$$G_2 = (Q_{12}Q_{22}^{-1}Q_{12}^T - Q_{11} - G_1G_3^{-2}G_1^T)^{\frac{1}{2}}, \tag{3.24}$$

$$G_3 = (-MQ_{22}^{-1}M^T)^{-\frac{1}{2}}, \tag{3.25}$$

$$Q_{11} = \begin{bmatrix} -I & 0 \\ 0 & -I \end{bmatrix}, \ Q_{12} = \begin{bmatrix} C & D & 0 & 0 \\ A_1 & B_1 & 0 & 0 \end{bmatrix}, \tag{3.26}$$

$$Q_{22} = \begin{bmatrix} -X & 0 & A^TX & A_0^TX \\ 0 & -\gamma^2 I & B^TX & B_0^TX \\ XA & XB & -X & 0 \\ XA_0 & XB_0 & 0 & -X \end{bmatrix}, \tag{3.27}$$

$$M = \begin{bmatrix} 0 & -I & 0 & 0 \end{bmatrix}, \tag{3.28}$$

where L is any matrix satisfying $\bar{\sigma}(L) < 1$.

Proof. The proof can be carried out by using Lemma 3.4 and following a similar argument as in the proof of Theorem 2.8 and thus is omitted. □

4. An illustrative example. In this section, we present an illustrative example to demonstrate the applicability of the proposed approach.

Consider a continuous-time stochastic system (Σ_c) with parameters as follows:

$$A = \begin{bmatrix} -1.5 & 1 & -1 & 1 & 0 \\ 1 & -3.5 & 1 & 0 & 0.5 \\ 1 & 1 & -2 & -1 & 1 \\ 1 & 0 & 0.5 & -2 & 0 \\ -1 & 0 & 0 & 1 & -2.6 \end{bmatrix}, \quad A_0 = \begin{bmatrix} 0 & 0.2 & -0.2 & 0 & -0.3 \\ -1 & 1 & 0 & 0 & 1 \\ -0.6 & 0.1 & 0 & -0.5 & 0 \\ 1 & 0 & -0.6 & 0 & 0 \\ 0.5 & 0.1 & -0.5 & 0.3 & -0.4 \end{bmatrix},$$

$$B = \begin{bmatrix} -0.1 & 0 & 0.3 \\ 0.5 & -1 & 0.2 \\ 0.6 & 1 & 0.5 \\ 0 & 1 & -0.2 \\ 1 & -0.2 & 0 \end{bmatrix}, \quad B_0 = \begin{bmatrix} 0 & -0.1 & 0.1 \\ 1 & 0.5 & 0 \\ 1 & -0.6 & 0.2 \\ 0.5 & -1 & 0 \\ -0.4 & -0.8 & 0.5 \end{bmatrix},$$

$$C = \begin{bmatrix} 0 & -0.1 & 0.6 & 0 & 1 \\ -0.5 & 0 & 0.5 & -0.3 & 0 \end{bmatrix}, \quad D = \begin{bmatrix} 0 & 1 & -1 \\ -1 & 1 & 0 \end{bmatrix},$$

$$A_1 = \begin{bmatrix} 0 & 0.3 & 0.1 & -0.5 & 0 \\ 0 & 0.6 & -0.8 & 0.2 & -0.2 \end{bmatrix}, \quad B_1 = \begin{bmatrix} -1 & 0 & -1 \\ 0 & 1 & 1 \end{bmatrix}.$$

It can be shown that this continuous stochastic system is mean-square stable. The purpose of this example is to find a first-order mean-square stable stochastic system in the form of (2.6) and (2.7) such that the error system is mean-square stable and (2.8) is satisfied. In this example, the H_∞ performance bound γ is required to be 1.5. By solving (2.13)–(2.16), we obtain

$$X = \begin{bmatrix} 2.1126 & 0.1145 & -0.5027 & 0.4792 & -0.3174 \\ 0.1145 & 0.3060 & -0.1633 & 0.1056 & 0.1476 \\ -0.5027 & -0.1633 & 0.6472 & -0.4421 & 0.2837 \\ 0.4792 & 0.1056 & -0.4421 & 0.8905 & -0.3450 \\ -0.3174 & 0.1476 & 0.2837 & -0.3450 & 0.9093 \end{bmatrix},$$

$$Y = \begin{bmatrix} 0.8436 & -0.0300 & 0.4938 & -0.1746 & 0.0791 \\ -0.0300 & 4.9692 & 1.6507 & -0.3162 & -1.4521 \\ 0.4938 & 1.6507 & 3.2800 & 0.8601 & -0.7925 \\ -0.1746 & -0.3162 & 0.8601 & 1.8450 & 0.4221 \\ 0.0791 & -1.4521 & -0.7925 & 0.4221 & 1.7705 \end{bmatrix}.$$

Then, from Theorem 2.6, we have that the H_∞ model reduction problem is solvable. It is easy to show that

$$X - Y^{-1} = \operatorname{diag}(0.5, 0, 0, 0, 0), \ \ \operatorname{rank}(X - Y^{-1}) = 1.$$

Therefore, we can choose

$$S = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \end{bmatrix}^T, \quad U = 2.$$

In this case, we have

$$\Psi^T = \left[\begin{array}{ccccc|c|ccc|ccc|ccc|ccc|c} 0&0&0&0&0&0&0&0&0&-1&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0&-1&0&0&0&0&0&0&0&0\\ \hline 1&0&0&0&0&2&0&0&0&0&0&0&0&0&0&0&0&0&0\\ \hline 0&0&0&0&0&0&0&0&0&0&0&-1&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0&0&0&-1&0&0&0&0&0&0\\ \hline 0&0&0&0&0&0&0&0&0&0&0&0&0&1&0&0&0&0&2 \end{array}\right],$$

$$\Phi = \left[\begin{array}{ccccc|c|ccc|ccc|ccc|ccc|c} 0&0&0&0&0&0&1&0&0&0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&1&0&0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&1&0&0&0&0&0&0&0&0&0&0\\ \hline 0&0&0&0&0&1&0&0&0&0&0&0&0&0&0&0&0&0&0 \end{array}\right].$$

Furthermore, if we choose

$$L = \begin{bmatrix} 0.6 & 0 & 0 & 0 \\ 0 & 0.6 & 0 & 0 \\ 0 & 0 & 0.6 & 0 \\ 0 & 0 & 0 & 0.6 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

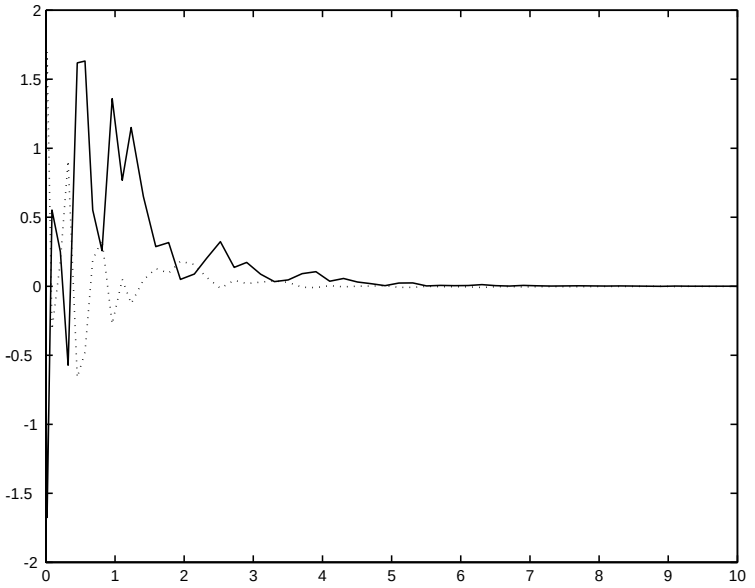

FIG. 4.1. $y_1(t)$ (—) *and* $y_2(t)$ $(\cdots)$.

$$W = \begin{bmatrix} 0.2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0.2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0.2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0.2 \end{bmatrix},$$

then, according to Theorem 2.6, a desired reduced model is given by

$$\left[\begin{array}{c|c} \hat{D} & \hat{C} \\ \hline \hat{B} & \hat{A} \\ \hline \hat{B}_1 & \hat{A}_1 \\ \hline \hat{B}_0 & \hat{A}_0 \end{array}\right] = \left[\begin{array}{rrr|r} 0.6095 & 1.3235 & -0.8778 & -0.3896 \\ -0.6180 & 1.1462 & -0.0091 & 0.4345 \\ \hline 0.5173 & 0.2807 & 0.6798 & -2.9245 \\ \hline -0.8248 & -0.1522 & -0.8731 & 1.1514 \\ -0.0830 & 0.5068 & 1.0020 & -0.0939 \\ \hline 0.0033 & 0.1111 & -0.0705 & 0.0377 \end{array}\right].$$

That is,

$$\begin{aligned} d\hat{x}(t) &= \left(-2.9245\hat{x}(t) + \begin{bmatrix} 0.5173 & 0.2807 & 0.6798 \end{bmatrix} u(t)\right) dt \\ &\quad + \left(0.0377\hat{x}(t) + \begin{bmatrix} 0.0033 & 0.1111 & -0.0705 \end{bmatrix} u(t)\right) d\omega(t), \\ \hat{y}(t)dt &= \left(\begin{bmatrix} -0.3896 \\ 0.4345 \end{bmatrix} \hat{x}(t) + \begin{bmatrix} 0.6095 & 1.3235 & -0.8778 \\ -0.6180 & 1.1462 & -0.0091 \end{bmatrix} u(t)\right) dt \\ &\quad + \left(\begin{bmatrix} 1.1514 \\ -0.0939 \end{bmatrix} \hat{x}(t) + \begin{bmatrix} -0.8248 & -0.1522 & -0.8731 \\ -0.0830 & 0.5068 & 1.0020 \end{bmatrix} u(t)\right) d\omega(t). \end{aligned}$$

The simulation results of the output of the original system and the error system are given in Figures 4.1 and 4.2, respectively, where the input is specified as $\exp(-t)I$.

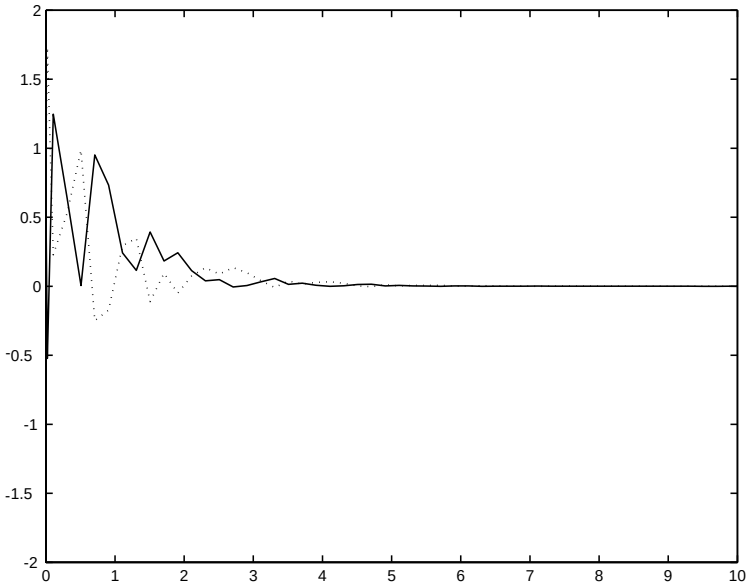

FIG. 4.2. $\hat{y}_1(t)$ (—) *and* $\hat{y}_2(t)$ $(\cdots)$.

5. Conclusions. In this paper, we have studied the problems of H_∞ model reduction for both continuous-time and discrete-time stochastic systems. Necessary and sufficient conditions for the solvability of these problems have been obtained in terms of certain LMIs and a coupling nonconvex rank constraint set. An explicit parametrization of all reduced-order models corresponding to feasible solutions has been given. Results on the zeroth-order H_∞ approximation have also been provided, which involve only LMIs without any rank constraints. The results in this paper can be viewed as extensions of existing results on H_∞ model reduction from deterministic systems to stochastic systems.

FRICTIONAL VERSUS VISCOELASTIC DAMPING IN A SEMILINEAR WAVE EQUATION*

MARCELO MOREIRA CAVALCANTI† AND HIGIDIO PORTILLO OQUENDO‡

Abstract. In this article we show exponential and polynomial decay rates for the partially viscoelastic nonlinear wave equation subject to a nonlinear and localized frictional damping. The equation that models this problem is given by

$$u_{tt} - \kappa_0 \Delta u + \int_0^t \operatorname{div}[a(x)g(t-s)\nabla u(s)]ds + f(u) + b(x)h(u_t) = 0 \text{ in } \Omega \times \mathbb{R}^+, \tag{0.1}$$

where a, b are nonnegative functions, $a \in C^1(\overline{\Omega})$, $b \in L^\infty(\Omega)$, satisfying the assumption

$$a(x) + b(x) \geq \delta > 0 \quad \forall x \in \Omega, \tag{0.2}$$

and f and h are power-like functions.

We observe that the assumption (0.2) gives us a wide assortment of possibilities from which to choose the functions $a(x)$ and $b(x)$, and the most interesting case occurs when one has simultaneous and complementary damping mechanisms. Taking this point of view into account, a distinctive feature of our paper is exactly to consider different and localized damping mechanisms acting in the domain but not necessarily "strategically localized dissipations" as considered in the prior literature.

Key words. stability, wave equation, frictional damping, viscoelasticity

1. Introduction.

Let Ω be an open bounded set of $\mathbb{R}^n$ with smooth boundary Γ. Stability for the wave equation

$$u_{tt} - \Delta u + b(x)h(u_t) = 0 \text{ in } \Omega \times \mathbb{R}^+$$

has been studied for a long time by many authors. For example, Zuazua [15] and Nakao [14] established the uniform decay of solutions provided the function b is positive in the whole domain. When the feedback term depends on the velocity in a linear way, Zuazua [16] proved that the energy related to the above equation decays exponentially if the damping region contains a neighborhood of the boundary Γ or at least contains a neighborhood ω of the particular part given by $\{x \in \Gamma : (x - x_0) \cdot \nu(x) \geq 0\}$. In the same direction, it is important to mention the result of Bardos, Lebeau, and Rauch [2], based on microlocal analysis, that ensures a necessary and sufficient condition to obtain exponential decay; namely, the damping region satisfies the well-known *geometric control condition.* The classical example of an open subset ω verifying this condition is when ω is a neighborhood of the boundary. Later, Nakao [12, 13] extended the results of Zuazua [16], treating first the case of a linear degenerate equation and then the case of a nonlinear dissipation $\rho(x, u_t)$, assuming, as usual, that the function ρ has a polynomial growth near the origin. More recently, Martinez [8] improved the previous results mentioned above in what concerns the linear wave equation subject

to a nonlinear dissipation $\rho(x, u_t)$, avoiding the polynomial growth of the function $\rho(x, s)$ in zero. His proof is based on the piecewise multiplier technique developed by Liu [7] combined with nonlinear integral inequalities to show that the energy of the system decays to zero with a precise decay rate estimate if the damping region satisfies some geometrical conditions. It is important to mention that Lasiecka and Tataru [6] studied the nonlinear wave equation subject to a nonlinear feedback acting on a part of the boundary of the system, and they were the first to prove that the energy decays to zero as fast as the solution of some associated differential equation and without assuming that the feedback has a polynomial growth in zero, although no decay rate has been shown in the general case.

On the other hand, the uniform decay of solutions for the viscoelastic wave equation

$$u_{tt} - \Delta u + \int_0^t \operatorname{div}[a(x)g(t-s)\nabla u(s)]\, ds = 0 \text{ in } \Omega \times \mathbb{R}^+,$$

was obtained by Muñoz Rivera, Barbosa Sobrinho, and Peres Salvatierra [9, 10]. Here, they also assumed that the function a is positive in the whole domain or in ω. At this point it is important to mention some papers in connection with viscoelastic effects; among them are Aassila, Cavalcanti, and Soriano [1], Cavalcanti et al. [4], Dafermos and Nohel [5], Munõz Rivera and Oquendo [11], and references therein.

The goal of the present paper is to study the wave equation with both frictional and viscoelastic dampings, where every one of these dissipations can vanish in a part of Ω and ω. Moreover, we investigate the influence of these dissipations on the rate of decay of the solutions. Our results generalize substantially the results in Cavalcanti, Domingos Cavalcanti, and Soriano [3] and complement the previous ones in the prior literature. The equation that models this problem is given by

$$(1.1)\quad u_{tt} - \kappa_0\Delta u + \int_0^t \operatorname{div}[a(x)g(t-s)\nabla u(s)]\, ds + f(u) + b(x)h(u_t) = 0 \text{ in } \Omega \times \mathbb{R}^+,$$

satisfying the Dirichlet boundary condition, i.e.,

$$(1.2)\qquad u = 0 \text{ on } \Gamma \times \mathbb{R}^+,$$

and initial data

$$(1.3)\qquad u(x,0) = u^0(x), \quad u_t(x,0) = u^1(x) \text{ in } \Omega.$$

Here, k_0 is a positive constant, the functions $a,\ b$ are nonnegative, $a \in C^1(\overline{\Omega})$, $b \in L^\infty(\Omega)$, satisfying

$$(1.4)\qquad meas\{x \in \Gamma : a(x) > 0\} > 0,$$

the relaxation function $g : [0, \infty[\to \mathbb{R}^+$ is nonincreasing and satisfies

$$(1.5)\qquad \|a\|_{L^\infty} \int_0^\infty g(s)\, ds < \kappa_0,$$

and the functions $f,\ h : \mathbb{R} \to \mathbb{R}$ satisfy

$$f(s)s \geq 0, \quad h(s)s \geq 0 \quad \forall s \in \mathbb{R}.$$

Additionally, we suppose that f is superlinear, that is,

$$(\rho+1)F(s) \le f(s)s, \quad F(z) := \int_0^z f(s)ds \quad \forall s \in \mathbb{R},$$

with the growth conditions

$$|f(x) - f(y)| \le C(1 + |x|^{\rho-1} + |y|^{\rho-1})|x-y| \quad \forall x, y \in \mathbb{R},$$

for some $C > 0$ and $\rho \ge 1$ such that $(n-2)\rho \le n$.

To make our calculations more simple, we introduce the following binary operators:

$$\begin{aligned}
(g * w)(t) &:= \int_0^t g(t-s)w(s)\,ds, \\
(g \square w)(t) &:= \int_0^t g(t-s)|w(t) - w(s)|^2\,ds, \\
(g \diamond w)(t) &:= \int_0^t g(t-s)\big(w(t) - w(s)\big)\,ds.
\end{aligned}$$

Some important relations between these operators are given by the following lemma.

LEMMA 1.1. *For any two functions $g, w \in C^1(\mathbb{R})$ and $\theta \in [0,1]$, the following inequalities hold:*

$$\begin{aligned}
2\,[g * w]\,w' &= g' \square w - g(t)|w|^2 - \frac{d}{dt}\left\{ g \square w - \left(\int_0^t g\,ds \right) |w|^2 \right\}, \\
|(g \diamond w)(t)|^2 &\le \left[\int_0^t |g(s)|^{2(1-\theta)}\,ds \right] |g|^{2\theta} \square w.
\end{aligned}$$

Proof. Differentiating the expression

$$g \square h - \left(\int_0^t g\,ds \right) |w|^2,$$

the first part of our conclusion follows. The second part is a consequence of Hölder's inequality. ∎

The existence and regularity of solutions of (1.1)–(1.3) is given by the following theorem.

THEOREM 1.2. *If $(u^0, u^1) \in [H^2(\Omega) \cap H_0^1(\Omega)] \times H_0^1(\Omega)$, then there exists a unique regular solution of* (1.1)–(1.3) *in the class*

$$u \in L^\infty_{loc}(0,\infty; H_0^1(\Omega) \cap H^2(\Omega)),\, u' \in L^\infty_{loc}(0,\infty; H_0^1(\Omega)),\, u'' \in L^\infty_{loc}(0,\infty; L^2(\Omega)).$$

The proof of the above theorem can be easily obtained, making use, for instance, of the Faedo–Galerkin method.

Now, if $\big(u^0, u^1\big) \in H_0^1(\Omega) \times L^2(\Omega)$ and considering standard arguments of density, we can prove that problem (1.1)–(1.3) has a unique solution in the class

$$u \in C^0\left([0,\infty); H_0^1(\Omega)\right) \cap C^1\left([0,\infty); L^2(\Omega)\right).$$

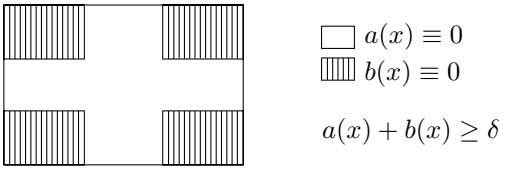

FIG. 1. *A set Ω without geometric control condition for $a(x)$ and $b(x)$.*

2. Exponential decay. In this section we shall prove that the solution of system (1.1)–(1.3) decays exponentially to zero provided the relaxation function g decays exponentially to zero and the function h is linear. In the remainder of this paper, we denote by C a positive constant independent of the initial data (u^0, u^1) which takes different values in different places. Also, we denote by C_σ a positive constant depending on the parameter σ.

The precise assumptions on the coefficients of viscoelastic and frictional dissipations are given in what follows.

Let us assume that

$$a(x) + b(x) \geq \delta \quad \forall x \in \Omega, \tag{2.1}$$

for some $\delta > 0$.

We observe that the assumption (2.1) gives us a wide assortment of possibilities from which to choose the functions $a(x)$ and $b(x)$, and the most interesting case occurs when one has simultaneous and complementary damping mechanisms. Taking this point of view into account, a distinctive feature of our paper is exactly to consider different and localized damping mechanisms acting in the domain but not necessarily "strategically localized dissipations" as considered in the prior literature (see Figure 1).

For the relaxation function g and the function h, we assume that

$$g'(t) \leq -c_1 g(t) \quad \forall t \geq 0, \tag{2.2}$$

$$c_2|w| \leq |h(w)| \leq c_3|w| \quad \forall w \in \mathbb{R}, \tag{2.3}$$

for some positive constants c_1, c_2, c_3.

Additionally, we will need the technical inequalities

$$g''(t) \leq Cg(t), \quad g'''(t) \geq Cg'(t) \quad \forall t \geq 0, \tag{2.4}$$

for some $C > 0$. We will study the asymptotic behavior of system (1.1)–(1.3) when the initial data, for an arbitrary positive λ, satisfy

$$\|u^0\|^2_{H^1} + \|u^1\|^2_{L^2} \leq \lambda. \tag{2.5}$$

Remark 1. We would like to observe that assumption (2.5) does not imply that we are considering small initial data since λ is arbitrary. Indeed, this hypothesis is required because the decay is not uniform for all arbitrary initial data. In other words, we prove that the decay is uniform for initial data taken in bounded sets.

The first order energy of system (1.1)–(1.3) is given by

$$E(t) := \frac{1}{2}\int_\Omega \left(|u_t|^2 + \kappa(x,t)|\nabla u|^2 + g\Box\nabla u\right) dx + \int_\Omega F(u)\, dx,$$

where $\kappa(x,t) := \kappa_0 - a(x)\int_0^t g(s)\,ds$. Note that, in view of (1.5), we have that

$$0 < \kappa_0 - \|a\|_{L^\infty}\int_0^\infty g(s)\,ds \le \kappa(x,t) \le \kappa_0 \quad \forall (x,t) \in \Omega \times \mathbb{R}_0^+.$$

The main result of this section is given by the following theorem.

THEOREM 2.1. *Let us consider the assumptions* (2.1)–(2.4). *If* (u^0, u^1) *satisfy* (2.5)*, then there exists a positive constant* γ *such that*

$$E(t) \le 4E(0)e^{-\frac{\gamma t}{1+\lambda\rho^{-1}}}.$$

Remark 2. The hypothesis (2.2) implies that the relaxation function g decays exponentially, that is, $g(t) \le g(0)e^{c_1 t}$. Consequently we may conjecture that the associated energy decays exponentially, where the function $a(x)$ is, in fact, effective. This kind of conjecture was first introduced by Muñoz Rivera, Barbosa Sobrinho, and Peres Salvatierra [9, 10]. In these works the authors considered the case $b(x) \equiv 0$, while $a(x)$ is effective on the whole domain Ω or at least on a strategic subset $\omega \subset \Omega$. On the other hand, the assumption (2.3) implies that $h(v)$ is similar to a linear function or, in other words, that the dissipation is *almost proportional* to the velocity u_t. We observe that, taking Zuazua's work [16] into account, where $a(x) \equiv 0$ was considered, the energy decays exponentially if $b(x)$ is effective at least on a strategic region $\omega \subset \Omega$. In the present work and keeping in mind that one has complementary dissipations given by the hypothesis (2.1), the above mentioned restrictions on Ω are unnecessary in order to obtain the exponential decay of the energy.

We shall prove Theorem 2.1 for strong solutions, that is, for solutions with initial data $(u^0, u^1) \in [H^2(\Omega) \cap H_0^1(\Omega)] \times H_0^1(\Omega)$. Our conclusion follows by a density argument. We shall apply a piecewise multiplier method to obtain appropriate inequalities for the strong solutions of system (1.1)–(1.3).

The dissipative property of the solutions of system (1.1)–(1.3) is given by the following lemma.

LEMMA 2.2. *The first order energy satisfies the following identity:*

$$\frac{d}{dt}E(t) = \frac{1}{2}\int_\Omega a(x)\big[g'\Box\nabla u - g(t)|\nabla u|^2\big]\,dx - \int_\Omega b(x)h(u_t)u_t\,dx.$$

Proof. Multiplying (1.1) by u_t, performing an integration by parts, and using Lemma 1.1, our conclusion follows. □

Let us consider a nonnegative function $\varphi \in C^1(\bar{\Omega})$, $\operatorname{supp}(\varphi) \subset \operatorname{supp}(a)$ and such that

$$\begin{aligned} &\varphi(x) \ge \delta/2 \quad \text{if} \quad x \in a^{-1}([\delta/2, \infty[), \\ &\varphi(x) = 0 \qquad \text{if} \quad x \in a^{-1}([0, \delta/4]). \end{aligned}$$

Observe that if $a(x) \le \delta/2$ for all $x \in \Omega$, this implies that $b(x) > \delta/2$ for all $x \in \Omega$, since, on the contrary, if $b(x) \le \delta/2$ for some $x \in \Omega$, then

$$a(x) + b(x) \le \delta/2 + \delta/2 = \delta \quad \text{for some } x \in \Omega,$$

which contradicts the assumption (2.1), namely,

$$a(x) + b(x) > \delta \quad \forall x \in \Omega.$$

Consequently, $a(x) \le \delta/2$ for all $x \in \Omega$ implies that $b(x) > \delta/2$ for all $x \in \Omega$. Therefore, we have the frictional damping acting on the whole domain Ω. Analogously,

$b(x) \leq \delta/2$ for all $x \in \Omega$ implies that $a(x) > \delta/2$ for all $x \in \Omega$, which shows us that the viscoelastic damping acts on the whole domain Ω. Now, when one has $a(x) > \delta/2$ for some $x \in \Omega$, and, having in mind that a is a continuous function, then, $a(x) > \delta/2$ holds for a neighborhood W of Ω (which can be considered the maximal one satisfying the property $a(x) > \delta/2$ for all $x \in W$). This means at least that $b(x) > \delta/2$ in $\Omega \backslash W$. Of course the most interesting case occurs when one has simultaneous but complementary damping effects.

Next, we will present two inequalities that will play an essential role when establishing the desired decay rates. First, in view of (2.1), we find that

$$\varphi(x) + b(x) \geq \frac{\delta}{2} \quad \forall x \in \Omega. \tag{2.6}$$

Indeed, we have two cases to consider.

(i) $x \in a^{-1}([\delta/2, +\infty))$. In this case, since $\varphi(x) \geq \delta/2$ and $b(x) \geq 0$, we obtain

$$\varphi(x) + b(x) \geq \delta/2 \quad \forall x \in \Omega.$$

(ii) $x \notin a^{-1}([\delta/2, +\infty))$. We have $0 \leq a(x) < \delta/2$, which implies that $-a(x) > -\delta/2$. From this last inequality and taking assumption (2.1) into account, we deduce

$$\varphi(x) + b(x) \geq b(x) \geq \delta - a(x) > \delta - \delta/2 = \delta/2 \quad \forall x \in \Omega,$$

which proves the inequality (2.6)

Second, from assumption (1.4) and Poincaré's inequality, we have that

$$\int_\Omega \big(\varphi(x) + |\nabla\varphi(x)|\big)|w|^2\,dx \leq C \int_\Omega a(x)|\nabla w|^2\,dx \quad \forall w \in H_0^1(\Omega), \tag{2.7}$$

for some positive constant C.

Indeed, before proving the above inequality, let us remember a useful result which is, in fact, a variant of the Poincaré inequality: *Let Ω_1, Ω_2, and Ω be subsets of $\mathbb{R}^n$ with positive measure and such that $\overline{\Omega}_1 \subset \Omega_2$, $\Omega_2 \subset \Omega$. Then, assuming that Ω is bounded and moreover that meas $(\partial\Omega_2 \cap \partial\Omega) \neq 0$, we have*

$$\int_{\Omega_1} |\omega|^2\,dx \leq C \int_{\Omega_2} |\nabla\omega|^2\,dx \quad \forall \omega \in H_0^1(\Omega),$$

where C is a positive constant.

The proof of the above inequality is immediate. Indeed, it is sufficient to observe that $\omega|_{\partial\Omega_2 \cap \partial\Omega} = 0$ and *meas* $(\partial\Omega_2 \cap \partial\Omega) > 0$.

On the other hand, from assumption (1.4) and since a is continuous, there exist $\varepsilon_0 > 0$ and $V \subset \overline{\Omega}$, a neighborhood of $\partial\Omega$ such that $meas(\partial V \cap \partial\Omega) > 0$ and $a(x) \geq \varepsilon_0$ for all $x \in V$. Setting $\Omega_1 := \text{supp}(\varphi)$, $\Omega_2 := \{x \in \Omega; a(x) > \min\{\delta/4, \epsilon_0\}\}$

and considering $\omega \in H_0^1(\Omega)$, from the above statements we deduce that

$$\begin{aligned}\int_\Omega (\varphi(x)+|\nabla\varphi(x)|)\,|\omega|^2\,dx &= \int_{\Omega_1} (\varphi(x)+|\nabla\varphi(x)|)\,|\omega(x)|^2\\ &\le \max_{x\in\overline{\Omega}} (\varphi(x)+|\nabla\varphi(x)|)\int_{\Omega_1}|\omega(x)|^2\,dx\\ &\le C_1 \max_{x\in\overline{\Omega}} (\varphi(x)+|\nabla\varphi(x)|)\int_{\Omega_2}|\nabla\omega(x)|^2\,dx\\ &\le C_2 \max_{x\in\overline{\Omega}} (\varphi(x)+|\nabla\varphi(x)|)\int_{\Omega_2} a(x)|\nabla\omega(x)|^2\,dx\\ &\le C\int_\Omega a(x)|\nabla\omega(x)|^2\,dx,\end{aligned}$$

which proves (2.7). Let us introduce the following functional:

$$R_1(t) := -\int_\Omega \varphi(x)\left\{u_t(g*u)_t + \frac{1}{2}g''\Box u - \frac{1}{2}g'(t)|u|^2 - \frac{1}{2}a(x)|g*\nabla u|^2\right\}dx.$$

The following lemma retrieves a part of the energy.

LEMMA 2.3. *Given $\epsilon>0$, there exists a positive constant C such that*

$$\begin{aligned}\frac{d}{dt}R_1(t) \le -g(0)\int_\Omega \frac{\delta}{2}|u_t|^2\,dx + \epsilon(1+\lambda^{\rho-1})\int_\Omega \kappa(x,t)|\nabla u|^2\,dx\\ + \frac{C}{\epsilon}\int_\Omega a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big)\,dx + C\int_\Omega a(x)g\Box\nabla u\,dx\\ + C\int_\Omega b(x)\big(|u_t|^2+|h(u_t)|^2\big)\,dx\end{aligned}$$

for any strong solutions of (1.1)–(1.3).

Proof. Multiplying (1.1) by $\varphi(x)(g*u)_t$, integrating by parts, and using Lemma 1.1, we obtain the following identity:

$$\begin{aligned}\frac{d}{dt}R_1(t) = -\int_\Omega \varphi(x)\left\{g(0)|u_t|^2 + \frac{1}{2}g'''\Box u - \frac{1}{2}g''(t)|u|^2\right\}dx\\ + \int_\Omega (\kappa(x,t)\nabla u + a(x)g\diamond\nabla u)\cdot\nabla\varphi(x)(g*u)_t\,dx\\ + \int_\Omega \kappa_0\nabla u\cdot[\varphi(x)(g*\nabla u)_t]\,dx + \int_\Omega [f(u)+b(x)h(u_t)]\varphi(x)(g*u)_t\,dx.\end{aligned}$$

Using hypothesis (2.4), inequality (2.7), the identity $(g*u)_t = g(t)u - g'\diamond u$, Lemma 1.1, and the Young inequality, we get, for $\eta>0$,

$$\begin{aligned}\frac{d}{dt}R_1(t) \le -g(0)\int_\Omega \varphi(x)|u_t|^2\,dx + C\int_\Omega \big(a(x)g\Box\nabla u + b(x)|h(u_t)|^2\big)\,dx\\ + \eta\int_\Omega \big(\kappa(x,t)|\nabla u|^2 + |f(u)|^2\big)\,dx + \frac{C}{\eta}\int_\Omega a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big)\,dx. \qquad (2.8)\end{aligned}$$

On the other hand, from the growth conditions of function f and Sobolev imbedding,

we obtain

$$\begin{aligned}\int_\Omega |f(u)|^2\,dx &\le C\left\{\int_\Omega |u|^2\,dx + \int_\Omega |u|^{2\rho}\,dx\right\}\\ &\le C\left\{\int_\Omega |\nabla u|^2\,dx + \left(\int_\Omega |\nabla u|^2\,dx\right)^\rho\right\}\\ &\le C\big(1+E(0)^{\rho-1}\big)\int_\Omega |\nabla u|^2\,dx.\end{aligned}$$

Substituting this inequality into (2.8) and considering (2.6), we arrive at

$$\begin{aligned}\frac{d}{dt}R_1(t) \le -g(0)\int_\Omega \frac{\delta}{2}|u_t|^2\,dx + \eta C\big(1+E(0)^{\rho-1}\big)\int_\Omega \kappa(x,t)|\nabla u|^2\,dx\\ + \frac{C}{\eta}\int_\Omega a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big)\,dx + C\int_\Omega a(x)g\Box\nabla u\,dx\\ + C\int_\Omega b(x)\big(|u_t|^2+|h(u_t)|^2\big)\,dx.\end{aligned}$$

From (2.5) our conclusion follows. □

Let us introduce the following functional:

$$R_2(t) := \int_\Omega u_t u\,dx.$$

The following lemma retrieves the complementary part of the energy of that given in the previous lemma.

LEMMA 2.4. *There exists a positive constant C such that*

$$\begin{aligned}\frac{d}{dt}R_2(t) \le \int_\Omega |u_t|^2\,dx - \frac{1}{2}\int_\Omega \kappa(x,t)|\nabla u|^2\,dx - (\rho+1)\int_\Omega F(u)\,dx\\ + C\int_\Omega \big(a(x)g\Box\nabla u + b(x)|h(u_t)|^2\big)\,dx\end{aligned}$$

for any strong solutions of (1.1)–(1.3).

Proof. Multiplying (1.1) by u and integrating by parts, we get

$$\frac{d}{dt}R_2(t) = \int_\Omega |u_t|^2 - \kappa(x,t)|\nabla u|^2 - a(x)g\diamond\nabla u\cdot\nabla u\,dx - \int_\Omega [f(u)+b(x)h(u_t)]u\,dx.$$

Applying Young's inequality and using Lemma 1.1, we obtain

$$\begin{aligned}\frac{d}{dt}R_2(t) \le \int_\Omega |u_t|^2\,dx - \frac{1}{2}\int_\Omega \kappa(x,t)|\nabla u|^2\,dx - \int_\Omega f(u)u\,dx\\ + C\int_\Omega \big(a(x)g\Box\nabla u + b(x)|h(u_t)|^2\big)\,dx.\end{aligned}$$

From the superlinearity of the function f, our conclusion follows. □

Let us consider the following functional:

$$R(t) := R_1(t) + \frac{\delta g(0)}{4}R_2(t).$$

The following lemma summarizes the results obtained in the previous lemmas.

LEMMA 2.5. *There exist positive constants k_1 and C such that*

$$\frac{d}{dt}R(t) \le -k_1E(t) + C(1+\lambda^{\rho-1})\int_\Omega a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u + g\Box\nabla u\big)\,dx + C\int_\Omega b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx$$

for any strong solutions of (1.1)–(1.3).

Proof. Let us fix ϵ_0 such that

$$-\frac{1}{2}\frac{\delta g(0)}{4} + \epsilon_0(1+\lambda^{\rho-1}) = -\frac{1}{4}\frac{\delta g(0)}{4}.$$

Taking $\epsilon = \epsilon_0$ in Lemma 2.3 and combining it with Lemma 2.4, we get

$$\begin{aligned}\frac{d}{dt}R(t) \le -\frac{\delta g(0)}{4}\int_\Omega\left(|u_t|^2 + \frac{1}{4}\kappa(x,t)|\nabla u|^2 + (\rho+1)F(u)\right)dx \\ + C(1+\lambda^{\rho-1})\int_\Omega a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u + g\Box\nabla u\big)\,dx \\ + C\int_\Omega b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx,\end{aligned}$$

from which our conclusion follows. □

Proof of Theorem 2.1 Using hypotheses (2.2) and (2.3) in Lemma 2.5, we get

$$\frac{d}{dt}R(t) \le -k_1E(t) + C(1+\lambda^{\rho-1})\int_\Omega a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big)\,dx \tag{2.9}$$

$$+ C\int_\Omega b(x)h(u_t)u_t\,dx. \tag{2.10}$$

Let N be a positive constant, and let us introduce the Lyapunov functional

$$F(t) := N(1+\lambda^{\rho-1})E(t) + R(t).$$

It is easy to verify that, for N large, we get

$$\frac{N}{2}(1+\lambda^{\rho-1})E(t) \le F(t) \le 2N(1+\lambda^{\rho-1})E(t) \quad \forall t \ge 0. \tag{2.11}$$

From Lemma 2.2, inequality (2.10), and taking N large, we obtain

$$\frac{d}{dt}F(t) \le -k_1E(t),$$

from which follows, in view of inequality (2.11), that

$$\frac{d}{dt}F(t) \le -\frac{k_1}{2N(1+\lambda^{\rho-1})}F(t).$$

This inequality implies that

$$F(t) \le F(0)e^{-\frac{k_1t}{2N(1+\lambda^{\rho-1})}},$$

and in view of inequality (2.11), we conclude that

$$E(t) \le 4E(0)e^{-\frac{k_1t}{2N(1+\lambda^{\rho-1})}}.$$

Hence the proof is complete. □

3. Polynomial decay. Here our attention will be focused on the uniform rate of decay when the function $g(t)$ is polynomially decreasing as $(1+t)^{-p}$ or the function $h(w)$ is nonlinear of the type $|w|^{1+\frac{1}{q}}$ on a neighborhood of zero. In this case, we will show that the solution decays polynomially.

The hypotheses we will use in this section for the functions g and h are

$$g'(t) \leq -c_1 g^{1+\frac{1}{p}}(t) \quad \forall t \geq 0, \tag{3.1}$$

$$\begin{aligned} c_2|w| \leq |h(w)| \leq c_3|w| \qquad &\text{for} \qquad |w| > 1, \\ c_4|w|^{1+\frac{1}{q}} \leq |h(w)| \leq c_5|w|^{\frac{q}{q+1}} \qquad &\text{for} \qquad |w| \leq 1, \end{aligned} \tag{3.2}$$

where $p > 2$, $q > 1/2$, and $c_1, \ldots, c_5$ are positive.

We summarize the main result of this section in the following theorem.

THEOREM 3.1. *Let us consider the assumptions* (2.1), (2.4), (3.1)–(3.2). *If* (u^0, u^1) *satisfy* (2.5), *then there exists a positive constant* $M = M(\lambda)$ *such that*

$$E(t) \leq \frac{M}{(1+t)^r}$$

for $r = \min\{p,\ 2q\}$.

Remark 3. The above theorem states that the decay rate of the energy is driven by the weakest dissipation, that is, the slowest one. When $b(x) \equiv 0$ and assuming that $a(x) \geq \delta > 0$ for all $x \in \Omega$ (that is, the viscoelastic dissipation acts on the whole domain Ω), and $g(t) = \frac{1}{(1+t)^p}$, Muñoz Rivera [9] proved that the energy decays with the same rate, namely, $E(t) \leq \frac{C}{(1+t)^p}$. On the other hand, if $a(x) \equiv 0$ and $h(w) = |w|^{\frac{1}{q}}w$, where $b(x)$ is effective at least on a strategic part $\omega \subset \Omega \subset \mathbb{R}^2$, Nakao [12] showed that the energy decays with the following rate: $E(t) \leq \frac{C}{(1+t)^{2q}}$. In the present manuscript and taking into consideration that $a(x)$ e $b(x)$ are complementary, it is expected that the energy decays at least according to the weakest (slowest) dissipation, or, in other words, $E(t) \leq \frac{C}{(1+t)^r}$ com $r = \min\{p, 2q\}$.

We start by stating some technical lemmas.

LEMMA 3.2. *Suppose that* $g \in C([0,\infty[)$, $w \in L^1_{loc}(0,\infty)$, *and* $0 \leq \theta \leq 1$; *then we have that*

$$\int_0^t |g(\tau)w(\tau)|\, d\tau \leq \left\{\int_0^t |g(\tau)|^{1-\theta}|w(\tau)|\, d\tau\right\}^{\frac{1}{\sigma+1}} \left\{\int_0^t |g(\tau)|^{1+\frac{\theta}{\sigma}}|w(\tau)|\, d\tau\right\}^{\frac{\sigma}{\sigma+1}}.$$

Proof. For any fixed t we have

$$\int_0^t |g(\tau)w(\tau)|\, d\tau = \int_0^t \underbrace{|g(\tau)|^{\frac{1-\theta}{\sigma+1}}|w(\tau)|^{\frac{1}{\sigma+1}}}_{:=w_1} \underbrace{|g(\tau)|^{1-\frac{1-\theta}{\sigma+1}}|w(\tau)|^{\frac{\sigma}{\sigma+1}}}_{:=w_2}\, d\tau.$$

Note that $w_1 \in L^s_{loc}(0,\infty)$, $w_2 \in L^{s'}_{loc}(0,\infty)$, where $s = \sigma + 1$ and $s' = \frac{\sigma+1}{\sigma}$. Using Hölder's inequality, we get

$$\int_0^t |g(\tau)w(\tau)|\, d\tau \leq \left\{\int_0^t |g(\tau)|^{1-\theta}|w(\tau)|\, d\tau\right\}^{\frac{1}{\sigma+1}} \left\{\int_0^t |g(\tau)|^{1+\frac{\theta}{\sigma}}|w(\tau)|\, d\tau\right\}^{\frac{\sigma}{\sigma+1}}.$$

This completes the proof. ∎

LEMMA 3.3. *Let us suppose that $v \in L^\infty(0,T;H^1(\Omega))$ and g is a continuous function. Then, there exists $C>0$ such that*

$$\int_\Omega a(x) g \Box \nabla v \, dx \le C \left\{ \int_0^t \|v(\tau)\|^2_{H^1} \, d\tau + t\|v(t)\|^2_{H^1} \right\}^{\frac{1}{p+1}} \left\{ \int_\Omega a(x) g^{1+\frac{1}{p}} \Box \nabla v \, dx \right\}^{\frac{p}{p+1}}.$$

Moreover, if there exists $0<\theta<1$ such that $\int_0^\infty g^{1-\theta}(s)\,ds < \infty$, then we have

$$\int_\Omega a(x) g \Box \nabla v \, dx \le C \left\{ \left(\int_0^\infty g^{1-\theta} \, d\tau \right) \|v\|^2_{L^\infty(0,T;H^1(\Omega))} \right\}^{\frac{1}{\theta p+1}} \left\{ \int_\Omega a(x) g^{1+\frac{1}{p}} \Box \nabla v \, dx \right\}^{\frac{\theta p}{\theta p+1}}.$$

Proof. From the hypothesis on v and Lemma 3.2, we get

$$\begin{aligned}
&\int_\Omega a(x) g \Box \nabla v \, dx \\
&\quad = \int_\Omega \int_0^t g(t-\tau) \underbrace{a(x)|\nabla v(t) - \nabla v(\tau)|^2}_{=w(\tau)} \, d\tau \, dx \\
&\quad \le \left\{ \int_\Omega \int_0^t g^{1-\theta}(t-\tau) w(\tau) d\tau \, dx \right\}^{\frac{1}{\theta p+1}} \left\{ \int_\Omega \int_0^t g^{1+\frac{1}{p}}(t-\tau) w(\tau) d\tau \, dx \right\}^{\frac{\theta p}{\theta p+1}} \\
&\quad \le \left\{ \int_\Omega a(x) g^{1-\theta} \Box \nabla v \, dx \right\}^{\frac{1}{\theta p+1}} \left\{ \int_\Omega a(x) g^{1+\frac{1}{p}} \Box \nabla v \, dx \right\}^{\frac{\theta p}{\theta p+1}}. \qquad (3.3)
\end{aligned}$$

Now, for $0<\theta<1$, we have

$$\begin{aligned}
\int_\Omega a(x) g^{1-\theta} \Box \nabla v \, dx &= \int_0^t g^{1-\theta}(t-\tau) \int_\Omega a(x) |\nabla v(t) - \nabla v(\tau)|^2 \, dx d\tau \\
&\le C \left(\int_0^t g^{1-\theta}(\tau) \, d\tau \right) \|v\|^2_{L^\infty(0,T;L^2(\Gamma_2))},
\end{aligned}$$

from which the second inequality of this lemma follows. When $\theta = 1$, we get

$$\begin{aligned}
\int_\Omega a(x) 1 \Box \nabla v \, dx &= \int_0^t \int_\Omega a(x) |\nabla v(t) - \nabla v(\tau)|^2 \, dx \, d\tau \\
&\le C \left\{ t \int_\Omega |\nabla v(t)|^2 \, dx + \int_0^t \int_\Omega |\nabla v(\tau)|^2 \, dx \, d\tau \right\}.
\end{aligned}$$

Substitution of this inequality into (3.3) yields the first inequality. The proof is now complete. ∎

Proof of Theorem 3.1 We shall use some estimates of the previous section which do not depend on the behavior of the functions g and h. First, we will estimate the term $\int_\Omega b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx$. Let us consider the following decomposition of Ω:

$$\Omega^+ := \{x \in \Omega \ : \ |u_t(x)| > 1\} \quad \text{and} \quad \Omega^- := \{x \in \Omega \ : \ |u_t(x)| \le 1\}.$$

From the first hypothesis of (3.2), we get

$$\int_{\Omega^+} b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx \le C \int_\Omega b(x) h(u_t) u_t \, dx \qquad (3.4)$$

for some $C > 0$. On the other hand, the second part of the hypothesis (3.2) implies that

$$|u_t|^2 \le C[h(u_t)u_t]^{\frac{2q}{2q+1}}, \quad |h(u_t)|^2 \le C[h(u_t)u_t]^{\frac{2q}{2q+1}}$$

for any $x \in \Omega^-$. Moreover, using Holder's inequality, we have that

$$\int_{\Omega^-} b(x)[h(u_t)u_t]^{\frac{2q}{2q+1}}\,dx \le C\left(\int_\Omega b(x)h(u_t)u_t\,dx\right)^{\frac{2q}{2q+1}}.$$

Therefore, these two last inequalities imply that

$$\int_{\Omega^-} b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx \le C\left(\int_\Omega b(x)h(u_t)u_t\,dx\right)^{\frac{2q}{2q+1}}. \tag{3.5}$$

Finally, from inequalities (3.4) and (3.5), we conclude that

$$\begin{aligned}
&\int_\Omega b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx \\
&\qquad = \int_{\Omega^+} b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx + \int_{\Omega^-} b(x)\big(|u_t|^2 + |h(u_t)|^2\big)\,dx \\
&\qquad \le C\left\{\int_\Omega b(x)h(u_t)u_t\,dx + \left(\int_\Omega b(x)h(u_t)u_t\,dx\right)^{\frac{2q}{2q+1}}\right\}. \qquad (3.6)
\end{aligned}$$

Next, we will estimate the term $\int_\Omega a(x)g\Box\nabla u\,dx$. From hypothesis (3.1), it is easy to verify that $g(t) \le C(1+t)^{-p}$ for some $C > 0$. Let us fix $\theta = 1/2$, and then $(1-\theta)p > 1$, from which follows that

$$\int_0^\infty g^{1-\theta}(s)\,ds \le C\int_0^\infty \frac{1}{(1+s)^{(1-\theta)p}}\,ds < \infty.$$

Using this estimate in the second part of Lemma 3.3, we get

$$\int_\Omega a(x)g\Box\nabla u\,dx \le CE(0)^{\frac{1}{\theta p+1}}\left(\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx\right)^{\frac{\theta p}{\theta p+1}}. \tag{3.7}$$

Substituting (3.6) and (3.7) into Lemma 2.5, we arrive at

$$\begin{aligned}
\frac{d}{dt}R(t) &\le -k_1E(t) + C_\lambda\int_\Omega \big[a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big) + b(x)h(u_t)u_t\big]\,dx \\
&\quad + C_\lambda\left\{\left(\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx\right)^{\frac{\theta p}{\theta p+1}} + \left(\int_\Omega b(x)h(u_t)u_t\,dx\right)^{\frac{2q}{2q+1}}\right\}.
\end{aligned}$$

Let us take $r := \min\{\theta p,\ 2q\}$. Since $R(t) \le CE(t)$ for some $C > 0$, the above

inequality implies that

$$\begin{aligned}\frac{d}{dt}[E^{\frac{1}{r}}R](t) =& \frac{1}{r}R(t)E^{\frac{1}{r}-1}(t)\frac{d}{dt}E(t) + E^{\frac{1}{r}}(t)\frac{d}{dt}R(t)\\ \leq& -CE^{\frac{1}{r}}(t)\frac{d}{dt}E(t) + E^{\frac{1}{r}}(t)\frac{d}{dt}R(t)\\ \leq& -k_2\frac{d}{dt}E^{1+\frac{1}{r}}(t) - k_1E^{1+\frac{1}{r}}(t)\\ &+ C_\lambda E^{\frac{1}{r}}(0)\int_\Omega \big[a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big) + b(x)h(u_t)u_t\big]\,dx\\ &+ C_\lambda E^{\frac{1}{r}}(t)\left\{\left(\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx\right)^{\frac{\theta p}{\theta p+1}} + \left(\int_\Omega b(x)h(u_t)u_t\,dx\right)^{\frac{2q}{2q+1}}\right\} \end{aligned} \tag{3.8}$$

for some positive constant k_2. Now, we will estimate the two last terms of the above inequality. Since

$$E^{\frac{1}{r}}(t)\left(\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx\right)^{\frac{\theta p}{\theta p+1}} \leq E^{\frac{\theta p-r}{r(\theta p+1)}}(0)E^{\frac{r+1}{r(\theta p+1)}}(t)\left(\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx\right)^{\frac{\theta p}{\theta p+1}},$$

applying Young's inequality yields, for $\epsilon > 0$,

$$E^{\frac{1}{r}}(t)\left(\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx\right)^{\frac{\theta p}{\theta p+1}} \leq \epsilon E^{\frac{r+1}{r}}(t) + C_\epsilon E^{\frac{\theta p-r}{r\theta p}}(0)\int_\Omega a(x)g^{1+\frac{1}{p}}\Box\nabla u\,dx. \tag{3.9}$$

Similarly, we have the following estimate:

$$E^{\frac{1}{r}}(t)\left(\int_\Omega b(x)h(u_t)u_t\,dx\right)^{\frac{2q}{2q+1}} \leq \epsilon E^{\frac{r+1}{r}}(t) + C_\epsilon E^{\frac{2q-r}{r(2q)}}(0)\int_\Omega b(x)h(u_t)u_t\,dx. \tag{3.10}$$

Substituting (3.9) and (3.10) into (3.8) and taking ϵ small, we arrive at

$$\begin{aligned}\frac{d}{dt}[E^{\frac{1}{r}}(R+k_2E)](t) \leq& -\frac{k_1}{2}E^{1+\frac{1}{r}}(t)\\ &+ C_\lambda\int_\Omega \big[a(x)\big(g(t)|\nabla u|^2 - g'\Box\nabla u\big) + b(x)h(u_t)u_t\big]\,dx.\end{aligned} \tag{3.11}$$

Let N be a positive constant, and let us introduce the Lyapunov functional

$$F(t) := NE(t) + E^{\frac{1}{r}}(t)\big(R(t) + k_2E(t)\big).$$

It is easy to verify that, for N large, we have

$$\frac{N}{2}E(t) \leq F(t) \leq 2NE(t) \quad \forall t \geq 0. \tag{3.12}$$

From Lemma 2.2 and inequality (3.11), we get, for $N = N(\lambda)$ large,

$$\frac{d}{dt}F(t) \leq -\frac{k_1}{2}E^{1+\frac{1}{r}}(t),$$

from which follows, in view of (3.12), that

$$\frac{d}{dt}F(t) \leq -k_3F^{1+\frac{1}{r}}(t) \tag{3.13}$$

for some $k_3 = k_3(\lambda) > 0$. Hence we obtain

$$F(t) \le \frac{C_\lambda}{(1+t)^r} \quad \text{and consequently} \quad E(t) \le \frac{C_\lambda}{(1+t)^r}.$$

Since $p > 2,\ \theta = 1/2$, and $q > 1/2$, we have that $r > 1$. Therefore,

$$\int_0^\infty \|u(\tau)\|_{H^1}^2\, d\tau + t\|u(t)\|_{H^1}^2 \le C\left\{\int_0^\infty E(\tau)\, d\tau + tE(t)\right\} < \infty.$$

From the first part of Lemma 3.3, we get the following estimate:

$$\int_\Omega a(x) g \Box \nabla u\, dx \le C_\lambda \left(\int_\Omega a(x) g^{1+\frac{1}{p}} \Box \nabla u\, dx\right)^{\frac{p}{p+1}}.$$

Using this inequality instead of (3.7) and repeating the same calculations and changing θp to p, we conclude that

$$E(t) \le \frac{C_\lambda}{(1+t)^r}$$

for $r := \min\{p,\ 2q\}$. This completes the proof. □

APPROXIMATION OF TIME-OPTIMAL CONTROL PROBLEMS VIA NONLINEAR POWER MOMENT PROBLEMS*

G. M. SKLYAR† AND S. YU. IGNATOVICH‡

Abstract. In this paper, we continue the construction of the time-optimal control problems classification for nonlinear affine analytic systems in a neighborhood of the equilibrium. The moment approach is the basis of this investigation. All possible asymptotics for solutions of the nonlinear time-optimal control problems are described in terms of special right ideals in the algebra of nonlinear power moments. We demonstrate the possible asymptotic behavior of the time-optimal control for a certain class of essentially nonlinear three-dimensional systems.

Key words. nonlinear time-optimal control problem, nonlinear power moment min-problem, algebra of nonlinear power moments

AMS subject classifications. 93B10, 93B25

DOI. 10.1137/S0363012901398253

1. Introduction.

One of the most powerful tools in nonlinear control theory is the representation of nonlinear control systems in the form of the series of Volterra type [4]. This approach gives the proper language for the analysis of mappability and approximation of nonlinear systems. Such problems are studied in many remarkable works. In addition, the study of the problem of realizability of the series as certain systems became a special area where control systems are treated as abstract algebraic structures.

It turns out that the series method may be useful in the analysis of specific problems of optimal control theory such as the time-optimal problem.

In this paper, we consider the problem of time-optimal control to the equilibrium for the nonlinear affine control system given in the form (2.1). Applying the series method for the system (2.1), we get the formula which expresses each initial point x^0 via the control $u(t)$, steering this point to the equilibrium in terms of *the series of nonlinear power moments* (Theorem 2.1). As a result, the steering problem is reduced to the *nonlinear power moment problem*. We note that such a reduction is generally accepted for linear systems.

One can see that, like in the linear case, in steering to the equilibrium the (nonautonomous) system corresponding to the nonlinear power moment problem is not uniquely defined.

From the technique viewpoint, the representation given in Theorem 2.1 can be obtained by certain transformations of the Fliess formula for a trajectory of the system [9]. However, from the algebraic point of view, the series of nonlinear power moments turns out to be essentially different. Thus in [25] we show that the structure of the algebra of nonlinear power moments differs from the Fliess one.

Extending the approach proposed for the linear time optimality [15], we consider the nonlinear time-optimal control problem in terms of *the Markov moment min-problem* (Definition 2.2).

In [16, 17, 18], the technique of the moment theory was developed and applied to obtain the *exact* solutions of several special linear time-optimal control problems. Further, in [23], the time-optimal control problem for arbitrary *linear* systems with real analytic coefficients was considered, and the possible asymptotic behavior of its solution in a neighborhood of the equilibrium was completely described. In analyzing the case of *affine nonlinear* systems [24], the conditions under which the nonlinear time-optimal control problem is equivalent to a linear one in the sense of asymptotic behavior of their solutions were given.

In the present paper, the asymptotic approximation of time-optimal control problems in a neighborhood of the equilibrium for *arbitrary affine nonlinear* control systems is studied (Definition 2.3).

The question of approximation of nonlinear systems has been of interest for the last three decades. In this context, the problem of approximation can be regarded as follows: for the given control system, construct a new system having the simpler structure and preserving certain properties of the initial system [19, 10]. In a number of works, the set of vector fields corresponding to a control system is approximated by the set of vector fields whose Lie algebra is nilpotent [11]. The construction is applied first to the problems of controllability [26, 2] and stabilization [12]. On the other hand, in [6], the method of lifting the system to a greater dimension space is proposed, and the approximating system is constructed as the realization of a truncated Volterra series of the system. In the present paper, we suggest another approach to the problem of approximation of the nonlinear systems—namely, an approximation in the sense of time optimality. More specifically, we say that *a certain system approximates the given one in the sense of time optimality* in a neighborhood of the equilibrium if the asymptotic behavior of the solutions of the time-optimal control problems for these two systems is the same.

The paper is organized as follows. Background and the main results are given in section 2. The first step in our consideration is the representation of the series of nonlinear power moments in a *canonical form* with homogeneous *principal part.* The main result concerning *the approximation* is given in Theorem 2.4. We prove that the asymptotic behavior of the solution of the moment min-problem is preserved when the series of nonlinear power moments is substituted by its *principal part.* The proof of the theorem is given in section 3. Theorem 2.6 is the main result *on the classification of the canonical forms.* In this theorem, feasible principal parts of series of nonlinear power moments are given, and the corresponding approximating nonlinear control systems are constructed. The method of the series transformation to the canonical form given in Theorem 2.6 is based on the study of the properties of *the algebra of nonlinear power moments* and is given in section 4. The essential point of this method is Theorem 4.5, which develops the result obtained by Ree [22] (see our Theorem 2.5). Section 5 contains the proof of Theorem 2.6.

In section 6, we construct the series of nonlinear power moments and the canonical form for the system of the Euler equations for a spacecraft. In section 7, we analyze carefully the problem of time-optimal control to the origin for the following two systems:

$$\text{(A)}\ \dot{x}_1 = u,\ \dot{x}_2 = \frac{1}{2}x_1^2,$$

$$\text{(B)}\ \dot{x}_1 = u,\ \dot{x}_2 = x_1,\ \dot{x}_3 = \frac{1}{2}x_1^2.$$

It turns out that in case (B) the optimal control is not the bang-bang. However, we show that for these two systems all conditions of Theorem 2.6 are satisfied, and, therefore, they approximate certain classes of nonlinear systems in the sense of time optimality. We also give a simulation of the time-optimal control.

2. Background and the main results. We consider the class $\mathcal{U}$ of the affine control systems of the form

$$\dot{x} = a(t,x) + ub(t,x), \qquad a(t,0) \equiv 0, \qquad |u(t)| \le 1 \quad \text{a.e.}, \tag{2.1}$$

where $a(t,x)$, $b(t,x)$ are real analytic vector functions defined on some neighborhood of the origin of $\mathbb{R}^{n+1}$. Further, we denote the system (2.1) by $\{a,b\}$.

2.1. Series of nonlinear power moments. For a sufficiently small $\theta > 0$, the system (2.1) naturally generates the mapping $S_{a,b} : (\theta, u) \to x^0$, where $|u(t)| \le 1$ a.e. for $t \in [0,\theta]$ and $x^0 = x(0)$ is the initial point transferred to the origin by the control $u(t)$ in time θ by virtue of the system (2.1). The basic point for our consideration is the following representation of $S_{a,b}$ which can be obtained by transforming the Fliess formula [9].

THEOREM 2.1. *Assume that the functions $a(t,x)$, $b(t,x)$ are analytic on some neighborhood of the origin of $\mathbb{R}^{n+1}$. Then there exists $T_0 > 0$ such that for any $\theta \in (0,T_0)$ the operator $S_{a,b}(\theta,\cdot)$ admits the representation in the form of a series of nonlinear power moments,*

$$S_{a,b}(\theta,u) = \sum_{m=1}^{\infty} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\ge 1, m_j \ge 0}} v_{m_1\dots m_k} \xi_{m_1\dots m_k}(\theta,u), \tag{2.2}$$

where $\xi_{m_1\dots m_k}(\theta,u)$ are nonlinear power moments of the function $u(t)$ of the form

$$\xi_{m_1\dots m_k}(\theta,u) = \int_0^\theta \int_0^{\tau_1} \cdots \int_0^{\tau_{k-1}} \tau_1^{m_1}\tau_2^{m_2}\cdots\tau_k^{m_k} \prod_{j=1}^{k} u(\tau_j)\, d\tau_k \cdots d\tau_2 d\tau_1, \tag{2.3}$$

and $v_{m_1\dots m_k}$ are constant vector coefficients defined as follows. Let R_a, R_b be the operators acting by the rule

$$R_a d(t,x) = d_t(t,x) + d_x(t,x)\cdot a(t,x), \qquad R_b d(t,x) = d_x(t,x)\cdot b(t,x)$$

for any vector function $d(t,x)$ analytic on some neighborhood of the origin of $\mathbb{R}^{n+1}$ and

$$\operatorname{ad}_{R_a}^{m+1} R_b = [R_a, \operatorname{ad}_{R_a}^m R_b],\ m \ge 0;\ \operatorname{ad}_{R_a}^0 R_b = R_b,$$

where $[\cdot,\cdot]$ is the operator commutator. Then

$$v_{m_1\dots m_k} = \frac{(-1)^k}{m_1!\cdots m_k!} \operatorname{ad}_{R_a}^{m_1} R_b \circ \operatorname{ad}_{R_a}^{m_2} R_b \circ \cdots \circ \operatorname{ad}_{R_a}^{m_k} R_b E(x) \Big|_{\substack{t=0 \\ x=0}}, \tag{2.4}$$

where $E(x) \equiv x$. Moreover, there exists a constant $C_0 > 0$ such that for any $\theta \in (0,T_0)$ and any $u(t)$ such that $|u(t)| \le 1$ a.e., $t \in [0,\theta]$, the following estimate holds:

$$\sum_{m=1}^{\infty} \left\| \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\ge 1, m_j \ge 0}} v_{m_1\dots m_k} \xi_{m_1\dots m_k}(\theta,u) \right\| \le C_0. \tag{2.5}$$

Further, under $S_{a,b}$, we mean the series in the right-hand side of (2.2).

Throughout the paper, we refer to the number $m = m_1 + \cdots + m_k + k$ as *the order of the nonlinear power moment* $\xi_{m_1 \ldots m_k}$. Thus the method of summation of the series $S_{a,b}$ corresponds to the order of its terms.

2.2. Nonlinear Markov moment min-problem. Following the approach first proposed for the linear case in [15], we reformulate the time-optimal control problem for the system $\{a, b\}$ as *the nonlinear Markov moment min-problem* for the series $S_{a,b}$.

DEFINITION 2.2. *The nonlinear Markov moment min-problem for the series $S_{a,b}$ of the form* (2.2) *is as follows: for a given vector $s \in \mathbb{R}^n$ find (if possible) the smallest interval $[0, \theta_s]$ such that the set $U_s^{a,b}(\theta_s)$ of functions $\tilde{u}(t)$, $|\tilde{u}(t)| \le 1$, $t \in [0, \theta_s]$, satisfying for $\theta = \theta_s$ the moment equalities*

$$s = S_{a,b}(\theta, \tilde{u}) \tag{2.6}$$

is nonempty.

Further on, we identify the time-optimal control problem for the system $\{a, b\}$ and the Markov moment min-problem for the series $S_{a,b}$.

Note that for any $\{a, b\} \in \mathcal{U}$ and any analytic transformation F of a neighborhood of the origin in $\mathbb{R}^n$, $F(0) = 0$, there exists the number T_1 such that for $\theta \in (0, T_1)$ the mapping $\tilde{S}(\theta, \cdot) = F(S_{a,b}(\theta, \cdot))$ is expanded in the series of nonlinear power moments that represents the system

$$\dot{z} = \tilde{a}(t, z) + \tilde{b}(t, z)u, \qquad \text{where} \quad z = F(x), \tag{2.7}$$

i.e., $\tilde{S} = S_{\tilde{a},\tilde{b}}$. Thus the representation of the time-optimal control problem in the form of the nonlinear moment min-problem allows us to consider transformations of the series instead of changes of variables in the system.

2.3. Approximation in the sense of time optimality. Developing the approach of [23, 24], we adopt the following definition.

DEFINITION 2.3. *Consider two systems $\{a, b\}, \{a^*, b^*\} \in \mathcal{U}$, and suppose there exists such an open domain $\Omega \subset \mathbb{R}^n \backslash \{0\}$, $0 \in \overline{\Omega}$, that for any $x_0 \in \overline{\Omega}$ there exists the unique solution $(\theta^*_{x_0}, u^*_{x_0}(t))$ of the time-optimal control problem for the system $\{a^*, b^*\}$. Denote by $U_s^{a,b}(\theta)$ the set of all admissible controls which transfer the point s to the origin by virtue of the system $\{a, b\}$ in time θ, and denote by θ_s the optimal time for the system $\{a, b\}$, i.e., $\theta_s = \min\{\theta : U_s^{a,b}(\theta) \ne \emptyset\}$.*

We say that the nonlinear time-optimal control problem for the system $\{a^*, b^*\}$ approximates the time-optimal control problem for the system $\{a, b\}$ (in the domain Ω) if there exist a nonsingular transformation Φ of a neighborhood of the origin of $\mathbb{R}^n$, $\Phi(0) = 0$, and a set of pairs $(\tilde{\theta}_s, \tilde{u}_s(t))$, $s \in \Omega$, such that $\tilde{u}_s(t) \in U^{a,b}_{\Phi(s)}(\tilde{\theta}_s)$ and

$$\frac{\theta_{\Phi(s)}}{\theta^*_s} \to 1, \qquad \frac{\tilde{\theta}_s}{\theta^*_s} \to 1, \tag{2.8}$$

$$\frac{1}{\theta} \int_0^\theta |u^*_s(t) - \tilde{u}_s(t)| dt \to 0 \qquad as \qquad s \to 0, \quad s \in \Omega, \tag{2.9}$$

where $\theta = \min\{\tilde{\theta}_s, \theta^*_s\}$.

The first main result of the paper is the following theorem on approximation of time-optimal control problems.

THEOREM 2.4 (on approximation). *Let a transformation F reduce the series $S_{a,b}$ of the form* (2.2) *representing a system $\{a,b\} \in \mathcal{U}$ to the form*

$$S_{\widetilde{a,b}} = F(S_{a,b}) = \Xi + \rho, \tag{2.10}$$

such that the qth component Ξ_q of Ξ contains nonlinear power moments of order r_q only, and the qth component ρ_q of ρ contains moments of order greater than r_q, $q = 1, \dots, n$. Let $\Omega \subset \mathbb{R}^n$, $0 \in \overline{\Omega}$, be an open domain such that

(i) *the moment min-problem*

$$s = \Xi(\theta, u) \tag{2.11}$$

has the unique solution $(\theta_s^*, u_s^*(t))$ for any $s \in \Omega$;

(ii) *the function θ_s^* is continuous at any $s \in \Omega$;*

(iii) *for the set $K = \{u_s^*(t\theta_s^*),\ t \in [0,1] : s \in \Omega\}$, the following condition* (C) *holds:*

(C) *in considering K as a set in the space $L_2[0,1]$, the weak convergence of a sequence of elements from K implies the strong convergence.*

Then there exists such a set $\{\Omega(\delta)\}_{\delta>0}$ of embedded domains ($\Omega(\delta_1) \subset \Omega(\delta_2)$ for $\delta_1 > \delta_2$) that the moment min-problem (2.11) *approximates the time-optimal control problem for the system $\{a,b\}$ in any domain $\Omega(\delta)$ (with $\Phi = F^{-1}$) and $\cup_{\delta>0}\Omega(\delta) = \Omega$.*

In other words, if after *a certain* transformation of the series (what is equivalent to the change of variables in the control system) it turns out that the moment min-problem for the *principal* part Ξ (with homogeneous components) satisfies conditions (i)–(iii), then the solution of this homogeneous moment min-problem asymptotically approximates the solution of the initial time-optimal control problem.

The proof of this theorem can be found in section 3.

2.4. Algebra of nonlinear power moments. The statement of Theorem 2.4 leads us to the problem of description of *all possible* principal parts Ξ in *the canonical form* (2.10). To this end, we propose the following algebraic approach. Consider the linear span $\mathcal{A}$ of all nonlinear power moments $\xi_{m_1 \dots m_k}$ over $\mathbb{R}$ as the free algebra with the basis

$$\{\xi_{m_1 \dots m_k} :\ k \geq 1,\ m_1, \dots, m_k \geq 0\} \tag{2.12}$$

and the multiplication of the form

$$\xi_{m_1 \dots m_k} \xi_{n_1 \dots n_s} = \xi_{m_1 \dots m_k n_1 \dots n_s}.$$

Consider also *the Lie algebra* L over $\mathbb{R}$ generated by the elements $\{\xi_m\}_{m=0}^{\infty}$ with the commutation $[\ell_1, \ell_2] = \ell_1\ell_2 - \ell_2\ell_1$, $\ell_1, \ell_2 \in L$.

