in \Lambda$, $f(\cdot,\lambda), g(\cdot,\lambda)$ are C^∞ mappings $U \to \mathbb{R}^m$, and $X(\cdot,\lambda)$, $Y(\cdot,\lambda)$ are C^∞ vector fields $U \to \mathbb{R}^n$. Write μ to denote any of these mappings. Then the following hold:*

(i) $\mathrm{Ord}(f) \ge 0$, $\mathrm{Ord}(X) \ge -1$.
(ii) *If $k \in \mathbb{R}$ and $k \le \mathrm{Ord}(\mu)$, then $\mu(x,\lambda) = \mathrm{O}(\|x\|^k)$.*
(iii) $\mathrm{Ord}(f+g) \ge \min\{\mathrm{Ord}(f), \mathrm{Ord}(g)\}$ *(where $(f+g)(x,\lambda) = f(x,\lambda)+g(x,\lambda)$).*
(iv) $\mathrm{Ord}(fg) = \mathrm{Ord}(f) + \mathrm{Ord}(g)$ *(where $fg(x,\lambda) = f(x,\lambda)g(x,\lambda)$).*
(v) $\mathrm{Ord}(Xf) \ge \mathrm{Ord}(X) + \max\{\mathrm{Ord}(f), 1\}$. *In particular* $\mathrm{Ord}(Xf) \ge 0$.

6.1.2. Iterated differential operators and iterated integrals. Assume that $U \subset \mathbb{R}^n$ is open. Let $\boldsymbol{X} = (X_1, \dots, X_m)$ be a family of real-analytic vector fields $X_i \in C^\omega(U;\mathbb{R}^n)$, and $\phi \in C^\omega(U;\mathbb{R})$ be a real-analytic function. Every element of $\mathcal{I}_{[0,m]} = \bigcup_{k\in\{0,1,2,\dots\}} \{0,1,\dots,m\}^k$ is called a *multi-index*. If $I = (i_1, \dots, i_r) \in \{0,1,\dots,m\}^r$, the multi-index I is said to have *length* r, and this is denoted by $|I| = r$. By convention, $I = \emptyset$ is regarded as a multi-index having zero length.

Let $I = (i_1, \dots, i_r) \in \mathcal{I}_{[0,m]}$ be a multi-index. The *iterated differential operator* $X_I = X_{i_1} \cdots X_{i_r}$ is defined so that the function $X_I\phi \in C^\omega(U;\mathbb{R})$ is given by $X_{i_1} \cdots X_{i_r}\phi$ (each vector field regarded as a first-order differential operator). By convention one sets $X_\emptyset\phi = \phi$. We use $X_I\mathrm{id} : U \to \mathbb{R}^n$ to denote the n-tuple

of functions $(X_I \mathrm{id}_i)_{i=1,\dots,n}$, where $\mathrm{id} : U \to \mathbb{R}^n$ is defined by $\mathrm{id}_i(x) = x_i$ for $x = (x_1, \dots, x_n) \in U$. Given $\alpha \in C^0(U \times \mathbb{R}; \mathbb{R}^m)$ (e.g., a time-varying feedback law), a multi-index $I = (i_1, \dots, i_r)$, and real numbers t_0, t, one defines the *iterated integral* $\int_{t_0}^t \alpha_I : U \to \mathbb{R}$ as follows:

$$\int_{t_0}^t \alpha_I(x) = \int_{t_0}^t \int_{t_0}^{t_r} \cdots \int_{t_0}^{t_2} \alpha_{i_r}(x, t_r) \alpha_{i_{r-1}}(x, t_{r-1}) \cdots \alpha_{i_1}(x, t_1) dt_1 \cdots dt_r.$$

By convention, $\int_{t_0}^t \alpha_\emptyset(x) = 1$ for every $x \in U$.

6.2. Auxiliary lemmas.

6.2.1. Proof of Lemma 3.2. Since the result is local we may assume, without loss of generality, that M is an open subset of $\mathbb{R}^n$ and that $\overline{x} = 0$. We shall appeal to the following two technical lemmas; for improved readability, the proof of Lemma 6.2 is relegated to section 6.2.4, whereas Lemma 6.3 follows from a trivial adaptation of the proof of [10, Theorem 2.6].

LEMMA 6.2. *Let $f_0, \dots, f_m$ be real-analytic vector fields on a real-analytic manifold M, with $\overline{x} \in M$, and let $\phi : M \to \mathbb{R}$ be a real-analytic function. Assume that $f_0(\overline{x}) = 0$. Then there is a constant $C > 0$ with the property that, for every $\eta > 0$, there exists a neighborhood K of $\overline{x}$ such that ϕ and the vector fields $g_0 = (1/\eta) f_0$, $g_i = f_i$ $(i = 1, \dots, m)$ satisfy the estimate*

$$|(g_{i_1} \cdots g_{i_r} \phi)(x)| \leq C^r r!$$

for every $x \in K$ and every multi-index $I = (i_1, \dots, i_r) \in \{0, \dots, m\}^r$ of length $r \geq 1$.

LEMMA 6.3. *Let $f \in C^0(U \times \Lambda \times [t_0, t_1]; \mathbb{R}^n)$, where $U \subset \mathbb{R}^n$ is open and connected, $\Lambda \subset \mathbb{R}^m$ is compact, and $t_0 < t_1$. Assume that $(x_0, \lambda_0) \in U \times \Lambda$ and that* (i) *$f(\cdot, \lambda, t)$ is locally Lipschitz on U, uniformly for $(\lambda, t) \in \Lambda \times [t_0, t_1]$, and* (ii) *$y : [t_0, t_1] \to U$ is a solution to $\dot{y} = f(y, \lambda_0, t)$, with $y(t_0) = x_0$. Then, given $\varepsilon > 0$, there are compact neighborhoods $U' \subset U$ and $\Lambda' \subset \Lambda$ of x_0 and λ_0, respectively, such that for every $x \in U'$ and every function $\varphi \in PC([t_0, t_1]; \Lambda')$, the system $\dot{z} = f(z, \varphi(t), t)$ admits a unique solution $z : [t_0, t_1] \to U$ which satisfies $z(t_0) = x$ and $\|z(t) - y(t)\| \leq \varepsilon$ for all $t \in [t_0, t_1]$.*

Fix $t_0 \in \mathbb{R}$. Let $C > 0$ be the constant whose existence is guaranteed by Lemma 6.2 above, and define $\eta > 0$ such that $CT(m+1)^{\frac{3}{2}} \eta < 1$. Setting $g_0 = \frac{1}{\eta} f_0$ and $g_i = f_i$, $i = 1, \dots, m$, we apply Lemma 6.2 again to deduce that there is a neighborhood K of $0 \in \mathbb{R}^n$ such that $|g_I \phi(x)| \leq C^r r!$ for every $x \in K$ and every multi-index I of length $r \geq 1$. Moreover, by defining $F(x, v, t) = \sum_{i=0}^m g_i(x) v_i$, with $v = (v_0, \dots, v_m)$, we see that F satisfies the assumptions of Lemma 6.3 if one takes $\lambda_0 = (\eta, 0, \dots, 0) \in \mathbb{R}^{m+1}$ and $y : t \mapsto 0 \in \mathbb{R}^n$. Therefore, there exists a constant $\delta' \in (0, \eta)$ such that if $x_0 \in \mathbb{R}^n$, with $\|x_0\| < \delta'$, and if v is a piecewise-continuous function on $[t_0, t_0 + T]$ taking values in $\{u \in \mathbb{R}^m : \|u\| < \delta'\}$, then the solution to $\dot{z} = g_0(z)\eta + \sum_{i=1}^m g_i(z) v_i(t)$ with initial value $z(t_0) = x_0$ satisfies $z(t) \in K$ for $t \in [t_0, t_0 + T]$. But since $\alpha(x, t) \to 0$ as $x \to 0$, uniformly for $t \in \mathbb{R}$, there exists $\delta \in (0, \delta')$ such that $\|\alpha(x, t)\| < \delta'$ whenever $\|x\| < \delta$ and $t \in \mathbb{R}$. It follows that if $\|x_0\| < \delta$, then the solution to system $\dot{x} = f_0(x) + \sum_{i=1}^m \alpha_i(x_0, t) f_i(x)$, $x(t_0) = x_0$, rewritten as $\dot{x} = g_0(x)\eta + \sum_{i=1}^m g_i(x) \alpha_i(x_0, t)$, satisfies $\pi(t, t_0, x_0) \in K$ for $t \in [t_0, t_0 + T]$. Note that, by denoting $v(x, t) = (\eta, \alpha(x, t))$, one has $\|v(x, t)\| < (m+1)^{\frac{1}{2}} \eta$ for $(x, t) \in K \times [t_0, t_0 + T]$. On the other hand, the difference between the

Nth partial sum of the Chen–Fliess expansion $\mathrm{Ser}^N_{\phi,\mathbf{f},\alpha}(t,t_0,x_0)$ and the actual value of ϕ along that solution is (cf. [27, section 4])

$$|\mathrm{Ser}^N_{\phi,\mathbf{f},\alpha}(t,t_0,x_0)-\phi(\pi(t,t_0,x_0))| \quad \le \\ \frac{((m+1)^{\frac{1}{2}}\eta(t-t_0))^{N+1}}{(N+1)!}(m+1)^{N+1}\sup\{|g_I\phi(x)| : x\in K\}.$$

But $\sup\{|f_I\phi(x)| : x\in K\} < C^{N+1}(N+1)!$ so

$$|\mathrm{Ser}^N_{\phi,\mathbf{f},\alpha}(t,t_0,x_0)-\phi(\pi(t,t_0,x_0))| \le (C(m+1)^{\frac{3}{2}}\eta(t-t_0))^{N+1}.$$

Since $t\in[t_0,t_0+T]$, one has $C(m+1)^{\frac{3}{2}}\eta(t-t_0)<1$; hence the series converges uniformly. It is readily checked that the series is absolutely convergent as well. ∎

6.2.2. Proof of Lemma 3.3. (i) Let $U'\subset\mathbb{R}^6$ be a compact set containing 0. From the continuity of α, the T-periodicity of $t\mapsto\alpha(x,t)$, and the definition of ρ, which implies that $\rho(x)=O(\|x\|^{\frac{1}{2}})$, one deduces that $\|\alpha_i(x,t)\|/\|x\|^{\frac{1}{2}}$ $(i=1,2)$ is bounded, say, by $K'>0$, for every $(x,t)\in U'\times\mathbb{R}$. Thus the claim holds for any $K>K'$.

(ii) Set $\alpha_0=1$ and write $\alpha_i(x,t)=U_i(x)+V_i(x)\cos(\omega t)$, $i=0,1,2$, with $U_0=1$, $V_0=0$, and U_1,U_2,V_1,V_2 defined in the obvious way. Note that $\mathrm{Ord}(U_0)=0$, $\mathrm{Ord}(U_1)=\mathrm{Ord}(U_2)=1$, and $\mathrm{Ord}(V_1)=\mathrm{Ord}(V_2)=1/2$. If $I=(i)\in\{1,2\}$, then $\int_0^T\alpha_I(x_0)=U_i(x)T+V_i(x)\int_0^T\cos(\omega\tau)d\tau=U_i(x)T$, so $\int_0^T\alpha_I(x_0)=\mathrm{O}(\|x_0\|)$. If $I=(i,j)\in\{0,1,2\}^2$, then

$$\begin{aligned}\int_0^T\alpha_I(x_0) &= \frac{1}{2}U_i\cdot U_j(x_0)T^2+U_i\cdot V_i(x_0)\int_0^T\int_0^{t_2}\cos(\omega t_1)dt_1dt_2 \\ &\quad + U_j\cdot V_i(x_0)\int_0^T\tau\cos(\omega\tau)d\tau+V_i\cdot V_j(x_0)\int_0^T\cos(\omega t_2)\int_0^{t_2}\cos(\omega t_1)dt_1dt_2 \\ &= \frac{1}{2}U_i\cdot U_j(x_0)T^2,\end{aligned}$$

since the three integrals indicated on the right member of this equation vanish. But then, if $I=(i,j)\neq(0,0)$, one gets $\mathrm{Ord}(\int_0^T\alpha_I)=\mathrm{Ord}(U_i)+\mathrm{Ord}(U_j)\ge 1$, so $\int_0^T\alpha_I(x_0)=\mathrm{O}(\|x_0\|)$.

(iii) One easily shows that if a function $v\in C^0(U\times\mathbb{R};\mathbb{R})$ satisfies $v(x_0,t)=\mathrm{O}(\|x_0\|^\ell)$, then $\int_0^t v(x_0,\tau)d\tau=\mathrm{O}(\|x_0\|^\ell)$ for every $t\in\mathbb{R}$. By writing $\mathrm{Ord}(\alpha_j)=k_j$, with $k_0=0$ and $k_1=k_2=\frac{1}{2}$, one gets

$$\int_0^t\alpha_j(x_0,t_2)\int_0^{t_2}v(x_0,t_1)dt_1dt_2=\mathrm{O}(\|x_0\|^{k_j+\ell}),\quad j=0,1,2. \tag{31}$$

Using these facts and an induction argument, one readily deduces that $\mathrm{Ord}(\int_0^T\alpha_I)\ge\sum_{j=1}^{|I|}k_{i_j}$.

(iv) This is verified directly by induction on the length of I using the fact that, for fixed $T\in\mathbb{R}$, $x_0\mapsto\int_0^T f(x_0,\tau)d\tau$ is continuous whenever $f\in C^0(U\times\mathbb{R};\mathbb{R})$.

(v) This claim follows immediately by inspecting the components of b_0, b_1, and b_2 as defined in (2), and from the definition of the set $\mathcal{A}$.

(vi) It suffices to show (by induction) that for any $x \in U$

$$b_0^k \phi(x) = \underbrace{b_0 \cdots b_0}_{k \text{ times}} \phi(x) = \sum_{\mu \in \{1,2,3\}^k} x_{2\mu} \frac{\partial^k \phi}{\partial x_{2\mu-1}}(x), \tag{32}$$

where we write $x_{2\mu} = x_{2\mu_1} \cdots x_{2\mu_k}$ and $x_{2\mu-1} = x_{2\mu_1-1} \cdots x_{2\mu_k-1}$ for any multi-index $\mu \in \{1,2,3\}^k$. Indeed, (v) follows from (32) since every term $f_\mu(x) = x_{2\mu} \partial^k \phi / \partial x_{2\mu-1}(x)$ in the sum satisfies $\mathrm{Ord}(f_\mu) \geq k$. Using (2), one gets $b_0 \phi(x) = \sum_{i=1}^3 x_{2i} \partial \phi / \partial x_{2i-1}(x)$, i.e., (32) with $k = 1$. If (32) holds for $k = m \geq 1$, then

$$\begin{aligned} b_0(b_0^m \phi)(x) &= \sum_{i=1}^3 x_{2i} \left(\sum_{\mu \in \{1,2,3\}^m} \frac{\partial x_{2\mu}}{\partial x_{2i-1}} \frac{\partial^m \phi}{\partial x_{2\mu-1}}(x) + x_{2\mu} \frac{\partial^{m+1} \phi}{\partial x_{2i-1} \partial x_{2\mu-1}}(x) \right) \\ &= \sum_i \sum_\mu x_{2i} x_{2\mu} \frac{\partial^{m+1} \phi}{\partial x_{2i-1} \partial x_{2\mu-1}}(x) = \sum_{\mu \in \{1,2,3\}^{m+1}} x_{2\mu} \frac{\partial^{m+1} \phi}{\partial x_{2\mu-1}}(x), \end{aligned}$$

since each of the terms $\partial x_{2\mu} / \partial x_{2i-1}$ is zero. Hence (32) holds for all $k \geq 1$. ∎

6.2.3. Proof of Lemma 3.4. (1) Note that, given the finiteness of $\mathcal{I}$, if for every $I \in \mathcal{I}$ the conclusion holds for $(x, \varepsilon) \mapsto a_I(x, \varepsilon) b_I(x)$ and some compact neighborhood $U_I \subset U$ of 0, then the conclusion holds for f by setting $U' = \bigcap_{I \in \mathcal{I}} U_I$. Let us then fix $I \in \mathcal{I}$.

(1)(i) Since a_I is real-analytic, we can write $a_I(x, \varepsilon) b_I(x) = [\frac{\partial a_I}{\partial x}(0, \varepsilon) x + \widetilde{a}_I(x, \varepsilon)] b_I(x)$, where $\varepsilon \mapsto \frac{\partial a_I}{\partial x}(0, \varepsilon)$ is continuous and vanishes at 0, and $(x, \varepsilon) \mapsto \widetilde{a}_I(x, \varepsilon)$ is a continuous mapping satisfying

$$(\forall \varepsilon \in E) \quad \lim_{x \to 0} \frac{\|\widetilde{a}_I(x, \varepsilon)\|}{\|x\|} = 0 \quad \text{and} \quad \widetilde{a}_I(\cdot, 0) = 0.$$

Given any compact neighborhood $U_I \subset U$ of 0, define $q(x, \varepsilon) = \frac{\|\widetilde{a}_I(x, \varepsilon)\|}{\|x\|}$, with $q(0, \cdot) = 0$, so that q is continuous—hence bounded—on $U_I \times E$ and $q(\cdot, 0) = 0$. We claim that $\sup_{x U_I} q(x, \varepsilon) \to 0$ as $\varepsilon \to 0$. Otherwise there would be $\eta > 0$ and a sequence $(\varepsilon_k)_{k \in \mathbb{N}}$, converging to zero, such that $\sup_{x \in U_I} q(x, \varepsilon_k) > 2\eta$ for every $k \in \mathbb{N}$. By the properties of sup, for every $k \in \mathbb{N}$ there would exist $x_k \in U_I$ such that

$$(\forall k \in \mathbb{N}) \quad q(x_k, \varepsilon_k) > \sup_{x \in U_I} q(x, \varepsilon_k) - \eta > \eta. \tag{33}$$

The compactness of U_I would imply the existence of a subsequence $(x_{k_j}, \varepsilon_{k_j})_{j \in \mathbb{N}}$, convergent towards a point $(\overline{x}, 0) \in U_I \times E$. But then, since q is continuous, $q(x_{k_j}, \varepsilon_{k_j})$ should converge to $q(\overline{x}, 0) = 0$, in contradiction to (33). Therefore, in view of the continuity of b_I, the conclusion follows since

$$\frac{\|a_I(x, \varepsilon) b_I(x)\|}{\|x\|} \leq \left(\left\| \frac{\partial a_I}{\partial x}(0, \varepsilon) \right\| + \sup_{x \in U_I} q(x, \varepsilon) \right) \sup_{x \in U_I} \|b_I(x)\|,$$

the right-hand member of which tends to zero as $\varepsilon \to 0$, uniformly for $x \in U_I$.

(1)(ii) The assumption $b_I(x) = \mathrm{O}(\|x\|)$ implies the existence of a constant $K_I > 0$ and a compact neighborhood $U_I \subset U$ of 0 such that $\|b_I(x)\| / \|x\| \leq K_I$ for every $x \in U_I$. Furthermore, by the real-analyticity of a_I, and using $a_I(\cdot, 0) = 0$, one can write $a_I(x, \varepsilon) b_I(x) = [\frac{\partial a_I}{\partial \varepsilon}(x, 0) \varepsilon + \widetilde{a}_I(x, \varepsilon)] b_I(x)$, with $\frac{\partial a_I}{\partial \varepsilon}(\cdot, 0)$ continuous and hence

bounded on U_I, say, $\|\frac{\partial a_I}{\partial \varepsilon}(x,0)\| \le K'$. Moreover, for every $x \in U_I$, the function $q(x,\varepsilon) = \frac{\|\tilde{a}_I(x,\varepsilon)\|}{|\varepsilon|}$ tends to 0 as $\varepsilon \to 0$, so q is also continuous on $U_I \times E$. Proceeding as in the proof of (1)(i) above, one readily shows that $\sup_{x\in U_I} q(x,\varepsilon) \to 0$ as $\varepsilon \to 0$. The conclusion then follows directly from the inequality

$$\begin{aligned}\frac{\|a_I(x,\varepsilon)b_I(x)\|}{\|x\|} &\le \left(\left\|\frac{\partial a_I}{\partial \varepsilon}(x,0)\right\| + q(x,\varepsilon)\right)|\varepsilon|\frac{\|b_I(x)\|}{\|x\|}\\ &\le K_I\left(K' + \sup_{x\in U_I} q(x,\varepsilon)\right)|\varepsilon|.\end{aligned}$$

(2) Let $U' \subset U$ be any compact neighborhood of 0. We claim that if a number $\eta > 0$ exists such that, for every $I \in \mathcal{I}$,

$$(x,\varepsilon) \mapsto \frac{\|a_I(x,\varepsilon)b_I(x)\|}{\|x\|^{1+\eta}} \quad \text{is continuous on } U' \times E, \tag{34}$$

then the conclusion holds for f and U'. Indeed, $\sum_{I\in\mathcal{I}} a_I(x,\varepsilon)b_I(x)$ converges absolutely and uniformly; therefore

$$\frac{\|f(x,\varepsilon)\|}{\|x\|} \le \|x\|^{\eta}\sum_{I\in\mathcal{I}}\frac{\|a_I(x,\varepsilon)b_I(x)\|}{\|x\|^{1+\eta}}, \tag{35}$$

and the series on the right side of (35) converges to a function that is bounded on $U' \times E$. Consequently, the term on the left side of (35) tends to zero as $x \to 0$, uniformly for $\varepsilon \in E$, and this proves the claim. The rest of the proof simply consists of exhibiting such a number η, independent of I, for each case.

(2)(i) The assumption $a_I(x,\varepsilon) = \mathrm{o}(\|x\|)$ and the real-analyticity of a_I imply that all terms in x of degrees < 2 in the Taylor expansion of $x \mapsto a_I(x,\varepsilon)$ at 0 vanish identically. Thus, for every $\varepsilon \in E$, $\|a_I(x,\varepsilon)\|/\|x\|^{1+\eta} \to 0$ as $x \to 0$ whenever $\eta \le 1$. By continuity of b_I, (34) holds with $\eta = 1/2$.

(2)(ii) Since $b_I(x) = \mathrm{O}(\|x\|^{1+c})$, then $\|b_I(x)\|/\|x\|^{1+c/2} \to 0$ as $x \to 0$. Taking $\eta = c/2$ we see that (34) holds.

(2)(iii) The assumptions imply that both $\|a_I(x,\varepsilon)\|/\|x\|^{1-d/3}$ and $\|b_I(x)\|/\|x\|^{2d/3}$ tend to zero as $x \to 0$. Thus, (34) holds with $\eta = d/3$. □

6.2.4. Proof of Lemma 6.2. This is a straightforward adaptation of the proof of [27, Lemma 4.2]. Since the result is local one may assume, without loss of generality, that M is an open subset of $\mathbb{R}^n$ and that $\overline{x} = 0$. By real-analyticity, the mappings ϕ and $f_0, \dots, f_m$ may be extended to complex analytic mappings defined on a polydisc $D(n,\alpha) = \{(z_1,\dots,z_n) \in \mathbb{C}^n : |z_i| < \alpha,\ i = 1,\dots,n\}$ for some $\alpha > 0$. Denote the corresponding extensions by $\tilde{\phi}$ and $\tilde{f}_0, \dots, \tilde{f}_m$, respectively.

By Stirling's formula, there is a constant C'' such that $r^r \le C'' e^r r!$ for all $r \ge 1$. Let $C' = \max\{|\tilde{\phi}(q)| : q \in D(n, \frac{2}{3}\alpha)\}$ and define

$$C = e\max\{1, C'C''\}.$$

Select $\eta > 0$ arbitrarily. Then the vector fields $\tilde{g}_0 = (1/\eta)\tilde{f}_0$, $\tilde{g}_i = \tilde{f}_i$ $(i = 1,\dots,m)$ are analytic extensions of the vector fields $g_0, \dots, g_m$, respectively, to the set $D(n,\alpha)$. Consider the complex control system

$$\dot{z} = \sum_{i=0}^{m} v_i \tilde{g}_i(z), \quad z \in \mathbb{C}^n, \quad v = (v_0,\dots,v_m) \in \mathbb{C}^{m+1}. \tag{36}$$

Clearly, if $v = (\eta, 0, \dots, 0)$, then $(z, v) = (0, v)$ is an equilibrium point; hence the corresponding constant solution $t \mapsto (0, v)$ is defined for $t \in [0, 1]$. Since (36) may be rewritten as a real control system on $\mathbb{R}^{2n}$, one can apply Lemma 6.3 to conclude that there is $\delta \in (0, \frac{2}{3}\alpha)$ with the property that, whenever $z_0 \in D(n, \delta)$, $v_0 \in A = \{w \in \mathbb{C} : |w - \eta| < \delta\}$, and $v_i \in D(1, \delta)$ $(i = 1, \dots, m)$, the system (36) has a unique solution $z : [0, 1] \to \mathbb{C}^n$ satisfying $z(t_0) = z_0$ and $z(t) \in D(n, \frac{2}{3}\alpha)$ for $t \in [0, 1]$.

Let us fix a multi-index $I = (i_1, \dots, i_r) \in \{0, \dots, m\}^r$, $r \geq 1$, and define the set $D^I = \prod_{j=1}^r D_j^I$, where $D_j^I = A$ if $i_j = 0$ and $D_j^I = D(1, \delta)$ otherwise. D^I is thus an open subset of $\mathbb{C}^r$. For any $z \in D^I$, define the input function $v^{I,z} : [0, 1] \to A \times D(m, \delta)$ by setting, for $j = 1, \dots, r$ and $t \in [\frac{j-1}{r}, \frac{j}{r})$, $v^{I,z}(t) = z_j e_{i_j}$ (here $\{e_0, \dots, e_m\}$ denotes the canonical basis of the $\mathbb{C}$-vector space $\mathbb{C}^{m+1}$). The function $v^{I,z}$ thus defined is a piecewise-constant function on $[0, 1]$ taking values in $A \times D(m, \delta)$. Therefore, for any $q \in D(n, \delta)$, the solution $t \mapsto \xi_q^{I,z}(t)$ to system (36), with input $v^{I,z}$ and initial condition $\xi_q^{I,z}(0) = q$, is defined and satisfies $\xi_q^{I,z}(t) \in D(n, \frac{2}{3}\alpha)$ for all $t \in [0, 1]$. Moreover, for $i = 1, \dots, r$, $\xi_q^{I,z}(i/r)$ is analytic in q and z for $(q, z) \in D(n, \delta) \times D^I$ (cf. [27, proof of Lemma 4.2]). Now define a mapping $\psi_I : D(n, \delta) \times D^I \to \mathbb{C}$ by setting $\psi_I(q, z) = \tilde{\phi}(\xi_q^{I,z}(1))$. Then

$$\frac{\partial^r \psi_I}{\partial z_r \cdots \partial z_1}(q, 0) = \left(\frac{1}{r}\right)^r (\tilde{g}_{i_1} \cdots \tilde{g}_{i_r} \tilde{\phi})(q).$$

This is readily shown by extending the following basic argument using induction on the length r of $I = (i_1, \dots, i_r)$. For a vector field $X = (X_1, \dots, X_n)$ defined on some subset B of $\mathbb{C}^n$, denote by $t \mapsto \Phi_q^X(t)$ the local flow of X satisfying $\Phi_q^X(0) = q \in B$. Hence $d\Phi_{q,k}^X/dt = X_k(\Phi_q^X(t))$ for $k = 1, \dots, n$. It is easy to check that $\Phi_q^{zX}(t) = \Phi_q^X(zt)$ when $z \in \mathbb{C}$ and $|z|$ is small enough. Thus, by setting $\psi_{(i)}(q, z) = \tilde{\phi}(\Phi_q^{z\tilde{g}_i}(\tau)) = \tilde{\phi}(\Phi_q^{\tilde{g}_i}(z\tau))$, with $i \in \{0, \dots, m\}$, one gets

$$\begin{aligned}\frac{\partial \psi_{(i)}}{\partial z}(q, z) &= \sum_{k=1}^n \frac{\partial \tilde{\phi}}{\partial r_k}\left(\Phi_q^{\tilde{g}_i}(z\tau)\right) \frac{d\Phi_{q,k}^{\tilde{g}_i}}{dt}(z\tau) \frac{d}{dz}(z\tau) \\ &= \tau \sum_{k=1}^n \frac{\partial \tilde{\phi}}{\partial r_k}\left(\Phi_q^{\tilde{g}_i}(z\tau)\right) \tilde{g}_{i,k}(\Phi_q^{\tilde{g}_i}(z\tau)),\end{aligned}$$

and then, if $\tau = 1$ and $z = 0$ (and since r=1 because $I = (i)$),

$$\frac{\partial \psi_I}{\partial z}(q, 0) = \sum_{k=1}^n \frac{\partial \tilde{\phi}}{\partial r_k}(q) \tilde{g}_{i,k}(q) = \left(\frac{1}{r}\right)^r (\tilde{g}_i \tilde{\phi})(q).$$

Since $q \mapsto \psi_I(q, z)$ is analytic on $D(n, \delta)$ for $z \in D^I$, Cauchy's estimates yield

$$\left|\frac{\partial^r \psi_I}{\partial z_r \cdots \partial z_1}(q, 0)\right| \leq \max\left\{|\tilde{\phi}(q')| : q' \in D\left(n, \frac{2}{3}\alpha\right)\right\} = C',$$

and this implies in turn that $|\tilde{g}_{i_1} \cdots \tilde{g}_{i_r} \tilde{\phi}(q)| \leq C' r^r$ for any $q \in D(n, \frac{2}{3}\alpha)$. By definition of C'', one has $C' r^r \leq C' C'' e^r r!$ Also, $C' C'' \leq \max\{1, C' C''\} = C/e$. Using the fact that $1 \leq C/e$, and hence $C/e \leq (C/e)^r$, one gets $C' C'' e^r r! \leq C^r r!$ for $r \geq 1$. Therefore, by setting $K = D(n, \delta) \cap \mathbb{R}^n$, one concludes that

$$|(g_{i_1} \cdots g_{i_r} \phi)(x)| \leq C^r r!$$

for $x \in K$ and $r \geq 1$. Since the constant C was selected independently of η, r, and I, this finishes the proof. □

ANALYSIS AND CONTROL OF HOPF BIFURCATIONS*

BOUMEDIENE HAMZI†, WEI KANG‡, AND JEAN-PIERRE BARBOT§

Abstract. In this paper, control systems with two uncontrollable modes on the imaginary axis are studied. The main contributions include the local orientation control of periodic solutions and center manifolds, the quadratic normal form of systems with two imaginary uncontrollable modes, the stabilization of the Hopf bifurcation by state feedback, and the quadratic invariants that characterize the nonlinearity of a system and its Hopf bifurcation.

Key words. nonlinear systems, normal forms, quadratic invariants, Hopf bifurcation, center manifold, control

1. Introduction. Nonlinear dynamical systems exhibit complicated performance around bifurcation points. As the parameter of a system is varied, changes may occur in the qualitative structure of its solutions around a point of bifurcation. Using a feedback to stabilize a system with a bifurcation has been studied by many authors (see, for instance, [1], [2], [7], [10], [12], [21], and [23]). Bifurcation phenomenon appears in a large family of engineering systems. The control of bifurcations has attracted increasing attention in recent years, motivated by engineering applications such as the control of surge and rotating stall in engine compressors [20], [21], and the control of voltage instabilities and collapse [25]. It is known that bifurcations in a linearly controllable system can be delayed or stabilized by a linear feedback [1], [8]. However, nonlinear feedback is essential for systems with uncontrollable bifurcation modes. The authors of [3], [1], [2], [5], [9], and [12] studied the bifurcation and/or stability of systems with one and two uncontrollable modes. Using normal forms, the author of [16], [17], [18] developed the analysis and control design algorithm for systems with one uncontrollable mode.

In this paper, control systems with two uncontrollable modes on the imaginary axis are studied. The main contributions include the local orientation control of periodic solutions and center manifolds, the quadratic normal form of systems with the Hopf bifurcation, the stabilization of the Hopf bifurcation by state feedback, and the quadratic invariants that characterize the nonlinearity of a system and its Hopf bifurcation. In this paper, "bifurcation control" means the control of the local orientation of the periodic solution and the stabilization of the Hopf bifurcation. The results in this paper focus on local bifurcations. Global bifurcations are not addressed here.

The Hopf bifurcation studied in this paper occurs in the Moore–Greitzer model of axial flow engine compressors. A simple version of this model is a four-dimensional ordinary differential equation with nonlinear dynamics exhibiting several kinds of

bifurcations. When the pressure rise in the system arrives at a critical value, the operating point loses its linear stability, and a Hopf bifurcation takes place. Meanwhile, the critical modes are not linearly controllable. The resulting limit cycle in the system is called a rotating stall, which significantly reduces the efficiency of the compressor [22], [20], [21].

The mathematical analysis in this paper is based on the linear and quadratic normal form of control systems. In section 2, we derive the linear normal form of the control system and its linear center manifold. Then we derive the relationship between the local orientation of center manifold and the state feedback. A necessary and sufficient condition is found in order for the local orientation of center manifold to be achievable by state feedback. In section 3, the quadratic normal form is found for control systems with two imaginary uncontrollable modes. The theorem is proved in the appendix. Then an explicit formula of the quadratic center manifold is derived for the normal form. Sufficient conditions are derived for the tuning of a nonlinear control law to render the Hopf bifurcation supercritical. In section 4, the explicit formula for the coefficients in the normal form is derived based on the Lie operator and the Lie bracket. A set of invariants is found, the value of which does not change under the quadratic change of coordinates and feedback. It is proved that two systems have equivalent quadratic parts if and only if their invariants have the same value. Furthermore, the value of the invariants equals the value of the coefficients in the normal form.

The normal form approach adopted in this paper generalizes Poincaré's normal form method, commonly used in dynamical systems theory, to the area of control systems. It was first introduced in [19], [14]. The results proved in this paper indicate that the linear control determines the local orientation of the periodic solution around the origin, and the quadratic feedback is critical to stabilize the periodic solution. The analysis is based on the center manifold theorem [6] and the Poincaré–Andronov–Hopf theorem [26]. The results in this paper are part of the Ph.D. thesis [13].

2. The orientation of center manifold. Consider the following nonlinear system:

$$\dot{\zeta} = f(\zeta, \mu) + g(\zeta, \mu)\, v. \tag{2.1}$$

The variable $\zeta \in \mathbb{R}^n$ is the state, $v \in \mathbb{R}$ is the input variable, and $\mu \in \mathbb{R}$ is the parameter. The vector fields $f(\zeta, \mu)$ and $g(\zeta, \mu)$ are assumed to be C^k for some sufficiently large k.

Assume $f(0,0) = 0$, $g(0,0) \neq 0$. Suppose that the linearization of the system at the origin is (A, B),

$$A = \frac{\partial f}{\partial \zeta}(0,0), \quad B = g(0,0),$$

with

$$\operatorname{rank}([B\ AB\ A^2B\ \cdots\ A^{n-1}B]) = n - 2. \tag{2.2}$$

Thus, the system is not linearly controllable at the origin. If the uncontrollable modes have nonzero real parts, the stabilizability of the system is determined by the real part of the uncontrollable modes. However, if the real part of the uncontrollable modes is zero, bifurcation occurs even with feedback control. In this paper, we assume that $\pm i\,\omega$ are the uncontrollable modes.

Assumption 1. The linearization of (2.1) has two uncontrollable modes, $\pm i\,\omega$, at the origin.

In this paper, a general nonlinear system is transformed to a simpler system, which is called normal form. Bifurcation analysis based on the Poincaré normal form is a well-known theory in dynamical systems. The control system normal form derived in the present paper is different from those used in the literature of nonlinear dynamical systems without control inputs. Why is it necessary to introduce the control system normal form instead of adopting the Poincaré normal form of vector fields? In fact, even for a linear control system $\dot{x} = Ax + Bu$, the controller normal form is more useful than the diagonal form of A in the feedback design. The normal form of nonlinear control systems generalizes the linear controller form. An affine control system $\dot{x} = f(x) + g(x)u$ has two vector fields $f(x)$ and $g(x)$. Therefore, the normal form of a control system requires the simplification of both f and g simultaneously. The simplification of f does not necessarily result in a simple form for g. Furthermore, the transformation group of control systems consists of changes of coordinates and feedbacks. This is different from the normal form theory of dynamical systems where feedbacks are not considered.

The first step of the analysis is to simplify the linear part of the system (i.e., the determination of the linear normal form). There exist a linear change of coordinates and a feedback independent of μ transforming the system (2.1) into

$$\begin{aligned} \begin{bmatrix} \dot{z}_1 \\ \dot{z}_2 \end{bmatrix} &= A_1 \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} + \Gamma_1 \mu + O(z,\mu,x,u)^2, \\ \dot{x} \quad &= A_2 x + B_2 u + \Gamma_2 \mu + O(z,\mu,x,u)^2, \end{aligned} \tag{2.3}$$

with $\Gamma_1 = \begin{bmatrix} \gamma_{1\,1} & \gamma_{1\,2} \end{bmatrix}^T$, $\Gamma_2 = \begin{bmatrix} \gamma_{2\,1} & \gamma_{2\,2} & \cdots & \gamma_{2\,n-2} \end{bmatrix}^T$, and $z \in \mathbb{R}^2$, $x \in \mathbb{R}^{n-2}$:

$$A_1 = \begin{bmatrix} 0 & -\omega \\ \omega & 0 \end{bmatrix},\ A_2 = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{bmatrix}_{(n-2)\times(n-2)},\ B_2 = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}_{(n-2)\times 1}. \tag{2.4}$$

The subsystem (A_2, B_2) is the Brunovsky form of controllable linear systems.

The system can be simplified further. The μ-terms can be canceled by the change of coordinates: $\bar{z}_1 = z_1 + \frac{\gamma_{1\,2}}{\omega}\mu$, $\bar{z}_2 = z_2 - \frac{\gamma_{1\,1}}{\omega}\mu$, $\bar{x}_1 = x_1$, $\bar{x}_i = x_i + \gamma_{2\,i-1}\mu$ for $i = 2, \ldots, n$ and a feedback $\bar{u} = u + \gamma_{2\,n}\mu$. The linear normal form of (2.1) is summarized in the following lemma

LEMMA 2.1. *There exists a linear change of coordinates and feedback which transforms* (2.1) *into*

$$\begin{aligned} \dot{z} &= A_1 z + f_1^{[2]}(z,\mu,x) + g_1^{[1]}(z,\mu,x)u + O(z,\mu,x,u)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z,\mu,x) + g_2^{[1]}(z,\mu,x)\,u + O(z,\mu,x,u)^3. \end{aligned} \tag{2.5}$$

2.1. The linear center manifold. Consider

$$\begin{aligned} \dot{z} &= A_1 z + O(z,\mu,x,u)^2, \\ \dot{x} &= A_2 x + B_2 u + O(z,\mu,x,u)^2, \end{aligned} \tag{2.6}$$

and the feedback

$$u = F_1 z_1 + F_2 z_2 + F_3 \mu + \sum_{i=1}^{n-2} a_i x_i + O(z,\mu,x)^2. \tag{2.7}$$

To stabilize the system around the bifurcation point, the controllable part has to be stable. So, we assume the following.

Assumption 2. The matrix $A_2 + B_2 \begin{bmatrix} a_1 & \cdots & a_{n-2} \end{bmatrix}$ is Hurwitz.

Suppose that the center manifold of the closed-loop system (2.6)–(2.7) is

$$x = \Pi(z,\mu).$$

Suppose that the linear part of Π is

$$\Pi^{[1]}(z,\mu) = \Pi^{[1]} \begin{bmatrix} z \\ \mu \end{bmatrix}, \qquad \Pi^{[1]} = \begin{bmatrix} \Pi_{11}^{[1]} & \Pi_{12}^{[1]} & \Pi_{13}^{[1]} \\ \vdots & \vdots & \vdots \\ \Pi_{n-2,1}^{[1]} & \Pi_{n-2,2}^{[1]} & \Pi_{n-2,3}^{[1]} \end{bmatrix} \in \mathbb{R}^{(n-2)\times 3}, \tag{2.8}$$

where $\Pi^{[1]}(z,\mu)$ is a function and $\Pi^{[1]}$ represents the matrix of the linear function. The center manifold equation is

$$\frac{\partial \Pi(z,\mu)}{\partial (z,\mu)} \begin{bmatrix} \dot z \\ \dot\mu \end{bmatrix} = A_2 \Pi + B_2 \left(\sum_{i=1}^{n-2} a_i \Pi_i(z,\mu) + F_1 z_1 + F_2 z_2 + F_3 \mu \right) + O(z,\mu,x)^2.$$

The linear part of the equation is equivalent to

$$\begin{aligned} &\Pi_{i+1}^{[1]}(z,\mu) = \frac{\partial \Pi_i^{[1]}}{\partial (z,\mu)} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} z \\ \mu \end{bmatrix}, \quad i \le n-3, \\ &\sum_{i=1}^{n-2} a_i \Pi_i^{[1]}(z,\mu) + F_1 z_1 + F_2 z_2 + F_3 \mu = \frac{\partial \Pi_{n-2}^{[1]}}{\partial (z,\mu)} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} z \\ \mu \end{bmatrix}, \end{aligned}$$

where $\Pi_i^{[1]}$ represents the ith row of $\Pi^{[1]}$. So,

$$\begin{aligned} &\Pi_{i+1}^{[1]} = \Pi_i^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}, \quad i \le n-3, \\ &\sum_{i=1}^{n-2} a_i \, \Pi_i^{[1]} + \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix} = \Pi_{n-2}^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}. \end{aligned}$$

Hence,

$$\begin{aligned} &\Pi_{i+1}^{[1]} = \Pi_1^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}^i, \quad i \le n-3, \\ &\sum_{i=1}^{n-2} a_i \, \Pi_1^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}^{i-1} + \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix} = \Pi_1^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}^{n-2}. \end{aligned}$$

Let $P(\lambda)$ be the characteristic polynomial of $A_2 + B_2 \begin{bmatrix} a_1 & \cdots & a_{n-2} \end{bmatrix}$; then

$$P(\lambda) = \lambda^{n-2} - \sum_{i=1}^{n-2} a_i \lambda^{i-1}. \tag{2.9}$$

So

$$\begin{cases} \Pi_1^{[1]} P\left(\begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}\right) = \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix}, \\ \Pi_{i+1}^{[1]} = \Pi_1^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}^i. \end{cases} \tag{2.10}$$

If $a_1 \neq 0$, from the expression of $P(\lambda)$ we obtain

$$\begin{cases} \Pi_1^{[1]} = \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix} \begin{bmatrix} P(A_1)^{-1} & 0 \\ 0 & -\frac{1}{a_1} \end{bmatrix}, \\ \Pi_{i+1}^{[1]} = \Pi_1^{[1]} \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}^i. \end{cases} \tag{2.11}$$

This formula holds only if $P(A_1)$ is invertible, and $a_1 \neq 0$. This is always true. Because of Assumption 2, the eigenvalues of $A_2 + B_2[a_1 \ a_2 \ \cdots \ a_{n-2}]$ are not on the imaginary axis. Therefore, the roots of the characteristic polynomial $P(\lambda)$ are not on the imaginary axis. Therefore, $P(\pm i\omega) \neq 0$. On the other hand, the eigenvalues of $P(A_2)$ are $P(\pm i\omega)$, which are nonzero. Therefore, the matrix $P(A_2)$ is invertible. Furthermore, the value $(-1)^{n-1}a_1$ equals the product of all eigenvalues of $A_2 + B_2[a_1 \ a_2 \ \cdots \ a_{n-2}]$. If all the eigenvalues are on the left half plane, it is easy to check that $a_1 < 0$.

THEOREM 2.2. *Suppose* $\begin{bmatrix} a_1, \ldots, a_{n-2} \end{bmatrix}$ *stabilizes the x-subsystem. Given any vector* $\Pi_1^{[1]} \in \mathbb{R}^{1\times 3}$*, there exist unique vectors* $\Pi_i^{[1]} \in \mathbb{R}^{1\times 3}$*,* $i > 1$*, and* $\begin{bmatrix} F_1, F_2, F_3 \end{bmatrix}$ *given by* (2.11)*, such that*

$$x = \Pi^{[1]} \begin{bmatrix} z \\ \mu \end{bmatrix} \tag{2.12}$$

is the linear part of the center manifold of the closed-loop system.

2.2. Orientation. In this subsection, a center manifold $x = \Pi(z, \mu)$ is treated as a submanifold in the space of $(z, \mu, x) \in \mathbb{R}^{n+1}$. A row vector in $\mathbb{R}^{n+1}$ is orthogonal to the manifold at the origin if the vector is orthogonal to the tangent space of the manifold at the origin. The orientation of a center manifold at the origin is a set of vectors. The vectors are orthogonal to the manifold, linearly independent, and they generate a complement subspace of the manifold. In other words, the orientation of the center manifold at the origin is a basis of the orthogonal complement subspace of the tangent space of the center manifold.

THEOREM 2.3. *Given any* $(n-2) \times (n+1)$ *matrix of the form*

$$[\mathcal{M}_{(n-2)\times 3} \ \mathcal{N}_{(n-2)\times(n-2)}],$$

its row vectors define the center manifold orientation at the origin for (2.6)–(2.7) *if and only if* $\mathcal{N}^{-1}$ *exists and* $\Pi^{[1]} = -\mathcal{N}^{-1}\mathcal{M}$ *satisfies* (2.11)*.*

Proof. Suppose that $[\mathcal{M}_{(n-2)\times 3} \ \mathcal{N}_{(n-2)\times(n-2)}]$ defines the orientation of a center manifold. Then it is orthogonal to the tangent space of the center manifold.It is

known that the tangent space of the center manifold is given by its linear part,

$$x - \Pi^{[1]} \begin{bmatrix} z \\ \mu \end{bmatrix} = 0,$$

where $\Pi^{[1]}$ satisfies (2.11). In the (z, μ, x) space, a set of orthogonal vectors of the tangent space is the row vectors of $[-\Pi^{[1]}\ I]$. Therefore, both $[-\Pi^{[1]}\ I]$ and $[\mathcal{M}_{(n-2)\times 3}\ \mathcal{N}_{(n-2)\times(n-2)}]$ generate the same space, which is orthogonal to the tangent space of the center manifold. Therefore, the row vectors of $[-\Pi^{[1]}\ I]$ are linear combinations of the row vectors in $[\mathcal{M}_{(n-2)\times 3}\ \mathcal{N}_{(n-2)\times(n-2)}]$, i.e.,

$$[-\Pi^{[1]}\ I] = \mathcal{N}^{-1}[\mathcal{M}_{(n-2)\times 3}\ \mathcal{N}_{(n-2)\times(n-2)}].$$

So, $\Pi^{[1]} = -\mathcal{N}^{-1}\mathcal{M}$, and it satisfies (2.11).

On the other hand, suppose $-\mathcal{N}^{-1}\mathcal{M}$ satisfies (2.11). By Lemma 2.2, the linear space

$$\mathcal{N}^{-1}\mathcal{M} \begin{bmatrix} z \\ \mu \end{bmatrix} + x = 0$$

represents the linear part of the center manifold. It is the tangent space of the center manifold. Therefore, $[\mathcal{N}^{-1}\mathcal{M}\ \ I]$, the row vectors in the coefficient matrix of this equation, forms a basis of the orthogonal space. It is easy to check that the row vectors of $[\mathcal{M}\ \mathcal{N}]$ and $[\mathcal{N}^{-1}\mathcal{M}\ \ I]$ generate the same vector space. Therefore, $[\mathcal{M}\ \ \mathcal{N}]$ defines the orientation of the center manifold. □

3. Quadratic normal form and Hopf bifurcation. This section has two parts. The quadratic normal form is introduced in the first part. Then the relationship between the quadratic feedback and the stability of the Hopf bifurcation is derived. As a corollary, a design algorithm is found. The feedback designed using this method stabilizes the periodic solution in the Hopf bifurcation.

3.1. Quadratic normal form and center manifold. The following quadratic transformations are employed to simplify the quadratic part of a system into its normal form while leaving the linear part invariant:

$$\begin{bmatrix} z_1 \\ z_2 \\ x \end{bmatrix} = \begin{bmatrix} \bar{z}_1 \\ \bar{z}_2 \\ \bar{x} \end{bmatrix} + \phi^{[2]}(\bar{z}, \mu, \bar{x}), \tag{3.1}$$

$$\bar{u} = u + \alpha^{[2]}(\bar{z}, \mu, \bar{x}) + \beta^{[1]}(\bar{z}, \mu, \bar{x})u. \tag{3.2}$$

The normal form is given in the following theorem.

THEOREM 3.1. *Consider system* (2.5). *There exist a quadratic change of coordinates* (3.1) *and feedback* (3.2) *that transform the system into a unique system of the form*

$$\begin{aligned} \dot{z} &= A_1 z + f_1^{[2,0]}(z, \mu) + f_1^{[1,1]}(z, \mu, x_1) + f_1^{[0,2]}(x) + O(z, \mu, x)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[0,2]}(x) + O(z, \mu, x, u)^3, \end{aligned} \tag{3.3}$$

where

$$
\begin{aligned}
f_1^{[2,0]}(z,\mu) &= \sum_{i=1}^{2}\sum_{j=1}^{2} \beta_i^j e_1^i\, z_j\, z_3, \quad \beta_1^1 = \beta_2^2,\ \beta_1^2 = -\beta_2^1,\\
f_1^{[1,1]}(z,\mu,x_1) &= \sum_{i=1}^{2}\sum_{j=1}^{3} \gamma_i^j e_1^i\, z_j\, x_1,\\
f_1^{[0,2]}(x) &= \sum_{i=1}^{2}\sum_{j=1}^{n-2} \delta_i^j e_1^i\, x_j^2,\\
f_2^{[0,2]}(x) &= \sum_{i=1}^{n-2}\sum_{j=i+2}^{n-2} \rho_i^j e_2^i\, x_j^2.
\end{aligned}
\tag{3.4}
$$

For reasons of simplicity, we use (z,μ,x) instead of $(\bar{z},\mu,\bar{x})$ for the variables in the normal form. In the notation, $z_3 = \mu$. We will continue to use both z_3 and μ in the rest of this paper. The notation e_1^i is the ith unit vector in z space. The vector e_2^i is the ith unit vector in x space. The superscript $[2,0]$ implies that $f_i^{[2,0]}(z,\mu)$ is quadratic in (z,μ), and the variable x does not appear in $f_i^{[2,0]}(z,\mu)$. The superscript $[1,1]$ implies that $f_i^{[1,1]}(z,\mu,x)$ consists of quadratic terms in which both the degree of (z,μ) and the degree of x equal one, i.e., the cross terms of x and (z,μ). Similarly, $f_i^{[0,2]}(x)$ consists of quadratic terms of x. A typical quadratic normal form of dimension five is given in the following example:

$$
\begin{aligned}
\dot{z}_1 &= -\omega z_2 + z_1\mu + z_2\mu + z_1x_1 + z_2x_1 + \mu x_1 + x_1^2 + x_2^2 + x_3^2,\\
\dot{z}_2 &= \omega z_1 - z_1\mu + z_2\mu + z_1x_1 + z_2x_1 + \mu x_1 + x_1^2 + x_2^2 + x_3^2,\\
\dot{x}_1 &= x_2 + x_3^2,\\
\dot{x}_2 &= x_3,\\
\dot{x}_3 &= u.
\end{aligned}
$$

In this example,

$$
f_1^{[2,0]} = \begin{bmatrix} z_1\mu + z_2\mu \\ -z_1\mu + z_2\mu \end{bmatrix}, \quad f_1^{[1,1]} = \begin{bmatrix} z_1x_1 + z_2x_1 + \mu x_1 \\ z_1x_1 + z_2x_1 + \mu x_1 \end{bmatrix},
$$

$$
f_1^{[0,2]} = \begin{bmatrix} x_1^2 + x_2^2 + x_3^2 \\ x_1^2 + x_2^2 + x_3^2 \end{bmatrix}, \quad f_2^{[0,2]} = \begin{bmatrix} x_3^2 \\ 0 \\ 0 \end{bmatrix}.
$$

The normal form is used to develop an algorithm of feedback design to stabilize the Hopf bifurcation. The proof of the quadratic normal form is not used in the feedback design. So, the proof of Theorem 3.1 is given in the appendix.

