In the following, we shall occasionally use the term n*-braid* to indicate the number of curves in the braid. The set of all braids joining $\mathbf{a}$ to $\mathbf{b}$ is denoted by $\mathbf{B}(\mathbf{a}, \mathbf{b})$. If i and j are required to be identical in the first condition of Definition 2.2, the corresponding braid is called a *pure braid*. The set of all pure braids joining $\mathbf{a}$ to $\mathbf{b}$ is denoted by $\mathbf{PB}(\mathbf{a}, \mathbf{b})$. An example of a pure 3-braid is shown in the right-hand side of Figure 2.1.

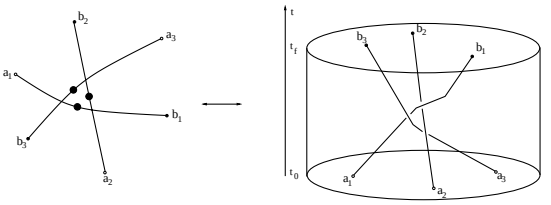

FIG. 2.1. *A 3-maneuver in* $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ *and its braid representation.*

There is a simple equivalence relation defined on $\mathbf{B}(\mathbf{a}, \mathbf{b})$ and hence on $\mathbf{PB}(\mathbf{a}, \mathbf{b})$ as well [32].

DEFINITION 2.3 (string isotopy). *Two braids in* $\mathbf{B}(\mathbf{a}, \mathbf{b})$ *are said to be* string isotopic *if the n curves of one of them can be continuously deformed to those of the other such that the n curves in* $\mathbb{R}^2 \times T$ *obtained throughout the deformation satisfy all the conditions in Definition* 2.2.

The reason for introducing the notion of braids is that there exists a very natural one-to-one correspondence between joint maneuvers in $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ and pure braids in $\mathbf{PB}(\mathbf{a}, \mathbf{b})$. To see this, for each joint maneuver $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbf{P}(0, \mathbf{a}, \mathbf{b})$, let $\hat{\alpha}_i$ be the curve in $\mathbb{R}^2 \times T$ joining (a_i, t_0) to (b_i, t_f) defined as the image of the map $t \mapsto (\alpha_i(t), t)$, $t \in T$. Then, it is clear from the definition of $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ that the n-tuple $\langle \hat{\alpha}_i \rangle_{i=1}^n$ of curves is indeed a pure braid in $\mathbf{PB}(\mathbf{a}, \mathbf{b})$, which we shall denote by $\hat{\alpha}$. (See Figure 2.1 for a 3-maneuver in $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ and its braid representation.) The map $\alpha \mapsto \hat{\alpha}$ can be verified to be a bijection between $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ and $\mathbf{PB}(\mathbf{a}, \mathbf{b})$. Furthermore, the following result is an immediate consequence of the above definitions.

PROPOSITION 2.4 (equivalence of 0-homotopy and string isotopy). *α and $\beta \in \mathbf{P}(0, \mathbf{a}, \mathbf{b})$ are 0-homotopic if and only if $\hat{\alpha}$ and $\hat{\beta}$ are string isotopic in $\mathbf{PB}(\mathbf{a}, \mathbf{b})$.*

As a result of Proposition 2.4, there is a one-to-one correspondence between the 0-homotopy classes of $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ and the (string) isotopy classes of $\mathbf{PB}(\mathbf{a}, \mathbf{b})$.

We next show that the isotopy classes of braids with identical starting and ending points, say $\mathbf{B}(\mathbf{a}, \mathbf{a})$, form a group under a suitable product operation. For each $\hat{\alpha} \in \mathbf{B}(\mathbf{a}, \mathbf{b})$ and $\hat{\beta} \in \mathbf{B}(\mathbf{b}, \mathbf{c})$, define the product $\hat{\gamma} \triangleq \hat{\alpha} \cdot \hat{\beta}$ as the braid $\hat{\gamma} \in \mathbf{B}(\mathbf{a}, \mathbf{c})$ obtained by first concatenating the n curves of $\hat{\alpha}$ with those of $\hat{\beta}$ and then renormalizing the t axis linearly such that the resultant n curves connect $\langle (a_i, t_0) \rangle_{i=1}^n$ to $\langle (c_i, t_f) \rangle_{i=1}^n$ via $\langle (b_i, \frac{t_0 + t_f}{2}) \rangle_{i=1}^n$. Note that the ending points of $\hat{\alpha}$ and the starting points of $\hat{\beta}$ have to coincide for the product to be well defined. It can be easily checked that this product operation preserves string isotopy, i.e., if $\hat{\alpha}'$ is string isotopic to $\hat{\alpha}$ in $\mathbf{B}(\mathbf{a}, \mathbf{b})$ and $\hat{\beta}'$ is string isotopic to $\hat{\beta}$ in $\mathbf{B}(\mathbf{b}, \mathbf{c})$, then $\hat{\alpha}' \cdot \hat{\beta}'$ is string isotopic to $\hat{\alpha} \cdot \hat{\beta}$ in $\mathbf{B}(\mathbf{a}, \mathbf{c})$. Therefore, it induces a product operation on the isotopy classes of braids. This induced product operation makes the isotopy classes of $\mathbf{B}(\mathbf{a}, \mathbf{a})$ into a group, with the inverse operation being the reflection of the n curves across the plane $t = \frac{t_0 + t_f}{2}$. We denote this group by $\mathbf{B}_n$. Similarly the isotopy classes of pure braids $\mathbf{PB}(\mathbf{a}, \mathbf{a})$ form under the same induced product operation a group, which we denote by $\mathbf{PB}_n$. $\mathbf{PB}_n$ is a normal subgroup of $\mathbf{B}_n$. Readers are referred to [12] or [32] for a detailed derivation of the above claims.

Now if we fix a braid $\hat{\beta}$ in $\mathbf{PB}(\mathbf{b}, \mathbf{a})$, then $\hat{\alpha} \mapsto \hat{\alpha} \cdot \hat{\beta}$ defines a map from $\mathbf{PB}(\mathbf{a}, \mathbf{b})$ to $\mathbf{PB}(\mathbf{a}, \mathbf{a})$. Since this map preserves string isotopy, it induces a map from the isotopy classes of $\mathbf{PB}(\mathbf{a}, \mathbf{b})$ to the isotopy classes of $\mathbf{PB}(\mathbf{a}, \mathbf{a})$, i.e., $\mathbf{PB}_n$. The induced map is easily verified to be a bijection. This fact combined with the result in Proposition 2.4

FIG. 2.2. 2-*agent encounter. Left: Maneuver* 1. *Right: Maneuver* 2.

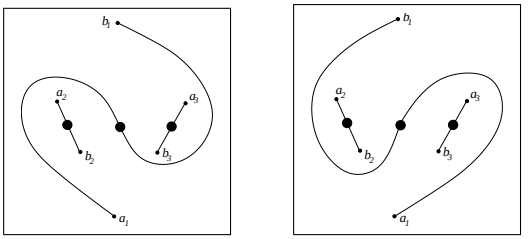

FIG. 2.3. *Two* 3-*maneuvers with the same turning angle but belonging to different types.*

implies that there exists a bijection between the 0-homotopy classes of $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ and the elements of $\mathbf{PB}_n$.

The above conclusions remain valid for the case of an arbitrary $R > 0$. Hence, the following theorem.

THEOREM 2.5 (classification of conflict-free n-maneuvers). *The R-homotopy classes of conflict-free maneuvers in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ have a one-to-one correspondence with the elements of the group of pure n-braids $\mathbf{PB}_n$.*

In Remark 1 of section 3, we give an alternative interpretation of the above result. For a discussion on the use of braid groups to classify motions on a graph, see [1].

The group $\mathbf{PB}_n$ is described by a set of generators together with a set of relations defined on them [32, 33]. Therefore, Theorem 2.5 completely characterizes the structure of the homotopy types of conflict-free maneuvers for n-agent encounters. On the other hand, the characterization is unsatisfactory in practical terms since the description of $\mathbf{PB}_n$ is very complicated. However, when n is small, the result in Theorem 2.5 may have simple interpretations. Consider, for example, the 2-agent encounter shown in Figure 2.2. Theorem 2.5 says that each maneuver in $\mathbf{P}(0, \mathbf{a}, \mathbf{b})$ is 0-homotopic to maneuver 1, or maneuver 2, or one of the following two maneuvers:

- Maneuver 1 followed by the motions where agent 2 stays at b_2 and agent 1 starts from b_1, circles around agent 2 counterclockwise k times for some integer $k \geq 1$, and returns to b_1.
- Maneuver 2 followed by the motions where agent 2 stays at b_2 and agent 1 starts from b_1, circles around agent 2 clockwise k times for some integer $k \geq 1$, and returns to b_1.

The angle that one agent turns with respect to the other during T plays a decisive role in determining the homotopy type of the conflict-free 2-maneuvers. Maneuver 1 and maneuver 2 are representatives of the only two types for which the absolute values of this angle do not exceed 360°. We shall call such types *fundamental*. Then there are exactly two fundamental types for any 2-agent encounter.

It is tempting to extend this definition to the n-agent case and conclude that there are exactly $2^{\frac{n(n-1)}{2}}$ fundamental types of conflict-free maneuvers, since there are two fundamental types for each of the $\frac{n(n-1)}{2}$ agent pairs. Unfortunately this is not the case. Shown in Figure 2.3 are the plots of two conflict-free maneuvers for a 3-agent

encounter that have the same turning angle within the range $(-360°, 360°)$ between any pair of agents, but in fact belong to different types.

3. Optimal conflict-free maneuvers. In this section, the problem of finding "optimal" conflict-free maneuvers for multi-agent encounters is formulated and studied. To ensure that the problem is well defined and admits a solution, we modify some of the notation introduced in the previous section. In particular, the set of maneuvers for agent i, $\mathbf{P}_i$, is redefined to be the set of all continuous *and piecewise* C^2 maps[1] from T to $\mathbb{R}^2$ that take the values a_i and b_i at times t_0 and t_f, respectively. The set of joint maneuvers $\mathbf{P}(\mathbf{a}, \mathbf{b})$ and the MSE $\Delta(\alpha)$, $\alpha \in \mathbf{P}(\mathbf{a}, \mathbf{b})$, are defined in section 2, whereas $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is redefined to be the set of all joint maneuvers with an MSE greater than *or equal to* R. Note that the results in section 2 on the qualitative classification of conflict-free maneuvers still hold for the newly defined $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ by the compactness of T.

3.1. Statement of the problem. Consider a maneuver of a single agent, say $\alpha_i \in \mathbf{P}_i$, $i \in \{1, \ldots, n\}$. The *energy* of α_i is defined as

$$J(\alpha_i) = \frac{1}{2} \int_{t_0}^{t_f} ||\dot{\alpha}_i(t)||^2 dt. \tag{3.1}$$

Let $L(\alpha_i)$ be the arc length of the curve α_i, i.e., $L(\alpha_i) = \int_{t_0}^{t_f} ||\dot{\alpha}_i(t)|| dt$. Then the application of the Cauchy–Schwarz inequality to (3.1) yields [31]

$$J(\alpha_i) \geq \frac{1}{2} \frac{L(\alpha_i)^2}{(t_f - t_0)}, \tag{3.2}$$

where the equality holds if and only if $\|\dot{\alpha}_i(t)\|$ is constant. This implies that if agent i is forced to move along some fixed curve and if we ignore the presence of other agents temporarily, then of all the different parameterizations, the one with a constant speed has the minimal energy, and the minimal energy is proportional to the square of the curve length. Therefore, in the presence of *static* obstacles, the maneuver of agent i with the least energy between two points is the shortest curve between them parameterized proportionally to the arc length. In particular, if there are no obstacles, the energy-minimizing maneuver of agent i is the constant speed motion along the line segment from a_i to b_i. It follows from this discussion that the energy-minimizing maneuvers tend to be straighter and smoother, which has practical implications, for example, in terms of passenger comfort, brake erosion, fuel consumption, etc.

The *μ-energy* of a joint maneuver $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbf{P}(\mathbf{a}, \mathbf{b})$ is defined as

$$J_\mu(\alpha) \triangleq \sum_{i=1}^{n} \mu_i J(\alpha_i), \tag{3.3}$$

where $\mu_1, \ldots, \mu_n$ are n positive numbers adding up to 1 (i.e., $\sum_{i=1}^{n} \mu_i = 1$) representing the priorities of the agents.

Our goal is to find the conflict-free maneuver with the least μ-energy, i.e.,

$$\text{minimize } J_\mu(\alpha) \text{ subject to } \alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b}). \tag{3.4}$$

[1] Piecewise C^2 means that there is a finite subdivision of T such that the map is continuously differentiable till the second order on each (open) subinterval. In what follows, when we use $\dot{\alpha}_i(t), \ddot{\alpha}_i(t)$, we shall mean at those t where they are well defined, i.e., except at a finite set of time instants t.

If α is required to belong to a certain type in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$, then we get a restricted version of problem (3.4). All the necessary conditions obtained in this section remain valid for the restricted problem, with the only exception of Proposition 3.8.

Remark 1 (geodesics in a manifold with boundary). Problem (3.4) can be formulated in an alternative way. By viewing $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbf{P}(\mathbf{a}, \mathbf{b})$ as a curve in $\mathbb{R}^{2n}$, and $\mathbf{a}, \mathbf{b}$ as two points in $\mathbb{R}^{2n}$, a conflict-free maneuver in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ corresponds to a curve in $\mathbb{R}^{2n}$ joining $\mathbf{a}$ to $\mathbf{b}$ and avoiding the obstacle W defined by

$$W = \{(p_1, \ldots, p_n) \in \mathbb{R}^{2n} : p_i \in \mathbb{R}^2, 1 \le i \le n, \text{ and } \|p_j - p_k\| < R \text{ for some } j \ne k\}.$$

If the coefficients μ_i, $i = 1, \ldots, n$, are identical, then the μ-energy of a joint maneuver is proportional to the energy of the corresponding curve in $\mathbb{R}^{2n}$. Therefore, problem (3.4) is equivalent to finding the curve in $\mathbb{R}^{2n} \setminus W$ joining $\mathbf{a}$ to $\mathbf{b}$ with the least energy, which is a minimizing geodesic of $\mathbb{R}^{2n} \setminus W$ connecting $\mathbf{a}$ to $\mathbf{b}$. Note that $\mathbb{R}^{2n} \setminus W$ is a manifold with nonsmooth boundary whose fundamental group is isomorphic to $\mathbf{PB}_n$ by Theorem 2.5. The general case of arbitrary $\langle \mu_i \rangle_{i=1}^n$ can be reduced to this special case by scaling the p_i axes of $\mathbb{R}^{2n}$ by a factor of $\sqrt{\mu_i}$, $i = 1, \ldots, n$. The interested readers are referred to [17] for further details.

The rest of this section is devoted to the solution of problem (3.4), a variational problem with complicated and nonsmooth constraints. Inspired by the braid representation introduced in section 2, we propose various transformations of joint maneuvers that preserve the MSE and use these transformations in the variational analysis to obtain necessary conditions for a maneuver $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ to be optimal.

3.2. μ-alignment of optimal conflict-free maneuvers. As explained in section 2, each conflict-free maneuver $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ has a natural braid representation $\hat{\alpha} \in \mathbf{PB}(\mathbf{a}, \mathbf{b})$, whose n strings are determined by the images of the maps $t \mapsto (\alpha_i(t), t)$, $t \in T$, $i = 1, \ldots, n$. Furthermore, $\hat{\alpha}$ satisfies the *R-separation property* in that the intersection of $\hat{\alpha}$ with the plane $t = \tau$ for any $\tau \in T$ consists of n points whose pairwise minimum distance is at least R. All the operations on conflict-free maneuvers we shall introduce in the following preserve this separation property in the braid representation; hence they are indeed transformations of conflict-free maneuvers.

For each $w \in \mathbb{R}^2$, denote by $\mathbf{b} + w$ the n-tuple $(b_1 + w, \ldots, b_n + w)$.

DEFINITION 3.1 (tilt operator $\mathcal{T}_w$). *The tilt operator* $\mathcal{T}_w : \mathbf{P}(R, \mathbf{a}, \mathbf{b}) \to \mathbf{P}(R, \mathbf{a}, \mathbf{b} + w)$ *is a map such that for any* $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$, $\beta = \mathcal{T}_w(\alpha)$ *is defined by*

$$\beta_i(t) = \alpha_i(t) + \frac{t - t_0}{t_f - t_0} w, \quad t \in T, \quad i = 1, \ldots, n.$$

It is easily seen that $\mathcal{T}_w$ is *MSE-preserving* in the sense that α and $\mathcal{T}_w(\alpha)$ have the same MSE. Hence $\mathcal{T}_w$ maps $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ into $\mathbf{P}(R, \mathbf{a}, \mathbf{b} + w)$. In fact, $\mathcal{T}_w$ is a bijection from $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ to $\mathbf{P}(R, \mathbf{a}, \mathbf{b} + w)$ since $\mathcal{T}_w \circ \mathcal{T}_{-w} = \mathcal{T}_{-w} \circ \mathcal{T}_w = \mathrm{id}$. In the braid representation, $\hat{\beta}$ is obtained by tilting $\hat{\alpha}$ linearly; hence the name for the operator $\mathcal{T}_w$. More precisely, in order to get $\hat{\beta}$ from $\hat{\alpha}$, the plane $t = t_0$ is kept invariant (shifted by 0), the plane $t = t_f$ is shifted by w, and each intermediate plane $t = \tau$, $\tau \in (t_0, t_f)$, is shifted by an amount determined by the linear interpolation of 0 and w according to the position of τ in T. Figure 3.1 illustrates the effect of the $\mathcal{T}_w$ operator on the braid representation of a 2-maneuver.

The importance of introducing $\mathcal{T}_w$ lies in the following result.

PROPOSITION 3.2. *Suppose that* α^* *is a conflict-free maneuver in* $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ *with the least* μ*-energy. Fix* $w \in \mathbb{R}^2$. *Then* $\beta^* = \mathcal{T}_w(\alpha^*)$ *is a conflict-free maneuver in* $\mathbf{P}(R, \mathbf{a}, \mathbf{b} + w)$ *with the least* μ*-energy.*

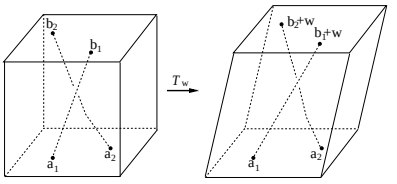

FIG. 3.1. *Tilt operation $\mathcal{T}_w$ on a 2-maneuver.*

Proof. For any $\beta \in \mathbf{P}(R, \mathbf{a}, \mathbf{b}+w)$, let $\alpha = \mathcal{T}_{-w}(\beta)$. Then $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ and $J_\mu(\beta)$ can be expressed as

$$\begin{aligned} J_\mu(\beta) &= \frac{1}{2}\int_{t_0}^{t_f} \sum_{i=1}^n \mu_i \|\dot\beta_i(t)\|^2 dt = \frac{1}{2}\int_{t_0}^{t_f} \sum_{i=1}^n \mu_i \left\|\dot\alpha_i(t) + \frac{w}{t_f - t_0}\right\|^2 dt \\ &= \frac{1}{2}\int_{t_0}^{t_f} \sum_{i=1}^n \mu_i \|\dot\alpha_i(t)\|^2 dt + \int_{t_0}^{t_f} \frac{w^T}{t_f - t_0} \sum_{i=1}^n \mu_i \dot\alpha_i(t) dt + \frac{\|w\|^2}{2(t_f - t_0)} \\ &= J_\mu(\alpha) + \frac{w^T[\sum_{i=1}^n \mu_i(b_i - a_i) + w/2]}{t_f - t_0}. \end{aligned} \tag{3.5}$$

Note that the second term in (3.5) is a constant independent of β. Denote it by C. It follows by (3.5) and the optimality of α^* that $J_\mu(\beta) \geq J_\mu(\alpha^*) + C$ for all $\beta \in \mathbf{P}(R, \mathbf{a}, \mathbf{b}+w)$, with the equality if $\alpha = \alpha^*$, i.e., $\beta = \beta^*$. □

Consider arbitrary starting and destination positions $\mathbf{a}$ and $\mathbf{b}$, and set $\mathbf{b}' \triangleq \mathbf{b} + w$ where $w = \sum_{i=1}^n \mu_i(a_i - b_i)$. Then $\mathbf{a}$ and $\mathbf{b}'$ are *μ-aligned* in the sense that they have the same μ-centroid, i.e.,

$$\sum_{i=1}^n \mu_i a_i = \sum_{i=1}^n \mu_i b_i'. \tag{3.6}$$

By Proposition 3.2, solutions to problem (3.4) for general $\mathbf{a}$ and $\mathbf{b}$ can be obtained from solutions to problem (3.4) for μ-aligned $\mathbf{a}$ and $\mathbf{b}'$ by applying the tilt operator $\mathcal{T}_{-w}$ with $w = \sum_{i=1}^n \mu_i(a_i - b_i)$. This is the reason why we shall focus on the special case of μ-aligned $\mathbf{a}$ and $\mathbf{b}$.

The next transformation we shall introduce is the *drift operation*. Let $\gamma : T \to \mathbb{R}^2$ be a continuous and piecewise C^2 map such that $\gamma(t_0) = \gamma(t_f) = 0$.

DEFINITION 3.3 (drift operator $\mathcal{D}_\gamma$). *The drift operator $\mathcal{D}_\gamma : \mathbf{P}(R, \mathbf{a}, \mathbf{b}) \to \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is a map such that for any $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$, $\beta = \mathcal{D}_\gamma(\alpha)$ is defined by*

$$\beta_i(t) = \alpha_i(t) + \gamma(t), \quad t \in T, \quad i = 1, \ldots, n.$$

In the braid representation, $\hat\beta$ is obtained from $\hat\alpha$ by drifting each plane $t = \tau$, $\tau \in T$, by an offset $\gamma(\tau) \in \mathbb{R}^2$. It can be verified that $\mathcal{D}_\gamma$ is MSE-preserving and a bijection of $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ onto itself since $\mathcal{D}_\gamma \circ \mathcal{D}_{-\gamma} = \mathcal{D}_{-\gamma} \circ \mathcal{D}_\gamma = \mathrm{id}$. By using the drift operator, we can prove the following result.

PROPOSITION 3.4. *Suppose that $\mathbf{a}$ and $\mathbf{b}$ are μ-aligned and $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is an optimal solution to problem* (3.4). *Then*

$$\sum_{i=1}^n \mu_i \alpha_i^*(t) = \sum_{i=1}^n \mu_i a_i = \sum_{i=1}^n \mu_i b_i \qquad \forall t \in T.$$

Proof. For each $\lambda \in \mathbb{R}$ define $\beta_\lambda \triangleq \mathcal{D}_{\lambda\gamma}(\alpha^*)$. Note that $\beta_\lambda \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ and $\beta_0 = \alpha^*$. Moreover,

$$\begin{aligned} J_\mu(\beta_\lambda) &= \frac{1}{2}\int_{t_0}^{t_f} \sum_{i=1}^{n} \mu_i \|\dot{\alpha}_i^*(t) + \lambda\dot{\gamma}(t)\|^2 dt \\ &= J_\mu(\alpha^*) + \frac{\lambda^2}{2}\int_{t_0}^{t_f} \|\dot{\gamma}(t)\|^2 dt + \lambda \int_{t_0}^{t_f} \dot{\gamma}(t)^T \sum_{i=1}^{n} \mu_i \dot{\alpha}_i^*(t) dt. \end{aligned}$$

The difference $J_\mu(\beta_\lambda) - J_\mu(\alpha^*)$ is a quadratic function of λ, which, by the optimality of α^*, must be nonnegative for all λ. Hence we have $\int_{t_0}^{t_f} \dot{\gamma}(t)^T \sum_{i=1}^{n} \mu_i \dot{\alpha}_i^*(t) dt = 0$, which must hold for any choice of γ such that $\gamma(t_0) = \gamma(t_f) = 0$. Since $\mathbf{a}$ and $\mathbf{b}$ are μ-aligned, we can choose $\gamma(t) = \sum_{i=1}^{n} \mu_i \alpha_i^*(t) - \sum_{i=1}^{n} \mu_i a_i$. Given that α^* is piecewise C^2, this leads to $\sum_{i=1}^{n} \mu_i \dot{\alpha}_i^*(t) = 0$ for almost all $t \in T$, and hence, by integration, to the desired conclusion. □

We can now use Proposition 3.2 to get the formulation of Proposition 3.4 for arbitrary $\mathbf{a}$ and $\mathbf{b}$.

COROLLARY 3.5. *Suppose that $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is an optimal solution to problem* (3.4). *Then*

$$\sum_{i=1}^{n} \mu_i \alpha_i^*(t) = \sum_{i=1}^{n} \mu_i a_i + \frac{t - t_0}{t_f - t_0}\left(\sum_{i=1}^{n} \mu_i b_i - \sum_{i=1}^{n} \mu_i a_i\right) \qquad \forall t \in T.$$

In other words, the μ-centroid of $\langle \alpha_i^*(t) \rangle_{i=1}^n$ moves from the μ-centroid of $\mathbf{a}$ at time t_0 to the μ-centroid of $\mathbf{b}$ at time t_f with constant velocity.

Remark 2. The results in Proposition 3.2, Proposition 3.4, and Corollary 3.5 for conflict-free maneuvers in $\mathbb{R}^2$ are still valid when the underlying space is $\mathbb{R}^k$ with $k > 2$. These can be proved by following exactly the same procedure as in the $\mathbb{R}^2$ case.

Remark 3. A geometric interpretation of Corollary 3.5 can be given in the case when the μ_i's are identical. Let W be the obstacle in $\mathbb{R}^{2n}$ defined as in Remark 1. An important observation is that W is cylindrical in the direction of the two-dimensional subspace N spanned by vectors $(1, 0, 1, 0, \ldots, 1, 0)^T$ and $(0, 1, 0, 1, \ldots, 0, 1)^T$ in $\mathbb{R}^{2n}$, in the sense that for any $x \in \mathbb{R}^{2n}$, $x \in W$ if and only if $x + N \subset W$. Let V be the orthogonal complement of N in $\mathbb{R}^{2n}$. Then $\mathbf{a}$ and $\mathbf{b}$ are μ-aligned if and only if $\mathbf{a}$ and $\mathbf{b}$ are on the same V-slice in $\mathbb{R}^{2n}$, i.e., if and only if $\mathbf{a} - \mathbf{b} \in V$. The conclusions of Proposition 3.2 and Corollary 3.5 say that for $\mathbf{a}$ and $\mathbf{b}$ that are not necessarily μ-aligned, the shortest geodesic in $\mathbb{R}^{2n} \setminus W$ from $\mathbf{a}$ to $\mathbf{b}$ can be decomposed into two parts: its projection onto N, which is a constant speed motion along the straight line from $\pi_N(\mathbf{a})$ to $\pi_N(\mathbf{b})$, where $\pi_N : \mathbb{R}^{2n} \to N$ denotes the orthogonal projection map onto N; and its projection onto V, which is the shortest geodesic in $V \cap W^c$ connecting $\pi_V(\mathbf{a})$ and $\pi_V(\mathbf{b})$, where $\pi_V : \mathbb{R}^{2n} \to V$ denotes the orthogonal projection map onto V. Since V is of dimension $2n - 2$, this effectively reduces the dimension of the problem by 2.

3.3. Optimal conflict-free maneuvers for two agents. We now show that the solution to problem (3.4) in the case when there are only two agents follows directly from Corollary 3.5.

Assume that $\mathbf{a} = (a_1, a_2)$ and $\mathbf{b} = (b_1, b_2)$ are μ-aligned, and denote by c their common μ-centroid. If $\alpha^* = (\alpha_1^*, \alpha_2^*) \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is an optimal solution to problem

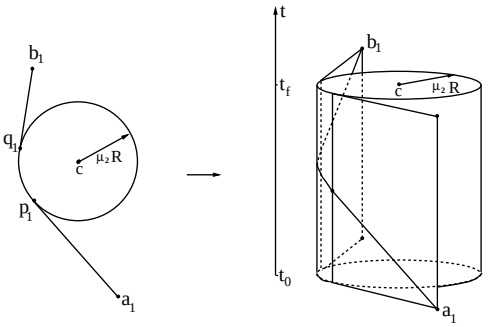

FIG. 3.2. *Optimal 2-maneuver and its braid representation.*

(3.4), then, by Proposition 3.4, the μ-centroid of $\alpha_1^*(t)$ and $\alpha_2^*(t)$ is equal to c for any $t \in T$, or equivalently,

$$\alpha_1^*(t) - c = -\frac{\mu_2}{\mu_1}(\alpha_2^*(t) - c) \qquad \forall t \in T. \tag{3.7}$$

From (3.7), it then follows that the energies of α_1^* and α_2^* are related by $\mu_1^2 J(\alpha_1^*) = \mu_2^2 J(\alpha_2^*)$ and that the separation constraint $\|\alpha_1^*(t) - \alpha_2^*(t)\| \geq R$ is equivalent to $\|\alpha_1^*(t) - c\| \geq \mu_2 R$. Therefore, problem (3.4) can be reduced to

$$\text{minimize } J(\alpha_1) \text{ subject to } \alpha_1 \in \mathbf{P}_1 \text{ and } \alpha_1 : T \to B^c(c, \mu_2 R), \tag{3.8}$$

where $B^c(c, \mu_2 R)$ denotes the complement in $\mathbb{R}^2$ of the open disk of radius $\mu_2 R$ centered at c. Thus the problem becomes finding the minimum energy maneuver for a single agent in the presence of the static obstacle $B(c, \mu_2 R)$.

By assumption, both a_1 and b_1 belong to $B^c(c, \mu_2 R)$ since otherwise the problem is infeasible. From the discussion at the beginning of section 3.1, we know that the optimal solution to problem (3.8) is a constant speed motion along the shortest curve joining a_1 to b_1 while avoiding the obstacle $B(c, \mu_2 R)$. Let ∂B be the boundary of the disk $B(c, \mu_2 R)$. The geometric construction of the shortest curve within a given fundamental type is shown in Figure 3.2. The curve is composed of three pieces: first from a_1 to $p_1 \in \partial B$ along a straight line tangent to ∂B, then from p_1 to q_1 along ∂B, and finally from q_1 to b_1 along another straight line tangent to ∂B. Here choosing a fundamental type is equivalent to choosing a side of the cylinder in the braid representation. The globally optimal solution α_1^* is the one of the two locally optimal solutions with shorter arc length (or any one of them if they have the same length). α_2^* is then obtained from α_1^* by (3.7). This is for the μ-aligned case. Denote by $\gamma_i^*(\mathbf{a}, \mathbf{b})$, $i = 1, 2$, the obtained optimal maneuvers. For the general case when $\mathbf{a}$ and $\mathbf{b}$ are not necessarily μ-aligned, we have by Proposition 3.2 the following theorem.

THEOREM 3.6 (optimal conflict-free 2-maneuver). *If $n = 2$, then the optimal solution $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ to problem* (3.4) *is given by*

$$\begin{cases} \alpha_1^*(t) = \gamma_1^*(\mathbf{a}, \mathbf{b} + w)(t) - \frac{t - t_0}{t_f - t_0} w, \\ \alpha_2^*(t) = \gamma_2^*(\mathbf{a}, \mathbf{b} + w)(t) - \frac{t - t_0}{t_f - t_0} w \end{cases} \qquad \forall t \in T, \tag{3.9}$$

where $w = \mu_1 a_1 - \mu_1 b_1 + \mu_2 a_2 - \mu_2 b_2$.

Consider the case when the priority of agent 1 is much higher than that of agent 2, which can be modeled by $\mu_2 \simeq 0$. In the μ-aligned case, this implies $a_1 \simeq b_1 \simeq c$

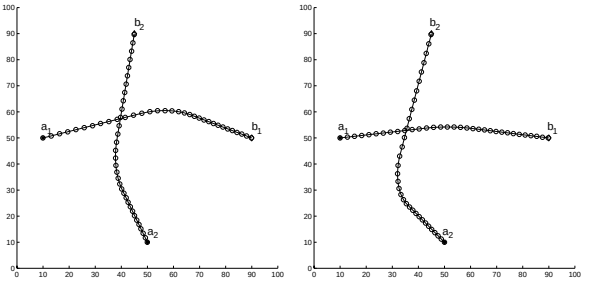

FIG. 3.3. *Optimal 2-maneuvers ($R = 30$). Left: $\mu_1 = \mu_2 = 0.5$. Right: $\mu_1 = 0.8$, $\mu_2 = 0.2$.*

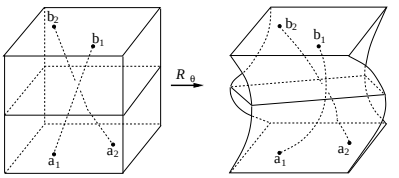

FIG. 3.4. *Twist operation $\mathcal{R}_\theta$ on a 2-maneuver.*

and that the radius of the disk $B(c, \mu_2 R)$ is about 0. Therefore, γ_1^* is nearly a zero motion. For general $\mathbf{a}$ and $\mathbf{b}$, it follows from Theorem 3.6 that the optimal maneuver for agent 1 is almost a constant speed motion along the line segment from a_1 to b_1. Hence, as expected, agent 2 is the one assuming most of the responsibility of avoiding conflicts.

Shown in Figure 3.3 are the plots of optimal conflict-free maneuvers for a typical 2-agent encounter with two different sets of priorities. The circles represent the positions of the two agents at evenly distributed time instants. The plots show that, in the case when $\mathbf{a}$ and $\mathbf{b}$ are not μ-aligned, the speeds of the agents in the optimal maneuvers are not constant. As the priority of agent 1 increases, however, its optimal maneuver gets closer to the constant speed motion along the straight line connecting a_1 to b_1.

3.4. Twist optimality. Another MSE-preserving operator can be introduced as follows. Suppose that $\theta : T \to \mathbb{R}$ is a continuous and piecewise C^2 map satisfying $\theta(t_0) = 0$, $\theta(t_f) = 2k\pi$ for some $k \in \mathbb{Z}$.

DEFINITION 3.7 (twist operator $\mathcal{R}_\theta$). *The twist operator $\mathcal{R}_\theta : \mathbf{P}(R, \mathbf{a}, \mathbf{b}) \to \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is a map such that for any $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$, $\beta = \mathcal{R}_\theta(\alpha)$ is defined by*

$$\beta_i(t) = T_{\theta(t)}\alpha_i(t), \quad t \in T, \quad i = 1, \ldots, n,$$

where $T_{\theta(t)}$ is the matrix corresponding to a rotation of $\theta(t)$ counterclockwise:

$$T_{\theta(t)} = \begin{pmatrix} \cos[\theta(t)] & -\sin[\theta(t)] \\ \sin[\theta(t)] & \cos[\theta(t)] \end{pmatrix}.$$

The constraints on $\theta(t_0)$ and $\theta(t_f)$ ensure that $\mathcal{R}_\theta(\alpha)$ and α have the same starting and ending positions. It is easy to see that $\mathcal{R}_\theta$ is MSE-preserving and hence has its image in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$. Figure 3.4 shows the effect of $\mathcal{R}_\theta$ ($k = 0$) on the braid representation of a 2-maneuver, which motivates the name "twist operator" for it.

By considering the perturbed maneuvers generated by $\mathcal{R}_\theta$, we have the following proposition.

PROPOSITION 3.8. *Suppose that* $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ *is an optimal solution to problem* (3.4). *Fix* $s \in \mathbb{R}^2$. *Then*

$$\frac{1}{2}\sum_{i=1}^{n} \mu_i (\alpha_i^*(t) - s)^T T_{-\frac{\pi}{2}} \dot{\alpha}_i^*(t) = C \qquad \forall t \in T, \tag{3.10}$$

where C *is a constant belonging to* $[-\frac{\pi}{z}, \frac{\pi}{z}]$, *with* $z \triangleq 2\int_{t_0}^{t_f} \left[\sum_{i=1}^{n} \mu_i \|\alpha_i^*(t) - s\|^2\right]^{-1} dt$.

Proof. See Appendix A. □

If $k \neq 0$, then the operator $\mathcal{R}_\theta$ changes the homotopy type of conflict-free maneuvers in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$, thus enabling us to compare the performance of conflict-free maneuvers of different types. In this sense, the result in Proposition 3.8 is global. We illustrate this statement by the following example.

Example 1. Assume that $n = 2$ and $\mu_1 = \mu_2 = \frac{1}{2}$. Let $t_0 = 0$ and $t_f = \tau$ for some $\tau \in (0, 2\pi)$. Set $a_1 = \frac{R}{2}(1, 0)^T$, $b_1 = \frac{R}{2}(\cos\tau, \sin\tau)^T$, $a_2 = -a_1$, and $b_2 = -b_1$. Consider the conflict-free maneuvers α and β in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ defined by $\alpha_1(t) = \frac{R}{2}(\cos t, \sin t)^T$, $\alpha_2(t) = -\alpha_1(t)$, and $\beta_1(t) = \frac{R}{2}(\cos(\frac{\tau - 2\pi}{\tau}t), \sin(\frac{\tau-2\pi}{\tau}t))^T$, $\beta_2(t) = -\beta_1(t)$ for all $t \in [0, \tau]$. The two agents under maneuver α (β) rotate around the origin at constant angular velocity counterclockwise (clockwise) during $[0, \tau]$. Note that β can be obtained from α by applying the twist operator $\mathcal{R}_\theta$ with $\theta(t) = -2\pi t/\tau$ satisfying $\theta(\tau) = -2\pi$ and that α and β belong to different types. Since $\mathbf{a}$ and $\mathbf{b}$ are μ-aligned, the results in section 3.3 imply that α and β are the optimal solutions to problem (3.4) restricted to the two fundamental types. The global optimal solution is the one of them with smaller arc length, which can be easily seen to be α if $\tau \in (0, \pi)$ and β if $\tau \in (\pi, 2\pi)$. This conclusion can also be reached directly by an application of Proposition 3.8. In fact, if we choose $s = 0$ and compute C and z defined in Proposition 3.8 with α in the place of α^*, we get $C = R^2/8$ and $z = 8\tau/R^2$, and the inequality $|C| \leq \pi/z$ becomes $\tau \leq \pi$, which implies that α is not globally optimal for $\tau \in (\pi, 2\pi)$. If we compute C and z with β in the place of α^*, we get $C = R^2(\tau - 2\pi)/8\tau$ and $z = 8\tau/R^2$, and the inequality $|C| \leq \pi/z$ becomes $\tau \geq \pi$. Hence β is not globally optimal for $\tau \in (0, \pi)$.

Note that by choosing different $s \in \mathbb{R}^2$, Proposition 3.8 provides a family of inequalities of the form $-\frac{\pi}{z} \leq C \leq \frac{\pi}{z}$ that an optimal solution α^* to problem (3.4) must satisfy, where C and z are functions of s and α^*. In the case when $\mathbf{a}$ and $\mathbf{b}$ are μ-aligned, by Proposition 3.4, we have $\sum_{i=1}^{n} \mu_i s^T T_{-\frac{\pi}{2}} \dot{\alpha}_i^*(t) \equiv 0$. Hence the inequality becomes

$$\left| \frac{1}{2}\sum_{i=1}^{n} \mu_i \alpha_i^*(t)^T T_{-\frac{\pi}{2}} \dot{\alpha}_i^*(t) \right| \leq \frac{\pi}{2} \left\{ \int_{t_0}^{t_f} \left[\sum_{i=1}^{n} \mu_i \|\alpha_i^*(t) - s\|^2 \right]^{-1} dt \right\}^{-1}.$$

The most restrictive bound is obtained by setting s equal to the common μ-centroid of $\mathbf{a}$ and $\mathbf{b}$, which minimizes the right-hand side of the above equation. Moreover, one can derive further optimality conditions by applying Proposition 3.8 to $\mathcal{T}_w(\alpha^*)$ for any $w \in \mathbb{R}^2$, since by Proposition 3.2, $\mathcal{T}_w(\alpha^*)$ is optimal in $\mathbf{P}(R, \mathbf{a}, \mathbf{b} + w)$.

3.5. Analysis by partial operators. Further optimality conditions can be derived by considering those transformations that change the maneuvers of only a subset of the n agents (partial operators).

Let α be an arbitrary conflict-free maneuver in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$. At each time $t \in T$, we can construct an undirected graph $G_\alpha(t)$ as follows: $G_\alpha(t)$ has n vertices, numbered from 1 to n, corresponding to the n agents, and an edge connects vertices i and j if

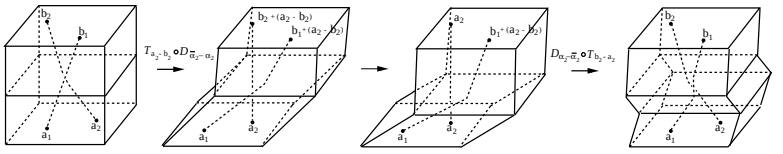

FIG. 3.5. *Slide operation* $\mathcal{L}_h^{12}$ *on braids.*

and only if $\|\alpha_i(t) - \alpha_j(t)\| = R$. If there does exist an edge between vertex i and vertex j in $G_\alpha(t)$, we say that agent i and agent j *contact* at time t. $G_\alpha(t)$ is then called the *contact graph* of α at time t.

We start from a very special case. Assume that α is a conflict-free maneuver in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ such that during the whole encounter the distance of agent 1 from any of the other agents is strictly greater than R except possibly from agent 2, i.e., $\|\alpha_1(t) - \alpha_i(t)\| > R$ for all $t \in T$, $i = 3, \ldots, n$. We shall introduce operators that leave α_i unchanged for $i = 2, 3, \ldots, n$ and perturb α_1 slightly, so that the perturbed α_1 has the same minimum distance from α_2 in the time interval T. If such a perturbation is small enough, then the perturbed α_1 does not cause a conflict between agent 1 and any of the agents with index $i \geq 3$, given that their original minimum distance in the time interval T was strictly greater than R.

Let $h : T \to T$ be a reparameterization of T, i.e., a bijection such that both h and h^{-1} are continuous and piecewise C^2, and $h(t_0) = t_0$ and $h(t_f) = t_f$.

DEFINITION 3.9 (partial slide operator $\mathcal{L}_h^{12}$). *The partial slide operator* $\mathcal{L}_h^{12} : \mathbf{P}(R, \mathbf{a}, \mathbf{b}) \to \mathbf{P}(\mathbf{a}, \mathbf{b})$ *is a map such that for any* $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$, $\beta = \mathcal{L}_h^{12}(\alpha)$ *is defined by*

$$\begin{cases} \beta_1(t) = \alpha_1[h(t)] - \alpha_2[h(t)] + \alpha_2(t), & t \in T, \\ \beta_i(t) = \alpha_i(t), & t \in T, \quad i = 2, \ldots, n. \end{cases} \tag{3.11}$$

Note that $\inf_{t \in T} \|\beta_1(t) - \beta_2(t)\| = \inf_{t \in T} \|\alpha_1(t) - \alpha_2(t)\|$, and that for h sufficiently close to the identity map, the minimum distance in the time interval T between β_1 and β_i is greater than R for $i \geq 3$ by our assumption on α. These two conditions together imply that $\beta \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$.

Figure 3.5 shows how β is constructed geometrically. First, the operator $\mathcal{D}_{\bar{\alpha}_2 - \alpha_2}$ is performed on (α_1, α_2) to "straighten" the string corresponding to α_2, where $\bar{\alpha}_2$ denotes the constant velocity motion along the straight line between a_2 and b_2. Next, the operator $\mathcal{T}_{a_2 - b_2}$ is applied to the resulting 2-maneuver to get a 2-maneuver $\gamma = (\gamma_1, \gamma_2)$ with $\gamma_1 = \alpha_1 - \alpha_2 + a_2$ and $\gamma_2 \equiv a_2$. Then, γ is reparameterized by h to obtain $\eta = (\eta_1, \eta_2)$ with $\eta_1 = (\alpha_1 \circ h) - (\alpha_2 \circ h) + a_2$ and $\eta_2 \equiv a_2$. Finally, the reverse procedures of the second and first steps are applied subsequently to obtain (β_1, β_2) from η. Roughly speaking, $\hat{\beta}$ is obtained by "sliding" $\hat{\alpha}_1$ along $\hat{\alpha}_2$; hence the name "slide operator" for $\mathcal{L}_h^{12}$. Note that the superscript and the subscript in $\mathcal{L}_h^{12}$ indicate, respectively, the two strings the operator works on and the reparameterization used.

By using the partial slide operator to generate the perturbation in the variational analysis, we get the following proposition. (See [12] for the detailed proof.)

PROPOSITION 3.10. *Suppose that* $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ *is an optimal solution to problem* (3.4) *and that there exists a subinterval* $(t_0', t_f') \subset T$ *such that* $\|\alpha_1^*(t) - \alpha_i^*(t)\| > R$, $i = 3, \ldots, n$, *for all* $t \in (t_0', t_f')$. *Then* α^* *satisfies*

$$\ddot{\alpha}_1^*(t)^T (\dot{\alpha}_1^*(t) - \dot{\alpha}_2^*(t)) \equiv 0 \qquad \forall t \in (t_0', t_f'). \tag{3.12}$$

Instead of sliding α_1 along α_2, we can rotate it. Let $\theta : T \to \mathbb{R}$ be a continuous and piecewise C^2 map with $\theta(t_0) = \theta(t_f) = 0$.

DEFINITION 3.11 (partial rotation operator $\mathcal{R}^{12}_\theta$). *The partial rotation operator* $\mathcal{R}^{12}_\theta : \mathbf{P}(R, \mathbf{a}, \mathbf{b}) \to \mathbf{P}(\mathbf{a}, \mathbf{b})$ *is a map such that for any* $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$, $\beta = \mathcal{R}^{12}_\theta(\alpha)$ *is defined by*

$$\begin{cases} \beta_1(t) = T_\theta(t)[\alpha_1(t) - \alpha_2(t)] + \alpha_2(t), & t \in T, \\ \beta_i(t) = \alpha_i(t), & t \in T, \quad i = 2, \dots, n. \end{cases}$$

In the braid representation, $\hat{\beta}$ is obtained by rotating the string $\hat{\alpha}_1$ around the string $\hat{\alpha}_2$. If θ is close enough to the zero map, $\beta = \mathcal{R}^{12}_\theta(\alpha) \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$. Similarly to the proof of Proposition 3.10, by using the partial rotation operator, we get the following proposition [12].

PROPOSITION 3.12. *Under the hypotheses of Proposition* 3.10, α^* *satisfies*

$$\ddot{\alpha}^*_1(t)^T T_{\frac{\pi}{2}}(\alpha^*_1(t) - \alpha^*_2(t)) \equiv 0 \qquad \forall t \in (t'_0, t'_f). \tag{3.13}$$

It can be verified that the optimal solution for the 2-agent case obtained in Theorem 3.6 indeed satisfies both conditions (3.12) and (3.13). Moreover, if one of the two agents has a predetermined maneuver throughout T, equations (3.12) and (3.13) will govern the motion of the other agent. Note also that if, in addition, $\|\alpha^*_1 - \alpha^*_2\| = R$ on (t'_0, t'_f), then these two equations are equivalent, since in this case $\|\alpha^*_1 - \alpha^*_2\|^2 \equiv R^2$ implies that $(\dot{\alpha}^*_1 - \dot{\alpha}^*_2)^T(\alpha^*_1 - \alpha^*_2) \equiv 0$, i.e., $\dot{\alpha}^*_1 - \dot{\alpha}^*_2$ and $T_{\frac{\pi}{2}}(\alpha^*_1 - \alpha^*_2)$ have the same direction. The intuitive understanding is that, in the braid representation, the slide and rotation operations of a string on the surface of a cylinder lead to the same orthogonal perturbation.

The above idea can be carried out even further. Suppose that the contact graph of an optimal maneuver $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ remains constant on some subinterval $(t'_0, t'_f) \subset T$. We can perturb α^* by sliding (rotating) slightly the maneuvers of a subset of the n agents with respect to that of agent i in the time subinterval (t'_0, t'_f). To ensure that the perturbed joint maneuver belongs to $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$, any agent in this subset should have a minimum distance strictly greater than R from any of the agents not belonging to the subset, except possibly from agent i, in the time interval (t'_0, t'_f). Since α^* is optimal, its μ-energy cannot be decreased by such a perturbation. By using the same arguments leading to Proposition 3.10 and Proposition 3.12, we then have the following proposition [12].

PROPOSITION 3.13. *Suppose that* $\alpha^* \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$ *is an optimal solution to problem* (3.4) *and that its contact graph remains constant on some subinterval* $(t'_0, t'_f) \subset T$. *Pick any agent, say, agent* i, *and let* $\mathcal{I} \subset \{1, 2, \dots, n\} \setminus \{i\}$ *be a subset of the remaining agents that corresponds to a maximal connected component of the graph obtained by removing node* i *and all the edges connected with it from the contact graph during* (t'_0, t'_f). *Then for all* $t \in (t'_0, t'_f)$,

$$\begin{aligned} &\sum_{j \in \mathcal{I}} \mu_j \ddot{\alpha}^*_j(t)^T(\dot{\alpha}^*_j(t) - \dot{\alpha}^*_i(t)) \equiv 0, \\ &\sum_{j \in \mathcal{I}} \mu_j \ddot{\alpha}^*_j(t)^T T_{\frac{\pi}{2}}(\alpha^*_j(t) - \alpha^*_i(t)) \equiv 0. \end{aligned} \tag{3.14}$$

Note that (3.12) and (3.13) are special cases of (3.14) when $i = 2$ and $\mathcal{I} = \{1\}$.

Proposition 3.13 is the most comprehensive optimality condition we have obtained so far. Next, in section 3.6 we will show by a simple example how it can be used (together with the global optimality conditions) to determine the optimal maneuver with a particular contact graph. This example will also serve as a counterexample to the conjecture that for each multi-agent encounter, there is a unique optimal conflict-free maneuver within each homotopy type, which is true for $n = 2$ by Theorem 3.6.

Remark 4. All the optimality conditions we have obtained so far admit mechanical interpretations, as will be shown in section 3.8. However, it should be pointed out that, in general, they cannot completely characterize the optimal maneuver with an arbitrary contact graph. A complete set of local optimality conditions can be derived by considering all possible local perturbations of maneuvers that preserve the contact graph, or in the light of Remark 1, by writing down the geodesics equation in a suitable Riemannian manifold.

3.6. An interesting example. Consider three agents with equal priorities $\mu_1 = \mu_2 = \mu_3 = \frac{1}{3}$ and $R = 1$. Suppose that α^* is an optimal conflict-free maneuver for some starting position $\mathbf{a} = (a_1, a_2, a_3)$ and destination position $\mathbf{b} = (b_1, b_2, b_3)$ that are μ-aligned with a common μ-centroid at the origin, and suppose that on some subinterval of T (which we may assume without loss of generality to be T itself), its contact graph $G_{\alpha^*}(t)$ is constant with edges between vertices 1 and 3 and between vertices 2 and 3 but no edges between vertices 1 and 2. Then, by Corollary 3.5 and Proposition 3.13, $\alpha^* = (\alpha_1^*, \alpha_2^*, \alpha_3^*)$ must satisfy for $t \in T$

$$\begin{cases} \sum_{i=1}^{3} \alpha_i^*(t) = 0, \\ \ddot{\alpha}_1^*(t)^T T_{\frac{\pi}{2}}(\alpha_1^*(t) - \alpha_3^*(t)) = 0, \\ \ddot{\alpha}_2^*(t)^T T_{\frac{\pi}{2}}(\alpha_2^*(t) - \alpha_3^*(t)) = 0, \\ \|\alpha_1^*(t) - \alpha_3^*(t)\| = \|\alpha_2^*(t) - \alpha_3^*(t)\| = 1. \end{cases} \tag{3.15}$$

We now show that (3.15) is equivalent to the geodesics equation of a suitable Riemannian manifold (a differential manifold together with a smoothly varying positive definite quadratic form on its tangent bundle [8]). Hence, for any set of initial conditions $\alpha_i^*(t_0), \dot{\alpha}_i^*(t_0)$, $i = 1, 2, 3$, it has a unique solution for t belonging to a neighborhood of t_0. First, notice that α^* as a curve in $\mathbb{R}^6$ lies in the submanifold Q of $\mathbb{R}^6$ determined by the first and the last equations of (3.15), namely the set of all those points $(x_1, y_1, x_2, y_2, x_3, y_3)$ in $\mathbb{R}^6$ such that $\sum_{i=1}^{3} x_i = \sum_{i=1}^{3} y_i = 0$, $(x_1 - x_3)^2 + (y_1 - y_3)^2 = 1$, and $(x_2 - x_3)^2 + (y_2 - y_3)^2 = 1$. Q is a compact two-dimensional submanifold of $\mathbb{R}^6$ and admits a global coordinate (θ_1, θ_2) defined by

$$\theta_1 = \arctan \frac{y_1 - y_3}{x_1 - x_3}, \qquad \theta_2 = \arctan \frac{y_2 - y_3}{x_2 - x_3}.$$

(θ_1, θ_2) takes values in the rectangle $[0, 2\pi] \times [0, 2\pi]$ with opposite edges identified, i.e., the 2-torus $\mathbb{T}^2$. In order to satisfy our assumption that the distance between agent 1 and agent 2 is greater than R during T, α^* must lie in an open subset Q_0 of Q consisting of all those points $(x_1, y_1, x_2, y_2, x_3, y_3)$ in Q such that $(x_1 - x_2)^2 + (y_1 - y_2)^2 > 1$. In the (θ_1, θ_2) coordinate, Q_0 corresponds to an open subset $\mathbb{T}_0^2$ of $\mathbb{T}^2$ obtained by removing from $\mathbb{T}^2$ the shaded region shown in Figure 3.6. Hence topologically Q_0 is homeomorphic to $S^1 \times (0, 1)$, an untwisted ribbon whose boundary consists of two disjoint circles.

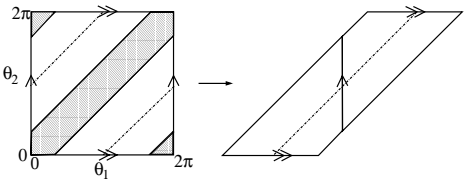

FIG. 3.6. $\mathbb{T}^2_0$ *as a subset of* $\mathbb{T}^2$ *in the* (θ_1, θ_2) *coordinate.*

Each $(\theta_1, \theta_2) \in \mathbb{T}^2$ determines a unique point $f(\theta_1, \theta_2)$ in Q by

$$f(\theta_1,\theta_2) = \frac{1}{3}(2\cos\theta_1 - \cos\theta_2, 2\sin\theta_1 - \sin\theta_2, -\cos\theta_1 + 2\cos\theta_2, \\ -\sin\theta_1 + 2\sin\theta_2, -\cos\theta_1 - \cos\theta_2, -\sin\theta_1 - \sin\theta_2)^T, \tag{3.16}$$

which is an embedding of $\mathbb{T}^2$ (respectively, $\mathbb{T}^2_0$) into $\mathbb{R}^6$ whose image is Q (respectively, Q_0).

By using f as the coordinate map, it can be verified that in the (θ_1, θ_2) coordinate, (3.15) is reduced to the following second order ODE:

$$\begin{cases} 2\ddot{\theta}_1 - \cos(\theta_1 - \theta_2)\ddot{\theta}_2 = \sin(\theta_1 - \theta_2)(\dot{\theta}_2)^2, \\ 2\ddot{\theta}_2 - \cos(\theta_1 - \theta_2)\ddot{\theta}_1 = -\sin(\theta_1 - \theta_2)(\dot{\theta}_1)^2. \end{cases} \tag{3.17}$$

Equation (3.17) is the geodesics equation of $\mathbb{T}^2$ with a suitably chosen metric g. In fact, let $\mathbb{R}^6$ be equipped with the standard Riemannian metric. Q as a submanifold inherits from $\mathbb{R}^6$ a metric by restriction. Let g be the corresponding metric on $\mathbb{T}^2$ obtained by pulling back the metric on Q via f, so that f becomes an isometry. Then, it can be proved (see Appendix B) that (3.17) is indeed the equation for geodesics of $\mathbb{T}^2$ under the metric g. As a result, each solution α^* of (3.15) is a geodesic of Q, which is not surprising by Remark 1. Since $\mathbb{T}^2$ (hence Q) is compact, a solution to (3.15) is defined for all duration of time, provided that it stays inside Q_0. Equation (3.17) can be solved by two integrals; see [13] for details.

Deeper optimality conditions of conflict-free maneuvers can be obtained in this interpretation. For example, it is computed in Appendix B that at each point $(\theta_1, \theta_2) \in \mathbb{T}^2$ the sectional curvature of the tangent plane spanned by the basis $\frac{\partial}{\partial\theta_1}$ and $\frac{\partial}{\partial\theta_2}$ at that point is

$$K(\theta_1,\theta_2) = \frac{-9\cos(\theta_1 - \theta_2)}{[4 - \cos^2(\theta_1 - \theta_2)]^2}. \tag{3.18}$$

Now consider the curve θ in $\mathbb{T}^2$ defined by $\theta(t) = (\theta_1(t), \theta_2(t)) = (t, \pi + t)$ for $t \in [0, \tau]$, where τ is positive. θ is a trivial solution to (3.17), hence a geodesic of $\mathbb{T}^2$ that is contained completely in $\mathbb{T}^2_0$. θ determines a 3-maneuver $\alpha^* = f \circ \theta$, i.e.,

$$\alpha_1^*(t) = (\cos t, \sin t)^T, \quad \alpha_2^*(t) = (-\cos t, -\sin t)^T, \quad \alpha_3^*(t) = (0,0)^T,\ t \in [0,\tau]. \tag{3.19}$$

In the motions specified by α^*, agent 3 stays at the origin, while agent 1 and agent 2 are at unit distance from agent 3 but on the opposite side of it so that three of them are always collinear, and both agent 1 and agent 2 rotate at the same constant angular velocity around agent 3. α^* thus defined is a solution to (3.15). An application of

Proposition 3.8 implies that α^* is no longer optimal if $\tau > \pi$, for otherwise a better maneuver can be obtained by rotating agent 1 and agent 2 the opposite way around agent 3. The following proposition improves this result.

PROPOSITION 3.14. *Maneuver α^* defined by* (3.19) *is not optimal if $\tau > \frac{\sqrt{2}}{2}\pi$.*

Proof. Since f is an isometry, we need only to prove that the geodesic θ is no longer distance-minimizing between its end points $\theta(0) = (0, \pi)$ and $\theta(\tau) = (\tau, \pi + \tau)$ once $\tau > \tau_0 = \frac{\sqrt{2}}{2}\pi$. To this end, it suffices to prove that $\theta(\tau_0)$ is a conjugate point of $\theta(0)$ along θ; in other words, there exists a nontrivial Jacobi field X along θ that vanishes at both $\theta(0)$ and $\theta(\tau_0)$ [20].

Define two vector fields along θ by $W_1 = \frac{\partial}{\partial\theta_1} + \frac{\partial}{\partial\theta_2}$ and $W_2 = \frac{\partial}{\partial\theta_1} - \frac{\partial}{\partial\theta_2}$. Then, it is easy to verify that W_1 and W_2 are orthogonal and that W_1 coincides with the velocity field $\dot\theta$ of the geodesic θ. Moreover, using the Christoffel symbols calculated in Appendix B, we conclude that $\nabla_{\dot\theta} W_2 \equiv 0$; hence, W_2 is parallel along θ.

A Jacobi field X along θ and orthogonal to $\dot\theta$ is necessarily of the form $X(t) = h(t)W_2(t)$ for some function h defined on $[0, \tau]$ and satisfies the Jacobi equation $\nabla_{\dot\theta}\nabla_{\dot\theta} X + R(\dot\theta, X)\dot\theta = 0$, where R is the curvature tensor of $\mathbb{T}^2$. Since $\nabla_{\dot\theta}\nabla_{\dot\theta} X = \ddot h W_2$ and $R(\dot\theta, X)\dot\theta$ are both orthogonal to $\dot\theta$, the Jacobi equation is equivalent to $\langle \ddot h W_2, W_2\rangle + \langle R(\dot\theta, hW_2)\dot\theta, W_2\rangle = 0$. By (3.18), the sectional curvature K of $\mathbb{T}^2$ along θ is constant 1. Using the relation $\langle R(\dot\theta, hW_2)\dot\theta, W_2\rangle = hK[\langle\dot\theta,\dot\theta\rangle\langle W_2, W_2\rangle - \langle\dot\theta, W_2\rangle^2]$, we have $\ddot h + 2h = 0$. A solution of h vanishing at 0 is $h(t) = \sin(\sqrt{2}t)$, so $X(t) = \sin(\sqrt{2}t)W_2(t)$ is a Jacobi field along θ vanishing at $t = 0$ and $t = \frac{\sqrt{2}}{2}\pi = \tau_0$. Therefore, $\theta(\tau_0)$ is a conjugate point of $\theta(0)$ along θ. □

A more intuitive way of obtaining the conclusion of Proposition 3.14 is through variational analysis of α^* using perturbations of the following form. Recall that $\theta(t) = (\theta_1(t), \theta_2(t)) = (t, \pi + t)$, $t \in T = [0, \tau]$, is the curve in $\mathbb{T}^2_0$ that α^* corresponds to. Let $\xi_1 : T \times (-\epsilon, \epsilon) \to \mathbb{R}$ be a *proper variation* of the map $\theta_1 : T \to \mathbb{R}$; i.e., ξ_1 is a smooth map such that $\xi_1(t, 0) = \theta_1(t)$, $\xi_1(0, s) = \theta_1(0)$, $\xi_1(\tau, s) = \theta_1(\tau)$ for $t \in T$ and $s \in (-\epsilon, \epsilon)$, where ϵ is a small positive number. Let $\xi_2 : T \times (-\epsilon, \epsilon) \to \mathbb{R}$ be a proper variation of the map $\theta_2 : T \to \mathbb{R}$. Consider joint maneuvers β_s defined in the (θ_1, θ_2) coordinate by $(\xi_1(\cdot, s), \xi_2(\cdot, s))$ for $s \in (-\epsilon, \epsilon)$, which all start from $\alpha^*(0)$ and end in $\alpha^*(\tau)$. In the braid representation, $\hat\beta_s$ is obtained from $\hat\alpha^*$ by rotating the strings $\hat\alpha_1^*$ and $\hat\alpha_2^*$ by certain angles with respect to the string $\hat\alpha_3^*$ and then realigning the three strings to the origin. β_s is conflict-free if the variations ξ_1 and ξ_2 are small enough. Then, a necessary condition for α^* to be optimal is that the μ-energy of β_s be minimized at $s = 0$ for all possible ξ_1 and ξ_2. After a lengthy calculation, this will lead to the conclusion of Proposition 3.14.

If we consider only conflict-free maneuvers with this particular contact graph, then it is proved in [17] that, after τ passes the critical value $\frac{\sqrt{2}}{2}\pi$, the optimal conflict-free maneuver from $\alpha^*(0)$ to $\alpha^*(\tau)$ bifurcates from α^* into two conflict-free maneuvers with identical energy. Shown in the first row of Figure 3.7 are the plots of α^* for some $\tau > \frac{\sqrt{2}}{2}\pi$. The middle column is its plot in the (θ_1, θ_2) coordinate, and the right column is its braid representation. In the second and third rows, we plot by numerical simulations the two bifurcated optimal conflict-free maneuvers with this contact graph, which in the (θ_1, θ_2) coordinate are the mirror image of each other with respect to the line $\theta_1 - \theta_2 = \frac{\pi}{2}$. For more details on the above claims and the general problem of conjugate points in manifolds with boundary, see [17].

One can also consider $n \geq 3$ agents with equal priorities, which are originally in a straight line with distance between successive agents being R and which rotate at a

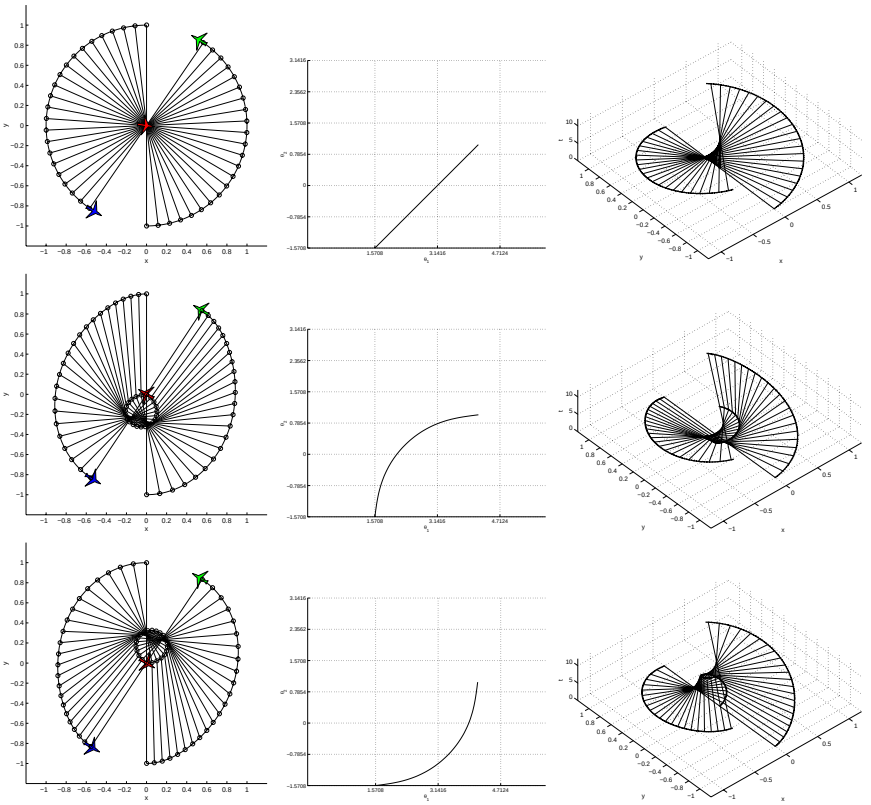

FIG. 3.7. *Bifurcation of minimizing geodesics in* $\mathbb{T}^2$. *Left column:* 3*-maneuvers. Middle column:* (θ_1, θ_2) *phase plots. Right column: braids.*

constant angular velocity around their centroid. This defines a geodesic in a certain submanifold of $\mathbb{R}^{2n}$ as we have discussed before. The maximal angle they can rotate before the first conjugate point of this geodesic is encountered in the submanifold is denoted by τ_n^*. It can be expected that τ_n^* decreases with n. We conjecture that $\tau_n^* = \pi/\sqrt{\frac{n(n-1)}{2} - 1}$. The case $n = 3$ is proved in Proposition 3.14. The cases $n = 4, 5, 6, 7$ are verified symbolically using MAPLE.

It is worthwhile at this point to summarize the optimality conditions we have derived so far. All of them, with the exception of Proposition 3.8 and Proposition 3.14, are *local* in the sense that they can be obtained by using spike-like perturbations in the variational analysis, which only change maneuvers in a neighborhood of a fixed time epoch. Proposition 3.14 is *semiglobal* in that its conclusion can be reached only by perturbations that change maneuvers throughout a subinterval of the encounter with positive length. Proposition 3.8 is the only global one, in the sense that it enables us to compare the performance of maneuvers belonging to different homotopy types.

3.7. Regularity of optimal conflict-free maneuvers. The regularity of optimal conflict-free maneuvers is a tricky issue. For example, it is unknown whether for each optimal α^* there exists a *finite* subdivision of T, $t_0 < t_1 < \cdots < t_m = t_f$, such that the contact graph $G_{\alpha^*}(t)$ remains constant during each subinterval (t_k, t_{k+1}) and contiguous subintervals correspond to different contact graphs. It is proved in [2]

that, in a Euclidean space under the presence of open obstacles with locally analytic boundary, a geodesic can have, in any segment of finite arc length, only a finite number of *switch points* where it switches from an interior segment to a segment on the boundary of an obstacle or vice versa. Unfortunately, this result does not apply in our case, since the obstacle W as defined in Remark 1 has nonsmooth boundary.

On the other hand, it can be proved that an optimal α^* is always C^1; i.e., there are no sharp turns in the optimal conflict-free maneuvers. In fact, this follows from a general result proved in [13], which states that if a manifold M with (nonsmooth) boundary is a subset of $\mathbb{R}^k$ obtained by removing from $\mathbb{R}^k$ a finite union of open convex subsets, each of which has a smooth boundary, then any geodesic of M is of class C^1. Note that the convex subsets are not required to be disjoint for this conclusion. In our case, by Remark 1, the obstacle is the union of $\frac{n(n-1)}{2}$ convex cylinders in $\mathbb{R}^{2n}$.

3.8. Two mechanical analogies. We now give two mechanical analogies of the above results. It should be pointed out that they serve only as analogies to gain more insights into the results obtained, and are not rigorous proofs themselves.

First, consider the following experiment. Instead of n agents, we have n particles of mass $\mu_1, \ldots, \mu_n$ on a horizontal plane with no external forces acting on them. At time t_0, they are at the initial positions $a_1, \ldots, a_n$ with certain initial velocities. Each particle i moves with constant velocity until the distance between it and some other particle j becomes R. Then a rigid rod of zero mass is introduced between particle i and particle j to prevent their distance from further decreasing, and the two particles move together with the rod at velocities determined by the law of conservation of momentum and angular momentum. We refer to the above process where a rigid rod is introduced between two particles as a (two-particle) *join*. There are two types of joins: *tangential* and *nontangential*. A join is tangential if the time derivative of the distance between the two particles at the time of join is zero, otherwise the join is nontangential. It is evident that some kinetic energy is lost for a nontangential join since there is a collision between the two particles along the direction of the rod. As time goes on, more particles can join to form larger groups. In addition to joins, a group of particles connected by rods can *split* at any time, in the sense that some or all of the rods disappear instantly at that time. So when a split occurs, neither the positions nor the velocities of the particles change, but the group separates into several independent subgroups.

It is claimed that by appropriately choosing the initial velocities, time, and order of the joins and splits, one can get from such an experiment the optimal maneuver α^*. In fact, during any time interval I in which there are neither joins nor splits, the system of particles naturally corresponds to a contact graph with edges between vertices representing rods between particles. Moreover, if I is sufficiently small, the motions of the particles correspond to the optimal conflict-free maneuver associated with such a contact graph. To see this, recall that by the principle of least action [3], the motion of the interconnected particles system is an extremal of the action integral $\int_I (E - U)dt$. Here $E = \frac{1}{2}\sum_{i=1}^n \mu_i v_i^2$ represents the kinetic energy, and U is the potential, which is zero by our assumption on the absence of external forces. So, for a sufficiently small time interval I, the motions of the interconnected particles minimize $\frac{1}{2}\sum_{i=1}^n \mu_i \int_I v_i^2 dt$; hence they specify precisely the optimal maneuver over I by definition. Equation (3.15) determines, for example, the motions of three particles connected by two rigid rods with zero masses. For discussions on the general problem of kinematically coupled structures composed of rigid and flexible bodies, see [22] and other references in the same book.

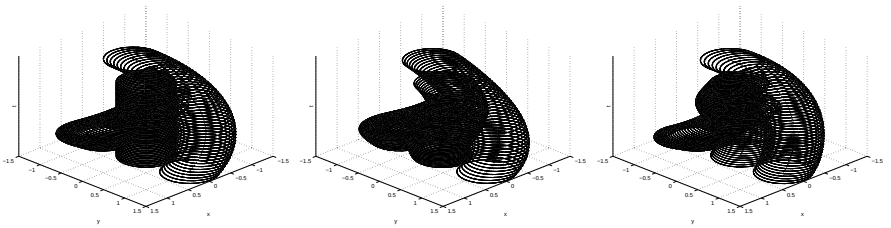

FIG. 3.8. *Examples of elastic (enlarged) braids in equilibrium positions. Left: unstable. Center and right: stable.*

In this mechanical interpretation, the conclusion of Proposition 3.2 is simply the invariance of the motions of a mechanical system with respect to changes of inertial coordinates. Since the total momentum and the total angular momentum of the system are conserved in each time interval with constant configuration (contact graph) and do not change during joins or splits, they are constant during the whole time interval T, which are the conclusions of Corollary 3.5 and Proposition 3.8, respectively. Proposition 3.8 further imposes an upper bound on the total angular momentum, implying that the whole system cannot spin "too fast." In addition, the assertion in section 3.7 that α^* is C^1 implies that all the joins should be tangential; hence there is no kinetic energy lost during joints and splits and the total kinetic energy $\frac{1}{2}\sum_{i=1}^{n}\mu_i v_i^2$ is also conserved, as it is shown in [12] by using a reparameterization operator.

In mechanics, there is a systematic way of using symmetry on the configuration space to reduce the degree of freedom [3, 26]. In our case, the symmetry is $\mathbf{SE}_2$, the group of rigid motions in $\mathbb{R}^2$, acting on $\mathbb{R}^2$. Hence the analysis leading to Corollary 3.5 and Proposition 3.8 (except the bound in Proposition 3.8) is simply the application of the symmetry reduction method uniformly to all the configuration spaces of a system with time-varying configurations. Compared with more advanced techniques such as those based on the Hamiltonian, symplectic, and Poisson viewpoints, our approach, which is Lagrangian in nature, deals with the nonsmoothness of the boundary constraints directly, thus avoiding the trouble of solving for each smooth component of the boundary constraints individually before piecing them together properly to get the final solution. In [16], the corresponding method is generalized to an arbitrary Riemannian manifold with a group of isometries. For application of Lagrangian reduction to holonomic and nonholonomic mechanical systems, see [21].

A major drawback of the above mechanical model is that it is local; hence little insight can be obtained about the global optimality conditions. In this sense, the second model we are going to present is more "faithful" and once again demonstrates the advantage of adopting the braid point of view. As we have shown in section 2, each conflict-free maneuver α of the n agents corresponds to an n-braid $\hat{\alpha}$, whose intersection with any *horizontal* plane $t = \tau$ ($\tau \in T$) consists of n points satisfying the R-separation property. Therefore, if we enlarge the radius of strings in $\hat{\alpha}$ to $R/2$, or more precisely if we think of each of the n strings in $\hat{\alpha}$ as consisting of an infinite number of horizontal disks of radius $R/2$ and height 0 mounting vertically, with each disk confined to move in a fixed horizontal plane $t = t_1$ for some $t_1 \in T$, then the condition that α is conflict-free is equivalent to that the n enlarged strings in $\hat{\alpha}$ do not overlap. Examples of such enlarged braids are shown in Figure 3.8 for the three conflict-free maneuvers in Figure 3.7.

Assume that, for each $i = 1, \ldots, n$, the enlarged string $\hat{\alpha}_i$ in $\hat{\alpha}$ is elastic with

elasticity coefficient μ_i and has a smooth surface so that any two strings can slide along each other without frictions. Under these assumptions, the elastic energy of this n-string system is proportional to the μ-energy of the corresponding conflict-free maneuver. If we fix the strings in $\hat{\alpha}$ at both the bottom ($t = t_0$) and the top ($t = t_f$) horizontal planes and leave free the remaining parts, then for certain choices of α this elastic n-string system will be in an equilibrium (stationary) position. The optimal conflict-free maneuvers have minimal energy, hence necessarily correspond to equilibrium positions.

Suppose that $\hat{\alpha}$ is in an equilibrium position. Pick any disk in $\hat{\alpha}$ that belongs to the string $\hat{\alpha}_i$ and lies on the horizontal plane $t = t_1$ for some $i = 1, \ldots, n$ and $t_0 < t_1 < t_f$. Denote this disk by $D_i(t_1)$. Then $D_i(t_1)$ is subject to two types of forces: forces enacted by disks in the same string that are immediately above and below $D_i(t_1)$, i.e., $D_i(t_1^+)$ and $D_i(t_1^-)$; and forces enacted by disks in the same horizontal plane $t = t_1$ but belonging to different strings, i.e., $D_j(t_1)$ with $j \neq i$. Since $D_i(t_1)$ is confined to move on the plane $t = t_1$, we are concerned with only the projection of the forces onto this plane. The contribution of the forces of the first type is easily seen to be proportional to $\mu_i \ddot{\alpha}_i(t_1)$. As for the forces of the second type, say, the force enacted by disk $D_j(t_1)$ ($j \neq i$) that contacts $D_i(t_1)$, by our assumption of no frictions this force is directed from the center of $D_j(t_1)$ to the center of $D_i(t_1)$, i.e., from $(\alpha_j(t_1), t_1)$ to $(\alpha_i(t_1), t_1)$. Now the conclusion of Proposition 3.13 can be explained as follows. Let $\mathcal{I}$ be a subset of $\{1, \ldots, n\} \setminus \{i\}$ that corresponds to a maximal connected component of the graph obtained by removing node i and all the edges connected with it from the contact graph of α at time t_1. Since $\hat{\alpha}$ is in an equilibrium position, the subsystem $D_{\mathcal{I}}(t_1)$ consisting of disks $D_j(t_1)$ for $j \in \mathcal{I}$ is stationary. So the total moment (torque) of external forces acting on $D_{\mathcal{I}}(t_1)$ is zero, which is exactly the conclusion of Proposition 3.13. Note that here we choose $(\alpha_i(t_1), t_1)$ as the origin and use the fact that torque of forces enacted by $D_i(t_1)$ on disks in $D_{\mathcal{I}}(t_1)$ is zero by our above analysis.

Other optimality conditions can also be explained in this model. For example, the conclusion of Corollary 3.5 is, after differentiation with respect to t twice, simply that on any horizontal plane $t = t_1$, $t_0 < t_1 < t_f$, the combined external forces acting on the subsystem consisting of disks $D_i(t_1)$, $i = 1, \ldots, n$, is zero. For the example in section 3.6, the semiglobal conclusion of Proposition 3.14 can be intuitively understood as that, after a rotation of more than $\frac{\pi}{\sqrt{2}}$, the cumulative force of the two neighboring strings on the central one exceeds the critical value so that the equilibrium position of $\hat{\alpha}^*$ becomes unstable. Any slight perturbation will then render the system to settle in one of the two bifurcated positions with minimal elastic energy (see Figure 3.8), provided that there exists very small but nonzero air frictions to avoid persistent oscillation.

4. Optimal multilegged conflict-free maneuvers. Due to the difficulty in computing analytically the optimal conflict-free maneuver when the number n of agents is greater than two, we now restrict our attention to those maneuvers specified by a set of waypoints, which might well be the only feasible form of joint maneuvers that a central controller can specify to the participating agents in practice.

To be precise, consider n agents with starting position $\mathbf{a} = (a_1, \ldots, a_n)$ and destination position $\mathbf{b} = (b_1, \ldots, b_n)$. Assume that a set of epochs $\{t_j\}_{j=0}^m$, $t_0 < t_1 < \cdots < t_{m-1} < t_m = t_f$, where m is a positive integer, has been fixed. For each agent i, choose a set of waypoints $\{c_{i,j}\}_{j=0}^m$ in $\mathbb{R}^2$ such that $c_{i,0} = a_i$ and $c_{i,m} = b_i$. Then, an *m-legged maneuver* of agent i is a maneuver consisting of m stages, where at each

stage $j \in \{0, 1, \ldots, m-1\}$ agent i starts from $c_{i,j}$ at time t_j and reaches $c_{i,j+1}$ at time t_{j+1} with constant velocity. Denote by $\mathbf{P}_i^m$ the set of all m-legged maneuvers of agent i and by $\mathbf{P}^m(\mathbf{a}, \mathbf{b}) = \prod_{i=1}^n \mathbf{P}_i^m$ the set of all m-legged joint maneuvers. In the braid representation, an m-legged joint maneuver corresponds to n strings, each one consisting of m line segments pieced together. The set of *m-legged conflict-free maneuvers* consists of all elements of $\mathbf{P}^m(\mathbf{a}, \mathbf{b})$ with MSE at least R and is denoted by $\mathbf{P}^m(R, \mathbf{a}, \mathbf{b})$.

In this section, we shall try to solve the following version of problem (3.4):

$$\text{minimize } J_\mu(\alpha) \text{ subject to } \alpha \in \mathbf{P}^m(R, \mathbf{a}, \mathbf{b}). \tag{4.1}$$

By using similar arguments, one can show that some of the optimality conditions in section 3, such as Corollary 3.5, still apply for solutions to problem (4.1). In general, a solution to problem (4.1) is only suboptimal for problem (3.4).

4.1. Optimal 2-legged conflict-free maneuver for two agents. We start from the simplest case when $n = 2$ and $m = 2$. Consider two agents with starting position $\mathbf{a} = (a_1, a_2)$ and destination position $\mathbf{b} = (b_1, b_2)$. Let $\alpha = (\alpha_1, \alpha_2)$ be a 2-legged conflict-free maneuver in $\mathbf{P}^2(R, \mathbf{a}, \mathbf{b})$ with three waypoints $c_{i,j}$, $j = 0, 1, 2$, for each agent $i = 1, 2$. Since $c_{i,0} = a_i$ and $c_{i,2} = b_i$ are fixed for each agent i, the middle waypoints $c_{i,1}$ will be denoted by c_i to simplify the notation. Let $t_c \in (t_0, t_f)$ be the epoch corresponding to the middle waypoints. Then, the motions of the two agents are described by

$$\alpha_i(t) = \begin{cases} a_i + (c_i - a_i)\frac{t-t_0}{t_c-t_0}, & t_0 \le t \le t_c, \\ b_i + (c_i - b_i)\frac{t-t_f}{t_c-t_f}, & t_c \le t \le t_f, \end{cases} \quad i = 1, 2.$$

After some calculations, the μ-energy of a maneuver $\alpha \in \mathbf{P}^2(\mathbf{a}, \mathbf{b})$ as the function of c_1 and c_2 can be expressed as follows:

$$J_\mu(\alpha) = \frac{t_f - t_0}{(t_f - t_c)(t_c - t_0)}[\mu_1 \|c_1 - c_1^u\|^2 + \mu_2 \|c_2 - c_2^u\|^2] + C, \tag{4.2}$$

where C is a constant and c_i^u, $i = 1, 2$, are defined by

$$c_i^u = \frac{(t_f - t_c)a_i + (t_c - t_0)b_i}{t_f - t_0}, \quad i = 1, 2. \tag{4.3}$$

Note that c_1^u and c_2^u are the optimal waypoints when minimizing $J_\mu(\alpha)$ without the MSE constraint. In the braid representation, c_1^u and c_2^u correspond to the intersections of the plane $t = t_c$ with the lines joining (a_i, t_0) to (b_i, t_f) for $i = 1$ and 2, respectively.

The MSE constraint can be simplified as well. The minimal distance d_l between the two agents during the time interval $[t_0, t_c]$ is given by

$$d_l = \begin{cases} \|c_1 - c_2\| & \text{if } \lambda < -\|c_1 - c_2 - a_1 + a_2\|^2, \\ \sqrt{\|a_1 - a_2\|^2 - \lambda^2/\|c_1 - c_2 - a_1 + a_2\|^2} & \text{if } -\|c_1 - c_2 - a_1 + a_2\|^2 \le \lambda \le 0, \\ \|a_1 - a_2\| & \text{if } \lambda > 0, \end{cases}$$

where $\lambda \triangleq (a_1 - a_2)^T(c_1 - c_2 - a_1 + a_2)$. Note that d_l is a function of the relative positions $a_1 - a_2$ and $c_1 - c_2$ only and is independent of the epoch t_c. We then use $d_l(a_1 - a_2, c_1 - c_2)$ to denote it explicitly. Similarly, the minimum distance between the two agents during the time interval $[t_c, t_f]$ is $d_l(c_1 - c_2, b_1 - b_2)$.

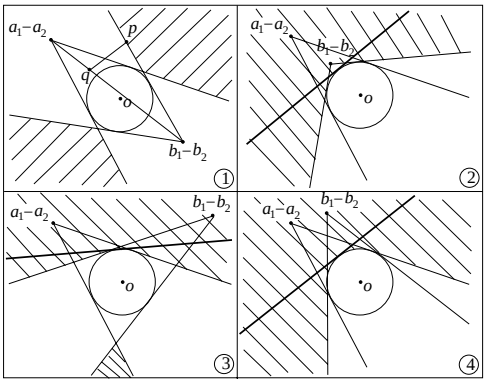

FIG. 4.1. *The four configurations of the feasible set A for $c_1 - c_2$.*

For α to be a conflict-free maneuver, both $d_l(a_1 - a_2, c_1 - c_2)$ and $d_l(c_1 - c_2, b_1 - b_2)$ have to be at least R, yielding two constraints on $c_1 - c_2$. Depending on the relative position of $a_1 - a_2$ and $b_1 - b_2$, the feasible set A for $c_1 - c_2$ has four possible configurations, which are numbered from 1 to 4 and represented by shaded regions in Figure 4.1. Notice that A consists of two connected components in configurations 1 and 3, which correspond to the two fundamental types of conflict-free maneuvers. In configurations 2 and 4, however, only one fundamental type can be achieved by 2-legged maneuvers.

Remark 5. The feasible set A for $c_1 - c_2$ can be characterized as the subset of $\mathbb{R}^2$ consisting of all those points that are "visible" to both $a_1 - a_2$ and $b_1 - b_2$ in the presence of the open disk $B(0, R)$ as an obstacle. In fact, by applying an appropriate tilt operator $\mathcal{T}_w$ that preserves the MSE and $c_1 - c_2$, one can assume that $c_2 = a_2$, i.e., agent 2 stays at a_2 during $[t_0, t_c]$. Thus the MSE constraint during $[t_0, t_c]$ is equivalent to the constraint that the line segment from a_1 to c_1 does not intersect $B(a_2, R)$, or alternatively, the line segment from $a_1 - a_2$ to $c_1 - c_2$ does not intersect $B(0, R)$. Similar arguments apply to the second stage of α.

As a result of the above simplifications, problem (4.1) is reduced to

$$\text{minimize } \mu_1\|c_1 - c_1^u\|^2 + \mu_2\|c_2 - c_2^u\|^2 \text{ subject to } c_1 - c_2 \in A. \tag{4.4}$$

THEOREM 4.1. *Define $q \triangleq c_1^u - c_2^u = \frac{t_f - t_c}{t_f - t_0}(a_1 - a_2) + \frac{t_c - t_0}{t_f - t_0}(b_1 - b_2)$. Let p be a point in A at minimum distance from q. An optimal solution to problem* (4.4) *is then given by*

$$c_1^* = \mu_1 c_1^u + \mu_2 c_2^u + \mu_2 p, \quad c_2^* = \mu_1 c_1^u + \mu_2 c_2^u - \mu_1 p.$$

Moreover, if problem (4.4) *is restricted to one of the two fundamental types of conflict-free maneuvers that is achievable by 2-legged maneuvers, then c_1^* and c_2^* are unique.*

Proof. Set $\Delta c = c_1 - c_2$. Then we have

$$\begin{aligned}
&\min\{\mu_1\|c_1 - c_1^u\|^2 + \mu_2\|c_2 - c_2^u\|^2 : c_1, c_2 \text{ such that } \Delta c \in A\} \\
&\quad = \min_{\Delta c \in A} \min_{c_2} \{\mu_1\|c_2 + \Delta c - c_1^u\|^2 + \mu_2\|c_2 - c_2^u\|^2\} \\
&\quad = \min_{\Delta c \in A} \min_{c_2} \{\|c_2 - \mu_1(c_1^u - \Delta c) - \mu_2 c_2^u\|^2 + \mu_1\mu_2\|c_1^u - c_2^u - \Delta c\|^2\} \\
&\quad = \min_{\Delta c \in A} \mu_1\mu_2\|q - \Delta c\|^2 \\
&\quad = \mu_1\mu_2\|q - p\|^2,
\end{aligned}$$

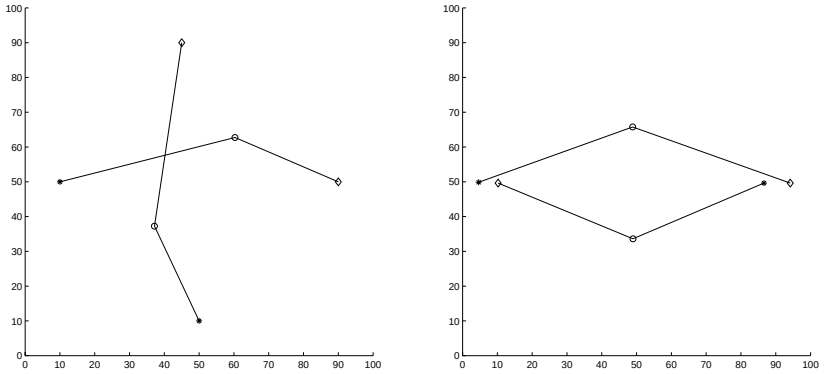

FIG. 4.2. 2-*legged optimal conflict-free maneuvers for* 2-*agent encounters* ($\mu_1 = \mu_2 = 0.5$, $R = 30$).

where the last two equalities follow by choosing $c_2 = \mu_1(c_1^u - \Delta c) + \mu_2 c_2^u$ and $\Delta c = p$. Together they imply the desired expressions of c_1^* and c_2^*. The uniqueness of c_1^* and c_2^* given a particular fundamental type is a consequence of the fact that p is unique, since either the connected component of A corresponding to that type is convex, or q is contained in it since it lies on the line segment connecting $a_1 - a_2$ to $b_1 - b_2$. □

Note that in configurations 2, 3, and 4, $p = q$ since q lies on the line segment connecting $a_1 - a_2$ and $b_1 - b_2$ that is contained entirely in A. Hence c_1^* and c_2^* are equal to c_1^u and c_2^u, respectively. In configuration 1, the set A is the union of two disjoint convex sets, so there might be up to two points in A nearest to q, with two being the case when there is an exact collision for the unconstrained optimal joint maneuver. In this case, we can choose either of the two points as p.

Figure 4.2 shows the optimal 2-legged conflict-free maneuvers for some typical 2-agent encounters when the agents have equal priorities. In each plot, the starting points are marked with stars and the ending points with diamonds. The circles are the waypoints specified by Theorem 4.1.

4.2. Optimal 2-legged conflict-free maneuver for multiple agents. Consider the case $m = 2$ and $n \geq 3$. Roughly speaking, the nature of problem (4.1) is mainly combinatorial in that the major task is to choose the type of conflict-free maneuvers in which one can find the optimal solution. In this section, we deal only with the problem of finding the optimal conflict-free maneuver within a *given* type. We postpone to section 4.4 the discussion on how to choose the maneuver type.

Fix $t_c \in (t_0, t_f)$ and denote by A_{ij} the feasible set for $c_i - c_j$ when only the agent pair (i, j) is present. A_{ij} is computed as set A in the last subsection with a_i, b_i, a_j, b_j in the place of a_1, b_1, a_2, b_2. Suppose that we have chosen a type of conflict-free maneuver. Then, the problem is to find the waypoints $c_1, \ldots, c_n$ that

$$\text{minimize } \sum_{i=1}^{n} \mu_i \|c_i - c_i^u\|^2 \text{ subject to } c_i - c_j \in A_{ij}^{\pm}, \quad 1 \leq i < j \leq n, \tag{4.5}$$

where c_i^u is defined as in (4.3) for $i = 1, \ldots, n$, and $A_{ij}^{\pm}$ denotes the connected component of the set A_{ij} matching the desired type. Note that only a finite subset of types of conflict-free maneuvers can be represented in this way, and we assume that the given type belongs to this subset.

Notice that in all but the first configuration shown in Figure 4.1 representing

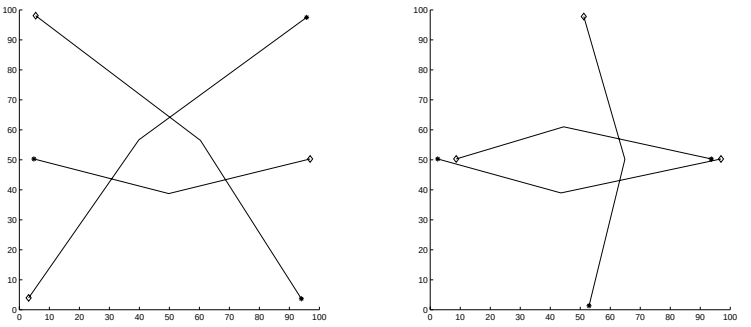

FIG. 4.3. *Globally optimal* 2*-legged conflict-free* 3*-maneuvers* ($\mu_1 = \mu_2 = 0.5, R = 20$).

A_{ij} for $i = 1$ and $j = 2$, one of the connected components of A_{ij} is nonconvex, posing a great challenge for the efficient solution of problem (4.5). Therefore, in configurations 2, 3, and 4, we linearize the nonconvex component of A_{ij} by using a half-space inner approximation, as it is shown in Figure 4.1 by the black lines tangential to the boundary of $B(0, R)$. The choice of the black line may not be unique, and one should ensure that the inner approximated feasible region of $c_i - c_j$ contains the unconstrained optimal value $c_i^u - c_j^u$.

Remark 6. Problem (4.5) is a linearly constrained convex optimization problem in the special case when any pair of agents is in the first configuration, i.e., when the unconstrained optimal joint maneuver will cause a conflict between any pair of agents. Therefore, our linear approximation scheme is tight for the most critical encounters.

After the linearization, if necessary, we have a linearly constrained quadratic optimization problem that can be solved efficiently. In the case when the number of agents is relatively small, we can afford the luxury of running the optimization algorithm for each type achievable by 2-legged maneuvers so as to find the globally optimal 2-legged conflict-free maneuver. Simulation results using MATLAB are shown in Figure 4.3 for two 3-agent encounters. In both cases, each pair of agents is in the first configuration, so linearizations are not necessary and the obtained maneuvers are actually the globally optimal 2-legged conflict-free maneuvers.

4.3. Optimal m-legged conflict-free maneuver for multiple agents. The algorithm described in section 4.2 can be used in an iterative way in the general case when the number m of legs is greater than two. Fix a set of epochs $t_0 < t_1 < \cdots < t_{m-1} < t_m = t_f$. A necessary condition for a set of waypoints $c_{i,j}$, $i = 1, \ldots, n$, $j = 0, \ldots, m$, with $c_{i,0} = a_i$, $c_{i,m} = b_i$, to be an optimal solution to problem (4.1) is that

$$c_{i,j} = c_i^*((c_{1,j-1}, \ldots, c_{n,j-1}), (c_{1,j+1}, \ldots, c_{n,j+1}), t_{j-1}, t_j, t_{j+1}) \tag{4.6}$$

for $1 \le j \le m - 1$. Here $c_i^*((c_{1,j-1}, \ldots, c_{n,j-1}), (c_{1,j+1}, \ldots, c_{n,j+1}), t_{j-1}, t_j, t_{j+1})$ denotes the waypoint of agent i for the optimal 2-legged maneuver when the starting and destination positions of the agents are $(c_{1,j-1}, \ldots, c_{n,j-1})$ and $(c_{1,j+1}, \ldots, c_{n,j+1})$, and the starting, middle, and ending epochs are t_{j-1}, t_j, t_{j+1}, respectively. This condition inspires the following algorithm.

ALGORITHM 1.

1. *Pick any feasible set of waypoints* $c_{i,j}^{(0)}$, $1 \le i \le n$, $0 \le j \le m$, *such that* $c_{i,0}^{(0)} = a_i, c_{i,m}^{(0)} = b_i$ *for* $1 \le i \le n$ *and such that the MSE constraint is*

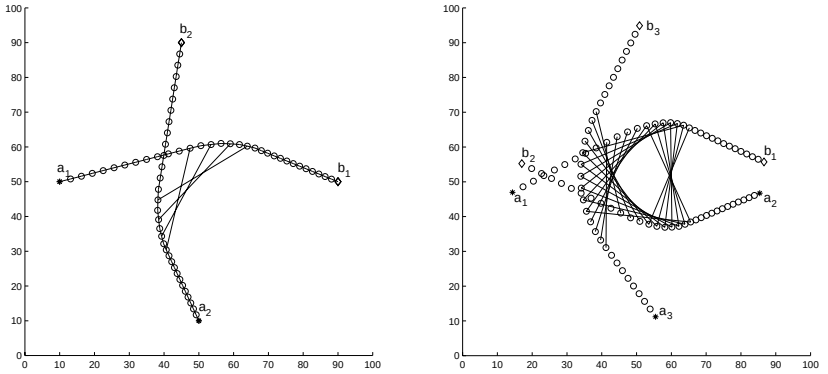

FIG. 4.4. *Simulation results of Algorithm* 1 *for two and three agents encounters* ($R = 30$).

satisfied over T.

2. *For* $j = 1, \ldots, m-1$ *compute for* $i = 1, \ldots, n$

$$c_{i,j}^{(k+1)} = c_i^*((c_{1,j-1}^{(k)}, \ldots, c_{n,j-1}^{(k)}), (c_{1,j+1}^{(k)}, \ldots, c_{n,j+1}^{(k)}), t_{j-1}, t_j, t_{j+1}).$$

3. *Repeat procedure* 2 *with* $k := k + 1$ *until the decrease in* μ*-energy is below some threshold* ε.

It is easily seen that the μ-energy of the conflict-free maneuvers obtained by Algorithm 1 is nonincreasing as a function of the iteration number k and is strictly decreasing whenever condition (4.6) is not satisfied. Therefore, the iteration procedure converges asymptotically to a conflict-free maneuver satisfying condition (4.6). A convergence analysis of Algorithm 1 is yet to be achieved. Besides the issue of local minima suggested by the example in section 3.6, the situation is further complicated by the fact that the convex optimization procedure introduced in section 4.2 yields only an approximation of c_i^*. Another open issue is the suboptimality of optimal m-legged maneuvers in $\mathbf{P}^m(R, \mathbf{a}, \mathbf{b})$ with respect to optimal solutions in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$. Although in theory the performance gap decreases to zero as $m \to \infty$, in practice, it is not easy to quantify the performance degradation for a finite m.

In Figure 4.4, some simulation results for Algorithm 1 when the agents have identical priorities and $R = 30$ are shown. The epochs are chosen to evenly divide $[t_0, t_f]$, and the corresponding waypoints are marked with small circles. In the plots, whenever two agents are at distance R, their positions are joined by a line segment. Note that the result shown in the left figure is a good approximation to the optimal maneuvers plotted in Figure 3.3.

4.4. Randomized optimization. In [12, 34], a decentralized algorithm for multi-agent conflict resolution is proposed in the context of ATC. By modeling the agent motion as a Brownian motion with drift, the probability of conflict between two agents is estimated and then used to generate repulsive forces between the agents, inspired by the potential and vortex field methodology for path planning [27, 36]. Compared with traditional potential field methods that use only the positions of the agents, this algorithm considers also their headings and speeds, and hence generates maneuvers with less abrupt turns.

Although the stochastic algorithm can be run in real time regardless of the number n of agents involved, one of its drawbacks is that absolute safety cannot be guaranteed with probability one. On the other hand, the convex optimization algorithm we

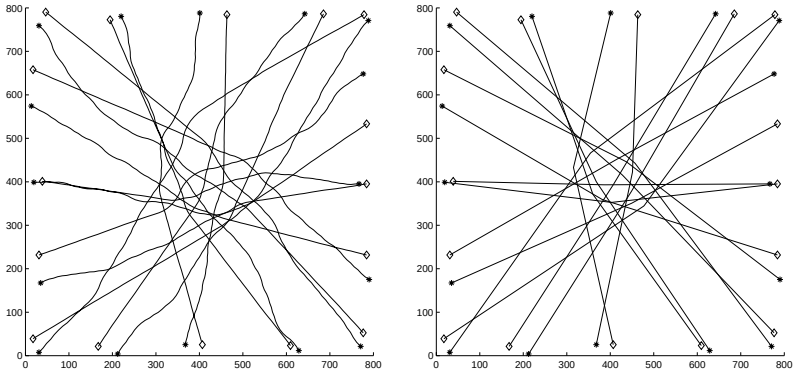

FIG. 4.5. 16-*maneuvers generated by stochastic (left) and convex optimization algorithms (right).*

propose in this paper can ensure absolute safety, but it cannot handle the explosively increasing number of types when n is large. We then suggest a solution that combines the positive features of these two algorithms; hence it both guarantees safety and is computationally feasible. The proposed algorithm uses the stochastic algorithm as the random "type chooser." More specifically, for a given multi-agent encounter, first the stochastic algorithm is run to generate a joint maneuver corresponding to a particular type, and then the convex optimization algorithm is utilized to obtain an approximation of the optimal multilegged maneuver within the type selected by the stochastic algorithm.

Simulation results for a 16-agent symmetric encounter are shown in Figure 4.5, in which 16 agents with identical priorities pass approximatively through a common point at angles evenly distributed in $[0, 2\pi]$ and $R = 30$. The one on the left is the joint maneuver generated by the stochastic algorithm, whereas the one on the right is the optimal 2-legged conflict-free maneuver within this type generated by the convex optimization algorithm.

Remark 7. When the number of agents is small, say, $n = 2, 3$, experiments show that the stochastic algorithm tends to choose with higher probability those types with lower μ-energy. However, when n is large, such as in the previous example, it is hard to evaluate the performance of the randomized algorithm, since currently no theoretical result exists that can exhaust the explosively increasing number of resolution types and find the optimal one (or ones). Much more work is needed in this respect.

5. Conclusions and future directions. In this paper, the problem of optimal coordinated motion planning for multiple agents moving on a plane is studied. After a classification of the homotopy types of conflict-free maneuvers, a weighted energy is proposed as the cost function to select the optimal one. Various local and global optimality conditions are derived. For 2-agent encounters, analytical solutions are obtained both for the optimal continuous and piecewise-C^2 maneuvers and the optimal 2-legged maneuvers. For the general multi-agent case, a randomized convex optimization algorithm is proposed to find the optimal multilegged maneuvers numerically.

To completely characterize the optimal conflict-free maneuvers, many issues remain to be solved. The results in this paper could serve as a good starting point. Possible directions of future research include the analysis of the proposed numerical algorithm in terms of its performance and its robustness with respect to uncertainty

on the agents' positions and velocities and the study of more realistic (and more complicated) models for the agent dynamics than the kinematic one adopted in this paper. Some contribution in this direction can be found in [15], which focuses exclusively on air traffic management systems.

Appendix A. Proof of Proposition 3.8. Consider first the case when $s = 0$. For each $\alpha \in \mathbf{P}(R, \mathbf{a}, \mathbf{b})$, let $\beta = \mathcal{R}^0_\theta(\alpha)$. Then

$$\dot{\beta}_i(t) = T_{\theta(t)}\dot{\alpha}_i(t) + \frac{d}{dt}T_{\theta(t)}\alpha_i(t) = T_{\theta(t)}\dot{\alpha}_i(t) + \dot{\theta}(t)T_{\frac{\pi}{2}+\theta(t)}\alpha_i(t), \quad i = 1, \dots, n.$$

Since $T_{\theta(t)}$ and $T_{\frac{\pi}{2}+\theta(t)}$ are orthonormal matrices and $T^T_{\frac{\pi}{2}+\theta(t)} = T_{-\frac{\pi}{2}-\theta(t)}$, we have

$$\|\dot{\beta}_i(t)\|^2 = \|\dot{\alpha}_i(t)\|^2 + \|\alpha_i(t)\|^2|\dot{\theta}(t)|^2 + 2\dot{\theta}(t)\alpha_i^T(t)T_{-\frac{\pi}{2}}\dot{\alpha}_i(t), \quad i = 1, \dots, n.$$

Integrating and summing over i, we can write the cost difference $\Delta J_\mu(\theta)$ as

$$\Delta J_\mu(\theta) = J_\mu(\beta) - J_\mu(\alpha) = \int_{t_0}^{t_f} [f(t)|\dot{\theta}(t)|^2 + 2g(t)\dot{\theta}(t)]dt, \tag{A.1}$$

where f and g are functions defined by

$$f(t) \triangleq \frac{1}{2}\sum_{i=1}^{n} \mu_i \|\alpha_i(t)\|^2, \quad g(t) \triangleq \frac{1}{2}\sum_{i=1}^{n} \mu_i \alpha_i^T(t)T_{-\frac{\pi}{2}}\dot{\alpha}_i(t) \qquad \forall t \in T. \tag{A.2}$$

Note that we use the notation $\Delta J_\mu(\theta)$ to indicate that it is a function of θ. We next compute the optimal twist θ^* such that $\Delta J_\mu(\theta)$ is minimized. θ is subject to the constraint that $\theta(t_0) = 0$, $\theta(t_f) = 2k\pi$ for some *fixed* $k \in \mathbb{Z}$. For $\dot{\theta}$, this translates into $\int_{t_0}^{t_f} \dot{\theta}(t)dt = 2k\pi$. We can then write the Lagrangian function for this problem as

$$\begin{aligned}\mathcal{L}(\theta, \lambda) &\triangleq \Delta J_\mu(\theta) + \lambda\left[\int_{t_0}^{t_f} \dot{\theta}(t)dt - 2k\pi\right] \\ &= \int_{t_0}^{t_f} \left\{ f(t)\left[\dot{\theta}(t) + \frac{g(t) + \frac{\lambda}{2}}{f(t)}\right]^2 - \frac{[g(t) + \frac{\lambda}{2}]^2}{f(t)} \right\} dt - 2\lambda k\pi.\end{aligned}$$

Thus $\dot{\theta}^*(t) = -[g(t) + \lambda^*/2]/f(t)$ where, since $\int_{t_0}^{t_f} \dot{\theta}(t)dt = 2k\pi$, λ^* is given by

$$\lambda^* = -2\left[\int_{t_0}^{t_f} \frac{g(t)}{f(t)}dt + 2k\pi\right] \Big/ \int_{t_0}^{t_f} \frac{1}{f(t)}dt.$$

Then, we have the following expression for $\dot{\theta}^*(t)$:

$$\dot{\theta}^*(t) = -\frac{g(t)}{f(t)} + \left[\int_{t_0}^{t_f} \frac{g(t)}{f(t)}dt + 2k\pi\right] \Big/ \left[f(t)\int_{t_0}^{t_f} \frac{1}{f(t)}dt\right].$$

Substituting this into (A.1), we get the minimal $\Delta J_\mu(\theta)$:

$$\Delta J_\mu(\theta^*) = \left[\int_{t_0}^{t_f} \frac{g(t)}{f(t)}dt + 2k\pi\right]^2 \Big/ \int_{t_0}^{t_f} \frac{1}{f(t)}dt - \int_{t_0}^{t_f} \frac{g^2(t)}{f(t)}dt.$$

If $\alpha = \alpha^*$ is an optimal maneuver, then $\Delta J_\mu(\theta^*) \geq 0$. Hence,

$$\left[\int_{t_0}^{t_f} \frac{g(t)}{f(t)}dt + 2k\pi\right]^2 \geq \int_{t_0}^{t_f} \frac{1}{f(t)}dt \cdot \int_{t_0}^{t_f} \frac{g^2(t)}{f(t)}dt. \tag{A.3}$$

In the case when $k = 0$, the equality holds in (A.3) since the lower bound $\Delta J_\mu(\theta^*) \geq 0$ can be strictly achieved by choosing $\theta^*(t) \equiv 0$. Therefore,

$$\left[\int_{t_0}^{t_f} \frac{g(t)}{f(t)}dt\right]^2 = \int_{t_0}^{t_f} \frac{1}{f(t)}dt \cdot \int_{t_0}^{t_f} \frac{g^2(t)}{f(t)}dt.$$

Applying the Cauchy–Schwarz inequality to functions $1/\sqrt{f(t)}$ and $g(t)/\sqrt{f(t)}$, we have that the above equality holds if and only if $g(t)/\sqrt{f(t)} = C/\sqrt{f(t)}$ for some constant C, i.e., if and only if $g(t) \equiv C$. In this case, (A.3) degenerates into

$$(Cz + 2k\pi)^2 \geq C^2 z^2 \qquad \forall k \in \mathbb{Z},$$

where $z = \int_{t_0}^{t_f} 1/f(t)dt$, or equivalently $k\pi Cz + k^2\pi^2 \geq 0$ for all $k \in \mathbb{Z}$. This is possible if and only if $-\pi \leq Cz \leq \pi$, thus completing the proof for the case $s = 0$.

The general case when $s \neq 0$ can be reduced to the above case by first noticing that the optimality of α^* in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ implies the optimality of $\alpha^* - s = (\alpha_1^* - s, \ldots, \alpha_n^* - s)$ in $\mathbf{P}(R, \mathbf{a} - s, \mathbf{b} - s)$ and then applying the results proved for the case $s = 0$ to the optimal maneuver $\alpha^* - s$.

Appendix B. Geometry of $\mathbb{T}^2$ under metric g. In section 3.6, we define a Riemannian metric g on the 2-torus $\mathbb{T}^2$. Here we will derive some useful quantities characterizing its geometry.

At each point $(\theta_1, \theta_2) \in \mathbb{T}^2$, a basis $\frac{\partial}{\partial\theta_1}$ and $\frac{\partial}{\partial\theta_2}$ of the tangent space of $\mathbb{T}^2$ is mapped by the differential of the coordinate map f defined in (3.16) to

$$\begin{cases} df(\frac{\partial}{\partial\theta_1}) = \frac{1}{3}(-2\sin\theta_1, 2\cos\theta_1, \sin\theta_1, -\cos\theta_1, \sin\theta_1, -\cos\theta_1)^T, \\ df(\frac{\partial}{\partial\theta_2}) = \frac{1}{3}(\sin\theta_2, -\cos\theta_2, -2\sin\theta_2, 2\cos\theta_2, \sin\theta_2, -\cos\theta_2)^T, \end{cases} \tag{B.1}$$

which is a basis of the tangent space of Q at $f(\theta_1, \theta_2)$. Here we have identified the tangent space of $\mathbb{R}^6$ at $f(\theta_1, \theta_2)$ with $\mathbb{R}^6$ itself, and the tangent space of Q at $f(\theta_1, \theta_2)$ becomes a subspace of $\mathbb{R}^6$. The standard metric of $\mathbb{R}^6$ induces by f isometrically the metric g on $\mathbb{T}^2$ of the form

$$g = \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix} = \frac{1}{3}\begin{bmatrix} 2 & -\cos(\theta_1 - \theta_2) \\ -\cos(\theta_1 - \theta_2) & 2 \end{bmatrix}, \tag{B.2}$$

where $g_{ij} \triangleq \langle \frac{\partial}{\partial\theta_i}, \frac{\partial}{\partial\theta_j} \rangle$ for $i = 1, 2$, $j = 1, 2$. The inverse of g can be written as

$$g^{-1} = \begin{bmatrix} g^{11} & g^{12} \\ g^{21} & g^{22} \end{bmatrix} = \frac{3}{4 - \cos^2(\theta_1 - \theta_2)}\begin{bmatrix} 2 & \cos(\theta_1 - \theta_2) \\ \cos(\theta_1 - \theta_2) & 2 \end{bmatrix}.$$

The covariant derivative ∇ of $\mathbb{T}^2$ with respect to the Levi–Civita connection is defined by [8]

$$\nabla_{\frac{\partial}{\partial\theta_i}} \frac{\partial}{\partial\theta_j} = \sum_{m=1}^{2} \Gamma_{ij}^m \frac{\partial}{\partial\theta_m} \qquad \forall 1 \leq i, j \leq 2,$$

where Γ_{ij}^m, $1 \le i, j, m \le 2$, are the *Christoffel symbols* that can be computed by

$$\Gamma_{ij}^m = \frac{1}{2}\sum_{k=1}^{2}\left\{\frac{\partial g_{jk}}{\partial \xi_i} + \frac{\partial g_{ki}}{\partial \xi_j} - \frac{\partial g_{ij}}{\partial \xi_k}\right\} g^{km}, \qquad 1 \le i, j, m \le 2.$$

It is easy to verify that

$$\Gamma_{11}^1 = -\Gamma_{22}^2 = \frac{\sin(\theta_1-\theta_2)\cos(\theta_1-\theta_2)}{4-\cos^2(\theta_1-\theta_2)}, \qquad \Gamma_{11}^2 = -\Gamma_{22}^1 = \frac{2\sin(\theta_1-\theta_2)}{4-\cos^2(\theta_1-\theta_2)},$$

and $\Gamma_{12}^m = \Gamma_{21}^m = 0$ for $m = 1, 2$. The equations for geodesics in $\mathbb{T}^2$ are $\ddot{\xi}_k + \sum_{i,j}\Gamma_{ij}^k \dot{\xi}_i \dot{\xi}_j = 0$, $k = 1, 2$, which yield

$$\begin{aligned}
[4-\cos^2(\theta_1-\theta_2)]\ddot{\theta}_1 &= -\sin(\theta_1-\theta_2)\cos(\theta_1-\theta_2)(\dot{\theta}_1)^2 + 2\sin(\theta_1-\theta_2)(\dot{\theta}_2)^2,\\
[4-\cos^2(\theta_1-\theta_2)]\ddot{\theta}_2 &= -2\sin(\theta_1-\theta_2)(\dot{\theta}_1)^2 + \sin(\theta_1-\theta_2)\cos(\theta_1-\theta_2)(\dot{\theta}_2)^2.
\end{aligned}$$

The above equations are readily seen to be equivalent to (3.17).

Next, we will compute the curvature of $\mathbb{T}^2$. Let R be the curvature tensor of $\mathbb{T}^2$. Let R_{ijkl} be its value in basis $\frac{\partial}{\partial\theta_1}, \frac{\partial}{\partial\theta_2}$ defined by [8]

$$\begin{aligned}
R_{ijkl} &\triangleq \left\langle R\left(\frac{\partial}{\partial\theta_i}, \frac{\partial}{\partial\theta_j}\right)\frac{\partial}{\partial\theta_k}, \frac{\partial}{\partial\theta_l}\right\rangle\\
&= \left\langle \left(\nabla_{\frac{\partial}{\partial\theta_j}}\nabla_{\frac{\partial}{\partial\theta_i}} - \nabla_{\frac{\partial}{\partial\theta_i}}\nabla_{\frac{\partial}{\partial\theta_j}} + \nabla_{[\frac{\partial}{\partial\theta_i}, \frac{\partial}{\partial\theta_j}]}\right)\frac{\partial}{\partial\theta_k}, \frac{\partial}{\partial\theta_l}\right\rangle
\end{aligned}$$

for all $1 \le i, j, k, l \le 2$. Then $R_{ijkl} = \sum_{s=1}^{2} R_{ijk}^s g_{sl}$, where R_{ijk}^s can be computed by

$$R_{ijk}^s = \sum_{m=1}^{2}\Gamma_{ik}^m\Gamma_{jm}^s - \sum_{m=1}^{2}\Gamma_{jk}^m\Gamma_{im}^s + \frac{\partial}{\partial\theta_j}\Gamma_{ik}^s - \frac{\partial}{\partial\theta_i}\Gamma_{jk}^s.$$

In our case, calculation shows that

$$R_{121}^1 = R_{122}^2 = \frac{-3\cos^2(\theta_1-\theta_2)}{[4-\cos^2(\theta_1-\theta_2)]^2}, \qquad R_{121}^2 = R_{122}^1 = \frac{-6\cos(\theta_1-\theta_2)}{[4-\cos^2(\theta_1-\theta_2)]^2},$$

and $R_{21k}^s = -R_{12k}^s$, $R_{11k}^s = R_{22k}^s = 0$ for all $1 \le k, s \le 2$. Hence,

$$R_{1212} = \frac{-\cos(\theta_1-\theta_2)}{4-\cos^2(\theta_1-\theta_2)}.$$

Therefore, the sectional curvature of $\mathbb{T}^2$ is

$$K = \frac{R_{1212}}{g_{11}g_{22} - g_{12}^2} = \frac{-9\cos(\theta_1-\theta_2)}{[4-\cos^2(\theta_1-\theta_2)]^2}. \tag{B.3}$$

K depends only on $\theta_1 - \theta_2$ since the map $(\theta_1, \theta_2) \mapsto (\theta_1 + \xi, \theta_2 + \xi) \bmod 2\pi$ is an isometry of $\mathbb{T}^2$ for each ξ. In the special case when $\theta_1 - \theta_2 = \pi$, we have $K = 1$. For further analysis, see [17].

Acknowledgment. The first author would like to thank Alan Weinstein for his insightful comments and discussions on the results of this paper.

EXISTENCE OF OPTIMAL CONTROLS FOR A GENERAL CLASS OF IMPULSIVE SYSTEMS ON BANACH SPACES*

N. U. AHMED†

Abstract. This paper presents some results on the question of existence of optimal controls for a large class of semilinear impulsive systems in infinite dimensional spaces with admissible controls from the space of vector measures. This also includes, as a special case, the class of purely impulsive controls. Two physical examples are presented for illustration.

Key words. impulsive systems, Banach spaces, vector measures, optimal control, existence

1. Introduction.

In this paper we present some results on existence of optimal controls for systems governed by nonlinear impulsive evolution equations on Banach spaces. The general description of such systems was proposed in [1, 2, 3] as given below:

$$dx = Axdt + f(t,x)dt + g(t,x)\nu(dt) + C(t,x)u(dt), \qquad t \in I, \tag{1}$$

$$x(0) = x_0. \tag{2}$$

In general the operator A is the infinitesimal generator of a C_0-semigroup in a Banach space E, f and g are nonlinear operators mapping $I \times E$ to E, ν is a countably additive bounded signed measure on I, C is an operator valued function mapping $I \times E$ into $\mathcal{L}(F,E)$, and u is an F-valued vector measure representing the control.

This model includes all the standard models used by many authors in the field [9, 10, 11, 12, 13, 14] (including the references therein). It also includes the models considered in [1, 2, 4, 5, 6]. Inclusion of delay in our model by considering f as a functional mapping $I \times C([-\tau,0],E)$ to E and specifying initial data $\zeta \in C([-\tau,0],E)$ does not complicate the problem in any substantial way.

Returning to the control problem, we assume that the objective functional is given by

$$J(u) = \int_I \ell(t,x(t))dt + \Psi(x(T)) + \varphi(u), \tag{3}$$

where ℓ, Ψ, φ are suitable functions to be defined later. In a recent paper of the author, some results on the question of existence of optimal controls were proved in [1] under the assumption that C is independent of x. In a more recent paper, necessary conditions of optimality also were developed for this class of systems. In [1], the control appears linearly, that is, the control operator C is independent of the state. Once this operator is dependent on the state x, the problem becomes more difficult. Our concern here is to study the question of existence of optimal controls

for this nonlinear case. This was stated as an open problem in our paper [6], where necessary conditions of optimality were developed.

The rest of the paper is organized as follows. In section 2, some basic notations and terminologies are presented. In section 3, we present a result on existence and uniqueness of solutions for the system (1)–(2). In section 4, we develop our main results on the question of existence of optimal controls. The first result given in Theorem 4.2 assumes a decomposability property which is somewhat restrictive. Conditions guaranteeing this property are stated in the remark following the introduction of admissible controls. This assumption is disposed of in Theorem 4.3 and Corollary 4.4 by imposing some conditions on the control operator C. In section 5, we present some comments and questions on open problems. The article concludes with several physical examples.

2. Some notations and terminologies. Let X be a Banach space with dual X^*, and let $\mathcal{B}$ denote the sigma algebra of Borel subsets of the interval $I \equiv [0,T]$. Let $\mathcal{M}_c(I,X)$ denote the space of bounded countably additive X-valued vector measures on the sigma algebra $\mathcal{B}$ having bounded total variation as defined below. That is, for each $\mu \in \mathcal{M}_c(I,X)$, we write

$$|\mu|_v \equiv |\mu|(I) \equiv \sup_{\pi}\Big\{\sum_{J\in\pi} \parallel \mu(J) \parallel_X\Big\},$$

where the supremum is taken over all partitions π of the interval I into a finite number of disjoint members of $\mathcal{B}$. With respect to this topology, $\mathcal{M}_c(I,X)$ is a Banach space. For any $J \in \mathcal{B}$, define the variation of μ on J by

$$V(\mu)(J) \equiv V(\mu,J) \equiv |\mu|(J).$$

Since μ is countably additive and bounded, this defines a countably additive bounded positive measure on $\mathcal{B}$. In case $X = R$, the real line, we have the space of real valued signed measures. We denote this by simply $\mathcal{M}_c(I)$ in place of $\mathcal{M}_c(I,R)$. Clearly for $\nu \in \mathcal{M}_c(I)$, $V(\nu)$ is also a countably additive bounded positive measure. For uniformity of notation we use λ to denote the Lebesgue measure. Strong convergence of a sequence $\{\xi_n\} \in X$ to an element $\xi \in X$ is denoted by $\xi_n \overset{s}{\longrightarrow} \xi$, and its weak convergence (weak star convergence) by $\xi_n \overset{w(w^*)}{\longrightarrow} \xi$. For any pair of Banach spaces X, Y, $\mathcal{L}(X,Y)$ will denote the space of bounded linear operators from X to Y.

For any Banach space X, we use $B(I,X)$ to denote the linear space of all bounded X-valued functions on the interval I, and $C(I,X)$ the space of continuous functions with values in X. The space $B(I,X)$, furnished with the sup norm topology,

$$\parallel z \parallel_0 \equiv \sup\{\parallel z(t) \parallel_X, t \in I\}, \qquad z \in B(I,X),$$

is a Banach space, and $C(I,X)$ is a closed subspace of $B(I,X)$; hence it is also a Banach space. It is clear that, with respect to the above topology, $B(I,X)$ is a normed vector space. To see that it is complete, let $\{x_n\}$ be a Cauchy sequence. Then, for every $\varepsilon > 0$, there exists an integer $m(\varepsilon) \in N$ such that $\parallel x_n - x_m \parallel_0 < \varepsilon$ for all $m, n \geq m(\varepsilon)$. For each $t \in I$, let $x(t) = s - \lim x_n(t)$. Since E is a Banach space, the limit indicated does exist. Then, for each $t \in I$, there is an integer $r \geq m(\varepsilon)$ with $\parallel x(t) - x_r(t) \parallel < \varepsilon$, and thus, for $n \geq m(\varepsilon)$,

$$\parallel x(t) - x_n(t) \parallel \leq \parallel x(t) - x_r(t) \parallel + \parallel x_r(t) - x_n(t) \parallel < 2\varepsilon \text{ for all } t \in I.$$

Since $\varepsilon > 0$ is arbitrary, this proves that every Cauchy sequence in $B(I, X)$ has a limit with respect to the norm topology and hence is a Banach space.

This is a very general Banach space. For application we need measurability. Let $B_\infty(I, X)$ denote the space of bounded strongly measurable X-valued functions on I. Furnished with the same sup norm topology, it is a closed subspace of $B(I, X)$ and hence a Banach space. This is the Banach space used throughout this paper.

The space of bounded piecewise continuous functions (with the sup norm topology), denoted by $PWC(I, X)$, is certainly a linear subspace of $B_\infty(I, X)$, but it is not clear if it is a closed subspace. In any case we can choose the space $B_\infty(I, X)$ for the space of solutions of all our impulsive systems. However, in many cases the solutions may posses stronger regularity properties such as piecewise continuity. This certainly happens in case all the measures including the control measures are all purely atomic. Further regularity is expected if ν is absolutely continuous with respect to Lebesgue measure λ, and given that both F and F^* satisfy the Radon–Nikodým property, the control measures are λ continuous. In this case the solutions are in $C(I, X)$.

3. Existence and regularity of solutions. For study of the question of existence of optimal controls, it is certainly necessary to guarantee the existence (and possibly uniqueness) of solutions of the controlled evolution equation for each and every control from the admissible class. Here in this section, we present a simple existence and uniqueness theorem for the purpose. First let us recall that by a mild solution of the system (1)–(2) we mean a function $x \in B_\infty(I, E)$ that satisfies the integral equation

$$x(t) = S(t)x_0 + \int_0^t S(t-s)f(s, x(s))ds + \int_0^t S(t-s)g(s, x(s))\nu(ds) + \int_0^t S(t-s)C(s, x(s))u(ds), \qquad t \in I. \tag{4}$$

We can prove the following result along the same lines as in [1, 3].

THEOREM 3.1. *Consider the system* (1)–(2) *and suppose that* E, F *are Banach spaces,* A *is the infinitesimal generator of a* C_0*-semigroup* $S(t), t \geq 0$*, in* E*,* $\nu \in \mathcal{M}_c(I)$*, and* $u \in \mathcal{M}_c(I, F)$*. Suppose that both* f *and* g *map* $I \times E$ *into* E *and are measurable in* t *on* I *and continuous in* x *on* E *and that there exist two nonnegative functions* $K \in L_1^+(I, \lambda)$ *and* $L \in L_1^+(I, V(\nu))$ *such that, for all* $x, y \in E$*,*

$$\| f(t,x) - f(t,y) \|_E \leq K(t) \| x - y \|_E, \qquad \| f(t,x) \| \leq K(t)(1 + \| x \|), \tag{5}$$

$$\| g(t,x) - g(t,y) \|_E \leq L(t) \| x - y \|_E, \qquad \| g(t,x) \| \leq L(t)(1 + \| x \|), \tag{6}$$

where the first set of inequalities hold λ *a.e. and those of the second set hold* $V(\nu)$ *a.e. The operator valued function* C *mapping* $I \times E$ *to* $\mathcal{L}(F, E)$ *is measurable in* t *on* I *and continuous in* x *on* E*, all with respect to the uniform operator topology of* $\mathcal{L}(F, E)$*; and there exists an* $R \in L_1^+(I, V(u))$ *(possibly dependent on* u*) so that*

$$\| C(t,x) - C(t,y) \|_{\mathcal{L}(F,E)} \leq R(t) \| x - y \|_E, \quad \| C(t,x) \|_{\mathcal{L}(F,E)} \leq R(t)(1 + \| x \|). \tag{7}$$

Then, for each $x_0 \in E$ *and* $u \in \mathcal{M}_c(I, F)$*, the system* (1) *has a unique mild solution in* $B_\infty(I, E)$*.*

Proof. The proof is similar to that of [1, Theorem 1]. We present a very brief outline. Since S is a C_0 semigroup on E, there exists a finite number $M \geq 1$ such that

$$\sup\{\| S(t) \|_{\mathcal{L}(E)}, t \in I\} = M.$$

Define the operator G as follows:

$$(Gx)(t) \equiv S(t)x_0 + \int_0^t S(t-s)f(s,x(s))ds + \int_0^t S(t-s)g(s,x(s))\nu(ds) + \int_0^t S(t-s)C(s,x(s))u(ds). \tag{8}$$

Using the growth and continuity assumptions of the operators f, g, C with respect to the state $x \in E$, it is easy to verify that G maps $B_\infty(I,E)$ into itself. Define the scalar measure α on $\mathcal{B}$ by

$$\alpha(\sigma) \equiv \int_\sigma K(s)ds + \int_\sigma L(s)V(\nu,ds) + \int_\sigma R(s)V(u,ds), \qquad \sigma \in \mathcal{B}. \tag{9}$$

Note that this is a countably additive positive measure. For any $x, y \in B_\infty(I,E)$ define

$$\rho_t(x,y) \equiv \sup_{0\le s\le t} \| x(s) - y(s) \| \tag{10}$$

and set $\rho(x,y) \equiv \rho_T(x,y)$. Clearly $\rho(x,y)$ defines a metric on $B_\infty(I,E)$, and with respect to this metric $B_\infty(I,E)$ is a complete metric space. For any pair of elements $x, y \in B_\infty(I,E)$, it follows from the expressions (8), (9), and (10) that

$$\rho_t(Gx,Gy) \le M\int_0^t \rho_s(x,y)\alpha(ds), \qquad t \in I. \tag{11}$$

Define

$$W(t) \equiv \int_0^t \alpha(ds), \qquad t \in I. \tag{12}$$

By repeated substitution, it follows from (11) and (12) that

$$\rho_t(G^n x, G^n y) \le \big(M^n W^n(t)/\Gamma(n+1)\big)\rho_t(x,y), \qquad t \in I.$$

This implies that

$$\rho(G^n x, G^n y) \le \big(M^n W^n(T)/\Gamma(n+1)\big)\rho(x,y).$$

Hence, for sufficiently large n, G^n is a contraction, and by the Banach fixed point theorem it has a unique fixed point $x^* \in B_\infty(I,E)$ which is also the unique fixed point of the operator G itself. Hence x^* is the unique mild solution of the evolution equation (1)–(2). This completes the outline of our proof. □

Remark. The conclusions of Theorem 3.1 also remain valid under local Lipschitz conditions, given that the growth assumption remains in force.

Remark. This result has been substantially generalized in [3], where continuous dependence of solutions on initial data and control measures also is studied. However, the result presented above is sufficient for our purpose.

In [6], a set of necessary conditions of optimality was developed for similar systems. In that the operator C was assumed to be independent of the state. By imposing appropriate regularity property for C with respect to the state $x \in E$, it is possible to develop similar necessary conditions of optimality once we have the existence result. Thus our primary objective here is to prove existence of optimal controls. This we do in the next section. This problem was left open in [6].

4. Existence of optimal controls. For convenience of the reader we state a result from Diestel and Uhl [7] that gives the necessary and sufficient conditions for weak compactness of subsets of the space $\mathcal{M}_c(I,F)$. This is a celebrated result due to Bartle, Dunford, and Schwartz. An elegant proof of this result is given in Diestel and Uhl [7]. We present here a special version of their result.

THEOREM 4.1 (Bartle–Dunford–Schwartz [7]). *Let $\mathcal{B}$ be a sigma-field of subsets of the set I. Suppose that F is a Banach space such that both F and its dual F^* satisfy the Radon–Nikodým property. A subset $\mathcal{U}$ of $\mathcal{M}_c(I,F)$ is weakly compact if and only if*

(i) *$\mathcal{U}$ is bounded,*

(ii) *there exists a nonnegative countably additive finite scalar valued measure μ on $\mathcal{B}$ such that $\lim_{\mu(\sigma)\to 0}|u|(\sigma)=0$ uniformly with respect to $u\in\mathcal{U}$,*

(iii) *for each $\sigma\in\mathcal{B}$, the set $\{u(\sigma), u\in\mathcal{U}\}$ is a relatively weakly compact subset of F.*

For details on Banach spaces satisfying the Radon–Nikodým property see Diestel and Uhl [7]. We simply mention here that all Hilbert spaces, reflexive Banach spaces, Gelfand spaces, and many more satisfy the Radon–Nikodým property. The spaces L_1, L_∞, C do not satisfy the Radon–Nikodým property. For a comprehensive list of Banach spaces that satisfy the Radon–Nikodým property see [7, p. 218].

Let $L_1(\mu,F)$ denote the space of μ-measurable F-valued functions on I which are Lebesgue–Bochner integrable with respect to the measure μ, and suppose this is furnished with the standard norm topology making it into a Banach space. Define the map Γ from $L_1(\mu,F)$ to $\mathcal{M}_c(I,F)$ by

$$\Gamma(g)(\sigma)\equiv\int_\sigma g(t)\mu(dt),\qquad \sigma\in\mathcal{B}.$$

Clearly Γ is a linear operator continuous with respect to the norm topologies and hence also continuous with respect to the weak topologies. Thus Γ maps weakly compact subsets of $L_1(\mu,F)$ into weakly compact subsets of $\mathcal{M}_c(I,F)$.

Admissible controls. Now we are prepared to prove our main results. First, let us recall that a set $K\subset L_1(\mu,F)$ is said to be decomposable if, for every measurable set $\sigma\subset I$ and every pair $f_1,f_2\in K$, the function

$$f\equiv\chi_\sigma f_1+\chi_{I\setminus\sigma}f_2\in K,$$

where χ_σ denotes the indicator function of the set σ. In general, this definition is also used for the larger space $L_0(\mu,F)\supset L_1(\mu,F)$. For admissible controls we choose a set $\mathcal{U}_{ad}\subset\mathcal{M}_c(I,F)$ satisfying the following properties:

(P1) $\mathcal{U}_{ad}$ is weakly compact satisfying Theorem 4.1.

(P2) $\Gamma^{-1}(\mathcal{U}_{ad})$ is a decomposable subset of $L_1(\mu,F)$.

These assumptions are relaxed later in Theorem 4.3 and Corollary 4.4 by imposing stronger assumptions on the operator C.

Remark. Even though the class of admissible controls chosen is somewhat restrictive, it covers a fairly large class. For example, take any nonnegative countably additive finite measure μ and choose any decomposable weakly compact set K_{ad} of $L_1(\mu,F)$ and define $\mathcal{U}_{ad}=\Gamma(K_{ad})$. Clearly this set satisfies the properties (P1) and (P2).

For our purpose we introduce the following basic assumptions.

Assumption A1. The operator L with values

$$L_t(u) \equiv \int_0^t S(t-s)C(s,x(s))u(ds), \qquad t \in I, \tag{13}$$

maps every weakly convergent sequence $\{u_n\} \subset \mathcal{M}_c(I,F)$ into a strongly convergent sequence in E for each $t \in I$ and for any fixed but arbitrary $x \in B(I,E)$.

Assumption A2. The function ℓ is measurable in t on I and lower semicontinuous in x on E, and Ψ is lower semicontinuous on E. There exist $h \in L_1(I), c_2 \in R$ so that

$$\ell(t,x) \geq h(t) \text{ a.e. for all } x \in E, \tag{14}$$

$$\Psi(x) \geq c_2 \text{ for all } \ x \in E, \tag{15}$$

and the functional φ is weakly lower semicontinuous on $\mathcal{M}_c(I,F)$.

THEOREM 4.2. *Consider the system given by* (1)–(2) *with the cost functional* (3) *and admissible controls* $\mathcal{U}_{ad}$ *satisfying properties* (P1) *and* (P2) *where both* F *and its dual* F^* *satisfy the Radon–Nikodým property. Suppose Assumptions* A1 *and* A2 *and further that the assumptions of Theorem* 3.1 *hold with* $R(t) = R$ *a constant positive number possibly dependent on the set* $\mathcal{U}_{ad}$. *Then there exists an optimal control, that is, a control* $u_o \in \mathcal{U}_{ad}$ *that minimizes the functional* $J(u)$ *given by* (3).

Proof. If $J(u) \equiv +\infty$ for all $u \in \mathcal{U}_{ad}$, there is nothing to prove. Again, by virtue of Assumption A2, we have

$$\inf\{J(u), u \in \mathcal{U}_{ad}\} = m > -\infty. \tag{16}$$

Let $\{u_n\} \subset \mathcal{U}_{ad}$ be a minimizing sequence so that

$$\lim_{n\to\infty} J(u_n) = m.$$

Since $\mathcal{U}_{ad}$ is weakly compact, by the Eberlein–Smulian theorem [8, Theorem V.6.1], it is also weakly sequentially compact. Hence there exists a subsequence of the sequence $\{u_n\}$, relabeled as $\{u_n\}$, and an element $u_o \in \mathcal{U}_{ad}$ so that $u_n \overset{w}{\longrightarrow} u_o$. We show that u_o is an optimal control. Let $\{x_n, x_o\} \in B_\infty(I,E)$ denote the mild solutions of the evolution equation (1)–(2) corresponding to the controls $\{u_n, u_o\}$, respectively. In other words, these functions satisfy the following integral equations:

$$\begin{aligned} x_n(t) = S(t)x_0 &+ \int_0^t S(t-s)f(s,x_n(s))ds + \int_0^t S(t-s)g(s,x_n(s))\nu(ds) \\ &+ \int_0^t S(t-s)C(s,x_n(s))u_n(ds), \qquad n \in N, \end{aligned} \tag{17}$$

$$\begin{aligned} x_o(t) = S(t)x_0 &+ \int_0^t S(t-s)f(s,x_o(s))ds + \int_0^t S(t-s)g(s,x_o(s))\nu(ds) \\ &+ \int_0^t S(t-s)C(s,x_o(s))u_o(ds). \end{aligned} \tag{18}$$

First we show that there exists a ball $B_r \subset E$ of finite radius $r > 0$, centered at the origin, so that $x_n(t), x_o(t) \in B_r$ for all $t \in I$. Considering the first equation, and recalling the bound M of the semigroup S on I, we have

$$\begin{aligned} \| x_n(t) \| \leq M \| x_0 \| &+ M \int_0^t K(s)(1+ \| x_n(s) \|)ds \\ &+ M \int_0^t L(s)(1+ \| x_n(s) \|)V(\nu, ds) + M \int_0^t R(1+ \| x_n(s) \|)V(u_n, ds). \end{aligned} \tag{19}$$

Introducing the sequence of measures $\{\gamma_n\}$ as

$$\begin{aligned}\gamma_n(\sigma) &\equiv \int_\sigma K(s)ds + \int_\sigma L(s)V(\nu, ds) + \int_\sigma RV(u_n, ds),\\ &\equiv \int_\sigma K(s)ds + \int_\sigma L(s)V(\nu, ds) + RV(u_n, \sigma),\end{aligned} \tag{20}$$

it follows from the preceding inequality that

$$(1+ \parallel x_n(t) \parallel) \leq (1 + M \parallel x_0 \parallel) + M \int_0^t (1+ \parallel x_n(s) \parallel)\gamma_n(ds). \tag{21}$$

Since ν and $\{u_n\}$ are countably additive measures of bounded total variation, it follows from our assumptions on K and L that $\{\gamma_n\}$ is a sequence of countably additive positive measures of bounded total variation. By virtue of an inequality recently proved by the author [2, Lemma 5, p. 268], it follows from (21) that

$$(1+ \parallel x_n(t) \parallel) \leq (1 + M \parallel x_0 \parallel)\exp\left\{M \int_0^t \gamma_n(ds)\right\}, \qquad t \in I. \tag{22}$$

Similarly, using (18), we obtain

$$(1+ \parallel x_o(t) \parallel) \leq (1 + M \parallel x_0 \parallel)\exp\left\{M \int_0^t \gamma_o(ds)\right\}, \qquad t \in I, \tag{23}$$

where the measure γ_o is given by

$$\gamma_o(\sigma) \equiv \int_\sigma K(s)ds + \int_\sigma L(s)V(\nu, ds) + RV(u_o, \sigma), \qquad \sigma \in \mathcal{B}. \tag{24}$$

Since $\mathcal{U}_{ad}$ is bounded (Theorem 4.1 (i)), it follows from (22), (23), and (24) that there exists a finite positive number r such that $x_o(t), x_n(t) \in B_r(E) \equiv \{e \in E :\parallel e \parallel_E \leq r\}$ for all $t \in I$ and for all $n \in N$. Now define

$$e_n(t) \equiv \parallel x_n(t) - x_o(t) \parallel, \qquad t \in I, \quad n \in N, \tag{25}$$

$$y_n(t) \equiv \int_0^t S(t-s)C(s, x_0(s))(u_0 - u_n)(ds), \qquad t \in I, \quad n \in N, \tag{26}$$

$$z_n(t) \equiv \parallel y_n(t) \parallel, \qquad t \in I, \quad n \in N. \tag{27}$$

Using (17) and (18), subtracting one from the other, and utilizing the above notations, one can easily verify that

$$\begin{aligned}e_n(t) \leq z_n(t) &+ M \int_0^t K(s)e_n(s)ds + \int_0^t L(s)e_n(s)V(\nu, ds)\\ &+MR \int_0^t e_n(s)V(u_n, ds), \qquad t \in I, \quad n \in N.\end{aligned} \tag{28}$$

Introduce the nonnegative set function

$$\beta(\sigma) \equiv \sup\{V(u, \sigma) \equiv |u|(\sigma), u \in \mathcal{U}_{ad}\}, \qquad \sigma \in \mathcal{B}. \tag{29}$$

Since $\mathcal{U}_{ad}$ is weakly compact, it follows from the Bartle–Dunford–Schwartz theorem—in particular Theorem 4.1(iii)—that the set $\{u(\sigma), u \in \mathcal{U}_{ad}\}$ is relatively weakly compact and thus a bounded subset of F for each $\sigma \in \mathcal{B}$. Thus the set function β is

well defined for each $\sigma \in \mathcal{B}$. In fact it is a finitely additive measure. This follows from (i) and (ii) of Theorem 4.1. Indeed, since the elements of $\mathcal{U}_{ad}$ are μ continuous (F-valued) vector measures and both F and F^* satisfy the Radon–Nikodým property, for every $u \in \mathcal{U}_{ad}$ there exists a $g \in L_1(\mu, F)$ such that

$$u(\sigma) = \int_\sigma g(t)\mu(dt),$$

and thus the operator Γ, as defined above, is an isometric isomorphism of $L_1(\mu, F)$ onto a subspace of $\mathcal{M}_c(I, F)$ with Range$(\Gamma) \supset \mathcal{U}_{ad}$. Since $\mathcal{U}_{ad}$ is weakly compact, it is clear that $\Gamma^{-1}(\mathcal{U}_{ad})$ is a weakly compact subset of $L_1(\mu, F)$.

Hence, for any disjoint members $\sigma_1, \sigma_2 \in \mathcal{B}$, it follows from the decomposability assumption (P2) that

$$\begin{aligned}
\beta(\sigma_1 \cup \sigma_2) &= \sup\{V(u, \sigma_1 \cup \sigma_2), u \in \mathcal{U}_{ad}\} \\
&= \sup\left\{\int_{\sigma_1\cup\sigma_2} \| g(t) \| \mu(dt), g \in \Gamma^{-1}(\mathcal{U}_{ad})\right\} \\
&= \sup\left\{\int_{\sigma_1} \| g(t) \| \mu(dt), g \in \Gamma^{-1}(\mathcal{U}_{ad})\right\} \\
&\quad + \sup\left\{\int_{\sigma_2} \| g(t) \| \mu(dt), g \in \Gamma^{-1}(\mathcal{U}_{ad})\right\} \\
&= \beta(\sigma_1) + \beta(\sigma_2). \qquad (30)
\end{aligned}$$

Clearly this identity holds for any finite family of disjoint members from the sigma-field $\mathcal{B}$. Thus β is a finitely additive positive measure. Since I is a compact interval, it follows from the extension theorem for finitely additive set functions [8, Theorem III.5.13, III.5.14] that β has a countably additive extension which we denote by β again. Using this fact, it follows from (28) that

$$\begin{aligned}
e_n(t) \le z_n(t) &+ M\int_0^t K(s)e_n(s)ds + \int_0^t L(s)e_n(s)V(\nu, ds) \\
&+MR\int_0^t e_n(s)\beta(ds), \qquad t \in I, \quad n \in N. \qquad (31)
\end{aligned}$$

Defining

$$\beta_o(\sigma) \equiv \int_\sigma K(s)ds + \int_\sigma L(s)V(\nu, ds) + R\beta(\sigma) \qquad (32)$$

and recalling that $M \ge 1$, (31) reduces to

$$e_n(t) \le z_n(t) + M\int_0^t e_n(s)\beta_o(ds), \qquad t \in I. \qquad (33)$$

Again using Lemma 5 of [2], it follows from this that

$$e_n(t) \le z_n(t) + \int_0^t M\exp\left\{\int_s^t M\beta_o(dr)\right\} z_n(s)\beta_o(ds). \qquad (34)$$

Since $x_o \in B(I, E)$ is bounded with $x_o(t) \in B_r$, and $u_n \xrightarrow{w} u_o \in \mathcal{U}_{ad}$, it follows from Assumption A1 and (26) that $y_n(t) \xrightarrow{s} 0$ in E pointwise in t for each $t \in I$. Hence $z_n(t) \longrightarrow 0$ pointwise in t on I. Further, it follows from the boundedness of $\mathcal{U}_{ad}$ that

$$\sup_{n\in N}\sup\{\| y_n(t) \|, t \in I\} = \sup_{n\in N}\sup\{z_n(t) : t \in I\} < \infty.$$

Thus, by virtue of the dominated convergence theorem, it follows from (34), upon letting $n \to \infty$, that

$$\lim_{n\to\infty} e_n(t) = 0$$

for each $t \in I$. In other words, $x_n(t) \xrightarrow{s} x_o(t)$ in E for each $t \in I$. By using this result, Fatou's lemma, and Assumption A2, we conclude that

$$\liminf_{n\to\infty} J(u_n) \geq J(u_o).$$

Thus J is weakly lower semicontinuous on $\mathcal{U}_{ad}$. Since $u_o \in \mathcal{U}_{ad}$ and $\{u_n\}$ is a minimizing sequence, we have

$$m \leq J(u_o) \leq \liminf_{n\to\infty} J(u_n) \leq \lim_{n\to\infty} J(u_n) = m.$$

This shows that J attains its minimum at $u_o \in \mathcal{U}_{ad}$ and hence proves the existence. This completes the proof. □

By imposing a stronger assumption on the operator C we can eliminate the requirement of decomposability of the set $\Gamma^{-1}(\mathcal{U}_{ad})$. These results are stated in the following theorem and its corollary.

THEOREM 4.3. *Consider the system given by* (1)–(2) *with the cost functional* (3) *and admissible controls* $\mathcal{U}_{ad}$ *a weakly compact subset of* $\mathcal{M}_c(I, F)$ *satisfying the Bartle–Dunford–Schwartz theorem, Theorem* 4.1. *Suppose that all the other assumptions of Theorem* 4.2 *hold except that* $R(\cdot)$ *is uniformly bounded and Assumption* A1 *is replaced by the following.*

Assumption B1. The operator L_t, given by

$$L_t(u) \equiv \int_0^t S(t-s)C(s,\xi)u(ds), \qquad t \in I,$$

maps every weakly convergent sequence $\{u_n\} \subset \mathcal{M}_c(I, F)$ into a strongly convergent sequence in E for each $t \in I$, uniformly with respect to $\xi \in B_r(E)$. Then there exists an optimal control, that is, a control $u_o \in \mathcal{U}_{ad}$ that minimizes the functional $J(u)$ given by (3).

Proof. The proof is essentially identical. We give a brief outline. Subtracting (18) from (17) and writing

$$\begin{aligned}\int_0^t S(t-s)C(s,x_n(s))u_n(ds) - \int_0^t S(t-s)C(s,x_o(s))u_0(ds)\\ = \int_0^t S(t-s)C(s,x_n(s))(u_n(ds) - u_o(ds))\\ + \int_0^t S(t-s)\{C(s,x_n(s)) - C(s,x_o(s))\}u_o(ds),\end{aligned}$$

the inequality (34) takes the form

$$e_n(t) \leq \tilde{z}_n(t) + M\int_0^t \exp\Big\{M\int_s^t \tilde{\beta}_o(dr)\Big\}\tilde{z}_n(s)\tilde{\beta}_o(ds), \qquad t \in I, \tag{35}$$

where

$$\tilde{z}_n(t) \equiv \| \tilde{y}_n(t) \|_E, \quad \tilde{y}_n(t) \equiv \int_0^t S(t-s)C(s,x_n(s))(u_n(ds) - u_o(ds)),$$

and the measure $\tilde{\beta}_o$ is given by

$$\tilde{\beta}_o(\Delta) \equiv \int_\Delta K(s)ds + \int_\Delta L(s)V(\nu, ds) + \int_\Delta R(s)V(u_o, ds), \qquad \Delta \in \mathcal{B}.$$

Since R is uniformly bounded and $V(\nu)$ and $V(u_o)$ are countably additive bounded positive measures, it is clear that $\tilde{\beta}_o$ is also a countably additive bounded positive measure. Recalling that $x_n(t) \in B_r$ for all integers n and all $t \in I$, it follows from the current assumption on the operator $L_t, t \in I$, that $\tilde{z}_n(t) \to 0$ for each $t \in I$. Again using dominated convergence theorem, it follows from inequality (35) that $e_n(t) \longrightarrow 0$ for each $t \in I$. The rest of the proof is identical to that of Theorem 4.2. □

In case the operator C is independent of the state, system (1) reduces to

$$dx = Axdt + f(t,x)dt + g(t,x)\nu(dt) + C(t)u(dt), \qquad t \in I, \tag{36}$$

$$x(0) = x_0. \tag{37}$$

In this case also we do not require the decomposability condition, and we have the following result.

COROLLARY 4.4. *Consider the system given by* (36)–(37) *with the cost functional* (3) *and admissible controls* $\mathcal{U}_{ad}$ *a weakly compact subset of* $\mathcal{M}_c(I,F)$ *satisfying the Bartle–Dunford–Schwartz theorem, Theorem* 4.1. *Suppose all the other assumptions of Theorem* 4.3 *hold except those related to the operator* C. *Suppose the operator* $L_t, t \in I$, *given by*

$$L_t(u) \equiv \int_0^t S(t-s)C(s)u(ds), \qquad t \in I,$$

maps every weakly convergent sequence $\{u_n\} \subset \mathcal{M}_c(I,F)$ *into a strongly convergent sequence in* E *for each* $t \in I$. *Then there exists an optimal control, that is, a control* $u_o \in \mathcal{U}_{ad}$ *that minimizes the functional* $J(u)$ *given by* (3).

By imposing a stronger continuity condition on both ℓ and Ψ, as functions of x on E, it is possible to relax the requirements (14) and (15). This is presented below as a corollary after we have introduced Assumption A3, replacing A2.

Assumption A3. For each $x \in E$, the function ℓ is measurable in t on I and, for almost all $t \in I$, is continuous and bounded in x on bounded sets of E, and the function Ψ is also continuous and bounded on bounded sets of E satisfying the following conditions: For each finite $r > 0$, there exists an $h_r \in L_1(I)$ and $C_r \in R$ such that

$$\ell(t,x) \geq h_r(t) \text{ for all } x \in B_r \subset E,$$
$$\Psi(x) \geq C_r \text{ for all } \ x \in B_r \subset E,$$

and the functional φ is weakly lower semicontinuous on $\mathcal{M}_c(I,F)$.

COROLLARY 4.5. *Suppose that all the assumptions of Theorem* 4.2, *except* A2, *hold and that* A2 *is replaced by Assumption* A3 *as stated above. Then there exists an optimal control.*

Remarks on Assumptions A1 *and* A2.

(R1) The lower semicontinuity of ℓ and Ψ on E, as stated in Theorem 4.2, is always satisfied if they are convex and once Gâteaux differentiable.

(R2) One choice of the cost functional φ is

$$\varphi(u) \equiv \Phi(|u|_v)$$

with $\Phi : [0,\infty] \longrightarrow [0,\infty]$, a nondecreasing extended real valued function. With this hypothesis, it is easy to verify [1] that the functional φ is weakly lower semicontinuous on $\mathcal{M}_c(I,F)$. This is a good measure of impulsive energy spent in the control process. Another possibility is

$$\varphi(u) \equiv \Phi(u(\phi_1), u(\phi_2), \ldots, u(\phi_m)),$$

where $\Phi \in C(R^m)$ is a real valued lower semicontinuous function on R^m bounded away from $-\infty$; and $\phi_i \in C_b(I,F^*)$, the space of bounded continuous functions on I with values in F^*, or $\phi_i \in B_m(I,F^*)$, the space of bounded Borel measurable maps from I to F^*. The action of u on ϕ_i is given by

$$u(\phi_i) \equiv \int_I \langle \phi_i(t), u(dt)\rangle.$$

This is a useful functional if one wishes to minimize or maximize control efforts over selected periods of time.

(R3) Assumption A1 is critical. It is satisfied if $C_0(s) \equiv C(s, x_o(s))$ is a compact operator from F to E for μ-almost all $s \in I$. This can be verified as follows. Assume for simplicity that the compactness property holds for all $s \in I$ and not just for μ-a.e. Let $u_n \xrightarrow{w} u^o$. Define $v_n \equiv u_n - u^o$. Clearly then $v_n \xrightarrow{w} 0$. It suffices to show that

$$\langle L_T v_n, e^*\rangle \longrightarrow 0 \tag{38}$$

uniformly with respect to $e^* \in B_1(E^*)$, the unit ball of E^*. This can be proved by establishing a contradiction. Suppose this is false. Then there exists a sequence $\{e_n^*\} \in B_1(E^*)$ and a $\delta > 0$ such that

$$\begin{aligned} |\langle L_T v_n, e_n^*\rangle| &= \left| \int_I \langle C_0^*(t) S^*(T-t) e_n^*, v_n(dt)\rangle \right| \\ &\equiv \left| \int_I \langle \Gamma(t) e_n^*, v_n(dt)\rangle \right| \ \geq \delta. \end{aligned} \tag{39}$$

Since C_0 and hence C_0^* are compact operator valued functions and the semigroup $S(t), t \in I$, is a family of bounded linear operators, Γ is a compact operator valued function on I. Thus Γe_n^* has a Cauchy subsequence (relabeled as such) in the space $L_\infty(I,F^*)$ which is the dual of $L_1(I,F)$ since F^* has the Radon–Nikodým property. Hence, for any $\varepsilon > 0$, there exists an integer $n(\varepsilon)$ such that, for all $n, m > n(\varepsilon)$,

$$\| \Gamma e_n^* - \Gamma e_m^* \|_{L_\infty(I,F^*)} < \varepsilon. \tag{40}$$

Since v_n converges weakly, it is bounded in the norm, and let this bound be $\sup_n |v_n|_v \leq \tilde{M}$. Using this it follows from (39) and (40) that, for $n, m > n(\varepsilon)$, we have

$$0 < \delta \leq \left| \int_I \langle \Gamma(t) e_n^*, v_n(dt)\rangle \right| \leq \tilde{M}\varepsilon + \left| \int_I \langle \Gamma(t) e_m^*, v_n(dt)\rangle \right|. \tag{41}$$

For fixed m, letting $n \to \infty$, we arrive at the inequality $0 < \delta \leq \tilde{M}\varepsilon$. Since $\varepsilon > 0$ is completely arbitrary, this leads to the contradiction that $\delta > 0$, thereby proving the statement. A similar proof applies in the general case, provided that we subtract a μ-null set from the set I, on which Γ lies outside the space of compact operators, and use the fact that by BDS the sequence $\{u_n\}$ is μ continuous.

Apparently, another possibility is that the semigroup $S(t), t > 0$, is compact. But this condition does not seem to lead to compactness of the integral operator L_t as defined in A1. The problem arises from the fact that the measure μ appearing in the Bartle–Dunford–Schwartz theorem (Theorem 4.1) need not be absolutely continuous with respect to the Lebesgue measure. If it were, the compactness of the operator L_t would follow from that of the semigroup $S(t), t > 0$. But this absolute continuity assumption would rule out inclusion of Dirac measures in the class of admissible controls.

A third possibility obtains if the semigroup $S(t), t > 0$, is nuclear (and thus compact). Suppose the dual pair of Banach spaces $\{E, E^*\}$ admits a biorthogonal basis $\{e_n, e_n^*\}$. If the semigroup $S(t), t > 0$, is nuclear, it has the representation

$$S(t) = \sum_{k=1}^{\infty} \lambda_k(t) e_k \bigotimes e_k^*, \tag{42}$$

where $e_k \bigotimes e_k^* \in \mathcal{L}(E)$ and for each $\xi \in E$, $(e_k \bigotimes e_k^*)(\xi) = (e_k^*, \xi)e_k$. The sequence $\{\lambda_k\}$ is a family of continuous scalar valued functions satisfying the functional equation

$$\lambda_k(t+s) = \lambda_k(t)\lambda_k(s), \lambda_k(0) = 1 \text{ for all } t, s \geq 0, k \geq 1. \tag{43}$$

The reader can easily verify that these conditions guarantee that $S(t), t \geq 0$, is a C_0-semigroup on E. Now returning to the operator L_t (see Assumption A1), we have

$$L_t(u_n - u_o) = \int_0^t S(t-s)C(s, x(s))(u_n - u_o)(ds) \tag{44}$$

$$= \sum_{k\geq 1} \left\{ \int_0^t \lambda_k(t-s) \langle C^*(s, x(s))e_k^*, u_n(ds) - u_o(ds) \rangle_{F^*,F} \right\} e_k \tag{45}$$

$$= \sum_{k\geq 1} \alpha_{k,n}(t)e_k = \sum_{k=1}^{m} \alpha_{k,n}(t)e_k + \sum_{k\geq m+1} \alpha_{k,n}(t)e_k \tag{46}$$

for any sequence $\{u_n, u_o\} \in \mathcal{U}_{ad}$. Since the semigroup is nuclear, it is clear that $\sum_{k\geq 1} |\lambda_k(t)| < \infty$ for $t > 0$. In view of the functional equation (43), we must have

$$\lambda_k(t) = e^{\varpi_k t}, \qquad \varpi_k \in (R/C).$$

Nuclearity of the semigroup demands that the exponents $\{\varpi_k\}$ have only finitely many terms with positive real parts and that $\varpi_k \to -\infty$. From this it follows that

$$\sum_{k\geq 1} \sup_{t\in(0,T]} |\lambda_k(t)| = \sum_{k\geq 1} \sup_{t\in(0,T]} \lambda_k(t) < \infty. \tag{47}$$

Further, for each $x \in B(I, E)$, the operator valued function $C(t, x(t))$ is also bounded in the sense that

$$\sup\{\| C(t, x(t)) \|_{\mathcal{L}(F,E)}, t \in I\} < \infty.$$

Since $\mathcal{U}_{ad}$ is bounded, the sequence $\{u_n, u_o\}$ is also bounded. Suppose $u_n \xrightarrow{w} u_o$ in $\mathcal{M}_c(I, F)$. Then in view of (47), for each $\varepsilon > 0$ one can choose $m \in N$ sufficiently large but finite so that the second term in the expression (46) has E-norm less than ε. Then letting $n \to \infty$, the first term of (46) converges to zero strongly in E. Since $\varepsilon > 0$, is arbitrary, this shows that nuclearity of the semigroup is a sufficient condition for weak to strong continuity of the operator L_t from $\mathcal{M}_c(I, F)$ to E.

5. Some open questions.

(Q1) Our main results, Theorems 4.2 and 4.3 and Corollary 4.4, are based on the assumption that the operator $L_t, t \in I$, maps a weakly convergent sequence of $\mathcal{M}_c(I,F)$ into a strongly convergent sequence in E. We have presented some remarks with regards to sufficient conditions that guarantee this hypothesis. To the knowledge of the author, this seems to be an open problem in the theory of vector measures. The general problem can be stated as follows. Under what conditions a weakly compact operator $L \in \mathcal{L}(\mathcal{M}_c(I,F),E)$ is actually compact in the sense that it maps every weakly convergent sequence from the Banach space $\mathcal{M}_c(I,F)$ into a strongly convergent sequence in the Banach space E. For closely related problems see [7, Chapters IV, VI]. For similar problems with respect to operators $T \in \mathcal{L}(L_1(S,\Sigma,\mu),E)$ see Dunford and Schwartz [8, Theorem VI.8.12].

(Q2) Our first result on existence of optimal control given by Theorem 4.2 depends on the decomposability property (P2) of the set $\Gamma^{-1}(\mathcal{U}_{ad})$. Thus the full generality of the Bartle–Dunford–Schwartz theorem is not utilized, although we have stated a sufficient condition under which this property holds. The decomposability assumption is disposed of in Theorem 4.3 and Corollary 4.4 by imposing some stronger conditions on the operator C. It would be desirable to relax these assumptions further.

(Q3) Frequent switching of controls is costly. It would be interesting to include the cost of switching. This requires a functional that maps the control space into the set of nonnegative integers signifying the number of jumps in the control used. In general this seems to be a difficult problem. As mentioned by one of the reviewers, controls cannot be changed too frequently since otherwise it should be possible to stabilize any system. This is certainly true. In optimization problems, however, given the maximum admissible number of switchings, one may find an optimal control with fewer switchings, depending on the relative weights given to cost of switchings and the running cost.

6. Examples. For illustration we present two examples.

Example 1. The dynamics of transverse vibration of a mast attached to a rigid body satellite on one end and carrying an antenna at the free end is described by the following system of equations [15, Li, p. 138]:

$$
\begin{aligned}
&W_{tt}(t,\xi) + D_\xi^4 W + f_1(t,\xi,W,W_t) = g_1(t,\xi,W), \qquad \xi \in \Omega \equiv (0,1),\\
&W(t,0) = D_\xi W(t,1) = 0,\\
&W_{tt}(t,1) = D_\xi^3 W(t,1) + C_1 u_1,\\
&(D_\xi W)_{tt} = -D_\xi^2 W(t,1) + C_2 u_2,
\end{aligned}
\tag{48}
$$

where D_ξ^k denotes the spatial derivative and $()_t$ and $()_{tt}$ denote the first and second partials with respect to the time variable. The function W denotes the transverse displacement. This is a normalized system where system parameters such as the mass density, the flexural rigidity, and the length of the mast have all been set equal to one. This is purely for convenience of presentation. Here f_1 takes into account all nonconservative forces, including damping. The functions $\{g_1, C_1u_1, C_2u_2\}$ are external forces: the first one distributed along the body of the mast, and the second and the third representing the shear and torsional forces applied at the end of the mast. We shall model them as impulsive forces as explained later. The operators C_1 and C_2 may depend nonlinearly on the state at the boundary and determine the effectiveness of control forces on the motion of the system. Define $y(t) \equiv (y_1(t), y_2(t), y_3(t))' \equiv$

$(W(t,\cdot), W(t,1), D_\xi W(t,1))'$ and A as the differential operator

$$Ay = (-D_\xi^4 W, D_\xi^3 W(t,1), -D_\xi^2 W(t,1))'$$

subject to the clamped boundary conditions at the fixed end attached to the spacecraft body, as given by the second set of expressions above. Using this operator, we can write this system as a second order evolution equation,

$$(d^2y/dt^2) = Ay + \tilde{f}_1(t,y,\dot{y}) + \tilde{g}_1(t,y) + \tilde{C}(t,y)u, \tag{49}$$

in the Hilbert space $H \equiv L_2(\Omega) \times R \times R$, where $\tilde{f}_1 \equiv (f_1, 0, 0)'$, $\tilde{g}_1 \equiv (g_1, 0, 0)'$, and $\tilde{C}u \equiv (0, C_1u_1, C_2u_2)$. Note that the domain of the operator A is given by

$$D(A) = \{\phi \in H^4(\Omega) \times R \times R : \phi(0) = D_\xi\phi(0) = 0, \phi(1) = \phi_2, D_\xi\phi(1) = \phi_3\}$$

and that $-A$ is a positive unbounded self-adjoint operator in the Hilbert space H. Using the standard approach, we may convert this into a first order system. Defining $x_1 = y$ and $x_2 = \dot{y}$ and $x \equiv (x_1, x_2)'$, we can rewrite this as a first order evolution equation:

$$(dx/dt) = \mathcal{A}x + f(t,x) + g(t,x) + C(t,x)u, \tag{50}$$

with the operators $\{\mathcal{A}, f, g, C\}$ given by

$$\mathcal{A} = \begin{pmatrix} 0 & I \\ A & 0 \end{pmatrix}, \quad f = \begin{pmatrix} 0 \\ \tilde{f} \end{pmatrix}, \quad g = \begin{pmatrix} 0 \\ \tilde{g} \end{pmatrix}, \quad Cu = \begin{pmatrix} 0 \\ \tilde{C}u \end{pmatrix}. \tag{51}$$

In view of the physical nature of the problem we may choose the energy space as the state space

$$E \equiv D(\sqrt{-A}) \times H$$

with the natural scalar product given by

$$(x,z)_E = (x_1, z_1)_{D(\sqrt{-A})} + (x_2, z_2)_H.$$

The domain of the operator $\mathcal{A}$ is given by

$$D(\mathcal{A}) = D(A) \times D(\sqrt{-A}).$$

It is easy to show that $\mathcal{A}$ is skew adjoint and hence that $i\mathcal{A}$ is self-adjoint, and it follows from Stone's theorem that $\mathcal{A}$ generates a unitary group of operators $S(t), t \in R$, in E. Returning to the problem, it is well known that satellites in space are subject to disturbances caused by forces such as solar pressure, geomagnetic forces, and impulsive forces imparted by bombardment of micrometeorites. To control vibration, thrusters or jets are used for producing shear force and torsional moments (a twister). These thrusters are fired on and off for very short intervals of time, like impulses imparting a burst of energy to the mast. Thus a more appropriate formulation of the system, replacing (50), is given by

$$dx = \mathcal{A}xdt + f(t,x)dt + g(t,x)\nu(dt) + C(t,x)u(dt), \tag{52}$$

where ν may represent the impulsive forces caused by micrometeorites and u is the impulsive control generated by thruster firings. Here $F = R^2$, and $C(t,x) \in \mathcal{L}(F,E)$. The objective functional may be taken as

$$J(u) = (1/2)\int_I \| x(t) \|_E^2 \, dt + \Phi(|u|_v),$$

where Φ is any monotone nondecreasing function on the positive half of the real line with $\Phi(0) = 0$. Minimizing this cost functional is equivalent to minimizing vibration. Clearly this is a special case and our theory applies.

Example 2. Phased array pulsed radars are used to search and track targets simultaneously. This is possible because the phased array radars use an array of transmit-receive antennas which are distributed around the operating site. Thus it can switch back and forth from one antenna to the other and scan the whole horizon in a matter of seconds, and all these actions are done by electronic switching, not mechanically (as in the old system). Hence one radar station can search, detect, and track multiple targets at the same time. The antennas transmit electromagnetic energy in the form of sharp pulses which are generated at the site, and also receive the signals reflected back from the targets. These electrical signals are governed by Maxwell's equations. Using the vector and scalar potentials denoted by (a,ϕ) and the Lorentz gauge, the Maxwell's equation is given by a system of wave equations:

$$\partial^2 a/\partial t^2 - (1/\mu\epsilon)\triangle a = (1/\epsilon)i, \qquad t \geq 0, \quad \xi \in \Omega \equiv R^3, \tag{53}$$

$$\partial^2 \phi/\partial t^2 - (1/\mu\epsilon)\triangle \phi = (1/\mu\epsilon^2)\rho, \qquad t \geq 0, \quad \xi \in \Omega, \tag{54}$$

where i and ρ are the sources, the first denoting the current density (vector) and the second the charge density. These are the sources that can be controlled by radar operators in terms of short bursts of pulses, thereby producing sharp and short bursts of electromagnetic energy directed to the target. Define $H \equiv L_2(\Omega, R^3) \times L_2(\Omega, R)$, denote $y \equiv (a,\phi)'$, and define the formal differential operator B by $By \equiv -(1/\mu\epsilon)(\triangle a, \triangle\phi)'$. Then introduce the operator A as follows:

$$\begin{aligned} &D(A) \equiv \{y \in H : By \in H\} = H^2(\Omega, R^3) \times H^2(\Omega, R) \\ &\text{and set } Az = Bz \text{ for } z \in D(A). \end{aligned} \tag{55}$$

Again, one can verify that $-A$ is an unbounded positive self-adjoint operator in H.

Define the state space as $E \equiv D(\sqrt{-A}) \times H$ and the state as $x = (y, \dot{y})'$. Then following exactly the procedure in the first example, one defines the operator $\mathcal{A}$ as in (51). The control operator C is a constant (8×4) matrix with the first four rows being all zero, while the last (4×4) matrix is a diagonal matrix with the first three entries being equal to $(1/\mu\epsilon)$ and the last one being $(1/\mu\epsilon^2)$. This leads to the abstract differential equation

$$dx = \mathcal{A}x\,dt + C(t)u(dt), \qquad t \geq 0, \tag{56}$$

on the Hilbert space E. Again $\mathcal{A}$ is the infinitesimal generator of a unitary group of operators $S(t), t \in R$, on E.

For the control space F, one may choose $F \equiv L_2(\Omega_0, R^3) \times L_2(\Omega_0, R)$, where Ω_0 is any open bounded (connected) subset of Ω representing the domain of the electromagnetic source and the wave guides. Let $\mathcal{T}(t)$ denote the surface area of the target as seen by the radar at any moment of time $t \in I$ and σ denote the surface

measure. We may assume that $t \longrightarrow \mathcal{T}(t)$ is continuous in the Hausdorff metric. Then the electromagnetic energy hitting the target at time t is given by the functional

$$\begin{aligned}\ell(x(t)) &\equiv \int_{\mathcal{T}(t)} \{|E(t,\xi)|^2 + |B(t,\xi)|^2\} d\sigma(\xi) \\ &\equiv \int_{\mathcal{T}(t)} \{|\dot{a} + \nabla\phi|^2 + |\nabla \times a|^2\} d\sigma(\xi),\end{aligned}$$

where in the last expression we have used the fact that $E = -\dot{a} - \nabla\phi$ and $B = \nabla \times a$ [17]. Using the energy norm, one can easily verify that

$$\ell(x(t)) \leq \| x(t) \|_E^2.$$

The objective is to maximize the energy delivered to the target so that the reflected energy received by the receiving antenna is maximized. Hence the cost functional for this problem can be taken as

$$J(u) \equiv \int_I -\ell(x(t))dt + \Phi(|u|_v).$$

Our problem is to find a control that minimizes this functional. Since ℓ is continuous, the existence follows from Corollary 4.4.

Similar models involving Maxwell's equation arise in the field of optical communication [16, 17], where the optical beams are modulated by message signals to be transmitted by optical fibers. Since optical spectrum is extraordinarily wide, extra-high-speed data transmission is now possible. These data bits entering the fiber network could be considered as a train of impulses. The response of the optical devices and the network to such ultra-high-speed data traffic is an interesting area where the theory of impulsive systems may find interesting applications.

Similar examples can be found in population dynamics involving reaction, convection, and diffusion, where unexpected events may occur and last for a very short time. Considering biochemical time scales, such events may be considered impulsive and may require impulsive controls.

Acknowledgments. The author would like to thank the anonymous reviewers for their valuable comments and suggestions, which led to significant improvement of the original presentation of this paper.

VARIATIONAL INEQUALITIES FOR COMBINED CONTROL AND STOPPING*

HIROAKI MORIMOTO†

Abstract. We study the variational inequality associated with the combined stochastic control problem and establish the existence of a unique viscosity solution without uniform ellipticity. An application to the quasi-variational inequality is given.

Key words. variational inequality, viscosity solution, combined control, quasi-variational inequality

1. Introduction.

We are concerned with the variational inequality in the combined control problem and stopping for diffusions. We are given two bounded continuous functions f, g, and $a > 0$. The variational inequality we deal with can be written as

$$\begin{aligned} &-Lv + f - \frac{a}{4}|Dv|^2 \geq 0, \\ &v \leq g \qquad\qquad \text{in } \mathbf{R^N}, \\ &\left(-Lv + f - \frac{a}{4}|Dv|^2\right)(v-g)^- = 0, \end{aligned} \tag{1}$$

where $L = L_0 + \alpha$, L_0 denotes the second order differential operator

$$L_0 = -\frac{1}{2}\mathrm{tr}(\sigma\sigma^* D^2) - b \cdot D$$

for two Lipschitz continuous functions $b(x)$ and $\sigma(x)$ on $\mathbf{R^N}$, taking values in $\mathbf{R^N}$ and $\mathbf{R^N} \otimes \mathbf{R^N}$, α is a positive constant, $|\cdot|$ is the Euclidean norm, σ^* is the transpose of σ, $x^- = \max(-x, 0)$, and $D = (\partial/\partial x_1, \ldots, \partial/\partial x_N)$.

If $-L_0$ is uniformly elliptic and $a = 0$, the variational inequality (1) has been studied by Bensoussan [2], Bensoussan and Lions [3], Friedman [6], and Kinderlehrer and Stampacchia [9]. We also refer to Menaldi [10, 11] for the variational inequality associated with the stopping time problem for degenerate diffusions and Karatzas and Wang [8] for the combined control problem applied to mathematical finance.

The purpose of this paper is to show the existence of a unique viscosity solution of the variational inequality (1) without uniform ellipticity and then characterize the solution v. From the point of view of Bensoussan and Lions [3] and a simple relation

$$\min_c(a^{-1}|c|^2 + c \cdot Dv) = -\frac{a}{4}|Dv|^2,$$

this variational inequality is relevant to the combined stochastic control problem to minimize the cost:

$$J(\theta, c) = E\left[\int_0^\theta e^{-\alpha t}\left\{f(x_t) + a^{-1}|c_t|^2\right\}dt + e^{-\alpha\theta}g(x_\theta)\right] \tag{2}$$

over $\mathcal{S} \times \mathcal{A}$ subject to the stochastic differential equation

$$dx_t = [b(x_t) + c_t]dt + \sigma(x_t)dW_t, \qquad x_0 = x \in \mathbf{R^N}, \tag{3}$$

where W_t is an N-dimensional standard Brownian motion defined on a complete probability space $(\Omega, \mathcal{F}, P)$ endowed with the natural filtration $\mathcal{F}_t$ generated by $\sigma(W(s), s \le t)$, $\mathcal{S}$ is the class of all stopping times θ, and $\mathcal{A}$ denotes the class of all N-dimensional $\mathcal{F}_t$-progressively measurable processes $c = (c_t)$ with $E[\int_0^\infty e^{-\alpha s}|c_s|^2 ds] < \infty$. For simplicity, we take $a = 1$ throughout the paper.

The content of this paper is as follows. In section 2 we study the penalized problem. We show that the penalty equation admits a unique viscosity solution u_ε. In section 3 we give the definition of the viscosity solutions to the variational inequality (1). It is shown that u_ε converges to a unique viscosity solution of (1). In section 4 we study the quasi-variational inequality associated with impulsive control.

2. Penalized problem.

2.1. Existence.

We consider the equation of the form

$$u(x) = \inf_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left\{\left(f + \frac{1}{\varepsilon}u \wedge g\right)(x_t) + |c_t|^2\right\}dt\right], \qquad \varepsilon > 0. \tag{4}$$

Let $\mathcal{C} = \mathcal{C}(\mathbf{R^N})$ denote the Banach space of all bounded uniformly continuous functions h on $\mathbf{R^N}$ with norm $\|h\| = \sup_x |h(x)|$, and $\mathcal{C}_+ = \{h \in \mathcal{C} : \ h \ge 0\}$.

We assume that

$$b,\ \sigma : \text{ Lipschitz continuous, bounded,} \tag{5}$$

$$\alpha > \nu := \sup\left\{\operatorname{tr}\left[\frac{(\sigma(x) - \sigma(y))(\sigma(x) - \sigma(y))^*}{|x-y|^2}\right] + \frac{2(x-y)\cdot(b(x) - b(y))}{|x-y|^2} : \ x,\ y \in \mathbf{R^N},\ x \ne y\right\}, \tag{6}$$

and

$$f,\ g \in \mathcal{C}_+. \tag{7}$$

THEOREM 2.1. *Under* (5), (6), *and* (7), *equation* (4) *admits a unique solution* $u \in \mathcal{C}_+$.

Proof. We first note that $\mathcal{C}_+$ is a closed subset of $\mathcal{C}$. Define

$$Tw(x) = \inf_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left\{\left(f + \frac{1}{\varepsilon}w \wedge g\right)(x_t) + |c_t|^2\right\}dt\right] \quad \text{for } w \in \mathcal{C}. \tag{8}$$

We shall show

$$T : \ \mathcal{C}_+ \ \to \ \mathcal{C}_+. \tag{9}$$

It is easy to see that

$$\begin{aligned} 0 \le Tw(x) &\le E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left\{\left(f + \frac{1}{\varepsilon}g\right)(\bar{x}_t)\right\}dt\right] \\ &\le \frac{\varepsilon}{\alpha\varepsilon + 1}\left(\|f\| + \frac{1}{\varepsilon}\|g\|\right), \qquad w \in \mathcal{C}_+, \end{aligned}$$

for the response $\bar{x}_t$ to $c_t = 0$. Moreover, it follows from (8) that

$$\begin{aligned}
&|Tw(x) - Tw(y)| \\
&\quad \le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left\{|f(x_t) - f(y_t)| + \frac{1}{\varepsilon}(|w(x_t) - w(y_t)| + |g(x_t) - g(y_t)|)\right\} dt\right] \\
&\quad \le I_f + \frac{1}{\varepsilon}(I_w + I_g),
\end{aligned}$$

where y_t is the solution of (3) with $y_0 = y$, and

$$I_h = \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}|h(x_t) - h(y_t)|dt\right] \quad \text{for} \quad h \in \mathcal{C}.$$

By (6) we can choose $\eta > 0$ such that $-\alpha + \nu + \eta < 0$, and Ito's formula applied to the function $|x|^2 e^{(-\alpha+\eta)t}$ gives

$$E[|x_t - y_t|^2 e^{(-\alpha+\eta)t}] \le |x - y|^2. \tag{10}$$

Also, we note that there exists a constant $C_{\zeta,h} > 0$, for any $\zeta > 0$, such that

$$|h(x) - h(y)| \le \zeta + C_{\zeta,h}|x - y|, \qquad x, y \in \mathbf{R}^{\mathbf{N}}. \tag{11}$$

Then

$$\begin{aligned}
I_h &\le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}(\zeta + C_{\zeta,h}|x_t - y_t|)dt\right] \\
&\le \zeta/\alpha + 2C_{\zeta,h}|x - y|/(\alpha + \eta). \qquad (12)
\end{aligned}$$

Thus, letting $\delta \to 0$ and $\zeta \to 0$, we get

$$\lim_{\delta\to 0} \sup_{|x-y|<\delta} I_h = 0, \tag{13}$$

and hence

$$\lim_{\delta\to 0} \sup_{|x-y|<\delta} |Tw(x) - Tw(y)| = 0,$$

which implies (9).

Now, we have by (8)

$$\begin{aligned}
|Tw_1(x) - Tw_2(x)| &\le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left(\frac{1}{\varepsilon}|w_1 \wedge g(x_t) - w_2 \wedge g(x_t)|\right) dt\right] \\
&\le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left(\frac{1}{\varepsilon}|w_1(x_t) - w_2(x_t)|\right) dt\right] \\
&\le \frac{1}{\alpha\varepsilon + 1}\|w_1 - w_2\|.
\end{aligned}$$

Therefore T is a contraction mapping, which completes the proof.

2.2. Viscosity solutions. We are here concerned with the penalty equation:

$$-Lu + f - \frac{1}{\varepsilon}(u-g)^+ - \frac{1}{4}|Du|^2 = 0 \quad \text{in } \mathbf{R^N}. \tag{14}$$

DEFINITION 2.2. *$w \in \mathcal{C}$ is called a viscosity solution of* (14) *if the following assertions are satisfied:*

For any $\varphi \in C^2$ and any local maximum point z of $w - \varphi$,

$$-\alpha w(z) - L_0\varphi(z) + f(z) - \frac{1}{\varepsilon}(w-g)^+(z) - \frac{1}{4}|D\varphi(z)|^2 \geq 0. \tag{15}$$

For any $\varphi \in C^2$ and any local minimum point z of $w - \varphi$,

$$-\alpha w(z) - L_0\varphi(z) + f(z) - \frac{1}{\varepsilon}(w-g)^+(z) - \frac{1}{4}|D\varphi(z)|^2 \leq 0. \tag{16}$$

As is well known in Fleming and Soner [5] and Crandall, Ishii, and Lions [4], Definition 2.2 turns out to be equivalent to the following.

DEFINITION 2.3. *$w \in \mathcal{C}$ is called a viscosity solution of* (14) *if the following assertions are satisfied:*

$$-\alpha w + \frac{1}{2}\mathrm{tr}(\sigma\sigma^* X) + b\cdot p + f - \frac{1}{\varepsilon}(w-g)^+ - \frac{1}{4}|p|^2 \geq 0 \quad \forall (p,X) \in J^{2,+}w(x), \quad \forall x \in \mathbf{R^N}, \tag{17}$$

$$-\alpha w + \frac{1}{2}\mathrm{tr}(\sigma\sigma^* X) + b\cdot p + f - \frac{1}{\varepsilon}(w-g)^+ - \frac{1}{4}|p|^2 \leq 0 \quad \forall (p,X) \in J^{2,-}w(x), \quad \forall x \in \mathbf{R^N}, \tag{18}$$

where $J^{2,+}$ and $J^{2,-}$ are the second order superjets and subjets defined by

$$J^{2,+}w(x) = \left\{ (p,X) \in \mathbf{R^N} \times \mathbf{S^N} : \limsup_{y\to x} \frac{w(y) - w(x) - p\cdot(y-x) - \frac{1}{2}X(y-x)\cdot(y-x)}{|y-x|^2} \leq 0 \right\},$$

$$J^{2,-}w(x) = \left\{ (p,X) \in \mathbf{R^N} \times \mathbf{S^N} : \liminf_{y\to x} \frac{w(y) - w(x) - p\cdot(y-x) - \frac{1}{2}X(y-x)\cdot(y-x)}{|y-x|^2} \geq 0 \right\},$$

and $\mathbf{S^N}$ is the space of symmetric $N \times N$ matrices.

In order to show that u is a viscosity solution of (14), we define $u_k \in \mathcal{C}$ by

$$u_k(x) = \inf\left\{ E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t} \left\{ F(x_t) + |c_t|^2 \right\} dt \right] :\ c \in \mathcal{A}_k \right\} \tag{19}$$

for every $k > 0$, where $\mathcal{A}_k = \{c \in \mathcal{A} :\ |c_t| \leq k\ \forall t\}$ and

$$F = f + \frac{1}{\varepsilon} u \wedge g \in \mathcal{C}_+. \tag{20}$$

LEMMA 2.4. *Under* (5), (6), *and* (7), *u_k is a viscosity solution of*

$$-\left(\alpha + \frac{1}{\varepsilon}\right) u_k - L_0 u_k + F + \min_{|c|\leq k}(|c|^2 + c\cdot Du_k) = 0. \tag{21}$$

Proof. We recall a standard result of the theory of viscosity solutions in Fleming and Soner [5, Thm. 3.1, p. 220] and Soner [13, pp. 149–151]. To prove (15) and (16), it is sufficient to show that the dynamic programming principle holds, i.e.,

$$u_k(x) = \inf\left\{ E\left[\int_0^\theta e^{-(\alpha+\frac{1}{\varepsilon})t}\{F(x_t)+|c_t|^2\}dt + e^{-(\alpha+\frac{1}{\varepsilon})\theta}u_k(x_\theta)\right]:\ c\in\mathcal{A}_k \right\} \tag{22}$$

for any $\theta \in \mathcal{S}$, which may depend on $c \in \mathcal{A}_k$. Indeed, we denote by $u^r(x)$ the right-hand side of (22) and we may suppose that θ is bounded. By (19) we have

$$\begin{aligned} u_k(x) &= \inf\Bigg(E\Bigg[\int_0^\theta e^{-(\alpha+\frac{1}{\varepsilon})t}\Big\{F(x_t)+|c_t|^2\Big\}dt \\ &\qquad + \int_\theta^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\Big\{F(x_t)+|c_t|^2\Big\}dt\Bigg]\Bigg) \\ &= \inf\Bigg(E\Bigg[\int_0^\theta e^{-(\alpha+\frac{1}{\varepsilon})t}\Big\{F(x_t)+|c_t|^2\Big\}dt \\ &\qquad + e^{-(\alpha+\frac{1}{\varepsilon})\theta}\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\Big\{F(\tilde{x}_t)+|\tilde{c}_t|^2\Big\}dt\Bigg]\Bigg) \\ &\geq u^r(x), \end{aligned}$$

where

$$\begin{aligned} d\tilde{x}_t &= [b(\tilde{x}_t)+\tilde{c}_t]dt + \sigma(\tilde{x}_t)d\tilde{W}_t, \qquad \tilde{x}_0 = x_\theta, \\ \tilde{c}_t &= c_{t+\theta}. \end{aligned}$$

To prove the reverse inequality, let $\zeta > 0$ be arbitrary and we set

$$U_c(x) = E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\Big\{F(x_t)+|c_t|^2\Big\}dt\right], \qquad c\in\mathcal{A}_k. \tag{23}$$

By analogy with (12) and (13), we observe that there exists $\delta > 0$ (independent of c) such that

$$|x-y|<\delta \quad\Rightarrow\quad |u_k(x)-u_k(y)| \leq \sup_c |U_c(x)-U_c(y)| \leq \zeta. \tag{24}$$

We consider a sequence $\{S_i\}$ of disjoint subsets of $\mathbf{R^N}$ such that

$$\operatorname{diam}(S_i) < \delta \quad \text{and} \quad \bigcup_i S_i = \mathbf{R^N}.$$

For any i, we take $x_i \in S_i$ and $c^{(i)} \in \mathcal{A}_k$ such that

$$U_{c^{(i)}}(x_i) \leq \inf_c U_c(x_i) + \zeta. \tag{25}$$

Define $c^\theta \in \mathcal{A}_k$ by

$$c^\theta_t = c_t 1_{\{t<\theta\}} + c^{(i)}_{t-\theta} 1_{\{t\geq\theta\}}$$

for $x_\theta \in S_i$. Hence, by (24) and (25)

$$\begin{aligned} U_{c^{(i)}}(x_\theta) &= U_{c^{(i)}}(x_\theta) - U_{c^{(i)}}(x_i) + U_{c^{(i)}}(x_i) \\ &\le \zeta + U_{c^{(i)}}(x_i) \\ &\le 2\zeta + \inf_c U_c(x_i) \\ &= 2\zeta + u_k(x_i) \\ &\le 3\zeta + u_k(x_\theta). \end{aligned}$$

Now, we can find $c \in \mathcal{A}_k$ such that

$$u^r(x) + \zeta \ge E\left[\int_0^\theta e^{-(\alpha+\frac{1}{\varepsilon})t}\{F(x_t) + |c_t|^2\}dt + e^{-(\alpha+\frac{1}{\varepsilon})\theta}u_k(x_\theta)\right].$$

Thus

$$\begin{aligned} u^r(x) + \zeta &\ge \sum_i E\left[\int_0^\theta e^{-(\alpha+\frac{1}{\varepsilon})t}\{F(x_t) + |c_t|^2\}dt + e^{-(\alpha+\frac{1}{\varepsilon})\theta}(U_{c^{(i)}}(x_\theta) - 3\zeta) : x_\theta \in S_i\right] \\ &\ge E\left[\int_0^\theta e^{-(\alpha+\frac{1}{\varepsilon})t}\{F(x_t^\theta) + |c_t^\theta|^2\}dt + \int_\theta^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\{F(x_t^\theta) + |c_t^\theta|^2\}dt\right] - 3\zeta \\ &= U_{c^\theta}(x) - 3\zeta \\ &\ge u_k(x) - 3\zeta, \end{aligned}$$

where

$$dx_t^\theta = [b(x_t^\theta) + c_t^\theta]dt + \sigma(x_t^\theta)dW_t, \qquad x_0^\theta = x.$$

Consequently we deduce $u^r(x) \ge u_k(x)$, completing the proof of (22).

LEMMA 2.5. *Under* (5), (6), *and* (7), *we have*

$$u_k \quad \to \quad u \quad \textit{locally uniformly in } \mathbf{R^N}.$$

Proof. By (4) and (19), it is clear that $u_k \ge u$. By Dini's theorem, it suffices to show that

$$u_k(x) \quad \downarrow \quad u(x) \quad \text{as } k \to \infty \ \text{ for each } x. \tag{26}$$

Let $c_t^k = c_t 1_{\{|c_t| \le k\}}$ for any $c \in \mathcal{A}$ and x_t^k be the solution of

$$dx_t^k = [b(x_t^k) + c_t^k]dt + \sigma(x_t^k)dW_t, \qquad x_0^k = x.$$

Applying Ito's formula and localizing the stochastic integral, we observe by (5) and (6) that for any $\theta \in \mathcal{S}$,

$$\begin{aligned} E[e^{-\alpha\theta}|x_\theta|^2] &\le E\left[\int_0^\theta e^{-\alpha t}\left\{-\alpha|x|^2 + 2x\cdot(b(x)+c_t) + \mathrm{tr}(\sigma\sigma^*(x))\right\}\Big|_{x=x_t} dt\right] \\ &\le E\left[\int_0^\theta e^{-\alpha t}\left\{-\frac{\alpha}{2}|x_t|^2 + \frac{4}{\alpha}(\sup_x |b(x)|^2 + |c_t|^2) + \sup_x |\sigma(x)|^2\right\}dt\right] < \infty \end{aligned}$$

and

$$E[e^{-\alpha\theta}|x_\theta^k - x_\theta|^2] \le E\left[\int_0^\theta e^{-\alpha t}\{(-\alpha+\nu)|x_t^k - x_t|^2 + 2(x_t^k - x_t)\cdot(c_t^k - c_t)\}dt\right]$$
$$\le E\left[\int_0^\theta e^{-\alpha t}\{-\eta|x_t^k - x_t|^2 + 2(x_t^k - x_t)\cdot(c_t^k - c_t)\}dt\right]$$
$$\le E\left[\int_0^\theta e^{-\alpha t}\left\{-\frac{\eta}{2}|x_t^k - x_t|^2 + \frac{2}{\eta}|c_t^k - c_t|^2\right\}dt\right].$$

By (4) there exists $c \in \mathcal{A}$, for any $\zeta > 0$, such that $u(x) + \zeta > U_c(x)$. Then, by (11), (23), and (20)

$$|U_c(x) - U_{c^k}(x)| \le E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\{\zeta + C_{\zeta,F}|x_t - x_t^k| + |c_t|^2 - |c_t^k|^2\}dt\right]$$
$$\le \zeta/\alpha + C_{\zeta,F}\left(E\left[\int_0^\infty e^{-\alpha t}|x_t - x_t^k|^2 dt\right]\right)^{1/2}\left(\int_0^\infty e^{-\alpha t}dt\right)^{1/2}$$
$$+E\left[\int_0^\infty e^{-\alpha t}(|c_t|^2 - |c_t^k|^2)dt\right]$$
$$\le (1/\alpha + 2)\zeta$$

for sufficiently large k. Thus

$$u(x) + \zeta \ge U_{c^k}(x) - [U_{c^k}(x) - U_c(x)|$$
$$\ge u_k(x) - (1/\alpha + 2)\zeta.$$

Letting $k \to \infty$ and $\zeta \to 0$, we obtain (26).

Remark. Taking into account the proof of Lemma 2.5, we notice that for any $\theta \in \mathcal{S}$,

$$E[e^{-\alpha\theta}|u_k(x_\theta^k) - u(x_\theta)|] \le E[e^{-\alpha\theta}|u_k(x_\theta^k) - u(x_\theta^k)|] + E[e^{-\alpha\theta}u(x_\theta^k) - u(x_\theta)|]$$
$$\le \sup_{|x|\le R}|u_k(x) - u(x)| + 2\|u_1\|E[e^{-\alpha\theta}|x_\theta^k|^2]/R^2$$
$$+ E[\zeta + C_{\zeta,u}e^{-\alpha\theta}|x_\theta^k - x_\theta|] \quad \to \quad 0,$$

as $k \to \infty$ and $R, \zeta^{-1} \to \infty$. Then, passing to the limit in (22), we can show that the dynamic programming principle holds for u.

THEOREM 2.6. *We make the assumptions of Theorem* 2.1. *Then the solution* u *of* (4) *is a viscosity solution of* (14).

Proof. Combining Lemma 2.4 with 2.5, we get the assertion by the stability result [5, Lem. 6.2, p. 73] as follows.

Let $\varphi \in C^2$ and z be the maximizer of $u - \varphi$ such that

$$u(z) - \varphi(z) > u(x) - \varphi(x)$$

in the closed ball $\bar{B}(z,\delta)$ with radius δ of $z \ne x$. By Lemma 2.5, $u_k - \varphi$ attains a local maximum at some $z_k \in \bar{B}(z,\delta)$. Take a subsequence $z_{k'}$ of z_k such that

$$z_{k'} \quad \to \quad z' \in \bar{B}(z,\delta).$$

By Lemma 2.5

$$(u_{k'} - \varphi)(z_{k'}) \quad \to \quad (u - \varphi)(z').$$

Since

$$(u_{k'} - \varphi)(z_{k'}) > (u_{k'} - \varphi)(x), \qquad x \in \bar{B}(z, \delta),$$

we have

$$(u - \varphi)(z') \geq (u - \varphi)(x), \qquad x \in \bar{B}(z, \delta).$$

Thus we deduce

$$z = z'$$

and the convergence of the whole sequence.

Now, it follows from Lemma 2.4 that

$$-\left(\alpha + \frac{1}{\varepsilon}\right) u_k(z_k) - L_0\varphi(z_k) + F(z_k) + \min_{|c| \leq k}(|c|^2 + c \cdot D\varphi(z_k)) \geq 0.$$

Note that

$$\min_{|c| \leq k}(|c|^2 + c \cdot \xi) \to \min_{c}(|c|^2 + c \cdot \xi) \quad \text{ locally uniformly in } \mathbf{R^N} \text{ as } k \to \infty.$$

Letting $k \to \infty$, we get

$$-\left(\alpha + \frac{1}{\varepsilon}\right) u(z) - L_0\varphi(z) + F(z) + \min_{c}(|c|^2 + c \cdot D\varphi(z)) \geq 0.$$

By a simple relation

$$u \wedge g = u - (u - g)^+,$$

we see that u satisfies (15). By a similar argument, we conclude that u fulfills (16).

2.3. Another representation of u. In this subsection, we shall show that the unique solution u of (4) admits another representation

$$u(x) = \inf_{c} E\left[\int_0^\theta e^{-\alpha t}\left\{f(x_t) - \frac{1}{\varepsilon}(u - g)^+(x_t) + |c_t|^2\right\}dt + e^{-\alpha\theta}u(x_\theta)\right] \tag{27}$$

for any $\theta \in \mathcal{S}$. We set $H(x) = f(x) - \frac{1}{\varepsilon}(u - g)^+(x)$ and consider

$$-L\xi + H(x) - \frac{1}{4}|D\xi|^2 = 0, \qquad x \in \mathbf{R^N}. \tag{28}$$

Define

$$\xi(x) = \inf_{c} E\left[\int_0^\infty e^{-\alpha t}\left\{H(x_t) + |c_t|^2\right\}\, dt\right], \tag{29}$$

which belongs to $\mathcal{C}$. By the same arguments as in subsection 2.2, we can see that ξ satisfies the dynamic programming principle

$$\xi(x) = \inf_{c} E\left[\int_0^\theta e^{-\alpha t}\{H(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}\xi(x_\theta)\right], \qquad \theta \in \mathcal{S},$$

and then ξ is a viscosity solution of (28).

THEOREM 2.7. *Under the assumptions of Theorem* 2.1, *we have* (27).

Proof. By Theorem 2.6, the relation (27) follows from the uniqueness of viscosity solutions of (28). Dividing the proof into several steps, we claim

$$\xi_1 \le \xi_2 \tag{30}$$

for two viscosity solutions $\xi_i \in \mathcal{C}$, $i = 1, 2$, of (28).

Step 1. Suppose there exists $\bar{x} \in \mathbf{R^N}$ such that

$$\xi_1(\bar{x}) - \xi_2(\bar{x}) > 0,$$

which implies

$$\xi_1(\bar{x}) - \xi_2(\bar{x}) \ge \delta \tag{31}$$

for some $\delta > 0$.

Define

$$\Psi_k(x, y) = \xi_1(x) - \xi_2(y) - \frac{k}{2}|x - y|^2 - \frac{1}{k}(\psi(x) + \psi(y)), \tag{32}$$

where $\psi(x) = \frac{1}{2}\log(1 + |x|^2)$ and $k > 0$. Since

$$\Psi_k(x, y) \quad \to \quad -\infty \quad \text{as} \quad |x|, |y| \to \infty,$$

we find $(x_k, y_k) \in \mathbf{R^N} \times \mathbf{R^N}$ such that

$$\begin{aligned}
\Psi_k(x_k, y_k) &= \sup \Psi_k(x, y) \\
&\ge \Psi_k(\bar{x}, \bar{x}) \\
&= \xi_1(\bar{x}) - \xi_2(\bar{x}) - \frac{2}{k}\psi(\bar{x}) \\
&\ge \delta - \frac{2}{k}\psi(\bar{x}) \\
&\ge \frac{\delta}{2} \quad \text{for} \quad k \ge \exists k_0 > 0.
\end{aligned}$$

Thus

$$\begin{aligned}
\frac{\delta}{2} &\le \xi_1(x_k) - \xi_2(y_k) - \frac{k}{2}|x_k - y_k|^2 - \frac{1}{k}(\psi(x_k) + \psi(y_k)) \\
&\le \xi_1(x_k) - \xi_2(y_k).
\end{aligned} \tag{33}$$

Step 2. By the definition of (x_k, y_k), we have

$$2\Psi_k(x_k, y_k) \ge \Psi_k(x_k, x_k) + \Psi_k(y_k, y_k),$$

or equivalently

$$\begin{aligned}
2\Big[\xi_1(x_k) - \xi_2(y_k) - \frac{k}{2}|x_k - y_k|^2 - \frac{1}{k}(\psi(x_k) + \psi(y_k))\Big] \\
\ge \xi_1(x_k) - \xi_2(x_k) - \frac{2}{k}\psi(x_k) \\
+ \xi_1(y_k) - \xi_2(y_k) - \frac{2}{k}\psi(y_k).
\end{aligned}$$

Hence

$$k|x_k - y_k|^2 \le \xi_1(x_k) - \xi_2(y_k) + \xi_2(x_k) - \xi_1(y_k) \le C \qquad (C > 0).$$

Thus

$$|x_k - y_k| \le (C/k)^{1/2}. \tag{34}$$

By the uniform continuity of ξ_i, we deduce

$$\begin{aligned} k|x_k - y_k|^2 &\le \sup_{|x-y|\le (C/k)^{1/2}} |\xi_1(x) - \xi_1(y)| + |\xi_2(x) - \xi_2(y)| \\ &\to \quad 0 \quad \text{as} \quad k \to \infty. \end{aligned} \tag{35}$$

Step 3. We here invoke the following lemma (see Crandall, Ishii, and Lions [4, Thm. 3.2], Fleming and Soner [5, Lem. 6.1, p. 238], and Ishii [7, Lem. 1, p. 149] for the proof).

LEMMA 2.8 (Ishii [7]). *Let $U, -V$ be upper semicontinuous in an open domain, and set*

$$W(x,y) = U(x) - V(y) - \frac{k}{2}|x-y|^2.$$

Let $(\hat{x}, \hat{y})$ be the local maximizer of W. Then there exist $X, Y \in \mathbf{S^N}$ such that

$$(k(\hat{x} - \hat{y}), X) \in \bar{J}^{2,+}U(\hat{x}), \tag{36}$$

$$(k(\hat{x} - \hat{y}), Y) \in \bar{J}^{2,-}V(\hat{y}), \tag{37}$$

$$-3k \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \le \begin{pmatrix} X & 0 \\ 0 & -Y \end{pmatrix} \le 3k \begin{pmatrix} I & -I \\ -I & I \end{pmatrix}, \qquad I = \textit{identity}, \tag{38}$$

where

$$\begin{aligned} \bar{J}^{2,\pm}U(x) = \{(p,X) : \exists x_n \to x, \exists (p_n, X_n) \in J^{2,\pm}U(x_n), \\ (U(x_n), p_n, X_n) \to (U(x), p, X)\}. \end{aligned}$$

Now we take

$$\begin{aligned} U(x) &= \xi_1(x) - \frac{1}{k}\psi(x), \\ V(y) &= \xi_2(y) + \frac{1}{k}\psi(y) \end{aligned}$$

and note that

$$J^{2,+}\xi_1(x) = \left\{ (\underline{p}, \underline{X}) + \left(\frac{1}{k} D\psi(x), \frac{1}{k} D^2\psi(x) \right) : \ (\underline{p}, \underline{X}) \in J^{2,+}U(x) \right\},$$

$$J^{2,-}\xi_2(y) = \left\{ (\underline{p}, \underline{X}) - \left(\frac{1}{k} D\psi(y), \frac{1}{k} D^2\psi(y) \right) : \ (\underline{p}, \underline{X}) \in J^{2,-}V(y) \right\}.$$

Then it follows from (36), (37), and the definition of $\bar{J}^{2,+}\xi_1(x_k), \bar{J}^{2,-}\xi_2(y_k)$ that

$$(p_1, \bar{X}) := (k(x_k - y_k), X) + \left(\frac{1}{k} D\psi(x_k), \frac{1}{k} D^2\psi(x_k) \right) \in \bar{J}^{2,+}\xi_1(x_k), \tag{39}$$

$$(p_2, \bar{Y}) := (k(x_k - y_k), Y) - \left(\frac{1}{k} D\psi(y_k), \frac{1}{k} D^2\psi(y_k) \right) \in \bar{J}^{2,-}\xi_2(y_k). \tag{40}$$

Step 4. We have by (28) and (40) that

$$-\alpha\xi_2(y_k) + \frac{1}{2}\mathrm{tr}(\sigma\sigma^*(y_k)\bar{Y}) + b(y_k)\cdot p_2 + H(y_k) - \frac{1}{4}|p_2|^2 \le 0. \tag{41}$$

Also, by (28) and (39)

$$\alpha\xi_1(x_k) \le \frac{1}{2}\mathrm{tr}(\sigma\sigma^*(x)\bar{X}) + b(x_k)\cdot p_1 + H(x_k) - \frac{1}{4}|p_1|^2. \tag{42}$$

Thus, adding (42) to (41), we obtain

$$\begin{aligned}\alpha(\xi_1(x_k) - \xi_2(y_k)) &\le \mathrm{tr}(\sigma\sigma^*(x_k)X - \sigma\sigma^*(y_k)Y)/2 \\ &\quad + \mathrm{tr}(\sigma\sigma^*(x_k)D^2\psi(x_k) + \sigma\sigma^*(y_k)D^2\psi(y_k))/2k \\ &\quad + [b(x_k)\cdot p_1 - b(y_k)\cdot p_2] \\ &\quad + [H(x_k) - H(y_k)] \\ &\quad - [|p_1|^2 - |p_2|^2]/4. \\ &\equiv I_1/2 + I_2/2 + I_3 + I_4 - I_5/4.\end{aligned} \tag{43}$$

Step 5. We claim that

$$I_j \quad \to \quad 0 \quad \text{as} \quad k \to \infty \qquad (j = 1, 2, \ldots, 5),$$

which leads to a contradiction with (33).

According to Fleming and Soner [5, Lem. 6.2, p. 240], we know that (38) implies

$$\mathrm{tr}(\sigma\sigma^*(x)X - \sigma\sigma^*(y)Y) \le 3k|\sigma(x) - \sigma(y)|^2.$$

Hence, we have by the Lipschitz continuity of $\sigma(x)$ and (35)

$$I_1 \le 3kC|x_k - y_k|^2 \quad \to \quad 0 \quad \text{as} \quad k \to \infty.$$

By a simple manipulation, we get

$$|D\psi(x)| = \frac{|x|}{1+|x|^2}, \quad |D^2\psi(x)| \le \frac{C}{1+|x|^2}, \quad C > 0.$$

Then

$$\begin{aligned}I_2 &\le \frac{1}{k}\left[|\sigma\sigma^*(x_k)D^2\psi(x_k)| + |\sigma\sigma^*(y_k)D^2\psi(y_k)|\right] \\ &\le \frac{C}{k}\left[\frac{(|\sigma(0)| + |x_k|)^2}{1+|x_k|^2} + \frac{(|\sigma(0)| + |y_k|)^2}{1+|y_k|^2}\right] \quad \to \quad 0 \quad \text{as} \quad k \to \infty.\end{aligned}$$

By the Lipschitz continuity of $b(x)$, we see that

$$\begin{aligned}|I_3| &\le kC|x_k - y_k|^2 + (|b(x_k)||D\psi(x_k)| + |b(y_k)||D\psi(y_k)|)/k \\ &\le kC|x_k - y_k|^2 + C\sup_x\left(\frac{(|b(0)| + |x|)|x|}{1+|x|^2}\right)/k \\ &\quad \to \quad 0 \quad \text{as} \quad k \to \infty.\end{aligned}$$

By (34), we have

$$|I_4| \le \sup_{|x-y|\le(C/k)^{1/2}} |H(x) - H(y)| \to 0.$$

Finally, by (35)

$$\begin{aligned}|I_5| &\le \frac{2}{k}|k(x_k - y_k)\cdot(D\psi(x_k) + D\psi(y_k))| \\ &\quad + \left| |\tfrac{1}{k}D\psi(x_k)|^2 - |\tfrac{1}{k}D\psi(y_k)|^2 \right| \\ &\le \frac{2}{k}|k(x_k - y_k)| + \frac{C}{k^2} \quad \to \quad 0 \ \text{ as } \ k \to \infty.\end{aligned}$$

Therefore the theorem is established.

3. Viscosity solutions of variational inequalities.

3.1. Convergence as $\varepsilon \to 0$. We study the convergence of $u_\varepsilon = u$ as $\varepsilon = \varepsilon_n = 2^{-n} \to 0$. Define

$$G_\beta h(x) = E\left[\int_0^\infty e^{-\beta t} h(\bar{x}_t)dt\right], \qquad \beta > 0, \tag{44}$$

and

$$\mathcal{D} = \{G_\beta(\beta h) : \ h \in \mathcal{C}, \ \beta > \alpha\}, \tag{45}$$

where $\bar{x}_t$ is the unique solution of

$$d\bar{x}_t = b(\bar{x}_t)dt + \sigma(\bar{x}_t)dW_t, \qquad \bar{x}_0 = x. \tag{46}$$

LEMMA 3.1. *Under* (5) *and* (6), $\mathcal{D}$ *is dense in* $\mathcal{C}$.

Proof. We claim that

$$\mathcal{D} \subset \mathcal{C}. \tag{47}$$

Let $h \in \mathcal{C}$ be arbitrary. It is clear that $\|G_\beta(\beta h)\| \le \|h\|$. Further, (10) gives

$$E[|\bar{x}_t - \bar{y}_t|^2 e^{(-\beta+\eta)t}] \le |x - y|^2$$

for the solution $\bar{y}_t$ of (46) with $\bar{y}_0 = y$. By the same calculations as (12) and (13), we can get

$$|G_\beta(\beta h)(x) - G_\beta(\beta h)(y)| \le \zeta + 2C_{\zeta,h}|x - y|\beta/(\beta + \eta) \qquad \forall \zeta > 0,$$

and hence

$$\lim_{\delta \to 0} \sup_{|x-y|<\delta} |G_\beta(\beta h)(x) - G_\beta(\beta h)(y)| = 0,$$

which implies (47). Moreover, by (11), (46), and (5)

$$\begin{aligned}E[h(\bar{x}_t) - h(x)|] &\le \zeta + C_{\zeta,h}E[|\bar{x}_t - x|] \\ &\le \zeta + \bar{C}(t + \sqrt{t}),\end{aligned}$$

where $\bar{C} = C_{\zeta,h}[\sup_x |b(x)| + \sup_x |\sigma(x)|]$. Therefore, letting $\beta \to \infty$ and then $\zeta \to 0$, we deduce

$$\begin{aligned}\|G_\beta(\beta h) - h\| &\le \zeta + \bar{C}\int_0^\infty \beta e^{-\beta t}(t + \sqrt{t})dt \\ &= \zeta + \bar{C}\int_0^\infty e^{-s}(s/\beta + \sqrt{s/\beta})ds \quad \to \quad 0,\end{aligned}$$

which completes the proof.

LEMMA 3.2. *Let $\tilde{u}_\varepsilon$ be the solution of* (4) *corresponding to $\tilde{g} \in \mathcal{C}_+$. Then we have, under* (5), (6), *and* (7),

$$\|u_\varepsilon - \tilde{u}_\varepsilon\| \le \|g - \tilde{g}\|. \tag{48}$$

Proof. We shall show the assertion by the same line as Bensoussan [2, Lem. 5.5, p. 320]. Let $w, \tilde{w} \in \mathcal{C}$ verify

$$\|w - \tilde{w}\| \le \|g - \tilde{g}\|.$$

Then, it is easy to check that

$$\|w \wedge g - \tilde{w} \wedge \tilde{g}\| \le \|g - \tilde{g}\|,$$

and then, by (8),

$$\begin{aligned} |Tw(x) - \tilde{T}\tilde{w}(x)| &\le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\frac{1}{\varepsilon}|w \wedge g - \tilde{w} \wedge \tilde{g}|(x_t)dt\right] \\ &\le \|g - \tilde{g}\|, \end{aligned}$$

where $\tilde{T}$ denotes T with $\tilde{g}$ replacing g. But

$$\begin{aligned} |T0 - \tilde{T}0| &\le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\frac{1}{\varepsilon}|g^- - \tilde{g}^-|(x_t)dt\right] \\ &\le \|g - \tilde{g}\|. \end{aligned}$$

Taking $w = T0$, $\tilde{w} = \tilde{T}0$, we have

$$\|T^2 0 - \tilde{T}^2 0\| \le \|g - \tilde{g}\|,$$

and then

$$\|T^n 0 - \tilde{T}^n 0\| \le \|g - \tilde{g}\|, \qquad n = 1, 2, \ldots.$$

Letting $n \to \infty$, we deduce (48) by Theorem 2.1.

LEMMA 3.3. *Under* (5), (6), *and* (7), *we have*

$$u_\varepsilon(x) = \inf_c \inf_\theta E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}\{g + (u_\varepsilon - g)^+\}(x_\theta)\right]. \tag{49}$$

Proof. By Theorem 2.7

$$\begin{aligned} u_\varepsilon(x) &= \inf_c E\left[\int_0^\theta e^{-\alpha t}\left\{f(x_t) - \frac{1}{\varepsilon}(u - g)^+(x_t) + |c_t|^2\right\}dt + e^{-\alpha\theta}u_\varepsilon(x_\theta)\right] \\ &\le \inf_c E\left[\int_0^\theta e^{-\alpha t}\left\{f(x_t) + |c_t|^2\right\}dt + e^{-\alpha\theta}u_\varepsilon \vee g(x_\theta)\right] \qquad \forall\theta \in \mathcal{S}. \end{aligned}$$

On the other hand, we take $\theta = \tau = \inf\{t : \ u_\varepsilon(x_t) \ge g(x_t)\}$. Since

$$e^{-\alpha\tau}g(x_\tau) = e^{-\alpha\tau}u_\varepsilon \vee g(x_\tau) = e^{-\alpha\tau}[g + (u_\varepsilon - g)^+](x_\tau),$$

we have

$$\begin{aligned} u_\varepsilon(x) &= \inf_c E\left[\int_0^\tau e^{-\alpha t}\left\{f(x_t) - \frac{1}{\varepsilon}(u - g)^+(x_t) + |c_t|^2\right\}dt + e^{-\alpha\tau}u_\varepsilon(x_\tau)\right] \\ &= \inf_c E\left[\int_0^\tau e^{-\alpha t}\left\{f(x_t) + |c_t|^2\right\}dt + e^{-\alpha\tau}g(x_\tau)\right], \end{aligned}$$

which completes the proof.

THEOREM 3.4. *Under* (5), (6), *and* (7), *we have*

$$u_{\varepsilon_n} \quad \to \quad v \in \mathcal{C}, \tag{50}$$

where $\varepsilon_n = 2^{-n}$.

Proof. Let $g = G_\beta(\beta\hat{h}) \in \mathcal{D}$ for some $\hat{h} \in \mathcal{C}$. In view of Theorems 2.6 and 2.7, we observe that g is a unique viscosity solution of

$$-\beta g - L_0 g + \beta\hat{h} = 0 \quad \text{in} \quad \mathbf{R^N},$$

or equivalently

$$-\left(\alpha + \frac{1}{\varepsilon}\right) g - L_0 g + \beta h + \frac{1}{\varepsilon} g = 0 \quad \text{in} \quad \mathbf{R^N},$$

where $\beta h = \beta\hat{h} + (\alpha - \beta)g$. Hence we have $g = G_{\alpha+\frac{1}{\varepsilon}}(\beta h + \frac{1}{\varepsilon} g)$. Therefore

$$\begin{aligned} u_\varepsilon - g &\le u_\varepsilon - \inf_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left\{\beta h(x_t) + \frac{1}{\varepsilon} g(x_t) + |c_t|^2\right\} dt\right] \\ &\le \sup_c E\left[\int_0^\infty e^{-(\alpha+\frac{1}{\varepsilon})t}\left\{f - \beta h + \frac{1}{\varepsilon}(u_\varepsilon \wedge g - g)\right\}(x_t) dt\right] \\ &\le \varepsilon \|f - \beta h\|. \end{aligned} \tag{51}$$

Applying (49) to $u_{\varepsilon_{n+1}}(x)$ and $u_{\varepsilon_n}(x)$, we have by (51)

$$\begin{aligned} |u_{\varepsilon_{n+1}}(x) - u_{\varepsilon_n}(x)| &\le \sup_c \sup_\theta E[e^{-\alpha\theta} |(u_{\varepsilon_{n+1}} - g)^+ - (u_{\varepsilon_n} - g)^+|(x_\theta)] \\ &\le (\varepsilon_{n+1} + \varepsilon_n)\|f - \beta h\|. \end{aligned}$$

Thus

$$\sum_{n=1}^\infty \|u_{\varepsilon_{n+1}} - u_{\varepsilon_n}\| \le \sum_{n=1}^\infty (\varepsilon_{n+1} + \varepsilon_n)\|f - \beta h\| < \infty.$$

This implies that $\{u_{\varepsilon_n}\}$ is a Cauchy sequence in $\mathcal{C}$, and we get (50).

In the case $g \in \mathcal{C}_+$, there exists a sequence $\{g_m\} \subset \mathcal{D}$ such that $g_m \to g$ by Lemma 3.1. Let u_ε^m be the solution of (4) corresponding to g_m. By the above argument, we see that

$$u_{\varepsilon_n}^m \quad \to \quad v^m \in \mathcal{C} \quad \text{as} \quad n \to \infty. \tag{52}$$

By (48),

$$\|u_{\varepsilon_n}^m - u_{\varepsilon_n}^{m'}\| \le \|g_m - g_{m'}\|.$$

Letting $n \to \infty$, we have

$$\|v^m - v^{m'}\| \le \|g_m - g_{m'}\|.$$

Hence $\{v^m\}$ is a Cauchy sequence, and

$$v^m \quad \to \quad v \in \mathcal{C}. \tag{53}$$

Thus

$$\begin{aligned} \|u_{\varepsilon_n} - v\| &\le \|u_{\varepsilon_n} - u_{\varepsilon_n}^m\| + \|u_{\varepsilon_n}^m - v^m\| + \|v^m - v\| \\ &\le \|g - g_m\| + \|u_{\varepsilon_n}^m - v^m\| + \|v^m - v\|. \end{aligned}$$

Letting $n \to \infty$ and then $m \to \infty$, we obtain (50).

3.2. Existence. In this subsection we consider the variational inequality:

$$
\begin{aligned}
&-Lv + f - \frac{1}{4}|Dv|^2 \geq 0, \\
&v \leq g \qquad\qquad \text{in } \mathbf{R^N}, \\
&\left(-Lv + f - \frac{1}{4}|Dv|^2\right)(v-g)^- = 0.
\end{aligned} \tag{54}
$$

We present the definition of the viscosity solutions of the variational inequality in the following.

DEFINITION 3.5. *$w \in \mathcal{C}$ is called a viscosity solution of* (54) *if the following assertions are satisfied:*

$$
\begin{aligned}
&\text{For any } \varphi \in C^2 \text{ and any local maximum point } z \text{ of } w - \varphi, \\
&-\alpha w(z) - L_0\varphi(z) + f(z) - \frac{1}{4}|D\varphi(z)|^2 \geq 0, \\
&w(x) \leq g(x), \qquad x \in \mathbf{R^N}. \\
&\text{For any } \varphi \in C^2 \text{ and any local minimum point } z \text{ of } w - \varphi, \\
&\left(-\alpha w(z) - L_0\varphi(z) + f(z) - \frac{1}{4}|D\varphi(z)|^2\right)(w-g)^-(z) \leq 0.
\end{aligned} \tag{55}
$$

THEOREM 3.6. *We make the assumptions of Theorem* 3.4. *Then the limit v of* (50) *is a viscosity solution of* (54).

Proof. Let $\varphi \in C^2$ and z be the maximizer of $v - \varphi$ such that

$$v(z) - \varphi(z) > v(x) - \varphi(x), \quad x \in \bar{B}(z,\delta), \quad z \neq x.$$

By the uniform convergence in Theorem 3.4, $u_{\varepsilon_n} - \varphi$ attains a local maximum at $x_n \in \bar{B}(z,\delta)$. By the same argument as Theorem 2.6, we deduce

$$x_n \quad \to \quad z.$$

Now, we have by Theorem 2.6 and (15)

$$-\alpha u_{\varepsilon_n}(x_n) - L_0\varphi(x_n) + f(x_n) - \frac{1}{\varepsilon_n}(u_{\varepsilon_n} - g)^+(x_n) - \frac{1}{4}|D\varphi(x_n)|^2 \geq 0,$$

from which

$$-\alpha u_{\varepsilon_n}(x_n) - L_0\varphi(x_n) + f(x_n) - \frac{1}{4}|D\varphi(x_n)|^2 \geq 0.$$

Letting $n \to \infty$, we get

$$-\alpha v(z) - L_0\varphi(z) + f(z) - \frac{1}{4}|D\varphi(z)|^2 \geq 0. \tag{56}$$

Next, by (51)

$$(u^m_{\varepsilon_n} - g_m)^+ \leq \varepsilon_n \|f - h_m\|,$$

where $g_m = G_\beta h_m$ for some $h_m \in \mathcal{C}$. Letting $n \to \infty$, we have by (52)

$$v^m \leq g_m,$$

and then by (53)

$$v \le g. \tag{57}$$

Finally, let $\bar{z}$ be the minimizer of $v-\varphi$, and $\bar{x}_n$ be the local minimizer of $u_{\varepsilon_n}-\varphi$ with $\bar{x}_n \to \bar{z}$. Then, by Theorem 2.6 and (16)

$$-\alpha u_{\varepsilon_n}(\bar{x}_n) - L_0\varphi(\bar{x}_n) + f(\bar{x}_n) - \frac{1}{\varepsilon_n}(u_{\varepsilon_n}-g)^+(\bar{x}_n) - \frac{1}{4}|D\varphi(\bar{x}_n)|^2 \le 0.$$

Multiply both sides by $(u_{\varepsilon_n}-g)^-$ to obtain

$$\left(-\alpha u_{\varepsilon_n}(\bar{x}_n) - L_0\varphi(\bar{x}_n) + f(\bar{x}_n) - \frac{1}{4}|D\varphi(\bar{x}_n)|^2\right)(u_{\varepsilon_n}-g)^-(\bar{x}_n) \le 0.$$

Letting $n \to \infty$, we deduce

$$\left(-\alpha v(\bar{z}) - L_0\varphi(\bar{z}) + f(\bar{z}) - \frac{1}{4}|D\varphi(\bar{z})|^2\right)(v-g)^-(\bar{z}) \le 0. \tag{58}$$

The assertions (56), (57), and (58) verify that v is a viscosity solution of (54) in the sense of (55).

3.3. Uniqueness.

THEOREM 3.7. *The assumptions are those of Theorem* 3.4. *Let* $v_i \in \mathcal{C}$, $i=1,2$, *be two viscosity solutions of* (54). *Then we have*

$$v_1 = v_2.$$

Proof. We shall show that

$$\left(-\alpha v_2(y) + \frac{1}{2}\mathrm{tr}(\sigma\sigma^*(y)\tilde{X}) + b(y)\cdot p + f(y) - \frac{1}{4}|p|^2\right)(v_2-v_1)^-(y) \le 0 \tag{59}$$
$$\forall (p,\tilde{X}) \in \bar{J}^{2,-}v_2(y), \quad \forall y \in \mathbf{R^N},$$

or equivalently

$$\left(-\alpha v_2(\tilde{z}) - L_0\varphi(\tilde{z}) + f(\tilde{z}) - \frac{1}{4}|D\varphi(\tilde{z})|^2\right)(v_2-v_1)^-(\tilde{z}) \le 0, \tag{60}$$

where $\varphi \in C^2$ and $\tilde{z}$ is the minimizer of $v_2-\varphi$. If $v_2 \ge v_1$, then $(v_2-v_1)^- = 0$. If $v_2 < v_1$, then $v_2 < v_1 \le g$, and thus $(v_2-g)^- > 0$. By (58) we recall

$$\left(-\alpha v_2(\tilde{z}) - L_0\varphi(\tilde{z}) + f(\tilde{z}) - \frac{1}{4}|D\varphi(\tilde{z})|^2\right)(v_2-g)^-(\tilde{z}) \le 0.$$

Then we deduce

$$-\alpha v_2(\tilde{z}) - L_0\varphi(\tilde{z}) + f(\tilde{z}) - \frac{1}{4}|D\varphi(\tilde{z})|^2 \le 0,$$

which implies (60).

Now, we prove the theorem by the same line as Theorem 2.7. Suppose there exists $\bar{x} \in \mathbf{R^N}$ such that

$$v_1(\bar{x}) - v_2(\bar{x}) > 0,$$

which implies

$$v_1(\bar{x}) - v_2(\bar{x}) \geq \delta \tag{61}$$

for some $\delta > 0$. We define

$$\Phi_k(x,y) = v_1(x) - v_2(y) - \frac{k}{2}|x-y|^2 - \frac{1}{k}(\psi(x) + \psi(y))$$

as in (32). Then the maximizer (x_k, y_k) of $\Phi_k(x,y)$ satisfies

$$\frac{\delta}{2} \leq v_1(x_k) - v_2(y_k) \tag{62}$$

for sufficiently large k. As in Steps 2 and 3 of Theorem 2.7 we have

$$k|x_k - y_k|^2 \quad \to \quad 0 \quad \text{as} \quad k \to \infty$$

and

$$(\hat{p}_1, \hat{X}) := (k(x_k - y_k), X) + \left(\frac{1}{k}D\psi(x_k), \frac{1}{k}D^2\psi(x_k)\right) \in \bar{J}^{2,+}v_1(x_k),$$

$$(\hat{p}_2, \hat{Y}) := (k(x_k - y_k), Y) - \left(\frac{1}{k}D\psi(y_k), \frac{1}{k}D^2\psi(y_k)\right) \in \bar{J}^{2,-}v_2(y_k).$$

By (62) we get

$$\begin{aligned} v_1(y_k) - v_2(y_k) &\geq v_1(x_k) - v_2(y_k) - |v_1(x_k) - v_1(y_k)| \\ &\geq \frac{\delta}{2} - |v_1(y_k) - v_1(x_k)| \\ &\geq \frac{\delta}{4} \quad \text{for sufficiently large } k, \end{aligned}$$

which implies

$$(v_2(y_k) - v_1(y_k))^- > 0.$$

From (59) it follows that

$$-\alpha v_2(y_k) + \frac{1}{2}\mathrm{tr}(\sigma\sigma^*(y_k)\hat{Y}) + b(y_k)\cdot\hat{p}_2 + f(y_k) - \frac{1}{4}|\hat{p}_2|^2 \leq 0. \tag{63}$$

Also, by (56)

$$\alpha v_1(x_k) \leq \frac{1}{2}\mathrm{tr}(\sigma\sigma^*(x_k)\hat{X}) + b(x_k)\cdot\hat{p}_1 + f(x_k) - \frac{1}{4}|\hat{p}_1|^2. \tag{64}$$

Hence we see that (63) and (64) are the similar relations to (41) and (42). Thus, we deduce by the same calculations as in Steps 4 and 5 of Theorem 2.7

$$\alpha(v_1(x_k) - v_2(y_k)) \quad \to \quad 0 \ \text{ as } \ k \ \to \infty,$$

which is contrary with (62). The proof is complete.

3.4. A stochastic interpretation of v. We here give a stochastic interpretation of the viscosity solution v of (54).

THEOREM 3.8. *The assumptions are those of Theorem* 3.4. *Then we have*

$$v(x) = \inf_c \inf_\theta E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}g(x_\theta)\right]. \tag{65}$$

Proof. We extend the technique of Morimoto [12] for the proof. Let $\hat{v}$ denote the right-hand side of (65). By (27) we have

$$\begin{aligned} u_{\varepsilon_n}(x) &= \inf_c E\left[\int_0^\theta e^{-\alpha t}\left\{f(x_t) - \frac{1}{\varepsilon_n}(u_{\varepsilon_n} - g)^+(x_t) + |c_t|^2\right\}dt + e^{-\alpha\theta}u_{\varepsilon_n}(x_\theta)\right] \\ &\le \inf_c E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}u_{\varepsilon_n}(x_\theta)\right] \qquad \forall\theta \in \mathcal{S}. \end{aligned}$$

Letting $n \to \infty$, we have by (50)

$$\begin{aligned} v(x) &\le \inf_c E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}v(x_\theta)\right] \\ &\le \inf_c E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}g(x_\theta)\right], \end{aligned}$$

which yields $v \le \hat{v}$. For the reverse inequality, we take any $c \in \mathcal{A}$ and set

$$R_m = \inf\left\{t : \ v(x_t) + \frac{1}{m} \ge g(x_t)\right\}.$$

Since

$$v(x_t) + \frac{1}{m} < g(x_t) \ \text{ on } \ \{t < R_m\},$$

we get

$$\begin{aligned} E\left[\int_0^{R_m} e^{-\alpha t}(u_{\varepsilon_n} - g)^+(x_t)dt\right] &\le E\left[\int_0^{R_m} e^{-\alpha t}\left(u_{\varepsilon_n} - \left(v + \frac{1}{m}\right)\right)^+(x_t)dt\right] \\ &\le E\left[\int_0^{R_m} e^{-\alpha t}\left(\|u_{\varepsilon_n} - v\| - \frac{1}{m}\right)^+(x_t)dt\right] \\ &= 0 \end{aligned}$$

for sufficiently large n. Hence, by (27)

$$\begin{aligned} u_{\varepsilon_n}(x) &= \inf_c E\left[\int_0^{R_m} e^{-\alpha t}\{f(x_t) - \frac{1}{\varepsilon_n}(u_{\varepsilon_n} - g)^+(x_t) + |c_t|^2\}dt + e^{-\alpha R_m}u_{\varepsilon_n}(x_{R_m})\right] \\ &= \inf_c E\left[\int_0^{R_m} e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha R_m}u_{\varepsilon_n}(x_{R_m})\right]. \end{aligned}$$

Letting $n \to \infty$, we have by (50) and the definition of R_m

$$\begin{aligned} v(x) &= \inf_c E\left[\int_0^{R_m} e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha R_m} v(x_{R_m})\right] \\ &= \inf_c E\left[\int_0^{R_m} e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha R_m}\left\{g(x_{R_m}) - \frac{1}{m}\right\}\right] \\ &\geq \inf_c E\left[\int_0^{R_m} e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha R_m} g(x_{R_m})\right] - \frac{1}{m} \\ &\geq \hat{v}(x) - \frac{1}{m}. \end{aligned}$$

Letting $m \to \infty$, we deduce $v(x) \geq \hat{v}(x)$, which completes the proof.

4. Impulsive control.

4.1. Setting of the problem. We consider an application of the variational inequality to the impulsive control problem. Impulsive control is described by a set (Θ, γ):

$$\begin{aligned} &\Theta = \{\theta_n\}, \qquad \theta_n \in \mathcal{S} \ \uparrow \infty, \\ &\gamma = \{\gamma_n\}, \qquad \gamma_n \in \mathbf{R}_+^{\mathbf{N}} : \ \mathcal{F}_{\theta_n} - \text{measurable}. \end{aligned}$$

The controlled equation becomes

$$d\chi_t = [b(\chi_t) + c_t]dt + \sigma(\chi_t)dW_t + \sum_{n=1}^{\infty} \delta(t - \theta_n)\gamma_n, \qquad \chi_0 = x,$$

where $\delta(\cdot)$ is the Dirac measure. More precisely we define a sequence of processes:

$$\begin{aligned} &d\chi_t^n = [b(\chi_t^n) + c_t]dt + \sigma(\chi_t^n)dW_t, \quad \chi^n(\theta_n) = \chi^{n-1}(\theta_n) + \gamma_n, \quad n \geq 1, \\ &d\chi_t^0 = [b(\chi_t^0) + c_t]dt + \sigma(\chi_t^0)dW_t, \quad \chi^0(0) = x. \end{aligned}$$

Then we write

$$\chi_t = \chi_t^n, \qquad \theta_n \leq t < \theta_{n+1}.$$

The aim is to minimize the cost

$$J(c, \theta, \gamma) = E\left[\int_0^{\infty} e^{-\alpha t}\{f(\chi_t) + |c_t|^2\}dt + \sum_{n=1}^{\infty} e^{-\alpha\theta_n}\rho(\gamma_n)\right],$$

where f and ρ are assumed to satisfy

$$\begin{aligned} &f \in \mathcal{C}_+, \\ &\rho(x) = k + \rho_0(x) \quad \text{for} \quad x \in \mathbf{R}_+^{\mathbf{N}}, \\ &k > 0, \quad \rho_0 \in \mathcal{C}_+(\mathbf{R}_+^{\mathbf{N}}), \quad \rho_0 > (0) = 0. \end{aligned} \tag{66}$$

Now, the quasi-variational inequality associated with the impulsive control problem is given by

$$\begin{aligned} &-Lv + f - \frac{1}{4}|Dv|^2 \geq 0, \\ &v \leq Mv \qquad\qquad \text{in} \quad \mathbf{R}^{\mathbf{N}}, \\ &\left(-Lv + f - \frac{1}{4}|Dv|^2\right)(v - Mv)^- = 0, \end{aligned} \tag{67}$$

where $Mv(x) := \inf_{\gamma \in \mathbf{R}_+^{\mathbf{N}}}[v(x + \gamma) + \rho(\gamma)]$.

4.2. Quasi-variational inequalities. In this subsection we show the existence of a unique viscosity solution of the quasi-variational inequality (67).

Define

$$Qw(x) = \inf_c \inf_\theta E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta} Mw(x_\theta)\right], \qquad w \in \mathcal{C}_+, \tag{68}$$

where x_t is as in (3).

LEMMA 4.1. *For all $w, \tilde{w} \in \mathcal{C}_+$ we have, under* (5), (6), *and* (66),

$$0 \le Qw \le \|f\|/\alpha, \tag{69}$$

$$Qw \in \mathcal{C}_+, \tag{70}$$

$$w \le \tilde{w} \quad \Rightarrow \quad Qw \le Q\tilde{w}, \tag{71}$$

$$Q(\mu w + (1-\mu)\tilde{w}) \ge \mu Qw + (1-\mu)Q\tilde{w}, \qquad \mu \in [0,1]. \tag{72}$$

Proof. As is shown in Bardi and Capuzzo-Dolcetta [1], we can easily see that

$$\begin{aligned}
&0 \le Mw \le \|w\| + k,\\
&Mw \in \mathcal{C}_+,\\
&\|Mw - M\tilde{w}\| \le \|w - \tilde{w}\|,\\
&w \le \tilde{w} \quad \Rightarrow \quad Mw \le M\tilde{w},\\
&M(\mu w + (1-\mu)\tilde{w}) \ge \mu Mw + (1-\mu)M\tilde{w}, \qquad \mu \in [0,1].
\end{aligned}$$

Hence (69) and (71) are obvious. (72) is an easy consequence of the concavity of M. (70) follows from Theorems 3.6–3.8.

LEMMA 4.2. *If $w, \tilde{w} \in \mathcal{C}_+$ satisfy $w - \tilde{w} \le \lambda w$ for some $\lambda \in [0,1]$, then we have, under* (5), (6), *and* (66),

$$Qw - Q\tilde{w} \le \lambda(1-\mu)Qw \qquad \forall \mu \in \left(0, \frac{k}{\|v^0\|} \wedge 1\right), \tag{73}$$

where

$$v^0(x) := \inf_c E\left[\int_0^\infty e^{-\alpha t}\left\{f(x_t) + |c_t|^2\right\}dt\right].$$

Proof. By (72) we see

$$Q((1-\lambda)w + \lambda 0) \ge (1-\lambda)Qw + \lambda Q0.$$

Since

$$(1-\lambda)w \le \tilde{w},$$

we have

$$Q\tilde{w} \ge (1-\lambda)Qw + \lambda Q0,$$

or equivalently

$$Qw - Q\tilde{w} \le \lambda(Qw - Q0).$$

By virtue of (11) and (12) we note that

$$v^0 \in \mathcal{C}_+,$$

and by (68)

$$Qw \le v^0.$$

To complete the proof, it suffices to show that

$$Q0 \ge \mu v^0 \qquad \forall \mu \in \left(0, \frac{k}{\|v^0\|} \wedge 1\right). \tag{74}$$

By (66) we have $M0 = k$, and then

$$Q0 = \inf_c \inf_\theta E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}k\right].$$

It is obvious that

$$\mu v^0(x_t) \le \mu\|v^0\| \le \frac{k}{\|v^0\|}\|v^0\| = k.$$

Thus, we get by the dynamic programming principle for $v^0(x)$

$$\begin{aligned} Q0 &\ge \inf_c \inf_\theta E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta}\mu v^0(x_\theta)\right] \\ &\ge \mu \inf_c \inf_\theta E\left[\int_0^\theta e^{-\alpha t}\{f(x_t) + |c_t|^2\}dt + e^{-\alpha\theta} v^0(x_\theta)\right] \\ &= \mu v^0(x), \end{aligned}$$

which implies (74).

THEOREM 4.3. *We assume* (5), (6), *and* (66). *Then there exists one and only one viscosity solution* $\bar{v} \in \mathcal{C}_+$ *of* (67).

Proof. Set $v^n = Q^n v^0 \in \mathcal{C}_+$. It is clear that

$$0 \le v^1 = Qv^0 \le v^0,$$

and then

$$0 \le v^n \le v^{n-1} \le v^0.$$

Moreover,

$$v^1 - v^0 \le v^1.$$

By (73) we have

$$Qv^1 - Qv^0 \le (1-\mu)Qv^1 \qquad \forall \mu \in \left(0, \frac{k}{\|v^0\|} \wedge 1\right),$$

from which

$$v^2 - v^1 \le (1-\mu)v^2.$$

By iteration, we get

$$v^{n+1} - v^n \le (1-\mu)^n v^{n+1} \le (1-\mu)^n v^0.$$

Thus we deduce

$$v^n \quad \to \quad \bar{v} \quad \text{in } \mathcal{C}_+.$$

We recall by Theorems 3.6–3.8 that v^n is a unique viscosity solution of

$$\begin{aligned} &-Lv^n + f - \frac{1}{4}|Dv^n|^2 \ge 0, \\ &v^n \le Mv^{n-1} \qquad\qquad \text{in } \mathbf{R^N}, \\ &\left(-Lv^n + f - \frac{1}{4}|Dv^n|^2\right)(v^n - Mv^{n-1})^- = 0, \end{aligned}$$

and we apply the stability result on viscosity solutions as in Theorem 2.6. Letting $n \to \infty$, we see that $\bar{v}$ is a viscosity solution of (67) in the sense of Definition 3.5 with $M\bar{v}$ replacing g.

To prove uniqueness, let $v_i \in \mathcal{C}_+$, $i = 1, 2$, be two viscosity solutions of (67). By Theorems 3.7 and 3.8, we see

$$v_i = Qv_i, \qquad i = 1, 2.$$

Clearly

$$v_1 - v_2 \le v_1.$$

Applying (73) with $\lambda = 1$, we have

$$Qv_1 - Qv_2 \le (1-\mu)Qv_1 \qquad \forall \mu \in \left(0, \frac{k}{\|v^0\|} \wedge 1\right).$$

Hence

$$v_1 - v_2 \le (1-\mu)v_1.$$

By iteration,

$$v_1 - v_2 \le (1-\mu)^n v_1, \qquad n = 1, 2, \ldots.$$

Letting $n \to \infty$, we get $v_1 \le v_2$, which completes the proof.

Concluding remarks. In this paper we have investigated the nonlinear variational inequality associated with the combined control problem with discretionary stopping. We have shown the existence of a unique viscosity solution to the variational inequality by the improved methods of the theory of linear variational inequalities. Further we have applied the technique of viscosity solutions to solve quasi-variational inequalities.

This paper presents the definition of viscosity solutions to the variational inequality, which is different from the ordinary one in [1, p. 196; 4]. As seen in Definition 3.5, the viscosity solution w coincides with a viscosity solution V of the boundary value problem

$$\begin{aligned} -LV + f(x) - \frac{1}{4}|DV|^2 = 0 \quad &\text{in} \quad \mathcal{O}, \\ V = w \qquad\qquad\qquad\quad &\text{on} \quad \partial\mathcal{O}, \end{aligned}$$

on any open domain $\mathcal{O} \subset \{x : w(x) < g(x)\}$. It seems possible to have the smoothness of w from the classical results on the smoothness of V together with the properties of g and the boundary $\partial\mathcal{O}$. We need to study the regularity of viscosity solutions of the variational inequality under milder conditions on b, σ, f, g for the optimization problem (2), (3).

Acknowledgments. The author would like to thank two anonymous referees for their valuable and helpful comments that led to an improved version of the paper.

REGIONAL NULL CONTROLLABILITY OF A LINEARIZED CROCCO-TYPE EQUATION*

P. MARTINEZ†, J.-P. RAYMOND†, AND J. VANCOSTENOBLE†

Abstract. We are interested in controllability problems of equations coming from a boundary layer model. We simplify the problem by considering only equations with constant coefficients. The problem is described by a degenerate parabolic equation (a linearized Crocco-type equation) where phenomena of diffusion and transport are coupled.

First we give a geometric characterization of the influence domain of a locally distributed control. Then we prove *regional* null controllability results on this domain. The proof is based on an adequate observability inequality for the homogeneous adjoint problem. This inequality is obtained by decomposition of the space-time domain and Carleman-type estimates along characteristics.

In the second part of this paper, we treat the case of a boundary control.

Key words. regional null controllability, parabolic degenerate equation, transport equation, heat equation, Carleman estimates

1. Introduction.

The velocity field of a laminar flow on a flat plate can be described by the Prandtl equations [23]. For a two dimensional flow, these equations are stated in an unbounded domain $(0, L) \times (0, \infty)$, where $(0, L)$ represents the part of the plate where the flow is laminar, and $(0, \infty)$ represents the "thickness" of the boundary layer. The matching conditions with the external flow are stated at $+\infty$.

By using the so-called Crocco transformation, these equations are transformed into a nonlinear degenerate parabolic equation (the Crocco equation; see [23]) which is stated in a bounded domain $\Omega = (0, L) \times (0, 1)$. The linearization of the Crocco equation around a stationary solution is an equation of the form

$$\begin{cases} u_t + au_x - bu_{yy} + cu = g, & (x, y, t) \in \Omega \times (0, T), \\ u(x, 0, t) = 0, & (x, t) \in (0, L) \times (0, T), \\ u_y(x, 1, t) = \chi_{(x_0, x_1)}(x) f(x, t), & (x, t) \in (0, L) \times (0, T), \\ u(0, y, t) = u_1(y, t), & (y, t) \in (0, 1) \times (0, T), \\ u(x, y, 0) = u_0(x, y), & (x, y) \in \Omega, \end{cases} \tag{1.1}$$

where g and u_1 depend on the incident velocity of the flow, and where the function f is the control used to stabilize the velocity in the boundary layer. The coefficients a, b, and c are regular, but degenerate, and have the following behavior [6, 5]:

$$0 < a_1 \leq \frac{a(y)}{y} \leq a_2, \quad 0 < b_1 \leq \frac{b(x, y)}{-(y-1)^2 \ln(\mu(1-y))} \leq b_2, \quad c(x, y) \geq 0,$$

where $0 < \mu < 1$. Since the coefficient b is degenerate, the Dirichlet boundary condition at $y = 1$ has to be correctly interpreted (see [5]).

†Laboratoire M.I.P., U.M.R. 5640, Université Paul Sabatier Toulouse III, 118 route de Narbonne, 31 062 Toulouse Cedex 4, France (martinez@mip.ups-tlse.fr, raymond@mip.ups-tlse.fr, vancoste@mip.ups-tlse.fr).

This linearized model has been used to study stabilization problems of boundary layers in [4]. The perturbations of the velocity field in the boundary layer are controlled by a suction velocity f through the plate, localized on a slot (x_0, x_1).

In this paper we are interested in the null controllability problem for an equation of the type (1.1), but with constant coefficients. For simplicity, we first study a problem with homogeneous Dirichlet boundary conditions and a locally distributed control (see section 2). The cases of the other kinds of boundary conditions (Neumann or mixed Dirichlet–Neumann conditions) together with the case of a boundary control are treated in a second part of the paper (see sections 3 and 4).

Let $\omega = (x_0, x_1) \times \omega_y$, where $0 < x_0 < x_1 < L$ and ω_y is an open subset of $(0, 1)$, and let χ_ω be the characteristic function of ω.

For $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1) \times (0,T))$, and $f \in L^2(\omega \times (0,T))$, we consider the following control problem:

$$
\begin{cases}
u_t + u_x - u_{yy} = \chi_\omega(x,y) f(x,y,t), & (x,y,t) \in \Omega \times (0,T), \\
u(x,0,t) = u(x,1,t) = 0, & (x,t) \in (0,L) \times (0,T), \\
u(0,y,t) = u_1(y,t), & (y,t) \in (0,1) \times (0,T), \\
u(x,y,0) = u_0(x,y), & (x,y) \in \Omega.
\end{cases} \tag{1.2}
$$

First one can prove that the problem is well-posed: for all $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1)\times(0,T))$, and $f \in L^2(\omega\times(0,T))$, problem (1.2) has a unique solution that satisfies $u \in \mathcal{C}^0([0,T]; L^2(\Omega)) \cap \mathcal{C}^0([0,L]; L^2((0,T)\times(0,1))) \cap L^2((0,T)\times(0,L); H_0^1(0,1))$.

Then we study the following *regional* null controllability problem: *for all* $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1) \times (0,T))$, *does there exist* $f \in L^2(\omega \times (0,T))$ *such that the solution* u *of* (1.2) *satisfies* $u(x,y,T) = 0$ *for* $(x,y) \in \Omega_C(T)$, *where* $\Omega_C(T)$ *denotes a part of* Ω*?*

Note that for nondegenerate parabolic equations stated in a bounded domain Ω, (*global*) null controllability is by now well known: for all nonempty $\omega \subset \Omega$ and for all $T > 0$, there exists $f \in L^2((0,T) \times \omega)$ such that the corresponding solution of the heat equation satisfies $u(T) \equiv 0$ in the *whole* domain Ω. These results are, in general, obtained via Carleman estimates (see, for example, [16, 14, 2]). But to our knowledge it seems that no result was known concerning a degenerate case.

Note also that, in the case studied in this paper, due to transport phenomenon, the influence domain of the control $\chi_\omega f$ is not the whole domain Ω at time $T > 0$. Thus (global) null controllability does not occur. For this reason, we introduce the notion of *regional* null controllability.

As a first step, we give a geometric characterization of the influence domain of the control $\chi_\omega f$ in order to determine the region $\Omega_C(T)$ of Ω on which it will be possible to control $u(\cdot, T)$ (see section 2.1).

Then we prove a result of *regional* null controllability on the domain $\Omega_C(T)$ (see section 2.3). This result is obtained via the introduction of an adequate penalized problem and the obtaining of a suitable observability inequality (given in section 2.2) for the homogeneous adjoint problem. This inequality is obtained by decomposition of the space-time domain and by using Carleman-type estimates along characteristics.

In the second part of this paper, we treat the case of a Dirichlet *boundary control*. We also prove a *regional* null controllability result via the obtaining of a similar boundary observability inequality. However, due to a lack of regularity of the solutions of the boundary value problem, the penalized problem that we introduce has to be modified.

2. The case of a localized distributed control.

2.1. Domain of influence of the control. Let $T > 0$ be fixed and define

$$\Omega_C(T) := \begin{cases} (x_0, x_1 + T) \times (0,1) & \text{if } T < L - x_1, \\ (x_0, L) \times (0,1) & \text{if } T > L - x_1. \end{cases}$$

Using spectral decomposition of the solution of (1.2), one can prove that the domain of influence of $\chi_\omega f$ at time T is the domain $\Omega_C(T)$ represented in Figure 2.1 (in the case $T < L - x_1$). Indeed, due to the phenomenon of diffusion in the direction y, the region of influence in y at time T of a control supported in y in ω_y is the whole interval $(0,1)$. On the other hand, due to the transport phenomenon (at speed equal to 1) in the x-direction, the region of influence in x at time T of a control supported in x in (x_0, x_1) is only $(x_0, x_1 + T)$ in the case $T < L - x_1$ and is only (x_0, L) in the case $T > L - x_1$. This means that a control localized in $\omega \times (0,T)$ has no influence at time T on the solution in $\Omega \setminus \Omega_c(T)$.

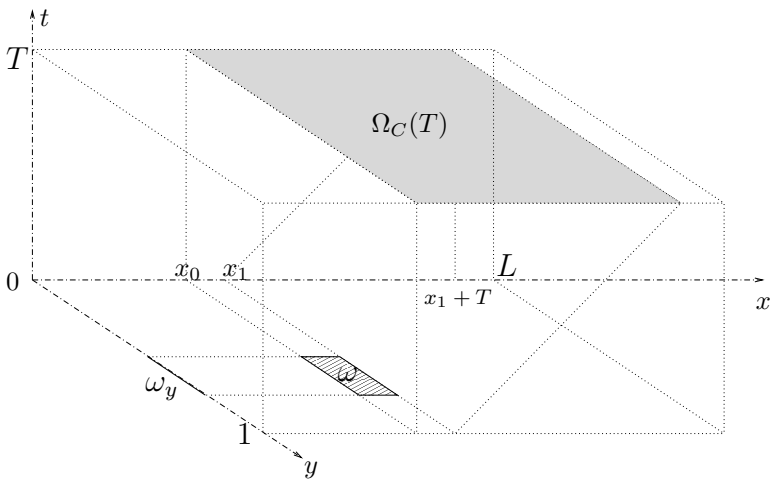

FIG. 2.1.

More precisely, we prove the following proposition.

PROPOSITION 2.1. *Assume that $\tilde{\Omega}$ is such that $\Omega_C(T) \subset \tilde{\Omega} \subset \Omega$ and $\Omega_C(T) \neq \tilde{\Omega}$. Then there exists $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1) \times (0,T))$ such that for all $f \in L^2(\omega \times (0,T))$, the solution u of (1.2) is not identically equal to zero in $\tilde{\Omega}$.*

Thus we will finally prove a *regional* null controllability result in a set $\Omega_C(T, \delta)$ that will be arbitrarily close to $\Omega_C(T)$. For this, we first need an adequate observability estimate for the homogeneous adjoint problem.

2.2. Observability inequality. Assume that $T > 0$ and for all δ such that $0 < \delta < (x_1 - x_0)/2$ define

$$\Omega_C(T, \delta) := \begin{cases} (x_0 + \delta, x_1 + T - \delta) \times (0,1) & \text{if } 0 < T < L - x_1 + \delta, \\ (x_0 + \delta, L) \times (0,1) & \text{if } T > L - x_1 + \delta. \end{cases} \tag{2.1}$$

Then we prove the following observability estimate.

THEOREM 2.1. *Under the previous assumptions, there exists* $C(T,\delta,\omega_y)>0$ *such that the solutions* v *of the adjoint equation*

$$v_t + v_x + v_{yy} = 0, \quad (x,y,t)\in\Omega\times(0,T), \tag{2.2}$$

belonging to $\mathcal{C}^0([0,T];L^2((0,L)\times(0,1)))\cap\mathcal{C}^0([0,L];L^2((0,T)\times(0,1)))\cap L^2((0,L)\times(0,T);H_0^1(0,1))$ *satisfy*

$$\begin{aligned}\iint_{(0,L)\times(0,1)} v(x,y,0)^2\,dydx \;+\; \iint_{(0,1)\times(0,T)} v(0,y,t)^2\,dtdy \\ \le\; C\,(T,\delta,\omega_y)\left(\iiint_{\omega\times(0,T)} v(x,y,t)^2\,dtdydx\right. \\ \left. +\iint_{\Omega\setminus\Omega_C(T,\delta)} v(x,y,T)^2\,dydx \;+\; \iint_{(0,1)\times(0,T)} v(L,y,t)^2\,dtdy\right).\end{aligned} \tag{2.3}$$

Remark. The proof is first based on a decomposition of the domain $\Omega\times(0,T)$. Moreover, we notice that, along characteristics, v is solution of a nondegenerate parabolic equation for which Carleman's estimates are known. Then, on each subdomains and along characteristics, we apply Carleman's estimates.

2.3. Null controllability result. Finally we deduce the following result of null controllability.

THEOREM 2.2. *Under the previous assumptions, for all* $u_0\in L^2(\Omega)$, $u_1\in L^2((0,1)\times(0,T))$, *there exists* $f\in L^2(\omega\times(0,T))$ *such that the solution* u^f *of* (1.2) *satisfies*

$$u^f(x,y,T)=0 \quad \textit{for } (x,y)\in\Omega_C(T,\delta). \tag{2.4}$$

Remarks. 1. In the proof, we use the following penalized problem

$$\inf_{f\in L^2(\omega\times(0,T))}\Big(\frac{1}{2}\iiint_{\omega\times(0,T)} f^2\,dtdydx \;+\; \frac{1}{2\varepsilon}\iint_{\Omega_C(T,\delta)} u^f(x,y,T)^2\,dydx\Big),$$

where u^f is the solution of (1.2) associated with f.

2. In the case $T>L-x_1+\delta$, it is easy to see that there exists $f\in L^2(\omega\times(0,T))$ such that the solution u^f of (1.2) satisfies the stronger property

$$u^f(x,y,t)=0 \quad \text{for } (x,y,t)\in\Big(\Omega_C(T,\delta)\times\{T\}\Big)\cup\Big(\{L\}\times(0,1)\times(L-x_1+\delta,T)\Big).$$

This means that if we extend the solution to $[0,L']$ with $L'>T-x_1+\delta$, the corresponding domain on which the null controllability result is true at time T is the domain $(x_0+\delta,x_1+T-\delta)\times(0,1)$.

3. Lot of results are known concerning nondegenerate parabolic equations. But to our knowledge it seems that very few results were known concerning a degenerate case.

First, a quite similar problem was recently studied in [1]. The authors consider a model of age-dependent population dynamics with diffusion. The structure of the equation is quite similar to the structure of (1.2): there is a diffusion phenomenon in one direction while there is a transport phenomenon in the other one. For this model, the authors prove a null controllability result on the whole domain. This comes from the fact that the control is globally distributed in the direction of transport (while in our case, the control is locally distributed in (x_0,x_1)) and to the fact that the boundary condition in [1] is an integral equation with suitable support properties.

On the other hand, another result of regional null controllability was also recently obtained in [7, 8] for an other degenerate parabolic equation but with a type of degeneracy that is quite different of the one that we study in this paper. We studied the (strongly) degenerate equation

$$u_t - (a(x)u_x)_x = \chi_{(\alpha,\beta)} f,$$

where a may vanish on $[0, \alpha']$ for $0 \leq \alpha' < \beta$. For all $T > 0$, we proved a result of regional null controllability at time T in the region $(\alpha + \delta, 1)$ (for all $\delta > 0$ such that $\alpha + \delta \leq 1$).

4. For nondegenerate parabolic equations, (*global*) null controllability holds. Then, since the energy of the uncontrolled energy is nonincreasing, once the system has been driven to zero in time T, it remains indefinitely at zero without being controlling anymore.

In our case, the situation is not the same. First, if the boundary condition u_1 is equal to zero and if $T > x_0$, then the solution u^f which satisfies (2.4) is also equal to zero on the domain $\mathcal{R}_1 \cup \mathcal{R}_2$ (see Figure 2.2 below) without being controlling anymore. Now in the general case, given $u_1 \in L^2_{\text{loc}}([0, +\infty); L^2(0, 1))$, due to the transport phenomenon, the solution u remains equal to zero on the domain $\mathcal{R}_2$.

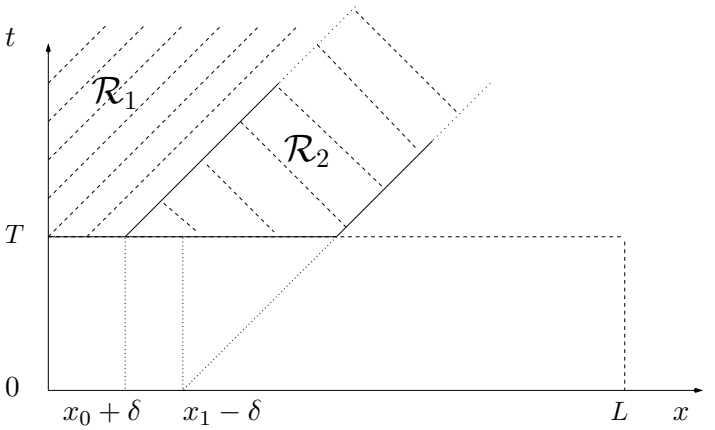

FIG. 2.2.

Since, given $\tau \geq T$, it is possible to find a control f^τ that drives the system to rest at time τ on the set $(x_0 + \delta, x_1 - \delta + \tau) \times (0, 1)$, it would be interesting to know if, given $T' > T$, it is possible to find a control $f^{T,T'}$ that drives the system to rest on the time-space domain $\{(x, y, \tau), \tau \in (T, T'), (x, y, \tau) \in (x_0 + \delta, x_1 - \delta + \tau) \times (0, 1) \times \{\tau\}\}$.

3. The case of a boundary control. Let $0 < x_0 < x_1 < L$ be fixed. For $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0, 1) \times (0, T))$, and $f \in L^2((x_0, x_1) \times (0, T))$, we consider the following control problem:

$$\begin{cases} u_t + u_x - u_{yy} = 0, & (x, y, t) \in \Omega \times (0, T), \\ u(x, 0, t) = 0, & (x, t) \in (0, L) \times (0, T), \\ u(x, 1, t) = \chi_{(x_0,x_1)}(x) f(x, t), & (x, t) \in (0, L) \times (0, T), \\ u(0, y, t) = u_1(y, t), & (y, t) \in (0, 1) \times (0, T), \\ u(x, y, 0) = u_0(x, y), & (x, y) \in \Omega. \end{cases} \tag{3.1}$$

First one can prove that the problem is well-posed: for all $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1)\times(0,T))$, and $f \in L^2((x_0,x_1)\times(0,T))$, problem (3.1) has a unique solution that satisfies $u \in \mathcal{C}^0([0,T];L^2(0,L;H^{-1}(0,1))) \cap \mathcal{C}^0([0,L];L^2(0,T;H^{-1}(0,1))) \cap L^2(\Omega\times(0,T))$.

Then we study the problem of regional null controllability. (As in the distributed case, due to the transport phenomenon in the x-direction, the region of influence in x of a control supported in x in (x_0,x_1) is only (x_0,x_1+T) in the case $T<L-x_1$ and is only (x_0,L) in the case $T>L-x_1$.) We assume that $T>0$, and we still define $\Omega_C(T,\delta)$ by (2.1) for all $0<\delta<(x_1-x_0)/2$. Then we prove the following observability estimate.

THEOREM 3.1. *Under the previous assumptions, there exists $C(T,\delta)>0$ such that the solutions v of the adjoint equation (2.2) belonging to $\mathcal{C}^0([0,T];L^2((0,L)\times(0,1))) \cap \mathcal{C}^0([0,L];L^2((0,T)\times(0,1))) \cap L^2((0,L)\times(0,T);H^2\cap H_0^1(0,1))$ satisfy*

$$\begin{aligned}(3.2)\quad &\iint_{(0,L)\times(0,1)} v(x,y,0)^2\,dydx \;+\; \iint_{(0,1)\times(0,T)} v(0,y,t)^2\,dtdy\\ &\le\; C\,(T,\delta)\left(\iint_{(0,T)\times(x_0,x_1)} v_y(x,1,t)^2\,dxdt\right.\\ &\quad\left.+\iint_{\Omega\setminus\Omega_C(T,\delta)} v(x,y,T)^2\,dydx \;+\; \iint_{(0,1)\times(0,T)} v(L,y,t)^2\,dtdy\right).\end{aligned}$$

Then we deduce the following result of null controllability.

THEOREM 3.2. *Under the previous assumptions, for all $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1)\times(0,T))$, there exists $f \in L^2((x_0,x_1)\times(0,T))$ such that the solution u of (3.1) satisfies*

$$u(x,y,T)=0 \quad \textit{for } (x,y)\in\Omega_C(T,\delta).$$

4. The case of Neumann or mixed boundary conditions.

4.1. Locally distributed control. It is easy to adapt the proof of Theorem 2.2 to Neumann–Dirichlet or Neumann boundary conditions: let u^f be the solution of

$$(4.1)\qquad \begin{cases} u_t+u_x-u_{yy}=\chi_\omega(x,y)f(x,y,t), & (x,y,t)\in\Omega\times(0,T),\\ u_y(x,0,t)=u(x,1,t)=0, & (x,t)\in(0,L)\times(0,T),\\ u(0,y,t)=u_1(y,t), & (y,t)\in(0,1)\times(0,T),\\ u(x,y,0)=u_0(x,y), & (x,y)\in\Omega, \end{cases}$$

or of

$$(4.2)\qquad \begin{cases} u_t+u_x-u_{yy}=\chi_\omega(x,y)f(x,y,t), & (x,y,t)\in\Omega\times(0,T),\\ u_y(x,0,t)=u_y(x,1,t)=0, & (x,t)\in(0,L)\times(0,T),\\ u(0,y,t)=u_1(y,t), & (y,t)\in(0,1)\times(0,T),\\ u(x,y,0)=u_0(x,y), & (x,y)\in\Omega. \end{cases}$$

Then we have the following result of null controllability.

THEOREM 4.1. *Under the previous assumptions, for all $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1)\times(0,T))$, there exists $f\in L^2(\omega\times(0,T))$ such that the solution u^f of (4.1) (or the solution u^f of (4.2)) satisfies*

$$(4.3)\qquad u^f(x,y,T)=0 \quad \textit{for } (x,y)\in\Omega_C(T,\delta).$$

The proof of Theorem 4.1 is very close to the one of Theorem 2.2, and we leave it to the reader.

4.2. Boundary control. It is easy to adapt the proof of Theorem 3.2 to consider Neumann–Dirichlet or Neumann boundary conditions: consider the solution u^f of

$$\begin{cases} u_t + u_x - u_{yy} = 0, & (x,y,t) \in \Omega \times (0,T), \\ u_y(x,0,t) = 0, & (x,t) \in (0,L) \times (0,T), \\ u(x,1,t) = \chi_{(x_0,x_1)}(x) f(x,t), & (x,t) \in (0,L) \times (0,T), \\ u(0,y,t) = u_1(y,t), & (y,t) \in (0,1) \times (0,T), \\ u(x,y,0) = u_0(x,y), & (x,y) \in \Omega, \end{cases} \tag{4.4}$$

or of

$$\begin{cases} u_t + u_x - u_{yy} = 0, & (x,y,t) \in \Omega \times (0,T), \\ u_y(x,0,t) = 0, & (x,t) \in (0,L) \times (0,T), \\ u_y(x,1,t) = \chi_{(x_0,x_1)}(x) f(x,t), & (x,t) \in (0,L) \times (0,T), \\ u(0,y,t) = u_1(y,t), & (y,t) \in (0,1) \times (0,T), \\ u(x,y,0) = u_0(x,y), & (x,y) \in \Omega. \end{cases} \tag{4.5}$$

Then we have the following result of null controllability.

THEOREM 4.2. *Under the previous assumptions, for all $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1) \times (0,T))$, there exists $f \in L^2((x_0,x_1) \times (0,T))$ such that the solution u^f of (4.4) (or the solution u^f of (4.5)) satisfies*

$$u^f(x,y,T) = 0 \quad \textit{for } (x,y) \in \Omega_C(T,\delta). \tag{4.6}$$

The proof of Theorem 4.2 is very close to the one of Theorem 3.2. In section 6.3, we indicate how to derive the observability inequality needed for the proof of Theorem 4.2.

5. Proofs in the distributed case.

5.1. Proof of Proposition 2.1. Consider the eigenvalues $\lambda_k = k^2\pi^2$ and the eigenfunctions $\phi_k(y) = \sqrt{2}\sin(k\pi y)$ of the problem

$$-(\phi_k)_{yy} = \lambda_k \phi_k \text{ for } y \in (0,1) \text{ and } \phi_k(0) = \phi_k(1) = 0.$$

Let $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1) \times (0,T))$, and $f \in L^2(\omega \times (0,T))$ and consider u the solution of (1.2). Since $(\phi_k)_k$ forms an orthonormal basis of $L^2(0,1)$, we can write

$$u_1(y,t) = \sum_{k=0}^{\infty} u_1^k(t)\phi_k(y), \qquad u_0(x,y) = \sum_{k=0}^{\infty} u_0^k(x)\phi_k(y)$$

$$\text{and } \chi_\omega(x,y) f(x,y,t) = \sum_{k=0}^{\infty} f^k(x,t)\phi_k(y), \qquad u(x,y,t) = \sum_{k=0}^{\infty} u^k(x,t)\phi_k(y).$$

Note that for all k, f^k is supported in x in (x_0,x_1). Then for all $k \in \mathbb{N}$, $u^k(x,t)$ is solution of

$$\begin{cases} u_t^k + u_x^k + \lambda_k u^k = f^k, & (x,t) \in (0,L) \times (0,T), \\ u^k(0,t) = u_1^k(t), & t \in (0,T), \\ u^k(x,0) = u_0^k(x), & x \in (0,L). \end{cases}$$

Consequently, we obtain

$$u^k(x,t) = \begin{cases} e^{-\lambda_k x}\, u_1^k(t-x) + \displaystyle\int_{t-x}^{t} e^{-\lambda_k (t-s)} f^k(x-(t-s),s)\, ds & \text{if } x < t, \\ e^{-\lambda_k t}\, u_0^k(x-t) + \displaystyle\int_{0}^{t} e^{-\lambda_k (t-s)} f^k(x-(t-s),s)\, ds & \text{if } x > t. \end{cases}$$

Since $\mathrm{supp}\,(f^k) \subset (x_0,x_1)\times(0,T)$, we deduce that for all $(x,T) \notin \Omega_C(T)$,

$$u^k(x,T) = \begin{cases} e^{-\lambda_k x}\, u_1^k(T-x) & \text{if } x < T, \\ e^{-\lambda_k T}\, u_0^k(x-T) & \text{if } x > T. \end{cases}$$

For all $\tilde\Omega$ such that $\Omega_C(T) \subset \tilde\Omega \subset \Omega$ and $\Omega_C(T) \neq \tilde\Omega$, this allows us to construct $u_0 \in L^2(\Omega)$ and $u_1 \in L^2((0,1)\times(0,T))$ such that for all $f \in L^2(\omega\times(0,T))$, the solution u of (1.2) is not identically equal to zero in $\tilde\Omega$. □

5.2. Proof of Theorem 2.1.

Step 1. In a first step, we prove that it is sufficient to establish (2.3) for *regular* solutions v of (2.2).

Let $v \in \mathcal{C}^0([0,T];L^2((0,L)\times(0,1))) \cap \mathcal{C}^0([0,L];L^2((0,T)\times(0,1))) \cap L^2((0,L)\times(0,T);H_0^1(0,1))$ be a solution of the adjoint problem (2.2). Let $v_L \in L^2((0,T)\times(0,1))$ and $v_T \in L^2((0,L)\times(0,1))$ be the functions defined by $v_L(y,t) := v(L,y,t)$ and $v_T(x,y) := v(x,y,T)$. Then v is a weak solution of the equation

$$\begin{cases} v_t + v_x + v_{yy} = 0, & (x,y,t) \in \Omega\times(0,T), \\ v(x,0,t) = v(x,1,t) = 0, & (x,t) \in (0,L)\times(0,T), \\ v(L,y,t) = v_L(y,t), & (y,t) \in (0,1)\times(0,T), \\ v(x,y,T) = v_T(x,y), & (x,y) \in \Omega. \end{cases}$$

Let $(v_L^n)_n$ be a sequence in $\mathcal{C}_c^1((0,1)\times[0,T)) \cap \mathcal{C}^2([0,1]\times[0,T])$ converging to v_L in $L^2((0,T)\times(0,1))$, and let $(v_T^n)_n$ be a sequence in $\mathcal{C}_c^1([0,L)\times(0,1)) \cap \mathcal{C}^2([0,L]\times[0,1])$ converging to v_T in $L^2((0,L)\times(0,1))$. Denote by v^n the solution of the equation

$$\begin{cases} v_t^n + v_x^n + v_{yy}^n = 0, & (x,y,t) \in \Omega\times(0,T), \\ v^n(x,0,t) = v^n(x,1,t) = 0, & (x,t) \in (0,L)\times(0,T), \\ v^n(L,y,t) = v_L^n(y,t), & (y,t) \in (0,1)\times(0,T), \\ v^n(x,y,T) = v_T^n(x,y), & (x,y) \in \Omega. \end{cases}$$

Using the explicit expression of v^n, we verify that $v^n \in \mathcal{C}^1([0,L]\times[0,T];L^2(0,1)) \cap \mathcal{C}^0([0,L]\times[0,T];H^2 \cap H_0^1(0,1))$ and that $v^n \to v$ in $\mathcal{C}^0([0,T];L^2((0,L)\times(0,1))) \cap \mathcal{C}^0([0,L];L^2((0,T)\times(0,1))) \cap L^2((0,L)\times(0,T);H_0^1(0,1))$ as $n \to +\infty$. Consequently, it is sufficient to prove (2.3) only for solutions having the regularity of v^n. Then (2.3) follows for v by passing to the limit as $n \to +\infty$.

Step 2. Now we assume $v \in \mathcal{C}^1([0,L]\times[0,T];L^2(0,1)) \cap \mathcal{C}^0([0,L]\times[0,T];H^2 \cap H_0^1(0,1))$ and we prove (2.3). We only treat the case $T < L - x_1 + \delta$ and $T \geq x_0 + \delta$ and we use a decomposition of the domain represented in Figure 5.1. (The other cases can be treated with a slightly different decomposition of the domain.)

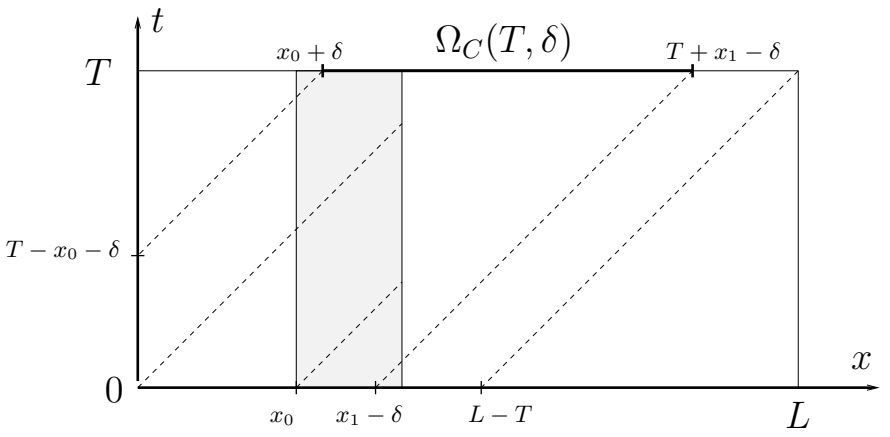

FIG. 5.1.

First we decompose the left-hand side of (2.3) as follows:

$$\begin{aligned}(5.1)\quad &\iint_{(0,L)\times(0,1)} v(x,y,0)^2\,dydx\\ &= \iint_{(0,x_0)\times(0,1)} v(x,y,0)^2\,dydx \;+\; \iint_{(x_0,x_1-\delta)\times(0,1)} v(x,y,0)^2\,dydx\\ &+ \iint_{(x_1-\delta,L-T)\times(0,1)} v(x,y,0)^2\,dydx \;+\; \iint_{(L-T,L)\times(0,1)} v(x,y,0)^2\,dydx\end{aligned}$$

and

$$\begin{aligned}(5.2)\quad &\iint_{(0,1)\times(0,T)} v(0,y,t)^2\,dtdy\\ &= \iint_{(0,1)\times(0,T-x_0-\delta)} v(0,y,t)^2\,dtdy \;+\; \iint_{(0,1)\times(T-x_0-\delta,T)} v(0,y,t)^2\,dtdy.\end{aligned}$$

Then we prove the following inequalities:

$$(5.3)\qquad \iint_{(0,x_0)\times(0,1)} v(x,y,0)^2\,dydx \;\le\; C\int_{x_0}^{x_1}\int_{\omega_y}\int_{x-x_0}^{x} v(x,y,t)^2\,dtdydx,$$

$$(5.4)\qquad \iint_{(x_0,x_1-\delta)\times(0,1)} v(x,y,0)^2\,dydx \;\le\; C\int_{x_0}^{x_1}\int_{\omega_y}\int_{0}^{x-x_0} v(x,y,t)^2\,dtdydx,$$

$$(5.5)\qquad \iint_{(x_1-\delta,L-T)\times(0,1)} v(x,y,0)^2\,dydx \;\le C\int_{x_1-\delta+T}^{L}\int_{0}^{1} v(x,y,T)^2\,dydx,$$

$$(5.6)\qquad \iint_{(L-T,L)\times(0,1)} v(x,y,0)^2\,dydx \;\le C\int_{0}^{1}\int_{0}^{T} v(L,y,t)^2\,dtdy,$$

$$\iint_{(0,1)\times(0,T-x_0-\delta)} v(0,y,t)^2\,dtdy \;\le C\int_{x_0}^{x_1}\int_{\omega_y}\int_x^T v(x,y,t)^2\,dtdydx, \tag{5.7}$$

$$\iint_{(0,1)\times(T-x_0-\delta,T)} v(0,y,t)^2\,dtdy \;\le C\int_0^{x_0+\delta}\int_0^1 v(x,y,T)^2\,dydx. \tag{5.8}$$

Theorem 2.1 follows clearly from (5.1)–(5.8). Note that the proofs of (5.5), (5.6), and (5.8) are similar. Thus we will prove only (5.8). The proofs of (5.3), (5.4), and (5.7) are also similar. And we will prove only (5.3) and (5.4). (We add the proof of (5.4) to show where we use the assumption $\delta > 0$.)

In order to prove these inequalities, we first note that if we consider the solution v of (2.2) along the characteristics, then v is solution of a nondegenerate parabolic equation.

Indeed, let $v \in \mathcal{C}^1([0,L]\times[0,T];L^2(0,1))\cap\mathcal{C}^0([0,L]\times[0,T];H^2\cap H_0^1(0,1))$ be a solution of (2.2). For all $\xi\in(-T,L), t\in(0,T), y\in(0,1)$ with $\xi+t\in(0,L)$, we introduce $w(\xi,y,t) := v(\xi+t,y,t)$. Then we verify that

$$w_t + w_{yy} = v_t + v_x + v_{yy} = 0, \quad (\xi,y,t)\in D,$$

where $D = \{(\xi,y,t)\in(-T,L)\times(0,1)\times(0,T) \;\mid\; \xi+t\in(0,L)\}$.

In particular, for all $\xi\in(-T,L)$ fixed, $w^\xi(y,t) := w(\xi,y,t)$ is the solution of a nondegenerate parabolic equation:

$$\begin{cases} w^\xi_t + w^\xi_{yy} = 0, & (y,t)\in(0,1)\times(t_0^\xi,t_1^\xi),\\ w^\xi(0,t) = w^\xi(1,t) = 0, & t\in(t_0^\xi,t_1^\xi), \end{cases} \tag{5.9}$$

where $t_0^\xi = \max(0,-\xi)$, $t_1^\xi = \min(T,L-\xi)$, and $w^\xi\in\mathcal{C}^0([t_0^\xi,t_1^\xi];H^2\cap H_0^1(0,1))$.

Note that, for all $\xi\in(-T,L)$, the energy of w^ξ is increasing, i.e.,

$$\text{for all } t_0^\xi\le T_0\le T_1\le t_1^\xi, \quad \int_0^1 w^\xi(y,T_0)^2\,dy \le \int_0^1 w^\xi(y,T_1)^2\,dy. \tag{5.10}$$

Then the proof of (5.5), (5.6), and (5.8) will be deduced from the fact that the energy of solutions of (5.9) is increasing. And the proof of (5.3), (5.4), and (5.7) will follow from Carleman estimates for the solutions of (5.9), using also the fact that the energy of solutions of (5.9) is increasing.

Proof of (5.8). From the definition of w, it follows that

$$\int_{T-x_0-\delta}^T\int_0^1 v(0,y,t)^2\,dydt \;=\; \int_{T-x_0-\delta}^T\int_0^1 w(-t,y,t)^2\,dydt.$$

Moreover, using that the energy of w^{-t} is increasing (we apply (5.10) to $\xi = -t\in(-T,-T+x_0+\delta)$, $T_0 = t$ and $T_1 = T$), for all $t\in(T-x_0-\delta,T)$, we have

$$\int_0^1 w(-t,y,t)^2\,dy \;\le\; \int_0^1 w(-t,y,T)^2\,dy.$$

We deduce that

$$\int_{T-x_0-\delta}^T\int_0^1 v(0,y,t)^2\,dydt \;\le\; \int_{T-x_0-\delta}^T\int_0^1 w(-t,y,T)^2\,dydt.$$

Since

$$\int_{T-x_0-\delta}^{T}\int_0^1 w(-t,y,T)^2\,dydt \;=\; \int_0^{x_0+\delta}\int_0^1 v(x,y,T)^2\,dydx,$$

we deduce (5.8). □

Proof of (5.3). We will use the following classical lemma.

LEMMA 5.1. *Let $\tilde T>0$ and let ω_y be an nonempty open set of $(0,1)$. Then there exists $C(\tilde T,\omega_y)>0$ such that the solutions $w\in\mathcal{C}^0([0,\tilde T];H^2(0,1)\cap H_0^1(0,1))$ of*

$$w_t(y,t)+w_{yy}(y,t)=0,\quad (y,t)\in(0,1)\times(0,\tilde T), \tag{5.11}$$

satisfy

$$\int_0^1 w(y,0)^2\,dy \;\le\; C(\tilde T,\omega_y)\int_0^{\tilde T}\int_{\omega_y} w(y,t)^2\,dydt. \tag{5.12}$$

This is by now a well-known observability inequality for the nondegenerate parabolic equation (5.11), and it follows from Carleman's estimates (see, for example, [16, 14, 2]).

In order to prove (5.3), we use w defined as previously. Let $\xi\in(0,x_0)$ be given. Then using that the energy of w^ξ is increasing (we apply (5.10) to $T_0=0$ and $T_1=x_0-\xi$), we have

$$\int_0^1 w(\xi,y,0)^2\,dy\le\int_0^1 w(\xi,y,x_0-\xi)^2\,dy.$$

Thus taking the integral over $\xi\in(0,x_0)$, we have

$$\int_0^{x_0}\int_0^1 w(\xi,y,0)^2\,dyd\xi \;\le\; \int_0^{x_0}\int_0^1 w(\xi,y,x_0-\xi)^2\,dyd\xi.$$

On the other hand, we note that (5.9) is a nondegenerate parabolic equation; we deduce from Lemma 5.1 that for all ξ, the solutions of (5.9) satisfy

$$\text{for all } t_0^\xi\le T_0\le T_1\le t_1^\xi,\quad \int_0^1 w^\xi(y,T_0)^2\,dy \;\le\; C\int_{T_0}^{T_1}\int_{\omega_y} w^\xi(y,t)^2\,dydt, \tag{5.13}$$

where C is a constant independent of ξ that depends on T_1-T_0 and on ω_y. Applying (5.13) for all $\xi\in(0,x_0)$ to $T_0=x_0-\xi$ and $T_1=x_1-\xi$, we deduce that

$$\int_0^1 w(\xi,y,x_0-\xi)^2\,dy \;\le\; C\int_{x_0-\xi}^{x_1-\xi}\int_{\omega_y} w(\xi,y,t)^2\,dydt,$$

where C is independent of ξ (it depends on x_1-x_0 and ω_y). Hence

$$\begin{aligned}\int_0^{x_0}\int_0^1 v(x,y,0)^2\,dydx \;&=\; \int_0^{x_0}\int_0^1 w(\xi,y,0)^2\,dyd\xi\\ &\le\; \int_0^{x_0}\int_0^1 w(\xi,y,x_0-\xi)^2\,dyd\xi\\ &\le\; C\int_0^{x_0}\int_{x_0-\xi}^{x_1-\xi}\int_{\omega_y} w(\xi,y,t)^2\,dydtd\xi.\end{aligned}$$

Making the change of variables $(x,t) := (\xi + t, t)$ and observing that

$$\begin{cases} 0 \le \xi \le x_0, \\ x_0 - \xi \le t \le x_1 - \xi \end{cases} \iff \begin{cases} x_0 \le x \le x_1, \\ x - x_0 \le t \le x, \end{cases}$$

we deduce that

$$\begin{aligned} \int_0^{x_0} \int_0^1 v(x,y,0)^2 \, dydx &\le C \int_{x_0}^{x_1} \int_{x-x_0}^{x} \int_{\omega_y} w(x-t,y,t)^2 \, dydtdx \\ &= C \int_{x_0}^{x_1} \int_{x-x_0}^{x} \int_{\omega_y} v(x,y,t)^2 \, dydtdx. \qquad \square \end{aligned}$$

Proof of (5.4). More precisely, we will prove

$$\iint_{(x_0,x_1-\delta)\times(0,1)} v(x,y,0)^2 \, dydx \le C \int_{x_1-\delta}^{x_1} \int_{\omega_y} \int_{x-(x_1-\delta)}^{x-x_0} v(x,y,t)^2 \, dtdydx.$$

We use w defined as previously. Let $\xi \in (x_0, x_1 - \delta)$ be given. Then using that the energy of w^ξ is increasing (we apply (5.10) to $T_0 = 0$ and $T_1 = x_1 - \delta - \xi$), we have

$$\int_0^1 w(\xi,y,0)^2 \, dy \le \int_0^1 w(\xi,y,x_1-\delta-\xi)^2 \, dy.$$

Thus taking the integral over $\xi \in (x_0, x_1 - \delta)$, we have

$$\int_{x_0}^{x_1-\delta} \int_0^1 w(\xi,y,0)^2 \, dyd\xi \le \int_{x_0}^{x_1-\delta} \int_0^1 w(\xi,y,x_1-\delta-\xi)^2 \, dyd\xi.$$

On the other hand, applying (5.13) for all $\xi \in (x_0, x_1 - \delta)$ to $T_0 = x_1 - \delta - \xi$ and $T_1 = x_1 - \xi$, we deduce that

$$\int_0^1 w(\xi,y,x_1-\delta-\xi)^2 \, dy \le C \int_{x_1-\delta-\xi}^{x_1-\xi} \int_{\omega_y} w(\xi,y,t)^2 \, dydt,$$

where C depends on $T_1 - T_0 = \delta$ (and is independent of ξ). Hence

$$\begin{aligned} \int_{x_0}^{x_1-\delta} \int_0^1 v(x,y,0)^2 \, dydx &= \int_{x_0}^{x_1-\delta} \int_0^1 w(\xi,y,0)^2 \, dyd\xi \\ &\le \int_{x_0}^{x_1-\delta} \int_0^1 w(\xi,y,x_1-\delta-\xi)^2 \, dyd\xi \\ &\le C \int_{x_0}^{x_1-\delta} \int_{x_1-\delta-\xi}^{x_1-\xi} \int_{\omega_y} w(\xi,y,t)^2 \, dydtd\xi \\ &= C \int_{x_1-\delta}^{x_1} \int_{x-(x_1-\delta)}^{x-x_0} \int_{\omega_y} w(x-t,y,t)^2 \, dydtdx \\ &= C \int_{x_1-\delta}^{x_1} \int_{x-(x_1-\delta)}^{x-x_0} \int_{\omega_y} v(x,y,t)^2 \, dydtdx. \qquad \square \end{aligned}$$

5.3. Proof of Theorem 2.2. For all $\varepsilon > 0$, consider the penalized problem

$$\text{Min } \{J_\varepsilon(f) \ \mid \ f \in L^2(\omega \times (0,T))\}, \tag{5.14}$$

where

$$J_\varepsilon(f) \ := \ \frac{1}{2} \iiint_{\omega\times(0,T)} f(x,y,t)^2 \, dtdydx \ + \ \frac{1}{2\varepsilon} \iint_{\Omega_C(T,\delta)} u^f(x,y,T)^2 \, dydx,$$

with u^f the solution of (1.2) associated with f.

Step 1 (characterization of the solution). The functional J_ε is continuous on $L^2(\Omega \times (0,T))$ and strictly convex, and $J_\varepsilon(f) \to \infty$ as $\|f\|_{L^2(\Omega\times(0,T))} \to \infty$. Thus, for all $\varepsilon > 0$, problem (5.14) has a unique solution f^ε. And we can verify that it is characterized by

$$f^\varepsilon(x,y,t) = -v^\varepsilon(x,y,t)\chi_\omega(x,y), \tag{5.15}$$

where v^ε is the solution of the adjoint problem

$$\begin{cases} v^\varepsilon_t + v^\varepsilon_x + v^\varepsilon_{yy} = 0, & (x,y,t) \in \Omega \times (0,T), \\ v^\varepsilon(x,0,t) = v^\varepsilon(x,1,t) = 0, & (x,t) \in (0,L) \times (0,T), \\ v^\varepsilon(L,y,t) = 0, & (y,t) \in (0,1) \times (0,T), \\ v^\varepsilon(x,y,T) = \frac{1}{\varepsilon}\chi_{\Omega_C(T,\delta)} u^{f^\varepsilon}(x,y,T), & (x,y) \in \Omega. \end{cases} \tag{5.16}$$

Indeed, f^ε is characterized by $DJ_\varepsilon(f^\varepsilon) \cdot h = 0$ for all $h \in L^2(\omega \times (0,T))$. (As usual, $DJ_\varepsilon(f^\varepsilon) \cdot h = 0$ denotes the differential of the functional J_ε computed at the point f^ε and applied to the element h.) By classical computations, we obtain

$$DJ_\varepsilon(f) \cdot h \ = \ \iiint_{\omega\times(0,T)} fh \, dtdydx + \ \frac{1}{\varepsilon} \iint_{\Omega_C(T,\delta)} u^f(T) z^h(T) \, dydx,$$

where z^h is the solution of

$$\begin{cases} z^h_t + z^h_x - z^h_{yy} = \chi_\omega h, & (x,y,t) \in \Omega \times (0,T), \\ z^h(x,0,t) = z^h(x,1,t) = 0, & (x,t) \in (0,L) \times (0,T), \\ z^h(0,y,t) = 0, & (y,t) \in (0,1) \times (0,T), \\ z^h(x,y,0) = 0, & (x,y) \in \Omega. \end{cases} \tag{5.17}$$

On the other hand, we multiply (5.16) by z^h and (5.17) by v^ε. We add these two relations and we take the integral over $\Omega \times (0,T)$. This gives

$$\begin{aligned} &\iint_\Omega v^\varepsilon(x,y,T) z^h(x,y,T) \, dydx - \iint_\Omega v^\varepsilon(x,y,0) z^h(x,y,0) \, dydx \\ &\quad + \int_0^T \int_0^1 v^\varepsilon(L,y,t) z^h(L,y,t) \, dydt - \int_0^T \int_0^1 v^\varepsilon(0,y,t) z^h(0,y,t) \, dydt \\ &\quad = \iiint_{\Omega\times(0,T)} \chi_\omega(x,y) h(x,y,t) v^\varepsilon(x,y,t) \, dtdydx. \end{aligned}$$

Since $z^h(0,y,t) = 0$, $z^h(x,y,0) = 0$, $v^\varepsilon(x,y,T) = \frac{1}{\varepsilon}\chi_{\Omega_C(T,\delta)} u^{f^\varepsilon}(x,y,T)$, and $v^\varepsilon(L,y,t) = 0$, we deduce

$$\frac{1}{\varepsilon} \iint_{\Omega_C(T,\delta)} u^{f^\varepsilon}(T) z^h(T) \, dydx = \iiint_{\omega\times(0,T)} h v^\varepsilon \, dtdydx.$$

Thus f^ε is characterized as follows: for all $h \in L^2(\omega \times (0,T))$,

$$\iiint_{\omega\times(0,T)} f^\varepsilon h \, dtdydx + \iiint_{\omega\times(0,T)} v^\varepsilon h \, dtdydx = 0,$$

which gives (5.15).

Step 2 (a priori estimates). Now we need suitable a priori estimates independent of ε to let $\varepsilon \to 0$. We multiply (1.2) by v^ε and (5.16) by u^{f^ε}. Then we add these identities, and we take the integral over $\Omega \times (0,T)$ to obtain

$$\begin{aligned}
&\iint_\Omega u^{f^\varepsilon}(x,y,T)v^\varepsilon(x,y,T)\,dydx \;-\; \iint_\Omega u_0(x,y)v^\varepsilon(x,y,0)\,dydx \\
&+ \iint_{(0,1)\times(0,T)} u^{f^\varepsilon}(L,y,t)v^\varepsilon(L,y,t)\,dtdy \;-\; \iint_{(0,1)\times(0,T)} u_1(y,t)v^\varepsilon(0,y,t)\,dtdy \\
&= \iiint_{\Omega\times(0,T)} \chi_\omega f^\varepsilon(x,y,t)v^\varepsilon(x,y,t)\,dtdydx \;=\; -\iiint_{\omega\times(0,T)} f^\varepsilon(x,y,t)^2\,dtdydx.
\end{aligned}$$

Since $v^\varepsilon(L,y,t) = 0$ and $v^\varepsilon(x,y,T) = \frac{1}{\varepsilon}u^{f^\varepsilon}(x,y,T)\chi_{\Omega_C(T,\delta)}(x,y)$, with Young's inequality, we obtain

$$\begin{aligned}
&\frac{1}{\varepsilon}\iint_{\Omega_C(T,\delta)} u^{f^\varepsilon}(x,y,T)^2\,dydx \;+\; \iiint_{\omega\times(0,T)} f^\varepsilon(x,y,t)^2\,dtdydx \\
&\quad= \iint_\Omega u_0(x,y)v^\varepsilon(x,y,0)\,dydx \;+\; \iint_{(0,1)\times(0,T)} u_1(y,t)v^\varepsilon(0,y,t)\,dtdy \\
&\quad\le \frac{1}{4\gamma}\iint_\Omega u_0(x,y)^2 dydx \;+\; \frac{1}{4\gamma}\iint_{(0,1)\times(0,T)} u_1(y,t)^2\,dtdy \\
&\qquad+ \gamma\iint_\Omega v^\varepsilon(x,y,0)^2\,dydx \;+\; \gamma\iint_{(0,1)\times(0,T)} v^\varepsilon(0,y,t)^2\,dtdy
\end{aligned}$$

for all $\gamma > 0$. From Theorem 2.1, it follows that we can choose $\gamma > 0$ small enough to have

$$\begin{aligned}
&\frac{1}{\varepsilon}\iint_{\Omega_C(T,\delta)} u^{f^\varepsilon}(x,y,T)^2\,dydx \;+\; \iiint_{\omega\times(0,T)} f^\varepsilon(x,y,t)^2\,dtdydx \\
&\quad\le C\left(\|u_0\|^2_{L^2(\Omega)} \;+\; \|u_1\|^2_{L^2((0,1)\times(0,T))}\right) \;+\; \frac{1}{2}\iiint_{\omega\times(0,T)} v^\varepsilon(x,y,t)^2\,dtdydx \\
&\qquad+ C\iint_{\Omega\setminus\Omega_C(T,\delta)} v^\varepsilon(x,y,T)^2\,dydx \;+\; C\iint_{(0,1)\times(0,T)} v^\varepsilon(L,y,t)^2\,dtdy.
\end{aligned}$$

Since $v_\varepsilon(x,y,T) = 0$ on $\Omega\setminus\Omega_C(T,\delta)$, $v_\varepsilon(L,y,t) = 0$ on $(0,1)\times(0,T)$, and $v_\varepsilon = -\chi_\omega f^\varepsilon$, we obtain

$$\begin{aligned}
&\frac{1}{\varepsilon}\iint_{\Omega_C(T,\delta)} u^{f^\varepsilon}(x,y,T)^2\,dydx \;+\; \frac{1}{2}\iiint_{\omega\times(0,T)} f^\varepsilon(x,y,t)^2\,dtdydx \\
&\quad\le C\left(\|u_0\|^2_{L^2(\Omega)} \;+\; \|u_1\|^2_{L^2((0,1)\times(0,T))}\right).
\end{aligned}$$

This gives the a priori estimates that allows us to pass to the limit in (1.2) as $\varepsilon \to 0$, which gives a solution to the null controllability problem. Indeed, since the sequence

$(f^\varepsilon)_\varepsilon$ is bounded in $L^2(\omega\times(0,T))$, there exists a subsequence still denoted by $(f^\varepsilon)_\varepsilon$ and there exists $\tilde f\in L^2(\omega\times(0,T))$ such that

$$f^\varepsilon \rightharpoonup \tilde f \text{ weakly in } L^2(\omega\times(0,T)) \text{ as } \varepsilon\to 0.$$

We denote by $\tilde u$ the solution of (1.2) associated with $\tilde f$. From the convergence of $(f^\varepsilon)_\varepsilon$ to $\tilde f$, it follows that $\left(\chi_{\Omega_C(T,\delta)}u^{f^\varepsilon}(T)\right)_\varepsilon$ converges to $\chi_{\Omega_C(T,\delta)}\tilde u(T)$ weakly in $L^2(\Omega)$. Moreover the sequence $\left(\varepsilon^{-1/2}\chi_{\Omega_C(T,\delta)}u^{f^\varepsilon}(T)\right)_\varepsilon$ is also bounded in $L^2(\Omega)$. Thus there exists a subsequence still indexed by ε and there exists $v_T\in L^2(\Omega)$ such that

$$\varepsilon^{-1/2}\chi_{\Omega_C(T,\delta)}u^{f^\varepsilon}(T)\rightharpoonup v_T \text{ weakly in } L^2(\Omega) \text{ as } \varepsilon\to 0.$$

Thus $\left(\chi_{\Omega_C(T,\delta)}u^{f^\varepsilon}(T)\right)_\varepsilon$ also converges to 0 weakly in $L^2(\Omega)$. Therefore we have $\chi_{\Omega_C(T,\delta)}\tilde u(T)\equiv 0$, which proves Theorem 2.2. ∎

6. Proofs in the boundary case.

6.1. Proof of Theorem 3.1. As in the proof of Theorem 2.1, it is sufficient to prove (3.2) only for *regular* solutions of (2.2). Thus we assume that $v\in\mathcal{C}^1([0,L]\times[0,T];L^2(0,1))\cap\mathcal{C}^0([0,L]\times[0,T];H^2\cap H_0^1(0,1))$.

We only treat the case $T<L-x_1+\delta$ and $T\geq x_0+\delta$ and we still use the decomposition of the domain represented in Figure 5.1. First we decompose the left-hand side of (3.2) as in the proof of Theorem 2.1 (see (5.1) and (5.2)).

Then we remark that (5.5), (5.6), and (5.8) still hold (with the same proof). Next, instead of (5.3), (5.4), and (5.7), it is sufficient to prove, respectively, the following inequalities:

$$\iint_{(0,x_0)\times(0,1)} v(x,y,0)^2\,dydx \;\leq\; C\int_{x_0}^{x_1}\int_{x-x_0}^{x} v_y(x,1,t)^2\,dtdx, \tag{6.1}$$

$$\iint_{(x_0,x_1-\delta)\times(0,1)} v(x,y,0)^2\,dydx \;\leq\; C\int_{x_0}^{x_1}\int_{0}^{x-x_0} v_y(x,1,t)^2\,dtdx, \tag{6.2}$$

$$\iint_{(0,1)\times(0,T-x_0-\delta)} v(0,y,t)^2\,dtdy \;\leq C\int_{x_0}^{x_1}\int_{x}^{T} v_y(x,1,t)^2\,dtdx. \tag{6.3}$$

Since the proofs are similar, we will just completely prove (6.1).