We introduce *the inner product* in $\mathcal{A}$ considering the basis (2.12) as *the orthonormal one*. Given a subspace $P \subset \mathcal{A}$, by $P^\perp$ we denote its orthogonal complement, $P^\perp = \{a \in \mathcal{A} :\ (a, y) = 0 \text{ for all } y \in P\}$.

Introduce further the graded structure in the algebra $\mathcal{A}$ putting the order of basis elements by the formula

$$\operatorname{ord}(\xi_{m_1 \dots m_k}) = m_1 + \dots + m_k + k.$$

We say that the element $x \in \mathcal{A}$ has an order iff x is a linear combination of basis elements of the same order. We write $\operatorname{ord}(x) = m$ iff x is a linear combination of

basis elements of order m. Obviously, the subspaces $\mathcal{A}_m = \{x \in \mathcal{A} : \operatorname{ord}(x) = m\}$ are *finite-dimensional and orthogonal to each other.*

The main tool of our further construction is the operation of the *shuffle product* [22, 1, 5, 13] given in $\mathcal{A}$ by the following recursion formula:

$$\begin{aligned} &\xi_m * \xi_n = \xi_{mn} + \xi_{nm}, \\ &\xi_{m_1 \dots m_k} * \xi_n = (\xi_{m_1 \dots m_{k-1}} * \xi_n)\xi_{m_k} + \xi_{m_1 \dots m_k}\xi_n, \\ &\xi_{m_1 \dots m_k} * \xi_{n_1 \dots n_s} = (\xi_{m_1 \dots m_{k-1}} * \xi_{n_1 \dots n_s})\xi_{m_k} + (\xi_{m_1 \dots m_k} * \xi_{n_1 \dots n_{s-1}})\xi_{n_s}. \end{aligned} \tag{2.13}$$

For a given $P \subset \mathcal{A}$, we denote $P^{\mathrm{sh}} = \operatorname{Lin}\{a_1 * \cdots * a_n : \ n \geq 2, a_1, \dots, a_n \in P\}$.

The shuffle product operation is associative and commutative; if $\xi_{m_1 \dots m_k}$ are considered as the nonlinear power moments (2.3), then the shuffle product corresponds to the "usual" product of moments (i.e., integrals) *as functionals of* u.

The connection among the Lie algebra, the shuffle product operation, and the inner product of $\mathcal{A}$ is described by the remarkable theorem given by Ree, which is reformulated under the introduced notation as follows.

THEOREM 2.5 (See Ree [22, Theorem 2.2]). *The Lie algebra L allows the representation*

$$L = (\mathcal{A} * \mathcal{A})^{\perp},$$

where $\mathcal{A} * \mathcal{A} = \operatorname{Lin}\{a_1 * a_2 : \ a_1, a_2 \in \mathcal{A}\}$.

2.5. The structure of the right ideal induced by the system in the algebra and canonical forms classification. We consider now the system $\{a, b\} \in \mathcal{U}$. The series $S_{a,b}$ (of the form (2.2)) naturally defines the linear mapping $v : \mathcal{A} \to \mathbb{R}^n$ by the rule $v(\xi_{m_1 \dots m_k}) = v_{m_1 \dots m_k}$. We note that under this definition each element of the Lie algebra L is mapped to the vector field from the Lie algebra generated by the sequence of operators $\operatorname{ad}^m_{R_a} R_b$, $m \geq 0$, applied to $E(x) \equiv x$ and evaluated at the point $t = 0$, $x = 0$. Namely, denote $R = \frac{(-1)^k}{m_1! \dots m_k!}[\operatorname{ad}^{m_1}_{R_a} R_b, \cdots [\operatorname{ad}^{m_{k-1}}_{R_a} R_b, \operatorname{ad}^{m_k}_{R_a} R_b] \cdots]$. Then $v([\xi_{m_1}, \cdots [\xi_{m_{k-1}}, \xi_{m_k}] \cdots]) = RE(x)\big|_{\substack{t=0 \\ x=0}}$. In addition, $Rd(t, x) = d_x(t, x) \cdot R\,E(x)$ for any analytic vector function $d(t, x)$. This results for any $\ell \in L$ in the condition

$$v(\ell \xi_{m_1 \dots m_k}) = \frac{(-1)^k}{m_1! \dots m_k!} (\operatorname{ad}^{m_1}_{R_a} R_b \circ \cdots \circ \operatorname{ad}^{m_k}_{R_a} R_b E(x))'_x \Big|_{\substack{t=0 \\ x=0}} v(\ell), \tag{2.14}$$

which gives the certain relations between coefficients $v_{m_1 \dots m_k}$ of the series $S_{a,b}$. So, if $v(\ell) = 0$, then $v(\ell z) = 0$ for any element $z \in \mathcal{A}$. This observation leads us to the following concept of *the right ideal* $J_{a,b}$ generated by the system.

Further, throughout the paper, we assume the system $\{a, b\}$ to be *n-dimensional,* i.e., $\dim v(L) = n$. For a given n-dimensional system $\{a, b\}$, consider the sequence of subspaces $D^r_{a,b} = v(L \cap (\mathcal{A}_1 + \cdots + \mathcal{A}_r)) \subset \mathbb{R}^n$, denote $d_r = \dim D^r_{a,b}$, $r \geq 1$, and put $r_{a,b} = \min\{r : d_r = n\}$. For any $1 \leq r \leq r_{a,b}$ there exist exactly $c_r = \dim(L \cap \mathcal{A}_r) - (d_r - d_{r-1})$ linearly independent elements $p^r_i \in L \cap \mathcal{A}_r$, $1 \leq i \leq c_r$, such that $v(p^r_i) \in D^{r-1}_{a,b}$. (We assume $D^0_{a,b} = \{0\}$, $d_0 = 0$.) We define the right ideal as

$$J_{a,b} = J = \operatorname{Lin}\{p^r_i x, \ 1 \leq i \leq c_r, \ 1 \leq r \leq r_{a,b}, \ x \in \mathcal{A} + \mathbb{R}\}.$$

If $c_1 = \cdots = c_{r_{a,b}} = 0$, then we assume $J = J_{a,b} = \{0\}$.

Thus (2.14) implies the following property of elements of the ideal $J = J_{a,b}$:

$$\text{if } z \in J \cap \mathcal{A}_m, \quad \text{then } v(z) \in v(\mathcal{A}_1 + \cdots + \mathcal{A}_{m-1}). \tag{2.15}$$

We note also that if a nonsingular transformation reduces the system $\{a, b\}$ to the system $\{a', b'\}$, then $J_{a,b} = J_{a',b'}$.

Further on, *the "tilde" symbol means the projection on* $J^\perp$; i.e., $\widetilde{x}$ and $\widetilde{L}$ denote the projections of the element x and the Lie algebra L on $J^\perp$, respectively. We see that $\dim(\sum_{r=1}^{r_{a,b}}(\widetilde{L} \cap \mathcal{A}_r)) = \sum_{r=1}^{r_{a,b}}(\dim(L \cap \mathcal{A}_r) - \dim(J \cap L \cap \mathcal{A}_r)) = d_{r_{a,b}} = n$.

On the other hand, we consider any $r_0 \geq 1$ and an arbitrary sequence of subspaces $M = \{M_r\}_{r=1}^{r_0}$, $M_r \subset L \cap \mathcal{A}_r$, such that $\sum_{r=1}^{r_0}(\dim(L \cap \mathcal{A}_r) - \dim(J_M \cap L \cap \mathcal{A}_r)) = n$, where $J_M = \mathrm{Lin}\{px : p \in \sum_{r=1}^{r_0} M_r, x \in \mathcal{A} + \mathbb{R}\}$. We denote by $\mathcal{J}$ the family of all such right ideals J_M. Obviously, the right ideal $J = J_{a,b}$ corresponding to the system $\{a, b\} \in \mathcal{U}$ belongs to $\mathcal{J}$.

The second main result of the present paper is the following theorem, which describes *all possible canonical forms* of the series of nonlinear power moments.

THEOREM 2.6 (on classification of canonical forms).

(i) *Let* $\{a, b\} \in \mathcal{U}$ *be* n*-dimensional, and let* $\widetilde{\ell}_1, \ldots, \widetilde{\ell}_n$ *be a basis Lof* $\sum_{r=1}^{r_{a,b}}(\widetilde{L} \cap \mathcal{A}_r)$ *such that* $\mathrm{ord}(\widetilde{\ell}_i) \leq \mathrm{ord}(\widetilde{\ell}_j)$ *as* $i < j$. *Then there exists a nonsingular analytic transformation* F *of a neighborhood of the origin which reduces* $S_{a,b}$ *to the canonical form*

$$F(S_{a,b}) = \begin{pmatrix} \widetilde{\ell}_1 \\ \cdots \\ \widetilde{\ell}_n \end{pmatrix} + \rho, \tag{2.16}$$

where the components of ρ *equal*

$$\rho_q = \sum_{m=\mathrm{ord}(\widetilde{\ell}_q)+1}^{\infty} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\geq 1, m_j \geq 0}} \mu_{q,m_1\ldots m_k} \xi_{m_1\ldots m_k}, \qquad \mu_{q,m_1\ldots m_k} \in \mathbb{R}, \tag{2.17}$$

and $|\rho_q(\theta, u)| \leq C\theta^{\mathrm{ord}(\widetilde{\ell}_q)+1}$ *as* $|u(t)| \leq 1$ *a.e.,* $t \in [0, \theta]$, $q = 1, \ldots, n$.

(ii) *Let* $J = J_M \in \mathcal{J}$. *Then there exists a (homogeneous) system* $\{a^*, b^*\} \in \mathcal{U}$ *such that* $J = J_{a^*,b^*}$ *and, moreover,*

$$S_{a^*,b^*} = \begin{pmatrix} \widetilde{\ell}_1 \\ \cdots \\ \widetilde{\ell}_n \end{pmatrix},$$

where $\widetilde{\ell}_1, \ldots, \widetilde{\ell}_n$ *is a basis of* $\sum_{r=1}^{r_0}(\widetilde{L} \cap \mathcal{A}_r)$.

One can find the proof of this theorem in section 5. It is based on the properties of the algebra of nonlinear power moments discussed in section 4.

COROLLARY 2.7. *For any* n*-dimensional system* $\{a, b\} \in \mathcal{U}$ *there exists a homogeneous system* $\{a^*, b^*\} \in \mathcal{U}$ *(canonical approximation) whose series coincides with the principal part of the canonical form of* $\{a, b\}$.

COROLLARY 2.8. *Two* n*-dimensional systems* $\{a, b\}, \{\widetilde{a}, \widetilde{b}\} \in \mathcal{U}$ *have the same canonical approximation iff* $J_{a,b} = J_{\widetilde{a},\widetilde{b}}$.

COROLLARY 2.9. *The set of all possible principal parts of series of nonlinear power moments representing systems from* $\mathcal{U}$ *(up to changes of variables) is in one-to-one correspondence with the family of right ideals* $\mathcal{J}$.

3. Proof of Theorem 2.4. Consider moment min-problem (2.11), and introduce the operator $H_\varepsilon(x) = (\varepsilon^{r_1}x_1, \dots, \varepsilon^{r_n}x_n)$. Obviously, if $(\theta_s^*, u_s^*(t))$ is the solution of this problem for the point $s \in \Omega$, then $(\varepsilon\theta_s^*, u_s^*(t/\varepsilon))$ is the solution of (2.11) for the point $H_\varepsilon(s)$. Denote $\omega = \{\Xi(1, u_s^*(t\theta_s^*)) : s \in \Omega\}$. Then conditions (i)–(iii) hold in the set $\cup_{\varepsilon>0} H_\varepsilon(\omega)$. Hence, without loss of generality, we assume $\Omega = \cup_{\varepsilon>0} H_\varepsilon(\omega)$. Now introduce $\omega(\delta) = \{s \in \omega : s + U_\delta \subset \Omega\}$, where $U_\delta = \{x : |x_k| \le \delta, k = 1, \dots, n\}$ and $\Omega(\delta) = \cup_{\varepsilon>0} H_\varepsilon(\omega(\delta))$. Then $\cup_{\varepsilon>0} H_\varepsilon(\omega(\delta) + U_{\delta/2}) \subset \cup_{\varepsilon\ge 0} H_\varepsilon(\overline{\omega(\delta) + U_{\delta/2}}) = \widehat{\Omega} \subset \Omega \cup \{0\}$, where $\widehat{\Omega}$ is closed.

We put $\Phi = F^{-1}$. Then the set of solutions $(\theta_{\Phi(s)}, u(t)) : u(t) \in U^{a,b}_{\Phi(s)}(\theta_{\Phi(s)})$ of the time-optimal problem for the system $\{a, b\}$ coincides with the set of solutions of the moment min-problem $s = \Xi(\theta, u) + \rho(\theta, u)$. Following [15], [24], we introduce the operator $D : \Omega \to (\mathbb{R}, L_2[0, \infty))$ which associates the pair $(\theta_x^*, u_x^*(t))$ with the point $x \in \Omega$ and consider the operator $G_s(x) = s - \rho(D(x)) : \Omega \to \mathbb{R}^n$. We show that the operator G_s has a stationary point in a certain domain when $s \in \Omega(\delta)$ is rather small.

We prove first that the operator $G_s = G_s(x)$ is continuous in Ω. Let $x_p \to x$, where $x_p, x \in \Omega$. Consider the sequence $\hat{u}_{x_p}(t) = u^*_{x_p}(t\theta^*_{x_p}) \in K$. Since $|\hat{u}_{x_p}(t)| \le 1$ and due to condition (C), there exists a subsequence $\hat{u}_{x_{p_q}}(t)$ which strongly converges in $L_2[0, 1]$ to some function $\hat{v}(t)$, $|\hat{v}(t)| \le 1$, $t \in [0, 1]$. Since $\theta^*_{x_{p_q}} \to \theta^*_x$, we get

$$\xi_{m_1\dots m_k}(\theta^*_{x_{p_q}}, u^*_{x_{p_q}}) = {\theta^*_{x_{p_q}}}^m \xi_{m_1\dots m_k}(1, \hat{u}_{x_{p_q}}) \to {\theta^*_x}^m \xi_{m_1\dots m_k}(1, \hat{v}) = \xi_{m_1\dots m_k}(\theta^*_x, v)$$

as $q \to \infty$, where $v(t) = \hat{v}(t\theta^*_x)$, $m = m_1 + \dots + m_k + k$. In particular, this means that $x_{p_q} = \Xi(\theta^*_{x_{p_q}}, u^*_{x_{p_q}}) \to \Xi(\theta^*_x, v) = x$, and therefore, $v(t) = \hat{v}(t\theta^*_x) = u^*_x(t)$. This yields that the strong limit of the sequence $\hat{u}_{x_p}(t) = u^*_{x_p}(t\theta^*_{x_p})$ exists and equals $\hat{v}(t) = u^*_x(t\theta^*_x)$. Thus we get $\rho(D(x_p)) \to \rho(D(x))$; hence the operator $G_s = G_s(x)$ is continuous at any $x \in \Omega$ for an arbitrary s.

Further on, we denote $V^\varepsilon = \{x : |x_k| \le \varepsilon^{r_k}, k = 1, \dots, n\}$. Now we show that the operator G_s maps the set $V^\varepsilon \cap \widehat{\Omega}$ into itself when ε is rather small. Denote $C_1 = \max\{\theta^*_z : z \in V^1 \cap \Omega\}$, $C_2 = \min\{\theta^*_z : z \in \Omega, z \notin V^{1/3}\} > 0$. Then for any $z \in V^\varepsilon \backslash V^{\varepsilon/3}$ we get $C_2\,\varepsilon \le \theta^*_z \le C_1\varepsilon$. Due to (2.5), one has $|\rho_k(D(x))| \le C(\theta^*_x)^{r_k+1}$, $C > 0$, as $\theta^*_x < T_0$. Now, we fix $\varepsilon \in (0, T_0/C_1)$ such that $\varepsilon \le \min_{1\le k\le n}\{\frac{\delta C_2^{r_k}}{2CC_1^{r_k+1}}, \frac{1}{2CC_1^{r_k+1}}\}$ and consider any $x \in V^\varepsilon \cap \widehat{\Omega}$. Then $|\rho_k(D(x))| \le C(C_1\varepsilon)^{r_k+1} \le \frac{1}{2}\varepsilon^{r_k}$. Therefore, for $s \in \frac{1}{2}V^\varepsilon$ we get $|s_k + \rho_k(D(x))| \le \varepsilon^{r_k}$; hence $G_s(x) \in V^\varepsilon$. Now let us give conditions under which $G_s(x) \in \widehat{\Omega}$. Namely, choose $s \in \Omega\backslash V^{\varepsilon/3}$; then $|(H^{-1}_{\theta^*_s}(\rho(D(x))))_k| \le \frac{C(\theta^*_x)^{r_k+1}}{(\theta^*_s)^{r_k}} \le \frac{C(C_1\varepsilon)^{r_k+1}}{(C_2\varepsilon)^{r_k}} \le \delta/2$. Hence we get $H^{-1}_{\theta^*_s}(s - \rho(D(x))) \in \omega(\delta) + U_{\delta/2}$, so $G_s(x) = s - \rho(D(x)) \in \widehat{\Omega}$.

Thus we claim that if ε is rather small and $s \in (\frac{1}{2}V^\varepsilon \backslash V^{\varepsilon/3}) \cap \Omega$, then the operator $G_s = G_s(x)$ is continuous and maps the closed set $V^\varepsilon \cap \widehat{\Omega}$ into itself. Hence this operator has a stationary point $s^1 \in V^\varepsilon \cap \widehat{\Omega}$, i.e., $G_s(s^1) = s^1$. That means that $s = \Xi(\theta^*_{s^1}, u^*_{s^1}) + \rho(\theta^*_{s^1}, u^*_{s^1})$. In particular, this yields that $u^*_{s^1}(t) \in U^{a,b}_{\Phi(s)}(\theta^*_{s^1})$; hence, due to [7, 8], there exists the solution of the time-optimal problem for the system $\{a, b\}$, that is, $s = \Xi(\theta_{\Phi(s)}, u) + \rho(\theta_{\Phi(s)}, u)$, $u \in U^{a,b}_{\Phi(s)}(\theta_{\Phi(s)}) \ne \emptyset$. Therefore,

$$\theta_{\Phi(s)} \le \theta^*_{s^1}. \tag{3.1}$$

Note that $s^1 \to 0$ as $s \to 0$. On the other hand, denote $s^0 = s - \rho(\theta_{\Phi(s)}, u)$, where $u \in U^{a,b}_{\Phi(s)}(\theta_{\Phi(s)})$. Then due to (3.1) for s indicated above we have $|(H^{-1}_{\theta^*_s}(\rho(\theta_{\Phi(s)}, u)))_k| \le$

$\delta/2$; hence $s^0 \in \Omega$, and, therefore, the equality $s^0 = \Xi(\theta_{\Phi(s)}, u)$ gives

$$\theta^*_{s^0} \le \theta_{\Phi(s)}. \tag{3.2}$$

In addition, by the arguments analogous to [24], one obtains

$$\frac{\theta^*_s}{\theta^*_{s^1}} \to 1, \qquad \frac{\theta^*_{s_0}}{\theta^*_{s^1}} \to 1 \qquad \text{as} \quad s \to 0,\ s \in \Omega(\delta). \tag{3.3}$$

Denote $\tilde\theta_s = \theta^*_{s^1}$, $\tilde u_s = u^*_{s^1} \in U^{a,b}_{\Phi(s)}(\tilde\theta_s)$, $s \in \Omega(\delta)$. Then (3.1)–(3.3) give (2.8).

We prove (2.9) now. Let $s_p \to 0$, $s_p \in \Omega(\delta)$. Then there exists a subsequence s_{p_q} such that the sequences $u^*_{s_{p_q}}(t\theta^*_{s_{p_q}}), \tilde u_{s_{p_q}}(t\tilde\theta_{s_{p_q}}) \in K$ strongly converge to $v^*(t)$ and $\tilde v(t)$, respectively. Since $s_{p_q} = \Xi(\theta^*_{s_{p_q}}, u^*_{s_{p_q}}) = \Xi(\tilde\theta_{s_{p_q}}, \tilde u_{s_{p_q}}) + \rho(\tilde\theta_{s_{p_q}}, \tilde u_{s_{p_q}})$, we get

$$\Xi_k(1, u^*_{s_{p_q}}(t\theta^*_{s_{p_q}})) = \left(\frac{\tilde\theta_{s_{p_q}}}{\theta^*_{s_{p_q}}}\right)^{r_k} \Xi_k(1, \tilde u_{s_{p_q}}(t\tilde\theta_{s_{p_q}})) + \theta^*_{s_{p_q}} \left(\frac{\rho_k(\tilde\theta_{s_{p_q}}, \tilde u_{s_{p_q}})}{(\theta^*_{s_{p_q}})^{r_k+1}}\right),$$

$k = 1, \dots, n$. Note that $\Xi(1, u^*_{s_{p_q}}(t\theta^*_{s_{p_q}})) \in \widehat\Omega$. Hence, by use of (2.8) and putting $q \to \infty$, we get $\Xi(1, v^*) = \Xi(1, \tilde v) \in \Omega$, which gives $v^*(t) = \tilde v(t)$. We denote $v = v^* = \tilde v$ and then $\int_0^1 |u^*_{s_{p_q}}(t\theta^*_{s_{p_q}}) - v(t)|dt \to 0$ and $\int_0^1 |\tilde u_{s_{p_q}}(t\tilde\theta_{s_{p_q}}) - v(t)|dt \to 0$. However, it is easy to see that $\int_0^1 |v(t) - v(t\theta^*_{s_{p_q}}/\tilde\theta_{s_{p_q}})|dt \to 0$ as $q \to \infty$. (We continue $v(t)$ by zero on $[1, \theta^*_{s_{p_q}}/\tilde\theta_{s_{p_q}}]$ if $\tilde\theta_{s_{p_q}} < \theta^*_{s_{p_q}}$.) Finally, $\frac{1}{\theta}\int_0^\theta |u^*_{s_{p_q}}(t) - \tilde u_{s_{p_q}}(t)|dt \to 0$, where $\theta = \min\{\theta^*_{s_{p_q}}, \tilde\theta_{s_{p_q}}\}$. Since for any sequence $s_p \to 0$, $s_p \in \Omega(\delta)$, there exists such a subsequence s_{p_q}, we get (2.9). □

Note that for the class K of the bang-bang functions condition (C) holds. Hence we obtain the following corollary.

COROLLARY 3.1. *In the case when K contains only the bang-bang functions, the statement of Theorem* 2.4 *holds if* (i) *and* (ii) *are valid. In particular, it occurs when Ξ contains linear moments only.*

Remark. If the moment min-problem (2.11) corresponds to the time-optimal control problem for a certain system $\{a^*, b^*\}$ (such a construction is given by Theorem 2.6), it is sufficient to check that the condition (C) holds for the set of controls which satisfy the maximum principle. The class of such controls can be described constructively in a number of cases.

If the system $\{a^*, b^*\}$ is autonomous and the origin belongs to the interior of its controllability set, then the function θ^*_s is continuous in a neighborhood of the origin [14].

If there exists a class K_1 which satisfies condition (C) and includes the time-optimal controls for both systems $\{a, b\}$ and $\{a^*, b^*\}$ and conditions (i), (ii) are satisfied, then one can choose $\tilde\theta_s = \theta_{\Phi(s)}$, $\tilde u_s = u_{\Phi(s)}$. As it follows from [24], if Ξ contains only linear moments, then one can choose $\tilde\theta_s = \theta_{\Phi(s)}$, $\tilde u_s = u_{\Phi(s)}$ as well.

4. Generalization of Ree's theorem. Consider now the algebra $\mathcal{A}$ of nonlinear power moments introduced in section 2. Observe that Ree's theorem (our Theorem 2.5) is equivalent to the following theorem.

THEOREM 4.1 (decomposition theorem).

(i) *The algebra $\mathcal{A}$ admits the following orthogonal decomposition:*

$$\mathcal{A} = L \oplus L^{\mathrm{sh}}.$$

(ii) *Let* $\{\ell_j\}_{j=1}^{\infty}$ *be a basis of* L. *Then the elements*

$$\{\ell_{j_1} * \cdots * \ell_{j_s} : \ s \geq 2, \ \ 1 \leq j_1 \leq \cdots \leq j_s\} \tag{4.1}$$

form a basis of L^{sh}.

Proof. Really, consider any basis element $\xi_{m_1 \ldots m_k} \in \mathcal{A}_m$. Due to Theorem 2.5, it admits the (orthogonal) decomposition $\xi_{m_1 \ldots m_k} = \ell_1 + \sum x'_{1j} * x''_{1j}$, where $\ell_1 \in L$ and x'_{1j}, x''_{1j} are basis elements (up to the constant coefficients). However, it is easy to see that $\ell_1 \in \mathrm{Lin}\{\xi_{j_1 \ldots j_k} : \{j_i\}_{i=1}^k = \{m_i\}_{i=1}^k\}$; hence $\ell_1 \in \mathcal{A}_m$, and therefore, $\mathrm{ord}(x'_{1j}) \leq m-1$, $\mathrm{ord}(x''_{1j}) \leq m-1$. Then, decomposing elements x'_{1j}, x''_{1j}, we get $\xi_{m_1 \ldots m_k} = \ell_1 + \sum \ell'_{2j} * \ell''_{2j} + \sum x'_{2j} * x''_{2j} * x'''_{2j}$, where $\ell'_{2j}, \ell''_{2j} \in L$ and $\mathrm{ord}(x'_{2j}) \leq m-2$, $\mathrm{ord}(x''_{2j}) \leq m-2$, $\mathrm{ord}(x'''_{2j}) \leq m-2$, and so on. After m such steps, we decompose $\xi_{m_1 \ldots m_k}$ in the linear combination of $\ell_1 \in L$ and elements of (4.1).

On the other hand, consider any subspace $\mathcal{A}_m$, and note that due to the theorem of Birkhoff and Witt concerning the basis of the associative algebra, the number of all such elements from (4.1) that $\sum \mathrm{ord}(\ell_{j_k}) = m$ equals $\dim(\mathcal{A}_m) - \dim(L \cap \mathcal{A}_m)$. ∎

Fix N linearly independent *Lie elements* $p_1, \ldots, p_N \in L$, each of which has an order, and denote by J the right ideal generated by them,

$$J = \mathrm{Lin}\,\{p_j x : \ 1 \leq j \leq N, \ x \in \mathcal{A} + \mathbb{R}\}, \quad p_j \in L \cap \mathcal{A}_{\mathrm{ord}(p_j)}, j = 1, \ldots, N. \tag{4.2}$$

Recall that we denote by $\widetilde{x}$ the projection of $x \in \mathcal{A}$ onto $J^{\perp}$ and by $\widetilde{L}$ the projection of L onto $J^{\perp}$. We observe the properties of $J^{\perp}$ in the following three lemmas.

LEMMA 4.2. *Let* J *be a right ideal of the form* (4.2). *Then*

(i) *it is represented as* $J = \sum_{m=1}^{\infty}(J \cap \mathcal{A}_m)$; *therefore,* $J^{\perp} = \sum_{m=1}^{\infty}(J^{\perp} \cap \mathcal{A}_m)$ *and* $\mathcal{A} = J \oplus J^{\perp}$;

(ii) *an element* $x \in \mathcal{A}$ *belongs to* $J^{\perp}$ *iff for any* $j = 1, \ldots, N$ *it admits the representation* $x = \sum_{k=1}^{n_j} p'_{kj} x'_{kj} + x''_j$, *where* $p'_{kj} \in \mathcal{A}_{\mathrm{ord}(p_j)}$, $(p'_{kj}, p_j) = 0$, $x'_{kj} \in \mathcal{A} + \mathbb{R}$, $x''_j \in Z_j = \{a \in \mathcal{A} : \ (a, yb) = 0$ *for all* $y \in \mathcal{A}_{\mathrm{ord}(p_j)}, b \in \mathcal{A} + \mathbb{R}\}$.

The proof of the lemma follows from the definitions immediately.

LEMMA 4.3. *Suppose* $a, b \in J^{\perp}$. *Then* $a * b \in J^{\perp}$.

Proof. Without loss of generality, assume $J = \{p\,x : \ x \in \mathcal{A} + \mathbb{R}\}$, where $\mathrm{ord}(p) = d$. We note that

$$\xi_{m_1 \ldots m_n} * \xi_{k_1 \ldots k_s} = \textstyle\sum_{r,q}(\xi_{m_1 \ldots m_r} * \xi_{k_1 \ldots k_q})(\xi_{m_{r+1} \ldots m_n} * \xi_{k_{q+1} \ldots k_s}) + \widetilde{z}, \tag{4.3}$$

where $\widetilde{z} \in Z = \{a \in \mathcal{A} : \ (a, yb) = 0$ for all $y \in \mathcal{A}_d, b \in \mathcal{A} + \mathbb{R}\}$ and the sum is taken over all $r \geq 0$, $q \geq 0$ such that $m_1 + \cdots + m_r + r + k_1 + \cdots + k_q + q = d$. The following cases are possible.

Case 1. $\xi_{m_1 \ldots m_n}, \xi_{k_1 \ldots k_s} \in Z$. Then obviously $r \geq 1$ and $q \geq 1$ in the sum in (4.3). In this case $(\xi_{m_1 \ldots m_r} * \xi_{k_1 \ldots k_q}, \ p) = 0$ due to Theorem 2.5; hence $\xi_{m_1 \ldots m_n} * \xi_{k_1 \ldots k_s} \in J^{\perp}$ due to Lemma 4.2.

Case 2. $\xi_{m_1 \ldots m_{r_0}} \in \mathcal{A}_d$ for a certain $1 \leq r_0 \leq n$, and $\xi_{k_1 \ldots k_s} \in Z$. Then $r \geq 1$ and q can equal 0 in (4.3); hence $\xi_{m_1 \ldots m_n} * \xi_{k_1 \ldots k_s} = \xi_{m_1 \ldots m_{r_0}} y + z'$, where $y \in \mathcal{A} + \mathbb{R}$ and $z' \in J^{\perp}$ as in Case 1.

Case 3. $\xi_{m_1 \ldots m_{r_0}} \in \mathcal{A}_d$ and $\xi_{k_1 \ldots k_{q_0}} \in \mathcal{A}_d$ for certain $1 \leq r_0 \leq n$ and $1 \leq q_0 \leq s$. Then r and q can equal 0 in (4.3); hence $\xi_{m_1 \ldots m_n} * \xi_{k_1 \ldots k_s} = \xi_{m_1 \ldots m_{r_0}} y_1 + \xi_{k_1 \ldots k_{q_0}} y_2 + z''$, where $y_1, y_2 \in \mathcal{A} + \mathbb{R}$, $z'' \in J^{\perp}$.

Suppose now $a, b \in J^{\perp}$; hence, due to Lemma 4.2, $a = \sum_{k=1}^{n_p} p'_k a'_k + a''$, $b = \sum_{k=1}^{n_p} p'_k b'_k + b''$, where $p'_k \in \mathcal{A}_d$, $(p'_k, p) = 0$, $a'_k, b'_k \in \mathcal{A} + \mathbb{R}$, $a'', b'' \in Z$. Then from

Cases 1–3 it follows that $a * b = \sum_{k=1}^{n_p} p'_k y'_k + z$, where $y'_k \in \mathcal{A} + \mathbb{R}$, $z \in J^\perp$, which yields $a * b \in J^\perp$ due to Lemma 4.2. □

LEMMA 4.4. *Denote $L_p = L \cap J$. Then*

(i) *the following direct decomposition is valid:*

$$\mathcal{A} = (L_p \oplus \widetilde{L}) \dot{+} (L_p \oplus \widetilde{L})^{\mathrm{sh}};$$

(ii) *if $B_p = \{b_m\}_{m=-\infty}^{-1}$ is a basis of L_p ($M = 0, 1$, or ∞, if $N = 0, 1$ or ≥ 2, respectively) and $B = \{b_j\}_{j=1}^{\infty}$ complements B_p to the basis of L, then the elements*

$$\begin{gathered} \{b_{m_1} * \cdots * b_{m_n} * \widetilde{b}_{j_1} * \cdots * \widetilde{b}_{j_s} \ : \ n, s \geq 0, n + s \geq 1, \\ m_1 \leq \cdots \leq m_n < 0 < j_1 \leq \cdots \leq j_s\} \end{gathered} \tag{4.4}$$

form a basis of $\mathcal{A}$.

Proof. Note that L_p equals the Lie subalgebra generated by $\{p_1, \ldots, p_N\}$ (the linear span of all Lie brackets including $p_1, \ldots, p_N$ only). Obviously, we can choose the basis B_p so that its elements have an order. Without loss of generality, we assume that elements of B also have an order as well as elements of $\widetilde{B}$.

In view of Theorem 4.1, it is sufficient to prove that any element $\ell \in L$ having an order can be represented as a linear combination of elements from (4.4) in the unique way. Since $\mathcal{A}_1 = \mathrm{Lin}\,\{\xi_0\}$, for elements from $\mathcal{A}_1$ the mentioned fact is trivial. Assume it is valid for any $\ell' \in L$ such that $\mathrm{ord}(\ell') < m$, and consider an arbitrary element $\ell \in L \cap \mathcal{A}_m$. Then due to Lemma 4.2,

$$\ell = \widetilde{\ell} + x, \tag{4.5}$$

where $\widetilde{\ell} \in \widetilde{L} \cap \mathcal{A}_m$ and $x \in J \cap \mathcal{A}_m$. Further, due to Theorem 4.1,

$$x = \ell^* + y, \tag{4.6}$$

where $\ell^* \in L \cap \mathcal{A}_m$, $y \in L^{\mathrm{sh}} \cap \mathcal{A}_m$ are defined uniquely. Thus

$$\ell - \ell^* = \widetilde{\ell} + y. \tag{4.7}$$

The condition $y \in L^{\mathrm{sh}} \cap \mathcal{A}_m$ means that y is a linear combination of elements of the form $\ell_1 * \cdots * \ell_s$, $s \geq 2$, $\ell_i \in L$, and $\mathrm{ord}(\ell_1) + \cdots + \mathrm{ord}(\ell_s) = m$. Hence $\mathrm{ord}(\ell_i) < m$, and due to the induction assumption the right part of (4.7) is represented as a linear combination of elements of (4.4).

On the other hand, formulas (4.5) and (4.6) associate to any basis element $b_i \in (B_p \cup B) \cap \mathcal{A}_m$ the unique element $b_i - b_i^* \in L \cap \mathcal{A}_m$ which equals 0 iff $b_i \in B_p$. Suppose $B_p \cap \mathcal{A}_m = \{b_{m_i}\}_{i=1}^q$ and $B \cap \mathcal{A}_m = \{b_{j_i}\}_{i=1}^r$, and consider the subset of $L \cap \mathcal{A}_m$

$$\{b_{m_i}\}_{i=1}^q \cup \{b_{j_i} - b_{j_i}^*\}_{i=1}^r. \tag{4.8}$$

Note that the number of elements in this set is equal to $\dim(L \cap \mathcal{A}_m)$. Let us show that these elements are linearly independent. Suppose the contrary; then

$$\sum_{i=1}^r \mu_i (b_{j_i} - b_{j_i}^*) \in L_p = L \cap J,$$

where $\sum_{i=1}^r \mu_i^2 > 0$. Since $b_{j_i} - b_{j_i}^* = \widetilde{b}_{j_i} + y_i$, where $\widetilde{b}_{j_i} \in J^\perp \subset L_p^\perp$, $y_i \in L^\perp \subset L_p^\perp$,

$$\sum_{i=1}^r \mu_i (b_{j_i} - b_{j_i}^*) = \sum_{i=1}^r \mu_i \widetilde{b}_{j_i} + \sum_{i=1}^r \mu_i y_i = 0.$$

This yields that $\sum_{i=1}^{r}\mu_i\widetilde{b}_{j_i}\in L^{\perp}$. In particular, the element $\sum_{i=1}^{r}\mu_i b_{j_i}\in L$ is orthogonal to its projection $\sum_{i=1}^{r}\mu_i\widetilde{b}_{j_i}$ on $J^{\perp}$. Hence $\sum_{i=1}^{r}\mu_i b_{j_i}\in J\cap L=L_p$, which gives $\mu_1=\cdots=\mu_r=0$. So we have that (4.8) is a basis of $L\cap\mathcal{A}_m$, and due to (4.7) all elements of this basis are represented as certain linear combinations of elements of (4.4), which proves the lemma. □

The following theorem is based on Lemmas 4.2–4.4 and generalizes Theorem 4.1.

THEOREM 4.5 (generalized decomposition theorem).

(i) *The following orthogonal decomposition is valid:*

$$J^{\perp}=\widetilde{L}\oplus\widetilde{L}^{\mathrm{sh}}.$$

(ii) *Let $B=\{b_j\}_{j=1}^{\infty}$ complement a basis of $L_p=L\cap J$ to a basis of L. Then the elements*

$$\{\widetilde{b}_{j_1}*\cdots*\widetilde{b}_{j_n}:\ n\geq 2,\quad 0<j_1\leq\cdots\leq j_n\}$$

form a basis of $\widetilde{L}^{\mathrm{sh}}$.

Proof. Assume $B_p=\{b_m\}_{m=-M}^{-1}$ is a basis of L_p and $B=\{b_j\}_{j=1}^{\infty}$ complements it to a basis of L. Let the elements B_p have an order as well as the elements of B. Then $\mathrm{ord}(\widetilde{b}_j)=\mathrm{ord}(b_j)$, $j>0$. Due to Lemma 4.4, $\dim(\mathcal{A}_m)$ equals the number of elements in the set

$$\left\{\begin{array}{l} b_{m_1}*\cdots*b_{m_n}*\widetilde{b}_{j_1}*\cdots*\widetilde{b}_{j_s}:n,s\geq 0,\ n+s\geq 1,\\ m_1\leq\cdots\leq m_n<0<j_1\leq\cdots\leq j_s,\sum_{i=1}^{n}\mathrm{ord}(b_{m_i})+\sum_{i=1}^{s}\mathrm{ord}(b_{j_i})=m\end{array}\right\}. \tag{4.9}$$

Further, by use of the theorem of Birkhoff and Witt on the basis of the associative algebra one can prove that $\dim(J\cap\mathcal{A}_m)$ equals the number of elements of (4.9) such that $n\geq 1$. Hence (see Lemma 4.2) $\dim(J^{\perp}\cap\mathcal{A}_m)$ equals the number of elements of (4.9) such that $n=0$,

$$\left\{\widetilde{b}_{j_1}*\cdots*\widetilde{b}_{j_s}:\ s\geq 1,\ 0<j_1\leq\cdots\leq j_s,\sum_{i=1}^{s}\mathrm{ord}(b_{j_i})=m\right\}. \tag{4.10}$$

On the other hand, elements (4.10) are linearly independent (see Lemma 4.4) and belong to $J^{\perp}\cap\mathcal{A}_m$ (see Lemma 4.3); hence, they form a basis of $J^{\perp}\cap\mathcal{A}_m$, which proves (ii) and the fact that $J^{\perp}=\widetilde{L}\dot{+}\widetilde{L}^{\mathrm{sh}}$.

It remains to prove that $\widetilde{L}$ is orthogonal to $\widetilde{L}^{\mathrm{sh}}$. Consider any $\widetilde{b}_j\in\widetilde{B}$; under our construction it is a projection of the element $b_j\in B$ on $J^{\perp}$; that is (see Lemma 4.2), $\widetilde{b}_j=b_j+x$, $x\in J$. Since $b_j\in L$, then b_j is orthogonal to $\widetilde{L}^{\mathrm{sh}}$ (see Theorem 2.5). At the same time, $\widetilde{L}^{\mathrm{sh}}\subset J^{\perp}$ (see Lemma 4.3); hence $x\in(\widetilde{L}^{\mathrm{sh}})^{\perp}$. Thus $\widetilde{b}_j\in(\widetilde{L}^{\mathrm{sh}})^{\perp}$, which completes the proof of the theorem. □

5. Proof of Theorem 2.6. (i) Without loss of generality we assume that $\{\widetilde{\ell}_i\}_{i=1}^{n}$ is an orthonormal basis of $\sum_{r=1}^{r_{a,b}}(\widetilde{L}\cap\mathcal{A}_r)$. We note that $\mathrm{ord}(\widetilde{\ell}_q)=r$ for any q such that $d_{r-1}+1\leq q\leq d_r$, $q=1,\ldots,n$, $r=1,\ldots,r_{a,b}$.

We construct the required transformation F by $r_{a,b}$ steps.

Let $S^{(0)} = S_{a,b}$ and $F^{(0)}$ be the identical map. Suppose after $r-1$ steps, where $1 \le r \le r_{a,b}$, the series $S_{a,b}$ has been transformed to the form $S^{(r-1)} = F^{(r-1)}(S_{a,b})$,

$$\begin{aligned} S_1^{(r-1)} &= \widetilde{\ell}_1 + \rho_1 \\ \cdots &\quad \cdots \\ S_{d_{r-1}}^{(r-1)} &= \widetilde{\ell}_{d_{r-1}} + \rho_{d_{r-1}}, \\ S_{d_{r-1}+1}^{(r-1)} &= \rho_{d_{r-1}+1}^{(r-1)} \\ \cdots &\quad \cdots \\ S_n^{(r-1)} &= \rho_n^{(r-1)}, \end{aligned}$$

where $\rho_1, \dots, \rho_{d_{r-1}}$ are of the form (2.17), and

$$\rho_q^{(r-1)} = \sum_{m=r}^{\infty} \sum_{\substack{m_1+\cdots+m_k+k=m \\ k\ge 1, m_j \ge 0}} (v_{m_1\dots m_k}^{(r-1)})_q \xi_{m_1\dots m_k}, \qquad q = d_{r-1}+1, \dots, n.$$

Here $(v)_q$ denotes the qth component of the vector v and $v_{m_1\dots m_k}^{(r-1)}$ are of the form (2.4) with $a = a^{(r-1)}$, $b = b^{(r-1)}$, where vector fields $a^{(r-1)}(t,z)$, $b^{(r-1)}(t,z)$ are such that the system $\dot z = a^{(r-1)}(t,z) + ub^{(r-1)}(t,z)$ is obtained from the system $\{a,b\}$ after substitution of the variables $z = F^{(r-1)}(x)$. Represent $\rho_q^{(r-1)} = \varphi_q + \hat\rho_q$, where

$$\varphi_q = \sum_{\substack{m_1+\cdots+m_k+k=r \\ k\ge 1, m_j \ge 0}} (v_{m_1\dots m_k}^{(r-1)})_q \xi_{m_1\dots m_k}, \qquad q = d_{r-1}+1, \dots, n.$$

Due to Theorem 4.5, the subspace $\mathcal{A}_r$ admits the orthogonal decomposition $\mathcal{A}_r = (J \cap \mathcal{A}_r) \oplus (\widetilde{L} \cap \mathcal{A}_r) \oplus (\widetilde{L}^{\mathrm{sh}} \cap \mathcal{A}_r)$. Let $\{x_i\}$ and $\{y_i\}$ be the orthonormal basis of $J \cap \mathcal{A}_r$ and $\widetilde{L}^{\mathrm{sh}} \cap \mathcal{A}_r$, respectively. Then

$$\varphi_q = \sum_i \alpha_{qi} x_i + \sum_{j=d_{r-1}+1}^{d_r} \beta_{qj} \widetilde{\ell}_j + \sum_i \gamma_{qi} y_i,$$

where $\alpha_{qi} = \big(v^{(r-1)}(x_i)\big)_q$, $\beta_j = \big(v^{(r-1)}(\widetilde{\ell}_j)\big)_q$, $\gamma_{qi} = \big(v^{(r-1)}(y_i)\big)_q$. It follows from (2.15) that $v^{(r-1)}(x_i) \in v^{(r-1)}\big(\sum_{k=1}^{r-1} \mathcal{A}_k\big) = \operatorname{Lin}\{e_k\}_{k=1}^{d_{r-1}}$ (e_k is the unit vector with 1 on the kth place), which yields $\alpha_{qi} = 0$, $d_{r-1}+1 \le q \le n$. Further, due to (2.15), one has $v^{(r-1)}(\widetilde{\ell}_j) - v^{(r-1)}(\ell_j) = v^{(r-1)}(\widetilde{\ell}_j - \ell_j) \in \operatorname{Lin}\{e_k\}_{k=1}^{d_{r-1}}$; hence $\beta_{qj} = (v^{(r-1)}(\ell_j))_q$, $d_{r-1}+1 \le j \le d_r$, $d_{r-1}+1 \le q \le n$. Finally, $\sum_i \gamma_{qi} y_i$ equals the linear combination of elements of the form $\widetilde{\ell}_{i_1} * \cdots * \widetilde{\ell}_{i_k}$, $k \ge 2$, where $\sum_{j=1}^{k} \operatorname{ord}(\widetilde{\ell}_{i_j}) = r$; hence $\operatorname{ord}(\widetilde{\ell}_{i_j}) < r$. Therefore, there exist polynomials $P_q = P_q(x_1, \dots, x_{d_{r-1}})$ such that $P_q(\widetilde{\ell}_1, \dots, \widetilde{\ell}_{d_{r-1}}) = \sum_i \gamma_{qi} y_i$, $q = d_{r-1}+1, \dots, n$.

Define $\widehat{F}^{(r)}(x)_q = x_q - P_q(x_1, \dots, x_{d_{r-1}})$, $q = d_{r-1}+1, \dots, n$; then

$$\widehat{F}^{(r)}(S^{(r-1)})_q = S_q^{(r-1)} - P_q\big(S_1^{(r-1)}, \dots, S_{d_{r-1}}^{(r-1)}\big) = \sum_{j=d_{r-1}+1}^{d_r} (v^{(r-1)}(\ell_j))_q \widetilde{\ell}_j + \widetilde{\rho}_q,$$

where $\widetilde{\rho}_q$ contains terms of order greater than r. Complete the definition of $\widehat{F}^{(r)}$, putting $\widehat{F}^{(r)}(x)_q = x_q$, $q = 1, \dots, d_{r-1}$. Since $\{v^{(r-1)}(\ell_j)\}_{j=d_{r-1}+1}^{d_r}$ are linearly independent, we can find a nonsingular matrix $H^{(r)}$ such that $H^{(r)} e_j = e_j$, $j = 1, \dots, d_{r-1}$,

and $H^{(r)}v^{(r-1)}(\ell_j) = e_j$, $j = d_{r-1}+1, \dots, d_r$. Choosing finally $F^{(r)} = H^{(r)}\widehat{F}^{(r)}$, we obtain that the series $S^{(r)} = F^{(r)}(S^{(r-1)})$ is of the form

$$\begin{aligned} S_1^{(r)} &= \widetilde{\ell}_1 + \rho_1 \\ \dots &\quad \dots \\ S_{d_r}^{(r)} &= \widetilde{\ell}_{d_r} + \rho_{d_r}, \\ S_{d_r+1}^{(r)} &= \rho_{d_r+1}^{(r)} \\ \dots &\quad \dots \\ S_n^{(r)} &= \rho_n^{(r)}, \end{aligned}$$

where $\rho_1, \dots, \rho_{d_r}$ are of the form (2.17), and

$$\rho_q^{(r)} = \sum_{m=r+1}^{\infty} \sum_{\substack{m_1+\dots+m_k+k=m \\ k\ge 1, m_j\ge 0}} (v_{m_1\dots m_k}^{(r)})_q \xi_{m_1\dots m_k}, \qquad q = d_r+1, \dots, n.$$

Obviously, the series $F(S_{a,b}) = F^{(r_{a,b})}\cdots F^{(1)}(S_{a,b})$ constructed after $r_{a,b}$ steps has the form (2.16).

(ii) We construct *a time-optimal canonical approximation* $\{a^*, b^*\} \in \mathcal{U}$ such that $a^*(t,x) \equiv 0$. Consider the linear span of integrals

$$\xi_{m_1\dots m_k}(t) = \xi_{m_1\dots m_k}(t,\theta,u) = \int_t^\theta \int_t^{\tau_1} \cdots \int_t^{\tau_{k-1}} \tau_1^{m_1}\tau_2^{m_2}\cdots\tau_k^{m_k} \prod_{j=1}^{k} u(\tau_j) d\tau_k \cdots d\tau_2 d\tau_1.$$

It also may be considered as the realization of $\mathcal{A}$, and the shuffle product in $\mathcal{A}$ also corresponds to the product of $\xi_{m_1\dots m_k}(t)$ as functionals of u. Further, for any element $y = \sum \mu_{m_1\dots m_k}\xi_{m_1\dots m_k} \in \mathcal{A}$, we denote by $y(t)$ the functional $\sum \mu_{m_1\dots m_k}\xi_{m_1\dots m_k}(t)$.

We construct $b^*(t,x)$ by r_0 steps. Let $1 \le r \le r_0$ and the first d_{r-1} components of the vector function $b^*(t,x)$ be chosen already so that the trajectory $x(t)$ of the system $\{a^*, b^*\}$ satisfies $x_q(t) = \widetilde{\ell}_q(t)$, $q = 1, \dots, d_{r-1}$. Then $(S_{a^*,b^*})_q = x_q(0) = \widetilde{\ell}_q$, $q = 1, \dots, d_{r-1}$. On the rth step let us construct the $d_{r-1}+1, \dots, d_r$th components of $b^*(t,x)$ to satisfy the equalities $(S_{a^*,b^*})_q = x_q(0) = \widetilde{\ell}_q$, $q = d_{r-1}+1, \dots, d_r$.

Consider the elements $\widetilde{\ell}_q$, $q = d_{r-1}+1, \dots, d_r$. Since $\widetilde{\ell}_q \in \mathcal{A}_r$, they allow the representation $\widetilde{\ell}_q = \sum_{m=0}^{r-2} y_m^q \xi_m + \alpha^q \xi_{r-1}$, where $\alpha^q \in \mathbb{R}$ and $y_m^q \in \mathcal{A}_{r-m-1}$. Let us show that $y_m^q \in J^\perp$. Really, for any $x \in J \cap \mathcal{A}_{r-m-1}$, we have $(y_m^q, x) = (y_m^q\xi_m, x\xi_m) = (\widetilde{\ell}_q, x\xi_m) = 0$ since $\widetilde{\ell}_q \in J^\perp$. Due to Theorem 4.5 and since $\{\widetilde{\ell}_j\}_{j=1}^{d_{r-1}}$ form a basis of $\widetilde{L} \cap (\mathcal{A}_1 + \dots + \mathcal{A}_{r-1})$, we obtain $y_m^q = P_m^q(\widetilde{\ell}_1, \dots, \widetilde{\ell}_{d_{r-1}})$, where P_m^q are polynomials. By our assumptions, $y_m^q(t) = P_m^q(x_1(t), \dots, x_{d_{r-1}}(t))$.

Put $(b^*(t,x))_q = -\sum_{m=0}^{r-2} t^m P_m^q(x_1, \dots, x_{d_{r-1}}) - \alpha^q t^{r-1}$, $q = d_{r-1}+1, \dots, d_r$; then

$$\begin{aligned} x_q(t) = -\int_t^\theta u(\tau)(b^*(\tau, x(\tau)))_q d\tau &= \int_t^\theta u(\tau) \sum_{m=0}^{r-2} \tau^m P_m^q(x_1(\tau), \dots, x_{d_{r-1}}(\tau)) d\tau \\ &\quad + \alpha^q \int_t^\theta \tau^{r-1} u(\tau) d\tau = \sum_{m=0}^{r-2} \int_t^\theta \tau^m u(\tau) y_m^q(\tau) d\tau + \alpha^q \xi_{r-1}(t). \end{aligned}$$

It follows from the obvious equality $\int_t^\theta \tau^m u(\tau)\xi_{j_1\dots j_k}(\tau)d\tau = \xi_{j_1\dots j_k m}(t)$ that $x_q(t) = \sum_{m=0}^{r-2}(y_m^q\xi_m)(t) + \alpha^q\xi_{r-1}(t) = \widetilde{\ell}_q(t)$. Hence $(S_{a^*,b^*})_q = x_q(0) = \widetilde{\ell}_q$, $q = d_{r-1}+1, \dots, d_r$, and after r_0 steps we construct the required system. ∎

6. Example of a series and its canonical form. Consider the system of the Euler equations for a spacecraft [21, Example 3.24.]:

$$\dot\omega_1 = \omega_2\omega_3 + u, \qquad \dot\omega_2 = -\omega_1\omega_3 + u, \qquad \dot\omega_3 = u. \tag{6.1}$$

One has

$$a(\omega) = \begin{pmatrix} \omega_2\omega_3 \\ -\omega_1\omega_3 \\ 0 \end{pmatrix}, \qquad b(\omega) = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix};$$

hence $a(0) = 0$. Denote $\delta_m = (-1)^{[\frac{m}{2}]}$. It is easy to see that

$$\mathrm{ad}_{R_a} R_b E(\omega) = \begin{pmatrix} -\omega_2 - \omega_3 \\ \omega_1 + \omega_3 \\ 0 \end{pmatrix}, \qquad \mathrm{ad}^m_{R_a} R_b E(\omega) = \begin{pmatrix} \delta_{m+1}\omega_3^m \\ \delta_m\omega_3^m \\ 0 \end{pmatrix}, \quad m \ge 2.$$

Hence $\mathrm{ad}^{m_1}_{R_a} R_b \circ \mathrm{ad}^{m_2}_{R_a} R_b D\omega = 0$ as $m_1 \ge 1$ and $m_2 \ge 2$ for any matrix D. That means that all the coefficients of the series (2.2) equal zero except $v_{0\dots0i1\dots1}$. Further,

$$(R_b)^q \circ \mathrm{ad}^i_{R_a} R_b \circ (\mathrm{ad}_{R_a} R_b)^j E(\omega) = \begin{pmatrix} \frac{i!}{(i-q)!}\delta_{i+j+1}\omega_3^{i-q} \\ \frac{i!}{(i-q)!}\delta_{i+j}\omega_3^{i-q} \\ 0 \end{pmatrix}, \quad i \ge q;$$

that is, $v_{\underbrace{0\dots0}_{q} i \underbrace{1\dots1}_{j}} = 0$ as $i \ne q$. Hence all nonzero coefficients are as follows:

$$v_0, v_{\underbrace{01\dots1}_{j}} = (-1)^{j+1}\begin{pmatrix} 2\delta_{j+1} \\ 2\delta_j \\ 0 \end{pmatrix}, \quad v_{\underbrace{0\dots0}_{i} i \underbrace{1\dots1}_{j}} = (-1)^{i+j+1}\begin{pmatrix} \delta_{i+j+1} \\ \delta_{i+j} \\ 0 \end{pmatrix}, \qquad i > 1.$$

That implies that series (2.2) corresponding to system (6.1) is of the form

$$S_{a,b} = -\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}\xi_0 + \sum_{N=1}^{\infty}(-1)^{N+1}\begin{pmatrix} \delta_{N+1} \\ \delta_N \\ 0 \end{pmatrix}\left(\sum_{j=1}^{N}\xi_{\underbrace{0\dots0}_{j} j \underbrace{1\dots1}_{N-j}} + \xi_{\underbrace{01\dots1}_{N}}\right).$$

Further, let us separate the first terms of the series,

$$S_{a,b} = -\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}\xi_0 + 2\begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}\xi_{01} + \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}(2\xi_{011} + \xi_{002}) + \rho,$$

where ρ includes terms of order greater than 5. Then

$$\begin{aligned}
&D^1_{a,b} = \mathrm{Lin}\,\{(-1,-1,-1)\},\ d_1 = 1; \qquad D^2_{a,b} = D^1_{a,b},\ d_2 = 1, \quad p^2_1 = \xi_1;\\
&D^3_{a,b} = D^1_{a,b} + \mathrm{Lin}\,\{(-1,1,0)\},\ d_3 = 2, \quad p^3_1 = \xi_2;\\
&D^4_{a,b} = D^3_{a,b},\ d_4 = 2, \quad p^4_1 = \xi_3, \quad p^4_2 = [\xi_0,\xi_2], \quad p^4_3 = [\xi_0,[\xi_0,\xi_1]];\\
&D^5_{a,b} = D^3_{a,b} + \mathrm{Lin}\,\{(1,1,0)\},\ d_5 = 3,\ r_{a,b} = 5,\\
&\quad p^5_1 = \xi_4, \quad p^5_2 = [\xi_0,\xi_3], \quad p^5_3 = [\xi_0,[\xi_0,[\xi_0,\xi_1]]], \quad p^5_4 = 2[\xi_0,[\xi_0,\xi_2]] - [\xi_1,[\xi_1,\xi_0]].
\end{aligned}$$

Hence the right ideal $J_{a,b}$ for system (6.1) is generated by the elements $p_1^2, p_1^3, \{p_k^4\}_{k=1}^3$, $\{p_k^5\}_{k=1}^4$, and the principal part of the canonical form of the series $S_{a,b}$ equals

$$\Xi = \begin{pmatrix} \widetilde{\ell}_1 \\ \widetilde{\ell}_2 \\ \widetilde{\ell}_3 \end{pmatrix} = \begin{pmatrix} \xi_0 \\ \xi_{01} \\ 2\xi_{011} + \xi_{002} \end{pmatrix},$$

where $\ell_1 = \xi_0$, $\ell_2 = [\xi_0, \xi_1]$, $\ell_3 = [\xi_0, [\xi_0, \xi_2]] + 2[\xi_1, [\xi_1, \xi_0]]$. The system $\{a^*, b^*\}$ (canonical approximation) with the series $S_{a^*,b^*} = \Xi$ constructed by the method given in the proof of Theorem 2.6 is of the form

$$\dot{x}_1 = -u, \quad \dot{x}_2 = -tux_1, \quad \dot{x}_3 = -2tux_2 - \frac{1}{2}t^2ux_1^2.$$

Note that from the results of [25] it follows that there exists the autonomous system corresponding to the series S_{a^*,b^*}, namely,

$$\dot{x}_1 = -u, \quad \dot{x}_2 = -\frac{1}{2}x_1^2, \quad \dot{x}_3 = -x_1x_2.$$

7. Examples of solutions of nonlinear time-optimal control problems.

(A) Consider the system $\{a, b\}$ of the form

$$\dot{x}_1 = u, \ \dot{x}_2 = \frac{1}{2}x_1^2. \tag{7.1}$$

The series $S_{a,b}$ is of the form $S_{a,b} = (-\xi_0, -\xi_{01})$. The controllability set for this system is of the form $D = \{x : \ x_2 \le -\frac{1}{6}|x_1|^3\}$. The maximum principle gives

$$H = u\psi_1 + \frac{1}{2}x_1^2\psi_2, \qquad \dot{\psi}_1 = -x_1\psi_2, \quad \dot{\psi}_2 = 0.$$

Hence the optimal control $u_{x^0}(t)$ can be singular and, therefore, equals $u_{x^0}(t) \equiv 0$ iff $\psi_1 \equiv 0$, $\psi_2 \neq 0$, which yields $x_1 \equiv 0$, $x_2 \equiv \text{const}$. Since the optimal trajectory cannot be stationary, the optimal control is the bang-bang and such that $u_{x^0}(t) = \operatorname{sign}(\psi_1(t))$, where $\ddot{\psi}_1 = -u_{x^0}\psi_2$. Hence, if $\{t_i\}_{i=1}^N$ are the switchings of the optimal controls, then one has $t_{i+1} - t_i = t_i - t_{i-1}$, $i = 1, \dots, N-1$, and $t_1 \le t_2 - t_1$, $\theta_{x^0} - t_N \le t_2 - t_1$. It is easy to check that the optimal control really has no more than one switching and is unique except in the case $x_1^0 = 0$, when there exist two optimal controls.

Further, the optimal time equals $\theta_{x^0} = 2\left(\frac{1}{2}|x_1^0|^3 - 3x_2^0\right)^{1/3} - |x_1^0|^3$. In other words, $\theta_{x^0} = \left|x_1^0\right|(2(3\mu+1)^{1/3} - 1)$ on any curve $x_2^0 = -(\mu + \frac{1}{6})\left|x_1^0\right|^3$, $\mu \ge 0$. Hence the optimal time is continuous in the controllability set. For example, that means that due to Theorem 2.4 the time-optimal problem for system (7.1) approximates the time-optimal problem for the locally controllable system

$$\dot{x}_1 = u, \qquad \dot{x}_2 = \frac{1}{2}x_1^2 + x_1^3$$

in the domains $\Omega_1 = \{x : -\delta_1 x_1^3 < x_2 < -\delta_2 x_1^3, x_1 > 0\}$ and $\Omega_2 = \{x : \delta_1 x_1^3 < x_2 < \delta_2 x_1^3, x_1 < 0\}$ for arbitrary $\delta_1 > \delta_2 > \frac{1}{6}$.

(B) Consider the system $\{a, b\}$ of the form

$$\dot{x}_1 = u, \ \dot{x}_2 = x_1, \ \dot{x}_3 = \frac{1}{2}x_1^2. \tag{7.2}$$

Its series is of the form $S_{a,b} = (-\xi_0, \xi_1, -\xi_{01})$. The canonical form mentioned in Theorem 2.6 equals $F(S_{a,b}) = (\xi_0, \xi_1, \xi_{01} - \xi_{10})$, where $F(z) = (-z_1, z_2, -2z_3 + z_1 z_2)$.

For the sake of convenience, we introduce the following notation.

Notation. Denote by $u(t; a^+)$, $u(t; a^-)$, and $u(t; a^0)$ the constant functions defined on the interval $(0, a)$, and taking values $+1$, -1, and 0, respectively. For $f_i(t)$ defined on the intervals $(0, a_i)$, $i = 1, 2$, let $f = f_1 \circ f_2$ be the function defined on the interval $(0, a_1 + a_2)$ and satisfying the equalities $f(t) = f_1(t)$, $t \in (0, a_1)$, and $f(t) = f_2(t - a_1)$, $t \in (a_1, a_1 + a_2)$. Finally, for $a_1, \ldots, a_m \geq 0$, $p_1, \ldots, p_m \in \{+, -, 0\}$, denote

$$u(\cdot; a_1^{p_1}, \ldots, a_m^{p_m}) = u(\cdot; a_1^{p_1}) \circ \ldots \circ u(\cdot; a_m^{p_m}).$$

We formulate the properties of system (7.2) in the following statements.

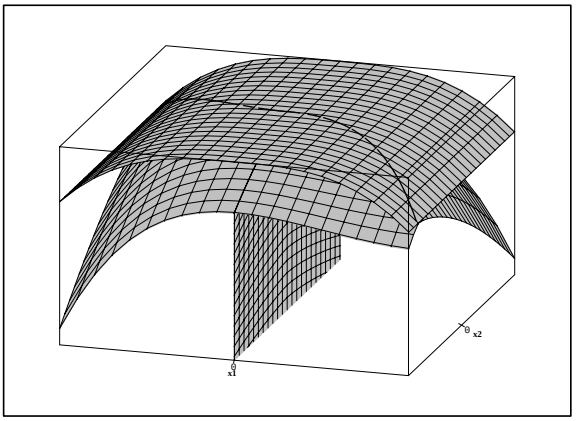

FIG. 7.1. *The upper surface is* $\partial D = \{x : x_3 = -\frac{1}{6}|x_1|^3\}$. *The lower surface is* M. *The vertical plane is* $\{x : x_1 = 0\}$. *The heavily drawn curve is* $M \cap \partial D$.

PROPOSITION 7.1. *The controllability set* D *for the system* (7.2) *equals*

$$D = \left\{x : x_3 < -\frac{1}{6}|x_1|^3\right\} \cup \left\{x = \left(x_1, -\frac{1}{2}x_1|x_1|, -\frac{1}{6}|x_1|^3\right)\right\}.$$

Proof. Really, $\frac{d}{dt}(x_3 \pm \frac{1}{6}x_1^3) = \frac{1}{2}x_1^2(1 \pm u) \geq 0$; hence $x_3^0 \pm \frac{1}{6}(x_1^0)^3 \leq 0$. Moreover, $x_3^0 = \frac{1}{6}(x_1^0)^3$ iff $u \equiv 1$ and $x_3^0 = -\frac{1}{6}(x_1^0)^3$ iff $u \equiv -1$. In these cases $x_2^0 = -\frac{1}{2}x_1^0|x_1^0|$, $x_3^0 = -\frac{1}{6}|x_1^0|^3$. On the other hand, consider the surface

$$M = \left\{x : x_3 = -\frac{1}{6}\sigma x_1^3 - \frac{1}{3}\left(\frac{1}{2}x_1^2 + \sigma x_2\right)^{3/2}\right\},$$

where $\sigma = \operatorname{sign}(x_2 + \frac{1}{2}x_1|x_1|)$, which intersects the ∂D at the points $x = (x_1, -\frac{1}{2}x_1|x_1|, -\frac{1}{6}|x_1|^3)$ (see Figure 7.1). This surface consists of the points from which the origin can be reached by the bang-bang control with no more than one switching. The surface M breaks the set $\{x : x_3 < -\frac{1}{6}|x_1|^3\}$ into two parts:

$$D_0 = \left\{x : -\frac{1}{6}\sigma x_1^3 - \frac{1}{3}\left(\frac{1}{2}x_1^2 + \sigma x_2\right)^{3/2} < x_3 < -\frac{1}{6}|x_1|^3\right\},$$

$$D_1 = \left\{x : x_3 < -\frac{1}{6}\sigma x_1^3 - \frac{1}{3}\left(\frac{1}{2}x_1^2 + \sigma x_2\right)^{3/2}\right\}.$$

Let $x' \in M$ be steered to the origin by the control $u'(t) = u(t; a^+, b^-)$, where $\sigma = -1$, $b = \left(\frac{1}{2}(x_1')^2 - x_2'\right)^{1/2}$, $a = b - x_1'$. Then by the controls $u_\alpha(t) = u(t; a^+, (b+\alpha)^-, (2\alpha)^+, \alpha^-)$ with $\alpha > 0$, we can achieve the origin from the points of the form $(x_1', x_2', x_3' - \frac{2}{3}\alpha^3)$, i.e., from all points of D_1.

For $x' \in D_0$ consider two cases. For $x_1' \le 0$ (i.e., $a \ge b$) introduce controls $u_{\alpha,\beta}(t) = u(t; (a-\alpha)^+, (2\alpha)^0, (b-\alpha)^-, \beta^+, \gamma^0, \beta^-)$ with $0 < \alpha \le b$, $\beta > 0$, $\gamma = \alpha^2/\beta - \beta > 0$. For $x_1' > 0$ (i.e., $a < b$) consider

$$u_{\alpha,\beta}(t) = \begin{cases} u(t; (a-\alpha)^+, (2\alpha)^0, (b-\alpha)^-, \beta^+, \gamma^0, \beta^-) & \text{for } 0 < \alpha \le a, \\ \quad \text{where } \beta > 0, \gamma = \alpha^2/\beta - \beta > 0, & \\ u(t; (\alpha-a)^-, (2a)^0, (b-\alpha)^-, \beta^+, \gamma^0, \beta^-) & \text{for } a < \alpha \le b, \\ \quad \text{where } \beta > 0, \gamma = (\alpha^2 - (\alpha-a)^2)/\beta - \beta > 0. & \end{cases}$$

By these controls we achieve the origin from the points $(x_1', x_2', x_3' + \phi(\alpha) + \varepsilon)$ with $\phi(\alpha) = \alpha^2(b - \frac{2}{3}\alpha)$, $0 < \alpha \le b$, if $x_1' \le 0$ and

$$\phi(\alpha) = \begin{cases} \alpha^2\left(b - \dfrac{2}{3}\alpha\right) & \text{as} \quad 0 < \alpha \le a \\ -\alpha^2 a + 2ab\alpha - ba^2 + \dfrac{1}{3}a^3 & \text{as} \quad a < \alpha \le b \end{cases} \qquad \text{if } x_1' > 0,$$

and $\varepsilon = \frac{1}{3}\beta^3 + \frac{1}{2}\beta^2\gamma$. We note that $\varepsilon \to 0$ as $\beta \to 0$. Hence the value $\phi(\alpha) + \varepsilon$ runs through the interval $(0, \frac{1}{3}b^3)$ for $x_1' \le 0$ and $(0, \frac{1}{3}b^3 - \frac{1}{3}(b-a)^3)$ for $x_1' > 0$. Since $b = \left(\frac{1}{2}(x_1')^2 - x_2'\right)^{1/2}$, $x_3' = \frac{1}{6}(x_1')^3 - \frac{1}{3}(\frac{1}{2}(x_1')^2 - x_2')^{3/2}$, and $b - a = x_1'$, we achieve the origin from any point of D_0. □

PROPOSITION 7.2. *Points of D_0 satisfy the following property: if the control u steers $x^0 \in D_0$ to the origin in time T and there exists a control u' which steers the point $(x_1^0, x_2^0, x_3^0 + \varepsilon)$ to the origin in time T where $\varepsilon > 0$, then T is not the optimal time for the point x^0.*

Proof. Denote by x' the trajectory of system (7.2) beginning at the point x^0 with the control u'. Then obviously $x_3'(T) = -\varepsilon < 0$. Introduce the family of controls

$$u_\lambda(t) = \begin{cases} u'(t) & \text{as} \quad t \le \lambda, \\ \hat{u}_\lambda(t - \lambda) & \text{as} \quad \lambda < t \le \lambda + \hat{\theta}_\lambda, \end{cases}$$

where $\hat{\theta}_\lambda$ and $\hat{u}_\lambda(t)$ are the optimal time and the time-optimal control which steers the point $(x_1'(\lambda), x_2'(\lambda)) \in \mathbb{R}^2$ to the origin by virtue of the two-dimensional linear system $\dot{x}_1 = u$, $\dot{x}_2 = x_1$.

Consider the trajectory $x(t; \lambda)$ of system (7.2) with the control u_λ, and denote $f(\lambda) = x_3(\lambda + \hat{\theta}_\lambda; \lambda)$. Then f is a continuous function and $f(0) = x_3^0 + \frac{1}{6}\sigma(x_1^0)^3 + \frac{1}{3}\left(\frac{1}{2}(x_1^0)^2 + \sigma x_2^0\right)^{3/2} > 0$, $f(T) = -\varepsilon < 0$. Then there exists λ' such that $f(\lambda') = 0$; hence $x(\lambda' + \hat{\theta}_{\lambda'}; \lambda') = 0$. Note that $\lambda' + \hat{\theta}_{\lambda'} < T$ since $\lambda' + \hat{\theta}_{\lambda'} = T$ iff $u'(t) \equiv \hat{u}_{\lambda'}(t)$ as $t > \lambda'$, which gives $f(\lambda') = f(T) < 0$. Thus we construct the control $u_{\lambda'}$, which steers the point x^0 to the origin in time less than T. □

COROLLARY 7.3. *For $x^0 \in D_0$ the optimal control is unique.*

The proof follows arguments completely analogous to [20, p. 447].