Now let us determine the quadratic part of the center manifold. In the following, $ad_X(Y)$ represents the Lie bracket of two matrices X and Y, i.e.,

$$
ad_X(Y) = XY - YX.
$$

THEOREM 3.2. *Suppose* $\begin{bmatrix} a_1, \dots, a_{n-2} \end{bmatrix}$ *stabilizes the x-subsystem, and suppose $F_i = 0$ for $i = 1,2,3$. The linear part of the center manifold has been determined as in Theorem* 2.2. *Given any matrix Q_1 and a quadratic function $\Pi_i^{[2]}$, $i = 1,\dots,n-2$, defined by*

$$
\Pi_i^{[2]}(z,\mu) = \begin{bmatrix} z & \mu \end{bmatrix} (-1)^{i-1} ad^{i-1}_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_1) \begin{bmatrix} z \\ \mu \end{bmatrix},
\tag{3.5}
$$

there exists a unique quadratic feedback

$$u(z,x,\mu)=\sum_{i=1}^{n-2}a_ix_i+\begin{bmatrix} z & \mu \end{bmatrix}Q_{fb}\begin{bmatrix} z \\ \mu \end{bmatrix}+O(z,\mu,x)^3, \tag{3.6}$$

with

$$Q_{fb}=P\Big(-ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}\Big)(Q_1), \tag{3.7}$$

such that (3.5) *is the quadratic part of the center manifold.* $P(\lambda)$ *is the characteristic polynomial of* A_2+B_2K *for* $K=\begin{bmatrix} a_1 & \cdots & a_{n-2} \end{bmatrix}$.

Remark. Theorem 3.2 implies that for any given matrix Q_1, there always exists Q_{fb} given by (3.7) so that the feedback (3.6) yields a center manifold satisfying (3.5). In the next section it will be proved that the stability of the Hopf bifurcation is determined by Q_1 and the invariants. Theorem 3.2 guarantees that if a Q_1 stabilizes a Hopf bifurcation, then Q_1 is always achievable by a suitable quadratic feedback. Thus, the problem of finding the stabilizing feedback is converted to the problem of maneuvering the quadratic part of the center manifold.

Remark. The spectrum of the operator $ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}$ consists of $\{\pm i\omega,\pm 2i\omega,0\}$, all on the imaginary axis. The spectrum of $P(-ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]})$ is

$$\{P(\pm i\omega),P(\pm 2i\omega),P(0)\}.$$

Since the roots of $P(\lambda)$ are all in the left half plane, the spectrum of $P(-ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]})$ does not contain zero. So, $P(-ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]})$ is an invertible linear operator.

Proof. Consider

$$\begin{aligned}
\dot z &= A_1z+f_1^{[2,0]}(z,\mu)+f_1^{[1,1]}(z,\mu,x)+f_1^{[0,2]}(x)+O(z,\mu,x)^3,\\
\dot x &= A_2x+B_2\left(\sum_{i=1}^{n-2}a_ix_i+\begin{bmatrix} z & \mu \end{bmatrix}Q_{fb}\begin{bmatrix} z \\ \mu \end{bmatrix}\right)+f_2^{[0,2]}(x)+O(z,\mu,x)^3.
\end{aligned}$$

Since $F_1=F_2=F_3=0$, the linear part of the center manifold vanishes (Theorem 2.2). The quadratic part of the center manifold has the form

$$\begin{aligned}
x_i &= \Pi_i(z,\mu),\\
\Pi_i^{[2]} &= \begin{bmatrix} z & \mu \end{bmatrix}Q_i\begin{bmatrix} z \\ \mu \end{bmatrix},
\end{aligned}$$

where Q_i, $i=1,\dots,n-2$, are real 3×3 symmetric matrices. From the center manifold equation

$$\frac{\partial\Pi}{\partial(z\ \mu)}\begin{bmatrix} \dot z \\ \dot\mu \end{bmatrix}=A_2\Pi+Bu+O(z,\mu,x)^2$$

we have

$$\begin{aligned}
&\begin{bmatrix} z & \mu \end{bmatrix}\left(Q_i\begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}-\begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}Q_i\right)\begin{bmatrix} z \\ \mu \end{bmatrix}\\
&\quad=\begin{bmatrix} z & \mu \end{bmatrix}Q_{i+1}\begin{bmatrix} z \\ \mu \end{bmatrix}\quad\text{for } 1\le i\le n-3,
\end{aligned}$$

$$\begin{bmatrix} z & \mu \end{bmatrix}\left(Q_{n-2}\begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix} - \begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix} Q_{n-2}\right)\begin{bmatrix} z \\ \mu \end{bmatrix} = \sum_{i=1}^{n-2} a_i \begin{bmatrix} z & \mu \end{bmatrix} Q_i \begin{bmatrix} z \\ \mu \end{bmatrix} + \begin{bmatrix} z & \mu \end{bmatrix} Q_{fb} \begin{bmatrix} z \\ \mu \end{bmatrix}.$$

In this equation, we used the fact that

$$\begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}^T = -\begin{bmatrix} A_1 & 0 \\ 0 & 0 \end{bmatrix}.$$

This equation is equivalent to

$$\begin{aligned} Q_{i+1} &= -ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_i), \\ Q_{fb} &= -ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_{n-2}) - \sum_{i=1}^{n-2} a_i Q_i, \end{aligned}$$

hence,

$$\begin{aligned} Q_{i+1} &= (-1)^i ad^i_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_1), \\ Q_{fb} &= (-1)^{n-2} ad^{n-2}_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_1) - \sum_{i=1}^{n-2} a_i (-1)^{i-1} ad^{i-1}_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_1). \end{aligned} \tag{3.8}$$

So

$$\begin{aligned} Q_{i+1} &= (-1)^i ad^i_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_1), \\ Q_{fb} &= P\Big(-ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}\Big)(Q_1). \end{aligned}$$ □

In Theorem 3.2, we assume that the linear feedback is independent of (z, μ). However, it does not mean that we lose any generality. The next theorem shows that if a closed-loop system has nonzero F_i terms, it can be transformed into a system in which the linear part of the controllable system is not explicitly a function of (z, μ). Then, the formulae in Theorem 3.2 are applicable to the new system.

PROPOSITION 3.3. *Given a system*

$$\begin{aligned} \dot{z} &= A_1 z + O(z, x)^2, \\ \dot{x} &= A_2 x + B_2\left(F_1 z_1 + F_2 z_2 + F_3 z_3 + \sum_{i=1}^{n-2} a_i x_i\right) + O(z, x)^2, \end{aligned} \tag{3.9}$$

there exists a linear change of coordinates to transform the system into the form

$$\begin{aligned} \dot{\tilde{z}} &= A_1 \tilde{z} + O(\tilde{z}, \tilde{x})^2, \\ \dot{\tilde{x}} &= A_2 \tilde{x} + B_2\left(\sum_{i=1}^{n-2} a_i \tilde{x}_i\right) + O(\tilde{z}, \tilde{x})^2. \end{aligned} \tag{3.10}$$

Proof. Consider the following change of coordinates:

$$\begin{aligned}
\tilde{x}_1 &= x_1 + \begin{bmatrix} \varphi_1 & \varphi_2 \end{bmatrix} z + \varphi_3 \mu,\\
\tilde{x}_2 &= x_2 + \begin{bmatrix} \varphi_1 & \varphi_2 \end{bmatrix} A_1 z,\\
&\vdots\\
\tilde{x}_{n-2} &= x_{n-2} + \begin{bmatrix} \varphi_1 & \varphi_2 \end{bmatrix} A_1^{n-3} z.
\end{aligned}$$

In the new coordinates, the system has the form

$$\begin{aligned}
\dot{\tilde{x}}_1 &= \tilde{x}_2,\\
\dot{\tilde{x}}_2 &= \tilde{x}_3,\\
&\vdots\\
\dot{\tilde{x}}_{n-2} &= \sum_{i=1}^{n-2} a_i \tilde{x}_i + (F_3 - a_1\varphi_3)\mu\\
&\quad + \left\{ \begin{bmatrix} F_1 & F_2 \end{bmatrix} + \begin{bmatrix} \varphi_1 & \varphi_2 \end{bmatrix} A_1^{n-2} - \sum_{i=1}^{n-2} a_i \begin{bmatrix} \varphi_1 & \varphi_2 \end{bmatrix} A_1^{i-1} \right\} z\\
&= \sum_{i=1}^{n-2} a_i \tilde{x}_i + (F_3 - a_1\varphi_3)\mu + \left(\begin{bmatrix} F_1 & F_2 \end{bmatrix} + \begin{bmatrix} \phi_1 & \phi_2 \end{bmatrix} P(A_1) \right) z. \qquad (3.11)
\end{aligned}$$

Define

$$\varphi_3 = \frac{F_3}{a_1}, \qquad \begin{bmatrix} \varphi_1 & \varphi_2 \end{bmatrix} = - \begin{bmatrix} F_1 & F_2 \end{bmatrix} P(A_1)^{-1}.$$

Then we obtain a dynamics possessing the form (3.10). ∎

Remark. When $F_i \neq 0$, the quadratic part of the center manifold is given by

$$Q_{i+1} = -ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_i) + \sum_{j=i+2}^{n-2} \rho_i^j {\Pi_j^{[1]}}^T \Pi_j^{[1]} - \sum_{j=2}^{2} \Pi_{i,j}^{[1]} P_j, \qquad (3.12)$$

$$Q_{fb} = -ad_{\left[\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right]}(Q_{n-2}) - \sum_{i=1}^{n-2} a_i Q_i + \sum_{j=i+2}^{n-2} \rho_i^j {\Pi_j^{[1]}}^T \Pi_j^{[1]}, \qquad (3.13)$$

with $P_i \in \mathbb{R}^{3\times 3}$ given by

$$P_i = \begin{bmatrix} 0 & 0 & \frac{\beta_i^1}{2} \\ 0 & 0 & \frac{\beta_i^2}{2} \\ \frac{\beta_i^1}{2} & \frac{\beta_i^2}{2} & 0 \end{bmatrix} + \begin{bmatrix} \gamma_i^1 \\ \gamma_i^2 \\ \gamma_i^3 \end{bmatrix} \Pi_1^{[1]} + \sum_{j=1}^{n-2} \delta_i^j {\Pi_j^{[1]}}^T \Pi_j^{[1]}.$$

3.2. Control of the Hopf bifurcation. The center manifold has dimension two. To determine its stability we use the Poincaré–Andronov–Hopf theorem. Let us recall the following result.

THEOREM 3.4 (see [11]). *Consider the system*

$$\begin{bmatrix} \dot{z}_1 \\ \dot{z}_2 \end{bmatrix} = \begin{bmatrix} 0 & -\omega \\ \omega & 0 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} + \begin{bmatrix} \Psi(z_1, z_2, \mu) \\ \tilde{\Psi}(z_1, z_2, \mu) \end{bmatrix}. \qquad (3.14)$$

If

$$\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} \neq 0,$$
$$\breve{a} \neq 0,$$

where $\breve{a}$ *is a constant defined below, a curve of periodic solutions bifurcates from the origin into* $\mu < 0$ *if* $\breve{a}(\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2}) > 0$ *or* $\mu > 0$ *if* $\breve{a}(\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2}) < 0$.

The periodic solution is stable if $\breve{a} < 0$. *The periodic solution is unstable if* $\breve{a} > 0$. *The origin is stable for* $\mu > 0$ *(resp.,* $\mu < 0$*) and unstable for* $\mu < 0$ *(resp.,* $\mu > 0$*) if* $\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} < 0$ *(resp.,* $\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} > 0$*).*

The coefficient $\breve{a}$ is a constant involving partial derivatives evaluated at the bifurcation point, i.e., $(z_1, z_2, \mu) = (0, 0, 0)$. It is given by

$$\begin{aligned}\breve{a} = {} & \frac{1}{16}(\Psi_{z_1 z_1 z_1} + \tilde{\Psi}_{z_1 z_1 z_2} + \Psi_{z_1 z_2 z_2} + \tilde{\Psi}_{z_2 z_2 z_2}) \\ & + \frac{1}{16\omega}(\Psi_{z_1 z_2}(\Psi_{z_1 z_1} + \Psi_{z_2 z_2}) - \tilde{\Psi}_{z_1 z_2}(\tilde{\Psi}_{z_1 z_1} + \tilde{\Psi}_{z_2 z_2}) \\ & \quad - \Psi_{z_1 z_1}\tilde{\Psi}_{z_1 z_1} + \Psi_{z_2 z_2}\tilde{\Psi}_{z_2 z_2}).\end{aligned} \tag{3.15}$$

Remark. When $\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} > 0$ (resp., $\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} < 0$), if $\breve{a} < 0$, then a stable periodic orbit of amplitude approximately

$$R = \left(\frac{(\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2})\mu}{|\breve{a}|}\right)^{\frac{1}{2}} \tag{3.16}$$

bifurcates from the origin into $\mu > 0$ (resp., $\mu < 0$) as μ passes through zero. The origin itself is a stable focus if $\mu < 0$ (resp., $\mu > 0$).

If $\breve{a} > 0$, then an unstable periodic orbit of amplitude

$$R = \left(\frac{(\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2})\mu}{\breve{a}}\right)^{\frac{1}{2}} \tag{3.17}$$

bifurcates into $\mu < 0$ (resp., $\mu > 0$), where the origin is a stable focus, and there are no periodic orbits in a small neighborhood of the origin of $\mu > 0$ (resp., $\mu < 0$).

Remark. If $\breve{a} < 0$, a stable periodic solution attracts local trajectories when the origin is an unstable equilibrium point. Hence, the local trajectories of the system stay around the origin even if the origin is not a stable point. In this case, the bifurcation is called *supercritical Hopf bifurcation.*

Using the expressions of the center manifold (3.5) and the normal form (3.3), we can determine the dynamics of (2.1) on the center manifold. A straightforward application of Theorem 3.4 permits us to compute the feedback coefficients to stabilize the Hopf bifurcation. Substituting (3.5) into the $\dot{z}$ dynamics of the normal form (3.3), the critical coefficients in the reduced system can be found. In this case,

$$\begin{aligned}\breve{a} = {} & \frac{1}{16}\Bigg(2(Q_{11}(3\gamma_1^1 + \gamma_2^2) + 2Q_{12}(\gamma_1^2 + \gamma_2^1) + Q_{22}(3\gamma_2^2 + \gamma_1^1)) \\ & + \frac{\partial^3 f_{11}^{[3]}}{\partial z_1^3} + \frac{\partial^3 f_{12}^{[3]}}{\partial z_1^2 \partial z_2} + \frac{\partial^3 f_{11}^{[3]}}{\partial z_1 \partial z_2^2} + \frac{\partial^3 f_{12}^{[3]}}{\partial z_2^3}\Bigg), \\ \Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} = {} & 2\,\beta_1^1,\end{aligned} \tag{3.18}$$

where

$$Q_1 = \begin{bmatrix} Q_{11} & Q_{12} & Q_{13} \\ Q_{12} & Q_{22} & Q_{23} \\ Q_{13} & Q_{23} & Q_{33} \end{bmatrix}$$

is the matrix of the quadratic center manifold, and

$$f_1^{[3]} = \begin{bmatrix} f_{11}^{[3]} \\ f_{12}^{[3]} \end{bmatrix}$$

represents the cubic part of the $\dot{z}$ equation in (3.3). The next theorem of bifurcation control is a straightforward corollary of Theorem 3.4 and (3.18).

THEOREM 3.5. *Given a system in the normal form* (3.3)*, suppose* $\beta_1^1 \neq 0$*. If one of the following conditions is satisfied,*

(1) $3\gamma_1^1 + \gamma_2^2 \neq 0$,
(2) $\gamma_1^2 + \gamma_2^1 \neq 0$,
(3) $3\gamma_2^2 + \gamma_1^1 \neq 0$,

then there always exists a nonlinear feedback (3.6) *that renders the Hopf bifurcation supercritical. The feedback coefficient* Q_{fb} *is determined by* (3.7)*, in which* Q_1 *is any symmetric matrix satisfying* $\breve{a} < 0$.

Remark. In some cases where $\beta_1^1 = 0$, it may be possible to use the feedback (F_1, F_2, F_3) in (2.7) to modify the value of $\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2}$. Indeed, using this feedback we find that

$$\Psi_{\mu z_1} + \tilde{\Psi}_{\mu z_2} = 2\beta_1^1 + (\gamma_1^1 + \gamma_2^2)\Pi_{13}^{[1]} + \sum_{j=1}^{n-2} \left(\delta_1^j \Pi_{j1}^{[1]} + \delta_2^j \Pi_{j2}^{[1]}\right) \Pi_{j3}^{[1]},$$

where $\Pi_{ji}^{[1]}$ for $i = 1, 2, 3$ and $j = 1, \ldots, n-2$ are given by (2.8) and (2.11).

4. Invariants. Given a system in the form of (2.5), how do we find its normal form? In this section, a set of numbers associated with (2.5) is found. The numbers are invariant under any quadratic change of coordinates and feedback. They are called the quadratic invariants. It is also proved that these invariants equal the coefficients in the normal form. Two systems are equivalent under a quadratic change of coordinates and feedback if and only if the invariants of the systems are equal. Therefore, the set of quadratic invariants completely characterizes the quadratic part of a nonlinear control system. For a given system (2.5), the values of the invariants are the coefficients in the normal form.

Consider a system in the form of (2.5). Denote by C_x, C_z the following row vector and matrix:

$$C_x = \begin{bmatrix} 0 & 0 & 1 & 0 & \cdots & 0 \end{bmatrix}_{1 \times n}, \quad C_z = \begin{bmatrix} 1 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 0 & \cdots & 0 \end{bmatrix}_{2 \times n}. \tag{4.1}$$

Given two vector fields $X(\xi)$ and $Y(\xi)$ defined in $\mathbb{R}^n$, the operator ad_X is defined by

$$ad_X(Y) = [X, Y] = \frac{\partial Y}{\partial \xi} X - \frac{\partial X}{\partial \xi} Y.$$

The Lie operator L_X is defined by

$$L_X(\kappa(\xi)) = \frac{\partial \kappa(\xi)}{\partial \xi} X$$

for C^1 functions defined in $\mathbb{R}^n$.

DEFINITION 4.1. *Given a system* (2.5)*, the quadratic invariants are defined by*

$$\rho_t^{n-r-1} = \frac{1}{2} C_x A^{t-1} \left[ad_f^r(g), ad_f^{r-1}(g) \right] \Big|_{z=0,x=0,\mu=0}, \qquad \begin{array}{l} 1 \le r \le n-4, \\ 1 \le t \le n-r-3, \end{array}$$

$$\begin{bmatrix} \delta_1^{n-r-1} \\ \delta_2^{n-r-1} \end{bmatrix} = \frac{1}{2} C_z \left[ad_f^r(g), ad_f^{r-1}(g) \right] \Big|_{z=0,x=0,\mu=0}, \quad 1 \le r \le n-2,$$

$$\begin{bmatrix} \gamma_1^j \\ \gamma_2^j \end{bmatrix} = (-1)^n C_z \frac{\partial}{\partial z_j} ad_f^{n-2}(g) \big|_{x=0,\ z=0,\ \mu=0}, \quad j = 1, 2, 3,$$

$$\begin{bmatrix} \beta_1^1 \\ \beta_1^2 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} \dfrac{\partial^2 f_{11}}{\partial z_3 \partial z_1} + \dfrac{\partial^2 f_{12}}{\partial z_3 \partial z_2} \\ \dfrac{\partial^2 f_{11}}{\partial z_3 \partial z_2} - \dfrac{\partial^2 f_{12}}{\partial z_3 \partial z_1} \end{bmatrix} \Bigg|_{x=0,\ z=0,\ \mu=0},$$

(4.2)

where f and g are the right hand side of (2.5)*. The vector*

$$f_1 = \begin{bmatrix} f_{11} \\ f_{12} \end{bmatrix}$$

represents the vector field of $\dot{z}$ in (2.5).

Notation such as ρ_i^j, δ_i^j, γ_i^j, and β_i^j are used for both the invariants and the coefficients in the normal form (3.3). In the following, it is proved that they are actually equal to each other.

THEOREM 4.2. *Consider a system in the form of* (2.5)*.*

(i) *The quadratic transformation* (3.1)–(3.2) *does not change the value of quadratic invariants.*

(ii) *For a system in normal form* (3.3)*, its quadratic invariants* (4.2) *are equal to the coefficients of the quadratic terms in the normal form.*

(iii) *Given two systems in the form of* (2.5) *with the same linearization (same ω), the quadratic part of one system can be transformed into that of another system by a suitable transformation* (3.1)–(3.2) *if and only if they have the same quadratic invariants.*

Proof. (i) Suppose the system (2.5) is transformed into the following system by a quadratic change of coordinates (3.1)–(3.2):

$$\begin{bmatrix} \dot{\bar{z}}_1 \\ \dot{\bar{z}}_2 \end{bmatrix} = A_1 \begin{bmatrix} \bar{z}_1 \\ \bar{z}_2 \end{bmatrix} + \begin{bmatrix} \bar{f}_{11}^{[2]}(\bar{z}, \mu, \bar{x}) \\ \bar{f}_{12}^{[2]}(\bar{z}, \mu, \bar{x}) \end{bmatrix} + \begin{bmatrix} \bar{g}_{11}^{[1]}(\bar{z}, \mu, \bar{x}) \\ \bar{g}_{12}^{[1]}(\bar{z}, \mu, \bar{x}) \end{bmatrix} \bar{u} + O(\bar{z}, \mu, \bar{x}, \bar{u})^3,$$

$$\dot{\bar{x}} = A_2 \bar{x} + B_2 \bar{u} + \bar{f}_2^{[2]}(\bar{z}, \mu, \bar{x}) + \bar{g}_2^{[1]}(\bar{z}, \mu, \bar{x})\, u + O(\bar{z}, \mu, \bar{x}, \bar{u})^3. \tag{4.3}$$

Denote the invariants of (2.5) and (4.3) by ρ_i^j, δ_i^j, γ_i^j, β_1^j, and $\bar{\rho}_i^j$, $\bar{\delta}_i^j$, $\bar{\gamma}_i^j$, $\bar{\beta}_1^j$, respectively. Notice that if we treat $f(z, \mu, x)$ and $g(z, \mu, x)$ as vector fields in $\mathbb{R}^n$, then f and $\bar{f}$ represent the same vector field. Similarly, g and $\bar{g}$ represent the same vector field. Since Lie bracket and Lie operators are independent of the choice of coordinate systems, sometimes we use f and g to represent these two vector fields without mentioning the coordinate system (z, x or $\bar{z}$, $\bar{x}$). On a manifold, the operators $\frac{\partial}{\partial z_j}$ and $\frac{\partial}{\partial \bar{z}_j}$ are equivalent to vector fields. They depend on the selection of coordinate

systems. The invariants can be expressed in the following way using Lie brackets and Lie operators:

$$\rho_t^{n-r-1} = \tfrac{1}{2} L_{[ad_f^r(g), ad_f^{r-1}(g)]} L_f^{t-1}(x_1)|_{z=0,x=0,\mu=0}, \qquad \begin{matrix} 1 \le r \le n-4, \\ 1 \le t \le n-r-3, \end{matrix}$$

$$\begin{bmatrix} \delta_1^{n-r-1} \\ \delta_2^{n-r-1} \end{bmatrix} = \tfrac{1}{2} L_{[ad_f^r(g), ad_f^{r-1}(g)]}(z)|_{z=0,x=0,\mu=0}, \quad 1 \le r \le n-2, \tag{4.4}$$

$$\begin{bmatrix} \gamma_1^j \\ \gamma_2^j \end{bmatrix} = (-1)^n L_{[\frac{\partial}{\partial z_j}, \mathrm{ad}_f^{n-2}(g)]}(z)\big|_{x=0,\ z=0,\ \mu=0}, \quad j = 1,2,3.$$

Under the new coordinates, we have

$$x_1 = \bar{x}_1 + O(\bar{z},\mu,\bar{x})^2, \quad z = \bar{z} + O(\bar{z},\mu,\bar{x})^2, \quad \frac{\partial}{\partial z_j} = \frac{\partial}{\partial \bar{z}_j} + O(\bar{z},\mu,\bar{x})^2. \tag{4.5}$$

From (4.4) and (4.5),

$$\begin{aligned} \rho_t^{n-r-1} = {} & \frac{1}{2} L_{[ad_f^r(g), ad_f^{r-1}(g)]} L_f^{t-1}(\bar{x}_1)|_{z=0,x=0,\mu=0} \\ & + \frac{1}{2} L_{[ad_f^r(g), ad_f^{r-1}(g)]} L_f^{t-1}(O(\bar{z},\mu,\bar{x})^2)|_{z=0,x=0,\mu=0}. \end{aligned}$$

In this relation, the second term on the right side is zero. The first term on the right side is $\bar{\rho}_t^{n-r-1}$. This proves $\rho_t^{n-r-1} = \bar{\rho}_t^{n-r-1}$. Similarly, we can prove that $\delta_i^j = \bar{\delta}_i^j$ for all feasible i and j.

Now let us consider γ_i^j. By (4.4) and (4.5), we have

$$\begin{aligned} \begin{bmatrix} \gamma_1^j \\ \gamma_2^j \end{bmatrix} = (-1)^n \Bigg(& L_{[\frac{\partial}{\partial \bar{z}_j}, \mathrm{ad}_f^{n-2}(g)]}(\bar{z})\Big|_{\bar{x}=0,\ \bar{z}=0,\ \mu=0} + L_{[\frac{\partial}{\partial \bar{z}_j}, \mathrm{ad}_f^{n-2}(g)]}(O(\bar{z},\mu,\bar{x})^2)\Big|_{\bar{x}=0,\ \bar{z}=0,\ \mu=0} \\ & + L_{[O(\bar{z},\mu,\bar{x}), \mathrm{ad}_f^{n-2}(g)]}(\bar{z} + O(\bar{z},\mu,\bar{x})^2)\Big|_{\bar{x}=0,\ \bar{z}=0,\ \mu=0} \Bigg). \end{aligned} \tag{4.6}$$

By (4.4), we know that

$$L_{[\frac{\partial}{\partial \bar{z}_j}, \mathrm{ad}_f^{n-2}(g)]}(\bar{z})\Big|_{\bar{x}=0,\bar{z}=0,\mu=0} = \begin{bmatrix} \bar{\gamma}_1^j \\ \bar{\gamma}_2^j \end{bmatrix}. \tag{4.7}$$

It is easy to check that

$$L_{[\frac{\partial}{\partial \bar{z}_j}, \mathrm{ad}_f^{n-2}(g)]}(O(\bar{z},\mu,\bar{x})^2)\Big|_{\bar{x}=0,\bar{z}=0,\mu=0} = 0 \tag{4.8}$$

and

$$ad_f^r(g) = (-1)^r \begin{bmatrix} 0 \\ A_2^r B_2 \end{bmatrix} + O(\bar{z},\mu,\bar{x}).$$

Therefore,

$$ad_f^{n-2}(g) = O(\bar{z},\mu,\bar{x}).$$

So

$$L_{[O(\bar{z},\mu,\bar{x}),\mathrm{ad}_f^{n-2}(g)]}(\bar{z}+O(\bar{z},\mu,\bar{x})^2)\Big|_{\bar{x}=0,\bar{z}=0,\mu=0}=0. \tag{4.9}$$

Equations (4.7), (4.8), and (4.9) imply $\gamma_i^j=\bar{\gamma}_i^j$.

Now, let us consider β_1^1 and β_1^2. The homological equation (A.2) in the appendix for $f_1^{[2,0]}(\bar{z},\mu)$ is

$$f_1^{[2,0]}(z,\mu)-\bar{f}_1^{[2,0]}(z,\mu)=\frac{\partial\phi_1^{[2,0]}}{\partial z}A_1z-A_1\phi_1^{[2,0]},$$

where the change of coordinates $\phi_1^{[2,0]}$ is

$$\phi_1^{[2,0]}=\begin{bmatrix} a_1^1z_1\mu+a_1^2z_2\mu \\ a_2^1z_1\mu+a_2^2z_2\mu \end{bmatrix}.$$

Straightforward computation shows that

$$f_1^{[2,0]}(z,\mu)-\bar{f}_1^{[2,0]}(z,\mu)=\begin{bmatrix} \omega(a_2^1+a_1^2)z_1\mu+\omega(a_2^2-a_1^1)z_2\mu \\ \omega(a_2^2-a_1^1)z_1\mu-\omega(a_1^2+a_2^1)z_2\mu \end{bmatrix}.$$

From the definition (4.2),

$$\begin{bmatrix} \beta_1^1-\bar{\beta}_1^1 \\ \beta_1^2-\bar{\beta}_1^2 \end{bmatrix}=\begin{bmatrix} \dfrac{\partial^2 f_{11}-\bar{f}_{11}}{\partial z_3\partial z_1}+\dfrac{\partial^2 f_{12}-\bar{f}_{12}}{\partial z_3\partial z_2} \\ \dfrac{\partial^2 \bar{f}_{11}-\bar{f}_{11}}{\partial z_3\partial z_2}-\dfrac{\partial^2 f_{12}-\bar{f}_{12}}{\partial z_3\partial z_1} \end{bmatrix}=\begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

This proves that β_i^j is invariant.

(ii) The proof of the second part of Theorem 4.2 is based on calculation. Suppose that the vectors f and g are in the normal form (3.3). By mathematical induction we can prove that for $1\le r\le n-4$, we have

$$\mathrm{ad}_f^r(g)=(-1)^r\left(\begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}\Bigg\}\begin{matrix} n-r \\ \end{matrix}+\begin{bmatrix} 2\delta_1^{n-r-1}x_{n-r-1} \\ 2\delta_2^{n-r-1}x_{n-r-1} \\ 2\rho_1^{n-r-1}x_{n-r-1} \\ \vdots \\ 2\rho_{n-r-3}^{n-r-1}x_{n-r-1} \\ 0 \\ \vdots \\ 0 \end{bmatrix}\Bigg\}n-r-1\right)$$
$$+\,h_r(x_{n-r},\dots,x_{n-2},z,\mu)+O(x,z,\mu)^2.$$

Similarly, we can derive that

$$\mathrm{ad}_f^{n-3}(g)=(-1)^{n-3}\begin{bmatrix} 2\delta_1^2x_2 \\ 2\delta_2^2x_2 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}+h_{n-3}(x_3,\dots,x_{n-2},\mu,z)+O(z,\mu,x)^2,$$

$$\mathrm{ad}_f^{n-2}(g) = (-1)^{n-2} \begin{bmatrix} \gamma_1^1 z_1 + \gamma_1^2 z_2 + \gamma_1^3 \mu + 2\delta_1^1 x_1 \\ \gamma_2^1 z_1 + \gamma_2^2 z_2 + \gamma_2^3 \mu + 2\delta_2^1 x_1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} + h_{n-2}(x_2, \ldots, x_{n-2}, \mu, z) + O(z, \mu, x)^2.$$

Therefore,

$$\begin{aligned} &\left[ad_f^r(g), ad_f^{r-1}(g)\right] \\ &\quad = \begin{bmatrix} 2\delta_1^{n-r-1} & 2\delta_2^{n-r-1} & 2\rho_1^{n-r-1} & \cdots & 2\rho_{n-r-3}^{n-r-1} & 0 & \cdots & 0 \end{bmatrix}^T \\ &\qquad + O(z, \mu, x), \quad r < n-3, \left[ad_f^r(g), ad_f^{r-1}(g)\right] \\ &\quad = \begin{bmatrix} 2\delta_1^{n-r-1} & 2\delta_2^{n-r-1} & 0 & \cdots & 0 \end{bmatrix}^T + O(z, \mu, x), \quad r = n-3, n-2. \end{aligned}$$

This implies

$$\begin{aligned} \rho_t^{n-r-1} &= \frac{1}{2} C_x A^{t-1} \left[ad_f^r(g), ad_f^{r-1}(g)\right] \Big|_{z=0, x=0, \mu=0}, \quad 1 \le r \le n-4, \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad 1 \le t \le n-r-3, \\ \begin{bmatrix} \delta_1^{n-r-1} \\ \delta_2^{n-r-1} \end{bmatrix} &= \frac{1}{2} C_z \left[ad_f^r(g), ad_f^{r-1}(g)\right] \Big|_{z=0, x=0, \mu=0}, \quad 1 \le r \le n-2, \\ \begin{bmatrix} \gamma_1^j \\ \gamma_2^j \end{bmatrix} &= (-1)^n C_z \left[\frac{\partial}{\partial z_j}, \mathrm{ad}_f^{n-2}(g)\right] \Big|_{x=0,\ z=0,\ \mu=0}, \quad j = 1, 2, 3. \end{aligned}$$

The formula for the invariants β_1^1 and β_1^2 of the normal form is a straightforward corollary of the definition of invariants.

(iii) By (i) and (ii), the value of the invariants of a system uniquely determines the coefficients of its normal form. On the other hand, Theorem 3.1 implies that one system can be transformed into another system by quadratic transformation if and only if they have the same normal form. Therefore, a system can be transformed into another system by quadratic transformation if and only if they have the same values of invariants. □

5. Conclusion. In this paper, linear and quadratic normal forms of nonlinear systems with a pair of imaginary uncontrollable modes are derived. Based on the normal form, formulae of feedbacks are found to control the bifurcation of the system. The Hopf bifurcation cannot be removed from the closed-loop system because the imaginary eigenvalues are uncontrollable. However, it is proved that both the orientation and the stability of the periodic solution can be controlled by state feedback. It is proved in this paper that a linear feedback determines the local orientation of the periodic solution around the bifurcation point, and the quadratic feedback controls the stability of the periodic solution. The explicit relations between the feedback and the performance of the periodic solution, such as the local orientation and stability, are derived. A set of formulae is derived which computes the coefficients in the normal form of systems with two imaginary uncontrollable modes.

Appendix. Proof of normal form theorem. Given a system (2.5), the quadratic functions $f_1^{[2]}(z,\mu,x)$ and $f_2^{[2]}(z,\mu,x)$ have a decomposition denoted by

$$f_i^{[2]}(z,\mu,x) = f_i^{[2,0]}(z,\mu) + f_i^{[1,1]}(z,\mu,x) + f_i^{[0,2]}(x), \qquad i=1,2.$$

The superscript $[2,0]$ implies that $f_i^{[2,0]}(z,\mu)$ is quadratic in (z,μ), and the variable x does not appear in $f_i^{[2,0]}(z,\mu)$. The superscript $[1,1]$ implies that $f_i^{[1,1]}(z,\mu,x)$ consists of quadratic terms in which both the degree of (z,μ) and the degree of x equal one, i.e., the cross terms of x and (z,μ). Similarly, $f_i^{[0,2]}(x)$ consists of quadratic terms of x. For example, z_1x_1 and μx_2 are terms of $f_i^{[1,1]}$, and x_2x_4 is a term in $f_i^{[0,2]}(x)$. The subscript $i=1$ implies that the vector has 2 components, representing the uncontrollable dynamics, i.e., the right side of $\dot z$ equation in (2.5). The subscript $i=2$ implies that the vector has $n-2$ components. It represents the vector in the $\dot x$ equation of (2.5). Similar notation applies to other vector fields and functions, such as the change of coordinates $\phi^{[2]}(z,\mu,x)$ and the feedback $\alpha^{[2]}(z,\mu,x)$ and $\beta^{[1]}(z,\mu,x)$.

Let us consider the system

$$\begin{bmatrix} \dot z \\ \dot x \end{bmatrix} = A \begin{bmatrix} z \\ x \end{bmatrix} + Bu + f^{[2]}(z,\mu,x) + g^{[1]}(z,\mu,x)u.$$

In [14], it was proved that this system can be transformed into

$$\begin{bmatrix} \dot{\bar z} \\ \dot{\bar x} \end{bmatrix} = A \begin{bmatrix} \bar z \\ \bar x \end{bmatrix} + Bv + \bar f^{[2]}(\bar z,\mu,\bar x) + \bar g^{[1]}(\bar z,\mu,\bar x)v$$

by the change of coordinates and feedback

$$\begin{aligned} \begin{bmatrix} z \\ x \end{bmatrix} &= \begin{bmatrix} \bar z \\ \bar x \end{bmatrix} + \phi^{[2]}(\bar z,\mu,\bar x) + O(\bar z,\mu,\bar x)^2, \\ v &= u + \alpha^{[2]}(\bar z,\mu,\bar x) + \beta^{[1]}(\bar z,\mu,\bar x)u \end{aligned} \tag{A.1}$$

if and only if the following equation holds,

$$\begin{aligned} &\left[A\begin{bmatrix} z \\ x \end{bmatrix}, \phi^{[2]}(z,\mu,x)\right] + B\alpha^{[2]}(z,\mu,x) = f^{[2]}(z,\mu,x) - \bar f^{[2]}(z,\mu,x), \\ &\left[B, \phi^{[2]}(z,\mu,x)\right] + B\beta^{[1]}(z,\mu,x) = g^{[1]}(z,\mu,x) - \bar g^{[1]}(z,\mu,x), \end{aligned} \tag{A.2}$$

where the Lie bracket between two vectors $X_1(\xi)$ and $X_2(\xi)$ is defined by $[X_1,X_2] = \frac{\partial X_1}{\partial \xi}X_2 - \frac{\partial X_2}{\partial \xi}X_1$. Following the terminology of Poincaré's normal form theory, (A.2) is called the homological equation. For a system in the form of (2.5), the homological equation (A.2) is equivalent to equation

$$\begin{aligned} &\frac{\partial \phi_i^{[j,k]}}{\partial z}A_1 z + \frac{\partial \phi_i^{[j,k]}}{\partial x}A_2 x - A_i\phi_i^{[j,k]} + B_i\alpha^{[j,k]} = f_i^{[j,k]} - \bar f_i^{[j,k]}, \\ &\frac{\partial \phi_i^{[2]}}{\partial x_{n-2}} + B_i\beta^{[1]} = g_i^{[1]} - \bar g_i^{[1]}, \qquad i=1,2,3,\ \ j=0,1,2,\ \ j+k=2. \end{aligned} \tag{A.3}$$

In this equation,

$$\phi(z,\mu,x) = \begin{bmatrix} \phi_1(z,\mu,x) \\ \phi_2(z,\mu,x) \end{bmatrix} = \begin{bmatrix} \phi_1^{[2,0]}(z,\mu) + \phi_1^{[1,1]}(z,\mu,x) + \phi_1^{[0,2]}(x) \\ \phi_2^{[2,0]}(z,\mu) + \phi_2^{[1,1]}(z,\mu,x) + \phi_2^{[0,2]}(x) \end{bmatrix}.$$

Notice that B_1 is actually a zero vector. The following remark is a corollary of the homological equation (A.3). In [15], the remark is called the *separation principle*.

Remark. The homological equation (A.3) implies that $f_i^{[j,k]} - \bar{f}_i^{[j,k]}$ is determined by the corresponding $\phi_i^{[j,k]}$. For example, the transformation $\phi_1^{[2,0]}$ changes the term $f_1^{[2,0]}$ but leaves the other $f_i^{[j,k]}$ invariant. The homological equation also implies that $(\phi_2, \alpha^{[2]}, \beta^{[1]})$ does not change anything in f_1 and g_1, and ϕ_1 does not change anything in f_2 and g_2.

To prove Theorem 3.1, we will prove that for any $f^{[2]}$ and $g^{[1]}$ in (2.5), there always exists $(\phi(z,\mu,x), \alpha^{[2]}(z,\mu,x), \beta^{[1]}(z,\mu,x))$ so that the homological equation (A.3) is satisfied for a unique pair of vectors $\bar{f}^{[2]}$ and $\bar{g}^{[1]}$ in the normal form (3.3)–(3.4). To study the solvability of (A.3), we consider the set of all vectors $f^{[2]}(z,\mu,x)$ and $g^{[1]}(z,\mu,x)$ as linear spaces, denoted by $W(f^{[2]})$ and $W(g^{[1]})$, respectively. Similarly, the linear spaces consisting of $\phi^{[2]}$, $\alpha^{[2]}$, and $\beta^{[1]}$ are denoted by $V(\phi^{[2]})$, $V(\alpha^{[2]})$, and $V(\beta^{[1]})$. These linear spaces have subspace decomposition corresponding to the decomposition of the vector fields. For example, $W(f_1^{[2,0]})$ is a subspace of $W(f^{[2]})$ consisting of all the vectors $f_1^{[2,0]}(z,\mu)$. The linear spaces of the vectors in normal form are denoted by $W(\bar{f}^{[2]})$ and $W(\bar{g}^{[1]})$, where $\bar{f}^{[2]}$ and $\bar{g}^{[1]}$ satisfy the formulae in (3.3) and (3.4).

The left side of (A.3) can be considered as a linear mapping from $V(\phi^{[2]}) \times V(\alpha^{[2]}) \times V(\beta^{[1]})$ to $W(f^{[2]}) \times W(g^{[2]})$, denoted by Π. So,

$$\Pi\left(\begin{bmatrix}\phi_1^{[2]}\\ \phi_2^{[2]}\end{bmatrix}, \alpha^{[2]}, \beta^{[1]}\right) = \left(\begin{bmatrix} \dfrac{\partial \phi_1^{[2]}}{\partial z} A_1 z + \dfrac{\partial \phi_1^{[2]}}{\partial x} A_2 x - A_1 \phi_1^{[2]} \\ \dfrac{\partial \phi_2^{[2]}}{\partial z} A_1 z + \dfrac{\partial \phi_2^{[2]}}{\partial x} A_2 x - A_2 \phi_2^{[2]} + B_2 \alpha^{[2]} \end{bmatrix} \begin{bmatrix} \dfrac{\partial \phi_1^{[2]}}{\partial x_{n-2}} \\ \dfrac{\partial \phi_2^{[2]}}{\partial x_{n-2}} + B_2 \beta^{[1]} \end{bmatrix}\right). \tag{A.4}$$

Given $(f^{[2]}, g^{[1]})$ from (2.5), there exist a transformation (A.1) and a unique normal form $(\bar{f}^{[2]}, \bar{g}^{[1]})$ satisfying the homological equation (A.3) if and only if

$$\begin{aligned} &\mathrm{Im}(\Pi) \cap \left(W(\bar{f}^{[2]}) \times W(\bar{g}^{[1]})\right) = \{0\}, \\ &\mathrm{Im}(\Pi) + \left(W(\bar{f}^{[2]}) \times W(\bar{g}^{[1]})\right) = W(f^{[2]}) \times W(g^{[1]}). \end{aligned}$$

It is equivalent to the conditions

$$\begin{aligned} &\mathrm{Im}(\Pi) \cap \left(W(\bar{f}^{[2]}) \times W(\bar{g}^{[1]})\right) = \{0\}, \\ &\dim(\mathrm{Im}(\Pi)) + \dim\left(W(\bar{f}^{[2]}) \times W(\bar{g}^{[1]})\right) = \dim\left(W(f^{[2]}) \times W(g^{[1]})\right). \end{aligned} \tag{A.5}$$

From (A.4) and the separation principle,

$$\begin{aligned} &\Pi\left(\begin{bmatrix}\phi_1^{[2]}\\ 0\end{bmatrix}, 0, 0\right) \in W(f_1^{[2]}) \times W(g_1^{[1]}), \\ &\Pi\left(\begin{bmatrix}0\\ \phi_2^{[2]}\end{bmatrix}, \alpha^{[2]}, \beta^{[1]}\right) \in W(f_2^{[2]}) \times W(g_2^{[1]}). \end{aligned}$$

Therefore, the condition (A.5) can be proved separately for the controllable part involving $V(\phi_2^{[2]})$, $\alpha^{[2]}$, $\beta^{[1]}$, and $W(f_2^{[2]}) \times W(g_2^{[1]})$, and the uncontrollable part involving

$V(\phi_1^{[2]})$ and $W(f_1^{[2]}) \times W(g_1^{[1]})$. The proof for the controllable part can be found in [15]. In the following, we focus on the proof of (A.5) for the restriction of Π on $V(\phi_1^{[2]})$. In this case, $W(\bar{g}_1^{[1]}) = \{0\}$ and $W(\bar{f}_1^{[0,2]}) \times W(\bar{g}_1^{[1]}) = W(\bar{f}_1^{[0,2]})$. Equation (A.5) is reduced to

$$\begin{aligned} &W(\bar{f}_1^{[2]}) \cap \Pi\left(V(\phi_1^{[2]})\right) = \{0\}, \\ &\dim\left(\Pi(V(\phi_1^{[2]}))\right) + \dim\left(W(\bar{f}_1^{[2]})\right) = \dim\left(W(f_1^{[2]})\right). \end{aligned} \tag{A.6}$$

Once again, by the separation principle, (A.6) can be proved separately for $\phi_1^{[2,0]}$, $\phi_1^{[1,1]}$, and $\phi_1^{[0,2]}$.

Given any $\phi_1^{[2]} \neq 0$ in the subspace $V(\phi_1^{[1,1]}) + V(\phi_1^{[0,2]})$, let j be the largest integer so that

$$\frac{\partial \phi_1^{[2]}}{\partial x_j} \neq 0. \tag{A.7}$$

Now, we prove that $\ker(\Pi)$ in $V(\phi_1^{[1,1]}) + V(\phi_1^{[0,2]})$ is $\{0\}$. Suppose this is not true, and suppose $\Pi(\phi_1^{[2]}) = 0$. Then (A.4) implies

$$\begin{aligned} &\frac{\partial \phi_1^{[2]}}{\partial z} A_1 z + \frac{\partial \phi_1^{[2]}}{\partial x} A_2 x - A_1 \phi_1^{[2]} = 0, \\ &\frac{\partial \phi_1^{[2]}}{\partial x_{n-2}} = 0. \end{aligned} \tag{A.8}$$

The second equation of (A.8) and the condition (A.7) imply that $1 \leq j < n-2$. Because

$$A_2 x = \begin{bmatrix} x_2 & x_3 \cdots x_{n-2} & 0 \end{bmatrix}^T, \tag{A.9}$$

the first equation of (A.8) implies that

$$\frac{\partial}{\partial x_{j+1}} \left(\frac{\partial \phi_1^{[2]}}{\partial x} A_2 x \right) \neq 0. \tag{A.10}$$

Therefore,

$$\frac{\partial \phi_1^{[2]}}{\partial z} A_1 z + \frac{\partial \phi_1^{[2]}}{\partial x} A_2 x - A_1 \phi_1^{[2]} \neq 0.$$

This contradicts (A.8). Therefore, $\ker(\Pi) = \{0\}$ in $V(\phi_1^{[1,1]}) + V(\phi_1^{[0,2]})$. So,

$$\dim\left(\Pi(V(\phi_1^{[1,1]}) + V(\phi_1^{[0,2]}))\right) = \dim\left(V(\phi_1^{[1,1]}) + V(\phi_1^{[0,2]})\right). \tag{A.11}$$

If Π is restricted to $V(\phi_1^{[2,0]})$, the mapping (A.4) is reduced to

$$\Pi\left(\phi_1^{[2,0]}(z,\mu)\right) = [A_1 z, \ \ \phi_1^{[2,0]}] \in W\left(f_1^{[2,0]}\right).$$

This is the homological equation of Poincaré normal form in the classical theory of dynamical systems (see [4]). It is a known fact that

$$\dim\left(\Pi(V(\phi_1^{[2,0]}))\right) = \dim\left(V(\phi_1^{[2,0]})\right) - 2. \tag{A.12}$$

Notice that the dimension of the normal form for the uncontrollable part, i.e., the dimension of $W(\bar{f}_1^{[2]})$ in (3.3), is $2n+4$. The dimension of $W(g_1^{[1]})$ is $2(n+1)$. In summary, (3.3), (A.11), and (A.12) imply

$$\begin{aligned}
&\dim\left(\Pi(V(\phi_1^{[2]})\right) + \dim\left(W(\bar{f}_1^{[2]})\right) \\
&\quad = \left(\dim(V(\phi_1^{[2]})) - 2\right) + 2n + 4 \\
&\quad = \dim\left(W(f_1^{[2]})\right) + 2n + 2 \\
&\quad = \dim\left(W(f_1^{[2]})\right) + \dim\left(W(g_1^{[1]})\right).
\end{aligned}$$

This equality proves the second equation in (A.6).

We complete the proof by proving the first equation of (A.6). By the separation principle, it can be proved separately for the three components in

$$V\left(\phi_1^{[2]}\right) = V\left(\phi_1^{[2,0]}\right) + V\left(\phi_1^{[1,1]}\right) + V\left(\phi_1^{[0,2]}\right).$$

Equation (A.6) holds if and only if the normal form is not in the image space of Π. From the classical normal form theory of dynamical systems, it is known that the subspace $W(\bar{f}_1^{[2,0]})$ is not in $\Pi(V(\phi_1^{[2,0]}))$ given any $\Pi(\phi_1^{[1,1]})$ in $\Pi(V(\phi_1^{[1,1]}))$. From (A.10), x_{j+1} appears in $\Pi(\phi_1^{[1,1]})$. However, no $x_2, x_3, \ldots, x_{n-2}$ appears in the normal form $W(\bar{f}_1^{[1,1]})$. Therefore,

$$W\left(\bar{f}_1^{[1,1]}\right) \cap \Pi\left(V(\phi_1^{[1,1]})\right) = \{0\}.$$

Given any $\phi_1^{[0,2]}$ in $V(\phi_1^{[0,2]})$, suppose that j is the largest integer satisfying (A.7). Let $x_i x_j$ be any term in $\phi_1^{[0,2]}$ with nonzero coefficient. If $j < n-2$, then

$$\frac{\partial x_i x_i}{\partial x} A_2 x = x_{i+1} x_j + x_i x_{j+1}.$$

Since $i \le j$, we know that x_{j+1}^2 does not appear in $\Pi(\phi_1^{[0,2]})$. Since $f_1^{[0,2]}$ consists of x_i^2 terms only, we know that $\Pi(V(\phi_1^{[0,2]}))$ is not in normal form. If $j = n-2$, then

$$\Pi(\phi_1^{[0,2]}) = \left(\begin{bmatrix} \dfrac{\partial \phi_1^{[0,2]}}{\partial x} A_2 x - A_1 \phi_1^{[0,2]} \\ 0 \end{bmatrix}, \begin{bmatrix} \dfrac{\partial \phi_1^{[0,2]}}{\partial x_{n-1}} \\ 0 \end{bmatrix} \right).$$

Since

$$\frac{\partial \phi_1^{[0,2]}}{\partial x_{n-1}} \neq 0$$

and

$$W(\bar{g}_1^{[1]}) = 0,$$

we know that $\Pi(\phi_1^{[0,2]})$ is not in normal form. Therefore,

$$W(\bar{f}_1^{[0,2]}) \cap \Pi\left(V(\phi_1^{[0,2]})\right) = \{0\}.$$

GLOBAL ASYMPTOTIC CONTROLLABILITY IMPLIES INPUT-TO-STATE STABILIZATION*

MICHAEL MALISOFF†, LUDOVIC RIFFORD‡, AND EDUARDO SONTAG§

Abstract. The main problem addressed in this paper is the design of feedbacks for globally asymptotically controllable (GAC) control affine systems that render the closed-loop systems input-to-state stable (ISS) with respect to actuator errors. Extensions for fully nonlinear GAC systems with actuator errors are also discussed. Our controllers have the property that they tolerate small observation noise as well.