Proof of (6.1). Let v be a regular solution of (2.2). We use w and w^ξ defined in the proof of Theorem 2.1. As in the proof of (5.3), we have

$$\int_0^{x_0}\int_0^1 w(\xi,y,0)^2\,dyd\xi \;\leq\; \int_0^{x_0}\int_0^1 w(\xi,y,x_0-\xi)^2\,dyd\xi.$$

On the other hand, we recall the classical boundary observability inequality for nondegenerate parabolic equations that follows from classical Carleman's estimates (see for example [16, 14, 2]):

LEMMA 6.1. *For all $\tilde T>0$, there exists $C(\tilde T)>0$ such that the solutions $w\in\mathcal{C}^0([0,\tilde T];H^2\cap H_0^1(0,1))$ of*

$$w_t(y,t)+w_{yy}(y,t)=0,\qquad (y,t)\in(0,1)\times(0,\tilde T),$$

satisfy

$$\int_0^1 w(y,0)^2\,dy \;\le\; C(\tilde T)\;\int_0^{\tilde T} w_y(1,t)^2\,dt.$$

From Lemma 6.1, we deduce that for all ξ the solutions of (5.9) satisfy the following *boundary* observability inequality:

$$\text{for all } T_1 > T_0 \ge 0, \qquad \int_0^1 w^\xi(y,T_0)^2\,dy \;\le\; C\;\int_{T_0}^{T_1} w_y^\xi(1,t)^2\,dt, \tag{6.4}$$

where C is a constant independent of ξ that depends on $T_1 - T_0$. Applying (6.4) for all $\xi \in (0,x_0)$ to $T_0 = x_0 - \xi$ and $T_1 = x_1 - \xi$, we deduce that

$$\int_0^1 w(\xi,y,x_0-\xi)^2\,dy \;\le\; C\;\int_{x_0-\xi}^{x_1-\xi} w_y(\xi,1,t)^2\,dt.$$

Hence

$$\begin{aligned}\int_0^{x_0}\int_0^1 v(x,y,0)^2\,dydx \;&=\; \int_0^{x_0}\int_0^1 w(\xi,y,0)^2\,dyd\xi\\ &\le\; \int_0^{x_0}\int_0^1 w(\xi,y,x_0-\xi)^2\,dyd\xi \;\le\; C\int_0^{x_0}\int_{x_0-\xi}^{x_1-\xi} w_y(\xi,1,t)^2\,dtd\xi\\ &=\; C\int_{x_0}^{x_1}\int_{x-x_0}^{x} w_y(x-t,1,t)^2\,dtdx \;=\; C\int_{x_0}^{x_1}\int_{x-x_0}^{x} v_y(x,1,t)^2\,dtdx. \qquad \square\end{aligned}$$

6.2. Proof of Theorem 3.2. First, we note that for all $u_0 \in L^2(\Omega)$, $u_1 \in L^2((0,1)\times(0,T))$ and $f \in L^2((x_0,x_1)\times(0,T))$; then the weak solution u of (3.1), defined by the transposition method (see Lions [21]), belongs to $\mathcal{C}^0([0,T];L^2(0,L;H^{-1}(0,1)))\cap\mathcal{C}^0([0,L];L^2(0,T;H^{-1}(0,1)))\cap L^2(\Omega\times(0,T))$. Since we only know that $u(\cdot,T)$ belongs to $L^2(0,L;H^{-1}(0,1))$, we will introduce a modified penalized problem (so that the solution will be characterized via an adjoint problem with a regular terminal condition).

We denote by $(-\Delta_y)^{-1}$ the inverse of the isomorphism $-\Delta_y : p \in H_0^1(0,1) \mapsto -p_{yy} \in H^{-1}(0,1)$. We also denote by $\langle\cdot,\cdot\rangle$ the duality product $\langle\cdot,\cdot\rangle_{H^{-1}(0,1)\times H_0^1(0,1)}$. We recall that $q \mapsto \langle q,(-\Delta_y)^{-1}q\rangle^{1/2}$ defines a norm that is equivalent to the norm $q \mapsto \|q\|_{H^{-1}(0,1)}$ on $H^{-1}(0,1)$. Indeed, using that $\|(-\Delta_y)^{-1}q\|_{H_0^1(0,1)}$ is a norm equivalent to the norm $\|q\|_{H^{-1}(0,1)}$ on $H^{-1}(0,1)$, we deduce

$$\begin{aligned}C_1\|q\|^2_{H^{-1}(0,1)} \le \|(-\Delta_y)^{-1}q\|^2_{H_0^1(0,1)} &= \langle(-\Delta_y)(-\Delta_y)^{-1}q,(-\Delta_y)^{-1}q\rangle\\ &= \langle q,(-\Delta_y)^{-1}q\rangle \le \|q\|_{H^{-1}(0,1)}\|(-\Delta_y)^{-1}q\|_{H_0^1(0,1)} \le C_2\|q\|^2_{H^{-1}(0,1)}.\end{aligned}$$

Finally, we also set $\mathcal{O} := (x_0+\delta, x_1+T-\delta)$; we recall that $\Omega_C(T,\delta) = \mathcal{O}\times(0,1)$. Thus $\chi_{\Omega_C(T,\delta)}(x,y) = \chi_{\mathcal{O}}(x)$ for all $(x,y) \in (0,L)\times(0,1)$.

Then for all $\varepsilon > 0$, we consider the penalized problem

$$\text{Min } \{J_\varepsilon(f) \;\mid\; f \in L^2((x_0,x_1)\times(0,T))\}, \tag{6.5}$$

where

$$\begin{aligned}J_\varepsilon(f) \;:=\; &\frac12\iint_{(0,T)\times(x_0,x_1)} f(x,t)^2\,dxdt\\ &+\;\frac{1}{2\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle u^f(x,\cdot,T),(-\Delta_y)^{-1}u^f(x,\cdot,T)\Big\rangle\,dx,\end{aligned}$$

with u^f the solution of (3.1) associated with f.

Step 1 (characterization of the solution). This problem has a unique solution f^ε that it is characterized by

$$f^\varepsilon(x,t) = v_y^\varepsilon(x,1,t)\chi_{(x_0,x_1)}(x), \tag{6.6}$$

where v^ε is the solution of the adjoint problem

$$\begin{cases} v_t^\varepsilon + v_x^\varepsilon + v_{yy}^\varepsilon = 0, & (x,y,t) \in \Omega \times (0,T), \\ v^\varepsilon(x,0,t) = v^\varepsilon(x,1,t) = 0, & (x,t) \in (0,L) \times (0,T), \\ v^\varepsilon(L,y,t) = 0, & (y,t) \in (0,1) \times (0,T), \\ v^\varepsilon(x,y,T) = \frac{1}{\varepsilon}\chi_{\mathcal{O}}(x)(-\Delta_y)^{-1}u^{f^\varepsilon}(x,y,T), & (x,y) \in \Omega. \end{cases} \tag{6.7}$$

Indeed, f^ε is characterized by $DJ_\varepsilon(f^\varepsilon)\cdot h = 0$ for all $h \in L^2((x_0,x_1)\times(0,T))$. By classical computations, we obtain

$$\begin{aligned} DJ_\varepsilon(f)\cdot h \;=\; & \int_0^T \int_{x_0}^{x_1} fh\,dxdt \\ & + \frac{1}{2\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle u^f(x,\cdot,T), (-\Delta_y)^{-1}z^h(x,\cdot,T)\Big\rangle\,dx \\ & + \frac{1}{2\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle z^h(x,\cdot,T), (-\Delta_y)^{-1}u^f(x,\cdot,T)\Big\rangle\,dx \\ =\; & \int_0^T \int_{x_0}^{x_1} fh\,dxdt + \frac{1}{\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle z^h(x,\cdot,T), (-\Delta_y)^{-1}u^f(x,\cdot,T)\Big\rangle\,dx, \end{aligned}$$

where z^h is the solution of

$$\begin{cases} z_t^h + z_x^h - z_{yy}^h = 0, & (x,y,t) \in \Omega \times (0,T), \\ z^h(x,0,t) = 0, & (x,t) \in (0,L) \times (0,T), \\ z^h(x,1,t) = \chi_{(x_0,x_1)}(x)h(x,t), & (x,t) \in (0,L) \times (0,T), \\ z^h(0,y,t) = 0, & (y,t) \in (0,1) \times (0,T), \\ z^h(x,y,0) = 0, & (x,y) \in \Omega. \end{cases} \tag{6.8}$$

On the other hand, we multiply (6.7) by z^h and (6.8) by v^ε and we add these two relations. Then using the initial and terminal data of z^h and v^ε, this gives

$$\begin{aligned} & \frac{1}{\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle z^h(x,\cdot,T), (-\Delta_y)^{-1}u^{f^\varepsilon}(x,\cdot,T)\Big\rangle\,dx \\ & = \int_0^L \Big\langle z^h(x,\cdot,T), v^\varepsilon(x,\cdot,T)\Big\rangle\,dx \;=\; -\int_0^T\int_0^L \chi_{(x_0,x_1)}(x)v_y(x,1,t)h(x,t)\,dxdt. \end{aligned}$$

Thus f^ε is characterized as follows: for all $h \in L^2((x_0,x_1)\times(0,T))$,

$$\int_0^T \int_{x_0}^{x_1} f(x,t)h(x,t)\,dxdt - \int_0^T \int_{x_0}^{x_1} v_y(x,1,t)h(x,t)\,dxdt = 0,$$

which gives (6.6).

Step 2 (a priori estimates). Now we need suitable a priori estimates to let $\varepsilon \to 0$. We multiply (3.1) by v^ε and (6.7) by u^{f^ε}. Then we add these identities, and we integrate over $\Omega \times (0,T)$ to obtain

$$\begin{aligned}
&\int_0^L \Big\langle u^{f^\varepsilon}(x,\cdot,T), v^\varepsilon(x,\cdot,T)\Big\rangle\, dx - \int_0^L \Big\langle u^{f^\varepsilon}(x,\cdot,0), v^\varepsilon(x,\cdot,0)\Big\rangle\, dx \\
&\quad + \int_0^T \Big\langle u^{f^\varepsilon}(L,\cdot,t), v^\varepsilon(L,\cdot,t)\Big\rangle\, dt - \int_0^T \Big\langle\ u^{f^\varepsilon}(0,\cdot,t), v^\varepsilon(0,\cdot,t)\Big\rangle\, dt \\
&\quad = -\int_0^T \int_0^L v_y^\varepsilon(x,1,t) u^{f^\varepsilon}(x,1,t)\, dxdt = -\int_0^T \int_0^L \chi_{(x_0,x_1)}(x) f^\varepsilon(x,t)^2\, dxdt.
\end{aligned}$$

Since $v^\varepsilon(L,y,t) = 0$ and $v^\varepsilon(x,y,T) = \frac{1}{\varepsilon}\chi_{\mathcal{O}}(x)(-\Delta_y)^{-1} u^{f^\varepsilon}(x,y,T)$, with Young's inequality we obtain

$$\begin{aligned}
&\frac{1}{\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle u^{f^\varepsilon}(x,\cdot,T), (-\Delta_y)^{-1} u^{f^\varepsilon}(x,\cdot,T)\Big\rangle\, dx \ +\ \iint_{(0,T)\times(x_0,x_1)} f^\varepsilon(x,t)^2\, dxdt \\
&\quad =\ \iint_\Omega u_0(x,y) v^\varepsilon(x,y,0)\, dydx \ +\ \iint_{(0,1)\times(0,T)} u_1(y,t) v^\varepsilon(0,y,t)\, dtdy \\
&\quad \le\ \frac{1}{4\gamma}\left(\|u_0\|^2_{L^2(\Omega)} \ +\ \|u_1\|^2_{L^2((0,1)\times(0,T)}\right) \\
&\qquad +\ \gamma \iint_\Omega v^\varepsilon(x,y,0)^2\, dydx \ +\ \gamma \iint_{(0,1)\times(0,T)} v^\varepsilon(0,y,t)^2\, dtdy
\end{aligned}$$

for all $\gamma > 0$. From Theorem 3.1, it follows that we can choose $\gamma > 0$ small enough to have

$$\begin{aligned}
&\frac{1}{\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle u^{f^\varepsilon}(x,\cdot,T), (-\Delta_y)^{-1} u^{f^\varepsilon}(x,\cdot,T)\Big\rangle\, dx \ +\ \iint_{(0,T)\times(x_0,x_1)} f^\varepsilon(x,t)^2\, dxdt \\
&\quad \le\ C\left(\|u_0\|^2_{L^2(\Omega)} \ +\ \|u_1\|^2_{L^2((0,1)\times(0,T))}\right) \ +\ \frac{1}{2}\iint_{(0,T)\times(x_0,x_1)} v_y^\varepsilon(x,1,t)^2\, dxdt \\
&\qquad +\ C\iint_{\Omega\setminus\Omega_C(T,\delta)} v^\varepsilon(x,y,T)^2\, dydx \ +\ C\iint_{(0,1)\times(0,T)} v^\varepsilon(L,y,t)^2\, dtdy.
\end{aligned}$$

Since $v_\varepsilon(x,y,T) = 0$ on $\Omega \setminus \Omega_C(T,\delta)$, $v_\varepsilon(L,y,t) = 0$ on $(0,1)\times(0,T)$, and $f^\varepsilon(x,t) = v_y^\varepsilon(x,1,t)\chi_{(x_0,x_1)}(x)$, we obtain that

$$\begin{aligned}
&\frac{1}{\varepsilon}\int_0^L \chi_{\mathcal{O}}(x)\Big\langle u^{f^\varepsilon}(x,\cdot,T), (-\Delta_y)^{-1} u^{f^\varepsilon}(x,\cdot,T)\Big\rangle\, dx \ +\ \frac{1}{2}\iint_{(0,T)\times(x_0,x_1)} f^\varepsilon(x,t)^2\, dxdt \\
&\quad \le\ C\left(\|u_0\|^2_{L^2(\Omega)} \ +\ \|u_1\|^2_{L^2((0,1)\times(0,T))}\right).
\end{aligned}$$

Since $\chi_{\mathcal{O}}(x) = \chi_{\Omega_C(T,\delta)}(x,y)$, this implies

$$\begin{aligned}
&\frac{1}{\varepsilon}\int_0^L \|\chi_{\Omega_C(T,\delta)} u^{f^\varepsilon}(x,\cdot,T)\|^2_{H^{-1}(0,1)}\, dx \ +\ \frac{1}{2}\iint_{(0,T)\times(x_0,x_1)} f^\varepsilon(x,t)^2\, dxdt \\
&\qquad \le\ C\left(\|u_0\|^2_{L^2(\Omega)} \ +\ \|u_1\|^2_{L^2((0,1)\times(0,T))}\right).
\end{aligned}$$

Finally we deduce that the sequence $(f^\varepsilon)_\varepsilon$ is bounded in $L^2((x_0,x_1)\times(0,T))$ and that the sequence $\left(\varepsilon^{-1/2}\chi_{\Omega_C(T,\delta)} u^{f^\varepsilon}(T)\right)_\varepsilon$ is also bounded in $L^2(0,L;H^{-1}(0,1))$. This gives a priori estimates that allows us to pass to the limit in (3.1) as $\varepsilon \to 0$, which gives a solution to the null controllability problem. ∎

6.3. Main tool for the proof of Theorem 4.2. To prove Theorem 4.2, we need to combine the previous proof with a suitable observability estimate. In the case of Neumann boundary conditions (4.5), we use the following.

LEMMA 6.2. *For all $\tilde{T} > 0$, there exists $C(\tilde{T}) > 0$ such that the solutions $w \in \mathcal{C}^0([0,\tilde{T}]; H^2(0,1))$ of*

$$\begin{cases} w_t(y,t) + w_{yy}(y,t) = 0, & (y,t) \in (0,1) \times (0,\tilde{T}), \\ w_y(0,t) = 0 = w_y(1,t), & t \in (0,\tilde{T}), \end{cases} \tag{6.9}$$

satisfy

$$\int_0^1 w(y,0)^2 \, dy \;\le\; C(\tilde{T}) \int_0^{\tilde{T}} w(1,t)^2 \, dt. \tag{6.10}$$

This result follows from the well-known equivalence between null controllability and observability (see, for example, [26, Theorem 2.6, p. 213]). For the reader's convenience, we give a short proof of (6.10): first consider the solution u of

$$\begin{cases} u_t - u_{yy} = 0, & (y,t) \in (0,1) \times (0,T), \\ u_y(0,t) = 0, & (y,t) \in (0,L) \times (0,T), \\ u_y(1,t) = h(t), & t \in (0,T), \\ u(0,t) = u_0(y), & y \in (0,1), \\ u(y,T) = 0, & y \in (0,1). \end{cases} \tag{6.11}$$

Using, e.g., [12], given $u_0 \in L^2(0,1)$, there always exists $h \in L^2(0,T)$ such that the problem (6.11) has a solution. Moreover, h can be determined so that

$$\|h\|_{L^2(0,T)} \le C \|u_0\|_{L^2(0,1)}$$

for some positive constant C independent of u_0. Now we multiply (6.9) by u, and after some integrations by parts, we obtain that

$$\int_0^1 w(y,0) u_0(y) \, dy = -\int_0^T w(1,t) h(t) \, dt.$$

Using the Cauchy–Schwarz inequality

$$\left| \int_0^1 w(y,0) u_0(y) \, dy \right| \le \|h\|_{L^2(0,T)} \|w(1,\cdot)\|_{L^2(0,T)} \le C \|u_0\|_{L^2(0,1)} \|w(1,\cdot)\|_{L^2(0,T)}.$$

Since this is true for all $u_0 \in L^2(0,1)$, it implies that

$$\|w(\cdot,0)\|_{L^2(0,1)} \le C \|w(1,\cdot)\|_{L^2(0,T)}. \qquad \square$$

OPTIMALITY CONDITIONS FOR DEGENERATE EXTREMUM PROBLEMS WITH EQUALITY CONSTRAINTS*

OLGA A. BREZHNEVA† AND ALEXEY A. TRET'YAKOV‡

Abstract. In this paper we consider an optimization problem with equality constraints given in operator form as $F(x) = 0$, where $F : X \to Y$ is an operator between Banach spaces. The paper addresses the case when the equality constraints are not regular in the sense that the Fréchet derivative $F'(x^*)$ is not onto. In the first part of the paper, we pursue an approach based on the construction of p-regularity. For p-regular constrained optimization problems, we formulate necessary conditions for optimality and derive sufficient conditions for optimality. In the second part of the paper, we consider a generalization of the concept of p-regularity and derive *generalized* necessary conditions for optimality for an optimization problem that is neither regular nor p-regular. For this problem, we show that the tangent cone to a level surface of F can consist of rays (rather than lines). This is in contrast to the regular and the p-regular cases, for which the tangent cone is always "two-sided." We state that if the gradient of the generalized p-regular problem is nonzero, it can belong to an open set, despite the fact that all constructions are usually closed. Both p-regular and *generalized* conditions for optimality reduce to classical conditions for regular cases, but they give new and nontrivial conditions for nonregular cases. The presented results can be considered as a part of the p-regularity theory.

Key words. Lyusternik theorem, constrained optimization, nonregular problems, optimality conditions

1. Introduction.

In this paper we consider the nonlinear optimization problem

$$\begin{array}{ll} \underset{x\in X}{\text{minimize}} & f(x) \\ \text{subject to} & F(x) = 0, \end{array} \tag{1.1}$$

where $f : X \to \mathbb{R}$ is a sufficiently smooth function in a Banach space X, and $F : X \to Y$ is a sufficiently smooth mapping from a Banach space X to a Banach space Y.

We will be interested in the case when the equality constraints are not regular at a solution x^* of (1.1) in the sense that the Fréchet derivative $F'(x^*)$ is not onto. In this case, Euler–Lagrange necessary conditions for optimality,

$$\lambda_0 f'(x^*) + F'(x^*)^* y^* = 0,$$

are trivially satisfied with $\lambda_0 = 0$ and $y^* \in \mathrm{Ker} F'(x^*)$ and provide no additional information about solutions of (1.1).

The development of optimality conditions for nonregular problems has become an active research topic (see [1, 2, 3, 4, 5, 10, 12, 14, 15, 16, 20, 21, 23, 24] and references therein). In this paper we develop an approach based on the construction of p-regularity introduced in [25, 26, 27]. The main idea of this approach is to replace

the operator $F'(x^*)$, which is not onto, with a linear operator $\Psi_p(x^*)$, related to the pth order Taylor polynomial of F at x^*, which is onto. The operator $\Psi_p(x^*)$ contains up to the pth order derivative of F, so in our consideration F is p-times continuously Fréchet differentiable in a neighborhood of x^*. The order p is chosen as the minimum number for which the operator $\Psi_p(x^*)$ is regular.

In [11, 26, 27] a generalization of the Lyusternik theorem for p-regular mappings was first derived and proved. Using this theorem, nontrivial necessary and sufficient p-order optimality conditions for p-regular problems were obtained in [6, 18, 26]. These conditions contain the gradient of the objective function with a nonzero multiplier. Note that in [6, 18, 26], the sufficient conditions for optimality for p-regular problems were proposed in terms of the Euler–Lagrange function,

$$L(x, y) = f(x) + \langle y, F(x)\rangle.$$

In this paper, we obtain new sufficient conditions for optimality in terms of the generalized Lagrange function or p-factor–Lagrange function. This result is complementary to the necessary optimality conditions proposed in [6, 18, 26].

A new class of nonregular problems that satisfy a *generalized* condition of 2-regularity was introduced in [17, 18]. In contrast to regular and p-regular cases, the results obtained for the *generalized* 2-regular problems allow us to analyze nonregular problems by means of curves $x(t) = x^* + th + t^\alpha \tilde{h} + r(t)$ that lie in $M(x^*) = \{x \in X \mid F(x) = F(x^*)\}$, $t > 0$, and $h, \tilde{h} \in X$. Note that α is not necessarily integer. It can be fractional. For example, problem (1.1) with $F(x_1, x_2) = x_1^2 - x_2^3$ is neither 2-regular nor 3-regular, but the mapping F satisfies the *generalized* condition of 2-regularity. In [7, 8], new necessary optimality conditions were derived for optimization problems where the constraint mapping $F(x)$ satisfies the *generalized* condition of 2-regularity at the solution. Here we extend this approach to $p \geq 2$ and derive new necessary optimality conditions for problem (1.1) that satisfies the *generalized* condition of p-regularity.

To compare our approach with others, we can note that Ledzewicz and Schättler [21, 23] use the terminology p-regular, but in a different sense. A mapping is called p-regular at a point x^* along an element h_1 in our sense if it is p-regular in the direction of the sequence $H_{p-1} = (h_1, 0, \ldots, 0)$ in the sense of Ledzewicz and Schättler [21, 23]. But both our definition and the definition from [21, 23] reduce to the same definition of 2-regularity for $p = 2$. Furthermore, some problems that satisfy the *generalized* condition of 2-regularity could not be treated using the approach presented in [21, 23]. For example, problem (1.1) with $F(x_1, x_2) = x_1^2 - x_2^{5/2}$ satisfies the *generalized* condition of 2-regularity, but this problem is not p-regular in any direction in the sense of the definition given in [21, 23].

The organization of the paper is as follows. In section 2, we recall the definition of p-regularity and formulate a generalization of the Lyusternik theorem for p-regular problems. In section 3, we formulate necessary conditions for optimality [18] and derive new sufficient conditions for optimality for p-regular optimization problems (1.1). In section 4, we consider a generalization of the concept of p-regularity [17, 18] and obtain new necessary optimality conditions for problem (1.1) that satisfy the *generalized* condition of p-regularity.

Our results are applicable to a variety of extremum and optimal control problems with nonregular constraints [2, 21, 22]. Moreover, the approach presented in the paper extends to inequality-constraint optimization problems. In the future we are going to

prove conditions for optimality for these problems using techniques proposed in this paper.

Notation. We denote by $\mathcal{L}(X, Y)$, the space of all continuous linear operators from X to Y. Further, $\operatorname{Ker}\Lambda = \{x \in X \mid \Lambda x = 0\}$ denotes the null-space (kernel) of a given linear operator $\Lambda : X \to Y$, and $\operatorname{Im}\Lambda = \{y \in Y \mid y = \Lambda x \text{ for some } x \in X\}$ is its image space. Also, $\Lambda^* : Y^* \to X^*$ denotes the adjoint of Λ , where X^* and Y^* denote the dual spaces of X and Y, respectively. $M^\perp = \{h^* \in X^* \mid \langle h^*, x\rangle = 0 \quad \forall x \in M\}$ denotes the annihilator of the set M. For a subset S of a space X, we denote by $\operatorname{Sp}(S)$, the linear space spanned (generated) by S, and by $\operatorname{cl} S$, the closure of S.

If F is a p-times Fréchet differentiable mapping at x^*, then $F^{(p)}(x^*)$ denotes the pth order derivative that is pth order mapping from $X \times X \times \cdots \times X$ to Y. By definition of p-order mapping, we have

$$F^{(p)}(x^*)[h]^p = F^{(p)}(x^*)[h, \dots, h].$$

In our consideration, $\operatorname{Ker}^p F^{(p)}(x^*) = \{h \in X \mid F^{(p)}(x^*)[h]^p = 0\}$ denotes the *p-kernel* of the p-order mapping $F^{(p)}(x^*)$.

2. *P*-regular mappings and a generalization of the Lyusternik theorem. As is well known, the Lyusternik theorem provides a useful tool for constructive description of the tangent cone to the set $M(x^*) = \{x \in X : F(x) = F(x^*)\}$ at a given point x^* for the regular mapping F. Let us recall some definitions and the Lyusternik theorem [13].

We say a mapping F is *regular* at some point x^* if

$$\operatorname{Im} F'(x^*) = Y. \tag{2.1}$$

The mapping F is called *nonregular (irregular, degenerate, abnormal)* if the regularity condition (2.1) is not satisfied.

Definition 2.1. *Let M be a subset of a Banach space X. A vector $h \in X$ is said to be tangent to the set M at a point x^* if there exists an $\varepsilon > 0$ and a mapping $t \to r(t)$ of the interval $[0, \varepsilon]$ into X such that*

$$x^* + th + r(t) \in M \qquad \forall t \in [0, \varepsilon],$$

$$\lim_{t \to 0} \frac{\|r(t)\|}{t} = 0.$$

A set of vectors tangent to the set M at a point x^* is called the *tangent cone* to the set M at the point x^* and is denoted by $T_1 M$.

Theorem 2.2 (Lyusternik theorem). *Let X and Y be Banach spaces, U a neighborhood of a point $x^* \in X$, and let $F : U \to Y$ be a continuously Fréchet differentiable mapping of U into Y. Assume that F is regular at x^*, and its derivative $F' : U \to \mathcal{L}(X, Y)$ is continuous at x^*.*

Then the tangent cone to the set $M(x^*) = \{x \in U \mid F(x) = F(x^*)\}$ at the point x^* coincides with the kernel of the operator $F'(x^*)$,

$$T_1 M(x^*) = \operatorname{Ker} F'(x^*). \tag{2.2}$$

We consider the case when the regularity condition (2.1) does not hold, but the mapping F is p-regular. For this case a generalization of the Lyusternik theorem was derived in [26, 27]. First let us review the definition of p-regularity and construction

of a p-factor-operator. Throughout the paper we assume that $F : U \to Y$ is a p-times continuously Fréchet differentiable mapping in U, where U is a neighborhood of a point $x^* \in X$.

We construct here a p-factor-operator under an assumption that the space Y is decomposed into a direct sum

$$Y = Y_1 \oplus \cdots \oplus Y_p, \tag{2.3}$$

where $Y_1 = \operatorname{cl} \operatorname{Im} F'(x^*)$, $Y_i = \operatorname{cl} \operatorname{Sp} (\operatorname{Im} P_{Z_i} F^{(i)}(x^*)[\cdot]^i)$, $i = 2, \ldots, p-1$, $Y_p = Z_p$, Z_i is a closed complementary subspace for $(Y_1 \oplus \cdots \oplus Y_{i-1})$ with respect to Y, $i = 2, \ldots, p$, and $P_{Z_i} : Y \to Z_i$ is the projection operator onto Z_i along $(Y_1 \oplus \cdots \oplus Y_{i-1})$ with respect to Y, $i = 2, \ldots, p$.

Define the mappings [18]

$$f_i(x) : U \to Y_i, \quad f_i(x) = P_{Y_i} F(x), \quad i = 1, \ldots, p,$$

where $P_{Y_i} : Y \to Y_i$ is the projection operator onto Y_i along $(Y_1 \oplus \cdots \oplus Y_{i-1} \oplus Y_{i+1} \oplus \cdots \oplus Y_p)$ with respect to Y, $i = 1, \ldots, p$.

The consideration of another case, when (2.3) is not satisfied, is given in detail, for example, in [18].

DEFINITION 2.3. *The linear operator* $\Psi_p(h) \in \mathcal{L}(X, Y_1 \oplus \cdots \oplus Y_p)$, $h \in X$,

$$\Psi_p(h) = f_1'(x^*) + \frac{1}{2!} f_2''(x^*)[h] + \cdots + \frac{1}{p!} f_p^{(p)}(x^*)[h]^{p-1},$$

is called a p-factor-operator.

DEFINITION 2.4. *We say the mapping F is p-regular at x^* along an element h if* $\operatorname{Im} \Psi_p(h) = Y$.

DEFINITION 2.5. *We say the mapping F is p-regular at x^* if it is p-regular along any h from the set*

$$H_p(x^*) = \left\{ \bigcap_{i=1}^{p} \operatorname{Ker} f_i^{(i)}(x^*) \right\} \setminus \{0\}.$$

DEFINITION 2.6. *The mapping F is called strongly p-regular at the point x^* if there exists $\gamma > 0$ such that*

$$\sup_{h \in H_\gamma} \|\{\Psi_p(h)\}^{-1}\| < \infty,$$

where

$$H_\gamma = \{h \in X \mid \|f_i^{(i)}(x^*)[h]^i\|_{Y_i} \le \gamma \quad \forall i = 1, \ldots, p, \quad \|h\|_X = 1\}.$$

Remark. Not only Ψ_p, but also every Y_i, $i = 2, \ldots, p$, in $Y_1 \oplus \cdots \oplus Y_p$ depends on the element h. To simplify our notation, we use Y_i instead of $Y_i(h)$, $i = 2, \ldots, p$.

We are ready to formulate a generalization of the Lyusternik theorem [27] that is applied to prove necessary optimality conditions for p-regular mappings. This theorem differs from the p-order Lyusternik theorem formulated and proven by Ledzewicz and Schättler in [21].

THEOREM 2.7 (generalization of the Lyusternik theorem). *Let X and Y be Banach spaces, U a neighborhood of a point $x^* \in X$, and let $F : U \to Y$ be a p-times*

continuously Fréchet differentiable mapping in U. Assume that F is p-regular at x^*. Then

$$T_1 M(x^*) = H_p(x^*).$$

At about the same time, in the case $F^{(r)}(x^*) \equiv 0$, $r = 1, \dots, p-1$, Theorem 2.7 was proved in [9] for finite dimensional spaces and in [25] for Banach spaces. In a general case, when there exists $F^{(r)}(x^*) \neq 0$, $r < p$, the theorem was presented in [27].

The following theorem [27] will be used in our analysis.

THEOREM 2.8. *Let X and Y be Banach spaces, U a neighborhood of a point $x^* \in X$, and let $F : X \to Y$ be a p-times continuously Fréchet differentiable mapping in U. Assume that F is strongly p-regular at x^*. Then there exists a neighborhood $U' \subseteq U$ of the point x^*, a mapping $\eta \to x(\eta) : U' \to X$, and constants $\delta_1 > 0$ and $\delta_2 > 0$ such that*

$$F(\eta + x(\eta)) = F(x^*) \qquad \forall \eta \in U',$$

$$\|x(\eta)\|_X \leq \delta_1 \sum_{i=1}^{p} \frac{\|f_i(\eta) - f_i(x^*)\|_{Y_i}}{\|\eta - x^*\|^{i-1}} \qquad \forall \eta \in U', \tag{2.4}$$

$$\|x(\eta)\|_X \leq \delta_2 \sum_{i=1}^{p} \|f_i(\eta) - f_i(x^*)\|_{Y_i}^{1/i} \qquad \forall \eta \in U'.$$

3. Optimality conditions for p-regular problems. In this section we formulate necessary optimality conditions [18] and pursue new sufficient optimality conditions for p-regular constrained optimization problems.

We define the *p-factor–Lagrange function*,

$$\mathcal{L}_p(x, h, \lambda_0(h), y(h)) = \lambda_0(h) f(x) + \sum_{i=1}^{p} \left\langle y_i(h),\, f_i^{(i-1)}(x)[h]^{i-1} \right\rangle, \tag{3.1}$$

where $x \in X$, $h \in X$, $\lambda_0(h) \in \mathbb{R}$, $y_i(h) \in Y_i^*$, $i = 1, \dots, p$. Note that the function (3.1) is a generalization of the Lagrange function and it reduces to the Lagrange function for the regular case.

THEOREM 3.1 (necessary conditions for optimality). *Let X and Y be Banach spaces, U a neighborhood of the point $x^* \in X$, $f : U \to \mathbb{R}$ a twice continuously Fréchet differentiable function in U, and let $F : U \to Y$ be a p-times continuously Fréchet differentiable mapping in U. Assume that for an element $h \in H_p(x^*)$ the set $\operatorname{Im} \Psi_p(h)$ is closed in $Y_1 \oplus \cdots \oplus Y_p$.*

If x^* is a local solution to problem (1.1), then there exist $\lambda_0(h) \in \mathbb{R}$ and multipliers $y_i(h) \in Y_i^*$, $i = 1, \dots, p$, such that they do not all vanish, and

$$\mathcal{L}'_{p\,x}(x^*, h, \lambda_0(h), y(h)) = \lambda_0(h)\, f'(x^*) + \sum_{i=1}^{p} (f_i^{(i)}(x^*)[h]^{i-1})^* y_i(h) = 0.$$

If, moreover, $\operatorname{Im} \Psi_p(h) = Y_1 \oplus \cdots \oplus Y_p$, then $\lambda_0(h) \neq 0$.

If $f'(x^*) = 0$, then the necessary conditions for optimality given in Theorem 3.1 are trivially satisfied with $y^* = 0$ and any $\lambda_0 \neq 0$. In the following theorem, we

formulate other informative necessary optimality conditions for p-regular problems, which were derived for $q = 2$ in [6] and for any q in [18].

THEOREM 3.2. *Let X and Y be Banach spaces, U a neighborhood of $x^* \in X$, $f : U \to \mathbb{R}$ a q-times continuously Fréchet differentiable function in U, and let $F : U \to Y$ be a p-times continuously Fréchet differentiable mapping in U. Assume that for $h \in H_p(x^*)$, $\operatorname{Im}\Psi_p(h) = Y_1 \oplus \cdots \oplus Y_p$. Assume also that $f^{(i)}(x^*) = 0$ for all $i = 1, \dots, q-1$.*

If x^* is a local solution to problem (1.1), *then either $f^q(x^*)[h]^q > 0$ or $f^q(x^*)[h]^q = 0$ and, in the last case, there exist multipliers $y_i(h) \in Y_i^*$, $i = 1, \dots, p$, such that*

$$f^q(x^*)[h]^{q-1} + \sum_{i=1}^{p} (f_i^{(i)}(x^*)[h]^{i-1})^* y_i(h) = 0.$$

In the following theorem we present new sufficient optimality conditions for p-regular problems.

THEOREM 3.3 (sufficient conditions for optimality). *Let X and Y be Banach spaces, U be a neighborhood of a point $x^* \in X$, $f : U \to \mathbb{R}$ be a twice continuously Fréchet differentiable function in U, and $F : U \to Y$ be a $(p+1)$-times continuously Fréchet differentiable mapping in U. Assume that the set $\operatorname{Im}\Psi_p(h)$ is closed in $Y_1 \oplus \cdots \oplus Y_p$ for any element $h \in H_p(x^*)$ and $\operatorname{Im}\Psi_p(h) = Y_1 \oplus \cdots \oplus Y_p$. Assume also that F is strongly p-regular at x^*.*

If there exist $\alpha > 0$ and multipliers $y_i(h) \in Y_i^*$, $i = 1, \dots, p$, such that

$$\mathcal{L}'_{p\,x}(x^*, h, 1, y(h)) = 0 \tag{3.2}$$

and

$$\mathcal{L}''_{p\,xx}(x^*, h, 1, y(h))[h_p]^2 \geq \alpha \|h_p\|^2 \qquad \forall h_p \in H_p(x^*), \tag{3.3}$$

then x^* is a strict local minimizer to problem (1.1).

Proof. We consider an element $x \in U$ such that $F(x) = 0$. We must prove that x can be represented as

$$x = x^* + th + \xi, \tag{3.4}$$

where $\|\xi\| \leq C\,t^2$, $|t| = \|x - x^*\| + o(\|x - x^*\|)$, $h \in H_p(x^*)$, $\|h\| = 1$, and $C > 0$.

Since $F(x) = 0$ and $f_i^{(k)}(x^*) = 0$ for all $k < i$, we have

$$0 = f_i(x) = \frac{1}{i!} f_i^{(i)}(x^*)[x - x^*]^i + \omega_i(x) \qquad \forall i = 1, \dots, p,$$

where $\|\omega_i(x)\| \leq \alpha_i \|x - x^*\|^{i+1}$, $\alpha_i \geq 0$. Hence,

$$\|f_i^{(i)}(x^*)[x - x^*]^i\| \leq i!\alpha_i \|x - x^*\|^{i+1} \leq \beta_i \|x - x^*\|^{i+1}, \qquad \beta_i > 0. \tag{3.5}$$

Consider the equation

$$\Psi(z) = \sum_{i=1}^{p} \frac{1}{i!} f_i^{(i)}(x^*)[z]^i = 0.$$

Note that any solution z to the last equation belongs to the set H_p. Apply Theorem 2.8 to $\Psi(\eta + x(\eta)) = \Psi(0)$ with

$$\eta = x - x^*, \qquad x(\eta) = x - x^* - th,$$

where $h \in H_p$, $\|h\| = 1$, $t \geq 0$. By virtue of (2.4) and (3.5), we have

$$\|x - x^* - th\| \leq \delta_1 \sum_{i=1}^{p} \frac{\|f_i^{(i)}(x^*)[x - x^*]^i - 0\|}{\|x - x^*\|^{i-1}}$$
$$\leq \delta_1 \sum_{i=1}^{p} \frac{\beta_i \|x - x^*\|^{i+1}}{\|x - x^*\|^{i-1}} \leq C\|x - x^*\|^2, \qquad C > 0.$$

Hence,

$$\|x - x^* - th\| \leq C\|x - x^*\|^2, \tag{3.6}$$

where h is an element from the set H_p, $\|h\| = 1$, and $t > 0$. By virtue of the last relation, the representation (3.4) is proved.

Let $y_i \in Y_i^*$ be functionals such that (3.2) and (3.3) are satisfied. Using $t \neq 0$ and $F(x) = 0$, represent $f(x)$ as

$$f(x) = f(x) + \langle y_1, F(x)\rangle + \frac{\langle y_2, P_2 F(x)\rangle}{t} + \cdots + \frac{\langle y_p, P_p F(x)\rangle}{t^{p-1}},$$

where P_i is the projection operator onto Y_i, defined at the point x^*. Then

$$f(x) - f(x^*) = f(x) - f(x^*) + \langle y_1, F(x^* + th + \xi)\rangle$$
$$+ \frac{\langle y_2, P_2 F(x^* + th + \xi)\rangle}{t} + \cdots + \frac{\langle y_p, P_p F(x^* + th + \xi)\rangle}{t^{p-1}}.$$

Consider the Taylor expansion of f and F. We have

$$f(x) - f(x^*) = f'(x^*)[th + \xi] + \frac{1}{2} f''(x^*)[th + \xi]^2 + o(t^2)$$
$$+ \left\langle y_1, F(x^*) + F'(x^*)[th + \xi] + \frac{F''(x^*)}{2}[th + \xi]^2 + o(t^2) \right\rangle$$
$$+ \left\langle y_2, P_2 \left(\frac{F'(x^*)[th + \xi]}{t} + \frac{F''(x^*)}{2t}[th + \xi]^2 \right.\right.$$
$$\left.\left. + \frac{F'''(x^*)}{6t}[th + \xi]^3 + o(t^2) \right) \right\rangle + \cdots$$
$$+ \left\langle y_p, P_p \left(\frac{F'(x^*)[th + \xi]}{t^{p-1}} + \frac{F''(x^*)}{2\,t^{p-1}}[th + \xi]^2 + \cdots \right.\right.$$
$$\left.\left. + \frac{F^{(p+1)}(x^*)}{p!\,t^{p-1}}[th + \xi]^{p+1} + o(t^2) \right) \right\rangle.$$

Transform the last relation into a new form, using the property $P_i F^{(j)}(x^*) = 0$ for

$i > j$. We then have an expression of the form

$$\begin{aligned} f(x) - f(x^*) = {} & f'(x^*)[th+\xi] + \frac{1}{2}f''(x^*)[th+\xi]^2 + o(t^2) \\ & + \left\langle y_1, F'(x^*)[th+\xi] + \frac{F''(x^*)}{2}[th+\xi]^2 + o(t^2) \right\rangle \\ & + \left\langle y_2, P_2\frac{F''(x^*)}{2t}[th+\xi]^2 + P_2\frac{F'''(x^*)}{6t}[th+\xi]^3 + o(t^2) \right\rangle \\ & + \cdots \\ & + \left\langle y_p, P_p\frac{F^{(p)}(x^*)}{p!t^{p-1}}[th+\xi]^p + P_p\frac{F^{(p+1)}(x^*)}{(p+1)!t^{p-1}}[th+\xi]^{p+1} \right. \\ & \qquad \left. + o(t^2) \right\rangle. \end{aligned}$$

We can represent the right part of the last equality as $(A_1 + A_2)$ where

$$\begin{aligned} A_1 = {} & f'(x^*)[th+\xi] + \langle y_1, F'(x^*)[th+\xi]\rangle + \left\langle y_2, P_2\frac{F''(x^*)}{2t}[th+\xi]^2 \right\rangle \\ & + \cdots + \left\langle y_p, P_p\frac{F^{(p)}(x^*)}{p!t^{p-1}}[th+\xi]^p \right\rangle + o(t^2) \end{aligned}$$

and

$$\begin{aligned} A_2 = {} & \frac{1}{2}f''(x^*)[th+\xi]^2 + \left\langle y_1, \frac{F''(x^*)}{2}[th+\xi]^2 \right\rangle \\ & + \left\langle y_2, P_2\frac{F'''(x^*)}{6t}[th+\xi]^3 \right\rangle + \cdots + \left\langle y_p, P_p\frac{F^{(p+1)}(x^*)}{(p+1)!t^{p-1}}[th+\xi]^{p+1} \right\rangle. \end{aligned}$$

By definitions of $\mathcal{L}_p(x^*, h, 1, y(h))$ and ξ, we obtain

$$\begin{aligned} A_1 = {} & \left\langle f'(x^*) + (F'(x^*))^* y_1 + \left(P_2\frac{F''(x^*)}{2}[h]\right)^* y_2 + \cdots \right. \\ & \left. + \left(P_p\frac{F^{(p)}(x^*)}{p!}[h]^{(p-1)}\right)^* y_p, th+\xi \right\rangle + o(t^2) \\ = {} & \langle \mathcal{L}'_{p\,x}(x^*, h, 1, y(h)), th+\xi\rangle + o(t^2) = o(t^2), \end{aligned}$$

since $\mathcal{L}'_{p\,x}(x^*, h, 1, y(h)) = 0$. But also

$$A_2 = \mathcal{L}''_{p\,xx}(x^*, h, 1, y(h))[th]^2 + o(t^2) \geq \alpha\|th\|^2 + o(t^2).$$

The last inequality follows from the condition that $h \in H_p(x^*)$ and (3.3). Finally, we thus have

$$f(x) - f(x^*) = A_1 + A_2 \geq \alpha\|th\|^2 + o(t^2) > 0 \qquad \forall x \in U(x^*),$$

and, therefore, x^* is a strict local minimizer to problem (1.1). □

4. Generalization of the concept of *p*-regularity. In this section we consider a generalization of the concept of p-regularity and derive new necessary optimality conditions for problem (1.1) that is neither regular nor p-regular. We are interested

only in the case $f'(x^*) \neq 0$, since otherwise the classical Euler–Lagrange-type necessary conditions are trivially satisfied with $\lambda_0 \neq 0$ and $y = 0$.

We construct necessary optimality conditions for problem (1.1) under an assumption that F does not satisfy the definition of p-regularity and $F^{(r)}(x^*) \equiv 0$, $r = 1, \dots, p-1$, $p \geq 2$. We believe that this case of absolute degeneration is the most important in analysis of properties of degenerate problems. Moreover, it was proved in [18] that the case of general degeneration, when there exists $F^{(r)}(x^*) \neq 0$, $r < p$, can be reduced to the absolute degeneration case.

Assume that, for some element $h \in X$, the space Y can be decomposed into a direct sum of subspaces

$$Y = Y_1(h) \oplus Y_2(h), \tag{4.1}$$

where $Y_1(h) = \mathrm{Im} F^{(p)}(x^*)[h]^{p-1}$, $Y_2(h)$ is a linear subspace that complements $Y_1(h)$ with respect to Y, and both $Y_1(h)$ and $Y_2(h)$ are closed in Y.

The projection operators onto $Y_1(h)$ along $Y_2(h)$ and onto $Y_2(h)$ along $Y_1(h)$ are denoted by $\mathrm{P}_1(h)$ and $\mathrm{P}_2(h)$, respectively.

We introduce

$$\Lambda(F, h, x^*) = \{h^* \in X^* \,|\, \langle h, h^* \rangle \leq 0\}, \qquad h \in \mathrm{Ker}^{\,\mathrm{p}} F^{(p)}(x^*),$$

$$\overset{0}{\Lambda}(F, h, x^*) = \{h^* \in X^* | \langle h, h^* \rangle < 0\} \cup \{0\}, \qquad h \in \mathrm{Ker}^{\,\mathrm{p}} F^{(p)}(x^*).$$

Define

$$Z = \mathrm{Im}(F^{(p)}(x^*)[h]^{p-1} + P_2(h) F^{(p)}(x^*)\,[h]^{p-2}\,[\widetilde{h}])^*, \qquad \widetilde{h} \in X,$$

and assume that, for $\widetilde{h} \in X$, the space Z is decomposed into a direct sum

$$Z = Z_1(\widetilde{h}) \oplus Z_2(\widetilde{h}), \tag{4.2}$$

where

$$Z_1(\widetilde{h}) = \{z \in Z \,|\, \langle z, \widetilde{h} \rangle = 0\}$$

and $Z_2(\widetilde{h})$ is its complementary subspace with respect to Z. Furthemore, assume that both $Z_1(\widetilde{h})$ and $Z_2(\widetilde{h})$ are closed in Z. Denote by $P_1(\widetilde{h})$, the projection operator onto $Z_1(\widetilde{h})$ along $Z_2(\widetilde{h})$.

Note that under our assumptions all necessary decompositions and constructions are possible in Hilbert spaces. Moreover, they take place in Banach spaces using factorization of spaces.

Under these assumptions, the following theorem holds for problem (1.1).

THEOREM 4.1. *Let X and Y be Banach spaces, x^* a solution to problem* (1.1)*, and U a neighborhood of x^* in X. Suppose that the mapping $F : U \to Y$ is p-times continuously Fréchet differentiable and the function $f : U \to \mathbb{R}$ is twice continuously Fréchet differentiable. Suppose that condition* (4.1) *is satisfied for $h \in \mathrm{Ker}^{\,\mathrm{p}} F^{(p)}(x^*)$ and there exists an element $\widetilde{h} \in X$ $(c \leq \|h\|, \|\widetilde{h}\| \leq C)$, $0 < c \leq C < \infty$ and $D > 0$ such that* (4.2) *is fulfilled and*

$$\|F^{(p)}(x^*)\,[h]^{p-1}\,[\widetilde{h}]\,\| = 0, \tag{4.3}$$

$$\|P_2(h)F(x^* + th + t^\alpha \widetilde{h})\| \le t^{\,(p-2)+2\alpha+\varepsilon}, \quad 1 < \alpha \le \frac{3}{2}, \quad \varepsilon \in (0,1), \tag{4.4}$$

$$\|\{F^{(p)}(x^*)\,[h]^{p-1} + P_2(h)F^{(p)}(x^*)\,[h]^{p-2}\,[\widetilde{h}]\}^{-1}\| \le D, \tag{4.5}$$

where $t \in (0, \delta)$ and $\delta > 0$ is sufficiently small.

Then

(1) *we have $h \in T_1 M(x^*)$; moreover,*

$$\alpha^{\,+}(t) = x^* + th + t^{\,\alpha}\widetilde{h} + r^+(t) \in M(x^*),$$

$$\alpha^{\,-}(t) = x^* + th - t^{\,\alpha}\widetilde{h} + r^-(t) \in M(x^*),$$

so that $\| r^{\pm}(t) \| = o(t^{\,\alpha})$;

(2) *the following inclusion holds:*

$$-f'(x^*) \in \left\{ \overset{0}{\Lambda}(F, h, x^*) \cup \operatorname{Im}((F^{(p)}(x^*)\,[h]^{p-1} + P_2(h)F^{(p)}(x^*)\,[h]^{p-2}\,[\widetilde{h}])\,P_1{}^*(\widetilde{h}))^* \right\}. \tag{4.6}$$

Proof. (1) Consider the case $(+\widetilde{h})$. Define the mapping

$$\Phi(x) = x - (F^{(p)}(x^*)\,[th]^{p-1} + P_2(h)F^{(p)}(x^*)\,[th]^{p-2}\,[t^\alpha \widetilde{h}])^{-1} F(x^* + th + t^\alpha \widetilde{h} + x).$$

Taking into account (4.3) and applying the contraction multimapping principle [13] to the mapping Φ under $x_0 = 0$, there exists a function $r^+(t)$ such that

$$F(x^* + th + t^\alpha \widetilde{h} + r^+(t)) = 0$$

and

$$\|r^+(t)\| \le D\left(\frac{\|P_1(h)F(x^* + th + t^\alpha \widetilde{h})\|}{t^{p-1}} + \frac{\|P_2(h)F(x^* + th + t^\alpha \widetilde{h})\|}{t^{p-2}\,t^\alpha} \right) \le D(t^{2\alpha-1} + t^{\alpha+\varepsilon}) = o(t^\alpha).$$

The case $(-\widetilde{h})$ is considered in a similar way.

(2) First let us note that $\langle -f'(x^*), h\rangle \le 0$, since otherwise x^* would not be a local minimizer.

If $\langle -f'(x^*), h\rangle < 0$, then, by the definition of $\overset{0}{\Lambda}(F, h, x^*)$,

$$-f'(x^*) \in \overset{0}{\Lambda}(F, h, x^*), \tag{4.7}$$

which proves inclusion (4.6). It remains to consider the case $\langle f'(x^*), h\rangle = 0$, $f'(x^*) \ne 0$. Let us show that, in this case,

$$f'(x^*) \in \operatorname{Im}((F^{(p)}(x^*)[h]^{(p-1)} + P_2(h)F^{(p)}(x^*)\,[h]^{(p-2)}\,[\widetilde{h}])\,P_1{}^*(\widetilde{h}))^*. \tag{4.8}$$

By assertion (1) of the theorem, the arcs $\alpha^+(t)$ and $\alpha^-(t)$ belong to $M(x^*)$ for the vector $\widetilde{h} \in \operatorname{Ker} F^{(p)}(x^*)\,[h]^{p-1}$. Using the Taylor formula, we obtain $\langle f'(x^*), \widetilde{h}\rangle = 0$,

since otherwise x^* would not be a local minimizer for problem (1.1), because the function $f(x)$ would decrease along either $\alpha^+(t)$ or $\alpha^-(t)$.

It can be proved in a similar way that the equality $\langle f'(x^*), \widehat{h}\rangle = 0$ holds for any $\widehat{h} \in \operatorname{Ker}(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])$. This follows from the existence of $\delta \in (0,1)$ and $\alpha < 2-\delta$ such that

$$\beta^{\pm}(t) = x^* + th \pm t^{\alpha}\widetilde{h} \pm t^{\alpha+\delta}\widehat{h} + \omega^{\pm}(t) \in M(x^*),$$

where $\|\omega^{\pm}(t)\| = o(t^{\alpha+\delta})$ (see, for instance, [8]).

We define

$$L = \operatorname{Sp}\{\operatorname{Ker}(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}]), \widetilde{h}\}.$$

Since $\langle f'(x^*), \widehat{h}\rangle = 0$ and $\langle f'(x^*), \widetilde{h}\rangle = 0$, then, by definitions of the vectors $\widehat{h}$ and $\widetilde{h}$, we have

$$\langle f'(x^*), \xi\rangle = 0 \qquad \forall \xi \in L. \tag{4.9}$$

Let us show that $Z_1^{\perp}(\widetilde{h}) = L$. By virtue of the annihilator lemma [13],

$$\begin{aligned} Z &= \operatorname{Im}(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])^* \\ &= \operatorname{Ker}(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])^{\perp}. \end{aligned}$$

Hence, $Z_1(\widetilde{h})$ can be represented as

$$\begin{aligned} Z_1(\widetilde{h}) = \{z \in Y^* | \langle z, \widetilde{h}\rangle = 0, \quad \langle z, y\rangle = 0 \\ \forall y \in \operatorname{Ker}(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])\}. \end{aligned}$$

By virtue of a corollary from the bipolar theorem [19], the last relation implies that

$$Z_1^{\perp}(\widetilde{h}) = \operatorname{Sp}\{y, \widetilde{h}\}, \tag{4.10}$$

where $y \in \operatorname{Ker}(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])$.

By the definition of $Z_1(\widetilde{h})$, we obtain

$$Z_1(\widetilde{h}) = \operatorname{Im}(P_1(\widetilde{h})(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])^*);$$

hence, by the annihilator lemma [13],

$$Z_1^{\perp}(\widetilde{h}) = \operatorname{Ker}((F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])P_1^*(\widetilde{h})).$$

By virtue of (4.9) and (4.10), this yields

$$\begin{aligned} &\langle f'(x^*), \xi\rangle = 0 \\ &\quad \forall \xi \in \operatorname{Ker}((F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])\,P_1^*(\widetilde{h})), \end{aligned}$$

so, again by the annihilator lemma [13],

$$f'(x^*) \in \operatorname{Im}(P_1(\widetilde{h})\,(F^{(p)}(x^*)[h]^{p-1} + P_2(h)\,F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}])^*),$$

which proves the inclusion (4.8) in the case under consideration. Together with (4.7), this proves the theorem. □

Remark. Note that according to (4.6), the gradient $-f'(x^*)$ belongs to an open set, despite the fact that all constructions are closed. This is related to condition (4.4), which yields a deterministic structure of the arc $\alpha(t)$. It can be proved that the open set becomes closed when condition (4.4) is not satisfied.

Remark. Relation (4.5) is a new condition which is weaker than the p-regularity condition. We say the operator in the left part of (4.5) is *a generalization of a p-factor-operator* for $p \geq 2$ and condition (4.5) is a *a generalization of the concept of p-regularity* for $p \geq 2$.

COROLLARY 4.2. *If there exists an element $h \neq 0$ such that the conditions of Theorem* 4.1 *are satisfied for h and $-h$, then*

(4.11)
$$\begin{aligned} f'(x^*) \in \ & \mathrm{Im}((F^{(p)}(x^*)[-h]^{p-1} + P_2(-h)F^{(p)}(x^*)[-h]^{p-2}[\widetilde{h}^-])P_1{}^*(\widetilde{h}^-))^* \\ & \cap \mathrm{Im}((F^{(p)}(x^*)[h]^{p-1} + P_2(h)F^{(p)}(x^*)[h]^{p-2}[\widetilde{h}^+])P_1{}^*(\widetilde{h}^+))^*. \end{aligned}$$

The approach considered in this section can be extended to the case of general degeneration. Then, the corresponding *generalized* p-factor-operators $\Psi(h)$ can be constructed by analogy with (4.5) and are generated by elements $h = (h_1, h_2, \dots)$ in such a way that $\mathrm{Im}\Psi(h) = Y$.

5. Examples. In this section we give several examples which illustrate how Theorem 3.3 and Theorem 4.1 can be applied to analyze wide classes of problems that could not be investigated before. In these examples $p = 2$.

The first example illustrates the application of Theorem 3.3.

Example 5.1. Consider the problem

$$\begin{aligned} & x_2^2 + x_3 \to \min, \\ & F(x) = \begin{pmatrix} 0,5(x_1^2 - x_2^2 + x_3^2) + x_2^3 \\ 0,5(x_1^2 - x_2^2 + x_3^2) + x_1x_3 + x_2^3 \end{pmatrix} = 0. \end{aligned} \tag{5.1}$$

As is easy to verify, the point $x^* = 0$ is a local minimum to problem (5.1). Let us prove that the sufficient conditions for optimality given in Theorem 3.3 are satisfied at $x^* = 0$.

For $x^* = 0$, we have $F'(0) = 0$,

$$\mathrm{Ker}^2 F''(0) = \mathrm{Sp}\left\{\begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}\right\} \bigcup \mathrm{Sp}\left\{\begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}\right\}.$$

Consider the element $h = (1, 1, 0)^T$. Since $\mathrm{Im}F''(0)h = \mathbb{R}^2$, the mapping $F(x)$ is 2-regular at $x^* = 0$ along the element h. Consider the 2-factor–Lagrange function with $\alpha_0 = 1$. After some transformations we obtain

$$\begin{aligned} L_2(x, h, y(h)) = x_2^2 + x_3 + \alpha(x_1 - x_2 + 3x_2^2) \\ + \beta(x_1 - x_2 + x_3 + 3x_2^2), \end{aligned} \tag{5.2}$$

where $y(h) = (y_1(h), y_2(h))$, $y_2(h) = (\alpha, \beta)$. Let us calculate the coefficients α and β. Using the equality $L'_{2\,x}(x^*, h, y(h)) = 0$, we obtain $\alpha = 1, \beta = -1$. Putting the coefficients into (5.2), we have

$$L_2(x, h, y(h)) = x_2^2.$$

Therefore, $L''_{2\,xx}(x^*, h, y(h))[h]^2 = 2 \geq 0$.

For the element $h = (1, -1, 0)^T$, all conditions of Theorem 3.3 are verified in the same way.

Hence, we proved that sufficient conditions for optimality are satisfied at the point $x^* = 0$. This means that x^* is a strict local minimizer to (5.1). □

The following examples illustrate the application of Theorem 4.1.

Example 5.2. Consider problem (1.1) with $x^* = 0$ and

$$F(x) = F(x_1, x_2) = x_1^2 - x_2^3 + x_2^{7/2} = 0.$$

We have $F'(x) = (2x_1, -3x_2^2 + \frac{7}{2}x_2^{5/2})$, $F'(x^*) = (0, 0)$,

$$F''(x) = \begin{pmatrix} 2 & 0 \\ 0 & -6x_2 + \frac{35}{4}x_2^{3/2} \end{pmatrix}, \qquad F'''(x^*)\,[h]^2 = (0, -6h_2^2).$$

Therefore,

$$\operatorname{Ker}{}^2 F''(x^*) = \{h \in \mathbb{R}^2 \,|\, h_1 = 0,\ h_2 \in \mathbb{R}\},$$

and we obtain $F''(x^*)\,[h] = (0, 0)$ for all $h \in \operatorname{Ker}{}^2 F''(x^*)$; i.e., the mapping F is not 2-regular along the elements of the kernel of the second derivative, and

$$\operatorname{Im} F''(x^*)[h] = \{0\}.$$

Hence,

$$Y_1(h) = \{0\}, \quad Y_2(h) = \mathbb{R}, \quad P_2(h) = 1.$$

For the element $h = (0, \pm 1) \in \operatorname{Ker}{}^2 F''(x^*)$, there exists an element $\widetilde{h} = (1, 0)$ such that

$$F''(x^*)[h] + F''(x^*)[\widetilde{h}] = (2\widetilde{h}_1, 0)^T$$

and

$$F''(x^*)\,[h, \widetilde{h}] = 0, \qquad F''(x^*)\,[\widetilde{h}]^2 = 2,$$

$$\operatorname{Im}(F''(x^*)\,[h] + P_2(h)\,F''(x^*)\,[\widetilde{h}]) = \mathbb{R},$$

$$\begin{aligned} P_2(h)\,F(x^* + th + t^\alpha \widetilde{h}) = F(t^\alpha \widetilde{h}_1,\, th_2) &= t^{2\alpha}\widetilde{h}_1^2 - t^3 h_2^3 + t^{7/2} h_2^{7/2} \\ &= t^3(\widetilde{h}_1^2 - h_2^3) + t^{7/2} h_2^{7/2}, \qquad \alpha = \frac{3}{2}. \end{aligned}$$

By virtue of the latter relations, for all the conditions of Theorem 4.1 to be satisfied, it is necessary that the equation

$$\widetilde{h}_1^2 - h_2^3 = 0 \tag{5.3}$$

has a nonzero solution. This holds for $h_2 > 0$. However, (5.3) does not have a nonzero solution if $h_2 < 0$. Hence, the arc

$$x^* + th + t^\alpha \widetilde{h} + r_1(t), \qquad \| r_1(t) \| = o(t^\alpha)$$

belongs to $M(x^*)$ only for $h = (0, +1)$. This example illustrates the essential difference from the p-regular case, where a tangent cone is always two-sided. In the case under study, half-spaces may come into play, which will extend the scope of the analysis.

Furthermore, $F''(x^*)[\widetilde{h}] = (2, 0)$,

$$Z_1 = \{z \in \operatorname{Im}(F''(x^*)[\widetilde{h}])^* \mid \langle z, \widetilde{h}\rangle = 0\}$$
$$= \left\{ z = t \begin{pmatrix} 2 \\ 0 \end{pmatrix} \;\middle|\; 2t + 0 = 0, \quad t \in \mathbb{R} \right\} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

i.e.,

$$P_1(\widetilde{h}) = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Hence,

$$\operatorname{Im}((F''(x^*)[h] + P_2(h)F''(x^*)[\widetilde{h}])\, P_1{}^*(\widetilde{h}))^* = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

$$f'(x^*) \in \overset{0}{\Lambda}(F, h, x^*) \cup \{0\} = \{z \in \mathbb{R}^2 \mid \langle z, h\rangle < 0\} \cup \{0\}.$$

Thus, the gradient $f'(x^*)$ must either be situated strictly in the lower half-plane $X_2 < 0$ or be equal to zero. □

Example 5.3. Consider problem (1.1) with $x^* = 0$ and

$$F(x) = F(x_1, x_2) = \begin{pmatrix} x_1^2 - |x_2|^3 - x_3^4 \\ x_1 x_3 \end{pmatrix} = 0.$$

We have

$$\operatorname{Ker}{}^2 F''(x^*) = \{(0, h_2, h_3) \mid h_2 \in \mathbb{R}, h_3 \in \mathbb{R}\}$$

and

$$F''(x^*)[h] = \begin{pmatrix} 0 & 0 & 0 \\ h_3 & 0 & 0 \end{pmatrix}$$

for all $h \in \operatorname{Ker}{}^2 F''(x^*)$; i.e., the mapping F is not 2-regular along the elements of the kernel of the second derivative. For the element $h = (0, \pm 1, 0) \in \operatorname{Ker}{}^2 F''(x^*)$ we have

$$\operatorname{Im} F''(x^*)[h] = \{0\}.$$

Hence,

$$Y_1(h) = \{0\}, \quad Y_2(h) = \mathbb{R}^2, \quad P_2(h) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

For the element h and $\alpha = \frac{3}{2}$ there exists an element $\widetilde{h} = (1, 0, 0)$ such that

$$F''(x^*)[h] + P_2(h)F''(x^*)[\widetilde{h}] = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

$$F(x^* + th + t^\alpha \widetilde{h}) = F(t^\alpha \widetilde{h}_1,\, th_2) = \begin{pmatrix} t^3 - t^3|h_2|^3 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \qquad t > 0.$$

Hence, all conditions of Theorem 4.1 are satisfied.

Furthermore, $Z = (0, 0, z),\ z \in \mathbb{R}$, and

$$P_1(\widetilde{h}) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \qquad P_1(\widetilde{h})\,(F''(x^*)[\widetilde{h}])^T = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

On the one hand, by (4.6), we have for $h = (0, 1, 0)$

$$f'(x^*) \in \overset{0}{\Lambda}\,(F, h, x^*) \cup \operatorname{Im}(P_1(\widetilde{h})(F''(x^*)[\widetilde{h}])^T).$$

On the other hand, for the element $-h = (0, -1, 0)$,

$$f'(x^*) \in \overset{0}{\Lambda}\,(F, -h, x^*) \cup \operatorname{Im}(P_1(\widetilde{h})(F''(x^*)[\widetilde{h}])^T).$$

From the definition of $\overset{0}{\Lambda}$ and the last inclusions we obtain

$$f'(x^*) \in \operatorname{Im}(P_1(\widetilde{h})(F''(x^*)[\widetilde{h}])^T) = (0, 0, z)^T, \qquad z \in \mathbb{R}. \qquad \square$$

Let us note, by virtue of Corollary 4.2, if there exists an element h such that the intersection of the sets in (4.11) is empty, then

$$f'(x^*) = 0.$$

We illustrate this by the following example.

Example 5.4. Consider problem (1.1) with $x^* = 0$ and

$$F : \mathbb{R}^3 \to \mathbb{R}, \qquad F(x) = F(x_1, x_2, x_3) = x_1^2 - x_2^3 - x_3^2.$$

For the element $h = (0, \pm 1, 0)^T \in \operatorname{Ker}^2 F''(x^*)$ we obtain

$$\widetilde{h}^+ = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad \widetilde{h}^- = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad P_1(\widetilde{h}^+) = 0, \quad P_1(\widetilde{h}^-) = 0.$$

Hence, for any problem (1.1) with

$$F(x) = F(x_1, x_2, x_3) = x_1^2 - x_2^3 - x_3^2 = 0,$$

the following assertion holds:

$$f'(x^*) = 0. \qquad \square$$

6. Conclusions. In this paper we derived new optimality conditions for problems with nonregular equality constraints. Our approach is based on constructions of p-regularity. In the first part of the paper, we derived new sufficient conditions for optimality for p-regular constrained optimization problems. This result complements necessary conditions for optimality which were obtained earlier. In the second part of the paper, we proved new necessary conditions for optimality for problems that satisfy a *generalized* condition of p-regularity. Both p-regular and *generalized* conditions for optimality reduce to classical conditions for regular cases, but they give new and nontrivial conditions for nonregular cases. The presented results can be considered as a part of the p-regularity theory.

SPILLOVER STABILIZATION IN FINITE-DIMENSIONAL CONTROL AND OBSERVER DESIGN FOR DISSIPATIVE EVOLUTION EQUATIONS*

GREGORY HAGEN† AND IGOR MEZIĆ‡

Abstract. We consider the problem of global stabilization of a semilinear dissipative evolution equation by finite-dimensional control with finite-dimensional outputs. Coupling between the system modes occurs directly through the nonlinearity and also through the control influence functions. Similar modal coupling occurs in the infinite-dimensional error dynamics through the nonlinearity and measurements. For both the control and observer designs, rather than decompose the original system into Fourier modes, we consider Lyapunov functions based on the infinite-dimensional dynamics of the state and error systems, respectively. The inner product terms of the Lyapunov derivative are decomposed into Fourier modes. Upper bounds on the terms representing control and observation spillover are obtained. Linear quadratic regulator (LQR) designs are used to stabilize the state and error systems with these upper bounds. Relations between system and LQR design parameters are given to ensure global stability of the state and error dynamics with robustness with respect to control and observation spillover, respectively. It is shown that the control and observer designs can be combined to yield a globally stabilizing compensator. The control and observer designs are numerically demonstrated on the problem of controlling stall in a model of axial compressors.

Key words. linear-quadratic control, nonlinear reaction-diffusion equations, Lyapunov stability

1. Introduction.

Modeling and control of infinite-dimensional systems is commonly practiced by approximating the underlying system by a finite-dimensional lumped system (via Galerkin projection [33], proper orthogonal decomposition [28, 20, 21, 30], inertial manifolds [45], etc.). This is not necessary when the control is also infinite-dimensional and the system is spatially invariant [4, 25], which simplifies the analysis of the infinite-dimensional system. However, for practical reasons, it is desirable to obtain finite-dimensional controllers that will stabilize the entire system (see, e.g., [3, 26, 34]). The problem inherent in decomposing a nonlinear infinite-dimensional system into Fourier modes is that the nonlinearity couples all of the modes, often making the decomposed system just as intractable as the original infinite-dimensional one. Common to all dissipative systems, the higher modes of the system often exhibit some form of stability which allows for the treatment of a truncated system of a finite number of modes. Control design can then be systematically carried out to stabilize the reduced order system. However, a systematic and quantifiable method of determining the minimum order of truncation remains elusive. The high modes of the system cannot be completely neglected due to the fact that modes are still coupled through the nonlinearity and that the control can inadvertently introduce energy into these high modes. This energy can act to destabilize the high modes or can be transferred to the low modes through nonlinear coupling. This phenomenon is referred to as spillover [2]. Analysis of reduced order systems [10, 17]

and control spillover has since become a topic of work dealing with the control of flexible structures and/or robust control (see, e.g., [9, 39, 41]).

In particular, recent work has employed the use of singular perturbation theory [12] to construct globally stabilizing finite-dimensional controllers [13] and locally stabilizing finite-dimensional controller/observers [1] for dissipative parabolic PDEs. However, the use of singular perturbation methods requires a priori knowledge of the initial conditions of the system [31] before such controllers can be constructed. Additionally, the use of approximate inertial manifolds and the nonlinear Galerkin method [33] has been utilized to derive reduced order models. These methods require the eigenspectrum of the linear parts of the system to satisfy a gap condition in which consecutive stable eigenvalues have a sufficiently large difference between them. This often requires the controller to stabilize modes that are already stable (see the appendix of [12]). Furthermore, the gap condition is even more difficult to satisfy when the system has strong convective terms and/or a small diffusion parameter [45].

In the present work, to alleviate some of the problems created by the coupling of modes through the nonlinearity of the system, we avoid directly decomposing the system into Fourier modes and instead consider a control Lyapunov function (CLF) for the original infinite-dimensional system and an observer Lyapunov function (OLF) for the infinite-dimensional error system. Details concerning Lyapunov stability theory in the context of infinite-dimensional systems can be found in [6, 14]. By applying a linear bound of the system nonlinearity, as in [25], we obtain an upper bound on the CLF derivative in terms of the Fourier coefficients of the state. This in turn provides for the direct construction of a linear finite-dimensional controller of the low modes of the system. The CLF derivative explicitly shows the destabilizing effects of the high modal content of the controller. Upper bounds of the high modes of the CLF derivative are obtained to quantify the effects of control spillover. A linear quadratic regulator (LQR) control design is used to make the CLF derivative negative with these upper bounds, and we state relations between the system and LQR parameters that are sufficient for global stability and robustness with respect to control spillover. The infinite-dimensional observer based on finite-dimensional measurements is designed by similar analysis of the OLF derivative. Furthermore, we show that the controller and observer can be combined while maintaining global stability.

The paper is organized as follows. Section 2 contains the problem setup and description. We first consider the control problem with full state information. In section 3, we state the CLF to be used and show that coupling between modes occurs through the nonlinearity and the control terms. The analysis of the nonlinear coupling is eliminated by considering a linear bound of the nonlinearity. This essentially diagonalizes the CLF derivative as in [25]; however, coupling still occurs through the control inputs. In section 4, we provide sufficient conditions on the control design and the system parameters to ensure that the closed loop system is robust to the destabilizing effects of control spillover. In section 5, we consider the estimation problem with finite-dimensional outputs in the absence of control. We consider an OLF, and the analysis is similar to that of sections 3 and 4. In section 6, we show that the closed loop system is globally stable when the controller and observer are combined. The duality principles between the control and observer designs and the respective spillover analyses are illustrated in section 7. In section 8, we apply the control and observer designs and spillover analyses to the problem of stabilizing a nonlocal evolution equation describing the rotating stall phenomena in axial compressors by a finite-dimensional controller with finite-dimensional outputs.

2. Problem formulation. We consider the following type of nonlocal dissipative evolution equation with periodic boundary conditions:

$$\frac{\partial y}{\partial t} = a^2 \frac{\partial^2 y}{\partial \theta^2} - \beta \frac{\partial y}{\partial \theta} + f(y) - \alpha \overline{f(y)} + B\mathcal{V}, \tag{1}$$

$$z = Hy,$$

$$y(t,0) = y(t,2\pi), \quad y(0,\theta) = y_0(\theta), \tag{2}$$

where a^2, β, and α are positive constants, the function $f(y)$ is a polynomial of odd degree with a strictly negative highest order coefficient, and

$$\overline{f(y)} = \frac{1}{2\pi} \int_0^{2\pi} f(y)\, d\theta. \tag{3}$$

This system describes the rotating stall phenomenon in axial compressors [25, 23], phase separation in binary mixtures [40, 36], chemical reaction systems [43, 45], as well as other systems [11, 19]. From now on, we shall take $\alpha = 1$ for convenience. This will restrict the average of $y(t,\theta)$ over θ to be constant for all time. Therefore, without loss of generality, we can assume that $y(t,\theta)$ is zero-average over θ for all time. The analysis in this paper is applicable to cases where $\alpha \neq 1$. In this case, the control design would have to incorporate stabilization of the zeroth Fourier mode of the system. The control $\mathcal{V} \in \mathbb{R}^N$ and the linear operator $B : \mathbb{R}^N \to \bar{L}_2(0,2\pi)$, where $\bar{L}_2(0,2\pi)$ is the space of square integrable functions that are 2π-periodic and have zero-average. We write $B\mathcal{V} = \sum_{i=1}^N v^i b^i(\theta)$, so the controls enter the system additively through N different amplitudes v^i with shape functions $b^i(\theta)$. The output $z \in \mathbb{R}^N$ and the linear operator $H : \bar{L}_2(0,2\pi) \to \mathbb{R}^N$. The required regularity results for the feedback system (1) can be found in [5, 25, 38]. We note that the superscripts i are for notation and do not represent powers. The control objective is to globally stabilize the equilibrium solution $y(\theta) = 0$.

3. Modal decomposition and Lyapunov stability analysis. We first consider the control problem with full state information. Assuming $y(t,\theta)$ is zero-average over θ for all t, we decompose the function $y(t,\theta)$ into Fourier modes,

$$y(t,\theta) = \sum_{n=1}^{\infty} y_n(t)\phi_n(\theta), \tag{4}$$

where $y_n(t) = \langle y(t,\theta), \phi_n(\theta)\rangle$ is the nth Fourier coefficient of $y(t,\theta)$ and $\phi_n(\theta)$ is the nth orthonormal function of the Fourier series satisfying the boundary conditions. The expression $\langle \cdot, \cdot \rangle$ is the inner product on $\bar{L}_2(0,2\pi)$. If we immediately substitute (4) into (1), we obtain for each $n \geq 1$

$$\dot{y}_n = (-a^2 n^2 - \beta j n) y_n + f_n\left(\sum_{n=1}^{\infty} y_n \phi_n\right) + \sum_{i=1}^{N} v^i b_n^i; \quad j = \sqrt{-1}. \tag{5}$$

It is easy to see that the modes are coupled through $f(y)$ and the shape functions $b^i(\theta)$. We consider the CLF

$$V(y) = \frac{1}{2}\|y\|^2 = \frac{1}{2}\langle y, y\rangle, \tag{6}$$

where $\|\cdot\|$ is the usual norm in $\bar{L}_2(0,2\pi)$.

In order to bypass the difficulty caused by nonlinear modal coupling in (5), we apply a linear bound of the system nonlinearity before decomposing into Fourier modes. For a given polynomial $f(x)$ of odd degree with a strictly negative highest order coefficient and $f(0) = 0$, there exists a constant C such that

$$xf(x) \leq Cx^2 \quad \forall x \in \mathbb{R}. \tag{7}$$

Since $f(y)$ is independent of the spatial variable θ, we can extend this inequality to the infinite-dimensional case,

$$\langle y, f(y) \rangle \leq C\|y\|_2^2 \quad \forall y \in \bar{L}_2(0, 2\pi). \tag{8}$$

Now we take the time derivative of the CLF:

$$\begin{aligned}
\dot{V} &= \left\langle y, a^2 \frac{\partial^2 y}{\partial \theta^2} - \beta \frac{\partial y}{\partial \theta} + f(y) - \overline{f(y)} + \sum_{i=1}^{N} v^i b^i(\theta) \right\rangle \\
&= -a^2 \left\| \frac{\partial y}{\partial \theta} \right\|^2 + \langle y, f(y) \rangle - \langle y, \overline{f(y)} \rangle + \left\langle y, \sum_{i=1}^{N} v^i b^i(\theta) \right\rangle \qquad (9) \\
&= -a^2 \left\| \frac{\partial y}{\partial \theta} \right\|^2 + \langle y, f(y) \rangle + \left\langle y, \sum_{i=1}^{N} v^i b^i(\theta) \right\rangle \qquad (10) \\
&\leq -a^2 \left\| \frac{\partial y}{\partial \theta} \right\|^2 + C\|y\|^2 + \left\langle y, \sum_{i=1}^{N} v^i b^i(\theta) \right\rangle, \qquad (11)
\end{aligned}$$

where (9) is obtained from integrating by parts and applying the boundary conditions and (10) is obtained from the fact that $\overline{f(y)}$ is a constant and $y(t, \theta)$ is zero-average over θ for all time. Inequality (11) is obtained by using the linear bound (8).

REMARK 1. *The CLF given with the periodic boundary conditions cancels the term $\beta \frac{\partial y}{\partial \theta}$. Similarly, the presence of the Burgers nonlinearity in the system* (1), (2) *is inconsequential to the forthcoming stability analysis because, by integration by parts, $\langle y, y \frac{\partial y}{\partial \theta} \rangle = 0$.*

REMARK 2. *If $\beta = 0$, then the forthcoming analysis also applies for homogeneous Dirichlet and Neumann boundary conditions.*

Instead of dealing directly with (5), we now decompose $y(t, \theta)$ into Fourier modes and substitute into (6) and (11) to get

$$V(y) = \frac{1}{2} \left\langle \sum_{n=1}^{\infty} y_n \phi_n, \sum_{n=1}^{\infty} y_n \phi_n \right\rangle = \frac{1}{2} \sum_{n=1}^{\infty} (y_n)^2 \tag{12}$$

and

$$\begin{aligned}
\sum_{n=1}^{\infty} (y_n) \dot{y}_n = \dot{V} &\leq \sum_{n=1}^{\infty} -a^2 n^2 y_n^2 + C \sum_{n=1}^{\infty} y_n^2 + \sum_{i=1}^{N} v^i \left(\sum_{n=1}^{\infty} y_n b_n^i \right) \\
&= \sum_{n=1}^{\infty} \left[\left(-a^2 n^2 + C \right) y_n^2 + y_n \sum_{i=1}^{N} v^i b_n^i \right], \qquad (13)
\end{aligned}$$

where we have also decomposed the input shape functions $b^i(\theta)$ into Fourier modes. In (13), we can directly compare the stabilizing $(-a^2 n^2)$ term with the destabilizing (C) term for each n. The last term on the right side of (13) shows how the control can introduce energy into the high modal content $\dot{V}$.

4. Linear control with spillover analysis. We use (13) to design a linear controller. We define $\dot{V}_n$ to be the nth term of the summation in (13),

$$\dot{V}_n = (-a^2n^2 + C)y_n^2 + y_n \sum_{i=1}^{N} v^i \; b_n^i, \tag{14}$$

and note that $\dot{V} \leq \sum_{n=1}^{\infty} \dot{V}_n$. Because the modes are coupled, we stabilize the entire system by stabilizing $\dot{V}_n$ for every n. Consider the uncontrolled system. We have, for sufficiently large values of n,

$$\dot{V}_n = (-a^2n^2 + C)y_n^2 \leq 0. \tag{15}$$

This shows that for the purpose of control design, the high modes exhibit some form of stability. We assume that N is such that

$$-a^2N^2 + C > 0 > -a^2(N+1)^2 + C. \tag{16}$$

Note that we have assumed that there are N actuators. This assumption states that the number of actuators must be at least the number of unstable modes of the operator $(a^2 \frac{\partial^2}{\partial \theta^2} + C)$. We now consider stabilizing the first N terms in the upper estimate of the CLF derivative. We define

$$\mathbf{Y}_N := [y_1 \dots y_N]^T, \;\; \mathcal{V} := \left[v^1 \dots v^N\right]^T, \;\; \mathbf{V}_N := \sum_{n=1}^{N} V_n, \;\; \mathbf{V}_{n>N} := \sum_{n>N} V_n,$$

$$A_N := \begin{bmatrix} -a^2 + C & 0 & \dots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & -a^2N^2 + C \end{bmatrix}, \tag{17}$$

$$b_n := [b_n^1 \dots b_n^N]^T, \;\; \mathcal{B}_N := \begin{bmatrix} b_1^1 & \dots & b_1^N \\ \vdots & \ddots & \vdots \\ b_N^1 & \dots & b_N^N \end{bmatrix}. \tag{18}$$

Thus we have $\dot{V} \leq \dot{\mathbf{V}}_N + \dot{\mathbf{V}}_{n>N}$. We let $\mathcal{V}$ be a linear controller

$$\mathcal{V} = -K\mathbf{Y}_N, \tag{19}$$

where K is an $N \times N$ gain matrix. Using (17)–(19), the first N terms of the estimate (13) become

$$\dot{\mathbf{V}}_N = \sum_{i=1}^{N} \dot{V}_i \leq \frac{1}{2}\mathbf{Y}_N^T \left([A_N - \mathcal{B}_N K] + [A_N - \mathcal{B}_N K]^T \right) \mathbf{Y}_N := \mathbf{Y}_N^T \Lambda_N \mathbf{Y}_N. \tag{20}$$

Assuming that $\mathcal{B}_N$ is such that the system is controllable, we can design K such that Λ_N is negative definite. This can be achieved by an LQR design on the finite-dimensional system (see, e.g., [4, 25]).

$$\text{Minimize: } J(\mathcal{V}, \mathbf{Y}_N) = \int_0^{\infty} \left(\mathbf{Y}_N^T Q \mathbf{Y}_N + \mathcal{V}^T R \mathcal{V} \right) \, dt$$

$$\text{Subject to: } \dot{\mathbf{Y}}_N = A_N \mathbf{Y}_N + \mathcal{B}_N \mathcal{V}.$$

The LQR problem gives a feedback law

$$\mathcal{V} = -R^{-1}\mathcal{B}_N^T P \mathbf{Y}_N, \tag{21}$$

where P is the solution of the algebraic Riccati equation (ARE),

$$0 = A_N^T P + P A_N + Q - P\mathcal{B}_N R^{-1}\mathcal{B}_N^T P. \tag{22}$$

Substituting $K = R^{-1}\mathcal{B}_N^T P$ into (22), we obtain the Lyapunov equation,

$$(A_N - \mathcal{B}_N K)^T P + P(A_N - \mathcal{B}_N K) = -Q - K^T R K. \tag{23}$$

By applying (23) with $P = \frac{1}{2}I$ to (20), we have

$$\dot{\mathbf{V}}_N = \mathbf{Y}_N^T \left[-Q - K^T R K\right] \mathbf{Y}_N. \tag{24}$$

Now that we have constructed a control law that will stabilize the first N terms of the summation in (13), we analyze the possibly destabilizing effect the control has on the higher modes of the system. We repeat (14) here,

$$\dot{V}_n = (-a^2 n^2 + C) y_n^2 + y_n \sum_{i=1}^{N} v^i \; b_n^i. \tag{25}$$

For $n > N$, the first term is always ≤ 0, and the second term is sign indefinite. This term quantifies the control spillover onto the higher modes of the system. Specifically, if the input shape functions $b^i(\theta)$ have high frequency content, there is the possibility of more control spillover. We define the following scalars:

$$c_n := a^2 n^2 - C, \quad d_n := -b_n^T K \mathbf{Y}_N. \tag{26}$$

Substituting (19) and (26) into (25) results in

$$\dot{V}_n = -c_n y_n^2 + d_n y_n. \tag{27}$$

It is easy to see that this expression reaches its maximum value at $y_n = \frac{1}{2}\frac{d_n}{c_n}$, and so for each $n > N$,

$$\dot{V}_n \leq \frac{1}{4}\frac{d_n^2}{c_n} = \frac{1}{4c_n}\mathbf{Y}_N^T K^T b_n b_n^T K \mathbf{Y}_N. \tag{28}$$

We see from (28) how high frequency content of the input shape functions and high controller gains can destabilize the entire system. Since each $\dot{V}_n$ corresponds to the possible destabilization of a high mode, the stabilization provided by (24) must be such that $\dot{V}$ remains negative with the addition of terms such as (28). We will show that this is guaranteed given certain LQR design parameters and some conditions on the reduced order model $(A_N, \mathcal{B}_N)$.

Recall that $\dot{V}$ is majorized by summing the terms $\dot{V}_n$. The controller (21) stabilizes the first N modes of the system with stability given by (24), while the rest of the terms of the summation of the CLF derivative estimate are each bounded according to (28). The total possible destabilizing effect produced by control spillover is given by summing over the all the terms for $n > N$,

$$\dot{\mathbf{V}}_{n>N} \leq \frac{1}{4}\mathbf{Y}_N^T K^T \left[\sum_{n>N} \frac{1}{c_n} b_n b_n^T\right] K \mathbf{Y}_N. \tag{29}$$

Since the input operators are bounded, the summation in (29) exists, and we define the $N \times N$ matrix

$$\Xi := \sum_{n>N} \frac{1}{c_n} b_n b_n^T. \tag{30}$$

REMARK 3. *Given sufficient regularity of solutions of* (1), (2), *the assumption of bounded input operators may be lifted. For example, since* $c_n = \mathcal{O}(n^2)$, *the summation exists for unbounded "point" operators.*

This gives

$$\dot{\mathbf{V}}_{n>N} \leq \frac{1}{4} \mathbf{Y}_N^T K^T \Xi K \mathbf{Y}_N. \tag{31}$$

The $N \times N$ matrix Ξ quantifies the destabilizing effects of the control spillover. Notice that increasing the control gain K and the high frequency content of the input functions $b^i(\theta)$ both contribute to the destabilizing effect. We can now go back and analyze the original CLF (13). Adding (24) and (31), we get

$$\dot{V} \leq \mathbf{Y}_N^T \left[-Q - K^T R K + \frac{1}{4} K^T \Xi K \right] \mathbf{Y}_N. \tag{32}$$

We now point out that we need to solve the LQR design problem in reverse order. That is, we have specified $P = \frac{1}{2} I$ in deriving (24). We will specify the positive definite matrix R to account for the effects of control spillover and then solve the ARE for an admissible positive definite matrix Q.

Motivated by (32), we specify a positive definite matrix

$$R \geq \frac{1}{4} \Xi \tag{33}$$

to cancel the effects of control spillover. If we can solve the ARE for a positive definite Q with our choices of P and R, then we have

$$\dot{V} \leq -\mathbf{Y}_N^T Q \mathbf{Y}_N \leq 0. \tag{34}$$

When $\mathbf{Y}_N^T Q \mathbf{Y}_N = 0$, the control is zero, and from (15) we see that the high modes decay naturally. Therefore, $\dot{V} = 0$ only if $y_n = 0$ for all n. We now solve the ARE (22) for Q with our choice of $P = \frac{1}{2} I$. Since A_N is diagonal,

$$Q = -A_N + \frac{1}{4} \mathcal{B}_N R^{-1} \mathcal{B}_N^T, \tag{35}$$

which is positive definite if and only if

$$A_N < \frac{1}{4} \mathcal{B}_N R^{-1} \mathcal{B}_N^T. \tag{36}$$

The control design is now reduced to finding a positive definite matrix R that satisfies (33) and (36). Note that A_N is positive definite (see (16), (17)), and therefore $\mathcal{B}_N$ must be invertible. Equation (36) is equivalent to requiring $R < \frac{1}{4} \mathcal{B}_N^T A_N^{-1} \mathcal{B}_N$, and combining this with (33), it is necessary that

$$\mathcal{B}_N^T A_N^{-1} \mathcal{B}_N > \Xi. \tag{37}$$

This inequality can be checked by computing the eigenvalues of $\mathcal{B}_N^T A_N^{-1} \mathcal{B}_N - \Xi$ (see [29]), and the matrix R can be chosen accordingly. We have just shown the following result.

THEOREM 4. *Given the system* (1)*, with* $f(y)$ *satisfying* (8)*, along with the definitions* (17), (18)*, and* (30)*, if the matrix inequality* (37) *is satisfied, then there exists* $R > 0$ *such that the closed loop system* (1) *with feedback control* (21)*, with* $P = \frac{1}{2} I$*, is globally stable.*

Controller synthesis. We outline the synthesis of the controllers resulting from Theorem 4:

1. Given the system nonlinearity $f(x)$, determine C according to (7).
2. Given the operators $\mathcal{A} := a^2 \frac{\partial^2 \cdot}{\partial \theta^2} - \beta \frac{\partial \cdot}{\partial \theta}$ and B, compute the matrices $A_N, \mathcal{B}_N$, and b_n according to (17), (18).
3. Compute Ξ according to (30).
4. Choose $R \geq \Xi$. For example, take $R = \Xi + \delta I$, with $\delta > 0$.
5. According to (37), check if $\mathcal{B}_N^T A_N^{-1} \mathcal{B}_N - R > 0$. If so, then the controller $\mathcal{V} = -\frac{1}{2} R^{-1} \mathcal{B}_N^T \mathbf{Y}_N$ is globally stabilizing. If not, then the construction may not stabilize the control spillover.

5. Linear observation with spillover analysis. In this section, we consider the system (1) with a finite-dimensional output. Our goal is to construct an observer based on the available finite-dimensional measurements that is robust to observation spillover. By the linear principle of duality, we expect to find requirements similar to (33) and (36). We consider (1), (2) with no control and with $\alpha = 1$,

$$\frac{\partial y}{\partial t} = a^2 \frac{\partial^2 y}{\partial \theta^2} - \beta \frac{\partial y}{\partial \theta} + f(y) - \overline{f(y)}, \tag{38}$$

with a finite-dimensional output $z \in \mathbb{R}^N$ given by

$$z = Hy, \tag{39}$$

where $H : \bar{L}_2(0, 2\pi) \to \mathbb{R}^N$ is linear. For the control design of section 4, we used only the Fourier coefficients y_n of $y(t, \theta)$ for feedback. This motivates us to consider directly estimating the finite number of Fourier coefficients. However, just as it was necessary to analyze the stability of the high modes of the state in the control design, in order to achieve global results, we will need to analyze the decay of the high modes of the error. Thus, in order to analyze the observation spillover, we need to construct an estimate of the full state, $\hat{y}(t, \theta)$. We write the estimator system,

$$\frac{\partial \hat{y}}{\partial t} = a^2 \frac{\partial^2 \hat{y}}{\partial \theta^2} - \beta \frac{\partial \hat{y}}{\partial \theta} + f(\hat{y}) - \overline{f(\hat{y})} + LH(y - \hat{y}), \tag{40}$$

$$\hat{y}(t, 0) = \hat{y}(t, 2\pi), \quad \hat{y}(0, \theta) = 0, \tag{41}$$

where L will be the linear observer gain that is to be designed. For reasons that will be evident later, we choose L such that $L : \mathbb{R}^N \to \text{Span}\{\phi_1 \dots \phi_N\}$. If $H : \bar{L}_2(0, 2\pi) \to \mathbb{R}^N$, we can write

$$H := \left[H^1 \dots H^N\right]^T ; H^i : \bar{L}_2(0, 2\pi) \to \mathbb{R}, \tag{42}$$

and L is represented by

$$L := \left[L^1(\theta) \dots L^N(\theta)\right]. \tag{43}$$

We can immediately see the duality between the control and observer designs. In the control design, the input shape functions $b^i(\theta)$ are given, and the design objective is to determine the vector v. In the observer design, the vector output Hy is given, and the objective is to determine the estimation shape functions $L^i(\theta)$. We note that the superscripts in (42) and (43) are for notation and do not represent exponents.

In constructing the observer, we will use an inequality similar to the linear bound given by (7) in order to simplify the spillover analysis. We will stabilize the zero solution of the error state,

$$\tilde{y} := y - \hat{y}, \tag{44}$$

whose dynamics are governed by

$$\frac{\partial \tilde{y}}{\partial t} = a^2 \frac{\partial^2 \tilde{y}}{\partial \theta^2} - \beta \frac{\partial \tilde{y}}{\partial \theta} + f(y) - \overline{f(y)} - (f(\hat{y}) - \overline{f(\hat{y})}) - LH\tilde{y}, \tag{45}$$

$$\tilde{y}(t,0) = \tilde{y}(t,2\pi), \;\; \tilde{y}(0,\theta) = y_0(\theta). \tag{46}$$

Note that we have subtracted the averaged quantities which enforce $\overline{\tilde{y}}(t,\theta) = 0$ for all $t > 0$. Since y is evolving in time, we need to consider the linear bound of $f(y)$ for all y. We assume that the constant C_L is the maximum positive slope of $f(y)$, so

$$(x-y)(f(x) - f(y)) \leq C_L (x-y)^2 \;\; \forall x, y \in \mathbb{R}. \tag{47}$$

This inequality is less conservative than the Lipschitz property. We extend this inequality to the infinite-dimensional case

$$\langle x - y, f(x) - f(y) \rangle \leq C_L \|x - y\|_2^2 \;\; \forall x, y \in \bar{L}_2(0, 2\pi). \tag{48}$$

We will now follow a process similar to that of section 4. We consider an OLF

$$W(\tilde{y}) = \frac{1}{2}\|\tilde{y}\|_2^2 = \frac{1}{2}\langle \tilde{y}, \tilde{y} \rangle \tag{49}$$

and take the time derivative

$$\begin{aligned}
\dot{W} &= \left\langle \tilde{y}, a^2 \frac{\partial^2 \tilde{y}}{\partial \theta^2} - \beta \frac{\partial \tilde{y}}{\partial \theta} + f(y) - \overline{f(y)} - (f(\hat{y}) - \overline{f(\hat{y})}) - LH\tilde{y} \right\rangle \\
&= -a^2 \left\| \frac{\partial \tilde{y}}{\partial \theta} \right\|^2 + \langle \tilde{y}, f(y) - \overline{f(y)} - (f(\hat{y}) - \overline{f(\hat{y})}) \rangle - \langle \tilde{y}, LH\tilde{y} \rangle \qquad (50) \\
&= -a^2 \left\| \frac{\partial \tilde{y}}{\partial \theta} \right\|^2 + \langle \tilde{y}, f(y) - f(\hat{y}) \rangle - \langle \tilde{y}, LH\tilde{y} \rangle \qquad (51) \\
&\leq -a^2 \left\| \frac{\partial \tilde{y}}{\partial \theta} \right\|^2 + C_L \|\tilde{y}\|_2^2 - \langle \tilde{y}, LH\tilde{y} \rangle, \qquad (52)
\end{aligned}$$

where (50) is obtained from integrating by parts and applying the boundary conditions and (51) is obtained from the fact that $\overline{f(y)}$ and $\overline{f(\hat{y})}$ are constants and $\tilde{y}(t,\theta)$ is zero-average over θ for all time. Inequality (52) is obtained by using the inequality (48). Just as in section 4, we now decompose $\tilde{y}(t,\theta)$ into Fourier modes, $\tilde{y}(t,\theta) = \sum_{n=1}^{\infty} \tilde{y}_n(t)\phi_n(\theta)$, and substitute into (49) and (52) to get

$$W(\tilde{y}) = \frac{1}{2}\left\langle \sum_{n=1}^{\infty} \tilde{y}_n \phi_n, \sum_{n=1}^{\infty} \tilde{y}_n \phi_n \right\rangle = \frac{1}{2} \sum_{n=1}^{\infty} (\tilde{y}_n)^2, \tag{53}$$

$$\dot{W} \leq \sum_{n=1}^{\infty} \left[(-a^2 n^2 + C_L)\tilde{y}_n^2 - \tilde{y}_n \left(LH\tilde{y}\right)_n \right], \tag{54}$$

where $(LH\tilde{y})_n = \langle LH\tilde{y}, \phi_n \rangle$. From (42) and (43),

$$(LH\tilde{y})_n = \left\langle \sum_{i=1}^{N} L^i(\theta) H^i \tilde{y}, \phi_n \right\rangle = \sum_{i=1}^{N} L_n^i H^i \tilde{y} = \left[L_n^1 \dots L_n^N \right] H\tilde{y}, \tag{55}$$

where $L_n^i = \langle L^i(\theta), \phi_n \rangle$. Just as in section 4, we take N such that $-a^2N^2 + C_L > 0 > -a^2(N+1)^2 + C_L$. We define $\dot{W}_n$ to be the nth term in the summation of the estimate (54),

$$\dot{W}_n = (-a^2n^2 + C_L)\hat{y}_n^2 - \tilde{y}_n \left(LH\tilde{y}\right)_n, \tag{56}$$

and note that $\dot{W} \leq \sum_{n=1}^{\infty} \dot{W}_n$. We define

$$\tilde{\mathbf{Y}}_N := [\tilde{y}_1 \dots \tilde{y}_N]^T, \quad \mathbf{W}_N := \sum_{n=1}^{N} W_n, \quad \mathbf{W}_{n>N} := \sum_{n>N} W_n,$$

$$A := \begin{bmatrix} -a^2 + C_L & 0 & \dots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & -a^2N^2 + C_L \end{bmatrix}, \quad \mathbf{L}_N = \begin{bmatrix} L_1^1 & \dots & L_1^N \\ \vdots & \ddots & \vdots \\ L_N^1 & \dots & L_N^N \end{bmatrix}, \tag{57}$$

$$h_n := H\phi_n, \quad \mathbf{H}_N := [h_1 \dots h_N]. \tag{58}$$

Thus we have $\dot{W} \leq \dot{\mathbf{W}}_N + \dot{\mathbf{W}}_{n>N}$. We write $H\tilde{y}$ as

$$H\tilde{y} = LH\left(\sum_{n=1}^{\infty} \tilde{y}_n \phi_n \right) = \sum_{n=1}^{\infty} \tilde{y}_n H\phi_n = \mathbf{H}_N \tilde{\mathbf{Y}}_N + \sum_{n>N} \tilde{y}_n h_n, \tag{59}$$

so

$$\dot{\mathbf{W}}_N = \frac{1}{2}\tilde{\mathbf{Y}}_N^T (A - \mathbf{H}_N^T \mathbf{L}_N^T)\tilde{\mathbf{Y}}_N + \frac{1}{2}\tilde{\mathbf{Y}}_N^T (A - \mathbf{H}_N^T \mathbf{L}_N^T)^T \tilde{\mathbf{Y}}_N - \tilde{\mathbf{Y}}_N^T \mathbf{L}_N \sum_{m>N} \tilde{y}_m h_m, \tag{60}$$

$$\dot{\mathbf{W}}_{n>N} = \sum_{n>N} (-a^2n^2 + C_L)\tilde{y}_n^2. \tag{61}$$

The term $\sum_{m>N} \tilde{y}_m h_m$ in (60) represents the projection of the high modes of the state onto the output operator H, which quantifies the observation spillover. The analysis now follows in a similar fashion as in section 4. However, in this case, the observation spillover affects the stabilization of the first N terms of the OLF derivative, as is shown in (60). Adding (60) and (61) and rearranging the terms give

$$\begin{aligned} \dot{W} \leq \dot{\mathbf{W}}_N + \dot{\mathbf{W}}_{n>N} = {} & \frac{1}{2}\tilde{\mathbf{Y}}_N^T (A - \mathbf{H}_N^T \mathbf{L}_N^T)\tilde{\mathbf{Y}}_N + \frac{1}{2}\tilde{\mathbf{Y}}_N^T (A - \mathbf{H}_N^T \mathbf{L}_N^T)^T \tilde{\mathbf{Y}}_N \\ & + \sum_{n>N} \left[-\tilde{\mathbf{Y}}_N^T \mathbf{L}_N \tilde{y}_n h_n + (-a^2n^2 + C_L)\tilde{y}_n^2 \right]. \end{aligned} \tag{62}$$

We define for $n \geq N$

$$c_n := a^2n^2 - C_L, \quad d_n := -\tilde{\mathbf{Y}}_N^T \mathbf{L}_N h_n \tag{63}$$

and see that the expression $-c_n\tilde{y}_n^2 + d_n\tilde{y}_n$ attains its maximum at $\tilde{y}_n = \frac{d_n}{2c_n}$, so the terms of the summation in (62) are bounded by

$$-(a^2n^2 - C_L)\tilde{y}_n^2 - \tilde{\mathbf{Y}}_N^T\mathbf{L}_N h_n\tilde{y}_n \leq \frac{1}{4c_n}\tilde{\mathbf{Y}}_N^T\mathbf{L}_N h_n h_n^T\mathbf{L}_N^T\tilde{\mathbf{Y}}_N. \tag{64}$$

We define the $N \times N$ matrix

$$\Omega := \sum_{n>N} \frac{1}{c_n} h_n h_n^T, \tag{65}$$

and it follows that

$$\dot{W} \leq \frac{1}{2}\tilde{\mathbf{Y}}_N^T(A - \mathbf{H}_N^T\mathbf{L}_N^T)\tilde{\mathbf{Y}}_N + \frac{1}{2}\tilde{\mathbf{Y}}_N^T(A - \mathbf{H}_N^T\mathbf{L}_N^T)^T\tilde{\mathbf{Y}}_N + \frac{1}{4}\tilde{\mathbf{Y}}_N^T\mathbf{L}_N\Omega\mathbf{L}_N^T\tilde{\mathbf{Y}}_N. \tag{66}$$

We now construct a linear optimal observer based on the following problem:

$$\text{Minimize: } J(\tilde{\mathbf{Y}}_N) = \int_0^\infty (\tilde{\mathbf{Y}}_N^T Q\tilde{\mathbf{Y}}_N + \tilde{\mathbf{Y}}_N\mathbf{L}_N R\mathbf{L}_N^T\tilde{\mathbf{Y}}_N)\, dt$$
$$\text{Subject to: } \dot{\tilde{\mathbf{Y}}}_N = A\tilde{\mathbf{Y}}_N - \mathbf{H}_N^T\mathbf{L}_N^T\tilde{\mathbf{Y}}_N.$$

The resulting observer gain is

$$\mathbf{L}_N^T = R^{-1}\mathbf{H}_N P, \tag{67}$$

where $P > 0$ solves the ARE

$$0 = A^T P + PA + Q - P\mathbf{H}_N^T R^{-1}\mathbf{H}_N P. \tag{68}$$

We note here that (68) is the control version of the ARE and is not the dual (or observer) form of the ARE (see, e.g., [44]). If the underlying system were linear, then the two would be equivalent. In this case, we are using the solution of the ARE as a tool to cancel the observation spillover. We discuss the duality between control and observation spillover further in section 7. Substituting (67) into (68), we obtain the closed loop Lyapunov equation,

$$(A - \mathbf{H}_N^T\mathbf{L}_N^T)^T P + P(A - \mathbf{H}_N^T\mathbf{L}_N^T) = -Q - \mathbf{L}_N R\mathbf{L}_N^T. \tag{69}$$

We take $P = \frac{1}{2}I$ and substitute (69) into (66) to obtain

$$\dot{W} \leq \tilde{\mathbf{Y}}_N^T\left[-Q - \mathbf{L}_N R\mathbf{L}_N^T + \frac{1}{4}\mathbf{L}_N\Omega\mathbf{L}_N^T\right]\tilde{\mathbf{Y}}_N. \tag{70}$$

We now obtain the requirements on R as in (33) and (36),

$$R \geq \frac{1}{4}\Omega, \tag{71}$$

$$A < \frac{1}{4}\mathbf{H}_N^T R^{-1}\mathbf{H}_N, \tag{72}$$

where (72) is to ensure that $Q > 0$. As in the previous section, if A is positive definite, then H_N must be invertible, and hence it is necessary that

$$\mathbf{H}_N A^{-1}\mathbf{H}_N^T > \Omega. \tag{73}$$

This inequality can be checked by computing the eigenvalues of $\mathbf{H}_N A^{-1}\mathbf{H}_N^T - \Omega$ (see [29]), and the matrix R can be chosen accordingly. We have just shown the following result.

THEOREM 5. *Given the estimation system* (38)–(46)*, where* $f(y)$ *satisfies* (48)*, along with the definitions* (57)*,* (58)*,* (65)*, if the matrix inequality* (73) *is satisfied, then there exists* $R > 0$ *such that the closed loop system* (45) *with* L *parameterized by* (58)*,* (67)*, with* $P = \frac{1}{2}I$*, is globally stable.*

Observer synthesis. We outline the synthesis of the observers resulting from Theorem 5:

1. Given the system nonlinearity $f(x)$, determine C_L according to (48).
2. Given the operators $\mathcal{A} := a^2 \frac{\partial^2 \cdot}{\partial \theta^2} - \beta \frac{\partial \cdot}{\partial \theta}$ and H, compute the matrices $A, \mathbf{H}_N$, and h_n according to (57), (58).
3. Compute Ω according to (65).
4. Choose $R \geq \Omega$. For example, take $R = \Omega + \epsilon I$.
5. According to (73), check if $\mathbf{H}_N A^{-1}\mathbf{H}_N^T - R > 0$. If so, then the observer gain $\mathbf{L}_N^T = \frac{1}{2}R^{-1}\mathbf{H}_N$ globally stabilizes the error system (45). If not, then the observer construction may not stabilize the observation spillover.

6. Combined control and observation. In this section, we combine the controller derived in section 4 and the observer derived in section 5. For a linear system, we can simply combine the controller with the observer with no additional analysis. Since the system we are dealing with is nonlinear, we need to check the stability of the closed loop system. The state and error dynamics are

$$\frac{\partial y}{\partial t} = a^2 \frac{\partial^2 y}{\partial \theta^2} - \beta \frac{\partial y}{\partial \theta} + f(y) - \overline{f(y)} + Bv(y) - Bv(\tilde{y}), \tag{74}$$

$$\frac{\partial \tilde{y}}{\partial t} = a^2 \frac{\partial^2 \tilde{y}}{\partial \theta^2} - \beta \frac{\partial \tilde{y}}{\partial \theta} + f(y) - \overline{f(y)} - (f(\hat{y}) - \overline{f(\hat{y})}) - LH\tilde{y}, \tag{75}$$

with periodic boundary conditions. We will use the combined Lyapunov function

$$V(y, \tilde{y}) = \frac{1}{2}\|y\|_2^2 + \frac{\gamma}{2}\|\tilde{y}\|_2^2 = \frac{1}{2}\sum_{n=1}^{\infty} y_n^2 + \frac{\gamma}{2}\sum_{n=1}^{\infty} \tilde{y}_n^2,$$

where γ is a positive constant, and we will take the time derivative

$$\dot{V} = \frac{1}{2}\sum_{n=1}^{\infty} y_n \dot{y}_n + \frac{1}{2}\sum_{n=1}^{\infty} \dot{y}_n y_n + \frac{\gamma}{2}\sum_{n=1}^{\infty} \dot{\tilde{y}}_n \tilde{y}_n + \frac{\gamma}{2}\sum_{n=1}^{\infty} \tilde{y}_n \dot{\tilde{y}}_n.$$

For ease of notation, we will assume that A_N and A are $N \times N$ matrices. In general these matrices can be of different dimensions because $C_L \geq C$. The forthcoming stability analysis can be easily modified for this case. Using the notation of the previous sections, we have

$$\dot{V} \leq \mathbf{Y}_N^T \frac{1}{2}\left([A_N - \mathcal{B}_N K] + [A_N - \mathcal{B}_N K]^T\right)\mathbf{Y}_N \tag{76}$$

$$+ \sum_{n>N} -(a^2 n^2 - C) y_n^2 - y_n b_n^T K \mathbf{Y}_N + \sum_{n>N} y_n b_n^T K \tilde{\mathbf{Y}}_N \tag{77}$$

$$+ \frac{1}{2}\mathbf{Y}_N^T \mathcal{B}_N K \tilde{\mathbf{Y}}_N + \frac{1}{2}\tilde{\mathbf{Y}}_N^T K^T \mathcal{B}_N^T \mathbf{Y}_N \tag{78}$$

$$+ \tilde{\mathbf{Y}}_N^T \frac{\gamma}{2}\left([A - \mathbf{H}_N^T \mathbf{L}_N^T] + [A - \mathbf{H}_N^T \mathbf{L}_N^T]^T\right)\tilde{\mathbf{Y}}_N + \frac{\gamma}{4}\tilde{\mathbf{Y}}_N^T \mathbf{L}_N \Omega \mathbf{L}_N^T \tilde{\mathbf{Y}}_N. \tag{79}$$

We see that the terms in (76) and (79) are exactly the terms from the previous sections. However, there are extra dynamics due to the fact that the controller v is now a function of the estimate $\hat{y}$. These effects are quantified by the last term in (77) and the terms in (78). Following the reasoning of (25)–(31), we see that

$$\sum_{n>N} -(a^2n^2 - C)y_n^2 - \sum_{n>N} y_n b_n^T K(\mathbf{Y}_N - \tilde{\mathbf{Y}}_N) \leq \frac{1}{4}(\mathbf{Y}_N - \tilde{\mathbf{Y}}_N)^T K^T \Xi K(\mathbf{Y}_N - \tilde{\mathbf{Y}}_N).$$

We will use the control and observer designs of the previous sections. With $P = \frac{1}{2}I$, we have from (23)

$$\frac{1}{2}\left[A_N - \mathcal{B}_N K\right]^T + \frac{1}{2}\left[A_N - \mathcal{B}_N K\right] = -Q_c - K^T R_c K < -K^T R_c K,$$

and from (69) we have

$$\frac{\gamma}{2}\left[A - \mathbf{H}_N^T \mathbf{L}_N^T\right]^T + \frac{\gamma}{2}\left[A - \mathbf{H}_N^T \mathbf{L}_N^T\right] = -\gamma Q_o - \gamma \mathbf{L}_N R_o \mathbf{L}_N^T < -\gamma \mathbf{L}_N R_o \mathbf{L}_N^T.$$

Now, (76)–(79) becomes

$$\dot{V} \leq -\begin{bmatrix} \mathbf{Y}_N^T & \tilde{\mathbf{Y}}_N^T \end{bmatrix} M \begin{bmatrix} \mathbf{Y}_N \\ \tilde{\mathbf{Y}}_N \end{bmatrix},$$

$$M := \begin{bmatrix} K^T R_c K - \frac{1}{4}K^T \Xi K & -\frac{1}{2}\mathcal{B}_N K + \frac{1}{4}K^T \Xi K \\ -\frac{1}{2}K^T \mathcal{B}_N^T + \frac{1}{4}K^T \Xi K & \gamma \mathbf{L}_N R_o \mathbf{L}_N^T - \frac{\gamma}{4}\mathbf{L}_N \Omega \mathbf{L}_N^T - \frac{1}{4}K^T \Xi K \end{bmatrix}.$$

Just as in the previous designs, we will choose R_c and R_o to make M positive semidefinite and then determine the further requirements to find positive definite matrices Q_c and Q_o. We state a useful theorem from [29].

THEOREM 6. *If M is a Hermitian matrix partitioned as*

$$M = \begin{bmatrix} A & B \\ B^* & C \end{bmatrix}$$

such that A and C are square and A is invertible, then M is positive semidefinite if and only if A is positive semidefinite and $C \geq B^* A^{-1} B$.

Note that the condition that A be invertible can be lifted by using the pseudoinverse of A (see [32]). However, for the purpose of this analysis, this restriction is minor. In order to satisfy the first part of the theorem, we must choose R_c such that

$$S_c := R_c - \frac{1}{4}\Xi \geq 0, \tag{80}$$

which is exactly the requirement (33). We similarly define

$$S_o := R_o - \frac{1}{4}\Omega \geq 0, \tag{81}$$

where we note that at this point R_o is unspecified. Also note that (81) is exactly the requirement (71). We note that $K = \frac{1}{2}R_c^{-1}\mathcal{B}_N^T$, so $\mathcal{B}_N = 2K^T R_c$ so that the cross terms of the matrix M can be written as

$$-\frac{1}{2}\mathcal{B}_N K + \frac{1}{4}K^T \Xi K = -K^T R_c K + \frac{1}{4}K^T \Xi K = -K^T S_c K.$$

Similarly, $\left(K^T S_c K\right)^{-1} = K^{-1} S_c^{-1} K^{-T}$. In order to satisfy the second part of the theorem, we must choose R_o such that

$$\begin{aligned}\gamma \mathbf{L}_N S_o \mathbf{L}_N^T &\geq K^T \left[\frac{1}{4}\Xi + S_c K \left(K^T S_c K\right)^{-1} K^T S_c\right] K \\ &= K^T \left[\frac{1}{4}\Xi + S_c\right] K \\ &= K^T R_c K = \frac{1}{4}\mathcal{B}_N R_c^{-1} \mathcal{B}_N^T, \qquad (82)\end{aligned}$$

where (82) is obtained by substituting (80). If (81) is satisfied, then we can always find a $\gamma > 0$ such that (82) is satisfied. We must now solve the AREs (22) and (68) with the choices for R_c and R_o, respectively. In solving (22), we have the same requirements (80) and

$$4\mathcal{B}_N^{-1} A_N \mathcal{B}_N^{-T} < R_c^{-1}.$$

This requirement is exactly (36), which shows that we can directly apply the control design of section 4 with no changes. In solving (68) with (81), we must have

$$A < \frac{1}{4}\mathbf{H}_N^T R_o^{-1} \mathbf{H}_N, \qquad (83)$$

and, since A is positive definite, (83) with (82) implies that we need

$$\mathbf{H}_N A^{-1} \mathbf{H}_N^T > \Omega + \frac{1}{\gamma}\mathbf{L}_N^{-1} \mathcal{B}_N R_c^{-1} \mathcal{B}_N^T \mathbf{L}_N^{-T}. \qquad (84)$$

We also see that if (73) is satisfied, then we can find a $\gamma > 0$ such that (84) is satisfied. Therefore, we have shown the following corollary to Theorems 4 and 5.

COROLLARY 7. *If the conditions of Theorems* 4 *and* 5 *are satisfied, then the resulting controller and observer can be combined with no alterations, and the closed loop system with dynamic compensator* (74), (75) *is globally stable.*

7. Duality of control and observation spillover. In this section, we briefly discuss the apparent duality between control and observation spillover. In the construction of finite-dimensional controllers and observers, there are two obstacles in each of the problems. The first obstacle is the nonlinearity, and the second obstacle is spillover. We point out here that in [42], finite-dimensional compensators were constructed for linear systems with no spillover. We have constructed a compensator with finite-dimensional inputs and outputs with infinite-dimensional internal dynamics (the infinite-dimensional estimator) that globally stabilizes systems with linearly bounded nonlinearities with the possibility of spillover destabilization.

In both designs, we consider a Lyapunov function that is the squared $\bar{L}_2(0, 2\pi)$-norm of the state or error. The given Lyapunov functions provide the uniform decay of the Fourier modes. This allows the use of the linear bounds on $f(y)$, so the controller and observer can be constructed to stabilize the respective systems governed by the linear equations. In both cases, the gains were determined by solving the control version of the ARE. These gains were determined to stabilize the low modes of the respective Lyapunov derivatives, with robustness to spillover.

The control design can be stated as follows. Given a linear operator $B : \mathbb{R}^N \to \bar{L}_2(0, 2\pi)$, determine the vector $\mathcal{V} \in \mathbb{R}^N$, where $\mathcal{V} = \mathcal{V}(\mathbf{Y}_N)$, to stabilize the solution

$y(\theta) = 0$. The observer design can be stated as follows: Given a vector $Hy \in \mathbb{R}^N$, determine the linear operator $L : \mathbb{R}^N \to \bar{L}_2(0, 2\pi)$, which depends on the projection of the low modes of $y(\theta)$ onto H, that stabilizes the error solution $\hat{y}(\theta) = 0$.

The control $\mathcal{V} \in \mathbb{R}^N$ and the linear operator $B : \mathbb{R}^N \to \bar{L}_2(0, 2\pi)$, while the output $z \in \mathbb{R}^N$ and the linear operator $H : \bar{L}_2(0, 2\pi) \to \mathbb{R}^N$. The control spillover is given by the high modal content of $B\mathcal{V}$ for a given control $\mathcal{V}$. In our construction, $\mathcal{V} = \mathcal{V}(\mathbf{Y}_N)$, and hence the spillover was quantified by the high modal content of the influence functions $b^i(\theta)$. The observation spillover is given by the projection of the high modes of $y(\theta)$ onto the output operator H. The observer was constructed to stabilize the low modes of the error $\tilde{y}(\theta)$, and hence the observation spillover is given by the vectors $H\phi_n$ for $n > N$. These definitions of control and observation spillover are in accordance with [3]. In both cases, an upper bound on the possible destabilizing effects of spillover was quantified by summing over the high modal content of the Lyapunov derivatives. The ARE was used to determine lower bounds on the positive definite matrix R to cancel the effects of the spillover. Upper bounds on R were determined to ensure the existence of a positive definite matrix Q such that $\dot{V} \leq \mathbf{Y}_N^T Q \mathbf{Y}_N$. These upper bounds relate the unstable nature of the plant matrices A_N and A to the low modal content of the operators $\mathcal{B}_N$ and $\mathbf{H}_N$, respectively. The control and observer designs were combined by using the combined Lyapunov function $V(y, \tilde{y}) = \frac{1}{2}\|y\|_2^2 + \frac{\gamma}{2}\|\tilde{y}\|_2^2$. This discussion is summarized in Table 1.

TABLE 1
Duality between control and observation spillover analysis.

	Control	Observation
Lyapunov function	$V(y) = \frac{1}{2}\|y\|_2^2$	$V(\tilde{y}) = \frac{1}{2}\|\tilde{y}\|_2^2$
Linear bound	$\langle y, f(y)\rangle \leq C\|y\|_2^2$	$\langle \tilde{y}, f(y) - f(\hat{y})\rangle \leq C_L\|\tilde{y}\|_2^2$
Given	$B : \mathbb{R}^N \to \bar{L}_2(0, 2\pi)$	$H : \bar{L}_2(0, 2\pi) \to \mathbb{R}^N$
Design	$\mathcal{V} : \bar{L}_2(0, 2\pi) \to \mathbb{R}^N$	$L : \mathbb{R}^N \to \bar{L}_2(0, 2\pi)$
Gain	$K = R^{-1}\mathcal{B}_N^T P$	$\mathbf{L}_N^T = R^{-1}\mathbf{H}_N P$
Spillover matrix	$\Xi := \sum_{n>N} \frac{1}{c_n} b_n b_n^T$	$\Omega := \sum_{n>N} \frac{1}{c_n} h_n h_n^T$
R Lower bound	$R \geq \frac{1}{4}\Xi$	$R \geq \frac{1}{4}\Omega$
R Upper bound	$A_N < \frac{1}{4}\mathcal{B}_N R^{-1}\mathcal{B}_N^T$	$A < \frac{1}{4}\mathbf{H}_N^T R^{-1}\mathbf{H}_N$
Combined Lyapunov function	$V(y, \tilde{y}) = \frac{1}{2}\|y\|_2^2 + \frac{\gamma}{2}\|\tilde{y}\|_2^2$	

8. Application: Control of axial compressor stall with air injection actuation. In this section, we apply the control and observer designs with their respective spillover analyses to the problem of controlling a model describing rotating stall in axial compressors. We use a model of axial compressors with air injectors derived in [25, 23]. The model bears close resemblance to the familiar Moore–Greitzer model [35] with air injection actuation [8, 15]. A description of the physical setup of compression system control with air injection actuation and flow sensors is given in [27]. Continuous air injection was employed by Day [16] in one of the earliest studies of compressor stall control, where a finite number of air injectors were used. Further experimental investigations of stall control appear in [7, 15, 22]. These works cite a number of physical limitations involved with the implementation of stall control systems. In particular, limitations due to finite-dimensional implementation are

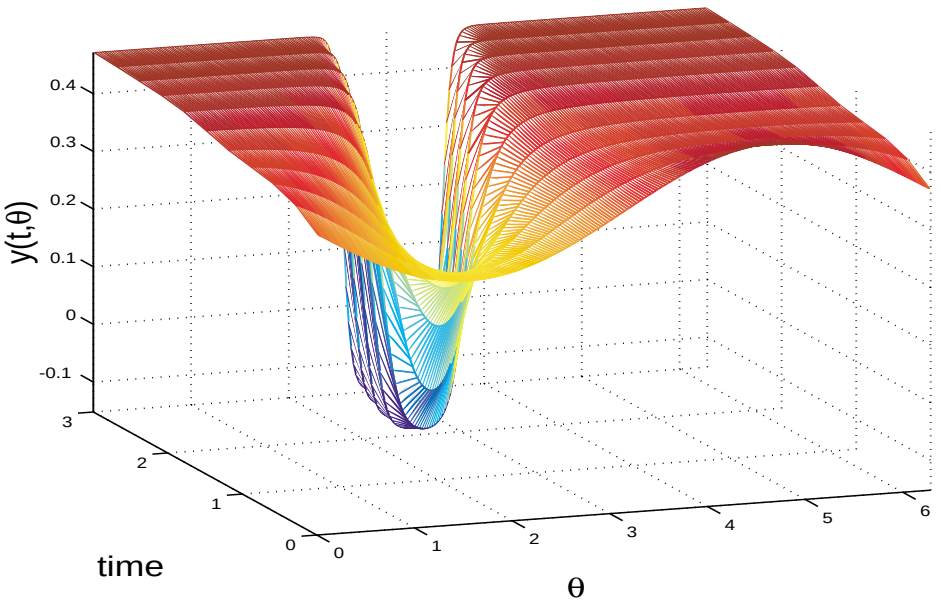

FIG. 1. *An initial sinusoidal disturbance develops into a stable piecewise constant solution, representing stalled flow.*

described in [37]. Other limiting factors such as actuator rate limits and noise are discussed in [18, 47, 46], and for further discussion of some of these issues, the reader is referred to [25]. In this work, we address only the issue of finite-dimensional implementation as it relates to the present theoretical results.

In this model, $y(t,\theta)$ denotes the axial flow through the compressor, and the constants appearing in (1) are

$$a^2 = 10^{-2}, \quad \beta = 0.5, \quad \alpha = 1.$$

The polynomial $f(y)$ is referred to as the compressor characteristic function (see [35]) and is given by

$$f(y) = 0.86 - 0.3y - 15.64y^2 - 27.43y^3, \tag{85}$$

where the numerical values are the same as those used in [5]. This system exhibits stable steady state (in a rotating reference frame) piecewise constant solutions which signify the stalling phenomena (see [25]). The evolution of an initial sinusoidal disturbance to stalled flow is shown in Figure 1. The goal is to control the axial flow such that the uniform flow $y(t,\theta) = M$ is stable. We take note of two things. First, since $\alpha = 1$, the first mode of the system remains constant, and hence the control design is directly applicable to this problem. Second, the polynomial given by (85) does not exhibit the property of $f(0) = 0$. However, if we look at our original system (1), we see that its average over θ is subtracted. Therefore, for practical purposes, we can add or subtract any constant to the polynomial, and the dynamics of the system would not change.

The linear bound (48) will be more restrictive than (8). In this model, the compressor characteristic satisfies the inequality (48) with $C_L = 2.7$. Taking $N = 16$

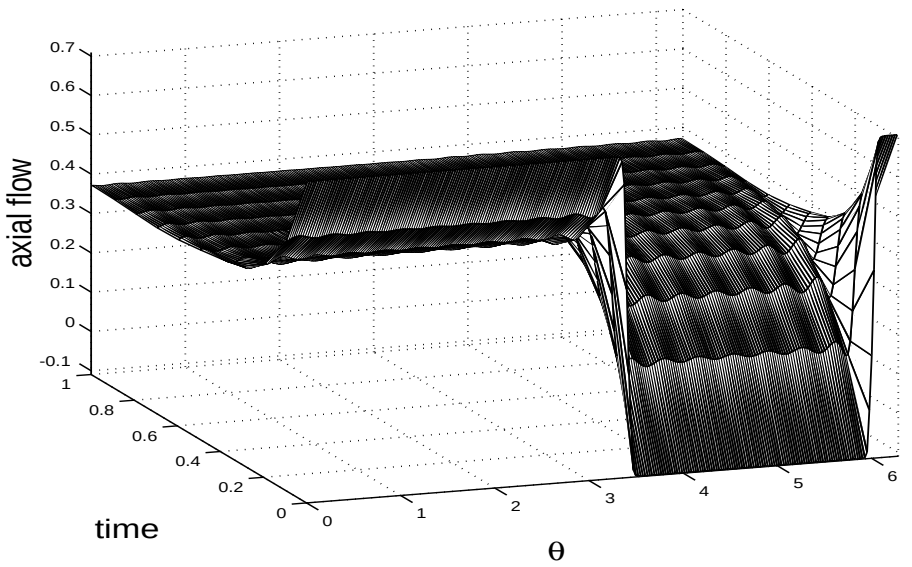

FIG. 2. *Stall cell decay for truncated LQR design. The initial condition is set to a piecewise constant function (stalled flow). The finite-dimensional controller constructed from the eigenmodes of the diffusion operator stabilizes the flow to a uniform value.*

satisfies $-a^2N^2 + C_L > 0 > -a^2(N+1)^2 + C_L$. We will first present some results of the controlled system with full state information to illustrate the role of the influence functions $b^i(\theta)$. Then we will present simulation results of the observer system in the absence of control. Finally, we will present results of the combined controller with the observer.

We present two cases with different input functions $b^i(\theta)$. For the first case, we simply take the first N eigenmodes of the diffusion operator as the input functions. In this trivial case, the high frequency content of the input functions is zero, i.e., $\Xi = 0$, and thus it is impossible for the control to destabilize the higher modes of the system. As stated before, we are not restricted to choosing P and R as in section 4. In [25], an infinite-dimensional LQR controller was constructed to stabilize the linear part of this system. It was shown that the sufficient conditions for this LQR control design to globally stabilize the system are equivalent to optimally stabilizing the linear system governed by the sector condition of the nonlinear function. This is exactly how we constructed the feedback controller in section 4, so we can simply truncate the LQR design derived in [25] after the 16th mode and be guaranteed global stability. The response of the system with this truncated controller is shown in Figure 2. The initial condition is set at a piecewise constant solution (stalled flow). We see that controller stabilizes the flow, eliminating the stall cell.

For the second case, we consider input shape functions with high frequency content. We consider an array of 16 injectors that are evenly spaced about the circumference of the compressor. Corresponding with this physical setup, the shape functions will be given by

$$b^i(\theta) = \begin{cases} 1, & \theta_i - \frac{\Delta}{2} < \theta < \theta_i + \frac{\Delta}{2}, \\ 0 & \text{otherwise}, \end{cases} \tag{86}$$

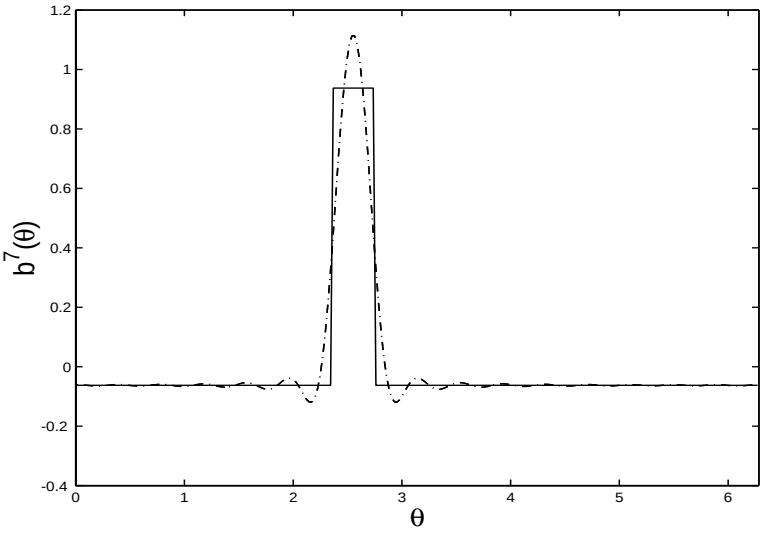

FIG. 3. *Shape function for* $b^7(\theta)$ *(shown as solid) and its reconstruction from its first* 16 *Fourier modes (shown as dotted).*

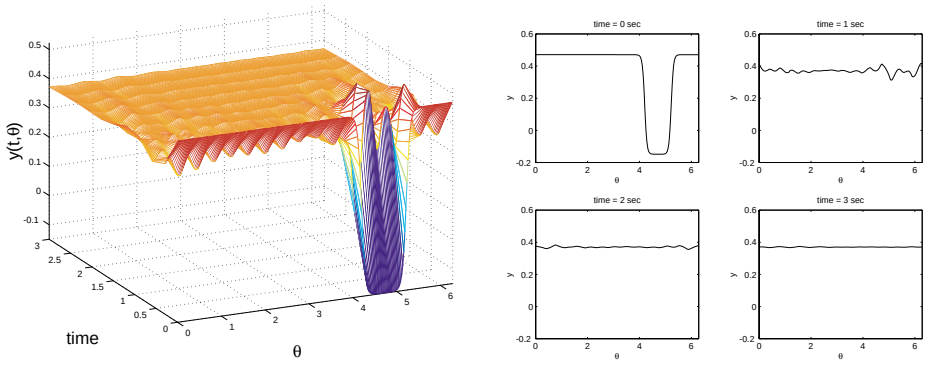

FIG. 4. *Left: Stall cell decay with controller constructed from* 16 *injectors spanning the circumference of the compressor. The initial condition is set to a piecewise constant function representing stalled flow. The control design eliminates control spillover from the high frequency content of the input shape functions, stabilizing the flow to a uniform value. Right: Stall cell decay of the left figure at different times.*

where the width of each injector is given by $\Delta \approx \frac{1}{18.25} 2\pi$. We point out here that the input shape functions given in (86) are not zero-average functions. In this case, it would be necessary to have a separate control to cancel out the zeroth mode of these shape functions. This is a common practice in the theoretical control of PDEs [1, 13], and for control of compression systems, this can be implemented by a throttle control [5]. Figure 3 shows a zero-average version of the input function for $i = 7$ along with its reconstruction from the first 16 Fourier modes. We can see that these shape functions have high frequency content. We apply the synthesis algorithm of section 4 for the linear control design. Figure 4 shows the closed loop system response with the linear controller. The initial condition is set at the open loop steady state piecewise constant solution (stalled flow). We see that the controller stabilizes the

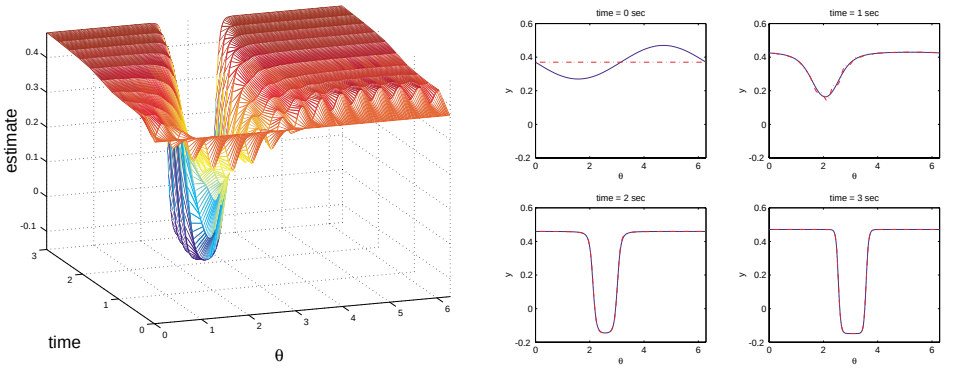

FIG. 5. *Left: Estimate evolution for the uncontrolled system. The estimate quickly matches the actual state shown in Figure* 1 *which is evolving into stall. Right: State (solid, from Figure* 1*) and estimate (dashed, from left figure) shown at different times. The estimate is very close to the state at time* = 3 *and* 4.

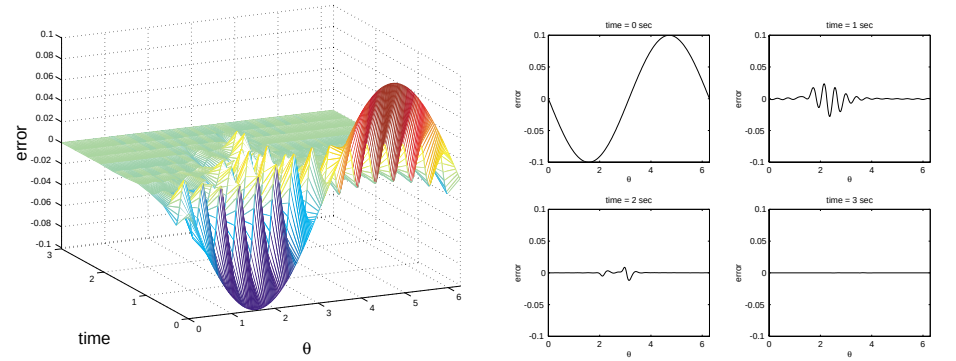

FIG. 6. *Left: Error evolution for the uncontrolled observer system. Right: Error evolution from the left figure shown at different times. The error decays to zero as the estimate matches the state.*

flow, eliminating the stall cell.

We now discuss the results of the observer without control. We consider the physical setup of an array of 16 flow sensors that span the circumference. Corresponding to the physical setup, each element of the output z will be the spatial average of $y(t,\theta)$ over a finite width Δ, and the output kernels $h^i(\theta)$ are given by

$$h^i(\theta) = \begin{cases} \frac{1}{\Delta}, & \theta_i - \frac{\Delta}{2} < \theta < \theta_i + \frac{\Delta}{2}, \\ 0 & \text{otherwise.} \end{cases}$$

Just as in the control design, we used the ARE (68) with $R > 0$ satisfying (71) and (72). The results of the numerical simulations are shown in Figure 1 (showing the uncontrolled state evolution) and Figures 5 and 6 (showing the estimation and error evolutions, respectively). The evolution of the estimate is shown in Figure 5 with the initial condition $\hat{y}(0,\theta) = 0$. We see that the estimate quickly matches the original state shown in Figure 1. This is also shown in Figure 6, which shows the evolution of the error $\tilde{y}(t,\theta)$. We see that the error quickly goes to zero uniformly in θ.

We now present simulation results for the system with finite-dimensional controls and observation. The B and H operators are the same as those given before. By the

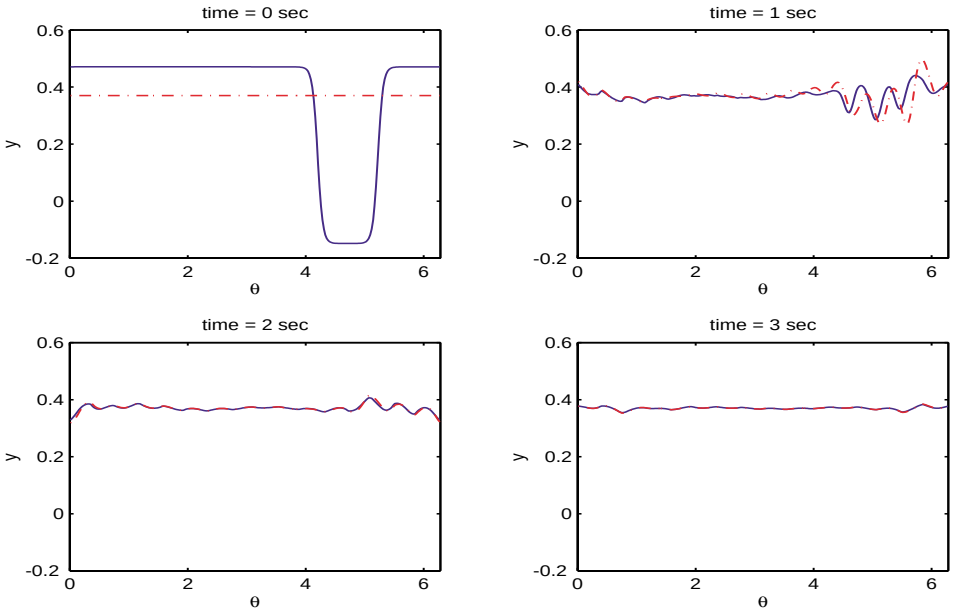

FIG. 7. *State and estimate evolution at different times. The state is shown as a solid line, and the estimate is shown as a dashed line. The estimate is very close to the state at time = 2 and 3 seconds.*

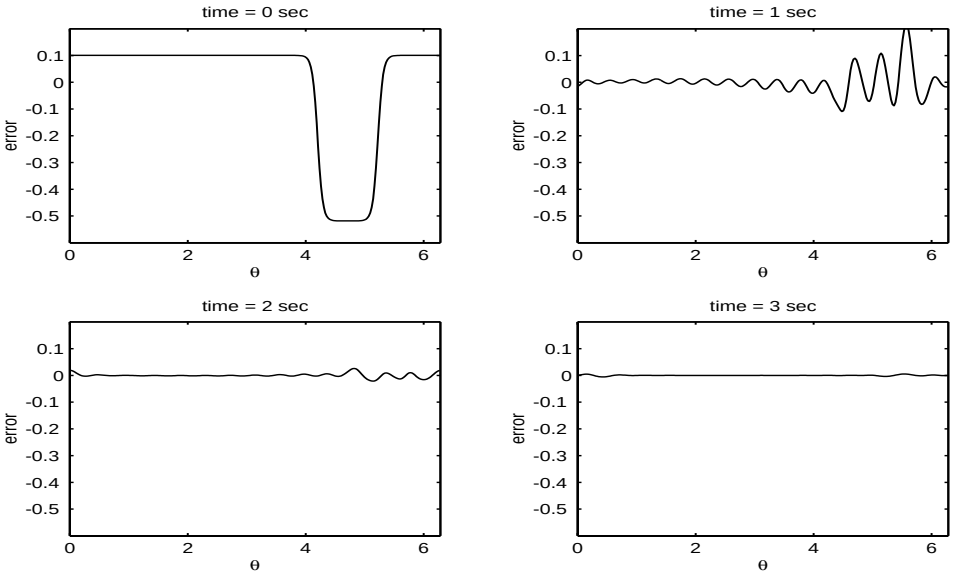

FIG. 8. *Error between state and estimate at different times.*

analysis given in section 6, we can directly combine the two designs. Figures 7 and 8 show $y(t,\theta)$, $\hat{y}(t,\theta)$, and $\tilde{y}(t,\theta)$ at different times. We see that stability of the state and error are maintained when the two designs are combined. The estimate $\hat{y}(t,\theta)$ converges to the state $y(t,\theta)$, and the controller stabilizes $y(t,\theta) = 0$.

9. Conclusion. We have considered the problem of controlling semilinear dissipative evolution equations with additive control input of finite dimension and the dual problem of observation with finite-dimensional output. The control input enters the equation through a finite number of shape functions and their respective amplitude values, while the output is given by a finite-dimensional vector. For the control design, we used a CLF based on the infinite-dimensional dynamics. The derivative of the CLF was decomposed into Fourier modes and was diagonalized by application of the linear bound of the nonlinearity. Since the system is coupled through the terms representing the control input, there is a possibility of destabilizing control spillover. The modal CLF derivative was split into low and high modes. An LQR control design technique was employed to stabilize the low modal content of the CLF derivative. An upper bound on the destabilizing terms representing control spillover was obtained. Sufficient conditions on the system and LQR design parameters were stated to ensure global stability and robustness with respect to control spillover. Unlike reduced order model control formulations, which employ Galerkin truncation, the control design of this paper is based on the global stabilization of the infinite-dimensional dynamics of the full system. A similar design and analysis were conducted for the finite-dimensional observation problem. It was shown that the closed loop system with the controller and observer was globally stable and furthermore that the control and observer designs could be combined with no changes in the separate designs. Duality properties between the control and observer designs and respective spillover analyses were discussed. The finite-dimensional controller and observer were demonstrated on a model describing rotating stall in axial compressors. The control methodology outlined in this paper is extended to decentralized and nonlinear controllers in [24].

SOLVING SEMI-INFINITE OPTIMIZATION PROBLEMS WITH INTERIOR POINT TECHNIQUES*

OLIVER STEIN† AND GEORG STILL‡

Abstract. We introduce a new numerical solution method for semi-infinite optimization problems with convex lower level problems. The method is based on a reformulation of the semi-infinite problem as a Stackelberg game and the use of regularized nonlinear complementarity problem functions. This approach leads to central path conditions for the lower level problems, where for a given path parameter a smooth nonlinear finite optimization problem has to be solved. The solution of the semi-infinite optimization problem then amounts to driving the path parameter to zero.

We show convergence properties of the method and give a number of numerical examples from design centering and from robust optimization, where actually so-called generalized semi-infinite optimization problems are solved. The presented method is easy to implement, and in our examples it works well for dimensions of the semi-infinite index set at least up to 150.

Key words. generalized semi-infinite optimization, convexity, Stackelberg game, nonlinear complementarity problem function, smoothing, optimality condition

1. Introduction.

In this article we introduce a bi-level solution method for so-called *generalized semi-infinite optimization problems*. These problems have the form

$$GSIP: \qquad \text{minimize} \quad f(x) \quad \text{subject to} \quad x \in M$$

with

$$M \;=\; \{x \in \mathbb{R}^n |\; g_j(x,y) \le 0,\; y \in Y(x),\; j \in J\}$$

and

$$Y(x) \;=\; \{y \in \mathbb{R}^m |\; v_\ell(x,y) \le 0,\; \ell \in L\}\,.$$

All defining functions $f, g_j\,,\; j \in J = \{1,\dots,p\},\; v_\ell\,,\; \ell \in L = \{1,\dots,s\}\,$, are assumed to be real-valued and d times continuously differentiable on their respective domains with $d \ge 2$.

As opposed to a standard semi-infinite optimization problem *SIP*, the possibly infinite index set $Y(x)$ of inequality constraints is x-dependent in a *GSIP*. For surveys about *standard* semi-infinite optimization we refer to [10, 18, 37].

Engineering applications that give rise to generalized semi-infinite optimization problems include robot design [12, 19], reverse Chebyshev approximation [29], time-optimal control [31], and design centering [35, 36]. In finite optimization with uncertainty about parameters y from a fixed set Y, the robust (i.e., worst-case) formulation of inequality constraints gives rise to a standard semi-infinite problem [1]. If the set

of uncertain parameters is state-dependent, then the worst-case formulation takes the form of *GSIP*. Furthermore, min-max problems can be reformulated as either standard or generalized semi-infinite programs, depending on whether the feasible set of the maximization (inner) problem depends on the minimization (outer) variable.

The growing interest in *GSIP* over recent years has resulted in various contributions on the structure of the feasible set M [25, 41, 48, 49, 50, 57] and on first and second order optimality conditions [19, 25, 29, 40, 51, 53, 57]. The articles [55] and [57] investigate how the known methods from *SIP* have to be modified in order to cover the more general situation of *GSIP*. The Newton-SQP approach, which works well in standard semi-infinite programming (see, e.g., [13]), can be transferred to *GSIP* if the so-called reduction ansatz holds. In [16] such a Newton-type method is applied to the terminal variational problems from [29]. Since the reduction ansatz is of local nature, also generalizations of the discretization and exchange methods from *SIP* are desired. In [55] it is shown that discretization methods converge if the x-dependent grid points are chosen such that they depend continuously on x. Moreover, [56] studies how for a discretization method the rate of convergence depends on a consistent treatment of the boundary points of $Y(x)$.

As these generalized discretization methods are not easy to implement, in the present article we concentrate on the case of convex lower level problems. Based upon the observation that, under natural assumptions, *GSIP* can be reformulated as a special Stackelberg game (cf. also [54]), we design a numerical solution method, which exploits the lower level convexity. As opposed to the exchange and discretization methods presented in [55], this approach is not a generalization of known methods from standard semi-infinite programming, but it provides a new and different way of numerical treatment. Moreover, as standard semi-infinite programming is a special case of *GSIP*, as a by-product we obtain a new solution method for standard semi-infinite optimization problems, too. Our point of view also was implicitly taken in [33], where a branch and bound method is developed for generalized semi-infinite optimization problems with linear-quadratic lower level problems and additional convexity in the upper level. An approach using exact penalization to transform *GSIP* to *SIP* is given in [32].

We remark that the inclusion of equality constraints in the definitions of M and $Y(x)$, as well as a j-dependence of the index set $Y(x)$, is straightforward and will not be considered here for ease of presentation.

The article is organized as follows. In section 2 we recall the so-called reduction ansatz and the resulting first order optimality condition for *GSIP*. Furthermore, we give analogous results under a convexity assumption and recall the concept of nonlinear complementarity problem (NCP) functions. Section 3 presents the numerical method, and in section 4 we study its convergence properties. A number of numerical results conclude the article in section 5.

2. Preliminaries.

2.1. The reduction ansatz. In this section we briefly recall the reduction ansatz and explain the concept of Fritz John points for *GSIP*. Since optimality conditions are well known for points from the topological interior of M, in the following we focus our attention on a given feasible boundary point of M, i.e., a point $\bar{x} \in M \cap \partial M$, where ∂M denotes the topological boundary of M.

Recall that the set-valued mapping Y is called locally bounded around $\bar{x}$ if there exists a neighborhood U of $\bar{x}$ such that the set $\cup_{x \in U} Y(x)$ is bounded.

Assumption 1 (local boundedness). The set-valued mapping Y is locally bounded around $\bar{x}$.

Let Assumption 1 hold throughout this article, and fix U to be some corresponding bounded open neighborhood of $\bar{x}$.

The n-parametric so-called lower level problems of *GSIP* are given by

$$Q^j(x): \qquad \text{maximize} \quad g_j(x,y) \quad \text{subject to} \quad y \in Y(x)$$

with $j \in J$. Associated with $Q^j(x)$ are its optimal value function

$$\varphi_j(x) \;=\; \begin{cases} \max\limits_{y \in Y(x)} g_j(x,y) & \text{if} \quad Y(x) \neq \emptyset, \\ -\infty & \text{else} \end{cases}$$

and, in case of solvability, its solution set

$$Y_\star^j(x) \;=\; \{y \in Y(x) |\; g_j(x,y) = \varphi_j(x)\}.$$

It is easily seen that M and the set $\{x \in \mathbb{R}^n |\; \varphi_j(x) \leq 0\,,\; j \in J\}$ coincide.

Since the defining functions of $Y(x)$ are continuous, the set-valued mapping Y is closed. Together with Assumption 1 this means that Y is upper semicontinuous in the sense of Berge [2] around $\bar{x}$. As a consequence (cf., e.g., [21]), the $\varphi_j\,,\; j \in J$, are upper semicontinuous on U. From this it is not hard to derive that the sets $M \cap U$ and $\{x \in U |\; \varphi_j(x) \leq 0\,,\; j \in J_0(\bar{x})\}$ coincide (possibly after shrinking U), where $J_0(\bar{x}) = \{j \in J |\; \varphi_j(\bar{x}) = 0\}$ denotes the set of active indices at $\bar{x}$. Since for $j \in J_0(\bar{x})$ the problem $Q^j(\bar{x})$ has vanishing optimal value, the set of its solution points can be described as

$$Y_\star^j(\bar{x}) \;=\; Y_0^j(\bar{x}) \;=\; \{y \in Y(\bar{x}) |\; g_j(\bar{x},y) = 0\},$$

and we have $j \in J_0(\bar{x})$ if and only if $Y_0^j(\bar{x}) \neq \emptyset$.

Next, we give a local description of M by finitely many *smooth* constraints for the case when certain regularity assumptions hold in the lower level problems.

The *linear independence constraint qualification (LICQ)* is said to hold at a point $\bar{y} \in Y(\bar{x})$ if the family of vectors $D_y v_\ell(\bar{x},\bar{y})\,,\; \ell \in L_0(\bar{x},\bar{y})$, is linearly independent, and the weaker *Mangasarian–Fromovitz constraint qualification (MFCQ)* holds if there exists some vector $\eta \in \mathbb{R}^m$ such that $D_y v_\ell(\bar{x},\bar{y})\,\eta < 0\,,\; \ell \in L_0(\bar{x},\bar{y})$. Here $L_0(\bar{x},\bar{y}) = \{\ell \in L |\; v_\ell(\bar{x},\bar{y}) = 0\}$ denotes the set of lower level active indices, and $D_y v_\ell$ stands for the row vector of partial derivatives of v_ℓ with respect to y.

In what follows, let v be the column vector of the functions $v_\ell\,,\; \ell \in L = \{1,\ldots,s\}$, let $\operatorname{diag}(\gamma)$ stand for the (s,s)-diagonal matrix with diagonal vector $\gamma \in \mathbb{R}^s$, and let $j \in J_0(\bar{x})$. Since each $\bar{y} \in Y_0^j(\bar{x})$ is a solution of $Q^j(\bar{x})$, upon definition of the lower level Lagrange function

$$\mathcal{L}_j(x,y,\gamma) \;=\; g_j(x,y) - \gamma^\top v(x,y)$$

the Karush–Kuhn–Tucker theorem states that the following system of equalities and inequalities has a solution γ if the MFCQ holds at such a $\bar{y}$:

$$D_y^\top \mathcal{L}_j(\bar{x},\bar{y},\gamma) = 0, \tag{2.1}$$

$$-\operatorname{diag}(\gamma)\, v(\bar{x},\bar{y}) = 0, \tag{2.2}$$

$$\gamma \geq 0, \tag{2.3}$$

$$-v(\bar{x},\bar{y}) \geq 0. \tag{2.4}$$

Note that γ is uniquely determined under the LICQ. We denote the set of Kuhn–Tucker multipliers corresponding to $\bar{x}$ and $\bar{y} \in Y_0^j(\bar{x})$ by

$$KT^j(\bar{x}, \bar{y}) \;=\; \{\gamma \in \mathbb{R}^s |\ \gamma \text{ satisfies (2.1)–(2.4)}\}.$$

The point $\bar{y}$ is said to satisfy the *strict complementary slackness (SCS)* condition if $\gamma_\ell > 0\,,\ \ell \in L_0(\bar{x}, \bar{y})$.

Under the LICQ the tangent space to $Y(\bar{x})$ at $\bar{y}$ can be described as $T_{\bar{y}}Y(\bar{x}) = \{\eta \in \mathbb{R}^m |\ D_y v_\ell(\bar{x}, \bar{y})\,\eta = 0\,,\ \ell \in L_0(\bar{x}, \bar{y})\}$. Let $\bar{y} \in Y_0^j(\bar{x})$ and let $\bar{\gamma}$ be the corresponding solution of (2.1)–(2.4). The point $\bar{y}$ is said to satisfy the *second order sufficiency condition (SOSC)* if the matrix $D_y^2 \mathcal{L}_j(\bar{x}, \bar{y}, \bar{\gamma})|_{T_{\bar{y}}Y(\bar{x})}$ possesses only negative eigenvalues. Here, $D_y^2 \mathcal{L}_j = D_y D_y^\top \mathcal{L}_j$ denotes the Hessian matrix of $\mathcal{L}_j$ with respect to y, and $D_y^2 \mathcal{L}_j(\bar{x}, \bar{y}, \bar{\gamma})|_{T_{\bar{y}}Y(\bar{x})} = V^\top D_y^2 \mathcal{L}_j(\bar{x}, \bar{y}, \bar{\gamma}) V$ for any matrix V of m-vectors which form a basis of the tangent space $T_{\bar{y}}Y(\bar{x})$.

Definition 2.1. *Let $\bar{x} \in \partial M \cap M$ and $j \in J_0(\bar{x})$. A point $\bar{y} \in Y_0^j(\bar{x})$ is called the* nondegenerate global maximizer *of $Q^j(\bar{x})$ if the LICQ holds at $\bar{y}$ and if SCS and the SOSC are valid with the vector γ from* (2.1)–(2.4).

Assumption 2 (reduction ansatz). For each $j \in J_0(\bar{x})$ all global maximizers of $Q^j(\bar{x})$ are nondegenerate.

The reduction ansatz was originally formulated for standard semi-infinite optimization problems in [58, 17] under weaker regularity assumptions and was transferred to generalized semi-infinite optimization problems in [19]. For standard semi-infinite optimization problems the reduction ansatz is a natural assumption in the sense that for problems with defining functions in general position *it holds at each local minimizer* (cf. [59, 47]). For *GSIP* this result could be transferred to local minimizers $\bar{x}$ with $\sum_{j \in J_0(\bar{x})} |Y_0^j(\bar{x})| \geq n$ in [49]. Moreover, in [54] it is shown that it holds in the "completely linear" case, i.e., when all defining functions f, $g_j\,,\ j \in J$, $v_\ell\,,\ \ell \in L$, of *GSIP* are affine linear on their respective domains.

As under Assumption 2 the global maximizers of $Q^j(\bar{x})$ are isolated points in $Y(\bar{x})$, and the latter set is compact, there are only finitely many global maximizers, say

$$Y_0^j(\bar{x}) \;=\; \{\bar{y}^{j,k},\ k \in J_0^j(\bar{x})\}$$

with $|J_0^j(\bar{x})| < \infty$. An application of the implicit function theorem (cf. [7]) shows that for each $\bar{y}^{j,k}$ with $k \in J_0^j(\bar{x})$ and corresponding multiplier vector $\bar{\gamma}^{j,k}$ there are locally defined C^{d-1}-functions $y^{j,k}$ and $\gamma^{j,k}$ with $y^{j,k}(\bar{x}) = \bar{y}^{j,k}$ and $\gamma^{j,k}(\bar{x}) = \bar{\gamma}^{j,k}$ such that $y^{j,k}(x)$ is the locally unique local maximizer of $Q^j(x)$ with multiplier $\gamma^{j,k}(x)$. Hence, we may introduce the locally defined optimal value functions

$$\varphi_{j,k}(x) \;=\; g_j(x, y^{j,k}(x))\,, \quad k \in J_0^j(\bar{x})\,,\ j \in J_0(\bar{x}).$$

Lemma 2.2 (cf., e.g., [24]). *The functions $\varphi_{j,k}$ are of differentiability class C^d, and their gradients satisfy*

$$D\varphi_{j,k}(\bar{x}) = D_x \mathcal{L}_j(\bar{x}, \bar{y}^{j,k}, \bar{\gamma}^{j,k})\,.$$

The next result follows from a more general reduction lemma that we shall prove in section 4 (cf. Lemma 4.2).

Theorem 2.3 (reduction lemma; cf. [19, 47]). *Let Assumption* 2 *be satisfied at $\bar{x}$. Then the sets M and*

$$M_{\bar{x}} \;=\; \{x \in U |\ \varphi_{j,k}(x) \leq 0,\ k \in J_0^j(\bar{x})\,,\ j \in J_0(\bar{x})\}$$

coincide locally around $\bar{x}$.

Theorem 2.3 shows that under the reduction ansatz the original problem *GSIP* is locally equivalent to the reduced problem $\min f|_{M_{\bar{x}}}$. Hence, local optimality conditions from finite optimization may be applied to yield results for the semi-infinite case. In particular, we obtain a Fritz John–type first order necessary optimality condition (cf. [23]).

THEOREM 2.4. *Let* $\bar{x}$ *be a local minimizer of GSIP, and let Assumption* 2 *hold. Then there exist multipliers* $\kappa \geq 0,\ \lambda_{j,k} \geq 0,\ k \in J_0^j(\bar{x})\,,\ j \in J_0(\bar{x})$*, not all vanishing, such that*

$$\kappa\, Df(\bar{x}) \ + \sum_{j \in J_0(\bar{x})} \sum_{k \in J_0^j(\bar{x})} \lambda_{j,k}\, D_x \mathcal{L}_j(\bar{x}, \bar{y}^{j,k}, \bar{\gamma}^{j,k}) \ = \ 0. \tag{2.5}$$

Note that in Theorem 2.4 we do not need to impose a complementarity condition since all appearing constraints are active by definition. Moreover, recall that due to Carathéodory's theorem at most $n+1$ nonvanishing multipliers $\lambda_{j,k}$ are required in (2.5). In what follows we will call each point $\bar{x}$ that satisfies the reduction ansatz and the necessary optimality condition from Theorem 2.4 a *Fritz John point* for *GSIP*.

2.2. Convex lower level problems. We call a problem $Q^j(x),\ j \in J$, convex if the functions $-g_j(x,\cdot)\,,\ v_\ell(x,\cdot),\ \ell \in L$, are convex on $\mathbb{R}^m$. The main assumption of the present article is the following.

Assumption 3. The lower level problems $Q^j(x),\ j \in J$, are convex for all $x \in \mathbb{R}^n$.

Under Assumption 3 a set $Y(x)$ with $x \in \mathbb{R}^n$ is said to satisfy the Slater condition if there exists $y^\star$ such that $v_\ell(x, y^\star) < 0$ for all $\ell \in L$.

Assumption 4. The sets $Y(x)$ are bounded and satisfy the Slater condition for all $x \in \mathbb{R}^n$.

Under Assumptions 3 and 4 the sets $Y_\star^j(x)$ are nonempty and locally bounded around each $\bar{x} \in \mathbb{R}^n$ (cf. [22, Lemma 2]), so that the optimal value functions $\varphi_j(x) = \max_{y \in Y(x)} g_j(x,y)\,,\ j \in J,$ are well defined and continuous on $\mathbb{R}^n$ [22]. Hence, the feasible set M is closed, and as in section 2.1 we have that M and the set $\{x \in \mathbb{R}^n |\ \varphi_j(x) \leq 0\,,\ j \in J_0(\bar{x})\}$ coincide around each boundary point $\bar{x}$.

For the next theorem, which is a slight generalization of [42, Theorem 4.2], recall that the sets $KT^j(\bar{x}),\ j \in J_0(\bar{x})$, do not depend on the variable y in the convex case (cf., e.g., [11]). Without loss of generality we set $J_0(\bar{x}) = \{1, \ldots, p_0\}$.

THEOREM 2.5. *Let* $\bar{x}$ *be a local minimizer of GSIP and let Assumptions* 3 *and* 4 *be satisfied. Then for each selection* $(\bar{\gamma}^1, \ldots, \bar{\gamma}^{p_0}) \in KT^1(\bar{x}) \times \cdots \times KT^{p_0}(\bar{x})$ *there exist* $y^{j,k} \in Y_0^j(\bar{x}),\ k = 1, \ldots, p_j\,,\ j \in J_0(\bar{x}),\ \sum_{j \in J_0(\bar{x})} p_j \leq n+1$*, and multipliers* $\kappa \geq 0\,,\ \lambda_{j,k} \geq 0\,,$ *not all equal to zero, such that*

$$\kappa\, Df(\bar{x}) \ + \sum_{j \in J_0(\bar{x})} \sum_{k=1}^{p_j} \lambda_{j,k}\, D_x \mathcal{L}^j(\bar{x}, y^{j,k}, \bar{\gamma}^j) \ = \ 0\,.$$

If, in addition to Assumptions 3 and 4, the reduction ansatz (Assumption 2) also holds, then the sets $KT^j(\bar{x}) = \{\bar{\gamma}^j\}$ and $Y_0^j(\bar{x}) = \{\bar{y}^j\}$, $j \in J_0(\bar{x})$, are singletons. In this case, Theorems 2.4 and 2.5 obviously simplify to the following result.

COROLLARY 2.6. *Let* $\bar{x}$ *be a local minimizer of GSIP and let Assumptions* 2, 3, *and* 4 *be satisfied. Then there exist multipliers* $\kappa \geq 0\,,\ \lambda_j \geq 0\,,\ j \in J_0(\bar{x})$*, not all equal to zero, such that*

$$\kappa\, Df(\bar{x}) \ + \sum_{j \in J_0(\bar{x})} \lambda_j\, D_x \mathcal{L}^j(\bar{x}, \bar{y}^j, \bar{\gamma}^j) \ = \ 0\,.$$

The following lemma is well known. A short proof can be found in [52].

LEMMA 2.7. *Let Assumptions* 3 *and* 4 *be satisfied. Then a point* $\bar{y}^j$ *is a nondegenerate global maximizer of* $Q^j(\bar{x})$ *with corresponding multiplier vector* $\bar{\gamma}^j$ *if and only if* (2.1)–(2.4) *hold and if the Jacobian of* (2.1), (2.2) *with respect to* (y^j, γ^j),

$$A^j \;=\; A^j(\bar{x}, \bar{y}^j, \bar{\gamma}^j) \;=\; \begin{pmatrix} D_y^2 \mathcal{L}_j(\bar{x}, \bar{y}^j, \bar{\gamma}^j) & -D_y^\top v(\bar{x}, \bar{y}^j) \\ -\operatorname{diag}(\bar{\gamma}^j) D_y v(\bar{x}, \bar{y}^j) & -\operatorname{diag}(v(\bar{x}, \bar{y}^j)) \end{pmatrix},$$

is nonsingular.

2.3. NCP functions. A function $\psi : \mathbb{R}^2 \to \mathbb{R}$ with

$$\psi(a,b) \;=\; 0 \quad \text{if and only if} \quad a \geq 0\,,\; b \geq 0\,,\; ab \;=\; 0$$

is called an *NCP function*. Let us remark that the existence of a C^∞-NCP function is clear from a theorem by Whitney [3]. However, as smooth NCP functions are degenerate at the origin, in the following we will work with the nonsmooth NCP functions

$$\psi^{NR}(a,b) \;=\; \frac{1}{2}\left(a + b - \sqrt{(a-b)^2}\right)$$

and

$$\psi^{FB}(a,b) \;=\; a + b - \sqrt{a^2 + b^2}\;.$$

The function ψ^{NR} is the so-called natural residual or min-function since it coincides with $\min(a,b)$, and ψ^{FB} is known as the Fischer–Burmeister function [8].

For numerical purposes one can regularize these nondifferentiable NCP functions. The so-called Chen–Harker–Kanzow–Smale function [4, 27, 46] is given by

$$\psi_\tau^{NR}(a,b) \;=\; \frac{1}{2}\left(a + b - \sqrt{(a-b)^2 + 4\tau^2}\right),$$

whereas the so-called smoothed Fischer–Burmeister function is

$$\psi_\tau^{FB}(a,b) \;=\; a + b - \sqrt{a^2 + b^2 + 2\tau^2}\;.$$

Obviously, ψ_τ^{NR} and ψ_τ^{FB} are continuously differentiable for all $\tau \neq 0$, and for $\tau = 0$ they coincide with ψ^{NR} and ψ^{FB}, respectively. Moreover, both functions share the following important properties.

LEMMA 2.8. *Let* $\tau \neq 0$, *and let* ψ_τ *denote one of the functions* ψ_τ^{NR} *and* ψ_τ^{FB}. *Then the following assertions hold:*

(i) *We have* $\psi_\tau(a,b) \;=\; 0$ *if and only if* $a > 0\,,\; b > 0\,,\; ab \;=\; \tau^2$.

(ii) *For a zero* (a,b) *of* ψ_τ *the gradient* $D\psi_\tau(a,b)$ *does not explicitly depend on* τ *and is given by* $(a+b)^{-1}\,(b,a)$.

Proof. Part (i) was observed in [27], and part (ii) is easily verified. □

In what follows we mainly need the results of Lemma 2.8, so we will not distinguish between ψ_τ^{NR} and ψ_τ^{FB} but simply write ψ_τ.

3. The numerical approach. The aim of our numerical method is to replace *GSIP* by a sequence of finite nonlinear programming problems which are numerically tractable and whose solutions or stationary points converge to a solution or a stationary point of *GSIP*, respectively. Unlike other numerical methods for semi-infinite

programming, our approach does not discretize the index set $Y(x)$, but we take advantage of the fact that the solution set of a regular convex lower level problem is characterized by its first order optimality condition. Thus, let Assumptions 3 and 4 hold throughout this section.

In a first step we reformulate *GSIP* as a special Stackelberg game:

$$SG: \quad \min_{x,y^1,\ldots,y^p} f(x) \text{ subject to (s.t.) } g_j(x,y^j) \le 0\,, \text{ and } y^j \text{ solves } Q^j(x),\ j \in J.$$

Note that the *SG* possesses two special features: its objective function f does not depend on the variables $y^j,\ j \in J$, and its upper level inequality constraint functions coincide with its lower level objective functions. In [54] it is shown that *GSIP* and *SG* are equivalent problems whenever the index set $Y(x)$ is nonempty for all $x \in \mathbb{R}^n$. The latter is the case under Assumption 4. We point out that for $Y(x) = \emptyset$ the point x would be feasible for *GSIP* but infeasible for *SG*.

Next, since the problems $Q^j(x)$ are convex, we may replace the restrictions "y^j solves $Q^j(x)$" in *SG* equivalently by their first order optimality conditions: for each $j \in J$ there is a solution γ^j of (2.1)–(2.4). The latter statement is true under Assumption 4, since Slater's condition guarantees the existence of Kuhn–Tucker multipliers. However, unlike in the case of the LICQ, these multipliers are not necessarily uniquely determined. By this reformulation, *SG* is equivalent to the following mathematical programming problem with equilibrium constraints:

$$\begin{aligned} MPEC: \quad \min_{x,y^1,\gamma^1,\ldots,y^p,\gamma^p} f(x) \text{ s.t. } \quad & g_j(x,y^j) && \le && 0, \\ & D_y^\top \mathcal{L}_j(x,y^j,\gamma^j) && = && 0, \\ & -\operatorname{diag}(\gamma^j)\, v(x,y^j) && = && 0, \\ & \gamma^j && \ge && 0, \\ & -v(x,y^j) && \ge && 0,\ j \in J. \end{aligned}$$

At this point, *GSIP* has been replaced by an equivalent finite nonlinear programming problem. However, numerical standard software cannot be expected to solve this problem since due to the appearance of complementarity conditions the MFCQ is violated at all points of the feasible set of *MPEC* (cf. [43]). In [26, 38] it is shown that the MFCQ is a necessary condition for the stability of smooth nonlinear programs under data perturbations and thus for the stability of numerical methods in the presence of round-off errors.

Given an NCP function ψ and $a, b \in \mathbb{R}^s$ we define the vectorization

$$\Psi(a,b) \;=\; (\psi(a_1\,,\,b_1), \ldots, \psi(a_s\,,\,b_s))^\top$$

so that *MPEC* can be equivalently rewritten as

$$\begin{aligned} P: \quad \min_{x,y^1,\gamma^1,\ldots,y^p,\gamma^p} f(x) \text{ s.t. } \quad & g_j(x,y^j) && \le && 0, \\ & D_y^\top \mathcal{L}_j(x,y^j,\gamma^j) && = && 0, \\ & \Psi(\gamma^j, -v(x,y^j)) && = && 0,\ j \in J. \end{aligned}$$

We now apply an interior point approach to the lower level problems $Q^j(x)$. For $j \in J$ we replace the Karush–Kuhn–Tucker system (2.1)–(2.4) at y^j and its corresponding multiplier vector γ^j by the perturbed system

$$D_y^\top \mathcal{L}_j(x,y^j,\gamma^j) = 0, \tag{3.1}$$

$$-\operatorname{diag}(\gamma^j)\, v(x,y^j) = \tau^2\, e_s, \tag{3.2}$$

$$\gamma^j \geq 0, \tag{3.3}$$

$$-v(x,y^j) \geq 0, \tag{3.4}$$

depending on $\tau \in \mathbb{R}$ (and on x). Here we set $e_s = (1,\ldots,1)^\top \in \mathbb{R}^s$. With one of the regularized NCP functions Ψ_τ in vector form, P is thus embedded into the parameterized family of optimization problems

$$\left\{ \begin{array}{lll} P_\tau : & \min\limits_{x,y^1,\gamma^1,\ldots,y^p,\gamma^p} f(x) \ \text{ s.t. } & \begin{array}{rcl} g_j(x,y^j) & \leq & 0, \\ D_y^\top \mathcal{L}_j(x,y^j,\gamma^j) & = & 0, \\ \Psi_\tau(\gamma^j, -v(x,y^j)) & = & 0,\ j \in J, \end{array} \end{array} \right. \tag{3.5}$$

with $P_0 = P$. We note that a similar approach for the solution of *MPEC*s is presented in [6].

The following proposition shows that problem P_τ is numerically tractable in the sense that the inherent singularity in the equality constraints of problem P has now been removed. Its proof follows straightforwardly from Lemma 2.8(ii). We remark that more detailed proofs of this and the following results can be found in [52].

PROPOSITION 3.1. *Let $\tau \neq 0$ and let $(x,y^1,\gamma^1,\ldots,y^p,\gamma^p)$ be a feasible point of P_τ such that for each $j \in J$ the matrix*

$$A^j \;=\; A^j(x,y^j,\gamma^j) \;=\; \begin{pmatrix} D_y^2 \mathcal{L}_j(x,y^j,\gamma^j) & -D_y^\top v(x,y^j) \\ -\operatorname{diag}(\gamma^j) D_y v(x,y^j) & -\operatorname{diag}(v(x,y^j)) \end{pmatrix}$$

is nonsingular. Then the gradients of the equality constraints of P_τ are linearly independent in $(x,y^1,\gamma^1,\ldots,y^p,\gamma^p)$.

We now recall the connection of the perturbed Karush–Kuhn–Tucker systems (3.1)–(3.4) with the barrier problems

$$Q_\tau^j(x): \qquad \max_y \; b_\tau^j(x,y) \;:=\; g_j(x,y) + \tau^2 \sum_{\ell \in L} \ln(-v_\ell(x,y))$$

(depending on x and τ) for $j \in J$. A necessary and in the convex case also sufficient optimality condition for $Q_\tau^j(x)$ is

$$0 \;=\; D_y b_\tau^j(x,y) \;=\; D_y g_j(x,y) + \sum_{\ell \in L} \frac{\tau^2}{v_\ell(x,y)} D_y v_\ell(x,y)\ .$$

Furthermore, the Hessian of $b_\tau^j(x,y)$ with respect to y reads as

$$\begin{aligned} D_y^2 b_\tau^j(x,y) = D_y^2 g_j(x,y) &+ \sum_{\ell \in L} \frac{\tau^2}{v_\ell(x,y)} D_y^2 v_\ell(x,y) \\ &- \sum_{\ell \in L} \frac{\tau^2}{[v_\ell(x,y)]^2} D_y^\top v_\ell(x,y) D_y v_\ell(x,y)\ . \end{aligned}$$

LEMMA 3.2. *Let $j \in J$ and $\tau \neq 0$.*

(i) *The point y^j is a solution of $Q^j_\tau(x)$ if and only if (y^j, γ^j) with $\gamma^j_\ell = -\tau^2/v_\ell(x, y^j)$, $\ell \in L$, is a solution of (3.1)–(3.4). Moreover, for the latter solutions $D^2_y b^j_\tau(x, y^j)$ is nonsingular if and only if $A^j(x, y^j, \gamma^j)$ is nonsingular.*

(ii) *If at least one of the matrices $D^2_y g_j(x, y^j)$, $D^2_y v_\ell(x, y^j)$, $\ell \in L$, is nonsingular, then $A^j(x, y^j, \gamma^j)$ is nonsingular, too.*

Proof. The first part of (i) is evident from a comparison between the relations $D_y \mathcal{L}_j(x, y^j, \gamma^j) = 0$ and $D_y b^j_\tau(x, y^j) = 0$. For the second part note that in view of Lemma 2.8(i) the matrix $\operatorname{diag}(v(x, y^j))$ is nonsingular so that $A^j = A^j(x, y^j, \gamma^j)$ is nonsingular if and only if the Schur complement S^j of $\operatorname{diag}(v(x, y^j))$ in A^j is nonsingular. This Schur complement is just $S^j = D^2_y b^j_\tau(x, y^j)$.

Due to our convexity assumptions (Assumption 3) it is easily seen that S^j is the sum of negative semidefinite matrices. Under the assumption of part (ii), at least one of the matrices $D^2_y g_j(x, y^j)$, $-D^2_y v_\ell(x, y^j)$, $\ell \in L$, is actually negative definite and, since all numbers $\tau^2/v_\ell(x, y^j)$, $\ell \in L$, are negative, S^j is negative definite, too. Together with part (i) this shows the assertion of part (ii). ∎

A different proof for a weaker result related to part (ii) of the preceding lemma can be found in [28]. Let us point out that Lemma 3.2 provides sufficient conditions for the assumption of nonsingular matrices $A^j(x, y^j, \gamma^j)$, $j \in J$, in Proposition 3.1. From Lemma 2.7 and a simple continuity argument it follows that $A^j(x, y^j, \gamma^j)$ is also nonsingular if (x, y^j, γ^j) is sufficiently close to a point $(\bar{x}, \bar{y}^j, \bar{\gamma}^j)$ such that $\bar{y}^j$ is a nondegenerate solution of $Q^j(\bar{x})$ with corresponding multiplier vector $\bar{\gamma}^j$.

The ideas presented so far lead to a simple continuation method for the numerical solution of *GSIP* which is easy to implement and can be given conceptually in the following form.

Numerical method.

Step 1. Choose a sequence $\{\tau_\nu\}$ of nonzero reals with $\lim_{\nu\to\infty} \tau_\nu = 0$ and a starting point $x^0 \in \mathbb{R}^n$.

Step 2. Compute a starting point $(x^{0,0}, y^{1,0,0}, \gamma^{1,0,0}, \ldots, y^{p,0,0}, \gamma^{p,0,0})$ of P_{τ_0} and set $\nu = 0$.

Step 3. Find a solution $(x^{\nu,\star}, y^{1,\nu,\star}, \ldots, \gamma^{p,\nu,\star})$ of P_{τ_ν}.

Step 4. Set $(x^{\nu+1,0}, y^{1,\nu+1,0}, \ldots, \gamma^{p,\nu+1,0}) = (x^{\nu,\star}, y^{1,\nu,\star}, \ldots, \gamma^{p,\nu,\star})$, $\nu := \nu + 1$, and go to Step 3.

In Step 2, we clearly choose $x^{0,0} = x^0$. In order to obtain the corresponding values $(y^{1,0,0}, \ldots, \gamma^{p,0,0})$ numerically, one might try to find a zero of

$$\begin{pmatrix} D_y^\top \mathcal{L}_j(x^0, y^j, \gamma^j) \\ \Psi_{\tau_0}(\gamma^j, -v(x^0, y^j)) \end{pmatrix}$$

for each $j \in J$. Another method will be given below.

Step 3 is a "black box" which stands for any standard solution method for nonlinear finite optimization problems. In view of Steps 2 and 4, a minimal requirement is that the method should be able to process infeasible starting points.

Conceptually, termination criteria might be the relative error of optimal points or of optimal values, as well as the error in the first order optimality condition for *GSIP* (cf. Corollary 2.6) and combinations thereof. We emphasize that the availability of an easily checkable first order optimality condition is crucial for the numerical performance of the method.

4. Convergence results. Recall that in section 3 we reformulated *GSIP* equivalently first as an *SG* and then as a finite optimization problem *P*. Then we embedded *P* in the parametric family P_τ with $\tau \in \mathbb{R}$. Let us now clarify what the equivalent embedding for *GSIP* is. Throughout this section, let Assumptions 3 and 4 hold.

With the observations in section 3 the problem P_τ with $\tau \neq 0$ can equivalently be written in the form of an *SG*:

$$SG_\tau: \quad \min_{x,y^1,\dots,y^p} f(x) \ \text{ s.t. } \ g_j(x,y^j) \le 0\,, \ \text{ and } \ y^j \ \text{ solves } \ Q_\tau^j(x),\ j \in J.$$

Under the reduction ansatz, locally near a feasible point $\bar{x}$ of *GSIP* (i.e., for $\bar{\tau} = 0$) there exists a unique solution of (3.1)–(3.4) with $\tau \neq 0$.

PROPOSITION 4.1. *Let $\bar{x} \in M$ and $j \in J$ be given. Assume that $\bar{y}^j$ is a solution of $Q^j(\bar{x})$ with corresponding multiplier vector $\bar{\gamma}^j$ such that $A^j(\bar{x},\bar{y}^j,\bar{\gamma}^j)$ is nonsingular. Then there exist neighborhoods U of $\bar{x}$ and T of $\bar{\tau} = 0$ as well as C^{d-1}-functions $y^j : V \to \mathbb{R}^m$, $\gamma^j : V \to \mathbb{R}^s$ ($V := U \times T$) such that $y^j(\bar{x},0) = \bar{y}^j$, $\gamma^j(\bar{x},0) = \bar{\gamma}^j$ and such that for all $(x,\tau) \in V$ $(y^j(x,\tau),\gamma^j(x,\tau))$ is the unique solution of* (3.1)–(3.4).

Proof. The proof follows directly by applying the implicit function theorem to the system of equations (3.1), (3.2), and using that $A^j(\bar{x},\bar{y}^j,\bar{\gamma}^j)$, its Jacobian with respect to (y,γ) at $(\bar{x},\bar{y}^j,\bar{\gamma}^j,\bar{\tau})$, is nonsingular. Note that (3.3) and (3.4) hold thanks to continuity arguments. ∎

Under the reduction ansatz (Assumption 2) the assumptions of Proposition 4.1 are satisfied for $j \in J_0(\bar{x})$ due to Lemma 2.7. Because of Lemma 3.2(i) for all $x \in U$, $\tau \in T$ the condition

$$g_j(x,y^j) \le 0 \quad \text{and} \quad y^j \quad \text{solves} \quad Q_\tau^j(x)$$

is equivalent with

$$g_j(x,y^j(x,\tau)) \le 0.$$

Note that under Assumptions 3 and 4 for $j \in J \setminus J_0(\bar{x})$ the value function $\tilde{\varphi}_j(x,\tau)$ of $Q_\tau^j(x)$ is continuous in the neighborhood $U \times T$ of $(\bar{x},0)$. So for all $\tau \in T$ the problem P_τ, locally restricted to $x \in U$, is equivalent to the reduced problem

$$GSIP_\tau(\bar{x}): \quad \min_{x \in U} f(x) \ \text{ s.t. } \ g_j(x,y^j(x,\tau)) \le 0 \text{ for all } j \in J_0(\bar{x}).$$

Summarizing, we have obtained the following reduction lemma, which provides the basis for our convergence analysis.

LEMMA 4.2 (parametric reduction lemma). *Let the reduction ansatz hold at a point $\bar{x} \in M$. Then locally in a neighborhood $U \times T$ of $(\bar{x},0)$ (cf. Proposition* 4.1*) the problems P_τ and $GSIP_\tau(\bar{x})$ are equivalent in the sense that for all $\tau \in T$ the vector $x_\tau \in U$ is a solution of $GSIP_\tau(\bar{x})$ if and only if $(x_\tau,y^1,\dots,y^p)$ with $x_\tau \in U$ solves SG_τ. In particular, problem $GSIP_0(\bar{x})$ is locally in U equivalent with $SG_0 = SG$ and, hence, with GSIP.*

The above lemma yields local reductions for all problems P_τ when (x,τ) is sufficiently close to $(\bar{x},0)$, which shows that the parametric reduction lemma implies the reduction lemma (Theorem 2.3).

The following theorem is related to a result by Shimizu and Aiyoshi [45] about the convergence behavior of the solutions of SG_τ for $\tau \to 0$. However, our proof relies only on the parametric reduction lemma and some well-known results from parametric optimization.

THEOREM 4.3. *Let* $(\tau_\nu)_{\nu\in\mathbb{N}}$ *be a sequence with* $\lim_{\nu\to\infty}\tau_\nu = 0$, *and let* $(x^\nu, y^{1,\nu}, \gamma^{1,\nu}, \ldots, y^{p,\nu}, \gamma^{p,\nu})_{\nu\in\mathbb{N}}$ *be a sequence of global solutions of* P_{τ_ν}, $\nu\in\mathbb{N}$ *(cf.* (3.5)*). If* $x^\star$ *is an accumulation point of the sequence* $(x^\nu)_{\nu\in\mathbb{N}}$ *such that Assumption* 2 *holds at* $x^\star$ *and such that the MFCQ holds at some solution of* $GSIP_0(x^*)$, *then* $x^\star$ *is a global solution of GSIP.*

Proof. Without loss of generality, let (x^ν, τ_ν) converge to $(x^\star, 0)$ for $\nu\to\infty$. By Proposition 4.1 for the solutions $y^{j,\nu}$, $j\in J_0(x^*)$, we have (for sufficiently large ν) $y^{j,\nu} = y(x^\nu, \tau_\nu)$, and x^ν is a solution of $GSIP_{\tau_\nu}(x^*)$. By continuity x^* is feasible for $GSIP_0(x^*) = GSIP$ (locally in U). As the MFCQ holds at some solution of $GSIP_0(x^\star)$, by a result due to Gauvin and Dubeau [9] the value function $\omega(\tau)$ of $GSIP_\tau(x^\star)$ is continuous in τ. Consequently $\omega(\tau_\nu) = f(x^\nu)\to\omega(0)$ and $x^\star$ is a solution of *GSIP*. □

Theorem 4.3 is primarily of theoretical interest, as numerical standard software may usually not find global solution points of the problems P_{τ_ν}, $\nu\in\mathbb{N}$. One can at most expect a point which satisfies a first order optimality condition like the one of Fritz John. Consequently, a numerical solution method for *GSIP* can also only be expected to find Fritz John points in the sense of section 2.

In the following we study how Fritz John points of the finite problems P_τ $(\tau\neq 0)$ are related to the Fritz John points of $GSIP_\tau(\bar{x})$ and *GSIP*.

LEMMA 4.4. *Let the reduction ansatz hold at a point* $\bar{x}\in M$, *and let* $(x, y^1, \gamma^1, \ldots, y^p, \gamma^p)$ *be a Fritz John point of* P_τ *(cf.* (3.5)*) with* (x,τ) *sufficiently close to* $(\bar{x}, 0)$. *Moreover, let the matrices*

$$A^j = \begin{pmatrix} D_y^2\mathcal{L}_j(x, y^j, \gamma^j) & -D_y^\top v(x, y^j) \\ -\operatorname{diag}(\gamma^j) D_y v(x, y^j) & -\operatorname{diag}(v(x, y^j)) \end{pmatrix}, \quad j\in J\setminus J_0(\bar{x}),$$

be nonsingular. Then x *is a Fritz John point of* $GSIP_\tau(\bar{x})$.

Proof. It is not hard to see that x is feasible for $GSIP_\tau(\bar{x})$. The feasibility of $(x, y^1, \gamma^1, \ldots, y^p, \gamma^p)$ for P_τ implies particularly that y^j solves $Q_\tau^j(x)$. Since the matrices A^j are nonsingular for all $j\in J$, for (x,τ) sufficiently close to $(\bar{x}, 0)$ the point y^j coincides with the unique solution $y^j(x,\tau)$ of $Q_\tau^j(x)$ (cf. Proposition 4.1). These observations, together with some simple continuity arguments, yield the reduction of the Fritz John condition of P_τ to the one of $GSIP_\tau(\bar{x})$. □

Now we can prove the main result of this section.

THEOREM 4.5. *Let* $(\tau_\nu)_{\nu\in\mathbb{N}}$ *be a sequence with* $\lim_{\nu\to\infty}\tau_\nu = 0$, *and let* $(x^\nu, y^{1,\nu}, \gamma^{1,\nu}, \ldots, y^{p,\nu}, \gamma^{p,\nu})$ *be Fritz John points of* P_{τ_ν}, $\nu\in\mathbb{N}$ *(cf.* (3.5)*), with an accumulation point* $(x^\star, y^{1,\star}, \gamma^{1,\star}, \ldots, y^{p,\star}, \gamma^{p,\star})$. *Let the reduction ansatz (Assumption* 2*) hold at* $x^\star$, *and let the matrices*

$$A^j = \begin{pmatrix} D_y^2\mathcal{L}_j(x^\star, y^{j,\star}, \gamma^{j,\star}) & -D_y^\top v(x^\star, y^{j,\star}) \\ -\operatorname{diag}(\gamma^{j,\star}) D_y v(x^\star, y^{j,\star}) & -\operatorname{diag}(v(x^\star, y^{j,\star})) \end{pmatrix}, \quad j\in J\setminus J_0(x^\star),$$

be nonsingular. Then $x^\star$ *is a Fritz John point of GSIP.*

Proof. For sufficiently large $\nu\in\mathbb{N}$ all assumptions of Lemma 4.4 are satisfied so that x^ν is a Fritz John point of $GSIP_{\tau_\nu}(x^\star)$. By a continuity argument and Lemma 2.2 $x^\star$ is thus a Fritz John point for *GSIP* in the sense of Corollary 2.6. □

The following proposition gives a criterion for the existence of an accumulation point in the assumption of Theorem 4.5.

PROPOSITION 4.6. *Let* $(\tau_\nu)_{\nu\in\mathbb{N}}$ *be a sequence with* $\lim_{\nu\to\infty}\tau_\nu = 0$, *and let* $(x^\nu, y^{1,\nu}, \gamma^{1,\nu}, \ldots, y^{p,\nu}, \gamma^{p,\nu})$ *be feasible points of* P_{τ_ν}, $\nu\in\mathbb{N}$ *(cf.* (3.5)*). Moreover, let* $x^\star$ *be an accumulation point of the sequence* $(x^\nu)_{\nu\in\mathbb{N}}$ *such that the LICQ holds*

everywhere in $Y(x^\star)$. *Then the sequence* $(x^\nu, y^{1,\nu}, \gamma^{1,\nu}, \ldots, y^{p,\nu}, \gamma^{p,\nu})_{\nu\in\mathbb{N}}$ *possesses an accumulation point* $(x^\star, y^{1,\star}, \gamma^{1,\star}, \ldots, y^{p,\star}, \gamma^{p,\star})$.

Proof. After taking a subsequence, let $x^\nu \to x^\star$ for $\nu \to \infty$. For $\nu \in \mathbb{N}$ the feasibility of $(x^\nu, y^{1,\nu}, \gamma^{1,\nu}, \ldots, y^{p,\nu}, \gamma^{p,\nu})$ for P_{τ_ν} implies $\psi_{\tau_\nu}(\gamma_\ell^{j,\nu}, -v_\ell(x^\nu, y^{j,\nu})) = 0$ and thus, by Lemma 2.8(i), $v_\ell(x^\nu, y^{j,\nu}) < 0$ for all $\ell \in L,\ j \in J$. Hence, $y^{j,\nu} \in Y(x^\nu)$, $j \in J$, and the upper semicontinuity of Y yields that an accumulation point $y^{j,\star}$ of $y^{j,\nu}, \nu \in \mathbb{N}$, exists and is contained in $Y(x^\star)$, $j \in J$.

Next assume that for some $j \in J$ the sequence $(\gamma^{j,\nu})_{\nu\in\mathbb{N}}$ is unbounded. Then for sufficiently large ν we can consider the vectors $\|\gamma^{j,\nu}\|^{-1}\gamma^{j,\nu}$, which converge to a vector η^j with $\|\eta^j\| = 1$, possibly after taking a subsequence.

The feasibility of $(x^\nu, y^{1,\nu}, \gamma^{1,\nu}, \ldots, y^{p,\nu}, \gamma^{p,\nu})$ for P_{τ_ν} yields

$$D_y g_j(x^\nu, y^{j,\nu}) - \gamma^{j,\nu} D_y v(x^\nu, y^{j,\nu}) \;=\; 0 \tag{4.1}$$

and, by Lemma 2.8(i),

$$-\gamma_\ell^{j,\nu} \cdot v_\ell(x^\nu, y^{j,\nu}) \;=\; \tau_\nu^2\ , \quad \ell \in L\ . \tag{4.2}$$

Division of (4.2) by $\|\gamma^{j,\nu}\|$ and taking the limit for $\nu \to \infty$ yields $\eta_\ell^j = 0$ for $\ell \in L \setminus L_0(x^\star, y^{j,\star})$. However, in the same way (4.1) then implies that the LICQ is violated at $y^{j,\star}$ in $Y(x^\star)$, contradicting our assumptions. Consequently, for each $j \in J$ the sequence $(\gamma^{j,\nu})_{\nu\in\mathbb{N}}$ is bounded and, thus, has an accumulation point. ∎

The existence of some accumulation point $x^\star$ in the assumption of Proposition 4.6 can of course be guaranteed if an additional restriction $x \in X$ is incorporated into *GSIP*, with X nonempty and compact.

We end this section with a result on the rate of convergence of the method.

LEMMA 4.7. *For* $\bar{x} \in M$ *and* $j \in J$ *let* y^j *be a nondegenerate solution of* $Q^j(\bar{x})$, *and let* $(y^j(x,\tau), \gamma^j(x,\tau))$ *denote the locally unique solution of* (3.1)–(3.4) *around* $(\bar{x}, 0)$. *Then we have*

$$\begin{pmatrix} D_\tau y^j(x,0) \\ D_\tau \gamma^j(x,0) \end{pmatrix} \;=\; \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

for x *sufficiently close to* $\bar{x}$.

In the following proposition we call $\bar{x} \in M$ a nondegenerate solution of *GSIP* if the reduction ansatz holds at $\bar{x}$ and if $\bar{x}$ is a nondegenerate local minimizer for the locally reduced problem $GSIP_0(\bar{x})$.

PROPOSITION 4.8. *Let the assumptions of Theorem* 4.3 *hold, and let the solution* $x^\star$ *of GSIP be nondegenerate. Then for each subsequence of* $(x^\nu)_{\nu\in\mathbb{N}}$ *that converges to* $x^\star$, *the optimal values of* P_{τ_ν} *satisfy*

$$f(x^\nu) - f(x^\star) \;=\; O(\tau_\nu^2).$$

Proof. Let $\omega(\tau)$ denote the optimal value of P_τ. In the proof of Theorem 4.3 we have seen that $\omega(\tau)$ coincides with the optimal value of $GSIP_\tau(x^\star)$ if τ is sufficiently close to zero. Now Lemma 2.2, Lemma 4.7, and a Taylor expansion of ω around 0 yield the assertion. ∎

5. Numerical examples. For the numerical illustrations we implemented the method from section 3 in *Matlab* 5.3 and used the routine *fmincon* from its *Optimization Toolbox* 2.0, i.e., an SQP method with BFGS updates for the Hessian of the

Lagrangian, to replace the "black box" in Step 3 of the method. All examples were run on an 800 MHz Linux PC.

In Step 2 we do *not* solve the nonlinear problems

$$\begin{pmatrix} D_y^\top \mathcal{L}_j(x^0, y^j, \gamma^j) \\ \Psi_{\tau_0}(\gamma^j, -v(x^0, y^j)) \end{pmatrix} = 0\,, \quad j \in J\,,$$

since an appropriate starting point for an iteration procedure is not at hand. Instead we solve the unconstrained, concave problems

$$Q^j_{\tau_0}(x^0): \qquad \max_y \; g_j(x^0, y) + \tau_0^2 \sum_{\ell \in L} \ln(-v_\ell(x^0, y))\,, \quad j \in J\,,$$

by the routine *fminunc* to obtain $y^{j,0,0},\ j \in J$, and put

$$\gamma_\ell^{j,0,0} \;=\; -\frac{\tau_0^2}{v_\ell(x^0, y^{j,0,0})}\,,\ \ell \in L\,,\ j \in J\,.$$

Here the problem of finding an appropriate starting point is solved easily by the determination of some Slater point of the set $Y(x^0)$. The latter task can be fulfilled by solving the convex problem

$$\min_{y,\eta} \; \eta \quad \text{s.t.} \quad v_\ell(x^0, y) - \eta \;\le\; 0\,, \quad \ell \in L\,,$$

where the choice of a starting point is obvious.

As an a priori τ-sequence we use $\tau_\nu = 10 \cdot 100^{-\nu},\ \nu \in \mathbb{N}$. The iteration terminates if either the relative error in the optimal point or in the optimal value is less than 10^{-6}. If the method is provided with the gradients of f, g, and v with respect to x, then also the first order condition for *GSIP* from Corollary 2.6 is checked (in the Euclidean norm).

5.1. Design centering in two dimensions. The general design centering problem (see also [14]) consists of maximizing some measure, e.g., the volume, of a parameterized body $B(x)$ which is contained in a second body G:

$$\max_{x \in \mathbb{R}^n} \; \mathit{Vol}(B(x)) \;\; \text{s.t.} \;\; B(x) \subset G\,.$$

In the first examples we let $G = \{y \in \mathbb{R}^2 |\ g(y) \le 0\}$ with

$$g(y) = \begin{pmatrix} -y_1 - y_2^2 \\ y_1/4 + y_2 - 3/4 \\ -y_2 - 1 \end{pmatrix}\,.$$

The two-dimensional volume of the resulting body is easily calculated to be 20/3. An equivalent formulation of the general design centering problem as *GSIP* is

$$\max_{x \in \mathbb{R}^n} \; \mathit{Vol}(B(x)) \;\; \text{s.t.} \;\; g(y) \le 0 \;\; \text{for all} \;\; y \in B(x)\,.$$

Problem 1. We look for the largest ball with free center and radius that is contained in G. Thus, we have $n = 3$ and

$$B(x) \;=\; \{y \in \mathbb{R}^2 |\ (y_1 - x_1)^2 + (y_2 - x_2)^2 - x_3^2 \le 0\}\,, \quad \mathit{Vol}(B(x)) \;=\; \pi\, x_3^2\,.$$

TABLE 1
Approximation of G with ψ^{NR}.

Problem	ov	$\varepsilon_{\mathtt{ov}}$	$\varepsilon_{\mathtt{op}}$	$\varepsilon_{\mathtt{FOC}}$	$\mathtt{CPU}_{\mathtt{init}}$	$\mathtt{CPU}_{\mathtt{iter}}$	$\#_{\mathtt{iter}}$
1	1.8606	2.5596e-06	$\star$	$\star$	2.94	1.04	3
2	3.4838	$\star$	$\star$	4.8781e-06	2.96	3.55	4
3	3.7234	$\star$	$\star$	n.a.	3.31	7.50	4
4	3.0792	3.9278e-06	$\star$	2.1812e-06	3.76	1.85	3

As an initial point we use the infeasible point $x^0 = (0, 0, 1)^\top$.

Problem 2. We search the largest ellipsoid with free center and axis lengths that is contained in G. The axes are supposed to be parallel to the coordinate axes. We have $n = 4$ and

$$B(x) \;=\; \left\{ y \in \mathbb{R}^2 \;\middle|\; \frac{(y_1 - x_1)^2}{x_3^2} + \frac{(y_2 - x_2)^2}{x_4^2} - 1 \le 0 \right\}, \;\; \mathit{Vol}(B(x)) \;=\; \pi\, x_3 x_4 \;.$$

The initial point is $x^0 = (0, 0, 1, 1)^\top$.

Problem 3. Now the ellipsoid from Problem 2 is allowed to have axes in arbitrary position, and with $n = 6$ we can set

$$B(x) \;=\; \left\{ y \in \mathbb{R}^2 \;\middle|\; \left(y - \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}\right)^\top \left(\begin{pmatrix} x_3 & x_4 \\ x_5 & x_6 \end{pmatrix} \begin{pmatrix} x_3 & x_5 \\ x_4 & x_6 \end{pmatrix} \right)^{-1} \left(y - \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}\right) - 1 \;\le\; 0 \right\}.$$

Then we have

$$\mathit{Vol}(B(x)) \;=\; \pi \left| \det \begin{pmatrix} x_3 & x_4 \\ x_5 & x_6 \end{pmatrix} \right|,$$

and we choose the initial point $x^0 = (0, 0, 1, 0, 0, 1)^\top$.

Problem 4. In this problem we inscribe the largest box with sides parallel to the coordinate axes into G. For $n = 4$ we have

$$B(x) \;=\; \{ y \in \mathbb{R}^2 |\; y_1 - x_1 \;\le\; 0, \quad y_2 - x_2 \;\le\; 0, \; -y_1 + x_3 \;\le\; 0, \; -y_2 + x_4 \;\le\; 0 \}$$

with

$$\mathit{Vol}(B(x)) \;=\; (x_1 - x_3) \cdot (x_2 - x_4)\,,$$

and we choose the infeasible initial point $x^0 = (1, 1, -1, -1)^\top$.

The columns of the following tables are labeled as follows: ov, optimal value; $\varepsilon_{\mathtt{ov}}$, relative error in optimal value; $\varepsilon_{\mathtt{op}}$, relative error in optimal point; $\varepsilon_{\mathtt{FOC}}$, error in first order optimality condition; $\mathtt{CPU}_{\mathtt{init}}$, CPU time for initialization step in seconds; $\mathtt{CPU}_{\mathtt{iter}}$, CPU time for iterations in seconds; $\#_{\mathtt{iter}}$, number of outer iterations. If (relative) errors are below 10^{-6}, we replace the actual number by the symbol "$\star$". In Problem 3 the gradients entering the first order optimality condition are not available for the method, so this criterion is not checked.

For the results in Table 1 we used the natural residual function ψ^{NR} as the NCP function. In this example the performance of the method does not change significantly if the NCP function ψ^{NR} is replaced by ψ^{FB} (see [52] for more details).

Concerning the solution of Problem 4 it is worth mentioning, as expected, we have $x_4^\star = -1$. This means that the method converges although $Q^3(x^\star)$ clearly is a *degenerate* problem. In fact, the computed "maximal box" in G is the set $B(x^\star) = [-0.024, 3.619] \times [-1, -0.155]$, so that the solution set of $Q^3(x^\star)$ coincides with the facet $[-0.024, 3.619] \times \{-1\}$ of $B(x^\star)$. From all these optimal points the method chooses their "midpoint" as $y^{3,\star} = (1.7975, -1)$. In fact, in our approach the lower level linear problems are solved by the central path method. It is well known in linear programming that under weak assumptions the interior point sequence converges to the so-called analytic center of the optimal facet (cf. [39]).

5.2. Robust optimization. Robustness questions arise when an optimization problem is subject to uncertain data. If an inequality constraint function $g(x, y)$ depends on some uncertain parameter vector $y \in Y \subset \mathbb{R}^m$, then the "most cautious" way to deal with this constraint is to use its worst-case reformulation

$$g(x, y) \ \leq 0 \ \text{ for all } \ y \in Y\,,$$

which is clearly of semi-infinite type. When the uncertainty set Y also depends on the state variable x, we arrive at a generalized semi-infinite constraint.

The following robust optimization problem is studied in [1] for elliptic uncertainty sets. In the case of ellipticity the lower level optimal value functions can be computed explicitly in such a way that the semi-infinite problem is reduced to a nonsmooth finite problem which can be tackled by SDP methods (cf. [1] for details). We will show that our numerical method solves not only this specially structured problem but also two nontrivial generalizations.

Let 1 euro be invested in a portfolio comprised of N shares. At the end of a given period the return per 1 euro invested in share i is $y_i > 0$. The goal is to determine the amount x_i to be invested in share i, $i = 1, \ldots, N$, so as to maximize the end-of-period portfolio value $y^\top x$.

If the vector y was certain, the solution of this optimization problem would be evident. A more realistic assumption is that y varies in some nonempty compact set $Y \subset \mathbb{R}^N$. Upon moving the objective function to the constraint set we obtain the following standard semi-infinite optimization problem with $n = N + 1$ and $m = N$:

$$\max_{x, x_{N+1}} \ x_{N+1} \quad \text{s.t.} \quad x_{N+1} - y^\top x \leq 0\,,\ y \in Y\,,\ \sum_{i=1}^{N} x_i = 1\,,\ x \geq 0.$$

Apart from its special structure used in [1] for the case of an ellipsoidal set Y, this is also a linear semi-infinite optimization problem, meaning that the semi-infinite constraint function is linear in the variable (x, x_{N+1}). Solution methods for these types of problems are described, e.g., in [10, 20]. Note, however, that the index set of the semi-infinite constraint is N-dimensional, where N might be a large number.

Problem 5. In [1] the set Y has the form

$$Y \ = \ \left\{ y \in \mathbb{R}^N \,\middle|\, \sum_{i=1}^{N} \frac{(y_i - \bar{y}_i)^2}{\sigma_i^2} \ \leq \ \theta^2 \right\},$$

where $\bar{y}_i$ is some "nominal" value of y_i, σ_i is a scaling parameter, $i = 1, \ldots, N$, and θ measures the risk aversion of the decision maker. With the particular choices

$$\bar{y}_i = 1.15 + i \cdot \frac{0.05}{N}\,, \quad i = 1, \ldots, N,$$

$$\sigma_i = \frac{0.05}{3\,N}\sqrt{2N(N+1)i}\,, \quad i = 1, \ldots, N,$$
$$\theta = 1.5,$$

one can show that the optimal policy is to invest equally in all shares, i.e., $x_i = 1/N\,,\ i = 1, \ldots, N$, with optimal value $1.15\,$. We use the starting point $x^0 = (1, 0, \ldots, 0)$ in $\mathbb{R}^{N+1}$.

Having the large dimensions of Y in mind, the method performs very well when ψ^{NR} is used (cf. Table 2). In the case of ψ^{FB} as the NCP function, the "black box" part of the method (i.e., the *Matlab* routine *fmincon*) does not converge for $N = 100$ (cf. Table 3), so that we solved this particular problem with the a priori sequence $\tau_\nu = 10^{-\nu},\ \nu \in \mathbb{N}$.

Problem 6. A more general choice of Y is

$$Y_\delta \;=\; \{\; y \in \mathbb{R}^N \,|\; \|\operatorname{diag}(\sigma)^{-1}(y - \bar{y})\|_\delta \;\leq\; \theta \;\}$$

with $\delta \in [1, \infty]$. Whereas Y_2 is the ellipsoid from Problem 5, the sets Y_1 and Y_∞ are polytopes. For all other choices of δ we still obtain a nonempty compact convex set $Y_\delta\,$. As polytopes can be considered as ellipsoidal sets in the sense of [1], let us use our method for a *nonellipsoidal* set like $Y_{10}\,$. Tables 4 and 5 show the results for the starting point $x^0 = 1/N \cdot (1, \ldots, 1, 0)$. The method performs well for dimensions up to $N = 150$. In this example the initialization phase takes about as long as the main iterations. Note that for increasing dimensions the attainment of the first order condition becomes worse when the method terminates because of a small relative error in the optimal value.

Problem 7. Finally, since our method works for x-dependent sets Y, we can also consider the case in which the risk aversion of the decision maker depends on the point x. If for instance his risk aversion increases when the values x_i deviate from $1/N$, $i = 1, \ldots, N$, we can replace θ by the expression

$$\Theta(x) \;=\; \theta \cdot \left(1 + \sum_{i=1}^{N} \left(x_i - \frac{1}{N}\right)^2\right)$$

and obtain the *generalized* semi-infinite optimization problem

$$\max_{x, x_{N+1}} \; x_{N+1} \quad \text{s.t.} \quad x_{N+1} - y^\top x \leq 0\,,\ y \in Y(x)\,,\ \sum_{i=1}^{N} x_i = 1\,,\ x \geq 0,$$

with

$$Y(x) \;=\; \left\{ y \in \mathbb{R}^N \;\middle|\; \sum_{i=1}^{N} \frac{(y_i - \bar{y}_i)^2}{\sigma_i^2} \;\leq\; \Theta(x)^2 \right\} .$$

The choice $\sigma_i = 1,\ i = 1, \ldots, N$, prevents the solution of the original Problem 5 to be $x_i = 1/N\,,\ i = 1, \ldots, N$, so that the modified term $\Theta(x)$ can take effect, and we observe a good performance of our method in Tables 6 and 7 up to dimension $N = 150$. Note, however, that in this example the initialization phase takes considerably longer than the main iterations.

6. Final remarks. The essential idea behind the numerical method presented in section 3 is to reformulate the generalized semi-infinite optimization problem as a Stackelberg game and to make use of the convexity in the lower level problems. Starting at this point, there are several possible routes to the design of a numerical method.

First, there are other ways to treat the convex lower level problems than the one used in this article, e.g., penalty, barrier, or cutting plane methods. Furthermore, if one decides to replace the convex optimization problems by their first order optimality conditions and obtain a mathematical program with equilibrium constraints, this

program does not necessarily have to be solved with regularized NCP functions. Instead, the exact penalization approaches from [34, 44] or nonsmooth Newton methods (see, e.g., [30]) could be promising alternatives. Finally, in the case when one uses NCP functions, there are a multitude of functions other than the natural residual and the Fischer–Burmeister function to choose from. For a survey see, e.g., [5].

Further questions concern the required accuracy for the solution of the auxiliary problems by the "black box" method, the implementation of an active set strategy, and the design of a pathfollowing method (cf. [15]) to solve the finite parametric optimization problems P_τ for parameter values tending to $\tau = 0$. Let us point out, however, that the resulting numerical method will then not just solve a sequence of finite dimensional optimization problems that are easily constructed from the problem data, so that the implementation effort for the user increases drastically.

Moreover, generalizations of the convergence proofs from section 4 to cases such as convex lower level problems in which the reduction ansatz is not necessarily satisfied (recall Problem 4 in section 5.1) will be the subject of future research. We finally remark that a direct application of the presented ideas to semi-infinite optimization problems with *nonconvex* lower level problems results, in general, only in a *relaxation* of the original problem, since lower level optimality can then not be replaced equivalently with a first order optimality condition. However, our method can then still be used to obtain lower bounds for the optimal value of *GSIP*.

Acknowledgment. We express our thanks to the referee, whose precise and substantial remarks led to an improved version of the article.

MINIMUM TIME WITH BOUNDED ENERGY, MINIMUM ENERGY WITH BOUNDED TIME*

MONICA MOTTA† AND CATERINA SARTORI‡

Abstract. Necessary and sufficient conditions for the regularity of the minimum time function and minimum energy function for a control system with controls in $L^p([0,+\infty[,\mathbb{R}^m)$ and $p \geq 1$ are given in terms of topological properties of the reachable sets. In particular, standard local controllability assumptions are sufficient to yield the continuity of both value functions for linear systems and $p \geq 1$ and the Hölder continuity of the minimum time function for nonlinear systems and $p > 1$.

Key words. nonlinear control systems, reachable sets, minimum time, minimum energy

1. Introduction.

In this paper we consider the system

$$(\hat{S})_p \qquad \dot{y}(t) = f(y(t)) + \sum_{i=1}^{m} g_i(y(t))u_i(t), \quad t > 0, \quad u \in L^p([0,+\infty[,\mathbb{R}^m)$$

for $p \geq 1$ and give results on the regularity of the functions $\hat{T}_p(x,K)$ and $\hat{E}_p(x,T)$, which are, respectively, the minimum time needed to steer a point $x \in \mathbb{R}^n$ to the origin, along the trajectories of $(\hat{S})_p$, under the constraint $\int_0^{+\infty} |u(s)|^p\, ds \leq K^p$ and the minimum of the needed energy, defined as $(\int_0^T |u(s)|^p\, ds)^{1/p}$, under the constraint $t \leq T$ ($T, K > 0$ given). Strictly related to the regularity of such value functions are the topological properties of the reachable sets defined as

$$\hat{\mathcal{R}}_p(T,K) \doteq \left\{ x \in \mathbb{R}^n : \ \exists u \text{ such that (s.t.) } \int_0^T |u(s)|^p\, ds \leq K^p \text{ and } y_x(T,u) = 0 \right\}.$$

We point out that the cases $p > 1$ and $p = 1$ are very different. In fact, for $p > 1$, the following three properties are obtained among the results of section 2: the sets $\hat{\mathcal{R}}_p(T,K)$ are compact, an optimal control exists for the above minimization problems, and $\hat{T}_p$ and $\hat{E}_p$ are lower semicontinuous. On the other hand, for $p = 1$, we give an example (Example 2.1) in which the sets $\hat{R}_1(T,K)$ are not closed, an optimal control for the minimum time problem does not exist, and $\hat{T}_1$ is not lower semicontinuous. This difference is mainly due to the fact that for $p = 1$ the limit of minimizing sequences of trajectories can be a discontinuous function. However, following [3] all the results obtained for $p > 1$ can be proven also in the case $p = 1$ by considering an *extended system* $(S)_1$ whose trajectories are graphs or limits of graphs of solutions to $(\hat{S})_1$. We then embed the two original minimization problems into two *extended minimization problems* related to the system $(S)_1$ which in general are not equivalent to the original problems. Indeed, in section 2 we show that the *extended reachable sets*

‡Dipartimento di Metodi e Modelli Matematici per le Scienze Applicate, Università di Padova, via Belzoni 7, 35131 Padova, Italy (sartori@dmsa.unipd.it).

are the closure of the original reachable sets and that the *extended minimum time and minimum energy functions*, denoted by $T_1(x,K)$ and $E_1(x,T)$, respectively, are the lower semicontinuous envelopes of $\hat{T}_1$ and $\hat{E}_1$, respectively. The extended problems are in fact equivalent to the original problems if some controllability around the origin is assumed.

In section 3 we begin by giving necessary and/or sufficient conditions for the upper semicontinuity, Lipschitz continuity, and Hölder continuity of the maps $\hat{T}_p$ and $\hat{E}_p$ for $p>1$, and of T_1 and E_1 in terms of *global topological properties* of the reachable sets and of the extended reachable sets, respectively. In subsection 3.2 we show that, for $p=1$, assuming in addition a controllability condition of the original system around the target, many of the previous properties hold also for the original functions $\hat{T}_1$ and $\hat{E}_1$ in the interior of their domains. In subsection 3.3 we show via a dynamic programming approach that assuming just local controllability around the origin is sufficient to yield the local Hölder continuity of $\hat{E}_p$ and $\hat{T}_p$ in the state variable x for $p>1$, while an example (Example 3.3) shows that this is not possible in the case $p=1$ neither for the function $\hat{T}_1$ nor for T_1.

In section 4 we show that controllable linear systems have reachable sets that verify all the global topological properties introduced in the previous section. In particular, this yields that $\hat{T}_1$ and $\hat{E}_1$ are at least continuous in the interior of their domains. In the nonlinear case we show that a classical local controllability condition used for systems with compact valued controls (see, e.g., [8]) implies the local Hölder continuity of $\hat{T}_p$ in the state variable x for $p>1$.

A huge literature treats the regularity of the minimum time and minimum energy functions, mainly under the assumption that the admissible controls are compact valued. To our knowledge, there are results on the regularity of the value functions $\hat{T}_p$ and $\hat{E}_p$ only for linear systems (also in infinite dimension) and for $p>1$ (see, e.g., [4], [6] and the references therein). In fact, in the case $p=1$, the Lipschitz continuity of T_1 has been proved by Rampazzo and Sartori [14] but under assumptions not verified by system $(S)_1$ if the target is a point. The bibliography that we give does not intend to be complete. Besides the articles to which we referred above, we mention here just those papers most related to our point of view. For nonlinear systems Petrov [13] gives the Lipschitz continuity of the minimum time function. For linear systems and for symmetric polysystems the Hölder continuity can be found in Liverovskii [9]. For nonlinear systems the problem is treated in the framework of more general issues on controllability by Bianchini and Stefani [2], Sussmann [18], and many others. All of these last results concern the case of compact valued controls. For linear systems and L^p-constraints on the controls, very sharp estimates on the energy needed to reach the origin as time approaches zero are given by Seidman [16] and by Seidman and Yong [17].

Notation. In what follows p' will denote the integer such that $\frac{1}{p}+\frac{1}{p'}=1$, with the usual convention that $p'=\infty$ and $\frac{1}{p'}=0$ if $p=1$; A° will denote the interior of a given subset $A\subset\mathbb{R}^n$ and $\bar{A}$ its closure; moreover, given a function $u: X\to[-\infty,+\infty]$, $X\subseteq\mathbb{R}^N$, u_* and u^* will denote, respectively, the lower and the upper semicontinuous envelopes.

2. Reachable sets. Minimum time and minimum energy functions.

2.1. Statement of the problems. For any integer $p\geq 1$ we consider the affine control system given by

$$(\hat{S})_p \qquad \dot{y}(t)=f(y(t))+\sum_{i=1}^{m} g_i(y(t))u_i(t), \quad t>0, \quad u\in L^p([0,+\infty[,\mathbb{R}^m),$$

where $f, g_1, \dots, g_m : \mathbb{R}^n \to \mathbb{R}^n$. Throughout the paper we assume that $f, g_1, \dots, g_m$ are locally Lipschitz continuous, sublinear functions. More precisely, if $\varphi \doteq f$ or $\varphi \doteq g_1, \dots, \varphi \doteq g_m$ and $N > 0$, there are some constants $L_\varphi \equiv L_{\varphi,N}$ and M_φ such that

$$\begin{aligned} &|\varphi(x_1) - \varphi(x_2)| \le L_\varphi |x_1 - x_2| \qquad \forall x_1, x_2 \text{ s.t. } |x_1|, |x_2| \le N \\ &|\varphi(x)| \le M_\varphi(1 + |x|) \qquad \forall x \in \mathbb{R}^n. \end{aligned} \tag{2.1}$$

Hence for any $x \in \mathbb{R}^n$ and any control u, we will denote by $y_x(\cdot, u)$ the unique solution to $(\hat{S})_p$ corresponding to u such that $y(0) = x$.

For any $p \ge 1$, $T \ge 0$, and $K \ge 0$ we denote by $\hat{\mathcal{U}}_p(T, K)$ the *set of admissible controls* given by

$$\hat{\mathcal{U}}_p(T, K) \doteq \left\{ u \in L^p([0, T], \mathbb{R}^m) : \int_0^T |u(t)|^p \, dt \le K^p \right\}$$

and define the *reachable set in time T and with energy K* as the subset of $\mathbb{R}^n$ given by

$$\hat{\mathcal{R}}_p(T, K) \doteq \left\{ x \in \mathbb{R}^n : \exists u \in \hat{\mathcal{U}}_p(T, K) \text{ s.t. } y_x(T, u) = 0 \right\}.$$

We also define the *minimum time function with p-energy K* and the *minimum p-energy function in time T* as

$$\hat{T}_p(x, K) \doteq \inf\{T > 0 : \ x \in \hat{\mathcal{R}}_p(T, K)\}, \quad \hat{E}_p(x, T) \doteq \inf\{K > 0 : \ x \in \hat{\mathcal{R}}_p(T, K)\},$$

respectively. For $p > 1$ we will prove that the reachable sets $\hat{\mathcal{R}}_p(T, K)$ are compact and an optimal control for the minimum time and minimum energy problems always exists. For $p = 1$ instead, the following simple example shows that even for linear systems, the reachable sets $\hat{\mathcal{R}}_1(T, K)$ might not be closed and also that minimizing sequences of trajectories can converge to a discontinuous function.

Example 2.1. Consider the system

$$\begin{cases} \dot{y}_1 = -y_2, \\ \dot{y}_2 = -u \end{cases}$$

with scalar control $u \in \hat{\mathcal{U}}_1(T, K)$ for $T, K > 0$. For any u, the solution is given by $(y_1, y_2)_{(x_1,x_2)}(t, u) = (x_1 - \int_0^t (t - s)u(s)\, ds, x_2 - \int_0^t u(s)\, ds)$. As shown in [5, Chap. III, Ex. 3], one has

$$\hat{\mathcal{R}}_1(T, K) = \left\{ (x_1, x_2) \in \mathbb{R}^2 : |Tx_2 - 2x_1| < TK, |x_2| \le K \right\}.$$

Therefore $\hat{\mathcal{R}}_1(T, K)$ is not closed. Moreover, there exists a minimizing sequence for the minimum time problem which does not converge to a solution of the system. Indeed, fix $P = (x_1, x_2) = (\hat{t}, 1)$, $\hat{t} > 0$. We have that $P \in \hat{\mathcal{R}}_1(T, 1)$ for every $T > \hat{t}$ in that the control

$$\hat{u}_T(t) = \begin{cases} (T - \hat{t})^{-1} - (T)^{-1} & \text{for } t \in [0, T - \hat{t}[\\ (\hat{t})^{-1} - T^{-1} & \text{for } t \in [T - \hat{t}, T[\end{cases}$$

belongs to $\hat{\mathcal{U}}_1(T, 1)$ and is such that $y_P(T, \hat{u}_T) = (0, 0)$, but P does not belong to $\hat{\mathcal{R}}_1(\hat{t}, 1)$. Consider now the sequence of controls $(u_n)_{n \in \mathbb{N}}$ where $u_n \doteq \hat{u}_{\hat{t} + \frac{1}{n}}$. It is clear

that $y_P(\hat{t}+\frac{1}{n},u_n)=(0,0)$. Notice though that $\lim_{n\to+\infty}(y_2)_P(\frac{1}{n},u_n)=0$ while for every n one has $(y_2)_P(0,u_n)=1$. Thus the limit function of our minimizing sequence is discontinuous.

Moreover, $\hat{T}_1$ is not lower semicontinuous on the closure of its domain, where the domain is given by

$$\cup_{K>0}\left(\left(\{(x_1,x_2)\in\mathbb{R}^2:\ |x_2|<K\}\cup\{(x_1,sgn(x_1)K):x_1\neq 0\}\right)\times\{K\}\right).$$

In fact, $\hat{T}_1((0,K),K)=+\infty$ while clearly $(\hat{T}_1)_*((0,K),K)=0$.

2.2. Extended system and extended problems. The facts addressed in Example 2.1 lead us to introduce for $p=1$ an *extended system,* whose corresponding *extended reachable sets* coincide with the closure of the original reachable sets and whose trajectories allow us to represent the (eventually discontinuous) limit function of sequences of solutions to $(\hat{S})_1$. In fact, in order to unify the proofs relative to the two cases $p>1$ and $p=1$, let us introduce the following *extended system* for any $p\geq 1$ (see also [15] and Remark 2.1 below):

$$(S)_p\quad\begin{cases}t'(s)=w_0^p(s),\\ k'(s)=|w(s)|^p,\\ y'(s)=f(y(s))w_0^p(s)+\displaystyle\sum_{i=1}^m g_i(y(s))w_i(s)w_0^{p-1}(s),\quad s\in[0,1],\end{cases}$$

where the controls $(w_0,w):[0,1]\to[0,+\infty[\times\mathbb{R}^m$ are measurable functions. For any control (w_0,w) and any $x\in\mathbb{R}^n$ we will denote by $(t(s),k(s),y_x(s))$ (or by $(t(s,w_0,w),$ $k(s,w_0,w),$ $y_x(s,w_0,w))$ if we want to specify the control) the solution to $(S)_p$ corresponding to (w_0,w) such that $(t(0),k(0),y(0))=(0,0,x)$. We will sometimes refer to such a solution as *forward solution* to $(S)_p$. The solution to $(S)_p$ where the third equation is replaced by $y'(s)=-f(y(s))w_0^p(s)-\sum_{i=1}^m g_i(y(s))w_i(s)w_0^{p-1}(s)$ such that $(t(0),k(0),y(0))=(0,0,x)$ will be denoted by $(t(s),k(s),$ $y_x^-(s))$, and we will refer to it as *backward solution* to $(S)_p$.

For any $p\geq 1$, $T\geq 0$, and $K\geq 0$, we denote by $\mathcal{U}_p(T,K)$ the *set of extended admissible controls* given by

$$\mathcal{U}_p(T,K)\doteq\left\{(w_0,w)\in L^p([0,1],[0,+\infty[\times\mathbb{R}^m):\ \int_0^1 w_0^p\,ds\leq T,\quad \int_0^1|w|^p\,ds\leq K^p\right\}$$

and define the *extended reachable set in time T and with energy K* as the subset of $\mathbb{R}^n$ given by

$$\mathcal{R}_p(T,K)\doteq\{x\in\mathbb{R}^n:\ \exists(w_0,w)\in\mathcal{U}_p(T,K)\text{ s.t. }y_x(1,w_0,w)=0\}.$$

We define also the *extended minimum time function with p-energy K* and the *extended minimum p-energy function in time T* as

$$T_p(x,K)\doteq\inf\{T>0:\ x\in\mathcal{R}_p(T,K)\},\quad E_p(x,T)\doteq\inf\{K>0:\ x\in\mathcal{R}_p(T,K)\},$$

respectively. We refer to the appendix for the technical propositions that relate the solution to $(\hat{S})_p$ to the solution of $(S)_p$.

Remark 2.1. In view of Proposition A.1 in the appendix, if $p > 1$, the (t, y)-components of the trajectories of $(S)_p$ are substantially only time reparametrizations of graphs of trajectories of $(\hat{S})_p$, in the sense that when $(w_0, w) = (0, w)$ on some set $[s_1, s_2]$ one has $y_x(\cdot, 0, w) =$ constant on $[s_1, s_2]$. Hence for any $T > 0$, $K > 0$ the reachable set $\mathcal{R}_p(T, K)$ coincides with $\hat{\mathcal{R}}_p(T, K)$, and $T_p(x, K)$ and $E_p(x, T)$ coincide with $\hat{T}_p(x, K)$ and $\hat{E}_p(x, T)$, respectively. In the case $p = 1$ instead, one has $y'(s) = \sum_{i=1}^m g_i(y(s))w_i(s)$ $\forall s \in [s_1, s_2]$. Hence the set of the extended trajectories is larger than the set of the graphs reparametrizations of trajectories of $(\hat{S})_1$. Notice that such extension of $(\hat{S})_1$ is equivalent to an *extension in measure* only in the special case of commutative control systems, i.e., when the Lie brackets $[g_i, g_j] \equiv 0 \ \ \forall i \neq j$. (See, e.g., [8] for an extension in measure in the special case of linear systems; see [3] and [10] for an approach to the general case which agrees with the one followed here.) We point out that system $(S)_p$ is introduced even in the case $p > 1$, not only to give the same proof for several results which are valid for any $p \geq 1$, but also because in the extended problems we can consider extended controls belonging to a compact set, as it follows from Proposition A.2 in the appendix.

2.3. New results. As anticipated before, in this subsection we prove that the reachable sets (the extended reachable sets in the case $p = 1$) are compact; that a bounded optimal control for the extended minimum time and minimum energy problems does always exist; and that the minimum time and the minimum energy functions (the extended functions in the case $p = 1$) are lower semicontinuous. Similar results were already proven in [6] only for $p > 1$ and (infinite dimensional) linear systems. Moreover, for $p = 1$ we show that the extended reachable sets coincide with the closure of the original sets and that the extended functions turn out to be the lower semicontinuous envelopes of the original functions.

PROPOSITION 2.1. *Let $p \geq 1$. For any T, $K \geq 0$ the set $\mathcal{R}_p(T, K)$ is compact. Furthermore, if $p = 1$, one has $\mathcal{R}_1(T, K) = \overline{\cap_{S>T} \hat{\mathcal{R}}_1(S, K)}$. Moreover, if $T > 0$, one has $\mathcal{R}_1(T, K) = \overline{\hat{\mathcal{R}}_1(T, K)}$.*

Proof. The assumptions on f and g_i, $i = 1, \ldots, m$, imply easily that $\mathcal{R}_p(T, K)$ is bounded. To prove that $\mathcal{R}_p(T, K)$ is closed, let us consider a sequence $(x_n)_n \subset \mathcal{R}_p(T, K)$ such that $\lim_n x_n = x$. For any x_n, let $(w_{0n}, w_n) \in \mathcal{U}_p(T, K)$ be a control such that $y_{x_n}(1, w_{0n}, w_n) = 0$. In view of Proposition A.2 in the appendix, we can assume that $|(w_{0n}, w_n)|^p \leq 2^p(K^p + T)$ a.e. Hence the sequence of extended trajectories $((t_n, k_n, y_n))_n$ (where $t_n \doteq t(\cdot, w_{0n}, w_n)$, $k_n \doteq k(\cdot, w_{0n}, w_n)$, $y_n \doteq y_{x_n}(\cdot, w_{0n}, w_n)$ $\forall n$) is equibounded and equi-Lipschitz. By the Ascoli–Arzelà theorem it has a subsequence uniformly converging to a function (t, k, y) such that $(t(0), k(0), y(0)) = (0, 0, x)$, $t(1) \leq T$, $k(1) \leq K^p$, and $y(1) = 0$. Moreover, by a well-known result (see, e.g., [8, Chap. IV]) (t, k, y) is in fact a trajectory of $(S)_p$ since for all $z \in \mathbb{R}^n$ the set $\{(w_0, f(z)w_0 + \sum_{i=1}^m g_i(z)w_i, |w|) : \ w_0 \geq 0, \ w \in \mathbb{R}^m, |(w_0, w)|^p \leq 2^p(K^p + T)\}$ is convex and compact. Then $x \in \mathcal{R}_p(T, K)$. (In the case of linear systems and for $p = 1$ a proof of the above result in terms of an approach in measure can be found in [8].)

The fact that $\mathcal{R}_1(T, K) = \overline{\cap_{S>T} \hat{\mathcal{R}}_1(S, K)}$ can be shown using the same arguments as in [14, Theorem 3.1]. In order to prove the last statement, it suffices to prove that the inclusion $\mathcal{R}_1(T, K) \subset \overline{\hat{\mathcal{R}}_1(T, K)}$ holds for any $T > 0$. Let $x \in \mathcal{R}_1(T, K)$, let $(w_0, w) \in \mathcal{U}_1(T, K)$ be a control such that $|(w_0, w)|^p \leq 2^p(T + K^p)$, and $y_0^-(1, w_0, w) = x$. For any n let us define $w_{0n} \doteq \left(w_0^p + \frac{1}{n}\right)^{1/p}$, and let $\sigma_n \doteq \sup\{\sigma \in [0, 1] : \ \int_0^\sigma w_{0n}^p(s)\, ds \leq T\}$. Hence the backward trajectories $(t_n, k, y_n^-)(\cdot) = (t, k, y_0^-)(\cdot, w_{0n}, w)$ and $(t_{\sigma_n}, k, y_{\sigma_n}^-)(\cdot) = (t, k, y_0^-)(\cdot, w_{0n}\chi_{[0,\sigma_n]}, w)$ of $(S)_1$ satisfy the

estimates

$$|t_{\sigma_n}(s) - t(s)| \le |t_{\sigma_n}(s) - t_n(s)| + |t_n(s) - t(s)| \le \int_{\sigma_n}^1 w_{0n}^p(s)\,ds + \frac{1}{n} \le \frac{2}{n},$$
$$|y^-_{\sigma_n}(1) - x| \le |y^-_{\sigma_n}(1) - y^-_n(1)| + |y^-_n(1) - x| \le \omega\left(\frac{1}{n}\right) \quad \forall s \in [0,1],$$

where $\omega : [0,+\infty[\to [0,+\infty[$ is an increasing function, continuous at 0, such that $\omega(0) = 0$. This concludes the proof in that $x_n \doteq y^-_{\sigma_n}(1) \in \hat{\mathcal{R}}_1(T,K)$ by definition and $\lim_{n\to+\infty} x_n = x$. □

PROPOSITION 2.2. *Let $T \ge 0$, $K \ge 0$, and $p \ge 1$. Then for any $x \in \mathcal{R}_p(T,K)$ there exists a* bounded *optimal control (w_0, w) for the* extended minimum time problem *and a* bounded *optimal control $(\tilde{w}_0, \tilde{w})$ for the* extended minimum energy problem.

Proof. We show the existence of a bounded optimal control only for the extended minimum time problem, the proof for the extended minimum energy problem being analogous. Let $p \ge 1$, and for $x \in \mathcal{R}_p(T,K)$ let $((w_{0n}, w_n))_n$ be a minimizing sequence of controls, i.e., assume that the backward trajectories $(t_n, k_n, y_n^-)(\cdot) \doteq (t,k,y_0^-)(\cdot, w_{0n}, w_n)$ of $(S)_p$ satisfy

$$\lim_n t_n(1) = T_p(x,K), \qquad k_n(1) \le K^p, \quad y_n^-(1) = x \quad \forall n.$$

On the basis of Proposition A.2 in the appendix, we can suppose that $|(w_{0n}, w_n)|^p \le 2^p(T_p(x,K) + K^p) + 1$. At this point, the same arguments used in the proof of Proposition 2.1 allow us to conclude that there exists a subsequence of $(t_n, k_n, y_n^-)(\cdot)$ which converges uniformly to a backward solution (t,k,y^-) of $(S)_p$ associated to a bounded admissible control $(w_0, w) \in \mathcal{U}_p(T_p(x,K),K)$, optimal in that $\int_0^1 w_0^p(s)\,ds = T_p(x,K)$ (and $y^-(1) = x$, $\int_0^1 |w|^p\,ds \le K^p$). □

Remark 2.2. In Proposition 2.2 we proved the existence of an extended optimal control (w_0, w). If $p > 1$, in fact, one could also prove the existence of an optimal control in the original setting (either directly or using the arguments of Remark 2.1). If $p = 1$ instead, as already shown in Example 2.1, an optimal control for the original problem might not exist.

For any $p \ge 1$, $T, K > 0$ we define the sets

$$\mathcal{R}_p(K) \doteq \cup_{T\ge 0}\mathcal{R}_p(T,K), \qquad \mathcal{S}_p(T) \doteq \cup_{K\ge 0}\mathcal{R}_p(T,K), \tag{2.2}$$
$$\hat{\mathcal{R}}_1(K) \doteq \cup_{T\ge 0}\hat{\mathcal{R}}_1(T,K), \qquad \hat{\mathcal{S}}_1(T) \doteq \cup_{K\ge 0}\hat{\mathcal{R}}_1(T,K).$$

Hence the domains of the functions T_p, E_p, $\hat{T}_1$, and $\hat{E}_1$ are given, respectively, by

$$Dom(T_p) = \cup_{K>0}(\mathcal{R}_p(K) \times \{K\}), \quad Dom(E_p) = \cup_{T>0}(\mathcal{S}_p(T) \times \{T\}),$$
$$Dom(\hat{T}_1) = \cup_{K>0}(\hat{\mathcal{R}}_1(K) \times \{K\}), \quad Dom(\hat{E}_1) = \cup_{T>0}(\hat{\mathcal{S}}_1(T) \times \{T\}).$$

As a consequence of Propositions 2.1 and 2.2 we will prove that the functions T_p and E_p are lower semicontinuous. We remark that this holds not only in the state variable x but in their whole domains.

THEOREM 2.1. *For any $p \ge 1$, the functions $T_p : \overline{Dom(T_p)} \to [0,+\infty]$ and $E_p : \overline{Dom(E_p)} \to [0,+\infty]$ are lower semicontinuous. Furthermore, in the case $p = 1$ one has that $(\hat{E}_1)_* = E_1$ and $(\hat{T}_1)_* = T_1$.*

Proof. Let $p \geq 1$. We prove only the statements for T_p, the proofs for E_p being analogous. In order to show that T_p is lower semicontinuous, let us fix $(x, K) \in \overline{Dom(T_p)}$. We argue by contradiction and suppose that there are $T < T_p(x, K)$ and $(x_n, K_n) \in \overline{Dom(T_p)}$ such that $T_p(x_n, K_n) < T$, and $\lim_n (x_n, K_n) = (x, K)$. Hence for all n sufficiently large one has $K_n \leq K + 1$ and $x_n \in \mathcal{R}_p(T, K_n) \subset \mathcal{R}_p(T, K+1)$. By Proposition 2.2, there exist optimal controls $(w_{0n}, w_n) \in \mathcal{U}_p(T, K_n)$ uniformly bounded, e.g., by $2^p(T + (K+1)^p)$, such that the backward trajectories $(t_n, k_n, y_n^-)(\cdot) = (t, k, y_0^-)(\cdot, w_{0n}, w_n)$ to $(S)_p$ satisfy

$$t_n(1) \leq T, \qquad k_n(1) \leq K_n, \qquad y_n^-(1) = x_n.$$

As in Proposition 2.1, known theorems imply that there is a subsequence of $(t_n, k_n, y_n^-)(\cdot)$ uniformly converging to a backward trajectory of $(S)_p$ steering 0 to x in time not greater than T and with energy not greater than K, in contradiction with the hypothesis that $T < T_p(x, K)$.

In order to prove that $(\hat{T}_1)_* = T_1$, we observe that $T_1 \leq (\hat{T}_1)_*$ follows from the inequality $T_1 \leq \hat{T}_1$ and from the lower semicontinuity of T_1. The reverse inequality, instead, is an easy consequence of the fact that $\mathcal{R}_1(T, K) = \overline{\cap_{S>T} \hat{\mathcal{R}}_1(S, K)}$ for each $T \geq 0, K \geq 0$. □

Remark 2.3. The fact that T_p and E_p are lower semicontinuous functions for any $p \geq 1$ allowed us to characterize them together with their domains as the unique lower semicontinuous solutions, in the viscosity sense, of suitable boundary value problems (see [12]). Incidentally, the equalities $(\hat{T}_1)_* = T_1$ and $(\hat{E}_1)_* = E_1$ follow also as a by-product of the results in [12].

We end this section by stating the following last remarkable property of the reachable sets, which is well known if $p = +\infty$.

PROPOSITION 2.3. *For any $p \geq 1$, the set valued map $(T, K) \mapsto \mathcal{R}_p(T, K)$ is a continuous map from $[0, +\infty[\times[0, +\infty[$ to the space of compact subsets of $\mathbb{R}^n$, endowed with the Hausdorff distance.*

Proof. Let (T_0, K_0), $(T, K) \in [0, +\infty[\times[0, +\infty[$. If $T_0 \leq T$ and $K_0 \leq K$, one has $\mathcal{R}_p(T_0, K_0) \subset \mathcal{R}_p(T, K)$ and $\mathcal{R}_p(T_0, K_0) \subset B(\mathcal{R}_p(T, K), \varepsilon)$ $\forall \varepsilon > 0$. If $T_0 > T$ or $K_0 > K$, for any $x \in \mathcal{R}_p(T_0, K_0)$ let $(w_0, w) \in \mathcal{U}_p(T_0, K_0)$ be a control such that $|(w_0, w)|^p \leq 2^p(T_0 + K_0^p)$, and $y_0^-(1, w_0, w) = x$. Let us define the values $\sigma_1 \doteq \sup\{\sigma \in [0,1] : \int_0^\sigma w_0^p(s)\, ds \leq T\}$ and $\sigma_2 \doteq \sup\{\sigma \in [0,1] : \int_0^\sigma |w(s)|^p\, ds \leq K^p\}$. Hence the backward trajectories $(t, k, y^-)(\cdot) = (t, k, y_0^-)(\cdot, w_0, w)$ and $(t_{\sigma_1}, k_{\sigma_2}, y^-_{\sigma_1,\sigma_2})(\cdot) = (t, k, y_0^-)(\cdot, w_0\chi_{[0,\sigma_1]}, w\chi_{[0,\sigma_2]})$ of $(S)_p$ satisfy the estimates

$$|t_{\sigma_1}(s) - t(s)| \leq \int_{\sigma_1}^1 w_0^p(s)\, ds \leq |T_0 - T|,$$

$$|k_{\sigma_2}(s) - k(s)| \leq \int_{\sigma_2}^1 |w(s)|^p\, ds \leq |K_0^p - K^p| \quad \forall s \in [0,1],$$

$$|y^-_{\sigma_1,\sigma_2}(1) - x| \leq \omega(|K_0^p - K^p| + |T_0 - T|),$$

where $\omega : [0, +\infty[\to [0, +\infty[$ is an increasing function, continuous at 0, such that $\omega(0) = 0$. This concludes the proof in that $\bar{x} \doteq y^-_{\sigma_1,\sigma_2}(1) \in \mathcal{R}_p(T, K)$ by definition and $\mathcal{R}_p(T_0, K_0) \subset B(\mathcal{R}_p(T, K), \omega([K_0^p - K^p] + [T_0 - T]))$. The proof is completed by switching (T_0, K_0) with (T, K). □

3. Main results. We split this section into three subsections. In subsection 3.1 we begin by showing that the upper semicontinuity and the Hölder continuity of $x \mapsto$

$T_p(x,K)$ and of $x \mapsto E_p(x,T)$ are equivalent to certain global topological properties of the reachable sets (see Theorems 3.1, 3.2). Furthermore, we give sufficient conditions for the upper semicontinuity of $T_p(x,K)$ and $E_p(x,T)$ in the pair of variables (x,K) and (x,T), respectively (see Theorem 3.3). After that we characterize the reachable sets and their boundaries by means of T_p and E_p (see Propositions 3.1, 3.2), and we get also a maximality property for T_p and E_p (see Proposition 3.3).

In subsection 3.2 we deal with the critical case $p = 1$. Here we prove that the original functions coincide with the extended functions under a (very natural) local controllability assumption (see Lemma 3.1 and Theorem 3.4). Therefore under such an assumption all the regularity results obtained in subsection 3.1 in the extended setting hold also for $\hat{E}_1$, $\hat{T}_1$, and $\hat{\mathcal{R}}_1(T,K)$ (see Corollaries 3.1, 3.2).

In subsection 3.3 we consider only the case $p > 1$, and we show that local controllability assumptions are sufficient for the local Hölder continuity of $x \mapsto E_p(x,T)$ and $x \mapsto T_p(x,K)$ (see Theorems 3.5, 3.6).

3.1. Global topological properties and regularity results for $p \geq 1$. Let us introduce and briefly comment on the *global topological properties* of the reachable sets that we will use in what follows.

(C.1) Fix $p \geq 1$ and $T > 0$. Then

$$\mathcal{R}_p(T,K) \subset \mathcal{R}_p^\circ(T, K+H) \qquad \forall K \geq 0 \ \forall H > 0.$$

(C.2) Fix $p \geq 1$ and $T > 0$. Then there exist $C_2(T)$ and $\bar{\delta} > 0$ such that

$$B(\mathcal{R}_p(T,K), C_2(T)H) \subset \mathcal{R}_p(T, K+H) \quad \forall K \geq 0,\ 0 \leq H \leq \bar{\delta}.$$

(C.3) Fix $p \geq 1$ and $K > 0$. Then

$$\mathcal{R}_p(T,K) \subset \mathcal{R}_p^\circ(T+S, K) \qquad \forall T \geq 0 \ \forall S > 0.$$

(C.4) Fix $p \geq 1$ and $K > 0$. Then there exist $\alpha \geq 1$ (*independent of* K), $C_4(K)$, and $\bar{\delta} > 0$ such that

$$B(\mathcal{R}_p(T,K), C_4(K)S^\alpha) \subset \mathcal{R}_p(T+S, K) \quad \forall T \geq 0,\ 0 \leq S \leq \bar{\delta}.$$

(C.5) Fix $p \geq 1$ and $K > 0$. Then

$$\mathcal{R}_p(T,K) \cap \mathcal{R}_p^\circ(K) \subset \mathcal{R}_p^\circ(T+S, K) \qquad \forall T \geq 0 \ \forall S > 0,$$

where $\mathcal{R}_p(K)$ is defined as in (2.2).

(C.6) Fix $p \geq 1$. Then for any T, $K > 0$ one has that

$$x \in \mathcal{R}_p^\circ(T,K) \Longrightarrow \exists \varepsilon > 0 \ \text{ s.t. } \ x \in \mathcal{R}_p^\circ(T-\varepsilon, K-\varepsilon).$$

Taking into account that the reachable sets depend here on *two* variables, conditions (C.1) and (C.3) are the natural generalization of the classical "expansion property" of the reachable sets defined, e.g., in [7]. Loosely speaking, they say that $\mathcal{R}_p(T,K)$ expands "well" if one increases either the variable K or the variable T at disposal. Conditions (C.2) and (C.4) are stronger than (C.1) and (C.3), respectively, giving also an estimate on the rate of such an expansion.

Condition (C.5) is a weaker version of (C.3), coinciding with it when the set $\mathcal{R}_p(K)$ is open. We are led to introduce it by the fact that in the case $p = 1$ condition (C.3) may be too strong a requirement (see Example 3.1 below). Condition (C.5)

instead is fulfilled, for instance, as soon as the reachable sets are convex and (C.1) holds (see Proposition 3.2). Hence in particular it always holds for linear controllable systems (see section 4). Incidentally, Example 3.2 shows that (C.5) can hold even if the reachable sets are not convex (and (C.3) does not hold).

In the classical minimum time problem for linear systems with compact valued controls, the convexity of the reachable sets yields the so-called maximality property, that is, for all points belonging to the boundary of the reachable set at time T the minimum time turns out to be equal to T (see, e.g., [7]). In what follows we will prove that, assuming (C.6), similar maximality properties for E_p and T_p hold also for our system. Notice that when the reachable sets $\mathcal{R}_p(T,K)$ are convex, condition (C.6) turns out to be verified in view of Proposition 2.3. This fact can be proved exactly as for $p=+\infty$ (see, e.g., [7]). Hence in particular (C.6) is always fulfilled if the control system is linear. However, Example 3.2 again shows that it can be fulfilled even if the reachable sets are not convex.

Example 3.1. Let us consider the (controllable) linear system $x'=\lambda x+u$, where $\lambda\in\mathbb{R}$, x, $u\in\mathbb{R}^n$.

(a) Let $p>1$ and consider $u\in\hat{\mathcal{U}}_p(T,K)$ for some T, $K>0$. It is not difficult to show that if $\lambda\neq 0$, one has

$$\mathcal{R}_p(T,K)=\hat{\mathcal{R}}_p(T,K)=\left\{x\in\mathbb{R}^n:\ |x|\le K\left(\frac{1-e^{-\lambda T p'}}{\lambda p'}\right)^{\frac{1}{p'}}\right\},$$

while if $\lambda=0$, one gets

$$\mathcal{R}_p(T,K)=\hat{\mathcal{R}}_p(T,K)=\left\{x\in\mathbb{R}^n:\ |x|\le KT^{\frac{1}{p'}}\right\}.$$

Therefore conditions (C.2) and (C.3) turn out to be always verified, while (C.4) is in force only in the case $\lambda<0$.

(b) Let $p=1$ and $u\in\hat{\mathcal{U}}_1(T,K)$ for some T, $K>0$. In this case one recovers that

$$\mathcal{R}_1(T,K)=\overline{\hat{\mathcal{R}}_1(T,K)}=\begin{cases}\{x\in\mathbb{R}^n:\ |x|\le e^{-\lambda T}K\} & \text{if } \lambda<0,\\ \{x\in\mathbb{R}^n:\ |x|\le K\} & \text{if } \lambda\ge 0.\end{cases}$$

Hence conditions (C.1) and (C.2) are always verified, while conditions (C.3) and (C.4) hold only in the case $\lambda<0$.

This example suggests that, at least for linear controllable systems, conditions (C.1), (C.2) for $p\ge 1$, and condition (C.3) in the case $p>1$, should be verified (see also section 4), while (C.3) for $p=1$ and condition (C.4) for all $p\ge 1$ are in fact very strong.

Example 3.2. Let us consider in $\mathbb{R}^2$ the system

$$\begin{cases}\dot{x}=-yu+(x+1)v,\\ \dot{y}=(x+1)u+yv\end{cases}$$

with $(u,v)\in\mathcal{U}_p(T,K)$ for T, $K>0$, and $p\ge 1$. With an obvious change of coordinates one can study the system

$$\begin{cases}\dot{x}=-yu+xv,\\ \dot{y}=xu+yv\end{cases}$$

with target $(-1,0)$, which in polar coordinates is given by $\dot\rho = \rho v$, $\dot\theta = u$. In these coordinates for each $T>0$ and $K>0$ the reachable set is given by

$$\mathcal{R}_p(T,K) - \{(-1,0)\} = \bigcup_{0\le k\le K^p} \left\{ (\rho,\theta) : |\theta| \le kT^{\frac{1}{p'}}, e^{-(K^p-k)^{\frac{1}{p}}T^{\frac{1}{p'}}} \le \rho \le e^{(K^p-k)^{\frac{1}{p}}T^{\frac{1}{p'}}} \right\}.$$

Therefore $\mathcal{R}_p(T,K)$ is not convex for every $T,K\ge 0$, but still condition (C.6) is verified for all $p\ge 1$. If $p>1$, condition (C.3) is also verified, while if $p=1$, only the weaker condition (C.5) is fulfilled. Incidentally, notice that in the case of controls (u,v) such that $|u|\le 1, |v|\le 1$, and without L^p-constraints, (C.6) is not verified (see, e.g., [1]).

THEOREM 3.1. *Fix $T>0$. For any $p\ge 1$, the function $E_p(\cdot,T)$ is upper semicontinuous in the set $\mathcal{S}_p(T)$ (defined as in* (2.2)*) and the set $\mathcal{S}_p(T)$ is open if and only if condition* (C.1) *is verified.*

Furthermore, condition (C.2) *is a necessary and sufficient condition for E_p to verify the inequality*

$$|E_p(x_1,T) - E_p(x_2,T)| \le |x_1-x_2|/C_2(T) \qquad \forall x_1,x_2\in\mathbb{R}^n,$$

where $C_2(T)$ is the same as in (C.2).

Proof. Let $x\in\mathcal{S}_p(T)$. In view of the existence of an optimal control for the minimum energy problem stated in Proposition 2.2, $x\in\mathcal{R}_p(T,E_p(x,T))$. Condition (C.1) easily implies that $\mathcal{S}_p(T)$ is open and it is verified if and only if for any $\varepsilon>0$ there is some $\delta>0$ such that $B(x,\delta)\subset\mathcal{R}_p(T,E_p(x,T)+\varepsilon)$ or equivalently if and only if $E_p(y,T)\le E_p(x,T)+\varepsilon \ \ \forall y\in B(x,\delta)$, that is, $E_p(\cdot,T)$ is upper semicontinuous in $\mathcal{S}_p(T)$. Notice that (C.2) implies $\mathcal{S}_p(T)=\mathbb{R}^n$. Furthermore, let $x_1,x_2\in\mathbb{R}^n$ be such that $|x_2-x_1|\le C_2(T)\bar\delta$, where $C_2(T)$ and $\bar\delta$ are the same as in (C.2), let $K \doteq E_p(x_1,T)$, and suppose that $E_p(x_2,T)>K$. In view of Proposition 2.2, $x_1\in\mathcal{R}_p(T,K)$ and, if (C.2) is verified, setting $H\doteq |x_1-x_2|/C_2(T)$ one has that $x_2\in\mathcal{R}_p(T,K+H)$. Hence $E_p(x_2,T)\le E_p(x_1,T)+|x_1-x_2|/C_2(T)$ and the statement of the second sufficient condition holds. The proof of the necessity can be obtained by reversing the previous arguments.

Finally, it is easy to extend these results to all $x_1,x_2\in\mathbb{R}^n$. □

THEOREM 3.2. *Fix $K>0$. For any $p\ge 1$ the function $T_p(\cdot,K)$ is upper semicontinuous in the set $\mathcal{R}_p(K)$ (defined as in* (2.2)*) and the set $\mathcal{R}_p(K)$ is open if and only if condition* (C.3) *is verified.*

Furthermore, condition (C.4) *is a necessary and sufficient condition for T_p to verify the inequality*

$$|T_p(x_1,K) - T_p(x_2,K)| \le \left(\frac{|x_1-x_2|}{C_4(K)}\right)^{1/\alpha}$$

$\forall x_1,x_2\in\mathbb{R}^n$ such that $|x_1-x_2|\le C_4(K)\bar\delta^\alpha$, where $C_4(K)$, $\bar\delta$, and α are the same as in (C.4).

We omit the proof, since it is completely analogous to the proof of Theorem 3.1.

PROPOSITION 3.1. *Let $p\ge 1$ and $T,\ K>0$.*

(a) *One has*

$$\mathcal{R}_p(T,K) = \{x\in\mathbb{R}^n :\ T_p(x,K)\le T\} = \{x\in\mathbb{R}^n :\ E_p(x,T)\le K\}.$$

(b) (Characterization by means of E_p.) *If one assumes* (C.1) *and* (C.6), *one has*

$$\begin{aligned}\mathcal{R}_p^\circ(T,K) &= \{x\in\mathbb{R}^n:\ E_p(x,T)<K\},\\ \partial\mathcal{R}_p(T,K) &= \{x\in\mathbb{R}^n:\ E_p(x,T)=K\},\\ \mathcal{S}_p^\circ(T) &= \mathcal{S}_p(T)=\{x\in\mathbb{R}^n:\ E_p(x,T)<+\infty\}.\end{aligned}$$

(c) (Characterization by means of T_p.) *If one assumes* (C.3) *and* (C.6), *one has*

$$\begin{aligned}\mathcal{R}_p^\circ(T,K) &= \{x\in\mathbb{R}^n:\ T_p(x,K)<T\},\\ \partial\mathcal{R}_p(T,K) &= \{x\in\mathbb{R}^n:\ T_p(x,K)=T\},\\ \mathcal{R}_p^\circ(K) &= \mathcal{R}_p(K)=\{x\in\mathbb{R}^n:\ T_p(x,K)<+\infty\}.\end{aligned}$$

(d) *If* (C.1) *is assumed and the reachable sets are convex, then*

$$\mathcal{R}_p^\circ(K)=\{x\in\mathbb{R}^n : T_p(x,K)<+\infty \text{ and } E_p(x,T)<K \quad \forall T>T_p(x,K)\}. \tag{3.1}$$

(e) *If* (C.6) *is assumed, the relation* (3.1) *is equivalent to* (C.5).

Proof. Statement (a) is immediate because of the existence of extended optimal controls. The inclusions $\mathcal{R}_p^\circ(T,K)\subset\{x\in\mathbb{R}^n:\ E_p(x,T)<K\}$ and $\mathcal{R}_p^\circ(T,K)\subset\{x\in\mathbb{R}^n:\ T_p(x,K)<T\}$ follow by (C.6). To prove the first equality in (b) let us observe that (C.1) implies that

$$\mathcal{R}_p(S,H)\subset\mathcal{R}_p(T,H)\subset\mathcal{R}_p^\circ(T,K)\quad\forall 0<S<T\ \text{ and }\ \forall 0<H<K.$$

Let $x\in\mathbb{R}^n$ be such that $K'\doteq E_p(x,T)<K$. In view of the above inclusions, it suffices to show that

$$x\in\mathcal{R}_p(S,H)\qquad\text{for some } S<T \text{ and } H<K. \tag{3.2}$$

If the optimal control (w_0,w) associated with $E_p(x,T)$ is such that $T'\doteq\int_0^1 w_0^p\,ds<T$, (3.2) is verified for $S=T'$, and $H=K'$. Otherwise, i.e., in the case $T'=T$, then $x\in\mathcal{R}_p(T,K')$ and by (C.1) $x\in\mathcal{R}_p^\circ(T,H)$ for any $K'<H<K$. Hence by (C.6) there exists some $\varepsilon>0$ such that $x\in\mathcal{R}_p(T-\varepsilon,H-\varepsilon)$ and (3.2) is verified for $S=T-\varepsilon$ and $H=H$. The second statement of (b) follows from (a) and from the first part of (b), in view of the fact that the sets $\mathcal{R}_p(T,K)$ are closed. The third statement is a straightforward consequence of (C.1). All the equalities in (c) can be proved in a similar way. To prove (3.1), notice that the inclusion $\mathcal{R}_p^\circ(K)\supset\cup_{T>0}\mathcal{R}_p^\circ(T,K)$ is always verified. If the sets $\mathcal{R}_p(T,K)$ are convex, the converse inclusion is a consequence of the fact that they are closed. Otherwise, since from the previous characterization of $\mathcal{R}_p^\circ(T,K)$ it follows that $\cup_{T>0}\mathcal{R}_p^\circ(T,K)=\{x\in\mathbb{R}^n : T_p(x,K)<+\infty \text{ and } E_p(x,T)<K \text{ for some } T>T_p(x,K)\}$, thus, to conclude, it remains to show that $T_p(x,K)=\inf\{T>0:\ E_p(x,T)<K\}$. Suppose that $\bar T\doteq\inf\{T>0:\ E_p(x,T)<K\}>T_p(x,K)$. Since the function E_p is lower semicontinuous and decreasing in T, $\bar T$ is in fact a minimum and $K'\doteq E_p(x,\bar T)<K$. Thus $x\in\mathcal{R}_p(\bar T,K')$ and (C.1) implies that $x\in\mathcal{R}_p^\circ(\bar T,K)$. By (C.6), $x\in\mathcal{R}_p(\bar T-\varepsilon,K-\varepsilon)$ for some $\varepsilon>0$, so that $E_p(x,S)\le K-\varepsilon$ for all $S\in[\bar T-\varepsilon,\bar T[$, in contradiction with the definition of $\bar T$.

The implication (3.1) $\Longrightarrow$ (C.5) is clear. Conversely, condition (C.5) means that for all $x\in\mathcal{R}_p^\circ(K)$ one has $x\in\mathcal{R}_p^\circ(T,K)\ \ \forall T>T_p(x,K)$, and (C.6) yields that $x\in\mathcal{R}_p(T-\varepsilon,K-\varepsilon)$ for some $\varepsilon>0$. Hence $E_p(x,T)<K\ \forall T>T_p(x,K)$ and the equivalence is proved. ∎

PROPOSITION 3.2. *Let $p \geq 1$.*

(a) *If* (C.1) *and* (C.6) *are assumed, $Dom(E_p)$ is an open set.*

(b) *If* (C.3) *and* (C.6) *are assumed, $Dom(T_p)$ is an open set.*

(c) *If* (C.1) *is assumed and either the reachable sets are convex or* (C.6) *and* (C.5) *are assumed, then $Dom(T_p)$ is not necessarily open but one has that*

$$Dom(T_p)^\circ = \cup_{K>0} \mathcal{R}_p^\circ(K) \times \{K\},$$

where $\mathcal{R}_p^\circ(K)$ is given in (3.1).

Proof. We prove only (c), the proofs of (a) and (b) being similar and, in fact, easier. We begin by showing that for all $p \geq 1$, $\cup_{K>0} \mathcal{R}_p^\circ(K) \times \{K\}$ is an open set. Indeed, given $x \in \mathcal{R}_p^\circ(K)$, by (C.6) and Proposition 3.1 it follows that there exist ε and $\delta > 0$ such that $B(x,\delta) \subset \mathcal{R}_p^\circ(K-\varepsilon)$. Hence $(y,H) \in R_p^\circ(H) \times \{H\}$ $\forall (y,H) \in B(x,\delta) \times]K-\varepsilon, +\infty[$. This concludes the proof if the sets $\mathcal{R}_p(H)$ are open; otherwise, it remains to show that $Dom(T_p)^\circ \subset \cup_{K>0} \mathcal{R}_p^\circ(K) \times \{K\}$. Let $(x,K) \in Dom(T_p)^\circ$. Since $B((x,K),\delta) \subset Dom(T_p)$ for some $\delta > 0$, we have, in particular, that $x \in \mathcal{R}_p(K-\delta)$, so that $E_p(x,T) < K$ for some T. In view of Proposition 3.1, this is equivalent to claim that $x \in \mathcal{R}_1^\circ(K)$. ∎

As already remarked, the controllability assumptions (C.1)–(C.4) yield continuity results only for the maps $x \mapsto E_p(x,T)$ and $x \mapsto T_p(x,K)$. However, the dependence of $E_p(x,T)$ and $T_p(x,K)$ on the scalar variables T and K, respectively, is not trivial. For instance, the Hamilton–Jacobi–Bellman equations associated with E_p and T_p involve the derivatives $\partial E_p/\partial T$ and $\partial T_p/\partial K$, respectively, as suggested in the case $p > 1$ by the dynamic programming principles (TDPP) and (EDPP) stated in Proposition 3.4 below (see also Remark 2.3). Together with condition (C.5) and (C.1), condition (C.6) yields the continuity of the minimum time and of the minimum energy function on its whole domain, respectively, as shown in Theorem 3.3, and also the maximality properties stated in Proposition 3.3.

THEOREM 3.3. *Let $p \geq 1$.*

(a) *Assume* (C.5) *and* (C.6). *Then the minimum time function $T_p : Dom(T_p)^\circ \to [0, +\infty[$ is upper semicontinuous.*

(b) *Assume* (C.1) *and* (C.6). *Then the minimum energy function $E_p : Dom(E_p) \to [0, +\infty[$ is upper semicontinuous.*

Proof. Let $(x,K) \in Dom(T_p)^\circ$. Propositions 3.1 and 3.2 imply that $x \in \mathcal{R}_p^\circ(T_p(x,K) + \varepsilon, K)$ for any $\varepsilon > 0$, and by (C.6) it follows that there exists $\varepsilon' > 0$ such that $x \in \mathcal{R}_p^\circ(T_p(x,K) + \varepsilon - \varepsilon', K - \varepsilon')$, so that $B(x,\delta) \subset \mathcal{R}_p(T_p(x,K) + \varepsilon - \varepsilon', K - \varepsilon')$ for some $\delta > 0$. Hence $T_p(y,H) \leq T_p(x,K) + \varepsilon$ $\forall y \in B(x,\delta)$ $\forall H > K - \varepsilon'$ and this concludes the proof. The proof concerning E_p follows the same lines. ∎

PROPOSITION 3.3. *Let $p \geq 1$, and assume* (C.1), (C.6).

(a) *Fix $K > 0$. Then*

$$E_p(x, T_p(x,K)) = K \qquad \forall x \in \mathcal{R}_p(K) \setminus \mathcal{R}_p(0,K).$$

(b) *Assume* (C.3) *and fix $T > 0$. Then*

$$T_p(x, E_p(x,T)) = T \qquad \forall x \in \mathcal{S}_p(T) \setminus \mathcal{R}_p(T,0).$$

(c) *Assume* (C.5) *and fix $T > 0$. Then*

$$T_p(x, E_p(x,T)) = T \qquad \forall x \in \mathcal{R}_p^\circ(K) \setminus \mathcal{R}_p(T,0), \quad \text{where } K \doteq E_p(x,T).$$

Proof. Let $p \geq 1$, and let (x,K) be such that $T_p(x,K) > 0$. By the existence of the optimal control for the minimum time problem, we can assume that $E_p(x, T_p(x,K)) \leq$

K. Suppose that $E_p(x, T_p(x,K)) < K$. Since by definition one has that $E_p(x,T) \geq K$ $\forall T \in]0, T_p(x,K)[$, in view of Theorem 3.3 we find a contradiction with the fact that E_p is upper semicontinuous and decreasing in T. This yields statement (a). Since the function T_p is decreasing in K, the proof of (b) and (c) follows in an analogous way from Proposition 3.1(c) and Theorem 3.3. □

By the results in the appendix it follows that $\mathcal{R}_p(0,K) = \{0\}$ $\forall p > 1$. For $p = 1$ instead, the set $\mathcal{R}_1(0,K)$ is in general nontrivial, as shown, e.g., by Example 3.1(b). In this case the maximality property (a) above fails if $T_1(x,K) = 0$, that is, for $x \in \mathcal{R}_1(0,K)$. Indeed, $T_1(x,K') = 0$ $\forall K' \geq K$, so that $E_1(x, T_1(x,K')) = K < K'$ $\forall K' > K$. Analogous remarks hold for (b) and (c). Notice that under the assumptions made on the drift f in section 2, for any $p \geq 1$ the set $\mathcal{R}_p(T,0) = \{0\}$ if $f(0) = 0$.

3.2. Regularity results for $\hat{E}_1$ and $\hat{T}_1$. Our goal in this subsection is to prove that the original minimum time and minimum energy functions coincide, in fact, with the extended functions under the following *local controllability condition*:

(C.7) $\exists \hat{\varepsilon} > 0$ such that $\forall \varepsilon < \hat{\varepsilon}:$ $B(0,\delta) \subset \hat{\mathcal{R}}_1(\varepsilon,\varepsilon)$ for some $\delta > 0$.

LEMMA 3.1. *Let $p = 1$ and assume* (C.6) *and* (C.7). *Then*

$$\hat{\mathcal{R}}_1^\circ(T,K) = \mathcal{R}_1^\circ(T,K) \qquad \forall T, K > 0.$$

Proof. The inclusion $\hat{\mathcal{R}}_1^\circ(T,K) \subset \mathcal{R}_1^\circ(T,K)$ is trivial. To prove the converse inclusion, fix $x \in \mathcal{R}_1^\circ(T,K)$. Then (C.6) implies that $x \in \mathcal{R}_1^\circ(T-2\varepsilon, K-2\varepsilon)$ for some positive $\varepsilon < \hat{\varepsilon}$, where $\hat{\varepsilon}$ is the same as in (C.7). Fix $z \in B(x,\mu) \subset \mathcal{R}_1(T-2\varepsilon, K-2\varepsilon)$. Let (w_0, w) be a control such that $\int_0^1 w_0(s)\,ds \leq T-2\varepsilon$, $\int_0^1 |w(s)|\,ds \leq K-2\varepsilon$, and $y_z(1, w_0, w) = 0$. Consider then the control $(w_0 + \frac{1}{n}, w)$ and denote by (t_n, k_n, y_n) the corresponding solution to $(S)_1$. In view of (C.7), let δ be such that $B(0,\delta) \subset \hat{\mathcal{R}}_1(\varepsilon,\varepsilon)$. By standard estimates it follows that $|y_n(1)| < \delta$ and $1/n \leq \varepsilon$ for n large enough, so that $y_n(1) \in \hat{\mathcal{R}}_1(\varepsilon,\varepsilon)$ and hence $z \in \hat{\mathcal{R}}_1(T, K-\varepsilon)$ $\forall z \in B(x,\mu)$. Hence $x \in \hat{\mathcal{R}}_1^\circ(T,K)$. □

THEOREM 3.4. *Let $p = 1$ and assume* (C.6), (C.7).

(a) *If* (C.1) *is verified, then $\hat{E}_1 \equiv E_1$ in $\mathbb{R}^n \times]0, +\infty[$.*

(b) *If* (C.5) *is verified, then $\hat{T}_1 \equiv T_1$ in $Dom(\hat{T}_1)^\circ$. Moreover, $Dom(\hat{T}_1)^\circ = Dom(T_1)^\circ$.*

Proof. (a) Let $(x,T) \in \mathbb{R}^n \times]0, +\infty[$ and set $K \doteq E_1(x,T)$. If $K = +\infty$, then $\hat{E}_1(x,T) = +\infty$. Let $K < +\infty$. Since $x \in \mathcal{R}_1(T,K)$, in view of (C.1) one has that $x \in \mathcal{R}_1^\circ(T, K+\varepsilon)$ $\forall \varepsilon > 0$, and by Lemma 3.1 it follows also that $x \in \hat{\mathcal{R}}_1^\circ(T, K+\varepsilon)$ $\forall \varepsilon > 0$. Hence $\hat{E}_1(x,T) \leq E_1(x,T) + \varepsilon$ $\forall \varepsilon > 0$, and since ε is arbitrary we get $\hat{E}_1(x,T) = E_1(x,T)$.

(b) Let $x \in \mathcal{R}_1^\circ(K)$ and assume (C.5). By Proposition 3.2(e), it follows that $E_1(x,T) < K$ $\forall T > T_1(x,K)$, or equivalently that x belongs to $\mathcal{R}_1^\circ(T_1(x,K) + \varepsilon, K)$ for any $\varepsilon > 0$. In view of Lemma 3.1, this implies that $x \in \hat{\mathcal{R}}_1^\circ(T_1(x,K) + \varepsilon, K)$. Hence $\hat{T}_1(x,K) \leq T_1(x,K) + \varepsilon$ for any $\varepsilon > 0$, which yields $\hat{T}_1(x,K) = T_1(x,K)$ $\forall (x,K) \in Dom(T_1)^\circ$ and also $Dom(\hat{T}_1)^\circ = Dom(T_1)^\circ$, in that $T_1(x,K) = +\infty$ implies $\hat{T}_1(x,K) = +\infty$. □

Taking into account Lemma 3.1 and Theorem 3.4, the following results for $\hat{E}_1$ and $\hat{T}_1$ are straightforward consequences of Propositions 3.1 and 3.3 and Theorems 2.1 and 3.3.

COROLLARY 3.1. *Let $p = 1$ and assume* (C.1), (C.6), *and* (C.7). *Then*

(a) *$Dom(\hat{E}_1)$ is an open set and $\hat{E}_1$ is upper semicontinuous in $Dom(\hat{E}_1)$ and lower semicontinuous in $\overline{Dom(\hat{E}_1)}$;*

(b) *if* (C.5) *holds, then for any $K > 0$ one has $\hat{E}_1(x, \hat{T}_1(x, K)) = K$ $\forall x \in \hat{\mathcal{R}}_1^\circ(K) \setminus \mathcal{R}_1(0, K)$.*

(c) *If* (C.2) *holds, then for any $T > 0$ one has $\hat{\mathcal{S}}_1(T) = \mathbb{R}^n$ and there exists $L_1 > 0$ such that for all $x_1, x_2 \in \mathbb{R}^n$ one has*

$$|\hat{E}_1(x_2, T) - \hat{E}_1(x_1, T)| \le L_1 |x_2 - x_1|.$$

COROLLARY 3.2. *Let $p = 1$ and assume* (C.5), (C.6), *and* (C.7). *Then we have the following:*

(a) *$Dom(\hat{T}_1)^\circ = \cup_{K>0}(\hat{\mathcal{R}}_1^\circ(K) \times \{K\})$, and $\hat{T}_1$ is upper semicontinuous in $Dom(\hat{T}_1)^\circ$ and lower semicontinuous in $\overline{Dom(\hat{T}_1)}$. If* (C.3) *holds, then $Dom(\hat{T}_1)$ is open.*

(b) *If* (C.1) *holds, then $\hat{T}_1(x, \hat{E}_1(x, T)) = T$ $\forall x \in \hat{\mathcal{R}}_1^\circ(K) \setminus \hat{\mathcal{R}}_1(T, 0)$, where $K = \hat{E}_1(x, T)$. If* (C.3) *holds, then $\hat{T}_1(x, \hat{E}_1(x, T)) = T$ $\forall x \in \hat{\mathcal{S}}_1(T) \setminus \hat{\mathcal{R}}_1(T, 0)$.*

(c) *If* (C.4) *holds, then for any $K \ge 0$ one has $\hat{\mathcal{R}}_1(K) = \mathbb{R}^n$ and there exists $L_2 > 0$ such that*

$$|\hat{T}_1(x_1, K) - \hat{T}_1(x_2, K)| \le L_2 |x_1 - x_2|^{1/\alpha}$$

$\forall x_1, x_2 \in \mathbb{R}^n$ such that $|x_1 - x_2|$ is small enough and where α is the same as in (C.4).

3.3. Local controllability conditions and regularity results for $p > 1$. In line with what has already been done for linear systems in the case $p > 1$ and for nonlinear systems for $p = \infty$, we prove *local* versions of Theorems 3.1 and 3.2 for $p > 1$ (see Theorems 3.5 and 3.6, respectively) using the following *local controllability conditions:*

(C.8) Fix $p > 1$. Assume that there are a constant $\bar{\varepsilon} > 0$ and an increasing function τ with $\tau(0) = 0$ such that for all $x_0 \in \mathcal{R}_p(T, K) \cap \{x : \ |x| \le \bar{\varepsilon}\}$ for some T, $K > 0$, one has

$$B(x_0, \tau(T)H) \subset \mathcal{R}_p(T, K + H) \qquad \forall \tau(T)H \le \bar{\varepsilon}.$$

(C.9) Fix $p > 1$. Assume that there are some σ, $\bar{\varepsilon} > 0$, and $\alpha \ge 1$ such that

$$B(0, \sigma K S^\alpha) \subset \mathcal{R}_p(S, K) \quad \forall S, K \ge 0 \quad \text{such that} \quad \sigma K S^\alpha \le \bar{\varepsilon}.$$

Notice that, even if (C.8) is a local condition, it differs essentially from assumption (C.9) and, more generally, from the usual local controllability conditions, where one assumes that there exists a ball centered at the origin contained in any reachable set in small time (and with small energy, in our case). Indeed, condition (C.8) requires that around the origin the reachable sets display a "good expandability" property in the K-variable. More precisely, one has to have that for any x_0 near the origin and belonging to some $\mathcal{R}_p(T, K)$, there exists some $\sigma > 0$ such that all the points in $B(x_0, \sigma H)$ can reach the origin using controls with energy less than or equal to $K + H$. Finally, we refer to Remark 3.1 and Example 3.3 below for some considerations about the local controllability conditions and the regularity for $p = 1$.

The proofs of Theorems 3.5 and 3.6 below are based on the following dynamic programming principles.

PROPOSITION 3.4. *Let $p > 1$. For every $(x, T) \in (\mathbb{R}^n \setminus \{0\}) \times [0, +\infty[$ and every $S \le T$ one has*

$$\text{(EDPP)} \quad E_p^p(x,T) = \inf \left\{ \int_0^S |u|^p \, dt + E_p^p\big(y_x(S,u), T-S\big) : \ u \in L^p([0,S], \mathbb{R}^m) \right\}.$$

For every $(x, K) \in (\mathbb{R}^n \setminus \{0\}) \times [0, +\infty[$ and every $T \le T_p(x, K)$ one has

$$T_p(x,K) = \inf \left\{ T + T_p \left(y_x(T,u), \left(K^p - \int_0^T |u|^p \, dt \right)^{\frac{1}{p}} \right) : \right.$$

$$\text{(TDPP)} \qquad \left. u \in L^p([0,T], \mathbb{R}^m), \quad \int_0^T |u|^p \, dt \le K^p \right\}.$$

THEOREM 3.5. *Let $p > 1$, and suppose that condition* (C.8) *is verified. Then for fixed T, $K > 0$, and $N > 0$ there exists some $L_2 > 0$ such that for all $x_1, x_2 \in R_p(T,K) \cap \{x : \ |x| \le N\}$ one has*

$$|E_p(x_2,T) - E_p(x_1,T)| \le L_2 |x_2 - x_1|^{\frac{1}{p}}.$$

Moreover, $\mathcal{S}_p(T)$ is an open set.

Proof.

Step 1. Let $x_1, x_2 \in S_p(T) \cap \{x : \ |x| \le N\}$, let $K_1 \doteq E_p(x_1, T)$, and suppose that $E_p(x_2, T) > K_1$. In view of Proposition 2.2 and Remark 2.2, there exists an optimal control u such that $E_p(x_1, T) = (\int_0^T |u|^p \, dt)^{1/p}$. Let $\bar{t} < T$ be the first time such that $y_{x_1}(\bar{t}, u) \in \partial B(0, \bar{\varepsilon})$. Since $p > 1$, by the estimates

$$\sup_{t \in [0,T]} |y_{x_1}(t,u)| \le \bar{C}_1 \doteq \left(M_f + \sum_{i=1}^m M_{g_i} \right) (1+N) e^{M_f T + \sum_{i=1}^m M_{g_i} K_1 T^{1/p'}} \tag{3.3}$$

and

$$\begin{aligned} \bar{\varepsilon} = |y_{x_1}(\bar{t},u)| &= \left| \int_{\bar{t}}^T \left[f(y_{x_1}(t,u)) + \sum_{i=1}^m g_i(y_{x_1}(t,u)) u_i(t) \right] dt \right| \\ &\le (1 + \bar{C}_1) \left[M_f (T - \bar{t}) + K_1 \sum_{i=1}^m M_{g_i} (T - \bar{t})^{1/p'} \right] \end{aligned}$$

it follows that there is some positive constant $\bar{C}_2$ such that

$$T - \bar{t} \ge \left[\frac{\bar{\varepsilon}}{\bar{C}_2} \right]^{p'}. \tag{3.4}$$

Moreover, similar standard estimates yield that

$$|y_{x_2}(\bar{t},u) - y_{x_1}(\bar{t},u)| \le |x_2 - x_1| e^{L_f \bar{t} + \sum_{i=1}^m L_{g_i} K_1 \bar{t}^{1/p'}},$$

where L_f and L_{g_i} $(i = 1, \dots, n)$ depend on the compact set to which $y_{x_1}(t,u)$ and $y_{x_2}(t,u)$ belong for all $t \in [0,T]$.

Step 2. Let us first consider only x_1, x_2 such that

$$|x_2 - x_1| \le \rho_{x_1} \doteq \bar\varepsilon / e^{L_f T + \sum_{i=1}^m L_{g_i} K_1 T^{1/p'}},$$

and let

$$H \doteq \frac{|x_2 - x_1| e^{L_f T + \sum_{i=1}^m L_{g_i} K_1 T^{1/p'}}}{\tau\left(\left[\frac{\bar\varepsilon}{\bar C_2}\right]^{p'}\right)}.$$

Hence by applying (C.8) to $x_0 \doteq y_{x_1}(\bar t, u) \in \mathcal{R}_p(T - \bar t, (K^p - \int_0^T |u|^p\, dt)^{1/p})$ we have that $y_{x_2}(\bar t, u) \in \mathcal{R}_p(T - \bar t, (K_1^p - \int_0^T |u|^p\, dt)^{1/p} + H)$, which, in view of (EDPP), yields

$$E_p(x_2, T) - E_p(x_1, T) \le \left(\int_0^T |u|^p\, dt + \left[\left(K_1^p - \int_0^T |u|^p\, dt\right)^{1/p} + H\right]^p\right)^{1/p} - K_1.$$

By assuming $H \le 1$, straightforward calculations lead to the local Hölder continuity estimate of the statement for some $L_2 > 0$.

Step 3. By a standard compactness argument, the above estimate on the local Lipschitz continuity can be easily extended to the whole set $\mathcal{R}_p(T, K) \cap \{x : |x| \le N\}$. Moreover, since for any $x_1 \in \mathcal{S}_p(T)$ there are some $K > 0$ and some $N > 0$ such that $x_1 \in \mathcal{R}_p(T, K) \subset \{x : |x| \le N\}$, by the previous steps it follows that there is some $\rho_{x_1} > 0$ such that $B(x_1, \rho_{x_1}) \subset \mathcal{S}_p(T)$. Hence $\mathcal{S}_p(T)$ turns out to be open. ∎

THEOREM 3.6. *Let $p > 1$, and suppose that condition* (C.9) *is verified. Then, for fixed T, K, and $N > 0$ there exists some $L_4 > 0$ such that for all $x_1, x_2 \in \mathcal{R}_p(T, K) \cap \{x : |x| \le N\}$ one has*

$$|T_p(x_1, K) - T_p(x_2, K)| \le L_4 |x_1 - x_2|^{\frac{1}{\alpha p'}}.$$

Moreover, $\mathcal{R}_p(K)$ is an open set.

Proof.

Step 1. Let $x_1, x_2 \in \mathcal{R}_p(K) \cap \{x : |x| \le N\}$ such that $|x_1 - x_2| \le 1$, let $T_1 \doteq T_p(x_1, K)$, and suppose that $T_p(x_2, K) > T_1$. In view of Proposition 2.2 and Remark 2.2, there exists an optimal control u such that $(\int_0^{T_1} |u|^p\, dt)^{1/p} \le K$ and $y_{x_1}(T_1, u) = 0$. Following [6], let $\lambda \doteq 1 - |x_2 - x_1|$ and consider the trajectory $y_{x_2}(\cdot, \lambda u)$. Since $(K^p - \lambda^p K^p)^{1/p} > K(1 - \lambda)^{1/p}$, by (TDPP) it follows that

$$T_p(x_2, K) \le T_1 + T_p\left(y_{x_2}(T_1, \lambda u), K(1 - \lambda)^{1/p}\right).$$

Standard estimates yield that

$$|y_{x_2}(T_1, \lambda u)| \le (1 + \bar C_1)\left[K T_1^{1/p'} \sum_{i=1}^m M_{g_i} e^{L_f + \sum_{i=1}^m L_{g_i} K T_1^{1/p'}}\right] |x_2 - x_1|$$

for some constant $\bar C_1 > 0$, where L_f and L_{g_i} $(i = 1, \dots, n)$ depend on the compact set to which $y_{x_2}(t, \lambda u)$ and $y_{x_1}(t, u)$ belong for all $t \in [0, T]$.

Step 2. Let us first consider only x_1, x_2 such that

$$|x_2 - x_1| \le \rho_{x_1} \doteq \bar\varepsilon / (1 + \bar C_1)\left[K T_1^{1/p'} \sum_{i=1}^m M_{g_i} e^{L_f + \sum_{i=1}^m L_{g_i} K T_1^{1/p'}}\right],$$

so that by (C.9) and by the definition of λ it follows that

$$T_p\left(y_{x_2}(T_1,\lambda u),K(1-\lambda)^{1/p}\right)\le\left[\frac{|y_{x_2}(T_1,\lambda u)|}{\sigma K(1-\lambda)^{1/p}}\right]^{1/\alpha}$$

$$\le\left[\frac{(1+\bar C_1)\left[T_1^{1/p'}\sum_{i=1}^m M_{g_i}e^{L_f+\sum_{i=1}^m L_{g_i}KT_1^{1/p'}}\right]}{\sigma}|x_2-x_1|^{1/p'}\right]^{1/\alpha}. \tag{3.5}$$

At this point (TDPP) leads to the local Hölder continuity estimate

$$T_p(x_2,K)-T_p(x_1,K)\le L_4|x_2-x_1|^{\frac{1}{\alpha p'}},$$

where L_4 denotes the constant written above.

Step 3. In the same way as in Theorem 3.5, this result can be extended to the whole set $\mathcal{R}_p(T,K)\cap\{x:\ |x|\le N\}$, and $\mathcal{R}_p(K)$ turns out to be open. □

We point out that under condition (C.4) the exponent of Hölder continuity of the minimum time function $T_p(\cdot,K)$ obtained in Theorem 3.2 is $1/\alpha$, which is larger than the exponent $1/\alpha p'$ given in Theorem 3.6 under the weaker condition (C.9). For instance, in Example 3.1 and for $\lambda<0$, Theorem 3.2 yields the local Lipschitz continuity of $T_p(\cdot,K)$ for every $p>1$. Notice though that if only (C.9) is in force, the exponent $1/\alpha p'$ cannot be, in general, improved (see [6]). Analogously, condition (C.2) yields the Lipschitz continuity of E_p (this is the case of controllable linear systems) while condition (C.8) yields only its Hölder continuity.

As straightforward consequences of Theorems 3.1, 3.5 and of Theorems 3.2, 3.6, respectively, one has the following results.

COROLLARY 3.3. *Let $p>1$ and assume* (C.8). *Then the global topological property* (C.1) *turns out to be verified.*

COROLLARY 3.4. *Let $p>1$ and assume* (C.9). *Then the global topological property* (C.3) *turns out to be verified.*

Remark 3.1. If $p=1$, the arguments used in the proofs of Theorems 3.5 and 3.6 do not work, even if we consider the extended minimum time and minimum energy functions (and the corresponding dynamic programming principles). More precisely, both the crucial estimates (3.4) and (3.5) are in force thanks only to the fact that $1-\frac{1}{p}>0$. In fact, no regularity property of $T_1(\cdot,K)$ can be propagated in the whole set $\mathcal{R}_1(K)$ from properties of the system in a neighborhood of the target, as shown by the following example.

Example 3.3. Let us consider the (controllable) linear control system introduced in Example 3.1(b). In the case $\lambda\ge 0$ one has that $\mathcal{R}_1(K)=\mathcal{R}_1(T,K)=\overline{B(0,K)}$. Hence the set $\mathcal{R}_1(K)$ turns out to be closed even if (C.9) is verified. On the contrary, a regularity result for $\hat T_1$ similar to the one obtained in Theorem 3.6 for $p>1$ would actually imply that $\mathcal{R}_1(K)$ is open.

4. Sufficient controllability conditions. In this section we prove that for linear systems the classical Kalman condition implies the topological properties and the local controllability conditions introduced in the previous sections. In the general case of nonlinear systems, we show how a well-known controllability condition around the target yields some of the local controllability assumptions introduced in section 3.

We start by considering a linear control system of the form

$$\dot{y} = Ay + Bu, \tag{L}$$

where A is an $n \times n$ and B is an $n \times m$-real matrix. Let us introduce the Kalman condition

$$\{i : \ \mathrm{rank}[B, AB, \dots, A^i B] = n\} \neq \emptyset, \tag{$\mathcal{K}$}$$

and let $r \doteq \min\{i : \ \mathrm{rank}[B, AB, \dots, A^i B] = n\}$. If $p = +\infty$, it is well known that ($\mathcal{K}$) is necessary and sufficient for the continuity, in fact, for the Hölder continuity, of the minimum time function—see, e.g., [9]. Results on the continuity of $(x, T) \mapsto E_p(x, T)$ for $T > 0$ and on the Hölder continuity of $x \mapsto T_p(x, K)$ for $K > 0$ (for linear control systems) can already be found in [4] and [6] but only in the case $p > 1$.

LEMMA 4.1. *Consider system* (L).

(a) *For every $p \geq 1$, $T > 0$, and $K > 0$, the set $\hat{\mathcal{R}}_p(T, K)$ is convex and*

$$\mathcal{R}_p(T, K) = K\mathcal{R}_p(T, 1). \tag{4.1}$$

(b) *Assume* ($\mathcal{K}$). *Then conditions* (C.1), (C.2), (C.5), *and* (C.6) *are verified for all $p \geq 1$. If $p = 1$, condition* (C.7) *also holds.*

(c) *Assume* ($\mathcal{K}$), *and let $p > 1$. Then condition* (C.9), *with $\alpha \doteq \frac{1}{p'} + r$, and condition* (C.3) *are verified.*

Proof. The homogeneity property (4.1) is proved for $p = 1$ in [8], and one can easily extend the proof to the case $p > 1$. By ($\mathcal{K}$) the dimension of $\mathcal{R}_p(T, K)$ is n, and this together with (4.1) implies (C.1) for $p \geq 1$. In order to prove (C.2), fix $T > 0$ and let $x \in \mathcal{R}_p(T, K)$ for some $K > 0$. By ($\mathcal{K}$), for any $H > 0$ it is possible to find (see, e.g., [8]) $n+1$ controls $u_1, \dots, u_{n+1}$ such that $\int_0^T |u_i(t)|^p \, dt \leq H^p$, with $|u_i(t)| = \frac{H}{T^{1/p}}$ for $t \in [0, T]$, $i = 1, \dots, n+1$, and such that, denoting by $y_i \doteq \int_0^T e^{(T-t)A} B u_i(t) \, dt$, the convex hull generated by $\{x + y_i, i = 1, \dots, n+1\}$ contains a ball $B(x, \delta)$. Moreover it is also easy to show following [9] that there exist some constants $\bar{\delta} > 0$ and $C_0 > 0$ such that for any $T > 0$ one has $\delta \geq C_0 \frac{H}{T^{1/p}} T^r$ for all $H \leq \bar{\delta}$. Hence (C.2) turns out to be verified by setting, e.g., $C_2(T) = C_0 \frac{T^r}{T^{1/p}}$. Since the (original) reachable sets are convex and $\overline{\hat{\mathcal{R}}_1(T, K)} = \mathcal{R}_1(T, K)$ the previous result yields (C.7) for $p = 1$, and by Proposition 3.2 it also follows that (C.6) is verified and (C.1) implies (C.5). The proof of (C.9) follows from [17] (see also [6]). Finally, by Corollary 3.4 it follows that (C.9) implies (C.3). □

Owing to Lemma 4.1, the following results on the minimum time and the minimum energy functions are straightforward consequences of the propositions and the theorems in section 3.

COROLLARY 4.1. *Consider system* (L), *assume* ($\mathcal{K}$), *and let $p > 1$. Then we have the following:*

(a) *$Dom(E_p) = \mathbb{R}^n \times]0, +\infty[$, and the map E_p is continuous on it and lower semicontinuous on $\mathbb{R}^n \times [0, +\infty[$.*

(b) *For any $K > 0$, $E_p(x, T_p(x, K)) = K \ \ \forall x \in \mathcal{R}_p(K) \setminus \{0\}$, and $\mathcal{R}_p(K)$ is an open set.*

(c) *For any fixed $T > 0$ there exists $L_1 > 0$ such that for all $x_1, x_2 \in \mathbb{R}^n$ one has*

$$|E_p(x_2, T) - E_p(x_1, T)| \leq L_1 |x_2 - x_1|.$$

(d) *$Dom(T_p)$ is an open set and the map T_p is continuous on it and lower semicontinuous on $\overline{Dom(T_p)}$.*

(e) *For any* $T > 0$, $T_p(x, E_p(x,T)) = T \quad \forall x \in \mathbb{R}^n \setminus \mathcal{R}_p(T,0)$.

(f) *For any fixed* T, K, *and* $N > 0$ *there exists* $L_2 > 0$ *such that for every* $x_1, x_2 \in \mathcal{R}_p(T,K) \cap \{x : |x| \le N\}$ *one has*

$$|T_p(x_1,K) - T_p(x_2,K)| \le L_2 |x_1 - x_2|^{\frac{1}{\alpha p'}}.$$

COROLLARY 4.2. *Consider system* (L), *assume* ($\mathcal{K}$), *and let* $p = 1$. *Then we have the following:*

(a) $Dom(\hat{E}_1) = \mathbb{R}^n \times]0, +\infty[$, $\hat{E}_1$ *is continuous on* $\mathbb{R}^n \times]0,+\infty[$ *and lower semicontinuous on* $\mathbb{R}^n \times [0, +\infty[$.

(b) *For any* $K > 0$ $\hat{E}_1(x, \hat{T}_1(x,K)) = K \quad \forall x \in \hat{\mathcal{R}}_1^\circ(K) \setminus \mathcal{R}_1(0,K)$.

(c) *For any* $T > 0$ *there exists* $L_1 > 0$ *such that for all* $x_1, x_2 \in \mathbb{R}^n$ *one has*

$$|\hat{E}_1(x_2,T) - \hat{E}_1(x_1,T)| \le L_1 |x_2 - x_1|.$$

(d) $Dom(\hat{T}_1)^\circ = \cup_{K>0}(\hat{\mathcal{R}}_1^\circ(K) \times \{K\})$ *and* $\hat{T}_1$ *is continuous in* $Dom(\hat{T}_1)^\circ$ *and lower semicontinuous in* $\overline{Dom(\hat{T}_1)}$.

(e) *For any* $T > 0$ $\hat{T}_1(x, \hat{E}_1(x,T)) = T \quad \forall x \in \hat{\mathcal{R}}_1^\circ(K) \setminus \hat{\mathcal{R}}_1(T,0)$, *where* $K = \hat{E}_1(x,T)$. *If* (C.3) *holds, then* $\hat{T}_1(x, \hat{E}_1(x,T)) = T \quad \forall x \in \mathbb{R}^n \setminus \hat{\mathcal{R}}_1(T,0)$.

(f) *If* (C.4) *holds, then for any* $K \ge 0$ *the set* $\hat{\mathcal{R}}_1(K) = \mathbb{R}^n$ *and there exists* $L_2 > 0$ *such that*

$$|\hat{T}_1(x_1,K) - \hat{T}_1(x_2,K)| \le L_2 |x_1 - x_2|^{1/\alpha}$$

$\forall x_1, x_2 \in \mathbb{R}^n$ *such that* $|x_1 - x_2|$ *is small enough, where* α *is the same as in* (C.4).

In the framework of nonlinear control systems we prove that the following well-known assumption ($\mathcal{H}$) implies some of the *local* controllability conditions introduced in subsections 3.2 and 3.3 (see, e.g., [8]).

($\mathcal{H}$) $f(0) = 0$ and f is continuously differentiable in a neighborhood of the origin. Let $A \doteq \partial_x f(0)$ ($\partial_x f(0)$ denotes the Jacobian matrix of f in the origin) and $B \doteq (g_1(0), \dots, g_m(0))$; A and B verify ($\mathcal{K}$).

Let us recall that, as shown in section 3, local conditions alone are sufficient in order to obtain some partial regularity results for T_p and E_p only in the case $p > 1$ (see Theorems 3.5, 3.6). Any result for $p = 1$, instead, requires us to assume also some global topological properties of the reachable sets.

LEMMA 4.2. *Consider system* $(\hat{S})_p$ *and assume* ($\mathcal{H}$). *Then conditions* (C.9) *and* (C.3) *hold for* $p > 1$; *condition* (C.7) *holds for* $p = 1$.

Proof. The proof is based on an analogous result proved by Bianchini and Stefani in [1] for compact valued controls. In fact, it is possible to deduce from [1] that for any T and $K > 0$, denoting by $\mathcal{U}_\infty(T) \doteq \{u \in L^\infty([0,T], \mathbb{R}^m) : \ |u_i| \le K,\ i = 1, \dots, m\}$ and by $\mathcal{R}_\infty(T)$ the corresponding reachable set, for sufficiently small ε one has $B(0, \sigma K \varepsilon^\alpha) \subset \mathcal{R}_\infty(\varepsilon)$, where $\alpha \doteq 2r + 1 + \rho$. It is clear that if $u \in \mathcal{U}_\infty(T)$, then for $p \ge 1$ one has that $\frac{u}{m} \in \hat{\mathcal{U}}_p(T,K)$ if $T \le 1$. Therefore for sufficiently small ε, there exists a constant σ' such that $B(0, \sigma' K \varepsilon^\alpha) \subset \hat{\mathcal{R}}_p(\varepsilon, K)$. This implies (C.9) for $p > 1$ and (C.7) for $p = 1$; (C.3) follows by Corollary 3.2. □

As a consequence of this lemma, one has that under the hypotheses of Theorem 3.4 the extended problems are equivalent to the original ones for $p = 1$. Moreover, in view of Theorem 3.6, ($\mathcal{H}$) yields the regularity of $T_p(\cdot, K)$ for $p > 1$ and for any $K > 0$.

COROLLARY 4.3. *Assume* ($\mathcal{H}$). *Then for* $p > 1$, *fixed* T, K, *and* $N > 0$ *there exists* $L_4 > 0$ *such that for every* $x_1, x_2 \in \mathcal{R}_p(T,K) \cap \{x : |x| \le N\}$ *one has*

$$|T_p(x_1,K) - T_p(x_2,K)| \le L_4 |x_1 - x_2|^{\frac{1}{\alpha p'}},$$

with $\alpha = 2r + 1 + \rho$ $\forall \rho > 0$. *Moreover,* $\mathcal{R}_p(K)$ *is an open set.*

Remark 4.1. Due to Theorem 3.5, in order to check the local Hölder continuity of $E_p(\cdot, T)$, one should prove directly condition (C.8). As already remarked at the beginning of subsection 3.3, this condition is essentially different from usual local controllability conditions (for bounded valued control systems), and hence it cannot be easily deduced from them. We just mention that in Example 3.2 conditions (C.8) for $p > 1$ (in fact, also the stronger condition (C.2)) and (C.7) for $p = 1$ turn out to be verified. Moreover, for any control system which is linear just in a neighborhood of the origin and here verifies the Kalman condition, (C.8) for $p > 1$ holds.

Appendix. The following propositions clarify the relation between $(\hat{S})_p$ and $(S)_p$. We omit the proofs in the case $p > 1$, in that they are completely similar to the proofs given for more general nonlinear systems and for $p = 1$ in [11].

PROPOSITION A.1. *Fix* $p \geq 1$. *For every* $y(\cdot) = y(\cdot, u)$ *solution to* $(\hat{S})_p$ *in* $[0, T]$ *and for every increasing and surjective absolutely continuous map* $t : [0, 1] \to [0, T]$, *the graph parametrization* $(t, y \circ t)$ *of* y *is the* (t, y)*-component of a solution of* $(S)_p$ *associated with the control* $(w_0(s), w(s)) \doteq (\sqrt[p]{t'(s)}, \sqrt[p]{t'(s)}u(t(s)))$ *for a.e.* $s \in [0, 1]$.[1]

Moreover, if $s : [0, 1] \to [0, 1]$, $\sigma \mapsto s(\sigma)$, *is a nondecreasing and surjective absolutely continuous map, for every trajectory* $(t, k, y)(s) = (t, k, y)(s, w_0, w)$ *of* $(S)_p$ *the map* $(\hat{t}, \hat{k}, \hat{y})(\sigma) \doteq (t, k, y)(s(\sigma))$ $\forall \sigma \in [0, 1]$ *is still a solution to* $(S)_p$, *corresponding to the control* $(\hat{w}_0, \hat{w})$ *defined by* $\hat{w}_0(\sigma) \doteq w_0(s(\sigma))\frac{ds}{d\sigma}(\sigma)$ *and* $\hat{w}(\sigma) \doteq w(s(\sigma))\frac{ds}{d\sigma}(\sigma)$.