PROPOSITION 7.4. *In D_1 the following property holds: if the control u steers $x^0 \in D_1$ to the origin in time T and there exists a control u' which steers the point $(x_1^0, x_2^0, x_3^0 - \varepsilon)$ to the origin in time T where $\varepsilon > 0$, then T is not the optimal time for the point x^0.*

The proof is analogous to the proof of Proposition 7.2.

PROPOSITION 7.5. *The maximum principle gives the two possible kinds of the optimal control:*

$$\begin{aligned} &\textit{singular type:} && u(t) = u(t; a^{\pm}, b^0, c^{\pm}); \\ &\textit{bang-bang type:} && u(t) = \pm u(t; a^+, b^-, b^+, \cdots, b^+, c^-) \\ &\textit{or} && u(t) = \pm u(t; a^+, b^-, b^+, \ldots, b^+, b^-, c^+), \quad a \le b,\ c \le b. \end{aligned}$$

Proof. For the maximum principle we consider

$$H = u\psi_1 + x_1\psi_2 + \frac{1}{2}x_1^2\psi_3, \qquad \dot\psi_1 = -\psi_2 - x_1\psi_3, \quad \dot\psi_2 = 0, \quad \dot\psi_3 = 0.$$

Hence the extremal control equals $u = \operatorname{sign}(\psi_1)$, and its singular value is $u = 0$. Moreover, note that $\ddot\psi_1 = -\psi_3 u$, $\psi_3 = \text{const}$. So, the smooth function $\psi_1(t)$, $t \in (0, T)$, can be of one of the following forms:

$$\psi_1(t) = \begin{cases} \pm\dfrac{1}{2}(t-a)^2 & \text{as} \quad t \in [0, a], \\ 0 & \text{as} \quad t \in (a, b), \\ \pm\dfrac{1}{2}(t-b)^2 & \text{as} \quad t \in (b, T), \end{cases}$$

or $\psi_1(t) = \pm\frac{(-1)^i}{2}(t-(a+(i-1)b))(t-(a+ib))$ as $t \in (a+(i-1)b, a+ib]$, $i = 0, \ldots, N$, where $a - b \le 0$ and $a + Nb \ge T$. These correspond to the two possible kinds of the optimal control given in the proposition. ∎

PROPOSITION 7.6. *For $x^0 \in D_0$ the optimal control is of singular type, while for $x^0 \in D_1$ the optimal control is of the bang-bang type.*

Proof. Let the control u of *singular type* steer the point x^0 to the origin, $b > 0$. Denote $A = |x_1^0 + u(+0)a| > 0$, and consider the control $u'(t) = u(t) + v_\alpha(t)$, where $v_\alpha(t) = u(t; a^0, \alpha^+, (2\alpha)^-, \alpha^+, (b + c - 4\alpha)^0)$ as $0 < \alpha < \min\{A, \frac{1}{4}b\}$. One can see that the control $u'(t)$ steers the point $x' = (x_1^0, x_2^0, x_3^0 - \frac{2}{3}\alpha^3)$ to the origin in the same time. Hence, due to Proposition 7.4, the control $u(t)$ cannot be optimal in D_1.

Let the control $u(t)$, $t \in (0, T)$, be of bang-bang type and have no less than two switchings. Without loss of generality, assume $u(+0) = +1$. Denote $A = x_1^0 + a \ge 0$; it follows from the maximum principle that $b \ge A$. Consider the control $u'(t) = u(t) + v_\alpha(t)$, where $v_\alpha(t) = u(t; (a-\alpha)^0, \alpha^-, \alpha^+, (b-2\alpha)^0, \alpha^+, \alpha^-, (T-a-b-\alpha)^0)$ as $0 < \alpha < \min\{a, b - A\}$ for the case $b > A$ and $0 < \alpha < a$ when $b = A$. One can see that the control $u'(t)$ steers the point $x' = (x_1^0, x_2^0, x_3^0 + \varepsilon)$ to the origin in the same time, where $\varepsilon = \alpha^2(b - \frac{4}{3}\alpha) > 0$. Hence, due to Proposition 7.2, the control $u(t)$ is not optimal in D_0. ∎

PROPOSITION 7.7. *In D_1 the optimal controls (which are of bang-bang type) have two switchings.*

Proof. The proof follows [3]. Really, consider the control $u'(t) = u(t; c^-, b^+, a^-)$, where $b \ge a > 0$, $b \ge c > 0$, which steers the point x' to the origin in time $T = a+b+c$. As it can be calculated,

$$\begin{aligned} &x_1^0 = a - b + c, \quad x_2^0 = -\frac{1}{2}(a+b+c)^2 + (b+c)^2 - c^2, \\ &x_3^0 = -\frac{1}{3}\left(a^3 + (b-a)^3 + \frac{1}{2}(a-b+c)^3\right). \end{aligned}$$

Construct the control $u''(t) = u(t; \gamma^+, \beta^-, \alpha^+)$, which steers the point $x'' = (x_1', x_2', x_3'')$ to the origin in the same time. As it is calculated in [3, p.182], these conditions give $x_3' - x_3'' = (a - b + c)abc/(a + c)$. Obviously, $x_3'' < x_3'$ iff $a + c > b$, and in this case Proposition 7.4 yields that u' cannot be optimal for the point x'.

Assume now that the optimal control $\hat{u}$ which steers the point x^0 to the origin along the trajectory $x(t)$ has three switchings, $\hat{u}(t) = u(t; d^+, c^-, b^+, a^-)$. Since it is of bang-bang type, one has $b = c$, $a \le b$, $d \le b$. Consider the point on the optimal trajectory $x' = x(d)$. Since $a + c = a + b > b$, the control $u'(t) = \hat{u}(t + d)$ is not optimal for this point. Hence the control $\hat{u}$ cannot be optimal for the point x^0. □

COROLLARY 7.8. *If $x_1^0 \in D_1$ and $x_1^0 > 0$, then the optimal control initially equals $+1$; if $x_1^0 < 0$, then the optimal control initially equals -1.*

Proof. Really, it follows from the proof of Proposition 7.7 that if the optimal control equals $u(t; c^-, b^+, a^-)$, then $x_1^0 = a - b + c$ and $b \ge a + c$. Hence this control can be optimal in the case $x_1^0 \le 0$ only. □

COROLLARY 7.9. *In D_1 the optimal control is unique except at points x^0 such that $x_1^0 = 0$, for which there exist two optimal controls.*

Proof. One can easily see that there exists only one set of numbers a, b, c such that the control $u(t; c^-, b^+, a^-)$ steers the point x^0 to the origin in time $T = a + b + c$. Further, there exists the control $u(t; \gamma^+, \beta^-, \alpha^+)$ which steers this point to the origin in the same time iff $b = a + c$, which corresponds to the case $x_1^0 = 0$. In this case, $\alpha = c$, $\beta = b$, and $\gamma = a$. □

PROPOSITION 7.10. *The optimal time θ_x is a continuous function as $x \in \operatorname{int} D$.*

Proof. (i) Consider a point $x^0 \in D_0$, and assume $x_1^0 \ge 0$. Then the optimal control is described by three parameters a, b, c, where $a \ge 0$, $b > 0$, $c > 0$, and is of one of the following three forms: $u_1(t) = u(t; a^-, b^0, c^-)$, $u_2(t) = u(t; a^+, b^0, c^-)$, $u_3(t) = u(t; a^-, b^0, c^+)$. In each of these cases, one can calculate the Jacobian of the function $x^0 = x^0(a, b, c)$. It is easy to see that it is nonzero; hence this function is nonsingular. That means that for any $\varepsilon > 0$ there exists a neighborhood $V \subset D_0$ of x^0 such that for any point $x \in V$ one has $\theta_x \le a + b + c + \varepsilon = \theta_{x^0} + \varepsilon$. The lower semicontinuity of θ_x is evident; hence the function θ_x is continuous in $x^0 \in D_0$.

(ii) The analogous arguments prove the continuity of θ_{x^0} for any point $x^0 \in D_1$ such that $x_1^0 \ne 0$. Let now $x^0 \in D_1$ and $x_1^0 = 0$. Then the optimal control $u_{x^0}(t)$ is of the form $u_{x^0}(t) = \pm u(t; a^-, (a + c)^+, c^-)$, and the optimal time equals $\theta_{x^0} = 2(a + c)$. Since the function $(x_2^0, x_3^0) = (x_2^0(a, c), x_3^0(a, c))$ is nonsingular as $a > 0$, $c > 0$, then for any $\varepsilon > 0$ one can choose a neighborhood $V \subset D_1$ of x^0 such that for any $x' \in V$, $x_1' = 0$, one has $\theta_{x'} \le \theta_{x^0} + \varepsilon$. Let $V_1 \subset V$ be such a subneighborhood and $\tau = \tau(\varepsilon) > 0$ be such a number that for any $x \in V_1$ the point $x' = (0, x_2 - \frac{1}{2}\tau^2, x_3 - \frac{1}{6}\tau^3) \in V$. Consider any $x \in V_1$; without loss of generality, assume $x_1 > 0$. Then the origin is reached from the point x in time $\theta_{x'} + \tau$ by the control $u(t) = u(t; \tau^-) \circ u'(t)$, where u' steers x' to the origin. Hence $\theta_x \le \theta_{x^0} + \varepsilon + \tau$, which proves the continuity of θ_x when $x \to x^0$, $x_1 > 0$. The same can be proved for $x \to x^0$, $x_1 < 0$.

(iii) Finally, consider $x^0 \in M \backslash \partial D$. The continuity of θ_x as $x \to x^0$ for $x \in D_0$ and $x \in D_1$ can be shown by means of the families of controls used in the proof of Proposition 7.1. □

Remark. Note that the optimal time is obviously discontinuous at points of the form $(x_1, -\frac{1}{2}x_1|x_1|, -\frac{1}{3}|x_1|^3) \in \partial D \cap M$.

Thus, Propositions 7.1, 7.2, 7.4, 7.5, 7.6, 7.7, and 7.10 and Corollaries 7.3, 7.8, and 7.9 yield all conditions of Theorem 2.4. For example, that means that the time-optimal problem for system (7.2) approximates the time-optimal problem for the

locally controllable system

$$\dot{x}_1 = u, \qquad \dot{x}_2 = x_1, \qquad \dot{x}_3 = \frac{1}{2}x_1^2 + x_1^3$$

in the domains $\Omega_1 = \{x : -\delta_1 x_1^3 < x_3 < -\delta_2 x_1^3, x_1 > 0\}$ and $\Omega_2 = \{x : \delta_1 x_1^3 < x_3 < \delta_2 x_1^3, x_1 < 0\}$ for arbitrary $\delta_1 > \delta_2 > \frac{1}{6}$.

ORTHONORMAL BASIS FUNCTIONS IN TIME AND FREQUENCY DOMAIN: HAMBO TRANSFORM THEORY*

PETER S. C. HEUBERGER†, THOMAS J. DE HOOG‡, PAUL M. J. VAN DEN HOF†, AND BO WAHLBERG§

Abstract. The class of finite impulse response (FIR), Laguerre, and Kautz functions can be generalized to a family of rational orthonormal basis functions for the Hardy space H_2 of stable linear dynamical systems. These basis functions are useful for constructing efficient parameterizations and coding of linear systems and signals, as required in, e.g., system identification, system approximation, and adaptive filtering. In this paper, the basis functions are derived from a transfer function perspective as well as in a state space setting. It is shown how this approach leads to alternative series expansions of systems and signals in time and frequency domain. The generalized basis functions induce signal and system transforms (Hambo transforms), which have proved to be useful analysis tools in various modelling problems. These transforms are analyzed in detail in this paper, and a large number of their properties are derived. Principally, it is shown how minimal state space realizations of the system transform can be obtained from minimal state space realizations of the original system and vice versa.

Key words. orthogonal basis functions, Hambo transform, cascade inner network, expansion coefficients

1. Introduction.

Orthonormal bases and the transformations that are related to them are useful tools in many branches of science. Well-known examples are the trigonometric bases which induce the various Fourier transforms or the more recently developed orthonormal wavelet bases and their associated transforms. Within the field of systems and control theory, *rational* orthonormal bases play an important role. By approximating the impulse response of a linear time-invariant (LTI) system by a finite sum of exponentials, the problem of modelling and identification is considerably simplified. This comes down to using rational basis functions in the model structure.

Over the last years a general theory has been developed for the construction and analysis of generalized orthonormal rational basis functions for the class of stable linear systems, which extends the work on Laguerre filters by Wiener in the thirties [19]. The corresponding filters are parameterized in terms of prespecified poles, which makes it possible to incorporate a priori information about time constants in the model structure. The main applications are in system identification and adaptive signal processing, where the parameterization of models in terms of finite expansion coefficients is attractive because it is linear-in-the-parameters. This allows the use of simple linear regression estimation techniques to identify the system from observed data, thus avoiding nonconvex optimization problems. Orthonormality is associated with white

noise input signals. However, the special shift structure of generalized orthonormal basis functions gives a certain Toeplitz structure for general quasi-stationary input signals, which can be utilized to construct efficient algorithms and to derive statistical performance results. The use of orthogonal basis functions has also resulted in intuitive expressions for the variance of estimated transfer functions and noise models. Here the basis functions and related reproducing kernels are used to analyze and simplify complicated variance expressions. See [46, 27, 28] for the most recent contributions. For the field of adaptive filtering, see, for instance, [2, 9, 21].

The application potentials of orthogonal basis functions go beyond the areas of system identification and adaptive signal processing. Many problems in circuit theory, signal processing, telecommunication, systems and control theory, estimation, and optimization theory benefit from an efficient representation or parameterization of particular classes of signals/systems. See, for instance, [31, 5] for applications in audio processing and [24, 23, 36] for the use of orthogonal basis functions in nonlinear modelling and estimation.

By exploiting prior knowledge of the object (signal/system) to be described, a decomposition of signals/systems in terms of flexibly chosen orthogonal (independent) components leads to efficient and robust estimation and prediction algorithms. Orthogonality is the key principle in linear estimation; see [16]. Orthogonal filters, which correspond to orthogonal rational functions, are of capital importance in filter design and robust filter implementation, as discussed in, e.g., [32].

In this paper a comprehensive account is given of the unitary transforms that result when considering series expansion representations of signals and systems in terms of a special class of generalized rational orthonormal basis functions, the so-called Hambo[1] functions. This transform generalizes the Z- and the Laguerre transforms and will be shown to have very intriguing structural properties. Preliminary results on this transform have appeared earlier in the analysis of system identification algorithms [39], in system approximation [13], and in minimal partial realization [37, 8]. In these papers, the transform results were shown to be instrumental in the statistical analysis of system identification and in solving partial realization problems. The present paper is the first to give a comprehensive account of the development and the properties of the considered transform, including analysis and algorithms in state space form.

The technique of transformation, or, equivalently, the choice of an alternative domain of representation, has been used successfully for the solution of a wide range of problems in various scientific areas; cf. Laplace and Fourier transformations in the fields of system and control theory or signal processing. It is expected that the transformation which is proposed in this paper and that has the powerful property that it can be adapted to the dynamics of a specific problem will open new possibilities for the solution of a broad class of problems.

The remainder of the paper is constructed as follows. First, in section 2, the considered basis functions will be specified and reviewed. After considering series expansion expressions in section 3, the related signal and system transforms are presented in section 4. In section 5, the constituting expressions for calculating the transforms are presented. Additional properties are discussed in section 6, while in section 7 some extensions are briefly indicated.

[1]The word Hambo originated as an acronym for Hankel matrix based orthogonality. In the remainder of the paper, these Hambo functions will also be referred to as generalized basis functions.

Notation.

$A^T, \overline{A}, A^*$ Transpose, respectively, complex conjugate and complex conjugate transpose of the matrix A.

$\mathbb{T}$ Unit circle.

$L_2^{p\times m}(\mathbb{T})$ Hilbert space of complex matrix functions of dimension $p\times m$ that are square integrable on the unit circle. The superscript $p\times m$ will be suppressed if $p=m=1$.

$H_2^{p\times m}$ Hardy space of all functions which are analytic in the exterior of the unit disc such that[2]

$$\lim_{r\to 1}\frac{1}{2\pi}\int_0^{2\pi}\mathrm{Trace}(f(re^{i\omega})f(re^{i\omega})^*)d\omega<\infty.$$

$RH_2^{p\times m}$ Subspace of *rational* transfer functions of $H_2^{p\times m}$.

$H_2^\perp$ The orthogonal complement of H_2 in L_2.

$H_{2-}^{p\times m}$ The same as $H_2^{p\times m}$, with the restriction that the functions must be zero at infinity (i.e., $f_0=0$).

$RH_{2-}^{p\times m}$ Subspace of *rational* transfer functions of $H_{2-}^{p\times m}$.

$\ell_2^n(J)$ The space of square summable vector sequences, of vector dimension n, where J denotes the index set of the sequence. The superscript n will be omitted if $n=1$.

$\langle F,G\rangle$ Inner product of F and G in $L_2^{p\times m}(\mathbb{T})$:

$$\frac{1}{2\pi i}\int_0^{2\pi}\mathrm{Trace}\{F^T(e^{i\omega})\overline{G(e^{i\omega})}\}d\omega.$$

$\langle x,y\rangle$ Inner product of x and y in $\ell_2^n(J)$: $\sum_{k\in J}x^T(k)\overline{y(k)}$.

$[\![x,y]\!]$ ℓ_2 Matrix "inner product" $\sum_{k\in J}x(k)y^T(k)$, with $x\in\ell_2^{n\times p}(J)$, $y\in\ell_2^{m\times p}(J)$.

$[\![X,Y]\!]$ L_2 Matrix "inner product" $\frac{1}{2\pi i}\oint X(z)Y^*(1/z)\frac{dz}{z}$, with $X\in L_2^{n\times p}(\mathbb{T})$, $Y\in L_2^{m\times p}(\mathbb{T})$.[3]

$\mathbf{P}_X$ Orthogonal projection onto the subspace X.

$\mathbf{e}_i$ ith canonical Euclidean basis (column) vector.

q shift operator; for $x\in\ell_2$, $n\in\mathbb{Z}$: $(q^nx)(t)=x(t+n)$.

In this paper, ℓ_2 signals will be generally denoted by small characters, whereas capitals will be used for their Z-transforms, i.e., $x(t)$, respectively, $X(z)$. Expansion coefficients of a signal in a nonstandard basis are characterized with the $\breve{}$ symbol, as in $x(t)=\sum_k\breve{x}(k)f_k(t)$. By abuse of notation, systems and operators will generally be denoted with arguments; for instance, $x(t), G(z)$ will denote elements of ℓ_2, respectively, H_2.

Unless otherwise mentioned, the notion of orthonormality will be used with respect to the ℓ_2 or L_2 inner products, as defined above.

2. Basis construction. In this section, we will present the basis functions under consideration, first in transfer function form, followed by an interpretation in a state space setting.

[2]Here H_2 is identified with the subspace of L_2 with vanishing negative Fourier coefficients. More precisely, for $F\in H_2, F(z)=f(0)+f(1)z^{-1}+f(2)z^{-2}+\cdots$, and $\sum_{k=0}^\infty|f(k)|^2<\infty$.

[3]Here $Y^*(1/z)=\sum_k y(k)^*z^{-k}$.

2.1. Transfer function approach. The main idea of constructing rational orthonormal basis functions is to generate a set of orthonormal functions that have exponential decay. A straightforward approach to this problem is to orthonormalize the set of functions

$$F_{i,j}(z) = \frac{1}{(z-a_i)^j}, \quad i \in \mathbb{N}, \quad 1 \le j \le m_i, \tag{2.1}$$

where the poles a_i can be any complex number with $|a_i| < 1$, such that $a_i \neq a_k$, $i \neq k$, and where m_i is the multiplicity of pole a_i. Obviously any rational function in H_{2-} can be described as a weighted sum of these functions if the poles a_i are chosen appropriately.

PROPOSITION 2.1. *Application of the Gram–Schmidt procedure to the sequence of functions, given by* (2.1)*, yields the orthonormal functions*

$$\Phi_k(z) = \frac{\sqrt{1-|\xi_k|^2}}{z-\xi_k} \prod_{j=1}^{k-1} \frac{1-\bar{\xi}_j z}{z-\xi_j}, \quad k \in \mathbb{N}, \tag{2.2}$$

where $\xi_{N_i+l} = a_i$, $1 \le l \le m_i$, *with* $N_i = \sum_{j=1}^{i-1} m_j$.

According to [45], this sequence of orthonormal functions was originally derived in the 1920s by Takenaka [38] and Malmquist [20] and will henceforth be referred to as the Takenaka–Malmquist functions. In the 1950s, the continuous-time version of these functions was derived by Kautz [18] in the context of network synthesis. They emerged again in the work of Ninness and Gustafsson [26] in the context of system identification. See also [4]. Orthonormality of these functions can easily be established using residue calculus. A more fundamental question is whether the orthonormal set is complete in H_{2-}. The following result, already given in [38] and [20], gives necessary and sufficient conditions for completeness.

PROPOSITION 2.2. *Let* $\{\xi_k\}_{k\in\mathbb{N}}$ *be such that* $|\xi_k| < 1$ *for all* $k \in \mathbb{N}$. *The set of Takenaka–Malmquist functions* $\{\Phi_k(z)\}_{k\in\mathbb{N}}$, *as given in* (2.2)*, is complete in* H_{2-} *if and only if*

$$\sum_{k=1}^{\infty} (1-|\xi_k|) = \infty. \tag{2.3}$$

In other words, if the sequence of poles does not converge to the unit circle "too fast," then the set of Takenaka–Malmquist functions constitutes an orthonormal basis for H_{2-}. Until the early 1990s, only special cases of these functions have been used extensively, especially in the context of system identification and signal processing. Of these special cases, the pulse and Laguerre functions are the best known examples. Consider the case where for all $k, \xi_k = a \in \mathbb{R}$, with $|a| < 1$. The corresponding basis functions are the discrete Laguerre functions

$$\Phi_k(z) = \frac{\sqrt{1-a^2}}{z-a} \left[\frac{1-az}{z-a}\right]^{k-1} \tag{2.4}$$

that reduce to the pulse functions $\Phi_k(z) = z^{-k}$ for $a = 0$.

A second special case that is discussed in detail in this paper considers the situation where all poles are taken in a repetitive manner from a finite set $\{\xi_1, \xi_2, \dots, \xi_{n_b}\}$, such that $\xi_{k\cdot n_b+j} = \xi_j$, where $k \in \mathbb{N}$ and $j = 1, \dots, n_b$. When the poles appear in

complex conjugate pairs, this results in the class of so-called generalized orthonormal basis functions, or Hambo functions [13]. For ease of notation, we introduce the inner (stable all-pass) function $G_b(z) = \prod_{i=1}^{n_b}[\frac{1-\bar{\xi}_i z}{z-\xi_i}]$. Now since $\xi_{n_b+1} = \xi_1$, it follows that $\Phi_{n_b+1}(z) = \frac{\sqrt{1-|\xi_1|^2}}{z-\xi_1}G_b(z) = \Phi_1(z)G_b(z)$, and it is easy to see that an equivalent relation holds for the next functions, $\Phi_{n_b+j}(z) = \Phi_j(z)G_b(z), j \in \mathbb{N}$. From these relations it is straightforward to derive the so-called generalized shift property:

$$\Phi_{k\cdot n_b+j}(z) = \Phi_j(z)G_b^{k-1}(z), \quad k \in \mathbb{N}, \quad j = 1, \ldots, n_b.$$

For convenience of notation, these functions are often grouped into vector functions

$$V_k(z) = \begin{bmatrix}\Phi_{(k-1)\cdot n_b+1}(z) & \Phi_{(k-1)\cdot n_b+2}(z) & \cdots & \Phi_{k\cdot n_b}(z)\end{bmatrix}^T, \tag{2.5}$$

in which case the shift property comes down to $V_k(z) = V_1(z)G_b^{k-1}(z)$. This shift property will be of paramount importance in the remainder of this paper.

In the context of system approximation and identification, it is often desired that the system responses are real-valued, and for that reason it will be advantageous to restrict the basis functions to being real-valued as well. Ninness and Gustafsson [26] showed that if the poles appear in complex conjugate pole pairs, all basis functions can be made real-valued by a simple unitary transformation of the set of basis functions.

2.2. State space interpretation. An alternative way to interpret or derive these basis functions employs state space models. Consider a (single input) stable state space model

$$x(t+1) = Ax(t) + Bu(t). \tag{2.6}$$

The function $V(z) = [zI - A]^{-1}B$ is the transfer function from the input $u(t)$ to the states $x(t)$. Now assume that the input signal $u(t)$ is a zero mean white noise process with variance 1, i.e., $\mathbb{E}\{u(t)u(t+k)\} = \delta_k$. The state covariance matrix $P = \mathbb{E}\{x(t)x^T(t)\}$ satisfies the Lyapunov equation $P = APA^T + BB^T$. P also equals the so-called controllability Gramian of the state space model. The reason why we are interested in the state covariance matrix is that

$$P = \frac{1}{2\pi i}\oint_{\mathbb{T}} V(z)V^T(1/z)\frac{dz}{z} = [\![V, V]\!]. \tag{2.7}$$

The basic idea now is to find a new state space realization for which the state covariance equals the identity matrix, $P = I$. The corresponding input to state transfer functions will then be orthonormal and will span the same space as the original functions, as only linear transformations are considered. A state space realization for which $P = I$ is called input balanced [22].

In order to extend this resulting finite set of orthonormal functions, we consider the class of square inner functions, i.e., stable transfer functions $G_b(z)$ that satisfy

$$G_b(z)G_b^T\left(\frac{1}{z}\right) = I.$$

It was shown in [33] that square inner functions can be realized by so-called orthogonal state space realizations; i.e., they satisfy $G_b(z) = D + C(zI - A)^{-1}B$, where

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix}^T \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix}\begin{bmatrix} A & B \\ C & D \end{bmatrix}^T = I. \tag{2.8}$$

From this orthogonality property, it directly follows that the controllability Gramian P and the observability Gramian Q, which are defined as $P = APA^T + BB^T$ and $Q = A^TQA + C^TC$, satisfy $P = Q = I$, and so realizations with this property are balanced in the sense of [22]. Thus it follows that the input-to-state functions (i.e., the elements of $V(z) = [zI - A]^{-1} B$) are mutually orthonormal with respect to the H_{2-} inner product (assuming $G_b(z)$ is scalar).

Example 2.3. We consider first and second order inner functions.

1. Let $G_b(z) = \frac{1-az}{z-a}$, with $|a| < 1$. Then $\{a, \sqrt{1-a^2}, \sqrt{1-a^2}, -a\}$ is a balanced realization for G_b, and the input to state transfer is $\frac{\sqrt{1-a^2}}{z-a}$, the first Laguerre function with pole in a.
2. Let $G_b(z) = \frac{-cz^2+b(c-1)z+1}{z^2+b(c-1)z-c}$ with some real-valued b, c satisfying $|c|, |b| < 1$. A balanced realization (see, e.g., [39]) results in $V(z) = \frac{\sqrt{1-c^2}}{z^2+b(c-1)z-c}[(z-b) \cdot \sqrt{(1-b^2)}]^T$, which represents the first two functions of the so-called 2-parameter Kautz construction.

On the other hand, when given an arbitrary pair (A, B) with controllability Gramian $P = I$, it is easy to show that there exist matrices (C, D) such that the transfer function $G(z) = D + C(zI - A)^{-1}B$ is an inner function [12]. Note that this realization is automatically balanced.

Hence, when the state space approach is used to create orthonormal functions, these functions can be considered as the input-to-state functions of a balanced realization of an inner function.

A second result from [33] as indicated in [3] is that for two inner functions $G_i(z) \in H_2$ $(i = 1, 2)$, with corresponding balanced realizations (A_i, B_i, C_i, D_i), the product $G_2(z)G_1(z)$ has a balanced realization (A, B, C, D) with

$$\left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right] = \left[\begin{array}{cc|c} A_1 & 0 & B_1 \\ B_2C_1 & A_2 & B_2D_1 \\ \hline D_2C_1 & C_2 & D_2D_1 \end{array}\right]. \tag{2.9}$$

For any input signal $u(t)$, the state sequence $x(t)$ related to this realization can be decomposed by $x(t) = [x_1(t) \quad x_2(t)]^T$, where $x_1(t)$ is the state trajectory related to the realization of $G_1(z)$ separately:

$$x_1(t) = [qI - A_1]^{-1}B_1u(t) \qquad \text{and} \qquad x_2(t) = [qI - A_2]^{-1}B_2G_1(q)u(t).$$

Here q denotes the shift operator, as defined in our notation.

In other words, there exists a recursive structure, where concatenating inner functions provide an increasing number of state functions that are orthogonal to each other with respect to the standard ℓ_2 inner product, i.e., $\sum_t x_k^T(t)\overline{x_j(t)} = \delta_{kj}$ or, equivalently, $\frac{1}{2\pi i}\int_0^{2\pi} X_k^T(e^{i\omega})\overline{X_j(e^{i\omega})}d\omega = \delta_{kj}$. This leads to the following construction.

PROPOSITION 2.4. *Given a sequence of inner functions $G_i(z), i = 1, 2, \dots,$ each with balanced realization (A_i, B_i, C_i, D_i), the collection of functions $\{X_i(z), i = 1, 2, \dots\}$ with*

$$X_1(z) = [zI - A_1]^{-1}B_1, \qquad X_i(z) = [zI - A_i]^{-1}B_iG_1(z)G_2(z)\cdots G_{i-1}(z),$$

is mutually orthonormal.

With this property and the balanced realizations of Example 2.3, it is straightforward to rederive the Takenaka–Malmquist functions (2.2) as well as the Laguerre

functions and the Hambo functions (see (2.5)). Both approaches lead to the same class of functions. Hence the completeness condition (2.3) is valid for both approaches. The special case of Proposition 2.4, where all $G_i(z)$ are equal to the same second order inner function with a complex conjugate pole pair (see Example 2.3 2) is known in the literature as the 2-parameter Kautz construction [42, 14, 26].

3. Related bases and series expansions. Since the Takenaka–Malmquist functions constitute a basis for H_{2-}, a basis for the related space $\ell_2(\mathbb{N})$ follows by considering the inverse Z-transform, which is isomorphic. With $\{\phi_k(t)\}$ the impulse response (Fourier coefficients) of $\Phi_k(z)$, according to $\Phi_k(z) := \sum_{t=1}^{\infty} \phi_k(t) z^{-t}$, the functions $\{\phi_k(t)\}$ will constitute an orthonormal basis for $\ell_2(\mathbb{N})$. Note that these basis functions exhibit the property that they can incorporate system dynamics in a very general way. One can construct inner functions from any given set of poles, and thus the resulting basis can incorporate dynamics of any complexity, combining, e.g., both fast and slow dynamics in damped and resonant modes. Considering the Takenaka–Malmquist basis functions, for any system $H(z) \in H_{2-}$ or signal $y(t) \in \ell_2(\mathbb{N})$, there exist unique series expansions:

$$H(z) = \sum_{k=1}^{\infty} \langle H, \Phi_k \rangle \Phi_k(z), \tag{3.1a}$$

$$y(t) = \sum_{k=1}^{\infty} \langle y, \phi_k \rangle \phi_k(t). \tag{3.1b}$$

In the remainder of this paper, attention will be focused on the Hambo functions, as introduced in section 2.1, i.e., the subclass of Takenaka–Malmquist functions where the basis poles are taken in a repetitive manner from a finite set $\{\xi_1, \ldots, \xi_{n_b}\}$. When these poles $\{\xi_i\}_{i=1}^{n_b}$ are stable, i.e., $|\xi_i| < 1$, it follows from Proposition 2.2 that the set of Hambo functions constitutes a basis for H_{2-}. In what follows, we will also assume that the basis poles appear in complex conjugate pairs only. Furthermore, we will primarily consider the real-rational form of these functions that results from the application of Proposition 2.4, using a real-valued state space realization of the inner function

$$G_b(z) = \prod_{i=1}^{n_b} \frac{1 - \bar{\xi}_i z}{z - \xi_i}. \tag{3.2}$$

Definition 3.1. *Let $G_b(z)$ be a real-rational inner function, with real-valued minimal balanced realization (A_b, B_b, C_b, D_b). Let for $k \in \mathbb{N}$ the vector functions $V_k(z)$ be defined as $V_k(z) = [zI - A_b]^{-1} B_b G_b^{k-1}(z)$. Then the collection of all scalar elements of the vectors $V_k(z)$, $\Phi_{k,i}(z) = e_i^T V_k(z)$, $k \in \mathbb{N}$, $1 \le i \le n_b$, is referred to as a Hambo basis of H_{2-}. The corresponding vectors with basis functions for $\ell_2(\mathbb{N})$ will be denoted by $\{v_k(t)\}$.*

It is straightforward to recognize the shift structure in the functions $v_k(t)$:

$$v_{k+1}(t) = G_b(q) \cdot v_k(t), \quad k = 1, 2, \ldots, \tag{3.3a}$$

$$v_1(t) = A_b^{t-1} B_b. \tag{3.3b}$$

For the class of Hambo functions, based on an inner function $G_b(z)$, the series expansions (3.1) can be rewritten such that the vector structure is maintained:

$$H(z) = \sum_{k=1}^{\infty} \breve{h}^T(k) V_k(z), \quad \breve{h}(k) = [\![V_k, H]\!], \tag{3.4a}$$

$$y(t) = \sum_{k=1}^{\infty} \breve{y}^T(k) v_k(t), \quad \breve{y}(k) = [\![v_k, y]\!]. \tag{3.4b}$$

The vector coefficient sequence $\breve{y} = \{\breve{y}(k)\}_{k\in\mathbb{N}}$ in (3.4) is called the Hambo signal transform of y. This transform will play a fundamental role in this paper. A formal definition will be given in section 4. The next proposition shows that the Parseval identity holds for this transform.

PROPOSITION 3.2 (Parseval's identity). *For any pair $x(t), y(t) \in \ell_2(\mathbb{N})$ and corresponding expansion coefficient sequences $\breve{x}, \breve{y}$, taken with respect to the basis vectors $\{v_k(t)\}_{k\in\mathbb{N}}$ as in* (3.4)*, it holds that $\langle x, y\rangle = \langle \breve{x}, \breve{y}\rangle$.*

Proof. $\langle x, y\rangle = [\![\sum_k \breve{x}^T(k) v_k, \sum_{k'} \breve{y}^T(k') v_{k'}]\!] = \sum_k \sum_{k'} \breve{x}^T(k) [\![v_k, v_{k'}]\!] \breve{y}(k') = \sum_k \breve{x}^T(k)\breve{y}(k)$. ∎

A dual orthonormal basis of $\ell_2^{n_b}(\mathbb{N})$. One consequence of Proposition 3.2 is that an orthonormal basis of $\ell_2^{n_b}(\mathbb{N})$ can be obtained by taking the signal transform of the standard orthonormal basis functions of $\ell_2(\mathbb{N})$: $\delta(t-k)$, $k > 0$. The resulting basis functions w_l are given by

$$w_l(k) = [\![v_k(t), \delta(t-l)]\!] = \sum_{t=1}^{\infty} v_k(t)\delta(t-l) = v_k(l). \tag{3.5}$$

Therefore, we can state the following.

PROPOSITION 3.3 (dual orthonormal basis). *Consider the basis function vectors $v_k(t)$ with $k \in \mathbb{N}$, as defined in Definition* 3.1*. The vector functions $w_t(k) \in \ell_2^{n_b}$, $t \in \mathbb{N}$, defined by $w_t(k) = v_k(t)$, constitute an orthonormal basis of the space $\ell_2^{n_b}(\mathbb{N})$.*

It turns out that—as is the case with $v_k(t)$ (see (3.3))— these functions $w_k(t)$ can be calculated using a shift structure.

PROPOSITION 3.4. *Let $G_b(z)$ be a scalar inner function with McMillan degree $n_b > 0$, having a minimal balanced realization (A_b, B_b, C_b, D_b). Consider $v_k(t), w_k(t)$ as before, and let $N(z) = A_b + B_b[zI - D_b]^{-1}C_b$. Then*

$$w_{k+1}(t) = N(q) \cdot w_k(t), \quad k = 1, 2, \ldots, \tag{3.6a}$$

$$w_1(t) = B_b D_b^{t-1}, \tag{3.6b}$$

where the shift operator q operates on the time sequence w_k, i.e., $(qw_k)(t) = w_k(t+1)$.

Proof. The proof uses the balanced state space realization $(A_{k+1}, B_{k+1}, C_{k+1}, D_{k+1})$ of $G_b^{k+1}(z)$ (see (2.9)), where

$$A_{k+1} = \begin{bmatrix} A_b & 0 & \cdots & \cdot & 0 \\ B_bC_b & A_b & 0 & \cdot & 0 \\ B_bD_bC_b & B_bC_b & \cdot & \cdot & 0 \\ \vdots & \vdots & \cdot & \ddots & 0 \\ B_bD_b^{k-1}C_b & B_bD_b^{k-2}C_b & \cdots & B_bC_b & A_b \end{bmatrix},$$

$$B_{k+1} = \begin{bmatrix} B_b \\ B_bD_b \\ B_bD_b^2 \\ \vdots \\ B_bD_b^k \end{bmatrix}. \tag{3.7}$$

It is straightforward that $\left[v_1^T(t) \ \cdots \ v_{k+1}^T(t)\right]^T = A_{k+1}^{t-1} B_{k+1}$, and hence $w_1(t) = B_b D_b^{t-1}$. For $t \geq 1$

$$\begin{aligned} w_{k+1}(t+1) = v_{t+1}(k+1) &= A_b v_{t+1}(k) + B_b C_b v_t(k) + \cdots + B_b D_b^{k-1} C_b v_1(k) \\ &= A_b w_k(t+1) + \sum_{i=1}^{t} B_b D_b^{i-1} C_b w_k(t+1-i), \end{aligned}$$

which proves the result. □

We will denote the Z-transform of the functions $w_k(t)$ by $W_k(z) := \sum_{t=1}^{\infty} w_k(t) z^{-t}$, while as a direct result of Proposition 3.4 it holds that $W_k(z) = N^{k-1}(z) \cdot W_1(z)$, with $W_1(z) := (zI - D_b)^{-1} B_b$. Note the duality between the functions $G_b(z)$ and $N(z)$, which are simply related by ordering the state space realizations in reverse.

As a consequence, for any strictly proper system $\breve{H}(z) \in H_{2-}^{n_b}$ or signal $\breve{y}(t) \in \ell_2^{n_b}[1, \infty)$, there exist unique series expansions:

$$\breve{H}(z) = \sum_{k=1}^{\infty} h(k) W_k(z), \quad h(k) = \langle \breve{H}, W_k \rangle, \tag{3.8}$$

$$\breve{y}(t) = \sum_{k=1}^{\infty} y(k) w_k(t), \quad y(k) = \langle \breve{y}, w_k \rangle. \tag{3.9}$$

In fact, these are exactly the inverses of the expansions given by (3.4).

Extension to L_2. The bases for H_{2-} that we introduced can be extended to $L_2(\mathbb{T})$, i.e., to include $(H_{2-})^{\perp}$ (see, e.g., [1]). First observe that given a basis $\{F_k(z)\}$ for H_{2-}, $\{z^{-1} F_k(\frac{1}{z})\}$ is a basis for $(H_{2-})^{\perp}$. In fact, given two bases for H_{2-}, say, $\{F_k(z)\}$ and $\{G_k(z)\}$, the set of functions $\{F_k(z), z^{-1} G_k(\frac{1}{z}), k = 1, 2, \dots\}$ is a basis for $H_{2-} \cup (H_{2-})^{\perp} = L_2(\mathbb{T})$. Using an inner function $G_b(z)$ with balanced realization (A_b, B_b, C_b, D_B), the Hambo functions have been defined as $\{V_1(z) G_b(z)^{k-1}, k \in \mathbb{N}\}$, where $V_1(z) = [zI - A_b]^{-1} B$. Another Hambo basis is created by $\{U_1(z) G_b(z)^{k-1}, k \in \mathbb{N}\}$, where $U_1(z) = [zI - A_b^T]^{-1} C_b^T$. In line with the forgoing, it follows that $\{z^{-1} U_1(\frac{1}{z}) G_b^{k-1}(\frac{1}{z}), k \in \mathbb{N}\}$ is a basis for $H_{2-}^{\perp}$. Now an interesting observation is given by the following lemma.

LEMMA 3.5. *Let $G_b(z), V_1(z), U_1(z)$ be defined as above. Then $U_1(z)$ and $V_1(z)$ are related by $z^{-1} U_1(\frac{1}{z}) = V_1(z) G_b(\frac{1}{z})$.*

Proof. Using (2.9), it is easy to show that $C_b^T G_b(z) = \left(I - z A_b^T\right) [zI - A_b]^{-1} B_b$. Substituting this relation in the expression $U_1(\frac{1}{z}) G_b(z)$ yields $U_1(\frac{1}{z}) G_b(z) = z[I - zA_b^T]^{-1} \left(I - zA_b^T\right) [zI - A_b]^{-1} B_b = z[zI - A_b]^{-1} B_b = z V_1(z)$. □

COROLLARY 3.6. *Let $G_b(z)$ and $V_1(z)$ be defined as above. The set $\{V_1(z) G_b^k(z), k \in J\}$ defines a basis, respectively, for H_{2-} if $J = \mathbb{N}$, for $H_{2-}^{\perp}$ if $J = \mathbb{Z} \setminus \mathbb{N}$, and for $L_2(\mathbb{T})$ if $J = \mathbb{Z}$.*

Analogously the dual Hambo basis of $H_{2-}^{n_b}$ can be complemented with a set of basis functions of $H_{2-}^{n_b \perp}$ such that a basis of $L_2^{n_b}(\mathbb{T})$ is obtained. A dual basis of $H_{2-}^{n_b \perp}$ is given by the functions $W_{-t}(z) = \left(N^T(\frac{1}{z})\right)^t W_0(z)$, $t > 0$, with $W_0(z)$ given by $C_b^T z^{-1} \ (z^{-1} \ I - D_b^T)^{-1}$. The vector $W_0(z)$ can be related to $W_1(z)$ (the first basis element of the dual basis of $H_{2-}^{n_b}$) as follows.

LEMMA 3.7. *With $N(z)$ a square inner function with orthogonal realization (D_b, C_b, B_b, A_b) and $W_1(z) = B_b(zI - D_b)^{-1}$, it holds that $W_0(z) = C_b^T z^{-1} \ (z^{-1} \ I - D_b^T)^{-1} = N^T(\frac{1}{z}) W_1(z)$.*

Proof. The proof is similar to that of Lemma 3.5. It is straightforward to show that $N(z)W_0(z) = W_1(z)$, using the fact that $N(z)$ is inner. ∎

As a consequence, the inner function $N(z)$ generates a basis of $L_2^{n_b}(\mathbb{T})$ in the same way that G_b generates a basis of $L_2(\mathbb{T})$. We use that $N^T(\frac{1}{z})$ is the inverse of $N(z)$.

PROPOSITION 3.8. *The set of vector functions* $\{W_k(z), k \in J\}$*, with* $W_k \in L_2^{n_b}(\mathbb{T})$*, defined as* $W_k(z) = N(z)^{k-1}B_b(zI - D_b)^{-1}$*, constitutes an orthonormal basis of* $H_{2-}^{n_b}$ *if* $J = \mathbb{N}$*, of* $H_{2-}^{n_b\perp}$ *if* $J = \mathbb{Z} \setminus \mathbb{N}$*, and of* $L_2^{n_b}(\mathbb{T})$ *if* $J = \mathbb{Z}$*.*

4. Signal and operator transforms. In this section, the fundamentals of the transform theory that underlies expansions in the generalized basis are given. It is an extension of the work that was started in [13, 39] and can be viewed as a generalization of the Laguerre transform theory for signals and systems that was developed in [30] and [29].

4.1. Signals. In the previous section, it was shown how ℓ_2 signals can be expanded in terms of general rational orthonormal basis functions that are generated by an inner function $G_b(z)$ in balanced state space form.

It will turn out to be expedient to have a definition of the Hambo signal transform that also applies to multivariable signals. Also, we will need a definition that not only applies to the Hambo basis of $\ell_2(\mathbb{N})$ but also to the Hambo bases of $\ell_2(\mathbb{Z} \setminus \mathbb{N})$ and $\ell_2(\mathbb{Z})$, as discussed in section 3. Therefore, the definitions in this section will be given for $\ell_2(J)$ signals, where J is either $\mathbb{N}, \mathbb{Z}$ or $\mathbb{Z} \setminus \mathbb{N}$.

Consider a vector signal $x(t) \in \ell_2^n(J)$ such that $x(t) = \begin{bmatrix} x_1(t) & x_2(t) & \cdots & x_n(t) \end{bmatrix}^T$. Each scalar signal $x_i(t)$ can be expanded in the corresponding Hambo basis, yielding the expansion sequences $\breve{x}_i(k)$ which are elements of $\ell_2^{n_b}(J)$. Hence it holds that

$$x(t) = \sum_{k=1}^{\infty} \begin{bmatrix} \breve{x}_1(k) & \breve{x}_2(k) & \cdots & \breve{x}_n(k) \end{bmatrix}^T v_k(t) = \sum_{k\in J} \breve{x}^T(k) v_k(t). \tag{4.1}$$

DEFINITION 4.1 (multivariable Hambo signal transform). *Given a signal* $x(t) \in \ell_2^n(J)$*, its Hambo signal transform is defined as the matrix sequence* $\{\breve{x}(k)\}_{k\in J}$*, with* $\breve{x}(k) \in \mathbb{R}^{n_b \times n}$ *given by*

$$\breve{x}(k) = [\![v_k, x]\!]. \tag{4.2}$$

Furthermore, we define the λ*-domain representation of the Hambo signal transform as*

$$\breve{X}(\lambda) = \sum_{k\in J} \breve{x}(k)\lambda^{-k}.$$

Note that $\breve{X}(\lambda)$ is simply the Z-transform of $\breve{x}(k)$ with Z replaced by λ to avoid confusion. As $\breve{X}(\lambda)$ is just a representation of the Hambo signal transform $\breve{x}(k)$ in an alternative domain, it is also commonly called the Hambo signal transform [13].

For purposes of calculation, we will also need a definition for the Hambo transform of a signal $y(t) \in \ell_2^{1\times n_b}$. This is defined through Definition 4.1 by using $x(t) = y^T(t)$ and defining

$$\breve{Y}(\lambda) := \breve{X}^T(\lambda).$$

With the multivariable signal transform as defined above, the following isomorphic relation holds.

PROPOSITION 4.2 (multivariable Hambo signal transform isomorphism). *With* $X(z) \in L_2^{n_x}(\mathbb{T})$ *and* $Y(z) \in L_2^{n_y}(\mathbb{T})$, *it holds that* $[\![X, Y]\!] = [\![\breve{X}^T, \breve{Y}^T]\!]$.

Proof. The (i, j) element of $[\![X, Y]\!]$ is equal to $\langle X_i, Y_j \rangle$. By the isomorphism of the Hambo signal transform for scalar signals, it holds that this is equal to $\langle \breve{X}_i, \breve{Y}_j \rangle$. Then, with $\breve{X}(\lambda)$ and $\breve{Y}(\lambda)$ as defined before, it follows that $[\![X, Y]\!] = \frac{1}{2\pi} \int_0^{2\pi} \breve{X}^T(e^{i\omega}) \overline{\breve{Y}(e^{i\omega})} d\omega$ $= [\![\breve{X}(\lambda)^T, \breve{Y}^T(\lambda)]\!]$. ∎

4.2. Systems. A system $G(z) \in L_2^n(\mathbb{T})$ is uniquely described by its impulse response $\{g(k)\} \in \ell_2^n$. We will use this property to define the *Hambo signal transform of a system* as the Hambo signal transform of the impulse response of the system.

DEFINITION 4.3. *Consider a system* $G(z) \in L_2^n(\mathbb{T})$ *and a Hambo basis* $\{V_k(z)\}_{k \in \mathbb{Z}}$. *The Hambo signal transform of* $G(z)$, *denoted as* $\breve{G}(\lambda)$, *is defined as*

$$\breve{G}(\lambda) = \sum_{k=-\infty}^{\infty} \breve{g}(k) \lambda^{-k}, \quad \textit{where} \quad \breve{g}(k) = [\![V_k, G]\!].$$

Example 4.4. Consider the Hambo signal transform of the basis function vector $G(z) = V_j(z)$. Obviously, in this simple case, the expansion vector coefficients are given by $\breve{g}(k) = \delta(k - j)I$. Hence it holds that the Hambo signal transform of $V_j(z)$ is equal to $\lambda^{-j} I$.

Another transform of the system $G(z)$ that is closely related to the signal transform but essentially different is the so-called *Hambo operator transform*, which describes the relationship between the signal transforms of the input and output signals of a *scalar* stable and causal system.

DEFINITION 4.5 (Hambo operator transform). *Consider a system* $G(z) \in H_2$ *and a Hambo basis* $\{V_k(z)\}_{k \in \mathbb{N}}$, *associated with the inner function* $G_b(z)$. *We define the* Hambo operator transform *of* $G(z)$, *denoted by* $\widetilde{G}(\lambda)$, *as*

$$\widetilde{G}(\lambda) = \sum_{\tau=0}^{\infty} M_\tau \lambda^{-\tau}, \tag{4.3}$$

$$\textit{where} \quad M_\tau = [\![V_1(z) G_b^\tau(z), V_1(z) G(z)]\!]. \tag{4.4}$$

PROPOSITION 4.6. *Consider signals* $u(t), y(t) \in \ell_2(\mathbb{N})$ *and a system* $G(z) \in H_2$ *such that* $y(t) = G(q)u(t)$. *With* $\widetilde{G}(\lambda)$ *the Hambo operator transform of* $G(z)$, *it holds that* $\breve{Y}(\lambda) = \widetilde{G}(\lambda) \breve{U}(\lambda)$.

Proof. Let $\breve{u}(k), \breve{y}(k)$ be the expansion coefficients of $u(t)$ and $y(t)$. $\breve{y}(k)$ can be expressed as $\breve{y}(k) = [\![V_k, G \sum_{j=1}^{\infty} \breve{u}^T(j) V_j]\!] = \sum_{j=1}^{\infty} [\![V_k, V_j G]\!] \breve{u}(j) = \sum_{j=1}^{\infty} [\![V_1 G_b^{k-1}, V_1 G_b^{j-1} G]\!] \breve{u}(j)$. Consider the inner product term for the case where $j \leq k$. Use is made of the fact that the adjoint of $G_b(z)$ by its inner property is equal to $G_b^{-1}(z)$. Hence $[\![V_1 G_b^{k-1}, V_1 G_b^{j-1} G]\!] = [\![V_1 G_b^{k-j}, V_1 G]\!]$. Now consider the inner product term for the case where $j > k$. Then, with the same argument, one finds that it holds that $[\![V_1 G_b^{k-1}, V_1 G_b^{j-1} G]\!] = [\![V_1, V_1 G_b^{j-k} G]\!]$. This latter expression is equal to zero, which follows from the fact that the elements of the transfer function $V_1(z)$ constitute an orthonormal set which exactly spans the orthogonal complement in H_2 of the shift-invariant subspace $G_b(z) H_2$. The right-hand side argument of the inner product is an element of that subspace. Applying the signal transform of Definition 4.1 to $\breve{y}(k)$

(with $J = \mathbb{N}$) reveals that it holds that

$$\breve{Y}(\lambda) = \left(\sum_{\tau=0}^{\infty} M_\tau \lambda^{-\tau} \right) \breve{U}(\lambda). \qquad \square \tag{4.5}$$

The parameters M_τ are matrices of dimension $n_b \times n_b$. They can be viewed as the Markov parameters of the multivariable transfer function $\widetilde{G}(\lambda)$. The expansion coefficients $\{\breve{y}(k)\}$ and the Markov parameters $\{M_\tau\}$, as given by Definitions 4.3 and 4.5, are closely connected through a linear relation; see [37, 8, 7] for details.

The Hambo operator transform of the system $G_b(z)$ has a particularly simple form. It holds for all $U \in H_{2-}$ that

$$G_b(z)U(z) = \sum_{k=1}^{\infty} \breve{u}^T(k) V_k(z) G_b(z) = \sum_{k=1}^{\infty} \breve{u}^T(k) V_{k+1}(z).$$

Hence, with $Y(z) = G_b(z)U(z) = \sum_{k=1}^{\infty} \breve{y}^T(k) V_k(z)$, it follows that $\breve{y}(k) = \breve{u}(k-1)$ for $k > 1$ and $\breve{y}(1) = 0$. Therefore, it holds that $M_1 = I$ and $M_\tau = 0$ for all $\tau \neq 1$, and consequently

$$\widetilde{G_b}(\lambda) = \lambda^{-1} I. \tag{4.6}$$

We can hence conclude that a multiplication with $G_b(z)$ in the Z-domain corresponds to applying a canonical shift in the λ-domain.

Although the Hambo operator transform is defined only for SISO systems, there is a simple multivariable case in which it can also be used. We will need it in the next section.

PROPOSITION 4.7. *Consider a signal $u(t) \in \ell_2^m(J)$ and an SISO system $G(z) \in H_2$. Let $y(t) \in \ell_2^m(J)$ be given by $y(t) = G(q) \cdot I\ u(t)$. Then it holds that $\breve{Y}(\lambda) = \widetilde{G}(\lambda)\breve{U}(\lambda)$.*

Proof. Denoting the elements of $U(z)$ and $Y(z)$ as $U_i(z)$ and $Y_i(z)$ according to $U(z) = \begin{bmatrix} U_1(z) & U_2(z) & \cdots & U_m(z) \end{bmatrix}^T$ and $Y(z) = \begin{bmatrix} Y_1(z) & Y_2(z) & \cdots & Y_m(z) \end{bmatrix}^T$, we have that $Y_i(z) = G(z)U_i(z)$ for $1 \leq i \leq m$. Then the Hambo signal transform of $Y_i(z)$ satisfies, by definition of the Hambo operator transform, $\breve{Y}_i(\lambda) = \widetilde{G}(\lambda)\breve{U}_i(\lambda)$. The result then follows from the fact that

$$\breve{Y}(\lambda) = \begin{bmatrix} \breve{Y}_1(\lambda) & \breve{Y}_2(\lambda) & \cdots & \breve{Y}_m(\lambda) \end{bmatrix} = \widetilde{G}(\lambda)\breve{U}(\lambda). \qquad \square$$

5. Operator transform expressions. As shown, the Hambo operator transform of a system $G(z) \in H_2$ is a causal LTI system. Furthermore, the transform of a rational transfer function is again rational. We will now derive expressions by which the operator transform can actually be computed. First it is shown that an expression for $\widetilde{G}(\lambda)$ is obtained by making a variable substitution in the Laurent expansion of $G(z)$. Next it is shown how a state space realization of $\widetilde{G}(\lambda)$ can be derived on the basis of a state space realization of $G(z)$.

5.1. Variable substitution property. The Hambo operator transform, as defined in Definition 4.5, can be obtained from the original transfer function $G(z) \in H_2$ by applying a variable substitution in its Laurent expansion, which is given by

$$G(z) = \sum_{\tau=0}^{\infty} g(\tau) z^{-\tau}. \tag{5.1}$$

This variable substitution consists of a replacement of the shift operation z^{-1} by the causal linear time-invariant operator $N(\lambda)$.

PROPOSITION 5.1 (variable substitution property [39]). *Let $N(\lambda)$ be as in Proposition* 3.4. *Then the Hambo operator transform $\widetilde{G}(\lambda)$ of a given system $G(z) \in H_2$ is equal to*

$$\widetilde{G}(\lambda) = \sum_{\tau=0}^{\infty} g(\tau) N^{\tau}(\lambda). \tag{5.2}$$

With slight abuse of notation, (5.2) is sometimes stated as $\widetilde{G}(\lambda) = G(z)|_{z^{-1}=N(\lambda)}$. An immediate consequence of Proposition 5.1 is that the operator transform of the canonical shift z^{-1} is equal to $N(\lambda)$. This means that a shift in the time domain corresponds to the application of the operator $N(\lambda)$ in the signal transform domain. Another immediate consequence of this proposition is that $N(\lambda)$ and $\widetilde{G}(\lambda)$ are commuting operators. A third consequence of Proposition 5.1 is the following relation between the Hambo signal transform and the Hambo operator transform.

COROLLARY 5.2. *The Hambo signal transform $\breve{G}(\lambda)$ and Hambo operator transform $\widetilde{G}(\lambda)$ of a given system $G(z) \in H_{2-}$ are related through $\breve{G}(\lambda) = \widetilde{G}(\lambda) W_0(\lambda)$, with $W_0(\lambda) \in H_2^{n_b \perp}$ equal to $C_b^T \frac{1}{\lambda} (\frac{1}{\lambda} I - D_b^T)^{-1}$, in accordance with Proposition* 3.8.

Proof. As the functions $\{W_t(\lambda)\}_{t\in\mathbb{N}}$ constitute the dual Hambo basis, $\breve{G}(\lambda)$ satisfies $\breve{G}(\lambda) = \sum_{t=1}^{\infty} g(t) W_t(\lambda)$, with $g(t)$ the impulse response coefficients of $G(z)$. By Proposition 3.4 and the fact that $N(\lambda)$ is inner, we can write $\breve{G}(\lambda) = \sum_{t=1}^{\infty} g(t) N(\lambda)^t \cdot N^T(\frac{1}{\lambda}) W_1(\lambda)$. By Lemma 3.7 and Proposition 5.1, it then follows that $\breve{G}(\lambda) = \sum_{t=1}^{\infty} g(t) N(\lambda)^t W_0(\lambda) = \widetilde{G}(\lambda) W_0(\lambda)$. ∎

It was shown in [13] that, inversely, $G(z)$ can also be obtained from $\widetilde{G}(\lambda)$ by means of a variable substitution:

$$G(z) = z V_1^T(z)\, \widetilde{G}(\lambda) W_1(\lambda) \lambda \Big|_{\lambda^{-1}=G_b(z)}. \tag{5.3}$$

Using the multivariable signal transform Definition 4.1 one can establish an isomorphic relation that involves the Hambo operator transform.

PROPOSITION 5.3 (Hambo operator transform isomorphism). *Consider the Hambo basis of $L_2(\mathbb{T})$, generated by an inner function $G_b(z)$. Hence we have that $V_k(z) = V_1(z) G_b(z)^{k-1}$ and $W_k(\lambda) = N(\lambda)^{k-1} W_1(\lambda)$. Then for all $G_1(z), G_2(z) \in H_2$, $k \in \mathbb{Z}$,*

$$[\![V_k G_1, V_k G_2]\!] = [\![\widetilde{G}_1^T, \widetilde{G}_2^T]\!], \tag{5.4}$$

$$\textit{and} \qquad \langle G_1, G_2 \rangle = \langle \widetilde{G}_1 W_k, \widetilde{G}_2 W_k \rangle. \tag{5.5}$$

Proof. We will prove both assertions for the case $k = 1$. The other cases follow immediately from the inner property of $G_b(z)$, and $N(\lambda)$. By Proposition 4.2, it holds that $[\![V_1 G_1, V_1 G_2]\!] = [\![(V_1 \breve{G}_1)^T, (V_1 \breve{G}_2)^T]\!]$. The elements of the vector $V_1(z) G_k(z)$, $k = 1, 2$, are equal to $G_k(z) \Phi_{1,i}(z)$, $1 \le i \le n_b$, where $\Phi_{1,i}(z)$ are the first n_b scalar basis functions. The Hambo signal transform of $G_k(z)\Phi_{1,i}(z)$ is, by definition of the operator transform, equal to $\widetilde{G}_k(\lambda) \breve{\Phi}_{1,i}(\lambda) = \widetilde{G}_k(\lambda) e_i^T \lambda^{-1}$. By Definition 4.1, it then follows that $(V_1 \breve{G}_k) = \widetilde{G}_k(\lambda) \lambda^{-1}$. Hence $[\![V_1 G_1, V_1 G_2]\!] = [\![\widetilde{G}_1^T(\lambda) \lambda^{-1}, \widetilde{G}_2^T(\lambda) \lambda^{-1}]\!] = [\![\widetilde{G}_1^T, \widetilde{G}_2^T]\!]$. The second assertion is proved as follows. It holds that $\langle G_1, G_2 \rangle = \langle G_1 z^{-1}, G_2 z^{-1} \rangle = \langle (G_1 \breve{z}^{-1}), (G_2 \breve{z}^{-1}) \rangle$. The last equality follows from the isomorphism of the signal transform. Using the fact that $W_1(\lambda)$ is the Hambo signal transform of z^{-1} and by definition of the Hambo operator transform, the result follows. ∎

5.2. Hankel operator representations. The Hankel operator associated with an LTI system $G(z)$ can be represented in a number of ways, depending on the (orthonormal) coordinate systems that are used for the input and output signal spaces. The Hankel operator of a scalar system maps from $\ell_2(-\infty, 0]$ to $\ell_2[1, \infty)$. Usually, the canonical bases of these spaces are employed to represent the input and output signals. In that case, the Hankel operator can be represented as a Hankel matrix $\mathbf{H}$ that contains the Markov parameters $g(k), k > 0$, of $G(z)$, as $\mathbf{H}_{i,j} = g(i+j-1)$. Now define $\mathbf{y} = \begin{bmatrix} y(1) & y(2) & \cdots \end{bmatrix}^T$, $\mathbf{u} = \begin{bmatrix} u(0) & u(-1) & \cdots \end{bmatrix}^T$. Then it holds that

$$\mathbf{y} = \mathbf{H}\mathbf{u}. \tag{5.6}$$

Alternative representations of the Hankel operator would be obtained if one were to use other orthonormal bases for the representation of the input and output signals. A particularly interesting case occurs when we use a Hambo basis for the output space $\ell_2[1, \infty)$ and the complementary Hambo basis for $\ell_2(-\infty, 0]$ for the input space. Consider the expansion of the output signal $y(t) \in \ell_2[1, \infty)$ and the input signal $u(t) \in \ell_2(-\infty, 0]$ in terms of a Hambo basis. We then obtain the coefficients $\breve{y}(k) = [\![y, v_k]\!]^T$ with $k \in \mathbb{N}$ and $\breve{u}(k) = [\![u, v_k]\!]^T$ with $k \in \mathbb{Z} \setminus \mathbb{N}$. We collect these coefficients in column vectors $\breve{\mathbf{y}}, \breve{\mathbf{u}}$ defined as

$$\breve{\mathbf{y}}^T = \begin{bmatrix} \breve{y}^T(1) & \breve{y}^T(2) & \breve{y}^T(3) & \cdots \end{bmatrix}, \tag{5.7}$$

$$\breve{\mathbf{u}}^T = \begin{bmatrix} \breve{u}^T(0) & \breve{u}^T(-1) & \breve{u}^T(-2) & \cdots \end{bmatrix}. \tag{5.8}$$

Defining the block row vectors $\mathbf{v}_k$ with $k \in \mathbb{Z}$ as

$$\mathbf{v}_k = \begin{cases} \begin{bmatrix} v_k(1) & v_k(2) & v_k(3) & \cdots \end{bmatrix}, & k \geq 1, \\ \begin{bmatrix} v_k(0) & v_k(-1) & v_k(-2) & \cdots \end{bmatrix}, & k < 1, \end{cases}$$

and defining $V_f = \begin{bmatrix} \mathbf{v}_1^T & \mathbf{v}_2^T & \cdots \end{bmatrix}^T$ and $V_p = \begin{bmatrix} \mathbf{v}_0^T & \mathbf{v}_{-1}^T & \cdots \end{bmatrix}^T$, we can write

$$\breve{\mathbf{y}} = \mathbf{V}_f \mathbf{y} \quad \text{and} \quad \breve{\mathbf{u}} = \mathbf{V}_p \mathbf{u}. \tag{5.9}$$

It is clear that the infinite dimensional matrices $\mathbf{V}_f$ and $\mathbf{V}_p$ are unitary (orthogonal) matrices as their rows are orthogonal vectors. It hence follows that we can also write $\mathbf{y} = \mathbf{V}_f^T \breve{\mathbf{y}}$ and $\mathbf{u} = \mathbf{V}_p^T \breve{\mathbf{u}}$. Substituting this in (5.6) gives the relation $\mathbf{V}_f^T \breve{\mathbf{y}} = \mathbf{H}\mathbf{V}_p^T \breve{\mathbf{u}}$. Again using the fact that $\mathbf{V}_f$ is orthogonal, this can be rephrased as $\breve{\mathbf{y}} = \widetilde{\mathbf{H}} \breve{\mathbf{u}}$, with $\widetilde{\mathbf{H}} = \mathbf{V}_f \mathbf{H}\, \mathbf{V}_p^T$. The matrix operator $\widetilde{\mathbf{H}}$ is an alternative representation of the Hankel operator of $G(z)$. If we partition the matrix $\widetilde{\mathbf{H}}$ in blocks of dimension $n_b \times n_b$ corresponding to the partitioning of $\breve{\mathbf{u}}$ and $\breve{\mathbf{y}}$, then we find that the (i, j) block element equals $\widetilde{\mathbf{H}}_{(i,j)} = \mathbf{v}_i \mathbf{H}\, \mathbf{v}_{-j+1}^T$, with $\mathbf{v}_k$ the vector representations of the basis functions v_k as defined above. It is then clear that $\widetilde{\mathbf{H}}_{(i,j)}$ is equal to the matrix inner product between $V_i(z)$ and the Z-transform expression for the vector $\mathbf{H}\mathbf{v}_{-j+1}^T$. This leads to the following proposition.

PROPOSITION 5.4. *Let $\widetilde{\mathbf{H}}$ be the matrix representation of the Hankel operator of a system $G(z) \in H_2$, in terms of a Hambo basis associated with an inner function $G_b(z)$, such that $\breve{\mathbf{y}} = \widetilde{\mathbf{H}} \breve{\mathbf{u}}$, where $\breve{\mathbf{y}}$ and $\breve{\mathbf{u}}$ are as defined by* (5.7) *and* (5.8). *Let $\widetilde{\mathbf{H}}$ be partitioned in blocks of dimension $n_b \times n_b$, and let $\widetilde{\mathbf{H}}_{(i,j)}$ denote the (i, j)th block*

element. Then it holds that $\widetilde{\mathbf{H}}_{(i,j)} = M_{i+j-1}$*, where* M_k *represents the* k*th Markov parameter of* $\widetilde{G}(\lambda)$*, as defined in* (4.4).

Proof. By definition of the Hankel map, the term $\mathbf{H}\mathbf{v}_{-j+1}^T$ is the output of the system $G(z)$ in response to the input $v_{-j+1} \in \ell_2^{n_b}(-\infty, 0]$, restricted to the space of future signals $\ell_2^{n_b}[1, \infty)$. In Z-transform notation, this output can be expressed as $\mathbf{P}_{H_{2-}^{n_b}} G(z) V_{-j+1}^T(z) = \mathbf{P}_{H_{2-}^{n_b}} G(z) G_b^{-j} V_1^T(z)$. The last equality follows from the fact that $V_k(z) = G_b^{k-1}(z) V_1(z)$ for all $k \in \mathbb{Z}$. It then follows that $\widetilde{\mathbf{H}}_{(i,j)} = [\![V_i, \mathbf{P}_{H_{2-}^{n_b}} G G_b{}^{-j} V_1]\!] = [\![G_b^{i-1} V_1, G G_b^{-j} V_1]\!]$. Because $G_b(z)$ is inner, this expression simplifies to $\widetilde{\mathbf{H}}_{(i,j)} = [\![G_b^{i+j-1} V_1, G V_1]\!]$, which is equal to M_{i+j-1}, as was established earlier; see (4.4). □

Proposition 5.4 shows that $\widetilde{\mathbf{H}}$ has a block Hankel form, which coincides with the standard block Hankel matrix representation of the Hambo operator transform $\widetilde{G}(\lambda)$. One consequence of this observation is that Hankel singular values and the McMillan degree are invariant under Hambo operator transformation.

5.3. State space expressions for the Hambo operator transform and its inverse. In this section, we will derive the expressions by which a minimal realization of the Hambo operator transform can be obtained from a minimal state space realization of the original system and vice versa. The derivation is based on the isomorphic relation that exists between such state space realizations. We will first establish this relation. Consider the (block) Hankel matrix representation $\mathbf{H}$ of the Hankel operator of an LTI system $G(z)$. It is a well-known result from realization theory that *any* full rank decomposition $\mathbf{H} = \mathbf{\Gamma}\mathbf{\Delta}$ corresponds to a minimal realization of $G(z)$ [15, 17]. That is, there exists a minimal realization (A, B, C, D) of $G(z)$ such that $\mathbf{\Gamma} = \begin{bmatrix} C^T & (CA)^T & (CA^2)^T & \cdots \end{bmatrix}^T$ and $\mathbf{\Delta} = \begin{bmatrix} B & AB & A^2B & \cdots \end{bmatrix}$. We define the transfer functions $\Gamma(z) \in H_{2-}^n$ and $\Delta(z) \in H_{2-}^{n\,\perp}$ as

$$\Gamma(z) = \sum_{k=1}^{\infty} CA^{k-1} z^{-k} = C(zI - A)^{-1}, \qquad \Delta(z) = \sum_{k=0}^{\infty} A^k B z^k = z^{-1}\ (z^{-1}\ I - A)^{-1} B.$$

The following lemma establishes an important relation between these functions and their counterparts in the transform domain.

LEMMA 5.5. *Consider a system* $G(z) \in RH_2$ *with minimal realization* (A, B, C, D)*. Let* $\Gamma(z)$ *and* $\Delta(z)$ *be defined as* $\Gamma(z) = C(zI - A)^{-1}$*,* $\Delta(z) = z^{-1}\ (z^{-1}\ I - A)^{-1} B$*. Then the Hambo operator transform* $\widetilde{G}(\lambda)$ *of* $G(z)$ *has a minimal state space realization* $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ *such that it holds that*

$$\tilde{C}(\lambda I - \tilde{A})^{-1} = \breve{\Gamma}^T(\lambda) \ \text{ and } \ \lambda^{-1}\ (\lambda^{-1}\ I - \tilde{A})^{-1} \tilde{B} = \breve{\Delta}^T(\lambda), \tag{5.10}$$

where $\breve{\Gamma}(\lambda)$ *and* $\breve{\Delta}(\lambda)$ *are the (multivariable) Hambo signal transforms of* $\Gamma(z)$*, respectively* $\Delta(z)$*, as defined in Definition* 4.3.