Key words. asymptotic controllability, Lyapunov functions, input-to-state stability, nonsmooth analysis

AMS subject classifications. 93B52, 93D15, 93D20

DOI. 10.1137/S0363012903422333

1. Introduction.

The theory of input-to-state stability (ISS) forms the basis for much of the current research in mathematical control theory (see [15, 22, 23]). The ISS property was introduced in [19]. In the past decade, there has been a great deal of research done on the problem of finding ISS stabilizing control laws (see [7, 8, 9, 12]). This paper is concerned with the ISS of control systems of the form

$$\dot{x} = f(x) + G(x)u, \tag{1.1}$$

where f and G are locally Lipschitz vector fields on $\mathbb{R}^n$, $f(0) = 0$, and the control u is valued in $\mathbb{R}^m$ (but see also section 5 for extensions for fully nonlinear systems). We assume throughout that (1.1) is globally asymptotically controllable (GAC), and we construct a feedback $K : \mathbb{R}^n \to \mathbb{R}^m$ for which

$$\dot{x} = f(x) + G(x)K(x) + G(x)u \tag{1.2}$$

is ISS. As pointed out in [3, 24], a continuous stabilizing feedback K fails to exist in general. This fact forces us to consider discontinuous feedbacks K, so our solutions will be taken in the more general sense of sampling and Euler solutions for dynamics that are discontinuous in the state. By an Euler solution, we mean a uniform limit of sampling solutions, taken as the frequency of sampling becomes infinite (see section 2 for precise definitions). This will extend [19, 20], which show how to make C^o-stabilizable systems ISS to actuator errors. In particular, our results apply to the nonholonomic integrator (see [3, 10] and section 4 below) and other applications where

Brockett's condition is not satisfied, and which therefore cannot be stabilized by continuous feedbacks (see [21, 22, 25]).

Our results also *strengthen* [6], which constructed feedbacks for GAC systems that render the closed-loop systems globally asymptotically stable (GAS). Our main tool will be the recent constructions of semiconcave control Lyapunov functions (CLFs) for GAC systems from [16, 17]. Our results also apply in the more general situation where measurement noise may occur. In particular, our feedback K will have the additional feature that the *perturbed* system

$$\dot{x} = f(x) + G(x)K(x+e) + G(x)u \tag{1.3}$$

is also ISS when the observation error $e : [0,\infty) \to \mathbb{R}^n$ in the controller is *sufficiently small*. In this context, the precise value of $e(t)$ is unknown to the controller, but information about upper bounds on the magnitude of $e(t)$ can be used to design the feedback. We will prove the following:

THEOREM 1.1. *If* (1.1) *is GAC, then there exists a feedback* K *for which* (1.3) *is ISS for Euler solutions.*

The preceding theorem characterizes the uniform limits of sampling solutions of (1.3) (see section 2 for the precise definitions of Euler and sampling solutions). From a computational standpoint, it is also desirable to know how frequently to sample in order to achieve ISS for sampling solutions. This information is provided in the following semidiscrete version of Theorem 1.1 for sampling solutions:

THEOREM 1.2. *If* (1.1) *is GAC, then there exists a feedback* K *for which* (1.3) *is ISS for sampling solutions.*

This paper is organized as follows. In section 2, we review the relevant background on CLFs, ISS, nonsmooth analysis, and discontinuous feedbacks. In section 3, we prove our main results. This is followed in section 4 by a comparison of our feedback construction with the known feedback constructions for C^o-stabilizable systems, and an application of our results to the nonholonomic integrator. We close in section 5 with an extension for fully nonlinear systems.

2. Definitions and main lemmas. Let $\mathcal{K}_\infty$ denote the set of all continuous functions $\rho : [0,\infty) \to [0,\infty)$ for which (i) $\rho(0) = 0$ and (ii) ρ is strictly increasing and unbounded. Note for future reference that $\mathcal{K}_\infty$ is closed under inverse and composition (i.e., if $\rho_1, \rho_2 \in \mathcal{K}_\infty$, then $\rho_1^{-1}, \rho_1 \circ \rho_2 \in \mathcal{K}_\infty$). We let $\mathcal{KL}$ denote the set of all continuous functions $\beta : [0,\infty) \times [0,\infty) \to [0,\infty)$ for which (1) $\beta(\cdot, t) \in \mathcal{K}_\infty$ for each $t \geq 0$, (2) $\beta(s,\cdot)$ is nonincreasing for each $s \geq 0$, and (3) $\beta(s,t) \to 0$ as $t \to +\infty$ for each $s \geq 0$.

For each $k \in \mathbb{N}$ and $r > 0$, we define

$$\mathcal{M}^k = \{\text{measurable } u : [0,\infty) \to \mathbb{R}^k : |u|_\infty < \infty\}$$

and $\mathcal{M}^k_r := \{u \in \mathcal{M}^k : |u|_\infty \leq r\}$, where $|\cdot|_\infty$ is the essential supremum. We let $\|u(s)\|_I$ denote the essential supremum of a function u restricted to an interval I. Let $|\cdot|$ denote the Euclidean norm, in the appropriate dimension, and

$$r\mathcal{B}_k := \{x \in \mathbb{R}^k : |x| < r\}$$

for each $k \in \mathbb{N}$ and $r > 0$. The closure of $r\mathcal{B}_k$ is denoted by $r\bar{\mathcal{B}}_k$, and $\mathrm{bd}(S)$ denotes the boundary of any subset S in Euclidean space. We also set

$$\mathcal{O} := \{e : [0,\infty) \to \mathbb{R}^n\}, \ \ \sup(e) = \sup\{|e(t)| : t \geq 0\}$$

for all $e \in \mathcal{O}$, and $\mathcal{O}_\eta := \{e \in \mathcal{O} : \sup(e) \leq \eta\}$ for each $\eta > 0$. For any compact set $\mathcal{F} \subseteq \mathbb{R}^n$ and $\varepsilon > 0$, we define the compact set

$$\mathcal{F}^\varepsilon := \{x \in \mathbb{R}^n : \min\{|x - p| : p \in \mathcal{F}\} \leq \varepsilon\},$$

i.e., the "ε-enlargement of $\mathcal{F}$." Given a continuous function

$$h : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n : (x, u) \mapsto h(x, u)$$

that is locally Lipschitz in x uniformly on compact subsets of $\mathbb{R}^n \times \mathbb{R}^m$, we let $\phi_h(\cdot, x_o, u)$ denote the trajectory of $\dot{x} = h(x, u)$ starting at $x_o \in \mathbb{R}^n$ for each choice of $u \in \mathcal{M}^m$. In this case, $\phi_h(\cdot, x_o, u)$ is defined on some maximal interval $[0, t)$, with $t > 0$ depending on u and x_o. Let C^k denote the set of all continuous functions $\varphi : \mathbb{R}^n \to \mathbb{R}$ that have at least k continuous derivatives (for $k = 0, 1$). We use the following controllability notion, which was introduced in [18] and later reformulated in terms of $\mathcal{KL}$ functions in [22]:

DEFINITION 2.1. *We call the system $\dot{x} = h(x, u)$* globally asymptotically controllable (GAC) *provided there are a nondecreasing function $\sigma : [0, \infty) \to [0, \infty)$ and a function $\beta \in \mathcal{KL}$ satisfying the following: for each $x_o \in \mathbb{R}^n$, there exists $u \in \mathcal{M}^m$ such that*

(a) $|\phi_h(t, x_o, u)| \leq \beta(|x_o|, t)$ *for all $t \geq 0$; and*
(b) $|u(t)| \leq \sigma(|x_o|)$ *for a.e. $t \geq 0$.*

In this case, we call σ the GAC modulus *of $\dot{x} = h(x, u)$.*

In our main results, the controllers will be taken to be discontinuous feedbacks, so the dynamics will be discontinuous in the state variable. Therefore, we will form our trajectories through sampling and through uniform limits of sampling trajectories, as follows. We say that $\pi = \{t_o, t_1, t_2, \ldots\} \subset [0, \infty)$ is a *partition* of $[0, \infty)$ provided $t_o = 0$, $t_i < t_{i+1}$ for all $i \geq 0$, and $t_i \to \infty$ as $i \to +\infty$. The set of all partitions of $[0, \infty)$ is denoted by Par. Let

$$F : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m \to \mathbb{R}^n : (x, p, u) \mapsto F(x, p, u)$$

be a continuous function that is locally Lipschitz in x uniformly on compact subsets of $\mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m$. A *feedback* for F is defined to be any locally bounded function $K : \mathbb{R}^n \to \mathbb{R}^m$ for which $K(0) = 0$. In particular, we allow discontinuous feedbacks. The arguments x, p, and u in F are used to represent the state, feedback value, and actuator error, respectively.

Given a feedback $K : \mathbb{R}^n \to \mathbb{R}^m$, $\pi = \{t_o, t_1, t_2, \ldots\} \in \text{Par}$, $x_o \in \mathbb{R}^n$, $e \in \mathcal{O}$, and $u \in \mathcal{M}^m$, the *sampling solution* for the initial value problem (IVP)

$$\dot{x}(t) = F(x(t), K(x(t) + e(t)), u(t)), \tag{2.1}$$

$$x(0) = x_o \tag{2.2}$$

is the continuous function defined by recursively solving

$$\dot{x}(t) \;=\; F(x(t), K(x(t_i) + e(t_i)), u(t)) \tag{2.3}$$

from the initial time t_i up to time $s_i = t_i \vee \sup\{s \in [t_i, t_{i+1}] : x(\cdot) \text{ is defined on } [t_i, s)\}$, where $x(0) = x_o$. In this case, the sampling solution of (2.1)–(2.2) is defined on the right-open interval from time zero up to time $\bar{t} = \inf\{s_i : s_i < t_{i+1}\}$. This sampling solution will be denoted by $t \mapsto x_\pi(t; x_o, u, e)$ to exhibit its dependence on $\pi \in \text{Par}$,

$x_o \in \mathbb{R}^n$, $u \in \mathcal{M}^m$, and $e \in \mathcal{O}$, or simply by x_π, when the dependence is clear from the context. Note that if $s_i = t_{i+1}$ for all i, then $\bar{t} = +\infty$ (as the infimum of the empty set), so in that case, the sampling solution $t \mapsto x_\pi(t; x_o, u, e)$ is defined on $[0, \infty)$.

We also define the *upper diameter* and the *lower diameter* of a given partition $\pi = \{t_o, t_1, t_2, \ldots\}$ by

$$\overline{\mathbf{d}}(\pi) = \sup_{i \geq 0}(t_{i+1} - t_i), \quad \underline{\mathbf{d}}(\pi) = \inf_{i \geq 0}(t_{i+1} - t_i),$$

respectively. We let $\mathrm{Par}(\delta) := \left\{\pi \in \mathrm{Par} : \overline{\mathbf{d}}(\pi) < \delta\right\}$ for each $\delta > 0$. We will say that a function $y : [0, \infty) \to \mathbb{R}^n$ is an *Euler solution (robust to small observation errors)* of

$$\dot{x}(t) = F(x(t), K(x(t)), u(t)), \quad x(0) = x_o \tag{2.4}$$

for $u \in \mathcal{M}^m$ provided there are sequences $\pi_r \in \mathrm{Par}$ and $e_r \in \mathcal{O}$ such that

(a) $\overline{\mathbf{d}}(\pi_r) \to 0$;
(b) $\sup(e_r)/\underline{\mathbf{d}}(\pi_r) \to 0$; and
(c) $t \mapsto x_{\pi_r}(t; x_o, u, e_r)$ converges uniformly to y as $r \to +\infty$.

Note that the approximating trajectories in the preceding definition all use the same input u (but see Remark 2.4 for a more general notion of Euler solutions, which also involves sequences of inputs).

This paper will design feedbacks that make closed-loop GAC systems ISS with respect to actuator errors. More precisely, we will use the following definition:

Definition 2.2. *We say that* (2.1) *is* ISS for sampling solutions *provided there are* $\beta \in \mathcal{KL}$ *and* $\gamma \in \mathcal{K}_\infty$ *satisfying: For each* $\varepsilon, M, N > 0$ *with* $0 < \varepsilon < M$*, there exist positive* $\delta = \delta(\varepsilon, M, N)$ *and* $\kappa = \kappa(\varepsilon, M, N)$ *such that for each* $\pi \in \mathrm{Par}(\delta)$*,* $x_o \in M\bar{\mathcal{B}}_n$*,* $u \in \mathcal{M}^m_N$*, and* $e \in \mathcal{O}$ *for which* $\sup(e) \leq \kappa \underline{\mathbf{d}}(\pi)$*,*

$$|x_\pi(t; x_o, u, e)| \leq \max\{\beta(M, t) + \gamma(N), \varepsilon\} \tag{2.5}$$

for all $t \geq 0$.

Roughly speaking, condition (2.5) says that the system is ISS, modulo small overflows, if the sampling is done "quickly enough," as determined by the condition $\pi \in \mathrm{Par}(\delta)$, but "not too quickly," as determined by the additional requirement that $\underline{\mathbf{d}}(\pi) \geq (1/\kappa)\sup(e)$. In the special case where the observation error $e \equiv 0$, the condition on $\underline{\mathbf{d}}(\pi)$ in Definition 2.2 is no longer needed; our results are new even for this particular case.

Notice that the bounds on e are in the supremum, not the essential supremum. It is easy to check that Definition 2.2 remains unchanged if we replace the right-hand side in (2.5) by $\beta(M, t) + \gamma(N) + \varepsilon$. We also use the following analogue of Definition 2.2 for Euler solutions:

Definition 2.3. *We say that the system* (2.1) *is* ISS for Euler solutions *provided there exist* $\beta \in \mathcal{KL}$ *and* $\gamma \in \mathcal{K}_\infty$ *satisfying: If* $u \in \mathcal{M}^m$ *and* $x_o \in \mathbb{R}^n$*, and if* $t \mapsto x(t)$ *is an Euler solution of* (2.4)*, then*

$$|x(t)| \leq \beta(|x_o|, t) + \gamma(|u|_\infty) \tag{2.6}$$

for all $t \geq 0$.

Remark 2.4. In the definition of Euler solutions we gave above, all of the approximating trajectories $t \mapsto x_{\pi_r}(t; x_o, u, e_r)$ use the same input $u \in \mathcal{M}^m$. A different way to define Euler solutions, which gives rise to a more general class of limiting solutions, is as follows: A function $y : [0, \infty) \to \mathbb{R}^n$ is a *generalized Euler solution* of (2.4) for $u \in \mathcal{M}^m$ provided there are sequences $\pi_r \in \mathrm{Par}$, $e_r \in \mathcal{O}$, and $u_r \in \mathcal{M}^m$ such that

(a) $\overline{\mathbf{d}}(\pi_r) \to 0$;
(b) $\sup(e_r)/\underline{\mathbf{d}}(\pi_r) \to 0$;
(c) $|u_r|_\infty \leq |u|_\infty$ for all r; and
(d) $t \mapsto x_{\pi_r}(t; x_o, u_r, e_r)$ converges uniformly to y as $r \to +\infty$.

We can then define ISS for generalized Euler solutions exactly as in Definition 2.3, by merely replacing "Euler solution" with "generalized Euler solution" throughout the definition. Our proof of Theorem 1.1 will actually show the following slightly more general result: If (1.1) is GAC, then there exists a feedback K for which (1.3) is ISS for generalized Euler solutions.

Our main tools in this paper will be nonsmooth analysis and nonsmooth Lyapunov functions. The following definitions will be used. Let Ω be an arbitrary open subset of $\mathbb{R}^n$. Recall the following definition:

DEFINITION 2.5. *Let $g : \Omega \to \mathbb{R}$ be a continuous function on Ω; it is said to be* semiconcave *on Ω provided for each point $x_o \in \Omega$, there exist $\rho, C > 0$ such that*

$$g(x) + g(y) - 2g\left(\frac{x+y}{2}\right) \leq C||x-y||^2$$

for all $x, y \in x_o + \rho\mathcal{B}_n$.

The *proximal superdifferential* (respectively, *proximal subdifferential*) of a function $V : \Omega \to \mathbb{R}$ at $x \in \Omega$, which is denoted by $\partial^P V(x)$ (resp., $\partial_P V(x)$), is defined to be the set of all $\zeta \in \mathbb{R}^n$ for which there exist $\sigma, \eta > 0$ such that

$$V(y) - V(x) - \sigma|y-x|^2 \leq \langle \zeta, y-x\rangle \quad (\text{resp., } V(y) - V(x) + \sigma|y-x|^2 \geq \langle \zeta, y-x\rangle)$$

for all $y \in x + \eta\mathcal{B}_n$. The *limiting subdifferential* of a continuous function $V : \Omega \to \mathbb{R}$ at $x \in \Omega$ is

$$\partial_L V(x) := \{q \in \mathbb{R}^n : \exists x_n \to x \quad \text{and} \quad q_n \in \partial_P V(x_n) \ \text{ s.t. } \ q_n \to q\}.$$

In what follows, we assume $h : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n : (x,u) \mapsto h(x,u)$ is continuous, that it is locally Lipschitz in x uniformly on compact subsets of $\mathbb{R}^n \times \mathbb{R}^m$, and that $h(0,0) = 0$. The following definition was introduced in [18] and reformulated in proximal terms in [22].

DEFINITION 2.6. *A* control-Lyapunov function (CLF) *for*

$$\dot{x} = h(x,u) \tag{2.7}$$

is a continuous, positive definite, proper function $V : \mathbb{R}^n \to \mathbb{R}$ for which there exist a continuous, positive definite function $W : \mathbb{R}^n \to \mathbb{R}$, and a nondecreasing function $\alpha : [0,\infty) \to [0,\infty)$, satisfying

$$\forall \zeta \in \partial_P V(x), \quad \inf_{|u| \leq \alpha(|x|)} \langle \zeta, h(x,u)\rangle \leq -W(x)$$

for all $x \in \mathbb{R}^n$. In this case, we call (V,W) a Lyapunov pair *for* (2.7).

Recall the following lemmas (see [17]):

LEMMA 2.7. *If* (2.7) *is GAC, then there exist a CLF V for* (2.7) *that is semiconcave on $\mathbb{R}^n \setminus \{0\}$ and a nondecreasing function $\alpha : [0,\infty) \to [0,\infty)$ that satisfy*

$$\forall \zeta \in \partial_L V(x), \quad \min_{|u| \leq \alpha(|x|)} \langle \zeta, h(x,u)\rangle \leq -V(x) \tag{2.8}$$

for all $x \in \mathbb{R}^n$.

LEMMA 2.8. *Let $V : \Omega \to \mathbb{R}$ be semiconcave. Then V is locally Lipschitz, and $\emptyset \neq \partial_L V(x) \subseteq \partial^P V(x)$ for all $x \in \Omega$. Moreover, for each compact set $Q \subset \Omega$, there exist constants $\sigma, \mu > 0$ such that $V(y) - V(x) - \sigma|y - x|^2 \leq \langle \zeta, y - x \rangle$ for all $y \in x + \mu\mathcal{B}_n$, all $x \in Q$, and all $\zeta \in \partial^P V(x)$.*

Notice that Lemma 2.8 allows the constants in the definition of $\partial^P V(x)$ to be chosen uniformly on compact sets.

Remark 2.9. In [17], the controls u take all their values in a given compact metric space U. The precise version of the CLF existence theorem in [17] is the same as our Lemma 2.7, except that the infimum in the decay condition (2.8) is replaced by the infimum over all $u \in U$. The version of Lemma 2.7 we gave above follows from a slight modification of the arguments of [16, 17], using the GAC modulus in the GAC definition (see Definition 2.1). The existence theory [16] for semiconcave CLFs is a strengthening of the proof that continuous CLFs exist for any GAC system (see [18]).

3. Proofs of theorems. Let V be a CLF satisfying the requirements of Lemma 2.7 for the dynamics

$$h(x, u) = f(x) + G(x)u. \tag{3.1}$$

Define the functions $\underline{\alpha}, \overline{\alpha} \in \mathcal{K}_\infty$ by

$$\underline{\alpha}(s) = \min\{|x| : V(x) \geq s\} \text{ and } \overline{\alpha}(s) = \max\{|x| : V(x) \leq s\}. \tag{3.2}$$

One can easily check that

$$\forall x \in \mathbb{R}^n, \quad \underline{\alpha}(V(x)) \leq |x| \text{ and } \overline{\alpha}(V(x)) \geq |x|. \tag{3.3}$$

Moreover, by reducing $\underline{\alpha}$, we may assume that $\underline{\alpha}(s) \leq s$ for all $s \geq 0$, while still satisfying (3.3).

Let $x \mapsto \zeta(x)$ be any selection of $\partial_L V(x)$ on $\mathbb{R}^n$ and let $\zeta(0) \in \mathbb{R}^n$ be arbitrary. For each $x \in \mathbb{R}^n$, we can choose $u = u_x \in \alpha(|x|)\mathcal{B}_m$ that satisfies the inequality in (2.8) for the dynamics (3.1) and $\zeta = \zeta(x)$. Define the feedback $K_1 : \mathbb{R}^n \to \mathbb{R}^m$ by $K_1(x) = u_x$ for all $x \neq 0$ and $K_1(0) = 0$. We use the functions

$$\begin{array}{l} a(x) = \langle \zeta(x), f(x) + G(x)K_1(x) \rangle, \;\; b_j(x) = \langle \zeta(x), g_j(x) \rangle \quad \forall j, \\ K_2(x) = -V(x)(\operatorname{sgn}\{b_1(x)\}, \operatorname{sgn}\{b_2(x)\}, \ldots, \operatorname{sgn}\{b_m(x)\})^T, \end{array} \tag{3.4}$$

where g_j is the jth column of G for $j = 1, 2, \ldots, m$, and

$$\operatorname{sgn}\{s\} \;\; = \;\; \begin{cases} 1, & s > 0, \\ -1, & s < 0, \\ 0, & s = 0. \end{cases}$$

We remark that our results remain true, with minor changes in the proofs, if the factor $-V(x)$ in the definition of K_2 is replaced by $-W(x)$ for an arbitrary positive definite proper continuous function $W : \mathbb{R}^n \to \mathbb{R}$. In particular, $K := K_1 + K_2$ is a feedback for the dynamics

$$F(x, p, u) = f(x) + G(x)(p + u).$$

Moreover,

$$a(x) \leq -V(x) < 0 \;\; \forall x \in \mathbb{R}^n \setminus \{0\}. \tag{3.5}$$

We next show that

$$\dot{x}(t) = F(x(t), K(x(t) + e(t)), u(t)) \tag{3.6}$$

is ISS for sampling solutions.

To this end, choose $\varepsilon, M, N > 0$ for which $0 < \varepsilon < M$. It clearly suffices to verify the ISS property (2.5) for $\varepsilon < 1$, since that would imply the property for *all* overflows $\varepsilon > 0$. Choose

$$u \in \mathcal{M}_N^m, \;\; e \in \mathcal{O}_{\varepsilon/16}, \;\; x_o \in M\bar{\mathcal{B}}_n. \tag{3.7}$$

In what follows, x_π denotes the sampling solution for (3.6) for the choices (3.7) and $\pi \in \mathrm{Par}$, and $\tilde{x}_\pi$ is the (possibly discontinuous) function that is inductively defined by solving the IVP

$$\dot{x}(t) = f(x(t)) + G(x(t))[K(\tilde{x}_i) + u(t)], \;\; x(t_i) = \tilde{x}_i$$

on $[t_i, t_{i+1})$, where $\tilde{x}_i := x_i + e(t_i)$, $x_i := x_\pi(t_i)$, and $\pi = \{t_o, t_1, t_2, \ldots\}$. We later restrict the choice of π so that x_π and $\tilde{x}_\pi$ are defined on $[0, \infty)$. We will use the compact set

$$Q = \left\{ \left[\overline{\alpha} \circ \underline{\alpha}^{-1}(N + M) + 1 \right] \bar{\mathcal{B}}_n \right\} \setminus \varepsilon \mathcal{B}_n.$$

Notice that $Q, Q^{\varepsilon/2} \subseteq \mathbb{R}^n \setminus \{0\}$, and that $x_o \in Q^\varepsilon$. Using Lemma 2.8 and the semiconcavity of V on $\mathbb{R}^n \setminus \{0\}$, we can find $\sigma, \mu > 0$ such that

$$V(y) - V(x) \leq \langle \zeta(x), y - x \rangle + \sigma |y - x|^2 \tag{3.8}$$

for all $y \in x + \mu \mathcal{B}_n$ and $x \in Q^{\varepsilon/2}$. Let $\mathcal{L}_\varepsilon > 1$ be a Lipschitz constant for V on $Q^{\varepsilon/2}$, the existence of which is also guaranteed by Lemma 2.8. It follows from the definition of a CLF that

$$\begin{aligned} \lambda_- &:= \min \left\{ V(p) : p \in Q^{\varepsilon/2} \right\}, \\ \lambda_+ &:= \max \left\{ V(p) : p \in Q^{\varepsilon} \right\} \end{aligned} \tag{3.9}$$

are finite positive numbers. Therefore, we can choose $\tilde{\varepsilon} \in (0, \varepsilon)$ for which

$$\overline{\alpha}\left(p + \frac{\mathcal{L}_\varepsilon}{4} \tilde{\varepsilon} \right) \leq \overline{\alpha}(p) + \frac{\varepsilon}{8} \qquad \forall p \in \left[0, \underline{\alpha}^{-1}(N) + \lambda_+ \right]. \tag{3.10}$$

We can also find

$$\delta = \delta(\varepsilon, M, N) \in \left(0, \frac{\tilde{\varepsilon}}{16 + \lambda_+ + 16\lambda_+} \right) \tag{3.11}$$

such that if

$$\pi \in \mathrm{Par}(\delta), \;\; e \in \mathcal{O}_{\tilde{\varepsilon}/16}, \;\; x_i \in Q^\varepsilon, \tag{3.12}$$

and if $t \in [t_i, t_{i+1})$ is such that $x_\pi(s)$ and $\tilde{x}_\pi(s)$ remain in $Q^{2\varepsilon}$ for all $s \in [t_i, t]$, then

$$\max\{|x_\pi(t) - x_i|, |\tilde{x}_\pi(t) - \tilde{x}_i|\} \leq \min \left\{ \mu, \frac{\tilde{\varepsilon}}{16(1 + \mathcal{L}_\varepsilon)}, \sqrt{\frac{\lambda_-}{8\sigma}(t - t_i)} \right\}. \tag{3.13}$$

This follows from the local boundedness of K, f, and G. It follows from (3.13) that $\tilde{x}_\pi(t) \in Q^{\varepsilon/4}$ (resp., $x_\pi(t) \in Q^{\varepsilon/4}$) for all $t \in [t_i, t_{i+1})$ and all i such that $\tilde{x}_i \in Q$ (resp., $x_i \in Q$), since the trajectories cannot move the initial value more than $\frac{\varepsilon}{16}$ and there are no blow up times for the trajectories. In particular, (3.13) will show that x_π and $\tilde{x}_\pi$ are defined on $[0, \infty)$, since the argument we are about to give shows that $x_i \in Q^\varepsilon$ for all i. By reducing δ as necessary, we can assume

$$\begin{array}{l} \|\zeta(\tilde{x}_i) \cdot (F(\tilde{x}_i, K(\tilde{x}_i), u(s)) - f(\tilde{x}_\pi(s)) \\ -G(\tilde{x}_\pi(s))[u(s) + K(\tilde{x}_i)]) \|_{[t_i, t_{i+1})} \leq \frac{\lambda_-}{8} \end{array} \tag{3.14}$$

for all i such that $\tilde{x}_i \in Q^{\varepsilon/2}$. This follows from the Lipschitzness of f and G on Q^ε. Having chosen δ to satisfy the preceding requirements, pick any $\pi \in \mathrm{Par}(\delta)$. It follows from (3.8) and (3.13) that

$$\begin{array}{rcl} V(\tilde{x}_\pi(t)) - V(\tilde{x}_i) & \leq & \langle \zeta(\tilde{x}_i), \tilde{x}_\pi(t) - \tilde{x}_i \rangle + \sigma |\tilde{x}_\pi(t) - \tilde{x}_i|^2 \\ & \leq & \langle \zeta(\tilde{x}_i), \tilde{x}_\pi(t) - \tilde{x}_i \rangle + \frac{\lambda_-}{8}(t - t_i) \end{array} \tag{3.15}$$

for all $t \in [t_i, t_{i+1})$ and all i such that $\tilde{x}_i \in Q^{\varepsilon/4}$. Moreover, if $\tilde{x}_i \in Q^{\varepsilon/4}$ and $t \in [t_i, t_{i+1})$, and if

$$V(\tilde{x}_i) \geq N, \tag{3.16}$$

then

$$\begin{array}{rcl} \langle \zeta(\tilde{x}_i), \tilde{x}_\pi(t) - \tilde{x}_i \rangle & \leq & \left\langle \zeta(\tilde{x}_i), \displaystyle\int_{t_i}^{t} F(\tilde{x}_i, K(\tilde{x}_i), u(s)) \mathrm{d}s \right\rangle + \frac{\lambda_-}{8}(t - t_i) \quad \text{(by (3.14))} \\ & = & (t - t_i) \langle \zeta(\tilde{x}_i), f(\tilde{x}_i) + G(\tilde{x}_i) K(\tilde{x}_i) \rangle \\ & & + \displaystyle\int_{t_i}^{t} \langle \zeta(\tilde{x}_i), G(\tilde{x}_i) u(s) \rangle \mathrm{d}s + \frac{\lambda_-}{8}(t - t_i) \\ & \leq & (t - t_i) a(\tilde{x}_i) - (t - t_i) V(\tilde{x}_i) \displaystyle\sum_{j=1}^{m} |b_j(\tilde{x}_i)| \\ & & + N(t - t_i) \displaystyle\sum_{j=1}^{m} |b_j(\tilde{x}_i)| + \frac{\lambda_-}{8}(t - t_i) \\ & \leq & (t - t_i) a(\tilde{x}_i) + \frac{\lambda_-}{8}(t - t_i) \quad \text{(by (3.16))} \\ & \leq & -(t - t_i) V(\tilde{x}_i) + \frac{\lambda_-}{8}(t - t_i) \quad \text{(by (3.5))}. \end{array} \tag{3.17}$$

Let

$$S = \{x \in \mathbb{R}^n : V(x) \leq \underline{\alpha}^{-1}(N)\}.$$

Then $S \subset Q^\varepsilon$. Indeed, $x \in S$ implies

$$\underline{\alpha} \circ \overline{\alpha}^{-1}(|x|) \leq \underline{\alpha} \circ \overline{\alpha}^{-1} \circ \overline{\alpha} \circ V(x) \leq N,$$

and therefore $|x| \leq \overline{\alpha} \circ \underline{\alpha}^{-1}(N)$. By further reducing ε, we can assume $(2\varepsilon)\mathcal{B}_n \subset S$. If $\tilde{x}_i \in Q^{\varepsilon/4}$ but $\tilde{x}_i \notin S$, then $V(\tilde{x}_i) \geq \underline{\alpha}^{-1}(N) \geq N$, so (3.9) and (3.15) give

$$\begin{array}{rcl} V(\tilde{x}_\pi(t)) - V(\tilde{x}_i) & \leq & -(t - t_i) \dfrac{V(\tilde{x}_i)}{2} + (t - t_i) \dfrac{\lambda_-}{4} \\ & \leq & -(t - t_i) \dfrac{V(\tilde{x}_i)}{4} \qquad \forall t \in [t_i, t_{i+1}). \end{array} \tag{3.18}$$

Let $\mathcal{L}_f$ and $\mathcal{L}_G$ be Lipschitz constants for f and G restricted to Q^ε, respectively. Define the constants

$$\begin{aligned} &R = N + \sup\left\{|K(x)| : x \in Q^{\varepsilon/2}\right\}, \\ &L = \mathcal{L}_f + R\mathcal{L}_G, \quad \kappa = \kappa(\varepsilon, M, N) := \frac{\min\{\lambda_-, \varepsilon\}}{16\mathcal{L}_\varepsilon(e^{L\delta}+1)}. \end{aligned} \tag{3.19}$$

We will presently show that

$$\sup_{t_i \le t < t_{i+1}} |x_\pi(t) - \tilde{x}_\pi(t)| \le |e(t_i)|e^{L\delta} \qquad \forall i \text{ s.t. } x_i \in Q^{\varepsilon/4}. \tag{3.20}$$

Using (3.20), we will now find $\beta \in \mathcal{KL}$ and $\gamma \in \mathcal{K}$ to satisfy the ISS estimate

$$|x_\pi(t)| \le \beta(|x_o|, t) + \gamma(N) + \varepsilon \ \ \forall t \ge 0 \tag{3.21}$$

which will prove Theorem 1.2.

To this end, assume $x_i \in Q$, but that $x_i \notin S^{\tilde{\varepsilon}/16}$. Then (3.13) implies $x_\pi(t)$ and $\tilde{x}_\pi(t)$ both remain in $Q^{\varepsilon/4}$ on $[t_i, t_{i+1})$. Moreover, $\tilde{x}_i \in Q^{\varepsilon/4} \setminus S$, by the choice of e in (3.12). Therefore, if $t \in [t_i, t_{i+1})$, and if

$$\sup(e) \le \kappa \underline{\mathbf{d}}(\pi), \tag{3.22}$$

then the choice of κ gives

$$\begin{aligned} V(x_{i+1}) - V(x_i) &= V(x_{i+1}) - V(\tilde{x}_\pi(t_{i+1}^-)) + V(\tilde{x}_\pi(t_{i+1}^-)) - V(\tilde{x}_i) \\ &\quad + V(\tilde{x}_i) - V(x_i) \\ &\le \mathcal{L}_\varepsilon |x_{i+1} - \tilde{x}_\pi(t_{i+1}^-)| - \frac{t_{i+1}-t_i}{4} V(\tilde{x}_i) \\ &\quad + \mathcal{L}_\varepsilon |e(t_i)| \ \text{(by (3.18))} \\ &\le \mathcal{L}_\varepsilon |e(t_i)| e^{L\delta} - \frac{t_{i+1}-t_i}{4} V(\tilde{x}_i) + \mathcal{L}_\varepsilon |e(t_i)| \ \text{(by (3.20))} \\ &\le \frac{\lambda_-}{16}(t_{i+1}-t_i) - \frac{t_{i+1}-t_i}{4} V(\tilde{x}_i) \ \text{(by (3.22))} \\ &\le -\frac{t_{i+1}-t_i}{8} V(\tilde{x}_i) \ \text{(by (3.9))} \\ &\le -\frac{t_{i+1}-t_i}{8} V(x_i) + \frac{t_{i+1}-t_i}{8} |e(t_i)| \mathcal{L}_\varepsilon \\ &\le -\frac{t_{i+1}-t_i}{8} V(x_i) + \frac{(t_{i+1}-t_i)^2}{16} \lambda_- \\ &\le -\frac{t_{i+1}-t_i}{16} V(x_i), \end{aligned} \tag{3.23}$$

where we use

$$t_{i+1} - t_i \ \le \ \overline{\mathbf{d}}(\pi) \ \le \ \delta < 1$$

to get the last inequality. Set

$$J(t) = \frac{16}{16+t}$$

for all $t \ge 0$. One can easily check that Q^ε contains the set

$$S_V := \{p : V(p) \le \max\{V(q) : |q| \le M + N\}\}.$$

In fact, $p \in S_V$ implies

$$\begin{aligned} |p| &\leq \overline{\alpha}\,(\max\{V(q) : |q| \leq M+N\}) \\ &= \max\{\overline{\alpha} \circ \underline{\alpha}^{-1} \circ \underline{\alpha}(V(q)) : |q| \leq M+N\} \\ &\leq \overline{\alpha} \circ \underline{\alpha}^{-1}(M+N). \end{aligned}$$

In particular, $x_o \in S_V$. It follows from (3.23) that if none of $x_o, x_1, \ldots, x_j$ lies in $S^{\tilde{\varepsilon}/16}$, then

$$\begin{aligned} V(x_1) - V(x_0) &\leq -\frac{t_1}{16} V(x_j), \\ V(x_2) - V(x_1) &\leq -\frac{t_2 - t_1}{16} V(x_j), \\ &\vdots \\ V(x_j) - V(x_{j-1}) &\leq -\frac{t_j - t_{j-1}}{16} V(x_j). \end{aligned}$$

Summing the preceding inequalities would then give

$$V(x_j) - V(x_o) \;\leq\; -\frac{t_j}{16} V(x_j), \quad \text{so} \quad V(x_j) \;\leq\; J(t_j) V(x_o)\,.$$

Hence,

$$V(x_i) \leq J(t_i) V(x_o) \quad \text{for} \quad i = 0, 1, \ldots, j.$$

By the choice of δ in (3.11), it would then follow from (3.13) that

$$V(x_\pi(t)) \leq J(t) V(x_o) + \frac{\tilde{\varepsilon}}{8}$$

up to the least time t at which $x_\pi(t) \in S^{\tilde{\varepsilon}/16}$. Hence, for such t, the choice of $\tilde{\varepsilon}$ (see (3.10)) gives

$$\begin{aligned} |x_\pi(t)| &\leq \overline{\alpha}\left(J(t)V(x_o) + \tfrac{\tilde{\varepsilon}}{8}\right), \\ &\leq \overline{\alpha}\,(J(t)V(x_o)) + \tfrac{\varepsilon}{8}. \end{aligned}$$

On the other hand, (3.23) also shows that if $x_\pi(t) \in S^{\tilde{\varepsilon}/8}$ for some t, then

$$|x_\pi(s)| \leq \overline{\alpha} \circ \underline{\alpha}^{-1}(N) + \varepsilon \;\; \forall s \geq t. \tag{3.24}$$

Indeed, let s_1 be the first sample time above such a time t. Assume $x_\pi(t) \notin \varepsilon \mathcal{B}_n$. By (3.13), $x_\pi(s_1) \in S^{\tilde{\varepsilon}/4}$ and $x_\pi(s_1) \notin \frac{\varepsilon}{2}\mathcal{B}_n$. Therefore, there exists $p \in S$ for which

$$\begin{aligned} V(x_\pi(s_1)) &= V(x_\pi(s_1)) - V(p) + V(p) \\ &\leq \mathcal{L}_\varepsilon \frac{\tilde{\varepsilon}}{4} + \underline{\alpha}^{-1}(N). \end{aligned}$$

In fact, we can pick $p = x_\pi(s_1)$ if $x_\pi(s_1) \in S$ and $p \in \partial S$ otherwise, so $p \notin \frac{\varepsilon}{2}\mathcal{B}_n$. It follows from (3.13) and (3.23) that for the next sample time s_i, we either have $x_\pi(s_i) \in S^{\tilde{\varepsilon}/8}$, or else we have

$$V(x_\pi(s_i)) \leq \mathcal{L}_\varepsilon \frac{\tilde{\varepsilon}}{4} + \underline{\alpha}^{-1}(N).$$

In the first case,

$$|x_\pi(s_i)| \le \overline{\alpha} \circ \underline{\alpha}^{-1}(N) + \frac{\varepsilon}{8},$$

while in the second case,

$$|x_\pi(s_i)| \le \overline{\alpha}\left(\frac{\tilde{\varepsilon}\mathcal{L}_\varepsilon}{4} + \underline{\alpha}^{-1}(N)\right) \le \overline{\alpha} \circ \underline{\alpha}^{-1}(N) + \frac{\varepsilon}{8},$$

by the choice of $\tilde{\varepsilon}$. If $x_\pi(s_i) \notin S^{\tilde{\varepsilon}/16}$, then $V(x_\pi(s_{i+1})) \le V(x_\pi(s_i))$ (by (3.23)), so the preceding argument also gives

$$|x_\pi(s_{i+1})| \le \overline{\alpha} \circ \underline{\alpha}^{-1}(N) + \frac{\varepsilon}{8}.$$

By repeating this argument for subsequent sample times, the assertion (3.24) then follows from (3.13). Defining $\beta \in \mathcal{KL}$ and $\gamma \in \mathcal{K}_\infty$ by

$$\beta(s,t) = \overline{\alpha}\left(\underline{\alpha}^{-1}(s)J(t)\right), \quad \gamma(s) = \overline{\alpha} \circ \underline{\alpha}^{-1}(s), \tag{3.25}$$

it follows that (3.21) holds for all $x_o \in M\bar{\mathcal{B}}_n$, $u \in \mathcal{M}_N^m$, $\pi \in \mathrm{Par}(\delta)$, and $e \in \mathcal{O}$ for which $\sup(e) \le \kappa \underline{\mathbf{d}}(\pi)$. Therefore, Theorem 1.2 will follow once we check (3.20), which is a consequence of Gronwall's inequality.

To this end, notice that if $x_i \in Q^{\varepsilon/4}$, then

$$|x_\pi(t) - \tilde{x}_\pi(t)| \le |x_i - \tilde{x}_i| + \int_{t_i}^t (\mathcal{L}_f|x_\pi(s) - \tilde{x}_\pi(s)| + R\mathcal{L}_G|x_\pi(s) - \tilde{x}_\pi(s)|)\,\mathrm{d}s$$

for all $t \in [t_i, t_{i+1})$, where we are using the constants in (3.19). It follows from Gronwall's inequality that

$$|x_\pi(t) - \tilde{x}_\pi(t)| \le |x_i - \tilde{x}_i| e^{L|t_i - t_{i+1}|} \le |x_i - \tilde{x}_i| e^{L\overline{\mathbf{d}}(\pi)} \le |e(t_i)| e^{L\delta}$$

for all $t \in [t_i, t_{i+1})$, which is (3.20). This proves Theorem 1.2.

We turn next to Theorem 1.1. We need to show the ISS property (2.6) for all Euler solutions $x(t)$ of (2.4). We will actually prove the slightly stronger version of the theorem for generalized Euler solutions, as asserted in Remark 2.4. To this end, choose $u \in \mathcal{M}^m$, $x_o \in \mathbb{R}^n$, and $\varepsilon > 0$. Using our previous conclusion that (1.3) is ISS for sampling solutions, we can let

$$\delta_\varepsilon = \delta(\varepsilon, |x_o|, |u|_\infty) \quad \text{and} \quad \kappa_\varepsilon = \kappa(\varepsilon, |x_o|, |u|_\infty)$$

be the constants from Definition 2.2. Let $x(t)$ be a generalized Euler solution of (2.4), and let π_r, u_r, and e_r satisfy the requirements of the generalized Euler solution definition. It follows from the definition that there is an $\bar{r} \in \mathbb{N}$ such that

$$\overline{\mathbf{d}}(\pi_r) \le \delta_\varepsilon, \quad \sup(e_r) \le \kappa_\varepsilon \underline{\mathbf{d}}(\pi_r)$$

for all $r \ge \bar{r}$. It then follows from (3.21) that

$$|x_{\pi_r}(t; x_o, u_r, e_r)| \le \beta(|x_o|, t) + \gamma(|u|_\infty) + \varepsilon \tag{3.26}$$

for all $t \ge 0$ and $r \ge \bar{r}$, where β and γ are in (3.25). The ISS condition (2.6) now follows by passing to the limit in (3.26) as $r \to \infty$, since $\varepsilon > 0$ was arbitrary. This concludes the proof of Theorem 1.1.

4. Stabilization of the nonholonomic integrator. In this section, we illustrate how the feedback constructed in section 3 can be used to stabilize Brockett's nonholonomic integrator control system (see [3, 10, 22]). We will also use the nonholonomic integrator to compare our feedback construction to the feedbacks from [19, 20]. The nonholonomic integrator was introduced in [3], as an example of a system that cannot be stabilized using continuous feedback. It is well known that if the state space of a system contains obstacles (e.g., if the state space is $\mathbb{R}^2 \setminus (-1,1)^2$, and therefore has a topological obstacle around the origin), then it is impossible to stabilize the system using continuous feedback. In fact, this is a special case of a theorem of Milnor, which asserts that the domain of attraction of an asymptotically stable vector field must be diffeomorphic to Euclidean space, and therefore cannot be the complement $\mathbb{R}^2 \setminus (-1,1)^2$ (see [21]).

Brockett's example illustrates how, even if we assume that the state evolves in Euclidean space, similar obstructions to stabilization may occur. These obstructions are not due to the topology of the state space, but instead arise from "virtual obstacles" that are implicit in the form of the control system (see [22]). Such obstacles occur when it is impossible to move *instantly* in some directions, even though it is possible to move *eventually* in every direction ("nonholonomy"). This gives rise to Brockett's criterion (see [3]), which is a necessary condition for the existence of a continuous stabilizer, in terms of the vector fields that define the system (see [21, 22, 25]). The nonholonomic integrator does not satisfy Brockett's criterion, and therefore cannot be stabilized by continuous feedbacks.

The physical model for Brockett's example is as follows. Consider a three-wheeled shopping cart whose front wheel acts as a castor. The state variable is $(x_1, x_2, \theta)^T$, where $(x_1, x_2)^T$ is the midpoint of the rear axle of the cart, and θ is the cart's orientation. The front wheel is free to rotate, but there is a "nonslipping" constraint that $(\dot{x}_1, \dot{x}_2)^T$ must always be parallel to $(\cos(\theta), \sin(\theta))^T$. This gives the equations

$$\begin{aligned} \dot{x}_1 &= v_1 \cos(\theta), \\ \dot{x}_2 &= v_1 \sin(\theta), \\ \dot{\theta} &= v_2, \end{aligned} \tag{4.1}$$

where v_1 is a "drive" command and v_2 is a steering command. Using the feedback transformation

$$\begin{aligned} &z_1 := \theta,\ z_2 := x_1 \cos(\theta) + x_2 \sin(\theta),\ z_3 := x_1 \sin(\theta) - x_2 \cos(\theta), \\ &u_1 := v_2,\ u_2 := v_1 - v_2 z_3 \end{aligned}$$

followed by a second transformation brings the equations (4.1) into the form

$$\begin{aligned} \dot{x}_1 &= u_1, \\ \dot{x}_2 &= u_2, \\ \dot{x}_3 &= x_1 u_2 - x_2 u_1, \end{aligned} \tag{4.2}$$

which is called the nonholonomic integrator control system.

One can show (see [11]) that (4.2) is a GAC system. However, since Brockett's condition is not satisfied for (4.2), the system has no continuous stabilizer. While there does not exist a C^1 CLF for the system (4.2) (see [11]), it is now well known that every GAC system admits a continuous CLF (see [18]). In fact, it was shown in [10] that the nonholonomic integrator dynamics (4.2) has the nonsmooth CLF

$$V(x) = \max\left\{ \sqrt{x_1^2 + x_2^2}, |x_3| - \sqrt{x_1^2 + x_2^2} \right\}, \tag{4.3}$$

which is semiconcave outside the cone $x_3^2 = 4(x_1^2+x_2^2)$ (see [17] for a detailed discussion of some special properties of this CLF). For the special case of the dynamics (4.2) and CLF (4.3), the feedback $K = K_1 + K_2$ we constructed in section 3 is as follows.

To simplify notation, we use the radius $r(x) := \sqrt{x_1^2 + x_2^2}$. We also use the sets

$$\begin{array}{rcl} S_o & = & \{x \in \mathbb{R}^3 : \ x_3 \neq 0, \ r(x) = 0\}, \\ S_+ & = & \{x \in \mathbb{R}^3 : \ x_3^2 \geq 4r^2(x) > 0\}, \\ S_- & = & \{x \in \mathbb{R}^3 : \ x_3^2 < 4r^2(x)\}, \end{array}$$

which form a partition of $\mathbb{R}^3 \setminus \{0\}$. Notice that $V(x) = r(x)$ on S_-, and also that $V(x) = |x_3| - r(x)$ on $\mathbb{R}^3 \setminus S_-$. To find our selection $\zeta(x) \in \partial_L V(x)$, we first choose $\zeta(0) = 0$, and $\zeta(x) = (0, -1, \mathrm{sgn}\{x_3\})^T$ for all $x \in S_o$. Using the notation of (3.4), this gives

$$b(x) = \begin{cases} (\, -x_2 \mathrm{sgn}\{x_3\} - x_1/r(x), \ x_1 \mathrm{sgn}\{x_3\} - x_2/r(x)\,)^T, & x \in S_+, \\ (\, x_1/r(x), \ x_2/r(x)\,)^T, & x \in S_-, \\ (0, -1)^T, & x \in S_o, \end{cases} \tag{4.4}$$

and $b(0) = 0$. Notice that $1 \leq |b(x)|^2 \leq r^2(x) + 1$ for all $x \neq 0$. We also have

$$K_1(x) = \begin{cases} \mu_1(x)\,(\, -x_2 \mathrm{sgn}\{x_3\} - x_1/r(x), \ x_1 \mathrm{sgn}\{x_3\} - x_2/r(x)\,)^T, & x \in S_+, \\ -\,(x_1, x_2)^T, & x \in S_-, \\ (0, |x_3|)^T, & x \in S_o, \end{cases}$$

with $K_1(0) = 0$, where we have set

$$\mu_1(x) := \frac{r(x) - |x_3|}{r^2(x) + 1}.$$

In this case, we have taken

$$K_1(x) = -b(x)V(x)/|b(x)|^2$$

for $x \neq 0$, where $b(x)$ is defined in (4.4), and K_1 is continuous at the origin. On the other hand, our feedback K_2 from (3.4) becomes

$$K_2(x) = -\begin{cases} (\, \mu_2(x_1, -x_2, x), \ \mu_2(x_2, x_1, x)\,)^T, & x \in S_+, \\ r(x)\,(\, \mathrm{sgn}\{x_1\}, \ \mathrm{sgn}\{x_2\}\,)^T, & x \in S_-, \\ |x_3|\,(0, \ -1)^T, & x \in S_0, \end{cases}$$

with $K_2(0) = 0$, where we have set

$$\mu_2(a, b, x) \ := \ (|x_3| - r(x)) \,\mathrm{sgn}\{\, b\, r(x) \,\mathrm{sgn}\{x_3\} - a\,\}.$$

Since V is semiconcave on $\Omega := \mathbb{R}^3 \setminus \mathrm{bd}(S_-)$, the argument from section 3 applies to sampling solutions that satisfy the additional requirement that $\tilde{x}_\pi(s) \in \Omega$ for all $s \geq 0$. It follows from the proof of Theorem 1.2 that the nonholonomic integrator system (4.2) can be stabilized for both actuator errors and small observation errors (for this restricted set of sampling solutions), using the combined feedback $K = K_1 + K_2$.

Remark 4.1. In this example, we chose to work with the CLF (4.3) because it has been explicitly proven in [10] to be a CLF for the control system (4.2). The

example illustrates how to extend our results to more general CLFs that may not be semiconcave on $\mathbb{R}^3 \setminus \{0\}$. For such cases, the ISS estimates hold for those sampling solutions that remain in the domain of semiconcavity of the CLF. On the other hand, we let the reader prove that the nonholonomic integrator system also has the CLF

$$\tilde{V}(x) = \left(\sqrt{x_1^2 + x_2^2} - |x_3|\right)^2 + x_3^2,$$

which is semiconcave on $\mathbb{R}^3 \setminus \{0\}$ (as the sum of the smooth function $x_1^2 + x_2^2 + 2x_3^2$ and a semiconcave function). Therefore, if we use $\tilde{V}$ to form our feedbacks, instead of the CLF (4.3), then our theorems apply directly, without any state restrictions on the sampling solutions.

Remark 4.2. The results in [19] designed feedbacks that make C^o-stabilizable systems ISS with respect to actuator errors. For the case of C^o-stabilizable systems, a smooth (i.e., C^∞) Lyapunov function is known to exist (see [1]). In [19], the system was rendered ISS using the feedback

$$\hat{K}(x) := -L_G V(x) = -\nabla V(x) G(x), \tag{4.5}$$

where V is a smooth CLF for the dynamics (1.1). In that case, (4.5) is continuous at the origin. However, in the more general situation where the system is merely GAC, there may not exist a smooth Lyapunov function, so V must be taken to be nonsmooth. In this case, the use of the nonsmooth analogue

$$\tilde{K}(x) := -\zeta(x) G(x) \tag{4.6}$$

of (4.5) (where $\zeta(x) \in \partial_L V(x)$ for all $x \neq 0$) could give rise to a feedback that would not be continuous at the origin. For example, if we use the nonholonomic integrator (4.2) and the CLF (4.3), then $\tilde{K}$ takes the values

$$\tilde{K}\left((\varepsilon, \varepsilon, 0)^T\right) = -\left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)^T, \quad \tilde{K}\left((\varepsilon, \varepsilon, 3\sqrt{2}\varepsilon)^T\right) = \left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)^T + \varepsilon(1, -1)^T,$$

so $\tilde{K}$ is discontinuous at the origin. On the other hand, our choice of K_2 is automatically continuous at the origin.