Due to the first part of Proposition A.1, the set of graphs of trajectories of $(\hat{S})_p$ can be identified with the subset of (t, y)-components of trajectories of $(S)_p$ with the corresponding control (w_0, w) such that $w_0 > 0$ a.e. In this sense $(S)_p$ can be considered as an extension of $(\hat{S})_p$.

For any $p \geq 1$, let $(w_0, w) \in L^p([0, 1], [0, +\infty[\times\mathbb{R}^m)$. If $(w_0, w) = 0$ a.e. in $[0, 1]$, we set

$$(w_0^c(s), w^c(s)) = (w_0(s), w(s)) \qquad \text{for a.e. } s \in [0, 1];$$

otherwise let $\sigma : [0, 1] \to [0, 1]$ be defined by

$$\sigma(s) \doteq \frac{\int_0^s |(w_0, w)(s')|^p \, ds'}{\int_0^1 |(w_0, w)(s')|^p \, ds'} \qquad \forall s \in [0, 1].$$

We set

$$\left(w_0^c(\sigma(s))\frac{d\sigma}{ds}(s), w^c(\sigma(s))\frac{d\sigma}{ds}(s)\right) = (w_0(s), w(s)) \qquad \text{for a.e. } s \in [0, 1]. \tag{A.1}$$

In principle (A.1) defines a multivalued control map. Yet (w_0^c, w^c) turns out to be uniquely determined a.e.

PROPOSITION A.2. *Fix* $p \geq 1$. *Given a control* $(w_0, w) \in L^p([0, 1], [0, +\infty[\times\mathbb{R}^m)$, *the expression* (2.2) *defines a measurable map* (w_0^c, w^c) *a.e. on* $[0, 1]$ *and* $|(w_0^c, w^c)|^p(s) = \int_0^1 |(w_0, w)|^p(s)\, ds$ *for a.e.* $s \in [0, 1]$. *The control* (w_0^c, w^c) *and the corresponding solution* $(t^c, k^c, y^c)(\cdot) \doteq (t, k, y)(\cdot, w_0^c, w^c)$ *to* $(S)_p$ *will be called the* canonical representatives *of* (w_0, w) *and of* $(t, k, y)(\cdot, w_0, w)$, *respectively. Moreover, the relation*

$$(t, k, y)\left(\sigma^{-1}(\{\xi\})\right) = (t^c, k^c, y^c)(\xi)$$

[1] If a control z is Lebesgue measurable, here and in what follows we assume to replace it with a Borel measurable control ζ such that $\zeta = z$ a.e., so that the composition with $t(s)$ is still measurable.

holds true for all $\xi \in [0,1]$.

Remark A.1. Due to Proposition A.2, the canonical representative of any control $(w_0, w) \in \mathcal{U}_p(T,K)$ is bounded, in that $|(w_0^c, w^c)|^p(s) \leq 2^p(T + K^p)$ for a.e. $s \in [0,1]$. Moreover, the reachable set $\mathcal{R}_p(T,K)$ and the minimum time and the minimum energy functions do not change if one considers only canonical representatives of controls. Hence in the extended problems one deals in fact with *bounded valued* controls.

Acknowledgment. We would like to sincerely thank Rosa Maria Bianchini for giving us very useful information about the controllability conditions in nonlinear systems and for her kind help.

LARGE DEVIATIONS FOR A RANDOM WALK MODEL WITH STATE-DEPENDENT NOISE*

MICHELLE BOUÉ†, DANIEL HERNÁNDEZ-HERNÁNDEZ‡, AND RICHARD S. ELLIS§

Abstract. In this paper we prove the large deviation principle for a class of random walks with state-dependent noise. This type of model has important applications in queueing and communication theory and in the area of stochastic approximation.

Key words. stochastic algorithms, large deviations, Laplace principle, weak convergence

AMS subject classifications. 60F10, 60K30

DOI. 10.1137/S0363012901396618

1. Introduction.

This paper is concerned with proving a large deviation principle for a certain class of random walks, where the evolution of the noise process depends on the state of the random walk. This type of model arises in a natural way in the study of recursive algorithms, which have important applications in queueing and communication theory and in the area of stochastic approximation. In fact, our main motivation for the study of these models is their application to the state-dependent stochastic approximation algorithms presented in [10]. The convergence and rate of convergence analysis of algorithms is, in general, difficult, and it is associated with the solution of a deterministic differential equation. This approach is developed in detail in [10], where a number of different models are analyzed, including classical models like Robbins–Monro and ARMAX. Further examples arising from nonlinear filtering and off-line identification can be found in [12] and from parameter tracking in [9].

A general recursive algorithm has the form

$$\theta_{k+1} = \theta_k + \gamma_k F(\theta_k, \eta_{k+1}), \quad k = 0, 1, \ldots, \tag{1.1}$$

with $\theta_k \in \mathbb{R}^d$, $\eta_k \in \mathbb{R}^m$, and $\{\gamma_k, k = 0, 1, \ldots\}$ is a sequence of positive numbers such that $\gamma_k \to 0$ as $k \to \infty$. As in the Robbins–Monro algorithm, θ_k represents an "estimate" of an object of interest, while η_k is a random variable (or observation) with distribution function possibly depending on previous estimates and observations. In our model η_k will represent the noise entering the system (1.1) and its distribution may be affected by θ_{k-1} and η_{k-1}. The sequence $\{\eta_k, k \in \mathbb{N}\}$ has its own structure, depending on the type of application at hand. It can have a linear structure, as in the identification problem described in [11], or nonlinear, as in the random direction problem in [10, p. 16]. Let us suppose that observations are given by the recursive formula

$$\eta_{k+1} = G(\theta_k, \eta_k, \nu_{k+1}), \quad k = 0, 1, \ldots, \tag{1.2}$$

where ν_k are $\mathbb{R}^d$ valued independent and identically distributed random variables with strictly positive density g and, for each k, ν_{k+1} is independent of $\theta_j,\ \eta_j,\ \ j \le k$. Assume that, given θ and η, $G(\theta,\eta,\cdot)$ is a diffeomorphism on $\mathbb{R}^m$ with inverse $H(\theta,\eta,\cdot)$. Then, given A, a Borel set in $\mathbb{R}^d$,

$$\begin{aligned}
&\text{Prob}[\eta_{k+1} \in A | \theta_0, \dots, \theta_k,\ \eta_0, \dots, \eta_k] \\
&= \text{Prob}[\nu_{k+1} \in H(\theta_k, \eta_k, A) | \theta_0, \dots, \theta_k,\ \eta_0, \dots, \eta_k] \\
&= \int_{H(\theta_k,\eta_k,A)} g(y)dy \\
&= \int_A g(H(\theta_k,\eta_k,y))|J(\theta_k,\eta_k,y)|dy,
\end{aligned}$$

where J is the Jacobian of H and $|J|$ denotes its determinant. From this argument it can be seen that, under broad general conditions on F, G, and g, the algorithm (1.1)–(1.2) satisfies Hypothesis H.1 below, so that the conclusions of our main theorem apply.

The model. Let $\mathcal{S}$ be a Polish space, and let $p(d\zeta|x,\xi)$ be a stochastic kernel on $\mathcal{S}$ given $\mathbb{R}^d \times \mathcal{S}$. For each $n \in \mathbb{N}$, we consider a sequence of random variables $\{(X_j^n, Z_j^n), j = 0, \dots, n\}$ defined on a probability space $(\Omega, \mathcal{F}, P)$ and taking values in $\mathbb{R}^d \times \mathcal{S}$. For $x \in \mathbb{R}^d$, $\xi \in \mathcal{S}$, and b a function mapping $\mathbb{R}^d \times \mathcal{S}$ into $\mathbb{R}^d$, this sequence is defined by setting $X_0^n \doteq x$, $Z_0^n \doteq \xi$, and letting

$$X_{j+1}^n \doteq X_j^n + \frac{1}{n} b(X_j^n, Z_{j+1}^n),$$

where for $j \in \{0, 1, \dots, n-1\}$ the conditional distribution of Z_{j+1}^n given the past is given by

$$P_{x,\xi}\left\{Z_{j+1}^n \in d\zeta | (X_i^n, Z_i^n), i = 0, \dots, j\right\} = p(d\zeta | X_j^n, Z_j^n). \tag{1.3}$$

Here $P_{x,\xi}$ denotes probability conditioned on $X_0^n = x$, $Z_0^n = \xi$. We assume that the stochastic kernel p and the function b satisfy the following hypothesis.

Hypothesis H.1.

(a) $b(x,\xi)$ is bounded, continuous in ξ, and Lipschitz continuous with constant K in x, uniformly in ξ.

(b) $p(d\zeta|x,\xi)$ is weakly continuous in (x,ξ), and there exist a probability measure ϑ on $\mathcal{S}$ and a measurable function $\tilde{p}^x(\xi,\zeta)$ on $\mathcal{S} \times \mathcal{S}$ such that

$$p(d\zeta|x,\xi) = \tilde{p}^x(\xi,\zeta)\vartheta(d\zeta).$$

(c) Given any compact set $\Delta \subset \mathbb{R}^d$, there exist constants $0 < a \le A < \infty$ such that

$$a \le \tilde{p}^x(\xi,\zeta) \le A$$

for all $x \in \Delta$. Moreover, $\tilde{p}^x(\xi,\zeta)$ is continuous in x uniformly in ξ and ζ, for $x \in \Delta$.

Let $X^n = \{X^n(t), 0 \le t \le 1\}$ be the piecewise linear interpolation on $[0,1]$ of $\{X_j^n, j = 0, \dots, n\}$. More precisely, for $t \in [j/n, (j+1)/n]$ and $j = 0, \dots, n-1$,

$$X^n(t) \doteq X_j^n + \left(t - \frac{j}{n}\right) b(X_j^n, Z_{j+1}^n). \tag{1.4}$$

The main result of the paper, Theorem 2.1, states the large deviation principle for the sequence $\{X^n, n \in \mathbb{N}\}$. Although our main theorem, Theorem 2.1, is closely related to

the results in [3], the proof there relies on technical assumptions for the function Λ (see (2.1) and (2.3) below), which is assumed to exist. Under Hypothesis H.1, the function Λ indeed exists and satisfies the technical assumptions required there (see section 4.3 in [3]), thereby implying the large deviation principle. However, our aim is to establish a more direct connection with the applications. The proof presented here depends on assumptions made on the evolution of the process itself (the transition kernels and the function b). This has several advantages. First, for the purposes of using the results in applications, assumptions must be made on the processes, since these are the type of assumptions that can be used there. Moreover, knowledge about the process provides a lot of intuition concerning the averaging procedure required for the proof. This intuition has been heavily exploited by some of the proofs of convergence of state-dependent stochastic algorithms (see [8, 10]), and we have incorporated some of their underlying ideas into the proof. Finally, seeing where each one of the properties of the process is needed in the proof has enabled us to understand the ergodicity properties required to extend our results to more general state-dependent processes. Extensions will be dealt with elsewhere.

2. The main theorem.

THEOREM 2.1. *Let $\mathcal{S}$ be compact. Under Hypothesis* H.1 *the sequence $\{X^n, n \in \mathbb{N}\}$ defined in* (1.4) *satisfies a large deviation principle with rate function $I_x(\cdot)$, where*

$$I_x(\phi) \doteq \begin{cases} \int_0^1 L(\phi, \dot{\phi})dt & \text{if } \phi \text{ is absolutely continuous and } \phi(0) = x, \\ \infty & \text{otherwise.} \end{cases}$$

Here $L(x, \cdot)$ is the Legendre–Fenchel transform with respect to the second variable of the function $\Lambda(x, \cdot)$, which is solution to the eigenvalue problem given by

$$e^{\Lambda(x,\alpha)+\Psi(\xi)} = \int_{\mathcal{S}} e^{\langle \alpha, b(x,\zeta)\rangle + \Psi(\zeta)} p(d\zeta|x, \xi). \tag{2.1}$$

That is, for x and β in $\mathbb{R}^d$,

$$L(x, \beta) \doteq \sup_{\alpha \in \mathbb{R}^d} \{\langle \alpha, \beta\rangle - \Lambda(x, \alpha)\}. \tag{2.2}$$

Remarks.

(1) We have made the strong assumption of compactness of the state space $\mathcal{S}$ in order to guarantee tightness of the measures involved in the proof (see part (a) of Theorem C.1). If the state space is not compact, further assumptions are required. These are discussed in section 5.

(2) $\mathcal{C}([0, 1] : \mathbb{R}^d)$ maps this space into $[0, \infty]$ and has compact level sets.

(3) For a fixed $x \in \mathbb{R}^d$, define the operator T on the set of bounded and measurable functions $\psi : \mathcal{S} \to \mathbb{R}$ as

$$T\psi(\xi) = \int_{\mathcal{S}} e^{\langle \alpha, b(x,\zeta)\rangle} \psi(\zeta) p(d\zeta|x, \xi).$$

The eigenvalue problem mentioned in (2.1) consists in finding the largest eigenvalue of this operator. Under Hypothesis H.1, Theorem 10.1 in [6] guarantees the existence and uniqueness of a solution to this problem, with a bounded and uniformly positive associated eigenfunction, corresponding to e^{Ψ} in (2.1). In fact, we can identify the solution function $\Lambda(x, \alpha)$ in a very explicit manner. Given $x \in \mathbb{R}^d$ and $\xi \in \mathcal{S}$, set

$\xi_0^x = \xi$ and let $\{\xi_j^x, j \geq 0\}$ be a Markov process with transition kernel $p(\cdot|x, \xi_j^x)$. Then the function $\Lambda(x, \alpha)$ satisfies

$$\Lambda(x,\alpha) = \lim_{N\to\infty} \frac{1}{N} \log E_\xi \left\{ \exp\left\langle \alpha, \sum_{j=1}^{N} b(x, \xi_j^x) \right\rangle \right\}, \tag{2.3}$$

where E_ξ denotes expectation conditioned on $\xi_0^x = \xi$. We refer to the process $\{\xi_j^x, j \geq 0\}$ as the "fixed x" process. As can be seen, it is the Markov chain that results if the parameter X_j^n in (1.3) is held constant at value x. This process is intimately connected with the process $\{X_j^n\}$. Indeed, if n is large, then X_j^n varies slowly and thus the "local" evolution of $b(X_j^n, Z_{j+1}^n)$ is very similar to the evolution of the same quantity but with X_j^n taken to be constant (see [10, sections 2.5 and 8.4]). This idea will be exploited heavily throughout the paper; we especially refer the reader to the proof of part (e) of Theorem C.1.

Let $W^n(x,\xi) \doteq -1/n \log E_{x,\xi} \{\exp[-nh(X^n)]\}$, with h in $\mathcal{C}([0,1] : \mathbb{R}^d)$. The proof of Theorem 2.1 is done in two parts. We start by proving an upper bound of the form

$$\liminf_{n\to\infty} W^n(x,\xi) \geq \inf_{\phi\in\mathcal{C}([0,1]:\mathbb{R}^d)} \{I_x(\phi) + h(\phi)\}. \tag{2.4}$$

This is the content of section 3. The lower bound

$$\limsup_{n\to\infty} W^n(x,\xi) \leq \inf_{\phi\in\mathcal{C}([0,1]:\mathbb{R}^d)} \{I_x(\phi) + h(\phi)\} \tag{2.5}$$

is then proved in section 4. These two inequalities are equivalent to a large deviation principle, as is proved in Theorems 2.2.1 and 2.2.3 in [4]. In both cases, a key step in the proof is based on studying (via weak convergence arguments) the limit properties of a sequence of associated stochastic control problems. The underlying simplicity of the basic arguments will be made clear below.

3. Proof of the upper bound. This section is devoted to the proof of (2.4). The proof can be summarized simply as follows. Based on the variational representation given in the next theorem, we associate with $W^n(x,\xi)$ an appropriate sequence of controlled processes and of control measures. The limit properties of this sequence, derived in Theorem C.1, will yield (2.4).

Let us start by introducing all the relevant quantities appearing in the representation for $W^n(x,\xi)$ (obtained in Theorem 3.1 below). The representation can be derived easily by following the same steps as those given in [4, section 4.4].

We define a discrete-time controlled process taking values in $\mathbb{R}^d \times \mathcal{S}$ denoted by $\{(\bar{X}_j^n, \bar{Z}_j^n), j = 0, \ldots, n\}$. The control at time j is the distribution of the controlled random variable $\bar{Z}_j^n$. It is given by a stochastic kernel $\nu_j^n(d\zeta|\bar{X}_0^n, \ldots, \bar{X}_j^n, \bar{Z}_j^n)$ on $\mathcal{S}$ given $(\mathbb{R}^d)^{j+1} \times \mathcal{S}$. That is, ν_j^n is a random variable mapping $(\mathbb{R}^d)^{j+1} \times \mathcal{S}$ into $\mathcal{P}(\mathcal{S})$.[1] A sequence of controls $\{\nu_j^n, j = 0, \ldots, n-1\}$ is what we refer to as an admissible control sequence. Now, setting $\bar{Z}_0^n = \xi$ and $\bar{X}_0^n = x$, the evolution of the controlled process is through the relation

$$\bar{X}_{j+1}^n = \bar{X}_j^n + \frac{1}{n} b(\bar{X}_j^n, \bar{Z}_{j+1}^n),$$

[1] For ease of presentation, the dependence on the underlying probability space of all stochastic kernels appearing in this paper is not made explicit in the notation.

where the conditional distribution of $\bar{Z}^n_{j+1}$ is given by

$$\bar{P}_{x,\xi}\left\{\bar{Z}^n_{j+1} \in d\zeta | \bar{X}^n_0, \ldots, \bar{X}^n_j, \bar{Z}^n_0, \ldots, \bar{Z}^n_j\right\} = \nu^n_j(d\zeta | \bar{X}^n_0, \ldots, \bar{X}^n_j, \bar{Z}^n_j).$$

Finally, we let $\bar{X}^n = \{\bar{X}^n(t), t \in [0,1]\}$ be the piecewise linear interpolation of $\{\bar{X}^n_j, j = 0, \ldots, n\}$.

THEOREM 3.1. *Let h be a bounded measurable function mapping $\mathcal{C}([0,1] : \mathbb{R}^d) \mapsto \mathbb{R}$. Then for all $n \in \mathbb{N}$, $x \in \mathbb{R}^d$, and $\xi \in \mathcal{S}$ we have the representation*

$$W^n(x,\xi) = \inf_{\{\nu^n_j\}} \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu^n_j(\cdot)\|p(\cdot|\bar{X}^n_j, \bar{Z}^n_j)) + h(\bar{X}^n)\right\}. \tag{3.1}$$

Here R is the relative entropy function; $\nu^n_j(\cdot) = \nu^n_j(\cdot|\bar{X}^n_0, \ldots, \bar{X}^n_j, \bar{Z}^n_j)$; the infimum is taken over all admissible control sequences $\{\nu^n_j, j = 0, \ldots, n-1\}$; $\bar{E}_{x,\xi}$ denotes expectation conditioned on $\bar{X}^n_0 = x$ and $\bar{Z}^n_0 = \xi$; and $\{(\bar{X}^n_j, \bar{Z}^n_j), j = 0, \ldots, n\}$ is the controlled process associated with a particular control sequence $\{\nu^n_j\}$.

Let $\varepsilon > 0$ be given. For each $n \in \mathbb{N}$, let $\{\nu^n_j, j = 0, \ldots, n-1\}$ be a sequence of nearly optimal admissible controls for the variational problem in (3.1), so that

$$W^n(x,\xi) + \varepsilon \geq \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu^n_j(\cdot)\|p(\cdot|\bar{X}^n_j, \bar{Z}^n_j)) + h(\bar{X}^n)\right\}. \tag{3.2}$$

Here $\{(\bar{X}^n_j, \bar{Z}^n_j), j = 0, \ldots, n\}$ is the controlled process associated with the nearly optimal sequence of controls.

We will obtain the limit inferior of the right-hand side of (3.2) by rewriting it in terms of a new sequence of control measures. These are defined as conveniently averaged controls in a space that is independent of n. For that purpose, let $\{m_n, n \in \mathbb{N}\}$ be a sequence of real numbers satisfying $m_n \to \infty$ as $n \to \infty$ and such that if $k_n \doteq m_n/n$, then $\lim_{n\to\infty} k_n = 0$. Also, suppose that 1 is an integer multiple of k_n. Given $\xi \in \mathcal{S}$, let δ_ξ denote the unit point measure at ξ. For $l = 0, \ldots, 1/k_n - 1$, and Borel subsets B_1 and B_2 of $\mathcal{S}$, let

$$\tilde{\nu}^n_l(B_1 \times B_2) \doteq \frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} \delta_{\bar{Z}^n_j}(B_1) \times \nu^n_j(B_2|\bar{X}^n_j, \bar{Z}^n_j).$$

The quantity $\tilde{\nu}^n_l$ is a stochastic kernel on $\mathcal{S} \times \mathcal{S}$ with marginals

$$(\nu^n_l)_1(B_1) = \frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} \delta_{\bar{Z}^n_j}(B_1) \quad \text{and} \quad (\nu^n_l)_2(B_2) = \frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} \nu^n_j(B_2|\bar{X}^n_j, \bar{Z}^n_j).$$

These definitions naturally result when one thinks of collecting terms of the sum appearing in (3.2) in groups of size m_n for the purposes of averaging. As was mentioned earlier, this technique is common in the proofs of convergence of state-dependent stochastic algorithms (see [8, 10]).

Now for each $n \in \mathbb{N}$ and $t \in [0,1]$ define

$$\nu^n(B_1 \times B_2|t) \doteq \begin{cases} \tilde{\nu}^n_l(B_1 \times B_2) \text{ if } t \in [lk_n, (l+1)k_n) \text{ for } l = 0, \ldots, 1/k_n - 2, \\ \tilde{\nu}^n_{(\frac{1}{k_n}-1)}(B_1 \times B_2) \text{ if } t \in [1-k_n, 1]. \end{cases}$$

Finally define the admissible control measure ν^n to be the random probability measure defined for Borel subsets B_1, B_2 of $\mathcal{S}$ and C of $[0,1]$ through

$$\nu^n(B_1 \times B_2 \times C) \doteq \int_C \nu^n(B_1 \times B_2|t)dt. \tag{3.3}$$

If for $B_1 \in \mathcal{B}(\mathcal{S})$ we define the first marginal $\hat{\nu}_1^n(d\zeta|t)$ of $\nu^n(d\zeta \times dy|t)$ through $\hat{\nu}_1^n(B_1|t) \doteq \nu^n(B_1 \times \mathcal{S}|t)$, then for Borel subsets B_1, B_2 of $\mathcal{S}$ and C of $[0,1]$, Theorem A.5.6 in [4] gives the decomposition

$$\nu^n(B_1 \times B_2 \times C) = \int_C \int_{B_1 \times B_2} \hat{\nu}_1^n(d\zeta|t)\hat{\nu}_2^n(dy|\zeta,t)dt = \int_C \int_{B_1} \hat{\nu}_2^n(B_2|\zeta,t)\hat{\nu}_1^n(d\zeta|t)dt, \tag{3.4}$$

where $\hat{\nu}_2^n(dy|\zeta,t)$ is a stochastic kernel on $\mathcal{S}$ given $\mathcal{S} \times [0,1]$. Following the notation in [4], we summarize this decomposition as $\nu^n(d\zeta \times dy \times dt) = \hat{\nu}_1^n(d\zeta|t) \otimes \hat{\nu}_2^n(dy|\zeta,t) \otimes \lambda$, where λ is Lebesgue measure on $[0,1]$.

We can now rewrite the right-hand side of (3.2) in terms of the control measures ν^n. We first use the fact (see [4, Lemma 1.4.3(f)]) that $R(\beta\|\gamma) = R(\alpha \times \beta\|\alpha \times \gamma)$ for any probability measures α, β, and γ on $\mathcal{S}$. This formula applied term by term enables us to write

$$\begin{aligned}
&\bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu_j^n(\cdot)\|p(\cdot|\bar{X}_j^n, \bar{Z}_j^n))\right\} \\
&= \bar{E}_{x,\xi}\left\{\sum_{l=0}^{\frac{1}{k_n}-1} k_n \frac{1}{m_n} \sum_{j=lm_n}^{(l+1)m_n-1} R\left(\delta_{\bar{Z}_j^n}(\cdot) \times \nu_j^n(\cdot) \,\|\, \delta_{\bar{Z}_j^n}(d\zeta) \otimes p(\cdot|\bar{X}_j^n, \zeta)\right)\right\},
\end{aligned}$$

where we have used the notation $\delta_{\bar{Z}_j^n}(\cdot) \times p(\cdot|\bar{X}_j^n, \bar{Z}_j^n) = \delta_{\bar{Z}_j^n}(d\zeta) \otimes p(\cdot|\bar{X}_j^n, \zeta)$. Applying Jensen's inequality to the convex function $R(\cdot\|\cdot)$, the right-hand side of the preceding display is no less than

$$\bar{E}_{x,\xi}\left\{\sum_{l=0}^{\frac{1}{k_n}-1} k_n R\left(\frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} \delta_{\bar{Z}_j^n}(d\zeta) \times \nu_j^n(\cdot|\bar{X}_j^n, \zeta) \middle\| \frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} \delta_{\bar{Z}_j^n}(d\zeta) \otimes p\left(\cdot|\bar{X}_j^n, \zeta\right)\right)\right\},$$

which is clearly equal to

$$\bar{E}_{x,\xi}\left\{\int_0^1 R(\nu^n(\cdot|t)\|\gamma^n(\cdot|t))dt\right\}. \tag{3.5}$$

In (3.5), for each $n \in \mathbb{N}$ and $t \in [0,1]$, we have defined

$$\gamma^n(B_1 \times B_2|t) \doteq \frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} \delta_{\bar{Z}_j^n}(B_1) \otimes p(B_2|\bar{X}_j^n, \zeta) \text{ if } t \in [lk_n, (l+1)k_n),$$

for $l = 0, \ldots, 1/k_n - 1$. Now define the measure γ^n on $\mathcal{S} \times \mathcal{S} \times [0,1]$ through $\gamma^n(B_1 \times B_2 \times C) \doteq \int_C \gamma^n(B_1 \times B_2|t)dt$. Since for all stochastic kernels α and β on $\mathcal{S}$ given $[0,1]$ and probability measures γ on $[0,1]$, we have (see [4, Lemma 1.4.3(f)])

$$\int_{[0,1]} R(\alpha(\cdot|x)\|\beta(\cdot|x))\gamma(dx) = R(\alpha \otimes \gamma\|\beta \otimes \gamma); \tag{3.6}$$

(3.5) can be rewritten as $\bar{E}_{x,\xi}\{R(\nu^n\|\gamma^n)\}$. (Recall the definition of ν^n given in (3.3).)

Combining this series of inequalities with (3.2), we obtain

$$W^n(x,\xi)+\varepsilon \geq \bar{E}_{x,\xi}\left\{R(\nu^n\|\gamma^n)+h(\bar{X}^n)\right\}.$$

We now wish to take the limit inferior as $n\to\infty$ of both terms in the last inequality. The asymptotic properties of the sequence $\{(\nu^n,\gamma^n,\bar{X}^n),n\in\mathbb{N}\}$ required to do this are proved in Theorem C.1. According to that theorem, there exists a probability space on which a subsequence of $\{(\nu^n,\gamma^n,\bar{X}^n),n\in\mathbb{N}\}$ converges in distribution to some limit $(\nu,\gamma,\bar{X})$. The stochastic kernels ν and γ and the random variable $\bar{X}$ satisfy all the conclusions stated in Theorem C.1. Thanks to the Skorohod representation theorem [5, p. 102] we can assume that convergence takes place with probability 1 (w.p.1). Along the convergent subsequence we thus have that

$$\begin{aligned}
&\liminf_{n\to\infty} W^n(x,\xi)+\varepsilon\\
&\geq \bar{E}_{x,\xi}\left\{R(\nu\|\gamma)+h(\bar{X})\right\}\\
&=\bar{E}_{x,\xi}\left\{R(\hat{\nu}_1(d\zeta|t)\otimes\hat{\nu}_2(dy|\zeta,t)\otimes dt\|\hat{\nu}_1(d\zeta|t)\otimes p(dy|\bar{X}(t),\zeta)\otimes dt)+h(\bar{X})\right\}\\
&=\bar{E}_{x,\xi}\left\{\int_0^1\int_{\mathcal{S}} R(\hat{\nu}_2(dy|\zeta,t)\|p(dy|\bar{X}(t),\zeta))\hat{\nu}_1(d\zeta|t)dt+h(\bar{X})\right\}\\
&\geq \bar{E}_{x,\xi}\left\{\int_0^1 L\left(\bar{X}(t),\int_{\mathcal{S}} b(\bar{X}(t),\zeta)\hat{\nu}_1(d\zeta|t)\right)dt+h(\bar{X})\right\}\\
&=\bar{E}_{x,\xi}\left\{I_x(\bar{X})+h(\bar{X})\right\}\geq \inf_{\phi\in\mathcal{C}([0,1]:\mathbb{R}^d)}\left\{I_x(\phi)+h(\phi)\right\}.
\end{aligned}$$

Lower semicontinuity of $R(\cdot\|\cdot)$, Fatou's lemma, and continuity of h yield the second line of the above display. The third line uses parts (b) and (f) of Theorem C.1 and the fourth uses (3.6). Finally, part (b) of Lemma B.2 and part (e) of Theorem C.1 give the fifth and sixth lines, respectively. Since the above inequality is valid for all $\varepsilon>0$, (2.4) follows, concluding the proof of the upper bound. □

4. Proof of the lower bound. This section is devoted to showing that (2.5) holds for all h in $\mathcal{C}([0,1]:\mathbb{R}^d)$ that are Lipschitz continuous. Thanks to [4, Corollary 1.2.5(b)], this is enough to show that (2.5) holds for all h in $\mathcal{C}([0,1]:\mathbb{R}^d)$. As in the proof of Proposition 6.6.1 in [4], the proof of (2.5) is done by introducing a perturbation to the original random walk by means of a random walk with Gaussian noise. This allows one to obtain necessary smoothness properties for a function L_σ, which is the analogue of the function L defined in (2.2) but for the perturbed process. Weak convergence arguments make use of these continuity properties, implying the desired lower bound when taking the perturbation to be sufficiently small.

Let us first focus on the perturbed problem; the connection with (2.5) will be clear after (4.3). Given $\sigma>0$, let $\{G_{j,\sigma},j\in\mathbb{N}_0\}$ be a sequence of independent and identically distributed random variables on $\mathbb{R}^d$ with common Gaussian distribution ρ_σ, with mean zero and variance σI. We assume them to be independent of $\{\xi_j^x,x\in\mathbb{R}^d,j\in\mathbb{N}_0\}$, where ξ_j^x is the "fixed x" Markov process with transition kernel $p(\cdot|x,\xi_j^x)$. Given $n\in\mathbb{N}$ and $j\in\{0,1,\dots,n-1\}$, let X_j^n and Z_j^n be as before, and define

$$U_{0,\sigma}^n\doteq 0,\qquad U_{j+1,\sigma}^n\doteq U_{j,\sigma}^n+\frac{1}{n}\,G_{j,\sigma}.$$

Denote by $X^n(t)$ and $U_\sigma^n(t)$ the piecewise linear interpolations of $\{X_j^n,j=1,\dots,n\}$ and $\{U_{j,\sigma}^n,j=0,\dots,n\}$ on $[0,1]$, respectively (see (1.4)). Also, define

$$Y_\sigma^n(t)\doteq X^n(t)+U_\sigma^n(t), \tag{4.1}$$

which is the piecewise linear interpolation of $\{X_j^n + U_{j,\sigma}^n\}$. As was mentioned earlier, the point of introducing a perturbation is to replace the function L by a continuous function L_σ. This latter function is defined as the Legendre–Fenchel transform of some convex function Λ_σ. Once again, the function Λ_σ is identified via an eigenvalue problem, which we now describe.

For fixed $x \in \mathcal{S}$, we can identify an additive component of the process (see [7, p. 376]), namely, $b(x, \xi_j^x) + G_{j,\sigma}$. Here ξ_j^x is the "fixed x" Markov process described earlier. Let Q_σ^x be the stochastic kernel on $\mathcal{S} \times \mathbb{R}^d$ given $\xi \in \mathcal{S}$ defined by

$$Q_\sigma^x(B_1 \times B_2|\xi) = \int_{B_1} \int_{\mathbb{R}^d} 1_{B_2}(b(x,\zeta) + y)\rho_\sigma(dy)p(d\zeta|x,\xi),$$

where $B_1 \in \mathcal{B}(\mathcal{S})$ and $B_2 \in \mathcal{B}(\mathbb{R}^d)$. Then, letting

$$\upsilon_\sigma(B_1 \times B_2|x) \doteq \int_{B_1} \int_{\mathbb{R}^d} 1_{B_2}(b(x,\zeta) + y)\rho_\sigma(dy)\vartheta(d\zeta),$$

with ϑ as in Hypothesis H.1, $B_1 \in \mathcal{B}(\mathcal{S})$, and $B_2 \in \mathcal{B}(\mathbb{R}^d)$, we have

$$a\upsilon_\sigma(B_1 \times B_2|x) \le Q_\sigma^x(B_1 \times B_2|\xi) \le A\upsilon_\sigma(B_1 \times B_2|x).$$

These bounds on $Q_\sigma^x(\cdot,\cdot|\xi)$ and the fact that the convex hull of the support of $\upsilon_\sigma(\mathcal{S} \times \cdot|x)$ is $\mathbb{R}^d$ guarantee the existence of a solution to the eigenvalue problem for each $x, \alpha \in \mathbb{R}^d$ [7, Lemma 3.1]. That is, for each $x, \alpha \in \mathbb{R}^d$, there exist a unique $\Lambda_\sigma(x,\alpha) \in \mathbb{R}$ and a bounded function $\Psi_\sigma(x;\alpha,\cdot) : \mathcal{S} \mapsto \mathbb{R}$ such that

$$e^{\Lambda_\sigma(x,\alpha)+\Psi_\sigma(x;\alpha,\xi)} = \int_{\mathcal{S}} \int_{\mathbb{R}^d} e^{\langle \alpha, b(x,\zeta)+y\rangle + \Psi_\sigma(x;\alpha,\zeta)}\rho_\sigma(dy)p(d\zeta|x,\xi).$$

Furthermore, $\Lambda_\sigma(x,\alpha) = \Lambda(x,\alpha) + \frac{\sigma^2}{2}||\alpha||^2$, and $\Psi_\sigma(x;\alpha,\xi) = \Psi(x;\alpha,\xi)$, where $\Psi(x;\alpha,\xi)$ is the eigenfunction associated with $\Lambda(x,\alpha)$ (see (2.1)). The Legendre–Fenchel transform of Λ_σ is given by

$$L_\sigma(x,\beta) \doteq \sup_{\alpha \in \mathbb{R}^d} \{\langle \alpha, \beta\rangle - \Lambda_\sigma(x,\alpha)\}. \tag{4.2}$$

Having introduced the necessary definitions, we now proceed to relate the original and the perturbed processes. Let K_1 be the Lipschitz constant of h and define $B \doteq 2||h||_\infty$. Then

$$h(Y_\sigma^n) = h(X^n + U_\sigma^n) \ge h(X^n) - (K_1||U_\sigma^n||_\infty \wedge B),$$

and, because of independence,

$$\begin{aligned}\frac{1}{n}\log E_{x,\xi}\{\exp[-nh(Y_\sigma^n)]\} &\le \frac{1}{n}\log E_{x,\xi}\{\exp[-nh(X^n)]\cdot\exp[n(K_1||U_\sigma^n||_\infty \wedge B)]\} \\ &= -W^n(x,\xi) + \frac{1}{n}\log E_{x,\xi}\{\exp[n(K_1||U_\sigma^n||_\infty \wedge B)]\}.\end{aligned}$$

Hence

$$\limsup_{n\to\infty} W^n(x,\xi) \le \limsup_{n\to\infty}\left(-\frac{1}{n}\log E_{x,\xi}\{\exp[-nh(Y_\sigma^n)]\}\right) + \frac{K_1^2\sigma^2}{2},$$

where the second term of the inequality follows from [4, p. 189]. This implies that (2.5) holds as long as we can show that

$$\limsup_{n\to\infty} W_\sigma^n(x,\xi) \le \inf_{\varphi\in C([0,1]:\mathbb{R}^d)}\{I_x(\varphi)+h(\varphi)\}+\theta(\sigma), \tag{4.3}$$

with $W_\sigma^n \doteq -\frac{1}{n}\log E_{x,\xi}\exp[-nh(Y_\sigma^n)]$ and $\theta(\sigma)\to 0$ when $\sigma\to 0$. What we will show in fact is that, given $\varepsilon>0$ and $\psi\in\mathcal{C}([0,1]:\mathbb{R}^d)$ satisfying

$$I_x(\psi)+h(\psi) \le \inf_{\varphi\in C([0,1]:\mathbb{R}^d)}\{I_x(\varphi)+h(\varphi)\}+\varepsilon<\infty, \tag{4.4}$$

we have

$$\limsup_{n\to\infty} W_\sigma^n(x,\xi) \le \int_0^1 L_\sigma(\psi(t),\dot\psi(t))dt + h(\psi)+\theta(\sigma). \tag{4.5}$$

Since $L_\sigma(x,\beta)\le L(x,\beta)$ for all x and $\beta\in\mathbb{R}^d$ (part (a) of Lemma B.3), (4.3) will follow after that.

The steps in the proof of (4.5) can be described in simple terms. Starting with the nearly optimal function ψ in (4.4), we construct a sequence of nearly optimal admissible controls for the stochastic control problem that is associated with $W_\sigma^n(x,\xi)$ through the representation in Theorem A.1. The limit properties of this sequence, as well as estimates on the associated sequence of running costs (where continuity of L_σ is required), will lead directly to (4.5).

Let ψ satisfy (4.4), and let ψ^* be as in part (e) of Lemma B.3. The admissible control sequence that we define based on ψ^* (see (4.20) below) has the following properties: the running costs are nearly optimal in (A.3), and, with probability converging to 1, the associated controlled process $\bar Y^n \doteq \bar X^n + \bar U^n$ (see (A.1)) enters a small neighborhood of ψ^* as $n\to\infty$. The construction is given in the following paragraphs.

Define the compact set

$$\Delta \equiv \cup_{t\in[0,1]}\{y\in\mathbb{R}^d : ||y-\psi^*(t)||\le 1\}.$$

Let $\eta=\eta(\Delta,\sigma)\in(0,1)$ satisfy the conclusions of part (d) of Lemma B.3 when taking $\varepsilon=\sigma$. Also, let $\{x_j, j=1,\dots,n\}$ be a sequence in Δ satisfying $\|\psi^*(j/n)-x_j\|<\eta$. For every $n\in\mathbb{N}$, $j=1,\dots,n$, and with $x=\psi^*(j/n)$, $y=x_j$, and $\beta=\dot\psi^*(j/n)$, part (d) of that lemma implies that there exists $\bar\beta_j^n\in\mathbb{R}^d$ such that

$$L_\sigma(x_j,\bar\beta_j^n) - L_\sigma(\psi^*(j/n),\dot\psi^*(j/n)) \le \sigma \tag{4.6}$$

and

$$||\bar\beta_j^n - \dot\psi^*(j/n)|| \le K\|\psi^*(j/n)-x_j\|.$$

Further, $\bar\beta_j^n = \bar\beta_j^{1,n}+\bar\beta_j^{2,n}$, with

$$\bar\beta_j^{1,n} = \int_{\mathcal{S}} b(x_j,\xi)\mu_{j,n}^*(d\xi) \quad \text{and} \quad \bar\beta_j^{2,n} = \int_{\mathbb{R}^d} y\nu_{j,n}^*(dy).$$

Here $\mu_{j,n}^*$ is the invariant measure corresponding to the kernel $\gamma_{j,n}^*$ defined for $B_1\in\mathcal{B}(\mathcal{S})$ as

$$\gamma_{j,n}^*(B_1|\psi^*(j/n),\xi) = \int_{B_1}\exp\{\langle\alpha,b(\psi^*(j/n),\zeta)\rangle - \Lambda(\psi^*(j/n),\alpha) + \Psi_\sigma(\psi^*(j/n);\alpha,\zeta)-\Psi_\sigma(\psi^*(j/n);\alpha,\xi)\}p(d\zeta|\psi^*(j/n),\xi),$$

and for $B_2 \in \mathcal{B}(\mathbb{R}^d)$ as

$$\nu^*_{j,n}(B_2) = \int_{B_2} \exp\left\{ \langle \alpha, y\rangle - \frac{\sigma^2||\alpha||^2}{2} \right\} \rho_\sigma(dy).$$

Note that $\alpha = \alpha(\psi^*(j/n), \dot\psi^*(j/n))$ and $\dot\psi^*(j/n) = \int_{\mathcal{S}} b(\psi^*(j/n),\xi)\mu^*_{j,n}(d\xi) + \int_{\mathbb{R}^d} y\nu^*_{j,n}(dy)$. We observe that, from part (b) of Lemma B.2 in Appendix B,

$$\begin{aligned} L(x_j, \bar\beta^{1,n}_j) &\le \int_{\mathcal{S}} R(\gamma^*_{j,n}(\cdot|\psi^*(j/n),\xi)\|p(\cdot|x_j,\xi))\mu^*_{j,n}(d\xi) \\ &= \langle \alpha(\psi^*(j/n), \dot\psi^*(j/n)), \bar\beta^n_j - \bar\beta^{2,n}_j\rangle - \Lambda(\psi^*(j/n), \alpha(\psi^*(j/n), \dot\psi^*(j/n))) \\ &\le L(\psi^*(j/n), \bar\beta^n_j - \bar\beta^{2,n}_j). \end{aligned}$$

Now, from part (c) of Lemma B.3 and for $\bar\beta^n_j$ as in (4.6), the stochastic kernel $\gamma^{1,n}_j(\cdot|x_j,\xi)$ on $\mathcal{S}$ given $\mathcal{S}\times\mathbb{R}^d$ (with invariant measure μ^n_j) and the measure $\gamma^{2,n}_j$ on $\mathbb{R}^d$ given by

$$\gamma^{1,n}_j(B_1|x_j,\xi) = \int_{B_1} e^{\langle \alpha, b(x_j,\zeta)\rangle + \Psi_\sigma(x_j;\alpha,\zeta) - \Psi_\sigma(x_j;\alpha,\xi) - \Lambda(x_j,\alpha)} p(d\zeta|x_j,\xi) \tag{4.7}$$

and

$$\gamma^{2,n}_j(B_2) = \int_{B_2} e^{\langle \alpha, y\rangle - \frac{\sigma^2}{2}\|\alpha\|^2} \rho_\sigma(dy)$$

achieve the infimum in the representation for L_σ. That is,

$$L_\sigma(x_j, \bar\beta^n_j) = \int_{\mathcal{S}} R(\gamma^{1,n}_j(\cdot|x_j,\xi)||p(\cdot|x_j,\xi))\mu^n_j(d\xi) + R(\gamma^{2,n}_j(\cdot)||\rho_\sigma(\cdot)), \tag{4.8}$$

and

$$\bar\beta^n_j = \int_{\mathcal{S}} b(x_j,\xi)\mu^n_j(d\xi) + \int_{\mathbb{R}^d} y\gamma^{2,n}_j(dy) = \bar\beta^{1,n}_j + \bar\beta^{2,n}_j,$$

where we have used the fact that [4, Corollary C.3.3] for any probability measures γ and θ on $\mathcal{S}$, and λ and μ on $\mathbb{R}^d$,

$$R(\gamma\times\lambda\|\theta\times\mu) = R(\gamma\|\theta) + R(\lambda\|\mu). \tag{4.9}$$

Note that $\alpha = \alpha(x_j, \bar\beta^n_j) = \alpha(x_j, \psi^*(j/n), \dot\psi^*(j/n))$ in both $\gamma^{1,n}_j$ and $\gamma^{2,n}_j$. Hence $\gamma^{2,n}_j$ depends implicitly on x_j (through α), but we do not write this dependence explicitly for ease of notation.

We now use the kernels $\gamma^{1,n}_j$ and $\gamma^{2,n}_j$ to finish the definition of the required sequence of admissible controls. As was the case in section 3, grouping for the purposes of averaging motivates part of the construction. Let $\{m_n, n\in\mathbb{N}\}$ be a sequence as the one used there, so that $m_n\to\infty$ and $k_n = m_n/n \to 0$ as $n\to\infty$. Let $l \in \{0,\dots,\frac{1}{k_n} - 1\}$. Then for $lm_n \le j < (l+1)m_n - 1$ we define

$$\nu^{1,n}_j(d\zeta|x_0,\dots,x_j,u_0,\dots,u_j,\xi_j) \doteq \begin{cases} \gamma^{1,n}_{lm_n}(d\zeta|x_{lm_n},\xi_j) & \text{if } \max\limits_{0\le i\le j}\|x_i - \psi^*(i/n)\| \le \eta, \\ p(d\zeta|x_j,\xi_j) & \text{if } \max\limits_{0\le i\le j}\|x_i - \psi^*(i/n)\| > \eta \end{cases} \tag{4.10}$$

and

$$\nu_j^{2,n}(dy|x_0,\dots,x_j,u_0,\dots,u_j,\xi_j) \doteq \begin{cases} \gamma_{lm_n}^{2,n}(dy) & \text{if} \quad \max_{0\le i\le j}\|x_i-\psi^*(i/n)\|\le\eta, \\ \rho_\sigma(dy) & \text{if} \quad \max_{0\le i\le j}|x_i-\psi^*(i/n)|>\eta. \end{cases} \tag{4.11}$$

To simplify notation we have not made explicit the dependence on σ of $\nu_j^{1,n}$ and $\nu_j^{2,n}$. Finally, we define the required admissible control sequence $\{\nu_{j,prod}^n, j=0,\dots,n-1\}$ on $\mathcal{S}\times\mathbb{R}^d$ as

$$\nu_{j,prod}^n(d\zeta\times dy) = \nu_j^{1,n}(d\zeta)\times\nu_j^{2,n}(dy). \tag{4.12}$$

To show that the control sequence just constructed is nearly optimal in (A.3), we compute the associated running cost directly. In what follows, $\bar X_j^n$, $\bar Z_j^n$, $j=0,\dots,n$, are controlled random variables associated with the sequence $\{\nu_j^n\}$ through definitions (A.1) and (A.2).

Let $\tau^n \doteq \frac{1}{n}(\min\{j\in\{0,1,\dots,n\} : \|\bar X_j^n-\psi^*(j/n)\|>\eta\}\wedge n)$. Then (4.9) and the definition of τ^n give

$$\begin{aligned}
&\bar E_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu_{j,prod}^n(\cdot)||(p\times\rho_\sigma)(\cdot|\bar X_j^n,\bar Z_j^n))\right\} \\
&= \bar E_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n\tau^n-1}\left[R(\nu_j^{1,n}(\cdot)\|p(\cdot|\bar X_j^n,\bar Z_j^n)) + R(\nu_j^{2,n}(\cdot)\|\rho_\sigma(\cdot))\right]\right\} \\
&= \bar E_{x,\xi}\left\{\sum_{l=0}^{q_n-1} k_n\left[\frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} R(\gamma_{lm_n}^{1,n}(\cdot|\bar X_{lm_n}^n,\bar Z_j^n)\|p(\cdot|\bar X_j^n,\bar Z_j^n)) + R(\gamma_{lm_n}^{2,n}(\cdot)\|\rho_\sigma(\cdot))\right]\right. \\
&\qquad \left. + \frac{1}{n}\sum_{j=q_nm_n}^{n\tau^n-1}\left[R(\gamma_{q_nm_n}^{1,n}(\cdot|\bar X_{q_nm_n}^n,\bar Z_j^n)\|p(\cdot|\bar X_j^n,\bar Z_j^n)) + R(\gamma_{q_nm_n}^{2,n}(\cdot)||\rho_\sigma(\cdot))\right]\right\},
\end{aligned} \tag{4.13}$$

where q_n is such that $n\tau^n = q_nm_n + r_n$, with $0\le r_n<m_n$ and $q_n, r_n\in\mathbb{N}_0$.

To continue our estimates on the running costs, we must prove the following claim: for each $j\le n\tau^n-1$, $lm_n\le j\le (l+1)m_n-1$ for some $l\in\{0,\dots,q_n\}$, and n large enough,

$$R(\gamma_{lm_n}^{1,n}(\cdot|\bar X_{lm_n}^n,\bar Z_j^n)\|p(\cdot|\bar X_j^n,\bar Z_j^n)) \le R(\gamma_{lm_n}^{1,n}(\cdot|\bar X_{lm_n}^n,\bar Z_j^n)\|p(\cdot|\bar X_{lm_n}^n,\bar Z_j^n)) + \sigma. \tag{4.14}$$

We first note that part (c) of Hypothesis H.1 implies that for any $x,y\in\Delta$, there exists $\delta>0$ such that for $\|x-y\|<\delta$

$$\frac{\tilde p^y(\xi,\zeta)}{\tilde p^x(\xi,\zeta)} = 1+\frac{\tilde p^y(\xi,\zeta)-\tilde p^x(\xi,\zeta)}{\tilde p^x(\xi,\zeta)} \le 1+\frac{\tilde p^y(\xi,\zeta)-\tilde p^x(\xi,\zeta)}{a} \le e^\sigma. \tag{4.15}$$

Then taking n large enough so that $m_n\|b\|_\infty/n<\delta$, we have $\|\bar X_{lm_n+i}^n - \bar X_{lm_n}^n\|\le \frac{i}{n}\|b\|_\infty<\delta$ for $0\le i<m_n$, and hence

$$\begin{aligned}
&\gamma_{lm_n}^{1,n}(B_1|\bar X_{lm_n}^n,\bar Z_j^n) \\
&= \int_{B_1} e^{\langle\alpha,b(\bar X_{lm_n}^n,\zeta)\rangle+\Psi_\sigma(\bar X_{lm_n}^n;\alpha,\zeta)-\Psi_\sigma(\bar X_{lm_n}^n;\alpha,\xi)-\Lambda(\bar X_{lm_n}^n,\alpha)} p(d\zeta|\bar X_{lm_n}^n,\bar Z_j^n) \\
&\le e^\sigma\int_{B_1} e^{\langle\alpha,b(\bar X_{lm_n}^n,\zeta)\rangle+\Psi_\sigma(\bar X_{lm_n}^n;\alpha,\zeta)-\Psi_\sigma(\bar X_{lm_n}^n;\alpha,\xi)-\Lambda(\bar X_{lm_n}^n,\alpha)} \tilde p^{\bar X_j^n}(\bar Z_j^n,\zeta)\vartheta(d\zeta)
\end{aligned}$$

for any $B_1 \in \mathcal{B}(\mathcal{S})$. From the above we get that $\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)$ is absolutely continuous with respect to $p(\cdot|\bar{X}^n_j, \bar{Z}^n_j)$ and that

$$\frac{d\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)}{dp(\cdot|\bar{X}^n_j, \bar{Z}^n_j)} \leq e^{\sigma} \cdot \frac{d\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)}{dp(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)},$$

which implies (4.14).

Now fix $\bar{\xi} \in \mathcal{S}$ and normalize Ψ_σ in such a way that $\Psi_\sigma(x;\alpha,\bar{\xi}) = 0$. Then, observing that

$$\frac{a}{A} e^{\Psi_\sigma(x;\alpha,\xi_1)} \leq e^{\Psi_\sigma(x;\alpha,\xi_2)} \leq \frac{A}{a} e^{\Psi_\sigma(x;\alpha,\xi_1)}$$

for all $\xi_1, \xi_2 \in \mathcal{S}$, and taking $\xi_1 = \bar{\xi}$, we get that

$$\frac{a}{A} \leq e^{\Psi_\sigma(x;,\alpha,\xi)} \leq \frac{A}{a} \quad \forall \xi \in \mathcal{S},\ x,\ \alpha \in \mathbb{R}^d.$$

Then, from (4.7),

$$\gamma^{1,n}_{lm_n}(d\zeta|x,\xi) = e^{\langle \alpha, b(x,\zeta)\rangle + \Psi_\sigma(x;\alpha,\zeta) - \Psi_\sigma(x;\alpha,\xi) - \Lambda(x,\alpha)} \tilde{p}^x(\xi,\zeta)\vartheta(d\zeta),$$

with $\alpha = \alpha(x, \bar{\beta}^n_{lm_n})$, $x \in \Delta$, and $\bar{\beta}^n_{lm_n}$ to satisfy (4.6), and hence

$$\gamma^{1,n}_{lm_n}(d\zeta|x,\xi) \geq \frac{a^3}{A^2} e^{\langle \alpha, b(x,\zeta)\rangle - \Lambda(x,\alpha)} \vartheta(d\zeta) \geq \frac{a^3}{A^2} e^{-2||b||_\infty \max\limits_{x\in\Delta,\beta\in\Theta}\{\|\alpha(x,\beta)\|\}} \vartheta(d\zeta),$$

where $\Theta \doteq \cup_{t\in[0,1]}\{\beta \in \mathbb{R}^d : ||\beta - \dot{\psi}^*(t)|| \leq K\}$. Using the fact that $(x,\beta) \mapsto \alpha(x,\beta)$ is continuous (part (f) of Lemma B.3), we get that for $x \in \Delta$, $\bar{\beta}^n_{\ell m_n}$ belongs to Θ and, moreover, that $\max_{x\in\Delta,\beta\in\Theta}\{\|\alpha(x,\beta)\|\}$ is bounded. Denoting the jth iteration of the kernel $\gamma^{1,n}_{lm_n}$ by $\gamma^{1,n,j}_{lm_n}$, we observe that [13, Theorem 16.0.2]

$$\|\gamma^{1,n,j}_{lm_n}(\cdot|x,\zeta) - \mu^n_{lm_n}(\cdot)\| \leq \left(1 - \frac{a^3}{A^2} e^{-2\max_{x,\zeta}|\langle \alpha, b(x,\zeta)\rangle|}\right)^j. \tag{4.16}$$

We complete the estimate on the running cost for our admissible control sequence in the inequalities that follow, using (4.14), standard properties of conditional expectation, and (4.7). We have that (4.13) is less than or equal to

$$\begin{aligned}
&\bar{E}_{x,\xi}\left\{\sum_{l=0}^{q_n-1} k_n \left[\frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} R(\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)||p(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)) + R(\gamma^{2,n}_{lm_n}(\cdot)||\rho_\sigma(\cdot))\right]\right.\\
&\quad \left. + \frac{1}{n}\sum_{j=q_nm_n}^{n\tau^n-1}\left[R(\gamma^{1,n}_{q_nm_n}(\cdot|\bar{X}_{q_nm_n}, \bar{Z}^n_{q_nm_n})||p(\cdot|\bar{X}^n_{q_nm_n}, \bar{Z}^n_j)) + R(\gamma^{2,n}_{q_nm_n}(\cdot)||\rho_\sigma(\cdot))\right]\right\}\\
&\quad + \sigma\\
&\leq \sum_{r=1}^{1/k_n} k_n \bar{E}_{x,\xi}\left\{\sum_{l=0}^{r-1}\left[\frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} R(\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)||p(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j))\right.\right.\\
&\qquad \left.\left. + R(\gamma^{2,n}_{lm_n}(\cdot)||\rho_\sigma(\cdot))\right] 1_{[(r-1)m_n < n\tau^n \leq rm_n]}\right\} + \sigma
\end{aligned} \tag{4.17}$$

$$
\begin{aligned}
&= \sum_{r=1}^{1/k_n} k_n \sum_{l=0}^{r-1} \bar{E}_{x,\xi} \Bigg\{ 1_{[(r-1)m_n < n\tau^n \le r m_n]} \\
&\qquad \cdot \bar{E}_{x,\xi} \Bigg\{ \frac{1}{m_n} \sum_{j=lm_n}^{(l+1)m_n-1} R(\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)||p(\cdot|\bar{X}^n_{lm_n}, \bar{Z}^n_j)) \\
&\qquad\qquad + \; R(\gamma^{2,n}_{lm_n}(\cdot)||\rho_\sigma(\cdot))|\bar{Z}^n_0, \ldots, \bar{Z}^n_{lm_n}, \bar{X}^n_0, \ldots, \bar{X}^n_{rm_n} \Bigg\} \Bigg\} \\
&\quad + \sigma \\
&= \sum_{r=1}^{1/k_n} k_n \sum_{l=0}^{r-1} \bar{E}_{x,\xi} \Bigg\{ 1_{[(r-1)m_n < n\tau^n \le r m_n]} \\
&\qquad \cdot \bar{E}_{x,\xi} \Bigg\{ \frac{1}{m_n} \sum_{j=lm_n}^{(l+1)m_n-1} \Bigg[\Big\langle \alpha_{lm_n}, \int_{\mathcal{S}} b(\bar{X}^n_{lm_n}, \zeta) \gamma^{1,n}_{lm_n}(d\zeta|\bar{X}^n_{lm_n}, \bar{Z}^n_j) \Big\rangle \\
&\qquad\qquad + \int_{\mathcal{S}} \Psi_\sigma(\bar{X}^n_{lm_n}; \alpha_{lm_n}, \zeta) \gamma^{1,n}_{lm_n}(d\zeta|\bar{X}^n_{lm_n}, \bar{Z}^n_j) \\
&\qquad\qquad - \Psi_\sigma(\bar{X}^n_{lm_n}; \alpha_{lm_n}, \bar{Z}^n_j) \\
&\qquad\qquad - \Lambda(\bar{X}^n_{lm_n}, \alpha_{lm_n}) \Bigg] \\
&\qquad\qquad + \; R(\gamma^{2,n}_{lm_n}(\cdot)||\rho_\sigma(\cdot))|\bar{Z}^n_0, \ldots, \bar{Z}^n_{lm_n}, \bar{X}^n_0, \ldots, \bar{X}^n_{lm_n} \Bigg\} \Bigg\} \\
&\quad + \sigma.
\end{aligned}
$$

Now, adding and subtracting $\int_{\mathcal{S}} R(\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \xi)||p(\cdot|\bar{X}^n_{lm_n}, \xi))\mu^n_{lm_n}(d\xi)$ inside the expectation and collecting terms, we get that the above expression is less than or equal to

$$
\begin{aligned}
&\sum_{r=1}^{1/k_n} k_n \sum_{l=0}^{r-1} \bar{E}_{x,\xi} \Bigg\{ \Bigg[\frac{1}{m_n} \sum_{j=lm_n}^{(l+1)m_n-1} \Big\langle \alpha_{lm_n}, \int_{\mathcal{S}} b(\bar{X}^n_{lm_n}, \zeta) \gamma^{1,n,j+1}_{lm_n}(d\zeta|\bar{X}^n_{lm_n}, \bar{Z}^n_{lm_n}) \\
&\qquad\qquad - \int_{\mathcal{S}} b(\bar{X}^n_{lm_n}, \zeta) \mu^n_{lm_n}(d\zeta) \Big\rangle \\
&\qquad + \int_{\mathcal{S}} R(\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n}, \xi)||p(\cdot|\bar{X}^n_{lm_n}, \xi)) \mu_{lm_n}(d\xi) \\
&\qquad + \; R(\gamma^{2,n}_{lm_n}(\cdot)||\rho_\sigma(\cdot)) \Bigg] 1_{[(r-1)m_n < n\tau^n \le r m_n]} \Bigg\} + \frac{4}{n} \ln \frac{A}{a} + \sigma \qquad (4.18) \\
&\le \frac{4}{n} \ln \frac{A}{a} + \sigma + \sum_{r=1}^{1/k_n} k_n \sum_{l=0}^{r-1} \bar{E}_{x,\xi} \Big\{ 1_{[(r-1)m_n < n\tau^n \le r m_n]} \\
&\quad \cdot \Big[\frac{||b||_\infty A^2}{m_n a^3} \max_{x \in \Delta, \beta \in \Theta} \{\|\alpha(x,\beta)\|\} e^{2||b||_\infty \max_{x \in \Delta, \beta \in \Theta} \{\|\alpha(x,\beta)\|\}}
\end{aligned}
$$

$$
\begin{aligned}
&+ \int_{\mathcal{S}} R(\gamma^{1,n}_{lm_n}(\cdot|\bar{X}^n_{lm_n},\xi)||p(\cdot|\bar{X}^n_{lm_n},\xi))\mu^n_{lm_n}(d\xi) + R(\gamma^{2,n}_{lm_n}(\cdot)||\rho_\sigma(\cdot))\Big]\Big\} \\
&\le \frac{4}{n}\ln\frac{A}{a} + \sigma + \frac{||b||_\infty A^2}{na^3}\max_{x\in\Delta,\beta\in\Theta}\{||\alpha(x,\beta)||\}e^{2||b||_\infty \max_{x\in\Delta,\beta\in\Theta}\{\|\alpha(x,\beta)\|\}} \\
&\quad + \sum_{r=1}^{1/k_n} k_n \sum_{l=0}^{r-1} \bar{E}_{x,\xi}\Big\{1_{[(r-1)m_n<n\tau^n\le rm_n]}\Big[L_\sigma(\bar{X}^n_{lm_n},\bar{\beta}^n_{lm_n})\Big]\Big\} \\
&\le \sum_{r=1}^{1/k_n} k_n \sum_{l=0}^{r-1} \bar{E}_{x,\xi}\Big\{1_{[(r-1)m_n<n\tau^n\le rm_n]}L_\sigma(\psi^*(lm_n/n),\dot{\psi}^*(lm_n/n))\Big\} \\
&\quad + \frac{4}{n}\ln\frac{A}{a} + 2\sigma + \frac{||b||_\infty A^2}{na^3}\max_{x\in\Delta,\beta\in\Theta}\{\|\alpha(x,\beta)\|\}e^{2||b||_\infty \max_{x\in\Delta,\beta\in\Theta}\{\|\alpha(x,\beta)\|\}} \\
&\le \bar{E}_{x,\xi}\left\{\sum_{l=0}^{[\frac{\tau^n}{k_n}]} k_n L_\sigma(\psi^*(lm_n/n),\dot{\psi}^*(lm_n/n))\right\} + 3\sigma \ \text{ for } n \text{ large enough,} \\
&\le k_n \sum_{l=0}^{[1/k_n]} L_\sigma(\psi^*(lm_n/n),\dot{\psi}^*(lm_n/n)) + 3\sigma.
\end{aligned}
$$

In the first, second, and third inequalities we have used (4.16), (4.8), and (4.6), respectively. We conclude that the admissible control sequence that we constructed has a running cost which is nearly optimal, as we had claimed.

We can now return to the proof of (4.5). Using (A.3), (4.18), and Lemma B.3(e) (with $\varepsilon = \sigma$), we get that

$$
\begin{aligned}
&\limsup_{n\to\infty} W^n_\sigma(x,\xi) \\
&\le \limsup_{n\to\infty} \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=1}^{n-1}[R(\nu^{1,n}_j(\cdot)||p(\cdot|\bar{X}^n_j,\bar{Z}^n_j)) + R(\nu^{2,n}_j(\cdot)||\rho(\cdot))] + h(\bar{Y}^n)\right\} \\
&\le \int_0^1 L_\sigma(\psi^*(t),\dot{\psi}^*(t))dt + 3\sigma + \limsup_{n\to\infty}\bar{E}_{x,\xi}\{h(\bar{Y}^n)\} \\
&\le \int_0^1 L_\sigma(\psi(t),\dot{\psi}(t))dt + 4\sigma + \limsup_{n\to\infty}\bar{E}_{x,\xi}\{h(\bar{Y}^n)\}.
\end{aligned}
$$

Thus, the proof of (4.5) will be complete once we prove that

$$
\limsup_{n\to\infty}\bar{E}_{x,\xi}\{h(\bar{Y}^n)\} \le h(\psi) + \tilde{\theta}(\sigma),
$$

with $\tilde{\theta}(\sigma)\to 0$ when $\sigma\to 0$. This in turn will be implied by

$$
\lim_{\sigma\to 0}\limsup_{n\to\infty}\bar{P}_{x,\xi}\left\{\sup_{t\in[0,1]}||\bar{Y}^n(t) - \psi^*(t)|| \ge \sigma\right\} = 0, \tag{4.19}
$$

because of the Lipschitz property of h and part (e) of Lemma B.3.

To show (4.19), it is convenient to define a sequence of control measures associated with the controls $\nu^{1,n}_j$ and $\nu^{2,n}_j$ given in (4.10) and (4.11). For $B_1, B_2 \in \mathcal{B}(S)$, $B \in$

$\mathcal{B}(\mathbb{R}^d)$, define

$$\tilde{\nu}_l^{1,n}(B_1 \times B_2) \doteq \frac{1}{m_n} \sum_{j=l_n}^{(l+1)m_n-1} \delta_{\bar{Z}_j^n}(B_1) \times \nu_j^{1,n}(B_2|\bar{X}_0^n, \ldots, \bar{X}_j^n, \bar{Z}_j^n),$$

$$\tilde{\nu}_l^{2,n}(B) \doteq \frac{1}{m_n} \sum_{j=lm_n}^{(l+1)m_n-1} \nu_j^{2,n}(B|\bar{X}_0^n, \ldots, \bar{X}_j^n),$$

$$\tilde{\nu}^{1,n}(\cdot|t) \doteq \begin{cases} \tilde{\nu}_l^{1,n}(\cdot) & \text{if} \quad t \in [lk_n, (l+1)k_n) \quad \text{for } l = 0, \ldots, 1/k_n - 2, \\ \tilde{\nu}_{(\frac{1}{k_n}-1)}^{1,n}(\cdot) & \text{if} \quad t \in [1-k_n, 1], \end{cases}$$

and

$$\tilde{\nu}^{2,n}(\cdot|t) \doteq \begin{cases} \tilde{\nu}_l^{2,n}(\cdot) & \text{if} \quad t \in [lk_n, (l+1)k_n) \quad \text{for } l = 0, \ldots, 1/k_n - 2, \\ \tilde{\nu}_{(\frac{1}{k_n}-1)}^{2,n}(\cdot) & \text{if} \quad t \in [1-k_n, 1]. \end{cases}$$

With B_1, B_2, and B as before, and with $C \in \mathcal{B}([0,1])$, now define the random measures $\nu^{1,n}$ and $\nu^{2,n}$ on $\mathcal{S} \times \mathcal{S} \times [0,1]$ and $\mathbb{R}^d \times [0,1]$, respectively, by

$$\nu^{1,n}(B_1 \times B_2 \times C) \doteq \int_C \nu^{1,n}(B_1 \times B_2|t)dt \quad \text{and} \quad \nu^{2,n}(B \times C) \doteq \int_C \nu^{2,n}(B|t)dt.$$

Finally, let ν_{prod}^n be the random measure on $\mathcal{S} \times \mathcal{S} \times \mathbb{R}^d \times [0,1]$ defined as

$$\nu_{prod}^n(B_1 \times B_2 \times B \times C) = \int_C \nu^{1,n}(B_1 \times B_2|t)\nu^{2,n}(B|t)dt. \tag{4.20}$$

Let us also define

$$S^{1,n}(t) \doteq x + \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(S^{1,n}(s), y)\nu^{1,n}(d\zeta \times dy \times ds)$$

and

$$S^{2,n}(t) \doteq \int_{\mathbb{R}^d\times[0,t]} y\nu^{2,n}(dy \times ds).$$

Since L_σ is continuous, ψ^* is continuous and $\dot{\psi}^*$ has only a finite number of discontinuities,

$$\sup_n \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu_j^{1,n}(\cdot) \times \nu_j^{2,n}(\cdot)||p(\cdot|\bar{X}_j^n, \bar{Z}_j^n) \times \rho_\sigma(\cdot))\right\} < \infty.$$

Theorem 5.3.5 in [4], the fact that $\mathcal{S}$ and $[0,1]$ are compact, and arguments analogous to the proof of Theorem C.1(e) then imply that given any subsequence of $\{(\nu^{1,n}, \nu^{2,n}, \bar{X}^n, \bar{U}^n, \tau^n, S^{1,n}, S^{2,n}), n \in \mathbb{N}\}$ there exists a subsubsequence such that $(\nu^{1,n}, \nu^{2,n}, \bar{X}^n, \bar{U}^n, \tau^n, S^{1,n}, S^{2,n})$ converges in distribution to $(\nu^1, \nu^2, \bar{X}, \bar{U}, \tau, \bar{X}, \bar{U})$ when $n \to \infty$. We define $\bar{Y}(t) \doteq \lim_{n\to\infty}(\bar{X}^n(t) + \bar{U}^n(t))$.

From the definition of $\bar{\beta}_j^{1,n}$ and Lemma B.3(d), for each $l \in \{0, \ldots, [\frac{\tau^n}{k_n}]\}$,

$$\begin{aligned} ||\bar{\beta}_{lm_n}^n - \dot{\psi}^*(lm_n/n)|| &= ||\bar{\beta}_{lm_n}^{1,n} + \bar{\beta}_{lm_n}^{2,n} - \dot{\psi}^*(lm_n/n)|| \\ &= \left\| \int_{\mathcal{S}} b(\bar{X}_{lm_n}^n, \xi)\mu_{lm_n}^n(d\xi) + \int_{\mathbb{R}^d} y\tilde{\nu}_{lm_n}^{2,n}(dy) - \dot{\psi}^*(lm_n/n) \right\| \\ &\leq K||\bar{X}_{lm_n}^n - \psi^*(lm_n/n)||. \end{aligned}$$

Then for $t \in [0,\tau]$

$$
\begin{aligned}
||\bar{Y}(t) - \psi^*(t)|| = \lim_{n\to\infty} \Bigg\| & \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(S^{1,n}(s),y)\nu^{1,n}(d\zeta\times dy\times ds) \\
& - \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\tilde{X}^n(s),y)\nu^{1,n}(d\zeta\times dy\times ds) \\
& + \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\tilde{X}^n(s),y)\nu^{1,n}(d\zeta\times dy\times ds) \\
& + \sum_{l=0}^{[\frac{t}{k_n}]} k_n \int_{\mathbb{R}^d} y\tilde{\nu}^{2,n}_{lm_n}(dy) - \sum_{l=0}^{[\frac{t}{k_n}]} k_n \int_{\mathcal{S}} b(\tilde{X}^n_{lm_n},\xi)\mu^n_{lm_n}(d\xi) \\
& + \sum_{l=0}^{[\frac{t}{k_n}]} k_n \int_{\mathcal{S}} b(\tilde{X}^n_{lm_n},\xi)\mu^n_{lm_n}(d\xi) - \int_0^t \dot{\psi}^*(s)ds \Bigg\| \\
\le \limsup_{n\to\infty} & \int_0^1 (K||S^{1,n}(s) - \tilde{X}^n(s)|| \wedge 2\|b\|_\infty)ds \\
& + \limsup_{n\to\infty} \sum_{l=0}^{[\frac{t}{k_n}]} k_n \Bigg\| \frac{1}{m_n} \sum_{j=l}^{(l+1)m_n} \int_{\mathcal{S}} b(\bar{X}_{lm_n},\zeta)\gamma^{1,n,j}_{lm_n}(d\zeta|\bar{X}^n_{lm_n},\bar{Z}_{lm_n}) \\
& \qquad\qquad - \int_{\mathcal{S}} b(\bar{X}^n_{lm_n},\xi)\mu^n_{lm_n}(d\xi) \Bigg\| \\
& + \limsup_{n\to\infty} K\int_0^t ||\bar{X}^n(s) - \psi^*(s)||ds \\
\le \limsup_{n\to\infty} & \sum_{l=0}^{[\frac{t}{k_n}]} k_n||b||_\infty \frac{A^2}{na^3} e^{2||b||_\infty \max_{x\in\Delta,\beta\in\Theta}\{\|\alpha(x,\beta)\|\}} \\
& + K\int_0^t ||\bar{X}(s) - \psi^*(s)||ds \\
\le K & \sup_{s\in[0,\tau]} ||\bar{X}(s) - \bar{Y}(s)|| + K\int_0^t ||\bar{Y}(s) - \psi^*(s)||ds.
\end{aligned}
$$

Gronwall's inequality with $\bar{K} \doteq Ke^K$ gives

$$
\sup_{s\in[0,\tau]} ||\bar{Y}(s) - \psi^*(s)|| \le \bar{K} \sup_{s\in[0,\tau]} ||\bar{X}(s) - \bar{Y}(s)|| = \bar{K} \sup_{s\in[0,\tau]} ||\bar{U}(s)||,
$$

which together with Lemma C.2 implies that

$$
\lim_{\sigma\to 0} \bar{P}_{x,\xi}\left\{ \sup_{s\in[0,\tau]} ||\bar{Y}(s) - \psi^*(s)|| \ge \frac{\sigma}{2} \right\} \le \lim_{\sigma\to 0} \bar{P}_{x,\xi}\left\{ \sup_{s\in[0,\tau]} ||\bar{U}(s)|| \ge \frac{\sigma}{2\bar{K}} \right\} = 0.
$$

Finally, writing $\tau = \tau_\sigma$ and following the same arguments given in [4, pp. 205–206], it is proved that $\lim_{\sigma\to 0} \bar{P}_{x,\xi}\{\tau_\sigma < 1\} = 0$. Since $\bar{Y}^n \to \bar{Y}$ w.p.1 uniformly on $[0,1]$, we obtain (4.19), which completes the proof of the lower bound. □

5. The case of noncompact $\mathcal{S}$. Without the assumption of compactness of $\mathcal{S}$, a strong positive recurrence hypothesis on $p(d\zeta|x,\xi)$ is required to guarantee tightness of the measures appearing in the proof of Theorem 2.1. This hypothesis is analogous to Condition 8.2.2 in [4].

Hypothesis H.2. There exists a measurable function $U : \mathcal{S} \to [0,\infty)$ with the following properties:

(a) $\inf_{\zeta\in\mathcal{S}} \left\{U(\zeta) - \log \int_{\mathcal{S}} e^{U(\zeta)} p(d\zeta|x,\xi)\right\} > -\infty$.

(b) For each $M < \infty$ and compact set $\Delta \subset \mathbb{R}^d$, the set

$$Z(M,\Delta) = \left\{(\xi,y) \in \mathcal{S}\times\Delta \,:\, c(\xi,y) := U(\xi) - \log \int_{\mathcal{S}} e^{U(\zeta)} p(d\zeta|y,\xi) \le M\right\}$$

is a compact subset of $\mathcal{S}\times\mathbb{R}^d$.

(c) U is bounded above on every compact subset of $\mathcal{S}$.

Under Hypothesis H.2, part (a) of Theorem C.1 remains valid for $\mathcal{S}$ noncompact, which implies Theorem 2.1 as well. Because the proof requires only small changes in the proofs of Lemma 8.2.4 and Proposition 8.2.5 in [4], we omit the details.

Appendix A. A representation formula. In this appendix we state the variational representation formula required in the proof of the lower bound. It can be derived easily by following the same steps as those given in [4, section 4.4].

Let $p\times\rho_\sigma$ be the stochastic kernel on $S\times\mathbb{R}^d$ given $\xi\in\mathcal{S}$, $x\in\mathbb{R}^d$ defined by $(p\times\rho_\sigma)(d\zeta\times dy|x,\xi) \doteq p(d\zeta|x,\xi)\times\rho_\sigma(dy)$. We consider admissible control sequences consisting of stochastic kernels $\nu_j^n(d\zeta\times dy|\bar X_0^n,\dots,\bar X_j^n,\bar U_0^n,\dots,\bar U_j^n,\bar Z_j^n)$ on $\mathcal{S}\times\mathbb{R}^d$ given $(\mathbb{R}^d)^{j+1}\times(\mathbb{R}^d)^{j+1}\times\mathcal{S}$. For each admissible control sequence $\{\nu_j^n, j=0,\dots,n-1\}$, the controlled system is defined by setting $\bar X_0^n \doteq x$, $\bar U_0^n \doteq 0$ and for $j=0,\dots,n-1$ through

$$\bar X_{j+1}^n \doteq \bar X_j^n + \frac{1}{n}\, b(\bar X_j^n, \bar Z_{j+1}^n),\ \bar U_{j+1}^n \doteq \bar U_j^n + \frac{1}{n}\,\bar G_j^n, \text{ and } \bar Y_j^n = \bar X_j^n + \bar U_j^n, \tag{A.1}$$

where the conditional distribution of $(\bar Z_{j+1}^n, \bar G_j^n)$ is given by

$$\begin{aligned}\bar P_{x,\xi}\left\{(\bar Z_{j+1}^n,\bar G_j^n)\in(d\zeta\times dy)|\bar X_0^n,\dots,\bar X_j^n,\bar U_0^n,\dots,\bar U_j^n,\bar Z_j^n\right\}\\ = \nu_j^n(d\zeta\times dy|\bar X_0^n,\dots,\bar X_j^n,\bar U_0^n,\dots,\bar U_j^n,\bar Z_j^n).\end{aligned} \tag{A.2}$$

We define the processes $\bar X^n \doteq \{\bar X^n(t), t\in[0,1]\}$, $\bar U^n = \{\bar U^n(t), t\in[0,1]\}$, and $\bar Y^n \doteq \{\bar Y^n(t), t\in[0,1]\}$ as the linear interpolations of $\{\bar X_j^n\}$, $\{\bar U_j^n\}$, and $\{\bar Y_j^n\}$, respectively.

THEOREM A.1. *Let $W_\sigma^n(x,\xi) \doteq -1/n \log E_{x,\xi}\{\exp[-nh(Y_\sigma^n)]\}$, where Y_σ^n is defined by* (4.1), *$E_{x,\xi}$ denotes expectation conditioned on $X_0^n = x$ and $Z_0^n = \xi$, and h is a bounded measurable function mapping $\mathcal{C}([0,1]:\mathbb{R}^d)\mapsto\mathbb{R}$. Then for all $n\in\mathbb{N}$, $x\in\mathbb{R}^d$, $\xi\in\mathcal{S}$, and $\sigma>0$, we have the representation*

$$W_\sigma^n(x,\xi) = \inf_{\{\nu_j^n\}} \bar E_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu_j^n(\cdot)||(p\times\rho_\sigma)(\cdot|\bar X_j^n,\bar Z_j^n)) + h(\bar Y^n)\right\}. \tag{A.3}$$

Appendix B. Properties of the functions Λ, L, and L_σ. In this appendix we establish properties of the functions $\Lambda(x,\alpha)$ and $L(x,\beta)$ defined in (2.3) and (2.2), respectively, and of the function L_σ defined in (4.2).

LEMMA B.1. *Under Hypothesis* H.1, *the function* $\Lambda(x,\alpha)$ *defined in* (2.3) *satisfies the following properties. For each* $x \in \mathbb{R}^d$, $\Lambda(x,\alpha)$ *is a finite strictly convex function of* $\alpha \in \mathbb{R}^d$ *which is differentiable for all* α. *In addition,* $\Lambda(x,\alpha)$ *is a continuous function of* $(x,\alpha) \in \mathbb{R}^d \times \mathbb{R}^d$.

These properties follow from Lemmas 3.1 and 3.4 in [7] given the relation between the function Λ and the solution to the eigenvalue problem given in (2.1).

Lemma 2.1 in [3] gives a list of properties that are satisfied by the function L, the Legendre–Fenchel transform of Λ. These include convexity and lowersemicontinuity in β, positivity, and uniqueness. Part (a) of the following lemma is also among those properties, and we state it here for use in the proof of part (b), which provides an important variational representation for the function L.

LEMMA B.2. *Under Hypothesis* H.1, *the function* $L(x,\beta)$ *defined in* (2.2) *satisfies the following properties.*

(a) *If* $L(x,\beta)$ *is finite in a neighborhood of* β', *then* $\nabla L(x,\beta')$ *exists and* $L(x,\beta') = \langle \alpha, \beta' \rangle - \Lambda(x,\alpha)$ *if and only if* $\alpha = \nabla L(x,\beta')$.

(b) *For each* x *and* β *in* $\mathbb{R}^d$,

$$L(x,\beta) = \inf \left\{ \int_{\mathcal{S}} R(\gamma(\cdot|x,\xi) \| p(\cdot|x,\xi)) \mu(d\xi) : \gamma\mu = \mu, \int_{\mathcal{S}} b(x,\xi) d\mu = \beta \right\}.$$

If L *is finite, then the infimum is attained uniquely.*

Proof. (a) Since $\Lambda(x,\cdot)$ is strictly convex on $\mathbb{R}^d$, $L(x,\cdot)$ is differentiable on $\mathrm{int}(\mathrm{dom} L(x,\cdot))$. See Theorem D.2.8 in [4]. The last part follows from standard results.

(b) First we consider the case when $\beta \in \mathrm{ri}(\mathrm{dom} L(x,\cdot))$. For $\alpha \in \mathbb{R}^d$ let γ_α be the stochastic kernel defined by

$$\frac{d\gamma_\alpha(\cdot|x,\xi)}{dp(\cdot|x,\xi)}(\zeta) = \frac{e^{\langle \alpha, b(x,\zeta)\rangle + \psi(\zeta)}}{\int_{\mathcal{S}} e^{\langle \alpha, b(x,\zeta)\rangle + \psi(\zeta)} p(d\zeta|x,\xi)}.$$

In terms of the function Λ defined in (2.1) we can write

$$\frac{d\gamma_\alpha(\cdot|x,\xi)}{dp(\cdot|x,\xi)}(\zeta) = e^{-\Lambda(x,\alpha) - \psi(\xi) + \langle \alpha, b(x,\zeta)\rangle + \psi(\zeta)}.$$

Let μ^α be the unique invariant measure of γ_α. (Proposition 4.1 in [7] guarantees that such a measure exists.) Part (a) of the present lemma and the fact that $\Lambda(x,\cdot)$ is strictly convex and differentiable imply that there exists a unique $\alpha = \alpha(x,\beta)$ such that

$$L(x,\beta) = \langle \alpha(x,\beta), \beta \rangle - \Lambda(x, \alpha(x,\beta)) \tag{B.1}$$

with $\alpha(x,\beta) \in \partial L(\beta)$ if and only if $\beta = \nabla \Lambda(x, \alpha(x,\beta))$ (see Corollary 26.3.1 in [14]). Then, Proposition 4.1 in [7] gives

$$E^{\gamma_\alpha}_{\mu^\alpha} b(x,\xi) = \int_{\mathcal{S}} b(x,\xi) \mu^\alpha(d\xi) = \beta. \tag{B.2}$$

Now let γ be any kernel (with corresponding invariant measure μ^γ) satisfying

$$\int_{\mathcal{S}} b(x,\xi) \mu^\gamma(d\xi) = \beta \quad \text{and} \quad \int_{\mathcal{S}} R(\gamma(\cdot|\xi) \| p(\cdot|x,\xi)) \mu^\gamma(\xi) < \infty.$$

Then $\gamma(\cdot|x,\xi) \ll p(\cdot|x,\xi)$ for μ^γ-almost all ξ. Since $\frac{d\gamma_\alpha}{dp}$ is strictly positive, $\gamma(\cdot|x,\xi) \ll \gamma_\alpha(\cdot|x,\xi)$ for almost all ξ (with respect to μ^γ) and

$$\begin{aligned}
&\int_{\mathcal{S}} R(\gamma(\cdot|x,\xi)\|p(\cdot|x,\xi))\mu^\gamma(d\xi)\\
&= \int_{\mathcal{S}}\int_{\mathcal{S}} \log\frac{d\gamma(\cdot|x,\xi)}{dp(\cdot|x,\xi)}(\zeta)\gamma(d\zeta|x,\xi)\mu^\gamma(d\xi)\\
&= \int_{\mathcal{S}}\left[\int_{\mathcal{S}} \log\frac{d\gamma(\cdot|x,\xi)}{d\gamma_\alpha(\cdot|x,\xi)}(\zeta)\gamma(d\zeta|x,\xi) + \int_{\mathcal{S}} \log\frac{d\gamma_\alpha(\cdot|x,\xi)}{dp(\cdot|x,\xi)}(\zeta)\gamma(d\zeta|x,\xi)\right]\mu^\gamma(d\xi)\\
&= \int_{\mathcal{S}} R(\gamma(\cdot|x,\xi)\|\gamma_\alpha(\cdot|x,\xi))\mu^\gamma(d\xi)\\
&\quad + \int_{\mathcal{S}}\int_{\mathcal{S}} \log\Big[\exp\big[\langle\alpha, b(x,\zeta)\rangle + \psi(\zeta) - \psi(\xi) - \Lambda(x,\alpha)\big]\Big]\gamma(d\zeta|x,\xi)\mu^\gamma(d\xi)\\
&= \int_{\mathcal{S}} R(\gamma(\cdot|x,\xi)\|\gamma_\alpha(\cdot|x,\xi))\mu^\gamma(d\xi) - \Lambda(x,\alpha)\\
&\quad - \int_{\mathcal{S}}\psi(\xi)\mu^\gamma(d\xi) + \int_{\mathcal{S}}\int_{\mathcal{S}}\left[\langle\alpha, b(x,\zeta)\rangle + \psi(\zeta)\right]\gamma(d\zeta|x,\xi)\mu^\gamma(d\xi)\\
&= \int_{\mathcal{S}} R(\gamma(\cdot|x,\xi)\|\gamma_\alpha(\cdot|x,\xi))\mu^\gamma(d\xi) - \Lambda(x,\alpha) + \int_{\mathcal{S}}\langle\alpha, b(x,\xi)\rangle\mu^\gamma(d\xi)\\
&= \int_{\mathcal{S}} R(\gamma(\cdot|x,\xi)\|\gamma_\alpha(\cdot|x,\xi))\mu^\gamma(d\xi) + L(x,\beta) \geq L(x,\beta).
\end{aligned}$$

Equality is obtained if and only if $\gamma \equiv \gamma_\alpha$. If β does not belong to $\mathrm{ri}(\mathrm{dom}L(x,\cdot))$, analogous arguments to those given in Appendix C.5 in [4] can be adapted. □

The next result establishes properties of the function L_σ defined in (4.2) that are needed in the proof of the lower bound.

LEMMA B.3. *Given $\sigma > 0$, the function $L_\sigma(x,\beta)$ satisfies the following properties:*

(a) $L_\sigma(x,\beta) = \inf_{z\in\mathbb{R}^d}\{L(x,\beta - z) + \frac{||z||^2}{2\sigma^2}\}$ *and* $L_\sigma(x,\beta) \leq L(x,\beta)$.

(b) $L_\sigma(x,\beta)$ *is a finite, nonnegative, continuous function of* $(x,\beta) \in \mathbb{R}^d \times \mathbb{R}^d$. *Moreover,* $L_\sigma(x,\cdot)$ *is differentiable on* $\mathbb{R}^d$.

(c)

$$\begin{aligned}
L_\sigma(x,\beta) = \inf\Big\{&\int_{\mathcal{S}} R(\gamma(\cdot|x,\xi)\times\upsilon(\cdot)||p(\cdot|x,\xi)\times\rho_\sigma(\cdot))\mu(d\xi) :\\
&\mu\gamma = \mu, \int_{\mathcal{S}} b(x,\xi)\mu(d\xi) + \int_{\mathbb{R}^d} y\upsilon(dy) = \beta\Big\}.
\end{aligned}$$

Further, for each $x,\beta \in \mathbb{R}^d$ there exist a stochastic kernel γ^* and a measure υ^* such that the infimum on the right-hand side is achieved. For Borel sets B_1 of $\mathcal{S}$ and B_2 of $\mathbb{R}^d$, these are given by

$$\gamma^*(B_1|x,\xi) \doteq \int_{B_1} e^{\langle\alpha,b(x,\zeta)\rangle - \Lambda(x,\alpha) - \Psi_\sigma(x;\alpha,\xi) + \Psi_\sigma(x;\alpha,\zeta)} p(d\zeta|x,\xi)$$

and

$$\upsilon^*(B_2) \doteq \int_{B_2} e^{\langle\alpha,y\rangle - \frac{\sigma^2||\alpha||^2}{2}}\rho_\sigma(dy),$$

with $\alpha = \alpha(x,\beta) \in \mathrm{argmax}\{\langle\alpha,\beta\rangle - \Lambda_\sigma(x,\alpha) : \alpha\in\mathbb{R}^d\}$.

(d) *Given any compact set* $\Delta \subset \mathbb{R}^d$ *and* $\varepsilon \in (0,1)$, *there exists* $\eta \in (0,1)$ *such that, whenever* $x, y \in \Delta$, $\beta \in \mathbb{R}^d$, *and* $||x-y|| \le \eta$, *there exists* $\bar{\beta} \in \mathbb{R}^d$ *such that*

$$L_\sigma(y,\bar{\beta}) - L_\sigma(x,\beta) \le \varepsilon \quad \text{and} \quad ||\bar{\beta}-\beta|| \le K||x-y||,$$

where K *is the Lipschitz constant of* b.

(e) *Given* $\psi \in \mathcal{C}([0,1] : \mathbb{R}^d)$ *satisfying* $I_x(\psi) < \infty$ *and* $\varepsilon > 0$, *there exists* $\psi^* \in \mathcal{C}([0,1] : \mathbb{R}^d)$, *with* $\dot{\psi}^*$ *piecewise constant with only finitely many jumps in the interval* $(0,1)$, *such that* $||\psi - \psi^*||_\infty < \varepsilon$ *and*

$$\int_0^1 L_\sigma(\psi^*(t), \dot{\psi}^*(t))dt \le \int_0^1 L_\sigma(\psi(t), \dot{\psi}(t))dt + \varepsilon \le I_x(\psi) + \varepsilon.$$

(f) *The function* $(x,\beta) \to \alpha(x,\beta) \in \operatorname{argmax}\{\langle \alpha, \beta\rangle - \Lambda_\sigma(x,\alpha) : \alpha \in \mathbb{R}^d\}$ *is continuous.*

Proof. (a) The first statement follows from Corollary D.4.2 in [4], while for the second part we take $z = 0$.

(b) From Theorem 26.4 in [14] and Lemma 3.4(iv) in [7], we have that $\operatorname{int}(\operatorname{Dom} L_\sigma(x,\cdot)) = \operatorname{Range}(\nabla\Lambda_\sigma(x,\cdot)) = \mathbb{R}^d$. So $L_\sigma(x,\beta) < \infty$ for all $(x,\beta) \in \mathbb{R}^d \times \mathbb{R}^d$. The nonnegativity of $L_\sigma(x,\beta)$ follows from the nonnegativity of $L(x,\beta)$. The continuity follows from Lemma C.8.1 in [4] and the continuity of $\Lambda(x,\alpha)$ in both variables. Finally, the differentiability follows from the strict convexity of Λ and Theorem D.2.8 in [4].

(c) Let $x, \beta \in \mathbb{R}^d$. From part (b) there exists $\alpha \in \mathbb{R}^d$, with $\alpha = \alpha(x,\beta)$, such that $\beta = \nabla_\alpha \Lambda_\sigma(x,\alpha)$ and $L_\sigma(x,\beta) = \langle \alpha, \beta\rangle - \Lambda_\sigma(x,\alpha)$. Let

$$\gamma_\alpha(d\zeta \times dy|x,\xi) = \exp\Big\{\langle \alpha, b(x,\zeta)\rangle + \Psi(x;\alpha,\zeta) - \Psi(x;\alpha,\xi) - \Lambda(x,\alpha) - \frac{\sigma^2}{2}||\alpha||^2\Big\} p(d\zeta|x,\xi)\rho_\sigma(dy).$$

From Proposition 4.1 in [7],

$$\beta = \int_{\mathcal{S}} b(x,\xi)\mu(d\xi) + \int_{\mathcal{S}} y e^{\langle \alpha, y\rangle - \frac{\sigma^2}{2}||\alpha||^2}\rho_\sigma(dy),$$

where μ is the unique invariant measure of the first marginal of γ_α given by

$$\gamma_{\alpha,1}(d\zeta|x,\xi;\alpha) = \exp\{\langle \alpha, b(x,\zeta)\rangle + \Psi(x;\alpha,\zeta) - \Psi(x;\alpha,\xi) - \Lambda(x,\alpha)\} p(d\zeta|x,\xi).$$

The rest of the proof follows the same arguments given in the proof of Lemma B.2(b) after (B.2).

(d) Let $\Delta \subset \mathbb{R}^d$ compact, $x, y \in \Delta$, $\beta \in \mathbb{R}^d$, and $\varepsilon \in (0,1)$. We know from part (c) that there exist γ^* and υ^* such that the infimum in part (c) is attained for (x,β). Define $\bar{\beta} \doteq \int_{\mathcal{S}} b(y,\xi)\mu^{\gamma^*}(d\xi) + \int_{\mathbb{R}^d} y\nu^*(dy)$. Then, from the representation formula given in part (c),

$$||\beta - \bar{\beta}|| \le \left|\int_{\mathcal{S}} (b(x,\xi) - b(y,\xi))\mu^{\gamma^*}(d\xi)\right| \le K\|x-y\|.$$

Now, for any Borel set B of $\mathcal{S}$, we can use part (c) of Hypothesis H.1 to write

$$\gamma^*(B|x,\xi) = \int_B \exp\Big\{\langle \alpha, b(x,\zeta)\rangle + \Psi_\sigma(x;\alpha,\zeta) - \Psi_\sigma(x;\alpha,\xi) - \Lambda(x,\alpha)\Big\}\tilde{p}^x(\xi,\zeta)\vartheta(d\zeta).$$

From the bound that we have on $\tilde{p}^x(\cdot,\cdot)$, it follows that $\gamma^*(\cdot|x,\xi)$ is absolutely continuous with respect to $p(\cdot|y,\xi)$; from the uniform continuity of $\tilde{p}^x(\xi,\zeta)$, there exists $\eta > 0$ such that $\|x-y\| < \eta$ implies that $\tilde{p}^x(\xi,\zeta) \le \tilde{p}^y(\xi,\zeta)e^{\varepsilon}$ (this is as in (4.15)). Then, from the variational equivalence given in part (c), $L_\sigma(y,\bar{\beta}) < \infty$ and

$$\begin{aligned} L_\sigma(y,\bar{\beta}) &\le \int_{\mathcal{S}} R(\gamma^*(\cdot|x,\xi)\times\nu^*(\cdot)||p(\cdot|y,\xi)\times\rho_\sigma(\cdot))\mu^{\gamma^*}(d\xi) \\ &\le \Big\langle \alpha, \int_{\mathcal{S}} b(x,\xi)\mu^{\gamma^*}(d\xi)\Big\rangle - \Lambda(x,\alpha) + \Big\langle \alpha, \int_{\mathbb{R}^d} y\nu^*(dy)\Big\rangle - \frac{\sigma^2}{2}||\alpha||^2 + \varepsilon \\ &= \langle \alpha,\beta\rangle - \Lambda_\sigma(x,\alpha) + \varepsilon = L_\sigma(x,\beta) + \varepsilon. \end{aligned}$$

(e) The proof of this part is based on Lemmas 6.5.3 and 6.5.5 of [4], which in our case also hold due to the structural properties given in parts (a) and (b).

(f) Given x, $\beta \in \mathbb{R}^d$, part (b) and the differentiability of $\alpha \to \Lambda_\sigma(x,\alpha)$ imply that there exists a unique $\alpha(x,\beta)$ such that $L_\sigma(x,\beta) = \langle \alpha(x,\beta),\beta\rangle - \Lambda_\sigma(x,\alpha(x,\beta))$, $\beta = \nabla_\alpha\Lambda_\sigma(x,\alpha(x,\beta))$, and $\alpha(x,\beta) = \nabla_\beta L_\sigma(x,\beta)$. We observe that $\beta \to L_\sigma(x,\beta)$ is continuously differentiable thanks to [14, Corollary 25.5.1]. Moreover, $x \to \nabla_\beta L_\sigma(x,\beta)$ is continuous [14, Theorem 25.7] and, in fact, $(x,\beta) \to \nabla_\beta L_\sigma(x,\beta)$ is continuous by the same theorem. Therefore, $(x,\beta) \to \alpha(x,\beta)$ is continuous in both variables. This completes the proof of the lemma. □

Appendix C. Proofs of some limit results. This appendix is dedicated to the proofs of some limit results needed in the proof of Theorem 2.1.

THEOREM C.1. *Let $\mathcal{S}$ be compact. For any $x \in \mathbb{R}^d$, $\xi \in \mathcal{S}$ and each $n \in \mathbb{N}$, consider any admissible control sequence such that*

$$\sup_{n\in\mathbb{N}} \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1} R(\nu_j^n(\cdot)\|p(\cdot|\bar{X}_j^n,\bar{Z}_j^n))\right\} < \infty,$$

where $\nu_j^n(\cdot) = \nu_j^n(\cdot|\bar{X}_0^n,\dots,\bar{X}_j^n,\bar{Z}_j^n)$. In terms of these sequences we define the piecewise linear interpolation $\{\bar{X}^n\}$, the piecewise constant interpolation $\{\tilde{X}^n\}$, the sequence of admissible control measures $\{\nu^n\}$ and its marginals $\{\hat{\nu}_2^n\otimes\lambda, \hat{\nu}_1^n\otimes\lambda\}$, and the measures $\{\gamma^n\}$ as in section 3. Also, for each $n \in \mathbb{N}$ we define the process $S^n = \{S^n(t), t\in[0,1]\}$ by

$$S^n(t) \doteq x + \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(S^n(s),y)\nu^n(d\zeta\times dy\times ds).$$

The following conclusions hold.

(a) *Given any subsequence of $\{(\nu^n, \hat{\nu}_2^n\otimes\lambda, \hat{\nu}_1^n\otimes\lambda, \gamma^n, \bar{X}^n, \tilde{X}^n, S^n), n\in\mathbb{N}\}$, there exist a subsubsequence, a stochastic kernel ν on $\mathcal{S}\times\mathcal{S}\times[0,1]$ (given $\bar{\Omega}$) with marginals μ_1, μ_2, a stochastic kernel γ on $\mathcal{S}\times\mathcal{S}\times[0,1]$, and random variables $\bar{X}$ and S mapping $\bar{\Omega}$ into $\mathcal{C}([0,1]:\mathbb{R}^d)$ such that the subsubsequence converges in distribution to $(\nu,\mu_1,\mu_2,\gamma,\bar{X},\bar{X},S)$.*

(b) *The stochastic kernel ν has the decomposition*

$$\nu(B_1\times B_2\times C) = \int_C \nu(B_1\times B_2|t)dt = \int_C\int_{B_1} \hat{\nu}_1(d\zeta|t)\hat{\nu}_2(B_2|\zeta,t)dt$$

for some stochastic kernels $\nu(\cdot|t)$ on $\mathcal{S}\times\mathcal{S}$ given $[0,1]$, $\hat{\nu}_1(\cdot|t)$ on $\mathcal{S}$ given $[0,1]$, and $\hat{\nu}_2(\cdot|\zeta,t)$ on $\mathcal{S}$ given $\mathcal{S}\times[0,1]$.

(c) *We have the equality $\hat{\nu}_1\otimes\lambda = \hat{\nu}_2\otimes\lambda$.*

(d) *$\hat{\nu}_1(d\zeta|t)$ is an invariant measure of $\hat{\nu}_2(dy|\zeta,t)$ for each $t\in[0,1]$.*

(e) *W.p.*1 *for every* $t \in [0,1]$

$$\bar{X}(t) = x + \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu(d\zeta \times dy \times ds) \tag{C.1}$$
$$= x + \int_0^t \int_{\mathcal{S}} b(\bar{X}(s), \zeta)\hat{\nu}_1(d\zeta|s)ds.$$

(f) *The stochastic kernel* γ *has the decomposition*

$$\gamma(B_1 \times B_2 \times C) = \int_C \int_{B_1\times B_2} \hat{\nu}_1(d\zeta|t) \otimes p(dy|\bar{X}(t), \zeta)dt.$$

Proof. (a) Given the compactness of $\mathcal{S}$, we immediately get tightness of ν^n, of γ^n, and of all the marginals. Tightness of $\{\bar{X}^n\}$ and of $\{\tilde{X}^n\}$ on $\mathcal{C}([0,1] : \mathbb{R}^d)$ follows from the bound

$$w_{\bar{X}^n}(\delta) \doteq \sup_{\{s,t\in[0,1]:|s-t|\le\delta\}} \|\bar{X}^n(t) - \bar{X}^n(s)\| \le 2\|b\|_\infty\delta, \tag{C.2}$$

and tightness of $\{S^n\}$ can be verified similarly. Since the function mapping ν^n into $(\nu^n, \hat{\nu}_1^n \otimes \lambda, \hat{\nu}_2^n \otimes \lambda)$ is continuous, there exist measures ν and γ over $\mathcal{S}\times\mathcal{S}\times[0,1]$, measures μ_1 and μ_2 over $\mathcal{S}\times[0,1]$, and random variables $\bar{X}$ and S on $\mathcal{C}([0,1] : \mathbb{R}^d)$ such that $(\nu^n, \hat{\nu}_1^n \otimes \lambda, \hat{\nu}_2^n \otimes \lambda, \gamma^n, \bar{X}^n, \tilde{X}^n, S^n) \xrightarrow{\mathcal{D}} (\nu, \mu_1, \mu_2, \gamma, \bar{X}, \bar{X}, S)$ [4, Theorem A.3.6]. Moreover, w.p.1 μ_1 and μ_2 equal the marginals of ν over (ζ, t) and over (y, t), respectively. For the developments below, we note that by the Skorohod representation theorem we can assume that convergence takes place w.p.1 on some probability space, which we also denote by $(\bar{\Omega}, \bar{\mathcal{F}}, \bar{P})$.

(b) We let μ_3 denote the marginal of ν over t. Using the fact that the marginal of ν^n over t is Lebesgue measure λ, we have that w.p.1 for any bounded continuous function g mapping $[0,1]$ into $\mathbb{R}$,

$$\begin{aligned}\int_0^1 g(t)\mu_3(dt) &= \int_{\mathcal{S}\times\mathcal{S}\times[0,1]} g(t)\nu(d\zeta \times dy \times dt)\\ &= \lim_{n\to\infty} \int_{\mathcal{S}\times\mathcal{S}\times[0,1]} g(t)\nu^n(d\zeta \times dy \times dt)\\ &= \lim_{n\to\infty} \int_0^1 g(t)dt\\ &= \int_0^1 g(t)dt.\end{aligned}$$

Since the class of bounded and continuous functions is a measure determining class [1, Theorem 1.3], this implies that w.p.1 $\mu_3(\cdot)$ equals $\lambda(\cdot)$. By Theorem A.5.6 in [4], there exists a stochastic kernel $\nu(d\zeta \times dy|t)$ on $\mathcal{S}\times\mathcal{S}$ given $[0,1]$ such that w.p.1

$$\nu(B_1 \times B_2 \times C) = \int_C \nu(B_1 \times B_2|t)\, dt.$$

Once more Theorem A.5.6 in [4] gives the existence of stochastic kernels $\hat{\nu}_2(dy|\zeta, t)$ on $\mathcal{S}$ given $\mathcal{S}\times[0,1]$ and $\hat{\nu}_1(d\zeta|t)$ on $\mathcal{S}$ given $[0,1]$ (the second and first marginals of $\nu(d\zeta \times dy|t)$, respectively) such that

$$\nu(B_1 \times B_2 \times C) = \int_C \int_{B_1} \hat{\nu}_1(d\zeta|t)\hat{\nu}_2(B_2|\zeta, t)dt.$$

This gives the decomposition of $\nu(d\zeta \times dy \times dt)$ given in part (b).

(c) Consider a function f of the form $f(y,t) = g(y)h(t)$, with $g \in \mathcal{C}(\mathcal{S} : \mathbb{R}^d)$ and $h \in \mathcal{C}([0,1] : \mathbb{R}^d)$. Since

$$\bar{E}_{x,\xi}\left\{g(\bar{Z}^n_{j+1}) - \int_{\mathcal{S}} g(y)\nu^n_j(dy|\bar{X}_0,\dots,\bar{X}^n_j,\bar{Z}^n_j)\right\} = 0,$$

we have that

$$\left\{g(\bar{Z}^n_{j+1}) - \int_{\mathcal{S}} g(y)\nu^n_j(dy|\bar{X}^n_0,\dots,\bar{X}^n_j,\bar{Z}^n_j)\right\}$$

is a martingale difference sequence. Moreover,

$$\begin{aligned}\int_{\mathcal{S}\times[0,1]} f(\zeta,t)(\hat{\nu}^n_1\otimes\lambda)(d\zeta\times dt) &= \sum_{l=0}^{\frac{1}{k_n}-1}\int_{lk_n}^{(l+1)k_n} h(t)dt\cdot\int_{\mathcal{S}} g(\zeta)(\tilde{\nu}^n_l)_1(d\zeta)\\ &= \sum_{l=0}^{\frac{1}{k_n}-1}\int_{lk_n}^{(l+1)k_n} h(t)dt\cdot\frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1} g(\bar{Z}^n_j)\end{aligned}$$

and similarly

$$\begin{aligned}&\int_{\mathcal{S}\times[0,1]} f(y,t)(\hat{\nu}^n_2\otimes\lambda)(dy\times dt)\\ &= \sum_{l=0}^{\frac{1}{k_n}-1}\int_{lk_n}^{(l+1)k_n} h(t)dt\cdot\left[\frac{1}{m_n}\sum_{j=lm_n}^{(l+1)m_n-1}\int_{\mathcal{S}} g(y)\nu^n_j(dy)\right].\end{aligned}$$

Noting that

$$\left\|\sum_{l=0}^{\frac{1}{k_n}-1}\frac{1}{m_n}\left[\int_{lk_n}^{(l+1)k_n} h(t)dt\right]\left[g(\bar{Z}^n_{lm_n}) - g(\bar{Z}^n_{(l+1)m_n})\right]\right\| \le \frac{2\|g\|\|h\|}{m_n},$$

we have that if $m_n \ge \frac{4\|g\|\|h\|}{\varepsilon}$, then

$$\begin{aligned}&\bar{P}_{x,\xi}\left\{\left|\int_{\mathcal{S}\times[0,1]} f d(\hat{\nu}^n_1\otimes\lambda) - \int_{\mathcal{S}\times[0,1]} f d(\hat{\nu}^n_2\otimes\lambda)\right| \ge \varepsilon\right\}\\ &\quad\le \bar{P}_{x,\xi}\left\{\left|\sum_{l=0}^{\frac{1}{k_n}-1}\frac{1}{m_n}\left[\int_{lk_n}^{(l+1)k_n} h(t)dt\right]\left[\sum_{j=lm_n}^{(l+1)m_n-1}\left(g(\bar{Z}^n_{j+1}) - \int g(y)\nu^n_j(dy)\right)\right]\right| \ge \frac{\varepsilon}{2}\right\}\\ &\quad\le \bar{P}_{x,\xi}\left\{\left|\frac{1}{n}\sum_{j=0}^{n-1}\left[g(\bar{Z}^n_{j+1}) - \int_{\mathcal{S}} g(y)\nu^n_j(dy)\right]\right| \ge \frac{\varepsilon}{2\|h\|}\right\}\\ &\le \frac{4\|h\|^2}{\varepsilon^2}\bar{E}_{x,\xi}\left\{\frac{1}{n^2}\left(\sum_{j=0}^{n-1}\left[g(\bar{Z}^n_{j+1}) - \int_{\mathcal{S}} g(y)\nu^n_j(dy)\right]\right)^2\right\}\\ &\le \frac{4\|h\|^2}{\varepsilon^2}\bar{E}_{x,\xi}\left\{\frac{1}{n^2}\sum_{j=0}^{n-1}\left(g(\bar{Z}^n_{j+1}) - \int_{\mathcal{S}} g(y)\nu^n_j(dy)\right)^2\right\} \le \frac{16\|h\|^2\|g\|^2}{n\varepsilon^2}. \qquad \text{(C.3)}\end{aligned}$$

This implies that $\int_{\mathcal{S}\times[0,1]} f d(\hat{\nu}_1^n \otimes \lambda) - \int_{\mathcal{S}\times[0,1]} f d(\hat{\nu}_2^n \otimes \lambda)$ converges to zero in probability and hence in distribution [1, Theorem 4.3]. Given the convergence w.p.1 of $\hat{\nu}_1^n \otimes \lambda$ and $\hat{\nu}_2^n \otimes \lambda$ to $\hat{\nu}_1 \otimes \lambda$ and $\hat{\nu}_2 \otimes \lambda$, respectively, we get w.p.1

$$\lim_{n\to\infty} \int_{\mathcal{S}\times[0,1]} f(y,t)(\hat{\nu}_r^n \otimes \lambda)(dy \times dt) = \int_{\mathcal{S}\times[0,1]} f(y,t)(\hat{\nu}_r \otimes \lambda)(dy \times dt)$$

for $r = 1, 2$. Therefore w.p.1

$$\int_{\mathcal{S}\times[0,1]} f(y,t)(\hat{\nu}_1 \otimes \lambda)(dy \times dt) = \int_{\mathcal{S}\times[0,1]} f(y,t)(\hat{\nu}_2 \otimes \lambda)(dy \times dt). \tag{C.4}$$

Theorem A.3.14 in [4] implies that we can extend the equality in (C.4) from f of the form $f(y,t) = g(y)h(t)$ to all $f : \mathcal{S} \times [0,1] \mapsto \mathbb{R}$ that are bounded and continuous. Since the class of bounded continuous functions is measure-determining, we have that $\hat{\nu}_1 \otimes \lambda = \hat{\nu}_2 \otimes \lambda$, as we wanted to show.

(d) We now show that for each $t \in [0,1]$ and Borel subset B_1 of $\mathcal{S}$, we have

$$\hat{\nu}_1(B_1|t) = \int_{\mathcal{S}} \hat{\nu}_2(B_1|\zeta, t)\hat{\nu}_1(d\zeta|t). \tag{C.5}$$

Let $\mathcal{U}_b(\mathcal{S})$ denote the space of bounded, uniformly continuous functions mapping $\mathcal{S}$ into $\mathbb{R}$. Since $\mathcal{S}$ is Polish, there exists an equivalent metric m under which $\mathcal{U}_b(\mathcal{S}, m)$ is separable with respect to the uniform metric. Let $\mathcal{E}$ be a countable dense subset of $\mathcal{U}_b(\mathcal{S}, m)$, and let g be any function in $\mathcal{E}$. For each $s \in [0,1]$ let $E_i \subset [0,1]$ be a sequence of sets which *shrinks nicely* to s (see [2, p. 353]), and define

$$f(t,y) \doteq g(y) \cdot \frac{1}{\lambda(E_i)} I_{E_i}(t).$$

Since $\hat{\nu}_1 \otimes \lambda = \hat{\nu}_2 \otimes \lambda$,

$$\frac{1}{\lambda(E_i)} \int_{E_i} \int_{\mathcal{S}} g(y)\hat{\nu}_1(dy|t)\lambda(dt) = \frac{1}{\lambda(E_i)} \int_{E_i} \int_{\mathcal{S}} \int_{\mathcal{S}} g(y)\hat{\nu}_2(dy|\zeta, t)\hat{\nu}_1(d\zeta|t)\lambda(dt).$$

Define $h_1(t) \doteq \int_{\mathcal{S}} g(y)\hat{\nu}_1(dy|t)$ and $h_2(t) \doteq \int_{\mathcal{S}} \int_{\mathcal{S}} g(y)\hat{\nu}_2(dy|\zeta, t)\hat{\nu}_1(d\zeta|t)$. Then we have

$$|h_1(s) - h_2(s)| \le \frac{1}{\lambda(E_i)} \int_{E_i} |h_1(t) - h_1(s)|\, dt + \frac{1}{\lambda(E_i)} \int_{E_i} |h_2(t) - h_2(s)|\, dt,$$

which tends to 0 as $n \to \infty$ for almost all $s \in [0,1]$ (see Theorem C.13 in [2]). This implies that $h_1(s) = h_2(s)$ a.s., so that there exists a set $B_g \in \mathcal{B}([0,1])$ with $\lambda(B_g) = 0$ and such that $\int_{\mathcal{S}} g(y)\hat{\nu}_1(dy|t) = \int_{\mathcal{S}} \int_{\mathcal{S}} g(y)\hat{\nu}_2(dy|\zeta, t)\hat{\nu}_1(d\zeta|t)$ for all $t \notin B_g$. Now define $B \doteq \cup_{g\in\mathcal{E}} B_g$. Then $\lambda(B) = 0$ and for all $t \notin B$ and $g \in \mathcal{E}$ the same equality holds. The equality can then be extended to $g \in \mathcal{U}_b(\mathcal{S}, m)$, which implies that $\hat{\nu}_1(dy|t) = \hat{\nu}_2(dy|t)$ for all $t \notin B$. Finally, redefining $\hat{\nu}_1$ and $\hat{\nu}_2$ in an obvious way for $t \in B$, we get (C.5).

(e) Let $\{\bar{Y}^n, n \in \mathbb{N}\}$ and $\{\tilde{Y}^n, n \in \mathbb{N}\}$ be the sequences of piecewise linear and piecewise constant interpolations, respectively, of the process $\{X_j^n, j = 0, \ldots, n\}$ but when observed only at the endpoints of the intervals of size k_n. That is, they are the interpolations of a process $\{\bar{Y}_j^n, j = 0, \ldots, n\}$ defined through $\bar{Y}_l^n \doteq \bar{X}_{lm_n}^n$ for $l = 0, \ldots, \frac{1}{k_n}$. The intuition behind this idea is described clearly below (2.3). We

will relate $\bar{Y}^n$ to $\bar{X}^n$, $\tilde{Y}^n$ to $\tilde{X}^n$, and both $\bar{Y}^n$ and $\tilde{Y}^n$ to S^n in a way that forces all five sequences to have the same limit [1, Theorem 4.1]. By showing that S and $\bar{X}$ as defined in (C.1) are the same w.p.1, the characterization of the limit process $\bar{X}$ will follow.

By definition, the process $\{\bar{Y}_l^n\}$ follows the evolution

$$\bar{Y}_{l+1}^n = \bar{Y}_l^n + \frac{1}{n} \sum_{j=lm_n}^{(l+1)m_n-1} b(\bar{X}_j^n, \bar{Z}_{j+1}^n).$$

Moreover, for every $l = 0, \ldots, \frac{1}{k_n} - 1$ and with $i = 1, \ldots, m_n - 1$, we have

$$\|\bar{Y}_l^n - \bar{X}_{lm_n+i}^n\| = \left\| \frac{1}{n} \sum_{j=0}^{i-1} b(\bar{X}_{lm_n+j}^n, \bar{Z}_{lm_n+j+1}^n) \right\| \le \frac{i\|b\|_\infty}{n}. \tag{C.6}$$

Hence

$$\begin{aligned} \sup_{t\in[0,1]} \|\bar{Y}^n(t) - \bar{X}^n(t)\| &\le w_{\bar{Y}^n}(k_n) + w_{\bar{X}^n}(1/n) \\ &\quad + \max_{l\in\{0,\ldots,\frac{1}{k_n}-1\}} \max_{i\in\{1,\ldots,m_n-1\}} \|\bar{Y}_l^n - \bar{X}_{lm_n+i}^n\| \\ &\le \left(3k_n + \frac{2}{n}\right) \|b\|_\infty, \end{aligned}$$

where we have used (C.6), (C.2), and the bound

$$w_{\bar{Y}^n}(k_n) \doteq \sup_{\{s,t\in[0,1]:|s-t|\le k_n\}} \|\bar{Y}^n(t) - \bar{Y}^n(s)\| \le 2k_n\|b\|_\infty. \tag{C.7}$$

This implies that in $\mathcal{C}([0,1] : \mathbb{R}^d)$ under the uniform metric, $d(\bar{X}^n, \bar{Y}^n)$ converges to 0 in probability. Similarly, in $\mathcal{D}([0,1] : \mathbb{R}^d)$ under the Skorohod metric, $d(\tilde{X}^n, \tilde{Y}^n)$ converges to 0 in probability.

Next we prove that

$$\lim_{n\to\infty} \bar{P}_{x,\xi} \left\{ \sup_{t\in[0,1]} \left\| S^n(t) - \bar{Y}^n(t) \right\| \ge \varepsilon \right\} = 0, \tag{C.8}$$

which immediately implies the limit $\lim_{n\to\infty} \bar{P}_{x,\xi}\{\sup_{t\in[0,1]} \|S^n(t) - \tilde{Y}^n(t)\| \ge \varepsilon\} = 0$. For any $t \in [0,1]$ with $lk_n \le t < (l+1)k_n$, we have

$$\begin{aligned} &\|\bar{Y}^n(t) - S^n(t)\| \\ &\le w_{\bar{Y}^n}(k_n) + w_{S^n}(k_n) + Kk_n\|b\|_\infty \\ &\quad + \left\| \sum_{j=0}^{l} \frac{1}{n} \sum_{i=jm_n}^{(j+1)m_n} b(\bar{Y}_j^n, \bar{Z}_{i+1}^n) - \int_{\mathcal{S}\times\mathcal{S}\times[0,lk_n]} b(\tilde{Y}^n(s), y)\nu^n(d\zeta \times dy \times ds) \right\| \\ &\quad + \left\| \int_{\mathcal{S}\times\mathcal{S}\times[0,lk_n]} \left[b(\tilde{Y}^n(s), y) - b(\bar{Y}^n(s), y) \right] \nu^n(d\zeta \times dy \times ds) \right\| \\ &\quad + \left\| \int_{\mathcal{S}\times\mathcal{S}\times[0,lk_n]} \left[b(\bar{Y}^n(s), y) - b(S^n(s), y) \right] \nu^n(d\zeta \times dy \times ds) \right\| \\ &\le 3(1+K)k_n\|b\|_\infty + A(t) + \int_0^t K\|\bar{Y}^n(s) - S^n(s)\| ds, \end{aligned}$$

where we have defined

$$A(t) \doteq \left\| \sum_{j=0}^{l} \frac{1}{n} \sum_{i=jm_n}^{(j+1)m_n} b(\bar{Y}_j^n, \bar{Z}_{i+1}^n) - \int_{\mathcal{S}\times\mathcal{S}\times[0,lk_n]} b(\tilde{Y}^n(s), y)\nu^n(d\zeta \times dy \times ds) \right\|.$$

(Note that dependence on t comes through l.) By Gronwall's inequality we can then write

$$\begin{aligned}
&\|\bar{Y}^n(t) - S^n(t)\| \\
&\leq 3(1+K)k_n\|b\|_\infty + A(t) + \int_0^t K\left[3(1+K)k_n\|b\|_\infty + A(s)\right] e^{K(t-s)} ds. \\
&\leq e^K\left[3(1+K)k_n\|b\|_\infty + A(lk_n)\right] + \sum_{j=0}^{l-1} A(jk_n) K e^{Kt} \int_{jk_n}^{(j+1)k_n} e^{-Ks} ds \\
&\leq e^K\left[3(1+K)k_n\|b\|_\infty + (1+K)\max_{j\in\{0,\ldots,1/k_n\}} A(jk_n)\right], \qquad \text{(C.9)}
\end{aligned}$$

where in the last step we have used the inequality $e^{jk_n} - e^{(j+1)k_n} \leq k_n K e^{-Kjk_n}$, valid because of the mean value theorem. Given (C.9), all that remains to show is that $\{\max_{l\in\{0,\ldots,1/k_n\}} A(lk_n), n \in \mathbb{N}\}$ converges to zero in probability as $n \to \infty$.

Now for all $l = 0, \ldots, 1/k_n$ we have that

$$\int_{\mathcal{S}\times\mathcal{S}\times[0,lk_n]} b(\tilde{Y}^n(s), y)\nu^n(d\zeta \times dy \times ds) = \sum_{j=0}^{l} k_n \frac{1}{m_n} \sum_{i=jm_n}^{(j+1)m_n} \int_{\mathcal{S}} b(\bar{Y}_j^n, y)\nu_i^n(dy|\bar{X}_i^n, \bar{Z}_i^n).$$

Moreover, the sequence

$$\left\{ b(\bar{Y}_j^n, \bar{Z}_{i+1}^n) - \int_{\mathcal{S}} b(\bar{Y}_j^n, y)\nu_i^n(dy|\bar{X}_i^n, \bar{Z}_i^n), j = 0, \ldots, \frac{1}{k_n}, i = jm_n, \ldots, (j+1)m_n - 1 \right\}$$

forms a martingale difference sequence with respect to the sequence of sigma fields generated by $\{(\bar{X}_r^n, \bar{Z}_r^n), r = 0, \ldots, i\}$ for $i = 0, \ldots, n-1$. Therefore, the submartingale inequality [5, Lemma 2.2.3] applied to the submartingale

$$\left\{ \left\| b(\bar{Y}_j^n, \bar{Z}_{i+1}^n) - \int_{\mathcal{S}} b(\bar{Y}_j^n, y)\nu_i^n(dy|\bar{X}_i^n, \bar{Z}_i^n) \right\|^2 \right\}$$

implies that for any $\varepsilon > 0$

$$\begin{aligned}
&\bar{P}_{x,\xi}\left\{ \max_{l\in\{0,\ldots,1/k_n\}} A(lk_n) \geq \varepsilon \right\} \\
&\leq \frac{1}{\varepsilon^2} \bar{E}_{x,\xi}\{A(1)^2\} \\
&\leq \frac{1}{\varepsilon^2} \sum_{j=0}^{l} \frac{1}{n^2} \sum_{i=jm_n}^{(j+1)m_n} \bar{E}_{x,\xi} \left\| b(\bar{Y}_j^n, \bar{Z}_{i+1}^n) - \int_{\mathcal{S}} b(\bar{Y}_j^n, y)\nu_i^n(dy|\bar{X}_i^n, \bar{Z}_i^n) \right\|^2 \\
&\leq \frac{4\|b\|_\infty^2}{\varepsilon^2 n},
\end{aligned}$$

which gives (C.8).

Having shown that all five sequences must converge to the same limit, it remains to show that S and $\bar{X}$ as defined in (C.1) are the same w.p.1. We will show that for each fixed t, $S(t) = \bar{X}(t)$ w.p.1. Equality for all $t \in [0,1]$ w.p.1 follows by considering the rationals and then extending by continuity.

Fix $t \in [0.1]$. We have

$$\|S^n(t) - \bar{X}(t)\| \leq \int_0^t K \left\|S^n(s) - \bar{X}(s)\right\| ds$$
$$+ \left\| \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu^n(d\zeta \times dy \times ds) - \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu(d\zeta \times dy \times ds) \right\|.$$

Using Gronwall's inequality if follows that

$$\text{(C.10)} \qquad \left\|S^n(t) - \bar{X}(t)\right\|$$
$$\leq \left\| \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu^n(d\zeta \times dy \times ds) - \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu(d\zeta \times dy \times ds) \right\|$$
$$+ K \int_0^t \left\| \int_{\mathcal{S}\times\mathcal{S}\times[0,r]} b(\bar{X}(s), y)\nu^n(d\zeta \times dy \times ds) - \int_{\mathcal{S}\times\mathcal{S}\times[0,r]} b(\bar{X}(s), y)\nu(d\zeta \times dy \times ds) \right\| e^{K(t-r)} dr.$$

Weak convergence of ν^n to ν implies that w.p.1

$$\lim_{n\to\infty} \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu^n(d\zeta \times dy \times ds) = \int_{\mathcal{S}\times\mathcal{S}\times[0,t]} b(\bar{X}(s), y)\nu(d\zeta \times dy \times ds).$$

This statement is true since we can identify the points of discontinuity of the bounded function $b(\bar{X}(s), y)1_{[0,t]}(s)$ to be $\mathcal{S} \times \mathcal{S} \times \{t\}$, which form a set of measure zero under the limit ν. Hence it follows from (C.10) and the dominated convergence theorem that for any given $\varepsilon > 0$

$$\lim_{n\to\infty} \bar{P}_{x,\xi} \left\{ \|S^n(t) - \bar{X}(t)\| \geq \varepsilon \right\} \leq \lim_{n\to\infty} \frac{1}{\varepsilon} \bar{E}_{x,\xi} \left\{ \left\|S^n(t) - \bar{X}(t)\right\| \right\} = 0.$$

Uniqueness of limits implies $S(t) = \bar{X}(t)$ w.p.1, as we wanted to show.

(f) Let $f : \mathcal{S} \times \mathcal{S} \times [0,1]$ be bounded and continuous. Then for each $n \in \mathbb{N}$ the function g_n mapping (ζ, t) to $\int_{\mathcal{S}} f(\zeta, y, t)p(dy|\bar{Y}^n(t), \zeta)$ is also bounded and continuous. Define the bounded and continuous function g mapping (ζ, t) into $\int_{\mathcal{S}} f(\zeta, y, t)$ $p(dy|\bar{X}(t), \zeta)$. Weak continuity of p and a.s. convergence of $\bar{Y}^n$ to $\bar{X}$ imply that for all $t \in [0,1]$ and $\zeta \in \mathcal{S}$ we have $\lim_{n\to\infty} g_n(\zeta, t) = g(\zeta, t)$ a.s. We argue that convergence is, in fact, uniform in $\mathcal{S} \times [0,1]$.

Indeed, let $\varepsilon > 0$ be given. Fix $N \in \mathbb{N}$ satisfying $k_N < \varepsilon/(3\|b\|_\infty)$ so that (see (C.7)) for all $n > N$ and r, s with $|r - s| \leq k_N$, we have $\|\bar{Y}^n(r) - \bar{Y}^n(s)\| < \varepsilon/3$ and $\|\bar{X}(r) - \bar{X}(s)\| < \varepsilon/3$. Further, N can be chosen so that for all $n \geq N$ and $i = 0, \ldots, \frac{1}{k_N} - 1$ we have $\|\bar{Y}^n(ik_N) - \bar{X}(ik_N)\| < \varepsilon/3$. Hence we have that for all $t \in [0,1]$ and any $n \geq N$, $\|\bar{Y}^n(t) - \bar{X}(t)\| < \varepsilon$. By Hypothesis H.1 we can then write

$$g_n(\zeta, t) = \int_{\mathcal{S}} f(\zeta, y, t)p(dy|\bar{Y}^n(t), \zeta) = \int_{\mathcal{S}} f(\zeta, y, t)\tilde{p}^{\bar{Y}^n(t)}(\zeta, y)\vartheta(dy).$$

By the dominated convergence theorem, this last quantity converges (a.s. uniformly in ζ and t) to $\int_{\mathcal{S}} f(\zeta, y, t)\tilde{p}^{\bar{X}(t)}(\zeta, y)\vartheta(dy) = g(\zeta, t)$.

It now follows from the weak convergence of $\hat{\nu}_1^n \otimes \lambda$ to $\hat{\nu}_1 \otimes \lambda$ that

$$\lim_{n\to\infty} \int_0^1 \int_{\mathcal{S}} g_n(\zeta,t)\hat{\nu}_1^n(d\zeta|t)dt = \int_0^1 \int_{\mathcal{S}} g(\zeta,t)\hat{\nu}_1(d\zeta|t)dt.$$

This in turn implies that

$$\lim_{n\to\infty} \int_{\mathcal{S}\times\mathcal{S}\times[0,1]} f(\zeta,y,t)\gamma^n(d\zeta\times dy\times dt) = \int_{\mathcal{S}\times\mathcal{S}\times[0,1]} f(\zeta,y,t)\gamma(d\zeta\times dy\times dt),$$

which completes the proof. □

The last lemma in this section establishes an estimate needed in the proof of the lower bound.

LEMMA C.2. *For any $\delta > 0$,*

$$\lim_{\sigma\to 0} \bar{P}_{x,\xi}\left\{\sup_{t\in[0,1]} ||\bar{U}(t)|| \geq \delta\right\} = 0.$$

Proof. As was discussed in the proof of the lower bound, $S^{2,n} \to \bar{U}$ in distribution in $\mathcal{C}([0,1] : \mathbb{R}^d)$, so that by the Skorohod representation theorem and Fatou's lemma,

$$\bar{E}_{x,\xi}\left\{\left(\sup_{t\in[0,1]} ||\bar{U}(t)||\right)^2\right\} \leq \liminf_{n\to\infty} \bar{E}_{x,\xi}\left\{\left(\sup_{t\in[0,1]} ||S^n(t)||\right)^2\right\}.$$

Hence we have that for any $\delta > 0$,

$$\begin{aligned}
\bar{P}_{x,\xi}\left\{\sup_{t\in[0,1]} ||\bar{U}(t)|| \geq \delta\right\} &\leq \frac{1}{\delta^2}\bar{E}_{x,\xi}\left\{\left(\sup_{t\in[0,1]} ||\bar{U}(t)||\right)^2\right\} \\
&\leq \frac{1}{\delta^2}\liminf_{n\to\infty} \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n-1}\left\|\int_{\mathbb{R}^d} y\nu_j^{2,n}(dy)\right\|^2\right\} \\
&= \frac{1}{\delta^2}\liminf_{n\to\infty} \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n\tau^n-1}||\beta_j^{2,n}||^2\right\} \\
&\leq \frac{2\sigma^2}{\delta^2}\liminf_{n\to\infty} \bar{E}_{x,\xi}\left\{\frac{1}{n}\sum_{j=0}^{n\tau^n-1} R(\gamma_j^{2,n}(\cdot)||\rho_\sigma(\cdot))\right\} \\
&\leq \frac{2\sigma^2}{\delta^2}\liminf_{n\to\infty}\left\{k_n\sum_{l=0}^{[1/k_n]} L_\sigma(\psi^*(lm_n/n),\dot{\psi}^*(lm_n/n)) + 3\sigma\right\} \\
&\leq \frac{2\sigma^2}{\delta^2}[I_x(\psi) + 4\sigma].
\end{aligned}$$

The fourth inequality follows from $\frac{1}{2\sigma^2}||\beta_j^{2,n}||^2 = \hat{L}_\sigma(\beta_j^{2,n}) \leq R(\gamma_j^{2,n}(\cdot)||\rho_\sigma(\cdot))$, where $\hat{L}_\sigma$ is the Legendre–Fenchel of the moment generating function of ρ_σ. The fifth line follows from (4.13) and (4.18), while in line six we have used part (e) of Lemma B.3 with $\varepsilon = \sigma$. Letting $\sigma \to 0$ completes the proof. □

CONTINUITY AND EXPONENTIAL STABILITY OF MIXED CONSTRAINED MODEL PREDICTIVE CONTROL*

JINHOON CHOI† AND WOOK HYUN KWON‡

Abstract. For the infinite horizon cost function mixed constrained model predictive control, the largest possible stabilizable region for stable plants is the entire state space for both state and output feedback cases. However, for marginal or unstable cases, the largest possible stabilizable region is the constrained m-step stabilizable set for the state feedback case, and it is the region where the estimated state is in the constrained m-step stabilizable set throughout the trajectory for the output feedback case. Only attractivity over the largest stabilizable region is established for the state feedback case with stable or marginal plants and the output feedback case with stable plants [A. Zheng and M. Morari, *IEEE Trans. Automat. Control*, 40 (1995), pp. 1818–1823]. In this paper we show, for both state and output feedback cases, that the closed loop system with the mixed constrained model predictive controller possesses the exponential stability property, much stronger than the attractivity, on the largest possible stabilizable region. Here the exponential stability on the largest possible stabilizable region means that we can find the exponentially converging envelope for any initial condition in the region. Clearly this is much stronger than local exponential stability, for which the region for the envelope is not known and can be arbitrarily small. Moreover, the continuity properties of the mixed constrained model predictive control are also established.

Key words. model predictive control, continuity, exponential stability

1. Introduction.

Model predictive control, also called receding horizon control, is a technique for implementing the finite horizon open loop optimal control in the infinite horizon feedback settings. Such implementation has been tried since the early 1960s when the open loop optimal control problem was vigorously studied [12], [32]. However, the first complete formulation of stabilizing finite horizon cost function model predictive control and its comprehensive stability result were obtained by Kwon and his coworkers [19], [20] in the late 1970s. They showed that the stability of unconstrained model predictive control is assured if the terminal state is constrained to be zero in the associated open loop optimal control problem. This result is particularly important since, as mentioned in [2], the closed loop stability with the primitive model predictive controller is not guaranteed in general.

Constraints are always present in any practical control problems. For instance, the input cannot assume its value outside a bounded region due to the physical limitations of manipulated variables. Moreover, it is desirable that the states of the plant lie within a designated area in the state space because of safety, environmental regulation, and so on. As a way to handle these ever existing constraints, constrained model predictive control strategies have been proposed and successfully applied to chemical processes [10], [26]. Driven by these successes in practice, the constrained model predictive control problem has been the core research topic within the chem-

ical engineering control community since the late 1970s. Irrespective of this interest in the constrained model predictive control problem within the chemical engineering control community, the asymptotic stability of a hard constrained nonlinear model predictive control law was first established by Keerthi and Gilbert [18] in an effort to extend the terminal state constraint idea by Kwon and his coworkers to the hard constrained nonlinear system case. In the early 1990s, Rawlings and Muske [25] proposed an alternate formulation of hard constrained model predictive control for linear systems employing the infinite horizon cost function instead of terminal state condition and established its attractivity over the set of all initial conditions for which the model predictive control law is defined. Their result was then extended by Zheng and Morari [38] to the mixed constrained stable and marginal linear system cases where, as proposed in [37], hard input constraints and soft state constraints are employed. For output feedback cases, the perturbed system stability theory [16] was employed in [24], [27] to show the local asymptotic stability of the closed loop system with a hard constrained output feedback model predictive controller. On the other hand, Zheng and Morari [38] established that the closed loop system with a mixed constrained output feedback model predictive controller is globally attractive for the stable plant case.

From the pioneering work of maximal output admissible set by Gilbert and Tan [13] and the well-known result by Kalman that the global optimal solution of the unconstrained linear quadratic regulation problem is linear, it is easy to conclude that the mixed constrained model predictive control is linear in a neighborhood of the origin, where the constraints are not active throughout the trajectory and the penalty term for softening is zero, and thus is exponentially stable on the neighborhood. The explicit statement of this result was pointed out first by Sznaier and Damborg [31] and played a key role in solving the hard constrained infinite horizon linear quadratic regulation problem [4], [28] as well as the mixed constrained one [8], [9]. However, this local exponential stability result is not very interesting since the important stability result in the constrained case is the one in the nonlinear region where the constraints play some roles. To this end, in the infinite horizon cost function and mixed constraints cases, no stability over the largest stabilizable region is proven for the state feedback case with unstable plants and the output feedback case with marginal[1] or unstable plants, and attractivity over the largest stabilizable region is only established for the state feedback case with stable or marginal plants and the output feedback case with stable plants. Moreover, exponential stability over the set of all initial conditions for which the model predictive control law is defined cannot be concluded from local exponential stability and attractivity over the set. In this paper we will show, for both state and output feedback cases, that the closed loop system with the mixed constrained model predictive controller possesses the exponential stability property, much stronger than the attractivity, on the set of all initial conditions for which the mixed constrained model predictive control law is defined throughout the trajectory. Moreover, the continuity properties of the mixed constrained model predictive control are also established.

This paper deals with mixed constrained model predictive control, and the control input to the process is limited by the hard constraints such as saturation. Then the stability of mixed constrained model predictive control corresponds to the stabilization of a hard input constrained linear system by mixed constrained model predictive

[1] A linear system is marginal if it has some poles on the unit circle and all the others inside the unit circle.

control. Hence, the general results on the stabilization of a hard input constrained linear system will provide some possible guidelines for study of the stability of the specific constrained model predictive control. Contrary to the unconstrained linear system cases, the global asymptotic stabilization of a hard input constrained linear system is not always possible. Indeed, as shown in [30], [35], a hard input constrained linear discrete time system can be globally asymptotically stabilizable iff all its poles are located inside or on the unit circle. Clearly, a hard input constrained stable linear system is globally exponentially stable without any control and, thus, is globally exponentially stabilizable. It is shown in [5] that the global asymptotic stabilization of a hard input constrained linear system is possible through linear feedback if the linear system is marginally stable; i.e., Jordan blocks associated with eigenvalues on the unit circle are diagonal and all the other eigenvalues are in the open unit disk. However, Yang [36] showed that the global asymptotic stabilization of hard input constrained marginal systems is, in general, impossible through linear feedback. Instead, Yang [35] was able to construct a nonlinear (nonpredictive) globally asymptotically stabilizing control law for such systems. It is shown in [9] that the mixed constrained infinite horizon linear quadratic optimal control that is nonlinear also achieves global asymptotic stability. On the other hand, Lin and Saberi [22] and Lin [21] showed that there exists a linear controller that exponentially stabilizes a hard input constrained marginal system on any bounded subset of the state space. Nevertheless, it is shown in [6] that the global exponential stabilization of a hard input constrained marginal system is not possible by any control law. For unstable systems, it was established in [5] that any input constrained unstable systems can be exponentially stabilized by a linear periodic variable structure controller on any compact subset of the constrained asymptotically stabilizable set,[2] i.e., the set of all initial states whose unstable subspace part can be driven asymptotically to zero with constrained inputs. Moreover, it is shown in [9] that the mixed constrained infinite horizon linear quadratic optimal control that is nonlinear achieves asymptotic stability on the constrained asymptotically stabilizable set. However, Choi [7] showed that the asymptotic stabilization of a hard input constrained unstable system on the constrained asymptotically stabilizable set is not possible in general by linear feedback. Moreover, it is shown in [6] that the exponential stabilization of a hard input constrained unstable system on the constrained asymptotically stabilizable set is not possible by any control law.

In this paper, we first adopt the point-to-set map theory to explore the continuity properties of the optimal solution to the quadratic program associated with the mixed constrained state feedback model predictive control law, which are useful for the rest of the paper. It was brought to the authors' attention by a reviewer that the continuity properties of the hard constrained state feedback model predictive control law were reported using multiparametric programming [1] and a geometric approach [29]. We then establish the exponential stability properties of the mixed constrained model predictive control law under the assumption that the linear plant in the absence of the input saturation is stabilizable and detectable. For the state feedback case, the exponential stability is established by proving that the optimal cost function is an appropriate Lyapunov function for the closed loop system. Indeed, an input constrained stable system is shown to be globally exponentially stabilized in the sense of Lyapunov by the mixed constrained state feedback model predictive control law. Moreover, an input constrained marginal or unstable system is proven to be exponentially stable

[2]Let $\Omega_\infty = \{u : u^{min} \le u_i \le u^{max},\ i = 0, 1, \ldots\}$. Then the maximal Ω_∞-invariant set w.r.t. $\mathbf{R}^n$, proposed in [14], coincides with the constrained asymptotically stabilizable set.

on the constrained m-step stabilizable set that converges to the constrained asymptotically stabilizable set as the control horizon m increases. Hence, a marginal system is semiglobally stabilized by the mixed constrained model predictive control and an unstable system is exponentially stabilized by the mixed constrained model predictive control law on any compact subset of the constrained asymptotically stabilizable set. We also demonstrate that the sum of the optimal objective associated with state feedback model predictive control and a positive definite quadratic term of the observer error forms a Lyapunov function from which one can conclude the exponential stability of the mixed constrained output feedback model predictive control. Even if output is only available for feedback, a stable plant is globally exponentially stabilized. For the marginal and unstable plant cases, the exponential stability is established on the set of all initial conditions for which the mixed constrained model predictive control law is defined throughout the trajectory.

This paper is structured as follows. In the next section, the preliminaries on the point-to-set map theory are summarized. In section 3, the formulation of the mixed constrained model predictive control law is presented. The continuity properties of the quadratic program associated with the mixed constrained model predictive control law are established in section 4. The exponential stability of mixed constrained state feedback model predictive control is established in section 5, whereas the output feedback case is presented in section 6. Finally, the conclusions of the paper are drawn in section 7.

2. Preliminaries. Later in this paper, the point-to-set map theory is employed to establish the continuity properties of the quadratic program associated with the mixed constrained model predictive control law. Hence, in this section, some preliminaries on the point-to-set map theory are summarized as exposed in [17].

DEFINITION 2.1. *A point-to-set map Ω from a set X into a set Y is a map which associates a subset of Y with each point of X.*

DEFINITION 2.2. *Ω is open at a point $\bar{x}$ in X if $\{x_k\}_{k=0}^{\infty} \subset X$, $x_k \to \bar{x}$, and $\bar{y} \in \Omega(\bar{x})$ imply the existence of an integer m and a sequence $\{y_k\}_{k=0}^{\infty} \subset Y$ such that $y_k \in \Omega(x_k)$ for $k \geq m$ and $y_k \to \bar{y}$.*

DEFINITION 2.3. *Ω is closed at a point $\bar{x}$ in X if $\{x_k\}_{k=0}^{\infty} \subset X$, $x_k \to \bar{x}$, $y_k \in \Omega(x_k)$, and $y_k \to \bar{y}$ imply that $\bar{y} \in \Omega(\bar{x})$.*

DEFINITION 2.4. *Ω is continuous at a point $\bar{x}$ in X if it is both open and closed at $\bar{x}$.*

DEFINITION 2.5. *Ω is uniformly compact near $\bar{x}$ if there is a neighborhood N of $\bar{x}$ such that the closure of the set $\cup_{x \in N} \Omega(x)$ is compact.*

Consider the following infimal value function associated with an optimization problem:

$$v(x) = \inf_{y \in \Omega(x)} f(x, y). \tag{1}$$

Within the point-to-set map framework, we have the following theorem for the continuity of a infimal value function.

THEOREM 2.1 (see [17]). *If Ω is continuous at $\bar{x}$ and uniformly compact near $\bar{x}$, and if f is continuous on $\bar{x} \times \Omega(\bar{x})$, then v is continuous at $\bar{x}$.*

Let M be the solution set of (1), defined as

$$M(x) := \{y \in \Omega(x) : v(x) \geq f(x, y)\}.$$

Then we have the following theorem for the continuity of the optimal solution to (1).

THEOREM 2.2 (see [17]). *Suppose Ω is continuous at $\bar{x}$, f is continuous on $\bar{x} \times \Omega(\bar{x})$, M is nonempty and uniformly compact near $\bar{x}$, and M is single-valued. Then M is continuous at $\bar{x}$.*

Before we proceed to the next section, we set up some notations that are used throughout the paper. Given a vector x, $|x|$ and $|x|_\infty$ denote the 2 and ∞ norms of x, respectively. Given a matrix A, $\|A\|$ denotes the induced 2 norm of A. For a given set Ω, intΩ denotes the interior of Ω. Given a p-dimensional vector w, w_l denotes the lth element of w.

3. Formulation. Consider the input constrained linear discrete time system:

$$x_{k+1} = Ax_k + B\sigma(u_k), \tag{2}$$

$$y_k = Cx_k,$$

where $x_k \in \mathbf{R}^n$, $u_k \in \mathbf{R}^q$, $y_k \in \mathbf{R}^l$, and

$$\sigma_i(u_k) := \begin{cases} u_i^{min} & \text{if } u_{ki} < u_i^{min}, \\ u_i & \text{if } u_i^{min} \le u_{ki} \le u_i^{max}, \\ u_i^{max} & \text{if } u_{ki} > u_i^{max}. \end{cases}$$

Throughout the paper, system (2) is assumed to be stabilizable and detectable in the absence of the input saturation.

Assumption 3.1. (A, B) and (A, C) are stabilizable and detectable pairs, respectively.

It is assumed that the control and the state of the system are desired to satisfy the following inequalities:

$$u^{min} \le u_k \le u^{max}, \qquad k = 0, 1, \ldots,$$

$$Gx_k \le g, \qquad k = 0, 1, \ldots,$$

where $G \in \mathbf{R}^{p \times n}$ and $g \in \mathbf{R}^p$.

Associated with system (2), consider the following quadratic program (QP):

$$J_m(x_k) = \min_{U_k^m, \epsilon_k} \sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k} + \sum_{i=0}^{m-1} u_{k+i|k}^T S u_{k+i|k} + \epsilon_k^T Q \epsilon_k \tag{3}$$

subject to

$$x_{k+i+1|k} = Ax_{k+i|k} + Bu_{k+i|k}, \quad x_{k|k} = x_k, \tag{4}$$

$$u^{min} \le u_{k+i|k} \le u^{max}, \qquad i = 0, 1, \ldots, m-1,$$

$$u_{k+i|k} = 0, \qquad i = m, m+1, \ldots,$$

$$G\hat{x}_{k+i|k} \le g + \epsilon_k, \qquad i = 1, \ldots,$$

$$\epsilon_k \ge 0,$$

where $R > 0$ and $S > 0$ are symmetric matrices, $Q > 0$ is a diagonal matrix, $\epsilon_k \in \mathbf{R}^p$, m is finite, and $U_k^m := [u_{k|k}^T \; u_{k+1|k}^T \; \cdots \; u_{k+m-1|k}^T]^T$.

Then mixed constrained model predictive control with horizon m ($\mathrm{MPC_m}$) is a nonlinear static state feedback control law whose control output at the kth sampling time, u_k, is the first q elements $u_{k|k}^{m*}$ of the optimal solution U_k^{m*} to the quadratic optimization problem $J_m(x_k)$. Since we consider the regulation problem throughout the paper, the following conditions are assumed to hold for the well-posedness of the problem.

Assumption 3.2.

$$0 \in \mathrm{int}\{[v_0 \cdots v_{m-1}]^T : v_i \in \mathbf{R}^q, \;\; u^{min} \le v_i \le u^{max}, \;\; i = 0, 1, \ldots, m-1\},$$

$$0 \in \mathrm{int}\left\{z : z \in \mathbf{R}^n, \;\; Gz \le g\right\}.$$

Note that the first condition implies $u^{min} < 0 < u^{max}$ and the second condition dictates $g > 0$.

The incremental input constraints

$$\Delta u^{min} \le \Delta u_k \le \Delta u^{max}, \qquad k = 0, 1, \ldots,$$

where $\Delta u_k := u_k - u_{k-1}$, are also considered in some formulations of model predictive control. In this paper, the exponential stability of the mixed constrained model predictive control law is established by showing that the optimal cost function is indeed a Lyapunov function. However, if the incremental input constraints are considered, the optimal cost function depends not only on x_k but also on u_{k-1} and, thus, it is not a Lyapunov function for the exponential stability of the mixed constrained model predictive control law. Even if the state is augmented with u_{k-1}, the resulting state constraints are not in the form considered above and, although we consider the difference form of constraints as well, they may not satisfy Assumption 3.2. Hence, the results in this paper are not applicable in the presence of the incremental input constraints.

4. Continuity properties. In this section, we establish the continuity properties of J_m[3] and the associated optimal solution employing the point-to-set map theory presented in the preliminaries section.

4.1. Stable plants. Let

$$\Phi_m(x_k, U_k^m, \epsilon_k) := \sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k} + \sum_{i=0}^{m-1} u_{k+i|k}^T S u_{k+i|k} + \epsilon_k^T Q \epsilon_k,$$

where

$$x_{k+i|k} = \begin{cases} A^i x_k + \sum_{j=0}^{i-1} A^{i-j-1} B u_{k+j|k}, & i = 1, \ldots, m-1, \\ A^i x_k + A^{i-m} \sum_{j=0}^{m-1} A^{m-j-1} B u_{k+j|k}, & i = m, m+1, \ldots. \end{cases}$$

[3]The Lyapunov theorem for exponential stability doesn't require the continuity of the Lyapunov function. But the continuity of J_m follows trivially in the middle of establishing the continuity of the optimal solution and is included.

Clearly, $\Phi_m(x_k, U_k^m, \epsilon_k)$ is continuous w.r.t. (x_k, U_k^m, ϵ_k) iff $\sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k}$ is continuous w.r.t. (x_k, U_k^m). To see the continuity of $\sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k}$, first observe that

$$\sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k} = \sum_{i=1}^{m-1} x_{k+i|k}^T R x_{k+i|k} + x_{k+m|k}^T \left[\sum_{i=0}^{\infty} (A^T)^i R A^i \right] x_{k+m|k}. \tag{5}$$

Then the first term on right-hand side (RHS) of (5) is clearly continuous w.r.t. (x_k, U_k^m). Moreover, since A is stable, $\sum_{i=0}^{\infty} (A^T)^i R A^i =: T$ is simply a unique positive definite solution of the following Lyapunov equation [3, p. 215]:

$$T = A^T T A + R.$$

Hence, the second term on the RHS of (5) is also continuous w.r.t. (x_k, U_k^m), and, in turn, left-hand side (LHS) of (5) is continuous w.r.t. (x_k, U_k^m).

We now define a point-to-set map. For this, we need the following fact.

Fact 4.1 (see [3, p. 213]). If every eigenvalue of A has magnitude strictly less than one, there exist $\rho \in [0, 1)$ and $D \geq 1$ such that

$$\|A^i\| \leq D\rho^i.$$

Define

$$\Omega_m(x_k) := \left\{ \begin{array}{l} (U_k^m, \epsilon_k) \in \mathbf{R}^{p+mq} : u^{min} \leq u_{k+i|k} \leq u^{max}, \qquad i = 0, 1, \ldots, m-1, \\ \\ GA^i x_k + G \sum_{j=0}^{i-1} A^{i-j-1} B u_{k+j|k} \leq g + \epsilon_k, \qquad i = 1, \ldots, m-1, \\ \\ GA^i x_k + GA^{i-m} \sum_{j=0}^{m-1} A^{m-j-1} B u_{k+j|k} \leq g + \epsilon_k, \qquad i = m, m+1, \ldots, \\ g + \epsilon_k \leq (\max\{|g|_\infty, K_1|x_k| + K_2\} + 1)\mathbf{1}, \\ \epsilon_k \geq 0 \end{array} \right\},$$

where

$$\mathbf{1} := [1\ 1\ \cdots\ 1]^T,$$

$$K_1 := \|G\|D \geq \|G\| \max_{i \geq 1} D\rho^i,$$

$$K_2 := \max \left\{ \begin{array}{c} \max\limits_{1 \leq i \leq m-1} \max\limits_{U_k^m \in \Psi_k^m} \|G\| \sum\limits_{j=0}^{i-1} D\rho^{i-j-1} \|B\| \sqrt{m} |u_{k+j|k}|_\infty \\ \\ \max\limits_{i \geq m} \max\limits_{U_k^m \in \Psi_k^m} \|G\| \sum\limits_{j=0}^{m-1} D\rho^{i-j-1} \|B\| \sqrt{m} |u_{k+j|k}|_\infty \end{array} \right\}$$

$$= \|G\| D \frac{1 - \rho^m}{1 - \rho} \|B\| \sqrt{m} \vartheta,$$

$$\Psi_k^m := \left\{ U_k^m \in \mathbf{R}^{mq} : u^{min} \le u_{k+i|k} \le u^{max}, \quad i = 0, 1, \ldots, m-1 \right\},$$

$$\vartheta := \max \left\{ \begin{array}{l} |u_{min}|_\infty \\ |u_{max}|_\infty \end{array} \right\}.$$

Associated with $\Omega_m(x_k)$, consider the following QP:

$$\tilde{J}_m(x_k) := \min_{(U_k^m, \epsilon_k) \in \Omega_m(x_k)} \Phi_m(x_k, U_k^m, \epsilon_k). \tag{6}$$

QP (6) contains some additional constraints compared to QP (3). Hence, $\Omega_m(x_k)$ is a subset of the feasible region of QP (3) and, thus, $J_m(\cdot) \le \tilde{J}_m(\cdot)$. However, K_1 and K_2 in the aforementioned additional constraints are chosen such that any optimal feasible point for QP (3) satisfies them due to the penalty term of ϵ_k. Hence, $J_m(\cdot) = \tilde{J}_m(\cdot)$.

THEOREM 4.1. *$\tilde{J}_m(\cdot) = J_m(\cdot)$ is continuous on $\mathbf{R}^n$.*

Proof. $\Phi_m(x_k, U_k^m, \epsilon_k)$ is shown to be continuous w.r.t. (x_k, U_k^m, ϵ_k) right before Fact 4.1. Hence, from Theorem 2.1, it suffices to show that $\Omega_m(\cdot)$ is open and closed on $\mathbf{R}^n$, and $\Omega_m(\cdot)$ is uniformly compact near any $\bar{x} \in \mathbf{R}^n$.

We first establish that $\Omega_m(\cdot)$ is open on $\mathbf{R}^n$. To see this, consider $\bar{x} \in \mathbf{R}^n$. Let $\{x_k\}_{k=0}^\infty \subset \mathbf{R}^n$, $x_k \to \bar{x}$, and $(\bar{U}^m, \bar{\epsilon}) \in \Omega_m(\bar{x})$. Let $\{\delta_j\}_{j=0}^\infty$ be a monotonically decreasing sequence of positive integers such that $\delta_0 = 1$ and $\delta_j \to 0$ as $j \to \infty$. Then there exists N_0 such that $|x_k - \bar{x}| < \frac{\delta_0}{3\max\{K_1, \|G\|D\}}$ for all $k \ge N_0$. Moreover, for each $j \ge 1$, there exists $N_j > N_{j-1}$ such that $|x_k - \bar{x}| < \frac{\delta_j}{3\max\{K_1, \|G\|D\}}$ for all $k \ge N_j$. Define

$$f_i(U_k^m) := \begin{cases} G\sum_{j=0}^{i-1} A^{i-j-1} B u_{k+j|k}, & 1 \le i \le m-1, \\ GA^{i-m} \sum_{j=0}^{m-1} A^{m-j-1} B u_{k+j|k}, & i \ge m. \end{cases}$$

For each $1 \le l \le p$, let $\gamma_l \ge 0$ be such that

$$(GA^i \bar{x} + f_i(\bar{U}^m))_l = g_l + \bar{\epsilon}_l - \gamma_l, \qquad i \ge 1.$$

For $N_j \le k < N_{j+1}$, let $U_k^m := \bar{U}^m$ and

$$\epsilon_{kl} := \begin{cases} \bar{\epsilon}_l - \frac{\delta_j}{3} & \text{if } g_l + \bar{\epsilon}_l \ge \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3}, \\ \bar{\epsilon}_l + \frac{\delta_j}{3} & \text{if } \gamma_l \le \frac{\delta_j}{3}, \\ \bar{\epsilon}_l & \text{otherwise.} \end{cases} \qquad 1 \le l \le p.$$

The first two cases in the definition of ϵ_{kl} are disjoint because $\gamma_l \le \frac{\delta_j}{3}$ implies

$$g_l + \bar{\epsilon}_l \le \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + \gamma_l < \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3}.$$

It clearly holds that

$$u^{min} \le u_{k+i|k} \le u^{max}, \qquad i = 0, 1, \ldots, m-1.$$

Moreover, all the other constraints are also satisfied for each case considered in the definition of ϵ_{kl} because, for each $N_j \le k < N_{j+1}$, $1 \le l \le p$, the following inequalities hold.

The $g_l + \bar{\epsilon}_l \geq \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3}$ *case.*

$$(GA^i x_k + f_i(U_k^m))_l \leq (GA^i \bar{x} + f_i(\bar{U}^m))_l + \frac{\delta_i}{3} \leq K_1|\bar{x}| + K_2 + \frac{\delta_j}{3}$$

$$\leq g_l + \bar{\epsilon}_l - 1 + \frac{2\delta_j}{3} \leq g_l + \bar{\epsilon}_l - \frac{\delta_j}{3} = g_l + \epsilon_{kl}, \qquad i \geq 0.$$

$$g_l + \epsilon_{kl} = g_l + \bar{\epsilon}_l - \frac{\delta_j}{3} \leq \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3} \leq \max\{|g|_\infty, K_1|x_k| + K_2\} + 1.$$

$$\epsilon_{kl} = \bar{\epsilon}_l - \frac{\delta_j}{3} \geq \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{2\delta_j}{3} - g_l \geq \max\{|g|_\infty, K_1|x_k| + K_2\} - g_l \geq 0.$$

The $\gamma_l \leq \frac{\delta_j}{3}$ *case.*

$$(GA^i x_k + f_i(U_k^m))_l \leq (GA^i \bar{x} + f_i(\bar{U}^m))_l + \frac{\delta_j}{3} \leq g_l + \bar{\epsilon}_l + \frac{\delta_j}{3} = g_l + \epsilon_{kl}, \quad i \geq 0.$$

$$g_l + \epsilon_{kl} = g_l + \bar{\epsilon}_l + \frac{\delta_j}{3} \leq g_l + \bar{\epsilon}_l + 1 - \frac{2\delta_j}{3} \leq g_l + \bar{\epsilon}_l - \gamma_l + 1 - \frac{\delta_j}{3} = (GA^i \bar{x} + f_i(\bar{U}^m))_l + 1 - \frac{\delta_j}{3}$$

$$\leq \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3} \leq \max\{|g|_\infty, K_1|x_k| + K_2\} + 1.$$

$$\epsilon_{k,l} = \bar{\epsilon}_l + \frac{\delta_j}{3} \geq 0.$$

The $g_l + \bar{\epsilon}_l < \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3}$ and $\gamma_l > \frac{\delta_j}{3}$ *case.*

$$(GA^i x_k + f_i(U_k^m))_l \leq (GA^i \bar{x} + f_i(\bar{U}^m))_l + \frac{\delta_j}{3} = g_l + \bar{\epsilon}_l - \gamma_l + \frac{\delta_j}{3} < g_l + \bar{\epsilon}_l = g_l + \epsilon_{kl}, \quad i \geq 0.$$

$$g_l + \epsilon_{kl} = g_l + \bar{\epsilon}_l < \max\{|g|_\infty, K_1|\bar{x}| + K_2\} + 1 - \frac{\delta_j}{3} \leq \max\{|g|_\infty, K_1|x_k| + K_2\} + 1.$$

$$\epsilon_{k,l} = \bar{\epsilon}_l \geq 0.$$

Hence, for $k \geq N_0$, $(U_k^m, \epsilon_k) \in \Omega_m(x_k)$ and $(U_k^m, \epsilon_k) \to (\bar{U}^m, \bar{\epsilon})$.

Next we show that $\Omega_m(\cdot)$ is closed on $\mathbf{R}^n$. For this, let $\{x_k\}_{k=0}^\infty \subset \mathbf{R}^n$, $x_k \to \bar{x}$, $(U_k^m, \epsilon_k) \in \Omega_m(x_k)$, and $(U_k^m, \epsilon_k) \to (\bar{U}^m, \bar{\epsilon})$. Then since all the functionals in the inequalities that define $\Omega_m(\cdot)$ are continuous w.r.t. (x_0, U_k^m, ϵ_k), it holds that $(\bar{U}^m, \bar{\epsilon}) \in \Omega_m(\bar{x})$.

Finally, we show that $\Omega_m(\cdot)$ is uniformly compact near any $\bar{x} \in \mathbf{R}^n$. To see this, consider the closed unit ball $B^n(1)$ around $\bar{x}$. A set in a finite-dimensional space is compact iff it is closed and bounded. Hence, we only prove that $\cup_{x \in B^n(1)} \Omega_m(x)$ is bounded. But, for any $x \in B^n(1)$, $\Omega_m(x)$ is contained in the bounded set $\Psi_k^m \times \{\epsilon_k \in \mathbf{R}^p : \epsilon_k \geq 0, \text{ and } g + \epsilon_k \leq (\max\{|g|_\infty, K_1(|\bar{x}| + 1) + K_2\} + 1)\mathbf{1}\}$. ∎

We now show that U_k^{m*} is continuous on $\mathbf{R}^n$.

THEOREM 4.2. *U_k^{m*} is continuous on $\mathbf{R}^n$.*

Proof. We first show that U_k^{m*} is uniformly compact near any $\bar{x} \in \mathbf{R}^n$. Similar to the uniform compactness proof of $\Omega_m(\cdot)$ in Theorem 4.2, we only prove that $\cup_{x \in B^n(1)} U_k^{m*}$ is bounded. But, for any $x \in B^n(1)$, U_k^{m*} is contained in the bounded set Ψ_k^m.

Since S is positive definite and inputs are upper and lower bounded, it is well known that the optimal solution U_k^{m*} to $J_m = \tilde{J}_m$ for each $x_k \in \mathbf{R}^n$ exists and is unique. This implies U_k^{m*} is nonempty and single-valued on $\mathbf{R}^n$. Since U_k^{m*} is also uniformly compact near any $\bar{x} \in \mathbf{R}^n$, the continuity of U_k^{m*} follows from Theorem 2.2. ∎

4.2. Marginal or unstable plants. If A contains marginal and unstable modes, we partition A as follows:

$$A = V \mathcal{J} V^{-1} = [V_u V_s] \begin{bmatrix} \mathcal{J}_u & 0 \\ 0 & \mathcal{J}_s \end{bmatrix} \begin{bmatrix} \tilde{V}_u \\ \tilde{V}_s \end{bmatrix},$$

where $\mathcal{J}_s$ contains the eigenvalues of A that lie in the open unit disk and $\mathcal{J}_u$ contains the rest. Then for any U_k^m such that the objective of $\mathrm{MPC_m}$ is bounded, the following equation must be satisfied:

$$\tilde{V}_u x_{k+m|k} = 0 \tag{7}$$

since the objective would be unbounded otherwise. Hence, the necessary and sufficient condition for the finiteness of the optimum of QP (3) is the existence of $U_k^m \in \Psi_k^m$ for which (7) is satisfied. Clearly, the addition of (7) as constraints to QP (3) does not alter the optimal solution.

Define the constrained m-step null controllable set as

$$\chi_m := \left\{ x \in \mathbf{R}^n : 0 = A^m x + \sum_{i=0}^{m-1} A^{m-i-1} B u_{k+i|k}, \right.$$
$$\left. u^{min} \le u_{k+i|k} \le u^{max}, \;\; i = 0, 1, \ldots, m-1 \right\}.$$

Assumption 3.2 dictates that χ_m contains an open neighborhood of the origin in the stabilizable subspace of (A, B) for sufficiently large m. Notice that, from Assumption 3.1, the marginal and unstable subspace of (A, B) is contained in the stabilizable subspace of (A, B). Define

$$\mathcal{E} := \{x : \tilde{V}_u A^m x = 0\}.$$

Then $\mathcal{E}$ is independent of m and is indeed the stable subspace of (A, B), because the following equalities hold:

$$\mathcal{E} = \left\{ x : \tilde{V}_u [V_u V_s] \begin{bmatrix} \mathcal{J}_u^m & 0 \\ 0 & \mathcal{J}_s^m \end{bmatrix} \begin{bmatrix} \tilde{V}_u \\ \tilde{V}_s \end{bmatrix} x = 0 \right\}$$

$$= \left\{ x : \tilde{V}_u V_u \mathcal{J}_u^m \tilde{V}_u x + \tilde{V}_u V_s \mathcal{J}_s^m \tilde{V}_s x = 0 \right\}$$

$$= \left\{ x : \mathcal{J}_u^m \tilde{V}_u x = 0 \right\} = \left\{ x : \tilde{V}_u x = 0 \right\}.$$

Notice that the second last equality follows from the facts that $\tilde{V}_u V_u = I$ and $\tilde{V}_u V_s = 0$.

THEOREM 4.3. *There exists* $U_k^m \in \Psi_k^m$ *such that* $\tilde{V}_u x_{k+m|k} = 0$ *iff*

$$x_k \in \pi_m := \{x \in \mathbf{R}^n : x = y + z,\ \ y \in \chi_m,\ z \in \mathcal{E}\},$$

where π_m *is called constrained* m*-step stabilizable set.*[4]

Proof. The sufficiency part is obvious. To show the necessity, suppose $\tilde{V}_u x_{k+m|k} = 0$. Since $U_k^m \in \Psi_k^m$, there exists y in χ_m such that

$$0 = A^m y + \sum_{i=0}^{m-1} A^{m-i-1} B u_{k+i|k}.$$

Let

$$z := x_k - y.$$

Then $z \in \mathcal{E}$ since $\tilde{V}_u z \neq 0$ implies $0 \neq \mathcal{J}_u^m \tilde{V}_u z = \tilde{V}_u A^m z = \tilde{V}_u x_{k+m|k}$. Hence, the theorem follows. □

Notice that π_m contains an open neighborhood of the origin in $\mathbf{R}^n$ for sufficiently large m because $\mathcal{E}$ is the stable subspace of (A, B) and χ_m contains an open neighborhood of the origin in the marginal and unstable subspace of (A, B) for sufficiently large m.

From Fact 4.1 and the stability of $\mathcal{J}_s$, there exist $\nu \in [0, 1)$ and $H \in [1, \infty)$ such that

$$\|\mathcal{J}_s^i\| \leq H\nu^i.$$

Then a compact set of feasible points for QP (3) that contains the optimal solution is

$$\bar{\Omega}_m(x_k) := \left\{ \begin{array}{ll} (U_k^m, \epsilon_k) \in \mathbf{R}^{p+mq} : u^{min} \leq u_{k+i|k} \leq u^{max}, & i = 0, 1, \ldots, m-1, \\ GA^i x_k + G\sum_{j=0}^{i-1} A^{i-j-1} B u_{k+j|k} \leq g + \epsilon_k, & i = 1, \ldots, m-1, \\ GA^i x_k + GA^{i-m}\sum_{j=0}^{m-1} A^{m-j-1} B u_{k+j|k} \leq g + \epsilon_k, & i = m, m+1, \ldots, \\ g + \epsilon_k \leq (\max\{|g|_\infty, \bar{K}_1|x_k| + \bar{K}_2\} + 1)\mathbf{1}, & \\ \epsilon_k \geq 0, & \\ \tilde{V}_u x_{k+m|k} = 0 \end{array} \right\},$$

where

$$\bar{K}_1 := \|G\|\|V_s\|\|\tilde{V}_s\| H \mathcal{A},$$

$$\bar{K}_2 := \|G\|\|V_s\|\|\tilde{V}_s\| H m \mathcal{A}\|B\|\sqrt{q}\vartheta.$$

[4]Let $\Omega_m = \{u : u^{min} \leq u_i \leq u^{max},\ i = 0, 1, \ldots, m-1,\ u_j = 0,\ j = m, m+1, \ldots\}$. Then the maximal Ω_m-invariant set w.r.t. $\mathbf{R}^n$, proposed in [14], coincides with the constrained m-step stabilizable set.

Then, for any $x_k \in \pi_m$ and $(U_k^m, \epsilon_k) \in \bar{\Omega}_m(x_k)$, it holds that

$$\sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k} = \sum_{i=1}^{m-1} x_{k+i|k}^T R x_{k+i|k} + x_{k+m|k}^T \left[\sum_{i=0}^{\infty} \tilde{V}_s^T \mathcal{J}_s^{iT} V_s^T R V_s \mathcal{J}_s^i \tilde{V}_s \right] x_{k+m|k}.$$

Hence, through the same arguments as the stable plant case, $\Phi_m(\cdot,\cdot,\cdot)$ is continuous w.r.t. (x_k, U_k^m, ϵ_k) on $\{x_k\} \times \bar{\Omega}_m(x_k)$ for each $x_k \in \pi_m$. We now show that $\bar{\Omega}_m(\cdot)$ is open on π_m.

For this, we need the following fact, which is proven similarly to Theorem 6.3.

Fact 4.2. Suppose $x_k, \bar{x} \in \pi_m$, $(\bar{U}^m, \bar{\epsilon}) \in \bar{\Omega}_m(\bar{x})$, and

$$\Xi_m(\bar{U}^m, x_k - \bar{x}) := \min_{V_k^m \in \Upsilon^m(\bar{U}^m)} \sum_{i=1}^{\infty} \xi_{k+i|k}^T R \xi_{k+i|k} + \sum_{i=0}^{m} v_{k+i|k}^T S v_{k+i|k},$$

where

$$\Upsilon^m(\bar{U}^m) := \{V_k^m \in \mathbf{R}^{mq} : u^{min} - \bar{u} \le v_{k+i|k} \le u^{max} - \bar{u}\},$$

$$\xi_{k+i+1|k} = A\xi_{k+i|k} + B v_{k+i|k}, \quad i \ge 0,$$

$$\xi_{k|k} = x_k - \bar{x}.$$

Then the solution V_k^{m*} to $\Xi_m(\bar{U}^m, \cdot)$ is Lipschitz continuous on $\{x : x + \bar{x} \in \pi_m\}$.

THEOREM 4.4. *$J_m(\cdot) = \bar{J}_m(\cdot)$ is continuous on π_m, where*

$$\bar{J}_m(x_k) := \min_{(U_k^m, \epsilon_k) \in \bar{\Omega}_m(x_k)} \Phi_m(x_k, U_k^m, \epsilon_k). \tag{8}$$

Proof. We first show that $\bar{\Omega}_m(\cdot)$ is open on π_m. For this, consider $\bar{x} \in \pi_m$. Let $\{x_k\}_{k=0}^{\infty} \subset \pi_m$, $x_k \to \bar{x}$, $(\bar{U}^m, \bar{\epsilon}) \in \bar{\Omega}_m(\bar{x})$, and $U_k^m = \bar{U}^m + V_k^{m*}$. Let $\{\delta_j\}_{j=0}^{\infty}$ be a monotonically decreasing sequence of positive integers such that $\delta_0 = 1$ and $\delta_j \to 0$ as $j \to \infty$. Define

$$f_i(x_k, U_k^m) := \begin{cases} GA^i x_k + G\sum_{j=0}^{i-1} A^{i-j-1} B u_{k+j|k}, & 1 \le i \le m-1, \\ GA^i x_k + GA^{i-m} \sum_{j=0}^{m-1} A^{m-j-1} B u_{k+j|k}, & i \ge m. \end{cases}$$

Notice that

$$f_i(x_k, \bar{U}^m + V_k^{m*}) - f_i(\bar{x}, \bar{U}^m) = GA^{i-m} \left\{ A^m (x_k - \bar{x}) + \sum_{j=0}^{m-1} A^{m-j-1} B v_{k+j|k}^{m*} \right\}, \quad i \ge m.$$

Hence, from Fact 4.2, $f_i(x_k, \bar{U}^m + V_k^{m*}) - f_i(\bar{x}, \bar{U}^m)$ is Lipschitz continuous w.r.t. $x_k - \bar{x}$. Let κ_i denote the smallest Lipschitz constant for given i. We now claim that $\kappa := \max_i \kappa_i$ is finite. To prove this claim, we first notice that for $i \ge m$,

$$f_i(x_k, \bar{U}^m + V_k^{m*}) - f_i(\bar{x}, \bar{U}^m) = GA^{i-m} \xi_{k+m|k}.$$

Since $\tilde{V}_u \xi_{k+m|k} = 0$, it follows that

$$f_i(x_k, \bar{U}^m + V_k^{m*}) - f_i(\bar{x}, \bar{U}^m) = GV_s \mathcal{J}_s^{i-m} \tilde{V}_s \xi_{k+m|k}.$$

Hence, the claim follows from the stability of $\mathcal{J}_s$.

Now there exists N_0 such that $|x_k - \bar{x}| < \frac{\delta_0}{3\max\{\bar{K}_1,\kappa\}}$ for all $k \geq N_0$. Moreover, for each $j \geq 1$, there exists $N_j > N_{j-1}$ such that $|x_k - \bar{x}| < \frac{\delta_j}{3\max\{\bar{K}_1,\kappa\}}$ for all $k \geq N_j$.

Let γ_l and ϵ_{kl} be defined similarly to the stable plant case. Then, the following inequalities hold.

The $g_l + \bar{\epsilon}_l \geq \max\{|g|_\infty, \bar{K}_1|\bar{x}| + \bar{K}_2\} + 1 - \frac{\delta_j}{3}$ *case.*

$$(f_i(x_k, U_k^m))_l \leq (f_i(\bar{x}, \bar{U}^m))_l + \frac{\delta_i}{3} \leq \bar{K}_1|\bar{x}| + \bar{K}_2 + \frac{\delta_j}{3}$$

$$\leq g_l + \bar{\epsilon}_l - 1 + \frac{2\delta_j}{3} \leq g_l + \bar{\epsilon}_l - \frac{\delta_j}{3} = g_l + \epsilon_{kl}, \qquad i \geq 0.$$

The $\gamma_l \leq \frac{\delta_j}{3}$ *case.*

$$(f_i(x_k, U_k^m))_l \leq (f_i(\bar{x}, \bar{U}^m))_l + \frac{\delta_j}{3} \leq g_l + \bar{\epsilon}_l + \frac{\delta_j}{3} = g_l + \epsilon_{kl}, \qquad i \geq 0.$$

The $g_l + \bar{\epsilon}_l \leq \max\{|g|_\infty, \bar{K}_1|\bar{x}| + \bar{K}_2\} + 1 - \frac{\delta_j}{3}$ and $\gamma_l \geq \frac{\delta_j}{3}$ *case.*

$$(f_i(x_k, U_k^m))_l \leq (f_i(\bar{x}, \bar{U}^m))_l + \frac{\delta_j}{3} \leq g_l + \bar{\epsilon}_l - \gamma_l + \frac{\delta_j}{3} \leq g_l + \bar{\epsilon}_l = g_l + \epsilon_{kl}, \qquad i \geq 0.$$

Moreover, similar to the stable plant case, all the other constraints are satisfied. Hence, for $k \geq N_0$, $(U_k^m, \epsilon_k) \in \bar{\Omega}_m(x_k)$ and $(U_k^m, \epsilon_k) \to (\bar{U}^m, \bar{\epsilon})$.

Similar to the stable plant case, $\bar{\Omega}_m(\cdot)$ is closed and thus continuous on π_m and is uniformly compact near any $\bar{x} \in \pi_m$. Hence, the theorem follows. □

THEOREM 4.5. *U_k^{m*} is uniformly compact on π_m and, thus, is continuous on π_m.*

Proof. Notice that, for any $x_k \in \pi_m$ and $(U_k^m, \epsilon_k) \in \bar{\Omega}_m(x_k)$,

$$\Phi_m = \sum_{i=1}^{m-1} x_{k+i|k}^T R x_{k+i|k} + x_{k+m|k}^T \tilde{V}_s^T \mathcal{R}_s \tilde{V}_s x_{k+m|k} + \sum_{i=0}^{m-1} u_{k+i|k}^T S u_{k+i|k},$$

where $\mathcal{R}_s$ is a unique positive definite solution of the following Lyapunov equation:

$$\mathcal{R}_s = \mathcal{J}_s^T \mathcal{R}_s \mathcal{J}_s + V_s^T R V_s.$$

Hence, the similar arguments to the stable plant case establish that U_k^{m*} is nonempty and single-valued on π_m. Moreover, similar to the stable plant case, it can be shown that U_k^{m*} is uniformly compact on π_m. Hence the theorem follows. □

5. Exponential stability of state feedback model predictive control.

5.1. Stable plants.

THEOREM 5.1. *The closed loop system with* $\mathrm{MPC_m}$ *is globally exponentially stable.*

From the Lyapunov theorem for global exponential stability [34, p. 267], the global exponential stability can be established if we can find a Lyapunov function for which there exist $a, b, c > 0$ such that

$$a|x_k|^2 \leq J_m(x_k) \leq b|x_k|^2,$$

$$\Delta J_m(x_k) \leq -c|x_k|^2.$$

We will show that $J_m(\cdot)$ is such a Lyapunov function for the closed loop system with $\mathrm{MPC_m}$.

We first show that there exists $a > 0$ such that $J_m(x_k) \geq a|x_k|^2$ for all $x_k \in \mathbf{R}^n$. For this, consider the following infinite horizon quadratic optimal control problem:

$$J_{um}(x_k) = \min_{U_k^m} \sum_{i=1}^{\infty} x_{k+i|k}^T R x_{k+i|k} + \sum_{i=0}^{m-1} u_{k+i|k}^T S u_{k+i|k}$$

subject to (4) and

$$u_{k+i|k} = 0, \qquad i = m, m+1, \ldots.$$

It is shown in [25] that

$$J_{um}(x_k) = x_k^T P_{m+1} x_k,$$

where P_{m+1} is a positive definite symmetric matrix which is the solution of the following recursion relation:

$$P_N = R + A^T \left[P_{N-1} - P_{N-1} B (B^T P_{N-1} B + S)^{-1} B^T P_{N-1} \right] A, \quad N > 1,$$

$$P_1 = \sum_{i=1}^{\infty} (A^T)^i R A^i.$$

Hence, it holds that $J_m(x_k) \geq J_{um}(x_k) \geq \lambda_{min}(P_{m+1})|x_k|^2$ for all $x_k \in \mathbf{R}^n$.

We next establish that there exists $b > 0$ such that $J_m(x_k) \leq b|x_k|^2$ for all $x_k \in \mathbf{R}^n$. Suppose $u_{k+i|k} = 0$, $i \geq 0$. Then $x_{k+i|k} = A^i x_k$ and, thus, $(0, \|G\|D|x_k|\mathbf{1})$ is a feasible point for J_m. Thus, it holds that

$$J_m(x_k) \leq \sum_{i=1}^{\infty} x_k^T A^{iT} R A^i x_k + D^2 \|G\|^2 |x_k|^2 \mathbf{1}^T Q \mathbf{1}$$

$$\leq x_k^T A^T T A x_k + D^2 \|G\|^2 |x_k|^2 \mathbf{1}^T Q \mathbf{1} \leq (\lambda_{max}(A^T T A) + D^2 \|G\|^2 \lambda_{max}(Q)\sqrt{q})|x_k|^2.$$

Finally, similar to the result in [38], it can be shown that

$$\Delta J_m(x_k) := J_m(x_k) - J_m(x_{k-1}) \leq -x_k^T R x_k - u_{k-1}^T S u_{k-1} \leq -x_k^T R x_k \leq -\lambda_{max}(R)|x_k|^2.$$

To this end, $J_m(\cdot)$ is a continuous Lyapunov function of the closed loop system with $\mathrm{MPC_m}$, and we have established the global exponential stability of the closed loop system with $\mathrm{MPC_m}$.

Remark 5.1. From Theorem 5.1, $x_k \to 0$ as $k \to 0$. Hence it holds that $u_k \to 0$ as $k \to 0$ since the optimal solution to QP (3) is 0 at $x_k = 0$ and is continuous w.r.t. x_k as established in section 4.

5.2. Marginal or unstable plants.

THEOREM 5.2. *The closed loop system with* $\mathrm{MPC_m}$ *is exponentially stable on* π_m.

To show the exponential stability on π_m of the closed loop system with $\mathrm{MPC_m}$, we will first show that $J_m(\cdot)$ is a Lyapunov function on π_m for the closed loop system

with $\mathrm{MPC_m}$. However, this establishes local exponential stability only. Exploiting the fact that $x_k \in \pi_m$ implies $x_{k+1} \in \pi_m$, we show that an exponentially converging envelope can be found that is valid for all $x_0 \in \pi_m$.

It can be shown similarly to the stable plant case that there exist $a, c > 0$ such that for any $x_k \in \pi_m$,

$$a|x_k|^2 \le J_m(x_k), \qquad \Delta J_m(x_k) \le -c|x_k|^2.$$

However, contrary to the stable plant case, the cost function of J_m with $U_k^m = 0$ is finite only if $x_k \in \mathcal{E}$. Hence, the similar arguments to the stable plant case establish that there exists $b > 0$ such that for any $x_k \in \mathcal{E} \subset \pi_m$,

$$J_m(x_k) \le b|x_k|^2.$$

We now show that such a constant indeed exists for all $x_k \in \pi_m$. Given $x \in \pi_m \setminus \mathcal{E}$, let

$$y := x - P_{\mathcal{E}}x \neq 0,$$

where $P_{\mathcal{E}}x$ denotes the projection of x on $\mathcal{E}$. Then y is perpendicular to $\mathcal{E}$. Let $r_{max} := \max_{x \in \chi_m} |x|$. Then, from Theorem 4.3, it holds that

$$\pi_m \subset \{x \in \mathbf{R}^n : dist(x, \mathcal{E}) \le r_{max}\}.$$

Hence, since $y \neq 0$, there exists $\alpha_x \in [1, \infty)$ such that $\alpha_x x \in \partial\pi_m$. Notice that there exists $(\hat{U}_k^m, \hat{\epsilon}_k) \in \bar{\Omega}_m(\alpha_x x)$ that drives $\alpha_x x$ to a point $z \in \mathcal{E}$ in m steps. Then, from the linearity of the plant, $(\frac{1}{\alpha_x}\hat{U}_k^m, \frac{1}{\alpha_x}\hat{\epsilon}_k) \in \bar{\Omega}_m(x)$ drives x to the point $\frac{1}{\alpha_x} z \in \mathcal{E}$ in m steps. Notice that

$$|\hat{U}_k^m| \le \sqrt{mq}\vartheta.$$

Hence it holds that

$$\left|\frac{1}{\alpha_x}\hat{U}_k^m\right| \le \sqrt{mq}\vartheta\frac{1}{\alpha_x} \le \frac{\sqrt{mq}\vartheta}{r_{min}}|x|,$$

where $r_{min} := \min_{x \in \partial\pi_m} |x|$ is greater than 0 because π_m contains an open neighborhood of the origin in $\mathbf{R}^n$. Hence, for any $x \in \pi_m \setminus \mathcal{E}$, there exists $\tilde{U}_k^m$ such that $\tilde{V}_u x_{k+m|k} = 0$ and

$$|\tilde{U}_k^m| \le \frac{\sqrt{mq}\vartheta}{r_{min}}|x|.$$

Indeed, this property holds for all $x \in \pi_m$ since, for any $x \in \mathcal{E}$, $\tilde{U}_k^m = 0$ results in $\tilde{V}_u x_{k+m|k} = 0$. Notice that

$$\tilde{x}_{k+i|k} = \begin{cases} A^i x_k + \sum_{j=0}^{i-1} A^{i-j-1} B\tilde{u}_{k+j|k}, & i = 1, \ldots, m-1, \\ V_s \mathcal{J}_s^{i-m} \tilde{V}_s A^m x_k + V_s \mathcal{J}_s^{i-m} \tilde{V}_s \sum_{j=0}^{m-1} A^{m-j-1} B\tilde{u}_{k+j|k}, & i = m, m+1, \ldots. \end{cases}$$

Define

$$\tilde{\epsilon}_k := \mathcal{H}\mathcal{A}\left(1 + m\|B\|\frac{\sqrt{mq}\vartheta}{r_{min}}\right)|x_k|\mathbf{1},$$

where

$$\mathcal{H} := \max\{1, \|V_s\|\|\tilde{V}_s\|H\},$$

$$\mathcal{A} := \max_{0\le i\le m} \|A^i\|.$$

Then $(\tilde{U}_k^m, \tilde{\epsilon}_k)$ is a feasible point for $J_m(x_k)$. Hence, for any $x_k \in \pi_m$,

$$J_m(x_k) \le \sum_{i=1}^{m-1} \tilde{x}_{k+i|k}^T R \tilde{x}_{k+i|k} + \sum_{i=0}^{\infty} \tilde{x}_{k+m|k}^T \tilde{V}_s^T \mathcal{J}_s^{iT} V_s^T R V_s \mathcal{J}_s^i \tilde{V}_s \tilde{x}_{k+m|k}$$

$$+ \sum_{i=0}^{m-1} \tilde{u}_{k+i|k}^T S \tilde{u}_{k+i|k} + \tilde{\epsilon}_k^T Q \tilde{\epsilon}_k$$

$$\le \left[\left(m - 1 + \frac{H^2\|V_s\|^2\|\tilde{V}_s\|^2}{1-\nu^2} \right) \mathcal{A}^2 \left(1 + m\|B\| \frac{\sqrt{mq}\vartheta}{r_{min}} \right)^2 \lambda_{max}(R) + \frac{mq\vartheta^2}{r_{min}^2} \lambda_{max}(S) \right.$$

$$\left. + \mathcal{H}^2\mathcal{A}^2 \left(1 + m\|B\| \frac{\sqrt{mq}\vartheta}{r_{min}} \right)^2 p\lambda_{max}(Q) \right] |x_k|^2.$$

To this end, on π_m, $J_m(\cdot)$ is a continuous Lyapunov function of the closed loop system with $\mathrm{MPC_m}$ for which there exist $a, b, c > 0$ such that for all $x_k \in \pi_m$,

$$a|x_k|^2 \le J_m(x_k) \le b|x_k|^2,$$

$$\Delta J_m(x_k) \le -c|x_k|^2.$$

Hence, we have established the exponential stability of the closed loop system with $\mathrm{MPC_m}$. It is now well known that $x_k \in \pi_m$ implies $x_{k+1} \in \pi_m$ because, in the absence of disturbances, $x_{k+1} = x_{k+1|k}^* \in \pi_{m-1} \subset \pi_m$.[5] Hence, following the standard procedure to find the exponentially converging envelope for the trajectory from a, b, c information [34], there exist $\sigma > 0$ and $\rho \in (0, 1)$ such that for all $x_0 \in \pi_m$,

$$|x_k| \le \sigma\rho^k |x_0|.$$

Notice that π_m is the largest possible domain of attraction of the closed loop system because the control law is not defined outside π_m from Theorem 4.3. To this end, we have established Theorem 5.2.

Remark 5.2. Similar to Remark 5.1, it holds that $U_k^{m*} \to 0$ as $k \to \infty$.

We now discuss what kind of constrained stabilization is achieved by the mixed constrained state feedback model predictive controller. In [33], Tsirukis and Morari showed that if all unstable eigenvalues of A are in the closed unit disk, for any $x \in \mathbf{R}^n$ there exists M such that $x \in \pi_m$ for all $m \ge M$. Hence, a marginal system subject to input constraints is semiglobally exponentially stabilized by the mixed constrained state feedback model predictive control law; for any bounded subset W of $\mathbf{R}^n$, there exists $m < \infty$ such that the closed loop with $\mathrm{MPC_m}$ is exponentially stable on W. Moreover, it is shown in [5] that π_m converges to π_∞ as $m \to \infty$. Hence, any unstable system can be exponentially stabilized by the mixed constrained model predictive control law on any compact subset of π_∞.

[5] $\{u_{k+1|k}^*, \ldots, u_{k-m+1|k}^*\}$ forms a possible $m-1$ input sequence for $x_{k+1|k}^* \in \pi_{m-1}$ to be true.

6. Exponential stability of output feedback model predictive control. In many cases, the states of a physical system are not all measurable. Under these circumstances, a state feedback controller is often cascaded with an asymptotic observer to form an output feedback control strategy. In this section, we will investigate the exponential stability properties of the output feedback closed loop system obtained by combining the mixed constrained state feedback model predictive controller and an asymptotic observer.

Suppose the state of the plant is estimated by an asymptotic observer:

$$\hat{x}_{k+1} = A\hat{x}_k + Bu_k + L\{C[A\hat{x}_k + Bu_k] - y_{k+1}\},$$

where $\hat{x}_k$ denotes the state estimated at the sampling time k. Notice that such an observer always exists under Assumption 3.1. Then the dynamics of the error $e_k := \hat{x}_k - x_k$ becomes

$$e_{k+1} = (I + LC)Ae_k.$$

Then mixed constrained output feedback model predictive control with horizon m ($\mathrm{OFMPC_m}$) is a nonlinear output feedback control law whose control output at the kth sampling time, u_k, is the first q elements $u_{k|k}^{m*}$ of the optimal solution U_k^{m*} of the quadratic optimization problem $J_m(\hat{x}_k)$.

For notational convenience, the state evolution constraints (4) in $J_m(\cdot)$ are replaced with

$$\hat{x}_{k+1|k+1} = \hat{x}_{k+1} = A\hat{x}_k + Bu_k + L\{C[A\hat{x}_k + Bu_k] - y_{k+1}\},$$

$$\hat{x}_{k+i+1|k+1} = A\hat{x}_{k+i|k+1} + Bu_{k+i|k+1}, \quad i \geq 1,$$

where $\hat{x}_k = \hat{x}_{k|k}^{m*}$ and $u_k = u_{k|k}^{m*}$. Define

$$\xi_{k+i|k+1} := \hat{x}_{k+i|k+1} - \hat{x}_{k+i|k}^{m*} \qquad \forall i \geq 1.$$

Then

$$\xi_{k+i+1|k+1} = A\xi_{k+i|k+1} + Bv_{k+i|k+1}, \quad i \geq 1, \tag{9}$$

$$\xi_{k+1|k+1} = LCAe_k,$$

where $v_{k+i|k+1} := u_{k+i|k+1} - u_{k+i|k}^{m*}$.

It can be easily shown that $\hat{V}(\hat{x}_k, e_k)$ is a Lyapunov function for the closed loop system of the estimated state and the observer error on $\mathcal{R}$ iff $V(\hat{x}_k, x_k) := \hat{V}(\hat{x}_k, \hat{x}_k - x_k)$ is a Lyapunov function for the closed loop system of the estimated state and the actual state on $\mathcal{P} := \left[\begin{smallmatrix} I & 0 \\ I & -I \end{smallmatrix}\right]\mathcal{R}$. Hence, we will construct a Lyapunov function for the closed loop system of the estimated state and the observer error in what follows.

6.1. Stable plants.

THEOREM 6.1. *If A and $(I + LC)A$ are stable, then the closed loop system with* $\mathrm{OFMPC_m}$ *is globally exponentially stable.*

To establish the global exponential stability of the closed loop system with $\mathrm{OFMPC_m}$, consider the following Lyapunov function candidate:

$$\hat{V}_m(\hat{x}_k, e_k) := J_m(\hat{x}_k) + \sum_{i=0}^{\infty} e_{k+i|k}^T O e_{k+i|k} = J_m(\hat{x}_k) + e_k^T \mathcal{O} e_k,$$

where

$$e_{k+i+1|k} = (I + LC)Ae_{k+i|k}, \qquad e_{k|k} = e_k,$$

O is a positive definite $n \times n$ matrix, and $\mathcal{O}$ is a unique positive definite solution of the following Lyapunov equation [3, p. 215]:

$$\mathcal{O} = A^T(I + LC)^T\mathcal{O}(I + LC)A + O.$$

It can be easily shown that $\hat{V}_m(\cdot, \cdot)$ is continuous and there exist $a, b > 0$ such that

$$a(|\hat{x}_k|^2 + |e_k|^2) \leq \hat{V}_m(\hat{x}_k, e_k) \leq b(|\hat{x}_k|^2 + |e_k|^2)$$

because both $J_m(\hat{x}_k)$ and $e_k^T\mathcal{O}e_k$ have such characteristics.

Now from the Lyapunov stability theorem [34, p. 267], the global exponential stability follows if there exists $c > 0$ such that

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \leq -c(|\hat{x}_k|^2 + |e_k|^2).$$

To show this, we first establish a series of lemmas.

Let F denote the feedback gain of unconstrained model predictive control. Associated with F, consider the maximal output admissible set O_∞ [13]:

$$O_\infty := \left\{ x \in \mathbf{R}^n \,\middle|\, (A - BF)^k x = \bar{A}^k x \in Y, k \geq 0 \right\},$$

where

$$Y := \left\{ x \in \mathbf{R}^n \,\middle|\, Gx \leq g, u^{min} \leq -Fx \leq u^{max} \right\}.$$

From Assumption 3.2, Y contains a neighborhood of the origin. Hence, the maximal output admissible set also contains a neighborhood of the origin. This implies U_k^{m*} is linear w.r.t. $\hat{x}_k$ in the neighborhood of the origin. Thus, U_k^{m*} is Lipschitz continuous in the neighborhood of the origin. Let γ be the radius of a closed ball contained in the maximal output admissible set and κ be the smallest Lipschitz constant for U_k^{m*} on $B(\gamma)$. Then, for all $\hat{x}_k \in B(\gamma)$,

$$|U_k^{m*}| \leq \kappa|\hat{x}_k|.$$

Moreover, since U_k^{m*} in J_m is always contained in a compact set, there exists a constant $\mathcal{K} > 0$ such that for all $\hat{x}_k \in \mathbf{R}^n$,

$$|U_k^{m*}| \leq \mathcal{K}.$$

To this end, it holds that for all $\hat{x}_k \in \mathbf{R}^n$,

$$|U_k^{m*}| \leq K|\hat{x}_k|,$$

where $K := \max\{\kappa, \frac{\mathcal{K}}{\gamma}\}$. To this end, it is trivial to show the following lemma.

LEMMA 6.1.

$$|\hat{x}_{k+1|k}^{m*}| \leq (\|A\| + \|B\|K)\,|\hat{x}_k|.$$

LEMMA 6.2. *Suppose A and $(I + LC)A$ are stable and $v_{k+i|k+1} = 0$ for all $i \geq 1$. Define $\eta_k := \max_{i \geq 1} |G\xi_{k+i|k+1}|_\infty \mathbf{1}$. Then, the following hold:*

(i) $|\xi_{k+i|k+1}| \le D\rho^{i-1}\|LCA\||e_k|$.
(ii) $|\eta_k| \le \sqrt{p}\|G\|D\|LCA\||e_k|$.

Proof. (i) is obvious because $\xi_{k+i|k+1} = A^{i-1}LCAe_k$. Then (ii) follows from the following inequalities:

$$\begin{aligned}|\eta_k| &= \max_{i\ge 1}\sqrt{p}|G\xi_{k+i|k+1}|_\infty \le \max_{i\ge 1}\sqrt{p}\|G\|D\rho^{i-1}\|LCA\||e_k| \\ &= \sqrt{p}\|G\|D\|LCA\||e_k|. \qquad \square\end{aligned}$$

LEMMA 6.3. *Suppose Z is a positive semidefinite $n \times n$ matrix and a, b are n-dimensional vectors. Then given $\delta > 0$,*

$$(a+b)^T Z(a+b) \le (1+\delta)a^T Za + \left(1+\frac{1}{\delta}\right) b^T Zb.$$

Proof.

$$0 \le \left(a - \frac{b}{\delta}\right)^T Z\left(a - \frac{b}{\delta}\right) = a^T Za + \frac{1}{\delta^2}b^T Zb - \frac{2}{\delta}a^T Zb$$

or

$$2a^T Zb \le \delta a^T Za + \frac{1}{\delta}b^T Zb.$$

From this inequality,

$$(a+b)^T Z(a+b) = a^T Za + b^T Zb + 2a^T Zb \le (1+\delta)a^T Za + \left(1+\frac{1}{\delta}\right) b^T Zb. \qquad \square$$

THEOREM 6.2. *There exists $c > 0$ such that*

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \le -c(|\hat{x}_k|^2 + |e_k|^2).$$

Proof. Let

$$u_{k+i|k+1} = u^{m*}_{k+i|k}, \quad i = 1, \dots, m,$$

$$\epsilon_{k+1} = \epsilon^{m*}_k + \eta_k,$$

where $u^{m*}_{k+m|k} = 0$. Then $(U^m_{k+1}, \epsilon_{k+1})$ is a feasible point for $J_m(\hat{x}_{k+1})$. Let

$$\mathcal{U}_k := \sum_{i=1}^{m-1} u^{m*T}_{k+i|k} S u^{m*}_{k+i|k},$$

$$\hat{V}_k := \hat{x}^{m*T}_{k+1|k} R\hat{x}^{m*}_{k+1|k} + u^{m*T}_{k|k} S u^{m*}_{k|k}.$$

Then,

$$J_m(\hat{x}_{k+1}) \le \sum_{i=2}^{\infty} \hat{x}^T_{k+i|k+1} R\hat{x}_{k+i|k+1} + \mathcal{U}_k + \epsilon^T_{k+1} Q\epsilon_{k+1} \tag{10}$$

$$= \sum_{i=2}^{\infty} (\hat{x}^{m*}_{k+i|k} + \xi_{k+i|k+1})^T R(\hat{x}^{m*}_{k+i|k} + \xi_{k+i|k+1}) + \mathcal{U}_k + (\epsilon^{m*T}_k + \eta_k)Q(\epsilon^{m*}_k + \eta_k)$$

$$\leq (1+\delta)\left(\sum_{i=2}^{\infty} \hat{x}^{m*T}_{k+i|k} R \hat{x}^{m*}_{k+i|k} + \mathcal{U}_k + \epsilon^{m*T}_k Q \epsilon^{m*}_k\right)$$

$$+ \left(1 + \frac{1}{\delta}\right)\left(\sum_{i=2}^{\infty} \xi^T_{k+i|k+1} R \xi_{k+i|k+1} + \eta^T_k Q \eta_k\right)$$

$$\leq J_m(\hat{x}_k) - \hat{V}_k + \delta J_m(\hat{x}_k) + \left(1 + \frac{1}{\delta}\right)\left(\sum_{i=2}^{\infty} \lambda_{max}(R)|\xi_{k+i|k+1}|^2 + \lambda_{max}(Q)|\eta_k|^2\right),$$

where δ will be chosen later. As shown in section 5, there exists $\mathcal{F} > 0$ such that $J_m(\hat{x}_k) \leq \mathcal{F}|\hat{x}_k|^2$ for all $\hat{x}_k \in \mathbf{R}^n$. Hence,

$$\Delta J_m(\hat{x}_k) := J_m(\hat{x}_{k+1}) - J_m(\hat{x}_k)$$

$$\leq -\hat{V}_k + \delta J_m(\hat{x}_k) + \left(1 + \frac{1}{\delta}\right)\left(\sum_{i=2}^{\infty} \lambda_{max}(R)|\xi_{k+i|k+1}|^2 + \lambda_{max}(Q)|\eta_k|^2\right)$$

$$\leq -\lambda_{min}(R)|\hat{x}^{m*}_{k+1|k}|^2 + \delta\mathcal{F}|\hat{x}_k|^2 + \left(1 + \frac{1}{\delta}\right)\left(\sum_{i=2}^{\infty} \lambda_{max}(R)|\xi_{k+i|k+1}|^2 + \lambda_{max}(Q)|\eta_k|^2\right)$$

$$\leq -\alpha|\hat{x}_k|^2 + \beta|e_k|^2,$$

where

$$\alpha := \lambda_{min}(R)\left[\|A\| + \|B\|K\right]^2 - \delta\mathcal{F},$$

$$\beta := \left(1 + \frac{1}{\delta}\right)\left[\lambda_{max}(R)D^2\frac{\rho^2}{1-\rho^2}\|LCA\|^2 + \lambda_{max}(Q)p\|G\|^2D^2\|LCA\|^2\right].$$

This implies

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \leq -\alpha|\hat{x}_k|^2 + \beta|e_k|^2 - \lambda_{min}(O)|e_k|^2.$$

Thus, there exists $c > 0$ such that

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \leq -c(|\hat{x}_k|^2 + |e_k|^2)$$

if δ and O are chosen such that $\delta < \frac{\lambda_{min}(R)[\|A\|+\|B\|K]^2}{\mathcal{F}}$ and $\beta < \lambda_{min}(O)$. ∎

To this end, $\hat{V}_m(\cdot,\cdot)$ is a continuous Lyapunov function for the closed loop system with OFMPC$_\mathrm{m}$ for which there exist $a, b, c > 0$ such that

$$a(|\hat{x}_k|^2 + |e_k|^2) \leq \hat{V}_m(\hat{x}_k, e_k) \leq b(|\hat{x}_k|^2 + |e_k|^2),$$

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \leq -c(|\hat{x}_k|^2 + |e_k|^2).$$

Hence, we established Theorem 6.1.

Remark 6.1. Similar to Remark 5.1, it holds that $u_k \to 0$ as $k \to 0$.

6.2. Marginal or unstable plants. For the marginal or unstable plant case, the $\hat{x}_k$ sequence may leave π_m due to the estimation error e_k although $x_k \in \pi_m$. Clearly, J_m is well-posed iff $\hat{x}_k \in \pi_m$. Hence, a trajectory that starts from an initial condition $(\hat{x}_0, e_0)$ is well-posed iff $\hat{x}_k \in \pi_m$ for all k. Suppose $\hat{x}_k \in \pi_m$. Then it holds that $\hat{x}_{k+1} \in \pi_m$ iff $(\hat{x}_k, e_k) \in \Sigma$, where

$$\Sigma := \left\{ (\hat{x}_k, e_k) \in \mathbf{R}^{2n} : \exists V_{k+1}^m \in \Pi_k^m(U_k^{m*}), \right.$$
$$\left. \tilde{V}_u \xi_{k+m+1|k+1} = \tilde{V}_u A^m LCAe_k + \tilde{V}_u \sum_{i=1}^{m} A^{m-i} B v_{k+i|k+1} = 0 \right\},$$

$$V_{k+1}^m := [v_{k+1|k+1} \cdots v_{k+m|k+1}],$$

$$\Pi_k^m(U_k^{m*}) := \{V_{k+1}^m \in \mathbf{R}^{mq} : u^{min} - u_{k+i|k}^{m*} \le v_{k+i|k+1} \le u^{max} - u_{k+i|k}^{m*}, \;\; i = 1, \ldots, m\}.$$

This well-posedness requirement sets up the largest possible stabilizable region with $\mathrm{MPC_m}$. However, the quantification of Σ is not possible in general and is an open question. Notice that $\Sigma \subset \pi_m \times \mathbf{R}^n$. Define

$$\mathcal{X}_m(U_k^{m*}) := \left\{ w \in \mathbf{R}^n : A^m w + \sum_{i=1}^{m} A^{m-i} B v_{k+i|k+1} = 0, \right.$$
$$\left. u^{min} - u_{k+i|k}^{m*} \le v_{k+i|k+1} \le u^{max} - u_{k+i|k}^{m*}, \;\; i = 1, \ldots, m \right\}.$$

Consider the null space of A^m:

$$\mathcal{N}(A^m) = \{\varpi : A^m \varpi = 0\}.$$

Let

$$\mathcal{Q} := \{\varphi : \varphi = w - P_{\mathcal{N}(A^m)} w, \; w \in \mathcal{X}_m(U_k^{m*})\}.$$

Hence given $w \in \mathcal{X}_m(U_k^{m*})$, there exist $\varpi \in \mathcal{N}(A^m)$, $\varphi \in \mathcal{Q}$ such that

$$w = \varpi + \varphi.$$

We now partition A as follows:

$$A = V \mathcal{J} V^{-1} = [V_z V_n] \begin{bmatrix} \mathcal{J}_z & 0 \\ 0 & \mathcal{J}_n \end{bmatrix} \begin{bmatrix} \tilde{V}_z \\ \tilde{V}_n \end{bmatrix},$$

where $\mathcal{J}_z$ contains the zero eigenvalues of A and $\mathcal{J}_n$ contains the rest. Notice that $\mathcal{J}_z$ is nilpotent and $\mathcal{J}_n$ is invertible. In all the practical situations, m is greater than the number of rows of the square matrix $\mathcal{J}_z$. Hence we assume $J_z^m = 0$ in the rest of this paper. Then

$$0 = A^m \varpi = V_n \mathcal{J}_n^m \tilde{V}_n \varpi$$

or equivalently

$$0 = \begin{bmatrix} \tilde{V}_z \\ \tilde{V}_n \end{bmatrix} A^m \varpi = \begin{bmatrix} 0 \\ \mathcal{J}_n^m \tilde{V}_n \varpi \end{bmatrix}.$$

Hence,

$$\mathcal{N}(A^m) = \{\varpi : \tilde{V}_n \varpi = 0\}. \tag{11}$$

Clearly,

$$0 = A^m w + \sum_{i=1}^{m} A^{m-i} B v_{k+i|k+1}$$

is equivalent to

$$\begin{aligned} 0 &= \begin{bmatrix} \tilde{V}_z \\ \tilde{V}_n \end{bmatrix} A^m w + \begin{bmatrix} \tilde{V}_z \\ \tilde{V}_n \end{bmatrix} \sum_{i=1}^{m} A^{m-i} B v_{k+i|k+1} \\ &= \begin{bmatrix} 0 \\ \mathcal{J}_n^m \tilde{V}_n w \end{bmatrix} + \sum_{i=1}^{m} \begin{bmatrix} \mathcal{J}_z^{m-i} \tilde{V}_z B v_{k+i|k+1} \\ \mathcal{J}_n^{m-i} \tilde{V}_n B v_{k+i|k+1} \end{bmatrix}. \end{aligned}$$

Moreover, since $\varphi = w - P_{\mathcal{N}(A^m)} w$ is always in the span of the transposes of rows of $\tilde{V}_n$ from (11),

$$\varphi = \tilde{V}_n^T \varepsilon.$$

Hence,

$$\begin{aligned} \mathcal{Q} = \Bigg\{ & \tilde{V}_n^T \varepsilon : \mathcal{J}_n^m \tilde{V}_n \tilde{V}_n^T \varepsilon + \sum_{i=1}^{m} \mathcal{J}_n^{m-i} \tilde{V}_n B v_{k+i|k+1} = 0, \quad \sum_{i=1}^{m} \mathcal{J}_z^{m-i} \tilde{V}_z B v_{k+i|k+1} = 0, \\ & u^{min} - u^{m*}_{k+i|k} \le v_{k+i|k+1} \le u^{max} - u^{m*}_{k+i|k}, \ \ i = 1, \dots, m \Bigg\} \\ = \{ & \tilde{V}_n^T \varepsilon : \varepsilon \in \mathcal{Q}_n \}, \end{aligned}$$

where

$$\begin{aligned} \mathcal{Q}_n = \Bigg\{ & \varepsilon : \varepsilon = (\tilde{V}_n \tilde{V}_n^T)^{-1} \left(-\mathcal{J}_n^{-1} \tilde{V}_n B v_{k+1|k+1} - \cdots - \mathcal{J}_n^{-m} \tilde{V}_n B v_{k+m|k+1} \right), \\ & \sum_{i=1}^{m} \mathcal{J}_z^{m-i} \tilde{V}_z B v_{k+i|k+1} = 0, \\ & u^{min} - u^{m*}_{k+i|k} \le v_{k+i|k+1} \le u^{max} - u^{m*}_{k+i|k}, \ \ i = 1, \dots, m \Bigg\}. \end{aligned}$$

Let

$$\begin{aligned} \mathcal{L}_k^m (U_k^{m*}) := \Bigg\{ & V_{k+1}^m \in \mathbf{R}^{mq} : \sum_{i=1}^{m} \mathcal{J}_z^{m-i} \tilde{V}_z B v_{k+i|k+1} = 0, \\ & u^{min} - u^{m*}_{k+i|k} \le v_{k+i|k+1} \le u^{max} - u^{m*}_{k+i|k}, \ \ i = 1, \dots, m \Bigg\}. \end{aligned}$$

Since $\mathcal{Q}_n$ is the set of all points that are linear combinations of $-(\tilde{V}_n\tilde{V}_n^T)^{-1}\mathcal{J}_n^{-i-1}\tilde{V}_nB$, $i=0,\dots,m-1$, whose coefficients are in $\mathcal{L}_k^m(U_k^{m*})$, it is a polyhedron. Let $\{w_i\}_{i=1}^{p_m}$ be the set of all vertices of $\mathcal{Q}_n$. For each i, w_i can be represented as

$$w_i = -\sum_{j=0}^{m-1}(\tilde{V}_n\tilde{V}_n^T)^{-1}\mathcal{J}_n^{-i-1}\tilde{V}_nBv_i(j),$$

where $v_i(j)\in\mathcal{L}_k^m(U_k^{m*})$.

THEOREM 6.3. *There exists a positive constant $\mathcal{Z}$ such that for all $y\in\mathcal{X}_m(U_k^{m*})$, there exists $\tilde{V}_{k+1}^m\in\Pi_k^m(U_k^{m*})$ for which*

$$|\tilde{V}_{k+1}^m|\le\mathcal{Z}|y|$$

and

$$A^m y+\sum_{i=1}^{m}A^{i-1}Bv_{k+i|k+1}=0.$$

Proof. Notice that

$$y=\varpi+\tilde{V}_n^T\varepsilon,\qquad \varpi\in\mathcal{N}(A^m),\qquad \varepsilon\in\mathcal{Q}_n,$$

and, thus,

$$|\varepsilon|=|V_n^T\tilde{V}_n^T\varepsilon|\le\|V_n^T\||\tilde{V}_n^T\varepsilon|\le\|V_n^T\||y|.$$

Notice that the last inequality follows from the fact that the angle between ϖ and $\tilde{V}_n^T\varepsilon$ is right. Hence, the above claim follows if there exists a positive constant $\mathcal{Z}_n$ such that for all $\varepsilon\in\mathcal{Q}_n$, there exists $\tilde{V}_{k+1}^m\in\mathcal{L}_k^m(U_k^{m*})$ for which

$$|\tilde{V}_{k+1}^m|\le\mathcal{Z}_n|\varepsilon|$$

and

$$\varepsilon=-\sum_{j=0}^{m-1}(\tilde{V}_n\tilde{V}_n^T)^{-1}\mathcal{J}_n^{-i-1}\tilde{V}_nBv_i(j).$$

Suppose $\varepsilon\in\mathcal{Q}_n$. Then there exists a face,[6] S_j, of the polyhedron $\mathcal{Q}_n$ such that ε is contained in the polyhedral sector defined by the origin and S_j. Let n_1 denote the number of vertices of S_j. Then there exists a unique set of nonnegative real numbers $a_{\varepsilon l}^j$'s for which $\sum_{l=1}^{n_1}a_{\varepsilon l}^j\le 1$ such that

$$\varepsilon=\sum_{l=1}^{n_1}a_{\varepsilon l}^j w_l^j=[w_1^j\cdots w_{n_1}^j]\begin{bmatrix}a_{\varepsilon 1}^j\\ \vdots\\ a_{\varepsilon n_1}^j\end{bmatrix},$$

where $\{w_l^j\}$ is the set of all vertices of S_j. Now define

$$\hat{v}_{k+i|k+1}:=\sum_{l=1}^{n_1}a_{\varepsilon l}^j v_l^j(i-1)=[v_1^j(i-1)\cdots v_{n_1}^j(i-1)][w_1^j\cdots w_{n_1}^j]^{\dagger}\varepsilon,$$

[6] In this paper, a face is a simplice that is obtained by possibly dividing a face into simplices.

where $v_l^j(j) \in \mathcal{L}_k^m(U_k^{m*})$ such that

$$w_l^j = -\sum_{i=0}^{m-1} (\tilde{V}_n \tilde{V}_n^T)^{-1} \mathcal{J}_n^{-i-1} \tilde{V}_n B v_l^j(i),$$

and $M^\dagger$ denotes the pseudo-inverse of M. Notice that

$$[w_1^j \cdots w_{n_1}^j]$$

$$= \left[-\sum_{i=0}^{m-1} (\tilde{V}_n \tilde{V}_n^T)^{-1} \mathcal{J}_n^{-i-1} \tilde{V}_n B v_1^j(i) \;\; \cdots \;\; -\sum_{i=0}^{m-1} (\tilde{V}_n \tilde{V}_n^T)^{-1} \mathcal{J}_n^{-i-1} \tilde{V}_n B v_{n_1}^j(i) \right]$$

$$= -(\tilde{V}_n \tilde{V}_n^T)^{-1} \left[\mathcal{J}_n^{-1} \tilde{V}_n B \cdots \mathcal{J}_n^{-m} \tilde{V}_n B \right] \begin{bmatrix} v_1^j(0) & \cdots & v_{n_1}^j(0) \\ \vdots & \ddots & \vdots \\ v_1^j(m-1) & \cdots & v_{n_1}^j(m-1) \end{bmatrix}.$$

Hence,

$$\tilde{V}_{k+1}^m := \Gamma_j \varepsilon \in \mathcal{L}_k^m(U_k^{m*}),$$

where Γ_j is a linear mapping from $\mathcal{Q}_n$ to $\mathcal{L}_k^m(U_k^{m*})$, defined by

$$\Gamma_j := -\begin{bmatrix} v_1^j(0) & \cdots & v_{n_1}^j(0) \\ \vdots & \ddots & \vdots \\ v_1^j(m-1) & \cdots & v_{n_1}^j(m-1) \end{bmatrix}$$

$$\times \left\{ (\tilde{V}_n \tilde{V}_n^T)^{-1} \left[\mathcal{J}_n^{-1} \tilde{V}_n B \cdots \mathcal{J}_n^{-m} \tilde{V}_n B \right] \begin{bmatrix} v_1^j(0) & \cdots & v_{n_1}^j(0) \\ \vdots & \ddots & \vdots \\ v_1^j(m-1) & \cdots & v_{n_1}^j(m-1) \end{bmatrix} \right\}^\dagger.$$

This implies

$$|\hat{V}_{k+1}^m| \le \mathcal{Z}_n |\varepsilon|,$$

where $\mathcal{Z}_n := \max_j \|\Gamma_j\|$. Moreover,

$$\varepsilon = \sum_{l=1}^{n_1} a_{\varepsilon l}^j w_l^j = \sum_{l=1}^{n_1} -a_{\varepsilon l}^j \sum_{i=0}^{m-1} (\tilde{V}_n \tilde{V}_n^T)^{-1} \mathcal{J}_n^{-i-1} \tilde{V}_n B v_j^l(i)$$

$$= \sum_{i=0}^{m-1} -(\tilde{V}_n \tilde{V}_n^T)^{-1} \mathcal{J}_n^{-i-1} \tilde{V}_n B \left(\sum_{l=1}^{n_1} a_{\varepsilon l}^j v_j^l(i) \right)$$

$$= \sum_{i=0}^{m-1} -(\tilde{V}_n \tilde{V}_n^T)^{-1} \mathcal{J}_n^{-i-1} \tilde{V}_n B \hat{v}_{k+i|k+1}.$$

Hence, the theorem follows. □

Similar to Theorem 4.3, one can show the following theorem.

THEOREM 6.4. *There exists* $V_{k+1}^m \in \Pi_k^m(U_k^{m*})$ *such that* $\tilde{V}_u \xi_{k+m|k} = 0$ *iff*

$$\xi_{k+1|k+1} = LCAe_k \in \mathcal{M}_m(U_k^{m*}),$$

where

$$\mathcal{M}_m(U_k^{m*}) := \{w \in \mathbf{R}^n : w = y + z,\ \ y \in \mathcal{X}_m(U_k^{m*}),\ z \in \mathcal{E}\}.$$

Clearly, $\mathcal{M}_m(U_k^{m*})$ contains a nonempty interior in $\mathbf{R}^n$ for sufficiently large m.

Now we can easily establish the following theorem.

THEOREM 6.5. *Given* e_k *such that* $LCAe_k \in \mathcal{M}_m(U_k^{m*})$, *there exists* $\hat{V}_{k+1}^m \in \Pi_k^m(U_k^{m*})$ *such that*

$$|\hat{V}_{k+1}^m| \le \zeta |e_k|,$$

where $\zeta = \mathcal{Z}\|LCA\|$.

Proof. If $LCAe_k \in \mathcal{E}$, choose $\hat{V}_{k+1}^m = 0 \in \Pi_k^m(U_k^{m*})$. If $LCAe_k \in \mathcal{M}_m(U_k^{m*}) \setminus \mathcal{E}$, let

$$y := LCAe_k - P_{\mathcal{E}} LCAe_k \neq 0.$$

Then y is perpendicular to $\mathcal{E}$ and is contained in $\mathcal{X}_m(U_k^{m*})$. Moreover, it holds that

$$|y| = |LCAe_k - P_{\mathcal{E}} LCAe_k| \le |LCAe_k|.$$

Notice that the inequality follows from the fact that the angle between $LCAe_k$ and $P_{\mathcal{E}} LCAe_k$ is acute. Now choose $\hat{V}_{k+1}^m = \Gamma_j (I - P_{\mathcal{E}}) LCAe_k$. Then it holds that, for all $LCAe_k \in \mathcal{M}_m(U_k^{m*}) \setminus \mathcal{E}$,

$$|\hat{V}_{k+1}^m| \le \mathcal{Z}|y| \le \mathcal{Z}|LCAe_k| \le \mathcal{Z}\|LCA\||e_k|.$$

Hence the theorem follows. □

As mentioned before, a trajectory starting from $(\hat{x}_0, e_0) \in \Sigma$ is well-posed iff $(\hat{x}_k, e_k) \in \Sigma$ for all k. Hence,

$$\mathcal{D} := \{(\hat{x}_0, e_0) \in \Sigma : (\hat{x}_k, e_k) \in \Sigma\ \forall k\}$$

is the largest possible domain of attraction.

THEOREM 6.6. *If* $(I+LC)A$ *is stable, then the closed loop system with* $\mathrm{OFMPC_m}$ *is exponentially stable on* $\mathcal{D}$.

To prove Theorem 6.6, we first show that the following Lyapunov function candidate is indeed a Lyapunov function of the closed loop system on Σ:

$$\hat{V}_m(\hat{x}_k, e_k) := J_m(\hat{x}_k) + \sum_{i=0}^{\infty} e_{k+i|k}^T O e_{k+i|k} = J_m(\hat{x}_k) + e_k^T \mathcal{O} e_k,$$

where O and $\mathcal{O}$ are defined similar to the stable plant case. Then using the fact that $(\hat{x}_k, e_k) \in \mathcal{D}$ implies $(\hat{x}_{k+1}, e_{k+1}) \in \mathcal{D}$, we will show that the exponentially converging envelope is valid for all $(\hat{x}_0, e_0) \in \mathcal{D}$.

As shown in section 4, $J_m(\cdot)$ is continuous on π_m. Hence, $\hat{V}_m(\cdot,\cdot)$ is continuous on $\pi_m \times \mathbf{R}^n$. Now similar to the stable plant case, it is clear that there exists $a > 0$ such that for all $(\hat{x}_k, e_k) \in \pi_m \times \mathbf{R}^n$,

$$a(|\hat{x}_k|^2 + |e_k|^2) \le \hat{V}_m(\hat{x}_k, e_k).$$

Moreover, as shown in section 5, there exists $K > 0$ such that for all $\hat{x}_k \in \pi_m$,

$$|U_k^{m*}| \le K|\hat{x}_k|.$$

Hence, similar to the stable plant case, there exists $b > 0$ such that for all $(\hat{x}_k, e_k) \in \pi_m \times \mathbf{R}^n$,

$$\hat{V}_m(\hat{x}_k, e_k) \le b(|\hat{x}_k|^2 + |e_k|^2)$$

because such constants also exist for $J_m(\cdot)$ and $e_k^T \mathcal{O} e_k$ on π_m and $\mathbf{R}^n$, respectively.

Now the exponential stability of OFMPC$_\mathrm{m}$ follows if there exists $c > 0$ such that for all $(\hat{x}_k, e_k) \in \Sigma$,

$$\Delta\hat{V}_m(\hat{x}_k) \le -c(|\hat{x}_k|^2 + |e_k|^2).$$

To show this, we need the following lemma.

LEMMA 6.4. *Suppose $(I + LC)A$ is stable and $\hat{V}_{k+1}^m = \Gamma_j(I - P_{\mathcal{E}})LCAe_k$. Define*

$$\eta_k := \max_{i \ge 1} |G\xi_{k+i|k+1}|_\infty \mathbf{1},$$

$$\mathcal{V}_k := \sum_{i=1}^{m} \hat{v}_{k+i|k+1}^T S \hat{v}_{k+i|k+1}.$$

Then, it holds that

(i)

$$|\xi_{k+i|k+1}| \le \begin{cases} \mathcal{A}(\|LCA\| + \|B\|\zeta)|e_k| & \text{if } 1 \le i \le m, \\ H\nu^{i-m-1}\|V_s\|\|\tilde{V}_s\|\mathcal{A}(\|LCA\| + \|B\|\zeta)|e_k| & \text{if } i \ge m+1, \end{cases}$$

where $\mathcal{A} = \max_{0 \le i \le m} \|A^i\|$;

(ii) $|\eta_k| \le \sqrt{p}\|G\|H\|V_s\|\|\tilde{V}_s\|\mathcal{A}(\|LCA\| + \|B\|\zeta)|e_k|$;

(iii) $\mathcal{V}_k \le \lambda_{max}(S)\zeta^2|e_k|^2$.

Proof. Notice that the norms of the terms associated with e_k and $\hat{V}_{k+1}^m$ in $\xi_{k+i+1|k+1}$ are bounded by $\mathcal{A}\|LCA\||e_k|$ and $\mathcal{A}\|B\|\zeta|e_k|$ for each $i \in \{1, \ldots, m\}$, whereas they are bounded by $H\nu^{i-m-1}\|V_s\|\|\tilde{V}_s\|\mathcal{A}\|LCA\||e_k|$ and $H\nu^{i-m-1}\|V_s\|\|\tilde{V}_s\|$ $\mathcal{A}\|B\|\zeta|e_k|$ for each $i \ge m+1$. Hence, (i) follows. From (i), it is trivial to show (ii). Finally, (iii) follows from the inequalities

$$\mathcal{V}_k \le \lambda_{max}(S)|\tilde{V}_{k+1}^m|^2 \le \lambda_{max}(S)\zeta^2|e_k|^2. \qquad \square$$

THEOREM 6.7. *There exists $c > 0$ such that for all $(\hat{x}_k, e_k) \in \Sigma$,*

$$\Delta \hat{V}_m(\hat{x}_k, e_k) \leq -c(|\hat{x}_k|^2 + |e_k|^2).$$

Proof. Let

$$u_{k+i|k+1} = u^{m*}_{k+i|k} + \hat{v}_{k+i|k+1}, \qquad i = 1, \ldots, m,$$

$$\epsilon_{k+1} = \epsilon^{m*}_k + \eta_k.$$

Then $(U^m_{k+1}, \epsilon_{k+1})$ is a feasible point for $J_m(\hat{x}_{k+1})$. Suppose $\mathcal{U}_k$ and V_k are defined as before and

$$\mathcal{V}_{k+1} := \sum_{i=1}^{m} \hat{v}^T_{k+i|k+1} S \hat{v}_{k+i|k+1},$$

$$\mathcal{W}_{k+1} := \sum_{i=1}^{m} u^T_{k+i|k+1} S u_{k+i|k+1}.$$

Then,

$$J_m(\hat{x}_{k+1}) \leq \sum_{i=2}^{\infty} \hat{x}^T_{k+i|k+1} R \hat{x}_{k+i|k+1} + \mathcal{W}_{k+1} + \epsilon^T_{k+1} Q \epsilon_{k+1}$$

$$\leq J_m(\hat{x}_k) - \hat{V}_k + \delta J_m(\hat{x}_k) + \left(1 + \frac{1}{\delta}\right) \left(\sum_{i=2}^{\infty} \lambda_{max}(R) |\xi_{k+i|k+1}|^2 + \lambda_{max}(Q) |\eta_k|^2 + \mathcal{V}_{k+1} \right),$$

where δ will be chosen later. Similar to the stable plant case, it is trivial to establish that there exists $\mathcal{F} > 0$ such that $J_m(\hat{x}_k) \leq \mathcal{F}|\hat{x}_k|^2$ for all $\hat{x}_k \in \pi_m$. Hence, it holds that for all $(\hat{x}_k, e_k) \in \Sigma$,

$$\Delta J_m(\hat{x}_k) \leq -V_k + \delta J_m(\hat{x}_k)$$

$$+ \left(1 + \frac{1}{\delta}\right) \left(\sum_{i=2}^{\infty} \lambda_{max}(R) |\xi_{k+i|k+1}|^2 + \lambda_{max}(Q) |\eta_k|^2 + \mathcal{V}_{k+1} \right)$$

$$\leq -\lambda_{min}(R) |\hat{x}^{m*}_{k+1|k}|^2 + \delta \mathcal{F} |\hat{x}_k|^2$$

$$+ \left(1 + \frac{1}{\delta}\right) \left(\sum_{i=2}^{\infty} \lambda_{max}(R) |\xi_{k+i|k+1}|^2 + \lambda_{max}(Q) |\eta_k|^2 + \mathcal{V}_{k+1} \right)$$

$$\leq -\alpha |\hat{x}_k|^2 + \beta |e_k|^2,$$

where

$$\alpha := \lambda_{min}(R) \left[\|A\| + \|B\| K \right] - \delta \mathcal{F},$$

$$\beta := \left(1+\frac{1}{\delta}\right)\lambda_{max}(R)m\mathcal{A}^2(\|LCA\|+\|B\|\zeta)^2$$

$$+\left(1+\frac{1}{\delta}\right)\lambda_{max}(R)H\|V_s\|^2\|\tilde{V}_s\|^2\frac{\nu^2}{1-\nu^2}\mathcal{A}^2(\|LCA\|+\|B\|\zeta)^2$$

$$+\left(1+\frac{1}{\delta}\right)\lambda_{max}(Q)p\|G\|^2H\|V_s\|^2\|\tilde{V}_s\|^2\mathcal{A}^2(\|LCA\|+\|B\|\zeta)^2$$

$$+\left(1+\frac{1}{\delta}\right)\lambda_{max}(S)\zeta^2.$$

This implies for all $(\hat{x}_k, e_k) \in \Sigma$,

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \le -\alpha|\hat{x}_k|^2 + \beta|e_k|^2 - \lambda_{min}(O)|e_k|^2.$$

Thus, there exists $c > 0$ such that for all $(\hat{x}_k, e_k) \in \Sigma$,

$$\Delta\hat{V}_m(\hat{x}_k, e_k) \le -c(|\hat{x}_k|^2 + |e_k|^2)$$

if δ and O are chosen such that $\delta < \frac{\lambda_{min}(R)}{F}$ and $\beta < \lambda_{min}(O)$. □

Since $(\hat{x}_k, e_k) \in \mathcal{D}$ implies $(\hat{x}_{k+1}, e_{k+1}) \in \mathcal{D}$, there exist $\sigma > 0$ and $\rho \in (0,1)$ such that for all $(\hat{x}_0, e_0) \in \mathcal{D}$,

$$|(\hat{x}_k, e_k)| \le \sigma\rho^k|(\hat{x}_0, e_0)|.$$

To this end, we have proven Theorem 6.6.

Remark 6.2. Similar to the comment following Theorem 5.1, it holds that $U_k^{m*} \to 0$ as $k \to \infty$.

The necessary and sufficient condition for constrained stabilizability is $x_k \in \pi_\infty$ for all k. The above claim dictates that $(\hat{x}_0, e_0) \in \mathcal{D}$ implies $x_k \in \pi_\infty$ for all k. However, $x_k \in \pi_m$ for all k is not necessary and there may exist an initial condition $x_0 \in \pi_\infty \setminus \pi_m$ for which there exists e_0 such that (x_0, e_0) is in the domain of attraction of the closed loop system.

7. Comparison with nonconstructive approach. In the previous section, the exponential stability of mixed constrained model predictive control is established by constructing a Lyapunov function of the closed loop system. However, a nonconstructive approach to the asymptotic stability of hard constrained output feedback model predictive control with the state constraint dropping scheme has also been proposed [24], [23] based on the stability theory of perturbed systems [16]. In this section, we comment on this nonconstructive approach to mixed constrained state feedback model predictive control.

When the unperturbed system is not globally stable, the existing stability theory of perturbed systems establishes the local stability of the perturbed system but doesn't give any explicit information on the corresponding domain of attraction. Hence, for the marginal and unstable plant cases, the largest possible domain of attraction cannot be in general identified via the nonconstructive approach. Indeed, such local stability of the closed loop system without explicit quantification is straightforward since, near the origin, the output feedback system is linear.

When a state feedback law is combined with an asymptotic observer, the key requirement for the perturbed system stability theory to be applicable is the Lipschitz

continuity of the state feedback law. The result in [15] is identified as a vehicle to establish the Lipschitz continuity of hard constrained state feedback model predictive control with the state constraint dropping scheme [24]. In the original version of the paper, we have pointed out that the results in [15] are not in general applicable to mixed constrained state feedback model predictive control. The first reason was the requirement of the results in [15] that the gradients of binding constraints must be linearly independent. The example in the appendix was given as the example where this linear independence condition is violated. The second reason was that the result in [15] is concerned with a finite-dimensional QP whereas the QP associated with constrained state feedback model predictive control contains infinite number of constraints. Although all but a finite number of constraints are redundant for a given state [25], [38], the required finite horizon may increase indefinitely with the size of the state. Thus, the applicability of the result in [15] to the global exponential stability of constrained model predictive control for stable plants is not clear. There exists an extension of the result in [15] to infinite-dimensional QPs [11]. However, the result in [11] requires that the linear map in the constraints be surjective and again is not applicable to J_m. From one of the reviews, we found that our first concern has been resolved and the second one has also been pointed out since the submission of this paper. Indeed it was shown in [1] and [29] that the solution of a hard constrained model predictive control with a finite number of constraints is continuous and piecewise affine on a compact set and thus is Lipschitz continuous over the set. Moreover, it is also mentioned in [1] that the same is also true for the mixed constrained case. However, the results in [1] and [29] are only applicable to the problem with a finite number of constraints, and the required global Lipschitz continuity for stable plants hasn't been established yet. We conjecture that the mixed constrained state feedback model predictive control is globally Lipschitz for stable plants. However, this needs to be proven before we discuss the applicability of nonconstructive approach to the stable plant case.

8. Conclusion. In this paper, we established the continuity of mixed constrained model predictive control. Moreover, the stability properties of mixed constrained model predictive control for both state feedback and output feedback cases is addressed as well. The previous efforts in this direction established only the attractivity of the closed loop system for limited class of plants. However, despite the presence of nonlinear elements such as the mixed constrained model predictive controller and the saturation of input, we were able to show that for both state and output feedback cases with any plant, the closed loop system with the mixed constrained model predictive controller possesses the strongest stability property, exponential stability on the largest possible candidate for the domain of attraction, which is the set of all initial conditions for which the mixed constrained model predictive control law is defined throughout the trajectory.

Appendix. Consider the following stable second order plant:

$$x_{k+1} = \begin{bmatrix} 0 & 0.5 \\ 0.5 & 0 \end{bmatrix} x_k + \begin{bmatrix} 10 \\ 0 \end{bmatrix} \sigma(u_k),$$

where

$$\sigma(u) := \begin{cases} -1 & \text{if } u < -1, \\ u & \text{if } -1 \le u \le 1, \\ 1 & \text{if } u > 1. \end{cases}$$

Suppose the control and the state of the system are desired to satisfy the following inequalities:

$$-1 \le u_k \le 1, \qquad k = 0, 1, \ldots,$$

$$x_k \le \begin{bmatrix} 15 \\ 50 \end{bmatrix}, \qquad k = 0, 1, \ldots.$$

Associated with the plant, consider MPC_2 defined by the following QP:

$$J_2(x_k) = \min_{U_k^m, \epsilon_k} \sum_{i=1}^{\infty} x_{k+i|k}^T x_{k+i|k} + \sum_{i=0}^{1} u_{k+i|k}^T u_{k+i|k} + \epsilon_k^T \epsilon_k$$

subject to

$$x_{k+i+1|k} = \begin{bmatrix} 0 & 0.5 \\ 0.5 & 0 \end{bmatrix} x_{k+i|k} + \begin{bmatrix} 10 \\ 0 \end{bmatrix} u_{k+i|k}, \qquad x_{k|k} = x_k,$$

$$-1 \le u_{k+i|k} \le 1, \qquad i = 0, 1,$$

$$u_{k+i|k} = 0, \qquad i = 2, \ldots,$$

$$x_{k+i|k} \le \begin{bmatrix} 15 \\ 50 \end{bmatrix} + \epsilon_k, \qquad k = 1, \ldots,$$

$$\epsilon_k \ge 0, \qquad k = 1, \ldots.$$

Suppose

$$x_0 = \begin{bmatrix} 100 \\ 50 \end{bmatrix}.$$

Then the optimal solution of the QP is $u_{0|0}^* = u_{1|0}^* = -1, \epsilon_0 = 0$. Thus the binding constraints are

$$-1 \le u_{0|0}^*,$$

$$-1 \le u_{1|0}^*,$$

$$25 + 10u_{0|0}^* \le 15 + \epsilon_{01},$$

$$50 \le 50 + \epsilon_{02},$$

$$25 + 10u_{1|0}^* \le 15 + \epsilon_{01},$$

$$\epsilon_{01} \ge 0,$$

$$\epsilon_{02} \ge 0.$$

Clearly, the gradients of the binding constraints are not linearly independent.

Acknowledgment. The authors are grateful to the anonymous reviewers for many useful comments in improving the paper.

A TWO-LEVEL ENERGY METHOD FOR INDIRECT BOUNDARY OBSERVABILITY AND CONTROLLABILITY OF WEAKLY COUPLED HYPERBOLIC SYSTEMS*

FATIHA ALABAU-BOUSSOUIRA†

Abstract. This work is concerned with the boundary observability of an abstract system of two coupled second order evolution equations, the coupling operator being a compact perturbation of the uncoupled system. We assume that only one of the two components of the unknown is observed. This is indirect observability. We prove that by observing only one component, one can get back a full weakened energy of both components under a compatibility condition linking the operators of each equation and for small coupling. Using the Hilbert uniqueness method, we then establish an indirect exact controllability result. We apply this abstract result to several coupled systems of partial differential equations (wave-wave, coupled elastodynamic systems, Petrowsky-Petrowsky, and wave-Petrowsky systems).

Key words. boundary observability, indirect controllability, hyperbolic systems, abstract linear evolution equations

1. Introduction: Motivations. Let T be a given positive time and Ω be a bounded open set of $\mathbb{R}^N$ with a boundary Γ of class $\mathcal{C}^2$. It is well known that the energy of weak solutions of the wave equation, in Ω,

$$\begin{cases} u_{tt} - \Delta u = 0 \text{ in } \Omega \times (0,T), \\ u(.,0) = u_0(.),\ u_t(.,0) = u_1(.) \text{ in } \Omega, \end{cases} \tag{1.1}$$

when subjected to homogeneous Dirichlet conditions on $\partial\Omega \times (0,T)$, is conserved through time, that is, $E(u(t)) = E(u(0))$ for all $t \geq 0$. Here Δ stands for the Laplacian with respect to the spatial variables and the subscript t stands for the partial derivative with respect to the t-variable. We recall that the energy of the solutions u of the wave equation is defined by

$$E(u(t)) = \frac{1}{2}\int_\Omega (|u_t|^2 + |\nabla u|^2)\, dx.$$

Moreover, these solutions satisfy the following direct inequality (see [25], [26]):

$$\int_0^T \int_\Gamma \left|\frac{\partial u}{\partial \nu}\right|^2 d\gamma\, dt \leq c_2\, E(u(0)), \tag{1.2}$$

where ν stands for the unit outward normal vector to Γ; the positive constant c_2 depends on T and on the geometry of Ω. This result implies, in particular, a hidden regularity result saying that the weak solutions u of the wave equation satisfy, in addition,

$$\frac{\partial u}{\partial \nu} \in L^2(\Gamma \times (0,T)).$$

Moreover, if Γ_1 is a part of the boundary which satisfies certain geometric conditions (for instance, it is the exterior boundary of an annulus; see, e.g., [25], [26], [17], and see [6] for more general conditions), then these solutions satisfy the inverse inequality (see [25], [26])

$$\int_0^T \int_{\Gamma_1} \left| \frac{\partial u}{\partial \nu} \right|^2 d\gamma \, dt \geq c_1 \, E(u(0)) \tag{1.3}$$

for $T \geq T_0$, where T_0 is sufficiently large, and for a positive constant c_1 which depends only on T and on the geometry of Ω. This inequality is also called the "observability inequality." In this context, the observed quantity is the L^2-norm of the trace of the solution's normal derivative, and one wants to get back information on the initial state of the solution. In particular, if one observes the same quantities, one wants to make sure that they correspond to the same initial data (unique continuation results). Of course, an inequality such as (1.3) is more precise.

The above results hold for all initial data (u_0, u_1) of finite energy. Moreover, using the Hilbert uniqueness method (HUM), Lions showed that the direct and inverse inequalities lead to the following exact controllability result: for any $T \geq T_0$ and all initial data $(y_0, y_1) \in L^2(\Omega) \times H^{-1}(\Omega)$ there exists a control $v \in L^2(\Gamma_1 \times (0,T))$ such that the solution of

$$\begin{cases} y_{tt} - \Delta y = 0 \text{ in } \Omega \times (0,T), \\ y = v \text{ on } \Sigma_1 = \Gamma_1 \times (0,T), \quad y = 0 \text{ on } \Sigma_0 = (\Gamma - \Gamma_1) \times (0,T), \\ y(.,0) = y_0(.), \quad y_t(.,0) = y_1(.) \text{ in } \Omega \end{cases} \tag{1.4}$$

satisfies, in addition, $y(T,\cdot) = y_t(T,\cdot) = 0$ in Ω; i.e., the control v drives back the system to equilibrium at time T.

In this paper we consider the case of coupled systems. Our goal here is to establish indirect observability estimates for weakly coupled systems. In this case, one observes a single component of the solution on Γ_1, and one wants to get back the energy of both components.

To be more precise, we consider the following weakly coupled system of two wave equations:

$$\begin{cases} u_{1,tt} - \Delta u_1 + \alpha u_2 = 0 \text{ in } \Omega \times (0,T), \\ u_{2,tt} - \Delta u_2 + \alpha u_1 = 0 \text{ in } \Omega \times (0,T), \\ u_1 = 0 \text{ on } \Sigma = \Gamma \times (0,T), \ u_2 = 0 \text{ on } \Sigma, \\ u_i(0) = u_i^0, \ u_{i,t}(0) = u_i^1, \end{cases} \tag{1.5}$$

where α is a coupling parameter. We then wonder if it is possible to get, for sufficiently large time T, the following type of observability inequality:

$$\int_0^T \int_{\Gamma_1} \left| \frac{\partial u_1}{\partial \nu} \right|^2 d\gamma \, dt \geq c \Big(e_1(u_1(0)) + e_2(u_2(0)) \Big), \tag{1.6}$$

where $e_i(u_i(t))$ stands for some energy of the corresponding component of the unknown.

We assume that Ω is a nonempty bounded open set in $\mathbb{R}^N$ having a boundary Γ of class C^2. Moreover, $\{\Gamma_0, \Gamma_1\}$ is a partition of Γ such that $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$ and x_0 is a

point in $\mathbb{R}^N$ such that $m\cdot\nu\le 0$ on Γ_0 and $m\cdot\nu\ge 0$ on Γ_1, where $m(x)=x-x_0$. We denote by $|\ |$ the L^2-norm on Ω. Then, we prove in this paper the following result.

THEOREM 1.1. *We assume the above hypotheses on* Γ_1 *and* Γ_0. *Then there exists* $\alpha^\star>0$ *such that for all* $0<|\alpha|<\alpha^\star$, *there exists* $T_0=T_0(\alpha)>0$ *such that for all* $T>T_0$ *and all* $U^0=(u_1^0,u_1^1,u_2^0,u_2^1)\in\mathcal{H}=(H_0^1(\Omega)\times L^2(\Omega))^2$ *the solution* (u_1,u_2) *of* (1.5) *satisfies*

$$2\int_0^T\int_{\Gamma_1}\left|\frac{\partial u_1}{\partial\nu}\right|^2 d\gamma\,dt\ge\frac{c_1}{2}\left(|u_1^1|^2+|\nabla u_1^0|^2\right)+\frac{c_3}{2}\left(|u_2^1|^2_{H^{-1}(\Omega)}+|u_2^0|^2\right),\tag{1.7}$$

where the constants c_1, c_3 *are given by*

$$c_1(\alpha,T)=\frac{a_1(T-T_3)}{(1+\alpha T)(1+\alpha T_3)},\qquad c_3(\alpha,T)=\frac{\alpha a_2(T-T_2)(T-T_2^-)}{1+\alpha T},$$

where a_1,a_2 *are constants independent on* α *and* T. *If we denote by* C *a generic positive constant, then* T_0, $|T_2|,|T_2^-|$ *behave as* $C\alpha^{-1}$ *and* T_3 *behaves as* C *as* α *goes to zero.*

Moreover, if the solution of (1.5) *satisfies*

$$\frac{\partial u_1}{\partial\nu}=0\ \text{ on }\Gamma_1\times(0,T),$$

then one has $u_1=u_2=0$ *in* $\Omega\times[0,T]$.

By duality, the above result can be translated into an exact *indirect* controllability result. For this, we consider the system

$$\begin{cases} y_{1,tt}-\Delta y_1+\alpha y_2=0 \quad\text{in}\quad \Omega\times(0,T),\\ y_{2,tt}-\Delta y_2+\alpha y_1=0 \quad\text{in}\quad \Omega\times(0,T),\\ y_1=v \quad\text{on}\quad \Sigma_1=\Gamma_1\times(0,T),\quad y_1=0 \quad\text{on}\quad \Sigma_0=\Gamma_0\times(0,T),\\ y_2=0 \quad\text{on}\quad \Sigma=\Gamma\times(0,T),\\ (y_1,y_{1,t})(0)=(y_1^0,y_1^1),\quad (y_2,y_{2,t})(0)=(y_2^0,y_2^1) \quad\text{on}\quad \Omega. \end{cases}\tag{1.8}$$

We prove the following theorem.

THEOREM 1.2. *Assume the hypotheses of Theorem* 1.1. *Then there exists* $\alpha^\star>0$ *such that for all* $0<|\alpha|<\alpha^\star$, *there exists* $T_0=T_0(\alpha)>0$ *such that for all* $T>T_0$ *and all* $Y^0=(y_1^0,y_1^1,y_2^0,y_2^1)\in L^2(\Omega)\times H^{-1}(\Omega)\times H_0^1(\Omega)\times L^2(\Omega)$, *there exists a control* $v\in L^2([0,T];L^2(\Gamma_1))$ *such that the solution* $Y(t)=(y_1,y_1',y_2,y_2')$ *of* (1.8) *satisfies*

$$y_i(.,T)=\partial_t y_i(.,T)=0\ \text{ in }\Omega\text{ for }i=1,2.$$

For such systems, we remark that several notions of observability (and by duality arguments of controllability) have already been considered. In [25], [26], Lions introduces three notions of observability, namely complete, partial, and simultaneous observability. He proved that such complete and partial observability inequalities can be obtained when one couples a wave equation to a Petrowsky equation, provided that the coupling parameter is sufficiently small. These results have been extended to a larger set of coupling parameters in [18] (case of zero order coupling). In the case of complete observability, one observes both components of the unknown on Γ_1 and one wants to know whether this observation can give back the initial energy of

both components of the solution. More precisely, for system (1.5), this means that one wants an estimate of the form

$$\int_0^T \int_{\Gamma_1} \left|\frac{\partial u_1}{\partial \nu}\right|^2 d\gamma\, dt + \int_0^T \int_{\Gamma_1} \left|\frac{\partial u_2}{\partial \nu}\right|^2 d\gamma\, dt \geq c\left(|u_1^1|^2 + |\nabla u_1^0|^2 + |u_2^1|^2 + |\nabla u_2^0|^2\right).$$

This inequality holds for sufficiently small α (adapting Lions's method given for a wave equation coupled with a Petrowsky one). Note that this inequality has been established in [18] for a set of parameters larger than a single parameter α and with no smallness restrictions on the parameters. In the partial observability case, one observes only a single component on the boundary and one wants to get back only the energy of the first component, while the energy of the second component at the initial time is set equal to zero. More precisely, this means that one wants to establish an inequality for the solutions of system (1.5) of the form

$$\int_0^T \int_{\Gamma_1} \left|\frac{\partial u_1}{\partial \nu}\right|^2 d\gamma\, dt \geq c\left(|u_1^1|^2 + |\nabla u_1^0|^2\right)$$

for initial data $u_2^0 = u_2^1 = 0$ in Ω. Comparing this result to our result, one sees that the inequality given in (1.7) represents a substantial improvement. Another notion of observability, the so-called simultaneous observability, has been introduced in [25], [26]. In this case, one wants to observe simultaneously both components of the system and to get back the total initial energy of the solutions. The purpose of this paper is to consider the case of a fourth observability notion, namely the indirect observability, as was stated before. Since the answer is positive for the system (1.5), then a natural subsequent question of interest is, *Is it possible to obtain a somehow general result for abstract systems of second order evolution equations*? The abstract model we refer to in this paper is

$$\begin{cases} u_1'' + A_1 u_1 + \alpha C u_2 = 0 \quad \text{in } V_1', \\ u_2'' + A_2 u_2 + \alpha C^\star u_1 = 0 \quad \text{in } V_2', \\ (u_1, u_1')(0) = (u_1^0, u_1^1) = U_1^0 \in V_1 \times H, \\ (u_2, u_2')(0) = (u_2^0, u_2^1) = U_2^0 \in V_2 \times H, \end{cases} \tag{1.9}$$

where H, $V_1 \subset H$, and $V_2 \subset H$ are separable Hilbert spaces; A_1, A_2 are coercive self-adjoint unbounded operators in H, whereas the coupling operator C is assumed to be bounded in H; $C^\star$ is the adjoint operator of C; and α is a coupling parameter. The total energy of a solution (u_1, u_2) is defined by

$$E(u_1(t), u_2(t)) = \frac{1}{2}\left(|u_1'(t)|^2 + |u_2'(t)|^2 + |A_1^{1/2} u_1(t)|^2 + |A_2^{1/2} u_2(t)|^2\right) + \alpha(u_1, C u_2),$$

where $|\cdot|$ and $(\cdot)$ denote, respectively, the norm and scalar product in H and $A_i^{1/2}$, $i \in \{1, 2\}$, denotes the usual fractional power of a coercive self-adjoint operator A_i in H (see [28]).

Now the question of interest is, *Is the above full system indirectly observable*? That is, does there exist a time $T_0 > 0$ such that for any T larger than T_0 there exists a positive constant c depending only on T and on Ω such that the inverse inequality for $T \geq T_0$,

$$\int_0^T ||B^\star u_1||_G^2\, dt \geq c\, \widetilde{E}(u_1(0), u_2(0)), \tag{1.10}$$

holds for a certain energy $\widetilde{E}$ and a certain linear observation operator $B^\star$ acting from $D(A_1)$ into a Hilbert space G which involves only the first component u_1 of the solution? Indeed, the energy in (1.10) cannot be the natural one. This is due to the fact that the coupling in (1.9) is compact. One needs couplings which are not compact to hope to obtain the natural energy when observing only one component of the solution.

Of course, we are also interested in the dual exact controllability result, which means that we want to drive back the full coupled physical system to equilibrium by only controlling the first component of the system. Many questions arise then: In which spaces can one hope to obtain such results? If so, can the constants T_0 and c be explicitly given?

Let us also remark that if $\alpha = 0$, then an inequality such as (1.10) does not hold. Hence, the results we are looking for cannot be obtained by a perturbation argument with respect to the case $\alpha = 0$. Let us now tell more about the method for proving such results. Three steps are required. The first step is the estimate given in Lemma 4.1. It gives a hidden property of the system, namely that the second component of the system can be "controlled" in some way by the first one. The coercivity property (2.8) and the restrictive assumption (2.9) are required for this result. Let us also mention that we have already used, in a slightly different way, these properties in [1]. Here, however, it is very important to have an estimate where only the weakened partial energy of the second component is involved, that is, where the hypothesis (2.10) is required. The second step is the obtaining of intermediate estimates, which allows us to compare the quantity to observe to the time integral of the natural partial energy of the first component and to the partial natural energy of the first component and partial weakened energy of the second component at the initial time. Namely, we want to obtain an estimate of the form

$$2\int_0^T ||B^\star u_1||_G^2\,dt \geq \int_0^T e_1(t)\,dt - c\Big[e_1(0) + \tilde{e_2}(0)\Big],$$

where c is an explicit positive constant. Note that the hypotheses (2.12) and (2.13) for the nonhomogeneous uncoupled equation (2.11) are crucial for this second step. Moreover, the fact that the involved constants δ_i and η_i do not depend on time T is essential for the third step. Once the second step is performed, the main difficulty of establishing the final desired estimate clearly appears. How do we balance the lack of information on the second component of the system, since in the above estimate we have a "good" term (which is the time integral of the energy of the first component, together with its energy at the initial time) and a "bad" term (which is the weakened energy of the second component)? This is the third step. The key point to overcome this difficulty is to use a two-level energy balance between the natural and weakened energies. For this, we have to "sacrifice" an ε-portion of the energy of the first component to get a positive contribution of the total weakened energy of both components. The conservation of this total weakened energy is then the crucial point to absorb the "bad" term represented by the weakened energy of the second component at initial time. Note that in the course of this third step, the estimates have to be performed carefully; the sizes of ε and of α have to be chosen with caution as well.

To conclude this introduction, let us recall some results existing in the literature which are related to the present paper. Several papers (see, e.g., [9], [27], [31], [23], [29], [8]) concern the stabilization of hyperbolic-parabolic coupled systems, such as thermoelasticity, thermoplates. For such systems, the main purpose is to determine if the dissipation induced by the heat-type equation is sufficient for stabilizing the

full system obtained by coupling it to an hyperbolic-type equation. Observability results for coupled hyperbolic-parabolic systems have been obtained in [5] (see also references therein). Concerning coupled hyperbolic-hyperbolic systems, several results concerning both stabilization and observability via two control forces have been obtained. Complete and partial observability (respectively, controllability) results for coupled systems either of hyperbolic-hyperbolic type or of hyperbolic-parabolic type can be found in [25], [26]. These results assume that the coupling parameter is sufficiently small. They have been extended in [18] to the cases of arbitrary coupling parameters (assuming bounded coupling operators). For both references, the multiplier method was the main ingredient for obtaining the desired estimates. Complete observability (respectively, controllability) results have also been obtained in [24] for systems of coupled second order hyperbolic equations containing first order terms in both the original and the coupled unknowns. These results are based on Carleman estimates. One can also look at [16], [20], [22] for stabilization results. Stabilization and observability results for hyperbolic-hyperbolic systems via a single control force have been considered more recently. In [14] and [15], wave-wave systems having the same principal part are coupled through velocity terms. The coupling is therefore not compact. Indirect observability and uniform stabilization results are established. In [4] (see also references therein), polynomial decay estimates in the case of indirect internal stabilization case are given. These results have been extended to several cases (wave-wave coupling, Petrowsky-Petrowsky coupling) for the locally distributed indirect stabilization case in [7].

This paper is organized as follows. In section 2, we give the main results of this paper, which are the indirect observability, uniqueness, and indirect exact controllability for the abstract system. We also give two examples of application of these abstract results. In section 3, we establish the well-posedness of the abstract system and the conservation of the total natural and weakened energies of solutions of this abstract system, and we prove that they satisfy the direct inequality. We also establish well-posedness of the inhomogenous abstract system. In section 4, we prove several intermediate estimates, which will be useful for what follows. In section 5, we give the proof of the main results, based on the two-level energy method. Applications of these results to concrete systems such as wave-wave, Petrowsky-Petrowsky, coupled elastodynamic, wave-wave with different speeds of propagation, and wave-Petrowsky are given in section 6.

2. Main results. Let V_i, $i = 1, 2$, and H be separable real Hilbert spaces such that the injections $V_i \subset H$ are dense, compact, and continuous for $i = 1, 2$.

In what follows we identify H with its dual space, so that the injections $V_i \subset H \subset V_i'$ hold and are continuous, dense, and compact. The scalar products on V_i, $i = 1, 2$, and H are, respectively, denoted by $(,)_i$ and $(,)$, whereas the corresponding norms are, respectively, denoted by $|\ |_i$ and $|\ |$. Moreover, we denote by $|\ |_{V_i'}$ the norm on V_i', by $\langle , \rangle_{V_i', V_i}$ the duality product, and by A_i, $i = 1, 2$ the duality mapping from V_i to V_i' defined by

$$\langle A_i w, z\rangle_{V_i', V_i} = (w, z)_i \qquad \forall w, z \in V_i.$$

To avoid too much notation we will still denote by A_i the unbounded operator in H, acting from $D(A_i) = \{u \in V_i, A_i u \in H\}$ into H. Note that these operators are self-adjoint. For $i = 1, 2$, we denote by ν_i the smallest positive constant such that

$$|u|^2 \leq \nu_i^2 \, |u|_i^2 \qquad \forall\, u \in V_i.$$

Hence, we have for $i = 1, 2$

$$|u|^2 \leq \nu_i^2 |A_i^{1/2} u|^2 \qquad \forall\, u \in V_i, \tag{2.1}$$

which is equivalent to

$$|A_i^{-1/2} u|^2 \leq \nu_i^2 |u|^2 \qquad \forall\, u \in H. \tag{2.2}$$

Moreover, let C be a given linear continuous operator on H. We denote by β_2 the smallest positive constant such that

$$|Cu| \leq \beta_2 |u| \qquad \forall\, u \in H. \tag{2.3}$$

Hence, we also have

$$|C^\star u| \leq \beta_2 |u|. \tag{2.4}$$

Set

$$\alpha_0 = (\beta_2 \nu_1 \nu_2)^{-1}. \tag{2.5}$$

Finally, let α be a given nonzero parameter. For the sake of clarity we will assume that α is positive; nevertheless, the results in this paper are valid for negative α as well. We consider the following weakly coupled system:

$$\begin{cases} u_1'' + A_1 u_1 + \alpha C u_2 = 0 \quad \text{in } V_1', \\ u_2'' + A_2 u_2 + \alpha C^\star u_1 = 0 \quad \text{in } V_2', \\ (u_1, u_1')(0) = (u_1^0, u_1^1) = U_1^0 \in V_1 \times H, \\ (u_2, u_2')(0) = (u_2^0, u_2^1) = U_2^0 \in V_2 \times H. \end{cases} \tag{2.6}$$

As will be seen in the next section, this problem is well-posed in the sense of semigroup theory in the energy space $\mathcal{H} = \mathcal{H}_1 \times \mathcal{H}_2$, where $\mathcal{H}_i = V_i \times H$ for $i = 1, 2$. We define an unbounded operator linear operator $\mathcal{A}_\alpha$ on $\mathcal{H}$ by

$$\mathcal{A}_\alpha U = (-v_1, A_1 u_1 + \alpha C u_2, -v_2, A_2 u_2 + \alpha C^\star u_1),$$

$$\begin{aligned} D(\mathcal{A}_\alpha) &= \{U = (u_1, v_1, u_2, v_2) \in V_1 \times V_1 \times V_2 \times V_2,\ A_i u_i \in H, i = 1, 2\} \\ &= D(A_1) \times V_1 \times D(A_2) \times V_2. \end{aligned}$$

We can now reformulate the system (2.6) as the abstract first order equation

$$\begin{cases} U' + \mathcal{A}_\alpha U = 0, \\ U(0) = U^0 \in \mathcal{H}. \end{cases} \tag{2.7}$$

Let $U = (u_1, u_1', u_2, u_2')$ be a solution of (2.6). (See the next section for more details.) Then we define the partial and total (natural) energy of the solution U as

$$e_i(u(t)) = \frac{1}{2}(|u'|^2 + |u|_i^2)$$

and

$$E(U(t)) = e_1(u_1(t)) + e_2(u_2(t)) + \alpha(u_1, C u_2).$$

Moreover, in what follows we will also need to use the partial and total weakened energies defined, respectively, by

$$\tilde{e}_i(u(t)) = \frac{1}{2}(|u'|^2_{V_i'} + |u|^2)$$

and

$$\widetilde{E}(U(t)) = \tilde{e}_1(u_1(t)) + \tilde{e}_2(u_2(t)) + \alpha(u_1, A_1^{-1}Cu_2).$$

We now give the assumptions on A_1, A_2, C and the observability operator $B^\star$ under which our main results are valid.

We first assume the following hypothesis, to which we will refer in what follows as hypothesis (H1):

$$\exists \beta_1 > 0 \text{ such that } \beta_1|u| \le |Cu| \qquad \forall\, u \in H. \tag{2.8}$$

Moreover, we assume the following (strong) compatibility hypothesis on the operators A_1, A_2, and C, to which we will refer in what follows as hypothesis (H2):

$$CV_2 \subset V_1, CD(A_2) \subset D(A_1) \text{ and } A_1Cu = CA_2u \qquad \forall u \in D(A_2)\,, \tag{2.9}$$

$$\exists\, \beta_3 > 0 \text{ such that } |A_1^{1/2}CA_2^{-1/2}u| \le \beta_3|u| \qquad \forall\, u \in H\,. \tag{2.10}$$

Moreover, let G be a given Hilbert space with norm $||\ ||_G$ and scalar product $\langle\ \rangle_G$. The space G will be identified with its dual space in all that follows. Also let $B^\star \in \mathcal{L}(D(A_1), G)$ be the observability operator. We assume that there exist positive constants $\delta_i, i = 1, 2, 3$, $\eta_i, i = 1, 2, 3, 4$, such that for all $T > 0$, all $f \in \mathcal{C}^1([0, T]; H)$, and all $U_1^0 = (u_1^0, u_1^1) \in D(A_1) \times V_1$, the solution u_1 of

$$\begin{cases} u_1'' + A_1u_1 = f, \\ (u_1, u_1')(0) = U_1^0 \end{cases} \tag{2.11}$$

satisfies the next two inequalities (respectively, direct and inverse inequalities), denoted, respectively, by hypothesis (H3),

$$\int_0^T ||B^\star u_1||^2_G\, dt \le \delta_1 \int_0^T e_1(t)\, dt + \delta_2(e_1(T) + e_1(0)) + \delta_3 \int_0^T |f|^2\, dt, \tag{2.12}$$

and by hypothesis (H4),

$$\eta_4 \int_0^T ||B^\star u_1||^2_G\, dt \ge (1 - \eta_1\beta) \int_0^T e_1(t)\, dt - \eta_2(e_1(T) + e_1(0)) - \eta_3\beta^{-1} \int_0^T |f|^2\, dt \quad \forall \beta \in (0, \eta_1^{-1}). \tag{2.13}$$

Before giving our main results, let us make some comments.

Comments. First, the assumption (H4) (i.e., inequality (2.13)) implies that the first equation of (2.6) decoupled from the second one satisfies an observability inequality. This can be seen by setting $f = 0$ in (2.11). Thanks to (2.13), we deduce that e_1, which is conserved through time, satisfies the classical inverse inequality

$$\eta_4 \int_0^T ||B^\star u_1||^2_G\, dt \ge [(1 - \eta_1\beta)T - 2\eta_2]\ e_1(0) \qquad \forall \beta \in (0, \eta_1^{-1}).$$

As will be seen later (in section 6), this property is satisfied for most systems (e.g., wave, Petrowsky, etc.).

Second, the hypotheses (2.9) and (2.10) give a condition on which types of equations can be coupled and for which we are able to prove an indirect observability result for the full system. We will give two abstract conditions, under which these hypotheses are satisfied (see Corollaries 2.2 and 2.3 below).

Third, note that for $u \in H$, $A_2^{-1/2}u \in V_2$. Hence, thanks to the hypothesis (2.9), $CA_2^{-1/2}u \in V_1$, so that the left-hand side of inequality (2.10) makes sense. Moreover, for $v \in V_2$ we have $u = A_2^{-1/2}v \in D(A_2)$. Hence, using hypothesis (2.9) we deduce that

$$A_1 C A_2^{-1/2} v = C A_2^{1/2} v \qquad \forall\, v \in V_2,$$

so that

$$A_1^{1/2} C A_2^{-1/2} v = A_1^{-1/2} C A_2^{1/2} v \qquad \forall\, v \in V_2.$$

Using (2.10) together with this last equality, we obtain

$$|A_1^{-1/2} C A_2^{1/2} u| \le \beta_3 |u| \qquad \forall\, u \in V_2. \tag{2.14}$$

We now state the main result of this paper.

THEOREM 2.1. *Assume that A_1, A_2, and $B^\star$ satisfy the hypotheses* (H1)–(H4). *Then there exists $\alpha^\star > 0$ such that for all $0 < |\alpha| < \alpha^\star$, there exists $T_0 = T_0(\alpha) > 0$ such that for all $T > T_0$ and all $U^0 \in \mathcal{H}$ the solution $U(t) = \exp(-\mathcal{A}_\alpha t)U^0$ of* (2.6) *satisfies*

$$2\eta_4 \int_0^T ||B^\star u_1||_G^2 \, dt \ge c_1(\alpha, T)\mathbf{e_1}(\mathbf{0}) + c_3(\alpha, T)\tilde{\mathbf{e_2}}(\mathbf{0}), \tag{2.15}$$

with

$$c_1(\alpha, T) = \frac{a_1(T - T_3)}{(1 + \alpha T)(1 + \alpha T_3)}, \qquad c_3(\alpha, T) = \frac{\alpha a_2 (T - T_2)(T - T_2^-)}{1 + \alpha T}, \tag{2.16}$$

where T_2, T_2^-, T_3 are explicit constants depending only on α, and the numbers ν_i, $i = 1, 2$, β_i for $i = 1, 2, 3$, and a_1 and a_2 are positive fixed constants.

If we denote by C a generic positive constant independent on α, then $|T_2|$, $|T_2^-|$ behave as $C\alpha^{-1}$ and T_3 behaves as C as α goes to zero.

Hence, indirect observability holds for the full system (2.6).

Remarks. The constants in the above theorem are given as follows. The constants T_2, T_2^- are defined, respectively, as the positive and negative root of the second order polynomial Q_α defined in (5.9). The constant T_3 is defined by (5.10). The time T_0 is defined as $T_0 = \max(T_2, T_3)$. Moreover, the fixed constants a_1 and a_2 are given in (5.5) and (5.6).

Thanks to the well-known hidden regularity property of weak solutions of (2.6), the application J which maps $U^0 \in D(\mathcal{A}_\alpha)$ to $B^\star u_1 \in L^2_{loc}([0, +\infty); G)$ can be extended to all $\mathcal{H}$ (see the proof in Proposition 3.3). We will not recall this extension further but will use it in what follows.

This result, together with the other results of this paper, are valid under larger hypotheses on the observability operator $B^\star$. It may act on both u_1 and u_1' or on

u_1' only. It may also only be defined and continuous in a space smaller than $D(A_1)$, provided that this space is dense in V_1.

We now give, as in [1], two abstract examples for which the assumptions (H1) and (H2) are satisfied.

Example 1. Case $A_1 = A_2$.

COROLLARY 2.2. *Assume the hypotheses* (H3)–(H4). *Assume, moreover, that*

$$A_1 = A_2 \text{ with } D(A_1) = D(A_2) \text{ and } V_2 \subset V_1.$$

Choose $C = \mathrm{Id}$. *Then for all* $0 < |\alpha| < \alpha^\star$, *there exists* $T_0 = T_0(\alpha) > 0$ *such that for all* $T > T_0$ *and all* $U^0 \in \mathcal{H}$ *the solution* $U(t) = \exp(-\mathcal{A}_\alpha t)U^0$ *of* (2.6) *satisfies the estimate* (2.15).

Proof. The proof is immediate since with $C = \mathrm{Id}$, the hypotheses (H1)–(H2) are satisfied with $\beta_1 = \beta_3 = 1$. We then conclude by applying Theorem 2.1. One can remark that one can also choose operators C more general than the identity operator on H (see the next corollary). □

Example 2. Case $A_1 \neq A_2$. We recall the following result partially proved in [1]; the full proof is left to the reader.

COROLLARY 2.3. *Assume the hypotheses* (H3)–(H4). *Assume, moreover, that* $V_2 \subset V_1$ *and that there exists a common orthonormal basis* $\{e_k\}_{k=1}^\infty$ *of eigenfunctions of the operators* A_i *in* H, *for* $i = 1, 2$, *with*

$$A_i e_k = \lambda_{i,k} e_k, \qquad k = 1, \ldots, i = 1, 2.$$

Assume, moreover, that the following hypothesis holds:

$$\text{(H5)} \qquad \begin{cases} \exists r : \mathbb{N}^\star \mapsto \mathbb{N}^\star, \text{ one-to-one, such that} \\ \lambda_{2,k} = \lambda_{1,r(k)} \quad \forall\, k \in \mathbb{N}^\star. \end{cases}$$

Choose the coupling operator C *arbitrarily under the form*

$$Cu = \sum_{k=1}^{\infty} u_k w_k e_{r(k)}, \tag{2.17}$$

where the sequence of real numbers $(w_k)_k$ *satisfies*

$$\exists w_- > 0,\ w_+ > 0 \text{ such that } w_- \leq w_k \leq w_+ \qquad \forall\, k \in \{1, \ldots\}.$$

Then there exists $\alpha^\star > 0$ *such that for all* $0 < |\alpha| < \alpha^\star$, *there exists* $T_0 = T_0(\alpha) > 0$ *such that for all* $T > T_0$ *and all* $U^0 \in \mathcal{H}$ *the solution* $U(t) = \exp(-\mathcal{A}_\alpha t)U^0$ *of* (2.6) *satisfies the estimate* (2.15).

As a corollary of Theorem 2.1, we immediatly deduce the following uniqueness result.

THEOREM 2.4. *Assume either the hypotheses of Theorem* 2.1 *or that of Corollary* 2.2 *(or of Corollary* 2.3*) and define* $\alpha^\star$ *as in Theorem* 2.1. *For all* $0 < |\alpha| < \alpha^\star$, *define* $T_0 = T_0(\alpha)$ *as in Theorem* 2.1; *then for all* $T > T_0$ *and all* $U^0 \in \mathcal{H}$, *we have the following uniqueness (or continuation) result: if the solution* $U(t) = \exp(-\mathcal{A}_\alpha t)U^0$ *of* (2.6) *satisfies, in addition,*

$$B^\star u_1(t) = 0 \text{ a.e. in } t \in [0, T],$$

then $U(t) = 0$ *for all* $t \in [0, T]$.

Proof. The proof follows immediately from the observability estimate (2.15). ∎

We now formulate our exact controllability results for the dual problem. We denote by $\mathcal{H}' = V_1' \times H \times V_2' \times H$ the dual space of $\mathcal{H}$. For $Y^0 = (y_1^1, -y_1^0, y_2^1, -y_2^0) \in \mathcal{H}'$ and $v \in L^2_{loc}([0,+\infty); G)$, we consider the problem

$$\left\{ \begin{array}{l} y_1'' + A_1 y_1 + \alpha C y_2 = Bv, \\ y_2'' + A_2 y_2 + \alpha C^\star y_1 = 0, \\ (y_1, y_1')(0) = (y_1^0, y_1^1), \\ (y_2, y_2')(0) = (y_2^0, y_2^1), \end{array} \right. \tag{2.18}$$

where $B \in \mathcal{L}(G, D(A_1)')$ is the adjoint of $B^\star$. An easy computation allows us to see that the adjoint of $\mathcal{A}_\alpha$ is the unbounded operator $\mathcal{A}_\alpha^\star$ defined by $D(\mathcal{A}_\alpha^\star) = V_1 \times D(A_1) \times V_2 \times D(A_2)$ and

$$\mathcal{A}_\alpha^\star Z = (A_1 w_1 + \alpha C w_2, -z_1, A_2 w_2 + \alpha C^\star w_1, -z_2)$$

for $Z = (z_1, w_1, z_2, w_2) \in D(\mathcal{A}_\alpha^\star)$. We set $Y = (y_1', -y_1, y_2', -y_2)$, and we define an operator $\widetilde{B} \in \mathcal{L}(G, (D(\mathcal{A}_\alpha)')$ by setting $\widetilde{B}v = (Bv, 0, 0, 0)$. Then the coupled system (2.18) can be written under the abstract form

$$\left\{ \begin{array}{l} Y' - \mathcal{A}_\alpha^\star Y = \widetilde{B} v, \\ Y(0) = Y^0 \in \mathcal{H}'. \end{array} \right. \tag{2.19}$$

This is precisely the dual problem of (2.7). The solution of (2.19) is defined as usual by the method of transposition (see, e.g., [25], [26], [19]). That is, fixing $Y^0 \in \mathcal{H}'$ and $v \in L^2_{loc}([0,\infty); G)$ arbitrarily, we define a solution of (2.19) as a continuous function Y defined from $[0,\infty)$ with values in $\mathcal{H}'$, such that the equality

$$\langle Y(T), U(T) \rangle_{\mathcal{H}',\mathcal{H}} = \langle Y^0, U^0 \rangle_{\mathcal{H}',\mathcal{H}} + \int_0^T \langle v(t), B^\star u_1(t) \rangle_G \, dt \tag{2.20}$$

holds for every $U^0 \in \mathcal{H}$ where $U(t) = \exp(-t\mathcal{A}_\alpha) U^0 = (u_1, u_1', u_2, u_2')(t)$. One can remark that we used the fact that $\widetilde{(B)}^\star U = B^\star u_1$. We will establish well-posedness (that is, existence, uniqueness, and continuous dependence with respect to the data Y^0 and v) in the next section by a standard procedure. We are concerned by the exact controllability problem for (2.18) in a controllability space $\mathcal{F}'$ that will be specified later on. That is, we are looking for a time $T > 0$ such that for every initial data $Y^0 \in \mathcal{F}'$ there exists a control $v \in L^2([0,T]; G)$ such that the solution of (2.18) satisfies in addition

$$y_i(T) = y_i'(T) = 0, \qquad i = 1, 2. \tag{2.21}$$

We can now state our exact controllability result.

THEOREM 2.5. *Assume either the hypotheses of Theorem* 2.1 *or that of Corollary* 2.2 *(or of Corollary* 2.3*), and let $\alpha^\star$ be as in Theorem* 2.1. *For $0 < |\alpha| < \alpha^\star$, we define T_0 as in Theorem* 2.1. *Then for all $0 < |\alpha| < \alpha^\star$, all $T > T_0$, and all $Y^0 = (y_1^1, -y_1^0, y_2^1, -y_2^0) \in V_1' \times H \times H \times V_2$, there exists a control $v \in L^2([0,T]; G)$ such that the solution $Y = (y_1', -y_1, y_2', -y_2)$ of* (2.19) *(or equivalently of* (2.18)*) satisfies* (2.21). *Hence, exact indirect controllability in time T holds for initial data $(y_1^0, y_1^1, y_2^0, y_2^1) \in H \times V_1' \times V_2 \times H$ for the coupled system* (2.18).

Remark. The above exact controllability result holds in fact in a larger set $\mathcal{F}'$, but we do not have a characterization of this space in terms of Sobolev spaces. We will see in the course of the proof that it contains the space $V_1' \times H \times H \times V_2$, thanks to the observability inequality (2.15).

3. Abstract coupled model. We denote by $((\cdot))$ the standard scalar product on the product space $\mathcal{H}$, i.e.,

$$((U, \widetilde{U})) = \sum_{i=1}^{2} \Big((u_i, \tilde{u_i})_i + (v_i, \tilde{v_i}) \Big)$$

for $U = (u_1, v_1, u_2, v_2)$ and $\widetilde{U} = (\tilde{u_1}, \tilde{v_1}, \tilde{u_2}, \tilde{v_2})$ in $\mathcal{H}$. The associated norm is denoted by $||\cdot||$. We also consider on $\mathcal{H}$ the bilinear form given by

$$(U, \widetilde{U})_\alpha = ((U, \widetilde{U})) + \alpha(Cu_2, \tilde{u_1}) + \alpha(u_1, C\tilde{u_2})$$

for $U = (u_1, v_1, u_2, v_2)$ and $\widetilde{U} = (\tilde{u_1}, \tilde{v_1}, \tilde{u_2}, \tilde{v_2})$ in $\mathcal{H}$. One can remark that

$$2E(U(t)) = ||U(t)||_\alpha^2. \tag{3.1}$$

Then we have the following.

PROPOSITION 3.1. *Assume the above hypotheses on the spaces V_1, V_2, H and the operators A_1, A_2. Moreover, define $\beta_1, \beta_2, \nu_1, \nu_2$ as, respectively, in* (2.8), (2.3), *and* (2.2) *and α_0 by* (2.5). *Then for all $0 \le |\alpha| < \alpha_0$, there exist constants $c_1(\alpha) > 0$ and $c_2(\alpha) > 0$ such that*

$$c_1(\alpha)||U||^2 \le (U, U)_\alpha \le c_2(\alpha)||U||^2 \qquad \forall U \in \mathcal{H}. \tag{3.2}$$

Hence, for all $0 \le |\alpha| < \alpha_0$, the application

$$U \in \mathcal{H} \mapsto ||U||_\alpha = (U, U)_\alpha^{1/2}$$

defines a norm on $\mathcal{H}$ which is equivalent to the norm $||\ ||$.

Proof. Let $U \in \mathcal{H}$ be given. Then one has, thanks to (2.2)–(2.3),

$$|(U, U)_\alpha - ||U||^2| = 2|\alpha \Re((u_1, Cu_2))| \le 2|\alpha|\beta_2\nu_1\nu_2|u_1|_1|u_2|_2,$$

where $\Re$ denotes the real part of a complex number. Hence, the desired estimates hold with $c_1(\alpha) = (1 - \alpha/\alpha_0)$ and $c_2(\alpha) = (1 + \alpha/\alpha_0)$. □

We recall that we defined an unbounded linear operator $\mathcal{A}_\alpha$ on $\mathcal{H}$ in section 2 by

$$\begin{aligned} \mathcal{A}_\alpha U &= (-v_1, A_1u_1 + \alpha Cu_2, -v_2, A_2u_2 + \alpha C^\star u_1), \\ D(\mathcal{A}_\alpha) &= \{U = (u_1, v_1, u_2, v_2) \in V_1 \times V_1 \times V_2 \times V_2,\ A_iu_i \in H, i = 1, 2\} \\ &= D(A_1) \times V_1 \times D(A_2) \times V_2. \end{aligned}$$

We set $D(\mathcal{A}_i) = D(A_i) \times V_i$ and denote by $\mathcal{A}_i$ the unbounded operator with domain $D(\mathcal{A}_i)$ and defined by $\mathcal{A}_i(u_i, v_i) = (-v_i, A_iu_i)$. We can now reformulate the system (2.6) as the abstract first order equation (2.7) (see section 2). We have the following classical well-posedness result.

PROPOSITION 3.2. *Assume the hypotheses of Proposition* 3.1, *and let α_0 be given as in Proposition* 3.1. *Then $-\mathcal{A}_\alpha$ is a skew-adjoint operator on $\mathcal{H}$ which generates a $\mathcal{C}^0$ unitary group $T_0(t) = \exp(-t\mathcal{A}_\alpha)$, $t \in \mathbb{R}$, on $\mathcal{H}$. As a consequence, for all $0 \le |\alpha| < \alpha_0$*

and for every $U^0 \in \mathcal{H}$, the problem (2.7) *has a unique solution $U \in \mathcal{C}([0,+\infty);\mathcal{H})$. If, in addition, $U^0 \in D({\mathcal{A}_\alpha}^k)$ for $k \in \mathbb{N}^\star$, then the solution is in $\mathcal{C}^{k-j}([0,+\infty);D(\mathcal{A}_\alpha^j))$ for $j = 0,\dots,k$. Moreover, the total natural energy of the solution is conserved, i.e., for $U^0 \in \mathcal{H}$, we have*

$$E(U(t)) = E(U(0)) \qquad \forall\, t \geq 0, \tag{3.3}$$

and the total weakened energy of the solution is also conserved, i.e., for $U^0 \in \mathcal{H}$, we have

$$\widetilde{E}(U(t)) = \widetilde{E}(U(0)) \qquad \forall\, t \geq 0. \tag{3.4}$$

Proof. The operator $\mathcal{A}_\alpha$ satisfies

$$(\mathcal{A}_\alpha U, \widetilde{U})_\alpha = -(U, \mathcal{A}_\alpha \widetilde{U})_\alpha \qquad \forall U, \widetilde{U} \in D(\mathcal{A}_\alpha).$$

Hence, $D(\mathcal{A}_\alpha^\star) = D(\mathcal{A}_\alpha)$ and the adjoint of $\mathcal{A}_\alpha$ in $\mathcal{H}$ is equal to $-\mathcal{A}_\alpha$. Thus, $\mathcal{A}_\alpha$ is skew-adjoint in $\mathcal{H}$. Applying Stone's theorem (see, e.g., [10]), we deduce that $-\mathcal{A}_\alpha$ generates a $\mathcal{C}^0$ unitary group $T_0(t) = \exp(-t\mathcal{A}_\alpha)$, $t \in \mathbb{R}$, on $\mathcal{H}$. The well-posedness and regularity of solutions follow at once from classical semigroup theory. Since $T_0(t)$, $t \in \mathbb{R}$, is unitary on $\mathcal{H}$ and since (3.1) holds, we deduce that the natural energy of all solutions with initial data in $\mathcal{H}$ is conserved. For the conservation of the total weakened energy, we proceed as follows. For $U^0 \in D(\mathcal{A}_\alpha)$ the solution $U = (u_1, u_1', u_2, u_2')$ is such that $u_i(t) \in D(A_i)$ for any $t \geq 0$. Moreover, both equations of (2.6) are satisfied in H. Hence we have

$$\tilde{e_i}'(t) = (u_i'' + A_i u_i, A_i^{-1} u_i')$$

for $i = 1, 2$. Now using the two equations of (2.6), we deduce that

$$\tilde{e_1}'(t) = -\alpha\,(u_1', A_1^{-1} C u_2),$$

$$\tilde{e_2}'(t) = -\alpha\,(u_1, C A_2^{-1} u_2').$$

Now using (2.9), we deduce that $Cu = A_1^{-1} C A_2 u$ for all $u \in D(A_2)$. Remarking that for any $v \in H$, $u = A_2^{-1} v \in D(A_2)$, we get that $C A_2^{-1} v = A_1^{-1} C v$ for all $v \in H$. Using this relation in the two previous equations, we obtain $\widetilde{E}'(t) = 0$. Hence, the total weakened energy of solutions with initial data in $D(\mathcal{A}_\alpha)$ is conserved. By density of $D(\mathcal{A}_\alpha)$ in $\mathcal{H}$, we conclude that the same result holds true for any solution with initial data in $\mathcal{H}$. ∎

Remark. The well-posedness of problem (2.7) holds true for any α, since $\mathcal{A}_\alpha$ is a compact perturbation of the corresponding decoupled operator (obtained by setting $\alpha = 0$). Of course, in this case, $\mathcal{H}$ should be equipped with the scalar product $(U, \widetilde{U}) = ((U, \widetilde{U}))$ and the corresponding norm.

We now prove the following direct inequality.

PROPOSITION 3.3. *Assume the above hypotheses on the spaces V_1, V_2, and H and the operators A_1, A_2, and C. Assume, moreover, that the assumption* (H3) *holds and let α_0 be defined by* (2.5). *Then for all $0 \leq |\alpha| < \alpha_0$ and all $U^0 \in D(\mathcal{A}_\alpha)$ the solution $U(t) = \exp(-t\mathcal{A}_\alpha)U^0 = (u_1, u_1', u_2, u_2')$ of* (2.6) *satisfies*

$$\int_0^T ||B^\star u_1||_G^2\, dt \leq M_T E(U^0), \tag{3.5}$$

where

$$M_T = T\,M + \frac{2\delta_2}{c_1(\alpha)},$$

$c_1(\alpha)$ *being defined as in the proof of Proposition* 3.1*, with*

$$M = \frac{\max(\delta_1, 2\delta_3\alpha^2\beta_2^2\nu_2^2)}{c_1(\alpha)}.$$

Moreover, if we denote by J *the operator defined from* $D(\mathcal{A}_\alpha)$ *equipped with the* $||\,||_\alpha$*-norm into* $L^2_{loc}([0,+\infty);G)$*, which maps* U^0 *to the function* $B^\star u_1$*, where* $U(t) = \exp(-t\mathcal{A}_\alpha)U^0 = (u_1, u_1', u_2, u_2')$*, then one can extend* J *to all* $\mathcal{H}$*.*

Proof. Let $U^0 \in D(\mathcal{A}_\alpha)$ be given and denote by $U(t) = (u_1, u_1', u_2, u_2')$ the corresponding solution of (2.6). Then u_1 satisfies

$$\begin{cases} u_1'' + A_1 u_1 = f, \\ (u_1, u_1')(0) = U_1^0 = (u_1^0, u_1^1) \end{cases}$$

with $f = -\alpha C u_2$. Hence, using the assumption (H3) together with (2.3) and (2.1) we obtain

$$\int_0^T ||B^\star u_1||_G^2\,dt \le \delta_1 \int_0^T e_1(t)\,dt + \delta_2(e_1(T) + e_1(0)) + \delta_3\alpha^2\beta_2^2\nu_2^2 \int_0^T |u_2|_2^2\,dt.$$

Hence we have

$$\int_0^T ||B^\star u_1||_G^2\,dt$$
$$\le \max(\delta_1, 2\delta_3\alpha^2\beta_2^2\nu_2^2) \int_0^T (e_1(t) + e_2(t))\,dt + \delta_2((e_1(T) + e_1(0)) + (e_2(T) + e_2(0))).$$

However, thanks to Proposition 3.1 we have

$$e_1(t) + e_2(t) = \frac{||U(t)||^2}{2} \le \frac{||U(t)||_\alpha^2}{2c_1(\alpha)} = \frac{E(U(t))}{c_1(\alpha)}.$$

Using this last inequality in the previous estimate, together with the conservation of energy given in Proposition 3.2, we obtain the desired estimate. The direct inequality, by a density argument of $D(\mathcal{A}_\alpha)$ in $\mathcal{H}$, allows us to prove a hidden regularity result for the solutions of (2.6) with initial data in $\mathcal{H}$ and to extend the operator J to $\mathcal{H}$. □

PROPOSITION 3.4. *Assume the hypotheses of Proposition* 3.1 *and let* α_0 *be given as in Proposition* 3.1*. Then for all* $0 \le |\alpha| < \alpha_0$ *for every* $Y^0 \in \mathcal{H}'$ *and all* $v \in L^2_{loc}([0,+\infty);G)$*, the problem* (2.19) *has a unique solution* $Y \in \mathcal{C}([0,+\infty);\mathcal{H}')$*. Moreover, for every* $T > 0$ *the application* Ψ *defined from* $\mathcal{H}' \times L^2([0,T)];G)$ *into* $\mathcal{C}([0,T];\mathcal{H}')$*, which maps* (Y^0, v) *to* Y*, is continuous.*

Proof. Let $Y^0 \in \mathcal{H}'$ and $v \in L^2_{loc}([0,+\infty);G)$ be fixed arbitrarily. For $T > 0$, we denote by L_T the linear form defined on $\mathcal{H}$ by

$$L_T(U^0) = \langle Y^0,\, U^0\rangle_{\mathcal{H}',\mathcal{H}} + \int_0^T \langle v(t),\, B^\star u_1\rangle_G dt, \tag{3.6}$$

where $U(t) = \exp(-t\mathcal{A}_\alpha)U^0 = (u_1, u_1', u_2, u_2')$. Thanks to the direct inequality proved in Proposition 3.3, we have the estimate

$$|L_T(U^0)| \le \left(||Y^0||_{\mathcal{H}'} + \sqrt{\frac{M_T}{2}} ||v||_{L^2([0,T];G)} \right) ||U^0||_\alpha \tag{3.7}$$

for all $U^0 \in \mathcal{H}$, where the constant M_T depends continuously on T (see Proposition 3.3). Hence $L_T \in \mathcal{H}'$. On the other hand, we proved in Proposition 3.2 that $-\mathcal{A}_\alpha$ generates a unitary group on $\mathcal{H}$. Hence, we have $U^0 = \exp(T\mathcal{A}_\alpha)U(T)$ so that the linear form on $\mathcal{H}$ which maps $U(T)$ to $L_T(U^0)$ is well defined and continuous on $\mathcal{H}$. Therefore, there exists a unique $Y(T) \in \mathcal{H}'$ such that $L_T(U^0) = \langle Y(T), U(T)\rangle_{\mathcal{H}',\mathcal{H}}$ for all $U^0 \in \mathcal{H}$. Moreover, thanks again to the direct inequality proved in Proposition 3.3, and since M_T is continuous with respect to T, one can check that the application from $[0, +\infty)$ to $\mathcal{H}'$ which maps T to L_T is continuous. Therefore, since $||U(T)||_\alpha = ||U^0||_\alpha$, we deduce that $Y \in \mathcal{C}([0, +\infty); \mathcal{H}')$. Finally, thanks to (3.7) we have for all bounded intervals I in $\mathbb{R}$ and all $T \in I$

$$||Y(T)||_{\mathcal{H}'} \le C\Big(||Y^0||_{\mathcal{H}'} + |v||_{L^2(I;G)} \Big),$$

where C is a constant depending only on I. Hence, the application Ψ defined from $\mathcal{H}' \times L^2_{loc}([0, +\infty); G)$ into $\mathcal{C}([0, +\infty); \mathcal{H}')$, which maps (Y^0, v) to Y, is continuous. □

To prove the main result of this paper we first need to prove several intermediate estimates. This is the purpose of next section.

4. Technical intermediate estimates. In what follows, $U = (u_1, u_1', u_2, u_2')$ will stand for a solution of (2.6) corresponding to the initial data $U^0 \in \mathcal{H}$. Moreover, in the remainder of this section, we will denote by C_i, $i = 1, \ldots,$ positive constants which depend only on $\beta_i, i = 1, 2, 3$, ν_1, ν_2 but not on α.