Conversely, any Hambo operator transform $\widetilde{G}(\lambda)$ *with minimal state space realization* $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ *has a preimage* $G(z)$ *with minimal realization* (A, B, C, D) *such that* (5.10) *holds.*

Proof. From the analysis in the previous section, it follows that, given a full rank factorization $\mathbf{H} = \mathbf{\Gamma}\mathbf{\Delta}$, a full rank factorization of $\widetilde{\mathbf{H}}$ can be obtained according to $\widetilde{\mathbf{H}} = (\mathbf{V}_f \mathbf{\Gamma})(\mathbf{\Delta} \mathbf{V}_p^T)$. Denote the minimal state space realization of $\widetilde{G}(\lambda)$ that corresponds

to this realization by $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$. We then denote $(\mathbf{V}_f\mathbf{\Gamma})_{(k)} = \tilde{C}\tilde{A}^{k-1}$, $k \geq 1$, and $(\mathbf{\Delta}\mathbf{V}_p^T)_{(-k)} = \tilde{A}^k\tilde{B}$, $k \geq 0$. It holds that $(\mathbf{V}_f\mathbf{\Gamma})_{(k)} = \mathbf{v}_k\mathbf{\Gamma}$, $k \geq 1$, and $(\mathbf{\Delta}\mathbf{V}_p^T)_{(k)} = \mathbf{\Delta}\mathbf{v}_k^T$, $k < 1$. With $\Gamma(z)$ and $\Delta(z)$ as defined above, we then see that

$$(\mathbf{V}_f\mathbf{\Gamma})_{(k)} = [\![\Gamma^T(z), V_k(z)]\!], \quad k \geq 1, \quad \text{and} \quad (\mathbf{\Delta}\mathbf{V}_p^T)_{(k)} = [\![\Delta(z), V_k(z)]\!], \quad k < 1,$$

where the last equation holds under the assumption that the realization of $\Delta(z)$ is real. This shows, using (4.2), that $\{(\mathbf{V}_f\mathbf{\Gamma})_{(k)}\}$ and $\{(\mathbf{\Delta}\mathbf{V}_p^T)_{(k)}\}$ constitute the multivariable Hambo signal transforms of $\Gamma^T(z)$ and $\Delta(z)$, respectively. Since any minimal realization of $G(z)$ corresponds to a full rank factorization of $\mathbf{H}$, the first part of the lemma is proven. The last statement of the lemma follows from the fact that the Hambo signal transform is a bijective map. ∎

Lemma 5.5 is a very powerful result as it permits us to derive very compact expressions for computing the Hambo operator transform and its inverse, using the isomorphism relation for the multivariable Hambo signal transform given in Proposition 4.2.

Suppose that the realizations (A, B, C, D) and $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ are linked to each other via the Hambo signal transform as described in Lemma 5.5. Let us denote the controllability Gramians associated with these realizations as X_c and $\tilde{X}_c$ and the observability Gramians as X_o and $\tilde{X}_o$, respectively. Then, by the Hambo signal transform isomorphism, it holds for the functions $\Gamma(z)$ and $\Delta(z)$ that

$$X_o = [\![\Gamma^T(z), \Gamma^T(z)]\!] = [\![\breve{\Gamma}^T(\lambda), \breve{\Gamma}^T(\lambda)]\!] = \tilde{X}_o, \tag{5.11}$$

$$X_c = [\![\Delta(z), \Delta(z)]\!] = [\![\breve{\Delta}(\lambda), \breve{\Delta}(\lambda)]\!] = \tilde{X}_c. \tag{5.12}$$

Using the Hambo signal transform isomorphism, we can now establish a matrix inner product expression for the realization $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$, as follows.

PROPOSITION 5.6. *With $\Gamma(z)$ and $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ as defined in Lemma 5.5 and X_o the controllability Gramian of this realization, it holds that*

$$\begin{bmatrix} X_o & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{bmatrix} = \left[\!\!\left[\begin{bmatrix} \Gamma^T(z)G_b(z) \\ V_1(z) \end{bmatrix}, \begin{bmatrix} \Gamma^T(z) \\ V_1(z)G(z) \end{bmatrix} \right]\!\!\right]. \tag{5.13}$$

Proof. The system $\widetilde{G}^T(\lambda)$ is described by the equation

$$\begin{bmatrix} X(\lambda)\lambda \\ Y(\lambda) \end{bmatrix} = \begin{bmatrix} \tilde{A}^T & \tilde{C}^T \\ \tilde{B}^T & \tilde{D}^T \end{bmatrix} \begin{bmatrix} X(\lambda) \\ U(\lambda) \end{bmatrix}.$$

It holds that

$$\left[\!\!\left[\begin{bmatrix} X(\lambda) \\ U(\lambda) \end{bmatrix}, \begin{bmatrix} X(\lambda)\lambda \\ Y(\lambda) \end{bmatrix} \right]\!\!\right] = \left[\!\!\left[\begin{bmatrix} X(\lambda) \\ U(\lambda) \end{bmatrix}, \begin{bmatrix} X(\lambda) \\ U(\lambda) \end{bmatrix} \right]\!\!\right] \begin{bmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{bmatrix}.$$

Let the input $u(t)$ be equal to $e_i\delta(t)$, with e_i the ith Euclidean basis vector of $\mathbb{R}^{n_b}$. Then $X(\lambda) = [\lambda I - \tilde{A}^T]^{-1}\tilde{C}^T e_i = \breve{\Gamma}(\lambda)e_i$, and by Lemma 5.5 this last equation can be written as

$$\left[\!\!\left[\begin{bmatrix} \breve{\Gamma}(\lambda)e_i \\ e_i \end{bmatrix}, \begin{bmatrix} \breve{\Gamma}(\lambda)e_i\lambda \\ \widetilde{G}^T(\lambda)e_i \end{bmatrix} \right]\!\!\right] = \left[\!\!\left[\begin{bmatrix} \breve{\Gamma}(\lambda)e_i \\ e_i \end{bmatrix}, \begin{bmatrix} \breve{\Gamma}(\lambda)e_i \\ e_i \end{bmatrix} \right]\!\!\right] \begin{bmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{bmatrix}.$$

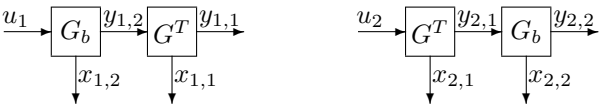

FIG. 5.1. *Systems for proof of Corollary* 5.7.

Because this holds for all i such that $1 \le i \le n_b$, we can also write (after summation of the latter equation over all $i = 1, \dots, n_b$)

$$\left[\!\left[\begin{bmatrix}\breve{\Gamma}(\lambda)\\ I\end{bmatrix}, \begin{bmatrix}\breve{\Gamma}(\lambda)\lambda\\ \widetilde{G}^T(\lambda)\end{bmatrix}\right]\!\right] = \left[\!\left[\begin{bmatrix}\breve{\Gamma}(\lambda)\\ I\end{bmatrix}, \begin{bmatrix}\breve{\Gamma}(\lambda)\\ I\end{bmatrix}\right]\!\right] \begin{bmatrix}\tilde{A} & \tilde{B}\\ \tilde{C} & \tilde{D}\end{bmatrix} = \begin{bmatrix}\tilde{X}_o & 0\\ 0 & I\end{bmatrix} \begin{bmatrix}\tilde{A} & \tilde{B}\\ \tilde{C} & \tilde{D}\end{bmatrix}.$$

The term on the left-hand side of this equation equals

$$\left[\!\left[\begin{bmatrix}\breve{\Gamma}(\lambda)\lambda^{-1}\\ I\lambda^{-1}\end{bmatrix}, \begin{bmatrix}\breve{\Gamma}(\lambda)\\ \widetilde{G}^T(\lambda)\lambda^{-1}\end{bmatrix}\right]\!\right].$$

We observe that $\lambda^{-1}I$ is equal to the Hambo operator transform of $G_b(z)$ (see (4.6)). Further, $\lambda^{-1}I$ is the Hambo signal transform of $V_1(z)$, as was demonstrated in Example 4.4. From Proposition 4.7 it then follows that $\lambda^{-1}I\,\breve{\Gamma}^T(\lambda)$ is the Hambo signal transform of $G_b(z)\cdot I\Gamma^T(z)$. Similarly, $\lambda^{-1}I\widetilde{G}(\lambda)$ is the signal transform of $V_1(z)G(z)$. Using the Hambo signal transform isomorphism (Proposition 4.2), it therefore holds that

$$\left[\!\left[\begin{bmatrix}\breve{\Gamma}(\lambda)\lambda^{-1}\\ I\lambda^{-1}\end{bmatrix}, \begin{bmatrix}\breve{\Gamma}(\lambda)\\ \widetilde{G}^T(\lambda)\lambda^{-1}\end{bmatrix}\right]\!\right] = \left[\!\left[\begin{bmatrix}\Gamma^T(z)G_b(z)\\ V_1(z)\end{bmatrix}, \begin{bmatrix}\Gamma^T(z)\\ V_1(z)G(z)\end{bmatrix}\right]\!\right]. \qquad \square$$

Obviously, a dual formulation of this proposition that uses expressions involving $\Delta(z)$ and X_c is possible.

Proposition 5.6 can also be formulated in the form of a Sylvester equation.

COROLLARY 5.7. *Consider a system $G(z) \in RH_2$, with minimal realization (A, B, C, D) and observability Gramian X_o. Then $\widetilde{G}(\lambda)$ has a minimal realization $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ that satisfies the following Sylvester equation:*

$$\begin{bmatrix}A^T & C^TC_b\\ 0 & A_b\end{bmatrix} \begin{bmatrix}X_o\tilde{A} & X_o\tilde{B}\\ \tilde{C} & \tilde{D}\end{bmatrix} \begin{bmatrix}A & BB_b^T\\ 0 & A_b^T\end{bmatrix} + \begin{bmatrix}C^TD_b\\ B_b\end{bmatrix} \begin{bmatrix}C & DB_b^T\end{bmatrix} = \begin{bmatrix}X_o\tilde{A} & X_o\tilde{B}\\ \tilde{C} & \tilde{D}\end{bmatrix}. \tag{5.14}$$

Proof. The Sylvester equation is obtained by formulating (5.13) in the time domain using straightforward state space realizations of the transfer functions that appear in the inner product. Consider the systems shown in Figure 5.1. State equations of these systems are

$$\begin{bmatrix}x_{1,1}(t+1)\\ x_{1,2}(t+1)\end{bmatrix} = \begin{bmatrix}A^T & C^TC_b\\ 0 & A_b\end{bmatrix} \begin{bmatrix}x_{1,1}(t)\\ x_{1,2}(t)\end{bmatrix} + \begin{bmatrix}C^TD_b\\ B_b\end{bmatrix} u(t)$$

and

$$\begin{bmatrix}x_{2,1}(t+1)\\ x_{2,2}(t+1)\end{bmatrix} = \begin{bmatrix}A^T & 0\\ B_bB^T & A_b\end{bmatrix} \begin{bmatrix}x_{2,1}(t)\\ x_{2,2}(t)\end{bmatrix} + \begin{bmatrix}C^T\\ B_bD^T\end{bmatrix} u(t),$$

respectively. The solution of (5.13) is then equal to

$$\left[\!\!\left[\begin{bmatrix} x_{1,1} \\ x_{1,2} \end{bmatrix}, \begin{bmatrix} x_{2,1} \\ x_{2,2} \end{bmatrix} \right]\!\!\right],$$

which results in (5.14). ∎

Existence of a solution to this Sylvester equation (5.14) is guaranteed if the systems in the inner product expression in (5.13) are stable. This is true by assumption for $\Gamma(z)$ and $G(z)$ and by definition for $G_b(z)$ and $V_1(z)$.

Note that (5.14) can be simplified further in the case where $X_o = I$, i.e., when the realization (A, B, C, D) is output balanced.

Using the Hambo signal transform isomorphism, it is equally simple to derive a matrix inner product expression for the realization (A, B, C, D) that involves $\breve{\Gamma}(\lambda)$.

PROPOSITION 5.8. *With $\Gamma(z)$ and (A, B, C, D) as defined in Lemma 5.5, it holds that*

$$\begin{bmatrix} \tilde{X}_o & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \left[\!\!\left[\begin{bmatrix} \breve{\Gamma}^T(\lambda) N^T(\lambda) \\ W_1^T(\lambda) \end{bmatrix}, \begin{bmatrix} \breve{\Gamma}^T(\lambda) \\ W_1^T(\lambda) \widetilde{G}^T(\lambda) \end{bmatrix} \right]\!\!\right]. \tag{5.15}$$

Proof. The system $G^T(z)$ is described by the state equation

$$\begin{bmatrix} X(z)z \\ Y(z) \end{bmatrix} = \begin{bmatrix} A^T & C^T \\ B^T & D^T \end{bmatrix} \begin{bmatrix} X(z) \\ U(z) \end{bmatrix}.$$

It holds that

$$\left[\!\!\left[\begin{bmatrix} X(z) \\ U(z) \end{bmatrix}, \begin{bmatrix} X(z)z \\ Y(z) \end{bmatrix} \right]\!\!\right] = \left[\!\!\left[\begin{bmatrix} X(z) \\ U(z) \end{bmatrix}, \begin{bmatrix} X(z) \\ U(z) \end{bmatrix} \right]\!\!\right] \begin{bmatrix} A & B \\ C & D \end{bmatrix}.$$

Let the input $u(t)$ be equal to $\delta(t)$. Then this last equation can be written as

$$\left[\!\!\left[\begin{bmatrix} \Gamma^T(z) \\ 1 \end{bmatrix}, \begin{bmatrix} \Gamma^T(z)z \\ G^T(z) \end{bmatrix} \right]\!\!\right] = \left[\!\!\left[\begin{bmatrix} \Gamma(z) \\ 1 \end{bmatrix}, \begin{bmatrix} \Gamma(z) \\ 1 \end{bmatrix} \right]\!\!\right] \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} X_o & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix}.$$

The term on the left-hand side of this equation equals

$$\left[\!\!\left[\begin{bmatrix} \Gamma^T(z) z^{-1} \\ z^{-1} \end{bmatrix}, \begin{bmatrix} \Gamma^T(z) \\ G^T(z) z^{-1} \end{bmatrix} \right]\!\!\right].$$

We observe that z^{-1} is equal to the inverse Hambo operator transform of $N(\lambda)$ (as follows from Proposition 5.1). At the same time, z^{-1} is the inverse Hambo signal transform of $W_1(\lambda)$. Then it follows from Proposition 4.7 that $z^{-1}I\ \Gamma(z)$ is the Hambo inverse signal transform of $N(\lambda)\breve{\Gamma}(\lambda)$. Similarly, by definition of the Hambo operator transform, $G(z)z^{-1}$ is then the inverse signal transform of $\widetilde{G}(\lambda)W_1(\lambda)$. Using the Hambo signal transform isomorphism (Proposition 4.2), it therefore holds that

$$\left[\!\!\left[\begin{bmatrix} \Gamma^T(z) z^{-1} \\ z^{-1} \end{bmatrix}, \begin{bmatrix} \Gamma^T(z) \\ G^T(z) z^{-1} \end{bmatrix} \right]\!\!\right] = \left[\!\!\left[\begin{bmatrix} \breve{\Gamma}^T(\lambda) N^T(\lambda) \\ W_1^T(\lambda) \end{bmatrix}, \begin{bmatrix} \breve{\Gamma}^T(\lambda) \\ W_1^T(\lambda) \widetilde{G}^T(\lambda) \end{bmatrix} \right]\!\!\right]. \qquad \blacksquare$$

Again a dual formulation of this proposition is possible that uses expressions involving $\Delta(z)$ and X_c. Expression (5.15) can also be put in Sylvester equation form.

COROLLARY 5.9. *Consider a Hambo transform $\widetilde{G}(\lambda)$ of a system $G(z) \in RH_2$, with minimal state space realization $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ and observability Gramian $\tilde{X}_o$. Then*

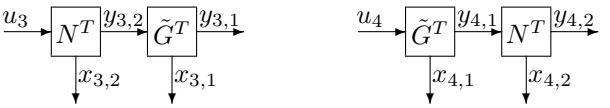

FIG. 5.2. *Systems for proof of Corollary* 5.9.

$G(z)$ has a minimal state space realization (A, B, C, D) that satisfies the following Sylvester equation:

$$\begin{bmatrix} \tilde{A}^T & \tilde{C}^T C_b^T \\ 0 & D_b^T \end{bmatrix} \begin{bmatrix} \tilde{X}_o A & \tilde{X}_o B \\ C & D \end{bmatrix} \begin{bmatrix} \tilde{A} & \tilde{B} B_b \\ 0 & D_b \end{bmatrix} + \begin{bmatrix} \tilde{C}^T A_b^T \\ B_b^T \end{bmatrix} \begin{bmatrix} \tilde{C} & \tilde{D} B_b \end{bmatrix} = \begin{bmatrix} \tilde{X}_o A & \tilde{X}_o B \\ C & D \end{bmatrix}. \tag{5.16}$$

Proof. The proof is similar to that of Corollary 5.7. Consider the systems shown in Figure 5.2. State equations of these systems are

$$\begin{bmatrix} x_{3,1}(t+1) \\ x_{3,2}(t+1) \end{bmatrix} = \begin{bmatrix} \tilde{A}^T & \tilde{C}^T C_b^T \\ 0 & D_b^T \end{bmatrix} \begin{bmatrix} x_{3,1}(t) \\ x_{3,2}(t) \end{bmatrix} + \begin{bmatrix} \tilde{C}^T A_b^T \\ B_b^T \end{bmatrix} u(t)$$

and

$$\begin{bmatrix} x_{4,1}(t+1) \\ x_{4,2}(t+1) \end{bmatrix} = \begin{bmatrix} \tilde{A}^T & 0 \\ B_b^T \tilde{B}^T & D_b^T \end{bmatrix} \begin{bmatrix} x_{4,1}(t) \\ x_{4,2}(t) \end{bmatrix} + \begin{bmatrix} \tilde{C}^T \\ B_b^T \tilde{D}^T \end{bmatrix} u(t),$$

respectively. The solution of (5.15) is then equal to

$$\left[\!\!\left[\begin{bmatrix} x_{3,1} \\ x_{3,2} \end{bmatrix}, \begin{bmatrix} x_{4,1} \\ x_{4,2} \end{bmatrix} \right]\!\!\right],$$

which results in (5.16). □

Existence of a solution to this Sylvester equation (5.16) is guaranteed if the systems in the inner product expression in (5.15) are stable. That this is true for $\breve{\Gamma}(\lambda)$ follows from the assumption that $G(z)$ is stable and the fact that $\Gamma^T(z)$ is stable. Consequently $\widetilde{G}(\lambda)$ is also stable. $W_1(\lambda)$ and $N^T(\lambda)$ are stable by definition.

Equation (5.16) can again be simplified further when $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ is output balanced.

Note that formulas (5.14) and (5.16) look very similar. Also note that the formulas are reciprocal: using a realization (A, B, C, D) in (5.14) results in a realization $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$, which, when used in (5.16), yields the original (A, B, C, D) again. This follows from the fact that the functions $\Gamma^T(z)$ and $\breve{\Gamma}(\lambda)$ correspond uniquely through the Hambo signal transform.

As stated, similar results as those given by Corollaries 5.7 and 5.9 can be given using a controllability approach. We state the results here without proof. Details can be found in [7].

COROLLARY 5.10 (Hambo system transform—controllability form [7]). *Consider a system $G(z) \in RH_2$ with minimal state space realization (A, B, C, D) and controllability Gramian X_c. Then its Hambo transform $\widetilde{G}(\lambda)$ has a minimal state*

space realization $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ *with controllability Gramian* $\tilde{X}_c = X_c$ *that satisfies the following Sylvester equation:*

$$\begin{bmatrix} A & 0 \\ C_b^T & A_b^T \end{bmatrix} \begin{bmatrix} \tilde{A}X_c & \tilde{B} \\ \tilde{C}X_c & \tilde{D} \end{bmatrix} \begin{bmatrix} A^T & 0 \\ B_b B^T & A_b \end{bmatrix} + \begin{bmatrix} B \\ C_b^T D \end{bmatrix} \begin{bmatrix} D_b B^T & C_b \end{bmatrix} = \begin{bmatrix} \tilde{A}X_c & \tilde{B} \\ \tilde{C}X_c & \tilde{D} \end{bmatrix}. \tag{5.17}$$

COROLLARY 5.11 (inverse Hambo system transform—controllability form [7]). *Consider a Hambo transform* $\widetilde{G}$ *of a system* $G(z) \in RH_2$ *with minimal state space realization* $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ *and controllability Gramian* $\tilde{X}_c$*. Then* $G(z)$ *has a minimal state space realization* (A, B, C, D) *with controllability Gramian* $X_c = \tilde{X}_c$ *that satisfies the following Sylvester equation:*

$$\begin{aligned} &\begin{bmatrix} \tilde{A} & 0 \\ C_b\tilde{C} & D_b \end{bmatrix} \begin{bmatrix} A\tilde{X}_c & B \\ C\tilde{X}_c & D \end{bmatrix} \begin{bmatrix} \tilde{A}^T & 0 \\ B_b^T\tilde{B}^T & D_b^T \end{bmatrix} + \begin{bmatrix} \tilde{B} \\ C_b\tilde{D} \end{bmatrix} \begin{bmatrix} A_b^T\tilde{B}^T & C_b^T \end{bmatrix} \\ &\qquad = \begin{bmatrix} A\tilde{X}_c & B \\ C\tilde{X}_c & D \end{bmatrix}. \end{aligned} \tag{5.18}$$

There are various formulas that can be derived in this context. For instance, it is straightforward to derive a generic formula for $\tilde{D}$ that is a direct result of substituting $\lambda = \infty$ in (5.2):

$$\tilde{D} = \sum_{k=0}^{\infty} g(k) A_b^k. \tag{5.19}$$

An equivalent relation (see [7]) can be derived for $\tilde{A}$ as defined by (5.14), (5.17) when we define $g_b(k)$ as the impulse response sequence of $G_b(z)$:

$$\tilde{A} = \sum_{k=0}^{\infty} g_b(k) A^k. \tag{5.20}$$

This expression can be verified as follows. Define $F = \sum_{k=0}^{\infty} g_b(k) A^k$, and consider the expression $A^T X_o F A$, where X_o is the observability Gramian of the realization (A, B, C, D). It follows that

$$\begin{aligned} A^T X_o F A &= \sum_{k=0}^{\infty} g_b(k)(A^T X_o A) A^k = \sum_{k=0}^{\infty} g_b(k)(X_o - C^T C) A^k \\ &= X_o F - C^T C \cdot D_b - \sum_{k=1}^{\infty} C^T C_b A_b^{k-1} B_b C A^k \\ &= X_o F - C^T D_b C - C^T C Y A, \quad \text{where} \quad A_b Y A + B_b C = Y. \end{aligned}$$

Evaluation of the terms in (5.14) yields that it must hold that $Y = \tilde{C}$ and $F = \tilde{A}$, as defined by (5.14). Analogously, evaluation of AFX_cA^T shows that $F = \tilde{A}$, as defined by (5.17).

6. Properties of Hambo transforms. We proceed with demonstrating a number of interesting properties of Hambo transforms that ensue from the theory developed in the preceding sections. These properties are of interest because they are instrumental to the application of the basis function theory in the context of system modelling [39, 8, 7].

6.1. Calculation rules. The Hambo operator transform obeys the following rules:

$$\text{(6.1)}\quad \text{if}\quad H(z) = (\alpha G_1(z) + \beta G_2(z)),\quad \text{then}\quad \widetilde{H}(\lambda) = \alpha\widetilde{G_1}(\lambda) + \beta\widetilde{G_2}(\lambda),$$

$$\text{(6.2)}\qquad \widetilde{G_1G_2}(\lambda) = \widetilde{G_1}(\lambda)\widetilde{G_2}(\lambda) = \widetilde{G_2}(\lambda)\widetilde{G_1}(\lambda),$$

$$\text{(6.3)}\qquad \widetilde{G^{-1}}(\lambda) = \big(\widetilde{G}(\lambda)\big)^{-1},$$

where $G_1(z), G_2(z), G(z), G^{-1}(z) \in H_2$, and $\alpha, \beta \in \mathbb{R}$.

Proof. (6.1): The proof follows trivially from the definition of the Hambo operator transform and the linearity of the Hambo signal transform.

(6.2): Let $Y(z) = G_1(z)G_2(z)U(z)$. Define $X(z) = G_2(z)U(z)$. By definition of the operator transform, it holds that $\breve{Y}(\lambda) = \widetilde{G_1}(\lambda)\breve{X}(\lambda) = \widetilde{G_1}(\lambda)\widetilde{G_2}(\lambda)\breve{U}(\lambda)$. Since this holds for all $U(z), Y(z)$, (6.2) follows. The second equality follows from the fact that the scalar systems $G_1(z)$ and $G_2(z)$ commute.

(6.3): Assuming that $G^{-1}(z) \in H_2$, we have by definition of the Hambo transform that $\breve{U}(\lambda) = \widetilde{G^{-1}}(\lambda)\breve{Y}(\lambda)$. We also know that $\breve{Y}(\lambda) = \widetilde{G}(\lambda)\breve{U}(\lambda)$. Hence $(\widetilde{G}(\lambda))^{-1} = \widetilde{G^{-1}}(\lambda)$. □

On the basis of these properties, it holds, for instance, that if $H(z) = (G(z)(1 + G(z))^{-1})$, then $\widetilde{H}(\lambda) = \widetilde{G}(\lambda)(I + \widetilde{G}(\lambda))^{-1} = (I + \widetilde{G}(\lambda))^{-1}\widetilde{G}(\lambda)$, assuming that $(1 + G(z))^{-1} \in H_2$.

These properties thus imply that parallel and series interconnections of systems remain unchanged under Hambo operator transformation. Feedback interconnections also remain unchanged under the condition that the inverse taken is also in H_2. It follows immediately that the same goes for linear fractional transformations (LFT), where we assume a pointwise definition of the operator transform for multivariable systems, i.e.,

$$\begin{bmatrix} \widetilde{G_{11}(z)\ G_{12}(z)} \\ G_{21}(z)\ \ G_{22}(z) \end{bmatrix} = \begin{bmatrix} \widetilde{G}_{11}(z) & \widetilde{G}_{12}(z) \\ \widetilde{G}_{21}(z) & \widetilde{G}_{22}(z) \end{bmatrix}.$$

6.2. Pole locations. It was established in section 5.2 that the McMillan degree of a Hambo operator transform is equal to the McMillan degree of the original system. Hence the number of poles of $\widetilde{G}(\lambda)$ is equal to that of $G(z)$. The locations of the poles of $\widetilde{G}(\lambda)$ are determined as follows.

PROPOSITION 6.1. *Consider a system $G(z) \in RH_2$ and a Hambo basis generated by an inner function $G_b(z)$. If $G(z)$ has a pole at $z = a_i$, its Hambo operator transform $\widetilde{G}(\lambda)$ will have a pole at $\mu_i = G_b(\frac{1}{a_i}) = G_b^{-1}(a_i)$.*

Proof. This assertion can be proved on the basis of (5.20). That is, if $G(z)$ has a state space realization (A, B, C, D), $\widetilde{G}(\lambda)$ will have a state space realization $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ with

$$\text{(6.4)}\qquad \tilde{A} = \sum_{k=0}^{\infty} g_b(k)A^k,$$

where $g_b(k)$ represents the impulse response sequence of $G_b(z)$. Consider any eigenvalue a_i of A and a corresponding eigenvector $x_i \in \mathbb{C}^n$, $Ax_i = x_i a_i$. If we multiply (6.4) from the right with x_i, we find $\tilde{A}x_i = x_i \sum_{k=0}^{\infty} g_b(k)a_i^k = x_i G_b(\frac{1}{a_i}) = x_i G_b^{-1}(a_i)$. Therefore, $\tilde{A}$ has eigenvalue $G_b(\frac{1}{a_i})$ with corresponding eigenvector x_i. □

COROLLARY 6.2. *The Hambo operator transform $\widetilde{G}(\lambda)$ of a system $G(z) \in H_2$ is stable.*

Proof. By the maximum modulus theorem [34] it holds that for an inner function $G_b(z)$, $|G_b(z)| < 1$ outside the unit disk. Hence $|G_b(\frac{1}{a})| < 1$ for all $a < 1$. Consequently, $\widetilde{G}(\lambda)$ is stable if $G(z)$ is stable. □

Corollary 5.2 showed that for $G(z) \in H_{2-}$, $\breve{G}(\lambda) = \widetilde{G}(\lambda)W_0(\lambda)$. Since this must be an element of $H_2^{n_b}$, it therefore must hold that the unstable pole of W_0 which lies at $\frac{1}{D_b}$ is cancelled by a zero at $\frac{1}{D_b}$ of $\det \widetilde{G}(\lambda)$, and hence we can immediately conclude that the poles of $\breve{G}(\lambda)$ constitute a subset of the poles of $\widetilde{G}(\lambda)$.

COROLLARY 6.3. *Let $G(z) \in H_{2-}$ have McMillan degree n with poles at a_i with $1 \leq i \leq n$. Then the Hambo signal transform $\breve{G}(\lambda)$ is stable, and its poles form a subset of $\{\mu_i\}_{1 \leq i \leq n}$ with $\mu_i = G_b(\frac{1}{a_i})$. Hence the McMillan degree of $\breve{G}(\lambda)$ is smaller than or equal to n.*

On the basis of Corollary 6.3, one can make the following statement about the convergence rate of an expansion in terms of Hambo basis functions [13].

PROPOSITION 6.4. *Let a Hambo basis function expansion of $G(z) \in H_{2-}$ be given by $G(z) = \sum_{k \in \mathbb{N}} \breve{g}^T(k) V_k(z) = \sum_{k \in \mathbb{N}} \sum_{i=1}^{n_b} \breve{g}(k)_i \Phi_{k,i}(z)$. Further, let $G(z)$ have McMillan degree n and poles $a_i, 1 \leq i \leq n$. Then with μ defined as $\mu = \max_{1 \leq i \leq n} |G_b(\frac{1}{a_i})|$, it holds that there exists a positive constant $c \in \mathbb{R}$ such that $\max_{1 \leq i \leq n_b} |\breve{g}(k)_i| \leq c\mu^{k-1}$.*

This is simply a result of the well-known fact that the convergence of an impulse response sequence is dominated by the pole with the largest modulus. If the poles of $G(z)$ are a subset of the poles $\xi_j, 1 \leq j \leq n_b$, of $G_b(z)$, then it holds that $G_b(\frac{1}{a_i}) = 0$ for $1 \leq i \leq n$. Hence it follows that in this case $\breve{g}(k) = 0$ for all $k > 1$, and the basis function expansion converges to zero in one step. This illustrates the mechanism that the convergence becomes very fast when the poles in the basis generating inner function lie close to the poles of $G(z)$.

6.3. Eigenstructure of Hambo operator transforms. In this section, we analyze some of the structural properties of Hambo operator transforms. A direct relation between the eigenvalues of a Hambo operator transform $\widetilde{G}(\lambda)$ and its preimage $G(z)$ is established. It is further shown how $\widetilde{G}(\lambda)$, evaluated on the unit circle, can be diagonalized by means of a similarity transformation with an orthogonal matrix, thus revealing information about the singular values of the Hambo operator transform. We first observe the following result which was previously shown to hold in [43, 44].

LEMMA 6.5. *Given a Hambo basis generating inner function $G_b(z)$ and its corresponding dual basis generating inner function $N(\lambda)$, for $z \neq 0$*

$$zV_1^T(z)\, N(\lambda)|_{\lambda^{-1}=G_b(z)} = V_1^T(z). \tag{6.5}$$

Proof. The proof follows by direct evaluation of $N(G_b(z))V_1(z)$ using $G_b(z) = C_b(zI - A_b)^{-1}B_b + D_b$, making the assumption that $z \notin \sigma(A_b)$:

$$\begin{aligned} N(G_b(z))V_1(z) &= \left(A_b + B_b(G_b(z) - D_b)^{-1}C_b\right)(zI - A_b)^{-1}B_b \\ &= A_b(zI - A_b)^{-1}B_b + B_b\left(C_b(zI - A_b)^{-1}B_b\right)^{-1} C_b(zI - A_b)^{-1}B_b \\ &= A_b(zI - A_b)^{-1}B_b + B_b = V_1(z)z. \end{aligned}$$

By the inner property of $N(\lambda)$ and $G_b(z)$, this latter equation can be rephrased as (6.5). Since A_b has only a finite number of eigenvalues, continuity shows that the result is valid for all $z \in \mathbb{C}$. ∎

We see that for $z \neq 0$, $V_1^T(z)$ is a left eigenvector of $N(\lambda)|_{\lambda^{-1}=G_b(z)}$, with z^{-1} the corresponding eigenvalue. This has the following consequence.

PROPOSITION 6.6. *Consider a Hambo basis generated by the inner function $G_b(z)$ and a transfer function $G(z) \in H_2$. Then the Hambo operator transform $\widetilde{G}(\lambda)$ satisfies*

$$V_1^T(z)\ \widetilde{G}(\lambda)\Big|_{\lambda^{-1}=G_b(z)} = G(z)V_1^T(z) \tag{6.6}$$

for all $z \neq 0$.

Proof. It follows by direct substitution of Lemma 6.5 in Proposition 5.1 that

$$V_1^T(z)\ \widetilde{G}(\lambda)\Big|_{\lambda^{-1}=G_b(z)} = \sum_{\tau=0}^{\infty} g(\tau)V_1^T(z)\ N(\lambda)^\tau|_{\lambda^{-1}=G_b(z)} = \sum_{\tau=0}^{\infty} g(\tau)z^{-\tau}V_1^T(z). \qquad ∎$$

Consider a certain fixed value of λ denoted as λ_0. Because $G_b(z)$ is an inner function of McMillan degree n_b, the equation ${\lambda_0}^{-1} = G_b(z)$ will have n_b solutions which we will denote as z_i. Defining the matrix $X(\{z_i\})$ as $X(\{z_i\}) = \begin{bmatrix} V_1(z_1)\ V_1(z_2)\ \cdots\ V_1(z_{n_b}) \end{bmatrix}$, one can write, using Proposition 6.6, $X^T(\{z_i\})\widetilde{G}(\lambda_0) = \operatorname{diag} G(z_i)X^T(\{z_i\})$. If the solutions z_i to ${\lambda_0}^{-1} = G_b(z)$ are distinct, it holds that $V_1^T(z_i)V_1(\frac{1}{z_j}) = 0$ for $z_i \neq z_j$. This follows directly from the following result, which is known as the *Christoffel–Darboux* formula [6, 4] for the Hambo basis. It gives an expression for the reproducing kernel of the subspace spanned by the functions $\Phi_{1,i}(z), 1 \leq i \leq n_b$, which is equal to $K(z, z') = V_1^T(z')V_1(\frac{1}{z})$.

LEMMA 6.7 (Christoffel–Darboux formula). *Consider a Hambo basis generating inner function $G_b(z)$. It holds for all $z_1, z_2 \in \mathbb{C}$, $z_1 \neq z_2$, that*

$$V_1^T(z_1)V_1\left(\frac{1}{z_2}\right) = \frac{G_b(z_1)G_b(\frac{1}{z_2}) - 1}{1 - \frac{z_1}{z_2}}. \tag{6.7}$$

Proof. The proof follows from the properties of the orthogonal realization (A_b, B_b, C_b, D_b). Using that $zV_1(z) = A_bV_1(z) + B_b$, we have that

$$\begin{aligned} z_1V_1^T(z_1)V_1\left(\frac{1}{z_2}\right)\ \frac{1}{z_2} &= (V_1^T(z_1)A_b^T + B_b^T)\left(A_bV_1\left(\frac{1}{z_2}\right) + B_b\right) \\ &= V_1^T(z_1)A_b^TA_bV_1\left(\frac{1}{z_2}\right) + V_1^T(z_1)A_b^TB_b + B_b^TA_bV_1\left(\frac{1}{z_2}\right) + B_b^TB_b. \end{aligned}$$

Substituting $A_b^TA_b = I - C_b^TC_b$, $A_b^TB_b = -C_b^TD_b$, and $B_b^TB_b = 1 - D_b^TD_b$ results in

$$z_1V_1^T(z_1)V_1\left(\frac{1}{z_2}\right)\ \frac{1}{z_2} = V_1^T(z_1)V_1\left(\frac{1}{z_2}\right) - G_b(z_1)G_b\left(\frac{1}{z_2}\right) + 1,$$

which can be rephrased as (6.7). ∎

We now have that, if the solutions z_i to $\lambda_0^{-1} = G_b(z)$ are distinct, it holds that

$$X^T(\{z_i\})\widetilde{G}(\lambda_0)X\left(\left\{\frac{1}{z_i}\right\}\right) = \operatorname{diag} G(z_i) \operatorname{diag} V_1^T(z_i)V_1\left(\frac{1}{z_i}\right).$$

The case where $|\lambda_0| = 1$ is a simple but important situation for which it holds that the solutions z_i to $\lambda_0^{-1} = G_b(z)$ are all distinct. This follows directly from the fact that any scalar inner function with McMillan degree n_b can be written as a Blaschke product $G_b(z) = \pm\prod_{k=1}^{n_b} \frac{1-\xi_k^* z}{z-\xi}$, and thus the map $e^{i\omega} \to G_b(e^{i\omega})$ will go through the unit circle n_b times as ω goes from 0 to 2π, and hence there are n_b different solutions $0 \le \omega_1 < \omega_2 < \cdots < \omega_{n_b} < 2\pi$ with $G_b(e^{i\omega_k}) = 1$.

A further consequence of the observation that $V_1^T(z)V_1(\frac{1}{z}) > 0$ if $|z| = 1$ is that for $|\lambda_0| = 1$, the matrix $X(\{\frac{1}{z_i}\})(\operatorname{diag}\sqrt{V_1^T(z_i)V_1(\frac{1}{z_i})})^{-1}$ is an orthogonal matrix. This brings us the following diagonal decomposition of $\widetilde{G}(\lambda_0)$.

PROPOSITION 6.8. *Let z_i, with $1 \le i \le n_b$, be the solutions to $\lambda_0^{-1} = G_b(z_i)$ with $|\lambda_0| = 1$. Then, defining $R = \operatorname{diag}\sqrt{V_1^T(z_i)V_1(\frac{1}{z_i})}$, it holds that*

$$R^{-1}X^T(\{z_i\})\widetilde{G}(\lambda_0)X\left(\left\{\frac{1}{z_i}\right\}\right)R^{-1} = \operatorname{diag} G(z_i).$$

$X(\{\frac{1}{z_i}\})R^{-1}$ is an orthogonal matrix. Hence the singular values of $\widetilde{G}(\lambda_0)$ are equal to $|G(z_i)|$.

This proposition also shows that $\widetilde{G}(\lambda)$ is Hermitian when $|\lambda| = 1$.

6.4. Norm invariance under Hambo operator transformation. It was shown before that the Hambo transforms of scalar stable finite dimensional LTI systems are again stable finite dimensional LTI systems, albeit that they have input/output dimension $n_b \times n_b$. For the particular case of the Hambo operator transform, it was further shown that the McMillan degree, Hankel singular values, and ℓ_2-gain are also invariant under Hambo operator transformation. This leads to the following observations.

COROLLARY 6.9. *The Hankel and H_∞-norms of a system $G(z) \in H_\infty$ are invariant under Hambo operator transformation.*

The assertion for the Hankel norm follows from invariance of the Hankel singular values. Invariance of the H_∞-norm follows from the fact that the H_∞-norm is equal to the ℓ_2-gain. Alternatively, it follows from Proposition 6.8, which shows that $\sup_{\omega\in[0,2\pi)} \bar{\sigma}(\widetilde{G}(e^{i\omega})) = \sup_{\omega\in[0,2\pi)} |G(e^{i\omega})|$. Given the definition of the Hambo operator transform, it is not surprising that these norms are invariant as they are both norms that are induced by the ℓ_2-norm for signals, which is invariant under Hambo signal transformation as follows, e.g., from Proposition 4.2. It is important to take notice of the fact that the H_2-norm is *not* invariant under Hambo *operator* transformation. On the basis of Proposition 5.3, we can, however, conclude the following.

COROLLARY 6.10. *The H_2-norm of the Hambo operator transform of $G(z) \in H_2$ satisfies*

$$\|\widetilde{G}\|_2 = \|V_k G\|_2 \quad \forall k \in \mathbb{Z}.$$

Proof. The proof follows by taking the trace of both sides of (5.4) with $G_1(z) = G_2(z) = G(z)$. ∎

7. Extensions and derivatives. In this section, we briefly discuss some closely related subjects in the context of the Hambo transform theory.

Time-varying transforms. In [7] a more generalized transform theory is developed, where the transforms are directly based on the Takenaka–Malmquist functions, as discussed in section 2. The main difference with the Hambo transforms is that the

transforms for the generalized case turn out to be scalar time-varying operators instead of multivariable time-invariant systems.

Multivariable systems. In this paper, the Hambo operator transform has been restricted to the class of scalar systems. An important issue here is that for scalar systems the transformed system turns out to be an element of $H_2^{n_b \times n_b}$. While it is straightforward (see, e.g., [25, 7]) to define Hambo transforms for multivariable $p \times m$ systems, the transform will blow up to dimensions $pn_b \times mn_b$. An alternative method which does not increase the input/output dimension, using a time-varying transformation, is discussed in [7].

Unstable systems. This paper primarily considers stable systems. It is not difficult to extend the transformation formulas of section 5.3 to unstable systems as well. In fact, the same formulas are valid with the exception of systems that contain poles that are reciprocals of basis poles. The problem in the latter case is that the resulting transform may be a noncausal system. This is explained by the following example for the Laguerre basis functions.

Let a be the (stable) pole of the Laguerre basis functions (2.4), and let $G(z) \in H_2^\perp$ be given by $G(z) = \frac{1}{z^{-1}-a}$. The Hambo transform of $G(z)$ can be calculated with (5.2), using that $N(\lambda) = \frac{1+a\lambda}{\lambda+a}$. This results in a noncausal $\widetilde{G}(\lambda) = \frac{\lambda-a}{1+a^2}$. So, while the Hambo transform is still well defined, the state space formulas cannot be used as is.

Realization. In [37, 8, 7], the problems of exact and partial realization in terms of Hambo functions have been solved. This concerns the situation where a sequence of expansion coefficients $\{\breve{g}(k), k = 1, \ldots, N\}$ is given and a system $G(z)$ of minimal degree is sought such that the first N expansion coefficients of $G(z)$ coincide with the given set. Such a situation typically arises in an identification setting, as described in [39]. In fact, the state space relations described in section 5.3 are a direct spin-off of this research.

Frequency warping. The variable substitution of (5.3) is sometimes referred to as a *frequency transformation*, as it maps $\mathbb{T}$ to $\mathbb{T}$. With $z = e^{i\omega}$ and $\lambda = e^{i\vartheta}$, it holds that this transformation, defined as $\vartheta = \beta(\omega)$, constitutes a continuously differentiable nondecreasing (hence bijective) mapping from $\omega \in [0, 2\pi)$ to $\vartheta \in [0, 2n_b\pi)$. The properties of this β mapping, and in particular its inverse β^{-1}, are analyzed in [35], where it is used in a frequency domain approach to Hambo basis function modelling. A discrete set of equidistantly distributed frequency points in the ϑ domain is mapped by β^{-1} to a nonequidistantly distributed set of frequency points in the ω domain. This frequency distortion, or "warping" property, is exploited in [41] for the case $n_b = 1$ to enable the application of the fast Fourier transform (FFT) algorithm to nonuniformly spaced samples of a discrete time Fourier transform (DTFT).

(Future) applications. The theory on Hambo transforms proved to be a powerful tool in the derivation of variance expressions for identification in terms of orthogonal basis functions [39]. Furthermore, as stated before, this theory has been instrumental in the derivation of approximate realization algorithms that are based on expansions in orthonormal basis functions. In [7] it is shown that these algorithms can also be used to solve certain classes of interpolation problems. Other promising future directions for use of the transform theory are, for instance, the application of system identification in the transform domain, extending the results of [40, 11, 10], and control design in the transform domain, utilizing the property that any linear system can be transformed into a system with all poles located at the origin.

8. Conclusions. In this paper, we have analyzed a signals and systems transform that is induced by the Hambo functions. These functions, which are a special

case of the Takenaka–Malmquist functions, are induced by the balanced states of scalar inner (stable all-pass) functions and encompass the classical pulse, Laguerre, and Kautz functions. The induced signals and systems transforms generalize the Z-transform and the Laguerre transform to a multidimensional representation. The transforms have been analyzed in detail, providing insight into their structural properties. Explicit and efficient algorithms have been provided that enable the calculation of minimal state space realizations of the operator transform and its inverse.

WHEN IS A STORAGE FUNCTION A STATE FUNCTION IN DISCRETE TIME?*

OSAMU KANEKO† AND TAKAO FUJII†

Abstract. The purpose of this paper is to investigate when a storage function is a state function *in discrete time*. As shown by Trentelman and Willems [*Systems Control Lett.*, 32 (1997), pp. 249–259], [*SIAM J. Control Optim.*, 36 (1998), pp. 1703–1749], every storage function is a state function in continuous time. At first glance, the same claim seems to hold also in discrete time. Contrary to this expectation, this is not true in general. In fact, the discrete time counterpart involves not only some different but also some more difficult issues compared with the continuous time case. This paper addresses these issues exactly and shows that every nonnegative storage function is a state function of a supply rate with a linear time-invariant dynamical system in discrete time.

Key words. dissipativeness, storage functions, state functions, discrete time, quadratic difference forms, two-variable polynomial matrices, behavioral approach, polynomial matrices

1. Introduction. Dissipativeness is one of the most important properties in dynamical systems (cf. [1], [2], [10], [14], [15], [16], [17], [23], [24]). The reason for this is that various important system characteristics, such as bounded realness, positive realness, and so on, can be formalized as dissipativeness. Intuitively, dissipativeness means that a dynamical system always dissipates energy at a *dissipation rate* for a given supplied power called a *supply rate*. This is equivalent to saying that an increase in stored energy, called a *storage function*, cannot exceed the supplied power. A storage function measures the amount of energy that is stored inside the system at any instant of time. Thus it is reasonable to expect that a storage function can be described by using an internal variable that stores the information of past trajectories, that is, state variables. In the standard system theory, it is presumed that *a storage function is described by a quadratic function of state variables.* By using such a static quadratic form, control system synthesis and analysis based on dissipativeness can be reduced to solve certain linear matrix inequalities, or equalities, which can be handled easily by numerical computations. From a theoretical point of view, the above presumption should be proved. In this connection, Trentelman and Willems proved the fundamental fact based on quadratic differential forms in [10] and [23] that *every storage function is a state function.* This result is very interesting in that the proof is self-contained via quadratic differential forms in a behavioral framework. Furthermore, this result has been used to develop various applications of dissipativeness via quadratic differential forms, for instance the generalized Pick matrix condition for halfline nonnegativity (cf. [23]), H^∞ control in a behavioral context (cf. [11]), J-spectral factorization (cf. [13]), deterministic Kalman filtering (cf. [3]), H^∞ filtering (cf. [12]), the KYP lemma, and so on. Similarly to the standard system theory, these applications are very effective for synthesizing desired systems or

filters in a behavioral framework. In view of the fact that the behavioral approach is more general than the standard systems approach, these applications are also useful in more generalized settings.

The above types of results for dissipativeness are usually obtained in continuous time. The discrete time version of dissipativeness also plays a crucial role, since it is used to derive various synthesis and analysis tools for discrete time systems. In particular, the filtering problems are included in specific topics in discrete time. The reason for this is that filters are used to obtain desired signals from noisy discrete time data. If we can develop discrete time dissipativeness, it may enable us, as in the continuous time case (cf. [3], [12]), to obtain useful filtering algorithms which are applicable to the actual discrete time data in a behavioral framework. Moreover, interpolation problems like Nevanlinna–Pick are also deeply related to discrete time dissipativeness. In fact, Rapisarda and Willems considered subspace Nevanlinna–Pick interpolation problems and derived the most powerful unfalsified model based on dissipativeness and quadratic differential forms in continuous time (cf. [9]). The notion of the most powerful unfalsified model is also a topic relevant to discrete time data. Thus, discrete time dissipativeness will be useful for solving discrete time interpolation problems and obtaining effective algorithms applicable to actual data.

From this motivation, the authors suggested quadratic difference forms in [5] in order to develop discrete time dissipativeness. Although we derived basic properties there, many important properties that should be clarified still remain to be studied. In general, some of the important results in the continuous time case can be easily connected to those in the discrete time case (cf. [1], [6]). It is, however, probable that there do exist some differences in other important results related to dissipativeness between the continuous and the discrete time cases. From a theoretical point of view, they must be clarified. The relationship between states and storage functions is one such topic. In the continuous time case, as stated above, Trentelman and Willems have shown in [10] and [23] that every storage function is a state function. At first glance, it seems easy to prove that every storage function is a state function in discrete time in a similar way as in the continuous time case. If this is true, many applications of discrete time dissipativeness can be developed. The fact is, however, that every storage function is not always a state function in discrete time, as shown by a counterexample in section 4. There may be not only different issues from the continuous time case but also even more difficult issues. This paper addresses such issues by clarifying when a storage function is a state function in discrete time. With regard to this problem, we show that every *nonnegative* storage function is a static quadratic function of any state variable of a given dynamical system augmented with a given supply rate in discrete time. Similarly to the continuous time case, various applications of discrete time dissipativeness involve conditions on storage functions. Therefore, the results in this paper enable us to obtain more treatable conditions. Moreover, our results are obtained using only quadratic difference forms and some materials within behavioral system theory. Their derivations are thus self-contained in a behavioral framework, and hence interesting and meaningful from a theoretical point of view.

This paper is organized as follows. In section 2, some pertinent facts related to discrete time dynamical systems and quadratic difference forms are prepared by using the results obtained in [5], [7], [8], [10], [21], [22], and [23]. In section 3, the basic properties of discrete time dissipativeness are explained and the existence of extremal storage functions is shown for a certain class of supply rates, which is used as a lemma

to prove our main result. In section 4, we explain the problem we are trying to attack here. We then provide an illustrative example to demonstrate that *not* every storage function is a storage function for a given supply rate in discrete time. In section 5, we provide a sufficient condition for a storage function to be a state function by showing that *every nonnegative storage function is a state function in discrete time.* We also provide another sufficient condition on dissipation rates. Since the nonnegativity of storage functions is a key concept in this paper, we derive a necessary and sufficient condition for the existence of nonnegative storage functions as well as that for a storage function to be nonnegative in section 6. In section 7, we apply the results obtained in the previous sections to a more general case. Concluding remarks and open issues are stated in section 8. Notations and a brief review of behavioral system theory are given in Appendices A and B, respectively. The detailed proofs of theorems are shown in Appendix C.

2. Preliminaries.

2.1. Discrete time dynamical systems and state functions. In this paper, we assume that a dynamical system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ is linear, time-invariant, complete, and controllable. We note that Σ is controllable if and only if $\mathfrak{B}$ can be represented by

$$w = M(\sigma)\ell, \tag{1}$$

where $M(\xi) \in \mathbb{R}^{q\times d}[\xi]$. Here, ℓ is observable from w if and only if $M(\lambda)$ is full column rank for all $\lambda \in \mathbb{C}$. In the following, we give a necessary and sufficient condition for a given $f = F(\sigma)\ell$ to be a state function of a system represented by (1).

PROPOSITION 2.1. *Let $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ denote a controllable dynamical system and* (1) *be an image representation of $\mathfrak{B}$. Assume that $M(\lambda)$ is full column rank for all $\lambda \in \mathbb{C}$, which implies that there exists a partition of $M(\xi)$ into $M(\xi) = col\big[\, U(\xi), \quad Y(\xi)\,\big]$ such that $U(\xi)$ is nonsingular and $Y(\xi)U(\xi)^{-1}$ is proper, possibly after permuting the components of w appropriately and, accordingly, the rows of $M(\xi)$. Let $\mathfrak{B}_s$ denote the full behavior of a minimal state space system whose manifest behavior is $\mathfrak{B}$. Let $F(\xi) \in \mathbb{R}^{\bullet\times d}[\xi]$ induce $f = F(\sigma)\ell$, and consider the following new image representation*:

$$\operatorname{col}\begin{bmatrix} w, & f \end{bmatrix} = \operatorname{col}\begin{bmatrix} M(\sigma), & F(\sigma) \end{bmatrix}\ell.$$

Let $\mathfrak{B}_{ext}$ be the manifest behavior of the above image representation. Then, there exists a real constant matrix H such that $f = Hx$ for all f and x for which there exists $w \in \mathfrak{B}$ such that $(w, f) \in \mathfrak{B}_{ext}$ and $(w, x) \in \mathfrak{B}_s$ if and only if $F(\xi)U(\xi)^{-1}$ is strictly proper.

Proof. The statement is straightforward from the continuous time case in section 8 in [8] and Theorem 5.2 in [10]. □

2.2. Quadratic difference forms and two-variable polynomial matrices. Quadratic difference forms are appropriate mathematical tools related to discrete time dissipativeness. They are used throughout this paper, so here we briefly introduce some necessary definitions and properties. See [23] and [5] for more details of the continuous time case and the discrete time case, respectively.

An element of $\mathbb{R}^{p\times q}[\zeta, \eta]$ is given by

$$\Phi(\zeta, \eta) = \sum_{k,l=0} \Phi_{kl}\zeta^k\eta^l. \tag{2}$$

The sum in (2) ranges over nonnegative integers and is assumed to be finite, and $\Phi_{kl} \in \mathbb{R}^{q\times q}$. For $\Phi(\zeta,\eta) \in \mathbb{R}^{p\times q}[\zeta,\eta]$, let $\mathbb{R}_s^{q\times q}[\zeta,\eta]$ denote the set of two-variable polynomial matrices satisfying $\Phi(\zeta,\eta) = \Phi(\eta,\zeta)^T$. For all $w \in (\mathbb{R}^q)^Z$, $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ induces a quadratic difference form $Q_\Phi : (\mathbb{R}^q)^Z \mapsto \mathbf{R}^Z$ as defined by

$$Q_\Phi(w)(t) := \sum_{k,l=0} w(t+k)^T \Phi_{kl} w(t+l).$$

Given $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$, by replacing the indeterminates ζ and η with ξ^{-1} and ξ, respectively, we obtain a one-variable dipolynomial matrix $\Phi(\xi^{-1},\xi) \in \mathbb{R}^{q\times q}[\xi^{-1},\xi]$.

For a given arbitrary $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$, we define the following infinite matrix:

$$\tilde{\Phi} := \begin{bmatrix} \Phi_{0,0} & \Phi_{0,1} & \cdots & \Phi_{0,l} & \cdots \\ \Phi_{0,1}^T & \Phi_{1,1} & \cdots & \Phi_{0,l} & \cdots \\ \vdots & & & \vdots & \\ \Phi_{k,0} & & \cdots & \Phi_{k,l} & \cdots \\ \vdots & & & \vdots & \end{bmatrix}.$$

Here all but a finite number of the elements of $\tilde{\Phi}$ are zero. Since we concentrate on the finite nonzero block of $\tilde{\Phi}$ in this paper, we regard $\tilde{\Phi}$ as an element of $\mathbb{R}^{q(N(\Phi)+1)\times q(N(\Phi)+1)}$, where $N(\Phi) := \min\{n' \in \mathbb{Z} \text{ such that } \Phi_{kl} = 0, \forall k \text{ and } l > n'\}$. We call $\tilde{\Phi}$ the coefficient matrix of $\Phi(\zeta,\eta)$.

In a similar way to the constant symmetric matrix case, the nonnegativity and the positivity of a quadratic difference form induced by $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ are defined by

$$\Phi(\zeta,\eta) \geq 0 :\Leftrightarrow Q_\Phi(w)(t) \geq 0 \ \ \forall w \in (\mathbb{R}^q)^Z \text{ and } \forall t \in Z$$

and

$$\Phi(\zeta,\eta) > 0 :\Leftrightarrow \Phi(\zeta,\eta) \geq 0 \text{ and } Q_\Phi(w) = 0 \Rightarrow w = 0,$$

respectively. It follows from Proposition 2.1 in [5] that $\Phi(\zeta,\eta) \geq 0$ is equivalent to $\tilde{\Phi} \geq 0$.

For $\Phi(\zeta,\eta) = \sum_{k,l=0}^{N(\Phi)} \Phi_{kl}\zeta^k\eta^l \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$, factorize $\tilde{\Phi} = \tilde{M}^T\Sigma_\Phi\tilde{M}$ such that $\tilde{M} \in \mathbb{R}^{\bullet\times q(N(\Phi)+1)}$ is full row rank and $\det(\Sigma_\Phi) \neq 0$, i.e., $\operatorname{rank}(\Sigma_\Phi) = \operatorname{rank}(\tilde{\Phi})$. With such a factorization of $\tilde{\Phi}$, we obtain a canonical factorization (cf. [10], [23]) of $\Phi(\zeta,\eta)$ as

$$\Phi(\zeta,\eta) = M(\zeta)^T\Sigma_\Phi M(\eta), \tag{3}$$

where $M(\xi) := \tilde{M}\operatorname{col}\begin{bmatrix} I, & \xi I, & \ldots, & \xi^{n-1}I, & \xi^n I \end{bmatrix} \in \mathbb{R}^{\bullet\times q}[\xi]$. We call $M(\xi)$ a canonical factor of $\Phi(\zeta,\eta)$. Note that $\Phi(\zeta,\eta)$ has many canonical factors, and all of them can be obtained from one canonical factor by replacing $M(\xi)$ by $PM(\xi)$, where P is a nonsingular matrix such that $\Sigma_\Phi = P^T\Sigma_\Phi P$. Moreover, for an arbitrary canonical factor $M(\xi)$ and an arbitrary factor, say $M'(\xi)$, which is not necessarily a canonical factor, it is easy to show that there exists a constant matrix L such that $M(\xi) = LM'(\xi)$.

For our last point, we explain the observability of a quadratic difference form. Let $\Phi(\zeta,\eta) = M(\zeta)^T\Sigma_\Phi M(\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ denote a canonical factorization. It is easy to show that if one canonical factor is full column rank for all $\lambda \in \mathbb{C}$, then the other canonical factors are also full column rank for all $\lambda \in \mathbb{C}$. In view of this fact, we call $\Phi(\zeta,\eta)$ *observable* if a canonical factor is observable.

3. Discrete time dissipativeness. First, we can regard Q_Φ induced by $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ as the power entering into the physical system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$. The reason for this is that the power can be described by characterizing a quadratic expression involving system variables and shifted variables. By using quadratic difference forms, we can formalize dissipativeness of dynamical systems in discrete time as follows (cf. Definition 3.1 in [5], Definition 4.2 in [10], and Definition 5.1 in [23]).

DEFINITION 3.1. *Let $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ induce a supply rate Q_Φ.*

1. *$\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ is said to be dissipative for Q_Φ if $\sum_{t=-\infty}^{t=\infty} Q_\Phi(w)(t) \geq 0$ for all $w \in \mathfrak{B} \bigcap l_2^q$.*
2. *Q_Ψ induced by $\Psi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ is said to be a storage function for Q_Φ and $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ if $Q_\Psi(w)(t+1) - Q_\Psi(w)(t) \leq Q_\Phi(w)(t)$ (called a dissipation inequality) holds for all $t \in \mathbb{Z}$ and for all $w \in \mathfrak{B}$.*
3. *Q_Δ induced by $\Delta(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ is said to be a dissipation rate for Q_Φ and $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ if $\sum_{t=-\infty}^{t=\infty} Q_\Phi(w)(t) = \sum_{t=-\infty}^{t=\infty} Q_\Delta(w)(t)$ and $Q_\Delta(w)(t) \geq 0$ for all $t \in \mathbb{Z}$ and for all $w \in \mathfrak{B} \bigcap l_2^q$.*

In the case of $\mathfrak{B} = (\mathbb{R}^q)^Z$, it follows from Lemma 3.1 in [5] that $\sum_{t=-\infty}^{t=\infty} Q_\Phi(w)(t) = \sum_{t=-\infty}^{t=\infty} Q_\Delta(w)(t)$ for all $w \in l_2^q$ is equivalent to the condition

$$\Phi(\lambda^{-1}, \lambda) = \Delta(\lambda^{-1}, \lambda) \tag{4}$$

for all nonzero $\lambda \in \mathbb{C}$.

Another important notion is "lossless," which means that the power supplied to the system can be stored as an increase of the internal energy of the system without dissipation.

DEFINITION 3.2. *$\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ is said to be lossless for a supply rate Q_Φ induced by $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ if $\sum_{t=-\infty}^{t=\infty} Q_\Phi(w)(t) = 0$ for all $w \in \mathfrak{B} \bigcap l_2^q$.*

The next theorem gives an interrelation between a supply rate, a storage function, and a dissipation rate (cf. Proposition 3.3 in [5], Theorem 4.3 in [10], and Proposition 5.2 in [23]).

THEOREM 3.3. *Let $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ induce a supply rate Q_Φ. Assume that a dynamical system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ has an image representation $w = W(\sigma)\ell$, where $W(\lambda) \in \mathbb{R}^{q\times\bullet}[\lambda]$is full column rank for all $\lambda \in \mathbb{C}$. Then, the following four conditions are equivalent.*

1. *For all $w \in l_2^q \bigcap \mathfrak{B}$, $\sum_{t=-\infty}^{\infty} Q_\Phi(w)(t) \geq 0$.*
2. *$W(e^{-j\omega})^T \Phi(e^{-j\omega}, e^{j\omega}) W(e^{j\omega}) \geq 0$ for all $\omega \in [0, 2\pi)$.*
3. *Q_Φ and $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ admit a storage function.*
4. *Q_Φ and $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ admit a dissipation rate.*

Moreover, for the supply rate Q_Φ, the following one-one relation holds between storage functions Q_Ψ induced by $\Psi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ and dissipation rates Q_Δ induced by $\Delta(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$:

$$Q_\Psi(w)(t+1) - Q_\Psi(w)(t) = Q_\Phi(w)(t) - Q_\Delta(w)(t) \tag{5}$$

for all time $t \in \mathbb{Z}$ and $w \in \mathfrak{B}$ or, equivalently,

$$(\zeta\eta - 1) W(\zeta)^T \Psi(\zeta,\eta) W(\eta) = W(\zeta)^T \Phi(\zeta,\eta) W(\eta) - W(\zeta)^T \Delta(\zeta,\eta) W(\eta). \tag{6}$$

In the case of $\Sigma = (\mathbb{Z}, \mathbb{R}^q, (\mathbb{R}^q)^Z)$, (5) holds for all $w \in (\mathbb{R}^q)^Z$ and (6) is described by

$$(\zeta\eta - 1)\Psi(\zeta,\eta) = \Phi(\zeta,\eta) - \Delta(\zeta,\eta). \tag{7}$$

Here, we introduce some notation. For a supply rate Q_Φ induced by $\Phi(\zeta,\eta)$, we define

$$\mathcal{S}(\Phi) := \{\Psi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta] \mid Q_\Psi \text{ induced by } \Psi(\zeta,\eta) \text{ is a storage function for } Q_\Phi \text{ and } \Sigma = (\mathbb{Z},\mathbb{R}^q,(\mathbb{R}^q)^Z)\}$$

and

$$\mathcal{D}(\Phi) := \{\Delta(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta] \mid Q_\Delta \text{ induced by } \Delta(\zeta,\eta) \text{ is a dissipation rate for } Q_\Phi \text{ and } \Sigma = (\mathbb{Z},\mathbb{R}^q,(\mathbb{R}^q)^Z)\}.$$

Next, for a fixed $\Delta(\zeta,\eta) \in \mathcal{D}(\Phi)$, let $\Psi(\Phi,\Delta)$ denote a two-variable polynomial matrix inducing the storage function corresponding to the dissipation rate induced by $\Delta(\zeta,\eta)$ for Q_Φ and Σ. Similarly, for a fixed $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$, let $\Delta(\Phi,\Psi)$ denote a two-variable polynomial matrix inducing the dissipation rate corresponding to the storage function induced by $\Psi(\zeta,\eta)$ for Q_Φ and Σ.

Finally, we present the following theorem on the existence of extremal storage functions. This is not only a preparation of the proof of our main results (detailed discussions are given in the proof of Theorem 5.1) but also the self-standing important result.

THEOREM 3.4. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce a supply rate Q_Φ for $\Sigma = (\mathbb{R},\mathbb{R}^q,(\mathbb{R}^q)^Z)$. Assume that $\Phi(e^{-j\omega},e^{j\omega}) > 0$ for all $\omega \in [0,2\pi)$. Then, there exist $\Psi^+(\zeta,\eta)$ and $\Psi^-(\zeta,\eta) \in \mathcal{S}(\Phi)$ satisfying $\Psi^-(\zeta,\eta) \le \Psi(\zeta,\eta) \le \Psi^+(\zeta,\eta)$ for any other $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. In addition, $\Psi^+(\zeta,\eta)$ and $\Psi^-(\zeta,\eta)$ are expressed by $\Psi^+(\zeta,\eta) = (\Phi(\zeta,\eta) - A(\zeta)^T A(\eta))/(\zeta\eta - 1)$ and $\Psi^-(\zeta,\eta) = (\Phi(\zeta,\eta) - H(\zeta)^T H(\eta))/(\zeta\eta - 1)$. Here $A(\xi)$ and $H(\xi)$ are spectral factors of $\Phi(\xi^{-1},\xi)$ such that $\Phi(\xi^{-1},\xi) = A(\xi^{-1})^T A(\xi) = H(\xi^{-1})^T H(\xi)$ and, moreover, $\det(A(\xi))$ is anti-Hurwitz and $\det(H(\xi))$ is Hurwitz.*

Proof. See Appendix C. □

4. Problem formulation. In the following sections, we treat a quadratic supply rate Q_Φ induced by $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ and a (trivial) dynamical system $\Sigma = (\mathbb{Z},\mathbb{R}^q,(\mathbb{R}^q)^Z)$ for the purpose of simplifying discussions. In section 7, we show that simple modifications of discussions for the case of $\mathfrak{B} = (\mathbb{R}^q)^Z$ yield similar results in the case where $\mathfrak{B}$ can be described by an image representation $w = W(\sigma)\ell$.

First, we define a dynamical system induced by $\Phi(\zeta,\eta)$ and $\Sigma = (\mathbb{Z},\mathbb{R}^q,(\mathbb{R}^q)^Z)$ as

$$\Sigma_{supply} := (\mathbb{Z},\mathbb{R}^r,\mathrm{Im}(M(\sigma))),$$

where $M(\xi) \in \mathbb{R}^{r\times q}[\xi]$ is obtained from a canonical factorization $\Phi(\zeta,\eta) = M(\zeta)^T \Sigma_\Phi \times M(\eta)$, and $r := \mathrm{rank}(\Sigma_\Phi)$. In other words, the manifest behavior of Σ_{supply} can be described by an image representation $v = M(\sigma)w$ (we should note from the definition of Σ_{supply} that manifest variables "w" of Σ are regarded as latent variables of Σ_{supply}). Let $\mathfrak{B}_{\Phi,s}$ denote the full behavior of a minimal state space system whose manifest behavior is $\mathrm{Im}(M(\sigma))$. Under this setting, for $\Psi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$, we investigate whether there exists a constant matrix $K = K^T \in \mathbb{R}^{\bullet\times\bullet}$ such that $(M(\sigma)w,x) \in \mathfrak{B}_{\Phi,s}$ implies $Q_\Psi(w) = x^T K x$. We denote the set of two-variable polynomial matrices inducing quadratic state functions of Σ_{supply} by

$$\mathcal{F}_s(\Phi) := \{\Psi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta] \mid \exists K = K^T \in \mathbb{R}^{\bullet\times\bullet} \text{ such that } (M(\sigma)w,x) \in \mathfrak{B}_{\Phi,s} \text{ implies } Q_\Psi(w) = x^T K x\}. \tag{8}$$

For any state x there exists a constant matrix H such that Hx is a minimal state (cf. Proposition 7.10 in [22]); thus $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$ implies that Q_Ψ can also be described by a quadratic function of any state variables of Σ_{supply}.

Under the above preparations, the problem we attack in this study is formulated as follows.

PROBLEM 4.1. *Let* $\Phi(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ *induce a supply rate, and consider* $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. *When is* $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$ *in discrete time?*

Next, we make a comparison between the continuous and the discrete time cases. Let $\Psi(\zeta,\eta) = F(\zeta)^T\Sigma_\Psi F(\eta)$ and $\Delta(\zeta,\eta) = D(\zeta)^T D(\eta)$ denote canonical factorizations of two-variable polynomial matrices inducing a storage function and a dissipation rate, respectively. In continuous time, the dissipation equation can be described by

$$(\zeta+\eta)\Psi(\zeta,\eta) = \Phi(\zeta,\eta) - \Delta(\zeta,\eta) \tag{9}$$

(cf. Theorem 4.3 in [10]). To prove that a storage function is a state function, it suffices to show that $F(\xi)U(\xi)^{-1}$ is strictly proper in the case where $\Phi(\zeta,\eta)$ is observable (cf. Theorem 6.1 in [10]). First, by setting $\zeta = -\xi$ and $\eta = \xi$, (9) can be described by $M(-\xi)\Sigma_\Phi M(\xi) = D(-\xi)^T D(\xi)$. Next, premultiplying and postmultiplying it by $U(-\xi)^{-T}$ and $U(\xi)^{-1}$, respectively, we can see that $U(-\xi)^{-T}D(\xi)^T D(\xi)U(\xi)^{-1}$ is proper, which implies that $D(\xi)U(\xi)^{-1}$ is also proper. By using this properness and (9), we can also see that $U(\zeta)^{-T}F(\zeta)^T\Sigma_\Psi F(\eta)U(\eta)^{-1}$ is strictly proper with respect to ζ and η. It then follows from Theorem 6.1 in [10] that every storage function is a state function. Of course, even if $M(\xi)$ is not observable, the same property holds (cf. Theorem 6.1 in [10]). In discrete time, by using Theorem 3.3 and (4), the dissipation equation (7) can be described by $M(\xi^{-1})^T\Sigma_\Phi M(\xi) = D(\xi^{-1})^T D(\xi)$, which yields $U(\xi^{-1})^{-T}M(\xi^{-1})^T\Sigma_\Phi M(\xi)U(\xi)^{-1} = U(\xi^{-1})^{-T}D(\xi^{-1})^T D(\xi)U(\xi)^{-1}$. Here we should note that, unlike the continuous time case, the properness of $U(\xi^{-1})^{-T}D(\xi^{-1})^T \times D(\xi)U(\xi)^{-1}$ does not necessarily imply that of $D(\xi)U(\xi)^{-1}$. Hence, $U(\zeta)^{-T}F(\zeta)^T\Sigma_\Psi \times F(\eta)U(\eta)^{-1}$ is not necessarily proper with respect to ζ and η. In fact, we can give a simple counterexample as follows.