Remark 4.3. Under the additional hypothesis that (1.1) satisfies the small control property (see [21]), the system can be stabilized by a feedback that is continuous at the origin (see [17]). More precisely, suppose there exists a semiconcave CLF V satisfying the following: For each $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon) > 0$ such that $0 < |x| \leq \delta$ implies

$$\exists u_x \in \varepsilon \mathcal{B}_m \quad \text{s.t. } \forall \zeta \in \partial_P V(x), \ \ \langle \zeta, f(x) + G(x) u_x \rangle \leq -V(x).$$

Then the system can be rendered GAS by a feedback that is continuous at the origin (see [17]). For the case of the nonholonomic integrator (4.2), the system is GAS under the feedback K_1, which is continuous at the origin, so our total feedback $K = K_1 + K_2$ is continuous at the origin as well.

5. ISS for fully nonlinear GAC systems. We conclude with an extension of our results for fully nonlinear GAC systems

$$\dot{x} = f(x, u), \tag{5.1}$$

where we assume for simplicity that the observation error e in the controller is zero. We assume throughout this section that

$$f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n : (x, u) \mapsto f(x, u)$$

is continuous and locally Lipschitz in x uniformly on compact subsets of $\mathbb{R}^n \times \mathbb{R}^m$ and $f(0, 0) = 0$. It is natural to ask whether these hypotheses are sufficient for the existence of a continuous feedback $K(x)$ for which

$$\dot{x} = f(x, K(x) + u) \tag{5.2}$$

is ISS for Euler solutions. However, one can easily construct examples for which such feedbacks cannot exist. Here is an example from [20] where this situation occurs. Consider the GAC system $\dot{x} = -x + u^2 x^2$ on $\mathbb{R}$. If $K(x)$ is any continuous feedback for which

$$\dot{x} = -x + (K(x) + u)^2 x^2 \tag{5.3}$$

is ISS, then $|K(x)| < x^{-1/2}$ for all $x > 0$. It follows that the solution of

$$\dot{x} = -x + (K(x) + 1)^2 x^2$$

starting at $x(0) = 4$ is unbounded. Therefore, there does not exist a continuous feedback K for which (5.3) is ISS. On the other hand, one *can* find a (possibly discontinuous) feedback that makes (5.1) ISS. We use the following weaker sense of ISS for fully nonlinear systems that was introduced in [20].

DEFINITION 5.1. *We say that* (5.1) *is* input-to-state stabilizable in the weak sense *provided there exist a feedback K, and an $m \times m$ matrix G of continuously differentiable functions which is invertible at each point, such that*

$$\dot{x} = F(x, K(x), u)$$

is ISS for sampling and Euler solutions, where $F(x, p, u) = f(x, p + G(x)u)$.

We will prove the following.

PROPOSITION 5.2. *If* (5.1) *is GAC, then* (5.1) *is also input-to-state stabilizable in the weak sense.*

Proof. We modify the proof from section 3. We define V, ζ, $\underline{\alpha}$, $\overline{\alpha}$, and K_1 as in the proof of Theorem 1.2, except we use the fully nonlinear dynamics $h = f$ from (5.1). Next we follow the proof of the main result in [20], with the following modifications. Define the (possibly discontinuous) function $\mathcal{D}$ by

$$\mathcal{D}(s, r) = \sup \left\{ \langle \zeta(x), f(x, K_1(x) + p) \rangle + \frac{V(x)}{2} : |x| = s, |p| = r \right\}. \tag{5.4}$$

For any interval I of the form $[i, i+1]$, or of the form $[\frac{1}{i+1}, \frac{1}{i}]$, for $i \in \mathbb{N}$, one can find $r = r(i) > 0$ such that $s \in I$ implies $\mathcal{D}(s, b) < 0$ for all $b \in [0, r]$. This follows from the positive definiteness of V, the local Lipschitzness of f, and the local boundedness of $\partial_P V$ on compact subsets of $\mathbb{R}^n \setminus \{0\}$.

The argument of [20] therefore gives $\alpha_4 \in \mathcal{K}_\infty$ and a smooth, everywhere invertible matrix-valued function $G : \mathbb{R}^n \to \mathbb{R}^{m \times m}$ satisfying the following: If

$$|x| > \alpha_4(|u(s)|_\infty), \tag{5.5}$$

then for a.e. $t \geq 0$,

$$\langle \zeta(x), f(x, K_1(x) + G(x)u(t))\rangle + \frac{V(x)}{2} \ \leq \ \mathcal{D}(|x|, |G(x)u(s)|_\infty) < 0.$$

(See Remark 5.3 for a characterization of the set of matrices G for which ISS can be expected, in terms of $\mathcal{D}$.) We can evidently assume that $\alpha_4(s) \geq s$ for all $s \geq 0$ (e.g., by replacing $\alpha_4(s)$ by $\max\{\alpha_4(s), s\}$, which makes the condition (5.5) more restrictive). Fix M, N, $\varepsilon \in (0, M)$, $u \in \mathcal{M}_N^m$, and $x(t) = x_\pi(t)$ as before, with $e = 0$. Define the compact sets

$$S := \left\{x \in \mathbb{R}^n : V(x) \leq \underline{\alpha}^{-1} \circ \alpha_4(N)\right\}, \quad Q = \left\{(\overline{\alpha} \circ \underline{\alpha}^{-1}(M + \alpha_4(N)) + 1)\bar{\mathcal{B}}_n\right\} \setminus \varepsilon\mathcal{B}_n.$$

Notice that $S \subseteq Q^\varepsilon$. We choose $\tilde{\varepsilon}$ as before, and we choose $\delta = \delta(\varepsilon, M, N)$, satisfying (3.11), such that if $\overline{\mathbf{d}}(\pi) < \delta$, then

$$|x_\pi(t) - x_i| \ \leq \ \min\left\{\mu, \frac{\tilde{\varepsilon}}{16(1 + \mathcal{L}_\varepsilon)}, \sqrt{\frac{\lambda_-}{8\sigma}(t - t_i)}\right\} \tag{5.6}$$

for all indices i such that $x_i \in Q^\varepsilon$ and all $t \in [t_i, t_{i+1}]$, where σ and μ are as defined before, and $\lambda_- = \min\{V(x) : x \in Q^{\varepsilon/4}\}$. Reducing δ as necessary, we can assume

$$\|\zeta(x_i) \cdot [f(x_i, K_1(x_i) + G(x_i)u(s)) - f(x(s), K_1(x_i) + G(x(s))u(s))]\|_{[t_i, t_{i+1}]} \leq \frac{\lambda_-}{8}$$

for all indices i satisfying $x_i \in Q^{\varepsilon/2}$. Reasoning as in the earlier proof gives

$$V(x_\pi(t)) - V(x_i) \leq -(t - t_i)\frac{V(x_i)}{16} \quad \forall t \in [t_i, t_{i+1}]$$

for all i such that $x_i \in Q^{\varepsilon/4} \setminus S$. The remainder of the proof is as before, except with $\overline{\alpha} \circ \underline{\alpha}^{-1}(N)$ replaced by $\overline{\alpha} \circ \underline{\alpha}^{-1}(\alpha_4(N))$, and with $\overline{\alpha} \circ \underline{\alpha}^{-1}(s)$ replaced by $\overline{\alpha} \circ \underline{\alpha}^{-1}(\alpha_4(s))$ in the definition of γ. This proves Proposition 5.2. □

Remark 5.3. The statement of Proposition 5.2 is an existence result in terms of the invertible matrix G. However, we can strengthen the proposition by using the function $\mathcal{D}$ in (5.4) to characterize the class of G for which ISS can be expected, as follows. Following [20], we first choose strictly decreasing sequences $\{r_i\}$ and $\{r_i'\}$ of positive numbers such that $0 < r_{i+1} < r_i' < r_i$ for all $i \in \mathbb{N}$, and such that

$$\mathcal{D}(s, r) < 0 \quad \forall (s, r) \in ([i, i + 1] \times [0, r_i]) \cup ([1/(i + 1), 1/i] \times [0, r_i'])$$

for all $i \in \mathbb{N}$. The existence of these sequences follows from the argument we gave in the proof of the proposition. Define $\rho : [0, \infty) \to [0, \infty)$ by setting

($\rho 1$) $\rho(s) = r_k$ for all $s \in [k, k + 1)$ and $k \in \mathbb{N}$;
($\rho 2$) $\rho(s) = r_k'$ for all $s \in [1/(k + 1), 1/k)$ and $k \in \mathbb{N}$; and
($\rho 3$) $\rho(0) = 0$.

We then choose any smooth function $g : [0, \infty) \to (0, \infty)$ satisfying

($g1$) $g(s) = 1$ for all $s \in [0, 1]$;
($g2$) $g(s) \leq \rho(s)/s$ for all $s \geq 2$; and
($g3$) $g(s) \leq 1$ for all $s \geq 0$.

The existence of such a function g follows from exactly the same argument used in [20]. It then also follows from the argument of [20] that we can satisfy the conditions of the proposition by choosing $G(\xi) = g(|\xi|)I$.

Proposition 5.2 allows us to characterize GAC for fully nonlinear systems in terms of feedback equivalence, as follows. First recall that two systems $\dot{x} = f(x,u)$ and $\dot{x} = h(x,u)$, evolving on $\mathbb{R}^n \times \mathbb{R}^m$, are called *feedback equivalent* provided there exist a locally bounded function $K : \mathbb{R}^n \to \mathbb{R}^m$ and an everywhere invertible function $G : \mathbb{R}^n \to \mathbb{R}^{m\times m}$ for which

$$h(x,u) = f(x, K(x) + G(x)u)$$

for all $x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$. In this case, we also say $\dot{x} = f(x,u)$ is feedback equivalent to (2.1) with $e = 0$ and $F(x,p,u) = f(x,p+G(x)u)$. The following elegant statement follows directly from Proposition 5.2.

COROLLARY 5.4. *The fully nonlinear system* (5.1) *is GAC if and only if it is feedback equivalent to a system which is ISS for sampling and Euler solutions.*

Remark 5.5. Although, as shown by the counterexample (5.3), it is in general impossible to obtain input-to-state stabilization (in the nonweak sense) for systems that are not affine in controls, it is still the case that for some restricted classes of systems this objective can be attained, under appropriate neutral-stability assumptions on the dynamics. One such class is that of systems in which the input appears inside a saturation nonlinearity, such as $\dot{x} = f(x,u) = f_0(x) + g(x)\sigma(u)$. The papers [14] and [5] (see [26] for an application of these results to the recursive design of stabilizers for a large class of systems with saturation) as well as [4] and [13] dealt with such questions, for systems that are linear in the absence of the saturation (the f_0 and g vector fields are linear and constant, respectively), while [2] obtained similar results for more general nonlinear systems.

SECOND ORDER SUFFICIENT CONDITIONS FOR TIME-OPTIMAL BANG-BANG CONTROL*

HELMUT MAURER† AND NIKOLAI P. OSMOLOVSKII‡

Abstract. We study second order sufficient optimality conditions (SSC) for optimal control problems with control appearing linearly. Specifically, time-optimal bang-bang controls will be investigated. In [N. P. Osmolovskii, *Sov. Phys. Dokl.*, 33 (1988), pp. 883–885; *Theory of Higher Order Conditions in Optimal Control*, Doctor of Sci. thesis, Moscow, 1988 (in Russian); *Russian J. Math. Phys.*, 2 (1995), pp. 487–516; *Russian J. Math. Phys.*, 5 (1997), pp. 373–388; *Proceedings of the Conference "Calculus of Variations and Optimal Control*," Chapman & Hall/CRC, Boca Raton, FL, 2000, pp. 198–216; A. A. Milyutin and N. P. Osmolovskii, *Calculus of Variations and Optimal Control*, Transl. Math. Monogr. 180, AMS, Providence, RI, 1998], SSC have been developed in terms of the positive definiteness of a quadratic form on a critical cone or subspace. No systematical numerical methods for verifying SSC are to be found in these papers. In the present paper, we study explicit representations of the critical subspace. This leads to an easily implementable test for SSC in the case of a bang-bang control with one or two switching points. In general, we show that the quadratic form can be simplified by a transformation that uses a solution to a linear matrix differential equation. Particular conditions even allow us to convert the quadratic form to perfect squares. Three numerical examples demonstrate the numerical viability of the proposed tests for SSC.

1. Introduction.

Second order sufficient optimality conditions (SSC) for optimal control problems subject to mixed control-state constraints have been studied by various authors; cf. Dunn [8, 9]; Malanowski [22]; Maurer and Pickenhain [30]; Maurer and Oberle [29]; Milyutin and Osmolovskii [31]; Osmolovskii [35, 36, 37, 38, 39, 40]; and Zeidan [48]. SSC amount to testing the positive definiteness of a certain quadratic form on the so-called critical cone or subspace. Provided that the strict Legendre–Clebsch condition holds, a well-known numerical recipe allows the conversion of the quadratic form to a perfect square. Namely, it suffices to check that an associated Riccati matrix differential equation has a bounded solution along the extremal trajectory. This test has been performed in a number of practical examples and has played a crucial role in sensitivity analysis of parametric control problems; cf., e.g., Augustin, Malanowski, and Maurer [2, 21, 22, 23, 24, 25, 27, 28]. Recently, the Riccati approach has been also extended to discontinuous controls (broken extremals) by Osmolovskii and Lempio [42].

The above mentioned tests for SSC are not applicable to optimal control problems with control appearing *linearly*. Bang-bang controls do belong to this class of problems. Though first and higher order *necessary* optimality conditions for bang-bang controls have been studied, e.g., in Bressan [3], Schättler [44], and Sussmann

[45, 46, 47], there is no systematic study of *sufficient* optimality conditions and their numerical verification. A general set of second order necessary and sufficient conditions for an extremal with a discontinuous control (cf. Osmolovskii [37]) can be derived from the theory of higher order conditions in Levitin, Milyutin, and Osmolovskii [20]. The main results for bang-bang controls which follow from these general conditions are given in Milyutin and Osmolovskii [31]. Some proofs missing in that book will appear in Osmolovskii [40]. Only recently, other authors have derived SSC for general bang-bang control problems with *fixed* final time (cf. Agrachev, Stefani, and Zezza [1]; Ledzewicz and Schättler [19]; and Noble and Schättler [33]).

In this paper, we shall consider the special class of *time-optimal* bang-bang controls with given initial and terminal state. To our knowledge, the paper of Sarychev [43] seems to be the only study on SSC for this class of problems. However, it is not clear how one might apply the SSC in this article to practical examples. Thus our aim is to derive SSC in a form that is also suitable for practical verification. The two main tools to achieve this goal will be (1) a detailed study of the critical subspace and (2) an adaptation of the above mentioned Riccati approach to bang-bang controls. The organization of the paper then is as follows. In section 2, Pontryagin's minimum principle and the bang-bang property are discussed. The accessory problem, respectively, the quadratic form and the critical subspace are introduced in section 3. SSC are given in a general form that is evaluated particularly for bang-bang controls with one or two switching points. Section 4 presents the Q-transformation whereby the quadratic form is simplified with the help of the solution Q of a linear differential equation. Positive definiteness conditions are given under which the quadratic form can be transformed into perfect squares. In section 5, we shall discuss three numerical examples that illustrate several numerical procedures for verifying positive definiteness of the corresponding quadratic forms.

2. Time-optimal bang-bang control problems.

2.1. Statement of the problem, strong minimum. We consider time-optimal control problems with control appearing linearly. Let $x(t) \in \mathbb{R}^{d(x)}$ denote the state variable and $u(t) \in \mathbb{R}^{d(u)}$ the control variable in the time interval $t \in \Delta = [0, T]$ with a nonfixed final time $T > 0$. For simplicity, the initial and terminal states are fixed in the following control problem:

$$\text{Minimize the final time} \quad T \tag{2.1}$$

subject to the constraints on the interval $\Delta = [0, T]$,

$$dx/dt = \dot{x} = f(t, x, u) = a(t, x) + B(t, x)u, \tag{2.2}$$

$$x(0) = x_0, \quad x(T) = x_1, \tag{2.3}$$

$$u(t) \in U, \quad (t, x(t)) \in \mathcal{Q}\,. \tag{2.4}$$

Here, x_0, x_1 are given points in $\mathbb{R}^{d(x)}$, $\mathcal{Q} \subset \mathbb{R}^{1+d(x)}$ is an open set, and $U \subset \mathbb{R}^{d(u)}$ is a convex polyhedron. The functions a, B are twice continuously differentiable on $\mathcal{Q}$ with B being a $d(x) \times d(u)$ matrix function. A trajectory or control process

$$\mathcal{T} = \{\, (x(t), u(t)) \mid t \in [0, T] \,\}$$

is said to be *admissible* if $x(\cdot)$ is absolutely continuous, $u(\cdot)$ is measurable and essentially bounded, and the pair of functions $(x(t), u(t))$ satisfies the constraints (2.2)–(2.4)

on the interval $\Delta = [0, T]$. The component $x(t)$ will be called the *state trajectory.*

DEFINITION 2.1. *An admissible trajectory* $\mathcal{T}^0 = \{(x^0(t), u^0(t)) \mid t \in [0, T^0]\}$ *is said to be strongly (resp., strictly strongly) locally time-optimal if there exists* $\varepsilon > 0$ *such that* $T \geq T^0$ *(resp.,* $T > T^0$*) holds for all admissible* $\mathcal{T} = \{(x(t), u(t)) \mid t \in [0, T]\}$ *(resp., different from* $\mathcal{T}^0$*) with* $|T - T^0| < \varepsilon$ *and* $\max_{[0,T^0]\cap[0,T]} |x(t) - x^0(t)| < \varepsilon$.

2.2. Minimum principle. Let

$$\mathcal{T} = \{\, (x(t), u(t)) \mid t \in [0, T] \,\}$$

be a fixed admissible trajectory such that the control $u(\cdot)$ is a piecewise constant function on the interval $\Delta = [0, T]$ with *finitely many* points of discontinuity. In order to simplify notation we shall not use such symbols and indices as zero, hat, or asterisk to distinguish this trajectory from others. Denote by

$$\theta = \{t_1, \ldots, t_s\}, \quad 0 < t_1 < \cdots < t_s < T\,,$$

the finite set of all discontinuity points (jump points) of the control $u(t)$. Then $\dot{x}(t)$ is a piecewise continuous function whose discontinuity points belong to the set θ and, thus, $x(t)$ is a piecewise smooth function on Δ. Henceforth, we shall use the notation

$$[u]^k = u^{k+} - u^{k-}$$

to denote the jump of the function $u(t)$ at the point $t_k \in \theta$, where

$$u^{k-} = u(t_k - 0), \quad u^{k+} = u(t_k + 0)$$

are, respectively, the left-hand and the right-hand values of the control $u(t)$ at t_k. Similarly, we denote by $[\dot{x}]^k$ the jump of the function $\dot{x}(t)$ at the same point.

Let us formulate the first order necessary conditions of optimality for the trajectory $\mathcal{T}$, the *Pontryagin minimum principle.* To this end we introduce the *Pontryagin function* or Hamiltonian function

$$H(t, x, u, \psi) = \psi f(t, x, u) = \psi a(t, x) + \psi B(t, x) u, \tag{2.5}$$

where ψ is a row-vector of dimension $d(x)$, while x, u, f are column-vectors. In what follows, partial derivatives of the Pontryagin function and all other functions will be denoted by subscripts referring to the respective variables.

The factor of the control u in the Pontryagin function is called the *switching function*

$$\sigma(t, x, \psi) = \psi B(t, x).$$

Consider the pair of functions

$$\psi_0(\cdot) : \Delta \to \mathbb{R}^1, \quad \psi(\cdot) : \Delta \to \mathbb{R}^{d(x)},$$

which are continuous on Δ and continuously differentiable on each interval of the set $\Delta \setminus \theta$. Denote by M_0 the set of normed pairs of functions $(\psi_0(\cdot), \psi(\cdot))$ satisfying the conditions

$$\psi_0(T) \geq 0, \quad |\psi(0)| = 1, \tag{2.6}$$

$$\dot{\psi}(t) = -H_x(t, x(t), u(t), \psi(t)) \quad \forall\, t \in \Delta \setminus \theta, \tag{2.7}$$

$$\dot{\psi}_0(t) = -H_t(t, x(t), u(t), \psi(t)) \quad \forall\, t \in \Delta \setminus \theta, \tag{2.8}$$

$$\min_{u \in U} H(t, x(t), u, \psi(t)) = H(t, x(t), u(t), \psi(t)) \quad \forall\, t \in \Delta \setminus \theta, \tag{2.9}$$

$$H(t, x(t), u(t), \psi(t)) + \psi_0(t) = 0 \quad \forall\, t \in \Delta \setminus \theta\,. \tag{2.10}$$

Then the condition $M_0 \neq \emptyset$ is equivalent to the Pontryagin minimum principle. We assume that this condition is satisfied for the trajectory $\mathcal{T}$. We say in this case that $\mathcal{T}$ is an *extremal trajectory* for the problem. M_0 is a finite-dimensional *compact* set since in (2.6) the initial values $\psi(0)$ are assumed to belong to the unit ball of $\mathbb{R}^{d(x)}$. The case that there exists a multiplier $(\psi_0, \psi) \in M_0$ with $\psi_0(T) > 0$ will be called the *nondegenerate* or *normal* case.

Henceforth, it will be convenient to use the simple abbreviation (t) for all arguments $(t, x(t), u(t), \psi(t))$, e.g., $H(t) = H(t, x(t), u(t), \psi(t))$, $\sigma(t) = \sigma(t, x(t), \psi(t))$. The continuity of the pair of functions $(\psi_0(t), \psi(t))$ at the points $t_k \in \theta$ constitutes the Weierstrass–Erdmann necessary conditions for nonsmooth extremals. We formulate one more important condition of this type. Namely, for $(\psi_0, \psi) \in M_0$ and $t_k \in \theta$ consider the function

$$(\Delta_k H)(t) = H(t, x(t), u^{k+}, \psi(t)) - H(t, x(t), u^{k-}, \psi(t)) = \sigma(t, x(t), \psi(t))[u]^k.$$

This function has a derivative

$$D^k(H) := -\frac{d}{dt}(\Delta_k H)(t_k) = -\dot\sigma(t_k^{\pm})[u]^k,$$

where the values on the right-hand side are the same for the derivative $\dot\sigma(t_k^+)$ from the right and the derivative $\dot\sigma(t_k^-)$ from the left. In the case of a *scalar* control u, the total derivative $\sigma_t + \sigma_x \dot x + \sigma_\psi \dot\psi$ does not contain the control variable explicitly [17, 18] and, hence, the derivative of the switching function $\dot\sigma(t)$ is *continuous* at t_k. Then the minimum condition (2.9) immediately implies the following property.

PROPOSITION 2.2. *For each $(\psi_0, \psi) \in M_0$ the following conditions hold:*

$$D^k(H) = -\dot\sigma(t_k^{\pm})[u]^k \geq 0 \quad \textit{for } k = 1, \dots, s. \tag{2.11}$$

2.3. Bang-bang control. The classical definition of a bang-bang control is that of a control which assumes values in the vertex set of the admissible polyhedron U in (2.4). We need a slightly more restrictive definition of a bang-bang control to obtain the sufficient conditions in Theorem 3.3. Let

$$\operatorname{Arg\,min}_{v \in U} \sigma(t)v$$

be the set of points $v \in U$ where the minimum of the linear function $\sigma(t)v$ is attained. For a given extremal trajectory $\mathcal{T} = \{\, (x(t), u(t)) \mid t \in \Delta \,\}$ with piecewise constant control $u(t)$ we shall say that $u(t)$ is a *bang-bang control* if there exists $(\psi_0, \psi) \in M_0$ such that

$$\operatorname{Arg\,min}_{v \in U} \sigma(t)v = [u(t-0), u(t+0)]\,, \tag{2.12}$$

where $[u(t-0), u(t+0)] = \{\alpha u(t-0) + (1-\alpha)u(t+0) \mid 0 \leq \alpha \leq 1\}$ denotes the line segment in $\mathbb{R}^{d(u)}$. Notice that $[u(t-0), u(t+0)]$ is a singleton $\{u(t)\}$ at each continuity point of the control $u(t)$ with $u(t)$ being a vertex of the polyhedron U. Only at the points $t_k \in \theta$ does the line segment $[u^{k-}, u^{k+}]$ coincide with an edge of the polyhedron.

If the control is *scalar*, $d(u) = 1$ and $U = [u_{min}, u_{max}]$, then the bang-bang property is equivalent to

$$\sigma(t, x(t), \psi(t)) \neq 0 \quad \forall\, t \in \Delta \setminus \theta,$$

which implies the following control law:

$$u(t) = \left\{ \begin{array}{ll} u_{min} & \text{if} \quad \sigma(t) > 0 \\ u_{max} & \text{if} \quad \sigma(t) < 0 \end{array} \right\} \quad \forall\, t \in \Delta \setminus \theta. \tag{2.13}$$

For vector-valued control inputs, condition (2.12) imposes further restrictions. For example, if U is the unit cube in $\mathbb{R}^{d(u)}$, condition (2.12) precludes simultaneous switching of the control components. However, this property holds for most examples; cf., e.g., the time-optimal control of a robot manipulator with $d(u) = 2$ in Chernousko, Akulenko, and Bolotnik [6]. Moreover, condition (2.12) will be indispensable in the sensitivity analysis of optimal bang-bang controls, a topic that we are currently investigating.

3. Critical subspace, quadratic form, and sufficient optimality conditions for bang-bang controls. In order to formulate quadratic sufficient optimality conditions for a given extremal $\mathcal{T}$ with bang-bang control $u(\cdot)$ we shall introduce the space $\mathcal{Z}(\theta)$, the critical subspace $\mathcal{K} \subset \mathcal{Z}(\theta)$, and the quadratic form Ω defined in $\mathcal{Z}(\theta)$.

3.1. Critical subspace. Denote by $P_\theta C^1(\Delta, R^n)$ the space of piecewise continuous functions

$$\bar{x}(\cdot) : \Delta \to \mathbb{R}^n$$

that are continuously differentiable on each interval of the set $\Delta \setminus \theta$. For each $\bar{x} \in P_\theta C^1(\Delta, R^n)$ and for $t_k \in \theta$ we use the abbreviation

$$[\bar{x}]^k = \bar{x}^{k+} - \bar{x}^{k-}, \quad \text{where} \quad \bar{x}^{k-} = \bar{x}(t_k - 0), \quad \bar{x}^{k+} = \bar{x}(t_k + 0).$$

Putting

$$\bar{z} = (\bar{T}, \xi, \bar{x}) \quad \text{with} \quad \bar{T} \in R^1, \quad \xi = (\xi_1, \dots, \xi_s) \in R^s, \quad \bar{x} \in P_\theta C^1(\Delta, R^n),$$

we have

$$\bar{z} \in \mathcal{Z}(\theta) := \mathbb{R}^1 \times \mathbb{R}^s \times P_\theta C^1(\Delta, \mathbb{R}^n).$$

Denote by $\mathcal{K}$ the set of all $\bar{z} \in \mathcal{Z}(\theta)$ satisfying the following conditions:

$$\dot{\bar{x}}(t) = f_x(t, x(t), u(t))\bar{x}(t), \qquad [\bar{x}]^k = [\dot{x}]^k \xi_k, \quad k = 1, \dots, s, \tag{3.1}$$

$$\bar{x}(0) = 0, \quad \bar{x}(T) + \dot{x}(T)\bar{T} = 0\,. \tag{3.2}$$

Then $\mathcal{K}$ is a subspace of the space $Z(\theta)$ which we call the *critical subspace*. Each element $\bar{z} \in \mathcal{K}$ is uniquely defined by the number $\bar{T}$ and the vector ξ. Consequently, the subspace $\mathcal{K}$ is *finite-dimensional*.

An explicit representation of the variations $\bar{x}(t)$ in (3.1) is obtained as follows. For each $k = 1, \dots, s$, define the vector functions $y^k(t)$ as the solutions to the system

$$\dot{y} = f_x(t)y, \quad y(t_k) = [\dot{x}]^k, \quad t \in [t_k, T]. \tag{3.3}$$

For $t < t_k$ we put $y^k(t) = 0$ which yields the jump $[y^k]^k = [\dot{x}]^k$. It follows from the superposition principle for linear ODEs that

$$\bar{x}(t) = \sum_{k=1}^{s} y^k(t)\xi_k \tag{3.4}$$

from which we obtain the representation

$$\bar{x}(T) + \dot{x}(T)\bar{T} = \sum_{k=1}^{s} y^k(T)\xi_k \; + \dot{x}(T)\bar{T}\,. \tag{3.5}$$

Furthermore, denote by $x(t; t_1, \ldots, t_s)$ the solution of the state equation (2.2) using the optimal bang-bang control with switching points $t_1, \ldots, t_s$. It easily follows from elementary properties of ODEs that the partial derivatives of state trajectories w.r.t. the switching points are given by

$$\frac{\partial x}{\partial t_k}(t; t_1, \ldots, t_s) = -y^k(t) \quad \text{for } \; t \geq t_k, \;\; k = 1, \ldots, s. \tag{3.6}$$

This relation holds for all $t \in [0, T] \setminus \{t_k\}$, because for $t < t_k$ we have $\frac{\partial x}{\partial t_k}(t) = 0$ and $y^k(t) = 0$. Hence, (3.4) yields

$$\bar{x}(t) = -\sum_{k=1}^{s} \frac{\partial x}{\partial t_k}(t)\xi_k \; . \tag{3.7}$$

In the nondegenerate case $\psi_0(T) > 0$, the critical subspace simplifies as follows.

PROPOSITION 3.1. *If there exists $(\psi_0, \psi) \in M_0$ such that $\psi_0(T) > 0$, then $\bar{T} = 0$ holds for each $\bar{z} = (\bar{T}, \xi, \bar{x}) \in \mathcal{K}$.*

Proof. For arbitrary $(\psi_0, \psi) \in M_0$ and $\bar{z} = (\bar{T}, \xi, \bar{x}) \in \mathcal{K}$ we have

$$\frac{d}{dt}(\psi\bar{x}) = \dot{\psi}\bar{x} + \psi\dot{\bar{x}} = -\psi f_x(t)\bar{x} + \psi f_x(t)\bar{x} = 0,$$

and also

$$[\psi\bar{x}]^k = \psi(t_k)[\bar{x}]^k = \psi(t_k)[\dot{x}]^k\xi_k = [\psi\dot{x}]^k\xi_k = -[\psi_0]^k\xi_k = 0.$$

Consequently, $\psi(t)\bar{x}(t)$ is a constant function on $[0, T]$ which yields in view of (3.2)

$$0 = (\psi\bar{x})(0) = (\psi\bar{x})(T) = -\psi(T)\dot{x}(T)\bar{T} = \psi_0(T)\bar{T}.$$

Hence the inequality $\psi_0(T) > 0$ implies that $\bar{T} = 0$.

In section 3.2, we shall conclude from Theorem 3.3 that the property $\mathcal{K} = \{0\}$ essentially represents a first order sufficient condition. Since $\bar{x}(T) + \dot{x}(T)\bar{T} = 0$ by (3.2), the representations (3.4), (3.5), and Proposition 3.1 induce the following conditions for $\mathcal{K} = \{0\}$.

PROPOSITION 3.2. *Assume that one of the following conditions is satisfied:*

(a) *the $s+1$ vectors $y^k(T) = -\frac{\partial x}{\partial t_k}(T)$, $k = 1, \ldots, s$, $\dot{x}(T)$, are linearly independent,*
(b) *there exists $(\psi_0, \psi) \in M_0$ with $\psi_0(T) > 0$, and the s vectors $y^k(T) = -\frac{\partial x}{\partial t_k}(T)$, $k = 1, \ldots, s$, are linearly independent,*
(c) *there exists $(\psi_0, \psi) \in M_0$ with $\psi_0(T) > 0$, and the bang-bang control has one switching point, i.e., $s = 1$.*

Then the critical subspace is $\mathcal{K} = \{0\}$.

Now we discuss the case of two switching points, i.e., $s = 2$, to prepare the numerical example in section 5.2. Let us assume that $\psi_0(T) > 0$ and $[\dot{x}]^1 \neq 0$, $[\dot{x}]^2 \neq 0$.

By virtue of Proposition 3.1, we have $\bar{T} = 0$ and hence $\bar{x}(T) = 0$ for each element $\bar{z} \in \mathcal{K}$. Then the relations (3.2) and (3.4) yield

$$0 = \bar{x}(T) = y^1(T)\xi_1 + y^2(T)\xi_2\,. \tag{3.8}$$

The conditions $[\dot{x}]^1 \neq 0$ and $[\dot{x}]^2 \neq 0$ imply that $y^1(T) \neq 0$ and $y^2(T) \neq 0$, respectively. Futhermore, assume that $\mathcal{K} \neq \{0\}$. Then (3.8) shows that the nonzero vectors $y^1(T)$ and $y^2(T)$ are collinear, i.e.,

$$y^2(T) = \alpha y^1(T) \tag{3.9}$$

with some factor $\alpha \neq 0$. As a consequence, the relation $y^2(t) = \alpha y^1(t)$ is valid for all $t \in (t_2, T]$ since the functions $y^1(t)$ and $y^2(t)$ are continuous solutions to the system $\dot{y} = f_x(t)y$ in $(t_2, T]$. In particular, we have $y^2(t_2 + 0) = \alpha y^1(t_2)$ and thus

$$[\dot{x}]^2 = \alpha y^1(t_2) \tag{3.10}$$

which is equivalent to (3.9). In addition, the equalities (3.8) and (3.9) imply that

$$\xi_2 = -\frac{1}{\alpha}\xi_1. \tag{3.11}$$

We shall use these formulas in the next subsection.

3.2. Quadratic form. In the sequel, second order partial derivatives will be denoted by double subscripts, e.g., $H_{xx} = D_x^2 H$. For $(\psi_0, \psi) \in M_0$ and $\bar{z} \in \mathcal{K}$ we define the functional

$$\begin{aligned}\Omega(\psi_0, \psi, \bar{z}) = {} & \sum_{k=1}^{s}(D^k(H)\xi_k^2 + 2[H_x]^k \bar{x}^k_{\mathrm{av}}\xi_k) + \int_0^T \langle H_{xx}(t)\bar{x}(t), \bar{x}(t)\rangle\, dt \\ & -(\dot{\psi}_0(T) - \dot{\psi}(T)\dot{x}(T))\bar{T}^2\,,\end{aligned} \tag{3.12}$$

where

$$\bar{x}^k_{\mathrm{av}} := \frac{1}{2}(\bar{x}^{k-} + \bar{x}^{k+}).$$

Note that the functional $\Omega(\psi_0, \psi, \bar{z})$ is linear in ψ_0 and ψ and quadratic in $\bar{z}$.

Now we introduce SSC for a bang-bang control which have been obtained by Osmolovskii; see [31, Part 2, chapter 3, section 12.4]. Some proofs missing in this book will appear in Osmolovskii [40].

THEOREM 3.3. *Let the following Condition $\mathcal{B}$ be fulfilled for the trajectory $\mathcal{T}$:*

(a) *$u(t)$ is a bang-bang control such that (2.12) holds;*

(b) *there exists $(\psi_0, \psi) \in M_0$ such that $D^k(H) > 0$ for $k = 1, \ldots, s$;*

(c) $\max_{(\psi_0,\psi)\in M_0} \Omega(\psi_0, \psi, \bar{z}) > 0 \quad \forall\, \bar{z} \in \mathcal{K} \setminus \{0\}$.

Then $\mathcal{T}$ is a strict strong minimum.

Remarks.

1. In this theorem, the sufficient Condition $\mathcal{B}$ is a natural strengthening of the corresponding necessary quadratic condition in the same problem; see [31, Part 2].
2. Condition (c) is automatically fulfilled if $\mathcal{K} = \{0\}$ holds (cf. Proposition 3.2), which gives a first order sufficient condition for a strong minimum.

3. If there exists $(\psi_0, \psi) \in M_0$ such that

$$\Omega(\psi_0, \psi, \bar{z}) > 0 \quad \forall \bar{z} \in \mathcal{K} \setminus \{0\},$$

then condition (c) is obviously fulfilled.

For boxes $U = \{u = (u_1, \dots, u_{d(u)}) \in \mathbb{R}^{d(u)} \,|\, u_i^{\min} \le u_i \le u_i^{\max},\ i = 1, \dots, d(u)\}$, condition (b) is equivalent to the property $\dot{\sigma}_i(t_k) \neq 0$ if t_k is a switching point of the ith control component $u_i(t)$. Note again that condition (2.12) precludes the simultaneous switching of two or more control components. A further remark concerns the case that the set M_0 of Pontryagin multipliers is not a singleton. This case has been illustrated in Osmolovskii [38, pp. 377–380] by the following time-optimal control problem for a linear system:

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = x_3, \quad \dot{x}_3 = x_4, \quad \dot{x}_4 = u, \quad |u| \le 1, \quad x(0) = a, \quad x(T) = b,$$

where $x = (x_1, x_2, x_3, x_4)$. It was shown in this paper that for some a and b there exists an extremal in this problem with two switching points of the control such that, under an appropriate normalization, the set M_0 is a segment. For this extremal, the maximum of the quadratic forms Ω over M_0 is positive on each nonzero element of the critical subspace and hence the sufficient conditions of Theorem 3.3 are satisfied.

3.3. Nondegenerate case. Let us assume the *nondegenerate* or *normal* case that there exists $(\psi_0, \psi) \in M_0$ such that the cost function multiplier $\psi_0(T)$ is positive. By virtue of Proposition 3.1 we have in this case that $\bar{T} = 0$ for all $\bar{z} \in \mathcal{K}$. Thus the critical subspace $\mathcal{K}$ is defined by the conditions

$$\dot{\bar{x}} = f_x(t)\bar{x}, \quad [\bar{x}]^k = [\dot{x}]^k \xi_k \quad (k = 1, \dots, s), \quad \bar{x}(0) = 0, \quad \bar{x}(T) = 0. \tag{3.13}$$

In particular, these conditions imply $\bar{x}(t) \equiv 0$ on $[0, t_1)$ and $(t_s, T]$. Hence, we have $\bar{x}^{1-} = \bar{x}^{s+} = 0$ for all $\bar{z} \in \mathcal{K}$. Then the quadratic form (3.12) is equal to

$$\Omega(\psi, \bar{z}) = \sum_{k=1}^{s} (D^k(H)\xi_k^2 + 2[H_x]^k \bar{x}^k_{\mathrm{av}} \xi_k) + \int_{t_1}^{t_s} \langle H_{xx}(t)\bar{x}(t), \bar{x}(t)\rangle \, dt. \tag{3.14}$$

Just this case of a time-optimal (autonomous) control problem was studied by Sarychev [43]. He used a special transformation of the problem and obtained sufficient optimality condition for the transformed problem. It is not easy but possible to reformulate his results in terms of the original problem. The comparison of both types of conditions reveals that Sarychev used the same critical subspace, but his quadratic form is a lower bound for Ω. Namely, in his quadratic form the positive term $D^k(H)\xi_k^2$ has the factor $\frac{1}{4}$ instead of the factor 1 for the same term in Ω. Therefore, the sufficient Condition $\mathcal{B}$ is always fulfilled whenever Sarychev's condition is fulfilled. However, Osmolovskii has constructed an example of a control problem where the optimal solution satisfies Condition $\mathcal{B}$, but does not satisfy Sarychev's condition. Finally, Sarychev proved that his condition is sufficient for an L_1-minimum w.r.t. the control (which is a "Pontryagin minimum" [31] in this problem). In fact it could be proved that his condition is sufficient for a strong minimum.

3.4. Cases of one or two switching points of the control. From Theorem 3.3 and Proposition 3.2(c) we immediately deduce sufficient conditions for a bang-bang control with one switching point. The result will be used for the example in section 5.1 and is also applicable to the time-optimal control of an image converter discussed in Kim et al. [15].

THEOREM 3.4. *Let the following conditions be fulfilled for the trajectory* $\mathcal{T}$*:*

(a) *$u(t)$ is a bang-bang control with one switching point;*

(b) *there exists $(\psi_0, \psi) \in M_0$ such that $\psi_0(T) > 0$ and $D^1(H) > 0$.*

Then $\mathcal{T}$ is a strict strong minimum.

Now we turn our attention to the case of two switching points where $s = 2$. Assume the nondegenerate case $\psi_0(T) > 0$ and suppose that $[\dot{x}]^1 \neq 0$, $[\dot{x}]^2 \neq 0$ and $y^2(T) = \alpha y^1(T)$ as in (3.9). Otherwise, $\mathcal{K} = \{0\}$ holds and, hence, the first order sufficient condition for a strong minimum is satisfied. For any element $\bar{z} \in \mathcal{K}$ we have $\bar{T} = 0$, $\bar{x}^{1-} = 0$, $\bar{x}^{2+} = 0$. Consequently,

$$\bar{x}^1_{\rm av} = \frac{1}{2}[\bar{x}]^1 = \frac{1}{2}[\dot{x}]^1\xi_1, \quad \bar{x}^2_{\rm av} = \frac{1}{2}\bar{x}^{2-} = \frac{1}{2}y^1(t_2)\xi_1 = \frac{1}{2\alpha}[\dot{x}]^2\xi_1$$

in view of $\bar{x}(t) = y^1(t)\xi_1 + y^2(t)\xi_2$, $y^2(t_2 - 0) = 0$ and (3.10). Using these relations in the quadratic form (3.14) together with (3.11) and the conditions $y^2(t) = 0$ for all $t < t_2$, $[H_x]^k = -[\dot{\psi}]^k$, $k = 1, 2$, we compute the quadratic form for an element of the critical subspace as

$$\begin{aligned}
\Omega &= D^1(H)\xi_1^2 + D^2(H)\xi_2^2 - 2[\dot{\psi}]^1\bar{x}^1_{\rm av}\xi_1 - 2[\dot{\psi}]^2\bar{x}^2_{\rm av}\xi_2 + \int_{t_1}^{t_2}\langle H_{xx}\bar{x}, \bar{x}\rangle\, dt \\
&= D^1(H)\xi_1^2 + \tfrac{1}{\alpha^2}D^2(H)\xi_1^2 - [\dot{\psi}]^1[\dot{x}]^1\xi_1^2 + \tfrac{1}{\alpha^2}[\dot{\psi}]^2[\dot{x}]^2\xi_1^2 + \left(\int_{t_1}^{t_2}\langle H_{xx}y^1, y^1\rangle\, dt\right)\xi_1^2 \\
&= \rho\xi_1^2,
\end{aligned}$$

where

$$\rho := \left(D^1(H) - [\dot{\psi}]^1[\dot{x}]^1\right) + \frac{1}{\alpha^2}\left(D^2(H) + [\dot{\psi}]^2[\dot{x}]^2\right) + \int_{t_1}^{t_2}\langle H_{xx}y^1, y^1\rangle\, dt. \tag{3.15}$$

Thus, we obtain the following proposition.

PROPOSITION 3.5. *Assume that $\psi_0(T) > 0$, $s = 2$, $[\dot{x}]^1 \neq 0$, $[\dot{x}]^2 \neq 0$, and $y^2(T) = \alpha y^1(T)$ (which is equivalent to* (3.10)*) with some factor α. Then the condition of the positive definiteness of Ω on $\mathcal{K}$ is equivalent to the inequality $\rho > 0$, where ρ is defined by* (3.15).

4. Sufficient conditions for positive definiteness of the quadratic form Ω on the critical subspace $\mathcal{K}$. In this section we consider the nondegenerate case in section 3.3 and assume

(i) $u(t)$ is a bang-bang control with $s > 1$ switching points;

(ii) there exists $(\psi_0, \psi) \in M_0$ such that $\psi_0(T) > 0$ and $D^k(H) > 0$, $k = 1, \ldots, s$.

Under these assumptions the critical subspace $\mathcal{K}$ is defined by (3.13). Let $(\psi_0, \psi) \in M_0$ be a fixed element (possibly, different from that in assumption (ii)) and denote by $\Omega = \Omega(\psi_0, \psi, \cdot)$ the quadratic form for this element. Recall that Ω is given by (3.14). According to Theorem 3.3 *the positive definiteness of the quadratic form* (3.14) *on the subspace $\mathcal{K}$ in* (3.13) *is a sufficient condition for a strict strong minimum of the trajectory.* Now our aim is to find conditions that guarantee this property of positive definiteness. In what follows we shall use some ideas and results presented in Osmolovskii and Lempio [42], who have extended the Riccati approach in [4, 30, 22, 48] to broken extremals.

4.1. Q-transformation of Ω on $\mathcal{K}$. Let $Q(t)$ be a symmetric matrix on $[t_1, t_s]$ with piecewise continuous entries which are absolutely continuous on each interval of the set $[t_1, t_s] \setminus \theta$. Therefore, Q may have a jump at each point $t_k \in \theta$ including t_1, t_s, and thus the symmetric matrices Q^{1-} and Q^{s+} are also defined.

For $\bar{z} \in \mathcal{K}$ we obviously have

$$\int_{t_1}^{t_s} \frac{d}{dt}\langle Q\bar{x}, \bar{x}\rangle \, dt = \langle Q\bar{x}, \bar{x}\rangle \Big|_{t_1-0}^{t_s+0} - \sum_{k=1}^{s} \left[\langle Q\bar{x}, \bar{x}\rangle\right]^k,$$

where $\left[\langle Q\bar{x}, \bar{x}\rangle\right]^k$ is the jump of the function $\langle Q\bar{x}, \bar{x}\rangle$ at the point $t_k \in \theta$. Using the conditions

$$\dot{\bar{x}} = f_x(t)\bar{x}, \quad \bar{x}^{1-} = \bar{x}^{s+} = 0,$$

we obtain

$$\sum_{k=1}^{s} \left[\langle Q\bar{x}, \bar{x}\rangle\right]^k + \int_{t_1}^{t_s} \langle (\dot{Q} + f_x^* Q + Q f_x)\bar{x}, \bar{x}\rangle \, dt = 0, \tag{4.1}$$

where the asterisk denotes transposition. Adding this zero-form to Ω we get

$$\Omega = \sum_{k=1}^{s} \Big(D^k(H)\xi_k^2 - 2[\dot{\psi}]^k \bar{x}_{\mathrm{av}}^k \xi_k + \left[\langle Q\bar{x}, \bar{x}\rangle\right]^k \Big) + \int_{t_1}^{t_s} \langle (H_{xx} + \dot{Q} + f_x^* Q + Q f_x)\bar{x}, \bar{x}\rangle \, dt. \tag{4.2}$$

We shall call this formula the *Q-transformation of* Ω *on* $\mathcal{K}$.

In order to eliminate the integral term in Ω we assume that $Q(t)$ satisfies the following linear matrix differential equation:

$$\dot{Q} + f_x^* Q + Q f_x + H_{xx} = 0 \quad \text{on } [t_1, t_s] \setminus \theta. \tag{4.3}$$

It is interesting to note that the same equation is obtained from the modified Riccati equation in [30, equation (47)] when all control variables are on the boundary of the control constraints. Using (4.3) the quadratic form (4.2) reduces to

$$\Omega = \sum_{k=1}^{s} \omega_k, \quad \omega_k := D^k(H)\xi_k^2 - 2[\dot{\psi}]^k \bar{x}_{\mathrm{av}}^k \xi_k + \left[\langle Q\bar{x}, \bar{x}\rangle\right]^k. \tag{4.4}$$

Thus, we have proved the following statement.

PROPOSITION 4.1. *Let $Q(t)$ satisfy the linear differential equation* (4.3) *on $[t_1, t_s]\setminus\theta$. Then for each $\bar{z} \in \mathcal{K}$ the representation* (4.4) *holds.*

Now our goal is to derive conditions such that $\omega_k > 0$ holds on $\mathcal{K} \setminus \{0\}$ for $k = 1, \ldots, s$. We shall transform ω_k as in [42]. First we shall express it via the vector $(\xi_k, \bar{x}^{k-})$ and then via $(\xi_k, \bar{x}^{k+})$. To express ω_k as a quadratic form of $(\xi_k, \bar{x}^{k-})$, we use the formula

$$\bar{x}^{k+} = \bar{x}^{k-} + [\dot{x}]^k \xi_k, \tag{4.5}$$

which implies

$$\langle Q^{k+}\bar{x}^{k+}, \bar{x}^{k+}\rangle = \langle Q^{k+}\bar{x}^{k-}, \bar{x}^{k-}\rangle + 2\langle Q^{k+}[\dot{x}]^k, \bar{x}^{k-}\rangle \xi_k + \langle Q^{k+}[\dot{x}]^k, [\dot{x}]^k\rangle \xi_k^2.$$

Consequently,

$$\left[\langle Q\bar{x}, \bar{x}\rangle\right]^k = \langle [Q]^k \bar{x}^{k-}, \bar{x}^{k-}\rangle + 2\langle Q^{k+}[\dot{x}]^k, \bar{x}^{k-}\rangle \xi_k + \langle Q^{k+}[\dot{x}]^k, [\dot{x}]^k\rangle \xi_k^2.$$

Using this relation together with

$$\bar{x}^k_{\rm av} = \bar{x}^{k-} + \frac{1}{2}[\dot{x}]^k \xi_k$$

in the definition (4.4) of ω_k, we obtain

$$\begin{aligned} \omega_k &= \{D^k(H) + \left(([\dot{x}]^k)^* Q^{k+} - [\dot{\psi}]^k\right)[\dot{x}]^k\}\,\xi_k^2 \\ &\quad +2\left(([\dot{x}]^k)^* Q^{k+} - [\dot{\psi}]^k\right)\bar{x}^{k-}\xi_k + (\bar{x}^{k-})^*[Q]^k\bar{x}^{k-}. \end{aligned} \tag{4.6}$$

Here $[\dot{x}]^k$ and $\bar{x}^{k-}$ are column-vectors while $([\dot{x}]^k)^*$, $(\bar{x}^{k-})^*$, and $[\dot{\psi}]^k$ are row-vectors. Putting

$$q_{k+} = ([\dot{x}]^k)^* Q^{k+} - [\dot{\psi}]^k \tag{4.7}$$

we get

$$\omega_k = \left(D^k(H) + (q_{k+})[\dot{x}]^k\right)\xi_k^2 + 2(q_{k+})\bar{x}^{k-}\xi_k + (\bar{x}^{k-})^*[Q]^k\bar{x}^{k-}. \tag{4.8}$$

We immediately see from this representation that one way to enforce $\omega_k > 0$ is to impose the following conditions:

$$D^k(H) > 0, \quad q_{k+} = ([\dot{x}]^k)^* Q^{k+} - [\dot{\psi}]^k = 0, \quad [Q]^k \geq 0. \tag{4.9}$$

In practice, however, it might be difficult to check these conditions since it is necessary to satisfy the $d(x)$ equality constraints $q_{k+} = ([\dot{x}]^k)^* Q^{k+} - [\dot{\psi}]^k = 0$ together with the inequality constraints $[Q]^k \geq 0$. It is more convenient to express ω_k as a quadratic form in the variables $(\xi_k, \bar{x}^{k-})$ with the matrix

$$M_{k+} = \begin{pmatrix} D^k(H) + (q_{k+})[\dot{x}]^k & q_{k+} \\ (q_{k+})^* & [Q]^k \end{pmatrix}, \tag{4.10}$$

where q_{k+} is a row-vector and $(q_{k+})^*$ is a column-vector.