LEMMA 4.1. *Assume the hypotheses of Theorem* 2.1 *and let* α_0 *be given by* (2.5). *Then for all* $0 < |\alpha| < \alpha_0$ *and all* $U^0 \in \mathcal{H}$ *the solution* $U(t) = \exp(-t\mathcal{A}_\alpha)U^0 = (u_1, u_1', u_1, u_2')$ *of* (2.6) *satisfies*

$$\begin{aligned} &\alpha \int_S^T |u_2|^2 \, dt \\ &\le \alpha C_9 \int_S^T |u_1|^2 \, dt + \frac{C_{10}}{\gamma_1}(e_1(T) + e_1(0)) + C_{10}\gamma_1(\tilde{e_2}(T) + \tilde{e_2}(0)) \qquad \forall\ \gamma_1 > 0. \end{aligned} \tag{4.1}$$

Proof. By density of $D(\mathcal{A}_\alpha)$ in $\mathcal{H}$ and since $||U(t)||_\alpha = ||U^0||_\alpha$ for any $t \ge 0$, it is sufficient to prove the desired inequality for $U^0 \in D(\mathcal{A}_\alpha)$. Hence, let $U^0 \in D(\mathcal{A}_\alpha)$ be given. We evaluate the term

$$\int_S^T (u_1'' + A_1u_1 + \alpha C u_2,\ Cu_2) - (u_2'' + A_2u_2 + \alpha C^\star u_1,\ C^\star u_1)\, dt = 0. \tag{4.2}$$

This gives

$$\int_S^T (u_1'', Cu_2) - (u_1, Cu_2'') + (A_1u_1, Cu_2) - (u_1, CA_2u_2) + \alpha|Cu_2|^2 - \alpha|C^\star u_1|^2 \, dt.$$

Hence, integrating by parts the first two terms and using hypothesis (2.9), saying that $A_1C = CA_2$ on $D(A_2)$, we have

$$\alpha \int_S^T |Cu_2|^2 \, dt = \alpha \int_S^T |C^\star u_1|^2 \, dt + [(u_1, Cu_2') - (u_1', Cu_2)]_0^T. \tag{4.3}$$

Remarking that $u_2' \in V_2$ and using the inequality (2.14), we estimate the right-hand side of this inequality as follows:

$$|(u_1, Cu_2')| = \left|\Big(A_1^{1/2}u_1, (A_1^{-1/2}CA_2^{1/2})(A_2^{-1/2}u_2')\Big)\right| \le \beta_3 |A_1^{1/2}u_1|\,|u_2'|_{V_2'}.$$

Hence, we have

$$|(u_1, Cu_2')| \le \beta_3 \left(\frac{|u_1|_1^2}{2\gamma_1} + \frac{\gamma_1 |u_2'|_{V_2'}^2}{2}\right) \qquad \forall\, \gamma_1 > 0. \tag{4.4}$$

Moreover, thanks to (2.3) we have

$$|(u_1', Cu_2)| \le \beta_2 |u_1'|\,|u_2| \le \beta_2 \frac{|u_1'|^2}{2\gamma_1} + \beta_2 \frac{\gamma_1 |u_2|^2}{2} \qquad \forall\, \gamma_1 > 0.$$

Therefore, we have

$$\left|\Big((u_1, Cu_2') - (u_1', Cu_2)\Big)(t)\right| \le \frac{\max(\beta_3, \beta_2)}{\gamma_1} e_1(t) + \max(\beta_3, \beta_2)\gamma_1 \tilde{e_2}(t) \qquad \forall\, \gamma_1 > 0. \tag{4.5}$$

Using (4.5) together with (2.8) and (2.4) in (4.3), we obtain the desired result. □

LEMMA 4.2. *Assume the hypotheses of Theorem* 2.1 *and set*

$$\alpha_1 = \min(\alpha_0, \nu_2^{-1}), \tag{4.6}$$

where α_0 *is given by* (2.5). *Then for all* $0 < |\alpha| < \alpha_1$ *and all* $U^0 \in \mathcal{H}$ *the solution* $U(t) = \exp(-t\mathcal{A}_\alpha)U^0$ *of* (2.6) *satisfies the following estimates:*

$$e_1(T) + e_1(0) \le C_1(e_1(0) + \tilde{e_2}(0)) + \frac{C_2\alpha}{1-\alpha\nu_2}\int_0^T (|u_1'|^2 + |u_1|^2)\,dt, \tag{4.7}$$

$$\tilde{e_2}(T) + \tilde{e_2}(0) \le \frac{C_3}{1-\alpha\nu_2}(e_1(0) + \tilde{e_2}(0)) + \frac{C_4\alpha}{(1-\alpha\nu_2)^2}\int_0^T (|u_1'|^2 + |u_1|^2)\,dt, \tag{4.8}$$

$$\int_0^T |A_2^{-1/2}u_2'|^2\,dt \le \frac{C_5}{\alpha(1-\alpha\nu_2)}(e_1(0) + \tilde{e_2}(0)) + \frac{C_6}{(1-\alpha\nu_2)^2}\int_0^T (|u_1'|^2 + |u_1|^2)\,dt, \tag{4.9}$$

$$\int_0^T |u_2|^2\,dt \le \frac{C_7}{\alpha(1-\alpha\nu_2)}(e_1(0) + \tilde{e_2}(0)) + \frac{C_8}{(1-\alpha\nu_2)^2}\int_0^T (|u_1'|^2 + |u_1|^2)\,dt. \tag{4.10}$$

Proof. As in the previous result it is sufficient to prove the result for $U^0 \in D(\mathcal{A}_\alpha)$. Hence, let $U^0 \in D(\mathcal{A}_\alpha)$ be given. As a first step, we obtain an estimate of $\int_0^T |A_2^{-1/2}u_2'|^2\,dt$. For this, we evaluate

$$\int_0^T (u_2'' + A_2u_2 + \alpha C^\star u_1, A_2^{-1}u_2)\,dt = 0.$$

This gives

$$\begin{aligned}
\int_0^T |A_2^{-1/2}u_2'|^2\,dt &= \int_0^T |u_2|^2\,dt + \alpha\int_0^T (C^\star u_1, A_2^{-1}u_2)\,dt + [(A_2^{-1/2}u_2', (A_2^{-1/2}u_2)]_0^T \\
&\le \int_0^T |u_2|^2\,dt + \alpha\int_0^T |C^\star u_1|\,|A_2^{-1}u_2|\,dt \\
&\quad + \frac{1}{2\gamma}\Big(|A_2^{-1/2}u_2'|^2(T) + |A_2^{-1/2}u_2'|^2(0)\Big) \\
&\quad + \frac{\gamma}{2}\Big(|A_2^{-1/2}u_2|^2(T) + |A_2^{-1/2}u_2|^2(0)\Big) \qquad \forall\, \gamma > 0.
\end{aligned}$$

Using (2.4) together with (2.2) for $i = 2$, we obtain

$$\int_0^T |A_2^{-1/2}u_2'|^2\,dt \le \left(1+\frac{\alpha\beta_2\nu_2^4}{2}\right)\int_0^T |u_2|^2\,dt + \frac{\alpha\beta_2}{2}\int_0^T |u_1|^2\,dt + \frac{1}{2}\left(\frac{|A_2^{-1/2}u_2'|^2(T)}{\gamma}+\gamma\nu_2^2|u_2|^2(T)\right) + \frac{1}{2}\left(\frac{|A_2^{-1/2}u_2'|^2(0)}{\gamma}+\gamma\nu_2^2|u_2|^2(0)\right) \qquad \forall\,\gamma>0.$$

We now choose $\gamma = \nu_2^{-1}$. This gives

$$\int_0^T |A_2^{-1/2}u_2'|^2\,dt \le \left(1+\frac{\alpha\beta_2\nu_2^4}{2}\right)\int_0^T |u_2|^2\,dt + \frac{\alpha\beta_2}{2}\int_0^T |u_1|^2\,dt + \nu_2(\tilde{e_2}(T)+\tilde{e_2}(0)).$$

Inserting (4.1) into this last inequality, we obtain

$$\int_0^T |A_2^{-1/2}u_2'|^2\,dt \le C_{11}\int_0^T |u_1|^2\,dt + \frac{C_{12}}{\alpha\gamma_1}(e_1(T)+e_1(0)) + \left(\frac{C_{13}\gamma_1}{\alpha}+\nu_2\right)(\tilde{e_2}(T)+\tilde{e_2}(0)) \qquad \forall\,\gamma_1>0. \tag{4.11}$$

As a second step, we estimate $\tilde{e_2}(T)+\tilde{e_2}(0)$. We proceed as follows. Since $U^0 \in D(\mathcal{A}_\alpha)$ we have $u_2 \in D(A_2)$. Moreover, recall that $\tilde{e_2}$ is given by the relation

$$\tilde{e_2} = \frac{1}{2}(|u_2|^2 + |A_2^{-1/2}u_2'|^2).$$

Hence, we have

$$\tilde{e_2}'(t) = (u_2, u_2') + (A_2^{-1/2}u_2'', A_2^{-1/2}u_2').$$

Using the second equation of (2.6), we deduce that

$$\tilde{e_2}'(t) = -\alpha(A_2^{-1/2}C^\star u_1, A_2^{-1/2}u_2'). \tag{4.12}$$

Integrating this last equality between 0 and T, we obtain

$$\tilde{e_2}(T)+\tilde{e_2}(0) = 2\tilde{e_2}(0) - \alpha\int_0^T (A_2^{-1/2}C^\star u_1, A_2^{-1/2}u_2')\,dt \le 2\tilde{e_2}(0) + \frac{\alpha}{2}\int_0^T |A_2^{-1/2}C^\star u_1|^2\,dt + \frac{\alpha}{2}\int_0^T |A_2^{-1/2}u_2'|^2\,dt.$$

We use (4.11) in this last inequality together with (2.4) and (2.2). This gives

$$\Big(1-\frac{\alpha\nu_2}{2}-\frac{C_{13}\gamma_1}{2}\Big)(\tilde{e_2}(T)+\tilde{e_2}(0)) \le 2\tilde{e_2}(0) + \frac{\alpha}{2}\Big(C_{11}+\nu_2^2\beta_2\Big)\int_0^T |u_1|^2\,dt + \frac{C_{12}}{2\gamma_1}(e_1(T)+e_1(0)).$$

Choose

$$\gamma_1 = C_{13}^{-1}$$

in the above inequality. This gives

$$\tilde{e_2}(T)+\tilde{e_2}(0)\leq \frac{4\tilde{e_2}(0)}{1-\alpha\nu_2}+\frac{C_{14}\alpha}{1-\alpha\nu_2}\int_0^T|u_1|^2\,dt + \frac{C_{15}}{1-\alpha\nu_2}(e_1(T)+e_1(0)). \tag{4.13}$$

Using (4.13) in (4.11) and in (4.1) (with $\gamma_1=1$), we can improve both estimates. This gives

$$\int_0^T|A_2^{-1/2}u_2'|^2\,dt\leq \frac{C_{16}}{1-\alpha\nu_2}\int_0^T|u_1|^2\,dt+\frac{C_{17}}{\alpha(1-\alpha\nu_2)}(e_1(T)+e_1(0)) + \frac{C_{18}}{\alpha(1-\alpha\nu_2)}\tilde{e_2}(0) \tag{4.14}$$

and

$$\alpha\int_0^T|u_2|^2\,dt\leq\frac{\alpha C_{19}}{1-\alpha\nu_2}\int_0^T|u_1|^2\,dt+\frac{C_{20}}{1-\alpha\nu_2}(e_1(T)+e_1(0))+\frac{C_{21}}{1-\alpha\nu_2}\tilde{e_2}(0). \tag{4.15}$$

For the third step, we estimate $e_1(T)+e_1(0)$ as follows. Since $U^0\in D(\mathcal{A}_\alpha)$ we have $u_1\in D(A_1)$. Moreover, we recall that e_1 is given by the relation

$$e_1=\frac{1}{2}(|u_1|_1^2+|u_2'|^2).$$

Hence, we have

$$e_1'(t)=(A_1^{1/2}u_1,A_1^{1/2}u_1')+(u_2'',u_2').$$

Using the first equation of (2.6), we deduce that

$$e_1'(t)=-\alpha(Cu_2,u_1'). \tag{4.16}$$

Integrating this last equality between 0 and T, and using (2.3), we obtain

$$\begin{aligned}e_1(T)+e_1(0)&=2e_1(0)-\alpha\int_0^T(Cu_2,u_1')\,dt\\&\leq 2e_1(0)+\frac{\alpha}{2\varepsilon_2}\int_0^T|u_1'|^2\,dt+\frac{\alpha\varepsilon_2\beta_2^2}{2}\int_0^T|u_2|^2\,dt.\end{aligned}$$

We use (4.15) in this last inequality. This gives

$$\begin{aligned}&\left(1-\frac{C_{20}\beta_2^2\varepsilon_2}{2(1-\alpha\nu_2)}(e_1(T)+e_1(0))\right)\\&\quad\leq 2e_1(0)+\frac{\alpha}{2\varepsilon_2}\int_0^T|u_1'|^2\,dt+\frac{C_{19}\varepsilon_2\beta_2^2\alpha}{2(1-\alpha\nu_2)}\int_0^T|u_1|^2\,dt+\frac{C_{21}\varepsilon_2\beta_2^2}{2(1-\alpha\nu_2)}\tilde{e_2}(0).\end{aligned}$$

Choose

$$\varepsilon_2=\frac{1-\alpha\nu_2}{C_{20}\beta_2^2}$$

in the above inequality. This gives the estimate

$$e_1(T) + e_1(0) \leq 4e_1(0) + \frac{C_{22}\alpha}{1-\alpha\nu_2}\int_0^T (|u_1'|^2 + |u_1|^2)\,dt + C_{23}\tilde{e_2}(0).$$

Hence, we have proved the estimate (4.7). We now use the estimate (4.7) successively in (4.13), (4.14), and (4.15). This gives the desired estimates (4.8), (4.9), and (4.10). □

LEMMA 4.3. *Assume the hypotheses of Theorem* 2.1 *and let* α_1 *be defined as in* (4.6). *We set*

$$\alpha_2 = \min(\alpha_1, (2\nu_2)^{-1}). \tag{4.17}$$

Then for all $0 < |\alpha| < \alpha_2$ *and all* $U^0 \in \mathcal{H}$ *the solution* $U(t) = \exp(-t\mathcal{A}_\alpha)U^0$ *of* (2.6) *satisfies for all* $\gamma_2 > 0$

$$\int_0^T e_1(t)\,dt \geq \frac{C_{27}T}{2(1+\alpha T)}(e_1(0) - \tilde{e_2}(0)). \tag{4.18}$$

Proof. Using (4.16), we have

$$\int_0^T e_1(t)\,dt = Te_1(0) - \alpha\int_0^T (T-t)(Cu_2, u_1')\,dt.$$

Hence, using (2.3) in this equality, we obtain for all $\gamma_2 > 0$

$$\int_0^T e_1(t)\,dt \geq Te_1(0) - \frac{\alpha T}{2\gamma_2}\int_0^T |u_1'|^2\,dt - \frac{\gamma_2\beta_2^2\alpha T}{2}\int_0^T |u_2|^2\,dt.$$

Thanks to (4.10) together with (2.1) used in this last inequality, we obtain

$$\begin{aligned}\int_0^T e_1(t)\,dt \geq{}& T\left(1 - \frac{\gamma_2\beta_2^2 C_7}{2(1-\alpha\nu_2)}\right)e_1(0) - T\frac{\gamma_2\beta_2^2 C_7}{2(1-\alpha\nu_2)}\tilde{e_2}(0)\\ &- \frac{\alpha T}{2}\left(\frac{1}{\gamma_2}\int_0^T |u_1'|^2\,dt\frac{\gamma_2\beta_2^2 C_8}{1-\alpha\nu_2}\int_0^T (|u_1'|^2 + \nu_1^2|u_1|_1^2)\,dt\right).\end{aligned}$$

We choose $\gamma_2 = \frac{1-\alpha\nu_2}{\beta_2^2 C_7}$ in the above inequality. This leads to

$$\int_0^T e_1(t)\,dt \geq \frac{T}{2}(e_1(0) - \tilde{e_2}(0)) - \frac{\alpha T C_{28}}{1-\alpha\nu_2}\int_0^T e_1(t)\,dt.$$

Since $\alpha \in (0, \alpha_2)$ and thanks to our choice of α_2, we have $1 \leq (1-\alpha\nu_2)^{-1} \leq 2$. Using these two inequalities in the previous inequality, we obtain the desired inequality with a new constant C_{27}. □

Remark. Note that our choice of α_2 is not optimal, but this choice has the advantage of simplifying the next computations by avoiding keeping track of the dependence of the constants with respect to $(1-\alpha\nu_2)$ in the next estimates. Indeed, from now on we will not care any longer about the restrictions on the size of α. Hence, in what follows α will be assumed to be sufficiently small in order to shorten the computations.

COROLLARY 4.4. *Assume the hypotheses of Theorem* 2.1 *and let* α_2 *be defined as in* (4.17). *Then there exists* $\alpha_3 \in (0, \alpha_2)$ *such that for all* $0 < |\alpha| < \alpha_3$ *and all* $U^0 \in \mathcal{H}$ *the solution* $U(t) = \exp(-t\mathcal{A}_\alpha)U^0$ *of* (2.6) *satisfies*

$$\int_0^T (e_1(t) + \tilde{e_2}(t))\, dt \geq \frac{\delta_2 T}{2}\, (\tilde{e_1}(0) + \tilde{e_2}(0)), \tag{4.19}$$

where $\delta_2 = \min(1, \nu_1^{-2})$. *Moreover, we have*

$$e_1(T) + e_1(0) \leq C_1(e_1(0) + \tilde{e_2}(0)) + C_{29}\alpha \int_0^T e_1(t)\, dt, \tag{4.20}$$

$$\int_0^T |u_2|^2\, dt \leq 2\frac{C_7}{\alpha}(e_1(0) + \tilde{e_2}(0)) + C_{30} \int_0^T e_1(t)\, dt, \tag{4.21}$$

$$\int_0^T \tilde{e_2}(t)\ dt \leq 2\frac{C_{24}}{\alpha}(e_1(0) + \tilde{e_2}(0)) + C_{36} \int_0^T e_1(t)\, dt. \tag{4.22}$$

Proof. We first remark that thanks to (2.1)–(2.2) we have

$$\int_0^T (e_1(t) + \tilde{e_2}(t))\, dt \geq \delta_2 \int_0^T (\tilde{e_1}(t) + \tilde{e_2}(t))\, dt, \tag{4.23}$$

where $\delta_2 = \min(1, \nu_1^{-2})$. On the other hand, we have

$$\widetilde{E}(t) = \tilde{e_1}(t) + \tilde{e_2}(t) + \alpha(A_1^{-1/2}u_1, (A_1^{-1/2}CA_2^{1/2})\, A_2^{-1/2}u_2).$$

Hence, thanks to (2.2), (2.14) we obtain

$$|\widetilde{E}(t) - (\tilde{e_1}(t) + \tilde{e_2}(t))| \leq \alpha\beta_3\nu_1\nu_2 \left(\frac{|u_1|^2 + |u_2|^2}{2}\right) \leq \alpha\delta_1(\tilde{e_1}(t) + \tilde{e_2}(t)),$$

where $\delta_1 = \nu_1\nu_2\beta_3$. Integrating this last estimate between 0 and T, and since the energy $\widetilde{E}$ is conserved through time, we obtain

$$\int_0^T (\tilde{e_1}(t)+\tilde{e_2}(t))\, dt \geq \frac{1}{1+\alpha\delta_1} \int_0^T \widetilde{E}(t)\, dt = \frac{T}{1+\alpha\delta_1}\widetilde{E}(0) \geq T\frac{1-\alpha\delta_1}{1+\alpha\delta_1}(\tilde{e_1}(0)+\tilde{e_2}(0)).$$

Using this last inequality together with (4.23) and choosing $\alpha_3 \in (0, \alpha_2)$ such that for all $\alpha \in (0, \alpha_3)$

$$\frac{1-\alpha\delta_1}{1+\alpha\delta_1} \geq \frac{1}{2},$$

we obtain (4.19). Moreover, recalling the definition of $\tilde{e_2}$, i.e.,

$$\tilde{e_2} = \frac{1}{2}(|u_2|^2 + |A_2^{-1/2}u_2'|^2),$$

we easily obtain from (4.10) and (4.9)

$$\int_0^T \tilde{e_2}(t)\ dt \leq \frac{C_{24}}{\alpha(1-\alpha\nu_2)}(e_1(0) + \tilde{e_2}(0)) + \frac{C_{25}}{(1-\alpha\nu_2)^2} \int_0^T (|u_1'|^2 + |u_1|^2)\, dt. \tag{4.24}$$

The estimates (4.20), (4.21), and (4.22) are easily obtained from the corresponding estimates (4.7), (4.10), and (4.24), using (2.1) since $\alpha \in (0, \alpha_2)$. ∎

5. Proof of the main result. We are now able to prove the main estimate of this paper. We assume from now on that $\alpha \in (0, \alpha^\star)$, where $0 < \alpha^\star < \alpha_3$ will be chosen explicitly sufficiently small in the course of the proof. We first remark that u_1 is the solution of

$$\begin{cases} u_1'' + A_1 u_1 = f, \\ (u_1, u_1')(0) = (u_1^0, u_1^1) \in D(\mathcal{A}_1), \end{cases}$$

where $f = -\alpha C u_2$. Hence, from our assumption (H1), u_1 satisfies the inequality (2.13) with the corresponding f. Using (4.20) and (4.21) in the resulting inequality, we obtain

$$\eta_4 \int_0^T ||B^\star u_1||_G^2 \, dt \geq \left(1 - \eta_1\beta - \frac{C_{31}\alpha}{1-\alpha\nu_2} - \frac{C_{32}\alpha^2}{\beta(1-\alpha\nu_2)^2}\right) \int_0^T e_1(t)\, dt - C_{33}\left(1 + \frac{\alpha}{\beta(1-\alpha\nu_2)}\right)(e_1(0) + \tilde{e_2}(0)) \qquad \forall\, \beta \in (0, \eta_1).$$

We now choose $\beta = \alpha$ in the above inequality, and we remark that

$$\left(1 - \eta_1\beta - \frac{C_{31}\alpha}{1-\alpha\nu_2} - \frac{C_{32}\alpha^2}{\beta(1-\alpha\nu_2)^2}\right) \geq \frac{1}{2}$$

and

$$- C_{33}\left(1 + \frac{\alpha}{\beta(1-\alpha\nu_2)}\right) \geq -\frac{C_{34}}{2}$$

for sufficiently small α. Using this in the above estimate, we obtain

$$2\eta_4 \int_0^T ||B^\star u_1||_G^2 \, dt \geq \int_0^T e_1(t)\, dt - C_{34}\Big[e_1(0) + \tilde{e_2}(0)\Big].$$

Now let ε be an arbitrary fixed number in $(0, \varepsilon^\star)$, where $\varepsilon^\star$ is chosen sufficiently small. (This will be defined in the course of the proof.) Then using the above inequality, we can write

$$2\eta_4 \int_0^T ||B^\star u_1||_G^2 \, dt \geq (1-\varepsilon)\int_0^T e_1(t)\, dt + \varepsilon \int_0^T (e_1(t) + \tilde{e_2}(t))\, dt - \varepsilon \int_0^T \tilde{e_2}(t)\, dt - C_{34}\Big[e_1(0) + \tilde{e_2}(0)\Big]. \tag{5.1}$$

Using then (4.22) together with (4.19) in the above inequality, we deduce that

$$2\eta_4 \int_0^T ||B^\star u_1||_G^2 \, dt \geq (1 - \varepsilon C_{37}) \int_0^T e_1(t)\, dt + \varepsilon \frac{\delta_2}{2} T \tilde{e_1}(0) - C_{38}\frac{\varepsilon+\alpha}{\alpha} e_1(0) + \Big[\varepsilon\frac{\delta_2}{2}\, T - C_{38}\frac{\varepsilon+\alpha}{\alpha}\Big]\tilde{e_2}(0). \tag{5.2}$$

We set $\varepsilon_0 = C_{37}^{-1}$ and assume from now on that

$$0 < \varepsilon^\star < \varepsilon_0, \tag{5.3}$$

and we use (4.18) in (5.2) to give a lower bound for $\int_0^T e_1(t)\,dt$. This gives the following estimate:

$$\begin{aligned} 2\eta_4 \int_0^T ||B^\star u_1||_G^2\,dt \geq & \left[\frac{a_1\,T}{1+\alpha T} - C_{38}\frac{\varepsilon+\alpha}{\alpha}\right] e_1(0) + \varepsilon\frac{\delta_2}{2}\,T\tilde{e_1}(0) \\ & + \left[\left(a_2 - \frac{a_1}{1+\alpha T}\right)T - \frac{C_{38}(\varepsilon+\alpha)}{\alpha}\right]\tilde{e_2}(0), \end{aligned} \tag{5.4}$$

where a_i for $i = 1, 2$ are given by

$$a_1 = \frac{(1 - C_{37}\varepsilon)\,C_{27}}{2} > 0, \tag{5.5}$$

$$a_2 = \frac{\varepsilon\delta_2}{2} > 0. \tag{5.6}$$

We remark that the coefficient of $\tilde{e_1}(0)$ in (5.4) is strictly positive. Hence, the proof of the theorem will be complete if we can prove that the coefficients of $e_1(0)$ and $\tilde{e_2}(0)$ which depend only on T, α, and ε are positive for sufficiently large T and sufficiently small α and $\varepsilon^\star$. We will show now that this is possible and give the order in which the parameters T, α, and $\varepsilon^\star$ have to be made large enough, and small enough, respectively. We set

$$T_1 = T_1(\alpha) = \left(\frac{a_1}{a_2} - 1\right)\alpha^{-1}. \tag{5.7}$$

One can notice that $T_1(\alpha)$ goes to $+\infty$ as either ε or α goes to zero. Then for any $T \geq T_1(\alpha)$ we have

$$0 < a_2 - \frac{a_1}{1+\alpha\,T}. \tag{5.8}$$

Let us now denote by Q_α the second order polynomial with respect to T defined by

$$Q_\alpha(T) = \alpha a_2 T^2 + [a_2 - a_1 - C_{38}(\varepsilon+\alpha)]\,T - \frac{C_{38}(\varepsilon+\alpha)}{\alpha}. \tag{5.9}$$

This polynomial has two real roots. Moreover, one can remark that the coefficient of T in this polynomial is negative for sufficiently small ε independently on α. Hence, one root is negative whereas the other one is positive. We denote the negative root by $T_2^-(\alpha)$ and the positive root by $T_2(\alpha)$. Then the coefficient of $\tilde{e_2}(0)$ in (5.4) is given by

$$\frac{Q_\alpha(T)}{1+\alpha\,T}.$$

Let us further remark that $T_2(\alpha) > T_1(\alpha)$ since Q_α can be rewritten under the form

$$Q_\alpha = \frac{a_1\alpha(T - T_1(\alpha))T}{1+\alpha T_1(\alpha)} - \frac{C_{38}(\varepsilon+\alpha)(1+\alpha T)}{\alpha}.$$

Hence, for $T \geq T_2(\alpha)$ the coefficient of $\tilde{e_2}(0)$ is positive. It is given by

$$\alpha \frac{a_2(T - T_2(\alpha))(T - T_2^-(\alpha))}{1 + \alpha T}.$$

We now turn to the coefficient of $e_1(0)$ in (5.4). This coefficient will be positive for sufficiently large T if $a_1 - C_{38}(\varepsilon + \alpha)$ can be made positive for sufficiently small ε and α. This can be easily realized by assuming that $\alpha^\star < C_{27}(2C_{38})^{-1}$ and by choosing $\varepsilon^\star = \min(\varepsilon_0, \varepsilon_1)$ with

$$\varepsilon_1 = \frac{C_{27} - 2C_{38}\alpha^\star}{2C_{38} + C_{27}C_{37}}.$$

Now for $\alpha \in (0, \alpha^\star)$ and $\varepsilon \in (0, \varepsilon^\star)$ we set

$$T_3(\alpha) = \frac{C_{38}(\varepsilon + \alpha)}{a_1 - C_{38}(\varepsilon + \alpha)} > 0. \tag{5.10}$$

Then remarking that $T_3 = T_3(\alpha)$ is such that

$$\frac{C_{38}(\varepsilon + \alpha)}{\alpha} = \frac{a_1 T_3}{1 + \alpha T_3},$$

the coefficient of $e_1(0)$ in (5.4) is given by

$$\left[\frac{a_1(T - T_3(\alpha))}{(1 + \alpha T)(1 + \alpha T_3(\alpha)}\right]$$

and is positive for $T \geq T_3(\alpha)$. Using the above expressions for the coefficients of $\tilde{e_2}(0)$ and $e_1(0)$ in (5.4), we obtain the following observability inequality with positive coefficients for $T \geq \max(T_2(\alpha), T_3(\alpha))$:

$$\begin{aligned} 2\eta_4 \int_0^T ||B^\star u_1||_G^2 \, dt \geq & \left[\frac{a_1(T - T_3(\alpha))}{(1 + \alpha T)(1 + \alpha T_3(\alpha)}\right] e_1(0) \\ & + \left[\alpha \frac{a_2(T - T_2(\alpha))(T - T_2^-(\alpha))}{1 + \alpha T}\right] \tilde{e_2}(0). \end{aligned} \tag{5.11}$$

□

Proof of Theorem 2.5. We apply the HUM. Let $U^0 \in D(\mathcal{A}_\alpha)$ be given. We denote by $U = (u_1, u_1', u_2, u_2')$ the corresponding solution of (2.7). Thanks to the observability inequality proved in Theorem 2.1, the seminorm defined by

$$||U^0||_{\mathcal{F}} = \left(\int_0^T ||B^\star u_1||_G^2 \, dt\right)^{1/2} \tag{5.12}$$

is a norm on $D(\mathcal{A}_\alpha)$. We denote by $\mathcal{F}$ the completion of $D(\mathcal{A}_\alpha)$ with respect to this norm. Thanks to the direct and inverse inequalities proved, respectively, in Proposition 3.3 and in Theorem 2.1, we have the following continuous and dense imbeddings:

$$D(\mathcal{A}_\alpha) \subset \mathcal{H} \subset \mathcal{F} \subset \widetilde{\mathcal{H}} \subset \widehat{\mathcal{H}}, \tag{5.13}$$

where $\widetilde{\mathcal{H}} = V_1 \times H \times H \times V_2'$ and $\widehat{\mathcal{H}} = H \times V_1' \times H \times V_2'$. Hence, by duality, we have the following continuous imbeddings:

$$\widetilde{\mathcal{H}}' \subset \mathcal{F}' \subset \mathcal{H}'. \tag{5.14}$$

For every $U^0 \in \mathcal{H}$, we associate a linear form on $\mathcal{H}$ defined by

$$\langle \Lambda(U^0), \widetilde{U^0} \rangle = \int_0^T \langle B^\star u_1(t), B^\star \tilde{u_1}(t) \rangle_G dt. \tag{5.15}$$

By definition of the norm on $\mathcal{F}$ we have the estimate

$$|\langle \Lambda(U^0), \widetilde{U^0} \rangle| \leq ||U^0||_{\mathcal{F}} ||\widetilde{U^0}||_{\mathcal{F}} \qquad \forall U^0 \in \mathcal{H},\ \forall \widetilde{U^0} \in \mathcal{H}.$$

Hence, since $\mathcal{H}$ is dense in $\mathcal{F}$ by definition of $\mathcal{F}$, the map $\Lambda(U^0)$ can be extended in a unique way to a continuous map on $\mathcal{F}$ and $\Lambda(U^0) \in \mathcal{F}'$. Moreover, thanks to the above inequality, the linear map Λ that maps $U^0 \in \mathcal{H}$ to $\Lambda U^0 \in \mathcal{F}'$ is continuous when $\mathcal{H}$ is equipped with the norm $||\cdot||_{\mathcal{F}}$. Hence, by density, Λ can be extended in a unique way to a continuous linear map, still denoted by Λ, from $\mathcal{F}$ to $\mathcal{F}'$. Moreover, we have

$$\langle \Lambda(U^0), \widetilde{U^0} \rangle_{\mathcal{F}',\mathcal{F}} = \langle U^0, \widetilde{U^0} \rangle_{\mathcal{F}} \qquad \forall U^0 \in \mathcal{H},\ \forall \widetilde{U^0} \in \mathcal{H}, \tag{5.16}$$

where $\langle , \rangle_{\mathcal{F}}$ denotes the scalar product associated with the norm on $\mathcal{F}$. Therefore Λ is coercive and continuous on $\mathcal{F}$, so that thanks to the Lax–Milgram lemma, Λ is an isomorphism from $\mathcal{F}$ onto $\mathcal{F}'$. Let us now apply the HUM. Let $Y^0 \in \mathcal{F}'$ be fixed arbitrarily. We set $U^0 = \Lambda^{-1} Y^0$. Then $U^0 \in \mathcal{F}$. Since $\mathcal{H}$ is dense in $\mathcal{F}$, there exists a sequence $(U_n^0)_n \subset \mathcal{H}$ which converges to U^0 in $\mathcal{F}$. We set $Y_n^0 = \Lambda U_n^0$ for all $n \in \mathbb{N}$. Then, since Λ is continuous, Y_n^0 converges to Y^0 in $\mathcal{F}'$. Thanks to (5.14), we have that $Y_n^0 \in \mathcal{H}'$ and converges to Y^0 in $\mathcal{H}'$. We set $U_n = \exp(-t\mathcal{A}_\alpha) U_n^0$ and $v_n = -B^\star u_{1,n}$ for all $n \in \mathbb{N}$, where $u_{1,n}$ denotes the first component of U_n. Then by definition of the norm on $\mathcal{F}$ and since $(U_n^0)_n$ converges in $\mathcal{F}$, $(v_n)_n$ is a Cauchy sequence in $L^2([0,T];G)$. Hence, it converges to a function v in $L^2([0,T];G)$. We associate with U_n the solutions Y_n of the dual problem in $\mathcal{H}'$:

$$\begin{cases} Y_n' - \mathcal{A}_\alpha^\star Y_n = \widetilde{B} v_n, \\ Y_n(T) = 0. \end{cases} \tag{5.17}$$

One can remark that this retrograde problem is well-posed, thanks to the change of time variable $t \mapsto T - t$ and since this first order abstract equation is equivalent to a time second order (and therefore reversible in time) equation. Therefore, by definition of the solutions of this dual problem by transposition, and thanks to the definition of Λ and to our choice of v_n, we have

$$\langle Y_n(0), \widetilde{U^0} \rangle_{\mathcal{H}',\mathcal{H}} = \langle \Lambda(U_n^0), \widetilde{U^0} \rangle_{\mathcal{H}',\mathcal{H}} \qquad \forall\ \widetilde{U^0} \in \mathcal{H}.$$

Hence, we have $Y_n(0) = \Lambda(U_n^0) = Y_n^0$. Hence, we solved the exact controllability problem for the initial data Y_n^0, since Y_n satisfies

$$\begin{cases} Y_n' - \mathcal{A}_\alpha^\star Y_n = \widetilde{B} v_n, \\ Y_n(0) = Y_n^0, \quad Y_n(T) = 0. \end{cases}$$

Now for every $T > T_0$ the map Ψ defined in Proposition 3.4 is continuous; hence, $(Y_n)_n$ converges Y in $\mathcal{C}([0,T];\mathcal{H}')$, where $Y = \Psi(Y^0, v)$ is the solution of

$$\begin{cases} Y' - \mathcal{A}_\alpha^\star Y = \widetilde{B} v, \\ Y(0) = Y^0. \end{cases}$$

Therefore we have $(Y_n(T))_n$ in particular, which converges to $Y(T)$ in $\mathcal{H}'$, but since $Y_n(T) = 0$ for all n, we deduce that Y satisfies, in addition, $Y(T) = 0$. Hence, we solved the exact controllability problem for any initial data in $\mathcal{F}'$. Thanks to the first imbedding in (5.14), we conclude the proof. □

Remark. In the course of the above proof, we approximated the initial data $U^0 \in \mathcal{F}$ by a sequence of initial data $(U_n^0)_n \subset \mathcal{H}$. Indeed, using the HUM, it is not necessary to prove well-posedness of the homogeneous problem in $\mathcal{F}$ for solving the exact controllability problem in $\mathcal{F}'$. This is due to the fact that we just need to use the associated control, which is itself well defined for initial data in $\mathcal{F}$ (by extension by continuity). However, we still need to solve the homogeneous equation in a space larger than the energy space. To avoid this step, we prefer to approximate the initial data in $\mathcal{F}$ by a sequence of data in the energy space. We conjecture that well-posedness of (2.7) does not hold in general in $\mathcal{F}$, unless for instance in cases for which one can show that $\mathcal{F}$ does not depend on T. This difficulty does not appear when direct and inverse inequalities are obtained with the usual energy, which is not the case here. Indeed, using extrapolation theory (we refer the reader to [10] for a clear exposition on this subject), one can solve the homogeneous problem in the space $\mathcal{H}_{-1}$. (One can also solve the homogeneous equation in the dual space of the energy space.) Since one can easily show that for $|\alpha| \leq \alpha_0$ $\mathcal{A}_\alpha$ is invertible, $\mathcal{H}_{-1}$ is defined as the completion of $\mathcal{H}$ with respect to the norm $||\ ||_{-1}$, where the norm $||\ ||_{-1}$ is given on $\mathcal{H}$ by

$$||U||_{-1} = ||\mathcal{A}_\alpha^{-1} U||_\alpha.$$

This extrapolated space contains the energy space $\mathcal{H}$ and $\mathcal{F}$ as dense subspaces. Then, one can prove that the semigroup $\exp(-t\mathcal{A}_\alpha)$, $t \geq 0$, can be extended in a unique way to a strongly continuous semigroup $T_{-1}(t)$, $t \geq 0$, on the extrapolated space $\mathcal{H}_{-1}$ for $t \geq 0$. However, since in general the space $\mathcal{F}$ depends on T, one cannot show that $\mathcal{F}$ is invariant under the action of the semigroup $T_{-1}(t)$.

6. Applications.

6.1. The case $A_1 = A_2$. In all that follows, Ω is a nonempty bounded open set in $\mathbb{R}^N$ having a boundary Γ of class C^2, $\{\Gamma_0, \Gamma_1\}$ is a partition of Γ such that $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$, and x_0 is a point in $\mathbb{R}^N$ such that $m \cdot \nu \leq 0$ on Γ_0 and $m \cdot \nu \geq 0$ on Γ_1, where $m(x) = x - x_0$. We set $\sup_\Omega ||m|| = R$.

Coupled wave equations with same speed of propagation. We consider the following system:

$$\text{(6.1)} \qquad \begin{cases} u_{1,tt} - \Delta u_1 + \alpha u_2 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ u_{2,tt} - \Delta u_2 + \alpha u_1 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ u_1 = u_2 = 0 \quad \text{on} \quad \Sigma = \Gamma \times (0,T), \\ (u_1, u_{1,t})(0) = (u_1^0, u_1^1), \quad (u_2, u_{2,t})(0) = (u_2^0, u_2^1) \quad \text{on} \quad \Omega. \end{cases}$$

We set $H = L^2(\Omega)$ and $V_1 = V_2 = H_0^1(\Omega)$, equipped, respectively, with the L^2 scalar product and the scalar product $(u,z)_i = \int_\Omega \nabla u \cdot \nabla z$ for $i = 1, 2$ and the corresponding norms. We define the duality mappings A_1 and A_2 as in section 2. As we said before, we still denote by $A_1 = A_2 = -\Delta$ the operators A_1, A_2 viewed as unbounded operators in H acting from $D(A_1) = D(A_2) = H^2(\Omega) \cap H_0^1(\Omega)$ into H.

We define the partial natural and weakened energies by

$$e_i(t) = \frac{|u_i'(t)|^2 + |\nabla u_i(t)|^2}{2},$$

$$\tilde{e_i}(t) = \frac{|u_i'(t)|^2_{H^{-1}(\Omega)} + |u_i(t)|^2}{2}.$$

The inequalities (2.1), (2.3), (2.8), (2.9), and (2.10) are satisfied with ν_i equal to the Poincaré's constant and $\beta_1 = \beta_2 = \beta_3 = 1$. Hence, in order to apply Corollary 2.2, we just need to check the assumptions (H3) and (H4). For this, we have to consider the inhomogeneous problem

$$\left\{\begin{array}{l} u_{1,tt} - \Delta u_1 = f \quad \text{in} \quad \Omega \times (0,T), \\ u_1 = 0 \quad \text{on} \quad \Gamma \times (0,T), \\ (u_1, u_{1,t})(0) = (u_1^0, u_1^1) \in D(A_1) \times V_1 \quad \text{on} \quad \Omega, \end{array}\right. \tag{6.2}$$

where $f \in \mathcal{C}^1([0,T]; H)$. We set $G = L^2(\Gamma_1)$. Moreover, we define a continuous linear operator $B^\star$ from $D(A_1)$ to G by

$$B^\star u = \left.\frac{\partial u}{\partial \nu}\right|_{\Gamma_1},$$

where ν stands for the normal derivative to Γ. The direct inequality (2.12) can be easily obtained following [25], [26]. For this, we choose a vector field h with $h \in (\mathcal{C}^1(\overline{\Omega}))^N$ such that $h_{|\Gamma} = \nu$. (See, e.g., [25], [26] for the proof of existence of such a vector field.) Then we evaluate, as usual, the expression

$$\int_0^T \int_\Omega (u_{1,tt} - \Delta u_1) h \,.\, \nabla u_1 \, dx \, dt = \int_0^T \int_\Omega f \, h \,.\, \nabla u_1 \, dx \, dt;$$

we then obtain the usual equality with an additional term due to the fact that f is nonvanishing. For the sake of completeness we give it below:

$$\begin{aligned} \int_0^T \int_\Gamma h \,.\, \nu \left|\frac{\partial u_1}{\partial \nu}\right|^2 d\gamma \, dt = \int_0^T \int_\Omega \Big(\mathrm{div}(h)(|u_1'|^2 - |\nabla u_1|^2) + 2 \frac{\partial h_j}{\partial x_i} \frac{\partial u_1}{\partial x_i} \frac{\partial u_1}{\partial x_j} \Big) \\ + 2 \left[\int_\Omega u_1' h \,.\, \nabla u_1 \right]_0^T - 2 \int_0^T \int_\Omega f \, h \,.\, \nabla u_1 \, dx \, dt, \end{aligned}$$

where we used the convention summation of repeated indices. We then easily obtain (2.12).

We now turn to the proof of (2.13). For this we use the classical multiplier $Mu_1 = m \,.\, \nabla u_1 + \frac{N-1}{2} u_1$ and compute

$$\int_0^T \int_\Omega (u_{1,tt} - \Delta u_1) \, Mu_1 \, dx \, dt = \int_0^T \int_\Omega f \, Mu_1 \, dx \, dt,$$

$$\begin{aligned} \frac{1}{2} \int_0^T \int_\Gamma m \,.\, \nu \left|\frac{\partial u_1}{\partial \nu}\right|^2 d\gamma \, dt = \int_0^T e_1(t) \, dt - \int_0^T (f, Mu_1) \, dt \\ + \left[\int_\Omega u_{1,t} M u_1 \, dx \right]_0^T. \end{aligned} \tag{6.3}$$

Now recalling that the following two inequalities hold for all $t \geq 0$ (see [17, pp. 38–39]),

$$|Mu_1| \leq R|\nabla u_1|, \qquad |(u_{1,t}, Mu_1)| \leq Re_1(t),$$

and using the estimate

$$\int_0^T |(f, Mu_1)|\, dt \leq \int_0^T \frac{R|f|^2}{2\beta}\, dt + \int_0^T \frac{R\beta|\nabla u_1|^2}{2}\, dt \leq \int_0^T \frac{R|f|^2}{2\beta}\, dt + R\beta \int_0^T e_1(t)\, dt$$

for all $\beta > 0$ in the above equality, we obtain (2.13). Hence, assumptions (H3)–(H4) are satisfied, and we can therefore apply Corollary 2.2. This gives Theorem 1.1. By duality, we derive Theorem 1.2 for the exact controllability of system (1.8).

Coupled Kirchhoff–Petrowsky plates. Let $N = 2$ (for physical validity of the model) and assume that Ω is a nonempty bounded open set in $\mathbb{R}^N$ having a boundary Γ of class C^4. We assume as before that $\{\Gamma_0, \Gamma_1\}$ is a partition of Γ such that $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$ and x_0 is a point in $\mathbb{R}^N$ such that $m \cdot \nu \leq 0$ on Γ_0 and $m \cdot \nu \geq \beta > 0$ on Γ_1, where $m(x) = x - x_0$. We set $\sup_\Omega ||m|| = R$.

We consider the following system:

$$\begin{cases} u_{1,tt} + \Delta^2 u_1 + \alpha u_2 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ u_{2,tt} + \Delta^2 u_2 + \alpha u_1 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ u_1 = u_2 = 0 = \dfrac{\partial u_1}{\partial \nu} = \dfrac{\partial u_2}{\partial \nu} \quad \text{on} \quad \Sigma = \Gamma \times (0,T), \\ (u_1, u_{1,t})(0) = (u_1^0, u_1^1), \quad (u_2, u_{2,t})(0) = (u_2^0, u_2^1) \quad \text{on} \quad \Omega. \end{cases} \tag{6.4}$$

We set $H = L^2(\Omega)$ (equipped with the usual norm and scalar product) and $V_1 = V_2 = H_0^2(\Omega)$ equipped with the scalar product

$$(u, z)_1 = (u, z)_2 = \int_\Omega \Delta u \Delta z \; dx \; dy$$

and the associated norm. We define the duality mappings A_1, A_2 as in section 2. As said before, we still denote by $A_1 = A_2 = -\Delta$ the operators A_1, A_2 viewed as unbounded operators in H acting from $D(A_1) = D(A_2) = H^4(\Omega) \cap H_0^2(\Omega)$ into H.

We define the partial natural and weakened energies by

$$e_i(t) = \frac{|u_i'(t)|^2 + |\Delta u_i(t)|^2}{2},$$

$$\tilde{e_i}(t) = \frac{|u_i'(t)|^2_{H^{-2}(\Omega)} + |u_i(t)|^2}{2}.$$

The inequalities (2.1), (2.3), (2.8), (2.9), and (2.10) are satisfied and $\beta_1 = \beta_2 = \beta_3 = 1$. Hence, in order to apply Corollary 2.2, we just need to check assumptions (H3) and (H4). For this, we have to consider the inhomogeneous problem

$$\begin{cases} u_{1,tt} + \Delta^2 u_1 = f \quad \text{in} \quad \Omega \times (0,T), \\ u_1 = \dfrac{\partial u_1}{\partial \nu} = 0 \quad \text{on} \quad \Gamma \times (0,T), \\ (u_1, u_{1,t})(0) = (u_1^0, u_1^1) \in D(A_1) \times V_1 \quad \text{on} \quad \Omega, \end{cases} \tag{6.5}$$

where $f \in \mathcal{C}^1([0,T];H)$. We set $G = L^2(\Gamma_1)$. Moreover, we define a continuous linear operator $B^\star$ from $D(A_1)$ to G by

$$B^\star u = \Delta u|_{\Gamma_1}.$$

The direct inequality (2.12) can be easily obtained following [25], [26]. For this, we choose as before a vector field h as in the previous example. Then, we evaluate, as usual, the expression

$$\int_0^T \int_\Omega (u_{1,tt} + \Delta^2 u_1) h \,.\, \nabla u_1 \, dx \, dt = \int_0^T \int_\Omega f \, h \,.\, \nabla u_1 \, dx \, dt,$$

and we then obtain the usual equality with an additional term on the right-hand side due to the fact that f is nonvanishing. This additional term is

$$\int_0^T \int_\Omega f \, h \,.\, \nabla u_1 \, dx \, dt.$$

We then easily obtain (2.12).

We now turn to the proof of (2.13). We define μ^2 as the smallest positive constant such that

$$|\nabla u|^2 \le \mu^2 \, |\Delta u|^2 \qquad \forall \, u \in V_1.$$

We then use the multiplier $Mu_1 = m \,.\, \nabla u_1$ and compute

$$\int_0^T \int_\Omega (u_{1,tt} + \Delta^2 u_1) \, Mu_1 \, dx \, dt = \int_0^T \int_\Omega f \, Mu_1 \, dx \, dt.$$

Then proceeding as in [25], [26], one obtains

$$\frac{1}{2} \int_0^T \int_{\Gamma_1} m \,.\, \nu |\Delta u_1|^2 \, d\gamma \, dt = [(u_1', m \,.\, \nabla u_1)]_0^T + 2 \int_0^T e_1(t) \, dt + \int_0^T \int_\Omega f \, m \,.\, \nabla u_1 \, dx \, dt.$$

Using now the estimate

$$|(u_1', m \,.\, \nabla u_1)(t)| \le R\mu e_1(t),$$

together with the definition of R and μ, in the above equality, we obtain for all $\beta > 0$

$$\frac{R}{2} \int_0^T \int_{\Gamma_1} |\Delta u_1|^2 \, d\gamma \, dt \ge (2 - R\beta\mu^2) \in_0^T e_1(t) - R\mu(e_1(0) + e_1(T)) - \frac{1}{2\beta} \int_0^T \int_\Omega |f|^2 \, dx \, dt.$$

Hence, (2.13) holds.

Hence, assumptions (H3)–(H4) are satisfied; we can therefore apply Corollary 2.2. This gives the following results.

THEOREM 6.1. *There then exists $\alpha^\star > 0$ such that for all $0 < |\alpha| < \alpha^\star$, there exists $T_0 = T_0(\alpha) > 0$ such that for all $T > T_0$ and all $U^0 \in \mathcal{H}$ the solution $U(t) = \exp(-\mathcal{A}_\alpha t)U^0 = (u_1, u_1', u_2, u_2')$ of (6.4) satisfies*

$$2 \int_0^T \int_{\Gamma_1} |\Delta u_1|^2 \, d\gamma \, dt \ge \frac{c_1}{2} \left(|u_1^1|^2 + |\Delta u_1^0|^2 \right) + \frac{c_3}{2} \left(|u_2^1|^2_{H^{-2}(\Omega)} + |u_2^0|^2 \right), \tag{6.6}$$

where the constants c_i for $i = 1, 3$ are given in Theorem 2.1.

Moreover, if in addition the solution of (6.4) *satisfies*

$$\Delta u_1 = 0 \text{ on } \Gamma_1 \times (0,T),$$

then one has $u_1 = u_2 = 0$ *in* $\Omega \times [0,T]$.

We now give the dual exact controllability result. For this, we consider the system

$$\text{(6.7)} \quad \begin{cases} y_{1,tt} + \Delta^2 y_1 + \alpha y_2 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ y_{2,tt} + \Delta^2 y_2 + \alpha y_1 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ y_1 = 0 \quad \text{on} \quad \Sigma = \Gamma \times (0,T), \qquad \dfrac{\partial y_1}{\partial \nu} = v \quad \text{on} \quad \Sigma_1 = \Gamma_1 \times (0,T), \\ \qquad y_1 = 0 \quad \text{on} \quad \Sigma_0 = \Gamma_0 \times (0,T), \\ y_2 = \dfrac{\partial y_2}{\partial \nu} = 0 \quad \text{on} \quad \Sigma, \\ (y_1, y_{1,t})(0) = (y_1^0, y_1^1), \quad (y_2, y_{2,t})(0) = (y_2^0, y_2^1) \quad \text{on} \quad \Omega. \end{cases}$$

Since the hypotheses of Theorem 2.5 are satisfied, we have the following result.

THEOREM 6.2. *There exists* $\alpha^\star > 0$ *such that for all* $0 < |\alpha| < \alpha^\star$, *there exists* $T_0 = T_0(\alpha) > 0$ *such that for all* $T > T_0$ *and all* $Y^0 = (y_1^0, y_1^1, y_2^0, y_2^1) \in L^2(\Omega) \times H^{-2}(\Omega) \times H_0^2(\Omega) \times L^2(\Omega)$ *there exists a control* $v \in L^2([),T]; L^2(\Gamma_1))$ *such that the solution* $Y(t) = (y_1, y_1', y_2, y_2')$ *of* (6.7) *satisfies*

$$y_i(.,T) = \partial_t y_i(.,T) = 0 \text{ in } \Omega \text{ for } i = 1,2.$$

Coupled linear elastodynamic systems. In all that follows, we shall use the summation convention for repeated indices. Let (a_{ijkl}) be a tensor such that

$$a_{ijkl} = a_{jikl} = a_{klij} \qquad \forall\, i,j,k,l \in \{1,\dots,N\},$$

satisfying for some $\gamma_0 > 0$

$$a_{ijkl}\varepsilon_{ij}\varepsilon_{kl} \geq \gamma_0 \varepsilon_{ij}\varepsilon_{ij}$$

for every symmetric tensor (ε_{ij}). Given a function u defined from Ω with values in $\mathbb{R}^N$, we set

$$\varepsilon_{ij}(u) = \frac{1}{2}(u_{i,j} + u_{j,i}), \qquad \sigma_{ij}(u) = a_{ijkl}\varepsilon_{kl}(u),$$

where

$$u_{i,j} = \frac{\partial u_i}{\partial x_j}, \qquad u_{j,i} = \frac{\partial u_j}{\partial x_i}.$$

We consider the following system:

$$\text{(6.8)} \quad \begin{cases} u_{i,tt} - \sigma_{ij,j}(u) + \alpha v_i = 0 \quad \text{in} \quad \Omega \times (0,T), \qquad 1 \leq i \leq N, \\ v_{i,tt} - \sigma_{ij,j}(v) + \alpha u_i = 0 \quad \text{in} \quad \Omega \times (0,T), \qquad 1 \leq i \leq N, \\ u_i = v_i = 0 \quad \text{on} \quad \Sigma = \Gamma \times (0,T), \qquad 1 \leq i \leq N, \\ (u_i, u_{i,t})(0) = (u_i^0, u_i^1), (v_i, v_{i,t})(0) = (v_i^0, v_i^1) \quad \text{on} \quad \Omega, \quad 1 \leq i \leq N. \end{cases}$$

We set $H = (L^2(\Omega))^N$ and $V_1 = V_2 = (H_0^1(\Omega))^N$. The space H is equipped with the usual product norm. We recall that thanks to Korn's and Poincaré's inequalities, the bilinear form

$$(u, \tilde{u})_k = \int_\Omega \sigma_{ij}(u)\varepsilon_{ij}(\tilde{u})\, dx$$

is a scalar product on V_k for $k = 1, 2$ and that the associated norm is equivalent to the usual product norm on V_k. We equip V_k with the above bilinear form and the corresponding norm. We define the duality mappings A_1, A_2 as in section 2. Moreover, we still denote by $A_1 = A_2 = -\sigma_{ij,j}$ the operators A_1, A_2 viewed as unbounded operators in H acting from $D(A_1) = D(A_2) = (H^2(\Omega) \cap H_0^1(\Omega))^N$ into H.

We define the partial natural and weakened energies by

$$e_1(t) = \frac{|u'(t)|^2 + |u(t)|_1^2}{2},$$

$$e_2(t) = \frac{|v'(t)|^2 + |v(t)|_2^2}{2},$$

$$\tilde{e_1}(t) = \frac{|u'(t)|_{V_1'}^2 + |u(t)|^2}{2},$$

$$\tilde{e_2}(t) = \frac{|v'(t)|_{V_2'}^2 + |v(t)|^2}{2}.$$

The inequality (2.1) is satisfied thanks to Korn's and Poincaré's inequalities for some constants $\nu_1 = \nu_2 > 0$. The inequalities (2.3), (2.8), (2.9), and (2.10) are satisfied with $\beta_1 = \beta_2 = \beta_3 = 1$. Hence, in order to apply Corollary 2.2, we just need to check the assumptions (H3) and (H4). For this, we have to consider the inhomogeneous problem

$$\text{(6.9)} \qquad \begin{cases} u_{i,tt} - \sigma_{ij,j}(u) = f \quad \text{in} \quad \Omega \times (0,T), \qquad 1 \le i \le N, \\ u_i = 0 \quad \text{on} \quad \Gamma \times (0,T), \qquad 1 \le i \le N, \\ (u_i, u_{i,t})(0) = (u_i^0, u_i^1) \in D(A_1) \times V_1 \quad \text{on} \quad \Omega, \qquad 1 \le i \le N, \end{cases}$$

where $f \in \mathcal{C}^1([0,T]; H)$. We set $G = (L^2(\Gamma_1))^N$. Moreover, we define a continuous linear operator $B^\star$ from $D(A_1)$ to G by

$$(B^\star u)_i = \sigma_{ij}(u)\nu_j|_{\Gamma_1}, \qquad i \in \{1, \dots, N\},$$

where $\nu = (\nu_1, \dots, \nu_N)$ stands for the normal derivative to Γ. We recall the following result proved in [2] (see Lemma 2.1) for any strong solution u of (6.9):

$$\text{(6.10)} \qquad \frac{\gamma_0}{2}\sigma_{ij}(u)\varepsilon_{ij}(u) \le \sum_{i=1}^N |\sigma_{ij}(u)\nu_j|^2 \le \frac{\gamma_1}{\gamma_0}\sigma_{ij}(u)\varepsilon_{ij}(u) \text{ on } \Gamma,$$

where $\gamma_1 = \sum_{i,j,k,l} |a_{ijkl}|^2$. The direct inequality (2.12) can be easily obtained following [2]. For this, we choose a vector field h as before. Then, we evaluate the expression

$$\int_0^T \int_\Omega (u_{i,tt} - \sigma_{ij,j}(u))h \,.\, \nabla u_i \, dx \, dt = \int_0^T \int_\Omega f_i \, h \,.\, \nabla u_i \, dx \, dt.$$

We obtain the usual equality with an additional term due to the fact that f is nonvanishing. This additional term can be easily treated using a Cauchy–Schwarz inequality, whereas the other terms are treated exactly as in [2]. Hence, we obtain the desired inequality (2.12).

We now turn to the proof of (2.13). For this, we use the classical multiplier $Mu_i = m \cdot \nabla u_i + \frac{N-1}{2} u_i$ and compute

$$\int_0^T \int_\Omega (u_{i,tt} - \sigma_{ij,j}(u))\, Mu_i \, dx\, dt = \int_0^T \int_\Omega f_i \, Mu_i \, dx\, dt,$$

Following the computations in [2], we obtain

$$\begin{aligned} \frac{1}{2} \int_0^T \int_\Gamma m \cdot \nu \sigma_{ij}(u) \varepsilon_{ij}(u)\ d\gamma\, dt &= \int_0^T e_1(t)\, dt - \int_0^T (f_i, Mu_i)\, dx\, dt \\ &\quad + \left[\int_\Omega u_{i,t} Mu_i \right]_0^T . \end{aligned} \tag{6.11}$$

Using (6.10) together with Young's inequality in the second term of the right-hand side in the above inequality, we obtain (2.13). (We refer the reader to [2] for estimating the other terms.) Hence, assumptions (H3)–(H4) are satisfied; we can therefore apply Corollary 2.2. This gives the following results.

THEOREM 6.3. *There exists $\alpha^\star > 0$ such that for all $0 < |\alpha| < \alpha^\star$, there exists $T_0 = T_0(\alpha) > 0$ such that for all $T > T_0$ and all $U^0 \in \mathcal{H}$ the solution $U(t) = \exp(-\mathcal{A}_\alpha t) U^0 = (u_1, u_1', u_2, u_2')$ of (6.8) satisfies*

$$\begin{aligned} 2 \int_0^T \int_{\Gamma_1} |\sigma_{ij}(u)\nu_j|^2\, d\gamma\, dt &\geq \frac{c_1}{2} \left(|u^1|^2 + ||u^0||_1^2 \right) \\ &\quad + \frac{c_3}{2} \left(|v^1|_{V_2'}^2 + |v^0|^2 \right), \end{aligned} \tag{6.12}$$

where the constants c_i for $i = 1, 3$ are given in Theorem 2.1.

Moreover, if in addition the solution of (6.8) satisfies

$$\sigma_{ij}(u)\nu_j = 0 \text{ on } \Gamma_1 \times (0,T), \qquad 1 \leq i \leq N,$$

then one has $u = v = 0$ in $\Omega \times [0,T]$.

We now give the dual exact controllability result. For this we consider the system

(6.13)

$$\begin{cases} y_{i,tt} - \sigma_{ij,j}(y) + \alpha z_i = 0 \quad \text{in} \quad \Omega \times (0,T), & 1 \leq i \leq N, \\ z_{i,tt} - \sigma_{ij,j}(z) + \alpha y_i = 0 \quad \text{in} \quad \Omega \times (0,T), & 1 \leq i \leq N, \\ y_i = w_i \quad \text{on} \quad \Sigma_1 = \Gamma_1 \times (0,T),\ y_i = 0 \quad \text{on} \quad \Sigma_0 = \Gamma_0 \times (0,T), & 1 \leq i \leq N, \\ z_i = 0 \quad \text{on} \quad \Sigma = \Gamma \times (0,T), & 1 \leq i \leq N, \\ (y_i, y_{i,t})(0) = (y_i^0, y_i^1), \quad (z_i, z_{i,t})(0) = (z_i^0, z_i^1) \quad \text{on} \quad \Omega, & 1 \leq i \leq N. \end{cases}$$

Since the hypotheses of Theorem 2.5 are satisfied, we have the following result.

THEOREM 6.4. *There exists $\alpha^\star > 0$ such that for all $0 < |\alpha| < \alpha^\star$, there exists $T_0 = T_0(\alpha) > 0$ such that for all $T > T_0$ and all $Y^0 = (y^0, y^1, z^0, z^1) \in (L^2(\Omega))^N \times V_1' \times (H_0^1(\Omega))^N \times (L^2(\Omega))^N$ there exists a control $w = (w_1, \ldots, w_N) \in L^2([0,T]; (L^2(\Gamma_1))^N)$ such that the solution $Y(t) = (y, y', z, z')$ of (6.13) satisfies*

$$y(.,T) = \partial_t y(.,T) = z(.,T) = \partial_t z(.,T) = 0 \text{ in } \Omega.$$

6.2. Case of different operators A_1 and A_2. In order to avoid loss of regularity of solutions, we will assume in all of this subsection that $\Gamma_0 = \emptyset$. Hence, we do not treat the case of mixed boundary conditions. Nevertheless, the results are still valid for a more general situation (see [11], [12], [13]).

Coupled wave equations with different speed of propagation. We consider the following system:

$$\begin{cases} u_{1,tt} - r_1\Delta u_1 + \alpha C u_2 = 0 \quad \text{in} \quad \Omega\times(0,T), \\ u_{2,tt} - r_2\Delta u_2 + \alpha C^\star u_1 = 0 \quad \text{in} \quad \Omega\times(0,T), \\ u_1 = 0,\ u_2 = 0 \quad \text{on} \quad \Sigma = \Gamma\times(0,T), \\ (u_1,u_{1,t})(0) = (u_1^0,u_1^1), \quad (u_2,u_{2,t})(0) = (u_2^0,u_2^1) \quad \text{on} \quad \Omega, \end{cases} \tag{6.14}$$

where $r_i > 0, i = 1,2$. We mainly keep the notation of section 6.1. We set $H = L^2(\Omega)$ and $V_1 = V_2 = H_0^1(\Omega)$ equipped, respectively, with the L^2 scalar product and the scalar product $(u,z)_i = r_i\int_\Omega \nabla u\cdot\nabla z$ and the corresponding norms for $i = 1,2$. We define the duality mappings A_1 and A_2 as in section 2. In order to apply Corollary 2.3, we just need to check that the operators A_1 and A_2 have a common basis of eigenfunctions. In [1], we proved that this holds true only for specific geometries of Ω. More precisely for domains Ω which are N-dimensional intervals $\prod_{i=1}^N(a_i,b_i)$, where $a_i < b_i$, $i = 1,\dots,N$, and $N \le 3$. The operator C is then chosen as in Corollary 2.3.

We still denote by $A_i = -r_i\,\Delta$ for $i = 1,2$ the operators A_i viewed now as unbounded operators in H acting from $D(A_1) = D(A_2) = H^2(\Omega)\cap H_0^1(\Omega)$ in H. Then, Grisvard's results imply in particular that $D(A_1) = D(A_2) = H^2(\Omega)\cap H_0^1(\Omega)$.

We define the partial natural and weakened energies by

$$e_i(t) = \frac{|u_i'(t)|^2 + r_i\,|\nabla u_i(t)|^2}{2},$$

$$\tilde{e_i}(t) = \frac{|u_i'(t)|^2_{H^{-1}(\Omega)} + |u_i(t)|^2}{2}.$$

The inequalities (2.1), (2.3), (2.8), (2.9), and (2.10) are satisfied. We set $G = L^2(\Gamma)$. Moreover, we define a continuous linear operator $B^\star$ from $D(A_1)$ to G by

$$B^\star u = \left.\frac{\partial u}{\partial\nu}\right|_\Gamma.$$

We have the following result.

THEOREM 6.5. *Assume now that Ω is an N-dimensional interval $\prod_{i=1}^N(a_i,b_i)$, where $a_i < b_i$, $i = 1,\dots,N$, with $N \le 3$, and that there exists a positive integer k_0 such that $r_2 = k_0^2 r_1$. Choose, moreover, C as in Corollary 2.3. Then there exists $\alpha^\star > 0$ such that for all $0 < |\alpha| < \alpha^\star$, there exists $T_0 = T_0(\alpha) > 0$ such that for all $T > T_0$ and all $U^0 \in \mathcal{H}$ the solution $U(t) = \exp(-\mathcal{A}_\alpha t)U^0 = (u_1, u_1', u_2, u_2')$ of (6.14) satisfies*

$$2\int_0^T\int_\Gamma \left|\frac{\partial u_1}{\partial\nu}\right|^2 d\gamma\,dt \ge \frac{d_1}{2}\left(|u_1^1|^2 + |\nabla u_1^0|^2\right) + \frac{d_3}{2}\left(|u_2^1|^2_{H^{-1}(\Omega)} + |u_2^0|^2\right), \tag{6.15}$$

where the constants d_i for $i = 1,3$, are of the form $d_i = D_i c_i$ for $i = 1,3$, where the constants c_i are given in Theorem 2.1, and where the constants D_i are independent of α and T.

Moreover, if in addition the solution of (6.14) *satisfies*

$$\frac{\partial u_1}{\partial \nu} = 0 \text{ on } \Gamma \times (0,T),$$

then one has $u_1 = u_2 = 0$ *in* $\Omega \times [0,T]$.

The proof follows the ideas of [1] and will not be detailed here. Of course, we can also derive a dual exact controllability property from the above theorem, which we do not formulate here for the sake of brevity.

Coupled wave-Petrowsky equations. We consider the following system:

$$\text{(6.16)} \qquad \begin{cases} u_{1,tt} - \Delta u_1 + \alpha C u_2 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ u_{2,tt} + \Delta^2 u_2 + \alpha C^\star u_1 = 0 \quad \text{in} \quad \Omega \times (0,T), \\ u_1 = 0,\ u_2 = \Delta u_2 = 0 \quad \text{on} \quad \Sigma = \Gamma \times (0,T), \\ (u_1, u_{1,t})(0) = (u_1^0, u_1^1), \quad (u_2, u_{2,t})(0) = (u_2^0, u_2^1) \quad \text{on} \quad \Omega, \end{cases}$$

where the coupling operator C is chosen in the next theorem. We mainly keep the notation of section 6.1. We set $H = L^2(\Omega)$ and $V_1 = H_0^1(\Omega)$ equipped, respectively, with the L^2 scalar product and the scalar product $(u,z)_1 = \int_\Omega \nabla u \cdot \nabla z$ and the corresponding norms. Moreover, we set $V_2 = H^2(\Omega) \cap H_0^1(\Omega)$ equipped with the scalar product $(u,z)_2 = \int_\Omega \Delta u \cdot \Delta z$ and the associated norm. We define the duality mappings A_1 and A_2 as in section 2. As said before, we still denote by A_i the operators A_i viewed as unbounded operators in H. We already know from the previous wave-wave case with different speeds of propagation that for domains Ω which are N-dimensional intervals, $D(A_1) = H^2(\Omega) \cap H_0^1(\Omega)$. Moreover, we proved in [1], thanks to Grisvard's regularity results, that $D(A_2) = \{u \in H^4(\Omega) \cap H_0^1(\Omega), \Delta u = 0 \text{ on } \Gamma\}$. Hence, all the integration by parts required for the definition of weak solutions of the above coupled wave-Petrowsky system are justified for data in the domain of the operator. We define the partial natural and weakened energies by

$$e_1(t) = \frac{|u_1'(t)|^2 + |\nabla u_1(t)|^2}{2},$$

$$e_2(t) = \frac{|u_2'(t)|^2 + |\Delta u_2(t)|^2}{2},$$

$$\tilde{e_1}(t) = \frac{|u_1'(t)|^2_{H^{-1}(\Omega)} + |u_1(t)|^2}{2},$$

$$\tilde{e_2}(t) = \frac{|u_2'(t)|^2_{V_2'} + |u_2(t)|^2}{2}.$$

The inequalities (2.1), (2.3), (2.8), (2.9), and (2.10) are satisfied. We set $G = L^2(\Gamma)$. Moreover, we define a continuous linear operator $B^\star$ from $D(A_1)$ to G by

$$B^\star u = \left. \frac{\partial u}{\partial \nu} \right|_\Gamma .$$

We have the following result.

THEOREM 6.6. *Let Ω be a N-dimensional interval $\prod_{i=1}^N (a_i, b_i)$, where $a_i < b_i$, $i = 1, \dots, N$, with $N \leq 3$. Assume, moreover, that there exists $d > 0$ for which $b_i - a_i = d$ for all $i = 1, \dots, N$ such that $\frac{\pi}{d\sqrt{N}} \in N^\star$. In addition, assume that for $u = \sum_{k \in (N^\star)^N} u_k e_k$ in H, Cu is defined by*

$$Cu = \sum_{k \in (N^\star)^N} w_k u_k e_{r(k)},$$

where $(w_k)_k$ is an arbitrary sequence of real numbers such that there exist w_-, w_+ with $0 < w_- \leq w_k \leq w_+$ for all k and where r is the one-to-one application defined by $r(k) = (\ell, \dots, \ell)$ for $k \in (N^\star)^N$, where $\ell = \frac{\pi}{d\sqrt{N}} \sum_{i=1}^N k_i^2$. Then, there exists $\alpha^\star > 0$ such that for all $0 < |\alpha| < \alpha^\star$, there exists $T_0 = T_0(\alpha) > 0$ such that for all $T > T_0$ and all $U^0 \in \mathcal{H}$ the solution $U(t) = (u_1, u_1', u_2, u_2')$ of (6.16) satisfies

$$2 \int_0^T \int_\Gamma \left| \frac{\partial u_1}{\partial \nu} \right|^2 d\gamma \, dt \geq \frac{c_1}{2} \left(|u_1^1|^2 + |\Delta u_1^0|^2 \right) + \frac{c_3}{2} \left(|u_2^1|_{V_2'}^2 + |u_2^0|^2 \right), \tag{6.17}$$

where the constants c_i for $i = 1, 3$ are given in Theorem 2.1.

Moreover, if in addition the solution of (6.16) satisfies

$$\frac{\partial u_1}{\partial \nu} = 0 \text{ on } \Gamma \times (0, T),$$

then one has $u_1 = u_2 = 0$ in $\Omega \times [0, T]$.

As before, we do not give the details of the proof. Moreover, a dual exact controllability result can also be stated.

Remarks and open questions. The main restrictive assumption under which the results presented in this paper are valid is the compatibility assumption (2.9). In the case of different operators A_1 and A_2 in the two coupled equations, this assumption requires, in particular, the existence of a common orthonormal basis of eigenfunctions of A_1 and A_2 and that the eigenvalues of A_2 (which in the present paper is the operator acting on the unobserved component) are, in a unique way, eigenvalues of A_1 (see Lemma 2.3). This above-mentioned compatibility assumption is required only in the starting estimate given in Lemma 4.1. The argument in the proof of this lemma is, in some sense, of "algebraic" nature. It would be interesting to know if this estimate still holds true under more general assumptions using more sophisticated tools. If it is not the case, it would be interesting to know if other weaker estimates can still lead to indirect observability and exact controllability results, and if so, in which spaces.

Another important aspect of the abstract model studied in this paper is the coercivity property given by the zero order coupling terms. It would be interesting to know if a coercivity assumption with first order coupling operators can still lead to positive indirect observability estimates. Of course, it would also be interesting to explore others classes of couplings with no coercivity properties, for instance. Finally, in subsection 6.2 we give some applications for which the involved operators do not have the same principal part. Nevertheless, the restrictions on the geometry and on the coupling term are then very severe. We conjecture that positive observability results can still be obtained in more general situations. One can note that the papers treating observability, exact controllability, or stabilization for coupled hyperbolic equations assume in general that both equations have the same principal part (see, e.g., [14], [15]).

Acknowledgments. The author is very grateful to the referees and the associate editor for their valuable comments and suggestions.

HOW TO GET A CONSERVATIVE WELL-POSED LINEAR SYSTEM OUT OF THIN AIR. PART II. CONTROLLABILITY AND STABILITY*

MARIUS TUCSNAK† AND GEORGE WEISS‡

Abstract. Let A_0 be a possibly unbounded positive operator on the Hilbert space H, which is boundedly invertible. Let C_0 be a bounded operator from $\mathcal{D}(A_0^{1/2})$ (with the norm $\|z\|_{1/2}^2 = \langle A_0 z, z\rangle$) to another Hilbert space U. In Part I of this work we have proved that the system of equations

$$\ddot{z}(t) + A_0 z(t) + \frac{1}{2} C_0^* C_0 \dot{z}(t) = C_0^* u(t),$$
$$y(t) = -C_0 \dot{z}(t) + u(t)$$

determines a well-posed linear system Σ with input u and output y, input and output space U, and state space $X = \mathcal{D}(A_0^{1/2}) \times H$. Moreover, Σ is conservative, which means that a certain energy balance equation is satisfied both by the trajectories of Σ and by those of its dual system. In this paper we show that Σ is exactly controllable if and only if it is exactly observable, if and only if it is exponentially stable. Moreover, if we denote by A the generator of the contraction semigroup associated with Σ (which acts on X), then Σ is exponentially stable if and only if one of the entries in the second column of $(i\omega I - A)^{-1}$ is uniformly bounded as a function of $\omega \in \mathbb{R}$. We also show that, under a mild assumption, Σ is approximately controllable if and only if it is approximately observable, if and only if it is strongly stable, if and only if the dual system is strongly stable. We prove many related results and we give examples based on wave and beam equations.

Key words. well-posed linear system, exponential stability, strong stability, conservative system, exact controllability, beam equation, wave equation

1. Introduction and main results.

This paper is a continuation of our paper [35] in which we have investigated a class of conservative linear systems with a special structure, which occur often in applications. These systems are described by a second order differential equation (in a Hilbert space) and an output equation, and they may have unbounded control and observation operators. The main aim of [35] was to prove the wellposedness, conservativity, and other regularity properties of such systems. Here we investigate conditions under which such systems are exponentially stable or strongly stable. It turns out that these stability properties are equivalent to certain controllability and observability properties as well as to certain estimates.

We recall the construction from the paper [35] in order to be able to state the new results. Let H be a Hilbert space, and let $A_0 : \mathcal{D}(A_0) \to H$ be a self-adjoint, positive, and boundedly invertible operator. We introduce the scale of Hilbert spaces H_α, $\alpha \in \mathbb{R}$, as follows: for every $\alpha \geq 0$, $H_\alpha = \mathcal{D}(A_0^\alpha)$, with the norm $\|z\|_\alpha = \|A_0^\alpha z\|_H$. The space $H_{-\alpha}$ is defined by duality with respect to the pivot space H as follows: $H_{-\alpha} = H_\alpha^*$ for $\alpha > 0$. Equivalently, $H_{-\alpha}$ is the completion of H with respect to the

norm $\|z\|_{-\alpha} = \left\|A_0^{-\alpha} z\right\|_H$. The operator A_0 can be extended (or restricted) to each H_α such that it becomes a bounded operator

$$A_0 : H_\alpha \to H_{\alpha-1} \qquad \forall\, \alpha \in \mathbb{R}.$$

Let C_0 be a bounded linear operator from $H_{\frac{1}{2}}$ to U, where U is another Hilbert space. We identify U with its dual, so that $U = U^*$. We denote $B_0 = C_0^*$ so that $B_0 \in \mathcal{L}(U, H_{-\frac{1}{2}})$. The class of systems studied in [35] and also here is described by

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2} z(t) + A_0 z(t) + \frac{1}{2} B_0 \frac{\mathrm{d}}{\mathrm{d}t} C_0 z(t) = B_0 u(t), \tag{1.1}$$

$$z(0) = z_0, \qquad \dot{z}(0) = w_0, \tag{1.2}$$

$$y(t) = -\frac{\mathrm{d}}{\mathrm{d}t} C_0 z(t) + u(t), \tag{1.3}$$

where $t \in [0, \infty)$ is the time. The equation (1.1) is understood as an equation in $H_{-\frac{1}{2}}$, i.e., all the terms are in $H_{-\frac{1}{2}}$. Most of the linear equations modelling the damped vibrations of elastic structures can be written in the form (1.1), where z stands for the displacement field and the term $B_0 \frac{\mathrm{d}}{\mathrm{d}t} C_0 z(t)$, informally written as $B_0 C_0 \dot{z}(t)$, represents a viscous feedback damping. The signal $u(t)$ is an external input with values in U (often a displacement, a force, or a moment acting on the boundary), and the signal $y(t)$ is the output (measurement) with values in U as well. The state $x(t)$ of this system and its state space X are defined by

$$x(t) = \begin{bmatrix} z(t) \\ \dot{z}(t) \end{bmatrix}, \qquad X = H_{\frac{1}{2}} \times H.$$

We will use some fairly standard notation for certain function spaces: we refer to [35, section 1] for the meaning of $\mathcal{H}^p(0,\infty;W)$, $\mathcal{H}^p_{loc}(0,\infty;W)$ (with $p \in \mathbb{N}$), $C^n(0,\infty;W)$, and $BC^n(0,\infty;W)$ (with $n \in \{0,1,2,\ldots\}$). We write C instead of C^0.

We assume that the reader understands the concepts of a well-posed linear system and of a conservative linear system. These were explained in [35, sections 1, 3, 4] with suitable references to the literature. We will often use results from [35], which we refer to as "Part I." In such cases, we put the prefix I in front of the number of the item quoted. For example, Theorem I.1.4 refers to Theorem 1.4 in Part I, and (I.4.2) refers to formula (4.2) in Part I. The first main result of [35] has been the following (Theorem I.1.1).

THEOREM 1.1. *With the above assumptions, the equations* (1.1)–(1.3) *determine a conservative linear system* Σ *in the following sense:*

There exists a conservative linear system Σ *whose input and output spaces are both* U *and whose state space is* X. *If* $u \in L^2([0,\infty), U)$ *is the input function,* $x_0 = \left[\begin{smallmatrix} z_0 \\ w_0 \end{smallmatrix}\right] \in X$ *is the initial state,* $x = \left[\begin{smallmatrix} z \\ w \end{smallmatrix}\right]$ *is the corresponding state trajectory, and* y *is the corresponding output function, then*

(1)

$$z \in BC(0,\infty; H_{\frac{1}{2}}) \cap BC^1(0,\infty; H) \cap \mathcal{H}^2_{loc}(0,\infty; H_{-\frac{1}{2}}).$$

(2) *The two components of* x *are related by* $w = \dot{z}$.

(3) $C_0 z \in \mathcal{H}^1(0,\infty;U)$ *and the equations* (1.1) *(in* $H_{-\frac{1}{2}}$*) and* (1.3) *(in* U*) hold for almost every* $t \geq 0$ *(hence,* $y \in L^2([0,\infty),U)$*).*

If $\dot{z}$ is a continuous function of t with values in $H_{\frac{1}{2}}$ (see Theorems I.1.2 and I.1.4 for sufficient conditions for this to be true), then (1.1) and (1.3) can be rewritten as

$$\ddot{z}(t) + A_0 z(t) + \frac{1}{2} B_0 C_0 \dot{z}(t) = B_0 u(t), \tag{1.4}$$

$$y(t) = -C_0 \dot{z}(t) + u(t). \tag{1.5}$$

We introduce the space $Z_0 = H_1 + A_0^{-1} B_0 U$, which is a Hilbert space if we define on it a suitable norm; see Theorem I.1.2. We can rewrite the equations (1.4), (1.5) as a first order system as follows:

$$\begin{cases} \dot{x}(t) &= Ax(t) + Bu(t), \\ y(t) &= \overline{C}x(t) + u(t), \end{cases} \tag{1.6}$$

where

$$A = \begin{bmatrix} 0 & I \\ -A_0 & -\frac{1}{2} B_0 C_0 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 \\ B_0 \end{bmatrix}, \tag{1.7}$$

$$\mathcal{D}(A) = \left\{ \begin{bmatrix} z \\ w \end{bmatrix} \in H_{\frac{1}{2}} \times H_{\frac{1}{2}} \;\middle|\; A_0 z + \frac{1}{2} B_0 C_0 w \in H \right\}, \tag{1.8}$$

$$\overline{C} : Z_0 \times H_{\frac{1}{2}} \to U, \qquad \overline{C} = \begin{bmatrix} 0 & -C_0 \end{bmatrix}. \tag{1.9}$$

We denote by C the restriction of $\overline{C}$ to $\mathcal{D}(A)$. A is the generator of a strongly continuous semigroup of contractions on X, denoted $\mathbb{T} = (\mathbb{T}_t)_{t \geq 0}$. For the concepts of semigroup generator, control operator, observation operator, and transfer function of a well-posed linear system, we refer to Weiss [31, 32] or to section I.3. We denote by $\mathbb{C}_\omega$ the open right half-plane in $\mathbb{C}$ where $\operatorname{Re} s > \omega$. We know from Proposition I.5.3 that for any $s \in \rho(A)$ (in particular, for any $s \in \mathbb{C}_0$) the operator $s^2 I + A_0 + \frac{s}{2} B_0 C_0 \in \mathcal{L}(H_{\frac{1}{2}}, H_{-\frac{1}{2}})$ has a bounded inverse denoted $V(s)$:

$$V(s) = \left(s^2 I + A_0 + \frac{s}{2} B_0 C_0 \right)^{-1} \in \mathcal{L}(H_{-\frac{1}{2}}, H_{\frac{1}{2}}). \tag{1.10}$$

The following proposition is a restatement of a part of Theorem I.1.3.

PROPOSITION 1.2. *With the notation of Theorem* 1.1 *and* (1.7)–(1.10)*, the semigroup generator of* Σ *is* A*, its control operator is* B*, and its observation operator is* C*. The transfer function of* Σ *is given for all* $s \in \mathbb{C}_0$ *by*

$$\mathbf{G}(s) = \overline{C}(sI - A)^{-1} B + I = I - C_0 s V(s) B_0,$$

and we have $\|\mathbf{G}(s)\| \leq 1$ *for all* $s \in \mathbb{C}_0$*.*

Now we have all the necessary ingredients to state the new results of this paper. The following theorems use various controllability, observability, and stability concepts. The precise definition of these concepts is given in section 2.

THEOREM 1.3. *With the above notation, the following assertions are equivalent:*

(1) *The pair* (A, B) *is exactly controllable (in some finite time).*
(2) *The pair* (A, C) *is exactly observable (in some finite time).*
(3) *The semigroup* $\mathbb{T}$ *is exponentially stable.*
(4) *The pair* (A, B) *is optimizable.*
(5) *The pair* (A, C) *is estimatable.*
(6) *We have* $\sup_{s\in\mathbb{C}_0} \|A_0^{\frac{1}{2}} V(s)\|_{\mathcal{L}(H)} < \infty$.
(7) *We have* $\sup_{s\in\mathbb{C}_0} \|sV(s)\|_{\mathcal{L}(H)} < \infty$.
(8) *For a dense subset* E *of* $\mathbb{R}$, *we have* $iE \subset \rho(A)$ *and* $\sup_{\omega\in E} \|A_0^{\frac{1}{2}} V(i\omega)\|_{\mathcal{L}(H)} < \infty$.
(9) *For a dense subset* E *of* $\mathbb{R}$, *we have* $iE \subset \rho(A)$ *and* $\sup_{\omega\in E} \|\omega V(i\omega)\|_{\mathcal{L}(H)} < \infty$.

A more precise statement concerning the equivalence of (1), (2), and (3), which gives some information on the time of exact controllability and observability, and which is valid for any conservative system, is Proposition 3.2. The equivalence of (1)–(5) remains valid for *every* conservative system; see Proposition 3.3.

By a well-known theorem of Prüss and Falun, an operator semigroup $\mathbb{T}$ with generator A is exponentially stable if and only if $(sI - A)^{-1}$ is uniformly bounded on $\mathbb{C}_0$. We refer to section 2 for precise references, further comments, and related results (Propositions 2.4 and 2.5). In the specific case of the semigroup generated by A from (1.7)–(1.8), the resolvent $(sI - A)^{-1}$ can be written as a 2×2 matrix of operators; see Proposition I.5.3 (or formula (4.1) later in this paper). Thus, to verify the exponential stability of $\mathbb{T}$, we would have to verify that the four entries of this 2×2 matrix are all uniformly bounded on $\mathbb{C}_0$. However, conditions (6) and (7) in Theorem 1.3 tell us that, in fact, we have to verify only one of the two entries in the second column of the matrix of $(sI - A)^{-1}$. Conditions (8) and (9) tell us that, in fact, it suffices to check the boundedness of one of these entries on a dense subset of the imaginary axis, and we can still conclude exponential stability.

The version of this theorem corresponding to bounded B and C, i.e., with $C_0 \in \mathcal{L}(H, U)$, is in Liu [22, sections 2–3] but without conditions (4)–(7). Using the boundedness of C_0 (and hence also of B_0), Liu was able to give in [22, Theorem 3.4] also other, Hautus-type conditions which are equivalent to the exponential stability of $\mathbb{T}$. For unbounded C_0, we were only able to obtain a Hautus-type estimate as a necessary condition for exponential stability; see Proposition 4.1.

We mention that semigroups of the type discussed in this paper do not necessarily satisfy the spectrum determined growth condition. For a counterexample (a damped wave equation on a compact manifold) see Lebeau [19].

In the proof of Theorem 1.3 (more precisely, to show that (6)$\Longrightarrow$(3)) we use the following proposition, which is of independent interest. For bounded C_0 this proposition follows easily from [22, Theorem 3.4], but for unbounded C_0 the proof is more delicate (see section 4). Related results for a bounded (possibly not positive) operator in place of $C_0^* C_0$ were given in Liu, Liu, and Rao [23].

PROPOSITION 1.4. *With the above notation, suppose that* C_0 *is bounded from below in the sense that there exists a* $c > 0$ *such that* $\|C_0 z\|_U \geq c\|z\|_H$ *for all* $z \in H_{\frac{1}{2}}$.

Then $\mathbb{T}$ *is exponentially stable.*

A result similar to Theorem 1.3 holds also for strong stability, with an additional assumption on the spectrum $\sigma(A_0)$.

THEOREM 1.5. *With the above notation, assume that* $\sigma(A_0)$ *is countable. (This happens, e.g., if* A_0^{-1} *is compact.) Then the following assertions are equivalent:*

(1) $\mathbb{T}$ *is strongly stable.*
(2) *The pair* (A, C) *is exactly observable in infinite time.*

(3) *The pair* (A, C) *is approximately observable in infinite time.*
(4) $\mathbb{T}$ *is weakly stable (equivalently,* $\mathbb{T}^*$ *is weakly stable).*
(5) $\mathbb{T}^*$ *is strongly stable.*
(6) *The pair* (A, B) *is exactly controllable in infinite time.*
(7) *The pair* (A, B) *is approximately controllable in infinite time.*
(8) *For any* $z \in H_1$*, if* z *is an eigenvector of* A_0*, then* $C_0 z \neq 0$*.*

Note that the statement "A_0^{-1} is compact" does *not* imply that $(sI - A)^{-1}$ is compact (to see this, take $U = H$ and $C_0 = A_0^{1/2}$). This theorem follows from a more general result concerning all conservative systems; see Proposition 3.4 here. In the proof, we also use the famous strong stability theorem of Arendt and Batty [2].

Systems with A and B as above have been studied in Guo and Luo [10, 11], establishing connections between the exponential stability of A and the exact controllability of the undamped system $\ddot{z}(t) + A_0 z(t) = B_0 u(t)$, under the additional hypothesis that the undamped system is well-posed. (Unfortunately, the main result on diagonal systems in [10] (Theorem 4) is incorrectly formulated, and it is also incorrectly quoted in [11].) In [11] the emphasis is on eigenvalues and eigenvectors of A, assuming that the eigenvalues of A_0 satisfy a gap condition and $u(t)$ is scalar.

In section 2 we give the background needed here. Section 3 concerns the stability properties of conservative systems so that the results there refer to a more general context than the main results stated earlier. In section 4 we prove our main results, while section 5 is devoted to two examples: a system involving the beam equation and another one based on the wave equation.

2. Background on controllability, observability, optimizability, estimatability, and stability. In this section we recall some controllability, observability, and stability concepts, quoting the relevant literature. Throughout this section, U, X, and Y are Hilbert spaces and $A : \mathcal{D}(A) \to X$ is the generator of a strongly continuous semigroup $\mathbb{T} = (\mathbb{T}_t)_{t \geq 0}$ on X. The space X_1 is $\mathcal{D}(A)$ with the norm $\|z\|_1 = \|(\beta I - A)z\|$, where $\beta \in \rho(A)$ is fixed, while X_{-1} is the completion of X with respect to the norm $\|z\|_{-1} = \|(\beta I - A)^{-1} z\|$. We assume that the reader understands the concept of an admissible (in particular, infinite-time admissible) control operator for $\mathbb{T}$. This has been presented in section I.2 with suitable references. If $B \in \mathcal{L}(U, X_{-1})$ is admissible, then for every $\tau \geq 0$ we denote by Φ_τ the operator

$$\Phi_\tau u = \int_0^\tau \mathbb{T}_{t-\sigma} B u(\sigma)\, \mathrm{d}\sigma \tag{2.1}$$

as in (I.2.3). We have $\Phi_\tau \in \mathcal{L}(L^2([0,\infty), U), X)$. If B is admissible, then for every $x_0 \in X$ and every $u \in L^2([0,\infty), U)$, the function $x(t) = \mathbb{T}_t x_0 + \Phi_t u$ is called the *state trajectory* corresponding to the initial state x_0 and the input function u. We have $x \in \mathcal{H}^1_{loc}(0,\infty; X)$ and $\dot{x}(t) = Ax(t) + Bu(t)$ (equality in X_{-1}) for almost every $t \geq 0$. If, moreover, B is infinite-time admissible, then we denote, as in (I.2.5),

$$\tilde{\Phi} u = \lim_{\tau \to \infty} \int_0^\tau \mathbb{T}_t B\, u(t)\, \mathrm{d}t, \tag{2.2}$$

and we have $\tilde{\Phi} \in \mathcal{L}(L^2([0,\infty), U), X)$.

Similarly, we assume that the reader understands the concepts of an admissible (in particular, infinite-time admissible) observation operator for $\mathbb{T}$, also presented in section I.2. If $C \in \mathcal{L}(X_1, Y)$ is admissible, then we denote by Ψ the unique continuous

operator from X to $L^2_{loc}([0,\infty),Y)$ such that

$$(\Psi x_0)(t) = C\mathbb{T}_t x_0 \qquad \forall\, x_0 \in \mathcal{D}(A). \tag{2.3}$$

In particular, if C is infinite-time admissible, then $\Psi \in \mathcal{L}(X, L^2([0,\infty),Y))$. Recall that B is an (infinite-time) admissible control operator for $\mathbb{T}$ if and only if B^* is an (infinite-time) admissible observation operator for $\mathbb{T}^*$.

DEFINITION 2.1. *Let A be the generator of a strongly continuous semigroup $\mathbb{T}$ on X, and let $B \in \mathcal{L}(U, X_{-1})$ be an admissible control operator for $\mathbb{T}$.*

The pair (A,B) is exactly controllable *in time $T>0$ if for every $x_0 \in X$, there exists a $u \in L^2([0,T],U)$ such that $\Phi_T u = x_0$.*

(A,B) is exactly controllable *if the above property holds for some $T>0$.*

(A,B) is exactly controllable in infinite time *if B is infinite-time admissible and the operator $\tilde{\Phi}$ from (2.2) is onto.*

(A,B) is approximately controllable *in time $T>0$ if $Ran\Phi_T$ is dense in X.*

(A,B) is approximately controllable in infinite time *if $\cup_{\tau>0}\mathrm{Ran}\,\Phi_\tau$ is dense in X.*

(A,B) is optimizable *if for any $x_0 \in X$, there exists $u \in L^2([0,\infty),U)$ such that the state trajectory corresponding to x_0 and u is in $L^2([0,\infty),X)$.*

Note that the exact (or approximate) controllability in infinite time of (A,B) does *not* imply its exact (or approximate) controllability in time T for some $T>0$. Clearly, exact controllability implies optimizability and also approximate controllability in some finite time. Optimizability is one possible generalization of the concept of stabilizability, as known from finite-dimensional control theory.

Remark 2.1. Let $B \in \mathcal{L}(U, X_{-1})$ be an infinite-time admissible control operator for $\mathbb{T}$. Then (A,B) is approximately controllable in infinite time if and only if the range of $\tilde{\Phi}$ from (2.2) is dense in X. The proof is easy.

Now we introduce the corresponding observability concepts via duality.

DEFINITION 2.2. *Suppose that $C \in \mathcal{L}(X_1,Y)$ is an admissible observation operator for $\mathbb{T}$. (Equivalently, C^* is an admissible control operator for the adjoint semigroup $\mathbb{T}^*$.) We say that (A,C) is* exactly observable *(in time T) (in infinite time) if (A^*,C^*) is exactly controllable (in time T) (in infinite time). Similarly, (A,C) is* approximately observable *(in time T) (in infinite time) if (A^*,C^*) is approximately controllable (in time T) (in infinite time). Finally, the pair (A,C) is called* estimatable *if (A^*,C^*) is optimizable.*

Let Ψ be the operator defined in (2.3), and for every $\tau \geq 0$ put $\Psi_\tau = \mathbf{P}_\tau \Psi$. Then (A,C) is exactly observable in time $T>0$ if and only if Ψ_T is bounded from below. (A,C) is exactly observable in infinite time if and only if C is infinite-time admissible and Ψ is bounded from below. (A,C) is approximately observable in time T (or in infinite time) if and only if $\Psi_T x_0 = 0$ (or $\Psi x_0 = 0$) implies $x_0 = 0$.

Recall that the *growth bound* of a strongly continuous semigroup $\mathbb{T}$ is $\omega_0(\mathbb{T}) = \lim_{t\to\infty} \frac{1}{t}\log\|\mathbb{T}_t\| = \inf_{t>0}\frac{1}{t}\log\|\mathbb{T}_t\|$; see, for example, Pazy [24].

DEFINITION 2.3. *The semigroup $\mathbb{T}$ is* exponentially stable *if its growth bound is negative: $\omega_0(\mathbb{T})<0$. $\mathbb{T}$ is* strongly stable *if*

$$\lim_{t\to\infty}\|\mathbb{T}_t x_0\| = 0 \qquad \forall\, x_0 \in X.$$

Finally, $\mathbb{T}$ is weakly stable *if $\lim_{t\to\infty}\langle \mathbb{T}_t x_0, y_0\rangle = 0$ for all $x_0, y_0 \in X$.*

Let $\mathbb{T}$ be a strongly continuous semigroup on X with generator A. A well-known spectral mapping result of Prüss [25, p. 852] implies that if the function $\|(sI-A)^{-1}\|$ is bounded on $\mathbb{C}_0$, then $\mathbb{T}$ is exponentially stable. A little later and independently, this

result was explicitly stated and proved by Falun [13]. A short proof was given in Weiss [30, section 4]. Here we need a result which is closely related to the one just mentioned, without being an obvious consequence of it. The result is very slightly more general than another result of Falun; see [13, Theorem 3]. Moreover, the proposition below gives an estimate for the growth bound $\omega_0(\mathbb{T})$.

PROPOSITION 2.4. *Let $\mathbb{T}$ be a strongly continuous semigroup on X with generator A. Assume that $\omega_0(\mathbb{T}) \le 0$ and E is a dense subset of $\mathbb{R}$ such that $iE \subset \rho(A)$ and*

$$\|(i\omega I - A)^{-1}\| \le M \qquad \forall\, \omega \in E$$

for some $M > 0$. Then $\mathbb{T}$ is exponentially stable; more precisely, $\omega_0(\mathbb{T}) \le -\frac{1}{M}$.

Proof. By a result in Butzer and Berens [7, p. 31] all numbers $s \in \mathbb{C}$ with $|\operatorname{Re} s| < \frac{1}{M}$ (this is a vertical strip) belong to $\rho(A)$, and we have

$$\|(sI - A)^{-1}\| \le \frac{M}{1 - |\operatorname{Re} s| \cdot M} \quad \text{for} \quad |\operatorname{Re} s| < \frac{1}{M}. \tag{2.4}$$

On the other hand, we know from the Hille–Yosida theorem that $\|(sI - A)^{-1}\|$ is bounded on any half-plane $\mathbb{C}_\gamma$ with $\gamma > 0$. This fact, combined with (2.4), shows that $\|(sI - A)^{-1}\|$ is bounded on any half-plane $\mathbb{C}_\alpha$ with $\alpha > -\frac{1}{M}$. Now by yet another result of Falun [13, Theorem 4] we conclude that $\omega_0(\mathbb{T}) \le -\frac{1}{M}$. (The last step is equivalent to applying the Prüss–Huang result mentioned before the proposition for the semigroups generated by $A + \lambda I$ with $\lambda < \frac{1}{M}$.) ∎

PROPOSITION 2.5. *Suppose that X, $\mathbb{T}$, A, U, and B are as in Definition 2.1. Then the following three statements are equivalent:*

(1) *$\mathbb{T}$ is exponentially stable.*

(2) *(A, B) is optimizable, $\mathbb{C}_0 \subset \rho(A)$, and for some $M > 0$*

$$\left\|(sI - A)^{-1}B\right\|_{\mathcal{L}(U,X)} \le M \qquad \forall\, s \in \mathbb{C}_0.$$

(3) *(A, B) is optimizable, $\omega_0(\mathbb{T}) \le 0$, there exists a dense subset of $\mathbb{R}$, denoted E, such that $iE \subset \rho(A)$, and for some $M > 0$*

$$\left\|(i\omega I - A)^{-1}B\right\|_{\mathcal{L}(U,X)} \le M \qquad \forall\, \omega \in E.$$

Proof. The equivalence of (1) and (2) is exactly Proposition 5.1 in Weiss and Rebarber [33]. It is easy to see that (1) implies (3) with $E = \mathbb{R}$ (by also using (2) and limits as $s \to i\omega$). Now suppose that (3) holds (this implies $\mathbb{C}_0 \subset \rho(A)$). We argue as in the proof of [33, Proposition 5.1], obtaining formula (5.1) from [33] valid for all $s \in \mathbb{C}_0$. Taking limits, we see that this formula holds also with $i\omega$ in place of $s \in \mathbb{C}_0$, where $\omega \in E$. Continuing to reason as in [33], we obtain that $(i\omega I - A)^{-1}$ is uniformly bounded as a function of $\omega \in E$. Since $\omega_0(\mathbb{T}) \le 0$, we can apply Proposition 2.4 to conclude that $\mathbb{T}$ is exponentially stable. ∎

Observability (or dually, controllability) and strong stability concepts are linked to properties of Lyapunov equations, and we state in dual form the following result from section 3 of Hansen and Weiss [12].

PROPOSITION 2.6. *Let A be the generator of the strongly continuous semigroup $\mathbb{T}$ on X, and let $C \in \mathcal{L}(X_1, Y)$ be an admissible observation operator for $\mathbb{T}$. Then the following three statements are equivalent:*

(a) *There exist operators $\Pi \in \mathcal{L}(X)$, $\Pi \ge 0$, which satisfy the following equation:*

$$A^*\Pi z + \Pi A z = -C^*Cz \qquad \forall\, z \in \mathcal{D}(A). \tag{2.5}$$

(b) *C is an infinite-time admissible observation operator for $\mathbb{T}$.*
(c) *There exists an operator $P \in \mathcal{L}(X)$ such that for any $z \in \mathcal{D}(A)$*

$$Pz = \lim_{\tau \to \infty} \int_0^\tau \mathbb{T}_t^* C^* C \mathbb{T}_t z \, \mathrm{d}t. \tag{2.6}$$

Moreover, if C is infinite-time admissible, then the following statements hold:
(d) *P from (2.6) is the smallest nonnegative solution of (2.5).*
(e) *If P is invertible, then $\mathbb{T}$ is strongly stable.*
(f) *If $\mathbb{T}$ is strongly stable, then P is the unique self-adjoint solution of (2.5).*
(g) *If $\mathbb{T}$ is uniformly bounded and $P > 0$, then $\mathbb{T}$ is weakly stable.*

The operator P introduced above is called *the observability Gramian* of (A, C), and (2.5) is called a *Lyapunov equation*. Note that, in terms of the operator Ψ from (2.3), we have $P = \Psi^* \Psi$. The following is well known and easy to prove.

PROPOSITION 2.7. *Suppose that C is an infinite-time admissible observation operator for the semigroup $\mathbb{T}$ generated by A. Then (A, C) is approximately observable in infinite time if and only if $P > 0$ (where P is the observability Gramian of (A, C)).*

The *controllability Gramian* of (A, B) is, by definition, the observability Gramian of (A^*, B^*). Thus, the controllability Gramian of (A, B) is defined by

$$Rx = \lim_{\tau \to \infty} \int_0^\tau \mathbb{T}_t B B^* \mathbb{T}_t^* x \, \mathrm{d}t \qquad \forall\, x \in \mathcal{D}(A^*), \tag{2.7}$$

we have $R = \tilde{\Phi}\tilde{\Phi}^*$, and the Lyapunov equation satisfied by R is

$$RA^* z + ARz = -BB^* z \qquad \forall\, z \in \mathcal{D}(A^*).$$

The dual version of Proposition 2.6 is straightforward.

For more details on Gramians we refer to Hansen and Weiss [12], Jacob and Partington [14], Russell and Weiss [28], and Grabowski [8]. For more details on exact controllability in an operator-theoretic setting we also refer to Avdonin and Ivanov [3], Jacob and Zwart [15], Rebarber and Weiss [27], Tucsnak and Weiss [29], and the references therein. In the PDE setting, the relevant literature is overwhelming, and we mention the books of Lions [20], Lagnese and Lions [17], Bensoussan et al. [6], Komornik [16], and the paper of Bardos, Lebeau, and Rauch [5].

3. Conservative linear systems. Recall from section I.3 that for any well-posed system Σ with input function u, state trajectory x, and output function y,

$$\begin{bmatrix} x(\tau) \\ \mathbf{P}_\tau y \end{bmatrix} = \Sigma_\tau \begin{bmatrix} x(0) \\ \mathbf{P}_\tau u \end{bmatrix}, \tag{3.1}$$

where $\mathbf{P}_\tau$ denotes the truncation of a function to $[0, \tau]$ and

$$\Sigma_\tau = \begin{bmatrix} \mathbb{T}_\tau & \Phi_\tau \\ \Psi_\tau & \mathbb{F}_\tau \end{bmatrix}. \tag{3.2}$$

We denote the input, state, and output spaces of Σ by U, X, and Y, respectively. Then the operators Σ_τ appearing above are bounded from $X \times L^2([0,\tau], U)$ to $X \times L^2([0,\tau], Y)$, which means that for some $c_\tau \geq 0$

$$\|x(\tau)\|^2 + \int_0^\tau \|y(t)\|^2 \, \mathrm{d}t \leq c_\tau^2 \left(\|x(0)\|^2 + \int_0^\tau \|u(t)\|^2 \, \mathrm{d}t \right).$$

As explained in section I.1, the system Σ is *conservative* if the operators Σ_τ are unitary from $X \times L^2([0,\tau],U)$ to $X \times L^2([0,\tau],Y)$. This implies that for any input function $u \in \mathcal{H}^1(0,\infty;U)$ and any initial state $x(0) = x_0 \in X$ with $Ax_0 + Bu(0) \in X$, the function $\|x(t)\|^2$ is in $C^1[0,\infty)$ and

$$\frac{\mathrm{d}}{\mathrm{d}t}\|x(t)\|^2 = \|u(t)\|^2 - \|y(t)\|^2 \qquad \forall\, t \geq 0; \tag{3.3}$$

see Proposition I.4.3. Conversely, if (3.3) holds for both the system Σ and for its dual system Σ^d, then Σ is conservative; see Corollary I.4.4.

PROPOSITION 3.1. *Let Σ be a conservative linear system with input space U, state space X, output space Y, semigroup $\mathbb{T}$, control operator B, observation operator C, and transfer function $\mathbf{G}$. Then the following statements are true:*

(1) *$\mathbb{T}$ is a semigroup of contractions.*
(2) *B is infinite-time admissible.*
(3) *C is infinite-time admissible.*
(4) *$\|\mathbf{G}(s)\| \leq 1$ for all $s \in \mathbb{C}_0$.*

Indeed, the above proposition is an immediate consequence of Proposition I.4.5 (which concerns the larger class of dissipative linear systems). The following proposition is probably well known (especially the equivalence of (2) and (3)), but we are not aware of a reference which states the equivalence of all three conditions.

PROPOSITION 3.2. *With the notation of Proposition* 3.1 *and denoting the generator of $\mathbb{T}$ by A for each $\tau > 0$, the following statements are equivalent:*

(1) *The pair (A,B) is exactly controllable in time τ.*
(2) *The pair (A,C) is exactly observable in time τ.*
(3) *$\|\mathbb{T}_\tau\| < 1$ (in particular, $\mathbb{T}$ is exponentially stable).*

Proof. (3) $\Longrightarrow$ (2) With the notation from (3.2), it is clear that for all $x_0 \in X$

$$\|\mathbb{T}_\tau x_0\|^2 + \|\Psi_\tau x_0\|^2 = \|x_0\|^2 \qquad \forall\, \tau \geq 0. \tag{3.4}$$

If (3) holds, then $\|\mathbb{T}_\tau\|^2 = 1 - \varepsilon^2$ with $\varepsilon > 0$. Now (3.4) implies that $\|\Psi_\tau x_0\|^2 \geq \varepsilon^2\|x_0\|^2$, so that Σ is exactly observable in time τ.

(2) $\Longrightarrow$ (3) If (2) holds, then there exists $\varepsilon > 0$ such that $\|\Psi_\tau x_0\| \geq \varepsilon\|x_0\|$ for all $x_0 \in X$. Now (3.4) implies that $\|\mathbb{T}_\tau x_0\|^2 \leq (1-\varepsilon^2)\|x_0\|^2$; hence $\|\mathbb{T}_\tau\| < 1$.

(3) $\Longleftrightarrow$ (1) (3) is equivalent to the fact that $\|\mathbb{T}_\tau^*\| < 1$. (1) is equivalent to the fact that (A^*,B^*) is exactly observable in time τ. Since the dual system Σ^d is conservative, according to Proposition I.4.2 and the equivalence of (2) and (3) proved earlier, we get that (1) is equivalent to (3). ∎

The equivalence of (1)–(5) in Theorem 1.3 is an immediate consequence of Theorem 1.1, Proposition 1.2, and the following simple result about conservative systems.

PROPOSITION 3.3. *With the notation of Proposition* 3.2*, the following five statements are equivalent:*

(1) *The pair (A,B) is exactly controllable.*
(2) *The pair (A,C) is exactly observable.*
(3) *$\mathbb{T}$ is exponentially stable.*
(4) *The pair (A,B) is optimizable.*
(5) *The pair (A,C) is estimatable.*

Proof. The equivalence of (1)–(3) follows from the previous proposition. It is well known and easy to see that (1) implies (4) and (2) implies (5) (for any well-posed system). Suppose that (5) holds. We know from Proposition 3.1 that C is infinite-time admissible. Now it follows from [33, Proposition 5.5] that (3) holds. The proof of (4)$\Longrightarrow$(3) is similar, by using the dual version of [33, Proposition 5.5]. ∎

Another result linking strong stability, observability, and controllability of conservative systems is the following. It is related to Proposition 6 in [34].

PROPOSITION 3.4. *Let Σ, $\mathbb{T}$, A, B, and C be as in Proposition 3.2. Assume that the intersection $\sigma(A) \cap i\mathbb{R}$ is countable. (This happens, for example, if $(\beta I - A)^{-1}$ is compact for some $\beta \in \rho(A)$.) Then the following seven assertions are equivalent:*

(1) *$\mathbb{T}$ is strongly stable.*

(2) *The pair (A, C) is exactly observable in infinite time.*

(3) *The pair (A, C) is approximately observable in infinite time.*

(4) *$\mathbb{T}$ is weakly stable (equivalently, $\mathbb{T}^*$ is weakly stable).*

(5) *$\mathbb{T}^*$ is strongly stable.*

(6) *The pair (A, B) is exactly controllable in infinite time.*

(7) *The pair (A, B) is approximately controllable in infinite time.*

Proof. (1) $\Longrightarrow$ (2) If $\mathbb{T}$ is strongly stable, then we see from (3.4) that $\lim_{\tau \to \infty} \|\Psi_\tau x_0\| = \|x_0\|$. This implies that Ψ is an isometry from X to $L^2([0,\infty), Y)$.

(2) $\Longrightarrow$ (3) This implication is obvious.

(3) $\Longrightarrow$ (4) The fact that Σ is conservative implies that C is infinite-time admissible. According to Proposition 2.7, (3) means that $P > 0$, where P is the observability Gramian. By the last part of Proposition 2.6, $\mathbb{T}$ is weakly stable.

(4) $\Longrightarrow$ (1) Since $\mathbb{T}$ is weakly stable, A has no eigenvalues on $i\mathbb{R}$. Together with the assumption that $\sigma(A) \cap i\mathbb{R}$ is countable, this means that the conditions of the famous stability theorem of Arendt and Batty [2] are satisfied. According to this theorem, $\mathbb{T}$ is strongly stable.

(4) $\Longleftrightarrow$ (5) $\Longleftrightarrow$ (6) $\Longleftrightarrow$ (7) This is similar to the equivalence of (1)–(4) but with the dual system Σ^d in place of Σ. (Recall that Σ^d is also conservative.) ∎

4. Proof of the main results. In this section we prove Theorems 1.3, 1.4, 1.5 as well as other related results. We use the assumptions and the notation from section 1: The conservative linear system Σ is the one constructed in Theorem 1.1 from the operators $A_0 \in \mathcal{L}(H_1, H)$ and $C_0 \in \mathcal{L}(H_{\frac{1}{2}}, U)$. The spaces H_α with $\alpha \in \mathbb{R}$ are constructed from the fractional powers of A_0. The notation $\|z\|_\alpha$ means the norm of z in H_α; in particular, $\|z\|_0$ is the norm of z in H. We put $B_0 = C_0^*$. The operators A and B are defined in (1.7), (1.8) and $\overline{C}$ is defined in (1.9). C is the restriction of $\overline{C}$ to $\mathcal{D}(A)$. The semigroup of contractions generated by A on $X = H_{\frac{1}{2}} \times H$ is denoted by $\mathbb{T}$, and the transfer function of Σ is denoted by $\mathbf{G}$. Recall also the $\mathcal{L}(H_{-\frac{1}{2}}, H_{\frac{1}{2}})$-valued function $V(s)$ from (1.10) and the space Z_0 defined after (1.5).

PROPOSITION 4.1. *With the above notation, if $\mathbb{T}$ is exponentially stable, then denoting $M = \sup_{\omega \in \mathbb{R}} \|(i\omega I - A)^{-1}\|_{\mathcal{L}(X)}$ we have for every $z \in H_{\frac{1}{2}}$*

$$\|(\omega^2 I - A_0)z\|_{-\frac{1}{2}} + \frac{\omega}{2}\|B_0 C_0 z\|_{-\frac{1}{2}} \geq \frac{1}{M}\|z\|_0 \qquad \forall\, \omega \in [0,\infty).$$

Proof. We know from Proposition I.5.3 that on $H_{\frac{1}{2}} \times H_{-\frac{1}{2}}$ (in particular, on X) we have for all $s \in \rho(A)$ with $s \neq 0$

$$(sI - A)^{-1} = \begin{bmatrix} \frac{1}{s}\,[I - V(s)A_0] & V(s) \\ -V(s)A_0 & sV(s) \end{bmatrix}. \tag{4.1}$$

For $s = 0$ the formula remains valid if we replace the left upper block in the matrix with $\frac{1}{2}A_0^{-1}B_0C_0$; see (I.5.4). Since $\mathbb{T}$ is exponentially stable, any point $i\omega$ (with

$\omega \in \mathbb{R}$) is in $\rho(A)$ and $(i\omega I - A)^{-1}$ is uniformly bounded. Looking at the left lower block of $(i\omega I - A)^{-1}$, we have

$$\sup_{\omega\in\mathbb{R}} \|V(i\omega)A_0^{\frac{1}{2}}\|_{\mathcal{L}(H)} = \sup_{\omega\in\mathbb{R}} \|V(i\omega)A_0\|_{\mathcal{L}(H_{\frac{1}{2}},H)} \le \sup_{\omega\in\mathbb{R}} \|(i\omega I - A)^{-1}\|_{\mathcal{L}(X)} = M.$$

The last estimate means that for any $g \in H$ and any $\omega \in \mathbb{R}$,

$$\|V(i\omega)A_0^{\frac{1}{2}} g\|_0 \le M\|g\|_0 .$$

If we choose $g = A_0^{-\frac{1}{2}}\left(-\omega^2 I + A_0 + \frac{i\omega}{2}B_0C_0\right)z$ with $z \in H_{\frac{1}{2}}$ fixed, then we get that for all $\omega \in \mathbb{R}$

$$M\left\|A_0^{-\frac{1}{2}}\left(-\omega^2 I + A_0 + \frac{i\omega}{2}B_0C_0\right)z\right\|_0 \ge \|z\|_0 .$$

From here, using the triangle inequality, we get the estimate in the proposition. ∎

Proof of Proposition 1.4. Recall that the inner product on X is defined by

$$\left\langle \begin{bmatrix} z_1 \\ w_1 \end{bmatrix}, \begin{bmatrix} z_2 \\ w_2 \end{bmatrix} \right\rangle_X = \langle A_0^{\frac{1}{2}} z_1, A_0^{\frac{1}{2}} z_2\rangle_H + \langle w_1, w_2\rangle_H .$$

In what follows, we drop the subscript H when writing the inner product on H (but we use subscripts for other spaces). We define a new inner product on X by

$$\begin{aligned}\left\langle \begin{bmatrix} z_1 \\ w_1 \end{bmatrix}, \begin{bmatrix} z_2 \\ w_2 \end{bmatrix} \right\rangle_{\text{new}} &= \langle A_0^{\frac{1}{2}} z_1, A_0^{\frac{1}{2}} z_2\rangle + \delta\langle w_1, z_2\rangle + \delta\langle z_1, w_2\rangle + \langle w_1, w_2\rangle \\ &= \left\langle \begin{bmatrix} I & \delta A_0^{-1} \\ \delta I & I \end{bmatrix} \begin{bmatrix} z_1 \\ w_1 \end{bmatrix}, \begin{bmatrix} z_2 \\ w_2 \end{bmatrix} \right\rangle_X ,\end{aligned}$$

where $\delta > 0$ is such that $\delta\|A_0^{-\frac{1}{2}}\| < 1$. (Later we shall impose further restrictions on δ.) The 2×2 matrix J appearing above defines a self-adjoint and positive bounded operator on X. Indeed, $J \ge 0$ follows from the Cauchy–Schwarz inequality:

$$\begin{aligned}\left\langle \begin{bmatrix} I & \delta A_0^{-1} \\ \delta I & I \end{bmatrix} \begin{bmatrix} z \\ w \end{bmatrix}, \begin{bmatrix} z \\ w \end{bmatrix} \right\rangle_X &\ge \|A_0^{\frac{1}{2}} z\|^2 - 2\delta\|z\| \cdot \|w\| + \|w\|^2 \\ &\ge \|A_0^{\frac{1}{2}} z\|^2 - 2\delta\|A_0^{-\frac{1}{2}}\| \cdot \|A_0^{\frac{1}{2}} z\| \cdot \|w\| + \|w\|^2 \\ &\ge \|A_0^{\frac{1}{2}} z\|^2 - 2\|A_0^{\frac{1}{2}} z\| \cdot \|w\| + \|w\|^2 \\ &= \left(\|A_0^{\frac{1}{2}} z\| - \|w\|\right)^2 \ge 0.\end{aligned}$$

It is easy to check that J is boundedly invertible, hence $J > 0$, which shows that our definition of a new inner product is correct, and the new norm on X defined by $\|x\|_{\text{new}} = \sqrt{\langle x, x\rangle_{\text{new}}}$ is equivalent to the original norm. Thus, it will suffice to prove that $\mathbb{T}$ is exponentially stable with respect to the new norm.

We shall estimate $\langle Ax, x\rangle_{\text{new}}$, where $x = \left[\begin{smallmatrix} z \\ w \end{smallmatrix}\right] \in \mathcal{D}(A)$. We have

$$\operatorname{Re}\langle Ax, x\rangle_{\text{new}} = \operatorname{Re}\langle (J - I)Ax, x\rangle_X + \operatorname{Re}\langle Ax, x\rangle_X .$$

We know from (I.5.3) that $\operatorname{Re}\langle Ax,x\rangle_X = -\frac{1}{2}\|C_0w\|_U^2$. Computing the product $(J-I)A$, we get that

$$\operatorname{Re}\langle Ax,x\rangle_{\text{new}} = -\delta\left\|A_0^{\frac{1}{2}}z\right\|^2 - \frac{\delta}{2}\operatorname{Re}\langle C_0w,C_0z\rangle_U + \delta\|w\|^2 - \frac{1}{2}\|C_0w\|_U^2.$$

Now remember that C_0 is bounded from below, so that $\|w\| \le \frac{1}{c}\|C_0w\|_U$. Therefore, the above estimate and the Cauchy–Schwarz inequality imply

$$\operatorname{Re}\langle Ax,x\rangle_{\text{new}} \le -\delta\left\|A_0^{\frac{1}{2}}z\right\|^2 + \frac{\delta}{2}\|C_0w\|_U\cdot\|C_0z\|_U - \left(\frac{1}{2}-\frac{\delta}{c^2}\right)\|C_0w\|_U^2.$$

Let $k>0$ be such that $\|C_0z\|_U \le k\|A_0^{\frac{1}{2}}z\|$ for all $z\in H_{\frac{1}{2}}$. Then

$$\operatorname{Re}\langle Ax,x\rangle_{\text{new}} \le -\delta\left\|A_0^{\frac{1}{2}}z\right\|^2 + \frac{\delta k}{2}\|C_0w\|_U\cdot\|A_0^{\frac{1}{2}}z\| - \left(\frac{1}{2}-\frac{\delta}{c^2}\right)\|C_0w\|_U^2.$$

The right-hand side above is a quadratic form in the two numbers $\|A_0^{\frac{1}{2}}z\|$ and $\|C_0w\|_U$. The matrix of this quadratic form is

$$Q = -\begin{bmatrix} \delta & -\frac{\delta k}{4} \\ -\frac{\delta k}{4} & \frac{1}{2}-\frac{\delta}{c^2}\end{bmatrix}.$$

This Q will be negative definite if

$$\frac{1}{2}-\frac{\delta}{c^2}>0 \quad\text{and}\quad 16\left(\frac{1}{2}-\frac{\delta}{c^2}\right) > \delta k^2.$$

Both of these conditions can be satisfied if we choose δ sufficiently small. Suppose that δ has been correctly chosen so that $Q\le -\gamma I$ for some $\gamma>0$. Then we obtain

$$\begin{aligned}\operatorname{Re}\langle Ax,x\rangle_{\text{new}} &\le -\gamma\left(\left\|A_0^{\frac{1}{2}}z\right\|^2 + \|C_0w\|_U^2\right)\\ &\le -\gamma\left(\left\|A_0^{\frac{1}{2}}z\right\|^2 + c^2\|w\|^2\right) \le -\gamma\min(1,c^2)\|x\|_X^2.\end{aligned}$$

Recall that the two norms on X are equivalent so that $\|x\|_X \ge m\|x\|_{\text{new}}$ for some $m>0$. Denoting $\eta = \gamma\min(1,c^2)m^2$ (so that $\eta>0$), we obtain

$$\operatorname{Re}\langle Ax,x\rangle_{\text{new}} \le -\eta\|x\|_{\text{new}}^2$$

so that $A+\eta I$ is dissipative with respect to the new inner product. Hence, the growth bound of $\mathbb{T}$ (which does not depend on the norm) is $\omega_0(\mathbb{T})\le -\eta$. □

LEMMA 4.2. *If we define $B_b = \left[\begin{smallmatrix}0\\ I\end{smallmatrix}\right] \in \mathcal{L}(H,X)$, then (A,B_b) is optimizable.*

Proof. Consider a new conservative linear system $\tilde{\Sigma}$ obtained from the same operator A_0 on the same Hilbert space H but with a larger input space $\tilde{U}$ and with C_0 replaced by $\tilde{C}_0$, which are defined as follows:

$$\tilde{U} = U\times H, \qquad \tilde{C}_0 = \begin{bmatrix} C_0 \\ I\end{bmatrix}.$$

Thus, following the standard construction from section 1, B_0 will be replaced by $\tilde{B}_0 = \tilde{C}_0^* = [B_0\ I]$. According to (1.7), the semigroup $\tilde{\mathbb{T}}$ of $\tilde{\Sigma}$ is generated by

$$\tilde{A} = \begin{bmatrix} 0 & I \\ -A_0 & -\frac{1}{2}B_0C_0 - \frac{1}{2}I \end{bmatrix},$$

with $\mathcal{D}(\tilde{A}) = \mathcal{D}(A)$ as defined in (1.8). It is clear that $\tilde{C}_0$ is bounded from below, so that $\tilde{\mathbb{T}}$ is exponentially stable according to Proposition 1.4.

Now consider the system Σ_b with input space H, state space X, and output space H described by

$$\begin{cases} \dot{x}(t) = Ax(t) + B_b u(t), \\ y(t) = B_b^* x(t). \end{cases}$$

Clearly Σ_b is well-posed, since B_b is bounded. The static output feedback $u = -\frac{1}{2}y$ applied to this system leads to a closed-loop system whose semigroup generator is $A - \frac{1}{2}B_b^*B_b = \tilde{A}$, which (as we already know) is exponentially stable. In particular, it follows that for any initial state $x_0 \in X$, the functions u and x defined by $u(t) = -\frac{1}{2}B_b^*\tilde{\mathbb{T}}_t x_0$ and $x(t) = \tilde{\mathbb{T}}_t x_0$ are both in L^2. Thus, (A, B_b) is optimizable. □

Proof of Theorem 1.3. According to Theorem 1.1 and Proposition 1.2, Σ is a conservative linear system with semigroup generator A, control operator B, and observation operator C. Now the equivalence of (1)–(5) in Theorem 1.3 follows from Proposition 3.3. It is also easy to see that (3) implies (6), (7), (8), and (9). Indeed, if $\mathbb{T}$ is exponentially stable, then $(sI - A)^{-1}$ exists and is uniformly bounded on $\mathbb{C}_\alpha$ for some $\alpha < 0$; see the proof of Proposition 2.4. Looking at the right column of $(sI - A)^{-1}$ in (4.1), we obtain that (6)–(9) all hold.

We prove the equivalence of (6) and (7). Suppose that (7) is false; i.e., there is a sequence (s_n) in $\mathbb{C}_0$ such that $\|s_nV(s_n)\| \to \infty$. Since $\mathbb{T}$ is uniformly bounded, $\|(sI - A)^{-1}\|$ is bounded on any right half-plane $\mathbb{C}_\gamma$ with $\gamma > 0$. Since $sV(s)$ is one of the entries of $(sI - A)^{-1}$, it follows that for large n the sequence (s_n) must be outside $\mathbb{C}_\gamma$. Since this is true for each $\gamma > 0$, we must have $\operatorname{Re} s_n \to 0$. Since $0 \in \rho(A)$, $\|sV(s)\|$ is bounded on a neighborhood of 0. Thus, without loss of generality we may assume that $|\operatorname{Im} s_n| \geq \varepsilon > 0$.

By the uniform boundedness theorem, there exists a vector $x \in H$ such that

$$\lambda_n = \|s_nV(s_n)x\| \to \infty.$$

Denote $z_n = \frac{1}{\lambda_n}V(s_n)x$; then clearly $z_n \in H_{\frac{1}{2}}$, $\|s_nz_n\| = 1$ (hence $\|z_n\|$ is bounded), and

$$\frac{1}{\lambda_n}\, x = s_n^2 z_n + A_0 z_n + \frac{s_n}{2}B_0C_0z_n \to 0 \ \text{ in } \ H.$$

Taking inner products with z_n, we obtain

$$\frac{1}{\lambda_n}\,\langle x, z_n\rangle = s_n^2\|z_n\|^2 + \left\|A_0^{\frac{1}{2}}z_n\right\|^2 + \frac{s_n}{2}\|C_0z_n\|^2 \to 0. \tag{4.2}$$

Looking here only at the imaginary parts and dividing by $\operatorname{Im} s_n$, we obtain

$$2(\operatorname{Re} s_n)\|z_n\|^2 + \frac{1}{2}\|C_0z_n\|^2 \to 0; \tag{4.3}$$

in particular, $\|C_0 z_n\| \to 0$. Now we look at the real parts of the terms in (4.2):

$$-|s_n|^2\|z_n\|^2 + 2(\operatorname{Re} s_n)^2\|z_n\|^2 + \left\|A_0^{\frac{1}{2}} z_n\right\|^2 + \frac{\operatorname{Re} s_n}{2}\|C_0 z_n\|^2 \to 0. \tag{4.4}$$

Recalling that $\operatorname{Re} s_n \to 0$ and $\|s_n z_n\| = 1$, we conclude that $\lim_{n\to\infty} \|A_0^{\frac{1}{2}} z_n\| = 1$. Thus, $\lim_{n\to\infty} \frac{1}{\lambda_n}\|A_0^{\frac{1}{2}} V(s_n)x\| = 1$ so that $\|A_0^{\frac{1}{2}} V(s_n)\| \to \infty$. We have obtained that assertion (6) is false, so (6) implies (7). The proof of the fact that (7) implies (6) is similar with the following modifications: x and λ_n are now chosen such that $\lambda_n = \|A_0^{\frac{1}{2}} V(s_n)x\| \to \infty$. We take again $z_n = \frac{1}{\lambda_n} V(s_n)x$, and now $\|A_0^{\frac{1}{2}} z_n\| = 1$ (instead of $\|s_n z_n\| = 1$). Now the reasoning up to (4.4) remains the same, and from (4.4) we conclude that $\lim_{n\to\infty} \|s_n z_n\| = 1$, which implies that $\|s_n V(s_n)\| \to \infty$.

To prove the equivalence of (8) and (9), we argue similarly as in the proof of the equivalence of (6) and (7), but now $\operatorname{Re} s_n = 0$. This makes the proof simpler, since now we do not need (4.3) and in (4.4) two terms disappear.

We prove that (6) implies (3). If (6) (and hence also (7)) holds, then we see from (4.1) that $(sI - A)^{-1}B_b$ is uniformly bounded on $\mathbb{C}_0$, where B_b is the operator from Lemma 4.2. Since, by the same lemma, (A, B_b) is optimizable, we can apply Proposition 2.5 (the equivalence of points (1) and (2) in that proposition) to conclude that $\mathbb{T}$ is exponentially stable, i.e., (3) holds.

Finally, we prove that (8) implies (3). If (8) (and hence also (9)) holds, then we see from (4.1) that $(i\omega I - A)^{-1}B_b$ is uniformly bounded for $\omega \in E$, where B_b is the operator from Lemma 4.2. Since (A, B_b) is optimizable, and since $\mathbb{T}$ is uniformly bounded, the conditions in point (3) of Proposition 2.5 are satisfied. According to Proposition 2.5, $\mathbb{T}$ is exponentially stable. □

In order to prove Theorem 1.5, we have to prove several preliminary results. We denote by $\sigma_p(A)$ the set of eigenvalues (the point spectrum) of A.

LEMMA 4.3. *If $\lambda \in \sigma_p(A)$ and $x \in \mathcal{D}(A)$ is a corresponding eigenvector (i.e., $(\lambda I - A)x = 0$ and $x \neq 0$), then x is of the form*

$$x = \begin{bmatrix} z \\ \lambda z \end{bmatrix}, \qquad z \in Z_0, \tag{4.5}$$

where $Z_0 = H_1 + A_0^{-1}B_0 U$ and

$$\left(\lambda^2 I + A_0 + \frac{\lambda}{2} B_0 C_0\right) z = 0. \tag{4.6}$$

If $\lambda \notin \mathbb{R}$, then this implies

$$\|C_0 z\|^2 = 4|\operatorname{Re}\lambda| \cdot \|z\|^2, \qquad \langle A_0 z, z\rangle = |\lambda|^2 \cdot \|z\|^2. \tag{4.7}$$

Proof. The formulas (4.5) and (4.6) are an immediate consequence of $\mathcal{D}(A) \subset Z_0 \times H_{\frac{1}{2}}$ (which follows from (1.8)) and of $(\lambda I - A)x = 0$. If we take the scalar product of the sides of (4.6) with z and use the extension of the scalar product to the duality pairing between $H_{-\frac{1}{2}}$ and $H_{\frac{1}{2}}$, we obtain

$$\left\langle \left(\lambda^2 I + A_0\right) z, z\right\rangle + \frac{\lambda}{2}\|C_0 z\|^2 = 0.$$

Since $\mathbb{T}$ is a contraction semigroup, λ must be in the closed left half-plane. Denoting $\lambda = -\sigma + i\omega$ with $\sigma \geq 0$ and $\omega \in \mathbb{R}$, this means

$$\left\langle \left((\sigma^2 - \omega^2)I + A_0\right) z, z\right\rangle - 2i\sigma\omega\|z\|^2 + \frac{-\sigma + i\omega}{2}\|C_0 z\|^2 = 0. \tag{4.8}$$

Looking at the imaginary part of this, we see that $\omega \neq 0$ implies

$$-2\sigma\|z\|^2 + \frac{1}{2}\|C_0 z\|^2 = 0\,,$$

which is the same as the first equality in (4.7). Now we look at the real part of (4.8), using the expression for $\|C_0 z\|^2$ that we have just found, obtaining (after a short computation) the second equality in (4.7). □

LEMMA 4.4. *Suppose that $\omega \in \mathbb{R}$ is such that $i\omega \in \sigma_p(A)$. Then also $-i\omega \in \sigma_p(A)$ and $\omega^2 \in \sigma_p(A_0)$. In this case, z from (4.5) is an eigenvector of A_0 corresponding to the eigenvalue ω^2 (in particular, $z \in H_\alpha$ for all $\alpha > 0$) and we have $C_0 z = 0$.*

Proof. Suppose that $i\omega \in \sigma_p(A)$, and let $z \in Z_0$ be the first component of a corresponding eigenvector as in (4.5). We know from (I.5.4) that $0 \in \rho(A)$ so that $\omega \neq 0$. According to the first part of (4.7) we have $C_0 z = 0$. Now (4.6) (with $\lambda = i\omega$) shows that z is an eigenvector of A_0 corresponding to the eigenvalue ω^2. It is now easy to see that the vector with components z and $-i\omega z$ is also an eigenvector of A corresponding to the eigenvalue $-i\omega$. □

We denote by $\sigma_a(A)$ the set of those $\lambda \in \sigma(A)$ for which λ is not an eigenvalue of A, but $\lambda I - A$ is not bounded from below. In other words, $\lambda \in \sigma_a(A)$ if $\lambda \notin \sigma_p(A)$ and there exists a sequence (x_n) in $\mathcal{D}(A)$ with

$$\|x_n\|_X = 1 \quad \text{and} \quad \lim_{n\to\infty} \|(\lambda I - A)x_n\|_X = 0\,. \tag{4.9}$$

LEMMA 4.5. *If $\omega \in \mathbb{R}$ is such that $i\omega \in \sigma(A)$, then*

$$i\omega \in \sigma_p(A) \cup \sigma_a(A)\,.$$

Proof. Suppose that $i\omega \in \sigma(A)$. We prove that $i\omega \in \sigma_p(A) \cup \sigma_a(A)$ by showing that the contrary statement leads to a contradiction. Indeed, the contrary statement means that $i\omega I - A$ is bounded from below. In this case, the range of $i\omega I - A$ is not dense in X (because if it were dense, then it were all of X, and hence $i\omega I - A$ would have a bounded inverse). Let N be the orthogonal complement of the range of $i\omega I - A$; then it is easy to see that N is invariant under $\mathbb{T}^*$: $\mathbb{T}_t^* N \subset N$ for all $t \geq 0$. Considering the restriction of $\mathbb{T}^*$ to N, we see that $\mathcal{D}(A^*) \cap N$ must be dense in N, so that, in particular, there exist elements $q \in \mathcal{D}(A^*) \cap N$ with $q \neq 0$. From the definition of N we now see that for such q we have $(-i\omega I - A^*)q = 0$ so that $-i\omega \in \sigma_p(A^*)$. Introduce the isomorphism $J \in \mathcal{L}(X)$ defined by the matrix

$$J = \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix}.$$

We have $J^{-1} = J$ and $A^* = JAJ$; see the fourth step in the proof of Theorems I.1.1 and I.1.3 (in section I.6). Thus, A and A^* have the same eigenvalues so that $-i\omega \in \sigma_p(A)$. According to Lemma 4.4, we obtain that $i\omega \in \sigma_p(A)$, which contradicts our "contrary statement" at the beginning of this proof. □

LEMMA 4.6. *If $\omega \in \mathbb{R}$ is such that $i\omega \in \sigma_a(A)$, then also $-i\omega \in \sigma_a(A)$ and, moreover, $\omega^2 \in \sigma_p(A_0) \cup \sigma_a(A_0)$.*

Proof. Assume that $i\omega \in \sigma_a(A)$ so that for some sequence (x_n) in $\mathcal{D}(A)$ we have (4.9) (with $\lambda = i\omega$). Denoting $x_n = \left[\begin{smallmatrix} z_n \\ w_n \end{smallmatrix}\right]$ and $(i\omega I - A)x_n = \left[\begin{smallmatrix} \nu_n \\ \varepsilon_n \end{smallmatrix}\right]$ so that $\nu_n \to 0$ (in $H_{\frac{1}{2}}$) and $\varepsilon_n \to 0$ (in H), we have

$$\begin{bmatrix} i\omega I & -I \\ A_0 & i\omega I + \frac{1}{2}B_0 C_0 \end{bmatrix} \begin{bmatrix} z_n \\ w_n \end{bmatrix} = \begin{bmatrix} \nu_n \\ \varepsilon_n \end{bmatrix}.$$

From the first row we have $w_n = i\omega z_n - \nu_n$. Substituting this into the equation representing the second row, we get

$$A_0 z_n - \omega^2 z_n - i\omega\,\nu_n + \frac{i\omega}{2} B_0 C_0 z_n - \frac{1}{2} B_0 C_0 \nu_n = \varepsilon_n\,. \tag{4.10}$$

The two sides of this equation are in H, but some terms are in $H_{-\frac{1}{2}}$. Taking the scalar product with z_n and using the duality pairing between $H_{-\frac{1}{2}}$ and $H_{\frac{1}{2}}$, we get

$$\left\langle \left(A_0 - \omega^2 I\right) z_n, z_n \right\rangle - i\omega \langle \nu_n, z_n\rangle + \frac{i\omega}{2} \|C_0 z_n\|^2 - \frac{1}{2} \langle C_0\nu_n, C_0 z_n\rangle = \langle \varepsilon_n, z_n\rangle\,,$$

which shows that

$$\lim_{n\to\infty} \left[\left\langle \left(A_0 - \omega^2 I\right) z_n, z_n \right\rangle + \frac{i\omega}{2} \|C_0 z_n\|^2 \right] = 0\,.$$

Remember that A is invertible (see (I.5.4)) so that $\omega \neq 0$. Taking the imaginary part of the last limit, we conclude that $\lim_{n\to\infty} C_0 z_n = 0$. Now going back to (4.10), we conclude that

$$\lim_{n\to\infty} \left\| \left(\omega^2 I - A_0\right) z_n \right\|_{-\frac{1}{2}} = 0\,. \tag{4.11}$$

Now recall from (4.9) that

$$\|x_n\|_X^2 = \|z_n\|_{\frac{1}{2}}^2 + \|w_n\|_0^2 = 1\,.$$

Since $w_n = i\omega z_n - \nu_n$ with $\lim_{n\to\infty} \|\nu_n\|_{\frac{1}{2}} = 0$, we have $\lim_{n\to\infty} \left(\|w_n\|_0^2 - \omega^2 \|z_n\|_0^2\right) = 0$ so that $\lim_{n\to\infty} (\|z_n\|_{\frac{1}{2}}^2 + \omega^2 \|z_n\|_0^2) = 1$. Since $\|z_n\|_0 \leq \|A_0^{-\frac{1}{2}}\| \cdot \|z_n\|_{\frac{1}{2}}$ and $\|A_0^{-\frac{1}{2}}\|^2 = \|A_0^{-1}\|$, we obtain $\liminf_{n\to\infty} \left(1 + \omega^2 \|A_0^{-1}\|\right) \cdot \|z_n\|_{\frac{1}{2}}^2 \geq 1$ so that the sequence $(\|z_n\|_{\frac{1}{2}})$ is eventually bounded from below:

$$\|z_n\|_{\frac{1}{2}} \geq m > 0 \quad \text{for} \quad n \geq n_0\,.$$

We have for $n \geq n_0$

$$m \leq \|z_n\|_{\frac{1}{2}} = \|A_0 z_n\|_{-\frac{1}{2}} = \|(\omega^2 I - A_0) z_n - \omega^2 z_n\|_{-\frac{1}{2}}$$

$$\leq \|(\omega^2 I - A_0) z_n\|_{-\frac{1}{2}} + \omega^2 \|z_n\|_{-\frac{1}{2}}\,.$$

Now (4.11) implies that the sequence $(\|z_n\|_{-\frac{1}{2}})$ is eventually bounded from below. This together with (4.11) implies that $\omega^2 I - A_0$ is not bounded from below as an (unbounded) operator on $H_{-\frac{1}{2}}$ (with domain $H_{\frac{1}{2}}$). Since $\omega^2 I - A_0$ as an operator on $H_{-\frac{1}{2}}$ is isomorphic to $\omega^2 I - A_0$ as an operator on H (with domain H_1), we conclude that the latter is also not bounded from below. Thus, $\omega^2 \in \sigma_p(A_0) \cup \sigma_a(A_0)$.

It remains to prove that $-i\omega \in \sigma_a(A)$. Define

$$\xi_n = \begin{bmatrix} z_n \\ -w_n \end{bmatrix} \in H_{\frac{1}{2}} \times H_{\frac{1}{2}}$$

so that $\|\xi_n\|_X = \|x_n\|_X = 1$. We will use the extension of A which maps X into X_{-1}. In particular, this extension maps $H_{\frac{1}{2}} \times H_{\frac{1}{2}} \subset X$ into $H_{\frac{1}{2}} \times H_{-\frac{1}{2}} \subset X_{-1}$, as it is easy to see (see Proposition I.5.2 for the inclusion $H_{\frac{1}{2}} \times H_{-\frac{1}{2}} \subset X_{-1}$). We have

$$(-i\omega I - A)\xi_n = \begin{bmatrix} -i\omega I & -I \\ A_0 & -i\omega I + \frac{1}{2}B_0C_0 \end{bmatrix} \begin{bmatrix} z_n \\ -w_n \end{bmatrix} = \begin{bmatrix} -\nu_n \\ \varphi_n \end{bmatrix},$$

where $\varphi_n \in H_{-\frac{1}{2}}$ is given by a formula similar to (4.10):

$$\varphi_n = (A_0 - \omega^2 I)z_n - i\omega\nu_n - \frac{i\omega}{2}B_0C_0z_n + \frac{1}{2}B_0C_0\nu_n.$$

Remember that $\nu_n \to 0$ (in $H_{\frac{1}{2}}$) and $C_0z_n \to 0$ (in U). Using also (4.11), we conclude from the above formula that $\varphi_n \to 0$ (in $H_{-\frac{1}{2}}$). From here we see that

$$\lim_{n\to\infty}(-i\omega I - A)\xi_n = 0 \quad \text{in} \quad H_{\frac{1}{2}} \times H_{-\frac{1}{2}}.$$

Since the sequence (ξ_n) is bounded from below in $H_{\frac{1}{2}} \times H_{\frac{1}{2}}$, it follows that $(-i\omega I - A)$ is not bounded from below (as an operator from $H_{\frac{1}{2}} \times H_{\frac{1}{2}}$ to $H_{\frac{1}{2}} \times H_{-\frac{1}{2}}$). According to point (1) of Proposition I.5.3, it follows that $-i\omega \in \sigma(A)$. Now we can apply Lemma 4.5 to conclude that $-i\omega \in \sigma_p(A) \cup \sigma_a(A)$. If we would have $-i\omega \in \sigma_p(A)$, then it would follow from Lemma 4.4 that also $i\omega \in \sigma_p(A)$, which would contradict our assumption that $i\omega \in \sigma_a(A)$. Thus, we must have $-i\omega \in \sigma_a(A)$. □

Proof of Theorem 1.5. According to Lemmas 4.4, 4.5, and 4.6, if $\omega \in \mathbb{R}$ is such that $i\omega \in \sigma(A)$, then $\omega^2 \in \sigma(A_0)$. Thus, if $\sigma(A_0)$ is countable, as assumed in the theorem, then also $\sigma(A) \cap i\mathbb{R}$ must be countable, as required in Proposition 3.4. Now the equivalence of points (1)–(7) in the theorem follows from Proposition 3.4.

It remains to prove the equivalence between point (8) and the other points. Suppose that (8) holds. We claim that A has no eigenvalues on the imaginary axis. Indeed, if $\omega \in \mathbb{R}$ were such that $i\omega \in \sigma_p(A)$, then according to Lemma 4.4 $\omega^2 \in \sigma_p(A_0)$ and for a corresponding eigenvector $z \in H_1$ we would have $C_0z = 0$, which would contradict (8). Now we can apply the main theorem of Arendt and Batty [2]: our earlier claim together with the fact that $\sigma(A) \cap i\mathbb{R}$ is countable implies that $\mathbb{T}$ is strongly stable. Thus, point (1) of the theorem holds and with it all the others.

Conversely, suppose that point (8) is false, i.e., there exists an $\omega \in \mathbb{R}$ such that $\omega^2 \in \sigma_p(A_0)$, and for a corresponding eigenvector $z \in H_1$ we have $C_0z = 0$. Let x be defined by (4.5) with $\lambda = i\omega$. Then it is easy to verify that $x \in \mathcal{D}(A)$ and $Ax = i\omega x$, whence $\mathbb{T}_t x = e^{i\omega t}x$. This shows that $\mathbb{T}$ is not strongly stable, so in this case the points (1)–(7) are all false. □

5. Examples. The aim of this section is to apply the general stability results derived earlier to some models based on PDEs. We will consider an Euler–Bernoulli beam with an exponentially stabilizing feedback acting in one point followed by an n-dimensional wave equation with boundary control and a nonlocal feedback term entering a Dirichlet boundary condition.

5.1. An Euler–Bernoulli beam with pointwise control. The physical system that we have in mind consists of two rigidly joined beams with both velocity and angular velocity damping at the joint. The other end of both beams is hinged. The inputs are a force and a torque acting at the joint (in addition to the damping force and torque), and the measurements depend linearly on the velocity and the angular

velocity at the joint as well as on the inputs. The fact that we apply both a force and a torque feedback at the joint prevents the well-known lack of robustness of stability concerning the location of the joint: we obtain exponential stability for any location. For the case when only force feedback or only torque feedback is applied, lack of robustness of exponential stability was demonstrated in Rebarber [26]. (We refer to [26] for earlier references on this subject.)

Our system consists of two homogeneous Euler–Bernoulli beams situated along the intervals $[0,\xi]$ and $[\xi,\pi]$ with the joint at the point $\xi \in (0,\pi)$. Denoting by $[f]_\xi$ the jump of the function f at $x=\xi$, we get the equations

$$\frac{\partial^2 z}{\partial t^2}+\frac{\partial^4 z}{\partial x^4}=0,\quad x\in(0,\pi)\setminus\{\xi\},\quad [z]_\xi=0,\quad \left[\frac{\partial z}{\partial x}\right]_\xi=0, \tag{5.1}$$

$$\left[\frac{\partial^3 z}{\partial x^3}\right]_\xi+\frac{\alpha^2}{2}\frac{\partial z}{\partial t}(\xi,t)=\alpha u_1(t),\quad -\left[\frac{\partial^2 z}{\partial x^2}\right]_\xi+\frac{\beta^2}{2}\frac{\partial^2 z}{\partial x\partial t}(\xi,t)=\beta u_2(t), \tag{5.2}$$

$$\left[\frac{\partial^3 z}{\partial x^3}\right]_\xi-\frac{\alpha^2}{2}\frac{\partial z}{\partial t}(\xi,t)=\alpha y_1(t),\quad -\left[\frac{\partial^2 z}{\partial x^2}\right]_\xi-\frac{\beta^2}{2}\frac{\partial^2 z}{\partial x\partial t}(\xi,t)=\beta y_2(t), \tag{5.3}$$

$$z(x,0)=z_0(x),\quad \frac{\partial z}{\partial t}(x,0)=w_0(x),\quad x\in(0,\pi)\setminus\{\xi\}, \tag{5.4}$$

$$z(0,t)=z(\pi,t)=0,\quad \frac{\partial^2 z}{\partial x^2}(0,t)=\frac{\partial^2 z}{\partial x^2}(\pi,t)=0. \tag{5.5}$$

Here, z stands for the transverse displacement of the beam and $\alpha,\beta>0$ are damping coefficients. The external force is αu_1 and the external torque is βu_2, both acting at ξ. The output signals are y_1 and y_2.

An equivalent formulation of (5.1)–(5.5) can be obtained by considering a single homogeneous Euler–Bernoulli beam situated along the interval $[0,\pi]$ with a force and a torque acting at the point $\xi\in(0,\pi)$. (The equivalence is proved in Proposition 5.2 below.) In this case the equations (5.1)–(5.2) are replaced by

$$\begin{aligned}\frac{\partial^2 z}{\partial t^2}+\frac{\partial^4 z}{\partial x^4}+\frac{\alpha^2}{2}\frac{\partial}{\partial t}(z(\xi,t))\,\delta_\xi-\frac{\beta^2}{2}\frac{\partial}{\partial t}\left(\frac{\partial z}{\partial x}(\xi,t)\right)\frac{\mathrm{d}\delta_\xi}{\mathrm{d}x}\\ =\alpha u_1(t)\delta_\xi-\beta u_2(t)\frac{\mathrm{d}\delta_\xi}{\mathrm{d}x}.\end{aligned} \tag{5.6}$$

Here, δ_ξ is the Dirac mass concentrated at ξ and (5.6) is understood as an equation in $\mathcal{D}'(0,\pi)$ (distributions on $(0,\pi)$). The outputs are equivalently given by

$$y_1(t)=-\alpha\frac{\partial z}{\partial t}(\xi,t)+u_1(t),\quad y_2(t)=-\beta\frac{\partial^2 z}{\partial t\,\partial x}(\xi,t)+u_2(t). \tag{5.7}$$

The well-posedness of the system described by (5.4)–(5.7) can be obtained by using Theorem 1.1 if we introduce the appropriate spaces and operators. We start by defining $H=L^2[0,\pi]$ and the operator $A_0:\mathcal{D}(A_0)\to H$ by

$$\mathcal{D}(A_0)=\left\{\phi\in\mathcal{H}^4(0,\pi)\;\middle|\;\phi(0)=\phi(\pi)=0,\ \frac{\mathrm{d}^2\phi}{\mathrm{d}x^2}(0)=\frac{\mathrm{d}^2\phi}{\mathrm{d}x^2}(\pi)=0\right\},$$

$$A_0\phi = \frac{\mathrm{d}^4\phi}{\mathrm{d}x^4} \qquad \forall\ \phi \in \mathcal{D}(A_0).$$

It is well known that A_0 is self-adjoint, positive, and boundedly invertible. As in section 1, we put $H_1 = \mathcal{D}(A_0)$ and we introduce the spaces H_α ($\alpha \in \mathbb{R}$) by considering fractional powers of A_0 and duality. A simple calculation shows that

$$H_{\frac{1}{2}} = \mathcal{D}(A_0^{\frac{1}{2}}) = \mathcal{H}^2(0,\pi) \cap \mathcal{H}_0^1(0,\pi)$$

with the norm

$$\|z\|_{\frac{1}{2}}^2 = \int_0^\pi \left|\frac{\mathrm{d}^2 z}{\mathrm{d}x^2}(x)\right|^2 \mathrm{d}x.$$

PROPOSITION 5.1. *The equations* (5.4)–(5.7) *determine a conservative linear system* Σ *with input and output space* $\mathbb{C}^2$ *and with state space* $X = H_{\frac{1}{2}} \times H$. *For* $z_0 \in H_{\frac{1}{2}}$, $w_0 \in H$, *and* $u_1, u_2 \in L^2[0,\infty)$ *the equations* (5.4)–(5.6) *admit a unique solution*

$$z \in BC\left(0,\infty; H_{\frac{1}{2}}\right) \cap BC^1\left(0,\infty; H\right) \cap \mathcal{H}_{loc}^2\left(0,\infty; H_{-\frac{1}{2}}\right).$$

Moreover, we have $z(\xi,\cdot), \frac{\partial z}{\partial x}(\xi,\cdot) \in \mathcal{H}^1(0,\infty)$.

Proof. We take $U = \mathbb{C}^2$, and $B_0 \in \mathcal{L}(U, H_{-\frac{1}{2}})$ is defined by

$$B_0 \begin{bmatrix} \mathrm{v}_1 \\ \mathrm{v}_2 \end{bmatrix} = \alpha\,\mathrm{v}_1\delta_\xi - \beta\,\mathrm{v}_2\frac{\mathrm{d}\delta_\xi}{\mathrm{d}x} \qquad \forall\ \begin{bmatrix} \mathrm{v}_1 \\ \mathrm{v}_2 \end{bmatrix} \in \mathbb{C}^2.$$

By the definition of B_0, for each $\mathrm{v}_1, \mathrm{v}_2 \in \mathbb{C}$, $B_0\left[\begin{smallmatrix} \mathrm{v}_1 \\ \mathrm{v}_2 \end{smallmatrix}\right]$ is a bounded linear functional acting on $H_{\frac{1}{2}}$ so that indeed B_0 maps $\mathbb{C}^2$ into $H_{-\frac{1}{2}}$. The adjoint of B_0 is

$$C_0\phi = B_0^*\phi = \begin{bmatrix} \alpha\phi(\xi) \\ \beta\frac{\mathrm{d}\phi}{\mathrm{d}x}(\xi) \end{bmatrix} \qquad \forall\ \phi \in H_{\frac{1}{2}}. \tag{5.8}$$

Now it is clear that the problem (5.4)–(5.7) can be written in the form (1.1)–(1.3). Thus, this proposition follows from Theorem 1.1. ∎

Note that since Σ is conservative, for every $t \geq 0$ we have

$$\left\|\begin{bmatrix} z(t) \\ \dot{z}(t) \end{bmatrix}\right\|_X^2 - \left\|\begin{bmatrix} z(0) \\ \dot{z}(0) \end{bmatrix}\right\|_X^2 = \int_0^t \left[|u_1(\sigma)|^2 + |u_2(\sigma)|^2\right] \mathrm{d}\sigma - \int_0^t \left[|y_1(\sigma)|^2 + |y_2(\sigma)|^2\right] \mathrm{d}\sigma.$$

The space Z_0 defined after (1.5) (see also Theorem I.1.2) is now given by

$$Z_0 = \left\{ z \in H_{\frac{1}{2}} \;\middle|\; z|_{(0,\xi)} \in \mathcal{H}^4(0,\xi),\ z|_{(\xi,1)} \in \mathcal{H}^4(\xi,1) \right\}.$$

The systems (5.1)–(5.5) and (5.4)–(5.7) are equivalent in the following sense.

PROPOSITION 5.2. *Consider the functions*

$$z \in C\left(0,\infty; Z_0\right) \cap C^1\left(0,\infty; H_{\frac{1}{2}}\right) \cap C^2\left(0,\infty; H\right), \qquad u, y \in C\left(0,\infty; U\right).$$

Then z, u, *and* y *satisfy* (5.1)–(5.5) *if and only if they satisfy* (5.4)–(5.7).

Proof. We denote by $z^{(\mathrm{iii})}$ (respectively, by $z^{(\mathrm{iv})}$) the third (respectively, the fourth) derivative of z computed in $\mathcal{D}'((0,\pi)\setminus\{\xi\})$. Roughly speaking, these derivatives are calculated almost everywhere, ignoring the possible jumps at $x=\xi$. Hence they are, in general, different from $\frac{\mathrm{d}^3 z}{\mathrm{d}x^3}$ and $\frac{\mathrm{d}^4 z}{\mathrm{d}x^4}$ computed in the sense of distributions, i.e., in $\mathcal{D}'(0,\pi)$. We define $L_0 \in \mathcal{L}\left(Z_0, L^2[0,\pi]\right)$ and $G_0 \in \mathcal{L}(Z_0, U)$ by

$$L_0 z = z^{(\mathrm{iv})} \quad \text{and} \quad G_0 z = \begin{bmatrix} \frac{1}{\alpha}\left[z^{\mathrm{iii}}\right]_\xi & -\frac{1}{\beta}\left[\frac{d^2 z}{dx^2}\right]_\xi \end{bmatrix}^T \tag{5.9}$$

(T stands for transpose). Simple calculations show that

$$L_0 = A_0 - B_0 G_0, \quad G_0 H_1 = \{0\}, \quad G_0 A_0^{-1} B_0 = I\,. \tag{5.10}$$

By Theorem I.1.4 we obtain that the functions z, u, y satisfy (5.4)–(5.7) (which are the same, in this example, as (1.1)–(1.3)) if and only if they satisfy

$$\ddot{z}(t) + L_0 z(t) = 0\,, \quad G_0 z(t) + \frac{1}{2} C_0 \dot{z}(t) = u(t), \quad G_0 z(t) - \frac{1}{2} C_0 \dot{z}(t) = y(t)$$

(which are the same as (5.1)–(5.3) and (5.5)) as well as (5.4). □

The main result of this section is the following.

THEOREM 5.3. *For all $\xi \in (0,\pi)$, (5.4)–(5.7) define an exponentially stable well-posed system with input and output space $U = \mathbb{C}^2$ and state space X.*

Proof. Let $A : \mathcal{D}(A) \to X$ be defined as in (1.7), (1.8). If $\psi = \left[\begin{smallmatrix} z \\ w \end{smallmatrix}\right] \in \mathcal{D}(A)$, then $w \in H_{\frac{1}{2}}$ and z is piecewise in H^4 (on $(0,\xi)$ and on (ξ,π)). Thus, $\mathcal{D}(A)$ is compactly included in X so that A has a compact resolvent, hence $\sigma(A)$ consists of eigenvalues of A. We prove that $\sigma(A) \cap i\mathbb{R} = \emptyset$. Arguing by contradiction, suppose that $i\beta \in \sigma(A)$ with $\beta \in \mathbb{R}$. According to Lemma 4.4, if ψ is an eigenvector of A corresponding to $i\beta$, then $\psi = \left[\begin{smallmatrix} z \\ i\beta z \end{smallmatrix}\right]$, where $(\beta^2 I - A_0)z = 0$. This implies that

$$\frac{\mathrm{d}^4 z}{\mathrm{d}x^4} - \beta^2 z = 0, \quad z(0) = z(\pi) = 0, \quad \frac{\mathrm{d}^2 z}{\mathrm{d}x^2}(0) = \frac{\mathrm{d}^2 z}{\mathrm{d}x^2}(\pi) = 0.$$

It follows that $z(x) = c\sin(nx)$ for some $c \in \mathbb{C}$ and $n \in \mathbb{N}$ (with $n^4 = \beta^2$). Moreover, by Lemma 4.4 we also have $C_0 z = 0$ which, by (5.8), yields that $z(\xi) = 0$, $\frac{\mathrm{d}z}{\mathrm{d}x}(\xi) = 0$. This implies that $z = 0$, which is a contradiction. Thus, $\sigma(A) \cap i\mathbb{R} = \emptyset$.

By the equivalence of (3) and (9) in Theorem 1.3, it suffices to show that

$$\sup_{\omega\in\mathbb{R}} \|\omega V(i\omega)\|_{\mathcal{L}(H)} < \infty. \tag{5.11}$$

Suppose that this condition is false. By the uniform boundedness theorem, there exist a sequence of real numbers (β_n) with $|\beta_n| \to \infty$ and $h \in H$ such that $\lambda_n = \|\beta_n V(i\beta_n)h\| \to \infty$. Denoting $z_n = \frac{1}{\lambda_n} V(i\beta_n)h$ and $g_n = \frac{1}{\lambda_n} h$ (so that $g_n \to 0$ in H), we have

$$\|\beta_n z_n\|_H = 1 \qquad \forall\, n \in \mathbb{N}, \tag{5.12}$$

$$-\beta_n^2 z_n + A_0 z_n + \frac{i\beta_n}{2} B_0 C_0 z_n = g_n \in H\,. \tag{5.13}$$

We show (in four steps) that (5.12) and (5.13) lead to a contradiction.

First step. Taking the inner product in H of the sides of (5.13) with $\beta_n z_n$, taking the imaginary parts, and using (5.12), we obtain that $\beta_n C_0 z_n \to 0$. According to (5.8) this means

$$|\beta_n z_n(\xi)| \to 0, \qquad \left|\beta_n \frac{\mathrm{d}z_n}{\mathrm{d}x}(\xi)\right| \to 0. \tag{5.14}$$

On the other hand, (5.13) implies that $z_n \in Z_0$ so that by (5.10) we have

$$A_0 z_n = L_0 z_n + B_0 G_0 z_n .$$

Substituting this into (5.13) and using the fact that $B_0 u \in H$ iff $u = 0$, we obtain

$$-\beta_n^2 z_n + L_0 z_n = g_n \quad \text{and} \quad G_0 z_n = \frac{-i\beta_n}{2} C_0 z_n .$$

The above relations together with (5.8) and (5.9) imply that

$$-\beta_n^2 z_n + z_n^{(\mathrm{iv})} = g_n \to 0 \ \text{ in } L^2[0,\pi], \tag{5.15}$$

$$z_n^{(\mathrm{iii})}(\xi^+) - z_n^{(\mathrm{iii})}(\xi^-) = -i\beta_n \frac{\alpha^2}{2} z_n(\xi), \tag{5.16}$$

$$\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+) - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-) = i\beta_n \frac{\beta^2}{2} \frac{\mathrm{d}z_n}{\mathrm{d}x}(\xi). \tag{5.17}$$

Second step. Define $f_n \in H$ by $f_n(x) = x \frac{\mathrm{d}z_n}{\mathrm{d}x}(x)$ for $x \in [0,\xi]$ and $f_n(x) = 0$ for $x > \xi$. We take the inner product of the sides of (5.15) with f_n to get

$$\int_0^\xi \left(-\beta_n^2 z_n(x) + z_n^{(\mathrm{iv})}(x)\right) x \frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(x)\mathrm{d}x = \int_0^\xi x\, g_n(x) \frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(x)\mathrm{d}x . \tag{5.18}$$

By a straightforward calculation, the terms on the left-hand side become

$$\mathrm{Re}\left\{\int_0^\xi -\beta_n^2 z_n(x) x \frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(x)\mathrm{d}x\right\} = -\frac{1}{2}\xi|\beta_n z_n(\xi)|^2 + \frac{1}{2}\int_0^\xi |\beta_n z_n(x)|^2 \mathrm{d}x,$$

$$\mathrm{Re}\left\{\int_0^\xi z_n^{(\mathrm{iv})}(x) x \frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(x)\mathrm{d}x\right\} = \mathrm{Re}\left[\left(\xi z_n^{(\mathrm{iii})}(\xi^-) - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right)\frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(\xi)\right] - \frac{\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right|^2 + \frac{3}{2}\int_0^\xi \left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(x)\right|^2 \mathrm{d}x .$$

The two relations above and (5.18) yield

$$-\frac{1}{2}\xi|\beta_n z_n(\xi)|^2 + \frac{1}{2}\int_0^\xi |\beta_n z_n(x)|^2 \mathrm{d}x + \mathrm{Re}\left[\left(\xi z_n^{(\mathrm{iii})}(\xi^-) - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right)\frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(\xi)\right]$$

$$-\frac{\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right|^2 + \frac{3}{2}\int_0^\xi \left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(x)\right|^2 \mathrm{d}x = \mathrm{Re}\int_0^\xi x\, g_n(x) \frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(x)\mathrm{d}x .$$

Since g_n converges to zero in $L^2[0,\xi]$, we deduce that the right-hand side of the last formula converges to zero. This implies that

$$-\frac{1}{2}\xi|\beta_n z_n(\xi)|^2+\frac{1}{2}\int_0^\xi|\beta_n z_n(x)|^2\mathrm{d}x+\mathrm{Re}\left[\left(\xi z_n^{(\mathrm{iii})}(\xi^-)-\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right)\frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(\xi)\right]$$

$$-\frac{\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right|^2+\frac{3}{2}\int_0^\xi\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(x)\right|^2\mathrm{d}x\to 0. \tag{5.19}$$

On the other hand, from (5.15) and the fact that $\|\beta_n z_n\|_H=1$ we deduce that $(z_n^{(\mathrm{iv})}/\beta_n)$ is a bounded sequence in $L^2[0,\xi]$. This further implies the boundedness of the sequences of complex numbers $(z_n^{(\mathrm{iii})}(\xi^-)/\beta_n)$ and $(\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)/\beta_n)$. Then, by (5.14) we obtain that

$$-\frac{1}{2}\xi|\beta_n z_n(\xi)|^2+\mathrm{Re}\left[\left(\xi z_n^{(\mathrm{iii})}(\xi^-)-\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right)\frac{\mathrm{d}\bar{z}_n}{\mathrm{d}x}(\xi)\right]\to 0. \tag{5.20}$$

Relations (5.19) and (5.20) lead to

$$\frac{1}{2}\int_0^\xi|\beta_n z_n(x)|^2\,\mathrm{d}x+\frac{3}{2}\int_0^\xi\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}\right|^2\mathrm{d}x-\frac{\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right|^2\to 0.$$

Similarly, we take the inner product of the sides of (5.15) with $(x-\pi)\frac{\mathrm{d}z_n}{\mathrm{d}x}$ truncated to $[\xi,\pi]$, and then we repeat the above argument. This gives

$$\frac{1}{2}\int_\xi^\pi|\beta_n z_n(x)|^2\,\mathrm{d}x+\frac{3}{2}\int_\xi^\pi\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}\right|^2\mathrm{d}x-\frac{\pi-\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+)\right|^2\to 0.$$

If we add the last two formulas and we use (5.13), we obtain

$$\int_0^\pi|\beta_n z_n(x)|^2\,\mathrm{d}x+3\int_0^\pi\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(x)\right|^2\mathrm{d}x-\frac{\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)\right|^2-\frac{\pi-\xi}{2}\left|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+)\right|^2\to 0. \tag{5.21}$$

Third step. We show that both $|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-)|$ and $|\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+)|$ converge to zero. We use an idea of Liu; see, for instance, [1]: we take the inner product of the sides of (5.15) with $\frac{1}{\phi_n}e^{-\phi_n(\xi-x)}$ truncated to $[0,\xi]$, where $\phi_n=\sqrt{|\beta_n|}$. Thus, we obtain

$$-\int_0^\xi\phi_n^3 z_n(x)e^{-\phi_n(\xi-x)}\mathrm{d}x+\int_0^\xi\frac{z_n^{(\mathrm{iv})}(x)}{\phi_n}e^{-\phi_n(\xi-x)}\mathrm{d}x=\int_0^\xi g_n(x)\frac{e^{-\phi_n(\xi-x)}}{\phi_n}\mathrm{d}x.$$

By using (5.12), (5.15) again and the fact that $\phi_n e^{-\phi_n(\xi-x)}$ is bounded in $L^1[0,\pi]$, we obtain that

$$-\int_0^\xi\phi_n^3 z_n(x)e^{-\phi_n(\xi-x)}\mathrm{d}x+\int_0^\xi\frac{z_n^{(\mathrm{iv})}(x)}{\phi_n}e^{-\phi_n(\xi-x)}\mathrm{d}x\to 0. \tag{5.22}$$

Integrating by parts the second term above four times, we obtain

$$\int_0^\xi\frac{z_n^{(\mathrm{iv})}(x)}{\phi_n}e^{-\phi_n(\xi-x)}\mathrm{d}x$$

$$= \left(\frac{z_n^{(\mathrm{iii})}(x)}{\phi_n} - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(x) + \phi_n \frac{\mathrm{d}z_n}{\mathrm{d}x}(x) - \phi_n^2 z_n \right) e^{-\phi_n(\xi - x)} \Bigg|_0^{\xi} + \int_0^{\xi} \phi_n^3 z_n e^{-\phi_n(\xi - x)} \mathrm{d}x .$$

By using (5.22) we obtain from here that

$$\left(\frac{z_n^{(\mathrm{iii})}(x)}{\phi_n} - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(x) + \phi_n \frac{\mathrm{d}z_n}{\mathrm{d}x}(x) - \phi_n^2 z_n \right) e^{-\phi_n(\xi - x)} \Bigg|_0^{\xi} \to 0 . \tag{5.23}$$

Among the boundary terms in (5.23), those at $x = 0$ all converge to zero due to the exponential decay of $e^{-\phi_n \xi}$ and to the boundedness of $(z_n^{(\mathrm{iv})}/\beta_n)$ in $L^2[0, \xi]$; the terms containing $z_n(\xi)$, $\frac{\mathrm{d}z_n}{\mathrm{d}x}(\xi)$ also converge to zero due to (5.14). Thus, (5.23) yields

$$\frac{z_n^{(\mathrm{iii})}}{\phi_n}(\xi^-) - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-) \to 0. \tag{5.24}$$

Similarly, we take the inner product of the sides of (5.15) with $\frac{1}{\phi_n} e^{-\phi_n(x - \xi)}$ in $L^2[\xi, \pi]$. Repeating the above analysis, we obtain

$$\frac{z_n^{(\mathrm{iii})}}{\phi_n}(\xi^+) + \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+) \to 0 . \tag{5.25}$$

On the other hand, by using (5.14) and (5.16), we obtain

$$z_n^{(\mathrm{iii})}(\xi^+) - z_n^{(\mathrm{iii})}(\xi^-) \to 0 . \tag{5.26}$$

Then the difference of (5.24) and (5.25) leads, by using (5.26), to

$$\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+) + \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-) \to 0 .$$

Recall that, by (5.14) and (5.17), we have $\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+) - \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-) \to 0$. Therefore,

$$\frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^-) \to 0, \qquad \frac{\mathrm{d}^2 z_n}{\mathrm{d}x^2}(\xi^+) \to 0. \tag{5.27}$$

Fourth step. Relations (5.21) and (5.27) imply that $\|\beta_n z_n\|_H \to 0$, which clearly contradicts (5.12). This contradiction shows that (5.11) holds. □

Theorem 5.3 can be generalized for coupled beams described by a version of (5.6) containing variable coefficients; see Ammari, Liu, and Tucsnak [1].

Theorem 5.3 together with Theorem 1.3 implies the following.

PROPOSITION 5.4. *The system from Theorem* 5.3 *is exactly controllable.*

5.2. The wave equation with Dirichlet-type nonlocal boundary feedback. The physical system that we have in mind consists of a vibrating membrane which is fixed on a part of the boundary, while on the other part of the boundary the vibrations are damped by a feedback control acting on the Dirichlet boundary condition. The input is the displacement field on the controlled part of the boundary, and the measurement depends linearly on the velocity field as well as on the input. A membrane could be modelled in a domain in $\mathbb{R}^2$, but we consider a more general wave equation on an n-dimensional (possibly unbounded) domain Ω. The boundary Γ of $\Omega \subset \mathbb{R}^n$ is assumed to be of class C^2 and to have a decomposition

as $\Gamma = \overline{\Gamma_0 \cup \Gamma_1}$, where Γ_0, Γ_1 are disjoint open parts of Γ with $\Gamma_1 \neq \emptyset$. We also assume that the Poincaré inequality holds for all $f \in \mathcal{H}^1_0(\Omega)$, which is always true if Ω is bounded, but it also holds for some unbounded domains (see section I.7). The operator $G : \mathcal{H}^{-1}(\Omega) \to \mathcal{H}^1_0(\Omega)$ is defined by

$$Gf = \phi \text{ if and only if } \phi \in \mathcal{H}^1_0(\Omega) \text{ and } -\Delta\phi = f.$$

Thus, in a certain sense, $G = -\Delta^{-1}$. We denote by $\gamma_0 : \mathcal{H}^1(\Omega) \to \mathcal{H}^{\frac{1}{2}}(\Gamma)$ the Dirichlet trace operator, which is onto, and by $\gamma_1 : \mathcal{H}^2(\Omega) \to \mathcal{H}^{\frac{1}{2}}(\Gamma)$ the outward normal derivative operator. Using Green's formula,

$$\langle \gamma_1 f, \gamma_0 g\rangle_{L^2} = \langle \Delta f, g\rangle_{L^2} + \langle \nabla f, \nabla g\rangle_{L^2} \tag{5.28}$$

for all $f \in \mathcal{H}^2(\Omega)$ and $g \in \mathcal{H}^1(\Omega)$, γ_1 can be extended so that $\gamma_1 f$ is defined as a distribution in $\mathcal{H}^{-\frac{1}{2}}(\Gamma)$ for every $f \in \mathcal{H}^1(\Omega)$ for which $\Delta f \in L^2(\Omega)$. Here, Δf denotes the Laplacian of f in the sense of distributions on Ω, i.e., in the space $\mathcal{D}'(\Omega)$.

We consider the system described by the equations

$$\ddot{z} = \Delta z \text{ in } \Omega \times (0,\infty), \tag{5.29}$$

$$z = 0 \quad \text{on } \Gamma_0 \times (0,\infty), \tag{5.30}$$

$$z - \frac{1}{2}\gamma_1(G\dot{z}) = u \text{ on } \Gamma_1 \times (0,\infty), \tag{5.31}$$

$$z(x,0) = z_0(x), \quad \dot{z}(x,0) = w_0(x) \text{ for } x \in \Omega. \tag{5.32}$$

The input of this system is the function u in (5.31). The output associated with this system is

$$y = z + \frac{1}{2}\gamma_1(G\dot{z}) \text{ on } \Gamma_1 \times (0,\infty). \tag{5.33}$$

Some comments about the domain Ω follow: It is not really necessary to assume that Γ is of class C^2. What we really need is that G maps $L^2(\Omega)$ onto $\mathcal{H}^2(\Omega) \cap \mathcal{H}^1_0(\Omega)$ and that γ_1 maps $\mathcal{H}^2(\Omega) \cap \mathcal{H}^1_0(\Omega)$ onto $\mathcal{H}^{\frac{1}{2}}(\Gamma)$. These properties hold also for some less regular domains, for example, for convex sets in $\mathbb{R}^2$ (see Grisvard [9, Theorem 3.2.1.2, p. 147]) or for rectangular domains in $\mathbb{R}^n$. We will need the following simple result, a direct consequence of the Riesz representation theorem in $L^2(\Omega)$.

PROPOSITION 5.5. *For every* $\mathrm{v} \in L^2(\Gamma)$ *there exists a unique function* $D\mathrm{v} \in L^2(\Omega)$ *such that*

$$\int_\Omega (D\mathrm{v})(x)\overline{\psi(x)}\,dx = -\int_\Gamma \mathrm{v}\,\overline{\gamma_1(G\psi)}\,d\Gamma \qquad \forall\, \psi \in L^2(\Omega). \tag{5.34}$$

Moreover, the operator D *defined above (called the Dirichlet map) is linear and bounded from* $L^2(\Gamma)$ *into* $L^2(\Omega)$.

Due to the Poincaré inequality, the norm on $\mathcal{H}^1_0(\Omega)$ can be defined as $\|f\|_{\mathcal{H}^1_0} = \|\nabla f\|_{L^2}$. Then it is easy to see (using (5.28)) that the corresponding dual norm on $\mathcal{H}^{-1}(\Omega)$ (with respect to the pivot space $L^2(\Omega)$) can be written as

$$\|g\|_{\mathcal{H}^{-1}} = \sup_{\|f\|_{\mathcal{H}^1_0}=1} \langle g, f\rangle_{\mathcal{H}^{-1},\mathcal{H}^1_0} = \|\nabla(Gg)\|_{L^2}.$$

Define $W = \{f \in L^2(\Omega) \mid \Delta f \in \mathcal{H}^{-1}(\Omega)\}$. Since γ_1 maps $\mathcal{H}^2(\Omega) \cap \mathcal{H}_0^1(\Omega)$ onto $\mathcal{H}^{\frac{1}{2}}(\Gamma)$ (see Lions and Magenes [21, Chapter 2, Theorem 5.4]), the Dirichlet trace operator γ_0 can be extended to an operator $\gamma_0 : W \to \mathcal{H}^{-\frac{1}{2}}(\Gamma)$ by putting

$$\langle \gamma_0 f, \gamma_1(G\psi)\rangle_{\mathcal{H}^{-\frac{1}{2}},\mathcal{H}^{\frac{1}{2}}} = -\langle \Delta f, G\psi\rangle_{\mathcal{H}^{-1},\mathcal{H}_0^1} - \langle f, \psi\rangle_{L^2} \qquad \forall\, \psi \in L^2(\Omega).$$

The operators D and γ_0 defined above are related as follows.

PROPOSITION 5.6. *If* $\mathrm{v} \in L^2(\Gamma)$, *then* $\Delta(D\mathrm{v}) = 0$ *in* $\mathcal{D}'(\Omega)$ *(which implies that* $D\mathrm{v} \in W$*). Moreover, we have that* $\gamma_0(D\mathrm{v}) = \mathrm{v}$.

Proof. The fact that $\Delta(D\mathrm{v}) = 0$ (in the sense of distributions) follows directly from (5.34) by taking $\psi = \Delta\varphi$, where $\varphi \in \mathcal{D}(\Omega) = C_0^\infty(\Omega)$. Now using the definition of the extended γ_0, we have that

$$\langle \gamma_0(D\mathrm{v}), \gamma_1(G\psi)\rangle_{\mathcal{H}^{-\frac{1}{2}},\mathcal{H}^{\frac{1}{2}}} = -\langle D\mathrm{v}, \psi\rangle_{L^2} \qquad \forall\, \psi \in L^2(\Omega). \tag{5.35}$$

Since $\gamma_1(G\psi)$ in (5.35) can be any function in $\mathcal{H}^{\frac{1}{2}}(\Gamma)$ and $\mathcal{H}^{\frac{1}{2}}(\Gamma)$ is dense in $L^2(\Omega)$, equations (5.34) and (5.35) imply that $\gamma_0(D\mathrm{v}) = \mathrm{v}$. ∎

To discuss the well-posedness and conservativity of the system (5.29)–(5.33) (using Theorem 1.1), we have to introduce the appropriate spaces and operators. Denote

$$X = L^2(\Omega) \times \mathcal{H}^{-1}(\Omega), \quad U = L^2(\Gamma_1).$$

We also define the Hilbert space

$$Z_0 = \left\{ f \in W \;\middle|\; \gamma_0 f \in L^2(\Gamma) \text{ and } \gamma_0 f|_{\Gamma_0} = 0 \right\}, \tag{5.36}$$

with the norm $\|f\|_{Z_0}$ given by

$$\|f\|_{Z_0}^2 = \|f\|_{L^2}^2 + \|\Delta f\|_{\mathcal{H}^{-1}}^2 + \|\gamma_0 f\|_{L^2}^2.$$

The precise statement of the well-posedness and conservativity of the system described by (5.29)–(5.33) is given in the following proposition.

PROPOSITION 5.7. *The equations* (5.29)–(5.33) *determine a conservative linear system* Σ *with input and output space* U *and state space* X. *If* $z_0 \in Z_0$, $w_0 \in L^2(\Omega)$, $u \in \mathcal{H}^1(0,\infty;U)$, *and the compatibility condition*

$$z_0(x) - \frac{1}{2}\gamma_1\left(Gw_0\right)(x) = u(x,0) \quad \text{for} \quad x \in \Gamma_1$$

holds, then (5.29)–(5.33) *have a unique solution* z, y *satisfying*

$$z \in BC\left(0,\infty;Z_0\right) \cap BC^1\left(0,\infty;L^2(\Omega)\right) \cap BC^2\left(0,\infty;\mathcal{H}^{-1}(\Omega)\right),$$

$$y \in \mathcal{H}^1(0,\infty;U).$$

Proof. We define the following spaces and operators:

- The space H is defined by $H = \mathcal{H}^{-1}(\Omega)$ endowed with the norm

$$\|f\|_H = \|\nabla(Gf)\|_{L^2(\Omega)}.$$

- The operator $A_0 : \mathcal{D}(A_0) \to H$ is defined by

$$\mathcal{D}(A_0) = \mathcal{H}_0^1(\Omega), \quad A_0\phi = -\Delta\phi \qquad \forall\, \phi \in \mathcal{D}(A_0).$$

It is well known that A_0 is self-adjoint, positive, and boundedly invertible.

- As in section 1, we put $H_1 = \mathcal{D}(A_0)$ and we introduce the spaces H_α ($\alpha \in \mathbb{R}$) by considering powers of A_0 and duality so that $A_0 : H_\alpha \to H_{\alpha-1}$. In order to identify the space $H_{\frac{1}{2}} = \mathcal{D}(A_0^{\frac{1}{2}})$, we recall that $H_{\frac{1}{2}}$ is the completion of $\mathcal{D}(A_0)$ with respect to the norm

$$\|z\|_{\frac{1}{2}} = \left\|A_0^{\frac{1}{2}} z\right\|_H = \sqrt{\langle A_0 z, z\rangle_H}.$$

  Since for any $z \in \mathcal{D}(A_0) = \mathcal{H}_0^1(\Omega)$, we have

$$\langle A_0 z, z\rangle_H = -\left\langle \nabla z, \nabla\left(\Delta^{-1} z\right)\right\rangle_{L^2(\Omega)} = \|z\|^2_{L^2(\Omega)};$$

  the space $H_{\frac{1}{2}}$ is given by $H_{\frac{1}{2}} = L^2(\Omega)$.
- Notice that $H_{\frac{3}{2}} = \mathcal{H}^2(\Omega) \cap \mathcal{H}_0^1(\Omega)$. We define the space

$$\widetilde{\mathcal{H}}^{-2}(\Omega) = \left(\mathcal{H}^2(\Omega) \cap \mathcal{H}_0^1(\Omega)\right)'.$$

  (This dual is computed with respect to the pivot space $L^2(\Omega)$.) It can be checked that G can be extended so that $G : \widetilde{\mathcal{H}}^{-2}(\Omega) \to L^2(\Omega)$ and the norm on $\widetilde{\mathcal{H}}^{-2}(\Omega)$ is

$$\|g\|_{\widetilde{\mathcal{H}}^{-2}} = \sup_{\|\Delta f\|_{L^2(\Omega)}=1} \langle g, f\rangle = \|Gg\|_{L^2}.$$

- By definition, the space $H_{-\frac{1}{2}}$ is the completion of H with respect to the norm $\|z\|_{-\frac{1}{2}} = \left\|A_0^{-\frac{1}{2}} z\right\|_H$. Since $G = A_0^{-1}$ on H, the last equality and the definition of the norm on H imply that

$$\|z\|_{-\frac{1}{2}} = \left\|\nabla\left(A_0^{-\frac{3}{2}} z\right)\right\|_{L^2}.$$

  The above relation and the obvious fact that $\|A_0^{\frac{1}{2}} w\|_{L^2} = \|\nabla w\|_{L^2}$ for any $w \in \mathcal{H}_0^1(\Omega)$ imply that

$$\|z\|_{-\frac{1}{2}} = \|A_0^{-1} z\|_{L^2} = \|Gz\|_{L^2} \qquad \forall\, z \in H.$$

  We have thus shown that $H_{-\frac{1}{2}} = \widetilde{\mathcal{H}}^{-2}(\Omega)$.
- We denote by $P \in \mathcal{L}\left(L^2(\Gamma), L^2(\Gamma_1)\right)$ the operator of truncation to Γ_1. Then $P^* \in \mathcal{L}\left(L^2(\Gamma_1), L^2(\Gamma)\right)$ is the operator defined by extending the functions in $L^2(\Gamma_1)$ by zero outside Γ_1. The operator $B_0 \in \mathcal{L}(U, H_{-\frac{1}{2}})$ is defined by

$$B_0 \mathrm{v} = A_0 D P^* \mathrm{v},$$

  where A_0 is considered as an operator from $H_{\frac{1}{2}}$ to $H_{-\frac{1}{2}}$ and $D : U \to L^2(\Omega)$ is the Dirichlet map defined in Proposition 5.5.
- Let $\phi \in \mathcal{H}_0^1(\Omega) = H_1$ and $\mathrm{v} \in L^2(\Gamma_1)$. Then we have

$$\langle B_0 \mathrm{v}, \phi\rangle_{H_{-\frac{1}{2}}, H_{\frac{1}{2}}} = \langle D P^* \mathrm{v}, A_0 \phi\rangle_H = \langle D P^* \mathrm{v}, \phi\rangle_{H_{\frac{1}{2}}}.$$

  By using the fact that $H_{\frac{1}{2}} = L^2(\Omega)$, the density of $\mathcal{H}_0^1(\Omega)$ in $L^2(\Omega)$, and (5.34), it follows that for every $\phi \in L^2(\Omega)$ and for every $\mathrm{v} \in L^2(\Gamma_1)$

$$\langle B_0 \mathrm{v}, \phi\rangle_{H_{-\frac{1}{2}}, H_{\frac{1}{2}}} = \langle D P^* \mathrm{v}, \phi\rangle_{L^2} = -\int_{\Gamma_1} \mathrm{v}\overline{\gamma_1\left(G\phi\right)}\,\mathrm{d}\Gamma.$$

We conclude that the adjoint of B_0 (using the pivot space $H = \mathcal{H}^{-1}(\Omega)$) is $C_0 \in \mathcal{L}(H_{\frac{1}{2}}, U)$ given by

$$C_0\phi = B_0^*\phi = -P\gamma_1(G\phi) \qquad \forall\, \phi \in H_{\frac{1}{2}} = L^2(\Omega).$$

It is clear that the spaces U, H, H_α, X and the operators A_0, C_0, B_0 fit into the simple general framework of section 1. Thus, by Theorem 1.1, they determine via the equations (1.1)–(1.3) a conservative linear system Σ. The state of this system is

$$\xi(t) = \begin{bmatrix} z(t) \\ \dot{z}(t) \end{bmatrix}.$$

To show that Σ is described by (5.29)–(5.33), first we notice that the space $Z_0 = H_1 + A_0^{-1}B_0U$ defined after (1.5) (see also Theorem I.1.2) is given in our case by $Z_0 = H_1 + DP^*U$. By using Lemma 5.6, it can be checked that this space coincides with that defined by (5.36). We define the operator $G_0 \in \mathcal{L}(Z_0, U)$ by

$$G_0 f = P\gamma_0 f \qquad \forall\, f \in Z_0.$$

Clearly, we have $G_0H_1 = \{0\}$, and by Lemma 5.6 we have in $\mathcal{L}(U)$

$$G_0A_0^{-1}B_0 = P\gamma_0A_0^{-1}(A_0DP^*) = P\gamma_0DP^* = I.$$

Hence, all the assumptions in Theorem I.1.4 are satisfied. We define on Z_0 the operator $L_0 = A_0 - B_0G_0$ as in Theorem I.1.4, and it is easy see that $L_0z = -\Delta z$.

If we write the system of equations (I.1.16) in our specific framework, we obtain the system of equations (5.29)–(5.33). Hence, by Theorem I.1.4 the compatibility condition in our proposition is equivalent to (I.1.9), and the equations (5.29)–(5.33) are equivalent to (I.1.11) and (I.1.12). Now by Theorem I.1.2, the equations have a solution z, y with the claimed smoothness properties. □

This system has also been considered in Lasiecka and Triggiani [18, pp. 669–671] but without considering outputs. They have proved the well-posedness of the mapping from the input function to the state, and they have discussed the exponential stability of the system for suitable Γ_1.

THEOREM 5.8. *If Ω is bounded, then the system defined by* (5.29)–(5.33) *is strongly stable, exactly controllable in infinite time, and exactly observable in infinite time.*

Proof. The fact that the equations (5.29)–(5.33) define a conservative linear system with input space U, state space X, and output space Y has been said in Proposition 5.7. The boundedness of Ω implies that the spectrum of A_0 is countable. Thus, according to assertion (8) of Theorem 1.5, in order to check the properties claimed in the theorem it suffices to prove that for any $\phi \in H_1$ if ϕ is an eigenvector of A_0, then $C_0\phi \neq 0$. Due to the particular form of A_0 and C_0, this means that we have to show that if $\phi \in \mathcal{H}_0^1(\Omega)$ is such that for some $\lambda > 0$

$$-\Delta\phi = \lambda\phi \ \text{ in } \ \mathcal{H}^{-1}(\Omega), \qquad \frac{\partial}{\partial\nu}(G\phi) = 0 \ \text{ on } \ \Gamma_1, \tag{5.37}$$

then $\phi = 0$. By denoting $\psi = G\phi$, we see that (5.37) is equivalent to

$$-\Delta\psi = \lambda\psi \ \text{ in } \ \mathcal{H}_0^1(\Omega), \qquad \frac{\partial\psi}{\partial\nu} = 0 \ \text{ on } \ \Gamma_1. \tag{5.38}$$

By classical elliptic regularity results, (5.38) implies that $\psi \in \mathcal{H}^2(\Omega)$ (see, for instance, Grisvard [9, Theorem 2.2.2.5]). This fact combined with (5.38) implies, by a classical unique continuation argument (see, for instance, Komornik [16, Corollary 6.2]), that $\psi = 0$. Thus, (5.37) implies that $\phi = \Delta\psi = 0$ in $\mathcal{H}_0^1(\Omega)$. □

The exponential stability of the system (5.29)–(5.32) was studied in Bardos et al. [4]. By combining Proposition 5.7 and [4, Theorem 1], we obtain the following.

THEOREM 5.9. *Suppose that Ω is bounded and there exists a time $T_0 > 0$ such that every geometric ray in $\Omega \times (0, T_0)$ intersects $\Gamma_1 \times (0, T_0)$ in a nondiffractive point. Then the equations* (5.29)–(5.33) *define an exponentially stable, conservative system with input space U, state space X, and output space Y. This system is also exactly controllable and exactly observable in time T_0.*

The last sentence of the above theorem follows from the exponential stability (stated in the first part of the theorem) using Theorem 1.3.

Acknowledgments. We have had useful discussions on this research with Olof Staffans, Arjan van der Schaft, and Peng-Fei Yao.

A CONVERSE LYAPUNOV THEOREM FOR NONUNIFORM IN TIME GLOBAL ASYMPTOTIC STABILITY AND ITS APPLICATION TO FEEDBACK STABILIZATION*

I. KARAFYLLIS† AND J. TSINIAS†

Abstract. Lyapunov-like characterizations for the concepts of nonuniform in time robust global asymptotic stability and input-to-state stability for time-varying systems are established. The main result of our work enables us to derive (1) necessary and sufficient conditions for feedback stabilization for affine in the control systems and (2) sufficient conditions for the propagation of the input-to-state stability property through integrators.

Key words. nonuniform in time asymptotic stability, input-to-state stability, Lyapunov functions, feedback stabilization

1. Introduction.

The notion of nonuniform in time *robust global asymptotic stability* (RGAS) is basically motivated by the problem of feedback stabilization for a class of nonlinear systems that, although fail to be stabilized at a specific equilibrium by continuous static time-invariant feedback, a *time-varying* feedback controller can be constructed in such a way that the equilibrium for the resulting closed-loop time-varying system is asymptotically stable, in general being nonuniform with respect to the initial values of time. The notion of RGAS—without uniformity with respect to time—is also motivated by problems related to feedback stabilization, such as

- stabilization of systems with uncertainties,
- stabilization of systems at a reference trajectory.

In the problems mentioned above, the analysis is reduced to studying asymptotic stability at a specific equilibrium of a time-varying system, whose dynamics are in general unbounded with respect to time. Particularly, in [40, 41] it is shown that for a class of triangular systems whose dynamics contain time-varying unknown parameters, it is possible to find, by applying a backstepping design procedure, a smooth time-varying feedback controller in such a way that the equilibrium of the resulting closed-loop system is RGAS, in general nonuniform with respect to initial values of time. Further progress has been obtained in [12, 13, 14, 15, 16, 17] for a large class of nonlinear systems that in general fail to be uniformly asymptotically stabilized by smooth static time-invariant feedback at a specific equilibrium. It is worthwhile to note that among other things in the works [12, 14], by employing the concept of nonuniform in time RGAS and its Lyapunov characterizations, we derive sufficient conditions for the solvability of the state feedback tracking control problem for a class of nonholonomic systems that includes the nonholonomic case in chained form. The corresponding results generalize those obtained in the literature for the same problem, since they are based on much weaker hypotheses. We finally mention the

recent work [16], where various equivalent descriptions of nonuniform in time input-to-state stability are proposed and a generalization of the well-known "small-gain theorem" of Jiang, Teel, and Praly in [11] is established for time-varying composite systems.

The main purpose of the present paper is to establish a Lyapunov characterization for the notion of nonuniform in time RGAS. Lyapunov functions play an important role to synthesis and design in control theory, and several important results have been recently established concerning Lyapunov-like descriptions of *robust uniform global asymptotic stability* (RUGAS) and *input-to-state stability* (ISS) (see [2, 4, 5, 6, 8, 9, 19, 20, 21, 24, 25, 33, 34, 43]), *forward completeness* [1], and *asymptotic controllability* (see, for instance, [23, 30]). Our goal is to establish converse Lyapunov theorems for the concepts of *nonuniform in time RGAS* and *nonuniform in time ISS* and give some applications to feedback stabilization. In [42] a converse Lyapunov theorem is established for the particular case of nonuniform in time exponential robust stability and exp-ISS. In the present paper, by extending the approach employed in [20, 34], we establish a Lyapunov characterization for the general concept of RGAS for time-varying systems:

$$\begin{aligned} &\dot{x} = f(t,x,d) \\ &x \in \Re^n, \quad d \in D, \quad t \geq 0. \end{aligned} \tag{1.1}$$

We assume that $D \subset \Re^m$ is a nonempty compact set and $f : \Re^+ \times \Re^n \times D \to \Re^n$ is mapping with $f(t,0,d) = 0$ for all $(t,d) \in \Re^+ \times D$ that satisfies the following hypotheses:

H1. The function $f(t,x,d)$ is measurable in t for all $(x,d) \in \Re^n \times D$.

H2. The function $f(t,x,d)$ is continuous in d for all $(t,x) \in \Re^+ \times \Re^n$.

H3. The function $f(t,x,d)$ is locally Lipschitz with respect to x, uniformly in $d \in D$, in the sense that for every bounded interval $I \subset \Re^+$ and for every compact subset S of $\Re^n$, there exists a constant $L \geq 0$ such that

$$\begin{aligned} &|f(t,x,d) - f(t,y,d)| \leq L|x-y| \\ &\forall t \in I, \quad (x,y) \in S \times S, \quad d \in D. \end{aligned}$$

It turns out from H3 that there exists a positive C^0 function $L : \Re^+ \times \Re^+ \to \Re^+$ such that for each fixed $s \geq 0$ the mappings $L(\cdot, s)$ and $L(s, \cdot)$ are nondecreasing and the following holds:

$$\begin{aligned} &|f(t,x,d) - f(t,y,d)| \leq L(t, |x| + |y|)|x-y| \\ &\forall (t,x,y,d) \in \Re^+ \times \Re^n \times \Re^n \times D. \end{aligned} \tag{1.2}$$

In section 2, we provide some equivalent characterizations for the concept of RGAS for systems (1.1) (Proposition 2.2), and in section 3, we establish its Lyapunov characterization (Theorem 3.1). Section 4 is devoted to various equivalent descriptions of the nonuniform in time ISS property based on the results obtained for RGAS. The results of section 4 are applicable to the ISS feedback stabilization problem. In section 5.1 we derive a necessary and sufficient Lyapunov-based condition for ISS feedback stabilization for systems of the form

$$\begin{aligned} &\dot{x} = f(t,x,v) + g(t,x)u, \\ &x \in \Re^n, \quad v \in \Re^l, \quad u \in \Re^m, \quad t \geq 0, \end{aligned} \tag{1.3}$$

where the dynamics $f(\cdot)$ and $g(\cdot) = (g_1(\cdot), g_2(\cdot), \dots, g_m(\cdot))$ are both C^0 and locally Lipschitz with respect to (x, v) with $f(\cdot, 0, 0) = 0$. (Throughout this paper, given a map $F : \Re^+ \times \Re^{l_1} \to \Re^{l_2}$, we say that it is locally Lipschitz with respect to $x \in \Re^{l_1}$ if for every bounded interval $I \subset \Re^+$ and for every compact subset S of $\Re^{l_1}$, there exists a constant $L \geq 0$ such that $|F(t, x) - F(t, y)| \leq L|x - y|$ for every $(t, x, y) \in I \times S \times S$.) The main results of section 5.1 (Theorem 5.1 and Proposition 5.2) constitute extensions of the well-known Artstein–Sontag theorem [3, 27, 35] for autonomous systems and guarantee existence of a C^∞ mapping $u = k(t, x)$ in such a way that the resulting system

$$\dot{x} = f(t, x, v) + g(t, x)k(t, x) \tag{1.4}$$

satisfies the nonuniform in time ISS property with v as input. An explicit formula for a time-varying feedback stabilizer is proposed in Proposition 5.2. We also prove that, even for autonomous systems for which uniform in time asymptotic stabilization is not feasible, it is possible to exhibit nonuniform in time asymptotic stabilization by means of a time-varying feedback. In section 5.2 we establish an extension of a well-known result concerning the autonomous case (see [11, 36]) for systems of the following form:

$$\dot{x} = f(t, x, y), \tag{1.5a}$$

$$\dot{y} = g(t, x, y) + h(t, x, y)u, \tag{1.5b}$$

$$x \in \Re^n, \quad y \in \Re, \quad u \in \Re, \quad t \geq 0,$$

where $f(\cdot)$, $g(\cdot)$, $h(\cdot)$ are C^0 and locally Lipschitz with respect to (x, y), with $f(\cdot, 0, 0) = 0$ and $g(\cdot, 0, 0) = 0$. Particularly, we show that, under the presence of the (nonuniform in time) ISS for the subsystem (1.5a) with y as input, there exists a feedback law exhibiting ISS stabilization for (1.5) (Proposition 5.6). This result enables us to examine the partial-state feedback stabilization problem for triangular systems. Particularly, by exploiting a Lyapunov function based approach we re-establish the main result in [40] for a special class of triangular systems whose dynamics are time-dependent.

Notations. Throughout this paper we adopt the following notations:

- By M_D we denote the set of all measurable functions from $\Re^+ := [0, +\infty)$ to D, where D is any given compact subset of $\Re^m$.
- For any $x \in \Re^n$, x^T denotes its transpose and $|x|$ its usual Euclidean norm.
- K^+denotes the class of positive nondecreasing C^∞ functions $\phi : \Re^+ \to (0, +\infty)$, and $\mathbf{E}$ denotes the class of nonnegative C^0 functions $\mu : \Re^+ \to \Re^+$, for which $\int_0^{+\infty} \mu(t)dt < +\infty$ and $\lim_{t \to +\infty} \mu(t) = 0$ hold.
- $\mathbf{L}^\infty_{loc}$ denotes the set of all measurable functions $u : \Re^+ \to \Re^m$ that are essentially bounded on any nonempty compact subset of $\Re^+$, and $\mathbf{L}^\infty$ denotes the set of all measurable functions $u : \Re^+ \to \Re^m$ that are essentially bounded on $\Re^+$.
- By $B[x, r]$, where $x \in \Re^n$ and $r > 0$, we denote the closed sphere in $\Re^n$ of radius r centered at x.
- By $x(t) = x(t, t_0, x_0; d)$ we denote the solution of (1.1) at time t that corresponds to some input $d \in M_D$ initiated from x_0 at time t_0. For convenience, in certain parts of the text we prefer the notation $\phi(\cdot)$ instead of $x(\cdot)$.
- For definitions of classes K, K_∞, KL, see [18, 20].
- By Π we denote the subclass of K_∞ consisting of all functions $r : \Re^+ \to \Re^+$, for which $r(s) = \sum_{i=1}^m a_i s^i$ with $a_i \geq 0$ for $i = 1, \dots, m$, $a_1 > 0$ for some positive integer m.

2. The notion of RGAS. In this section we provide a general concept of global asymptotic stability (GAS) and establish some facts that will be used in proofs of main results in sections 3 and 5.

DEFINITION 2.1. *We say that zero $0 \in \Re^n$ is RGAS for* (1.1) *if for every $t_0 \geq 0$, $d \in M_D$, and $x_0 \in \Re^n$, the corresponding solution $x(\cdot)$ of* (1.1) *exists for all $t \geq t_0$ and satisfies the following properties:*

P1 (stability). *For every $\varepsilon > 0$, $T \geq 0$, it holds that*

$$\sup\{|x(t)| : d \in M_D, t \geq t_0, |x_0| \leq \varepsilon, t_0 \in [0,T]\} < +\infty \quad \text{(Lagrange stability)} \tag{2.1a}$$

and there exists a $\delta := \delta(\varepsilon, T) > 0$ such that

$$|x_0| \leq \delta, \quad t_0 \in [0,T] \Rightarrow |x(t)| \leq \varepsilon \quad \forall t \geq t_0, \quad d \in M_D \quad \text{(Lyapunov stability).} \tag{2.1b}$$

P2 (attractivity). *For every $\varepsilon > 0$, $T \geq 0$, and $R \geq 0$, there exists a $\tau := \tau(\varepsilon, T, R) \geq 0$ such that*

$$|x_0| \leq R, \quad t_0 \in [0,T] \Rightarrow |x(t)| \leq \varepsilon \quad \forall t \geq t_0 + \tau, \quad d \in M_D. \tag{2.1c}$$

As in the case of uniform in time RUGAS (see [20]) we have the following proposition.

PROPOSITION 2.2. *The origin $0 \in \Re^n$ is RGAS for* (1.1) *if and only if there exist a pair of functions a_1, a_2 of class K_∞, a_1 being locally Lipschitz on $(0, +\infty)$, and a function β of class K^+ such that for every $d \in M_D$, $t_0 \geq 0$, and $x_0 \in \Re^n$ the following holds:*

$$a_1(|x(t)|) \leq \exp(-t + t_0)\beta(t_0)a_2(|x_0|) \quad \forall t \geq t_0. \tag{2.2}$$

The proof of Proposition 2.2 requires the following technical result.

LEMMA 2.3. *Let $a : \Re^+ \times \Re^+ \to \Re^+$ be a function with $a(\cdot, 0) = 0$ that satisfies the following properties:*

(1) *For each fixed $t \geq 0$, the mapping $a(t, \cdot)$ is nondecreasing.*
(2) *For each fixed $s \geq 0$, the mapping $a(\cdot, s)$ is nondecreasing.*
(3) $\lim_{s \to 0^+} a(t,s) = 0$ *for all $t \geq 0$.*

Then there exists a pair of functions $\zeta \in K_\infty$ and $\gamma \in K^+$ such that

$$a(t,s) \leq \zeta(\gamma(t)s) \qquad \forall (t,s) \in (\Re^+)^2. \tag{2.3}$$

Proof of Lemma 2.3. Without loss of generality we may assume that a is $C^0(\Re^+ \times \Re^+)$. Indeed, otherwise we may consider the function

$$\hat{a}(t,s) := \begin{cases} \dfrac{1}{s} \displaystyle\int_s^{2s} \int_t^{t+1} a(\tau, \xi) d\tau \, d\xi & \text{for } s > 0, \\ 0 & \text{for } s = 0, \end{cases}$$

which by virtue of the inequality $a(t,s) \leq \hat{a}(t,s) \leq a(t+1, 2s)$ is $C^0(\Re^+ \times \Re^+)$ and satisfies $\hat{a}(\cdot, 0) = 0$. Notice that $\hat{a}$ has the same properties (1)–(3) of our statement with a. By invoking property (3), there exists a C^0 strictly decreasing function $\eta : \Re^+ \to (0, +\infty)$ with $\lim_{t \to +\infty} \eta(t) = 0$ such that

$$s \leq \eta(t) \Rightarrow a(t,s) \leq \frac{1}{t+1}. \tag{2.4a}$$

Let μ be the inverse function of η defined on $(0, \eta(0)]$ being nonnegative, continuous, strictly decreasing with $\lim_{t\to 0^+} \mu(t) = +\infty$. Define

$$\tilde{\mu}(s) := \begin{cases} \mu(s) & \text{if} \quad s \in (0, \eta(0)], \\ 0 & \text{if} \quad s > \eta(0). \end{cases} \tag{2.4b}$$

It turns out that $\tilde{\mu} : (0, +\infty) \to \Re^+$ is nonincreasing, continuous, and nonnegative and satisfies $\lim_{t\to 0^+} \tilde{\mu}(t) = +\infty$. Additionally, define

$$\beta(s) := s + \begin{cases} 0 & \text{if} \quad s = 0, \\ \sup\limits_{0<\tau\leq s} a(\tilde{\mu}(\tau), \tau) & \text{if} \quad s > 0. \end{cases} \tag{2.5}$$

We show that $\beta \in K_\infty$. Indeed, by definition (2.5) it follows that $\beta(0) = 0$ and β is strictly increasing with $\lim_{s\to+\infty} \beta(s) = +\infty$. Continuity of β on $(0, +\infty)$ follows from the fact that both a and $\tilde{\mu}$ are C^0 on $(0, +\infty)$. Furthermore, notice that (2.4a) and (2.4b) imply

$$a(\tilde{\mu}(\tau), \tau) \leq \frac{1}{\tilde{\mu}(\tau) + 1} \leq \frac{1}{\tilde{\mu}(s) + 1} \qquad \forall \tau \in (0, s] \text{ and } s \leq \eta(0). \tag{2.6}$$

Since $\lim_{s\to 0^+} \tilde{\mu}(s) = +\infty$ it follows from (2.6) that $\lim_{s\to 0^+} \beta(s) = 0$, and this establishes continuity of β at zero. Let $\zeta(s) := a(s, s) + \beta(s)$. Obviously, $\zeta(\cdot)$ is of class K_∞. Moreover, when $s \geq t$, by virtue of property (2) it holds that $a(t, s) \leq a(s, s) \leq \zeta(s)$, which implies

$$\sup_{s\geq t>0} \frac{\zeta^{-1}(a(t, s))}{s} \leq 1. \tag{2.7}$$

Also, when $0 < s \leq \eta(t)$, it follows from (2.4b) that $\tilde{\mu}(s) \geq t$; hence, by virtue of property (2) and (2.5), $a(t, s) \leq a(\tilde{\mu}(s), s) \leq \zeta(s)$. The latter implies that

$$\sup_{0<s\leq\eta(t)} \frac{\zeta^{-1}(a(t, s))}{s} \leq 1. \tag{2.8}$$

Using property (1), (2.7), and (2.8) we get

$$\sup_{s>0} \frac{\zeta^{-1}(a(t, s))}{s} \leq 1 + \sup_{\eta(t)\leq s\leq t} \frac{\zeta^{-1}(a(t, s))}{s} \leq 1 + \frac{\zeta^{-1}(a(t, t))}{\eta(t)}. \tag{2.9}$$

Finally let γ be any function of class K^+ which satisfies

$$\gamma(t) \geq \frac{\zeta^{-1}(a(t, t))}{\eta(t)} + 1 \qquad \forall t \geq 0. \tag{2.10}$$

The desired (2.3) is a consequence of (2.9) and (2.10). □

We are in a position to establish Proposition 2.2. Its proof is based on Lemma 2.3 and is inspired by the analysis made in [32].

Proof of Proposition 2.2. ($\Rightarrow$) Suppose that $0 \in \Re^n$ is RGAS for (1.1). Let $\xi, T, s \geq 0$ and define

$$a(T, s) := \sup\{|x(t)| : d \in M_D, t \geq t_0, |x_0| \leq s, 0 \leq t_0 \leq T\}, \tag{2.11a}$$

$$M(\xi, T, s) := \sup\{|x(t_0 + \xi)| : d \in M_D, |x_0| \leq s, 0 \leq t_0 \leq T\}. \tag{2.11b}$$

Obviously, our hypothesis that $0 \in \Re^n$ is RGAS guarantees that both $a(\cdot)$ and $M(\cdot)$ are well defined. Moreover, $a(\cdot)$ satisfies all hypotheses of the Lemma 2.3; namely, for each fixed $s \geq 0$, $a(\cdot, s)$ is nondecreasing, and for each fixed $T \geq 0$, $a(T, \cdot)$ is nondecreasing and satisfies $a(\cdot, 0) = 0$. Furthermore, stability of zero asserts that, for every $T \geq 0$, $\lim_{s \to 0^+} a(T, s) = 0$. It turns out from Lemma 2.3 that there exist functions $\zeta_1 \in K_\infty$ and $\gamma_1 \in K^+$ such that

$$a(T, s) \leq \zeta_1(\gamma_1(T)s) \qquad \forall (T, s) \in (\Re^+)^2. \tag{2.12}$$

The previous inequality in conjunction with (2.11a) and (2.11b) implies

$$M(\xi, T, s) \leq \zeta_1(\gamma_1(T)s) \qquad \forall (\xi, T, s) \in (\Re^+)^3. \tag{2.13}$$

Moreover, attractivity of zero guarantees that for every $\varepsilon > 0$, $T \geq 0$, and $R \geq 0$, there exists a $\tau = \tau(\varepsilon, T, R) \geq 0$ such that

$$M(\xi, T, s) \leq \varepsilon \qquad \forall \xi \geq \tau(\varepsilon, T, R) \text{ and } 0 \leq s \leq R. \tag{2.14}$$

Let

$$g(s) := \sqrt{s} + s^2 \tag{2.15a}$$

and let p be a function of class K^+ with $p(0) = 1$ and

$$\lim_{t \to +\infty} p(t) = +\infty. \tag{2.15b}$$

Define

$$\mu(\xi) := \sup \left\{ \frac{M(\xi, T, s)}{p(T)g(\zeta_1(\gamma_1(T)s))}, T \geq 0, s > 0 \right\}. \tag{2.16}$$

Obviously, by (2.12) and (2.15a), the function $\mu : \Re^+ \to \Re^+$ is well defined and satisfies $\mu(\cdot) \leq 1$. We show that $\lim_{\xi \to +\infty} \mu(\xi) = 0$; equivalently, we establish that for any given $\varepsilon > 0$, there exists a $\delta = \delta(\varepsilon) \geq 0$ such that

$$\mu(\xi) \leq \varepsilon \text{ for } \xi \geq \delta(\varepsilon). \tag{2.17}$$

Notice first that for any given $\varepsilon > 0$ there exist constants $a := a(\varepsilon)$ and $b := b(\varepsilon)$ with $0 < a < b$ such that

$$x \notin (a, b) \Rightarrow \frac{x}{\sqrt{x} + x^2} \leq \varepsilon. \tag{2.18}$$

We next recall (2.15b), which asserts that, for the above ε for which (2.18) holds, there exists a $c := c(\varepsilon) \geq 0$ such that $p(T) \geq \frac{1}{\varepsilon}$ for all $T \geq c$. This by virtue of (2.13) and (2.15a) yields

$$\frac{M(\xi, T, s)}{p(T)g(\zeta_1(\gamma_1(T)s))} \leq \varepsilon \qquad \forall \xi \geq 0 \tag{2.19a}$$

$$\text{when either } T \geq c \text{ or } \zeta_1(\gamma_1(T)s) \notin (a, b). \tag{2.19b}$$

Hence, in order to establish (2.17), it remains to consider the case

$$a \leq \zeta_1(\gamma_1(T)s) \leq b \quad \text{and} \quad 0 \leq T \leq c. \tag{2.20}$$

Since, for each fixed $(\xi, s) \in (\Re^+)^2$, the mappings $M(\xi, \cdot, s)$, $M(\xi, T, \cdot)$, $\gamma_1(\cdot)$, and $p(\cdot)$ are nondecreasing, we have that

$$\frac{M(\xi, T, s)}{p(T)g(\zeta_1(\gamma_1(T)s))} \leq \frac{M\left(\xi, c, \frac{\zeta_1^{-1}(b)}{\gamma_1(0)}\right)}{g(a)} \tag{2.21}$$

provided that (2.20) holds. By using (2.14) and (2.21) with

$$\varepsilon := \varepsilon g(a), \quad T := c, \quad R := \frac{\zeta_1^{-1}(b)}{\gamma_1(0)},$$

it follows that

$$M\left(\xi, c, \frac{\zeta_1^{-1}(b)}{\gamma_1(0)}\right) \leq \varepsilon g(a) \quad \text{for } \xi \geq \delta(\varepsilon) := \tau\left(\varepsilon g(a), c, \frac{\zeta_1^{-1}(b)}{\gamma_1(0)}\right). \tag{2.22}$$

By taking into account (2.19), (2.20), (2.21), (2.22), and definition (2.16) of $\mu(\cdot)$, it follows that (2.17) holds with $\delta = \delta(\varepsilon)$ as selected in (2.22). Since $\varepsilon > 0$ was arbitrary we conclude that $\lim_{\xi \to +\infty} \mu(\xi) = 0$. Consequently, there exists a continuous strictly decreasing function $\bar{\mu} : \Re^+ \to (0, +\infty)$ such that $\bar{\mu}(\xi) \geq \mu(\xi)$ for all $\xi \geq 0$ and $\lim_{\xi \to +\infty} \bar{\mu}(\xi) = 0$. Thus, by recalling definition (2.16) we obtain

$$M(\xi, T, s) \leq \bar{\mu}(\xi)\theta(T, s) \qquad \forall (T, s) \in (\Re^+)^2, \quad \forall \xi \geq 0, \tag{2.23}$$

where $\theta(T, s) := p(T)g(\zeta_1(\gamma_1(T)s))$. Clearly, θ satisfies all hypotheses of Lemma 2.3 and therefore there exist $\zeta_2 \in K_\infty$ and $\gamma_2 \in K^+$ such that

$$\theta(T, s) \leq \zeta_2(\gamma_2(T)s) \qquad \forall (T, s) \in (\Re^+)^2. \tag{2.24}$$

Moreover, by recalling Proposition 7 in [32] there exist functions a_1, ρ of class K_∞, a_1, being locally Lipschitz on $(0, +\infty)$, such that the KL function $\mu(t)\zeta_2(s)$ is dominated by $a_1^{-1}(\exp(-t)\rho(s))$. Thus, by taking into account (2.11b), (2.23), and (2.24) we have

$$|x(t)| \leq a_1^{-1}(\exp(-t + t_0)\rho(\gamma_2(t_0)|x_0|)) \quad \forall t \geq t_0 \geq 0,\ x_0 \in \Re^n,\ d \in M_D. \tag{2.25}$$

By Corollary 10 in [32] a pair of functions a_2, $\tilde{\beta}$ of class K_∞ can be found such that

$$\rho(rs) \leq \tilde{\beta}(r)a_2(s) \qquad \forall r, s \geq 0, \tag{2.26}$$

and finally, let β be a function of class K^+ with

$$\tilde{\beta}(\gamma_2(t)) \leq \beta(t), \qquad t \geq 0. \tag{2.27}$$

The desired (2.2) is a consequence of (2.25), (2.26), and (2.27).

($\Leftarrow$) Conversely, assume that (2.2) holds. Existence of $x(\cdot)$ for all $t \geq t_0$ as well as (2.1a) are both immediate consequences of (2.2). Let $\varepsilon > 0$ and $T \geq 0$ be arbitrary constants. By selecting $\delta(\varepsilon, T) := a_2^{-1}(\frac{a_1(\varepsilon)}{\beta(T)})$ the desired (2.1b) is fulfilled; thus property P1 holds (stability). Moreover, for any arbitrary positive constants R, ε, T, we may select $\tau = \tau(\varepsilon, T, R) := -\log(\frac{a_1(\varepsilon)}{\beta(T)a_2(R)})$, and by using (2.2) it follows that (2.1c) is fulfilled, and this establishes property P2 (attractivity). ∎

Remark 2.4.

- The notion of RGAS above is an extension of the well-known Sontag's robust uniform GAS (RUGAS) for autonomous systems, namely, when the solution $x(\cdot)$ satisfies $|x(t)| \le G(|x_0|, t-t_0)$ for certain G of class KL (see, for instance, [18, 20]). To justify this, we may recall Proposition 7 in [32], which asserts that for any $G \in KL$ there exist functions a_1 and a_2 of class K_∞ with $G(s,t) \le a_1^{-1}(\exp(-t)a_2(s))$. It turns out that RUGAS is characterized by the inequality $a_1(|x(t)|) \le \exp(-t+t_0)a_2(|x_0|)$, which obviously is a special case of (2.2).
- It is also straightforward to see that, if (2.2) holds with β being bounded over $\Re^+$, then zero is RUGAS and thus it turns out that for this case RGAS is equivalent to RUGAS.

Finally, we provide the following proposition, which generalizes the well-known fact that for autonomous differential equations equi-attractivity implies stability (see [10]). The result of this proposition will be used in sections 3 and 5.

PROPOSITION 2.5. *The origin $0 \in \Re^n$ is RGAS for* (1.1) *if for every $t_0 \ge 0$, $d \in M_D$, and $x_0 \in \Re^n$, the corresponding solution $x(\cdot)$ of* (1.1) *exists for all $t \ge t_0$ and satisfies property* P2 *(attractivity) of Definition* 2.1 *and* (1.1) *is Lagrange stable; namely, for every $\varepsilon > 0$ and $T \ge 0$,* (2.1a) *holds. It turns out that, if there exist a constant $M \ge 0$, functions $a_2 \in K_\infty$, $\sigma \in KL$, and $\beta \in K^+$ such that the estimate*

(2.28)
$$|x(t)| \le \sigma(a_2(\beta(t_0)|x_0|) + M, t-t_0) \qquad \forall t \ge t_0,\ (t_0,x_0) \in \Re^+ \times \Re^n,\ d(\cdot) \in M_D,$$

holds for the solution $x(\cdot)$ of (1.1)*, then $0 \in \Re^n$ is RGAS for* (1.1).

Proof. It suffices to show that for every $\varepsilon > 0$, $T \ge 0$, there exists a $\delta := \delta(\varepsilon, T) > 0$ such that (2.1b) holds. Let $\varepsilon > 0$, $T \ge 0$ be arbitrary. Define

$$R(\varepsilon, T) := \sup\{|x(t)| : d \in M_D, t \ge t_0, |x_0| \le \varepsilon, t_0 \in [0,T]\}. \tag{2.29}$$

By taking into account (1.2), (2.29), completeness of solutions, and our assumption that zero $0 \in \Re^n$ is an equilibrium for (1.1), it follows by use of Gronwall's inequality that

(2.30)
$$|x(t)| \le \exp\left(\int_{t_0}^{t} L(s, R(\varepsilon,T))ds\right)|x_0| \quad \forall t \ge t_0,\ d(\cdot) \in M_D,\ |x_0| \le \varepsilon,\ t_0 \in [0,T].$$

Moreover, property P2 of Definition 2.1 implies that for every $\varepsilon > 0$, $T \ge 0$, there exists a $\tau := \tau(\varepsilon, T) \ge 0$ such that

$$|x_0| \le \varepsilon,\ t_0 \in [0,T] \Rightarrow |x(t)| \le \varepsilon \quad \forall t \ge t_0 + \tau,\ d \in M_D. \tag{2.31}$$

Define

$$\delta(\varepsilon, T) := \varepsilon \exp\left(-\int_0^{T+\tau(\varepsilon,T)} L(s, R(\varepsilon,T))ds\right) \le \varepsilon \tag{2.32}$$

and notice that estimate (2.30) and definition (2.32) guarantee the following implication:

$$|x_0| \le \delta(\varepsilon,T),\ t_0 \in [0,T] \Rightarrow |x(t)| \le \varepsilon \quad \forall t \in [t_0, t_0 + \tau(\varepsilon,T)],\ d(\cdot) \in M_D. \tag{2.33}$$

The desired implication (2.1b) is an immediate consequence of (2.31) and (2.33).

Finally, notice that when estimate (2.28) holds, then property P2 holds and (1.1) is Lagrange stable; hence zero is RGAS. ∎

3. A converse Lyapunov theorem for RGAS. We next establish a Lyapunov characterization of the notion of RGAS, which constitutes generalization of the main result in [20] for the RUGAS case. Its proof is inspired from the analysis employed in [6, 20, 34].

THEOREM 3.1. *For the system* (1.1) *suppose that* H1, H2, H3 *are fulfilled and further* $f \in C^0(\Re^+ \times \Re^n \times D; \Re^n)$. *Then the following statements are equivalent:*

(i) *Zero* $0 \in \Re^n$ *is RGAS.*

(ii) *There exist a* C^∞ *function* $V : \Re^+ \times \Re^n \to \Re^+$, *functions* $\bar{a}_1$, $\bar{a}_2$ *of class* K_∞, $\bar{\beta}$ *of class* K^+ *such that for all* $(t, x, d) \in \Re^+ \times \Re^n \times D$ *it holds that*

$$\bar{a}_1(|x|) \leq V(t,x) \leq \bar{a}_2(\bar{\beta}(t)|x|), \tag{3.1a}$$

$$\dot{V}(t,x,d)\big|_{(1.1)} := \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x) f(t,x,d) \leq -V(t,x). \tag{3.1b}$$

(iii) *There exist a* C^1 *function* $V : \Re^+ \times \Re^n \to \Re^+$, *functions* $\bar{a}_1$, $\bar{a}_2$ *of class* K_∞, $\bar{\beta}$ *of class* K^+, μ *of class* $\mathbf{E}$ *(see notations for the definition of class* $\mathbf{E}$*), and a* C^0 *positive definite function* $\rho : \Re^+ \to \Re^+$ *such that for all* $(t, x, d) \in \Re^+ \times \Re^n \times D$ *it holds that*

$$\bar{a}_1(|x|) \leq V(t,x) \leq \bar{a}_2(\bar{\beta}(t)|x|), \tag{3.2a}$$

$$\dot{V}(t,x,d)\big|_{(1.1)} := \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x) f(t,x,d) \leq -\rho(V(t,x)) + \mu(t). \tag{3.2b}$$

For the proof of Theorem 3.1 we need a pair of technical lemmas. The first constitutes an extension of [20, Lemma 4.4] and was inspired by the main result in [22].

LEMMA 3.2. *Let* $y_d : \Re^+ \to \Re^+$ *be a family of absolutely continuous functions parameterized by* $d \in A$ *that satisfies the following differential inequality for almost all* $t \geq t_0$*:*

$$\dot{y}_d(t) \leq -\rho(y_d(t)) + \mu(t), \tag{3.3}$$

where $\rho : \Re^+ \to \Re^+$ *is a* C^0 *positive definite function and* μ *is of class* $\mathbf{E}$. *Then there exists a* KL *function* $\sigma : (\Re^+)^2 \to \Re^+$ *such that for all* $y_d(t_0) = y_0 \geq 0$ *and* $d \in A$ *it holds that*

$$y_d(t) \leq \sigma\left(y_0 + \int_{\Re^+} \mu(t)dt, t - t_0\right) \qquad \forall t \geq t_0. \tag{3.4}$$

Proof. Without loss of generality we may assume that $\int_{\Re^+} \mu(t)dt > 0$ (otherwise $\mu(t) = 0$ for all $t \geq 0$ and this is exactly the case of [20, Lemma 4.4]). First, notice that (3.3) yields

$$y_d(t) \leq y_0 + M \qquad \forall t \geq t_0,\ d \in A, \tag{3.5}$$

$$M := \int_{\Re^+} \mu(t)dt, \tag{3.6}$$

and this shows that $y_d(t)$ is bounded. Let $R \geq 0$ and $0 < \varepsilon \leq R + M$. Since $\lim_{t \to +\infty} \mu(t) = 0$ for any constants $r, \varepsilon > 0$ there exists a time $\tau := \tau(\varepsilon, r) \geq 0$ such that

$$t \geq \tau \Rightarrow \mu(t) \leq \min\left\{\frac{1}{2}\rho(s); \frac{\varepsilon}{2} \leq s \leq r\right\}. \tag{3.7}$$

We now show that the region

$$L_{\varepsilon,R} := \big\{(t,y) \in \Re^+ \times \Re^+ : y \le \varepsilon, t \ge \tau(\varepsilon, R+M)\big\} \tag{3.8}$$

is positively invariant. To see this, notice that, when $R + M \ge y_d(t) \ge \frac{\varepsilon}{2}$ and $t \ge \tau(\varepsilon, R+M)$ for some $d \in A$, then by (3.3) and (3.7) we have

$$\dot{y}_d(t) \le -\rho(y_d(t)) + \mu(t) \le -\frac{1}{2}\rho(y_d(t)) < 0 \tag{3.9}$$

and this establishes positive invariance of $L_{\varepsilon,R}$. We next establish that, if we define

$$T(\varepsilon, r) := \tau(\varepsilon, r) + \frac{2r}{\min_{\varepsilon \le s \le r} \rho(s)}, \tag{3.10}$$

then the following is fulfilled:

$$\text{For every } t \ge t_0 + T(\varepsilon, R+M), \quad d \in A \text{ and } y_0 \le R \Rightarrow (t, y_d(t)) \in L_{\varepsilon,R}. \tag{3.11}$$

Indeed, otherwise, by positive invariance of $L_{\varepsilon,R}$ there would exist $d \in A$ and $y_0 \le R$ such that

$$(t, y_d(t)) \notin L_{\varepsilon,R} \qquad \forall t \in [t_0 + \tau(\varepsilon, R+M), t_0 + T(\varepsilon, R+M)],$$

and since $t \ge \tau(\varepsilon, R, M)$, we would have

$$y_d(t) > \varepsilon \qquad \forall t \in [t_0 + \tau, t_0 + T]. \tag{3.12}$$

On the other hand, by (3.3), (3.5), (3.7) and (3.12), it follows that

$$\dot{y}_d(t) \le -\frac{1}{2} \min_{\varepsilon \le s \le R+M} \rho(s) \qquad \forall t \in [t_0 + \tau, t_0 + T]. \tag{3.13}$$

It turns out from (3.12) and (3.13) that

$$\varepsilon < y_d(t) \le R + M - \frac{1}{2}(t - t_0 - \tau) \min_{\varepsilon \le s \le R+M} \rho(s) \qquad \forall t \in [t_0 + \tau, t_0 + T]. \tag{3.14}$$

Using (3.14) and taking into account definition (3.10) of $T(\cdot)$ we get $\varepsilon < y_d(t_0 + T) \le 0$, which is a contradiction. This establishes (3.11).

Positive invariance of $L_{\varepsilon,R}$ and property (3.11) guarantee that the following attractivity property holds:

$$\begin{aligned} &\text{For all } (\varepsilon, R, t_0, d) \in (0, +\infty) \times \Re^+ \times \Re^+ \times A \text{ and} \\ &t \ge t_0 + T(\varepsilon, R+M), y_0 \le R \Rightarrow 0 \le y_d(t) \le \varepsilon. \end{aligned} \tag{3.15}$$

In order to establish inequality (3.4), we exploit (3.15) and apply an approach similar to that used in Proposition 2.2. We proceed as follows. Define

$$g(s) := \sqrt{s} + s^2, \tag{3.16a}$$

$$v(t) := \sup\left\{\frac{y_d(t_0 + \xi)}{g(y_0 + M)}; d \in A, y_0 \ge 0, t_0 \ge 0, \xi \ge t\right\}, \tag{3.16b}$$

where $M > 0$ is defined by (3.6). Since $M > 0$, the denominator in (3.16b) is strictly positive and (3.5), (3.16a) imply that $v(t) \le 1$ for all $t \ge 0$. We show that

$\lim_{t\to+\infty} v(t) = 0$. Let $\varepsilon > 0$ and let $a := a(\varepsilon)$, $b := b(\varepsilon)$ be a pair of constants with $0 < a < b$ and being defined in such a way that $x \notin [a, b] \Rightarrow x/(\sqrt{x} + x^2) < \varepsilon$. Then by (3.5) it follows that

$$\begin{aligned} &\frac{y_d(t_0+\xi)}{g(y_0+M)} < \varepsilon \quad \forall \xi \geq 0,\ d \in A,\ \text{and } t_0 \geq 0, \\ &\text{provided that either } y_0 + M < a \text{ or } y_0 + M > b. \end{aligned} \tag{3.17a}$$

It remains to consider the case $a \leq y_0 + M \leq b$. By (3.15) we get

$$\frac{y_d(t_0+\xi)}{g(y_0+M)} \leq \frac{y_d(t_0+\xi)}{g(a)} \leq \varepsilon \quad \forall \xi \geq T(\varepsilon g(a), b),\ \forall (t_0, d) \in \Re^+ \times A. \tag{3.17b}$$

It turns out from (3.16b), (3.17a), and (3.17b) that

$$v(t) \leq \varepsilon \qquad \forall t \geq T(\varepsilon g(a), b). \tag{3.18}$$

Since $\varepsilon > 0$ was arbitrary, (3.18) asserts that $\lim_{t\to+\infty} v(t) = 0$. Finally, let $\bar{v} : \Re^+ \to (0, +\infty)$ be a C^0, strictly decreasing function, with $v(t) \leq \bar{v}(t)$ for all $t \geq 0$ and in such a way that $\lim_{t\to+\infty} \bar{v}(t) = 0$. Then, obviously (3.4) is fulfilled with $\sigma(s, t) := g(s)\bar{v}(t)$. □

The second technical lemma provides a Lyapunov characterization of RGAS for (1.1) when its dynamics $f(\cdot)$ satisfy hypotheses H1, H2, and H3.

LEMMA 3.3. *Consider system* (1.1) *where its dynamics satisfy hypotheses* H1, H2 *and* H3 *and assume that* $0 \in \Re^n$ *is RGAS for* (1.1)*; particularly, there exists a pair of functions* a_1, a_2 *of class* K_∞, a_1 *being locally Lipschitz on* $(0, +\infty)$, *and a function* β *of class* K^+ *in such a way that* (2.2) *is satisfied. Then there exists a* C^0 *function* $U : \Re^+ \times \Re^n \to \Re^+$, *which is locally Lipschitz on* $\Re^+ \times (\Re^n \setminus \{0\})$, *such that for all* $(t, x) \in \Re^+ \times \Re^n$, $h \geq 0$, *and* $d(\cdot) \in M_D$ *it holds that*

$$a_1(|x|) \leq U(t, x) \leq \beta(t) a_2(|x|), \tag{3.19a}$$

$$\begin{aligned} &U(t+h, \phi(t+h, t, x; d)) \leq \exp\left(-\frac{h}{2}\right) U(t, x) \\ &\forall (t, x) \in \Re^+ \times \Re^n,\ h \geq 0,\ d(\cdot) \in M_D, \end{aligned} \tag{3.19b}$$

where for convenience we adopt the notation $\phi(\cdot, t, x; d)$ *to denote the solution of* (1.1) *that corresponds to the input* $d(\cdot) \in M_D$, *with* $\phi(t, t, x; d) = x$.

Proof. For the proof we need the following elementary properties for the solution of (1.1), which are immediate consequences of (1.2) and (2.2):

$$|\phi(t, t_0, x; d) - \phi(t, t_0, y; d)| \leq \exp\left(\int_{t_0}^{t} \tilde{L}(s, |x| + |y|) ds\right) |x - y|, \tag{3.20}$$

$$|\phi(t, t_0, x; d) - x| \leq \left(\exp\left(\int_{t_0}^{t} \tilde{L}(s, |x|) ds\right) - 1\right) |x|, \tag{3.21}$$

$$|\phi(t, t_0, x; d)| \geq \exp\left(-\int_{t_0}^{t} \tilde{L}(s, |x|) ds\right) |x|, \tag{3.22}$$

$$\begin{aligned} &|\phi(t, t_1, x; d) - \phi(t, t_2, x; d)| \leq \exp\left(\int_{\min(t_1,t_2)}^{t} \tilde{L}(s, |x|) ds\right) \tilde{L}(\max(t_1, t_2), |x|) |x| |t_1 - t_2| \\ &\forall t \geq t_0 \text{ and } (t_0, x, y; d) \in \Re^+ \times \Re^n \times \Re^n \times M_D, \end{aligned} \tag{3.23}$$

where

$$\tilde{L}(t,s) := L(t, 2a_1^{-1}(\beta(t)a_2(s))).$$

We define

$$U(t,x) := \sup\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right) : \tau \geq t, d \in M_D\right\}. \tag{3.24}$$

The desired properties (3.19a) and (3.19b) are then immediate consequences of (2.2) and definition (3.24). Inequality (3.19a) asserts that $U : \Re^+ \times \Re^n \to \Re^+$ is continuous at $x = 0$ with $U(t,0) = 0$ for all $t \geq 0$. We next establish that $U(\cdot)$ is locally Lipschitz on $\Re^+ \times (\Re^n \setminus \{0\})$. By (2.2) and (3.24) it follows that for any $T > 0$ the following holds:

(3.25)
$$\begin{aligned} U(t,x) = \max\Bigg\{&\sup\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right) : t \leq \tau \leq t+T, d \in M_D\right\}, \\ &\sup\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right) : \tau \geq t+T, d \in M_D\right\}\Bigg\} \\ \leq \max\Bigg\{&\sup\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right) : t \leq \tau \leq t+T, d \in M_D\right\}, \\ &\beta(t)a_2(|x|)\exp\left(-\frac{1}{2}T\right)\Bigg\}. \end{aligned}$$

Let $T_i : \Re^+ \times (0,+\infty) \to (0,+\infty)$, $i = 1,2$, be a pair of positive, C^0 functions, defined as

$$T_1(t,s) := 2\log\left(\frac{2\beta(t)a_2(s)}{a_1(s)}\right), \qquad T_2(t,s) := 2\log\left(\frac{2\beta(t)a_2(2s)}{a_1\left(\frac{s}{2}\right)}\right). \tag{3.26}$$

Notice that for every $s > 0$ each $T_i(\cdot,s)$ is nondecreasing and the following holds:

$$T_2(t,|x|) \geq \sup\left\{T_1(t,|y|) : y \in B\left[x, \frac{1}{2}|x|\right]\right\}, \qquad x \neq 0. \tag{3.27}$$

It turns out from (3.25) and (3.26) that

$$\begin{aligned} U(t,x) \leq \max\Bigg\{&\sup\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right) : t \leq \tau \leq t+\xi, d \in M_D\right\}, \\ &\frac{1}{2}a_1(|x|)\Bigg\} \qquad \text{for } \xi \geq T_1(t,|x|),\ x \neq 0, \end{aligned} \tag{3.28}$$

which by virtue of (3.19a) gives

$$\begin{aligned} U(t,x) = \sup&\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right) : t \leq \tau \leq t+\xi, d \in M_D\right\} \\ &\text{for } \xi \geq T_1(t,|x|),\ x \neq 0. \end{aligned} \tag{3.29}$$

It follows by taking into account (2.2), (3.22), (3.27) and (3.29) that

(3.30)
$$\begin{aligned}|U(t,y)-U(t,x)| &= \left|\sup\left\{a_1(|\phi(\tau,t,y;d)|)\exp\left(\frac{1}{2}(\tau-t)\right): t\le\tau\le t+T_2(t,|x|), d\in M_D\right\}\right.\\ &\qquad \left.-\sup\left\{a_1(|\phi(\tau,t,x;d)|)\exp\left(\frac{1}{2}(\tau-t)\right): t\le\tau\le t+T_2(t,|x|), d\in M_D\right\}\right|\\ &\le \sup\left\{\exp\left(\frac{1}{2}(\tau-t)\right)|a_1(|\phi(\tau,t,y;d)|)-a_1(|\phi(\tau,t,x;d)|)|: t\le\tau\le t+T_2(t,|x|), d\in M_D\right\}\\ &\le M_I\sup\left\{\exp\left(\frac{1}{2}(\tau-t)\right)|\phi(\tau,t,y;d)-\phi(\tau,t,x;d)|: t\le\tau\le t+T_2(t,|x|), d\in M_D\right\}\\ &\qquad \forall y\in B\left[x,\frac{1}{2}|x|\right],\ x\neq 0,\end{aligned}$$

where M_I is any Lipschitz constant for $a_1(\cdot)$ on the interval

$$I := \left[\frac{1}{2}\exp\left\{-\int_t^{t+T_2(t,|x|)}\tilde{L}\left(s,\frac{3}{2}|x|\right)ds\right\}|x|, a_1^{-1}\left(\beta(t)a_2\left(\frac{3}{2}|x|\right)\right)\right],$$

namely, $|a_1(s_1)-a_1(s_2)|\le M_I|s_1-s_2|$ for every $s_1,s_2\in I$. From (3.20) and (3.30) we deduce

$$|U(t,y)-U(t,x)|\le G_1(t,|x|)|y-x|, \qquad \forall y\in B\left[x,\frac{1}{2}|x|\right],\ x\neq 0, \tag{3.31a}$$

$$G_1(t,|x|) := M_I\exp\left(\frac{1}{2}T_2(t,|x|)+\int_t^{t+T_2(t,|x|)}\tilde{L}\left(s,\frac{5}{2}|x|\right)ds\right). \tag{3.31b}$$

This establishes that, for each $t\ge 0$, $U(t,\cdot)$ is locally Lipschitz on $\Re^n\setminus\{0\}$.

Likewise, we may establish that for each fixed nonzero $x\in\Re^n$, the map $U(\cdot,x)$ is locally Lipschitz on $\Re^+$. Indeed, consider a compact interval $I\subset\Re^+$ and let $t_1,t_2\in I$. Then, according to (3.29), for any $\varepsilon>0$, there exists a $d_\varepsilon\in M_D$ and time τ with $t_2\le\tau\le t_2+T_1(t_2,|x|)$ such that

$$U(t_2,x)-\varepsilon\le a_1(|\phi(\tau,t_2,x;d_\varepsilon)|)\exp\left(\frac{1}{2}(\tau-t_2)\right)\le U(t_2,x). \tag{3.32}$$

We distinguish three cases. The first is

$$t_1<t_2\le\tau. \tag{3.33}$$

It then follows by virtue of definition (3.24) that

$$a_1(|\phi(\tau,t_1,x;d_\varepsilon)|)\exp\left(\frac{1}{2}(\tau-t_1)\right)\le U(t_1,x); \tag{3.34}$$

hence, by (3.32) and (3.34) we get

(3.35)
$$U(t_2,x)-U(t_1,x)\le\exp\left(\frac{1}{2}(\tau-t_2)\right)|a_1(|\phi(\tau,t_2,x;d_\varepsilon)|)-a_1(|\phi(\tau,t_1,x;d_\varepsilon)|)|+\varepsilon.$$

Using (3.22) and (3.23) and exploiting the fact that $a_1(\cdot)$ is locally Lipschitz on $(0,+\infty)$, we deduce from (3.35) that for any compact $\Delta \subset \Re^n \setminus \{0\}$ a constant $L_1 > 0$ (being independent of ε and τ) can be found such that

$$\begin{aligned} U(t_2,x) - U(t_1,x) &\le L_1|t_2 - t_1| + \varepsilon \\ \forall t_2 > t_1, t_1,\ t_2 \in I,\ x \in \Delta. \end{aligned} \tag{3.36}$$

The second case is

$$t_2 \le t_1 \le \tau. \tag{3.37}$$

We may recall again (3.32), (3.34) and estimate

$$\begin{aligned} U(t_2,x) - U(t_1,x) &\le a_1(|\phi(\tau,t_2,x;d_\varepsilon)|)\exp\left(\frac{1}{2}(\tau - t_2)\right) \\ &\quad - a_1(|\phi(\tau,t_1,x;d_\varepsilon)|)\exp\left(\frac{1}{2}(\tau - t_1)\right) + \varepsilon \\ &= \exp\left(\frac{1}{2}(\tau - t_2)\right)\left(a_1(|\phi(\tau,t_2,x;d_\varepsilon)|) - a_1(|\phi(\tau,t_1,x;d_\varepsilon)|)\right) \\ &\quad + a_1(|\phi(\tau,t_1,x;d_\varepsilon)|)\left(\exp\left(\frac{1}{2}(\tau - t_2)\right) - \exp\left(\frac{1}{2}(\tau - t_1)\right)\right) + \varepsilon, \end{aligned} \tag{3.38}$$

and, as previously, it follows by (3.23) and (3.38) that there exists a constant $L_2 > 0$ (being independent of ε and τ) such that

$$\begin{aligned} U(t_2,x) - U(t_1,x) &\le L_2|t_2 - t_1| + \varepsilon \\ \forall x \in \Delta, \quad t_1, t_2 \in I,& \text{ provided that (3.37) holds.} \end{aligned} \tag{3.39}$$

Finally, consider the case

$$t_2 \le \tau < t_1 \tag{3.40}$$

for certain τ and d_ε such that (3.32) holds. We now invoke the left-hand-side inequality of (3.19a):

$$a_1(|x|) \le U(t_1,x). \tag{3.41}$$

It follows by virtue of (3.32), (3.40), and (3.41) that

$$\begin{aligned} U(t_2,x) - U(t_1,x) &\le a_1(|\phi(\tau,t_2,x;d_\varepsilon)|)\exp\left(\frac{1}{2}(\tau - t_2)\right) - a_1(|x|) \\ &\le \exp\left(\frac{1}{2}(\tau - t_2)\right)\left(a_1(|\phi(\tau,t_2,x;d_\varepsilon)|) - a_1(|x|)\right) \\ &\quad + a_1(|x|)\left(\exp\left(\frac{1}{2}(t_1 - t_2)\right) - 1\right). \end{aligned} \tag{3.42}$$

Using (3.21) and (3.22) and the fact that $a_1(\cdot)$ is locally Lipschitz on $(0,+\infty)$, we deduce from (3.42) that for any compact $\Delta \subset \Re^n \setminus \{0\}$ a constant $L_3 > 0$ (being independent of ε and τ) can be found such that

$$\begin{aligned} U(t_2,x) - U(t_1,x) &\le L_3|t_2 - t_1| + \varepsilon \\ \forall x \in \Delta, \quad t_1, t_2 \in I,& \text{ provided that (3.40) holds.} \end{aligned} \tag{3.43}$$

From (3.37), (3.39), and (3.43) it follows that $U(t_2,x)-U(t_1,x)\leq \max(L_1,L_2,L_3)|t_2-t_1|+\varepsilon$ for all $t_1,t_2\in I$, $\varepsilon>0$, and $x\in\Delta$. Similarly, we handle the case $U(t_1,x)-U(t_2,x)$ and conclude that for any compact sets $I\subset\Re^+$ and $\Delta\subset\Re^n\setminus\{0\}$, there is a constant $C>0$ such that

$$|U(t_2,x)-U(t_1,x)|\leq C|t_2-t_1|+\varepsilon \quad \forall t_1,t_2\in I,\ x\in\Delta. \tag{3.44}$$

Since $\varepsilon>0$ is arbitrary, inequalities (3.31) and (3.44) establish that $U(\cdot)$ is locally Lipschitz. The proof is complete. □

We are now in a position to prove Theorem 3.1.

Proof of Theorem 3.1. (i) ⇒ (ii) For convenience we still adopt here the notation $\phi(t,t_0,x_0;d)$ to denote the solution of (1.1) that corresponds to the input $d\in M_D$, initiated from $x_0\in\Re^n$ at time $t_0\geq 0$. Suppose first that $0\in\Re^n$ is RGAS and establish existence of $V(\cdot)$ satisfying (3.1). Since $0\in\Re^n$ is RGAS for (1.1), it follows by Lemma 3.3 that there exists a C^0 function $U:\Re^+\times\Re^n\to\Re^+$, which is locally Lipschitz on $\Re^n\times(\Re^n\setminus\{0\})$; a pair of functions a_1, a_2 of class K_∞, a_1 being locally Lipschitz on $(0,+\infty)$; and a function β of class K^+, such that for all $(t,x)\in\Re^+\times\Re^n$, $h\geq 0$, and $d(\cdot)\in M_D$ both (3.19a), (3.19b) hold. The proof is divided into two parts. In Part I we construct a function $W:\Re^+\times\Re^n\to\Re^+$ of class $C^0(\Re^+\times\Re^n)\cap C^\infty(\Re^+\times(\Re^n\setminus\{0\}))$, which satisfies

$$\frac{1}{2}a_1(|x|)\leq W(t,x)\leq\frac{3}{2}\beta(t)a_2(|x|)\qquad\forall(t,x)\in\Re^+\times\Re^n, \tag{3.45a}$$

$$\frac{\partial W}{\partial t}(t,x)+\frac{\partial W}{\partial x}(t,x)f(t,x,d)\leq-\frac{1}{4}W(t,x)$$
$$\forall(t,x,d)\in\Re^+\times(\Re^n\setminus\{0\})\times D, \tag{3.45b}$$

where a_1, $a_2\in K_\infty$ and $\beta\in K^+$ are the functions defined in (3.19a), (3.19b).

In Part II, by exploiting (3.45), we build the desired Lyapunov function $V:\Re^+\times\Re^n\to\Re^+$ that satisfies (3.1) for appropriate functions $\bar a_1$, $\bar a_2$ of class K_∞ and $\bar\beta$ of class K^+.

Part I. We proceed to the construction of an "almost smooth" W satisfying (3.45a), (3.45b). If the dynamics $f(\cdot)$ were Lipschitzian in both t and x, then the smoothing approach of [20] applied to the time-extended system $\dot x=f(t,x,d)$, $\dot t=1$, would lead to the existence of a function W satisfying both (3.45a) and (3.45b). However, we have assumed that $f(\cdot)$ is continuous in t, so we need to make a modification of the approach in [20]. We proceed as follows. Let $\psi_1:\Re^n\to\Re^+$, $\psi_2:\Re\to\Re^+$ be a pair of C^∞ functions with $\psi_1(\xi)=0$ and $\psi_2(\tau)=0$ when $|\xi|\geq 1$ and $\tau\notin(0,1)$, respectively, in such a way that

$$\int_{\Re^n}\psi_1(\xi)d\xi=\int_{\Re}\psi_2(\tau)d\tau=1.$$

Let S be a compact subset of $\Re^+\times(\Re^n\setminus\{0\})$. We consider the following family of functions:

$$W_\sigma(t,x):=\int_{\Re}\int_{\Re^n}U(t+\sigma\tau,x+\sigma\xi)\psi_1(\xi)\psi_2(\tau)d\xi d\tau,\qquad\sigma>0, \tag{3.46}$$

where $U(\cdot)$ is the function provided by Lemma 3.3. Let

$$r:=\min_{(t,x)\in S}|x|>0,$$
$$\tilde S:=\left\{(t+c\tau,x+c\xi)\in\Re^+\times\Re^n:(t,x)\in S,c\in\left[0,\frac{1}{2}r\right],\xi\in B[0,1],\tau\in[0,1]\right\}. \tag{3.47}$$

Obviously, $S \subseteq \tilde{S} \subseteq \Re^+ \times (\Re^n \setminus \{0\})$, $\tilde{S}$ is compact, and let C be a Lipschitz constant for U on $\tilde{S}$. It follows by virtue of (3.46) and (3.47) that for $\sigma < \frac{1}{2}r$, W_σ is well defined and C^∞ on S and satisfies

$$|W_\sigma(t,x) - U(t,x)| \le C\sigma \quad \forall (t,x) \in S, \quad \sigma < \frac{1}{2}r. \tag{3.48}$$

We also obtain the following by recalling (3.21) and (3.47):

$$(t+h+\sigma\tau, \phi(t+h,t,x;d) + \sigma\xi) \in \tilde{S}, \quad (t+h+\sigma\tau, \phi(t+h+\sigma\tau, t+\sigma\tau, x+\sigma\xi; d)) \in \tilde{S} \tag{3.49a}$$

$$\forall (t,x) \in S,\ d \in M_D,\ (\tau,\xi) \in [0,1] \times B[0,1], \quad \sigma \le \frac{1}{4}r,\ h > 0, \text{ sufficiently small.} \tag{3.49b}$$

Then by using (3.19b), (3.46), (3.49a) and (3.49b) we get

$$\begin{aligned} W_\sigma(t+h, \phi(t+h,t,x;d)) - W_\sigma(t,x) &\le \left(\exp\left(-\frac{h}{2}\right) - 1\right) W_\sigma(t,x) \\ &+ \int_{\Re}\int_{\Re^n} (U(t+h+\sigma\tau, \phi(t+h,t,x;d)+\sigma\xi) \\ &\qquad - U(t+h+\sigma\tau, \phi(t+h+\sigma\tau, t+\sigma\tau, x+\sigma\xi; d)))\psi_1(\xi)\psi_2(\tau)d\xi d\tau \\ &\le \left(\exp\left(-\frac{h}{2}\right) - 1\right) W_\sigma(t,x) \\ &+ C\int_{\Re}\int_{\Re^n} |\phi(t+h,t,x;d)+\sigma\xi - \phi(t+h+\sigma\tau, t+\sigma\tau, x+\sigma\xi; d)|\psi_1(\xi)\psi_2(\tau)d\xi d\tau \\ &\qquad \forall (t,x) \in S,\ d \in M_D,\ h > 0 \text{ sufficiently small.} \end{aligned} \tag{3.50}$$

Since f is C^0 and therefore uniformly continuous on compact sets, there exists a function $\delta_1 : \Re^+ \to \Re^+$ of class K such that

$$\sup\{|f(t+\sigma\tau, x, d) - f(t,x,d)| : (t,x) \in \tilde{S}, \tau \in [0,1], d \in D\} \le \delta_1(\sigma). \tag{3.51}$$

Using (1.2) and (3.51) and applying Gronwall's inequality, a function $\delta_2 : \Re^+ \to \Re^+$ of class K can be found such that

$$\begin{aligned} &|\phi(t+h,t,x;d) + \sigma\xi - \phi(t+h+\sigma\tau, t+\sigma\tau, x+\sigma\xi; d)| \le \delta_2(\sigma)h \\ &\forall (t,x) \in S,\ d \in M_D,\ (\tau,\xi) \in [0,1] \times B[0,1],\ h > 0 \text{ sufficiently small.} \end{aligned} \tag{3.52}$$

Specifically, in order to establish (3.52), define $p(s) := |\phi(t+s,t,x;d) + \sigma\xi - \phi(t+s+\sigma\tau, t+\sigma\tau, x+\sigma\xi; d)|$ and let L be a Lipschitz constant for f on $\tilde{S} \times D$, namely, $|f(t,x,d) - f(t,y,d)| \le L|x-y|$ for all $(t,x,d) \in \tilde{S} \times D$ and $(t,y,d) \in \tilde{S} \times D$. We then obtain by (3.51)

$$\begin{aligned} p(h) &\le \int_0^h |f(t+s, \phi(t+s,t,x;d), d) - f(t+\sigma\tau+s, \phi(t+\sigma\tau+s, t+\sigma\tau, x+\sigma\xi; d), d)| ds \\ &\le \delta_1(\sigma)h + \int_0^h |f(t+\sigma\tau+s, \phi(t+s,t,x;d), d) \\ &\qquad - f(t+\sigma\tau+s, \phi(t+\sigma\tau+s, t+\sigma\tau, x+\sigma\xi; d), d)|\, ds \\ &\le \delta_1(\sigma)h + L\int_0^h |\phi(t+s,t,x;d) - \phi(t+\sigma\tau+s, t+\sigma\tau, x+\sigma\xi; d)|\, ds \\ &\le \delta_1(\sigma)h + L\int_0^h p(s) ds + \sigma L h. \end{aligned}$$

The desired (3.52) is then a straightforward consequence of the previous inequality and Gronwall's lemma.

From (3.50) and (3.52) it follows that

$$\lim_{h\to 0^+} \frac{W_\sigma(t+h,\phi(t+h,t,x;d))-W_\sigma(t,x)}{h} = \frac{\partial W_\sigma}{\partial t}(t,x)+\frac{\partial W_\sigma}{\partial x}(t,x)f(t,x,d) \leq -\frac{1}{2}W_\sigma(t,x)+C\delta_2(\sigma). \tag{3.53}$$

By (3.48) and (3.53) we conclude that for any compact $S \subseteq \Re^+ \times (\Re^n \setminus \{0\})$ and $\varepsilon > 0$, there exists a constant $\sigma_0 > 0$ such that for every $\sigma < \sigma_0$ the function W_σ is well defined and C^∞ on S and satisfies for all $(t,x,d) \in S \times D$

$$|W_\sigma(t,x)-U(t,x)| \leq \varepsilon, \tag{3.54a}$$

$$\frac{\partial W_\sigma}{\partial t}(t,x)+\frac{\partial W_\sigma}{\partial x}(t,x)f(t,x,d) \leq -\frac{1}{2}W_\sigma(t,x)+\varepsilon. \tag{3.54b}$$

We may use (3.19a), (3.54a) and (3.54b) and apply partition of unity, as in the proof of [20, Theorem B.1], to build a function $W : \Re^+ \times \Re^n \to \Re^+$ of class $C^0(\Re^+ \times \Re^n) \cap C^\infty(\Re^+ \times (\Re^n \setminus \{0\}))$ that satisfies both (3.45a) and (3.45b).

Part II. We finally proceed to the construction of an everywhere C^∞ function V satisfying (3.1a), (3.1b). This part of proof is based on [34, Lemma 17], which in conjunction with (3.45a) and (3.45b) guarantees the existence of a function $\eta : \Re^+ \to \Re^+$ of class K_∞ with $\eta(s) \leq \frac{d\eta}{ds}(s)s$, such that the map

$$V(t,x) := (\eta(W(t,x)))^4 \tag{3.55}$$

is everywhere C^∞ and satisfies (3.1b). Furthermore, by Lemma 2.3 there exist functions $\tilde{a}_2 \in K_\infty$, $\bar{\beta} \in K^+$ such that

$$\frac{3}{2}\beta(t)a_2(s) \leq \tilde{a}_2(\bar{\beta}(t)s) \qquad \forall t,s \geq 0. \tag{3.56a}$$

Define

$$\bar{a}_1(s) := \left(\eta\left(\frac{1}{2}a_1(s)\right)\right)^4, \qquad \bar{a}_2(s) := (\eta(\tilde{a}_2(s)))^4. \tag{3.56b}$$

By using (3.56a), (3.56b) and invoking (3.45a), (3.45b), it follows that the function V as defined by (3.55) satisfies the desired inequalities (3.1a), (3.1b).

(ii) $\Rightarrow$ (iii) The implication is obvious since (3.1a), (3.1b) implies (3.2a), (3.2b) with $\rho(s) = s$, $\mu(t) \equiv 0 \in \mathbf{E}$, and some $\bar{a}_1 \in K_\infty$, $\bar{a}_2 \in K_\infty$, and $\bar{\beta} \in K^+$.

(iii) $\Rightarrow$ (i) We finally establish the converse part of our theorem, namely, that $0 \in \Re^n$ is RGAS with respect to (1.1) when both (3.2a) and (3.2b) are fulfilled. Define $A := M_D$ and let us again denote the solution of (1.1) by $\phi(t,t_0,x_0;d)$. Then using (3.2a), (3.2b) and applying the result of Lemma 3.2 with $y_d(t) := V(t,\phi(t,t_0,x_0;d))$, it follows that (3.3) holds; thus there exists a KL function σ and a constant $M = \int_0^{+\infty} \mu(t)dt \geq 0$ such that

$$|\phi(t,t_0,x_0;d)| \leq \bar{a}_1^{-1}(\sigma(\bar{a}_2(\bar{\beta}(t_0)|x_0|)+M,t-t_0)) \quad \forall t \geq t_0,\ d(\cdot) \in M_D$$

The latter estimate in conjunction with the result of Proposition 2.5 implies that $0 \in \Re^n$ is RGAS with respect to (1.1). The proof is complete. □

4. The nonuniform in time ISS property for time-varying systems. The results of the previous section enable us to characterize the nonuniform in time notion of ISS in terms of Lyapunov functions. We first introduce the notion of (nonuniform in time) ISS, as an extension of the notion of uniform in time ISS as presented in [36, 37]. In [16] we establish further equivalent descriptions of nonuniform in time ISS that constitute extensions of Sontag's ISS.

DEFINITION 4.1. *Consider the system*

$$\begin{aligned} \dot{x} &= f(t,x,u), \\ x \in \Re^n, &\quad u \in \Re^m, \quad t \geq 0, \end{aligned} \tag{4.1}$$

where $f(t,x,u)$ is measurable in $t \geq 0$ for all $(x,u) \in \Re^n \times \Re^m$ and is locally Lipschitz with respect to (x,u) with $f(\cdot,0,0) = 0$; denote $x(t) = x(t,t_0,x_0;u)$ its solution at time t that corresponds to some input $u \in \mathbf{L}^\infty_{loc}$, initiated from x_0 at time t_0. Let $\gamma(t,s) : (\Re^+)^2 \to \Re^+$ be a C^0 function, which is locally Lipschitz in s, such that for each fixed $t \geq 0$ the map $\gamma(t,\cdot)$ is positive definite. We say that (4.1) *satisfies the weak (nonuniform in time) input-to-state stability property (wISS) from the input u with gain $\gamma(\cdot)$ if each solution of* (4.1) *exists for all $t \geq t_0$ and satisfies properties* P1 *and* P2 *of Definition* 2.1 *provided that*

$$|u(t)| \leq \gamma(t,|x(t)|) \quad \text{a.e. for } t \geq t_0. \tag{4.2}$$

We say that (4.1) *satisfies the (nonuniform in time) ISS from the input u with gain $\gamma(\cdot)$ if it is wISS from the input u with gain $\gamma(\cdot)$ and in addition for each fixed $t \geq 0$ the map $\gamma(t,\cdot)$ is of class K_∞.*

As in the autonomous case (see [29, 37]) we can easily establish the following elementary fact.

Fact 4.2. System (4.1) satisfies the nonuniform in time wISS property from the input u with gain $\gamma(\cdot)$ if and only if $0 \in \Re^n$ is RGAS for the system

$$\begin{aligned} \dot{x} &= f(t,x,\gamma(t,|x|)d), \\ x \in \Re^n, &\quad d \in B[0,1] \subset \Re^m, \quad t \geq 0. \end{aligned} \tag{4.3}$$

The following theorem summarizes some useful equivalent descriptions of nonuniform in time wISS. Its proof is a direct consequence of Proposition 2.2, Lemma 3.2, Theorem 3.1, and Fact 4.2.

PROPOSITION 4.3. *Consider the system* (4.1) *whose dynamics satisfy the regularity assumptions of Definition* 4.1*, and let $\gamma(t,s) : (\Re^+)^2 \to \Re^+$ be a C^0 function, which is locally Lipschitz in s, such that for each fixed $t \geq 0$ the map $\gamma(t,\cdot)$ is positive definite. Then the following statements are equivalent:*

(i) *System* (4.1) *satisfies the nonuniform in time wISS property from the input with gain $\gamma(\cdot)$.*

(ii) *There exists a pair of functions a_1, a_2 of class K_∞, a_1 being locally Lipschitz on $(0,+\infty)$, and a function β of class K^+ such that the following property holds:*

$$\begin{aligned} &|u(t)| \leq \gamma(t,|x(t)|) \text{ a.e. for } t \geq t_0 \Rightarrow a_1(|x(t)|) \leq \exp(-t+t_0)\beta(t_0)a_2(|x_0|), \\ &\qquad\qquad \forall t \geq t_0,\ x_0 \in \Re^n. \end{aligned} \tag{4.4}$$

(iii) *There exists a C^0 function $U : \Re^+ \times \Re^n \to \Re^+$, which is locally Lipschitz on $\Re^+ \times (\Re^n \setminus \{0\})$ and satisfies*

$$a_1(|x|) \leq U(t,x) \leq \beta(t)a_2(|x|) \qquad \forall (t,x) \in \Re^+ \times \Re^n, \tag{4.5a}$$

$$|u(t)| \leq \gamma(t,|x(t)|) \text{ a.e. for } t \geq t_0 \Rightarrow U(t,x(t)) \leq \exp\left(-\frac{1}{2}(t-t_0)\right) U(t_0,x_0) \quad \forall (t_0,x_0) \in \Re^+ \times \Re^n \text{ and } t \geq t_0 \tag{4.5b}$$

with the some a_1, a_2, and β as defined in (4.4).
If in addition $f(\cdot) \in C^0(\Re^+ \times \Re^n; \Re^n)$, then the following are equivalent to the previous statements:

(iv) *There exist a C^∞ function $V : \Re^+ \times \Re^n \to \Re^+$ and functions $\bar{a}_1$, $\bar{a}_2 \in K_\infty$, $\bar{\beta} \in K^+$ such that the following hold for all $(t,x,u) \in \Re^+ \times \Re^n \times \Re^m$:*

$$\bar{a}_1(|x|) \leq V(t,x) \leq \bar{a}_2(\bar{\beta}(t)|x|), \tag{4.6a}$$

$$|u| \leq \gamma(t,|x|) \Rightarrow \dot{V}(t,x,u)|_{(4.1)} \leq -V(t,x). \tag{4.6b}$$

(v) *There exist a C^∞ function $V : \Re^+ \times \Re^n \to \Re^+$ and functions $\bar{a}_1$, $\bar{a}_2 \in K_\infty$, $\bar{\beta} \in K^+$, $\mu \in \mathbf{E}$ and a C^0 positive definite function $\rho : \Re^+ \to \Re^+$ such that the following hold for all $(t,x,u) \in \Re^+ \times \Re^n \times \Re^m$:*

$$\bar{a}_1(|x|) \leq V(t,x) \leq \bar{a}_2(\bar{\beta}(t)|x|), \tag{4.7a}$$

$$|u| \leq \gamma(t,|x|) \Rightarrow \dot{V}(t,x,u)|_{(4.1)} \leq -\rho(V(t,x)) + \mu(t). \tag{4.7b}$$

5. Applications to feedback stabilization. In this section we apply the converse Lyapunov Theorem 3.1 in order to derive necessary and sufficient conditions for ISS-feedback stabilization for affine in the control time-varying systems. For the general case (1.3) we extend the Artstein–Sontag theorem by introducing the concept of time-varying control Lyapunov function (Theorem 5.1). Among other things we establish that, even for a class of autonomous systems, it is possible to achieve nonuniform in time ISS stabilization by smooth time-varying feedback, although an everywhere smooth time-independent feedback exhibiting uniform in time stabilization does not exist (Corollary 5.4).

For the special case (1.5) an extension of a well-known result concerning autonomous systems (see [11, 36]) is established (Proposition 5.6). This result generalizes [40, Lemma 2.3] since is based on weaker hypotheses. Its Lyapunov function based establishment extremely simplifies the analysis made in [40].

5.1. A necessary and sufficient condition for ISS-feedback stabilization. The following theorem is an extension of the Artstein–Sontag theorem (see, for instance, [3, 27, 35]). We consider here the time-varying case (1.3) and in what follows assume that the dynamics f, g are C^0 and locally Lipschitz with respect to $(x,v) \in \Re^n \times \Re^l$, with $f(\cdot,0,0) = 0$.

THEOREM 5.1. *Consider the system* (1.3) *and let $\gamma(t,s) : (\Re^+)^2 \to \Re^+$ be a function, which is C^0, locally Lipschitz in s, and in such a way that for each $t \geq 0$ the mapping $\gamma(t,\cdot)$ is positive definite. Then the following statements are equivalent:*

(i) *There exists a C^∞ function $k : \Re^+ \times \Re^n \to \Re^m$ with $k(t,0) = 0$ for all $t \geq 0$, in such a way that the resulting system* (1.3) *with $u = k(t,x)$, namely, system* (1.4)*, satisfies the nonuniform in time wISS property with gain $\gamma(\cdot)$ from the input v. It turns out that* (1.4) *satisfies the nonuniform in time ISS property with gain $\gamma(\cdot)$ from the input v, provided that for each fixed $t \geq 0$ the map $\gamma(t,\cdot)$ is of class K_∞.*

(ii) *There exists a* C^0 *function* $k : \Re^+ \times \Re^n \to \Re^m$ *with* $k(t,0) = 0$ *for all* $t \geq 0$, *being locally Lipschitz in* x, *in such a way that the resulting system* (1.4) *satisfies the same property as in statement* (i).

(iii) *System* (1.3) *admits a "control Lyapunov function," namely, there exists a* C^1 *function* $V : \Re^+ \times \Re^n \to \Re^+$, *functions* $a_1, a_2 \in K_\infty$, $\beta \in K^+$, $\mu \in \mathbf{E}$, *and a* C^0 *positive definite function* $\rho : \Re^+ \to \Re^+$, *such that*

$$a_1(|x|) \leq V(t,x) \leq a_2(\beta(t)|x|), \tag{5.1a}$$

$$\begin{aligned} &\frac{\partial V}{\partial x}(t,x)g(t,x) = 0, \ |v| \leq \gamma(t,|x|) \\ &\qquad \Rightarrow \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)f(t,x,v) \leq -\rho(V(t,x)) + \mu(t). \end{aligned} \tag{5.1b}$$

Proof. The implication (i) $\Rightarrow$ (ii) is obvious. We establish implication (ii) $\Rightarrow$ (iii). Suppose that there exists a map $k(\cdot)$, as in statement (ii) of the theorem, such that system (1.4) satisfies the wISS property with gain $\gamma(\cdot)$. By recalling (iv) of Proposition 4.3, there exists a C^∞ function $V : \Re^+ \times \Re^n \to \Re^+$ in such a way that (5.1a) holds and

$$|v| \leq \gamma(t,x) \Rightarrow \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)(f(t,x,v) + g(t,x)k(t,x)) \leq -V(t,x). \tag{5.2}$$

The latter implies (5.1b) with $\mu(t) \equiv 0 \in \mathbf{E}$ and $\rho(s) = s$. We next establish (iii) $\Rightarrow$ (i). Consider the functions a_1, a_2, β, V, and μ as defined in (5.1a), (5.1b) and without any loss of generality assume

$$\mu(t) > 0 \qquad \forall t \geq 0. \tag{5.3}$$

Notice, by virtue of (5.1a), that

$$\frac{\partial V}{\partial t}(t,0) = 0, \qquad \frac{\partial V}{\partial x}(t,0) = 0. \tag{5.4}$$

Condition (5.1b) in conjunction with (5.3) and (5.4) enables us to build by standard partition of unity arguments a C^∞ map $k : \Re^+ \times \Re^n \to \Re^m$ with $k(\cdot,0) = 0$ such that

$$\begin{aligned} &\frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)f(t,x,v) + \frac{\partial V}{\partial x}(t,x)g(t,x)k(t,x) \leq -\rho(V(t,x)) + \mu(t) \\ &\qquad \forall (t,x) \in \Re^+ \times \Re^n, \quad |v| \leq \gamma(t,|x|). \end{aligned} \tag{5.5}$$

Define $v = \gamma(t,|x|)d$, where $d(\cdot) \in A := M_{B[0,1]}$. Then using (5.5) it follows that for the solution $x(t,t_0,x_0;d)$ of the system $\dot{x} = f(t,x,\gamma(t,|x|)d) + g(t,x)k(t,x)$ it holds that $\dot{y}_d(t) \leq -\rho(y_d(t)) + \mu(t)$ for all $t \geq t_0$, where $y_d(t) := V(t,x(t,t_0,x_0;d))$. It turns out from Lemma 3.2 that there exists a KL function $\sigma : (\Re^+)^2 \to \Re^+$ such that

$$V(t,x(t,t_0,x_0;d)) \leq \sigma(M + V(t_0,x_0), t - t_0) \qquad \forall t \geq t_0, \quad d(\cdot) \in M_{B[0,1]},$$

where $M := \int_{\Re^+} \mu(t)dt$, and thus by virtue of (5.1a)

$$|x(t,t_0,x_0;d)| \leq a_1^{-1}(\sigma(M + a_2(\beta(t_0)|x_0|), t - t_0)) \qquad \forall t \geq t_0, \quad d(\cdot) \in M_{B[0,1]}, \tag{5.6}$$

for any initial (t_0,x_0). Inequality (5.6) in conjunction with Proposition 2.5 implies that $0 \in \Re^n$ is RGAS with respect to (1.4). The desired wISS property for system (1.4) is a consequence of Fact 4.2. ∎

The next proposition establishes the existence of an *explicit* formula of a feedback law exhibiting ISS stabilization for system (1.3).

PROPOSITION 5.2. *Consider the system* (1.3) *and suppose that statement* (iii) *of Theorem* 5.1 *is fulfilled for some positive function* $\mu \in \mathbf{E}$*, certain* $V : \Re^+ \times \Re^n \to \Re^+$ *of class* $C^2(\Re^+ \times \Re^n)$*, and some positive definite, locally Lipschitz function* $\rho : \Re^+ \to \Re^+$*. Let* $\theta : \Re \to \Re^+$ *be any* C^∞ *nondecreasing map with*

$$\theta(s) \begin{cases} = 0, & s \le 0, \\ < 1, & s < 1, \\ = 1, & s \ge 1, \end{cases} \tag{5.7}$$

and let

$$\zeta(t,x) := \left| \frac{\partial V}{\partial t}(t,x) + \max_{|v| \le \gamma(t,|x|)} \frac{\partial V}{\partial x}(t,x) f(t,x,v) + \rho(V(t,x)) \right|, \tag{5.8a}$$

$$W(t,x) := \frac{\partial V}{\partial t}(t,x) + \max_{|v| \le \gamma(t,|x|)} \frac{\partial V}{\partial x}(t,x) f(t,x,v) + \frac{1}{2}\rho(V(t,x)) - \mu(t). \tag{5.8b}$$

Then the feedback law

$$k(t,x) := -\left\{ \frac{\left(\frac{\partial V}{\partial x}(t,x) g(t,x)\right)^T}{1 - \theta\left(\frac{W(t,x)}{\mu(t)}\right) + \left|\frac{\partial V}{\partial x}(t,x) g(t,x)\right|^2} \right\} \zeta(t,x), \tag{5.9}$$

which is everywhere continuous and locally Lipschitz with respect to x *and satisfies* $k(\cdot,0) = 0$*, exhibits wISS stabilization for* (1.4) *with gain* $\gamma(\cdot)$ *from the input* v*.*

Proof. From (5.1b) and definition (5.8b) of $W(\cdot)$ it follows that

$$\frac{\partial V}{\partial x}(t,x) g(t,x) = 0 \Rightarrow W(t,x) \le 0, \tag{5.10a}$$

$$W(t,x) \le \mu(t) \Rightarrow \frac{\partial V}{\partial t}(t,x) + \max_{|v| \le \gamma(t,|x|)} \frac{\partial V}{\partial x}(t,x) f(t,x,v) \le -\frac{1}{2}\rho(V(t,x)) + 2\mu(t). \tag{5.10b}$$

Notice that k is well defined for all (t,x), since the denominator in (5.9) is strictly positive for all $(t,x) \in \Re^+ \times \Re^n$, and is of class $C^0(\Re^+ \times \Re^n)$. Indeed, $\theta\left(\frac{W(t,x)}{\mu(t)}\right) \le 1$ for all $(t,x) \in \Re^+ \times \Re^n$, and suppose that $\theta\left(\frac{W(t,x)}{\mu(t)}\right) = 1$ for certain $(t,x) \in \Re^+ \times \Re^n$. It then follows from (5.7) that $W(t,x) \ge \mu(t)$, and thus by virtue of (5.8a) $\frac{\partial V}{\partial x}(t,x) g(t,x)$ is nonzero. Furthermore, according to regularity assumptions made for $V(\cdot)$, $f(\cdot)$, $\gamma(\cdot)$, $g(\cdot)$, and $\rho(\cdot)$, the map $k(t,x)$ as defined by (5.9) is C^0 on $\Re^+ \times \Re^n$ and locally Lipschitz with respect to $x \in \Re^n$, with $k(t,0) = 0$ for all $t \ge 0$. We next estimate the derivative $\dot{V}(\cdot)$ of $V(\cdot)$ along the trajectories of the solutions of the closed-loop system (1.4). We find

$$\begin{aligned} \dot{V}(t,x) &:= \frac{\partial V}{\partial t}(t,x) + \max_{|v| \le \gamma(t,|x|)} \frac{\partial V}{\partial x}(t,x) f(t,x,v) + \frac{\partial V}{\partial x}(t,x) g(t,x) k(t,x) \\ &\le -\frac{1}{2}\rho(V(t,x)) + 2\mu(t). \end{aligned} \tag{5.11}$$

Indeed, for those t, x for which $W(t,x) \le \mu(t)$, we have by taking into account (5.9) and (5.10b) that

$$\frac{\partial V}{\partial t}(t,x) + \max_{|v| \le \gamma(t,|x|)} \frac{\partial V}{\partial x}(t,x) f(t,x,v) \le -\frac{1}{2}\rho(V(t,x)) + 2\mu(t),$$

$$\frac{\partial V}{\partial x}(t,x) g(t,x) k(t,x) \le 0,$$

which implies (5.11). On the other hand, for those t, x for which $W(t,x) \geq \mu(t)$, it follows from (5.7), (5.9), and (5.10a) that

$$\frac{\partial V}{\partial x}(t,x)g(t,x) \neq 0,$$
$$\frac{\partial V}{\partial x}(t,x)g(t,x)k(t,x) = -\zeta(t,x),$$

and thus by taking into account definition (5.8a) of $\zeta(\cdot)$ it follows that

$$\dot{V}(t,x) \leq -\rho(V(t,x)) \leq -\frac{1}{2}\rho(V(t,x)) + 2\mu(t).$$

This establishes (5.11). We complete the proof by applying Lemma 3.2 as exactly done in the proof of Theorem 5.1. □

We next specialize the result of Theorem 5.1 to the following case of time-varying systems:

$$\begin{aligned} \dot{x} &= f(t,x) + g(t,x)u, \\ x \in \Re^n, \quad u \in \Re^m, \quad t \geq 0, \end{aligned} \tag{5.12}$$

where the mappings f, g are C^0 and locally Lipschitz with respect to x with $f(t,0) = 0$ for all $t \geq 0$.

COROLLARY 5.3. *The following statements are equivalent:*

(i) *There exist a C^1 function $V : \Re^+ \times \Re^n \to \Re^+$, functions $a_1, a_2 \in K_\infty$, $\beta \in K^+$, $\mu \in \mathbf{E}$, and a C^0 positive definite map $\rho : \Re^+ \to \Re^+$, such that for all $(t,x) \in \Re^+ \times \Re^n$*

$$a_1(|x|) \leq V(t,x) \leq a_2(\beta(t)|x|), \tag{5.13a}$$
$$\frac{\partial V}{\partial x}(t,x)g(t,x) = 0 \Rightarrow \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)f(t,x) \leq -\rho(V(t,x)) + \mu(t). \tag{5.13b}$$

(ii) *There exists a C^∞ function $k : \Re^+ \times \Re^n \to \Re^m$ with $k(t,0) = 0$ for all $t \geq 0$, such that $0 \in \Re^n$ is GAS for the system*

$$\dot{x} = f(t,x) + g(t,x)k(t,x).$$

(iii) *For every C^0 function $\gamma(t,s) : (\Re^+)^2 \to \Re^+$, being locally Lipschitz in s and such that, for each $t \geq 0$, $\gamma(t,\cdot)$ is positive definite, there exists a C^∞ function $\tilde{k} : \Re^+ \times \Re^n \to \Re^m$ with $\tilde{k}(t,0) = 0$ for all $t \geq 0$, in such a way that the system*

$$\dot{x} = f(t,x) + g(t,x)\left(\tilde{k}(t,x) + v\right)$$

satisfies the wISS property with gain $\gamma(\cdot)$ from the input $v \in \Re^m$.

Proof. Equivalence between (i) and (ii) is an immediate consequence of Theorem 5.1. In order to establish (i) ⇔ (iii) consider the system

$$\dot{x} = \tilde{f}(t,x,v) + g(t,x)u, \tag{5.14}$$

where $\tilde{f}(t,x,v) := f(t,x) + g(t,x)v$, which has the form (1.3). The equivalence between (i) and (iii) follows directly from Theorem 5.1 and the obvious consequence of (5.14):

$$\frac{\partial V}{\partial x}(t,x)g(t,x) = 0, |v| \leq \gamma(t,|x|) \Rightarrow \frac{\partial V}{\partial t}(t,x) + \frac{\partial V}{\partial x}(t,x)\tilde{f}(t,x,v) \leq -\rho(V(t,x)) + \mu(t).$$

The rest part of proof is straightforward and is left to the reader. □

COROLLARY 5.4. *Consider the system*

$$\begin{aligned} &\dot{x} = f(x) + g(x)u, \\ &x \in \Re^n, \quad u \in \Re, \end{aligned} \tag{5.15}$$

where f and g are locally Lipschitz with $f(0) = 0$, and suppose that (5.15) is globally uniformly asymptotically stabilized at the origin by means of a C^0 static feedback $u = k(x)$ with $k(0) = 0$. Then for every C^0 function $\gamma(t, s) : (\Re^+)^2 \to \Re^+$, being locally Lipschitz in s and such that, for each $t \geq 0$, $\gamma(t, \cdot)$ is positive definite, there exists a C^∞ time-varying feedback law $u = k(t, x)$ with $k(\cdot, 0) = 0$ such that the system

$$\dot{x} = f(x) + g(x)(k(t, x) + u)$$

satisfies the wISS property with gain $\gamma(\cdot)$ from the input $u \in \Re$.

Proof. Using Kurzweil's converse Lyapunov theorem in [19] we may find a C^1 radially unbounded, positive definite function $V : \Re^n \to \Re^+$ that satisfies $\frac{\partial V}{\partial x}(x)(f(x) + g(x)k_0(x)) < 0$ for $x \neq 0$. It then follows that

$$\frac{\partial V}{\partial x}(x)g(x) = 0 \Rightarrow \frac{\partial V}{\partial x}(x)f(x) \leq -\rho(V(x)) + \mu(t) \tag{5.16}$$

for a certain C^0 positive definite function $\rho : \Re^+ \to \Re^+$ and for arbitrary $\mu \in \mathbf{E}$. The rest of the proof is straightforward consequence of (5.16) and Corollary 5.3 (implication (i) $\Rightarrow$ (iii)). □

Example 5.5. Consider the affine in the control system

$$\begin{aligned} &\dot{x} = x + y^3, \\ &\dot{y} = u, \\ &(x, y) \in \Re^2, \quad u \in \Re. \end{aligned} \tag{5.17}$$

It is known that there is no C^1 static feedback exhibiting uniform in time asymptotic stabilization at the origin for (5.17). However, a C^0 static feedback law exhibiting global uniform in time asymptotic stability exists, and several approaches can be used to obtain such a feedback. Alternatively, we may apply Corollary 5.3 to establish existence of a locally Lipschitz time-varying feedback $k(t, x, y)$ that guarantees nonuniform in time ISS for any given gain function $\gamma(\cdot)$ for the resulting system:

$$\begin{aligned} &\dot{x} = x + y^3, \\ &\dot{y} = k(t, x, y) + u, \\ &(x, y) \in \Re^2, \quad u \in \Re, \end{aligned} \tag{5.18}$$

with u as input. We may also use Proposition 5.2 to determine an explicit formula for a stabilizing feedback. Indeed, let $f(t, x, y) = (x + y^3, 0)$, $g(t, x, y) = (0, 1)$ and define

$$V(t, x, y) := 2\exp(2t)x^2 + (y + \exp(t)x)^2. \tag{5.19}$$

A simple calculation shows that

$$\frac{\partial V}{\partial y}(t, x, y) = 0 \Leftrightarrow y = -\exp(t)x. \tag{5.20}$$

For those (t,x,y) for which (5.20) holds we have $V(t,x,y) = 2\exp(2t)x^2$ and thus

$$\begin{aligned}\frac{\partial V}{\partial t}(t,x,y) + \frac{\partial V}{\partial x}(t,x,y)(x+y^3) &= 8\exp(2t)x^2 - 4\exp(5t)x^4 \\ &= 4V(t,x,y) - \exp(t)V^2(t,x,y) \\ &\le -\frac{1}{2}V^2(t,x,y) + 4\exp(-t).\end{aligned}$$

Therefore, both (5.13a) and (5.13b) are satisfied with $\rho(s) = \frac{1}{2}s^2$, $\mu(t) = 4\exp(-t)$, $a_1(s) := \frac{1}{2}s^2$, $a_2(s) := 4s^2$, and $\beta(t) := \exp(t)$, and thus, according to Corollary 5.3, for any gain function $\gamma(t,|(x,y)|)$, there exists a C^∞ time-varying feedback $k(t,x,y)$ with $k(\cdot,0,0) = 0$ such that the ISS property with gain $\gamma(\cdot)$ is fulfilled for (5.18). Finally, we may invoke Proposition 5.2 to find an explicit formula for a locally Lipschitz time-varying feedback. Indeed, by (5.7), (5.8), and (5.9) we find

$$k(t,x,y) = \frac{-(y+\exp(t)x)|16\exp(-t)D(t,x,y) + V^4(t,x,y)|}{2 - 2\theta(D(t,x,y)-1) + 8(y+\exp(t)x)^2},$$

where $V(\cdot)$ is defined by (5.19) and

$$\begin{aligned}D(t,x,y) := {} & 3\exp(3t)x^2 + \exp(2t)xy + \frac{3}{2}\exp(3t)xy^3 + \frac{1}{4}\exp(2t)y^4 \\ & + \frac{1}{2}\exp(t)|y+\exp(t)x|\gamma(t,|(x,y)|) + \frac{1}{16}\exp(t)V^4(t,x,y). \qquad \square\end{aligned}$$

5.2. Propagating the ISS property through integrators. In this section we apply Proposition 4.3 in order to derive sufficient conditions for ISS feedback stabilization for the particular class of systems (1.5), where $f(\cdot)$, $g(\cdot)$, $h(\cdot)$ are C^0 and locally Lipschitz with respect to (x,y) with $f(\cdot,0,0) = 0$ and $g(\cdot,0,0) = 0$. In addition to the regularity assumptions made for f,g,h, we further assume that there exists an everywhere strictly positive C^0 function $h_0 : \Re^+ \to (0,+\infty)$, such that

$$h(t,x,y) \ge h_0(t) \qquad \forall (t,x,y) \in \Re^+ \times \Re^n \times \Re. \tag{5.21}$$

As in the time-invariant case (see, for instance, [11, 36]), we impose ISS for the subsystem (1.5a); particularly, we make the following assumptions:

(A1) There exists a C^∞ function $k : \Re^+ \times \Re^n \to \Re$, with $k(\cdot,0) = 0$, such that the system

$$\dot{x} = f(t,x,k(t,x)+y) \tag{5.22}$$

satisfies the nonuniform in time ISS property from the input y. Specifically, assume that there exist functions a_1, a_2 of class K_∞, with a_1 being a locally Lipschitz function; a function β of class K^+; and a C^0 function $\gamma(t,s) : (\Re^+)^2 \to \Re^+$, which is locally Lipschitz in s and for each fixed $t \ge 0$ the map $\gamma(t,\cdot)$ is of class K_∞, in such a way that the following holds:

(5.23)
$$|y(t)| \le \gamma(t,|x(t)|) \text{ a.e. for } t \ge t_0 \Rightarrow a_1(|x(t)|) \le \exp(-t+t_0)\beta(t_0)a_2(|x_0|),$$

where $x(t) := x(t,t_0,x_0;y)$ denotes the trajectory of (5.22) with input y.

(A2) For the function $k(\cdot)$ above we make the following additional hypothesis. There exists a function $E : (\Re^+)^2 \to \Re^+$, with $E(\cdot, 0) = 0$, being nondecreasing in s for each fixed $t \geq 0$ in such a way that

$$|k(t,x)| \leq E(t,|x|) \qquad \forall (t,x) \in \Re^+ \times \Re^n, \tag{5.24a}$$

$$\lim_{t \to +\infty} E\left(t, a_1^{-1}\left(c \exp\left(-\frac{1}{2}t\right)\right)\right) = 0 \qquad \forall c \geq 0. \tag{5.24b}$$

(A3) There exist constants $R > 0$, $m \geq 1$ and a C^0 function $M : \Re^+ \to (0, +\infty)$ such that

$$a_2(s) \leq R s^{2m} \quad \text{for } s \text{ near zero}, \tag{5.25a}$$

$$M(t) s^m \leq \gamma(t,s) \quad \forall t \geq 0, \quad s \text{ near zero}. \tag{5.25b}$$

The following proposition generalizes a well-known result concerning ISS-feedback stabilization for autonomous systems under the presence of uniform in time ISS (see, for instance, [36]). It also constitutes an extension of the main result in [40] under the presence of "exponential," nonuniform in time ISS.

PROPOSITION 5.6. *Under* (A1), (A2), *and* (A3), *for any gain function* $\bar{\gamma}(t,s) : (\Re^+)^2 \to \Re^+$ *with the same properties as* γ *there exists an everywhere* C^∞ *function* $\bar{k} : \Re^+ \times \Re \to \Re$, *with* $\bar{k}(t,0) = 0$ *for all* $t \geq 0$, *such that system* (1.5) *with* $u := \bar{k}(t, y - k(t,x)) + u$ *satisfies the nonuniform in time ISS property with gain* $\bar{\gamma}$ *from the input* u.

Proof. The proof is based on the Lyapunov characterization of wISS (Proposition 4.3). The corresponding analysis is similar to that employed in [38, 39] and extremely simplifies the approach in [40], where ISS stabilization is exhibited under stricter assumptions. We proceed as follows. Our hypothesis (A1) guarantees, according to Proposition 4.3(iii), the existence of a C^0 function $U : \Re^+ \times \Re^n \to \Re^+$, which is locally Lipschitz on $\Re^+ \times (\Re^n \setminus \{0\})$, such that

$$a_1(|x|) \leq U(t,x) \leq \beta(t) a_2(|x|) \qquad \forall (t,x) \in \Re^+ \times \Re^n, \tag{5.26a}$$

$$\begin{aligned} &|y(t) - k(t, x(t))| \leq \gamma(t, |x(t)|) \text{ a.e. for } t \geq t_0 \\ &\Rightarrow U(t, x(t)) \leq \exp\left(-\frac{1}{2}(t - t_0)\right) U(t_0, x_0) \qquad \forall (t_0, x_0) \in \Re^+ \times \Re^n \text{ and } t \geq t_0, \end{aligned} \tag{5.26b}$$

where $(x(t), y(t))$ denotes the trajectory of the closed-loop system (1.5) with $u := \bar{k}(t, y - k(t,x)) + u$. Let us denote by $\gamma^{-1}(t,s)$ the inverse function of $\gamma(t,s)$ with respect to s; i.e., $\gamma^{-1}(\cdot)$ satisfies

$$\gamma\left(t, \gamma^{-1}(t,s)\right) = \gamma^{-1}(t, \gamma(t,s)) = s \qquad \forall (t,s) \in \Re^+ \times \Re^+.$$

Clearly, $\gamma^{-1}(t,s)$ is C^0 and for each fixed $t \geq 0$ the mapping $\gamma^{-1}(t,\cdot)$ is of class K_∞ as well. By Lemma 2.3, a pair of functions $a \in K_\infty \cap C^\infty((0,+\infty))$ and $\kappa \in K^+ \cap C^\infty(\Re^+)$ can be found in such a way that

$$\beta(t) a_2\left(\gamma^{-1}(t,s)\right) \leq a(\kappa(t)s) \qquad \forall (t,s) \in \Re^+ \times \Re^+. \tag{5.27}$$

We define

$$W(t,s) := a(\kappa(t)s). \tag{5.28}$$

Notice that, according to (A3), the function $W(\cdot)$ can be constructed in such a way that, in addition to (5.27), the following holds:

$$W(t,s) = \bar{M}(t)s^2, \quad t \geq 0,\ s \text{ near zero}, \tag{5.29}$$

for a certain function $\bar{M}(\cdot)$ of class $K^+ \cap C^\infty(\Re^+)$. Therefore without loss of generality we may assume that $W(\cdot)$ as defined by (5.28) is of class $C^\infty(\Re^+ \times \Re; \Re^+)$. It follows by (5.26a) and (5.27) that

$$W(t,|y-k(t,x)|) \leq U(t,x) \Rightarrow |y-k(t,x)| \leq \gamma(t,|x|), \tag{5.30a}$$

$$U(t,x) \leq W(t,|y-k(t,x)|) \Rightarrow |x| \leq a_1^{-1}(W(t,|y-k(t,x)|)). \tag{5.30b}$$

Next define

$$\begin{aligned} S_1 &:= \{(t,x,y) \in \Re^+ \times \Re^n \times \Re : W(t,|y-k(t,x)|) \leq U(t,x)\}, \\ S_2 &:= (\Re^+ \times \Re^n \times \Re) \setminus S_1, \end{aligned} \tag{5.31}$$

$$\Phi(t,x,y) := \begin{cases} U(t,x), & (t,x,y) \in S_1, \\ W(t,|y-k(t,x)|), & (t,x,y) \in S_2. \end{cases} \tag{5.32}$$

From (5.27), (5.28), (5.31), and definition (5.32) of Φ, it follows that Φ is C^0 and satisfies

$$\begin{aligned} \bar{a}_1(|(x,y-k(t,x))|) \leq \Phi(t,x,y) \leq \bar{\beta}(t)\bar{a}_2(|(x,y-k(t,x))|) \\ \forall (t,x,y) \in \Re^+ \times \Re^n \times \Re \end{aligned} \tag{5.33}$$

for certain $\bar{a}_1$, $\bar{a}_2 \in K_\infty$ and $\bar{\beta} \in K^+$. By taking into account (5.21) and (5.29) and applying standard partition of unity arguments, it follows that for every gain $\bar{\gamma}$ with the same properties as γ, a $C^\infty(\Re^+ \times \Re^n)$ function $\bar{k}(t,z)$ can be determined in such a way that $\bar{k}(t,0) = 0$ for all $t \geq 0$, and furthermore, for every $(t,z) \in \Re^+ \times (\Re \setminus \{0\})$, the following holds:

$$\begin{aligned} &\frac{\partial W}{\partial t}(t,|z|) + \frac{\partial W}{\partial s}(t,|z|)\mathrm{sgn}(z)\Big(g(t,x,k(t,x)+z) + h(t,x,k(t,x)+z)\big(\bar{k}(t,z)+u\big) \\ &\qquad - \frac{\partial k}{\partial t}(t,x) - \frac{\partial k}{\partial x}(t,x) f(t,x,k(t,x)+z)\Big) \\ &\leq -\frac{1}{2}W(t,|z|) + \exp(-t) \qquad \forall |u| \leq \bar{\gamma}(t,|(x,k(t,x)+z)|), |x| \leq a_1^{-1}(W(t,|z|)). \end{aligned} \tag{5.34}$$

We are now in a position to establish the ISS property for the resulting system

$$\begin{aligned} \dot{x} &= f(t,x,y), \\ \dot{y} &= g(t,x,y) + h(t,x,y)\bar{k}(t,y-k(t,x)) + h(t,x,y)u. \end{aligned} \tag{5.35}$$

Particularly, we show that, if $(x(t),y(t))$ denotes the trajectory of (5.35) initiated from (x_0,y_0) at time t_0 with input $v \in \mathbf{L}^\infty_{loc}$, then the following holds:

$$\begin{aligned} &|u(t)| \leq \bar{\gamma}(t,|(x(t),y(t))|) \text{ a.e. for } t \geq t_0 \\ &\qquad \Rightarrow \Phi(t,x(t),y(t)) \leq \exp\left(-\frac{1}{2}(t-t_0)\right)(\Phi(t_0,x_0,y_0)+2). \end{aligned} \tag{5.36}$$

Indeed, by taking into account (5.26b), (5.30a), (5.31), and (5.32) it follows that

$$\begin{aligned}\Phi(t,x(t),y(t)) = U(t,x(t)) &\le \exp\left(-\frac{1}{2}(t-t_0)\right) U(t_0,x(t_0)) \\ &\le \exp\left(-\frac{1}{2}(t-t_0)\right) \Phi(t_0,x(t_0),y(t_0)) \\ &\text{for the case } (t,x(t),y(t)) \in S_1,\ t \ge t_0,\end{aligned} \tag{5.37a}$$

whereas, by virtue of (5.30b), (5.31), (5.32), and (5.34) we obtain

$$\begin{aligned}\Phi(t,x(t),y(t)) &= W(t,|y(t)-k(t,x(t))|) \\ &\le \exp\left(-\frac{1}{2}(t-t_0)\right)\left(W(t_0,|y(t_0)-k(t_0,x(t_0))|)\right. \\ &\qquad \left. + \int_{t_0}^{t} \exp\left(-\frac{1}{2}(\tau+t_0)\right) d\tau\right) \\ &\le \exp\left(-\frac{1}{2}(t-t_0)\right)\left(\Phi(t_0,x(t_0),y(t_0)) + \int_{t_0}^{t} \exp\left(-\frac{1}{2}(\tau+t_0)\right) d\tau\right) \\ &\quad \text{for the case } (t,x(t),y(t)) \in S_2,\ t \ge t_0.\end{aligned} \tag{5.37b}$$

Combining both cases (5.37a), (5.37b) above and exploiting continuity of Φ, we get (5.36). It turns out by taking into account (5.24a), (5.26a), (5.28), (5.32), and (5.33) that

$$|u(t)| \le \bar{\gamma}(t,|(x(t),y(t))|) \text{ a.e. for } t \ge t_0 \Rightarrow a_1(|x(t)|) \le D(t,t_0,|(x_0,y_0)|), \tag{5.38}$$

$$|u(t)| \le \bar{\gamma}(t,|(x(t),y(t))|) \text{ a.e. for } t \ge t_0 \Rightarrow a(|y-k(t,x)|) \le D(t,t_0,|(x_0,y_0)|), \tag{5.39}$$

where $D(t,t_0,s) := \exp(-\frac{1}{2}(t-t_0))(1+\bar{\beta}(t_0)\bar{a}_2(s+E(t_0,s)))$. It follows from (5.24a), (5.38), and (5.39) that

$$\begin{aligned}|u(t)| \le \bar{\gamma}(t,|(x(t),y(t))|) &\text{ a.e. for } t \ge t_0 \\ &\Rightarrow |y(t)| \le E(t,a_1^{-1}(D(t,t_0,|(x_0,y_0)|))) + a^{-1}(D(t,t_0,|(x_0,y_0)|)),\end{aligned}$$

which by virtue of (5.24b), (5.38), and (5.39) guarantee the ISS property for (5.35) with gain $\bar{\gamma}$ from the input u. □

Conditions (A1), (A2), and (A3) do not in general guarantee that the feedback stabilizer $\bar{k}(\cdot)$ satisfies the same property (A2) imposed for the original feedback $k(\cdot)$. This is a drawback for the achievement of ISS partial-state feedback stabilization for higher dimensional triangular time-varying systems by applying backstepping design. Therefore, some additional conditions should be imposed for the original subsystem (1.5a) and the map $k(\cdot)$ in order to propagate (A2) to the new feedback $\bar{k}(\cdot)$, like those imposed in [40]. For instance, in [40] it was assumed that (1.5a) satisfies an exponential type of ISS from the input y and the dynamics have polynomial structure with respect to (t,x). Further generalizations of Proposition 5.6, as well as conditions weaker than those imposed in [40], which enable us to construct a smooth feedback with the same properties as $k(\cdot)$, are presented in [15]. We limited ourselves instead, to the case examined in [40], by re-establishing ISS stabilization for (1.5) by means of a smooth feedback $\bar{k}(\cdot)$ for which (A2) holds. We next show that the main result in [40] is a straightforward consequence of Proposition 5.6.

PROPOSITION 5.7. *Consider the system* (1.5) *with* $h(t,x,y) \equiv 1$, *and in addition to the regularity properties for* f, g, k, γ *imposed in Proposition* 5.6, *we assume that*

there exists a function r of class Π (see "Notations" for the definition of class Π) and constants a, $K > 0$ such that

$$|f(t,x,y)| + |g(t,x,y)| \le (1+t)^a r(|(x,y)|), \tag{5.40a}$$

$$|k(t,x)| + \left|\frac{\partial k}{\partial t}(t,x)\right| \le (1+t)^a r(|x|), \tag{5.40b}$$

$$\left|\frac{\partial k}{\partial x}(t,x)\right| \le (1+t)^a (1+r(|x|)), \tag{5.40c}$$

$$\frac{1}{K(1+t)^a} s \le \gamma(t,s) \le (1+t)^a r(s). \tag{5.40d}$$

Moreover, assume that subsystem (1.5a) *satisfies assumption* (A1) *with $a_1(s) = a_2(s) = s^2$ and $\beta(t) = M(1+t)^a$ for some constant $M > 0$. Then for any $\Gamma(\cdot) \in \Pi$ there exist a function $\bar r \in \Pi$, constants $\bar a \ge a$ and $\bar M \ge M$, and a feedback $\bar k(\cdot)$ as in statement of Proposition* 5.6 *such that property* (A1) *holds for* (1.5) *with $u := u + \bar k(t, y - k(t,x))$, $\gamma := \Gamma$, and some $a_1(\cdot)$, $a_2(\cdot)$, and $\bar\beta(t) = \bar M(1+t)^{\bar a}$, as well as inequalities* (5.40a), (5.40b), (5.40c), (5.40d), *are fulfilled with $\bar k(t, y - k(t,x))$, Γ, (x,y), $\bar a$, and $\bar r$ instead of $k(t,x)$, γ, x, a, and r, respectively.*

Proof (outline). It can be easily verified that all hypotheses (A1), (A2), and (A3) of Proposition 5.6 are fulfilled for (1.5). Particularly, (A2) holds as a consequence of (5.40b) and the fact that $r \in \Pi$. In order to establish our statement we proceed exactly as in the proof of Proposition 5.6. In our case we may use

$$W(t,s) = C(1+t)^{3a} s^2 \tag{5.41}$$

for some constant $C > 0$ (the constant a is defined in (5.40)) and we can find a polynomial $R \in \Pi$ of the form $R(s) = R_0(s + s^l)$ for $R_0 > 0$ and l being an odd positive integer and a constant $\theta \ge a$ such that (5.34) is fulfilled with

$$\bar k(t,y) := -(1+t)^\theta R(y) \tag{5.42}$$

and with $W(\cdot)$ as given by (5.41). The rest of the proof is the same as that given in proof of Proposition 5.6. Finally, it is immediate to see that, according to definition (5.42), the feedback $\bar k(\cdot)$ satisfies the same properties as those imposed for $k(\cdot)$; hence, it turns out that (A2) holds for the map $\bar k(\cdot)$. □

We may use the result of Proposition 5.7 and apply the induction procedure in order to re-establish Theorem 2.4 in [40], concerning partial-state feedback stabilization for a class of triangular systems.

Corollary 5.8. *Consider the system*

$$\dot x = f(t,x,y), \tag{5.43a}$$

$$\begin{gathered} \dot y_i = g_i(t,x,y_1,\dots,y_i) + y_{i+1}, \qquad i = 1,\dots,m, \\ x \in \Re^n, \quad y = (y_1,\dots,y_m)^T \in \Re^m, \quad t \ge 0, \quad u = y_{m+1} \in \Re, \end{gathered} \tag{5.43b}$$

where f, g_i are C^0 everywhere and locally Lipschitz with respect to (x,y) with $f(t,0,0) = 0$, $g_i(t,0,\dots,0) = 0$ for $i = 1,\dots,m$ and for all $t \ge 0$. Suppose that there exists a function r of class Π and a constant $a > 0$ such that

$$|f(t,x,y)| \le (1+t)^a r(|(x,y)|), \tag{5.44a}$$

$$|g_i(t,x,y_1,\dots,y_i)| \le (1+t)^a r(|(x,y_1,\dots,y_i)|). \tag{5.44b}$$

Moreover, assume that subsystem (5.43a) *satisfies assumption* (A1) *with* $k \equiv 0$, $a_1(s) = a_2(s) = s^2$, *and* $\beta(t) = M(1+t)^a$ *for some constant* $M > 0$ *and gain* $\gamma(t,s)$, *which is* C^0 *on* $\Re^+ \times \Re^+$ *and locally Lipschitz with respect to* $s \geq 0$ *and satisfies* $\gamma(t,\cdot) \in K_\infty$ *for all* $t \geq 0$, *in such a way that the following holds for some constant* $K > 0$*:*

$$\frac{1}{K(1+t)^a} s \leq \gamma(t,s) \leq (1+t)^a r(s). \tag{5.44c}$$

Then for any $\Gamma(\cdot) \in \Pi$ *there exists a* C^∞ *feedback law* $u = \bar{k}(t, y_1, \ldots, y_m)$ *such that system* (5.43) *with* $u := \bar{k}(t,y) + u$ *satisfies the ISS property with gain* Γ *from the input* u.

6. Conclusions. We have provided equivalent characterizations for the concept of robust global asymptotic stability (RGAS) for time-varying systems. Lyapunov characterizations for this concept as well as for the concept of nonuniform in time input-to-state stability (ISS) are given. Moreover, we have provided necessary and sufficient conditions for nonuniform in time ISS stabilization of affine in the control systems by means of a smooth time-varying feedback. An explicit formula for the time-varying feedback stabilizer is also presented. The problem of partial-state nonuniform in time ISS-feedback stabilization for triangular systems is considered.

RIESZ BASIS PROPERTY OF EVOLUTION EQUATIONS IN HILBERT SPACES AND APPLICATION TO A COUPLED STRING EQUATION*

GEN-QI XU† AND BAO-ZHU GUO‡

Abstract. Suppose that $\{\lambda_n\}$ is the set of zeros of a sine-type generating function of the exponential system $\{e^{i\lambda_n t}\}$ in $L^2(0,T)$ and is separated. Levin and Golovin's classical theorem claims that $\{e^{i\lambda_n t}\}$ forms a Riesz basis for $L^2(0,T)$. In this article, we relate this result with Riesz basis generation of eigenvectors of the system operator of the linear time-invariant evolution equation in Hilbert spaces through its spectrum. A practically favorable necessary and sufficient condition for the separability of zeros of function of sine type is derived. The result is applied to get Riesz basis generation of a coupled string equation with joint dissipative feedback control.