Example 4.1. Consider a supply rate induced by

$$\Phi(\zeta,\eta) = 1+\zeta+\eta+2\zeta\eta \tag{10}$$

and a dynamical system $\Sigma = (\mathbb{Z},\mathbb{R},\mathbb{R}^Z)$. One canonical factorization of $\Phi(\zeta,\eta)$ is given by $\Phi(\zeta,\eta) = M(\zeta)^T\Sigma_\Phi M(\eta)$, where $M(\xi) :=\mathrm{col}\begin{bmatrix} 1+\xi, & \xi \end{bmatrix}$ and $\Sigma_\Phi := I_2$. Defining $U(\xi) := 1+\xi$ enables us to observe that $M(\xi)U(\xi)^{-1}$is proper. Moreover, $(M(\xi^{-1})U(\xi^{-1}))^T$ is also proper, so $U(\xi^{-1})^{-T}\Phi(\xi^{-1},\xi)U(\xi)^{-1}$ is proper. Note that $u := U(\sigma)w = (1+\sigma)w$ is an input variable of $\Sigma_{supply} = (\mathbb{Z},\mathbb{R},\mathrm{Im}(M(\sigma)))$, with w being a latent variable of Σ_{supply}. Moreover, by taking $f = w$ in Proposition 2.1, we can see that w is a state variable of Σ_{supply}.

Here, as one $\Delta(\zeta,\eta)$ in $\mathcal{D}(\Phi)$, we can take $\Delta(\zeta,\eta) = 1+\zeta+\eta+\zeta\eta+\zeta^3\eta^3$. One canonical factorization of it is given by $\Delta(\zeta,\eta)=D(\zeta)^T D(\eta)$, where $D(\xi) :=\mathrm{col}[1+\xi, \xi^3]$.

It is clear that $D(\xi)U(\xi)^{-1}$ is not proper, while $U(\xi^{-1})^{-T}\Delta(\xi^{-1},\xi)U(\xi)^{-1}$ is proper. By using (7), $\Psi(\zeta,\eta) := \Psi(\Phi,\Delta)$ can be described by $\Psi(\zeta,\eta) = -\zeta\eta - \zeta^2\eta^2$. One canonical factorization of it is given by $\Psi(\zeta,\eta) = F(\zeta)^T\Sigma_\Psi F(\eta)$, where $F(\xi) :=\mathrm{col}[\xi,\xi^2]$, and $\Sigma_\Psi := -I_2$. Clearly, $F(\xi)U(\xi)^{-1} = \mathrm{col}[\frac{-1}{\xi+1}+1, \frac{1}{\xi+1}-(1-\xi)]$ is not strictly proper. Thus, it follows from Proposition 2.1 that $F(\sigma)w$ cannot be described by a static function of a state x. In addition, $F(\sigma)w$ can be written by

$F(\sigma)w = \mathrm{col}\begin{bmatrix} -x+u,\ x-(1-\sigma)u \end{bmatrix}$, implying $Q_\Psi(w) = -(-x+u)^2 - (x-(1-\sigma)u)^2$. Hence, we can see that $\Psi(\zeta,\eta) \notin \mathcal{F}_s(\Phi)$, which means that this storage function Q_Ψ cannot be described by a static quadratic function of a state x of Σ_{supply}.

5. Sufficient conditions for a storage function to be a state function. In this section, we show the sufficient conditions for Problem 4.1 as the main results of this paper. First, we give a sufficient condition for Problem 4.1 related to nonnegative storage functions.

THEOREM 5.1. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce a supply rate Q_Φ. Assume that $\Phi(\zeta,\eta)$ is observable. Consider $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. If $\Psi(\zeta,\eta) \geq 0$, then $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$.*

Proof. See Appendix C. □

Remark 5.1. We should consider the relationship between Theorem 5.1 and related studies on discrete time dissipativeness. In [2] (see also [1]), the notion of dissipative scattering (or passive scattering, respectively) was introduced as a particular dissipativeness and defined by $\|u(t)\|^2 - \|y(t)\|^2 \geq \|x(t+1)\|^2 - \|x(t)\|^2, (t \geq 0)$, where $u(t)$, $y(t)$, and $x(t)$ are inputs, outputs, and *states*, respectively, of the dynamical system described by $x(t+1) = Ax(t) + Bu(t)$, $y(t) = Cx(t) + Du(t)$. This inequality is a specific example of the dissipation inequality stated in Definition 3.1. In this special class of dissipativeness, a nonnegative state function was used as a starting point to characterize the storage function. Accordingly, Theorem 5.1 guarantees the validity of this notion of dissipative scattering based on the standard state space representation.

We give an example validating Theorem 5.1 as follows.

Example 5.1. Again, consider the supply rate Q_Φ induced by (10). In view of Theorem 5.1, we can take $\Psi(\zeta,\eta) = \frac{1}{2} = F(\zeta)^T F(\eta) \geq 0$, where $F(\xi) := \frac{1}{\sqrt{2}}$. Since $F(\xi)U(\xi)^{-1} = 1/(\sqrt{2}(1+\xi))$ is strictly proper, it follows from Proposition 2.1 that $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$.

Next, we give another sufficient condition for Problem 4.1 by imposing a certain assumption on dissipation rates.

THEOREM 5.2. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce a supply rate Q_Φ. Assume that $\Phi(\zeta,\eta)$ is observable. For this supply rate, consider $\Delta(\zeta,\eta) \in \mathcal{D}(\Phi)$. Assume that*

$$\mathrm{rank}(\tilde{\Delta}) = \mathrm{rank}(\Delta(0,0)), \tag{11}$$

where $\tilde{\Delta}$ is the coefficient matrix of $\Delta(\zeta,\eta)$. Then $\Psi(\Phi,\Delta) \in \mathcal{F}_s(\Phi)$.

Proof. See Appendix C. □

The following example also illustrates that a storage function whose corresponding dissipation rate satisfies the rank condition (11) is a state function.

Example 5.2. Again, consider the supply rate Q_Φ induced by (10). In view of Theorem 5.2, we can take $\Delta(\zeta,\eta) = \frac{3+\sqrt{5}}{2} + \zeta + \eta + \frac{3-\sqrt{5}}{2}\zeta\eta$ as one element of $\mathcal{D}(\Phi)$. One of the canonical factorizations of $\Delta(\zeta,\eta)$ is given by $\Delta(\zeta,\eta) = D(\zeta)^T D(\eta)$, where $D(\xi) := \frac{\sqrt{5}+1}{2} + \frac{\sqrt{5}-1}{2}\xi$. It is easy to verify that (11) holds and $D(\xi)U(\xi)^{-1}$ is proper. By using (7), $\Psi(\zeta,\eta) := \Psi(\Phi,\Delta)$ can be described by $\Psi(\zeta,\eta) = \frac{1+\sqrt{5}}{2} = F(\zeta)^T \Sigma_\Psi F(\eta)$, where $F(\xi) := \sqrt{\frac{1+\sqrt{5}}{2}}$ and $\Sigma_\Psi = 1$. Since $F(\xi)U(\xi)^{-1} = \sqrt{\frac{1+\sqrt{5}}{2}}(1+\xi)^{-1}$ is strictly proper, it follows from Proposition 2.1 that $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$.

It follows from Proposition 3.2 in [5] that a dissipation rate is equal to zero in the discrete time lossless case. In this case, (11) holds automatically. Thus, we obtain the following theorem.

THEOREM 5.3. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce a supply rate Q_Φ. Assume that $\Sigma = (\mathbb{Z}, \mathbb{R}^q, (\mathbb{R}^q)^Z)$ is lossless for Q_Φ and $\Phi(\zeta,\eta)$ is observable. Then $\mathcal{S}(\Phi) \subseteq \mathcal{F}_s(\Phi)$.*

In other words, "every storage function is a state function in the discrete time lossless case." In the lossless case, the supplied power to the system can be stored as an increase of the internal energy of the system without dissipation.

Remark 5.2. For simplicity and conciseness, we have supposed that $\Phi(\zeta,\eta)$ is observable in the above three theorems. However, it is neither true in the observable case nor in the nonobservable case that a storage function is a function of the state. Thus, we need to mention the results in the nonobservable case. First, consider the case in which the rank of a canonical factor $M(\lambda)$ is invariant for all $\lambda \in \mathbb{C}$. Similarly to the proof of Theorem 6.1 in [10], we can show that the same results as in the above three theorems also hold in this case. Second, consider the case where we have no assumption about $\Phi(\zeta,\eta)$. Similarly to (8), define

$$\mathcal{F}_{sa}(\Phi) := \{\Psi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta] \mid \exists K = K^T \in \mathbb{R}^{\bullet\times\bullet} \text{ such that } ((M(\sigma)w, w), x) \in \mathfrak{B}_{\Phi,a,s} \text{ implies } Q_\Psi(w) = x^T K x\},$$

where $\mathfrak{B}_{\Phi,a,s}$ is the full behavior of a minimal state space system whose manifest behavior is $\mathrm{Ker}(\begin{bmatrix} I & -M(\sigma) \end{bmatrix})$. Then the same statement holds in each of the above three theorems without the observability assumption on $\Phi(\zeta,\eta)$ if we replace $\mathcal{F}_s(\Phi)$ with $\mathcal{F}_{sa}(\Phi)$. The proofs are omitted because of their similarity to those in the observable case as well as space limitations.

6. Existence of nonnegative storage functions. In Theorem 5.1, the existence of nonnegative storage functions is assumed, so we need to consider when there exists a nonnegative storage function for a given supply rate. The following theorem provides a solution to this problem.

THEOREM 6.1. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce a supply rate Q_Φ. Then, there exists a nonnegative storage function for Q_Φ if and only if $\sum_{t=-\infty}^{T} Q_\Phi(w)(t) \geq 0$ for all $T \in \mathbb{Z}$ and $w \in l_2^q$.*

Proof. See Appendix C. □

Next, we consider when a storage function is nonnegative.

THEOREM 6.2. *Let $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce a supply rate Q_Φ. Let $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. Then, Q_Ψ induced by $\Psi(\zeta,\eta)$ is nonnegative if and only if $\Delta(\zeta,\eta) := \Delta(\Phi,\Psi)$ satisfies $\sum_{t=-\infty}^{T} Q_\Phi(w)(t) \geq \sum_{t=-\infty}^{T} Q_\Delta(w)(t)$ for all $T \in \mathbb{Z}$ and $w \in l_2^q$.*

Proof. This equivalence relation follows immediately by summing the dissipation equation of (5) along $w \in l_2$ from $-\infty$ to T. □

The above result means that the difference between the supplied energy to the system and the dissipated energy to its environment can be wholly stored as the internal net energy of the system. At the same time, a state indicates the internal status of the system. Thus, the above internal net energy should be described by a state function. Although Theorem 5.1 is a sufficient condition, we can observe that the statement of this theorem fits the above physical situation.

7. Discussions for a general case. In this section, we treat a general case; i.e., the behavior $\mathfrak{B}$ of a given dynamical system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ can be described by an image representation $w = W(\sigma)\ell$ with $W(\xi) \in \mathbb{R}^{q\times d}[\xi]$ and a latent variable $\ell \in (\mathbb{R}^d)^Z$. Let $\Phi(\zeta,\eta) = M(\zeta)^T \Sigma_\Phi M(\eta)$ denote a canonical factorization. In this section, let $\mathfrak{B}_{\Phi,s}$ denote the full behavior of a minimal state space system whose manifest behavior can be represented by $\{v = M(\sigma)w, w \in \mathfrak{B}\}$ (i.e., $\mathrm{Im}(M(\sigma)W(\sigma))$). Our aim in this section is to investigate whether a storage function for Q_Φ and Σ can be described by a static quadratic function of any state of $\mathfrak{B}_{\Phi,s}$. As in the proof of Theorem 6.2 in [10], we can apply the results and discussions for the case of $\mathfrak{B} = (\mathbb{R}^q)^Z$

in the previous sections to this case. The following lemma guarantees the validity of these applications.

LEMMA 7.1. *Define* $\hat{\Phi}(\zeta,\eta):=W(\zeta)^T\Phi(\zeta,\eta)W(\eta) \in \mathbb{R}^{d\times d}_s[\zeta,\eta]$. *Let* $\hat{M}(\zeta)^T\Sigma_{\hat{\Phi}}\hat{M}(\eta)$ *denote a canonical factorization of* $\hat{\Phi}(\zeta,\eta)$. *Let* $\mathfrak{B}_{\hat{\Phi},s}$ *denote the full behavior of a minimal state space system whose manifest behavior is* $\mathrm{Im}(\hat{M}(\sigma))$. *Consider* $\Psi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *and define* $\hat{\Psi}(\zeta,\eta) := W(\zeta)^T\Psi(\zeta,\eta)W(\eta)$. *If there exists a constant matrix* $K = K^T \in \mathbb{R}^{\bullet\times\bullet}$ *such that* $(\hat{M}(\sigma)\ell, x_m) \in \mathfrak{B}_{\hat{\Phi},s}$ *implies* $Q_{\hat{\Psi}}(\ell) = x_m^T K x_m$, *then there also exists a constant matrix* $K' = K'^T \in \mathbb{R}^{\bullet\times\bullet}$ *such that* $(M(\sigma)w, x) \in \mathfrak{B}_{\Phi,s}$ *implies* $Q_\Psi(w) = x^T K' x$.

Proof. This lemma can be shown by using the proof of Theorem 6.2 in [10], and hence the proof is omitted here. □

Clearly, if $\Psi(\zeta,\eta)$ induces a storage function for Q_Φ and $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathrm{Im}(M(\sigma)))$, then $\hat{\Psi}(\zeta,\eta)$ induces a storage function for $Q_{\hat{\Phi}}$ and a (trivial) dynamical system $\hat{\Sigma} := (\mathbb{Z}, \mathbb{R}^d, (\mathbb{R}^d)^{\mathbb{Z}})$. Note that $\hat{\Phi}(\zeta,\eta)$ and $\hat{\Sigma} = (\mathbb{Z}, \mathbb{R}^d, (\mathbb{R}^d)^{\mathbb{Z}})$ correspond to $\Phi(\zeta,\eta)$ and $\Sigma = (\mathbb{Z}, \mathbb{R}^q, (\mathbb{R}^q)^{\mathbb{Z}})$, respectively, in sections 4, 5, and 6. By Lemma 7.1 and these facts, it is sufficient to investigate whether a storage function $Q_{\hat{\Psi}}$ is described by a static quadratic function of any minimal state of $\mathfrak{B}_{\hat{\Phi},s}$. It is clear that $\Psi(\zeta,\eta) \geq 0$ implies $\hat{\Psi}(\zeta,\eta) \geq 0$. Together with Theorem 5.1, these observations show that if $\Psi(\zeta,\eta) \geq 0$, then Q_Ψ is a state function of this original supply rate Q_Φ with this dynamical system Σ. This result can be formalized as the following theorem, which corresponds to Theorem 5.1.

THEOREM 7.2. *Let* $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *induce a supply rate. Consider a dynamical system* $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathrm{Im}(W(\sigma)))$. *Let* $\Psi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *induce a storage function for* Q_Φ *and* Σ. *Assume that* $W(\zeta)^T\Phi(\zeta,\eta)W(\eta)$ *is observable. If* $\Psi(\zeta,\eta) \geq 0$, *then there exists a constant matrix* $K = K^T \in \mathbb{R}^{\bullet\times\bullet}$ *such that* $(M(\sigma)w, x) \in \mathfrak{B}_{\Phi,s}$ *implies* $Q_\Psi(w) = x^T K x$.

Remark 7.1. In the case where $W(\zeta)^T\Phi(\zeta,\eta)W(\eta)$ is not observable, it is sufficient for us to slightly change the statement of theorem, similarly to that of Theorem 5.1 as stated in Remark 5.2.

In connection with the existence of nonnegative storage functions, we have the following theorem that corresponds to Theorem 6.1. The proof is an immediate consequence of that of Theorem 6.1.

THEOREM 7.3. *Let* $\Phi(\zeta,\eta) \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *induce a supply rate* Q_Φ. *Consider a dynamical system* $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathrm{Im}(W(\sigma)))$. *Then, there exists a nonnegative storage function for* Q_Φ *and* Σ *if and only if* $\sum_{t=-\infty}^{T} Q_{W^T\Phi W}(\ell)(t) \geq 0$ *for all* $T \in \mathbb{Z}$ *and* $\ell \in l_2^d$.

Finally, the following theorem clarifies when a storage function is nonnegative, which corresponds to Theorem 6.2. The proof is also an immediate consequence of that of Theorem 6.2.

THEOREM 7.4. *Let* $\Phi(\zeta,\eta)$ *induce a supply rate* Q_Φ. *Consider a dynamical system* $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathrm{Im}(W(\sigma)))$. *Let* $\Psi(\zeta,\eta)$ *induce a storage function* Q_Ψ *for* Q_Φ *and* Σ. *Let* $\Delta(\zeta,\eta)$ *induce the dissipation rate corresponding to* Q_Ψ. *Then,* Q_Ψ *is nonnegative if and only if* $\Delta(\zeta,\eta)$ *satisfies* $\sum_{t=-\infty}^{T} Q_{W^T\Phi W}(\ell)(t) \geq \sum_{t=-\infty}^{T} Q_{W^T\Delta W}(\ell)(t)$ *for all* $T \in \mathbb{Z}$ *and* $\ell \in l_2^d$.

8. Conclusions. In this paper, for a given supply rate Q_Φ, we have investigated when a discrete time storage function is a state function of a given dynamical system augmented with a given supply rate. As the main solution to this problem, we have

shown that if a storage function is nonnegative, then it is also described by a static quadratic function of any state of the augmented system. In addition to this sufficient condition, we have also shown another sufficient condition for a storage function to be a state function. This condition is related to dissipation rates and guarantees that every storage function is a state function in the discrete time lossless case.

In our opinion, the above sufficient condition involving nonnegativities of storage functions can be connected with physical situations intuitively. Therefore, we conclude that every nonnegative storage function is a state function, and this finding is the most useful and interesting result of this paper. Since the conditions obtained in this paper are sufficient conditions, we must notice that a storage function satisfying the conditions neither in Theorem 5.1 nor in Theorem 5.2 may be a state function. However, the results of this paper will be useful for expanding the discrete time dissipation theory from both practical and theoretical viewpoints.

Further studies are as follows. First, we will derive not only sufficient conditions but also necessary conditions for a storage function to be a state function. Second, we will consider the physical meaning of the assumption on dissipation rates implied by (11). Third, we will study how Theorems 5.1 and 5.2 are related to each other. Finally, by using the results of the above investigations, we will develop various applications stated in section 1.

Appendix A. Notation. Let $\mathbb{Z}$, $\mathbb{R}$, and $\mathbb{C}$ denote the set of integers, real numbers, and complex numbers, respectively. Let $\mathbb{R}^q$ ($\mathbb{C}^q$) denote the set of real (complex, respectively) vectors of size q. For $\lambda \in \mathbb{C}$, $\bar{\lambda}$ denotes the conjugate of λ. For $a \in \mathbb{R}^q$, $\|a\|^2 := a^T a$. For $a \in \mathbb{C}^q$, a^* denotes the conjugated transpose of a and $\|a\|^2 := a^* a$. Let $\mathbb{R}^{p\times q}$ denote the set of real matrices of size $p \times q$. Let $\mathbb{R}^{\bullet\times\bullet}$ ($\mathbb{R}^{\bullet}$) denote the set of matrices (vectors, respectively) whose size are suitable. For a constant matrix A, let "rank(A)" denote the rank of A. Let I_q and $0_{p\times q}$ denote the identity matrix of size $q \times q$ and the zero matrix of size $p \times q$, respectively. If the size of an identity matrix or a zero matrix is transparent, we omit its suffix. For an arbitrary subset $\mathbb{Z}'$ of $\mathbb{Z}$, let "min$\{\mathbb{Z}'\}$" denote the minimum integer of $\mathbb{Z}'$.

Let $\mathbb{R}[\xi]$ denote the set of polynomials in the indeterminate ξ with coefficients in $\mathbb{R}$. Similarly, let $\mathbb{R}[\zeta, \eta]$ denote the set of two-variable polynomials in the indeterminates ζ and η with coefficients in $\mathbb{R}$. In addition, let $\mathbb{R}[\xi^{-1}, \xi]$ denote the set of (one-variable) dipolynomials with coefficients in $\mathbb{R}$; i.e., an element of $\mathbb{R}[\xi^{-1}, \xi]$ consists of not only nonnegative but also negative powers of indeterminate ξ. The set of their matrix versions are written, respectively, by $\mathbb{R}^{p\times q}[\xi]$, $\mathbb{R}^{p\times q}[\zeta, \eta]$, and $\mathbb{R}^{p\times q}[\xi^{-1}, \xi]$ for real coefficient matrices of size $p \times q$. We use the symbol "λ" in order to denote an element of $\mathbb{C}$ and "ξ" in order to denote the indeterminate of one-variable polynomials and dipolynomials. For a nonsingular dipolynomial matrix $D(\xi^{-1}, \xi) \in \mathbb{R}^{\bullet\times\bullet}[\xi^{-1}, \xi]$, we call it a unimodular matrix on $\mathbb{R}^{\bullet\times\bullet}[\xi^{-1}, \xi]$ if there exist a nonzero $\alpha \in \mathbb{R}$ and $d \in \mathbb{Z}$ such that $\det(D(\xi^{-1}, \xi)) = \alpha\xi^d$. For a nonsingular polynomial matrix $D(\xi) \in \mathbb{R}^{\bullet\times\bullet}[\xi]$, we call it Hurwitz (anti-Hurwitz) if $\det(D(\lambda)) \neq 0$ for all $\lambda \in \mathbb{C}$ such that $|\lambda| \geq 1$ ($|\lambda| \leq 1$, respectively). For given matrices A_i $(i = 1, \ldots, n)$ having the same number of columns, col$[A_1, A_2, \ldots, A_n]$ denotes the matrix $[A_1^T, \quad A_2^T, \quad \ldots, \quad A_n^T\ ]^T$.

Let $(\mathbb{R}^q)^Z$ denote the set of real time series vectors of size q. For $w \in (\mathbb{R}^q)^Z$, the shift operator σ is defined by $(\sigma w)(t) := w(t + 1)$. The backward shift of w is also defined by $(\sigma^{-1}w)(t) := w(t - 1)$. Let l_2^q denote the set defined by $\{w \in (\mathbb{R}^q)^Z | \sum_{t=-\infty}^{t=\infty} \|w(t)\|^2 < \infty\}$. For $T \in \mathbb{Z}$, let $l_2^q|_T$ denote the set defined by $\{w \in (\mathbb{R}^q)^Z | \sum_{t=-\infty}^{t=T} \|w(t)\|^2 < \infty\}$. For $w_1, w_2 \in (\mathbb{R}^q)^Z$ and $T \in \mathbb{Z}$, let $w_1 \wedge_T w_2$ denote the

trajectory defined by $(w_1 \wedge_T w_2)(t) = w_1(t)$ for $t \leq T$ and $(w_1 \wedge_T w_2)(t) = w_2(t)$ for $t > T$. For $w \in (\mathbb{R}^q)^Z$ and $i, j \in \mathbb{Z}$ $(i \leq j)$, we use the notation $w|_{[i,j]} := \mathrm{col}[w(i), w(i+1), \ldots, w(j)] \in \mathbb{R}^{q(j-i+1)}$. For an arbitrary $R(\xi) \in \mathbb{R}^{p\times q}[\xi]$, let $\mathrm{Ker}(R(\sigma))$ denote the set defined by $\{w \in (\mathbb{R}^q)^Z | R(\sigma)w = 0\}$. Similarly, for an arbitrary $M(\xi) \in \mathbb{R}^{q\times d}[\xi]$, let $\mathrm{Im}(M(\sigma))$ denote the set defined by $\{w \in (\mathbb{R}^q)^Z | {}^{\exists}\ell \in (\mathbb{R}^d)^Z$ such that $w = M(\sigma)\ell\}$.

Appendix B. Behavioral system theory. In this section, we give a review of the behavioral system theory briefly. For more details, see these useful references: [8], [18], [19], [20], [21], and [22].

A discrete time dynamical system is defined as a triple $\Sigma = (\mathbb{Z}, \mathbb{W}, \mathfrak{B})$, where $\mathbb{Z}$ is the discrete time axis, $\mathbb{W}$ is the signal space (e.g., $\mathbb{W} = \mathbb{R}^q$), and $\mathfrak{B} \subseteq \mathbb{W}^Z$ is the (manifest) behavior. From Proposition 4.1 A in [21], a dynamical system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ is linear, time-invariant, and complete if and only if Σ can be described by a kernel representation $R(\sigma^{-1}, \sigma)w = 0$ with $R(\xi^{-1}, \xi) \in \mathbb{R}^{\bullet\times q}[\xi^{-1}, \xi]$ for all $w \in \mathfrak{B}$. In addition to manifest variables w, there are many cases in which some auxiliary variables, say ℓ, are required to describe a dynamics. It is called a latent variable, and a dynamical system with latent variables is defined as a quadruple $\Sigma_a = (\mathbb{Z}, \mathbb{W}, \mathbb{A}, \mathfrak{B}_a)$, where $\mathbb{A}$ is the signal space of latent variables and $\mathfrak{B}_a \subseteq \mathbb{W}^Z \times \mathbb{A}^Z$ is the full behavior.

A dynamical system $\Sigma = (\mathbb{Z}, \mathbb{R}^q, \mathfrak{B})$ is said to be controllable if for all $w_1, w_2 \in \mathfrak{B}$ there exist $w \in \mathfrak{B}$ and $T(\in \mathbb{Z}) \geq 0$ such that $w(t) = w_1(t)$ for $t < 0$ and $w(t) = (\sigma^{-T} w_2)(t)$ for $t \geq T$. As stated in Proposition 4.3 in [21], a linear time-invariant complete system Σ is controllable if and only if it can be described by an image representation $w = M(\sigma^{-1}, \sigma)\ell$ with $M(\xi^{-1}, \xi) \in \mathbb{R}^{q\times\bullet}[\xi^{-1}, \xi]$ for all $(w, \ell) \in \mathfrak{B}_a$. If $\{(w, \ell_1), (w, \ell_2) \in \mathfrak{B}_a\}$ implies $\ell_1 = \ell_2$, ℓ is said to be observable from w. If Σ has an image representation $w = M(\sigma^{-1}, \sigma)\ell$, ℓ is observable from w if and only if $M(\lambda^{-1}, \lambda)$ is full column rank for all nonzero $\lambda \in \mathbb{C}$. A controllable system has many observable image representations. If $M(\xi^{-1}, \xi)$ is full column rank, then there exists a nonsingular matrix $P \in \mathbb{R}^{q\times q}$ such that $PM(\xi^{-1}, \xi) = \mathrm{col}\left[\ U(\xi^{-1}, \xi), Y(\xi^{-1}, \xi)\ \right]$, where $\det(U(\xi^{-1}, \xi)) \neq 0$ and $Y(\xi^{-1}, \xi)U(\xi^{-1}, \xi)^{-1}$ is proper. We can regard $u := U(\sigma^{-1}, \sigma)\ell$ $(y := Y(\sigma^{-1}, \sigma)\ell)$ as inputs (outputs, respectively).

In $w = M(\sigma^{-1}, \sigma)\ell$ induced by $M(\xi^{-1}, \xi) \in \mathbb{R}^{q\times d}[\xi^{-1}, \xi]$, $\mathfrak{B} = \mathrm{Im}(M(\sigma))$ is invariant under postmultiplying $M(\xi^{-1}, \xi)$ by an arbitrary unimodular matrix of $\mathbb{R}^{d\times d}[\xi^{-1}, \xi]$ in the time axis $T = \mathbb{Z}$. In particular, if $M(\xi^{-1}, \xi)$ induces an observable image representation, it is easy to see that there exists a unimodular matrix $V(\xi^{-1}, \xi)$ such that $M(\xi^{-1}, \xi)V(\xi^{-1}, \xi)$ is a polynomial matrix and $M(\lambda^{-1}, \lambda)V(\lambda^{-1}, \lambda)$ is full column rank for all $\lambda \in \mathbb{C}$. Moreover, in the case where $M(\xi^{-1}, \xi)$ does not induce an observable image representation, the set of nonzero unobservable modes including multiplicities is also invariant. Thus, it is enough to focus on mathematical representations induced by polynomial matrices if we consider $\mathfrak{B}$. Of course, the same discussion holds for kernel representations. Hence, we treat representations induced by polynomial matrices in this paper.

Finally, we prepare the notions of state space systems. Let $\Sigma_s = (\mathbb{Z}, \mathbb{R}^q, \mathbb{R}^n, \mathfrak{B}_s)$ denote a system with latent variables. Then Σ_s is said to be a state space system if $\{(w_1, x_1), (w_2, x_2) \in \mathfrak{B}_s$ and $x_1(0) = x_2(0)\} \Longrightarrow \{(w_1, x_1) \wedge_0 (w_2, x_2) \in \mathfrak{B}_s\}$. Here, a latent variable x is said to be a state variable of Σ. A state variable x plays a role as a memory that stores the information of the past trajectory. It follows from Proposition 4.10 in [21] that Σ_s is a state space system if and only if there exist constant matrices $E \in \mathbb{R}^{\bullet\times n}$, $F \in \mathbb{R}^{\bullet\times n}$, and $G \in \mathbb{R}^{\bullet\times q}$ such that Σ_s can be represented by $E\sigma x + Fx + Gw = 0$ for all $(w, x) \in \mathfrak{B}_s$. It is referred to as a state representation of $\mathfrak{B}$. Of course, a state space representation of $\mathfrak{B}$ is not unique. Let

$\Sigma_s = (\mathbb{Z}, \mathbb{R}^q, \mathbb{R}^n, \mathfrak{B}_s)$ denote a state space system whose manifest behavior is $\mathfrak{B}$. For all state space systems $\Sigma'_s = (\mathbb{Z}, \mathbb{R}^q, \mathbb{R}^{n'}, \mathfrak{B}'_s)$ inducing the same manifest behavior $\mathfrak{B}$, Σ_s is said to be minimal if $n \leq n'$ holds.

Appendix C. Proofs.

Proof of Theorem 3.4. As is well known, it follows from $\Phi(e^{-j\omega}, e^{j\omega}) > 0$ for all $\omega \in [0, 2\pi)$ that there exist spectral factors such that $\Phi(\xi^{-1}, \xi) = A(\xi^{-1})^T A(\xi) = H(\xi^{-1})^T H(\xi)$, where $\det(A(\xi))$ is anti-Hurwitz and $\det(H(\xi))$ is Hurwitz. It is also clear that $A(\zeta)^T A(\eta) \geq 0$, so this is an element of $\mathcal{D}(\Phi)$. Define $\Psi^+(\zeta, \eta) := \Psi(\Phi, A(\zeta)^T A(\eta))$. From (7), we can write their relation as

$$Q_{\Psi^+}(w)(t+1) - Q_{\Psi^+}(w)(t) = Q_\Phi(w)(t) - \|A(\sigma)w(t)\|^2 \tag{12}$$

for all $t \in \mathbb{Z}$ and $w \in (\mathbb{R}^q)^Z$. Consider another $\Psi(\zeta, \eta) \in \mathcal{S}(\Phi)$ and $\Delta(\zeta, \eta) := \Delta(\Phi, \Psi)$. Define $\Psi_d(\zeta, \eta) := \Psi^+(\zeta, \eta) - \Psi(\zeta, \eta)$ and $h := N(\Psi_d)$. Subtracting the dissipation relation for $\Psi(\zeta, \eta)$ and $\Delta(\zeta, \eta)$ from (12) yields

$$w|^T_{[1,h+1]} \tilde{\Psi}_d w|_{[1,h+1]} - w|^T_{[0,h]} \tilde{\Psi}_d w|_{[0,h]} = Q_\Delta(w)(t) - \|(A(\sigma)w)(t)\|^2, \tag{13}$$

where $\tilde{\Psi}_d$ is the coefficient matrix of $\tilde{\Psi}_d(\zeta, \eta)$.

Here, suppose that $A(\xi)$ is described by $A(\xi) =: A_m\xi^m + \cdots + A_1\xi + A_0$. Since $\det(A(\xi))$ is an anti-Hurwitz polynomial, it has no poles in the unit disk. Thus, $\det(A(0)) = \det(A_0) \neq 0$. This enables us to observe that for arbitrary $w(m)$, ..., $w(1)$, there exists $w(0)$ such that $w(0) = -A_0^{-1}(A_m w(m) + \cdots + A_1 w(1))$. Similarly, we have $w(t) = -A_0^{-1}(A_m w(t+m) + \cdots + A_1 w(t+1))$ for all $t < 0$. That is, there exists a trajectory $w \in l_2^q|_m$ such that $A(\sigma)w(t) = 0$ in $t \leq 0$ for arbitrary $w(m)$, ..., $w(1) \in \mathbb{R}^q$. Define ν as the maximum integer of $h+1$, m, and $N(\Delta)$. Then we can see that there exists $w \in l_2^q|_\nu$ such that $w(\nu), \ldots, w(1) \in \mathbb{R}^q$ are arbitrary and $w(t)$ in $t \leq 0$ satisfies the difference equation $A(\sigma)w(t) = 0$. Substituting this w into (13) and summing it from $t = -\infty$ to 0 yields $w|^T_{[1,h+1]} \tilde{\Psi}_d w|_{[1,h+1]} = \sum_{t=-\infty}^{0} Q_\Delta(w)(t) \geq 0$. It follows from the arbitrariness of $w(h+1), \ldots, w(1) \in \mathbb{R}^q$ that this inequality means $a^T \tilde{\Psi}_d a \geq 0$ for all $a \in \mathbb{R}^{q(h+1)}$. Hence, we conclude that $\Psi_d(\zeta, \eta) \geq 0$, which implies $\Psi^+(\zeta, \eta) \geq \Psi(\zeta, \eta)$.

Regarding the minimum storage function, the proof is analogous and is left to the reader. □

Proof of Theorem 5.2. Theorem 5.2 is used to prove Theorem 5.1. Thus, we prove Theorem 5.2 before the proof of Theorem 5.1.

Without loss of generality, the observability of $\Phi(\zeta, \eta)$ enables us to split a canonical factor $M(\xi)$ into $M(\xi) = \mathrm{col}\left[\ U(\xi),\ \ Y(\xi)\ \right]$, where $U(\xi)$ is nonsingular and $Y(\xi)U(\xi)^{-1}$ is proper, after appropriate permutations of rows. Here, consider the following two additional assumptions:

(a) $U(\xi)$ is column reduced.

(b) $U(0)$ is nonsingular.

Under these assumptions, we show that Theorem 5.2 holds. Next, we eliminate these assumptions step by step.

1. *Proof under the assumptions.* First, we prepare the following lemma. It is easy to see that the statement is true, so we leave the proof to the reader.

LEMMA C.1. *Let* $M(\xi) \in \mathbb{R}^{\bullet \times q}[\xi]$ *and* $U(\xi) \in \mathbb{R}^{q \times q}[\xi]$. *Assume that* $\det(U(\xi)) \neq 0$, $\det(U(0)) \neq 0$, *and* $M(\xi)U(\xi)^{-1}$ *is proper. Then* $U(\xi^{-1})^{-T} M(\xi^{-1})^T$ *is proper.*

Let $\Phi(\zeta,\eta) = M(\zeta)^T\Sigma_\Phi M(\eta)$, $\Psi(\zeta,\eta) = F(\zeta)^T\Sigma_\Psi F(\eta)$, and $\Delta(\zeta,\eta) = D(\zeta)^T D(\eta)$ denote canonical factorizations. Consider a dissipation equation

$$(\zeta\eta - 1)F(\zeta)^T\Sigma_\Psi F(\eta) = M(\eta)^T\Sigma_\Phi M(\zeta) - D(\zeta)^T D(\eta). \tag{14}$$

By replacing ζ and η with ξ^{-1} and ξ in (14), respectively, we obtain $M(\xi^{-1})^T\Sigma_\Phi M(\xi) = D(\xi^{-1})^T D(\xi)$. Premultiplying this equation by $U(\xi^{-1})^{-T}$ and postmultiplying it by $U(\xi)^{-1}$ yields

$$U(\xi^{-1})^{-T}M(\xi^{-1})^T\Sigma_\Phi M(\xi)U(\xi)^{-1} = U(\xi^{-1})^{-T}D(\xi^{-1})^T D(\xi)U(\xi)^{-1}. \tag{15}$$

Since $M(\xi)U(\xi)^{-1}$ is proper and $U(0)$ is nonsingular, it follows from Lemma C.1 that $U(\xi^{-1})^{-T}M(\xi^{-1})^T$ is proper. Thus the two matrices on both sides of (15) are proper.

Next, we show that $D(\xi)U(\xi)^{-1}$ is proper. Here, assume that $D(\xi)U(\xi)^{-1}$ is nonproper; i.e., there exist $L(\xi) \in \mathbb{R}^{\bullet\times q}[\xi]$, $\pi(\xi) \in \mathbb{R}[\xi]$, and $S_j \in \mathbb{R}^{\bullet\times q}$ $(j = 0,\dots,p)$ satisfying

$$D(\xi)U(\xi)^{-1} = \frac{L(\xi)}{\pi(\xi)} + S_0 + S_1\xi + \cdots + S_{p-1}\xi^{p-1} + S_p\xi^p, \tag{16}$$

where $L(\xi)/\pi(\xi)$ is strictly proper. Notice that $\pi(0) \neq 0$ because of $\det(U(0)) \neq 0$. Substitute $L(\xi)$ and $\pi(\xi)I_q$ into $M(\xi)$ and $U(\xi)$, respectively, in Lemma C.1. It then follows from $\pi(0) \neq 0$ that $L(\xi^{-1})^T/\pi(\xi^{-1})$ is proper. By noting this fact and some algebraic manipulations, the right-hand side of (15) can be written by

$$\begin{aligned}
&U(\xi^{-1})^{-T}D(\xi^{-1})^T D(\xi)U(\xi)^{-1}\\
&= \left\{\frac{L(\xi^{-1})^T}{\pi(\xi^{-1})} + S_0^T + \frac{S_1^T}{\xi} + \cdots + \frac{S_p^T}{\xi^p}\right\}\left\{\frac{L(\xi)}{\pi(\xi)} + S_0 + S_1\xi + \cdots + S_p\xi^p\right\}\\
&= \left\{\left(\frac{L(\xi^{-1})^T}{\pi(\xi^{-1})} + S_0^T\right)S_p\right\}\xi^p + \left\{\left(\frac{L(\xi^{-1})^T}{\pi(\xi^{-1})} + S_0^T\right)S_{p-1} + S_1^T S_p\right\}\xi^{p-1}\\
&\qquad + \left\{\left(\frac{L(\xi^{-1})^T}{\pi(\xi^{-1})} + S_0^T\right)S_{p-2} + S_1^T S_{p-1} + S_2^T S_p\right\}\xi^{p-2}\\
&\cdots + \left\{\left(\frac{L(\xi^{-1})^T}{\pi(\xi^{-1})} + S_0^T\right)S_1 + S_1^T S_2 + S_2^T S_3 + \cdots + S_{p-1}^T S_p\right\}\xi + \text{proper part.}
\end{aligned} \tag{17}$$

It is easy to see that the constant part of $L(\xi^{-1})^T/\pi(\xi^{-1}) + S_0^T$ is equal to $L(0)^T/\pi(0) + S_0^T$. Let $D(\lambda)$ be described by $D(\xi) = \sum_{i=0}^h D_i\xi^i$. Then $\operatorname{rank}\left(\begin{bmatrix} D_0 & D_1 & \cdots & D_h \end{bmatrix}\right) = \operatorname{rank}(\tilde{\Delta})$ holds, because $D(\lambda)$ is obtained by a canonical factorization of $\Delta(\zeta,\eta)$. Moreover, $D_0^T D_0 = \Delta(0,0)$, and thus $\operatorname{rank}(\Delta(0,0)) = \operatorname{rank}(D_0)$ holds. By using these facts and (11), we can obtain

$$\operatorname{rank}\left(\begin{bmatrix} D_0 & D_1 & \cdots & D_h \end{bmatrix}\right) = \operatorname{rank}(\tilde{\Delta}) = \operatorname{rank}(\Delta(0,0)) = \operatorname{rank}(D_0). \tag{18}$$

Since $\Delta(\zeta,\eta) = D(\zeta)^T D(\eta)$ is a canonical factorization, the matrix on the left-hand side of (18) is full row rank. Thus (18) implies that D_0 $(= D(0))$ is also full row rank. In addition, $U(0)^{-T}D(0)^T$ is full column rank due to $\det(U(0)) \neq 0$. Substituting $\xi = 0$ to (16) and transposing it yields $U(0)^{-T}D(0)^T = L(0)^T/\pi(0) + S_0^T$, so $L(0)^T/\pi(0) + S_0^T$ is full column rank. At the same time, the left-hand side of (17) has no polynomial

part due to the properness of (15). This implies that the highest order term of the right-hand side of (17) vanishes; that is, $(L(0)^T/\pi(0)+S_0^T)S_p$ must be a zero matrix. Thus S_p is equal to $0_{\bullet\times q}$. Substituting $S_p = 0_{\bullet\times q}$ into (17), the highest order term is described by $\{(L(0)^T/\pi(0)+S_0^T)S_{p-1}\}\xi^{p-1}$. This term must also vanish, so it follows from the same reason that $S_{p-1} = 0_{\bullet\times q}$. In the same way, by repeating the above discussion up to the first order term in (17), we obtain $S_i = 0_{\bullet\times q}$, $i = 1,\dots,p$ in (16). Consequently, $D(\xi)U(\xi)^{-1}$ is proper.

Next, we show that $F(\xi)U(\xi)^{-1}$ is strictly proper. The technique of this part is similar to that of the continuous time case (cf. the proofs of Theorem 5.5 in [23] and Theorem 6.1 in [10]). Postmultiplying (14) by $U(\eta)^{-1}$ yields

$$(\zeta\eta-1)F(\zeta)^T\Sigma_\Psi F(\eta)U(\eta)^{-1} = M(\zeta)^T\Sigma M(\eta)U(\eta)^{-1} - D(\zeta)^T D(\eta)U(\eta)^{-1}. \tag{19}$$

From the above discussions, the right-hand side of (19) is proper with respect to η. Assume that $F(\eta)U(\eta)^{-1}$ is described by $F(\eta)U(\eta)^{-1} = R(\eta)+P_0+P_1\eta+\cdots+P_l\eta^l$, where $R(\xi)$ is the strictly proper rational function of column size q and $P_i \in \mathbb{R}^{\bullet\times q}$ $(i=0,\dots,l)$. Substituting this expression into (19) and equating powers of η in (19) enables us to obtain that $F(\zeta)^T\Sigma_\Psi P_i = 0_{q\times q}$, $i=0,\dots,l$. At the same time, the columns of $F(\zeta)^T \in \mathbb{R}^{q\times\bullet}[\zeta]$ are linearly independent over $\mathbb{R}$, so $\Sigma_\Psi P_i = 0_{\bullet\times q}$ for all i. This implies $P_i = 0_{\bullet\times q}$ for all i because of the nonsingularity of Σ_Ψ. Thus $F(\xi)U(\xi)^{-1}$ is strictly proper. It then follows from Proposition 2.1 that $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$ under assumptions (a) and (b).

2. *Elimination of assumption* (b). If $U(0)$ is *not nonsingular*, then it is impossible to use the above discussion to show that $D(\xi)U(\xi)^{-1}$ is proper. In order to overcome this difficulty, we first modify the original $U(\xi)$ to $U(\xi)+\epsilon I_q$ for some $\epsilon \in \mathbb{R}$ so as to satisfy assumption (b). Next, by using assumption (a), we prove the properness of $(U(\xi)+\epsilon I_q)^{-T}D(\xi^{-1})^TD(\xi)(U(\xi)+\epsilon I_q)^{-1}$. Finally, we show that this properness implies that of $D(\xi)U(\xi)^{-1}$. The remaining proof is similar to that stated in the above discussion.

First, we modify the original $\Phi(\zeta,\eta)$ so as to satisfy assumption (b). Before going to this modification, we prepare some notation as a matter of convenience of the following proof. In a canonical factorization $\Phi(\zeta,\eta) = M(\zeta)^T\Sigma_\Phi M(\eta)$, let r denote the size of Σ_Φ. Moreover, Σ_Φ is a signature matrix, so it can be described by $\Sigma_\Phi = \mathrm{diag}\{\Gamma_{11},\Gamma_{22}\}$, where $\Gamma_{11} \in \mathbb{R}^{q\times q}$ and $\Gamma_{22} \in \mathbb{R}^{(r-q)\times(r-q)}$. Note that the observability of $\Phi(\zeta,\eta)$ guarantees $r \geq q$. Under these preparations, factorize $\Phi(\zeta,\eta) = M_\epsilon(\zeta)^T\Sigma_{\Phi_\epsilon}M_\epsilon(\eta)$ for an arbitrary $\epsilon \in \mathbb{R}$, where $M_\epsilon(\xi) := \mathrm{col}[U_\epsilon(\xi), Y(\xi), I_q, -\epsilon U(\xi)]$, $U_\epsilon(\xi) := U(\xi)+\epsilon I_q$, $\Sigma_{\Phi_\epsilon} := \begin{bmatrix} \Sigma_\Phi & 0_{r\times(r+q)} \\ 0_{(r+q)\times r} & \Sigma_\epsilon \end{bmatrix}$, and $\Sigma_\epsilon := \begin{bmatrix} -\epsilon^2\Gamma_{11} & \Gamma_{11} \\ \Gamma_{11} & 0_{q\times q} \end{bmatrix}$.

Next, we prove that $U_\epsilon(\xi^{-1})^{-T}D(\xi^{-1})^TD(\xi)U_\epsilon(\xi)^{-1}$ is proper. Note that $M_\epsilon(\xi)U_\epsilon(\xi)^{-1}$ can be written by

$$M_\epsilon(\xi)U_\epsilon(\xi)^{-1} = \begin{bmatrix} U(\xi)+\epsilon I_q \\ Y(\xi) \\ I_q \\ -\epsilon U(\xi) \end{bmatrix}(U(\xi)+\epsilon I_q)^{-1} = \begin{bmatrix} I_q \\ Y(\xi)U(\xi)^{-1}(I_q+\epsilon U(\xi)^{-1})^{-1} \\ U(\xi)^{-1}(I_q+\epsilon U(\xi)^{-1})^{-1} \\ -\epsilon(I_q+\epsilon U(\xi)^{-1})^{-1} \end{bmatrix}. \tag{20}$$

It follows from Lemma 6.3.11 in [4] and assumption (a) that $U(\xi)^{-1}$ is proper. Since $U(\xi)^{-1}$ is proper, $I_q+\epsilon U(\xi)^{-1}$ is biproper or, equivalently, $(I_q+\epsilon U(\xi)^{-1})^{-1}$ is biproper for almost every $\epsilon \in \mathbb{R}$. Thus, by (20), $M_\epsilon(\xi)U_\epsilon(\xi)^{-1}$ is also proper for almost every $\epsilon \in \mathbb{R}$. Furthermore, it is also possible to take this ϵ so that

$\det(U_\epsilon(0)) = \det(U(0) + \epsilon I_q) \neq 0$. Applying Lemma C.1 with the properness of $M_\epsilon(\xi)U_\epsilon(\xi)^{-1}$ and $\det(U_\epsilon(0)) \neq 0$ enables us to observe that $U_\epsilon(\xi^{-1})^{-T}M_\epsilon(\xi^{-1})^T$ is proper, which implies that $U_\epsilon(\xi^{-1})^{-T}\Phi(\xi^{-1},\xi)U_\epsilon(\xi)^{-1}$ is also proper. By premultiplying and postmultiplying $\Phi(\xi^{-1},\xi) = D(\xi^{-1})^T D(\xi)$ by $U_\epsilon(\xi^{-1})^{-T}$ and $U_\epsilon(\xi)^{-1}$, respectively, we can see that $U_\epsilon(\xi^{-1})^{-T}D(\xi^{-1})^T D(\xi)U_\epsilon(\xi)^{-1}$ is also proper.

Finally, we prove the properness of $D(\xi)U(\xi)^{-1}$. For $U_\epsilon(\xi^{-1})^{-T}D(\xi^{-1})^T D(\xi)U_\epsilon(\xi)^{-1}$, notice that $D(0)$ is full row rank and $\det(U_\epsilon(0)) \neq 0$ holds. In this point, repeating the same technique in the proof under the assumptions leads to the conclusion that $D(\xi)U_\epsilon(\xi)^{-1}$ is proper. Rewriting this proper rational function as $D(\xi)U_\epsilon(\xi)^{-1} = D(\xi)U(\xi)^{-1}(I_q + \epsilon U(\xi)^{-1})^{-1}$ and using the fact that $(I + \epsilon U(\xi)^{-1})^{-1}$is biproper, we can see that $D(\xi)U(\xi)^{-1}$ is proper. The strictly properness of $F(\xi)U(\xi)^{-1}$ can be shown by applying the same technique in the previous argument.

3. *Elimination of assumption* (a). We first prepare the following lemma. The proof is based on algebraic computations of polynomial matrices, so we leave the proof to the reader.

LEMMA C.2. *Let* $\Delta(\zeta,\eta) \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$. *For an arbitrary unimodular matrix* $V(\xi) \in \mathbb{R}^{q\times q}[\xi]$, *define* $\Delta'(\zeta,\eta) := V(\zeta)^T\Delta(\zeta,\eta)V(\eta)$. *Then,*

$$\operatorname{rank}(\Delta(0,0)) = \operatorname{rank}(\Delta'(0,0)) \text{ and } \operatorname{rank}(\tilde{\Delta}) = \operatorname{rank}(\tilde{\Delta}'),$$

where $\tilde{\Delta}$ *and* $\tilde{\Delta}'$ *are the coefficient matrices of* $\Delta(\zeta,\eta)$ *and* $\Delta'(\zeta,\eta)$, *respectively.*

We suppose that $U(\xi)$ is *not column reduced*. In this case, there exists a unimodular matrix $V(\xi) \in \mathbb{R}^{q\times q}[\xi]$ such that $U(\xi)V(\xi)$ is column reduced (cf. p. 386 of [4]). By using this $V(\xi)$, consider $(\zeta\eta - 1)V(\zeta)^T\Psi(\zeta,\eta)V(\eta) = V(\zeta)^T\Phi(\zeta,\eta)V(\eta) - V(\zeta)^T\Delta(\zeta,\eta)V(\eta)$. Since $U(\xi)V(\xi)$ is column reduced, it follows from Lemma 6.3.11 in [4] that $(U(\xi)V(\xi))^{-1}$ is proper. In addition, it follows from Lemma C.2 and the unimodularity of $V(\xi)$ that $V(\zeta)^T\Delta(\zeta,\eta)V(\eta)$ satisfies (11). Hence, by repeating the previous discussion, we can observe that $(U(\zeta)V(\zeta))^{-T}(V(\zeta)^T\Psi(\zeta,\eta)V(\eta))(U(\eta)V(\eta))^{-1} = U(\zeta)^{-T}\Psi(\zeta,\eta)U(\eta)^{-1}$ is strictly proper with respect to ζ and η. This completes the proof of Theorem 5.2. □

Proof of Theorem 5.1. Similarly to Theorem 5.2, the observability of $\Phi(\zeta,\eta)$ enables us to split a canonical factor $M(\xi)$ into $M(\xi) = \operatorname{col}\begin{bmatrix} U(\xi), & Y(\xi) \end{bmatrix}$, where $U(\xi)$ is nonsingular and $Y(\xi)U(\xi)^{-1}$ is proper, after appropriate permutations of rows. Here, consider the following two additional assumptions:

(a') $U(\xi)$ is column reduced.

(b') $\Phi(e^{-j\omega}, e^{j\omega}) > 0$ for all $\omega \in [0, 2\pi)$.

As in the proof of Theorem 5.2, we show that the statement holds under the above assumptions. Next, we eliminate these assumptions. Note that the nonnegativity of $\Psi(\zeta,\eta)$ is invariant after postmultiplying and premultiplying it by $V(\zeta)^T$ and $V(\eta)$, respectively, where $V(\xi)$ is an arbitrary unimodular matrix of $\mathbb{R}^{q\times q}[\xi]$. Thus, the elimination of (a') is similar to that of (a) in the proof of Theorem 5.2. For this reason, we consider only the elimination of (b') here.

1. *Proof under the assumptions.* Using assumption (b'), we can obtain $\Phi(\xi^{-1},\xi) =: A(\xi^{-1})^T A(\xi)$, where $A(\xi) =: A_0 + \cdots + A_m\xi^m$ is an anti-Hurwitz spectral factor. It then follows from Theorem 3.4 that the maximum storage function is induced by $\Psi^+(\zeta,\eta) = \Psi(\Phi, A(\zeta)^T A(\eta))$. In addition, the existence of nonnegative storage functions yields $\Psi^+(\zeta,\eta) \geq 0$, so a canonical factorization of $\Psi^+(\zeta,\eta)$ can be described by $\Psi^+(\zeta,\eta) = F^+(\zeta)^T F^+(\eta)$, where $F^+(\xi) \in \mathbb{R}^{\bullet\times q}[\xi]$.

Consider an arbitrary nonnegative storage function induced by $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. A canonical factorization of $\Psi(\zeta,\eta)$ can also be described by $\Psi(\zeta,\eta) = F(\zeta)^T F(\eta)$, where

$F(\xi) \in \mathbb{R}^{\bullet \times q}[\xi]$. As in the proof of Theorem 3.4, define $\Psi_d(\zeta,\eta) = \Psi^+(\zeta,\eta) - \Psi(\zeta,\eta)$ and $\tilde{\Psi}_d$. It follows from $\Psi^+(\zeta,\eta) \geq \Psi(\zeta,\eta)$ that $\tilde{\Psi}_d \geq 0$. Here, for an arbitrary $\lambda \in \mathbb{C}$ and $\alpha \in \mathbb{C}^q$, define a complex vector $a := \mathrm{col}\left[\begin{array}{cccc} I_q, & \lambda I_q, & \ldots, & \lambda^h I_q \end{array}\right] \alpha \in \mathbb{C}^{q(h+1)}$, where $h := N(\Psi_d)$. The nonnegativity of $\tilde{\Psi}_d$ implies $\alpha^* \Psi_+(\bar{\lambda},\lambda)\alpha - \alpha^* \Psi(\bar{\lambda},\lambda)\alpha \geq 0$; i.e.,

$$\alpha^* F^+(\bar{\lambda})^T F^+(\lambda)\alpha \geq \alpha^* F(\bar{\lambda})^T F(\lambda)\alpha \geq 0 \tag{21}$$

for all $\lambda \in \mathbb{C}$ and $\alpha \in \mathbb{C}^q$. Next, by using an arbitrary $u \in \mathbb{C}^q$, define $\alpha' := U(\lambda)^{-1}u$. Since we can apply an arbitrary complex vector α in (21), substituting α' into α in (21) leads to

$$\|F^+(\lambda)U(\lambda)^{-1}u\|^2 \geq \|F(\lambda)U(\lambda)^{-1}u\|^2 \geq 0 \tag{22}$$

for all $u \in \mathbb{C}^q$ and almost every $\lambda \in \mathbb{C}$, i.e., λ satisfying $\det(U(\lambda)) \neq 0$.

At the same time, consider the anti-Hurwitz spectral factor $A(\xi)$ of $\Phi(\xi^{-1},\xi)$. Since $A(0)$ is nonsingular, it is easy to see that $A(\zeta)^T A(\eta)$ satisfies (11). Hence, it then follows from $F^+(\zeta)^T F^+(\eta) = \Psi(\Phi, A(\zeta)^T A(\eta))$ and Theorem 5.2 that $F^+(\xi)U(\xi)^{-1}$ is strictly proper. By using this fact, $|\lambda| \to \infty$ in (22) leads to

$$\lim_{|\lambda|\to\infty} \|F(\lambda)U(\lambda)^{-1}u\|^2 = 0$$

for all $u \in \mathbb{C}^q$. Due to the arbitrariness of u, $F(\xi)U(\xi)^{-1}$ is strictly proper. It then follows from Proposition 2.1 that $\Psi(\zeta,\eta) \in \mathcal{F}_s(\Phi)$ under the assumptions (a') and (b').

2. *Elimination of assumption* (b). We suppose that (b') does not hold. By using a canonical factor $M(\xi)$ of $\Phi(\zeta,\eta)$, we introduce $\Phi_\alpha(\zeta,\eta) := \left[\begin{array}{cc} U(\zeta)^T & Y(\zeta)^T \end{array}\right]\left[\begin{array}{c} U(\eta) \\ Y(\eta) \end{array}\right] + \alpha I_q$ for an arbitrary positive real α. Note that $\Phi_\alpha(\zeta,\eta) > 0$. Let $M_\alpha(\xi)$ denote a canonical factor of $\Phi_\alpha(\zeta,\eta)$. Suppose that $M_\alpha(\xi)$ is not full column rank; i.e., there exists a nonzero $a \in \mathbb{R}^q$ such that $M_\alpha(\xi)a = 0$. This contradicts the positivity of $\Phi_\alpha(\zeta,\eta) = M(\zeta)^T M(\eta) + \alpha I_q = M_\alpha(\zeta)^T M_\alpha(\eta)$. Thus, $M_\alpha(\xi)$ is full column rank, which implies that $M_\alpha(\xi)$ is described by $M_\alpha(\xi) = \mathrm{col}\left[\begin{array}{cc} U_\alpha(\xi), & Y_\alpha(\xi) \end{array}\right]$, where $\det(U_\alpha(\xi)) \neq 0$ and $Y_\alpha(\xi)U_\alpha(\xi)^{-1}$ is proper after appropriate permutations of rows.

It is clear that $\Phi_\alpha(e^{-j\omega}, e^{j\omega}) > 0$ for all $\omega \in [0, 2\pi)$, which implies that $\Phi_\alpha(\zeta,\eta)$ satisfies assumption (b'). It then follows from Theorem 3.4 that the maximum storage function for Q_{Φ_α} can be described by using an anti-Hurwitz spectral factor of $\Phi_\alpha(\xi^{-1},\xi)$, say $A_\alpha(\xi)$, as $\Psi^+_\alpha(\zeta,\eta) = (\Phi_\alpha(\zeta,\eta) - A_\alpha(\zeta)^T A_\alpha(\eta))/(\zeta\eta - 1)$, where $\Psi^+_\alpha(\zeta,\eta)$ induces the maximum storage function. Due to this fact, the same discussion in the proof under the assumptions enables us to observe that $U_\alpha(\zeta)^{-T}\Psi^+_\alpha(\zeta,\eta)U_\alpha(\eta)^{-1}$ is strictly proper with respect to ζ and η.

Here we consider

$$(\zeta\eta - 1)\Psi(\zeta,\eta) \leq \Phi(\zeta,\eta) \leq \Phi_\alpha(\zeta,\eta). \tag{23}$$

The first inequality is the dissipation inequality for the original supply rate induced by $\Phi(\zeta,\eta)$, and the second one is transparent from the definition of $\Phi_\alpha(\zeta,\eta)$. Equation (23) also means that $\mathcal{S}(\Phi) \subseteq \mathcal{S}(\Phi_\alpha)$. Thus, $\Psi(\zeta,\eta) \leq \Psi^+_\alpha(\zeta,\eta)$ holds for all $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. Assume that $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$ is nonnegative. In addition, let $\Psi(\zeta,\eta) = F(\zeta)^T F(\eta)$ and $\Psi^+_\alpha(\zeta,\eta) = F^+_\alpha(\zeta)^T F^+_\alpha(\eta)$ denote canonical factorizations. Then, similarly to (22), $\|F^+_\alpha(\lambda)U_\alpha(\lambda)^{-1}u\|^2 \geq \|F(\lambda)U_\alpha(\lambda)^{-1}u\|^2 \geq 0$ holds for all

$u \in \mathbb{C}^q$ and almost every $\lambda \in \mathbb{C}$, i.e., λ satisfying $\det(U_\alpha(\lambda)) \neq 0$. Since $F_\alpha^+(\lambda)U_\alpha(\lambda)^{-1}$ is strictly proper, taking $|\lambda| \to \infty$ leads to $\lim_{|\lambda|\to\infty} \|F(\lambda)U_\alpha(\lambda)^{-1}u\|^2 = 0$. Due to the arbitrariness of u, $F(\xi)U_\alpha(\xi)^{-1}$ is strictly proper.

In the following, in order to show that $F(\xi)U(\xi)^{-1}$ is also strictly proper, we investigate the properness of $U_\alpha(\xi)U(\xi)^{-1}$. Since $M_\alpha(\xi)$ is a canonical factor and $\Phi_\alpha(\zeta,\eta) > 0$, we can see that

$$\Phi_\alpha(\zeta,\eta) = \begin{bmatrix} U(\zeta)^T & Y(\zeta)^T \end{bmatrix} \begin{bmatrix} U(\eta) \\ Y(\eta) \end{bmatrix} + \alpha I_q = \begin{bmatrix} U_\alpha(\zeta)^T & Y_\alpha(\zeta)^T \end{bmatrix} \begin{bmatrix} U_\alpha(\eta) \\ Y_\alpha(\eta) \end{bmatrix}. \tag{24}$$

By premultiplying and postmultiplying (24) by $U(\zeta)^{-T}$ and $U(\eta)^{-1}$, respectively, we also obtain

$$\begin{aligned} &U(\zeta)^{-T} \begin{bmatrix} U(\zeta)^T & Y(\zeta)^T \end{bmatrix} \begin{bmatrix} U(\eta) \\ Y(\eta) \end{bmatrix} U(\eta)^{-1} + \alpha U(\zeta)^{-T}U(\eta)^{-1} \\ &\quad = U(\zeta)^{-T}U_\alpha(\zeta)^T \left(I_q + U_\alpha(\zeta)^{-T}Y_\alpha(\zeta)^T Y_\alpha(\eta)U_\alpha(\eta)^{-1}\right) U_\alpha(\eta)U(\eta)^{-1}. \end{aligned} \tag{25}$$

In (25), it follows from assumption (b') that $U(\xi)^{-1}$ is proper, so the left-hand side is also proper with respect to the indeterminates of ζ and η. Moreover, it is easy to see that $(I_q + U_\alpha(\zeta)^{-T}Y_\alpha(\zeta)^T Y_\alpha(\eta)U_\alpha(\eta)^{-1})$ in the right-hand side is proper with respect to ζ and η and its constant term is a positive definite matrix, say V. Suppose that $U_\alpha(\xi)U(\xi)^{-1}$ is not proper. Let $P(\xi) =: P_1\xi + \cdots + P_k\xi^k \in \mathbb{R}^{q\times q}[\xi]$ denote the pure polynomial part of $U_\alpha(\xi)U(\xi)^{-1}$. This means that there exists a term described by $P_k^T V P_k(\zeta\eta)^k$ and $P_k^T V P_k \neq 0$, which contradicts the properness of the left-hand side. Thus, we obtain $P_k^T V P_k = 0$ and then $P_k = 0$ due to $V > 0$. Repeating the same technique, we can see that the matrices P_i $(i = k-1, \ldots, 1)$ are equal to zero. Thus, $U_\alpha(\xi)U(\xi)^{-1}$ is proper. By using this result, we conclude that $F(\xi)^{-1}U_\alpha(\xi)^{-1}U_\alpha(\xi)U(\xi)^{-1} = F(\xi)U(\xi)^{-1}$ is strictly proper. This completes the proof of Theorem 5.1.

Proof of Theorem 6.1. (Only if). Assume that there exists a nonnegative $\Psi(\zeta,\eta) \in \mathcal{S}(\Phi)$. Summing $Q_\Psi(w)(t+1) - Q_\Psi(w)(t) \leq Q_\Phi(w)(t)$ from $t = -\infty$ to an arbitrary $t = T$ along an arbitrary $w \in l_2^q$ yields $0 \leq Q_\Psi(w)(T+1) \leq \sum_{t=-\infty}^{t=T} Q_\Phi(w)(t)$.

(If). Since $\sum_{t=-\infty}^{T} Q_\Phi(w)(t) \geq 0 (\forall T \in \mathbb{Z})$ implies $\sum_{t=-\infty}^{\infty} Q_\Phi(w)(t) \geq 0$ for all $w \in l_2^q$, it also implies $\Phi(e^{-j\omega}, e^{j\omega}) \geq 0$ for all $\omega \in [0, 2\pi)$ (cf. Proposition 3.1 (1) in [5]).

First, suppose that $\Phi(e^{-j\omega}, e^{j\omega}) > 0$ for all $\omega \in [0, 2\pi)$. In this case, it is possible to calculate an anti-Hurwitz spectral factorization $\Phi(\xi^{-1}, \xi) = A(\xi^{-1})^T A(\xi)$. Moreover, it follows from the proof of Theorem 3.4 that $A(\zeta)^T A(\eta)$ is one dissipation rate in $\mathcal{D}(\Phi)$. Define $\Psi^+(\zeta,\eta) := \Psi(\Phi, A(\zeta)^T A(\eta))$. Then, we can write their relation as (12). Substituting an arbitrary $w \in l_2^q$ to (12) and summing it from $t = -\infty$ to 0 yields

$$w|_{[1,h+1]}^T \tilde{\Psi}^+ w|_{[1,h+1]} = \sum_{t=-\infty}^{0} \left\{ Q_\Phi(w)(t) - \|(A(\sigma)w)(t)\|^2 \right\}, \tag{26}$$

where $\tilde{\Psi}^+$ is the coefficient matrix of $\Psi^+(\zeta,\eta)$ and $h :=N(\Psi^+)$. Again, by using the proof of Theorem 3.4, we can see that there exists a trajectory $w \in l_2^q|_\nu$ such that $(A(\sigma)w)(t) = 0$ from 0 to $-\infty$ for arbitrary $w(1), \ldots, w(\nu)$, where ν is the maximum integer of $h+1$, $N(\Phi)$, and the degree of $A(\xi)$. Substituting this w into (26) allows us to obtain $\tilde{\Psi}^+ \geq 0$, which also implies $\Psi^+(\zeta,\eta) \geq 0$.

Next, we consider the general case; i.e., $\Phi(e^{-j\omega}, e^{j\omega}) \geq 0$ for all $\omega \in [0, 2\pi)$. Define $\Phi_\alpha(\zeta, \eta) := \Phi(\zeta, \eta) + \alpha I$ for an arbitrary real $\alpha > 0$. Then, $\Phi_\alpha(e^{-j\omega}, e^{j\omega}) > 0$ for all $\omega \in [0, \pi)$ holds, so the assumption in the statement of Theorem 3.4 is satisfied. Thus, there exist storage functions $\Psi^+_\alpha(\zeta, \eta)$ and $\Psi^-_\alpha(\zeta, \eta) \in \mathcal{S}(\Phi_\alpha)$ such that $\Psi^-_\alpha(\zeta, \eta) \leq \Psi_\alpha(\zeta, \eta) \leq \Psi^+_\alpha(\zeta, \eta)$ for any other $\Psi(\zeta, \eta) \in \mathcal{S}(\Phi_\alpha)$. At the same time, $\Psi^+_\alpha(\zeta, \eta) \geq 0$ is an immediate consequence of the previous discussion. Since our purpose is to show the existence of nonnegative storage functions for Q_Φ, it suffices to show that $\Psi^+_0(\zeta, \eta) := \lim_{\alpha \to +0} \Psi^+_\alpha(\zeta, \eta) \in \mathcal{S}(\Phi)$ and $\Psi^+_0(\zeta, \eta) \geq 0$.

We show the convergence of $\lim_{\alpha \to +0} \Psi^+_\alpha(\zeta, \eta)$. For arbitrary real numbers α_1 and α_2 such that $0 < \alpha_2 < \alpha_1$, we define $\Phi_{\alpha i}(\zeta, \eta) := \Phi(\zeta, \eta) + \alpha_i I$, where $i = 1, 2$. Since $\Phi_{\alpha_i}(\lambda^{-1}, \lambda)$ $(i = 1, 2)$ are positive on the unit circle, it follows from Theorem 3.4 that there exist maximum and minimum storage functions for $Q_{\Phi_{\alpha i}}$. For each $i = 1, 2$, let $\Psi^+_{\alpha i}(\zeta, \eta) \in \mathcal{S}(\Phi_{\alpha i})$ denote the maximum storage functions and $h_i := N(\Psi^+_{\alpha i})$. Then, the corresponding dissipation relation can be described by

$$Q_{\Psi^+_{\alpha i}}(w)(t+1) - Q_{\Psi^+_{\alpha i}}(w)(t) = Q_{\Phi_{\alpha i}}(w)(t) - \|A_{\alpha i}(\sigma) w(t)\|^2, \tag{27}$$

where $A_{\alpha i}(\xi) \in \mathbb{R}^{q \times q}[\xi]$ is an anti-Hurwitz spectral factor of $\Phi_{\alpha i}(\xi^{-1}, \xi)$ $(i = 1, 2)$. For each $i = 1, 2$, summing (27) from $-\infty$ to 0 along an arbitrary $w \in l^q_2$ and subtracting one from the other yields

$$Q_{\Psi^+_{\alpha 1}}(w)(1) - Q_{\Psi^+_{\alpha 2}}(w)(1) = \sum_{t=-\infty}^{0} \left\{ (\alpha_1 - \alpha_2)\|w(t)\|^2 + \|A_{\alpha 2}(\sigma) w(t)\|^2 - \|A_{\alpha 1}(\sigma) w(t)\|^2 \right\}. \tag{28}$$

Let m_i denote the degree of $A_{\alpha_i}(\xi)$ $(i = 1, 2)$. In the same way as the proof of Theorem 3.4, it follows from $|A_{\alpha 1}(0)| \neq 0$ that there exists an anti-Hurwitz trajectory w such that $A_{\alpha 1}(w)(t) = 0$ from $-\infty$ to 0 for an arbitrary $w(1), \ldots, w(m_1)$. Consider $w \in l^q_2|_\nu$ such that $w(\nu), \ldots, w(1)$ are arbitrary and $w(t)$ in $t \leq 0$ satisfies $A_{\alpha 1}(\sigma) w(t) = 0$, where ν is the maximum integer of $h_1 + 1$, $h_2 + 1$, m_1, and m_2. Then, substituting this $w \in l^q_2|_\nu$ into (28) yields

$$Q_{\Psi_{\alpha 1+}}(w)(1) - Q_{\Psi_{\alpha 2+}}(w)(1) = \sum_{t=-\infty}^{0} \left\{ (\alpha_1 - \alpha_2)\|w(t)\|^2 + \|A_{\alpha 2}(\sigma) w(t)\|^2 \right\} > 0$$

for arbitrary $w(1), \ldots, w(\nu)$. This implies $\Psi^+_{\alpha 1}(\zeta, \eta) > \Psi^+_{\alpha 2}(\zeta, \eta)$. Similarly, we obtain $\Psi^-_{\alpha_2}(\zeta, \eta) > \Psi^-_{\alpha_1}(\zeta, \eta)$. Hence, we can see that $\Psi^-_{\alpha_1}(\zeta, \eta) < \Psi^-_{\alpha_2}(\zeta, \eta) < \Psi^+_{\alpha_2}(\zeta, \eta) < \Psi^+_{\alpha_1}(\zeta, \eta)$ for arbitrary real numbers α_1 and α_2 such that $0 < \alpha_2 < \alpha_1$. This implies the convergence of $\lim_{\alpha \to +0} \Psi^+_\alpha(\zeta, \eta)$ and $\lim_{\alpha \to +0} \Psi^-_\alpha(\zeta, \eta)$.