Similarly, using the relation

$$\bar{x}^{k-} = \bar{x}^{k+} - [\dot{x}]^k \xi_k,$$

we obtain

$$[\langle Q\bar{x}, \bar{x}\rangle]^k = \langle [Q]^k \bar{x}^{k+}, \bar{x}^{k+}\rangle + 2\langle Q^{k-}[\dot{x}]^k, \bar{x}^{k+}\rangle \xi^k - \langle Q^{k-}[\dot{x}]^k, [\dot{x}]^k\rangle \xi_k^2.$$

This formula together with the relation

$$\bar{x}^k_{\rm av} = \bar{x}^{k+} - \frac{1}{2}[\dot{x}]^k \xi_k$$

leads to the representation

$$\begin{aligned} \omega_k &= \{D^k(H) - \left(([\dot{x}]^k)^* Q^{k-} - [\dot{\psi}]^k\right)[\dot{x}]^k\}\,\xi_k^2 \\ &\quad +2\left(([\dot{x}]^k)^* Q^{k-} - [\dot{\psi}]^k\right)\bar{x}^{k+}\xi_k + (\bar{x}^{k+})^*[Q]^k\bar{x}^{k+}. \end{aligned} \tag{4.11}$$

Defining

$$q_{k-} = ([\dot{x}]^k)^* Q^{k-} - [\dot{\psi}]^k, \tag{4.12}$$

we get

$$\omega_k = \left(D^k(H) - (q_{k-})[\dot{x}]^k\right)\xi_k^2 + 2(q_{k-})\bar{x}^{k+}\xi_k + (\bar{x}^{k+})^*[Q]^k\bar{x}^{k+}. \tag{4.13}$$

Again, we see that $\omega_k > 0$ holds if we require the conditions

$$D^k(H) > 0, \quad q_{k-} = ([\dot{x}]^k)^* Q^{k-} - [\dot{\psi}]^k = 0, \quad [Q]^k \geq 0. \tag{4.14}$$

To find a more general condition for $\omega_k > 0$, we consider (4.13) as a quadratic form in the variables $(\xi_k, \bar{x}^{k+})$ with the matrix

$$M_{k-} = \begin{pmatrix} D^k(H) - (q_{k-})[\dot{x}]^k & q_{k-} \\ (q_{k-})^* & [Q]^k \end{pmatrix}. \tag{4.15}$$

Since the right-hand sides of equalities (4.8) and (4.13) are connected by the relation (4.5), the following statement obviously holds.

PROPOSITION 4.2. *For each $k = 1, \dots, s$, the positive (semi)definiteness of the matrix M_{k-} is equivalent to the positive (semi)definiteness of the matrix M_{k+}.*

Now we can prove the following theorem.

THEOREM 4.3. *Let $Q(t)$ be a solution of the linear differential equation* (4.3) *on $[t_1, t_s] \setminus \theta$ which satisfies the following conditions:*

(a) *the matrix M_{k+} is positive semidefinite for each $k = 2, \dots, s$;*

(b) $b_{k+} := D^k(H) + (q_{k+})[\dot{x}]^k > 0$ *for each $k = 1, \dots, s-1$.*

Then Ω is positive on $\mathcal{K} \setminus \{0\}$.

Proof. Take an arbitrary element $\bar{z} = (\xi, \bar{x}) \in \mathcal{K}$. Let us show that $\Omega \geq 0$ for this element. Condition (a) implies that $\omega_k \geq 0$ for $k = 2, \dots, s$. Condition (b) for $k = 1$ together with condition $\bar{x}^{1-} = 0$ implies that $\omega_1 \geq 0$. Consequently, $\Omega \geq 0$.

Assume that $\Omega = 0$. Then $\omega_k = 0$ for $k = 1, \dots, s$. The conditions $\omega_1 = 0$, $\bar{x}^{1-} = 0$, and $b_{1+} > 0$ by formula (4.8) (with $k = 1$) yield $\xi_1 = 0$. Then $[\bar{x}]^1 = 0$ and hence $\bar{x}^{1+} = 0$. The last equality together with equation $\dot{\bar{x}} = f_x(t)\bar{x}$ shows that $\bar{x}(t) = 0$ in (t_1, t_2) and hence $\bar{x}^{2-} = 0$. Similarly, the conditions $\omega_2 = 0$, $\bar{x}^{2-} = 0$ and $b_{2+} > 0$ by formula (4.8) (with $k = 2$) imply that $\xi_2 = 0$ and $\bar{x}(t) = 0$ in (t_2, t_3). Therefore, $\bar{x}^{3-} = 0$, etc. Continuing this process we get $\bar{x} \equiv 0$ and $\xi_k = 0$ for $k = 1, \dots, s-1$. Now using formula (4.4) for $\omega_s = 0$, as well as the conditions $D^s(H) > 0$ and $\bar{x} \equiv 0$, we obtain that $\xi_s = 0$. Consequently, we have $\bar{z} = 0$ which means that Ω is positive on $\mathcal{K} \setminus \{0\}$.

Similarly, using representation (4.13) for ω_k we can prove the following statement.

THEOREM 4.4. *Let $Q(t)$ be a solution of the linear differential equation* (4.3) *on $[t_1, t_s] \setminus \theta$ which satisfies the following conditions:*

(a) *the matrix M_{k-} is positive semidefinite for each $k = 1, \dots, s-1$,*

(b) $b_{k-} := D^k(H) - (q_{k-})[\dot{x}]^k > 0$ *for each $k = 2, \dots, s$.*

Then Ω is positive on $\mathcal{K} \setminus \{0\}$.

4.2. Q-transformation of Ω to perfect squares. We shall formulate special jump conditions for the matrix Q at each point $t_k \in \theta$. This will make it possible to transform Ω to perfect squares and thus to prove its positive definiteness on $\mathcal{K}$.

PROPOSITION 4.5 (see [42]). *Suppose that*

$$b_{k-} := D^k(H) - (q_{k-})[\dot{x}]^k > 0 \tag{4.16}$$

and that Q satisfies the jump condition at t_k

$$b_{k-}[Q]^k = (q_{k-})^*(q_{k-}), \tag{4.17}$$

where $(q_{k-})^*$ is a column-vector while q_{k-} is a row-vector. Then ω_k can be written as the perfect square

$$\omega_k = (b_{k-})^{-1}\left((b_{k-})\xi_k + (q_{k-})(\bar{x}^{k+})\right)^2 = (b_{k-})^{-1}\left(D^k(H)\xi_k + (q_{k-})(\bar{x}^{k-})\right)^2. \tag{4.18}$$

Proof. Using (4.13) and (4.17), we obtain

$$\begin{aligned}\omega_k &= (b_{k-})\xi_k^2 + 2(q_{k-})\bar{x}^{k+}\xi_k + (\bar{x}^{k+})^*[Q]^k\bar{x}^{k+}\\ &= (b_{k-})^{-1}\left((b_{k-})^2\xi_k^2 + 2(q_{k-})\bar{x}^{k+}(b_{k-})\xi_k + \left((q_{k-})\bar{x}^{k+}\right)^2\right)\\ &= (b_{k-})^{-1}\left((b_{k-})\xi_k + (q_{k-})(\bar{x}^{k+})\right)^2.\end{aligned}$$

Since

$$(b_{k-})\xi_k + (q_{k-})\bar{x}^{k+} = \left(D^k(H) - (q_{k-})[\dot{x}]^k\right)\xi_k + (q_{k-})\bar{x}^{k+}$$

$$= D^k(H)\xi_k - (q_{k-})[\bar{x}]^k + (q_{k-})\bar{x}^{k+} = D^k(H)\xi_k + (q_{k-})\bar{x}^{k-},$$

we see that equality (4.18) holds.

THEOREM 4.6. *Let $Q(t)$ satisfy the linear differential equation* (4.3) *on $[t_1, t_s]\setminus\theta$. Let condition* (4.16) *hold for each $k = 1, \dots, s$ and condition* (4.17) *hold for each $k = 1, \dots, s-1$. Then Ω is positive on $\mathcal{K}\setminus\{0\}$.*

Proof. By Proposition 4.5 and formulae (4.13), (4.15) the matrix M_{k-} is positive semidefinite for each $k = 1, \dots, s-1$, and hence both conditions (a) and (b) of Theorem 4.4 are fulfilled. Then by this theorem, Ω is positive on $\mathcal{K}\setminus\{0\}$.

Similar assertions hold for the jump conditions that use right-hand values of Q at each point $t_k \in \theta$.

PROPOSITION 4.7 (see [42]). *Suppose that*

$$b_{k+} := D^k(H) + (q_{k+})[\dot{x}]^k > 0 \tag{4.19}$$

and that Q satisfies the jump condition at point t_k

$$b_{k+}[Q]^k = (q_{k+})^*(q_{k+}). \tag{4.20}$$

Then

$$\omega_k = (b_{k+})^{-1}\left((b_{k+})\xi_k + (q_{k+})(\bar{x}^{k-})\right)^2 = (b_{k+})^{-1}\left(D^k(H)\xi_k + (q_{k+})(\bar{x}^{k+})\right)^2. \tag{4.21}$$

THEOREM 4.8. *Let $Q(t)$ satisfy the linear differential equation* (4.3) *on $[t_1, t_s]\setminus\theta$. Let condition* (4.19) *hold for each $k = 1, \dots, s$ and condition* (4.20) *hold for each $k = 2, \dots, s$. Then Ω is positive on $\mathcal{K}\setminus\{0\}$.*

4.3. Case of two switching points of the control. Let $s = 2$, i.e., $\theta = \{t_1, t_2\}$, and let $Q(t)$ be a symmetric matrix with absolutely continuous entries on $[t_1, t_2]$. Put

$$Q^k = Q(t_k), \quad q_k = ([\dot{x}]^k)^*Q^k - [\dot{\psi}]^k, \quad k = 1, 2.$$

THEOREM 4.9. *Let $Q(t)$ satisfy the linear differential equation* (4.3) *on (t_1, t_2) such that the following inequalities hold at t_1, t_2:*

$$D^1(H) + q_1[\dot{x}]^1 > 0, \quad D^2(H) - q_2[\dot{x}]^2 > 0. \tag{4.22}$$

Then Ω is positive on $\mathcal{K} \setminus \{0\}$.

Proof. In the case considered we have

$$Q^{1+} = Q^1, \quad q_{1+} = q_1, \quad Q^{2-} = Q^2, \quad q_{2-} = q_2$$

and

$$b_{1+} := D^1(H) + q_1[\dot{x}]^1 > 0, \quad b_{2-} := D^2(H) - q_2[\dot{x}]^2 > 0. \tag{4.23}$$

Define the jumps $[Q]^1$ and $[Q]^2$ by the conditions

$$b_{1+}[Q]^1 = (q_{1+})^*(q_{1+}), \quad b_{2-}[Q]^2 = (q_{2-})^*(q_{2-}). \tag{4.24}$$

Then $[Q]^1$ and $[Q]^2$ are symmetric matrices. Put

$$Q^{1-} = Q^{1+} - [Q]^1, \quad Q^{2+} = Q^{2-} + [Q]^2.$$

Then Q^{1-} and Q^{2+} are also symmetric matrices. Thus, we obtain a symmetric matrix $Q(t)$ satisfying (4.3) on (t_1, t_2), the inequalities (4.23), and the jump conditions (4.24). By Propositions 4.7 and 4.5, the terms ω_1 and ω_2 are nonnegative. In view of (4.4) we see that $\Omega = \omega_1 + \omega_2$ is nonnegative on $\mathcal{K}$. Suppose that $\Omega = 0$ for some $\bar{z} = (\xi, \bar{x}) \in \mathcal{K}$. Then $\omega_k = 0$ for $k = 1, 2$ and thus Propositions 4.7 and 4.5 give

$$b_{1+}\xi_1 + (q_{1+})\bar{x}^{1-} = 0, \quad b_{2-}\xi_2 + (q_{2-})\bar{x}^{2+} = 0.$$

But $\bar{x}^{1-} = 0$ and $\bar{x}^{2+} = 0$. Consequently, $\xi_1 = \xi_2 = 0$ and then conditions $\bar{x}^{1-} = 0$ and $[\bar{x}]^1 = 0$ imply that $\bar{x}^{1+} = 0$. The last equality together with equation $\dot{\bar{x}} = f_x(t)\bar{x}$ implies that $\bar{x}(t) = 0$ on (t_1, t_2). Thus $\bar{x} \equiv 0$ and then $\bar{z} = 0$. We have proved that Ω is positive on $\mathcal{K} \setminus \{0\}$.

4.4. Control system with a constant matrix B. In the case that $B(t, x) = B$ is a constant matrix, the adjoint equation has the form

$$\dot{\psi} = -\psi a_x,$$

which implies that

$$[\dot{\psi}]^k = 0, \quad k = 1, \dots, s.$$

Therefore,

$$\begin{aligned} q_{k-} &= ([\dot{x}]^k)^* Q^{k-}, & q_{k+} &= ([\dot{x}]^k)^* Q^{k+}, \\ (q_{k-})^* q_{k-} &= Q^{k-}[\dot{x}]^k([\dot{x}]^k)^* Q^{k-}, & (q_{k+})^* q_{k+} &= Q^{k+}[\dot{x}]^k([\dot{x}]^k)^* Q^{k+}, \\ b_{k-} &= D^k(H) - ([\dot{x}]^k)^* Q^{k-}[\dot{x}]^k, & b_{k+} &= D^k(H) + ([\dot{x}]^k)^* Q^{k+}[\dot{x}]^k, \end{aligned}$$

where

$$D^k(H) = \dot{\psi}(t_k) B[u]^k, \quad k = 1, \dots, s.$$

In case of two switching points with $s = 2$, the conditions (4.22) take the form

$$D^1(H) + \langle Q^1[\dot{x}]^1, [\dot{x}]^1) \rangle > 0\,, \quad D^2(H) - \langle Q^2[\dot{x}]^2, [\dot{x}]^2) \rangle > 0. \tag{4.25}$$

Now assume, in addition, that u is one-dimensional and that with $n = d(x)$

$$B = \beta e_n := \begin{pmatrix} 0 \\ \vdots \\ 0 \\ \beta \end{pmatrix}, \quad \beta > 0, \qquad U = [-c, c], \quad c > 0\,.$$

In this case we get

$$[\dot{x}]^k = B[u]^k = \beta e_n [u]^k, \quad k = 1, \dots, s,$$

and thus

$$\langle Q^k [\dot{x}]^k, [\dot{x}]^k) \rangle = \beta^2 \langle Q^k e_n, e_n \rangle |[u]^k|^2 = 4\beta^2 c^2\, Q_{nn}(t_k),$$

where Q_{nn} is the element of matrix

$$Q = \begin{pmatrix} Q_{11} & \dots & Q_{1n} \\ \vdots & \vdots & \vdots \\ Q_{n1} & \dots & Q_{nn} \end{pmatrix}.$$

Moreover, in the last case we obviously have

$$D^k(H) = 2\beta c\, |\dot{\psi}_n(t_k)|, \quad k = 1, \dots, s. \tag{4.26}$$

For $s = 2$ conditions (4.25) then yield the estimates

$$Q_{nn}(t_1) > -\frac{|\dot{\psi}_n(t_1)|}{2\beta c}\,, \qquad Q_{nn}(t_2) < \frac{|\dot{\psi}_n(t_2)|}{2\beta c}\,. \tag{4.27}$$

5. Numerical examples. In this section, we shall discuss three time-optimal control problems with fixed initial and final states $x(0) = x_0$ and $x(T) = x_1$. To solve these problems numerically, we need to reduce them to control problems with *fixed* final time. The procedure to achieve this goal is well known [11, 29] and consists of introducing a new time variable $\tau \in [0, 1]$ according to the transformation

$$t = \tau \cdot T\,, \quad \tau \in [0, 1]\,. \tag{5.1}$$

In what follows, we shall identify the function $y(\tau)$ with the function $y(\tau \cdot T)$ for all $y \in \{x, u, \psi\}$. This time transformation leads to the *augmented* state variable

$$\tilde{x} := \begin{pmatrix} x \\ T \end{pmatrix} \in \mathbb{R}^{d(x)+1}$$

for which we obtain the ODE and boundary conditions

$$\begin{aligned} &dx/d\tau = T \cdot f(\tau \cdot T, x(\tau), u(\tau)), \quad dT/d\tau = 0, \quad \tau \in [0, 1]\,, \\ &x(0) = x_0, \quad x(1) = x_1. \end{aligned} \tag{5.2}$$

In the same way, the adjoint equation (2.7) is rewritten as

$$d\psi/d\tau = -T \cdot H_x(\tau \cdot T, x(\tau), u(\tau), \psi(\tau)). \tag{5.3}$$

All examples in this section will treat *autonomous* problems for which we will be able to compute *nondegenerate* solutions with $\psi_0(T) > 0$ in (2.6). Then we may scale the equations such that $\psi_0(T) = 1$ holds. Furthermore, in the autonomous case it follows from (2.8) that $\psi_0(t) \equiv \psi_0(T) = 1$. Hence, (2.10) yields the following condition expressed in the new time variable τ:

$$\psi(\tau)\, f(x(\tau), u(\tau)) + 1 \equiv 0 \quad \forall\, \tau \in [0,1]\,. \tag{5.4}$$

Moreover, u can be expressed via x and ψ from the minimum principle (2.9),

$$\min_{u \in U} \psi(\tau)\, f(x(\tau), u) + 1 = 0 \quad \forall\, \tau \in [0,1]\,. \tag{5.5}$$

In the following examples, we shall use shooting methods (cf. Bulirsch [5] and Oberle and Grimm [34]) for solving the boundary value problem (5.2)–(5.5). Shooting methods are known to provide highly accurate solutions for which we shall carry out the second order test.

5.1. Time-optimal control of a Van der Pol oscillator. The following time-optimal control of a Van der Pol oscillator has been treated by several authors; cf., e.g., Kaya and Noakes [13, 14]. The state variables are the voltage $x_1(t) = U(t)$ at time $t \in [\,0, T\,]$ and $x_2(t) := \dot{x}_1(t)$. The control $u(t)$ is the voltage at the generator; cf. the tunneldiode oscillator in [29, Figure 5.1 in section 5].

The control problem is to minimize the endtime T subject to the constraints

$$\dot{x}_1(t) = x_2(t)\,,\ \dot{x}_2(t) = -x_1(t) + x_2(t)(1 - x_1^2(t)) + u(t)\,, \tag{5.6}$$

$$x_1(0) = -0.4,\ x_2(0) = 0.6\,, \quad x_1(T) = 0.6,\ x_2(T) = 0.4\,, \tag{5.7}$$

$$|\,u(t)\,| \le 1 \quad \text{for } \ t \in [0, T\,]\,. \tag{5.8}$$

The Pontryagin function or Hamiltonian (2.5) becomes

$$H(x, u, \psi) = \psi_1 x_2 + \psi_2\,(-x_1 + x_2(1 - x_1^2) + u)\,. \tag{5.9}$$

The time transformation (5.1) yields the transformed state and adjoint equations (5.2), (5.3) in the time interval $\tau \in [0,1]$; for simplicity, the time argument τ will be omitted:

$$\begin{array}{rclcrcl} dx_1/d\tau &=& T \cdot x_2\,, & & dx_2/d\tau &=& T \cdot \big(-x_1 + x_2(1 - x_1^2) + u\big)\,, \\ d\psi_1/d\tau &=& T \cdot \psi_2(1 + 2x_1\, x_2)\,, & & d\psi_2/d\tau &=& -T \cdot (\psi_1 + \psi_2(1 - x_1^2))\,, \\ dT/d\tau &=& 0\,. & & & & \end{array} \tag{5.10}$$

The boundary conditions (5.7) and the condition (5.4) yield

$$\begin{aligned} &x_1(0) = -0.4,\ x_2(0) = 0.6, \quad x_1(1) = 0.6,\ x_2(1) = 0.4, \\ &0.4\psi_1(1) + \psi_2(1)(-0.344 + u(1)) + 1 = 0\,. \end{aligned} \tag{5.11}$$

The switching function $\sigma(x, \psi) = \psi_2$ determines the optimal control according to the control law (2.13),

$$u(\tau) = \left\{ \begin{array}{rcl} 1 & \text{if} & \psi_2(\tau) < 0 \\ -1 & \text{if} & \psi_2(\tau) > 0 \end{array} \right\}\,. \tag{5.12}$$

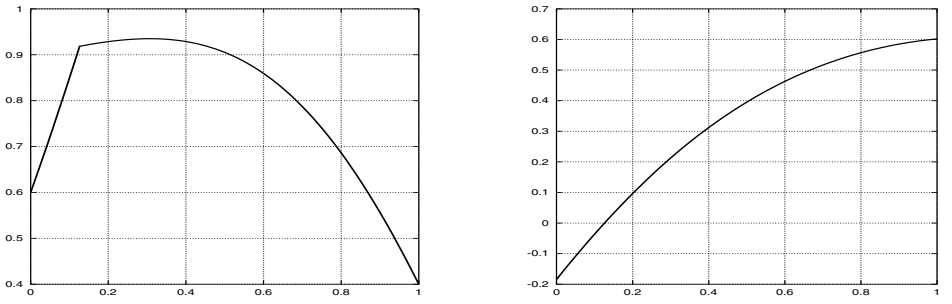

FIG. 5.1. *Van der Pol oscillator: state $x_2(\tau)$ and switching function $\sigma(\tau) = \psi_2(\tau)$, $\tau \in [0,1]$.*

It can easily be seen that the *singular case*, where $\psi_2(\tau) \equiv 0$ holds in a time interval $[\tau_1, \tau_2]$, does not occur. In fact, $\psi_2(\tau) \equiv 0$ would imply $\psi_1(\tau) \equiv 0$ and thus $H[\tau] \equiv 0$ which would contradict the condition (5.4) in the autonomous case. Computations show that the optimal bang-bang control has the following structure with two bang-bang arcs and only one switching point τ_1:

$$u(\tau) = \left\{ \begin{array}{rll} 1 & \text{for} & 0 \le \tau \le \tau_1 \\ -1 & \text{for} & \tau_1 \le \tau \le 1 \end{array} \right\}. \tag{5.13}$$

Hence, we have to impose the switching condition

$$\sigma[\tau_1] = \psi_2(\tau_1) = 0 \tag{5.14}$$

to determine the switching point τ_1.

The task now is to solve the boundary value problem with the following components: the state and adjoint equations (5.10) using the optimal control structure (5.13), the boundary conditions (5.11) and the switching condition (5.14). Employing the code BNDSCO in [34] we obtain the state variables and adjoint variables displayed in Figure 5.1. The optimal final time, the switching point, and some selected values for the adjoint variables are

$$\begin{array}{lll} T = 1.25407473, & \tau_1 = 0.12624458, & t_1 = \tau_1 \cdot T = 0.1583201376, \\ \psi_1(0) = -1.08160561, & \psi_2(0) = -0.18436798, & \psi_1(\tau_1) = -1.08863205, \\ \psi_1(1) = -0.47781383, & \psi_2(1) = 0.60184112\,. & \end{array} \tag{5.15}$$

Since the bang-bang control has only one switching point, we are in the position to apply Theorem 3.4. To check the assumptions of this theorem it remains to verify the condition $D^1(H) = |\dot\sigma(t_1)[u]^1| > 0$. Indeed, in view of the adjoint equation (5.10) and the switching condition $\psi_2(\tau_1) = 0$ we find for the original time variable $t_1 = \tau_1 \cdot T$,

$$D^1(H) = |\dot\sigma(t_1)[u]^1| = 2|\psi_1(t_1)| = 2 \cdot 1.08863205 > 0\,.$$

Then Theorem 3.4 asserts that the computed solution is a strict strong minimum.

Let us briefly discuss the optimal solution for the following boundary values (cf. Kaya and Noakes [14]) different from those in (5.7),

$$x_1(0) = x_2(0) = 1, \quad x_1(T) = x_2(T) = 0\,. \tag{5.16}$$

The optimal bang-bang control has two bang-bang arcs with one switching point τ_1. However, the control structure is reversed as compared to the one in (5.13):

$$u(\tau) = \left\{ \begin{array}{rll} -1 & \text{for} & 0 \le \tau \le \tau_1 \\ 1 & \text{for} & \tau_1 \le \tau \le 1 \end{array} \right\}. \tag{5.17}$$

We get the following numerical results,

$$\begin{array}{lll} T = 3.09520234, & \tau_1 = 0.23358852, & t_1 = \tau_1 \cdot T = 0.72300373, \\ \psi_1(0) = 0.94728449, & \psi_2(0) = 0.97364224, & \psi_1(\tau_1) = 1.70467637, \\ \psi_1(1) = 0.19669125, & \psi_2(1) = -1\,, & \end{array}$$

for which we obtain

$$D^1(H) = |\dot\sigma(t_1)[u]^1| = 2|\psi_1(t_1)| = 2 \cdot 1.70467637 > 0\,.$$

Theorem 3.4 shows again that the computed solution is a strict strong minimum.

5.2. Time-optimal control of the Rayleigh problem. The Rayleigh problem is concerned with the same electric circuit as treated in the previous section. However, the state variables are different since now the state variable $x_1(t) = I(t)$ denotes the electric current; cf. the dynamical model in [12, 27, 28, 29].

The control problem is to minimize the endtime T subject to

$$\dot x_1(t) = x_2(t)\,, \quad \dot x_2(t) = -x_1(t) + x_2(t)(1.4 - 0.14x_2(t)^2) + 4u(t)\,, \tag{5.18}$$

$$x_1(0) = x_2(0) = -5\,, \quad x_1(T) = x_2(T) = 0\,, \tag{5.19}$$

$$|\,u(t)\,| \le 1 \quad \text{for } t \in [0, T\,]\,. \tag{5.20}$$

The Pontryagin function (2.5) for this problem is

$$H(x, u, \psi) = \psi_1 x_2 + \psi_2\,(-x_1 + x_2(1.4 - 0.14x_2^2) + 4u). \tag{5.21}$$

The time transformation (5.1) and the transformed state and adjoint equations (5.2), (5.3) in the time interval $\tau \in [0, 1]$ lead to the following equations; again, the time argument τ will be omitted:

$$\begin{array}{rclrcl} dx_1/d\tau &=& T \cdot x_2\,, & dx_2/d\tau &=& T \cdot (-x_1 + x_2(1.4 - 0.14x_2^2) + 4u)\,, \\ d\psi_1/d\tau &=& T \cdot \psi_2\,, & d\psi_2/d\tau &=& -T \cdot (\psi_1 + \psi_2(1.4 - 0.42x_2^2))\,, \\ dT/d\tau &=& 0\,. & & & \end{array} \tag{5.22}$$

The boundary conditions (5.19) and the condition (5.4) yield, in view of (5.21),

$$x_1(0) = x_2(0) = -5, \quad x_1(1) = x_2(1) = 0, \quad 4\,\psi_2(1)\,u(1) + 1 = 0. \tag{5.23}$$

The switching function $\sigma(x, \psi) = 4\psi_2$ determines the optimal control via the minimum condition (2.13):

$$u(\tau) = \left\{ \begin{array}{rll} 1 & \text{if} & \psi_2(\tau) < 0 \\ -1 & \text{if} & \psi_2(\tau) > 0 \end{array} \right\}. \tag{5.24}$$

Again, the *singular case* with $\psi_2(\tau) \equiv 0$ holding in a time interval $[\tau_1, \tau_2]$ can be eliminated. Hence, the optimal control is bang-bang. In view of the special terminal

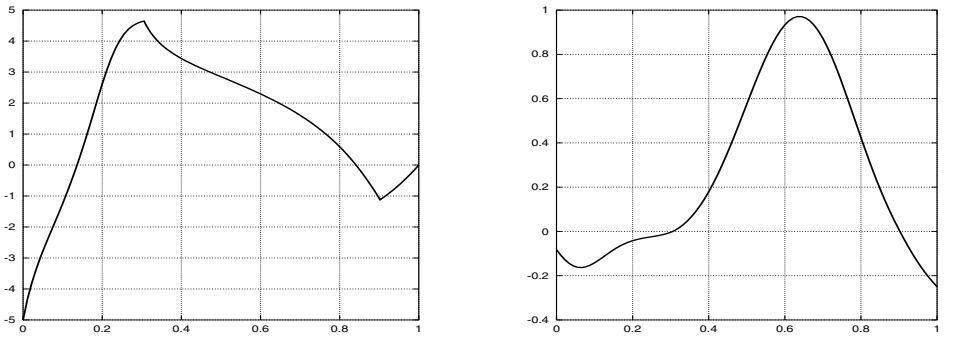

FIG. 5.2. *Rayleigh problem: state $x_2(\tau)$ and switching function $\psi_2(\tau) = \sigma(\tau)/4$, $\tau \in [0,1]$.*

conditions for the state, a simple reasoning reveals that the optimal control cannot be composed of only two bang-bang arcs. Computations show that the optimal control comprises the following three bang-bang arcs:

$$u(\tau) = \left\{ \begin{array}{rll} 1 & \text{for} & 0 \le \tau \le \tau_1 \\ -1 & \text{for} & \tau_1 \le \tau \le \tau_2 \\ 1 & \text{for} & \tau_2 \le \tau \le 1 \end{array} \right\}. \tag{5.25}$$

This control structure yields the two switching conditions

$$\psi_2(\tau_1) = 0\,, \quad \psi_2(\tau_2) = 0\,. \tag{5.26}$$

Thus we have to solve the multipoint boundary value problem consisting of the state and adjoint equations (5.22) with the optimal control structure (5.25), the boundary conditions (5.23), and the switching conditions (5.26).

The code BNDSCO in [34] yields the final time, the switching points, and some selected values for the adjoint variables as follows:

$$\begin{array}{rclrcl} T &=& 3.66817339\,, & & & \\ \tau_1 &=& 0.30546718\,, & \tau_2 &=& 0.90236928\,, \\ t_1 &=& \tau_1 \cdot T = 1.12050658\,, & t_2 &=& \tau_2 \cdot T = 3.31004698\,, \\ \psi_1(0) &=& -0.12234128\,, & \psi_2(0) &=& -0.08265161\,, \\ \psi_1(\tau_1) &=& -0.21521225\,, & \psi_1(\tau_2) &=& 0.89199176\,, \\ \psi_1(1) &=& 0.84276186\,, & \psi_2(1) &=& -0.25\,. \end{array} \tag{5.27}$$

Figure 5.2 displays the state variable $x_2(\tau)$ and the switching function $\psi_2(\tau)$ which match precisely the control laws (5.24) and (5.25).

We are going to show now in two different ways that the computed control provides a strict strong minimum. First, we compute the quantities $D^k(H) = -\dot\sigma(t_k)[u]^k$, $k = 1,2$, where $-\dot\sigma(t_k) = -4\dot\psi_2(t_k) = 4\psi_1(t_k)$ holds in view of the adjoint equation in (5.22) evaluated in the original time variable $t \in [0,T]$. Inserting the values from (5.27) we find

$$D^1(H) = 8 \cdot 0.21521225 = 1.7269800 > 0\,,\ D^2(H) = 8 \cdot 0.89199176 = 7.1359341 > 0\,.$$

The variational system $\dot y = f_x(t)y$ with $y = (y_1, y_2)$ in (3.3) reads explicitly

$$\dot y_1 = y_2, \quad \dot y_2 = -y_1 + (1.4 - 0.42x_2^2)y_2\,.$$

The initial values for the variations $y^1(t)$, $y^2(t)$ w.r.t. the switching points t_1, t_2 are

$$y^1(t_1) = [\dot{x}]^1 = \begin{pmatrix} 0 \\ -8 \end{pmatrix}, \quad y^2(t_2) = [\dot{x}]^2 = \begin{pmatrix} 0 \\ 8 \end{pmatrix}.$$

At the second switching point t_2 we find $y^1(t_2) = (0, 2.517130)$. In view of the initial value $y^2(t_2) = (0, 8)$, this already implies that the vectors $y^1(T)$ and $y^2(T)$ are *linearly dependent*. Explicitly, we get $y^1(T) = (1.084614, 3.656286)$, $y^2(T) = (3.447153, 11.620490)$ which gives $y^2(T) = \alpha y^1(T)$ with $\alpha = 3.17823$ in relation (3.9). Thus, condition (b) in Proposition 3.2 asserting the zero critical subspace is not satisfied here. Here, the critical subspace is a one-dimensional subspace and the test for optimality proceeds via Proposition 3.5 by verifying that the number ρ in (3.15) is positive. Using the above variational vectors we compute

$$\int_{t_1}^{t_2} \langle H_{xx}(t) y^1(t), y^1(t) \rangle \, dt = -0.84 \int_{t_1}^{t_2} x_2(t) \psi_2(t) (y_2^1(t))^2 dt \; = \; -0.97063758.$$

Finally, observing the relations $[\dot{\psi}]^1 = [\dot{\psi}]^2 = 0$ and inserting the computed values of $D^1(H)$, $D^2(H)$ and α we obtain

$$\rho = 1.726980 + 0.706448 - 0.970638 = 1.462790 > 0.$$

Hence, we have shown that the solution described by (5.27) is a strict strong minimum.

An alternative proof of optimality proceeds via Theorem 4.9. Consider the symmetric 2×2 matrix

$$Q(t) = \begin{pmatrix} Q_{11}(t) & Q_{12}(t) \\ Q_{12}(t) & Q_{22}(t) \end{pmatrix}.$$

The linear equation (4.3), $\dot{Q} = -Q f_x - f_x^* Q - H_{xx}$, in the original time variable $t \in [t_1, t_2]$ leads to the following three ODEs:

$$\begin{aligned} \dot{Q}_{11} &= 2\, Q_{12}, \\ \dot{Q}_{12} &= -Q_{11} - Q_{12}(1.4 - 0.42 x_2^2) + Q_{22}, \\ \dot{Q}_{22} &= -2\,(Q_{12} + Q_{22}(1.4 - 0.42 x_2^2)) + 0.84 \psi_2 x_2. \end{aligned} \tag{5.28}$$

We have to find a solution $Q(t)$ that satisfies the estimates (4.22), respectively, (4.27) at the switching points t_1 and t_2,

$$Q_{22}(t_1) > -\frac{|\psi_1(t_1)|}{8} = -0.026901531\,, \quad Q_{22}(t_2) < \frac{|\psi_1(t_2)|}{8} = 0.11149897\,. \tag{5.29}$$

These conditions hold if we choose, e.g., the following initial values at the switching point t_1,

$$Q_{11}(t_1) = 0, \quad Q_{12}(t_1) = 0, \quad Q_{22}(t_1) = -0.02,$$

which produce the value $Q_{22}(t_2) = -0.048826568$ at the second switching point. Then Theorem 4.9 assures us that the computed solution (5.27) provides a strict strong minimum.

5.3. Time-optimal control of a nuclear reactor. Hassan, Ghonaimy, and Abdel Malek [10] have presented a model for the time-optimal control of a nuclear reactor. A detailed solution has been given in Maurer [26]. Now our aim is to verify second order conditions for this specific solution. The model comprises the state variables x_1, neutron density; x_2, delayed neutron concentration; and x_3, reactivity. The control problem is to minimize the final time T subject to

$$\begin{array}{lll} \dot{x}_1(t) = k_1(x_3(t)-1)x_1(t) + k_2 x_2(t)\,, & x_1(0) = n_0, & x_1(T) = n_f, \\ \dot{x}_2(t) = k_1 x_1(t) - k_2 x_2(t)\,, & x_2(0) = n_0 k_1/k_2, & x_2(T) = n_f k_1/k_2, \\ \dot{x}_3(t) = u(t)\,, & x_3(0) = 0, & x_3(T) = 0, \\ |\,u(t)\,| \le 0.2 & \text{for } t \in [0, T\,]\,. & \end{array} \tag{5.30}$$

The constants are $k_1 = 5.0$, $k_2 = 0.1$, $n_0 = 0.04$, $n_f = 0.06$. The Pontryagin function or Hamiltonian (2.5) becomes

$$H(x, u, \psi) = \psi_1(k_1(x_3 - 1)x_1 + k_2 x_2) + \psi_2(k_1 x_1 - k_2 x_2) + \psi_3 u\,. \tag{5.31}$$

The time transformation (5.1) and the scaled equations (5.2)–(5.4) yield the following state and adjoint equations and boundary conditions:

$$\begin{array}{rcll} dx_1/d\tau &=& T\cdot(k_1(x_3-1)x_1 + k_2 x_2)\,, & x_1(0) = 0.04, \quad x_1(1) = 0.06, \\ dx_2/d\tau &=& T\cdot(k_1 x_1 - k_2 x_2)\,, & x_2(0) = 2, \quad x_2(1) = 3, \\ dx_3/d\tau &=& T\cdot u(\tau)\,, & x_3(0) = 0, \quad x_3(1) = 0, \\ d\psi_1/d\tau &=& -T\cdot(\psi_1 k_1(x_3-1) + \psi_2 k_1)\,, & \\ d\psi_2/d\tau &=& T\cdot k_2(\psi_2 - \psi_1)\,, & \\ d\psi_3/d\tau &=& -T\psi_1 k_1 x_1\,, & \psi_3(0) = -5\,, \quad \psi_3(1) = -5\,. \end{array} \tag{5.32}$$

The switching function $\sigma(x, \psi) = \psi_3(t)$ determines the optimal control via $u(t) = -0.2\,sign(\psi_3(t))$. The optimal control computed in [26] is composed of three bang-bang arcs,

$$u(\tau) = \left\{ \begin{array}{rcl} 0.2 & \text{for} & 0 \le \tau \le \tau_1 \\ -0.2 & \text{for} & \tau_1 \le \tau \le \tau_2 \\ 0.2 & \text{for} & \tau_2 \le \tau \le 1 \end{array} \right\}, \tag{5.33}$$

which imply the two further switching conditions

$$\psi_3(\tau_1) = 0, \quad \psi_3(\tau_2) = 0\,. \tag{5.34}$$

The earlier computations in [26] are confirmed by the code BNDSCO in [34] which yields the following solution of the boundary value problem (5.32)–(5.34):

$$\begin{array}{rcl@{\qquad}rcl} T &=& 7.04780685, & & & \\ \tau_1 &=& 0.47987830\,, & t_1 &=& \tau_1 \cdot T = 3.38208957\,, \\ \tau_2 &=& 0.97987830\,, & t_2 &=& \tau_2 \cdot T = 6.90599299\,, \\ \psi_1(0) &=& -2.97015515\,, & \psi_2(0) &=& -2.84546900\,, \\ \psi_1(\tau_1) &=& -5.22557130\,, & \psi_2(\tau_1) &=& -2.22864972\,, \\ x_1(\tau_1) &=& 0.11014294\,, & x_1(\tau_2) &=& 0.06078025\,, \\ \psi_1(\tau_2) &=& 78.6539693\,, & \psi_2(\tau_2) &=& -3.53032114\,, \\ \psi_1(1) &=& 165.786058\,, & \psi_2(1) &=& -5.25230261\,. \end{array} \tag{5.35}$$

The state variable $x_3(\tau)$ and the switching function $\sigma(\tau) = \psi_3(\tau)$ are displayed in Figure 5.3.

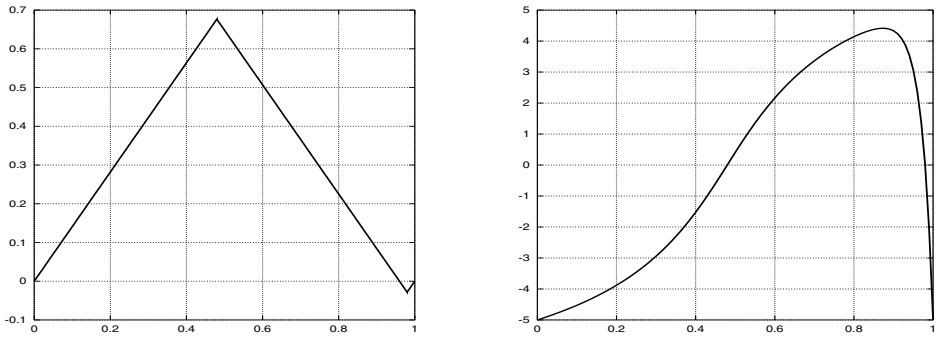

FIG. 5.3. *Nuclear reactor: state $x_3(\tau)$ and switching function $\sigma(\tau) = \psi_3(\tau)$.*

As in the foregoing example, we can show in two different ways that the computed control provides a strict strong minimum. The quantities

$$D^k(H) = -\dot\sigma(t_k)[u]^k = 0.4\,|\dot\psi_3(t_k)| = 0.4\,|\psi_1(t_k)k_1x_1(t_k)|, \quad k = 1, 2,$$

are computed on the basis of solution data in (5.35) as

$$D^1(H) = 1.15111957 > 0, \quad D^2(H) = 9.56121580 > 0\,.$$

Evaluating the variational system (3.3), $\dot y = f_x(t)y$ with $y = (y_1, y_2, y_3)$, we get

$$\dot y_1 = k_1(x_3 - 1)y_1 + k_2y_2 + k_1x_1y_3, \quad \dot y_2 = k_1y_1 - k_2y_2, \quad \dot y_3 = 0.$$

The initial values for the variations $y^1(t)$, $y^2(t)$ w.r.t. t_1, t_2 are

$$y^1(t_1) = [\dot x]^1 = \begin{pmatrix} 0 \\ 0 \\ -0.4 \end{pmatrix}, \quad y^2(t_2) = [\dot x]^2 = \begin{pmatrix} 0 \\ 0 \\ 0.4 \end{pmatrix}.$$

This leads to the following variational vectors at the terminal time T:

$$y^1(T) = \begin{pmatrix} -0.04508835 \\ -1.0424039 \\ -0.4 \end{pmatrix}, \quad y^2(T) = \begin{pmatrix} 0.012216498 \\ 0.0048217532 \\ 0.4 \end{pmatrix}, \quad \dot x(T) = \begin{pmatrix} 0 \\ 0 \\ 0.2 \end{pmatrix},$$

which obviously are *linearly independent*. Thus, either condition (a) or (b) in Proposition 3.2 implies that the critical cone is $\mathcal{K} = \{0\}$. Hence, Theorem 3.3 asserts that the solution candidate characterized by (5.35) provides indeed a strict strong minimum.

Alternatively, it is instructive to use also the test of optimality in Theorem 4.9. Since $d(x) = 3$ we consider the symmetric 3×3 matrix $Q(t) = (Q_{ik})_{1\le i,k\le 3}$. By evaluating the linear equation (4.3) one immediately recognizes that the equations for Q_{11}, Q_{12}, Q_{22} are homogeneous in these variables and can thus be satisfied by $Q_{11}(t) = Q_{12}(t) = Q_{22}(t) \equiv 0$. The remaining three equations then simplify to

$$\begin{aligned} \dot Q_{13} &= -Q_{13}k_1(x_3 - 1) - Q_{23}k_1 - \psi_1k_1, \\ \dot Q_{23} &= -Q_{13}k_2 + Q_{23}k_2, \\ \dot Q_{33} &= -2Q_{13}k_1x_1. \end{aligned} \tag{5.36}$$

Our task is to find a solution to these ODEs which satisfies the estimates (4.22) or (4.27) at the switching points t_1 and t_2. Since

$$\frac{|\dot{\psi}_3|}{2\beta c} = \frac{k_1|\psi_1 x_1|}{0.4} = 12.5|\psi_1 x_1|,$$

conditions (4.27) require that the following estimates be satisfied:

$$\begin{array}{rcrcr} Q_{33}(t_1) & > & -12.5\,|\psi_1(t_1)x_1(t_1)| & = & -7.1944973, \\ Q_{33}(t_2) & < & 12.5\,|\psi_1(t_2)x_1(t_2)| & = & 59.788260. \end{array} \tag{5.37}$$

The strategy for finding appropriate initial values at the point t_1 is the following: we fix the initial values

$$Q_{13}(t_1) = 0, \quad Q_{33}(t_1) = 0,$$

and determine $Q_{23}(t_1)$ in such a way that the inequality $Q_{33}(t_2) < 59.788260$ holds. We found that the initial value $Q_{23}(t_1) = 4.23$ produced the value $Q_{33}(t_2) = -96.953435$. Hence, the inequalities (5.37) hold and Theorem 4.9 asserts that the computed solution is a strict strong minimum.

6. Conclusion. We have considered time-optimal bang-bang control problems with finitely many switching points. SSC for such problems amount to the requirement that a certain quadratic form be positive on a finite-dimensional critical subspace. An explicit representation of the critical subspace has been derived in terms of the variations of the state trajectories w.r.t. the switching points. For bang-bang controls with one or two switching points, this approach results in a rather straightforward test of SSC. To treat the general case, we have shown that the so-called Q-transformation allows us to convert the quadratic form to another quadratic form which might be better suited for practical verification. The resulting numerical test then consists in determining a solution of a linear matrix differential equation which satisfies additional jump conditions at the switching points. The viability of the presented tests has been demonstrated by three numerical examples. Further examples with applications of bang-bang control to the design of lasers may be found in the dissertation of Kim [16].

Though the techniques have been developed in this paper only for time-optimal bang-bang controls with fixed terminal conditions, the basic ideas apply as well to arbitrary bang-bang control problems with general cost functionals and boundary conditions. Results for this general approach will be presented in a future paper that will also highlight a more detailed analysis of the boundary conditions.

During the revision of this paper we became aware of the work of Agrachev, Stefani, and Zezza [1], where a different approach to SSC for bang-bang controls is presented for problems with *fixed* final time. Agrachev and his coauthors reduce the bang-bang control problem to a finite-dimensional optimization problem w.r.t. the switching times and show that it suffices to test SSC for this optimization problem. Currently, we are implementing this approach and are in the process of comparing it with the numerical methods given in the present paper. Recently, we have been able to show that the SSC given in Theorem 3.3 are equivalent to the SSC in Agrachev, Stefani, and Zezza [1] in the case when the set M_0 of Lagrange multipliers is a singleton which is not assumed in Theorem 3.3. The SSC developed in this paper and in [1] will pave the way to a theoretical and computational sensitivity analysis for bang-bang control problems which is similar in spirit to that developed in [2, 21, 22, 23, 24, 25, 27, 28].

Acknowledgments. We are grateful to the referees for helpful remarks and suggestions to improve the paper. We are also indebted to Dirk Augustin for providing us the bang-bang control for the Rayleigh problem in section 5.2.

ON A GENERAL STRUCTURE OF THE STABILIZING CONTROLLERS BASED ON STABLE RANGE*

A. QUADRAT†

Abstract. In this paper, we prove that some stabilizing controllers of a plant, which admits a left/right-coprime factorization, have a special form where their stable and unstable parts are separated. The dimension of the unstable part depends on the algebraic concept of stable range of the ring A of SISO stable plants. Moreover, we prove that, if the stable range of A is equal to 1, then every plant—defined by a transfer matrix with entries in the quotient field of A and admitting a left/right-coprime factorization—can be stabilized by a stable controller (strong stabilization). In particular, using a result of Treil proving that the stable range of $H_\infty(\mathbb{D})$ is equal to 1, we show that every stabilizable plant—defined by a transfer matrix with entries in the quotient field of $H_\infty(\mathbb{D})$ or $H_\infty(\mathbb{C}_+)$—is strongly stabilizable and, equivalently, every couple of stabilizable plants can be simultaneously stabilized by a controller (simultaneous stabilization). Finally, using the fact that the topological stable range of $H_\infty(\mathbb{D})$ is equal to 2, a result due to Suárez, we show that every unstabilizable SISO plant—defined by a transfer function with entries in the quotient field of $H_\infty(\mathbb{D})$—is as close as we want to a stabilizable plant in the product topology.

Key words. stabilizing controllers, strong stabilization, simultaneous stabilization, stable range, k-stability, topological stable range, unit 1-stable range, n-fold rings, H_∞, K-theory

1. Introduction.

The fractional representation approach to analysis and synthesis problems was developed in the eighties in order to express in a unique mathematical framework several questions on stabilization problems. In that framework, we can study internal stabilization (existence of an internally stabilizing controller), parametrization of all stabilizing controllers, strong stabilization (possibility of stabilizing a plant by means of a stable controller), simultaneous stabilization (possibility of stabilizing a set of plants by means of a single controller), metrics of robustness (gap or graph topologies), H_∞ or H_2-optimal controllers, etc. See [2, 6, 42] for more details.

Recently, the reformulation of the fractional representation approach to analysis and synthesis problems within an *algebraic analysis approach* has allowed us to obtain new necessary and sufficient conditions for internal stabilizability and for the existence of (weakly) left/right/doubly coprime factorizations in the general setting [25, 26, 24]. Moreover, all the rings of SISO stable plants (used in this framework) over which one of the previous properties is satisfied were completely characterized [25, 26, 24]. In [27, 28], a new parametrization of all stabilizing controllers of a stabilizable plant was developed. It generalizes the Youla–Kučera parametrization [42] for stabilizable plants which do not necessarily admit doubly coprime factorizations. All these results show that a natural mathematical framework for the study of stabilization problems is the so-called *K-theory* [22, 32]. See [29] for more details.

The purpose of this paper is to show that the concept of *stable range* developed in K-theory also plays an important role in the study of the strong and simultaneous stabilization problems [42]. Using the fractional representation approach to synthesis problems [6, 42], we show that, if the transfer matrix P, with entries in the quotient field of an integral domain A of SISO stable plants (e.g., $A = RH_\infty$, $H_\infty(\mathbb{C}_+)$ or W_+), admits a left-coprime factorization $P = D^{-1}N$, then there exist some stabilizing controllers of P having separated stable and unstable parts. In particular, we show that the dimension of the unstable part is related to the concept of *k-stability* of the matrix $R = (D : -N)$ with entries in A [17, 41]. Moreover, using some relations between the k-stability of a matrix with entries in A and the concept of *stable range* $\mathrm{sr}(A)$ *of* A [1, 7, 41], we prove that there exist some stabilizing controllers of P which are such that their unstable parts are defined by $\mathrm{sr}(A) - 1$ unstable rows. Therefore, if the stable range $\mathrm{sr}(A)$ of A is 1, then every transfer matrix which admits a left-coprime factorization is strongly stabilizable; i.e., it is internally stabilized by a stable controller. In particular, using the fact that the stable range of $H_\infty(\mathbb{D})$ is equal to 1 (see [38]), we prove that every stabilizable plant, defined by means of a transfer matrix with entries in the quotient field of $H_\infty(\mathbb{D})$ or $H_\infty(\mathbb{C}_+)$, is strongly stabilizable (strong stabilization). Let us notice that this result answers one of the questions asked in [9]. Moreover, using a result of Vidyasagar [42], we prove that every couple of plants, defined by transfer matrices with entries in $H_\infty(\mathbb{D})$ or $H_\infty(\mathbb{C}_+)$, is simultaneously stabilized by a controller (simultaneous stabilization). Finally, introducing the concept of *topological stable range*, we show that every unstabilizable SISO plant, defined by a transfer function $p = n/d$, with $0 \neq d,\ n \in H_\infty(\mathbb{D})$, is as close as we want to a stabilizable plant in the product topology.

Plan of the paper. In section 2, we give the definition of the stable range of a ring A and present some examples which will be used in the rest of the paper. In section 3, we introduce the concept of k-stability of a matrix with entries in a ring A. We recall the fractional representation approach to analysis and synthesis problems in section 4. In section 5, we give the first main result of this paper concerning the form of certain stabilizing controllers (Theorem 5.1) and examples in order to illustrate this result. Exploiting the relations between k-stability of a matrix with entries in a ring A and the stable range of A, we give the second main result of the paper (Corollary 6.4) and its corollaries (Corollaries 6.5 and 6.6). In the last section, we introduce the definitions of topological stable range, unit 1-stable range, and n-fold ring, and give some applications of these concepts to some stabilization problems.

Notation. A will denote a commutative ring with a unit [33], $A^{q\times p}$ the set of $q \times p$ matrices with entries in A, I_p the identity matrix of $A^{p\times p}$, and

$$\mathrm{GL}_p(A) = \{R \in A^{p\times p} \mid \exists\, S \in A^{p\times p} :\ RS = SR = I_p\}$$

the group of invertible elements of $A^{p\times p}$. If $R \in A^{q\times p}$, then $R^T \in A^{p\times q}$ is the transposed matrix. If A is an integral domain (i.e., $a\,b = 0,\ a \neq 0 \Rightarrow b = 0$), then we shall denote the *field of fractions* of A by $K = Q(A) = \{n/d \mid d \neq 0,\ n \in A\}$. Finally, p and q will always denote two positive integers satisfying $p \geq q$ ($p - q$ will denote the number of input variables for the transfer matrices) and $\triangleq$ will mean "by definition."