Key words. Riesz basis, function of sine type, string equation

1. Introduction.

In a Hilbert space, the most important bases are orthonormal bases. Second in importance are Riesz bases that are bases equivalent to some orthonormal basis. Riesz basis is studied in the context of stabilization of linear infinite dimensional system $\dot{x}(t) = Ax(t)$, in some Hilbert space $\mathbf{H}$, where A is the generator of a C_0-semigroup on $\mathbf{H}$. The system is called a Riesz spectral system [2] if there is a set of eigenvectors of A, which forms a Riesz basis for $\mathbf{H}$. For this kind of system, not only the stability of system is usually determined by the spectrum of the system operator A, which is referred to as the spectrum-determined growth condition, but also the dynamic of the system can be described by eigenpairs under expansion of nonharmonic Fourier series. Riesz basis is also the basis of the so-called method of moment, a powerful method in the study of controllability of hyperbolic systems [19], [1]. A nice recent result on the relation of exact controllability and Riesz basis can be found in [9].

Recently, some progress has been made for the Riesz basis generation of single beam equations under boundary feedback controls [3], [4] and coupled beams under joint dissipative feedback controls [5]. The basic idea is to show that the generalized eigenfunctions of the closed-loop system is quadratically close to that of the free system. This is actually an application of Bari's classical theorem that if $\{\phi_n\}_1^\infty$ is a Riesz basis for a Hilbert space $\mathbf{H}$ and another ω-linearly independent sequence $\{\psi_n\}_1^\infty$ of $\mathbf{H}$ satisfying

$$\sum_{n=1}^{\infty} \|\psi_n - \phi_n\|^2 < \infty, \tag{1}$$

then $\{\psi_n\}_1^\infty$ also forms a Riesz basis itself. The success of this approach to beam equations is attributed to their higher order of eigenfrequencies. In this sense, we can roughly say that the closed-loop system is a "perturbed" system of the free counterpart. In other words, the boundary feedback previously studied for beam equations are "low order" perturbations of the corresponding free systems. Recently, this idea was generally developed for the second order hyperbolic systems with collocated actuator/sensor by [6]. For string equations, however, this is not the case in general. A simple example is the following one dimensional wave equation with boundary feedback control:

$$\begin{cases} y_{tt}(x,t) - y_{xx}(x,t) = 0, & 0 < x < 1,\ t > 0, \\ y(0,t) = 0, \quad y_x(1,t) = u(t), \quad u(t) = -ky_t(1,t). \end{cases} \tag{2}$$

When $k \neq 1$, system (2) is a Riesz spectral system. However, the eigenfunctions of this system are never quadratically close to that of the free system ($k = 0$ in (2)) (see, e.g., [18]). By this reason, we may say that this closed-loop system possesses the same order as the associated free system. Moreover, in some special case such as $k = 1$ in (2), the system is never a Riesz spectral system.

This special property results in many different approaches to deal with Riesz basis generation for string equations. The basic approach is to estimate eigenvalues and eigenfunctions and then find some invertible transformation to transform the set of eigenfunctions to be an orthonormal basis. We refer to [20], [21] as well as many references therein. Mathematically, the general Riesz basis theory is developed in the context of nonharmonic Fourier series, which originated from the works of Paley and Wiener [16] and was developed later by many former Soviet mathematicians. Earlier results are summarized in [24], [15]. A nice summary of the later development can be found in [1]. Among them, a powerful concept—the so-called function of sine type—was introduced by Levin [10]. The main result due to Levin and Golovin says that if $\{\lambda_n\}$ is the set of zeros of a sine-type generating function of the exponential system $\{e^{i\lambda_n t}\}$ in $L^2(0,T)$ and is separated, then $\{e^{i\lambda_n t}\}$ forms a Riesz basis for $L^2(0,T)$.

In this paper, we first relate Levin and Golovin's theorem (generally, Pavlov's theorem) with Riesz basis generation of eigenvectors of the system operator of the time-invariant evolution equation in Hilbert spaces through its spectrum. A remarkable characterization condition is obtained for the separability of zeros of functions of sine type, which is considered practically a hard problem in many applications. The result is then applied to study the Riesz basis property of a coupled string equation jointed by a span dissipative feedback control.

The organization of this paper is as follows: in the next section, we shall first introduce some basic facts about functions of sine type. The main results and some remarks are presented. The proofs of main results are given in section 3. Finally, in section 4, we will check how our string system satisfies the sufficient condition obtained in this article—to be a Riesz spectral system in the energy Hilbert space.

2. Basic notation and main results. To begin with, let us recall some basic facts about functions of sine type. An entire function $f(z)$ is said to be of *exponential type* if the inequality

$$| f(z) | \leq Ae^{B|z|} \tag{3}$$

holds for some positive constants A and B and all complex values of z. The smallest of constants B is said to be the *exponential type* of $f(z)$. For the exponential-type

function f, define a 2π-periodic function on $\mathbb{R}$ by the equality

$$h_f(\phi) = \lim_{r\to\infty} \sup \frac{1}{r} \log |f(re^{i\phi})| \tag{4}$$

as a growth indicator of f. The indicator diagram of f is a convex set G_f such that

$$h_f(\phi) = \sup_{k\in G_f} \mathrm{Re}(ke^{-i\phi}). \tag{5}$$

Furthermore, the entire function f of exponential type is said to be a function of the *Cartwright class* if

$$\int_{\mathbb{R}} \frac{\max\{\log|f|, 0\}}{1+x^2} dx < \infty. \tag{6}$$

In particular, the function f of exponential type satisfying the condition

$$\int_{\mathbb{R}} \frac{|f(x)|^2}{1+x^2} dx < \infty \tag{7}$$

belongs to the *Cartwright class*. The indicator diagram of a *Cartwright class* function is an interval $[i\alpha, i\beta], \alpha \le \beta$, of the imaginary axis. Its length is the width of the indicator diagram [1, pp. 59–60].

An entire function of exponential type with simple zeros $\{\lambda_n\}$ and with the width of the indicator diagram T is called a generating function of exponential family $\{e^{i\lambda_n t}\}_1^\infty$ in $L^2(0,T)$ [1, p. 101]. The following theorem on the basis property of the exponential family $\{e^{i\lambda_n t}\}$ was obtained by Pavlov [17]. (See also Proposition II.3.17 and Theorem II.4.8 of [1].)

THEOREM 1 (Pavlov). *Let $\Lambda := \{\lambda_n\}_1^\infty$ be a countable set of the complex numbers. The family $\{e^{i\lambda_n t}\}_1^\infty$ forms a Riesz basis for $L^2(0,T)$ if and only if the following conditions are satisfied:*

(i) *the sequence $\{\lambda_n\}_1^\infty$ lies in a strip parallel to the real axis:*

$$\sup_{n\ge 1} |\mathrm{Im}\lambda_n| < \infty; \tag{8}$$

(ii) *$\{\lambda_n\}_1^\infty$ is separated in the sense that*

$$\delta(\Lambda) := \inf_{n\ne m} \mid \lambda_n - \lambda_m \mid > 0; \tag{9}$$

(iii) *the generating function of the family $\{e^{i\lambda_n t}\}$ on the interval $(0,T)$ satisfies the Muckenhoupt condition*

$$\sup_{I\in\mathcal{J}} \left\{ \frac{1}{|I|^2} \int_I |f(x+ih)|^2 dx \int_I |f(x+ih)|^{-2} dx \right\} < \infty \tag{10}$$

for some $h \in \mathbb{R}$, where $\mathcal{J}$ is the set of all intervals of the real axis. □

According to Definition II.1.27 of [1], an entire function of exponential type is said to be of sine type if

(a) the zeros of f lie in a strip $\{z \in \mathbb{C} || \mathrm{Im} z| \le H\}$ for some $H > 0$;

(b) there exist $h \in \mathbb{R}$ and positive constants c_1, c_2 such that $c_1 \le |f(x+ih)| \le c_2$ for all $x \in \mathbb{R}$.

It is seen that if the generation function f of $\{e^{i\lambda_n t}\}_1^\infty$ is of sine type, conditions (i) and (iii) of Theorem 1 are always satisfied. In this case, Theorem 1 will reduce to Levin and Golovin's well-known theorem (Proposition II.4.3 of [1]).

In order to apply Pavlov's theorem to get Riesz basis generation of general linear systems in Hilbert spaces, we need to relate eigenvectors of the system operator with the exponential system through its spectrum. Our main result on this point is stated as Theorem 2 below.

Let us recall that for a closed linear operator A in a Hilbert space $\mathbf{H}$, a nonzero $x \in \mathbf{H}$ is called a generalized eigenvector of A, corresponding to an eigenvalue λ of A, if there is a positive integer n such that $(\lambda - A)^n x = 0$. The root subspace of A corresponding to λ is given by

$$\mathbf{H}_\lambda = \{x \mid \exists n \text{ such that } (\lambda - A)^n x = 0\}.$$

The dimension m_λ of $\mathbf{H}_\lambda$ is called the algebraic multiplicity of λ. When $m_\lambda = 1$, we say that λ is algebraically simple. Let $\mathrm{Sp}(A)$, the so-called root subspace of A, be the closed subspace spanned by all generalized eigenvectors of A.

THEOREM 2. *Suppose that a linear (usually unbounded) operator A generates a C_0-semigroup e^{At} on a separable Hilbert space $\mathbf{H}$. Assume that A is a discrete operator (that is, $(\lambda - A)^{-1}$ is compact for some $\lambda \in \rho(A)$) with eigenvalues $\{\lambda_n\}_1^\infty$. Suppose that*

(a) *each eigenvalue λ_n is algebraically simple;*

(b) $\mathrm{Sp}(A) = \mathrm{Sp}(A^*) = \mathbf{H}$;

(c) $\{e^{\lambda_n t}\}_1^\infty$ *forms a Riesz basis for $L^2(0,T)$ for some $T > 0$;*

then there is a set of eigenvectors of A corresponding to $\{\lambda_n\}$, which forms a Riesz basis for $\mathbf{H}$. □

Remark 1. Naturally, one expects that the converse of Theorem 2 is also true, that is, if there is a set of eigenvectors of A that forms a Riesz basis for $\mathbf{H}$, $\{e^{\lambda_n t}\}_1^\infty$ forms a Riesz basis for $L^2(0,T)$ for some $T > 0$. Unfortunately, this is not generally true. In fact, by Theorem 1, a necessary condition for $\{e^{\lambda_n t}\}_1^\infty$ to form a Riesz basis for $L^2(0,T)$ is that $\{\lambda_n\}$ lies in a strip parallel to the imaginary axis. □

By Theorem 2, in order to check whether the system $\dot{x}(t) = Ax(t)$ in the Hilbert space $\mathbf{H}$ is a Riesz spectral system, we need check only conditions (a)–(c). In many applications, the spectrum of A multiplied by $-i$ is the set of zeros of some sine-type function, and such a function can be produced by the characteristic equation for which the spectrum is satisfied. So, the difficulty of checking condition (c) of Theorem 2 lies in the *separability* of $\{\lambda_n\}$ required in Theorem 1. For this reason, finding a characterization condition for the *separability* of zeros of functions of sine type appears to be pressing. Actually, it is already known from Corollary 1 of [24] that if $f(z)$ is a function of sine type with simple separated zeros $\{\lambda_n\}$, then

$$\inf_n \mid f'(\lambda_n) \mid > 0. \tag{11}$$

Unexpectedly, we find that condition (11) also serves a sufficient condition for zeros of $f(z)$ to be separated. This is given in the following theorem.

THEOREM 3. *Let $f(z)$ be an entire function of exponential type satisfying* (3). *Suppose that $f(z)$ is bounded on the real axis and the zeros $\{\lambda_n\}_1^\infty$ of $f(z)$ satisfy*

$$\sup_n \mid \mathrm{Im}\lambda_n \mid = h < \infty, \qquad \sup_n m_n < \infty,$$

where m_n is the multiplicity of λ_n as a zero of $f(z)$.

(i) *If*

$$\inf_n \mid f^{(m_n)}(\lambda_n) \mid > 0, \tag{12}$$

then $\{\lambda_n\}_1^\infty$ *is separated:* $\inf_{n\neq m} \mid \lambda_n - \lambda_m \mid > 0$.

(ii) *Conversely, if* $\{\lambda_n\}_1^\infty$ *is separated and there is a* $y_0 \in \mathbb{R}$ *such that*

$$\inf_{x\in\mathbb{R}} \mid f(x+iy_0) \mid > 0, \tag{13}$$

then (12) *holds true.*

Consequently, the necessary and sufficient condition for zeros $\{\lambda_n\}$ *of a function of sine type to be separated is that condition* (12) *holds true.* □

The second difficulty in applying Theorem 2 is the completeness of the root subspace, which is condition (b) in Theorem 2. To do this, let us recall Lemma 5 of [8] that if A is a discrete operator, then

$$\mathbf{H} = \sigma_\infty(A^*) \oplus \mathrm{Sp}(A),$$

where $\sigma_\infty(A^*) = \{x \in \mathbf{H} | R(\lambda, A^*)x$ is analytic in $\mathbb{C}\}$ [8, Lemma 6, p. 2296]. Hence for a discrete operator A, $\mathrm{Sp}(A) = H$ if and only if $\sigma_\infty(A^*) = \{0\}$.

For an H-valued entire function $f(z)$, one can also define its order ρ_f as the infimum of real number a so that

$$\|f(z)\|_{\mathbf{H}} = \mathcal{O}(e^{|z|^a}) \text{ as } |z| \to \infty;$$

see [23]. We can now state our result on the completeness of the root subspace, which is characterized by the first order resolvent operator of the adjoint operator. Here we use order instead of type as it was used in [23] for operators with resolvent operator being of quotient of entire functions of exponential type. The advantage is that the order is more easily determined than type in applications (see also Theorem 2.6.2 of [13]).

THEOREM 4. *Let* A *be the generator of a* C_0*-semigroup in a Hilbert space* $\mathbf{H}$. *Assume that* A *is discrete (so is* A^**) and for* $\lambda \in \rho(A^*)$, $R(\lambda, A^*)$ *is of the form*

$$R(\lambda, A^*)x = \frac{G(\lambda)x}{F(\lambda)} \qquad \forall x \in \mathbf{H},$$

where for each $x \in \mathbf{H}$, $G(\lambda)x$ *is an H-valued entire function with order less than or equal to* ρ_1 *and* $F(\lambda)$ *is a scalar entire function of order* ρ_2. *Let* $\rho = \max\{\rho_1, \rho_2\} < \infty$ *and an integer* n *so that* $n - 1 \le \rho < n$. *If there are* $n+1$ *rays* γ_j, $j = 0, 1, 2, \ldots, n$, *on the complex plane*

$$\arg\gamma_0 = \frac{\pi}{2} < \arg\gamma_1 < \arg\gamma_2 \cdots < \arg\gamma_n = \frac{3\pi}{2}$$

with

$$\arg\gamma_{j+1} - \arg\gamma_j \le \frac{\pi}{n}, \qquad 0 \le j \le n-1,$$

so that $R(\lambda, A^*)x$ *is bounded on each ray* γ_j, $0 < j < n$, *as* $|\lambda| \to \infty$ *for any* $x \in \mathbf{H}$, *then* $\mathrm{Sp}(A) = \mathrm{Sp}(A^*) = \mathbf{H}$. □

3. Proof of main results. Before proving Theorem 2, we show the following lemma, which is a natural generalization of the well-known fact for $\mathbf{H} = \mathbb{C}$.

LEMMA 1. *Let* $\mathbf{H}$ *be a separable Hilbert space and* $\{e_n(t)\}_1^\infty$ *be a Riesz basis for* $L^2(0,T)$, $T > 0$. *Then for any* $\phi \in L^2(0,T;\mathbf{H})$ *there exists a sequence* $\{\phi_n\}_1^\infty \subset \mathbf{H}$ *such that*

(i)

$$\phi(t) = \sum_{n=1}^{\infty} e_n(t)\phi_n, \tag{14}$$

which holds in $L^2(0,T;\mathbf{H})$, *where* ϕ_n *is uniquely determined by*

$$\phi_n = \int_0^T e_n^*(t)\phi(t)dt \tag{15}$$

and $\{e_n^*(t)\}$ *is the biorthogonal system with respect to* $\{e_n(t)\}$ *in* $L^2(0,T)$ [24, p. 28],

$$\langle e_n^*(\cdot), e_m(\cdot)\rangle = \delta_{nm} \text{ whenever } n, m \geq 1;$$

(ii) *there are constants* $C_i > 0$, $i = 1, 2$, *such that*

$$C_1 \sum_{n=1}^{\infty} \|\phi_n\|_{\mathbf{H}}^2 \leq \|\phi\|_{L^2(0,T;H)}^2 \leq C_2 \sum_{n=1}^{\infty} \|\phi_n\|_{\mathbf{H}}^2. \tag{16}$$

Proof. Our proof is constructed by the following steps. First, take $\{\psi_n\}$ as an orthonormal basis of $\mathbf{H}$. Then for almost every $t \in [0,T]$, one can expand $\phi \in L^2(0,T;\mathbf{H})$ as

$$\phi(t) = \sum_{n=1}^{\infty} \langle \phi(t), \psi_n\rangle_{\mathbf{H}} \psi_n, \qquad t \in [0,T] \text{ a.e.},$$

and so

$$\|\phi(t)\|_{\mathbf{H}}^2 = \sum_{n=1}^{\infty} |\, \langle \phi(t), \psi_n\rangle_{\mathbf{H}} \,|^2 \qquad \forall t \in [0,T] \text{ a.e.} \tag{17}$$

Second, since $\langle \phi(t), \psi_m\rangle_{\mathbf{H}} \in L^2(0,T)$ for every $m \geq 1$, one can write

$$\langle \phi(t), \psi_m\rangle_{\mathbf{H}} = \sum_{n=1}^{\infty} a_n^{(m)} e_n(t) \qquad \forall m \geq 1 \text{ in } L^2(0,T), \tag{18}$$

where the coefficients $a_n^{(m)}$ are determined by

$$a_n^{(m)} = \int_0^T \langle \phi(t), \psi_m\rangle_{\mathbf{H}} e_n^*(t)dt \tag{19}$$

with the property that

$$C_1 \sum_{n=1}^{\infty} |\, a_n^{(m)} \,|^2 \leq \int_0^T |\, \langle \phi(t), \psi_m\rangle_{\mathbf{H}} \,|^2 \, dt \leq C_2 \sum_{n=1}^{\infty} |\, a_n^{(m)} \,|^2 \tag{20}$$

for some constants $C_i > 0$, $i = 1, 2$, which depend only on $\{e_n(t)\}$. Set

$$\phi_n = \sum_{m=1}^{\infty} a_n^{(m)} \psi_m. \tag{21}$$

We show that $\{\phi_n\}$ is the sequence required. Actually, (21) makes sense since by (19) and (17)

$$\sum_{m=1}^{\infty} \mid a_n^{(m)} \mid^2 \leq C \sum_{m=1}^{\infty} \int_0^T \mid \langle \phi(t), \psi_m \rangle_{\mathbf{H}} \mid^2 dt = C \int_0^T \|\phi(t)\|_{\mathbf{H}}^2 dt \tag{22}$$

for some positive constant $C > 0$. Thus $\phi_n \in \mathbf{H}$. Furthermore, by (20) and (22)

$$C_1 \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \mid a_n^{(m)} \mid^2 \leq \sum_{m=1}^{\infty} \int_0^T \mid \langle \phi(t), \psi_m \rangle_{\mathbf{H}} \mid^2 dt = \int_0^T \|\phi(t)\|_{\mathbf{H}}^2 dt. \tag{23}$$

This, together with (21), gives

$$\sum_{n=1}^{\infty} \|\phi_n\|_{\mathbf{H}}^2 = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \mid a_n^{(m)} \mid^2 < \infty. \tag{24}$$

Furthermore, for any integer $N > 1$ and almost any $t \in [0, T]$, it has

$$\begin{aligned} &\left\| \phi(t) - \sum_{n=1}^{N} e_n(t) \phi_n \right\|_{\mathbf{H}}^2 = \left\| \phi(t) - \sum_{n=1}^{N} e_n(t) \sum_{m=1}^{\infty} a_n^{(m)} \psi_m \right\|_{\mathbf{H}}^2 \\ &= \left\| \phi(t) - \sum_{m=1}^{\infty} \left(\sum_{n=1}^{N} a_n^{(m)} e_n(t) \right) \psi_m \right\|_{\mathbf{H}}^2 = \sum_{m=1}^{\infty} \left| \langle \phi(t), \psi_m \rangle - \sum_{n=1}^{N} a_n^{(m)} e_n(t) \right|^2, \end{aligned}$$

and hence there exists a $C_3 > 0$ such that

$$\begin{aligned} \int_0^T \left\| \phi(t) - \sum_{n=1}^{N} e_n(t) \phi_n \right\|_{\mathbf{H}}^2 dt &= \sum_{m=1}^{\infty} \int_0^T \left| \langle \phi(t), \psi_m \rangle - \sum_{n=1}^{N} a_n^{(m)} e_n(t) \right|^2 dt \\ &\leq C_3 \sum_{m=1}^{\infty} \sum_{n=N+1}^{\infty} |a_n^{(m)}|^2. \end{aligned}$$

Letting $N \to 0$, we obtain (14). Finally, by (23) and (24),

$$C_1 \sum_{n=1}^{\infty} \|\phi_n\|_{\mathbf{H}}^2 \leq \int_0^T \|\phi(t)\|_{\mathbf{H}}^2 dt.$$

By (23) and (20),

$$\int_0^T \|\phi(t)\|_{\mathbf{H}}^2 dt = \sum_{m=1}^{\infty} \int_0^T \mid \langle \phi(t), \psi_m \rangle_{\mathbf{H}} \mid^2 dt \leq C_2 \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \mid a_n^{(m)} \mid^2 = C_2 \sum_{n=1}^{\infty} \|\phi_n\|_{\mathbf{H}}^2.$$

The proof is complete. □

Proof of Theorem 2. Let $\{x_n\}_1^\infty$ be eigenvectors of A corresponding to $\{\lambda_n\}$, $\|x_n\| = 1$ for all $n \geq 1$. By assumption, $\{x_n\}_1^\infty$ is complete in $\mathbf{H}$, hence there exists a unique biorthogonal sequence $\{x_n^*\}_1^\infty$ of $\{x_n\}_1^\infty$:

$$\langle x_n, x_m^* \rangle = \delta_{nm}.$$

In order for $\{x_n\}_1^\infty$ to be a Riesz basis for $\mathbf{H}$, it suffices to show that $\{x_n^*\}$ is also complete in $\mathbf{H}$ and for any $\psi \in \mathbf{H}$,

$$\sum_{n=1}^{\infty} |\langle \psi, x_n^* \rangle|^2 < \infty, \qquad \sum_{n=1}^{\infty} |\langle \psi, x_n \rangle|^2 < \infty$$

[24, Thm. 9, p. 32]. Now, for any given $\psi \in \mathbf{H}$, find $\psi_m \to \psi$ as $m \to \infty$:

$$\psi_m = \sum_{n=1}^{m} b_n^{(m)} x_n,$$

where $b_n^{(m)}$ is constant. It is seen that

$$b_n^{(m)} = \langle \psi_m, x_n^* \rangle \to \langle \psi, x_n^* \rangle \text{ as } m \to \infty.$$

The associated solution to the Cauchy problem

$$\dot{x}(t) = Ax(t), x(0) = \psi_m \tag{25}$$

is

$$x(t) = \sum_{n=1}^{m} e^{\lambda_n t} b_n^{(m)} x_n.$$

It follows from the left inequality of (16) that

$$C_1 \sum_{n=1}^{m} |b_n^{(m)}|^2 \leq \int_0^T \|e^{At}\psi_m\|^2 dt \leq \frac{M^2}{2\omega}(e^{2\omega T} - 1)\|\psi_m\|^2$$

for some positive constant C_1, where we assume that the semigroup e^{At} satisfies $\|e^{At}\| \leq Me^{\omega t}$ for some $M, \omega > 0$. Letting $m \to \infty$ above yields

$$\sum_{n=1}^{\infty} |\langle \psi, x_n^* \rangle|^2 < \infty.$$

Finally, since $\{x_n^*\}$ are eigenvectors of A^* corresponding to $\{\overline{\lambda_n}\}$, which is complete on $\mathbf{H}$ by assumption, $\{e^{\overline{\lambda_n} t}\}$ also forms a Riesz basis for $\mathbf{H}$. Repeating the above process to A^*, we obtain

$$\sum_{n=1}^{\infty} |\langle \psi, x_n \rangle|^2 < \infty,$$

which completes the proof. □

To prove Theorem 3, we need the following lemma.

LEMMA 2. *Let $f(z)$ be an analytic function on $\mid z - z_0 \mid < \delta$, $\delta > 1$. Suppose that $\mid f(z) \mid \leq M$ on $\mid z - z_0 \mid \leq 1$ and z_0 is a kth order zero of $f(z)$ with*

$$\frac{f^{(k)}(z_0)}{k!} = a_k \neq 0. \tag{26}$$

Then z_0 is the unique zero point of $f(z)$ in the disc $\mid z - z_0 \mid \leq \frac{|a_k|}{4(|a_k|+M)}$.

Proof. By assumption, we can write the Taylor expansion of $f(z)$ at $z = z_0$ as

$$f(z) = \sum_{n=k}^{\infty} a_k (z - z_0)^k, \qquad \mid z - z_0 \mid \leq 1.$$

In view of the Cauchy inequality (see, e.g., section 2.5 of [22]) and by assumption, we have

$$\mid a_n \mid \leq M \qquad \forall n \geq k.$$

Now for $0 < \mid z - z_0 \mid \leq r = \frac{|a_k|}{4(|a_k|+M)}$, it has

$$\begin{aligned} \mid f(z) \mid &= \mid z - z_0 \mid^k \mid a_k + \textstyle\sum_{n=1}^{\infty} a_{k+n}(z - z_0)^n \mid \\ &\geq \mid z - z_0 \mid^k [\mid a_k \mid - \textstyle\sum_{n=1}^{\infty} \mid a_{k+n} \mid\mid z - z_0 \mid^n] \\ &\geq \mid z - z_0 \mid^k [\mid a_k \mid - M \textstyle\sum_{n=1}^{\infty} r^n] = \mid z - z_0 \mid^k [\mid a_k \mid - M \frac{r}{1-r}] \\ &= \mid z - z_0 \mid^k \frac{3|a_k|}{4(1-r)} > 0, \end{aligned}$$

proving the lemma. □

Proof of Theorem 3. By assumption, we may assume

$$\mid f(x) \mid \leq M_0 \qquad \forall x \in \mathbb{R}.$$

It follows from Theorem 11 of [24] that

$$\mid f(x + iy) \mid \leq M_0 e^{B|y|} \qquad \forall x, y \in \mathbb{R}.$$

In particular, for $H = h + 2$, it has

$$\mid f(z) \mid \leq M_0 e^{BH} = M \qquad \forall \mid \mathrm{Im} z \mid \leq H. \tag{27}$$

Obviously, $|\mathrm{Im} z| < H$ for $\mid z - \lambda_n \mid < 2$; it follows particularly that

$$\mid f(z) \mid \leq M \text{ in } \mid z - \lambda_n \mid \leq 1. \tag{28}$$

Now, since λ_n is an m_nth order zero of $f(z)$,

$$\frac{f^{(m_n)}(\lambda_n)}{m_n!} = a_n \neq 0. \tag{29}$$

Applying Lemma 1 to $f(z)$, we know that $f(z)$ has only one zero point in

$$\mid z - \lambda_n \mid \leq \frac{\mid a_n \mid}{4(\mid a_n \mid + M)} \geq \frac{C}{4(C + M)}, \qquad C = \inf_n \left| \frac{f^{(m_n)}(\lambda_n)}{m_n!} \right| > 0.$$

Consequently, $f(z)$ has only one zero point in $\mid z-\lambda_n \mid \leq \frac{C}{4(C+M)}$. Therefore,

$$\inf_{n\neq m} \mid \lambda_n - \lambda_m \mid > \frac{C}{4(C+M)} > 0.$$

(i) is thus proved.

Suppose (13). We may assume without loss of generality that $\mid y_0 \mid < H_0$, where $h+1 < H_0 <$H. Set

$$\inf_{n\neq m} \mid \lambda_n - \lambda_m \mid > 4\epsilon > 0, \qquad \epsilon < 1.$$

$B_n(\epsilon) = \{z \in \mathbb{C} \mid\mid z-\lambda_n \mid \leq \epsilon\}$. Define

$$\Omega = \{z \in \mathbb{C} \mid\mid \mathrm{Im}z \mid \leq H_0\} - \bigcup_{n=1}^{\infty} B_n(\epsilon). \tag{30}$$

We first show that

$$\mid f(z) \mid \geq \alpha \text{ on } \overline{\Omega} \tag{31}$$

for some $\alpha > 0$, where $\overline{\Omega}$ is the closure of Ω. Since otherwise, there is a sequence $\{z_m\}_1^\infty \subset \overline{\Omega}$ so that

$$\lim_{m\to\infty} f(z_m) = 0.$$

Write $z_m = x_m + iy_m$, $x_m, y_m \in \mathbb{R}$. Since $\mid y_m \mid \leq H_0$, we may assume without loss of generality that

$$y_m \to \eta \text{ as } m \to \infty. \tag{32}$$

For each $m \geq 1$, define

$$g_m(z) = f(z+x_m), \qquad z \in \{z \in \mathbb{C} \mid\mid \mathrm{Im}z \mid < H\}. \tag{33}$$

Then it follows from (27) that

$$\mid g_m(z) \mid \leq M \qquad \forall \mid \mathrm{Im}z \mid < H.$$

By Montel's theorem (Theorem 5.22 in [22]), there exist a subsequence of $\{g_m\}$ still denoted by $\{g_m\}$ and an analytic function $g(z)$ on |Im z|$< H$ such that

$$g_m(z) \to g(z) \text{ uniformly on any compact subset of } \mid \mathrm{Im}z \mid \leq H_0 \text{ as } m \to \infty. \tag{34}$$

Now that

$$g_m(iy_m) = f(z_m) \to 0 \text{ and } \inf_m \mid g_m(iy_0) \mid \geq \inf_{x\in\mathbb{R}} \mid f(x+iy_0) \mid > 0,$$

it follows that $g(i\eta) = 0, \mid g(iy_0) \mid > 0$. That is, g does not vanish identically on |Imz|$\leq H_0$. By Hurwitz's theorem (Theorem 3.45 in [22]) there is an $N > 0$ such that for each $m > N$, $g_m(z)$ has one zero point w_m so that

$$\mid w_m - i\eta \mid \leq \frac{\epsilon}{2} \qquad \forall m > \mathrm{N}. \tag{35}$$

That is,

$$f(x_m + w_m) = 0 \text{ and } \mid w_m - i\eta \mid \leq \frac{\epsilon}{2} \qquad \forall m > \mathrm{N}. \tag{36}$$

Since

$$\mid x_m + w_m - x_m - iy_m \mid = \mid w_m - iy_m \mid \leq \mid w_m - i\eta \mid + \mid iy_m - i\eta \mid \leq \frac{\epsilon}{2} \text{ as } m \to \infty,$$

we see that there exists an $N_0 > N$ such that as $m > N_0$,

$$\mid x_m + w_m - z_m \mid \leq \frac{\epsilon}{2} < \epsilon.$$

This is a contradiction since $x_m + w_m \in \{\lambda_n\}_1^\infty$ and $\{z_m\} \subset \overline{\Omega}$. (31) is thus verified.

Notice that $B_n(\epsilon)$ are nonoverlapping, the function $f(z)/(z-\lambda_n)^{m_n}$ is analytic and free of zero in $B_n(\epsilon)$, and

$$\left| \frac{f(z)}{(z-\lambda_n)^{m_n}} \right| \geq \frac{\alpha}{\epsilon^{m_n}} \text{ on } \mid z - \lambda_n \mid = \epsilon.$$

It follows from Jensen's formula [24, Thm. 2, p. 59] that

$$\log \left| \frac{f^{(m_n)}(\lambda_n)}{m_n!} \right| \geq \log \left(\frac{\alpha}{\epsilon^{m_n}} \right)$$

and hence

$$\left| \frac{f^{(m_n)}(\lambda_n)}{m_n!} \right| \geq \frac{\alpha}{\epsilon^{m_n}}.$$

The proof is complete. □

Proof of Theorem 4. First we show that $\sigma_\infty(A^*) = \{0\}$. Note that for any $x \in \sigma_\infty(A^*)$, $R(\lambda, A^*)x$ is an H-valued entire function of λ with order less than or equal to ρ. Since A^* also generates a C_0-semigroup on $\mathbf{H}$, we may assume without loss of generality that $R(\lambda, A^*)x$ is bounded on the right half complex plane, particularly on the imaginary axis. Set

$$S_j = \{\lambda \in \mathbb{C} \mid \arg \gamma_{j-1} \leq \arg \lambda \leq \arg \gamma_j\}, \qquad j = 1, 2, \ldots, n.$$

By assumption, $R(\lambda, A^*)x$ is bounded on the boundary of S_j, and

$$\|R(\lambda, A^*)x\| = \mathcal{O}(e^{|\lambda|^{\rho+\epsilon}}) \qquad \forall \lambda \in S_j,$$

where $\epsilon > 0$ is chosen so that $\rho + \epsilon < n$. Applying the Phragmén–Lindelöf theorem to $R(\lambda, A^*)x$ in each S_j [24, Thm. 10, p. 80], we know that $R(\lambda, A^*)x$ is uniformly bounded in S_j and so is in the whole complex plane. It follows from the Liouville's theorem that $R(\lambda, A^*)x$ is an constant element of $\mathbf{H}$. Furthermore, by the Hille–Yosida theorem,

$$\lim_{\lambda \to +\infty} R(\lambda, A^*)x = 0$$

and hence $R(\lambda, A^*)x = 0$ or $x = 0$, proving that $\sigma_\infty(A^*) = \{0\}$. Finally, since

$$R(\overline{\lambda}, A)x = \frac{G^*(\lambda)x}{\overline{F(\lambda)}} \qquad \forall x \in \mathbf{H},$$

it holds similarly that $\sigma_\infty(A) = \{0\}$. The proof is complete. □

4. Application to coupled strings. Since the game is almost the same for other types of boundary conditions and joint linear feedback controls, we demonstrate the whole process by considering the following string equation with one end fixed, one end free, and a force stabilizer at the joint d, $0 < d < 1$:

$$\begin{cases} y_{tt}(x,t) - y_{xx}(x,t) = 0, & 0 < x < d, d < x < 1, \\ y(0,t) = y_x(1,t) = 0, \\ y(d^-,t) = y(d^+,t), \\ y_x(d^-,t) - y_x(d^+,t) = -\alpha y_t(d,t), & \alpha > 0. \end{cases} \tag{37}$$

To turn system (37) into a framework of semigroups, we introduce the underlying state Hilbert space $\mathcal{H} = H_E^1(0,1) \times L^2(0,1)$ with the inner product induced norm:

$$\|(u,v)\|^2 = \int_0^1 [\mid u'(x) \mid^2 + \mid v(x) \mid^2] dx,$$

where $H_E^1(0,1) = \{u \mid u \in H^1(0,1), u(0) = 0\}$. System (37) is then written as an evolutionary equation in $\mathcal{H}$:

$$\frac{d}{dt} Y(t) = \mathcal{A} Y(t), \tag{38}$$

where $Y(t) = (y(\cdot,t), y_t(\cdot,t)) \in \mathcal{H}$ and $\mathcal{A}$ is defined by

$$\mathcal{A}(u,v) = (v(x), u''(x)) \tag{39}$$

with

$$\begin{aligned} D(\mathcal{A}) = \{&(u,v) \in H^1(0,1) \times H_E^1(0,1) \mid u(0) = u'(1) = 0, \\ &u \mid_{[0,d]} \in H^2(0,d), u \mid_{[d,1]} \in H^2(d,1), u'(d^-) - u'(d^+) = -\alpha v(d)\}, \end{aligned} \tag{40}$$

where $u \mid_{[a,b]}$ denotes the function u confined to $[a,b]$.

LEMMA 3.

(i) *$\mathcal{A}^{-1}$ exists and is compact on $\mathcal{H}$.*

(ii) *$\mathcal{A}$ is dissipative and hence $\mathcal{A}$ generates a C_0-semigroup of contractions on $\mathcal{H}$.*

(iii) *$\lambda \in \sigma(\mathcal{A})$ if and only if λ is a zero of $g(\lambda)$:*

$$g(\lambda) = 2\alpha^{-1} \cosh \lambda + \sinh \lambda - \sinh \lambda (1 - 2d). \tag{41}$$

(iv) *$\lambda \in \sigma(\mathcal{A})$ is algebraically simple if and only if $g(\lambda) = 0$, $g'(\lambda) \neq 0$.*

Proof. (i) and (ii) are straightforward. In particular, $0 \in \rho(\mathcal{A})$. We prove only (iii) and (iv). It is easy to know that for each $\lambda \in \sigma(\mathcal{A})$, the corresponding eigenfunction takes the form $(\phi, \lambda\phi)$ with $\phi \neq 0$ satisfying

$$\begin{cases} \lambda^2 \phi(x) - \phi''(x) = 0, & 0 < x < d, d < x < 1, \\ \phi(0) = \phi'(1) = 0, \\ \phi(d^-) = \phi(d^+), \\ \phi'(d^-) - \phi'(d^+) = -\alpha\lambda\phi(d), & \alpha > 0. \end{cases} \tag{42}$$

Solving (42) gives

$$\phi(x) = \begin{cases} c_1 \sinh \lambda x, & 0 < x < d, \\ c_2 \cosh \lambda (1 - x), & d < x < 1, \end{cases}$$

where c_1 and c_2 satisfy

$$\begin{cases} c_1 \sinh \lambda d - c_2 \cosh \lambda(1-d) = 0, \\ c_1(\cosh \lambda d + \alpha \sinh \lambda d) + c_2 \sinh \lambda(1-d) = 0. \end{cases}$$

Since c_1, c_2 cannot vanish simultaneously, solving the above equation yields (41).

As for (iv), since it is not the standard problem studied in [13], we give here a direct proof. There are two cases.

Case 1 ($|\sinh \lambda d| + |\cosh \lambda(1-d)| \neq 0$ for any λ). In this case, the eigenfunction corresponding to λ is $(\phi(x,\lambda), \lambda\phi(x,\lambda))$, where

$$\phi(x,\lambda) = \begin{cases} \cosh \lambda(1-d) \sinh \lambda x, & 0 < x < d, \\ \sinh \lambda d \cosh \lambda(1-x), & d < x < 1. \end{cases} \tag{43}$$

Notice that the function $\phi(x,\lambda)$ defined above satisfies

$$\begin{cases} \lambda^2 \phi(x,\lambda) - \phi''(x,\lambda) = 0, & 0 < x < d, d < x < 1, \\ \phi(0,\lambda) = \phi'(1,\lambda) = 0, \\ \phi(d^-,\lambda) = \phi(d^+,\lambda) \end{cases} \tag{44}$$

for all complex numbers λ. Differentiating the above equation with respect to λ, we obtain

$$\begin{cases} \lambda^2 \phi_\lambda(x,\lambda) - \phi''_\lambda(x,\lambda) = -2\lambda\phi(x,\lambda), & 0 < x < d, d < x < 1, \\ \phi_\lambda(0,\lambda) = \phi'_\lambda(1,\lambda) = 0, \\ \phi_\lambda(d^-,\lambda) = \phi_\lambda(d^+,\lambda). \end{cases} \tag{45}$$

Now confining $\lambda \in \sigma(\mathcal{A})$ and solving

$$(\lambda - \mathcal{A})(f,g) = (\phi, \lambda\phi), \tag{46}$$

we have $g = \lambda f - \phi$, and f satisfies

$$\begin{cases} \lambda^2 f(x) - f''(x) = 2\lambda\phi(x,\lambda), & 0 < x < d, d < x < 1, \\ f(0) = f'(1) = 0, \\ f(d^-) = f(d^+), \\ f'(d^-) - f'(d^+) = -\alpha\lambda f(d) + \alpha\phi(d,\lambda). \end{cases} \tag{47}$$

Since λ is geometrically simple, it is algebraically simple if and only if there is no solution to (47). Let

$$z(x) = f(x) + \phi_\lambda(x,\lambda).$$

Then z satisfies

$$\begin{cases} \lambda^2 z(x) - z''(x) = 0, & 0 < x < d, d < x < 1, \\ z(0) = z'(1) = 0, \\ z(d^-) = z(d^+), \\ z'(d^-) - z'(d^+) = -\alpha\lambda z(d) + \beta, \end{cases} \tag{48}$$

where

$$\beta = \alpha\phi(d,\lambda) + \alpha\lambda\phi_\lambda(d,\lambda) + \phi'_\lambda(d^-,\lambda) - \phi'_\lambda(d^+,\lambda). \tag{49}$$

On the one hand, solving (48), one finds that (48) admits a solution (so does (47)) if and only if

$$\frac{2\alpha^{-1}}{\lambda}\beta = g(\lambda) = 0,$$

and on the other hand, computing (49) from (43) directly, one finds

$$\frac{2\alpha^{-1}}{\lambda}\beta = g'(\lambda) = 0.$$

Thus we have proved that λ is algebraically simple if and only if $g(\lambda) = 0$ and $g'(\lambda) \neq 0$.

Case 2 ($\sinh \lambda d = \cosh \lambda(1-d) = 0$ for some λ). In this case, such a λ must be an eigenvalue and the corresponding eigenfunction is $(\phi(x), \lambda\phi(x))$, where

$$\phi(x) = \begin{cases} -\sinh \lambda(1-d) \sinh \lambda x, & 0 < x < d, \\ \cosh \lambda d \cosh \lambda(1-x), & d < x < 1. \end{cases} \tag{50}$$

Solving directly the following equation

$$(\lambda - \mathcal{A})(u, v) = (\phi, \lambda\phi), \tag{51}$$

we find that the solution to (51) must satisfy

$$u(d^-) = -\frac{d}{2}\cosh \lambda d \sinh \lambda(1-d) \neq u(d^+) = -\frac{1-d}{2}\cosh \lambda d \sinh \lambda(1-d).$$

($|\cosh \lambda d \sinh \lambda(1-d)| = 1$ under the assumption.) However, since $(u, v) \in D(\mathcal{A})$, it should have $u(d^-) = u(d^+)$. This contradiction shows that there is no solution to (51), i.e., λ must be algebraically simple. Finally, a simple calculation shows that $g'(\lambda) = 2\alpha^{-1} \sinh \lambda \neq 0$ since under the assumption, $\cosh \lambda = 0$ and so $|\sinh \lambda| = 1$. The proof is complete. □

Let $g(\lambda)$ be defined by (41). Define

$$f(\lambda) = g(i\lambda). \tag{52}$$

The zeros $\{\lambda_n\}$ of $g(\lambda)$ and $\{\mu_n\}$ of $f(\lambda)$ are related through

$$\lambda_n = i\mu_n. \tag{53}$$

Obviously, $f(\lambda)$ is uniformly bounded on the real axis, and hence f belongs to the *Cartwright class*. Thus, its indicator diagram is an interval.

Furthermore, it is easy to show that $g(\lambda)$ is of *exponential type* with type 1 and

$$\begin{cases} Ce^{|x|} \leq |\, g(x+iy)\, | \leq De^{|x|}, & \alpha \neq 2; \\ Ce^{|(1-2d)x|} \leq |\, g(x+iy)\, | \leq De^{|x|}, & \alpha = 2, d \neq 1/2; \\ |g(x+iy)| = e^x, & \alpha = 2, d = 1/2 \end{cases} \tag{54}$$

for some positive constants C, D and all $x \in \mathbb{R}$ whenever x is sufficiently large. Hence as $\alpha = 2, d = 1/2$, $g(\lambda)$ has no zero. In this case, $\sigma(\mathcal{A}) = \emptyset$ and we could not talk about a basis for system (37). For other cases, though, $g(\lambda)$ must have infinite number of zeros [24, pp. 88–89].

In what follows, we always assume that $\alpha \neq 2$ or $\alpha = 2$, $d \neq 1/2$. In both cases, (54) shows that f is of sine type and

$$h_f(\phi) = \begin{cases} |\sin\phi|, & \alpha \neq 2, \\ \begin{cases} \sin\phi, & \phi \in [0,\pi], \\ -|1-2d|\sin\phi, & \phi \in [-\pi,0], \end{cases} & \alpha = 2, d \neq 1/2, \end{cases} \tag{55}$$

$$G_f = \begin{cases} [-i,i], & \alpha \neq 2, \\ [-|1-2d|i, i], & \alpha = 2, d \neq 1/2. \end{cases} \tag{56}$$

Therefore, the width of the indicator diagram of f equals

$$T = \begin{cases} 2, & \alpha \neq 2, \\ 1+|1-2d|, & \alpha = 2, d \neq 1/2. \end{cases} \tag{57}$$

LEMMA 4. *If $\alpha \neq 2$, then both the root subspaces of $\mathcal{A}$ and $\mathcal{A}^*$ are complete in $\mathcal{H}$: $\mathrm{Sp}(\mathcal{A}) = \mathrm{Sp}(\mathcal{A}^*) = \mathcal{H}$.*

Proof. We apply Theorem 4 for the proof. To do this, we need the adjoint $\mathcal{A}^*$ of $\mathcal{A}$, which can be found using

$$\begin{cases} \mathcal{A}^*(u,v) = (-v(x), -u''(x)), \\ D(\mathcal{A}^*) = \{(u,v) \in H^1(0,1) \times H_E^1(0,1) \mid u(0) = u'(1) = 0, \\ \qquad\qquad u\,|_{[0,d]} \in H^2(0,d), u\,|_{[d,1]} \in H^2(d,1), u'(d^-) - u'(d^+) = \alpha v(d)\}. \end{cases} \tag{58}$$

Let $\mathcal{A}_0$ be the operator $\mathcal{A}$ with $\alpha = 0$. Then $\mathcal{A}_0$ is a skew-adjoint operator in $\mathcal{H}$: $\mathcal{A}_0^* = -\mathcal{A}_0$. $\mathcal{A}_0^*$ generates a unitary-group and hence

$$\|R(\lambda, \mathcal{A}_0^*)\| \leq \frac{1}{|\lambda|} \qquad \forall \lambda \in \mathbb{R}.$$

Now, for any $(u,v) \in \mathcal{H}, \lambda \in \rho(\mathcal{A}), \lambda < 0$, set

$$(\phi,\psi) = R(\lambda, \mathcal{A}_0^*)(u,v), (p,q) = R(\lambda, \mathcal{A}^*)(u,v) - (\phi,\psi).$$

Then $q = -\lambda p$ and p satisfies

$$\begin{cases} \lambda^2 p(x) - p''(x) = 0, & 0 < x < d, d < x < 1, \\ p(0) = p'(1) = 0, \\ p(d^-) = p(d^+), \\ p'(d^-) - p'(d^+) = -\alpha\lambda p(d) - \alpha\lambda\phi(d) + \alpha u(d). \end{cases} \tag{59}$$

Solving (59) gives

$$\begin{cases} p'(x) = \dfrac{-\alpha\lambda\phi(d) + \alpha u(d)}{\alpha/2g(\lambda)} \begin{cases} \cosh\lambda(1-d)\cosh\lambda x, & 0 < x < d, \\ -\sinh\lambda d \sinh\lambda(1-x), & d < x < 1, \end{cases} \\ q(x) = \dfrac{-\alpha\lambda\phi(d) + \alpha u(d)}{\alpha/2g(\lambda)} \begin{cases} \cosh\lambda(1-d)\sinh\lambda x, & 0 < x < d, \\ \sinh\lambda d\cosh\lambda(1-x), & d < x < 1. \end{cases} \end{cases} \tag{60}$$

Notice the following facts:

(a) $|\lambda\phi(d)| \leq |\lambda|\sqrt{d}\|\phi'\|_{H^1} \leq \sqrt{d}|\lambda|\|R(\lambda, \mathcal{A}_0^*)(u,v)\| \leq \sqrt{d}\|(u,v)\|$, $|u(d)| \leq \sqrt{d}\|(u,v)\|$;

(b) $g(\lambda) = e^{-\lambda}[\alpha^{-1} - 1/2 + o(1)]$ as $\lambda \to -\infty$;

(c) $\lim_{|\lambda|\to\infty} \|R(\lambda, \mathcal{A}_0^*)(u,v)\| = 0$.

We can easily check by a direct computation from (60) that $\|(p,q)\| = \|(p',q)\|_{L^2\times L^2}$ is uniformly bounded as $\lambda \to -\infty$. Since

$$\|R(\lambda,\mathcal{A}^*)(u,v)\| \le \|(p,q)\| + \|R(\lambda,\mathcal{A}_0^*)(u,v)\|,$$

we see that $\|R(\lambda,\mathcal{A}^*)(u,v)\|$ is also uniformly bounded as $\lambda \to -\infty$. Then, it is easily found that

$$\phi(x) = -\frac{\sinh\lambda x \int_0^1 \cosh\lambda(1-s)(v-\lambda u)ds}{\lambda\cosh\lambda} + \int_0^x \frac{\sinh\lambda(x-s)}{\lambda}(v-\lambda u)ds;$$

hence we can write

$$R(\lambda,\mathcal{A}^*)(u,v) = (p,q) + (\phi, u-\lambda\phi) = \frac{G(\lambda;u,v)}{F(\lambda)} \qquad \forall (u,v)\in\mathcal{H}, \tag{61}$$

where $G(\lambda;u,v)$ is an $\mathcal{H}$-valued entire function with order less than or equal to 1 and $F(\lambda)$ is a scalar entire function of order 1. Therefore, all conditions of Theorem 4 are satisfied with $\rho = 1, n = 2, \gamma_1 = \{\lambda|\arg\lambda = \pi\}$. The result follows. □

LEMMA 5. *Suppose $\alpha \neq 2$ or $\alpha = 2, d \neq 1/2$.*

(i) *When d is irrational or $\alpha^{-2} < d(1-d)$, all zeros of $g(\lambda)$ are simple and separated.*

(ii) *While $d = q/p$ is rational and $\alpha^{-2} \ge d(1-d)$, if*

$$\eta_0 = \pm\sqrt{\frac{\alpha^{-2}}{d(1-d)} - 1} \tag{62}$$

does not satisfy

$$\left(\frac{\eta_0 \pm (1-2d)\frac{\alpha^{-1}}{\sqrt{d(1-d)}}}{2\alpha^{-1}+1}\right)^{1-2d} = \eta_0 \pm \frac{\alpha^{-1}}{\sqrt{d(1-d)}}, \tag{63}$$

then all zeros of $g(\lambda)$ are simple and separated.

Proof. Suppose that $g(\lambda)$ has zeros $\{\lambda_n\}_1^\infty$. In view of Theorem 3, it suffices to show that

$$\inf_n |\, g'(\lambda_n)\,| > 0. \tag{64}$$

If λ is a zero point of $g(\lambda)$, then there exists an η such that

$$\begin{cases} 2\alpha^{-1}\cosh\lambda + \sinh\lambda = \eta, \\ \sinh\lambda(1-2d) = \eta. \end{cases} \tag{65}$$

Solving (65) yields

$$e^\lambda = \frac{\eta \pm \sqrt{\eta^2 - 4\alpha^{-2}+1}}{2\alpha^{-1}+1}, \qquad e^{\lambda(1-2d)} = \eta \pm \sqrt{\eta^2+1}. \tag{66}$$

Hence the necessary and sufficient condition for λ to be a zero of $g(\lambda)$ is that

$$\left(\frac{\eta \pm \sqrt{\eta^2 - 4\alpha^{-2}+1}}{2\alpha^{-1}+1}\right)^{1-2d} = \eta \pm \sqrt{\eta^2+1}. \tag{67}$$

In this case, λ can be found through the first or the second equality of (66). In what follows, we always relate λ to η via this method.

When η solves (67), one has

$$\begin{aligned} g'(\lambda) = g(\lambda) + g'(\lambda) &= (2\alpha^{-1}+1)e^{\lambda} + 2d\cosh\lambda(1-2d) - e^{\lambda(1-2d)} \\ &= \eta \pm \sqrt{\eta^2 - 4\alpha^{-2}+1} - \left(\eta \pm \sqrt{\eta^2+1}\right) + 2d\cosh\lambda(1-2d) \\ &= \pm\left[\sqrt{\eta^2-4\alpha^{-2}+1} - (1-2d)\sqrt{\eta^2+1}\right]. \end{aligned} \tag{68}$$

It is seen that $g(\lambda) = g'(\lambda) = 0$ if and only if the solution of (67), $\eta = \eta_0$, satisfies

$$\sqrt{\eta_0^2 - 4\alpha^{-2}+1} = (1-2d)\sqrt{\eta_0^2+1},$$

that is, η_0 satisfies (62). When $\eta = \eta_0$, (67) becomes (63). We have two cases.

Case 1 (η_0 does not satisfy (63)). Let

$$2\alpha^{-1}\cosh\lambda_n + \sinh\lambda_n = \eta_n. \tag{69}$$

Suppose that $\mid g'(\lambda_{n_k}) \mid \to 0$ as $k \to \infty$ for some subsequence $\{\lambda_{n_k}\}$ of $\{\lambda_n\}$. Since all $\{\lambda_{n_k}\}$ lie on the strip $-M < \mathrm{Re}\lambda_{n_k} \le 0$ for some $M > 0$, the corresponding $\{\eta_{n_k}\}$ are uniformly bounded: $\mid \eta_{n_k} \mid \le C$ for all n and some $C > 0$. Let η be an accumulation point of $\{\eta_{n_k}\}$. We may assume without loss of generality that

$$\eta_{n_k} \to \eta \text{ as } k \to \infty.$$

So η satisfies (67). On the other hand,

$$\begin{aligned} g'(\lambda_{n_k}) &= \pm\left[\sqrt{\eta_{n_k}^2 - 4\alpha^{-2}+1} - (1-2d)\sqrt{\eta_{n_k}^2+1}\right] \\ &\to \pm\left[\sqrt{\eta^2-4\alpha^{-2}+1} - (1-2d)\sqrt{\eta^2+1}\right] = 0 \text{ as } k \to \infty. \end{aligned}$$

Hence $\eta = \eta_0$. That is, η_0 satisfies (67) or (63), contradicting the assumption. Therefore,

$$\inf_n \mid g'(\lambda_n) \mid > 0.$$

By Theorem 3, $\{\lambda_n\}$ is separated.

Case 2 (η_0 does satisfy (63)). In this case, there is an λ_0 such that $g(\lambda_0) = g(\lambda_0) + g'(\lambda_0) = 0$ and

$$\begin{cases} 2\alpha^{-1}\cosh\lambda_0 + \sinh\lambda_0 = \eta_0, \\ \sinh\lambda_0(1-2d) = \eta_0. \end{cases} \tag{70}$$

Hence

$$\begin{aligned} 2\alpha^{-1}\sinh\lambda_0 + \cosh\lambda_0 &= (2\alpha^{-1}+1)(\sinh\lambda_0 + \cosh\lambda_0) - \eta_0 \\ &= \pm\sqrt{\eta_0^2 - 4\alpha^{-2}+1} = \pm(1-2d)\alpha^{-1}\sqrt{\frac{1}{d(1-d)}} \end{aligned} \tag{71}$$

and

$$\cosh\lambda_0(1-2d) = \pm\alpha^{-1}\sqrt{\frac{1}{d(1-d)}}. \tag{72}$$

Hence $\cosh \lambda_0(1-2d)$ is real and so is $\sinh \lambda_0(1-2d)$. (Its imaginary part equals zero; in particular, η_0 is real.) Let $\lambda_0 = x_0 + iy_0, x_0, y_0 \in \mathbb{R}$. Then since the right hands of (71) and (72) and

$$2\alpha^{-1} \cosh \lambda_0 + \sinh \lambda_0 = \sinh \lambda_0(1-2d) \tag{73}$$

are real numbers, comparing the imaginary parts of (71)–(73) gives

$$\begin{cases} \sinh x_0(1-2d) \sin y_0(1-2d) = 0, \\ (2\alpha^{-1} \cosh x_0 + \sinh x_0) \sin y_0 = 0, \\ (2\alpha^{-1} \sinh x_0 + \cosh x_0) \sin y_0 = 0. \end{cases} \tag{74}$$

Hence $\sin y_0(1-2d) = \sin y_0 = 0$. That is, d is rational. Furthermore, since η_0 solving (67) implies that η_0 is real, it must have

$$\alpha^{-1} \geq d(1-d).$$

The proof is complete. □

By virtue of Lemmas 3–5 and Theorem 2, we obtain the Riesz basis property for the system (37).

THEOREM 5. *Suppose that $\alpha \neq 2$. Assume that one of the following conditions is satisfied:*

(a) *d is irrational or d is rational but $\alpha^{-2} < d(1-d)$.*

(b) *d is rational and $\alpha^{-2} \geq d(1-d)$ but η_0 defined by (62) does not satisfy (63).*

Then each eigenvalue of $\mathcal{A}$ is algebraically simple and there is a set of eigenfunctions of $\mathcal{A}$ which forms a Riesz basis for the energy space $\mathcal{H}$.

Remark 2. Numerical simulation by MATLAB shows that some solution of (62) does satisfy (63), and in this case, $g(\lambda)$ may have multiple zeros with multiplicity at most 2. For the multiple zero case, we shall discuss it in a separate paper.

From Theorem 5, we know that when the system (37) is a Riesz spectral system, the spectrum-determined growth condition holds, which was obtained specifically by Liu in 1986 [11]. The general case can be found in [14] and [12]. We do not touch the stability here because once we have the spectrum-determined growth condition, simple spectral analysis can be made to get the stability of system (37). We refer readers to [7] for this.

ON THE POISSON EQUATION FOR PIECEWISE-DETERMINISTIC MARKOV PROCESSES*

OSWALDO L. V. COSTA† AND FRANÇOIS DUFOUR‡

Abstract. In this paper we study the problem of the existence of a solution for the Poisson equation (PE) associated to a piecewise-deterministic Markov process (PDP). It is well known that the long run average cost of a stochastic process can be obtained through a solution of the PE associated with the process. Our first result will show that the existence of a solution for the PE of a PDP is equivalent to the existence of a solution for the PE of an embedded discrete- time Markov chain associated with the PDP. It is important to point out that, due to the possibility of jumps from the boundary, the differential formula for the PDPs has a special form, so that general results for the PE of continuous- time stochastic processes cannot be directly applied. Usually discrete-time conditions for the existence of a solution of a PE of a Markov chain are easier to apply than the continuous-time counterpart. We follow this approach to derive our second result, which establishes sufficient conditions for the existence of a PE to the embedded Markov chain, and consequently for the PE of the PDP. The condition is illustrated with an application to the capacity expansion model.

1. Introduction.

Piecewise-deterministic Markov processes (PDPs) have been introduced in the literature by Davis [1] as a general class of stochastic models. PDPs are a family of Markov processes involving deterministic motion punctuated by random jumps. The motion of the PDP X_t depends on three local characteristics, namely the flow, the jump rate, and the transition measure Q, which specifies the postjump location. Starting from x the motion of the process follows the flow $\phi(t,x)$ until the first jump time T_1, which occurs either spontaneously in a Poisson-like fashion with rate $\lambda(t,x)$ or when the flow $\phi(t,x)$ hits the boundary of the state-space. In either case the location of the process at the jump time T_1 is selected by the transition measure $Q((T_1,x),.)$ and the motion restarts from this new point as before. A suitable choice of the state space and the local characteristics ϕ, λ, and Q provides stochastic models covering a great number of problems of operations research [1].

In this paper we are interested in studying the problem of the existence of a solution for a Poisson equation (PE) associated to a PDP. It is well known that the long run average cost associated with a process can be obtained by solving a PE. Several general results on PEs can be found in the literature, and we can mention [4, 5, 6] for a general overview on the subject. However, as we shall see below, due to

the special features of PDPs (mixture of deterministic and random jumps), general results cannot be directly applied to PDPs (see Remark 2.3).

As shown in [2], associated with the PDP we can define an embedded Markov chain Y_n, such that the existence of an invariant probability measure for the PDP X_t is equivalent to the existence of an invariant σ-finite measure for the embedded Markov chain Y_n. In this paper we somewhat extend this result and show that the existence of a solution of the PE for the PDP X_t is equivalent to the existence of a solution of the PE for the embedded Markov chain Y_n. The advantage of doing this is that conditions for the existence of a PE for discrete-time Markov chains are in general easier to check than those for continuous-time Markov processes. Following this approach we present conditions for the existence of a solution for a PE of the embedded Markov chain Y_n, which in turns implies the existence of a solution for a PE of the PDP X_t.

The paper is organized as follows. In section 2 we give the main definitions and assumptions. In section 3 we obtain the equivalence results linking the existence of a solution of a PE for the PDP and the embedded Markov chain. We also show that, as expected, when an invariant probability measure for the PDP exists (and consequently there exists a σ-finite measure for the embedded Markov chain), the stationary value costs obtained from these invariant measures coincide. In section 4 we provide a sufficient condition for the existence of a solution for the PE associated with the embedded Markov chain. This condition is written, as in [4], as a Lyapunov function criterion and also provides explicit bounds on the solution to the PE. We conclude the paper in section 5 by presenting an application to a capacity expansion model.

2. Notation and preliminary definitions.

2.1. Preliminaries. In this subsection we present some standard notation and some basic definitions related to the motion of a PDP (for further details, see [1]).

Let X be a metric space, $\mathcal{B}(X)$ the Borel σ-field of X, $\mathcal{P}(X)$ the set of probability measures on $(X, \mathcal{B}(X))$, and $\mathbb{B}(X)$ the set of all Borel measurable functions from X into R. For any $f \in \mathbb{B}(X)$ and $\mu \in \mathcal{P}(X)$, $\mu(f)$ denotes $\int_X f(x)\mu(dx)$.

Let X and Y be two metric spaces. Then a kernel $V(.,.)$ defined on $X \times \mathcal{Y}$ is a map from $X \times \mathcal{B}(Y)$ into $[0,1]$ such that for each $A \in \mathcal{B}(Y)$, $V(.,A)$ is a nonnegative bounded measurable function on X and for each $x \in X$, $V(x,.)$ is a bounded measure on $\mathcal{B}(Y)$. Consequently, for any measurable function $f \in \mathbb{B}(Y)$, $Vf(.)$ defined as

$$Vf(x) \doteq \int_Y f(y)V(x,dy) \tag{1}$$

belongs to $\mathbb{B}(X)$.

Let E^0 be an open nonempty subset of $\mathbb{R}^d$ and ∂E^0 its boundary. We consider $\phi(t,x)$ as being the flow of a Lipschitz continuous vector field $\mathcal{X}$. Define

$$\partial^{\pm} E^0 = \Big\{ z \in \partial E^0; z = \phi(\pm t, x) \text{ for some } x \in E^0, \text{ for some } t \geq 0 \Big\}$$

and $\partial_1 E^0 = \partial^- E^0 - \partial^+ E^0$ (where for sets A, B, $A - B = A \cap B^c$). Set $E = E^0 \cup \partial_1 E^0$, $\partial^* E = \partial^+ E^0$, and for each $x \in E$, write

$$t^*(x) = \inf\{t > 0; \phi(t,x) \in \partial^* E\},$$

where $\inf\{\emptyset\} := \infty$, and define $t^*(z) = 0$ for $z \in \partial^* E$. Note that the points in E are such that starting from $x \in E$, we have that $\phi(t,x) \in E$ for all t sufficiently small, that is, the flow stays inside E for all t sufficiently small. On the other hand the points in $\partial^* E$ are such that starting from $z \in \partial^* E$, we have that $\phi(t,z) \notin E$ for all t sufficiently small, that is, the flow leaves the set $E^0 \cup \partial E^0$.

We consider the following parameters for our problem:

(a) $\lambda(.) : E \mapsto R_+$ is a Borel measurable function;

(b) $Q(.,.)$ is a kernel defined on $E \cup \partial^* E \times \mathcal{B}(E)$ such that (for all $x \in E \cup \partial^* E$), $Q(x,.) \in \mathcal{P}(E)$.

Let D denote the space of right-continuous functions $\omega(.)$ on R_+ taking values in E such that the left limit exists for all $t > 0$. Denote by x_t the coordinate function $x_t(\omega) = \omega(t)$ for all $\omega \in D$. Let $\mathcal{F}_t^0 = \sigma\{x_s; 0 \le s \le t\}$ and $\mathcal{F}^0 = \vee_{t \ge 0} \mathcal{F}_t^0$. For $\omega \in \Omega$, set for $k = 0, 1, 2, \ldots$

$$
\begin{aligned}
&T_0(\omega) = 0,\\
&T_k(\omega) = \begin{cases} \inf\Big\{t > T_{k-1}(\omega); x_t(\omega) \ne x_{t-}(\omega)\Big\} & \text{if } T_{k-1}(\omega) < \infty,\\ \infty & \text{otherwise,} \end{cases}\\
&T_\infty(\omega) = \lim_{k \to \infty} T_k(\omega),\\
&Z_k(\omega) = \begin{cases} x_{T_k(\omega)}(\omega) & \text{if } T_k(\omega) < \infty,\\ \Delta & \text{if } T_k(\omega) = \infty, \end{cases}
\end{aligned}
$$

where Δ represents a cemetery state.

Let us consider $\Omega \subset D$ such that $\omega \in \Omega$ if

$$x_t(\omega) = \phi(t, Z_0(\omega)) I_{\{0 \le t < T_1(\omega)\}} + \sum_{k=2}^{\infty} I_{\{T_{k-1}(\omega) \le t < T_k(\omega)\}} \phi(t - T_{k-1}(\omega), Z_{k-1}(\omega)).$$

We define the motion of the process $\{X_t\}$ starting from a point $x \in E$ in the following way. Take a random variable T_1 such that

$$P_x(T_1 > t) = \begin{cases} \exp -\Lambda(t,x) & \text{for } t < t^*(x),\\ 0 & \text{for } t \ge t^*(x), \end{cases}$$

where

$$\Lambda(t,x) = \int_0^t \lambda(\phi(s,x)) ds. \tag{2}$$

If T_1 generated according to the above probability is equal to infinity, then for $t \in \mathbb{R}_+$, $X_t = \phi(t,x)$. Otherwise select independently an E-valued random variable having distribution $Q(\phi(T_1,x),.)$. The trajectory of $\{X_t\}$ starting at x, for $t \le T_1$, is given by

$$X_t = \begin{cases} \phi(t,x) & \text{for } t < T_1,\\ Z_1 & \text{for } t = T_1. \end{cases}$$

Starting from $X_{T_1} = Z_1$, we now select the next interjump time $T_2 - T_1$ and postjump location $X_{T_2} = Z_2$ in a similar way. This gives a piecewise-deterministic trajectory

for the process $\{X_t\}$ with jump times $T_1, T_2, \ldots$, and postjump location $Z_1, Z_2, \ldots$. It can be shown [1, pp. 62–66] that $\{X_t\}$ is a strong Markov process. The procedure above defines a family of measures $\{P_x; x \in E\}$ on $(\Omega, \mathcal{F}^0)$. The final assumption is that for every $x \in E$ and $t \in \mathbb{R}_+$

$$E_x[N_t] < \infty, \tag{3}$$

where

$$N_t := \sum_{k=1}^{\infty} I_{\{T_k \le t\}}. \tag{4}$$

In particular, (3) implies that $T_k \to \infty$ as $k \to \infty$ almost surely.

For any $\mu \in \mathcal{P}(E)$, define P_μ on $(\Omega, \mathcal{F}^0)$ as

$$P_\mu(A) = \int_A P_x(A)\mu(dx).$$

Let $\mathcal{F}_t^\mu$ be the completion of $\mathcal{F}_t^0$ with respect to all P_μ-null sets of $\mathcal{F}^0$, and

$$\mathcal{F}_t = \bigcap_{\mu \in \mathcal{P}(E)} \mathcal{F}_t^\mu.$$

By the same arguments as Theorem 25.3 in [1, p. 63], it follows that $\mathcal{F}_t$ is right-continuous.

2.2. The PDP differential formula. In this subsection we present the PDP differential formula, which will be used in what follows. In order to do this we need to make some initial definitions.

Define the operator $\mathfrak{C} : \mathbb{B}(\partial^* E) \to R$ as follows:

$$(\forall z \in \partial^* E)\ (\forall g \in \mathbb{B}(\partial^* E)) \quad \mathfrak{C}g(z) := Qg(z) - g(z). \tag{5}$$

Define also

$$\mathfrak{B}f(t, x, \omega) := f(x) - f(X_{t-}(\omega)).$$

It was shown in [1, p. 83] that $\mathfrak{B}h$ is in $\mathcal{L}_1^{loc}(p)$ if h satisfies the identity

$$E_x\left[\sum_i \left|h(X_{T_i \wedge \tau_n}) - h(X_{(T_i \wedge \tau_n)-})\right|\right] < \infty$$

for some sequence of stopping times $\tau_n \uparrow \infty$. In particular, this always holds if (see [1, p. 83]) for each $t \ge 0$,

$$E_x\left[\sum_{T_i \le t} \left|h(X_{T_i}) - h(X_{T_i-})\right|\right] < \infty. \tag{6}$$

Clearly from (3), if h is bounded, then (6) will hold.

Define

$$p^*(t) = \sum_{i=1}^{\infty} I_{\{t \ge T_i\}} I_{\{X_{T_i-} \in \partial^* E\}},$$

which is a measure that counts the number of jumps from the boundary, and for $A \in \mathcal{B}(E)$

$$p(t,A) := \sum_{k=1}^{\infty} I_{\{T_k \le t\}} I_{\{X_{T_k} \in A\}},$$

$$\widetilde{p}(t,A) := \int_0^t Q(X_s,A)(\lambda(X_s))ds + \int_0^t Q(X_{s-},A)dp^*(s),$$

and

$$q(t,A) := p(t,A) - \widetilde{p}(t,A).$$

Associated with the PDP we can define a multivalued operator (see chapter 1 in [3]) $\widetilde{\mathcal{A}}$. This multivalued operator $\widetilde{\mathcal{A}}$ is a subset of $\mathbb{B}(E) \times \mathbb{B}(E)$ with domain $\mathcal{D}(\widetilde{\mathcal{A}}) \subset \mathbb{B}(E)$ defined as follows: $f \in \mathcal{D}(\widetilde{\mathcal{A}})$ if the following conditions are satisfied:

(a) $(\exists \mathcal{X}f \in \mathbb{B}(E))$ such that

$$(\forall x \in E)\,(\forall t \in [0, t^*(x)))) \quad f(\phi(t,x)) = f(x) + \int_0^t \mathcal{X}f(\phi(s,x))ds.$$

(b) $\lim_{t \uparrow t^*(x)} f(\phi(t,x))$ exists whenever $t^*(x) < \infty$.

The range of $\widetilde{\mathcal{A}}$ is given by

$$\mathcal{R}(\widetilde{\mathcal{A}}) = \Big\{ g \in \mathbb{B}(E) : (\exists f \in \mathcal{D}(\widetilde{\mathcal{A}})) \quad \text{such that} \quad g = \mathcal{X}f + (Qf - f)\lambda \Big\}.$$

For $f \in \mathcal{D}(\widetilde{\mathcal{A}})$, $\mathcal{A}f$ will denote a function in $\mathcal{R}(\widetilde{\mathcal{A}})$ such that $(f, \mathcal{A}f) \in \widetilde{\mathcal{A}}$. Moreover, for $f \in \mathcal{D}(\widetilde{\mathcal{A}})$, we define

$$f(z) = \lim_{t \uparrow t^*(x)} f(\phi(t,x)) \qquad \forall z = \lim_{t \uparrow t^*(x)} \phi(t,x) \in \partial^* E.$$

Notice that the limit exists from (b) of the definition of $\mathcal{D}(\widetilde{\mathcal{A}})$.

Remark 2.1. (a) Note that $\widetilde{A}$ is a linear operator in the sense that $\alpha f + \beta g \in \mathcal{D}(\widetilde{\mathcal{A}})$ whenever $f \in \mathcal{D}(\widetilde{\mathcal{A}})$, $g \in \mathcal{D}(\widetilde{\mathcal{A}})$, and $(\alpha, \beta) \in \mathbb{R}^2$.

(b) We had to introduce here the notion of multivalued operator, which is different from the extended generator defined by Davis (see Theorem 26.14 in [1]), to ensure that the function $\mathcal{X}f(x)$ belongs to $\mathbb{B}(E)$.

We can now state the PDP differential formula.

THEOREM 2.2 (PDP differential formula; see [1, Thm. 31.3, p. 83]). *Suppose that $f \in \mathcal{D}(\widetilde{\mathcal{A}})$ and satisfies the condition in* (6). *Then for each $t \ge 0$*

$$f(X_t) - f(X_0) = \int_0^t \mathcal{A}f(X_s)ds + \int_0^t \int_E \mathfrak{B}f(s,x,.)q(ds,dx) + \int_0^t \mathfrak{C}f(X_{s-})dp^*(s). \tag{7}$$

Moreover, the stochastic integral term (the one with respect to $q(ds,dx)$) is a martingale.

Remark 2.3. The previous equation must be compared to the differential formula (see (11)) presented in [4]. In formula (7) there is an extra term, associated with the jumps from the boundary, given by $\int_0^t \mathfrak{C}f(X_{s-})dp^*(s)$. The expectation of this term cannot be expressed as an integral term with respect to the Lebesgue measure. Consequently, due to this special feature, more specific results have to be developed.

2.3. The embedded Markov chain and the PE. Associated with the PDP defined in section 2.1, the following stochastic kernels can be introduced (recall the definition of Λ in (2)): for all $x \in E \cup \partial^* E$ and $A \in \mathcal{B}(E)$

$$L(x,A) \doteq \int_0^{t^*(x)} e^{-s-\Lambda(s,x)} I_A(\phi(s,x))ds, \tag{8}$$

$$K(x,A) \doteq \int_0^{t^*(x)} e^{-s-\Lambda(s,x)} \lambda(\phi(s,x))Q(\phi(s,x),A)ds$$

$$+ e^{-t^*(x)-\Lambda(t^*(x),x)} Q(\phi(t^*(x),x),A), \tag{9}$$

$$G(x,A) \doteq L(x,A) + K(x,A). \tag{10}$$

It will be useful in what follows to define the function $\mathcal{L}(x)$ as follows:

$$\mathcal{L}(x) := L(x,E). \tag{11}$$

Note that for every $x \in E$, $0 < L(x,E) < 1$, and for every $x \in E \cup \partial^* E$, $G(x,E) = 1$. Thus $G(.,.)$ is a stochastic kernel of an embedded Markov chain associated with the PDP $\{X_t\}$, which we shall denote by $\{Y_n\}$.

In order to introduce the PE for the embedded Markov chain, we need to define the following kernel acting on the boundary: for all $x \in E \cup \partial^* E$ and $A \in \mathcal{B}(\partial^* E)$,

$$H(x,A) \doteq e^{-t^*(x)-\Lambda(t^*(x),x)} I_A(\phi(t^*(x),x)). \tag{12}$$

Moreover, it is easy to see from the definitions of the kernels L, H, and G (see (8), (12), (10)) that for $z \in \partial^* E$ and any functions $f \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$, we have

$$Lf(z) = 0, \qquad Hr(z) = r(z), \quad \text{and} \quad Gf(z) = Qf(z). \tag{13}$$

Next we define the PE for PDPs which, as we will see in Theorem 2.5, is associated with the long run average cost.

DEFINITION 2.4 (the PE for the PDP). *Let $f \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$. A pair of functions $(w,h) \in \mathcal{D}(\widetilde{\mathcal{A}}) \times \mathcal{D}(\widetilde{\mathcal{A}})$ is a solution for the PE for the PDP with charge (f,r) if*

(i) $(\forall x \in E) \quad \mathcal{A}w(x) = 0 \qquad$ *and* $\qquad (\forall z \in \partial^* E) \quad \mathfrak{C}w(z) = 0,$

(ii) $(\forall x \in E) \quad \mathcal{A}h(x) = w(x) - f(x) \quad$ *and* $\quad (\forall z \in \partial^* E) \quad \mathfrak{C}h(z) = -r(z).$

The next result shows the connection between the PE for the PDP and the long run average cost associated with cost functions f and r.

THEOREM 2.5. *For $f \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$, suppose that (w,h) is a solution for the PE for the PDP with charges (f,r) such that*

$$\liminf_{t\to\infty} \frac{1}{t} E_x[h(X_t)] = 0, \tag{14}$$

and assume that w and h satisfy the condition in (6). *Then for all $x \in E$*

$$w(x) = \liminf_{t\to\infty} \frac{1}{t} E_x \left[\int_0^t f(X_s)ds + \int_0^t r(X_{s-})dp^*(s) \right].$$

Proof. By the PDP differential formula (see Theorem 2.2) and from (i) in Definition 2.4,

$$\begin{aligned} w(X_t) - w(x) &= \int_0^t \mathcal{A}w(X_s)ds + \int_0^t \int_E \mathfrak{B}w(s,x,.)q(ds,dx) + \int_0^t \mathfrak{C}w(X_{s-})dp^*(s) \\ &= \int_0^t \int_E \mathfrak{B}w(s,x,.)q(ds,dx) \end{aligned}$$

and the stochastic integral term is a martingale. Thus for all $t \in R_+$,

$$E_x[w(X_t)] - w(x) = 0. \tag{15}$$

Again by the PDP differential formula (see Theorem 2.2) and from (ii) in Definition 2.4,

$$\begin{aligned} h(X_t) - h(x) &= \int_0^t \mathcal{A}h(X_s)ds + \int_0^t \int_E \mathfrak{B}h(s,x,.)q(ds,dx) + \int_0^t \mathfrak{C}h(X_{s-})dp^*(s) \\ &= \int_0^t (w(X_s) - f(X_s))ds + \int_0^t \int_E \mathfrak{B}h(s,x,.)q(ds,dx) \\ &\quad - \int_0^t r(X_{s-})dp^*(s) \end{aligned}$$

and the stochastic integral term is a martingale. From (15) we have for all $t \in R_+$

$$\begin{aligned} E_x[h(X_t)] - h(x) &= \int_0^t E_x[w(X_s)]ds - \int_0^t E_x[f(X_s)]ds - E_x\left[\int_0^t r(X_{s-})dp^*(s)\right] \\ &= w(x)t - \int_0^t E_x[f(X_s)]ds - E_x\left[\int_0^t r(X_{s-})dp^*(s)\right]. \end{aligned}$$

Therefore,

$$w(x) = \frac{1}{t}\left(E_x\left[\int_0^t f(X_s)ds + \int_0^t r(X_{s-})dp^*(s)\right]\right) + \frac{1}{t}\left(E_x\left[h(X_t)\right] - h(x)\right),$$

and taking the limit as $t \to \infty$ we have from (14) the desired result. □

We will show in the next section that the solution for the PE for the (continuous-time) PDP is closely related to the solution for the PE for the (discrete-time) embedded Markov chain with kernel G, defined next.

DEFINITION 2.6 (the PE for G). *Let $f \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$. A pair of functions $(w,h) \in \mathbb{B}(E \cup \partial^* E) \times \mathbb{B}(E \cup \partial^* E)$ is a solution for the PE for G with charge $Lf + Hr$ if for all $x \in E \cup \partial^* E$*

$$\begin{aligned} &\text{(i)} \quad Gw(x) = w(x), \\ &\text{(ii)} \quad Gh(x) = h(x) + Lw(x) - Lf(x) - Hr(x). \end{aligned}$$

3. Equivalence results. In this section we present some connections between the PE for the PDP and the Markov chain $\{Y_n\}$ associated with G.

The first result presents some relations between the kernel G and the operator $\mathcal{A}$.

According to the notation introduced in (1), if $V(.,.)$ is any stochastic kernel defined on $E \cup \partial^* E \times \mathcal{B}(E)$, then for any function $h \in \mathcal{D}(\widetilde{\mathcal{A}})$, $V\mathcal{A}h(x)$ denotes the

function in $\mathbb{B}(E \cup \partial^* E)$ defined by $\int_E \mathcal{A}h(y)\, V(x, dy)$. If V is a kernel such that $Vf \in \mathcal{D}(\widetilde{\mathcal{A}})$, then $\mathcal{A}Vf$ will denote a function in $\mathcal{R}(\widetilde{\mathcal{A}})$ such that $(Vf, \mathcal{A}Vf) \in \widetilde{\mathcal{A}}$, according to the definition of $\mathcal{A}$ presented in section 2.2.

THEOREM 3.1. *Assume that $h \in \mathcal{D}(\widetilde{\mathcal{A}})$. Then*

$$(\forall x \in E \cup \partial^* E) \qquad L\mathcal{A}h(x) = Gh(x) - h(x) - H(Q - I)h(x). \tag{16}$$

Assume that $h \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$. Then $Gh \in \mathcal{D}(\widetilde{\mathcal{A}})$, $Lh \in \mathcal{D}(\widetilde{\mathcal{A}})$, $Hr \in \mathcal{D}(\widetilde{\mathcal{A}})$ and

$$(\forall x \in E) \qquad \mathcal{A}Gh(x) = (I + \lambda(x)Q)(G - I)h(x), \tag{17}$$

$$\mathcal{A}Lh(x) = Lh(x) - h(x) + \lambda(x)QLh(x), \tag{18}$$

$$\mathcal{A}Hr(x) = (1 + \lambda(x))Hr(x) + \lambda(x)(Q - I)Hr(x). \tag{19}$$

Proof. First note that using the definition of L and $\mathcal{A}$, we have that

$$\begin{aligned} L\mathcal{A}h(x) = &\int_0^{t^*(x)} e^{-s-\Lambda(s,x)} \mathcal{X}h(\phi(s,x))ds \\ &+ \int_0^{t^*(x)} e^{-s-\Lambda(s,x)} \lambda(\phi(s,x))[Q - I]h(\phi(s,x))ds. \end{aligned} \tag{20}$$

Now subtracting $Lh(x)$ from both sides of (20), we obtain

$$\begin{aligned} L\mathcal{A}h(x) - Lh(x) = &\int_0^{t^*(x)} e^{-s-\Lambda(s,x)} [\mathcal{X}h(\phi(s,x)) - (1 + \lambda(\phi(s,x)))h(\phi(s,x))]ds \\ &+ \int_0^{t^*(x)} e^{-s-\Lambda(s,x)} \lambda(\phi(s,x))Qh(\phi(s,x))ds. \end{aligned}$$

Using the definition of $\mathcal{X}h$, it follows that

$$\begin{aligned} L\mathcal{A}h(x) - Lh(x) &= \left[e^{-s-\Lambda(s,x)} h(\phi(s,x))\right]_0^{t^*(x)} \\ &\quad + \int_0^{t^*(x)} e^{-s-\Lambda(s,x)} \lambda(\phi(s,x))Qh(\phi(s,x))ds \\ &= Hh(x) - h(x) + Kh(x) - HQh(x), \end{aligned} \tag{21}$$

and from the definition of G (see (10)), we obtain that (21) gives (16).

For (17), note that a short calculation using the fact that $t^*(\phi(t,x)) = t^*(x) - t$ for $t < t^*(x)$ shows that

$$\begin{aligned} Gh(\phi(t,x)) = e^{t+\Lambda(t,x)} \Bigg[&Gh(x) \\ &- e^{t+\Lambda(t,x)} \int_0^t e^{-s-\Lambda(s,x)} [h(\phi(s,x)) + \lambda(\phi(s,x))Qh(\phi(s,x))]ds \Bigg]. \end{aligned} \tag{22}$$

From (22), it is easy to deduce that $Gh \in \mathcal{D}(\widetilde{\mathcal{A}})$ and also that

$$\mathcal{X}Gh(x) = [1 + \lambda(x)]Gh(x) - h(x) - \lambda(x)Qh(x). \tag{23}$$

Consequently, from (23),

$$\mathcal{A}Gh(x) = [1 + \lambda(x)]Gh(x) - h(x) - \lambda(x)Qh(x) + \lambda(x)[Q - I]Gh(x) \tag{24}$$

and (17) follows from (24).

Now, using similar arguments as above, it follows that $Lh \in \mathcal{D}(\widetilde{\mathcal{A}})$, $Hr \in \mathcal{D}(\widetilde{\mathcal{A}})$. The last two identities, (18) and (19), are obtained similarly, yielding the desired results. □

The next result shows the connection between the PE for the PDP and the PE for G.

THEOREM 3.2. *Let $f \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$. Then (w, h) is a solution for the PE for the PDP with charges (f, r) if and only if (w, h) is a solution for the PE for G with charge $Lf + Hr$.*

Proof. Suppose that $(w, h) \in \mathbb{B}(E \cup \partial^* E) \times \mathbb{B}(E \cup \partial^* E)$ is a solution for the PE for the kernel G with charges $Lf + Hr$. From Definition 2.6, for all $x \in E \cup \partial^* E$,

$$Gw(x) = w(x), \tag{25}$$

$$Gh(x) = h(x) + Lw(x) - Lf(x) - Hr(x). \tag{26}$$

From Theorem 3.1, (17), and (25), it follows that $w = Gw \in \mathcal{D}(\widetilde{\mathcal{A}})$ and

$$\begin{aligned} \mathcal{A}w &= \mathcal{A}Gw \\ &= (I + \lambda Q)(G - I)w \\ &= (I + \lambda Q)(Gw - w) \\ &= 0. \end{aligned}$$

From (13) and (25), we have for all $z \in \partial^* E$, (see (5)) $\mathfrak{C}w(z) = Qw(z) - w(z) = Gw(z) - w(z) = 0$. From (26), we have for all $z \in \partial^* E$, $Gh(z) = Lw(z) - Lf(z) + h(z) - Hr(z)$. Using (13), we have

$$Gh(z) = Qh(z) = h(z) - r(z), \tag{27}$$

implying that $\mathfrak{C}h(z) = -r(z)$ for all $z \in \partial^* E$. From (26), it follows that $h \in \mathcal{D}(\widetilde{\mathcal{A}})$, by combining Theorem 3.1 and Remark 2.1. Moreover, applying the three identities (17), (18), (19) of Theorem 3.1 to the functions $\mathcal{A}Gh$, $\mathcal{A}L(w-f)$, and $\mathcal{A}Hr$, it follows from (26) that

$$\begin{aligned} \mathcal{A}h(x) &= \mathcal{A}\{Gh(x) - L(w - f)(x) + Hr(x)\} \\ &= (I + \lambda(x)Q)(G - I)h(x) \\ &\quad - L(w - f)(x) - (w - f)(x) + \lambda(x)QL(w - f)(x) \\ &\quad + (1 + \lambda(x))Hr(x) + \lambda(x)(Q - I)Hr(x) \\ &= \lambda(x)Q\{Gh - L(w - f) + Hr\}(x) \\ &\quad + \{Gh - L(w - f) + Hr\}(x) \\ &\quad + (1 + \lambda(x))(Hr(x) - Hr(x)) \\ &\quad + (w - f)(x) \\ &= (w - f)(x). \end{aligned}$$

Suppose now that (w, h) is a solution for the PE for the PDP with charges (f, r), so that according to Definition 2.4, for $x \in E, z \in \partial^* E$,

$$\mathcal{A}w(x) = 0 \text{ and } \mathfrak{C}w(z) = 0, \tag{28}$$

$$\mathcal{A}h(x) = w(x) - f(x) \text{ and } \mathfrak{C}h(z) = -r(z). \tag{29}$$

From (28) and (16) in Theorem 3.1, we obtain that

$$\begin{aligned} 0 &= L\mathcal{A}w(x) \\ &= Gw(x) - w(x) - H(Q-I)w(x) \\ &= Gw(x) - w(x) \end{aligned}$$

since from (28)

$$\begin{aligned} H(Q-I)w(x) &= e^{-t^*(x)-\Lambda(t^*(x),x)}(Qw(\phi(t^*(x),x)) - w(\phi(t^*(x),x))) \\ &= e^{-t^*(x)-\Lambda(t^*(x),x)}\mathfrak{C}w(\phi(t^*(x),x)) \\ &= 0. \end{aligned}$$

Now from (16) in Theorem 3.1 and (29), it follows that

$$\begin{aligned} L\mathcal{A}h(x) &= L(w-f)(x) \\ &= Gh(x) - h(x) - H(Q-I)h(x) \\ &= Gh(x) - h(x) + Hr(x) \end{aligned} \tag{30}$$

since from (29),

$$\begin{aligned} HQh(x) - Hh(x) &= e^{-t^*(x)-\Lambda(t^*(x),x)}(Qw(\phi(t^*(x),x)) - w(\phi(t^*(x),x))) \\ &= e^{-t^*(x)-\Lambda(t^*(x),x)}\mathfrak{C}h(\phi(t^*(x),x)) \\ &= -e^{-t^*(x)-\Lambda(t^*(x),x)}r(\phi(t^*(x),x)) \\ &= -Hr(x). \end{aligned}$$

Thus from (30), $L(w-f) = Gh - h + Hr$, which yields the desired result. □

Next we show that, if there exists an invariant probability measure for $\{X_t\}$ (equivalently a σ-finite invariant measure π for G; see [2]), then, as expected, the stationary cost values for the PDP and the Markov chain $\{Y_n\}$ are the same.

PROPOSITION 3.3. *Assume that an invariant probability measure for $\{X_t\}$, labeled μ, exists and satisfies (see* (4)*) $E_\mu[N_t] < \infty$. Denote by σ the associated boundary measure (see equation* (34.18) *in* [1]*) and by π the corresponding invariant σ-finite measure for $\{Y_n\}$. Then the following identity holds:*

$$\pi(Lf + Hr) = \int_E f(x)\mu(dx) + \int_{\partial^* E} r(z)\sigma(dz),$$

provided that one of the members exists.

Proof. Assume that f and r are positive real-valued functions. Let us define r_n and f_n as follows: $r_n(x) = r(x) \wedge n$, $f_n(x) = f(x) \wedge n$. Then by repeating the same arguments as in Proposition 34.13 and Theorem 34.15 of Davis [1, pp. 116–117], we obtain that

$$E_\mu\left[\int_0^t e^{-s} r_n(X_{s-})dp^*(s)\right] = (1 - e^{-t})\sigma(r_n).$$

From the monotone convergence theorem, it follows that

$$E_\mu\left[\int_0^\infty e^{-s} r_n(X_{s-})dp^*(s)\right] = \sigma(r_n).$$

Now using Fubini's theorem and the fact that μ is an invariant probability measure for $\{X_t\}$, we obtain that

$$E_\mu\left[\int_0^\infty e^{-s} f_n(X_s)ds + \int_0^\infty e^{-s} r_n(X_{s-})dp^*(s)\right] = \mu(f_n) + \sigma(r_n).$$

On the other hand, from Proposition 32.34 of [1], it is easy to show that

$$E_\mu\left[\int_0^\infty e^{-s} f_n(X_s)ds + \int_0^\infty e^{-s} r_n(X_{s-})dp^*(s)\right] = \mu \sum_{i=0}^{\infty} K^i(Lf_n + Hr_n).$$

Again using the monotone convergence theorem, it follows that

$$\mu(f) + \sigma(r) = \mu \sum_{i=0}^{\infty} K^i(Lf + Hr).$$

However, from the proof of Theorem 3.5 in [2], we have that $\mu \sum_{i=0}^{\infty} K^i = \pi$ and therefore

$$\mu(f) + \sigma(r) = \pi(Lf + Hr).$$

Now, for the general case, we consider the following classical decompositions,

$$f = (0 \wedge f) - (0 \wedge -f) \qquad \text{and} \qquad r = (0 \wedge r) - (0 \wedge -r),$$

so that we can apply the previous identity to obtain the final result. □

Remark 3.4. Combining the two previous results we have that $(\mu(f) + \sigma(r), h)$ is a solution for the PE for the PDP with charges (f, r) if and only if $(\pi(Lf + Hr), h)$ is a solution for the PE for G with charge $Lf + Hr$.

We conclude this section with a result about the uniqueness of the solution of the PE for PDPs.

PROPOSITION 3.5. *Assume that the process $\{X_t\}$ is irreducible and has an invariant probability measure, labeled μ, such that $E_\mu[N_t] < \infty$. Denote by σ the associated boundary measure. Suppose that $(\mu(f) + \sigma(r), h_1)$ and $(\mu(f) + \sigma(r), h_2)$ are two solutions for the PE for the PDP with charges (f, r) such that $\mu(|h_1| + |h_2|) < \infty$ and h_1, h_2 satisfy the condition in* (6). *Then for some constant c, $h_1(x) = h_2(x) + c$ for μ-almost every $x \in E$.*

Proof. Set $h = h_1 - h_2$, so that for all $x \in E$, $\mathcal{A}h(x) = 0$ and for all $z \in \partial^* E$, $\mathfrak{C}h(z) = 0$. By using Theorem 2.2 and the fact that h satisfies the condition in (6), we obtain that for all $t \in \mathbb{R}_+$, $h(x) = E_x[h(X_t)]$. Consequently, we obtain that $h(x) = Uh(x)$, where U denotes the resolvent kernel associated with $\{X_t\}$. Since U is positive recurrent, it follows that

$$\lim_{n\to\infty} \frac{1}{n} \sum_{k=1}^{n} U^k h(x) = \mu(h) \quad \mu\text{-a.s.}$$

Therefore,

$$h(x) = \mu(h) \quad \mu\text{-a.s.},$$

showing the desired result. □

4. Sufficient condition. In this section we present a sufficient condition for the existence of a solution for the PE for G. In order to do that, we recall now some classical definitions related to Markov chains. For a complete exposition on the subject the reader is referred to the book of Meyn and Tweedie [6].

In order to simplify the notation, let us define

$$X \doteq E \cup \partial^* E.$$

Let us denote by τ_A the first hitting time of the set $A \in \mathcal{B}(X)$ not including time 0:

$$\tau_A \doteq \inf\{n \geq 1 : Y_n \in A\}.$$

DEFINITION 4.1. *$\{Y_n\}$ is φ-irreducible, if there exists a measure φ defined on $(X, \mathcal{B}(X))$ such that, whenever $\varphi(A) > 0$, it follows that $P_x(\tau_A < \infty) > 0$ for all $x \in X$.*

If $\{Y_n\}$ is φ-irreducible, then there exists a maximal irreducibility measure (see [6, Proposition 4.2.2, p. 88]). In the following, we will use ψ to denote a maximal irreducibility measure for $\{Y_n\}$. Associated with a maximal irreducibility measure for $\{Y_n\}$ is the definition

$$\mathcal{B}(X)^+ \doteq \{A \in \mathcal{B}(X) : \psi(A) > 0\}.$$

DEFINITION 4.2. *$\{Y_n\}$ is called recurrent if it is ψ-irreducible and $\sum_{n=1}^{\infty} G^n(x, A) = \infty$ for all $x \in X$ and $A \in \mathcal{B}(X)^+$.*

DEFINITION 4.3. *A set $C \in \mathcal{B}(X)$ is called ν_a-petite if there exists a nontrivial measure ν_a on $(X, \mathcal{B}(X))$ such that*

$$(\forall x \in C)\,(\forall B \in \mathcal{B}(X)) \quad \sum_{n=1}^{\infty} a(n) G^n(x, B) \geq \nu_a(B),$$

where the positive sequence $\{a(n)\}$ satisfies $\sum_{n=0}^{\infty} a(n) = 1$.

The resolvent K_{a_ϵ} of the Markov chain G is defined for $0 < \epsilon < 1$ by

$$(\forall x \in X)\,(\forall A \in \mathcal{B}(X)) \quad K_{a_\epsilon}(x, A) \doteq (1 - \epsilon) \sum_{n=1}^{\infty} \epsilon^n G^n(x, B).$$

The following assumptions will be used in what follows:

(A.1) The Markov kernel G is recurrent.

(A.2) For a petite set $C \in \mathcal{B}(X)^+$ the Markov kernel G satisfies the following inequality for all $x \in X$,

$$GV(x) \leq V(x) - v(x) + bI_C(x),$$

for a function $v \geq \mathcal{L}$ and $V \geq 0$ everywhere finite and bounded in C.

The following results follow from (A.1) and (A.2) (recall the definition of $\mathcal{L}$ in (11)).

PROPOSITION 4.4. *Suppose that* (A.1) *and* (A.2) *hold. Then*

(i) *there exists a unique (up to constant multiples) σ-finite invariant measure π for G with $0 < \pi(C) < \infty$ and $\pi(\mathcal{L}) < \infty$;*

(ii) *$\pi(v) < \infty$.*

Proof. Since $v(x) \geq \mathcal{L}(x)$, it follows from (A.2) that $GV(x) \leq V(x) - \mathcal{L}(x) + bI_C(x)$, and from this result and (A.1) we have from Corollary 4.5 in [2] that (i) holds. From Theorem 2.2(iii) in [4] we obtain that for any $A \in \mathcal{B}(X)^+$ there exists $c(A)$ such that

$$E_x\left[\sum_{k=0}^{\tau_A-1} v(Y_k)\right] \leq V(x) + c(A).$$

Therefore, from Theorems 10.0.1 and 10.4.9 in [6], we have that

$$\begin{aligned}\pi(v) &= \int_C \pi(dx) E_x\left[\sum_{k=1}^{\tau_C} v(Y_k)\right] \\ &= \int_C \pi(dx) E_x\left[\sum_{k=0}^{\tau_C-1} v(Y_k)\right] \\ &\leq \left[\sup_{x\in C} V(x) + c(C)\right]\ \pi(C) < \infty,\end{aligned}$$

which gives (ii). □

There is no loss of generality in assuming that $\pi(\mathcal{L}) = 1$.

THEOREM 4.5. *Suppose that* (A.1) *and* (A.2) *hold. Then for any function* $g \in \mathbb{B}(X)$ *such that* $\sup_{x\in X} \frac{|g(x)|}{v(x)} < \infty$, *there exists* $h \in \mathbb{B}(X)$ *such that*

$$Gh(x) = h(x) - [g(x) - \pi(g)\mathcal{L}(x)], \tag{31}$$

and for some $R > 0$,

$$|h(x)| \leq R(V(x) + 1). \tag{32}$$

Proof. Since $|g(x)| \leq \beta v(x)$ for a constant $\beta > 0$, it follows from Proposition 4.4 (ii) that $\pi(|g|) < \infty$. Define $\bar{g}(x) \doteq g(x) - \pi(g)\mathcal{L}(x)$. Using the fact that $\mathcal{L}(x) \leq v(x)$, it is easy to obtain that $\sup_{x\in X} \frac{|\bar{g}(x)|}{v(x)} < \infty$.

In the case where the Markov chain G is strongly aperiodic, the proof of Theorem 2.3 in [4] can be used to show the existence of the function h satisfying (31) and (32).

In the general case, the K_{a_ϵ}-chain can be considered, and following the proof of Theorem 2.3 in [4] we have that

$$K_{a_\epsilon} V_\epsilon \leq V_\epsilon - v + b' K_{a_\epsilon} I_C, \tag{33}$$

where the function V_ϵ equals a constant multiple of V and b' is a strictly positive constant.

However, now we cannot follow the proof of Glynn and Meyn (see Theorem 2.3 in [4]) because the function v may be less than 1 and consequently we cannot adopt the proof of Theorem 14.2.9 in [6] to get the (V3) condition for the K_{a_ϵ}-chain. (For the definition of the (V3) condition, see page 337 in the book of Meyn and Tweedie [6].)

From now on we follow a different line from [4]. We adopt the notation of Meyn and Tweedie for the splitting technique of a Markov chain (see p. 103 in [6]).

Since $C \in \mathcal{B}(X)^+$ and using Theorem 5.2.2 in [6], there exist a set D, a probability ν, and a real $\delta > 0$ such that $D \subset C$, $D \in \mathcal{B}(X)^+$, $\nu(D) = 1$, and

$$(\forall x \in X)\ (\forall A \in \mathcal{B}(X)) \qquad K_{a_\epsilon}(x, A) \geq \delta I_D(x)\nu(A). \tag{34}$$

Note that V_ϵ is bounded on D since by hypothesis V is bounded on C. Since K_{a_ϵ} satisfies the minorization condition (34), we can introduce the split chain $\check{K}_{a_\epsilon}$ defined on $(\check{X}, \mathcal{B}(\check{X}))$. Let us define the function $\check{V}$ on $\check{X}$ by

$$(\forall x_0 \in X_0) \quad \check{V}(x_0) = V_\epsilon(x), \tag{35}$$

$$(\forall x_1 \in D_1) \quad \check{V}(x_1) = V_\epsilon(x), \tag{36}$$

$$(\forall x_1 \in X_1 - D_1) \quad \check{V}(x_1) = v(x_1) + [\delta\{\nu(V_\epsilon) - b'\} \vee 0]. \tag{37}$$

Using the fact that $\check{V}$ is bounded on $D_0 \cup D_1$ and (35)–(37), it can be shown that there exists a strictly positive number d such that

$$\check{K}_{a_\epsilon}\check{V} \le \check{V} - \check{v} + b'\check{K}_{a_\epsilon} I_{C_0 \cup C_1} + d I_{D_0 \cup D_1}, \tag{38}$$

where $\check{v}(x_i) = v(x)$ for $i = 0, 1$.

Let us introduce the following notation: $\check{H}_c \doteq \sum_{i=0}^{\infty} c(i)\check{K}^i_{a_\epsilon}$, where c is a distribution on $\mathbb{Z}_+$.

Since $C_0 \cup C_1$ is a petite set for the split chain $\check{K}_{a_\epsilon}$, it follows that for any set B in $\mathcal{B}(\check{X})^+$ we can find a measure Ψ_{a_ϵ} such that $\Psi_{a_\epsilon}(B) > 0$ and satisfies for $i = 0, 1$

$$I_{C_0 \cup C_1}(x_i) \le \Psi^{-1}_{a_\epsilon}(B)\check{H}_{a_\epsilon}(x_i, B). \tag{39}$$

Combining (38) and (39), we obtain that there exists a real $\beta > 0$ such that

$$\begin{aligned} \check{K}_{a_\epsilon}\check{V}(x_i) &\le \check{V}(x_i) - \check{v}(x_i) + \beta\Psi_a^{-1}(B)\frac{1}{2}\left[I + \check{K}_{a_\epsilon}\right]\check{H}_{a_\epsilon}(x_i, B) \\ &\le \check{V}(x_i) - \check{v}(x_i) + \beta\Psi_a^{-1}(B)\check{H}_{a * a_\epsilon}(x_i, B), \end{aligned} \tag{40}$$

where a is the distribution defined by $a(0) = a(1) = \frac{1}{2}$.

Now we can go back to the proof of Glynn and Meyn (see Theorem 2.2 in [4]). Indeed, by noting that $\sum_{i=0}^{\infty} i\, a * a_\epsilon(i) < \infty$, we can conclude from (40) that

$$\check{E}_{x_i}\left[\sum_{k=0}^{\tau_{\check{\alpha}}-1} f(\check{Y}_k)\right] \le \check{V}(x_i) + c, \tag{41}$$

where the Markov chain $\{\check{Y}_k\}$ is generated by $\check{K}_{a_\epsilon}$.

Consequently, we can claim that there exists a solution (labeled h_ϵ) for the PE $K_{a_\epsilon}h_\epsilon(x) = h_\epsilon(x) - [g(x) - \pi(g)\mathcal{L}(x)]$ satisfying $|h_\epsilon(x)| \le R_\epsilon(V_\epsilon(x) + 1)$ for some $R_\epsilon > 0$. Finally, the existence of a function h satisfying (31) and (32) follows from Theorem 2.2 in [4]. □

We present now a sufficient condition for the existence of a solution for the PE for G (and thus for the PDP).

COROLLARY 4.6. *Suppose that* (A.1) *and* (A.2) *hold. Then for all functions* $f \in \mathbb{B}(E)$ *and* $r \in \mathbb{B}(\partial^* E)$ *satisfying* $\sup_{x \in X} \frac{|Lf(x) + Hr(x)|}{v(x)} < \infty$, *there exists a function* $h \in \mathbb{B}(X)$ *such that*

$$Gh(x) = h(x) + Lw(x) - Lf(x) - Hr(x),$$

where $w(x) \doteq \pi(Lf + Hr)$.

Moreover, for some $R \in \mathbb{R}_+$, $|h(x)| \le R(V(x) + 1)$.

Proof. By noting that $Lw(x) = \mathcal{L}(x)\pi(Lf + Hr)$, the result follows as a direct consequence of Theorem 4.5. □

Remark 4.7. Notice that condition (A.2) in Theorem 4.5 does not imply that $\pi(E) < \infty$ (the invariant measure for G can be just σ-finite), since we are just requiring that $v \geq \mathcal{L}$. This condition (A.2) is very much similar to condition (V3) of [6], which has been used in several recent references to obtain f-regularity of a sampled process (see, for instance, [4], [6], [7]). However, note that since v may be less than 1, condition (A.2) implies neither f-regularity nor positive Harris recurrence for the Markov kernel G.

Remark 4.8. Suppose that for a petite set $C \in \mathcal{B}(X)^+$ there exists a function $V \in \mathcal{D}(\widetilde{\mathcal{A}})$ positive, everywhere finite and bounded in C such that for some functions $\alpha(x) \geq 1$, $\gamma(z) \geq 1$, and every $x \in C^c$,

$$\mathcal{A}V(\phi(s,x)) \leq -\alpha(\phi(s,x)) \tag{42}$$

for every $0 \leq s < t^*(x)$, and

$$QV(z) - V(z) \leq -\gamma(z) \tag{43}$$

for every $z = \phi(t^*(x), x)$. From (16) it follows that for every $x \in C^c$,

$$\begin{aligned} GV(x) - V(x) &= L\mathcal{A}V(x) + H(Q - I)V(x) \\ &\leq -(L\alpha(x) + H\gamma(x)) \\ &\leq -\mathcal{L}(x) \end{aligned}$$

so that condition (A.2) will be satisfied with $v(x) = L\alpha(x) + H\gamma(x)$ for $x \in C^c$. Thus whenever $f \in \mathbb{B}(E)$ and $r \in \mathbb{B}(\partial^* E)$ are such that $f(\phi(t,x))$ and $r(z)$ are bounded for every $x \in C$, $0 \leq t < t^*(x)$, $z = \phi(t^*(x), x)$, and $|f(\phi(t,x))| \leq a\alpha(\phi(t,x))$, $|r(z)| \leq a\gamma(z)$ for some $a > 0$ and every $x \in C^c$, $0 \leq t < t^*(x)$, $z = \phi(t^*(x), x)$, the PE with charges f and r will have a solution. Condition (42), obtained from the discrete-time condition (A.2), resembles the continuous-time condition in equation (15) of [4]. Note, however, that we need the extra boundary condition (43), and that (42) was defined over the petite set C for the discrete-time process $\{Y_n\}$. So in this sense the conditions in (42) and (43) can be seen as a continuous-time condition using the structure of petite sets for the discrete-time Markov process $\{Y_n\}$, usually easier to be checked.

5. Example. In this section we apply the results of the previous section to a capacity expansion model (see sections 21.13 and 34.45 in [1] for a complete and more detailed description of the model) to illustrate the relevance of our approach. The demand for some utility is modeled as a random point process, i.e., it increases by one unit at random times. This demand is met by consecutive construction of identical expansion projects. Each project meets K units of demand when completed. We assume that if there is an excess demand of at least N units then the construction of a new project is started at a rate of k_i per unit of time, where i corresponds to the present level of excess demand, which is completed after a lead time of p units of time; if the excess demand is less than N, then no construction takes place. New demands occur with rate $\lambda_i(\zeta)$, where ζ represents the elapsed construction time of the present project. We assume that $\lambda_i(\zeta)$ is a continuous function in $\zeta \in [0, p]$ and that there exists $\theta > 0$ such that $k_i \geq \theta$ for all $i \geq N$. This problem can be modeled

as a PDP with state space

$$E = \Big\{\{N-K,\dots,N-1\}\times\{0\}\Big\} \cup \Big\{\mathbb{N}_{\mathrm{N}}\times[0,p)\Big\},$$

where $\mathbb{N}_j$ denotes the set of integers greater than or equal to j.

We show that for this example the condition given by Corollary 4.6, through Remark 4.8, can be applied.

Suppose that there exists a sequence of positive numbers $\{c_i\}$ and $c>0$ such that

$$\limsup_{i\to\infty}\frac{c_i}{k_i}\max_{\zeta\in[0,p]}\lambda_i(\zeta) < \frac{c}{p}, \tag{44}$$

and for some i_0,

$$\sum_{j=0}^{K-1} c_{i-K+j} \geq c \tag{45}$$

for all $i\geq i_0$. In view of hypothesis (44), there exist $\varepsilon>0$ and $M>N, M>i_0$, such that for all $\zeta\in[0,p]$ and $i>M$ we have that

$$\frac{c_i}{k_i}\lambda_i(\zeta) \leq \frac{c}{p}-\varepsilon$$

and thus

$$\theta\varepsilon \leq k_i\varepsilon \leq \frac{c}{p}k_i - c_i\lambda_i(\zeta). \tag{46}$$

It is easy to see that $\{Y_n\}$ is irreducible. Set $a_{i+1}=a_i+c_i$, $i=N-K,N-K+1,\dots$, and define the function V as

$$(\forall x=(i,\zeta)\in E)\qquad V(x)=\begin{cases} a_i+\dfrac{c}{p}(p-\zeta), & i\geq N,\\ a_i+c, & i<N.\end{cases}$$

We have that for $x=(i,\zeta)\in E$, $i\geq N$,

$$\mathcal{A}V(x) = -\frac{c}{p}k_i + c_i\lambda_i(\zeta)$$

and for $z=(i,p)$,

$$QV(z)-V(z) = c - \sum_{j=0}^{K-1} c_{i-K+j},$$

so that from (45) and (46) we have that (42) and (43) are satisfied on the compact set $C:=\{x=(i,\zeta): N-K\leq i\leq M, 0\leq\zeta\leq p\}$. Set $\alpha(x)=\frac{c}{p}k_i-c_i\lambda_i(\zeta)$ for $z=(i,\zeta)\in E$, $i\geq N$, and $\gamma(z)=\sum_{j=0}^{K-1}c_{i-K+j}-c$ for $x=(i,p)$, $i\geq N$. From (ii) in Theorem 6.0.1 in [6], it follows that C is a petite set and thus from Remark 4.8 there exists a solution of the PE for the PDP with charge (f,r) whenever $f\in\mathbb{B}(E)$ and $r\in\mathbb{B}(\partial^* E)$ are bounded in C, and $|f(x)|\leq a\alpha(x)$, $|r(z)|\leq a\gamma(z)$ for some $a>0$, and every $x=(i,\zeta)\in C^c, z=(i,p)$.

Acknowledgment. The authors are grateful to anonymous referees for their suggestions which have greatly improved the presentation of the paper.

A NESTED COMPUTATIONAL APPROACH TO THE DISCRETE-TIME FINITE-HORIZON LQ CONTROL PROBLEM*

GIOVANNI MARRO†, DOMENICO PRATTICHIZZO‡, AND ELENA ZATTONI†

Abstract. A new algorithmic setting is proposed for the discrete-time finite-horizon linear quadratic (LQ) optimal control problem with constrained or unconstrained final state, no matter whether the problem is cheap, singular, or regular. The proposed solution, based on matrix pseudoinversion, is completed and made practically implementable by a nesting procedure for welding optimal subarcs that enables arbitrary enlargement of the control time interval.

Key words. linear quadratic problems, algorithms, discrete-time systems, pseudoinversion

1. Introduction. The linear quadratic (LQ) and linear quadratic regulator (LQR) optimal control problems have been extensively studied and are now well settled in the literature. In particular, the regular LQ and LQR problems are exhaustively treated in many well-known specialist books and textbooks, such as, for instance, those by Bryson and Ho [3], Kwakernaak and Sivan [12], Anderson and Moore [1], Chen and Francis [5], and Lewis and Syrmos [13]. Due to increasing interest in H_2 and H_∞ control problems, more recently much effort has been made to extend the solutions of LQ and LQR problems also to cheap and singular cases. In general, these new contributions concern the infinite-horizon problems, where optimality jointly with internal stability is required. The basic properties and algorithms referring to cheap and singular optimal control have been investigated by Arnold and Laub in [2], Van Dooren in [23], Ionescu, Oară, and Weiss in [11, 10, 9], Geerts in [6], Saberi, Sannuti, Chen, and Stoorvogel in [17, 18, 4, 22], and Soethoudt, Trentelman and Ran in [21, 16]. Extension to cheap and singular problems is obtained by using matrix pencils or linear matrix inequalities.

The above contributions mainly refer to continuous- or discrete-time *infinite-horizon* LQR problems. Conversely, this work focuses on the *finite-horizon* case for discrete-time systems. It applies to cheap, singular, or regular problems. Considering a *sharp* constraint on the final state, this paper extends the results given in [16], where the infinite-horizon case with *asymptotic* endpoint constraints is investigated. However, in the present paper, the requirement that the cost functions are positive semidefinite is still present, while in [16] it is not.

From the algorithmic viewpoint, the present work differs from those of the abovementioned papers and is inspired by the system structure algorithm introduced by Silverman in his well-known contribution [20]; see also [19, 8]. In the present work, the solution is achieved by the straightforward technique of pseudoinverting a particular system matrix as in [20], but the time interval considered can be arbitrarily

enlarged through a suitable multilevel computational scheme; this enables overcoming any dimensionality constraint thus achieving a certain interest with respect to computational practice.

The following notation will be used: $\mathbb{R}^n$ stands for the set of all n-tuples of real numbers, A' and $A^{\#}$ are used for the transpose and pseudoinverse of matrix A, respectively, and I stands for the identity matrix with a suitable dimension.

2. Statement of the problem. Consider the linear discrete-time-invariant dynamical system

$$\begin{aligned} x(k+1) &= A\,x(k) + B\,u(k), \quad x(0) = x_0, \\ e(k) &= C\,x(k) + D\,u(k), \end{aligned} \tag{1}$$

with $x \in \mathbb{R}^n$, $u \in \mathbb{R}^p$, $e \in \mathbb{R}^q$, $k \in [0, N-1]$, the cost function

$$J := \sum_{k=0}^{N-1} e(k)'e(k) + x(N)'Z'Z\,x(N), \tag{2}$$

and the constraint on the final state

$$G\,x(N) = y_f, \quad y_f \in \mathbb{R}^r. \tag{3}$$

Constraint (3) is assumed to be *feasible*; i.e., the initial state x_0, the constraint on the final state (G, y_f), and the number of steps N of the control time interval are assumed to be such that at least one N-step state trajectory from x_0 to an $x(N)$ satisfying (3) exists. It is worth noting that the final state can be completely assigned by assuming $G = I$ in (3); in this case, the terminal cost becomes irrelevant to the problem solution, and in (2) matrix Z can be assumed to be zero. On the other hand, assumptions $G = 0$ and $y_f = 0$ correspond to consider the final state as completely free. The discrete-time finite-horizon LQ optimal control problem with constrained final state can be stated as follows.

PROBLEM 1. *Consider the dynamic system* (1)*, and find a control sequence*[1] $u(k)$ $(k = 0, 1, \ldots, N-1)$ *such that the cost function* (2) *is minimized under the constraint* (3).

The solution of the above problem is given with no distinctions among cheap $(D'D = 0)$, singular $(\det(D'D) = 0)$, and regular cases $(\det(D'D) \neq 0)$. To this aim, it is convenient to introduce the following notation for the sequences of controls and of extended outputs (i.e., of the outputs completed with the square root of the terminal cost):

$$u_N := \begin{bmatrix} u(0) \\ u(1) \\ \vdots \\ u(N-1) \end{bmatrix}, \quad e_N := \begin{bmatrix} e(0) \\ e(1) \\ \vdots \\ e(N-1) \\ Z\,x(N) \end{bmatrix}. \tag{4}$$

Note that, owing to the above definition of e_N, the cost function (2) can also be given as

$$J = \|e_N\|_2^2, \tag{5}$$

[1]The control sequence corresponding to the minimum value of cost may be nonunique, particularly if the system (1) is not left-invertible.

where $\|e_N\|_2$ is the 2-norm of vector e_N. Furthermore, let us express the final state $x(N)$ as a function of the initial state x_0 and the control sequence u_N,

$$x(N) = A^N x_0 + A^{N-1} B\, u(0) + \cdots + B\, u(N-1) = A^N x_0 + L_N\, u_N,$$

with

$$L_N := \left[\begin{array}{cccc} A^{N-1}B & A^{N-2}B & \cdots & B \end{array} \right], \tag{6}$$

so that the constraint (3) can be written as

$$y_f - GA^N x_0 = GL_N u_N. \tag{7}$$

According to (4), (5), and (7), Problem 1 is restated as follows.

PROBLEM 1a. *Referring to the dynamic system* (1)*, find a vector* u_N *such that* $\|e_N\|_2$ *is minimized under the constraint* (7)*.*

An algorithmic solution of Problem 1 is derived through a constructive proof of the following theorem.

THEOREM 1. *Consider the dynamic system* (1)*. Assume that the constraint* (3) *is feasible. Let* K *be a matrix, the columns of which form a basis for* $\ker(GL_N)$*. Let*

$$T_N := -(I - K\,(B_N K)^{\#}\, B_N)\,(GL_N)^{\#}\, GA^N - K\,(B_N K)^{\#}\, A_N, \tag{8}$$

$$V_N := (I - K\,(B_N K)^{\#}\, B_N)\,(GL_N)^{\#}, \tag{9}$$

$$C_N := (I - B_N K\,(B_N K)^{\#})\,(A_N - B_N\,(GL_N)^{\#}\, GA^N), \tag{10}$$

$$D_N := (I - B_N K\,(B_N K)^{\#})\, B_N\,(GL_N)^{\#}, \tag{11}$$

with

$$A_N := \left[\begin{array}{c} C \\ CA \\ \vdots \\ CA^{N-1} \\ ZA^N \end{array} \right], \quad B_N := \left[\begin{array}{cccc} D & 0 & \cdots & 0 \\ CB & D & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ CA^{N-2}B & CA^{N-3}B & \cdots & D \\ ZA^{N-1}B & ZA^{N-2}B & \cdots & ZB \end{array} \right]. \tag{12}$$

Then

$$u_N^o := T_N\, x_0 + V_N\, y_f \tag{13}$$

is the optimal solution of Problem 1 *with the feasible constraint* (3)*, and vector*

$$e_N^o := C_N\, x_0 + D_N\, y_f \tag{14}$$

is the optimal extended output sequence providing the optimal cost $J^o = \|e_N^o\|_2^2$*.*

Proof. First, let us consider the plainer problem defined only by (1) and (2), i.e., with no constraints on the final state. The sequence of outputs $e(0), e(1), \ldots, e(N-1)$ and the square root $Z\,x(N)$ of the terminal cost are related to the input sequence $u(0), u(1), \ldots, u(N-1)$ by the set of equations

$$\begin{aligned} e(0) &= C\, x_0 + D\, u(0), \\ e(1) &= C\,(A\, x_0 + B\, u(0)) + D\, u(1), \\ &\vdots \\ e(N-1) &= C\,(A^{N-1} x_0 + A^{N-2} B\, u(0) + \cdots + B\, u(N-2)) + D\, u(N-1), \\ Z\, x(N) &= Z\,(A^N x_0 + A^{N-1} B\, u(0) + \cdots + B\, u(N-1)), \end{aligned}$$

which can be written in the compact form

$$e_N = A_N\, x_0 + B_N\, u_N. \tag{15}$$

The sequence of controls u_N minimizing $\|e_N\|_2$ is obtained by applying the pseudoinverse property to (15). Hence

$$u_N^o = -B_N^{\#} A_N\, x_0. \tag{16}$$

It is worth noting that, in the case of an unconstrained final state, the optimal control sequence depends solely on the initial state x_0. From (15) and (16), it follows that

$$e_N^o = (I - B_N B_N^{\#})\, A_N\, x_0.$$

Hence, in the absence of constraints on the terminal state, the theorem is proven with

$$T_N := -B_N^{\#} A_N,$$
$$C_N := (I - B_N B_N^{\#})\, A_N.$$

In this case, of course, V_N and D_N are not defined.

The complete optimal control problem, including the constraint on the final state, can easily be solved by using Lemma 1 in the appendix. In fact, (15) and (7) are taken from (23) and (24), respectively, under the correspondences

$$\zeta = e_N, \quad \Phi = B_N, \quad \lambda = u_N, \quad \bar{\rho} = A_N\, x_0, \quad \Gamma = GL_N, \quad \bar{\sigma} = y_f - GA^N x_0. \tag{17}$$

The optimal control sequence u_N^o, as expressed in (13), can then be derived from (25) by taking into account the correspondences in (17). Similarly, the optimal extended output sequence e_N^o, as expressed in (14), can be derived from (26). □

REMARK 1. *Note that the optimal cost J^o can be expressed in terms of the matrices C_N and D_N defined in* (10) *and* (11) *as the quadratic form*

$$J^o = \begin{bmatrix} x_0 \\ y_f \end{bmatrix}' \begin{bmatrix} C_N' C_N & C_N' D_N \\ D_N' C_N & D_N' D_N \end{bmatrix} \begin{bmatrix} x_0 \\ y_f \end{bmatrix}. \tag{18}$$

The results of Theorem 1 apply whether the system (A, B) is stable or not, or stabilizable or not. However, stability of system (1) is usually required to avoid numerical problems concerning powers of dynamic matrix A arising in (12). A deep discussion on the ill-conditioning of powers of matrices with eigenvalues greater than one is provided in [7]. In the case of stabilizable systems, the following remark applies to overcome the ill-conditioning of matrices involved in Theorem 1.

REMARK 2. *If the system* (1) *is stabilizable, a preliminary pole placement is performed through feedback $u(k) = \bar{u}(k) + Hx(k)$ such that $\bar{A} := A + BH$ is stable and powers of $\bar{A}$ can be robustly computed. Now, let $\bar{u}^o(k)$ be the input in* (13) *which solves the optimal control problem for $(\bar{A}, B, C + DH, D)$. Then the solution for the original system (A, B, C, D) is simply computed as $u^o(k) = \bar{u}^o(k) + H\, x^o(k)$, where $x^o(k)$ is the optimal state time history, which is the same for both systems.*

REMARK 3. *Let P be a basis matrix of* $\ker B_N \cap \ker GL_N$*; see* (12) *and* (6). *From* (25) *of Lemma* 1 *in the appendix, it follows that all the solutions of Problem* 1 *lie on the linear variety*

$$u_N^o(\gamma) = T_N\, x_o + V_N\, y_f + P\, \gamma.$$

According to Remark 5 *in the appendix, the minimum* 2*-norm vector solving Problem* 1 *is*

$$\hat{u}_N^o = \hat{T}_N\, x_o + \hat{V}_N\, y_f,$$

with

$$\begin{aligned} \hat{T}_N &= (I - PP^{\#})\, T_N, \\ \hat{V}_N &= (I - PP^{\#})\, V_N. \end{aligned}$$

It is worth noting that, if the final state is unconstrained, i.e., $G = 0$ and $y_f = 0$ in (3), the technique herein devised proves to be an effective alternative to the solution of the difference (possibly generalized) Riccati equation. The main difference with respect to the Riccati equation is that the pseudoinversion procedure is not recursive in nature and, as already mentioned, is more general since it also works for constrained final state problems.

LQ optimal control problems with hard constraints on the final states are usually approached by means of dynamic programming techniques or gradient methods, which, although formalized in a wide nonlinear setting, always provide solutions through recursive procedures.

The results of Theorem 1 and Remarks 2 and 3 are summarized in the following algorithm solving Problem 1.

ALGORITHM 1.

Step 1. *Check the stability of matrix* A*, and stabilize it by a state feedback according to Remark* 2 *if necessary.*

Step 2. *Evaluate the matrices* A_N*,* B_N*, and* L_N *as defined in* (12) *and* (6)*. Note that if the final state* $x(N)$ *is completely assigned, the computation of the last row of* A_N *and* B_N *is skipped.*

Step 3. *Evaluate a basis matrix* K *for* $\ker(GL_N)$ *and the matrices* T_N*,* V_N*,* C_N*, and* D_N *as defined by* (8)*,* (9)*,* (10)*, and* (11)*. Compute the basis matrix* P *and the matrices* $\hat{T}_N$ *and* $\hat{V}_N$ *defined in Remark* 3 *if* u_N^o *is required to be minimum* 2*-norm.*

Step 4. *Evaluate the optimal control sequence* u_N^o *as defined by* (13) *and the optimal cost* J^o *as defined by* (18)*.*

3. The problem nesting procedure. In the proposed solution, the optimal control sequence is computed as a function of x_0 and y_f by pseudoinverting suitably defined matrices. Since the dimensions of the matrices to be pseudoinverted are proportional to the number of steps N of the control time interval, this technique is subject to a dimensionality constraint: N cannot be greater than a maximum which depends on the available computational capability. However, this drawback can be overcome by resorting to the contrivance of nesting problems of the same type at different levels, as described below for a two-level nesting procedure.

In what follows, extension of (4), (6), (12), (10), (11) is used to denote the variables defined on a generic N_1-step (or N_2-step) control time interval; i.e., the variable subscript is intended for denoting the control interval length.

Refer to Problem 1. For the sake of simplicity, assume that $N_1, N_2 \in \mathbb{Z}^+$ exist, satisfying the pseudoinversion dimensionality constraint and such that $N_1 N_2 = N$. Then the following corollary of Theorem 1 can be stated.

COROLLARY 1. *The solution of Problem* 1 *can be obtained through* N_2 *optimal control problems with* N_1 *steps and the final state sharply assigned* (first level problems) *and one optimal control problem with* N_2 *steps and the final state weighted*

and/or constrained as in the original problem (second level problem). *Let* R_{N_1} *be a basis matrix of the subspace* $\operatorname{im} L_{N_1}$. *Denote the initial and final states of the* j*th* $(j=1,\dots,N_2-1)$ *first level problem, respectively, by* $\tilde{x}(j)$ *and* $\tilde{x}(j+1)$, *and let them belong to the optimal state trajectory of the second level optimal control problem defined by the system*

$$\begin{aligned} \tilde{x}(j+1) &= \tilde{A}\tilde{x}(j)+\tilde{B}\alpha(j), \quad \tilde{x}(0)=x_0, \\ \tilde{e}(j) &= \tilde{C}\tilde{x}(j)+\tilde{D}\alpha(j), \end{aligned} \tag{19}$$

with

$$\begin{aligned} \tilde{A} &:= A^{N_1}, \\ \tilde{B} &:= R_{N_1}, \\ \tilde{C} &:= C_{N_1}+D_{N_1}A^{N_1}, \\ \tilde{D} &:= D_{N_1}R_{N_1}, \end{aligned} \tag{20}$$

and $\tilde{x}$, α, $\tilde{e}$ *vectors of suitable dimension, by the cost function*

$$\tilde{J}=\sum_{j=0}^{N_2-1}\tilde{e}(j)'\,\tilde{e}(j)+\tilde{x}(N_2)'\,Z'\,Z\,\tilde{x}(N_2) \tag{21}$$

and by the constraint

$$G\,\tilde{x}(N_2)=y_f. \tag{22}$$

Proof. Note that the optimal cost J_j of the jth first level N_1 steps problem is equal to the jth contribution to the optimal cost of the second level problem (this latter also equal to the original problem optimal cost). In fact,

$$\begin{aligned} J_j &= \begin{bmatrix} \tilde{x}(j) \\ \tilde{x}(j+1) \end{bmatrix}' \begin{bmatrix} C_{N_1}'C_{N_1} & C_{N_1}'D_{N_1} \\ D_{N_1}'C_{N_1} & D_{N_1}'D_{N_1} \end{bmatrix} \begin{bmatrix} \tilde{x}(j) \\ \tilde{x}(j+1) \end{bmatrix} \\ &= (C_{N_1}\tilde{x}(j)+D_{N_1}\tilde{x}(j+1))'\,(C_{N_1}\tilde{x}(j)+D_{N_1}\tilde{x}(j+1)), \end{aligned}$$

and

$$C_{N_1}\tilde{x}(j)+D_{N_1}\tilde{x}(j+1)=C_{N_1}\tilde{x}(j)+D_{N_1}\left(A^{N_1}\tilde{x}(j)+R_{N_1}\,\alpha(j)\right)=\tilde{C}\tilde{x}(j)+\tilde{D}\alpha(j)=\tilde{e}(j).$$

Hence the thesis is an immediate consequence of Theorem 1. □

For the nesting procedure to be convenient from the computational viewpoint, the row dimension of matrices $\tilde{C}$ and $\tilde{D}$ appearing in (19), equal to the row dimension of matrices C_{N_1} and D_{N_1}, should be reduced according to the following property.

PROPERTY 1. *Matrices* $\bar{C}_{N_1}\in\mathbb{R}^{(r\times n)}$ *and* $\bar{D}_{N_1}\in\mathbb{R}^{(r\times n)}$ *exist such that*

$$\begin{bmatrix} \bar{C}_{N_1}' \\ \bar{D}_{N_1}' \end{bmatrix} \begin{bmatrix} \bar{C}_{N_1} & \bar{D}_{N_1} \end{bmatrix} = \begin{bmatrix} C_{N_1}' \\ D_{N_1}' \end{bmatrix} \begin{bmatrix} C_{N_1} & D_{N_1} \end{bmatrix},$$

and whose row dimension is $r=\operatorname{rank}\,[C_{N_1}\ D_{N_1}]\le 2n$.

Matrices $\bar{C}_{N_1}$ and $\bar{D}_{N_1}$ can easily be evaluated through a standard singular value decomposition procedure. Note that their row dimension is not directly related to the value of N_1 and is $2n$ at most, while that of C_{N_1} and D_{N_1} is $q\,(N_1+1)$. On the other hand, substitution does not affect the optimal control inputs and the optimal cost for

the finite-horizon N_1N_2-step LQ problem. This is due to the way matrices C_N and D_N enter the optimal cost (18).

REMARK 4. *The assumption of $N = N_1N_2$ does not affect the generality of the proposed approach because, if this is not the case, one can divide the interval N into two parts of lengths N_a and $N_b = N_1N_2$ not violating the computational capability limits. Find the cost and the optimal control matrices on the two intervals, and then simply weld the N_a and N_b intervals by optimizing the overall cost with respect to the unknown state variable $x(N_a)$. Note that $x(N_a)$ must belong to the linear variety reachable in N_a steps from x_0.*

The following algorithm, based on Corollary 1, solves Problem 1 in a nested computational framework.

ALGORITHM 2.

Step 1. *Divide the control time interval into N_2 parts of N_1 steps each, where N_1 and N_2 are such that the maximum computational capability condition is met.*

Step 2. *Consider any of the N_2 subintervals and the corresponding N_1-step optimal control problem with the final state completely assigned and zero weighting matrix Z, referred to as the first level LQ problem. Note that, at this stage, both the initial and final states are assumed to be fixed, but they are, in general, unknown. Compute the resolvent matrices T_{N_1}, V_{N_1}, C_{N_1}, and D_{N_1} for the first level problem as described in steps* 1 *and* 2 *of Algorithm* 1 *and, if convenient, reduce the row dimension of C_{N_1} and D_{N_1} according to Property* 1. *These matrices are common to all the N_1-step optimal control problems.*

Step 3. *Solve the second level problem, defined by* (19), (21), *and* (22), *with Algorithm* 1, *thus obtaining the sequence of the intermediate states (i.e., the initial/terminal state of each pair of subsequent first level subintervals) as $\tilde{x}(j)$, $j \in [0, N_2]$.*

Step 4. *Use the jth pair of initial/terminal states $\tilde{x}(j), \tilde{x}(j+1)$ to solve the jth first level N_1-step problem as described in step* 3 *of Algorithm* 1. *Note that the matrices in* (13) *and* (15) *are equal for all the N_1-step problems and have been computed at step* 1.

Step 5. *The optimal control sequence and the optimal cost for the original control problem are simply obtained by grouping in a unique vector the optimal control sequences and summing up the optimal costs of all the N_1-step optimal control subproblems.*

The nesting idea enables extending the pseudoinversion procedure to finite-horizon LQ optimal control problems with a large value of N. However, the nesting procedure is subject to a dimensionality constraint, as well, which depends on the available computational capability and limits the admissible value of N_1 and N_2.

3.1. The multilevel nesting algorithm. This section shows how to overcome the drawback on the size of N_1 and N_2 for the two-level nesting procedure by means of a multi-level nesting algorithm whose innermost procedure is represented by the simple nesting procedure of Corollary 1.

The multilevel nesting algorithm reduces the computational effort needed to solve a finite-horizon LQ problem. The multilevel procedure basically corresponds to iteratively solving the second level N_2-step optimal control problem, stated in Step 2, by means of a further nesting procedure.

It is an easy matter to verify that the simple implementation of the iteration idea leads to increasing at each level the dimension of the matrices needed to compute the optimal cost $\|e_N^o\|_2^2$. Property 1 enables overcoming the dimensionality drawback

while iterating Algorithm 2 in the multilevel case. The multilevel nesting algorithm solves the N-step LQ optimal control problem as follows.

ALGORITHM 3.

Step 1. *Set* $k=1$ *and* $N_k=N$.

Step 2. *Divide the control time interval into* $N_k=N_{k,1}\,N_{k,2}$ *steps each, where* $N_{k,1}$ *is such that the computational complexity needed to evaluate the resolvent matrices* $T_{N_{k,1}}$, $V_{N_{k,1}}$, $C_{N_{k,1}}$, *and* $D_{N_{k,1}}$ *is met. Compute these matrices.*

Step 3. *Compute the reduced-size cost matrices* $\bar{C}_{N_{k,1}}\in\mathbb{R}^{(r_k\times n)}$ *and* $\bar{D}_{N_{k,1}}\in\mathbb{R}^{(r_k\times n)}$ *as described in Property* 1.

Step 4. *State the second-level* $N_{k,2}$*-step problem as defined in* (19), (21), *and* (22) *with these reduced-size cost matrices.*

Step 5. *Solve the* $N_{k,2}$ *step problem if this is computationally possible. If not, set* $k=k+1$ *and* $N_k=N_{k,2}$, *and go back to step* 1.

Step 6. *Move back over all the nested levels, and assess the optimal control input and the cost for the original* N*-step problem.*

Table 1 illustrates a four-level nesting algorithm. At the second and third levels, $k=2$ and $k=3$, only basic matrices for the innermost problems are evaluated. The two-level nested problem is completely solved only at the last nesting level, i.e., $k=4$. It is worth noting that if matrix factorization of Property 1 were not applied, the dimensions of the matrices $C_{N_{k,1}}$ and $D_{N_{k,1}}$ would significantly increase with k. In fact, at the nesting level $k+1$, both would be $q\prod_{j=1}^{k}N_{j,1}\times n$, while factorization implies the maximum value $r_{k+1}\times n$ with $r_{k+1}\le 2n$ at every step.

TABLE 1

A four-level nested procedure. Matrices are evaluated only for problems with $N_{1,1}$, $N_{2,1}$, $N_{3,1}$, *and* $N_{3,2}$ *steps.*

$k=1$	$N=N_{1,1}N_{1,2}$			
$k=2$	$\mathbf{N_1=N_{1,1}}$	$N_{1,2}=N_{2,1}N_{2,2}$		
$k=3$		$\mathbf{N_1=N_{2,1}}$	$N_{2,2}=N_{3,1}N_{3,2}$	
$k=4$			$\mathbf{N_1=N_{3,1}}$	$\mathbf{N_2=N_{3,2}}$

4. An example. As an illustrative example, let us consider the following constrained LQ optimal control problem for the system:

$$A=\begin{bmatrix} 0.5 & 1 & -0.4 & 0 \\ 0.1 & 0.7 & 0 & -0.5 \\ 0 & 0 & 0.4 & 0 \\ 0 & 0 & 0 & 0.6 \end{bmatrix},\quad B=\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 0 \\ 0 & 1 \end{bmatrix},\quad C=\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix},\quad D=\begin{bmatrix} 1 & 0 \\ 1 & 0.5 \end{bmatrix},$$

with initial condition $x_0=[1,\ 2,\ 3,\ 4]'$ and constrained final state and weighting matrix as

$$y_f=\begin{bmatrix} 1 \\ 1 \end{bmatrix}=\begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix}x(N),\quad Z=\begin{bmatrix} 1 & 0 & 2 & 1 \\ 0 & 0 & 3 & 1 \end{bmatrix}.$$

Problem 1 was first solved according to Algorithm 1 implemented in Matlab© 5.3 running on a 350 MhZ Pentium© II. The corresponding CPU time was 77.72 s. Instead, the CPU time corresponding to the implementation of Algorithm 2, with $N_1=25$ and $N_2=8$, was 0.676 s. Note that the three-level nesting procedure, with $N_{1,1}=8$, $N_{2,1}=5$, and $N_{2,2}=5$, yields a dramatic reduction of the CPU time: 0.16 s. The results for CPU times are summarized in Table 2.

TABLE 2
CPU time is compared for different nesting level algorithms.

Simple pseudoinversion	$N = 200$	CPU time $= 77.72\,s$
Two-level nesting	$N_1 = 8;\ N_2 = 25$	CPU time $= 0.676\,s$
Three-level nesting	$N_{1,1} = 8;\ N_{2,1} = 5;\ N_{2,2} = 5$	CPU time $= 0.16\,s$

It can be seen that the multilevel nesting algorithm greatly reduces the computational burden for the finite-horizon LQ optimal control problem.

The optimal cost is

$$\min_{u_{200}} J = 0.687,$$

and the final state is

$$x(200) = \begin{bmatrix} -0.4821 \\ 1.4821 \\ -0.5109 \\ 1.5109 \end{bmatrix}.$$

5. Concluding remarks. The problem considered in this paper is out of the standard scheme of LQ optimal control problems considered in the literature, not only because of the completely general approach which makes it possible to deal with cheap, singular, and regular problems with no distinction, but also because the state of the system can be sharply assigned at both the initial and final time instants. Furthermore, the proposed nesting procedure is very easily implementable thus making feasible the pseudoinversion solution of optimal control problems on a time interval of finite, but arbitrary, length.

A practical application of the algorithms described herein are the computations of convolution profiles for H_2-optimal tracking and H_2-optimal rejection of an N-step previewed signal in the nonminimum phase case. These problems were described by the authors in [14, 15], where geometric-type conditions for perfect or almost perfect tracking or rejection with stability were derived.

The possibility of using the algorithmic setting described in this paper for the solution of the standard discrete-time infinite-horizon LQR problem is under investigation.

Appendix. This appendix briefly presents the manipulations used in the proof of Theorem 1.

LEMMA 1. *The problem of finding a vector λ which minimizes the 2-norm of the vector*

$$\zeta := \Phi\,\lambda + \bar{\rho} \tag{23}$$

and satisfies the constraint

$$\Gamma\,\lambda = \bar{\sigma}, \tag{24}$$

where the matrices Φ, Γ and the column vectors $\bar{\rho}$, $\bar{\sigma}$ are given and the constraint (24) *is assumed to be feasible (i.e., satisfying $\bar{\sigma} \in \operatorname{im} \Gamma$), admits as the set of all solutions the linear variety*

$$\lambda^o(\gamma) := \left(I - K\,(\Phi K)^{\#}\,\Phi\right)\Gamma^{\#}\bar{\sigma} - K\,(\Phi K)^{\#}\,\bar{\rho} + P\,\gamma, \tag{25}$$

where K is a basis matrix for $\ker \Gamma$*, P is a basis matrix for* $\operatorname{im} K \cap \ker \Phi$*, and* γ *is a free vector parameterizing the solution* λ *in the column space of* P*.*

The corresponding ζ *vector with minimum* 2*-norm is given by*

$$\zeta^o := \left(I - \Phi K \left(\Phi K\right)^{\#}\right) \left(\Phi \Gamma^{\#} \bar{\sigma} + \bar{\rho}\right). \tag{26}$$

Proof. The constraint (24) can be solved with respect to λ as

$$\lambda = \Gamma^{\#} \bar{\sigma} + K \nu, \tag{27}$$

where ν parameterizes the solution in $\ker \Gamma$ whose basis matrix is K. Then the following expression for vector ζ can be obtained by substituting (27) into (23):

$$\zeta = \Omega \nu + \bar{\eta}, \tag{28}$$

where

$$\Omega := \Phi K, \qquad \bar{\eta} := \Phi \Gamma^{\#} \bar{\sigma} + \bar{\rho}. \tag{29}$$

The expression for ν minimizing the 2-norm of ζ is simply obtained as

$$\nu = -\Omega^{\#} \bar{\eta} + H \gamma, \tag{30}$$

where vector γ parameterizes the solution in $\ker \Omega$ whose basis matrix is H. The expression

$$\zeta^o = \left(I - \Omega \Omega^{\#}\right) \bar{\eta} \tag{31}$$

of the minimum norm vector ζ can then be obtained by substituting (30) into (28). Expression (26) for ζ^o is derived from (31) and (29). By substituting (30) into (27), it follows that

$$\lambda = \Gamma^{\#} \bar{\sigma} - K \Omega^{\#} \bar{\eta} + K H \gamma. \tag{32}$$

Moreover, since

$$\operatorname{im} H := \ker \left(\Phi K\right) = \ker K + \operatorname{im} Y,$$

with Y such that

$$\operatorname{im} \left(K Y\right) = \operatorname{im} K \cap \ker \Phi,$$

(32) can also be written as

$$\lambda = \Gamma^{\#} \bar{\sigma} - K \Omega^{\#} \bar{\eta} + P \gamma, \tag{33}$$

where P has been defined in the statement of the lemma. Finally, by substituting (29) into (33), linear variety (25) is obtained. □

Remark 5. *The minimum* 2*-norm vector* λ *minimizing the cost function* (23) *is*

$$\lambda^o = \left(I - P P^{\#}\right) \left(\left(I - K \left(\Phi K\right)^{\#} \Phi\right) \Gamma^{\#} \bar{\sigma} - K \left(\Phi K\right)^{\#} \bar{\rho}\right),$$

obtained by choosing

$$\gamma = -P^{\#} \left(\left(I - K \left(\Phi K\right)^{\#} \Phi\right) \Gamma^{\#} \bar{\sigma} - K \left(\Phi K\right)^{\#} \bar{\rho}\right);$$

see (25)*. If the minimum norm is not required, a plainer expression for* λ *follows by assuming that* $\gamma = 0$*.*

NULL CONTROLLABILITY WITH VANISHING ENERGY*

ENRICO PRIOLA† AND JERZY ZABCZYK‡

Abstract. Linear, null controllable systems, for which an arbitrary initial state can be transferred to the origin with arbitrarily small energy, are characterized. Theorems are stated in terms of an associated algebraic Riccati equation and in terms of the spectrum of the linear part of the system. The results so obtained allow us to determine Ornstein–Uhlenbeck operators for which the Liouville theorem about bounded harmonic functions holds.

Key words. null controllability, minimal energy, algebraic Riccati equation

1. Introduction.

In this paper we are concerned with the following infinite dimensional linear control system:

$$\frac{dy}{dt} = Ay(t) + Bu(t), \quad y(0) = x \in H, \tag{1.1}$$

$t \geq 0$, where H denotes a *complex* Hilbert space, with inner product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$, and A is a possibly unbounded linear operator on H, which generates a $\mathcal{C}_0$-semigroup e^{tA} on H. Moreover, B is a bounded linear operator from another Hilbert space U into H, i.e., $B \in \mathcal{L}(U, H)$, and $u : [0, +\infty) \to U$ is a locally square integrable function, which represents the control on the system. For any control function u, there exists a weak solution $y^{x,u}(t)$ of (1.1), which is given by

$$y^{x,u}(t) = e^{tA}x + \int_0^t e^{(t-s)A}Bu(s)ds, \quad t \geq 0;$$

see, for instance, [10]. The system (1.1) is called *null controllable* if it is null controllable at some universal time $\tilde{T} > 0$. This means that for any state $a \in H$, we can find a control u such that $y^{a,u}(\tilde{T}) = 0$ (the control u transfers a to 0 at time $\tilde{T}$); see [28], [1], [2], [5], [17], [18], [25]. Throughout the paper we will assume that the system (1.1) is null controllable. Taking into account that 0 is an equilibrium point for our system, the following definition has a clear control-theoretic meaning. We say that the system (1.1) is *null controllable with vanishing energy*, *an NCVE system* for short, if it is null controllable and for any $x \in H$ there exists a sequence of controls (u_n) and of times (T_n) such that $y^{x,u_n}(T_n) = 0$ for any $n \in \mathbf{N}$, and

$$\lim_{n\to\infty} \int_0^{T_n} |u_n(s)|^2 ds = 0. \tag{1.2}$$

The purpose of this paper is to characterize NCVE systems. This characterization will be given in terms of spectral properties of A as well as in terms of *maximal solutions* to an associated algebraic Riccati equation. To the best of our knowledge, the concept of an NCVE system is formulated for the first time in this paper. However, important examples of NCVE systems have been already investigated; see, for instance, [14] and references therein.

Let us recall that the *spectral bound* $s(A)$ of the operator A is given by the formula $s(A) = \sup\{\mathrm{Re}(\lambda) : \lambda \in \sigma(A)\}$, where $\sigma(A)$ denotes the spectrum of A. (If $\sigma(A) = \emptyset$, then $\mathrm{s}(A) = -\infty$.) A vector $x \neq 0$ is called a *generalized eigenvector* of the operator A if there exists $\lambda \in \mathbf{C}$ and a natural number k such that $(\lambda - A)^k x = 0$. Note that necessarily $x \in D(A^k)$ and if $k = 1$, then x is an eigenvector of A. A $\mathcal{C}_0$-semigroup e^{tA} is said to be *exponentially stable* if there exist $M > 0$, $\omega < 0$ such that for all $t \geq 0$, $\|e^{tA}\|_{\mathcal{L}(H)} \leq Me^{\omega t}$. To formulate our first main result we need the following assumptions.

Hypothesis 1.1.

(i) There exists a sequence $(\lambda_n) \subset \sigma(A)$ such that each λ_n is isolated in $\sigma(A)$ and $\lim_{n\to\infty} \mathrm{Re}(\lambda_n) = s(A)$.

(ii) There exist closed linear subspaces H_s and H_u invariant for e^{tA}, $t \geq 0$, such that their direct sum is H, i.e., $H = H_s \oplus H_u$ and, moreover,
   (a) the semigroup e^{tA} restricted to H_s is exponentially stable on H_s,
   (b) the set of all generalized eigenvectors of A contained in H_u is linearly dense in H_u.

THEOREM 1.1. *Let the system* (1.1) *be null controllable and assume that Hypothesis* 1.1 *holds. Then the following statements are equivalent:*

(a) *the system* (1.1) *is NCVE;*

(b) $s(A) = \sup\{\mathrm{Re}(\lambda) : \lambda \in \sigma(A)\} \leq 0$.

What seems surprising, even in the finite dimensional case, is that the solutions of the uncontrolled linear system may have a polynomial growth, but nevertheless any state can be transferred to 0 with arbitrarily small energy. As we shall see in section 5.2, the index $s(A)$ cannot be replaced by $\omega(A)$, the growth bound of the semigroup e^{tA}, $\omega(A) = \inf\{\omega \in \mathbf{R} : \|e^{tA}\|_{\mathcal{L}(H)} \leq Me^{\omega t}$ for some M and all $t \geq 0\}$. We will comment on Hypothesis 1.1 in section 5.3.

Let us consider a smaller class of the so-called exactly controllable systems. The system (1.1) is called *exactly controllable* if it is exactly controllable at some $\tilde{T} > 0$, i.e., for any $a, b \in H$, there exists a control $\hat{u} = u_{a,b}$ such that $y^{a,\hat{u}}(\tilde{T}) = b$. We say that (1.1) is *exactly controllable with vanishing energy, an ECVE system* for short, if it is exactly controllable and for any a, $b \in H$, there exists a sequence of controls (u_n) and of times (T_n) such that $y^{a,u_n}(T_n) = b$, $n \in \mathbf{N}$, and (1.2) holds. An analogue of Theorem 1.1 for exactly controllable systems is stated below.

THEOREM 1.2. *Assume the system* (1.1) *is exactly controllable, the operator A generates a $\mathcal{C}_0$-group on H, and Hypothesis* 1.1 *holds. Then the following statements are equivalent:*

(a) *the system* (1.1) *is ECVE;*

(b) $\sigma(A) \subset \{i\lambda : \lambda \in \mathbf{R}\}$.

Applications of these theorems to delay systems and hyperbolic and parabolic equations are given in section 6. In order to prove Theorems 1.1 and 1.2, we combine arguments from both control theory and spectral theory. Moreover, we will apply our third main result, which requires only the null controllability of (1.1).

THEOREM 1.3. *A null controllable system* (1.1) *is NCVE if and only if the algebraic Riccati equation*

$$PA + A^*P - PBB^*P = 0, \quad P \geq 0, \tag{1.3}$$

has a unique bounded nonnegative solution $P = 0$.

This theorem will be a consequence of a stronger result concerning a more general algebraic Riccati equation:

$$PA + A^*P - PBB^*P + R = 0, \tag{1.4}$$

where R is a symmetric, bounded, nonnegative operator on H. By a *solution* P of this equation we mean a bounded nonnegative operator P such that for any $x, y \in D(A)$,

$$\langle Px, Ay\rangle + \langle PAx, y\rangle - \langle PBB^*Px, y\rangle + \langle Rx, y\rangle = 0. \tag{1.5}$$

A solution $\hat{P}$ of (1.5) is called *maximal* if for any solution S of (1.5), we have $S \leq \hat{P}$, i.e., $\langle Sx, x\rangle \leq \langle \hat{P}x, x\rangle$, $x \in H$; see [3], [16], [2]. In the literature results close to the next theorem are available; see, for instance, [2, p. 283], [17], [18], and [9]. However, since we could not find the exact statement we needed, we decided to include it in the present paper.

THEOREM 1.4. *If the system* (1.1) *is null controllable, then for an arbitrary linear, bounded operator* $R \geq 0$ *there exists a maximal solution* $\hat{P} \geq 0$ *of the equation* (1.4)*, and it is given by the formula*

$$\langle \hat{P}x, x\rangle = \inf_{t \geq \tilde{T}} \inf_{u \in L^2(0,t;U),\ y^{x,u}(t)=0} \left\{ \int_0^t (\langle Ry^{x,u}(s), y^{x,u}(s)\rangle + |u(s)|^2) ds \right\}. \tag{1.6}$$

We conjecture that results similar to Theorems 1.1 and 1.2 could be true even for control systems in Banach spaces; however, the proofs should be different from ours. Indeed, a satisfactory theory of the linear quadratic problem involving the differential Riccati equation is not available in general Banach spaces, even in the reflexive case. It would be also interesting to extend our characterizations to systems with unbounded control operators B, in particular to boundary control systems described by linear PDEs; see [26], [1], [2], [17], [18]. This extension will be a subject of our future research.

There are close links between the results of the present paper and the theory of bounded harmonic functions for the so-called Ornstein–Uhlenbeck operator. Consider an H-valued Ornstein–Uhlenbeck process X satisfying the following equation:

$$dX(t) = AX(t)dt + BdW(t), \quad X(0) = x \in H,\ t \geq 0,$$

where W is a U-valued Wiener process. The generator $\mathcal{L}$ of the process X is called an Ornstein–Uhlenbeck operator. A function h such that $\mathcal{L}h = 0$ is called harmonic for $\mathcal{L}$. The problem of existence of bounded harmonic functions for differential operators is called the Liouville problem and is intensively studied; see, e.g., [20] and [23]. Roughly speaking, in our special situation, there exist nonconstant, bounded, harmonic functions for $\mathcal{L}$ if and only if the associated control system is not NCVE. We study this topic in a separate paper [21]. We also mention that a preliminary expanded version of our results is given in [22], which contains additional details.

Section 2 is devoted to preliminaries from spectral theory and linear control theory. Section 3 is on the proof of Theorems 1.4 and 1.3. In section 4 we will give a proof of Theorems 1.1 and 1.2. Comments and possible extensions are discussed in section 5. In section 6 we collect some examples which illustrate our results.

2. Preliminaries.

2.1. Basic concepts from spectral theory. Let us introduce some basic facts from spectral theory. Let $A : D(A) \subset H \to H$ be a closed operator with dense domain and denote by $\sigma(A)$ its spectrum. An element $\mu \in \sigma(A)$ is called *isolated* if there exists a neighborhood U of μ such that $U \cap \sigma(A) = \{\mu\}$.

Let $\lambda \in \mathbf{C}$ be an eigenvalue of A. The dimension of $\mathrm{Ker}(\lambda - A)$ is called the geometric multiplicity of λ. Remark that $\mathrm{Ker}(\lambda - A)^k \subset \mathrm{Ker}(\lambda - A)^{k+1}$, $k \in \mathbf{N}$. Hence we can say that v is a generalized eigenvector of A if

$$v \in \bigcup_{k \geq 1} \mathrm{Ker}(\lambda - A)^k.$$

If there exists p such that $\mathrm{Ker}(\lambda - A)^p = \mathrm{Ker}(\lambda - A)^{p+1}$ and $\dim(\mathrm{Ker}(\lambda - A)^p) = m < \infty$, then λ is named an eigenvalue with finite algebraic multiplicity m. (The integer p is named the index of λ.) We refer to [11] for more details on this subject.

Let $A : D(A) \subset H \to H$ be the generator of a $\mathcal{C}_0$-semigroup e^{tA}. A closed subspace $K \subset H$ is called *invariant* for e^{tA} if $e^{tA}(K) \subset K$, $t \geq 0$. In this case we have that $A(D(A) \cap K) \subset K$ and the restriction of e^{tA} to K is still a $\mathcal{C}_0$-semigroup on K with generator $A^K : (D(A) \cap K) \subset K \to K$, $A^K v = Av$, $v \in D(A) \cap K$.

In what follows we need the following theorem which provides the existence of useful invariant subspaces for e^{tA}; see Lemma 2.5.7 in [5] and [10, p. 245].

Assume that $\sigma(A) = \sigma_0 \cup \sigma_1$, where σ_0 and σ_1 are two disjoint closed subsets of $\mathbf{C}$ and, in addition, σ_0 is bounded. Since the distance between σ_0 and σ_1 is positive, there exists a bounded open set Ω containing σ_0 such that its closure is disjoint from σ_1. We may assume that the boundary γ of Ω consists of a finite number of rectifiable, closed simple Jordan paths oriented in the usual positive direction. Let us introduce the spectral Riesz projection P_0:

$$P_0 x = \frac{1}{2\pi i} \int_\gamma (w - A)^{-1} x \, dw, \quad x \in H. \tag{2.1}$$

Define $P_0 H = E_0$. (Note that E_0 can be equal to H.) We get the *spectral decomposition*

$$H = E_0 \oplus E_1, \quad E_1 = P_1 H, \ \text{ where } \ (I - P_0) = P_1. \tag{2.2}$$

The closed subspaces E_0 and E_1 are invariant for e^{tA} and, moreover, $E_0 \subset D(A)$. The restrictions A_i of A to E_i, $i = 0, 1$, satisfy $\sigma(A_i) = \sigma_i$. We have

$$A_0 : E_0 \to E_0, \quad A_1 : (D(A) \cap E_1) \subset E_1 \to E_1. \tag{2.3}$$

The operator A_0 generates a uniformly continuous group e^{tA_0} on E_0, and A_1 generates a $\mathcal{C}_0$-semigroup e^{tA_1} on E_1. The restrictions of e^{tA} to E_0 and E_1 coincide with e^{tA_0} and e^{tA_1}, respectively.

If H, K are two Hilbert spaces, we denote by $\mathcal{L}(H, K)$ the Banach space of all bounded linear operators from H into K endowed with the uniform norm $\|\cdot\|_{\mathcal{L}(H,K)}$. In particular, when $H = K$, we set $\mathcal{L}(H, H) = \mathcal{L}(H)$ and $\|\cdot\|_{\mathcal{L}(H)} = \|\cdot\|$. Let us consider the cone $\mathcal{K}_+(H)$ of $\mathcal{L}(H)$ consisting of all symmetric nonnegative bounded linear operators on H. On $\mathcal{K}_+(H)$, we will have the following order:

$$T \leq S \quad \Leftrightarrow \quad \langle Tx, x\rangle \leq \langle Sx, x\rangle, \quad x \in H, \ T, S \in \mathcal{K}_+(H).$$

Note that $\langle Tx, x\rangle = \langle Sx, x\rangle$, $x \in H$, implies that $T = S$. We will use the following result: if a family $(P_t) \subset \mathcal{K}_+(H)$, $t > 0$, is decreasing as t tends to 0^+, then there exists $P \in \mathcal{K}_+(H)$ such that P_t converges strongly to P (see [5, p. 606]), i.e.,

$$\lim_{t\to 0^+} P_t x = Px, \quad x \in H, \quad \text{or equivalently} \quad \lim_{t\to 0^+} \langle P_t x, x\rangle = \langle Px, x\rangle, \quad x \in H. \tag{2.4}$$

2.2. Control-theoretic concepts. Let us collect here some preliminaries from control theory which will be used throughout the paper; for more details, see [28] or [5]. The system (1.1) will often be denoted by the pair (A, B).

Set $Q = BB^*$ and introduce the *controllability operator* Q_t,

$$Q_t x = \int_0^t e^{sA}\, BB^*\, e^{sA^*} x\, ds \;=\; \int_0^t e^{sA} Q e^{sA^*} x\, ds, \quad t > 0,\ x \in H, \tag{2.5}$$

where B^* denotes the adjoint operator of B and the integral is in the Bochner sense. We remark that the null controllability of (1.1) at time $\tilde{T} > 0$ implies the null controllability at any $t \geq \tilde{T}$. It is known that the null controllability of (1.1) at $\tilde{T}$ is equivalent to the following condition:

$$e^{\tilde{T}A}(H) \subset Q_{\tilde{T}}^{1/2}(H). \tag{2.6}$$

By the closed graph theorem the operator $\Gamma_s = Q_s^{-1/2} e^{sA}$ is a well-defined bounded linear operator on H for any $s \geq \tilde{T}$. Fix $a \in H$; among the controls u steering a to 0 at time $t \geq \tilde{T}$, there exists a unique optimal control $\hat{u}$ which minimizes the energy functional $u \mapsto \int_0^t |u(s)|^2 ds$, and, moreover,

$$\int_0^t |\hat{u}(s)|^2 ds = |\Gamma_t a|^2 = \langle \Gamma_t^* \Gamma_t a, a\rangle, \quad \text{where } \Gamma_t a = Q_t^{-1/2} e^{tA} a. \tag{2.7}$$

Thus $|Q_t^{-1/2} e^{tA} a|^2$ is the minimal energy to attain 0 from a at time t, and Γ_t is sometimes called the *minimal energy operator*.

Since the map: $t \mapsto |\Gamma_t x|^2$ is decreasing, we get that the system (1.1) is NCVE *if and only if*

$$\lim_{t\to+\infty} |\Gamma_t x|^2 = 0, \quad x \in H.$$

Now let us deal with *exactly controllable systems*. It is known that the system (A, B) is *exactly controllable* at $t > 0$ if and only if Q_t is one to one and onto on H. When (A, B) is exactly controllable at $t > 0$, one can define the minimal energy $E_t(a, b)$, which is needed to transfer the state a into b at time $t > 0$,

$$E_t(a,b) = E_t^{(A,B)}(a,b) = \inf_{u\in L^2(0,t;U)} \left\{ \int_0^t |u(s)|^2 ds \,:\, y^{a,u}(t) = b \right\}, \quad a,\ b \in H, \tag{2.8}$$

where $y^{a,u}$ denotes the solution to (1.1) such that $y^{a,u}(0) = a$. Note that $|\Gamma_t a|^2 = E_t(a, 0)$, $a \in H$; see (2.7). It is known (see, e.g., [28]) that $E_t(a, b) = |Q_t^{-1/2}(e^{tA}a - b)|^2$ and that there exists an optimal control $\hat{u}$ such that $E_t(a, b) = \int_0^t |\hat{u}(s)|^2 ds$. It is clear that (1.1) is an ECVE system *if and only if* $\lim_{t\to+\infty} E_t(a, b) = 0$ for any a, $b \in H$.

We remark that if (A, B) is null controllable at $t > 0$ and, in addition, A generates a $\mathcal{C}_0$-group on H, then (A, B) is exactly controllable at $t > 0$. Moreover, if $H = \mathbf{R}^n$,

$U = \mathbf{R}^m$, and (A, B) is null controllable at some $t_0 > 0$, then (A, B) is exactly controllable at any $t > 0$.

Let us consider the *Lyapunov equation*:

$$\langle Ax, Ky\rangle + \langle Kx, Ay\rangle = -\langle Sx, y\rangle, \quad x,\, y \in D(A), \tag{2.9}$$

where $S \in \mathcal{K}_+(H)$ and A generates an exponentially stable semigroup e^{tA} on H, i.e., $\omega(A) < 0$. Then there exists a unique solution $K \in \mathcal{K}_+(H)$ to (2.9) which is given by

$$Kx = \int_0^\infty e^{sA} S e^{sA^*} x ds, \;\; x \in H.$$

Finally recall that a solution $P \in \mathcal{K}_+(H)$ to the *algebraic Riccati equation*

$$\langle Px, Ay\rangle + \langle PAx, y\rangle - \langle PBB^*Px, y\rangle + \langle Rx, y\rangle = 0, \;\; x,\, y \in D(A),$$

has the properties that $P(D(A)) \subset D(A^*)$ and, in addition, that $PAx + A^*Px - PBB^*Px + Rx = 0$ for any $x \in D(A)$.

3. Proofs of Theorems 1.4 and 1.3. Throughout this section we assume only that the system (1.1) is *null controllable at some* $\tilde{T} > 0$. Let $R,\, S \in \mathcal{K}_+(H)$, $Q = BB^*$. We introduce the infinite dimensional *differential Riccati equation*:

$$\frac{d}{dt}P_t = A^*P_t + P_tA + R - P_tQP_t, \;\; t > 0, \quad P_0 = S. \tag{3.1}$$

We say that a map $t \mapsto P_t \in \mathcal{L}(H)$, $t \geq 0$, such that $P_0 = S$ is a (global) solution of (3.1) if for any $h, k \in D(A)$ the real map $t \to \langle P_t h, k\rangle$ is absolutely continuous on $[0, +\infty)$ and it satisfies

$$\frac{d}{dt}\langle P_t h, k\rangle = \langle P_t h, Ak\rangle + \langle P_t Ah, k\rangle + \langle Rh, k\rangle - \langle P_t Q P_t h, k\rangle \tag{3.2}$$

for almost all $t > 0$. It is well known (see, e.g., [28]) that for any $S \in \mathcal{K}_+(H)$ there exists a unique solution $P_t = P_t^S \in \mathcal{L}(H)$ to (3.1). Moreover, $P_t^S \in \mathcal{K}_+(H)$ and

$$\langle P_t^S x, x\rangle = \inf_{u \in L^2(0,t;U)} \left\{ \int_0^t (|u(s)|^2 + \langle Ry^{x,u}(s), y^{x,u}(s)\rangle) ds + \langle Sy^{x,u}(t), y^{x,u}(t)\rangle \right\}, \tag{3.3}$$

$t \geq 0$, where $y^{x,u}$ is the solution of (1.1), $y^{x,u}(0) = x$.

Let us introduce the quantity $\Gamma_t^R(x)$ generalizing $|\Gamma_t x|^2$ as

$$\begin{aligned} \Gamma_t^R(x) &= \inf_{u \in L^2(0,t;U):\; y^{x,u}(t) = 0} J_t(u), \quad \text{where} \\ J_t(u) &= J_t^x(u) = \int_0^t (\langle Ry^{x,u}(s), y^{x,u}(s)\rangle + |u(s)|^2) ds, \quad t \geq \tilde{T}. \end{aligned} \tag{3.4}$$

Of course, choosing $R = 0$, we get $\Gamma_t = \Gamma_t^0$. We remark that the map $t \mapsto \Gamma_t^R(x)$ is decreasing on $[\tilde{T}, +\infty)$ for any $x \in H$.

In order to prove Theorem 1.4 we proceed as follows. First we show that $\Gamma_t^R(\cdot)$ is a quadratic functional on H. Then we prove that the map $t \mapsto (\Gamma_t^R)^*\Gamma_t^R \in \mathcal{L}(H)$ satisfies the differential Riccati equation (3.2). Finally we obtain that $(\Gamma_t^R)^*\Gamma_t^R$ *converges strongly* to the *maximal* solution $\hat{P}$ of the algebraic Riccati equation (1.4) as $t \to +\infty$.

We start to establish some properties of Γ_t^R (see also [4, Theorem 1.2]), where a related result is proved.

LEMMA 3.1. *For any $t \geq \tilde{T}$, the following statements hold:*

(i) *there exists a unique control $\hat{u}$ minimizing the functional J_t in* (3.4)*;*

(ii) *the map Γ_t^R is a quadratic functional of x; i.e., we have $\Gamma_t^R(x) = \langle \Gamma_t^R x, x\rangle$, where $\Gamma_t^R \in \mathcal{K}_+(H)$.*

Proof. (i) Inserting the explicit formula for $y^{x,u}$ into the functional J_t and using the linear operator $L_t : L^2(0,t;U) \to L^2(0,t;H)$, $L_t u(s) = \int_0^s e^{(s-r)A} Bu(r)dr$, $s \in (0,t)$, $u \in L^2(0,t;U)$, we get

$$J_t(u) = a + \langle v, u\rangle_{L^2(0,t;U)} + \langle Wu, u\rangle_{L^2(0,t;U)}, \tag{3.5}$$

where $a = \int_0^t \langle R(e^{sA}x), e^{sA}x\rangle ds$, $v = 2L_t^* R\,(e^{(\cdot)\,A}x)$, $Wu = u + L_t^* R(L_t u(\cdot))$. Noting that W is a coercive symmetric operator on $L^2(0,t;U)$ we obtain that J_t is a continuous, strictly convex, and coercive functional on $L^2(0,t;U)$. Hence the infimum of J_t over the nonempty affine set of all $u \in L^2(0,t;U)$ such that

$$\int_0^t e^{(t-r)A} Bu(r)dr = -e^{tA}x$$

is attained at exactly one point $\hat{u}$. This proves (i).

(ii) Let us define the cost functionals $J_t^\epsilon : L^2(0,t;U) \to \mathbf{R}$:

$$J_t^\epsilon(u) = \int_0^t (\langle Ry^{x,u}(s), y^{x,u}(s)\rangle + |u(s)|^2)ds + \frac{1}{\epsilon}\langle y^{x,u}(t), y^{x,u}(t)\rangle, \quad \epsilon > 0,$$

$u \in L^2(0,t;U)$. We know that the infimum of J_t^ϵ over all controls u is $\langle P_t^\epsilon x, x\rangle$, where P_t^ϵ verifies

$$\frac{d}{dt}P_t^\epsilon = A^* P_t^\epsilon + P_t^\epsilon A + R - P_t^\epsilon Q P_t^\epsilon, \quad t > 0, \quad P_0^\epsilon = \frac{1}{\epsilon} I.$$

By the definition of Γ_t^R it is clear that $P_t^\epsilon \leq \Gamma_t^R$ for any $\epsilon > 0$. Note that P_t^ϵ is increasing as ϵ tends to 0. Hence $\Gamma_t^R - P_t^\epsilon$ is decreasing in $\mathcal{K}_+(H)$. It follows that P_t^ϵ converges strongly to some $P_t \in \mathcal{K}_+(H)$ as $\epsilon \to 0^+$, i.e.,

$$\lim_{\epsilon \to 0^+} \langle P_t^\epsilon x, x\rangle = \langle P_t x, x\rangle, \quad x \in H,\ t > 0.$$

Our next goal will be to verify that $\Gamma_t^R = P_t$. This will give the assertion (ii). For this purpose, we show that

$$\lim_{\epsilon \to 0^+} \langle P_t^\epsilon x, x\rangle = \lim_{\epsilon \to 0^+} J_t^\epsilon(u_\epsilon) = J_t(\hat{u}), \quad t \geq \tilde{T}, \tag{3.6}$$

where u_ϵ are the controls which minimize J_t^ϵ and $\hat{u}$ is the control which minimizes J_t among all controls steering x to 0 in time t. We will also obtain that u_ϵ converges weakly to $\hat{u}$ as ϵ tends to 0.

First recall that, by (3.5), we have

$$\begin{aligned} J_t^\epsilon(u) &= a + \langle v, u\rangle_{L^2(0,t;U)} + \langle Wu, u\rangle_{L^2(0,t;U)} + \frac{1}{\epsilon}|e^{tA}x + \mathcal{L}_t u|^2 \\ &= J_t(u) + \frac{1}{\epsilon}|e^{tA}x + \mathcal{L}_t u|^2, \quad u \in L^2(0,t;U), \end{aligned}$$

where $\mathcal{L}_t : L^2(0,t;U) \to H$, $\mathcal{L}_t u = \int_0^t e^{(t-s)A} B u(s) ds$. It follows that

$$J_t^\epsilon(u_\epsilon) = J_t(u_\epsilon) + \frac{1}{\epsilon}|e^{tA}x + \mathcal{L}_t u_\epsilon|^2 \le J_t^\epsilon(\hat{u}) = J_t(\hat{u}), \quad \epsilon > 0.$$

Since W is coercive, we deduce that the set (u_ϵ), $\epsilon > 0$, is uniformly bounded in $L^2(0,t;U)$. Thus it is possible to extract from (u_ϵ) a sequence, still denoted by u_ϵ, such that u_ϵ converges weakly to $u_0 \in L^2(0,t;U)$. We prove that u_0 transfers x to 0 at time t, i.e.,

$$e^{tA}x + \mathcal{L}_t u_0 = 0. \tag{3.7}$$

Computing the directional derivative of J_t^ϵ in u_ϵ along any direction $v \in L^2(0,t;U)$, we get

$$0 = DJ_t^\epsilon(u_\epsilon, v) = \langle v, u_\epsilon \rangle_{L^2(0,t;U)} + 2\langle W u_\epsilon, v \rangle_{L^2(0,t;U)} + \frac{2}{\epsilon}\langle e^{tA}x + \mathcal{L}_t u_\epsilon, \mathcal{L}_t v \rangle, \ \epsilon > 0.$$

Since u_ϵ converges weakly to u_0, it is clear that the above identities can be true only if $\langle e^{tA}x + \mathcal{L}_t u_\epsilon, \mathcal{L}_t v \rangle$ converges to 0 as $\epsilon \to 0^+$. We have

$$\langle e^{tA}x + \mathcal{L}_t u_0, \mathcal{L}_t v \rangle = 0, \quad v \in L^2(0,t;U). \tag{3.8}$$

Now we can choose a control v_1 such that $\mathcal{L}_t v_1 = e^{tA}x$ because the system (1.1) is null controllable at time t. Taking the control $v = u_0 + v_1$ in (3.8), we obtain $|e^{tA}x + \mathcal{L}_t u_0|^2 = 0$ and so (3.7) is verified.

Using that J_t is weakly lower semicontinuous and $J_t(\hat{u}) \ge J_t^\epsilon(u_\epsilon)$, we get

$$J_t(\hat{u}) \ge \liminf_{\epsilon \to 0} \left(J_t(u_\epsilon) + \frac{1}{\epsilon}|e^{tA}x + \mathcal{L}_t u_\epsilon|^2 \right) \ge \liminf_{\epsilon \to 0} J_t(u_\epsilon) \ge J_t(u_0). \tag{3.9}$$

Since $y^{x,\hat{u}}(t) = y^{x,u_0}(t) = 0$ and $\hat{u}$ was the minimum point for J_t, we get that $\hat{u} = u_0$. Moreover, by (3.9) we achieve $\liminf_{\epsilon \to 0} J_t^\epsilon(u_\epsilon) = J_t(u_0)$. Using that $J_t^\epsilon(u_\epsilon)$ is increasing we finally get

$$\lim_{\epsilon \to 0^+} J_t^\epsilon(u_\epsilon) = J_t(\hat{u}). \qquad \square$$

LEMMA 3.2. *The following assertions hold:*

(i) *The map* $t \mapsto P_t = (\Gamma_t^R)^* \Gamma_t^R \in \mathcal{L}(H)$ *solves*

$$\frac{d}{dt}P_t = A^* P_t + P_t A + R - P_t Q P_t \ \text{ for any } \ t \ge \tilde{T}. \tag{3.10}$$

(ii) *For any* $S \in \mathcal{K}_+(H)$, *denoting by* P_t^S, $t \ge 0$, *the unique solution of* (3.1), *one has* $P_t^S \le (\Gamma_t^R)^* \Gamma_t^R$, $t \ge \tilde{T}$.

Proof. For simplicity of notation, we will write $\hat{\Gamma}_t$ instead of Γ_t^R.

(i) Fix any $t \ge \tilde{T}$. We prove the assertion by showing that

$$P_s^{\hat{\Gamma}_t^* \hat{\Gamma}_t} = \hat{\Gamma}_{t+s}^* \hat{\Gamma}_{t+s}, \quad s \ge 0. \tag{3.11}$$

Fix $x \in H$ and let $\hat{u}$ be the control which transfers x to 0 in time $t+s$ with the minimal energy. Then we have

$$\begin{aligned}
\langle \hat{\Gamma}_{t+s}x, \hat{\Gamma}_{t+s}x \rangle &= \int_0^{t+s} (\langle R y^{x,\hat{u}}(r), y^{x,\hat{u}}(r) \rangle + |\hat{u}(r)|^2) dr \\
&= \int_0^s (\langle R y^{x,\hat{u}}(r), y^{x,\hat{u}}(r) \rangle + |\hat{u}(r)|^2) dr + \int_s^{s+t} (\langle R y^{x,\hat{u}}(r), y^{x,\hat{u}}(r) \rangle + |\hat{u}(r)|^2) dr \\
&\ge \int_0^s (\langle R y^{x,\hat{u}}(r), y^{x,\hat{u}}(r) \rangle + |\hat{u}(r)|^2) dr + \langle \hat{\Gamma}_t y^{x,\hat{u}}(s), \hat{\Gamma}_t y^{x,\hat{u}}(s) \rangle \ge \langle P_s^{\hat{\Gamma}_t^* \hat{\Gamma}_t} x, x \rangle.
\end{aligned}$$

On the other hand, for any arbitrary control u, writing $z(s) = y^{x,u}(s)$, there results

$$\begin{aligned}
&\int_0^s (\langle Ry^{x,u}(r), y^{x,u}(r)\rangle + |u(r)|^2)dr + \langle \hat\Gamma_t^*\hat\Gamma_t y^{x,u}(s), y^{x,u}(s)\rangle \\
&= \int_0^s (\langle Ry^{x,u}(r), y^{x,u}(r)\rangle + |u(r)|^2)dr + \int_0^t (\langle Ry^{z(s),v}(r), y^{z(s),v}(r)\rangle + |v(r)|^2)dr \\
&= \int_0^s (\langle Ry^{x,u}(r), y^{x,u}(r)\rangle + |u(r)|^2)dr \\
&\quad + \int_s^{t+s} (\langle Ry^{z(s),v}(w-s), y^{z(s),v}(w-s)\rangle + |v(w-s)|^2)dw,
\end{aligned}$$

where v is the optimal control which transfers the state $z(s) = y^{x,u}(s)$ to 0 in time t with the minimal energy. Consequently the control $\tilde u$,

$$\tilde u(r) = u(r), \quad r \in [0,s], \quad \tilde u(r) = v(r-s), \quad r \in [s, s+t],$$

transfers x to 0 in time $t+s$. Therefore

$$\int_0^s (\langle Ry^{x,u}(r), y^{x,u}(r)\rangle + |u(r)|^2)dr + \langle \hat\Gamma_t^*\hat\Gamma_t y^{x,u}(s), y^{x,u}(s)\rangle \ \geq \ \langle \hat\Gamma_{t+s}^*\hat\Gamma_{t+s}x, x\rangle.$$

Taking the infimum over the controls u, it follows that $\langle P_s^{\hat\Gamma_t^*\hat\Gamma_t}x, x\rangle \geq \langle \hat\Gamma_{t+s}^*\hat\Gamma_{t+s}x, x\rangle$. This gives (3.11). The proof of (i) is complete.

(ii) Fix $x \in H$ and let $\hat u$ be the control which transfers x to 0 in time t with the minimal energy. Since $y^{x,\hat u}(t) = 0$, we have

$$\begin{aligned}
&\langle \hat\Gamma_t x, \hat\Gamma_t x\rangle = \int_0^t (\langle Ry^{x,\hat u}(s), y^{x,\hat u}(s)\rangle + |\hat u(s)|^2)ds \\
&= \int_0^t (\langle Ry^{x,\hat u}(s), y^{x,\hat u}(s)\rangle + |\hat u(s)|^2)ds + \langle Sy^{x,\hat u}(t), y^{x,\hat u}(t)\rangle \geq \langle P_t^S x, x\rangle, \quad t \geq \tilde T. \qquad \square
\end{aligned}$$

Proof of Theorem 1.4. Since $(\Gamma_t^R)^*\Gamma_t^R$ is decreasing for $t \geq \tilde T$, formula (1.6) is equivalent to the fact that there exists

$$\lim_{t\to+\infty} \langle (\Gamma_t^R)^*\Gamma_t^R x, x\rangle = \langle \hat P x, x\rangle, \quad x \in H, \tag{3.12}$$

where $\hat P$ is the maximal solution to (1.4). To prove this assertion, the proof is split up into two parts.

Step I. We show that the map $t \mapsto (\Gamma_t^R)^*\Gamma_t^R$ converges strongly to a solution of the algebraic Riccati equation (1.4) as $t \to +\infty$. Since $(\Gamma_t^R)^*\Gamma_t^R$ is decreasing on $(\tilde T, +\infty)$, applying (2.4), we find that there exists $\hat P \in \mathcal{K}_+(H)$ such that $(\Gamma_t^R)^*\Gamma_t^R$ converges strongly to $\hat P$. By Lemma 3.2, we know that $P_t = (\Gamma_t^R)^*\Gamma_t^R$ solves the differential Riccati equation

$$\frac{d}{dt}\langle P_t h, k\rangle = \langle P_t h, Ak\rangle + \langle P_t Ah, k\rangle + \langle Rh, k\rangle - \langle P_t Q P_t h, k\rangle, \quad t \geq \tilde T,$$

for any h, $k \in D(A)$. Passing to the limit as $t \to +\infty$, by elementary arguments we find that

$$\frac{d}{dt}\langle (\Gamma_t^R)^*\Gamma_t^R h, k\rangle \ \to \ 0 \ \text{ as } \ t \to +\infty.$$

This yields that $\hat P$ solves the algebraic Riccati equation.

Step II. We show that $\hat{P}$ is maximal. If $S \geq 0$ is a solution of the algebraic Riccati equation, then $P_t^S = S$, $t \geq 0$, where P_t^S solves (3.1). Thanks to (ii) in Lemma 3.2, we get $P_t^S \leq (\Gamma_t^R)^* \Gamma_t^R$, $t \geq \tilde{T}$. Letting $t \to +\infty$, we infer that $S \leq \hat{P}$, and the proof is complete. □

Proof of Theorem 1.3. Recall that the system (1.1) is NCVE if and only if the operators $\Gamma_t = \Gamma_t^0$ (see (2.7)) converge strongly to 0 as $t \to +\infty$. The assertion follows from Theorem 1.4 □

4. Proofs of Theorems 1.1 and 1.2.

Proof of Theorem 1.1. We will use hypothesis (i) in (1.1) in order to show that (a) implies (b) and hypothesis (ii) in (1.1) in order to prove the converse.

(a) ⇒ (b) We know that $\Gamma_t^* \Gamma_t \to 0$ strongly as $t \to +\infty$. Assume by contradiction that $s(A) > 0$. By hypothesis (i) in (1.1), this implies that there exists an *isolated* element $\mu \in \sigma(A)$ such that $\mathrm{Re}(\mu) > 0$. Let us introduce the spectral Riesz projection P_0 associated with μ (see the notation in (2.1)),

$$P_0 x = \frac{1}{2\pi i} \int_\gamma (w - A)^{-1} x \, dw, \quad x \in H, \tag{4.1}$$

where γ is a circle enclosing μ in its interior and $\sigma(A) \backslash \{\mu\}$ in its exterior. We get the decomposition $H = E_0 \oplus E_1$, where $P_0 H = E_0$, $E_1 = P_1 H$, $(I - P_0) = P_1$.

The subspaces E_0 and E_1 are both invariant for e^{tA}; moreover, $E_0 \subset D(A)$, $A(E_0) \subset E_0$, and $A(E_1 \cap D(A)) \subset E_1$. Consider the restrictions A_i of A to E_i, $i = 0, 1$, and define

$$B_0 = P_0 B, \quad B_1 = P_1 B;$$

we have $B_i \in \mathcal{L}(U, E_i)$, $i = 0, 1$. We know that A_0 generates a uniformly continuous group e^{tA_0} on E_0, $\sigma(A_0) = \{\mu\}$, and A_1 generates a $\mathcal{C}_0$-semigroup e^{tA_1} on E_1. Let us split (1.1) into two systems: (A_0, B_0) on E_0 and (A_1, B_1) on E_1.

$$\begin{cases} \text{(i)} \;\; y_0'(t) = A_0 y_0(t) + B_0 u(t), \;\; y_0(0) = x_0 \in E_0, \\ \text{(ii)} \;\; y_1'(t) = A_1 y_1(t) + B_1 u(t), \;\; y_1(0) = x_1 \in E_1. \end{cases} \tag{4.2}$$

Since (4.2) is null controllable at $t \geq \tilde{T}$, also (A_0, B_0) and (A_1, B_1) are *null controllable* at $t \geq \tilde{T}$. In addition, e^{tA_0} is a uniformly continuous group, and therefore we have that the system $(-A_0, B_0)$, i.e.,

$$\frac{dy_0}{dt} = -A_0 y_0(t) + B_0 u(t), \;\; y_0(0) = x_0 \in E_0,$$

is exactly controllable at $t \geq \tilde{T}$. Consequently, for any $t \geq \tilde{T}$, the controllability operator $R_t \in \mathcal{L}(E_0)$,

$$R_t x_0 = \int_0^t e^{-sA_0} B_0 B_0^* e^{-sA_0^*} x_0 ds, \;\; x_0 \in E_0, \tag{4.3}$$

is one to one and onto E_0. Since $\sigma(-A_0) = \{-\mu\}$, we also have that e^{-tA_0} is exponentially stable. Thus the bounded linear operator R,

$$R x_0 = \int_0^\infty e^{-sA_0} B_0 B_0^* e^{-sA_0^*} x_0 ds, \;\; x_0 \in E_0,$$

is well defined and one has $\lim_{t\to+\infty}\langle R_t x_0, x_0\rangle = \langle Rx_0, x_0\rangle$, $x_0 \in E_0$. We remark that (R_t) is an increasing family of symmetric bounded operators on E_0 and that (4.3) is equivalent to $\langle R_t x, x\rangle \geq C|x|^2$ for any $t \geq \tilde{T}$, $C > 0$. It follows that R is coercive on E_0. Moreover, since $-A_0$ is stable, the operator R is the unique symmetric nonnegative solution of the Lyapunov equation:

$$(-A_0)R + R(-A_0)^* = -B_0B_0^*.$$

Using that R is an isomorphism, we achieve

$$R^{-1}A_0 + A_0^*R^{-1} = R^{-1}B_0B_0^*R^{-1} \text{ on } E_0.$$

Now consider the minimal energy operator $\Gamma_t^{E_0} : E_0 \to E_0$ associated with the exactly controllable system (A_0, B_0); i.e.,

$$|\Gamma_t^{E_0}x_0|^2 = \inf_{u\in L^2(0,t;U)}\left\{\int_0^t |u(s)|^2 ds \ : \ y_0^{x_0,u}(t) = 0\right\}, \ \ t > 0, \ x_0 \in E_0,$$

where $y_0^{x_0,u}(t) = e^{tA_0}x_0 + \int_0^t e^{(t-s)A_0}B_0u(s)ds$. It is easy to verify that

$$|\Gamma_t x_0| \geq |\Gamma_t^{E_0}x_0|, \ \ t \geq \tilde{T}.$$

It follows that $|\Gamma_t^{E_0}x_0|$ converges to 0 as $t \to +\infty$ for any $x_0 \in E_0$. By Theorem 1.3, this contradicts the fact that $P = R^{-1}$ is a nonzero solution to the algebraic Riccati equation $PA_0 + A_0^*P = PB_0B_0^*P$ on E_0. This finishes the proof.

(a) $\Leftarrow$ (b) Here we assume that $s(A) \leq 0$. The proof uses hypothesis (ii) in (1.1) and Theorem 1.3. In order to prove that $\Gamma_t^*\Gamma_t$ converges strongly to 0 as $t \to +\infty$, we show that if $P \geq 0$ is a solution of

$$PA + A^*P = PBB^*P, \tag{4.4}$$

then P is identically 0. Since $H = H_s \oplus H_u$, we will separately verify that $P = 0$ on H_s and on H_u.

We first prove that $Px = 0$ for any $x \in H_s$. To this end, let us denote by e^{tA_s} the restriction of e^{tA} to the subspace H_s. We have that $P = P_t^P$, $t \geq 0$, where P_t^P is the unique solution of the differential Riccati equation (3.1) with $R = 0$ such that $P_0 = P$. It follows that

$$\langle Px, x\rangle = \inf_{u\in L^2_{loc}}\left\{\int_0^t |u(s)|^2 ds \ + \ \langle Py^{x,u}(t), y^{x,u}(t)\rangle\right\}, \ \ t > 0, \ x \in H. \tag{4.5}$$

Fix any $x \in H_s$ and take the control $u = 0$; we obtain for any $t > 0$,

$$|\sqrt{P}\,x|^2 = \langle Px, x\rangle \leq \langle Pe^{tA_s}x, e^{tA_s}x\rangle. \tag{4.6}$$

Since e^{tA_s} is exponentially stable on H_s, letting $t \to +\infty$, we infer $Px = 0$ for any $x \in H_s$.

In order to show that $Px = 0$ for any $x \in H_u$, it is enough to check that $Pv = 0$ for any generalized eigenvector v of A. Indeed, we assume that there exists a set of generalized eigenvectors which spans a linear dense subspace of H_u. Now the proof is split up into two steps.

Step I. *We prove that if v is an eigenvector of A, then $Pv = 0$.*
Let $Av = \lambda v$, $\lambda \in \mathbf{C}$, $\mathrm{Re}(\lambda) \leq 0$. We have

$$\langle A^*Pv, v\rangle + \langle PAv, v\rangle = |B^*Pv|^2 \;\; \Rightarrow \;\; 2\mathrm{Re}(\lambda)\langle Pv, v\rangle = |B^*Pv|^2. \tag{4.7}$$

Since $\mathrm{Re}(\lambda) \leq 0$, we get that $B^*Pv = 0$. By (4.4), we find

$$A^*Pv + PAv = A^*Pv + \lambda Pv = PBB^*Pv = 0 \;\; \Rightarrow \;\; A^*Pv = -\lambda Pv.$$

Let us recall that the null controllability at $t > 0$ is equivalent to the fact that there exists $C_t > 0$ such that

$$\int_0^t |B^*e^{sA^*}x|^2 ds \geq C_t |e^{tA^*}x|^2, \quad x \in H. \tag{4.8}$$

Because of $B^*Pv = 0$ and (4.8), one has

$$0 = \int_0^t |e^{-\lambda s}B^*Pv|^2 ds = \int_0^t |B^*e^{sA^*}Pv|^2 ds \;\geq\; C_t e^{-2Re(\lambda)t}|Pv|^2, \tag{4.9}$$

$t \geq \tilde{T}$. Hence $Pv = 0$, and the assertion is proved.

Step II. *We check that if w is a generalized eigenvector of A, then $Pw = 0$.*

We know that there exists an eigenvalue $\lambda \in \mathbf{C}$, $\mathrm{Re}(\lambda) \leq 0$, and $m \in \mathbf{N}$ such that $w \in \mathrm{Ker}(\lambda - A)^m$. We will use induction on k to show that P is identically 0 on each $N_k = \mathrm{Ker}(\lambda - A)^k$, $k \in \mathbf{N}$. This will imply $Pw = 0$.

By the previous step, P is identically 0 on N_1. Let us assume that P is identically 0 on N_k and prove that the same is true for N_{k+1}. If $(\lambda - A)^{k+1}u = 0$, then

$$(\lambda - A)u \in N_k.$$

By induction we get $P(\lambda - A)u = 0$, i.e., $PAu = \lambda Pu$. It follows that

$$2\mathrm{Re}\langle PAu, u\rangle = 2\mathrm{Re}(\lambda)\langle Pu, u\rangle = |B^*Pu|^2,$$

which yields $B^*Pu = 0$. Arguing as before, it follows that $Pu = 0$. This completes the proof. □

Proof of Theorem 1.2. We are assuming that (1.1) is exactly controllable and that the operator A generates a $\mathcal{C}_0$-group e^{tA}. (We remark that A generates a $\mathcal{C}_0$-group e^{tA} on H if and only if both A and $-A$ generate $\mathcal{C}_0$-semigroups on H; see [10].) Recall the definition of the minimal energy $E_t^{(A,B)}(a, b) = E_t(a, b)$, which is needed to transfer the state a into b at time $t \geq \tilde{T}$; see (2.8).

The assertion is equivalent to the following one:

$$\lim_{t\to+\infty} E_t^{(A,B)}(a, b) = 0 \;\; \text{for all} \;\; a,\, b \in H \;\; \Longleftrightarrow \;\; \sigma(A) \subset \{i\lambda \,:\, \lambda \in \mathbf{R}\}. \tag{4.10}$$

First we need to check that the system $(-A, -B)$ is exactly controllable at $t \geq \tilde{T}$. To this end, fix a, $b \in H$. Since (A, B) is exactly controllable at t, there exists a control u such that $y^{b,u}(t) = a$. Define $z(s) = y(t - s)$, $s \in [0, t]$. One verifies that

$$z'(s) = -Az(s) - Bv(s) \quad \text{with the control} \quad v(s) = u(t - s), \;\; s \in [0, t].$$

Hence z is a solution of the system $(-A,-B)$; we have $z = z^{a,v}$, $z(0) = a$, and $z(t) = b$. This proves that $(-A,-B)$ is exactly controllable at t. Moreover, we find

$$\int_0^t |u(s)|^2 ds = \int_0^t |v(s)|^2 ds.$$

It follows that $E_t^{(A,B)}(a,b) = E_t^{(-A,-B)}(b,a)$ for any a, $b \in H$. ($E_t^{(-A,-B)}$ denotes the minimal energy with respect to $(-A,-B)$.)

Now we prove $\Longrightarrow$ in (4.10). We know in particular that $E_t^{(A,B)}(a,0)$ tends to 0 as $t \to +\infty$. Thanks to Theorem 1.1, we deduce that $s(A) \le 0$. Moreover, $E_t^{(A,B)}(0,b) = E_t^{(-A,-B)}(b,0)$, which tends to 0 as $t \to +\infty$ for any $b \in H$. It follows that $s(-A) \le 0$ and the claim is proved.

We verify $\Longleftarrow$ in (4.10). Set $E_t = E_t^{(A,B)}$ and fix any $t \ge 2\tilde{T}$; we prove that

$$E_t(a,b) \le E_{t/2}(a,0) + E_{t/2}(0,b), \quad a,\, b \in H. \tag{4.11}$$

To this end, choose two optimal controls u, v such that $\int_0^{t/2} |u(s)|^2 ds = E_{t/2}(a,0)$, $\int_0^{t/2} |v(s)|^2 ds = E_{t/2}(0,b)$. Define the control $\hat{u}$ in $L^2(0,t;U)$:

$$\hat{u}(r) = u(r), \quad r \in [0,t/2]; \quad \hat{u}(r) = v(r-t/2), \quad r \in (t/2,t].$$

We have

$$\begin{aligned} y^{a,\hat{u}}(t) &= e^{tA}a + \int_0^t e^{(t-s)A} B\hat{u}(s) ds \\ &= e^{t/2A}\left(e^{t/2A}a + \int_0^{t/2} e^{(t/2-s)A} Bu(s) ds \right) + \int_0^{t/2} e^{(t/2-r)A} Bv(r) dr \\ &= e^{t/2A} y^{a,u}(t/2) \,+\, y^{0,v}(t/2) = b. \end{aligned}$$

Since $E_t(a,b) \le \int_0^t |\hat{u}(s)|^2 ds = \int_0^{t/2} |u(s)|^2 ds + \int_0^{t/2} |v(s)|^2 ds$, we obtain formula (4.11). We remark that

$$E_{t/2}(0,b) = E_{t/2}^{(A,B)}(0,b) = E_{t/2}^{(-A,-B)}(b,0).$$

Applying Theorem 1.1, we deduce that both (A,B) and $(-A,-B)$ are NCVE systems. Thus $E_{t/2}^{(-A,-B)}(b,0)$ tends to 0 as $t \to +\infty$. The assertion follows letting $t \to +\infty$ in (4.11). □

5. Possible extensions and comments.

5.1. Strongly stable semigroups. A $\mathcal{C}_0$-semigroup e^{tA} on H is called *strongly stable* if $\lim_{t\to+\infty} e^{tA}x = 0$ for any $x \in H$. Arguing as in (4.5) and (4.6), it is possible to prove the following.

PROPOSITION 5.1. *Let the system* (1.1) *be null controllable and assume that* e^{tA} *is strongly stable. Then* (1.1) *is an NCVE system.*

This result can be used to show that a null controllable system (1.1) is NCVE when the operator A is of the following type:

(i) A is self-adjoint, $\langle Ax, x\rangle \le 0$, $x \in D(A)$, and $\lambda = 0$ is not an eigenvalue of A. (Note that in this case e^{tA} is strongly stable; see [10, p. 324].)

(ii) A generates a *relatively strongly compact semigroup* e^{tA}; i.e., e^{tA} is relatively compact with respect to the strong topology in $\mathcal{L}(H)$, $t \geq 0$; see [10, p. 317]. These semigroups are uniformly bounded, i.e., $\|e^{tA}\| \leq M$, $t \geq 0$, and yield the following decomposition for H: $H = H_s \oplus H_r$, where

$$H_s = \{x \in H : \lim_{t \to +\infty} e^{tA}x = 0\}, \quad H_r = \overline{\text{lin}[\{x \in D(A) : Ax = i\alpha x,\ \alpha \in \mathbf{R}\}]}.$$

5.2. Growth bound. We show now that there exist NCVE systems (A, B) for which Hypothesis 1.1 holds but the growth bound $\omega(A)$ of the semigroup e^{tA} is *positive*.

We recall that the *growth bound* $\omega(A)$ of a $\mathcal{C}_0$-semigroup e^{tA} is equal to

$$\omega(A) = \lim_{t \to +\infty} \frac{1}{t} \log \|e^{tA}\|.$$

Following [27] (see also [28, pp. 224–225]), for any sequence $(\lambda_m) \subset \mathbf{R}$ such that $|\lambda_m| \to +\infty$ as $m \to \infty$, we can construct a semigroup e^{tA} on $H = l^2_{\mathbf{C}}$ such that

$$\|e^{tA}\| = e^t, \quad t \geq 0, \quad \sigma(A) = \{i\lambda_m, \quad m \in \mathbf{N}\}.$$

Moreover, each $i\lambda_m$ is an eigenvalue of A with finite algebraic multiplicity, and the system of all generalized eigenvectors of A is dense in H. Thus A satisfies Hypothesis 1.1 with $H_s = \{0\}$, $H_u = H$, and $s(A) = 0$.

The required semigroup e^{tA} is defined as follows. Regarding each $x \in H$ as an infinite column and writing x in the form (x^m), where $x^m \in \mathbf{C}^m$, i.e., $H = \{(x^m) : \sum_{m=1}^{+\infty} |x^m|^2 < +\infty\}$, we set

$$e^{tA} = \bigoplus_{m \in \mathbf{N}} e^{i\lambda_m t} e^{tA^m}, \ \text{ i.e., } \ e^{tA}x = (e^{i\lambda_m t} e^{tA^m} x^m),$$

where each $A^m = A^m_{ij}$ is a nilpotent matrix of order m on $\mathbf{C}^m$ such that $A^m_{ij} = 1$ if $j = i + 1$ $(i = 1, \dots, m-1)$, $A^m_{ij} = 0$ for the remaining (i, j). We get

$$(5.1) \quad D(A) = \left\{(x^m) \in H : \sum_{m=1}^{+\infty} |\lambda_m|^2 |x^m|^2 < +\infty\right\}, \ \ A(x^m) = ((\lambda_m i + A^m)x^m),$$

$x = (x^m) \in D(A)$. Let us consider any null controllable system (A, B) on H, where A is given in (5.1). For instance, take any $B \in \mathcal{L}(U, H)$ invertible such that $B^{-1} \in \mathcal{L}(H, U)$. (Note that for any $x \in H$, the control $u(s) = -\frac{1}{t} B^{-1} e^{sA} x$, $s \in [0, t]$, transfers x into 0 at time $t > 0$.) By Theorem 1.1, we get that the system (A, B) is NCVE.

5.3. Comments on Hypothesis 1.1. This hypothesis seems to be rather technical. However, compare it with assumptions $(\mathcal{P})$ in [2, p. 272]. Note that Hypothesis 1.1 holds in the following important cases:

(i) H is finite dimensional;

(ii) the semigroup e^{tA} is eventually compact (see below);

(iii) the system (1.1) is null controllable and the operator $B \in \mathcal{L}(U, H)$ is compact.

Case (ii) includes, in particular, delay systems. Case (iii) follows by a general result on stabilizable systems; see [10] and also [8] and [5].

We stress that in Hypothesis 1.1 it is possible that the subspace H_s or H_u is equal to $\{0\}$. In particular, if all the generalized eigenvectors of A are linearly dense in H, we have $H_u = H$ and we set $H_s = \{0\}$; see (5.1).

Eventually compact semigroups. A semigroup e^{tA} on H is called *eventually compact* if there exists $t_0 > 0$ such that $e^{t_0 A}$ is a compact operator. (It follows that e^{tA} is compact for any $t \geq t_0$.) For such semigroups, it is known that $\sigma(A)$ is discrete and at most countable; it consists entirely of eigenvalues of finite multiplicity; see [10, pp. 330 and 247]. Moreover, for any $r \in \mathbf{R}$, the set

$$\{\mu \in \sigma(A) \,:\, \mathrm{Re}(\mu) \geq r\} \text{ is finite.} \tag{5.2}$$

For any eventually compact semigroup e^{tA}, one has $\omega(A) = s(A)$ (i.e., any eventually compact semigroup satisfies the spectral determining growth condition).

PROPOSITION 5.2. *If the operator A in* (1.1) *generates an eventually compact semigroup e^{tA}, then Hypothesis* 1.1 *holds.*

Proof. According to (5.2), we denote by σ_0 the finite set of all eigenvalues of A: $\mu_1, \ldots, \mu_n$, such that $\mathrm{Re}(\mu_i) \geq 0$ and set $\sigma_1 = \sigma(A) \backslash \sigma_0$. Using the spectral decomposition (2.2), we get two closed e^{tA}-invariant subspaces E_0 and E_1, associated with σ_0 and σ_1, where E_0 is finite dimensional and spanned by all generalized eigenvectors associated with μ_i, $i = 1, \ldots, n$. Moreover, e^{tA_1}, the restriction of e^{tA} to E_1, is exponentially stable. (Indeed, note that $e^{t_0 A_1}$ is compact in $\mathcal{L}(E_1)$ since $e^{t_0 A}$ is compact in $\mathcal{L}(H)$, and so $\omega(A_1) = s(A_1)$.) □

We finally mention a useful result: if a semigroup e^{tA} is analytic on H and with compact resolvent, then e^{tA} is compact for any $t > 0$.

Completeness of generalized eigenvectors. An important problem related to condition (ii) in Hypothesis (1.1) is to establish when the system G of all generalized eigenvectors of A is *complete*, i.e., G spans a dense linear subspace of H. This is, of course, the case when A is self-adjoint and with compact resolvent. However, a deep result proved by Dunford and Schwartz states that G is complete also when A is not necessarily self-adjoint but has a Hilbert–Schmidt resolvent and the uniform norm of its resolvent satisfies a particular growth condition; see [11]. This is true, in particular, when A generates an analytic semigroup and has Hilbert–Schmidt resolvent. Other theorems on the completeness of generalized eigenvectors are known in special situations; see [11] and the references therein. Moreover, we mention [5, Theorem 2.5.10], which gives conditions on delay systems in order that the system of all generalized eigenvectors is complete.

Stabilizable systems. A system (A, B) is called *exponentially stabilizable* if there exists an operator $F \in \mathcal{L}(H, U)$ such that for some $\beta < 0,\ C > 0$,

$$\|e^{t(A+BF)}\| \leq Ce^{\beta t}, \quad t \geq 0.$$

It is known that if a system is null controllable, then it is also exponentially stabilizable. By [10, Theorem 8.24] (see also [8] and [5, Theorem 5.2.6] for the case in which B is of finite rank), we get the following proposition.

PROPOSITION 5.3. *If the system* (1.1) *is exponentially stabilizable and the operator $B \in \mathcal{L}(U, H)$ is compact, then Hypothesis* 1.1 *holds.*

Note that if the system (1.1) is exponentially stabilizable, then there always exists the maximal solution $\hat{P}$ to the algebraic Riccati equation (1.4); see [2, p. 283]. (We remark that this maximal solution in general does not exist; see [2, p. 285].) Moreover, by [2, Theorem III.4.1] one has

$$\langle \hat{P}x, x\rangle = \inf\left\{ \int_0^\infty (\langle Ry^{x,u}(s), y^{x,u}(s)\rangle + |u(s)|^2) ds \,:\, u \in L^2(0,\infty;U),\ \ y^{x,u} \in L^2(0,\infty;H) \right\}.$$

6. Examples.

6.1. Delay systems. Let us consider the following controlled discrete delay system; see [1], [5], and [13] for more details:

$$\begin{cases} y'(t) = A_0 y(t) + \sum_{i=1}^{p} A_i y(t-h_i) + Bu(t), \ \ t \geq 0, \\ y(0) = r \in \mathbf{C}^n, \qquad y(s) = f(s), \ \ -h_p \leq s < 0, \end{cases} \tag{6.1}$$

where $0 < h_1 < \cdots < h_p$ represent the point delays, $y(t) \in \mathbf{C}^n$, $A_i \in \mathcal{L}(\mathbf{C}^n)$, $i = 0, \dots, p$; the map $f \in L^2([-h_p, 0]; \mathbf{C}^n)$, $B \in \mathcal{L}(\mathbf{C}^m, \mathbf{C}^n)$, $u \in L^2([0,T]; \mathbf{C}^m)$ for any $T > 0$. System (6.1) is said to be *null controllable* in time $\tilde{T} > 0$ if for any $r \in \mathbf{C}^n$ and any $f \in L^2([-h_p, 0]; \mathbf{C}^n)$, there exists $u \in L^2([0,T]; \mathbf{C}^m)$ such that for the corresponding solution $y^{(r,f),u}$,

$$y^{(r,f),u}(t) = 0 \ \text{ for all } \ t \in [\tilde{T} - h_p, \tilde{T}].$$

It is known that if (6.1) is null controllable at some time $\tilde{T}$, then $\tilde{T} > h_p$. Moreover, (6.1) is null controllable at any $t > h_p$ if and only if

$$\operatorname{rank}\left[\lambda I - \sum_{i=1}^{p} A_i e^{-\lambda h_i}, \ B\right] = n \tag{6.2}$$

for any $\lambda \in \mathbf{C}$; see [19]. A direct sufficient condition for the null controllability of (6.1) is

$$\operatorname{rank}[B, A_0 B, \dots, A_0^{n-1} B] = n \ \text{ and } \ \operatorname{Im}(A_j) \subset \operatorname{Im}(B), \ \ j = 1, \dots, p;$$

see [7, p. 202]. We now deduce from Theorem 1.1 the following result.

PROPOSITION 6.1. *The null controllable system* (6.1) *is NCVE if and only if*

$$\sup\left\{ \operatorname{Re}(\lambda) \ : \ \lambda \in \mathbf{C}, \ \det\left[\lambda I - A_0 - \sum_{i=1}^{p} A_i e^{-\lambda h_i}\right] = 0 \right\} \ \leq \ 0.$$

Proof. It is well known (see, e.g., [5]) that the delay system (6.1) can be reformulated as a linear system (1.1). To this end we introduce the Hilbert space $H = M^2([-h_p, 0]) = \mathbf{C}^n \oplus L^2([-h_p, 0]; \mathbf{C}^n)$ and the family of operators T_t, $T_t \in \mathcal{L}(H)$,

$$T_t(r, f) = (y(t), y(t + \cdot)), \quad (r, f) \in H, \ \ t \geq 0,$$

where $y(t)$ is the solution of (6.1) with $B = 0$ and $y(s) = f(s)$, $s \in [-h_p, 0]$. The operators T_t form a $\mathcal{C}_0$-semigroup on H with generator $\mathcal{A}$, $\mathcal{A} : D(\mathcal{A}) \subset H \to H$,

$$D(\mathcal{A}) = \{(f(0), f) \in H, \ \ f \in W^{1,2}([-h_p, 0]; \mathbf{C}^n)\},$$

$\mathcal{A}(f(0), f) = (A_0 f(0) + \sum_{i=1}^{p} A_i f(-h_i), \ \ f')$ for any $(f(0), f) \in D(\mathcal{A})$; here f' stands for the derivative of f. The spectrum of $\mathcal{A}$ consists entirely of eigenvalues of finite multiplicity, and further

$$\sigma(\mathcal{A}) = \{\lambda \in \mathbf{C} \ : \ \det(N(\lambda)) = 0\}, \ \ N(\lambda) = \left[\lambda I - A_0 - \sum_{i=1}^{p} A_i e^{-\lambda h_i}\right].$$

We reformulate (6.1) as

$$Y'(t) = \mathcal{A}Y(t) + \mathcal{B}u(t),$$

where $Y(t) = (y(t), y(t+\cdot)) \in H$, $Y(0) = (r, f)$, $t \geq 0$, and $y(t)$ denotes the solution of (6.1). Moreover, $u : [0, +\infty) \to \mathbf{C}^m$ and $\mathcal{B} \in \mathcal{L}(\mathbf{C}^m, H)$, $\mathcal{B}a = (Ba, 0)$ for any $a \in \mathbf{C}^m$. The resolvent operator of $\mathcal{A}$ is compact for any $\lambda \notin \sigma(\mathcal{A})$; see [5, Corollary 2.4.7]. Moreover, T_t is differentiable in (h_p, ∞) (i.e., the map $t \mapsto T_t \in \mathcal{L}(H)$ is differentiable on (h_p, ∞)); see [1, p. 60]. In particular, it follows that T_t is compact for any $t > h_p$; see [10, Lemma 4.28]. Thus the operator $\mathcal{A}$ satisfies Hypothesis 1.1, and the proof of the proposition is complete. □

6.2. Commuting systems. The following example shows that Theorem 1.1 may hold even if Hypothesis 1.1 is *not* satisfied.

Let us consider $H = L^2(\mathbf{R}, \mu)$, where μ is a locally finite measure on $\mathbf{R}$, and introduce the multiplication operator A,

$$Ax(s) = sx(s),\ s \in \mathbf{R},\ x \in H,\ D(A) = \{x \in H \text{ such that } s \mapsto sx(s) \in H\}. \tag{6.3}$$

The operator A is self-adjoint on H. (Recall that by the spectral theorem each self-adjoint operator on a given Hilbert space is unitarily isomorphic to a multiplication operator on some L^2-space.) We assume that A generates a $\mathcal{C}_0$-semigroup on H. This is equivalent to supposing that the measure μ is concentrated on $(-\infty, a]$ for some $a \in \mathbf{R}$. (This implies that the essential range of the identity map $s \mapsto s$ is bounded from above; see for instance [10].) Let us introduce a bounded operator B on H,

$$Bx(s) = b(s)x(s), \quad s \in \mathbf{R},\ x \in H, \tag{6.4}$$

where b is a real measurable map on $\mathbf{R}$ which is assumed to be essentially bounded, i.e., the essential range of b, $b_{ess}(\mathbf{R}) = \{r \in \mathbf{R},\ \mu(h \in \mathbf{R} : |b(h) - r| < \epsilon) > 0 \text{ for all } \epsilon > 0\}$, is bounded. We consider (1.1), where A and B are the operators which we have just introduced above. Let us compute the controllability operator Q_t:

$$Q_t x(s) = \frac{e^{2ts} - 1}{2s} b^2(s)\, x(s), \quad s \in \mathbf{R},\ x \in H.$$

The null controllability of the system is equivalent to the fact that the map $s \mapsto \frac{e^{ts}}{|b(s)|}\sqrt{\frac{2|s|}{|e^{2ts}-1|}}$ is essentially bounded. We assume that $0 \notin b_{ess}(\mathbf{R})$; this yields the null controllability of (1.1). By the theory of multiplication operators, we have $\sigma(A) = (-\infty, a]$. In general, *A does not satisfy* Hypothesis 1.1. (For instance, it may have no point spectrum.) However, we can prove the following result.

PROPOSITION 6.2. *The null controllable system (A, B), where A, B are of the form* (6.3), (6.4)*, respectively, is NCVE if and only if $s(A) = a \leq 0$ or if and only if $\mu(0, \infty) = 0$.*

Proof. Let us assume that $a > 0$. This means that there exist $0 < p < q$ such that $\mu([p, q]) > 0$. Let us compute the minimal energy $|\Gamma_t x|^2$ which is needed to transfer x into 0 at time t. We have

$$|\Gamma_t x|^2 = 2\int_{-\infty}^{a} \frac{e^{2ts}}{b^2(s)} \frac{|s|}{|e^{2ts} - 1|} x^2(s)\mu(ds), \quad x \in H.$$

Choosing $\hat{x} = I_{[p,q]}$, we find

$$|\Gamma_t \hat{x}|^2 = 2\int_{p}^{q} \frac{e^{2ts}}{b^2(s)} \frac{s}{e^{2ts} - 1} \mu(ds).$$

Fix $T>0$. Since for any $s\in[p,q]$, $t\geq T$, one has $\frac{e^{2ts}}{e^{2ts}-1}\geq 1$, we obtain

$$\lim_{t\to\infty}|\Gamma_t\hat{x}|^2\geq 2\int_p^q\frac{|s|}{b^2(s)}\mu(ds)>0,$$

and the system is not NCVE. Now let $\mu(0,\infty)=0$. We have

$$|\Gamma_t x|^2=2\int_{-\infty}^0\frac{|s|}{b^2(s)}\frac{e^{2sT}}{1-e^{2Ts}}x^2(s)\,k(t,s)\mu(ds),$$

where $0\leq k(t,s)=\frac{1-e^{2sT}}{1-e^{2ts}}\,\frac{e^{2st}}{e^{2sT}}\leq 1$, $s<0$, $t>T>0$. Since $\lim_{t\to\infty}k(t,s)=0$, we get $\lim_{t\to\infty}|\Gamma_t x|^2=0$ by the Lebesgue theorem. The proof is complete. □

6.3. Hyperbolic systems. Let us consider the following generalized damped wave equation:

$$\left\{\begin{array}{l}\dfrac{d^2y}{dt^2}(t)+\Lambda y(t)=\rho\dfrac{dy}{dt}(t)+u(t),\quad t>0,\quad \rho\in\mathbf{R},\\ y(0)=x\in D(\sqrt{\Lambda}),\quad \dfrac{dy}{dt}(0)=x_1\in K,\end{array}\right. \tag{6.5}$$

where Λ is a positive definite self-adjoint operator on a Hilbert space K, $\Lambda:D(\Lambda)\subset K\to K$, $y,u:[0,+\infty)\to K$. We assume that Λ has a compact resolvent. This implies that $\sigma(\Lambda)$ consists of a sequence of eigenvalues $0<\lambda_1\leq\lambda_2\leq\cdots\leq\lambda_n\leq\cdots\to+\infty$. We denote by (e_k) the corresponding orthonormal basis of eigenvectors, i.e., $\Lambda e_k=\lambda_k e_k$, $k\in\mathbf{N}$. For a specific application, consider a bounded open subset Ω of $\mathbf{R}^n$ with regular boundary $\partial\Omega$ and introduce

$$K=L^2(\Omega),\quad \Lambda=-\triangle,\quad D(\Lambda)=H^2(\Omega)\cap H_0^1(\Omega),\ D(\sqrt{\Lambda})=H_0^1(\Omega),$$

$$\left\{\begin{array}{l}\dfrac{\partial^2y}{dt^2}(t,\xi)=\triangle_\xi y(t,\xi)+\rho\dfrac{\partial y}{\partial t}(t,\xi)+u(t,\xi),\quad t>0,\ \xi\in\Omega,\\ y(t,\xi)=0,\quad t>0,\ \xi\in\partial\Omega;\quad y(0,\xi)=x(\xi),\quad \dfrac{\partial y}{dt}(0,\xi)=x_1(\xi),\end{array}\right. \tag{6.6}$$

$x\in H_0^1(\Omega)$, $x_1\in L^2(\Omega)$. Equation (6.5) can be reformulated as a system like (1.1). To this end, let us introduce the Hilbert space H, $H=D(\sqrt{\Lambda})\oplus K$, with inner product

$$\langle X,Y\rangle_H=\langle\sqrt{\Lambda}x,\sqrt{\Lambda}y\rangle_K+\langle x_1,y_1\rangle_K,\quad \text{where } X=\begin{pmatrix}x\\x_1\end{pmatrix},\ Y=\begin{pmatrix}y\\y_1\end{pmatrix}\in H.$$

Define the operators $A_\rho:D(A_\rho)=D(\Lambda)\oplus D(\sqrt{\Lambda})\subset H\to H$ and $B\in\mathcal{L}(K,H)$,

$$A_\rho\begin{pmatrix}x\\x_1\end{pmatrix}=\begin{pmatrix}0&I\\-\Lambda&\rho I\end{pmatrix}\begin{pmatrix}x\\x_1\end{pmatrix},\quad Bu=\begin{pmatrix}0\\u\end{pmatrix},$$

$x\in D(\Lambda)$, $x_1\in D(\sqrt{\Lambda})$, $u\in K$. It is not difficult to prove that A_ρ generates a $\mathcal{C}_0$-group e^{tA_ρ} on H, $\rho\in\mathbf{R}$. We can write (6.5) as $Y'(t)=A_\rho Y(t)+Bu(t)$, $Y(0)=Y_0\in H$, where $Y(t)=\binom{y(t)}{y_1(t)}$ and $Y_0=\binom{x}{x_1}$. Note that if $\rho=0$, then $A=A_0$ is skew-adjoint (i.e., $A^*=-A$) and generates a unitary group. The spectrum of A_ρ consists entirely of eigenvalues and can be easily computed:

$$\sigma(A_\rho)=\left\{\frac{\rho\pm\sqrt{\rho^2-4\lambda_k}}{2}\ :\ \lambda_k\in\sigma(\Lambda)\right\}.$$

It is clear that $s(A_\rho) \le 0$ if and only if $\rho \le 0$. In the case $\rho = 0$, there exists an orthonormal basis $(E_k^\pm)$ of eigenvectors of A:

$$E_k^\pm = \frac{1}{\sqrt{2}} \begin{pmatrix} \frac{e_k}{\sqrt{\lambda_k}} \\ \pm i\, e_k \end{pmatrix}, \quad k \in \mathbf{N}, \quad AE_k^\pm = \pm i\sqrt{\lambda_k} E_k^\pm.$$

It is known (see [6] or [2]) that (A_ρ, B) is *exactly controllable* at any $t > 0$ for any $\rho \in \mathbf{R}$. Denote by $E_t(X, Y)$ the minimal energy which is needed to transfer the state X into Y at time t; see (2.8). Thanks to Theorems 1.1 and 1.2, we obtain the following result.

PROPOSITION 6.3. *The system (A_ρ, B) is NCVE if and only if $\rho \le 0$. Moreover, (A_ρ, B) is ECVE if and only if $\rho = 0$.*

Proof. Recall that $s(A_\rho) \le 0$ if and only if $\rho \le 0$. We consider three different cases.

(a) $\rho > 0$. Since (i) in Hypothesis 1.1 is verified, we can conclude that (A_ρ, B) is not NCVE.

(b) $\rho = 0$. In this case there exists the basis $(E_k^\pm)$ on H consisting of eigenvectors of A. It follows that (ii) in Hypothesis 1.1 holds. (We can take $H_s = \{0\}$, $H_u = H$.) Moreover, $\sigma(A) \subset \{i\mathbf{R}\}$. Hence the system is ECVE.

(c) $\rho < 0$. Following [6], we find that e^{tA_ρ} is exponentially stable. (Indeed, one verifies that the map $F(x, x_1) = |x_1|^2 - \rho \mathrm{Re}\langle x_1, x\rangle + \frac{\rho^2}{2}|x|^2 + \langle\sqrt{\Lambda}x, \sqrt{\Lambda}x\rangle$, $x \in D(\sqrt{\Lambda})$, $x_1 \in K$, is a Lyapunov function for (6.5) with $u = 0$.) Thus even in this case condition (ii) in Hypothesis 1.1 holds and the system is NCVE. However, by Theorem 1.2, the system is not ECVE. □

6.4. Parabolic systems. Important examples of null controllable systems are *parabolic systems*. In this case we assume that the operator A in (1.1) generates an analytic semigroup on H. (For instance, as A we can take a $-\Lambda$, where Λ is a positive definite self-adjoint, unbounded operator on H; see section 6.3.)

If, in addition, we take $U = H$ and $B = I$, then it is well known that the parabolic system (A, I) with A unbounded is null controllable at any $t > 0$ but not exactly controllable; see [6], [2], [17], [18]. Note that parabolic systems with a compact resolvent satisfy Hypothesis 1.1.

Remark 6.1. It is of some interest to establish the rate with which the minimal energy tends to 0 as the horizon t of the control tends to $+\infty$. For wave equations, this problem was recently studied in [14]. (We also mention [15, p. 171], which considers the case when BB^* is invertible and e^{tA} is uniformly bounded.)

The behavior of the minimal energy $|\Gamma_t x|$ as $t \to 0^+$ is completely characterized in [24] for finite dimensional systems. On the contrary, in infinite dimensions such a characterization is not possible and the behavior of Γ_t as $t \to 0^+$ becomes much more complicated; see [12] which also contains useful references on this subject.

Acknowledgments. The authors wish to thank Professors G. Da Prato and L. Pandolfi for useful discussions and suggestions. The first author wishes to thank the Mathematics Research Center of the Warwick University and the Institute of Mathematics of the Polish Academy of Sciences in Warsaw, where parts of this paper were discussed, for their warm hospitality. Finally, the authors thank the referees for their careful reports.

BOUNDARY FEEDBACK STABILIZATION OF AN UNSTABLE HEAT EQUATION*

WEIJIU LIU†

Abstract. In this paper we study the problem of boundary feedback stabilization for the unstable heat equation

$$u_t(x,t) = u_{xx}(x,t) + a(x)u(x,t).$$

This equation can be viewed as a model of a heat conducting rod in which not only is the heat being diffused (mathematically due to the diffusive term u_{xx}) but also the destabilizing heat is generating (mathematically due to the term au with $a > 0$). We show that for *any* given continuously differentiable function a and *any* given positive constant λ we can *explicitly* construct a boundary feedback control law such that the solution of the equation with the control law converges to zero exponentially at the rate of λ. This is a continuation of the recent work of Boskovic, Krstic, and Liu [*IEEE Trans. Automat. Control*, 46 (2001), pp. 2022–2028] and Balogh and Krstic [*European J. Control*, 8 (2002), pp. 165–176].

Key words. heat equation, boundary control, stabilization

1. Introduction.

In this paper we continue the study of boundary feedback control of an unstable heat equation

$$u_t(x,t) = u_{xx}(x,t) + \mu u(x,t) \quad \text{in } (0,1)\times(0,\infty).$$

Hereafter, the subscripts denote the derivatives. This equation can be viewed as a model of a heat conducting rod in which not only is the heat being diffused (mathematically due to the term u_{xx}) but also the destabilizing heat is generating (mathematically due to the term μu with $\mu > 0$). This feedback control problem was recently addressed by Boskovic, Krstic, and Liu in [5], and it was shown that the unstable rod can be exponentially stabilized by a boundary feedback control law if the constant $\mu < 3\pi^2/4$; that is, the destabilizing heat generation is not very big. More recently, Balogh and Krstic [3, 4] removed the condition $\mu < 3\pi^2/4$ and replaced μ by an arbitrarily large function $a(x)$:

$$u_t(x,t) = u_{xx}(x,t) + a(x)u(x,t) \quad \text{in } (0,1)\times(0,\infty). \tag{1.1}$$

They used a backstepping method for the finite difference semidiscretized approximation of the above equation to derive a Dirichlet boundary feedback control law that makes the closed-loop system stable with an arbitrary prescribed stability margin. They showed that the integral kernel in the control law is bounded. However, some problems like the smoothness of the kernel and Neumann boundary control (usually more difficult than the Dirichlet one) were left open. Using a different method, we completely solve these problems by solving a partial differential equation of the kernel

with strange boundary conditions (see (2.1) below). This strange boundary value problem has stood open since the work of [5] was started in 1998. We also derive Neumann boundary feedback control laws which seemingly cannot be achieved in [4]. From the proof of Lemma 2.2 below it can been seen that the feedback law is constructed explicitly and can be calculated numerically via a scheme of successive approximation. This makes its implementation possible in real problems.

The problem of boundary feedback control that we address here is not new. Some of the results on feedback stabilization of parabolic equations include the work of Amamm [2], Burns and Rubio [6], Burns, Rubio, and King [7], Day [8], Lasiecka and Triggiani [10, 11, 12, 13], and Triggiani [15]. For a detailed review of these references, we refer to [4] and [5]. In comparison with the existing literature, the novelty of the paper is the explicit construction of the feedback laws and the complete solving of the strange boundary value problem mentioned above.

The paper is organized as follows. Section 2 is devoted to the stabilization of unstable Dirichlet boundary value problems and section 3 to the stabilization of unstable Neumann boundary value problems. We raise an open problem in section 4.

2. Dirichlet boundary conditions. In what follows, we denote by $H^s(0,1)$ the usual Sobolev space (see, e.g., [1, 14]) for any $s \in \mathbf{R}$. For $s \geq 0$, $H_0^s(0,1)$ denotes the completion of $C_0^\infty(0,1)$ in $H^s(0,1)$, where $C_0^\infty(0,1)$ denotes the space of all infinitely differentiable functions on $(0,1)$ with compact support in $(0,1)$. We denote by $\|\cdot\|$ the norm of $L^2(0,1)$. $C^n[0,1]$ denotes the space of all n times continuously differentiable functions on $[0,1]$.

It is well known that the Dirichlet boundary value problem

$$\begin{cases} u_t(x,t) = u_{xx}(x,t) + a(x)u(x,t) & \text{in } (0,1)\times(0,\infty), \\ u(0,t) = u(1,t) = 0 & \text{in } (0,\infty) \end{cases}$$

is unstable if a is positive and large. To design a boundary feedback law to stabilize it for any function $a \in C^1[0,1]$, we consider the problem

$$\begin{cases} k_{xx}(x,y) - k_{yy}(x,y) = (a(y)+\lambda)k(x,y), & 0 \leq y \leq x \leq 1, \\ k(x,0) = 0, & 0 \leq x \leq 1, \\ k_x(x,x) + k_y(x,x) + \frac{d}{dx}(k(x,x)) = a(x) + \lambda, & 0 \leq x \leq 1, \end{cases} \tag{2.1}$$

where λ is any constant. From the proof of Lemma 2.4 below we will see why we want to consider this problem. For the moment, let us assume this problem has a unique solution k for $a \in C^1[0,1]$. (This will be proved in Lemma 2.2 below.) Using the solution k, we then obtain Dirichlet boundary feedback law

$$u(1,t) = -\int_0^1 k(1,y)u(y,t)dy \qquad \text{in } (0,\infty) \tag{2.2}$$

and Neumann boundary feedback law

$$u_x(1,t) = -k(1,1)u(1,t) - \int_0^1 k_x(1,y)u(y,t)dy \qquad \text{in } (0,\infty). \tag{2.3}$$

With one of the boundary feedback laws, the system

$$\begin{cases} u_t(x,t) = u_{xx}(x,t) + a(x)u(x,t) & \text{in } (0,1)\times(0,\infty), \\ u(0,t) = 0 & \text{in } (0,\infty), \\ u(x,0) = u^0(x) & \text{in } (0,1) \end{cases} \tag{2.4}$$

is exponentially stable. In this controlled system, the left-hand end of a rod is insulated while the temperature or the heat flux at the other end is adjusted according to the measurement of k-weighted averaged temperature over the whole rod. Physically, if the destabilizing heat is generating inside the rod, then we cool the right end of the rod so that it is not overheated. To state this result, we introduce the compatible conditions for the initial data:

$$u^0(0) = 0, \quad u^0(1) = -\int_0^1 k(1,y)u^0(y)dy, \tag{2.5}$$

$$u^0(0) = 0, \quad u_x^0(1) = -k(1,1)u^0(1) - \int_0^1 k_x(1,y)u^0(y)dy. \tag{2.6}$$

THEOREM 2.1. *Assume that $\lambda > 0$ is any positive constant and $a \in C^1[0,1]$ is any function. For arbitrary initial data $u^0(x) \in H^1(0,1)$ with compatible condition* (2.5) *or* (2.6)*, equation* (2.4) *with either* (2.2) *or* (2.3) *has a unique solution that satisfies*

$$\|u(t)\|_{H^1} \le M\|u^0\|_{H^1}e^{-\lambda t} \quad \forall t > 0, \tag{2.7}$$

where M is a positive constant independent of u^0.

The idea of proving the theorem is to carefully construct a transformation

$$w(x,t) = u(x,t) + \int_0^x k(x,y)u(y,t)dy$$

to convert the system (2.4) with either (2.2) or (2.3) into the exponentially stable system

$$\begin{cases} w_t = w_{xx} - \lambda w & \text{in } (0,1)\times(0,\infty), \\ w(0,t) = w(1,t) = 0 & \text{in } (0,\infty), \\ w(x,0) = w^0(x) & \text{in } (0,1) \end{cases} \tag{2.8}$$

or

$$\begin{cases} w_t = w_{xx} - \lambda w & \text{in } (0,1)\times(0,\infty), \\ w(0,t) = w_x(1,t) = 0 & \text{in } (0,\infty), \\ w(x,0) = w^0(x) & \text{in } (0,1), \end{cases} \tag{2.9}$$

where $w^0(x) = u^0(x) + \int_0^x k(x,y)u^0(y)dy$. This will be achieved in the following lemmas.

LEMMA 2.2. *Suppose that $a \in C^1[0,1]$. Then problem* (2.1) *has a unique solution which is twice continuously differentiable in $0 \le y \le x \le 1$.*

Proof. Using the variable changes

$$\xi = x + y, \quad \eta = x - y$$

and denoting

$$G(\xi,\eta) = k(x,y) = k\left(\frac{\xi+\eta}{2}, \frac{\xi-\eta}{2}\right),$$

problem (2.1) is transformed to

$$\begin{cases} G_{\xi\eta}(\xi,\eta) = \frac{1}{4}\left(a\left(\frac{\xi-\eta}{2}\right) + \lambda\right)G(\xi,\eta), & 0 \le \eta \le \xi \le 2, \\ G(\xi,\xi) = 0, & 0 \le \xi \le 2, \\ \frac{\partial}{\partial\xi}(G(\xi,0)) = \frac{1}{4}\left(a\left(\frac{\xi}{2}\right) + \lambda\right), & 0 \le \xi \le 2, \end{cases} \tag{2.10}$$

which is equivalent to the following integral equation:

$$G(\xi,\eta)=\frac{1}{4}\int_{\eta}^{\xi}\left(a\left(\frac{\tau}{2}\right)+\lambda\right)d\tau+\frac{1}{4}\int_{\eta}^{\xi}\int_{0}^{\eta}\left(a\left(\frac{\tau-s}{2}\right)+\lambda\right)G(\tau,s)dsd\tau. \tag{2.11}$$

By the method of successive approximations we can show that this equation has a unique continuous solution. In fact, set

$$G_0(\xi,\eta)=\frac{1}{4}\int_{\eta}^{\xi}\left(a\left(\frac{\tau}{2}\right)+\lambda\right)d\tau,$$
$$G_n(\xi,\eta)=\frac{1}{4}\int_{\eta}^{\xi}\int_{0}^{\eta}\left(a\left(\frac{\tau-s}{2}\right)+\lambda\right)G_{n-1}(\tau,s)dsd\tau$$

and denote $M=\sup_{0\le x\le 1}|a(x)+\lambda|$. Then one can readily show that

$$|G_0(\xi,\eta)|\le\frac{1}{4}M(\xi-\eta)\le M,$$
$$|G_1(\xi,\eta)|\le M^2\xi\eta,$$
$$|G_2(\xi,\eta)|\le\frac{M^3}{(2!)^2}\xi^2\eta^2,$$

and, by induction,

$$|G_n(\xi,\eta)|\le\frac{M^{n+1}}{(n!)^2}\xi^n\eta^n.$$

These estimates show that the series

$$G(\xi,\eta)=\sum_{n=0}^{\infty}G_n(\xi,\eta)$$

converges absolutely and uniformly in $0\le\eta\le\xi\le 2$, and then its sum is a continuous solution of (2.11). Moreover, it follows from (2.11) that G is twice continuously differentiable because $a\in C^1[0,1]$. Indeed, differentiating (2.11) with respect to ξ gives

$$\frac{\partial G(\xi,\eta)}{\partial\xi}=\frac{1}{4}\left(a\left(\frac{\xi}{2}\right)+\lambda\right)+\frac{1}{4}\int_{0}^{\eta}\left(a\left(\frac{\xi-s}{2}\right)+\lambda\right)G(\xi,s)ds,$$

which implies that $\frac{\partial G(\xi,\eta)}{\partial\xi}$ is continuous since $G(\xi,\eta)$ is continuous. By analogy, we can show that other derivatives of G are continuous. □

Remark 2.3. The proof of Lemma 2.2 provides a numeric computation scheme of successive approximation to compute the kernel function k in our feedback laws (2.2) and (2.3). This makes the feedback laws (2.2) and (2.3) implementable in real problems.

LEMMA 2.4. *Let $k(x,y)$ be the solution of problem* (2.1) *and define the linear bounded operator $K:H^i(0,1)\to H^i(0,1)$ $(i=0,1,2)$ by*

$$w(x)=(Ku)(x)=u(x)+\int_{0}^{x}k(x,y)u(y)dy\quad\text{for } u\in H^i(0,1). \tag{2.12}$$

Then

1. *K has a linear bounded inverse $K^{-1} : H^i(0,1) \to H^i(0,1)$ $(i = 0, 1, 2)$, and*
2. *K converts the system* (2.2) *and* (2.4) *and the system* (2.3) *and* (2.4) *into* (2.8) *and* (2.9)*, respectively.*

Proof. To prove that (2.12) has a bounded inverse, we set

$$v(x) = \int_0^x k(x,y)u(y)dy$$

and then

$$w(x) = u(x) + v(x).$$

Hence we have

$$\begin{aligned} v(x) &= \int_0^x k(x,y)[w(y) - v(y)]dy \\ &= \int_0^x k(x,y)w(y)dy - \int_0^x k(x,y)v(y)dy. \end{aligned} \tag{2.13}$$

To show that this equation has a unique continuous solution, we set

$$\begin{aligned} v_0(x) &= \int_0^x k(x,y)w(y)dy, \\ v_n(x) &= -\int_0^x k(x,y)v_{n-1}(y)dy \end{aligned}$$

and denote $M = \sup_{0 \le y \le x \le 1} |k(x,y)|$. Then

$$\begin{aligned} |v_0(x)| &\le M\|w\|, \\ |v_1(x)| &\le M^2\|w\|x, \\ |v_2(x)| &\le \frac{M^3\|w\|}{2!}x^2, \end{aligned}$$

and, by induction,

$$|v_n(x)| \le \frac{M^{n+1}\|w\|}{n!}x^n.$$

These estimates show that the series

$$v(x) = \sum_{n=0}^{\infty} v_n(x)$$

converges absolutely and uniformly in $0 \le x \le 1$ and that its sum is a continuous solution of (2.13). Moreover, there exists a constant $C > 0$ such that

$$\|v\| \le C\|w\|. \tag{2.14}$$

This implies that there exists a bounded linear operator $\Phi : L^2(0,1) \to L^2(0,1)$ such that

$$v(x) = (\Phi w)(x)$$

and then

$$u(x) = w(x) - v(x) = ((I - \Phi)w)(x) = (K^{-1}w)(x). \tag{2.15}$$

It is clear that $K^{-1} : L^2(0,1) \to L^2(0,1)$ is bounded. To show that $K^{-1} : H^1(0,1) \to H^1(0,1)$ is bounded, we take the derivative in (2.13) and obtain

$$v_x(x) = k(x,x)w(x) + \int_0^x k_x(x,y)w(y)dy - k(x,x)v(x) - \int_0^x k_x(x,y)v(y)dy,$$

which, combined with (2.14), implies that there exists constant $C > 0$ such that

$$\|v_x\| \le C\|w\|$$

and then by (2.15)

$$\|u\|_{H^1} \le \|w\|_{H^1} + \|v\|_{H^1} \le C\|w\|_{H^1}.$$

By analogy, we can show that $K^{-1} : H^2(0,1) \to H^2(0,1)$ is bounded.

To prove that the transformation (2.12) converts the system (2.2) and (2.4) and the system (2.3) and (2.4) into (2.8) and (2.9), respectively, we compute as follows:

$$\begin{aligned} w_t(x,t) &= u_t(x,t) + \int_0^x k(x,y)u_t(y,t)dy \\ &= u_t(x,t) + \int_0^x k(x,y)[u_{yy}(y,t) + a(y)u(y,t)]dy \\ &= u_t(x,t) + k(x,x)u_x(x,t) - k(x,0)u_x(0,t) \\ &\quad - k_y(x,x)u(x,t) + k_y(x,0)u(0,t) \\ &\quad + \int_0^x [k_{yy}(x,y)u(y,t) + k(x,y)a(y)u(y,t)]dy, \end{aligned} \tag{2.16}$$

$$w_x(x,t) = u_x(x,t) + k(x,x)u(x,t) + \int_0^x k_x(x,y)u(y,t)dy, \tag{2.17}$$

$$\begin{aligned} w_{xx}(x,t) &= u_{xx}(x,t) + \frac{d}{dx}(k(x,x))u(x,t) + k(x,x)u_x(x,t) \\ &\quad + k_x(x,x)u(x,t) + \int_0^x k_{xx}(x,y)u(y,t)dy. \end{aligned} \tag{2.18}$$

It then follows from (2.1) and (2.4) that

(2.19)

$$\begin{aligned} w_t - w_{xx} + \lambda w = {} & u_t(x,t) + k(x,x)u_x(x,t) - k(x,0)u_x(0,t) \\ & -k_y(x,x)u(x,t) + k_y(x,0)u(0,t) \\ & + \int_0^x [k_{yy}(x,y)u(y,t) + k(x,y)a(y)u(y,t)]dy \\ & -u_{xx}(x,t) - \frac{d}{dx}(k(x,x))u(x,t) - k(x,x,t)u_x(x,t) \\ & -k_x(x,x)u(x,t) - \int_0^x k_{xx}(x,y)u(y,t)dy \\ & +\lambda u(x,t) + \lambda \int_0^x k(x,y)u(y,t)dy \end{aligned}$$

$$
\begin{aligned}
&= \left(a(x) - k_x(x,x) - k_y(x,x) - \frac{d}{dx}(k(x,x)) + \lambda\right) u(x,t) \\
&\quad + k_y(x,0)u(0,t) - k(x,0)u_x(0,t) \\
&\quad + \int_0^x \left[k_{yy}(x,y) - k_{xx}(x,y,t) + (a(y)+\lambda)k(x,y,t)\right] u(y,t)dy \\
&= 0.
\end{aligned}
$$

By the boundary condition of (2.4), we deduce that $w(0,t) = 0$. Using feedback law (2.2) or (2.3), we obtain

$$w(1,t) = u(1,t) + \int_0^1 k(1,y)u(y,t)dy = 0$$

or

$$w_x(1,t) = u_x(1,t) + k(1,1)u(1,t) + \int_0^1 k_x(1,y)u(y,t)dy = 0. \qquad \square$$

We are now ready to prove Theorem 2.1.

Proof of Theorem 2.1. We first note that problem (2.4) with either (2.2) or (2.3) is well posed since, by Lemma 2.4, they can be transformed to the problem (2.8) or (2.9) via the isomorphism defined by (2.12), and the problem (2.8) or (2.9) is well posed (see, e.g., [9, Chap. IV]). Moreover, there exists a positive constant $C > 0$ such that

$$
\begin{aligned}
\|u(t)\|_{H^1} &\le C\|w(t)\|_{H^1}, \\
\|w^0\|_{H^1} &\le C\|u^0\|_{H^1}.
\end{aligned}
$$

Therefore, it is sufficient to prove (2.7) for the solution w of (2.8) or (2.9). We do so only for problem (2.8) since the situation for problem (2.9) is similar.

We define the energy

$$E(t) = \frac{1}{2}\int_0^1 w(x,t)^2 dx.$$

Multiplying the first equation of (2.8) by w and integrating from 0 to 1 by parts we get

$$
\begin{aligned}
\dot{E}(t) &= w_x w\Big|_0^1 - \int_0^1 w_x(x,t)^2 dx - \lambda\int_0^1 w(x,t)^2 dx \\
&= -\int_0^1 w_x(x,t)^2 dx - \lambda\int_0^1 w(x,t)^2 dx \\
&\le -2\lambda E(t),
\end{aligned}
$$

which implies

$$E(t) \le E(0)e^{-2\lambda t} \quad \text{for } t \ge 0.$$

Set

$$V(t) = \int_0^1 w_x(x,t)^2 dx.$$

Multiplying the first equation of (2.8) by w_{xx} and integrating from 0 to 1 by parts we obtain

$$\begin{aligned}\dot{V}(t) &= -2\int_0^1 w_{xx}^2 dx + 2\lambda\int_0^1 w w_{xx} dx \\ &= -2\int_0^1 w_{xx}^2 dx - 2\lambda\int_0^1 w_x^2 dx \\ &\le -2\lambda V(t),\end{aligned}$$

which implies that

$$V(t) \le V(0)e^{-2\lambda t}.$$

This shows that (2.7) holds. □

3. Neumann boundary conditions. To stabilize the Neumann boundary value problem

$$\begin{cases} u_t(x,t) = u_{xx}(x,t) + a(x)u(x,t) & \text{in } (0,1)\times(0,\infty), \\ u_x(0,t) = u_x(1,t) = 0 & \text{in } (0,\infty), \end{cases}$$

we consider the problem

$$\begin{cases} k_{xx}(x,y) - k_{yy}(x,y) = (a(y)+\lambda)k(x,y), & 0 \le y \le x \le 1, \\ k_y(x,0) = 0, & 0 \le x \le 1, \\ k_x(x,x) + k_y(x,x) + \frac{d}{dx}(k(x,x)) = a(x) + \lambda, & 0 \le x \le 1, \\ k(0,0) = 0, \end{cases} \tag{3.1}$$

where λ is any constant. Using the solution k, we then obtain Dirichlet boundary feedback law

$$u(1,t) = -\int_0^1 k(1,y)u(y,t)dy \qquad \text{in } (0,\infty) \tag{3.2}$$

and Neumann boundary feedback law

$$u_x(1,t) = -k(1,1)u(1,t) - \int_0^1 k_x(1,y)u(y,t)dy \qquad \text{in } (0,\infty). \tag{3.3}$$

With one of the boundary feedback laws, the system

$$\begin{cases} u_t(x,t) = u_{xx}(x,t) + a(x)u(x,t) & \text{in } (0,1)\times(0,\infty), \\ u_x(0,t) = 0 & \text{in } (0,\infty), \\ u(x,0) = u^0(x) & \text{in } (0,1) \end{cases} \tag{3.4}$$

is exponentially stable. To state this result, we introduce the compatible conditions for the initial data

$$u_x^0(0) = 0, \quad u^0(1) = -\int_0^1 k(1,y)u^0(y)dy, \tag{3.5}$$

$$u_x^0(0) = 0, \quad u_x^0(1) = -k(1,1)u^0(1) - \int_0^1 k_x(1,y)u^0(y)dy. \tag{3.6}$$

THEOREM 3.1. *Assume that $\lambda > 0$ is any positive constant and $a \in C^1[0,1]$ is any function. For arbitrary initial data $u^0(x) \in H^1(0,1)$ with the compatible condition* (3.5) *or* (3.6)*, equation* (3.4) *with either* (3.2) *or* (3.3) *has a unique solution that satisfies*

$$\|u(t)\|_{H^1} \le M\|u^0\|_{H^1}e^{-\lambda t},$$

where M is a positive constant independent of u^0.

Proof. The proof is the same as that of Theorem 2.1. The only thing we need to do is to show that problem (3.1) has a unique solution. This is given in Lemma 3.2 below. □

LEMMA 3.2. *Suppose that $a \in C^1[0,1]$. Then problem* (3.1) *has a unique solution which is twice continuously differentiable in $0 \le y \le x \le 1$.*

Proof. Using the variable changes

$$\xi = x + y, \quad \eta = x - y$$

and denoting

$$G(\xi,\eta) = k(x,y) = k\left(\frac{\xi+\eta}{2}, \frac{\xi-\eta}{2}\right),$$

problem (3.1) is transformed into

$$\text{(3.7)} \qquad \begin{cases} G_{\xi\eta}(\xi,\eta) = \frac{1}{4}\left(a\left(\frac{\xi-\eta}{2}\right)+\lambda\right)G(\xi,\eta), & 0 \le \eta \le \xi \le 2, \\ G_\xi(\xi,\xi) = G_\eta(\xi,\xi), & 0 \le \xi \le 2, \\ \frac{\partial}{\partial\xi}(G(\xi,0)) = \frac{1}{4}\left(a\left(\frac{\xi}{2}\right)+\lambda\right), & 0 \le \xi \le 2, \\ G(0,0) = 0. \end{cases}$$

Integrating the first equation of (3.7) with respect to η from 0 to ξ gives

$$\begin{aligned} G_\xi(\xi,\xi) &= G_\xi(\xi,0) + \frac{1}{4}\int_0^\xi \left(a\left(\frac{\xi-s}{2}\right)+\lambda\right)G(\xi,s)ds \\ &= \frac{1}{4}\left(a\left(\frac{\xi}{2}\right)+\lambda\right) + \frac{1}{4}\int_0^\xi \left(a\left(\frac{\xi-s}{2}\right)+\lambda\right)G(\xi,s)ds. \end{aligned}$$

It then follows from the second equation of (3.7) that

$$\begin{aligned} \frac{d}{d\xi}[G(\xi,\xi)] &= G_\xi(\xi,\xi) + G_\eta(\xi,\xi) \\ &= 2G_\xi(\xi,\xi) \\ &= \frac{1}{2}\left(a\left(\frac{\xi}{2}\right)+\lambda\right) + \frac{1}{2}\int_0^\xi \left(a\left(\frac{\xi-s}{2}\right)+\lambda\right)G(\xi,s)ds. \end{aligned}$$

Integrating from 0 to ξ and using the fourth equation of (3.7) gives

$$\text{(3.8)} \qquad G(\xi,\xi) = \frac{1}{2}\int_0^\xi \left(a\left(\frac{\tau}{2}\right)+\lambda\right)d\tau + \frac{1}{2}\int_0^\xi\int_0^\tau \left(a\left(\frac{\tau-s}{2}\right)+\lambda\right)G(\tau,s)dsd\tau.$$

Integrating twice the first equation of (3.7) first with respect to η from 0 to η and second with respect to ξ from η to ξ and using (3.8), we obtain the following integral equation:

$$G(\xi,\eta) = \frac{1}{2}\int_0^\eta \left(a\left(\frac{\tau}{2}\right)+\lambda\right)d\tau + \frac{1}{2}\int_0^\eta\int_0^\tau \left(a\left(\frac{\tau-s}{2}\right)+\lambda\right)G(\tau,s)dsd\tau + \frac{1}{4}\int_\eta^\xi \left(a\left(\frac{\tau}{2}\right)+\lambda\right)d\tau + \frac{1}{4}\int_\eta^\xi\int_0^\eta \left(a\left(\frac{\tau-s}{2}\right)+\lambda\right)G(\tau,s)dsd\tau. \tag{3.9}$$

As in the proof of Lemma 2.2, by the method of successive approximations we can show that this equation has a unique continuous solution. Moreover, it follows from (3.9) that G is twice continuously differentiable because $a \in C^1[0,1]$. □

Similar to Lemma 2.4, we have the following lemma.

LEMMA 3.3. *Let $k(x,y)$ be the solution of problem* (3.1) *and define the linear bounded operator $K : H^i(0,1) \to H^i(0,1)$ $(i = 0,1,2)$ by*

$$w(x) = (Ku)(x) = u(x) + \int_0^x k(x,y)u(y)dy \quad \text{for } u \in H^i(0,1).$$

Then

1. *K has a linear bounded inverse $K^{-1} : H^i(0,1) \to H^i(0,1)$ $(i = 0,1,2)$, and*
2. *K converts the system* (3.2) *and* (3.4) *and the system* (3.3) *and* (3.4) *into*

$$\begin{cases} w_t = w_{xx} - \lambda w & \text{in } (0,1)\times(0,\infty), \\ w_x(0,t) = w(1,t) = 0 & \text{in } (0,\infty), \\ w(x,0) = w^0(x) & \text{in } (0,1) \end{cases}$$

or

$$\begin{cases} w_t = w_{xx} - \lambda w & \text{in } (0,1)\times(0,\infty), \\ w_x(0,t) = w_x(1,t) = 0 & \text{in } (0,\infty), \\ w(x,0) = w^0(x) & \text{in } (0,1), \end{cases}$$

respectively, where $w^0(x) = u^0(x) + \int_0^x k(x,y)u^0(y)dy$.

4. Remarks. An interesting problem is to stabilize the problem

$$u_t(x,t) = u_{xx}(x,t) + a(x,t)u(x,t),$$

where the function a depends on t. To address the problem, it can been seen from the computations in (2.16)–(2.19) that we have to consider the problem

$$\begin{cases} k_{xx}(x,y,t) - k_{yy}(x,y,t) - k_t(x,y,t) = (a(y,t)+\lambda)k(x,y,t), & 0 \le y \le x \le 1, \\ k_y(x,0,t) = 0, & 0 \le x \le 1, \\ k_x(x,x,t) + k_y(x,x,t) + \frac{\partial}{\partial x}(k(x,x,t)) = a(x,t) + \lambda, & 0 \le x \le 1, \end{cases}$$

where λ is any constant. But we do not know if this problem has a solution. Once we can show that this problem has a solution, all the results in sections 2 and 3 hold immediately.

Acknowledgment. The author thanks the referee for bringing Balogh and Krstic [3, 4] to his attention.

ON REGULARITY OF TRANSPORT DENSITY IN THE MONGE–KANTOROVICH PROBLEM*

GIUSEPPE BUTTAZZO† AND EUGENE STEPANOV†

Abstract. We show that the optimal regularity result for the transport density in the classical Monge–Kantorovich optimal mass transport problem, with the measures having summable densities, is a Sobolev differentiability along transport rays.

Key words. Monge–Kantorovich transport problem, transport density, regularity

DOI. 10.1137/S036301290138568X

1. Introduction. Let φ^+, φ^- be some given finite positive Borel measures in $\mathbf{R}^n$ satisfying $\varphi^+(\mathbf{R}^n) = \varphi^-(\mathbf{R}^n)$. We assume $\operatorname{supp}\varphi^\pm = X^\pm \subset \Omega$ with $\Omega \subset \mathbf{R}^n$ some open bounded convex set and let $||\cdot||$ stand for the Euclidean norm in $\mathbf{R}^n$. The classical Monge–Kantorovich problem consists of finding a *transport map* ψ_{opt}: $X^+ \to X^-$ minimizing the functional

$$MK(\psi) := \int_{X^+} ||x - \psi(x)||\, d\varphi^+(x)$$

over all Borel measurable maps ψ: $X^+ \to X^-$ satisfying $\varphi^- = \psi_\# \varphi^+$, where $\psi_\#$ denotes the push forward operator acting on every Borel measure α according to the formula

$$\psi_\#\alpha(B) := \alpha(\psi^{-1}(B)) \text{ for all Borel } B \subset \Omega.$$

Although this problem may have no solutions, its relaxed setting always has ones. The latter setting consists of finding a Borel measure γ over $\Omega \times \Omega$ (called *optimal plan*) satisfying $\pi^\pm_\#\gamma = \varphi^\pm$, $\pi^\pm$: $\Omega \times \Omega \to \Omega$ being the projections on the first and second factor, respectively (i.e., $\pi^\pm(x^+, x^-) := x^\pm$), which minimizes the functional

$$MK_0(\gamma) := \int_{\Omega\times\Omega} ||x - y||\, d\gamma(x, y).$$

It is well known that an important role in the Monge–Kantorovich problem is played by the transport density μ, which is the measure defined by

$$\mu(B) := \int_{\Omega\times\Omega} \mathcal{H}^1((x, y) \cap B)\, d\gamma(x, y) \tag{1}$$

for all Borel $B \subset \Omega$, where γ is an optimal plan and $\mathcal{H}^k$ stands for the k-dimensional Hausdorff measure. Its physical meaning is the work for transporting the mass through the set B. It has been proven in [1] and in [11] (see also [5]) that when $\varphi^\pm \ll dx$, dx

standing for the Lebesgue measure, then also $\mu \ll dx$, and what is more important, μ is unique; that is, it depends only on $\varphi^{\pm}$ but not on a particular choice of the optimal plan γ (which on the contrary might not be unique). In this case we will denote by $f^{\pm}$ the density of $\varphi^{\pm}$ with respect to the Lebesgue measure and by a the density of μ with respect to the Lebesgue measure.

In this paper we study the higher regularity (namely, differentiability) of the transport density in the Monge–Kantorovich problem. We show that unless the transport problem is one-dimensional, then the optimal result one can get is a Sobolev regularity of restrictions of the density to the transport directions.

2. Preliminaries: dual problem and transport rays. It is well known that the dual setting for the Monge–Kantorovich problem consists of finding a $u \in W^{1,\infty}(\Omega)$ (called *transport potential*) which maximizes the functional

$$MK'(v) := \int_{X^+} v \, d\varphi^+(x) - \int_{X^-} v \, d\varphi^-(x)$$

over all $v \in \mathrm{Lip}_1(\Omega)$, where $\mathrm{Lip}_1(\Omega)$ stands for the set of Lipschitz continuous functions on Ω with Lipschitz constant one. We call a *transport ray* the maximal open (i.e., not containing the endpoints) interval $(x, y) := \{z \in \Omega \,:\, z = tx + (1-t)y,\ 0 < t < 1\}$ which satisfies

$$|u(x) - u(y)| = ||x - y||.$$

In other words, a transport ray is a maximal line segment along which the transport potential is decreasing at a maximal rate equal to one. Given a transport potential u, we denote by T the transport set (the union of all the transport rays without ray ends).

We recall the basic construction of the proof of existence of the optimal transport map from [4]. If u is a transport potential and R is a transport ray, then for every $p \in R$ the set

$$\{x \in \Omega \,:\, u(x) = p \text{ and } \exists \nabla u(x) \neq 0\}$$

admits a Borel covering $\{S_{pi}\}_{i=1}^{\infty}$ such that there exist Lipschitz coordinates $U\colon \mathbf{R}^n \to \mathbf{R}^{n-1}$ and $V\colon \mathbf{R}^{n-1} \to \mathbf{R}^n$ satisfying $V(U(x)) = x$ for all $x \in S_{pi}$. Enumerating the triples $(p, i, j) \in \mathbf{Q} \times \mathbf{N}^2$ and ordering them in the order of enumeration, we can define the countable sequence of disjoint clusters of transport rays T_{pij} as follows:

$$T_{pij} := \bigcup \{R = (a, b) \subset \Omega \,:\, R \cap S_{pi} = \{z\}, \min\{||z - a||, ||z - b||\} > 1/j\} \setminus \bigcup_{(p'i'j') < (p,i,j)} T_{p'i'j'}.$$

Each cluster T_{pij} admits coordinates $G := G_{pij}\colon T_{pij} \to \mathbf{R}^{n-1} \times \mathbf{R}$ (with Lipschitz inverse F), which are Lipschitz over

$$T^{\sigma}_{pij} := \{x \in T_{pij} \,:\, \min\{||z - a||, ||z - b||\} \geq \sigma > 0\},$$

where a and b stand for the ends of the unique transport ray R_x passing through x. Moreover, one has

$$G(x) = (U(z), u(x) - u(z)), \text{ where } \{z\} := R_x \cap S_{pi}.$$

In what follows we will make use of the following lemmata.

LEMMA 1. *Let $N \subset \mathbf{R}^n$ be a set with Lebesgue measure zero. Then for a.e. $x \in T$ one has $\mathcal{H}^1(R_x \cap N) = 0$.*

Proof. Observe that $\mathcal{H}^n(G(T_{pij}^{1/l} \cap N)) = 0$ for every $(p,i,j) \in \mathbf{Q} \times \mathbf{N}^2$ and $l \in \mathbf{N}$; hence by the Fubini theorem $\mathcal{H}^1(G(R_x \cap T_{pij}^{1/l}) \cap G(N)) = 0$ for a.e. $x \in T_{pij}$. Making the countable union over all $l \in \mathbf{N}$ we obtain $\mathcal{H}^1(G(R_x) \cap G(N)) = 0$ and hence $\mathcal{H}^1(R_x \cap N) = 0$ for a.e. $x \in T_{pij}$, which concludes the proof. □

LEMMA 2. *Let $\rho \in L^p_{loc}(\Omega)$. Then for a.e. $x \in T$ one has $\rho \in L^p_{loc}(R_x)$.*

Proof. Let $\rho \in L^p_{loc}(\Omega)$. The area formula gives

$$\int_{T_{pij}} \rho^p(x)\,dx = \int_{G(T_{pij})} \rho^p(F(x'))J_nF(x')\,dx',$$

where J_nF stands for the Jacobian of F. Since over $G(T^{\sigma}_{pij})$ one has $J_nF \geq c > 0$, then $\rho(F(\cdot)) \in L^p_{loc}(G(T_{pij}))$, and hence by the Fubini theorem

$$\rho(F(z,\cdot)) \in L^p_{loc}(G(T_{pij}) \cap (\{z\} \times \mathbf{R}))$$

for $\mathcal{H}^{n-1}$-a.e. $z \in \mathbf{R}^{n-1}$. This means $\rho \in L^p_{loc}(R_z)$ for $\mathcal{H}^{n-1}$-a.e. $z \in S_{pi}$, which implies the result. □

LEMMA 3. *Let $D \subset \Omega \times \Omega$ be a Borel set and γ_D stand for the restriction to D of the optimal transport plan γ. Then γ_D is an optimal plan for the Monge–Kantorovich problem of transporting the measure $\varphi^+_D := \pi^+_{\#}\gamma_D$ to $\varphi^-_D := \pi^-_{\#}\gamma_D$.*

Proof. Supposing the contrary we would have the existence of a better plan γ'_D with the same marginals (i.e., $\pi^{\pm}_{\#}\gamma'_D = \varphi^{\pm}_D$), which would then give rise to the better plan γ' for the original problem, according to the relationship

$$\gamma'(e) := \gamma'_D(e \cap D) + \gamma(e \setminus D)$$

for all Borel $e \subset \Omega \times \Omega$, which contradicts the optimality of γ. □

3. Nondifferentiability. It is a simple exercise to show that for one-dimensional transport (i.e., $n = 1$) the transport density has certain regularity properties. Namely, one has the following simple result.

PROPOSITION 1. *Let $\Omega \subset \mathbf{R}$ be a bounded interval. Then $f^{\pm} \in L^p(\Omega)$ implies $a \in W^{1,p}(\Omega)$. Moreover, $f^{\pm} \in W^{k,p}(\Omega)$ implies $a \in W^{k+1,p}(R)$ for every transport ray $R \subset \Omega$.*

Proof. According to [3], the pair (a,ν), where $a > 0$ with support in Ω is the transport density and ν is the unit direction of transport ray, solves the system

$$\begin{cases} -(a\nu)' &= f(x) \text{ in } \Omega, \\ |\nu(x)| &\leq 1 \text{ in } \Omega, \\ |\nu(x)| &= 1 \text{ a.e. where } a(x) > 0, \end{cases}$$

where $f := f^+ - f^-$. Let F stand for the primitive of f which has support in Ω. Clearly then, $a(x) := |F(x)|$, $\nu(x) := -\operatorname{sign} F(x)$ satisfies the above system, thus proving the first claim. To prove the second claim, observe that over each transport ray R (which is in this case just an open interval), either $\nu(x) \equiv 1$ or $\nu(x) \equiv -1$, and hence either $a(x) = F(x)$ or $a(x) = -F(x)$. □

Remark. It is clear from the proof that in the one-dimensional case one always has $a = 0$ in the ray ends.

Let us now show that, generally speaking, the result of Proposition 1 cannot hold for $n \geq 2$.

Example 1. Let $n = 2$ and

$$X^+ = \{(x, y) : 0 \leq x \leq g(y), 0 \leq y \leq L\}$$

for some bounded positive Borel function g, while $f^-(x, y) = f^+(x - b, y)$ (assuming b to be sufficiently large so that $X^+ \cap X^- = \emptyset$), so that

$$X^- = \{(x, y) : b \leq x \leq g(y) + b, 0 \leq y \leq L\}.$$

In this case the Monge–Kantorovich problem admits an exact solution $\psi'(x, y) = (x + b, y)$. In fact, setting $u(x, y) = -x$ in the dual problem, we obtain that the supremum of the latter is less than or equal to $b \int_{X^+} f^+(z)\, dz$, that is, the value $MK(\psi')$, whence the optimality follows. Now we can calculate the transport density a as

$$a(x, y) = \begin{cases} \displaystyle\int_0^x f^+(\xi, y)\, d\xi, & 0 \leq x \leq g(y), \\ \displaystyle\int_0^{g(y)} f^+(\xi, y)\, d\xi, & g(y) < x \leq b, \\ \displaystyle\int_{x-b}^{g(y)} f^+(\xi, y)\, d\xi, & b \leq x \leq g(y) + b \end{cases} = \int_{\max(x-b,0)}^{\min(x,g(y))} f^+(\xi, y)\, d\xi;$$

in particular,

$$a(x, y) = \int_0^{g(y)} f^+(\xi, y)\, d\xi \text{ in } \mathbf{R}^2 \setminus (X^+ \cup X^-).$$

Note that the above formula is valid, generally speaking, for a.e. $y \in [0, L]$. If one chooses now $g(y) = \text{const}$ and f^+ independent of x, namely $f^+ = f^+(y)$ such that $f^+ \in L^p(0, L)$, but $f^+ \notin L^{p+\alpha}(0, L)$, for all $\alpha > 0$, then clearly $a \notin L^{p+\alpha}(\Omega)$. In particular, this means, in view of the Sobolev imbedding theorem, that $a \notin W^{1,p}(\Omega)$, and hence Proposition 1 is not valid.

We remark that the same example but with nonconstant and discontinuous g shows that, generally speaking, even $f^\pm \in C^\infty(X^\pm)$ does not imply $a \in C(\Omega)$ or $a \in W^{1,1}(\Omega)$. Here the regularity of the solution is spoiled by the geometry of the problem (say, by the discontinuity of g).

Note that it has been shown in [5] that when $f^\pm \in L^p(X^\pm)$, $1 \leq p \leq +\infty$, while X^+ and X^- are disjoint, then $\mu \ll dx$ and for the respective density one has $a \in L^p(\Omega)$. The above example shows also that such a result cannot be improved.

4. Differentiability along transport rays. In spite of the above discouraging example, one can still claim that some regularization occurs in the direction of the transport rays. In fact, in [8] it has been proven that when $f^\pm$ are Lipschitz continuous with disjoint supports (and with some extra technical condition on the supports), then also the transport density is Lipschitz continuous along transport rays. We have the following more general result for the case of just summable $f^\pm$ without any extra conditions on supports.

THEOREM 1. *Let $f^\pm \in L^p(X^\pm)$. Then for a.e. $x \in T$ one has $a \in W^{1,p}_{loc}(R_x)$, where R_x is the transport ray passing through x.*

Proof. The result will be obtained in several steps.

Step 1. For each triple $(p,i,j) \in \mathbf{Q} \times \mathbf{N}^2$ we consider the restriction γ_{pij} of the optimal transport plan γ to the ray cluster $T_{pij} \times \Omega$, where T_{pij} is a ray cluster. It is clearly optimal for the Monge–Kantorovich problem of transporting the measure $\varphi^+_{pij} := \pi^+_{\#}\gamma_{pij}$ to the measure $\varphi^-_{pij} := \pi^-_{\#}\gamma_{pij}$. Note that the measures $\varphi^\pm_{pij}$ are just the restrictions of $\varphi^\pm$ to T_{pij}. Then the transport set for each such new problem is T_{pij}, while the respective transport density a_{pij} satisfies

$$-\operatorname{div} a_{pij}\nu = f_{pij}$$

weakly in Ω, where $f_{pij} := f^+_{pij} - f^-_{pij}$, $f^\pm_{pij}$ being the restrictions of $f^\pm$ to T_{pij}, and ν is the unit direction of the transport ray (both for the original and for the new problem). Note that $a = a_{pij}$ over T_{pij}; hence it is enough to prove the assertion of the theorem for each T_{pij}, but since in the latter problem the vector field ν varies Lipschitz continuously, it is enough to assume that in the original problem ν is Lipschitz continuous.

Step 2. In view of the Lemma 1, we may assume that $\mathcal{H}^1$-a.e. $z \in R_x$ is a Lebesgue point of the density a (this is true for a.e. $x \in T$). We also assume that the first Cartesian coordinate axis is directed along R_x (in the direction of transport), and, moreover, the origin of the coordinate system coincides with the upper end of R_x. Hence, the lower end of R_x is le_1, where e_1 is the unit vector of the first coordinate direction and $l > 0$ is the length of R_x. For $z \in R_x$ we denote by $B'_\varepsilon(z) \subset \mathbf{R}^{n-1}$ the $(n-1)$-dimensional ball in the plane perpendicular to R_x, which has radius $\varepsilon > 0$ and is centered at z. Let $\phi\colon \mathbf{R}^{n-1} \to \mathbf{R}$ be a smooth positive function with

$$\int_{\mathbf{R}^{n-1}} \phi(z')\,dz' = 1, \qquad B'_{1/2}(0) \subset \operatorname{supp}\phi \subset\subset B'_1(0).$$

Denote then

$$\begin{aligned} a_\varepsilon(z_1) &:= \frac{1}{2\varepsilon}\int_{z_1-\varepsilon}^{z_1+\varepsilon}\int_{B'_\varepsilon(0)} a(z_1,z')\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z')d\mathcal{H}^1(z_1),\\ f_\varepsilon(z_1) &:= \frac{1}{2\varepsilon}\int_{z_1-\varepsilon}^{z_1+\varepsilon}\int_{B'_\varepsilon(0)} f(z_1,z')\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z')d\mathcal{H}^1(z_1), \end{aligned}$$

where

$$\phi_\varepsilon(z') := \frac{1}{\varepsilon^n}\phi\left(\frac{z'}{\varepsilon}\right) \text{ and } f := f^+ - f^-.$$

Now we follow the lines of Steps 2–3 of Proposition 6.1 from [8]. In fact, using $\phi_\varepsilon\psi$, where $\psi\colon [\sigma, l-\sigma] \to \mathbf{R}$ is a positive Lipschitz function with compact support and $\sigma > 0$ is sufficiently small, as a test function to the equation

$$-\operatorname{div} a\nu = f \text{ in } \Omega,$$

where ν is the unit direction of the transport ray, we obtain

$$\begin{aligned} \int_0^{l-\sigma}\psi(z_1)\tilde f_\varepsilon(z_1)d\mathcal{H}^1(z_1) &= -\int_\sigma^{l-\sigma}\psi'(z_1)\tilde a_\varepsilon(z_1)d\mathcal{H}^1(z_1)\\ &+\int_\sigma^{l-\sigma}\psi'(z_1)\int_{B'_\varepsilon(0)} a(z_1,z')(\nu(z_1,z)+e_1)\cdot e_1\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z')d\mathcal{H}^1(z_1)\\ &+\int_\sigma^{l-\sigma}\psi(z_1)\int_{B'_\varepsilon(0)} a(z_1,z')\nu(z_1,z)\cdot\nabla\phi_\varepsilon(z')\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z')d\mathcal{H}^1(z_1), \end{aligned} \tag{2}$$

where

$$\begin{aligned}\tilde{f}_\varepsilon(z_1) &:= \int_{B'_\varepsilon(0)} f(z_1,z')\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z'),\\ \tilde{a}_\varepsilon(z_1) &:= \int_{B'_\varepsilon(0)} a(z_1,z')\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z').\end{aligned}$$

Since on Step 1 of the proof we supposed that ν is Lipschitz continuous, one can estimate

$$||\nu(z_1,z')+e_1|| = ||\nu(z_1,z')+\nu(z_1,0)|| \le C||z'|| \le C\varepsilon$$

for small $\varepsilon>0$, where $C=C(\sigma)$. This means that the second term on the right-hand side of (2) can be estimated as

$$\begin{aligned}&\left|\int_\sigma^{l-\sigma}\psi'(z_1)\int_{B'_\varepsilon(0)} a(z_1,z')(\nu(z_1,z)+e_1)\cdot e_1\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z')d\mathcal{H}^1(z_1)\right|\\ &\qquad\le C\varepsilon\int_\sigma^{l-\sigma}\psi'(z_1)\tilde{a}_\varepsilon(z_1)\,d\mathcal{H}^1(z_1).\end{aligned}$$

Analogously, the third term on the right-hand side of (2) can be estimated as

$$\begin{aligned}&\left|\int_\sigma^{l-\sigma}\psi(z_1)\int_{B'_\varepsilon(0)} a(z_1,z')\nu(z_1,z)\cdot\nabla\phi_\varepsilon(z')\phi_\varepsilon(z')\,d\mathcal{H}^{n-1}(z')d\mathcal{H}^1(z_1)\right|\\ &\qquad\le C\int_\sigma^{l-\sigma}\psi(z_1)\tilde{a}_{2\varepsilon}(z_1)\,d\mathcal{H}^1(z_1).\end{aligned}$$

Combining (2) with the above estimates and choosing ψ as in Step 4 of Proposition 6.1 from [8], we arrive at the relationship

$$\left|a_\varepsilon(s)-a_\varepsilon(t)+\int_s^t f_\varepsilon(s)\,d\mathcal{H}^1(s)\right| \le C\int_s^t a_{2\varepsilon}(s)\,d\mathcal{H}^1(s)+C\varepsilon \tag{3}$$

with some positive constant $C>0$ for all sufficiently small $\varepsilon>0$, whenever $\sigma<t<s<l-\sigma$.

Step 3. For an $m>0$ let $X_m^+ := \{f^+\le m\}$ and

$$f_m^+(x) := \begin{cases} f^+(x), & x\in X_m^+,\\ 0, & \text{elsewhere.}\end{cases}$$

If γ is an optimal plan, denote by γ_m the restriction of γ to $X_m^+\times X^-$, and set $\varphi_m^- := \pi_\#^-\gamma_m$, f_m^- denoting the density of the latter with respect to the Lebesgue measure. According to Lemma 3, γ_m is optimal for the mass optimization problem (MK_m) with respect to the measures $\varphi_m^\pm := f_m^\pm\,dx$. For each of such problems denote $a_m\in L^1(\Omega)$ the respective transport density. In the same way let f_{mk}^- stand for the restriction of f_m^- to the set $X_{mk}^- := \{f_m^-\le k\}$, $k>0$. Letting γ_{mk} stand for the restriction of γ_m to $X_m^+\times X_{mk}^-$, f_{mk}^+ stand for the density of $\varphi_{mk}^+ := \pi_\#^-\gamma_{mk}$ with respect to the Lebesgue measure, and $a_{mk}\in L^1(\Omega)$ stand for the transport density for the Monge–Kantorovich problem (MK_{mk}) with respect to the measures $\varphi_{mk}^\pm := f_{mk}^\pm\,dx$ (for which in view of Lemma 3 γ_{mk} is optimal), we see that the directions of the transport rays for each problem (MK_{mk}) coincide with those of the original problem;

namely, for each transport ray R^{mk} for the former there is a ray R for the latter such that $R^{mk} \subset R$. Hence one concludes that

$$-\mathrm{div}\,(a_{mk}\nu) = f_{mk} \text{ in } \Omega,$$

where $f_{mk} := f^+_{mk} - f^-_{mk}$. From (3) we derive

$$\left| a_{mk,\varepsilon}(s) - a_{mk,\varepsilon}(t) + \int_s^t f_{mk,\varepsilon}(s)\, d\mathcal{H}^1(s) \right| \le C \int_s^t a_{mk,2\varepsilon}(s)\, d\mathcal{H}^1(s) + C\varepsilon. \tag{4}$$

According to our choice of ϕ_ε we have that

$$a_{mk,\varepsilon}(s) \to a_{mk}(s,0) \text{ and } f_{mk,\varepsilon}(s) \to f_{mk}(s,0)$$

as $\varepsilon \to 0$. Moreover, the assertion (ii) of Lemma 4 shows that $a_{mk} \in L^\infty(\Omega)$; hence one has

$$a_{mk,\varepsilon}(s) \le C', \qquad f_{mk,\varepsilon}(s) \le C',$$

where the constant $C' = C'(m,k) > 0$ is independent of $\varepsilon > 0$. Thus one can pass to the limit in (4) as $\varepsilon \to 0$ obtaining

$$\left| a_{mk}(s,0) - a_{mk}(t,0) + \int_s^t f_{mk}(\xi,0)\, d\mathcal{H}^1(\xi) \right| \le C \int_s^t a_{mk}(\xi,0)\, d\mathcal{H}^1(\xi). \tag{5}$$

Step 4. Note that $a_{mk}(\cdot)$ is nondecreasing with respect to k, a_m is also nondecreasing, and $a_{mk} \le a_m \le a$. Moreover, since as $k \to \infty$, $m \to \infty$, the sets $X^+_{mk} \uparrow \Omega$, then $a_{mk} \to a$ a.e. on Ω. The same is true also for the sequence $\{f_{mk}\}$. We may assume that the ray R_x is chosen so that the latter convergences occur also $\mathcal{H}^1$-a.e. on R_x. Now, since $f \in L^1(\Omega)$ and $a \in L^1(\Omega)$ by the assertion (i) of Lemma 4, then one can pass to the consecutive limits as $m \to +\infty$ and as $k \to +\infty$ in (5), arriving at the inequality

$$\left| a(s,0) - a(t,0) + \int_s^t f(\xi,0)\, d\mathcal{H}^1(\xi) \right| \le C \int_s^t a(\xi,0)\, d\mathcal{H}^1(\xi).$$

The latter expression means

$$|a'_s(s,0) + f(s,0)| \le C a(s,0)$$

whenever $\sigma \le s \le l - \sigma$. Recall now that $a \in L^1(\Omega)$ by assertion (i) of Lemma 4, while $f \in L^p(\Omega)$ according to the conditions of the theorem being proven. Since according to Lemma 2 we may assume that $a(\cdot,0) \in L^1(\sigma, l-\sigma)$ and $f(\cdot,0) \in L^p(\sigma, l-\sigma)$, then the above inequality implies $a'_s(\cdot,0) \in L^1(\sigma, l-\sigma)$; hence $a(\cdot,0) \in L^\infty(\sigma, l-\sigma)$. Again using the same inequality one concludes $a'_s(\cdot,0) \in L^p(\sigma, l-\sigma)$, which shows the statement. □

LEMMA 4. *In the Monge–Kantorovich problem one has that*

(i) *if either $f^+ \in L^1(X^+)$ or $f^- \in L^1(X^-)$, then $a \in L^1(\Omega)$;*
(ii) *if $f^\pm \in L^\infty(X^\pm)$, then $a \in L^\infty(\Omega)$;*
(iii) *if, moreover, $X^+ \cap X^- = \emptyset$, then $f^+ \in L^\infty(X^+)$ (resp., $f^- \in L^\infty(X^-)$) implies $a \in L^\infty_{loc}(\Omega \setminus X^-)$ (resp., $a \in L^\infty_{loc}(\Omega \setminus X^+)$).*

The proof of this assertion can be found in [5].

We can also refine the above result in the following way.

THEOREM 2. *Let $f^+ \in L^{p^+}(X^+)$ (resp., $f^- \in L^{p^-}(X^-)$) and $X^+ \cap X^- = \emptyset$. Then for a.e. $x \in T$ one has $a \in W^{1,p^+}_{loc}(R_x \backslash X^-)$ (resp., $a \in W^{1,p^-}_{loc}(R_x \backslash X^+)$), where R_x is the transport ray passing through x.*

The proof just follows the scheme of that of Theorem 2 but uses the assertion (iii) of Lemma 4 rather than the assertion (ii).

5. Behavior of density at the ends of transport rays. It is also interesting to study the behavior of the transport density near the ray ends. In fact, the result on vanishing of transport density at the ends of transport rays for Lipschitz continuous $f^{\pm}$ was extensively used in [8] in the proof of existence of optimal transport maps via the ODE approach, as well as in [7, 10, 9] for deriving the law of evolution of a sandpile shape. In general the following result holds.

THEOREM 3. *Let $f^+ \in L^\infty(X^+)$ (resp., $f^- \in L^\infty(X^-)$). Then for a.e. $x \in T$ one has $a(z) \to 0$ when $z \to l^+$ (resp., $z \to l^-$) while $z \in R_x$, where l^+ and l^- are the upper and lower ends, respectively, of the transport ray R_x passing through x.*

Proof. As in the proof of Theorem 1, it is enough to consider the restrictions of a to each of the ray clusters T_{pij}. These restrictions in fact are transport densities for the Monge–Kantorovich problem with respect to the restrictions of $\varphi^{\pm}$ to T_{pij}. In the remaining part of the proof we will assume a ray cluster T_{pij} to be chosen and will be dealing with the respective restrictions without explicitly referring to the cluster.

Let $x \in T$ be such a point that both a and $f^{\pm}$ are continuous in the generalized (Lebesgue) sense $\mathcal{H}^1$-a.e. on R_x. (A.e. $x \in T$ will suit that purpose according to Lemma 1). Suppose $f^+ \in L^\infty(X^+)$. For every $z \in T$ denote by $d(z)$ the distance from z to the upper end of R_z. Suppose now $z \in R_x$, $d(z) = \theta$. Since d is an upper semicontinuous function according to Lemma 24 from [4], then for each sufficiently small $\varepsilon > 0$ one has $d(y) \le 2\theta$ for all $y \in B_\varepsilon(z) \cap T$, where $B_\varepsilon(z) \subset \mathbf{R}^n$ stands for the ball with radius ε centered at z.

We also remark that there exists a $\delta > 0$ such that

$$||l^+ - L^-|| \ge \delta \tag{6}$$

for all lower ray ends L^-. In fact, since we are working within the ray cluster T_{pij}, we have $u(l^+) \le p - 1/j$. If (6) were false, there would exist a sequence of lower ray ends $\{L^-_\nu\}$ such that $L^-_\nu \to l^+$. But $u(L^-_\nu) \ge p + 1/j$ by construction of the ray cluster, and hence, in view of continuity of u, one would have $u(l^+) \ge p + 1/j$ leading to a contradiction.

We use now the following slightly refined version of Lemma 4.6 from [5].

LEMMA 5. *Let l^+ and l^- be the upper and lower ends of the transport ray R_x, respectively, $z \in R_x$, and $\varepsilon > 0$ be sufficiently small. If (6) holds for some $\delta > 0$ and for all lower ray ends L^-, then the upper end of every transport ray R_y which intersects $B_\varepsilon(z)$ belongs to the cylinder with axis R_x and cross-sectional area $C\varepsilon^{n-1}/\delta^{n-1}$, where $C > 0$ is a constant depending only on the geometry of the problem.*

Applying the above lemma to our situation, one has that for $\varepsilon > 0$ sufficiently small, all the upper ends of transport rays R_y which intersect $B_\varepsilon(z)$ necessarily belong to the piece $C_{\theta,\varepsilon}$ of the cylinder mentioned in the lemma, with the length 4θ and with z being the middle point of its axis. From (1) one derives

$$\mu(B_\varepsilon(z)) \le 2\varepsilon \int_{C_{\theta,\varepsilon} \times \Omega} d\gamma = 2\varepsilon \varphi^+(C_{\theta,\varepsilon}).$$

Dividing the above relationship by ε^n and taking the limit as $\varepsilon \to 0$, we obtain $a(z) \le C'\theta$ for some $C' > 0$, which shows the statement for $f^+ \in L^\infty(X^+)$. The case $f^- \in L^\infty(X^-)$ is symmetric. □

Let us remark that the transport density may not vanish at the end of the transport ray when $f^+ \in L^p(X^+)$ with $1 \le p < \infty$, as the following example shows.

Example 2. Let $X^+ \subset \mathbf{R}^n$ be the unit ball centered at the origin, $f^+(x) := |x|^\alpha$ with $-n/p < \alpha < -1$. Then $f^+ \in L^p(X^+)$. Let also $X^- := \{x \in \mathbf{R}^n : l \le |x| \le L\}$ with $l > 1$ and

$$f^-(x) := \frac{n}{(n+\alpha)(L^n - l^n)} \text{ in } X^-.$$

Then one has $u(x) := -|x|$ and the transport is radial. In particular, for $x \in X^+$ one has

$$a(x) = \frac{1}{n+\alpha}|x|^{\alpha+1},$$

and hence $a(x) \not\to 0$ as $|x| \to 0$.

6. Application to *p*-Laplacian equations. In [6] it was proved that if u_p is a solution to the equation

$$-\text{div}\,(|\nabla u_p|^{p-2}\nabla u_p) = -\text{div}\,(|F|^{p-2}F) \text{ in } \Omega,$$

where $F \in L^s_{loc}(\Omega;\mathbf{R}^n)$, then $\nabla u_p \in L^s_{loc}(\Omega;\mathbf{R}^n)$, and, moreover, for $\Omega_0 \subset\subset \Omega$ one has

$$||\nabla u_p||^s_{s;\Omega_0} \le C^{1/p}(||F||^s_{s;\Omega_0} + ||u_p||^p_{p;\Omega_0}), \tag{7}$$

where $C = C(\Omega_0, p, s)$. (Further, we will omit the reference to Ω_0.) It is, however, important to know whether there is such an estimate with C bounded when $p \to +\infty$, while, say, $1 \le s/p \le \theta < +\infty$. In fact, similar estimates (called "uniform in p") on the gradient of the solution to the p-Laplacian equation play an important role in the study of limiting behavior of such solution as $p \to \infty$ (see, for instance, [2]). Unfortunately, the above discussion plus a known relation between the p-Laplacian equations and the Monge–Kantorovich problem shows that the desired estimates cannot be found.

THEOREM 4. *There is no estimate of the type* (7) *uniform in p (i.e., with C bounded), when* $p \to +\infty$.

Proof. The result will be shown in two steps.

Step 1. Consider $\varphi^\pm \ll dx$ be as in the previous discussion. Let $\{u_p\}_{p\ge 2}$ be the sequence of unique solutions to the problems

$$(\Lambda_p) \qquad \begin{cases} -\text{div}\,(|\nabla u_p|^{p-2}\nabla u_p) = f \text{ in } \Omega, \\ u_p = 0 \text{ on } \partial\Omega, \end{cases}$$

where $f := f^+ - f^-$, and suppose $f \in L^r(\Omega)$, $1 < r \le +\infty$. It is a matter of simple though slightly technical calculations to show that up to subsequences (not relabeled)

(A) $u_p \rightharpoonup u$ weakly in $W^{1,s}_0(\Omega)$ for every $s < +\infty$, while $u \in W^{1,\infty}(\Omega)$, and, moreover, u is a transport potential for the problem of transporting φ^+ to φ^-;

(B) $A_p := |\nabla u_p|^{p-2}\nabla u_p \to \alpha$, where α is a vector measure, $*$-weakly in the sense of measures.

In fact, to show (A), using u_p as a test function to (Λ_p) and applying the Hölder inequality, we get

$$\int_\Omega |\nabla u_p|^p \, dx = \int_\Omega f u_p \, dx \le ||f||_r \cdot ||u_p||_{r'}.$$

By the Sobolev inequality we have

$$||u_p||_{r'} \le C(r', n)||\nabla u_p||_q,$$

where $q = q(r', n)$ is such that $nq/(n-q) = r'$, and $C(r', n) = r'n/(n-1)$. Combining the above estimates and again using the Hölder inequality one arrives at

$$||\nabla u_p||_p^{p-1} \le C(r', n)||f||_r \cdot |\Omega|^{1/q(r',n)-1/p} \tag{8}$$

for p sufficiently large. Fix now an arbitrary $s > 2$. Since by Hölder inequality

$$||\nabla u_p||_s \le ||\nabla u_p||_p \cdot |\Omega|^{1/s-1/p}$$

for $p > s$, and in view of (8), one has that up to a subsequence $u_p \rightharpoonup u$ weakly in $W_0^{1,s}(\Omega)$. Note that also $u \in W_0^{1,t}(\Omega)$ for all $t > s$ and, moreover, using (8) we estimate

$$||\nabla u||_t \le \liminf_p ||\nabla u_p||_t \le |\Omega|^{1/t}.$$

The latter actually means $u \in W^{1,\infty}(\Omega)$ and $||\nabla u||_\infty \le 1$. It remains to note that u_p are minima of the functionals

$$I_p(v) := \frac{1}{p}\int_\Omega |\nabla v|^p \, dx - \int_\Omega v f \, dx$$

defined over some $W_0^{1,s}(\Omega)$ with $s > 1$ fixed. Since the sequence I_p Γ-converge to the functional

$$I(u) := \begin{cases} -\int_\Omega v f \, dx, & |\nabla v| \le 1 \text{ a.e. on } \Omega, \\ +\infty & \text{otherwise,} \end{cases}$$

defined over the same $W_0^{1,s}(\Omega)$, hence u is the minimum of the latter; in other words, it is a transport potential.

To show (B), we estimate by the Hölder inequality

$$||A_p||_1 = ||\nabla u_p||_{p-1}^{p-1} \le ||\nabla u_p||_p^{p-1} \cdot |\Omega|^{1/p}$$

to see that, in view of (8), the sequence $\{A_p\}$ is bounded in $L^1(\Omega; \mathbf{R}^n)$ and hence converges up to a subsequence $*$-weakly in the sense of measures.

Let $\mu := |\alpha|$. We show now $\alpha = \mu \nabla_\mu u$, and, moreover, the pair (μ, u) then satisfies

$$(\Lambda_\infty) \qquad \begin{cases} -\operatorname{div}(\mu \nabla_\mu u) &= f \text{ in } \Omega, \\ |\nabla_\mu u| &= 1 \quad \mu\text{-a.e. in } \Omega, \end{cases}$$

where ∇_μ is the tangential gradient operator with respect to μ defined in [3]. In other words, μ is the transport density of the Monge–Kantorovich problem of transporting

$\varphi^+ := f^+\,dx$ to $\varphi^- := f^-\,dx$. For this purpose recall that for all $\phi \in C_0^\infty(\Omega)$ one has $\int_\Omega A_p \nabla\phi\,dx = \int_\Omega f\phi\,dx$ and $A_p \rightharpoonup \alpha$ $*$-weakly in the sense of measures, which implies

$$\int_\Omega \nabla\phi\,d\alpha = \int_\Omega f\phi\,dx.$$

Consider now the sequence $\{\phi_\nu\} \subset C_0^\infty$ such that $\nabla\phi_\nu \to \nabla_\mu u$ in $L^2(\Omega,\mu;\mathbf{R}^n)$ and $\phi_\nu \to u$ uniformly. Passing to the limit in the above relationship, we have

$$\int_\Omega \nabla_\mu u\,d\alpha = \int_\Omega fu\,dx. \tag{9}$$

Let us estimate $\mu(\Omega) = |\alpha|(\Omega)$. We have

$$\mu(\Omega) \le \liminf_p ||A_p||_1 = \liminf_p ||\nabla u_p||_{p-1}^{p-1} \le |\Omega|^{1/p} \left(\int_\Omega |\nabla u_p|^p\,dx\right)^{(p-1)/p},$$

where to obtain the last estimate the Hölder inequality is used. From (Λ_p) using the convergence of $\{u_p\}$, we obtain

$$\int_\Omega |\nabla u_p|^p\,dx = \int_\Omega fu_p\,dx \to \int_\Omega fu\,dx.$$

Therefore, $\mu(\Omega) \le \int_\Omega fu\,dx$. Then from (9) we get

$$\mu(\Omega) \le \int_\Omega \nabla_\mu u\,d\alpha, \tag{10}$$

while on the other hand, since $||\nabla u||_\infty \le 1$, hence $||\nabla_\mu u||_\infty \le 1$, one has

$$\int_\Omega \nabla_\mu u\,d\alpha \le \mu(\Omega). \tag{11}$$

Thus in (10) and (11) in fact the equality holds, namely,

$$\mu(\Omega) = |\alpha|(\Omega) = \int_\Omega \nabla_\mu u\,d\alpha,$$

which implies $|\alpha| = \alpha \cdot \nabla_\mu u$, that is, $\alpha = |\alpha|\nabla_\mu u = \mu\nabla_\mu u$. Clearly, $|\nabla_\mu u| = 1$ μ-a.e.

Step 2. Since $\varphi^\pm \ll dx$, then $\mu \ll dx$ and (Λ_∞) assumes the form

$$(\Lambda'_\infty) \qquad \begin{cases} -\operatorname{div}(a\nabla u) &= f \text{ in } \Omega, \\ |\nabla u| &= 1 \text{ a.e. where } a \ne 0. \end{cases}$$

Consider now a function v such that

$$-\Delta v = f \text{ in } \Omega.$$

Clearly, since $f \in L^r(\Omega)$, such a function exists and the elliptic regularity theory implies $u \in W^{2,r}(\Omega)$. Define the vector field F over Ω by

$$F(x) := |\nabla v(x)|^{1/(p-1)} \frac{\nabla v(x)}{|\nabla v(x)|}$$

with $F(x) = 0$ whenever $\nabla v(x) = 0$. Since by the Sobolev embedding theorem $\nabla v \in L^{r^*}(\Omega; \mathbf{R}^n)$, r^* is the critical Sobolev exponent with respect to r, one has $F \in L^{r^*(p-1)}(\Omega; \mathbf{R}^n)$ and

$$-\mathrm{div}\,(|F|^{p-2}F) = -\Delta v = f \text{ in } \Omega,$$

while

$$|| \, |F|^{p-1} \, ||_{r^*} = ||\nabla v||_{r^*} \leq c(r)||f||_r. \tag{12}$$

Suppose now that the estimate (7) is uniform on p when $p \to +\infty$ (i.e., $C(p,s)$ is bounded, provided $1 \leq s/p \leq \theta \leq +\infty$). Then setting $s := t(p-1)$, where $r < t < r^*$, from (12) we conclude that $|\nabla u_p|^{p-2}\nabla u_p$ are bounded in $L^t(\Omega_0; \mathbf{R}^n)$ whenever $\Omega_0 \subset\subset \Omega$. Hence we would have $a \in L^t_{loc}(\Omega)$ with some $t > r$, and it is enough to refer to Example 1 to see the contradiction. □

BOUNDARY CONTROLLABILITY BETWEEN SUB- AND SUPERCRITICAL FLOW*

MARTIN GUGAT†

Abstract. There are several studies of the boundary controllability of quasi-linear hyperbolic systems where it is assumed that the eigenvalues of the system matrix do not change their signs during the controlled process.

In this paper we consider the flow through a frictionless horizontal rectangular channel that is governed by de St. Venant equations and show that the state can be controlled in finite time from a stationary initial state to a given stationary terminal state in such a way that during this transition, the state stays in the class of C^1 functions, so in particular no shocks occur. There is no restriction on the initial and terminal state, so in some cases it is necessary that one or both eigenvalues of the system matrix change the sign during the process. Various different cases occur: control between subcritical states, control between supercritical states, transition from a subcritical to a supercritical state, and transition from a supercritical to a subcritical state. In the last two cases of a control between states of a different type, one eigenvalue of the system matrix changes its sign during the process. When this happens at a boundary point during the process, it is necessary to switch the type of boundary conditions. We show how to construct controls where at each boundary at most one such switching is necessary.

Key words. de St. Venant equations, subcritical states, supercritical states, global controllability

1. Introduction.

In the study of boundary controllability of quasi-linear hyperbolic systems it is common practice to assume that the eigenvalues of the system matrix do not change their signs during the controlled process (see [3], [15], [14], [6], [5], [10], [7], [9], [12], [8]). In this paper we present a controllability result of a more general type where the number of positive eigenvalues is allowed to change during the control process; this is necessary if this is a different number for the initial state and for the target state.

To be specific, we consider the flow through a frictionless horizontal rectangular channel that is governed by de St. Venant equations. The system is controlled at the boundary points of the channel. For this system, the assumption that the number of positive eigenvalues and the number of negative eigenvalues of the system matrix remain constant during the control process means that the state is assumed to remain subcritical if the initial state is subcritical and to stay supercritical if the initial state is supercritical; in the supercritical case, also the direction of the flow has to be preserved. In some cases, however, for example, during a strong rainfall, the system goes from a subcritical to a supercritical state. The de St. Venant system is of practical interest on account of the trend to operate combined sewer systems and other channel networks, for example, in hydropower optimization, using model predictive control (see, for example, [1], [11]).

In this paper, we present a result on global controllability of de St. Venant system with no restriction on the stationary initial state and the target state. Although classical solutions generally break down in finite time as a result of collision of characteristic curves, we show that starting from a stationary initial state we can reach any other stationary state in finite time with boundary controls that can be chosen in such a way that the state remains continuously differentiable, that is, the state is a classical solution of our system. In order to achieve this, it is essential to change the state sufficiently slowly. To make this possible, the control period has to be chosen sufficiently long.

Apart from its mathematical interest, this result is relevant for applications where shocks have to be avoided. Our proofs are based upon the characteristic form of the equations. In the proofs, we show how the boundary control functions can be obtained. As these controls are not unique, there is some flexibility with respect to optimization. Our result is global in the sense that it holds for initial and terminal states that can be arbitrarily far away from each other.

If the type of the flow is not changed by the controls, that is, if the flow remains either sub- or supercritical, the nature of the boundary conditions also remains unchanged. In the case of a subcritical flow, one variable is controlled at each end of the channel whereas in the supercritical case, both variables are controlled at the end of the channel where inflow occurs. If the flow is controlled from a subcritical to a supercritical state, during this process the type of the boundary conditions changes: While we start with the control of one variable at each end of the channel, we switch to the control of both variables at the end of the channel where inflow occurs. We show that it is possible to do this with only one switching time for each end of the channel. This means that at each end of the channel, one eigenvalue of the system matrix is zero exactly at this switching time. The switching times for both ends can be different.

If the flow is controlled from a supercritical to a subcritical regime, the situation is similar. Also in this case it is possible to control the system with only one switching time for each end of the channel; this means that for each end there is exactly one point in time where one eigenvalue of the system matrix vanishes and the type of the boundary conditions changes.

Our paper has the following structure: In [7], we have shown that boundary control between arbitrary subcritical states is possible. Using similar methods, namely virtual prolongation of the channel in order to be able to work with Cauchy problems, we show that control between supercritical states with the same flow direction is possible. For our analysis it is necessary to show that also control between a subcritical and a supercritical state that are sufficiently close together is possible. The two cases are as follows: Control from a sub- to a supercritical regime and control from a super- to a subcritical state are treated separately. In the analysis of these two cases, also critical initial and target states are included.