Next, we show $\Psi^+_0(\zeta, \eta) := \lim_{\alpha \to +0} \Psi^+_\alpha(\zeta, \eta)$ and $\Psi^-_0(\zeta, \eta) := \lim_{\alpha \to +0} \Psi^-_\alpha(\zeta, \eta)$ are included in $\mathcal{S}(\Phi)$. For fixed $w \in (\mathbb{R}^q)^Z$ and $t \in \mathbb{Z}$, $Q_{\Psi^+_\alpha}(w)(t)$ and $Q_{\Psi^+_\alpha}(w)(t+1)$ converge to $Q_{\Psi^+_0}(w)(t)$ and $Q_{\Psi^+_0}(w)(t+1)$, respectively, as $\alpha \to 0$. By noting this fact, for $\alpha > 0$, define $g_{w(t)}(\alpha) := Q_\Phi(w)(t) + \alpha\|w(t)\|^2 - Q_{\Psi^+_\alpha}(w)(t+1) + Q_{\Psi^+_\alpha}(w)(t)$ and $g^0_{w(t)} := Q_\Phi(w)(t) - Q_{\Psi^+_0}(w)(t+1) + Q_{\Psi^+_0}(w)(t)$. It follows from the dissipation inequality that

$$g_{w(t)}(\alpha) \geq 0 \ \forall \alpha > 0. \tag{29}$$

Moreover, it is clear that $\lim_{\alpha \to +0} g_{w(t)}(\alpha) = g^0_{w(t)}$, so

$$\forall \epsilon > 0, \exists \delta(\epsilon) > 0 \text{ such that } 0 < \alpha < \delta(\epsilon) \Rightarrow g^0_{w(t)} - \epsilon < g_{w(t)}(\alpha) < g^0_{w(t)} + \epsilon. \tag{30}$$

By using these facts and notations, we show $\Psi_0^+(\zeta,\eta) \in \mathcal{S}(\Phi)$, which is equivalent to $g^0_{w(t)} \geq 0$. Suppose that $g^0_{w(t)} < 0$. Then, there exists a sufficiently small $\epsilon_1 > 0$ such that $g^0_{w(t)} + \epsilon_1 < 0$. By setting this ϵ_1 to ϵ in (30), we obtain $g_{w(t)}(\alpha) < g^0_{w(t)} + \epsilon_1 < 0$ for α satisfying $0 < \alpha < \delta(\epsilon_1)$. Thus, $g^0_{w(t)} < 0$ contradicts (29). Therefore, we conclude $\Psi_0^+(\zeta,\eta) \in \mathcal{S}(\Phi)$. Similarly, we can also obtain $\Psi_0^-(\zeta,\eta) \in \mathcal{S}(\Phi)$.

Finally, the remaining proof is to show $\Psi_0^+(\zeta,\eta) \geq 0$. Again, we prove it by a contradiction. Suppose that a canonical factorization of $\Psi_0^+(\zeta,\eta)$ is described by $\Psi_0^+(\zeta,\eta) = F(\zeta)^T \mathrm{diag}\{I_{r+}, -I_{r-}\}F(\eta)$, where $F(\xi) = \sum_{k=0}^{h_0} F^k \xi^k \in \mathbb{R}^{(r_- + r_+)\times q}[\xi]$ and r_+ (r_-) is the number of positive (negative, respectively) eigenvalues of the coefficient matrix of $\Psi_0^+(\zeta,\eta)$. Since $F(\xi)$ is a canonical factor, there exist $w_0, \ldots, w_{h_0}$ such that

$$\begin{bmatrix} 0 \\ f \end{bmatrix} = \begin{bmatrix} F^0 & F^1 & \cdots & F^{h_0} \end{bmatrix} \mathrm{col} \begin{bmatrix} w_0, & w_1, & \ldots, & w_{h_0} \end{bmatrix}$$

for an arbitrary nonzero $f \in \mathbb{R}^{r-}$. This implies that there exist $w \in (\mathbb{R}^q)^Z$ and $t \in \mathbb{Z}$ such that $Q_{\Psi_0^+}(w)(t) < 0$, where $w(t+k) = w_k$, $(k = 0, \ldots, h_0)$. This also means that there exists a sufficiently small $\epsilon_2 > 0$ such that $Q_{\Psi_0^+}(w)(t) + \epsilon_2 \|w(t)\|^2 < 0$ for this w and t. At the same time, $\Psi_\alpha^+(\zeta,\eta)$ is the decreasing function with respect to α and $\Psi_0^+(\zeta,\eta) = \lim_{\alpha\to 0} \Psi_\alpha^+(\zeta,\eta)$, so for all $\epsilon > 0$ there exists $\delta(\epsilon) > 0$ such that $0 < \alpha < \delta(\epsilon) \Rightarrow 0 < Q_{\Psi_\alpha^+}(w)(t) - Q_{\Psi_0^+}(w)(t) < \epsilon\|w(t)\|^2$. By setting ϵ_2 to ϵ, we obtain $Q_{\Psi_\alpha^+}(w)(t) < Q_{\Psi_0^+}(w)(t) + \epsilon_2\|w(t)\|^2 < 0$ for α satisfying $0 < \alpha < \delta(\epsilon_2)$. This contradicts $\Psi_\alpha^+(\zeta,\eta) \geq 0$ for $\alpha > 0$. By using the same technique again, we can also show that $\Psi_0^+(\zeta,\eta) < 0$ contradicts $\Psi_\alpha^+(\zeta,\eta) \geq 0$ for $\alpha > 0$. Therefore, $\Psi_0^+(\zeta,\eta) \geq 0$ holds. This completes the proof. □

MINIMIZING INFINITE TIME HORIZON DISCOUNTED COST WITH MEAN, VARIANCE, AND BOUNDED VARIATION CONTROLS*

ANANDA WEERASINGHE†

Abstract. We consider an infinite time horizon discounted cost minimization problem for a class of Itô processes. The available controls are drift and diffusion coefficients and the added bounded variation process. We show that the value function is twice continuously differentiable and derive an optimal policy which has feedback-type drift and diffusion coefficients. When the absolute value of the optimal drift grows faster than the running cost function, the optimal bounded variation process is identically zero. When it grows weaker than the running cost function, optimal bounded variation process is a local time-type process. In this case, we relate the control problem with an optimal stopping problem. We also establish the Abelian limit relations between the value functions of the discounted cost problem and the stationary problem.

Key words. stochastic optimal control, principle of smooth fit, optimal stopping, diffusion processes with reflections

1. Introduction. We consider a class of discounted stochastic control problems where the controlled state process is a one-dimensional Itô process. The controller is allowed to control the drift and diffusion parameters as well as an added bounded variation process. The controller's objective is to minimize the overall cost which is an infinite time horizon integral with two components: a running cost due to the location of the state process, and a cost for using the bounded variation process which is proportional to the increase in total variation. The running cost is minimal near the origin, and it grows as the state moves away from the origin. The precise mathematical model will be described in section 2.

The problem considered here is related to the seminal work of [4], which initiated the derivation of explicit optimal policies for bounded variation control problems. In an interesting article [9], Karatzas considered three stochastic control problems related to the Brownian motion: the discounted control problem, the finite horizon control problem, and the stationary (Ergodic) control problem. Explicit optimal policies are derived there, and the Abelian limit relationships among the value functions are also established. In our work, the case of zero mean and the constant diffusion agrees with the results of [9]. In [15], Ma considered the discounted cost problem for a diffusion process with a linear drift term, and the available control is the bounded variation process. There, the optimal control is a "local time"-type process which enforces the optimal process to take values in a finite interval. Our results in section 5 are similar. But in [15], the running cost function $h(x)$ described below in (2.4) is assumed convex and the "discount factor" α in (2.4) below has a positive lower bound. Thus, the consideration of the Abelian limit $\lim_{\alpha\to 0} \alpha V_\alpha(x)$ is not possible, where V_α is the value function. In contrast, here $h(x)$ need not be convex, α is allowed to take any positive

value, and we compute the Abelian limit in section 6. In [14], one can find a novel approach of relating similar stochastic control problems with linear programming problems over the space of probability measures to obtain general existence theorems for optimal Markovian controls. The higher dimensional discounted control problem for Brownian motion is considered in the articles of [5], [6], [13], [21], and [23]. The optimal process, in general, is a reflected Brownian motion, and the reflecting boundary turned out to be the free boundary associated with the Hamilton–Jacobi–Bellman (HJB) equation.

Arisawa and Lions [3] consider an ergodic control problem (also known as the stationary control problem) in a compact state space. They systematically analyze the stationary problem and establish the Abelian limit relationships of value functions. They also point out that the existence of a solution to the HJB equation related to the stationary problem, in general, is not known. We refer to a recent article [17] for some results in this direction. Here we also provide a solution to the HJB equation of the stationary problem in section 6. In [22], the author has analyzed the stationary control problem with the same control parameters and established the optimal policy under quite general conditions. We use the results in [22] to establish Abelian relationships for the value function.

In a series of articles (see [1] and [2]), Alvarez considered bounded variation control problems for diffusions with an absorbing barrier at the origin and with a controlled increasing process in place of the bounded variation process. He used the connection between stochastic control and optimal stopping to derive optimal policies. This is a known theme in stochastic control; see [10] and [11]. This relationship is used in [18] to derive an optimal policy for a discounted control problem with degenerate variance controls without the presence of a bounded variation process. In [19], the authors provide a solution to the stationary control problem for degenerate variance controls and establish the Abelian limit relationships of the value functions of the related control problems.

In section 2 we develop the mathematical model and state the basic assumptions. Section 3 is devoted to a simple verification lemma which enables us to find optimal strategies. In many of the above mentioned articles (see [1], [2], [4], [9], [15]), the optimal policy involves a local time-type process for the bounded variation control. However, with the generality of the problem considered here, the running cost function $h(x)$ may grow much slower than $\mu_0(x)$ as $|x|$ tend to infinity, where $\mu_0(x)$ represents the maximum magnitude of the drift that can be enforced at x as described in (2.3). In this case, it is optimal not to use the bounded variation process at all. This result is proved in section 4.

In section 5, we consider the situation where $h(x)$ grows faster than $\mu_0(x)$. Here our optimal state process is a reflecting diffusion on a finite interval. To obtain this result, first we solve an auxiliary optimal stopping problem whose value function is indeed the derivative of the value function of the control problem. In section 6, we establish the Abelian relationship between the value functions of the discounted control problem and the stationary control problem. We also derive a solution to the HJB equation of the stationary problem.

In [8], Fujita and Morimoto address an ergodic control problem without the presence of a bounded variation control process $A(t)$. They control only the drift process $u_1(t)$. With our notation, $|u_1(t) \leq 1,\ u_2(t) \equiv 1$, and $A(t) \equiv 0$. Their optimal policy is similar to our unbounded optimal process in section 4. They also derive explicit expressions for the optimal value λ_0. In a simple example with $h(x) = x^2$ their opti-

mal value $\lambda_0 = \frac{1}{2}$. In contrast, with our model $\mu_0(x) \equiv 1$ and $h(x) = x^2$; the optimal process is a reflecting diffusion in a finite interval as described in section 6. By solving (6.16)–(6.18) explicitly, we can show that the optimal value λ_0 is the positive root of the equation $(x^2 - 6)e^x + 2x + 2 = 0$ and $\lambda_0 \approx 0.33590$ approximately. Thus, the efficient use of the control $A(t)$ is justified since it lowers the overall cost.

In our problem, if the position of the state process at time $t-$ is r, then the available choices for mean-variance pair at time t can be considered as belonging to the control set $C(r) = \{(\mu, \sigma) : |\mu| \leq \mu_0(r),\ |\sigma| \geq \sigma_0(r)\}$. In contrast with many articles in stochastic control literature, our control sets $C(r)$ are not compact. In fact, each $C(r)$ is unbounded.

2. Problem formulation. Consider a stochastic process $X_x(t)$ which can be considered as a weak solution to a one-dimensional stochastic differential equation

$$X_x(t) = x + \int_0^t u_1(s)ds + \int_0^t u_2(s)dW(s) + A(t), \tag{2.1}$$

where x belongs to $\mathbb{R}$, and $\{W(t) : t \geq 0\}$ is a standard Brownian motion adapted to a right-continuous filtration $\{F_t : t \geq 0\}$ on some probability space (Ω, F, P). F_0 contains all the P-null sets in F; each F_t is contained in F and is independent of the increments $\{W(t+s) - W(t) : s \geq 0\}$. The processes $u_1(t)$ and $u_2(t)$ are real valued, progressively measurable with respect to $\{F_t\}$, and satisfy condition (2.2) below. The process $A(t)$ is also $\{F_t\}$-adapted, right continuous with left limits, and is of bounded variation on finite intervals. Hence $A(t)$ is also progressively measurable. Let $|A|(t)$ be the total variation of the process A on the interval $[0, t]$.

The processes $u_1(t), u_2(t)$, and $A(t)$ are considered to be control processes. We assume that there is an increasing sequence of stopping times (τ_n) with respect to $\{F_t\}$ such that $\lim_{n\to\infty} \tau_n = +\infty$ and for each $T > 0$,

$$\begin{aligned} &\text{(i)} \quad E\left[|A|(T \wedge \tau_n) + \int_0^{T\wedge\tau_n} \left(|u_1(s)| + |u_2(s)|^2\right) ds\right] < \infty \ \text{ and} \\ &\text{(ii)} \quad \lim_{n\to\infty} E\left[|X_x(\tau_n)|e^{-\alpha\tau_n}\right] = 0, \end{aligned} \tag{2.2}$$

where $\alpha > 0$ is a constant associated with the cost function in (2.4) below. Part (i) of (2.2) is imposed to make sense of (2.1). Both parts of (2.2) will be effectively used in the proof of the verification lemma in section 3. Both conditions of (2.2) are satisfied if $E[\int_0^T (|u_1(s)| + u_2^2(s))ds] < \infty$ for each $T > 0$ and if the cost $J(x, \underline{u}, A)$ defined in (2.4) is finite. With our assumption A.2 below, the finiteness of $J(x, u, A)$ implies that $E[|A|(T)] < \infty$ for each $T > 0$ and guarantees the existence of a sequence (T_n) such that $\lim_{n\to\infty} T_n = +\infty$ and $\lim_{n\to\infty} e^{-\alpha T_n} E\left[|X_x(T_n)|\right] = 0$.

We make the following basic assumptions on the functions $\mu_0(y), \sigma_0(y)$, and $h(y)$ throughout this article. Additional assumptions will be made in each section appropriately.

A.1. $\mu_0(y)$ and $\sigma_0(y)$ are nonnegative even functions and are continuously differentiable on $\mathbb{R}$. Furthermore, $\mu_0(y)$ is decreasing on $(-\infty, 0)$, increasing on $(0, +\infty)$, and $\sigma_0(y)$ satisfies $\inf_{\mathbb{R}} \sigma_0(y) > 0$.

A.2. $h(y)$ is a continuously differentiable, nonnegative even function and is decreasing on $(-\infty, 0)$ and increasing on $(0, \infty)$. Also we let $h(0) = 0$ and $h(y) \geq c_0 + c_1|y|$ for all y, where c_0 and c_1 are constants and $c_1 > 0$.

At each time instant $t \geq 0$, the controller is required to choose $A(t)$ as well as the drift-diffusion pair $(u_1(t), u_2(t))$ satisfying (2.2) and

$$|u_1(t)| \leq \mu_0(X(t-)) \text{ and } |u_2(t)| \geq \sigma_0(X(t-)) \text{ for each } t \geq 0. \tag{2.3}$$

(We let $X(0-) \equiv X(0)$ when $t = 0$.)

For a given x in $\mathbb{R}$, we call $((\Omega, F, P), (F_t), W(t), X_x(t), \underline{u}(t), A(t))$ an admissible control system if (i) $X_x(t)$ is a weak solution to (2.1) with respect to $\{F_t\}$-Brownian motion $W(t)$, and the control processes $\underline{u}(t) \equiv (u_1(t), u_2(t))$ and $A(t)$ in the probability space (Ω, F, P), and (ii) the control processes $\underline{u}(t)$ and $A(t)$ satisfy the above described assumptions and (2.2) and (2.3).

This definition of admissible control systems is quite standard; for example, see [7]. Let $\sum(x)$ be the collection of all available control systems. For each admissible control system we define the associated cost function by

$$J(x, \underline{u}, A) = E\left[\int_0^\infty e^{-\alpha t}(h(X_x(t))dt + c.d|A|(t))\right], \tag{2.4}$$

where $\alpha > 0$ is a constant. For simplicity we assume $c = 1$. Our control problem is to minimize $J(x, \underline{u}, A)$ over all available admissible control systems in $\sum(x)$. We define the value function

$$V(x) = \inf_{\sum(x)} J(x, \underline{u}, A). \tag{2.5}$$

We intend to characterize a set of optimal controls $\underline{u}^*(t) = (u_1^*(t), u_2^*(t)), A^*(t)$ and derive an optimal state process $X^*(t)$ which yields $J(x, \underline{u}^*, A^*) = V(x)$ for each x in $\mathbb{R}$.

The formal HJB equation for the value function $V(x)$ is given by

$$\min\left\{\inf_{|u_1| \leq \mu_0(x)} \frac{1}{2}u_2^2 V''(x) + u_1 V'(x) - \alpha V(x) + h(x),\ 1 - |V'(x)|\right\} = 0. \tag{2.6}$$

In sections 4 and 5 we verify that the value function is a C^2-function and that it satisfies (2.6).

In our approach, first we consider the case where the variance coefficient is not available for control. Hence we take $u_2(s) \equiv \sigma_0(X_x(s-))$ and obtain the optimal strategy. In the next step, we approach the general case.

Therefore, for each x in $\mathbb{R}$, we introduce a subcollection $\sum_1(x)$ of $\sum(x)$ by taking $u_2(s)$ identically equal to $\sigma_0(X(s-))$ in (2.1) where $\sum(x)$ is defined prior to (2.4). In this case, each admissible control system $((\Omega, F, P), (F_t), W(t), X_x(t), \underline{u}(t), A(t))$ in $\sum_1(x)$ satisfies

$$\text{(i) } X_x(t) = x + \int_0^t u_1(s)ds + \int_0^t \sigma_0(X_x(s-))dW(s) + A(t) \tag{2.7}$$

and

$$\text{(ii) conditions (2.2) and (2.3) with } u_2(t) \equiv \sigma_0(X_x(t-)) \text{ for all } t. \tag{2.8}$$

For this collection $\sum_1(x)$, we define the analogous value function $U(x)$ by

$$U(x) = \inf_{\sum_1(x)} J(x, \underline{u}, A), \tag{2.9}$$

where $J(x, \underline{u}, A)$ is defined in (2.4).

Our optimal policies also solve the following control problem of a more theoretical nature. Consider a weak solution

$$X_x(t) = x + \int_0^t u_2(s)dW(s) + \Lambda(t), \tag{2.10}$$

where $W(t)$ is a Brownian motion, the control $u_2(t)$ satisfies the previous assumptions, and $|u_2(t)| \geq \sigma_0(X_x(t-))$. The control $\Lambda(t)$ is a bounded variation process which satisfies all the assumptions of $A(t), \Lambda(0) = 0$, and, in addition, we assume the following conditions: Let

$$\Lambda(t) = \Lambda_1(t) + \Lambda_2(t) \tag{2.11}$$

be the Lebesgue decomposition of $\Lambda(t)$ with $\Lambda_1(t)$ the absolutely continuous control, and let $\Lambda_2(t)$ be the singular control (possibly with the jumps) with respect to the Lebesgue measure. We assume Λ_1 and Λ_2 are adapted to $\{F_t\}$ and let $\frac{d\Lambda_1}{dt} = u_1(t)$. We consider $\Lambda_1(t)$ as a cost-free control process subject to the constraint $|u_1(t)| \leq \mu_0(X_x(t-))$, where μ_0 is described in A.1. The singular control process $\Lambda_2(t)$ incurs a cost when used, but it is not subject to any further constraints. Consider the cost function

$$\widehat{J}(x, u_2, \Lambda) = E\left[\int_0^\infty e^{-\alpha t}(h(X_x(t))dt + d|\Lambda_2|(t))\right], \tag{2.12}$$

where $|\Lambda_2|(t)$ denotes the total variation process of Λ_2 on $[0, t]$. The control problem is to minimize $\widehat{J}(x, u_2, \Lambda)$ over all available controls u_2 and Λ. Observe that $\widehat{J}(x, u_2, \Lambda) = J(x, \underline{u}, \Lambda_2)$, where J is given in (2.4), and since our optimal bounded variation control process $A(t)$ for (2.5) is either identically zero or is a singular process with respect to the Lebesgue measure, it follows that $\inf_{u_2,\Lambda} \widehat{J}(x, u_2, \Lambda)$ is also equal to $V(x)$ and the same optimal policies minimize $\widehat{J}(x, u_2, \Lambda)$. Our results obtain the conditions under which it is optimal to choose Λ_2 identically zero. In the case when a nonzero Λ_2 is optimal, it is identical to the optimal $A(t)$ process described in section 5.

3. A verification lemma. Here we formulate a simple verification lemma which is adequate for the purpose of this paper. This lemma is closely related to Theorem 2.1 of [15]. For results on very general verification theorems, we refer to Chapter 8 of [7].

LEMMA 3.1. *Let $Q(x)$ be a twice continuously differentiable even function satisfying the following conditions:*

$$\text{(i)} \quad -1 \leq Q'(x) \leq 0 \text{ for } x \leq 0 \text{ and } 0 \leq Q'(x) \leq 1 \text{ for } x \geq 0. \tag{3.1}$$

$$\text{(ii)} \quad \frac{\sigma_0^2(x)}{2}Q''(x) - \mu_0(x)sign(x)Q'(x) - \alpha Q(x) + h(x) \geq 0 \quad \text{for every } x. \tag{3.2}$$

Then the following conclusions hold.

(a) *$U(x) \geq Q(x)$ for all x, where $U(x)$ is defined as in* (2.9).

(b) *In addition to* (i) *and* (ii), *assume $Q''(x) \geq 0$ for all x; then $V(x) \geq Q(x)$, where $V(x)$ is defined in* (2.5).

Proof. It suffices to consider the processes $X_x(t)$ satisfying (2.1) and that the corresponding cost $J(x, \underline{u}, A)$ given in (2.4) is finite; otherwise $J(x, \underline{u}, A) \geq Q(x)$ is trivial. This together with (A.2) implies that $E\int_0^\infty e^{-\alpha t}|X_x(t)|dt$, $E\int_0^\infty e^{-\alpha t}d|A|(t)$, and $E[|A(T)|]$ are all finite. Consequently, $\liminf_{t\to\infty} E|X_x(t)|e^{-\alpha t} = 0$. We use these facts in the proof below. Let (τ_n) be as in (2.2).

To prove (a), we apply the generalized Itô formula (cf. Meyer [16, p. 285]).

$$
\begin{aligned}
&Q(X_x(T\wedge\tau_k))e^{-\alpha(T\wedge\tau_k)}\\
&= Q(x) + \int_0^{T\wedge\tau_k} e^{-\alpha s}Q'(X_x(s-))\sigma_0(X_x(s-)dW(s) + \int_0^{T\wedge\tau_k} e^{-\alpha s}Q'(X_x(s-))dA(s)\\
&\quad + \int_0^{T\wedge\tau_k} e^{-\alpha s}\left(\frac{1}{2}\sigma_0^2(X_x(s-))Q'' + u_1(s)Q' - \alpha Q\right)(X_x(s-))ds\\
&\quad + \sum_{0<s\le T\wedge\tau_k} e^{-\alpha s}[\Delta Q(X_x(s)) - Q'(X_x(s-))\Delta A(s)],
\end{aligned}
\tag{3.3}
$$

where $\Delta Q(X_x(s)) = Q(X_x(s)) - Q(X_x(s-))$.

Since $|Q'(x)\le 1$ for all x, the quantities $E[\sum_{0<s\le T\wedge\tau_k} e^{-\alpha s}|\Delta Q(X_x(s))|]$ and $E[\sum_{0<s\le T\wedge\tau_k} e^{-\alpha s}|Q'(X_x(s-))|.|\Delta A(s)|]$ are all bounded above by $E\int_0^\infty e^{-\alpha t}d|A|(t)$, and hence they are finite. Let $\{A^c(t)\}$ be the continuous part of $\{A(t)\}$. Then since $|Q'(x)|\le 1$ for all x, we have

$$
\begin{aligned}
&E\int_0^{T\Lambda\tau_k} e^{-\alpha s}Q'(X_x(s-))dA(s) + E\sum_{0<s\le T} e^{-\alpha s}[\Delta Q(X_x(s)) - Q'(X_x(s-))\Delta A(s)]\\
&= E\int_0^{T\Lambda\tau_k} e^{-\alpha s}Q'(X_x(s-))dA^c(s) + E\sum_{0<s\le T} e^{-\alpha s}\Delta Q(X_x(s))\\
&\ge -E\int_0^{T\Lambda\tau_k} e^{-\alpha s}d|A|(s).
\end{aligned}
\tag{3.4}
$$

By (2.2) and (2.8), $E[\int_0^{T\wedge\tau_k} e^{-\alpha s}Q'(X_x(s-))\sigma_0(X_x(s-))dW(s)] = 0$, and by a straightforward computation using (3.1), (3.2), and (3.4) in (3.3), we obtain

$$
E\left[e^{-\alpha(T\wedge\tau_k)}\left[|Q(0)| + |X_x(T\wedge\tau_k)|\right]\right] + J(x,u,A) \ge Q(x).
$$

By (2.2), $\lim_{k\to\infty} E\left[|X_x(\tau_k)|e^{-\alpha\tau_k}\right] = 0$ and also $\lim_{T\to\infty}\inf e^{-\alpha T}E|X_x(T)| = 0$ as we observed above. Hence by letting $\tau_k\to+\infty$ and then $T\to+\infty$ we obtain $J(x,\underline{u},A)\ge Q(x)$ for each x and (a) follows.

Proof of (b) is essentially the same once we obtain the inequality described below by employing (3.2) and the fact $Q''(x)\ge 0$ for all x. For each x and (u_1,u_2) which satisfy $|u_1|\le\mu_0(x)$ and $|u_2|\ge\sigma_0(x)$,

$$
\begin{aligned}
&\frac{1}{2}u_2^2Q''(x) + u_1Q'(x) - \alpha Q(x) + h(x)\\
&\qquad \ge \frac{\sigma_0^2(x)}{2}Q''(x) - \mu_0(x)\ \mathrm{sign}(x)Q'(x) - \alpha Q(x) + h(x) \ge 0.
\end{aligned}
$$

The last inequality follows from (3.2). Now the proof of (b) follows from the same argument as in (a). □

4. An unbounded optimal process. Consider a weak solution

$$
Z_x(t) = x - \int_0^t \mu_0(Z_x(s))\ \mathrm{sign}(Z_x(s))ds + \int_0^t \sigma_0(Z_x(s))dW(s) \tag{4.1}
$$

on some probability space (Ω, F, P) with respect to a Brownian motion $\{W(t) : t \geq 0\}$. $Z_x(t)$ is satisfying (2.1) with feedback controls $u_1(s) = -\mu_0(Z_x(s))\ \mathrm{sign}(Z_x(s))$, $u_2(s) = \sigma_0(Z_x(s))$, and $A(t)$ is identically zero. Throughout this section, we assume the following assumptions in addition to A.1 and A.2 given in section 2, and they will guarantee that $Z_x(t)$ is an admissible state process satisfying (2.2) and $Z_x(t)$ is finite for each t.

(4.2) (i) For each $x > 0$, $\quad \alpha + \mu_0'(x) > h'(x)$.

(ii) Let $\rho_0(x) = \dfrac{\mu_0(x)}{\sigma_0^2(x)}$ for $x > 0$, and we assume *either*

(4.3) $$\text{(a)} \int_1^\infty \rho_0(u)du = +\infty \quad \text{or} \quad \text{(b)} \int_1^\infty \frac{u}{\sigma_0^2(u)}\, du = +\infty.$$

The assumptions (4.2) and (4.3) are restricted only to this section.

We introduce a sequence of stopping times $\{\tau_n\}$ for each $n > |x|$ by

(4.4) $$\begin{aligned} \tau_n &= \inf\{t \geq 0 : |Z_x(t)| \geq n\} \\ &= +\infty \ \text{ if the above set is empty.} \end{aligned}$$

PROPOSITION 4.1. *Assume* (4.3) *and let* $\{Z_x(t)\}$ *be defined by* (4.1).

Then $\lim_{N\to\infty} E[|Z_x(\tau_N)|e^{-\alpha\tau_N} I_{[\tau_N<\infty]}] = 0$, *and hence* $Z_x(t)$ *is finite for each* $t > 0$ *and* $Z_x(t)$ *satisfies the admissibility condition* (2.2) *with respect to the sequence* $\{\tau_n\}$ *defined in* (4.4).

Proof. Let $H_0(x)$ be the solution to the differential equation

(4.5) $$\frac{\sigma_0^2(x)}{2} H_0''(x) - \mu_0(x)H_0'(x) - \alpha H_0(x) = 0 \text{ for } x > 0, \quad H_0(0) = 1, \qquad H_0'(0) = 0.$$

First we establish

(4.6) $$\lim_{x\to\infty} H_0'(x) = +\infty \ \text{ and thus } \lim_{x\to\infty} \frac{H_0(x)}{x} = +\infty.$$

Since $\mu_0(x) \geq 0$, by elementary analysis, $H_0(x)$ has no positive local maxima, and hence $H_0(x)$ is increasing and therefore $H_0''(x)$ is positive. Therefore, $H_0(x)$ is convex and $\lim_{x\to\infty} H_0(x) = +\infty$. Let $\rho_0(x)$ be given in (4.3). Introduce $A(x) = \int_0^x \rho_0(r)dr$. Then using (4.5) we obtain

(4.7) $$H_0'(x) = e^{2A(x)} \int_0^x \frac{2\alpha H_0(r)}{\sigma_0^2(r)}\, e^{-2A(r)} dr.$$

Assume (4.3)(a). Since $H_0(r) \geq 1$ it follows that $H_0'(x) \geq e^{2A(x)} \int_0^1 \frac{2\alpha}{\sigma_0^2(r)}\, e^{-2A(r)} dr$ for $x > 1$, and thus $\lim_{x\to\infty} H_0'(x) = +\infty$ as $\lim_{x\to\infty} A(x) = +\infty$.

(4.8) $$\text{Now assume } \int_1^\infty \frac{u}{\sigma_0^2(u)} du = +\infty \text{ as in (4.3)(b).}$$

It suffices to consider that the case $\lim_{x\to\infty} A(x) = L$ is finite. Since $H_0(x)$ is strictly convex, $H_0(x) > m_0 + m_1(x-1)$, where $m_0 = H_0(1)$ and $m_1 = H_0'(1) > 0$. By (4.7) we have

(4.9) $$H_0'(x) > \left[\int_0^1 \frac{2\alpha H_0(r)}{\sigma_0^2(r)}\, dr + \int_1^x \frac{2\alpha(m_0 + m_1(u-1))}{\sigma_0^2(u)}\, du\right] \ \text{ for } x > 1.$$

By (4.8), the right-hand side of (4.9) also tends to infinity. Hence $\lim_{x\to\infty} H_0'(x) = +\infty$ also follows in this case. Since $\lim_{x\to\infty} H_0'(x) = +\infty$, by L'Hopital's rule, $\lim_{x\to\infty} \frac{H_0(x)}{x} = +\infty$. This proves (4.6).

Next we extend $H_0(x)$ to $\mathbb{R}$ as an even function. So for $x < 0$, $H_0(x) = H_0(-x)$. For each $N > |x|$, introduce $H_N(x) = \frac{H_0(x)}{H_0(N)}$. Then H_N satisfies

$$\begin{aligned} &\frac{\sigma_0^2(x)}{2} H_N''(x) - \mu_0(x)\ \mathrm{sign}(x) H_N'(x) - \alpha H_N(x) = 0 \text{ for all } x, \\ &\qquad H_N'(0) = 0,\ H_N(\pm N) = 1. \end{aligned} \tag{4.10}$$

$H_N(x)$ is an even function and by Itô's lemma, we observe that the process $Y(t) = H_N(Z_x(t \wedge \tau_N))e^{-\alpha(t\wedge\tau_N)}$ is a positive martingale. Consequently,

$$E[e^{-a\tau_N} I_{[\tau_N<T]} + e^{-\alpha T} I_{[T<\tau_N]}] \le H_N(x). \tag{4.11}$$

By letting T tend to infinity, we have $E[e^{-\alpha\tau_N} I_{[\tau_N<\infty]}] \le \frac{H_0(x)}{H_0(N)}$. Therefore $E[|Z_x(\tau_N)|e^{-\alpha\tau_N} I_{[\tau_N<\infty]}] \le (\frac{N}{H_0(N)})H_0(x)$. Hence using (4.6), $\lim_{N\to\infty} \frac{N}{H_0(N)} = 0$, and we obtain

$$\lim_{N\to\infty} E[|Z_x(\tau_N)|e^{-\alpha\tau_N} I_{[\tau_N<\infty]}] = 0. \tag{4.12}$$

This clearly implies $\tau_\infty \equiv +\infty$ a.s., where τ_∞ is the explosion time for $Z_x(t)$.

To verify the admissibility condition (2.2) with respect to $\{\tau_N\}$ defined above notice that

$$E\int_0^{T\wedge\tau_N} [\mu_0(Z_x(s)) + \sigma_0^2(Z_x(s))]ds \le \left[\max_{[-N,N]} (\mu_0(x) + \sigma_0^2(x))\right] T < \infty. \tag{4.13}$$

Hence by (4.12) and (4.13), condition (2.2) follows. □

Remark 1. Using the assumption (4.3), one can directly verify the Khasminski's criteria for nonexplosion [20, p. 297] of a diffusion process for $(Z_x(t))$.

Remark 2. Using Itô's lemma for $H_0(Z_x(T \wedge \tau_n))$ and Gronwall's inequality we can derive $E[H_0(Z_x(T))] \le H_0(x)e^{\alpha T}$, and thus $E|Z_x(T)|$ is finite.

Next, we assume A.1, A.2, and (4.2) above. For each $n \ge 1$, let $W_n(x)$ be the solution of the differential equation

$$\frac{\sigma_0^2(x)}{2} W_n''(x) + (\sigma_0(x)\sigma_0'(x) - \mu_0(x))W_n'(x) - (\alpha + \mu_0'(x))W_n(x) + h'(x) = 0 \tag{4.14}$$

for $0 < x < n$ and with the boundary conditions $W_n(0) = 0$ and $W_n(n) = 1$.

Since μ_0', σ_0' and h' are continuous and $\mu_0'(x) \ge 0$, we extend each $W_n(x)$ to $[0, +\infty)$ so that W_n satisfies (4.14) on $[0, \infty)$. We prove the following lemma which leads to our main theorem.

LEMMA 4.2. *Assume* (4.2). *Let* $W_n(x)$ *be defined on* $[0, \infty)$ *satisfying* (4.14).

(i) *For each* $n, 0 < W_n(x) < 1$ *for* $0 < x < n$ *and* $W_n(x) > 1$ *for* $x > n$.

(ii) *For any* $x > 0$, $\{W_n(x)\}$ *is decreasing in* n, *and hence* $W_\infty(x) = \lim_{n\to\infty} W_n(x)$ *exists.*

(iii) *For each* $x > 0$, $0 < W_\infty(x) < 1$, $W_\infty(0) = 0$, *and* W_∞ *satisfies the same differential equation* (4.14) *on* $(0, \infty)$ *as* W_n.

Proof. Let W_n be a solution to (4.14) and introduce $\phi(x)$ by

$$\phi(x) = \frac{h'(x)}{\alpha + \mu_0'(x)} \text{ for } x \geq 0. \tag{4.15}$$

For each $c > 0$ such that $W_n'(c) = 0$ we have

$$\frac{\sigma_0^2(c)}{2} W_n''(c) = (\alpha + \mu_0'(c))(W_n(c) - \phi(c)). \tag{4.16}$$

By (4.2), $\phi(x) < 1$ for all $x > 0$. Thus, (4.16) implies that W_n cannot have nonpositive local minima on $(0, n)$. Furthermore, if $x = c$ is a local maxima with $0 < c < n$, then $0 < W_n(c) < 1$. Hence $0 < W_n < 1$ on $(0, n)$ and $W_n'(n) \geq 0$. Using (4.16) again, it follows that $W_n'(n) > 0$ and W_n cannot have local maxima for $x > n$. This proves (i). To prove (ii) and (iii), let $n > m \geq 1$. Since W_m and W_n both satisfy (4.14), $W_m(0) = W_n(0) = 0$, and $W_n(m) < W_m(m) = 1$, it follows that $W_m(x) > W_n(x)$ for all $x > 0$ and $\{W_n\}$ is a decreasing sequence. Thus $W_\infty(x) = \lim_{n\to\infty} W_n(x)$ exists and $0 \leq W_\infty(x) < 1$. Now let $\psi(x) = W_1(x) - W_2(x)$ for all $x > 0$. Then $\psi(0) = 0$ and $\psi(x) > 0$ for all $x > 0$. For each $n \geq 1$, since W_n satisfy (4.14), we can represent W_n by $W_n(x) = W_1(x) - t_n\psi(x)$, where $t_n = \frac{1-W_n(1)}{1-W_2(1)} > 0$. Since $\{W_n\}$ is decreasing in n, the sequence (t_n) is increasing and is bounded above by $\frac{1}{1-W_2(1)}$. Thus $\lim_{n\to\infty} t_n = t_\infty$ exists and consequently $W_\infty(x) = W_1(x) - t_\infty\psi(x)$ for all $x > 0$ and W_∞ satisfies (4.14). Thus (ii) and (iii) are complete. □

Next we introduce an even function $F : \mathbb{R} \to \mathbb{R}$ as follows:

$$F(x) = \frac{\sigma_0^2(0)}{2\alpha} W_\infty'(0) + \int_0^x W_\infty(r)dr \text{ for } x \geq 0 \tag{4.17}$$

and

$$F(x) = F(-x) \text{ for } x < 0. \tag{4.18}$$

Clearly, $F'(x) = W_\infty(x)$, $F'(0) = W_\infty(0) = 0$, and $\frac{\sigma_0^2(0)}{2} F''(0) = \alpha F(0)$. Now we claim that F satisfies

$$\frac{\sigma_0^2(x)}{2} F''(x) - \mu_0(x)\ \text{sign}(x) F'(x) - \alpha F(x) + h(x) = 0 \text{ on } \mathbb{R} \tag{4.19}$$

and

$$F(0) = \frac{\sigma_0^2(0)}{2\alpha} W_\infty'(0) \geq 0, \qquad F'(0) = 0. \tag{4.20}$$

$$\text{Also, } F \geq 0, \quad -1 \leq F'(x) \leq 0 \text{ for } x \leq 0, \text{ and } \quad 0 \leq F'(x) \leq 1 \text{ for } x \geq 0. \tag{4.21}$$

Since F, μ_0, σ_0 and h are even functions, it suffices to verify (4.19) on $[0, \infty)$. Let $R(x)$ be the left-hand side of (4.19) on $[0, \infty)$. Then $R(0) = \frac{\sigma_0^2(0)}{2} W_\infty'(0) - \alpha F(0) = 0$, and $R'(x)$ is identically zero on $(0, \infty)$ since W_∞ satisfies (4.14). Thus (4.19) follows. (4.20) is obvious and (4.21) is a consequence of Lemma 4.2(iii). Next we state and prove the main theorem in this section.

THEOREM 4.3. *Assume* (4.2) *and* (4.3). *Let* F *be defined by* (4.17) *and* (4.18). *Then*

(i) $F(x) = U(x)$ *for all* x, *where* U *is the value function of the control problem defined in* (2.9). *Moreover,* $Z_x(t)$ *defined in* (4.1) *is an optimal process.*

(ii) *In addition to* (4.2) *and* (4.3), *assume that* $\phi(x)$ *defined in* (4.15) *is increasing. Then* $F(x) = V(x)$, *where* V *is the value function for the control problem described in* (2.5). *Moreover,* $Z_x(t)$ *is an optimal process.*

Proof. Step 1. First we show that $F(x)$ is the cost function due to process $Z_x(t)$ in (4.1). Let τ_N be defined by (4.4). By a direct application of Itô's lemma to $F(e^{-\alpha(T\wedge\tau_N)}Z_x(T\wedge\tau_N))$ and employing Proposition 4.1, we obtain

$$F(x) = E\left[\int_0^\infty e^{-\alpha t}h(Z_x(t))dt\right]. \tag{4.22}$$

Step 2. Next we prove $F(x) = U(x)$, where U is given in (2.9) by using the verification lemma, Lemma 3.1. By (4.21), F clearly satisfies Lemma 3.1(i). F also satisfies (4.19), and hence it satisfies the assumption (3.2) there. Consequently, $U(x) \geq F(x)$, but by (4.22) it follows that $F(x) = U(x)$ and $Z_x(t)$ in (4.1) define an optimal process.

Step 3. To prove (ii), we intend to apply Lemma 3.1. All we have to do is to verify $F''(x) \geq 0$ for all x. It suffices to show $F''(x) \geq 0$ for $x \geq 0$. Notice $F''(x) = W'_\infty(x)$, where W_∞ is given in Lemma 4.2. By (4.22), $F(0) > 0$, and thus $F''(0) > 0$ by (4.19). Now suppose that $F''(x_1) < 0$ for some $x_1 > 0$. Since $W_\infty(x) \equiv F'(x)$ for $x \geq 0$ and also $W_\infty(x)$ is the decreasing limit of $\{W_n(x)\}$, where $W_n(x)$ satisfy (4.14) with $W_n(0) = 0$, and $W_n(n) = 1$, it follows that there exist large N and two points $0 < \xi_1 < \xi_2$ such that W_N has a local maxima at $x = \xi_1$ and local minima at $x = \xi_2$. Hence $W''_N(\xi_1) \leq 0 \leq W''_N(\xi_2)$ and using (4.14) together with the fact $W'_N(\xi_1) = W'_N(\xi_2) = 0$ we obtain $\frac{\sigma_0^2(\xi_1)}{2}W''_N(\xi_1) = (\alpha + \mu'_0(\xi_1))[W_N(\xi_1) - \phi(\xi_1)] \leq 0$ and $\frac{\sigma_0^2(\xi_2)}{2}W''_N(\xi_2) = (\alpha + \mu'_0(\xi_2))[W_N(\xi_2) - \phi(\xi_2)] \geq 0$, where ϕ is given by (4.15). Since $\mu'_0(x) \geq 0$, we have $\phi(\xi_1) \geq W_N(\xi_1) > W_N(\xi_2) \geq \phi(\xi_2)$ which contradicts the fact that ϕ is increasing. Hence $F''(x) \geq 0$ for all x and $F(x) \leq V(x)$ for all x, using Lemma 3.1. Moreover, by (4.22), $Z_x(t)$ is an optimal process and $F(x) = V(x)$ for all x. This completes the proof. □

5. A bounded optimal process.

5.1. Assumptions and reflecting diffusions. In this section we make the following assumption regarding the functions μ_0 and h in addition to A.1 and A.2 of section 2. Let $\phi(x) = \frac{h'(x)}{\alpha+\mu'_0(x)}$ be the function defined on $\mathbb{R}$ as in (4.15). Notice $\phi(0) = 0$. We assume the following:

(i) There exist positive constants $R > \beta > 0$ and $\delta_0 > 0$ such that $\phi(x) < 1$ for
$x < \beta,\ \phi(\beta) = 1,\ \phi(x) > 1$ for $x > \beta$, and $\phi(x) > 1 + \delta_0$ for every $x > R$. (5.1)

Our candidate for an optimal policy is derived from the class of diffusion processes with reflecting barriers at $-a$ and $+a$. Therefore for each $a > 0$, we consider a weak solution to the equation

$$X_x^a(t) = x - \int_0^t \mu_0(X_x^a(s))\ \mathrm{sign}(X_x^a(s))ds + \int_0^t \sigma_0(X_x^a(s))dW(s) + K_a(t), \tag{5.2}$$

where the bounded variation process K_a is given by

$$dK_a(t) = dL_{-a}(t) - dL_a(t) \quad \text{for } t > 0 \tag{5.3}$$

and

$$d|K_a|(t) = dL_{-a}(t) + dL_a(t), \tag{5.4}$$

and $\{W(t) : t \geq 0\}$ is a Brownian motion process in some probability space (Ω, F, P) with respect to a filtration $\{F_t\}$. $L_{-a}(t)$ and $L_a(t)$ are local time processes of $X_x^a(t)$ at $-a$ and $+a$, respectively. If $x \in [-a, a]$, then $X_x^a(t) \in [-a, +a]$ for all $t \geq 0$. If $x \notin [-a, a]$, there will be an initial jump to the nearest point of $\{-a, +a\}$ at $t = 0$, and then (5.2) and (5.3) follow. In this case $X(0+) \in \{-a, +a\}$ and $K_a(0)$ corresponds to the jump size at $t = 0$. Clearly, $\{X_x^a(t)\}$ satisfies the assumptions (2.2)–(2.3), and hence they are admissible processes.

Let

$$V_a(x) = E \int_0^\infty e^{-\alpha t}(h(X_x^a(t))dt + d|K_a|(t)). \tag{5.5}$$

Then by Itô's lemma, it is easy to verify that V_a satisfies the following differential equation:

$$\frac{\sigma_0^2(x)}{2} V_a''(x) - \mu_0(x)\ \mathrm{sign}(x) V_a'(x) - \alpha V_a(x) + h(x) = 0 \quad \text{for } -a < x < a, \tag{5.6}$$

$$V_a'(x) = -1 \text{ for } x \leq -a \text{ and } V_a'(x) = 1 \text{ for } x \geq a. \tag{5.7}$$

By symmetry, V_a is an even function. We expect the optimal process reflects at $-a^*$ and a^* and the corresponding V_{a^*}'' vanishes at $-a^*$ and a^* so that the principle of smooth fit holds (see [4], [15]). Hence we expect to find a point $a^* > 0$ such that V_{a^*} satisfies (5.6) and (5.7), V_{a^*}' is continuous on $\mathbb{R}$, and $|V_{a^*}'(x)| \leq 1$ for all x. It suffices to consider (5.6) and (5.7) on $[0, \infty)$. Thus we let $W_a(x) = V_a'(x)$ on $(0, a)$, and it satisfies

$$\frac{\sigma_0^2(x)}{2} W_a''(x) + (\sigma_0(x)\sigma_0'(x) - \mu_0(x)) W_a'(x) - (\alpha + \mu_0'(x)) W_a(x) + h'(x) = 0, \tag{5.8}$$

$$W_a(0) = 0 \text{ and } W_a(a) = 1. \tag{5.9}$$

We need to find the point $a = a^*$ so that $W_{a^*}(x)$ satisfies an additional condition

$$W_{a^*}'(a^*) = 0 \text{ and } 0 < W_{a^*}(x) < 1 \text{ for } 0 < x < a^*. \tag{5.10}$$

We establish the existence of a unique point $a^* > 0$ with the aid of an optimal stopping problem.

5.2. An auxiliary stopping problem. By considering (5.8), (5.9), and (5.10), we formulate the following optimal stopping problem. For each $x > 0$, consider the process

$$Y_x(t) = x + \int_0^t [\sigma_0(Y_x(s))\sigma_0'(Y_x(s)) - \mu_0(Y_x(s))]ds + \int_0^t \sigma_0(Y_x(s))dW(s) \tag{5.11}$$

which is a weak solution to the above equation with respect to a Brownian motion $\{W(t)\}$ adapted to a filtration $\{F_t\}$ in a probability space (Ω, F, P). We introduce the stopping time τ_0 by

$$\begin{aligned} \tau_0 &= \inf\{t > 0 : Y_x(t) = 0\} \\ &= +\infty \ \text{ if the above set is empty.} \end{aligned} \tag{5.12}$$

Introduce the set

$$\prod = \{\tau \geq 0 : \tau \text{ is a stopping time with respect to } \{F_t\}\} \tag{5.13}$$

and consider the stopping problem

$$S(x) = \inf_{\tau \in \prod} E\left[e^{-R(\tau)} I_{[\tau < \tau_0]} + \int_0^{\tau \wedge \tau_0} e^{-R(u)} h'(Y_x(u)) du\right], \tag{5.14}$$

where

$$R(t) = \int_0^t (\alpha + \mu_0'(Y_x(s))) ds. \tag{5.15}$$

We claim that the optimal stopping time is of the form τ_{a^*}, where τ_{a^*} is the first hitting time of the level a^* by the process $Y_x(t)$ for some $a^* > 0$. V_{a^*} characterized by (5.5)–(5.7) turned out to be the value function for the control problem and $V_{a^*}'(x) = S(x)$ for each $x > 0$. To verify these assertions, first we define the stopping time τ_a by

$$\begin{aligned} \tau_a &= \inf\{t > 0 : Y_x(t) = a\} \\ &= +\infty \text{ if the above set is empty.} \end{aligned} \tag{5.16}$$

We introduce the stochastic representation for the solution $W_a(x)$ of (5.8) and (5.9):

$$W_a(x) = E\left[e^{-R(\tau_a)} I_{[\tau_a < \tau_0]} + \int_0^{\tau_a \wedge \tau_0} e^{-R(u)} h'(Y_x(u)) du\right] \tag{5.17}$$

for each x in $[0, a]$, where $R(t)$ is given in (5.15). By Itô's lemma, it is easy to verify that W_a also satisfies (5.8) and (5.9). We extend each W_a to $\mathbb{R}^+$ so that it satisfies the differential equation (5.8) on the interval $(0, \infty)$. On $[0, a]$, W_a has the representation (5.17) and $V_a'(x) = W_a(x)$. We use these facts in our next lemma which derives an upper bound for optimal a^*.

LEMMA 5.1. *Assume* (5.1). *Then there exists a constant* $a_1 > R$ *such that for each* $a > a_1$, $\sup_{[0,a]} W_a(x) > 1$, *where* R *is given in* (5.1).

Proof. We assume the contrary. Suppose that there exists a strictly increasing sequence (b_n) so that $b_n > R$ for all n, $\lim_{n\to\infty} b_n = +\infty$, and $\sup_{[0,b_n]} W_{b_n}(x) \leq 1$ for each n. We claim $0 < W_{b_n}(x) < 1$ for $0 < x < b_n$. Suppose $W_{b_n}(x_n) = 1$ and $0 < x_n < b_n$; then W_{b_n} has a local maximum at x_n. Hence we use (5.8) to obtain $h'(x_n) \geq \alpha + \mu_0'(x_n)$ and therefore by (5.1), $x_n \geq \beta$. Since $W_{b_n}(x_n) = W_{b_n}(b_n) = 1$ and W_{b_n} satisfies (5.8), it has a local minimum at a point $x = z_n$, where $\beta \leq x_n < z_n < b_n$ and $W_{b_n}(z_n) < 1$. Again using (5.8) at $x = z_n$ we obtain $\alpha + \mu_0'(z_n) > h'(z_n)$ which contradicts (5.1). Thus our claim is true and furthermore $W_{b_n}'(b_n) \geq 0$. Next we claim $W_{b_n}'(b_n) > 0$ for all n. Suppose that $W_{b_n}'(b_n) = 0$. By (5.8) and (5.1), since $b_n > \beta$ we have $W_{b_n}''(b_n) < 0$. First, as in the above argument, we observe that W_{b_n} cannot have any local minima at a point $x = z$ satisfying $z > \beta$ and $W_{b_n}(z) \leq 1$. Hence W_{b_n} achieves its maximum at $x = b_n$ and decreasing on $[b_n, \infty)$. Next we compare W_{b_n} and $W_{b_{n+1}}$. $W_{b_{n+1}}(b_n) < W_{b_n}(b_n) = 1$, $W_{b_n}(b_{n+1}) < W_{b_{n+1}}(b_{n+1}) = 1$, and $W_{b_n}(0) = W_{b_{n+1}}(0) = 0$. Therefore W_{b_n} and $W_{b_{n+1}}$ both satisfy (5.8) and meet at $x = 0$ and at a point $x = q_n$, where $b_n < q_n < b_{n+1}$. Hence $W_{b_n} \equiv W_{b_{n+1}}$, and this leads to a contradiction as $W_{b_{n+1}}(b_n) < 1$. Thus $W_{b_n}'(b_n) > 0$ for all n.

Our next claim is $W'_{b_n}(0) \le W'_{b_1}(0)$ for all n. Suppose not. Assume $W'_{b_m}(0) > W'_{b_1}(0)$ for some m. Since $W_{b_m}(0) = W_{b_1}(0) = 0$, there exist $c_1 > 0$ such that $W_{b_m}(c_1) > W_{b_1}(c_1)$. Again W_{b_m} and W_{b_1} satisfy (5.8) and meet at $x = 0$ and at another point on (c_1, b_1), and hence $W_{b_m} \equiv W_{b_1}$. This contradicts the fact $W_{b_m}(b_1) < W_{b_1}(b_1) = 1$. Consequently, we conclude that $\sup_n W'_{b_n}(0) \le W'_{b_1}(0)$.

By (5.6) we observe that $\alpha V_{b_n}(0) = \frac{\sigma_0^2(0)}{2} W'_{b_n}(0) \le \frac{\sigma_0^2(0)}{2} W'_{b_1}(0)$, where V_{b_n} is given in (5.5) and $V'_{b_n}(x) \equiv W_{b_n}(x)$ on $[0, b_n]$. Hence by (5.6) we obtain

$$\frac{\sigma_0^2(b_n)}{2} W'_{b_n}(b_n) + h(b_n) - \mu_0(b_n) = \frac{\sigma_0^2(0)}{2} W'_{b_n}(0) + \alpha \int_0^{b_n} W_{b_n}(r)dr. \tag{5.18}$$

Since $W'_{b_n}(b_n) > 0$ and $\sup_n W'_{b_n}(0) \le W'_{b_1}(0)$, and $\sup_{[0,b_n]} W_{b_n}(x) \le 1$, we obtain

$$h(b_n) - \mu_0(b_n) < \frac{\sigma_0^2}{2} W'_{b_1}(0) + \alpha b_n \quad \text{for all} \quad n. \tag{5.19}$$

But (5.1) implies that

$$h(b_n) - \mu_0(b_n) > \alpha(1 + \delta_0)(b_n - R) + \delta_0 \mu_0(b_n) + [h(R) - (1 + \delta_0)\mu_0(R)] \tag{5.20}$$

and consequently by (5.19) and (5.20)

$$\alpha(1 + \delta_0)\left(1 - \frac{R}{b_n}\right) - \frac{(1 + \delta_0)\mu_0(R)}{b_n} < \alpha + \frac{\sigma_0^2(0)}{2b_n} W'_{b_1}(0). \tag{5.21}$$

By letting $b_n \to +\infty$ we obtain $\alpha(1 + \delta_0) \le \alpha$ which is a contradiction as $\alpha > 0$ and $\delta_0 > 0$. This proves the lemma. □

Now we derive the solution to the stopping problem described in (5.14).

THEOREM 5.2. *Assume* (5.1). *Then*

(i) *there exist* $a^* > 0$ *such that the function* W_{a^*} *defined by* (5.17) *satisfies* (5.8), (5.9), *and* (5.10);

(ii) *let* $S(x)$ *be the value function for the stopping problem as in* (5.14) *for* $x \ge 0$. *Then*

$$S(x) = \begin{cases} W_{a^*}(x) & \text{for } x \le a^*, \\ 1 & \text{for } x > a^*. \end{cases} \tag{5.22}$$

Thus $S'(x)$ *is continuous on* $(0, \infty)$, *and* $S''(x)$ *is continuous on* $(0, \infty)$ *except at* $x = a^*$. *But* $S''(a^*-)$ *and* $S''(a^*+)$ *both exist finitely.*

Moreover, an optimal stopping time τ^* *is defined by*

$$\tau^* = \begin{cases} \tau_{a^*} & \text{if } 0 < x < a^*, \\ 0 & \text{if } x \ge a^*. \end{cases} \tag{5.23}$$

Proof. Let $\beta > 0$ be as in assumption (5.1). Thus for each a in $(0, \beta)$ we consider the function $W_a(x)$ which satisfies (5.8) and (5.9) on $(0, +\infty)$. By Lemma 4.2, $0 < W_a(x) < 1$ for each x in $(0, a)$. Thus $W'_a(a) \ge 0$, but if $W'_a(a) = 0$, then by (5.7) and

(5.8), W_a has a strict local minima at $x = a$, and this contradicts $0 < W_a(x) < 1$ on $(0, a)$. Hence $W'_a(a) > 0$. We let

$$a^* = \sup\{b < 0 : \text{ for each } 0 < a < b,\ W_a(x) \in (0,1) \text{ for } x \text{ in } (0,a)\}. \tag{5.24}$$

Thus, $0 < \beta < a^* < a_1 < \infty$, where a_1 is given in Lemma 5.1, and hence a^* is finite. We claim that $0 < W_{a^*}(x) < 1$ and $W'_{a^*}(a^*) = 0$. If (a_n) is a sequence increasing to a^*, then $W_{a_n}(x)$ is decreasing to $W_{a^*}(x)$ as in Lemma 4.2. Hence $W_{a^*}(x) < 1$. But W_{a^*} satisfies (5.17); hence $W_{a^*}(x) > 0$ on $(0, a^*)$ and $W_{a^*}(a^*) = 1$. Thus $W'_{a^*}(a^*) \geq 0$. But if $W'_{a^*}(a^*) > 0$, we extend W_{a^*} to $[0, \infty)$ satisfying (5.8) and consider $W_{a^*}(x) - t\psi(x)$, where $\psi(x)$ is a positive solution to homogeneous equation related to (4.14), $\psi(0) = 0$, and t is a parameter. Thus elementary arguments show that for $0 < t < \varepsilon_1$, $W_{a^*} - t\psi$ also satisfies the conditions of the set in (5.24), and hence $a^* + \varepsilon$ also belong to the set in (5.24) leading to a contradiction. Consequently, $W'_{a^*}(a^*) = 0$.

To prove (ii), we let

$$\widehat{S}(x) = \begin{cases} W_{a^*}(x) & \text{for } 0 \leq x < a^*, \\ 1 & \text{for } x \geq a^*. \end{cases} \tag{5.25}$$

By (i), $\widehat{S}$ is C^1, and $\widehat{S}''$ is continuous everywhere except at $x = a^*$. Also $\widehat{S}''(a^*-)$ is finite and negative by (5.8) and $\widehat{S}(a^*+) = 0$. Notice that

$$\begin{aligned} &\frac{1}{2}\sigma_0^2(x)\widehat{S}''(x) + (\sigma_0(x)\sigma_0'(x) - \mu_0(x))\widehat{S}'(x) - (\alpha + \mu_0'(x))\widehat{S}(x) \\ &\qquad = \begin{cases} -h'(x) & \text{if } x < a^*, \\ -(\alpha + \mu_0'(x)) & \text{if } x > a^*. \end{cases} \end{aligned} \tag{5.26}$$

But $a^* > \beta > 0$; hence $-(\alpha + \mu_0'(x)) > -h'(x)$ for $x > a^*$. Consequently, the right-hand side of (5.26) is greater than or equal to $-h'(x)$ for all $x \neq a^*$. For any τ in $\prod$, we apply Itô's lemma [12, p. 219] to $\widehat{S}(Y_x(t \wedge \tau \wedge \tau_0))e^{-R(t\wedge\tau\wedge\tau_0)}$ to obtain

$$E\left[e^{-R(\tau\wedge\tau_0)}\widehat{S}(Y_x(\tau \wedge \tau_0)) + \int_0^{\tau\wedge\tau_0} e^{-R(s)}h'(Y_x(s))ds\right] \geq \widehat{S}(x). \tag{5.27}$$

To obtain (5.27), we used a standard localization argument, the fact $0 \leq \widehat{S}(x) \leq 1$ on $[0, \infty)$, the bounded convergence theorem, and the montone convergence theorem. Since $\widehat{S}(0) = 0$ and $0 \leq \widehat{S}(x) \leq 1$, now it follows that

$$E\left[e^{-R(\tau)}I_{[\tau<\tau_0]} + \int_0^{\tau\wedge\tau_0} e^{-R(s)}h'(Y_x(s))ds\right] \geq \widehat{S}(x).$$

Consequently, $S(x) \geq \widehat{S}(x)$. But using $\tau = \tau^*$, where τ^* is given in (5.23) and Itô's lemma, we obtain

$$E\left[e^{-R(\tau^*)}I_{[\tau^*<\tau_0]} + \int_0^{\tau^*\wedge\tau_0} e^{-R(s)}h'(Y_x(s))ds\right] = \widehat{S}(x). \tag{5.28}$$

Thus $S(x) \equiv \widehat{S}(x)$ and τ^* is optimal. This completes Theorem 5.2. □

Now we are ready to prove the main theorem in this section. For the point $a^* > 0$ derived in the previous theorem, we consider the reflecting diffusion process $\{X_x^{a^*}(t)\}$

defined by (5.2)–(5.4) with values in $[-a^*, a^*]$ for $t > 0$. If the initial point x is outside $[-a^*, a^*]$ we allow a jump to $\{-a^*, a^*\}$ at $t = 0$ as described below (5.7). To simplify the notation we denote $X_x^{a^*}(t)$ by $X_x^*(t)$ in the next theorem.

THEOREM 5.3. *Assume* (5.1). *Let* $\{X_x^*(t)\}$ *be the above described reflecting diffusion process which satisfies* (5.2)–(5.4) *with values in* $[-a^*, a^*]$ *for* $t > 0$, *and let* $V_{a^*}(x)$ *be the associated cost defined by* (5.5). *Then the following holds.*

(i) $\{X_x^*(t)\}$ *is an optimal process for* (2.9) *and* $V_{a^*}(x) = U(x)$ *for all* x.

(ii) *In addition to* (5.1), *assume that* $\phi(x)$ *is increasing on* $[0, \infty)$, *where* ϕ *is given by* (4.15). *Then* $\{X_x^*(t)\}$ *is also optimal for the control problem* (2.5) *and* $V_{a^*}(x) = V(x)$ *for all* x.

(iii) *In each case, the value functions of stochastic control problem and optimal stopping problem* (5.14) *are related by* $V'_{a^*}(x) = S(x)$ *for all* x, *where* S *is given in* (5.14).

Proof. Let $V_{a^*}(x)$ be defined by (5.5). Clearly, V_{a^*} is an even function which satisfies (5.6) and (5.7). For $0 \le x \le a^*$, $V'_{a^*}(x) \equiv W_{a^*}(x)$ and it satisfies (5.8), (5.9), and (5.17). Moreover, W_{a^*} satisfies (5.10) by Theorem 5.2. For $x \ge a^*$, $V'_{a^*}(x) = 1$. Hence, by Theorem 5.2, $V'_{a^*}(x) = S(x)$ for $x > 0$, where $S(x)$ is the value function of the stopping problem (5.14). In particular, $S(x)$ completely determines $V_{a^*}(x)$ by (5.6)–(5.10). Since $h(0) = 0$, by (5.6) we obtain $\alpha V_{a^*}(0) = \frac{\sigma_0^2(0)}{2} W'_{a^*}(0)$ and

$$V_{a^*}(x) = \frac{\sigma_0^2(0)}{2\alpha} S'(0) + \int_0^x S(r)dr \quad \text{for } x > 0. \tag{5.29}$$

V_{a^*} is a twice continuously differentiable even function on $\mathbb{R}$, since $S(x)$ is C^1 on $[0, \infty)$ by Theorem 5.2. To establish (i) and (ii) of the theorem, we use the verification lemma, Lemma 3.1, and hence first we verify the conditions (i) and (ii) of Lemma 3.1. The condition (i) follows from (5.29), and it suffices to verify condition (ii).

By (5.6), condition (ii) holds for all x in $[0, a^*]$. By (5.6) and (5.10) we have $h(a^*) = \alpha V_{a^*}(a^*) + \mu_0(a^*)$. Since $a^* > \beta$, by (5.1), we also have $h'(x) > \alpha + \mu_0'(x)$ for $x > \beta$. Consequently, $h(x) = h(a^*) + \int_{a^*}^x h'(r)dr > \alpha V_{a^*}(a^*) + \mu_0(a^*) + \int_{a^*}^x (\alpha + \mu_0'(r))dr$ for $x > a^*$. This yields $h(x) > \alpha V_{a^*}(x) + \mu_0(x)$ for $x > a^*$. Since $V'_{a^*}(x) = 1$ for $x > a^*$, we see that $\frac{\sigma_0^2(x)}{2} V''_{a^*}(x) - \mu_0(x) V'_{a^*}(x) - \alpha V_{a^*}(x) + h(x) = h(x) - (\alpha V_{a^*}(x) + \mu_0(x)) > 0$ for $x > a^*$. Thus condition (ii) in Lemma 3.1 is satisfied, and consequently Theorem 5.3(i) follows.

To obtain (ii) of the theorem, again we can use Lemma 3.1, once we verify $V''_{a^*}(x) \ge 0$ for all x. By (5.29) it is clear that $V''_{a^*}(x) = 0$ if $|x| \ge a^*$. Since V_{a^*} is even, it remains to show $V''_{a^*}(x) \ge 0$ on $[0, a^*]$. By (5.29), $V''_{a^*}(0) = S'(0) > 0$ since $V_{a^*}(0) > 0$ by (5.5). Now $W_{a^*}(x) = V'_{a^*}(x)$ on $[0, a^*]$, we have $W'_{a^*}(0+) > 0$, and thus W_{a^*} is strictly increasing on an interval $[0, \varepsilon]$ for some $\varepsilon > 0$, $W_{a^*}(0) = 0$, and $W_{\alpha^*}(a^*) = 1$. Suppose that $W'_{a^*}(x) < 0$ for some $0 < x < a^*$. Thus, it is clear that there exist $0 < c_1 < c_2 < a^*$, where W_{a^*} has a local maxima at $x = c_1$, W_{a^*} has a local minima at $x = c_2$, and W_{a^*} is decreasing on $[c_1, c_2]$. Then by an argument similar to Step 3 of the proof of Theorem 4.3 we obtain

$$\phi(c_1) \ge W_a(c_1) > W_a(c_2) \ge \phi(c_2) \quad \text{and} \quad c_1 < c_2. \tag{5.30}$$

This contradicts the added assumption that ϕ is increasing on $[0, \infty)$. Consequently, $V''_{a^*}(x) \equiv W'_{a^*}(x) \ge 0$ on $[0, a^*)$ and now by Lemma 3.2(b), we can conclude Theorem 5.3(ii).

Part (iii) is immediate from (5.29) and Theorem 5.2. This completes the proof of this theorem. □

6. Abelian relations.

6.1. Main results. We intend to compute the asymptotic behavior of the value function as α tends to zero. In this section we write V_α for V and U_α for U to signify the dependence on α, where the value functions V and U are introduced in (2.5) and (2.9). We analyze the behavior of U_α here, and thus the same results hold for V_α as well. With the usual notation as similar to (2.4) and (2.9), we introduce the value of the stationary control problem by

$$\lambda_0 = \inf_{\sum_1(x)} \limsup_{T\to\infty} \frac{1}{T} E[|A|(T) + \int_0^T h(X_x(t))dt], \tag{6.1}$$

where $X_x(t)$ satisfies (2.1). The value λ_0 is independent of the initial point x because for any y, the process can jump to y within a very short time interval $[0,\varepsilon]$ using the $A(t)$ process, but the cost of this jump disappears in the limit of (6.1) as T tend to infinity.

Our aim here is to establish $\lim_{\alpha\to 0^+} \alpha U_\alpha(x) = \lambda_0$ (uniformly on compact sets) under the assumptions in sections 4 and 5. For our optimal policy of the stationary control problem described in Theorem 6.1 below, the limit in (6.1) (instead of lim sup) exists and is equal to λ_0. A similar result in the Brownian motion case was proved in [9]. Throughout this section we assume there is a small interval $[0,\eta]$ with $\eta > 0$ so that the assumption (2.2) holds for every α in $(0,\eta]$. Notice also that the sequence (τ_n) in (2.2) may depend on $\alpha > 0$. Furthermore, in section 4, the assumption (4.2) depends on α, and here we replace it by a slightly stronger condition

$$\mu_0'(x) \geq h'(x) \text{ for each } x \geq 0. \tag{6.2}$$

Similarly with regard to assumption (5.1) in section 5, we replace it by (6.3) below so that (5.1) holds uniformly for all α in $(0,\eta]$.

There exists positive constants $\delta_0 > 0$, $\varepsilon > 0$, and $R > 0$ such that the function $h'(x) - \mu_0'(x)$ is monotone increasing on $[0,R]$ and

$$h'(x) - \mu_0'(x) > \delta_0 \mu_0'(x) + \varepsilon \quad \text{for all} \quad x \geq R. \tag{6.3}$$

Now we state our main theorem in this section.

THEOREM 6.1. *Under the assumptions* A.1, A.2, (6.2), *and* (4.3) *related to section* 4 *or* A.1, A.2, *and* (6.3) *related to section* 5, *we have*

$$\lim_{\alpha\to 0} \sup_{|x|\leq M} |\alpha U_\alpha(x) - \lambda_0| = 0 \quad \textit{for each} \quad M > 0, \tag{6.4}$$

where λ_0 *is given in* (6.1). *Furthermore, an optimal strategy for the stationary problem* (6.1) *will be obtained.*

Our first step is to prove the following technical lemma.

LEMMA 6.2. *Under the assumptions of Theorem* 6.1, *the following results hold.*

(i) *For every* $\alpha > 0$, $|U_\alpha(x) - U_\alpha(0)| \leq |x|$ *for all* x.

(ii) *For each* $M > 0$, $\lim_{\alpha\to 0^+} \sup_{|x|\leq M} |\alpha U_\alpha(x) - \alpha U_\alpha(0)| = 0$.