2. Stable range of a commutative ring.

2.1. Definition. Let us give some definitions that will be constantly used in this paper.

Definition 2.1 (see [1, 4, 7, 41]). *We have the following definitions and notation:*

- *A vector* $a = (a_1 : \cdots : a_n) \in A^{1\times n}$ *is said to be* unimodular *if there exists a vector* $b = (b_1 : \cdots : b_n) \in A^{1\times n}$ *such that* $a\,b^T = \sum_{i=1}^n a_i\,b_i = 1$.
- *We denote the set of all the unimodular vectors of* $A^{1\times n}$ *by* $\mathrm{U}_n(A)$.

Let us notice that $\mathrm{U}_1(A)$ is the set of the units $\mathrm{U}(A) = \{a \in A \mid a^{-1} \in A\}$ of A.

Example 2.1. Let us take $A = H_\infty(\mathbb{C}_+)$, where $H_\infty(\mathbb{C}_+)$ is the algebra of $\mathbb{C}$-valued holomorphic functions on the open right half plane $\mathbb{C}_+ = \{s \in \mathbb{C} \mid \mathrm{Re}\, s > 0\}$ which are bounded w.r.t. the norm $\| f \|_\infty = \sup_{s\in\mathbb{C}_+} |f(s)|$. See [5] for more details. The vector $a = (\frac{s-1}{s+1} : \frac{e^{-s}}{s+1}) \in A^{1\times 2}$ is unimodular because we have

$$\left(\tfrac{s-1}{s+1}\right)\left(1 + 2\left(\tfrac{1-e^{-(s-1)}}{s-1}\right)\right) + \left(\tfrac{e^{-s}}{s+1}\right) 2\,e = 1, \qquad 1 + 2\left(\tfrac{1-e^{-(s-1)}}{s-1}\right),\ 2\,e \in A.$$

Definition 2.2 (see [1, 4, 7, 41]). *A vector* $a = (a_1 : \cdots : a_n) \in \mathrm{U}_n(A)$ *is called* stable *(or* reductible*) if there exists an* $(n-1)$*-tuple* $b = (b_1 : \cdots : b_{n-1}) \in A^{1\times(n-1)}$ *such that*

$$(a_1 + a_n\,b_1 : \cdots : a_{n-1} + a_n\,b_{n-1}) \in \mathrm{U}_{n-1}(A);$$

i.e., there exists $(c_1 : \cdots : c_{n-1}) \in A^{1\times(n-1)}$ *such that* $\sum_{i=1}^{n-1}(a_i + a_n\,b_i)\,c_i = 1$.

Example 2.2. We have the following examples:

- Let us consider $A = H_\infty(\mathbb{C}_+)$ and $a = (1 - e^{-2s} : 1 + e^{-2s}) \in A^{1\times 2}$. We have

  (2.1)
  $$\tfrac{1}{2}\,(1 - e^{-2s}) + \tfrac{1}{2}\,(1 + e^{-2s}) = 1 \Rightarrow (1 - e^{-2s}) + (1 + e^{-2s}) = 2 \in \mathrm{U}_1(A),$$

  and thus, a is a stable vector of $\mathrm{U}_2(A)$.
- Let $A = RH_\infty = \mathbb{R}(s) \cap H_\infty(\mathbb{C}_+)$ be the $\mathbb{R}$-algebra of proper and stable real rational functions [42]. The vector

  $$a = \left(\tfrac{(s-1)(s-2)}{(s+1)^2} : \tfrac{s}{(s+1)^2}\right) \in A^{1\times 2}$$

  is stable because we have

  (2.2)
  $$\tfrac{(s-1)(s-2)}{(s+1)^2} + \tfrac{6\,s}{(s+1)^2} = \tfrac{(s+2)}{(s+1)} \in \mathrm{U}_1(A).$$

Remark 2.1. If a vector $(a_1 : a_2) \in \mathrm{U}_2(A)$ is stable, then, in general, this is not the case for $(a_2 : a_1) \in \mathrm{U}_2(A)$. For instance, if $A = \mathbb{R}[s]$, then $(s^2 + 1 : s) \in A^{1\times 2}$ is a stable vector because we have $(s^2 + 1) + s\,(-s) = 1 \in \mathrm{U}_1(A)$, whereas the vector $(s : s^2 + 1) \in U_2(A)$ is not stable because there does not exist $b \in A$ such that $r \triangleq s + (s^2 + 1)\,b(s) \in A$ is invertible, i.e., is a nonzero real constant (the degree of the polynomial r is at least 1).

Definition 2.3 (see [31, 34, 38, 41]). *We call the* stable range $\mathrm{sr}(A)$ *of* A *the smallest* $n \in \mathbb{N} \cup \{+\infty\}$ *such that every vector of* $\mathrm{U}_{n+1}(A)$ *is stable.*

Let us notice that the stable range $\mathrm{sr}(A)$ is also called the *stable rank* of A.

Remark 2.2. Let us notice that if $\mathrm{sr}(A) = n$, then, for $m \geq n$, every element of $U_m(A)$ is stable [11]. Indeed, if $(a_1 : \cdots : a_{n+2}) \in U_{n+2}(A)$, then there exist $b_1, \ldots, b_{n+2} \in A$ such that $\sum_{i=1}^{n+2} a_i\,b_i = 1$. Hence, the vector

$$(a_1 : \cdots : a_n : a_{n+1}\,b_{n+1} + a_{n+2}\,b_{n+2}) \in A^{1\times(n+1)}$$

is unimodular. Using the fact that $\mathrm{sr}(A) = n$, there exist $c_1, \ldots, c_n \in A$ such that the vector

$$(a_1 + c_1\,(a_{n+1}\,b_{n+1} + a_{n+2}\,b_{n+2}) : \cdots : a_n + c_n\,(a_{n+1}\,b_{n+1} + a_{n+2}\,b_{n+2})) \in A^{1\times n}$$

is unimodular; i.e., there exist $d_1, \ldots, d_n \in A$ such that

$$\sum_{i=1}^{n} (a_i + c_i\,(a_{n+1}\,b_{n+1} + a_{n+2}\,b_{n+2}))\,d_i = 1$$

$$\Rightarrow \sum_{i=1}^{n} (a_i + c_i\,a_{n+2}\,b_{n+2})\,d_i + a_{n+1}\left(\sum_{i=1}^{n} b_{n+1}\,c_i\,d_i\right) = 1,$$

which shows that $(a_1 + (c_1\,b_{n+2})\,a_{n+2} : \cdots : a_n + (c_n\,b_{n+2})\,a_{n+2} :\ a_{n+1})$ is unimodular, and thus the vector $(a_1 : \cdots : a_{n+2}) \in U_{n+2}(A)$ is a stable vector. The result directly follows by induction on n.

Example 2.3. We have the following interpretations of $\mathrm{sr}(A) = 2$ and $\mathrm{sr}(A) = 1$:

- A ring A has a stable range $\mathrm{sr}(A) = 2$ iff, $\forall\, n \geq 3$, every element of $\mathrm{U}_n(A)$ is stable and there exists a vector $(a_1 :\ a_2) \in \mathrm{U}_2(A)$ such that, for every $b \in A$, $a_1 + a_2\,b \notin \mathrm{U}_1(A)$, i.e., $a_1 + a_2\,b$ is not invertible.
- A ring A has a stable range $\mathrm{sr}(A) = 1$ iff, for every $(a_1 :\ a_2) \in \mathrm{U}_2(A)$, there exists $b \in A$ such that $a_1 + a_2\,b \in \mathrm{U}_1(A)$, i.e., $a_1 + a_2\,b$ is invertible.

2.2. Examples.

THEOREM 2.4 (see [38]). *If $\mathbb{D}$ denotes the open unit disc and $H_\infty(\mathbb{D})$ the ring of $\mathbb{C}$-valued holomorphic functions on $\mathbb{D}$ which are bounded w.r.t. the norm $\| f \|_\infty = \sup_{z\in\mathbb{D}} |f(z)|$, then we have*

$$\mathrm{sr}(H_\infty(\mathbb{D})) = 1.$$

COROLLARY 2.5. *With the notation of Example* 2.1*, we have*

$$\mathrm{sr}(H_\infty(\mathbb{C}_+)) = 1.$$

Proof. Let us consider a unimodular matrix $a = (a_1 :\ a_2) \in U_2(H_\infty(\mathbb{C}_+))$. Let us denote by $(b_1 :\ b_2)^T \in H_\infty(\mathbb{C}_+)^{2\times 1}$ a right-inverse of a; i.e., we have

$$a_1(s)\,b_1(s) + a_2(s)\,b_2(s) = 1. \tag{2.3}$$

The fractional linear transformation $s = \psi(z) = (1+z)/(1-z)$ bijectively maps the open unit disc $\mathbb{D}$ on the open right half plane $\mathbb{C}_+$ and $z = \psi^{-1}(s) = (s-1)/(s+1)$. Moreover, from Lemma A.6.15 of [5], we have $f \in H_\infty(\mathbb{C}_+) \Leftrightarrow f \circ \psi \in H_\infty(\mathbb{D})$. Thus, from (2.3), we deduce

$$(a_1 \circ \psi)(z)\,(b_1 \circ \psi)(z) + (a_2 \circ \psi)(z)\,(b_2 \circ \psi)(z) = 1 \circ \psi = 1, \tag{2.4}$$

i.e., $(a_1 \circ \psi :\ a_2 \circ \psi) \in \mathrm{U}_2(\mathrm{H}_\infty(\mathbb{D}))$. By Theorem 2.4, we know that $\mathrm{sr}(H_\infty(\mathbb{D})) = 1$, and thus there exist $c,\, d \in H_\infty(\mathbb{D})$ such that

$$((a_1 \circ \psi)(z) + (a_2 \circ \psi)(z)\,c(z))\,d(z) = 1 \Leftrightarrow (a_1(s) + a_2(s)\,c(\psi^{-1}(s)))\,d(\psi^{-1}(s)) = 1;$$

i.e., $a = (a_1 :\ a_2)$ is 1-stable, and thus $\mathrm{sr}(H_\infty(\mathbb{C}_+)) = 1$. ∎

THEOREM 2.6 (see [1]). *If A is a principal ideal domain, namely, an integral domain such that every ideal of A can be generated by a single element of A, then* $\mathrm{sr}(A) \leq 2$.

COROLLARY 2.7. *Let RH_∞ be the ring of proper and stable real rational functions. Then, we have*

$$\mathrm{sr}(RH_\infty) = 2.$$

Proof. It is well known that RH_∞ is a principal ideal domain [42]. Therefore, by Theorem 2.6, we obtain that $\mathrm{sr}(RH_\infty) \leq 2$. Finally, let $(d:\ n) \in \mathrm{U}_2(RH_\infty)$ with $d \neq 0$ and let us define the transfer function $P = n/d \in \mathbb{R}(s) = Q(RH_\infty)$. Let us notice that $P = n/d$ is a coprime factorization of P because $(d:\ n) \in \mathrm{U}_2(RH_\infty)$. Now, it is also well known that there exists $c \in RH_\infty$ such that $d + c\,n$ is a unit of RH_∞ iff P has the *parity interlacing property* [2, 42], namely, P has an even number of real poles between every pair of real zeros in $\{\mathrm{Re}\, s \geq 0\} \cup \{\infty\}$. Hence, there exist vectors $(d:\ n) \in \mathrm{U}_2(RH_\infty)$ which are not stable in the sense of Definition 2.2 (e.g., $((s-1)/(s+1):\ s/(s+1)^2) \in \mathrm{U}_2(RH_\infty)$ is not stable because the transfer function $P = s/((s+1)\,(s-1))$ does not have the parity interlacing property—see Example 4 of section 3.2 of [42]). Therefore, we have $\mathrm{sr}(RH_\infty) = 2$. □

Let us give more examples of stable ranges of integral domains.

THEOREM 2.8. *We have the following results:*

- [12, 41] $\mathrm{sr}(\mathbb{R}[x_1, \ldots, x_n]) = n + 1$.
- [19] *The ring of entire functions*

$$E(k) = \left\{ f(s) = \sum_{n=0}^{+\infty} a_n\, s^n \;\middle|\; s \in \mathbb{C},\ a_n \in k,\ \lim_{n \to +\infty} |a_n|^{1/n} = 0 \right\}$$

  satisfies $\mathrm{sr}(E(k)) = 1$ *if* $k = \mathbb{C}$ *and* 2 *if* $k = \mathbb{R}$.
- [20] *The disc algebra* $A(\mathbb{D})$*, i.e., the ring of functions which are holomorphic in the open unit disc* $\mathbb{D}$ *and continuous on the unit circle* $\mathbb{T}$*, satisfies* $\mathrm{sr}(A(\mathbb{D})) = 1$.
- [34] *If we denote by* W_+ *the Wiener algebra defined by*

$$W_+ = \left\{ \sum_{n=0}^{+\infty} a_n\, z^n \;\middle|\; \sum_{n=0}^{+\infty} |\, a_n \,| < +\infty \right\},$$

  then we have $\mathrm{sr}(W_+) = 1$.

Let us recall that the polynomial ring $\mathbb{R}[x_1, \ldots, x_n]$ is used in the study of multidimensional systems, W_+ represents the sets of l_∞-stable (bounded input bounded output stability) shift-invariant causal digital filters [42], and the disc algebra $A(\mathbb{D})$ is used for interpolation problems and discrete-time control systems [42]. Finally, $E(\mathbb{R})$ is used in the study of a certain class of time-delay systems $\mathcal{E} = E(\mathbb{R}) \cap \mathbb{R}(s)[e^{-s}]$ [21].

3. *k*-stability for matrices. Let us extend the definition of k-stability for matrices with entries in A.

DEFINITION 3.1 (see [11, 17, 41]). *A matrix* $R \in A^{q \times p}$ *is* unimodular *if there exists a matrix* $S \in A^{p \times q}$ *such that* $R\,S = I_q$*, i.e.,* R *has a right-inverse* S.

Remark 3.1. First, let us notice that the previous concept of a unimodular matrix is standard in commutative algebra, whereas, in control theory, a unimodular matrix usually denotes a square matrix $R \in A^{p \times p}$ such that there exists $S \in A^{p \times p}$ satisfying $R\,S = S\,R = I_p$. The reader should be careful not to confuse these two different definitions (only Definition 3.1 will be used in the course of the paper).

Second, if $R \in A^{q \times p}$ is a unimodular matrix, then it is clear that R has *full row rank*, namely its rows are A-linearly independent. Moreover, the A-submodule $A^{1 \times q}\, R$ of $A^{1 \times p}$ generated by the A-linear combinations of the rows of R is isomorphic to $A^{1 \times q}$, and thus we have $1 \leq q \leq p$.

If $R_i \in A^{q \times 1}$ is a column vector, then we shall denote by $\mathrm{col}(R_1, \ldots, R_p)$ the $q \times p$ matrix R whose first column is R_1, whose second one is $R_2, \ldots$, and whose last column is R_p.

LEMMA 3.2. *$R = \mathrm{col}(R_1 : \cdots : R_p) \in A^{q\times p}$ is unimodular iff the A-module*

$$R\,A^p \triangleq \sum_{i=1}^{p} R_i\,A = \left\{ \sum_{i=1}^{p} R_i\,a_i \in A^q \mid a_i \in A \right\}$$

is equal to A^q.

Proof. $\Rightarrow$ Let R be unimodular. Then there exists $S \in A^{p\times q}$ such that $R\,S = I_q$. Therefore, for every $\lambda \in A^q$, the vector $\mu = S\,\lambda \in A^p$ is such that $\lambda = R\,\mu$, and thus $\lambda = \sum_{i=1}^{p} R_i\,\mu_i \in R\,A^p$, where $\mu = (\mu_1 : \cdots : \mu_p)^T$. Hence, we have $R\,A^p = A^q$.

$\Leftarrow$ Let us suppose that $R\,A^p = A^q$. Then, for every $\lambda \in A^q$, there exists $(a_i)_{1\leq i\leq p}$, with $a_i \in A$, such that $\lambda = \sum_{i=1}^{p} R_i\,a_i$. In particular, for $j = 1, \ldots, q$, let us consider the vector e_j of A^q defined by 1 in the jth component and 0 elsewhere. Then, for $j = 1, \ldots, q$, there exists $S_j \in A^p$ such that $e_j = R\,S_j$, and thus, if we define $S = \mathrm{col}(S_1 : \cdots : S_q) \in A^{p\times q}$, then we have $R\,S = I_q$; i.e., R is unimodular. □

Let us introduce the concept of k-stability for unimodular matrices.

DEFINITION 3.3 (see [17, 41]). *A unimodular matrix $R = \mathrm{col}(R_1, \ldots, R_p) \in A^{q\times p}$ is called* k-stable $(1 \leq k \leq p - q)$ *if there exists a $(p-k)$-tuple $(c_i)_{1\leq i\leq p-k}$ belonging to the A-module*

$$R_{p-k+1}\,A + \cdots + R_p\,A \triangleq \left\{ \sum_{i=1}^{k} R_{p-k+i}\,b_i \mid b_i \in A \right\} \tag{3.1}$$

such that the matrix

$$\mathrm{col}(R_1 + c_1 : R_2 + c_2 : \cdots : R_{p-k} + c_{p-k}) \in A^{q\times(p-k)}$$

is unimodular.

Remark 3.2. Let us notice that a vector $a \in \mathrm{U}_n(A)$ is 1-stable iff a is stable in the sense of Definition 2.2.

LEMMA 3.4. *A unimodular matrix $R \in A^{q\times p}$ is k-stable iff there exists a matrix $T_k \in A^{k\times(p-k)}$ such that the matrix*

$$R_k = \mathrm{col}(R_1 : \cdots : R_{p-k}) + \mathrm{col}(R_{p-k+1} : \cdots : R_p)\,T_k \in A^{q\times(p-k)} \tag{3.2}$$

is unimodular.

Proof. $\Rightarrow$ Let R be a k-stable matrix; then there exists a $(p-k)$-tuple $(c_i)_{1\leq i\leq p-k}$ of elements of the A-module (3.1) such that $\mathrm{col}(R_1 + c_1 : \cdots : R_{p-k} + c_k) \in A^{q\times(p-k)}$ is a unimodular matrix. By definition of the c_i, there exists $b_{ij} \in A$ such that

$$c_i = \sum_{j=1}^{k} R_{p-k+j}\,b_{i(p-k+j)}.$$

Therefore, we have

$$\mathrm{col}(R_1 + c_1 : \cdots : R_{p-k} + c_k) = \mathrm{col}(R_1 : \cdots : R_{p-k}) + \mathrm{col}(R_{p-k+1} : \cdots : R_p)\,T_k,$$

where $T_k \in A^{k\times(p-k)}$ is defined by

$$T_k = \begin{pmatrix} b_{1(p-k+1)} & b_{2(p-k+1)} & \cdots & b_{(p-k)(p-k+1)} \\ \vdots & \vdots & & \vdots \\ b_{1p} & b_{2p} & \cdots & b_{(p-k)p} \end{pmatrix}.$$

$\Leftarrow$ All the columns c_i of the matrix $\mathrm{col}(R_{p-k+1} : \cdots : R_p)\, T_k$ belong to the A-module (3.1). Thus, R_k has the form $\mathrm{col}(R_1 + c_1 : \cdots : R_{p-k} + c_k)$; i.e., R is k-stable. □

Example 3.1. Let us consider $A = RH_\infty$ and the following matrix:

$$R = \begin{pmatrix} \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \\ \frac{1}{s+1} & -\frac{s}{s+1} & 0 \end{pmatrix} \in A^{2\times 3}.$$

The matrix

$$R_1 = \begin{pmatrix} \frac{s+2}{s+1} & \frac{1}{s+1} \\ \frac{1}{s+1} & -\frac{s}{s+1} \end{pmatrix} = \begin{pmatrix} \frac{s-1}{s+1} & 0 \\ \frac{1}{s+1} & -\frac{s}{s+1} \end{pmatrix} + \begin{pmatrix} -\frac{1}{s+1} \\ 0 \end{pmatrix} (-3 : -1) \tag{3.3}$$

is invertible ($\det R_1 = -1$), and thus R is 1-stable.

PROPOSITION 3.5. *If R is k-stable, then R is $(k-1)$-stable.*

Proof. Using the fact that R is k-stable, then there exist

$$c_1, \ldots, c_{p-k} \in R_{p-k+1}\, A + \cdots + R_p\, A$$

such that $R_k = \mathrm{col}(R_1 + c_1 : \cdots : R_{p-k} + c_{p-k})$ is unimodular. Let us decompose c_i as $c_i = d_i + e_i$, where $d_i \in R_{p-k+1}\, A$ and $e_i \in R_{p-k+2}\, A + \cdots + R_p\, A$, and let us define $R_{k+1} = \mathrm{col}(R_1 + e_1 : \cdots : R_{p-k} + e_{p-k} : R_{p-k+1})$. Then we claim that R_{k+1} is unimodular, and thus R is $(k-1)$-stable. Indeed, we have

$$\sum_{i=1}^{p-k} (R_i + c_i)\, A \subseteq \sum_{i=1}^{p-k} (R_i + e_i)\, A + R_{p-k+1}\, A \subseteq A^q.$$

Then, applying Lemma 3.2 to R_k, we obtain that $\sum_{i=1}^{p-k} (R_i + c_i)\, A = A^q$, and thus $\sum_{i=1}^{p-k} (R_i + e_i)\, A + R_{p-k+1}\, A = A^q$, which proves that R_{k+1} is unimodular by Lemma 3.2. □

4. Internal stabilization. Let A be an integral domain and let its *field of fractions* be

$$K = Q(A) = \{n/d \mid n \in A,\, 0 \neq d \in A\}.$$

In *the fractional representation approach to analysis and synthesis problems* [5, 6, 42], we consider a class of plants which are defined by means of transfer matrices whose entries belong to the quotient field $K = Q(A)$ of an integral domain of stable SISO plants (see [25, 26, 24, 27] for more details).

Example 4.1. We have the following examples of algebras of SISO stable plants:

- For finite-dimensional systems, we usually consider the integral domain of proper and stable real rational functions $A = RH_\infty = \mathbb{R}(s) \cap H_\infty(\mathbb{C}_+)$ and $K = \mathbb{R}(s)$ [42]. Then, A corresponds to the set of proper and stable real rational transfer functions, whereas an element of $K \backslash A$ represents either an unstable or an improper transfer function. For instance,

  $$P = s/((s-1)\,(s-2)) \in \mathbb{R}(s)$$

  belongs to $K = Q(A)$ because we have $P = n/d$, where $n = s/(s+1)^2 \in A$ by $d = ((s-1)\,(s-2))/(s+1)^2 \in A$.

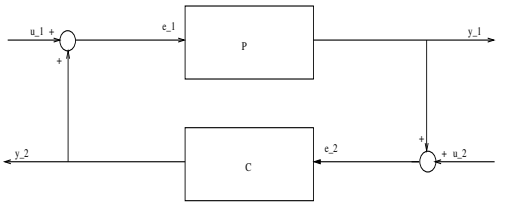

FIG. 4.1. *Closed-loop.*

- For infinite-dimensional systems, we can consider $A = H_\infty(\mathbb{C}_+)$ [36], which gives a class of unstable plants defined by transfer matrices with entries in the quotient field $K = Q(H_\infty(\mathbb{C}_+))$. For instance, the transfer function

$$P = (1 + e^{-2\,s})/(1 - e^{-2\,s})$$

of a wave equation (see, e.g., Exercise 4.24 of [5]) satisfies $P = n/d$, where $n = 1 + e^{-2\,s} \in A$ and $d = 1 - e^{-2\,s} \in A$, and thus we have $P \in K$.

Let us consider a plant defined by the transfer matrix $P \in K^{q\times(p-q)}$, a controller defined by $C \in K^{(p-q)\times q}$, and the closed-loop given by Figure 4.1. We have the following equations:

$$\begin{pmatrix} I_{p-q} & -C \\ -P & I_q \end{pmatrix} \begin{pmatrix} e_1 \\ e_2 \end{pmatrix} = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}.$$

DEFINITION 4.1 (see [5, 6, 42]). *A plant defined by the transfer matrix* $P \in K^{q\times(p-q)}$ *is* internally stabilizable *if there exists a controller* $C \in K^{(p-q)\times q}$ *such that all the entries of the matrix*

$$\begin{pmatrix} I_{p-q} & -C \\ -P & I_q \end{pmatrix}^{-1} = \begin{pmatrix} (I_{p-q} - C\,P)^{-1} & (I_{p-q} - C\,P)^{-1}\,C \\ P\,(I_{p-q} - C\,P)^{-1} & I_q + P\,(I_{p-q} - C\,P)^{-1}\,C \end{pmatrix} \tag{4.1}$$

$$= \begin{pmatrix} I_{p-q} + C\,(I_q - P\,C)^{-1}\,P & C\,(I_q - P\,C)^{-1} \\ (I_q - P\,C)^{-1}\,P & (I_q - P\,C)^{-1} \end{pmatrix} \tag{4.2}$$

belong to A. *Such a controller,* $C \in K^{(p-q)\times q}$, *is called a* stabilizing controller *of* P.

Example 4.2. The controller $C = -(s-1)/(s+1)$ is not a stabilizing controller of the plant $P = s/(s-1)$ because we have

$$\begin{cases} e_1 = \frac{(s+1)}{(2\,s+1)}\,u_1 + \frac{(-s+1)}{(2\,s+1)}\,u_2, \\ e_2 = \frac{s\,(s+1)}{(2\,s+1)(s-1)}\,u_1 + \frac{(s+1)}{(2\,s+1)}\,u_2, \end{cases}$$

and the transfer function between e_2 and u_1 has the unstable pole 1; i.e., it does not belong to RH_∞.

DEFINITION 4.2. *We have the following definitions* [5, 6, 42]:

- *A transfer matrix* $P \in K^{q\times(p-q)}$ *admits a* left-coprime factorization *if there exist* $R = (D : -N) \in A^{q\times p}$ *and* $S = (X^T : Y^T)^T \in A^{p\times q}$ *such that*

$$\begin{cases} P = D^{-1}\,N, \\ R\,S = D\,X - N\,Y = I_q. \end{cases}$$

- *A transfer matrix* $P \in K^{q\times(p-q)}$ *admits a* right-coprime factorization *if there exist* $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T \in A^{p\times(p-q)}$ *and* $\tilde{S} = (-\tilde{Y} : \tilde{X}) \in A^{(p-q)\times p}$ *such that*

$$\left\{ \begin{array}{l} P = \tilde{N}\,\tilde{D}^{-1}, \\ \tilde{S}\,\tilde{R} = -\tilde{Y}\,\tilde{N} - \tilde{X}\,\tilde{D} = I_{p-q}. \end{array} \right.$$

- *A transfer matrix* $P \in K^{q\times(p-q)}$ *admits a* doubly coprime factorization *if* P *admits both a left and right-coprime factorization.*

PROPOSITION 4.3 (see [42, Theorem 25, p. 105]). *Every transfer matrix* $P \in K^{q\times(p-q)}$ *which admits a left-coprime factorization* $P = D^{-1}\,N$, $D\,X - N\,Y = I_q$, $\det X \neq 0$, *is internally stabilized by the controller* $C = Y\,X^{-1}$.

If $P = D_1^{-1}\,N_1 = D_2^{-1}\,N_2$ are two left-coprime factorizations of P and $R_i = (D_i : -N_i)$, for $i = 1, 2$, then there exists a matrix $U \in \mathrm{GL}_q(A)$ such that $R_2 = U\,R_1$. Hence, we deduce that R_q is k-stable iff R_2 is k-stable. A similar result also holds for right-coprime factorizations.

DEFINITION 4.4. *We have the following definitions* [2, 42]:

- *A plant* $P \in K^{q\times(p-q)}$ *is* strongly stabilizable *if there exists a stable controller* $C \in A^{(p-q)\times q}$ *which internally stabilizes* P.
- *Two plants* P_1, $P_2 \in K^{q\times(p-q)}$ *are* simultaneously stabilizable *if there exists a controller* $C \in K^{(p-q)\times q}$ *which internally stabilizes* P_1 *and* P_2.

The next proposition is a reformulation of Lemma 7 of section 5.3 of [42] (we thank an anonymous associate editor for pointing out this reference to us).

PROPOSITION 4.5. *A transfer matrix* $P \in K^{q\times(p-q)}$ *is strongly stabilizable iff* P *admits a doubly coprime factorization* $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1}$ *such that the matrices* $(D : -N) \in A^{q\times p}$ *and* $(\tilde{D}^T : \tilde{N}^T) \in A^{(p-q)\times p}$ *are, respectively,* $(p-q)$ *and* q*-stable.*

In particular, $P \in K(A)$ *is strongly stabilizable iff there exists a coprime factorization* $P = n/d$ *such that the vector* $(d : n) \in U_2(A)$ *is* 1*-stable.*

Proof. Let us suppose that there exists a stable controller $C \in A^{(p-q)\times q}$ which internally stabilizes P. Then, all the entries of the matrix (4.1) belong to A and, in particular, $P\,(I_{p-q} - C\,P)^{-1} = (I_q - P\,C)^{-1}\,P = V \in A^{q\times(p-q)}$.

Then, from the fact that

$$I_{p-q} + C\,V = I_{p-q} + C\,(I_q - P\,C)^{-1}\,P = (I_{p-q} - C\,P)^{-1},$$

we deduce that $I_{p-q} + C\,V$ is an invertible matrix, and thus we have

$$P\,(I_{p-q} - C\,P)^{-1} = V \Leftrightarrow P = V\,(I_{p-q} + C\,V)^{-1}.$$

Then, P admits the right-coprime factorization $P = V\,(I_{p-q} + C\,V)^{-1}$ because

$$(-C : I_{p-q}) \left(\begin{array}{c} V \\ I_{p-q} + C\,V \end{array} \right) = I_{p-q}.$$

The matrix $((I_{p-q} + C\,V)^T : V^T)$ is q-stable because $I_{p-q} + V^T\,C^T - V^T\,C^T = I_{p-q}$.

Moreover, from the fact that

$$I_q + V\,C = I_q + P\,(I_{p-q} - C\,P)^{-1}\,C = (I_q - P\,C)^{-1},$$

we deduce that $I_q + V\,C$ is an invertible matrix, and thus we have

$$(I_q - P\,C)^{-1}\,P = V \Leftrightarrow P = (I_q + V\,C)^{-1}\,V.$$

Then, P admits the left-coprime factorization $P = (I_q + V\,C)^{-1}\,V$, and the matrix $(I_q + V\,C : -V)$ satisfies $I_q + V\,C - V\,C = I_q$; i.e., $(I_q + V\,C : -V)$ is $(p-q)$-stable.

Conversely, if P admits a left-coprime factorization $P = D^{-1}\,N$ such that the matrix $R = (D : -N) \in A^{q\times p}$ is $(p-q)$-stable, then there exists $T_1 \in A^{(p-q)\times q}$ such that $U \triangleq D - N\,T_1 \in \mathrm{GL}_q(A)$. In particular, we have $D\,U^{-1} - N\,(T_1\,U^{-1}) = I_q$, where $U^{-1} \in A^{q\times q}$. Thus, by Proposition 4.3, $C = (T_1\,U^{-1})\,(U^{-1})^{-1} = T_1$ is a stable controller which internally stabilizes P, and thus P is strongly stabilizable. □

5. A general structure of the stabilizing controllers. In the next theorem, we show that there exists a stabilizing controller C of P such that the dimension of its unstable part depends on the k-stability of the matrix $R = (D : -N) \in A^{q\times p}$, where $P = D^{-1}\,N$ is a left-coprime factorization of P. Moreover, the unstable part of C is isolated into a single transfer matrix $V\,U^{-1} \in K^{r\times(p-q)}$, where $r = p - q - k$.

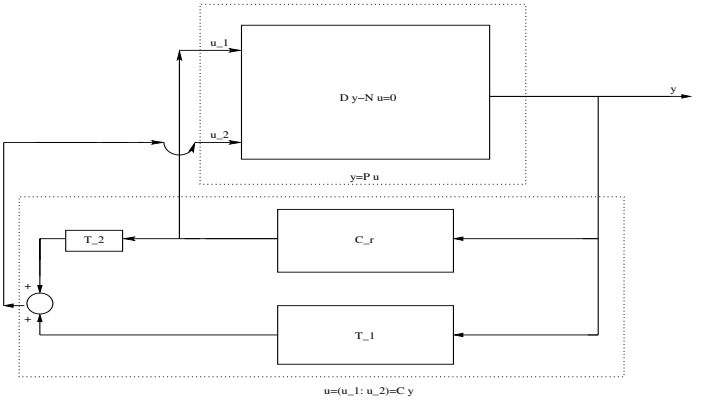

FIG. 5.1. *Closed-loop $y = P\,u$ and $u = C\,y$.*

THEOREM 5.1. *Let A be an integral domain of SISO stable plants, $K = Q(A)$, and let $P \in K^{q\times(p-q)}$ be a transfer matrix admitting a left-coprime factorization $P = D^{-1}\,N$ with $R = (D : -N) \in A^{q\times p}$. If R is k-stable and $r \triangleq p - q - k \geq 0$, then there exist two stable matrices*

$$\left\{ \begin{array}{l} T_1 \in A^{k\times q}, \\ T_2 \in A^{k\times r} \end{array} \right. \tag{5.1}$$

such that the matrix $R_k = (D - \Lambda\,T_1 : -(N_r + \Lambda\,T_2)) \in A^{q\times(p-k)}$ admits a right-inverse with entries in A, with the notation

$$R = (D : -N) = (\underset{\leftrightarrow\ q}{D} \quad : \underset{\leftrightarrow\ r}{-N_r} \quad : \underset{\leftrightarrow\ k}{-\Lambda}) \quad \in A^{q\times p}. \tag{5.2}$$

Let us define by $S_k = (U^T : V^T)^T \in A^{(p-k)\times q}$, $U \in A^{q\times q}$, $V \in A^{r\times q}$ any right-inverse of R_k such that $\det U \neq 0$. Then, the controller $C \in K^{(p-q)\times q}$ defined by

$$C = \left(\begin{array}{c} V\,U^{-1} \\ T_1 + T_2\,(V\,U^{-1}) \end{array} \right), \quad \begin{array}{l} \updownarrow\ r = p - q - k \\ \updownarrow\ k \end{array} \tag{5.3}$$

internally stabilizes P (see Figure 5.1). Moreover, if $\det(D - \Lambda\,T_1) \neq 0$, then the controller $C_r = V\,U^{-1} \in K^{r\times q}$ internally stabilizes the plant

$$P_r = (D - \Lambda\,T_1)^{-1}\,(N_r + \Lambda\,T_2) \in K^{q\times r} \tag{5.4}$$

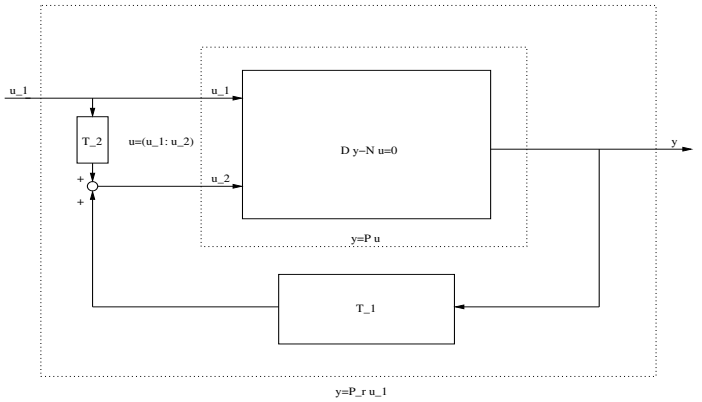

FIG. 5.2. *Plant* $y = P_r\, u_1$.

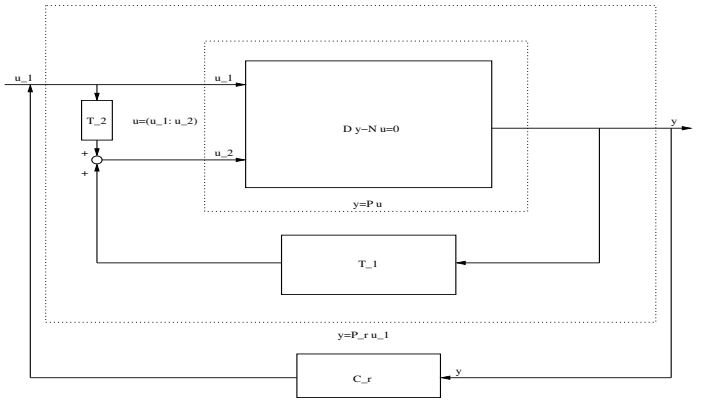

FIG. 5.3. *Closed-loop* $y = P_r\, u_1$ *and* $u_1 = C_r\, y$.

(see Figures 5.2 *and* 5.3*). The unstable part of the controller* (5.3) *corresponds to* $C_r = V\, U^{-1}$*, and its dimension is equal to* $r \times q$*.*

Similar results also hold for a transfer matrix P *admitting a right-coprime factorization* $P = \tilde{N}\, \tilde{D}^{-1}$ $(\tilde{R} = (\tilde{N}^T :\ \tilde{D}^T)^T \in A^{p\times(p-q)})$.

Proof. P admits a left-coprime factorization $P = D^{-1}\, N$, and thus the matrix $R = (D : -N) \in A^{q\times p}$ has a right-inverse $S = (X^T : Y^T)^T \in A^{p\times q}$; i.e., R is unimodular in the sense of Definition 3.1. Also, by hypothesis, R is k-stable, and thus, by Lemma 3.4, there exists $T_k \in A^{k\times(p-k)}$ such that the matrix $R_k \in A^{q\times(p-k)}$ defined by (3.2) is unimodular. Let us denote by $S_k \in A^{(p-k)\times q}$ a right-inverse of R_k; i.e., we have

$$R_k\, S_k = I_q. \tag{5.5}$$

Using expressions (3.2) and (5.5), we obtain that

$$\mathrm{col}(R_1 : \cdots : R_p) \begin{pmatrix} S_k \\ T_k\, S_k \end{pmatrix} = I_q \Leftrightarrow (D :\ -N) \begin{pmatrix} S_k \\ T_k\, S_k \end{pmatrix} = I_q.$$

If we write $S_k = (U_k^T : V_k^T)^T$, with $U_k \in A^{q\times q}$ and $V_k \in A^{r\times q}$, then we have

$$D\,U_k - N \begin{pmatrix} V_k \\ T_k\,S_k \end{pmatrix} = I_q.$$

If $\det U \neq 0$, then by Proposition 4.3, the controller C defined by

$$\begin{aligned} C &= \begin{pmatrix} V_k \\ T_k\,S_k \end{pmatrix} U_k^{-1} = \begin{pmatrix} V_k\,U_k^{-1} \\ T_k \begin{pmatrix} U_k \\ V_k \end{pmatrix} U_k^{-1} \end{pmatrix} \\ &= \begin{pmatrix} V_k\,U_k^{-1} \\ T_k \begin{pmatrix} I_q \\ V_k\,U_k^{-1} \end{pmatrix} \end{pmatrix} = \begin{pmatrix} V_k\,U_k^{-1} \\ T_{k1} + T_{k2}\,(V_k\,U_k^{-1}) \end{pmatrix} \end{aligned}$$

internally stabilizes $P = D^{-1}\,N$, where $T_k = (T_{k1} : T_{k2}) \in A^{k\times(q+r)}$ and the dimensions of T_{k1} and T_{k2} are defined by (5.1). With the notation of (5.2), we have

$$\begin{aligned} R_k &= \operatorname{col}(R_1 : \cdots : R_{p-k}) - \Lambda\,(T_{k1} : T_{k2}) \\ &= (\operatorname{col}(R_1 : \cdots : R_q) - \Lambda\,T_{k1} : \operatorname{col}(R_{q+1} : \cdots : R_{p-k}) - \Lambda\,T_{k2}) \\ &= (D - \Lambda\,T_{k1} : -(N_r + \Lambda\,T_{k2})). \end{aligned}$$

Using the fact that $R_k\,S_k = I_q$, by Proposition 4.3, we obtain that $C_r = V_k\,U_k^{-1}$ is a stabilizing controller of the plant $P_r = (D - \Lambda\,T_{k1})^{-1}\,(N_r + \Lambda\,T_{k2})$. □

Example 5.1. Let us consider $A = H_\infty(\mathbb{C}_+)$ and the following transfer matrix:

$$P = \begin{pmatrix} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s-1} \end{pmatrix} \in K^{2\times 2},$$

where $K = Q(A)$. In [25, 26], it is shown that P admits the left-coprime factorization $P = D^{-1}\,N$, where $R = (D : -N) \in A^{2\times 4}$ is defined by

$$R = \begin{pmatrix} 1 & 0 & -\frac{e^{-s}}{s+1} & -\frac{s-1}{s+1} \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{pmatrix}.$$

The matrix R_1, defined by

$$\begin{aligned} R_1 &= \begin{pmatrix} 1 & 0 & -\frac{e^{-s}}{s+1} \\ 0 & \frac{s-1}{s+1} & 0 \end{pmatrix} + \begin{pmatrix} -\frac{s-1}{s+1} \\ -\frac{1}{s+1} \end{pmatrix} \underbrace{\begin{pmatrix} 0 & -2 & 0 \end{pmatrix}}_{T_1} \\ &= \begin{pmatrix} 1 & 2\,\frac{(s-1)}{(s+1)} & -\frac{e^{-s}}{s+1} \\ 0 & 1 & 0 \end{pmatrix}, \end{aligned} \tag{5.6}$$

is unimodular because we have

$$\begin{pmatrix} 1 & 2\,\frac{(s-1)}{(s+1)} & -\frac{e^{-s}}{s+1} \\ 0 & 1 & 0 \end{pmatrix} \underbrace{\begin{pmatrix} 1 - \frac{e^{-s}}{s+1} & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \\ -1 & 0 \end{pmatrix}}_{S_1} = I_2. \tag{5.7}$$

Thus, the matrix R is 1-stable, and we can apply Theorem 5.1 to P with $p=4$, $q=2$, $k=1$, and $r=1$. We know that $(S_1^T : (T_1\, S_1)^T)^T$ is a left inverse of R; i.e., we have

$$\begin{pmatrix} 1 & 0 & -\frac{e^{-s}}{s+1} & -\frac{s-1}{s+1} \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{pmatrix} \begin{pmatrix} 1-\frac{e^{-s}}{s+1} & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \\ -1 & 0 \\ 0 & -2 \end{pmatrix} = I_3. \tag{5.8}$$

If we define

$$U_1 = \begin{pmatrix} 1-\frac{e^{-s}}{s+1} & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix}, \quad V_1 = (-1 :\ 0), \quad T_{11} = (0 :\ -2) \in A^{1\times 2}, \quad T_{12} = 0 \in A,$$

then a stabilizing controller C of P has the form

$$C = \begin{pmatrix} V_1\, U_1^{-1} \\ T_{11} + T_{12}\,(V_1\, U_1^{-1}) \end{pmatrix} = \begin{pmatrix} -\left(1-\frac{e^{-s}}{s+1}\right)^{-1} & -2\,\frac{(s-1)}{(s+1)}\left(1-\frac{e^{-s}}{s+1}\right)^{-1} \\ 0 & -2 \end{pmatrix}. \tag{5.9}$$

Let us notice that $\inf_{s\in\mathbb{C}_+} |1-\frac{e^{-s}}{s+1}| = 0$ (take the sequence $(s_n = 1/n)_{n\in\mathbb{N}}$), and thus, by the Corona theorem [16], we have $(1-\frac{e^{-s}}{s+1})^{-1} \notin A$. Therefore, the first row of the controller C is unstable, whereas its second row is stable. Now, we may wonder if P is strongly stabilizable. Let us notice that the matrix

$$R_2 = \begin{pmatrix} 1 & 2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} -\frac{e^{-s}}{s+1} \\ 0 \end{pmatrix} \begin{pmatrix} 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix}$$

is unimodular because we have

$$\begin{pmatrix} 1 & 2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix} = I_2. \tag{5.10}$$

Then, the matrix R_1 is 1-stable, and thus R is 2-stable:

$$R_2 = \begin{pmatrix} 1 & 0 \\ 0 & \frac{s-1}{s+1} \end{pmatrix} + \begin{pmatrix} -\frac{e^{-s}}{s+1} & -\frac{s-1}{s+1} \\ 0 & -\frac{1}{s+1} \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & -2 \end{pmatrix} = \begin{pmatrix} 1 & 2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix} \in \mathrm{U}_2(A). \tag{5.11}$$

By Theorem 5.1, we obtain that P is strongly stabilizable ($p=4$, $q=2$, $k=2$, $r=0$). From (5.11), we obtain

$$\begin{pmatrix} 1 & 0 & -\frac{e^{-s}}{s+1} & -\frac{s-1}{s+1} \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & -2 \end{pmatrix} \begin{pmatrix} 1 & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix} = I_2,$$

which shows that

$$S_2 = U_2 = \begin{pmatrix} 1 & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix}, \quad T_2 = T_{21} = \begin{pmatrix} 0 & 0 \\ 0 & -2 \end{pmatrix} \in A^{2\times 2},$$

and thus a stable stabilizing controller C' of P is defined by

$$C' = T_2 = \begin{pmatrix} 0 & 0 \\ 0 & -2 \end{pmatrix} \in A^{2\times 2}.$$

To finish, let us show how, using parametrization of all stabilizing controllers of the plant $P_1 = (D - \Lambda_1 T_{11})^{-1}(N_1 + \Lambda_1 T_{12})$, where

$$\Lambda_1 = \begin{pmatrix} \frac{s-1}{s+1} \\ \frac{1}{s+1} \end{pmatrix}, \quad N_1 = \begin{pmatrix} \frac{e^{-s}}{s+1} \\ 0 \end{pmatrix},$$

it was already possible to find C'. First, let us notice that we have

$$R_1 = (D - \Lambda_1 T_{11} : \ -(N_1 + \Lambda_1 T_{12})) \in A^{2\times 3}.$$

Now, from (5.7), we know that $S_1 = (U_1^T : V_1^T)^T$ is a right-inverse of R_1. Computing a doubly coprime factorization of P_1, we obtain the following parametrization of all right inverses of R_1 (see [25, 26] for more details):

$$S_1 = \begin{pmatrix} U_1(k_1, k_2) \\ V_1(k_1, k_2) \end{pmatrix} = \begin{pmatrix} 1 + (k_1 - 1)\frac{e^{-s}}{s+1} & -2\frac{(s-1)}{(s+1)} + \frac{e^{-s}}{s+1} k_2 \\ 0 & 1 \\ k_1 - 1 & k_2 \end{pmatrix} \quad \forall\, k_1,\, k_2 \in A.$$

Therefore, some stabilizing controllers of P are of the form

$$C = \begin{pmatrix} V_1 U_1^{-1} \\ T_{11} + T_{12}(V_1 U_1^{-1}) \end{pmatrix} = \begin{pmatrix} a(k_1 - 1) & a(2(k_1 - 1)\frac{(s-1)}{(s+1)} + k_2) \\ 0 & -2 \end{pmatrix}, \tag{5.12}$$

where $a = (1 + (k_1 - 1)\frac{e^{-s}}{s+1})^{-1}$. Then, taking $k_1 = 1$ and $k_2 = 0$, we recover the stable controller C' of P.

The first difficulty in computing the controllers of the form (5.3) is to be able to determine explicitly the k-stability of a given matrix whose entries belong to a ring A. In section 6, we shall see that it is possible to give a lower bound for it by studying the stable range of the ring A. The second main difficulty is to compute T_k such that R_k, defined by (3.2), satisfies (5.5). In the following corollary of Theorem 5.1, we study the particular case where $T_k = 0$.

COROLLARY 5.2. *Let $P = D^{-1}N \in K^{q\times(p-q)}$ be a transfer matrix. If there exists an integer k satisfying $0 \leq k \leq p - q$ such that $P_r = D^{-1}N_r$ admits a left-coprime factorization, $DX - N_r Y = I_q$, with $\det X \neq 0$ and*

$$R = (D : -N) = (\underset{\leftrightarrow\, q}{D} \ : \underset{\leftrightarrow\, r}{-N_r} \ : \underset{\leftrightarrow\, k}{-\Lambda}) \in A^{q\times p},$$

then the controller

$$C = \begin{pmatrix} Y X^{-1} \\ 0 \end{pmatrix}, \quad \begin{matrix} \updownarrow r = p - q - k \\ \updownarrow k \end{matrix} \tag{5.13}$$

internally stabilizes $P = D^{-1}N$.

Proof. Let us define $T_k = 0$. Then, by hypothesis, the matrix

$$R_k = (D : -N_r) - \Lambda T_k = (D : -N_r)$$

has a left-inverse; i.e., it is unimodular. Therefore, the hypothesis that $P_r = D^{-1} N_r$ admits a left-coprime factorization implies that $R = (D : -N)$ is k-stable. Then, the result directly follows from Theorem 5.1 and $T_k = (T_1 : T_2) = 0$. □

Example 5.2. Let us consider $A = RH_\infty$, $K = Q(A)$, and the transfer matrix

$$P = \begin{pmatrix} \frac{s+1}{s-1} & 0 \\ \frac{1}{(s-1)^2} & \frac{s+1}{s-1} \end{pmatrix} \in K^{2\times 2}.$$

P admits a fractional representation $P = D^{-1} N$, where $R = (D : -N) \in A^{2\times 4}$ is defined by

$$R = \begin{pmatrix} \frac{s-1}{s+1} & 0 & -1 & 0 \\ \frac{1}{(s+1)^2} & -\frac{(s-1)}{(s+1)} & 0 & 1 \end{pmatrix}.$$

The matrix formed by the first two columns of R is not unimodular, but

$$R_1 = \begin{pmatrix} \frac{s-1}{s+1} & 0 & -1 \\ \frac{1}{(s+1)^2} & -\frac{(s-1)}{(s+1)} & 0 \end{pmatrix}$$

is unimodular because we have

$$\begin{pmatrix} \frac{s-1}{s+1} & 0 & -1 \\ \frac{1}{(s+1)^2} & -\frac{(s-1)}{(s+1)} & 0 \end{pmatrix} \begin{pmatrix} \frac{s-1}{s+1} & 4 \\ \frac{1}{(s+1)^2} & -\frac{(s+3)}{(s+1)} \\ -\frac{4\,s}{(s+1)^2} & 4\,\frac{(s-1)}{(s+1)} \end{pmatrix} = I_3.$$

Thus, we can apply Corollary 5.2 to P with $p = 4$, $q = 2$, $k = 1$, $r = 1$ to obtain a stabilizing controller C of P defined by

$$C = \begin{pmatrix} Y\,X^{-1} \\ 0 \end{pmatrix} = -4 \begin{pmatrix} \frac{1}{s+1} & 1 \\ 0 & 0 \end{pmatrix}.$$

Finally, let us notice that P is strongly stabilizable because C is stable.

6. A general structure of the stabilizing controllers based on the stable range. In the rest of the paper, we shall need the following definition.

Definition 6.1 (see [17, 41]). *Let p and q be two positive integers which satisfy $1 \leq q \leq p$. The ring A is said to* satisfy $\mathrm{sr}_k(q, p, A)$ *if every unimodular matrix $R \in A^{q\times p}$ is k-stable. If no confusion arises, we shall write* $\mathrm{sr}_k(q, p)$ *for* $\mathrm{sr}_k(q, p, A)$.

In particular, if A satisfies $\mathrm{sr}(A) = n < +\infty$, then A satisfies $\mathrm{sr}_1(1, n + 1)$.

Theorem 6.2 (see [17, 41]). *We have the following equivalences:*

1. $\mathrm{sr}_1(1, n) \Leftrightarrow \mathrm{sr}_1(1, m)\ \forall\ m \geq n$,
2. $\mathrm{sr}_1(1, n) \Leftrightarrow \mathrm{sr}_k(1, n + k - 1)\ \forall\ k \geq 1$,
3. $\mathrm{sr}_k(1, n) \Leftrightarrow \mathrm{sr}_k(m, n + m - 1)\ \forall\ m \geq 1$.