Together, the four separate controllability results yield the desired general theorem about controllability without restriction on the stationary initial and target states.

2. De St. Venant equations. We consider the flow through a horizontal rectangular channel without friction. Let $b > 0$ denote the constant width of the channel. The channel is parametrized lengthwise by $x \in [0, L]$. Let $A(x, t)$ denote the wetted area at x at time t, and let $Q(x, t)$ denote the corresponding flow rate. Then the

conservation of mass yields the equation

$$\frac{d}{dt}A(x,t) + \frac{d}{dx}Q(x,t) = 0.$$

Let $U = Q/A$ denote the average velocity over the cross section of the channel and $h = A/b$ the average water height. The conservation of energy implies the equation

$$\frac{d}{dt}U(x,t) + \frac{d}{dx}\left[U(x,t)^2/2 + gh(x,t)\right] = 0.$$

In terms of the functions U and h, the quasi-linear system can be written as

$$\partial_t \begin{pmatrix} h \\ U \end{pmatrix} + \begin{pmatrix} U & h \\ g & U \end{pmatrix} \partial_x \begin{pmatrix} h \\ U \end{pmatrix} = 0.$$

The eigenvalues of the system matrix are $U + \sqrt{gh}$ and $U - \sqrt{gh}$. Let $c(x,t) = \sqrt{gh(x,t)}$ denote the corresponding wave celerity. In terms of the functions U and c, the system equation is

$$\partial_t \begin{pmatrix} c \\ U \end{pmatrix} + \begin{pmatrix} U & c/2 \\ 2c & U \end{pmatrix} \partial_x \begin{pmatrix} c \\ U \end{pmatrix} = 0.$$

With the Riemann invariants $R^+ = U + 2c$, $R^- = U - 2c$ and the diagonal matrix

$$A(R^+, R^-) := \begin{pmatrix} \frac{3}{4}R^+ + \frac{1}{4}R^- & 0 \\ 0 & \frac{1}{4}R^+ + \frac{3}{4}R^- \end{pmatrix},$$

de St. Venant equations can be written in the diagonal form

$$\partial_t \begin{pmatrix} R^+ \\ R^- \end{pmatrix} + A(R^+, R^-)\, \partial_x \begin{pmatrix} R^+ \\ R^- \end{pmatrix} = 0. \tag{2.1}$$

3. Controllability with phase transitions. In this section we present our central controllability result where phase transitions are admitted in the sense that the type of the state is allowed to change between sub- and supercritical. Also critical states are admitted. Note that for the system that we consider here, the stationary states are exactly the constant states.

THEOREM 3.1. *Consider the de St. Venant system with boundary controls on an interval $[0, L]$. Let a stationary initial state A and a stationary target state B be given. Then we can find boundary controls that steer the system in finite time from A to B in such a way that the state remains continuously differentiable.*

Moreover, this can be done in such a way that the absolute values of the first partial derivatives of the state remain below any given upper bound.

In the following four sections, we present partial controllability results that we combine in section 8 to prove Theorem 3.1.

4. Controllability between subcritical states. A state is called subcritical, if one eigenvalue of the system matrix is greater than zero and the other eigenvalue is less than zero. The question of controllability between subcritical states has been answered in [7], where the following theorem is proved.

THEOREM 4.1. *From a constant subcritical state (R^+, R^-) ($3/4R^+ + 1/4R^- > 0$ and $1/4R^+ + 3/4R^- < 0$), the system can be steered to any other constant subcritical state by boundary controls in finite time with a continuously differentiable state.*

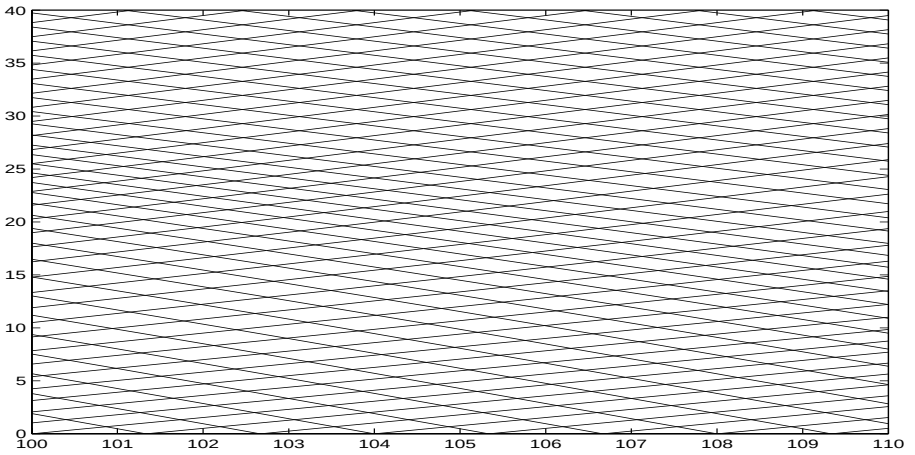

FIG. 1.

Moreover, for every given positive constant, the system can be steered in such a way that the maximum norms of the derivatives of the state and of the controls remain below this bound.

In the proof of the theorem, the considered channel of finite length is prolonged to an infinite channel, where a Cauchy problem can be considered. Under certain assumptions, this Cauchy problem has a classical, that is, continuously differentiable, solution; the essential assumption is that the maximum norm of the derivatives of the initial state is sufficiently small.

The controls are then obtained by cutting a strip whose width is the length of the channel from the x-t plane; the values on the boundary of the strip for positive times yield the desired boundary controls.

Example 1. Consider the subcritical initial state with $U = 0.3$ and $c = 1$, that is, $R_1^+ = 2.3$, $R_1^- = -1.7$, and the subcritical target state with $U = 0$ and $c = 1$, that is, $R_2^+ = 2$, $R_2^- = -2$. Note that for the target state, the water is at rest.

Figure 1 shows the characteristic curves (i.e., the curves whose slopes are the eigenvalues of the system matrix) for a control from the initial state (R_1^+, R_1^-) to the target state (R_2^+, R_2^-) where the water is still. For the target states, the absolute value of the slope of the leftgoing characteristic curves is the same as for the characteristic curves that go from left to right. The channel interval $[0, L]$ is shifted to $[100, 110]$.

At time $T = 40$, the system has reached the desired target state. So we see that our results imply that by boundary controls at both boundaries the water flow in a horizontal channel can be steered to a standstill.

5. Controllability between supercritical states. A state is called supercritical if both eigenvalues of the system matrix are greater than zero or both eigenvalues are less than zero. In this section we study the control between supercritical stationary flows with the same direction. In our result, we consider the problem of steering the system from an initial state for which the corresponding system matrix has two positive eigenvalues to a target state that has also two positive eigenvalues. The problem of steering the system from an initial state with two negative eigenvalues to a target state with two negative eigenvalues can be transformed to the first problem by changing the orientation of the channel. Controllability between supercritical states

has been studied in [9] in a more general framework with source terms on tree-shaped channel networks.

5.1. A local result. We start with a result about local controllability. In this result a compact set of initial states is considered. We show that a certain radius and a control time exist, such that for each of these initial states, it is possible to reach all target states in balls with this radius around the initial state within the control time. So this is a result about uniform local controllability. For the result it is essential that a uniform lower bound for the eigenvalues of the system matrix is valid.

THEOREM 5.1. *Consider the de St. Venant system* (2.1) *with boundary conditions of the form*

$$R^+(0,t) = g_1(t) \quad \textit{and } R^-(0,t) = g_2(t).$$

Let a nonempty compact rectangular set $\Omega = [a_+, b_+] \times [a_-, b_-] \subset R^2$ *be given such that for all* $(R^+, R^-) \in \Omega$, *we have* $3/4R^+ + 1/4R^- > 0$ *and* $1/4R^+ + 3/4R^- > 0$, *that is,* Ω *contains only supercritical states with the same flow direction. Let* $\delta > 0$ *be given. Define*

$$T = \max_{(R^+,R^-)\in\Omega} \max\left\{ \frac{L+\delta}{|(3/4)R^+ + (1/4)R^-|}, \frac{L+\delta}{|(1/4)R^+ + (3/4)R^-|} \right\}. \tag{5.1}$$

Then there exists a number $\alpha > 0$ *such that for all constant initial states* $(R_1^+, R_1^-) \in \Omega$ *and for all constant terminal states* $(R_2^+, R_2^-) \in \Omega$ *with*

$$\max\{|R_1^+ - R_2^+|,\ |R_1^- - R_2^-|\} \le \alpha, \tag{5.2}$$

the boundary controls g_1, g_2 *can be chosen such that in time* T *the system has reached the terminal state* (R_2^+, R_2^-) *and the corresponding solution is continuously differentiable.*

Moreover, by choosing α *sufficiently small, the maximal absolute values of the derivatives*

$$\partial_x R^+(x,t),\ \partial_x R^-(x,t),\ \partial_t R^+(x,t),\ \partial_t R^-(x,t),\ g_1'(t),\ g_2'(t)$$

for $(x,t) \in [0,L] \times [0,T]$ *can be made arbitrarily small.*

Proof. The proof is similar to the proof of the corresponding result for the subcritical case in [7]. We define an initial state $\varphi : R \to R^2$ on the real line in the following way. For $x \in [0,\infty)$, let $\varphi(x) = (R_1^+, R_1^-)$. For $x \in (-\infty, -\delta]$, let $\varphi(x) = (R_2^+, R_2^-)$. For $x \in (-\delta, 0)$, define φ in $C^1(R)$ such that the components φ_1 and φ_2 of φ are monotone functions on $(-\delta, 0)$ and

$$\max_{x\in R}\{|\varphi_1'(x)|,\ |\varphi_2'(x)|\} \le (3/\delta)\max\{|R_1^+ - R_2^+|,\ |R_1^- - R_2^-|\}. \tag{5.3}$$

Since the set Ω is compact, we can choose a number $c_0 > 0$ such that for all $(R^+, R^-) \in \Omega$ we have $|(R^+, R^-)| \le c_0$. Then we can choose a number $k \ge 1$ such that for all (R^+, R^-) with $|(R^+, R^-)| \le 2c_0$ we have $|A(R^+, R^-)| \le k$. Define $a = -kT$ and $b = L + kT$. Then $(A, 0) \in \Sigma([a,b] \times [0,T], 2, 2c_0, 1/2, k)$, where the class Σ is defined in the introduction of [4]. Theorem 3.IV from Cirina [4] implies the existence of a number $\beta > 0$ such that if

$$\max_{x\in\mathbb{R}}\{|\varphi_1'(x)|,\ |\varphi_2'(x)|\} \le \beta, \tag{5.4}$$

the de St. Venant system with initial state φ on $[a,b]$ has a unique continuously

differentiable solution on the convex hull of the two sets $[a,b]\times\{0\}$ and $[0,L]\times[0,T]$. Let τ denote this region.

Choose $\alpha \le \beta\delta/3$. Then (5.2) and (5.3) imply (5.4). Therefore by Theorem 3.IV from Cirina [4], a C^1 solution $(R^+(x,t), R^-(x,t))$ with initial state φ on $[a,b]$ exists on the set τ.

Moreover, Theorem 3.IV guarantees the existence of a constant $N>0$ such that for all $(x,t)\in[0,L]\times[0,T]$ we have

$$\max\{|\partial_x R^+(x,t)|,\ |\partial_x R^-(x,t)|\} \le N \max_{x\in\mathbb{R}}\{|\varphi_1'(x)|,\ |\varphi_2'(x)|\} \le 3N\alpha/\delta.$$

This implies that by choosing α sufficiently small, we can make the absolute values of the derivatives $\partial_x R^+(x,t)$, $\partial_x R^-(x,t)$ arbitrarily small.

Since the initial state φ_1 has values only between R_1^+ and R_2^+, this is also the case for the first component R^+ of the solution on $[0,T]$. Similarly, R^- can attain only values between R_1^- and R_2^-.

Define

$$M = \max_{(x,t)\in[0,L]\times[0,T]}\{|(3/4)R^+ + (1/4)R^-|,\ |(1/4)R^+ + (3/4)R^-|\}.$$

The system equation implies that

$$\max_{(x,t)\in[0,L]\times[0,T]}\{|\partial_t R^+|,\ |\partial_t R^-|\} \le M \max_{(x,t)\in[0,L]\times[0,T]}\{|\partial_x R^+|,\ |\partial_x R^-|\} \le 3MN\alpha/\delta.$$

So we can also make the absolute values of the time derivatives of (R^+, R^-) arbitrarily small by choosing α sufficiently small.

The slopes of the characteristic curves are given by $dx_+/dt = (3/4)R^+ + (1/4)R^-$ and $dx_-/dt = (1/4)R^+ + (3/4)R^-$, respectively. In the area of points above both of these characteristics starting at the point $(-\delta, 0)$, the component R^+ of the solution has the value R_2^+ and R^- has the value R_2^-. By the definition of T and on account of the rectangular shape of Ω, this implies that at time T the system has reached the terminal state (R_2^+, R_2^-) on the interval $[0,L]$.

This can be seen as follows. Since the set Ω contains only supercritical states, both the x_+ and the x_- characteristic curves have positive slope. Hence at time T both characteristic curves coming from the point $(x,t) = (-\delta, 0)$ have reached the point (L,T).

We now define the functions g_1, g_2 by setting $g_1(t) := R_+(0,t)$ and $g_2(t) := R_-(0,t)$ and have thus constructed the required boundary controls. □

5.2. A global result. Now we apply the same globalization technique as in [7] to our local result: The uniformity in the local result implies that boundary control between all elements of the set Ω is possible in finite time.

THEOREM 5.2. *Let a nonempty compact rectangular set Ω as in Theorem 5.1 be given.*

Then there exist boundary controls g_1, g_2 that steer the de St. Venant system in finite time from any constant initial state in the set Ω to any constant terminal state in Ω in such a way that the corresponding solution is continuously differentiable.

Moreover, this can be done in such a way that the absolute values of the derivatives of the state remain smaller than any given upper bound.

The proof is exactly as in [7]: The idea is to introduce a finite number of intermediate states on the line connecting the initial state with the target state and to control the system successively from one intermediate state to the next.

Now we can prove that it is possible to steer the system from any constant supercritical state to any other constant supercritical state with the same flow direction in finite time with a continuously differentiable state and bounds for the absolute values of the derivatives.

THEOREM 5.3. *The de St. Venant system can be steered from a constant supercritical state to any other constant supercritical state with the same flow direction in finite time with a continuously differentiable state by boundary controls at one end.*

Moreover, for every given positive constant the system can be steered in such a way that the maximum norms of the state derivatives and of the control derivatives remain below this bound.

Proof. Let two constant supercritical states (R_A^+, R_A^-) and (R_B^+, R_B^-) be given.

For a natural number n and $k \in \{0, \dots, n\}$ define $\lambda_{k,n} = k/n$ and let

$$R_{k,n}^+ = (1 - \lambda_{k,n})R_A^+ + \lambda_{k,n}R_B^+, \quad R_{k,n}^- = (1 - \lambda_{k,n})R_A^- + \lambda_{k,n}R_B^-.$$

Then $R_{0,n}^+ = R_A^+$, $R_{0,n}^- = R_A^-$, $R_{n,n}^+ = R_B^+$, $R_{n,n}^- = R_B^-$.

If the number n is chosen sufficiently large, for all $k \in \{1, \dots, n\}$ the nonempty sets

$$\Omega_k = [\min\{R_{k-1}^+, R_k^+\},\ \max\{R_{k-1}^+, R_k^+\}] \times [\min\{R_{k-1}^-, R_k^-\},\ \max\{R_{k-1}^-, R_k^-\}]$$

contain only supercritical states with the same flow direction; hence for all $k \in \{1, \dots, n\}$ Theorem 5.2 is applicable to Ω_k. So we can steer the system from the initial state $(R_A^+, R_A^-) \in \Omega_1$ to $(R_{1,n}^+, R_{1,n}^-) \in \Omega_1$, from $(R_{1,n}^+, R_{1,n}^-) \in \Omega_2$ to $(R_{2,n}^+, R_{2,n}^-) \in \Omega_2$, and so forth and finally from $(R_{n-1,n}^+, R_{n-1,n}^-) \in \Omega_n$ to the desired terminal state $(R_B^+, R_B^-) \in \Omega_n$ that we reach after n such steps.

The assertion about the maximum norms of the derivatives and the controls also follows from Theorem 5.2. ∎

Example 2. Consider the supercritical initial state with $U = 2$ and $c = 1$, that is, $R_1^+ = 4$, $R_1^- = 0$, and the supercritical target state with $U = 1.9$ and $c = 1$, that is, $R_2^+ = 3.9$, $R_2^- = -0.1$.

Define $p(a, \cdot)$ as the cubic polynomial that is determined by the four conditions $p(a, -\delta) = a$, $p'(a, -\delta) = p(a, 0) = p'(a, 0) = 0$, that is,

$$p(a, x) = \frac{6a}{\delta^3}\left(\frac{x^3}{3} + \delta\frac{x^2}{2}\right).$$

Note that $p(a, \cdot)$ is monotone on the interval $[-\delta, 0]$.

Define the function φ with the components

$$\varphi_1(x) = \begin{cases} R_2^+, & x \in (-\infty, -\delta), \\ R_1^+ + p(R_2^+ - R_1^+, x), & x \in [-\delta, 0), \\ R_1^+, & x \in [0, \infty), \end{cases}$$

and

$$\varphi_2(x) = \begin{cases} R_2^-, & x \in (-\infty, -\delta), \\ R_1^- + p(R_2^- - R_1^-, x), & x \in [-\delta, 0), \\ R_1^-, & x \in [0, \infty). \end{cases}$$

Then the function $\varphi = (\varphi_1, \varphi_2)$ satisfies the requirements of the proof of Theorem 5.1. Figure 2 shows the characteristic curves for the solution of the Cauchy problem with the initial data given by φ. The point zero is shifted to 180 and the point $-\delta$ is shifted

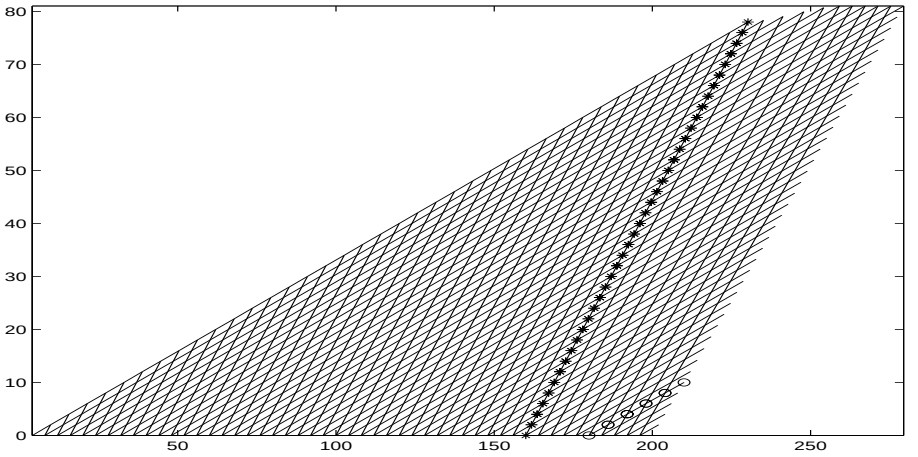

FIG. 2.

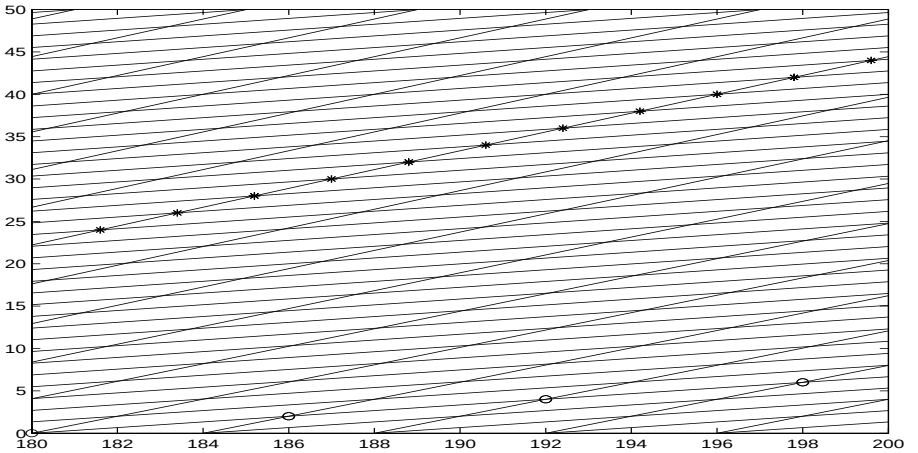

FIG. 3.

to 160. The channel goes from $x = 180$ to $x = 200$. Above the characteristic curve marked by asterisks the state is equal to the target state (R_2^+, R_2^-). Below the line marked by o's, the state equals the initial state (R_1^+, R_1^-).

The control is obtained by cutting the rectangle $[0, L] \times [0, T]$ from the x-t plane; the boundary values yield the control functions. In Figure 3, the rectangle is shifted to $[180, 200] \times [0, 50]$. At time $T = 50$, the system has reached the desired target state.

6. Controllability from super- to subcritical states. In this section we show how the system can be controlled from a given supercritical initial state to a subcritical state with the same value of the Riemann invariant R^-. We also admit critical initial or target states. A state is called critical if one eigenvalue of the corresponding system matrix is zero.

THEOREM 6.1. *Let a supercritical or critical initial state (R_1^+, R_1^-) with positive eigenvalues (that is, $3R_1^+ + R_1^- > 0$, $R_1^+ + 3R_1^- \geq 0$) and a subcritical or critical target state (R_2^+, R_1^-), where the second Riemann invariant has the same value as for the initial state and $R_2^+ > -R_1^-/3$, be given. Then there exists a boundary control*

that steers the system in finite time from the initial state to the target state with a continuously differentiable solution. During the process, the nature of the boundary conditions changes at each boundary at most once.

If the number $|R_2^+ - R_1^+|$ is sufficiently small, for every positive upper bound the system can be steered in such a way that the maximum norm of the derivatives of the state remains below this bound.

Proof. Let $R_2^- = R_1^-$. The assumptions imply that $(3/4)R_2^+ + (1/4)R_2^- > 0$. Since the terminal state is subcritical or critical, this implies that $(1/4)R_2^+ + (3/4)R_2^- \leq 0$. Hence $R_2^+ \leq -3R_2^- \leq R_1^+$, since the initial state is supercritical or critical.

Let $\delta > 0$ be given. Define the function φ_1 by $\varphi_1(x) = R_2^+$ if $x \in (-\infty, -\delta]$, $\varphi_1(x) = R_1^+$ if $x \in [0, \infty)$, and extend φ_1 to an increasing continuously differentiable function on the whole real axis. If $R_2^+ = R_1^+$, the initial state equals the terminal state and there is nothing to prove. So in what follows, we can assume that $R_2^+ < R_1^+$, and we can choose φ_1 in such a way that it is strictly increasing on the interval $[-\delta, 0]$. Define φ_2 by $\varphi_2(x) = R_1^-$ for all $x \in (-\infty, \infty)$.

Now we consider the Cauchy problem for our system (2.1) with the initial data given by the function φ. Since the components of the function φ are both increasing, Theorem 2.1 in [13] implies the existence of a unique continuously differentiable solution of the Cauchy problem for all $t \geq 0$ (see also Remark 2.4 in [13]).

Let (S^+, S^-) denote the solution of this Cauchy problem.

The slope of the characteristic curve with positive slope that starts at the point $(x, t) = (-\delta, 0)$ is at least $(3/4)R_2^+ + (1/4)R_2^- > 0$, since φ_1 is increasing. Hence after the time $T = (L+\delta)/((3/4)R_2^+ + (1/4)R_2^-)$, this curve has reached the x-value L, that is, the end L of the channel. In the area above this characteristic curve the Riemann invariants have the values (R_2^+, R_2^-); hence the state equals the desired target state in this area. This implies that the state in the points in $[0, L] \times [T, \infty)$ is the desired target state, i.e., after the time T the channel state has reached the target.

The initial values of the Riemann invariants are given by the increasing function φ_1 and the constant function φ_2, and the values of the Riemann invariants are constant on the characteristic curves. Therefore on the line (L, t), $t \geq 0$, the eigenvalue $(1/4)S^+ + (3/4)S^-$ is decreasing with time. Since $(1/4)R_1^+ + (3/4)R_1^- \geq 0$ and $(1/4)R_2^+ + (3/4)R_2^- \leq 0$, and $R_2^+ < R_1^+$, there exists an interval $[t_L^1, t_L^2]$ that consists exactly of the points where the eigenvalue $(1/4)S^+ + (3/4)S^-$ is equal to zero. If the initial state is critical, that is, if initially the eigenvalue is zero, that is, $(1/4)R_1^+ + (3/4)R_1^- = 0$, we have $t_L^1 = 0$. If the target state is critical, that is, if for the target state the eigenvalue is zero, that is, $(1/4)R_2^+ + (3/4)R_2^- = 0$, we have $t_L^2 = T$. If both the initial and the terminal state are not critical, the interval $[t_L^1, t_L^2]$ reduces to a single point t_L since φ_1 is strictly increasing on the interesting interval $[-\delta, 0]$; so in this case there is exactly one time t_L where this eigenvalue is zero at the right channel boundary.

Analogously, we see that on the line $(0, t)$, $t \geq 0$, the eigenvalue $(1/4)S^+ + (3/4)S^-$ is decreasing with time and vanishes exactly on an interval $[t_0^1, t_0^2]$. If the target state is critical, $t_0^2 = T$. If the initial state is critical, $t_0^1 = t_0^2 = 0$. If both the initial and the terminal state are not critical, the interval $[t_0^1, t_0^2]$ reduces to a single point t_0, that is, in this case there is exactly one time t_0 where this eigenvalue is zero at the left channel boundary.

For $t \in [0, \infty)$, define $g_1(t) = S^+(0, t)$, $g_2(t) = S^-(0, t) = R_1^-$, and $g_3(t) = S^-(L, t) = R_1^-$. The boundary conditions for the problem of flow control for the channel are then defined in the following way.

At the left channel–boundary 0, $R^+(0,t) = g_1(t)$ and if $g_1(t)+3R_1^- > 0$, $R^-(0,t) = g_2(t) = R_1^-$. Note that $g_1(t) + 3R_1^- = R^+(0,t) + 3R^-(0,t)$.

At the right channel–boundary L, if $R^+(L,t) + 3R_1^- < 0$, $R^-(L,t) = g_3(t) = R_1^-$.

Since the continuously differentiable function (S^+, S^-) satisfies the conditions defined above, it is clear that a classical solution of the initial-boundary problem on $[0, L]$, $t \geq 0$, with the above boundary conditions exists. Moreover, since the boundary conditions are such that the value of R^- is always R_1^- and the value of R^+ is prescribed at the left boundary for all times $t \geq 0$ to be the same as for S^+, the solution must in fact be equal to the restriction of (S^+, S^-) to $[0, L] \times [0, \infty)$. So we see that the system can be controlled from the initial state to the target state in finite time with a continuously differentiable solution and with only one switching time at each end.

The last part of the assertion follows from the a priori bound for the derivatives in Theorem 3.IV in [4], since for any given δ if $|R_2^+ - R_1^+|$ is sufficiently small, we can make the derivative φ_1' arbitrarily small. □

Remark 1. Note that throughout the solution the value of the Riemann invariant R^- remains constant. Our boundary conditions work in the following way: The values of the Riemann invariant R^+ are prescribed at the left boundary 0 at all times $t \geq 0$. The values of the other Riemann invariant R^- are at the beginning also described on the left boundary 0 to have the constant value R_1^-; then as time proceeds, by the change of the value of R^+ through the boundary conditions the slope $(1/4)R^+ + (3/4)R^-$ of the characteristic curves where R^- is constant becomes negative. In fact, the eigenvalue $(1/4)R^+ + (3/4)R^-$ is zero on the characteristic curve that travels from left to right with slope $(3/4)R^+ + (1/4)R^-$ where $R^+ = -3R_1^-$. If the initial state is supercritical (not critical) and the target state is subcritical (also not critical), the switching time for the boundary conditions is the time where this characteristic curve arrives at the right end.

Note that the boundary conditions for the control problem defined above are of similar character as the boundary conditions considered in [2] for scalar quasi-linear equations.

Example 3. Consider the supercritical initial state with $R_1^+ = 5.7$, $R_1^- = -1.5$ and the subcritical target state with $R_2^+ = 3.3$, $R_1^- = -1.5$.

As in Example 2, define the functions φ_1 and φ_2 by cubic polynomials on the interval $[-\delta, 0]$.

Figure 4 shows the characteristic curves for the solution of the Cauchy problem with the initial data given by φ. The point zero is shifted to 140 and the point $-\delta$ is shifted to 40. The channel goes from $x = 140$ to $x = 180$. Above the characteristic curve marked by asterisks, the state is equal to the target state (R_2^+, R_2^-). Below the line marked by o's, the state equals the initial state (R_1^+, R_1^-). The control is obtained by cutting the rectangle $[0, L] \times [0, T]$ from the x-t plane; the boundary values yield the control functions. In fact, only the control values for $g_1(t) = S^+(0,t)$ need to be obtained in this way. In Figure 5 the rectangle is shifted to $[140, 180] \times [0, 67.5]$. At time $T = 67.5$, the desired target state has been reached.

7. Controllability from sub- to supercritical states. To complete our analysis, in this section we study the control of the system between the sub- and the supercritical phase. Again we also admit critical target or initial states. It turns out that this case is more complicated than the situation treated in section 6 because for the corresponding Cauchy problem we cannot expect that the solution exists for all $t \geq 0$, since after a finite time shocks can occur. We present controls where this

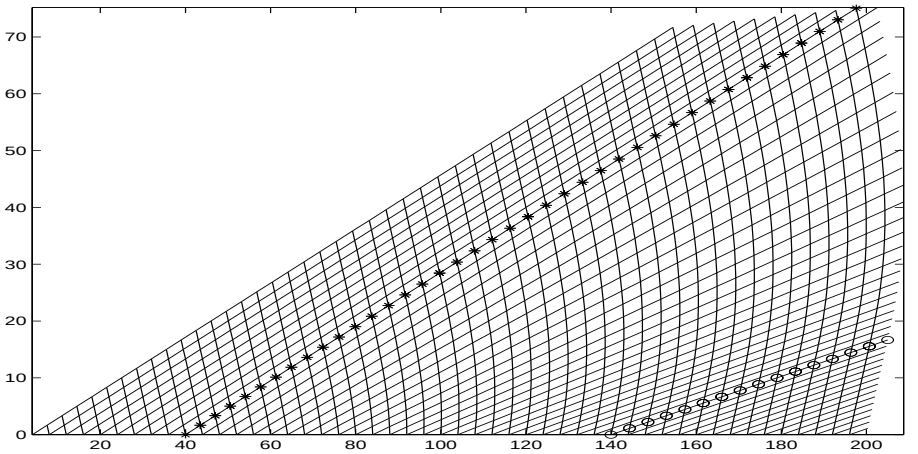

FIG. 4.

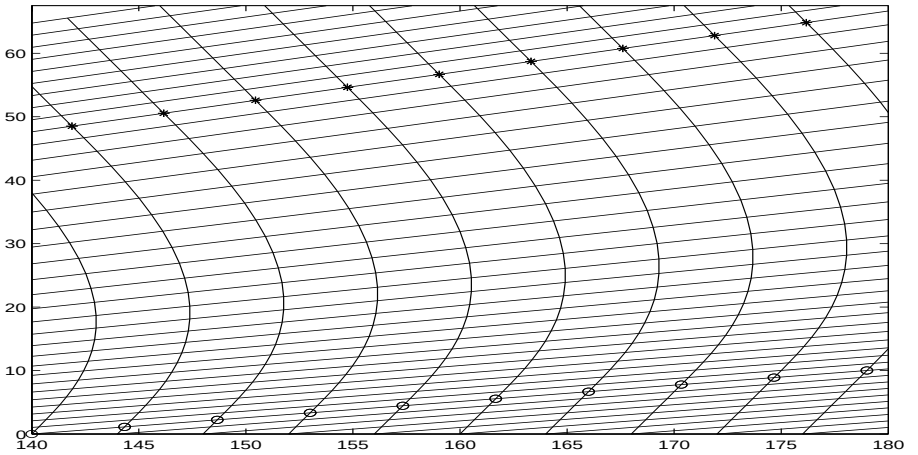

FIG. 5.

happens only after in the channel the target state has been reached, so the shock does not influence our control process.

THEOREM 7.1. *Let a subcritical or critical initial state* (R_1^+, R_1^-) *(with* $3R_1^+ + R_1^- > 0$, $R_1^+ + 3R_1^- \leq 0$*) and a supercritical or critical target state* (R_2^+, R_1^-)*, where the second Riemann invariant has the same value as for the initial state and* $R_2^+ > -R_1^-/3$*, be given. If the number* $|R_2^+ - R_1^+|$ *is sufficiently small, there exists a boundary control that steers the system in finite time from the initial state to the target state with a continuously differentiable solution. During the process, the nature of the boundary conditions changes at each boundary at most once. For every given positive constant the system can be steered in such a way from the initial to the target state that the absolute values of the derivatives of the state remain below this bound.*

Proof. Let $R_2^- = R_1^-$. The assumptions imply the inequality $R_2^+ \geq -3R_1^- \geq R_1^+$. If $R_2^+ = R_1^+$, the initial state equals the terminal state and there is nothing to prove. So in what follows, we can assume that $R_2^+ > R_1^+$. Let $\delta > 0$ be given. Define the function φ_1 by $\varphi_1(x) = R_2^+$ if $x \in (-\infty, -\delta]$, $\varphi_1(x) = R_1^+$ if $x \in [0, \infty)$, and extend φ_1

to a decreasing continuously differentiable function on the whole real axis such that

$$\varphi_1' \le (3/\delta)|R_2^+ - R_1^+|. \tag{7.1}$$

Moreover, choose φ_1 such that it is strictly decreasing on the interval $[-\delta, 0]$. Define φ_2 by $\varphi_2(x) = R_1^-$ for all $x \in (-\infty, \infty)$.

Now we consider the Cauchy problem for the de St. Venant system (2.1) with the initial data given by the function φ. Define the time T by the equation $T = (L+\delta)/[(3/4)R_2^+ + (1/4)R_1^-]$.

We can choose a number $c_0 > 0$ such that the following inequality is valid: $\max_{x\in(-\infty,\infty)}\{|\varphi_1(x)|,\ |\varphi_2(x)|\} \le c_0$. Then we can choose a number $k \ge 1$ such that for all (R^+, R^-) with $|(R^+, R^-)| \le 2c_0$ we have $\max\{|3R^+ + R^-|,\ |R^- + 3R^+|\}/4 \le k$. Define $a = -kT$ and $b = L + kT$. Then Theorem 3.IV from Cirina [4] implies the existence of a number $\beta > 0$ such that if

$$\max_{x\in\mathbb{R}}\{|\varphi_1'(x)|,\ |\varphi_2'(x)|\} \le \beta, \tag{7.2}$$

the de St. Venant system with initial state φ on $[a, b]$ has a unique continuously differentiable solution on the convex hull of the two sets $[a, b] \times \{0\}$ and $[0, L] \times [0, T]$. Let τ denote this region. Choose $\alpha = \beta\delta/3$. If $|R_2^+ - R_1^+| \le \alpha$, condition (7.1) implies (7.2). Therefore by Theorem 3.IV from [4], a C^1 solution with initial state φ on $[a, b]$ exists on the set τ. Let (S^+, S^-) denote this solution.

As in the proof of Theorem 5.1, the assertion that we can make the absolute values of the derivatives $\partial_x R^+$, $\partial_x R^-$, $\partial_t R^+$, $\partial_t R^-$ arbitrarily small by choosing α sufficiently small follows from the a priori bound in Theorem 3.IV from [4].

The slope of the characteristic curve that starts with slope $(3/4)R_2^+ + (1/4)R_2^-$ at the point $(x, t) = (-\delta, 0)$ is constant, since the Riemann invariant R^+ is constant on this curve and $R^- = R_1^-$. Hence after the time T, this curve has reached the x-value L, that is, the end L of the channel. In the area above this characteristic curve the Riemann invariants have the values (R_2^+, R_2^-); hence the state equals the desired target state in this area. This implies that the state in the points in $[0, L] \times \{T\}$ is the desired target state, i.e., after the time T the channel state has reached the target.

The initial values of the Riemann invariants are given by the decreasing function φ_1 and the constant function φ_2; so $R^-(x, t) = R_1^-$ is constant for the whole solution, and the values of the other Riemann invariant R^+ are constant on the corresponding characteristic curves. Therefore on the line (L, t), $t \ge 0$, the eigenvalue $(1/4)S^+ + (3/4)S^-$ is increasing with time. Since $(1/4)R_1^+ + (3/4)R_1^- \le 0$, $(1/4)R_2^+ + (3/4)R_2^- \ge 0$, and $R_2^+ > R_1^+$, there exists an interval $[t_L^1, t_L^2]$ consisting exactly of the points where the eigenvalue $(1/4)S^+ + (3/4)S^-$ is zero. If the initial state is critical, that is, if initially the eigenvalue is zero, that is, $(1/4)R_1^+ + (3/4)R_1^- = 0$, we have $t_L^1 = 0$. If the target state is critical, that is, if for the target state the eigenvalue is zero, that is, $(1/4)R_2^+ + (3/4)R_2^- = 0$, we have $t_L^2 = T$. If both the initial and the terminal state are not critical, the interval $[t_L^1, t_L^2]$ reduces to a single point t_L, since φ_1 is strictly decreasing on the interesting interval $[-\delta, 0]$; so in this case there is exactly one time t_L where this eigenvalue is zero at the right channel boundary.

Analogously, we see that also on the line $(0, t)$, $t \ge 0$, the eigenvalue $(1/4)S^+ + (3/4)S^-$ is increasing with time and vanishes exactly on an interval $[t_0^1, t_0^2]$. If the target state is critical, $t_0^2 = T$. If the initial state is critical, $t_0^1 = t_0^2 = 0$, and if both the initial and the terminal state are not critical, the interval $[t_0^1, t_0^2]$ reduces to a single point t_0, that is, in this case there is exactly one time t_0 where this eigenvalue is zero at the left channel boundary.

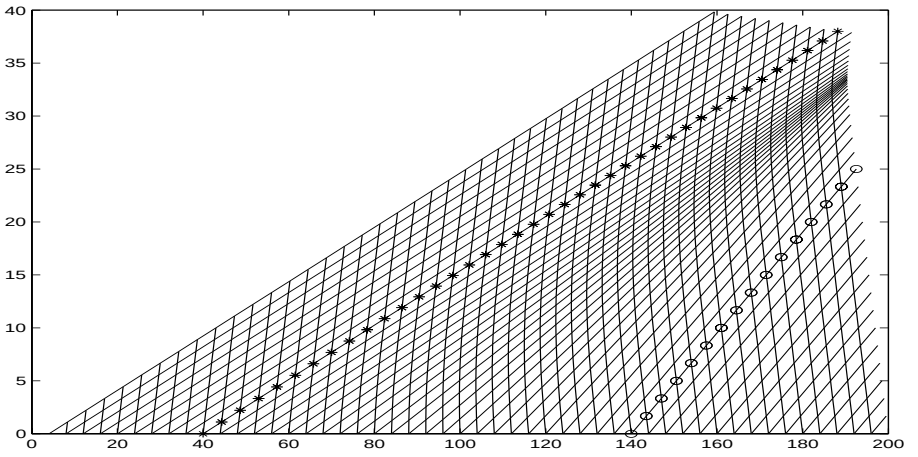

FIG. 6.

For $t \in [0, \infty)$, define $g_1(t) = S^+(0,t)$, $g_2(t) = S^-(0,t)$, and $g_3(t) = S^-(L,t)$. The boundary conditions for the problem of flow control for the channel are then defined in the following way:

At the left channel–boundary 0, $R^+(0,t) = g_1(t)$ and if $R^+(0,t) + 3R_1^- > 0$, $R^-(0,t) = g_2(t)$.

At the right channel–boundary L, if $R^+(L,t) + 3R_1^- < 0$, $R^-(L,t) = g_3(t)$.

Since the continuously differentiable function (S^+, S^-) satisfies the conditions defined above, it is clear that a classical solution of the initial-boundary problem on $[0, L]$, $t \geq 0$, with the above boundary conditions exists. Moreover, since the boundary conditions are such that the value of R^- remains always R_1^- and the value R^+ is prescribed at the left boundary for all times $t \geq 0$ to be the same as for S^+, the solution must in fact be equal to the restriction of (S^+, S^-) to $[0, L] \times [0, \infty)$. So we see that the system can be controlled from the initial state to the target state in finite time with a continuously differentiable solution and with at most one switching time at each end. □

Remark 2. If the initial state is subcritical (not critical) and the target state is supercritical (not critical), the switching points t_0 and t_L are connected by the line $M = \{(x,t) : (1/4)R^+(x,t) + (3/4)R^-(x,t) = 0\}$. This line is in fact a characteristic curve since $R^- = R_1^-$ is constant for the solution; hence (see also Remark 1)

$$M = \{(x,t) : R^+(x,t) = -3R_1^-\} = \{(x,t) : (3/4)R^+(x,t) + (1/4)R^-(x,t) = -2R_1^-\}.$$

Example 4. Consider the subcritical initial state with $R_1^+ = 3.3$, $R_1^- = -1.5$ and the supercritical target state with $R_2^+ = 5.7$, $R_1^- = -1.5$.

As in Example 2, define the functions φ_1 and φ_2 by cubic polynomials on the interval $[-\delta, 0]$.

Figure 6 shows the characteristic curves for the solution of the Cauchy problem with the initial data given by φ. The point zero is shifted to 140 and the point $-\delta$ is shifted to 40. The channel goes from $x = 140$ to $x = 180$. Above the characteristic curve marked by asterisks, the state is equal to the target state (R_2^+, R_2^-). Below the

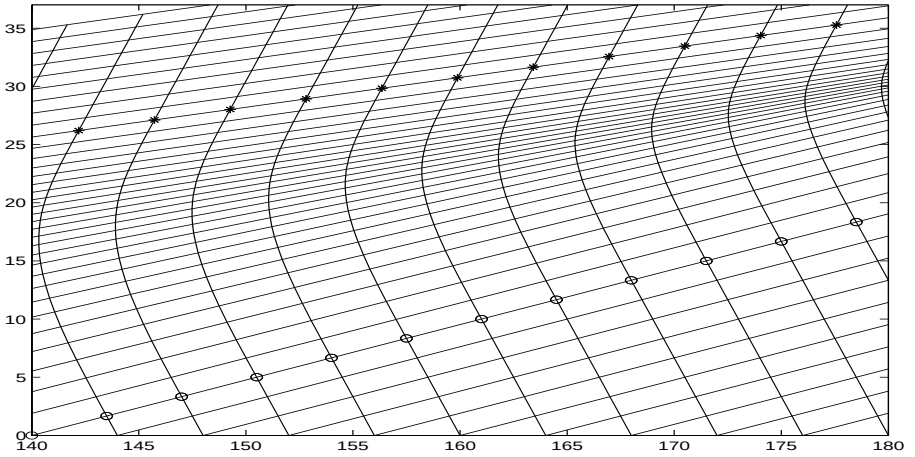

FIG. 7.

line marked by o's, the state equals the initial state (R_1^+, R_1^-). The control is obtained by cutting the rectangle $[0, L] \times [0, T]$ from the x-t plane; the boundary values yield the control functions. In Figure 7, the rectangle is shifted to $[140, 180] \times [0, 37]$. At time $T = 37$, the desired target state has been reached.

8. Proof of the general controllability result. For the proof of Theorem 3.1, we point out that starting with a critical state, we can reach any subcritical state as a consequence of Theorem 6.1 and Theorem 4.1. Starting from a subcritical state, we can reach any supercritical state with positive eigenvalues; this follows from Theorem 4.1, Theorem 7.1, and Theorem 5.3. From a supercritical state with positive eigenvalues, we can reach any subcritical state; this can be proved using Theorem 5.3, Theorem 6.1, and Theorem 4.1. Analogously, we see that starting from a subcritical state, we can reach any supercritical state with negative eigenvalues, and starting from a state of this type, we can go to any subcritical state.

Finally a combination of Theorem 4.1 and Theorem 7.1 implies that from a subcritical state we can control the system to any critical state. In this case Theorem 7.1 is applied in the following way: The critical target state (R_2^+, R_2^-) is prescribed and the initial state (R_1^+, R_2^-) in the statement of Theorem 7.1 is then chosen in such a way that it is subcritical: $R_1^+ = R_2^+ - \varepsilon$ with $\varepsilon > 0$ chosen sufficiently small. Since Theorem 4.1 implies that from any subcritical initial state we can reach this state (R_1^+, R_1^-), the assertion follows.

9. Conclusion. We have shown that for the de St. Venant system that describes the flow in a horizontal channel without friction, boundary control between arbitrary stationary states is possible in such a way that during the control process the system has a classical solution. This result raises many interesting questions: Can it be extended to the case of a system with a nonzero source term, for example, a steep channel with friction? Are phase transitions of the type that occur here, where eigenvalues of the system matrix change their sign during the control process, possible for general quasi-linear hyperbolic systems? These questions are left for future research.

DEGREES OF EFFICIENCY AND DEGREES OF MINIMALITY*

ALBERTO ZAFFARONI†

Abstract. In this work we characterize different types of solutions of a vector optimization problem by means of a scalarization procedure. Usually different scalarizing functions are used in order to obtain the various solutions of the vector problem. Here we consider different kinds of solutions of the *same* scalarized problem. Our results allow us to establish a parallelism between the solutions of the scalarized problem and the various efficient frontiers: stronger solution concepts of the scalar problem correspond to more restrictive notions of efficiency. Besides the usual notions of weakly efficient and efficient points, which are characterized as global and strict global solutions of the scalarized problem, we also consider some restricted notions of efficiency, such as strict and proper efficiency, which are characterized as Tikhonov well-posed minima and sharp minima for the scalarized problem.

Key words. vector optimization, scalarization, proper efficiency, strict efficiency, sharp minima, well-posed minima

1. Introduction.

Both theory and practice of vector optimization have always been closely related to scalarization procedures. The most widely used is probably the linear scalarization; for Pareto optimization problems, in which the outcome space is ordered componentwise, it consists of the consideration of a weighted sum of components of the objective function with nonnegative coefficients.

In the seminal paper by Kuhn and Tucker [21], for the first time the concept of proper efficiency was introduced, precisely in order to prove that the multipliers of all components of the objective function in the necessary optimality conditions are (strictly) positive. To reach this result one has to require, besides a constraint qualification, a further requirement on the efficient point to avoid anomalous features.

In this fashion properly efficient points can be characterized (under convexity assumptions) as the solutions of a linearly scalarized problem in which all coefficients are positive. From a geometric point of view this entails that an open halfplane exists, whose normal vector is strictly positive and is disjoint from the image set.

In the last fifty years the notion of proper efficiency has been described in a number of ways (see, e.g., [13, 27, 6] for references and comparisons); the various definitions emphasize different aspects (boundedness of trade-offs between objectives, disjointness between the ordering cone and some conical approximation of the image set, stability properties with respect to the ordering structure), but they can be seen as an extension of the primitive idea in that they can be geometrically described in terms of separation between the ordering cone and the image set by means of an open convex cone or an open convex set.

It is thus evident that the nature of proper efficiency, whose origin has a purely local nature (in the classical paper by Kuhn and Tucker its definition is given in terms of the derivatives of the objective and constraint functions), also entails a global character.

The deep connection with scalarization has always been stressed, and various ad hoc scalarization techniques have been devised to relate, in a nonconvex problem, proper efficiency according to the various definitions to an optimal scalar solution.

For instance, in the scalarization approach proposed by Jahn [17, 18], which consists in the minimization of the distance (according to an appropriate parametric norm) from some ideal point, two different families of norms are used to characterize efficient and properly efficient points, the former being related to the ordering cone and the latter to another cone which contains the ordering cone in its interior; more generally, to obtain more restrictive notions of efficiency as minimal solution of a scalarized problem, stronger monotonicity features must be imposed on the scalarizing function (see, for instance, [27, 6, 10, 28]).

Proceeding in this vein one finds that efficient and properly efficient points can be seen as minimal solutions of different scalar problems.

A different type of restriction on efficiency has been posed in order to control the asymptotic behavior of unbounded admissible sequences, thus obtaining the notion of strict efficiency [2].

The aim of this work is to characterize the various sets of solutions of a vector optimization problem by means of a unique scalarizing function. A solution belonging to a more restrictive set of solutions is found as an optimal scalar solution according to a more restrictive definition of minimality: we will consider strict (i.e., unique) minima, sharp minima, or others. In particular, we will refer to some growth conditions known in scalar optimization and to the notion of Tikhonov well-posedness.

In section 2 we will introduce six different types of solutions of a vector optimization problem and show their relationships. Section 3 is devoted to the scalarizing function; we point out that our scalarizing function (the Δ function, introduced by Hiriart-Urruty [14, 15] for obtaining nonsmooth optimality conditions) is a very simple tool which immediately emphasizes the geometry of the ordering relation and has a very simple form in specific problems, thus allowing for simple calculations. In section 4 the main results of the paper are given: the six types of efficient solutions presented above appear as solutions of the scalarized problem with increasingly more restrictive minimality properties. In section 5 we consider again the concepts introduced in section 2 with the aim of comparing them to other, maybe better known, notions of efficiency. Some equivalence results are proved there in infinite and finite dimensional spaces, which complement the results in [13].

2. Degrees of efficiency. Let Y be a normed space, $S \subset Y$ be the set of admissible points, and $K \subset Y$ a closed, convex, pointed cone inducing on Y the partial order relation given by $y_1 \geq y_2$ if and only if $y_1 - y_2 \in K$. We say that the set $\Theta \subset Y$ is a base for K if Θ is convex with $0 \notin \operatorname{cl}\Theta$ and $K \setminus \{0\} = \operatorname{cone}\Theta = \{y \in Y : y = \lambda\theta, \lambda > 0, \theta \in \Theta\}$, i.e., K is the cone generated by Θ. Here and in what follows, we denote with $\operatorname{cl} A$, $\operatorname{int} A$, ∂A, and A^c the closure, the interior, the boundary, and, respectively, the complement of the set $A \subseteq Y$. Moreover, we will denote with B (respectively, $\hat{B}$) the closed (respectively, open) unit ball in Y and with $d_A(y) = \inf\{\|a - y\|, a \in A\}$ the distance function to the set $A \subseteq Y$.

DEFINITION 2.1. *A point $y_0 \in S$ is said to be* efficient *(with respect to K) and denoted $y_0 \in E(S, K)$ (or $y_0 \in E(S)$ if no confusion arises) if*

$$(S - y_0) \cap -K = \{0\}.$$

DEFINITION 2.2. *In the case where* $\operatorname{int} K \neq \emptyset$, *a point* $y_0 \in S$ *is said to be* weakly efficient *(denoted* $y_0 \in WE(S)$*) if*

$$(S - y_0) \cap -\operatorname{int} K = \emptyset.$$

Various other conditions have been used to single out particular classes of efficient points with special features. The concept of strict efficiency was introduced in [2] in order to obtain upper semicontinuity of the section mapping $G(y) = S \cap (y - K)$ at an efficient point.

DEFINITION 2.3. *A point* $y_0 \in S$ *is called* strictly efficient *(denoted* $y_0 \in StE(S)$*) if for every* $\varepsilon > 0$ *there exists* $\delta > 0$ *such that*

$$(S - y_0) \cap (\delta B - K) \subseteq \varepsilon B.$$

An efficient point $y_0 \in S$ is strictly efficient if the points $y \in Y$, which are dominated by y_0, i.e., $y \leq y_0$, and are bounded away from y_0, cannot be arbitrarily close to the feasible region S.

Proper efficiency instead implies a control on the tangentially admissible directions close to the efficient point. It has been defined in a great number of ways; in [13] an attempt was made to classify the various definitions along three main classes whose elements are proved to be equivalent in Euclidean spaces. Further notions are analyzed in the paper by Zalinescu [27]. It readily becomes evident that most definitions of proper efficiency entail a restriction on the admissible region which has a global character. In what follows we will introduce a few of them; since the ones we will mention are often not the better known, we give in section 5 some comparisons with others, without any scope of completeness. The interested reader can refer to [6, 27, 13] for more details.

DEFINITION 2.4 (see [6]). *The point* $y_0 \in S$ *is called* superefficient *(*$y_0 \in SE(S)$*) if there exists* $M > 0$ *such that*

$$\operatorname{cl}\operatorname{cone}(S - y_0) \cap (B - K) \subseteq MB. \tag{2.1}$$

Remark 2.5. The inclusion (2.1) can be equivalently expressed (see [6]) as

$$\operatorname{cone}(S - y_0) \cap (B - K) \subseteq MB;$$

in what follows we will often use this equivalent formulation.

DEFINITION 2.6. *The point* $y_0 \in S$ *is* locally superefficient *(*$y_0 \in LSE(S)$*) if it is efficient and there exist* $\eta > 0$ *and* $M > 0$ *such that*

$$\operatorname{cl}\operatorname{cone}[(S - y_0) \cap \eta B] \cap (B - K) \subseteq MB.$$

It is obvious that $y_0 \in LSE(S)$ if and only if there exists $\eta > 0$ such that $y_0 \in SE(S \cap (y_0 + \eta B))$.

We will also refer to another notion of efficiency which is somehow intermediate between the previous ones.

DEFINITION 2.7. *The point* $y_0 \in S$ *is called* tightly properly efficient *(*$y_0 \in TPE(S)$*) if there exists an open convex set* $C \subset Y$ *with* $0 \in \partial C$ *satisfying* $(S - y_0) \cap C = \emptyset$ *and there exists* $\delta > 0$ *such that*

$$C^c \cap (\delta B - K) \subseteq B. \tag{2.2}$$

Our first aim is to clarify the relationships among the above concepts.

To understand the relation between superefficiency and tight efficiency, we will need the concept of a dilating cone. If Θ is a base for the cone K, then by definition $0 \notin \operatorname{cl}\Theta$ and $\|\theta\| > \delta > 0$ for some $\delta > 0$ and all $\theta \in \Theta$. For every $\varepsilon < \delta$ the cone $K_\varepsilon = \operatorname{cone}(\Theta + \varepsilon\hat{B})$, where $\hat{B}$ is the open unit ball in Y, is an open convex cone containing $K\backslash\{0\}$. Note that the assumption that a cone K has a base is equivalent to the existence of strictly positive continuous linear functionals, i.e., the set

$$K^{+i} = \{\ell \in Y' : \ell(k) > 0 \quad \forall k \in K \setminus \{0\}\}$$

is nonempty, where Y' is the (topological) dual space of Y. Moreover, if a closed cone K admits a base, then the base can be taken to be closed.

THEOREM 2.8. *If the cone K has a bounded base, then $SE(S) \subseteq TPE(S)$, i.e., every superefficient point is also tightly efficient.*

Proof. To simplify the presentation and without loss of generality, we will prove the result under the assumption that $y_0 = 0$. As the first step of the proof, we need to show that, if 0 is superefficient, there exists an open convex dilating cone K_ε such that

$$\operatorname{cl}\operatorname{cone} S \cap -K_\varepsilon = \emptyset.$$

This is exactly the content of Proposition 3.3 in [6].

Second, we prove that there exists $N > 0$ such that

$$(B - K) \cap (-K_\varepsilon)^c \subseteq NB. \tag{2.3}$$

Indeed, set $W = (-K_\varepsilon)^c$, and suppose relation (2.3) is false, i.e., there exists a sequence w_n, $n \in \mathbb{N}$, such that $w_n \in W$, $\|w_n\| > n$, and $w_n \in B - K$. The latter means that there exists a sequence $k_n \in K$ such that $\|w_n + k_n\| \leq 1$. Thus there exists a sequence $b_n \in B$ such that $w_n + k_n = b_n$, which can be rewritten as

$$w_n = b_n - k_n = b_n - \lambda_n\theta_n = \lambda_n(b_n/\lambda_n - \theta_n),$$

where $\theta_n \in \Theta$ and $\lambda_n > 0$. But this is a contradiction to $w_n \notin (-K_\varepsilon)^c$, since, by the boundedness of Θ, we have that $\lambda_n \to +\infty$ as $\|w_n\| \to +\infty$ and $1/\lambda_n$ becomes smaller than any fixed ε. Thus eventually $w_n \in \operatorname{cone}(\varepsilon B - \Theta)$.

Now the definition of tight efficiency is verified with $C = -K_\varepsilon$, by taking $\delta = 1/N$. ∎

Cones with a bounded base have been extensively used in the literature related to ordered spaces and vector optimization under a variety of different characterizations which were later proved to be equivalent. For instance, in [26] it is proved that a cone K has a bounded base if and only if it is supernormal (or nuclear) (see [16] for the definition) and if and only if there exists $\phi \in K^{+i}$ and a scalar α such that $\phi(k) \geq \alpha\|k\|$ for all $k \in K$ (Bishop–Phelps cone), and in [3] it is proved that a cone K has bounded base if and only if it allows plastering (see [20]).

To show that a tightly efficient point is both locally superefficient and strictly efficient, we need a preliminary result.

LEMMA 2.9. *The point y_0 is tightly efficient in S if and only if there exists an open convex set $C \subset Y$, with $0 \in \partial C$ satisfying $(S - y_0) \cap C = \{0\}$, and for every $\varepsilon > 0$ there exists $\delta' > 0$ such that*

$$C^c \cap (\delta' B - K) \subseteq \varepsilon B.$$

Proof. Possibly after a translation of S, assume that $y_0 = 0$ is a tightly properly efficient point for S and fix $\varepsilon > 0$. If $\varepsilon \geq 1$, the thesis follows with $\delta' = \delta$, as in Definition 2.7. So let $\varepsilon \in (0,1)$ and choose δ such that

$$(\delta B - K) \cap C^c \subseteq B.$$

This implies that

$$\varepsilon(\delta B - K) \cap \varepsilon(C^c) \subseteq \varepsilon B.$$

Noting that $\varepsilon(\delta B - K) = (\varepsilon\delta B - K)$, the "only if" part of the thesis follows by the observation that for an open convex set C with $0 \in \operatorname{cl} C$ and any $\varepsilon \in (0,1)$ it holds that $\varepsilon C \subseteq C$ and $C^c \subseteq (\varepsilon C)^c = \varepsilon(C^c)$. The reverse inclusion is obvious. ∎

THEOREM 2.10. *If the point y_0 is tightly efficient in S, then it is both strictly efficient and locally superefficient.*

Proof. Strict efficiency follows by simply comparing the definitions and using Lemma 2.9. Moreover, if $(\delta B - K) \cap C^c \subseteq \varepsilon B$, then it holds that $-K\backslash\{0\} \subseteq C$. Indeed, if $k \in K\backslash\{0\}$ and $-k \notin C$, then $-\alpha k \notin C$ for all $\alpha > 1$ (remember that $0 \in \operatorname{cl} C$) and $-\alpha k \in -K \subset \delta B - K$, and thus we have a contradiction.

To prove that $0 \in LSE(S)$ we first notice that

$$S \cap C = \emptyset \Rightarrow S \subset C^c \Rightarrow [1,\infty) \cdot S \subset C^c.$$

Hence $\operatorname{cone}(S \cap B) \subset B \cup [1,\infty) \cdot S \subset B \cup C^c$. Since $(\delta B - K) \cap C^c \subset B$ (for some $\delta > 0$), we have

$$(B - K) \cap C^c \subset (\delta B - K) \cap C^c \subset B$$

when $\delta \geq 1$ and

$$(B - K) \cap C^c \subset (B - K) \cap \delta^{-1} C^c \subset \delta^{-1} B$$

when $\delta < 1$. Thus, taking $M = \max\{1, \delta^{-1}\}$, we get

$$\operatorname{cone}(S \cap B) \cap (B - K) \subset (B \cap (B - K)) \cup (C^c \cap (B - K)) \subset MB. \qquad ∎$$

The opposite relation is true under the assumption that the cone K has a bounded base.

THEOREM 2.11. *If the cone K has a bounded base and the point y_0 is both strictly efficient and locally superefficient in S, then it is also tightly efficient.*

Proof. Take η such that the point y_0 is superefficient for the admissible set $S \cap (y_0 + \eta B)$ and, by strict efficiency, choose δ' such that

$$(S - y_0) \cap (\delta' B - K) \subseteq \eta B. \tag{2.4}$$

Then follow the proof of Theorem 2.8 to show that there exists $\varepsilon > 0$ such that

$$(S - y_0) \cap \eta B \cap (-K_\varepsilon) = \emptyset \tag{2.5}$$

(see again [6, Prop. 3.3]) and that there exists $N > 0$ such that

$$(B - K) \cap (-K_\varepsilon)^c \subseteq NB,$$

which is equivalent to

$$[(1/N)B - K] \cap (-K_\varepsilon)^c \subseteq B.$$

Now choose $\delta = \min(\delta', 1/N)$ and set $C = (\delta\hat{B} - K) \cap (-K_\varepsilon)$, where $\hat{B} = \operatorname{int} B$ denotes the open unit ball. Then C is open and convex, with $0 \in \partial C$. It follows from (2.4) that

$$(\delta B - K) \cap (S - y_0) \subseteq \eta B,$$

which, together with (2.5), yields

$$(\delta B - K) \cap (S - y_0) \cap -K_\varepsilon = \emptyset,$$

that is,

$$(S - y_0) \cap C = \emptyset.$$

Moreover,

$$\left[\frac{\delta}{2}B - K\right] \cap C^c = \left[\frac{\delta}{2}B - K\right] \cap [(\delta\hat{B} - K)^c \cup (-K_\varepsilon)^c] = \left[\frac{\delta}{2}B - K\right] \cap (-K_\varepsilon)^c \subseteq B,$$

which is our thesis. □

To summarize we can state that, if the cone K has a bounded base, then the following inclusions hold:

$$SE(S) \subseteq TPE(S) = LSE(S) \cap StE(S) \subseteq LSE(S) \cup StE(S) \subseteq E(S) \subseteq WE(S),$$

and simple examples in $\mathbb{R}^2$ show that all inclusions are strict. The six notions we introduced can thus be seen as six different degrees of efficiency for a vector optimization problem.

3. Scalarization. The theory and the methods of scalarization have always been of the utmost importance for solving a vector optimization problem. The linear scalarization is historically the first method proposed and the most widely known and used; it consists of the minimization, over the set S, of the function $\lambda \cdot y$, with $\lambda \in K^+$. Besides this, in order to treat nonconvex problems, the method of compromise solutions and its generalizations are of great relevance. It consists of the minimization of the distance from some reference objective, often not belonging to the admissible region, but dominating all available alternatives. This was originally done in the Paretian setting in which the ordering cone is simply the nonnegative orthant, with the use of the supremum norm of $Y = \mathbb{R}^p$. The main idea has successively been extended to the setting of general ordered vector space (see, e.g., [17, 18, 19] and references therein) by defining the norm as the Minkowski functional of the order interval $[-a, a] \equiv (-a + K) \cap (a - K)$, i.e.,

$$\|y\|_a = \inf\{\lambda > 0 : \lambda^{-1}y \in [-a, a]\},$$

where a is some point in the interior of the ordering cone K and the order interval $[-a, a]$ is a closed, convex set with nonempty interior.

For a fixed reference point $\ell \in Y$ such that $S \subset \ell + K$, Jahn characterizes weakly efficient (respectively, efficient) points as the nearest (respectively, unique nearest)

points to ℓ with respect to the distance induced by $\|\cdot\|_a$. To characterize properly efficient points, Jahn considers the nearest points to ℓ according to a different norm, defined by means of the dilating cone K_ε.

Closely related to this approach are some variants in which the scalarizing function is defined by means of a sort of Minkowski functional of sets related to the ordering cone, as, for instance, in [27, 10, 28]. In this case the scalarizing functional $\phi : X \to \overline{\mathbb{R}}$ is given by

$$\phi(x) = \inf\{\lambda \in \mathbb{R} : \ x \in \lambda e - A\},$$

where $e \in \operatorname{int} A$. If the set A coincides with the ordering cone K, then characterizations of efficient and weakly efficient points are obtained. However, to obtain properly efficient points as a minimal scalar solution, the scalarizing function must be defined with respect to some convex set or cone A which contains $K \setminus \{0\}$ in its interior, and hence every properly efficient point is the solution of a different scalarized problem.

The main results of this paper give a complete characterization of the different types of efficient points for a vector optimization problem by means of different degrees of minimality of a unique scalarized problem. This is obtained by means of a special scalarizing function.

DEFINITION 3.1. *For a set $A \subseteq Y$ let the function $\Delta_A : Y \to \mathbb{R} \cup \{\pm\infty\}$ be defined as*

$$\Delta_A(y) = d_A(y) - d_{Y\setminus A}(y),$$

with $d_\emptyset(y) = +\infty$.

The function Δ was introduced in [14, 15] to analyze the geometry of nonsmooth optimization problems and obtain necessary optimality conditions. It has later been used in [8, 1, 22, 23]. Its main properties are gathered together in the following proposition.

PROPOSITION 3.2. *If the set A is nonempty and $A \neq Y$, then*

(1) *Δ_A is real valued;*
(2) *Δ_A is 1-Lipschitzian;*
(3) *$\Delta_A(y) < 0$ for every $y \in \operatorname{int} A$, $\Delta_A(y) = 0$ for every $y \in \partial A$, and $\Delta_A(y) > 0$ for every $y \in \operatorname{int} A^c$;*
(4) *if A is closed, then it holds that $A = \{y : \ \Delta_A(y) \leq 0\}$;*
(5) *if A is convex, then Δ_A is convex;*
(6) *if A is a cone, then Δ_A is positively homogeneous;*
(7) *if A is a closed convex cone, then Δ_A is nonincreasing with respect to the ordering relation induced on Y, i.e., the following is true: if $y_1, y_2 \in Y$, then*

$$y_1 - y_2 \in A \qquad \Longrightarrow \qquad \Delta_A(y_1) \leq \Delta_A(y_2);$$

if A has a nonempty interior, then

$$y_1 - y_2 \in \operatorname{int} A \qquad \Longrightarrow \qquad \Delta_A(y_1) < \Delta_A(y_2).$$

Proof. Statements (1)–(4) and (6) are immediate. To prove (5) one can pass through a characterization (given in [15]) of Δ_A as an infimal convolution:

$$\Delta_A(y) = (\mu_A \nabla \|\cdot\|)(y) := \inf\{\mu_A(x) + \|y - x\| : \ x \in Y\}$$

, where the function $\mu_A(y) = +\infty$ for $y \notin A$ and $\mu_A(y) = -d_{Y\setminus A}(y)$ for $y \in A$ can be proved to be convex when A is convex. This result is stated without proof in [14]

and is equivalent to the concavity of the function d_{A^c} on A. To show that the latter holds when A is convex, one can notice that for any $x, y \in A$, the closed balls B_x and B_y centered in x and in y with radii $d_{A^c}(x)$ and $d_{A^c}(y)$, respectively, are contained in $\operatorname{cl} A$ (which is itself convex), as well as the set $H = \operatorname{conv}\{B_x \cup B_y\}$. Moreover, for every $\alpha \in [0,1]$, the ball centered in $\alpha x + (1-\alpha)y$ with radius $\alpha d_{A^c}(x) + (1-\alpha) d_{A^c}(y)$ is contained in H, and hence $d_{A^c}(\alpha x + (1-\alpha)y) \geq \alpha d_{A^c}(x) + (1-\alpha) d_{A^c}(y)$. The result then follows, since the convolution of a convex function with the norm is itself convex. To prove 7 use nonpositivity of Δ_A on A and subadditivity to write $0 \geq \Delta_A(y_1 - y_2) \geq \Delta_A(y_1) - \Delta_A(y_2)$; the second implication is proved analogously. □

For our purposes, let $A = -K$. Then the function $\Delta_{-K}(y)$ is sublinear and nondecreasing with respect to the ordering induced by K.

It is important to note that the use of the scalarizing function Δ_{-K} implies no assumption (explicit or implicit) of boundedness of the admissible region S. On the other hand such assumptions are required for most other scalarizations. For instance S has to be contained in a halfspace if the linear scalarization is used, or it has to be lower bounded, in the sense that there exists an element $\ell \in Y$ such that $s \geq \ell$ for every $s \in S$, if the distance from an ideal point is used.

This remark has some relevance in that the main differences among the different types of efficient points considered in our analysis disappear under boundedness assumptions.

We give now some examples of how the function Δ_{-K} looks for different choices of the space Y and its norm and the ordering cone K.

Examples.

1. Let $Y = \mathbb{R}^n$ with the Euclidean norm $\|\cdot\|_2$ and $K = \mathbb{R}^n_+$. Then it holds that $d_{-K}(y) = \|y^+\|$, where $y_i^+ = \max(y_i, 0)$, $i = 1, \ldots, n$, and

$$d_{Y\setminus -K}(y) = \begin{cases} 0 & \text{if} \quad y_i \geq 0 \text{ for some } i, \\ -\max_i y_i & \text{if} \quad y_i < 0 \ \forall i. \end{cases}$$

   Thus it holds that

$$\Delta_{-K}(y) = \begin{cases} \|y^+\| & \text{if} \quad y \notin -K, \\ \max y_i & \text{if} \quad y \in -K. \end{cases}$$

2. The function Δ_{-K} takes a more familiar form if we consider $Y = \mathbb{R}^n$ with the norm $\|y\|_\infty = \max |y_i|$; in this case we have

$$d_{-K}(y) = \begin{cases} \max_i y_i & \text{if} \quad y \notin -K, \\ 0 & \text{if} \quad y \in -K \end{cases}$$

   and

$$d_{Y\setminus -K}(y) = \begin{cases} 0 & \text{if} \quad y \notin -K, \\ -\max y_i & \text{if} \quad y \in -K, \end{cases}$$

   and thus, for all $y \in Y$,

$$\Delta_{-K}(y) = \max_i y_i.$$

3. The same reasoning can be applied to the case where $Y = \mathcal{C}(T)$, the space of continuous functions defined over the compact set T, with the supremum norm and the ordering cone of nonnegative functions $K = \{y \in Y : y(t) \geq$

$0\ \forall t \in T\}$. In this case, for those $y \in \mathcal{C}(T)$ for which there exists some $t \in T$ with $y(t) \geq 0$, it holds that $\Delta_{-K}(y) = d_{-K}(y) = \max_{t\in T} y(t)$, and for those $y \in \mathcal{C}(T)$ such that $y(t) < 0$ for all $t \in T$, then it holds that $\Delta_{-K}(y) = -d_{Y\setminus -K}(y) = \max\{y(t), t \in T\}$. Therefore

$$\Delta_{-K}(y) = \max_{t\in T} y(t)$$

for all $y \in Y$.

4. Analogously for the space $Y = L^\infty(I)$ of essentially bounded functions on the interval $I \subseteq \mathbb{R}$, with the usual norm and the cone K of nonnegative functions, it holds that

$$\Delta_{-K}(y) = \sup_{\omega\in I} y(\omega),$$

where sup means essential supremum.

5. For the spaces L^p, with $1 \leq p < \infty$ (with the usual norm $\|\cdot\|_p$), we have that the nonnegative orthant K has an empty interior. In this case we have $\Delta_{-K}(y) = d_{-K}(y) = \|y^+\|$, where $y^+ = \sup(y, 0)$ has the usual meaning of lattice theory.

4. Characterizations. We give in this section the main results of the paper. The various types of efficient solutions introduced in section 2 will be characterized by different degrees of minimality of the scalar solutions of the parametrized problem:

$$(P_p) \qquad \min_{y\in S} \Delta_{-K}(y - p),$$

with $p \in Y$.

Theorem 4.1 characterizes efficient solutions as the strict minimal points for the scalarized problem. This result is well known for other types of scalarizations and was proved in [22] with the scalarizing function Δ_{-K}. It also appears in [23] in an axiomatic setting. We prove it for completeness.

THEOREM 4.1. *Let $y_0 \in S$ be an admissible point. Then $y_0 \in E(S)$ if and only if there exists $\hat{y} \in Y$ such that y_0 is a unique (strict) global solution of $(P_{\hat{y}})$.*

Proof. If y_0 is efficient, then it is a strict minimum for (P_{y_0}). Indeed, if $y_0 \in E(S)$, then $y - y_0 \notin -K \setminus \{0\}$ for every $y \in S$, and we have that $\Delta_{-K}(y - y_0) = d_{-K}(y - y_0)$ is positive whenever $y \neq y_0$ and is null at $y = y_0$. To prove the converse, suppose that $\Delta_{-K}(y_0 - \hat{y}) < \Delta_{-K}(y - \hat{y})$ for all $y \in S$ with $y \neq y_0$. If there exists in S some point $y_1 \neq y_0$ such that $y_1 \leq y_0$, then it would hold that $y_1 - \hat{y} \leq y_0 - \hat{y}$ and, by Proposition 3.2(7) we get $\Delta_{-K}(y_1 - \hat{y}) \leq \Delta_{-K}(y_0 - \hat{y})$, which is absurd. □

THEOREM 4.2. *Let $y_0 \in S$ be an admissible point and suppose that $\operatorname{int} K \neq \emptyset$; then y_0 is weakly efficient in S if and only if there exists $\hat{y} \in Y$ such that y_0 is a global solution of $(P_{\hat{y}})$.*

Proof. The proof is analogous to the one of Theorem 4.1 and hence is omitted. □

We observe that, if the cone K has empty interior, then $\Delta_{-K} = d_{-K}$ and, for every $\hat{y} \in S$, $d_{-K}(y - \hat{y}) = d_{-K}(\hat{y} - \hat{y}) = 0$ for all $y \leq \hat{y}$, with $y \in S$. Hence if the point $\hat{y}$ is not itself efficient, then the scalarized problem will have solutions at all $y \in S$ with $y \leq \hat{y}$ and uniqueness will fail. In this case, Theorem 4.1 can be reformulated as follows.

THEOREM 4.3. *Let $y_0 \in S$ be an admissible point; then $y_0 \in E(S)$ if and only if y_0 is a unique (strict) global solution of (P_{y_0}).*

Proof. The proof is trivial. □

In what follows we will always use problem (P_{y_0}) to characterize efficiency properties of the point y_0. It is understood that, if $\operatorname{int} K \neq \emptyset$, then a greater generality can be achieved (as in Theorem 4.1) considering a different value $\hat{y}$ for the parameter.

If the point y_0 is strictly efficient, then we can prove a further property for the scalarizing function $\Delta_{-K}(\cdot - y_0)$.

THEOREM 4.4. *Let $y_0 \in S$ be an admissible point. Then y_0 is strictly efficient in S if and only if there exists a nondecreasing function $\gamma : \mathbb{R}^+ \to \mathbb{R}^+$ with $\gamma(0) = 0$ and $\gamma(t) > 0$ for all $t > 0$, such that $\Delta_{-K}(y - y_0) \geq \gamma(\|y - y_0\|)$ for all $y \in S$.*

Proof. Strict efficiency of y_0 can be rephrased as follows: for every $\varepsilon > 0$ there exists $\delta > 0$ such that $d_{-K}(y - y_0) > \delta$ for every $y \in S$ with $\|y - y_0\| > \varepsilon$. So suppose that the point y_0 is strictly efficient in S and consider the functions

$$\gamma_0(\varepsilon) = \inf\{d_{-K}(y - y_0) \,|\, y \in S, \|y - y_0\| \geq \varepsilon\}$$

and

$$\gamma(\varepsilon) = \min(\gamma_0(\varepsilon), 1).$$

It is easily seen that γ is nondecreasing, null at the origin, and positive elsewhere; moreover, for $y \in S$ it holds that

$$\Delta_{-K}(y - y_0) = d_{-K}(y - y_0) \geq \gamma(\|y - y_0\|).$$

If, on the other hand, there exists a nondecreasing function γ with the above properties and such that $\Delta_{-K}(y - y_0) \geq \gamma(\|y - y_0\|)$ for all $y \in S$, then it holds that $\Delta_{-K}(y - y_0) > 0$ for all $y \in S$ with $y \neq y_0$, yielding $y_0 \in E(S)$ and $\Delta_{-K}(y - y_0) = d_{-K}(y - y_0)$ for all $y \in S$. To show that $y_0 \in StE(S)$, with every $\varepsilon > 0$ we can associate $\delta = \inf\{d_{-K}(y - y_0) \,|\, \|y - y_0\| > \varepsilon\}$, and the result is proved. □

The definition of strict efficiency can be reformulated to offer a version of Tikhonov well-posedness (in the image) for a vector problem. The problem of minimizing an extended real valued function f defined over some metric space X is said to be Tikhonov well-posed when it admits a unique minimum x_0 and for every sequence x_n such that $f(x_n)$ converges to the infimal value $f(x_0)$, it holds that $x_n \to x_0$. We refer to the monograph by Dontchev and Zolezzi [11] for more details about well-posedness in optimization. A function γ with the properties mentioned in Theorem 4.4 is called a forcing function in [11] and a growth gage in [24].

Though it is well known by specialists in well-posedness and rather trivial, it should be recalled that the forcing property of a nondecreasing function $\gamma : \mathbb{R}^+ \to \mathbb{R}^+$ with $\gamma(0) = 0$ can be equivalently expressed as $\gamma(t) > 0$ for all $t > 0$ or $\gamma(t_n) \to 0 \Rightarrow t_n \to 0$.

In our formulation the objective function is $\Delta_{-K}(\cdot - y_0)$, defined over Y and extended to $+\infty$ outside the set S. The minimization problem (P_{y_0}) is Tikhonov well-posed if $\Delta_{-K}(y - y_0) > 0$ for all $y \in S$ with $y \neq y_0$ and

$$(\ y_n \in S, \quad d_{-K}(y_n - y_0) \to 0\ ) \qquad \Longrightarrow \qquad y_n \to y_0;$$

that is, if, when a sequence $y_n \in S$ is minimizing, i.e., it belongs to S and approaches the region dominated by y_0, then it must converge to y_0.

Theorem 4.5 makes clearer the interpretation of strict efficiency as a sort of well-posedness for the scalarized problem (P_{y_0}). Notice that the equivalence between

Tikhonov well-posedness and the existence of a forcing function is a known result; see, e.g., [29].

THEOREM 4.5. *The admissible point $y_0 \in S$ is strictly efficient for S if and only if y_0 is a solution of (P_{y_0}) and the problem (P_{y_0}) is Tikhonov well-posed.*

Proof. If y_0 is strictly efficient, then it is the unique solution for the scalarized problem (P_{y_0}) and there exists a forcing function γ such that $\Delta_{-K}(y - y_0) \geq \gamma(\|y - y_0\|)$. Hence all minimizing sequences, i.e., sequences $y_n \in S$ such that $\Delta_{-K}(y_n - y_0) \to 0$, must converge to y_0, since $\gamma(t_n) \to 0$ implies $t_n \to 0$. Conversely, if the problem (P_{y_0}) is well-posed, then y_0 is efficient and, for every $y \in S$, it holds that $d_{-K}(y - y_0) = \Delta_{-K}(y - y_0)$. Thus we can consider the function $\gamma(\varepsilon) = \inf\{d_{-K}(y - y_0) \mid \|y - y_0\| \geq \varepsilon\}$; it holds by construction that $d_{-K}(y - y_0) \geq \gamma(\|y - y_0\|)$, and it is easy to see that γ is nondecreasing on $[0, +\infty)$ with $\gamma(\varepsilon) > 0$ for $\varepsilon > 0$; hence y_0 is strictly efficient. ∎

As we have seen in Theorem 4.4, strict efficiency of the point y_0 guarantees the existence of a forcing function for $\Delta_{-K}(\cdot - y_0)$. But there is no control on the slope of such a function close to zero. This is where proper efficiency comes into the picture. Indeed, we will show that some properties of the forcing function γ can be strengthened when y_0 is properly efficient to obtain a linear growth for Δ_{-K}. This will hold near y_0 if y_0 is locally superefficient and will hold globally for $y_0 \in SE(S)$.

THEOREM 4.6. *Let $y_0 \in S$ be an admissible point. Then the following hold:*

(a) *y_0 is superefficient in S if and only if there exists $L > 0$ such that $\Delta_{-K}(y - y_0) \geq L\|y - y_0\|$ for all $y \in S$.*

(b) *y_0 is locally superefficient in S if and only if there exist $\eta > 0$ and $L > 0$ such that $\Delta_{-K}(y - y_0) \geq L\|y - y_0\|$ for all $y \in S \cap (y_0 + \eta B)$.*

Proof. (a) We first need to show that, for an efficient point $y_0 \in S$, the inclusion

$$\operatorname{cone}(S - y_0) \cap (B - K) \subseteq MB \tag{4.1}$$

can be expressed by saying that for each $y \in S$ and each $k \in K$ it holds that

$$\|y - y_0\| \leq M\|y + k - y_0\|. \tag{4.2}$$

Indeed, if (4.1) does not hold, then there exist a positive number λ and some $\bar{y} \in S$, $\bar{k} \in K$, and $\bar{b} \in B$ such that

$$\lambda(\bar{y} - y_0) = \bar{b} - \bar{k} \tag{4.3}$$

and

$$\lambda\|\bar{y} - y_0\| > M.$$

From (4.3) we derive

$$\|\lambda(\bar{y} - y_0) + \bar{k}\| \leq 1$$

and

$$\left\|\bar{y} - y_0 + \frac{\bar{k}}{\lambda}\right\| \leq \frac{1}{\lambda},$$

which, together with

$$\|\bar{y} - y_0\| > \frac{M}{\lambda},$$

give a contradiction to (4.2).

If conversely (4.2) does not hold, then there exist $\bar{y} \in S$ and $\bar{k} \in K$ such that

$$\|\bar{y} - y_0\| > M\|\bar{y} - y_0 + \bar{k}\|.$$

Then there exists $\bar{b} \in B$ such that

$$\bar{y} - y_0 + \bar{k} = \bar{b}\|\bar{y} - y_0 + \bar{k}\|,$$

and this yields

$$s = \frac{\bar{y} - y_0}{\|\bar{y} - y_0 + \bar{k}\|} = \bar{b} - \frac{\bar{k}}{\|\bar{y} - y_0 + \bar{k}\|} \in \operatorname{cone}(S - y_0) \cap B - K$$

and

$$\|s\| = \frac{\|\bar{y} - y_0\|}{\|\bar{y} - y_0 + \bar{k}\|} > M,$$

which means that (4.1) does not hold.

To conclude the proof it is enough to see that, given the point $y_0 \in S$, there exists $M > 0$ such that (4.2) holds if and only if $\|y + k - y_0\| \geq L\|y - y_0\|$ for $L = 1/M$, and this is equivalent to

$$d_{-K}(y - y_0) = \inf_{k \in K} \|y + k - y_0\| \geq L\|y - y_0\| \qquad \forall y \in S. \tag{4.4}$$

Notice at last that under each of the following assumptions separately, that $y_0 \in SE(S)$ or that Δ_{-K} is nonnegative, then d_{-K} coincides with Δ_{-K}, so that (4.4) proves the result.

(b) The proof of (b) is the same as in part (a) for $\|y - y_0\| \leq \eta$. □

We recall that in mathematical programming a point x_0 is called a sharp minimum for the function $f : X \to [-\infty, +\infty]$ relative to the set $A \subseteq X$ if there exists $\alpha > 0$ such that it holds that

$$f(x) \geq f(x_0) + \alpha\|x - x_0\|$$

for all $x \in A$. This has important consequences in convergence analysis of many iterative procedures (see, e.g., [25, 7] for details and references). Thus, if a point x_0 is a sharp minimum for the function f, then f admits a forcing function which is linear, $\gamma(t) = \alpha t$.

Obviously for a local sharp minimum there exists a forcing function with positive slope close to the minimum point.

On the other hand, note that the requirement that y_0 be locally superefficient does not imply that $\Delta_{-K}(\cdot - y_0)$ admits a forcing function, i.e., the largest nondecreasing function γ such that $\gamma(\|y - y_0\|)$ minorizes $\Delta_{-K}(y - y_0)$ might be identically zero. This is made clear by the following example.

Example 4.7. Let the function $G : \mathbb{R}^2 \to \mathbb{R}$ be defined as $G(y_1, y_2) = y_2 + y_1 e^{y_1}$ for $y_1 < y_2$ and $G(y_1, y_2) = y_1 + y_2 e^{y_2}$ for $y_1 \geq y_2$; take $S = \{(y_1, y_2) : G(y_1, y_2) \leq 0\}$ and $K = \mathbb{R}^2_+$. The origin is the only efficient point for S and it is also locally superefficient, but it is not strictly efficient. Indeed S is asymptotically close to $-K$ as shown by the sequence $y^n = (y^n_1, y^n_2) = (-n, ne^{-n}) \in S$, with $\|y^n\| \to +\infty$.

It follows from Theorems 2.10 and 2.11 that a tightly properly efficient solution $y_0 \in S$ can be characterized in terms of the scalarized problem (P_{y_0}) by requiring at

the same time the properties of the forcing function γ which hold for a well-posed minimum (γ is nondecreasing and positive outside the origin) and for a local sharp minimum (γ has a positive slope at the origin).

COROLLARY 4.8. *If the admissible point $y_0 \in S$ is tightly properly efficient, then for the problem (P_{y_0}) there exists a nondecreasing growth function with positive slope at the origin. If the cone K has a bounded base, then the converse is true.*

5. Further results about strict and proper efficiency. This concluding section is devoted to a deeper analysis of the notions of (restricted) efficiency defined in section 2. Indeed, the concept of strict efficiency has only recently been introduced and can be given an equivalent description in finite dimensional spaces, which sheds new light on the geometry of the admissible region. The concept of proper efficiency has a much longer history in vector optimization, and the underlying idea has been analytically described in a great number of ways. In [13] an attempt was made to classify the known definitions in three main classes, each collecting definitions which coincide in finite dimensional spaces. We will see that the notions of superefficiency, local superefficiency, and tight efficiency can be seen as representative examples of the three above-mentioned classes.

The reason why we restrict to finite dimensional spaces for some of the results of the present section is that we will need to assume that the ordering cone K has a (weakly) compact base Θ, and this is indeed true, in any Euclidean space, for any closed convex pointed cone K, while the same assumption proves to be very restrictive in infinite dimensional spaces (see [9]) and fails to hold for the nonnegative orthant in most common spaces.

It is immediately verified that, if K is pointed, $y_0 \in S$ is efficient exactly when $(S + K - y_0) \cap -K = \{0\}$ holds. In the case where S in unbounded, however, the set $S + K$ need not be closed even if both S and K are. Thus the condition $\mathrm{cl}\,(S + K - y_0) \cap -K = \{0\}$ is a stronger requirement on y_0 than only efficiency. We will see that the previous condition is related to strict efficiency.

THEOREM 5.1. *If Y is any normed space and $y_0 \in S$ is strictly efficient, then $\mathrm{cl}\,(S + K - y_0) \cap -K = \{0\}$. If Y is finite dimensional, the converse is true.*

Proof. The definition of strict efficiency can be rephrased as follows: for every $\varepsilon > 0$ there exists $\delta > 0$ such that $d_{-K}(y - y_0) > \delta$ for every $y \in S$ with $\|y - y_0\| > \varepsilon$. Hence, if there would exist sequences $y_n \in S$, $k_n \in K$, and some $k \in K\backslash\{0\}$ such that $y_n + k_n - y_0 \to -k$, then $y_n + k + k_n - y_0 \to 0$ and hence $d_{-K}(y_n - y_0) \to 0$; moreover, $y_n - y_0$ is outside some small ball around the origin since $y_n - y_0 = k + k_n$, $k \neq 0$, and K is pointed. This shows that y_0 is not strictly efficient.

On the other hand, if $y_0 \in S$ is not strictly efficient, then there exist $\varepsilon > 0$ and sequences $y_n \in S$ and $k_n \in K$ such that $\|y_n - y_0\| \geq \varepsilon$ and $\|y_n + k_n - y_0\| \to 0$. Write $k_n = \lambda_n \theta_n$ with $\lambda_n > 0$ and $\theta_n \in \Theta$, and take some $\alpha < \lambda_n$ for all $n \in \mathbb{N}$ (such a number α exists since $k_n \notin (\varepsilon/2)B$ and Θ is compact) to define $k'_n = (\lambda_n - \alpha)\theta_n$. Thus we obtain

$$y_n + k'_n - y_0 = y_n + k_n - y_0 - \alpha\theta_n \to -\alpha\theta \neq 0,$$

at least for some subsequence $\{\theta_{n_k}\} \subseteq \{\theta_n\}$. Hence $\mathrm{cl}\,(S + K - y_0) \cap -K\backslash\{0\} \neq \emptyset$. □

We come now to local superefficiency; we will show that a locally superefficient point can be described in terms of the definition of local proper efficiency given by Borwein in [5], based on the separation between the ordering cone and a local conical

approximation of the feasible region. For a set $A \subseteq Y$ and $x_0 \in \operatorname{cl} A$, we call the tangent cone to A at x_0 the set

$$T(A, x_0) = \{v \in X : \exists \beta_n > 0, \exists x_n \in A,\ x_n \to x_0 \text{ with } v = \lim_n \beta_n (x_n - x_0)\}.$$

THEOREM 5.2. *If Y is any normed space and the point y_0 is locally superefficient, then it is efficient and $T(S, y_0) \cap -K = \{0\}$. If Y is finite dimensional, the opposite relation is true.*

Proof. It has been proved in [6] that if $y_0 \in SE(S)$, then $\operatorname{cl}\operatorname{cone}(S - y_0) \cap -K = \{0\}$ (the last relation is another definition of proper efficiency, due to Borwein [5]), and hence $y_0 \in SE(S \cap (y_0 + \eta B))$ implies $\operatorname{cl}\operatorname{cone}[(S - y_0) \cap \eta B] \cap -K = \{0\}$; the first inclusion follows from the equality $T(S, y_0) = \cap_{\eta > 0} \operatorname{cl}\operatorname{cone}[(S - y_0) \cap \eta B]$. To prove the converse, we should show that there exist $M > 0$ and $\eta > 0$ such that

$$\operatorname{cone}[(S - y_0) \cap \eta B] \cap (B - K) \subseteq MB.$$

Suppose by contradiction that there exist sequences $\alpha_n > 0$ and $s_n \in S$ with $\|s_n - y_0\| \to 0$, $\|\alpha_n(s_n - y_0)\| \to +\infty$, and $d_{-K}(\alpha_n(s_n - y_0)) \leq 1$. The latter implies that there exists a sequence $k_n \in K$ such that $\|\alpha_n(s_n - y_0) + k_n\| \leq 1 + 1/n$, which can be rewritten as $\alpha_n(s_n - y_0) + k_n = (1 + 1/n)b_n$, with $b_n \in B$. Moreover, it holds that $K = \operatorname{cone}\Theta$, where Θ is compact, and then $k_n = \lambda_n \theta_n$ with $\lambda_n > 0$ and $\theta_n \in \Theta$. It also holds that $\lambda_n \to +\infty$, because $\|k_n\| \to +\infty$ and Θ is bounded. This yields

$$\alpha_n(s_n - y_0) = (1 + 1/n)b_n - \lambda_n \theta_n$$

and

$$\frac{\alpha_n}{\lambda_n}(s_n - y_0) = \frac{n+1}{n\lambda_n} b_n - \theta_n. \tag{5.1}$$

The right-hand side of (5.1) converges (up to subsequences) to $-\theta \in -\Theta \subset -K$, and the left-hand side converges to an element of $T(S, y_0)$. Since $0 \notin \Theta$ we have a contradiction. □

THEOREM 5.3. *Consider the following statements:*

(a) *the point y_0 is tightly properly efficient in S;*
(b) *there exists an open convex set $C \subset Y$ such that $-K \backslash \{0\} \subseteq C$ and $(S - y_0) \cap C = \emptyset$;*
(c) $T(S + K, y_0) \cap -K = \{0\}$.

If Y is any normed space, then it holds that (a) ⇒ (b) ⇒ (c). *If Y is finite dimensional, we have also that* (c) ⇒ (a) *and all statements are equivalent.*

Proof. To prove that (a) implies (b) it is enough to show that, since there exists an open convex set C with $0 \in \partial C$, and there exists δ such that $C^c \cap (\delta B - K) \subseteq B$, then it holds that $-K \backslash \{0\} \subseteq C$. If indeed $k \in K \backslash \{0\}$ and $-k \in C^c$, then $-\lambda k \in C^c$ for all $\lambda \geq 1$ and a contradiction arises.

For the proof that (b) implies (c) one can refer to [27]. To prove the last relation we will see that (c) implies both strict efficiency and local superefficiency, considering Theorem 2.11. The latter is trivial since, by Theorem 5.2, the tangent cone is isotone with respect to the set inclusion, and hence it satisfies the inclusion $T(S, y_0) \subseteq T(S + K, y_0)$. To finish suppose that $y_0 \notin StE(S)$; then there exists a sequence $y_n \in S$ such that $y_n - y_0 \notin \varepsilon B$ for some $\varepsilon > 0$ and $d_{-K}(y_n - y_0) \to 0$, which means that there exists a sequence $k_n \in K$ with $y_n + k_n - y_0 \to 0$ and $k_n \notin (\varepsilon/2)B$. Since we can

always write $k_n = \lambda_n \theta_n$ with $\theta_n \in \Theta$, it follows that λ_n does not converge to zero, i.e., there exists a subsequence (we again call it λ_n) with $\lambda_n > \beta$ for some $\beta > 0$.

Now take $\alpha_n = \|y_n + k_n - y_0\|^{1/2}$ (since λ_n is bounded away from zero and α_n vanishes, it eventually holds that $\alpha_n < \lambda_n$) and set $k'_n = (\lambda_n - \alpha_n)\theta_n$ to obtain $y_n + k'_n - y_0 = y_n + k_n - y_0 - \alpha_n \theta_n \to 0$ and $\alpha_n^{-1}(y_n + k'_n - y_0) \to -\theta \neq 0$. □

We observe that statement (c) in Theorem 5.3 is the definition of proper efficiency given by Borwein in [4] and that statement (b) is another definition of proper efficiency attributed to Gerstewitz in [27]. The equivalence between (b) and (c) was already proved in finite dimensional spaces in [12]. The results proved in this section complement the ones given in [13], to which we refer for more details on proper efficiency.

Acknowledgments. I wish to thank E. Miglierina and E. Molho for helpful discussion during the preparation of the paper and an anonymous referee whose suggestions have improved the presentation of some results.

OPTIMAL SHAPE DESIGN OF INDUCTOR COILS FOR SURFACE HARDENING*

DIETMAR HÖMBERG† AND JAN SOKOŁOWSKI‡

Abstract. We study a mathematical model for induction hardening of steel. It consists of a vector potential formulation of Maxwell's equations coupled with a heat equation and an evolution equation for the volume fraction of the high temperature phase in steel called *austenite*. An important task for practical applications of induction hardening is to find the optimal coupling distance between inductor and workpiece. To this end we control the volume fraction of austenite with respect to perturbations of the coupling distance. The coil is modeled as a tube and is defined by a regular curve. We formulate the shape optimization problem over the set of admissible curves and prove the existence of an optimal curve. We apply the material derivative method for the shape sensitivity analysis of the state system. Finally, the shape gradient is specified for an optimal curve and the first order necessary optimality conditions are established.

1. Introduction.

Electromagnetic induction provides a method of heating electrically conducting materials. The basic components of an induction heating system are depicted in Figure 1.1. An alternating current flows through the induction coil (in what follows called the inductor). It generates an alternating magnetic field which in turn induces eddy currents in the workpiece. These dissipate energy, bring about heating, and lead to the growth of the high temperature phase austenite in the workpiece made of steel.

Since the magnitude of the eddy currents decreases with growing distance from the workpiece surface because of the frequency dependent skin-effect, induction heating is a suitable heat source for surface hardening if the current frequency has been chosen big enough. After heating, the workpiece is quenched by spray-water cooling and another phase transition leads to the desired hardening effect in the boundary layers of the workpiece.

An important task during the planning of an induction heat treatment is to find the optimal coupling distance between inductor and workpiece in order to obtain a desired heating pattern. This is illustrated in Figure 1.2. In all the examples shown, the goal is to produce a uniform hardening depth. In (a) a conical workpiece shall be heated by an inductor of the shape of a cylindrical spiral. To compensate for the bigger distance between inductor and workpiece in the upper part, the turn spacing there is narrower compared to the lower part.

In (b), because of the workpiece's geometry, heat will concentrate in the lower corners of the workpiece cross-section if the coupling distance is everywhere the same.

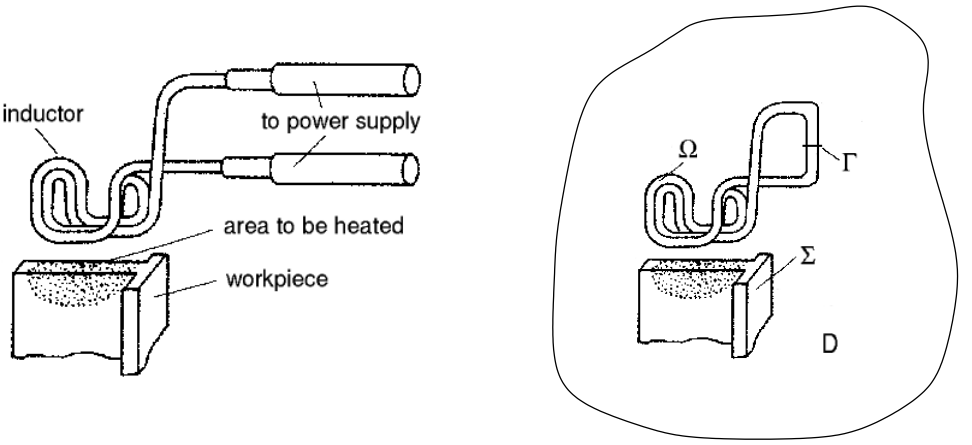

FIG. 1.1. *Induction heating: real process (left) and notation of domains in idealized setting.*

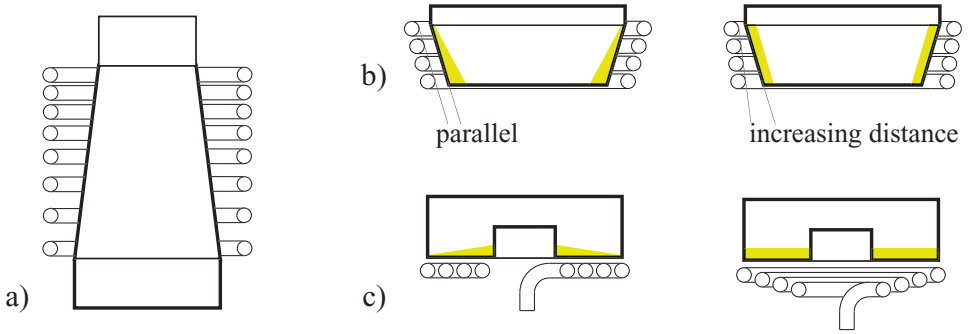

FIG. 1.2. *Adjustment of induction heating patterns by varying the turn spacing* (a) *or the coupling distance* (b), (c).

The remedy is to increase the coupling distance in the lower part of the workpiece leading to a uniform penetration depth.

Example (c) depicts the typical situation of a hole in an otherwise plane workpiece surface. The inductor on the left-hand side with a uniform coupling distance leads to an uneven hardening pattern and possibly even to a melting of hole edges. A better result can be achieved when the coupling distance between inductor and workpiece is increased locally around the hole.

There are already a lot of papers on modeling, analysis, and simulation of induction heating, e.g., [3], [4], [7], [10], [12], [13], [16], [17], [18], [19], [24], [25], [26]. In [2], an optimal control problem for a two-dimensional (2D) induction heating setting has been considered. Mathematical models for phase transitions in steel have been considered in, e.g., [15], [16], [17], [18], and [23].

In this paper, for the first time a design problem for the three-dimensional (3D) induction heating process including phase transitions is investigated. The main novelty of our approach is that we describe the inductor coil as a tube generated from a closed regular curve. To obtain information about the shape gradient, we first use the speed method. Then we show that we can relate the speed vector-field to

perturbations of the curve, which defines the coil. Probably this new procedure of characterizing the optimal configuration of tubes will admit further applications, for instance, in optimal design problems related to the flow of liquids through pipelines.

In the next section we derive a mathematical model for induction heating and prove its well-posedness. Moreover, we provide some numerical results showing the effect of varying coupling distance between workpiece and inductor. In section 3 we formulate the shape design problem for the inductor coil modeled as a tube with circular cross-section. Here, the main issue is to define a reasonable set of admissible domains excluding intersections of parts of the inductor. The existence of an optimal design is proved in section 4 using regularity results of sets with positive *reach* as introduced by Federer [11]. In section 5 we derive a necessary optimality condition and show how one can relate the shape gradient to perturbations of the generating curve. The necessary estimates for the sensitivity analysis are provided in section 6.

2. The mathematical model.

2.1. The state equations. Since we cannot model the hardening machine itself, we restrict ourselves to the following idealized geometric setting (cf. Figure 1.1 (right)). Let $D \subset \mathbb{R}^3$ be the hold-all domain, which contains the inductor Ω and the workpiece Σ. We call $G = \Omega \cup \Sigma$ the set of conductors and define the space-time cylinder $Q = \Sigma \times (0, T)$.

Since we do not consider the hardening machine in our model, we assume that the inductor Ω is a closed tube. Inside we fix a section Γ and model the current density which is generated by the hardening machine by an interface condition on Γ.

The following mathematical model is a simplified version of the electro-thermo-mechanical model of induction hardening derived in [18]. For further details about modeling, we refer the reader to this paper.

In eddy current problems we can neglect displacement currents, and hence we consider the following set of Maxwell equations:

$$\text{curl } H = J, \tag{2.1a}$$

$$\text{curl } E = -B_t, \tag{2.1b}$$

$$\text{div } B = 0. \tag{2.1c}$$

Here, E is the electric field, B the magnetic induction, H the magnetic field, and J the current density. In addition, we use the linear constitutive relations

$$J = \sigma E \quad \text{in } D, \tag{2.2a}$$

$$B = \mu H \quad \text{in } D, \tag{2.2b}$$

with the magnetic permeability μ and the electric conductivity σ. We assume zero current density outside conductors, i.e.,

$$\sigma(x) = \begin{cases} \sigma_0 > 0 & \text{in } \bar{G}, \\ 0 & \text{in } D \setminus \bar{G}. \end{cases}$$

The magnetic permeability takes different values in the workpiece made of steel and in the surrounding air. The coil is usually made of copper, which has approximately the same permeability as air. Hence we assume

$$\mu(x) = \begin{cases} \mu_1 & \text{in } D \setminus \bar{\Sigma}, \\ \mu_2 & \text{in } \bar{\Sigma}. \end{cases} \tag{2.3}$$

Using (2.1a)–(2.1c) one now introduces the magnetic vector potential A and the scalar potential ϕ such that

$$B = \text{ curl } A, \tag{2.4}$$

$$E = -A_t - \text{ grad } \phi. \tag{2.5}$$

Then, Maxwell's equations (2.1a)–(2.1c) can be rewritten in the following way:

$$\sigma A_t + \text{ curl } \Big(\frac{1}{\mu} \text{ curl } A\Big) + \sigma \text{ grad } \phi = 0 \quad \text{ in } D. \tag{2.6}$$

In view of Ohm's law (2.2a) and of (2.5) the current density can be viewed as the sum of an induced part $(-\sigma A_t)$ and an impressed part, stemming from the scalar potential $(-\sigma \text{ grad } \phi)$. Assuming the continuity equation to hold for the impressed part, the scalar potential ϕ is determined by

$$\text{div } (\sigma \text{ grad } \phi) = 0 \quad \text{ in } G. \tag{2.7a}$$

On the boundaries of the set of conductors, we assume a homogenous Neumann condition, i.e.,

$$\sigma_0 \frac{\partial \phi}{\partial \nu} = 0 \text{ in } \partial\Sigma \cup \partial\Omega. \tag{2.7b}$$

In the section Γ we supply current via an interface condition, i.e.,

$$\Big[\sigma_0 \frac{\partial \phi}{\partial \tilde{\nu}}\Big] = j_s \quad \text{ on } \Gamma. \tag{2.7c}$$

Here, j_s is the external source current density, $[f(x)]$ denotes the jump of a function $f(x)$ across the interface Γ, and $\tilde{\nu}$ is a unit normal vector on Γ.

The system (2.7a)–(2.7c) can be solved separately in each conductor. In the workpiece Σ, we obtain a homogenous, linear Neumann problem. Hence its solution is constant in Σ. Since only the gradient enters in (2.6), we can restrict the domain of ϕ to the coil Ω.

To solve the interface problem (2.7a)–(2.7c) in the coil Ω, we introduce the quotient space $H^1(\Omega)/\mathbb{R}$ with norm

$$\|\bar{u}\|_{H^1(\Omega)/\mathbb{R}} = \inf_{u \in \bar{u}} \|u\|_{H^1(\Sigma)}.$$

According to [14, Theorem 1.9], the functional

$$\bar{u} \mapsto \Big(\int_\Sigma |\nabla u|^2 \, dx \Big)^{1/2} \tag{2.8}$$

is an equivalent norm on $H^1(\Omega)/\mathbb{R}$. In what follows we will not distinguish between $\bar{u}$ and u.

Now we turn to the Maxwell equation (2.6). Assuming that the tangential component of A vanishes on ∂D, i.e.,

$$n \times A = 0, \tag{2.9}$$

we introduce the Hilbert space

$$\mathbf{X} = \{v \in \mathbf{L}^2(D)\,;\ \text{curl } v \in \mathbf{L}^2(D),\ \text{div } v \in \mathrm{L}^2(D) \text{ and } n \times v|_{\partial D} = 0\}.$$

Here and in what follows, $\mathbf{L}$ denotes the vector-valued counterpart $\mathbf{L} = [L]^3$ for any real-valued Sobolev space L. For ∂D of class $C^{1,1}$, $\mathbf{X}$ is a closed subspace of $\mathbf{H}^1(D)$, equipped with the norm

$$\|v\|^2_{\mathbf{X}} = \|\text{curl } v\|^2_{\mathbf{L}^2(D)} + \|\text{div } v\|^2_{L^2(D)}.$$

A good measure for the hardness penetration depth in the workpiece is the formation of austenite during heating, which can be described by the following initial value problem derived by Leblond and Devaux [23] (for details, we refer to [12]):

$$z(0) = 0, \tag{2.10a}$$

$$z_t(t) = \frac{1}{\mathcal{T}(\theta)}\Big[z_{eq}(\theta) - z\Big]^+. \tag{2.10b}$$

Here, z is the volume fraction of austenite and θ the temperature, $z_{eq}(\theta) \in [0,1]$ is an equilibrium fraction of austenite, and $\mathcal{T}(\theta)$ a time constant. The model is completed by a semilinear energy balance equation. For convenience, we recall the complete model of induction hardening of steel:

(P) Find $(A, \phi, \theta, z) \in L^\infty(0,T;\mathbf{X}) \times H^1(0,T;H^1(\Omega)/\mathbb{R}) \times W^{2,1}_3(Q)$
$\times W^{1,\infty}(0,T;L^\infty(\Sigma))$ such that

$$\sigma_0 \int_\Omega \nabla\phi \cdot \nabla u \; dx + \int_\Gamma j_s \varphi \, dx = 0 \text{ for all } \varphi \in H^1(\Omega)/\mathbb{R}, \tag{2.11a}$$

$$A(0) = A_0 \ \text{ in } D, \tag{2.11b}$$

$$\sigma_0 \int_G A_t \cdot v \; dx + \int_D \frac{1}{\mu} \text{ curl } A \cdot \text{ curl } v \; dx + \int_D \frac{1}{\mu} \text{ div } A \text{ div } v \, dx$$
$$+ \sigma_0 \int_\Omega \nabla\phi \cdot v \; dx = 0 \ \text{ for all } v \in \mathbf{X}, \text{ a.e. in } (0,T), \tag{2.11c}$$

$$\theta(0) = \theta_0 \quad \text{in } \Sigma, \tag{2.11d}$$

$$\frac{\partial\theta}{\partial\nu} = 0 \quad \text{in } \partial\Sigma \times (0,T), \tag{2.11e}$$

$$\rho c_p \theta_t - k\Delta\theta = -\rho L z_t + \sigma_0 |A_t|^2 \quad \text{in } Q, \tag{2.11f}$$

$$z(0) = 0 \quad \text{in } \Sigma, \tag{2.11g}$$

$$z_t = \frac{1}{\mathcal{T}(\theta)}[z_{eq}(\theta) - z]^+ \quad \text{in } Q, \tag{2.11h}$$

with $W^{2,1}_p(Q) = W^{1,p}(0,T;L^p(\Sigma)) \cap L^p(0,T;W^{2,p}(\Sigma))$.

The first term on the right-hand side of (2.11f) measures the latent heat inside the workpiece Σ, which is consumed during the formation of austenite. The second one describes the Joule heating $\sigma_0|E|^2$; cf. (2.5). Note that $\nabla\phi \equiv 0$ in Σ. ρ, c_p, k, L are density, specific heat at constant pressure, heat conductivity, and latent heat.

Remark 2.1. Usually, (2.6) is complemented by the Coulomb gauge $\operatorname{div} A = 0$ to ensure uniqueness (cf., e.g., [18]). To simplify the model, we have chosen here to include a divergence part in the bilinear form in (2.11c) as a penalty term, as it is often done in electrical engineering (cf., e.g., [21]). Otherwise, the shape sensitivity analysis requires the appropriate transformation of the vector potential A in the fixed domain setting and becomes technically involved.

We make the following assumptions:

(H1) $\bar\Omega \subset D$, $\bar\Sigma \subset D, \bar\Omega \cap \bar\Sigma = \emptyset$, and $\partial\Omega$, $\partial\Sigma$, ∂D are of class $C^{1,1}$.

(H2) σ_0, ρ, c_p, k, and L are positive constants.

(H3) $A_0 \in \mathbf{X} \cap \mathbf{H}^2(D)$, $\theta_0 \in W^{2,3}(\Sigma)$.

(H4) $\mu(x) = \mu_2\chi_\Sigma + \mu_1(1-\chi_\Sigma)$, with constants $0 < \mu_1 < \mu_2$.

(H5) $j_s \in H^1(0,T;H^{-1/2}(\Gamma))$, such that $\int_\Gamma j_s\,dx = 0$ and $\int_\Gamma j_{s,t}\,dx = 0$.

(H6) There exists $y_0 \in \mathbf{X}$, such that

$$\sigma_0 \int_G y_0 \cdot\ v\ dx + \int_D \frac{1}{\mu}\ \operatorname{curl} A_0 \cdot\ \operatorname{curl} v\,dx + \int_D \frac{1}{\mu}\ \operatorname{div} A_0\ \operatorname{div} v\,dx + \sigma_0 \int_\Omega \nabla\phi(0)\cdot v\ dx = 0$$

for all $v \in \mathbf{X}$.

(H7) $0 < \mathcal{T}_* \le \mathcal{T}(x) \le \mathcal{T}^* < \infty$ for all $x \in \mathbb{R}$, $\|\mathcal{T}\|_{C^2(\mathbb{R})} \le M$.

(H8) $0 \le z_{eq}(x) \le 1$ for all $x \in \mathbb{R}$; $\|z_{eq}\|_{C^2(\mathbb{R})} \le M$.

(H9) $[x]^+ = \frac{1}{2}(x + |x|)\mathcal{H}$ with $\mathcal{H} \in C^{2,1}(\mathbb{R})$, a monotone approximation of the Heaviside function.

Remark 2.2. The first part of assumption (H5) is the usual compatibility condition to ensure solvability of an elliptic Neumann problem. The second part of (H5) and (H6) are due to the fact that we will differentiate the equations for scalar and vector potential with respect to time to obtain higher regularity.

2.2. A weak solution to the state equations. Problem (P) is only sequentially coupled and can be solved by solving consecutively the subproblems (2.11a), (2.11b), (2.11c), and (2.11d)–(2.11h).

For the first one, we have the following lemma.

LEMMA 2.3. *Assume* (H1), (H2), *and* (H5); *then* (2.11a) *has a unique solution* $\phi \in H^1(0,T;H^1(\Omega)/\mathbb{R})$ *such that*

$$\|\nabla\phi\|_{H^1(0,T;\mathbf{L}^2(\Omega))} \le C\|j_s\|_{H^1(0,T;H^{-1/2}(\Gamma))}, \tag{2.12}$$

with a constant $C > 0$.

Proof. The proof follows from the Lax–Milgram lemma and the fact that we may differentiate (2.11a) with respect to time because of (H5). ∎

For the vector potential equation (2.11b), (2.11c) we have the following lemma.

LEMMA 2.4. *Assume* (H1)–(H6); *then* (2.11b), (2.11c) *has a unique solution* $A \in L^\infty(0,T;\mathbf{X})$, *satisfying the estimate*

$$\|A\|_{L^\infty(0,T;\mathbf{X})} + \|A_t\|_{L^\infty(0,T;\mathbf{L}^6(G))} \le C_1 + C_2\|j_s\|_{H^1(0,T;H^{-1/2}(\Gamma))}, \tag{2.13}$$

where the constant C_1 *depends on* A_0 *and* y_0 *(cf.* (H6)*).*

Proof. To prove the existence of a unique weak solution one can use, e.g., Rothe's method of implicit time discretization as described in the monograph [20]. The first part of the a priori estimate follows from inserting $v = A_t$ into (2.11c) and integrating

in time. To obtain the second part one can formally differentiate (2.11c) with respect to t. Then, we substitute $y = A_t$ and solve the system

$$y(0) = y_0 \quad \text{in } D,$$
$$\sigma_0 \int_G y_t \cdot v \, dx + \int_D \frac{1}{\mu} \operatorname{curl} y \cdot \operatorname{curl} v \, dx + \int_D \frac{1}{\mu} \operatorname{div} y \operatorname{div} v \, dx + \sigma_0 \int_\Omega \nabla \phi_t \cdot v \, dx = 0 \text{ for all } v \in \mathbf{X}, \text{ a.e. in } (0,T).$$

Testing with $v = y_t$ and integrating in time we obtain an estimate for y in $L^\infty(0,T;\mathbf{X})$. Owing to the compatibility condition (H6) we can recover that $y = A_t$ a.e. in G. Hence we can use the embedding $\mathbf{H}^1(G) \subset \mathbf{L}^6(G)$ and obtain the second part of (2.13). ∎

LEMMA 2.5. *Assume* (H7)–(H9)*; then the following are true:*

(1) *Let* $\theta \in L^1(Q)$*; then* (2.11g), (2.11h) *has a unique solution satisfying*

$$0 \le z(x,t) < 1 \quad \text{a.e. in } Q, \tag{2.14}$$

and

$$\|z\|_{W^{1,\infty}(0,T;L^\infty(\Sigma))} \le C, \tag{2.15}$$

with a constant $C > 0$ *independent of* θ.

(2) *Let* $\theta_k \to \theta$ *strongly in* $L^1(\Sigma)$. *Then*

$$z_k \longrightarrow z \quad \text{strongly in } W^{1,p}(0,T;L^p(\Sigma)) \text{ for } p \in [1,\infty),$$

where z_k *and* z *are the solution to* (2.11g), (2.11h) *corresponding to* θ_k *and* θ*, respectively.*

(3) *Let* $\theta_1, \theta_2 \in L^p(Q)$, $p \in [1,\infty)$, *and* z_1, z_2 *be the corresponding solutions to* (2.11g), (2.11h)*; then there exists a constant* $C > 0$ *such that*

$$\|z_1 - z_2\|_{W^{1,p}(0,T;L^p(\Sigma))} \le C \|\theta_1 - \theta_2\|_{W^{1,p}(0,T;L^p(\Sigma))}.$$

Proof. The existence of a unique local solution to (2.11g), (2.11h) is a direct consequence of the theorem of Carathéodory; see, e.g., [31, p. 1044]. Using (H7)–(H9) and the theory of differential inequalities (cf. [15, Lemma 2.1], we obtain (2.14), whereas (2.15) is a direct consequence of (H7)–(H9).

Assertion (2) follows from Lebesgue's lemma.

To prove (3), let $\theta^i \in L^p(Q)$, $i = 1, 2$, and define $\bar\theta = \theta_1 - \theta_2$; then $\bar z = z^1 - z^2$ solves

$$\bar z_t = f(\theta^1, z^1) - f(\theta^2, z^2), \tag{2.16}$$

where $f(\theta, z)$ denotes the right-hand side of (2.11h). In view of (H7)–(H9), f is Lipschitz continuous. Hence we can test (2.16) with $\bar z^{p-1}$ and apply Young's inequality to obtain

$$\begin{aligned} \frac{1}{p} \int_\Sigma \|\bar z(t)\|^p \, dx &\le c_1 \int_0^t \int_\Sigma |\bar z|^p \, dx \, ds + c_2 \int_0^t \int_\Sigma |\bar\theta| |\bar z|^{p-1} \, dx \, ds \\ &\le \Big(c_1 + c_2 \frac{p-1}{p} \Big) \int_0^t \int_\Sigma |\bar z|^p \, dx \, ds + \frac{c_2}{p} \int_0^t \int_\Sigma |\bar\theta|^p \, dx \, ds. \end{aligned}$$

Now we can apply Gronwall's lemma and use (2.16) once again to conclude the proof. ∎

Before considering the heat equation (2.11f), we recall the following results from the linear theory of parabolic equations.

LEMMA 2.6 (see [22, Theorem 9.1]). *Let $g \in L^p(Q)$ and $u_0 \in W^{1,p}(\Sigma)$ for some $p \in (1,\infty)$. Then there exists a constant $C > 0$ such that the unique solution to*

$$\begin{aligned} u_t - \Delta u &= g && \text{in } Q,\\ \frac{\partial u}{\partial \nu} &= 0 && \text{in } \partial\Sigma \times (0,T),\\ u(0) &= u_0 && \text{in } \Sigma \end{aligned}$$

satisfies the estimate

$$\|u\|_{W_p^{2,1}(Q)} \le C\Big(\|u_0\|_{W^{1,p}(\Sigma)} + \|g\|_{L^p(Q)}\Big).$$

For later use we also note the following embedding theorem [26, eq. (3.9)], written down for dim $\Sigma = 3$.

LEMMA 2.7. *Let $k = 0, 1$, $p \ge q$, $2 - k - 5(\frac{1}{q} - \frac{1}{p}) \ge 0$; then the embedding*

$$W_q^{2,1}(Q) \subset W_p^{k,0}(Q)$$

is continuous. The inclusion is compact if the last inequality is strict.

LEMMA 2.8. *Assume* (H1)–(H9)*; then* (2.11d)–(2.11h) *has a unique solution (θ, z), such that*

$$\|(\theta, z)\|_{W_3^{2,1}(Q)\times W^{1,\infty}(0,T;L^\infty(\Sigma))} \le C.$$

The constant C depends on A_t and θ_0.

Proof. The existence can be proved, e.g., using the Schauder fixed point theorem. The a priori estimate is a direct consequence of Lemma 2.5 and Lemma 2.6.

To prove uniqueness, we take the difference of two solutions $\bar\theta = \theta^1 - \theta^2$ which satisfies

$$\rho c_p \bar\theta_t - k\Delta\bar\theta = -\rho L(z_t^1 - z_t^2) \qquad \text{in } Q,$$

$$\frac{\partial\bar\theta}{\partial\nu} = 0 \text{ in } \partial\Sigma \times (0,T), \qquad \bar\theta(0) = 0 \text{ in } \Sigma.$$

Using Lemma 2.5(3), Lemma 2.6, and Hölder's inequality, we can infer

$$\|\bar\theta\|^3_{W_3^{2,1}(Q_t)} \le c_1 \int_0^t \int_\Sigma \left| \int_0^s \bar\theta_\xi \, d\xi \right|^3 dx\, ds \le T^2 c_1 \int_0^t \int_0^s \int_\Sigma |\bar\theta_\xi|^3 \, dx d\xi \, ds \le c_2 \int_0^t \|\bar\theta\|^3_{W_3^{2,1}(Q_s)} ds,$$

where $Q_t = \Sigma \times (0,t)$. Note that $\bar\theta_\xi$ is short for $\frac{\partial\bar\theta(x,\xi)}{\partial\xi}$. Now the assertion follows from Gronwall's lemma. ∎

Summarizing the results of Lemmas 2.3–2.5 and Lemma 2.8 we obtain the following theorem.

THEOREM 2.9. *Assume* (H1)–(H9)*; then problem* (P) *has a unique solution.*

FIG. 2.1. *Cylinder-symmetric workpiece with uniform inductor distance and the corresponding distribution of austenite.*

FIG. 2.2. *Cylinder-symmetric workpiece with varying inductor distance and the corresponding distribution of austenite.*

2.3. Numerical simulations for the state equations. The goal of this section is to demonstrate by numerical simulations that our model of induction hardening shows the correct behavior with respect to variations of the coupling distance between inductor and workpiece (cf. Figure 1.2), thereby justifying again the formulation of our shape optimization problem for induction hardening in the following section.

We use the commercial software package ANSYS to compute 3D simulations of the heating part of an induction hardening process, i.e., of equations (2.11a)–(2.11h). However, in order to avoid the problem of different time scales for the rapidly oscillating vector and scalar potentials on the one hand and for the slower heat diffusion on the other hand, we use harmonic approximation of (2.11c) for the numerical solution. This means we replace $A(x,t)$ with $A(x)e^{i\omega t}$ and make the same ansatz for ϕ. Moreover, we replace the Joule heat term $\sigma_0|A_t|^2$ in the energy balance (2.11f) by its average value for one period, i.e., by $\frac{\sigma_0\omega^2}{2}|A|^2$. The phase transition model (2.11h) has been added to ANSYS with the help of FORTRAN user routines. The physical data have been chosen for the steel 42 CrMo 4.

Owing to limitations in the number of nodes for this 3D problem, the results do not look as smooth and symmetric as they should. However, the principal behavior, which has already been discussed in connection with Figure 1.2, is clearly visible. In Figure 2.1 we have a cylinder-symmetric workpiece, and the inductor lies at a uniform distance from the workpiece. This geometric configuration produces a strip of austenite along the lateral cylinder boundary. Then in Figure 2.2, we have nearly the same situation except that the distance between inductor and workpiece now varies. The result is that austenite is only produced in the part of the cylinder that is close to the inductor.

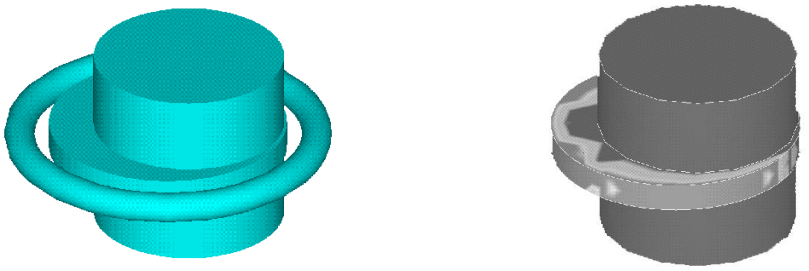

FIG. 2.3. *Nonsymmetric workpiece with uniform inductor distance and the corresponding distribution of austenite.*

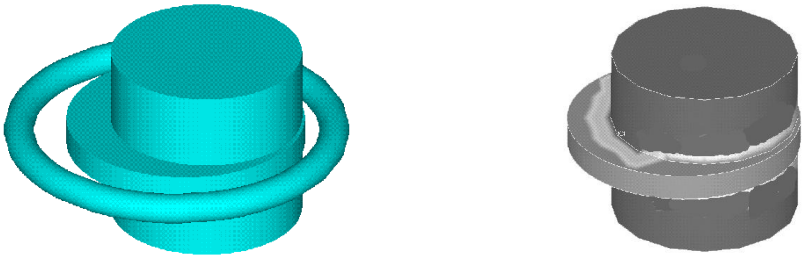

FIG. 2.4. *Nonsymmetric workpiece with varying inductor distance and the corresponding distribution of austenite.*

While Figures 2.1 and 2.2 are of rather academic nature, the next two figures depict more realistic situations. They show a nonsymmetric workpiece, where the center of mass is not in the middle, for instance, one might think of a camshaft. In Figure 2.3 the inductor is at a uniform distance from the workpiece. As a result, heat diffuses in the part with the bigger mass, and austenite is only produced in the parts with less mass.

Thus the strategy to achieve a uniform penetration of austenite should be to change the distance between inductor and workpiece, such that it is smaller on the side of the workpiece where the bigger part of the mass is concentrated. This has been done in Figure 2.4, and the result indeed is an approximately uniform distribution of austenite.

For the further implementation of a numerical procedure for the optimal design problem, the automatic geometry generation creates severe difficulties. For instance, it is easy to define a space curve as a B-spline using keypoints. Then one can create the tube by dragging a circle along the curve. These operations are standard in most CAD tools. However, to create disjoint domains necessary for grid generation, we have to apply Boolean operations. It turns out that these operations are not stable with respect to small perturbations of the curve defining the tube. This problem prevents the development of a solution strategy for the design problem using the same software as for the state equations. Hence an important step towards the solution of the design problem is the development of a stable CAD tool. However, this is beyond the scope of this paper and is the subject of current research.

3. The shape design problem. To decide whether the coupling distance between inductor and workpiece has been properly chosen, we measure the volume

fraction of austenite at the end-time T and compare it to a desired volume fraction $\bar{z}$; i.e., we consider the following cost functional of tracking type:

$$\mathcal{J}(\Omega) = \int_\Sigma \Big(z(x,T) - \bar{z}\Big)^2 \, dx. \tag{3.1}$$

Note that the cost functional depends on Ω only implicitly, through the solution to the Maxwell equation (2.11c).

Inductor coils are manufactured from copper tubes with approximately quadratic or circular cross-section. For convenience, we will only consider tubes with circular cross-section. These tubes can easily be generated from curves $\gamma : [0, 2\pi] \longrightarrow \mathbb{R}^3$, for which we assume

$$|\gamma'(s)| \neq 0 \text{ for all } s \in [0,2\pi],\ \gamma(0) = \gamma(2\pi), \text{ and } \frac{\gamma'(0)}{|\gamma'(0)|} = \frac{\gamma'(2\pi)}{|\gamma'(2\pi)|} = e_1. \tag{3.2}$$

Hence γ is a regular, closed curve, which starts and ends in the origin and has a tangent vector parallel to e_1 (the unit-vector in the x_1-direction) in the origin. In doing so we tacitly assume that the section Γ of the tube, where the source current is supplied, lies in a plane orthogonal to e_1 centered around the origin.

Then we define the corresponding tube of radius R by

$$\Omega(\gamma) = \{x \in \mathbb{R}^3 \,|\, d(\boldsymbol{\Gamma}_\gamma, x) \leq R\}, \tag{3.3}$$

whereas its lateral boundary is given by

$$\partial\Omega(\gamma) = \{x \in \mathbb{R}^3 \,|\, d(\boldsymbol{\Gamma}_\gamma, x) = R\}. \tag{3.4}$$

Here $d(\boldsymbol{\Gamma}_\gamma, x) = \inf\{|x - \gamma(s)| \,:\, s \in [0,2\pi]\}$ is the distance between x and the trace of γ, defined by

$$\boldsymbol{\Gamma}_\gamma = \{\gamma(s) \,|\, s \in [0,2\pi]\}.$$

From a physical point of view it is indispensable to avoid self-intersections of the tube. They can easily happen, for instance, when the curvature becomes too big (i.e., $> \frac{1}{R}$). But even if we exclude this by imposing an explicit bound on the curvature, it could happen that remote parts of the curve intersect with each other (cf. Figure 3.1).

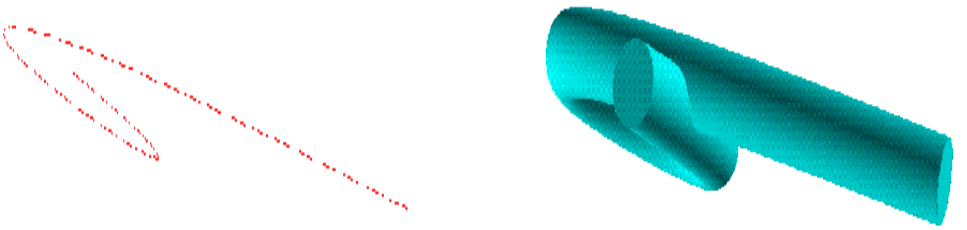

FIG. 3.1. *Curves without double point may lead to tubes with intersecting parts.*

Hence it is desirable to create a certain surrounding of the curve in which all points have a unique projection onto it. This can be achieved by adopting a concept from differential geometry introduced by Federer [11].

DEFINITION 3.1 (Federer [11]). *Let B be a closed subset of $\mathbb{R}^n$; then we call* Unp (B) *the set of all points $x \in \mathbb{R}^3$, for which there exists a unique projection onto B, and introduce the mapping ξ_B : Unp $(B) \longrightarrow B$, $x \mapsto b$, where b is uniquely given by $d(B,x) = |x-b|$.*

For $y \in B$ we define

$$\text{reach } (B,y) = \sup\Big\{ r \,\Big|\, \{x \in \mathbb{R}^3\,,\, |x-y| < r\} \subset \text{Unp } (B)\Big\}, \qquad \textit{and}$$
$$\text{reach } (B) = \inf\Big\{ \text{reach } (B,y) \,\Big|\, y \in B\Big\}.$$

In other words, *reach* of a subset $B \subset \mathbb{R}^n$ is the largest ε such that for all x in an ε-surrounding of B, there exists a unique projection onto B. If B is convex, then reach $(B) = \infty$. On the other hand, if B is concave with a re-entrant corner, e.g., an L-shaped domain, then reach $(B) = 0$.

For our purposes, we demand

$$\text{reach } (\boldsymbol{\Gamma}_\gamma) \geq R + \delta, \tag{3.5}$$

where $\delta > 0$ is a given positive parameter and R is the tube radius. Thus, we avoid situations as depicted in Figure 3.1 and also too narrow twists of the curve. Moreover, we gain a certain smoothness of $\partial\Omega(\gamma)$.

LEMMA 3.2. *Let $\boldsymbol{\Gamma}_\gamma$ be the trace of a curve γ satisfying* (3.2) *and* (3.5)*; then the boundary $\partial\Omega(\gamma)$ of the corresponding tube $\Omega(\gamma)$ is of class $C^{1,1}$.*

For the proof we need some differentiability properties of the distance function, which can be found in [11].

LEMMA 3.3. *For every closed and nonempty subset B of $\mathbb{R}^n$, there hold*

(1) $|d(B,x) - d(B,y)| \leq |x-y|$ *for all $x, y \in \mathbb{R}^n$;*

(2) $d(B,.)$ *is continuously differentiable on* Int(Unp $(B) \setminus B$) *and*

$$\text{grad } d(B,x) = \frac{1}{d(B,x)}(x - \xi_B(x));$$

(3) *if $0 < s < r <$ reach (B), then* grad $d(B,.)$ *is Lipschitzian on $\{x | s \leq d(B,x) \leq r\}$ and ξ_B is Lipschitzian on $\{x | d(B,x) \leq r\}$.*

Proof of Lemma 3.2. Let us define

$$F(x) = d(\boldsymbol{\Gamma}_\gamma, x) - R;$$

then $\partial\Omega(\gamma)$ is given by the zero level-set of F. In view of Lemma 3.3(3), F is $C^{1,1}$ in a surrounding of this level-set and grad $F(x) \neq 0$. Hence the assertion follows from a standard application of the implicit function theorem. ∎

The Hausdorff distance between two closed sets A, $B \subset \mathbb{R}^n$ can be defined as

$$d_H(A,B) = \sup_{x \in C} \Big| d(A,x) - d(B,x) \Big|$$

for any $C \subset \mathbb{R}^n$ such that $A \cup B \subset C$. The following lemma states that the family of bounded sets with reach bounded away from zero is closed with respect to the Hausdorff metric.

LEMMA 3.4. *Let $\varepsilon > 0$. If B_i, $i \in \mathbb{N}$, and B are closed subsets of $\mathbb{R}^n$ such that* reach $(B_i) \geq \varepsilon$ *for $i \in \mathbb{N}$ and $d(B_i,x) \longrightarrow d(B,x)$ uniformly for $x \in C$, whenever C is a compact subset of $\{x \in \mathbb{R}^n \,|\, d(B,x) < \varepsilon\}$, then*

$$\text{reach } (B) \geq \varepsilon$$

and

$$\xi_{B_i}(x) \xrightarrow[i\to\infty]{} \xi_B(x)$$

uniformly for $x \in C$.

Now we can introduce the set of admissible curves. Let δ be a positive constant; then we define

$$U_{ad} = \Big\{\gamma \in [W^{2,\infty}(0,2\pi)]^3 \,\Big|\, \gamma \text{ satisfies (3.2) and (3.5)}, \ \overline{\Omega}(\gamma) \subset (D \setminus \overline{B_\delta}(\Sigma)), \ \kappa_\gamma(s) \le \frac{1}{R} \text{ for a.e. } s \in [0,2\pi]\Big\}.$$

Note that for regular curves the curvature κ_γ is defined by

$$\kappa_\gamma(s) = \frac{|\gamma'(s) \times \gamma''(s)|}{|\gamma'|^3}.$$

Thus, admissible curves are regular and closed, with pointwise bounded curvature; the generated tubes do not touch the workpiece or ∂D and cannot have self-intersections because of the reach condition.

Remark 3.5. Note that there is no artificial boundedness assumption in the definition of U_{ad}. Choosing $\gamma \in [W^{2,\infty}(0,2\pi)]^3$ seems to be natural, because then the curve regularity corresponds to the $C^{1,1}$ regularity of the tube surface that could be obtained in Lemma 3.3 using the reach condition.

The curvature condition that we have imposed explicitly can also be derived from the reach condition. To this end one has to take a smooth approximation of the curve, parametrize the tube surface locally using the Frenet-frame, and compute a normal to the surface.

Now, we define the corresponding set of admissible domains by

$$\mathcal{U}_{ad} = \{\Omega(\gamma)\,,\ \gamma \in U_{ad}\}$$

and give a precise definition of our control problem, which reads as

(CP) minimize $J(\Omega)$, given by (3.1),
subject to
$\Omega \in \mathcal{U}_{ad}$
and the state equations (2.11a)–(2.11h).

Note that (CP) is a nonconvex optimization problem due to the nonconvexity of $\mathcal{U}_{ad}$ and of the cost functional.

4. The existence of an optimal domain Ω^*.

THEOREM 4.1. *Assume* (H1)–(H9)*; then* (CP) *admits a solution* $\Omega^* \in \mathcal{U}_{ad}$.

Proof. We take a minimizing sequence $\{\Omega_n\}$, such that $J(\Omega_n) \longrightarrow \inf J$ for $n \to \infty$. We have $\Omega_n = \Omega(\widetilde{\gamma}_n)$ and $\widetilde{\gamma}_n \in U_{ad}$. Owing to the embedding $W^{2,\infty}(0,2\pi) \subset C^{1,\alpha}[0,2\pi]$, which is compact for $\alpha < 1$, $\widetilde{\gamma}_n'$ is a continuous function and there exists a constant $\widetilde{c}_n > 0$ such that

$$|\widetilde{\gamma}_n'(s)| \ge \widetilde{c}_n \quad \text{for all } s \in [0,2\pi]. \tag{4.1}$$

Obviously, this estimate is not uniform in n, so we proceed as in [29] and introduce a reparametrization of $\widetilde{\gamma}_n$. Let $\varphi_n : [0,2\pi] \to [0,l_n]$ measure the length l_n of $\widetilde{\gamma}_n$, i.e.,

$$\varphi_n(s) = \int_0^s |\widetilde{\gamma}_n'| ds.$$

Owing to (4.1), φ_n is invertible and its inverse $\psi_n : [0, l_n] \to [0, 2\pi]$ satisfies

$$\psi_n'(\tau) = \frac{1}{|\widetilde{\gamma}_n'|},$$
$$\psi_n''(\tau) = -\frac{\widetilde{\gamma}_n' \cdot \widetilde{\gamma}_n''}{|\widetilde{\gamma}_n'|^4}$$

for $s = \psi_n(\tau)$ and a.e. $\tau \in [0, l_n]$.

Hence ψ_n is a C^1 diffeomorphism and the composition $\widetilde{\gamma}_n \circ \psi_n$ is in $W^{2,\infty}(0, l_n)$. Now we introduce the function

$$\Lambda_n : [0, 2\pi] \to [0, l_n], \quad \Lambda(s) = \frac{l_n}{2\pi} s$$

and define

$$\gamma_n = \widetilde{\gamma}_n \circ \psi_n \circ \Lambda_n. \tag{4.2}$$

It follows that $\gamma_n \in [W^{2,\infty}(0, 2\pi)]^3$,

$$|\gamma_n'(s)| = \frac{l_n}{2\pi} \text{ for all } s \in [0, 2\pi], \tag{4.3}$$

and $\gamma_n(0) = \gamma_n(l) = 0$, $\frac{\gamma_n'(0)}{|\gamma_n'(0)|} = \frac{\gamma_n'(2\pi)}{|\gamma_n'(2\pi)|} = e_1$. Moreover, since γ_n is just a reparametrization of $\widetilde{\gamma}_n$, both curves have the same trace. Hence $\Omega(\widetilde{\gamma}_n) = \Omega(\gamma_n)$, the reach condition is satisfied, and due to the parametric invariance of curvature we can conclude $\gamma_n \in U_{ad}$.

In order to obtain uniform estimates for γ_n we first remark that

$$2\pi(R + \delta) \le l_n \le \frac{|D|}{\pi R^2}, \tag{4.4}$$

where $|D|$ is the Lebesgue-measure of the domain D. The first part of the inequality follows directly from the reach condition. Suppose it would not hold. Since the curve γ_n is closed, we could take a ball with radius $\widetilde{R} < R + \delta$ and move it towards the curve until it has at least two different points of contact with the curve but no points where the curve intersects the ball. Hence the center of the ball has no unique projection on the curve; this implies reach $(\boldsymbol{\Gamma}_n) \le \widetilde{R}$, a contradiction to reach $(\boldsymbol{\Gamma}_n) \ge R + \delta$.

Due to the classical theorem of Pappus (see, e.g., [1, Corollary 6.9.10]) the tube volume is given by

$$|\Omega(\gamma_n)| = \pi R^2 l_n.$$

Since the tube cannot have self-intersections because of the reach condition, its volume is bounded by the volume of D. This is the second part of (4.4).

Now, we exploit the curvature functional. Utilizing (4.3), we see that

$$0 = \frac{\partial}{\partial s} |\gamma_n'(s)|^2 = 2\gamma_n' \cdot \gamma_n''.$$

Hence γ_n' is perpendicular to γ_n'', and we have for a.e. $s \in [0, 2\pi]$

$$\kappa_{\gamma_n}(s) = \frac{|\gamma_n'(s) \times \gamma_n''(s)|}{|\gamma_n'(s)|^3} = \frac{4\pi^2}{l_n^2} |\gamma_n''(s)|.$$

Taking into account also (4.3) and (4.4), there exists a constant c_1 independent of n such that

$$\|\gamma_n\|_{W^{2,\infty}(0,2\pi)} \le c_1,$$

and we can extract a subsequence such that

$$\gamma_{n'} \longrightarrow \gamma^* \quad \begin{array}{ll} \text{weakly* in} & W^{2,\infty}(0,2\pi), \\ \text{strongly in} & C^{1,\alpha}[0,2\pi] \text{ for } 0 \le \alpha < 1. \end{array} \tag{4.5}$$

Obviously, γ^* satisfies $\gamma^*(0) = \gamma^*(l) = 0$ and $\frac{\gamma^{*\prime}(0)}{|\gamma^{*\prime}(0)|} = \frac{\gamma^{*\prime}(2\pi)}{|\gamma^{*\prime}(2\pi)|} = e_1$. Invoking (4.3) and (4.4) we also find that γ^* is regular.

Next, we want to prove

$$\text{reach } (\boldsymbol{\Gamma}^*) \ge R + \delta, \tag{4.6}$$

where $\boldsymbol{\Gamma}^* = \boldsymbol{\Gamma}_{\gamma^*}$ is the trace of γ^* in $\mathbb{R}^n$. Utilizing Lemma 3.4, it suffices to show

$$d(\boldsymbol{\Gamma}_{n'}, x) \longrightarrow d(\boldsymbol{\Gamma}^*, x) \qquad \text{uniformly in } x \in C, \tag{4.7}$$

where

$$C \subset\subset \{x \in \mathbb{R}^3 \,:\, d(\boldsymbol{\Gamma}^*, x) < R + \delta\} \tag{4.8}$$

and $\boldsymbol{\Gamma}_n = \boldsymbol{\Gamma}_{\gamma_n}$. For $x \in C$, we define

$$f_{n'}(x) = d(\boldsymbol{\Gamma}_{n'}, x) \quad \text{ and } \quad f(x) = d(\boldsymbol{\Gamma}, x).$$

Since $C \subset \text{Unp } (\boldsymbol{\Gamma}^*)$, there exists exactly one $s \in [0, 2\pi]$ such that $d(\boldsymbol{\Gamma}^*, x) = |\gamma^*(s) - x|$. We obtain

$$\begin{aligned} |f_{n'}(x) - f(x)| &\le \big| |\gamma_{n'}(s) - x| - |\gamma^*(s) - x| \big| \\ &\le |\gamma_{n'}(s) - \gamma^*(s)|, \end{aligned}$$

and, invoking (4.5), we have

$$f_{n'}(x) \longrightarrow f(x) \quad \text{for } x \in C. \tag{4.9}$$

Moreover, since $\{f_{n'}\}$ is equicontinuous (cf. Lemma 3.3(1)), we can use the Arcela–Ascoli theorem to conclude that there exists a subsequence satisfying

$$f_{n''} \longrightarrow f \text{ uniformly in } C.$$

Since the limit does not depend on the subsequence, the whole sequence $\{f_{n'}\}$ converges to f.

Thus we have proved (4.7) and can apply Lemma 3.4 to get reach $(\boldsymbol{\Gamma}^*) \ge R + \delta$.

According to Lemma 3.2, all the domains $\Omega(\gamma)$ with reach $(\boldsymbol{\Gamma}) \ge R + \delta$ are of class $C^{1,1}$; in particular, they satisfy the uniform cone condition (cf., e.g., [30]). Hence we can conclude the following from Chenais [6]:

(1) All domains $\Omega \in \mathcal{U}_{ad}$ have the uniform extension property; i.e., for every $f \in H^m(\Omega)$ there exists an extension $\tilde{f} \in H^m(D)$ such that

$$\|\tilde{f}\|_{H^m(D)} \le K \|f\|_{H^m(\Omega)}, \tag{4.10}$$

where the constant K depends on M in our case.

(2) There exists a subsequence $\{\Omega_{n'}\}$ such that the corresponding characteristic functions satisfy

$$\chi_{\Omega_{n'}} \longrightarrow \chi_{\Omega^*} \quad \text{strongly in } L^p(D),\ p \in [1,\infty), \tag{4.11}$$

where χ_Ω is the characteristic function of Ω.

Note that (4.11) also implies $\overline{\Omega}(\gamma^*) \subset (D \setminus \overline{B_\delta}(\Sigma))$, which in turn implies $\gamma^* \in U_{ad}$ and $\Omega^* \in \mathcal{U}_{ad}$.

To finish the proof, we have to pass to the limit in the state equations. This will be done in the following lemmas using (4.10), (4.11). As a by-product we will obtain the strong convergence in $L^2(\Sigma)$ for $z_n(.,T)$; thus we can also pass to the limit in J, whence it follows that Ω^* is a solution to (CP). ∎

We begin with the equation for the scalar potential (2.11a). Denoting

$$\widetilde{\nabla\phi_{n'}}(x) = \begin{cases} \nabla\phi_{n'}(x), & x \in \Omega_n, \\ 0, & x \in D \setminus \Omega_n, \end{cases}$$

we have

$$\sigma_0 \int_D \chi_n \widetilde{\nabla\phi_{n'}} \cdot \nabla u \, dx + \int_\Gamma j_g u \, dx = 0 \qquad \text{for all } u \in H^1(D)/\mathbb{R} \tag{4.12}$$

and obtain the following lemma.

LEMMA 4.2. *There exists a subsequence satisfying*

$$\widetilde{\nabla\phi_{n'}} \longrightarrow \widetilde{\nabla\phi} \qquad \textit{strongly in } H^1(0,T;\mathbf{L}^2(D)). \tag{4.13}$$

Proof. Since $\{\widetilde{\nabla\phi_{n'}}\}$ is bounded in $L^2(0,T;\mathbf{L}^2(D))$, (4.13) holds weakly in $L^2(0,T;\mathbf{L}^2(D))$. Moreover, taking $\nabla u = \widetilde{\nabla\phi_{n'}}$ in (4.12) we have

$$\int_D |\widetilde{\nabla\phi_{n'}}|^2 \, dx = -\frac{1}{\sigma_0} \int_\Gamma j_g \phi_n \, dx \longrightarrow -\frac{1}{\sigma_0} \int_\Gamma j_g \phi \, dx = \int_D |\widetilde{\nabla\phi}|^2 \, dx$$

and, thus, strong convergence in $L^2(0,T;\mathbf{L}^2(D))$. Differentiating (4.12) formally with respect to t and reasoning as above completes the proof. ∎

Now, we consider the equation for the magnetic vector potential (2.11c). Note that the permeability μ is independent of n (cf. (H4)).

Defining $G_{n'} = \Omega_{n'} \cup \Sigma$, we rewrite (2.11c) as

$$\sigma_0 \int_{G_{n'}} A_{n',t} \cdot v \, dx + \int_D \frac{1}{\mu} \operatorname{curl} A_{n'} \cdot \operatorname{curl} v \, dx + \int_D \frac{1}{\mu} \operatorname{div} A_{n'} \operatorname{div} v \, dx + \sigma_0 \int_D \widetilde{\nabla\phi_{n'}} \cdot v \, dx = 0.$$

Proceeding as in the proof of Lemma 2.4, we can obtain a priori estimates similar to (2.13), where the bounds are independent of n'. In addition, a close inspection of the proof of Lemma 2.4 shows that we have the additional estimate

$$\|A_t^{n'}\|_{L^\infty(0,T;\mathbf{H}^1(\Sigma)) \cap H^1(0,T;L^2(\Sigma))} \le c_1$$

with a constant c_1 independent of n. Since the embedding $\mathbf{H}^1(\Sigma) \subset \mathbf{L}^p(\Sigma)$ is compact for $p < 6$, we can apply [27, Corollary 4] to conclude that the embedding $L^\infty(0,T;\mathbf{H}^1(\Sigma)) \cap H^1(0,T;L^2(\Sigma)) \subset C(0,T;\mathbf{L}^p(\Sigma))$ is compact for $p < 6$.

Thus, we obtain the following lemma.

LEMMA 4.3. *There exists a subsequence* $\{A^{n'}\}$ *satisfying*

$$\begin{aligned} A_{n'} &\longrightarrow A \ \textit{weakly-star in}\ L^\infty(0,T;\mathbf{X}),\\ \chi_{G_{n'}} A_{n',t} &\longrightarrow \chi_G A_t \ \ \textit{weakly in}\ L^2(0,T;L^2(D)),\\ A_{n',t_{|\Sigma}} &\longrightarrow A_{t_{|\Sigma}} \ \ \textit{strongly in}\ C(0,T;L^4(\Sigma)). \end{aligned}$$

The equations for temperature and phase transition (2.11d)–(2.11h) depend only implicitly on the shape of Ω_n, namely through A_n. From Lemma 2.8 we obtain

$$\|z_{n'}\|_{W^{1,\infty}(0,T;L^\infty(\Sigma))} + \|\theta_{n'}\|_{W_3^{2,1}(Q)} \le c_2,$$

with a constant c_2 independent of n'. In view of the compact embedding $W_3^{2,1}(Q) \subset L^p(0,T;W^{1,p}(\Sigma))$ for $p < 15/2$ (cf. Lemma 2.7), we obtain the following lemma.

LEMMA 4.4. *There exist subsequences* $\{\theta_{n'}\}$, $\{z_{n'}\}$ *satisfying*

$$\begin{aligned} \theta_{n'} &\longrightarrow \theta \qquad \textit{weakly in}\ W_3^{2,1}(Q),\\ &\qquad\quad \textit{strongly in}\ L^p(0,T;W^{1,p}(\Sigma))\ \textit{for}\ p < 15/2,\\ z_{n'} &\longrightarrow z \qquad \textit{weakly* in}\ W^{1,\infty}(0,T;L^\infty(\Sigma))\\ &\qquad\quad \textit{strongly in}\ W^{1,p}(0,T;L^p(\Sigma))\ \textit{for all}\ p \in [1,\infty). \end{aligned}$$

Utilizing Lebesgue's convergence theorem, we can pass to the limit in the state equations (2.11a)–(2.11h) and in the cost functional (3.1), which concludes the proof of Theorem 4.1.

5. Necessary optimality conditions.

5.1. Shape sensitivity analysis. To investigate the sensitivity of solutions to the state system (2.11a)–(2.11h) with respect to perturbations of the shape of the inductor Ω, we use the standard method (cf. [28, sect. 2.9]). To this end we forget for a moment that Ω has been generated from a curve γ.

We introduce a vector-field V satisfying

$$V \in C(-\tau_1,\tau_1;C_0^2(D,\mathbb{R}^3)), \qquad \operatorname{supp} V \subset (B_{\delta_1}(\Omega) \setminus B_{\delta_2}(\Gamma)), \tag{5.1}$$

with positive constants τ_1 and $\delta_{1,2}$.

Hence the velocity field is chosen in such a way that the inductor can be perturbed, except for a small region around the interface Γ, where current is supplied and in reality the inductor is fixed to the hardening machine. Moreover, we tacitly assume that δ_1 has been chosen small enough to assure $\bar{\Sigma} \cap \operatorname{supp} V = \emptyset$.

Now we construct a family of mappings

$$\mathcal{T}_\tau(V) : \mathbb{R}^3 \ni X \longrightarrow x_\tau \in \mathbb{R}^3,$$

where x_τ satisfies the initial value problem

$$\begin{aligned} \frac{dx_\tau}{d\tau} &= V(\tau, x_\tau),\\ x_0 &= X. \end{aligned}$$

Then we define a family of perturbations of a given initial configuration Ω by

$$\Omega_\tau = \mathcal{T}_\tau(V)(\Omega).$$

All equations defined in Ω_τ can be transported to the fixed domain Ω, using the transformation $T_\tau^{-1} : \Omega_\tau \to \Omega$. Note that, by construction, we have $\Omega_0 = \Omega$ and $\overline{\Omega_\tau} \cap \bar{\Sigma} = \emptyset$ for all $\tau \in (-\tau_1, \tau_1)$ if τ_1 has been chosen small enough. Moreover, the interface Γ, where the source current is supplied, remains invariant under the perturbations of Ω, and we have $\mathcal{T}_\tau(V)(D) = D$.

Remark 5.1. In what follows we indicate functions on Ω_τ with subscript τ and functions transported to the fixed domain Ω with superscript τ, i.e., $f^\tau = f_\tau \circ T_\tau$.

DEFINITION 5.2. *All the state variables depend on the shape of Ω_τ, either explicitly as A^τ and ϕ^τ or implicitly as θ^τ and z^τ. For all these quantities, we call*

$$\dot{f} = \lim_{\tau \to 0} \frac{f^\tau - f}{\tau}$$

the strong material derivative of f, whenever the limit exists in the strong sense.

In section 6 (Theorem 6.8) we will prove that the strong material derivatives exist. As a corollary to Theorem 6.8 we obtain the following estimate.

COROLLARY 5.3. *There exists a constant $C > 0$ such that*

$$\begin{aligned} &\|\nabla\dot{\phi}\|_{H^1(0,T;\mathbf{L}^2(\Omega))} + \|\dot{A}\|_{L^\infty(0,T;X)} + \|\dot{A}_t\|_{L^{10/3}(0,T;L^{10/3}(G))} \\ &\qquad + \|\dot{\theta}\|_{W^{2,1}_{5/3}(Q)} + \|\dot{z}\|_{W^{1,5}(0,T;L^5(\Sigma))} \le C\|V(0)\|_{C^1(D)}. \end{aligned} \tag{5.2}$$

Remark 5.4. We would like to emphasize that the same result on the shape differentiability can be derived using the perturbation of identity technique. In that case one has to consider

$$\Omega_\zeta = T_\zeta(\Omega), \quad \text{where } T_\zeta(x) = (I + \zeta\Theta)(x)$$

with the field Θ and the shape parameter ζ, which replaces the parameter τ.

5.2. The structure theorem. From Corollary 5.3 we can infer that the functional $J(\Omega)$ defined in (3.1) is differentiable, in the sense that there exists the limit

$$dJ(\Omega; V) = \lim_{\tau \to 0} \frac{1}{\tau}(J(\Omega_\tau) - J(\Omega)), \tag{5.3}$$

where $\Omega_\tau = T_\tau(V)(\Omega)$. Moreover, we can conclude the following corollary.

COROLLARY 5.5. *The mapping*

$$V \mapsto dJ(\Omega; V) : C_0^1(D; \mathbb{R}^3) \to \mathbb{R}$$

is linear and continuous.

Thus, we can apply the structure theorem (cf. [28]) and obtain the following lemma.

LEMMA 5.6. *Let $\partial\Omega$ be of class C^2; then there exists a distribution $g_{\partial\Omega}$ with support in $\partial\Omega$, the shape gradient, such that $g_{\partial\Omega} \in \mathcal{D}_1'(\partial\Omega)$, and for all $V \in C_0^1(D; \mathbb{R}^3)$ there holds*

$$dJ(\Omega; V) = \langle g_{\partial\Omega}, V \cdot \nu \rangle_{\mathcal{D}_1'(\partial\Omega) \times \mathcal{D}_1(\partial\Omega)},$$

where ν is the outer unit normal vector on the boundary of the tube Ω.

Now we relate the perturbations of $\partial\Omega$ by means of $T_\tau(V)$ with perturbations of the curve γ in the form $\gamma_\varepsilon = \gamma + \varepsilon\omega$, where $\omega : [0, 2\pi] \to \mathbb{R}^3$ is a given curve. To

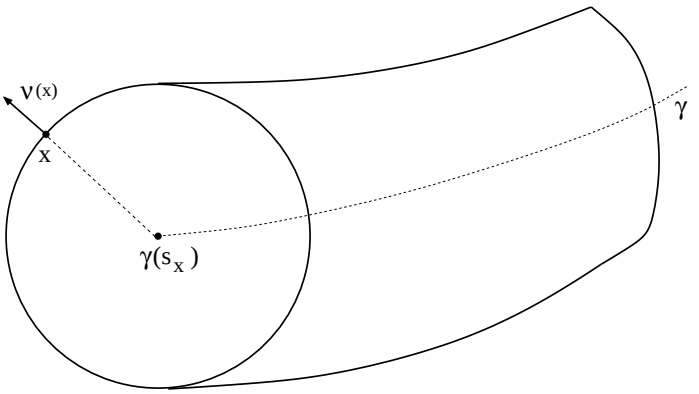

FIG. 5.1. *Computing a normal to the tube.*

ensure that the interface Γ, where the source current is supplied, remains unperturbed, we assume

(H10) $\omega(s) = \omega(2\pi - s) = 0 \quad$ for all $s \in [0, \delta]$ for some $\delta > 0$.

Note that although ω is not a regular curve, γ_ε is regular for ϵ small enough and for sufficiently smooth ω.

Now let $x(\varepsilon) \in \partial\Omega(\gamma_\varepsilon)$ be a point on the surface of the perturbed tube. We define a function $g(\varepsilon)$ by

$$\begin{aligned} g(\varepsilon) &= d\big(\boldsymbol{\Gamma}_{\gamma_\varepsilon}, x(\varepsilon)\big)^2 = \inf_{s\in[0,2\pi]} |x(\varepsilon) - \gamma_\varepsilon(s)|^2 \\ &= |x(\varepsilon) - \gamma(s_{x(\varepsilon)}) - \varepsilon\omega(s_{x(\varepsilon)})|^2. \end{aligned}$$

With the notation of Lemma 3.2, $\gamma(s_{x(\varepsilon)}) = \xi_{\Gamma_{\gamma_\varepsilon}}(x(\varepsilon))$ is the projection of $x(\varepsilon) \in \partial\Omega(\gamma_\varepsilon)$ on the curve γ_ε. Differentiating g at $\varepsilon = 0$ (cf., e.g., [9, Theorem 9.2.1]) and assuming tacitly that $x(\varepsilon)$ is differentiable at $\varepsilon = 0$, we obtain

$$\begin{aligned} 0 = g'(0) &= 2\Big(x(0) - \gamma(s_{x(0)})\Big) \cdot \Big(\dot{x}(0) - \omega(s_{x(0)})\Big) \\ &= 2R\nu(x) \cdot \Big(\dot{x} - \omega(s_x)\Big), \end{aligned}$$

where $\nu(x)$ is the outer unit normal vector to $\partial\Omega(\gamma)$ and $\gamma(s_x) = \xi_{\Gamma_\gamma}(x)$ is the projection of $x \in \partial\Omega(\gamma)$ on the curve γ (cf. Figure 5.1). Hence we obtain for the normal component of the speed vector-field

$$V_\nu(\omega)(x) = \frac{1}{R}\Big(x - \gamma(s_x)\Big) \cdot \omega(s_x). \tag{5.4}$$

Now, let $\eta \in C_0^\infty(B_\delta(\partial\Omega))$ such that $\eta(x) = 1$ if $x \in \partial\Omega$. Then we define the autonomous speed vector-field by

$$V(\omega)(x) = \frac{1}{R^2}\eta(x)\Big((x - \gamma(s_x)) \cdot \omega(s_x)\Big)\Big(x - \gamma(s_x)\Big). \tag{5.5}$$

Obviously, the normal component of the field V on $\partial\Omega$ coincides with $V_\nu(\omega)$ for $x \in \partial\Omega$. However, to obtain C^1 regularity for V, we have to increase the regularity of γ and ω. In addition to (3.2), we assume

(H11) $\gamma, \omega \in C^2[0,2\pi]$ and $\gamma''(0) = \gamma''(2\pi)$.

Since a curve has no interior points, the distance function with respect to a curve coincides with the signed distance function introduced by Delfour and Zolésio. According to [9, Theorem 5.4.3] and (H11), the distance function $d(\boldsymbol{\Gamma}_\gamma, .)$ is of class C^2 in an $(R+\delta)$-neighborhood of γ. Thus $\partial\Omega$ is of class C^2 and from Lemma 3.3(2) we can infer that the projection $\xi_{\boldsymbol{\Gamma}_\gamma} = \gamma(s_x)$, which shows up in (5.5), is a C^1 function.

Altogether we can conclude that the speed vector-field defined in (5.5) is admissible for Lemma 5.6.

Now let γ^* be an optimal solution to (CP) and $\gamma_\varepsilon = \gamma^* + \varepsilon\omega$ be an admissible perturbation of the curve γ^*. Then

$$J(\Omega(\gamma_\varepsilon)) \geq J(\Omega(\gamma^*)), \tag{5.6}$$

and in view of Corollaries 5.3 and 5.5 we have

$$J(\Omega(\gamma_\varepsilon)) = J(\Omega(\gamma^*)) + \varepsilon\, dJ(\Omega(\gamma^*); V(\omega)) + o(\varepsilon).$$

Hence from (5.6) it follows that

$$dJ(\Omega(\gamma^*); V(\omega)) \geq 0.$$

To summarize, we have the following necessary optimality condition.

THEOREM 5.7. *Assume* (H1)–(H11)*, and let the optimal curve* γ^* *satisfy* $\gamma^* \in \widetilde{U}_{ad} = U_{ad} \cap [C^2(0,2\pi)]^3$*; then there exists a shape gradient* $g_{\partial\Omega^*}$ *with support in* $\partial\Omega^*$*, such that*

$$\langle g_{\partial\Omega^*}, V_\nu(\omega)\rangle \mathcal{D}_1'(\partial\Omega^*) \times \mathcal{D}_1(\partial\Omega^*) \;\geq\; 0$$

for all $\omega \in T_{\widetilde{U}_{ad}}(\gamma^*)$*, where* $V_\nu(\omega)$ *is given by* (5.4) *and* $T_{\widetilde{U}_{ad}}(\gamma^*)$ *denotes the tangent set to* $\widetilde{U}_{ad}$ *at* γ^**.*

Remark 5.8. For numerical purposes it is possible to identify the shape gradient $g_{\partial\Omega^*}$ by using the Lagrange formalism [5]. However, this approach usually requires an additional regularity analysis of the state system to assure the differentiability of the corresponding Lagrangian and therefore is omitted in this paper.

Remark 5.9. It is not difficult to show, using similar arguments as in section 6, that the mapping $\gamma \mapsto dJ(\Omega(\gamma); V)$ is continuous with respect to weak-star convergence in $W^{2,\infty}$ on a sufficiently small open neighborhood of the set $U_{ad} \subset W^{2,\infty}(0,2\pi)$. Such a continuity implies the Frechet differentiability of the mapping $\gamma \mapsto J(\Omega(\gamma))$. Let us point out that the way we identify the gradient of the mapping $\gamma \mapsto J(\Omega(\gamma))$—taking into account the structure theorem—is important for numerical applications. By direct differentiation with respect to γ an equivalent form of the derivative can be obtained; however, the tangential component of the resulting vector-field on $\partial\Omega$ can be possibly taken into account, which may imply additional error when using the discretization of the continuous gradient for numerical solution of the optimization problem.

6. Strong material derivatives. In this section we provide all the estimates that finally lead to the proof of Corollary 5.3.

6.1. Transformation to the fixed domain. The following lemma describes the transport of div and grad to the fixed domain. The proof can be found in [28, sect. 2]. Note that the Jacobian of T_τ is denoted by $\mathcal{D}T_\tau$. Moreover, for any matrix B, the transposed one is denoted by ${}^*B$.

LEMMA 6.1. *Let* $B_1(\tau) = {}^*\mathcal{D}T_\tau^{-1}$*; then we have*
(1)

$$(\text{grad } \varphi) \circ T_\tau = \Big(B_1(\tau)\nabla\Big)\Big(\varphi \circ T_\tau\Big) \quad \textit{for all } \varphi \in H^1(D),$$

(2)

$$(\text{div } \psi) \circ T_\tau = \Big(B_1(\tau)\nabla\Big) \cdot \Big(\psi \circ T_\tau\Big) \quad \textit{for all } \psi \in \mathbf{H}^1(D).$$

(3)

$$(\text{curl } \psi) \circ T_\tau = \Big(B_1(\tau)\nabla\Big) \times \Big(\psi \circ T_\tau\Big) \quad \textit{for all } \psi \in \mathbf{H}^1(D).$$

Using Lemma 6.1, we obtain for (2.11a), with $\varphi \in H^1(\Omega_\tau)/\mathbb{R}$,

$$\begin{aligned} -\int_\Gamma j_g \varphi \, dx &= \sigma_0 \int_{\Omega_\tau} \nabla\phi_\tau \cdot \nabla\varphi \, dx \\ &= \sigma_0 \int_\Omega \det(\mathcal{D}T_\tau)\Big(\nabla\phi_\tau \cdot \nabla\varphi\Big) \circ T_\tau \, dx \\ &= \sigma_0 \int_\Omega B_2(\tau)\nabla\phi^\tau \cdot \nabla(\varphi \circ T_\tau) \, dx \end{aligned}$$

with

$$\beta(\tau) = \det(\mathcal{D}T_\tau) \text{ and } B_2(\tau) = \beta(\tau)\, {}^*B_1(\tau)B_1(\tau).$$

Hence (2.11a) is replaced with

$$-\int_\Gamma j_g \varphi \, dx = \alpha_0(\tau, \phi^\tau, \varphi) \qquad \text{for all } \varphi \in H^1(\Omega)/\mathbb{R}, \tag{6.1}$$

and

$$\alpha_0(\tau, \phi^\tau, \varphi) := \sigma_0 \int_\Omega B_2(\tau)\nabla\phi^\tau \cdot \nabla\varphi \, dx.$$

Now we turn to the Maxwell equation (2.11c). For the first term, we obtain

$$\begin{aligned} \sigma_0 \int_{G_\tau} \frac{\partial A_\tau}{\partial t} v \, dx \; &= \; \sigma_0 \int_G \beta(\tau) A_t^\tau \cdot (v \circ T_\tau) \, dx \\ &=: \alpha_1(\tau, A_t^\tau, v \circ T_\tau). \end{aligned}$$

For the next term, we utilize Lemma 6.1(2) and (3) to obtain

$$\begin{aligned} &\int_D \frac{1}{\mu} \text{ curl } A_\tau \cdot \text{ curl } v \, dx + \int_D \frac{1}{\mu} \text{ div } A_\tau \text{ div } v \, dx \\ &= \int_D \frac{\beta(\tau)}{\mu}\Big(\text{ curl } A_\tau \cdot \text{ curl } v\Big) \circ T_\tau \, dx + \int_D \frac{\beta(\tau)}{\mu}\Big(\text{ div } A_\tau \text{ div } v\Big) \circ T_\tau \, dx \\ &= \int_D \frac{\beta(\tau)}{\mu} \{(B_1(\tau)\nabla) \times A^\tau\} \cdot \{(B_1(\tau)\nabla) \times (v \circ T_\tau)\} \, dx \\ &\qquad + \int_D \frac{\beta(\tau)}{\mu} \{(B_1(\tau)\nabla) \cdot A^\tau\} \{(B_1(\tau)\nabla) \cdot (v \circ T_\tau)\} \, dx \\ &=: \alpha_2(\tau, A^\tau, v \circ T_\tau). \end{aligned}$$

For the last term in (2.11c), we have

$$\begin{aligned}\sigma_0 \int_{\Omega_\tau} \nabla\phi_\tau \cdot v \, dx &= \sigma_0 \int_\Omega \beta(\tau)\Big(\nabla\phi_\tau \cdot v\Big) \circ T_\tau \, dx \\ &= \sigma_0 \int_\Omega B_3(\tau)\nabla\phi^\tau \cdot (v \circ T_\tau) \, dx \\ &=: F(\tau, \phi^\tau, v \circ T_\tau),\end{aligned}$$

with $B_3(\tau) = \beta(\tau)B_1(\tau)$.

Altogether, we have replaced (2.11c) with

$$\alpha_1(\tau, A_t^\tau, v) + \alpha_2(\tau, A^\tau, v) + F(\tau, \phi^\tau, v) = 0 \qquad \text{for all } v \in X, \tag{6.2a}$$

$$A_0^\tau = A_0 \circ T_\tau. \tag{6.2b}$$

Remark 6.2. Another possibility to transport the divergence operator to the fixed domain is to use the formula (cf. [28])

$$(\operatorname{div} \psi) \circ T_\tau = \frac{1}{\beta(\tau)} \operatorname{div} \Big(\beta(\tau)\mathcal{D}T_\tau^{-1}(\psi \circ T_\tau)\Big) \quad \text{for all } \psi \in \mathbf{H}^1(D).$$

It shows that functions that are divergence free on Ω_τ generally lose this property when transported to the fixed domain. Hence the application of the Coulomb gauge $\operatorname{div} A = 0$ (cf. Remark 2.1) can be managed by the introduction of an auxiliary unknown function

$$\eta^\tau = \beta(\tau)\mathcal{D}T_\tau^{-1}A^\tau,$$

which in view of the above formula would give

$$\operatorname{div} A_\tau = 0 \quad \text{in } \Omega_\tau \quad \Longleftrightarrow \quad \operatorname{div} \eta^\tau = 0 \quad \text{in } \Omega.$$

However, we avoid such a transformation for the sake of simplicity.

6.2. Stability estimates.

LEMMA 6.3. *B_1, B_2, B_3, β are differentiable. For $|\tau| \le \tau_1$ and τ_1 small enough, we have*

$$\begin{aligned}\beta(\tau) &= 1 + \tau\beta'(0) + o(\tau), \\ B_i(\tau) &= I + \tau B_i'(0) + o(\tau), \qquad i = 1, \dots, 3.\end{aligned}$$

The derivatives at $\tau = 0$ are given by

$$\begin{aligned}\beta'(0) &= \operatorname{div} V(0), \\ B_1'(0) &= -{}^*\mathcal{D}V(0), \\ B_2'(0) &= \operatorname{div} V(0)I - 2\varepsilon(V(0)), \\ B_3'(0) &= \operatorname{div} V(0)I - {}^*\mathcal{D}V(0).\end{aligned}$$

Here, $\varepsilon(V(0))$ is the symmetrized part of $\mathcal{D}V(0)$, i.e., $\varepsilon(V(0)) = \frac{1}{2}(\mathcal{D}V(0) + {}^*\mathcal{D}V(0))$.

For the proof, we refer again to [28, sect. 2.13].

A particular consequence of Lemma 6.3 is the following corollary.

COROLLARY 6.4. *Let $|\tau| \le \tau_1$ and τ_1 be small enough. Then there exist real-valued functions g_i satisfying $g_i(\tau) = o(\tau)$, $i = 0, \dots, 3$, and bilinear forms $\tilde\alpha_i(\tau, \,.\,, \,.\,)$, $i = 0, 1, 2$, and $\tilde F(\tau, \,.\,, \,.\,)$ such that the following are valid:*

(1) *For all* $\varphi_1, \varphi_2 \in H^1(\Omega)/\mathbb{R}$, *we have*

$$\begin{aligned}
\alpha_0(\tau, \varphi_1, \varphi_2) &= \alpha_0(0, \varphi_1, \varphi_2) + \tau\alpha_{0,\tau}(0, \varphi_1, \varphi_2) + \tilde{\alpha}_0(\tau, \varphi_1, \varphi_2),\\
\alpha_{0,\tau}(0, \varphi_1, \varphi_2) &= \sigma_0 \int_\Omega B_2'(0)\nabla\varphi_1\nabla\varphi_2\, dx,\\
\left|\tilde{\alpha}_0(\tau, \varphi_1, \varphi_2)\right| &\le g_0(\tau)\|\nabla\varphi_1\|_{\mathbf{L}^2(\Omega)}\|\nabla\varphi_2\|_{\mathbf{L}^2(\Omega)}.
\end{aligned}$$

(2) *For all* $v_1, v_2 \in \mathbf{L}^2(D)$, *we have*

$$\begin{aligned}
\alpha_1(\tau, v_1, v_2) &= \alpha_1(0, v_1, v_2) + \tau\alpha_{1,\tau}(0, v_1, v_2) + \tilde{\alpha}_1(\tau, v_1, v_2),\\
\alpha_{1,\tau}(0, v_1, v_2) &= \sigma_0 \int_G \beta'(0) v_1 \cdot v_2\, dx,\\
\left|\tilde{\alpha}_1(\tau, v_1, v_2)\right| &\le g_1(\tau)\|v_1\|_{\mathbf{L}^2(G)}\|v_2\|_{\mathbf{L}^2(G)}.
\end{aligned}$$

(3) *For all* $v_1, v_2 \in \mathbf{X}$, *we have*

$$\begin{aligned}
\alpha_2(\tau, v_1, v_2) &= \alpha_2(0, v_1, v_2) + \tau\alpha_{2,\tau}(0, v_1, v_2) + \tilde{\alpha}_2(\tau, v_1, v_2),\\
\alpha_{2,\tau}(0, v_1, v_2) &= \int_D \frac{\beta'(0)}{\mu}\Big(\operatorname{curl} v_1 \cdot \operatorname{curl} v_2 + \operatorname{div} v_1 \operatorname{div} v_2\Big)\, dx\\
&\quad + \int_D \frac{1}{\mu}[(B_1'(0)\nabla) \times v_1] \cdot \operatorname{curl} v_2\, dx\\
&\quad + \int_D \frac{1}{\mu}\operatorname{curl} v_1 \cdot [(B_1'(0)\nabla) \times v_2]\, dx\\
&\quad + \int_D \frac{1}{\mu}[(B_1'(0)\nabla) \cdot v_1] \operatorname{div} v_2\, dx\\
&\quad + \int_D \frac{1}{\mu} \operatorname{div} v_1 \cdot [(B_1'(0)\nabla) \cdot v_2]\, dx,\\
|\tilde{\alpha}_2(\tau, v_1, v_2)| &\le g_2(\tau)\|v_1\|_{\mathbf{X}}\|v_2\|_{\mathbf{X}}.
\end{aligned}$$

(4) *For all* $\varphi \in H^1(\Omega)/\mathbb{R}$ *and* $v \in \mathbf{X}$, *we have*

$$\begin{aligned}
F(\tau, \varphi, v) &= F(0, \varphi, v) + \tau F_{,\tau}(0, \varphi, v) + \tilde{F}(\tau, \varphi, v),\\
F_{,\tau}(0, \varphi, v) &= \sigma_0 \int_\Omega B_3'(0)\nabla\varphi \cdot v\, dx,\\
\left|\tilde{F}(\tau, \varphi, v)\right| &\le g_4(\tau)\|\nabla\varphi\|_{\mathbf{L}^2(\Omega)}\|v\|_{\mathbf{X}}.
\end{aligned}$$

Using Corollary 6.4, we can prove the following stability result.

LEMMA 6.5. *Assume* (H1)–(H9) *and* (5.1)*; then there exists a constant* $C > 0$ *such that*

(1) $\|\nabla\phi^\tau - \nabla\phi\|_{H^1(0,T;\mathbf{L}^2(\Omega))} \le C \cdot |\tau|$,
(2) $\|A^\tau - A\|_{L^2(0,T;\mathbf{X})} + \|A_t^\tau - A_t\|_{L^{10/3}(0,T;\mathbf{L}^{10/3}(G))} \le C \cdot |\tau|$,
(3) $\|\theta^\tau - \theta\|_{W^{2,1}_{5/3}(Q)} \le C \cdot |\tau|$,
(4) $\|z^\tau - z\|_{W^{1,5}(0,T;L^5(\Sigma))} \le C \cdot |\tau|$.

Remark 6.6. (z^τ, θ^τ) is the solution to (2.11d)–(2.11h), where A_t in (2.11f) has been replaced with A_t^τ. In view of (5.1), we have $A_t^\tau = A_{\tau,t}$ on Σ.

For the proof, we need the following interpolation result.

LEMMA 6.7. *Let $u \in L^\infty(0,T;L^2(\Sigma)) \cap L^2(0,T;H^1(\Sigma))$; then there holds*

$$\int_0^T \|u(t)\|^{10/3}_{L^{10/3}(\Sigma)}\,dt \le \Big(\int_0^T \|u(t)\|^2_{L^6(\Sigma)}\,dt\Big)\,\|u\|^{4/3}_{L^\infty(0,T;L^2(\Sigma))}.$$

Proof. Owing to Riesz's convexity theorem (cf. [31, (A113)]), we have

$$\|u\|_{L^r(\Sigma)} \le \|u\|^{1-\Theta}_{L^{q_1}(\Sigma)}\|u\|^{\Theta}_{L^{q_2}(\Sigma)}$$

for all $u \in L^{q_1}(\Sigma) \cap L^{q_2}(\Sigma)$ with $1 \le q_1, q_2 < \infty$, $0 < \Theta < 1$, and $\frac{1}{r} = \frac{1-\Theta}{q_1} + \frac{\Theta}{q_2}$. Invoking the continuous embedding $H^1(\Sigma) \subset L^6(\Sigma)$, the assertion follows by defining $q_1 = 6$, $q_2 = 2$, $\Theta = \frac{2}{5}$, and $r = \frac{10}{3}$. ∎

Proof of Lemma 6.5. According to Lemma 6.3, we can write

$$\beta(\tau) = 1 + \tau\beta'(\xi_0), \quad B_i(\tau) = I + \tau B_i'(\xi_i), \quad i = 1,2,3, \tag{6.3}$$

for τ small enough and $\xi_i \in [0,\tau]$, $i = 0,\dots,3$. Note that $\beta(\tau) \ge c_{\tau_1} > 0$ for $|\tau| \le \tau_1$, if the latter has been chosen small enough, and that the B_i's are positive definite for $|\tau| \le \tau_1$.

Using (H2) and (H5), this immediately gives

$$\|\nabla\phi^\tau\|_{H^1(0,T;\mathbf{L}^2(\Omega))} \le c_1, \tag{6.4}$$

independent of τ. Moreover, we can use (6.1) and (6.3) to write

$$\begin{aligned} 0 &= \alpha_0(\tau,\phi^\tau,\varphi) - \alpha_0(0,\phi,\varphi) \\ &= \alpha_0(0,\phi^\tau-\phi,\varphi) + \tau\int_\Omega B_2'(\xi)\nabla\phi^\tau\cdot\nabla\varphi\,dx. \end{aligned}$$

Inserting $\varphi = \phi^\tau - \phi$ and using Young's inequality, we obtain

$$\|\nabla\phi^\tau - \nabla\phi\|_{L^2(0,T;\mathbf{L}^2(\Omega))} \le c_2|\tau|.$$

Since the same estimate holds true for $\phi_t^\tau - \phi_t$, assertion (1) is proved.

We insert $v = A_t^\tau$ into (6.2a), use (6.3), and integrate in time to obtain for the first term

$$\sigma_0\int_0^t\int_\Sigma \beta(\tau)A_s^\tau\cdot A_s^\tau\,dx\,ds \ge c_{\tau_1}\sigma_0\int_0^t\int_\Sigma |A_s^\tau|^2\,dx\,ds.$$

The second term gives

$$\begin{aligned} \int_0^t \alpha_2(\tau,A^\tau,A_s^\tau)\,ds &= \int_0^t\int_D \frac{\beta(\tau)}{\mu}\,\{(B_1(\tau)\cdot\nabla)\times A^\tau\}\cdot\{(B_1(\tau)\cdot\nabla)\times A_s^\tau\}\,dx\,ds \\ &\quad + \int_0^t\int_D \frac{\beta(\tau)}{\mu}\,\{(B_1(\tau)\cdot\nabla)\cdot A^\tau\}\,\{(B_1(\tau)\cdot\nabla)\cdot A_s^\tau\}\,dx\,ds \\ &= \frac{1}{2}\int_0^t\int_D \frac{\beta(\tau)}{\mu}\frac{\partial}{\partial s}\big|\,(B_1(\tau)\cdot\nabla)\times A^\tau\big|^2\,dx\,ds \\ &\quad + \frac{1}{2}\int_0^t\int_D \frac{\beta(\tau)}{\mu}\frac{\partial}{\partial s}\big|\,(B_1(\tau)\cdot\nabla)\cdot A^\tau\big|^2\,dx\,ds \\ &\ge \frac{1}{2\mu_2}\int_D \big|\,\mathrm{curl}\;A^\tau(t)\big|^2dx + \frac{1}{2\mu_2}\int_D \big|\,\mathrm{div}\;A^\tau(t)\big|^2\,dx + \tau\widetilde{g}(A^\tau(t)) - c_3, \end{aligned}$$

with a function $\widetilde{g}$ satisfying $\widetilde{g}(A^\tau(t)) \le c_4 \|A^\tau(t)\|^2_{\mathbf{X}}$. For the last term in (6.2a), we apply Young's inequality and obtain

$$\int_0^t F(\tau, \phi^\tau, A^\tau_s)\, ds \le \frac{c_{\tau_1}}{2}\sigma_0 \int_0^t \int_\Omega |A^\tau_s|^2\, dx\, ds + c_5 \int_0^t \int_\Omega |\nabla \phi^\tau|^2\, dx\, ds.$$

Invoking (6.4) and choosing τ small enough, we finally obtain

$$\|A^\tau\|_{L^\infty(0,T;\mathbf{X})} + \|A^\tau_t\|_{L^2(0,T;L^2(G))} \le c_6. \tag{6.5}$$

Now we differentiate (6.2a) formally with respect to time and insert $v = A^\tau_{tt}$. Defining

$$A^\tau_{0,t} = y \circ T_\tau \tag{6.6}$$

(cf. (H6) and (6.2b)), analogously to the derivation of the previous estimate, we get

$$\|A^\tau_t\|_{L^\infty(0,T;\mathbf{X})} + \|A^\tau_{tt}\|_{L^2(0,T;L^2(G))} \le c_7. \tag{6.7}$$

Next, we take the difference of (6.2a) for A^τ and A and obtain

$$\begin{aligned} 0 &= \alpha_1(\tau, A^\tau_t, v) + \alpha_2(\tau, A^\tau, v) + F(\tau, \phi^\tau, v) - \alpha_1(0, A_t, v) - \alpha_2(0, A, v) - F(0, \phi, v) \\ &= \alpha_1(0, A^\tau_t - A_t, v) + \alpha_2(0, A^\tau - A, v) + F(0, \phi^\tau - \phi, v) \\ &\qquad + G_0(\tau, \phi^\tau, v) + G_1(\tau, A^\tau_t, v) + G_2(\tau, A^\tau, v), \end{aligned} \tag{6.8}$$

with $G_0(\tau, \phi^\tau, v) = F(\tau, \phi^\tau, v) - F(0, \phi^\tau, v)$, $G_1(\tau, A^\tau_t, v) = \alpha_1(\tau, A^\tau_t, v) - \alpha_1(0, A^\tau_t, v)$, and $G_2(\tau, A^\tau, v) = \alpha_2(\tau, A^\tau, v) - \alpha_2(0, A^\tau, v)$ satisfying (cf. (6.3))

$$\begin{aligned} |G_0(\tau, \varphi, v)| &\le c_8 |\tau|\, \|\nabla \varphi\|_{\mathbf{L}^2(\Omega)} \|v\|_{\mathbf{X}}, \\ |G_1(\tau, v_1, v_2)| &\le c_9 |\tau|\, \|v_1\|_{\mathbf{L}^2(G)} \|v_2\|_{\mathbf{L}^2(G)}, \\ |G_2(\tau, v_1, v_2)| &\le c_{10} |\tau|\, \|v_1\|_{\mathbf{X}} \|v_2\|_{\mathbf{X}}. \end{aligned}$$

Inserting $v = A^\tau - A$ into (6.8) and integrating in time leads to

$$\begin{aligned} &\frac{\sigma_0}{2} \int_G |A^\tau(t) - A(t)|^2\, dx + \int_0^t \int_D \frac{1}{\mu} |\operatorname{curl}\,(A^\tau - A)|^2\, dx\, dt \\ &\le \sigma_0 \int_0^t \int_D |\nabla(\phi^\tau - \phi) \cdot (A^\tau - A)|\, dx\, dt + \frac{\sigma_0}{2} \int_G |A^\tau_0 - A_0|^2\, dx \\ &\quad + |\tau| c_8 \int_0^t \|\nabla \phi^\tau\|_{\mathbf{L}^2(\Omega)} \|A^\tau - A\|_{\mathbf{X}} + |\tau| c_9 \int_0^t \|A^\tau_t\|_{\mathbf{L}^2(G)} \cdot \|A^\tau - A\|_{\mathbf{L}^2(G)} \\ &\quad + |\tau| c_{10} \int_0^t \|A^\tau\|_{\mathbf{X}} \cdot \|A^\tau - A\|_{\mathbf{X}}. \end{aligned}$$

Applying the inequalities of Young and Gronwall and using (6.2b), we obtain

$$\|A^\tau - A\|_{L^\infty(0,T;L^2(G))} + \|A^\tau - A\|_{L^2(0,T;\mathbf{X})} \le c_{11} |\tau|. \tag{6.9}$$

Moreover, using (6.8) once again as well as (6.9), we obtain

$$\int_0^t \alpha_1(0, A^\tau_s - A_s, v)\, ds \le c_{12} |\tau| \|v\|_{L^2(0,t;\mathbf{X})}. \tag{6.10}$$

As before, we now differentiate (6.8) formally with respect to time, insert $v = A_t^\tau - A_t$, and make the same computations as before, but use (6.6) instead of (6.2b). Thus we obtain

$$\|A_t^\tau - A_t\|_{L^\infty(0,T;L^2(G))} + \|A_t^\tau - A_t\|_{L^2(0,T;\mathbf{X})} \le c_{13}|\tau|$$

and, similar to (6.10),

$$\int_0^t \alpha_1(0, A_{ss}^\tau - A_{ss}, v)\, ds \le c_{14}|\tau|\|v\|_{L^2(0,t;\mathbf{X})}. \tag{6.11}$$

To conclude the proof of assertion (2), we apply Lemma 6.7 with $u = A_t^\tau - A_t$, i.e.,

$$\|A_t^\tau - A_t\|_{L^{10/3}(0,T;\mathbf{L}^{10/3}(\Sigma))} \le c_{15} \cdot |\tau|. \tag{6.12}$$

To prove assertion (3), we define $\bar\theta = \theta^\tau - \theta$ and $\bar z = z^\tau - z$ (cf. Remark 6.6). Then $\bar\theta$ solves

$$\rho c_p \bar\theta_t - k\Delta\bar\theta = -\rho L \bar z_t + \sigma_0(A_t^\tau - A_t)\cdot(A_t^\tau + A_t) \text{ in } Q$$

$$\frac{\partial\bar\theta}{\partial\nu} = 0 \text{ in } \Sigma\times(0,T), \quad \bar\theta(0) = 0 \text{ in } \Sigma.$$

In view of Lemma 2.6, we can apply Hölder's inequality, Lemma 2.5(3), and (6.12) to infer

$$\begin{aligned}\|\bar\theta\|^{5/3}_{W^{2,1}_{5/3}(Q_t)} &\le c_{16}\int_0^t\int_\Sigma |\bar z_s|^{5/3}\,dx\,ds \\ &\quad + c_{17}\Big(\int_0^t\int_\Sigma |A_s^\tau - A_s|^{10/3}\,dx\,ds\Big)^{1/2}\Big(\int_0^t\int_\Sigma |A_s^\tau + A_s|^{10/3}\,dx\,ds\Big)^{1/2} \\ &\le c_{18}\int_0^t \|\bar\theta\|^{5/3}_{W^{2,1}_{5/3}(Q_s)} + c_{19}|\tau|^{5/3}.\end{aligned}$$

Then assertion (3) follows from Gronwall's lemma whereas assertion (4) is a direct consequence of (3), Lemma 2.5(3), and the continuous embedding $W^{2,1}_{5/3}(Q) \subset L^5(Q)$ (cf. Lemma 2.7). □

6.3. Material derivatives. Our main result in this section is the following theorem.

THEOREM 6.8. *Assume* (H1)–(H9) *and* (5.1)*; then the following are valid:*

(1) *The strong material derivative* $\nabla\dot\phi$ *exists in* $H^1(0,T;\mathbf{L}^2(\Omega))$,
$\dot A$ *exists in* $L^\infty(0,T;X)$ *and* $W^{1,10/3}(0,T;L^{10/3}(G))$,
$\dot z$ *exists in* $W^{1,5/2}(0,T;L^{5/2}(\Sigma))$,
$\dot\theta$ *exists in* $W^{2,1}_{5/3}(Q)$.

(2) $(\dot\phi, \dot A, \dot z, \dot\theta)$ *satisfy the linearized state equations*

$$\alpha_0(0,\dot\phi,\varphi) + \alpha_{0,\tau}(0,\phi,\varphi) = 0 \quad \textit{for all } \varphi \in H^1(\Omega)/\mathbb{R}, \tag{6.13a}$$

$$\begin{aligned}\alpha_1(0,\dot A_t, v) + \alpha_2(0,\dot A, v) + F(0,\dot\phi, v) + F_{,\tau}(0,\phi,v)\\ + \alpha_{1,\tau}(0,A_t,v) + \alpha_{2,\tau}(0,A,v) = 0 \quad \textit{for all } v \in \mathbf{X},\end{aligned} \tag{6.13b}$$

$$\dot A_0 - \mathcal{D}A_0 V(0) = 0 \quad \textit{in } D, \tag{6.13c}$$

$$\dot z_t - \frac{\partial f}{\partial\theta}\dot\theta - \frac{\partial f}{\partial z}\dot z = 0 \quad \textit{in } Q, \tag{6.13d}$$

$$\dot z(0) = 0 \quad \textit{in } \Sigma, \tag{6.13e}$$

$$\rho c_p \dot\theta_t - k\Delta\dot\theta + \rho L\dot z_t - 2\sigma_0 A_t\cdot\dot A_t = 0 \quad \textit{in } Q, \tag{6.13f}$$

$$\frac{\partial\dot\theta}{\partial\nu} = 0 \quad \textit{in } \partial\Sigma\times(0,T), \tag{6.13g}$$

$$\dot\theta(0) = 0 \quad \textit{in } \Sigma, \tag{6.13h}$$

where f is the right-hand side of (2.11h).

Proof. Similar to the proof of Theorem 2.9, one can show that (6.13a)–(6.13h) has a unique solution $(\dot\phi, \dot A, \dot z, \dot\theta)$; hence we omit this part of the proof. To prove assertion (3), we first test (6.13a) with $\dot\phi$. According to Corollary 6.4 and Lemma 6.3, we obtain

$$\sigma_0\int_0^t\int_\Omega |\nabla\dot\phi|^2\,dx\,ds \le \|B_2'(0)\|_{C^1(D)}\Big(\int_0^t\int_\Omega |\nabla\dot\phi|^2\,dx\,ds\Big)^{1/2}\Big(\int_0^t\int_\Omega |\nabla\phi|^2\,dx\,ds\Big)^{1/2}.$$

Using Young's inequality and (2.12), we obtain the estimate for $\nabla\dot\phi$. Then we again differentiate formally with respect to t and obtain the estimate for $\nabla\dot\phi_t$.

Next, we test (6.13b) with $\dot A$ and obtain

$$\begin{aligned}&\frac{\sigma_0}{2}\int_G |\dot A(t)|^2\,dx + \int_0^t\int_D \frac{1}{\mu}|\operatorname{curl}\dot A|^2\,dx\,ds + \int_0^t\int_D\frac{1}{\mu}|\operatorname{div}\dot A|^2\,dx\,ds\\ &\le \kappa_1\int_0^t \|\nabla\dot\phi\|_{\mathbf{L}^2(\Omega)}\|\dot A\|_{\mathbf{L}^2(\Omega)}\,ds + \kappa_1\|B_3'(0)\|_{C^1(D)}\int_0^t\|\nabla\phi\|_{\mathbf{L}^2(\Omega)}\|\dot A\|_{\mathbf{L}^2(\Omega)}\,ds\\ &\quad + \|\beta'(0)\|_{C^1(D)}\int_\Sigma \|A_s\|_{\mathbf{L}^2(G)}\|\dot A\|_{\mathbf{L}^2(G)}\,ds\\ &\quad + c_1\|B_1'(0)\|_{C^1(D)}\int_0^t\|A\|_{\mathbf{X}}\|\dot A\|_{\mathbf{X}}\,ds + \frac{\sigma_0}{2}\int_G|\dot A(0)|^2\,dx.\end{aligned}$$

Now we apply Young's inequality, Gronwall's lemma, and (6.13c) to infer

$$\|\dot A\|_{L^\infty(0,T;\mathbf{L}^2(G))} + \|\dot A\|_{L^2(0,T;\mathbf{X})} \le c_1\|V(0)\|_{C^1(D)}.$$

Using the corresponding initial condition for $\dot A_t$ (cf. (6.6)), we differentiate (6.13b) formally with respect to time and insert $v = \dot A$ to obtain

$$\|\dot A_t\|_{L^\infty(0,T;\mathbf{L}^2(G))} + \|\dot A_t\|_{L^2(0,T;\mathbf{X})} \le c_2\|V(0)\|_{C^1(D)}.$$

A further application of Lemma 6.7 then yields

$$\|\dot A_t\|_{L^{10/3}(0,T;L^{10/3}(G))} \le c_3\|V(0)\|_{C^1(D)}. \tag{6.14}$$

Next, we remark that similar to the derivation of Lemma 2.5(3), we can infer that

$$\|\dot{z}\|^p_{W^{1,p}(0,T;L^p(\Sigma))} \le c_4 \|\dot{\theta}\|_{L^p(Q)}.$$

Then in the light of (6.14), the last part of inequality (5.2) in Corollary 5.3 follows as in the proof of Lemma 6.5(3) and (4).

It remains to show that the solutions to (6.13a)–(6.13h) are the strong material derivatives. To this end, let

$$\psi^\tau = \frac{1}{\tau}(\phi^\tau - \phi) - \dot{\phi}; \tag{6.15}$$

then, according to Corollary 6.4, (6.1), and (6.13a), ψ^τ satisfies

$$\begin{aligned}\alpha_0(0,\psi^\tau,\varphi) &= -\frac{1}{\tau}\Big(\alpha_0(\tau,\phi^\tau,\varphi) - \alpha_0(0,\phi^\tau,\varphi)\Big) - \alpha_0(0,\dot{\phi},\varphi)\\ &= \alpha_{0,\tau}(0,\phi-\phi^\tau,\varphi) - \frac{1}{\tau}\tilde{\alpha}_0(\tau,\phi^\tau,\varphi).\end{aligned}$$

Integrating in time, inserting $\varphi = \psi^\tau$, and using Corollary 6.4 once again, we obtain

$$\|\nabla\psi^\tau\|_{L^2(0,T;\mathbf{L}^2(\Omega))} \xrightarrow[\tau\to 0]{} 0. \tag{6.16}$$

Since the same computations hold for $\nabla\phi_t$, the first part of assertion (1) is proved.

Next, defining

$$p^\tau = \frac{1}{\tau}(A^\tau - A) - \dot{A},$$

and using (6.13b) and Corollary 6.4, we see that p^τ satisfies

$$\begin{aligned}\alpha_1(0,p_t^\tau,v) + \alpha_2(0,p^\tau,v) &= -\frac{1}{\tau}\Big(F(\tau,\phi^\tau,v) - F(0,\phi,w)\Big)\\ &\quad -\frac{1}{\tau}\Big(\alpha_1(\tau,A_t^\tau,v) - \alpha_1(0,A_t^\tau,v)\Big) - \frac{1}{\tau}\Big(\alpha_2(\tau,A^\tau,v) - \alpha_2(0,A^\tau,v)\Big)\\ &\quad +F(0,\dot{\phi},v) + F_{,\tau}(0,\phi,v) + \alpha_{1,\tau}(0,A_t,v) + \alpha_{2,\tau}(0,A,v)\\ &= -F(0,\psi^\tau,v) - F_{,\tau}(0,\phi^\tau-\phi,v) + \frac{1}{\tau}\tilde{F}(\tau,\phi^\tau,v)\\ &\quad -\alpha_{1,\tau}(0,A_t^\tau - A_t,v) - \alpha_{2,\tau}(0,A^\tau - A,v)\\ &\quad -\frac{1}{\tau}\tilde{\alpha}_1(\tau,A_t^\tau,v) - \frac{1}{\tau}\tilde{\alpha}_2(\tau,A^\tau,v).\end{aligned} \tag{6.17}$$

We take $v = p^\tau$, integrate in time, and use Hölder's inequality to obtain

$$\begin{aligned}&\frac{\sigma_0}{2}\int_G |p^\tau|^2\,dx - \frac{\sigma_0}{2}\int_G |p_0^\tau|^2\,dx + \int_0^t\int_D \frac{1}{\mu}|\operatorname{curl} p^\tau|^2\,dxds + \int_0^t\int_D \frac{1}{\mu}(\operatorname{div} p^\tau)^2\,dxds\\ &\le \sigma_0\int_0^t \|\nabla\psi^\tau\|_{\mathbf{L}^2(\Omega)}\|p^\tau\|_{\mathbf{L}^2(\Omega)}\,ds + c_5\int_0^t \|\nabla\phi^\tau - \nabla\phi\|_{\mathbf{L}^2(\Omega)}\|p^\tau\|_{\mathbf{L}^2(\Omega)}\,ds\\ &\quad +\frac{1}{\tau}g_3(\tau)\int_0^t \|\nabla\phi^\tau\|_{\mathbf{L}^2(\Omega)}\|p^\tau\|_{\mathbf{L}^2(\Omega)}\,ds + \int_0^t\int_G \beta'(0)(A_s^\tau - A_s)\cdot p^\tau\,dx\,ds\\ &\quad +c_6\int_0^t \|A^\tau - A\|_{\mathbf{X}}\|p^\tau\|_{\mathbf{X}}\,ds + \frac{1}{\tau}g_1(\tau)\int_0^t \|A_s^\tau\|_{\mathbf{L}^2(G)}\|p^\tau\|_{\mathbf{L}^2(G)}\\ &\quad +\frac{1}{\tau}g_2(\tau)\int_0^t \|A^\tau\|_{\mathbf{X}}\|p^\tau\|_{\mathbf{X}}\,ds.\end{aligned}$$

Using (6.2b), the second term in (6.17) gives

$$\int_G |p_0^\tau|^2\,dx = \int_G \Big|\frac{1}{\tau}(A_0 \circ T_\tau - A_0) - \dot{A}_0\Big|^2\,dx.$$

According to [28, sect. 2.14], $\tau \mapsto A_0 \circ T_\tau$ is differentiable with

$$\frac{d}{d\tau}(A_0 \circ T_\tau)\Big|_{\tau=0} = DA_0V(0);$$

hence

$$A_0 \circ T_\tau = A_0 + \tau \mathcal{D}A_0V(0) + o(\tau).$$

Hence we obtain

$$\int_G |p_0^\tau|^2\,dx \xrightarrow[\tau\to 0]{} 0.$$

Regarding (5.1) and Lemma 6.3, $\beta'(0)p^\tau \in \mathbf{X}$ a.e. in $(0,T)$. Thus, we apply (6.10) to infer

$$\begin{aligned}\int_0^t \int_G \beta'(0)(A_s^\tau - A_s)\cdot p^\tau\,dx\,ds &= \frac{1}{\kappa_1}\int_0^t \alpha_1(0, A_s^\tau - A_s, \beta'(0)p^\tau)\,ds\\ &\le c_7|\tau|\|p^\tau\|_{L^2(0,t;\mathbf{X})}.\end{aligned}$$

Then we apply Young's inequality, Corollary 6.4, (6.16), and Gronwall's lemma to conclude

$$\|p^\tau\|^2_{L^\infty(0,T;\mathbf{L}^2(G))} + \|p^\tau\|^2_{L^2(0,T;\mathbf{X})} \xrightarrow[\tau\to 0]{} 0.$$

Now we differentiate (6.17) formally with respect to time, repeat the same considerations as before (but use (6.6) as initial value instead of (6.2b)), and obtain

$$\|p_t^\tau\|^2_{L^\infty(0,T;\mathbf{L}^2(G))} + \|p_t^\tau\|^2_{L^2(0,T;\mathbf{X})} \xrightarrow[\tau\to 0]{} 0.$$

A further application of Lemma 6.7 finally yields

$$\|p_t^\tau\|_{L^{10/3}(0,T;\mathbf{L}^{10/3}(G))} \xrightarrow[\tau\to 0]{} 0. \tag{6.18}$$

To prove the differentiability of θ^τ and z^τ, we define

$$\begin{aligned}q^\tau &= \frac{1}{\tau}(\theta^\tau - \theta) - \dot{\theta},\\ r^\tau &= \frac{1}{\tau}(z^\tau - z) - \dot{z};\end{aligned}$$

then (q^τ, r^τ) solve

$$\rho c_p q_t^\tau - k\Delta q^\tau = -\rho L r_t^\tau + \sigma_0\tau|\dot{A}_t|^2 + \sigma_0 p_t^\tau\cdot\Big(2A_t + 2\tau\dot{A}_t + \tau p_t^\tau\Big), \tag{6.19a}$$

$$\begin{aligned}r_t^\tau &= \frac{1}{\tau}\Big(f(\theta^\tau, z^\tau) + f(\theta, z)\Big) - \frac{\partial f}{\partial\theta}(\theta, z)\dot{\theta} - \frac{\partial f}{\partial z}(\theta, z)\dot{z}\\ &=: G(\tau),\end{aligned} \tag{6.19b}$$

$$\frac{\partial q^\tau}{\partial\nu} = 0, \qquad q^\tau = 0, \qquad r^\tau(0) = 0. \tag{6.19c}$$

Owing to (H7)–(H9), we can apply Taylor's formula to develop $G(\tau)$ and obtain (with a constant $\xi \in [0,1]$)

$$\begin{aligned}
|G(\tau)| &= \Big|\frac{1}{\tau}\Big(f(\theta+\tau(q^\tau+\dot\theta), z+\tau(r^\tau+\dot z)) - f(\theta,z)\Big) - \frac{\partial f}{\partial\theta}(\theta,z)\dot\theta - \frac{\partial f}{\partial z}(\theta,z)\dot z\Big| \\
&= \Big|(q^\tau+\dot\theta)\frac{\partial f}{\partial\theta}(\theta+\xi\tau(q^\tau+\dot\theta), z+\xi\tau(r^\tau+\dot z)) \\
&\qquad + (r^\tau+\dot z)\frac{\partial f}{\partial z}(\theta+\xi\tau(q^\tau+\dot\theta), z+\xi\tau(r^\tau+\dot z)) - \frac{\partial f}{\partial\theta}(\theta,z)\dot\theta - \frac{\partial f}{\partial z}(\theta,z)\dot z\Big| \\
&\le c_8|q^\tau| + c_9|r^\tau| + |\dot\theta|\Big|\frac{\partial f}{\partial\theta}(\theta+\xi(\theta^\tau-\theta), z+\xi(z^\tau-z)) - \frac{\partial f}{\partial\theta}(\theta,z)\Big| \\
&\qquad + |\dot z|\Big|\frac{\partial f}{\partial z}(\theta+\xi(\theta^\tau-\theta), z+\xi(z^\tau-z)) - \frac{\partial f}{\partial z}(\theta,z)\Big| \\
&\le c_8|q^\tau| + c_9|r^\tau| + c_{10}|\dot\theta||\theta^\tau-\theta| + c_{11}|\dot\theta||z^\tau-z| + c_{12}|\dot z||\theta^\tau-\theta| + c_{13}|\dot z||z^\tau-z|.
\end{aligned}$$

Owing to (6.18) and (5.2), the last term of the right-hand side of (6.19a) will be in $L^{5/3}(0,T;L^{5/3}(\Sigma))$. Thus we try to get an estimate for $G(\tau)$ in the same space. To this end, we apply the inequalities of Hölder and Young and use (5.2) to obtain

$$\begin{aligned}
&\int_0^t\int_\Sigma |G(\tau)|^{5/3}\,dx\,ds \le c_{14}\int_0^t\int_\Sigma |q^\tau|^{5/3}\,dx\,ds + c_{15}\int_0^t\int_\Sigma |r^\tau|^{5/3}\,dx\,ds \\
&+ c_{16}\Big(\int_0^t\int_\Sigma |\theta^\tau-\theta|^{10/3}\,dx\,ds\Big)^{1/2} + c_{17}\Big(\int_0^t\int_\Sigma |z^\tau-z|^{10/3}\,dx\,ds\Big)^{1/2}. \qquad (6.20)
\end{aligned}$$

Next, we test (6.19b) with $(r^\tau)^{2/3}$, use the estimate above, and apply the inequalities of Young and Gronwall, as well as the stability estimates of Lemma 6.5, to obtain

$$\frac{3}{5}\int_\Sigma |r^\tau|^{5/3}\,dx \le c_{18}|\tau|^{5/3} + c_{19}\int_0^t\int_\Sigma |q^\tau|^{5/3}\,dx\,ds.$$

Using the last estimate and (6.20) we go back to (6.19b) and conclude

$$\int_0^t\int_\Sigma |r_s^\tau|^{5/3}\,dx\,ds \le c_{20}|\tau|^{5/3} + c_{21}\int_0^t\int_\Sigma |q^\tau|^{5/3}\,dx\,ds. \qquad (6.21)$$

Now we can proceed again as in the proof of Lemma 6.5(3); i.e., we apply Lemma 2.6 to (6.19a) and use (6.21) and (5.2) to obtain (recall that $g(\tau) = o(1)$ if and only if $g(\tau) \to 0$ for $\tau \to 0$)

$$\|q^\tau\|_{W^{2,1}_{5/3}(Q)} = o(1). \qquad (6.22)$$

Using the embedding $W^{2,1}_{5/3}(Q) \subset L^5(Q)$ (cf. Lemma 2.7), we can go back, estimate $G(\tau)$ again (this time in $L^{5/2}(Q)$), and obtain finally

$$\|r^\tau\|_{W^{1,5/2}(0,T;L^{5/2}(\Sigma))} \xrightarrow[\tau\to 0]{} 0. \qquad \square$$

MINIMIZATION OF RISK AND LINEAR QUADRATIC OPTIMAL CONTROL THEORY*

MICHAEL KOHLMANN† AND SHANJIAN TANG‡

Abstract. This article is concerned with the optimal control problem for the linear stochastic system $X_t = x + \int_0^t (A_s X_s + B_s u_s + f_s)\,ds + \int_0^t \sum_{i=1}^d [C_i(s)X_s + D_i(s)u_s + g_i(s)]\,dw_i(s)$ with the convex risk functional $J(u) = EM(X_T) + E\int_0^T G(t, X_t, u_t)\,dt$. In order to guarantee the existence of an optimal control without any (weak) compactness assumption on the admissible control set, we assume that the risk function M is coercive and that $\sum_{i=1}^d D_i^* D_i$ is uniformly positive, rather than to assume like in the control literature that the running risk function G is coercive with respect to the control variable. In this new setting, the running risk function G may be independent of the control variable, and therefore the so-called singular linear-quadratic (LQ) stochastic control problem is included. A rigorous theory is developed for the general stochastic LQ problem with random coefficients, and the bounded mean oscillation–martingale theory is used to account for the concerned integrability. It plays a crucial role in the following exposition: (a) to connect the stochastic LQ problem to two associated backward stochastic differential equations (BSDEs)—one is an $n \times n$ symmetric matrix-valued nonlinear Riccati BSDE and the other is an n-dimensional linear BSDE with unbounded coefficients; (b) to show that the latter BSDE has an adapted solution pair of the suitably necessary regularity. This seems to be the first application in a stochastic LQ theory of the BMO-martingale theory, which roots in harmonic analysis. Furthermore, with the help of an a priori estimate on the risk functional, existence and uniqueness of the solutions of backward stochastic Riccati differential equations (BSRDEs) in the singular case is reduced to the regular case via a perturbation method, and then a new existence and uniqueness result on BSRDEs is obtained for the singular case.

Key words. minimization of risk, linear-quadratic stochastic control, nonlinear backward stochastic Riccati equation, BMO-martingale

1. Introduction.

Let $(\Omega, \mathcal{F}_T, P, \{\mathcal{F}_t, 0 \le t \le T\})$ be a fixed complete probability space on which is defined a standard $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted d-dimensional Brownian motion $\{w(t) \equiv (w_1(t), \dots, w_d(t))^*, 0 \le t \le T\}$. Assume that $\{\mathcal{F}_t, 0 \le t \le T\}$ is the completion, by the totality $\mathcal{N}$ of all null sets of $\mathcal{F}_T$, of the natural filtration $\{\mathcal{F}_t^w, 0 \le t \le T\}$ generated by w.

Consider the optimal control problem of the linear stochastic system

$$\text{(1.1)} \qquad \begin{cases} dX_s &= [AX_s + Bu(s) + f_s]\,ds \\ &\quad + \displaystyle\sum_{i=1}^d [C_i X_s + D_i u(s) + g_i(s)]\,dw_i(s), \quad 0 < s \le T, \\ X_0 &= x, \qquad u(t) \in R^m, \end{cases}$$

under the cost functional

$$J(u;0,x) = EM(X_T) + E\int_0^T G(s, X_s, u_s)\,ds. \tag{1.2}$$

Here $M(x)$ is $\mathcal{F}_T$-measurable for each $x \in R^n$ and is uniformly convex in x, and $G(t,x,u)$ is $\{\mathcal{F}_t, 0 \le t \le T\}$-measurable and convex in (x,u). Assume that all the coefficients A, B, C_i, D_i are $\{\mathcal{F}_t, 0 \le t \le T\}$-progressively measurable bounded matrix-valued processes, defined on $\Omega \times [0,T]$, of suitable dimensions. $u(\cdot)$ is the control, which is required to take values in a previously given nonempty closed convex subset U of the m-dimensional Euclidean space R^m and to be adapted to $\{\mathcal{F}_t, 0 \le t \le T\}$.

We are concerned with the existence of optimal controls without any direct (weak) compactness assumption on the admissible class of controls . In the control literature, to formulate such an existence theory, apart from the convexity assumption on M and G, it is usually assumed that G is *coercive* in the *control* variable u, that is, there are some constants $\delta_1 > 0, \delta_2 > 0$, and $p > 1$ such that

$$G(t,x,u) \ge \delta_1 |u|^p - \delta_2 \quad \forall\ (t,x,v) \in [0,T] \times R^n \times R^m.$$

The latter coercivity implies that the cost functional $J(\cdot;0,x)$ is coercive, and therefore an optimal control is a priori known to lie within a weakly compact subset of the admissible class of controls. Then with the obvious functional analytical arguments (see Ekeland and Temam [13, Corollary 2.1 and Proposition 2.12]), the existence of an optimal control is obtained. We refer the reader to Lions [24] for optimal control of systems governed by PDEs and to Bismut [4, 6] and to Yong and Zhou [35] for optimal control of stochastic systems.

In section 2, we shall formulate a different existence result. Rather than assume that G is *coercive* in the *control* variable u, we assume instead that M is *coercive* in the *state* variable x. Furthermore, we assume that $\sum_{i=1}^d D_i^* D_i$ is uniformly positive. Under the two assumptions, the cost functional $J(\cdot;0,x)$ is proved to be still coercive. The proof relies on an a priori estimate on the concerned stochastic system.

In the above new setting, the running risk functional may be independent of the control variable. Therefore, the so-called singular stochastic linear-quadratic (LQ) problem is included. In particular, the mean-variance hedging problem is covered as a special one-dimensional case. The two problems are important in stochastic control theory and mathematical finance, respectively.

Section 3 is devoted to the study of the general stochastic LQ problem. The first part aims at characterizing the solution of the LQ problem in terms of two associated backward stochastic differential equations (BSDEs). In this consideration, the routine arguments in the case of constant coefficients meet with, in our general case, new integrability difficulties due to the appearance of possibly unbounded coefficients. These difficulties reflect the essential feature of the general LQ problem with random coefficients. To have the necessary rigor, the BMO-martingale theory has to be introduced to account for the required integrability. Here, BMO is the abbreviation for "bounded mean oscillation." The second part is devoted to the reduction of backward stochastic Riccati differential equations (BSRDEs) in the singular case to the regular case via a perturbation method. As a by-product of this reduction, the generalization of the existence and uniqueness result on BSRDEs in the regular case of Bismut [6] and Peng [27] is obtained in the singular case.

Finally, we conclude the paper in section 4 by giving some comments.

In summary, the contributions of the paper include the following:

1. A new existence result is formulated, in which the singular stochastic LQ problem and the mean-variance hedging problem are included.

2. New difficulties are identified in the general nonhomogeneous stochastic LQ problem, and the BMO-martingale theory is introduced to overcome these difficulties.
3. The existence and uniqueness result for BSRDEs in the singular case is reduced to the regular case. A new existence and uniqueness result for BSRDEs in some singular case is established.

These results will find applications in the so-called mean-variance hedging (see, e.g., [12]), which is extensively studied in the mathematical finance literature.

We conclude this section by introducing some notations.

M^* is the transpose of the vector or matrix M. $|M| := \sqrt{\Sigma_{ij} m_{ij}^2}$ for any vector or matrix $M = (m_{ij})$. $\langle M_1, M_2 \rangle$ is the inner product of the two vectors M_1 and M_2. R^n is the n-dimensional Euclidean space. S^n is the Euclidean space of all $n \times n$ symmetric matrices. S_+^n is the set of all $n \times n$ nonnegative definite matrices. $C(t, T; H)$ is the H-valued continuous functions on $[t, T]$, endowed with the maximum norm for a given Hilbert space H.

Let H be a given Euclidean space and $p \geq 1$. $\mathcal{L}_{\mathcal{F}}^p(t, T; H)$ is the space of H-valued $\{\mathcal{F}_s, t \leq s \leq T\}$-adapted L^p-integrable stochastic processes f on $[t, T]$, endowed with the norm $(E \int_t^T |f_s|^p \, ds)^{1/p}$. $\mathcal{L}_{\mathcal{F}}^\infty(t, T; H)$ is the space of H-valued $\{\mathcal{F}_s, t \leq s \leq T\}$-adapted essentially bounded stochastic processes f on $[t, T]$, endowed with the norm $\operatorname{ess\,sup}_{s,\omega} |f_s|$. $L^p(\Omega, \mathcal{F}_T, P; H)$ is the space of H-valued L^p-integrable random variables on $(\Omega, \mathcal{F}_T, P)$. $R := R^1$; $\mathcal{L}_{\mathcal{F}}^p(t, T) := \mathcal{L}_{\mathcal{F}}^p(t, T; R)$; $C(t, T) := C(t, T; R)$. $L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; H))$ is the space of $C([0, T]; H)$-valued, essentially maximum-norm-bounded random variables f on the fixed probability space $(\Omega, \mathcal{F}_T, P)$, endowed with the norm $\operatorname{ess}_{\omega \in \Omega} \sup_{0 \leq t \leq T} |f(t, \omega)|$. $L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; S_+^n))$ consists of those elements of $L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; S^n))$ which take values in S_+^n. $\mathcal{M}_{\mathcal{F}}^p(t, T; H)$ is the set of all $\{\mathcal{F}_s, t \leq s \leq T\}$-adapted processes ψ which take values in H and are such that $\|\psi\|_{\mathcal{M}^p}^p := E |\int_t^T |\psi_s|^2 \, ds|^{p/2} < +\infty$. $\mathcal{S}_{\mathcal{F}}^p(t, T; H)$ is the set of all the continuous $\{\mathcal{F}_s, t \leq s \leq T\}$-adapted processes ψ which take values in H and are such that $\|\psi\|_{\mathcal{S}_{\mathcal{F}}^p}^p := E[\sup_{t \leq s \leq T} |\psi_s|^p] < +\infty$. Note also that $\mathcal{L}_{\mathcal{F}}^p(t, T; H), \mathcal{L}_{\mathcal{F}}^\infty(t, T; H)$, $L^p(\Omega, \mathcal{F}_T, P; H), \mathcal{M}_{\mathcal{F}}^p(t, T; H)$, and $\mathcal{S}_{\mathcal{F}}^p(t, T; H)$ are occasionally abbreviated as $\mathcal{L}_{\mathcal{F}}^p$, $\mathcal{L}_{\mathcal{F}}^\infty, L^p, \mathcal{M}_{\mathcal{F}}^p$, and $\mathcal{S}_{\mathcal{F}}^p$, respectively, when the context is clear. This often happens especially when they appear in the subscripts.

Throughout this paper, by a square integrable process f we mean that it satisfies $E \int_0^T |f_s|^2 \, ds < \infty$.

2. The risk minimization problem.

2.1. The linear stochastic control system. Let $(\Omega, \mathcal{F}_T, P, \{\mathcal{F}_t, 0 \leq t \leq T\})$ be a fixed complete probability space on which is defined a standard $\{\mathcal{F}_t, 0 \leq t \leq T\}$-adapted d-dimensional Brownian motion $\{w(t) := (w_1(t), \ldots, w_d(t))^*, 0 \leq t \leq T\}$. Assume that $\{\mathcal{F}_t, 0 \leq t \leq T\}$ is the completion, by the totality $\mathcal{N}$ of all null sets of $\mathcal{F}_T$, of the natural filtration $\{\mathcal{F}_t^w, 0 \leq t \leq T\}$ generated by w.

Consider the optimal control problem of the linear stochastic system parameterized by the initial data $(x, t) \in R^n \times [0, T]$:

$$
\left\{
\begin{array}{rcl}
dX_s &=& [AX_s + Bu(s) + f_s] \, ds \\
&& + \sum_{i=1}^d [C_i X_s + D_i u(s) + g_i(s)] \, dw_i(s), \quad t < s \leq T, \\
X_t &=& x.
\end{array}
\right. \tag{2.1}
$$

We introduce the following two assumptions on the control system (2.1).

(A1) Let A, B, C_i, D_i be $\{\mathcal{F}_t,\ 0 \le t \le T\}$-progressively measurable bounded matrix-valued processes, defined on $\Omega \times [0,T]$, of dimensions $n \times n$, $n \times m$, $n \times n$, $n \times m$, respectively. The $d+1$ processes $g_i, i = 1, \dots, d$, and f belong to $\mathcal{L}^2_{\mathcal{F}}(0,T;R^n)$.

(A2) There is a real deterministic positive number δ such that $\sum_{i=1}^d D_i^* D_i \ge \delta I_{m\times m}$.

For given initial data (t,x) and control u such that $\int_t^T |u|^2\,ds < \infty$ a.s., the above control system (2.1) has a unique strong solution X (see Gal'chuk [15]). It will be denoted by $X^{t,x;u}$ whenever it is necessary to indicate its dependence on the triplet (x,t,u). We have the following lemma.

LEMMA 2.1. *Let assumption* (A1) *be satisfied. Then, for* $1 \le p < \infty$, *there is a deterministic positive constant* β *such that for any* $u \in \mathcal{M}^p_{\mathcal{F}}(t,T;R^m)$, $f \in \mathcal{L}_{\mathcal{F}}(t,T;R^n)$, *and* $(g_1,\dots,g_d) \in (\mathcal{M}^p_{\mathcal{F}}(t,T;R^n))^d$, *we have*

$$E^{\mathcal{F}_t} \max_{t\le s\le T} |X_s|^p \le \beta\left(|x|^p + E^{\mathcal{F}_t}\left| \int_t^T |f_s|\,ds \right|^p + E^{\mathcal{F}_t}\left| \int_t^T (|g(s)|^2 + |u_s|^2)\,ds \right|^{p/2} \right).$$

For the proof the reader is referred to Protter [31, Chapter V, Lemma 2, p. 196].

We have the following a priori estimate for system (2.1).

LEMMA 2.2. *Let assumptions* (A1) *and* (A2) *be satisfied. If* $u \in \mathcal{M}^p(0,T;R^m)$ *for some* $p \in [1,\infty)$, *then there is a deterministic constant* $\beta_{p,\delta,T} > 0$ *which depends on* (p,δ,T) *and the uniform bound of* $A, B, C := (C_1,\dots,C_d)$ *such that*

$$\begin{aligned} &E^{\mathcal{F}_t}\left| \int_t^T |u_s|^2\,ds \right|^{p/2} + E^{\mathcal{F}_t} \sup_{t\le s\le T} |X_s|^p \\ &\le \beta_{p,\delta,T} E^{\mathcal{F}_t}\left(|X_T|^p + \int_t^T |f_s|^p\,ds + \left| \int_t^T |g(s)|^2\,ds \right|^{p/2} \right). \end{aligned} \tag{2.2}$$

The proof is an adaptation of El Karoui, Peng, and Quenez [14, pp. 54–57], incorporating assumption (A2). It is left to the diligent reader as an exercise.

Lemma 2.2 is an a priori estimate for BSDEs. We remark here that BSDEs were initially introduced by Bismut [3] for the linear case and were later developed by Pardoux and Peng [25] for the general Lipschitz nonlinear case.

Throughout this paper, we write $\beta_{\delta,T}$ for $\beta_{2,\delta,T}$.

2.2. Admissible class of controls. Assume that U is a nonempty closed convex subset of R^m. Denote by U^t_{ad} the set of all the $\{\mathcal{F}_s, t \le s \le T\}$-adapted processes $\{u_s, t \le s \le T\}$ with values in U such that $\int_t^T |u(s)|^2\,ds < \infty$ a.s. Define

$$U^{t,p}_{ad} := \left\{ u \in U^t_{ad} : E\left(\int_t^T |u_s|^2\,ds \right)^{p/2} < \infty \right\}; \tag{2.3}$$

it is convex and closed. For given initial data (t,x), the control system (2.1) has a unique strong solution $X^{t,x;u}$. The following presents a multidimensional generalization of the closedness of attainable contingent claims in Pham, Rheinländer, and Schweizer [30].

PROPOSITION 2.3. *Let assumptions* (A1) *and* (A2) *be satisfied. Then, for every* $x \in R^n$, *the attainable set* $\mathcal{R}_p(0,x;T)$ *at time* T *when starting from point* x *at time*

0, *of system* (2.1), *defined by*

$$\mathcal{R}_p(0,x;T) := \{X_T^{0,x;u} : u \in U_{ad}^{0,p}\} \tag{2.4}$$

is convex and closed in $\mathcal{L}_{\mathcal{F}}^p(0,T;R^m)$.

Proof. Let $\{\xi_k\}_{k=1}^{\infty}$ be a sequence of elements of $\mathcal{R}_p(0,x;T)$ converging to ξ strongly in $\mathcal{L}_{\mathcal{F}}^p(0,T;R^n)$. We shall show that there is $u \in U_{ad}^{0,p}$ such that $\xi = X_T^{0,x;u}$.

By the definition of $\mathcal{R}_p(0,x;T)$, there are $u_k \in U_{ad}^{0,p}$ such that

$$\xi_k = X_T^{0,x;u_k}, \quad k = 1,2\ldots.$$

Since the pair $(\delta X, \delta u) := (X^{0,x;u_k} - X^{0,x;u_l}, u_k - u_l)$ satisfies the SDE

$$d\delta X_t = (A_t \delta X_t + B_t \delta u_t)\,dt + \sum_{i=1}^{d} [C_i(t)\delta X_t + D_i(t)\delta u_t]\,dw_i(t) \tag{2.5}$$

with the terminal condition $\delta X_T = \xi_k - \xi_l$, we derive from Lemma 2.2

$$\|u_k - u_l\|^p_{\mathcal{M}_{\mathcal{F}}^p(0,T;R^m)} \le \beta_{p,\delta,T} E|\xi_k - \xi_l|^p, \quad k,l = 1,2,\ldots. \tag{2.6}$$

This last inequality implies that $\{u_k\}_{k=1}^{\infty}$ converges strongly in $\mathcal{M}^p(0,T;R^m)$. Since $\mathcal{M}_{\mathcal{F}}^p(0,T;R^m)$ is complete, there is necessarily a limit $u \in \mathcal{M}_{\mathcal{F}}^p(0,T;R^m)$ such that $u_k \to u$ strongly in $\mathcal{M}_{\mathcal{F}}^p(0,T;R^m)$. While $X^{0,x;u_k} - X^{0,x;u} = X^{0,x;u_k-u}$, we deduce from Lemma 2.2 that $\xi_k = X_T^{0,x;u_k} \to X_T^{0,x;u}$ strongly in $\mathcal{L}_{\mathcal{F}}^p(0,T;R^n)$. Therefore $\xi = X_T^{0,x;u}$. Since the set $U_{ad}^{0,p}$ is strongly closed in $\mathcal{M}_{\mathcal{F}}^p(0,T;R^m)$, we also have $u \in U_{ad}^{0,p}$. The proof is then complete. □

2.3. The risk functional. We make the following assumptions.

(A3)$_p$ Let $M : R^n \times \Omega \to R$ and $G : [0,T] \times R^n \times R^m \times \Omega \to R$ be convex in (x,u), and for each $(x,u) \in R^n \times R^m$, they are $\mathcal{F}_T$-measurable and $\{\mathcal{F}_t,\, 0 \le t \le T\}$-progressively measurable, respectively. Moreover, there are deterministic numbers $p > 1$ and $\delta_1 > 0$ such that for all $(t,x) \in [0,T] \times R^n$,

$$M(x) \le \delta_1(1 + |x|^p), \tag{2.7}$$

$$G(t,x,u) \le \delta_1(1 + |x|^p + |u|^{p\wedge 2}), \tag{2.8}$$

and

$$\begin{aligned} &|M(x_1) - M(x_2)| + |G(t,x_1,u_1) - G(t,x_2,u_2)| \\ &\quad \le \delta_1(1 + |x_1|^{p-1} + |x_2|^{p-1})|x_1 - x_2| \\ &\qquad + \delta_1(1 + |u_1|^{p\wedge 2-1} + |u_2|^{p\wedge 2-1})|u_1 - u_2|. \end{aligned} \tag{2.9}$$

(A4)$_p$ The coercivity condition with index $p > 1$ holds for the terminal cost function M: there are deterministic constants $\delta_2 > 0$ and $\delta_3 > 0$ such that

$$M(x) \ge -\delta_2 + \delta_3|x|^p. \tag{2.10}$$

There is a deterministic constant $\delta_4 > 0$ such that $G(t,x,u) \ge -\delta_4$ for all (t,x,u).

Note that $M(x) := |x|^p$ and $G(t,x,u) := |x|^p$ satisfy assumptions (A3)$_p$ and (A4)$_p$.

Consider the risk functional parameterized by the initial data $(t,x)\in[0,T]\times R^n$:

$$J(u;t,x):=E^{\mathcal{F}_t}M(X_T^{t,x;u})+E^{\mathcal{F}_t}\int_t^T G(s,X_s^{t,x;u},u_s)\,ds. \tag{2.11}$$

It has the following useful properties.

THEOREM 2.4. *Let assumptions* (A1), (A2), $(A3)_p$, *and* $(A4)_p$ *be satisfied for some* $p>1$. *Then, the risk functional* $J(\cdot;0,x)$ *defined on* $U_{ad}^{0,p}$ *is bounded from below, finite-valued, convex, continuous, and coercive, i.e.,*

$$J(u;0,x)\to+\infty \quad \text{if } ||u||_{\mathcal{M}_{\mathcal{F}}^p}\to+\infty. \tag{2.12}$$

Moreover, it has the following coercivity, growth, and continuity:

$$\begin{aligned}
&\beta_1(|x|^p+||u||_{\mathcal{M}_{\mathcal{F}}^p}^p)-\|f\|_{\mathcal{L}_{\mathcal{F}}^p}^p-\|g\|_{\mathcal{M}_{\mathcal{F}}^p}^p-\beta_2\le J(u;0,x)\\
&\quad\le\beta_3(1+|x|^p+||u||_{\mathcal{M}_{\mathcal{F}}^p}^{p\wedge 2}+\|f\|_{\mathcal{L}_{\mathcal{F}}^p}^p+\|g\|_{\mathcal{M}_{\mathcal{F}}^p}^p),\\
&|J(u_1;0,x_1)-J(u_2;0,x_2)|\\
&\quad\le\beta_4(1+|x_1|^{p-1}+|x_2|^{p-1}+||u_1||_{\mathcal{M}_{\mathcal{F}}^p}^{p-1}+||u_2||_{\mathcal{M}_{\mathcal{F}}^p}^{p-1}+\|f\|_{\mathcal{L}_{\mathcal{F}}^p}^{p-1}+\|g\|_{\mathcal{M}_{\mathcal{F}}^p}^{p-1})\\
&\quad\times(|x_1-x_2|+||u_1-u_2||_{\mathcal{M}_{\mathcal{F}}^p})\\
&\quad+\beta_4(1+\|u_1\|_{\mathcal{M}_{\mathcal{F}}^p}^{(p\wedge 2-1)}+\|u_2\|_{\mathcal{M}_{\mathcal{F}}^p}^{(p\wedge 2-1)})\|u_1-u_2\|_{\mathcal{M}_{\mathcal{F}}^p}.
\end{aligned} \tag{2.13}$$

Here β_1,β_2,β_3, *and* β_4 *are positive constants.*

Proof. The convexity of $J(\cdot;0,x)$ is obvious. The continuity and coercivity of $J(\cdot;0,x)$ can be derived from inequalities (2.13).

Inequalities (2.13) are consequences of the assumptions and an application of Hölder's inequality, Lemma 2.1, or Lemma 2.2. From the coercivity assumption on M, the lower bound assumption on G, and Lemma 2.2, we derive the first inequality of (2.13):

$$\begin{aligned}
J(u;0,x) &\ge \delta_3E|X_T|^p-\delta_2-\delta_4T\\
&\ge \delta_3\beta_{p,\delta,T}^{-1}(|x|^p+||u||_{\mathcal{M}_{\mathcal{F}}^p}^p)-\|f\|_{\mathcal{L}_{\mathcal{F}}^p}^p-\|g\|_{\mathcal{M}_{\mathcal{F}}^p}^p-\delta_2-\delta_4T.
\end{aligned} \tag{2.14}$$

From the continuity assumption on M and G, we have

$$\begin{aligned}
&|J(u_1;0,x_1)-J(u_2;0,x_2)|\\
&\quad\le\delta_1E[(1+|X_1(T)|^{p-1}+|X_2(T)|^{p-1})|X_1(T)-X_2(T)|]\\
&\qquad+\delta_1E\int_0^T[(1+|X_1|^{p-1}+|X_2|^{p-1})|X_1-X_2|\\
&\qquad\qquad+(1+|u_1|^{p\wedge 2-1}+|u_2|^{p\wedge 2-1})|u_1-u_2|]\,ds,
\end{aligned} \tag{2.15}$$

where $X_1(t)=X_t^{0,x_1;u_1}$ and $X_2(t)=X_t^{0,x_2;u_2}$. In view of the Schwarz inequality, we have (note that $p^{-1}+q^{-1}=1$)

$$\begin{aligned}
&|J(u_1;0,x_1)-J(u_2;0,x_2)|\\
&\quad\le\delta_1\|1+|X_1(T)|^{p-1}+|X_2(T)|^{p-1}\|_{L^q}\|X_1(T)-X_2(T)\|_{L^p}\\
&\qquad+\delta_1\|1+|X_1|^{p-1}+|X_2|^{p-1}\|_{\mathcal{L}_{\mathcal{F}}^q}\|X_1-X_2\|_{\mathcal{L}_{\mathcal{F}}^p}\\
&\qquad+\delta_1E\left\{\left(\int_0^T(1+|u_1|^{p\wedge 2-1}+|u_2|^{p\wedge 2-1})\,ds\right)^{1/2}\left(\int_0^T|u_1-u_2|\,ds\right)^{1/2}\right\}
\end{aligned}$$

$$
\begin{aligned}
&\le \delta_1(1+\||X_1(T)|^{p-1}\|_{L^q}+\||X_2(T)|^{p-1}\|_{L^q})\|X_1(T)-X_2(T)\|_{L^p}\\
&\quad+\beta_4(1+\||X_1|^{p-1}\|_{\mathcal{L}^q_{\mathcal{F}}}+\||X_2|^{p-1}\|_{\mathcal{L}^q_{\mathcal{F}}})\|X_1-X_2\|_{\mathcal{L}^p_{\mathcal{F}}}\\
&\quad+\beta_4 E\left[1+\left(\int_0^T|u_1|^{2(p\wedge 2-1)}\,ds\right)^{1/2}+\left(\int_0^T|u_2|^{2(p\wedge 2-1)}\,ds\right)^{1/2}\right]\\
&\quad\times\left(\int_0^T|u_1-u_2|^2\,ds\right)^{1/2}\\
&\le \delta_1(1+\|X_1(T)\|_{L^p}^{p-1}+\|X_2(T)\|_{L^p}^{p-1})\|X_1(T)-X_2(T)\|_{L^p}\\
&\quad+\beta_4(1+\|X_1\|_{\mathcal{L}^p_{\mathcal{F}}}^{p-1}+\|X_2\|_{\mathcal{L}^p_{\mathcal{F}}}^{p-1})\|X_1-X_2\|_{\mathcal{L}^p_{\mathcal{F}}}\\
&\quad+\beta_4 E\left[1+\left(\int_0^T|u_1|^2\,ds\right)^{(p\wedge 2-1)/2}+\left(\int_0^T|u_2|^2\,ds\right)^{(p\wedge 2-1)/2}\right]\\
&\quad\times\left(\int_0^T|u_1-u_2|^2\,ds\right)^{1/2}.
\end{aligned}
\tag{2.16}
$$

Since for $i=1,2$

$$
\begin{aligned}
&E\left\{\left(\int_0^T|u_i|^2\,ds\right)^{(p\wedge 2-1)/2}\left(\int_0^T|u_1-u_2|^2\,ds\right)^{1/2}\right\}\\
&\le\left(E\left(\int_0^T|u_i|^2\,ds\right)^{q(p\wedge 2-1)/2}\right)^{1/q}\left(E\left(\int_0^T|u_1-u_2|^2\,ds\right)^{p/2}\right)^{1/p}\\
&\le\|u_i\|^{(p\wedge 2-1)}_{\mathcal{M}^{q(p\wedge 2-1)}_{\mathcal{F}}}\|u_1-u_2\|_{\mathcal{M}^p_{\mathcal{F}}}\\
&\le\|u_i\|^{(p\wedge 2-1)}_{\mathcal{M}^p_{\mathcal{F}}}\|u_1-u_2\|_{\mathcal{M}^p_{\mathcal{F}}}\quad\text{(noting that } q(p\wedge 2-1)\le p),
\end{aligned}
\tag{2.17}
$$

we have

$$
\begin{aligned}
&|J(u_1;0,x_1)-J(u_2;0,x_2)|\\
&\quad\le\delta_1(1+\|X_1(T)\|_{L^p}^{p-1}+\|X_2(T)\|_{L^p}^{p-1})\|X_1(T)-X_2(T)\|_{L^p}\\
&\qquad+\beta_4(1+\|X_1\|_{\mathcal{S}^p_{\mathcal{F}}}^{p-1}+\|X_2\|_{\mathcal{S}^p_{\mathcal{F}}}^{p-1})\|X_1-X_2\|_{\mathcal{L}^p_{\mathcal{F}}}\\
&\qquad+\beta_4(1+\|u_1\|^{(p\wedge 2-1)}_{\mathcal{M}^p_{\mathcal{F}}}+\|u_2\|^{(p\wedge 2-1)}_{\mathcal{M}^p_{\mathcal{F}}})\|u_1-u_2\|_{\mathcal{M}^p_{\mathcal{F}}}.
\end{aligned}
\tag{2.18}
$$

Using Lemma 2.1, we get the last inequality of (2.13).

In a similar way, the second inequality of (2.13) can be proved. The proof is complete. □

2.4. Minimization of the risk. For given initial data $(0,x)$, consider the risk minimization problem:

$$
\min_{u\in U^0_{ad}} J(u;0,x). \tag{2.19}
$$

We have immediately the following theorem.

THEOREM 2.5. *Let assumptions* (A1), (A2), *and* $(\mathrm{A4})_p$ *for some* $p>1$ *be satisfied. Then, problem* (2.19) *is equivalent to the following:*

$$
\min_{u\in U^{0,p}_{ad}} J(u;0,x). \tag{2.20}
$$

THEOREM 2.6. *Let assumptions* (A1), (A2), $(A3)_p$, *and* $(A4)_p$ *be satisfied for some* $p > 1$. *Then, the risk minimization problem* (2.19) *has an optimal control* $u \in U_{ad}^{0,p}$ *for each* $x \in R^n$. *Furthermore, if* M *is strictly convex, then the problem has a unique optimal control* $u \in U_{ad}^{0,p}$ *for each* $x \in R^n$.

Proof. From Theorem 2.4 and Proposition 2.12 of Ekeland and Temam [13], the convex, coercive, and continuous (of course lower-semicontinuous) functional $J(\cdot; 0, x)$ defined on the strongly closed subset $U_{ad}^{0,p} \subset \mathcal{M}_{\mathcal{F}}^p(0, T; R^m)$ (note that $\mathcal{M}_{\mathcal{F}}^p(0, T; R^m)$ is a reflexive Banach space) attains its infimum.

It is easy to show that the strict convexity of M implies the uniqueness of the terminal optimal control state and thus the optimal control (in view of Lemma 2.2). The proof is complete. □

3. The quadratic case: Singular stochastic LQ problem.

3.1. Introduction. This section is devoted to the study of the singular stochastic LQ problem, as a particular case of the stochastic control problem discussed in the preceding section. That is, we consider the case in which the risk functions M and G are both quadratic functions, i.e.,

$$M(x) := \langle M(x - \xi), x - \xi \rangle, \quad G(t, x, u) = \langle N_t u, u \rangle + \langle Q_t(x - q_t), x - q_t \rangle. \tag{3.1}$$

We introduce the following assumptions.

(A5) The matrix-valued processes N, Q, M are nonnegative, uniformly bounded in (t, ω), and $\{\mathcal{F}_t, 0 \le t \le T\}$-progressively measurable, of dimensions $m \times m$, $n \times n$, $n \times n$, respectively. The admissible control class is $U_{ad} := \mathcal{L}_{\mathcal{F}}^2(0, T; R^m)$.

(A6) The control weighting process N is uniformly positive: $N \ge \delta I_{m \times m}$ for some positive constant δ.

(A6)′ The terminal state weighting process M is uniformly positive: $M \ge \delta I_{n \times n}$ for some positive constant δ.

(A7) The random variable $\xi \in L^2(\Omega, \mathcal{F}_T, P; R^n)$, and the process $q \in \mathcal{L}_{\mathcal{F}}^2(0, T; R^n)$.

For subsequent convenience of reference, we give the following definitions.

DEFINITION 3.1. *The underlying optimal control problem is called regular if assumption* (A6) *is required. It will be called singular if assumption* (A6)′ *is required.*

From Lemma 2.2, we get the following lemma.

LEMMA 3.2. *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A7) *be satisfied. Then, for every* $u \in \mathcal{L}_{\mathcal{F}}^2(0, T; R^m)$, *we have*

$$\begin{aligned} J(u; t, x) \quad \ge \quad & \frac{\delta}{2}[\beta_{\delta,T}^{-1}|x|^2 + \beta_{\delta,T}^{-1} E^{\mathcal{F}_t} \int_t^T |u_s|^2 \, ds - E^{\mathcal{F}_t} \int_t^T (|f_s|^2 + |g(s)|^2) \, ds] \\ & + (\delta - \frac{2}{\delta}) E|\xi|^2. \end{aligned} \tag{3.2}$$

Define the value function $V(t, x)$ of the above LQ problem as follows:

$$V(t, x) := \operatorname{ess} \inf_{u \in \mathcal{L}_{\mathcal{F}}^2(t, T; R^m)} J(u; t, x). \tag{3.3}$$

See Karatzas and Shreve [16] for the definition of infimum of a set of stochastic processes. From the definition, it follows that for each fixed $x \in R^n$, $V(t, x)$ is an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted real-valued stochastic process.

The rest of this section is organized as follows. The second subsection is devoted to existence and equivalent conditions of optimal controls, and a useful estimate, which states a dependence property of the optimal control and the pair of associated adjoint

processes on the 5-tuple (x, f, g, ξ, q). The third contains some useful properties of BMO-martingales. In the fourth, the LQ problem is explicitly solved in terms of the solutions of two associated BSDEs. Finally, in the fifth, the two BSDEs are studied.

3.2. Optimal controls: Existence, equivalent conditions, and dependence. A general existence and uniqueness of optimal controls was given in the regular case by Bismut [4, 6]. Concerning the singular case, Theorem 2.6 immediately implies the following theorem.

THEOREM 3.3. *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A7) *be satisfied. Then, there is a unique optimal control* $\widehat{u} \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$.

Proceeding identically as Bismut [4, 6], we can prove the following theorem.

THEOREM 3.4. *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A7) *be satisfied. Then* $\widehat{u} \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$ *is optimal if and only if there is a pair of processes* $(y, z := (z_1, \cdots, z_d))$ *which solves the BSDE (called the adjoint equation)*

$$(3.4)\quad \begin{cases} dy_t &= -\left[A_t^* y_t + \sum_{i=1}^d C_i(t)^* z_i(t) + Q_t(\widehat{X}_t - q_t)\right] dt + \sum_{i=1}^d z_i(t) dw_i(t), \\ y_T &= M(\widehat{X}_T - \xi) \end{cases}$$

with $\widehat{X} := X^{0,x;\widehat{u}}$ *and*

$$(3.5)\quad y \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^n) \cap L^2(\Omega, \mathcal{F}_T, P; C([0,T];R^n)),\ z \in (\mathcal{L}^2_{\mathcal{F}}(0,T;R^n))^d,$$

such that

$$(3.6)\quad y_s^* B_s + \sum_{i=1}^d z_i(s)^* D_i(s) + N_s \widehat{u}_s = 0 \quad a.s.a.e.$$

Also see Peng [29] and Tang and Li [34] for the necessity.

We have the following useful estimate.

THEOREM 3.5. *Let assumptions* (A1), (A2), (A5), *and* (A6)′ *be satisfied. Let* $\widehat{u}$ *be an optimal control and* (y, z) *be defined by* (3.4). *Then, there is a positive constant* β *such that*

$$(3.7)\quad \begin{aligned} &E \sup_{0\le t\le T} (|\widehat{X}_t|^2 + |y_t|^2) + E\int_0^T (|z(t)|^2 + |\widehat{u}_t|^2)\, dt \\ &\quad \le \beta \left[|x|^2 + E|\xi|^2 + E\int_0^T (|f_t|^2 + |g(t)|^2 + |q_t|^2)\, dt \right]. \end{aligned}$$

Proof. According to the classical a priori estimate for BSDE (3.4) (see El Karoui, Peng, and Quenez [14]), we have

$$(3.8)\quad \begin{aligned} &E \sup_{0\le t\le T} |y_t|^2 + E\int_0^T |z(t)|^2\, dt \\ &\quad \le \beta \left[E(|\widehat{X}_T|^2 + |\xi|^2) + E\int_0^T (|f_t|^2 + |g(t)|^2 + |\widehat{X}_t|^2 + |q_t|^2)\, dt \right]. \end{aligned}$$

Using Itô's formula to compute $\langle y_t, \widehat{X}_t\rangle$, in view of (3.6), we obtain

$$(3.9)\quad \begin{aligned} &E\langle M(\widehat{X}_T - \xi), \widehat{X}_T\rangle + E\int_0^T [\langle Q_t(\widehat{X}_t - q_t), \widehat{X}_t\rangle + \langle N_t \widehat{u}_t, \widehat{u}_t\rangle]\, dt \\ &\quad = E\int_0^T \left[\langle y_t, f_t\rangle + \sum_{i=1}^d \langle z_i(t), g_i(t)\rangle \right] dt + \langle y_0, x\rangle. \end{aligned}$$

Therefore, in view of assumptions (A6)′ and (A5),

$$\begin{aligned}\delta E|\widehat{X}_T|^2 &\le E\langle M\widehat{X}_T,\widehat{X}_T\rangle\\ &\le E\langle M\xi,\widehat{X}_T\rangle + E\int_0^T \langle Q_t q_t,\widehat{X}_t\rangle\,dt\\ &\quad + E\int_0^T \left[\langle y_t,f_t\rangle + \sum_{i=1}^d \langle z_i(t),g_i(t)\rangle\right] dt + \langle y_0,x\rangle.\end{aligned} \tag{3.10}$$

Using Cauchy's inequality, in view of (3.8), we have

$$\begin{aligned}\delta E|\widehat{X}_T|^2 &\le \frac{1}{2\varepsilon}E|M\xi|^2 + \frac{\varepsilon}{2}E|\widehat{X}_T|^2 + E\int_0^T \left(\frac{1}{2\varepsilon}|Q_t q_t|^2 + \frac{\varepsilon}{2}|\widehat{X}_t|^2\right) dt\\ &\quad + E\int_0^T \left[\frac{\varepsilon}{2}|y_t|^2 + \frac{1}{2\varepsilon}|f_t|^2 + \frac{\varepsilon}{2}|z(t)|^2 + \frac{1}{2\varepsilon}|g(t)|^2\right] dt + \frac{\varepsilon}{2}|y_0|^2 + \frac{1}{2\varepsilon}|x|^2\\ &\le \beta_\varepsilon\left[|x|^2 + E|\xi|^2 + E\int_0^T (|f_t|^2 + |g(t)|^2 + |q_t|^2)\,dt\right]\\ &\quad + \frac{\varepsilon}{2}(\beta T + \beta + 1)\left[E|\widehat{X}_T|^2 + E\int_0^T |\widehat{X}_t|^2\,dt\right]\end{aligned} \tag{3.11}$$

for arbitrarily small positive number ε and a positive real number β_ε. In view of Lemma 2.2, we conclude from the last inequality that for sufficiently small $\varepsilon > 0$ and another positive real number β'_ε

$$E|\widehat{X}_T|^2 \le \beta'_\varepsilon\left[|x|^2 + E|\xi|^2 + E\int_0^T (|f_t|^2 + |g(t)|^2 + |q_t|^2)\,dt\right]. \tag{3.12}$$

Again noting Lemma 2.2 and the estimate (3.8), we get the desired estimate (3.7). □

3.3. The BMO-martingale. In this subsection, we prove some properties for a BMO-martingale, which will be used in the next two subsections.

DEFINITION 3.6. *A $\{\mathcal{F}_t, 0 \le t \le T\}$-martingale $\{\mathcal{M}_t, 0 \le t \le T\}$ is called a BMO-martingale if there is a deterministic positive constant β such that for every stopping time $\tau \le T$,*

$$E^{\mathcal{F}_\tau}|\mathcal{M}_T - \mathcal{M}_\tau|^2 \le \beta \quad a.s. \tag{3.13}$$

A BMO-martingale has the following nice properties, which will be used in the next two subsections.

LEMMA 3.7. *Assume that $\int_0^\cdot \langle Y, dw\rangle \in L^2(\Omega,\mathcal{F}_T,P)$ is a BMO-martingale. Then, we have the following:*

(i) *If $X_1(t) = X_1(0) + \int_0^t x_1(s)\,ds$, where x_1 is $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted such that $\int_0^\cdot |x_1|\,ds \in L^2(\Omega,\mathcal{F}_T,P)$, then $YX_1 \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$. Moreover, there is a positive constant β_Y depending on Y while independent of X_1 such that*

$$E\int_0^T |YX_1|^2\,ds \le \beta_Y\left(E|X_1(0)|^2 + E|\int_0^T |x_1|\,ds|^2\right). \tag{3.14}$$

(ii) *If* $X_2(t) = X_2(0) + \int_0^t \langle x_2(s), dw(s)\rangle$, *where* $x_2 \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$, *then* $X_2 Y \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$. *Moreover, there is a positive constant* β_Y *depending on* Y *while independent of* X_2 *such that*

$$E\int_0^T |YX_2|^2\,ds \le \beta_Y\left(E|X_2(0)|^2 + E\int_0^T |x_2|^2\,ds\right). \tag{3.15}$$

(iii) *If* $X(t) := X(0) + \int_0^t x_1(s)\,ds + \int_0^t \langle x_2(s), dw(s)\rangle$ *such that* x_1 *is* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted satisfying* $\int_0^{\cdot} |x_1|\,ds \in L^2(\Omega,\mathcal{F}_T,P)$ *and* $x_2 \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$, *then* $YX \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$. *Moreover, there is a positive constant* β_Y *depending on* Y *while independent of* X *such that*

$$E\int_0^T |YX|^2\,ds \le \beta_Y\left(E|X(0)|^2 + E\int_0^T |x_2|^2\,ds + E\left|\int_0^T |x_1|\,ds\right|^2\right). \tag{3.16}$$

Proof. Assertion (iii) is a combination of assertions (i) and (ii). It follows directly from Bañuelos and Bennett [1, Theorem 1.1(i)] that $\int_0^T X_2(t)\langle Y_t, dw(t)\rangle$ is square-integrable and assertion (ii) then follows. It remains to prove assertion (i).

Define for $k = 1, 2, \ldots,$

$$\tau_k = \inf\left\{s \in [0,T] : \int_0^s |x_1(r)|\,dr \ge k\right\}$$

with $\tau_k = \infty$ if the underlying set is empty. Then, $\tau_k, k = 1, 2, \ldots,$ are stopping times. Denote by χ an indicator function. We have $YX_1\chi_{[0,\tau_k]} \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$ for $k = 1, 2, \ldots.$ In view of Fatou's lemma, it is sufficient to prove that the quantity $E\int_0^T |YX_1|^2\chi_{[0,\tau_k]}\,ds = E\int_0^{T_k} |YX_1|^2\,ds$ is uniformly bounded with respect to k with $T_k := T \wedge \tau_k$.

For all $a \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$, since $\int_0^{\cdot} |\langle Y, a\rangle|\,ds$ is the quadratic variation of the BMO-martingale $\int_0^{\cdot}\langle Y, dw\rangle$ and the square-integrable martingale $\int_0^{\cdot} \operatorname{sign}(\langle Y, a\rangle)\langle a, dw\rangle$, we have from Bañuelos and Bennett [1, Theorem 1.1(iii)] that $\int_0^T |\langle Y, a\rangle|\,ds \in L^2(\Omega,\mathcal{F}_T,P)$ and, moreover,

$$\left\|\int_0^T |\langle Y, a\rangle|\,ds\right\|_{L^2(\Omega,\mathcal{F}_T,P)} \le \beta\|a\|_{\mathcal{L}^2_{\mathcal{F}}(0,T;R^d)}. \tag{3.17}$$

Therefore,

$$\begin{aligned}
E\int_0^{T_k} \langle X_1 Y, a\rangle\,ds &= E\left\{\int_0^{T_k} X_1(t)\,d\int_0^t \langle Y_s, a_s\rangle\,ds\right\}\\
&= E\left\{X_1(T_k)\int_0^{T_k}\langle Y_s, a_s\rangle\,ds\right\} + E\left\{\int_0^{T_k} x_1(t)\int_0^t \langle Y_s, a_s\rangle\,ds\,dt\right\}\\
&\le E\left\{\left(|X_1(0)| + \int_0^T |x_1|\,ds\right)\int_0^T |\langle Y_s, a_s\rangle|\,ds\right\}\\
&\quad + E\left\{\int_0^T |\langle Y_s, a_s\rangle|\,ds\int_0^T |x_1|\,dt\right\}.
\end{aligned} \tag{3.18}$$

Using the Cauchy–Schwarz inequality, we have

$$
\begin{aligned}
&E\int_0^{T_k}\langle X_1 Y, a\rangle\,ds\\
&\quad\le \left\|\left(|X_1(0)|+\int_0^T |x_1|\,ds\right)\right\|_{L^2(\Omega,\mathcal{F}_T,P)} \left\|\int_0^T |\langle Y_s,a_s\rangle|\,ds\right\|_{L^2(\Omega,\mathcal{F}_T,P)}\\
&\qquad+\left\|\int_0^T |\langle Y_s,a_s\rangle|\,ds\right\|_{L^2(\Omega,\mathcal{F}_T,P)} \left\|\int_0^T |x_1|\,dt\right\|_{L^2(\Omega,\mathcal{F}_T,P)}\\
&\quad\le 2\left\|\left(|X_1(0)|+\int_0^T |x_1|\,ds\right)\right\|_{L^2(\Omega,\mathcal{F}_T,P)} \beta\|a\|_{\mathcal{L}^2_{\mathcal{F}}(0,T;R^d)}.
\end{aligned}
\tag{3.19}
$$

This implies that

$$
\left(E\int_0^{T_k}|YX_1|^2\,ds\right)^{1/2}\le 2\beta\left\|\left(|X_1(0)|+\int_0^T|x_1|\,ds\right)\right\|_{L^2(\Omega,\mathcal{F}_T,P)}. \qquad \square \tag{3.20}
$$

We refer the reader to Kazamaki [17] for further information on BMO-martingales.

3.4. Connection with two BSDEs. Define $\Gamma : [0,T]\times \mathcal{S}^n_+ \times R^{n\times d}\to R^{m\times n}$ by

$$
\Gamma(\cdot,S,L)=-\left(N+\sum_{i=1}^d D_i^*SD_i\right)^{-1}\left(B^*S+\sum_{i=1}^d D_i^*SC_i+\sum_{i=1}^d D_i^*L_i\right) \tag{3.21}
$$

and

$$
\widehat{A}:=A+B\Gamma(\cdot,K,L),\quad \widehat{C}_i:=C_i+D_i\Gamma(\cdot,K,L),\quad i=1,\dots,d. \tag{3.22}
$$

Observe that the function Γ also depends upon the coefficients B, C, D, and N. Occasionally in the following, we shall write $\Gamma(t,S,L;N)$ to indicate the dependence on N.

The optimal control and the value function of the LQ problem will be explicitly connected to the two BSDEs:

$$
\begin{cases}
dK_t=-\Bigg[A^*K_t+K_tA+\displaystyle\sum_{i=1}^d C_i^*K_tC_i+Q\\
\qquad\qquad+\displaystyle\sum_{i=1}^d (C_i^*L_i(t)+L_i(t)C_i)\\
\qquad\qquad-\Gamma(t,K_t,L(t))\left(N+\displaystyle\sum_{i=1}^d D_i^*K_tD_i\right)\Gamma(t,K_t,L(t))\Bigg)^*\Bigg]\,dt\\
\qquad\qquad+\displaystyle\sum_{i=1}^d L_i(t)\,dw_i(t),\qquad 0\le t<T,\\
K_T=M
\end{cases}
\tag{3.23}
$$

and

$$\begin{cases} d\psi_t = -\left[\widehat{A}^*\psi_t + \sum_{i=1}^d \widehat{C}_i^*(\phi_i - Kg_i) \right. \\ \qquad\qquad \left. - Kf - \sum_{i=1}^d L_i g_i + Qq\right] dt + \sum_{i=1}^d \phi_i\, dw_i, \\ \psi_T = M\xi, \end{cases} \tag{3.24}$$

where (K, L) is an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution of BSRDE (3.23). More precisely, we have the following theorem.

THEOREM 3.8. (i) *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A7) *be satisfied.* (ii) *Let* (K, L) *be an* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution of BSRDE* (3.23) *with* $K \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; S^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; S^n_+))$, $L \in (\mathcal{L}^2_{\mathcal{F}}(0, T; S^n))^d$, *and* K *being uniformly positive.* (iii) *Let* (ψ, ϕ) *be an* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution of BSDE* (3.24) *such that* $E \sup_{0\le t\le T} |\psi_t|^2 < \infty$ *and* $\phi \in (\mathcal{L}^2_{\mathcal{F}}(0, T; R^n))^d$.

Then the optimal control $\widehat{u}$ *exists uniquely with the feedback law*

$$\widehat{u} = \Gamma(\cdot; K, L)\widehat{X} + u^0, \tag{3.25}$$

where $\widehat{X} := X^{t,x;\widehat{u}}$ *and the functions* Γ *and* u^0 *are defined, respectively, by* (3.21) *and*

$$u^0 := \left(N + \sum_{i=1}^d D_i^* K D_i\right)^{-1} \left[B^*\psi + \sum_{i=1}^d D_i^*(\phi_i - Kg_i)\right], \quad t \le s \le T. \tag{3.26}$$

The value function $V(t, x), (t, x) \in [0, T] \times R^n$ *is given by*

$$V(t, x) = \langle K_t x, x\rangle - 2\langle \psi_t, x\rangle + V^0(t), \quad (t, x) \in [0, T] \times R^n, \tag{3.27}$$

where $V^0(t)$ *is defined by*

$$\begin{aligned} V^0(t) := {} & E^{\mathcal{F}_t}\langle M\xi, \xi\rangle + E^{\mathcal{F}_t}\int_t^T \langle Qq, q\rangle\, ds - 2E^{\mathcal{F}_t}\int_t^T \langle \psi, f\rangle\, ds \\ & + E^{\mathcal{F}_t}\int_t^T \sum_{i=1}^d [\langle Kg_i, g_i\rangle - 2\langle \phi_i, g_i\rangle]\, ds \\ & - E^{\mathcal{F}_t}\int_t^T \left\langle \left(N + \sum_{i=1}^d D_i^* K D_i\right) u^0, u^0 \right\rangle ds. \end{aligned} \tag{3.28}$$

Note that in view of the assumptions on the integrability of (K, L) and (ψ, ϕ), all the integrals appearing in the formulas are well defined.

Our proof of Theorem 3.8 requires the following BMO-property for BSRDE (3.23).

THEOREM 3.9. *Let assumptions* (A1) *and* (A5) *be satisfied. If* (K, L) *is an* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution of BSRDE* (3.23) *such that* $K \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; S^n_+)$, $L := (L_1, \dots, L_d) \in (\mathcal{L}^2_{\mathcal{F}}(0, T; S^n))^d$, *and* $(N + \sum_{i=1}^d D_i^* K D_i)$ *is uniformly positive, then* $\int_0^\cdot \sum_{i=1}^d L_i(s)\, dw_i(s)$ *is a BMO-martingale.*

The proof can be reduced to proving the following fact: there is a deterministic positive real number β such that for any stopping time τ

$$E^{\mathcal{F}_\tau}\int_\tau^T |L_s|^2\, ds \le \beta. \tag{3.29}$$

It is an a priori estimate for the second component L of any $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution (K, L) of BSRDE (3.23), but it involves stopping times. The reader is referred to Kohlmann and Tang [21] for further details of the proof.

In general, the martingale $\mathcal{M} =: \int_0^{\cdot} \sum_{i=1}^d L_i(s)\, dw_i(s)$ and L are not necessarily bounded. However, Theorem 3.9 states that any moment of the absolute increment $|\mathcal{M}_T - \mathcal{M}_\tau|$ has a bounded expectation conditioned on $\mathcal{F}_\tau$ uniformly with respect to any stopping time τ. Roughly speaking, Theorem 3.9 implies that the integrand L of the stochastic integral $\mathcal{M}$ is bounded in a sense of some mean values.

The following lemma will also be used in our proof of Theorem 3.8.

LEMMA 3.10. *Let all the assumptions of Theorem* 3.8 *be satisfied. Let u be an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted m-dimensional process such that $\int_0^T |u_s|^2\, ds < \infty$ a.s. and $X := X^{t,x;u}$. Define for $k = 1, 2, \ldots,$*

$$\tau_k = \inf\left\{ s \in [t,T] : \int_t^s |u_r|^2\, dr \ge k, \int_t^s |L(r)|^2\, dr \ge k, |X_s| \ge k, |\psi_s| \ge k \right\}$$

and $\tau_k = \infty$ if the underlying set is empty. Also define

$$T_k := T \wedge \tau_k, \quad k = 1, 2, \ldots.$$

Then,

$$\begin{aligned}
&E^{\mathcal{F}_t}[\langle K_{T_k} X_{T_k}, X_{T_k}\rangle - 2\langle \psi_{T_k}, X_{T_k}\rangle + \langle M\xi, \xi\rangle] \\
&\quad + E^{\mathcal{F}_t}\left[\int_t^{T_k} \langle Q(X-q), X-q\rangle\, ds + \int_t^{T_k} \langle Nu, u\rangle\, ds\right] \\
&= \langle K_t x, x\rangle - 2\langle \psi_t, x\rangle + E^{\mathcal{F}_t}\left[\langle M\xi, \xi\rangle + \int_t^{T_k} \langle Qq, q\rangle\, ds\right] \\
&\quad - 2E^{\mathcal{F}_t}\int_t^{T_k} \langle \psi, f\rangle\, ds + E^{\mathcal{F}_t}\int_t^{T_k} \sum_{i=1}^d [\langle K g_i, g_i\rangle - 2\langle \phi_i, g_i\rangle]\, ds \\
&\quad + E^{\mathcal{F}_t}\int_t^{T_k} \left\langle \left(N + \sum_{i=1}^d D_i^* K D_i\right)(\widetilde{u} - u^0), \widetilde{u} - u^0 \right\rangle ds \\
&\quad - E^{\mathcal{F}_t}\int_t^{T_k} \left\langle \left(N + \sum_{i=1}^d D_i^* K D_i\right) u^0, u^0 \right\rangle ds.
\end{aligned} \tag{3.30}$$

The proof is a straightforward adaptation of Yong and Zhou [35, pp. 315–317] in the case of constant coefficients to our case.

Now let us prove Theorem 3.8.

Proof. In what follows, we shall show that the control $\widehat{u}$ given by (3.25) is square-integrable.

First, it is well defined. To see this, putting it into system (2.1), we get

$$\begin{cases} d\widehat{X} = (\widehat{A}\widehat{X} + Bu^0 + f)\, ds + \sum_{i=1}^d (\widehat{C}_i \widehat{X} + D_i u^0 + g_i)\, dw_i, \ t < s \le T, \\ \widehat{X}_t = x. \end{cases} \tag{3.31}$$

Note that u^0, f, g are all square-integrable. The system (3.31) has a unique strong solution (see Gal'chuk [15]), simply denoted by $\widehat{X}$. Therefore, $\widehat{u}$ is well defined. However, it is not yet clear that it is square-integrable.

We now show that $\widehat{u}$ is square-integrable. Proceeding identically as in Lemma 3.10, we define the stopping times T_k, which are associated with $\widehat{u}$, and obtain the following:

$$\begin{aligned}
&E^{\mathcal{F}_t}[\langle K_{T_k}\widehat{X}_{T_k},\widehat{X}_{T_k}\rangle - 2\langle\psi_{T_k},\widehat{X}_{T_k}\rangle + \langle M\xi,\xi\rangle] \\
&+ E^{\mathcal{F}_t}\left[\int_t^{T_k}\langle Q(\widehat{X}-q),\widehat{X}-q\rangle\,ds + \int_t^{T_k}\langle N\widehat{u},\widehat{u}\rangle\,ds\right] \\
&= \langle K_t x,x\rangle - 2\langle\psi_t,x\rangle + E^{\mathcal{F}_t}\left[\langle M\xi,\xi\rangle + \int_t^{T_k}\langle Qq,q\rangle\,ds\right] \\
&- 2E^{\mathcal{F}_t}\int_t^{T_k}\langle\psi,f\rangle\,ds + E^{\mathcal{F}_t}\int_t^{T_k}\sum_{i=1}^{d}[\langle Kg_i,g_i\rangle - 2\langle\phi_i,g_i\rangle]\,ds \\
&- E^{\mathcal{F}_t}\int_t^{T_k}\left\langle\left(N+\sum_{i=1}^{d}D_i^*KD_i\right)u^0,u^0\right\rangle\,ds.
\end{aligned} \tag{3.32}$$

This equality is the basis of the subsequent analysis.

Note that K is uniformly positive, i.e., there is a deterministic positive real number γ such that $K \geq \gamma I_{n\times n}$ a.s.a.e. Therefore, we have

$$\begin{aligned}
&\langle K_{T_k}\widehat{X}_{T_k},\widehat{X}_{T_k}\rangle - 2\langle\psi_{T_k},\widehat{X}_{T_k}\rangle \\
&\geq \gamma|\widehat{X}_{T_k}|^2 - \left(\frac{\gamma}{2}|\widehat{X}_{T_k}|^2 + \frac{2}{\gamma}|\psi_{T_k}|^2\right) \\
&= \frac{\gamma}{2}|\widehat{X}_{T_k}|^2 - \frac{2}{\gamma}|\psi_{T_k}|^2.
\end{aligned} \tag{3.33}$$

Noting the equality (3.32) and the fact that $Q \geq 0$ and $N \geq 0$, we get

$$\begin{aligned}
&E^{\mathcal{F}_t}\left[\frac{\gamma}{2}|\widehat{X}_{T_k}|^2 - \frac{2}{\gamma}|\psi_{T_k}|^2\right] \\
&\leq \langle K_t x,x\rangle - 2\langle\psi_t,x\rangle + E^{\mathcal{F}_t}\int_t^{T_k}\langle Qq,q\rangle\,ds \\
&-2E^{\mathcal{F}_t}\int_t^{T_k}\langle\psi,f\rangle\,ds + E^{\mathcal{F}_t}\int_t^{T_k}\sum_{i=1}^{d}[\langle Kg_i,g_i\rangle - 2\langle\phi_i,g_i\rangle]\,ds.
\end{aligned} \tag{3.34}$$

Applying Lemma 2.2 for $p=2$, we have

$$\begin{aligned}
&E^{\mathcal{F}_t}\int_t^{T_k}|\widehat{u}_s|^2\,ds + E^{\mathcal{F}_t}\sup_{t\leq s\leq T_k}|\widehat{X}_s|^2 \\
&\leq \beta_{\delta,T}E^{\mathcal{F}_t}\left\{|\widehat{X}_{T_k}|^2 + \int_t^{T_k}|f_s|^2\,ds + \int_t^{T_k}|g(s)|^2\,ds\right\} \\
&\leq \frac{2\beta_{\delta,T}}{\gamma}E^{\mathcal{F}_t}\left\{\frac{2}{\gamma}|\psi_{T_k}|^2 + \langle K_t x,x\rangle - 2\langle\psi_t,x\rangle + \int_t^{T_k}\langle Qq,q\rangle\,ds\right\} \\
&-\frac{2\beta_{\delta,T}}{\gamma}E^{\mathcal{F}_t}\left\{2\int_t^{T_k}\langle\psi,f\rangle\,ds - \int_t^{T_k}\sum_{i=1}^{d}[\langle Kg_i,g_i\rangle - 2\langle\phi_i,g_i\rangle]\,ds\right\} \\
&+\beta_{\delta,T}E^{\mathcal{F}_t}\left\{\int_t^{T_k}|f_s|^2\,ds + \int_t^{T_k}|g(s)|^2\,ds\right\}.
\end{aligned} \tag{3.35}$$

Noting that

$$\lim_{k\to\infty}\tau_k=+\infty,\quad \lim_{k\to\infty}T_k=T\quad \text{a.s.},\tag{3.36}$$

and the fact that ψ is uniformly integrable, passing to the limit and applying Fatou's lemma, we have

$$\begin{aligned}
&E^{\mathcal{F}_t}\int_t^T|\widehat{u}_s|^2\,ds+E^{\mathcal{F}_t}\sup_{t\le s\le T}|\widehat{X}_s|^2\\
&\le\frac{2\beta_{\delta,T}}{\gamma}E^{\mathcal{F}_t}\left\{\frac{2}{\gamma}|\psi_T|^2+\langle K_tx,x\rangle-2\langle\psi_t,x\rangle+\int_t^T\langle Qq,q\rangle\,ds\right\}\\
&\quad-\frac{2\beta_{\delta,T}}{\gamma}E^{\mathcal{F}_t}\left\{2\int_t^T\langle\psi,f\rangle\,ds-\int_t^T\sum_{i=1}^d[\langle Kg_i,g_i\rangle-2\langle\phi_i,g_i\rangle]\,ds\right\}\\
&\quad+\beta_{\delta,T}E^{\mathcal{F}_t}\left\{\int_t^T|f_s|^2\,ds+\int_t^T|g(s)|^2\,ds\right\}.
\end{aligned}\tag{3.37}$$

In particular, take $t=0$, and we see that $\widehat{u}\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$.

Finally let us show that $\widehat{u}$ given by (3.25) is optimal and that the formula (3.27) holds. For every fixed $u\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$, since X is a semimartingale and $\int_0^{\cdot}\sum_{i=1}^d L_i\,dw_i$ is a BMO-martingale, then we deduce from Lemma 3.7 that $\widetilde{u}\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$. This is crucial in the following limiting arguments.

Note that ψ is uniformly square-integrable. X is uniformly square-integrable for every fixed $u\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$. Also note that $f,g:=(g_1,\dots,g_d)$, q are square-integrable, that K is uniformly bounded, $\phi:=(\phi_1,\dots,\phi_d)$, and u^0 are square-integrable. Then passing to the limit in (3.30), it follows from Lebesgue's dominated convergence theorem that for every $u\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$,

$$\begin{aligned}
J(u;t,x)&:=E^{\mathcal{F}_t}[\langle K_TX_T,X_T\rangle-2\langle\psi_T,X_T\rangle+\langle M\xi,\xi\rangle]\\
&\quad+E^{\mathcal{F}_t}\left[\int_t^T\langle Q(X-q),X-q\rangle\,ds+\int_t^T\langle Nu,u\rangle\,ds\right]\\
&=\langle K_tx,x\rangle-2\langle\psi_t,x\rangle+E^{\mathcal{F}_t}\left[\langle M\xi,\xi\rangle+\int_t^T\langle Qq,q\rangle\,ds\right]\\
&\quad-2E^{\mathcal{F}_t}\int_t^T\langle\psi,f\rangle\,ds+E^{\mathcal{F}_t}\int_t^T\sum_{i=1}^d[\langle Kg_i,g_i\rangle-2\langle\phi_i,g_i\rangle]\,ds\\
&\quad+E^{\mathcal{F}_t}\int_t^T\left\langle\left(N+\sum_{i=1}^d D_i^*KD_i\right)(\widetilde{u}-u^0),\widetilde{u}-u^0\right\rangle\,ds\\
&\quad-E^{\mathcal{F}_t}\int_t^T\left\langle\left(N+\sum_{i=1}^d D_i^*KD_i\right)u^0,u^0\right\rangle\,ds.
\end{aligned}\tag{3.38}$$

Since $\widehat{u}\in\mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$, we derive from the last equality that $\widehat{u}$ is optimal and the value function is given by (3.27). □

3.5. Solution of the two BSDEs.

3.5.1. The linear unbounded BSDE (3.24). Note that $\widehat{A}$ and $\widehat{C}$ depend on L in general, and thus they might not be uniformly bounded. In this case, we have no theorem to guarantee the existence and the uniqueness of an $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution, though BSDE (3.24) is linear.

We shall prove the following theorem.

THEOREM 3.11. *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A7) *be satisfied. Let* (K, L) *be an* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution of BSRDE* (3.23) *such that* $K \in \mathcal{L}^\infty_{\mathcal{F}}(0, T; S^n_+) \cap L^\infty(\Omega, \mathcal{F}_T, P; C([0, T]; S^n_+))$, $L \in (\mathcal{L}^2_{\mathcal{F}}(0, T; S^n_+))^d$, *and* K *is uniformly positive. Then, BSDE* (3.24) *has a unique* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted solution such that* $E \sup_{0\le t\le T} |\psi_t|^2 < \infty$ *and* $\phi \in (\mathcal{L}^2_{\mathcal{F}}(0, T; R^n))^d$. *Moreover, there is a deterministic positive constant* β *such that*

$$
\begin{aligned}
&E \sup_{0\le t\le T} |\psi_t|^2 + E \int_0^T |\phi(t)|^2 \, dt \\
&\quad \le \beta \left[E|\xi|^2 + E \int_0^T (|f_t|^2 + |g(t)|^2 + |q_t|^2) \, dt \right].
\end{aligned} \tag{3.39}
$$

Proof. From Theorem 2.6, the assumptions imply that there is a unique optimal control $\widehat{u} \in \mathcal{L}^2_{\mathcal{F}}(0, T; R^m)$. Let $x = 0$. From Theorem 3.4, it follows that there is a 4-tuple $(\widehat{X}, y, z, \widehat{u})$ such that (3.4), (3.5), and (3.6) are all satisfied. Using Itô's formula, we check out that the pair (ψ, ϕ) (with $\phi := (\phi_1, \dots, \phi_d)$) defined by

$$
\psi := K\widehat{X} - y, \ \phi_i := K(C_i\widehat{X} + D_i\widehat{u} + g_i) + L_i\widehat{X} - z_i \tag{3.40}
$$

solves BSDE (3.24).

Since K is uniformly positive, $N + \sum_{i=1}^d D_i^* K D_i$ is uniformly positive. From Theorem 3.9, it follows that $\int_0^\cdot \sum_{i=1}^d L_i(s) \, dw_i(s)$ is a BMO-martingale. From Lemma 3.7, it follows that $L_i\widehat{X} \in \mathcal{L}^2_{\mathcal{F}}(0, T; R^n)$ for $i = 1, \dots, d$. Therefore, $\phi \in (\mathcal{L}^2_{\mathcal{F}}(0, T; R^n))^d$.

Since K is uniformly bounded and $x = 0$, from (3.40) and Lemma 3.7(iii), we deduce

$$
\begin{aligned}
E \sup_{0\le t\le T} |\psi_t|^2 &\le \beta E \sup_{0\le t\le T} (|\widehat{X}_t|^2 + |y_t|^2), \\
E \int_0^T \sum_{i=1}^d |L_i\widehat{X}_t|^2 \, dt &\le \beta E \left| \int_0^T |A\widehat{X} + B\widehat{u} + f| \, dt \right|^2 \\
&\quad + \beta E \int_0^T \sum_{i=1}^d |C_i\widehat{X} + D_i\widehat{u} + g_i|^2 \, dt \\
&\le \beta E \int_0^T (|\widehat{X}| + |\widehat{u}|^2 + |f|^2 + |g|^2) \, dt, \\
E \int_0^T |\phi(t)|^2 \, dt &\le \beta E \int_0^T \sum_{i=1}^d |C_i\widehat{X} + D_i\widehat{u} + g_i - z_i|^2 \, dt \\
&\quad + \beta E \int_0^T \sum_{i=1}^d |L_i\widehat{X}_t|^2 \, dt \\
&\le \beta E \int_0^T (|\widehat{X}| + |\widehat{u}|^2 + |z|^2 + |f|^2 + |g|^2) \, dt.
\end{aligned} \tag{3.41}
$$

In view of Theorem 3.5 and the fact that $x = 0$, the desired estimate (3.39) is obtained.

Now it remains to show the uniqueness of adapted solutions for BSDE (3.24). Let $(\widetilde{\psi}, \widetilde{\phi})$ be any $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solution such that $E \sup_{0\le t\le T} |\widetilde{\psi}_t|^2 < \infty$ and $\widetilde{\phi} \in (\mathcal{L}^2_{\mathcal{F}}(0,T;R^n))^d$. Define

$$(3.42)\ \widetilde{y} := K\widehat{X} - \widetilde{\psi}, \quad \widetilde{z}_i := K(C_i\widehat{X} + D_i\widehat{u} + g_i) + L_i\widehat{X} - \widetilde{\phi}_i,\ \widetilde{z} := (\widetilde{z}_1, \dots, \widetilde{z}_d),$$

where $\widetilde{\phi}_i$ is the ith component of $\widetilde{\phi}$. Using Itô's formula, we can verify that $(\widetilde{y}, \widetilde{z})$ solves BSDE (3.4) in the sense of (3.5). According to the uniqueness of solutions of BSDE (3.4), we have $y = \widetilde{y}$ and $z = \widetilde{z}$. Therefore, in view of (3.40) and (3.42), we have $\psi = \widetilde{\psi}$ and $\phi = \widetilde{\phi}$. The desired uniqueness is proved. □

We remark that the square-integrability of ϕ is necessary for formulas (3.27) and (3.28) to make sense. (Note that $g \in (\mathcal{L}^2_{\mathcal{F}}(0,T;R^n))^d$.) In the above proof, it is far from being obvious, and it is derived from the BMO-property of $\int_0^{\cdot} \sum_{i=1}^d L_i\, dw_i(s)$.

3.5.2. BSRDE (3.23). We first give some historical comments.

When the coefficients A, B, C, D, M, Q, N are all deterministic, the second unknown variable L in BSRDE (3.23) can be taken to be zero. In this case, it reduces to an ordinary Riccati differential matrix equation, and the existence and uniqueness of its solution was proved by Wonham [36, 37] using Bellman's principle quasi linearization (see Bellman [2]) and a monotone argument. Also see Bismut [5] for a different approach.

The study concerning the case of random coefficients is dated back at least to Bismut [4, 6]. In the two papers, he derived the general form of BSRDE (3.23) starting from the stochastic maximum principle for the stochastic LQ problem. However, he could only treat a simple case in which the second unknown variable L does not appear in the nonlinear term of the drift. His method is to construct a contraction mapping. So, his method is quite different from Wonham's approach to the case of deterministic coefficients.

Later, Peng [27, 28] rediscovered the general form of BSRDE (3.23) starting from the dynamic programming principle and proved in the spirit of Wonham the existence and uniqueness result on BSRDE in the simple case.

The above-mentioned works are concerned only with the regular case, i.e., they make assumption (A6). For the singular case, i.e., under assumptions (A2) and (A6)′ instead of (A6), the study in the literature is concentrated on the case of deterministic coefficients: see Chen, Li, and Zhou [7], Kohlmann and Zhou [22], and Chen and Zhou [11] for a variety of results. Note also that Chen and Yong [8, 9, 10] contain a result on local solutions of BSRDEs in the case of random coefficients.

In the rest of this subsection, we shall first describe a general scheme to reduce BSRDE (3.23) in the singular case to the regular case, so that we can prove the existence and uniqueness result in the singular case from that in the regular case. Then, in view of Bismut and Peng's existence and uniqueness result on BSRDE (3.23) in the regular case, we derive from the above reduction scheme the counterpart in the singular case.

Throughout the rest of this subsection, we assume that $f = 0, g_i = 0, \xi = 0, q = 0$. We first describe the reduction scheme.

Consider a sequence of $m \times m$ uniformly positive, decreasing, symmetric matrix processes $\{N_k(t) : 0 \le t \le T\}_{k=1}^{\infty}$ of $\mathcal{L}^\infty(0,T;S^m)$ such that N_k converges to N strongly in $\mathcal{L}^\infty(0,T;S^m)$ as $k \to \infty$. Then consider the following perturbation of

BSRDE (3.23):

$$
\begin{cases}
dK^k = -\Bigg[A^*K^k + K^kA + \sum_{i=1}^d C_i^*K^kC_i + Q + \sum_{i=1}^d (C_i^*L_i^k + L_i^kC_i) \\
\qquad\qquad -\Gamma(t,K^k,L^k;N_k)\left(N_k + \sum_{i=1}^d D_i^*K^kD_i\right)\Gamma(t,K^k,L^k;N_k)^*\Bigg]\,dt \\
\qquad\quad + \sum_{i=1}^d L_i^k\,dw_i(t), \qquad 0 \le t < T, \\
K_T^k = M.
\end{cases} \tag{3.43}
$$

It is associated with the LQ problem, denoted by $\mathcal{P}_k$:

$$
\min_{u\in\mathcal{L}^2_{\mathcal{F}}(t,T;R^m)} J_k(u;t,x) \tag{3.44}
$$

with

$$
J_k(u;t,x) = E^{\mathcal{F}_t}\langle M\xi,\xi\rangle + E^{\mathcal{F}_t}\int_t^T (\langle Q_sX_s,X_s\rangle + \langle N_k(s)u_s,u_s\rangle)\,ds. \tag{3.45}
$$

The value function of problem $\mathcal{P}_k$ will be denoted by $V_k(t,x), (t,x)\in[0,T]\times R^n$.

We introduce the following assumption.

(A8) *If assumptions* (A1), (A2), (A5), *and* (A6)′ *are satisfied, then for each* $k = 1,2,\ldots$, *BSRDE* (3.43) *has a unique* $\{\mathcal{F}_t, 0\le t\le T\}$*-adapted solution* (K^k,L^k) *such that* $K^k\in\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+)\cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];S^n_+))$, K^k *is uniformly positive in* (t,ω), *and* $L^k\in(\mathcal{L}^2_{\mathcal{F}}(0,T;S^n))^d$.

We have the following theorem.

THEOREM 3.12. *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A8) *be satisfied. Then, BSRDE* (3.23) *has a unique* $\{\mathcal{F}_t, 0\le t\le T\}$*-adapted solution* (K,L) *such that*

$$
K\in\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+)\cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];S^n_+)) \quad\text{and}\quad L\in(\mathcal{L}^2_{\mathcal{F}}(0,T;S^n))^d.
$$

Moreover, $K(t,\omega)$ *is uniformly positive with respect to* (t,ω).

Proof. We develop a perturbation method.

Step 1. Note that if f,g,q,ξ are all zero objects, BSDE (3.24) associated with problem $\mathcal{P}_k$ has a unique zero solution. Assumption (A8) implies that BSRDE (3.43) has a unique $\{\mathcal{F}_t, 0\le t\le T\}$-adapted solution (K^k,L^k) such that $K^k\in\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+)$ and $L^k\in(\mathcal{L}^2_{\mathcal{F}}(0,T;S^n))^d$. Then, we conclude from Theorem 3.8 and the remarks in section 4 that problem $\mathcal{P}_k$ has a unique optimal control with the closed form:

$$
\widehat{u}^k := \Gamma(\cdot,K^k,L^k;N_k)\widehat{X}^k. \tag{3.46}
$$

The value function is

$$
V_k(t,x) := \langle K_t^kx,x\rangle. \tag{3.47}
$$

Moreover, we can show that $K_t^k(\omega)$ is uniformly positive in (t,ω,k), i.e., almost surely,

$$
K_t^k \ge \delta\beta_{\delta,T}^{-1}I_{n\times n} \quad \forall\, t\in[0,T]
$$

for a positive deterministic real number δ which is independent of k,t, and ω. Since $V_k(t,x) \le J_k(0;t,x) \le |x|^2\exp(\beta_1(T-t))$ for some positive constant β_1 which is

independent of k, K_t^k is also bounded from the above uniformly with respect to (t,ω,k): $K_t^k \le \exp(\beta_1 T) I_{n\times n}$.

In the next three steps, we show that the sequence $\{(K^k, L^k)\}_{k=1}^{\infty}$ converges to a limit (K,L) strongly in $\{\mathcal{L}_{\mathcal{F}}^{\infty}(0,T;S_+^n)\cap L^{\infty}(\Omega,\mathcal{F}_T,P;C([0,T];S_+^n))\}\times(\mathcal{L}_{\mathcal{F}}^{2}(0,T;S^n))^d$ with $K_t \ge \delta\beta_{\delta,T}^{-1} I_{n\times n}$.

Step 2. We shall prove in this step that for fixed $x\in R^n$, $V_k(t,x)$ converges to $V(t,x)$ strongly both in $\mathcal{L}_{\mathcal{F}}^{\infty}(0,T;R)$ and in $L^{\infty}(\Omega,\mathcal{F}_T,P;C([0,T];R))$.

Let $\widehat{u}$ be the optimal control of the original LQ problem, i.e., $V(t,x)=J(\widehat{u};t,x)$. Then,

$$\begin{aligned} V(t,x) &\le V_k(t,x) \le J_k(\widehat{u};t,x) \\ &= J(\widehat{u};t,x) + E^{\mathcal{F}_t}\int_t^T \langle (N_k-N)\widehat{u},\widehat{u}\rangle\, ds \\ &= V(t,x) + E^{\mathcal{F}_t}\int_t^T \langle (N_k-N)\widehat{u},\widehat{u}\rangle\, ds. \end{aligned} \tag{3.48}$$

Therefore,

$$\begin{aligned} |V_k(t,x)-V(t,x)| &\le E^{\mathcal{F}_t}\int_t^T \langle (N_k-N)\widehat{u},\widehat{u}\rangle\, ds \\ &\le \|N_k-N\|_{\mathcal{L}_{\mathcal{F}}^{\infty}} E^{\mathcal{F}_t}\int_t^T |\widehat{u}|^2\, ds. \end{aligned} \tag{3.49}$$

On the other hand, there is a constant $\beta_1>0$ such that

$$J(0;t,x) \le |x|^2 \exp(\beta_1(T-t)). \tag{3.50}$$

Noting the positivity of M and Lemma 3.2, we have

$$J(\widehat{u};t,x) \ge \delta E^{\mathcal{F}_t}|X_T^{t,x;\widehat{u}}|^2 \ge \delta\beta_{\delta,T}^{-1} E^{\mathcal{F}_t}\int_t^T |\widehat{u}_s|^2\, ds. \tag{3.51}$$

Since

$$J(\widehat{u};t,x) = V(t,x) \le J(0;t,x),$$

we have

$$\delta\beta_{\delta,T}^{-1} E^{\mathcal{F}_t}\int_t^T |\widehat{u}(s)|^2\, ds \le |x|^2 \exp(\beta_1(T-t)). \tag{3.52}$$

Concluding the above, we have

$$|V_k(t,x)-V(t,x)| \le \delta^{-1}\beta_{\delta,T}|x|^2 \exp(\beta_1(T-t))\|N_k-N\|_{\mathcal{L}_{\mathcal{F}}^{\infty}}.$$

This implies the desired result.

Step 3. From the preceding two steps, we conclude that the value function V has a quadratic expression. More precisely, there is an $\{\mathcal{F}_t, 0\le t\le T\}$-adapted stochastic process $K\in\mathcal{L}_{\mathcal{F}}^{\infty}(0,T;S_+^n)\cap L^{\infty}(\Omega,\mathcal{F}_T,P;C([0,T];S_+^n))$ such that

$$V(t,x) = \langle K_t x, x\rangle \quad \forall (t,x)\in[0,T]\times R^n \text{ a.s.} \tag{3.53}$$

Moreover, K^k converges to K strongly in the two spaces

$$\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+) \quad \text{and} \quad L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];S^n_+)),$$

and K is uniformly positive with respect to $(t,\omega)\in[0,T]\times\Omega : K_t \geq \delta\beta^{-1}_{\delta,T}I_{n\times n}$ (in view of Lemma 3.2).

Step 4. We shall prove that $\{L^k\}_{k=1}^\infty$ is a Cauchy sequence in $(\mathcal{L}^2_{\mathcal{F}}(0,T;S^n))^d$.

First, we show that $\{L^k\}_{k=1}^\infty$ is bounded in $\mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$. In view of BSRDE (3.43), use Itô's formula to compute $|K^k_t|^2$. Let $H(t,K,L)$ be the nonlinear term of the drift in (3.23). We observe that since $K^k\geq 0$, $H(\cdot,K^k,L^k)\leq 0$, we have

$$2\text{ tr }[K^kH(\cdot,K^k,L^k)] = 2\text{ tr }[(K^k)^{1/2}H(\cdot,K^k,L^k)(K^k)^{1/2}]\leq 0.$$

Therefore, this term can be left out in our subsequent arguments. Now it is standard to show that $\{L^k\}_{k=1}^\infty$ is bounded in $\mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$ (see Pardoux and Peng [26] and El Karoui, Peng, and Quenez [14], for example).

Now we show that $\{L^k\}_{k=1}^\infty$ is a Cauchy sequence in $\mathcal{L}^2_{\mathcal{F}}(0,T;R^d)$. For this purpose, use Itô's formula to compute $|K^k_t-K^l_t|^2$. We get the following:

$$\begin{aligned} &E|K^k_t-K^l_t|^2 + E\int_t^T |L^k(s)-L^l(s)|^2\,ds \\ &\quad = 2E\int_t^T \text{tr }\{(K^k_s-K^l_s)[\Delta_s(K^k_s-K^l_s,L^k(s)-L^l(s)) \\ &\qquad\qquad +H(s,K^k_s,L^k(s))-H(s,K^l_s,L^l(s))]\}\,ds, \end{aligned} \tag{3.54}$$

where the random matrix $\Delta_s(K,L)$ is defined for each triplet $(s,K,L)\in[0,T]\times S^n\times(S^n)^d$ by

$$\Delta_s(K,L) := A^*_sK + KA_s + \sum_{i=1}^d [C_i(s)^*L_i + C_i(s)^*KC_i(s) + L_iC_i(s)].$$

In view of assumption (A2) and the fact that K^k is uniformly bounded and uniformly positive (see Step 1), $(N_k+\sum_{i=1}^d D^*_iK^kD_i)^{-1}$ and $(N_l+\sum_{i=1}^d D^*_iK^lD_i)^{-1}$ are bounded uniformly in (k,l). Therefore the second integral in (3.54) is less than the product of $\|K^k-K^l\|_{\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+)}$ and

$$2E\int_0^T \left[(2|A|+|C|^2)|K^k-K^l| + 2|C||L^k-L^l| + |H(s,K^k,L^k)| + |H(s,K^l,L^l|\right]\,ds.$$

It is clear that the last quantity is less than a positive constant times the term $(1+\|K^k\|^2_{\mathcal{L}^\infty_{\mathcal{F}}}+\|K^l\|^2_{\mathcal{L}^\infty_{\mathcal{F}}}+\|L^k\|^2_{\mathcal{L}^2_{\mathcal{F}}}+\|L^l\|^2_{\mathcal{L}^2_{\mathcal{F}}})$, and it is thus bounded uniformly in (k,l) (since $\{(K^k,L^k)\}_{k=1}^\infty$ is bounded). Since

$$\lim_{k,l\to\infty}\|K_k-K_l\|_{\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+)}=0,$$

we conclude that the second integral in (3.54) converges to zero as k and l tend to ∞, and then we have the desired result.

Step 5. Let L be the limit in $(\mathcal{L}^2_{\mathcal{F}}(0,T;S^n))^d$ of the Cauchy sequence $\{L^k\}_{k=1}^\infty$. By Step 3, $K\in\mathcal{L}^\infty_{\mathcal{F}}(0,T;S^n_+)\cap L^\infty(\Omega,\mathcal{F}_T,P;C([0,T];S^n_+))$ is uniformly positive. Therefore, it is meaningful to take the limit in BSRDEs (3.43) by letting $k\to\infty$. As a result, (K,L) is shown to be an $\{\mathcal{F}_t, 0\leq t\leq T\}$-adapted solution to BSRDE (3.23).

Step 6. Finally, we show the uniqueness. It is a consequence of the representation (3.27). In fact, assume that (K, L) and $(\widetilde{K}, \widetilde{L})$ are two $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted solutions of BSRDE (3.23) with

$$K, \widetilde{K} \in \mathcal{L}^{\infty}_{\mathcal{F}}(0, T; S^n_+) \cap L^{\infty}(\Omega, \mathcal{F}_T, P; C([0, T]; S^n_+)) \quad \text{and} \quad L, \widetilde{L} \in (\mathcal{L}^2_{\mathcal{F}}(0, T; S^n))^d.$$

Then, we have

$$\begin{cases} d\delta K_s = -[\Delta_s(\delta K_s, \delta L(s)) + H(s, K_s, L(s)) - H(s, \widetilde{K}_s, \widetilde{L}(s))]\, ds \\ \qquad\qquad + \sum_{i=1}^{d} \langle \delta L_i(s), dw_i(s) \rangle, \\ \delta K_T = 0 \end{cases} \tag{3.55}$$

with $\delta K := K - \widetilde{K}$ and $\delta L := L - \widetilde{L}$. Moreover, in view of Theorem 3.8, the two symmetric $n \times n$ matrices K and $\widetilde{K}$ are uniformly positive. Therefore, in view of assumption (A2), both $(N + \sum_{i=1}^{d} D_i^* K D_i)^{-1}$ and $(N + \sum_{i=1}^{d} D_i^* \widetilde{K} D_i)^{-1}$ are bounded though the uniform positivity of the matrix N is not guaranteed (the nonnegativity is sufficient!). The two *difficult* terms $H(t, K_t, L(t))$ and $H(t, \widetilde{K}_t, \widetilde{L}(t))$—which appear in the drift of the last equation, distinct from $\Delta(\delta K, \delta L)$ due to the nonlinearity—are in $\mathcal{L}_{\mathcal{F}}(0, T; R^{n \times n})$. This integrability, together with the fact that $\delta K \in \mathcal{L}^{\infty}_{\mathcal{F}}(0, T; S^n)$, justify the following Itô's formula in its expected form:

$$\begin{aligned} &E|\delta K_0|^2 + E \int_0^T |\delta L|^2\, ds \\ &\quad = 2E \int_0^T \delta K_s [\Delta_s(\delta K_s, \delta L(s)) + H(s, K_s, L(s)) - H(s, \widetilde{K}_s, \widetilde{L}(s))]\, ds. \end{aligned} \tag{3.56}$$

Noting that K and $\widetilde{K}$ have the same representation (3.27), we have $V(t, x) = \langle Kx, x \rangle = \langle \widetilde{K} x, x \rangle$ for all $x \in R^n$, which implies $\delta K = 0$. Putting this equality into (3.56), we have $E \int_0^T |\delta L|^2\, ds = 0$. This implies that $L = \widetilde{L}$. □

In what follows, we address a case in which assumption (A8) is true automatically.

To avoid the appearance of L in the nonlinear term of the drift, Bismut [6] and Peng [27] imposed the following assumption.