Proof. In both sections 4 and 5 we observed that U_α' is continuous and $|U_\alpha'(x)| \leq 1$ for each $\alpha > 0$. Hence (i) holds. Part (ii) is immediate from (i). □

Thus, to establish (6.4) it suffices to show $\lim_{\alpha\to 0^+} \alpha U_\alpha(0) = \lambda_0$. We verify this in the next subsections.

6.2. Case of the unbounded optimal diffusion. Throughout this subsection we make the assumptions A.1, A.2, (6.2), and (4.3) to use the results in section 4. The function W_∞ obtained in Lemma 4.2 depends on α, and henceforth we write W_α instead of W_∞.

Proof of Theorem 6.1 (under the assumptions of A.1, A.2, (6.2), and (4.3)). By (4.19), (4.20), and Theorem 4.3 we obtain $\alpha U_\alpha(0) = \frac{\sigma_0^2(0)}{2} W'_\alpha(0)$ and $U'_\alpha(x) = W_\alpha(x)$ for $x > 0$. W_α satisfies the differential equation (4.14) for $x > 0$, together with $W_\alpha(0) = 0$ and $0 < W_\alpha(x) < 1$ for all $x > 0$. An elementary application of Itô's lemma yields the following stochastic representation for $W_\alpha(x)$ for $x > 0$:

$$W_\alpha(x) = E\left[\int_0^{\tau_0} e^{-\int_0^r (\alpha + \mu_0'(Y_x(s)))ds} h'(Y_x(r))dr\right], \tag{6.5}$$

where Y_x is given in (5.11) and the stopping time τ_0 is given by (5.12). Now with the same notation, we define

$$W_0(x) = E\left[\int_0^{\tau_0} e^{-\int_0^r \mu_0'(Y_x(s))ds} h'(Y_x(r))dr\right] \quad \text{for} \quad x \geq 0. \tag{6.6}$$

Clearly, $W_0(0) = 0$ and by (4.2) we have $0 < W_0(x) \leq 1$ for $x > 0$. Since $U'_\alpha \equiv W_\alpha$, by (4.19) we obtain

(6.7)

$$\begin{aligned} &\alpha U_\alpha(0) \int_0^x \frac{2}{\sigma_0^2(r)}\, dr \\ &\quad = W_\alpha(x) + 2\int_0^x \frac{(h(r) - \mu_0(r)W_\alpha(r))}{\sigma_0^2(r)}\, dr - 2\alpha \int_0^x \frac{1}{\sigma_0^2(r)} \int_0^r W_\alpha(u)du\, dr. \end{aligned}$$

Since W_α is increasing to W_0 as α tends to 0, the right-hand side of (6.7) converges to a finite quantity as $\alpha \to 0^+$. Hence $\lim_{\alpha \to 0^+} \alpha U_\alpha(0)$ exists and is finite. Let

$$\lim_{\alpha \to 0^+} \alpha U_\alpha(0) = \wedge_0, \quad \text{where} \quad 0 \leq \wedge_0 < +\infty. \tag{6.8}$$

Thus by letting $\alpha \to 0^+$ in (6.7) we obtain

$$\wedge_0 \int_0^x \frac{2}{\sigma_0^2(r)}\, dr = W_0(x) + 2\int_0^x \frac{h(r) - \mu_0(r)W_0(r)}{\sigma_0^2(r)}\, dr \text{ for } x > 0. \tag{6.9}$$

Consequently, W_0 satisfies the first order equation $\frac{\sigma_0^2(x)}{2} W_0'(x) - \mu_0(x)W_0(x) + h(x) = \wedge_0$ for $x > 0$, $W_0(0) = 0$, and $0 < W_0(x) \leq 1$.

Introduce $Q_0(x)$ on $\mathbb{R}$ by

$$\begin{aligned} Q_0(x) &= \int_0^x W_0(r)dr \quad \text{for} \quad x \geq 0 \\ &= Q_0(-x) \quad \text{for} \quad x < 0. \end{aligned} \tag{6.10}$$

Then Q_0 satisfies

$$\frac{\sigma_0^2(x)}{2} Q_0''(x) - \mu_0(x)\ \text{sign}(x) Q_0'(x) + h(x) = \wedge_0 \text{ for all } x, \tag{6.11}$$

$Q_0(0) = 0,\ Q_0'(0) = 0,\ 0 < Q_0'(x) \le 1$ for $x > 0$, and $-1 \le Q_0'(x) < 0$ for $x < 0$. Hence $|Q_0(x)| \le |x|$ for all x.

First we intend to show $\lambda_0 \ge \wedge_0$, where λ_0 is given in (6.1). Let $X_0(t)$ be any available process satisfying (2.1) and (2.2) for each $\alpha > 0$ with $X_0(0) = 0$ and which has a finite value for $\limsup_{T\to\infty} \frac{1}{T} E[|A|(T) + \int_0^T h(X_0(t))dt]$. Thus there are constants $M > 0$ and $T_0 > 0$ such that for all $T > T_0$,

$$MT > E\left[|A|(T) + \int_0^T h(X_0(t))dt\right].$$

Since h satisfies A.2 as similar to the proof of Lemma 3.1, this implies that the quantities $\limsup_{T\to\infty} \frac{E|A|(T)}{T}$ and $\limsup_{T\to\infty} \frac{1}{T} E\int_0^T |X_0(t)|dt$ are finite and, as a consequence, $\liminf_{T\to\infty} \frac{E|X_0(T)|}{T} = 0$. Next we apply Itô's formula to $Q_0(X_0(t\wedge\tau_n))$ as similar to the proof of Lemma 3.1, where (τ_n) as in (2.2). Using the above properties of Q_0, we obtain

$$E|X_0(T\wedge\tau_n)| + E\left[|A|(T) + \int_0^T h(X_x(s))ds\right] \ge \wedge_0 E[T\wedge\tau_n]. \tag{6.12}$$

Notice that $E|X_0(T\wedge\tau_n)| \le E|X_0(T)| + e^{\alpha T} E[|X_0(\tau_n)|e^{-\alpha\tau_n}]$. Hence we obtain

$$\begin{aligned} e^{\alpha T} E\left[|X_0(\tau_n)|e^{-\alpha\tau_n}\right] + E|X_0(T)| + E\left[|A|(T) + \int_0^T h(X_x(s))ds\right] \\ \ge \wedge_0 E[T\wedge\tau_n]. \end{aligned} \tag{6.13}$$

Now keeping T fixed and by letting τ_n tend to infinity and using (2.2) we have

$$E|X_0(T)| + E\left[|A|(T) + \int_0^T h(X_x(s))ds\right] \ge \wedge_0 T. \tag{6.14}$$

Since $\liminf_{T\to\infty} \frac{E|X_0(T)|}{T} = 0$, by (6.14) we derive

$$\limsup_{T\to\infty} \frac{1}{T} E\left[|A|(T) + \int_0^T h(X_0(t))dt\right] \ge \wedge_0,$$

and thus $\lambda_0 \ge \wedge_0$.

Next we consider our candidate for the optimal process of the stationary problem. Let $Z_x(t)$ be as in (4.1). In this case $A(t)$ is identically zero. Let (τ_n) be as in (4.4). Apply Itô's lemma to $Q_0(Z_x(T\wedge\tau_n))$ and use properties of Q_0 and (6.11) to obtain $E[\int_0^T h(Z_x(s))ds] \le Q_0(x) + \wedge_0 T$. Hence we obtain

$$\limsup_{T\to\infty} \frac{1}{T} E\int_0^T h(Z_x(s))ds \le \wedge_0. \tag{6.15}$$

Thus $\lambda_0 \le \wedge_0$, where λ_0 as in (6.1). Consequently, $\lambda_0 = \wedge_0$ and the process $Z_x(t)$ defined in (4.1) is also optimal for the stationary problem (6.1). This completes the proof. □

The proof of the above lemma also yields the following important corollary, which can be compared with the results obtained in [3] and [17].

COROLLARY 6.3. *Let Q_0 be as in* (6.10). *Then*

(i) *Q_0 is a C^2-solution to the HJB equation of the stationary control problem;*

(ii) $\lim_{\alpha\to 0^+}(U_\alpha(x) - U_\alpha(0)) = Q_0(x)$ *uniformly on compact sets.*

Proof. Part (i) follows from (6.10), (6.11), and the discussion therein. The proof of (ii) follows from (6.5), (6.6), and (6.11) and the fact that $W_\alpha(x)$ is increasing to $W_0(x)$. □

6.3. Case of the bounded optimal process. Throughout this subsection we assume A.1, A.2, and (6.3). The condition (6.3) implies (5.1), and therefore the results we derived in section 5 remain valid here. In [22] a general stationary control problem for singular stochastic controls is resolved, and here we rely on the results developed in [22].

Proof of Theorem 6.1 (under the assumptions A.1, A.2, and (6.3)). A.1, A.2, and (6.3) imply the assumptions of Theorem 2.1 of [22] and, in particular, Proposition 4.4 of [22]. In our case $x^* = 0$ and $a^* = -b^*$ with the notation there. (See the remark on page 6 of [22].) By Proposition 4.4 of [21], there exist a point $b^* > 0$ and a function Q_0 (we use Q_0 instead of V there) defined on $\mathbb{R}$, related to the stationary problem (6.1) and satisfying the following conditions:

(6.16) (i) $Q_0(x)$is a twice differentiable even function satisfying $0 \le Q_0'(x) \le 1$ on $[0, b^*]$ and $Q_0'(x) \equiv 1$ for $x \ge b^*$.

(6.17) (ii) $\lambda_0 = h(b^*) - \mu_0(b^*) > 0$, where λ_0 as in (6.1).

(6.18) (iii) $\frac{1}{2}\sigma_0^2(x)Q_0''(x) - \mu_0(x)\,\mathrm{sign}(x)Q_0'(x) + h(x) = \lambda_0$ for $|x| < b^*$ and $\ge \lambda_0$ for $|x| > b^*$.

(6.19) (iv) Also by (6.16) and the assumption (A.2), there exist two positive constants K_1, K_2 so that $|Q_0(x)| \le K_1 + |x| \le K_2(1 + h(x))$ for all x.

Furthermore, from Theorem 2.1 of [22], an optimal state process for the stationary control problem (6.1) is given by a reflecting diffusion with state space $[-b^*, b^*]$ and described by (5.2), (5.3), and (5.4) with $a = b^*$.

For each $\alpha > 0$, let $\{X_\alpha^*(t)\}$ be the optimal reflecting diffusion process described by Theorem 5.3 with initial data $X_\alpha^*(0) = 0$ with the value for the discounted problem $U_\alpha(0)$. We apply Itô's lemma to $Q_0(X_\alpha^*(t))e^{-\alpha t}$ and obtain

$$
\begin{aligned}
E[Q_0(X_\alpha^*(T))e^{-\alpha T}] &= Q_0(0) + E\int_0^T e^{-\alpha t}Q_0'(X_\alpha^*(t))dA_\alpha^*(t) \\
&+ E\int_0^T e^{-\alpha t}\left[\frac{1}{2}\sigma_0^2(X_\alpha^*(t))Q_0'' - \mu_0(X_\alpha^*(t))\,\mathrm{sign}(X_\alpha^*(t))Q_0' - \alpha Q_0\right](X_\alpha^*(t))dt.
\end{aligned} \tag{6.20}
$$

Using (6.16), (6.17), and (6.18) we obtain

(6.21)

$$
\begin{aligned}
U_\alpha(0) &\ge E\left[\int_0^T e^{-\alpha t}(h(X_\alpha^*(t))dt + d|A_\alpha^*|(t))\right] \\
&\ge Q_0(0) + \lambda_0\int_0^T e^{-\alpha t}dt - \alpha E\left[\int_0^T e^{-\alpha t}Q_0(X_\alpha^*(t))dt\right] - E\left[Q_0(X_\alpha^*(T))e^{-\alpha T}\right].
\end{aligned}
$$

By Theorem 5.3, $\{X_\alpha^*(t)\}$ take values in a compact interval, and hence $|Q_0(X_\alpha^*(t))| < M_\alpha$ for some constant $M_\alpha > 0$ which may depend on α. By (6.19), we obtain

$E\int_0^T e^{-\alpha t}Q_0(X_\alpha^*(t))dt \le K_2\left(\frac{1}{\alpha}+U_\alpha(0)\right)$. Using this with (6.22) we obtain

$$(1+\alpha K_2)U_\alpha(0) \ge Q_0(0)+\lambda_0\int_0^T e^{-\alpha t}dt-\alpha K_2\int_0^T e^{-\alpha t}dt - M_\alpha e^{-\alpha T}. \tag{6.22}$$

Next, first we let T tend to infinity and then multiply the inequality by α, and we let α tend to zero to obtain

$$\liminf_{\alpha\to 0^+}\alpha U_\alpha(0) \ge \lambda_0. \tag{6.23}$$

It remains to verify $\limsup_{\alpha\to 0^+}\alpha U_\alpha(0) \le \lambda_0$. Let $\{X_0^*(t)\}$ be the optimal state process for the stationary control problem (6.1) with the associated bounded variation process $\{A_0^*(t)\}$ and the initial position $X_0^*(0)=0$ with $|X_0^*(t)|\le b^*$ as described in Theorem 2.1 of [22]. We apply Itô's lemma to $Q_0(X_0^*(t))e^{-\alpha t}$ and as similar to (6.20) we obtain

$$\begin{aligned} E\left[\int_0^T e^{-\alpha t}[h(X_0^*(t))dt+d|A_0^*|(t)]\right] &= \lambda_0\int_0^T e^{-\alpha t}dt \\ &\quad -\alpha E\int_0^T e^{-\alpha t}Q_0(X_0^*(t))dt+Q_0(0). \end{aligned} \tag{6.24}$$

By (6.16), $Q_0(x)\ge Q_0(0)$ for all x, and hence $E[\int_0^T e^{-\alpha t}(h(X_0^*(t))dt+d|A_0^*|(t))] \le \lambda_0\int_0^T e^{-\alpha t}dt + Q_0(0)e^{-\alpha T}$. By letting T tend to infinity, we have $U_\alpha(0) \le E[\int_0^\infty e^{-\alpha t}(h(X_0^*(t))dt+d|A_0^*|(t))] \le \frac{\lambda_0}{\alpha}$, and we conclude that $\limsup_{\alpha\to 0^+}\alpha U_\alpha(0)\le \lambda_0$. Hence, using (6.23), it follows that $\lim_{\alpha\to 0^+}\alpha U_\alpha(0)=\lambda_0$, where λ_0 is the value of the stationary problem (6.1). This completes the proof. □

We also have the following important corollary, as similar to Corollary 6.3.

COROLLARY 6.4. *Let Q_0 be the function satisfying* (6.16)–(6.18) *and $Q_0(0)=0$. Then*

(i) *Q_0 is a C^2-solution to the HJB equation corresponding to the stationary control problem;*

(ii) *$\lim_{\alpha\to 0^+}(U_\alpha(x)-U_\alpha(0))=Q_0(x)$ uniformly on compact sets.*

Proof. Part (i) follows from (6.16)–(6.19). To prove (ii), since $|U_\alpha'(x)|\le 1$ for all x, it suffices to show $\lim_{\alpha\to 0^+}U_\alpha'(x)=Q_0'(x)$ for all $x>0$. We sketch the proof of this fact. In Theorem 5.2, the point a^* may depend on α, and hence we relabel it a_α^*. Using (5.6), (5.7), and (5.10), we obtain $h(a_\alpha^*)-\mu_0(a_\alpha^*)=\alpha U_\alpha(a_\alpha^*)>0$. By (6.3) and since $h(0)=0$, there is a $\beta_0>0$ so that $\sup_{[0,\beta_0]}(h(x)-\mu_0(x))<0$. Hence $a_\alpha^*>\beta_0>0$ for every α. Let a_∞^* be any limit point ($a_\infty^*=+\infty$ is allowed) of $\{a_\alpha^*:\alpha>0\}$. Thus $a_\infty^*\ge\beta_0>0$. Let (a_{α_n}) be a sequence so that $\lim_{\alpha_n\to 0^+}a_{\alpha_n}=a_\infty^*$. We consider (U_{α_n}'). Each U_{α_n}' satisfies (5.8) on $(0,a_{\alpha_n}^*)$ with $U_{\alpha_n}'(0)=0$ and $U_{\alpha_n}''(0)=\frac{2\alpha_n}{\sigma_0^2(0)}U_{\alpha_n}(0)$. By Theorem 6.1, $\lim_{\alpha_n\to 0^+}U_{\alpha_n}''(0)=\frac{2\lambda_0}{\sigma_0^2(0)}$. Hence by elementary arguments, $\lim_{\alpha_n\to 0^+}U_{\alpha_n}'(x)\equiv U_\infty'(x)$ exists for all $x\ge 0$ and U_∞' satisfies (5.8) together with $U_\infty'(0)=0, U_\infty''(0)=\frac{2\lambda_0}{\sigma_0^2(0)}$, and $U_\infty'(x)\equiv 1$ for $x>a_\infty^*$. But Q_0' also satisfies (5.8) on $(0,b^*)$ together with the same boundary conditions as U_∞' at the origin and $Q_0'(x)\equiv 1$ for $x>b^*$. Hence $U_\infty'(x)\equiv Q_0'(x)$ for $0\le x\le a_\infty^*\wedge b^*$. Now suppose $a_\infty^*<b^*$, then $Q_0'(a_\infty^*)=Q_0'(b^*)=1$. Using (6.17) and (6.18) we conclude $Q_0'(x)\equiv 1$ on $[a_\infty^*,+\infty)$, and thus $Q_0'(x)\equiv U_\infty'(x)$. A similar result holds if $b^*<a_\infty^*$. Consequently, $\lim_{\alpha_n\to 0^+}U_{\alpha_n}'(x)=Q_0'(x)$ for all $x\ge 0$. Thus, $\lim_{\alpha\to 0^+}U_\alpha'(x)=Q_0'(x)$ follows. □

PARAMETER IDENTIFICATION BY REGULARIZATION FOR SURFACE REPRESENTATION VIA THE MOVING GRID APPROACH*

STEFAN KINDERMANN† AND ANDREAS NEUBAUER†

Abstract. We consider the identification of a diffusion parameter in a second order elliptic equation in two dimensions by interior measurements. The diffusion parameter is assumed to have discontinuities. For its reconstruction we propose regularization algorithms with an adaptive grid. The grid is adapted according to a measure of the smoothness of the regularized solution. For the numerical computation we compare several iterative methods such as the minimal error method, the steepest descent method, and an inexact iteratively regularized Gauss–Newton method. The computations show that these algorithms can effectively identify the discontinuities.

Key words. parameter identification, regularization via moving grids, ill-posed problems

DOI. 10.1137/S0363012902408034

1. Introduction.

Our interest lies in the identification of a possibly discontinuous diffusion coefficient $\tilde{\gamma}$ defined on a domain $\Omega \subset \mathbb{R}^2$ in the equation

$$-\mathrm{div}(\tilde{\gamma}\nabla u) = f, \quad u_{|\partial\Omega} = 0, \tag{1.1}$$

where $f \in L^2(\Omega)$ is given, and $u(x), x \in \Omega$ is measured.

To ensure ellipticity, we assume that positive constants γ_1, γ_2 exist such that $\gamma_1 \leq \tilde{\gamma}(x) \leq \gamma_2$ almost everywhere. We want to find that part of $\tilde{\gamma}$ which differs from a constant background diffusivity which we assume to be 1, without loss of generality. Hence, our unknown is γ with $\tilde{\gamma} = 1 + \gamma$. In what follows, we denote the nonlinear operator that maps $\gamma = \tilde{\gamma} - 1$ to the solution of (1.1) by F. The problem we are faced with is an ill-posed equation

$$F(\gamma) = u, \tag{1.2}$$

where u are the given data.

It is well known that this parameter identification problem is ill-posed and that, for general data u, (1.2) does not necessarily have a solution. However, in the context of regularization theory often least squares solutions of (1.2) are considered.

For nonlinear problems, the question of whether a least squares solution is also a solution of (1.2) and if such a solution is unique is rather involved and is outside the scope of this work. For sufficient conditions for uniqueness of a solution see, e.g., [7, 18].

To avoid such problems with existence of a solution we will in the following always assume attainability; i.e., for exact data u there exists a $\gamma^\dagger$ for which (1.2) holds. Obviously in this case a least squares solution will also be a solution of (1.2).

In many cases a standard regularization using Hilbert space norms (see, e.g., [5]) implemented, for example, by Tikhonov regularization does not give satisfactory results, since the discontinuities either are smeared out, if regularization is too strong, or oscillations occur when the regularization norm is too weak.

In particular for discontinuous solutions, the use of the BV-seminorm has been quite effective for this kind of problem (cf., e.g., [4, 13]).

However, the BV-functional suffers from the drawback that it is not differentiable, so usually a differentiable approximation to this functional is used. Moreover, BV-regularization shows the so-called staircase effect [19]; i.e., regularized solutions have the tendency to become piecewise constant.

Our motivation to use an adaptive grid for discontinuous solutions comes from the work on regularization by curve and surface representations (cf. [10, 11, 12]). Here the discontinuous functions are regarded as curves or surfaces. Regularization is applied to their parameterizations. In the discretized case this has the effect that the unknown γ is always defined on a grid, which changes with the iteration and is adapted to the regularized solution.

In [8, 9] it was shown that in one and two dimensions H^1-functions and a suitably adaptive grid may be used to approximate any BV-function in the sense of weak convergence.

The methods in [10, 11, 12, 16, 17] used a grid which is defined via optimization problems. Unfortunately, in higher dimensions, these optimization functionals are rather flat, leading to slow convergence. The resulting grid has the property that the mesh size is small wherever the solution exhibits discontinuities, as expected. So instead of computing the grid via optimization it seems more efficient to adapt the mesh size directly to the smoothness of γ. This adaption can be implemented efficiently by the deformation method.

We show that with this moving grid method we can use standard algorithms from regularization theory in Hilbert spaces and still obtain good results for discontinuous solutions with a small extra amount of recalculating the grid in each step.

2. Moving grid method.

2.1. General algorithm. For a numerical approach to problem (1.2), we have to set up a discrete approximation to γ by, for instance, finite element functions defined on a suitable grid.

In particular, if γ has discontinuities, and if the grid is kept fixed, a reasonable approximation of γ requires a small mesh size leading to a large number of unknowns. On the other hand, an adaptive grid allows a better resolution of discontinuities with a moderate number of variables. Thus, it seems advantageous to combine regularization with an adaptive grid.

Moreover, by our method we may use a discretization of γ that is smoother than γ itself, for example continuous ansatz functions even for discontinuous γ. Since the grid will be adaptive to the solution, the grid size will be small wherever γ has jumps, and this compensates the approximation error at the nonsmooth parts.

In our examples we work with weakly differentiable ansatz functions. The grid will be made finer wherever some measure of smoothness indicates a large gradient of γ which is regarded as possible lack of differentiability.

This idea of a moving grid has been used for numerical computations in PDEs; see, e.g., [20]. For instance, in the framework of hyperbolic equations the development of shock waves and the corresponding lack of smoothness of the solutions may not be

handled efficiently by a fixed grid. In the context of ill-posed problems, an adaptive grid approach has been successfully applied in [14] to linear integral equations.

We restrict ourselves to a moving grid; i.e., the adaptive grid is a transformation of a fixed, uniform one. Therefore, we need a transformation function ϕ which is one-to-one and onto on Ω

$$\phi : \quad \Omega \to \Omega. \tag{2.1}$$

A sufficient condition for a C^1-function ϕ to fulfill these conditions is that

$$\phi(\partial\Omega) = \partial\Omega \quad \text{and} \quad \det D\phi > 0 \quad \text{in } \Omega. \tag{2.2}$$

If c is defined on Ω on a fixed uniform grid, then we can find an approximation to γ on an adaptive grid by $c(\phi^{-1})$, where ϕ is an appropriate transformation function (again defined on a uniform grid).

We briefly describe the main ideas of our algorithm. In each step we find an approximation $c_n(\phi_n^{-1})$ of the solution, which is obtained by applying regularization to the equation

$$F(c(\phi_n^{-1})) = u \tag{2.3}$$

with fixed ϕ_n. In the next step we compute an error estimator, which measures the smoothness of $c_n(\phi_n^{-1})$. Then we calculate a new transformation function ϕ_{n+1} depending on this error estimation.

Thus, the general steps of the algorithm look as follows:

1. Start with a uniform grid and the identity as transformation function $\phi_0(\xi) = \xi \in \Omega \subset \mathbb{R}^2$, $n = 0$.
2. Compute c_n by regularization of the equation
$$F(c(\phi_n^{-1})) = u;$$
set $\gamma_n := c_n(\phi_n^{-1})$.
3. If a stopping criterion is satisfied, set $\gamma = \gamma_n$; otherwise
4. update the transformation function
$$\phi_{n+1} = T(\phi_n, c_n), \tag{2.4}$$
where T is the method of choice to define the moving grid; go to step 2.

For the stopping rule in step 3 we used Morozov's well-known discrepancy principle (cf., e.g., [5]). A detailed description of steps 2 and 4 is given below.

2.2. Regularization method. Note that in step 2 we apply regularization only to the function c and not to $c(\phi_n^{-1})$. This motivation comes from the previously mentioned idea of regularization for surface representations, where it has been observed that $c(\xi) = \gamma(\phi(\xi))$ can be chosen in H^1 even for functions γ being merely in BV.

Using the estimates in [12], it can be shown that F is a continuous and Fréchet-differentiable operator from H^1 to L^2. Hence, we may use, e.g., Tikhonov regularization with the H^1-seminorm as regularization term. In this case c_n is computed by the minimization problem

$$c_n = \operatorname*{argmin}_{c \in H^1(\Omega)} J(c, \phi_n), \tag{2.5}$$

$$J(c, \phi_n) := \|F(c(\phi_n^{-1})) - u_\delta\|^2 + \alpha \|\nabla c\|^2_{L^2(\Omega)}. \tag{2.6}$$

Here u_δ denotes the measured data, possibly contaminated with noise, where δ is the noise level, i.e.,

$$\|u - u_\delta\|_{L^2} \le \delta.$$

With fixed ϕ_n, (2.5) is a convergent regularization method for the considered problem (cf. [5]).

If ϕ_n satisfies (2.2), then the minimization problem (2.5) can also be written as

$$c_n(\phi_n^{-1}) = \operatorname*{argmin}_{w \in H^1} \|F(w) - u\|^2 + \alpha \|([D\phi_n]^{-T} \nabla w)(\det D\phi_n^{-1})^{\frac{1}{2}}\|^2_{L^2(\Omega)} \tag{2.7}$$

with $w = c(\phi_n^{-1})$. Here and in the following $D\phi$ denotes the Jacobian matrix of ϕ.

Equation (2.7) indicates that each regularization step can be seen as usual Tikhonov regularization with a weighted norm that is adapted to the grid.

Note that in (2.7) $\gamma_n = c_n(\phi_n^{-1})$ is always in H^1. This does not contradict our aim to approximate discontinuous coefficients $\gamma \notin H^1$, since the algorithm does not yield a uniform bound of $\|\gamma_n\|_{H^1}$ for all n. In fact, only $\|([D\phi_n]^{-T} \nabla \gamma_n)(\det D\phi_n^{-1})^{\frac{1}{2}}\|_{L^2(\Omega)}$ will be bounded.

Although our algorithm uses ϕ_n, where $\det D\phi_n(\xi) > 0$ always holds in Ω, after some iterations regions will occur, where $\det D\phi_n$ is numerically close to 0. These will be the parts of γ_n corresponding to the discontinuities of γ.

If we allowed generalized diffeomorphisms with $\det D\phi_n = 0$ on some part of $\Omega_0 \subset \Omega$ (i.e., if the grid were degenerate in this case), then γ_n could have discontinuities that approximate the discontinuities of the exact unknown γ. This idea has been exploited in [10, 11, 12] in one and two dimensions.

Of course, we are not restricted to Tikhonov regularization; any other convergent regularization method will be appropriate; in fact, for the numerical realization we prefer iterative regularization methods. We implemented three of them: the minimal error method, the steepest descent method, and an inexact iteratively regularized Gauss–Newton method.

To describe the ideas we introduce some notation. In step 2 we have to solve (2.3), where ϕ_n is kept fixed and c is the unknown. We use $F_{\phi_n}(c) := F(c(\phi_n^{-1}))$, and $F'_{\phi_n}(c)$ for the Fréchet derivative with respect to c, and $F'_{\phi_n}(c)^*$ for its adjoint (in the space H_0^1).

For exact data the iterate c_n in step 2 is computed by

$$c_n = \lim_{k \to \infty} c_{n,k}\,,$$

where $c_{n,k}$ is obtained out of one of the following iteration methods.

The minimal error and the steepest descent method use the iteration

$$c_{n,k+1} = c_{n,k} + \alpha_k s_k, \qquad s_k = -F'_{\phi_n}(c_{n,k})^*(F'_{\phi_n}(c_{n,k}) - u_\delta) \tag{2.8}$$

with

$$\alpha_k = \begin{cases} \dfrac{\|F_{\phi_n}(c_{n,k}) - u_\delta\|^2_{L^2}}{\|s_k\|^2_{H_0^1}} & \text{for the minimal error method,} \\[2ex] \dfrac{\|s_k\|^2_{H_0^1}}{\|F'_{\phi_n}(c_{n,k}) s_k\|^2_{L^2}} & \text{for the steepest descent method.} \end{cases} \tag{2.9}$$

Both iteration methods start with an appropriate initial value $c_{n,0}$, which we set $c_{n,0} = \gamma_{n-1}(\phi_n)$, $c_{0,0} = 0$. These iterations can be seen as Landweber iteration with an iteration dependent steplength α_k. Convergence and convergence rates for these

two methods have been investigated in [15]. If the data are exact, i.e., $\delta = 0$, then $c_{n,k}$ converges under suitable conditions on F_{ϕ_n} to a minimal norm solution of (2.3). In the noisy case the iteration is stopped according to Morozov's discrepancy principle, i.e., at the first iterate $c_{n,k}$ satisfying

$$\|F_{\phi_n}(c_{n,k}) - u_\delta\|_{L^2} \leq \tau\delta$$

with a suitable parameter $\tau > 1$.

The third iteration method we use is a variant of the iteratively regularized Gauss–Newton algorithm. For the exact algorithm a new update for $c_{n,k+1}$ is defined by the equation

$$\begin{aligned}\left(F'_{\phi_n}(c_{n,k})^* F'_{\phi_n}(c_{n,k}) + \alpha_k I\right)(c_{n,k+1} - c_{n,k}) \\ = -F'_{\phi_n}(c_{n,k})^*(F_{\phi_n}(c_{n,k}) - u_\delta) + \alpha_k c_{n,k}\,.\end{aligned} \tag{2.10}$$

The sequence α_k plays the role of a regularization parameter and can be chosen as geometrically decaying sequence $\alpha_k = \alpha_0 r^k$ with $0 < r < 1$. Again Morozov's discrepancy principle is used to stop the iteration in the presence of data noise. For the iteratively regularized Gauss–Newton iteration, convergence and convergence rates have been proven in [1].

In our computations we prefer an inexact Gauss–Newton method: instead of solving system (2.10) exactly, we use a conjugate gradient (CG) method to approximate the exact solution. That means that $c_{n,k+1} = c_{n,k} + \nu_l$, where ν_l denotes the lth step of a CG method applied to the equation

$$\left(F'_{\phi_n}(c_{n,k})^* F'_{\phi_n}(c_{n,k}) + \alpha_k I\right)\nu = -F'_{\phi_n}(c_{n,k})^*(F_{\phi_n}(c_{n,k}) - u_\delta) + \alpha_k c_{n,k}. \tag{2.11}$$

In the CG method the operator on the left-hand side has to be applied to functions ν. This means that we have only to calculate directional derivatives and hence it is not necessary in the discretized version to compute and store the matrix corresponding to the operator $F'_{\phi_n}(c_{n,k})^* F'_{\phi_n}(c_{n,k})$.

Since for the evaluation of $F, F'h, F'^* z$ we always have to solve a PDE, we intend to use a limited number of CG-iterations to save computation time. Thus we propose to keep the number of CG-iterations fixed ($l = 10$ suffices). Alternatively, we stop the iteration if (2.11) is solved with a precision to 10% of the initial error. These stopping criteria keep the computational effort moderate; however, since the equation is not solved exactly, the question of convergence of the algorithm arises. Practically, the method shows convergence, and we expect that it could also be verified theoretically from the following reasons: Note that the first step in a CG-iteration for (2.11) is identical to a steepest descent step for the Tikhonov functional. On the other hand, an exact solution (i.e., $\lim_{l\to\infty} \nu_l$) of (2.11) is identical to one Gauss–Newton step for this functional. Both iterations—steepest descent and iteratively regularized Gauss–Newton—yield convergence under reasonable conditions, and our inexact iteration is somewhere in between. Thus, we expect convergence also for the iteration with a fixed number of CG-steps l.

2.3. Deformation method. We now turn to step 4 in our algorithm above: the transformation T is defined via the deformation method. It provides direct control over the cell size. We briefly describe the main ideas following [20].

Given a positive monitoring function $m(\zeta, t) > 0$ depending on the space variable ζ and time t, we want to construct a deformation function $\phi(\xi, t)$ such that

$$\begin{aligned}\det D\phi(\xi,t) &= m(\phi(\xi,t),t)\,, \quad \xi \in \Omega, t > 0\,, \\ \phi(\xi,0) &= \phi_{\text{init}}(\xi), \qquad\quad \xi \in \Omega.\end{aligned} \tag{2.12}$$

In numerical computations for PDEs m usually describes the smoothness of the solutions. If m is small—indicating lack of smoothness—then the volume of a grid element will be small too. A necessary solvability condition for m is the normalization property:

$$\int_\Omega \left(\frac{1}{m(\zeta,t)} - 1 \right) d\zeta = 0. \tag{2.13}$$

Although (2.12) is a highly nonlinear PDE there is an elegant algorithm to solve it (cf. [2]).

First, we define a velocity field $v(\zeta,t)$ by

$$\begin{aligned} \operatorname{div} v(\zeta,t) &= -\frac{\partial}{\partial t}\frac{1}{m(\zeta,t)}, \qquad \zeta \in \Omega, t \geq 0, \\ \langle\, v(\zeta,t), n(\zeta,t)\,\rangle &= 0 \quad \zeta \in \partial\Omega, t > 0; \end{aligned}$$

here $n(\zeta,t)$ denotes the unit outward normal to $\partial\Omega$. v may be calculated by the gradient $v = \nabla w$ of the solution of the Neumann problem (for fixed $t \geq 0$)

$$\begin{aligned} \Delta w(\zeta,t) &= -\frac{\partial}{\partial t}\frac{1}{m(\zeta,t)}\,, \quad \zeta \in \Omega\,, \\ \frac{\partial}{\partial n} w &= 0 \qquad\qquad\quad \text{on } \partial\Omega\,. \end{aligned} \tag{2.14}$$

Note that the solvability condition of the Neumann problem is satisfied by the normalization property (2.13). A function $\phi(\xi,t)$ satisfying (2.12) is obtained as solution of the system of ODEs (for fixed $\xi \in \Omega$)

$$\begin{aligned} \frac{d}{dt}\phi(\xi,t) &= v(\phi(\xi,t),t)m(\phi(\xi,t),t)\,, \quad t > 0\,, \\ \phi(\xi,0) &= \phi_{\text{init}}(\xi)\,. \end{aligned} \tag{2.15}$$

In our case, t plays the role of a homotopy parameter connecting the initial grid at $t = 0$ with the final grid satisfying (2.12).

In each iteration in step 4 of our algorithm, we compute the deformation function ϕ_{n+1} by

$$\det D\phi_{n+1}(\xi) = m_n(\phi_{n+1}(\xi)). \tag{2.16}$$

In our numerical realization we choose

$$m_n(\zeta) := \frac{C_n}{(1+\beta|\nabla\gamma_n(\zeta)|^2)^{\frac{1}{2}}}, \quad \gamma_n(\zeta) = c_n(\phi_n^{-1}(\zeta)), \tag{2.17}$$

$\beta > 0$ being a fixed parameter, and C_n such that the normalization property (2.13) holds.

Since we are using the monitoring function (2.17), this would require the inversion of ϕ_n. However, in [14] a variant of the above algorithm is described to circumvent this inversion. The idea is to include the transformation function ϕ_n from the previous step by defining

$$\phi_{n+1}(\xi) := \phi_n(\sigma(\xi,1))$$

with an unknown function $\sigma(\xi,t), t \in [0,1]$, such that (2.16) holds:

$$\det D\phi_{n+1}(\xi) = \det D\phi_n(\sigma(\xi,1)) \det D\sigma(\xi,1) = m_n(\phi_n(\sigma(\xi,1))).$$

This yields an equation for σ:

$$\det D\sigma(\xi,1) = \tilde{m}_n(\sigma(\xi,1)) \tag{2.18}$$

with

$$\tilde{m}_n(\xi) = \frac{m_n(\phi_n(\xi))}{\det D\phi_n(\xi)}.$$

If we denote components of the deformation function in the nth step by a, b, i.e., $\phi_n(\xi) = (a(\xi), b(\xi))$ and $\gamma_n(\zeta) = c(\phi_n^{-1}(\zeta))$, the chain rule yields ($\xi = (\xi_1, \xi_2)$)

$$\begin{aligned}\tilde{m}_n(\xi) &= \frac{C_n}{\det D(a(\xi), b(\xi))(1+\beta|\nabla\gamma_n(\phi_n(\xi))|^2)^{\frac{1}{2}}} \\ &= \frac{C_n}{(a_{\xi_1}b_{\xi_2} - a_{\xi_2}b_{\xi_1})^2 + \beta((b_{\xi_2}c_{\xi_1} - b_{\xi_1}c_{\xi_2})^2 + (a_{\xi_1}c_{\xi_2} - a_{\xi_2}c_{\xi_1})^2)^{\frac{1}{2}}}.\end{aligned}$$

We start with $\sigma(\xi,0) = \mathrm{id}(\xi) = \xi$ and use the parameter $t \in [0,1]$ to connect $\sigma(\xi,0)$ with $\sigma(\xi,1)$. The function $\sigma(\xi,t)$ is chosen to solve

$$\det \sigma(\xi,t) = \frac{1}{(1-t) + t\frac{1}{\tilde{m}(\sigma(\xi,t))}}, \quad t \in [0,1]. \tag{2.19}$$

This equation has the form (2.12) and can be solved as above (see (2.14), (2.15)). Note that by the choice of how the right-hand side in (2.19) depends on t, $w(x,t)$ in (2.14) will not depend on t and has to be solved only once in step 4.

3. Numerical realization.

3.1. Approximation of the direct problem. For the numerical computations we restrict ourselves to the unit square in $\mathbb{R}^2$, $\Omega = [0,1]^2$. Our algorithm requires solving (1.1) on Ω with $\tilde{\gamma} = 1+\gamma$. In the weak formulation we have to find $u \in H_0^1(\Omega)$ such that

$$\langle\, (1+\gamma)\nabla u, \nabla\psi \,\rangle = \langle\, f, \psi \,\rangle \qquad \forall \psi \in H_0^1(\Omega), \tag{3.1}$$

where $\langle\, \cdot, \cdot \,\rangle$ denotes the inner product on $L^2(\Omega)$. Since $\gamma = c(\phi^{-1})$ and since we want to avoid inverting ϕ, we transform the differential equation. In fact, if $u = F_\phi(c)$ solves (3.1), then $\tilde{u} := u \circ \phi$ solves

$$\langle\, (1+c)M\nabla\tilde{u}, \nabla\psi \,\rangle = \langle\, (f\circ\phi)\det D\phi, \psi \,\rangle \qquad \forall \psi \in H_0^1(\Omega), \tag{3.2}$$

with the matrix-valued function

$$M(\xi) = \det D\phi(\xi)[D\phi(\xi)]^{-1}[D\phi(\xi)]^{-T}.$$

For a numerical computation we use Courant (i.e., piecewise linear and continuous) elements for c and for the transformation function ϕ on the same uniform grid. The nodal points of the grid are given by

$$\xi_{i,j} = (\tfrac{i}{N}, \tfrac{j}{N}), \quad i,j = 0,\ldots,N. \tag{3.3}$$

This yields N^2 small squares, which are again subdivided into two triangles by the diagonal running from the lower left to the upper right corner. The $2N^2$ triangle elements are thus the triangles with corners and

$$\xi_{i,j}, \xi_{i,j+1}, \xi_{i+1,j+1}\,, \quad i,j = 0,\dots,N-1\,.$$

As usual the linear finite element basis functions $\psi_{i,j}(\xi)$ are first order polynomials on each triangle and satisfy $\psi_{i,j}(\xi_{k,l}) = \delta_{i,k}\delta_{j,l}$. $\psi_{i,j}$ is supported on at most 6 triangles which have $\xi_{i,j}$ as corner.

Given c, ϕ, then a numerical approximation $\tilde{u}_N$ of $\tilde{u}$ solving (3.2) is given as solution of

$$\begin{aligned} \langle\,(1+c)M\nabla\tilde{u}_N, \nabla\psi_{i,j}\,\rangle &= \langle\,(f\circ\phi)\det D\phi, \psi_{i,j}\,\rangle \quad \forall i,j = 1,\dots,N-1\,, \\ \tilde{u}_N &= \sum_{i,j=1}^{N-1} \tilde{u}_{i,j}\psi_{i,j}\,. \end{aligned} \tag{3.4}$$

This system is equivalent to a numerical approximation of the original weak form (3.1) on a transformed grid; i.e., the operator $F_\phi(c)$ is approximated by

$$F_\phi^N(c) := u_N = \sum_{i,j=1}^{N-1} \tilde{u}_{i,j}(\psi_{i,j}\circ\phi^{-1})\,. \tag{3.5}$$

Since we control only the cell size of the transformed grid and not the shape, the discretized equation (3.4) can be badly conditioned if the shape of the triangles on the transformed grid become nearly degenerate. This can be avoided by subdividing these degenerate triangles appropriately.

By our choice of ϕ and c, the Jacobian matrix $D\phi$ and $\nabla\psi_{i,j}$ are constant on each triangle, and c is a first order polynomial on each element; thus the integrals on the left-hand side of (3.4) can be evaluated exactly. For the right-hand side we calculate the values $f\circ\phi$ at the nodal points and then interpolate this function linearly on each triangle to evaluate the integral. By this procedure we obtain a $(N-1)^2 \times (N-1)^2$ linear system

$$A(c,\phi)\vec{u} = \vec{f}, \tag{3.6}$$

where $\vec{u}$ is a vector with entries $\tilde{u}_{i,j}$, $i,j = 1,\dots,N-1$, $A(c,\phi)$ is a sparse, band limited matrix with six nonzero off-diagonals, and $\vec{f}$ is a load vector with entries $\langle\,(f\circ\phi)\det D\phi, \psi_{i,j}\,\rangle$, $i,j = 1,\dots,N-1$. Equation (3.6) is solved using MATLAB's PCG method.

3.2. Realization of the regularization method. For the computation of the regularized solutions (cf. (2.8), (2.9), (2.11)) we have to replace the operator $F_{\phi_n}(c_{n,k})$ by $F_{\phi_n}^N(c_{n,k})$ (see (3.5)).

The effort for computing the derivative and its adjoint into one direction is of the same order as one evaluation of $F_{\phi_n}^N(c_{n,k})$. In fact, for a calculation of $u_N = F_{\phi_n}^N(c_{n,k})$ we have to solve the equation (see (3.5), (3.6))

$$A(c_{n,k},\phi_n)\vec{u} = \vec{f}$$

once, and for the derivative $w_N := (F_{\phi_n}^N)'(c_{n,k})h = \sum_{i,j=1}^{N-1} \tilde{w}_{i,j}(\psi_{i,j}\circ\phi^{-1})$ we additionally have to solve

$$A(c_{n,k},\phi_n)\vec{w} = -A(h-1,\phi_n)\vec{u}\,.$$

Note that we are interested only in elements h in the discretized space

$$X_N := \left\{ \sum_{i,j=1}^{N-1} h_{i,j}\psi_{i,j} \,:\, h_{i,j} \in \mathbb{R} \right\} \subset H_0^1 \,.$$

The adjoint of the operator $(F_{\phi_n}^N)'(c_{n,k}) : X_N \to L^2$ applied to some element $z = \sum_{i,j=1}^{N-1} z_{i,j}(\psi_{i,j} \circ \phi^{-1})$ is given by the solution of

$$\langle\, \nabla((F_{\phi_n}^N)'(c_{n,k})^* z), \nabla\psi_{i,j} \,\rangle = -\langle\, \nabla\tilde{u}^T M \nabla\tilde{\eta}, \psi_{i,j} \,\rangle \qquad \forall i,j = 1,\dots,N-1\,,$$

in X_N, where $\eta = \sum_{i,j=1}^{N-1} \eta_{i,j}\psi_{i,j}$ solves

$$A(c_{n,k},\phi)\vec{\eta} = G\vec{z}$$

with the Gramian matrix

$$G_{(i,j);(l,k)} = \langle\, \psi_{i,j} \det D\phi, \psi_{l,k} \,\rangle\,. \tag{3.7}$$

Note that $c_{n,k}$ has to satisfy $\gamma_1 \le 1 + c_{n,k} \le \gamma_2$. Therefore, we project $c_{n,k}$ onto this convex set, in each iteration step if necessary.

In our regularization methods we have two iteration loops: the index n corresponds to the update of the grid and the iteration indexed by k corresponds to the regularization step. An obvious improvement of the algorithm can be expected by including the information of the regularization iteration into the regridding step and combining these two iterations into one.

So instead of finishing the iteration with respect to k until the stopping rule is satisfied, we perform at most k_0 steps, where k_0 is a small fixed number. This means that even if the stopping rule is not yet satisfied after k_0 steps, we perform a regridding step and choose $c_{n+1,0}$ such that $\gamma_{n+1,0}$ is approximately equal to γ_{n,k_0}; i.e., $c_{n+1,0}$ equals the linear interpolant of $c_{n,k_0}(\phi_n^{-1} \circ \phi_{n+1})$. The numerical results indicate that this mixed iteration converges.

3.2.1. Realization of the deformation method. For the computation of the grid update $\phi_{n+1}(\xi) = \phi_n(\sigma(\xi,1))$ we have to solve a Neumann problem for the Poisson equation (2.14) once and the system of ODE (2.15). To do this we first compute the monitoring function $\tilde{m}_n$, which is piecewise constant on each triangle element. Note that the Poisson equation is defined on a uniform grid, and it is again solved by MATLAB's PCG algorithm. $\tilde{m}_n$ is scaled by taking C_n as $\int_\Omega \tilde{m}_n^{-1}(\xi)d\xi$ such that the solvability condition (2.13) holds. This integral can be evaluated exactly, because $\tilde{m}_n$ is piecewise constant.

The system of ODEs is solved by the classical fourth order Runge–Kutta method. Since the right-hand side of (2.15) is piecewise constant, we use bilinear interpolation on the triangles to obtain a continuous function.

Note that ϕ_n has to map the boundary of Ω onto itself. This is achieved by keeping ϕ_n fixed at the corner points of the unit square. Moreover, the first component of ϕ is not changed at the lines $y = 0$ and $y = 1$, and vice versa for the second component at $x = 0$ and $x = 1$.

Since, due to discretization, it may happen that the function σ has a negative determinant, we also include a smoothing step then by setting the values of σ at the corner points $\xi_{i,j}$ to the mean value of neighboring nodal points. However, it turned

out in our computations that such a smoothing step is rarely necessary as long as β is not too large. For large values of β a smaller step size in the Runge–Kutta method was sufficient to guarantee the positivity of the determinant.

If the grid is updated, i.e., a new transformation function ϕ_{n+1} is computed, we also have to recalculate several vectors and matrices depending on the grid. In fact, we have to compute the Gramian matrix (3.7) and the load vector $\vec{f}$ (3.6). The stiffness matrix $A(c_{n,k}, \phi_n)$ has to be updated in every step, too.

4. Numerical results. For the numerical experiments we used $f(x, y) = \sin(2\pi x)\sin(2\pi y)$ as right-hand side in (1.1).

The following examples were considered.

Example 4.1. Circle: $\gamma = 1 + 2\chi_{B_{0.55,0.45}(0.3)}$.

Example 4.2. Ramp: $\gamma(x, y) = 1 + 2\frac{x-0.25}{0.35}\chi_{\{(x,y)|0.25\le x\le 0.6, 0.2\le y\le 0.8\}}$.

Example 4.3. Moon: $\gamma = 1 + 2(\chi_{B_{0.55,0.5}(0.3)}(1 - \chi_{B_{0.4,0.5}(0.25)}))$.

Example 4.4. Rectangle (chosen from [6]): $\gamma = 1 + \chi_{\{(x,y)|0.3\le x\le 0.5, 0.3\le x+y\le 0.6\}}$.

Example 4.5. Circle and rectangle:

$$\gamma = 1 + 2(\chi_{B_{0.35,0.65}(0.15)} + \chi_{\{(x,y)|0.1\le x-y\le 0.6, 0.7\le x+y\le 1.1\}}.$$

($B_{x_0,y_0}(r)$ denotes the circle with midpoint at (x_0, y_0) and radius r.)

For all examples the data points were first computed using a fine uniform grid with $N = 120$ and then contaminated by random noise. This grid is much finer than the one used to calculate the regularized solutions (usually $N = 40$). By this we avoid so-called inverse crimes, namely, to use the same setup for the calculation of the simulated data and the regularization itself.

Since all matrices in our above algorithm are sparse we need a storage effort of order $\mathcal{O}(N^2)$. This shows the advantage of using a CG method for the iteratively regularized Gauss–Newton iteration, since the full matrix in (2.11) has $\mathcal{O}(N^4)$ entries.

Viewing computational time, the most expensive step is to solve (3.6). Basically, the PCG algorithm needs $\mathrm{cond}^{\frac{1}{2}} \log \epsilon^{-1}$ iterations to obtain an error reduction of ϵ. Here cond is the condition number of the preconditioned stiffness matrix $A(c, \phi)$. Each iteration needs a complexity of $\mathcal{O}(N^2)$ flops. Note that it is not necessary to solve the equation to a precision which is below the data noise.

We emphasize that the regridding step is not very expensive at all. In fact, it requires solving one PDE and the Runge–Kutta step. After all, its complexity is about of the same order as one function evaluation of $F^N_{\phi_n}(c_{n,k})$.

We first report about the differences of the iteration methods we used. Figures 4.1 and 4.2 show the relative L^2-error $\frac{\|\gamma_{n,k}-\gamma^\dagger\|}{\|\gamma_0-\gamma^\dagger\|}$ versus the iteration number for the minimal error method and the steepest descent method for Example 4.1 with discretization $N = 40$ and unperturbed data. Here every step of the form (2.8) is counted as one iteration. Hence if the grid is updated after k_0 steps of (2.8), then the total iteration number is $n_{tot} = (n-1)k_0 + k$ in the previous notation.

We chose different intervals for the grid update step. The dotted line indicates a grid update in every second step, i.e., $c_{n+1,0} \approx c_{n,2}$. The full lines correspond to a grid update in every 5th step and the dashed lines to one in every 10th step.

The two iteration methods show a different behavior: the error reduction for the minimal error method is not as smooth as for the steepest descent method. Moreover, the former exhibits a stronger dependence on the choice of the grid update intervals k_0, whereas the latter is quite insensitive to it. In fact, for the minimal error method we found the best results for $k_0 = 10$. However, the minimal error method performs better with respect to the required CPU-time. For an error reduction of 70% the

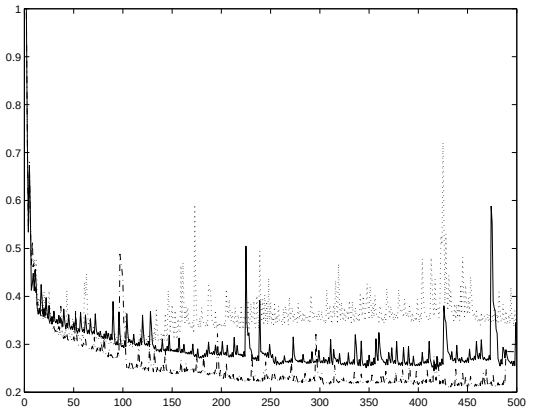

FIG. 4.1. *Error reduction vs. iteration: minimal error method.*

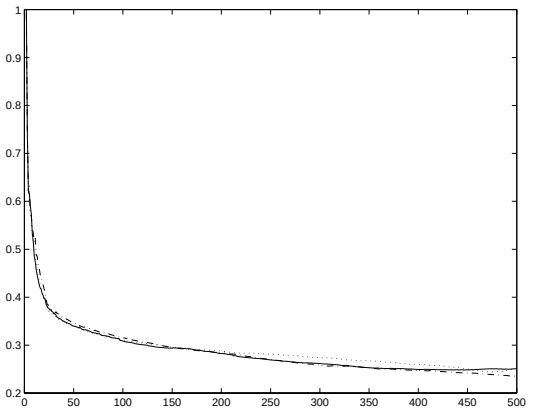

FIG. 4.2. *Error reduction vs. iteration: steepest descent method.*

steepest descent method needed more than three times the CPU-time for the minimal error method.

The inexact iteratively regularized Gauss–Newton iteration yields the best results. It is quite insensitive to the choice of k_0 compared to the steepest descent method and performs better with respect to the CPU-time than the minimal error method.

Figures 4.3–4.7 show the results for our examples with exact and noisy data (5% noise). We used $N = 40$, $\beta = 10$, and the inexact iteratively regularized Gauss–Newton method (2.11) with $\alpha_{k+1} = 0.9\alpha_k$. A grid update was done in every second step (i.e., $k_0 = 2$). For exact data the iteration was stopped at $\alpha_k = 10^{-10}$ and for noisy data we used the discrepancy principle as stopping rule.

The results show that we can identify the location of discontinuities quite well. Obviously, for noisy data the resolution is not as sharp as for exact ones. Note that even for exact data we have noise due to discretization. The second example exhibits that our algorithm does not suffer from the staircasing effect of several BV-regularizations. We observed that it is difficult to identify γ in regions where the gradient of u vanishes or is small. This effect can be expected, since γ is not identifiable at points where $\nabla u = 0$.

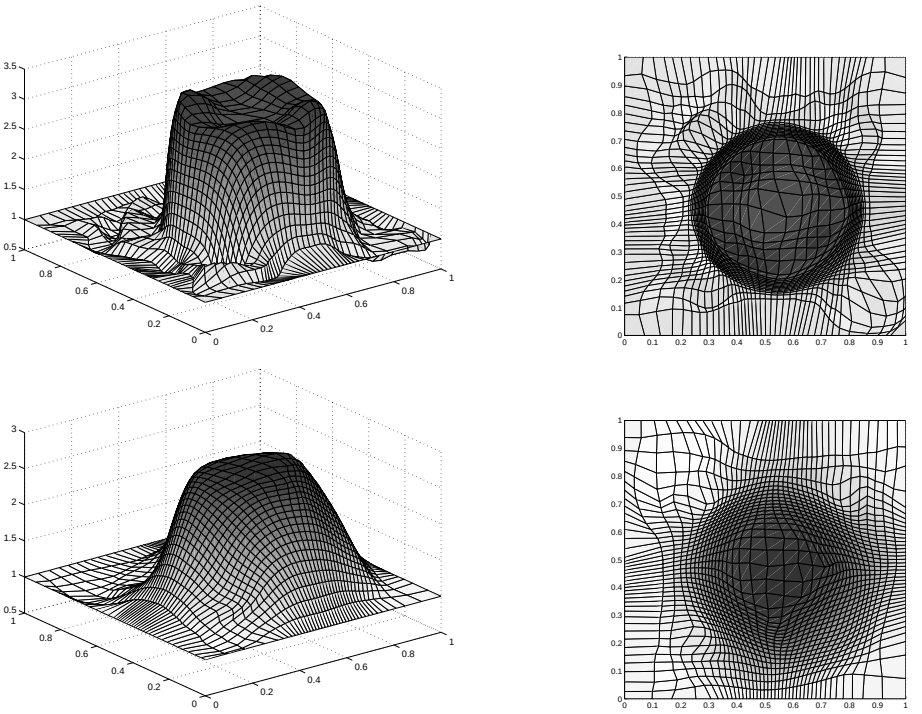

FIG. 4.3. *Reconstruction for Example* 4.1 *for exact data (above) and for* 5% *noise (below).*

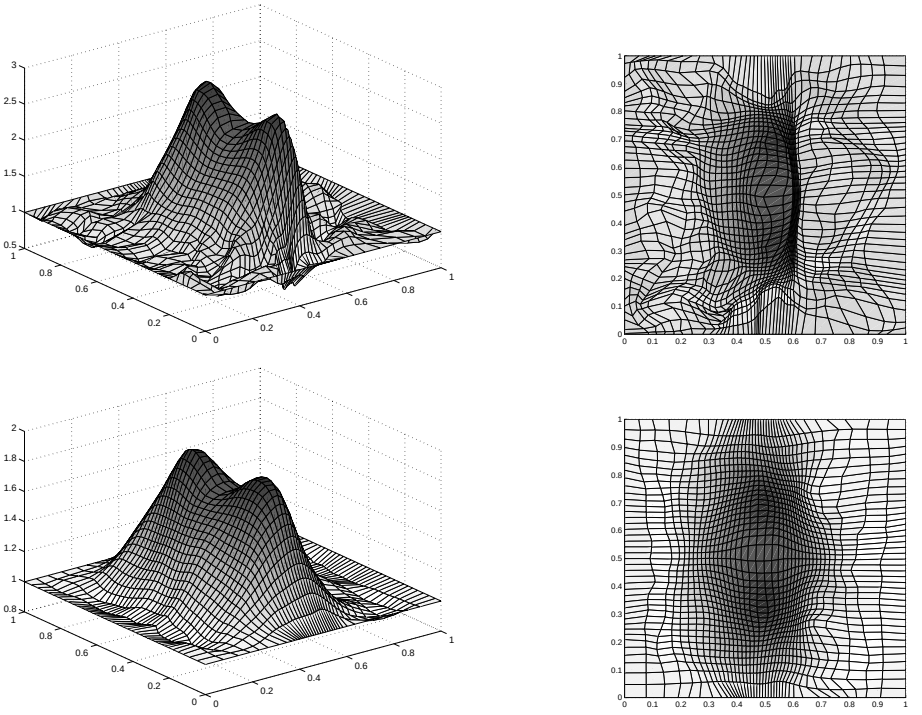

FIG. 4.4. *Reconstruction for Example* 4.2 *for exact data (above) and for* 5% *noise (below).*

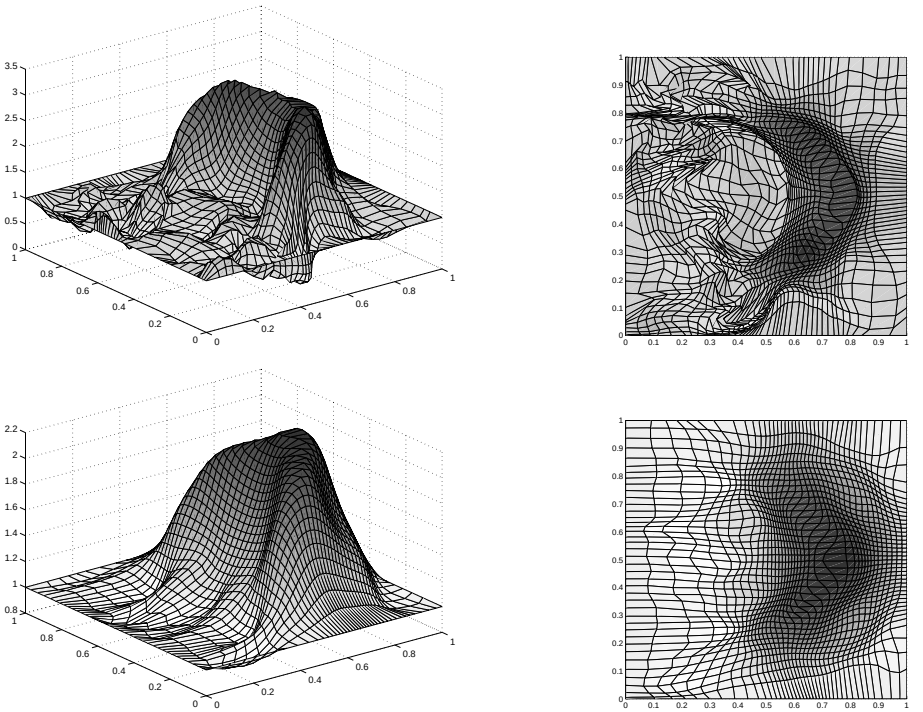

FIG. 4.5. *Reconstruction for Example* 4.3 *for exact data (above) and for* 5% *noise (below).*

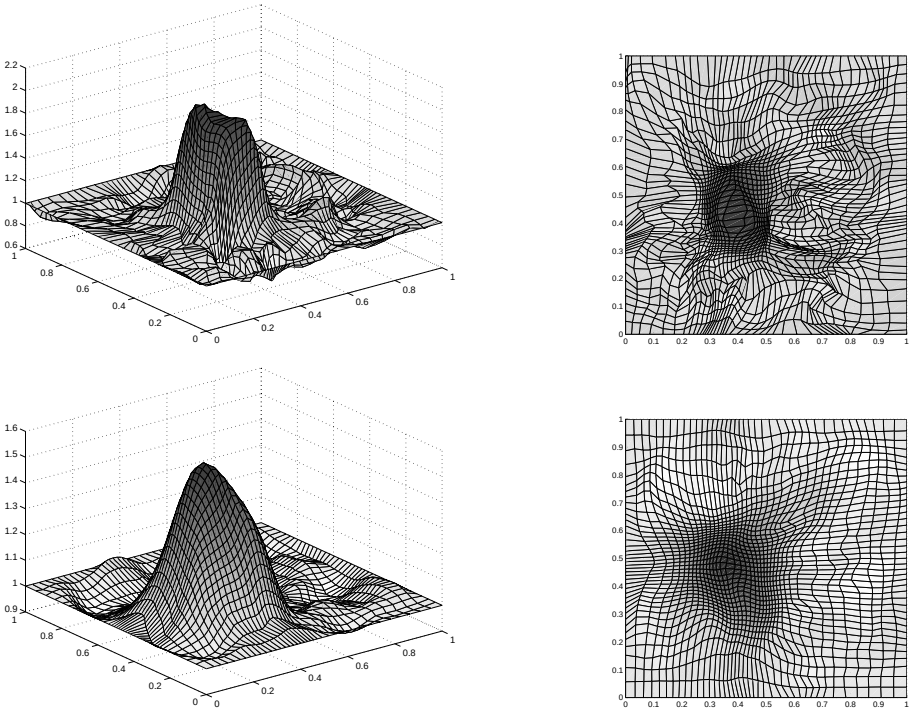

FIG. 4.6. *Reconstruction for Example* 4.4 *for exact data (above) and for* 5% *noise (below).*

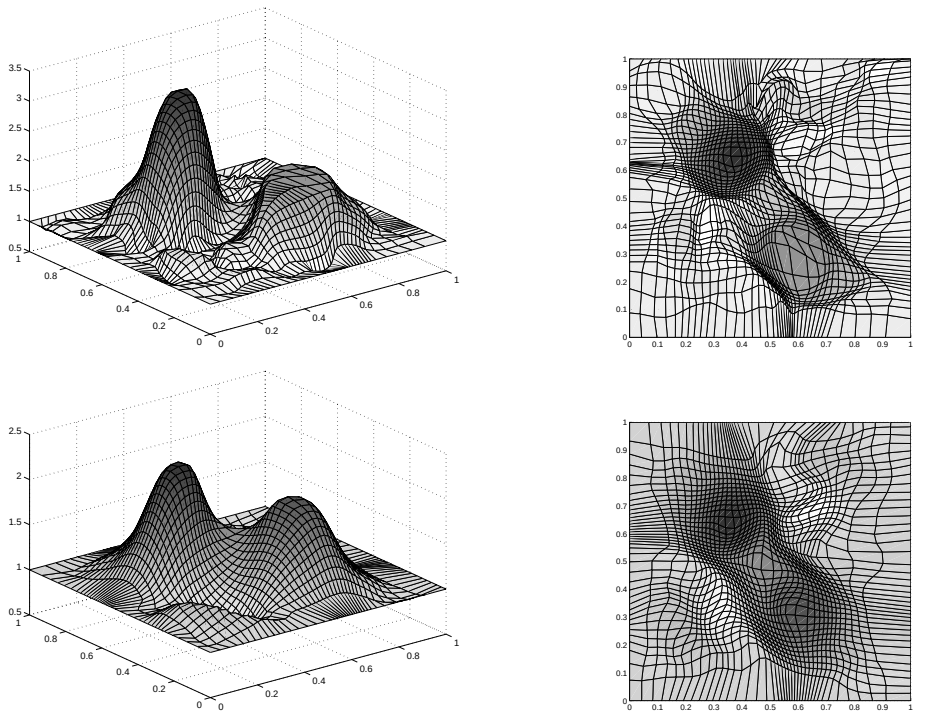

FIG. 4.7. *Reconstruction for Example* 4.5 *for exact data (above) and for* 5% *noise (below).*

Moreover, for exact data, the results for γ show a rather low dependence on the choice of the parameter β and the number of regridding steps. There seems to be a broad region of values of β yielding similar results. For noisy data we obtained slightly better results with respect to the resolution of discontinuities with larger values of β and more regridding steps.

The choice of the method for solving the ODE (2.15) is quite important. We additionally tried to use an explicit Euler method instead of the Runge–Kutta method, with unsatisfactory results. Using a method with lower order often yields negative determinants and requires smoothing steps of the grid, which makes the resolution of discontinuities not so sharp.

We want to compare our results of Example 4.4 with the ones in [6]: In the noise-free case we need about 40 iterations of Gauss–Newton steps. A rough comparison of the number of iterations to the augmented Lagrangian algorithm used in [6] shows that the latter method might be faster. However, a fair comparison seems to be hard, since the performance strongly depends on the regularization parameter and also on the regularization norm which was not BV-like in [6]. The quality of the results of both approaches is comparable. However, we think that the advantage of our approach is that good results will also be obtained if the discontinuity lines are not chosen parallel to the grid lines (see Example 4.5).

Of course the moving grid idea does not depend on any specific regularization method; hence a combination of the augmented Lagrangian method or SQP-like methods (cf. [3]) with a moving grid seems to be quite promising.

Finally, we want to mention that our regularization algorithm is less dependent on the choice of the size of the initial grid, since we are using a variable grid that is

adapted to the solution. A comparison of our results with numerical computations where the grid size was chosen as $N = 100$ instead of $N = 40$ showed practically no improvement for Examples 4.1–4.3. It is obvious that the possibility of choosing a coarser grid saves a lot of computation time. In Example 4.5 two disjoint regions of discontinuity have to be identified. For a good resolution more grid lines are needed for the gap between the two regions. Hence, the result was slightly better for the finer grid.

UNCONTROLLABILITY FOR LINEAR AUTONOMOUS MULTI-INPUT DYNAMICAL SYSTEMS DEPENDING ON PARAMETERS*

ALEXEI A. MAILYBAEV†

Abstract. Linear multi-input dynamical systems smoothly depending on parameters are considered. A set of parameter values corresponding to uncontrollable systems (an uncontrollability set) is studied. The typical (generic) structure of the uncontrollability set is described. A constructive method of perturbation analysis of the uncontrollability set is developed. Formulae of first-order approximations for the uncontrollability set and generalized eigenvalues (uncontrollable modes) are derived and used for numerical construction of the uncontrollability set. The method is based on the versal deformation theory for matrix pairs under feedback equivalence. As an example, the uncontrollability set is found for a three-parameter two-degree-of-freedom mechanical system.

Key words. uncontrollability, feedback equivalence, uncontrollable mode, perturbation, matrix pair, versal deformation

DOI. 10.1137/S0363012902405339

1. Introduction.

The concept of controllability is very important in the study of control problems. It describes the possibility of transferring a system to a required state using a given set of input (control) variables. Uncontrollability makes operation of a system in the whole state space impossible and signals the fundamental trouble with a control problem or underlying physical system. Similar difficulties appear for nearly uncontrollable systems, which require big control resources for control performance and which are strongly affected by imperfections and disturbances of the system.

The well-developed control theory exists for linear dynamical systems [3, 13]. Nevertheless, there are essential problems in using classical controllability criteria for numerical implementation. This is related to the structural instability of an uncontrollable system, which becomes controllable under an arbitrarily small perturbation. In this respect, it is important to know how far our system is from the nearest uncontrollable one. This problem was studied by many authors; see [2, 10, 11, 12] and references therein.

Design of a particular control system requires checking the controllability condition for different values of parameters. In this analysis, the knowledge on the structure of the uncontrollability set (a set of parameter values corresponding to uncontrollable systems) is very useful and helps in avoiding the dangerous nearness to uncontrollability. In this paper, basic qualitative properties of the uncontrollability set for a generic (typical) multi-input linear dynamical system depending on several parameters are investigated. This includes a description of a regular part of the uncontrollability set and its basic singularities. Then the quantitative perturbation method for local analysis of the uncontrollability set near its regular points is developed. Application

of this method to numerical calculation of a regular part of the uncontrollability set in the parameter space is proposed. As an example, an elastic mechanical system controlled by a force and dependent on three design parameters is studied. The results of the paper are based on the versal deformation theory for matrix pairs under state feedback equivalence [6, 8, 14].

The paper is organized as follows. Section 2 describes basic concepts and results of the mathematical control theory. Section 3 studies the qualitative structure of the uncontrollability set. Quantitative perturbation method for local analysis of the uncontrollability set is developed in section 4. In section 5, a numerical method for computation of a regular part of the uncontrollability set is constructed and applied to the analysis of a specific mechanical system. Section 6 is devoted to singularities of the uncontrollability set. The conclusion summarizes the contribution.

2. Controllability, feedback equivalence, and versal deformation. Let us consider a dynamical system described by the system of linear ordinary differential equations

$$\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{u}(t), \tag{2.1}$$

where $\mathbf{x} \in \mathbb{R}^n$ is a state vector, $\mathbf{u} \in \mathbb{R}^m$ is an input vector, and $\mathbf{A}$ and $\mathbf{B}$ are $n \times n$ and $n \times m$ real time-invariant matrices, respectively; the dot denotes differentiation with respect to time t. System (2.1) is called (state) *controllable* if it is possible to construct a control signal $\mathbf{u}(t)$ that will transfer an initial state to any final state in finite time [3, 13]. Otherwise, the system is said to be *uncontrollable*. The classical criterion of controllability says that the system is controllable if and only if the $n \times nm$ *controllability matrix* $\mathbf{C} = [\mathbf{B}, \mathbf{AB}, \dots, \mathbf{A}^{n-1}\mathbf{B}]$ has full rank [3, 13]

$$\operatorname{rank}[\mathbf{B}, \mathbf{AB}, \dots, \mathbf{A}^{n-1}\mathbf{B}] = n. \tag{2.2}$$

System (2.1) is determined by a matrix pair $(\mathbf{A}, \mathbf{B})$. Let us denote the set of all matrix pairs by $\mathcal{M} = \{(\mathbf{A}, \mathbf{B}) \mid \mathbf{A} \in \mathbb{R}^{n\times n}, \mathbf{B} \in \mathbb{R}^{n\times m}\}$. We will use the short notation $\alpha = (\mathbf{A}, \mathbf{B})$ for a matrix pair. The matrix pair α is called controllable (or uncontrollable) if the corresponding system (2.1) is controllable (or uncontrollable).