Corollary 6.3. *Let A be a ring satisfying* $\mathrm{sr}(A) < +\infty$. *Then, for every p, $q \in \mathbb{Z}_+$ which satisfies $p - q \geq \mathrm{sr}(A)$, we have*

$$\mathrm{sr}_{p-q-\mathrm{sr}(A)+1}(q, p);$$

namely, for every unimodular matrix $R = \mathrm{col}(R_1 : \cdots : R_p) \in A^{q\times p}$, there exists a matrix $T_{\mathrm{sr}(A)} \in A^{(p-q-\mathrm{sr}(A)+1)\times(q+\mathrm{sr}(A)-1)}$ such that

$$R_{\mathrm{sr}(A)} = \mathrm{col}(R_1 : \cdots : R_{q+\mathrm{sr}(A)-1}) + \mathrm{col}(R_{q+\mathrm{sr}(A)} : \cdots : R_p)\, T_{\mathrm{sr}(A)} \tag{6.1}$$

is a unimodular matrix.

Proof. Using the fact that we have $\mathrm{sr}(A) = n$, A satisfies $\mathrm{sr}_1(1, n+1)$, and thus, by 1 of Theorem 6.2, we have $\mathrm{sr}_1(1, m)\ \forall\, m \geq n+1$. Then, by 2 of Theorem 6.2, A satisfies $\mathrm{sr}_k(1, m+k-1)$ for $k \geq 1$. Finally, by 3 of Theorem 6.2, A satisfies $\mathrm{sr}_k(l, l+m+k-2)\ \forall\, k,\ l \geq 1$ and $m \geq n+1$.

Now, let $p,\ q \in \mathbb{Z}_+$ such that $p-q \geq \mathrm{sr}(A)$. Let us define $k = p-q-\mathrm{sr}(A)+1 \geq 1$. We have $p = q + (\mathrm{sr}(A)+1) + (p-q-\mathrm{sr}(A)+1) - 2$ and, if we define

$$\begin{cases} l = q \geq 1, \\ n = \mathrm{sr}(A), \\ m = \mathrm{sr}(A)+1, \\ p = l+m+k-2, \end{cases}$$

then A satisfies $\mathrm{sr}_k(l, l+m+k-2)$, i.e., $\mathrm{sr}_{p-q-\mathrm{sr}(A)+1}(q, p)$. Finally, from Lemma 3.4, there exists $T_{\mathrm{sr}(A)} \in A^{(p-q-\mathrm{sr}(A)+1)\times(p+\mathrm{sr}(A)-1)}$ such that the matrix $R_{\mathrm{sr}(A)}$ defined by (6.1) is unimodular. ∎

Now, we are in position to state the second main result of this paper.

Corollary 6.4. *Let $P \in K^{q\times(p-q)}$ be a transfer matrix which admits a left-coprime factorization $P = D^{-1}N$, $R = (D : -N) \in A^{q\times p}$ and satisfies $p-q \geq \mathrm{sr}(A)$. Then, there exist two stable matrices*

$$\begin{cases} T_1 \in A^{(p-q-\mathrm{sr}(A)+1)\times q}, \\ T_2 \in A^{(p-q-\mathrm{sr}(A)+1)\times(\mathrm{sr}(A)-1)} \end{cases} \tag{6.2}$$

such that the matrix $R_{p-q-\mathrm{sr}(A)+1} = (D - \Lambda T_1 : -(N_{\mathrm{sr}(A)-1} + \Lambda T_2)) \in A^{q\times(q+\mathrm{sr}(A)-1)}$ admits a right-inverse, with the notation

$$R = (D : -N) = (\underbrace{D}_{q} : \underbrace{-N_{\mathrm{sr}(A)-1}}_{\mathrm{sr}(A)-1} : \underbrace{-\Lambda}_{p-q-\mathrm{sr}(A)+1}) \in A^{q\times p}. \tag{6.3}$$

Let us denote by $S_{p-q-\mathrm{sr}(A)+1} = (U^T : V^T)^T \in A^{(q+\mathrm{sr}(A)-1)\times q}$ any right-inverse of $R_{p-q-\mathrm{sr}(A)+1}$ such that $\det U \neq 0$. Then, the controller C defined by

$$C = \begin{pmatrix} V\,U^{-1} \\ T_1 + T_2\,(V\,U^{-1}) \end{pmatrix}, \quad \begin{matrix} \updownarrow\, \mathrm{sr}(A)-1 \\ \updownarrow\, p-q-\mathrm{sr}(A)+1 \end{matrix} \tag{6.4}$$

internally stabilizes the plant $P = D^{-1}N$. Moreover, if $\det(D - \Lambda T_1) \neq 0$, then the controller $C_{\mathrm{sr}(A)-1} = V\,U^{-1}$ internally stabilizes the plant

$$P_{\mathrm{sr}(A)-1} = (D - \Lambda T_1)^{-1}\,(N_{\mathrm{sr}(A)-1} + \Lambda T_2).$$

Finally, the unstable part of the controller (6.4) is $C_{\mathrm{sr}(A)-1} = V\,U^{-1}$ and its dimension is equal to $(\mathrm{sr}(A)-1)\times q$.

Proof. By Corollary 6.3, every matrix of $A^{q\times p}$ is $k = (p-q-\mathrm{sr}(A)+1)$-stable. Then, the result directly follows from Theorem 5.1. ∎

Corollary 6.5. *Let us consider $A = RH_\infty$ and $K = Q(A) = \mathbb{R}(s)$. Then, every transfer matrix $P \in \mathbb{R}(s)^{q\times(p-q)}$ admits a stabilizing controller of the form*

$$C = \begin{pmatrix} V\,U^{-1} \\ T_1 + T_2\,(V\,U^{-1}) \end{pmatrix}, \quad \begin{matrix} \updownarrow\, 1 \\ \updownarrow\, p-q-1 \end{matrix},$$

where

$$\left\{ \begin{array}{l} T_1 \in A^{(p-q-1)\times q}, \\ T_2 \in A^{(p-q-1)\times 1}, \end{array} \right.$$

$P = D^{-1}\,N$ *is a left-coprime factorization of* P, $S_{p-q-1} = (U^T : V^T)^T \in A^{(q+1)\times q}$ *is any right-inverse of* $R_{p-q-1} = (D - \Lambda\,T_1 : -(N_1 + \Lambda\,T_2)) \in A^{q\times(q+1)}$ *such that* $\det U \neq 0$, *and*

$$R = (D : -N) = (\underbrace{\quad D \quad}_{q} : \underbrace{-N_1}_{1} : \underbrace{-\Lambda}_{p-q-1}) \in A^{q\times p}.$$

Proof. Every MIMO transfer matrix P with entries in $K = \mathbb{R}(s)$ admits a doubly coprime factorization $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1}$ over A,

$$\left(\begin{array}{cc} D & -N \\ -\tilde{Y} + Q\,D & \tilde{X} - Q\,N \end{array} \right) \left(\begin{array}{cc} X - \tilde{N}\,Q & \tilde{N} \\ Y - \tilde{D}\,Q & \tilde{D} \end{array} \right) = I,$$

where Q is an arbitrary matrix. See [42] for more details. Then, applying Lemma 17 on page 112 of [42], we obtain that there exists $Q^\star$ such that the matrix $\det(X - \tilde{N}\,Q^\star) \neq 0$. Using the facts that $\mathrm{sr}(RH_\infty) = 2$ (see Corollary 2.7) and

$$(U^T : V^T)^T = ((X - \tilde{N}\,Q^\star)^T : (Y - \tilde{D}\,Q^\star)^T)^T,$$

the result follows from Corollary 6.4. □

We have the following straightforward consequence of Corollary 6.4.

COROLLARY 6.6. *If* $\mathrm{sr}(A) = 1$, *then every transfer matrix which admits a left-coprime factorization is strongly stabilizable (i.e., it is internally stabilized by a stable controller). In particular, this result holds for* $A = W_+$ *or* $A(\mathbb{D})$.

Moreover, every internally stabilizable plant, defined by a transfer matrix P *with entries in the quotient field of* $A = H_\infty(\mathbb{D})$ *or* $H_\infty(\mathbb{C}_+)$, *is strongly stabilizable.*

Proof. The first part of the corollary directly follows from Corollary 6.4 and the fact that $\mathrm{sr}(A) = 1$. Moreover, by Theorem 2.8, we know that $\mathrm{sr}(W_+) = 1$ and $\mathrm{sr}(A(\mathbb{D})) = 1$. Finally, if $A = H_\infty(\mathbb{C}_+)$ or $H_\infty(\mathbb{D})$, then it is well known that P is internally stabilizable iff P admits a doubly coprime factorization [25, 26, 36]. The last result directly follows from this fact, Corollary 6.4, Theorem 2.4, and Corollary 2.5. □

Let us notice that the second part of Corollary 6.6 extends Treil's result [38] to MIMO systems. The question of the possibility of having the matrix analogous to Treil's result was asked in [9]. However, the issue consisting in computing effectively the stable stabilizing controllers of a stabilizable plant, defined by a transfer matrix with entries in $K = Q(H_\infty(\mathbb{D}))$ or $K = Q(H_\infty(\mathbb{C}_+))$, is still open.

COROLLARY 6.7. *If* $\mathrm{sr}(A) = 1$, *then every pair of plants, defined by two transfer matrices* P_0 *and* P_1 *with entries in* $K = Q(A)$, *having the same dimensions, and admitting doubly coprime factorizations, is simultaneously stabilized by a controller (simultaneous stabilization). In particular, this result holds for* $A = W_+$ *or* $A(\mathbb{D})$.

Moreover, if $A = H_\infty(\mathbb{D})$ *or* $H_\infty(\mathbb{C}_+)$ *and* P_0, P_1 *are two stabilizable plants with entries in* $K = Q(A)$, *then* P_0 *and* P_1 *are simultaneously stabilized by a controller.*

Proof. Following the proof of Theorem 14 of section 8.3 of [42], there exists a stabilizing controller of P_0 and P_1 iff there exists a matrix T with entries in A such that $U + V\,T$ is a square unimodular matrix, where

$$\left\{ \begin{array}{l} U = D_1\,X_0 - N_1\,Y_0, \\ V = -D_1\,\tilde{N}_0 + N_1\,\tilde{D}_0, \end{array} \right.$$

and $P_i = D_i^{-1} N_i = \tilde{N}_i \tilde{D}_i^{-1}$ is a doubly coprime factorization of P_i, $i = 0, 1$; i.e.,

$$\begin{pmatrix} D_i & -N_i \\ -\tilde{Y}_i & \tilde{X}_i \end{pmatrix} \begin{pmatrix} X_i & \tilde{N}_i \\ Y_i & \tilde{D}_i \end{pmatrix} = I, \quad \begin{pmatrix} X_i & \tilde{N}_i \\ Y_i & \tilde{D}_i \end{pmatrix} \begin{pmatrix} D_i & -N_i \\ -\tilde{Y}_1 & \tilde{X}_i \end{pmatrix} = I.$$

The matrix $(U : V)$ is unimodular because we have $U X - V Y = I$, where

$$\begin{cases} X = D_0 X_1 - N_0 Y_1, \\ Y = \tilde{Y}_0 X_1 + \tilde{X}_0 Y_1. \end{cases}$$

Using the fact that $\mathrm{sr}(A) = 1$, by Corollary 6.3, we obtain that there exists T with entries in A such that $U + V T$ is a square unimodular matrix, and thus every couple of plants is simultaneously stabilized by a controller. Finally, by Theorem 2.8, we know that $\mathrm{sr}(W_+) = 1$ and $\mathrm{sr}(A(\mathbb{D})) = 1$.

Let P_1 and P_2 be two stabilizable transfer matrices with entries in $A = H_\infty(\mathbb{D})$ or $H_\infty(\mathbb{C}_+)$. Then, from [25, 26, 36], we know that P_1 and P_2 admit doubly coprime factorizations. The results directly follow from Theorem 2.4, Corollary 2.5, and the previous point. □

7. Some more results based on stable range.

7.1. Topological stable range. Let us recall the definition of a Banach algebra.

DEFINITION 7.1 (see [13]). *A k-algebra A ($k = \mathbb{R}, \mathbb{C}$) is a* Banach algebra *if A is a Banach k-vector space w.r.t. the norm $\| \cdot \|_A$ and satisfies*

1. $\| 1 \|_A = 1$,
2. $\| a\, b \|_A \leq \| a \|_A \| b \|_A$ *(continuity of the product in each factor).*

Example 7.1. The Hardy space $H_\infty(\mathbb{C}_+)$ of the holomorphic functions in $\mathbb{C}_+$ bounded w.r.t. the norm $\| f \|_\infty = \sup_{s \in \mathbb{C}_+} |f(s)|$ is a Banach algebra [5]. Moreover, the disc algebra $A(\mathbb{D})$ (resp., the Wiener algebra W_+), defined in Theorem 2.8, with the norm $\| f \|_{A(\mathbb{D})} = \sup_{s \in \overline{\mathbb{D}}} |f(s)|$ (resp., $\| f \|_{W_+} = \sum_{n=0}^{+\infty} |a_n|$), are two Banach algebras [13, 42].

DEFINITION 7.2. *If A is a Banach algebra, then the* topological stable range $\mathrm{tsr}(A)$ *of A is the smallest $n \in \mathbb{N} \cup \{+\infty\}$ such that $\mathrm{U}_n(A)$ is dense in A^n for the product topology.*

As for the stable range, the topological stable range $\mathrm{tsr}(A)$ is sometimes called the *topological stable rank* of A.

THEOREM 7.3. *We have the following results:*

- [37] $\mathrm{tsr}(H_\infty(\mathbb{D})) = 2$,
- [31] $\mathrm{tsr}(A(\mathbb{D})) = 2$.

PROPOSITION 7.4. *If A is a Banach algebra such that $\mathrm{tsr}(A) = 2$, then every SISO plant, defined by the transfer function $P = n/d$ ($0 \neq d, n \in A$), satisfies*

$$\forall\, \epsilon > 0,\ \exists\, (d_\epsilon :\ n_\epsilon) \in \mathrm{U}_2(A) : \quad \begin{cases} \| n - n_\epsilon \|_A \leq \epsilon, \\ \| d - d_\epsilon \|_A \leq \epsilon. \end{cases}$$

If $d_\epsilon \neq 0$, then, in the product topology, P is as close as we want to a transfer function $P_\epsilon = n_\epsilon / d_\epsilon$ which admits a coprime factorization. In particular, this result holds for $A = H_\infty(\mathbb{D})$ or $A(\mathbb{D})$.

Proof. Let us consider the vector $(d :\ -n) \in A^{1 \times 2}$. Using the fact that $\mathrm{tsr}(A) = 2$, we obtain

$$\forall\, \epsilon > 0,\ \exists\, (d_\epsilon :\ -n_\epsilon) \in \mathrm{U}_2(A) : \quad \begin{cases} \| d - d_\epsilon \|_A \leq \epsilon, \\ \| n - n_\epsilon \|_A \leq \epsilon. \end{cases}$$

Finally, using the fact that $(d_\epsilon : -n_\epsilon) \in \mathrm{U}_2(A)$, there exist x_ϵ, $y_\epsilon \in A$ such that we have $d_\epsilon\, x_\epsilon - n_\epsilon\, y_\epsilon = 1$, and thus $p_\epsilon = n_\epsilon/d_\epsilon$ admits a coprime factorization. □

In particular, if P is not internally stabilizable, then there exists a stabilizable plant P_ϵ as close as we want to P in the product topology.

7.2. Unit 1-stable range and *n*-fold. Let us introduce a few definitions.

Definition 7.5. *We have the following definitions* [4, 14, 40]*:*

- [14] *A ring A satisfies* unit 1-stable range *if, for every $a = (a_1 : a_2) \in \mathrm{U}_2(A)$, there exists an element $u \in U(A)$ such that $a_1 + a_2\, u \in U(A)$.*
- [39] *A ring A is said to be* n-fold *if, for every n-tuple $a^i = (a_1^i : a_2^i) \in \mathrm{U}_2(A)$, $1 \leq i \leq n$, there exists $b \in A$ such that $a_1^i + a_2^i\, b \in \mathrm{U}(A)$ for $1 \leq i \leq n$.*

Example 7.2. Using a result of Handelman [15], one can easily prove that $\mathrm{sr}(L_\infty(\mathbb{T})) = 1$, where $\mathbb{T} = \{z \in \mathbb{C}\,|\,|z| = 1\}$ is the unit circle, because $L_\infty(\mathbb{T})$ is a *commutative von Neumann algebra* [23], and thus $L_\infty(\mathbb{T})$ has unit 1-stable range (for a $C^\star$-algebra A with a unit [23], it is well known that $\mathrm{sr}(A) = 1$ is equivalent to A has unit 1-stable range [14]). See [18] for the study of stabilization problems over $A = L_\infty(\mathbb{T})$. For the sake of simplicity, in this paper we have studied only the case of integral domains A of SISO stable plants. However, all the results can be easily extended to any ring A with zero divisors.

Proposition 7.6. *We have the following results:*

1. *If A satisfies unit* 1*-stable range, then any SISO plant—defined by the transfer function $P = n/d$ $(d \neq 0, n \in A)$—admitting a coprime factorization is* bistably stabilizable*; namely it is stabilized by a bistable controller (i.e., a stable and inverstable controller)* [2].
2. *If A is an n-fold ring, then every n-tuple of SISO plants—defined by the transfer function $P_i = n_i/d_i$ $(d_i \neq 0, n_i \in A)$ with $1 \leq i \leq n$—having coprime factorizations is stabilized by a stable controller.*

Proof. 1. Let $P = n/d$ be a plant which has a coprime factorization. We may assume that we have $d\, x + n\, y = 1$ with $x, y \in A$. Thus, we have $(d : -n) \in \mathrm{U}_2(A)$. Using the fact that A satisfies unit 1-stable range, there exists $u \in U(A)$ such that $d - n\, u \in \mathrm{U}(A)$, and thus a stabilizing controller is given by $C = u \in \mathrm{U}(A)$; i.e., P is bistably stabilizable.

2. Let $i = 1, \ldots, n$, and let $P_i = n_i/d_i$ be a transfer function admitting a coprime factorization. We may assume that we have $d_i\, x_i + n_i\, y_i = 1$ for certain $x_i, y_i \in A$. Thus, we have $(d_i : -n_i) \in \mathrm{U}_2(A)$. Using the fact that A is n-fold, there exists $y \in A$ such that we have $d_i - n_i\, y \in \mathrm{U}(A)$ for $i = 1, \ldots, n$. Thus, the stable controller defined by $C = y$ simultaneously stabilizes the family of plants $\{P_i\}_{1 \leq i \leq n}$. □

Conclusion. In this paper, we have shown that the concept of stable range was an interesting one in the study of the strong and simultaneous stabilization problems. In particular, we proved that a plant, defined by means of a transfer matrix which admits a left-coprime factorization $P = D^{-1}\, N$, is internally stabilized by a controller, where its unstable and stable parts are separated and the dimension of the unstable part depends only on the k-stability of the matrix $R = (D : -N) \in A^{q \times p}$. Then, using the fact that the stable range of A gives a lower bound of the k-stability of every matrix with entries in A, we proved that, if the stable range of A is 1, then every plant, defined by a transfer matrix admitting a left-coprime factorization, is strongly stabilizable. In particular, using the fact that the stable range of $H_\infty(\mathbb{D})$ is 1 (see [38]), we proved that every stabilizable plant, defined by a transfer matrix with entries in the quotient field of $H_\infty(\mathbb{C}_+)$ or $H_\infty(\mathbb{D})$, is strongly stabilizable. Moreover, we were able to prove that there always exists a stabilizing controller which stabilizes

simultaneously two stabilizable plants defined by a transfer matrix with entries in the quotient field of $H_\infty(\mathbb{C}_+)$ or $H_\infty(\mathbb{D})$. Finally, using the fact that the topological stable range of $H_\infty(\mathbb{D})$ is equal to 2 (see [37]), we proved that every unstabilizable SISO plant, defined by a transfer function with entries in $Q(H_\infty(\mathbb{D}))$, is as close as we want to a stabilizable plant in the product topology.

In this paper, we proved the existence of some particular stabilizing controllers. However, the algorithmical aspects of their constructions were not developed. In forthcoming publications, we shall try to develop this difficult problem.

The concept of a stable range of A was developed by Bass [1] in order to "stabilize" the computation of the group $K_1(A)$ which is the quotient of the group $GL(A)$ of invertible matrices with entries in A by its normal subgroup $EL(A)$ of elementary matrices with entries in A. The connections between the strong stabilization problem and the computation of this group $K_1(A)$ need to be clarified. Moreover, in [35], the obstruction of the simultaneous stabilization of two n-D plants is explicitly expressed in terms of the vanishing of a certain cohomology class. Using the concept of the *Chern character*, it would be interesting to study the links between the results developed in [35] and *topological K-theory*. More generally, it seems that some mathematical tools developed in *algebraic/topological/Hermetian K-theory* are useful for some stabilization problems. Hence, we believe that the study of stabilization problems within a K-theoretical approach should give new interesting results [29].

Finally, a necessary condition for strong stabilizability is the existence of a doubly coprime factorization for the plant (see Proposition 4.5). However, internal stabilizability is generally not equivalent to the existence of doubly coprime factorizations (see [24, 25, 26, 27, 28] and the references therein). Hence, if we do not assume the existence of doubly coprime factorizations for the plants, then the existence of a controller which simultaneously stabilizes two plants P_1 and P_2 is generally not equivalent to the existence of a stable controller for a certain plant P built from P_1 and P_2. For more details, see [30].

Acknowledgments. We would like to thank both Prof. V. Blondel of Louvain-la-Neuve University (Belgium) and Prof. A. Feintuch of the Ben-Gurion University (Israel) for interesting discussions on stable range and strong stabilization. Both of them already knew that the concept of stable range was interesting for the study of strong stabilization [3, 9, 10] (see also the bibliography of [2] and Chapter 6 of [8]). Independently and quite recently, we were led to the concept of stable range while we were developing a K-theoretical approach to stabilization problems (see the forthcoming [29] for more information). Finally, we would like to thank an anonymous referee and an associate editor for all their interesting comments that have improved the quality of the paper.

ORIENTED DISTANCE FUNCTION AND ITS EVOLUTION EQUATION FOR INITIAL SETS WITH THIN BOUNDARY*

MICHEL C. DELFOUR† AND JEAN-PAUL ZOLÉSIO‡

Abstract. The central result of this paper is a *new nonlinear equation* which describes the evolution of the oriented distance function b_Ω of a set Ω with thin boundary under the influence of a velocity field. We relate it to equations and constructions used in the context of *level set methods*. We further introduce a new *moving narrow-band method* which not only can be readily implemented to solve our evolution equation, but could also be used for equations of motion by curvatures. In the process we review and sharpen the characterization of smooth sets and manifolds and sets of positive reach (e.g., local semiconvexity in an extended sense of the oriented distance function of the closure of the set). For $W^{2,p}$-Sobolev domains a new characterization and a compactness theorem are given in terms of the Laplacian of the oriented distance function rather than its whole Hessian matrix.

Key words. oriented distance function, signed distance function, level set method, narrow-band method, extension velocity, nonlinear evolution equation, smooth sets, submanifold, shape, design, image, vision

1. Introduction.

In problems where a geometric object is the variable, the object can be identified with a family of functions indexed by the sets, such as the characteristic functions, the distance functions, the oriented distance functions, or the support functions. Such functions play the role of the *state variable* associated with the set. Special metrics can be constructed from such function to measure the distance between two objects and to induce topologies from which existence and characterization of optimal objects can be obtained for design, identification, or control purposes. The choice of the function and the metric is obviously problem dependent and corresponds to pertinent technological, physical, or geometric entities associated with the problem at hand. For instance, distance functions have been used for theoretical and computational purposes in free boundary problems [19, 20, 27], image processing and computer vision [31, 37, 38, 5, 4, 13], [32, 30, 1, 21], [41, 42], and robotics [23, 24, 25, 40].

In this paper we focus on the oriented distance function, its associated metric topologies, and its use in the characterization of special families of sets. The central result is a *new nonlinear equation* which describes the evolution of the oriented distance function of a set with thin boundary under the influence of a velocity field. It can be viewed as the *state equation* of the moving set under the influence of the velocity field which plays the role of a *distributed control function*. This equation and the associated technical results find applications in computing shape derivatives of objective functions involving the oriented distance function, the normal, or the curvatures

(cf. [12]). In the present paper we relate our new evolution equation to equations and constructions used in the context of *level set methods*. We further introduce a new *moving narrow-band method* which not only can be readily implemented to solve our evolution equation, but could also be used for equations of motion by curvatures.

Section 2 recalls basic definitions and results on the oriented distance function b_Ω of a set Ω. Section 3 reviews the families of sets which will be used in the paper and sharpens their characterizations and properties (sets of positive reach, smooth sets and submanifolds, and $W^{2,p}$-Sobolev domains). The function b_Ω is shown to be locally semiconvex in an extended sense[1] for sets of positive reach. For $W^{2,p}$-Sobolev domains a new characterization and a compactness theorem are given in terms of the Laplacian of b_Ω rather than its whole Hessian matrix. Their boundary is shown to have zero measure and, for $p > N$, the boundary integral to be continuous for special classes of functions. Section 4 reviews the *velocity method* which transforms an initial domain Ω into domains $\Omega_t(V)$ indexed by the real parameter t under the action of a velocity field V. We compute the partial derivative of the oriented distance function of $\Omega_t(V)$ with respect to t. Section 5 is devoted to the new *nonlinear evolution equation* for the oriented distance function for initial sets with thin boundary evolving in a velocity field and its connection with level set methods and the use of the zero-extension introduced in Definition 3.3 to create new *moving narrow-band methods* (cf. Remark 5.5).

2. Oriented distance function and metrics. Given an integer $N \geq 1$, m_N and H_{N-1} will denote the N-dimensional Lebesgue and $(N-1)$-dimensional Hausdorff measures. The inner product and the norm in $\mathbf{R}^{\mathrm{N}}$ will be written $x \cdot y$ and $|x|$. The *complement* $\{x \in \mathbf{R}^{\mathrm{N}} : x \notin \Omega\}$ and the boundary $\overline{\Omega} \cap \overline{\complement\Omega}$ of a subset Ω of $\mathbf{R}^{\mathrm{N}}$ will be, respectively, denoted by $\complement\Omega$ or $\mathbf{R}^{\mathrm{N}} \setminus \Omega$ and by $\partial\Omega$ or Γ. The *distance function* $d_A(x)$ from a point x to a subset $A \neq \varnothing$ of $\mathbf{R}^{\mathrm{N}}$ is defined as $\inf\{|y - x| : y \in A\}$.

Given $\Omega \subset \mathbf{R}^{\mathrm{N}}$, $\Gamma \neq \varnothing$, the *oriented distance function*[2] is defined as

$$b_\Omega(x) \stackrel{\text{def}}{=} d_\Omega(x) - d_{\complement\Omega}(x). \tag{2.1}$$

There is a one-to-one correspondence between b_Ω and the equivalence class[3]

$$[\Omega]_b \stackrel{\text{def}}{=} \left\{\Omega' \subset \mathbf{R}^{\mathrm{N}} \,:\, \Gamma' = \Gamma \text{ and } \overline{\Omega'} = \overline{\Omega}\right\}. \tag{2.2}$$

The function b_Ω is Lipschitz continuous of constant 1, and ∇b_Ω exists and $|\nabla b_\Omega| \leq 1$ almost everywhere in $\mathbf{R}^{\mathrm{N}}$. Thus $b_\Omega \in W^{1,p}_{\mathrm{loc}}(\mathbf{R}^{\mathrm{N}})$ for all p, $1 \leq p \leq \infty$. Definition (2.1) and the associated equivalence classes seem to have been first introduced in 1994 in [9]. This terminology and notation emphasize the fact that ∇b_Ω coincides with the exterior normal to the boundary (when it exists). In the literature, the *signed distance function* is defined for a closed submanifold M under the assumption that there exists an open set Ω such that $\Gamma = M$ as the distance d_Γ to the boundary Γ with a change

[1] Cf. footnote 10 and Theorem 3.1 (ii).

[2] The function b_Ω captures many of the geometric properties of the set Ω. For instance, in 1985 [3] showed that a proper closed domain Ω is convex if and only if $-b_\Omega$ is superharmonic and that, for $N = 2$, the result still holds if $-b_\Omega$ is superharmonic only on Ω. They also show that, for Ω compact, d_Γ *is subharmonic on* $\complement\Omega$ *if and only if* Ω *is convex* (cf. also [11], Chap. 5, Lem. 7.1). This work was pursued in 1987 by [33] and in 1988 by [34]. In 1994 it was shown in [9, 11] that the property that $\overline{\Omega}$ *is convex if and only if* d_Ω *is convex* remains true with b_Ω in place of d_Ω.

[3] In general $d_{\overline{\Omega}} = d_\Omega \leq d_{\operatorname{int}\Omega}$ and $d_{\overline{\complement\Omega}} = d_{\complement\Omega} \leq d_{\complement\overline{\Omega}}$, but we only have $b_{\overline{\Omega}} \leq b_\Omega \leq b_{\operatorname{int}\Omega}$. For convex sets we have $b_{\overline{\Omega}} = b_\Omega$; for sets verifying the segment property we have $b_{\overline{\Omega}} = b_\Omega = b_{\operatorname{int}\Omega}$.

of sign across Γ (cf., for instance, [28]). In some contexts this definition is ambiguous since once a submanifold M has been specified there are several choices of open sets Ω with the *same boundary* $\Gamma = M$ but *completely different* functions b_Ω.[4]

The function b_Ω offers definite advantages over the function d_Ω. It captures the geometric and smoothness properties of the set Ω. For instance, Ω is of class $C^{1,1}$ if and only if b_Ω is locally $C^{1,1}$ in a neighborhood of its boundary as we shall see in Theorem 3.2. This characterization is not possible with d_Ω whose gradient is discontinuous across the boundary Γ. It makes it possible to simultaneously deal with open N-dimensional subsets and embedded submanifolds of $\mathbf{R}^{\mathrm{N}}$ in the same framework. Indeed when Ω is a closed embedded submanifold of $\mathbf{R}^{\mathrm{N}}$ of codimension greater or equal to one, then $\Omega = \overline{\Omega} = \Gamma$ and $b_\Omega = d_\Omega = d_\Gamma$.[5]

DEFINITION 2.1.

(i) *Given a nonempty subset D of $\mathbf{R}^{\mathrm{N}}$, define the families*

(2.3)
$$C_b(D) \overset{\text{def}}{=} \{b_\Omega : \Omega \subset \overline{D} \text{ and } \Gamma \neq \varnothing\}, \quad C_b^0(D) \overset{\text{def}}{=} \{b_\Omega \in C_b(D) : \mathrm{m}_N(\Gamma) = 0\}.$$

(ii) *The boundary Γ of a subset Ω of $\mathbf{R}^{\mathrm{N}}$ is said to be* thin[6] *if* $\mathrm{m}_N(\Gamma) = 0$.

The space $C_b^0(D)$ corresponds to the subfamily of subsets of $\mathbf{R}^{\mathrm{N}}$ with a *thin boundary* that is a more natural family than the family $C_b(D)$ in applications.

In this paper we specialize to the following complete metrics[7] associated with b_Ω over the subsets Ω of a bounded open hold-all D

$$\rho_{C(D)}([\Omega'], [\Omega]) \overset{\text{def}}{=} \max_{x \in \overline{D}} |b_{\Omega'}(x) - b_\Omega(x)|, \tag{2.4}$$

$$\rho_{L^p(D)}([\Omega'], [\Omega]) \overset{\text{def}}{=} \left\{ \int_D |b_{\Omega'} - b_\Omega|^p \, dx \right\}^{1/p}, \tag{2.5}$$

$$\rho_{W^{1,p}(D)}([\Omega'], [\Omega]) \overset{\text{def}}{=} \left\{ \int_D |b_{\Omega'} - b_\Omega|^p + |\nabla b_{\Omega'} - \nabla b_\Omega|^p \, dx \right\}^{1/p}. \tag{2.6}$$

The space $C_b(D)$ is a complete metric space for the metrics (2.4), (2.5), and (2.6), but the space $C_b^0(D)$ is complete only with respect to the metric (2.6) (e.g., [11, Chap. 5]).[8] The metrics (2.6) are all equivalent for $1 \leq p < \infty$. The following theorem is central. It shows that convergence and compactness in the metric $\rho_{W^{1,p}(D)}$ will imply the same properties in all other topologies (cf. [11, Chap. 5, Thm. 5.1]).

THEOREM 2.1. *Let D be a bounded open subset of $\mathbf{R}^{\mathrm{N}}$. The map*

$$b_\Omega \mapsto (b_\Omega^+, b_\Omega^-, |b_\Omega|) = (d_\Omega, d_{\complement\Omega}, d_{\partial\Omega}) : C_b(D) \subset W^{1.p}(D) \to W^{1.p}(D)^3 \tag{2.7}$$

and, for all p, $1 \leq p < \infty$, the map

$$b_\Omega \mapsto (\chi_{\partial\Omega}, \chi_{\operatorname{int}\Omega}, \chi_{\operatorname{int}\complement\Omega}) : W^{1,p}(D) \to L^p(D)^3$$

are continuous.

---

[4]For instance, the unit circle C in $\mathbf{R}^2$ is the boundary of the open unit ball but it is also the boundary of the open set $\mathbf{R}^2 \setminus C$.

[5]Recall that $b_\Omega^+ = d_\Omega$, $b_\Omega^- = d_{\complement\Omega}$, and $|b_\Omega| = d_\Gamma$, and that $\chi_{\operatorname{int}\Omega} = |\nabla d_{\complement\Omega}|$, $\chi_{\operatorname{int}\complement\Omega} = |\nabla d_\Omega|$, and $\chi_\Gamma = 1 - |\nabla d_\Gamma|$ a.e. in $\mathbf{R}^{\mathrm{N}}$.

[6]This terminology is not to be confused with the one of thin set in *Capacity Theory*.

[7]Other complete metrics can be defined with d_Ω, $d_{\complement\Omega}$, d_Γ in place of b_Ω.

[8]The completeness of the metric (2.4) is not a trivial consequence of the proof by Dellacherie [14] in 1972 of the completeness of the Hausdorff metric associated with d_Ω which is different but equivalent to the classical definition of D. Pompéju [36] in 1905 and F. Hausdorff [22] in 1914. To our best knowledge, the metrics (2.4) and (2.6) were first introduced by [9] in 1994.

The weak $W^{1,p}$-topologies are all equivalent on $C_b(D)$ for $1 \le p < \infty$. For the convergence of sets with thin boundary, we have the following equivalence.

LEMMA 2.1. *Given a bounded open subset D of $\mathbf{R}^{\mathrm{N}}$, let $\{\Omega_n\}$ be a sequence of subsets of $\overline{D}$ such that $\Gamma_n \neq \varnothing$ and $\mathrm{m}(\Gamma_n) = 0$. Further assume that there exists $\Omega \subset \bar{D}$ such that $\Gamma \neq \varnothing$ and $\mathrm{m}(\Gamma) = 0$. Then*

$$b_{\Omega_n} \rightharpoonup b_\Omega \text{ in } W^{1,2}(D)\text{-weak} \quad \Rightarrow b_{\Omega_n} \to b_\Omega \text{ in } W^{1,2}(D)\text{-strong},$$

and hence in $W^{1,p}(D)$-strong for all p, $1 \le p < \infty$.

Proof. Same proof as in part (ii) of the proof of Theorem 10.1 in [11]. Since, for all $n \ge 1$, $\mathrm{m}(\Gamma_n) = 0 = \mathrm{m}(\Gamma)$, $|\nabla b_\Omega| = 1 = |\nabla b_{\Omega_n}|$ almost everywhere in D (cf. [11, Thm. 3.2, p. 215]). As a result

$$\int_D |\nabla b_{\Omega_n} - \nabla b_\Omega|^2 \, dx = \int_D |\nabla b_{\Omega_n}|^2 + |\nabla b_\Omega|^2 - 2\nabla b_{\Omega_n} \cdot \nabla b_\Omega \, dx$$
$$= 2\int_D (1 - \nabla b_{\Omega_n} \cdot \nabla b_\Omega) \, dx \to 2\int_D (1 - |\nabla b_\Omega|^2) \, dx = 2\int_D \chi_\Gamma \, dx = 0.$$

Therefore $\nabla b_{\Omega_n} \to \nabla b_\Omega$ in $L^2(D)^N$-strong and $b_{\Omega_n} \to b_\Omega$ in $W^{1,2}(D)$-strong, since the convergence $b_{\Omega_n} \to b_\Omega$ in $L^2(D)$-strong follows from the weak convergence in $W^{1,2}(D)$. The convergence in $W^{1,p}(D)$-strong follows from the equivalence of the topologies on $C_b(D)$ (cf. [11, Chap. 5, Thm. 5.1 (i)]). ∎

The points of $\mathbf{R}^{\mathrm{N}}$ where the gradient of b_Ω does not exist can be divided into two categories: the ones on the boundary Γ and the ones outside of Γ.

DEFINITION 2.2. *The set of* projections *of a point $x \in \mathbf{R}^{\mathrm{N}}$ onto the boundary Γ of a set Ω, $\Gamma \neq \varnothing$,*

$$\Pi_\Gamma(x) \stackrel{\text{def}}{=} \left\{p \in \mathbf{R}^{\mathrm{N}} \,:\, |b_\Omega(x)| = |p - x|\right\}$$

since $|b_\Omega(x)| = d_\Gamma(x)$; the skeleton *of Ω*

$$\mathrm{Sk}(\Omega) \stackrel{\text{def}}{=} \left\{x \in \mathbf{R}^{\mathrm{N}} \,:\, \Pi_\Gamma(x) \text{ is not a singleton}\right\} \tag{2.8}$$

(by definition $\mathrm{Sk}(\Omega) \subset \mathbf{R}^{\mathrm{N}} \setminus \Gamma$); the set of cracks *of Ω*

$$\mathrm{C}(\Omega) \stackrel{\text{def}}{=} \left\{x \in \mathbf{R}^{\mathrm{N}} \,:\, \nabla b_\Omega^2(x) \text{ exists but } \nabla b_\Omega(x) \text{ does not exist}\right\}.$$

The terminology *crack* is used here in a very broad sense and $C(\Omega)$ can contain subsets of arbitrary codimension. In dimension 2 the *corners* along a piecewise smooth boundary belong to the set of cracks.

THEOREM 2.2. *Let Ω be a subset of $\mathbf{R}^{\mathrm{N}}$ with $\Gamma \neq \varnothing$.*

(i) *For all $x \in \Gamma$, $\nabla b_\Omega^2(x)$ exists and $\nabla b_\Omega^2(x) = 0$; for all $x \notin \Gamma$*

$$\nabla b_\Omega^2(x) \text{ exists} \quad \Longleftrightarrow \quad \nabla b_\Omega(x) \text{ exists}.$$

Hence $\nabla b_\Omega(x)$ exists if and only if $x \notin \mathrm{Sk}(\Omega) \cup \mathrm{C}(\Omega)$. Moreover,

$$\mathrm{Sk}(\Omega) = \left\{x \in \mathbf{R}^{\mathrm{N}} \,:\, \nabla b_\Omega^2(x) \text{ does not exist}\right\}$$

and $\mathrm{Sk}(\Omega) \subset \mathbf{R}^{\mathrm{N}} \setminus \Gamma$ and $\mathrm{C}(\Omega) \subset \Gamma$ have zero m_N-measure.

(ii) *The* projection *$p_\Gamma(x)$ of a point $x \notin \mathrm{Sk}(\Omega)$ onto the boundary Γ is given by*

$$p_\Gamma(x) = x - \frac{1}{2}\nabla b_\Omega^2(x) = x - b_\Omega \, \nabla b_\Omega(x). \tag{2.9}$$

(iii) *The Hadamard semiderivative*[9] *of* b_Ω^2 *always exists:*

$$\forall v \in \mathbf{R}^N, \quad d_H b_\Omega^2(x;v) = 2 \min_{p\in\Pi_\Gamma(x)} (x-p)\cdot v. \tag{2.10}$$

(iv) *For all points* $x \notin \Gamma$*, the Hadamard semiderivative of* b_Ω *exists and*

$$\forall v \in \mathbf{R}^N, \quad d_H b_\Omega(x;v) = \frac{1}{b_\Omega(x)} \min_{p\in\Pi_\Gamma(x)} (x-p)\cdot v. \tag{2.11}$$

For all points $x \in \Gamma$*,* $d_H b_\Omega(x;v)$ *exists if and only if*

$$\forall v \in \mathbf{R}^N, \quad \lim_{t\searrow 0} \frac{b_\Omega(x+tv)}{t} \text{ exists.} \tag{2.12}$$

Proof. (i) and (ii) Cf. [11, Chap. 5, Thm. 4.4, and Chap. 8, Sects. 5, 2, 3, and p. 369]). (iii) Cf. [11, Thm. 3.1 (iii), p. 164]. (iv) The proof is obvious. □

3. Some families of sets and their properties. We review the families of sets which will be used in the paper and sharpen their characterization and properties (sets of positive reach, smooth sets and manifolds, and Sobolev domains). For instance, the distance function is shown to be locally semiconvex[10] for sets of positive reach. For $W^{2,p}$-Sobolev domains a new characterization and a compactness theorem are given in term of the Laplacian of b_Ω rather than on the whole Hessian matrix. Their boundary is thin.

Given $h > 0$ the *open and closed tubular neighborhoods* of a set A are defined as

$$U_h(A) \overset{\text{def}}{=} \left\{x \in \mathbf{R}^N \,:\, d_A(x) < h\right\}, \quad A_h \overset{\text{def}}{=} \left\{x \in \mathbf{R}^N \,:\, d_A(x) \le h\right\}. \tag{3.1}$$

Recalling that $d_\Gamma(x) = |b_\Omega(x)|$ we also have $U_h(\Gamma) = \left\{x \in \mathbf{R}^N : |b_\Omega(x)| < h\right\}$.

3.1. Sets and boundaries of positive reach. The sets of positive reach were introduced by Federer [18] in 1959.

Definition 3.1.

(i) $\Omega \subset \mathbf{R}^N$, $\Omega \neq \varnothing$, *is said to have* positive reach *greater or equal to* h *if the projection* $p_\Omega(x)$ *onto* $\overline{\Omega}$ *is unique for all points* x *in the open tubular neighborhood* $U_h(\Omega)$ *of* Ω.

(ii) *The boundary* $\Gamma \neq \varnothing$ *of a set* $\Omega \subset \mathbf{R}^N$ *is said to have* positive reach *greater or equal to* h *if the projection* $p_\Gamma(x)$ *onto* Γ *is unique for all points* x *in the open tubular neighborhood* $U_h(\Gamma)$ *of* Γ.

Theorem 3.1. *Let* Ω *be a nonempty subset of* $\mathbf{R}^N$.

(i) Ω *has positive reach greater or equal to* h *if and only if* $d_\Omega^2 \in C^{1,1}_{\text{loc}}(U_h(\Omega))$.

(ii) *If any one of the conditions of part* (i) *is verified, then for all* $0 < r < h$

$$\forall a \in \overline{\Omega}, \quad b_{\overline{\Omega}}(x) + \frac{1}{2r}\left[|x|^2 - b_{\overline{\Omega}}^2(x)\right] \text{ is convex in } B_h(a), \tag{3.2}$$

where $B_h(a)$ *denotes the open ball of radius* h *and center* a.

---

[9] A function $f : \mathbf{R}^N \to \mathbf{R}$ has a Hadamard semiderivative in x in the direction v if

$$d_H f(x;v) \overset{\text{def}}{=} \lim_{\substack{t\searrow 0 \\ w\to v}} \frac{f(x+tw)-f(x)}{t} \text{ exists}$$

(cf. [11, Chap. 8, Def. 2.1 (ii)]).

[10] Here the terminology *semiconvex* is used in the *extended sense* that there exists a convex function k such that $b_\Omega + k$ is convex as stated in Theorem 3.1 (ii).

Proof. (i) The proof is from Federer [18] or [11, Chap. 4, Thm. 7.1, p. 192]. (ii) For, $\Omega_r = \{x \in \mathbf{R}^N : d_\Omega(x) \le r\}$ the function $\left[|x|^2 - b^2_{\Omega_r}(x)\right]/2$ is convex and continuous. From [11, Chap. 5, Thm. 8.2 (ii), p. 244] for $0 < r < h$ we have $b_{\Omega_r}(x) = b_{\overline{\Omega}}(x) - r$ on $U_h(\Omega)$ and hence for each $a \in \overline{\Omega}$

$$\begin{aligned}\frac{1}{2}\left[|x|^2 - (b_{\overline{\Omega}}(x) - r)^2\right] &= \frac{1}{2}\left[|x|^2 - b^2_{\overline{\Omega}}(x) + 2r b_{\overline{\Omega}}(x) - r^2\right] \\ &= r\left[b_{\overline{\Omega}}(x) + \frac{1}{2r}\left[|x|^2 - b^2_{\overline{\Omega}}(x)\right] - \frac{r}{2}\right] \\ \Rightarrow\ & b_{\overline{\Omega}}(x) + \frac{1}{2r}\left[|x|^2 - b^2_{\overline{\Omega}}(x)\right]\end{aligned}$$

is convex and continuous in $B_h(a)$. □

When the boundary Γ of a set Ω has positive reach, both $\overline{\Omega}$ and $\overline{\complement\Omega}$ have positive reach and we get the following results since $b_{\overline{\complement\Omega}} = -b_{\operatorname{int}\Omega}$.

COROLLARY 3.1.1. *Let Ω be a subset of $\mathbf{R}^N$ such that $\Gamma \neq \varnothing$. Assume that there exists $h > 0$ such that $b^2_\Omega \in C^{1,1}_{\mathrm{loc}}(U_h(\Gamma))$ and $\{x \in \mathbf{R}^N : |b_\Omega(x)| \le h\} \neq \mathbf{R}^N$. For all r, $0 < r < h$, (3.2) is verified and*

$$\forall a \in \overline{\complement\Omega}, \quad -b_{\operatorname{int}\Omega}(x) + \frac{1}{2r}\left[|x|^2 - b^2_{\operatorname{int}\Omega}(x)\right] \text{ is convex in } B_h(a),$$

$$\forall a \in \Gamma, \quad b_\Gamma(x) + \frac{1}{2r}\left[|x|^2 - b^2_\Gamma(x)\right] \text{ is convex in } B_h(a).$$

3.2. Smooth sets and manifolds. First, recall the relation between the smoothness of a set Ω and the smoothness of b_Ω in a neighborhood of its boundary.

THEOREM 3.2. [11] *Let Ω be a subset of $\mathbf{R}^N$ such that $\Gamma \neq \varnothing$.*

(i) *The set Ω is of class $C^{1,1}$* (resp., C^k, $k \ge 2$) *in a neighborhood $U(x)$ of $x \in \Gamma$ if and only if $b_\Omega \in C^{1,1}(W(x))$* (resp., C^k, $k \ge 2$) *in some neighborhood $W(x)$ of x. Moreover, under the $C^{1,1}$ assumption,*

$$C(\Omega) \cap W(x) = \varnothing \text{ and } \nabla b_\Omega = n \circ p_\Gamma \text{ in } W(x),$$

where n is the unit exterior normal to Γ at the point $p_\Gamma(x)$.

(ii) *Let λ, $0 \le \lambda < 1$, be a real number. Ω is of class $C^{1,\lambda}$ and its boundary Γ has positive reach if and only if b_Ω is $C^{1,\lambda}$ in a neighborhood of Γ.*

Proof. (i) Cf. [11]. (ii) ($\Leftarrow$) See Theorem 4.2 in [11, Chap. 5, p. 218]. ($\Rightarrow$) The beginning of the proof of Theorem 4.3 (i) [11, Chap. 5, pp. 219–220] only requires that Ω be of class C^1, and we get for some neighborhood of $U(\Gamma)$ of Γ

$$\forall y \in U(\Gamma),\ \forall p \in \Pi_\Gamma(y), \quad p = y - b_\Omega(y)\, n(p),$$

[11] It is important to note that Theorem 3.2 is not true when b_Ω is replaced by d_Γ since its gradient ∇d_Γ is discontinuous across Γ. Part (i) in the direction ($\Rightarrow$) was asserted by Serrin [39] in 1969 for $N = 3$, proved in 1977 by Gilbarg and Trudinger [19] for $k \ge 2$ (provided that d_Γ is replaced by b_Ω in Lemma 1, p. 382, in [19] and Lemma 14.16, p. 355, in [20]) with a different proof by Krantz and Parks [28] in 1981. Another proof with the function b_Ω was given in 1994 by Delfour and Zolésio [9], who extended the result in the direction ($\Rightarrow$) down to the $C^{1,1}$ case and established the equivalence ($\Leftrightarrow$) in the whole range from C^∞ to $C^{1,1}$. The counterexample for domains of class $C^{1,1-\epsilon}$ given in [11] is the same as the one provided earlier in [28], where they only observe that the domain is $C^{2-\varepsilon}$ leaving the reader under the misleading impression that part (i) of the theorem would not be true for domains ranging from class $C^{1,1}$ to C^2. Part (ii) in the direction ($\Rightarrow$) was proved in the C^1 case by Krantz and Parks [28] in 1981. The equivalence ($\Leftrightarrow$) here for $C^{1,\lambda}$, $0 \le \lambda < 1$, seems to be new.

where $n(p)$ is the unit outward normal to Γ in p. But, by assumption, $\Pi_\Gamma(y) = \{p_\Gamma(y)\}$ is a singleton and

$$\forall y \in U(\Gamma), \quad p_\Gamma(y) = y - b_\Omega(y)\, n(p_\Gamma(y)).$$

Since Γ has positive reach we get from [11, Chap. 5, Lem. 8.2] that

$$\forall y \in U(\Gamma)\backslash\Gamma, \quad p_\Gamma(y) = y - b_\Omega(y)\, \nabla b_\Omega(y)),$$

and hence, for all y in $U(\Gamma)\backslash\Gamma$, $\nabla b_\Omega(y)) = n(p_\Gamma(y))$. But the boundary Γ of a C^1-domain has zero measure, and hence ∇b_Ω is a.e. equal to the $C^{1,\lambda}$ function $n \circ p_\Gamma$ on $U(\Gamma)$ as the composition of $n \in C^{0,\lambda}(U(\Gamma))$ and $p_\Gamma \in C^{0,1}(U(\Gamma))$. Hence $b_\Omega \in C^{1,\lambda}(U(\Gamma))$. □

For a domain Ω of class $C^{1,1}$ the unit exterior normal $n(x)$ to Ω in a point x of its boundary Γ coincides with the gradient of b_Ω, and the Hessian matrix $D^2 b_\Omega(x)$ on Γ coincides with the *second fundamental form* of Γ. The *additive curvature* H of Γ is the sum of the eigenvalues of the second fundamental form and coincides with the *tangential divergence* of n,

$$H \overset{\text{def}}{=} \operatorname{div}_\Gamma n = \Delta b_\Omega|_\Gamma, \quad H_{N-1}\text{-a.e. on } \Gamma.$$

Since 0 is an eigenvalue of $D^2 b_\Omega$ and H is the sum of the eigenvalues of $D^2 b_\Omega$, Δb_Ω is equal to $(N-1)$ times the standard *mean curvature* of Γ (cf. [8, 10]).

Theorem 3.2 covers only sets whose thin boundary is a submanifold of $\mathbf{R}^N$ of codimension one. For closed submanifolds M of $\mathbf{R}^N$ where ∇b_M does not exist on M, the smoothness of M is related to d_M^2 and the existence of ∇d_M^2 in a neighborhood of M implies that M is locally of positive reach. The following analysis of the smoothness of M was given by Poly and Raby [35] in 1984.