(A9) Let the nonnegative integer $d_0 \le d$. Denote by $\{\mathcal{G}_t, 0 \le t \le T\}$ the P-augmented natural filtration generated by the $(d - d_0)$-dimensional Brownian motion $(w_{d_0+1}, \ldots, w_d)$. Let the matrix-valued processes A, B, C, D, M, Q, N be $\{\mathcal{G}_t, 0 \le t \le T\}$-progressively measurable. The matrix-valued random variable M is $\mathcal{G}_T$-measurable. $D_{d_0+1} = \cdots = D_d = 0$.

Under assumption (A9), BSRDE (3.23) reduces to

$$\begin{cases} dK_t = -\Bigg[A^* K_t + K_t A + \sum_{i=1}^{d} C_i^* K_t C_i + Q \\ \qquad + \sum_{i=d_0+1}^{d} (C_i^* L_i(t) + L_i(t) C_i) - \left(K_t B + \sum_{i=1}^{d} C_i^* K_t D_i \right) \\ \qquad \times \left(N + \sum_{i=1}^{d_0} D_i^* K_t D_i \right)^{-1} \left(K_t B + \sum_{i=1}^{d} C_i^* K_t D_i \right)^* \Bigg]\, dt \\ \qquad + \sum_{i=d_0+1}^{d} L_i(t)\, dw_i(t), \qquad 0 \le t < T, \\ K_T = M. \end{cases} \tag{3.57}$$

The above Riccati equation is easier, for the second unknown variable L appears in the drift in a linear way.

Bismut [6] and Peng [27] showed that assumption (A8) is true if assumption (A9) is satisfied. According to Theorem 3.12, we obtain immediately the following theorem.

THEOREM 3.13. *Let assumptions* (A1), (A2), (A5), (A6)′, *and* (A9) *be satisfied. Then, BSRDE* (3.57) *has a unique* $\{\mathcal{G}_t, 0 \le t \le T\}$*-adapted solution* $(K; L_{d_0+1}, \dots, L_d)$ *such that* $K \in \mathcal{L}^{\infty}_{\mathcal{G}}(0,T;S^n_+) \cap L^{\infty}(\Omega, \mathcal{G}_T, P; C([0,T]; S^n_+))$ *and* $(L_{d_0+1}, \dots, L_d) \in (\mathcal{L}^2_{\mathcal{G}}(0,T;S^n))^{d-d_0}$. *Moreover,* $K(t,\omega)$ *is uniformly positive with respect to* (t,ω) *almost surely,* $K_t \ge \delta\beta^{-1}_{\delta,T} I_{n\times n}$, *for all* $t \in [0,T]$.

4. Concluding comments. In this paper, a new framework for the stochastic LQ problem is developed where the cost may be independent of the control variable and the coefficients are allowed to be random. In this setting, the two assumptions (A2) and (A6)′ play a crucial role. However, in Theorems 3.8 and 3.11, if both assumptions are replaced with assumption (A6) and the assumption that K is uniformly positive is removed, the assertions in both theorems are still true. To see this comment, it is sufficient to mention the following points.

In the regular case, $N + \sum_{i=1}^d D_i^* K D_i$ is still uniformly positive and $\int_0^{\cdot} \sum_{i=1}^d L_i\, dw_i$ is still a BMO-martingale (in view of Theorem 3.9).

In the regular case, to derive from the formula (3.32) the fact that $\widehat{u} \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$, it suffices to note the following points. We have for any deterministic constant $\alpha_1 > 0$,

$$
\begin{aligned}
&E^{\mathcal{F}_t}[\langle K_{T_k}\widehat{X}_{T_k}, \widehat{X}_{T_k}\rangle - 2\langle \psi_{T_k}, \widehat{X}_{T_k}\rangle] \\
&+ E^{\mathcal{F}_t}\left[\int_t^{T_k} \langle Q(\widehat{X}-q), \widehat{X}-q\rangle\, ds + \int_t^{T_k} \langle N\widehat{u}, \widehat{u}\rangle\, ds\right] \\
&\ge E^{\mathcal{F}_t}\left[-2\langle \psi_{T_k}, \widehat{X}_{T_k}\rangle + \int_t^{T_k} \langle N\widehat{u}, \widehat{u}\rangle\, ds\right] \\
&\ge E^{\mathcal{F}_t}\left[-\alpha_1^{-1}|\psi_{T_k}|^2 - \alpha_1 |\widehat{X}_{T_k}|^2 + \delta \int_t^{T_k} |\widehat{u}|^2\, ds\right].
\end{aligned} \tag{4.1}
$$

In view of Lemma 2.1, we have

$$
\begin{aligned}
&E^{\mathcal{F}_t}[\langle K_{T_k}\widehat{X}_{T_k}, \widehat{X}_{T_k}\rangle - 2\langle \psi_{T_k}, \widehat{X}_{T_k}\rangle] \\
&+E^{\mathcal{F}_t}\left[\int_t^{T_k} \langle Q(\widehat{X}-q), \widehat{X}-q\rangle\, ds + \int_t^{T_k} \langle N\widehat{u}, \widehat{u}\rangle\, ds\right] \\
\ge &E^{\mathcal{F}_t}\left[(\delta - \alpha_1\beta)\int_t^{T_k} |\widehat{u}|^2\, ds - \alpha_1^{-1}|\psi_{T_k}|^2 - \alpha_1\beta \int_t^{T_k} (T|f|^2 + |g|^2)\, ds - \alpha_1\beta |x|^2\right].
\end{aligned} \tag{4.2}
$$

We now choose a sufficiently small $\delta_1 > 0$, to say $\delta_1 = \frac{\delta}{2\beta}$, such that $\delta - \delta_1\beta > 0$. Then, combining (3.32) and (4.2), we conclude through the same limiting analysis as in the singular case that $\widehat{u} \in \mathcal{L}^2_{\mathcal{F}}(0,T;R^m)$.

The proof of Theorem 3.11 involves Theorem 3.5. However, in Theorem 3.5, the two assumptions (A2) and (A6)′ can be replaced with assumption (A6). To see this, it is enough to note the following. The formula (3.9) is still true. It implies the following:

$$\begin{aligned}\delta E\int_0^T |\widehat{u}_t|^2\,dt &\le E\int_0^T \langle N_t\widehat{u}_t,\widehat{u}_t\rangle\,dt\\ &\le E\int_0^T \left[\langle y_t,f_t\rangle+\sum_{i=1}^d\langle z_i(t),g_i(t)\rangle\right]dt+\langle y_0,x\rangle.\end{aligned}\tag{4.3}$$

In view of Lemma 2.1, we see that

$$\begin{aligned}E\sup_{0\le t\le T}|\widehat{X}_t|^2 &\le \frac{\beta}{\delta}\left(E\int_0^T\left[\langle y_t,f_t\rangle+\sum_{i=1}^d\langle z_i(t),g_i(t)\rangle\right]dt+\langle y_0,x\rangle\right)\\ &\quad+\beta\left(|x|^2+E\int_0^T(|f_t|^2+|g(t)|^2)\,dt\right).\end{aligned}\tag{4.4}$$

Then, combining the last inequality with (3.8), we have through a similar analysis as in the singular case the desired estimate (3.7).

Finally, we remark that the solution of BSRDE (3.23) in general is still left open in this paper. However, some subsequent works give new existence and uniqueness results on BSRDE (3.23). See, for instance, Kohlmann and Tang [18, 19, 20] and Lim and Zhou [23].

Note added in proof. The general existence and uniqueness for the solution of BSRDE (3.23) has been proved recently. The reader is referred to Tang [32, 33].

Acknowledgments. Both authors would like to thank the referees (especially the second referee) and the Associate Editor for their careful reading, critical comments, and helpful suggestions, which make the present version more readable.

ON ACTOR-CRITIC ALGORITHMS*

VIJAY R. KONDA† AND JOHN N. TSITSIKLIS†

Abstract. In this article, we propose and analyze a class of actor-critic algorithms. These are two-time-scale algorithms in which the critic uses temporal difference learning with a linearly parameterized approximation architecture, and the actor is updated in an approximate gradient direction, based on information provided by the critic. We show that the features for the critic should ideally span a subspace prescribed by the choice of parameterization of the actor. We study actor-critic algorithms for Markov decision processes with Polish state and action spaces. We state and prove two results regarding their convergence.

Key words. reinforcement learning, Markov decision processes, actor-critic algorithms, stochastic approximation

1. Introduction.

Many problems in finance, communication networks, operations research, and other fields can be formulated as dynamic programming problems. However, the dimension of the state space in these formulations is often too large for the problem to be tractable. Moreover, the underlying dynamics are seldom known and are often difficult to identify. Reinforcement learning and neuro-dynamic programming [5, 19] methods try to overcome these difficulties by combining simulation-based learning and compact representations of policies and value functions. The vast majority of these methods falls into one of the following two categories:

(a) Actor-only methods work with a parameterized family of policies. The gradient of the performance, with respect to the actor parameters, is directly estimated by simulation, and the parameters are updated in a direction of improvement [8, 10, 16, 23]. A possible drawback of such methods is that the gradient estimators may have a large variance. Furthermore, as the policy changes, a new gradient is estimated independently of past estimates. Hence, there is no "learning" in the sense of accumulation and consolidation of older information.

(b) Critic-only methods rely exclusively on value function approximation and aim at learning an approximate solution to the Bellman equation, which will then hopefully prescribe a near-optimal policy. Such methods are indirect in the sense that they do not try to optimize directly over a policy space. A method of this type may succeed in constructing a "good" approximation of the value function yet lack reliable guarantees in terms of near-optimality of the resulting policy.

Actor-critic methods [2] aim at combining the strong points of actor-only and critic-only methods. The critic uses an approximation architecture and simulation to learn a value function, which is then used to update the actor's policy parameters in a

direction of performance improvement. Such methods, as long as they are gradient-based, may have desirable convergence properties, in contrast to critic-only methods for which convergence is guaranteed in rather limited settings. They also hold the promise of delivering faster convergence (due to variance reduction) than actor-only methods. On the other hand, theoretical understanding of actor-critic methods has been limited to the case of lookup table representations of policies and value functions [12].

In this paper, we propose some actor-critic algorithms in which the critic uses linearly parameterized approximations of the value function, and we provide a convergence proof. The algorithms are based on the following important observation: since the number of parameters that the actor has to update is relatively small (compared to the number of states), the critic need not attempt to compute or approximate the exact value function, which is a high-dimensional object. In fact, we show that the critic should ideally compute a certain "projection" of the value function onto a low-dimensional subspace spanned by a set of "basis functions," which are *completely determined* by the parameterization of the actor. This key insight was also derived in simultaneous and independent work [20] that also included a discussion of certain actor-critic algorithms.

The outline of the paper is as follows. In section 2, we state a formula for the gradient of the average cost in a Markov decision process with finite state and action space. We provide a new interpretation of this formula, and use it in section 3 to derive our algorithms. In section 4, we consider Markov decision processes and the gradient of the average cost in much greater generality and describe the algorithms in this more general setting. In sections 5 and 6, we provide an analysis of the asymptotic behavior of the critic and actor, respectively. The appendix contains a general result concerning the tracking ability of linear stochastic iterations, which is used in section 5.

2. Markov decision processes and parameterized families of randomized stationary policies. Consider a Markov decision process with finite state space $\mathbb{X}$ and finite action space $\mathbb{U}$. Let $c : \mathbb{X} \times \mathbb{U} \to \mathbb{R}$ be a given one-stage cost function. Let $p(y|x,u)$ denote the probability that the next state is y, given that the current state is x and the current action is u. A *randomized stationary policy* (RSP) is a mapping μ that assigns to each state x a probability distribution over the action space $\mathbb{U}$. We consider a set of RSPs $\{\mu_\theta; \theta \in \mathbb{R}^n\}$, parameterized in terms of a vector θ. For each pair $(x,u) \in \mathbb{X} \times \mathbb{U}$, $\mu_\theta(u|x)$ denotes the probability of taking action u when the state x is encountered, under the policy corresponding to θ. Hereafter, we will not distinguish between the parameter of an RSP and the RSP itself. Therefore, whenever we refer to an "RSP θ," we mean the RSP corresponding to parameter vector θ. Note that, under any RSP, the sequence of states $\{X_k\}$ and the sequence of state-action pairs $\{X_k, U_k\}$ of the Markov decision process form Markov chains with state spaces $\mathbb{X}$ and $\mathbb{X} \times \mathbb{U}$, respectively. We make the following assumption about the family of policies.

Assumption 2.1 (finite case).

(a) For every $x \in \mathbb{X}$, $u \in \mathbb{U}$, and $\theta \in \mathbb{R}^n$, we have $\mu_\theta(u|x) > 0$.

(b) For every $(x,u) \in \mathbb{X} \times \mathbb{U}$, the mapping $\theta \mapsto \mu_\theta(u|x)$ is twice differentiable. Furthermore, the $\mathbb{R}^n$-valued function $\theta \to \nabla \ln \mu_\theta(u|x)$ is bounded and has a bounded first derivative, for any fixed x and u.*

*Throughout the paper, ∇ will stand for the gradient with respect to the vector θ.

(c) For every $\theta \in \mathbb{R}^n$, the Markov chains $\{X_k\}$ and $\{X_k, U_k\}$ are irreducible and aperiodic, with stationary probabilities $\pi_\theta(x)$ and $\eta_\theta(x,u) = \pi_\theta(x)\mu_\theta(u|x)$, respectively, under the RSP θ.

(d) There is a positive integer N, state $x^* \in \mathbb{X}$, and $\epsilon_0 > 0$ such that, for all $\theta_1, \ldots, \theta_N \in \mathbb{R}^n$,

$$\sum_{k=1}^{N} [P(\theta_1) \cdots P(\theta_k)]_{xx^*} \geq \epsilon_0 \qquad \forall x \in \mathbb{X},$$

where $P(\theta)$ denotes the transition probability matrix for the Markov chain $\{X_k\}$ under the RSP θ. (We use here the notation $[P]_{xx^*}$ to denote the (x, x^*) entry of a matrix P.)

The first three parts of the above assumption are natural and easy to verify. The fourth part assumes that the probability of reaching x^*, in a number of transitions that is independent of θ, is uniformly bounded away from zero. This assumption is satisfied if part (c) of the assumption holds, and the policy probabilities $\mu_\theta(u|x)$ are all bounded away from zero uniformly in θ (see [11]).

Consider the average cost function $\bar{\alpha} : \mathbb{R}^n \to \mathbb{R}$, defined by

$$\bar{\alpha}(\theta) = \sum_{x \in \mathbb{X}, u \in \mathbb{U}} c(x,u)\eta_\theta(x,u).$$

A natural approach to minimize $\bar{\alpha}(\theta)$ over RSPs θ is to start with a policy θ_0 and improve it using gradient descent. To do this, we will rely on a formula for $\nabla\bar{\alpha}(\theta)$ to be presented shortly.

For each $\theta \in \mathbb{R}^n$, let $V_\theta : \mathbb{X} \to \mathbb{R}$ be a "differential cost function," i.e., a solution of the Poisson equation:

$$\bar{\alpha}(\theta) + V_\theta(x) = \sum_u \mu_\theta(u|x) \left[c(x,u) + \sum_y p(y|x,u)V_\theta(y) \right].$$

Intuitively, $V_\theta(x)$ can be viewed as the "disadvantage" of state x: it is the expected future excess cost—on top of the average cost—incurred if we start at state x. It plays a role similar to that played by the more familiar value function that arises in total or discounted cost Markov decision problems. Finally, for every $\theta \in \mathbb{R}^n$, we define the Q-value function $Q_\theta : \mathbb{X} \times \mathbb{U} \to \mathbb{R}$ by

$$Q_\theta(x,u) = c(x,u) - \bar{\alpha}(\theta) + \sum_y p(y|x,u)V_\theta(y).$$

We recall the following result, as stated in [16]. (Such a result has been established in various forms in [7, 8, 10] and elsewhere.)

THEOREM 2.2. *We have*

$$\nabla\bar{\alpha}(\theta) = \sum_{x,u} \eta_\theta(x,u)Q_\theta(x,u)\psi_\theta(x,u), \tag{2.1}$$

where

$$\psi_\theta(x,u) = \nabla \ln \mu_\theta(u|x).$$

In [16], the quantity $Q_\theta(x,u)$ in the above formula is interpreted as the expected excess cost incurred over a certain renewal period of the Markov chain $\{X_n, U_n\}$, under the RSP μ_θ, and is then estimated by means of simulation, leading to actor-only algorithms. Here, we provide an alternative interpretation of the formula in Theorem 2.2, as an inner product, and arrive at a different set of algorithms.

For any $\theta \in \mathbb{R}^n$, we define the inner product $\langle \cdot, \cdot \rangle_\theta$ of two real-valued functions Q_1, Q_2 on $\mathbb{X} \times \mathbb{U}$, viewed as vectors in $\mathbb{R}^{|\mathbb{X}||\mathbb{U}|}$, by

$$\langle Q_1, Q_2 \rangle_\theta = \sum_{x,u} \eta_\theta(x,u) Q_1(x,u) Q_2(x,u).$$

(We will be using the above notation for vector- or matrix-valued functions as well.) With this notation, we can rewrite the formula (2.1) as

$$\frac{\partial}{\partial \theta_i} \bar{\alpha}(\theta) = \langle Q_\theta, \psi_\theta^i \rangle_\theta, \qquad i = 1, \ldots, n,$$

where ψ_θ^i stands for the ith component of ψ_θ. Let $\| \cdot \|_\theta$ denote the norm induced by this inner product on $\mathbb{R}^{|\mathbb{X}||\mathbb{U}|}$. For each $\theta \in \mathbb{R}^n$, let Ψ_θ denote the span of the vectors $\{\psi_\theta^i;\ 1 \le i \le n\}$ in $\mathbb{R}^{|\mathbb{X}||\mathbb{U}|}$.

An important observation is that although the gradient of $\bar{\alpha}$ depends on the function Q_θ, which is a vector in a possibly very high-dimensional space $\mathbb{R}^{|\mathbb{X}||\mathbb{U}|}$, the dependence is only through its inner products with vectors in Ψ_θ. Thus, instead of "learning" the function Q_θ, it suffices to learn its projection on the low-dimensional subspace Ψ_θ.

Indeed, let $\Pi_\theta : \mathbb{R}^{|\mathbb{X}||\mathbb{U}|} \mapsto \Psi_\theta$ be the projection operator defined by

$$\Pi_\theta Q = \arg \min_{\hat{Q} \in \Psi_\theta} \|Q - \hat{Q}\|_\theta.$$

Since

$$\langle Q_\theta, \psi_\theta^i \rangle_\theta = \langle \Pi_\theta Q_\theta, \psi_\theta^i \rangle_\theta, \qquad i = 1, \ldots, n, \tag{2.2}$$

it is enough to know the projection of Q_θ onto Ψ_θ to compute $\nabla \bar{\alpha}$.

3. Actor-critic algorithms. We view actor-critic algorithms as stochastic gradient algorithms on the parameter space of the actor. When the actor parameter vector is θ, the job of the critic is to compute an approximation of the projection $\Pi_\theta Q_\theta$, which is then used by the actor to update its policy in an approximate gradient direction. The analysis in [21, 22] shows that this is precisely what temporal difference (TD) learning algorithms try to do, i.e., to compute the projection of an exact value function onto a subspace spanned by feature vectors. This allows us to implement the critic by using a TD algorithm. (Note, however, that other types of critics are possible, e.g., based on batch solution of least squares problems, as long as they aim at computing the same projection.)

We note some minor differences with the common usage of TD. In our context, we need the projection of q-functions rather than value functions. But this is easily achieved by replacing the Markov chain $\{x_t\}$ in [21, 22] with the Markov chain $\{X_k, U_k\}$. A further difference is that [21, 22] assume that the decision policy and the feature vectors are fixed. In our algorithms, the decision policy as well as the features need to change as the actor updates its parameters. As suggested by the

results of [12, 6, 14], this need not pose any problems, as long as the actor parameters are updated on a slower time-scale.

We are now ready to describe two actor-critic algorithms, which differ only as far as the critic updates are concerned. In both variants, the critic is a TD algorithm with a linearly parameterized approximation architecture for the Q-value function, of the form

$$Q_\theta^r(x,u) = \sum_{j=1}^{m} r^j \phi_\theta^j(x,u),$$

where $r = (r^1, \ldots, r^m) \in \mathbb{R}^m$ denotes the parameter vector of the critic. The features ϕ_θ^j, $j = 1, \ldots, m$, used by the critic are dependent on the actor parameter vector θ and are chosen so that the following assumptions are satisfied.

Assumption 3.1 (critic features).

(a) For every $(x,u) \in \mathbb{X} \times \mathbb{U}$ the map $\theta \to \phi_\theta(x,u)$ is bounded and differentiable, with a bounded derivative.

(b) The span of the vectors ϕ_θ^j, $j = 1, \ldots, m$, in $\mathbb{R}^{|\mathbb{X}||\mathbb{U}|}$, denoted by Φ_θ, contains Ψ_θ.

Note that the formula (2.2) still holds if Π_θ is redefined as the projection onto Φ_θ, as long as Φ_θ contains Ψ_θ. The most straightforward choice would be to let the number m of critic parameters be equal to the number n of actor parameters, and $\phi_\theta^i = \psi_\theta^i$ for each i. Nevertheless, we allow the possibility that $m > n$ and that Φ_θ properly contains Ψ_θ, so that the critic can use more features than are actually necessary. This added flexibility may turn out to be useful in a number of ways:

(a) It is possible that for certain values of θ, the feature vectors ψ_θ^i are either close to zero or are almost linearly dependent. For these values of θ, the operator Π_θ becomes ill-conditioned, which can have a negative effect on the performance of the algorithms. This might be avoided by using a richer set of features ϕ_θ^i.

(b) For the second algorithm that we propose, which involves a TD(λ) critic with $\lambda < 1$, the critic can only compute an approximate—rather than exact—projection. The use of additional features can result in a reduction of the approximation error.

To avoid the above first possibility, we choose features for the critic so that our next assumption is satisfied. To understand that assumption, note that if the functions $\underline{1}$ and ϕ_θ^j, $j = 1, \ldots, m$, are linearly independent for each θ, then there exists a positive function $a(\theta)$ such that

$$||r'\hat{\phi}_\theta||_\theta^2 \geq a(\theta)|r|^2,$$

where $|r|$ is the Euclidean norm of r and $\hat{\phi}_\theta$ is the projection of ϕ_θ on the subspace orthogonal to the function $\underline{1}$. (Here and throughout the rest of the paper, $\underline{1}$ stands for a function which is identically equal to 1.) Our assumption below involves the stronger requirement that the function $a(\cdot)$ be uniformly bounded away from zero.

Assumption 3.2. There exists $a > 0$, such that for every $r \in \mathbb{R}^m$ and $\theta \in \mathbb{R}^n$

$$||r'\hat{\phi}_\theta||_\theta^2 \geq a|r|^2,$$

where

$$\hat{\phi}_\theta(x,u) = \phi_\theta(x,u) - \sum_{\bar{x},\bar{u}} \eta_\theta(\bar{x},\bar{u})\phi_\theta(\bar{x},\bar{u}).$$

Along with the parameter vector r, the critic stores some auxiliary parameters: a scalar estimate α of the average cost and an m-vector $\hat{Z}$ which represents Sutton's eligibility trace [5, 19]. The actor and critic updates take place in the course of a simulation of a single sample path of the Markov decision process. Let $r_k, \hat{Z}_k, \alpha_k$ be the parameters of the critic, and let θ_k be the parameter vector of the actor, at time k. Let $(\hat{X}_k, \hat{U}_k)$ be the state-action pair at that time. Let $\hat{X}_{k+1}$ be the new state, obtained after action $\hat{U}_k$ is applied. A new action $\hat{U}_{k+1}$ is generated according to the RSP corresponding to the actor parameter vector θ_k. The critic carries out an update similar to the average cost TD method of [22]:

$$\begin{aligned} \alpha_{k+1} &= \alpha_k + \gamma_k(c(\hat{X}_{k+1}, \hat{U}_{k+1}) - \alpha_k), \\ r_{k+1} &= r_k + \gamma_k d_k \hat{Z}_k, \end{aligned} \tag{3.1}$$

where the TD d_k is defined by

$$d_k = c(\hat{X}_k, \hat{U}_k) - \alpha_k + r_k' \phi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) - r_k' \phi_{\theta_k}(\hat{X}_k, \hat{U}_k),$$

and where γ_k is a positive step-size parameter. The two variants of the critic differ in their update of $\hat{Z}_k$, which is as follows.

TD(1) *critic.*

$$\begin{aligned} \hat{Z}_{k+1} &= \hat{Z}_k + \phi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) \qquad \text{if} \quad \hat{X}_{k+1} \neq x^* \\ &= \phi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) \qquad \text{otherwise,} \end{aligned}$$

where x^* is the special state introduced in Assumption 2.1.

TD(λ) *critic,* $0 < \lambda < 1$.

$$\hat{Z}_{k+1} = \lambda \hat{Z}_k + \phi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}).$$

Actor. Finally, the actor updates its parameter vector according to

$$\theta_{k+1} = \theta_k - \beta_k \Gamma(r_k) r_k' \phi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) \psi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}), \tag{3.2}$$

where $\Gamma(\cdot)$ is a scalar that controls the step-size β_k of the actor, taking into account the current estimate r_k of the critic.

Note that we have used $\hat{X}_k$, $\hat{U}_k$, and $\hat{Z}_k$ to denote the simulated processes in the above algorithm. Throughout the paper we will use hats to denote the simulated processes that are used to update the parameters in the algorithm, and X_k, U_k, and Z_k to denote processes in which a fixed RSP θ is used.

To understand the actor update, recall the formulas (2.1) and (2.2). According to these formulas, if the projection $\hat{Q}_\theta$ of Q_θ onto the subspace Φ_θ (which contains Ψ_θ) was known for the current value of $\theta \in \mathbb{R}^n$, then $\hat{Q}_{\theta_k}(\hat{X}_k, \hat{U}_k)\psi_{\theta_k}(\hat{X}_k, \hat{U}_k)$ would be a reasonable estimate of $\nabla \bar{\alpha}(\theta_k)$, because the steady-state expected value of the former is equal to the latter. However, $\hat{Q}_{\theta_k}(\hat{X}_k, \hat{U}_k)$ is not known, and it is natural to use in its place the critic's current estimate, which is $Q^{r_k}_{\theta_k}(\hat{X}_k, \hat{U}_k) = r_k' \phi_\theta(\hat{X}_k, \hat{U}_k)$. For the above scheme to converge, it is then important that the critic's estimate be accurate (at least asymptotically). This will indeed be established in section 5, under the following assumption on the step-sizes.

Assumption 3.3.

(a) The step-sizes β_k and γ_k are deterministic and nonincreasing and satisfy

$$\sum_k \beta_k = \sum_k \gamma_k = \infty,$$

$$\sum_k \beta_k^2 < \infty, \quad \sum_k \gamma_k^2 < \infty, \quad \text{and} \quad \sum_k \left(\frac{\beta_k}{\gamma_k}\right)^d < \infty$$

for some $d > 0$.

(b) The function $\Gamma(\cdot)$ is assumed to satisfy the following inequalities for some positive constants $C_1 < C_2$:

$$|r|\Gamma(r) \in [C_1, C_2] \quad \forall r \in \mathbb{R}^m,$$
$$|\Gamma(r) - \Gamma(\hat{r})| \leq \frac{C_2|r - \hat{r}|}{1 + |r| + |\hat{r}|} \quad \forall r, \hat{r} \in \mathbb{R}^n. \tag{3.3}$$

The following result on the convergence properties of the actor is established in section 6 in much greater generality.

THEOREM 3.4. *Under Assumptions* 2.1 *and* 3.1–3.3*, the following hold.*

(a) *In the actor-critic algorithm with a TD*(1) *critic,* $\liminf_k |\nabla\bar{\alpha}(\theta_k)| = 0$*, w.p.*1.

(b) *For each* $\epsilon > 0$*, there exists* λ *sufficiently close to* 1 *such that, in the actor-critic algorithm with a TD*(λ) *critic,* $\liminf_k |\nabla\bar{\alpha}(\theta_k)| < \epsilon$*, w.p.*1.

The algorithms introduced in this section are only two out of many possible variations. For instance, one can also consider "episodic" problems, in which one starts from a given initial state x^* and runs the process until a random termination time (at which time the process is reinitialized at x^*), with the objective of minimizing the expected total cost until termination. In this setting, the average cost estimate α_k is unnecessary and is removed from the critic update formula. If the critic parameter r_k were to be reinitialized each time that x^* is entered, one would obtain a method closely related to Williams's REINFORCE algorithm [23]. Such a method does not involve any value function learning, because the observations during one episode do not affect the critic parameter r during another episode. In contrast, in our approach, the observations from all past episodes affect the current critic parameter r, and in this sense, the critic is "learning." This can be advantageous because, as long as θ is changing slowly, the observations from recent episodes carry useful information on the Q-value function under the current policy.

The analysis of actor-critic methods for total and/or discounted cost problems is similar to (in fact, a little simpler than) that for the average cost case; see [20, 11].

4. Algorithms for Polish state and action spaces. In this section, we consider actor-critic algorithms for Markov decision processes with Polish (complete, separable, metric) state and action spaces. The algorithms are the same as for the case of finite state and action spaces and therefore will not be repeated in this section. However, we will restate our assumptions in the general setting, as the notation and the theory is quite technical. Throughout, we will use the abbreviation *w.p.*1 for the phrase *with probability* 1. We will denote norms on real Euclidean spaces with $|\cdot|$ and norms on Hilbert spaces by $||\cdot||$. For a probability measure ν and a ν-integrable function f, $\nu(f)$ will denote the expectation of f with respect to ν. Finally, for any Polish space $\mathbb{X}$, $\mathcal{B}(\mathbb{X})$ denotes its countably generated Borel σ-field.

4.1. Preliminaries. Consider a Markov decision process in which the state space $\mathbb{X}$ and the action space $\mathbb{U}$ are Polish spaces, and with a transition kernel $p(dy|x, u)$ which for every (x, u) defines a probability measure on $\mathbb{X}$. In the finite case, we had considered a parameterized family of randomized stationary policies (RSPs) described by a parameterized family of probability mass functions. Similarly, we now consider a family of parameterized RSPs specified by a parameterized family

of probability density functions. More specifically, let ν be a fixed measure on the action space $\mathbb{U}$. Let $\{\mu_\theta; \theta \in \mathbb{R}^n\}$ be a family of positive measurable functions on $\mathbb{X} \times \mathbb{U}$ such that for each $x \in \mathbb{X}$, $\mu_\theta(\cdot|x)$ is a probability density function with respect to $\nu(du)$, i.e.,

$$\int \mu_\theta(u|x)\nu(du) = 1 \quad \forall x, \theta.$$

This parameterized family of density functions can be viewed as a parameterized family of RSPs where, for each $\theta \in \mathbb{R}^n$, the probability distribution of an action at state x under RSP θ is given by $\mu_\theta(u|x)\nu(du)$.

Note that the state-action process $\{X_k, U_k\}$ of a Markov decision process controlled by any fixed RSP is a Markov chain. For each θ, let $\mathbf{P}_{\theta,x}$ denote the probability law of the state-action process $\{X_k, U_k\}$ in which the starting state X_0 is x. Let $\mathbf{E}_{\theta,x}$ denote expectation with respect to $\mathbf{P}_{\theta,x}$.

Assumption 4.1 (irreducibility and aperiodicity). For each $\theta \in \mathbb{R}^n$, the process $\{X_k\}$ controlled by RSP θ is irreducible and aperiodic.

For the details on the notion of irreducibility for general state space Markov chains, see [17]. Under Assumption 4.1, it follows from Theorem 5.2.2 of [17] that for each $\theta \in \mathbb{R}^n$, there exists a set of states $\mathbb{X}_0(\theta) \in \mathcal{B}(\mathbb{X})$, a positive integer $N(\theta)$, a constant $\delta_\theta > 0$, and a probability measure ϑ_θ on $\mathbb{X}$, such that $\vartheta_\theta(\mathbb{X}_0(\theta)) = 1$ and

$$\mathbf{P}_{\theta,x}(X_{N(\theta)} \in B) \geq \delta_\theta \vartheta_\theta(B) \qquad \forall \theta \in \mathbb{R}^n, \quad x \in \mathbb{X}_0(\theta), \quad B \in \mathcal{B}(\mathbb{X}).$$

We will now assume that such a condition holds uniformly in θ. This is one of the most restrictive of our assumptions. It corresponds to a "stochastic stability" condition, which holds uniformly over all policies.

Assumption 4.2 (uniform geometric ergodicity).

(a) There exists a positive integer N, a set $\mathbb{X}_0 \in \mathcal{B}(\mathbb{X})$, a constant $\delta > 0$, and a probability measure ϑ on $\mathbb{X}$, such that

$$\mathbf{P}_{\theta,x}(X_N \in B) \geq \delta \vartheta(B) \qquad \forall \theta \in \mathbb{R}^n, \quad x \in \mathbb{X}_0, \quad B \in \mathcal{B}(\mathbb{X}). \tag{4.1}$$

(b) There exists a function $L : \mathbb{X} \to [1, \infty)$ and constants $0 \leq \rho < 1$, $b > 0$, such that, for each $\theta \in \mathbb{R}^n$,

$$\mathbf{E}_{\theta,x}[L(X_1)] \leq \rho L(x) + b I_{\mathbb{X}_0}(x) \qquad \forall x \in \mathbb{X}, \tag{4.2}$$

where $I_{\mathbb{X}_0}(\cdot)$ is the indicator function of the set $\mathbb{X}_0$. We call a function L satisfying the above condition a stochastic Lyapunov function.

We note that in the finite case, Assumption 2.1(d) implies that Assumption 4.2 holds. Indeed, the first part of Assumption 4.2 is immediate, with $\mathbb{X}_0 = \{x^*\}$, $\delta_\theta = \epsilon_0$, and ϑ equal to a point mass at state x^*. To verify the second part, consider the first hitting time τ of the state x^*. For a sequence $\{\theta_k\}$ of values of the actor parameter, consider the time-varying Markov chain obtained by using policy θ_k at time k. For $s > 1$, consider the function

$$L(x) = \sup_{\{\theta_k\}} E\left[s^\tau \middle| X_0 = x \right].$$

Assumption 2.1(d) guarantees that $L(\cdot)$ is finite when s is sufficiently close to 1. Then it is a matter of simple algebraic calculations to see that $L(\cdot)$ satisfies (4.2).

Using geometric ergodicity results (Theorem 15.0.1) in [17], it can be shown that if Assumption 4.2 is satisfied, then for each $\theta \in \mathbb{R}^n$ the Markov chains $\{X_k\}$ and $\{X_k, U_k\}$ have steady-state distributions $\pi_\theta(dx)$ and

$$\eta_\theta(dx, du) = \pi_\theta(dx)\mu_\theta(u|x)\nu(du),$$

respectively. Moreover, the steady state is reached at a geometric rate (see Lemma 4.3 below). For any $\theta \in \mathbb{R}^n$, we will use $\langle \cdot, \cdot \rangle_\theta$ and $|| \cdot ||_\theta$ to denote the inner product and the norm, respectively, on $\mathcal{L}^2(\eta_\theta)$. Finally, for any $\theta \in \mathbb{R}^n$, we define the operator P_θ on $\mathcal{L}^2(\eta_\theta)$ by

$$\begin{aligned}(P_\theta Q)(x,u) &= \mathbf{E}_\theta[Q(X_1, U_1) \mid X_0 = x, U_0 = u] \\ &= \int Q(y, \bar{u})\mu_\theta(\bar{u}|y)p(dy|x,u)\nu(d\bar{u}) \quad \forall (x,u) \in \mathbb{X} \times \mathbb{U},\ Q \in \mathcal{L}^2(\eta_\theta).\end{aligned}$$

For the finite case, we introduced certain boundedness assumptions on the maps $\theta \mapsto \psi_\theta(x,u)$ and $\theta \mapsto \phi_\theta(x,u)$ and their derivatives. For the more general case considered here, these bounds may depend on the state-action pair (x,u). We wish to bound the rate of growth of such functions, as (x,u) changes, in terms of the stochastic Lyapunov function L. Toward this purpose, we introduce a class $\mathcal{D}$ of functions that satisfy the desired growth conditions.

We will say that a parameterized family of functions $f_\theta : \mathbb{X} \times \mathbb{U} \mapsto \mathbb{R}$ belongs to $\mathcal{D}$ if there exists a function $q : \mathbb{X} \times \mathbb{U} \mapsto \mathbb{R}$ and constants C, K_d $(d \geq 1)$, such that

$$f_\theta(x,u) \leq Cq(x,u) \qquad \forall\ x \in \mathbb{X},\ u \in \mathbb{U},\ \theta \in \mathbb{R}^n$$

and

$$\mathbf{E}_{\theta,x}\left[|q(x, U_0)|^d\right] \leq K_d L(x) \qquad \forall\ \theta, x, d \geq 1.$$

For easy reference, we collect here various useful properties of the class $\mathcal{D}$. The proof is elementary and is omitted.

LEMMA 4.3. *Consider a process $\{\hat{X}_k, \hat{U}_k\}$ driven by RSPs θ_k which change with time but in a nonanticipative manner (i.e., θ_k is completely determined by $(\hat{X}_l, \hat{U}_l)$, $l \leq k$). Assume that $\mathbf{E}[L(\hat{X}_0)] < \infty$.*

(a) *The sequence $\mathbf{E}[L(\hat{X}_k)]$, $k = 1, 2, \ldots$, is bounded.*

(b) *If the parametric class of functions f_θ belongs to $\mathcal{D}$, then for any $d \geq 1$ and any (possibly random) sequence $\{\tilde{\theta}_k\}$*

$$\sup_k \mathbf{E}\left[\left|f_{\tilde{\theta}_k}(\hat{X}_k, \hat{U}_k)\right|^d\right] < \infty.$$

(c) *In particular, the above boundedness property holds when θ_k and $\tilde{\theta}_k$ are held fixed at some θ, for all k, so that the process $\{\hat{X}_k, \hat{U}_k\}$ is time-homogeneous.*

(d) *If $f_\theta \in \mathcal{D}$, then the maps $(x,u) \to \mathbf{E}_{\theta,x}[f_\theta(x, U_0)]$ and $(x,u) \to (P_\theta f_\theta)(x,u)$ also belong to $\mathcal{D}$, and*

$$f_\theta \in \mathcal{L}^d(\eta_\theta) \qquad \forall \theta \in \mathbb{R}^n,\ d \geq 1.$$

(e) *For any function $f \in \mathcal{D}$, the steady-state expectation $\pi_\theta(f)$ is well-defined and a bounded function of θ, and there exists a constant $C > 0$ such that*

$$|\mathbf{E}_{\theta,x}[f(X_k, U_k)] - \pi_\theta(f)| \leq C\rho^k L(x) \qquad \forall x \in \mathbb{X},\ \theta \in \mathbb{R}^n. \tag{4.3}$$

(f) *If the parametric classes of functions f_θ and g_θ belong to $\mathcal{D}$, then*

$$f_\theta + g_\theta \in \mathcal{D}, \qquad f_\theta g_\theta \in \mathcal{D}.$$

The next two assumptions will be used to show that the average cost is a smooth function of the policy parameter θ. In the finite case, their validity is an automatic consequence of Assumption 2.1.

Assumption 4.4 (differentiability).

(a) For every $x \in \mathbb{X}$, $u \in \mathbb{U}$, and $\theta \in \mathbb{R}^n$, we have $\mu_\theta(u|x) > 0$.

(b) The mapping $\theta \mapsto \mu_\theta(u|x)$ is twice differentiable. Furthermore, $\psi_\theta(x,u) = \nabla \ln \mu_\theta(u|x)$ and its derivative belong to $\mathcal{D}$.

(c) For every θ_0, there exists $\epsilon > 0$ such that the class of functions

$$\{\nabla \mu_\theta(u|x)/\mu_{\bar\theta}(u|x),\ |\theta - \theta_0| \le \epsilon,\ |\bar\theta - \theta_0| \le \epsilon\}$$

(parameterized by θ and $\bar\theta$) belongs to $\mathcal{D}$.

Assumption 4.5. The cost function $c(\cdot,\cdot)$ belongs to $\mathcal{D}$.

Under the above assumptions we wish to prove that a gradient formula similar to (2.1) is again valid. By Assumption 4.5 and Lemma 4.3, $c \in \mathcal{L}^2(\eta_\theta)$ and therefore the average cost function can be written as

$$\bar\alpha(\theta) = \int c(x,u)\pi_\theta(dx)\mu_\theta(u|x)\nu(du) = \langle c, \underline{1}\rangle_\theta.$$

We say that $Q \in \mathcal{L}^2(\eta_\theta)$ is a solution of the Poisson equation with parameter θ if Q satisfies

$$Q = c - \bar\alpha(\theta)\underline{1} + P_\theta Q. \tag{4.4}$$

Using Proposition 17.4.1 from [17], one can easily show that a solution to the Poisson equation with parameter θ exists and is unique up to a constant. That is, if Q_1, Q_2 are two solutions, then $Q_1 - Q_2$ and $\underline{1}$ are collinear in $\mathcal{L}^2(\eta_\theta)$. One obvious family of solutions to the Poisson equation is

$$Q_\theta(x,u) = \sum_{k=0}^{\infty} \mathbf{E}_{\theta,x}\left[\,(c(X_k,U_k) - \bar\alpha(\theta))|\, U_0 = u\right].$$

(The convergence of the above series is a consequence of (4.3).)

There are other (e.g., regenerative) representations of solutions to the Poisson equation which are useful both for analysis and for derivation of algorithms. For example, Glynn and L'Ecuyer [9] use regenerative representations to show that the steady-state expectation of a function is differentiable under certain assumptions. We use similar arguments to prove that the average cost function $\bar\alpha(\cdot)$ is twice differentiable with bounded derivatives. Furthermore, it can be shown that there exist solutions $\hat{Q}_\theta(x,u)$ to the Poisson equation that are differentiable in θ. From a technical point of view, our assumptions are similar to those provided by Glynn and L'Ecuyer [9]. The major difference is that [9] concerns Markov chains $\{X_k\}$ that have the recursive representation

$$X_{k+1} = f(X_k, W_k),$$

where W_k are i.i.d., whereas we allow the distribution of W_k (which is U_k in our case) to depend on X_k. Furthermore, the formula for the gradient of steady-state

expectations that we derive here is quite different from that of [9] and makes explicit the role of the Poisson equation in gradient estimation. The following theorem holds for any solution $Q_\theta : \mathbb{X} \times \mathbb{U} \to \mathbb{R}$ of the Poisson equation with parameter θ. We provide only an outline of the proof and refer the reader to [15] for the details.

THEOREM 4.6. *Under Assumptions* 4.1, 4.2, 4.4, *and* 4.5,

$$\nabla \bar{\alpha}(\theta) = \langle \psi_\theta, Q_\theta \rangle_\theta.$$

Furthermore, $\nabla \bar{\alpha}(\theta)$ *has bounded derivatives.*

Proof. (Outline) Using regenerative representations and likelihood ratio methods, we can show that $\bar{\alpha}(\theta)$ is differentiable and that there exists a parameterized family $\{\hat{Q}_\theta(x,u)\}$ of solutions to the Poisson equation, belonging to $\mathcal{D}$, such that the map $\theta \to \hat{Q}_\theta(x,u)$ is differentiable for each (x,u), and such that the family of functions $\nabla \hat{Q}_\theta(x,u)$ belongs to $\mathcal{D}$ (see [15]). Then one can differentiate both sides of equation (4.4) with respect to θ to obtain

$$\nabla \bar{\alpha}(\theta) \underline{1} + \nabla \hat{Q}_\theta = P_\theta(\psi_\theta \hat{Q}_\theta) + P_\theta(\nabla \hat{Q}_\theta).$$

(This step involves an interchange of differentiation and integration justified by uniform integrability.) Taking inner product with $\underline{1}$ on both sides of the above equation and using that $\nabla \hat{Q}_\theta \in \mathcal{L}^2(\eta_\theta)$ and

$$\langle \underline{1}, P_\theta f \rangle_\theta = \langle \underline{1}, f \rangle_\theta \qquad \forall f \in \mathcal{L}^2(\eta_\theta),$$

we obtain $\nabla \bar{\alpha}(\theta) = \langle \hat{Q}_\theta, \psi_\theta \rangle_\theta = \langle Q_\theta, \psi_\theta \rangle_\theta$, where the second equality follows from the fact that $Q_\theta - \hat{Q}_\theta$ and $\underline{1}$ are necessarily collinear and the easily verified fact $\langle \underline{1}, \psi_\theta \rangle_\theta = 0$.

Since ψ_θ and $\hat{Q}_\theta$ are both differentiable with respect to θ, with the derivatives belonging to $\mathcal{D}$, the formula

$$\nabla \bar{\alpha}(\theta) = \langle \psi_\theta, Q_\theta \rangle_\theta = \langle \underline{1}, \psi_\theta Q_\theta \rangle$$

implies that $\nabla \bar{\alpha}(\theta)$ is also differentiable with bounded derivative. □

Before we move on to present the algorithms for Polish state and action spaces, we illustrate how the above assumptions can be verified in the context of a simple inventory control problem.

Example 4.7. Consider a facility with $X_k \in \mathbb{R}$ amount of stock at the beginning of the kth period, with negative stock representing the unsatisfied (or backlogged) demand. Let $D_k \geq 0$ denote the random demand during the kth period. The problem is to determine the amount of stock to be ordered at the beginning of the kth period, based on the current stock and the previous demands. If $U_k \geq 0$ represents the amount of stock ordered at the beginning of the kth period, then the cost incurred is assumed to be

$$c(X_k, U_k) = h \max(0, X_k) + b \max(0, -X_k) + pU_k,$$

where p is the price of the material per unit, b is the cost incurred per unit of backlogged demand, and h is the holding cost per unit of stock in the inventory. Moreover, the evolution of the stock X_k is given by

$$X_{k+1} = X_k + U_k - D_k, \quad k = 0, 1, \ldots.$$

If we assume that the demands $D_k, k = 0, 1 \ldots$, are nonnegative and i.i.d. with finite mean, then it is well known (e.g., see [4]) that there is an optimal policy μ^* of the form

$$\mu^*(x) = \max(S - x, 0)$$

for some $S > 0$ depending on the distribution of D_k. A good approximation for policies having the above form is the family of randomized policies in which S is chosen at random from the density

$$p_\theta(s) = \frac{1}{2T}\text{sech}^2\left(\frac{s - \bar{s}(\theta)}{T}\right),$$

where $\bar{s}(\theta) = e^\theta C/(1 + e^\theta)$. The constant C is picked based on our prior knowledge of an upper bound on the parameter S in an optimal policy. To define the family of density functions $\{\mu_\theta\}$ for the above family of policies, let $\nu(du)$ be the sum of the Dirac measure at 0 and the Lebesgue measure on $[0, \infty)$. Then the density functions are given by

$$\mu_\theta(0|x) = \frac{1}{2}\left(1 + \tanh\left(\frac{x - \bar{s}(\theta)}{T}\right)\right),$$
$$\mu_\theta(u|x) = \frac{1}{2T}\text{sech}^2\left(\frac{x + u - \bar{s}(\theta)}{T}\right), \qquad u > 0.$$

The dynamics of the stock in the inventory, when controlled by policy μ_θ, are described by

$$X_{k+1} = \max(X_k, S_k) - D_k, \qquad k = 0, 1 \ldots,$$

where the $\{S_k\}$ are i.i.d. with density p_θ and independent of the demands D_k and the stock X_k. It is easy to see that the Markov chain $\{X_k\}$ is irreducible. To prove that the Markov chain is aperiodic, it suffices to show that (4.1) holds with $N = 1$. Indeed, for $\mathbb{X}_0 = [-a, a]$, $x \in \mathbb{X}_0$, and a Borel set B consider

$$\begin{aligned}\mathbf{P}_{\theta,x}(X_1 \in B) &= \mathbf{P}_{\theta,x}(\max(x, S_0) - D_0 \in B),\\ &\geq \mathbf{P}_{\theta,x}(S_0 - D_0 \in B, S_0 \geq a),\\ &\geq \int_B \int_{a-t}^{\infty} \left(\inf_\theta p_\theta(t + y)\right) D(dy)dt,\end{aligned}$$

where $D(dy)$ is the probability distribution of D_0 and $\vartheta(dy)$ is the right-hand side appropriately normalized. This normalization is possible because the above integral is positive when $B = \mathbb{X}_0$.

To prove the Lyapunov condition (4.2), assume that D_k has exponentially decreasing tails. In other words, assume that there exists $\gamma > 0$ such that

$$\mathbf{E}[\exp(\gamma D_0)] < \infty.$$

We first argue intuitively that the function

$$L(x) = \exp(\bar{\gamma}|x|)$$

for some $\bar{\gamma}$ with $\min(\gamma, \frac{1}{T}) > \bar{\gamma} > 0$ is a good candidate Lyapunov function. To see this, note that the desired inequality (4.2) requires the Lyapunov function to decrease

by a common factor outside some set $\mathbb{X}_0$. Let us try the set $\mathbb{X}_0 = [-a, a]$ for a sufficiently larger than C. If the inventory starts with a stock larger than a, then no stock is ordered with very high probability (since S_0 is most likely less than C) and therefore the stock decreases by D_0, decreasing the Lyapunov function by a factor of $\mathbf{E}[\exp(-\bar{\gamma}D_0)] < 1$. If the inventory starts with a large backlogged demand, then most likely new stock will be ordered to satisfy all the backlogged demand decreasing the Lyapunov function to almost 1. This can be made precise as follows:

$$\begin{aligned}\mathbf{E}_{\theta,x}[L(X_1)] &= \mathbf{E}_{\theta,x}[\exp(\bar{\gamma}|\max(x, S_0) - D_0|)] \\ &= \exp(\bar{\gamma}x)\mathbf{P}_{\theta,x}(S_0 \le x)\mathbf{E}_{\theta,x}[\exp(-\bar{\gamma}D_0); D_0 \le x] \\ &\quad + \exp(-\bar{\gamma}x)\mathbf{P}_{\theta,x}(S_0 \le x)\mathbf{E}_{\theta,x}[\exp(\bar{\gamma}D_0); D_0 > x] \\ &\quad + \mathbf{E}_{\theta,x}[\exp(\bar{\gamma}|S_0 - D_0|); S_0 > x].\end{aligned}$$

Note that the third term is bounded uniformly in θ, x since $\bar{\gamma} < \min(\frac{1}{T}, \gamma)$. The first term is bounded when x is negative, and the second term is bounded when x is positive. Therefore the Lyapunov function decreases by a factor of $\mathbf{E}[\exp(-\bar{\gamma}D_0)] < 1$ when $x > a$ and decreases by a factor of $\mathbf{P}(S_0 \le -a)\mathbf{E}[\exp(\bar{\gamma}D_0)] < 1$ for a sufficiently large. The remaining assumptions are easy to verify.

4.2. Critic. In the finite case, the feature vectors were assumed to be bounded. This assumption is seldom satisfied for infinite state spaces. However, it is reasonable to impose some bounds on the growth of the feature vectors, as in the next assumption.

Assumption 4.8 (critic features).

(a) The family of functions $\phi_\theta(x, u)$ belongs to $\mathcal{D}$.

(b) For each (x, u), the map $\theta \mapsto \phi_\theta(x, u)$ is differentiable, and the family of functions $\nabla\phi_\theta(x, u)$ belongs to $\mathcal{D}$.

(c) There exists some $a > 0$, such that

$$||r'\hat{\phi}_\theta||_\theta^2 \ge a|r|^2 \qquad \forall\theta \in \mathbb{R}^n, r \in \mathbb{R}^m, \tag{4.5}$$

where $\hat{\phi}_\theta = \phi_\theta - \langle\phi_\theta, \underline{1}\rangle_\theta \underline{1}$.

(d) For each $\theta \in \mathbb{R}^n$, the subspace Φ_θ in $\mathcal{L}^2(\eta_\theta)$ spanned by the features ϕ_θ^i, $i = 1, \dots, m$, of the critic contains the subspace Ψ_θ spanned by the functions ψ_θ^j, $j = 1, \dots, n$, i.e.,

$$\Phi_\theta \supset \Psi_\theta \quad \forall\theta \in \mathbb{R}^n.$$

4.2.1. TD(1) critic. For the TD(1) critic, we will strengthen Assumption 4.2 by adding the following condition.

Assumption 4.9. The set $\mathbb{X}_0$ consists of a single state x^*, and

$$\mathbf{E}_{\theta,x^*}[\phi_\theta(x^*, U_0)] = 0 \quad \forall\theta \in \mathbb{R}^n.$$

The requirement that there is a single state that is hit with positive probability is quite strong but is satisfied in many practical situations involving queuing systems, as well as for systems that have been made regenerative using the splitting techniques of [1] and [18]. The assumption that the expected value of the features at x^* is zero is automatically satisfied in the special case where $\phi_\theta = \psi$. Furthermore, for features of the form $\phi_\theta(x)$ that do not depend on u, the assumption is easily satisfied by enforcing the condition $\phi_\theta(x^*) = 0$. It is argued in [11] that besides ψ_θ, there is little benefit in using additional features that depend on u. Therefore, the assumption imposed here is not a major restriction.

5. Convergence of the critic. In this section, we analyze the convergence of the critic in the algorithms described above, under the assumptions introduced in section 4, together with Assumption 3.3 on the step-sizes. If θ_k was held constant at some value θ, it would follow (similar to [22], which dealt with the finite case) that the critic parameters converge to some $\bar{r}(\theta)$. In our case, θ_k changes with k, but slowly, and this will allow us to show that $r_k - \bar{r}(\theta_k)$ converges to zero. To establish this, we will cast the update of the critic as a linear stochastic approximation driven by Markov noise, specifically in the form of (A.1) in Appendix A. We will show that the critic update satisfies all the hypotheses of Theorem A.7 of Appendix A, and the desired result (Theorem 5.7) will follow. The assumptions of the result in Appendix A are similar to the assumptions of a result (Theorem 2) used in [22]. Therefore, the proof we present here is similar to that in [22], modulo the technical difficulties due to more general state and action spaces. We start with some notation.

For each time k, let

$$\hat{Y}_{k+1} = (\hat{X}_k, \hat{U}_k, \hat{Z}_k),$$
$$R_k = \begin{pmatrix} L\alpha_k \\ r_k \end{pmatrix}$$

for some deterministic constant $L > 0$, whose purpose will be clear later. Let $\mathcal{F}_k$ be the σ-field generated by $\{Y_l, R_l, \theta_l,\ l \leq k\}$. For $y = (x, u, z)$, define

$$h_\theta(y) = \begin{pmatrix} Lc(x,u) \\ zc(x,u) \end{pmatrix},$$

$$G_\theta(y) = \begin{pmatrix} 1 & 0 \\ z/L & \tilde{G}_\theta(y) \end{pmatrix},$$

where

$$\tilde{G}_\theta(y) = z\left(\phi'_\theta(x,u) - (P_\theta \phi_\theta)'(x,u)\right).$$

It will be shown later that the steady-state expectation of $\tilde{G}_\theta(y)$ is positive definite. The constant L is introduced because when it is chosen small enough, we will be able to show that the steady-state expectation of $G_\theta(y)$ is also positive definite.

The update (3.1) for the critic can be written as

$$R_{k+1} = R_k + \gamma_k(h_{\theta_k}(\hat{Y}_{k+1}) - G_{\theta_k}(\hat{Y}_{k+1})R_k + \xi_k R_k),$$

which is a linear iteration with Markov-modulated coefficients and ξ_k is a martingale difference given by

$$\xi_k = \begin{bmatrix} 0 \\ \hat{Z}_k\left(\phi'_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) - (P_{\theta_k}\phi'_{\theta_k})(\hat{X}_k, \hat{U}_k)\right) \end{bmatrix}.$$

To apply Theorem A.7 to this update equation, we need to prove that it satisfies Assumptions A.1–A.6. We will verify these assumptions for the two cases $\lambda = 1$ and $\lambda < 1$ separately.

Assumption A.1 follows from our Assumption 3.3. Assumption A.2 is trivially satisfied. To verify Assumption A.4, we use the actor iteration (3.2) to identify H_{k+1} with $\Gamma(r_k) r'_k \phi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1})\psi_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1})$. Because of Assumption 3.3(b), the

term $\Gamma(r_k)r_k$ is bounded. Furthermore, since ψ_θ and ϕ_θ belong to $\mathcal{D}$ (Assumptions 4.4 and 4.8), Lemma 4.3(b) implies that $\mathbf{E}[|H_k|^d]$ is bounded. This, together with Assumption 3.3(a), shows that Assumption A.4 is satisfied. In the next two subsections, we will concentrate on showing that Assumptions A.3, A.5, and A.6 are satisfied.

5.1. TD(1) critic. Define a process Z_k in terms of the process $\{X_k, U_k\}$ of section 4.1 (in which the policy is fixed) as follows:

$$Z_0 = \phi_\theta(X_0, U_0), \quad Z_{k+1} = I\{X_{k+1} \neq x^*\}Z_k + \phi_\theta(X_{k+1}, U_{k+1}),$$

where I is the indicator function. Note that the process $\{Z_k\}$ depends on the parameter θ. Whenever we use this process inside an expectation or a probability measure, we will assume that the parameter of this process is the same as the parameter of the probability or expectation. It is easy to see that $Y_{k+1} = (X_k, U_k, Z_k)$ is a Markov chain. Furthermore, the transition kernel of this process, when the policy parameter is θ, is the same as that of $\{\hat{Y}_k\}$ when the actor parameter is fixed at θ.

Let τ be the stopping time defined by

$$\tau = \min\{k > 0 \mid X_k = x^*\}.$$

For any $\theta \in \mathbb{R}^n$, define T_θ and Q_θ by

$$T_\theta(x,u) = \mathbf{E}_{\theta,x}[\tau \mid U_0 = u],$$
$$Q_\theta(x,u) = \mathbf{E}_{\theta,x}\left[\sum_{k=0}^{\tau-1}(c(X_k,U_k) - \bar{\alpha}(\theta)) \;\Big|\; U_0 = u\right].$$

LEMMA 5.1. *The families of functions T_θ and Q_θ both belong to $\mathcal{D}$.*

Proof. The fact that $T_\theta \in \mathcal{D}$ follows easily from the assumption that $\mathbb{X}_0 = x^*$ (Assumption 4.9) and the uniform ergodicity Assumption 4.2. Using Theorem 15.2.5 of [17], we obtain that $\mathbf{E}_{\theta,x}[Q_\theta(x,U_0)]^d \leq K'_d L(x)$ for some $K'_d > 0$, so that $\mathbf{E}_{\theta,x}[Q_\theta(x,U_0)]^d$ also belongs to $\mathcal{D}$. Since

$$Q_\theta(x,u) = c(x,u) - \bar{\alpha}(\theta) + \mathbf{E}_{\theta,x}[Q_\theta(X_1,U_1)|U_0 = u]$$

is a sum of elements of $\mathcal{D}$, it follows that Q_θ also belongs to $\mathcal{D}$. □

Using simple algebraic manipulations and Assumption 4.9, we obtain, for every $\theta \in \mathbb{R}^n$,

$$\mathbf{E}_{\theta,x^*}\left[\sum_{k=0}^{\tau-1}\Big(\big(c(X_k,U_k) - \bar{\alpha}(\theta)\big)Z_k - \langle Q_\theta, \phi_\theta\rangle_\theta\Big)\right] = 0,$$
$$\mathbf{E}_{\theta,x^*}\left[\sum_{k=0}^{\tau-1}\Big(Z_k\big(\phi'_\theta(X_k,U_k) - \phi'_\theta(X_{k+1},U_{k+1})\big) - \langle \phi_\theta, \phi'_\theta\rangle_\theta\Big)\right] = 0.$$

This implies that the steady-state expectations of $h_\theta(y)$ and $G_\theta(y)$ are given by

$$\bar{h}(\theta) = \begin{pmatrix} L\bar{\alpha}(\theta) \\ \bar{h}_1(\theta) + \bar{\alpha}(\theta)\bar{Z}(\theta) \end{pmatrix},$$
$$\bar{G}(\theta) = \begin{pmatrix} 1 & 0 \\ \bar{Z}(\theta)/L & \bar{G}_1(\theta) \end{pmatrix},$$

where

$$\bar{h}_1(\theta) = \langle Q_\theta, \phi_\theta \rangle_\theta, \qquad \bar{Z}(\theta) = \langle T_\theta, \phi_\theta \rangle_\theta, \qquad \bar{G}_1(\theta) = \langle \phi_\theta, \phi'_\theta \rangle_\theta.$$

For $y = (x, u, z)$, we define

$$\hat{h}_\theta(y) = \mathbf{E}_{\theta,\bar{x}} \left[\sum_{k=0}^{\tau-1} (h_\theta(Y_k) - \bar{h}(\theta)) \;\Big|\; Y_0 = y \right],$$

$$\hat{G}_\theta(y) = \mathbf{E}_{\theta,\bar{x}} \left[\sum_{k=0}^{\tau-1} (G_\theta(Y_k) - \bar{G}(\theta)) \;\Big|\; Y_0 = y \right],$$

and it can be easily verified that part (a) of Assumption A.3 is satisfied. Note that we have been working with families of functions that belong to $\mathcal{D}$, and which therefore have steady-state expectations that are bounded functions of θ (Lemma 4.3(e)). In particular, $\bar{G}(\cdot)$ and $\bar{h}(\cdot)$ are bounded, and part (b) of Assumption A.3 is satisfied.

To verify the other parts of Assumption A.3, we will need the following result.

LEMMA 5.2. *For every $d > 1$, $\sup_k \mathbf{E}[|\hat{Z}_k|^d] < \infty$.*

Proof. Let $\hat{W}_k$ denote the vector $(\hat{X}_k, \hat{U}_k, \hat{Z}_k, r_k, \alpha_k, \theta_k)$. Since the step-size sequences $\{\gamma_k\}$ and $\{\beta_k\}$ are deterministic, $\{\hat{W}_k\}$ forms a time-varying Markov chain. For each k, let $\mathbf{P}_{k,\hat{w}}$ denote the conditional law of the process $\{\hat{W}_n\}$ given that $\hat{W}_k = \hat{w}$. Define a sequence of stopping times for the process $\{\hat{W}_n\}$ by letting

$$\hat{\tau}_k = \min\{n > k : \hat{X}_n = x^*\}.$$

For $1 < t < 1/\rho$, define

$$V_k^{(d)}(\hat{w}) = \mathbf{E}_{k,\hat{w}} \left[\sum_{l=k}^{\tau_k - 1} t^{l-k} (1 + |\hat{Z}_l|^d) \right],$$

which can be verified to be finite, due to uniform geometric ergodicity and the assumption that ϕ_θ belongs to $\mathcal{D}$. It is easy to see that $V_k^{(d)}(\hat{W}_k) \geq |\hat{Z}_k|^d$. Therefore, it is sufficient to prove that $\mathbf{E}[V_k^{(d)}(\hat{W}_k)]$ is bounded.

We will now show that $V_k^{(d)}(\hat{w})$ acts as a Lyapunov function for the algorithm. Indeed,

$$\begin{aligned}
V_k^{(d)}(\hat{w}) &\geq \mathbf{E}_{k,\hat{w}} \left[\sum_{l=k+1}^{\tau_k - 1} t^{l-k} (1 + |\hat{Z}_l|^d) \right] \\
&= \mathbf{E}_{k,\hat{w}} \left[\sum_{l=k+1}^{\tau_k - 1} t^{l-k} (1 + |\hat{Z}_l|^d) I\{\hat{X}_{k+1} \neq x^*\} \right] \\
&= t \mathbf{E}_{k,\hat{w}} \left[V_{k+1}^{(d)}(\hat{W}_{k+1}) I\{\hat{X}_{k+1} \neq x^*\} \right] \\
&= t \mathbf{E}_{k,\hat{w}} \left[V_{k+1}^{(d)}(\hat{W}_{k+1}) \right] - t \mathbf{E}_{k,\hat{w}} \left[V_{k+1}^{(d)}(\hat{W}_{k+1}) I\{\hat{X}_{k+1} = x^*\} \right].
\end{aligned}$$

Using the geometric ergodicity condition (4.2), some algebraic manipulations, and the fact that ϕ_θ belongs to $\mathcal{D}$, we can verify that $\mathbf{E}_{k,\hat{w}}[V_{k+1}^{(d)}(\hat{W}_1) I\{\hat{X}_1 = x^*\}]$ is bounded by some constant C. We take expectations of both sides of the preceding inequality, with $\hat{w}$ distributed as the random variable $\hat{W}_k$, and use the property

$$\mathbf{E}\Big[\mathbf{E}_{k,\hat{W}_k} \big[V_{k+1}^{(d)}(\hat{W}_{k+1}) \big] \Big] = \mathbf{E}[V_{k+1}^{(d)}(\hat{W}_{k+1})]$$

to obtain

$$\mathbf{E}[V_k^{(d)}(\hat{W}_k)] \geq t\mathbf{E}[V_{k+1}^{(d)}(\hat{W}_{k+1})] - C.$$

Since $t > 1$, $\mathbf{E}[V_k^{(d)}(\hat{W}_k)]$ is bounded, and the result follows. □

To verify part (c) of Assumption A.3, note that $\hat{h}_\theta(\cdot), \hat{G}_\theta(\cdot), h_\theta(\cdot)$, and $G_\theta(\cdot)$ are affine in z, of the form

$$f_\theta^{(1)}(\cdot) + z f_\theta^{(2)}(\cdot),$$

for some functions $f_\theta^{(i)}$ that belong to $\mathcal{D}$. Therefore, Holder's inequality and Lemma 5.2 can be used to verify part (c) of Assumption A.3. As in the proof of Theorem 4.6, likelihood ratio methods can be used to verify Assumptions parts (d) and (e) of Assumption A.3; see [15] for details. Assumption A.5 follows from Holder's inequality, Lemma 5.2, and part (b) of Lemma 4.3.

Finally, the following lemma verifies Assumption A.6.

LEMMA 5.3. *There exist L and $\epsilon > 0$ such that for all $\theta \in \mathbb{R}^n$ and $R \in \mathbb{R}^{m+1}$,*

$$R'\bar{G}(\theta)R \geq \epsilon |R|^2.$$

Proof. Let $R = (\alpha, r)$, where $\alpha \in \mathbb{R}$ and $r \in \mathbb{R}^m$. Using the definition of $\bar{G}(\theta)$, and Assumption 4.8(c) for the first inequality, we have

$$\begin{aligned} R'\bar{G}(\theta)R &= ||r'\phi_\theta||_\theta^2 + |\alpha|^2 + r'\bar{Z}(\theta)\alpha/L \\ &\geq a|r|^2 + |\alpha|^2 - r'\bar{Z}(\theta)\alpha/L \\ &\geq \min(a,1)|R|^2 - |\bar{Z}(\theta)|(|r|^2 + |\alpha|^2)/2L \\ &= \left(\min(a,1) - \frac{\bar{Z}(\theta)}{2L}\right)|R|^2. \end{aligned}$$

We can now choose $L > \sup_\theta |\bar{Z}(\theta)|/\min(a,1)$, which is possible because $\bar{Z}(\theta)$ is bounded (it is the steady-state expectation of a function in $\mathcal{D}$). □

5.2. TD(λ) critic. To analyze the TD(λ) critic, with $0 < \lambda < 1$, we redefine the process Z_k as

$$Z_{k+1} = \lambda Z_k + \phi_\theta(X_{k+1}, U_{k+1}).$$

As in the case of TD(1), we consider the steady-state expectations

$$\bar{h}(\theta) = \begin{pmatrix} L\bar{\alpha}(\theta) \\ \bar{h}_1(\theta) + \bar{\alpha}(\theta)\bar{Z}(\theta) \end{pmatrix}, \qquad \bar{G}(\theta) = \begin{pmatrix} 1 & 0 \\ \bar{Z}(\theta)/L & \bar{G}_1(\theta) \end{pmatrix}$$

of $h_\theta(Y_k)$ and $G_\theta(Y_k)$. For the present case, the entries of $\bar{h}$ and $\bar{G}$ are given by

$$\bar{h}_1(\theta) = \sum_{k=0}^{\infty} \lambda^k \langle P_\theta^k c - \bar{\alpha}(\theta)\underline{1}, \phi_\theta \rangle_\theta,$$

$$\bar{G}_1(\theta) = \langle \phi_\theta, \phi_\theta' \rangle_\theta - (1-\lambda)\sum_{k=0}^{\infty} \lambda^k \langle P_\theta^{k+1}\phi_\theta, \phi_\theta' \rangle_\theta,$$

and $\bar{Z}(\theta) = (1-\lambda)^{-1}\langle \underline{1}, \phi_\theta\rangle_\theta$. As in Assumption 4.8(c), let $\hat{\phi}_\theta = \phi_\theta - \langle \phi_\theta, \underline{1}\rangle_\theta \underline{1}$. Then, $P_\theta\phi_\theta - \phi_\theta = P_\theta\hat{\phi}_\theta - \hat{\phi}_\theta$, and $\bar{G}_1(\theta)$ can also be written as

$$\bar{G}_1(\theta) = \langle \hat{\phi}_\theta, \hat{\phi}'_\theta\rangle_\theta - (1-\lambda)\sum_{k=0}^{\infty}\lambda^k\langle P_\theta^{k+1}\hat{\phi}_\theta, \hat{\phi}'_\theta\rangle_\theta.$$

By an argument similar to the one used for the case of TD(1), we can see that $\bar{G}(\cdot)$ and $\bar{h}(\cdot)$ are bounded and, therefore, part (b) of Assumption A.3 is satisfied.

LEMMA 5.4. *There exists a positive constant C, such that for all $k \geq 0$, θ, x, λ, we have*

(a) $\left|\mathbf{E}_{\theta,x}\big[(c(X_k,U_k) - \bar{\alpha}(\theta))Z_k\big] - \bar{h}_1(\theta)\right| \leq Ck\max(\lambda,\rho)^k L(x)$,

(b) $\left|\mathbf{E}_{\theta,x}\big[Z_k(\phi'_\theta(X_k,U_k) - \phi'_\theta(X_{k+1},U_{k+1}))\big] - \bar{G}(\theta)\right| \leq Ck\max(\lambda,\rho)^k L(x)$.

Proof. We have

$$\begin{aligned}
&\left|\mathbf{E}_{\theta,x}\big[(c(X_k,U_k) - \bar{\alpha}(\theta))Z_k\big] - \bar{h}_1(\theta)\right| \\
&\quad\leq \sum_{l=0}^{k}\lambda^l\left|\mathbf{E}_{\theta,x}\big[(c(X_k,U_k) - \bar{\alpha}(\theta))\phi_\theta(X_{k-l},U_{k-l})\big] - \langle P_\theta^l c - \bar{\alpha}(\theta)\underline{1}, \phi_\theta\rangle_\theta\right| \\
&\qquad + C'\lambda^k \\
&\quad\leq \sum_{l=0}^{k} C'\lambda^l\rho^{k-l}L(x) + C'\lambda^k L(x) \\
&\quad\leq \sum_{l=0}^{k} 2C'\max(\lambda,\rho)^k L(x),
\end{aligned}$$

where the second inequality makes use of Lemma 4.3(e) and the assumption $L(x) \geq 1$. This proves part (a). The proof of part (b) is similar. □

From the previous lemma, it is clear that, for $\theta \in \mathbb{R}^n$ and $y = (x,u,z)$,

$$\begin{aligned}
\hat{h}_\theta(y) &= \sum_{k=0}^{\infty}\mathbf{E}_{\theta,x}\left[(h_\theta(Y_k) - \bar{h}(\theta))\ \middle|Y_0 = y\right], \\
\hat{G}_\theta(y) &= \sum_{k=0}^{\infty}\mathbf{E}_{\theta,x}\left[(G_\theta(Y_k) - \bar{G}(\theta))\ \middle|Y_0 = y\right],
\end{aligned}$$

are well-defined, and it is easy to check that part (a) of Assumption A.3 is satisfied.

To verify part (c) of Assumption A.3, we have the following counterpart of Lemma 5.2.

LEMMA 5.5. *For every $d > 1$, we have* $\sup_k \mathbf{E}[|\hat{Z}_k|^d] < \infty$.

Proof. We have, using Jensen's inequality,

$$\begin{aligned}
|\hat{Z}_k|^d &= \frac{1}{(1-\lambda)^d}\left|(1-\lambda)\sum_{l=0}^{k}\lambda^{k-l}\phi_{\theta_k}(\hat{X}_k,\hat{U}_k)\right|^d \\
&\leq \frac{1}{(1-\lambda)^d}(1-\lambda)\sum_{l=0}^{k}\lambda^{k-l}\left|\phi_{\theta_k}(\hat{X}_k,\hat{U})\right|^d.
\end{aligned}$$

We note that $\mathbf{E}[|\phi_{\theta_k}(\hat{X}_k, \hat{U}_k)|^d]$ is bounded (Lemma 4.3(b)), from which it follows that $\mathbf{E}[|\hat{Z}_k|^d]$ is bounded. □

The verification of parts (d) and (e) of Assumption A.3 is tedious, and we provide only an outline (see [15] for the details). The idea is to write the components of $\hat{h}_\theta(\cdot), \hat{G}_\theta(\cdot)$ that are linear in z in the form

$$\sum_{k=0}^{\infty} \lambda^k \mathbf{E}_{\theta,x}[f_\theta(Y_k) \mid U_0 = u, Z_0 = z]$$

for suitably defined functions f_θ, and show that the map $\theta \mapsto \mathbf{E}_\theta[f_\theta(Y_k) \mid U_0 = u, Z_0 = z]$ is Lipschitz continuous, with Lipschitz constant at most polynomial in k. The "forgetting" factor λ^k dominates the polynomial in k, and thus the sum will be Lipschitz continuous in θ. Assumption A.5 follows from Holder's inequality, the previous lemma and part (b) of Lemma 4.3. For the components that are not linear in z, likelihood ratio methods are used.

Finally, we will verify Assumption A.6 in the following lemma.

LEMMA 5.6. *There exist L and $\epsilon > 0$ such that, for all $\theta \in \mathbb{R}^n$ and $R \in \mathbb{R}^{m+1}$,*

$$R'\bar{G}(\theta)R \geq \epsilon |R|^2.$$

Proof. Recall the definition $\hat{\phi}_\theta = \phi_\theta - \langle \phi_\theta, \underline{1} \rangle_\theta \underline{1}$ of $\hat{\phi}_\theta$. Using Lemma 4.3(e) and the fact $\pi_\theta(\hat{\phi}_\theta) = 0$, we obtain, for some constant C,

$$||P_\theta^k \hat{\phi}_\theta^j||_\theta \leq C\rho^k \qquad \forall \theta,\ k.$$

Therefore, for any $r \in \mathbb{R}^m$, we have

$$\begin{aligned} \left\| P_\theta^k (r'\hat{\phi}_\theta) \right\|_\theta &= \left\| \sum_j r_j P_\theta^k \hat{\phi}_\theta^j \right\|_\theta \\ &\leq \sum_j |r_j| \cdot ||P_\theta^k \hat{\phi}_\theta^j||_\theta \\ &\leq C_1 \rho^k |r|. \end{aligned}$$

We note that the transition operator P_θ is nonexpanding, i.e., $\|P_\theta f\|_\theta \leq \|f\|_\theta$, for every $f \in \mathcal{L}^2(\eta_\theta)$; see, e.g., [21]. Using this property and some algebraic manipulations, we obtain

$$\begin{aligned} r'\bar{G}_1(\theta)r &= r'\langle \hat{\phi}_\theta, \hat{\phi}'_\theta \rangle_\theta r - (1-\lambda) \sum_{k=0}^{\infty} \lambda^k r' \langle P_\theta^k \hat{\phi}_\theta, \hat{\phi}'_\theta \rangle_\theta r \\ &= ||r'\hat{\phi}_\theta||_\theta^2 - (1-\lambda) \sum_{k=0}^{\infty} \lambda^k \langle P_\theta^k (r'\hat{\phi}_\theta), r'\hat{\phi}_\theta \rangle_\theta \\ &\geq ||r'\hat{\phi}_\theta||_\theta^2 - (1-\lambda) \left\{ \sum_{k=0}^{k_0-1} \lambda^k ||r'\hat{\phi}_\theta||_\theta^2 + \sum_{k \geq k_0} C_1 \lambda^k \rho^k ||r'\hat{\phi}_\theta||_\theta |r| \right\} \\ &\geq ||r'\hat{\phi}_\theta||_\theta^2 - (1-\lambda^{k_0}) ||r'\phi_\theta||_\theta^2 - C_1 (\lambda\rho)^{k_0} \frac{(1-\lambda)}{(1-\rho\lambda)} ||(r'\phi_\theta)||_\theta |r| \\ &\geq |r|^2 \lambda^{k_0} \left(a - \frac{C_2 \rho^{k_0} (1-\lambda)}{(1-\rho\lambda)} \right), \end{aligned}$$

where the last step made use of the uniform positive definiteness property (Assumption 4.8(c)). We choose k_0 so that

$$\rho^{k_0} < \frac{a(1-\rho\lambda)}{C_2(1-\lambda)}$$

and conclude that $\bar{G}_1(\theta)$ is uniformly positive definite. From this point on, the proof is identical to the proof of Lemma 5.3. □

Having verified all the hypotheses of Theorem A.7, we have proved the following result.

THEOREM 5.7. *Under Assumptions* 3.3, 4.1, 4.2, 4.4, 4.5, 4.8, and 4.9 *and for any TD critic, the sequence* R_k *is bounded, and* $\lim_k |\bar{G}(\theta_k)R_k - \bar{h}(\theta_k)| = 0$.

6. Convergence of the actor. For every $\theta \in \mathbb{R}^n$ and $(x,u) \in \mathbb{X} \times \mathbb{U}$, let

$$H_\theta(x,u) = \psi_\theta(x,u)\phi'_\theta(x,u), \qquad \bar{H}(\theta) = \langle \psi_\theta, \phi'_\theta \rangle_\theta.$$

Note that H_θ belongs to $\mathcal{D}$, and consequently $\bar{H}(\theta)$ is bounded. Let $\bar{r}(\theta)$ be such that $\bar{h}_1(\theta) = \bar{G}_1(\theta)\bar{r}(\theta)$, so that $\bar{r}(\theta)$ is the limit of the critic parameter r if the policy parameter θ was held fixed. The recursion for the actor parameter θ can be written as

$$\begin{aligned}\theta_{k+1} &= \theta_k - \beta_k H_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1})(r_k\Gamma(r_k)) \\ &= \theta_k - \beta_k \bar{H}(\theta_k)\left(\bar{r}(\theta_k)\Gamma(\bar{r}(\theta_k))\right) \\ &\quad -\beta_k(H_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) - \bar{H}(\theta_k))(r_k\Gamma(r_k)) \\ &\quad -\beta_k \bar{H}(\theta_k)(r_k\Gamma(r_k) - \bar{r}(\theta_k)\Gamma(\bar{r}(\theta_k))).\end{aligned}$$

Let

$$\begin{aligned} f(\theta) &= \bar{H}(\theta)\bar{r}(\theta), \\ e_k^{(1)} &= (H_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1}) - \bar{H}(\theta_k))r_k\Gamma(r_k), \\ e_k^{(2)} &= \bar{H}(\theta_k)(r_k\Gamma(r_k) - \bar{r}(\theta_k)\Gamma(\bar{r}(\theta_k))).\end{aligned}$$

Using Taylor's series expansion, one can see that

$$\begin{aligned}\bar{\alpha}(\theta_{k+1}) \le \bar{\alpha}(\theta_k) &- \beta_k\Gamma(\bar{r}(\theta))\nabla\bar{\alpha}(\theta_k)\cdot f(\theta_k) - \beta_k\nabla\bar{\alpha}(\theta_k)\cdot e_k^{(1)} \\ &-\beta_k\nabla\bar{\alpha}(\theta_k)\cdot e_k^{(2)} + C\beta_k^2\left|H_{\theta_k}(\hat{X}_{k+1}, \hat{U}_{k+1})(r_k\Gamma(r_k))\right|^2,\end{aligned} \tag{6.1}$$

where C reflects a bound on the Hessian of $\bar{\alpha}(\theta)$.

Note that $\bar{r}(\theta)$ and $f(\theta)$ depend on the parameter λ of the critic. The following lemma characterizes this dependence.

LEMMA 6.1. *If a TD(*λ*) critic is used, with* $0 < \lambda \le 1$, *then* $f(\theta) = \nabla\bar{\alpha}(\theta) + \varepsilon(\lambda,\theta)$, *where* $\sup_\theta |\varepsilon(\lambda,\theta)| \le C(1-\lambda)$, *and where the constant* $C > 0$ *is independent of* λ.

Proof. Consider first the case of a TD(1) critic. By definition, $\bar{r}(\theta)$ is the solution to the linear equation $\bar{G}_1(\theta)\bar{r}(\theta) = \bar{h}_1(\theta)$, or

$$\langle \phi_\theta, \phi'_\theta\bar{r}(\theta)\rangle_\theta = \langle \phi_\theta, Q_\theta\rangle_\theta.$$

Thus, $\phi_\theta' \bar{r}(\theta) - Q_\theta$ is orthogonal to ϕ_θ in $\mathcal{L}^2(\eta_\theta)$. By Assumption 4.8(d), the components of ψ_θ are contained in the subspace spanned by the components of ϕ_θ. It follows that $\phi_\theta' \bar{r}(\theta) - Q_\theta$ is also orthogonal to ψ_θ. Therefore,

$$\bar{H}(\theta)\bar{r}(\theta) = \langle \psi_\theta, \phi_\theta' \rangle_\theta \bar{r}(\theta) = \langle \psi_\theta, Q_\theta \rangle_\theta = \nabla \bar{\alpha}(\theta),$$

where the last equality is the gradient formula in Theorem 4.6.

For $\lambda < 1$, let us write $\bar{G}_1^\lambda(\theta)$ and $\bar{h}_1^\lambda(\theta)$ for $\bar{G}_1(\theta)$ and $\bar{h}_1(\theta)$, defined in section 5.2, to show explicitly the dependence on λ. Let $\hat{\phi}_\theta = \phi_\theta - \langle \phi_\theta, \underline{1} \rangle_\theta \underline{1}$. Then it is easy to see that

$$|\bar{G}_1^\lambda(\theta) - \langle \hat{\phi}_\theta, \hat{\phi}_\theta' \rangle_\theta| = (1-\lambda) \left| \sum_{k=0}^{\infty} \lambda^k \langle P_\theta^k \hat{\phi}_\theta, \hat{\phi}_\theta \rangle_\theta \right| \le C \left(\frac{1-\lambda}{1-\rho\lambda} \right),$$

where the inequality follows from the geometric ergodicity condition (4.3). Similarly, one can also see that $|\bar{h}_1^\lambda(\theta) - \langle Q_\theta, \hat{\phi}_\theta \rangle_\theta| \le C(1-\lambda)$. Let $\bar{r}(\theta)$ and $\bar{r}^\lambda(\theta)$ be solutions of the linear equations $\langle \hat{\phi}_\theta, \hat{\phi}_\theta' r \rangle_\theta = \langle Q_\theta, \phi_\theta \rangle_\theta$ and $\bar{G}_1^\lambda(\theta) r = \bar{h}_1^\lambda(\theta)$, respectively. Then

$$\langle \hat{\phi}_\theta, \hat{\phi}_\theta' \rangle_\theta (\bar{r}(\theta) - \bar{r}^\lambda(\theta)) = (\bar{h}_1(\theta) - \bar{h}_1^\lambda(\theta)) + (\bar{G}_1^\lambda(\theta) - \langle \hat{\phi}_\theta, \hat{\phi}_\theta' \rangle_\theta) \bar{r}^\lambda(\theta),$$

which implies that $|\bar{r}(\theta) - \bar{r}^\lambda(\theta)| \le C(1-\lambda)$. The rest follows from the observation that $\bar{H}(\theta)\bar{r}(\theta) = \nabla \bar{\alpha}(\theta)$. □

LEMMA 6.2 (convergence of the noise terms).

(a) $\sum_{k=0}^{\infty} \beta_k \nabla \bar{\alpha}(\theta_k) \cdot e_k^{(1)}$ *converges w.p.*1.

(b) $\lim_k e_k^{(2)} = 0$ *w.p.*1.

(c) $\sum_k \beta_k^2 |H_{\theta_k}(\hat{X}_k, \hat{U}_k) r_k \Gamma(r_k)|^2 < \infty$ *w.p.*1.

Proof. Since r_k is bounded and $\Gamma(\cdot)$ satisfies the condition (3.3), it is easy to see that $r\Gamma(r)$ is bounded and $|r\Gamma(r) - \hat{r}\Gamma(\hat{r})| < C|r - \hat{r}|$ for some constant C. The proof of part (a) is now similar to the proof of Lemma 2 on page 224 of [3]. Part (b) follows from Theorem 5.7 and the fact that $\bar{H}(\cdot)$ is bounded. Part (c) follows from the inequality

$$|H_{\theta_k}(\hat{X}_k, \hat{U}_k) r_k \Gamma(r_k)| \le C |H_{\theta_k}(\hat{X}_k, \hat{U}_k)|$$

for some $C > 0$ and the boundedness of $\mathbf{E}[|H_{\theta_k}(\hat{X}_k, \hat{U}_k)|^2]$ (from part (b) of Lemma 4.3). □

THEOREM 6.3 (convergence of actor-critic algorithms). *Let Assumptions* 3.3, 4.1, 4.2, 4.4, 4.5, 4.8, and 4.9 *hold.*

(a) *If a TD*(1) *critic is used, then* $\liminf_k |\nabla \bar{\alpha}(\theta_k)| = 0$ *w.p.*1.

(b) *For any* $\epsilon > 0$*, there exists some* λ *sufficiently close to* 1*, so that the algorithm that uses a TD*(λ) *critic (with* $0 < \lambda < 1$*) satisfies* $\liminf_k |\nabla \bar{\alpha}(\theta_k)| < \epsilon$ *w.p.*1.

Proof. The proof is standard [24], and we provide only an outline. Fix some $T > 0$, and define a sequence k_j by

$$k_0 = 0, \qquad k_{j+1} = \min \left\{ k \ge k_j \;\middle|\; \sum_{l=k_j}^{k} \beta_k \ge T \right\} \quad \text{for} \quad j > 0.$$

Using (6.1), we have

$$\bar{\alpha}(\theta_{k_{j+1}}) \le \bar{\alpha}(\theta_{k_j}) - \sum_{k=k_j}^{k_{j+1}-1} \beta_k \left(|\nabla \bar{\alpha}(\theta_k)|^2 - C(1-\lambda) |\nabla \bar{\alpha}(\theta_k)| \right) + \delta_j,$$

where δ_j is defined by

$$\delta_j = \sum_{k=k_j}^{k_{j+1}-1} \left(\beta_k \nabla \bar{\alpha}(\theta_k) \cdot (e_k^{(1)} + e_k^{(2)}) + C\beta_k^2 |H_{\theta_k}(\hat{X}_k, \hat{U}_k) r_k \Gamma(r_k)|^2 \right).$$

Lemma 6.2 implies that δ_j goes to zero. If the result fails to hold, it can be shown that the sequence $\bar{\alpha}(\theta_k)$ would decrease indefinitely, contradicting the boundedness of $\bar{\alpha}(\theta)$. The result follows easily. □

Appendix A. A result on linear stochastic approximation.

We recall the following result from [14]. Consider a stochastic process $\{\hat{Y}_k\}$ taking values in a Polish space $\mathbb{Y}$ with Borel σ-field denoted by $\mathcal{B}(\mathbb{Y})$. Let $\{P_\theta(y, d\bar{y}); \theta \in \mathbb{R}^n\}$ be a parameterized family of transition kernels on $\mathbb{Y}$. Consider the following iterations to update a vector $R \in \mathbb{R}^m$ and the parameter $\theta \in \mathbb{R}^n$:

$$\begin{aligned} R_{k+1} &= R_k + \gamma_k (h_{\theta_k}(\hat{Y}_{k+1}) - G_{\theta_k}(\hat{Y}_{k+1}) R_k + \xi_{k+1} R_k), \\ \theta_{k+1} &= \theta_k + \beta_k H_{k+1}. \end{aligned} \tag{A.1}$$

In the above iteration, $\{h_\theta(\cdot), G_\theta(\cdot) : \theta \in \mathbb{R}^n\}$ is a parameterized family of m-vector-valued and $m \times m$-matrix-valued measurable functions on $\mathbb{Y}$. We introduce the following assumptions.

Assumption A.1. The step-size sequence $\{\gamma_k\}$ is deterministic and nonincreasing and satisfies

$$\sum_k \gamma_k = \infty, \qquad \sum_k \gamma_k^2 < \infty.$$

Let $\mathcal{F}_k$ be the σ-field generated by $\{\hat{Y}_l, H_l, r_l, \theta_l, l \le k\}$.

Assumption A.2. For a measurable set $A \subset \mathbb{Y}$,

$$\mathbf{P}(\hat{Y}_{k+1} \in A \mid \mathcal{F}_k) = \mathbf{P}(\hat{Y}_{k+1} \in A \mid \hat{Y}_k, \theta_k) = P_{\theta_k}(\hat{Y}_k, A).$$

For any measurable function f on $\mathbb{Y}$, let $P_\theta f$ denote the measurable function $y \mapsto \int P_\theta(y, d\bar{y}) f(\bar{y})$, and for any vector r, let $|r|$ denote its Euclidean norm.

Assumption A.3 (existence and properties of solutions to the Poisson equation). For each θ, there exist functions $\bar{h}(\theta) \in \mathbb{R}^m$, $\bar{G}(\theta) \in \mathbb{R}^{m \times m}$, $\hat{h}_\theta : \mathbb{Y} \to \mathbb{R}^m$, and $\hat{G}_\theta : \mathbb{Y} \to \mathbb{R}^{m \times m}$ that satisfy the following:

(a) For each $y \in \mathbb{Y}$,

$$\begin{aligned} \hat{h}_\theta(y) &= h_\theta(y) - \bar{h}(\theta) + (P_\theta \hat{h}_\theta)(y), \\ \hat{G}_\theta(y) &= G_\theta(y) - \bar{G}(\theta) + (P_\theta \hat{G}_\theta)(y). \end{aligned}$$

(b) For some constant C and for all θ, we have

$$\max(|\bar{h}(\theta)|, |\bar{G}(\theta)|) \le C.$$

(c) For any $d > 0$, there exists $C_d > 0$ such that

$$\sup_k \mathbf{E}[|f_{\theta_k}(\hat{Y}_k)|^d] \le C_d,$$

where $f_\theta(\cdot)$ represents any of the functions $\hat{h}_\theta(\cdot), h_\theta(\cdot), \hat{G}_\theta(\cdot), G_\theta(\cdot)$.

(d) For some constant $C > 0$ and for all $\theta, \bar{\theta} \in \mathbb{R}^n$,

$$\max(|\bar{h}(\theta) - \bar{h}(\bar{\theta})|, |\bar{G}(\theta) - \bar{G}(\bar{\theta})|) \leq C|\theta - \bar{\theta}|.$$

(e) There exists a positive measurable function $C(\cdot)$ on $\mathbb{Y}$ such that, for each $d > 0$,

$$\sup_k \mathbf{E}[C(\hat{Y}_k)^d] < \infty$$

and

$$|P_\theta f_\theta(y) - P_{\bar{\theta}} f_{\bar{\theta}}(y)| \leq C(y)|\theta - \bar{\theta}|,$$

where $f_\theta(\cdot)$ is any of the functions $\hat{h}_\theta(\cdot)$ and $\hat{G}_\theta(\cdot)$.

Assumption A.4 (slowly changing environment). The (random) process $\{H_k\}$ satisfies

$$\sup_k \mathbf{E}\left[|H_k|^d\right] < \infty$$

for all $d > 0$. Furthermore, the sequence $\{\beta_k\}$ is deterministic and satisfies

$$\sum_k \left(\frac{\beta_k}{\gamma_k}\right)^d < \infty$$

for some $d > 0$.

Assumption A.5. The sequence $\{\xi_k\}$ is an $m \times m$-matrix-valued $\mathcal{F}_k$-martingale difference, with bounded moments, i.e.,

$$\mathbf{E}\left[\xi_{k+1}|\mathcal{F}_k\right] = 0, \qquad \sup_k \mathbf{E}\left[|\xi_{k+1}|^d\right] < \infty$$

for each $d > 0$.

Assumption A.6 (uniform positive definiteness). There exists $a > 0$ such that, for all $r \in \mathbb{R}^m$ and $\theta \in \mathbb{R}^n$,

$$r'\bar{G}(\theta)r \geq a|r|^2.$$

THEOREM A.7. *If Assumptions* A.1–A.6 *are satisfied, then the sequence R_k is bounded and*

$$\lim_k \left|R_k - \bar{G}(\theta_k)^{-1}\bar{h}(\theta_k)\right| = 0.$$

ON THE PARETO CONTROL AND NO-REGRET CONTROL FOR DISTRIBUTED SYSTEMS WITH INCOMPLETE DATA*

O. NAKOULIMA†, A. OMRANE†, AND J. VELIN†

Abstract. We discuss the control of distributed systems with incomplete data following the notion of no-regret control (or, equivalently, Pareto control) used by Lions in [*C. R. Acad. Sci. Paris Ser. I Math.*, 302 (1986), pp. 223–227] and [*C. R. Acad. Sci. Paris Ser. I Math.*, 302 (1992), pp. 1253–1257]. We associate with the no-regret control a sequence of low-regret controls defined by a quadratic perturbation previously used by Nakoulima, Omrane, and Velin in [*C. R. Acad. Sci. Paris Ser. I Math.*, 330 (2000), pp. 801–806].

In the first part, we prove that the perturbed system corresponds to a sequence of standard control problems and converges to the no-regret (or Pareto) control for which we obtain a singular optimality system. We give also some applications.

In the second part, we show how the method can be extended to the evolution case. Equations of parabolic type, Petrowsky type, or hyperbolic type are considered.

Key words. Pareto control, no-regret control, low-regret control, systems with incomplete data, cost function, quadratic perturbation

1. Introduction.

Let $\mathcal{V}$ be a real Hilbert space of dual $\mathcal{V}'$, $A \in \mathcal{L}(\mathcal{V};\mathcal{V}')$ an elliptic (parabolic or hyperbolic in the sections below) differential operator modeling a distributed system, $\mathcal{U}$ the Hilbert space of controls, and $B \in \mathcal{L}(\mathcal{U};\mathcal{V}')$. Let G be a nonempty closed vector subspace of the Hilbert space of uncertainties F, and $\beta \in \mathcal{L}(F,\mathcal{V}')$.

For $f \in \mathcal{V}'$, the state equation related to the control $v \in \mathcal{U}$ and to the uncertainty $g \in G$ is given by

$$A\,y(v,g) \;=\; f \;+ B\,v + \beta\,g. \tag{1.1}$$

Supposing that A is an isomorphism from $\mathcal{V}$ to $\mathcal{V}'$, (1.1) is well posed in $\mathcal{V}$. Denote by $y = y(v,g)$ the unique solution to (1.1). For every $g \in G$ we have then a possible state for which we rely on a cost function given by

$$J(v,g) = \Big\|C\,y - z_d\Big\|^2_{\mathcal{H}} + N\Big\|v\Big\|^2_{\mathcal{U}}, \tag{1.2}$$

where $C \in \mathcal{L}(\mathcal{V};\mathcal{H})$, $\mathcal{H}$ is a Hilbert space, $z_d \in \mathcal{H}$ fixed, $N > 0$, and $\|.\|_X$ is the norm on the real Hilbert space X. We are concerned with the optimal control of the problem (1.1)–(1.2); i.e., we want to solve

$$\inf_{v\in\mathcal{U}} J(v,g) \qquad \forall g \in G,$$

which clearly makes no sense when $G \neq \{0\}$ (G being an infinite space).

*Received by the editors October 30, 2000; accepted for publication (in revised form) February 24, 2003; published electronically August 6, 2003.

†Laboratoire de Mathématiques et Informatique, Université des Antilles et de La Guyane, Campus Fouillole 97159 Pointe-à-Pitre, Guadeloupe (FWI) (onakouli@univ-ag.fr, aomrane@univ-ag.fr, jvelin@univ-ag.fr).

The idea is to look for a solution for the following minimization problem:

$$\inf_{v\in\mathcal{U}}\left(\sup_{g\in G} J(v,g)\right),$$

but J is not upper bounded as $\sup_{g\in G} J(v,g) = +\infty$.

Lions used the notions of Pareto control [12] and no-regret control [14] in application to control the system (1.1)–(1.2).

The concept of Pareto[1] is motivated by a number of applications in economics, and also in ecology. In his book [9], Kotarski discussed the Pareto optimum problem, where some results of geometrical and numerical interest are obtained in the case of optimal control. In [8], he generalized the well-known Dubovicki–Milutin theorem (on the feasible sets of Pareto) and applied it to obtain a necessary condition for the Pareto *minimum*, or necessary and sufficient conditions on the Pareto optimum, extending a geometrical work of Censor [3]. Lions [12], [13] used the concept to obtain controls for distributed problems with incomplete data.

The no-regret concept was introduced many years later in statistics by Savage [18]. In several works, Lions applied this notion and a related idea called "low-regret" control to problems of incomplete data (see [14], [15], [16], [7], [6]) for various applications. In [14], for example, he extends the results of the work of Allwright [1] to the infinite dimension case. In [7] with Gabay, a decision criterion is added to the uncertainties closed subspace; it improves by extending the notion of low-regret to many agents: each agent wishes to act with least-regret and all agents wish to have minimum exchanges of information, in order to make things as local as possible. The low-regret control is applied to systems where there are *controls* and *unknown perturbations*. One then looks for the control not making things worse with respect to a nominal control u_0 (or to then doing nothing, $u_0 = 0$), independently of the perturbations which may be of infinite number.

We will see in section 2 that Pareto controls and no-regret controls are actually the same.

In this work, we give a characterization of the no-regret (or the Pareto) control for problems of incomplete data, in both the stationary and evolution cases. We improve the results of the work in [14] (and also [12]) of Lions by giving the precise optimality system for the low-regret control and by describing a number of applications. Thanks to a quadratic perturbation used by the authors in [17], the optimality system for the no-regret control appears clearly as the limit of a standard control problem.

Some of the results in this paper are summarized in [17]. The proofs in the present paper and the treatment of the evolution cases are new.

The paper is organized as follows. In section 2, we see the main definitions, we verify the equivalence between the two approaches of Lions, and we introduce the low-regret control method. We then give the optimality system for the perturbed problem and prove that the optimal controls for the perturbed problem converge to the no-regret (Pareto) control of original problem. Moreover, by passing to the limit in the associated optimality system of the perturbed problem, we obtain a singular optimality system for the no-regret (Pareto) control. In section 3, we give several examples of elliptic type. Section 4 is devoted to the evolution case. Here, we give

[1]Wifredo Pareto (1848–1923) was an Italian economist and a political sociologist. He defined the efficient optimum, and in particular was the one who devised the law of *trivial many* and *critical few* known as the 80:20 rule.

the theoretical results for parabolic and hyperbolic distributed systems. An example involving a parabolic system is considered in the last section.

2. No-regret control for stationary problems.

2.1. Definitions and preliminary results. We give definitions for the Pareto and no-regret controls related to a given control here, as well as the preliminary results.

DEFINITION 2.1. *We say that $u \in \mathcal{U}$ is a Pareto control for* (1.1)–(1.2) *(cf. Lions* [12]*) iff* $J(u,g) \leq J(v,g)\ \forall v \in \mathcal{U}, \forall g \in G$, *and if there exists at least* $g_0 \in G$ *such that* $J(u,g_0) < J(v,g_0)\ \forall v \in \mathcal{U}$.

DEFINITION 2.2. *Let $u \in \mathcal{U}$ be a Pareto control. We say that u is related to a control $u_0 \in \mathcal{U}$ if*

$$J(u,g) \leq J(u_0,g) \qquad \forall g \in G.$$

DEFINITION 2.3. *We say that $u \in \mathcal{U}$ is a no-regret control for* (1.1)–(1.2) *related to a control u_0 if u is a solution to the following problem:*

$$\inf_{v \in \mathcal{U}} \sup_{g \in G} \left(J(v,g) - J(u_0,g) \right). \tag{2.1}$$

When $u_0 = 0$, Definition 2.3 reduces to the definition of no-regret control of Lions [14].

LEMMA 2.4. *For any $u_0 \in \mathcal{U}$ and $v \in \mathcal{U}$ we have*

$$J(v,g) - J(u_0,g) = J(v,0) - J(u_0,0) + 2\langle \beta^* \zeta(v-u_0), g \rangle_{G',G} \qquad \forall g \in G,$$

where $\zeta(v) \in \mathcal{V}$ is defined for $v \in \mathcal{U}$ by

$$A^* \zeta(v) = C^* C(y(v,0) - y(0,0)),$$

A^* (resp., β^*) being the adjoint of A (resp., β).

Proof. We have in fact

$$J(v,g) - J(u_0,g) = J(v,0) - J(u_0,0) + 2\langle C(y(v-u_0,0) - y(0,0)), C(y(0,g) - y(0,0)) \rangle_{\mathcal{H},\mathcal{H}}$$

$\forall g \in G$. We then introduce $\zeta(v) \in \mathcal{V}$ defined by $A^* \zeta(v) = C^* C(y(v,0) - y(0,0))$, where A^* is the adjoint of A. Then

$$\begin{aligned} \langle C(y(v,0) - y(0,0)), C(y(0,g) - y(0,0)) \rangle_{\mathcal{H},\mathcal{H}} &= \langle A^* \zeta(v), y(0,g) - y(0,0) \rangle_{\mathcal{V}',\mathcal{V}}, \\ &= \langle \zeta(v), \beta g \rangle_{\mathcal{V},\mathcal{V}'} = \langle \beta^* \zeta(v), g \rangle_{G',G} \end{aligned}$$

(notice that $A(y(0,g) - y(0,0)) = \beta\, g$).

Remark 1. For sake of simplicity, we denote by $S(v) = \beta^* \zeta(v)$ the linear function for $v \in \mathcal{U}$. Then we have

$$J(v,g) - J(u_0,g) = J(v,0) - J(u_0,0) + 2\langle S(v-u_0), g \rangle_{G',G} \qquad \forall g \in G. \tag{2.2}$$

In the applications below $\beta = Id$, and we have $S(v) = \zeta(v)\ \forall v \in \mathcal{U}$.

Remark 2. Of course the problem (2.1) is defined only for the controls $v \in \mathcal{U}$ such that

$$\sup_{g \in G} \left(J(v,g) - J(u_0,g) \right) < \infty.$$

From (2.2) this is realized for the no-regret control (and the Pareto control) v iff $v \in K + u_0$, where $K = \{w \in \mathcal{U}, \langle S(w), g \rangle = 0 \ \forall g \in G\}$.

PROPOSITION 2.5 (cf. Lions [12]). *Let be $u_0 \in \mathcal{U}$. Then there exists a unique Pareto control related to u_0. Moreover, it is the unique element of the set $K + u_0$, which minimizes the functional $J(v, 0)$ on $K + u_0$.*

We can now prove the following.

THEOREM 2.6. *Let $u_0 \in \mathcal{U}$ be a given control. Then we have the following: a control $u \in \mathcal{U}$ is a Pareto control related to u_0 iff u is a no-regret control related to u_0.*

Proof. Let u be a Pareto control related to u_0, and let be $v \in K + u_0$. Then $\langle S(u - u_0), g\rangle = 0 = \langle S(v - u_0), g\rangle \ \forall g \in G$, and we have $J(u, 0) \leq J(v, 0)$ according to Proposition 2.5. Hence, using (2.2)

$$J(u, 0) - J(u_0, 0) + 2\langle S(u - u_0), g\rangle \leq \sup_{g\in G} (J(v, g) - J(u_0, g)) ;$$

that is, $\sup_{g\in G} (J(u, g) - J(u_0, g)) \leq \sup_{g\in G} (J(v, g) - J(u_0, g))$. So,

$$\sup_{g\in G} (J(u, g) - J(u_0, g)) = \inf_{v\in K+u_0} \Big(\sup_{g\in G} (J(v, g) - J(u_0, g)) \Big).$$

Now, let be $v \in \mathcal{U}\setminus \{K + u_0\}$. There is at least one $g_0 \in G$ such that $\langle S(v-u_0), g_0\rangle \neq 0$. Then we have

$$\sup_{g\in G} (J(v, g) - J(u_0, g)) = J(v, 0) - J(u_0, 0) + 2 \sup_{g\in G} \langle S(v - u_0), g\rangle = +\infty.$$

(Note that G is a vector space, and henceforth we have the only two possibilities: $\sup_{g\in G}\langle S(w), g\rangle = 0$ or $\sup_{g\in G}\langle S(w), g\rangle = +\infty$. Indeed, $\lim_{t\to+\infty}\langle S(v - u_0), tg_0\rangle = +\infty$.)

From another side, as u is a Pareto control we have $J(u, g) - J(u_0, g) \leq 0 \ \forall g \in G$; hence

$$J(u, g) - J(u_0, g) \leq 0 \leq \sup_{g\in G} (J(v, g) - J(u_0, g)) \qquad \forall g \in G.$$

Finally,

$$\sup_{g\in G} (J(u, g) - J(u_0, g)) = \inf_{v\in \mathcal{U}\setminus(K+u_0)} \Big(\sup_{g\in G} (J(v, g) - J(u_0, g)) \Big).$$

In conclusion, u is a no-regret control related to u_0.

Conversely, let u be a no-regret control related to u_0. We have

$$\sup_{g\in G} (J(u, g) - J(u_0, g)) \leq \sup_{g\in G} (J(v, g) - J(u_0, g)) \qquad \forall v \in \mathcal{U}.$$

Then for $v = u_0$,

$$J(u, 0) + \sup_{g\in G} \langle S(u - u_0), g\rangle \leq J(u_0, 0) = c \quad \text{constant}.$$

As $J(u, 0) \geq 0$, we have $\sup_{g\in G}\langle S(u - u_0), g\rangle \leq c$. We deduce that $\sup_{g\in G}\langle S(u - u_0), g\rangle = 0$. Consequently, $\langle S(u - u_0), g\rangle \leq 0 \ \forall g \in G$, and hence $\langle S(u - u_0), g\rangle = 0$. So, $u \in K + u_0$, and we have

$$J(u, 0) \leq J(v, 0) \qquad \forall v \in K + u_0.$$

In conclusion, u is a Pareto control related to u_0. ∎

Remark 3. By Proposition 2.5, we know that there exists a unique Pareto control related to u_0, and that is the only one which minimizes the functional $\inf_{v\in K+u_0} J(v,0)$. In the second part of Theorem 2.6, it is proved that the no-regret control related to u_0—if it exists—also minimizes this functional. As a matter of fact, that suffices to show the existence of a unique no-regret control related to u_0 and that the Pareto control and no-regret control for the problem (1.1)–(1.2) are actually the same.

We are interested in the existence and the characterization of the no-regret (or Pareto) control related to u_0. We follow the lines of [14] where Lions introduced the method of low-regret control.

2.2. Low-regret control. As in [17], we define the low-regret control by relaxing the problem (2.1) as follows:

$$\inf_{v\in\mathcal{U}} \sup_{g\in G} \left[J(v,g) - J(u_0,g) - \gamma\|g\|_G^2\right], \tag{2.3}$$

where $u_0 \in \mathcal{U}$ is a given control, and where γ is a strictly positive parameter. The solution to problem (2.3), if it exists, will be the low-regret control related to u_0, of the problem (1.1)–(1.2).

Remark 4 (cf. Lions [15]). With the "low-regret control," we admit the possibility of making a choice of controls v "slightly worse" ($J(v,g) - J(u_0,g) \le \gamma\|g\|_G^2$ and not $J(v,g) - J(u_0,g) \le 0$ as for the no-regret control) than by doing better than u_0—but not much better—if we choose γ small enough (compared to the worst things that could happen with the "pollution" g).

The best possible choice of v is then given by (2.3).

From (2.2) the problem (2.3) also writes

$$\inf_{v\in\mathcal{U}} \left[J(v,0) - J(u_0,0) + \sup_{g\in G} \left(\langle 2S(v-u_0), g\rangle - \gamma\|g\|_G^2\right)\right].$$

Remark 5. By the perturbation (2.3) we have explicitly the conjugate

$$\sup_{g\in G} \left(\langle 2S(v-u_0), g\rangle - \gamma\|g\|_G^2\right)$$

as we find

$$\sup_{g\in G} \left(\langle 2S(v-u_0), g\rangle - \gamma\|g\|_G^2\right) = \frac{1}{\gamma}\left\|S(v-u_0)\right\|_{G'}^2.$$

With this, if we identify G and G', the problem (2.3) takes the form

$$\inf_{v\in\mathcal{U}} \mathcal{J}^\gamma(v), \tag{2.4}$$

where

$$\mathcal{J}^\gamma(v) = J(v,0) - J(u_0,0) + \frac{1}{\gamma}\left\|S(v-u_0)\right\|_G^2. \tag{2.5}$$

We recognize then a standard optimization problem of a quadratic cost functional.

2.3. Approached optimality system. Now we give the optimality system for the low-regret control u_γ.

PROPOSITION 2.7. *The problem* (2.4)–(2.5) *admits a unique solution* u_γ *called the low-regret control related to* u_0.

Proof. We have $\mathcal{J}^\gamma(v) \geq -J(u_0,0)\ \forall v \in \mathcal{U}$. Then $d_\gamma = \inf_{v\in\mathcal{U}} \mathcal{J}^\gamma(v)$ exists. Let then $v_n = v_n(\gamma)$ be a minimizing sequence such that $d_\gamma = \lim_{n\to\infty} \mathcal{J}^\gamma(v_n)$. We have

$$-J(u_0,0) \leq \mathcal{J}^\gamma(v_n) = J(v_n,0) - J(u_0,0) + \frac{1}{\gamma}\Big\|S(v_n)\Big\|_G^2 \leq d_\gamma + 1.$$

Then we deduce the bounds

$$\Big\|v_n\Big\|_{\mathcal{U}} \leq c_\gamma, \qquad \frac{1}{\sqrt{\gamma}}\Big\|S(v_n - u_0)\Big\|_G \leq c_\gamma, \qquad \Big\|Cy(v_n,0) - z_d\Big\|_{\mathcal{H}} \leq c_\gamma,$$

where the constant c_γ (independent of n) is not the same each time.

There exists $u_\gamma \in \mathcal{U}$ such that $v_n \rightharpoonup u_\gamma$ weakly in the Hilbert space $\mathcal{U}$. Also, $y(v_n,0) \to y(u_\gamma,0)$ (continuity w.r.t the data). We also deduce from the strict convexity of the cost function $\mathcal{J}^\gamma$ that u_γ is unique. ∎

THEOREM 2.8. *The solution* u_γ *of the relaxed problem* (2.4)–(2.5) *weakly converges in* $\mathcal{U}$ *as* $\gamma \to 0$ *to the unique no-regret control related to* u_0.

Proof. Let u_γ be the solution to (2.4)–(2.5). Then

$$J(u_\gamma,0) - J(u_0,0) + \frac{1}{\gamma}\Big\|S(u_\gamma - u_0)\Big\|_G^2 \leq J(v,0) - J(u_0,0) + \frac{1}{\gamma}\Big\|S(v-u_0)\Big\|_G^2 \quad \forall v \in \mathcal{U}.$$

Particularly for $v = u_0$, we have

$$J(u_\gamma,0) - J(u_0,0) + \frac{1}{\gamma}\Big\|S(u_\gamma - u_0)\Big\|_G^2 \leq 0,$$

and the structure of $J(u_\gamma,0)$ in (1.2) gives

$$\Big\|Cy(u_\gamma,0) - z_d\Big\|_{\mathcal{H}}^2 + N\Big\|u_\gamma\Big\|_{\mathcal{U}}^2 + \frac{1}{\gamma}\Big\|S(u_\gamma - u_0)\Big\|_G^2 \leq J(u_0,0). \tag{2.6}$$

We deduce that $\|u_\gamma\|_{\mathcal{U}} \leq c$. Then we can extract a subsequence u_γ which weakly converges towards $u \in \mathcal{U}$, the solution to (2.4).

Now for $v \in \mathcal{U}$ we have

$$J(v,g) - J(u_0,g) - \gamma\|g\|^2 \leq J(v,g) - J(u_0,g) \quad \forall g \in G.$$

Then

$$J(u_\gamma,g) - J(u_0,g) - \gamma\|g\|^2 \leq \sup_{g\in G}\left(J(v,g) - J(u_0,g)\right) \quad \forall g \in G,$$

and passing to the limit in γ we obtain

$$J(u,g) - J(u_0,g) \leq \sup_{g\in G}\left(J(v,g) - J(u_0,g)\right) \qquad \forall g \in G.$$

We deduce easily that u is a no-regret control related to u_0. ∎

Now we give the optimality system for the low-regret control.

PROPOSITION 2.9. *The low-regret control u_γ solution to* (2.4)–(2.5) *is characterized by the unique solution $\{y_\gamma, \zeta_\gamma, \rho_\gamma, p_\gamma\}$ of the optimality system*

$$\begin{cases} A\, y_\gamma & = f + Bu_\gamma, \quad A^*\zeta_\gamma = C^*C(y_\gamma - y(0,0)), \\ A\, \rho_\gamma & = \frac{1}{\gamma}\beta\beta^*\zeta_\gamma, \quad A^*p_\gamma = C^*(Cy_\gamma - z_d) + C^*C\rho_\gamma, \\ B^*p_\gamma + Nu_\gamma & = 0 \quad in \quad \mathcal{U}. \end{cases}$$

Proof. Let u_γ be the solution of (2.4)–(2.5) on $\mathcal{U}$. The Euler–Lagrange necessary condition gives for every $w \in \mathcal{U}$

$$\langle C^*\left(Cy(u_\gamma,0) - z_d\right), y(w,0) - y(0,0)\rangle_{\mathcal{H}\times\mathcal{H}} + \langle Nu_\gamma, w\rangle_{\mathcal{U}\times\mathcal{U}} + 2\left\langle \frac{1}{\gamma}S(u_\gamma), S(w)\right\rangle_{G\times G} \geq 0.$$

Denoting $y_\gamma = y(u_\gamma, 0)$ and $\xi_\gamma(v) = \beta S(v)$ we have

$$A^*\xi_\gamma = C^*C(y_\gamma - y(0,0)).$$

Let ρ_γ be the solution to

$$A\rho_\gamma = \frac{1}{\gamma}\beta\beta^*\xi.$$

And as it is classical, we introduce the adjoint state p_γ defined by

$$B^*p_\gamma = C^*(Cy_\gamma - z_d) + C^*C\rho_\gamma$$

so that we obtain

$$\langle B^*p_\gamma + Nu_\gamma, w\rangle \geq 0 \qquad \forall w \in \mathcal{U}.$$

But also we have $\langle B^*p_\gamma + Nu_\gamma, w\rangle \leq 0 \ \forall w \in \mathcal{U}$. The optimality system follows. □

2.4. Singular optimality system. Now, we give the optimality system for the no-regret control.

As in [12] let $\mathcal{R}$ be an operator defined as follows.

We solve first

$$A\,\rho = \beta\, g, \quad g \in G, \quad \rho \in \mathcal{V},$$

then

$$A^*\sigma = C^*C\rho, \quad \sigma \in \mathcal{V},$$

and we set $\mathcal{R}\, g = B^*\,\sigma$. We suppose that

$$\left\|\mathcal{R}\, g\right\|_{\widehat{G}} \geq c\left\|g\right\|_G, \quad c > 0, \quad \text{for any} \quad g \in G, \tag{2.7}$$

where $\widehat{G}$ is the completion of G in F, containing the elements $\mathcal{R}g$.

Remark 6. The space $\widehat{G}$ is in fact the completion of G for a subspace $(H, \|.\|_{\|.\|})$ of F which can be bigger than G. This will be made precise in the applications below.

Remark 7. The hypothesis (2.7) is very useful theoretically but is not necessary in practice. We need only to make sure that the adjoint state p_γ of Proposition 2.9 is bounded in a suitable Hilbert space, which is the case in the applications given below.

THEOREM 2.10. *Suppose that* (2.7) *holds true. Then the no-regret control* u *related to* u_0*, solution to* (2.1)*, is characterized by the unique* $\{y, \lambda, \rho, p\}$ *solution to the singular optimality system*

$$\begin{cases} A\,y & = f + Bu, \\ A\,\rho & = \lambda, \\ B^*p + Nu & = 0, \end{cases} \qquad A^*p = C^*(Cy - z_d) + C^*C\rho,$$

with $\lambda \in \widehat{G}$.

Proof. From the relation (2.6) and Theorem 2.8, the sequence $\{u_\gamma\}$ weakly converges in $\mathcal{U}$ to u the unique no-regret control related to u_0. The operator B being continuous from $\mathcal{U}$ to $\mathcal{V}'$, $\{Bu_\gamma\}$ weakly converges in $\mathcal{V}'$ to Bu. Now, from the above optimality system of Proposition 2.9, the sequence $\{Ay_\gamma\}$ is bounded in $\mathcal{V}'$ and, as A is an isomorphism, weakly converges to Ay in $\mathcal{V}'$. Passing to the limit in the first equation we obtain $Ay = f + B\,u$. We also deduce from Proposition 2.9 that $B^*p_\gamma = -Nu_\gamma$ is bounded in $\mathcal{V}'$. According to the hypothesis (2.7), let $\mathcal{R}$ be the operator such that $\mathcal{R}(\frac{1}{\gamma}\beta^*\xi_\gamma) = B^*p_\gamma$. We deduce under (2.7) that $\{\frac{1}{\gamma}\beta^*\xi_\gamma\}$ is bounded in G subset of the Hilbert space F. Then it converges to $\lambda \in \widehat{G} \subset F$. Hence, $A\rho_\gamma = \frac{1}{\gamma}\beta^*\xi_\gamma$ is bounded, and then $\{\rho_\gamma\}$—also bounded thanks to the isomorphism of A—weakly converges to $\rho \in \mathcal{V}$. Consequently, $A\rho_\gamma \rightharpoonup A\rho$.

From the boundness of $\{\rho_\gamma\}$ and $\{y_\gamma\}$ we obtain that A^*p_γ is bounded. Then $\{p_\gamma\}$ converges to p. The optimality system follows. □

Remark 8. The situation described by Theorem 2.10, as indicated by Lions in [12], is completely general, but with λ which should be in the completion of G. This will be made precise in the following applications.

3. Application. In this section, we apply the above method throughout the examples given below in different situations: control and uncertainty given in the interior domain, as well as on the boundary.

Example 1. A distributed control, uncertain boundary values, and a boundary cost function.

Let Ω be a bounded open domain of $\mathbb{R}^N$ of regular boundary Γ. We consider the distributed system

$$\begin{cases} -\Delta y + y = f + v & \text{in } \Omega, \\ \dfrac{\partial y}{\partial \nu} = g & \text{on } \Gamma, \end{cases} \tag{3.1}$$

where $v \in \mathcal{U} = L^2(\Omega)$, and where $g \in G \subset F = L^2(\Gamma)$, G a closed subspace of F. If $f \in L^2(\Omega)$, there exists a unique $y(v, g) \in H^{3/2}(\Omega)$ solution to (3.1).

We associate with the state $y(v, g)$ the cost function

$$J(v, g) = \Big|y(v, g) - z_d\Big|^2_{L^2(\Gamma)} + N\Big\|v\Big\|^2_{L^2(\Omega)}. \tag{3.2}$$

For $u_0 \in \mathcal{U}$, there exists a unique no-regret control u related to u_0. For simplicity, take $u_0 = 0$. The problem now is to give the optimality system for the no-regret control u.

Notice that

$$J(v,g) - J(0,g) = J(v,0) - J(0,0) + 2\left(y(v,0) - y(0,0), y(0,g) - y(0,0)\right)_{L^2(\Gamma)}$$

and that the function $v \longmapsto y(v,0) - y(0,0)$ (resp., $g \longmapsto y(0,g) - y(0,0)$) is linear w.r.t v (resp., g) and is the solution to

$$\begin{cases} A\,z = v & \text{in } \Omega \\ \frac{\partial z}{\partial \nu} = 0 & \text{on } \Gamma \end{cases} \qquad \left(\text{resp.,} \quad \begin{cases} A\,z = 0 & \text{in } \Omega, \\ \frac{\partial z}{\partial \nu} = g & \text{on } \Gamma \end{cases}\right),$$

where $A = -\Delta + I$. Using the Green formula

$$(\varphi, A\psi)_{L^2(\Omega)} - (\psi, A\varphi)_{L^2(\Omega)} = \int_\Gamma \varphi \frac{\partial \psi}{\partial \nu_A} d\gamma - \int_\Gamma \psi \frac{\partial \varphi}{\partial \nu_A} d\gamma, \tag{3.3}$$

we find

$$0 = \int_\Gamma \left(y(0,g) - y(0,0)\right)\left(y(v,0) - y(0,0)\right) d\gamma - \int_\Gamma S(v)\, g\, d\gamma,$$

where $v \longmapsto S(v)$ is a linear function so that $AS = 0$, $\frac{\partial S}{\partial \nu} = y(v,0) - y(0,0)$.

Moreover, the following regularity result holds: We have $y(0,g) - y(0,0) \in H^{3/2}(\Omega)$ as $\frac{\partial}{\partial \nu_A}\left(y(0,g) - y(0,0)\right) \in L^2(\Gamma)$, and as $S(v) \in H^2(\Omega)$ we have also $\frac{\partial S}{\partial \nu} = y(v,0) - y(0,0) \in H^{3/2}(\Omega)$.

From section 2, the low-regret control method associated with (3.1)–(3.2) is defined by

$$\mathcal{J}^\gamma(v) = J(v,0) - J(0,0) + \frac{1}{\gamma}\left\|S(v)\right\|^2_{L^2(\Gamma)}, \tag{3.4}$$

where $S(v) = \zeta(v)$ is the solution of

$$\begin{cases} A\,S(v) = 0 & \text{in} \quad \Omega, \\ \frac{\partial S}{\partial \nu_A} = y(v,0) - y(0,0) & \text{on} \quad \Gamma. \end{cases}$$

The problem

$$\inf_{v \in \mathcal{U}} \mathcal{J}^\gamma(v) \tag{3.5}$$

admits a unique solution $v = u_\gamma$. Then the necessary condition of first order of Euler on $\mathcal{U}$ for every $w \in \mathcal{U}$ writes

$$\left(y(u_\gamma,0) - z_d, y(w,0) - y(0,0)\right) + (Nu_\gamma, w) + \left(\frac{1}{\gamma} S(u_\gamma), S(w)\right) \geq 0. \tag{3.6}$$

We have the following proposition.

Proposition 3.1. *The low-regret control u_γ solution to* (3.4)–(3.5) *is characterized by the unique $\{y_\gamma, \zeta_\gamma, \rho_\gamma, p_\gamma\}$ solution to*

$$\begin{cases} A\,y_\gamma = f + u_\gamma, & A\zeta_\gamma = 0, & A\,\rho_\gamma = 0, & A\,p_\gamma = 0, \\ \frac{\partial y_\gamma}{\partial \nu} = 0, & \frac{\partial \zeta_\gamma}{\partial \nu} = y_\gamma - y(0,0), & \frac{\partial \rho_\gamma}{\partial \nu} = \frac{1}{\gamma}\zeta_\gamma, & \frac{\partial p_\gamma}{\partial \nu} = y_\gamma - z_d + \rho_\gamma, \\ p_\gamma + Nu_\gamma = 0 & & & \text{in} \quad L^2(\Omega), \end{cases}$$

with

$$u_\gamma \in L^2(\Omega) \qquad \textit{and} \quad y_\gamma, \zeta_\gamma, \rho_\gamma, p_\gamma \in H^{3/2}(\Omega).$$

Proof. Denote $y_\gamma = y(u_\gamma, 0)$, and let $\zeta(u_\gamma)$ be the solution of $A\zeta_\gamma = 0$, $\frac{\partial \zeta_\gamma}{\partial \nu} = y_\gamma - y(0,0)$. Let now ρ_γ be the solution of $A\rho_\gamma = 0$, $\frac{\partial \rho_\gamma}{\partial \nu} = \frac{1}{\gamma}\zeta_\gamma$. Then by the above Green formula

$$\begin{aligned}\left(\frac{1}{\gamma}\zeta_\gamma(u_\gamma), \zeta_\gamma(w)\right)_{L^2(\Gamma)} &= (A\rho_\gamma, \zeta)_{L^2(\Omega)} - (\rho_\gamma, A\zeta_\gamma)_{L^2(\Omega)} + \left(\rho_\gamma, \frac{\partial \zeta_\gamma}{\partial \nu}\right)_{L^2(\Gamma)} \\ &= \left(\rho_\gamma, \frac{\partial \zeta_\gamma}{\partial \nu}\right)_{L^2(\Gamma)}.\end{aligned}$$

The inequality (3.6) becomes

$$(y_\gamma - z_d + \rho_\gamma, y(w,0) - y(0,0)) + (Nu_\gamma, w) \le 0.$$

Now, and as it is classical, we calculate the adjoint state p_γ such that $Ap_\gamma = 0$, $\frac{\partial p_\gamma}{\partial \nu} = y_\gamma - z_d + \rho_\gamma$.

This is for any w in the vector space $\mathcal{U}$. Then we have

$$p_\gamma \; + \; Nu_\gamma \; = 0. \qquad \square$$

Remark 9. The passage to the limit on γ for the no-regret control is an adaptation of the proof of the Theorem 2.10. Let us note that we do not need the hypothesis (2.7) as we have $B^* = B = Id$.

We obtain the following theorem.

THEOREM 3.2. *The no-regret control u related to $u_0 = 0$ of the problem* (3.1)–(3.2) *is characterized by the unique solution $\{y, \lambda, \rho, p\}$ of the optimality system*

$$\begin{cases} A\,y & = f + u, \quad A\,\rho = 0, \quad A\,p = 0 & \textit{in } \Omega, \\ \dfrac{\partial y}{\partial \nu} & = 0, \qquad \dfrac{\partial \rho}{\partial \nu} = \lambda, \quad \dfrac{\partial p}{\partial \nu} = y - z_d + \rho & \textit{on } \Gamma, \\ p + Nu & = 0 & \textit{in } L^2(\Omega), \end{cases}$$

with

$$\begin{cases} u \in L^2(\Omega),\ y \in H^{3/2}(\Omega), & p \in L^2(\Omega), \\ \lambda \in \widehat{G} \qquad \textit{completion of } G \textit{ for the norm } H^{-5/2}(\Gamma),\ \rho \in H^{-1}(\Omega). \end{cases} \qquad \square$$

Example 2. A boundary control, boundary uncertainty, boundary cost function.

Let Ω be an open domain from $\mathbb{R}^N$ of boundary $\partial\Omega = \Gamma_0 \cup \Gamma_1$, with Γ_0 and Γ_1 being two regular boundaries such that $\Gamma_0 \cap \Gamma_1 = \emptyset$.

We consider the distributed parameter system

$$\text{(3.7)} \qquad \begin{cases} -\Delta y + y = 0 & \text{in } \Omega, \\ \dfrac{\partial y}{\partial \nu} = v & \text{on } \Gamma_0, \\ \dfrac{\partial y}{\partial \nu} = g & \text{on } \Gamma_1. \end{cases}$$

For $v \in \mathcal{U} = L^2(\Gamma_0)$ and $g \in G \subset L^2(\Gamma_1)$, (3.7) admits a unique solution $y(v,g) \in H^{3/2}(\Omega)$.

We associate with the state $y(v,g)$ the cost function

$$J(v,g) = \Big|y(v,g) - z_d\Big|^2_{L^2(\Gamma_0)} + N\Big|v\Big|^2_{L^2(\Gamma_0)}. \tag{3.8}$$

For u_0 fixed in $\mathcal{U}$, there exists a unique no-regret control u related to u_0. We suppose that $u_0 = 0$.

The low-regret control associated is defined by the following cost function:

$$\mathcal{J}^\gamma(v) = J(v,0) - J(0,0) + \frac{1}{\gamma}\Big\|S(v)\Big\|^2_{L^2(\Gamma_1)}, \tag{3.9}$$

where $S(v) = \zeta(v)$ is the solution to

$$\begin{cases} A\,S(v) = 0 & \text{in } \Omega, \\ \dfrac{\partial S}{\partial \nu} = y(v,0) & \text{on } \Gamma_0, \\ \dfrac{\partial S}{\partial \nu} = 0 & \text{on } \Gamma_1 \end{cases} \tag{3.10}$$

and where $A = -\Delta + I$.

Indeed,

$$J(v,g) - J(0,g) = J(v,0) - J(0,0) + 2(y(v,0), y(0,g))_{L^2(\Gamma_0)\times L^2(\Gamma_0)}.$$

Then by the Green formula we obtain

$$(y(v,0), y(0,g))_{L^2(\Gamma_0)\times L^2(\Gamma_0)} = (S(v), g)_{L^2(\Gamma_0)\times L^2(\Gamma_0)},$$

with $S(.)$ the solution to (3.10). The problem

$$\inf_{v\in\mathcal{U}} \mathcal{J}^\gamma(v) \tag{3.11}$$

admits a unique solution u_γ called the low-regret control.

PROPOSITION 3.3. *The low-regret control u_γ solution to* (3.9)–(3.11) *is characterized by the unique solution $\{y_\gamma, \zeta_\gamma, \rho_\gamma, p_\gamma\}$ of the optimality system*

$$\begin{cases} A\,y_\gamma = 0, & A\zeta_\gamma = 0, & A\,\rho_\gamma = 0, & A\,p_\gamma = 0 & \text{in} \quad \Omega, \\ \dfrac{\partial y_\gamma}{\partial \nu} = u_\gamma, & \dfrac{\partial \zeta_\gamma}{\partial \nu} = y_\gamma, & \dfrac{\partial \rho_\gamma}{\partial \nu} = 0, & \dfrac{\partial p_\gamma}{\partial \nu} = y_\gamma - z_d + \rho_\gamma & \text{on} \quad \Gamma_0, \\ \dfrac{\partial y_\gamma}{\partial \nu} = 0, & \dfrac{\partial \zeta_\gamma}{\partial \nu} = 0, & \dfrac{\partial \rho_\gamma}{\partial \nu} = \frac{1}{\gamma}\zeta_\gamma, & \dfrac{\partial p_\gamma}{\partial \nu} = 0 & \text{on} \quad \Gamma_1, \\ p_\gamma + N u_\gamma = 0 & & & & \text{on} \quad \Gamma_0, \end{cases}$$

with, $u_\gamma \in L^2(\Gamma_0)$, and $y_\gamma \in H^{3/2}(\Omega), \zeta_\gamma \in H^{5/2}(\Omega), \rho_\gamma \in H^{7/2}(\Omega), p_\gamma \in H^{1/2}(\Omega)$.

Proof. The Euler condition gives

$$(y_\gamma - z_d, y(w,0))_{L^2(\Gamma_1)\times L^2(\Gamma_1)} + N\,(u_\gamma, w)_{L^2(\Gamma_0)\times L^2(\Gamma_0)} + \left(\frac{1}{\gamma}\xi(u_\gamma), \xi(w)\right)_{L^2(\Gamma_1)\times L^2(\Gamma_1)} \geq 0. \tag{3.12}$$

We first solve for ρ_γ: $A\,\rho_\gamma = 0$, with $\frac{\partial \rho_\gamma}{\partial \nu} = 0$ on Γ_0, and $\frac{\partial \rho_\gamma}{\partial \nu} = \frac{1}{\gamma}\xi(u_\gamma)$ on Γ_1. Hence

$$\left(\frac{1}{\gamma}\xi(u_\gamma), \xi(w)\right)_{L^2(\Gamma_1)\times L^2(\Gamma_1)} = (\rho_\gamma, y(w,0))_{L^2(\Gamma_0)\times L^2(\Gamma_0)}$$

so that (3.12) becomes

$$(y_\gamma - z_d + \rho_\gamma, y(w,0))_{L^2(\Gamma_0)\times L^2(\Gamma_0)} + N\,(u_\gamma, w)_{L^2(\Gamma_0)\times L^2(\Gamma_0)} \geq 0.$$

Let now p_γ be the solution of $A\,p_\gamma = 0$, with $\frac{\partial p_\gamma}{\partial \nu} = y_\gamma - z_d$ on Γ_0, and $\frac{\partial p_\gamma}{\partial \nu} = 0$ on Γ_1.

We have then

$$(y_\gamma - z_d + \rho_\gamma, y(w,0))_{L^2(\Gamma_0)\times L^2(\Gamma_0)} = (p_\gamma, w)_{L^2(\Gamma_0)\times L^2(\Gamma_0)}.$$

Finally, as $L^2(\Gamma_0)$ is a vector space, we have

$$p_\gamma \;+\; N u_\gamma \;= 0 \qquad \forall w \in L^2(\Gamma_0). \qquad \square$$

The passage to the limit on γ leads to the following theorem.

THEOREM 3.4. *The no-regret control u of the system* (3.7)–(3.8) *is characterized by the unique solution $\{y, \lambda, \rho, p\}$ of the optimality system*

$$\begin{cases} A\,y = 0, & A\,\rho = 0, & A\,p = 0 & \text{in} \quad \Omega, \\ \dfrac{\partial y}{\partial \nu} = u, & \dfrac{\partial \rho}{\partial \nu} = 0, & \dfrac{\partial p}{\partial \nu} = y - z_d + \rho & \text{on} \quad \Gamma_0, \\ \dfrac{\partial y}{\partial \nu} = 0, & \dfrac{\partial \rho}{\partial \nu} = \lambda, & \dfrac{\partial p}{\partial \nu} = 0 & \text{on} \quad \Gamma_1, \\ p + Nu = 0 & & & \text{in} \quad L^2(\Gamma_0), \end{cases}$$

with

$$\begin{cases} u \in L^2(\Omega), & y \in H^{3/2}(\Omega), & p \in H^{1/2}(\Omega), \\ \lambda \in \widehat{G} \text{ completion of } G \text{ in } H^{-2}(\Gamma), & \rho \in H^{-1/2}(\Omega). \end{cases} \qquad \square$$

4. The evolution case.

4.1. No-regret control for systems of parabolic type. In this section, $A \in \mathcal{L}(\mathcal{V}; \mathcal{V}')$ is an elliptic differential operator

$$(\,A\,v\,,\,v\,) \geq \alpha \left\|v\right\|^2, \quad \alpha > 0, \quad \left\|\;\right\| = \text{norm in} \quad \mathcal{V},$$

$B \in \mathcal{L}\left(\mathcal{U}; L^2(0,T;\mathcal{V}')\right)$, and F is the real Hilbert space of uncertainties such that

$$\mathcal{V} \;\subset\; F \;\subset\; \mathcal{V}'.$$

Let then G be the closed vector subspace of F.

For $f \in L^2(0,T;\mathcal{V}')$, the state equation that we consider is

$$\frac{\partial y}{\partial t} \;+\; A\,y \;=\; f \;+ B\,v, \tag{4.1}$$

with

$$y(t=0,v,g) = y_0 + g, \tag{4.2}$$

where y_0 is a given data in F and where $g \in G$.

For chosen v and g, the problem (4.1)–(4.2) admits a unique solution noted $y(v,g) \in L^2(0,T;\mathcal{V})$.

For a fixed $t \in (0,T)$, and for any $g \in G$ we have then a possible state for which we attach a cost function given by

$$J(v,g) = \int_0^T \|Cy(v,g) - z_d\|^2_{\mathcal{H}} dt + N \int_0^T \|v\|^2_{\mathcal{U}}\, dt, \tag{4.3}$$

where

$$C \in \mathcal{L}\,(\,L^2(0,T;\mathcal{V});\mathcal{H}\,), \tag{4.4}$$

the set $\mathcal{H}$ is a Hilbert space, $z_d \in \mathcal{H}$ fixed, $N > 0$, and $\|.\|_X$ represents the norm defined on the Hilbert space X.

When $G = \{0\}$, a standard control problem is to find

$$\inf_{v \in \mathcal{U}} J(v,0). \tag{4.5}$$

We now develop the approach of the first part to this evolution case, when $G \neq \{0\}$.

4.1.1. Least regret control. Approached optimality system. Following the lines of [13] and using the notations in [17], we have then

$$J(v,g) - J(u_0,g) = J(v,0) - J(u_0,0) + 2\langle\, \xi(v-u_0), g\,\rangle_{G' \times G}, \tag{4.6}$$

where

$$S(v) = \zeta(t=0,v) \tag{4.7}$$

and where ζ is the solution to the backwards problem

$$\begin{cases} -\zeta' + A^*\,\zeta \;= C^*C(y(v,0) - y(0,0)), \\ \zeta\,(t=T,v) = 0, \end{cases} \tag{4.8}$$

with $\zeta' = \frac{\partial \zeta}{\partial t}$.

Then the low-regret control associated with the problem (4.1)–(4.3) is defined by

$$\inf_{v \in \mathcal{U}} \mathcal{J}^\gamma(v), \tag{4.9}$$

$$\mathcal{J}^\gamma(v) = J(v,0) - J(u_0,0) + \frac{1}{\gamma}\Big\|\zeta(0,v-u_0)\Big\|^2_{G'}, \tag{4.10}$$

where G' is the dual of G which can be identified to G. The problem (4.9)–(4.10) has a unique solution u_γ called low-regret control.

PROPOSITION 4.1. *The low-regret control u_γ solution to* (4.9)–(4.10) *is characterized by the unique solution $\{y_\gamma, \zeta_\gamma, \rho_\gamma, p_\gamma\}$ of the optimality system*

$$\begin{cases} y'_\gamma \,+\, A\,y_\gamma & = f + Bu_\gamma, & -\zeta'_\gamma \,+\, A^*\zeta_\gamma \,=\, C^*C(y_\gamma - y(0,0)), \\ \rho'_\gamma \,+\, A\rho_\gamma & = 0, & -p'_\gamma \,+\, A^*p_\gamma \,=\, C^*(Cy_\gamma - z_d) + C^*C\rho_\gamma, \\ y_\gamma(t=0) = y_0, & \rho_\gamma(0) = \frac{1}{\gamma}\zeta_\gamma, & \zeta_\gamma(T) = 0, \qquad p_\gamma(T) = 0, \\ B^*p_\gamma + Nu_\gamma & = 0 \quad \textit{in} \quad \mathcal{U}. \end{cases}$$

Proof. Let u_γ be the solution of the problem (4.9)–(4.10). The Euler first order condition gives the following optimality system:

(4.11)

$$(\,Cy(u_\gamma,0)-z_d, C(y(w,0)-y(0,0))\,)_{\mathcal{H}\times\mathcal{H}} + (\,Nu_\gamma, w\,)_{\mathcal{U}\times\mathcal{U}} + \left(\frac{1}{\gamma}\zeta(0,u_\gamma-u_0),\zeta(0,w)\right)_{G\times G} \geq 0.$$

With this in mind, let $y_\gamma = y(u_\gamma,0)$, and look for $\zeta_\gamma = \zeta(0,u_\gamma-u_0)$ to be the solution of (4.8) and $\rho_\gamma \in \mathcal{V}$ the solution of

$$\begin{cases} \rho'_\gamma + A\rho_\gamma = 0, \\ \rho_\gamma(t=0) = \frac{1}{\gamma}\zeta_\gamma. \end{cases}$$

As it is classical, we introduce the adjoint state p_γ defined by

$$-p'_\gamma + A^* p_\gamma = C^*(Cy_\gamma - z_d) + C^*C\rho_\gamma, \qquad \text{with} \quad p_\gamma(T)=0.$$

Hence we deduce from (4.11)

$$B^* p_\gamma + Nu_\gamma = 0 \qquad \text{in} \quad \mathcal{U}. \tag{4.12}$$

This ends the proof. ∎

4.1.2. Singular optimality system. We now give the optimality system for the no-regret control. We need a supplementary hypothesis. Let $\rho \in L^2(0,T;V)$ be defined by

$$\rho' + A\,\rho = 0, \quad \rho(0) = g, \quad g \in G,$$

and $\sigma \in L^2(0,T;V)$ as

$$-\sigma' + A^*\sigma = C^*C\,\rho, \quad \sigma(T)=0.$$

Setting $R\,g = B^*\sigma$, then we define the continuous operator $g \mapsto Rg$ from F to $\mathcal{U}$, and we do the hypothesis

$$\Big\|R\,g\Big\|_{\mathcal{U}} \geq c\,\Big\|g\Big\|_{F} \quad c>0 \quad \forall g \in G. \tag{4.13}$$

THEOREM 4.2. *We suppose that* (4.13) *holds true. Then the no-regret control* u *related to* u_0*, for the system* (4.1)–(4.3)*, is characterized by the unique solution* $\{y,\lambda,\rho,p\}$ *to the optimality system*

$$\begin{cases} y' + Ay = f + Bu, & -\zeta' + A^*\zeta = C^*C(y-y(0,0)), \\ \rho' + A\rho = 0, & -p' + A^*p = C^*(Cy-z_d) + C^*C\rho, \\ y(0)=y_0, \quad \rho(0)=\lambda, & \zeta(T,u)=0, \quad p(T)=0, \\ B^*p + Nu = 0 \quad in \quad \mathcal{U}, & \end{cases}$$

with $\lambda \in \widehat{G}$.

Proof. The proof holds from the approached optimality system of Proposition 4.1 for which a priori estimates allow us to pass to the limit when $\gamma \to 0$ as in section 2. ∎

4.2. No-regret control for well-posed systems of Petrowsky type. We now consider an elliptic differential operator A such as

$$A^* = A,$$

and to simplify we consider the state equation

$$y'' + A\,y = v, \tag{4.14}$$

with

$$y \in L^\infty(0,T;V), \qquad y' \in L^\infty(0,T;F), \tag{4.15}$$

$$y(0) = y_0 + g_0, \qquad y'(0) = y_1 + g_1, \tag{4.16}$$

where $\{y_0, y_1\}$ is bounded in $\mathcal{V} \times F$ and where

$$\begin{cases} g_0 \in G_0, & G_0 = \text{ closed vector subspace of } \mathcal{V}, \\ g_1 \in G_1, & G_1 = \text{ closed vector subspace of } F. \end{cases} \tag{4.17}$$

Let $y(v,g)$ be the solution of (4.14)–(4.16), $g = (g_0, g_1)$. Let C be defined by (4.4) and the cost function $J(v,g)$ be defined by (4.3). We look for the no-regret control related to $u_0 = 0$. We define $y = y(v,0)$ and $\zeta(t,v)$ (or $\zeta(t)$), respectively, by

$$y'' + A\,y = v, \qquad y(t=0) = y_0, \qquad y'(t=0) = y_1, \tag{4.18}$$

$$\zeta'' + A\,\zeta = C^*C\,y(v,0), \qquad \zeta(T) = 0, \qquad \zeta'(T) = 0. \tag{4.19}$$

Set $z = y(0,g) - y(0,0)$. Then z is the solution of

$$\begin{cases} z'' + A\,z = 0, \\ z(0) = g_0, \\ z'(0) = g_1. \end{cases}$$

Then by the Green formula we obtain

$$\begin{aligned} J(v,g) - J(0,g) &= J(v,0) - J(0,0) + 2\int_0^T (\,\zeta'' + \Delta\zeta, z\,)\,dt \\ &= J(v,0) - J(0,0) + 2\,(\,\zeta(0), g_1\,)_{G_0,G_1} - 2\,(\,\zeta'(0), g_0\,)_{G_1,G_0}. \end{aligned}$$

As the low-regret control solution is defined by the

$$\inf_{v\in\mathcal{U}} \left(\sup_{g\in G_0\times G_1} \left(J(v,g) - J(0,g) + \gamma \left\| g_0 \right\|_{G_0}^2 - \gamma \left\| g_1 \right\|_{G_1}^2 \right) \right),$$

the low-regret control method reads

$$\inf_{v\in\mathcal{U}} \mathcal{J}^\gamma(v) = \inf_{v\in\mathcal{U}} \left(J(v,0) - J(0,0) + \frac{1}{\gamma} \left\| \zeta(0) \right\|_{G_1}^2 - \frac{1}{\gamma} \left\| \zeta'(0) \right\|_{G_0}^2 \right). \tag{4.20}$$

And we have for the Petrowsky systems the following result.

THEOREM 4.3. *The no-regret control u related to $u_0 = 0$ is characterized by the unique solution $\{y, \lambda_0, \lambda_1, \zeta, \rho, p\}$ to the optimality system*

$$\begin{cases} y'' + A\,y = 0, & \zeta'' + A\,\zeta = 0, & \rho'' + A\,\rho = 0, & p'' + A\,p = 0, \\ y(0) = y_0, & \zeta(T) = 0, & \rho(0) = \lambda_0, & p(T) = 0, \\ y'(0) = y_1, & \zeta'(T) = 0, & \rho'(0) = \lambda_1, & p'(T) = 0, \\ p + Nu = 0, & & & \end{cases}$$

with

$$\begin{cases} \lambda_0 = -\lim\limits_{\gamma\to 0} \dfrac{1}{\gamma}\zeta'(0),\ \lambda_0 \in \widehat{G_0} & \textit{completion of} \quad G_0 \quad \textit{for the norm} \quad \left\|.\right\|_{G_0}, \\ \lambda_1 = \lim\limits_{\gamma\to 0} \dfrac{1}{\gamma}\zeta(0), \quad \lambda_1 \in \widehat{G_1} & \textit{completion of} \quad G_1 \quad \textit{for the norm} \quad \left\|.\right\|_{G_1}. \end{cases} \qquad \square$$

Remark 10. These results are also valid for well-posed problems of hyperbolic type.

5. Application. Hereafter, we discuss an example of parabolic type with boundary control, boundary uncertainty, and cost function.

Let Ω be an open set of $\mathbb{R}^N$ of boundary $\Gamma_0 \cup \Gamma_1$, with Γ_0 and Γ_1 being two regular boundaries of empty set intersection. We consider the distributed system

$$\begin{cases} y' - \Delta\,y + y = 0 & \text{in } \Omega, \\ y(0,x,v,g) = 0 & \text{on } \{0\}\times\Omega, \\ \dfrac{\partial y}{\partial \nu} = v & \text{on }]0,T[\times\Gamma_0 = \Sigma_0, \\ \dfrac{\partial y}{\partial \nu} = g & \text{on }]0,T[\times\Gamma_1 = \Sigma_1. \end{cases} \tag{5.1}$$

For $v \in \mathcal{U} = L^2(\Sigma_0)$, $g \in G$, a vector closed subspace of $L^2(\Sigma_1)$, (5.1) has a unique solution $y(t,x,v,g)$ noted $y(v,g)$. We associate with the state $y(v,g)$ the cost function

$$J(v,g) = \Big|y(v,g) - z_d\Big|^2_{L^2(\Sigma_0)} + N\Big|v\Big|^2_{L^2(\Sigma_0)}. \tag{5.2}$$

For u_0 fixed in $\mathcal{U}$, there exists a unique control u related to u_0. Take $u_0 = 0$. Then the associated low-regret control is defined by the following cost function:

$$\mathcal{J}^\gamma(v) = J(v,0) - J(0,0) + \frac{1}{\gamma}\Big|\zeta(v)\Big|^2_{L^2(\Sigma_1)}, \tag{5.3}$$

where ζ is the solution of

$$\begin{cases} -\zeta' + A\,\zeta = 0 & \text{in } \Omega, \\ \zeta(T,v) = 0 & \text{on } \{T\}\times\Omega, \\ \dfrac{\partial \zeta}{\partial \nu_A} = y(v,0) & \text{on } \Sigma_0, \\ \dfrac{\partial \zeta}{\partial \nu_A} = 0 & \text{on } \Sigma_1 \end{cases}$$

and where $A = -\Delta + I = A^*$.

The problem

$$\inf_{v\in\mathcal{U}} \mathcal{J}^{\gamma}(v) \tag{5.4}$$

has a unique solution: the low-regret control u_γ. We set $y_\gamma = y(u_\gamma, 0)$ and $\zeta_\gamma = \zeta(u_\gamma)$. We then have immediately the following proposition.

PROPOSITION 5.1. *The low-regret control u_γ is characterized by the unique solution $\{y_\gamma, \zeta_\gamma, \rho_\gamma, p_\gamma\}$ of the optimality system*

$$\begin{cases} y_\gamma' + A\,y_\gamma = 0, & -\zeta_\gamma' + A\,\zeta = 0, & \rho_\gamma + A\,\rho_\gamma = 0, & -p_\gamma' + A\,p_\gamma = 0, \\ y_\gamma(0) = 0, & \zeta_\gamma(T) = 0, & \rho_\gamma(0) = 0, & p_\gamma(T) = 0, \\ \text{on}\quad \Sigma_0, \quad \dfrac{\partial y_\gamma}{\partial \nu} = u_\gamma, & \dfrac{\partial \zeta_\gamma}{\partial \nu} = y(v,0), & \dfrac{\partial \rho_\gamma}{\partial \nu} = 0, & \dfrac{\partial p_\gamma}{\partial \nu} = y_\gamma - z_d + \rho_\gamma, \\ \text{on}\quad \Sigma_1, \quad \dfrac{\partial y_\gamma}{\partial \nu} = 0, & \dfrac{\partial \zeta_\gamma}{\partial \nu} = 0, & \dfrac{\partial \rho_\gamma}{\partial \nu} = \frac{1}{\gamma}\zeta_\gamma, & \dfrac{\partial p_\gamma}{\partial \nu} = 0, \\ p_\gamma + N u_\gamma = 0 & & & \text{in}\quad L^2(\Sigma_0), \end{cases}$$

with,
$u_\gamma \in L^2(\Sigma_0)$, *and* $y_\gamma \in L^2((0,T); H^{3/2}(\Omega))$, $\zeta_\gamma \in L^2((0,T); H^{5/2}(\Omega))$, $\rho_\gamma \in L^2((0,T); H^{7/2}(\Omega))$, $p_\gamma \in L^2((0,T); H^{1/2}(\Omega))$.

For the proof, we use the same technique as detailed for the stationary Example 2 in section 3. □

We also deduce easily the following theorem.

THEOREM 5.2. *The no-regret control u related to $u_0 = 0$ of the system* (5.1)–(5.2) *is characterized by the unique solution $\{y, \lambda, \rho, p\}$ of the optimality system*

$$\begin{cases} y' + A\,y = 0, & -\zeta' + A\zeta = 0, & \rho' + A\rho = 0, & -p' + A\,p = 0 & \text{in}\quad \Omega, \\ y(0) = 0, & \zeta(T) = 0, & \rho(0) = 0, & p(T) = 0, & \\ \dfrac{\partial y}{\partial \nu} = u, & \dfrac{\partial \zeta}{\partial \nu} = y, & \dfrac{\partial \rho}{\partial \nu} = 0, & \dfrac{\partial p}{\partial \nu} = y - z_d + \rho & \text{on}\quad \Sigma_0, \\ \dfrac{\partial y}{\partial \nu} = 0, & \dfrac{\partial \zeta}{\partial \nu} = 0, & \dfrac{\partial \rho}{\partial \nu} = \lambda, & \dfrac{\partial p}{\partial \nu} = 0 & \text{on}\quad \Sigma_1, \\ p + N u = 0 & & & & \text{in}\quad L^2(\Sigma_0), \end{cases}$$

with

$$\begin{cases} u \in L^2((0,T); L^2(\Omega)), \quad y \in L^2((0,T); H^{3/2}(\Omega)), \\ \lambda \in \widehat{G}\ \textit{completion of}\ G\ \textit{in}\ L^2((0,T); H^{-2}(\Sigma_1)), \\ \rho \in L^2((0,T); H^{-1/2}(\Omega)), \quad p \in L^2((0,T); H^{1/2}(\Omega)). \end{cases}$$ □

Conclusion. As we have seen, the low-regret control method allows us to transform systematically a problem with uncertainty to a standard control problem. It is then easier to obtain optimality systems applying the Euler–Lagrange formula.

This method can be used for the control of singular distributed systems as in [4] (see also [5]). Here, the singularity of the backward heat equation is taken off by adding the needed data which may belong to the unknown vector closed subspace G of a given Hilbert space of uncertainties. The system becomes regular, but it contains incomplete data. We then give an optimality system to the no-regret control. In [4], the comparison with the classical penalization method for the control of the backward heat equation in Lions [11] is discussed.

STABILITY CRITERIA FOR LINEAR SYSTEMS WITH PARTLY UNCERTAIN PERIODIC COEFFICIENTS*

ALEXANDR ZEVIN† AND MARK PINSKY‡

Abstract. Stability criteria of partly uncertain linear systems with variable coefficients play an important part in various fields of robust control. In this paper we consider linear systems with periodic coefficients that may vary within their known lower and upper bounds depending upon time as well. Stability analysis of systems with variable coefficients is often based on the Lyapunov functions method leading in many cases to rigid sufficient stability conditions. A new approach to stability analysis of such systems is described in this paper. Using this method we obtain an upper bound for the real parts of the characteristic exponents of the system solutions yielding sufficient stability criteria and find the cases in which these bounds are reached. This explicitly determines the "worst" possible periodic coefficients yielding the largest value of the maximal real part of the characteristic exponents. Certain results are extended to the case of nonperiodic time-dependent bounded coefficients.

Key words. linear systems, uncertain periodic coefficients, stability criteria

1. Introduction.

We consider a linear system with uncertain periodic coefficients

$$\begin{gathered}\dot{x} = A(t)x,\\ x \in R^n,\ A(t) = [a_{ik}(t)]_{i,k=1}^n,\quad a_{ik}(t) = a_{ik}(t+T).\end{gathered} \tag{1.1}$$

It is assumed that the coefficients are piecewise continuous and lie within the prescribed limits:

$$a_{ik}^-(t) \le a_{ik}(t) \le a_{ik}^+(t). \tag{1.2}$$

Sometimes it is more convenient to represent the matrix $A(t)$ as a sum of fixed and uncertain matrices:

$$\begin{gathered}A(t) = A^0(t) + \Delta(t),\\ A^0(t) = [a_{ik}^0(t)]_{i,k=1}^n, \qquad \Delta(t) = [\delta_{ik}(t)]_{i,k=1}^n,\\ a_{ik}^0(t) = \tfrac{1}{2}\left[a_{ik}^-(t) + a_{ik}^+(t)\right],\quad |\delta_{ik}(t)| \le \tfrac{1}{2}\left[a_{ik}^+(t) - a_{ik}^-(t)\right].\end{gathered} \tag{1.3}$$

In the field of robust stability (see, for example, [1]) restrictions on uncertain entries of the matrix are often imposed on an upper bound δ_0 for the norm of the uncertain matrix $\Delta(t)$. Both of these assumptions are considered in this paper.

Stability problems for linear systems with partly uncertain periodic coefficients arise in numerous applications as well as in stability analysis of equilibrium or periodic solutions of nonlinear systems:

$$\begin{gathered}\dot{y} = f(y,t),\\ f(y,t) = f(y,t+T),\ f(0,t) = 0,\ y \in R^n,\end{gathered} \tag{1.4}$$

where the function $f(y,t)$ is not precisely known. Stability of equilibrium $y(t) \equiv 0$ is determined by variational equation (1.1) where $a_{ik}(t) = \partial f_i(y,t)/\partial y_k$ for $y = 0$. This problem turns out to be the one stated above if bilateral bounds for the elements $a_{ik}(t)$ are known.

A variation of the previous problem could be described as follows. Assume that system (1.4) is precisely defined and existence of its periodic solution within a compact region Ω is established, but the solution itself is unknown. Then one may find bilateral bounds for the elements of the Jacobian $f_y(y,t)$ in Ω which imply the considered problem.

Stability analysis of time-invariant linear systems with partly uncertain coefficients attracted a flood of publications in the last two decades, and a few approaches for estimating of robust stability of such systems have been developed. (See, for example, monograph [2] for a recent review on this subject.) Indeed, these techniques cannot be directly generalized on time-varying (in particular, periodic) uncertain systems since this problem turns out to be considerably more complicated. Mentioning that known results on stability of uncertain time-varying systems (see, e.g., [3], [4], and [5]) are based on applications of the Lyapunov functions method often yielding rigid sufficient stability criteria.

A new approach to stability analysis of partly uncertain linear periodic (and more general time-varying) systems is developed in this paper. This approach does not rely on availability of suitable Lyapunov functions and often yields more accurate and informative stability criteria leading to a robust stability control. Let us introduce briefly the main idea of this approach.

Let $W(t) = [x_1(t), \dots, x_n(t)]$ be a transition matrix of (1.1) with a periodic matrix $A(t) = A(t+T)$. ($W(0) = I$, where I is the unit matrix.) It is known (see, for example, [6]) that the stability of this system is determined by the eigenvalue (Floquet multiplier) ρ_{n} of the monodromy matrix $W(T)$ with the largest modulus. Namely, if $|\rho_n| < 1$ and, therefore, the real part of the characteristic exponent $\alpha_n = (\ln \rho_n)/T$ is negative, the system is asymptotically stable; if $|\rho_n| > 1$ ($\mathrm{Re}\alpha_n > 0$), the system is unstable.

Denote by $U(t)$ the set of $n \times n$ matrices $A(t)$ satisfying conditions (1.2); let $\alpha_+ = \sup \mathrm{Re}\alpha_{\mathrm{n}}(A)$ for $A(t) \in U(t)$. Equation (1.1) is asymptotically stable for any $A(t) \in U(t)$ if $\alpha_+ < 0$.

Our approach is based on deriving an upper bound ρ^* for the largest in modulus multiplier and, hence, the upper bound α^* for α_+. In contrast to the Lyapunov functions method, our approach also estimates the degree of system stability or instability of the initial system. In fact, if $\alpha^* < 0$, then the Euclidean norm of any solution of (1.1), $\|x(t)\| < C\exp(\alpha^* t)$ for some C and $t > 0$. The condition of $\alpha^* > 0$ leads to a sufficient stabilizing feedback control $u = C(t)x$; for example, the system $\dot{x}(t) = A(t)x - aIx$ with $a > \alpha^*$ is certainly asymptotically stable.

Theorem 1 determines an upper bound for the value $\mathrm{Re}\alpha_n(A)$ of a given matrix $A(t)$. This bound is defined by the largest real characteristic exponent $\alpha_n(B)$ of the system $\dot{x} = B(t)x$ with a matrix $B(t+T) = B(t)$ such that the entries $a_{ik}(t)$ and $b_{ik}(t)$ of matrices $A(t)$ and $B(t)$ satisfy inequalities (2.2). Its proof (section 4) is based on the following steps.

Let ρ_i be a real multiplier of (1.1); then there exists the real solution $x_i(t) = \exp(\alpha_i t)u_i(t)$, where $\alpha_i = (\ln \rho_i)/T$ and $u_i(t)$ is a T-periodic function. Using the corresponding Green's function, we transform (1.1) to the integral equation $u = R(A)u$. In the analogous equation for (2.1), the corresponding integral operator $R(B)$ is strongly

positive (transforms any nonnegative function $u(t)$ into positive one), which enables us to utilize some profound results in the theory of positive operators. (See [7] and [8] for additional information.) As a result, it is proved that the multiplier with largest modulus of the equation $\dot{x} = B(t)x$ is real and exceeds the multiplier ρ_i. Next, we extend this inequality to the value $|\rho_i|$ of any complex multiplier ρ_i. Using lower and upper bounds $a_{ik}^-(t)$ and $a_{ik}^+(t)$ of $a_{ik}(t)$, we construct a matrix $B(t)$ which satisfies inequalities (2.2) for any $A(t) \in U(t)$ and, thus, yields a required bound for the value α_+. We found cases in which the corresponding matrix $B(t) \in U(t)$. This implies that $A(t) = B(t)$ is the "worst" admissible matrix with the corresponding value $\alpha_n(A) = \alpha_+$.

Theorem 2 presents an upper bound for α_+ directly through the largest eigenvalues of symmetric components of the matrices $A^0(t)$ and $\Delta(t)$. In its proof we employ the known bound of the value $\mathrm{Re}\alpha_n$ of system (1.1) with a given matrix $A(t)$ (see [6]):

$$\mathrm{Re}\alpha_n \le \frac{1}{2T}\int_0^T q(t)\mathrm{d}t, \tag{1.5}$$

where $q(t)$ is the largest eigenvalue of the matrix $A(t)+A^\tau(t)$ ($^\tau$ means transposition).

Theorem 3 determines asymptotic stability of systems (1.1) and (1.3) via the norm of the transition matrix of the unperturbed system ($A(t) \equiv A^0(t)$) and an upper bound for the norm of the uncertain matrix $\Delta(t)$. These values also enable us to establish an upper bound for the value α_+ (Theorem 4).

The results of Theorem 1 are extended to the case in which the coefficients $a_{ik}(t)$ are bounded but not necessarily periodic (Theorem 5). In this case one may choose a constant matrix B satisfying inequalities (2.2) for all t; its largest real eigenvalue gives an upper bound for the supremal Lyapunov exponent of system (1.1). Theorem 6 extends Theorem 2 on the nonperiodic case.

This paper is organized as follows. The main results are formulated in section 2. In section 3 we include examples and a discussion of our theorems. All proofs are presented in section 4.

2. Main results. Consider the equation

$$\begin{gathered}\dot{x} = B(t)x,\\ B(t) = [b_{ik}(t)]_{i,k=1}^n, \quad b_{ik}(t) = b_{ik}(t+T).\end{gathered} \tag{2.1}$$

Suppose that for $t \in [0,T]$,

$$|a_{ik}(t)| \le b_{ik}(t), \quad i \ne k, \quad a_{ii}(t) \le b_{ii}(t), \quad i,k = 1,\dots,n. \tag{2.2}$$

Moreover, we assume that the matrix $B(t)$ is nondecomposable at some $t = t_0$, which means that system (2.1) with $B(t) \equiv B(t_0)$ does not contain an independent subsystem of order $p < n$. (Note that this condition may be reached by an arbitrary small perturbation of the matrix $B(t)$.) Since (2.2), the off-diagonal elements of the matrix $B(t)$ are nonnegative, so the largest in modulus multiplier $\rho_n(B)$ of system (2.1) is real, positive, and simple. (See, for example, Theorem 4.7 in [7] for more details.)

The following theorem compares the largest in modulus multipliers of (1.1) and (2.1).

THEOREM 1. *Let* (2.2) *be true; then*

$$|\rho_n(A)| \le \rho_n(B). \tag{2.3}$$

Thus, the corresponding characteristic exponent assumes the inequality

$$\mathrm{Re}\alpha_n(A) \le \alpha_n(B) = \frac{1}{T}\ln\rho_n(B). \tag{2.4}$$

Moreover, if (2.2) is true for any $A(t) \in U(t)$, then the corresponding value is

$$\alpha_+ \le \frac{1}{T}\ln\rho_n(B). \tag{2.5}$$

Suppose now that the matrix $A(t)$ is represented in the form (1.3). Let us define

$$\begin{aligned} &A_s^0(t) = \left[A^0(t) + A^{0\tau}(t)\right], \qquad \Delta_s(t) = \left[\Delta_+(t) + \Delta_+^\tau(t)\right], \\ &\Delta_+(t) = \left[\delta_{ik}^+(t)\right]_{i,k=1}^n, \qquad \delta_{ik}^+(t) = \tfrac{1}{2}\left[a_{ik}^+(t) - a_{ik}^-(t)\right]. \end{aligned} \tag{2.6}$$

Let $\beta_A(t)$ and $\beta_\Delta(t)$ be the largest eigenvalues of the matrices $A_s^0(t)$ and $\Delta_s(t)$. Note that all the eigenvalues of these matrices are real due to their symmetry. The next theorem gives an upper bound for α_+ directly through $\beta_A(t)$ and $\beta_\Delta(t)$.

THEOREM 2. *In problem* (1.1)–(1.3)

$$\alpha_+ \le \frac{1}{2T}\int_0^T [\beta_A(t) + \beta_\Delta(t)]\mathrm{d}t. \tag{2.7}$$

Consider now stability of system (1.1), (1.3) assuming that only an upper bound δ_0 for the norm $\|\Delta(t)\|$ of the uncertain matrix is known. Symbol $\|\Delta(t)\|$ assigns any matrix norm which satisfies, in addition to the standard norm conditions, the inequality

$$\|\Delta_1\Delta_2\| \le \|\Delta_1\|\,\|\Delta_2\|. \tag{2.8}$$

In particular, the norm could assume one of the following forms:

$$\|\Delta(t)\| = \sqrt{\sum_{i,k=1}^n \delta_{ik}^2(t)}, \tag{2.9}$$

$$\|\Delta(t)\| = \max_{1\le i\le n}\sum_{k=1}^n |\delta_{ik}|, \tag{2.10}$$

$$\|\Delta(t)\| = \max_{1\le k\le n}\sum_{i=1}^n |\delta_{ik}|. \tag{2.11}$$

We note that if the norm is determined by (2.9), Theorem 2 is extended to this case by exchanging in (2.7) $\beta_\Delta(t)$ by δ_0. In fact, the eigenvalues $\beta_i(t), i = 1,\dots n$, of the matrix $\Delta(t)$ satisfy the Schur inequality [9]

$$\sum_{i,k=1}^n \delta_{ik}^2(t) \ge \sum_{i=1}^n \beta_i^2(t). \tag{2.12}$$

Clearly, $\|\Delta_s(t)\| \le 2\|\Delta(t)\|$, so $2\delta_0 \ge \beta_\Delta(t)$.

Consider (1.1) in the absence of uncertain perturbations:

$$\dot{x} = A^0(t)x. \tag{2.13}$$

We assume that it is asymptotically stable, so the corresponding Floquet multipliers ρ_i^0, $i = 1, \dots, n$, lie within the unit circle (see [6]). Let $W^0(t,s)$ be the transition matrix of (2.1) ($W^0(s,s) = I$) and $w(t,s) = \|W^0(t,s)\|$. By supposition, $|\rho_i^0| < 1$, so $\mathrm{Re}\alpha_i^0 < 0$, where $\alpha_i^0 = (\ln \rho_i^0)/T$ are the characteristic exponents of system (2.13). In general, the elements of $W^0(t,s)$ tend to zero as $\exp(\mu t)P(t)$, where $\mu = \max_i \mathrm{Re}\alpha_i^0$ and $P(t)$ is a polynomial of order $k < p$. (p is the multiplicity of the corresponding multiplier.) Therefore, there exists

$$w_0 = \lim_{t\to\infty} \int_0^t w(t,s)\mathrm{d}s. \tag{2.14}$$

The following theorem gives sufficient stability condition for (1.3) expressed in the upper bound δ_0 for the norm of the uncertain matrix $\Delta(t)$.

THEOREM 3. *Equation* (1.3) *is asymptotically stable if*

$$\delta_0 < 1/w_0. \tag{2.15}$$

The next theorem gives an upper bound for the value $\alpha_+ = \sup \mathrm{Re}\alpha_{\mathrm{n}}(A)$ for $A(t) \in U(t)$.

THEOREM 4. *The value* α_+ *satisfies the inequality*

$$\alpha_+ \le \frac{\delta_0^2 w_*^2}{2}, \tag{2.16}$$

where

$$w_* = \lim_{t\to\infty} \left[\int_0^t w^2(t,s)\mathrm{d}s\right]^{1/2}.$$

Consider now the nonperiodic case, i.e., assume that the entries $a_{ik}(t)$ of the matrix $A(t)$ vary arbitrarily within bounds (1.2). Let $x(t, x_0, A)$ be the solution of (1.1) for some $A(t)$ with initial condition $x(0, x_0, A) = x_0$. The corresponding Lyapunov exponent is defined by

$$\lambda(x_0, A) = \overline{\lim_{t\to\infty}} \frac{1}{t} \ln \|x(t, x_0, A)\|. \tag{2.17}$$

Stability of such a system is determined by the supremal Lyapunov exponent

$$\lambda_+ = \sup_{x_0\neq 0,\ A(t)\in U(t)} \lambda(x_0, A). \tag{2.18}$$

If $\lambda_+ < 0$, then system (1.1) is exponentially stable for any admissible $A(t)$.

Let us consider the extensions of Theorems 1 and 2.

Suppose that a constant matrix B satisfies inequality (2.2) for any $t > 0$. Let $\lambda(B)$ be the largest real eigenvalue of the matrix B. The next theorem extends Theorem 1 to the nonperiodic case.

THEOREM 5. *Assume that* (2.2) *is true; then*

$$\lambda_+ \le \lambda(B). \tag{2.19}$$

Denote by Δ_m the matrix with the elements $\delta_{ik}^m = 0.5 \sup_t [a_{ik}^+(t) - a_{ik}^-(t)]$, $i, k = 1, \dots, n$; let β_m be the largest eigenvalue of the matrix $\Delta_m + \Delta_m^\tau$.

THEOREM 6. *The value λ_+ satisfies the inequality*

$$\lambda_+ \le \lim_{T\to\infty} \left[\frac{1}{2T} \int_0^T [\beta_A(t) + \beta_m] \mathrm{d}t \right]. \tag{2.20}$$

3. Discussion and example. The determination of an upper bound (2.3) for multipliers of system (1.1), (1.2) using Theorem 1 requires choosing a matrix $B(t)$ which assumes inequality (2.2) for any $A(t) \in U$ and the calculation of the largest real eigenvalue $\rho_n(B)$ of the corresponding monodromy matrix. In particular, one may choose

$$b_{ik}(t) \equiv \max |a_{ik}(t)| \quad \text{for } i \ne k, \quad b_{ii}(t) \equiv \max a_{ii}(t) = a_{ii}^+(t), \ i, k = 1, \dots, n. \tag{3.1}$$

If in the form (1.3) the off-diagonal elements of the matrix $A^0(t)$ are nonnegative, then $\max |a_{ik}(t)| = a_{ik}^+$ for $i \ne k$. Thus one may take

$$b_{ik}(t) \equiv a_{ik}^+(t), \quad i, k = 1, \dots, n, \tag{3.2}$$

which implies that the corresponding matrix $B(t) \in U(t)$. It follows that in this case the required bound α_+ is reached if all coefficients of the matrix $A(t)$ take their maximal admissible values.

The upper bound is also reached if for every $i = 1, \dots, n$, all off-diagonal elements of the ith row and column of the matrix $A^0(t)$ are both positive or negative for all t. Really, the change of the variable $x_i \to -x_i$ implies the change of the sign in the elements of these rows and columns. Hence, the system could be reduced to a system with nonnegative off-diagonal elements which does not affect the multipliers of the original system. So, the "worst" admissible matrix is such that the coefficients $a_{ik}(t)$ and $a_{ki}(t)$, $i, k = 1, \dots, n$; $k \ne i$, take their maximal values $a_{ik}^+(t)$ and $a_{ki}^+(t)$ when the elements $a_{ik}^0(t)$ and $a_{ki}^0(t)$ are positive; if they are negative, then $a_{ik}(t) \equiv a_{ik}^-$ and $a_{ki}(t) \equiv a_{ki}^-$; in both cases, $a_{ii}(t) \equiv a_{ii}^+(t)$.

Conditions of Theorem 2 avoid calculation of a monodromy matrix but require calculations of the eigenvalues $\beta_A(t)$ and $\beta_\Delta(t)$ of the matrices $A_s(t)$ and $\Delta_s(t)$ for every t. Though upper bound (2.7) is not generically reached for any admissible $A(t)$, it may provide a reasonable estimate, especially if the matrices $A^0(t)$ and $\Delta(t)$ are near-symmetric. (Note that for a constant symmetric matrix, the right-hand side of (2.7) equals its largest eigenvalue.)

Consider now Theorem 3. First of all we note that for scalar equation (1.3), stability condition (2.15) is precise. Really, let $A(t) = -h < 0$; then $w(t) = \exp(-ht)$, $w_0 = 1/h$ and inequality (2.15) becomes $|\Delta(t)| < h$. For $\Delta(t) \equiv h$, (1.3) is not asymptotically stable and condition (2.15) cannot be improved.

Systems in the following form are often found in various applications:

$$\ddot{y} + H(t)\dot{y} + A(t)y + \Delta(t)y = 0, \tag{3.3}$$

where $y \in R^k$, the matrices $H(t)$, $A(t)$, and $\Delta(t)$ are T-periodic, and $\Delta(t)$ is uncertain with $\|\Delta(t)\| \le \delta_0$. Suppose that for $\Delta(t) = 0$, the system is asymptotically stable. Let us derive a sufficient stability condition for (3.3) using reasoning similar to the proof of Theorem 3.

Setting $y = y_1$, $\dot{y} = y_2$, and $x = (y_1, y_2)$, one may reduce (3.3) to (1.1). Representing the corresponding transition matrix in the form

$$W(t,s) = \begin{bmatrix} W_{11}(t,s) & W_{12}(t,s) \\ W_{21}(t,s) & W_{22}(t,s) \end{bmatrix}, \tag{3.4}$$

we obtain

$$y_k(t) = W_{11}(t,0)y_k(0) + W_{12}(t,0)\dot{y}_k(0) - \int_0^t W_{12}(t,s)\Delta(s)y_k(s)\mathrm{d}s.$$

Assuming

$$y_k(t) = \exp(\alpha_k t)u_k(t), \quad u_k(t) = u_k(t+T), \quad \|u_k(0)\| = 1 \geq \|u_k(t)\|,$$

one can, analogously to the proof of Theorem 3, find that (3.3) is asymptotically stable if

$$\delta_0 < \frac{1}{w_{12}}, \quad w_{12} = \lim_{t\to\infty} \int_0^t \|W_{12}(t,s)\|\,\mathrm{d}s. \tag{3.5}$$

Theorem 5 provides a sufficient stability condition for system (1.1) with an uncertain nonperiodic matrix $A(t)$. Its utility requires finding a constant matrix B satisfying inequalities (2.2) for all t, which could be made if one takes

$$b_{ik} = \sup_t |a_{ik}(t)| \quad \text{for } i \neq k, \quad b_{ii} \equiv \sup_t a_{ii}(t), \quad i,k = 1,\ldots,n. \tag{3.6}$$

Note that the accuracy of the above bounds depends upon matrix $A(t)$. Hence it is worthwhile to find all of the bounds and to choose the best one in analysis of a specific system.

To illustrate the obtained results, consider a plane system, (1.1) ($n = 2$), with coefficients $a_{ik}(t) = a_{ik}(t+T)$ contained within constant intervals $[a_{ik}^-, a_{ik}^+]$, $i,k = 1,2$. To apply Theorem 1, we form the matrix B with the elements

$$b_{ik} = \max\left(\left|a_{ik}^-\right|, \left|a_{ik}^+\right|\right), \ i \neq k, \ b_{ii} = a_{ii}^+, \ i = 1,2. \tag{3.7}$$

Since B is a constant matrix, its largest real eigenvalue $\lambda(B)$ gives an upper bound for the largest characteristic exponent $\mathrm{Re}\alpha_n$ of system (1.1) with any admissible matrix $A(t)$. By Theorem 5, in the nonperiodic case, $\lambda(B)$ may serve as an upper bound for the supremal Lyapunov exponent λ_+. At the beginning of this section it is shown that this bound is reached if the signs of the elements $a_{12}^0 = 0.5(a_{12}^- + a_{12}^+)$ and $a_{21}^0 = 0.5(a_{21}^- + a_{21}^+)$ are identical. If they both are positive (negative), the coefficients $a_{12}(t)$ and $a_{21}(t)$ of the "worst" matrix $A(t)$ reach their maximal (minimal) admissible values; in the both cases, the diagonal elements $a_{ii}(t) \equiv a_{ii}^+$.

To apply Theorem 2, we form the matrices A^0 and Δ_+ with the elements

$$a_{\mathrm{ik}}^0 = \frac{1}{2}(a_{ik}^- + a_{ik}^+), \qquad \delta_{ik}^+ = \frac{1}{2}(a_{ik}^+ - a_{ik}^-), \qquad i,k = 1,2. \tag{3.8}$$

For any admissible matrix $A(t)$, $\mathrm{Re}\alpha_n \leq 0.5(\beta_A + \beta_\Delta)$, where β_A and β_Δ are the largest eigenvalues of the matrices $A^0 + A^{0\tau}$ and $\Delta_+ + \Delta_+^\tau$.

For example, assume $a_{11} = 0$, $a_{12} = 1$, $a_{2i} \in [a_{2i}^-, a_{2i}^+]$, $i = 1,2$. Setting $b_{21} = \max(|a_{21}^-|, |a_{21}^+|)$, $b_{22} = a_{22}^+$ and using Theorem 5, we find that $\lambda_+ \leq \lambda(B) = 0.5(a_{22}^+ +$

$\sqrt{a_{22}^{+2} + 4b_{21}}$). For $a_{21}^+ \geq |a_{21}^-|$, this bound is precise and is reached if $a_{21}(t) \equiv a_{21}^+$, $a_{22}(t) \equiv a_{22}^+$.

If $a_{21}^+ < |a_{21}^-|$, this upper bound could become overly conservative. In particular, since $\lambda(B) > 0$, the system could be stable if $a_{21}^+ < 0$ and $a_{22}^+ < 0$, but the upper bound derived using Theorem 5 is positive. In the periodic case ($a_{2i}(t+T) = a_{2i}(t)$), a better estimate could be found using Theorem 3. Assume $a_{22}(t) \equiv -2h$; setting $x_1 = x$, $x_2 = \dot{x}$, we write the considered system in the form

$$\begin{gathered} \ddot{x} + 2h\dot{x} + \omega_0^2 x + \delta(t)x = 0, \\ \omega_0^2 = 0.5(a_{21}^- + a_{21}^+),\ |\delta(t)| \leq \delta_0 = 0.5(a_{21}^+ - a_{21}^-). \end{gathered} \tag{3.9}$$

Next, the elements of matrix (3.4) are

$$W_{12}(t,s) = W_{12}(t-s) = \frac{1}{\omega^*} \exp[-h(t-s)] \sin \omega^*(t-s), \qquad \omega^* = \sqrt{\omega_0^2 - h^2},$$

and from (3.5) we get

$$\begin{aligned} w_{12} &= \lim_{t\to\infty} \int_0^t |W_{12}(t-s)|\, \mathrm{d}s = \int_0^\infty |W_{12}(v)|\, \mathrm{d}v \\ &= \frac{1}{\omega_0^2} \left[1 + 2 \sum_{k=1}^{\infty} \exp(k\beta) \right] = \frac{1 + \exp\beta}{\omega_0^2(1 - \exp\beta)}, \end{aligned} \tag{3.10}$$

where $\beta = -\pi h/\omega^*$.

Hence, according to (3.5), equation (3.9) is asymptotically stable if

$$\delta_0 < \delta_0^* = \frac{\omega_0^2(1 - \exp\beta)}{1 + \exp\beta}. \tag{3.11}$$

Note that obtained stability criteria could be used to check absolute stability of linear systems controlled by a nonlinear feedback function $f(\sigma, t)(\sigma = (c, x))$ (see, e.g., [11], [12], [13]), which might take any values within a prescribed sector, i.e.,

$$0 \leq f(\sigma, t)\sigma \leq K\sigma^2. \tag{3.12}$$

Really, this problem is equivalent to stability of the corresponding linear uncertain system with $f(\sigma, t) = u(t)\sigma$, where $0 \leq u(t) \leq K$.

In particular, inequality (3.11) provides sufficient criterion for absolute stability of the system

$$\begin{gathered} \ddot{x} + 2h\dot{x} + \omega_0^2 x + \varphi(x,t) = 0, \\ -\delta_0 x^2 \leq \varphi(x,t)x \leq \delta_0 x^2. \end{gathered} \tag{3.13}$$

Putting $f(x,t) = \varphi(x,t) + \delta_0 x$ and observing that $\omega_0^2 - \delta_0 = -a_{21}^+$, we reduce (3.13) to the form

$$\begin{gathered} \ddot{x} + 2h\dot{x} - a_{21}^+ x + f(x,t) = 0, \\ 0 \leq f(x,t)x \leq Kx^2,\ K = 2\delta_0. \end{gathered} \tag{3.14}$$

Suppose that $a_{21}^+ < 0$. (For $a_{21}^+ \geq 0$, system (3.14) with the admissible function $f(x,t) \equiv 0$ is not asymptotically stable.) Let us compare the accuracy of (3.11) with

TABLE

h	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
δ_0^P	0.20	0.39	0.57	0.73	0.87	0.96	1.00	0.96	0.08	0.0
δ_0^*	0.16	0.31	0.46	0.60	0.72	0.83	0.92	0.97	0.99	1.00

the classical Popov criteria [13]. The latter guarantees absolute stability of system (3.14) if for all $\omega \in [0, \infty)$,

$$\frac{1}{K} > \frac{\omega^2 + a_{21}^+}{(\omega^2 + a_{21}^+)^2 + 4\omega^2 h^2}. \tag{3.15}$$

The right-hand side of (3.15) reaches its maximal in ω value for $\omega^2 = -a_{12}^+ + 2h\sqrt{-a_{12}^+}$; thus (3.15) holds if

$$K < 4h\sqrt{-a_{21}^+} + 4h^2. \tag{3.16}$$

Putting here $-a_{21}^+ = \omega_0^2 - K/2$, we get

$$K < K_P = 2\delta_0^P = 4h\sqrt{\omega_0^2 - h^2}. \tag{3.17}$$

For $\omega_0^2 = 1$, the limit values $\delta_0^P(h)$ and $\delta_0^*(h)$ obtained by the Popov and developed criteria (formulas (3.17) and (3.11)) are compared in the table.

As is seen, the Popov condition is slightly less conservative for relatively small h, while for larger h, our approach provides better results. For $h \to 1$, $\delta_0^P(h) \to 0$, while $\delta_0^*(h)$ approaches the precise bound $\delta_0^*(1) = 1$. (Really, for $h = \omega_0 = 1$ and $\varphi = -x$, equation (3.13) admits the solution $x(t) = const$ and, thus, is not asymptotically stable.) Note that Theorem 3, unlike the Popov condition, could be equally applied to controlled systems with a periodic linear part.

4. Proof of Theorem 1. Suppose first that the largest in the modulus multiplier ρ_n of (1.1) is real; let $x_n(t)$ be the corresponding solution ($x_n(t+T) = \rho_n x(t)$). As is known, it may be represented in the form

$$\begin{gathered} x_n(t) = \exp(\alpha_n t) u_n(t), \qquad u_n(t) = u_n(t+T), \\ \alpha_n = (\ln \rho_n)/T. \end{gathered} \tag{4.1}$$

Substituting (4.1) in (1.1), we find that $u_n(t)$ satisfies the equation

$$\dot{u} + \alpha_n u = A(t)u, \tag{4.2}$$

which we rewrite it in the form

$$\dot{u} + (\alpha_n + r)u = (A(t) + rI)u, \tag{4.3}$$

where the constant r is chosen so that

$$\alpha_n + r > 0 \text{ and } r \geq b_{ii}(t),\ i = 1, \dots, n,\ t \in [0, T]. \tag{4.4}$$

Using Green's function $g(t, s, \alpha)$ for the problem

$$\dot{y} + (\alpha + r)y = p(t), \qquad y(0) = y(T), \tag{4.5}$$

we reduce (4.3) to the integral equation

$$u = R(\alpha_n, A)u,$$

$$R(\alpha_n, A)u = \int_0^T G(t, s, \alpha_n)[A(s) + rI]u(s)\mathrm{d}s,\ G(t, s, \alpha_n) = \mathrm{diag}(g(t, s, \alpha_n)),$$

$$g(t, s, \alpha) = \frac{\exp[\beta(\mathrm{s} - T)]}{\exp(\beta T) - 1} \text{ for } t < s; \tag{4.6}$$

$$g(t, s, \alpha) = \frac{\exp[\beta(\mathrm{s} + T - t)]}{\exp(\beta T) - 1} \text{ for } t > s, \qquad \beta = \alpha + r.$$

Observing that $g(t, s, \alpha_n) > 0$ for $t; s \in [0, T]$, from (2.2), (4.4), and (4.6) we find

$$|u_n(t)| \le \int_0^T G(t, s, \alpha_n)\,|A(s) + rI|\,|u_n(s)|\,\mathrm{d}s \le R(\alpha_n, B)\,|u_n(t)|\,,$$

$$R(\alpha_n, B)u_n = \int_0^T G(t, s, \alpha_n)[B(s) + rI]u_n(s)\mathrm{d}s. \tag{4.7}$$

In view of (2.1) and (4.4), the matrix $B(s) + rI$ is nonnegative; since, moreover, $B(t_0)$ is nondecomposable, the operator $R(\alpha_n, B)$ is strongly positive [7] (i.e., it transforms any nonnegative function $u(t)$ into a positive one). Hence, the eigenvalue problem

$$\lambda u = R(\alpha_n, B)u \tag{4.8}$$

possesses a unique positive eigenvalue $\lambda_0(\alpha_n)$ such that the corresponding solution $u_0(t) > 0$ for $t \in [0, T]$; any other eigenvalue of this problem obeys the inequality $|\lambda_i| < \lambda_0$ [7, Theorem 4.3]. For $\lambda > \lambda_0$ and any $v(t) \ge 0$, inequality $R(\alpha_n, B)v \ge \lambda v$ fails [8, Theorem 2.18]. Thus, inequality (4.7) implies that

$$1 \le \lambda_0(\alpha_n). \tag{4.9}$$

Let $x^*(t) = \exp(\alpha^* t)u^*(t)(\alpha^* = (\ln \rho^*)/T, u^*(t) = u^*(t + T))$ be the solution of (2.2) corresponding to the largest in modulus multiplier $\rho^* = \rho_n(B)$. Since the off-diagonal elements of the matrix $B(t)$ are nonnegative, $u^*(t) > 0$ [7, Theorem 4.7]. Analogously, we find that $u^*(t)$ satisfies the equation

$$\lambda u = R(\alpha^*, B)u \tag{4.10}$$

with $\lambda = 1$. Because $u^*(t) > 0$, $\lambda = 1$ is the largest in modulus eigenvalue of the operator $R(\alpha^*, B)$ [8], i.e.,

$$\lambda_0(\alpha^*) = 1. \tag{4.11}$$

It is follows from (4.6) that $g(t, s, \alpha)$ and thus—see [8]—the operator $R(\alpha, B)$ and the eigenvalue $\lambda_0(\alpha)$ decrease as α increases. Hence the required inequality $\alpha^* \ge \alpha_n$ follows immediately from (4.9) and (4.11).

Let us assume now that a multiplier $\rho_n = \exp[(\alpha_n + i\omega_n)T]$ is complex. Suppose first that $\omega_n T/(2\pi) = p/q$, where p and q are integers. Since (1.1) is T-periodic, the matrix $W(qT) = [W(T)]^q$ and its eigenvalues equal $\rho_i^q, i = 1, \ldots, n$, and, thus, ρ_n^q is real. Correspondingly it follows that $|\alpha_n^q| \le \alpha^{*q}$, and the required inequality holds true.

If the number $\omega_n T/(2\pi)$ is irrational, we put $\omega_n(\varepsilon) = \omega_n + \varepsilon$. The value ω_n appears in the matrix of fundamental solutions $W(t)$ in the form $\exp(\omega_n t)$; thus $W(t,\varepsilon)$ and the corresponding matrix $A(t,\varepsilon) = \dot{W}(t,\varepsilon)W^{-1}(t,\varepsilon)$ are continuous in ε. Setting $\varepsilon \to 0$ and observing that for rational values $(\omega_n + \varepsilon)T/(2\pi)$, the multiplier $\rho_n(\varepsilon)$ satisfies inequality (2.3), we find that the last is also true for $\varepsilon = 0$, which finally proves the theorem.

Proof of Theorem 2. The real part of a characteristic exponent α_n of (1.1) satisfies the inequality (1.5) (see [6]), where $q(t)$ is the largest eigenvalue of the matrix $A(t) + A^{\tau}(t)$. Using representation (1.3) we find that $q(t) \le \beta_A(t) + \beta_s(t)$, where $\beta_s(t)$ is the largest eigenvalue of the matrix $\Delta(t) + \Delta^{\tau}(t)$. Clearly, its elements satisfy the inequality $|\delta_{ik}(t) + \delta_{ki}(t)| \le 2\delta_{ik}^{+}(t)$; hence, according to a Wielandt lemma [10], $\beta_s(t) \le \beta_{\Delta}(t)$. The theorem is proved.

Proof of Theorem 3. If δ_0 is small, (1.1) is asymptotically stable. For the critical value, δ_0^*, there exists a matrix $\Delta(t)$ with $\|\Delta(t)\| \le \delta_0^*$ such that $|\rho_i| \le 1, i = 1, \dots, n$; $|\rho_{\mathrm{k}}| = 1$ for a certain k, where ρ_i are the multipliers of (1.1). The corresponding solution of (1.1) is

$$x_k(t) = \exp(\alpha_k t)u_k(t), \quad u_k(t) = u_k(t+T), \tag{4.12}$$

where the value α_k is purely imaginary. Without loss of generality, we assume that

$$\|x_k(0)\| = \|u_k(0)\| = 1 \ge \|x_k(t)\|. \tag{4.13}$$

Clearly, $x_k(t)$ may be represented in the form

$$x_k(t) = W^0(t,0)x_k(0) + \int_0^t W^0(t,s)\Delta(s)x_k(s)\mathrm{d}s. \tag{4.14}$$

Taking into account (4.13), we find that for any integer p,

$$\begin{aligned} \|x_k(pT)\| = 1 &\le \|W^0(pT,0)\| + \int_0^{pT} \|W^0(pT,s)\|\|\Delta(s)\|\|x_k(s)\|\mathrm{d}s \\ &< \|W^0(pT,0)\| + w_0\delta_0^*. \end{aligned} \tag{4.15}$$

Noticing that $\|W(pT,0)\| \to 0$ as $p \to \infty$, we derive from (4.15) that $w_0\delta_0^* \ge 1$. Thus, for $\delta_0 < 1/w_0$, a value α_k cannot be purely imaginary, and all multipliers of (1.1) lie within the unit circle.

Proof of Theorem 4. Representing a solution $x_k(t) = \exp(\alpha_k t + ivt)u_k(t)$ in the form (2.6) and assuming $\|u_k(0)\| = 1 \ge \|u_k(t)\|$, we get

$$\begin{aligned} \|x_k(pT)\| &= \exp(\alpha_{\mathrm{k}} pT) \\ &\le \left\|W^0(pT,0)\right\| + \int_0^{pT} \left\|W^0(pT,s)\right\| \|\Delta(s)\| \, \|x_k(s)\| \, \mathrm{d}s \\ &\le \left\|W^0(pT,0)\right\| + \delta_0 \left[\int_0^{pT} w^2(pT,s)\mathrm{d}s \int_0^{pT} \left[\exp(\alpha_k s)\right]^2 \mathrm{d}s\right]^{1/2} \\ &< \left\|W^0(pT,0)\right\| + \frac{\delta_0 w_* \exp(\alpha_{\mathrm{k}} pT)}{(2\alpha_k)^{1/2}}. \end{aligned} \tag{4.16}$$

Since $\|W(pT,0)\| \to 0$ as $p \to \infty$, we derive from (4.16) the required inequality (2.16).

Proof of Theorem 5. We rewrite (1.1) in the form

$$\dot{x} + rx = [A(t) + rI]x, \tag{4.17}$$

where the constant r is chosen to satisfy the following inequality:

$$r + a_{ii}(t) > 0 \text{ for } i = 1, \dots, n,\ t > 0. \tag{4.18}$$

Let $x(t, x_0, A)(x(0, x_0, A) = x_0)$ be a solution of (4.17); clearly, it satisfies the equation

$$x(t) = x_0 + \frac{1}{r}\int_0^t \exp[-r(t-s)][A(s) + rI]x(s)\mathrm{d}s. \tag{4.19}$$

Let $x^+(t, x_0^+)(x^+(0, x_0^+) = x_0^+)$ be a solution of the equation $\dot{x} + rx = (B + rI)x$ and, analogously,

$$x^+(t) = x_0^+ + \frac{1}{r}\int_0^t \exp[-r(t-s)](B + rI)x^+(s)\mathrm{d}s. \tag{4.20}$$

We take $x_0^+ > |x_0|$; then $x_0^+(t) > |x_0(t)|$ for small t. We now show that this inequality holds for any $t > 0$. Really, suppose, by contradiction, that it fails for some $t = t^*$; then due to (4.19) and (4.20),

$$\begin{aligned} x^+(t^*) - |x(t^*)| > x_0^+ - |x_0| \\ + \frac{1}{r}\int_0^{t^*} \exp[-r(t^* - s)][(B + rI)x^+(s) - |A(s) + rI||x(s)|]\mathrm{d}s. \end{aligned} \tag{4.21}$$

The integrand in (4.21) is positive since

$$x^+(s) > |x(s)| \text{ for } s \in [0, t^*),\ b_{ik} \geq |a_{ik}(s)|,\ i \neq k,\ b_{ii} + r \geq |a_{ii}(s) + r|\,,$$

and, therefore, $x_0^+(t^*) > |x_0(t^*)|$. This contradiction implies that $x_0^+(t) > |x_0(t)|$ for all $t > 0$, and the corresponding Lyapunov exponents satisfy the inequality

$$\lambda(x_0^+, B) \geq \lambda(x_0, A). \tag{4.22}$$

Hence, for any solution of (1.1), there exists a solution of (2.1) such that the corresponding Lyapunov exponents obey inequality (4.22), which implies that this inequality holds true for the supremal Lyapunov exponents.

For a constant matrix B, the supremal Lyapunov exponent $\lambda_+(B)$ equals the largest real part of the eigenvalues. Due to the Perron theorem [9], for the positive matrix $B + rI$, the largest in modulus eigenvalue is positive and real. Since the real parts of the eigenvalues of the matrices $B + rI$ and B differ by the same value r, the value $\lambda_+(B)$ is the largest real eigenvalue $\lambda(B)$.

Proof of Theorem 6. For any solution $x(t)$ of (1.1), one has

$$\frac{\mathrm{d}}{\mathrm{d}t}(x^\tau x) = [x^\tau(A^\tau(t) + A(t))x] \leq \lambda_m(t)(x^\tau x), \tag{4.23}$$

where λ_m is the largest eigenvalue of the matrix $A^\tau(t) + A(t)$. Hence,

$$x^\tau(t)x(t) = \|x(t)\|^2 \leq \|x(0)\|^2 \exp\int_0^t \lambda_m(s)\mathrm{d}s. \tag{4.24}$$

Taking into account that the elements of the matrices $\Delta(t)$ and Δ_m satisfy the inequality $|\delta_{ik}(t)| \le \delta_{ik}^m$, $i,k = 1,\dots,n$, and using a Wielandt lemma [10], we find that the largest eigenvalue of the matrix $\Delta_m + \Delta_m^\tau$, β_m exceeds that of the matrix $\Delta(t)+\Delta^\tau(t)$, and, hence, $\lambda_m(t) \le \beta_A(t)+\beta_m$. Now required inequality (2.20) follows from (4.24).

OPTIMALITY CONDITIONS FOR SIMULTANEOUS TOPOLOGY AND SHAPE OPTIMIZATION*

J. SOKOŁOWSKI† AND A. ŻOCHOWSKI‡

Abstract. New optimality conditions are derived for a class of shape optimization problems. The conditions are established on the boundary by an application of the boundary variations technique and in the interior of an optimal domain by exploiting the topological derivative method. An example is provided for which the classical second order sufficient optimality conditions are verified for an optimal simply connected domain. However, the value of the cost can be improved by the topology variations, and therefore, the optimal solution can be substantially changed by applying the topology optimization.

Key words. shape optimization, shape derivative, topological derivative, asymptotic expansion, domain differential

1. Introduction.

In classical theory of shape optimization the first order necessary optimality conditions account for boundary variations of an optimal domain. On the other hand the relaxed formulation based on the homogenization technique is used [1], [4], [19] in the topology optimization of energy functionals, the so-called compliances in structural optimization. For such a formulation the coefficients of an elliptic operator are selected in an optimal way and the resulting optimal design takes the form of a composite microstructure rather than any geometrical domain. The methods of topology optimization based on asymptotic analysis and related to the topological derivatives or topological asymptotics include the so-called *bubble method*, used for the topology optimization in structural mechanics [7], [26]. Numerical results based on topological asymptotics can be found in [8]. We refer also to [11], [12] for an application to inverse problems and to [18], [17] for the related results in the case of the cavity of arbitrary shape. Further applications in mechanics can be found in [6], [13], [15], [16]. It seems that in the literature on the subject there is a lack of general method or technique that can be applied in the process of optimization of an arbitrary shape functional for simultaneous boundary and topology variations. Such an approach would be very useful for numerical solution of, e.g., optimum design problems in structural mechanics. In the paper [29] the so-called topological derivative (TD) of an arbitrary shape functional is introduced. Such a derivative is evaluated by an application of the asymptotic analysis in singularly perturbed geometrical domains [10], [20], [21] for a class of elliptic equations including the two-dimensional (2D) elasticity system [33] and three-dimensional (3D) elasticity system [32]. TD determines

whether a change of topology by nucleation of a small hole, or in the similar setting of a small inclusion at a given point $\boldsymbol{x} \in \Omega$, would result in improving the value of a given shape functional or not. In the case of cavities in the form of 2D circles or 3D balls (in the case of Laplace equations in the form of balls in $\mathbb{R}^n$ for an arbitrary space dimension $n \geq 2$) the constructive results are obtained [29], [31], [32] by using the shape calculus combined with the asymptotic approximations of solutions to elliptic BVPs.

Asymptotic approximations of solutions for problems with small geometrical singularities are constructed by the method of matched and compound asymptotic expansions in [10], [14], [20], [21], [22], [23], [24]. We refer the reader to [25] for proofs of results on asymptotic analysis of elliptic BVPs and associated shape functionals in weighted Hölder spaces. The approach allows for the pointwise estimates of remainders during the process of constructions of asymptotic approximations. The results on asymptotic analysis of volume and surface shape functionals [25] are established in terms of the so-called *polarization tensor*—an integral attribute of cavities and inclusions [24], in particular for the anisotropic elasticity in three dimensions. Let us point out that in the framework of Lagrangian formalism in shape optimization [5], the fixed domain setting for elliptic BVPs is required in order to derive the first order optimality conditions. The topology variations of geometrical domains are defined as *functions* of small parameter ρ. Such a fixed domain setting with respect to the small parameter ρ can be introduced by an application of the theory of self-adjoint extensions of elliptic operators defined in domains with geometrical singularities [22]; we refer the reader to [25] for the related results in the case of shape functionals. The Lagrangian formalism in the fixed domain setting combined with the formal asymptotics of solutions is used, e.g., in [8] for the purposes of numerical methods in topology optimization.

In the present paper the approach of [29] is extended to the case of a finite number of circular holes treated by means of TD combined with simultaneous boundary variations by an application of the speed method [28] to Frechet differentiable shape functionals. We combine, for the first time, the topology variations with the boundary variations in order to derive the first order optimality conditions for shape optimization problems. Therefore, the first order necessary optimality conditions are established for a class of shape optimization problems in a more general setting compared to the classical theory [28], [5]. We restrict ourselves, for simplicity, to a scalar model problem and to a simple class of topology variations; however, the same procedure will result in the first order optimality conditions for more general shape and topology optimization problems.

To deal with various types of domain modification we introduce the following general notation for different types of variations of shape functionals and of solutions to partial differential equations:

Shape derivative is used in order to determine the variations of solutions to BVPs resulting from the boundary variations of geometrical domains. In this framework, first, the Frechet differentiability of shape functionals is established, and then the speed method is applied to determine the shape derivative. We refer to, e.g., [28] and the recent book [5] for a general description of the speed method and the related results on Frechet differentiability of shape functionals.

Topological derivative (also *topological differential*) accounts for variations of shape functionals resulting from the emerging of one or several small holes, cavities, or inclusions in the interior of the geometrical domain. We refer to

section 4 for a detailed description of TDs of shape functionals in the case of the Laplace equation.

Domain differential, introduced here, unifies the influence on shape functionals of boundary variations and, at the same time, of the nucleation of internal holes or cavities. We refer to section 6 for the definition and properties of the domain differential in the case of the Laplace equation and to section 7 for an application of our method to the derivation of the necessary optimality conditions for a shape optimization problem.

Let us recall briefly the definitions used in the shape calculus. In the formulae given below, $J(\Omega)$ is an integral functional depending on the solution of the BVP defined on Ω. We assume that $\Omega \subset \mathbb{R}^n$ is a domain with piecewise smooth boundary, $n \geq 2$, and we assume for simplicity that $n = 2$; however, most of the results of the paper are valid for $n = 3$. The elliptic equations with the so-called polynomial property [23] are well-suited BVPs for our analysis. We introduce the mapping $T_\tau : \Omega \to \Omega_\tau$ associated with the vector field $\boldsymbol{V}(\cdot,\cdot) \in C^1(0,\delta; C_0^2(\mathbb{R}^2,\mathbb{R}^2))$ supported in a small neighborhood of $\Gamma = \partial\Omega$. The domain Ω_τ is defined by [28]

$$\Omega_\tau = \{\, \boldsymbol{x} = \boldsymbol{x}(\tau, \boldsymbol{X}) \mid \boldsymbol{X} \in \Omega \,\},$$

where $\boldsymbol{x} = \boldsymbol{x}(\tau, \boldsymbol{X})$ denotes the solution to the system

$$\frac{d\boldsymbol{x}}{d\tau}(\tau) = \boldsymbol{V}(\tau, \boldsymbol{x}), \qquad \boldsymbol{x}(0) = \boldsymbol{X}.$$

Then the shape derivative of $J(\Omega)$ at Ω^* and in the direction $\boldsymbol{V}$ is given by

$$\mathcal{S}J(\Omega^*; \boldsymbol{V}) = \lim_{\tau \to 0} \frac{1}{\tau} \left[J(T_\tau(\Omega^*)) - J(\Omega^*) \right]. \tag{1.1}$$

Now, let us create a small hole $B(\boldsymbol{x}, \rho) = \{\boldsymbol{y} \in \mathbb{R}^2 |\ |\boldsymbol{x} - \boldsymbol{y}| < \rho\}$ at the point $\boldsymbol{x}$ in the interior of the domain Ω, and let us prescribe the Neumann homogeneous conditions on its boundary $\partial B(\boldsymbol{x}, \rho)$. The meaning of the Neumann condition can be made precise for a general elliptic BVP by using the Green formula associated with the problem. We denote by $\overline{B(\boldsymbol{x}, \rho)}$ the closure of the ball $B(\boldsymbol{x}, \rho)$ (circle for $n = 2$), and we define $\Omega_\rho = \Omega \setminus \overline{B(\boldsymbol{x}, \rho)}$. According to [29], the TD $\mathcal{T}J(\Omega^*; \boldsymbol{x})$ of $J(\Omega)$ at $\Omega^* \subset \mathbb{R}^2$ is a function depending on the center $\boldsymbol{x}$ of the small hole and in two dimensions is given by the following limit, if the limit exists:

$$\mathcal{T}J(\Omega^*; \boldsymbol{x}) = \lim_{\rho \to 0+} \frac{J(\Omega^* \setminus \overline{B(\boldsymbol{x}, \rho)}) - J(\Omega^*)}{\pi \rho^2}. \tag{1.2}$$

Remark 1.1. The following formula [32] is useful in applications, since it uses only the first order shape derivatives of the shape functional $J(\Omega)$ in order to evaluate the TDs of $J(\Omega)$ at $\Omega^* \subset \mathbb{R}^n$, $n \geq 2$:

$$\mathcal{T}J(\Omega^*; \boldsymbol{x}) = \lim_{\rho \downarrow 0} \frac{dJ(\Omega^* \setminus \overline{B(\boldsymbol{x}, \rho)})}{d(|B(\boldsymbol{x}, \rho)|)}, \tag{1.3}$$

where $|B(\boldsymbol{x}, \rho)|$ is the n-dimensional measure of the ball $B(\boldsymbol{x}, \rho)$.

Remark 1.2. It is an interesting and, it seems, difficult problem for further studies in asymptotic analysis to introduce, in addition to the *interior* topology variations, the *exterior* topology variations defined on the boundary of geometrical domain. Such exterior topology variations will, in particular, replace the boundary variations in the

procedure of derivation of necessary optimality conditions for the shape and topology optimization problems.

In section 6 we show that under the volume constraints $|\Omega|=const$ the necessary optimality conditions for the problem of minimization of the shape functional $J(\Omega)$ takes the form (6.6). Such first order necessary optimality conditions seem to be new in shape optimization.

In section 7 we present an example with the optimal solution known explicitly. For such a problem all the computations can be carried out analytically, in particular, for the TDs. The optimal shape in the form of a disk corresponds to the fixed topology, i.e., when only simply connected domains are admissible. When the requirement on the fixed topology is relaxed and still the symmetry of admissible domains is required, the disk remains optimal under the volume constraints. Finally, for the admissible domains which are no longer symmetric, the optimality conditions including the TD are not satisfied. Therefore, a topology variation in the precisely indicated region of the disk improves the value of the cost functional. It shows that the domain differential allows us to distinguish all the cases listed above. Thus, the optimality conditions we establish are more precise compared to the classical boundary variation technique. The similar results can be expected, as well, for the optimization problems with respect to the geometrical domain involving eigenvalues.

2. Preliminaries. We are going to analyze a class of shape optimization problems for the Laplace equation. Therefore, we need the precise results on asymptotic approximations of solutions to the equation with respect to small parameter $\rho > 0$ which defines the size of geometrical singularities. We consider in the paper a model problem; therefore the arguments are elementary, and we provide the proofs for the convenience of the reader.

Let us denote by $C(\boldsymbol{x}^0;\rho)$ a circle $C(\boldsymbol{x}^0;\rho) = \{\ \boldsymbol{x}\ |\ \ |\boldsymbol{x}-\boldsymbol{x}^0| = \rho\ \}$, by $P(\boldsymbol{x}^0;\rho,R)$ a ring $P(\boldsymbol{x}^0;\rho,R) = \{\ \boldsymbol{x}\ |\ \ \rho < |\boldsymbol{x}-\boldsymbol{x}^0| < R\ \}$, and finally $B(\boldsymbol{x}^0;R) = \{\ \boldsymbol{x}\ |\ \ |\boldsymbol{x}-\boldsymbol{x}^0| < R\ \}$, where the bar denotes the closure $\overline{B(\boldsymbol{x}^0;R)} = \{\ \boldsymbol{x}\ |\ \ |\boldsymbol{x}-\boldsymbol{x}^0| \le R\ \}$. If $\boldsymbol{x}^0 = 0$, we simplify the notation to $C(\rho)$, $P(\rho,R)$, and $B(R)$. We formulate the BVP

$$\Delta w_\rho = 0 \quad \text{in} \quad P(\rho,R), \tag{2.1a}$$

$$w_\rho = 0 \quad \text{on} \quad C(R), \tag{2.1b}$$

$$\frac{\partial}{\partial n} w_\rho = h_\rho \quad \text{on} \quad C(\rho). \tag{2.1c}$$

Then the following estimates can be established for solutions to (2.1). The estimates are classical, we provide the proof for convenience of the reader.

LEMMA 2.1. *Let $R_0 < R$ be fixed and h_ρ be the trace on $C(\rho)$ of the function $h \in C^1(\overline{B(R_0)})$. Then the solution w_ρ of (2.1) satisfies on $C(\rho)$, for $\rho < R_0$, the estimates*

$$\begin{aligned} |w_\rho| &\le \Lambda\rho|\log\rho|, \\ |\nabla w_\rho| &\le \Lambda \end{aligned}$$

and on $P(R_0,R)$

$$|w_\rho| \le \Lambda\rho.$$

Here Λ is a generic constant depending only on the norm of h in $C^1(\overline{B(R_0)})$ and on parameters R_0, R.

Proof. Let us recall that the Laplacian takes the following form in the polar coordinate system,

$$\Delta w = w_{rr} + \frac{1}{r} w_r + \frac{1}{r^2} w_{\phi\phi}, \tag{2.2}$$

and if w is radially symmetric,

$$\Delta w = w_{rr} + \frac{1}{r} w_r. \tag{2.3}$$

The function h_ρ admits the Fourier series expansion

$$h_\rho = c_\rho + \sum_{k=1}^{\infty} (a_{\rho,k} \sin k\phi + b_{\rho,k} \cos k\phi),$$

where in addition

$$c_\rho^2 + \sum_{k=1}^{\infty} (a_{\rho,k}^2 + b_{\rho,k}^2) \le \Lambda_1^2. \tag{2.4}$$

We determine the solution w_ρ of (2.1) in the form of a series.

The first term, corresponding to c_ρ, is radially symmetric and, taking (2.3) into account, has the following representation:

$$w_\rho^0 = A + B \ln r.$$

From the boundary condition

$$\frac{\partial w_\rho^0}{\partial n} = c_\rho \quad \text{on} \quad C(\rho),$$

it follows that

$$A + B \ln R = 0,$$
$$B \frac{1}{\rho} = c_\rho;$$

hence

$$B = \rho c_\rho, \qquad A = -\rho c_\rho \ln R,$$

where $|c_\rho| \le \Lambda_1$. Finally,

$$w_\rho^0 = \rho c_\rho \ln r - \rho c_\rho \ln R. \tag{2.5}$$

Consider now the terms corresponding to the boundary condition

$$\frac{\partial w_\rho^k}{\partial n} = a_{\rho,k} \cdot \sin k\phi \quad \text{on} \quad C(\rho)$$

for $k \ge 1$ (cosine terms can be treated in the same way). We seek the solution in the form

$$w_\rho^k = v(r) \cdot \sin k\phi,$$

and, in view of (2.2), we have the representation

$$v(r) = Ar^k + B\frac{1}{r^k}.$$

Again, taking into account the boundary conditions it follows that

$$AR^k + B\frac{1}{R^k} = 0,$$
$$kA\rho^{k-1} - kB\frac{1}{\rho^{k+1}} = a_{\rho,k}.$$

We obtain

$$w_\rho^k = \frac{\rho^{k+1}\cdot a_{\rho,k}}{k(R^{2k}+\rho^{k-1})}\left(r^k - \frac{R^{2k}}{r^k}\right)\sin k\phi, \tag{2.6}$$

where $|a_{\rho,k}| \le \Lambda_1$.

Substituting $r := \rho$ in (2.5), (2.6) we get

$$|w_\rho^0(\rho)| \le \Lambda_2(\Lambda_1)\rho|\ln\rho|,$$
$$|w_\rho^k(\rho)| \le \Lambda_3(\Lambda_1)\rho.$$

The convergence of the series for the solution w_ρ follows from (2.4) for sufficiently small ρ. □

Now we consider the bounded domain Ω which satisfies the following assumption.

(H1) Ω is a bounded domain with the boundary $\Gamma = \partial\Omega$ consisting of a finite number of smooth arcs; see Figure 1.

We define the BVP in Ω:

$$\Delta u_0 = f \quad \text{in} \quad \Omega, \tag{2.7a}$$
$$u_0 = g_D \quad \text{on} \quad \Gamma^D, \tag{2.7b}$$
$$\frac{\partial}{\partial n}u_0 = g_N \quad \text{on} \quad \Gamma^N, \tag{2.7c}$$

where $\Gamma^N \cup \Gamma^D = \Gamma = \partial\Omega$, and the data of the problem satisfy the following assumption: m is an integer which is selected in such a way that the solution to (2.7) enjoys the required regularity for our purposes.

(H2) $f \in H^m(\Omega)$, $g_D \in H^{m+3/2}(\Gamma^D)$, $g_N \in H^{m+1/2}(\Gamma^N)$, and the inclusions hold for every arc in Γ^D, Γ^N.

For such a BVP we shall use the regularity results obtained for the solutions to BVPs in nonsmooth domains given, e.g., in [9], [24]. The elliptic regularity of solutions is investigated in [24] in the weighted Sobolev spaces, with the weights defined as functions of the distance to the isolated singular boundary points (corners in the 2D case). For the sake of simplicity, we do not introduce here the specific notation required for the regularity analysis in such spaces. In the case of the scalar equation the related result is given in [24, Theorem 3.1, p. 32] for the Dirichlet problem and in [24, Theorem 4.2, p. 39] for the Neumann problem. The general case of elliptic BVPs in bounded domains is covered by [24, Theorem 3.2, p. 309]. The results established in [24] can be formulated for our purposes in the following theorem.

THEOREM 2.2. *Let* $\boldsymbol{p}^1 \dots \boldsymbol{p}^k$ *be vertices of* Γ *(endpoints of smooth arcs),*

$$\Omega_\delta = \Omega \setminus \bigcup_{i=1}^k \overline{B(\boldsymbol{p}^i;\delta)}, \qquad \Gamma_\delta = \Gamma \setminus \bigcup_{i=1}^k \overline{B(\boldsymbol{p}^i;\delta)}.$$

Then for a given, sufficiently small $\delta > 0$, the solution of (2.7) satisfies the estimate

$$\|u_0\|_{H^{m+2}(\Omega_\delta)} \leq \Lambda(\delta)\left(\|f\|_{H^m(\Omega_{\delta/2})} + \|g_D\|_{H^{m+3/2}(\Gamma_{\delta/2})} + \|g_N\|_{H^{m+1/2}(\Gamma_{\delta/2})}\right).$$

We can replace $\Omega_{\delta/2}, \Gamma_{\delta/2}$ by Ω, Γ in the right-hand side of the above inequality, provided the norms in the right-hand side over the specific sets are finite. □

In the rest of the paper we assume that all the regularity assumptions concerning the data f, g_D, g_N of the problem (2.7) are satisfied with the parameter m specified separately in every particular case.

3. Double asymptotic expansion. We consider the case of two distinct holes. The finite number of distinct holes can be treated in the same way. We establish the asymptotic approximations of solutions to the Laplace equation with respect to the radii of the holes. This is an extension of the results given [30] in the case of a single hole.

Let us select two different points $\boldsymbol{x}^1$ and $\boldsymbol{x}^2$ in the interior of Ω. Next we remove from Ω two balls, $B(\boldsymbol{x}^1;\rho_1)$ and $B(\boldsymbol{x}^2;\rho_2)$. There always exists $\delta > 0$ such that the set of pairs (ρ_1,ρ_2) satisfying the condition

$$0 < \rho_1, \rho_2 < \frac{1}{2}\max\left\{\ \mathrm{dist}(\boldsymbol{x}^1, \partial\Omega_\delta),\ \mathrm{dist}(\boldsymbol{x}^2, \partial\Omega_\delta),\ \frac{1}{2}|\boldsymbol{x}^2 - \boldsymbol{x}^1|\ \right\} \tag{3.1}$$

is nonempty. We define

$$\Omega_{\rho_1\rho_2} = \Omega \setminus (\overline{B(\boldsymbol{x}^1;\rho_1)} \cup \overline{B(\boldsymbol{x}^2;\rho_2)})$$

and denote by $u_{\rho_1\rho_2}$ the solution of the following BVP, which is a modification of (2.7) taking into account the existence of holes:

$$\Delta u_{\rho_1\rho_2} = f \quad \text{in} \quad \Omega_{\rho_1\rho_2}, \tag{3.2a}$$

$$u_{\rho_1\rho_2} = g_D \quad \text{on} \quad \Gamma^D, \tag{3.2b}$$

$$\frac{\partial}{\partial n}u_{\rho_1\rho_2} = g_N \quad \text{on} \quad \Gamma^N, \tag{3.2c}$$

$$\frac{\partial}{\partial n}u_{\rho_1\rho_2} = 0 \quad \text{on} \quad C(\boldsymbol{x}^1;\rho_1) \cup C(\boldsymbol{x}^2;\rho_2). \tag{3.2d}$$

Furthermore, we assume that the number m defining the regularity of the data as specified in Theorem 2.2 satisfies $m \geq 1$.

In view of condition (3.1) satisfied by the radii ρ_1, ρ_2 there exist constants R_0 and R, such that $R_0 > \max\{\rho_1,\rho_2\}$ and

$$\Omega \subset B(\boldsymbol{x}^1;R) \cap B(\boldsymbol{x}^2;R),$$

$$B(\boldsymbol{x}^1;R_0) \cap \partial\Omega_\delta = B(\boldsymbol{x}^2;R_0) \cap \partial\Omega_\delta = B(\boldsymbol{x}^1;R_0) \cap B(\boldsymbol{x}^2;R_0) = \emptyset.$$

All the geometrical objects introduced so far are presented in Figure 1. In order to formulate the main result of this section, we define the functions $s_{\rho_1},\ s_{\rho_2}$ of the form

$$s_{\rho_1}(\boldsymbol{x}) = \frac{\partial u_0}{\partial x_1}(\boldsymbol{x}^1)\cdot\frac{\rho_1^2}{r_1}\cos\theta_1 + \frac{\partial u_0}{\partial x_2}(\boldsymbol{x}^1)\cdot\frac{\rho_1^2}{r_1}\sin\theta_1,$$

$$s_{\rho_2}(\boldsymbol{x}) = \frac{\partial u_0}{\partial x_1}(\boldsymbol{x}^2)\cdot\frac{\rho_2^2}{r_2}\cos\theta_2 + \frac{\partial u_0}{\partial x_2}(\boldsymbol{x}^2)\cdot\frac{\rho_2^2}{r_2}\sin\theta_2.$$

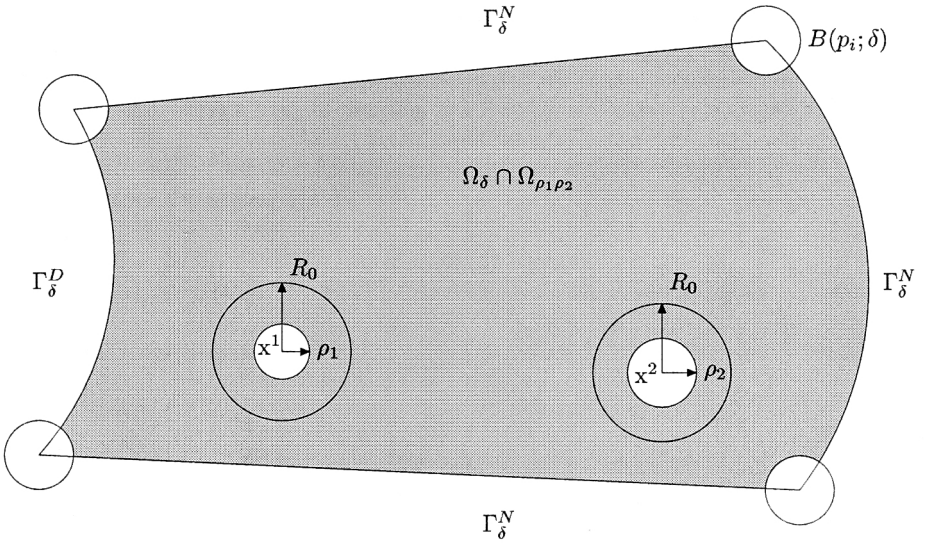

FIG. 1. *The domains Ω_δ, $\Omega_{\rho_1\rho_2}$ and related geometrical objects.*

Here u_0 is the solution of (2.7), while $(r_1 = |\boldsymbol{x} - \boldsymbol{x}^1|, \theta_1)$ and $(r_2 = |\boldsymbol{x} - \boldsymbol{x}^2|, \theta_2)$ are polar coordinate systems around $\boldsymbol{x}^1$ and $\boldsymbol{x}^2$, respectively.

We prove, modifying the argument given in [30] for a single hole, that the following asymptotic approximation is obtained in the case of two holes.

LEMMA 3.1. *The solution of* (3.2) *may be expressed as follows:*

$$u_{\rho_1\rho_2} = u_0 + s_{\rho_1} + s_{\rho_2} + z_{\rho_1\rho_2},$$

where $z_{\rho_1\rho_2}$ satisfies on $C(\boldsymbol{x}^1;\rho_1) \cup C(\boldsymbol{x}^2;\rho_2)$ the estimates

$$\begin{aligned} |z_{\rho_1\rho_2}| &\le \Lambda\left(\rho_1^2|\log\rho_1| + \rho_2^2|\log\rho_2|\right), \\ |\nabla z_{\rho_1\rho_2}| &\le \Lambda(\rho_1+\rho_2), \end{aligned}$$

and, in addition, on the set $P(\boldsymbol{x}^1;R_0,R) \cap P(\boldsymbol{x}^2;R_0,R) \cap \Omega$

$$|z_{\rho_1\rho_2}| \le \Lambda(\rho_1^2+\rho_2^2),$$

with $\Lambda = \Lambda(\Omega,\delta,R_0,R)$.

Proof. Let us set $\rho = \sqrt{\rho_1^2+\rho_2^2}$. We expand $z_{\rho_1\rho_2}$ in the form of the series

$$z_{\rho_1\rho_2} = p^1_{\rho_1} + p^1_{\rho_2} + q^1_\rho + \rho^2(p^2_{\rho_1} + p^2_{\rho_2} + q^2_\rho) + \cdots,$$

where the consecutive terms are defined by the BVPs specified below.

For $p^1_{\rho_1}$ we have

$$\begin{aligned} \Delta p^1_{\rho_1} &= 0 && \text{in} \quad P(\boldsymbol{x}^1;\rho_1,R), \\ p^1_{\rho_1} &= 0 && \text{on} \quad C(\boldsymbol{x}^1;R), \\ \frac{\partial}{\partial n}p^1_{\rho_1} &= -\frac{\partial}{\partial n}(u_0 + s_{\rho_1}) && \text{on} \quad C(\boldsymbol{x}^1;\rho_1), \end{aligned}$$

and for $p^1_{\rho_2}$ we have

$$\begin{aligned} \Delta p^1_{\rho_2} &= 0 && \text{in} \quad P(\boldsymbol{x}^2;\rho_2,R),\\ p^1_{\rho_2} &= 0 && \text{on} \quad C(\boldsymbol{x}^2;R),\\ \frac{\partial}{\partial n}p^1_{\rho_2} &= -\frac{\partial}{\partial n}(u_0+s_{\rho_2}) && \text{on} \quad C(\boldsymbol{x}^2;\rho_2), \end{aligned}$$

while

$$\begin{aligned} \Delta q^1_{\rho} &= 0 && \text{in} \quad \Omega,\\ q^1_{\rho} &= -s_{\rho_1}-s_{\rho_2}-p^1_{\rho_1}-p^1_{\rho_2} && \text{on} \quad \Gamma. \end{aligned}$$

The idea of such a construction can be explained as follows.

Functions $p^1_{\rho_1}$ and $p^1_{\rho_2}$ correct the normal derivatives of $z_{\rho_1\rho_2}$ on $C(\boldsymbol{x}^1;\rho_1)$ and $C(\boldsymbol{x}^2;\rho_2)$, respectively. However, $p^1_{\rho_1}$ introduces the discrepancy around $C(\boldsymbol{x}^2;\rho_2)$ and $p^1_{\rho_2}$ introduces the discrepancy around $C(\boldsymbol{x}^1;\rho_1)$. In addition, $p^1_{\rho_1}$ and $p^1_{\rho_2}$ disturb the Dirichlet boundary conditions on Γ. Therefore, q^1_{ρ} is introduced to correct the boundary conditions on Γ. In this way, further terms of the series for the expansion of $z_{\rho_1\rho_2}$ are introduced.

Now observe that due to the regularity of u_0 (see Theorem 2.2), the gradient ∇u_0 is continuous on the sets $\overline{B(\boldsymbol{x}^1;R_0)}$ and $\overline{B(\boldsymbol{x}^2;R_0)}$. Thus, the norm of the gradient $|\nabla u_0|$ is uniformly bounded on these sets, and we have

$$\left|\frac{\partial}{\partial n}(u_0+s_{\rho_1})\right| \le \Lambda\rho_1 \qquad \text{on} \quad C(\boldsymbol{x}^1;\rho_1),$$

$$\left|\frac{\partial}{\partial n}(u_0+s_{\rho_2})\right| \le \Lambda\rho_2 \qquad \text{on} \quad C(\boldsymbol{x}^2;\rho_2).$$

Therefore, by Lemma 2.1,

$$\begin{aligned} |p^1_{\rho_1}| &\le \Lambda\rho_1^2|\log\rho_1| && \text{on} \quad C(\boldsymbol{x}^1;\rho_1),\\ |p^1_{\rho_1}|+|\nabla p^1_{\rho_1}| &\le \Lambda\rho_1^2 && \text{on} \quad P(\boldsymbol{x}^1;R_0,R),\\ |p^1_{\rho_2}| &\le \Lambda\rho_2^2|\log\rho_2| && \text{on} \quad C(\boldsymbol{x}^2;\rho_2),\\ |p^1_{\rho_2}|+|\nabla p^1_{\rho_2}| &\le \Lambda\rho_2^2 && \text{on} \quad P(\boldsymbol{x}^2;R_0,R). \end{aligned}$$

Hence, $|q^1_{\rho}| \le \Lambda\rho^2$ on Γ, and also

$$|\nabla q^1_{\rho}| \le \Lambda\rho^2 \qquad \text{on} \quad P(\boldsymbol{x}^1;\rho_1,R_0)\cup P(\boldsymbol{x}^2;\rho_2,R_0).$$

In the next step we introduce the corrections of higher order with respect to ρ. As we have seen above, the Neumann boundary conditions on $C(\boldsymbol{x}^1;\rho_1)$ are perturbed by the functions $p^1_{\rho_2}$ and q^1_{ρ}. Therefore, the next set of functions $p^2_{\rho_1}, p^2_{\rho_2}, q^2_{\rho}$ is defined by solutions to the following BVPs.

For $p^2_{\rho_1}$

$$\begin{aligned} \Delta p^2_{\rho_1} &= 0 && \text{in} \quad P(\boldsymbol{x}^1;\rho_1,R),\\ p^2_{\rho_1} &= 0 && \text{on} \quad C(\boldsymbol{x}^1;R),\\ \frac{\partial}{\partial n}p^2_{\rho_1} &= -\frac{1}{\rho^2}\frac{\partial}{\partial n}(q^1_{\rho}+p^1_{\rho_2}) && \text{on} \quad C(\boldsymbol{x}^1;\rho_1), \end{aligned}$$

and for $p^2_{\rho_2}$

$$\begin{aligned} \Delta p^2_{\rho_2} &= 0 && \text{in} \quad P(\boldsymbol{x}^2;\rho_2,R),\\ p^2_{\rho_2} &= 0 && \text{on} \quad C(\boldsymbol{x}^2;R),\\ \frac{\partial}{\partial n}p^1_{\rho_2} &= -\frac{1}{\rho^2}\frac{\partial}{\partial n}(q^1_\rho + p^1_{\rho_1}) && \text{on} \quad C(\boldsymbol{x}^2;\rho_2), \end{aligned}$$

while q^2_ρ satisfies

$$\begin{aligned} \Delta q^2_\rho &= 0 && \text{in} \quad \Omega,\\ q^2_\rho &= -\frac{1}{\rho^2}(p^2_{\rho_1} + p^2_{\rho_2}) && \text{on} \quad \Gamma. \end{aligned}$$

In addition, from properties of $p^1_{\rho_1}, p^1_{\rho_2}, q^1_\rho$ it follows that

$$\left|\frac{\partial}{\partial n}(q^1_\rho + p^1_{\rho_2})\right| \le \Lambda\rho^2 \qquad \text{on} \quad C(\boldsymbol{x}^1;\rho_1),$$

$$\left|\frac{\partial}{\partial n}(q^1_\rho + p^1_{\rho_1})\right| \le \Lambda\rho^2 \qquad \text{on} \quad C(\boldsymbol{x}^2;\rho_2).$$

By Lemma 2.1 the terms $\rho^2(p^2_{\rho_1} + p^2_{\rho_2} + q^2_\rho)$ constitute the correction of the order $\rho^3|\log\rho|$. Finally, we again use Lemma 2.1 to obtain the estimates for $p^1_{\rho_1} + p^1_{\rho_2} + q^1_\rho$ and, therefore, for $z_{\rho_1\rho_2}$. □

4. Topological differential with respect to multiple holes. We shall restrict our analysis to the case of two holes, since the generalization to the case of a finite number of holes can be performed in the same way. Let us define the domain functionals I_u and I_g as follows:

$$I_u(\rho_1,\rho_2) = \int_{\Omega_{\rho_1\rho_2}} F(u_{\rho_1\rho_2})\,dx, \tag{4.1}$$

$$I_g(\rho_1,\rho_2) = \int_{\Omega_{\rho_1\rho_2}} |\nabla u_{\rho_1\rho_2}|^{2p}\,dx, \tag{4.2}$$

$p = 1, 2$, where $u_{\rho_1\rho_2}$ denotes the solution to (3.2) and $\Omega_{\rho_1\rho_2} = \Omega \setminus (\overline{B(\boldsymbol{x}^1;\rho_1)} \cup \overline{B(\boldsymbol{x}^2;\rho_2)})$. Our main result on the asymptotic approximation of the shape functionals with respect to multiple holes is given below.

THEOREM 4.1. *Assume that* (H1) *and* (H2) *are satisfied, with* $m \ge 1$, F *is a* C^2 *function, and* $\rho_1, \rho_2 > 0$ *are small enough.*

Then, the following representation is obtained for the topological variations of the shape functionals:

$$I_u(\rho_1,\rho_2) = I_u(0,0) + \mathcal{T}I_u(\boldsymbol{x}^1)\cdot|B(\boldsymbol{x}^1;\rho_1)| + \mathcal{T}I_u(\boldsymbol{x}^2)\cdot|B(\boldsymbol{x}^2;\rho_2)| + o(\rho^2), \tag{4.3}$$

$$I_g(\rho_1,\rho_2) = I_g(0,0) + \mathcal{T}I_g(\boldsymbol{x}^1)\cdot|B(\boldsymbol{x}^1;\rho_1)| + \mathcal{T}I_g(\boldsymbol{x}^2)\cdot|B(\boldsymbol{x}^2;\rho_2)| + o(\rho^2). \tag{4.4}$$

We omit here the dependence of the TDs $\mathcal{T}I_u(\cdot), \mathcal{T}I_g(\cdot)$ on the domain Ω (see (1.2)), because Ω is fixed in all subsequent considerations in this section. Formulae (4.3) and (4.4) define *the topological gradient* for the functional I_u,

$$\mathcal{T}I_u(\Omega; \boldsymbol{x}^1, \boldsymbol{x}^2) \;=\; \left[\mathcal{T}I_u(\Omega; \boldsymbol{x}^1), \mathcal{T}I_u(\Omega; \boldsymbol{x}^2)\right],$$

which contains the TDs evaluated at the centers $\boldsymbol{x}^1, \boldsymbol{x}^2$ of the holes.

The topological gradient contain TDs corresponding to the holes, and, therefore, it looks like the classical gradient of a multivariable function consisting of all partial derivatives. The topological gradient allows us to express the related variations of the shape functionals in terms of the product of volumes of the balls centered at $\boldsymbol{x}^1, \boldsymbol{x}^2$ multiplied by the TDs evaluated at the points $\boldsymbol{x}^1, \boldsymbol{x}^2$. (The procedure is the same, in general, only for a finite number of such points.)

We use the notation $\nabla u \cdot \nabla v = \sum_{i=1}^{2} \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_i}$ for the scalar product of two vectors and $\boldsymbol{n}^\top K \nabla u = \sum_{i,j=1}^{2} n_i K_{i,j} \frac{\partial u}{\partial x_j}$ for the product of a matrix with two vectors.

Proof. We evaluate the directional derivative of $I_u(\rho_1, \rho_2)$ at $\rho = 0^+$. Let us recall that in the case of a single hole the formula for $\mathcal{T}I_u(\boldsymbol{x}^0)$ has been derived in [29] and takes the form

$$\mathcal{T}I_u(\boldsymbol{x}^0) = -\left[F(u_0) + f w_0 + 2\nabla u_0 \cdot \nabla w_0\right]_{\boldsymbol{x}=\boldsymbol{x}^0}, \tag{4.5}$$

where w_0 is the adjoint function which satisfies (4.8).

Let us take $c_1, c_2 > 0$, $c_1^2 + c_2^2 = 1$, and the radii of balls in the form $\rho_1 = c_1\rho,\ \rho_2 = c_2\rho$. Then $\rho_1^2 + \rho_2^2 = \rho^2$ and $|B(\boldsymbol{x}^1; \rho_1)| + |B(\boldsymbol{x}^2; \rho_2)| = \pi\rho^2$. By varying the parameter ρ we change the boundaries of both holes simultaneously. Finally, we introduce the space

$$H_D^1(\Omega) = \{\ \phi \in H^1(\Omega) \mid \phi = 0 \quad \text{on} \quad \Gamma^D\ \}$$

and the convex set

$$H_g^1(\Omega) = \{\ \phi \in H^1(\Omega) \mid \phi = g_D \quad \text{on} \quad \Gamma^D\ \}.$$

In the first step we evaluate the derivative

$$\begin{aligned} \frac{d}{d\rho} I_u(\rho_1, \rho_2) = &\int_{\Omega_{\rho_1\rho_2}} F_u(u_{\rho_1\rho_2}) u'_{\rho_1\rho_2}\, dx \\ &- c_1 \int_{C(\boldsymbol{x}^1;\rho_1)} F(u_{\rho_1\rho_2})\, ds - c_2 \int_{C(\boldsymbol{x}^2;\rho_2)} F(u_{\rho_1\rho_2})\, ds, \end{aligned} \tag{4.6}$$

where $u'_{\rho_1\rho_2}$ is the shape derivative of $u_{\rho_1\rho_2}$ with respect to the change of radii of both circles; we refer to [28] for the details. By $d/d\rho$ we mean the Eulerian semiderivative of the shape functional $I_u(\rho_1, \rho_2)$ in the direction of the specific vector field $\boldsymbol{V}$ equal to the exterior unit normal field $-\boldsymbol{n}$ on $C(\boldsymbol{x}^1; \rho_1)$ and $C(\boldsymbol{x}^2; \rho_2)$. The result of the derivation conforms to the Hadamard formula [28] which says that in the case of differentiable shape functionals the shape derivatives actually depend on the normal component of the velocity field on the moving boundary.

We know that

$$u'_{\rho_1\rho_2} = \dot{u}_{\rho_1\rho_2} - \nabla u_{\rho_1\rho_2} \cdot \boldsymbol{V},$$

where $\boldsymbol{V}$ is an appropriate vector field introduced above by an extension of the normal field $-\boldsymbol{n}$ to the small neighborhoods of $C(\boldsymbol{x}^1;\rho_1)$ and $C(\boldsymbol{x}^2;\rho_2)$ and $\dot{u}$ denotes the material derivative in the direction V. Now, observe that we may take smooth $\boldsymbol{V}$ which vanishes outside Ω_δ, i.e., the only region where $\nabla u_{\rho_1\rho_2}$ actually may have singularities. Hence $u'_{\rho_1\rho_2}$ enjoys the same regularity as $\dot{u}_{\rho_1\rho_2}$, in particular, $u'_{\rho_1\rho_2} \in H^1_D(\Omega_{\rho_1\rho_2})$.

The shape derivative $u'_{\rho_1\rho_2} \in H^1_D(\Omega_{\rho_1\rho_2})$ satisfies for all $\phi \in H^1_D(\Omega_{\rho_1\rho_2})$ the following integral identity:

$$\begin{aligned}\int_{\Omega_{\rho_1\rho_2}} \nabla u'_{\rho_1\rho_2}\cdot\nabla\phi\,dx - c_1\int_{C(\boldsymbol{x}^1;\rho_1)} \nabla u'_{\rho_1\rho_2}\cdot\nabla\phi\,ds - c_2\int_{C(\boldsymbol{x}^2;\rho_2)} \nabla u'_{\rho_1\rho_2}\cdot\nabla\phi\,ds \\ = c_1\int_{C(\boldsymbol{x}^1;\rho_1)} f\phi\,ds + c_2\int_{C(\boldsymbol{x}^2;\rho_2)} f\phi\,ds.\end{aligned} \tag{4.7}$$

Now we introduce the adjoint variables w_0 and $w_{\rho_1\rho_2}$ defined by the following variational identities:

(1) Find $w_0 \in H^1_D(\Omega)$ such that

$$-\int_\Omega \nabla w_0\cdot\nabla\phi, dx = \int_\Omega F_u(u_0)\phi\,dx \quad \text{for all} \quad \phi \in H^1_D(\Omega). \tag{4.8}$$

(2) Find $w_{\rho_1\rho_2} \in H^1_D(\Omega_{\rho_1\rho_2})$ such that

$$-\int_{\Omega_{\rho_1\rho_2}} \nabla w_{\rho_1\rho_2}\cdot\nabla\phi, dx = \int_{\Omega_{\rho_1\rho_2}} F_u(u_{\rho_1\rho_2})\phi\,dx \quad \text{for all} \quad \phi \in H^1_D(\Omega_{\rho_1\rho_2}). \tag{4.9}$$

Taking into account the regularity of $u'_{\rho_1\rho_2}$, we make cross-substitutions in (4.7) and (4.9) which lead to

$$\begin{aligned}\int_{\Omega_{\rho_1\rho_2}} F_u(u_{\rho_1\rho_2})u'_{\rho_1\rho_2}\,dx = &- c_1\int_{C(\boldsymbol{x}^1;\rho_1)} [fw_{\rho_1\rho_2} + \nabla u_{\rho_1\rho_2}\cdot\nabla w_{\rho_1\rho_2}]\,ds \\ &- c_2\int_{C(\boldsymbol{x}^2;\rho_2)} [fw_{\rho_1\rho_2} + \nabla u_{\rho_1\rho_2}\cdot\nabla w_{\rho_1\rho_2}]\,ds.\end{aligned} \tag{4.10}$$

As a result, from (4.6) we obtain

$$\begin{aligned}\frac{d}{d\rho}I_u(\rho_1,\rho_2) = &- c_1\int_{C(\boldsymbol{x}^1;\rho_1)} [F(u_{\rho_1\rho_2}) + fw_{\rho_1\rho_2} + \nabla u_{\rho_1\rho_2}\cdot\nabla w_{\rho_1\rho_2}]\,ds \\ &- c_2\int_{C(\boldsymbol{x}^2;\rho_2)} [F(u_{\rho_1\rho_2}) + fw_{\rho_1\rho_2} + \nabla u_{\rho_1\rho_2}\cdot\nabla w_{\rho_1\rho_2}]\,ds.\end{aligned} \tag{4.11}$$

In the next step we observe that the derivative with respect to ρ^2 can be expressed by the derivative with respect to ρ in the following way:

$$\frac{dI_u(\rho_1,\rho_2)}{d(\pi\rho^2)} = \frac{1}{2\pi\rho}\cdot\frac{d}{d\rho}I_u(\rho_1,\rho_2). \tag{4.12}$$

Such an observation is very useful for applications, since we avoid any evaluation of the second order derivatives of shape functionals for the specific 2D problem.

In addition, it can be easily proved in the same way as it has been done in [29] by an application of the results given by [24] for the case of single hole, that $w_{\rho_1\rho_2}$ has the same kind of expansion as $u_{\rho_1\rho_2}$,

$$w_{\rho_1\rho_2} = w_0 + s_{\rho_1}(w_0) + s_{\rho_2}(w_0) + z_{\rho_1\rho_2}(w_0),$$

with $z_{\rho_1\rho_2}(w_0)$ satisfying the same type of estimates; namely on the set $C(\boldsymbol{x}^1;\rho_1)\cup C(\boldsymbol{x}^2;\rho_2)$

$$\begin{aligned} |z_{\rho_1\rho_2}(w_0)| &\le \Lambda\left(\rho_1^2|\log\rho_1| + \rho_2^2|\log\rho_2|\right),\\ |\nabla z_{\rho_1\rho_2}(w_0)| &\le \Lambda(\rho_1+\rho_2), \end{aligned}$$

and on the set $P(\boldsymbol{x}^1;R_0,R)\cap P(\boldsymbol{x}^2;R_0,R)\cap\Omega$

$$|z_{\rho_1\rho_2}(w_0)| \le \Lambda(\rho_1^2+\rho_2^2).$$

Taking into account both approximations for $u_{\rho_1\rho_2}$ and $w_{\rho_1\rho_2}$ we may compute the limit

$$\begin{aligned} \lim_{\rho\to 0+}\frac{(-1)}{2\pi\rho}\,c_1\int_{C(\boldsymbol{x}^1;\rho_1)}&\left[F(u_{\rho_1\rho_2})+fw_{\rho_1\rho_2}+\nabla u_{\rho_1\rho_2}\cdot\nabla w_{\rho_1\rho_2}\right]ds\\ &= -c_1^2\left[F(u_0)+fw_0+2\nabla u_0\cdot\nabla w_0\right]_{\boldsymbol{x}=\boldsymbol{x}^1} = c_1^2\,\mathcal{T}I_u(\boldsymbol{x}^1) \end{aligned} \tag{4.13}$$

and similarly for the integral on $C(\boldsymbol{x}^2;\rho_2)$. This gives for the increment of I_u the expression

$$dI_u = \pi\rho^2\cdot\left[c_1^2\,\mathcal{T}I_u(\boldsymbol{x}^1)+c_1^2\,\mathcal{T}I_u(\boldsymbol{x}^2)\right].$$

But $\pi\rho^2c_1^2=|B(\boldsymbol{x}^1;\rho_1)|$ and $\pi\rho^2c_2^2=|B(\boldsymbol{x}^2;\rho_2)|$; therefore the expansion (4.3) for I_u follows. The expansion for the functional I_g can be obtained in the same way. □

Remark 4.2. It is shown in [25] that the above procedure gives exactly the same result as the direct application of the asymptotic analysis to shape functionals under consideration. It means that the TDs can be obtained in a different way, but the form of such derivatives is always equivalent, which can be seen after the appropriate and involved transformations.

5. Dependence of solutions on boundary variations. We describe briefly the speed method in shape sensitivity analysis, referring the reader to [28] for details. The domains with moving boundaries are constructed in such a way that allows us to obtain expansions of solutions to BVPs in such domains with respect to the boundary perturbations.

Let us consider the BVP of the same form as the problem discussed in previous sections. Now, the Neumann part Γ^N of the boundary $\Gamma=\Gamma^N\cup\Gamma^D$ is divided into two parts: the fixed part, still denoted by Γ^N, with the nonhomogeneous Neumann conditions prescribed on Γ^N, and the part denoted by Γ^V, which is subjected to the boundary variations. For the sake of simplicity it is assumed that the homogeneous Neumann conditions are prescribed on Γ^V.

$$\Delta u_0 = f \qquad \text{in} \quad \Omega, \tag{5.1a}$$

$$u_0 = g_D \qquad \text{on} \quad \Gamma^D, \tag{5.1b}$$

$$\frac{\partial}{\partial n}u_0 = g_N \qquad \text{on} \quad \Gamma^N, \tag{5.1c}$$

$$\frac{\partial}{\partial n}u_0 = 0 \qquad \text{on} \quad \Gamma^V. \tag{5.1d}$$

In addition, we assume that Γ^V consists of a single smooth arc and the parameter m describing the regularity of the data in Theorem 2.2 now satisfies the stronger condition $m\ge 2$.

The evolution of Γ^V with respect to the parameter τ is governed by the transformation $T(\tau,\cdot) : \Omega \mapsto \Omega_\tau$ (see [28]), defined by the vector field $\boldsymbol{\Theta}$, of the form

$$T(\tau,\boldsymbol{x}) = \boldsymbol{x} + \tau\boldsymbol{\Theta}(\boldsymbol{x}), \qquad \boldsymbol{x} \in B(R) \supset \Omega. \tag{5.2}$$

We assume that the vector field $\boldsymbol{\Theta}$ satisfies the following assumption.

(H3) $\boldsymbol{\Theta} \in [C^4(\overline{B(R)})]^2$, and

$$\|\boldsymbol{\Theta}\|_{[C^4(\overline{B(R)})]^2} \le C_\theta.$$

Moreover, there exists $\delta > 0$ such that the field $\boldsymbol{\Theta}(\boldsymbol{x})$ vanishes in the region $U = \Omega \setminus (\Gamma^N \cup \Gamma^D + B(\delta))$ (see Figure 2) i.e., in an open neighborhood of the fixed part of the boundary.

The above assumptions imply several properties of the transformation $T(\tau,\cdot)$. Namely, there exists a constant $\tau_0 > 0$ such that for $0 \le \tau < \tau_0$ we have the following:

1. $T(\tau,\cdot)$ is invertible in $B(R)$;
2. $T(\tau,\boldsymbol{x}) = \boldsymbol{x}$ on U, and $T(\tau, B(R)\setminus U) = B(R)\setminus U$;
3. $T^{-1}(\tau,\boldsymbol{y}) = \boldsymbol{y} - \tau\boldsymbol{K}_1(\boldsymbol{y},\tau)$, where

$$\|\boldsymbol{K}_1(\boldsymbol{y},\tau)\|_{[C^3(\overline{B(R)})]^2} \le \Lambda C_\theta.$$

The third property requires short justification. Let $\boldsymbol{y} = T(\tau,\boldsymbol{x})$. Then

$$\begin{aligned}\boldsymbol{y} - \tau\boldsymbol{\Theta}(\boldsymbol{y}) &= \boldsymbol{x} + \tau\boldsymbol{\Theta}(\boldsymbol{x}) - \tau\boldsymbol{\Theta}(\boldsymbol{x} + \tau\boldsymbol{\Theta}(\boldsymbol{x})) \\ &= \boldsymbol{x} + \tau\boldsymbol{\Theta}(\boldsymbol{x}) - \tau\boldsymbol{\Theta}(\boldsymbol{x}) - \tau^2 D\boldsymbol{\Theta}(\boldsymbol{x} - \eta\tau\boldsymbol{\Theta}(\boldsymbol{x}))\cdot\boldsymbol{\Theta}(\boldsymbol{x}),\end{aligned}$$

where $\boldsymbol{x}^* := \boldsymbol{x} - \eta\tau\boldsymbol{\Theta}(\boldsymbol{x}) \in B(R)$ and $0 < \eta < 1$. Hence we have the representation $\boldsymbol{x} = \boldsymbol{y} - \tau\boldsymbol{K}_1(\boldsymbol{y},\tau)$, where $\boldsymbol{K}_1 = \boldsymbol{\Theta}(\boldsymbol{y}) - \tau D\boldsymbol{\Theta}(\boldsymbol{x}^*)\cdot\boldsymbol{\Theta}(\boldsymbol{x})$ as the function of y with $\boldsymbol{x} = T^{-1}(\tau,\boldsymbol{y})$ and $\boldsymbol{x}^* = T^{-1}(\tau,\boldsymbol{y}) - \eta\tau\boldsymbol{\Theta}(T^{-1}(\tau,\boldsymbol{y}))$ is bounded in the C^3-norm.

Let us now fix $\delta > 0$, and let $\boldsymbol{\Theta}(\boldsymbol{x})$ be a vector field satisfying all conditions listed above. We consider in the domain $\Omega_\tau = T(\tau,\Omega)$ the following BVP parametrized by $\tau \ge 0$:

$$\Delta u_\tau = f \qquad \text{in} \quad \Omega_\tau, \tag{5.3a}$$

$$u_\tau = g_D \qquad \text{on} \quad \Gamma^D, \tag{5.3b}$$

$$\frac{\partial}{\partial n}u_\tau = g_N \qquad \text{on} \quad \Gamma^N, \tag{5.3c}$$

$$\frac{\partial}{\partial n}u_\tau = 0 \qquad \text{on} \quad \Gamma^V_\tau = T(\tau,\Gamma^V). \tag{5.3d}$$

In the above system all the differentiations are performed with respect to the variable $\boldsymbol{y} \in \Omega_\tau$.

LEMMA 5.1. *Assume that the conditions* (H1)–(H3) *are satisfied and* $m \ge 2$. *Then, for* $\tau \ge 0$, τ *small enough, the solution of* (5.3) *can be expressed as a function of the parameter* τ *as follows:*

$$u_\tau = u_0 + \tau z,$$

where

$$\|z\|_{H^3(\Omega_\delta)} \le \Lambda(\Omega, C_\theta),$$

and we denote $C_\theta = \|\boldsymbol{\Theta}\|_{C^3(\overline{B(R)})}$.

Proof. After the change of variables defined by the transformation $\boldsymbol{y} = T(\tau, \boldsymbol{x})$, BVP (5.3) is transported in a standard way [28] to the fixed domain Ω, and the resulting BVP takes the form

$$\text{(5.4a)} \qquad \operatorname{div}\left[J(T)(D_y T^{-1} D_y^{-T})\nabla u_\tau\right] = J(T) f(T(\tau, \boldsymbol{x})) \qquad \text{in} \quad \Omega,$$

$$\text{(5.4b)} \qquad u_\tau = g_D \qquad \text{on} \quad \Gamma^D,$$

$$\text{(5.4c)} \qquad \frac{\partial}{\partial n} u_\tau = g_N \qquad \text{on} \quad \Gamma^N,$$

$$\text{(5.4d)} \qquad \boldsymbol{n}^\top (D_y T^{-1} D_y^{-T})\nabla u_\tau = 0 \qquad \text{on} \quad \Gamma^V.$$

The coefficients appearing in the above system may be expressed in the form suitable for further computations. Namely

$$\begin{aligned} D_y T^{-1}(\tau, \boldsymbol{y}) &= I - \tau D_y K_1(\boldsymbol{y}, \tau), \\ J(T) &= \det\left(I + \tau D\boldsymbol{\Theta}(\boldsymbol{x})\right) = 1 + \tau k_1(\tau, \boldsymbol{x}), \end{aligned}$$

where

$$\|k_1(\tau, \cdot)\|_{C^3(\overline{B(R)})} \leq \Lambda C_\theta.$$

Therefore, we have the representations

$$\begin{aligned} D_y T^{-1} D_y^{-T} &= (I - \tau D_y K_1)(I - \tau D_y K_1^\top) = I + \tau K_2(\tau, \boldsymbol{x}), \\ J(T)(D_y T^{-1} D_y^{-T}) &= I + \tau K_3(\tau, \boldsymbol{x}), \\ J(T) f(T(\tau, \boldsymbol{x})) &= f(\boldsymbol{x}) + \tau f_1(\boldsymbol{x}, \tau), \end{aligned}$$

with the estimates

$$\begin{aligned} &\|K_2(\tau, \cdot)\|_{\left[C^2(\overline{B(R)})\right]^4} \leq \Lambda C_\theta \ , \qquad \|K_3(\tau, \cdot)\|_{\left[C^2(\overline{B(R)})\right]^4} \leq \Lambda C_\theta, \\ &\quad \text{and} \quad \|f_1(\tau, \cdot)\|_{H^1(\Omega)} \leq \Lambda C_\theta. \end{aligned}$$

As a result the transformed BVP (5.4) takes on the form

$$\text{(5.5a)} \qquad \operatorname{div}\left[(I + \tau K_3)\nabla u_\tau\right] = f + \tau f_1 \qquad \text{in} \quad \Omega,$$

$$\text{(5.5b)} \qquad u_\tau = g_D \qquad \text{on} \quad \Gamma^D,$$

$$\text{(5.5c)} \qquad \frac{\partial}{\partial n} u_\tau = g_N \qquad \text{on} \quad \Gamma^N,$$

$$\text{(5.5d)} \qquad \boldsymbol{n}^\top (I + \tau K_2)\nabla u_\tau = 0 \qquad \text{on} \quad \Gamma^V.$$

It is important to observe that all the functions K_1, K_2, K_3, k_1 vanish on U.

Now we apply the method of matched asymptotics to the system (5.4), assuming that the solution u_τ can be expanded in the form of the series with respect to the parameter τ,

$$\text{(5.6)} \qquad u_\tau \ = \ \sum_{k=0}^{\infty} \tau^k u_k(\tau, \boldsymbol{x}).$$

Substituting (5.6) into (5.5) leads formally to the system

$$\sum_{k=0}^{\infty}\tau^k\Delta u_k+\sum_{k=0}^{\infty}\tau^{k+1}\operatorname{div}(K_3\nabla u_k)=f+\tau f_1 \qquad \text{in} \quad \Omega, \tag{5.7a}$$

$$\sum_{k=0}^{\infty}\tau^k u_k=g_D \qquad \text{on} \quad \Gamma^D, \tag{5.7b}$$

$$\sum_{k=0}^{\infty}\tau^k\frac{\partial}{\partial n}u_k=g_N \qquad \text{on} \quad \Gamma^N, \tag{5.7c}$$

$$\sum_{k=0}^{\infty}\tau^k\frac{\partial}{\partial n}u_k+\sum_{k=0}^{\infty}\tau^{k+1}\boldsymbol{n}^\top K_2\nabla u_k=0 \qquad \text{on} \quad \Gamma^V. \tag{5.7d}$$

In a standard way, comparing the terms with the powers of τ of the same order, we obtain the sequence of BVPs for subsequent functions u_k, $k=0,1,\dots$.

Thus u_0 satisfies (5.1); for $k=1$ we have

$$\begin{aligned}
\Delta u_1&=f_1-\operatorname{div}(K_3\nabla u_0) && \text{in} \quad \Omega,\\
u_1&=0 && \text{on} \quad \Gamma^D,\\
\frac{\partial}{\partial n}u_1&=0 && \text{on} \quad \Gamma^N,\\
\frac{\partial}{\partial n}u_1&=-\boldsymbol{n}^\top K_2\nabla u_0 && \text{on} \quad \Gamma^V,
\end{aligned}$$

and for $k>1$

$$\begin{aligned}
\Delta u_k&=-\operatorname{div}(K_3\nabla u_{k-1}) && \text{in} \quad \Omega,\\
u_k&=0 && \text{on} \quad \Gamma^D,\\
\frac{\partial}{\partial n}u_k&=0 && \text{on} \quad \Gamma^N,\\
\frac{\partial}{\partial n}u_k&=-\boldsymbol{n}^\top K_2\nabla u_{k-1} && \text{on} \quad \Gamma^V.
\end{aligned}$$

By the trace theorem

$$\|\operatorname{div}(K_3\nabla u_{k-1})\|_{H^1(\Omega_\delta)}+\|\boldsymbol{n}^\top K_2\nabla u_{k-1}\|_{H^{5/2}(\Gamma^V_\delta)}\le\Lambda_3\cdot C_\theta\|u_{k-1}\|_{H^3(\Omega_\delta)}.$$

Since K_3, K_2 vanish on U, we have

$$\|\operatorname{div}(K_3\nabla u_{k-1})\|_{H^1(\Omega_\delta)}=\|\operatorname{div}(K_3\nabla u_{k-1})\|_{H^1(\Omega_{\delta/2})},$$

$$\|\boldsymbol{n}^\top K_2\nabla u_{k-1}\|_{H^{5/2}(\Gamma^V_\delta)}=\|\boldsymbol{n}^\top K_2\nabla u_{k-1}\|_{H^{5/2}(\Gamma^V_{\delta/2})},$$

and therefore

$$\|\operatorname{div}(K_3\nabla u_{k-1})\|_{H^1(\Omega_{\delta/2})}+\|\boldsymbol{n}^\top K_2\nabla u_{k-1}\|_{H^{5/2}(\Gamma^V_{\delta/2})}\le\Lambda_3\cdot C_\theta\|u_{k-1}\|_{H^3(\Omega_\delta)}.$$

Thus, due to Theorem 2.2, we are able to obtain the recursive bounds for the consecutive solutions u_k:

for $k=1$ $\quad\|u_1\|_{H^3(\Omega_\delta)}\le\Lambda(\|f_1\|_{H^1(\Omega_{\delta/2})}+\Lambda C_\theta\|u_0\|_{H^3(\Omega_{\delta/2})})\le\Lambda C_\theta(1+\|u_0\|_{H^3(\Omega)})$;

for $k>1$ $\quad\|u_k\|_{H^3(\Omega_\delta)}\le\Lambda C_\theta\|u_{k-1}\|_{H^3(\Omega_\delta)}$.

As a result, there exists a constant $\tau_1 > 0$ such that for $\tau < \min[\tau_0, \tau_1]$ the series (5.6) converges in $H^3(\Omega_\delta)$.

The last step consists of verification that u_τ is indeed a solution. We take the truncated series

$$u_\tau^N = \sum_{k=0}^{N} \tau^k u_k(\tau, \boldsymbol{x})$$

and substitute it into the initial BVP (5.5), which leads to the equalities

$$\begin{aligned}
\sum_{k=0}^{N} \tau^k \Delta u_k + \sum_{k=0}^{N} \tau^{k+1} \operatorname{div}(K_3 \nabla u_k) &= f + \tau f_1 + \tau^{N+1} \operatorname{div}(K_3 \nabla u_\tau^N) \quad \text{in} \quad \Omega, \\
u_\tau^N &= g_D \quad \text{on} \quad \Gamma^D, \\
\frac{\partial}{\partial n} u_\tau^N &= g_N \quad \text{on} \quad \Gamma^N, \\
\boldsymbol{n}^\top (I + \tau K_2) \nabla u_\tau^N &= \tau^{N+1} \boldsymbol{n}^\top K_2 \nabla u_\tau^N \quad \text{on} \quad \Gamma^V.
\end{aligned}$$

Hence for the remainder of the series we have the estimate

$$\|u_\tau^N - u_\tau\|_{H^3(\Omega_\delta)} \leq \Lambda \tau^{N+1},$$

which completes the proof. □

Remark 5.2. The same result can be obtained for the nonhomogeneous Neumann condition or for the nonhomogeneous Dirichlet condition on the moving part of the boundary. The only difference in comparison to the proof of Lemma 5.1 is that the functions g and h are transported to the fixed domain and then expanded with respect to the parameter τ. The construction of the asymptotic approximations is performed in the same way as for the right-hand side of the equation in the proof of Lemma 5.1. Therefore, the method of matched asymptotic expansions with respect to τ is applicable to the problems with nonhomogeneous boundary conditions of Neumann or Dirichlet types.

6. Simultaneous topology and shape modification. In this section we shall investigate the variation of the shape functional resulting both from the nucleation of an internal hole and from the boundary variations. We assume that the volume $|\Omega|$ of the geometrical domain is preserved by such perturbations. Let us assume that all the requirements concerning the domain Ω and the field $\boldsymbol{\Theta}$ specified in (H1)–(H3) are satisfied. We assume, in addition, the following:

(H4) For a given $\delta > 0$ the support of the vector field $\boldsymbol{\Theta}$ is contained in the tubular neighborhood $\Gamma^V + B(\delta/2)$.

(H4) ensures that under our assumptions on $\boldsymbol{\Theta}(\boldsymbol{x})$ the following properties of the mapping $T(\tau, \cdot) : \mathbb{R}^2 \to \mathbb{R}^2$ are obtained for $|\tau|$ small enough:

- $T(\tau, \cdot)$ is a bijection of $\Gamma^V + B(\delta)$ onto itself;
- $T(\tau, \cdot)$ is the identity mapping on the set $\Omega \setminus (\Gamma^V + B(\delta))$.

For a given $\boldsymbol{x}^0 \in \Omega$, and $\delta > 0$ such that $\boldsymbol{x}^0 \in \Omega \setminus (\Gamma^V + B(\delta))$, we select a suitable field $\boldsymbol{\Theta}(\boldsymbol{x})$ and assume $|\tau|$ to be small enough. We denote by $\Omega_{\rho\tau}$ the domain $\Omega_\tau \setminus \overline{B(\boldsymbol{x}^0; \rho)}$.

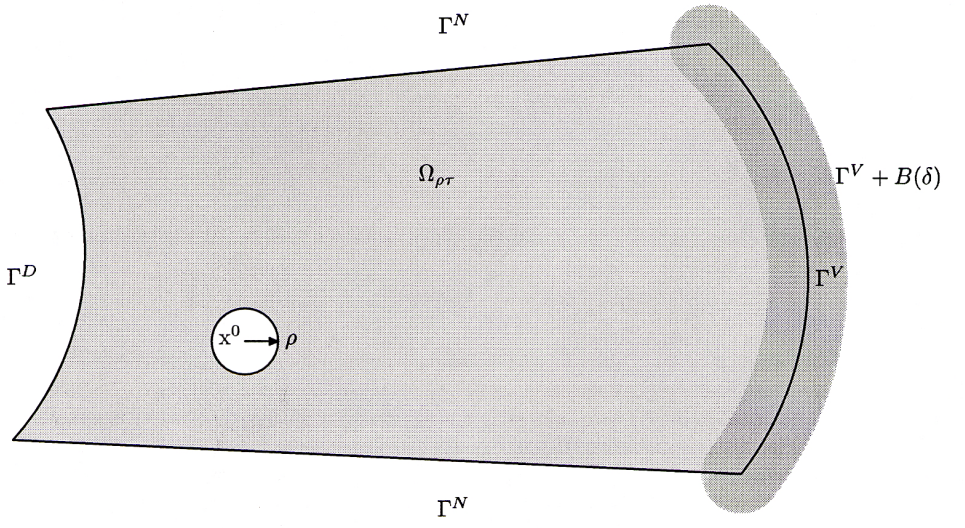

FIG. 2. *The configuration of the internal hole and variable boundary.*

Finally, $u_{\rho\tau}$ is a solution of the following BVP defined on $\Omega_{\rho\tau}$, with the regularity of the data specified in (H2) for $m \geq 2$:

$$\Delta u_{\rho\tau} = f \quad \text{in} \quad \Omega_{\rho\tau}, \tag{6.1a}$$

$$u_{\rho\tau} = g_D \quad \text{on} \quad \Gamma^D, \tag{6.1b}$$

$$\frac{\partial}{\partial n} u_{\rho\tau} = g_N \quad \text{on} \quad \Gamma^N, \tag{6.1c}$$

$$\frac{\partial}{\partial n} u_{\rho\tau} = 0 \quad \text{on} \quad C(\boldsymbol{x}^0; \rho) \cup \Gamma_\tau^V. \tag{6.1d}$$

The form of $\Omega_{\rho\tau}$ and the geometry of the problem under considerations is shown in Figure 2. Similarly, as in previous sections, we consider shape functionals of the form

$$I_u(\eta, \tau) = \int_{\Omega_{\rho\tau}} F(u_{\rho\tau})\, dx, \qquad I_g(\eta, \tau) = \int_{\Omega_{\rho\tau}} \|\nabla u_{\rho\tau}\|^{2p}\, dx\ , \tag{6.2}$$

where we denote $\eta = \pi\rho^2$.

Finally, according to (1.1), we denote by $\mathcal{S}I_u(\Omega; \boldsymbol{\Theta})$ and $\mathcal{S}I_g(\Omega; \boldsymbol{\Theta})$ the shape derivatives of the functionals $I_u(\eta, \tau)$ and $I_g(\eta, \tau)$ with respect to the variation of Γ^V taken at Ω, i.e., for $\eta = 0$, $\tau = 0$. It is well known [28] that these derivatives are given by the following formulae:

$$\mathcal{S}I_u(\Omega; \boldsymbol{\Theta}) = \int_{\Gamma^V} \left[F(u_{00}) + \nabla u_{00} \cdot \nabla w_{00}\right] (\boldsymbol{\Theta} \cdot \boldsymbol{n})\, ds, \tag{6.3a}$$

$$\mathcal{S}I_g(\Omega; \boldsymbol{\Theta}) = \int_{\Gamma^V} \left[\|\nabla u_{00}\|^{2p} + \nabla u_{00} \cdot \nabla v_{00}\right] (\boldsymbol{\Theta} \cdot \boldsymbol{n})\, ds. \tag{6.3b}$$

Furthermore, these derivatives depend only on a normal component $\Theta_n = \boldsymbol{\Theta} \cdot \boldsymbol{n}$ of $\boldsymbol{\Theta}$ on Γ^V. The adjoint variable w_{00} satisfies (4.8). The adjoint variable v_{00} is a solution

of the following adjoint equation depending on the gradient of the functional I_g: find $v_{00} \in H^1_D(\Omega)$ such that

$$-\int_\Omega \nabla v_{00} \cdot \nabla \phi, dx = \int_\Omega 2p|\nabla u_{00}|^{2p-2}(\nabla u_{00} \cdot \nabla \phi)\, dx \quad \text{for all} \quad \phi \in H^1_D(\Omega).$$

The next theorem gives the form of the variations of shape functionals resulting from modification of the geometrical domain by boundary variations as well as the nucleation of a small hole.

THEOREM 6.1. *Assume that conditions* (H1)–(H4) *are satisfied and* $m = 2$, *i.e.,* $f \in H^2(\Omega)$, *and* F *is a* C^2 *function. Then, the functionals* $I_u(\eta, \tau)$ *and* $I_g(\eta, \tau)$ *have the representation*

$$I_u(\eta, \tau) \;=\; I_u(0,0) + \eta \mathcal{T} I_u(\Omega; \boldsymbol{x}^0) + \tau \mathcal{S} I_u(\Omega; \boldsymbol{\Theta}) + r(\eta, \tau),$$

$$I_g(\eta, \tau) \;=\; I_g(0,0) + \eta \mathcal{T} I_u(\Omega; \boldsymbol{x}^0) + \tau \mathcal{S} I_g(\Omega; \boldsymbol{\Theta}) + r(\eta, \tau),$$

where the remainder is of the form $r(\eta, \tau) = o(\eta) + o(\tau) + O(\eta\tau)$ *and* $\eta = \pi\rho^2$.

Proof. The proof is given in the case of I_u, since for the second shape functional I_g the same argument applies.

Let us consider the expression

$$I_u(\eta, \tau) - I_u(0,0) = I_u(\eta, \tau) - I_u(0, \tau) + I_u(0, \tau) - I_u(0,0). \tag{6.4}$$

From the results on the shape sensitivity analysis [28] it follows that

$$I_u(0, \tau) - I_u(0,0) = \tau \mathcal{S} I_u(\Omega; \boldsymbol{\Theta}) + o(\tau).$$

It remains to analyze the first difference on the right-hand side of (6.4). By an application of Theorem 4.1 for a single hole we have

$$I_u(\eta, \tau) - I_u(0, \tau) = \eta \mathcal{T} I_u(\Omega_\tau; \boldsymbol{x}^0) + o(\eta), \tag{6.5}$$

and by Lemma 3.1 the term $o(\eta)$ is uniform with respect to τ for $|\tau|$ small enough. But we have the explicit form of the TD in Ω_τ:

$$\mathcal{T} I_u(\Omega_\tau; \boldsymbol{x}^0) = -\left[F(u_{0\tau}) + f w_{0\tau} + 2\nabla u_{0\tau} \cdot \nabla w_{0\tau}\right]_{\boldsymbol{x}=\boldsymbol{x}^0}.$$

Now using Lemma 5.1, we have

$$|u_{0\tau}(\boldsymbol{x}^0) - u_{00}(\boldsymbol{x}^0)| \le \Lambda\tau, \qquad \|\nabla u_{0\tau}(\boldsymbol{x}^0) - \nabla u_{00}(\boldsymbol{x}^0)\| \le \Lambda\tau,$$
$$|w_{0\tau}(\boldsymbol{x}^0) - w_{00}(\boldsymbol{x}^0)| \le \Lambda\tau, \qquad \|\nabla w_{0\tau}(\boldsymbol{x}^0) - \nabla w_{00}(\boldsymbol{x}^0)\| \le \Lambda\tau.$$

Substituting these estimates into (6.5) leads to

$$I_u(\eta, \tau) - I_u(0, \tau) = \eta \mathcal{T} I_u(\Omega; \boldsymbol{x}^0) + o(\eta) + O(\eta\tau),$$

and the required result for I_u follows. The case of I_g may be treated in an analogous way. □

Remark 6.2. Let us note that using the method proposed in the paper we can define the *domain differential* denoted by $\mathcal{D}J(\Omega; \boldsymbol{\Theta}, \boldsymbol{x})$ of an arbitrary shape functional $J(\Omega)$:

$$\mathcal{D}J(\Omega; \boldsymbol{\Theta}, \boldsymbol{x}^0)(\rho, \tau) = |B(\boldsymbol{x}^0; \rho)| \cdot \mathcal{T} J(\Omega; \boldsymbol{x}^0) + \tau \cdot \mathcal{S} J(\Omega; \boldsymbol{\Theta}).$$

Such a differential provides complete characterization of the variation of $J(\Omega)$ with respect to the variations of Ω, taking into account both the shape and topology changes.

From Theorem 6.1 it follows by standard arguments that an optimal domain Ω^* satisfies the condition

$$\mathcal{D}J(\Omega^*; \boldsymbol{\Theta}, \boldsymbol{x}^0)(\rho, \tau) = |B(\boldsymbol{x}^0; \rho)| \cdot \mathcal{T}J(\Omega^*; \boldsymbol{x}^0) + \tau \cdot \mathcal{S}J(\Omega^*; \boldsymbol{\Theta}) \geq 0$$

for all admissible (ρ, τ) and all admissible vector fields $\boldsymbol{\Theta}$ in an appropriate tangent set. In the case of volume constraints the above formula leads to the necessary optimality conditions of the form

$$\mathcal{T}J(\Omega^*; \boldsymbol{x}^0) \geq 0 \quad \text{in } \Omega^* \quad \text{and} \quad \mathcal{S}J(\Omega^*; \boldsymbol{\Theta}) \geq 0 \quad \text{for all } \boldsymbol{\Theta}. \tag{6.6}$$

The latter inequality follows since under the volume constraints $|\Omega_{\rho\tau}| = |\Omega|$ we have the relation [27], [28]

$$\pi\rho^2 = \tau \int_{\Gamma^V} \theta_n \, d\Gamma + o(\tau),$$

which can be neglected for the admissible tangent directions of $\boldsymbol{\Theta}$. Results on the form of tangent sets for pointwise constraints in L^∞ can be found, e.g., in [2].

7. Example. In the following example it is shown that using the method proposed in the paper we can verify that the shape which is optimal in the framework of classical theory can be improved using the topology variations. For the problem under consideration the second order sufficient optimality conditions have been established by Belov and Fujii in [3].

Let us consider the shape functional

$$J(\Omega) = \int_\Omega u^2 \, dx \quad \to \quad \max, \tag{7.1}$$

where $\Omega \subset \mathbb{R}^2$ is a ring with exterior boundary Γ and interior boundary Σ, as shown in Figure 3. The function u satisfies a BVP

$$\Delta u = -1 \qquad \text{in} \quad \Omega, \tag{7.2a}$$

$$u = 0 \qquad \text{on} \quad \Gamma, \tag{7.2b}$$

$$\frac{\partial u}{\partial n} = 0 \qquad \text{on} \quad \Sigma. \tag{7.2c}$$

We impose the volume constraints $|\Omega| = \pi$ for admissible domains. This example is motivated by optimum design problems concerning the elastic bars in torsion. First, we assume that $\Sigma = \emptyset$, i.e., only the Dirichlet boundary conditions are prescribed on the external boundary Γ. Then, it is known [3] that the unit ball $\Omega^* = B(1)$ maximizes $J(\Omega)$ over the family of simply connected domains with the Dirichlet boundary condition prescribed on the external boundary. We may easily check that the domain Ω^* is a critical point of the integral shape functional $J(\Omega)$. Let us introduce the mapping $T_\tau : \Omega \to \Omega_\tau$ associated with the vector field $\boldsymbol{V}(\cdot, \cdot)$ supported in a small neighborhood of $\Gamma^* = \partial\Omega^*$. In this section the speed vector field is denoted by $\boldsymbol{V}$ instead of $\boldsymbol{\Theta}$. If the volume of Ω_τ is to be preserved, $|\Omega_\tau| = |\Omega|$, then we have

$$\int_{\Gamma^*} (\boldsymbol{V} \cdot \boldsymbol{n}) \, ds = 0. \tag{7.3}$$

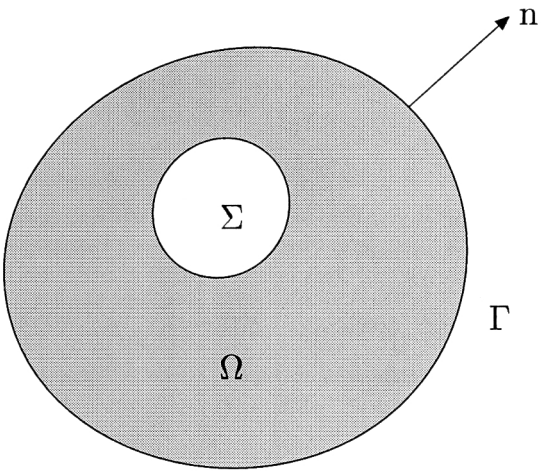

FIG. 3. *Domain* $\Omega \subset \mathbb{R}^2$.

The adjoint equation for the problem under considerations has the form

$$\Delta w = 2u \quad \text{in} \quad \Omega^*, \tag{7.4a}$$

$$w = 0 \quad \text{on} \quad \Gamma^*, \tag{7.4b}$$

$$\frac{\partial w}{\partial n} = 0 \quad \text{on} \quad \Sigma; \tag{7.4c}$$

however, the last condition can be omitted since $\Sigma = \emptyset$. For such a simple geometry of Ω^* both u and w have explicit representations in polar coordinates (r, θ):

$$u(\boldsymbol{x}) = \frac{1}{4}(1 - r^2),$$
$$w(\boldsymbol{x}) = \frac{1}{32}r^4 - \frac{1}{8}r^2 + \frac{3}{32}.$$

Therefore, the shape derivative of $J(\Omega)$ at Ω^* and in the direction $\boldsymbol{V}$ is given by

$$\begin{aligned} \mathcal{S}J(\Omega^*; \boldsymbol{V}) &= \int_{\Gamma^*} \frac{\partial w}{\partial n}\frac{\partial u}{\partial n}\,(\boldsymbol{V}\cdot\boldsymbol{n})\,ds \\ &= \frac{1}{16}\int_{\Gamma^*} (\boldsymbol{V}\cdot\boldsymbol{n})\,ds = 0 \qquad \text{due to (7.3).} \end{aligned} \tag{7.5}$$

Thus Ω^* is a critical point.

Let us consider the change of the topology by nucleation of a small circular hole $B(\rho)$ inside of the domain $\Omega^* = B(1)$, with the Neumann part of the boundary $\Sigma_\rho = \partial B(\rho)$. In order to preserve the volume we must move the exterior boundary Γ^* and expand Ω^*; thus we introduce for $\rho > 0$

$$\Omega_\rho = B(\sqrt{1+\rho^2}) \setminus \overline{B(\rho)}, \qquad \Gamma_\rho = \partial B(\sqrt{1+\rho^2})$$

and denote by u_ρ the solution to (7.2) in Ω_ρ. Again, we have the explicit expressions

$$u_\rho(\boldsymbol{x}) = u(\boldsymbol{x}) + \frac{1}{4}\rho^2 + \frac{1}{2}\rho^2 \log \frac{r}{\sqrt{1+\rho^2}},$$
$$J(\Omega_\rho) = \pi \left[\frac{1}{48} - \frac{3}{32}\rho^2 + \frac{1}{4}\rho^6 A^2 + \frac{1}{8}\rho^6 A - \frac{1}{4}\rho^4 A + \frac{1}{16}\rho^4 \right],$$

with

$$A = \log \frac{\rho}{\sqrt{1+\rho^2}}.$$

It is easy to see that both u_ρ and ∇u_ρ converge pointwise to u and ∇u in $B(1)$, with the removable singularity at $\boldsymbol{x} = 0$.

Moreover, the value $\rho = 0$, which corresponds to $\Omega_\rho = \Omega^* = B(1)$, still gives the maximum of the functional $J(\Omega_\rho)$ defined above; see Figure 4. Using explicit expression for $J(\Omega_\rho)$ we may directly compute the limit

$$\lim_{\rho\to 0+} \frac{dJ(\Omega_\rho)}{d(\pi\rho^2)} = \lim_{\rho\to 0+} \frac{1}{2\pi\rho}\frac{dJ(\Omega_\rho)}{d\rho} = -\frac{3}{32}. \tag{7.6}$$

The negative value indicates, as expected, that a hole of a sufficiently small area with the center at $\boldsymbol{x} = \mathbf{0}$ decreases the value of the functional.

Now we compute the same limit using the domain differential with the shape and topological parts. According to [29] and (4.5), the TD is given by

$$\mathcal{T}J(\Omega^*; 0) = -\left[(u(0))^2 - w(0) + 2\,\nabla u(0)\cdot\nabla w(0)\right] = -\frac{5}{32}.$$

In order to preserve the volume, we set $(\boldsymbol{V}\cdot\boldsymbol{n}) = 1$ in the shape derivative on Γ^* and select τ such that $2\pi\tau = \pi\rho^2$. Then, in view of (7.5),

$$\mathcal{S}J(\Omega^*; \boldsymbol{V}) = \frac{1}{16}\int_{\Gamma^*} (\boldsymbol{V}\cdot\boldsymbol{n})\, ds = \frac{1}{16} 2\pi.$$

Hence

$$\begin{aligned}\mathcal{D}J(\Omega^*; \boldsymbol{V}, 0)(\rho,\tau) &= \mathcal{T}J(\Omega^*;0)\cdot\pi\rho^2 + \tau\cdot\mathcal{S}J(\Omega^*;\boldsymbol{V}) \\ &= \left(-\frac{5}{32} + \frac{1}{16}\right)\pi\rho^2 = -\frac{3}{32}\pi\rho^2,\end{aligned}$$

in agreement with (7.6). This computation confirms the formula given by Theorem 6.1 for the simple case.

It is natural to ask whether without the assumption on the radial symmetry, i.e., with a small hole at $r \neq 0$, the value of the shape functional could possibly be improved. We compute the domain differential

$$\mathcal{D}J(\Omega^*; \boldsymbol{V}, \boldsymbol{x}) = \left[\frac{1}{16} - (u(r))^2 + w(r) - 2\,\frac{\partial u}{\partial r}(r)\cdot\frac{\partial w}{\partial r}(r)\right]\pi\rho^2 = f(r)\cdot\pi\rho^2.$$

The graph of the function $f(r)$ is given in Figure 5. We have $f(r) > 0$ for the location $r > r_0 \approx 0.45$, which means that the nucleation of a small hole near the edge increases $J(\Omega)$. Thus looking at the domain differential we conclude that the unit ball *is not* an optimal domain for the problem (7.1)–(7.2) with volume constraint if we change the topology and admit an arbitrarily located $\Sigma \neq \emptyset$.

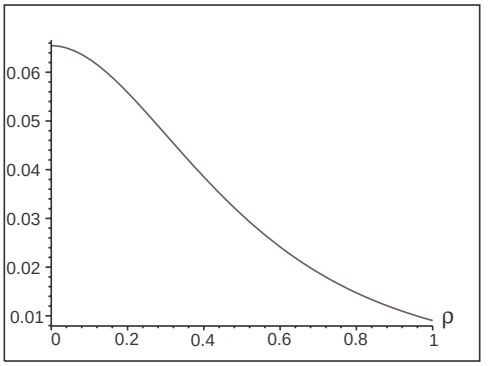

FIG. 4. *The dependence of the goal functional $J(\Omega_\rho)$ as a function of the radius of internal hole ρ.*

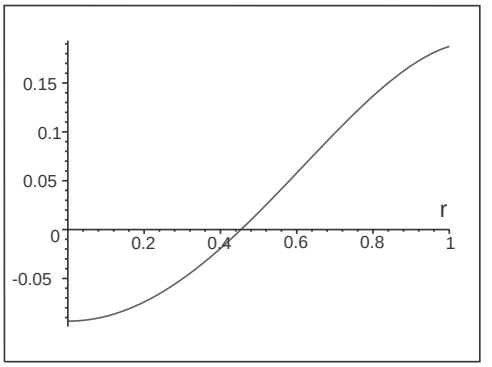

FIG. 5. *The dependence of the function $f(r)$ with respect to the location of the hole r, showing the possibility of increasing the functional.*

A CHARACTERIZATION OF BOUNDED-INPUT BOUNDED-OUTPUT STABILITY FOR LINEAR TIME-VARYING SYSTEMS WITH DISTRIBUTIONAL INPUTS*

DANIEL COBB† AND CHI-JO WANG‡

Abstract. We consider the problem of extending the concept of bounded-input bounded-output stability to linear time-varying systems with distributional inputs. In particular, the notion of impulse response is examined in a functional analytic setting. This requires that we first extend the classical notion of an integral operator to distribution space. Duality theory for several key normed spaces is then examined. Next, the adjoint operator corresponding to the given system is studied. Finally, necessary and sufficient conditions for stability are established, along with several expressions for the "gain" of the system.

Key words. bounded-input bounded-output stability, distributions, time-varying systems

AMS subject classification. 93D25

DOI. 10.1137/S0363012901384831

1. Introduction.

The concept of impulse response has traditionally played a central role in linear system theory. In spite of this fact, certain fundamental system-theoretic ideas have apparently not been developed on a mathematically rigorous level for systems with arbitrary distributional inputs and outputs. In a previous paper we addressed the problem of characterizing bounded-input bounded-output (BIBO) stability in the time-invariant case. In this paper we extend the theory to include time-varying linear systems.

To frame the problem, recall that in classical system theory a "system" is typically viewed as an integral operator

$$y(t) = \int_{-\infty}^{\infty} h(t,\tau)u(\tau)d\tau. \tag{1.1}$$

It can be shown (e.g., see [2, p. 109]) that (1.1) determines a bounded linear operator on L^∞ if and only if

$$\sup_t \int_{-\infty}^{\infty} |h(t,\tau)|\, d\tau < \infty. \tag{1.2}$$

Such a characterization is inadequate, however, for studying systems with distributional inputs u, since the integral (1.1) is not defined. In spite of this fact, the kernel $h(t,\tau)$ is often referred to as the system "impulse response." Furthermore, there are many common systems where h itself is a distribution. For example, consider the "time-varying gain"

$$y(t) = \beta(t)u(t).$$

Based on formal manipulations,

$$h(t,\tau) = \beta(t)\delta(t-\tau),$$

where δ is the unit impulse; condition (1.2) cannot be applied directly to distributions. Our goal is to develop a more general theory that characterizes stability for systems with distributional inputs and distributional impulse responses.

In section 2, we present basic analytic results that will be required in subsequent sections. In section 3, we study families of distributions in one variable satisfying certain smoothness properties in the index. These are then interpreted as distributions in two variables and used to generalize the notion of an integral operator. Section 4 applies the theory of normed-space extensions, developed in [1], to distributions in two variables. It is shown in Theorem 4.3 that the space of BIBO stable kernels (i.e., functions satisfying (1.2)) extends naturally to the space of distributions which are derivatives of functions of uniformly bounded variation $DUBV$. Section 5 contains the main results of the paper. Theorem 5.3 states that BIBO stable linear systems are precisely those with $DUBV$ kernels, Theorem 5.4 gives an expression for the adjoint system, and Theorem 5.5 establishes several equivalent representations of the system gain.

2. Preliminaries. First we present some pertinent facts concerning the theory of distributions. See [3], [4], and [5] for more detail. If $\phi : \mathbb{R}^n \to \mathbb{R}$, define the *support* of ϕ (denoted $\operatorname{supp}\phi$) to be the closure of the set $\{(t_1,\dots,t_n) \in \mathbb{R}^n | \phi(t_1,\dots,t_n) \neq 0\}$. Let K_n be the space of C^∞ functions $\phi : \mathbb{R}^n \to \mathbb{R}$ with $\operatorname{supp}\phi$ bounded. Convergence in K_n can be defined in several ways. When we assign a norm $\|\cdot\|$ to K_n we will refer to the pair $(K_n, \|\cdot\|)$. For example, $K_1 \subset L^p$, $1 \le p \le \infty$, so we may consider $(K_1, \|\cdot\|_p)$. Also,

$$\|\psi\|_{p\infty} = \left(\int_{-\infty}^{\infty} \sup_{\tau} |\psi(t,\tau)|^p \, dt \right)^{\frac{1}{p}} < \infty$$

for $\psi \in K_2$, so $(K_2, \|\cdot\|_{p\infty})$ is well defined for $1 \le p < \infty$. *Strong convergence* $\phi_k \to 0$ in K_n means that there exists $a < \infty$ such that $\operatorname{supp}\phi_k \subset [-a,a]$ for every k and $\|\phi_k\|_{C^p} \to 0$ for every integer $p \ge 0$, where

$$\|\phi\|_{C^p} = \max \left\{ \left| \frac{\partial^{i_1+\cdots+i_n}\phi(t_1,\dots,t_n)}{\partial t_1^{i_1}\cdots\partial t_n^{i_n}} \right| \mid 0 \le i_1+\cdots+i_n \le p; t_1,\dots,t_n \in \mathbb{R} \right\}.$$

A *distribution* f is an element of K_n', the dual space of K_n under strong convergence. For $f \in K_n'$, $\operatorname{supp} f$ is defined to be the complement of the largest open set $U \subset \mathbb{R}^n$ such that $\operatorname{supp}\phi \subset U$ implies $\langle f, \phi\rangle = 0$. Let K_{1+}' be the set of all $f \in K_1'$ such that there exists $a \in \mathbb{R}$ with $\operatorname{supp} f \subset [a,\infty)$. Also let K_{2+}' be the set of all $f \in K_2'$ such that there exists a function $a : \mathbb{R} \to \mathbb{R}$ with $a(\tau) \to \infty$ as $\tau \to \infty$ and $\operatorname{supp} f \subset \{t \ge a(\tau)\}$. Note that K_{2+}' is a subspace of K_2'. *Weak* convergence* $f_k \to 0$ in K_n' means that $\langle f_k, \phi\rangle \to 0$ for every $\phi \in K_n$. One basis of *weak** neighborhoods of 0 in K_n' consists of all sets of the form $\{f \mid |\langle f, \phi_i\rangle| < \varepsilon; i = 1,\dots,m\}$, where $\varepsilon > 0$ and $\phi_1,\dots,\phi_m \in K_n$ are arbitrary.

The *partial derivative* of $f \in K_n'$ with respect to t_i is defined by $\langle \frac{\partial f}{\partial t_i}, \phi\rangle = -\langle f, \frac{\partial \phi}{\partial t_i}\rangle$ for $\phi \in K_n$. It follows that the differentiation operator $f \to \frac{\partial f}{\partial t_i}$ is (*weak**) continuous. In case $n = 1$, we denote a derivative by $\frac{df}{dt}$ or by an overdot $\dot{f}$; the kth

derivative will denoted $\frac{d^k f}{dt^k}$ or $f^{(k)}$. For any $f \in K_1'$, define the t_0-*translation* $\Delta_{t_0} f$ by $\langle \Delta_{t_0} f, \phi \rangle = \langle f, \phi_{-t_0} \rangle$, where $\phi_{-t_0}(t) = \phi(t + t_0)$. By a routine calculation, $\frac{d}{dt} \Delta_{t_0} f = \Delta_{t_0} \dot{f}$. Multiplication of $f \in K_1'$ by a C^∞ function γ is defined by $\langle f\gamma, \phi \rangle = \langle f, \gamma\phi \rangle$.

A Lebesgue measurable function $f : \mathbb{R}^n \to \mathbb{R}$ is *locally integrable* if $\int_A |f| < \infty$ for every bounded interval $A \subset \mathbb{R}^n$. Every locally integrable f determines a distribution according to

$$\langle f, \phi \rangle = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} f(t_1, \ldots, t_n)\phi(t_1, \ldots, t_n)dt_1 \cdots dt_n.$$

Note that the *unit step function*

$$\theta(t) = \begin{cases} 1, & t \geq 0, \\ 0, & t < 0, \end{cases}$$

may be considered a distribution in K_1'; the *unit impulse* $\delta \in K_1'$ is defined by $\langle \delta, \phi \rangle = \phi(0)$. Translations of θ and δ will be denoted by θ_{t_0} and δ_{t_0}, respectively. It is easily verified that

$$\theta_{t_0}(t) = \theta(t - t_0), \qquad \langle \delta_{t_0}, \phi \rangle = \phi(t_0). \tag{2.1}$$

If f is an absolutely continuous function, f and its classical derivative $\dot{f}$ are locally integrable. In this case, the classical and distributional derivatives of f coincide, since

$$\left\langle \dot{f}, \phi \right\rangle = \int_{-\infty}^{\infty} \dot{f}\,(t)\,\phi(t)dt = -\int_{-\infty}^{\infty} f\,(t)\,\dot{\phi}(t)dt = \left\langle f, \dot{\phi} \right\rangle.$$

Consider the spaces

$$BV = \{g : \mathbb{R} \to \mathbb{R} \mid \operatorname*{var}_t g(t) < \infty\},$$
$$NBV = \{g \in BV \mid g \text{ is left-continuous and } g(\infty) = 0\}$$

with norm $\|g\|_{NBV} = \operatorname{var}_t g(t)$. (Note that we are deviating slightly from the conventional definition of NBV, as in [9, p. 171].)

In [1] we also considered the space $DBV = \{\dot{g} \mid g \in NBV\}$ with norm $\|\dot{g}\|_{DBV} = \|g\|_{NBV}$. We showed in [1, p. 989] that DBV is isometrically isomorphic to the dual space of $(K_1, \|\cdot\|_\infty)$. Furthermore, for any $g \in NBV$ and $\phi \in K_1$, $\langle \dot{g}, \phi \rangle = \int_{-\infty}^{\infty} \phi(t)dg(t)$. We need to generalize these ideas to distributions on $\mathbb{R}^2$. The appropriate construction requires a preliminary result.

LEMMA 2.1. *Let $g : \mathbb{R}^2 \to \mathbb{R}$ be Lebesgue measurable and $g(t, \cdot) \in NBV$ for a.e. t. Then the function*

$$v(t, \tau) = \operatorname*{var}_{\eta \geq \tau} g(t, \eta)$$

is Lebesgue measurable on $\mathbb{R}^2$.

Proof. Enumerate the rationals $\{r_n\}$, and consider the partition $\pi_n = (r_{k_1}, \ldots, r_{k_n})$ of $\mathbb{R}$, where $\{k_1, \ldots, k_n\} = \{1, \ldots, n\}$ and

$$r_{k_1} < r_{k_2} < \cdots < r_{k_n}.$$

Let $A = \{t \mid g(t,\cdot) \in NBV\}$. For each n , $j = 1, \ldots, n-1$, and $(t,\tau) \in A \times (r_{k_j}, r_{k_{j+1}}]$, define

$$v_n(t,\tau) = |g(t, r_{k_n})| + \sum_{i=j+1}^{n} \left|g(t, r_{k_i}) - g\left(t, r_{k_{i+1}}\right)\right| + \left|g(t,\tau) - g\left(t, r_{k_{j+1}}\right)\right|.$$

For other (t,τ), set $v_n(t,\tau) = 0$. Each v_n is Lebesgue measurable. Let $\varepsilon > 0$, $(t,\tau) \in A \times \mathbb{R}$, and $\pi = (\tau_1, \ldots, \tau_p)$ be any partition of (τ, ∞) such that

$$q(t,\tau) = |g(t,\tau_p)| + \sum_{i=1}^{p-1} |g(t,\tau_i) - g(t,\tau_{i+1})| + |g(t,\tau) - g(t,\tau_1)| > v(t,\tau) - \frac{\varepsilon}{2}.$$

Since g is left-continuous, there exists $N < \infty$ such that π_n contains rationals $r_{k_{j_i}}$ with $\tau < r_{k_{j_1}} < \cdots < r_{k_{j_p}}$ such that

$$\left|g\left(t, r_{k_{j_i}}\right) - g(t,\tau_i)\right| < \frac{\varepsilon}{4p}$$

for every i. Thus

$$\begin{aligned}
v_n(t,\tau) &\geq \left|g\left(t, r_{k_{j_p}}\right)\right| + \sum_{i=1}^{p-1} \left|g\left(t, r_{k_{j_i}}\right) - g\left(t, r_{k_{j_{i+1}}}\right)\right| + \left|g(t,\tau) - g\left(t, r_{k_{j_1}}\right)\right| \\
&\geq |g(t,\tau_p)| - \left|g\left(t, r_{k_{jp}}\right) - g(t,\tau_p)\right| \\
&\quad + \sum_{i=1}^{p-1} |g(t,\tau_i) - g(t,\tau_{i+1})| - \sum_{i=1}^{p-1} \left|g\left(t, r_{k_{j_i}}\right) - g(t,\tau_i)\right| \\
&\quad - \sum_{i=1}^{p-1} \left|g\left(t, r_{k_{j_{i+1}}}\right) - g(t,\tau_{i+1})\right| \\
&\quad + |g(t,\tau) - g(t,\tau_1)| - \left|g\left(t, r_{k_{j_1}}\right) - g(t,\tau_1)\right| \\
&\geq q(t,\tau) - \frac{\varepsilon}{2} \\
&> v(t,\tau) - \varepsilon.
\end{aligned}$$

So $v_n \to v$ a.e., and v is Lebesgue measurable. □

In particular, if g satisfies the conditions of Lemma 2.1, the map $t \to \operatorname{var}_\tau g(t,\tau)$ is Lebesgue measurable. Hence, we may define UBV to be the set of functions $g : \mathbb{R}^2 \to \mathbb{R}$ satisfying the following properties:

(UBV1) g is Lebesgue measurable.

(UBV2) $g(t,\cdot) \in NBV$ for a.e. t.

(UBV3) $\operatorname{ess\,sup}_t \operatorname{var}_\tau g(t,\tau) < \infty$.

We refer to UBV as the functions of *uniformly bounded variation*. Let $\|g\|_{UBV} = \operatorname{ess\,sup}_t \operatorname{var}_\tau g(t,\tau)$. Each $g \in UBV$ is bounded, since

$$|g(t,\tau)| \leq \operatorname*{var}_\tau g(t,\tau) \leq \|g\|_{UBV}.$$

Thus $g \in K_2'$, and we may also define the set of partial derivatives

$$DUBV = \left\{ \frac{\partial g}{\partial \tau} \mid g \in UBV \right\}.$$

It is routine to verify that UBV and $DUBV$ are linear spaces and that $\|\cdot\|_{UBV}$ and

$$\left\|\frac{\partial g}{\partial \tau}\right\|_{DUBV} = \|g\|_{UBV}$$

are norms on UBV and $DUBV$.

For $1 \leq p < \infty$, let UL^p be the space of Lebesgue measurable functions $f : \mathbb{R}^2 \to \mathbb{R}$ satisfying

$$\operatorname*{ess\,sup}_t \int_{-\infty}^{\infty} |f(t,\tau)|^p \, d\tau < \infty.$$

(Lebesgue measurability of the map $t \to \int_{-\infty}^{\infty} |f(t,\tau)|^p d\tau$ follows from [9, Theorem 7.8].) UL^p is the set of *uniformly* L^p functions and has norm

$$\|f\|_{\infty p} = \operatorname*{ess\,sup}_t \left(\int_{-\infty}^{\infty} |f(t,\tau)|^p \, d\tau \right)^{\frac{1}{p}}.$$

We may consider $UL^p \subset K_2'$, since, from Holder's inequality,

$$\begin{aligned}
\int_{-a}^{a}\int_{-a}^{a} |f(t,\tau)| \, d\tau dt &\leq \int_{-a}^{a} \left(\operatorname*{ess\,sup}_t \int_{-a}^{a} |f(t,\tau)| \, d\tau \right) dt \\
&= 2a \operatorname*{ess\,sup}_t \int_{-a}^{a} |f(t,\tau)| \, d\tau \\
&\leq (2a)^{2-\frac{1}{p}} \operatorname*{ess\,sup}_t \left(\int_{-a}^{a} |f(t,\tau)|^p \, d\tau \right)^{\frac{1}{p}}.
\end{aligned}$$

For $p = \infty$, we define UL^∞ to be the same as L^∞ on $\mathbb{R}^2$.

Support constraints may be placed on the spaces above by setting $L^p_+ = L^p \cap K'_{1+}$, $UBV_+ = UBV \cap K'_{2+}$, $DUBV_+ = DUBV \cap K'_{2+}$, and $UL^p{}_+ = UL^p \cap K'_{2+}$.

THEOREM 2.2. (1) *Let $g \in UBV$ and $g_t = g(t,\cdot)$. Then*

$$\left\langle \frac{\partial g}{\partial \tau}, \psi \right\rangle = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \psi(t,\tau) dg_t(\tau) dt$$

for every $\psi \in K_2$.

(2) *$UL^1 \subset DUBV$ with $\|f\|_{DUBV} = \|f\|_{\infty 1}$ for every $f \in UL^1$.*

(3) *$DUBV$ is the dual of $(K_2, \|\cdot\|_{1\infty})$.*

(4) *UBV and $DUBV$ are isometrically isomorphic.*

Proof. (1) Integration by parts yields

$$\left\langle \frac{\partial g}{\partial \tau}, \psi \right\rangle = -\left\langle g, \frac{\partial \psi}{\partial \tau} \right\rangle = -\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} g_t(\tau) \frac{\partial \psi(t,\tau)}{\partial \tau} d\tau dt = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \psi(t,\tau) dg_t(\tau) dt$$

for every ψ.

(2) If $f \in UL^1$, there exists a Lebesgue measurable $A \subset \mathbb{R}$ such that $f(t,\cdot) \in L^1$ for every $t \in A$. Let $g(t,\tau) = \int_{-\infty}^{\tau} f(t,\eta) d\eta$ for $t \in A$. Then g is Lebesgue measurable, $g(t,\cdot)$ is absolutely continuous, and $f = \frac{\partial g}{\partial \tau}$. The result follows from

$$\|f\|_{DUBV} = \operatorname*{ess\,sup}_t \operatorname*{var}_\tau g(t,\tau) = \operatorname*{ess\,sup}_t \int_{-\infty}^{\infty} |f(t,\tau)| \, d\tau = \|f\|_{\infty 1} < \infty.$$

(3) We first prove that $DUBV$ is contained in the dual of K_2. Let g and g_τ be as in (1) and $f = \frac{\partial g}{\partial \tau}$. We must show that

$$\sup_{\|\psi\|_{1\infty}=1} |\langle f, \psi\rangle| = \|f\|_{DUBV}.$$

From (1),

$$\begin{aligned}
|\langle f, \psi\rangle| &= \left| \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \psi(t,\tau) dg_t(\tau) dt \right| \\
&\le \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} |\psi(t,\tau)|\, |dg_t(\tau)|\, dt \\
&\le \int_{-\infty}^{\infty} \sup_{\tau} |\psi(t,\tau)| \operatorname*{var}_{\tau} g(t,\tau) dt \\
&\le (\operatorname*{ess\,sup}_{t} \operatorname*{var}_{\tau} g(t,\tau)) \int_{-\infty}^{\infty} \sup_{\tau} |\psi(t,\tau)|\, dt \\
&= \|f\|_{DUBV}\, \|\psi\|_{1\infty},
\end{aligned}$$

so

$$\sup_{\|\psi\|_{1\infty}=1} |\langle f, \psi\rangle| \le \|f\|_{DUBV}.$$

To establish the reverse inequality, observe that, for $\phi_1, \phi_2 \in K_1$, setting $\psi(t,\tau) = \phi_1(t)\phi_2(\tau)$ yields $\psi \in K_2$ and

$$\|\psi\|_{1\infty} = \int_{-\infty}^{\infty} \sup_{\tau} |\phi_1(t)\phi_2(\tau)|\, dt = \|\phi_1\|_1\, \|\phi_2\|_\infty.$$

Thus

$$\begin{aligned}
\sup_{\|\psi\|_{1\infty}=1} |\langle f, \psi\rangle| &= \sup_{\|\psi\|_{1\infty}=1} \left| \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \psi(t,\tau) dg_t(\tau) dt \right| \\
&\ge \sup_{\|\phi_2\|_\infty=1} \sup_{\|\phi_1\|_1=1} \left| \int_{-\infty}^{\infty} \left(\int_{-\infty}^{\infty} \phi_2(\tau) dg_t(\tau) \right) \phi_1(t) dt \right| \\
&= \sup_{\|\phi_2\|_\infty=1} \operatorname*{ess\,sup}_{t} \left| \int_{-\infty}^{\infty} \phi_2(\tau) dg_t(\tau) \right| \\
&= \operatorname*{ess\,sup}_{t} \sup_{\|\phi_2\|_\infty=1} |\langle \dot{g}_t, \phi_2\rangle| \\
&= \operatorname*{ess\,sup}_{t} \|\dot{g}_t\|_{DBV} \\
&= \|f\|_{DUBV}.
\end{aligned}$$

Next we show that $DUBV$ contains the dual of $(K_2, \|\cdot\|_{1\infty})$. Let f be any continuous linear functional on $(K_2, \|\cdot\|_{1\infty})$. ($f$ is also a distribution, since $\psi_k \to 0$ strongly in K_2 implies $\|\psi_k\|_{1\infty} \to 0$ and $\langle f, \psi_k\rangle \to 0$.) Let $\phi_1 \in K_1$. Then each $\phi_2 \in K_1$ determines $\psi \in K_2$ by $\psi(t,\tau) = \phi_1(t)\phi_2(\tau)$ (i.e., ψ is the "direct product" $\psi = \phi_1 \times \phi_2$). The map $\phi_2 \longmapsto \psi$ is continuous from $(K_1, \|\cdot\|_\infty)$ into $(K_2, \|\cdot\|_{1\infty})$, so $\phi_2 \longmapsto \langle f, \phi_1 \times \phi_2\rangle$ is a continuous linear functional on $(K_1, \|\cdot\|_\infty)$. Since K_1 is dense in C_0, there exists $G(\phi_1;\cdot) \in NBV$ such that

$$\langle f, \phi_1 \times \phi_2\rangle = \int_{-\infty}^{\infty} \phi_2(\tau) dG(\phi_1;\tau) \tag{2.2}$$

for every ϕ_2. It is routine to show that the operator $\phi_1 \mapsto G(\phi_1;\cdot)$ is linear. Continuity also holds, since

$$\begin{aligned}\sup_{\|\phi_1\|_1=1} \|G(\phi_1;\cdot)\|_{NBV} &= \sup_{\|\phi_1\|_1=1} \sup_{\|\phi_2\|_\infty=1} \left| \int_{-\infty}^{\infty} \phi_2(\tau) dG(\phi_1;\tau) \right| \\ &= \sup_{\|\phi_1\|_1=1} \sup_{\|\phi_2\|_\infty=1} |\langle f, \phi_1 \times \phi_2 \rangle| \\ &\leq \sup_{\|\psi\|_{1\infty}=1} |\langle f, \psi \rangle| \\ &< \infty.\end{aligned}$$

Therefore, $\phi_1 \mapsto G(\phi_1;\cdot)$ is a continuous linear operator from $(K_1, \|\cdot\|_1)$ into NBV. From [7, Theorem 2.3.1] and (2.2), there exists $g \in UBV$ such that

$$\langle f, \phi_1 \times \phi_2 \rangle = \int_{-\infty}^{\infty} \phi_2(\tau) d\left(\int_{-\infty}^{\infty} g(t,\tau)\phi_1(t)dt \right) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \phi_1(t)\phi_2(\tau) dg_t(\tau) dt$$

for every $\phi_1, \phi_2 \in K_1$. Let $\Pi = \{\phi_1 \times \phi_2 \mid \phi_1, \phi_2 \in K_1\}$. By linearity,

$$\langle f, \psi \rangle = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \psi(t,\tau) dg_t(\tau) dt \tag{2.3}$$

for every $\psi \in \operatorname{span}\Pi$. From [6, p. 65], $\operatorname{span}\Pi$ is strongly dense in K_2, so it is also dense relative to $\|\cdot\|_{1\infty}$. By continuity, (2.3) holds for all $\psi \in K_2$. From part (1), $f = \frac{\partial g}{\partial \tau} \in DUBV$.

(4) Note that the map $g \to \frac{\partial g}{\partial \tau}$ from UBV into $DUBV$ is defined to be linear, onto, and norm-preserving. It remains to show that the map is one-to-one. From part (1), if $\frac{\partial g}{\partial \tau} = 0$,

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \psi(t,\tau) dg_t(\tau) dt = 0$$

for all $\psi \in K_2$. Hence

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \phi_1(t)\phi_2(\tau) dg_t(\tau) dt = 0$$

for all $\phi_1, \phi_2 \in K_1$. Since

$$\left| \int_{-\infty}^{\infty} \phi_1(t) dg_t(\tau) \right| \leq \|\phi_1\|_\infty \operatorname*{var}_\tau g(t,\tau)$$

for a.e. t, the map $t \to \int_{-\infty}^{\infty} \phi_1(t) dg_t(\tau)$ may be viewed as a distribution $T(\phi_1)$. But $\langle T(\phi_1), \phi_2 \rangle = 0$ for every ϕ_2, so $T(\phi_1) = 0$ and

$$\int_{-\infty}^{\infty} \phi_1(t) dg_t(\tau) = 0$$

a.e. for every ϕ_1. Since NBV is the dual of $(K_1, \|\cdot\|_\infty)$, $g(t,\cdot) = 0$ for a.e. t and $g = 0$ a.e. □

3. Families and integral operators. In order to generalize the concept of an integral operator as in (1.1), we must study collections of distributions indexed by a real parameter. Let $\{f_t \mid t \in \mathbb{R}\}$ be a collection of distributions in K_1'. Suppose that, for each $a < \infty$, there exist an integer $p \geq 0$ and an L^1 function $M : [-a, a] \to \mathbb{R}$ such that

$$|\langle f_t, \phi \rangle| \leq M(t) \|\phi\|_{C^p}$$

for every $\phi \in K_1$ with $\operatorname{supp} \phi \subset [-a, a]$. Then we say that $\{f_t\}$ is an L^1 *family* of distributions on $\mathbb{R}$.

THEOREM 3.1. (1) *If $\{f_t\}$ is an L^1 family, then the map $\psi \to \int_{-\infty}^{\infty} \langle f_t, \psi(t, \cdot) \rangle dt$ is a distribution in K_2'.*

(2) *If $f = \{f_t\}$ is an L^1 family, then so is $\{\dot{f}_t\}$, and $\frac{\partial f}{\partial \tau} = \{\dot{f}_t\}$.*

(3) *If $f : \mathbb{R}^2 \to \mathbb{R}$ is locally integrable, then $\{f(t, \cdot)\}$ is an L^1 family.*

(4) *If $f \in UBV$, then $\{f(t, \cdot)\}$ is an L^1 family.*

Proof. (1) Let $\psi \in K_2$. Then $\|\psi(t, \cdot)\|_{C^p} \leq \|\psi\|_{C^p}$ for every t, so

$$\int_{-a}^{a} |\langle f_t, \psi(t, \cdot) \rangle| \, dt \leq \int_{-a}^{a} M(t) \|\psi(t, \cdot)\|_{C^p} \, dt \leq \int_{-a}^{a} M(t) dt \, \|\psi\|_{C^p} .$$

Thus the map $\psi \to \int_{-\infty}^{\infty} \langle f_t, \psi(t, \cdot) \rangle dt$ is well defined, linear, and, from [4, p. 34], continuous.

(2) There exist M, p such that, for any $\phi \in K_1$ with $\operatorname{supp} \phi \subset [-a, a]$,

$$\left| \left\langle \dot{f}_t, \phi \right\rangle \right| = \left| \left\langle f_t, \dot{\phi} \right\rangle \right| \leq M(t) \left\| \dot{\phi} \right\|_{C^p} \leq M(t) \|\phi\|_{C^{p+1}} .$$

For any $\psi \in K_2$,

$$\begin{aligned} \left\langle \frac{\partial \{f_t\}}{\partial \tau}, \psi \right\rangle &= - \left\langle \{f_t\}, \frac{\partial \psi(t, \tau)}{\partial \tau} \right\rangle \\ &= - \int_{-a}^{a} \left\langle f_t, \frac{\partial \psi(t, \tau)}{\partial \tau} \right\rangle dt \\ &= \int_{-a}^{a} \left\langle \dot{f}_t, \psi(t, \cdot) \right\rangle dt \\ &= \left\langle \left\{ \dot{f}_t \right\}, \psi \right\rangle . \end{aligned}$$

(3) Let $M(t) = \int_{-a}^{a} |f(t, \tau)| d\tau$. By Fubini's theorem, M is L^1 on $[-a, a]$. For any $\phi \in K_1$,

$$|\langle f(t, \cdot), \phi \rangle| = \left| \int_{-a}^{a} f(t, \tau) \phi(\tau) d\tau \right| \leq M(t) \|\phi\|_{C^0} .$$

(4) This follows immediately from part (3) and the fact that f is bounded on $\mathbb{R}^2$. □

A slight modification of the argument used in Theorem 3.1(1) shows that each L^1 family $\{f_\tau\}$ also determines a distribution according to $\psi \to \int_{-\infty}^{\infty} \langle f_\tau, \psi(\cdot, \tau) \rangle d\tau$. We will rely on the notation $\{f_t\}$ and $\{f_\tau\}$ to distinguish these two cases.

Consider a collection of distributions $\{f_\tau\}$ in K_1' with $\tau \to \langle f_\tau, \phi \rangle$ continuous for every $\phi \in K_1$. Then we say that $\{f_\tau\}$ is a C^0 *family.*

THEOREM 3.2. *Every C^0 family is an L^1 family.*

Proof. Let $\{f_\tau\}$ be a C^0 family. According to [4, p. 34], each f_τ has finite order on each bounded interval $[-a,a]$; i.e., for every $\tau \in [-a,a]$ there exist integers M_τ, $p_\tau < \infty$ such that

$$|\langle f_\tau, \phi\rangle| \leq M_\tau \|\phi\|_{C^{p_\tau}} \tag{3.1}$$

for every $\phi \in K_1$ with $\operatorname{supp}\phi \subset [-a,a]$. Suppose each M_τ and p_τ are chosen to minimize $q_\tau = \max\{M_\tau, p_\tau\}$. If the set $\{q_\tau \mid |\tau| \leq a\}$ is unbounded, there exist $\eta_k, \eta \in [-a,a]$ such that $\eta_k \to \eta$ and $q_{\eta_k} \to \infty$. On the other hand, since $\langle f_\tau, \phi\rangle$ is continuous, $\langle f_{\eta_k}, \phi\rangle \to \langle f_\eta, \phi\rangle$ for every ϕ. From [4, p. 57], there exist M, p such that

$$\left|\left\langle f_{\eta_k}, \phi\right\rangle\right| \leq M \|\phi\|_{C^p}$$

for every k, yielding a contradiction. Hence, $\{q_\tau\}$ is bounded, and there exist M, p such that

$$|\langle f_\tau, \phi\rangle| \leq M \|\phi\|_{C^p}$$

for every τ, ϕ. □

In addition to continuity, we might also consider families $\{f_\tau\}$ which are differentiable in τ. Define the *weak* derivative* $\frac{\partial f_\tau}{\partial \tau}|_{\tau_0} \in K_2'$ of $\{f_\tau\}$ at τ_0 according to

$$\left\langle \frac{\partial f_\tau}{\partial \tau}|_{\tau_0}, \phi \right\rangle = \frac{d}{d\tau} \langle f_\tau, \phi\rangle\,|_{\tau_0} = \lim_{\tau_n \to \tau_0} \left\langle \frac{f_{\tau_n} - f_{\tau_0}}{\tau_n - \tau_0}, \phi \right\rangle, \tag{3.2}$$

whenever the limit exists for every $\phi \in K_1$. According to [3, p. 368], (3.2) determines a distribution in K_1' for each τ_0. If $\{\frac{\partial f_\tau}{\partial \tau}|_{\tau_0} \mid \tau_0 \in \mathbb{R}\}$ is a C^0 family, we denote it by $\frac{\partial f_\tau}{\partial \tau}$ and say that $\{f_\tau\}$ is a C^1 *family.* Continuing in this way, if $\{\frac{\partial f_\tau}{\partial \tau}\}$ is a C^{p-1} family, $\{f_\tau\}$ is a C^p *family.* Applying (3.2), $\{f_\tau\}$ is a C^p family if and only if $\tau \to \langle f_\tau, \phi\rangle$ is a C^p function for each ϕ. We may interpret the latter statement as a definition for $p = \infty$. Since $\langle \dot{f}_\tau, \phi\rangle = -\langle f_\tau, \dot{\phi}\rangle$, $\{\dot{f}_\tau\}$ is a C^p family whenever $\{f_\tau\}$ is a C^p family.

Next we relate two notions of differentiation for C^1 families.

THEOREM 3.3. *Suppose $g = \{g_\tau\}$ is a C^1 family. Then $\frac{\partial g}{\partial \tau} = \{\frac{\partial g_\tau}{\partial \tau}\}$.*

Proof. Suppose

$$\left\langle \frac{g_\tau - g_{\tau_0}}{\tau - \tau_0}, \psi(\cdot,\tau) \right\rangle \not\to \left\langle \frac{\partial g_\tau}{\partial \tau}|_{\tau_0}, \psi(\cdot,\tau_0) \right\rangle \tag{3.3}$$

as $\tau \to \tau_0$. Then there exist $\tau_n \to \tau_0$ and $\varepsilon > 0$ such that

$$\sup_j \left| \left\langle \frac{g_{\tau_n} - g_{\tau_0}}{\tau_n - \tau_0} - \frac{\partial g_\tau}{\partial \tau}|_{\tau_n}, \psi(\cdot,\tau_j) \right\rangle \right| \geq \left| \left\langle \frac{g_{\tau_n} - g_{\tau_0}}{\tau_n - \tau_0} - \frac{\partial g_\tau}{\partial \tau}|_{\tau_n}, \psi(\cdot,\tau_n) \right\rangle \right| > \varepsilon \tag{3.4}$$

for every n. But $\psi(\cdot,\tau_n) \to \psi(\cdot,\tau_0)$ in K_1, so, from [4, p. 31], $\{\psi(\cdot,\tau_n)\} \subset K_1$ is a bounded set. Hence, from [4, p. 56], the left side of (3.4) must converge to 0. This yields a contradiction, so we have convergence in (3.3). Thus

$$\begin{aligned}
\frac{d}{d\tau} \langle g_\tau, \psi(\cdot,\tau)\rangle\,|_{\tau_0} &= \lim_{\tau \to \tau_0} \frac{\langle g_\tau, \psi(\cdot,\tau)\rangle - \langle g_{\tau_0}, \psi(\cdot,\tau_0)\rangle}{\tau - \tau_0} \\
&= \lim_{\tau \to \tau_0} \left\langle \frac{g_\tau - g_{\tau_0}}{\tau - \tau_0}, \psi(\cdot,\tau) \right\rangle + \lim_{\tau \to \tau_0} \left\langle g_{\tau_0}, \frac{\psi(\cdot,\tau) - \psi(\cdot,\tau_0)}{\tau - \tau_0} \right\rangle \\
&= \left\langle \frac{\partial g_\tau}{\partial \tau}|_{\tau_0}, \psi(\cdot,\tau_0) \right\rangle + \left\langle g_{\tau_0}, \frac{\partial \psi}{\partial \tau}|_{\tau_0} \right\rangle,
\end{aligned}$$

and, for every $\psi \in K_2$,

$$\begin{aligned}\left\langle \frac{\partial g}{\partial \tau}, \psi \right\rangle &= -\left\langle g, \frac{\partial \psi}{\partial \tau} \right\rangle \\ &= -\int_{-\infty}^{\infty} \left\langle g_\tau, \frac{\partial \psi}{\partial \tau} \right\rangle d\tau \\ &= -\int_{-\infty}^{\infty} \left(\frac{d}{d\tau} \langle g_\tau, \psi(\cdot,\tau)\rangle - \left\langle \frac{\partial g_\tau}{\partial \tau}, \psi(\cdot,\tau) \right\rangle \right) d\tau \\ &= -\lim_{\tau\to\infty} \langle g_\tau, \psi(\cdot,\tau)\rangle + \lim_{\tau\to-\infty} \langle g_\tau, \psi(\cdot,\tau)\rangle + \int_{-\infty}^{\infty} \left\langle \frac{\partial g_\tau}{\partial \tau}, \psi(\cdot,\tau) \right\rangle d\tau \\ &= \int_{-\infty}^{\infty} \left\langle \frac{\partial g_\tau}{\partial \tau}, \psi(\cdot,\tau) \right\rangle d\tau.\end{aligned}$$

Hence $\frac{\partial g}{\partial \tau} = \{\frac{\partial g_\tau}{\partial \tau}\}$. □

Note that

$$\left\langle \frac{\partial \theta_\tau}{\partial \tau}, \phi \right\rangle = \frac{\partial}{\partial \tau} \int_{\tau}^{\infty} \phi(\eta) d\eta = -\phi(\tau) = \langle -\delta_\tau, \phi \rangle$$

for every $\phi \in K_1$, where θ_τ is a translation of the unit step as in (2.1). In view of Theorem 3.3, $\frac{\partial}{\partial \tau}\{\theta_\tau\} = \{\frac{\partial \theta_\tau}{\partial \tau}\} = -\{\delta_\tau\}$. By a similar calculation, $\frac{\partial}{\partial \tau}\{\delta_\tau^{(n-1)}\} = -\{\delta_\tau^{(n)}\}$.

Any C^∞ family $\{h_\tau\}$ belonging to K'_{2+} determines a linear operator on K'_{1+} in the following way. For each $\phi \in K_1$, let $\xi(\tau) = \langle h_\tau, \phi \rangle$. Then $\xi(\tau)$ is C^∞ with $\xi(\tau) = 0$ for large τ. Suppose $u \in K'_{1+}$ with $\operatorname{supp} u \subset [a, \infty]$, and let $\bar{\xi} \in K_1$ with $\bar{\xi}(\tau) = \xi(\tau)$ for $\tau \geq a$. It is easy to show that $y(\phi) = \langle u, \bar{\xi} \rangle$ is independent of the choice of $\bar{\xi}$. Indeed, let $\bar{\xi}_1$ and $\bar{\xi}_2$ be two such functions. Then $\operatorname{supp}(\bar{\xi}_1 - \bar{\xi}_2) \subset (-\infty, a]$, and $\langle u, \bar{\xi}_1 \rangle - \langle u, \bar{\xi}_2 \rangle = \langle u, \bar{\xi}_1 - \bar{\xi}_2 \rangle = 0$.

THEOREM 3.4. *The map $u \longmapsto y$ defines a linear operator $T : K'_{1+} \to K'_{1+}$, where $T(\delta_{t_0}) = h_{t_0}$ for every t_0.*

Proof. Linearity is obvious. Since $\{h_\tau\} \in K'_{2+}$, there exists $b \in \mathbb{R}$ such that $\operatorname{supp} \phi \subset (-\infty, b]$ implies $\operatorname{supp} \xi \subset (-\infty, a)$. For any such ϕ, $y(\phi) = 0$, so $\operatorname{supp} y \subset [b, \infty)$. We must show that $y \in K'_1$.

The topological space K'_1 is not first-countable, so we must consider nets $\{\phi_\lambda\}$ in K_1. Suppose $\phi_\lambda \to 0$. Then there exists $b < \infty$ such that $\operatorname{supp} \phi_\lambda \subset [-b, b]$ for every λ. Let $\xi_\lambda(\tau) = \langle h_\tau, \phi_\lambda \rangle$. Since $\{h_\tau\} \in K'_{1+}$, there exists $c < \infty$ such that $\operatorname{supp} \xi_\lambda(\tau) \subset (-\infty, c]$ for every λ. Arguing as in the proof of Theorem 3.2, there exist $M_n, p_n < \infty$ such that

$$\left| \xi^{(n)}(\tau) \right| \leq M_n \|\phi\|_{C^{p_n}}$$

for every $\tau \in [a, c]$ and $\phi \in K_1$ with $\operatorname{supp} \phi \in [-b, b]$. Hence, $\xi_\lambda^{(n)} \to 0$ uniformly on $[a, c]$ for every n. $\bar{\xi}_\lambda \in K_1$ can be chosen so that $\bar{\xi}_\lambda(\tau) = \xi_\lambda(\tau)$ on $[a, \infty)$ and each $\bar{\xi}_\lambda^{(n)} \to 0$ uniformly on $[a, c]$. Thus $\bar{\xi}_\lambda \to 0$ strongly in K_1, and $y(\phi_\lambda) = \langle u, \bar{\xi}_\lambda \rangle \to 0$. Finally, for $u = \delta_{t_0}$ and any $\phi \in K_1$, $\langle T(\delta_{t_0}), \phi \rangle = \bar{\xi}(t_0) = \xi(t_0) = \langle h_{t_0}, \phi \rangle$. □

Suppose $h_\tau = h(\cdot, \tau)$. Then, under mild assumptions,

$$\langle T(u), \phi \rangle = \int_{-\infty}^{\infty} \left(\int_{-\infty}^{\infty} h(t,\tau)\phi(t)dt \right) u(\tau)d\tau = \int_{-\infty}^{\infty} \left(\int_{-\infty}^{\infty} h(t,\tau)u(\tau)d\tau \right) \phi(t)dt,$$

so the operator determined by Theorem 3.4 is "classical." For this reason, we call every operator of the type described by Theorem 3.4 a *generalized integral operator*. Suppose h_τ is the τ-translation of a fixed $h \in K'_{1+}$. Then $\{h_\tau\}$ is a C^∞ family and $\{h_\tau\} \in K'_{2+}$, so $\{h_\tau\}$ determines a generalized integral operator according to $\langle T(u), \phi\rangle = \langle u, \xi\rangle$, where $\xi(\tau) = \langle h_\tau, \phi\rangle = \langle h, \phi_{-\tau}\rangle$. From [3, p. 103], constructing $T(u)$ in this way yields the convolution operator $u \to h * u$. This sets up the time-invariant analysis we carried out in [1].

We next address the issue of continuity of generalized integral operators.

THEOREM 3.5. *Let $T : K'_{1+} \to K'_{1+}$ be any continuous linear operator, and suppose $\{T(\delta_\tau)\} \in K'_{2+}$ is a C^∞ family. Then T is a generalized integral operator.*

Proof. Let $\phi \in K_1$, $u \in K'_{1+}$, $\operatorname{supp} u \subset [a, \infty)$, $\xi(\tau) = \langle T(\delta_\tau), \phi\rangle$, and $\bar{\xi} \in K_1$ with $\bar{\xi}(\tau) = \xi(\tau)$ for $\tau \geq a$. We must show that $\langle T(u), \phi\rangle = \langle u, \bar{\xi}\rangle$. First, set $u = \delta_{t_0}$. Then

$$\langle T(\delta_{t_0}), \phi\rangle = \xi(t_0) = \bar{\xi}(t_0) = \left\langle \delta_{t_0}, \bar{\xi}\right\rangle.$$

For arbitrary $u \in K'_{1+}$, [1, Lemma 2.2] shows that there exist $t_{ik} \geq a$, $\beta_{ik} \in \mathbb{R}$, and integers $n_k > 0$ such that

$$u_k = \sum_{i=1}^{n_k} \beta_{ik} \delta_{t_{ik}} \to u,$$

where the limit is *weak**. For every k,

$$\langle T(u_k), \phi\rangle = \sum_{i=1}^{n_k} \beta_{ik} \langle T(\delta_{t_{ik}}), \phi\rangle = \sum_{i=1}^{n_k} \beta_{ik} \left\langle \delta_{t_{ik}}, \bar{\xi}\right\rangle = \left\langle u_k, \bar{\xi}\right\rangle.$$

Taking the limit yields

$$\langle T(u), \phi\rangle = \left\langle u, \bar{\xi}\right\rangle. \qquad \square$$

The next result establishes conditions under which generalized integral operators are continuous. In particular, it shows that the converse to Theorem 3.5 is false.

THEOREM 3.6. *Let $T : K'_{1+} \to K'_{1+}$ be a generalized integral operator.*

(1) *T is continuous if and only if there exists a function $b : \mathbb{R} \to \mathbb{R}$ such that $b(\tau) \to \infty$ as $\tau \to -\infty$ and $\operatorname{supp}\{T(\delta_\tau)\} \subset \{|t| \geq b(\tau)\}$.*

(2) *T is continuous on $\{u \in K'_{1+} \mid \operatorname{supp} u \subset [a, \infty)\}$ for every $a > -\infty$.*

Proof. (1) (Sufficient) Consider any basic neighborhood $Y = \{y \in K'_{1+} \mid |\langle y, \phi_i\rangle| < \varepsilon; i = 1, \ldots, n\}$ of 0 in K'_{1+}, and let $\xi_i(\tau) = \langle T(\delta_\tau), \phi_i\rangle$. Since T is a generalized integral operator, each ξ_i is C^∞. $\{h_\tau\} \in K'_{1+}$ guarantees that $\operatorname{supp} \xi_i$ is right-bounded. The condition $\operatorname{supp}\{T(\delta_\tau)\} \subset \{|t| \geq b(\tau)\}$ guarantees that $\operatorname{supp} \xi_i$ is left-bounded. Hence, $\xi_i \in K_1$, and $\langle T(u), \phi_i\rangle = \langle u, \xi_i\rangle$. It follows that the inverse image

$$\begin{aligned} T^{-1}(Y) &= \{u \in K'_{1+} \mid |\langle T(u), \phi_i\rangle| < \varepsilon; i = 1, \ldots, n\} \\ &= \{u \in K'_{1+} \mid |\langle u, \xi_i\rangle| < \varepsilon; i = 1, \ldots, n\} \end{aligned}$$

is open. Since $\varepsilon, \phi_1, \ldots, \phi_n$ are arbitrary, T is continuous.

(Necessary) Suppose no such function b exists. Then there exists a sequence $\tau_k \to -\infty$ and $c < \infty$ such that $\operatorname{supp} T(\delta_{\tau_k}) \cap [-c, c]$ is nonempty for every k. Hence, there exist $\phi_k \in K_1$ such that $\operatorname{supp} \phi_k \subset [-c, c]$ and $\beta_k = \langle T(\delta_{\tau_k}), \phi_k\rangle \neq 0$ for each k. Let

$$\xi_k = \frac{1}{k \left\|\phi_k\right\|_{C^k}} \phi_k.$$

Then, for any integers $p \geq 0$ and $k \geq p$,

$$\|\xi_k\|_{C^p} = \frac{1}{k\,\|\phi_k\|_{C^k}}\,\|\phi_k\|_{C^p} \leq \frac{1}{k},$$

so $\xi_k \to 0$. From [4, p. 31], $\{\xi_k\}$ is a bounded set. Let

$$u_k = \frac{k\,\|\phi_k\|_{C^k}}{\beta_k}\delta_{\tau_k}.$$

Then $u_k \to 0$. On the other hand,

$$\begin{aligned}\sup_m \langle T(u_k), \xi_m\rangle &\geq \langle T(u_k), \xi_k\rangle \\ &= \left\langle \frac{k\,\|\phi_k\|_{C^k}}{\beta_k} T(\delta_{\tau_k}), \xi_k \right\rangle \\ &= \frac{1}{\beta_k}\,\langle T(\delta_{\tau_k}), k\,\|\phi_k\|_{C^k}\,\xi_k\rangle \\ &= \frac{1}{\beta_k}\,\langle T(\delta_{\tau_k}), \phi_k\rangle = 1.\end{aligned}$$

From [4, p. 56], $T(u_k) \not\to 0$, which is a contradiction.

(2) Let $u_\lambda \to 0$ be a net with $\operatorname{supp} u_\lambda \subset [a, \infty)$, $\phi \in K_1$, and $\xi(\tau) = \langle T(\delta_\tau), \phi\rangle$. Select $\bar{\xi} \in K_1$ with $\bar{\xi}(\tau) = \xi(\tau)$ for $\tau \geq a$. This gives $\langle T(u_\lambda), \phi\rangle = \langle u_\lambda, \bar{\xi}\rangle \to 0$, so $T(u_\lambda) \to 0$. □

In view of Theorem 3.6, restricting attention to continuous linear operators on K'_{1+} would be inadequate for developing a sufficiently comprehensive theory of stable linear systems. For example, even the "integrator system" $T(\delta_\tau) = \theta_\tau$ is discontinuous. On the other hand, the class of all generalized integral operators on K'_{1+} contains the full range of operators normally considered in linear system theory, so we will adopt these as our space of systems.

We end this section with a result relating impulse response and step response.

THEOREM 3.7. *Let $T : K'_{1+} \to K'_{1+}$ be a generalized integral operator. Then $\{T(\theta_\tau)\}$ is a C^∞ family and $T(\delta_\tau) = -\frac{\partial T(\theta_\tau)}{\partial \tau}$.*

Proof. From Theorem 3.6(2), T is continuous on $\{u \in K'_{1+} \mid \operatorname{supp} u \subset [\tau_0 - 1, \infty)\}$ for any τ_0. Hence, for any $\phi \in K_1$,

$$\begin{aligned}\frac{\langle T(\theta_\tau), \phi\rangle - \langle T(\theta_{\tau_0}), \phi\rangle}{\tau - \tau_0} &= \left\langle T\left(\frac{\theta_\tau - \theta_{\tau_0}}{\tau - \tau_0}\right), \phi \right\rangle \to \langle -T(\delta_{\tau_0}), \phi\rangle\,, \\ \frac{\left\langle T(\delta_\tau^{(n)}), \phi\right\rangle - \left\langle T(\delta_{\tau_0}^{(n)}), \phi\right\rangle}{\tau - \tau_0} &= \left\langle T\left(\frac{\delta_\tau^{(n)} - \delta_{\tau_0}^{(n)}}{\tau - \tau_0}\right), \phi \right\rangle \to \left\langle -T(\delta_{\tau_0}^{(n+1)}), \phi\right\rangle\end{aligned}$$

as $\tau \to \tau_0$ for any n, so $\{T(\theta_\tau)\}$ is C^∞. The first derivative is given by

$$\left\langle \frac{\partial T(\theta_\tau)}{\partial \tau}, \phi \right\rangle = \frac{\partial}{\partial \tau}\,\langle T(\theta_\tau), \phi\rangle = \langle -T(\delta_\tau), \phi\rangle\,. \qquad \square$$

4. Extension of normed linear spaces. In [1] we considered the problem of imbedding a normed linear space Y into a Hausdorff topological vector space X and extending the norm to a maximal linear subspace of X. For example, we showed that

L^1 can be imbedded in K_1' and $\|\cdot\|_1$ can be extended to all of DBV. In particular, the extended L^1 norm applied to the unit impulse evaluates to $\|\delta\|_1^e = 1$. We will again need these results to construct our time-varying theory.

Let $\mathfrak{T}$ be the topology on X, $\|\cdot\|$ the norm on $Y \subset X$, and $B(y,r) \subset Y$ the closed norm-ball about $y \in Y$ with radius r. We make the following assumptions on the 4-tuple $(X, \mathfrak{T}, Y, \|\cdot\|)$:

T1. For every nonempty $U \in \mathfrak{T}$, $U \cap Y$ is nonempty.

T2. For every $U \in \mathfrak{T}$ and every $y \in U \cap Y$, there exists $r > 0$ such that $B(y,r) \subset U$.

T3. There exists $U \in \mathfrak{T}$ such that $U \cap Y = Y - B(0,1)$.

Condition T1 says that Y is dense in X. T2 requires that the norm topology on Y is at least as strong as the topology induced on Y by X. T3 says that $B(0,1)$ in Y is closed relative to X. Thus T2 and T3 give bounds on the topology induced on Y by X. Under assumptions T1–T3, there exists a natural extension $\|\cdot\|^e$ of $\|\cdot\|$ to a subspace $Y_e \supset Y$ of X. In particular, for any $y \in Y_e$, $\|y\|^e$ is equal to the minimum value of $\lim \|y_\lambda\|$ over all $\mathfrak{T}$-approximating nets $y_\lambda \to y$, $y_\lambda \in Y$. (See [1, section 3] for details.)

As mentioned in section 1, $h \in UL^1$ is the classical condition for BIBO stability. Therefore it makes sense to examine the extension UL_e^1 of $\|\cdot\|_{\infty 1}$ in K_2' and check whether UL_e^1 actually characterizes BIBO stability for generalized integral operators. First we must establish whether K_2' and UL^1 satisfy T1–T3.

LEMMA 4.1. (1) *If Y_1 is dense in Y relative to $\|\cdot\|$, then the 4-tuple $(X, \mathfrak{T}, Y_1, \|\cdot\|)$ satisfies* T1–T3 *and $Y_{1e} = Y_e$.*

(2) *Let $Y \subset X_1 \subset X$ and $\mathfrak{T}_1$ be the relative topology on X_1 induced by $\mathfrak{T}$. Then the 4-tuple $(X_1, \mathfrak{T}_1, Y, \|\cdot\|)$ satisfies* T1–T3 *and the corresponding extension of Y is $Y_e \cap X_1$.*

Proof. (1) From T1 and T2, Y_1 is dense in X relative to $\mathfrak{T}$, so T1 holds for Y_1. If $U \in \mathfrak{T}$ and $y \in U \cap Y_1$, then $y \in U \cap Y$, so there exists $r > 0$ such that $B(y,r) \subset U$, where $B(y,r)$ is a norm-ball in Y. The corresponding ball in Y_1 is $B(y,r) \cap Y_1 \subset U$, so T2 holds. Finally, if U satisfies T3 relative to Y, then U also satisfies T3 relative to Y_1, since

$$U \cap Y_1 = (U \cap Y) \cap Y_1 = (Y - B(0,1)) \cap Y_1 = Y_1 - (B(0,1) \cap Y_1).$$

Finally, we must show that $\|\cdot\|^e$ satisfies [1, Proposition 3.1(1)–(3)] using Y_1 in place of Y. To prove (1), note that, since $\|\cdot\|$ and $\|\cdot\|^e$ coincide on Y, they must coincide on Y_1. Condition (2) holds, since it does not involve Y. To prove (3), let $x \in X$ with $\|x\|^e < \infty$, $\varepsilon > 0$, and let U be a $\mathfrak{T}$-neighborhood of x. Then (3) applied to Y guarantees that there exists $y \in U \cap Y$ such that

$$\|y\| < \|x\|^e + \frac{\varepsilon}{2}.$$

Density of Y_1 in Y relative to $\|\cdot\|$ and T2 imply that there exists $y_1 \in U \cap Y_1$ such that $\|y_1 - y\| < \frac{\varepsilon}{2}$. Then

$$\|y_1\| < \|y\| + \frac{\varepsilon}{2} < \|x\|^e + \varepsilon.$$

(2) Restricting $\mathfrak{T}$ to X_1, T1–T3 are obvious. Suppose Y_e is the extension of Y using X, and $\|\cdot\|^e$ is the corresponding norm. Let $\|\cdot\|^f$ be the restriction of $\|x\|^e$ to X_1. We must show that $\|\cdot\|^f$ satisfies [1, Proposition 3.1(1)–(3)], using X_1. To prove (1) and (2), note that $\|x\|^e$ and $\|x\|^f$ coincide on X_1; hence, $\|y\|^f = \|y\|$ for

$y \in Y$ and $\|\cdot\|^f$ is lower semicontinuous. To establish (3), let $U \in \mathfrak{T}$ $x \in U \cap X_1$ with $\|x\|^f < \infty$, and $\varepsilon > 0$. Then $\|x\|^e < \infty$ and there exists $y \in U \cap Y$ such that

$$\|y\| < \|x\|^e + \varepsilon = \|x\|^f + \varepsilon.$$

But $Y \subset X_1$, so $y \in (U \cap X_1) \cap Y$. □

THEOREM 4.2. *Let $X = K_2'$ and $Y = UL^1$. Then* T1–T3 *are satisfied.*

Proof. First we note that $K_2 \subset UL^1$. From [4, p. 118], K_2 is dense in K_2', and T1 follows. If T2 holds for $y = 0$, then it holds for all y, since $B(0,r) \subset U$ implies $B(y,r) \subset y+U$. Thus it suffices to prove that, for every $n, \varepsilon > 0$, and $\psi_1, \ldots, \psi_n \in K_2$, there exists $r > 0$ such that $B(0,r) \subset U$, where

$$U = \{f \in K_2' \mid |\langle f, \psi_i\rangle| < \varepsilon; i = 1, \ldots, n\}.$$

Let

$$r < \varepsilon \min\left\{\frac{1}{\|\psi_i\|_{1\infty}}\right\}$$

and $f \in B(0,r)$. From Theorem 2.2,

$$|\langle f, \psi_i\rangle| \le \|f\|_{DUBV} \|\psi_i\|_{1\infty} = \|f\|_{\infty 1} \|\psi_i\|_{1\infty} \le r \max\{\|\psi_j\|_{1\infty}\} < \varepsilon$$

for every i, so $f \in U$.

To prove T3, let $y \in UL^1$ with $\|y\|_{\infty 1} > 1$, and choose $\varepsilon < \frac{1}{2}(\|y\|_{\infty 1} - 1)$. From Theorem 2.2, we may select $\psi \in K_2$ with $\|\psi\|_{1\infty} = 1$ such that $|\langle y, \psi\rangle| > \|y\|_{\infty 1} - \varepsilon$. Let

$$U = \{x \in K_2' \mid |\langle x - y, \psi\rangle| < \varepsilon\}.$$

Then $y \in U \in \mathfrak{T}$, and $f \in U \cap Y$ implies

$$\|f\|_{\infty 1} \ge |\langle f, \psi\rangle| \ge |\langle y, \psi\rangle| - |\langle f - y, \psi\rangle| > \|y\|_{\infty 1} - 2\varepsilon > 1,$$

so $U \cap Y \subset Y - B(0,1)$. □

We are now in a position to characterize the extension of UL^1 into K_2'.

THEOREM 4.3. $UL_e^1 = DUBV$.

Proof. Let

$$\|f\|^e = \begin{cases} \|f\|_{DUBV}, & f \in DUBV, \\ \infty, & f \in K_2' - DUBV. \end{cases}$$

We must verify that $\|\cdot\|^e$ satisfies [1, Lemma 3.1(1)–(3)] relative to $\|\cdot\|_{\infty 1}$. Condition (1) says that $\|\cdot\|_{\infty 1}$ and $\|\cdot\|_{DUBV}$ coincide on UL^1. This was established in Theorem 2.2.

Condition (2) requires that $\|\cdot\|^e$ be lower semicontinuous on K_2'. Equivalently, we must show that the set $\Sigma_M = \{f \in K_2' \mid \|f\|^e > M\}$ is open for each M. Suppose $\|f\|^e > M$. From Theorem 2.2(3), there exists $\psi \in K_2$ such that $\|\psi\|_{1\infty} = 1$ and $|\langle f, \psi\rangle| > M$. Let $U = \{g \in K_2' \mid |\langle g, \psi\rangle| < |\langle f, \psi\rangle| - M\}$. $f + U$ is open in K_2', and

$$\|f + g\|^e \ge |\langle f + g, \psi\rangle| \ge |\langle f, \psi\rangle| - |\langle g, \psi\rangle| > M$$

for every $g \in U$. Hence, Σ_M is open.

Finally, condition (3) says that, for any $f \in DUBV$, $\varepsilon > 0$, and neighborhood U of f, there exists $y \in U \cap UL^1$ such that $\|y\|_{\infty 1} < \|f\|^e + \varepsilon$. We accomplish this by constructing a sequence $f_n \to f$ with $f_n \in UL^1$ and $\|f_n\|_{\infty 1} \leq \|f\|_{DUBV}$. Then, for large n, $f_n \in U$, and $y = f_n$ satisfies the conditions.

Our construction of f_n proceeds as follows. Let $\phi_1, \phi_2 \in K_1$ with $\phi_1(t) \geq 0$ for all t, $\int_{-\infty}^{\infty} \phi_1(t)dt = 1$, $\phi_2(0) = 1$, and $\|\phi_2\|_\infty = 1$. Set $\psi_n(t,\tau) = n\phi_1(n(t-\tau))\phi_2(\frac{\tau}{n})$. Then $\psi_n \in C^\infty$. Suppose $\operatorname{supp}\phi_1, \operatorname{supp}\phi_2 \subset [-a,a]$. If $|\tau| \geq na$, then $|\frac{\tau}{n}| \geq a$, so $\phi_2(\frac{\tau}{n}) = 0$ and $\psi(t,\tau) = 0$. If $|\tau| < na$ and $|t| \geq (n + \frac{1}{n})a$, then

$$n\,|t-\tau| \geq n\,(|t| - |\tau|) > n\left(n + \frac{1}{n}\right)a - n^2 a = a,$$

so $\phi_1(n(t-\tau)) = 0$ and $\psi_n(t,\tau) = 0$. Hence, $\psi_n \in K_2$.

Let

$$f_n(t,\tau) = \int_{-\infty}^{\infty} \psi_n(\tau,\eta)dg_t(\eta)$$

and $f = \frac{\partial g}{\partial \tau}$. Then

$$\begin{aligned}
\int_{-\infty}^{\infty} |f_n(t,\tau)|\,d\tau &\leq \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} |\psi_n(\tau,\eta)|\,|dg_t(\eta)|\,d\tau \\
&= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} |\psi_n(\tau,\eta)|\,d\tau\,|dg_t(\eta)| \\
&= n\int_{-\infty}^{\infty} \left|\phi_2\left(\frac{\eta}{n}\right)\right| \left(\int_{-\infty}^{\infty} \phi_1(n(\tau-\eta))d\tau\right) |dg_t(\eta)| \\
&= \int_{-\infty}^{\infty} \left|\phi_2\left(\frac{\eta}{n}\right)\right| \left(\int_{-\infty}^{\infty} \phi_1(x)dx\right) |dg_t(\eta)| \\
&\leq \operatorname*{var}_{\eta} g(t,\eta),
\end{aligned}$$

$$\|f_n\|_{\infty 1} \leq \operatorname*{ess\,sup}_t \operatorname*{var}_\tau g(t,\tau) = \|f\|_{DUBV}.$$

To show $\langle f_n, \psi\rangle \to \langle f, \psi\rangle$, note that, for every $t, \eta, x \in \mathbb{R}$, $\psi(t, \frac{x}{n} + \eta) \to \psi(t,\eta)$ and

$$\int_{-\infty}^{\infty} \left|\phi_1(x)\psi\left(t, \frac{x}{n} + \eta\right)\right| dx \leq \|\psi\|_\infty.$$

By the dominated convergence theorem,

$$\begin{aligned}
\int_{-\infty}^{\infty} \psi_n(\tau,\eta)\psi(t,\tau)d\tau &= n\phi_2\left(\frac{\eta}{n}\right)\int_{-\infty}^{\infty} \phi_1(n(\tau-\eta))\psi(t,\tau)d\tau \\
&= \phi_2\left(\frac{\eta}{n}\right)\int_{-\infty}^{\infty} \phi_1(x)\psi\left(t, \frac{x}{n} + \eta\right)dx \\
&\to \phi_2(0)\int_{-\infty}^{\infty} \phi_1(x)\psi(t,\eta)dx \\
&= \psi(t,\eta)
\end{aligned}$$

for every t, η. Furthermore,

$$\begin{aligned}\left|\int_{-\infty}^{\infty}\psi_n(\tau,\eta)\psi(t,\tau)d\tau\right| &\le n\left|\phi_2\left(\frac{\eta}{n}\right)\right|\int_{-\infty}^{\infty}\phi_1(n(\tau-\eta))\,|\psi(t,\tau)|\,d\tau\\ &= \left|\phi_2\left(\frac{\eta}{n}\right)\right|\int_{-\infty}^{\infty}\phi_1(x)\left|\psi\left(t,\frac{x}{n}+\eta\right)\right|dx\\ &\le \|\psi(t,\cdot)\|_\infty,\end{aligned}$$

so, if $\operatorname{supp}\psi\subset[-a,a]^2$,

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\|\psi(t,\cdot)\|_\infty\,|dg_t(\eta)|\,dt \le \int_{-a}^{a}\|\psi(t,\cdot)\|_\infty \operatorname*{var}_\eta g(t,\eta)dt \le 2a\,\|\psi\|_\infty\,\|g\|_{UBV}.$$

Again, by the dominated convergence theorem,

$$\begin{aligned}\langle f_n,\psi\rangle &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\psi_n(\tau,\eta)\psi(t,\tau)d\tau dg_t(\eta)dt\\ &\to \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\psi(\tau,\eta)dg_t(\eta)dt = \langle f,\psi\rangle. \qquad \square\end{aligned}$$

COROLLARY 4.4. *Let $X = K_{2+}'$ and $Y = UL_+^1$. Then X and Y satisfy* T1–T3 *and $Y_e = DUBV_+$.*

Proof. We have $K_2 \subset UL_+^1 \subset UL^1 \subset K_2'$ with K_2 dense in K_2' (see [4, p. 118]). Hence, UL_+^1 is dense in UL^1. From Lemma 4.1(1) and Theorems 4.2 and 4.3, $(K_2', \mathfrak{T}, UL_+^1, \|\cdot\|_{\infty 1})$ satisfies T1–T3 and $UL_{+e}^1 = UL_e^1 = DUBV$. Furthermore, $UL_+^1 \subset K_{2+}' \subset K_2'$, so Lemma 4.1(2) implies that $(K_{2+}', \mathfrak{T}_1, UL_+^1, \|\cdot\|_{\infty 1})$ satisfies T1–T3 and $UL_{+e}^1 = DUBV \cap K_{2+}' = DUBV_+$. $\square$

5. BIBO stability. In this section, we consider stability of linear operators $T : K_{1+}' \to K_{1+}'$. (We must restrict our attention to K_{1+}' in order to have a consistent definition of generalized integral operators.) As in [2, p. 109], we define a *BIBO stable* linear operator T to be one such that

(S1) $T(L_+^\infty) = L_+^\infty$,

(S2) T is continuous on L_+^∞ relative to $\|\cdot\|_\infty$.

We have shown in [1] that, for time-invariant (i.e., convolution) operators, (S2) follows automatically from (S1). Unfortunately, this result does not extend to the time-varying setting. For example, let $h_\tau = e^{-\tau}\delta_\tau$. For any $u \in L_+^\infty$, $\phi \in K_1$,

$$\begin{aligned}\xi(\tau) = \langle h_\tau,\phi\rangle &= e^{-\tau}\langle\delta_\tau,\phi\rangle = e^{-\tau}\phi(\tau),\\ \langle y,\phi\rangle = \langle u,\xi\rangle &= \int_{-\infty}^{\infty}u(\tau)e^{-\tau}\phi(\tau)d\tau.\end{aligned}$$

Thus $y(t) = e^{-t}u(t)$ and $y \in L_+^\infty$. However, the map $u \mapsto y$ is not continuous on L_+^∞. Indeed, let $u_k(t) = \frac{1}{k}\theta(t+k)$; then $\|u_k\|_\infty = \frac{1}{k} \to 0$. But $y_k(t) = \frac{1}{k}e^{-t}\theta(t+k)$ and $\|y_k\|_\infty = \frac{e^k}{k} \to \infty$. Thus, as in [2], we adopt (S2) as an independent assumption.

Since classical integral operators satisfying $T(\delta_\tau) \in UL^1$ are known to be BIBO stable, a natural conjecture is that a generalized integral operator is BIBO stable if and only if $\{T(\delta_\tau)\} \in UL_{e+}^1$ ($= DUBV_+$ by Corollary 4.4). The following example lends support to this idea. Let $T(\delta_\tau) = \delta_\tau^{(n)}$. Then $\langle T(u),\phi\rangle = \langle u,\xi\rangle$, where $\xi(\tau) = \langle\delta_\tau^{(n)},\phi\rangle = (-1)^n\phi^{(n)}(\tau)$. Hence $\langle T(u),\phi\rangle = \langle u,(-1)^n\phi^{(n)}\rangle = \langle u^{(n)},\phi\rangle$, and $T(u) =$

$u^{(n)}$. In view of (S1), the n-times differentiator is BIBO stable if and only if $n = 0$, since $T(\theta) = \delta^{(n-1)} \notin L^\infty$ for $n > 0$. On the other hand, $\{\delta_\tau\} = -\frac{\partial}{\partial \tau}\{\theta_\tau\}$, and $\{\theta_\tau\} \in UBV_+$, so $\{\delta_\tau\} \in UL^1_{e+} = DUBV_+$. But $\{\delta^{(n)}_\tau\} = -\frac{\partial}{\partial \tau}\{\delta^{(n-1)}_\tau\}$ for $n > 0$, and $\delta^{(n-1)}_\tau \notin UBV$, so $\{\delta^{(n)}_\tau\} \notin UL^1_{e+}$.

Corresponding to each generalized integral operator T we may associate an operator $\tilde{T} : K_1 \to C^\infty$ defined by

$$\tilde{T}(\phi)(\tau) = \langle T(\delta_\tau), \phi \rangle .$$

Let $\phi \in K_1$, $u \in L^\infty_+$, $\xi = \tilde{T}(\phi)$. Then

$$\langle T(u), \phi \rangle = \left\langle u, \bar{\xi} \right\rangle = \int_{-\infty}^{\infty} u(\tau)\tilde{T}(\phi)(\tau)d\tau.$$

This suggests an adjoint relationship between T and $\tilde{T}$, which we will explore further in Theorem 5.4. First we need a result which shows that stability of T can be characterized in terms of $\tilde{T}$.

LEMMA 5.1. *T is BIBO stable if and only if*

$$\sup_{\substack{\phi \in K_1 \\ \|\phi\|_1 = 1}} \int_{-\infty}^{\infty} \left| \tilde{T}(\phi)(\tau) \right| d\tau < \infty.$$

Proof. The proof is identical to the proof of [1, Lemma 4.1(2)], replacing the phrase "convolution operator" by "generalized integral operator." ∎

If T is BIBO stable, Lemma 5.1 indicates that $\tilde{T}$ is a continuous linear operator from $(K_1, \|\cdot\|_1)$ into $(L_1, \|\cdot\|_1)$. Since $(K_1, \|\cdot\|_1)$ is dense in L^1, $\tilde{T}$ extends uniquely to a continuous linear operator $\tilde{T}_e : L^1 \to L^1$.

LEMMA 5.2. *Let $T : K'_{1+} \to K'_{1+}$ be a BIBO stable generalized integral operator, $s(\cdot, \tau) = T(\theta_\tau)$, $s_\tau(t) = \widehat{s}_t(\tau) = s(t, \tau)$, $\phi \in L^1$, and $u \in L^\infty$. Then*

(1) *$\tau \to \int_{-\infty}^{\infty} s(t, \tau)\phi(t)dt$ is absolutely continuous,*

(2) *$\tilde{T}_e(\phi)(\tau) = -\frac{d}{d\tau}\int_{-\infty}^{\infty} s(t, \tau)\phi(t)dt$ for every $\tau \in \mathbb{R}$,*

(3) *$\int_{-\infty}^{\infty} u(\tau)d\int_{-\infty}^{\infty} s(t, \tau)\phi(t)dt = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \phi(t)u(\tau)d\widehat{s}_t(\tau)dt$.*

Proof. From [7, Theorem 2.3.9], there exists $g : \mathbb{R}^2 \to \mathbb{R}$ such that $g(\cdot, \cdot) - g(\cdot, \infty)$ $\in UBV$, the map $\tau \to \int_{-\infty}^{\infty} g(t, \tau)\phi(t)dt$ is absolutely continuous, and

$$\tilde{T}_e(\phi)(t) = \frac{d}{d\tau}\int_{-\infty}^{\infty} g(t, \tau)\phi(t)dt$$

for each $\phi \in L^1$. Let $c = \int_{-\infty}^{\infty} g(t, \infty)\phi(t)dt$. Then

$$\begin{aligned}
\int_{-\infty}^{\infty} s\left(t, t_0\right)\phi\left(t\right)dt &= \int_{-\infty}^{\infty} \theta_{t_0}\left(\tau\right)\tilde{T}\left(\phi\right)\left(\tau\right)d\tau \\
&= \int_{t_0}^{\infty} \tilde{T}\left(\phi\right)\left(\tau\right)d\tau \\
&= \int_{t_0}^{\infty} \frac{d}{d\tau}\left(\int_{-\infty}^{\infty} g(t, \tau)\phi(t)dt\right)d\tau \\
&= \int_{-\infty}^{\infty} \left(g\left(t, \infty\right) - g\left(t, t_0\right)\right)\phi\left(t\right)dt \\
&= c - \int_{-\infty}^{\infty} g(t, t_0)\phi(t)dt,
\end{aligned}$$

from which (1) and (2) follow.

To prove (3), note that, for any $\phi \in L^1$, $|\phi(t)| < \infty$ a.e. and

$$\mu_t(-\infty, \tau] = \phi(t) s(t, \tau)$$

determines a finite signed Borel measure on $\mathbb{R}$ for a.e. t as does

$$\mu(-\infty, \tau] = g(\tau) = \int_{-\infty}^{\infty} \mu_t(-\infty, \tau] dt. \tag{5.1}$$

Consider the family $\mathcal{L}$ of sets $A \subset \mathbb{R}$ such that the map $t \to \mu_t(A)$ is Borel measurable for a.e. t. Since

$$\mu_t(\mathbb{R}) = \operatorname*{var}_{\tau} s(t, \tau),$$

$\mathbb{R} \in \mathcal{L}$. If $A, B \in \mathcal{L}$ with $A \subset B$, then

$$\mu_t(B - A) = \mu_t(B) - \mu_t(A),$$

so $B - A \in \mathcal{L}$. If $A_n \in \mathcal{L}$ with $A_n \uparrow A$, then

$$\mu_t(A) = \mu_t(A_1) + \sum_n \mu_t(A_{n+1} - A_n),$$

so $A \in \mathcal{L}$. From the $\pi - \lambda$ theorem (see [8, Theorem 4.2]), every Borel set in $\mathbb{R}$ belongs to $\mathcal{L}$. Hence, $t \to \mu_t(A)$ is Borel measurable for any Borel set A and

$$\int_{-\infty}^{\infty} |\mu_t(A)|\, dt = \int_{-\infty}^{\infty} \left| \int_A \phi(t) d\widehat{s}_t(\tau) \right| dt \le \int_{-\infty}^{\infty} \int_A |\phi(t)|\, |d\widehat{s}_t(\tau)|\, dt \le \|s\|_{UBV}\, \|\phi\|_1 .$$

Also, if the A_n are pairwise disjoint,

$$\int_{-\infty}^{\infty} \mu_t \left(\underset{n}{\cup} A_n \right) dt = \int_{-\infty}^{\infty} \sum_n \mu_t(A_n) dt = \sum_n \int_{-\infty}^{\infty} \mu_t(A_n) dt,$$

so the map

$$A \to \int_{-\infty}^{\infty} \mu_t(A) dt \tag{5.2}$$

is a finite signed Borel measure. Since μ and (5.2) have the same distribution function (5.1),

$$\mu(A) = \int_{-\infty}^{\infty} \mu_t(A) dt$$

for each A.

Let I_A be the indicator function on A. Then

$$\int_{-\infty}^{\infty} I_A(\tau) d\mu = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} I_A(\tau) d\mu_t dt,$$

$$\int_{-\infty}^{\infty} I_A(\tau) d \int_{-\infty}^{\infty} s(t, \tau) \phi(t) dt = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \phi(t) I_A(\tau) d\hat{s}_t(\tau) dt. \tag{5.3}$$

Both sides of (3) are bounded by $\|u\|_\infty \|s\|_{UBV} \|\phi\|_1$, so, as functions of u, they both represent continuous linear functionals on L^∞. Since the span of the indicators I_A is dense in L^∞, 5.3 implies (3). ∎

We are now in a position to prove our main result.

THEOREM 5.3. *Let $T : K'_{1+} \to K'_{1+}$ be a generalized integral operator. The following statements are equivalent:*

(1) *T is BIBO stable.*
(2) *$\{T(\delta_\tau)\} \in UL^1_{+e}$.*
(3) *$\{T(\theta_\tau)\} \in UBV_+$.*

Proof. From Theorem 3.7, $\{T(\theta_\tau)\} \in UBV_+$ if and only if $\{T(\delta_\tau)\} \in DUBV_+$. From Corollary 4.4, $DUBV_+ = UL^1_{+e}$. Thus (2) and (3) are equivalent.

To prove that (3) implies (1), let $u \in L^\infty_+$, $\phi \in K_1$, $s_\tau = T(\theta_\tau)$, $s(t,\tau) = s_\tau(t)$, and note that

$$\operatorname*{var}_\tau \langle s_\tau, \phi \rangle = \operatorname*{var}_\tau \int_{-\infty}^{\infty} s(t,\tau)\phi(t)dt \leq \int_{-\infty}^{\infty} \left(\operatorname*{var}_\tau s(t,\tau) \right) |\phi(t)|\, dt \leq \|s\|_{UBV} \|\phi\|_1 .$$

From Theorem 3.7 and Lemma 5.2,

$$\begin{aligned} \langle T(u), \phi \rangle &= \int_{-\infty}^{\infty} u(\tau) \langle T(\delta_\tau), \phi \rangle \, d\tau \\ &= -\int_{-\infty}^{\infty} u(\tau) \left\langle \frac{\partial s_\tau}{\partial \tau}, \phi \right\rangle d\tau \\ &= -\int_{-\infty}^{\infty} u(\tau) \frac{\partial}{\partial \tau} \langle s_\tau, \phi \rangle \, d\tau \\ &= -\int_{-\infty}^{\infty} u(\tau) d \langle s_\tau, \phi \rangle , \end{aligned}$$

$$|\langle T(u), \phi \rangle| \leq \|u\|_\infty \operatorname*{var}_\tau \langle s_t, \phi \rangle \leq \|u\|_\infty \|s\|_{UBV} \|\phi\|_1 .$$

Therefore,

$$\|T(u)\|_\infty = \sup_{\substack{\phi \in K_1 \\ \|\phi\|_1 = 1}} |\langle T(u), \phi \rangle| \leq \|u\|_\infty \|s\|_{UBV} .$$

Finally, we prove that (1) implies (2). Let $\phi_1, \phi_2 \in K_1$, and let $\psi \in K_2$ be given by $\psi(t,\tau) = \phi_1(t)\phi_2(\tau)$. From Lemma 5.2,

$$\begin{aligned} \langle \{T(\delta_\tau)\}, \psi \rangle &= \int_{-\infty}^{\infty} \langle T(\delta_\tau), \phi_1 \rangle \, \phi_2(\tau) d\tau \\ &= \int_{-\infty}^{\infty} \tilde{T}(\phi_1)(\tau)\phi_2(\tau) d\tau \\ &= -\int_{-\infty}^{\infty} \left(\frac{d}{d\tau} \int_{-\infty}^{\infty} s(t,\tau)\phi_1(t)dt \right) \phi_2(\tau) d\tau \\ &= -\int_{-\infty}^{\infty} \phi_2(\tau) d \left(\int_{-\infty}^{\infty} s(t,\tau)\phi_1(t)dt \right) \\ &= -\int_{-\infty}^{\infty} \phi_1(t) \left(\int_{-\infty}^{\infty} \phi_2(\tau) ds_t(\tau) \right) dt \\ &= -\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \psi(t,\tau) ds_t(\tau) dt. \end{aligned} \tag{5.4}$$

From linearity and continuity of the functionals in (5.4) and from [6, p. 65], (5.4) holds for any $\psi \in K_2$. Thus Theorem 2.2(1) implies

$$\{T(\delta_\tau)\} = -\frac{\partial s}{\partial \tau} \in DUBV. \qquad \square$$

We now examine a certain extension of the operator T and its relation to $\tilde{T}_e$. Consider the closure L_0^∞ of $L_+^\infty \subset L^\infty$. It is easy to show that L_0^∞ is a closed proper subspace of L^∞ and

$$L_0^\infty = \left\{ f \in L^\infty \mid \operatorname*{ess\,sup}_{t\in(-\infty,-n]} |f(t)| \to 0 \text{ as } n \to \infty \right\}.$$

If T is stable, T extends uniquely to a continuous linear operator $T_0 : L_0^\infty \to L_0^\infty$. This extension can be taken further.

THEOREM 5.4. *Suppose $T : K_{1+}' \to K_{1+}'$ is a BIBO stable generalized integral operator, $s(\cdot,\tau) = T(\theta_\tau)$, and $\hat{s}_t(\tau) = s(t,\tau)$. Let $T_e : L^\infty \to L^\infty$ be the continuous linear operator defined by*

$$T_e(u)(t) = -\int_{-\infty}^{\infty} u(\tau) d\hat{s}_t(\tau).$$

Then

(1) *$T_e(u) = T_0(u)$ for all $u \in L_0^\infty$,*

(2) *T_e is the adjoint of $\tilde{T}_e$.*

Proof. (1) Let $u \in L_+^\infty$, $\phi \in K_1$. From Lemma 5.2,

$$\begin{aligned}
\langle T(u), \phi \rangle &= \int_{-\infty}^{\infty} u(\tau) \tilde{T}(\phi)(\tau) d\tau \\
&= \int_{-\infty}^{\infty} u(\tau) \langle T(\delta_\tau), \phi \rangle d\tau \\
&= -\int_{-\infty}^{\infty} u(\tau) \left\langle \frac{\partial s_\tau}{\partial \tau}, \phi \right\rangle d\tau \\
&= -\int_{-\infty}^{\infty} u(\tau) \frac{\partial}{\partial \tau} \langle s_\tau, \phi \rangle d\tau \\
&= -\int_{-\infty}^{\infty} u(\tau) d \langle s_\tau, \phi \rangle \\
&= -\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} u(\tau) \phi(t) d\hat{s}_t(\tau) dt.
\end{aligned}$$

Since ϕ is arbitrary,

$$T(u)(t) = -\int_{-\infty}^{\infty} u(\tau) d\hat{s}_t(\tau)$$

a.e. Since L_+^∞ is dense in L_0^∞, the result follows.

(2) Let $\phi \in L^1$ and $u \in L^\infty$. From Lemma 5.2,

$$\begin{aligned}\langle T_e(u), \phi\rangle &= \int_{-\infty}^{\infty} T_e(u)(t)\phi(t)dt \\ &= -\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} u(\tau)\phi(t)d\hat{s}_t(\tau)dt \\ &= -\int_{-\infty}^{\infty} u(\tau)d\int_{-\infty}^{\infty} s(t,\tau)\phi(t)dt \\ &= -\int_{-\infty}^{\infty} u(\tau)\left(\frac{d}{d\tau}\int_{-\infty}^{\infty} s(t,\tau)\phi(t)dt\right)d\tau \\ &= \int_{-\infty}^{\infty} u(\tau)\tilde{T}_e(\phi)(\tau)d\tau \\ &= \left\langle u, \tilde{T}_e(\phi)\right\rangle. \qquad \square\end{aligned}$$

To conclude, we give several equivalent expressions for the "gain" of a BIBO stable linear operator.

THEOREM 5.5. *For any BIBO stable generalized integral operator* $T : K'_{1+} \to K'_{1+}$,

$$\begin{aligned}\sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \|T(u)\|_\infty &= \sup_{\substack{u\in L^\infty\\ \|u\|_\infty=1}} \|T_e(u)\|_\infty \\ &= \sup_{\substack{\phi\in L^1\\ \|\phi\|_1=1}} \left\|\tilde{T}_e(\phi)\right\|_1 = \|\{T(\theta_\tau)\}\|_{UBV} = \|\{T(\delta_\tau)\}\|^e_{UL^1}.\end{aligned} \tag{5.5}$$

Proof. Let $v \in L^\infty, \|v\|_\infty = 1, v_n(\tau) = v(\tau)\theta(\tau+n)$, and $\varepsilon > 0$. From Theorem 5.4, for a.e. t there exists $N < \infty$ such that $n > N$ implies

$$\begin{aligned}|T_e(v)(t)| - |T(v_n)(t)| &\le |T_e(v)(t) - T(v_n)(t)| \\ &= \left|\int_{-\infty}^{-n} v(\tau)d\hat{s}_t(\tau)\right| \le \int_{-\infty}^{-n} |v(\tau)|\,|d\hat{s}_t(\tau)| \le \operatorname*{var}_{\tau\le -n} s(t,\tau) < \varepsilon.\end{aligned}$$

Hence,

$$\sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \|T(u)\|_\infty \ge \|T(v_n)\|_\infty \ge |T(v_n)(t)| > |T_e(v)(t)| - \varepsilon.$$

Since v, t, ε are arbitrary,

$$\sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \|T(u)\|_\infty \ge \sup_{\substack{\varepsilon>0\\ u\in L^\infty\\ \|u\|_\infty=1}} \operatorname*{ess\,sup}_t(|T_e(u)(t)| - \varepsilon) = \sup_{\substack{u\in L^\infty\\ \|u\|_\infty=1}} \|T_e(u)\|_\infty.$$

The second equality in (5.5) follows from Theorem 5.4(2). For the third equality, set

$$s(t,\tau) = T(\theta_\tau)(t).$$

From Lemma 5.2,

$$\tilde{T}_e(\phi)(\tau) = -\frac{d}{d\tau}\int_{-\infty}^{\infty} s(t,\tau)\phi(t)dt$$

for every τ, and

$$\left\|\tilde{T}_e(\phi)\right\|_1 = \int_{-\infty}^{\infty}\left|\frac{d}{d\tau}\int_{-\infty}^{\infty} s(t,\tau)\phi(t)dt\right| d\tau = \operatorname*{var}_{\tau}\int_{-\infty}^{\infty} s(t,\tau)\phi(t)dt.$$

From [7, Theorem 2.3.9],

$$\sup_{\substack{\phi\in L^1\\ \|\phi\|_1=1}}\left\|\tilde{T}_e(\phi)\right\|_1 = \|s\|_{UBV}\,.$$

The last equality in (5.5) follows from Theorems 3.7 and 4.3. □

WELL-POSEDNESS OF BOUNDARY CONTROL SYSTEMS*

ADA CHENG† AND KIRSTEN MORRIS‡

Abstract. Continuity of the input/output map for boundary control systems is shown through the system transfer function. Our approach transforms the question of continuity of the input/output map of a boundary control system to uniform boundedness of the solution to a related elliptic problem. This is shown for a class of boundary control systems with Dirichlet, Neumann, or Robin boundary control.

Key words. infinite-dimensional systems, boundary control, input/output stability

1. Introduction.

Boundary control systems are an important class of infinite-dimensional control systems. Some important applications are control of annealing processes, control of structural vibrations, and active noise control.

Key questions are whether the mappings from input to state, input to output, initial state to input, and initial state to final state are well defined and bounded. When all four mappings are well defined and bounded, the system is said to be well-posed [19]. Salamon [20] showed that boundedness of the input/output map implies well-posedness of the control system with respect to some state space. (An alternative proof in [14] uses frequency domain analysis.) Since boundedness is equivalent to continuity for linear systems, ill-posedness of the input/output map indicates that the measured outputs are not continuously dependent on the inputs. This would lead to difficulties in the practical implementation of any such control system. Often, however, ill-posedness of the control system indicates modelling errors. An example illustrating this point is given in this paper. Thus, showing boundedness of the input/output map of a boundary control system is important. This problem is the focus of this paper.

Boundedness of the initial to final state map is equivalent to showing existence of a semigroup and is fairly well understood. A number of authors have obtained results on boundedness of the state/output map and input/state map. For more details see, e.g., [3, 8, 9, 10, 11, 12, 15, 16]

The literature on showing boundedness of the input/output map is less extensive. One technique for determining well-posedness is to use spectral expansion of the underlying semigroup. This technique is applicable to showing boundedness of the input/state and state/output maps as well as the input/output map. For example, in [7] it was shown that several examples of boundary control systems with one space dimension were well-posed. In [6], it was shown that the one-dimensional heat equation with Dirichlet boundary control and point observation is well-posed under a suitable choice of state space. In [18], well-posedness of an accelerometer control system was shown. The spectral expansion method requires the availability of the

eigenvalues and eigenvectors of the system (or at least estimates). Also, the eigenvectors must form a Riesz basis. For many multidimensional problems it is difficult to calculate the eigenfunctions and eigenvalues of the underlying semigroup. Hence there are difficulties in extending this method to more general problems.

Well-posedness of a structural acoustic control system has been considered in [1, 2]. The authors use a state-space formulation of the control system. Partial differential equation results lead to estimates of the regularity of the resolvant and hence of the transfer function in state-space form.

Another method to determine boundedness of the input/output map uses the system transfer function. The concept of the transfer function for finite-dimensional systems extends to general well-posed systems. This is discussed in detail in the next section. Curtain and Weiss [6] showed that the input/output map is bounded if and only if the transfer function is uniformly bounded in a right half-plane. In several papers [6, 18, e.g.] well-posedness is established by showing that the system transfer function is bounded in some right-half-plane. The difficulty with this approach is that the transfer function has been rigorously obtained for only a few systems.

In [3], boundedness of the input/output map was shown for a class of structural control systems with point measurement of acceleration by showing that the system transfer function is proper. However, unlike the examples given above, justification for the transfer function was not computed directly. Instead, it was shown that the fact that the infinitesimal generator generates an analytic semigroup implies properness of the system transfer function.

In the next section systems theory for boundary control systems is discussed. The nature of the input/output map and the transfer function for these systems is explained. We give a representation for the system transfer function purely in terms of the boundary control formulation.

In section 3 we present our approach. The question of boundedness of the input/output map of a boundary control system is transformed to uniform boundedness (in a sense defined later) of solutions to a related elliptic boundary value problem. We use this approach to obtain well-posedness of several large classes of boundary control systems. Section 4 contains some background on elliptic boundary value problems. In sections 5 and 6 we show boundedness of the input/output map for a several large classes of problems with Dirichlet, Neumann, or Robin boundary control.

Our approach has several advantages. It is not necessary to compute a state-space realization. Also, the analysis of an elliptic problem is simpler than that of the original problem, and the extensive literature available on boundary value problems may be used. Our method is particularly useful for multidimensional systems with variable coefficients where the state-space realization is tedious to obtain and the system transfer function is even more difficult to obtain from the realization.

2. Transfer functions for boundary control systems. We will use the following formal definition of a *boundary control system*:

$$\left.\begin{array}{rll} \frac{d}{dt}z(t) & = Lz, & z(0) = z_0, \\ \Gamma z(t) & = u(t), & \\ y(t) & = Kz(t). & \end{array}\right\} \tag{2.1}$$

The operators $L \in \mathcal{L}(\mathcal{Z}, \mathcal{H})$, $\Gamma \in \mathcal{L}(\mathcal{Z}, \mathcal{U})$, and $K \in \mathcal{L}(\mathcal{Z}, \mathcal{Y})$. The spaces $(\mathcal{Z}, \|\cdot\|_{\mathcal{Z}}), (\mathcal{H}, \|\cdot\|_{\mathcal{H}})$, $(\mathcal{U}, \|\cdot\|_{\mathcal{U}}), (\mathcal{Y}, \|\cdot\|_{\mathcal{Y}})$ are all Hilbert spaces, and $\mathcal{Z}$ is a dense subspace of $\mathcal{H}$ with continuous, injective embedding $\iota_{\mathcal{Z}}$. The triple (L, Γ, K) refers to a boundary control system with output operator K. We shall often refer to a boundary

control system by the double (L, Γ). (The operator K is in this case understood to be the identity operator.) We will assume throughout this paper that a boundary control system (2.1) satisfies the following assumptions:

(A1) The operator Γ is onto, $\ker \Gamma$ is dense in $\mathcal{H}$, and there exists $\mu \in R$ such that $\ker(\mu I - L) \cap \ker\Gamma = 0$ and $\mu I - L$ is onto $\mathcal{H}$.

(A2) For any $z_0 \in \mathcal{Z}$ with $\Gamma z_0 = 0$, $u(\cdot) = 0$, there exists a unique solution of (Γ, L) in $C^1[0, T; \mathcal{H}] \cap C[0, T; \mathcal{Z}]$ depending continuously on z_0.

In this paper, we are solely interested in the boundedness of the input/output map from $u \in L^2(0, T; \mathcal{U})$ to $y \in L^2(0, T; \mathcal{Y})$.

DEFINITION 2.1. *The input/output map is bounded if for all times $T > 0$ and $u \in H^2(0, T; \mathcal{U})$, $z(0) = 0$, the output y is well defined and there is a constant c_T such that $\|y\|_{L^2(0,T;\mathcal{Y})} \le c_T \|u\|_{L^2(0,T;\mathcal{U})}$.*

This implies that the input/output map $u \to y$ can be extended to a bounded map on all of $L^2(0, T; \mathcal{U})$. Alternatively, one can describe the relationship between the inputs and the outputs using the Laplace transform.

DEFINITION 2.2. *Let $\hat{y}(s)$ indicate the Laplace transform of the output of a system and indicate similarly the transform of the input by $\hat{u}(s)$. The system transfer function is the operator $G(s)$ such that*

$$\hat{y}(s) = G(s)\hat{u}(s)$$

for all s, Re $s > \sigma$ *for some real σ.*

Implicit in this definition is that the input/output map is well defined and that the output is Laplace transformable. Boundedness of the input/output map can be determined using the system transfer function.

THEOREM 2.3 (see [6]). *Let (L, Γ, K) define a boundary control system. The input/output map of the system is bounded if and only if there exists a real number σ such that the transfer function $G(s)$ associated with (L, Γ, K) satisfies*

$$\sup_{\text{Re } s > \sigma} \| G(s) \|_{\mathcal{L}(\mathcal{U}, \mathcal{Y})} < \infty.$$

The function $G(s)$ is said to be proper *if the above inequality holds.*

We now consider the definition of a transfer function for a boundary control system in detail. First, consider a control system in state-space form:

$$\dot{z}(t) = Az(t) + Bu(t), \qquad z(0) = z_0, \tag{2.2}$$

$$y(t) = Cz(t), \tag{2.3}$$

where A is an infinitesimal generator of a C_0-semigroup $T(t)$ on state space $\mathcal{H}$. Also, B and C are bounded operators: $B \in \mathcal{L}(\mathcal{U}, \mathcal{H})$, $C \in \mathcal{L}(\mathcal{H}, \mathcal{Y})$. The input/output map is

$$y(t) = C \int_0^t T(t - \sigma) B u(\sigma)\, d\sigma. \tag{2.4}$$

Defining $g(t) = CT(t)B$, the output is simply the convolution of $g(t)$ and $u(t)$. Taking the Laplace transform on both sides of (2.4) gives

$$\hat{y}(s) = G(s)\hat{u}(s). \tag{2.5}$$

Here $G(s) = C(sI - A)^{-1}B$ is the system transfer function. Note that it is the Laplace transform of the function $g(t)$ that defines the input/output map. This is a direct generalization of the theory for finite-dimensional systems.

Any boundary control system can be written in state-space form (A, B, C) [19]. The operator A that generates the semigroup $T(t)$ in the state-space formulation is defined from the boundary control system as follows. Define

$$\mathcal{W} = \{\, z \in \mathcal{Z} \mid \Gamma z = 0 \,\}, \tag{2.6}$$

and let ι denote the canonical injection from $\mathcal{W}$ to $\mathcal{Z}$. Then $A = L\iota$ and $\mathcal{W} = [D(A)]$, the completion of $D(A)$ in the graph norm of A. Assumptions (A1) and (A2) imply that A generates a C_0-semigroup on $\mathcal{H}$. Techniques to define B and C also exist [19], but the input and output operators are generally unbounded on the state space. The linear operator $C \in \mathcal{L}(\mathcal{W}, \mathcal{Y})$ is defined by $C = K\iota$ and $C \in \mathcal{L}(\mathcal{W}, \mathcal{Y})$. The definition of B is more complicated and not needed here, but $B \in \mathcal{L}(\mathcal{U}, \mathcal{V})$ where $\mathcal{V} = [D(A^*)]'$, the dual space of $[D(A^*)]$. The operator A extends to an operator that generates a C_0-semigroup on $\mathcal{V}$ with domain $\mathcal{H}$. However, (2.3) is no longer well defined since $z(t)$ may not be in the domain of C.

In the following theorem we show that the output of a boundary control system is well defined, and that this output can be defined via the convolution of a Laplace-transformable distribution with the input. The following results will be required.

LEMMA 2.4 (see [19, Cor. 2.9]). *Let* (A1) *and* (A2) *be satisfied. Then for every $z_o \in \mathcal{Z}$ and every $u \in H^2(0,T;\mathcal{U})$, with $\Gamma z_o = u(0)$, there is a unique solution $z(\cdot) \in C(0,T;\mathcal{Z}) \bigcap C^1(0,T;\mathcal{H})$ of* (2.1).

THEOREM 2.5 (see [23, Theorem 6.5-1]). *Necessary and sufficient conditions for a function $G(s) \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$ to be the Laplace transform of a distribution whose support is bounded on the left at $t = 0$ are that* (1) *there exists some half-plane* $\operatorname{Re} s > \sigma$ *on which $G(s)$ is analytic and* (2) *that there is a polynomial P such that for* $\operatorname{Re} s > \sigma$

$$\|G(s)\|_{\mathcal{L}(\mathcal{U},\mathcal{Y})} \le P(|s|).$$

THEOREM 2.6. *The input/output map of any boundary control system* (2.1) *is well defined for all inputs $u \in H^2(0,T;\mathcal{U})$, $u(0) = 0$. This output can be written as*

$$y(t) = g(t) * u(t),$$

where $g(t)$ is a distribution with Laplace transform $G(s)$. Let $A = L\iota$ with domain as in (2.6). *The operator $G(s) \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$ for each $s \in \rho(A)$ and $G(s)$ is the system transfer function.*

Proof. First, as mentioned above, construct the state-space realization (A, B, C) using the procedure in [19]. Equation (2.2) is valid if we consider it as a differential equation on $\mathcal{V} = [D(A^*)]'$. Rewriting, we obtain, for any $\mu \in \rho(A)$,

$$\begin{aligned} z(t) &= (\mu I - A)^{-1}(\mu I - A)z(t) \\ &= (\mu I - A)^{-1}(\mu z(t) - \dot{z}(t)) + (\mu I - A)^{-1}Bu(t). \end{aligned} \tag{2.7}$$

For all initial conditions $z(0) = 0$ and smooth controls $u \in H^2(0,T;\mathcal{U})$ with $u(0) = 0$, the first term in (2.7) is in $\mathcal{W} \subset \mathcal{Z}$ for each time t (Lemma 2.4). Regarding A as a generator on $\mathcal{V}$ with domain $\mathcal{H}$, we obtain that $(\mu I - A)^{-1}B \in \mathcal{L}(\mathcal{U}, \mathcal{H})$. Furthermore, for any $\mu \in \rho(A)$, $\operatorname{Range}(\mu I - A)^{-1}B \subset \mathcal{Z}$ and so $(\mu I - A)^{-1}B \in \mathcal{L}(\mathcal{U}, \mathcal{Z})$ [19, Prop. 2.8]. Thus we may apply the operator K to the solution $z(t)$ to obtain the output $y(t)$:

$$y(t) = K(\mu I - A)^{-1}(\mu z(t) - \dot{z}(t)) + K(\mu I - A)^{-1}Bu(t). \tag{2.8}$$

Since $\mathcal{W} \subset \mathcal{Z}$, $K(\mu I - A)^{-1} \in \mathcal{L}(\mathcal{H}, \mathcal{Y})$ and $K(\mu I - A)^{-1}B \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$. Since both u and z are Laplace transformable, we now take the Laplace transform of both sides of (2.8) to obtain

$$\hat{y}(s) = K(\mu I - A)^{-1}(\mu - s)(sI - A)^{-1}B\hat{u}(s) + K(\mu I - A)^{-1}B\hat{u}(s).$$

The system transfer function is thus

$$G(s) = K(\mu I - A)^{-1}(\mu - s)(sI - A)^{-1}B + K(\mu I - A)^{-1}B.$$

Setting $\mu = s$, we obtain that

$$G(s) = K(sI - A)^{-1}B \tag{2.9}$$

for any $s \in \rho(A)$. (This is formula (2.18) for the *generalized transfer function* in [19].)

For $s \in \rho(A)$, $G(s)$ is analytic and so condition (1) in Theorem 2.5 is satisfied. Since the norm on $\mathcal{H}$ is equivalent to the graph norm of A (as a generator on $\mathcal{V}$) on $\mathcal{V}$, $\|(s - A)^{-1}B\|_{\mathcal{L}(\mathcal{U},\mathcal{H})} \leq M$ for some constant M and all Re $s > \sigma$ for some σ. Thus, there is a polynomial $P(s)$ such that G satisfies condition (2) in Theorem 2.5. It follows from Theorem 2.5 that $G(s)$ is the Laplace transform of a distribution $g(t)$; hence the output $y(t)$ is the convolution of this distribution and the input. □

This representation of the input/output map is valid for any boundary control system and for $u \in H^2(0, T; \mathcal{U})$ with $u(0) = 0$. In order to extend the input/output map to all $u \in L^2(0, T; \mathcal{U})$ we need to show that the map is bounded or, equivalently, that the transfer function is proper.

We now obtain a representation of the transfer function of a boundary control system. This representation is based entirely on the boundary control description (2.1) and does not require construction of a state-space realization. The transfer function is defined in terms of an elliptic problem associated with the boundary control system.

DEFINITION 2.7. *The* abstract elliptic problem $(L, \Gamma)_e$ *corresponding to the boundary control system* (L, Γ), *as defined in* (2.1), *is*

$$\left.\begin{array}{ll} Lz & = sz, \quad s \in \mathbb{C}, \\ \Gamma z & = u. \end{array}\right\} \tag{2.10}$$

We denote the solution $z \in \mathcal{Z}$ *by* $z(s)$.

DEFINITION 2.8. *Let* $\mathcal{T}(t)$ *be a* C_0*-semigroup on* $\mathcal{H}$. *The constant* α *defined by*

$$\alpha = \inf_{t>0} \frac{1}{t} \log \|\mathcal{T}(t)\|$$

is called the growth bound *of the semigroup* $\mathcal{T}(t)$.

Let α indicate the growth bound of the semigroup associated with (L, Γ). The elliptic problem (2.13) has a unique solution $z(s)$ for all u and Re $s > \alpha$. The system transfer function may be described through the solutions to the abstract elliptic problem (2.13).

THEOREM 2.9. *Let* (L, Γ, K) *define a boundary control system. Define* $\mathcal{W}, A,$ *and* $D(A)$ *be as above. Then there exists an* $\alpha \in \Re$ *such that the transfer function,* $G(s)$, *of the boundary control system* (L, Γ, K) *is given by*

$$G(s)u = Kz(s) \quad \textit{for all } s \in \mathbb{C}, \ \textit{with } \text{Re } s > \alpha, \tag{2.11}$$

where $z(s)$ *is the solution to the abstract elliptic problem* (2.10) *with input* u.

Proof. Let α denote the growth bound of the C_0-semigroup generated by A. Then for all $s \in \mathbb{C}$ with Re $s > \alpha$, $s \in \rho(A)$.

The transfer function $G(s)$ is given by (2.9). However, $(sI-A)^{-1}B$ is the solution operator of abstract elliptic problem (2.10) with input u [19, Prop. 2.8, eqn. 2.20].

Alternatively, for any given $u \in \mathcal{U}$, choose $z \in \mathcal{Z}$ so that $\Gamma z = u$. Then $G \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$ is defined by [19, Rem. 2.7]

$$G(s)\Gamma z = Kz - C(sI - A)^{-1}(sz - Lz). \tag{2.12}$$

For any $u \in \mathcal{U}$ and any $s \in \mathbb{C}$, with Re $s > \alpha$, let z solve the associated elliptic problem. From (2.12) we have

$$G(s)u = Kz(s).$$

This is precisely (2.11). □

Thus, the solution to (2.11) gives a representation of the transfer function of a boundary control system. The representation of $G(s)$ obtained above is not as surprising as the abstract elliptic problem (2.10) is the formal Laplace transform (with respect to t) of the boundary control system. Theorem 2.9 is a justification of such a process. Thus the abstract elliptic problem $(L, \Gamma)_e$ corresponding to the boundary control system (L, Γ) can be written as

$$\left.\begin{array}{rl} L\hat{z} &= s\hat{z}, \quad s \in \mathbb{C}, \\ \Gamma\hat{z} &= \hat{u}. \end{array}\right\} \tag{2.13}$$

As a simple example, we compute the transfer function for a heat transfer problem on a unit interval using (2.11).

Example 2.10 (one-dimensional heat equation with Neumann boundary control). One of the simplest examples of a well-posed boundary control system is the problem of temperature control in a one-dimensional rod of length 1 with a controlled heat flow at one end. The output is the temperature measured at x_1, $0 \le x_1 \le 1$. The system equations are

$$\left.\begin{array}{rcll} \frac{\partial z}{\partial t} &=& \frac{\partial^2 z}{\partial x^2}, & x \in [0,1], \\ z(x,0) &=& 0, & x \in [0,1], \\ \frac{\partial z}{\partial x}(0,t) &=& 0, & t > 0, \\ \frac{\partial z}{\partial x}(1,t) &=& u(t), & t > 0, \\ y(t) &=& z(x_1,t). & \end{array}\right\} \tag{2.14}$$

In this example,

$$\mathcal{Z} = \{z \in H^2(0,1); z'(0) = 0\},$$

with the norm inherited from $H^2(0,1)$, $\mathcal{U} = \mathcal{Y} = \Re$, and $\mathcal{H} = L^2(0,1)$. It is easy to verify that (A1) and (A2) are satisfied. The elliptic problem corresponding to (2.14) is

$$\left.\begin{array}{rcl} \frac{d^2\hat{z}}{dx^2} &=& s\hat{z}, \\ \hat{z}'(0) &=& 0, \\ \hat{z}'(1) &=& \hat{u}, \end{array}\right\} \tag{2.15}$$

with output equation

$$\hat{y} = \hat{z}(x_1).$$

The solution to the abstract elliptic problem is

$$\hat{z}(x,s) = \frac{\hat{u}\ \cosh(\sqrt{s}\ x)}{\sqrt{s}\ \sinh\sqrt{s}}.$$

For this problem, the growth bound $\alpha = 0$. By Theorem 2.9 we have for all $s \in \mathbb{C}$ with $\operatorname{Re} s > 0$ that the transfer function of the system is given by

$$\begin{aligned} G(s)\hat{u} &= K\left(\frac{\hat{u}\ \cosh(\sqrt{s}\ x)}{\sqrt{s}\ \sinh\sqrt{s}}\right) \\ &= \frac{\hat{u}\ \cosh(\sqrt{s}\ x_1)}{\sqrt{s}\ \sinh\sqrt{s}}. \end{aligned}$$

This is exactly the transfer function one would obtain by formally taking the Laplace transform of (2.14). Moreover, the transfer function is proper; hence the input/output map is bounded.

The following example shows that if the boundary condition is not chosen correctly, it leads to an improper system transfer function. Hence examining the nature of the input/output map is useful in determining whether the mathematical model of the system is sensible. Some choices of sensing or control operations also lead to improper transfer functions.

Example 2.11 (Euler–Bernoulli beam with Kelvin–Voigt damping). Consider the Euler–Bernoulli beam with Kelvin–Voigt damping. The beam is assumed to be fixed at $x = 0$ and free at $x = 1$. Then the equation governing the motion of the transverse displacement is

$$\left.\begin{array}{rcll} \frac{\partial^2 w}{\partial t^2} + \frac{\partial^2}{\partial x^2}\left[EI\frac{\partial^2 w}{\partial x^2} + c_d I\frac{\partial^3 w}{\partial x^2 t}\right] &=& 0, & x \in (0,1), \\ w(0,t) &=& 0, & t \geq 0, \\ \frac{\partial w}{\partial x}(0,t) &=& 0, & t \geq 0, \\ \frac{\partial^2 w}{\partial x^2}(1,t) &=& 0, & t \geq 0, \\ \frac{\partial^3 w}{\partial x^3}(1,t) &=& u(t), & t \geq 0, \\ y(t) &=& \frac{\partial w}{\partial t}(1,t), & \end{array}\right\} \tag{2.16}$$

where E, I, and c_d are positive constants. We shall compute the system transfer function via Theorem 2.9. First, we will rewrite the problem in the standard form (2.1). Define

$$z(x,t) = \begin{bmatrix} z_1(x,t) \\ z_2(x,t) \end{bmatrix} = \begin{bmatrix} w(x,t) \\ \frac{dw(x,t)}{dt} \end{bmatrix},$$

$$\begin{aligned} \frac{d}{dt}\begin{bmatrix} z_1 \\ z_2 \end{bmatrix} &= \begin{bmatrix} 0 & I \\ -EI\frac{d^4}{dx^4} & -c_d I\frac{d^4}{dx^4} \end{bmatrix}\begin{bmatrix} z_1 \\ z_2 \end{bmatrix}, \\ z_1'''(1,t) &= u(t), \\ y(t) &= z_2(1,t). \end{aligned}$$

For this problem,

$$\mathcal{Z} = \{(z_1, z_2) \in H^4(0,1) \times H^4(0,1); z_1(0) = z_1'(0) = z_1''(1) = 0\}.$$

The space $\mathcal{H} = \bar{H}^2(0,1) \times L^2(0,1)$, where

$$\bar{H}^2(0,1) = \{H^2(0,1); z(0) = z_1'(0) = 0\}$$

and $\mathcal{U} = \mathcal{Y} = R$. It can be verified that assumptions (A1) and (A2) are satisfied. The elliptic problem associated with (2.16) is, writing $w = z_1$ and noting that $\hat{z}_2 = s\hat{z}_1$,

$$\left.\begin{array}{rcl} (EI + sc_dI)\frac{\partial^4 \hat{w}}{\partial x^4} & = & -s^2\hat{w}, \\ \hat{w}'''(1) & = & \hat{u}. \end{array}\right\} \tag{2.17}$$

This is to be solved for $(\hat{w}, s\hat{w}) \in \mathcal{Z}$. The output equation $\hat{y} = s\hat{w}(1,s)$. The solution to the abstract elliptic problem is

$$\hat{w}(s,x) = A(s)\cosh(m(s)x) + B(s)\sinh(m(s)x) - A(s)\cos(m(s)x) - B(s)\sin(m(s)x),$$

where, letting $i = \sqrt{-1}$,

$$\begin{aligned} m(s) &= \sqrt{i}\left(\frac{s^2}{EI + sc_dI}\right)^{\frac{1}{4}}, \\ A(s) &= \frac{-\hat{u}(\sinh(m(s)) + \sin(m(s)))}{2m^3(s)(1 + \cosh(m(s))\cos(m(s)))}, \\ B(s) &= \frac{-A(s)(\cosh(m(s)) + \cos(m(s)))}{\sinh(m(s)) + \sin(m(s))}. \end{aligned}$$

Thus the system transfer function is

$$G(s) = \frac{s(\sinh(m(s))\cos(m(s)) - \cosh(m(s))\sin(m(s)))}{m^3(s)(1 + \cosh(m(s))\cos(m(s)))}.$$

One can show that for Re $s > 0$,

$$\lim_{|s|\to\infty} 4\exp\left(\sqrt{\frac{2}{i}}m(s)\right)(\sinh(m(s))\cos(m(s)) - \cosh(m(s))\sin(m(s))) = 1 - i,$$

$$\lim_{|s|\to\infty} 4\exp\left(\sqrt{\frac{2}{i}}m(s)\right)(1 + \cosh(m(s))\cos(m(s))) = 1.$$

Thus, for Re $s > 0$,

$$\lim_{|s|\to\infty} \frac{(\sinh(m(s))\cos(m(s)) - \cosh(m(s))\sin(m(s)))}{(1 + \cosh(m(s))\cos(m(s)))} = 1 - i.$$

Thus $G(s)$ is improper since $|\frac{s}{m^3(s)}|$ is unbounded as $|s| \to \infty$.

The appropriate boundary conditions should be on the bending moments and shear forces in the beam:

$$\begin{aligned} EI\frac{\partial^2 w}{\partial x^2} + c_dI\frac{\partial^3 w}{\partial x^2 t}(1,t) &= 0, \qquad t \geq 0, \\ EI\frac{\partial^3 w}{\partial x^3} + c_dI\frac{\partial^4 w}{\partial x^3 t}(1,t) &= u(t), \qquad t \geq 0. \end{aligned}$$

The original set of boundary conditions is incorrect since the moment M is equal to $\frac{\partial w^2}{\partial x^2}$ only when there is no damping in the system. With these boundary conditions, the resulting transfer function is

$$G(s) = \frac{s\Big(\sinh(m(s))\cos(m(s)) - \cosh(m(s))\sin(m(s))\Big)}{m^3(s)\Big(EI + sc_dI\Big)\Big(1 + \cosh(m(s))\cos(m(s))\Big)}.$$

Now $G(s)$ is proper since

$$\lim_{|s|\to\infty} \frac{s}{m^3(s)(EI + sc_dI)} = 0.$$

3. Boundedness of the input/output map. Theorem 2.3 implies that the boundedness of the input/output map of a boundary control system can be determined from the properness of the system transfer function. For a given observation operator K, the properness of the transfer function depends entirely on the behavior of the solution to $(L,\Gamma)_e$ as the parameter s varies.

Since we will henceforth be working entirely with the Laplace transform, we shall drop the " ˆ "notation in the interest of clarity. The following theorem provides a sufficient condition for the properness of the transfer function of a boundary control system.

DEFINITION 3.1. *Let $(\mathcal{V}, \|\cdot\|_{\mathcal{V}})$ be a normed linear space with $\mathcal{V} \subset \mathcal{H}$. We say that the solution, $\hat{z}(s)$, to the abstract elliptic problem* (2.13) *is* uniformly bounded with respect to the $\mathcal{V}$ norm *if there exist constants $\mu_1 \in \Re$ and $M \in \Re^+$ such that*

$$\|z(s)\|_{\mathcal{V}} \le M\|u\|_{\mathcal{U}} \tag{3.1}$$

for all $u \in \mathcal{U}$ and for all $s \in \mathbb{C}$ with Re $s > \mu_1$.

The following sufficient condition for properness of the system transfer function is now immediate.

THEOREM 3.2. *Let (L,Γ,K) define a boundary control system. Let $\mathcal{V}$ be a normed linear space satisfying $\mathcal{Z} \subset \mathcal{V} \subset \mathcal{H}$. If the solution to $(L,\Gamma)_e$ is uniformly bounded with respect to the $\mathcal{V}$ norm, then for all observation operators $K \in \mathcal{L}(\mathcal{V},\mathcal{Y})$, the transfer function associated with the boundary control system (L,Γ,K) is proper.*

Proof. By assumption there exist constants μ_1 and M such that inequality (3.1) holds. Let A be as defined in Theorem 2.9 with growth bound ω_0. Choose $\mu = \max\{\mu_1, \omega_0\}$ and the result follows. □

Thus, continuity of the input/output map of a boundary control system can be established by determining uniform boundedness of the solution $z(s)$ to a family of elliptic problems. Continuity of the input/output map can be established without an explicit representation of the transfer function. Also, Theorem 3.2 states that uniform boundedness of the solution to the elliptic problem $(L,\Gamma)_e$ in the $\mathcal{V}$ norm implies boundedness of the input/output map for the class of boundary control systems $\{(L,\Gamma,K) \mid K \in \mathcal{L}(\mathcal{V},\mathcal{Y})\}$. This is advantageous since there exist a large literature of results on solutions to elliptic partial differential equations, although not on uniform boundedness of the solution. A major advantage of this approach is that it is not required to compute the linear operators (A,B,C) of a state-space realization.

Example 3.3 (one-dimensional heat equation with Neumann boundary control continued). The solution to the corresponding elliptic problem is

$$z(x,s) = \frac{u\ \cosh(\sqrt{s}\ x)}{\sqrt{s}\ \sinh\sqrt{s}}.$$

Let $\mathcal{V} = H^1(0,1)$, $\mathcal{U} = \Re$, and $\mu_1 = 1$. Then for all $s \in \mathbb{C}$ with Re $s > 1$ we have

$$\|z\|^2_{L^2(0,1)} \leq \frac{|u|^2 \cosh 2}{16 \sinh 2} + \frac{|u|^2}{8 \sinh^2 2},$$
$$\left\|\frac{dz}{dx}\right\|^2_{L^2(0,1)} \leq \frac{|u|^2 \cosh 2}{2 \sinh 2} + \frac{|u|^2}{2 \sinh^2 2.}$$

Hence $\|z\|_{H^1(0,1)} \leq \sqrt{\frac{2 \cosh 2}{\sinh 2}}|u|$. Thus by Theorem 3.2, the input/output map is bounded for all $\mathcal{K} \in \mathcal{L}(\mathcal{H}^1(0,1), \Re)$. In particular, this holds for $Kz = z(x_1, t)$.

We now provide some conditions for uniform boundedness of the solution to $(L,\Gamma)_e$ with respect to $\mathcal{V}$ by rewriting $(L,\Gamma)_e$ as two subproblems.

PROPOSITION 3.4. *Let (L,Γ) define a boundary control system as in* (2.1) *and let $\mathcal{V}$ be a normed linear space satisfying $\mathcal{Z} \subset \mathcal{V} \subset \mathcal{H}$. Let $\mu \in \Re^+$ and $\mu \notin \sigma(L)$ (spectrum of L), and define the problems $(L,\Gamma)_{e1}$ and $(L,\Gamma)_{e2}$ by*

$$(L,\Gamma)_{e1} := \begin{cases} Lf = \mu f, \\ \Gamma f = u. \end{cases} \tag{3.2}$$

$$(L,\Gamma)_{e2} := \begin{cases} Lw = sw + (s-\mu)f, & s \in \mathbb{C}, \\ \Gamma w = 0. \end{cases} \tag{3.3}$$

The solution to $(L,\Gamma)_e$ is uniformly bounded with respect to the $\mathcal{V}$ norm if the following two conditions hold:

1. *There exists $f \in \mathcal{Z}$ such that f solves $(L,\Gamma)_{e1}$ and*

$$\|f\|_{\mathcal{V}} \leq C_1 \|u\|_{\mathcal{U}} \tag{3.4}$$

   for some positive constant C_1.
2. *Let $f \in \mathcal{Z}$ denote the solution to $(L,\Gamma)_{e1}$. There exists $w \in \mathcal{Z}$ such that w solves $(L,\Gamma)_{e2}$ and*

$$\|w\|_{\mathcal{V}} \leq C_2 \|f\|_{\mathcal{V}} \tag{3.5}$$

   for some positive constant C_2, independent of s.

Proof. The result is immediate by noting that $w + f$ solves the original elliptic problem $(L,\Gamma)_e$. ∎

4. Uniformly elliptic boundary value problems. In the remaining sections, we shall look at boundedness of solutions to uniformly elliptic boundary value problems. We concentrate on linear second order differential operators. Unfortunately, the traditional estimates on solutions to elliptic problems of the form (2.10) are dependent on the argument s. Our focus lies in obtaining estimates that are independent of s. We begin with some background theory and then show that under certain standard assumptions, solutions to uniformly elliptic boundary value problems of order 2 with either Dirichlet, Neumann, or Robin boundary control are uniformly bounded. The results generalize to higher order uniformly elliptic operators [5].

Let Ω be an open set in $\Re^n$. A linear second order differential operator in Ω is defined by

$$L(x,D) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}(x) D_{ij} + \sum_{j=1}^{n} c_j(x) D_j + d(x). \tag{4.1}$$

We assume that the coefficients are sufficiently smooth and that the operator L is uniformly elliptic in Ω. More precisely,

[H1a] (smoothness condition 1) The coefficients $a_{ij}(x)$ are bounded and absolutely continuous in $\bar{\Omega}$, and the remaining coefficients are bounded and measurable in Ω.

[H1b] (uniform ellipticity) Define the principal part of L by

$$L^0(x,D) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}(x)D_{ij} = D'A(x)D,$$

where $A(x)$ is an $n \times n$ positive definite matrix with components $a_{ij}(x)$. We assume that L is *uniformly elliptic in* Ω. That is, there exists a positive constant c_L such that for all $x \in \Omega$, $\xi \in \Re^n$,

$$L^0(x,\xi) \geq c_L|\xi|^2.$$

Our analysis is based on the boundary control system formulation. We shall no longer refer to the state-space realization. The boundary operator Γ is defined by

$$\Gamma(x,D) = b_0(x) + \sum_{i=1}^{n} b_{1i}(x)D_i = b_0(x) + B_1'(x)D, \tag{4.2}$$

where $B_1'(x) = \big(b_{11}(x),\ldots,b_{1n}(x)\big)$ and $D' = (D_1,\ldots,D_n)$. So $B_1'(x) = 0$ for Dirichlet boundary control and $b_0(x) = 0$ for Neumann boundary control. We impose the following condition on the operator Γ:

[H2] (smoothness condition 2) The coefficients of Γ are real. Also, $b_0(x) \in C^2(\partial\Omega)$ and $b_{1i}(x) \in C^1(\partial\Omega)$ for $i = 1,\ldots,n$.

Estimates of the solution to a uniformly elliptic boundary value problem depend on regularity of the region Ω.

DEFINITION 4.1 (see [4]). *Let Ω be an open set in $\Re^n$ with boundary $\partial\Omega$. Then Ω is said to be* uniformly regular of class C^m *if there exists a family of open sets $\{O_i\}$ of $\Re^n$ and of homeomorphisms $\{\Phi_i\}$ of O_i onto the unit ball $\{y : \|y\| < 1\}$ in $\Re^n$ and an integer N such that the following conditions are satisfied:*

[UR1] *For each i,*

$$\Phi_i(O_i \cap \Omega) = \{y \ : \ \|y\| < 1, y_1 > 0\},$$
$$\Phi_i(O_i \cap \partial\Omega) = \{y \ : \ \|y\| < 1, y_1 = 0\}.$$

[UR2] *Let $O_i' = \Phi_i^{-1}(\{y \in \Re^n : \|y\| < 1/2\})$. Then $\bigcup_{i=1}^{\infty} O_i'$ contains the $1/N$ neighborhood of $\partial\Omega$.*

[UR3] *Any $(N+1)$ distinct sets of $\{O_i\}$ have an empty intersection.*

[UR4] *Let $\Psi_i = \Phi_i^{-1}$. Then Ψ_i, Φ_i are mappings of class C^m. Let Φ_{ik}, Ψ_{ik} be the kth components of Φ_i, Ψ_i, respectively. Then*

$$|D^\alpha \Phi_{ik}(x)| \leq M, \quad |D^\alpha \Psi_{ik}(y)| \leq M, \quad |\Phi_{i1}(x)| \leq M\mathrm{dist}(x,\partial\Omega)$$

for $|\alpha| \leq m$, $x \in O_i$, $\|y\| < 1, k = 1,\ldots,n$, and $i = 1,2,\ldots$.

In general, it is nontrivial to show that a region is uniformly regular of class C^m. For our work, we are concerned only with bounded sets Ω in $\Re^n$ and cylinders of the form $\Omega \times \Re$ in $\Re^{n+1}$. It was stated without details in [22, p. 237] that for bounded sets with sufficiently smooth boundary, there exist mappings $\{\Phi_i\}$ such that [UR2] holds. We give a more complete discussion of this point. If Ω is bounded, then there

is a finite open cover for the boundary. If the boundary is sufficiently smooth, then it is possible to choose a covering such that [UR1] and [UR2] hold. Conditions [UR3] and [UR4] then hold trivially since the covering is finite. Thus we have the following result.

THEOREM 4.2. *If Ω is bounded with sufficiently smooth boundary, then $\Omega \times \Re$ is also uniformly regular.*

In addition to [H1a], [H1b], and [H2], we assume, unless stated otherwise, that Ω, L, and Γ also satisfy the following:

[H3] Ω is bounded and uniformly regular of class C^2.

[H4] (root condition) Let $L^0(x, D)$ denote the principal part of $L(x, D)$. For every pair of linearly independent real vectors ξ and η, the polynomial $L^0(x, \xi+\tau\eta)$ in τ has an equal number of roots with positive and negative imaginary parts.

[H5] (complementing condition) Let $B^0(x,D)$ denote the principal part of $\Gamma(x,D)$. Let x be an arbitrary point on $\partial\Omega$ and n be the outward normal unit vector to $\partial\Omega$ at x. For each tangential vector $\xi \neq 0$ to $\partial\Omega$ at x, let $\hat{\tau}$ be the root of the polynomial $L^0(x, \xi + \tau n)$ with positive imaginary part. Then $\hat{\tau}$ is not a root of $B^0(x, \xi + \tau n)$.

If $n \geq 3$, then the root condition is satisfied for all uniformly elliptic operators [21, p. 130]. If the coefficients of L are real, then the root condition is also satisfied when $n = 2$.

5. Uniformly elliptic operators with Dirichlet boundary control. It is well known that the one-dimensional heat equation on a unit interval with Dirichlet boundary control and point observations is not well-posed with respect to the usual choice of state space $L^2(0, 1)$ [6]. Thus, showing well-posedness of more general Dirichlet control problems with state-space methods is hampered by the difficulty of first obtaining an appropriate state space.

In this section we will show that a class of control problems with Dirichlet boundary control do have a bounded input/output map by showing that the associated elliptic problem is uniformly bounded and hence the transfer function is proper.

Let $\Omega \subset \Re^n$, $n = 1, 2, 3$, let L be a second order differential operator as defined in (4.1) with $d(x) \leq 0$, and define the boundary operator to be

$$\Gamma(x, D) = b_0(x), \quad b_0(x) \neq 0 \qquad \text{for all } x.$$

We shall show that if Ω, L, Γ satisfy hypotheses [H1]–[H5] and Ω satisfies an additional assumption, then the solution to the abstract elliptic problem

$$\left.\begin{array}{rcll} Lz & = & sz & \text{in } \Omega, \\ \Gamma z & = & u & \text{on } \partial\Omega \end{array}\right\} \tag{5.1}$$

is uniformly bounded with respect to the $\sup_{x\in\Omega} |\cdot|$ norm. This will imply boundedness of the input/output map for the corresponding boundary control system. The following definition is due to Browder [4].

DEFINITION 5.1. *Let Ω be an open set in $\Re^n$. If for any $a \in \partial\Omega$ the part of Ω, $\partial\Omega$ in some neighborhood of a is expressed as*

$$x_i > \psi(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n), \qquad x_i = \psi(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n),$$

respectively, for some $i = 1, \ldots, n$ and a C^{2m} function ψ, then Ω is called locally regular of class C^{2m}.

In addition to uniformly regularity of class C^2, we further assume the following:

[H6] Ω is locally regular of class C^4.

We will use Proposition 3.4 to show that the solution to the elliptic Dirichlet problem is uniformly bounded in the $C(\Omega)$-norm. The following result will be used to show that the solution to the subproblem $(L,\Gamma)_{e2}$ satisfies the second condition in Proposition 3.4.

THEOREM 5.2 (see [21, p. 216]). *Let $F \in C(\bar{\Omega})$ and consider*

$$\begin{aligned} Lw &= sw + F && \text{in } \Omega, \\ \Gamma w &= 0 && \text{on } \partial\Omega. \end{aligned}$$

The solution w exists, and $w \in C(\Omega)$. Furthermore, we have

$$\sup_{x\in\Omega} |w(x)| \le \frac{C}{|s|} \sup_{x\in\Omega} |F(x)|. \tag{5.2}$$

To prove boundedness of the input/output map we also require the maximum principle and existence of a solution to $Lf = 0$ with a Dirichlet boundary condition. This will be used to show that the first condition in Proposition 3.4 holds.

The following theorem is an immediate consequence of Theorems 8.6 and 8.12 in [13]. (The assumptions imposed on L and Ω in [13] are weaker than [H1]–[H6].)

THEOREM 5.3. *Let L and Ω satisfy assumptions* [H1]–[H6], *$\mu \in \Re^+$, $\mu \notin \sigma(L)$ be fixed, and $u \in H^2(\Omega)$; then there exists a unique $f \in H^2(\Omega)$ that solves*

$$\begin{aligned} Lf &= \mu f && \text{in } \Omega, \\ f &= u && \text{on } \partial\Omega. \end{aligned} \tag{5.3}$$

Proof. For $u \in H^1(\Omega)$, Theorem 8.6 in [13] guarantees that (5.3) has a unique (weak) solution $f \in H^1(\Omega)$. Since [H1]–[H3] hold and $u \in H^2(\Omega)$, by Theorem 8.12 in [13] the solution is in $H^2(\Omega)$. ∎

The norm $[\cdot]_{q-1/2,\partial\Omega}$ is defined by

$$[u]_{q-1/2,\partial\Omega} = \inf\{\|z\|_{H^q(\Omega)}; z \in H^q(\Omega), z = u \text{ on } \partial\Omega\}. \tag{5.4}$$

The space $H^{q-\frac{1}{2}}(\partial\Omega)$ is the space of functions defined on $\partial\Omega$ such that this norm is finite. For $u \in H^{q-\frac{1}{2}}(\partial\Omega)$, u may be extended to $\tilde{u} \in H^q(\Omega)$ such that $\tilde{u}|_{\partial\Omega} = u$ and $\|\tilde{u}\|_{H^q(\Omega)} = [u]_{q-1/2,\partial\Omega}$.

COROLLARY 5.4. *Let L and Ω satisfy assumptions* [H1]–[H6]. *For any $\mu \in \Re^+$, $\mu \notin \sigma(L)$, and $u \in H^{\frac{3}{2}}(\partial\Omega)$, there exists a unique $f \in H^2(\Omega)$ that solves*

$$\begin{aligned} Lf &= \mu f && \text{in } \Omega, \\ b_0(x) f &= u && \text{on } \partial\Omega. \end{aligned} \tag{5.5}$$

Proof. Since $b_0(x) \in C^2(\partial\Omega)$ and $b_0(x) \neq 0$ for all $x \in \partial\Omega$, we have $\tilde{u} = \frac{u}{b_0} \in H^{\frac{3}{2}}(\partial\Omega)$. Thus it can be extended to an element in $H^2(\Omega)$ which we shall denote by the same symbol. By Theorem 5.3 there exists a unique $f \in H^2(\Omega)$ that solves

$$\begin{aligned} Lf &= \mu f && \text{in } \Omega, \\ f &= \tilde{u} && \text{on } \partial\Omega. \end{aligned}$$ ∎

The following maximum principle is required. The stated assumptions are stronger than those given in [13].

THEOREM 5.5 (see, e.g., [13, Thm. 8.1]). *Let $f \in H^2(\Omega)$ satisfy $Lf - \mu f = 0$ in Ω. Then*

$$\sup_{x\in\Omega} f(x) \le \sup_{x\in\partial\Omega} \max\{f(x), 0\}.$$

We can now state our main theorem for this section. It implies in particular that Dirichlet boundary control with point observation is a well-posed control system.

THEOREM 5.6. *Consider the pair L, Γ with Dirichlet control $\Gamma = b_0(x)$. Assume that assumptions* [H1]–[H6] *are satisfied on the region Ω. The operators L, Γ define a boundary control system with $\mathcal{U} = H^{\frac{3}{2}}(\partial\Omega)$, $\mathcal{Z} = H^2(\Omega)$, and $\mathcal{H} = L^2(\Omega)$. The input/output map of the boundary control system* (5.1) *is bounded for all observation operators $K \in \mathcal{L}(C(\Omega), \mathcal{Y})$.*

Proof. Let $\mu \in \Re^+$ and $\mu \notin \sigma(L)$, and write (L, Γ) as $(L, \Gamma)_{e1}$ and $(L, \Gamma)_{e2}$ as in Proposition 3.4. We will use $\mathcal{V} = C(\Omega)$. Since $\Omega \subset R^n$, $n \le 3$, Sobolev's imbedding theorem, e.g., [21, Thm. 3.20], implies that $\mathcal{V} \subset \mathcal{Z}$. Define $C_1 = \sup_{x\in\partial\Omega} \frac{1}{|b_0(x)|}$. Using Theorem 5.5, we have

$$\begin{aligned}\sup_{x\in\Omega} |f(x)| &\le \sup_{x\in\partial\Omega} |f(x)| \\ &\le C_1 \sup_{x\in\partial\Omega} |u(x)| \\ &\le C_1 \|u\|_{H^{\frac{3}{2}}}.\end{aligned}$$

The latter inequality also follows from Sobolev's imbedding theorem. Thus, the solution to the subproblem $(L, \Gamma)_{e1}$ satisfies inequality (3.4). Inequality (3.5) then follows from inequality (5.2). Therefore, by Theorem 3.2 the system transfer function associated with (L, Γ, K) is proper for all observation operators $K \in \mathcal{L}(C(\Omega), \mathcal{Y})$. That is, the input/output map of the boundary control system (L, Γ, K) is bounded. ∎

6. Uniformly elliptic operators with Neumann or Robin boundary control. In this section we will show that a class of control problems with Neumann/Robin boundary control have a bounded input/output map. In the interests of clarity and brevity we will give only the proofs for second order elliptic operators. The generalization to higher order operators is straightforward. Details are in [5].

In special cases results have been obtained to these problems by transforming the boundary control system to state-space form and then using the analyticity of the underlying semigroup to show well-posedness of the input/output map. The transformation to state-space form is not necessary. As for Dirichlet problems, well-posedness for general Neumann problems is shown by direct analysis of the boundary control formulation.

Let L and Γ be defined as in (4.1) and (4.2). In this section we will assume $B_1'(x) \neq 0$. Hence Γ represents a Neumann boundary control when $b_0(x) = 0$ and a Robin boundary control otherwise. We shall show that if Ω, L, and Γ satisfy hypotheses [H1]–[H5], then the solution to the abstract elliptic problem is uniformly bounded with respect to the $H^1(\Omega)$ norm. This implies boundedness of the input/output map for the corresponding boundary control system.

It is not enough to use regularity of the solution to elliptic problems. We must show that the solution is uniformly bounded in the parameter s. We first state two theorems concerning estimates of solutions to elliptic problems. These theorems are key to showing uniform boundedness of solutions to Neumann/Robin boundary control problems.

THEOREM 6.1 (see [21, Thm. 4.10]). *Let Ω be uniformly regular of class C^2 and $L(x,D)$, $B(x,D)$ be defined as in* (4.1) *and* (4.2). Assume that $L(x,D)$ and $\Gamma(x,D)$ satisfy assumptions [H2]–[H5]. Then there exists a positive constant m_1 such that for all $z \in H^2(\Omega)$ the following inequality holds:

$$\|z\|_{H^2(\Omega)} \leq m_1 \left[\|Lz\|_{L^2(\Omega)} + [\Gamma z]_{1/2,\partial\Omega} + \|z\|_{L^2(\Omega)} \right]. \tag{6.1}$$

THEOREM 6.2 (see [21, Lem. 5.7]). *Let L, Γ and Ω be as defined in* (4.1) *and* (4.2)*, and assume that they satisfy assumptions* [H1]–[H5]. *Let $\theta \in [-\pi, \pi)$ be fixed but arbitrary and t be a new real variable. Set*

$$Q = \Omega \times \Re,$$
$$\mathcal{L}_\theta(x,D) = \mathcal{L}_\theta(x,D_x,D_t) = L(x,D_x) + \exp(i\theta) D_t^2,$$

and define $\mathcal{B}(x,D_x)$ to be the extension of $\Gamma(x,D_x)$ to $\partial Q = \partial\Omega \times \Re$. If $\mathcal{L}_\theta, \mathcal{B}, Q$ also satisfy [H1]–[H5]*, then there exists a constant M_θ such that for any $z \in H^2(\Omega)$, $u \in H^{2-m_j}(\Omega)$[1] satisfying $\Gamma z = u$ on $\partial\Omega$ and any s satisfying* arg $s = \theta$, $|s| > M_\theta$, *the following inequality holds:*

$$|s|^{1/2} \|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \leq M_\theta \left[\|(L-s)z\|_{L^2(\Omega)} + |s|^{1-m_j/2} \|u\|_{L^2(\Omega)} + \|u\|_{H^{2-m_j}(\Omega)} \right]. \tag{6.2}$$

The outline of the proof is as follows: For any $\theta \in [-\pi, \pi)$, define $Q, \mathcal{L}_\theta$, and $\mathcal{B}$ by

$$\left.\begin{array}{rcl} Q & := & \Omega \times \Re, \\ \mathcal{L}_\theta(x,D) = \mathcal{L}_\theta(x,D_x,D_t) & := & L(x,D_x) + \exp(i\theta) D_t^2, \text{ and} \\ \mathcal{B}(x,D_x) & := & \text{the extension of } \Gamma(x,D_x) \text{ to } \partial Q = \partial\Omega \times \Re. \end{array}\right\} \tag{6.3}$$

From Theorem 6.2 we know that if $\{L, \Gamma, \Omega\}$ and $\{\mathcal{L}_\theta, \mathcal{B}, Q\}$ both satisfy [H1]–[H5], then there exists a constant M_θ such that the following a priori estimate holds for any $z \in H^2(\Omega)$, $u \in H^1(\Omega)$ satisfying $\Gamma z = u$ on $\partial\Omega$ and any s satisfying arg $s = \theta$, $|s| > M_\theta$, $\theta \in [-\pi, \pi)$:

$$|s|^{1/2} \|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \leq M_\theta \left[\|(L-s)z\|_{L^2(\Omega)} + |s|^{1/2} \|u\|_{L^2(\Omega)} + \|u\|_{H^1(\Omega)} \right].$$

If z solves $Lz = sz$, then

$$\|z\|_{H^1(\Omega)} \leq M_\theta \left(\|u\|_{L^2(\Omega)} + \frac{1}{|s|^{1/2}} \|u\|_{H^1(\Omega)} \right).$$

If in addition $|s| > 1$, then

$$\|z\|_{H^1(\Omega)} \leq 2M_\theta \|u\|_{H^1(\Omega)}.$$

We will show that for $\theta \in [-\pi/2, \pi/2]$, M_θ can be chosen independently of θ. This will imply that the solution to the elliptic problem is uniformly bounded with respect to the H^1-norm and thus the input/output map is bounded for any observation operator $K \in \mathcal{L}(\mathcal{H}^1(\Omega), \mathcal{Y})$.

[1] m_j=0 if Γ is the Dirichlet boundary condition, and $m_j = 1$ if Γ is a Neumann or Robin boundary condition.

First we show that Q is uniformly regular of class C^2 and for each $\theta \in [-\pi/2, \pi/2]$, $\mathcal{L}_\theta, \mathcal{B}, Q$ satisfy assumptions [H1], [H2], [H4], and [H5]. This ensures the existence of M_θ.

LEMMA 6.3. *Let $L(x, D_x), \Gamma(x, D_x)$, and Ω satisfy assumptions* [H1]–[H5]. *For any $\theta \in [-\pi/2, \pi/2]$, define $\mathcal{L}_\theta, \mathcal{B}$, and Q be as in* (6.3). *Then Q is uniformly regular of class C^2 and $\{\mathcal{L}_\theta, \mathcal{B}\}$ satisfy assumptions* [H1], [H2], [H4], *and* [H5] *in Q.*

Proof. Since Ω satisfies [H3], Q is uniformly regular. Next we show that $\mathcal{L}_\theta$ is uniformly elliptic. That is, there exists a positive constant c_1 such that for all $(\xi, \eta) \in \Re^n \times \Re$ and $x \in \Omega$ the following inequality holds:

$$|\mathcal{L}_\theta^0(x, \xi, \eta)| \geq c_1 \left(|\xi|^2 + \eta^2\right).$$

By assumption, there exists a positive constant c_L such that for all $x \in \Omega$, $\xi \in \Re^n$

$$|L^0(x, \xi)| \geq c_L |\xi|^2.$$

Since the matrix A associated with L^0 is positive definite, this means $L^0(x, \xi) \geq 0$ for all $x \in \Omega$ and $\xi \in \Re^n$. Let $c = \min\{c_L^2, 1\}$. Then for any $(x, t) \in \Omega \times \Re$, $(\xi, \eta) \in \Re^n \times \Re$, and $\theta \in [-\pi/2, \pi/2]$, we have

$$\begin{aligned}
\left|\mathcal{L}_\theta^0\big((x, t), (\xi, \eta)\big)\right|^2 &= |L^0(x, \xi) + \exp(i\theta)\eta^2|^2 \\
&= |L^0(x, \xi)|^2 + 2\cos(\theta) L^0(x, \xi)\eta^2 + \eta^4 \\
&\geq c_L^2 |\xi|^4 + \eta^4 \\
&\geq c\left(|\xi|^4 + \eta^4\right) \\
&\geq \frac{c}{2}\left(|\xi|^4 + 2|\xi|^2\eta^2 + \eta^4\right) \\
&= \frac{c}{2}\left(|\xi|^2 + \eta^2\right)^2.
\end{aligned}$$

This implies the inequality

$$|\mathcal{L}_\theta^0(x, \xi, \eta)| \geq \sqrt{\frac{c}{2}}\left(|\xi|^2 + \eta^2\right),$$

which proves that $\mathcal{L}$ is uniformly elliptic in Q. Clearly [H2] holds. Also since $n \geq 2$, $n + 1 \geq 3$, the root condition holds. It remains to show that [H5] is satisfied. Let (x, t) be an arbitrary point on ∂Q, n_1 be the unit outward normal vector to $\partial\Omega$ at x, and ξ_1 be any nonzero tangential vector to $\partial\Omega$ at x. The outward normal unit vector to ∂Q at (x, t) is then $n = (n_1', 0)$ and any nonzero tangential vector has the form $\xi = (\xi_1', 0)$. Let $\hat{\tau}$ be a root of $\bar{B}^0(x, \xi + \tau n)$. Then $\hat{\tau}$ is a root of $B^0(x, \xi_1 + \tau n_1)$, which by assumption is not a root of $L^0(x, \xi_1 + \tau n_1)$. This implies that

$$\mathcal{L}(x, \xi + \hat{\tau} n) = L(x, \xi_1 + \hat{\tau} n_1) + \exp(i\theta)(\xi_2 + \hat{\tau} n_2)^2 = L(x, \xi_1 + \hat{\tau} n_1) \neq 0.$$

Hence $\hat{\tau}$ is not a root of $\mathcal{L}(x, \xi + \hat{\tau} n)$. So $\{\mathcal{L}, \mathcal{B}\}$ satisfies [H5]. ∎

For each $\theta \in [-\pi/2, \pi/2]$, $\mathcal{L}, \mathcal{B}, Q$ satisfy [H1], [H2], [H4], and [H5]; thus the hypotheses of Theorem 6.2 have been justified. It remains to show that M_θ may be chosen independent of θ in this range. The following lemma is needed to prove this claim.

LEMMA 6.4. *Let $\mathcal{L}_\theta(x, D)$ be defined as in* (4.1). *Then $\mathcal{L}_\theta$ is continuous in θ. That is, for any $\epsilon > 0$, there exists $\delta > 0$ such that whenever $|\theta_1 - \theta_2| < \delta$, $\theta_1, \theta_2 \in [-\pi/2, \pi/2]$ we have*

$$\|\mathcal{L}_{\theta_1} v - \mathcal{L}_{\theta_2} v\|_{L^2(Q)} < \epsilon \|v\|_{H^2(Q)} \qquad \text{for all } v \in H^2(Q).$$

Proof. For any $0 < \epsilon < \sqrt{2}$, choose $\delta = \arccos(1 - \frac{\epsilon^2}{2})$, where arccos denotes the principal branch; then if $|\theta_1 - \theta_2| < \delta$ and $\theta_1, \theta_2 \in [-\pi/2, \pi/2]$), we have

$$\begin{aligned}\|\mathcal{L}_{\theta_1} v - \mathcal{L}_{\theta_2} v\|_{L^2(Q)} &\leq |\exp(i\theta_1) - \exp(i\theta_2)| \|v\|_{H^2(Q)} \\ &= \sqrt{(2 - 2\cos(\theta_1 - \theta_2))} \|v\|_{H^2(Q)} \\ &= \sqrt{(2 - 2\cos(|\theta_1 - \theta_2|))} \|v\|_{H^2(Q)}.\end{aligned}$$

Since $\epsilon < \sqrt{2}$, $\delta < \pi/2$; hence the function $f(x) = 2 - 2\cos(x)$ is nonnegative and monotone increasing on the interval $[0, \delta]$. Thus

$$\begin{aligned}\|\mathcal{L}_{\theta_1} v - \mathcal{L}_{\theta_2} v\|_{L^2(Q)} &< \sqrt{(2 - 2\cos(\delta))} \|v\|_{H^2(Q)} \\ &= \epsilon \|v\|_{H^2(Q)}.\end{aligned}$$

For any $\epsilon \geq \sqrt{2}$, choose $\delta = \pi/2$; then if $|\theta_1 - \theta_2| < \pi/2$ and $\theta_1, \theta_2 \in [-\pi/2, \pi/2]$) we have

$$\begin{aligned}\|\mathcal{L}_{\theta_1} v - \mathcal{L}_{\theta_2} v\|_{L^2(Q)} &\leq \sqrt{(2 - 2\cos(|\theta_1 - \theta_2|))} \|v\|_{H^2(Q)} \\ &< \sqrt{2} \|v\|_{H^2(Q)} \\ &< \epsilon \|v\|_{H^2(Q)}. \qquad \square\end{aligned}$$

Due to Theorem 6.1, for each $\theta \in [-\pi/2, \pi/2]$, there exists a constant m_θ such that for any $v \in H^2(Q)$,

$$\|v\|_{H^2(Q)} \leq m_\theta \left(\|\mathcal{L}_\theta v\|_{L^2(Q)} + [\mathcal{B}v]_{0,\partial Q} + \|v\|_{L^2(Q)} \right). \tag{6.4}$$

For each θ, define $m(\theta) = \inf\{m_\theta : \text{inequality (6.4) holds}\}$. The infimum exists since clearly 1 is a lower bound for m_θ. The next theorem proves that $m(\theta)$ is bounded above.

THEOREM 6.5. *Let $m(\theta)$ be as defined above. Then $\{m(\theta); -\pi/2 \leq \theta \leq \pi/2\}$ is bounded above. Hence there exists a positive constant $\bar{m}$ such that the following inequality holds for all $\theta \in [-\pi/2, \pi/2]$:*

$$\|v\|_{H^2(Q)} \leq \bar{m} \left(\|\mathcal{L}_\theta v\|_{L^2(Q)} + [\mathcal{B}v]_{1/2,\partial Q} + \|v\|_{L^2(Q)} \right). \tag{6.5}$$

Proof. Suppose not. Then for each n, there exists $\theta_n \in [-\pi/2, \pi/2]$ such that $m(\theta_n) > n$. The sequence $\{\theta_n\}$ is bounded; thus it contains a convergent subsequence $\{\theta_{k_n}\}$ which converges to $\bar{\theta} \in [-\pi/2, \pi/2]$. Theorem 6.1 ensures that $m(\bar{\theta})$ is positive and finite; thus there exists some n such that $m(\bar{\theta}) < n$. Let $\epsilon = \frac{1}{m(\bar{\theta})} - \frac{1}{n} > 0$. By Lemma 6.4, there exists $N > n$ such that for all $k_n > N$ (k_n are the indices of the convergent subsequence),

$$\|\mathcal{L}_{\bar{\theta}} v - \mathcal{L}_{\theta_{k_n}} v\|_{L^2(Q)} < \epsilon \|v\|_{H^2(Q)} \qquad \text{for all } v \in H^2(Q).$$

Pick a k_n such that $m(\theta_{k_n}) - 1 > n$. By definition, $m(\theta_{k_n})$ is the smallest constant such that for all $v \in H^2(Q)$, inequality (6.4) holds. Thus there exists some $v_0 \in H^2(Q)$ such that

$$\|v_0\|_{H^2(Q)} > (m_{\theta_{k_n}} - 1) \left(\|\mathcal{L}_{\theta_{k_n}} v_0\|_{L^2(Q)} + [\mathcal{B}v_0]_{1/2,\partial Q} + \|v_0\|_{L^2(Q)} \right).$$

But then

$$\begin{aligned}\epsilon\|v_0\|_{H^2(Q)} &= \left(\frac{1}{m(\bar\theta)} - \frac{1}{n}\right)\|v_0\|_{H^2(Q)}\\ &< \left(\frac{1}{m(\bar\theta)} - \frac{1}{m(\theta_{k_n})-1}\right)\|v_0\|_{H^2(Q)}\\ &< \left(\|\mathcal{L}_{\bar\theta}v_0\|_{L^2(Q)} + [\mathcal{B}v_0]_{1/2,\partial Q} + \|v_0\|_{L^2(Q)}\right)\\ &\quad - \left(\|\mathcal{L}_{\theta_{k_n}}v_0\|_{L^2(Q)} + [\mathcal{B}v_0]_{1/2,\partial Q} + \|v_0\|_{L^2(Q)}\right)\\ &\le \|\mathcal{L}_{\bar\theta}v_0 - \mathcal{L}_{\theta_{k_n}}v_0\|_{L^2(Q)}\\ &< \epsilon\|v_0\|_{H^2(Q)},\end{aligned}$$

a contradiction. Thus $m(\theta)$ is bounded above. Let $\bar m = \sup\{m(\theta), -\pi/2 \le \theta \le \pi/2\}$. Then for any $\theta \in [-\pi/2, \pi/2]$ and $v \in H^2(Q)$, inequality (6.5) holds. ∎

We now state a modification of Theorem 6.2.

THEOREM 6.6. *Let Ω, L, Γ, (4.1), (4.2) define a boundary control system with $\mathcal{H} = L^2(\Omega)$ and $\mathcal{U} = H^{\frac{1}{2}}(\partial\Omega)$. Assume that* [H1]–[H5] *are satisfied. Then there exists a positive constant R such that for any $z \in H^2(\Omega)$, $u \in \mathcal{U}$ satisfying $\Gamma z = u$ on $\partial\Omega$ and any complex number s on the open right half-plane $\mathbb{C}_{R^2} := \{s : \operatorname{Re} s > R^2\}$, the following inequality holds:*

$$|s|^{1/2}\|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \le m\left[\|(L-s)z\|_{L^2(\Omega)} + |s|^{1/2}\|u\|_{L^2(\Omega)} + \|u\|_{H^1(\Omega)}\right], \tag{6.6}$$

where m is a positive constant dependent only on L and Ω.

Proof. The proof is along the lines given in [21] except that we show that the constant is independent of θ. Let ζ be a function in $C^\infty(-\infty,\infty)$ such that $\zeta(t) = 0$ for $|t| > 1$, $\zeta(t) = 1$ for $|t| < 1/2$. Let m_1 be a constant chosen such that $\|\zeta\|_{H^2(\Re)} \le m_1$. Let $\bar m = \max\{m(\theta), -\pi/2 \le \theta \le \pi/2\}$ and $m_2 = \max\{\bar m, m_1\}$. Define

$$R := \text{largest root of the quadratic } r^2 - 6m_2^2 r - 6m_2^2.$$

We note that R is necessarily positive and real. In fact $R = \frac{6m_2^2 + m_2\sqrt{36m_2^2+24}}{2}$. Moreover, since $m(\theta)$ is bounded below by 1, $\bar m$ and hence m_2 is always greater than 1. Thus $R > 6$. For any $z \in H^2(\Omega)$ and any $s \in \mathbb{C}_{R^2}$, set $\theta = \arg s$, $r = |s|^{1/2}$, and $v(x,t) = \zeta(t)\exp(irt)z(x)$. Clearly $v \in H^2(Q)$; hence (6.5) implies

$$\begin{aligned}\|v\|_{H^2(Q)} &\le \bar m\left(\|\mathcal{L}_\theta v\|_{L^2(Q)} + [\mathcal{B}v]_{1/2,\partial Q} + \|v\|_{L^2(Q)}\right)\\ &\le m_2\left(\|\mathcal{L}_\theta v\|_{L^2(Q)} + [\mathcal{B}v]_{1/2,\partial Q} + \|v\|_{L^2(Q)}\right).\end{aligned} \tag{6.7}$$

Now a lower bound for $\|v\|_{H^2(Q)}$, an upper bound for $[\mathcal{B}v]_{1/2,\partial Q}$, and an upper bound for $\|\mathcal{L}_\theta v\|_{L^2(Q)}$ need to be computed. The final inequality is then obtained via simple algebra. First we compute a lower bound for $\|v\|_{H^2(Q)}$. By definition of $\|\cdot\|_{H^2(Q)}$ we have

$$\begin{aligned}\|v\|^2_{H^2(Q)} &= \sum_{|\alpha|+k\le 2}\int_{-\infty}^{\infty}\int_\Omega \left|D_x^\alpha D_t^k v(x,t)\right|^2 dxdt\\ &\ge \sum_{|\alpha|+k\le 2}\int_{-\frac{1}{2}}^{\frac{1}{2}}\int_\Omega \left|D_x^\alpha D_t^k \exp(irt)z(x)\right|^2 dxdt\end{aligned}$$

$$
\begin{aligned}
&= \sum_{k=0}^{2} (r)^{2k} \sum_{|\alpha|+k\leq 2} \int_{\Omega} \left| D_x^{\alpha} z(x) \right|^2 dx \\
&= \sum_{k=0}^{2} (r)^{2k} \left\| z \right\|^2_{H^{2-k}(\Omega)} \\
&\geq (r)^{2k} \left\| z \right\|^2_{H^{2-k}(\Omega)}
\end{aligned}
$$

for any $k = 0, 1, 2$. Hence

$$
\left\| v \right\|_{H^2(Q)} \geq (r)^k \left\| z \right\|_{H^{2-k}(\Omega)}
$$

for any $k = 0, 1, 2$. Thus

$$
3 \left\| v \right\|_{H^2(Q)} \geq \sum_{k=0}^{2} (r)^k \left\| z \right\|_{H^{2-k}(\Omega)} . \tag{6.8}
$$

Next we compute an upper bound for $[\mathcal{B}v]_{1/2,\partial Q}$. By definition of $[\cdot]_{1/2,\partial\Omega}$ we have for $\Gamma z \in H^2(\Omega)$ such that $z = u$ on $\partial\Omega$, and

$$
\begin{aligned}
[\mathcal{B}v]^2_{1/2,\partial Q} &= [\zeta(t) \exp(irt) B z(x)]^2_{1/2,\partial Q} \\
&= [\zeta(t) \exp(irt) u]^2_{1/2,\partial Q} \\
&\leq \left\| \zeta(t) \exp(irt) u \right\|^2_{H^1(Q)} \\
&= \sum_{|\alpha|+k\leq 1} \int_{-\infty}^{\infty} \int_{\Omega} \left| D_x^{\alpha} D_t^k \zeta(t) \exp(irt) u \right|^2 dx dt \\
&= \int_{-\infty}^{\infty} \int_{\Omega} |\zeta(t) \exp(irt) u|^2 \, dx dt + \int_{-\infty}^{\infty} \int_{\Omega} |\zeta(t) \exp(irt) Du|^2 \, dx dt \\
&\quad + \int_{-\infty}^{\infty} \int_{\Omega} |\zeta'(t) \exp(irt) u + ir\zeta(t) \exp(irt) u|^2 \, dx dt \\
&\leq m_1^2 \left\| u \right\|^2_{L^2(\Omega)} + m_1^2 \left\| Du \right\|^2_{L^2(\Omega)} + m_1^2 \left\| u \right\|^2_{L^2(\Omega)} + 2rm_1^2 \left\| u \right\|^2_{L^2(\Omega)} \\
&\quad + r^2 m_1^2 \left\| u \right\|^2_{L^2(\Omega)} \\
&= 2m_1^2 \left\| u \right\|^2_{L^2(\Omega)} + m_1^2 \left\| Du \right\|^2_{L^2(\Omega)} + (2r + r^2) m_1^2 \left\| u \right\|^2_{L^2(\Omega)} .
\end{aligned}
$$

Since $r = |s|^{1/2} > R > 6$, $2r < r^2$. Hence

$$
\begin{aligned}
[\mathcal{B}v]^2_{1/2,\partial Q} &\leq 2m_1^2 \left(\left\| u \right\|^2_{H^1(\Omega)} + r^2 \left\| u \right\|^2_{L^2(\Omega)} \right) \\
&\leq 2m_1^2 \left(r \left\| u \right\|_{L^2(\Omega)} + \left\| u \right\|_{H^1(\Omega)} \right)^2 \\
&\leq 2m_2^2 \left(r \left\| u \right\|_{L^2(\Omega)} + \left\| u \right\|_{H^1(\Omega)} \right)^2 .
\end{aligned}
$$

Thus

$$
[\mathcal{B}v]_{1/2,\partial Q} \leq \sqrt{2} m_2 \left(r \left\| u \right\|_{L^2(\Omega)} + \left\| u \right\|_{H^1(\Omega)} \right) . \tag{6.9}
$$

This is the upper bound on $[\mathcal{B}v]_{1/2,\partial Q}$. Now we calculate an upper bound on $\mathcal{L}_\theta v$. Substituting the expression for $v(x,t)$ into $\mathcal{L}_\theta v$, we find

$$
\mathcal{L}_\theta v = \zeta(t) \exp(irt)(L - r^2 \exp(i\theta)) z + 2ir \exp(i\theta) \zeta'(t) \exp(irt) z + \exp(i\theta) \zeta''(t) \exp(irt) z .
$$

Therefore

$$\begin{aligned}\|\mathcal{L}_\theta v\|_{L^2(Q)} &\le \left\|\zeta(t)\exp(irt)(L-r^2\exp(i\theta))z\right\|_{L^2(Q)} + 2\left\|r\exp(i\theta)\zeta'(t)\exp(irt)z\right\|_{L^2(Q)} \\ &\quad + \left\|\exp(i\theta)\zeta''(t)\exp(irt)z\right\|_{L^2(Q)} \\ &\le m_1\left(\left\|(L-r^2\exp(i\theta))z\right\|_{L^2(\Omega)} + 2r\|z\|_{L^2(\Omega)} + \|z\|_{L^2(\Omega)}\right) \\ &\le m_2\left(\left\|(L-r^2\exp(i\theta))z\right\|_{L^2(\Omega)} + 2r\|z\|_{L^2(\Omega)} + \|z\|_{L^2(\Omega)}\right). \qquad (6.10)\end{aligned}$$

Also,

$$\|v\|_{L^2(Q)} \le m_2\|z\|_{L^2(\Omega)}. \qquad (6.11)$$

Substituting inequality (6.8) into (6.7), we obtain

$$r^2\|z\|_{L^2(\Omega)} + r\|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \le 3m_2\left(\|\mathcal{L}_\theta v\|_{L^2(Q)} + [\mathcal{B}v]_{1/2,\partial Q} + \|v\|_{L^2(Q)}\right). \qquad (6.12)$$

Next, substitute inequalities (6.9), (6.10), and (6.11) into inequality (6.12) to obtain

$$\begin{aligned}r^2\|z\|_{L^2(\Omega)} &+ r\|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \\ &\le 3m_2^2\left(\left\|(L-r^2\exp(i\theta))z\right\|_{L^2(\Omega)} + 2r\|z\|_{L^2(\Omega)} + \|z\|_{L^2(\Omega)}\right. \\ &\qquad \left. + \sqrt{2}r\|u\|_{L^2(\Omega)} + \sqrt{2}\|u\|_{H^1(\Omega)} + \|z\|_{L^2(\Omega)}\right). \qquad (6.13)\end{aligned}$$

After rearrangement we obtain

$$\begin{aligned}(r^2 - 6m_2^2 r - 6m_2^2)\|z\|_{L^2(\Omega)} &+ r\|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \\ &\le 3\sqrt{2}m_2^2\left(\left\|(L-r^2\exp(i\theta))z\right\|_{L^2(\Omega)} + r\|u\|_{L^2(\Omega)} + \|u\|_{H^1(\Omega)}\right). \qquad (6.14)\end{aligned}$$

By definition of R we have $r^2 - 6m_2^2 r - 6m_2^2 \ge 0$. Hence (6.14) implies

$$r\|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \le 3\sqrt{2}m_2^2\left(\left\|(L-r^2\exp(i\theta))z\right\|_{L^2(\Omega)} + r\|u\|_{L^2(\Omega)} + \|u\|_{H^1(\Omega)}\right). \qquad (6.15)$$

Substituting back $s = r^2\exp(i\theta)$ above and defining $m = 3\sqrt{2}m_2^2$, we have the desired result. ∎

The boundedness of the input/output map for Neumann boundary control with observation now follows.

COROLLARY 6.7. *The input/output map of the boundary control system is bounded for all observation operators $K \in \mathcal{L}(H^1(\Omega), \mathcal{Y})$.*

Proof. By Theorem 6.6, the solution to the abstract elliptic problem (L, Γ) is uniformly bounded with respect to the $H^1(\Omega)$ norm. Hence by Theorem 3.2, the system transfer function associated with (L, Γ, K) is proper for all observation operators $K \in \mathcal{L}(H^1(\Omega), \mathcal{Y})$. Thus by Theorem 2.3 the input/output map is bounded to the boundary control system (L, Γ, K). ∎

Remark 6.8. The main result above is stated for a control space $\mathcal{U} = H^{\frac{1}{2}}(\partial\Omega)$. This space can be regarded as the traces of functions in $H^1(\Omega)$ (5.4). Consider the following characterization of these functions.

THEOREM 6.9 (see, e.g., [17, sect. 1.1.3]). *If a function u defined on Ω is absolutely continuous on almost all straight lines that are parallel to coordinate axes and the first classical derivatives of u belong to $L_2(\Omega)$, then $u \in H^1(\Omega)$.*

Thus, $H^{\frac{1}{2}}(\Omega)$ includes piecewise continuous functions, provided that Ω is such that we can extend u into the interior so that it satisfies the above theorem. The singularities on the boundary of Ω remain.

Remark 6.10. If Γ is Dirichlet boundary control, then $m_j = 0$ in Theorem 6.2. Using the same technique as Theorem 6.6 we can show that there exists a positive constant R such that for any $z \in H^2(\Omega)$, $u \in H^2(\Omega)$ satisfying $\Gamma z = u$ on $\partial\Omega$, and any complex number s on the open right half-plane $\mathbb{C}_{R^2} := \{s : \text{Re } s > R^2\}$, the following inequality holds:

$$|s|^{1/2} \|z\|_{H^1(\Omega)} + \|z\|_{H^2(\Omega)} \leq m \left[\|(L-s)z\|_{L^2(\Omega)} + |s| \|u\|_{L^2(\Omega)} + \|u\|_{H^2(\Omega)} \right],$$

where m is a positive constant dependent only on L and Ω. Unfortunately this implies the solution to $Lz = sz$ in Ω and $\Gamma z = u$ on $\partial\Omega$ satisfies only

$$\|z\|_{H^1(\Omega)} \leq m|s|^{1/2} \|u\|_{H^2(\Omega)}.$$

So we cannot conclude that the solution is uniformly bounded in the H^1-norm. In the case of Dirichlet boundary control on a one-dimensional rod, it can easily be shown that the solution to the elliptic problem is not uniformly bounded in the H^1-norm.

7. Conclusions. The input/output map and the transfer function are well defined for abstract boundary control systems. We showed that the question of continuity of the input/output map can be transformed to boundedness of solutions to a related elliptic problem. It is not necessary to construct a state-space realization.

This approach enabled us to show boundedness of the input/output map for general classes of boundary control systems involving uniformly elliptic operators with Dirichlet, Neumann, or Robin boundary control.

We are currently working on extending our approach to problems that are second order in time.

BARRIER OPERATORS AND ASSOCIATED GRADIENT-LIKE DYNAMICAL SYSTEMS FOR CONSTRAINED MINIMIZATION PROBLEMS*

JÉRÔME BOLTE† AND MARC TEBOULLE‡

Abstract. We study some continuous dynamical systems associated with constrained optimization problems. For that purpose, we introduce the concept of elliptic barrier operators and develop a unified framework to derive and analyze the associated class of gradient-like dynamical systems, called A-driven descent method (*A-DM*). Prominent methods belonging to this class include several continuous descent methods studied earlier in the literature such as steepest descent method, continuous gradient projection methods and Newton-type methods as well as continuous interior descent methods such as Lotka–Volterra-type differential equations and Riemannian gradient methods. Related discrete iterative methods such as proximal interior point algorithms based on Bregman functions and second order homogeneous kernels can also be recovered within our framework and allow for deriving some new and interesting dynamics. We prove global existence and strong viability results of the corresponding trajectories of (*A-DM*) for a smooth objective function. When the objective function is convex, we analyze the asymptotic behavior at infinity of the trajectory produced by the proposed class of dynamical systems (*A-DM*). In particular, we derive a general criterion ensuring the global convergence of the trajectory of (*A-DM*) to a minimizer of a convex function over a closed convex set. This result is then applied to several dynamics built upon specific elliptic barrier operators. Throughout the paper, our results are illustrated with many examples.

Key words. dynamical systems, continuous gradient-like systems, elliptic barrier operators, Lotka–Volterra differential equations, asymptotic analysis, viability, Lyapunov functionals, explicit and implicit discrete schemes, interior proximal algorithms, global convergence, constrained convex minimization, Riemannian gradient methods

1. Introduction.

This paper proposes to study some continuous dynamical systems in relation with the constrained optimization problem

$$(\mathcal{P}) \qquad \inf\{f(x) : \ x \in \overline{C}\},$$

where C is a nonempty *open* convex subset of $\mathbb{R}^n$, $n \geq 1$, $f : \mathbb{R}^n \mapsto \mathbb{R}$ is a convex function, and $\overline{C}$ denotes the closure of C.

Our first aim is to give a unified framework to smooth continuous interior descent methods studied earlier in the literature: the steepest descent method, Lotka–Volterra-type equations, the continuous Newton method, and the continuous gradient projection method. Another goal of this study is to enlighten the local geometric aspects of some discrete *implicit* dynamics related to $(\mathcal{P})$ (particularly proximal-type algorithms) by associating them to some adequate vector fields. More precisely, we will also show that one of our continuous models can be cast as a specific Riemannian gradient method.

This has led us to introduce the class of gradient-like dynamical systems

$$(A\text{-}DM) \qquad \begin{cases} \dot{x}(t) + A_{x(t)}\nabla f(x(t)) = 0 \quad \forall t \geq 0, \\ x(0) \in C, \end{cases}$$

with

$$A : \begin{cases} C \times \mathbb{R}^n & \mapsto & \mathbb{R}^n, \\ (x, v) & \mapsto & A_x v. \end{cases} \tag{1.1}$$

The notation (*A-DM*) stands for *A*-driven descent method. To make (*A-DM*) an interior descent method, we introduce a class of mappings of the type (1.1) called *elliptic barrier operators*. This is an alternative approach to the classical barrier methods (see, for instance, Auslender, Cominetti, and Haddou [9]), since the penalization does not act on the objective function f but on its gradient. Roughly speaking, this implies two major requirements on the map A:

• the mapping $x \in C \to A_x \nabla f(x)$ must preserve the local optimality information given by $\nabla f(\cdot)$, and

• the operator A has to vanish on $\{(x, -\nu)\,, x \in \overline{C},\ \nu \in N_{\overline{C}}(x)\}$, where $N_{\overline{C}}(x)$ is the normal cone to $\overline{C}$ at $x \in \overline{C}$.

In the next section, a formal definition and the basic properties of elliptic barrier operators are given. The relevance of this notion is first illustrated by the general properties of (*A-DM*) systems. We prove existence and viability results. If ∇f is locally Lipschitz continuous, then the trajectories of (*A-DM*) are defined for all $t \geq 0$ and remain in C. Let us emphasize the fact that, unlike in Nagumo-type theorems used in viability theory (Aubin and Cellina [7]), the trajectories never encounter the boundary of C and thus make (*A-DM*) an *interior* method.

In section 3, we propose a general and unifying framework to generate in a systematic way elliptic barrier operators. This is achieved by developing an abstract setting with the help of proximal-like maps involving appropriately defined distance-like functions. Given a convenient distance-like function $d : \mathbb{R}^n \times C \mapsto \mathbb{R} \cup \{+\infty\}$, closed, proper, and convex with respect of its first variable, we introduce the class of mappings

$$A^d_x v = x - \arg\min\left\{\langle u, v\rangle + d(u, x) \mid u \in \mathbb{R}^n\right\},\ (x, v) \in C \times \mathbb{R}^n, \tag{1.2}$$

where $\langle \cdot, \cdot \rangle$ stands for the Euclidean inner product of $\mathbb{R}^n$. Aside from the fact that slight assumptions on d allow us to make A^d an elliptic barrier operator, the associated A^d-driven descent method (*A-DM*) can be seen as another step toward a unified approach to both continuous and discrete gradient-like dynamics. Indeed, one of the main facts underlying the introduction of the d operator is that (A^d-*DM*) systems can be reformulated as the differential inclusion

$$\partial_1 d(\dot{x}(t) + x(t), x(t)) + \nabla f(x(t)) \ni 0,\ t \geq 0, \tag{1.3}$$

where, for each $t \geq 0$, $\partial_1 d(\cdot, x(t))$ denotes the subdifferential of $d(\cdot, x(t))$.

This structure is at the heart of the so-called proximal-like methods (see the examples below)

$$\partial_1 d(x^{k+1}, x^k) + \nabla f(x^{k+1}) \ni 0,\ x^0 \in C,\ k \geq 0. \tag{1.4}$$

For instance, with $d(u, x) = 2^{-1}|u - x|^2$, where $|\ \cdot\ |$ denotes the Euclidean norm, the inclusion (1.4) reduces to the proximal minimization algorithm; see, e.g., Martinet

[33], Lemaire [30], and references therein. Then, according to the classical idea that consists in interpreting an iterative scheme as some discretization of a continuous dynamical system, the differential inclusion (1.3), i.e., A^d-*DM*, can be proposed as a continuous model for the proximal method (1.4). This opens new perspectives on crossed investigations, and from that viewpoint it is important to realize that the interplay between discrete and continuous dynamical systems goes far beyond the fruitful finite-time approximation aspects. For instance, in Alvarez and Attouch [2] and Antipin [4] crucial features of the asymptotic analysis appear also as closely related matters.

To give the reader a concrete idea on the type of operators A that will emerge in this study, we outline below some specific models.

(a) *The gradient projection operator.* The first natural example is given by

$$A^P : \left\{ \begin{array}{lcl} C \times \mathbb{R}^n & \mapsto & \mathbb{R}^n, \\ (x, v) & \mapsto & x - P_{\overline{C}}(x - v), \end{array} \right. \tag{1.5}$$

where $P_{\overline{C}}$ is the orthogonal projection on $\overline{C}$. A^P-*DM* is the continuous gradient projection method as introduced in [4],

$$\dot{x}(t) + x(t) - P_{\overline{C}}[x(t) - \nabla f(x(t))] = 0,\ x(0) \in C \quad \forall t \geq 0. \tag{1.6}$$

The operator A^P ruling (1.6) can be recovered thanks to (1.2) with a distance-like function of the type $d : \mathbb{R}^n \times C \ni (u, x) \mapsto \frac{1}{2}|u - x|^2 + \delta_{\overline{C}}(u)$, where $\delta_{\overline{C}}$ is the indicator function of $\overline{C}$. Let us emphasize the fact that the trajectory of the continuous system (1.6) is interior, which is not the case for the well-known explicit discretization

$$x^{k+1} = P_{\overline{C}}[x^k - \mu_k \nabla f(x^k)],\ x^0 \in C,\ \mu_k > 0;$$

see, e.g., [31], [19].

(b) *The Bregman operators.* The Bregman proximal method (BPM) is obtained by replacing the quadratic kernel in the proximal minimization algorithm by a distance-like function based on a Bregman function $h : \overline{C} \to \mathbb{R}$. Defining

$$\forall (x, y) \in \overline{C} \times C,\ D_h(x, y) = h(x) - h(y) - \langle \nabla h(y), x - y \rangle \tag{1.7}$$

leads to the scheme

$$(BPM) \qquad x^{k+1} \in \arg\min \left\{ f(x) + c_k D_h(x, x_k) | x \in \overline{C} \right\},\ c_k > 0,\ x^0 \in \overline{C}.$$

(BPM) has been studied and generalized from many viewpoints; see, for instance, Censor and Zenios [17], Chen and Teboulle [18], Eckstein [20], Kiwiel [27], and Teboulle [37]. One of the corresponding continuous models that is proposed here is given by barrier operators A^{q_h} of the type

$$A^{q_h} : \left\{ \begin{array}{lcl} C \times \mathbb{R}^n & \mapsto & \mathbb{R}^n, \\ (x, v) & \mapsto & \nabla^2 h(x)^{-1} v, \end{array} \right.$$

where $\nabla^2 h(x)$ is the Hessian of some convenient Bregman function with zone C and with $q_h(u, x) = \langle \nabla^2 h(x)(u - x), u - x \rangle$, $(u, x) \in \mathbb{R}^n \times C$. The A^{q_h}-driven descent method (A^{q_h}-*DM*), actually a Riemannian gradient method, is then given by

$$(A^{q_h}\text{-}DM) \qquad \dot{x}(t) + \nabla^2 h(x(t))^{-1} \nabla f(x(t)) = 0,\ x(0) \in C.$$

Besides its links with (BPM) developed in section 4, the latter system allows us to recover several dynamics. With $h_1(x) = \frac{\alpha}{2}|x|^2 + \beta \sum_{i=1\dots N} x_i \log x_i$, α, $\beta > 0$ on $C = \mathbb{R}^n_{++} := \{x \in \mathbb{R}^n,\ x_i > 0\}$, we obtain the regularized Lotka–Volterra equation recently proposed, from a completely different viewpoint, in Attouch and Teboulle [6],

(1.8)
$$(A^{q_{h_1}}\text{-}DM) \qquad \dot{x}_i(t) + \frac{x_i(t)}{\beta + \alpha x_i(t)} \frac{\partial f}{\partial x_i}(x(t)) = 0 \quad \forall i = 1, \dots, n,\ x(0) \in \mathbb{R}^n_{++},$$

where f is to be optimized on $\mathbb{R}^n_+$.

If $h(x) = \frac{\alpha}{2}|x|^2$ and $C = \mathbb{R}^n$, $(A^{q_h}\text{-}DM)$ is the classical continuous steepest descent method $\dot{x}(t) + \nabla f(x(t)) = 0$, $t \geq 0$; see Brézis [14].

For $h(x) = f(x)$ and $C = \mathbb{R}^n$, we obtain the continuous Newton descent method studied in Alvarez and Pérez [3] (see also [7])

$$(A^{q_f}\text{-}DM) \qquad \dot{x}(t) + \nabla^2 f(x(t))^{-1} \nabla f(x(t)) = 0. \tag{1.9}$$

Another surprising fact of this dynamics is to be physically meaningful in infinite-dimensional spaces. Naturally those problems are out of the scope of the present paper, but the reader interested by thermodynamical evolution equations of the form $A^{q_h}\text{-}DM$ is referred to Kenmochi and Pawlow [26] and references therein.

(c) *Barrier operators based on interior methods for the positive orthant.* Another line of research pursued by Auslender, Teboulle, and Ben-Tiba [8] concerning proximal interior methods is based on the distance-like function

$$\forall (x, y) \in (\mathbb{R}^n_{++})^2 \ \ d_\varphi(x, y) = \sum_{i=1}^{n} y_i^2 \varphi\left(\frac{x_i}{y_i}\right), \tag{1.10}$$

where $\varphi : \mathbb{R}_{++} \to \mathbb{R}$ is some relevant convex function.

The associated iterative proximal interior method is given by

$$(RIPM) \qquad x^{k+1} \in \arg\min \left\{ f(x) + c_k d_\varphi(x, x_k) | x \in \mathbb{R}^n_+ \right\},\ c_k > 0,\ x^0 \in \mathbb{R}^n_{++},$$

where $(RIPM)$ stands for regularized interior proximal method. Like (BPM) this algorithm can be applied to a minimize a general closed convex function. However, it enjoys stronger convergence properties, particularly when applied to a dual problem of a convex program; see [8] for further details and results.

Our continuous approach to $(RIPM)$ is obtained by considering barrier operators of the form

$$A^{d_\varphi} : \left\{ \begin{array}{lll} \mathbb{R}^n_{++} \times \mathbb{R}^n & \mapsto & \mathbb{R}^n, \\ (x, v) & \mapsto & \left(x_i - x_i(\varphi^*)'(x_i^{-1} v_i)\right)_{i=1,\dots,n}, \end{array} \right.$$

where φ^* is the Legendre–Fenchel conjuguate of the function φ used in $(RIPM)$.

All these continuous models are derived and analyzed in section 4. Section 5 is devoted to the asymptotic analysis of $(A\text{-}DM)$ in the convex case. We derive a general criterion ensuring the global convergence of the trajectories of $(A\text{-}DM)$ to a minimizer of f over $\overline{C}$. We then apply this general result to the dynamics built upon A^P, A^{q_h}, and A^{d_φ}. The proof relies on the existence of Lyapunov functionals measuring a sort of distance between the state variable and the set of equilibria. This approach is inspired at the same time by Opial's lemma [35] and the techniques used in

monotone optimization algorithms. We also prove a general localization result for the limit point of the trajectories produced by (*A-DM*), which extends results of the same type obtained recently in [6] and in [30] for the classical continuous gradient descent scheme. Throughout this paper we give many examples exhibiting some explicit and new systems of the type (*A-DM*). For instance, with $C = \mathbb{R}^n_{++}$, one obtains the systems

$$(A^{q_h} - DM) \qquad \dot{x}_i(t) + \frac{2x_i(t)^{3/2}}{x_i(t)^{3/2}+1}\frac{\partial f}{\partial x_i}(x(t)) = 0,\ x_i(0) > 0 \quad \forall i \in \{1,\dots,n\}$$

or

$$(A^{d_\varphi} - DM) \qquad \dot{x}_i(t) + x_i(t) + \frac{1}{2}\frac{\partial f}{\partial x_i}(x(t)) - \sqrt{\frac{1}{4}\frac{\partial f}{\partial x_i}(x(t))^2 + x_i(t)^2} = 0,$$

with $i \in \{1,\dots,n\}$, $t \geq 0$, and $x(0) \in \mathbb{R}^n_{++}$. The first equation is given by the Bregman function $h(s) = s^2/4 - 2\sqrt{s}$, $s \geq 0$, while the second one corresponds to a continuous model of the logarithmic-quadratic method [8] obtained with the choice $\varphi(s) = 1/2(s-1)^2 - \log s + s - 1$, $s > 0$.

Notation. Our notation is fairly standard. The Euclidean space $\mathbb{R}^n$ is equipped with the scalar product $\langle \cdot, \cdot \rangle$; the related norm is denoted $|\cdot|$. The boundary of C is denoted $\mathrm{bd}C$. $N_{\overline{C}}(x)$ and $T_{\overline{C}}(x)$ denote, respectively, the normal cone and the tangent cone of $\overline{C}$ at $x \in \overline{C}$. We recall that $N_{\overline{C}}(x) = \{v \in \mathbb{R}^n \ \langle v, z - x\rangle \leq 0 \text{ for all } z \in \overline{C}\} = \{v \in \mathbb{R}^n | \text{ for all } u \in T_{\overline{C}}(x),\ \langle v, u\rangle \leq 0\}$. If $\phi : \mathbb{R}^p \to \mathbb{R} \cup \{+\infty\}$, $p \geq 1$, is a closed proper convex function, its domain is defined by $\mathrm{dom}\ \phi = \{x \in \mathbb{R}^p | \phi(x) < +\infty\}$, and its Legendre–Fenchel conjuguate, $y \in \mathbb{R}^p \to \sup\{\langle y, x\rangle - \phi(x) | x \in \mathbb{R}^p\}$, is denoted ϕ^*. If S is a closed convex subset of $\mathbb{R}^n$, the set of minimizers of ϕ on S is denoted $\arg\min_S \phi$. The indicator function of $\overline{C}$ is denoted by $\delta_{\overline{C}}$. Other notation and definitions not explicitly stated here can be found in the classical book of Rockafellar [36].

2. Elliptic barrier operators and viability results. In this section, the definition and the first properties of elliptic barrier operators are introduced. Then, in view of constrained minimization, we study the corresponding A-driven descent methods, proving in particular that the obtained trajectories $\{x(t)\}$ are *interior* and defined for any $t \in [0, +\infty)$.

2.1. Elliptic barrier operators: Definition and properties.

DEFINITION 2.1. *$A : C \times \mathbb{R}^n \to \mathbb{R}^n$ is an elliptic barrier operator on C if it satisfies the following:*

($r1$) A is Lipschitz continuous on every compact subset of $C \times \mathbb{R}^n$.

($r2$) There exists $\alpha > 0$, such that for every $(x, v) \in C \times \mathbb{R}^n$, $\langle A_x v, v\rangle \geq \alpha |A_x v|^2$.

($r3$) For all $x \in C$, $A_x v = 0$ implies $v = 0$.

(v) For all $b \in \mathrm{bd}\ C$, for all $\nu \in N_{\overline{C}}(b)$, for all $M > 0$, $\exists \epsilon, K > 0$ such that $|x - b| < \epsilon$, $x \in C$, $|v| \leq M$ implies

$$\langle -A_x v, \nu\rangle \leq K\langle b - x, \nu\rangle. \tag{2.1}$$

This definition is motivated by the study of (*A-DM*) systems. The *regularity* assumption ($r1$) naturally meets the conditions of the Cauchy–Lipschitz theorem. The *ellipticity* condition ($r2$) and the *nondegeneracy* assumption ($r3$) allow us to obtain a proper descent method. An important consequence of ($r2$) is that the term

$1/\alpha$ can be seen as an upper bound for the gradient stepsize in (*A-DM*). Indeed, it follows readily from $(r2)$ that $|A_x v| \leq \alpha^{-1}|v|$, and therefore a trajectory $x(\cdot)$ of (*A-DM*) satisfies

$$|\dot{x}(t)| \leq \alpha^{-1}|\nabla f(x(t))|$$

whenever $x(t)$ is defined and belongs to C.

The *normal boundary* property (v) is required to control the outward normal impulses near the boundary of C, making the trajectories of (*A-DM*) strongly viable; i.e., $x(t) \in C$, $t \geq 0$. The choice of the term $\langle b - x, \nu\rangle$ in (2.1) also has a regularizing effect. Indeed, as it will be proved in Theorem 2.4 (see also Remark 2.1 (b)), it contributes to the fact that the trajectories of (*A-DM*) are defined on $[0, +\infty)$.

Remark 2.1. (a) A natural extension of Definition 2.1 can be obtained by replacing assumptions $(r2)$ and $(r3)$, respectively, by

$(r2)'$ For every $(x, v) \in C \times \mathbb{R}^n$, $v \neq 0$ $\langle A_x v, v\rangle > 0$.

$(r3)'$ For all $x \in C$, $v = 0$ implies $A_x v = 0$.

Observing that $(r2)'$ and $(r3)'$ imply $(r3)$, it follows that an elliptic barrier operator satisfies this new definition. This widened concept opens new perspectives but also raises some difficulties in the study of (*A-DM*): finite-time solutions, loss of regularity (see Theorem 2.4 in the elliptic case), no upper bound for the gradient step-sizes, etc. The study of such a class of mappings will not be carried out in the present paper but appears as an interesting matter for future research.

(b) If the left term in (2.1) is replaced, for instance, by $\langle b-x, \nu\rangle^{1-\theta}$, $\theta \in (0, 1)$, the well-posedness of (*A-DM*) may fail: take, for instance, $A : (x, v) \in \mathbb{R}_+ \times \mathbb{R} \to x^{1-\theta}.v$, $\theta \in (0, 1)$, $f(x) = x + 1$, and observe that the maximal solutions of (*A-DM*) are not defined on $[0, +\infty)$.

In what follows, it is of interest to strengthen $(r1)$ by assuming the additional hypothesis

$(r4)$ A is continuous on $\overline{C} \times \mathbb{R}^n$.

The following result shows that an elliptic barrier operator on C can be continuously extended to

$$C \times \mathbb{R}^n \cup \big\{(x, v) | x \in \operatorname{bd} C,\ v \in -N_{\overline{C}}(x)\big\}$$

by setting $A_x v = 0$, if $x \in \operatorname{bd} C$, $v \in -N_{\overline{C}}(x)$.

PROPOSITION 2.2. *Let $A : C \times \mathbb{R}^n \to \mathbb{R}^n$ be an elliptic barrier operator. Assume that $(x^k, v^k), k \in N$, is a sequence in $C \times \mathbb{R}^n$ such that $x^k \to x \in \overline{C}$ and $v^k \to v \in -N_{\overline{C}}(x)$ as $k \to +\infty$. Then*

(i) *$A_{x^k} v^k \to 0$ as $k \to +\infty$.*

(ii) *In addition, if A satisfies $(r4)$, then for all $x \in \overline{C}$ one has*

$$A_x^{-1}(\{0\}) \supset -N_{\overline{C}}(x). \tag{2.2}$$

Proof. If $x \in C$, the conclusion follows from $(r1)$ and $(r3)$. Else $x \in \operatorname{bd} C$. $(r2)$ and the Cauchy–Schwarz inequality yield $|A_{x^k} v^k|.|v^k| \geq \alpha |A_{x^k} v^k|^2$ for all $k \in N$ and some $\alpha > 0$. Since the sequence $v^k, k \in N$, is bounded, so is $A_{x^k} v^k, k \in N$. From (v) it follows that for k large enough $\langle -A_{x^k} v^k, -v\rangle \leq K\langle x - x^k, -v\rangle$, and therefore

$$\limsup_{k \to +\infty} \langle A_{x^k} v^k, v\rangle \leq 0. \tag{2.3}$$

On the other hand, we have

$$\langle A_{x^k} v^k, v\rangle = \langle A_{x^k} v^k, v - v^k\rangle + \langle A_{x^k} v^k, v^k\rangle \quad \forall k \in N,$$

and since $A_{x^k}v^k, k \in N$, is bounded, we obtain

$$\liminf_{k\to+\infty}\langle A_{x^k}v^k, v\rangle = \liminf_{k\to+\infty}\langle A_{x^k}v^k, v^k\rangle \geq 0. \tag{2.4}$$

From (2.3) and (2.4), we deduce that $\lim_{k\to+\infty}\langle A_{x^k}v^k, v\rangle = \liminf_{k\to+\infty}\langle A_{x^k}v^k, v^k\rangle = 0$, and thus by $(r2)$, $\lim_{k\to+\infty}|A_{x^k}v^k|^2 = 0$. □

Remark 2.2. For simplicity, assume that f is convex, with $\arg\min_{\overline{C}} f \neq \emptyset$, and that A satisfies $(r4)$. Subdifferential calculus (see, e.g., [36]) allows us to associate to $(\mathcal{P})$ the following variational characterization:

$$x^* \text{ solves } (\mathcal{P}) \text{ iff } \nabla f(x^*) + N_{\overline{C}}(x^*) = 0.$$

Using (2.2), we know that the solutions of $(\mathcal{P})$ are contained in the set of zeros of the gradient-like map $x \in \overline{C} \to A_x\nabla f(x)$. This is only a necessary condition for optimality, and it can be written as

$$\text{if } x^* \text{ solves } (\mathcal{P}), \text{ then } A_{x^*}\,\nabla f(x^*) = 0. \tag{2.5}$$

The important point here is to realize that our approach to optimization is given *throughout (A-DM) dynamics*, and thus x^* is obtained as a limit point of some descent method. Indeed, as we shall see, most of the systems and examples of section 4 satisfy (2.2) with a *strict* inclusion, yet their orbits converge to a minimizer of f on $\overline{C}$; see section 5.

We conclude these introductory notions by stating a useful criterion implying assumption (v) of Definition 2.1.

LEMMA 2.3. *Let $A : C \times \mathbb{R}^n \to \mathbb{R}^n$, $m > 0$, and $k : C \times \mathbb{R}^n \to [m, +\infty)$ be such that*

$$x - k(x,v)A_x v \in \overline{C} \quad \forall (x,v) \in C \times \mathbb{R}^n.$$

Then A satisfies (v).

Proof. The proof relies on the fact that $x - k(x,v)A_x v - b \in T_{\overline{C}}(b)$ for every (x,v) in $C \times \mathbb{R}^n$ and for every $b \in \overline{C}$. By definition we have, for all $\nu \in N_{\overline{C}}(b)$, $\langle x - k(x,v)A_x v - b, \nu\rangle \leq 0$, and therefore

$$\langle -A_x v, \nu\rangle \leq \frac{1}{k(x,v)}\langle b - x, \nu\rangle \leq \frac{1}{m}\langle b - x, \nu\rangle. \qquad \square$$

2.2. Global existence and viability results. From now on, the function $f : \mathbb{R}^n \to \mathbb{R}$ is C^1 and satisfies

$(\mathcal{H}_1)$ ∇f is Lipschitz continuous on bounded sets;

$(\mathcal{H}_2)$ $\inf_{\overline{C}} f > -\infty$.

Observe that for the moment the function f is not supposed to be convex.

THEOREM 2.4. *Let A be an elliptic barrier operator. Then, the following hold:*

(i) *The system (A-DM) admits a unique C^1 solution x defined on $[0, +\infty)$.*

Moreover,

(ii) *for all $t \geq 0$, $x(t) \in C$.*

(iii) *The function $t \in [0, +\infty) \to f(x(t))$ is nonincreasing and has a limit as $t \to +\infty$.*

(iv) $\dot{x} \in L^2(0, +\infty; \mathbb{R}^n)$.

(v) *If A satisfies $(r4)$ and $x(\cdot)$ is bounded, then $\dot{x}(t) \to 0$ as $t \to 0$, and all limit points x^* of $x(\cdot)$ satisfy the weak optimality condition*

$$A_{x^*} \nabla f(x^*) = 0.$$

Proof. Fix $T > 0$ and consider the assertion $E(T)$: "There exists a solution of $(A\text{-}DM)$ defined on $[0, T]$, and such that $x(t) \in C$ for all $t \in [0, T]$."

Set $T_{max} := \sup\{T \mid E(T) \text{ is satisfied}\}$. From $(r1)$, $(\mathcal{H}_1)$, and the fact that $x(0) \in C$, it follows by Cauchy–Lipschitz theorem that $T_{max} > 0$ and that the solution of $(A\text{-}DM)$ defined on $[0, T_{max})$ is unique.

Let us derive some a priori estimates. Let $T \in (0, T_{max})$; by the $(A\text{-}DM)$ system we have for all $t \in [0, T]$

$$\langle \dot{x}(t), \nabla f(x(t)) \rangle + \langle A_{x(t)} \nabla f(x(t)), \nabla f(x(t)) \rangle = 0,$$

and thus by $(r2)$ and $(A\text{-}DM)$ again,

$$\frac{d}{dt} f(x(t)) + \alpha |\dot{x}(t)|^2 \leq 0. \tag{2.6}$$

Integrating over some interval $(0, t)$ with $t \leq T$ gives

$$f(x(t)) - f(x(0)) + \alpha \int_0^t |\dot{x}|^2 \leq 0. \tag{2.7}$$

Note that if $T_{max} = +\infty$, (iii) and (iv) follow from (2.6), (2.7), and $(\mathcal{H}_2)$. Let us argue by contradiction and assume that $T_{max} < +\infty$.

Using the Cauchy–Schwarz inequality and the fact that $\dot{x} \in L^2(0, T_{max}; \mathbb{R}^n)$, we obtain that x is a Cauchy net at T_{max}. Therefore, x can be continuously extended by an application still denoted by x. Set $x(T_{max}) := b \in \overline{C}$.

By definition of T_{max}, b necessarily belongs to $\operatorname{bd} C$. The function $t \in [0, T_{max}] \to \nabla f(x(t))$ is bounded by a positive constant M. Owing to the continuity of x and (v), there exist $t_0 \in (0, T_{max})$, $\epsilon > 0$, $K > 0$, and $\nu \in N_{\overline{C}}(b)$, $\nu \neq 0$, such that for all $t \in (t_0, T_{max})$

$$\langle -A_{x(t)} \nabla f(x(t)), \nu \rangle \leq K \langle b - x(t), \nu \rangle. \tag{2.8}$$

Let us project $(A\text{-}DM)$ on $\mathbb{R}\nu := \{\tau\nu \mid \tau \in \mathbb{R},\ 0 \neq \nu \in N_{\overline{C}}(b)\}$; this gives for all $t \in (t_0, T_{max})$

$$\frac{d}{dt} \langle x(t), -\nu \rangle + \langle A_{x(t)} \nabla f(x(t)), -\nu \rangle = 0,$$

and using (2.8) we obtain

$$\frac{d}{dt} \langle b - x(t), \nu \rangle + K \langle b - x(t), \nu \rangle \geq 0.$$

Multiplying the above inequality by $\exp Kt$ and integrating over (t_0, T_{max}), it follows that

$$\langle b - x(T_{max}), \nu \rangle \geq \exp[-K(T_{max} - t_0)] \langle b - x(t_0), \nu \rangle.$$

Observe that by definition, $b = x(T_{max})$; hence to draw a contradiction from the latter we just have to prove that the second term of the inequality is positive. Indeed,

$x(t_0) \in C$, which is open convex, and $0 \neq \nu \in N_{\overline{C}}(b)$; thus there exists $\eta > 0$ such that $x(t_0)+\eta\nu \in C$, and a fortiori $x(t_0)+\eta\nu-b \in T_{\overline{C}}(b)$. This implies $\langle x(t_0)+\eta\nu-b, \nu\rangle \leq 0$ or, equivalently, $\langle b - x(t_0), \nu\rangle \geq \eta|\nu|^2 > 0$, and (i) is proved.

Let us prove the last statement (v). From the boundedness property of x, along with $(r4)$ and $(\mathcal{H}_1)$, it follows that $\dot{x}$ is bounded, and therefore x is a Lipschitz continuous map. The properties $(r4)$, $(\mathcal{H}_1)$ imply that $t \geq 0 \to A_{x(t)}\nabla f(x(t))$ is uniformly continuous, and therefore so is $\dot{x}(\cdot)$. Combining this fact with (iv), it follows by a classical argument that $\dot{x}(t) \to 0$ as $t \to +\infty$. Using $(r4)$, it follows that a cluster point x^* of x satisfies $A_{x^*}\nabla f(x^*) = 0$. □

3. A general abstract framework for dynamical systems with elliptic barrier operators. In this section, we propose with the help of proximal maps a systematic and unifying way to generate elliptic barrier operators. We start with an informal motivation. Given a convenient distance-like function $d : \mathbb{R}^n \times C \mapsto \mathbb{R} \cup \{+\infty\}$, the idea is to realize the descent direction $-A_x\nabla f(x)$, $x \in C$, as a vector based on x and pointing on some proximal point $u^d(x, \nabla f(x))$.

Indeed, assume that d is convex with respect to its first variable, and for $x \in C$ define formally

$$u^d(x, \nabla f(x)) \in \arg\min \{\langle u, \nabla f(x)\rangle + d(u, x) | u \in \mathbb{R}^n\}. \tag{3.1}$$

In this definition, the objective function has been replaced by its first order approximation at the point x, the constraints are supposed to be naturally taken into account by $d(\cdot,\cdot)$, and the descent direction obtained is $-A^d_x\nabla f(x) := u^d(x, \nabla f(x)) - x$. It is of interest to note that this approach is akin to the following well-known fixed point reformulation of the optimization problem $(\mathcal{P})$:

$$x^* \text{ solves } (\mathcal{P}) \text{ iff } x^* \in \arg\min \{\langle u, \nabla f(x^*)\rangle \mid u \in \overline{C}\} \tag{3.2}$$

whenever f is convex. From that viewpoint, the formal definition (3.1) may appear as a proximal regularization of some possibly ill-posed problem. On the other hand, the corresponding A^d-DM can be written as a fixed-point-like dynamics

$$\dot{x}(t) + x(t) = u^d[x(t), \nabla f(x(t))],\ x(0) \in C \quad \forall t \geq 0. \tag{3.3}$$

The solution of (3.3) is then expected to asymptotically provide a solution of $x^* = u^d(x^*, \nabla f(x^*))$, and when it makes sense, this last problem corresponds to another formulation of (3.2).

As a first example, consider $d(u, x) = 1/2|u - x|^2 + \delta_{\overline{C}}(u)$, $(u, x) \in \mathbb{R}^n \times C$. The definition of u^d writes

$$\nabla f(x) + u^d(x, \nabla f(x)) - x + N_{\overline{C}}[u^d(x, \nabla f(x))] \ni 0,$$

which in turn is equivalent to

$$u^d(x, \nabla f(x)) \in (I + N_{\overline{C}})^{-1}(x - \nabla f(x)).$$

Recalling that $(I + N_{\overline{C}})^{-1} = P_{\overline{C}}$, the proximal point is thus given by $u^d(x, \nabla f(x)) = P_{\overline{C}}(x-\nabla f(x))$. This gives rise to the descent direction $-A^d_x\nabla f(x) = P_{\overline{C}}(x-\nabla f(x))-x$, and the projected gradient dynamics (1.6) is recovered. As mentioned in the above discussion, note that the reformulation of (3.2) throughout $d(\cdot,\cdot)$, that is, $x^* = u^d(x^*, \nabla f(x^*))$, leads to the fixed point problem $x^* = P_{\overline{C}}(x^* - \nabla f(x^*))$.

Let us now develop an abstract setting that shall be illustrated in the next section with various useful kernels $d(\cdot,\cdot)$.

Let $d_0 : \mathbb{R}^n \times C \mapsto \mathbb{R}_+ \cup \{+\infty\}$ be such that the following hold:

$(P1)$ d_0 is C^1 on $C \times C$.
$(P2)$ $\nabla_1 d_0(u,u) = 0$ for all $u \in C$.
$(P3)$ For every $x \in C$, the mapping $u \in \mathbb{R}^n \mapsto d_0(u,x)$ is a closed convex function.

In $(P1)$, $\nabla_1 d_0(\cdot, u)$ is the gradient of $d(\cdot, u)$, (more generally its subdifferential is denoted by $\partial_1 d_0(\cdot, u)$). Note that, since C is nonempty, $(P1)$ ensures that $u \in \mathbb{R}^n \mapsto d_0(u,x)$ is also proper.

Denote by $\mathcal{D}$ the set of mappings $d : \mathbb{R}^n \times C \mapsto \mathbb{R}_+ \cup \{+\infty\}$ that can be written

$$d(u,x) = \frac{\alpha}{2}|u-x|^2 + d_0(u,x), \tag{3.4}$$

with $\alpha > 0$ and with d_0 satisfying $(P1)$, $(P2)$, and $(P3)$.

DEFINITION 3.1. *Let d be in $\mathcal{D}$. For all $(x,v) \in C \times \mathbb{R}^n$, set*

$$u^d(x,v) \in \arg\min \{\langle u, v\rangle + d(u,x) | u \in \mathbb{R}^n\}, \tag{3.5}$$

and define A^d by

$$A^d_x v = x - u^d(x,v). \tag{3.6}$$

The following proposition justifies the second part (3.6) of this definition (u^d could be multivalued) and describes some of the properties of the operator A^d.

PROPOSITION 3.2. *Let $d \in \mathcal{D}$.*

(i) *For each $x \in C$, the map $v \in \mathbb{R}^n \mapsto u^d(x,v)$ is a single valued α^{-1}–Lipschitz continuous map.*
(ii) *A^d satisfies $(r2)$ and $(r3)$, and for each $x \in C$, $v \in \mathbb{R}^n \mapsto A^d_x v$ is Lipschitz continuous.*
(iii) *Moreover, if d satisfies the property*

$$(p) \quad \forall x \in C, \ \text{dom } d(\cdot\,, x) \subset \overline{C},$$

then A^d satisfies (v) *of Definition* 2.1.

Proof. Let $(x,v) \in C \times \mathbb{R}^n$. From $(P3)$ and the fact that $\alpha > 0$, it follows that $u \in \mathbb{R}^n \mapsto \langle u, v\rangle + d(u,x)$ is strongly convex and has a nonempty bounded lower level set. This implies that $u^d(x,v)$ exists and is unique. Using $(P1)$ and $(P3)$ allows us to write the optimality condition in (3.5) as

$$v + \partial_1 d(\cdot, x)(u^d(x,v)) \ni 0,$$

and therefore by uniqueness of $u^d(x,v)$ (recalling (cf. [36]) that for any closed proper convex function F, one has $(\partial F)^{-1} = \partial F^*$), it follows that

$$u^d(x,v) = \partial_1 d^*(\cdot, x)(-v). \tag{3.7}$$

Denoting by I the identity map of $\mathbb{R}^n$, we observe using the definition of $d \in \mathcal{D}$ that $\partial_1 d^*(\cdot, x)$ can also be written

$$(\alpha I + \partial_1 d_0(\cdot, x) - \alpha x)^{-1}$$

or, equivalently, as the composition

$$(I + \alpha^{-1}\partial_1 d_0(\cdot\,, x) - x)^{-1} \circ \alpha^{-1} I.$$

By $(P3)$, the operator $\alpha^{-1}\partial_1 d_0(\cdot\,,x) - x$ is maximal monotone, and therefore by [14, Proposition 2.2], $(I + \frac{1}{\alpha}\partial_1 d_0(\cdot\,,x) - x)^{-1}$ is a contraction defined on $\mathbb{R}^n$. Recalling that $u^d(x,v) = (I + \alpha^{-1}\partial_1 d_0(\cdot\,,x) - x)^{-1} \circ \alpha^{-1} I$ and $A^d_x v = x - u^d(x,v)$, the above arguments prove (i) and the second part of statement (ii).

Assume that d complies with the property (p). By the definition of u^d, this implies that $u^d(x,v) = x - A^d_x v \in \overline{C}$, and therefore (iii) is a consequence of Lemma 2.3. It remains to prove the first two assertions of (ii). Let us prove that A^d satisfies $(r3)$. Let $(x,v) \in C \times \mathbb{R}^n$ be such that $A_x v = 0$. Then by (3.7), $x = \partial_1 d^*(\cdot\,,x)(-v)$, which implies that $\partial_1 d(x,x) = \nabla_1 d(x,x) = -v$. Therefore, by $(P2)$ one has $v = 0$. Now to prove that $(r2)$ is also satisfied, we use the following lemma.

LEMMA 3.3 (Baillon–Haddad [10]). *Let H, $\langle\,,\,\rangle$ be a Hilbert space whose norm is denoted $|\,.\,|$, $\phi : H \mapsto \mathbb{R}$ a C^1 convex function, and $L > 0$. The following statements are equivalent:*

(i) *For all $(x,y) \in H^2$, $|\nabla\phi(x) - \nabla\phi(y)| \le L|x-y|$.*

(ii) *For all $(x,y) \in H^2$, $\langle \nabla\phi(x) - \nabla\phi(y), x - y\rangle \ge \frac{1}{L}|\nabla\phi(x) - \nabla\phi(y)|^2$.*

In view of (3.7) and (i), this result can be applied to $\phi := d^*(\cdot\,,x)$. Hence, for x fixed in C and for all $(v_1,v_2) \in \mathbb{R}^n \times \mathbb{R}^n$, it gives

$$\langle \partial_1 d^*(\cdot\,,x)(v_1) - \partial_1 d^*(\cdot\,,x)(v_2), v_1 - v_2\rangle \ge \alpha|\partial_1 d^*(\cdot\,,x)(v_1) - \partial_1 d^*(\cdot\,,x)(v_2)|^2.$$

Now, letting $v_1 = 0$ and $v_2 = -v$ in the latter yields

$$\langle x - u^d(x,v), v\rangle \ge \alpha|x - u^d(x,v)|^2,$$

which, according to (3.6), is exactly $(r2)$. ∎

4. Elliptic barrier operators and continuous models for proximal algorithms: Examples and properties. In this section, we show that for various minimization algorithms one can derive an elliptic barrier operator and construct the associated $(A\text{-}DM)$-dynamical system. It is worth mentioning that many of the examples to follow will generate convergent trajectories to the minimizer of a convex function f over the closed convex set $\overline{C}$. From now on α will always denote the positive parameter involved in the definition of the class $\mathcal{D}$; cf. (3.4).

4.1. Projection-like methods. Let $h_0 : \mathbb{R}^n \mapsto \mathbb{R}$ be a C^1 convex function whose gradient is Lipschitz continuous on bounded sets, and set

$$\tilde{D}_h : \begin{cases} \mathbb{R}^n \times C & \to & \mathbb{R}_+ \cup \{+\infty\}, \\ (u,x) & \mapsto & D_h(u,x) + \delta_{\overline{C}}(u), \end{cases}$$

with $h(u) = \frac{\alpha}{2}|u|^2 + h_0(u)$, $u \in \mathbb{R}^n$, and where D_h is given by (cf. (1.7))

$$\forall (x,y) \in \mathbb{R}^n \times C,\ D_h(x,y) = h(x) - h(y) - \langle \nabla h(y), x - y\rangle. \tag{4.1}$$

PROPOSITION 4.1. *Let $\tilde{D}_h$ be as defined above. Then $A^{\tilde{D}_h}$ is an elliptic barrier operator that satisfies $(r4)$. Moreover, we have for all $(x,v) \in C \times \mathbb{R}^n$*

$$A^{\tilde{D}_h}_x v = x - (\nabla h + N_{\overline{C}})^{-1}(\nabla h(x) - v). \tag{4.2}$$

Proof. An easy computation gives $\tilde{D}_h(u,x) = \frac{\alpha}{2}|u-x|^2 + D_{h_0}(u,x) + \delta_{\overline{C}}(u)$. Letting $d_0(u,x) = D_{h_0}(u,x) + \delta_{\overline{C}}(u)$, we obtain that d_0 satisfies $(P1)$ and $(P3)$. For $(u,x) \in C \times C$, we have $\nabla_1 d_0(u,x) = \nabla h_0(u) - \nabla h_0(x)$, and as a consequence $(P2)$

is satisfied as well. Therefore $\tilde{D}_h$ is in $\mathcal{D}$ and clearly verifies (p). Now applying Proposition 3.2, it follows that $A^{\tilde{D}_h}$ satisfies $(r2)$, $(r3)$, and (v). The explicit formula of $A^{\tilde{D}_h}$ follows from (3.7). To obtain $(r1)$ and $(r4)$, we just have to observe that $(\nabla h + N_{\overline{C}})^{-1}$ and ∇h_0 are locally Lipschitz continuous on $\mathbb{R}^n$. □

The terminology of projection relies on the fact that (4.2) can be seen as some twisted projection in the Bregman sense. Indeed, defining the projection of $z \in \mathbb{R}^n$ on $\overline{C}$ by

$$P^h_{\overline{C}}(z) := \arg\min \{D_h(u, z) \mid u \in \overline{C}\},$$

we obtain that $P^h_{\overline{C}}(z) = (\nabla h + N_{\overline{C}})^{-1}(\nabla h(z))$ (recall that $\alpha > 0$), and therefore since $\nabla h^* = (\nabla h)^{-1}$, one can write

$$A^{\tilde{D}_h}_x v = x - P^h_{\overline{C}}(\nabla h^*(\nabla h(x) - v)) \quad \forall (x, v) \in C \times \mathbb{R}^n.$$

It is worth noting that in the framework of convex minimization, the gradient-like map $x \mapsto A^{\tilde{D}_h}_x \nabla f(x)$ enjoys remarkable properties. As a matter of fact, assume that the objective function f is convex, and observe that the following characterization holds:

$$x^* \text{ solves } (\mathcal{P}) \text{ iff } A^{\tilde{D}_h}_{x^*} \nabla f(x^*) = 0.$$

The associated $A^{\tilde{D}_h}$-driven descent method ($A^{\tilde{D}_h}$-DM) leads to the following differential equation:

$$\dot{x}(t) + x(t) - P^h_{\overline{C}}(\nabla h^*[\nabla h(x(t)) - \nabla f(x(t))]) = 0,\ x(0) \in C,\ \forall t \geq 0. \tag{4.3}$$

Note that with $h_0 = 0$ and $\alpha = 1$, the corresponding dynamical system ($A^{\tilde{D}_h}$-DM) (with corresponding operator A^P) is nothing else but the continuous gradient projection method (1.6), that is,

$$\dot{x}(t) + x(t) - P_{\overline{C}}[x(t) - \nabla f(x(t))] = 0,\ x(0) \in C,\ \forall t \geq 0.$$

We remark that if $x(0) \notin C$, we still obtain convergent trajectories (with f convex) (see [4] or Bolte [13]) but the dynamical system is neither a descent nor an interior method.

4.2. Continuous models for Bregman proximal minimization algorithms. In this section, we give two quite different continuous models associated with proximal methods based on Bregman distances.

Continuous model I: A Riemannian gradient method. Our model appears as a particular case of Riemannian gradient methods on the smooth manifold C. Let us specify the setting. Denote by $S^{++}_n(\mathbb{R})$ the cone of real definite positive symmetric matrices and let $\mathcal{T}_x C$ be the tangent space to C at $x \in C$. In what follows, we make the usual identification $\mathcal{T}_x C \simeq \mathbb{R}^n$ for all $x \in C$. If g is some differentiable metric on C, there exists a unique differentiable application $\lambda : C \to S^{++}_n(\mathbb{R})$ such that, for all $(x, u, v) \in C \times \mathbb{R}^n \times \mathbb{R}^n$,

$$g_x(u, v) = \langle \lambda(x)u, v \rangle.$$

The gradient of a smooth function ϕ with respect to the metric g is then given by the formula $\nabla_g \phi(x) = \lambda(x)^{-1} \nabla \phi(x)$ for all $x \in C$, and the corresponding gradient method is

$$\begin{cases} \dot{x}(t) + \nabla_g \phi(x(t)) = 0, \\ x(0) \in C. \end{cases} \tag{4.4}$$

For $C = \mathbb{R}^n$, ϕ real analytic, and g differentiable, a deep result of Lojasiewicz [32] allows us to prove that all bounded trajectories are converging to a critical point of ϕ.

Readers interested in the use of geometric tools in optimization are referred to Bayer and Lagarias [11], [12] in the context of linear programming and for more general results to the recent monograph of Helmke and Moore [22] and references therein.

Remark 4.1. Although our primary concerns in this paper are far removed from the complexity analysis of optimization algorithms, let us mention that there exists an intimate relation between Riemannian geometry and the complexity analysis of interior point optimization methods (see, e.g., the work of Karmarkar [25] in the context of linear programming). More generally, in the context of convex programming, Nesterov and Nemirovskii [34] introduced the fundamental concept of self-concordant barrier functions for a constraint set C, which plays a central role in the design and analysis of interior methods with polynomial complexity. Thus an interesting topic which is left for future research would be to study a Riemannian metric defined on C, based, for example, on the Hessian of a self-concordant barrier, and which could lead to further insights on the performance or complexity of barrier methods.

We focus here on the special choice of the application $\lambda : C \to S_n^{++}(\mathbb{R})$ defined by $\lambda = \nabla^2 h$, where h is some C^3 Bregman function with zone C; see Definition 4.2. The idea is to penalize the Euclidean scalar product, rather than the objective function, and to study the corresponding Riemannian gradient method

$$\dot{x}(t) + \nabla^2 h(x(t))^{-1} \nabla f(x(t)) = 0 \tag{4.5}$$

or, *equivalently*,

$$\frac{d}{dt} \nabla h(x(t)) + \nabla f(x(t)) = 0. \tag{4.6}$$

When the objective function is linear, this differential equation has been considered in Iusem, Svaiter, and Da Cruz [24]; however, their approach to the asymptotic behavior strongly relies on the linear properties of f; see Remark 5.3 (b) for an insight. Observe that this dynamics has, in its first form (4.5), the structure of (*A-DMs*). We shall see actually that most of classical Bregman functions can generate a barrier operator. Moreover, as shown below, the general framework developed in section 3 allows us to recover those methods by considering families of quadratic forms.

For the moment, let us compare (4.6) with (BPM) as given in the introduction. By an Euler implicit discretization we formally obtain

$$\frac{1}{\Delta t_k} [\nabla h(x^{k+1}) - \nabla h(x^k)] + \nabla f(x^{k+1}) = 0,\ \Delta t_k > 0. \tag{4.7}$$

Now observe that (BPM) has exactly the form of (4.7), provided that the iterates remain in C [17, 18, 20].

Before going further, we need to recall some of the basic facts concerning Bregman functions. Their definition relies mainly on their D function, as specified in (1.7).

DEFINITION 4.2. *A function $h : \overline{C} \to \mathbb{R}$ is called a Bregman function with zone C if it satisfies the following:*

(i) *h is C^1 on C.*

(ii) *h is continuous and strictly convex on $\overline{C}$.*

(iii) *For every* $r \in \mathbb{R}$, *the partial level subset* $L_h(x_0, r) = \{y \in C | D_h(x_0, y) \leq r\}$ *is bounded for every* $x_0 \in \overline{C}$.

(iv) *Let* $(y^k, k \in N)$ *be a sequence in* C *and* $x \in \overline{C}$. *If* $y^k \to x$ *as* $k \to +\infty$, *then* $D_h(x, y^k) \to 0$ *as* $k \to +\infty$.

This definition weakens the usual definition of the Bregman function proposed by Censor and Lent in [16] and is actually inspired by the more general notion of the B-functions introduced by Kiwiel in [28]. Because of (iv) and the smoothness property of h, we have kept the terminology of the Bregman function.

For the asymptotic analysis of (4.6) which will be developed in section 5, we record here the following useful lemma due to Kiwiel [28, Lemma 2.16].

LEMMA 4.3. *Let* h *be a Bregman function with zone* C *and* $x \in \overline{C}$. *If* y^k, $k \in N$, *is a bounded sequence in* C *such that* $D_h(x, y^k) \to 0$ *as* $k \to +\infty$, *then* $y^k \to x$ *as* $k \to +\infty$.

In relation to the barrier operators to follow, let us now define a subclass of Bregman functions with zone C.

For $h : \overline{C} \to \mathbb{R}$, we consider the following assumptions:

(r_h) There exist $\alpha > 0$ and a C^3 Bregman function with zone C denoted by h_0 such that for all $x \in \overline{C}$,

$$h(x) = \frac{\alpha}{2}|x|^2 + h_0(x).$$

(v_h) For every $b \in \operatorname{bd} C$ and every $\nu \in N_{\overline{C}}(b)$, there exists $K, \epsilon > 0$ such that for every $x \in C$, $|x - b| < \epsilon$,

$$|\nabla^2 h(x)^{-1}\nu| \leq K\langle b - x, \nu\rangle.$$

The set of such functions is denoted by $\mathcal{B}_C$, and for each $h \in \mathcal{B}_C$ we define a family of quadratic forms by

$$q_h : \begin{cases} \mathbb{R}^n \times C & \to & \mathbb{R}^n, \\ (u, x) & \mapsto & \langle \nabla^2 h(x)(u - x), u - x\rangle. \end{cases}$$

PROPOSITION 4.4. *For every* $h \in \mathcal{B}_C$, A^{q_h} *is an elliptic barrier operator on* C. *Moreover, for all* $(x, v) \in C \times \mathbb{R}^n$, *the following formula holds:*

$$A_x^{q_h} v = \nabla^2 h(x)^{-1} v. \tag{4.8}$$

Proof. To prove that $q_h \in \mathcal{D}$, it suffices to note that by (r_h),

$$q_h(u, x) = \alpha/2|u - x|^2 + \langle \nabla^2 h_0(x)(u - x), u - x\rangle,$$

where $\langle \nabla^2 h_0(x)(u - x), u - x\rangle$ satisfies $(P1)$, $(P2)$, $(P3)$. This implies by Proposition 3.2 that the operator A^{q_h} satisfies $(r2)$, $(r3)$. Note that q_h never satisfies the property (p), which precludes the use of Proposition 3.2 (iii).

Applying Definition 3.1, formula (4.8) can be derived easily from

$$\nabla^2 h(x)[u^{q_h}(x, v) - x] + v = 0 \quad \forall (x, v) \in C \times \mathbb{R}^n.$$

Since the mapping $M \in S_n^{++}(\mathbb{R}) \to M^{-1}$ is C^∞, we obtain by (r_h) that A^{q_h} satisfies $(r1)$.

Let us prove that A^{q_h} complies with (v) of Definition 2.1. Take $b \in \operatorname{bd} C$ and ν in $N_{\overline{C}}(b)$, and let us apply (v_h). There exist $K, \epsilon > 0$ such that for every $v \in \mathbb{R}^n$, $x \in C$, $|x - b| < \epsilon$,

$$\langle -A_x^h v, \nu \rangle = -\langle \nabla^2 h(x)^{-1} v, \nu \rangle = -\langle v, \nabla^2 h(x)^{-1} \nu \rangle \leq K|v| \langle b - x, \nu \rangle.$$

Therefore, if v is bounded, the latter amounts exactly to (v). ∎

The next lemma gives a practical means to prove that a Bregman function is in the class $\mathcal{B}_{\mathcal{C}}$.

For $a < b$ in $\overline{\mathbb{R}}$, $\varphi : (a, b) \to \mathbb{R}$, a C^2 Bregman function with zone (a, b), consider the following assumptions.

(v_l) If a is finite, there exist a neighborhood U of a in $\mathbb{R}$ and a positive constant K_l such that

$$\forall u \in U \cap (a, b) \quad \varphi''(u) \geq K_l/(u - a).$$

(v_r) If b is finite, there exist a neighborhood V of b in $\mathbb{R}$ and a positive constant K_r such that

$$\forall u \in V \cap (a, b) \quad \varphi''(u) \geq K_r/(b - u).$$

LEMMA 4.5. *Let $\varphi_1, \ldots, \varphi_n$ be some C^3 Bregman functions on $\mathbb{R}$ with zones $(a_1, c_1), \ldots, (a_n, c_n)$, $a_i < c_i$, $a_i, c_i \in \overline{\mathbb{R}}$, for all $i \in \{1, \ldots, n\}$. Assume that $\varphi_1, \ldots, \varphi_n$ satisfy (v_l), (v_r) on their respective zones, and for $\alpha > 0$ set*

$$h(x) = \frac{\alpha}{2}|x|^2 + \sum_{i=1}^{n} \varphi_i(x_i).$$

Then h belongs to $\mathcal{B}_K$, where $K = \prod_{i=1}^n (a_i, c_i)$, and A^{q_h} is an elliptic barrier operator that satisfies $(r4)$.

Proof. The fact that h is a C^3 Bregman function with zone K follows from [28, Lemma 2.8(d)], and therefore (r_h) is satisfied.

To simplify the notation, let us assume that for all $i \in \{1, \ldots, n\}$, $a_i = 0$ and $c_i = +\infty$ (which implies $K = \mathbb{R}^n_+$). For $b = (b_1, \ldots, b_n) \in \operatorname{bd} \mathbb{R}^n_+$, set $I(b) = \{i \in \{1, \ldots, n\} | b_i = 0\} \neq \emptyset$ and $J(b) = \{i \in \{1, \ldots, n\} | b_i \neq 0\}$. For each $i \in I(b)$, (v_l) yields the existence of a neighborhood U_i of 0 in $\mathbb{R}$ and $K_i > 0$ such that

$$\forall u \in U_i \cap (0, +\infty) \quad \varphi''(u) \geq K_i/u. \tag{4.9}$$

Set $U_i = \mathbb{R}^n$ for each $i \in J(b)$, and $U = \mathbb{R}^n_{++} \cap \prod_{i=1\ldots n} U_i$. Let $\nu \in N_{\overline{K}}(b)$, and observe that $\nu_i = 0$ for all $i \in J(b)$ and that $\nu_i < 0$ for all $i \in I(b)$. Therefore, for $x \in \mathbb{R}^n$, an easy computation gives

$$|\nabla^2 h(x)^{-1} \nu| \leq \sum_{i \in I(b)} \frac{-v_i}{|\alpha + \varphi_i''(x_i)|}.$$

Now if $x \in U$, (4.9) implies that

$$\begin{aligned} |\nabla^2 h(x)^{-1} \nu| &\leq \sum_{i \in I(b)} -\frac{1}{K_i} \nu_i . x_i \\ &\leq \sup_{i \in I(b)} \frac{1}{K_i} \langle b - x, \nu \rangle. \end{aligned}$$

A direct computation gives for all $x \in K$, $i, j \in \{1, \dots, n\}$,

$$\left(\nabla^2 h(x)^{-1}\right)_{i,j} = \frac{\delta_{ij}}{\alpha + \varphi_i''(x_i)},$$

where $\delta_{ij} = 1$ if $i = j$ and $\delta_{ij} = 0$ otherwise. Applying again (v_l), we see that A^{q_h} can be continuously extended on $\overline{K}$. Hence A^{q_h} satisfies $(r4)$. □

Example 4.1 (Bregman-based Barrier operators and their dynamics). The list of examples below shows thanks to Lemma 4.5 that many classical Bregman functions can be used to provide an elliptic barrier operator. In what follows, α is the positive regularizing term as defined in (v_h), and β is a positive parameter. For a Bregman function h with zone $I \subset \mathbb{R}$, set $h_n(x) = \sum_{i=1}^n h(x_i)$ for all $x \in I^n$.

(a) For $\theta \in (0,1)$, consider $h(s) = \frac{\alpha}{2}s^2 - \beta\frac{s^\theta}{\theta}$, $s \in \mathbb{R}_+$. Then $h \in \mathcal{B}_{\mathbb{R}_{++}}$, $h_n \in \mathcal{B}_{\mathbb{R}^n_{++}}$, and the corresponding $(A^{q_{h_n}}\text{-}DM)$ system is

$$\dot{x}_i(t) + \frac{x_i(t)^{2-\theta}}{\alpha x_i(t)^{2-\theta} + \beta(1-\theta)} \frac{\partial f}{\partial x_i}(x(t)) = 0, \quad x_i(0) > 0, \quad \forall i \in \{1, \dots, n\}. \tag{4.10}$$

(b) $h(s) = \frac{\alpha}{2}s^2 + \beta s \log s$ on $\mathbb{R}_+$ is in $\mathcal{B}_{\mathbb{R}_{++}}$, $h_n \in \mathcal{B}_{\mathbb{R}^n_{++}}$, and the associated system is

$$\dot{x}_i(t) + \frac{x_i(t)}{\alpha x_i(t) + \beta} \frac{\partial f}{\partial x_i}(x(t)) = 0, \quad x_i(0) > 0, \quad \forall i \in \{1, \dots, n\}.$$

This system is exactly the regularized Lotka–Volterra equation (1.8) recently proposed in [6]. However, it is worth noting that (1.8) was introduced there as a continuous model based not on (BPM) but on the proximal-like method

$$x^{k+1} \in \arg\min \left\{ f(x) + c_k d_\varphi(x, x^k) | x \in \mathbb{R}^n_+ \right\}, \; c_k > 0,$$

where $\varphi(s) = s - \log s - 1$ and $d_\varphi(x,y) = \frac{\alpha}{2}|x-y|^2 + \beta \sum_{i=1}^n y_i \varphi(y_i^{-1}x_i)$ for all x, y in $\mathbb{R}^n_{++}$. For more results and applications on classical Lotka–Volterra systems, see, e.g., Hofbauer and Sigmund [23].

(c) $h(s) = \frac{\alpha}{2}s^2 - \beta\sqrt{1-s^2}$ on $[-1,1]$ is in $\mathcal{B}_{(-1,1)}$, $h_n \in \mathcal{B}_{(-1,1)^n}$, and the corresponding system is

$$\dot{x}_i(t) + \frac{\left(1 - x_i(t)^2\right)^{3/2}}{\alpha\left(1 - x_i(t)^2\right)^{3/2} + \beta} \frac{\partial f}{\partial x_i}(x(t)) = 0, \quad x_i(0) \in (-1,1), \quad \forall i \in \{1, \dots, n\}.$$

(d) $h(s) = \frac{\alpha}{2}s^2 - \beta\sqrt{s(1-s)}$ on $[0,1]$ is in $\mathcal{B}_{(0,1)}$, $h_n \in \mathcal{B}_{(0,1)^n}$, and the corresponding system is

$$\dot{x}_i(t) + \frac{4x_i(t)^{3/2}(1-x_i(t))^{3/2}}{4\alpha x_i(t)^{3/2}(1-x_i(t))^{3/2} + \beta} \frac{\partial f}{\partial x_i}(x(t)) = 0, \quad x_i(0) \in (0,1), \quad \forall i \in \{1, \dots, n\}.$$

Remark 4.2. For $\epsilon, \gamma \geq 0$, and $f \in C^3(\mathbb{R}^n, \mathbb{R})$, set $h_{\epsilon,\gamma}(x) = \frac{\epsilon}{2}|x|^2 + \gamma f(x)$ for all $x \in \mathbb{R}^n$. Then we have $h_{\epsilon,\gamma} \in \mathcal{B}_{\mathbb{R}^n}$, under one of the following assumptions:

($\star$) f is strongly convex, i.e., $\nabla^2 f - \lambda I$ is positive semidefinite, with $\lambda > 0$.

($\star$) f is convex and $\epsilon > 0$.

($\star$) $\gamma = 0$, $\epsilon > 0$.

Letting $\epsilon = 0$, $\gamma = 1$ in the first case yields the continuous Newton descent method (1.9). The second version can be seen, for ϵ small, as a regularized Newton method

$$(A^{q_{h_\epsilon,\gamma}} - DM) \qquad \dot{x}(t) + [\epsilon Id + \gamma \nabla^2 f(x(t))]^{-1} \nabla f(x(t)) = 0.$$

The last point with $\gamma = 0$, $\epsilon > 0$ gives rise to the classical steepest descent method.

In the examples just described, the $A^{q_{h_\epsilon,\gamma}}$ are elliptic barrier operators *on* $\mathbb{R}^n$ so that the feasible set $\overline{C}$ is the whole space $\mathbb{R}^n$, and $(v)_h$ holds vacuously. It actually raises another interesting aspect of barrier operators: they can also be used as a geometrical means to improve convergence rate as well as well-posedness properties. This suggests, for instance, to go further in the study of the Newton–Barrier methods

$$\dot{x}(t) + [\lambda \nabla^2 h(x(t)) + \mu \nabla^2 f(x(t))]^{-1} \nabla f(x(t)) = 0,\ t \geq 0,$$

with $\lambda, \mu > 0$ and where h is a C^3 Bregman function.

Continuous model II. The Bregman distances appearing in the definition of projection methods (section 4.1) can be used in a quite different way in order to provide some other continuous model of (BPM). Indeed, replacing the kernel h_0 defined on the whole space $\mathbb{R}^n$ by some essentially smooth convex function (see definition below) allows us to get rid of the normal cone and to reformulate (4.3) as

$$\nabla h(x(t) + \dot{x}(t)) - \nabla h(x(t)) + \nabla f(x(t)) = 0 \quad \forall t \geq 0.$$

This can be discretized as

$$\nabla h(x_{k+1}) - \nabla h(x_k) + \nabla f(x_{k+1}) = 0 \quad \forall k \in N,$$

and (BPM) is recovered with a sequence of step-sizes satisfying $c_k = 1$ for all $k \in N$.

This model will be derived from our general framework developed in section 3. First, we recall the definition of essentially smooth convex functions; see [36].

DEFINITION 4.6. *A proper convex function $\phi : \mathbb{R}^n \mapsto \mathbb{R} \cup \{+\infty\}$ is essentially smooth if it satisfies the following:*

(i) *The interior of* dom ϕ *is nonempty; i.e.,* int dom $\phi \neq \emptyset$.
(ii) ϕ *is differentiable on* int dom ϕ.
(iii) *For all b in the boundary of* int dom ϕ *and all sequence x_k, $k \in N$, in* int dom ϕ *such that $x_k \to b$ as $k \to +\infty$, we have $|\nabla \phi(x_k)| \to +\infty$ as $k \to +\infty$.*

As in subsection 4.1, we now study operators of the form A^{D_h} (cf. (4.1)) for some relevant kernels h. Let $h_0 : \mathbb{R}^n \mapsto \mathbb{R} \cup \{+\infty\}$ be a closed proper convex function such that

$(\mathrm{i})_{h_0}$ h_0 is essentially smooth with in addition int dom $h_0 = C$, and
$(\mathrm{ii})_{h_0}$ ∇h_0 is Lipschitz continuous on compact subsets of C.

For such a function h_0, we set $h(u) = \alpha/2|u|^2 + h_0(u)$ for all $u \in \mathbb{R}^n$. In the following proposition, it is important to recall that D_h is an extended real function defined on the whole of $\mathbb{R}^n \times C$.

PROPOSITION 4.7. *Let h be as above. Then A^{D_h} is an elliptic barrier operator on C, and for all $(x, v) \in C \times \mathbb{R}^n$ we have*

$$A_x^{D_h} v = x - \nabla h^*(\nabla h(x) - v). \tag{4.11}$$

Proof. From $(\mathrm{i})_{h_0}$ it follows that $D_h \in \mathcal{D}$. Using the fact that h is essentially smooth with int dom $h = C$, we deduce that (p) is satisfied. By Proposition 3.2, we

see that A^{D_h} verifies $(r2)$, $(r3)$, and (v). The formula (4.11) follows from (3.6), and $(r1)$ follows from $(\mathrm{ii})_{h_0}$. □

The associated A^{D_h}-DM is thus given by

$$\dot{x}(t) + x(t) - \nabla h^*[\nabla h(x(t)) - \nabla f(x(t))] = 0,\ x(0) \in C, \quad \forall t \geq 0, \tag{4.12}$$

or using $\nabla h^* = (\nabla h)^{-1}$ equivalently as

$$\nabla h(x(t) + \dot{x}(t)) - \nabla h(x(t)) + \nabla f(x(t)) = 0,\ x(0) \in C, \quad \forall t \geq 0.$$

Example 4.2. Consider the regularized Burg's entropy obtained with $g(s) = (\alpha/2)s^2 - \beta \log s,\ s > 0$, where β is a positive parameter. For $x \in \mathbb{R}^n_{++}$ set $h(x) = \sum_{i=1}^n g(x_i)$. The function h satisfies the requirements of Proposition 4.7. A direct computation shows that

$$(g^*)'(u) = \frac{u + \sqrt{u^2 + 4\alpha\beta}}{2\alpha} \quad \forall u \in \mathbb{R}.$$

Substituting in (4.12), the following descent method is derived: For all $i = 1, \ldots, n$,

$$\dot{x}_i(t) + x_i(t)/2 + (2\alpha)^{-1}\Bigg(\beta/x_i(t) + \frac{\partial f}{\partial x_i}(x(t)) - \sqrt{[\alpha x_i(t) - \beta/x_i(t) - \frac{\partial f}{\partial x_i}(x(t))]^2 + 4\alpha\beta}\Bigg) = 0$$

for all $t \geq 0$ and with $x_i(0) > 0$ for all $i \in \{1, \ldots, n\}$.

It is interesting to note that as $\alpha \to 0$ we do not recover here the Lotka–Volterra system; compare this with the system given in Example 4.1 (b).

4.3. A continuous model for proximal algorithms with second order kernels. The class of operators A^{d_φ} defined in this section are built upon the kernels φ which are used to realize the $(RIPM)$ method introduced in [8], and which we now recall. Let $\varphi : \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$ be a closed proper function whose domain dom φ is a subset of $[0, +\infty)$. Consider the following assumptions on φ:

- $(\mathrm{i})_\varphi$ φ is finite and C^2 on $(0, +\infty)$.
- $(\mathrm{ii})_\varphi$ φ is strictly convex on $(0, +\infty)$.
- $(\mathrm{iii})_\varphi$ $\lim_{s>0,\ s\to 0} \varphi'(s) = -\infty$.
- $(\mathrm{iv})_\varphi$ $\varphi(1) = \varphi'(1) = 0$ and $\varphi''(1) > 0$.
- $(\mathrm{v})_\varphi$ For all $s > 0$, $\varphi''(1)(1 - \frac{1}{s}) \leq \varphi'(s) \leq \varphi''(1)(s - 1)$.

Now for $\alpha, \beta > 0$, set

$$\varphi(s) = \frac{\alpha}{2}(s-1)^2 + \beta\varphi_0(s), \tag{4.13}$$

where φ_0 satisfies $(i)_\varphi - (v)_\varphi$, and denote by Φ the class of such functions. For $\varphi \in \Phi$, set

$$\forall (u, x) \in \mathbb{R}^n \times \mathbb{R}^n_{++} \quad d_\varphi(u, x) = \sum_{i=1}^n x_i^2 \varphi(x_i^{-1} u_i). \tag{4.14}$$

It is proved in [8] that the associated proximal method,

$$(RIPM) \qquad x^{k+1} \in \arg\min \left\{ f(x) + c_k d_\varphi(x, x_k) | x \in \mathbb{R}^n_+ \right\},\ c_k > 0,$$

generates a positive sequence $\{x^k\}$ provided that $x^0 \in \mathbb{R}^n_{++}$. As a consequence, an equivalent formulation of $(RIPM)$ is

$$c_k \partial_1 d_\varphi(x^{k+1}, x^k) + \nabla f(x^{k+1}) = 0 \quad \forall k \geq 1. \tag{4.15}$$

Under the additional assumptions that $\arg\min_{\mathbb{R}^n_+} f \neq \emptyset$, $\sum_{k=1}^{+\infty} c_k = \infty$, and

$$\alpha \geq \beta \varphi_0''(1), \tag{4.16}$$

it is proved in [8] that the sequence x^k, $k \in N$, converges to a minimizer of f.

Following the general framework developed in section 3, we generate the elliptic barrier operator and dynamical system associated with $(RIPM)$.

PROPOSITION 4.8. *Let $\varphi \in \Phi$. Then A^{d_φ} is an elliptic barrier operator, and one has for all $(x, v) \in \mathbb{R}^n_{++} \times \mathbb{R}^n$*

$$\left(A^{d_\varphi}_x v\right)_i = x_i - x_i(\varphi^*)'(-x_i^{-1} v_i) \quad \forall i = 1, \ldots, n. \tag{4.17}$$

Proof. For all $(u, x) \in \mathbb{R}^n_+ \times \mathbb{R}^n_{++}$ we have $d_\varphi(u, x) = \alpha/2|u - x|^2 + \beta d_{\varphi_0}(u, x)$, and therefore to prove that $d_\varphi \in \mathcal{D}$, we need to show that βd_{φ_0} satisfies $(P1)$, $(P2)$, and $(P3)$. $(P1)$ follows from $(\mathrm{i})_\varphi$, while $(P3)$ is a consequence of the definition of φ_0. Using $(\mathrm{iv})_\varphi$, we see by a direct computation that $(P2)$ is satisfied and thus that $d_\varphi \in \mathcal{D}$.

Using Definition 3.1 with $d := d_\varphi \in \mathcal{D}$, the optimality conditions for (3.5) yield

$$v_i + x_i \varphi'(u_i x_i^{-1}) = 0 \quad \forall i = 1, \ldots, n,$$

from which formula (4.17) follows easily using $(\varphi^*)' = (\varphi')^{-1}$. Since dom $\varphi \subset \mathbb{R}_+$, we have for all $x \in \mathbb{R}^n_{++}$, dom $d_\varphi(., x) \subset \mathbb{R}^n_+$, and therefore by Proposition 3.2 A^{d_φ} satisfies $(r2)$, $(r3)$, and (v).

It remains to prove that $(r1)$ holds. Using formula (4.17), and since $x \in \mathbb{R}^n_{++}$, it thus suffices to show that $(\varphi^*)'$ is Lipschitz continuous. However, since here φ is a smooth α-strongly convex function, one has

$$(t - s)(\varphi'(t) - \varphi'(s)) \geq \alpha(t - s)^2 \quad \forall t, s > 0,$$

and thus recalling that $(\varphi^*)' = (\varphi')^{-1}$, one easily deduces the required Lipschitz property for $(\varphi^*)'$ and $(r1)$ follows. ∎

Remark 4.3. (a) Requirement $(\mathrm{v})_\varphi$ allows acute controls on d_φ in the asymptotic analysis of $(RIPM)$ and $(A^{d_\varphi}\text{-}DM)$ (see section 5, Theorem 5.4) and is actually not needed for the above result. Technically those controls are the reason why our operator is based on φ and not on φ^*.

(b) The assumption $(\mathrm{iii})_\varphi$ reduces the computation of $(\varphi^*)'$ to the inversion of $\varphi'_{|(0,+\infty)}$.

(c) Note also that A^{d_φ} does not satisfy $(r4)$ in general, but as we shall see in the next section it has no consequence on the asymptotic study of $(A^{d_\varphi}\text{-}DM)$ when f is convex.

(d) One could also develop a similar construction with "regularized φ-divergence" distance-like functions, that is,

$$d(u, x) = \frac{\alpha}{2}|u - x|^2 + \sum_{i=1}^{n} x_i \varphi(u_i x_i^{-1}),\ u, x \in \mathbb{R}^n_+,$$

where $\varphi : \mathbb{R} \mapsto \mathbb{R} \cup \{+\infty\}$ is an essentially smooth convex function such that $(0, +\infty) \subset \operatorname{dom} \varphi \subset [0, +\infty)$. Unfortunately the parameter α forbids the computation of the Legendre conjugates of $\partial d(\cdot, x)$, $x \in C := \mathbb{R}^n_+$, and leads to purely theoretical conclusions. This gives new motivation to study barrier operators for which $\alpha = 0$ (see Remark 2.1 (a)).

The $(A^{d_\varphi}\text{-}DM)$ system is given by

$$\dot{x}_i(t) + x_i(t) - x_i(t)(\varphi^*)' \left(-x_i(t)^{-1} \frac{\partial f}{\partial x_i}(x(t)) \right) = 0 \quad \forall t \geq 0,$$

or, equivalently, as

$$x_i(t)\varphi' \left(\frac{\dot{x}_i(t) + x_i(t)}{x_i(t)} \right) + \frac{\partial f}{\partial x_i}(x(t)) = 0, \ t \geq 0.$$

To recover $(RIPM)$ by some discretization of $(A^{d_\varphi}\text{-}DM)$, the latter can be reformulated in the following way:

$$\partial_1 d_\varphi \left(x(t) + \dot{x}(t), x(t) \right) + \nabla f(x(t)) = 0, \ x(0) \in \mathbb{R}^n_{++}, \quad \forall t \geq 0. \tag{4.18}$$

Now, if we perform an implicit discretization of (4.18), it yields

$$\partial_1 d_\varphi \left(x^{k+1}, x^k \right) + \nabla f(x^{k+1}) = 0, x^0 = x(0), \ k \in N.$$

which is exactly (4.15), with $c_k = 1$.

Example 4.3. It is a delicate matter to build a function in Φ whose Fenchel conjuguate is easily computable. As in [8] we focus on the important special choice given by a logarithmic-quadratic kernel,

$$\varphi(s) = \frac{\alpha}{2}(s-1)^2 + \beta(-\log s + s - 1), \ s > 0,$$

which admits (see [8, p. 665]) an explicit conjugate $\varphi^* \in C^\infty(\mathbb{R})$, and with

$$(\varphi^*)'(s) = \frac{1}{2\alpha}[\alpha - \beta + s + \sqrt{(\alpha - \beta + s)^2 + 4\alpha\beta}] \quad \forall s \in \mathbb{R}.$$

The corresponding $(A^\varphi\text{-}DM)$ system is then given by

$$\dot{x}_i(t) + \frac{\alpha + \beta}{2\alpha} x_i(t) + \frac{1}{2\alpha} \frac{\partial f(x(t))}{\partial x_i} - \sqrt{\frac{1}{4\alpha^2} \left[(\alpha - \beta) x_i(t) + \frac{\partial f(x(t))}{\partial x_i} \right]^2 + 4\alpha\beta x_i(t)^2} = 0, \tag{4.19}$$

with $i \in \{1, \ldots, n\}$, $t \geq 0$, and $x(0) \in \mathbb{R}^n_{++}$. An interesting fact to note is that (4.19) has a sense for any $x(0) \in \mathbb{R}^n$; this suggests like in [13] a study of its properties for *nonfeasible* initial data.

5. Asymptotic analysis for a convex objective function. In what follows, f satisfies the additional assumptions

$$(\mathcal{H}') : \begin{cases} f \text{ is convex,} \\ \arg\min_{\overline{C}} f \neq \emptyset. \end{cases}$$

This section proposes a criterion concerning elliptic barrier operators to obtain the convergence of the trajectories of (*A-DM*). It is based on Lyapunov functionals and to their (theoretical) decreasing rate. This natural approach is inspired by the classical result of Bruck [15] on the generalized steepest descent method, and by the notions of Fejer or quasi-Fejer sequences which go back to the work of Ermoliev [21] and arise in monotone and generalized gradient optimization algorithms. Such techniques have also been applied successfully to second order in time systems by Alvarez [1] and Alvarez and Attouch [2]. Before stating the main result of this section, let us describe the typical properties of those Lyapunov functionals, sometimes called *relative entropy*, when working on systems in the nonnegative orthant; see, e.g., [23]. In what follows, S should be understood as the set of equilibria of some convex function.

We suggest the following general definition for viable Lyapunov functionals.

DEFINITION 5.1. *Let $S \subset \overline{C}$ be a nonempty set. A family of functions $\{e_a, a \in S\}$ is Lyapunov viable if it satisfies*

- $(\mathrm{i})_e$ *For all $a \in S$, $e_a : C \to \mathbb{R}$ is C^1.*
- $(\mathrm{ii})_e$ *The functions e_a are nonnegative for all $a \in S$.*
- $(\mathrm{iii})_e$ *For all $a \in S$, e_a is* inf *bounded. That is, for every $r \in \mathbb{R}$, the set $\{y \in C | e_a(y) \leq r\}$ is bounded.*
- $(\mathrm{iv})_e$ *Let $x^k, k \in N$ be a sequence in C. Then for all $a \in S$,*

$$e_a(x^k) \to 0 \text{ as } k \to +\infty \iff x^k \to a \text{ as } k \to +\infty.$$

The next result is a key lemma that can be used to establish convergence of trajectories of (*A-DM*). First, we recall the following classical result (see, e.g., [1, Lemma 2.2]) which will be useful to us.

LEMMA 5.2. *Let $h : \mathbb{R} \to \mathbb{R}^+$ be a C^1 function. If $(h')^+ := \max(0, h')$ is in $L^1(0, +\infty; \mathbb{R})$, then $\lim_{t \to +\infty} h(t)$ exists.*

Let us set $S := \arg\min_{\overline{C}} f$.

LEMMA 5.3. *Let A be an elliptic barrier operator on C and f a function satisfying $(\mathcal{H}_1)$, $(\mathcal{H}_2)$, $(\mathcal{H}')$. Assume that there exist $\lambda > 0$, $\mu \in \mathbb{R}$, and a family of functions $\{e_a, a \in S\}$ that is Lyapunov viable (i.e., satisfying $(\mathrm{i})_e - (\mathrm{iv})_e$). Suppose, in addition, that for all $x \in C$,*

$$\langle -A_x \nabla f(x), \nabla e_a(x) \rangle + \lambda \langle \nabla f(x), x - a \rangle \leq \mu |A_x \nabla f(x)|^2. \tag{5.1}$$

If $x(t)$ is the solution of (A-DM), then the following hold:

(i) *$f(x(t)) \to \inf_{\overline{C}} f$ as $t \to +\infty$, with the estimation*

$$f(x(t)) - \inf_{\overline{C}} f \leq Mt^{-1} \text{ for some } M > 0.$$

(ii) *$\dot{x}(t) \to 0$ as $t \to +\infty$.*

(iii) *There exists $x^* \in S$ such that $x(t) \to x^*$ as $t \to +\infty$.*

Proof. Let $a \in S$; by (5.1) and (*A-DM*) we obtain

$$\frac{d}{dt} e_a(x(t)) + \lambda \langle \nabla f(x(t)), x(t) - a \rangle \leq \mu |\dot{x}(t)|^2, \ t \geq 0. \tag{5.2}$$

From the convex inequality it follows that for all $y \in \overline{C}$,

$$0 \geq f(a) - f(y) \geq \langle \nabla f(y), a - y \rangle. \tag{5.3}$$

Combining (ii) of Theorem 2.4, (5.3), and (5.2) yields $[\frac{d}{dt}e_a(x(t))]^+ \leq \mu|\dot{x}(t)|^2$, $t \geq 0$. From $(\text{ii})_e$ and Lemma 5.2, we deduce that $e_a(x(t))$ converges as $t \to +\infty$. Hence, by $(\text{iii})_e$, $x(\cdot)$ is bounded.

Coming back to (5.2), we obtain for all $T \geq 0$

$$\lambda \int_0^T \langle \nabla f(x(t)), x(t) - a\rangle dt \leq \int_0^T |\dot{x}(t)|^2 dt + e_a(x(0)) - e_a(x(T)),$$

and since $\lambda > 0$,

$$\langle \nabla f(x(\cdot)), x(\cdot) - a\rangle \in L^1(0, \infty; \mathbb{R}). \tag{5.4}$$

From (5.4), $(\mathcal{H}_1)$, and the boundedness property of x, we obtain that there exist $x^* \in \overline{C}$ and a nondecreasing sequence $t_k, k \in N$ such that $\langle \nabla f(x(t_k)), x(t_k) - a\rangle \to 0$ and $x(t_k) \to x^*$ as $k \to +\infty$. Using (5.3), it follows that $f(x^*) \leq f(a)$ and thus $x^* \in S$.

By Theorem 2.4 (iii) and the continuity of f, we see that the latter argument implies $f(x(t)) \to \inf_{\overline{C}} f$ as $t \to +\infty$ and that all limit points of x are in S.

To prove the second part of (i), we first deduce from (5.2) and (5.3) that

$$\frac{d}{dt}e_a(x(t)) + \lambda(f(x(t)) - f(a)) \leq \mu|\dot{x}(t)|^2,\ t \geq 0.$$

By integration it follows from Theorem 2.4 (iii) that for $t \geq 0$, $t\lambda[f(x(t)) - \inf_{\overline{C}} f] \leq e_a(x(0)) - e_a(x(t)) + \mu \int_0^t |\dot{x}|^2$. Using $(\text{iii})_e$, we obtain for all $t > 0$

$$\lambda \left[f(x(t)) - \inf_{\overline{C}} f \right] \leq \frac{1}{t} \left[e_a(x(0)) + \mu \int_0^t |\dot{x}|^2 \right]. \tag{5.5}$$

The estimate announced in (i) is then a consequence of Theorem 2.4 (iv).

Let x_1^* and x_2^* be two cluster points of $x(\cdot)$ and $t_k, \tau_k, k \in N$, increasing sequences in $\mathbb{R}^+$, such that $x(t_k) \to x_1^*$, $x(\tau_k) \to x_2^*$ as $k \to +\infty$. From $(\text{iv})_e$, we deduce that $e_{x_1^*}(x(t_k)) \to 0$ as $k \to +\infty$. However, since the function $e_{x_1^*}(x(\cdot))$ has a limit as $t \to +\infty$, we also have $e_{x_1^*}(x(\tau_k)) \to 0$ as $k \to +\infty$, and by applying $(\text{iv})_e$ again, we obtain $x_1^* = x_2^*$.

Let x^* be the limit point of $x(\cdot)$, it verifies the classical relation $\nabla f(x^*) \in -N_{\overline{C}}(x^*)$, and therefore $(\mathcal{H}_1)$ implies that $(x(t), \nabla f(x(t)))$ has its limit point in $\{x^*\} \times -N_{\overline{C}}(x^*)$. Applying Proposition 2.2, it follows that $\dot{x}(t) \to 0$ as $t \to +\infty$. □

Remark 5.1. (a) If $\mu \leq 0$, we have by (5.5)

$$f(x(t)) - \inf_{\overline{C}} f \leq \frac{1}{\lambda t} e_a(x(0)) \quad \forall t > 0.$$

(b) Note that Lemma 5.3 allows us to handle the case $\mu > 0$ in (5.1), which corresponds to quasi-Fejer convergence.

(c) The property $(r3)$ has not been used, but it is implicitly contained in (5.1).

(d) Note also that the above result holds for an elliptic barrier operator which is possibly undefined on $\operatorname{bd} C \times \mathbb{R}^n$.

Let us apply this result to some of the operators defined in section 4. In what follows, *it is implicitly assumed that* $C = \mathbb{R}^n_{++}$ *when dealing with operators of the type* A^{d_φ}, $\varphi \in \Phi$, while A^P is the gradient projection operator (cf. subsection 4.1).

THEOREM 5.4. *Let $\varphi \in \Phi$ such that $\alpha \geq \beta\varphi_0''(1)$, $h \in \mathcal{B}_C$, and assume that f satisfies $(\mathcal{H}_1)$, $(\mathcal{H}_2)$, $(\mathcal{H}')$. Then the trajectories of $(A^P$-$DM)$, $(A^{q_h}$-$DM)$, and $(A^{d_\varphi}$-$DM)$ converge to some minimizer of f on $\overline{C}$. Moreover, for all trajectories x, the following properties hold:*

(i) $f(x(t)) \to \inf_{\overline{C}} f$ *as* $t \to +\infty$, *with the estimation*

$$f(x(t)) - \inf_{\overline{C}} f \leq Mt^{-1}, \quad \text{where } M > 0.$$

(ii) $\dot{x}(t) \to 0$ *as* $t \to +\infty$.

Proof. By Propositions 4.1, 4.4, and 4.8, we know that A^P, A^{q_h}, and $A^{d\varphi}$ are elliptic barrier operators. For every $a \in S$ and for all $x \in C$, set

$$\begin{aligned} e_a^P(x) &= f(x) - f(a) + \tfrac{1}{2}|x-a|^2, \\ e_a^h(x) &= D_h(a,x) = \tfrac{\alpha}{2}|x-a|^2 + D_{h_1}(a,x), \\ e_a^\varphi(x) &= f(x) - f(a) + \theta|x-a|^2, \end{aligned}$$

where $\theta = (\alpha + \varphi_0''(1))/2$. Naturally the idea is to apply Lemma 5.3 to the operators A^P, A^{q_h}, and A^{d_φ}. Let $a \in S$. The functions e_a^φ, e_a^h, and e_a^P clearly satisfy $(\mathrm{i})_e$, $(\mathrm{ii})_e$. To obtain $(\mathrm{iii})_e$, just notice that in the three cases, the structure of the functions has the form

$$\xi_a(x) = k|x-a|^2 + \rho_a(x) \quad \forall x \in C,$$

with $\rho_a \geq 0$, $k > 0$. By definition of a Bregman function and by Lemma 4.3, e_a^h verifies $(\mathrm{iv})_e$. To prove that e_a^P and e_a^φ satisfy $(\mathrm{iv})_e$, we just have to combine $(\mathcal{H})$ and the fact that a is a minimizer of f on $\overline{C}$. Let us prove that the property (5.1) holds for the couples (e_a^P, A^P), (e_a^h, A^{q_h}), and (e_a^P, A^{d_φ}).

• The continuous gradient projection method has already been studied from different viewpoints in [13], but for the sake of completeness we recall the argument. Let $x \in C$ and $a \in S$. The optimality property of the orthogonal projection operator gives, for all $\xi \in \overline{C}$, $\langle x - \nabla f(x) - P_{\overline{C}}(x - \nabla f(x)), \xi - P_{\overline{C}}(x - \nabla f(x))\rangle \leq 0$. Therefore, if $\xi = a$, we obtain

$$\langle -\nabla f(x) + A_x^P \nabla f(x), a - x + A_x^P \nabla f(x)\rangle \leq 0$$

or, equivalently, $\langle -A_x^P \nabla f(x), x - a + \nabla f(x)\rangle + |A_x^P \nabla f(x)|^2 + \langle \nabla f(x), x - a\rangle \leq 0$, which is (5.1) with $\mu = -1$.

• Now, let us consider A^{q_h}, where h is Bregman function that belongs to $\mathcal{B}_C$. Let us compute the gradient of e_a^h for all $a \in S$. For all $x \in C$, we have

$$\begin{aligned} \nabla e_a^h(x) &= \nabla[h(a) - h(\cdot) - \langle \nabla h(\cdot), a - \cdot\rangle](x) \\ &= \nabla^2 h(x)(x-a). \end{aligned}$$

And therefore, $\langle -A_x^{q_h} \nabla f(x), \nabla e_a^h(x)\rangle = -\langle \nabla^2 h(x)^{-1} \nabla f(x), \nabla^2 h(x)(x-a)\rangle = -\langle \nabla f(x), x - a\rangle$, which verifies (5.1) with $\mu = 0$ and $\lambda = 1$.

• Finally, let us deal with e_a^P, A^{d_φ}. Our approach relies on the following key lemma proven in [8, Lemma 3.4].

LEMMA 5.5. *For every $y_1 \in \mathbb{R}_+^n$ and for every $(y_1, y_2) \in \mathbb{R}_{++}^n \times \mathbb{R}_{++}^n$, we have*

$$\langle y_1 - y_2, \partial_1 d_\varphi(y_2, y_3)\rangle \leq \theta\left(|y_1 - y_3|^2 - |y_1 - y_2|^2\right).$$

Note that it is here that the property $(\mathrm{v})_\varphi$ is needed. Indeed, the proof of this lemma is based on that assumption, together with the condition $\alpha \geq \beta\varphi_0''(1)$.

For all $i \in \{1 \dots, n\}$ and all $x \in \mathbb{R}^n_{++}$, set $(v_x)_i = -(A^{d_\varphi}_x \nabla f(x))_i$. The A^{d_φ}-*DM* can be rewritten as

$$\partial_1 d_\varphi \left(x(t) + v_x, x\right) + \nabla f(x) = 0 \quad \forall x \in \mathbb{R}^n_{++}. \tag{5.6}$$

Observe that $x \in \mathbb{R}^n_{++}$ implies $x + v_x \in \mathbb{R}^n_{++}$. Now for $a \in \arg\min_{\mathbb{R}^n_+} f$ and for all $x \in \mathbb{R}^n_{++}$, let us multiply (5.6) by $a - x - v_x$; this gives

$$\langle a - (v_x + x), \partial_1 d_\varphi(x + v_x, x) \rangle + \langle \nabla f(x), a - x - v_x \rangle = 0,$$

and therefore by Lemma 5.5

$$\theta \left(|a - x|^2 - |a - x - v_x|^2 \right) + \langle \nabla f(x), a - x - v_x \rangle \geq 0.$$

After direct algebra, this reduces to

$$\langle v_x, 2\theta(x - a) + \nabla f(x) \rangle + \langle \nabla f(x), x - a \rangle + |v_x|^2 \leq 0 \quad \forall x \in \mathbb{R}^n_{++}.$$

Recalling that $v_x = -A^{d_\varphi}_x \nabla f(x)$, we easily see that (5.1) is satisfied. □

Remark 5.2. The convergence of the orbits generated by the other operators proposed in section 4 remains an open question.

Localization of the limit point. Let A be an elliptic barrier operator, and let e_a be a family of viable Lyapunov functionals satisfying (5.1) with $\mu \leq 0$. We assume, moreover, that for all a in $S \subset \overline{C}$, there exist a nonnegative convex function $\rho_a : C \mapsto \mathbb{R}$ and $k > 0$ such that

$$e_a(x) = k|x - a|^2 + \rho_a(x) \quad \forall x \in C. \tag{5.7}$$

As in Lemaire [29], and inspired by the recent non Euclidean extension given in [6], the limit point of the trajectory produced by (*A-DM*) can be localized.

PROPOSITION 5.6. *Let A be an elliptic barrier operator on C, and let $\{e_a, a \in S\}$ be as defined in* (5.7). *Then the trajectory of (A-DM), with $x(0) \in C$, converges to a minimizer x_∞ of f on $\overline{C}$, with the following estimation:*

$$|x_\infty - x(0)|^2 \leq \inf \left\{ 4|x(0) - a|^2 + \frac{2}{k} \rho_a(x(0)) \mid a \in S \right\}.$$

Proof. The convergence result of the trajectory $x(t)$ to $x_\infty \in S = \arg\min_{\overline{C}} f$ is a direct consequence of Lemma 5.3. To prove the estimation, let us come back to the inequality (5.2) proven in Lemma 5.3:

$$\frac{d}{dt} e_a(x(t)) + \lambda \langle \nabla f(x(t)), x(t) - a \rangle \leq \mu |\dot{x}(t)|^2, \; t \geq 0.$$

The convexity property of f and the fact that $\mu \leq 0$ imply that $\mathbb{R}_+ \ni t \mapsto e_a(x(t))$ is nonincreasing. Therefore, for all $a \in S$, we have $e_a(x(t)) \leq e_a(x(0))$, where $t \geq 0$. Since $\rho_a \geq 0$, by letting $t \to +\infty$, (5.7) yields

$$k|x_\infty - a|^2 \leq k|x(0) - a|^2 + \rho_a(x(0)). \tag{5.8}$$

Now for all $a \in S$, we have

$$\begin{aligned} |x_\infty - x(0)|^2 &\leq [|x_\infty - a| + |a - x(0)|]^2 \\ &\leq 2|x_\infty - a|^2 + 2|a - x(0)|^2 \\ &\leq 4|x(0) - a|^2 + \tfrac{2}{k} \rho_a(x(0)), \end{aligned}$$

where the third inequality is a consequence of (5.8). The desired result is then obtained by taking the infimum over all $a \in S$. □

As a consequence, we then have the following corollary.

COROLLARY 5.7. *Under the assumptions of Theorem* 5.4*, we have*

$$|x_\infty - x(0)|^2 \leq 4 \inf \left\{ |x(0) - a|^2 + \frac{1}{\alpha} D_{h_1}(a, x(0)) \mid a \in S \right\}$$

if $A = A^{q_h}, h(\cdot) = \alpha/2|\cdot|^2 + h_1(\cdot)$.

Defining $s : \mathbb{R}^n \mapsto \mathbb{R}$ *as* $s(y) := \inf\{|y - a|^2 \mid a \in S\}$*, we then also have*

$$|x_\infty - x(0)|^2 \leq 4 \left(s(x(0)) + f(x(0)) - \inf_{\overline{C}} f \right)$$

if $A = A^P$*, and*

$$|x_\infty - x(0)|^2 \leq 4s(x(0)) + \frac{2}{\theta} \left(f(x(0)) - \inf_{\overline{C}} f \right)$$

if $A = A^{d_\varphi}$.

Proof. The families $\{e_a^h, e_a^P, e_a^\varphi, a \in S\}$ introduced in the beginning of the proof of Theorem 5.4 satisfy the assumptions of Proposition 5.6, and thus the claimed results follow easily. □

Remark 5.3. (a) The estimations given in Corollary 5.7 for $A = A^{q_h}$ allow us to recover the results obtained in [6, 29].

(b) Assume that f is a linear function, that is, $f(x) = \langle c, x \rangle$ for all $x \in \mathbb{R}^n$, where $c \in \mathbb{R}^n$. Take h as in Theorem 5.4. A straightforward integration of (A^{q_h}-DM) in its form given in (4.6) yields

$$\nabla h(x(t)) - \nabla h(x(0)) + tc = 0 \quad \forall t \geq 0. \tag{5.9}$$

As already noted in [24], the trajectory of (A^{q_h}-DM) can be viewed as an optimal path relatively to the barrier function D_h. Indeed, since for all $(y, z) \in C \times C$, $\nabla_1 D_h(y, z) = \nabla h(y) - \nabla h(z)$, (5.9) can be reformulated as

$$x(t) \in \arg\min \left\{ \langle c, u \rangle + \frac{1}{t} D_h(u, x(0)) \mid u \in \mathbb{R}^n \right\}, \ t > 0.$$

The convergence techniques developed in [24] but also the viscosity methods studied in Attouch [5] allow us to fully characterize the limit point as

$$x_\infty \in \arg\min \{D_h(a, x(0)) \mid a \in S\}.$$

H_∞ MODEL REDUCTION IN THE STOCHASTIC FRAMEWORK*

SHENGYUAN XU† AND TONGWEN CHEN†

Abstract. This paper investigates the problems of H_∞ model reduction for both continuous and discrete stochastic systems. In terms of certain linear matrix inequalities (LMIs) and a coupling nonconvex rank constraint, necessary and sufficient conditions for the existence of solutions to such problems are obtained. An explicit parametrization of all reduced-order models corresponding to a feasible solution is also proposed. In particular, when a zeroth-order H_∞ approximation is desired, conditions are obtained using LMIs only without any rank constraints, and a parametrization of all solutions is also presented. Finally, an illustrative example is provided to demonstrate the effectiveness of the proposed approach.

Key words. H_∞ model reduction, linear matrix inequality, stochastic systems

1. Introduction.

The problem of model reduction has received considerable attention in the past decades due to the fact that mathematical modeling of physical systems often involves high-order models, and such high-order models will consequently result in high-order controllers, which may make simulation and physical implementation difficult. The purpose of model reduction is to obtain a lower-order system which approximates a high-order system according to some given criterion. Many results on the model reduction problem have been reported, and various approaches, such as the aggregation method, balanced truncation approach, optimal Hankel norm approximation method, to name just a few, have been proposed in the literature; see, e.g., [2, 8, 19, 21, 24, 25, 26] and the references therein.

Recently, the H_∞ model reduction problem has been studied by many researchers [9, 14, 15, 18, 20]. The essence of this problem is to find a desired lower-order system such that the H_∞ norm of the difference between the original system and the desired lower-order one satisfies a prescribed H_∞ norm bound constraint. By converting this problem into a Hankel norm model reduction through an imbedding process, [18] proposed a characterization of the optimal solutions to the H_∞ model reduction problem. Based on this, a suboptimal computational procedure for the general multivariable continuous optimal H_∞ model reduction problem was developed in [16]. The zeroth-order H_∞ model reduction problem was investigated in [14], [15], and [17], respectively, and solutions to this problem were presented. More recently, the H_∞ model reduction problem was dealt with in [9, 20], where a linear matrix inequality (LMI) approach was proposed and necessary and sufficient conditions for the existence of solutions to both the continuous-time and discrete-time cases were provided. When time-delay and parameter uncertainty appear in a system model, the H_∞ model reduction results for continuous systems in [9] were extended in [23]. It is worth noting that all these results were obtained in the context of deterministic systems.

On the other hand, stochastic systems have received much attention since stochastic modeling has come to play an important role in many branches of science and engineering. The problem of model reduction for stochastic systems was studied [1, 4, 5]. For example, based on the theory of stochastic realization, an algorithm for obtaining reduced-order models was proposed in [1], while in [5] a new and direct approach to stochastic model reduction problem was proposed by establishing an equivalence between canonical correlation analysis and solutions to algebraic Riccati equations, which was developed by using the balanced stochastic realization. For stochastic systems, however, as far as the H_∞ model reduction problem is concerned, it seems that no results on this topic are available in the literature.

In this paper, we deal with the H_∞ model reduction problem for stochastic systems. For a given stochastic system with mean-square stability, the purpose is to find a lower-order mean-square stable stochastic system such that the norm of the perturbation operator of the error system satisfies a prescribed H_∞ bound. To solve this problem, an algebraic method similar to the deterministic case [9] is adopted. The main contributions of the paper are as follows: necessary and sufficient conditions for the solvability of the mentioned problem are obtained for both continuous and discrete stochastic systems. These conditions are given in terms of certain LMIs and a coupling nonconvex rank constraint set. It is worth pointing out that although the solutions are expressed in some nonconvex inequalities, fortunately these can be solved by either an efficient numerical algorithm based on alternating projections given in [9, 10, 11, 20] or some other algorithms proposed in [3]. When these conditions are feasible, an explicit parametrization of all reduced-order models is derived. In particular, sole LMI conditions without any rank constraints are obtained for the zeroth-order H_∞ approximation problem, and a parametrization of all solutions is also presented. When a stochastic system reduces to a deterministic one, it is shown that the results in this paper coincide with those on H_∞ model reduction for deterministic systems in [9]; therefore, our results can be regarded as extensions of existing results on H_∞ model reduction from deterministic systems to stochastic systems.

2. H_∞ model reduction: Continuous time. Consider a continuous-time stochastic system described by

$$(\Sigma_c): \qquad dx(t) = [Ax(t) + Bu(t)]dt + [A_0x(t) + B_0u(t)]d\omega(t), \tag{2.1}$$

$$y(t)dt = [Cx(t) + Du(t)]dt + [A_1x(t) + B_1u(t)]d\omega(t), \tag{2.2}$$

where $x(t) \in \mathbb{R}^n$ is the state, $y(t) \in \mathbb{R}^p$ is the output, $u(t) \in \mathbb{R}^q$ is the control input, A, A_0, A_1, B, B_0, B_1, C, and D are known real constant matrices, $\omega(t)$ is a zero-mean real scalar Wiener process on a probability space $(\Omega, \mathcal{F}, \mathcal{P})$ relative to an increasing family $(\mathcal{F}_t)_{t>0}$ of σ-algebras $\mathcal{F}_t \subset \mathcal{F}$, where Ω is the sample space, $\mathcal{F}$ is the σ-algebra of subsets of the sample space, and $\mathcal{P}$ is the probability measure on $\mathcal{F}$. We assume

$$\mathcal{E}\{d\omega(t)\} = 0, \quad \mathcal{E}\{d\omega(t)^2\} = dt, \tag{2.3}$$

where $\mathcal{E}\{\cdot\}$ is the expectation operator. We denote by $L_2[\Omega, \mathbb{R}^k)$ the space of square-integrable $\mathbb{R}^k$-valued vector functions on the probability space $(\Omega, \mathcal{F}, \mathcal{P})$; we also denote by $L_{E_2}([0,\infty); \mathbb{R}^k)$ the space of nonanticipatory square-integrable stochastic processes $f(\cdot) = (f(t))_{t\in[0,\infty)}$ in $\mathbb{R}^k$ with respect to $(\mathcal{F}_t)_{t\in[0,\infty)}$ satisfying

$$\|f\|_{E_2}^2 = \mathcal{E}\left\{\int_0^\infty |f(t)|^2\, dt\right\} = \int_0^\infty \mathcal{E}\left\{|f(t)|^2\right\} dt < \infty,$$

where $|\cdot|$ is the standard Euclidean vector norm. In this paper we assume $u(t)$ belongs to $L_{E_2}([0,\infty);\mathbb{R}^q)$ and is $(\mathcal{F}_s)_{s<t}$ measurable [12].

DEFINITION 2.1 (see [12, 22]). *The stochastic system (Σ_c) is said to be mean-square stable if all initial states $x(0)$, subject to $u(t)=0$, yield*

$$\lim_{t\to\infty}\mathcal{E}\,|x(t)|^2=0.$$

DEFINITION 2.2 (see [12]). *The system (Σ_c) is said to be externally stable if, for every $u(t)\in L_{E_2}([0,\infty);\mathbb{R}^q)$,*

$$y(t)\in L_{E_2}([0,\infty);\mathbb{R}^p),$$

and there exists a scalar $\mu>0$ such that

$$\|y\|_{E_2}\le\mu\,\|u\|_{E_2},\quad u(t)\in L_{E_2}([0,\infty);\mathbb{R}^q). \tag{2.4}$$

DEFINITION 2.3 (see [12]). *Suppose that the system (Σ_c) is externally stable. Under the zero initial condition for the system (Σ_c), the operator*

$$\mathbb{L}_c: L_{E_2}([0,\infty);\mathbb{R}^q)\to L_{E_2}([0,\infty);\mathbb{R}^p),$$

defined by

$$(\mathbb{L}_c u)(t)=y(t), \tag{2.5}$$

is called the perturbation operator of the system (Σ_c). Its norm $\|\mathbb{L}_c\|$ is defined as the minimum $\mu\ge 0$ such that (2.4) holds.

Assume the system (Σ_c) is mean-square stable; then the H_∞ model reduction problem addressed in this section is as follows: given a scalar $\gamma>0$, find a mean-square stable system

$$(\hat\Sigma_c):\qquad d\hat x(t)=[\hat A\hat x(t)+\hat B u(t)]dt+[\hat A_0\hat x(t)+\hat B_0 u(t)]d\omega(t), \tag{2.6}$$

$$\hat y(t)dt=[\hat C\hat x(t)+\hat D u(t)]dt+[\hat A_1\hat x(t)+\hat B_1 u(t)]d\omega(t), \tag{2.7}$$

where $\hat x(t)\in\mathbb{R}^{\hat n}$, $\hat y(t)\in\mathbb{R}^p$, and $\hat n<n$ such that

$$\|\mathbb{L}_{\tilde c}\|<\gamma, \tag{2.8}$$

where $\mathbb{L}_{\tilde c}$ is the perturbation operator of the resulting error system from (Σ_c) and $(\hat\Sigma_c)$, which is defined as

$$(\mathbb{L}_{\tilde c}u)(t)=y(t)-\hat y(t). \tag{2.9}$$

If $\hat n=0$, then the reduced-order system in (2.6) and (2.7) becomes

$$\hat y(t)dt=\hat D u(t)dt+\hat B_1 u(t)d\omega(t). \tag{2.10}$$

In this case, the model reduction problem reduces to the zeroth-order H_∞ approximation problem. It should be pointed out that in the deterministic case, the zeroth-order H_∞ approximation problem involves only finding a constant matrix $\hat D$ [14, 15].

Before proceeding further, we give the following lemmas which will be used in the proof of our main results.

LEMMA 2.4. *The stochastic system* (Σ_c) *is mean-square stable and* $\|\mathbb{L}_c\| < \gamma$ *if and only if there exists a matrix* $P > 0$ *such that*

$$\begin{bmatrix} PA + A^TP + C^TC & C^TD + PB & A_1^T & A_0^TP \\ D^TC + B^TP & D^TD - \gamma^2 I & B_1^T & B_0^TP \\ A_1 & B_1 & -I & 0 \\ PA_0 & PB_0 & 0 & -P \end{bmatrix} < 0. \tag{2.11}$$

Proof. The proof can be carried out using the same argument as in the proof of Theorem 2.8 in [12], and thus is omitted. □

LEMMA 2.5 (see [7, 13]). *Given a symmetric matrix* Ξ *and two matrices* Γ *and* Π*, consider the problem of finding some matrix* Θ *such that*

$$\Xi + \Gamma\Theta\Pi + (\Gamma\Theta\Pi)^T < 0. \tag{2.12}$$

Then (2.12) *is solvable for* Θ *if and only if*

$$\Gamma^{\perp}\Xi\Gamma^{\perp T} < 0,\ \Pi^{T\perp}\Xi\Pi^{T\perp T} < 0.$$

Here, if $\Gamma \in \mathbb{R}^{n\times m}$ *and* $\operatorname{rank}\Gamma = r$*, the orthogonal complement* $\Gamma^{\perp}$ *is defined as a (possibly nonunique)* $(n-r)\times n$ *matrix with rank* $n-r$ *such that* $\Gamma^{\perp}\Gamma = 0$.

Now we are in a position to give the condition for the solvability of the H_∞ model reduction problem for continuous-time stochastic systems.

THEOREM 2.6. *There exists a stochastic system with* $\hat{n}$*th order in the form of* (2.6) *and* (2.7) *such that the* H_∞ *model reduction problem for the continuous stochastic system* (Σ_c) *is solvable if and only if there exist matrices* $X > 0$ *and* $Y > 0$ *satisfying*

$$\begin{bmatrix} XA + A^TX + C^TC & A_1^T & A_0^TX \\ A_1 & -I & 0 \\ XA_0 & 0 & -X \end{bmatrix} < 0, \tag{2.13}$$

$$\begin{bmatrix} AY + YA^T & B & YA_0^T \\ B^T & -\gamma^2 I & B_0^T \\ A_0Y & B_0 & -Y \end{bmatrix} < 0, \tag{2.14}$$

$$\begin{bmatrix} X & I \\ I & Y \end{bmatrix} \geq 0, \tag{2.15}$$

and

$$\operatorname{rank}\begin{bmatrix} X & I \\ I & Y \end{bmatrix} \leq n + \hat{n}. \tag{2.16}$$

In this case, all desired $\hat{n}$*th-order reduced systems corresponding to a feasible solution* (X, Y) *to* (2.13)–(2.16) *are given by*

$$\begin{bmatrix} \hat{D} & \hat{C} \\ \hat{B} & \hat{A} \\ \hat{B}_1 & \hat{A}_1 \\ \hat{B}_0 & \hat{A}_0 \end{bmatrix} = -W^{-1}\Psi^T\Lambda\Phi^T(\Phi\Lambda\Phi^T)^{-1} + W^{-1}S^{\frac{1}{2}}L(\Phi\Lambda\Phi^T)^{-\frac{1}{2}}, \tag{2.17}$$

where

$$S = W - \Psi^T\left[\Lambda - \Lambda\Phi^T\left(\Phi\Lambda\Phi^T\right)^{-1}\Phi\Lambda\right]\Psi,$$

$$\Lambda = (\Psi W^{-1}\Psi^T - \Omega)^{-1},$$

$$\Omega = \begin{bmatrix} A^TX + XA & A^TS & XB & C^T & A_1^T & A_0^TX & A_0^TS \\ S^TA & 0 & S^TB & 0 & 0 & 0 & 0 \\ B^TX & B^TS & -\gamma^2 I & D^T & B_1^T & B_0^TX & B_0^TS \\ C & 0 & D & -I & 0 & 0 & 0 \\ A_1 & 0 & B_1 & 0 & -I & 0 & 0 \\ XA_0 & 0 & XB_0 & 0 & 0 & -X & -S \\ S^TA_0 & 0 & S^TB_0 & 0 & 0 & -S^T & -U \end{bmatrix},$$

$$\Psi = \begin{bmatrix} 0 & S & 0 & 0 \\ 0 & U & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -I & 0 & 0 & 0 \\ 0 & 0 & -I & 0 \\ 0 & 0 & 0 & S \\ 0 & 0 & 0 & U \end{bmatrix},$$

$$\Phi = \begin{bmatrix} 0 & 0 & I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

and L is any matrix satisfying $\bar{\sigma}(L) < 1$, where $\bar{\sigma}(\cdot)$ is the maximum singular value of a matrix; moreover, $S \in \mathbb{R}^{n\times\hat{n}}$, $U \in \mathbb{R}^{\hat{n}\times\hat{n}}$, $W > 0$, and $U > 0$ satisfy

$$\Lambda > 0,\ X - Y^{-1} = SU^{-1}S^T \geq 0.$$

Proof. From (2.1), (2.2), (2.6), and (2.7), the error system resulting from the system (Σ_c) and $(\hat{\Sigma}_c)$ can be written as the augmented system

$$(\tilde{\Sigma}_c): \qquad d\tilde{x}(t) = [\tilde{A}\tilde{x}(t) + \tilde{B}u(t)]dt + [\tilde{A}_0\tilde{x}(t) + \tilde{B}_0u(t)]d\omega(t), \tag{2.18}$$

$$\tilde{y}(t)dt = [\tilde{C}\tilde{x}(t) + \tilde{D}u(t)]dt + [\tilde{A}_1\tilde{x}(t) + \tilde{B}_1u(t)]d\omega(t), \tag{2.19}$$

where

$$\tilde{x}(t) = \begin{bmatrix} x(t)^T & \hat{x}(t)^T \end{bmatrix}^T,\ \tilde{y}(t) = y(t) - \hat{y}(t), \tag{2.20}$$

$$\tilde{A} = \bar{A} + \bar{F}\bar{G}_c\bar{H},\ \tilde{B} = \bar{B} + \bar{F}\bar{G}_c\bar{N},\ \tilde{A}_0 = \bar{A}_0 + \bar{M}\bar{G}_c\bar{H},\ \tilde{B}_0 = \bar{B}_0 + \bar{M}\bar{G}_c\bar{N}, \tag{2.21}$$

$$\tilde{C} = \bar{C} + \bar{S}\bar{G}_c\bar{H},\ \tilde{D} = \bar{D} + \bar{S}\bar{G}_c\bar{N},\ \tilde{A}_1 = \bar{A}_1 + \bar{K}\bar{G}_c\bar{H},\ \tilde{B}_1 = \bar{B}_1 + \bar{K}\bar{G}_c\bar{N}, \tag{2.22}$$

$$\bar{A} = \begin{bmatrix} A & 0 \\ 0 & 0 \end{bmatrix},\ \bar{B} = \begin{bmatrix} B \\ 0 \end{bmatrix},\ \bar{A}_0 = \begin{bmatrix} A_0 & 0 \\ 0 & 0 \end{bmatrix},\ \bar{B}_0 = \begin{bmatrix} B_0 \\ 0 \end{bmatrix}, \tag{2.23}$$

$$\bar{C} = \begin{bmatrix} C & 0 \end{bmatrix},\ \bar{A}_1 = \begin{bmatrix} A_1 & 0 \end{bmatrix},\ \bar{D} = D,\ \bar{B}_1 = B, \tag{2.24}$$

$$\bar{F} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 \end{bmatrix},\ \bar{H} = \begin{bmatrix} 0 & 0 \\ 0 & I \end{bmatrix},\ \bar{M} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I \end{bmatrix},\ \bar{N} = \begin{bmatrix} I \\ 0 \end{bmatrix}, \tag{2.25}$$

$$\bar{K} = \begin{bmatrix} 0 & 0 & -I & 0 \end{bmatrix},\ \bar{S} = \begin{bmatrix} -I & 0 & 0 & 0 \end{bmatrix},\ \bar{G}_c = \begin{bmatrix} \hat{D} & \hat{C} \\ \hat{B} & \hat{A} \\ \hat{B}_1 & \hat{A}_1 \\ \hat{B}_0 & \hat{A}_0 \end{bmatrix}. \tag{2.26}$$

By Lemma 2.4, it is easy to see that the error system $(\tilde{\Sigma}_c)$ is mean-square stable and satisfies $\|\mathbb{L}_{\tilde{e}}\| < \gamma$ if and only if there exists a matrix $P > 0$ such that

$$\begin{bmatrix} P\tilde{A} + \tilde{A}^T P + \tilde{C}^T \tilde{C} & \tilde{C}^T \tilde{D} + P\tilde{B} & \tilde{A}_1^T & \tilde{A}_0^T P \\ \tilde{D}^T \tilde{C} + \tilde{B}^T P & \tilde{D}^T \tilde{D} - \gamma^2 I & \tilde{B}_1^T & \tilde{B}_0^T P \\ \tilde{A}_1 & \tilde{B}_1 & -I & 0 \\ P\tilde{A}_0 & P\tilde{B}_0 & 0 & -P \end{bmatrix} < 0. \tag{2.27}$$

Using the Schur complement lemma and noting the expressions in (2.21) and (2.22), it can be shown that the inequality (2.27) is equivalent to

$$\begin{bmatrix} P\left(\bar{A} + \bar{F}\bar{G}_c\bar{H}\right) + \left(\bar{A} + \bar{F}\bar{G}_c\bar{H}\right)^T P & P\left(\bar{B} + \bar{F}\bar{G}_c\bar{N}\right) \\ \left(\bar{B} + \bar{F}\bar{G}_c\bar{N}\right)^T P & -\gamma^2 I \\ \bar{C} + \bar{S}\bar{G}_c\bar{H} & \bar{D} + \bar{S}\bar{G}_c\bar{N} \\ \bar{A}_1 + \bar{K}\bar{G}_c\bar{H} & \bar{B}_1 + \bar{K}\bar{G}_c\bar{N} \\ P\left(\bar{A}_0 + \bar{M}\bar{G}_c\bar{H}\right) & P\left(\bar{B}_0 + \bar{M}\bar{G}_c\bar{N}\right) \end{bmatrix}$$

$$\begin{bmatrix} \left(\bar{C} + \bar{S}\bar{G}_c\bar{H}\right)^T & \left(\bar{A}_1 + \bar{K}\bar{G}_c\bar{H}\right)^T & \left(\bar{A}_0 + \bar{M}\bar{G}_c\bar{H}\right)^T P \\ \left(\bar{D} + \bar{S}\bar{G}_c\bar{N}\right)^T & \left(\bar{B}_1 + \bar{K}\bar{G}_c\bar{N}\right)^T & \left(\bar{B}_0 + \bar{M}\bar{G}_c\bar{N}\right)^T P \\ -I & 0 & 0 \\ 0 & -I & 0 \\ 0 & 0 & -P \end{bmatrix} < 0. \tag{2.28}$$

This can be rewritten as

$$\Omega_c + \Psi_c \bar{G}_c \Phi_c + (\Psi_c \bar{G}_c \Phi_c)^T < 0, \tag{2.29}$$

where

$$\Omega_c = \begin{bmatrix} P\bar{A} + \bar{A}^T P & P\bar{B} & \bar{C}^T & \bar{A}_1^T & \bar{A}_0^T P \\ \bar{B}^T P & -\gamma^2 I & \bar{D}^T & \bar{B}_1^T & \bar{B}_0^T P \\ \bar{C} & \bar{D} & -I & 0 & 0 \\ \bar{A}_1 & \bar{B}_1 & 0 & -I & 0 \\ P\bar{A}_0 & P\bar{B}_0 & 0 & 0 & -P \end{bmatrix},$$

$$\Psi_c = \begin{bmatrix} P\bar{F} \\ 0 \\ \bar{S} \\ \bar{K} \\ P\bar{M} \end{bmatrix},$$

$$\Phi_c = \begin{bmatrix} \bar{H} & \bar{N} & 0 & 0 & 0 \end{bmatrix}.$$

It is noted that the parameters of the unknown reduced-order model are included in the matrix $\bar{G}_c$. From Lemma 2.5 it is easy to see that a necessary and sufficient condition for the LMI in (2.29) to have a solution $\bar{G}_c$ is

$$\Psi_c^{\perp} \Omega_c \Psi_c^{\perp T} < 0, \ \Phi_c^{T\perp} \Omega_c \Phi_c^{T\perp T} < 0. \tag{2.30}$$

Now, by some calculations, it can be verified that

$$\Psi_c^{\perp} = \begin{bmatrix} [I & 0] & 0 & 0 & 0 & [0 & 0] \\ [0 & 0] & I & 0 & 0 & [0 & 0] \\ [0 & 0] & 0 & 0 & 0 & [I & 0] \end{bmatrix} \begin{bmatrix} P^{-1} & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 \\ 0 & 0 & 0 & I & 0 \\ 0 & 0 & 0 & 0 & P^{-1} \end{bmatrix},$$

$$\Phi_c^{T\perp} = \begin{bmatrix} [I \;\; 0] & 0 & 0 & 0 & [0 \;\; 0] \\ [0 \;\; 0] & 0 & I & 0 & [0 \;\; 0] \\ [0 \;\; 0] & 0 & 0 & I & [0 \;\; 0] \\ [0 \;\; 0] & 0 & 0 & 0 & [I \;\; 0] \\ [0 \;\; 0] & 0 & 0 & 0 & [0 \;\; I] \end{bmatrix}.$$

Partition P and P^{-1} as

$$P = \begin{bmatrix} X & X_{12} \\ X_{12}^T & X_{22} \end{bmatrix},$$

$$P^{-1} = \begin{bmatrix} Z & Z_{12} \\ Z_{12}^T & Z_{22} \end{bmatrix}, \tag{2.31}$$

where

$$X \in \mathbb{R}^{n\times n},\ X_{12} \in \mathbb{R}^{n\times\hat{n}},\ Z_{12} \in \mathbb{R}^{n\times\hat{n}},\ X_{22} \in \mathbb{R}^{\hat{n}\times\hat{n}},\ Z_{22} \in \mathbb{R}^{\hat{n}\times\hat{n}}.$$

Then we can show that

$$\Psi_c^{\perp}\Omega_c\Psi_c^{\perp T} = \begin{bmatrix} AZ + ZA^T & B & ZA_0^T \\ B^T & -\gamma^2 I & B_0^T \\ A_0 Z & B_0 & -Z \end{bmatrix}, \tag{2.32}$$

$$\Phi_c^{T\perp}\Omega_c\Phi_c^{T\perp T} = \begin{bmatrix} XA + A^TX & C^T & A_1^T & A_0^TX & A_0^TX_{12} \\ C & -I & 0 & 0 & 0 \\ A_1 & 0 & -I & 0 & 0 \\ XA_0 & 0 & 0 & -X & -X_{12} \\ X_{12}^TA_0 & 0 & 0 & -X_{12}^T & -X_{22} \end{bmatrix}. \tag{2.33}$$

Let $Y = Z$; then the inequality $\Psi_c^{\perp}\Omega_c\Psi_c^{\perp T} < 0$ gives (2.14). It can also be shown that using the Schur complement formula to $\Phi_c^{T\perp}\Omega_c\Phi_c^{T\perp T} < 0$ results in (2.13). On the other hand, noting the (1,1) block of P^{-1} in (2.31), we have

$$X - Y^{-1} = X_{12}X_{22}^{-1}X_{12}^T \geq 0. \tag{2.34}$$

This, by the Schur complement formula, is equivalent to (2.15). Also, (2.34) implies

$$\operatorname{rank}(X - Y^{-1}) \leq \hat{n}, \tag{2.35}$$

since $X_{22} \in \mathbb{R}^{\hat{n}\times\hat{n}}$ is a symmetric positive definite matrix. It then follows that (2.35) provides the condition (2.16). In addition, when (2.13)–(2.16) are satisfied, the parametrization (2.17) of all reduced models corresponding to a feasible solution can be obtained by using the results in [7] and [13]. This completes the proof. □

Remark 2.7. Theorem 2.6 presents a necessary and sufficient condition for the solvability of the H_∞ model reduction problem for continuous-time stochastic systems. It is noted that the inequalities in (2.13)–(2.16) are nonconvex though the constraints (2.13)–(2.15) are convex. For such nonconvex inequalities, either an efficient numerical algorithm based on alternating projections in [9, 10, 11, 20] or some other algorithms in [3] can be employed. Moreover, as in [9], a bisection approach can be used to seek the minimum H_∞ performance level γ in order to solve the optimal H_∞ model reduction problem for continuous-time stochastic systems.

Next, we shall establish a solvability condition based on LMIs only for the zeroth-order H_∞ approximation problem, which is given in the following theorem.

THEOREM 2.8. *There exist two matrices $\hat{B}_1$ and $\hat{D}$ solving the zeroth-order H_∞ approximation problem for the continuous-time stochastic system (Σ_c) if and only if there exists a matrix $X > 0$ satisfying*

$$\begin{bmatrix} XA + A^TX + C^TC & A_1^T & A_0^TX \\ A_1 & -I & 0 \\ XA_0 & 0 & -X \end{bmatrix} < 0, \tag{2.36}$$

$$\begin{bmatrix} XA + A^TX & XB & A_0^TX \\ B^TX & -\gamma^2 I & B_0^TX \\ XA_0 & XB_0 & -X \end{bmatrix} < 0. \tag{2.37}$$

In this case, all the solutions $\hat{B}_1$ and $\hat{D}$ to the zeroth-order H_∞ approximation problem corresponding to a feasible solution X to (2.36) *and* (2.37) *are given by*

$$\begin{bmatrix} \hat{D} \\ \hat{B}_1 \end{bmatrix} = G_1 + G_2LG_3, \tag{2.38}$$

$$G_1 = -Q_{12}Q_{22}^{-1}M^T(MQ_{22}^{-1}M^T)^{-1}, \tag{2.39}$$

$$G_2 = (Q_{12}Q_{22}^{-1}Q_{12}^T - Q_{11} - G_1G_3^{-2}G_1^T)^{\frac{1}{2}}, \tag{2.40}$$

$$G_3 = (-MQ_{22}^{-1}M^T)^{-\frac{1}{2}}, \tag{2.41}$$

$$Q_{11} = \begin{bmatrix} -I & 0 \\ 0 & -I \end{bmatrix},\ Q_{12} = \begin{bmatrix} C & D & 0 \\ A_1 & B_1 & 0 \end{bmatrix}, \tag{2.42}$$

$$Q_{22} = \begin{bmatrix} XA + A^TX & XB & A_0^TX \\ B^TX & -\gamma^2 I & B_0^TX \\ XA_0 & XB_0 & -X \end{bmatrix}, \tag{2.43}$$

$$M = \begin{bmatrix} 0 & -I & 0 \end{bmatrix}, \tag{2.44}$$

where L is any matrix satisfying $\bar{\sigma}(L) < 1$.

Proof. From (2.1), (2.2), and (2.10), we obtain the error system as

$$(\tilde{\Sigma}_{cd}):\quad dx(t) = [Ax(t) + Bu(t)]dt + [A_0x(t) + B_0u(t)]d\omega(t), \tag{2.45}$$

$$\tilde{y}(t)dt = [Cx(t) + (D - \hat{D})u(t)]dt + [A_1x(t) + (B_1 - \hat{B}_1)u(t)]d\omega(t), \tag{2.46}$$

where $\tilde{y}(t)$ is defined in (2.20). By Lemma 2.4, it is easy to see that this system is mean-square stable and satisfies a prescribed H_∞ performance level $\gamma > 0$ if and only if there exists a matrix $X > 0$ such that

$$\begin{bmatrix} XA + A^TX & XB & C^T & A_1^T & A_0^TX \\ B^TX & -\gamma^2 I & (D - \hat{D})^T & (B_1 - \hat{B}_1)^T & B_0^TX \\ C & D - \hat{D} & -I & 0 & 0 \\ A_1 & B_1 - \hat{B}_1 & 0 & -I & 0 \\ XA_0 & XB_0 & 0 & 0 & -X \end{bmatrix} < 0.$$

This can be rewritten as

$$\check{\Omega}_c + \check{\Psi}_c\check{G}_c\check{\Phi}_c + (\check{\Psi}_c\check{G}_c\check{\Phi}_c)^T < 0, \tag{2.47}$$

where

$$\check{G}_c = \begin{bmatrix} XA + A^TX & XB & C^T & A_1^T & A_0^TX \\ B^TX & -\gamma^2 I & D^T & B_1^T & B_0^TX \\ C & D & -I & 0 & 0 \\ A_1 & B_1 & 0 & -I & 0 \\ XA_0 & XB_0 & 0 & 0 & -X \end{bmatrix},$$

$$\check{\Psi}_c = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ I & 0 \\ 0 & I \\ 0 & 0 \end{bmatrix},$$
$$\check{\Phi}_c = \begin{bmatrix} 0 & -I & 0 & 0 & 0 \end{bmatrix}.$$

Therefore, by Lemma 2.5, we have that the necessary and sufficient condition for the above LMI to have a solution $\hat{B}_1$ and $\hat{D}$ is

$$\check{\Psi}_c^{\perp}\check{G}_c\check{\Psi}_c^{\perp T} < 0, \quad \check{\Phi}_c^{T\perp}\check{G}_c\check{\Phi}_c^{T\perp T} < 0. \tag{2.48}$$

By some algebraic manipulations, the LMIs in (2.36) and (2.37) can be established by using (2.48). Furthermore, note that

$$\check{\Psi}_c^T\check{\Psi}_c > 0, \quad \check{\Phi}_c\check{\Psi}_c^T\check{\Psi}_c\check{\Phi}_c^T > 0.$$

Then the parametrization in (2.38)–(2.44) of all $\hat{B}_1$ and $\hat{D}$ that satisfy the LMI in (2.47) can be obtained by using the results in [7] and [13] when (2.13)–(2.16) are satisfied. □

Remark 2.9. In the case when $A_0 = 0$, $A_1 = 0$, $B_0 = 0$, and $B_1 = 0$, that is, when the stochastic system (Σ_c) reduces to a deterministic system, it can be easily shown that Theorems 2.6 and 2.8 coincide with Theorems 1 and 2 in [9], respectively. Therefore, Theorems 2.6 and 2.8 can be viewed as extensions of existing results on H_∞ model reduction from deterministic systems to stochastic systems.

3. H_∞ model reduction: Discrete time. In this section, we consider the H_∞ model reduction problem for discrete-time stochastic systems. The system we consider is described by the following model:

$$(\Sigma_d): \qquad x(k+1) = Ax(k) + Bu(k) + [A_0x(k) + B_0u(k)]\omega(k), \tag{3.1}$$
$$y(k) = Cx(k) + Du(k) + [A_1x(k) + B_1u(k)]\omega(k), \tag{3.2}$$

where $x(k) \in \mathbb{R}^n$ is the state, $y(k) \in \mathbb{R}^p$ is the output, $u(k) \in \mathbb{R}^q$ is the control input, A, A_0, A_1, B, B_0, B_1, C, and D are known real constant matrices, and $\omega(k)$ is a zero-mean real scalar process on a probability space $(\Omega, \mathcal{F}, \mathcal{P})$ relative to an increasing family $(\mathcal{F}_k)_{k\in\mathbb{N}}$ of σ-algebras $\mathcal{F}_k \subset \mathcal{F}$. We assume

$$\mathcal{E}\{\omega(k)\} = 0, \quad \mathcal{E}\{\omega(k)^2\} = 1, \tag{3.3}$$

and $\omega(0)$, $\omega(1)$, ..., are independent. We denote by $l_2[\Omega, \mathbb{R}^k)$ the space of square-summable $\mathbb{R}^k$-valued vector functions on the probability space $(\Omega, \mathcal{F}, \mathcal{P})$, and we also denote by $l_{e_2}([0,\infty); \mathbb{R}^k)$ the space of k-dimensional nonanticipatory square-summable stochastic processes $f(\cdot) = (f(k))_{k\in\mathbb{N}}$ on $\mathbb{N}$ with respect to $(\mathcal{F}_k)_{k\in\mathbb{N}}$ satisfying

$$\|f\|_{e_2}^2 = \mathcal{E}\left\{\sum_{k\in\mathbb{N}} |f(k)|^2\right\} = \sum_{k\in\mathbb{N}} \mathcal{E}\left\{|f(k)|^2\right\} < \infty.$$

In this section we assume $u(k)$ belongs to $l_{e_2}([0,\infty); \mathbb{R}^q)$ and is $\mathcal{F}_{k-1}$ measurable for all $k \in \mathbb{N}$ [6].

DEFINITION 3.1 (see [6]). *The stochastic system* (Σ_d) *is said to be mean-square stable if all initial states* $x(0)$*, subject to* $u(k) = 0$*, yield*

$$\lim_{k\to\infty} \mathcal{E}\,|x(k)|^2 = 0.$$

DEFINITION 3.2 (see [6]). *The system* (Σ_d) *is said to be externally stable if, for every* $u(k) \in l_{e_2}([0,\infty);\mathbb{R}^q)$*,*

$$y(k) \in l_{e_2}([0,\infty);\mathbb{R}^p),$$

and there exists a scalar $\mu > 0$ *such that*

$$\|y\|_{e_2} \le \mu \|u\|_{e_2}, \quad u(k) \in l_{e_2}([0,\infty);\mathbb{R}^q). \tag{3.4}$$

DEFINITION 3.3 (see [6]). *Suppose that the system* (Σ_d) *is externally stable. Under the zero initial condition for the system* (Σ_d)*, the operator*

$$\mathbb{L}_d : l_{e_2}([0,\infty);\mathbb{R}^q) \to l_{e_2}([0,\infty);\mathbb{R}^p),$$

defined by

$$(\mathbb{L}_d u)(k) = y(k), \tag{3.5}$$

is called the perturbation operator of the system (Σ_d)*. Its norm* $\|\mathbb{L}_d\|$ *is defined as the minimum* $\mu \ge 0$ *such that* (3.4) *holds.*

Assume the system (Σ_d) is mean-square stable; then the H_∞ model reduction problem addressed in this section is as follows: given a scalar $\gamma > 0$, find a mean-square stable system

$$(\hat{\Sigma}_d): \quad \hat{x}(k) = \hat{A}\hat{x}(k) + \hat{B}u(k) + [\hat{A}_0\hat{x}(k) + \hat{B}_0u(k)]d\omega(k), \tag{3.6}$$

$$\hat{y}(k) = \hat{C}\hat{x}(k) + \hat{D}u(k) + [\hat{A}_1\hat{x}(k) + \hat{B}_1u(k)]d\omega(k), \tag{3.7}$$

where $\hat{x}(t) \in \mathbb{R}^{\hat{n}}$, $\hat{y}(t) \in \mathbb{R}^p$, and $\hat{n} < n$ such that

$$\left\|\mathbb{L}_{\tilde{d}}\right\| < \gamma, \tag{3.8}$$

where $\mathbb{L}_{\tilde{d}}$ is the perturbation operator of the resulting error system from (Σ_d) and $(\hat{\Sigma}_d)$ defined as

$$(\mathbb{L}_{\tilde{d}}u)(k) = y(k) - \hat{y}(k). \tag{3.9}$$

Similar to the continuous-time case, if $\hat{n} = 0$, then the reduced-order system (3.6) and (3.7) becomes

$$\hat{y}(k) = \hat{D}u(k) + \hat{B}_1u(k)\omega(k). \tag{3.10}$$

In this case, the model reduction problem reduces to the zeroth-order H_∞ approximation problem.

The following lemma is essential in the derivation of our main results in this section.

LEMMA 3.4. *The stochastic system* (Σ_d) *is mean-square stable and* $\|\mathbb{L}_d\| < \gamma$ *if and only if there exists a matrix* $P > 0$ *such that*

$$\begin{bmatrix} -P & 0 & A^TP & A_0^TP & C^T & A_1^T \\ 0 & -\gamma^2 I & B^TP & B_0^TP & D^T & B_1^T \\ PA & PB & -P & 0 & 0 & 0 \\ PA_0 & PB_0 & 0 & -P & 0 & 0 \\ C & D & 0 & 0 & -I & 0 \\ A_1 & B_1 & 0 & 0 & 0 & -I \end{bmatrix} < 0. \tag{3.11}$$

Proof. Following similar reasoning as in the proof of Theorem 2.5 in [6], the desired results can be obtained. □

Now we present the necessary and sufficient conditions for the solvability of the H_∞ model reduction problem for discrete stochastic systems in the following theorem.

THEOREM 3.5. *There exists a stochastic system with* $\hat{n}$*th order in the form of* (3.6) *and* (3.7) *such that the* H_∞ *model reduction problem for the discrete stochastic system* (Σ_d) *is solvable if and only if there exist matrices* $X > 0$ *and* $Y > 0$ *satisfying*

$$\begin{bmatrix} C^TC + A_1^TA_1 - X & A^TX & A_0^TX \\ XA & -X & 0 \\ XA_0 & 0 & -X \end{bmatrix} < 0, \tag{3.12}$$

$$\begin{bmatrix} -Y & 0 & YA^T & YA_0^T \\ 0 & -\gamma^2 I & B^T & B_0^T \\ AY & B & -Y & 0 \\ A_0Y & B_0 & 0 & -Y \end{bmatrix} < 0, \tag{3.13}$$

$$\begin{bmatrix} X & I \\ I & Y \end{bmatrix} \geq 0, \tag{3.14}$$

and

$$\operatorname{rank} \begin{bmatrix} X & I \\ I & Y \end{bmatrix} \leq n + \hat{n}. \tag{3.15}$$

In this case, all desired $\hat{n}$*th-order reduced systems corresponding to a feasible solution* (X, Y) *to* (3.12)–(3.15) *are given by*

$$\begin{bmatrix} \hat{D} & \hat{C} \\ \hat{B} & \hat{A} \\ \hat{B}_1 & \hat{A}_1 \\ \hat{B}_0 & \hat{A}_0 \end{bmatrix} = -W^{-1}\Psi^T\Lambda\Phi^T(\Phi\Lambda\Phi^T)^{-1} + W^{-1}S^{\frac{1}{2}}L(\Phi\Lambda\Phi^T)^{-\frac{1}{2}}, \tag{3.16}$$

where

$$S = W - \Psi^T\left[\Lambda - \Lambda\Phi^T\left(\Phi\Lambda\Phi^T\right)^{-1}\Phi\Lambda\right]\Psi,$$
$$\Lambda = (\Psi W^{-1}\Psi^T - \Omega)^{-1},$$

$$\Omega = \begin{bmatrix} -X & -S & 0 & A^TX & A^TS & A_0^TX & A_0^TS & C^T & A_1^T \\ -S^T & -U & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\gamma^2 I & B^TX & B^TS & B_0^TX & B_0^TS & D & B_1^T \\ XA & 0 & XB & -X & -S & 0 & 0 & 0 & 0 \\ S^TA & 0 & S^TB & -S^T & -U & 0 & 0 & 0 & 0 \\ XA_0 & 0 & XB_0 & 0 & 0 & -X & -S & 0 & 0 \\ S^TA_0 & 0 & S^TB_0 & 0 & 0 & -S^T & -U & 0 & 0 \\ C & 0 & D^T & 0 & 0 & 0 & 0 & -I & 0 \\ A_1 & 0 & B_1 & 0 & 0 & 0 & 0 & 0 & -I \end{bmatrix},$$

$$\Psi = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & S & 0 & 0 & 0 \\ 0 & U & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & S \\ 0 & 0 & 0 & 0 & U \\ -I & 0 & 0 & 0 & 0 \\ 0 & 0 & -I & 0 & 0 \end{bmatrix},$$

$$\Phi = \begin{bmatrix} 0 & 0 & I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

and L is any matrix satisfying $\bar{\sigma}(L) < 1$; $S \in \mathbb{R}^{n\times\hat{n}}$, $U \in \mathbb{R}^{\hat{n}\times\hat{n}}$, $W > 0$, and $U > 0$ satisfy

$$\Lambda > 0,\ X - Y^{-1} = SU^{-1}S^T \geq 0.$$

Proof. The error system from the systems (Σ_d) and $(\hat{\Sigma}_d)$ is given by

$$(\tilde{\Sigma}_d): \qquad \tilde{x}(k+1) = \tilde{A}\tilde{x}(k) + \tilde{B}u(k) + [\tilde{A}_0 x(k) + \tilde{B}_0 u(k)]\omega(k), \tag{3.17}$$

$$\tilde{y}(k) = \tilde{C}\tilde{x}(k) + \tilde{D}u(k) + [\tilde{A}_1 x(k) + \tilde{B}_1 u(k)]\omega(k), \tag{3.18}$$

where

$$\tilde{x}(k) = \begin{bmatrix} x(k)^T & \hat{x}(k)^T \end{bmatrix}^T,\ \tilde{y}(k) = y(k) - \hat{y}(k), \tag{3.19}$$

and $\tilde{A}$, $\tilde{A}_0$, $\tilde{A}_1$, $\tilde{B}$, $\tilde{B}_0$, $\tilde{B}_1$, $\tilde{C}$, and $\tilde{D}$ are defined in (2.21)–(2.26). It follows from Lemma 3.4 that the error system $(\tilde{\Sigma}_d)$ satisfies $\left\|\mathbb{L}_{\tilde{d}}\right\|_\infty < \gamma$ if and only if there exists a matrix $P > 0$ such that

$$\begin{bmatrix} -P & 0 & \tilde{A}^TP & \tilde{A}_0^TP & \tilde{C}^T & \tilde{A}_1^T \\ 0 & -\gamma^2 I & \tilde{B}^TP & \tilde{B}_0^TP & \tilde{D}^T & \tilde{B}_1^T \\ P\tilde{A} & P\tilde{B} & -P & 0 & 0 & 0 \\ P\tilde{A}_0 & P\tilde{B}_0 & 0 & -P & 0 & 0 \\ \tilde{C} & \tilde{D} & 0 & 0 & -I & 0 \\ \tilde{A}_1 & \tilde{B}_1 & 0 & 0 & 0 & -I \end{bmatrix} < 0.$$

Then, by using this inequality and following similar reasoning as in the proof of Theorem 2.6, the desired results can be deduced. □

Similar to the continuous-time case, where the zeroth-order H_∞ approximation problem is concerned, the conditions in (3.12)–(3.15) can be simplified and the sole LMI condition can be derived, which is provided in the following theorem.

THEOREM 3.6. *There exist two matrices $\hat{B}_1$ and $\hat{D}$ solving the zeroth-order H_∞ approximation problem for the discrete-time stochastic system (Σ_d) if and only if there exists a matrix $X > 0$ satisfying*

$$\begin{bmatrix} -X & 0 & A^TX & A_0^TX \\ 0 & -\gamma^2 I & B^TX & B_0^TX \\ XA & XB & -X & 0 \\ XA_0 & XB_0 & 0 & -X \end{bmatrix} < 0, \tag{3.20}$$

$$\begin{bmatrix} C^TC + A_1^TA_1 - X & A^TX & A_0^TX \\ XA & -X & 0 \\ XA_0 & 0 & -X \end{bmatrix} < 0. \tag{3.21}$$

In this case, all the solutions $\hat{B}_1$ and $\hat{D}$ to the zeroth-order H_∞ approximation problem corresponding to a feasible solution X to (3.20) *and* (3.21) *are given by*

$$\begin{bmatrix} \hat{D} \\ \hat{B}_1 \end{bmatrix} = G_1 + G_2LG_3, \tag{3.22}$$

$$G_1 = -Q_{12}Q_{22}^{-1}M^T(MQ_{22}^{-1}M^T)^{-1}, \tag{3.23}$$