THEOREM 3.3. *Let M be a closed nonempty subset of $\mathbf{R}^N$ and $k \geq 2$ be an integer ($k = \infty$ and ω[12] included). Then*

$$\operatorname{sing}_k M = M \cap \operatorname{sing}_k d_M^2,$$

where $\operatorname{sing}_k d_M^2 = \mathbf{R}^N \backslash \operatorname{reg}_k d_M^2$, $\operatorname{sing}_k M = \mathbf{R}^N \backslash \operatorname{reg}_k M$, *and*

$$\operatorname{reg}_k d_M^2 = \left\{x \in \mathbf{R}^N \,:\, d_M^2 \text{ is } C^k \text{ in a neighborhood of } x\right\}$$
$$\operatorname{reg}_k M = \left\{x \in M \,:\, M \text{ is a } C^k\text{-submanifold of } \mathbf{R}^N \text{ in a neighborhood of } x\right\}.$$

For $k = 1$ [35] gives the one-dimensional counterexample $\Omega =]-\infty, 0]$ for which $d_\Omega^2 \in C^{1,1}$, and this counterexample readily extends to a closed half space of $\mathbf{R}^N$. This can be fixed by using b_Ω for which $b_\Omega^2(x) = |x|^2 \in C^\infty$ recalling that $|b_\Omega(x)| = d_\Gamma(x)$. It yields the analogue of Theorem 3.2.

THEOREM 3.4. [13]*Let Ω be a subset of $\mathbf{R}^N$ with nonempty thin boundary Γ and $k \geq 2$ be an integer ($k = \infty$ and ω included), and x be a point of Γ. Then b_Ω^2 is C^k in a neighborhood of a point $x \in \Gamma$ if and only if Γ is a C^k-submanifold in a*

[12] ω indicates the analytical case.

[13] Note that Γ can have several connected components with the same smoothness k but different dimension. When $\Gamma = \mathbf{R}^N$ b_Ω is identically zero. Another set of results for Hölderian sets was obtained by [29] (see also [7]) by introducing a regularized distance function.

neighborhood of x. Moreover, the dimension of Γ in x is equal to the rank of $Dp_\Gamma(x)$ and $Dp_\Gamma(x)$ is the orthogonal projector onto the tangent space in x.

3.3. Sobolev domains. The notion of *Sobolev domain* has been introduced in [10] as an instrument to classify domains which fall in the gaps between Hölderian domains. We further characterize $(2,p)$-Sobolev domains by introducing a special extension of b_Ω by zero outside $U_h(\Gamma)$.

DEFINITION 3.2. *Given $m > 1$ and $p \geq 1$, a subset Ω of $\mathbf{R}^N$ is said to be an* (m,p)-Sobolev domain *if $\Gamma \neq \varnothing$ and*

$$\exists h > 0 \text{ such that } b_\Omega \in W^{m,p}_{\mathrm{loc}}(U_h(\Gamma)).$$

For sets Ω of locally bounded curvature

$$\forall p,\ 1 \leq p < \infty, \quad \forall \eta,\ 0 \leq \eta < 1/p, \quad b_\Omega \in W^{1+\eta,p}_{\mathrm{loc}}(\mathbf{R}^N),$$

and m can range from 1 to 2. It is convenient to introduce a special extension of b_Ω by zero outside of $U_h(\Gamma)$ to work in $\mathbf{R}^N$.

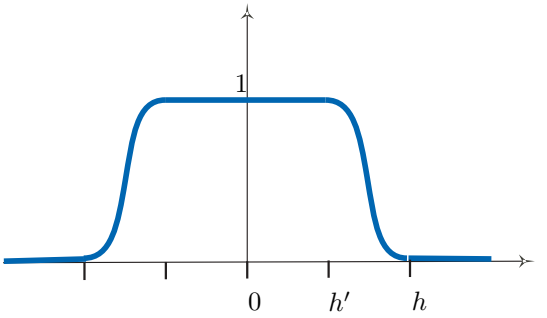

FIG. 3.1. *The function ρ_h with parameters (h',h), $0 < h' < h$.*

DEFINITION 3.3. *Given $h > 0$ and a subset Ω of $\mathbf{R}^N$ with nonempty boundary Γ, let $\rho_h \in \mathcal{D}(\,]-h,h[\,)$ be a nonnegative function which is equal to 1 in a neighborhood $V = \,]-h',h'[$, $0 < h' < h$, of 0. Define the* smooth h-extensions of b_Ω and 1 by zero:

$$b^h_\Omega \overset{\text{def}}{=} \rho_h \circ b_\Omega\, b_\Omega, \quad e^h_\Omega \overset{\text{def}}{=} \rho_h \circ b_\Omega + b_\Omega \rho'_h \circ b_\Omega. \tag{3.3}$$

It is readily seen that $b^h_\Omega = b_\Omega$ and $e^h_\Omega = 1$ in the tubular neighborhood $b_\Omega^{-1}(V) = U_{h'}(\Gamma) \subset U_h(\Gamma)$ of Γ. By construction $e^h_\Omega \in C^{0,1}_0(U_h(\Gamma))$. Moreover, the extension b^h_Ω preserves the smoothness properties of b_Ω in $U_h(\Gamma)$ and e^h_Ω can be viewed as an extension of 1 by zero outside $U_h(\Gamma)$ with the same smoothness as b_Ω in $U_h(\Gamma)$. By construction

$$\nabla b^h_\Omega = [\rho_h \circ b_\Omega + b_\Omega\, \rho'_h \circ b_\Omega]\, \nabla b_\Omega = e^h_\Omega \nabla b_\Omega. \tag{3.4}$$

If there exist $p \geq 1$ and $h > 0$ such that $\Delta b_\Omega \in L^p_{\mathrm{loc}}(U_h(\Gamma))$, then

$$\Delta b^h_\Omega = e^h_\Omega \Delta b_\Omega + \nabla e^h_\Omega \cdot \nabla b_\Omega \in L^p_{\mathrm{loc}}(\mathbf{R}^N) \quad (L^p(\mathbf{R}^N) \text{ if } \Gamma \text{ is bounded}).$$

Therefore by elliptic regularity

$$\begin{gathered} b^h_\Omega \in W^{2,p}_{\mathrm{loc}}(\mathbf{R}^N) \quad (W^{2,p}(\mathbf{R}^N) \text{ if } \Gamma \text{ is bounded}) \\ \Rightarrow\ \forall h',\ 0 < h' < h, \quad b_\Omega \in W^{2,p}_{\mathrm{loc}}(U_{h'}(\Gamma)) \quad (W^{2,p}(U_{h'}(\Gamma)) \text{ if } \Gamma \text{ is bounded}) \\ \Rightarrow\ b_\Omega \in W^{2,p}_{\mathrm{loc}}(U_h(\Gamma)). \end{gathered}$$

THEOREM 3.5. *Given an integer $N \geq 1$, let Ω be a subset of $\mathbf{R}^{\mathrm{N}}$, $\varnothing \neq \Gamma \neq \mathbf{R}^{\mathrm{N}}$.*
(i) *If there exist $p \geq 1$ and $h > 0$ such that $\Delta b_\Omega \in L^p_{\mathrm{loc}}(U_h(\Gamma))$, then*

$$b^h_\Omega \in W^{2,p}_{\mathrm{loc}}(\mathbf{R}^{\mathrm{N}}) \text{ and } b_\Omega \in W^{2,p}_{\mathrm{loc}}(U_h(\Gamma)) \tag{3.5}$$

and $\mathrm{m}_N(\Gamma) = 0$.[14] *The gradient ∇b_Ω exists in all points of $U_h(\Gamma)\backslash\Gamma$ and $|\nabla b_\Omega| = 1$. If Γ is compact*

$$b^h_\Omega \in W^{2,p}_0(\mathbf{R}^{\mathrm{N}}) \text{ and } \quad \forall h',\, 0 < h' < h, \quad b_\Omega \in W^{2,p}(U_{h'}(\Gamma)). \tag{3.6}$$

(ii) *If, in addition to the assumptions of part* (i), *$p > N$, then Ω is a Hölderian set of class $C^{1,1-N/p}$ and $b_\Omega \in C^{1,1-N/p}_{\mathrm{loc}}(U_h(\Gamma))$.*

Proof. For convenience we write b for b_Ω. (i) The proof is from the discussion preceding the theorem and [11, Chap. 5, Thm. 6.5, p. 235]. To show that $\mathrm{m}_N(\Gamma) = 0$, recall that $\nabla b \in [W^{1,p}_{\mathrm{loc}}(U_h(\Gamma)) \cap L^\infty_{\mathrm{loc}}(U_h(\Gamma))]^N$. Therefore, for each $x \in \Gamma$, $|\nabla b|^2 \in W^{1,p}(B(x,h)) \cap L^\infty(B(x,h))$ and $\nabla|\nabla b|^2 = 2\, D^2 b\, \nabla b$. But we have shown that ∇b exists and $|\nabla b|^2 = 1$ in $U_h(\Gamma)\backslash\Gamma$. This implies that $D^2 b \nabla b = 0$ in $U_h(\Gamma)\backslash\Gamma$. Moreover, we know that $\nabla b = 0$ a.e. in Γ. Therefore $\nabla|\nabla b|^2 = 2\, D^2 b\, \nabla b = 0$ a.e. in $U_h(\Gamma)$ and $|\nabla b|^2 \in W^{1,p}(B(x,h)) \cap L^\infty(B(x,h))$. Hence $|\nabla b|^2$ is constant in each connected component of $U_h(\Gamma)$ and the points of Γ can be divided into two categories,

$$\Gamma_0 = \{x \in \Gamma \,:\, B(x,h) \subset \Gamma\} \text{ and } \Gamma_1 = \{x \in \Gamma \,:\, B(x,h)\backslash\Gamma \neq \varnothing\}$$

$$\Rightarrow |\nabla b(x)|^2 = \begin{cases} 0, & x \in U_h(\Gamma_0) \\ 1, & x \in U_h(\Gamma_1) \end{cases} \Rightarrow U_h(\Gamma_0) \cap U_h(\Gamma_1) = \varnothing \text{ and } \Gamma_0 \cap \Gamma_1 = \varnothing,$$

and Γ splits into two closed disjoint subsets. Therefore $U_h(\Gamma_0) \cap \Gamma_1 = \varnothing$ and $U_h(\Gamma_0) \subset \Gamma$ necessarily imply $U_h(\Gamma_0) = \Gamma_0$. Thus Γ_0 is both open and closed. But this can only happen when Γ_0 is $\mathbf{R}^{\mathrm{N}}$ or $\varnothing$. By assumption, the first case cannot happen since $\mathbf{R}^{\mathrm{N}} = \Gamma_0 \subset \Gamma$. Therefore $\Gamma_0 = \varnothing$ and $|\nabla b|^2 = 1$ in $U_h(\Gamma)$. Finally $\chi_\Gamma = 1 - |\nabla b| = 1 - |\nabla b|^2 = 0$ and $\mathrm{m}_N(\Gamma) = 0$.

(ii) The proof is from [11, Chap. 5, Thm. 6.5 (i), p. 235]. □

We have the following new compactness theorem which relaxes the boundedness condition (3.7) from $D^2 b_{\Omega_n}$ in [11] to Δb_{Ω_n}.

THEOREM 3.6. *Let $D \subset \mathbf{R}^{\mathrm{N}}$ be nonempty bounded and open and $\{\Omega_n\}$, $\Gamma_n \neq \varnothing$, be a sequence of subsets of $\overline{D}$. Assume that there exist p, $1 \leq p < \infty$, h, and c such that*

$$\forall n,\ \|\Delta b_{\Omega_n}\|_{L^p(U_h(\Gamma_n))} \leq c. \tag{3.7}$$

Then there exist a subsequence $\{\Omega_{n_k}\}$ and a subset Ω, $\Gamma \neq \varnothing$, of $\overline{D}$ such that for all h', $0 < h' < h$, $b_\Omega \in W^{2,p}(U_{h'}(\Gamma))$ and for all $\bar{p}$, $1 \leq \bar{p} < \infty$,

$$b_{\Omega_{n_k}} \to b_\Omega \text{ in } W^{1,\bar{p}}(U_h(D))\text{-strong}. \tag{3.8}$$

[14] In order to further characterize a bounded $W^{2,p}$-domain, one could try to find the conditions on Γ under which $\nabla b^2_\Omega \in W^{1,p}_0(\Omega)^N$ and $b^{-1}_\Omega \nabla b^2_\Omega \in W^{1,p}(\Omega)^N$. This is the vectorial version of the problem of finding the conditions on Γ such that $W^{1,p}_0(\Omega) = \{f \in W^{1,p}(\Omega) : f\, d^{-1}_\Gamma \in L^p(\Omega)\}$ holds for some p, $1 \leq p < \infty$. The general problem of finding the conditions on Γ under which $W^{k,p}_0(\Omega) = \{f \in W^{k,p}(\Omega) : f\, d^{-k}_\Gamma \in L^p(\Omega)\}$, $1 \leq p < \infty$, $k = 1, 2, \ldots$ (especially $k = 1$), holds is studied in [17].

Moreover,[15] *for* $p > 1$, $\|\Delta b_\Omega\|_{L^p(U_h(\Gamma))} \le c$ *and for all* h', $0 < h' < h$,

$$D^2 b_{\Omega_{n_k}} \chi_{U_{h'}(\Gamma_{n_k})} \rightharpoonup D^2 b_\Omega \chi_{U_{h'}(\Gamma_n)} \text{ in } L^p(U_{h'}(\Gamma))\text{-weak} \tag{3.9}$$

and $\|D^2 b_\Omega\|_{L^p(U_{h'}(\Gamma))} \le c'$ *for some constant* c'.

Proof. (i) Since D is bounded, there exists $b_\Omega \in C_b^0(D)$ and a subsequence, still indexed by n, such that $b_{\Omega_n} \to b_\Omega$ in $C(\overline{U_h(D)})$. For convenience denote b_{Ω_n} and b_Ω by b_n and b. Hence for all p', $1 \le p' < \infty$, $b_n \rightharpoonup b$ in $W^{1,p'}(U_h(D))$-weak and $b_n^h \rightharpoonup b^h$ in $W_0^{1,p'}(\mathbf{R}^N)$-weak. By assumption from Theorem 3.5 (i), $b_n^h \in W_0^{2,p}(U_h(D))$ and

$$\Delta b_n^h = e_n^h \Delta b_n + \nabla e_n^h \cdot \nabla b_n = e_n^h \Delta b_n + (e_n^h)' \quad \Rightarrow \|\Delta b_n^h\|_{L^p(U_h(D))} \le c,$$

where $(e_n^h)' = 2\rho_h' \circ b_n + b_n\, \rho_h'' \circ b_n$. By equivalence of norms in $W_0^{2,p}(U_h(D))$, there exists another constant c' such that

$$\|D^2 b_{\Omega_n}^h\|_{L^p(U_h(D))} \le c' \quad \Rightarrow \forall h',\, 0 < h' < h, \quad \|D^2 b_{\Omega_n}\|_{L^p(U_{h'}(\Gamma_n))} \le c'.$$

From the last condition on the Hessian matrices, the assumptions of Theorem 9.2 [11, Chap. 5, p. 250] for sets of locally bounded curvature are satisfied and we get the compactness in the $W^{1,p}$-topology.

(ii) It remains to check condition (3.9). For all p, $1 \le p < \infty$, $b_{\Omega_n} \to b_\Omega$ in $W^{1,p}(U_h(D))$-strong and for each $\Phi \in \mathcal{D}^1(U_{h'}(\Gamma))^{N\times N}$,

$$\lim_{n\to\infty} \int_{U_{h'}(\Gamma)} \nabla b_{\Omega_n} \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx = \int_{U_{h'}(\Gamma)} \nabla b_\Omega \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx.$$

Each such Φ has compact support in $U_{h'}(\Gamma)$, and

$$\exists \varepsilon = \varepsilon(\Phi) > 0,\ 0 < 3\varepsilon < h, \text{ such that } \operatorname{supp}\Phi \subset U_{h'-2\varepsilon}(\Gamma).$$

Moreover, there exists $N(\varepsilon) > 0$ such that

$$\forall n \ge N(\varepsilon), \quad U_{h'-2\,\varepsilon}(\Gamma_n) \subset U_{h'-\varepsilon}(\Gamma) \subset U_{h'}(\Gamma_n)$$

(cf. part (i) of the proof of [11, Chap. 5, Thm. 9.2, pp. 251–252]. For $n \ge N(\varepsilon)$ consider the integral

$$\int_{U_{h'}(\Gamma)} \nabla b_{\Omega_n} \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx = \int_{U_{h'-2\varepsilon}(\Gamma)} \nabla b_{\Omega_n} \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx = \int_{U_{h'}(\Gamma_n)} \nabla b_{\Omega_n} \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx.$$

By assumption $D^2 b_{\Omega_n} \in L^p(U_{h'}(\Gamma))^{N\times N}$ and its norm is bounded by c'

$$\left| \int_{U_{h'}(\Gamma_n)} \nabla b_{\Omega_n} \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx \right| \le \|D^2 b_{\Omega_n}\|_{L^p(U_{h'}(\Gamma_n))} \|\Phi\|_{L^q(U_{h'}(\Gamma_n))} \le c\, \|\Phi\|_{L^q(U_{h'-2\varepsilon}(\Gamma))}$$

$$\Rightarrow \left| \int_{U_{h'}(\Gamma)} \nabla b_{\Omega_n} \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx \right| \le c\, \|\Phi\|_{L^q(U_{h'}(\Gamma))},$$

where $q^{-1} + p^{-1} = 1$. By convergence of ∇b_{Ω_n} to ∇b_Ω in the space $L^p(U_{h'}(D))^N$, then for all $\Phi \in \mathcal{D}^1(U_{h'}(\Gamma))^{N\times N}$

$$\left| \int_{U_{h'}(\Gamma)} \nabla b_\Omega \cdot \overrightarrow{\operatorname{div}}\, \Phi \, dx \right| \le c' \|\Phi\|_{L^q(U_{h'}(\Gamma))} \quad \Rightarrow \|D^2 b_\Omega\|_{L^p(U_{h'}(\Gamma))} \le c.$$

For $p > 1$ the weak L^p-convergence now follows by the same argument as in the proof of Theorem 3.5 (ii). This concludes the proof. ∎

[15] For $p = 1$ we get the convergence of $D^2 b_{\Omega_{n_k}}$ as a matrix of bounded measures.

4. Shape semiderivatives and application to b_Ω. In this section the elements of the velocity method and the notion of Eulerian semiderivative are briefly reviewed (cf., for instance, Chapter 8 of [11]) and applied to the computation of the semiderivative of $b_\Omega(x)$ which will be used in section 5.

4.1. Velocity method and shape semiderivative. In shape analysis the derivative of an objective function with respect to a set is obtained by generating perturbations of the set via a nonautonomous velocity field $V : [0,\tau] \times \mathbf{R}^N \to \mathbf{R}^N$, $0 < \tau < \infty$, verifying the conditions

$$\begin{aligned} &\forall x \in \mathbf{R}^N, \quad V(\cdot,x) \in C\big([0,\tau];\mathbf{R}^N\big), \\ &\exists c > 0,\ \forall x,y \in \mathbf{R}^N, \quad \|V(\cdot,y) - V(\cdot,x)\|_{C([0,\tau];\mathbf{R}^N)} \le c|y-x|, \end{aligned} \tag{4.1}$$

where $V(\cdot,x)$ is the function $t \mapsto V(t,x)$. The *parameter* t can be viewed as an artificial time. A point X is moved to the position $x(t) = x(t;X)$ via the differential equation

$$\frac{dx}{dt}(t) = V(t,x(t)), \quad 0 < t < \tau, \quad x(0) = X \in \mathbf{R}^N. \tag{4.2}$$

It will be convenient to define the velocity fields

$$x \mapsto V(t)(x) \overset{\text{def}}{=} V(t,x) : \mathbf{R}^N \to \mathbf{R}^N, \quad 0 \le t \le \tau. \tag{4.3}$$

This yields the families of transformations $\{T_t\}$ and perturbations $\{\Omega_t\}$

$$\forall t,\ 0 < t < \tau, \quad \left| \begin{aligned} &X \mapsto T_t(X) \overset{\text{def}}{=} x(t) = x(t;X) \\ &\forall \Omega \subset \mathbf{R}^N, \quad \Omega_t(V) \overset{\text{def}}{=} T_t(V)(\Omega). \end{aligned} \right. \tag{4.4}$$

THEOREM 4.1. *Given $\tau > 0$, assume that the map $V : [0,\tau] \times \mathbf{R}^N \to \mathbf{R}^N$ satisfy conditions* (4.1).

(i) *The transformation $T(t,x) = T_t(x)$ specified by* (4.2)–(4.4) *has the following properties:*

$$\begin{aligned} &\text{(T1)} && \forall X \in \mathbf{R}^N, \quad T(\cdot,X) \in C^1\big([0,\tau];\mathbf{R}^N\big) \text{ and } \exists c > 0, \\ &&& \forall X,Y \in \mathbf{R}^N, \quad \|T(\cdot,Y) - T(\cdot,X)\|_{C^1([0,\tau];\mathbf{R}^N)} \le c|Y-X|, \\ &\text{(T2)} && \forall t \in [0,\tau],\ X \mapsto T_t(X) : \mathbf{R}^N \to \mathbf{R}^N \text{ is bijective}, \\ &\text{(T3)} && \forall x \in \mathbf{R}^N, \quad T^{-1}(\cdot,x) \in C\big([0,\tau];\mathbf{R}^N\big) \text{ and } \exists c > 0, \\ &&& \forall x,y \in \mathbf{R}^N, \quad \|T^{-1}(\cdot,y) - T^{-1}(\cdot,x)\|_{C([0,\tau];\mathbf{R}^N)} \le c|y-x|, \end{aligned} \tag{4.5}$$

where $T^{-1}(t,y) = T_t^{-1}(y)$.

(ii) *Let Ω be a subset of $\mathbf{R}^N$. Then $\operatorname{int}\Omega_t = T_t(\operatorname{int}\Omega)$, $\Gamma_t = \Gamma_t = T_t(\Gamma)$, Γ_t is thin if and only if Γ is thin, $\overline{\Omega_t} = \Gamma_t$ if $\overline{\Omega} = \Gamma$, and Γ_t is of locally finite H_{N-1}-measure if and only if Γ is of locally finite H_{N-1}-measure.*

(iii) *If, in addition to conditions* (4.1),[16] *$V \in C([0,\tau];C^0(\overline{\mathbf{R}^N},\mathbf{R}^N))$, then for all bounded open subsets D of $\mathbf{R}^N$*

$$t \mapsto b_{\Omega_t} \text{ (resp., } b^2_{\Omega_t}) : [0,\tau] \to C(\overline{D}) \tag{4.6}$$

[16] $C^0(\overline{\mathbf{R}^N},\mathbf{R}^N)$ is the space of bounded uniformly continuous mappings from $\mathbf{R}^N$ to $\mathbf{R}^N$.

is continuous. If, in addition, Γ *is thin, then for all bounded open subsets* D *of* $\mathbf{R}^N$ *and all* p, $1 \le p < \infty$,

$$t \mapsto b_{\Omega_t} \text{ (resp., } b^2_{\Omega_t}) : [0,\tau] \to W^{1,p}(D) \tag{4.7}$$

is continuous.

(iv) *If* Ω *is of class* C^1 *and* $V \in C([0,\tau]; C^1(\overline{\mathbf{R}^N}, \mathbf{R}^N))$, *then* Ω_t *is of class* C^1 *for all* t *in a neighborhood of* $t = 0$. *If* Ω *is of class* $C^{1,1}$, $V \in C([0,\tau]; C^1(\overline{\mathbf{R}^N}, \mathbf{R}^N))$, *and there exists* $c > 0$ *such that for all* $t \in [0,\tau]$,

$$\forall x, y,\ |V(t,y) - V(t,x)| \le c|y-x| \text{ and } |DV(t,y) - DV(t,x)| \le c|y-x|,$$

then Ω_t *is of class* $C^{1,1}$ *for all* t *in a neighborhood of* $t = 0$.

Proof. (i) Cf. [11, Chap. 7, Thm. 4.1, p. 300]. (ii) From (T1)–(T2) the transformation T_t is bi-Lipschitzian. It transports interiors onto interiors, boundaries onto boundaries, and sets of zero measure onto sets of zero measure. Moreover, if $\overline{\Omega} = \Gamma$, then $\overline{\Omega_t} = T_t(\overline{\Omega}) = T_t(\Gamma) = \Gamma_t$.

(iii) Given $\varnothing \ne A \subset \mathbf{R}^N$, for any $t \in [0,\tau]$, $x \in \mathbf{R}^N$ and $y \in A$

$$|T_t(y) - x| \le |T_t(y) - y| + |y - x| \le \|T_t - I\|_{C(\mathbf{R}^N)} + |y - x|,$$
$$|y - x| \le |T_t(y) - y| + |T_t(y) - x| \le \|T_t - I\|_{C(\mathbf{R}^N)} + |T_t(y) - x|,$$

and by taking the infimum with respect to $y \in A$ on both sides

$$\left.\begin{array}{l} d_{T_t(A)}(x) \le \|T_t - I\|_{C(\mathbf{R}^N)} + d_A(x) \\ d_A(x) \le \|T_t - I\|_{C(\mathbf{R}^N)} + d_{T_t(A)}(x) \end{array}\right| \quad \Rightarrow \|d_{T_t(A)} - d_A\|_{C(\overline{D})} \le \|T_t - I\|_{C(\mathbf{R}^N)}.$$

Under conditions (4.1) and $V \in C([0,\tau]; C^0(\overline{\mathbf{R}^N}, \mathbf{R}^N))$, the map $f(t) = T_t - I$ belongs to $C^1([0,\tau]; C^0(\overline{\mathbf{R}^N}, \mathbf{R}^N)) \cap C^0([0,\tau]; C^{0,1}(\overline{\mathbf{R}^N}, \mathbf{R}^N))$ (cf. Theorem 4.3 in [11, p. 305]). Therefore $\|T_t - I\|_{C(\mathbf{R}^N)}$ goes to zero as t goes to 0 and we have the continuity. Of course the proof at $s = 0$ now extends to all $s \in [0,\tau]$. The continuity of b_{Ω_t} for $\Gamma \ne \varnothing$ now follows from the fact that $b_{\Omega_t} = d_{\Omega_t} - d_{\complement\Omega_t}$ and $\overline{T_t(\complement\Omega)} = \complement T_t(\Omega)$ for the homeomorphism T_t. By application of the result with A equal to Ω and $\complement\Omega$

$$\left.\begin{array}{l} d_{\Omega_t}(x) \le \|T_t - I\|_{C(\mathbf{R}^N)} + d_\Omega(x) \\ -d_{\complement\Omega_t}(x) \le \|T_t - I\|_{C(\mathbf{R}^N)} - d_{\complement\Omega}(x) \end{array}\right| \quad \Rightarrow b_{\Omega_t}(x) \le 2\|T_t - I\|_{C(\mathbf{R}^N)} + b_\Omega(x),$$

and we get the same inequalities by interchanging Ω_t and Ω. The continuity in $C(\overline{D})$ implies the continuity in $L^2(D)$ and since $|\nabla b_{\Omega_t}(x)|$ is a.e. bounded by 1, we get the weak continuity in $W^{1,2}(D)$. But we have seen in part (ii) that if $\mathrm{m}_N(\Gamma) = 0$, then $\mathrm{m}_N(\Gamma_t) = 0$. By Lemma 2.1 this implies the continuity in $W^{1,p}(D)$-strong for all finite $p \ge 1$.

(iv) By assumption on V, $t \mapsto T_t - I$ belong to $C([0,\tau]; C^1(\overline{\mathbf{R}^N}, \mathbf{R}^N))$ and $t \mapsto T_t^{-1} - I$ to $C([0,\tau']; C^1(\overline{\mathbf{R}^N}, \mathbf{R}^N))$ for some $0 < \tau' \le \tau$ (cf. [11, Thm. 4.5, p. 312]). Hence $\Omega_t = T_t(\Omega)$ is of class C^1 for a C^1-domain Ω and $t \in [0,\tau']$. Similarly the $C^{1,1}$ case follows from [11, Thm. 4.3, p. 305]. □

When the Ω's are subsets of a smooth open hold-all D, it is sufficient to work with velocity fields $V(t) : D \to \mathbf{R}^N$ such that $V(t) \cdot n_{\partial D} = 0$ on ∂D.

DEFINITION 4.1. *Given a* shape function $f(\Omega)$ *defined on the subsets* Ω *of* $\mathbf{R}^N$ *or* D, *we say that* f *has a* Eulerian semiderivative *at* Ω *in the direction* V *if the following limit exists*

$$df(\Omega; V) \stackrel{\text{def}}{=} \lim_{t \searrow 0} \frac{f(\Omega_t(V)) - f(\Omega))}{t}.$$

4.2. Partial derivative of b_Ω. In this section we compute the partial derivative of b_Ω which will be used, in the next subsection, to construct a new evolution equation for b_{Ω_t} when Ω has a thin boundary. First, introduce the notation

$$b'_\Omega(x) \overset{\text{def}}{=} \frac{\partial}{\partial t} b_{\Omega_t}(x)\bigg|_{t=0^+} \text{ and } (b^2_\Omega)' \overset{\text{def}}{=} \frac{\partial}{\partial t} b^2_{\Omega_t}(x)\bigg|_{t=0^+}.$$

THEOREM 4.2. *Let $\tau > 0$ and $V : [0,\tau] \times \mathbf{R}^N \to \mathbf{R}^N$ satisfying conditions (4.1) be given.*

(i) *Let Ω be a subset of $\mathbf{R}^N$ such that $\Gamma \neq \varnothing$. Then*

$$\begin{aligned} (b^2_\Omega)' &= -\nabla b^2_\Omega \cdot (V(0) \circ p_\Gamma) \text{ in } \mathbf{R}^N \setminus \mathrm{Sk}(\Omega), \\ b'_\Omega &= -\nabla b_\Omega \cdot (V(0) \circ p_\Gamma) \text{ in } \mathbf{R}^N \setminus (\Gamma \cup \mathrm{Sk}(\Omega)), \end{aligned} \tag{4.8}$$

and those identities are, respectively, verified a.e. in $\mathbf{R}^N$ and $\mathbf{R}^N \setminus \Gamma$. If, in addition, Γ has positive reach greater or equal to h, the above identities are, respectively, verified in $U_h(\Gamma)$ and $U_h(\Gamma) \setminus \Gamma$.

(ii) *Let Ω be a subset of $\mathbf{R}^N$ such that $\Gamma \neq \varnothing$ and $\mathrm{m}_N(\Gamma) = 0$. Then*

$$b'_\Omega = -\nabla b_\Omega \cdot (V(0) \circ p_\Gamma) \text{ a.e. in } \mathbf{R}^N. \tag{4.9}$$

If, in addition, $V \in C([0,\tau]; C^0(\overline{\mathbf{R}^N}, \mathbf{R}^N))$, for all bounded open subset D of $\mathbf{R}^N$, $b'_\Omega \in L^\infty(D)$ and

$$\forall \phi \in \mathcal{D}(\mathbf{R}^N), \quad \frac{d}{dt} \int_{\mathbf{R}^N} b_{\Omega_t} \phi \, dx\bigg|_{t=0^+} = \int_{\mathbf{R}^N} b'_\Omega \phi \, dx. \tag{4.10}$$

Remark 4.1. This theorem extends the earlier result of [15] and [16, Lem. 3.3, p. 248] from domains Ω of class C^2 to *arbitrary sets* with a thin boundary.

Proof. (i) First, compute the partial derivative of $b^2_{\Omega_t}(x)$,

$$\frac{\partial}{\partial t} b^2_{\Omega_t}(x)\bigg|_{t=0} = \frac{\partial}{\partial t} d^2_{\Gamma_t}(x)\bigg|_{t=0}, \quad d^2_{\Gamma_t}(x) = \min_{p_t \in \Gamma_t} |p_t - x|^2 = \min_{p \in \Gamma} |T_t(p) - x|^2.$$

Using the theorem on the derivative through a minimum (cf. [11, Chap. 9, Sect. 2.3, and Thm. 3.1, p. 164]) we get

$$\frac{\partial}{\partial t} d^2_{\Gamma_t}(x)\bigg|_{t=0} = \min_{p \in \Pi_\Gamma(x)} 2\,(p - x) \cdot \frac{\partial}{\partial t} T_t(p)\bigg|_{t=0} = \min_{p \in \Pi_\Gamma(x)} 2\,(p - x) \cdot V(0, p).$$

For $x \notin \mathrm{Sk}(\Omega)$ the semiderivative is linear with respect to $V(0)$ and the projection $p(x)$ of x onto Γ is unique and given by (2.9). Hence

$$\frac{\partial}{\partial t} b^2_{\Omega_t}(x)\bigg|_{t=0} = 2\,(p(x) - x) \cdot V(0, p(x)) = -\nabla b^2_\Omega(x) \cdot V(0, p(x)).$$

As for the second identity, for all $x \notin \Gamma \cup \mathrm{Sk}(\Omega)$, $b_\Omega(x) \neq 0$ and

$$\begin{aligned} \frac{\partial}{\partial t} b^2_{\Omega_t}(x)\bigg|_{t=0} &= 2\, b_{\Omega_t}(x)\, \frac{\partial}{\partial t} b_{\Omega_t}(x)\bigg|_{t=0} = 2\, b_\Omega(x)\, b'(x) \\ \Rightarrow\ b'(x) = \frac{\partial}{\partial t} b_{\Omega_t}(x)\bigg|_{t=0} &= \frac{1}{2 b_\Omega(x)}\, \frac{\partial}{\partial t} b^2_{\Omega_t}(x)\bigg|_{t=0} \ \Rightarrow\ b' = -\nabla b_\Omega \cdot (V(0) \circ p). \end{aligned}$$

Finally, since $\mathrm{Sk}(\Omega)$ has zero measure, the identities (4.8) are verified a.e. in $\mathbf{R}^{\mathrm{N}}$ and $\mathbf{R}^{\mathrm{N}}\setminus\Gamma$. If Γ has positive reach greater or equal to h, $U_h(\Gamma)\cap\mathrm{Sk}(\Omega)=\varnothing$ and (4.8) are verified everywhere in $U_h(\Gamma)$ and $U_h(\Gamma)\setminus\Gamma$.

(ii) From part (i) since $\mathrm{m}_N(\mathrm{Sk}(\Omega)\cup\Gamma)=0$. The a.e. derivative b'_Ω is in fact the $L^1(D)$-limit for all bounded open D of the differential quotients

$$\delta_t b(x) \stackrel{\text{def}}{=} \frac{b_{\Omega_t}(x)-b_\Omega(x)}{t}$$

as t goes to zero by Lebesgue dominated convergence theorem. First, the right-hand side of (4.9) is measurable as the inner product of $\nabla b_\Omega\in L^\infty(D)^N$ and $V(0)\circ p_\Gamma$ which is the composition of the Lipschitz continuous mapping $V(0)$ and the projection p_Γ which is itself the gradient of the continuous convex function $f(x)=(|x|^2-b_\Omega^2(x))/2$. Therefore f is uniformly Lipschizian on D, $p_\Gamma\in L^\infty(D)^N$, and $b'_\Omega\in L^\infty(D)$. We have already shown in part (i) that for a set with thin boundary $\delta_t b(x)\to b'_\Omega(x)$ for almost all x. As for the dominance, from Theorem 4.1 (iii)

$$|\delta_t b(x)| = \left|\frac{b_{\Omega_t}(x)-b_\Omega(x)}{t}\right| \le \left\|\frac{T_t-I}{t}\right\|_{C(\mathbf{R}^{\mathrm{N}})}.$$

Under conditions (4.1) and $V\in C([0,\tau];C^0(\overline{\mathbf{R}^{\mathrm{N}}},\mathbf{R}^{\mathrm{N}}))$, the map $f(t)=T_t-I$ belongs to $C^1([0,\tau];C^0(\overline{\mathbf{R}^{\mathrm{N}}},\mathbf{R}^{\mathrm{N}}))\cap C^0([0,\tau];C^{0,1}(\overline{\mathbf{R}^{\mathrm{N}}},\mathbf{R}^{\mathrm{N}}))$ (cf. Theorem 4.3 in [11, p. 305]). Therefore $(T_t-I)/t\to f'(0)$ in $C^0(\overline{\mathbf{R}^{\mathrm{N}}},\mathbf{R}^{\mathrm{N}})$ and the conditions of the Lebesgue dominated convergence theorem are satisfied. In particular, this establishes the property (4.10). □

5. Evolution equations for b_{Ω_t} and p_{Γ_t}. In this section we construct the new nonlinear evolution equation (5.2) of the oriented distance function b_{Ω_t} as a function of t for sets Ω with a thin boundary, along with a nonlinear evolution equation for the projection p_{Γ_t}. It applies not only to the evolution of open domains with thin boundaries, but also to arbitrary sets of zero N-dimensional Lebesgue measure such as a cloud of points, curves, objects of arbitrary codimension larger or equal to one, or a mixture of such objects. Equation (5.2) is to be compared with the weak evolution equation of the characteristic function χ_{Ω_t}: for any $\varphi\in\mathcal{D}(\mathbf{R}^{\mathrm{N}})$,

$$-\frac{d}{dt}\int_{\mathbf{R}^{\mathrm{N}}}\chi_{\Omega_t}\,\varphi\,dx+\int_{\mathbf{R}^{\mathrm{N}}}\chi_{\Omega_t}\,\mathrm{div}(V(t)\,\varphi)\,dx=0,\quad \chi_{\Omega_0}=\chi_\Omega. \tag{5.1}$$

This last equation is useless for sets with zero N-dimensional measure since their characteristic function is zero a.e. In what follows, it will be useful to introduce the notation $b'_{\Omega_t}(x)=\partial b_{\Omega_t}/\partial t(x)$.

THEOREM 5.1. *Let $\tau>0$ and $V:[0,\tau]\times\mathbf{R}^{\mathrm{N}}\to\mathbf{R}^{\mathrm{N}}$ be a map which satisfies the conditions* (4.1) *and, in addition, such that $V\in C([0,\tau];C^0(\overline{\mathbf{R}^{\mathrm{N}}},\mathbf{R}^{\mathrm{N}}))$. Assume that Ω is a subset of $\mathbf{R}^{\mathrm{N}}$ with nonempty thin boundary Γ.*

(i) *For all bounded open subsets D of $\mathbf{R}^{\mathrm{N}}$ and all finite $r\ge 1$, the function $t\mapsto b_{\Omega_t}$ belongs to $C^1([0,\tau];L^r(D))\cap C^0([0,\tau];W^{1,r}(D))$ and it satisfies*

$$\begin{aligned}&\frac{\partial}{\partial t}b_{\Omega_t}+\nabla b_{\Omega_t}\cdot(V(t)\circ p_{\Gamma_t})=0\ \forall t,\ 0\le t\le\tau,\ \text{and a.e. in }\ \mathbf{R}^{\mathrm{N}},\\ &b_{\Omega_0}=b_\Omega,\end{aligned} \tag{5.2}$$

where p_{Γ_t} is the projection onto Γ_t,

$$p_{\Gamma_t}(x)=x-\frac{1}{2}\nabla b^2_{\Omega_t}(x)\ \text{a.e. in }\ \mathbf{R}^{\mathrm{N}}. \tag{5.3}$$

(ii) *For all bounded open subsets D of $\mathbf{R}^N$ and all finite $r \geq 1$, the function $t \mapsto p_{\Gamma_t} : [0,\tau] \to L^r(D)^N$ is continuous and solution of*

$$\begin{aligned} &\frac{d}{dt}\int_{\mathbf{R}^N} p_{\Gamma_t}\cdot\vec{\phi}\,dx + \int_{\mathbf{R}^N}(p_{\Gamma_t}-I)\cdot(V(t)\circ p_{\Gamma_t})\ \mathrm{div}\,\vec{\phi}\,dx = 0, \\ &p_{\Gamma_0} = p_\Gamma \end{aligned} \tag{5.4}$$

for all $\vec{\phi} \in \mathcal{D}(\mathbf{R}^N)^N$ and $t \in [0,\tau]$.

Example 5.1. Let $\Omega = \{X\}$. Clearly $\Omega_t = \{x(t)\}$, where $x(t)$ is the solution of the differential equation $dx(t)/dt = V(t,x(t))$, $x(0) = X$. For all $x \in \mathbf{R}^N$, $p_{\Gamma_t}(x) = x(t)$ is a vector which only depends on t. Hence $V(t, p_{\Gamma_t}(x)) = V(t,x(t))$ is also a vector which only depends on t, and (5.4) reduces to

$$\frac{\partial}{\partial t}p_{\Gamma_t} = V(t)\circ p_{\Gamma_t} \text{ in } \mathbf{R}^N, \quad p_{\Gamma_0} = p_\Gamma.$$

Moreover, $b_{\Omega_t}(x) = |x - x(t)|$, and

$$\frac{\partial}{\partial t}|x-x(t)| + V(t,x(t))\cdot\frac{x-x(t)}{|x-x(t)|} = 0, \quad b_\Omega(x) = |x-X|.$$

For each t the equation is verified everywhere in $\mathbf{R}^N$ except on Γ_t.

Remark 5.1. To our best knowledge, the nonlinear equations (5.2) for b_{Ω_t} and (5.4) for the projection p_{Γ_t}, and the specification of their spaces of solution are new for initial sets with thin boundary. Once the velocity field has been specified it can describe the evolution of submanifolds in $\mathbf{R}^N$ in the spirit of the project of De Giorgi as referred to in [2]. In this paper the existence of solution for all $t \in [0,\tau]$ has been established in a constructive way by studying directly the properties of b_{Ω_t} and p_{Γ_t} and showing that they satisfy the equations. Upon substitution of expression (5.3) for p_{Γ_t}, (5.2) can be viewed as a form of Hamilton–Jacobi equation, but it is not the classical one for motion driven by curvatures since the velocity $V(t)$ on Γ_t is not constrained to be carried by the normal to Γ_t and that normal is not even assumed to exist on Γ_t as illustrated in Example 5.1. Note that the evolution equation for $b^2_{\Omega_t} = d^2_{\Gamma_t}$ is given by

$$\begin{aligned} &\frac{\partial}{\partial t}b^2_{\Omega_t} + \nabla b^2_{\Omega_t}\cdot\left(V(t)\circ\left[I - \frac{1}{2}\nabla b^2_{\Omega_t}\right]\right) = 0\ \forall t,\ 0\leq t\leq\tau,\ \text{a.e. in } \mathbf{R}^N, \\ &b^2_{\Omega_0} = b^2_\Omega. \end{aligned} \tag{5.5}$$

It only involves first order derivatives.

Remark 5.2. The solution of (5.4) determines p_{Γ_t}. Alternatively the level sets Γ_t can be constructively determined, from Γ by solving the equation

$$\frac{dx}{dt}(t) = V(t,x(t)), \quad x(0) = X \in \Gamma.$$

From the knowledge of Γ_t the projections p_{Γ_t} can be determined in a constructive manner a.e. in $\mathbf{R}^N$ and for all $t \in [0,\tau]$. Once p_{Γ_t} is determined, the velocity field $\tilde{V}(t) = V(t)\circ p_{\Gamma_t}$ is completely specified and (5.2) becomes a linear equation in b_{Ω_t}. If Γ and the Γ_t's have positive reach, the projection p_{Γ_t} and a fortiori $\tilde{V}(t)$ are Lipschitzian mappings from $\mathbf{R}^N$ to $\mathbf{R}^N$. Hence we can associate with the solution of the equation

$$\frac{dx}{dt} = \tilde{V}(t,x(t)), \quad x(0) = X,$$

the transformation $\tilde{T}_t$ of $\mathbf{R}^N$, and it is easy to verify by classical arguments that the solution of (5.2) is $b_{\Omega_t} = b_\Omega \circ \tilde{T}_t^{-1}$. Potential extensions of (5.2)–(5.4) to more general velocity fields would probably require techniques from set-valued differential equations and mutational analysis [4, 5].

Remark 5.3. Equation (5.2) describes the evolution of the zero-level sets, $\Gamma_t = \{x \in \mathbf{R}^N : b_{\Omega_t}(x) = 0\}$, of the function $(t,x) \mapsto \phi(t,x) = b_{\Omega_t}(x(t)) : [0,\tau] \times \mathbf{R}^N \to \mathbf{R}^N$ since for all $x(t) \in \Gamma_t$ we have $\phi(t,x(t)) = b_{\Omega_t}(x(t)) = 0$. But the displacement of the points of $\mathbf{R}^N$ is governed by the equation

$$\frac{dx}{dt}(t) = V(t,x(t)), \quad x(0) = X,$$

for some velocity field $V(t)$, and we formally get

$$\begin{aligned} &\frac{\partial \phi}{\partial t}(t,x(t)) + \nabla\phi(t,x(t)) \cdot V(t,x(t)) = 0 \\ &\Rightarrow \frac{\partial \phi}{\partial t}(t) + \nabla\phi(t) \cdot V(t) = 0 \text{ on } \Gamma_t. \end{aligned} \tag{5.6}$$

It would be tempting to say that for each t the above equation is verified not only on Γ_t but in all of $\mathbf{R}^N$. Yet (5.2) says that outside of Γ_t the velocity $V(t)$ has to be modified to the velocity $V(t) \circ p_{\Gamma_t}$. Furthermore, for smooth embedded submanifolds Ω of codimension strictly greater than one, ∇b_{Ω_t} does not exist on Γ_t and, a fortiori, (5.6) has no meaning. So it is really fascinating that, at each t, b_{Ω_t} be effectively determined by (5.2) *outside* of Γ_t.

Remark 5.4. In the context of the *level set method* which corresponds to a velocity constrained to be carried by the normal ∇b_{Ω_t} to the front Γ_t with a scalar speed $F(t)$ which is a function of the curvatures, the concept of *extension velocities* was formalized by Adalsteinsson and Sethian [1] in 1999 to "serve several purposes: (1) to provide a way of building velocities for neighboring level sets in the case where the velocity is defined only on the front itself; (2) to provide a sub-grid resolution in some cases not present in the standard level set approach; (3) to provide a way to update an interface according to a given velocity field prescribed on the front in such a way that the signed distance function is maintained and the front is never re-initialized." Among all the choices of extension velocities, the one constructed by Malladi, Sethian, and Vemuri [30] in 1995 corresponds to our velocity $\tilde{V}(t) = V(t) \circ p_{\Gamma_t}$. Quoting from [1]: "In cases where there is no available choice for an extension velocity, one approach is to simply extrapolate; standing at each grid point, the value of the speed function at the closest point on the front is used as the extension velocity at that point. This is the approach used in [30]." The same construction involving p_{Γ_t} was obtained by Gomes and Faugeras [21] in 2000 with several numerical implementations. Theorem 5.1 establishes, in the context of an unconstrained velocity and by completely independent arguments, that this is indeed the *right theoretical choice*. It is also interesting to observe that when all the functions involved are smooth the Jacobian matrix $D\tilde{V}(t)$ verifies the condition

$$\begin{aligned} D\tilde{V}(t)\,\nabla b_{\Omega_t} &= D\left(V(t) \circ p_{\Gamma_t}\right) \nabla b_{\Omega_t} = DV(t) \circ p_{\Gamma_t} Dp_{\Gamma_t} \nabla b_{\Omega_t} \\ &= DV(t) \circ p_{\Gamma_t} [I - \nabla b_{\Omega_t}\, {}^*\nabla b_{\Omega_t} - b_{\Omega_t} D^2 b_{\Omega_t}] \nabla b_{\Omega_t} \\ &= DV(t) \circ p_{\Gamma_t} [\nabla b_{\Omega_t} - \nabla b_{\Omega_t} - b_{\Omega_t} D^2 b_{\Omega_t} \nabla b_{\Omega_t}] = 0 \end{aligned}$$

since $|\nabla b_{\Omega_t}|^2 = 1$ and $D^2 b_{\Omega_t} \nabla b_{\Omega_t} = 0$. This is the generalization of the equation $\nabla F_{ext} \cdot \nabla\phi = 0$ given in [1, 21] for the scalar speed F, $V = F\nabla\phi/|\nabla\phi|$, to build an extension velocity from an extension F_{ext} of the scalar speed F.

Remark 5.5. Another interesting observation is that the zero-extension $b^h_{\Omega_t} = \rho_h \circ b_{\Omega_t}\, b_{\Omega_t}$ introduced in Definition 3.3 satisfies the evolution equation (5.2),

$$\begin{aligned} &\frac{\partial}{\partial t} b^h_{\Omega_t} + \nabla b^h_{\Omega_t} \cdot (V(t) \circ p_{\Gamma_t}) = 0 \ \forall t,\ 0 \le t \le \tau, \text{ and a.e. in } \mathbf{R}^{\mathrm{N}}, \\ &b^h_{\Omega_0} = b^h_{\Omega}, \end{aligned} \tag{5.7}$$

since $\partial b^h_{\Omega_t}/\partial t = e^h_{\Omega_t} \partial b_{\Omega_t}/\partial t$ and $\nabla b^h_{\Omega_t} = e^h_{\Omega_t} \nabla b_{\Omega_t}$. As the choice of the thickness h and the function ρ^h is independent of Ω and t, this suggests a new type of *narrow-band* method in the level set context where the band $U_h(\Gamma_t)$ naturally evolves with time as the support of $b^h_{\Omega_t}$. By construction, $b^h_{\Omega_t}$ coincides with b_{Ω_t} on the smaller tubular neighborhood $U_{h'}(\Gamma_t) \subset U_h(\Gamma_t)$, $0 < h' < h$. The other part of the solution can be thrown away.

Proof. (i) Equation (5.2) at time t is obtained by the same arguments as the one at $t = 0$ since Γ_t is thin for each t. Note that, in view of the linearity of the expression with respect to V, we get a derivative for all t in $]0.\tau[$ and not just a derivative from the right. Under the additional assumption that $V \in C([0,\tau]; C^0(\overline{\mathbf{R}^{\mathrm{N}}}, \mathbf{R}^{\mathrm{N}}))$, from Theorem 4.1 (iii), b_{Ω_t} is continuous in $W^{1,p}(D)$-strong which means that $t \mapsto \nabla b_{\Omega_t}$ is continuous in $L^p(D)^N$-strong. Moreover,

$$\begin{aligned} &\|V(t) \circ p_{\Gamma_t} - V(0) \circ p_{\Gamma}\|_{L^q(D)} \\ &\le \|(V(t) - V(0)) \circ p_{\Gamma_t}\|_{L^q(D)} + \|V(0) \circ p_{\Gamma_t} - V(0) \circ p_{\Gamma}\|_{L^q(D)} \\ &\le \|(V(t) - V(0))\|_{C(\overline{D})}\, \mathrm{m}_N(D)^{1/q} + c\|p_{\Gamma_t} - p_{\Gamma}\|_{L^q(D)} \\ &\le \|(V(t) - V(0))\|_{C(\overline{D})}\, \mathrm{m}_N(D)^{1/q} + c/2\|\nabla b^2_{\Omega_t} - \nabla b^2_{\Omega}\|_{L^q(D)}. \end{aligned}$$

But the assumption $V \in C([0,\tau]; C^0(\overline{\mathbf{R}^{\mathrm{N}}}, \mathbf{R}^{\mathrm{N}}))$ implies that $\|(V(t) - V(0))\|_{C(\overline{D})}$ goes to zero as t goes to zero and from the continuity of $t \mapsto \nabla b_{\Omega_t}$ we get the continuity of $t \mapsto \nabla b^2_{\Omega_t}$ for $1 \le q < \infty$. Finally since $b'_{\Omega_t} = -\nabla b_{\Omega_t} \cdot (V(t) \circ p_{\Gamma_t})$ we get the continuity of b'_{Ω_t} in $L^r(D)$ for $r \ge 1$ by choosing $p = q = 2r$ in the previous estimates. In view of those properties, (5.2) becomes an equation with values in $L^r_{\mathrm{loc}}(\mathbf{R}^{\mathrm{N}})$ and the solution $t \mapsto b_{\Omega_t}$ belongs to $C^1([0,\tau]; L^r(D)) \cap C^0([0,\tau]; W^{1,p}(D))$ for all bounded open subset D of $\mathbf{R}^{\mathrm{N}}$.

(ii) (5.4) is obtained by similar arguments and the previous properties of $b^2_{\Omega_t}$. ∎

Acknowledgments. The authors would like to thank one of the referees for constructive comments which led to a significant revision and expansion of section 5 and Anne Bourlioux from the Université de Montréal for pointing out the references [30, 1] to extension velocities.