2.1. Feedback equivalence. Let us apply a linear feedback transformation of the input vector and perform a change of basis in the state and input spaces. The new state vector $\bar{\mathbf{x}}$ and input vector $\bar{\mathbf{u}}$ are related to $\mathbf{x}$ and $\mathbf{u}$ by the expressions

$$\mathbf{x} = \mathbf{P}\bar{\mathbf{x}}, \quad \mathbf{u} = \mathbf{Q}\bar{\mathbf{u}} + \mathbf{R}\bar{\mathbf{x}}, \tag{2.3}$$

where $\mathbf{P}$ and $\mathbf{Q}$ are $n \times n$ and $m \times m$ nonsingular real matrices; $\mathbf{R}$ is an $m \times n$ real matrix. The substitution of (2.3) into (2.1) yields

$$\dot{\bar{\mathbf{x}}}(t) = \bar{\mathbf{A}}\bar{\mathbf{x}}(t) + \bar{\mathbf{B}}\bar{\mathbf{u}}(t), \tag{2.4}$$

where

$$\bar{\mathbf{A}} = \mathbf{P}^{-1}(\mathbf{AP} + \mathbf{BR}), \quad \bar{\mathbf{B}} = \mathbf{P}^{-1}\mathbf{BQ}. \tag{2.5}$$

Systems (2.1) and (2.4) (as well as the corresponding matrix pairs $\alpha = (\mathbf{A}, \mathbf{B})$ and $\bar{\alpha} = (\bar{\mathbf{A}}, \bar{\mathbf{B}})$) are called *feedback equivalent* (also called *block equivalent*) [9, 13]. The controllability property is invariant under the feedback equivalence transformation.

Let us introduce the short notation $\bar{\alpha} = \gamma \circ \alpha$ for the feedback equivalence transformation (2.5) applied to a matrix pair $\alpha = (\mathbf{A}, \mathbf{B})$, where γ denotes a triple $\gamma = (\mathbf{P}, \mathbf{Q}, \mathbf{R})$. We denote the set of all feedback equivalence transformations by $\mathcal{G} = \{(\mathbf{P}, \mathbf{Q}, \mathbf{R}) \mid \mathbf{P} \in \mathbb{R}^{n\times n}, \mathbf{Q} \in \mathbb{R}^{m\times m}, \mathbf{R} \in \mathbb{R}^{m\times n}, \det \mathbf{P} \neq 0, \det \mathbf{Q} \neq 0\}$. Note that relations (2.5) determine the Lie group structure in $\mathcal{G}$ with the multiplication and inversion of elements given by

$$\begin{gathered} \gamma_1\gamma_2 = (\mathbf{P}_1\mathbf{P}_2,\, \mathbf{Q}_1\mathbf{Q}_2,\, \mathbf{R}_1\mathbf{P}_2 + \mathbf{Q}_1\mathbf{R}_2) \in \mathcal{G}, \quad \gamma_i = (\mathbf{P}_i, \mathbf{Q}_i, \mathbf{R}_i) \in \mathcal{G}, \\ \gamma^{-1} = (\mathbf{P}^{-1},\, \mathbf{Q}^{-1},\, -\mathbf{Q}^{-1}\mathbf{R}\mathbf{P}^{-1}) \in \mathcal{G}, \quad \gamma = (\mathbf{P}, \mathbf{Q}, \mathbf{R}) \in \mathcal{G} \end{gathered} \tag{2.6}$$

such that $\gamma_1\gamma_2 \circ \alpha = \gamma_2 \circ (\gamma_1 \circ \alpha)$ and $\gamma\gamma^{-1} \circ \alpha = \alpha$ for any $\alpha \in \mathcal{M}$. The unit element of $\mathcal{G}$ is $e = (\mathbf{I}_n, \mathbf{I}_m, 0)$, where $\mathbf{I}_n$ and $\mathbf{I}_m$ are $n \times n$ and $m \times m$ identity matrices, respectively. This triple has the property $\alpha = e \circ \alpha$ for any pair $\alpha \in \mathcal{M}$.

2.2. Equivalence classes and their local structure. Let us consider a fixed matrix pair $\alpha_0 = (\mathbf{A}_0, \mathbf{B}_0) \in \mathcal{M}$. A set of all pairs α feedback equivalent to α_0 is called the *orbit* of α_0 and denoted by

$$\mathcal{O}(\alpha_0) = \{\alpha \in \mathcal{M} \mid \alpha = \gamma \circ \alpha_0,\ \gamma \in \mathcal{G}\}. \tag{2.7}$$

The orbit is a smooth submanifold of $\mathcal{M}$.

The orbit $\mathcal{O}(\alpha_0)$ can be represented by its arbitrary member $\alpha \in \mathcal{O}(\alpha_0)$. Therefore, to describe the orbit it is convenient to choose a pair α having, in some sense, the simplest form. One such form, called a *Brunovsky canonical form*, is represented by the matrix pair [9, 13]

$$\alpha_b = (\mathbf{A}_b, \mathbf{B}_b), \quad \mathbf{A}_b = \begin{pmatrix} \mathbf{N} & 0 \\ 0 & \mathbf{J} \end{pmatrix}, \quad \mathbf{B}_b = \begin{pmatrix} \mathbf{E} & 0 \\ 0 & 0 \end{pmatrix}, \tag{2.8}$$

where $\mathbf{J}$ is the real Jordan canonical form (real counterpart of the Jordan form); $\mathbf{N} = \operatorname{diag}(\mathbf{N}_1, \dots, \mathbf{N}_r)$; $\mathbf{E} = \operatorname{diag}(\mathbf{E}_1, \dots, \mathbf{E}_r)$; $\mathbf{N}_i$ and $\mathbf{E}_i$ are $k_i \times k_i$ and $k_i \times 1$ matrices, respectively, having the form

$$\mathbf{N}_i = \begin{pmatrix} 0 & 1 & & \\ & 0 & \ddots & \\ & & \ddots & 1 \\ & & & 0 \end{pmatrix}, \quad \mathbf{E}_i = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}. \tag{2.9}$$

The numbers $k_1 \geq \cdots \geq k_r > 0$ are called *controllability indices* or *Kronecker indices* of the system; $\mathbf{N}$ is called a *Kronecker part* and $\mathbf{J}$ is called a *Jordan part* of the Brunovsky form. Any matrix pair $\alpha \in \mathcal{M}$ is feedback equivalent to the corresponding Brunovsky form, which is unique up to the permutation of blocks in the Jordan matrix $\mathbf{J}$. Using condition (2.2), one can check that the matrix pair α is controllable if and only if its Brunovsky form has no Jordan part. If the pair is uncontrollable, then eigenvalues of the Jordan part $\mathbf{J}$ are called *generalized eigenvalues* or *uncontrollable modes*.

Let us introduce the function $f_{\alpha_0}(\gamma) = \gamma \circ \alpha_0$, which is a smooth function from $\mathcal{G}$ to $\mathcal{M}$. Then the orbit $\mathcal{O}(\alpha_0)$ can be seen as the range of the mapping f_{α_0}, i.e.,

$$\mathcal{O}(\alpha_0) = \operatorname{Im} f_{\alpha_0}. \tag{2.10}$$

Let us denote by $T_e\mathcal{G}$ the tangent space to $\mathcal{G}$ at the unit element e. Since $\mathcal{G}$ is an open set, we have $T_e\mathcal{G} = \{(\mathbf{U}, \mathbf{V}, \mathbf{W}) \mid \mathbf{U} \in \mathbb{R}^{n\times n}, \mathbf{V} \in \mathbb{R}^{m\times m}, \mathbf{W} \in \mathbb{R}^{m\times n}\}$. The linear spaces $\mathcal{M}$ and $T_e\mathcal{G}$ are equipped with the Euclidean scalar products

$$\begin{aligned} &\langle \alpha_1, \alpha_2\rangle_1 = \operatorname{trace}(\mathbf{A}_1\mathbf{A}_2^T) + \operatorname{trace}(\mathbf{B}_1\mathbf{B}_2^T),\\ &\langle \xi_1, \xi_2\rangle_2 = \operatorname{trace}(\mathbf{U}_1\mathbf{U}_2^T) + \operatorname{trace}(\mathbf{V}_1\mathbf{V}_2^T) + \operatorname{trace}(\mathbf{W}_1\mathbf{W}_2^T), \end{aligned} \tag{2.11}$$

where $\alpha_i = (\mathbf{A}_i, \mathbf{B}_i) \in \mathcal{M}$, $\xi_i = (\mathbf{U}_i, \mathbf{V}_i, \mathbf{W}_i) \in T_e\mathcal{G}$, and $\mathbf{A}^T$ denotes the transposed matrix. Let us introduce linear mappings $df_{\alpha_0} : T_e\mathcal{G} \longrightarrow \mathcal{M}$ and $df^*_{\alpha_0} : \mathcal{M} \longrightarrow T_e\mathcal{G}$ as follows:

$$\begin{aligned} &df_{\alpha_0}(\xi) = (\mathbf{A}_0\mathbf{U} - \mathbf{U}\mathbf{A}_0 + \mathbf{B}_0\mathbf{W},\ \mathbf{B}_0\mathbf{V} - \mathbf{U}\mathbf{B}_0), \quad \xi = (\mathbf{U}, \mathbf{V}, \mathbf{W}),\\ &df^*_{\alpha_0}(\alpha) = (\mathbf{A}_0^T\mathbf{A} - \mathbf{A}\mathbf{A}_0^T - \mathbf{B}\mathbf{B}_0^T,\ \mathbf{B}_0^T\mathbf{B},\ \mathbf{B}_0^T\mathbf{A}), \quad \alpha = (\mathbf{A}, \mathbf{B}). \end{aligned} \tag{2.12}$$

It is straightforward to check that df_{α_0} is the differential of the function f_{α_0} at the unit element $e = (\mathbf{I}_n, \mathbf{I}_m, 0)$ [6], and $df^*_{\alpha_0}$ is the adjoint function defined by the relation [7]

$$\langle df_{\alpha_0}(\xi), \alpha\rangle_1 = \langle \xi, df^*_{\alpha_0}(\alpha)\rangle_2, \quad \alpha \in \mathcal{M}, \quad \xi \in T_e\mathcal{G}. \tag{2.13}$$

A local structure of the orbit $\mathcal{O}(\alpha_0)$ near the point α_0 is determined by the range of the mapping df_{α_0} and null-space of $df^*_{\alpha_0}$ as follows [8]:

$$T_{\alpha_0}\mathcal{O}(\alpha_0) = \operatorname{Im} df_{\alpha_0}, \tag{2.14}$$

$$(T_{\alpha_0}\mathcal{O}(\alpha_0))^{\perp} = \operatorname{Ker} df^*_{\alpha_0}, \tag{2.15}$$

where $T_{\alpha_0}\mathcal{O}(\alpha_0)$ is the tangent space to $\mathcal{O}(\alpha_0)$ at the point α_0; $(T_{\alpha_0}\mathcal{O}(\alpha_0))^{\perp}$ denotes the normal complimentary subspace to $T_{\alpha_0}\mathcal{O}(\alpha_0)$ in $\mathcal{M}$. In addition, we denote by $(T_{\alpha_0}\mathcal{O}(\alpha_0))^c$ an arbitrary complimentary subspace to $T_{\alpha_0}\mathcal{O}(\alpha_0)$ in $\mathcal{M}$.

2.3. Versal deformation. A multiparameter dynamical system (2.1) is described by a matrix pair $\alpha(\mathbf{p})$ smoothly dependent on a vector of parameters $\mathbf{p} = (p_1, \dots, p_k) \in \mathbb{R}^k$. The function $\alpha(\mathbf{p})$ is called the *family* of matrix pairs. The family $\alpha(\mathbf{p})$ determined in the neighborhood of a point $\mathbf{p}_0$ is called a *deformation* of the matrix pair $\alpha_0 = \alpha(\mathbf{p}_0)$. Using feedback equivalence transformation $\gamma(\mathbf{p}) \circ \alpha(\mathbf{p})$, the family $\alpha(\mathbf{p})$ can be reduced to a more simple form. Nevertheless, a reduction to the Brunovsky form generally cannot be achieved by the feedback equivalence transformation $\gamma(\mathbf{p})$ smoothly dependent on parameters. The following theorem proved in [6, 8] provides another form called a versal deformation that can be used for multiparameter families of matrix pairs. Note that the concept of versal deformation was first introduced by Arnold [1] for families of square complex matrices; see also [14] for the generalization to the case of a Lie group acting on a complex manifold.

THEOREM 2.1. *Let $\alpha(\mathbf{p})$ be a family of matrix pairs. Then in the neighborhood of a point $\mathbf{p}_0$, the family $\alpha(\mathbf{p})$ can be represented in the form*

$$\alpha(\mathbf{p}) = \gamma(\mathbf{p}) \circ \left(\alpha_0 + \sum_{i=1}^{\ell} q_i(\mathbf{p})\, \alpha_i^c\right). \tag{2.16}$$

In this formula $\{\alpha_1^c, \dots, \alpha_\ell^c\}$, $\ell = \dim (T_{\alpha_0}\mathcal{O}(\alpha_0))^c$, is a basis of $(T_{\alpha_0}\mathcal{O}(\alpha_0))^c$; $\gamma(\mathbf{p})$ is a feedback equivalence transformation smoothly dependent on $\mathbf{p}$ such that $\gamma(\mathbf{p}_0) = e$; $q_1(\mathbf{p}), \dots, q_\ell(\mathbf{p})$ are smooth functions, whose values and derivatives at $\mathbf{p}_0$ are

$$q_1(\mathbf{p}_0) = \dots = q_\ell(\mathbf{p}_0) = 0, \tag{2.17}$$

$$\begin{pmatrix} \dfrac{\partial q_1}{\partial p_j} \\ \vdots \\ \dfrac{\partial q_\ell}{\partial p_j} \end{pmatrix} = \mathbf{Z}^{-1} \begin{pmatrix} \left\langle \dfrac{\partial \alpha}{\partial p_j}, \alpha_1^n \right\rangle_1 \\ \vdots \\ \left\langle \dfrac{\partial \alpha}{\partial p_j}, \alpha_\ell^n \right\rangle_1 \end{pmatrix}, \tag{2.18}$$

where $\{\alpha_1^n, \dots, \alpha_\ell^n\}$ *is a basis of the linear space* $(T_{\alpha_0}\mathcal{O}(\alpha_0))^\perp$*;* $\mathbf{Z}$ *is a nonsingular* $\ell \times \ell$ *matrix with the elements* $z_{ij} = \langle \alpha_j^c, \alpha_i^n \rangle_1$.

Formulae for derivatives of the functions $q_1(\mathbf{p}), \dots, q_\ell(\mathbf{p})$ and $\gamma(\mathbf{p})$ of any order were derived in [8]. The family of matrix pairs

$$\beta(\mathbf{q}) = \alpha_0 + \sum_{i=1}^{\ell} q_i \, \alpha_i^c, \quad \mathbf{q} = (q_1, \dots, q_\ell), \tag{2.19}$$

is called a *versal deformation* of the matrix pair α_0; $\mathbf{q}$ is a parameter vector of the versal deformation [1]. The main idea of the above theorem is that any matrix family $\alpha(\mathbf{p})$ with a given pair $\alpha_0 = \alpha(\mathbf{p}_0)$ can be transformed locally to the versal deformation $\beta(\mathbf{q})$, which has an explicit and simple form, by the feedback equivalence transformation $\gamma(\mathbf{p})$ smoothly dependent on $\mathbf{p}$ and smooth change of parameters $\mathbf{q} = \mathbf{q}(\mathbf{p})$. Note that the bases $\{\alpha_1^c, \dots, \alpha_\ell^c\}$ and $\{\alpha_1^n, \dots, \alpha_\ell^n\}$ have been found explicitly in [6] for matrix pairs reduced to the Brunovsky canonical form.

Example 2.1. Let us consider a one-parameter family of matrix pairs $\alpha(p) = (\mathbf{A}(p), \mathbf{B}(p))$, where

$$\mathbf{A}(p) = \begin{pmatrix} p & 0 & p^2 \\ 2p & p & -p \\ 3p & p & 2+p^3 \end{pmatrix}, \quad \mathbf{B}(p) = \begin{pmatrix} 1 & p \\ p & 1 \\ 0 & -p \end{pmatrix}. \tag{2.20}$$

Family (2.20) determines a one-parameter dynamical system (2.1) with three-dimensional state space and two-dimensional input vector. The pair $\alpha_0 = \alpha(p_0)$ for $p_0 = 0$ has the form

$$\alpha_0 = \left(\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 2 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix} \right), \tag{2.21}$$

which is the Brunovsky canonical form (2.8), (2.9) with $r = 2$, $k_1 = k_2 = 1$, and $\mathbf{J} = (2)$. Solving the linear equation $df^*_{\alpha_0}(\alpha) = 0$ with respect to α and using relation (2.15), we find that the space $(T_{\alpha_0}\mathcal{O}(\alpha_0))^\perp$ has dimension $\ell = 3$ and consists of the matrix pairs

$$\left(\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ q_1 & q_2 & q_3 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 2q_1 & 2q_2 \end{pmatrix} \right) \in (T_{\alpha_0}\mathcal{O}(\alpha_0))^\perp, \quad q_1, q_2, q_3 \in \mathbb{R}. \tag{2.22}$$

The complimentary subspace $(T_{\alpha_0}\mathcal{O}(\alpha_0))^c$ can be chosen in a more simple form as follows:

$$\left(\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ q_1 & q_2 & q_3 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right) \in (T_{\alpha_0}\mathcal{O}(\alpha_0))^c, \quad q_1, q_2, q_3 \in \mathbb{R}. \tag{2.23}$$

Expressions (2.22) and (2.23) generate the bases $\{\alpha_1^n, \alpha_2^n, \alpha_3^n\}$ and $\{\alpha_1^c, \alpha_2^c, \alpha_3^c\}$ as coefficients corresponding to q_1, q_2, q_3.

By Theorem 2.1, family (2.20) can be represented in the form $\alpha(p) = \gamma(p) \circ \beta(\mathbf{q}(p))$, where $\beta(\mathbf{q})$ is the versal deformation

$$\beta(\mathbf{q}) = \left(\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ q_1 & q_2 & 2+q_3 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix} \right), \quad \mathbf{q} = (q_1, q_2, q_3), \tag{2.24}$$

$\gamma(p)$ is a feedback equivalence transformation smoothly dependent on p, and $\mathbf{q} = \mathbf{q}(p)$ is a smooth change of parameters. Derivatives of the functions $q_1(p)$, $q_2(p)$, $q_3(p)$ at $p_0 = 0$ can be calculated by expression (2.18) as follows:

$$\frac{dq_1}{dp} = 3, \quad \frac{dq_2}{dp} = -1, \quad \frac{dq_3}{dp} = 0. \tag{2.25}$$

3. Structure of the uncontrollability set. Let us consider a multiparameter dynamical system described by a family of matrix pairs $\alpha(\mathbf{p})$. A set of values of the parameter vector $\mathbf{p}$ such that $\alpha(\mathbf{p})$ is uncontrollable is called the *uncontrollability set* and denoted by

$$\mathcal{N} = \{\mathbf{p} \mid \alpha(\mathbf{p}) \text{ is uncontrollable}\}. \tag{3.1}$$

It is known that $\mathcal{N}$ is typically a set of zero measure [13]. In particular, any uncontrollable system can be made controllable by an arbitrarily small perturbation of the matrices $\mathbf{A}$ and $\mathbf{B}$. Nevertheless, when the parameter vector is close to the uncontrollability set $\mathcal{N}$, the system becomes practically uncontrollable due to small perturbations and uncertainties existing in every physical system, and the necessity of using big control resources (large $\|\mathbf{u}\|$) or long time for control operation. This makes analysis and construction of the uncontrollability set in the parameter space important for the design of control systems.

As was mentioned in the previous section, for a fixed value of $\mathbf{p}$ the matrix pair $\alpha(\mathbf{p})$ can be transformed to the Brunovsky canonical form (2.8), and the uncontrollability of $\alpha(\mathbf{p})$ is equivalent to the existence of the Jordan part in this form. Let us consider two specific types of the Brunovsky form that will be important for further analysis. These two forms are represented by the 1×1 and 2×2 Jordan parts

$$\mathbf{J}_\sigma = (\sigma), \quad \mathbf{J}_{\sigma \pm i\omega} = \begin{pmatrix} \sigma & \omega \\ -\omega & \sigma \end{pmatrix}, \quad \sigma, \omega \in \mathbb{R},\ \omega > 0, \tag{3.2}$$

corresponding to a real simple eigenvalue σ and a pair of complex conjugate simple eigenvalues $\sigma \pm i\omega$, respectively. Structure of the Kronecker part can be arbitrary. We refer to matrix pairs having the described structures of the Brunovsky form as pairs of $\mathbf{J}_\sigma$ and $\mathbf{J}_{\sigma \pm i\omega}$ types.

To describe the qualitative structure of the uncontrollability set $\mathcal{N}$, it is reasonable to restrict our attention to the *generic* (typical) situation. This corresponds to a typical form of the set $\mathcal{N}$ such that small perturbations of the family $\alpha(\mathbf{p})$ do not lead to qualitative changes in the geometry and structure of $\mathcal{N}$ but result only in its small shift in the parameter space. For more precise mathematical formulation of the concept "generic," see [1]. Consideration of the generic case allows extracting the most typical and interesting information on the structure of the uncontrollability

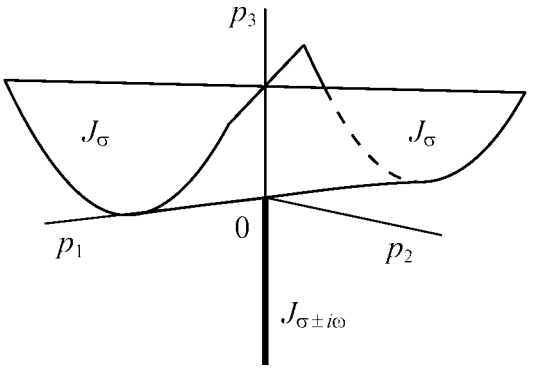

FIG. 3.1. *Structure of the uncontrollability set.*

set, which is valid for almost all multi-input linear dynamical systems dependent on parameters. The following theorem provides the basic qualitative description of this set.

THEOREM 3.1. *In the generic case the uncontrollability set $\mathcal{N}$ of the family of matrix pairs $\alpha(\mathbf{p})$ has a regular part, which consists of smooth surfaces of codimensions m and $2m$ corresponding to matrix pairs of $\mathbf{J}_\sigma$ and $\mathbf{J}_{\sigma\pm i\omega}$ types, respectively. Points $\mathbf{p} \in \mathcal{N}$ such that the matrix pair $\alpha(\mathbf{p})$ has a different type of the Brunovsky form belong to the boundary of these surfaces.*

Example 3.1. Let us consider the family of matrix pairs

$$\alpha(\mathbf{p}) = \left(\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ p_1 & 0 & 0 & 1 \\ p_2 & 0 & p_3 & 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} \right), \quad \mathbf{p} = (p_1, p_2, p_3). \tag{3.3}$$

Using the controllability condition (2.2), we find the uncontrollability set in the form

$$\mathcal{N} = \{\mathbf{p} \in \mathbb{R}^3 \mid p_1^2 p_3 - p_2^2 = 0\}. \tag{3.4}$$

This set is shown in Figure 3.1. It represents the well-known Whitney–Cayley umbrella [1]. The structure of $\mathcal{N}$ agrees with Theorem 3.1. Indeed, the set $\mathcal{N}$ has a "handle" (the ray $p_1 = p_2 = 0$, $p_3 < 0$), which has codimension $2m = 2$ and corresponds to pairs of $\mathbf{J}_{\sigma\pm i\omega}$ type with the generalized eigenvalues $\sigma \pm i\omega = \pm i\sqrt{-p_3}$. There are two smooth surfaces of codimension $m = 1$ determined by the equation $p_1^2 p_3 - p_2^2 = 0$ for $p_3 \geq 0$, $p_1 < 0$ and $p_3 \geq 0$, $p_1 > 0$, which correspond to the pairs of $\mathbf{J}_\sigma$ type; the generalized eigenvalue is $\sigma = -p_2/p_1$. The "handle" and two surfaces form a regular part of $\mathcal{N}$. There are also different types of uncontrollable pairs: at the point $\mathbf{p} = 0$ we have a pair with the Jordan part $\mathbf{J} = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, and points of the ray $p_1 = p_2 = 0$, $p_3 > 0$ correspond to pairs having two different real generalized eigenvalues $\sigma_{1,2} = \pm\sqrt{p_3}$. These points determine singularities of $\mathcal{N}$ and belong to the boundary of the regular part.

According to Theorem 3.1, we can expect to find a similar structure of the uncontrollability set for almost all families of matrix pairs. This means that for the construction of the uncontrollability set it is sufficient to find its regular part, i.e., points of $\mathbf{J}_\sigma$ and $\mathbf{J}_{\sigma\pm i\omega}$ types forming smooth surfaces of codimensions m and $2m$, respectively. Then the whole set $\mathcal{N}$ will be the closure of these surfaces.

Proof. The proof is based on general results of the singularity theory and uses versal deformations. In order to avoid special mathematical language, we describe general steps and ideas of the proof, while the details can be easily reconstructed by the reader using the cited literature.

The decomposition of the parameter space into subsets (*strata*) according to the Brunovsky structure of the corresponding matrix pair $\alpha(\mathbf{p})$ is called the *bifurcation diagram*. The singularity theory says that the qualitative local structure of the bifurcation diagram (and, hence, of the uncontrollability set) for a generic family $\alpha(\mathbf{p})$ is the same as for the versal deformation $\beta(\mathbf{q})$ [1]. In particular, codimensions of strata in the corresponding parameter spaces coincide. This follows from the relation $\alpha(\mathbf{p}) = \gamma(\mathbf{p}) \circ \beta(\mathbf{q}(\mathbf{p}))$ and the property that the Brunovsky canonical form is invariant under the feedback equivalence transformation $\gamma(\mathbf{p})$.

Let us consider a matrix pair $\alpha_0 = \alpha(\mathbf{p}_0)$. Without loss of generality, we can assume that α_0 is transformed to the Brunovsky canonical form (2.8). Then its versal deformation can be taken in the form

$$\beta(\mathbf{q}) = \left(\begin{pmatrix} \mathbf{N} & 0 \\ \mathbf{X}^c_{21} & \mathbf{J} + \mathbf{X}^c_{22} \end{pmatrix}, \begin{pmatrix} \mathbf{E} + \mathbf{Y}^c_{11} & \mathbf{Y}^c_{12} \\ 0 & \mathbf{Y}^c_{22} \end{pmatrix} \right), \tag{3.5}$$

where $\mathbf{X}^c_{ij}(\mathbf{q})$ and $\mathbf{Y}^c_{ij}(\mathbf{q})$ are matrices depending on a vector of parameters $\mathbf{q} \in \mathbb{R}^\ell$ such that every matrix is zero at $\mathbf{q} = 0$. Explicit form of these matrices depends on the structure of $\mathbf{N}$ and $\mathbf{J}$. In the case $\mathbf{J} = \mathbf{J}_\sigma$ we can take [6]

$$\mathbf{X}^c_{21} = \big(\mathbf{L}^c_1(q_1), \dots, \mathbf{L}^c_r(q_r)\big),\ \mathbf{Y}^c_{22} = (q_{r+1}, \dots, q_m),\ \mathbf{J} + \mathbf{X}^c_{22} = (\sigma + q_{m+1}), \tag{3.6}$$

where $\mathbf{L}^c_i(q_i) = (q_i, 0, \dots, 0)$ is a $1 \times k_i$ matrix; $k_1, \dots, k_r$ are the controllability indices of the Kronecker part $\mathbf{N}$. The matrices $\mathbf{Y}^c_{11}$ and $\mathbf{Y}^c_{12}$ depend on $q_{m+2}, \dots, q_\ell$. Using the controllability condition (2.2), one can show that in the vicinity of $\mathbf{q} = 0$ versal deformation (3.5), (3.6) is controllable if and only if at least one of the parameters $q_1, \dots, q_m$ is nonzero. Hence, the uncontrollability set for the versal deformation is given locally by the equalities

$$q_1 = \dots = q_m = 0. \tag{3.7}$$

Taking a point $\mathbf{q}$ such that (3.7) holds, it is easy to see that the pair $\beta(\mathbf{q})$ has $\mathbf{J}_\sigma$ type with the generalized eigenvalue $\sigma + q_{m+1}$. Since the uncontrollability set of a generic family of matrix pairs $\alpha(\mathbf{p})$ has the same local structure, we conclude that the set $\mathcal{N}$ in the neighborhood of a point $\mathbf{p}_0$, corresponding to a pair of $\mathbf{J}_\sigma$ type, is a smooth surface of codimension m, whose points correspond to pairs of $\mathbf{J}_\sigma$ type.

Analogously, in the case $\mathbf{J} = \mathbf{J}_{\sigma \pm i\omega}$ we can take [6]

$$\begin{gathered} \mathbf{X}^c_{21} = \big(\mathbf{L}^c_1(q_1, q_2), \dots, \mathbf{L}^c_r(q_{2r-1}, q_{2r})\big), \\ \mathbf{Y}^c_{22} = \begin{pmatrix} q_{2r+1} & \cdots & q_{2m-1} \\ q_{2r+2} & \cdots & q_{2m} \end{pmatrix}, \\ \mathbf{J} + \mathbf{X}^c_{22} = \begin{pmatrix} \sigma + q_{2m+1} & \omega + q_{2m+2} \\ -\omega - q_{2m+2} & \sigma + q_{2m+1} \end{pmatrix}, \end{gathered} \tag{3.8}$$

where $\mathbf{L}^c_i(q_{2i-1}, q_{2i})$ is a $2 \times k_i$ matrix of the form

$$\mathbf{L}^c_i(q_{2i-1}, q_{2i}) = \begin{pmatrix} q_{2i-1} & 0 & \cdots & 0 \\ q_{2i} & 0 & \cdots & 0 \end{pmatrix}. \tag{3.9}$$

The matrices $\mathbf{Y}_{11}^c$ and $\mathbf{Y}_{12}^c$ depend on $q_{2m+3}, \dots, q_\ell$. The uncontrollability set of this versal deformation in the vicinity of $\mathbf{q} = 0$ is given by the equations

$$q_1 = \cdots = q_{2m} = 0. \tag{3.10}$$

At the points $\mathbf{q}$ satisfying (3.10), the pair $\beta(\mathbf{q})$ has $\mathbf{J}_{\sigma\pm i\omega}$ type, and the complex conjugate generalized eigenvalues are equal to $\sigma + q_{2m+1} \pm i(\omega + q_{2m+2})$. Hence, the uncontrollability set of a generic family $\alpha(\mathbf{p})$ in the neighborhood of a point $\mathbf{p}_0$, corresponding to a pair of $\mathbf{J}_{\sigma\pm i\omega}$ type, is a smooth surface of codimension $2m$. Points of this surface correspond to matrix pairs of $\mathbf{J}_{\sigma\pm i\omega}$ type.

Now, let us consider a matrix pair α_0 having a different Jordan part $\mathbf{J}$. In this case the block $\mathbf{J} + \mathbf{X}_{22}^c$ is identical to the versal deformation of a square matrix $\mathbf{J}$ under the similarity equivalence in the space of square matrices [1, 6]. From [1] we know that, for any $\mathbf{J}$, taking arbitrarily small parameters $\mathbf{q}$, we can obtain the matrix $\mathbf{J} + \mathbf{X}_{22}^c(\mathbf{q})$ having only simple eigenvalues. Then, taking arbitrarily small parameters in the block $\mathbf{X}_{21}^c(\mathbf{q})$, we can destroy the Jordan structure corresponding to every simple eigenvalue, leaving only one real generalized eigenvalue σ or one pair of complex conjugate generalized eigenvalues $\sigma \pm i\omega$. Hence, an uncontrollable system of $\mathbf{J}_\sigma$ or $\mathbf{J}_{\sigma\pm i\omega}$ type can be found in any neighborhood of $\mathbf{q} = 0$. The same holds for a generic family of matrix pairs $\alpha(\mathbf{p})$; i.e., a point $\mathbf{p}_0 \in \mathcal{N}$ either lies on a surface represented by matrix pairs of $\mathbf{J}_\sigma$ or $\mathbf{J}_{\sigma\pm i\omega}$ types (regular points of $\mathcal{N}$) or belongs to a boundary of these surfaces. □

Remark. Let us consider matrix pairs α with a fixed Jordan part $\mathbf{J}$ in the Brunovsky form. In the generic case, a Kronecker part $\mathbf{N}$ in the Brunovsky form of almost all matrix pairs α has maximal possible number of blocks r, and the sizes $k_1, \dots, k_r$ of these blocks are different by no more than one, i.e., $k_1 = \cdots = k_{r'} = k_{r'+1} + 1 = \cdots = k_r + 1$ [6]. In this case $\mathbf{Y}_{11}^c = 0$ and $\mathbf{Y}_{12}^c = 0$ in versal deformation (3.5). Such a Kronecker part cannot be changed by a small perturbation of the parameters if we do not change the structure of the Jordan part. On the contrary, if the matrix pair has a different Kronecker part, then we can always find a nearby matrix pair with the generic Kronecker part, keeping the structure of the Jordan part [6].

4. Perturbation analysis of the uncontrollability set. Let us assume that we are given a point $\mathbf{p}_0 \in \mathcal{N}$ corresponding to a pair $\alpha(\mathbf{p}_0)$ of $\mathbf{J}_\sigma$ or $\mathbf{J}_{\sigma\pm i\omega}$ type. From Theorem 3.1 we know the generic structure of $\mathcal{N}$ in the neighborhood of $\mathbf{p}_0$. Nevertheless, some symmetry or degeneracy of the family $\alpha(\mathbf{p})$ may cause the appearance of a nongeneric structure. For example, the pair

$$\alpha(\mathbf{p}) = \left(\begin{pmatrix} 0 & 0 \\ 0 & p_1 + p_2 + p_3 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix} \right) \tag{4.1}$$

is uncontrollable for all $\mathbf{p} \in \mathbb{R}^3$, and $\alpha(\mathbf{p})$ has $\mathbf{J}_\sigma$ type for any $\mathbf{p}$. Clearly, an arbitrarily small perturbation of the family can result in the generic structure of $\mathcal{N}$. For example, taking the $(2,1)$th element of the first matrix to be ϵp_1 for an arbitrarily small $\epsilon > 0$, the set $\mathcal{N}$ becomes the plane $p_1 = 0$ of codimension 1, which is the generic case. Therefore, it would be useful to have a constructive criterion guaranteeing that the structure of $\mathcal{N}$ is generic for a given family $\alpha(\mathbf{p})$. For applications and numerical analysis of the uncontrollability set it is also important to have quantitative local information on $\mathcal{N}$, i.e., its tangent plane and perturbations of the generalized eigenvalues. The solution of these problems is given in the following theorems.

Let $\mathbf{p}_0$ be a point of the uncontrollability set $\mathcal{N}$ for a family of matrix pairs $\alpha(\mathbf{p})$. Let $\gamma_b = (\mathbf{P}, \mathbf{Q}, \mathbf{R}) \in \mathcal{G}$ be a triple determining the feedback equivalence transformation of the pair $\alpha_0 = \alpha(\mathbf{p}_0)$ to its Brunovsky canonical form $\alpha_b = \gamma_b \circ \alpha_0$.

For the pair α_0 of $\mathbf{J}_\sigma$ type with the generalized eigenvalue σ, we define real vectors $\mathbf{f}_i = (f_i^1, \dots, f_i^k)$, $i = 1, \dots, m$, and $\mathbf{f}_\sigma = (f_\sigma^1, \dots, f_\sigma^k)$ with the components

$$
\begin{aligned}
f_i^j &= \mathbf{P}^{-1}(n,:)\left[\frac{\partial \mathbf{A}}{\partial p_j}\sum_{s=1}^{k_i}\sigma^{s-1}\mathbf{P}(:,K_i+s)\right. \\
&\quad \left. + \frac{\partial \mathbf{B}}{\partial p_j}\left(\sum_{s=1}^{k_i}\sigma^{s-1}\mathbf{R}(:,K_i+s) + \sigma^{k_i}\mathbf{Q}(:,i)\right)\right], \quad i = 1, \dots, r; \\
f_i^j &= \mathbf{P}^{-1}(n,:)\frac{\partial \mathbf{B}}{\partial p_j}\mathbf{Q}(:,i), \quad i = r+1, \dots, m; \\
f_\sigma^j &= \mathbf{P}^{-1}(n,:)\left[\frac{\partial \mathbf{A}}{\partial p_j}\mathbf{P}(:,n) + \frac{\partial \mathbf{B}}{\partial p_j}\mathbf{R}(:,n)\right];
\end{aligned}
\tag{4.2}
$$

where $K_1 = 0$, $K_i = k_1 + \dots + k_{i-1}$; $\mathbf{P}^{-1}(n,:)$, $\mathbf{P}(:,i)$, $\mathbf{Q}(:,i)$, and $\mathbf{R}(:,i)$ denote the nth row of $\mathbf{P}^{-1}$ and the ith columns of $\mathbf{P}$, $\mathbf{Q}$, and $\mathbf{R}$, respectively.

THEOREM 4.1. *Let us assume that $\alpha_0 = \alpha(\mathbf{p}_0)$ is a matrix pair of $\mathbf{J}_\sigma$ type, and the vectors $\mathbf{f}_1, \dots, \mathbf{f}_m$ are linearly independent. Then in the vicinity of $\mathbf{p}_0$ the uncontrollability set $\mathcal{N}$ is a smooth surface of codimension m corresponding to matrix pairs of $\mathbf{J}_\sigma$ type. Its tangent plane at $\mathbf{p}_0$ is given by the equations*

$$
(\mathbf{f}_1, \mathbf{p} - \mathbf{p}_0) = \dots = (\mathbf{f}_m, \mathbf{p} - \mathbf{p}_0) = 0,
\tag{4.3}
$$

where $(\mathbf{f}_i, \mathbf{p} - \mathbf{p}_0) = \sum_{j=1}^k f_i^j (p_j - p_{0j})$ is a scalar product in $\mathbb{R}^k$. The generalized eigenvalue for $\mathbf{p} \in \mathcal{N}$ in the neighborhood of the point $\mathbf{p}_0$ is given by the expression

$$
\sigma + (\mathbf{f}_\sigma, \mathbf{p} - \mathbf{p}_0) + o(\|\mathbf{p} - \mathbf{p}_0\|).
\tag{4.4}
$$

For the pair α_0 of $\mathbf{J}_{\sigma \pm i\omega}$ type with the generalized eigenvalues $\sigma \pm i\omega$, we define real vectors $\mathbf{f}_s = (f_s^1, \dots, f_s^k)$, $s = 1, \dots, 2m$, $\mathbf{f}_\sigma = (f_\sigma^1, \dots, f_\sigma^k)$, and $\mathbf{f}_\omega = (f_\omega^1, \dots, f_\omega^k)$ with the components

$$
\begin{aligned}
f_{2s-1}^j + i f_{2s}^j &= \sum_{z=0}^{1} i^{1-z}\mathbf{P}^{-1}(n-z,:)\left[\frac{\partial \mathbf{A}}{\partial p_j}\sum_{v=1}^{k_s}(\sigma - i\omega)^{v-1}\mathbf{P}(:,K_s+v)\right. \\
&\quad \left. + \frac{\partial \mathbf{B}}{\partial p_j}\left(\sum_{v=1}^{k_s}(\sigma - i\omega)^{v-1}\mathbf{R}(:,K_s+v) + (\sigma - i\omega)^{k_s}\mathbf{Q}(:,s)\right)\right], \quad s = 1, \dots, r;
\end{aligned}
\tag{4.5}
$$

$$
f_{2s-1}^j + i f_{2s}^j = \sum_{z=0}^{1} i^{1-z}\mathbf{P}^{-1}(n-z,:)\frac{\partial \mathbf{B}}{\partial p_j}\mathbf{Q}(:,s), \quad s = r+1, \dots, m;
\tag{4.6}
$$

$$
f_\sigma^j + i f_\omega^j = \frac{1}{2}\sum_{z=0}^{1}\sum_{v=0}^{1} i^{z-v}\mathbf{P}^{-1}(n-z,:)\left[\frac{\partial \mathbf{A}}{\partial p_j}\mathbf{P}(:,n-v) + \frac{\partial \mathbf{B}}{\partial p_j}\mathbf{R}(:,n-v)\right];
\tag{4.7}
$$

where i is the imaginary unit.

THEOREM 4.2. *Let us assume that $\alpha_0 = \alpha(\mathbf{p}_0)$ is a matrix pair of $\mathbf{J}_{\sigma\pm i\omega}$ type, and the vectors $\mathbf{f}_1, \dots, \mathbf{f}_{2m}$ are linearly independent. Then in the vicinity of $\mathbf{p}_0$ the uncontrollability set $\mathcal{N}$ is a smooth surface of codimension $2m$ corresponding to matrix pairs of $\mathbf{J}_{\sigma\pm i\omega}$ type. Its tangent plane at $\mathbf{p}_0$ is given by the equations*

$$(\mathbf{f}_1, \mathbf{p} - \mathbf{p}_0) = \cdots = (\mathbf{f}_{2m}, \mathbf{p} - \mathbf{p}_0) = 0. \tag{4.8}$$

The generalized eigenvalues for $\mathbf{p} \in \mathcal{N}$ in the neighborhood of $\mathbf{p}_0$ are given by the expression

$$\sigma + (\mathbf{f}_\sigma, \mathbf{p} - \mathbf{p}_0) \pm i\big(\omega + (\mathbf{f}_\omega, \mathbf{p} - \mathbf{p}_0)\big) + o(\|\mathbf{p} - \mathbf{p}_0\|). \tag{4.9}$$

The important consequence of Theorems 4.1 and 4.2 is that to determine the local structure of the uncontrollability set we need only derivatives of the family $\alpha(\mathbf{p})$ with respect to the parameters at $\mathbf{p}_0$ and the triple $\gamma_b = (\mathbf{P}, \mathbf{Q}, \mathbf{R})$ transforming the pair α_0 to the Brunovsky canonical form. The triple γ_b can be found using the software developed in [4, 5], which provides the Kronecker canonical form of the matrix pencil $(\mathbf{A}_0, \mathbf{B}_0) - \lambda(\mathbf{I}_n, 0)$. The Brunovsky form can be obtained from the Kronecker canonical form by permutation of columns [9].

Example 4.1. Let us consider a three-parameter two-input system (2.1) with the matrices $\mathbf{A}$ and $\mathbf{B}$ given by the relations

$$\mathbf{A}(\mathbf{p}) = \begin{pmatrix} -p_3 & p_1p_2 & p_1p_2 \\ 2 - p_3 & 3 + p_1p_2 & 1 + p_1p_2 \\ -2 - 2p_2^2 & p_1 - 1 & 1 - p_2 \end{pmatrix}, \quad \mathbf{B}(\mathbf{p}) = \begin{pmatrix} 1 & -p_2 \\ 1 & 1 - p_2 \\ -1 & p_2 - 1 \end{pmatrix}.$$

The matrix pair $\alpha_0 = (\mathbf{A}(\mathbf{p}_0), \mathbf{B}(\mathbf{p}_0))$ at $\mathbf{p}_0 = (0, 0, 0)$ is uncontrollable and has $\mathbf{J}_\sigma$ type. Its Brunovsky form consists of two 1×1 blocks $\mathbf{N}_1 = \mathbf{N}_2 = (0)$ in the Kronecker part ($r = 2$, $k_1 = k_2 = 1$) and the Jordan part $\mathbf{J} = (\sigma)$ with the generalized eigenvalue $\sigma = 2$. The transformation of α_0 to the Brunovsky form is performed by the triple $\gamma_b = (\mathbf{P}, \mathbf{Q}, \mathbf{R})$ with the matrices

$$\mathbf{P} = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ -1 & -1 & 1 \end{pmatrix}, \ \mathbf{Q} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \ \mathbf{R} = \begin{pmatrix} 0 & 0 & 0 \\ -4 & -2 & -1 \end{pmatrix}. \tag{4.10}$$

Using formulae (4.2), we compute the vectors

$$\mathbf{f}_1 = (1, 1, -1), \quad \mathbf{f}_2 = (1, 1, 0), \quad \mathbf{f}_\sigma = (0, -1, 0). \tag{4.11}$$

Since the vectors $\mathbf{f}_1$ and $\mathbf{f}_2$ are linearly independent, by Theorem 4.1, the uncontrollability set $\mathcal{N}$ is a smooth curve in the neighborhood of $\mathbf{p}_0 = (0, 0, 0)$ with the tangent

$$(\mathbf{f}_1, \mathbf{p} - \mathbf{p}_0) = p_1 + p_2 - p_3 = 0, \quad (\mathbf{f}_2, \mathbf{p} - \mathbf{p}_0) = p_1 + p_2 = 0. \tag{4.12}$$

The generalized eigenvalue of the matrix pair $\alpha(\mathbf{p})$ for $\mathbf{p} \in \mathcal{N}$ is approximated by

$$\sigma + (\mathbf{f}_\sigma, \mathbf{p} - \mathbf{p}_0) + o(\|\mathbf{p} - \mathbf{p}_0\|) = 2 - p_2 + o(\|\mathbf{p}\|). \tag{4.13}$$

It is straightforward to check that $\alpha(\mathbf{p}) = \gamma(\mathbf{p}) \circ \beta(\mathbf{q}(\mathbf{p}))$, where

$$\beta(\mathbf{q}) = \left(\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ q_1 & q_2 & 2 + q_3 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix} \right), \qquad \begin{aligned} q_1(\mathbf{p}) &= p_1 + p_2 - p_3 - 2p_2^2, \\ q_2(\mathbf{p}) &= p_1 + p_2, \\ q_3(\mathbf{p}) &= -p_2 + p_1p_2, \end{aligned}$$

$$\gamma(\mathbf{p}) = \left(\begin{pmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & -p_2 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} -p_3 & p_1p_2 & p_1p_2 \\ 2 & 3 & 1 \end{pmatrix} \right).$$

Hence, we find exact expressions for the uncontrollability set and the generalized eigenvalue in the form

$$\begin{gathered} \mathcal{N} = \{\mathbf{p} \in \mathbb{R}^3 \mid p_1 + p_2 - p_3 - 2p_2^2 = 0,\ p_1 + p_2 = 0\}, \\ \sigma(\mathbf{p}) = 2 - p_2 + p_1p_2. \end{gathered} \tag{4.14}$$

This agrees with the results obtained by Theorem 4.1.

Proof of Theorem 4.1. Let us consider a family of matrix pairs $\widetilde{\alpha}(\mathbf{p}) = \gamma_b \circ \alpha(\mathbf{p})$. This family is a deformation of the Brunovsky canonical form $\widetilde{\alpha}(\mathbf{p}_0) = \alpha_b$. By Theorem 2.1, the family $\widetilde{\alpha}(\mathbf{p})$ can be represented in the form $\widetilde{\alpha}(\mathbf{p}) = \widetilde{\gamma}(\mathbf{p}) \circ \beta(\mathbf{q}(\mathbf{p}))$, where $\beta(\mathbf{q})$ is the versal deformation of α_b having the form (3.5), (3.6). Since the controllability property is invariant under the feedback equivalence transformation, the uncontrollability sets for the families $\alpha(\mathbf{p})$ and $\beta(\mathbf{q}(\mathbf{p}))$ coincide in the neighborhood of $\mathbf{p}_0$ and, according to (3.7), have the form

$$q_1(\mathbf{p}) = \cdots = q_m(\mathbf{p}) = 0, \tag{4.15}$$

where $q_1(\mathbf{p}_0) = \cdots = q_m(\mathbf{p}_0) = 0$ by construction. Derivatives of the functions $q_i(\mathbf{p})$ at $\mathbf{p}_0$ are given by expression (2.18) of Theorem 2.1, where we take $\widetilde{\alpha}(\mathbf{p})$ and α_b instead of $\alpha(\mathbf{p})$ and α_0, respectively. Formula (2.18) requires the basis $\{\alpha_1^n, \dots, \alpha_\ell^n\}$ of the subspace $(T_{\alpha_b}\mathcal{O}(\alpha_b))^\perp$. This subspace for a matrix pair in the Brunovsky canonical form was found explicitly in [6]. It is convenient to represent the basis of $(T_{\alpha_b}\mathcal{O}(\alpha_b))^\perp$ in the form of the family $\alpha_1^n q_1 + \cdots + \alpha_\ell^n q_\ell$, which, for the matrix pair α_b under consideration, takes the form

$$\left(\begin{pmatrix} \mathbf{X}_{11}^n & 0 \\ \mathbf{X}_{21}^n & \mathbf{X}_{22}^n \end{pmatrix}, \begin{pmatrix} \mathbf{Y}_{11}^n & \mathbf{Y}_{12}^n \\ \mathbf{Y}_{21}^n & \mathbf{Y}_{22}^n \end{pmatrix} \right), \tag{4.16}$$

where

$$\begin{aligned} &\mathbf{X}_{21}^n = \big(\mathbf{L}_1^n(q_1),\ \dots,\ \mathbf{L}_r^n(q_r)\big), \quad \mathbf{X}_{22}^n = (q_{m+1}), \\ &\mathbf{Y}_{21}^n = (\sigma^{k_1}q_1,\ \dots,\ \sigma^{k_r}q_r), \quad \mathbf{Y}_{22}^n = (q_{r+1},\ \dots,\ q_m); \end{aligned} \tag{4.17}$$

$\mathbf{L}_i^n(q_i) = (q_i,\ \sigma q_i,\ \dots,\ \sigma^{k_i-1}q_i)$ is a $1 \times k_i$ matrix. The blocks $\mathbf{X}_{11}^n(\mathbf{q})$, $\mathbf{Y}_{11}^n(\mathbf{q})$, and $\mathbf{Y}_{12}^n(\mathbf{q})$ depend on $q_{m+2}, \dots, q_\ell$. Comparing this basis with the basis $\{\alpha_1^c, \dots, \alpha_\ell^c\}$ defined by (3.5), (3.6), we see that $z_{ij} = \langle \alpha_j^c, \alpha_i^n \rangle_1 = \delta_{ij}$ if $i \le m+1$ or $j \le m+1$, where δ_{ij} is the Kronecker delta. Hence, using (2.18), we find the derivatives of $q_1(\mathbf{p}), \dots, q_{m+1}(\mathbf{p})$ at $\mathbf{p}_0$ in the form

$$\frac{\partial q_i}{\partial p_j} = \Big\langle \frac{\partial \widetilde{\alpha}}{\partial p_j}, \alpha_i^n \Big\rangle_1, \quad i = 1, \dots, m+1. \tag{4.18}$$

Using $\widetilde{\alpha}(\mathbf{p})$ in its original form $\gamma_b \circ \alpha(\mathbf{p}) = (\mathbf{P}^{-1}(\mathbf{A}(\mathbf{p})\mathbf{P} + \mathbf{B}(\mathbf{p})\mathbf{R}),\ \mathbf{P}^{-1}\mathbf{B}(\mathbf{p})\mathbf{Q})$ and the explicit form of α_i^n, we find

$$\frac{\partial q_i}{\partial p_j} = f_i^j, \ \ i = 1, \dots, m; \quad \frac{\partial q_{m+1}}{\partial p_j} = f_\sigma^j \tag{4.19}$$

with f_i^j and f_σ^j defined in (4.2). Therefore, $\mathbf{f}_1, \dots, \mathbf{f}_m$, and $\mathbf{f}_\sigma$ are the gradient vectors of the functions $q_1(\mathbf{p}), \dots, q_{m+1}(\mathbf{p})$ at $\mathbf{p}_0$:

$$\nabla q_i = \mathbf{f}_i, \quad i = 1, \dots, m; \quad \nabla q_{m+1} = \mathbf{f}_\sigma; \quad \nabla = \left(\frac{\partial}{\partial p_1}, \dots, \frac{\partial}{\partial p_k} \right). \tag{4.20}$$

If the gradient vectors $\nabla q_1, \dots, \nabla q_m$ are linearly independent, then, by the implicit function theorem, the set $\mathcal{N}$ determined by (4.15) is a smooth surface of codimension m with the tangent plane (4.3). If $q_1(\mathbf{p}) = \cdots = q_m(\mathbf{p}) = 0$, then we see from (3.5), (3.6) that $\beta(\mathbf{q})$ and, hence, $\alpha(\mathbf{p})$ is a matrix pair of $\mathbf{J}_\sigma$ type with the generalized eigenvalue $\sigma + q_{m+1}(\mathbf{p}) = \sigma + (\mathbf{f}_\sigma, \mathbf{p} - \mathbf{p}_0) + o(\|\mathbf{p} - \mathbf{p}_0\|)$. □

Proof of Theorem 4.2. The case when the pair α_0 has $\mathbf{J}_{\sigma \pm i\omega}$ type is studied analogously. In this case the versal deformation $\beta(\mathbf{q})$ takes the form (3.5), (3.8), (3.9), and the basis $\{\alpha_1^n, \dots, \alpha_\ell^n\}$ is represented by family (4.16) with

$$\begin{aligned}
\mathbf{X}_{21}^n &= \left[\mathbf{L}_1^n(q_1, q_2), \ \dots, \ \mathbf{L}_r^n(q_{2r-1}, q_{2r}) \right], \\
\mathbf{X}_{22}^n &= \begin{pmatrix} q_{2m+1}/2 & q_{2m+2}/2 \\ -q_{2m+2}/2 & q_{2m+1}/2 \end{pmatrix}, \\
\mathbf{Y}_{21}^n &= \begin{pmatrix} \operatorname{Re}(q_1 + iq_2)(\sigma + i\omega)^{k_1} & \cdots & \operatorname{Re}(q_{2r-1} + iq_{2r})(\sigma + i\omega)^{k_r} \\ \operatorname{Im}(q_1 + iq_2)(\sigma + i\omega)^{k_1} & \cdots & \operatorname{Im}(q_{2r-1} + iq_{2r})(\sigma + i\omega)^{k_r} \end{pmatrix}, \\
\mathbf{Y}_{22}^n &= \begin{pmatrix} q_{2r+1} & \cdots & q_{2m-1} \\ q_{2r+2} & \cdots & q_{2m} \end{pmatrix},
\end{aligned} \tag{4.21}$$

where $\mathbf{L}_s^n(q_{2s-1}, q_{2s})$ is a $2 \times k_s$ matrix of the form

$$\mathbf{L}_s^n = \begin{pmatrix} q_{2s-1} & \sigma q_{2s-1} - \omega q_{2s} & \cdots & \operatorname{Re}(q_{2s-1} + iq_{2s})(\sigma + i\omega)^{k_s - 1} \\ q_{2s} & \omega q_{2s-1} + \sigma q_{2s} & \cdots & \operatorname{Im}(q_{2s-1} + iq_{2s})(\sigma + i\omega)^{k_s - 1} \end{pmatrix}, \tag{4.22}$$

and the blocks $\mathbf{X}_{11}^n$, $\mathbf{Y}_{11}^n$, and $\mathbf{Y}_{12}^n$ depend on $q_{2m+3}, \dots, q_\ell$. The uncontrollability set is given by the equations

$$q_1(\mathbf{p}) = \cdots = q_{2m}(\mathbf{p}) = 0, \tag{4.23}$$

where the gradients $\nabla q_1, \dots, \nabla q_{2m+2}$ are equal to the vectors $\mathbf{f}_1, \dots, \mathbf{f}_{2m}$, $\mathbf{f}_\sigma$, $\mathbf{f}_\omega$ defined in (4.5)–(4.7). The generalized eigenvalues on the surface (4.23) are determined by the expression

$$\begin{aligned}
\sigma + q_{2m+1}(\mathbf{p}) \pm i(\omega + q_{2m+2}(\mathbf{p})) = \sigma &+ (\mathbf{f}_\sigma, \mathbf{p} - \mathbf{p}_0) \pm i\big(\omega + (\mathbf{f}_\omega, \mathbf{p} - \mathbf{p}_0)\big) \\
&+ o(\|\mathbf{p} - \mathbf{p}_0\|).
\end{aligned}$$ □

5. Numerical construction of the uncontrollability set. Perturbation analysis developed in the previous section can be applied to numerical construction of the uncontrollability set by continuation if one point of this set is known.

Let us illustrate the implementation of this procedure for a specific case of a three-parameter system with one-input variable ($k = 3$ and $m = 1$); dimension of the state space is arbitrary. Let us assume that we are given a point $\mathbf{p}_0 \in \mathcal{N}$ corresponding to

a matrix pair $\alpha(\mathbf{p}_0)$ of $\mathbf{J}_{\sigma\pm i\omega}$ type. By Theorem 3.1, in the generic case the set $\mathcal{N}$ is a smooth curve in a vicinity of the point $\mathbf{p}_0$. Let us introduce the length parameter y along the curve $\mathcal{N}$. Then the curve $\mathcal{N}$ is given by a smooth function $\mathbf{p}(y)$ such that $\|d\mathbf{p}/dy\| = 1$. By Theorem 4.2, the vectors $\mathbf{f}_1, \mathbf{f}_2 \in \mathbb{R}^3$ evaluated by expressions (4.5), (4.6) at $\mathbf{p}(y)$ are normal vectors to the curve $\mathcal{N}$ at $\mathbf{p}(y)$. The vector product $\mathbf{f}_1 \times \mathbf{f}_2$ is a tangent vector to $\mathcal{N}$. Hence, we find

$$\frac{d\mathbf{p}}{dy} = \mathbf{g}, \quad \mathbf{g} = \frac{\mathbf{f}_1 \times \mathbf{f}_2}{\|\mathbf{f}_1 \times \mathbf{f}_2\|}. \tag{5.1}$$

Using expressions (4.9) and (5.1), we find derivatives of the functions $\sigma(y)$ and $\omega(y)$, which determine the generalized eigenvalues $\sigma(y) \pm i\omega(y)$ of the matrix pair $\alpha(\mathbf{p}(y))$, as follows:

$$\frac{d\sigma}{dy} = (\mathbf{f}_\sigma, \mathbf{g}), \quad \frac{d\omega}{dy} = (\mathbf{f}_\omega, \mathbf{g}). \tag{5.2}$$

Equations (5.1) and (5.2) represent a system of ordinary differential equations with respect to $\mathbf{p}$, σ, and ω. Initial conditions at $y = 0$ are given by

$$\mathbf{p}(0) = \mathbf{p}_0, \quad \sigma(0) = \sigma_0, \quad \omega(0) = \omega_0, \tag{5.3}$$

where $\sigma_0 \pm i\omega_0$ are generalized eigenvalues of the matrix pair $\alpha(\mathbf{p}_0)$ at the given point $\mathbf{p}_0 \in \mathcal{N}$. Integrating this system forwards and backwards, we find a regular part of the uncontrollability set of $\mathbf{J}_{\sigma\pm i\omega}$ type. Since we use the local information on the uncontrollability set, there is no guarantee that we have found the whole set $\mathcal{N}$ in the parameter space. Nevertheless, we obtain a finite piece of the uncontrollability set containing the given point $\mathbf{p}_0$. The integration can be continued until we reach a physical boundary of the parameter space or arrive at a singularity (boundary of the regular part of $\mathcal{N}$). A singularity causes numerical instability of the integration procedure and can be recognized by the appearance of a matrix pair with a different Jordan structure.

To determine right-hand sides of system (5.1), (5.2), we need to find the transformation to the Brunovsky canonical form

$$\alpha_b(y) = \gamma_b(y) \circ \alpha(\mathbf{p}(y)) \tag{5.4}$$

at each y. This can be done using the software [4, 5] providing the Kronecker canonical form of the matrix pencil $\big(\mathbf{A}(\mathbf{p}(y)), \mathbf{B}(\mathbf{p}(y))\big) - \lambda(\mathbf{I}_n, 0)$. Then permutation of columns provides the Brunovsky canonical form [9]. In these calculations, the information on the generalized eigenvalues $\sigma(y) \pm i\omega(y)$ can be used.

Alternatively, we can calculate $\alpha_b(y)$ and $\gamma_b(y)$ by taking advantage of the remark in section 3. In the generic case, the Brunovsky form $\alpha_b(y)$ has one $(n-2) \times (n-2)$ block $\mathbf{N}_1$ in the Kronecker part:

$$\alpha_b(y) = \left(\begin{pmatrix} \mathbf{N}_1 & 0 \\ 0 & \mathbf{J}_{\sigma\pm i\omega} \end{pmatrix}, \begin{pmatrix} \mathbf{E}_1 \\ 0 \end{pmatrix} \right). \tag{5.5}$$

Taking the derivative of (5.4) with respect to y, we find

$$\frac{d\alpha_b}{dy} = df_{\alpha_b}\left(\gamma_b^{-1}\frac{d\gamma_b}{dy}\right) + \gamma_b \circ \frac{d\alpha(\mathbf{p}(y))}{dy}, \tag{5.6}$$

where $df_{\alpha_b}(\xi)$ is the differential of the function $f_{\alpha_b}(\gamma)$ at the unit element e defined by expression (2.12). Introducing the matrix triple $\xi = \gamma_b^{-1} d\gamma_b/dy$ and using expression (5.1), we find a linear algebraic equation

$$df_{\alpha_b}(\xi) = \frac{d\alpha_b}{dy} - \gamma_b \circ \left(\sum_{i=1}^{k} \frac{\partial \alpha}{\partial p_i} g_i \right). \tag{5.7}$$

Then the derivative of the function $\gamma_b(y)$ is given by the relation

$$\frac{d\gamma_b}{dy} = \gamma_b(y)\xi. \tag{5.8}$$

Equation (5.7) does not determine the triple ξ uniquely (transformation to the Brunovsky form is not unique). It is convenient to choose a particular solution satisfying the condition

$$\xi \in \left(\operatorname{Ker} df_{\alpha_b}\right)^{\perp}, \tag{5.9}$$

which determines a unique ξ. A numerical method for finding this solution is given in the appendix.

Differential equation (5.8) can be integrated together with system (5.1), (5.2). As a result, we find the Brunovsky canonical form $\alpha_b(y)$ and the feedback equivalence transformation $\gamma_b(y)$ at each point of the uncontrollability set represented by the curve $\mathbf{p}(y)$. The initial conditions are given by

$$\gamma_b(0) = \gamma_b^0, \tag{5.10}$$

where γ_b^0 transforms the matrix pair $\alpha(\mathbf{p}_0)$ to the Brunovsky form. Note that matrices of the triple $\gamma_b(y) = (\mathbf{P}_b(y), \mathbf{Q}_b(y), \mathbf{R}_b(y))$ may become ill-conditioned when approaching a singularity of $\mathcal{N}$. To control the accuracy of calculations and to detect a singularity it is convenient to use the norm $\|\alpha_b(y) - \gamma_b(y) \circ \alpha(\mathbf{p}(y))\|$, which describes the error in equality (5.4).

Similarly, we can calculate a regular part of the uncontrollability set, corresponding to matrix pairs of $\mathbf{J}_\sigma$ type, which is a smooth surface for a three-parameter one-input dynamical system. Recall that, by Theorem 3.1, the surfaces corresponding to matrix pairs of $\mathbf{J}_\sigma$ and $\mathbf{J}_{\sigma \pm i\omega}$ types, together with their boundaries, form the whole uncontrollability set of a generic multi-input linear dynamical system.

Example 5.1. Let us consider a mechanical system shown in Figure 5.1. The system consists of a thin uniform platform of mass m and length $2l$ supported at both ends by springs having elastic coefficients k_1, k_2 and viscous damping coefficients d_1, d_2. There is a vertical force F applied to the platform at the distance ξl from the middle. As generalized coordinates, we take a vertical coordinate z of the center of the platform and an angle φ between the platform and horizontal axis. The equilibrium of the system for zero external force $F = 0$ is assumed to be $z = 0$, $\varphi = 0$.

Equations of motion of the system linearized near the equilibrium take the form

$$\begin{aligned} &m\ddot{z} + d_1(\dot{z} + l\dot{\varphi}) + d_2(\dot{z} - l\dot{\varphi}) + k_1(z + l\varphi) + k_2(z - l\varphi) = F, \\ &I_m\ddot{\varphi} + d_1 l(\dot{z} + l\dot{\varphi}) - d_2 l(\dot{z} - l\dot{\varphi}) + k_1 l(z + l\varphi) - k_2 l(z - l\varphi) = -\xi l F, \end{aligned} \tag{5.11}$$

where $I_m = ml^2/3$ is the moment of inertia of the platform with respect to the center of mass; the dot denotes differentiation with respect to time t. If $F = 0$, then the

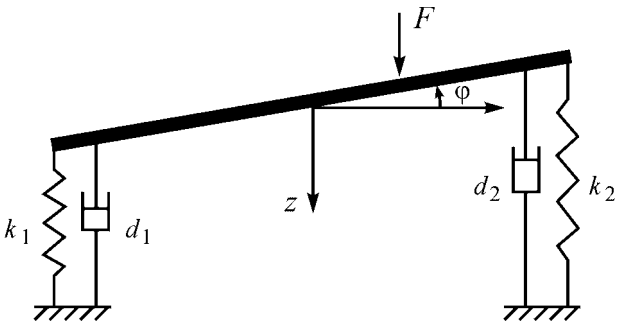

FIG. 5.1. *Mechanical system controlled by a vertical force.*

system oscillates with a decaying amplitude and comes to the equilibrium in infinite time $t \longrightarrow +\infty$. Let us consider the force F as a control parameter. If the system is controllable, then it can be damped (put into the equilibrium) in finite time. This task becomes difficult or impossible if the system is close to the uncontrollable system.

Let us introduce nondimensional variables

$$\begin{aligned} &\tau = t/\alpha, \quad f_1 = \frac{(d_1+d_2)\alpha}{m}, \quad f_2 = \frac{(d_1-d_2)\alpha}{m}, \\ &c_1 = \frac{(k_1+k_2)\alpha^2}{m}, \quad c_2 = \frac{(k_1-k_2)\alpha^2}{m}, \quad u = \frac{\alpha^2}{ml}\,F, \end{aligned} \tag{5.12}$$

where α is a time scale, and choose a state vector $\mathbf{x} \in \mathbb{R}^4$ in the form

$$x_1 = \frac{z}{l}, \quad x_2 = \varphi, \quad x_3 = \frac{\alpha \dot{z}}{l}, \quad x_4 = \alpha\dot{\varphi}. \tag{5.13}$$

Then system (5.11) can be written in the form $\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}u$, where derivative is taken with respect to nondimensional time τ, and the matrices $\mathbf{A}$ and $\mathbf{B}$ are

$$\mathbf{A} = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -c_1 & -c_2 & -f_1 & -f_2 \\ -3c_2 & -3c_1 & -3f_2 & -3f_1 \end{pmatrix}, \quad \mathbf{B} = \begin{pmatrix} 0 \\ 0 \\ 1 \\ -3\xi \end{pmatrix}. \tag{5.14}$$

Let us fix the parameters $c_1 = 25/12$ and $f_1 = 1$, characterizing the joint stiffness and damping of supports, and consider the parameter vector $\mathbf{p} = (c_2, f_2, \xi)$. Let us consider the point $\mathbf{p}_0 = (0, 0, 0)$ corresponding to equal supports and the force applied at the center of the platform. The matrix pair $\alpha(\mathbf{p}_0)$ is uncontrollable and has the Brunovsky canonical form

$$\mathbf{A}_b = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & \sigma_0 & \omega_0 \\ 0 & 0 & -\omega_0 & \sigma_0 \end{pmatrix}, \quad \mathbf{B}_b = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} \tag{5.15}$$

with the uncontrollable modes $\sigma_0 \pm i\omega_0 = -1.5 \pm i2$. The triple $\gamma_b^0 = (\mathbf{P}_b, \mathbf{Q}_b, \mathbf{R}_b)$

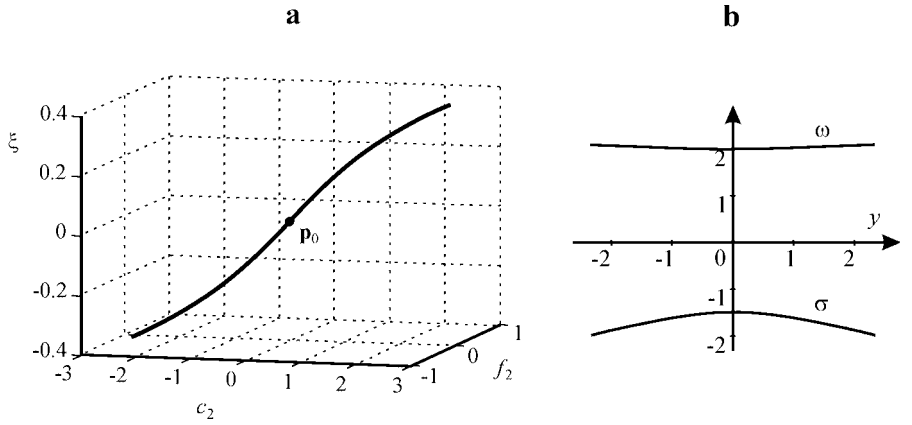

FIG. 5.2. (a) *Uncontrollability set in the parameter space;* (b) *uncontrollable modes* $\sigma(y) \pm i\omega(y)$.

transforming $\alpha(\mathbf{p}_0)$ to the Brunovsky form is

$$\mathbf{P}_b = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1.5 & 2 \end{pmatrix}, \quad \mathbf{Q}_b = (1), \quad \mathbf{R}_b = \begin{pmatrix} 25/12 & 1 & 0 & 0 \end{pmatrix}. \tag{5.16}$$

The point $\mathbf{p}_0$ belongs to the uncontrollability set and has $\mathbf{J}_{\sigma\pm i\omega}$ type. Integrating equations (5.1), (5.2), (5.8) with initial conditions (5.3), (5.10) numerically, we find the uncontrollability set $\mathcal{N}$ in the physical range of parameters $-c_1 < c_2 < c_1$ and $-f_1 < f_2 < f_1$ corresponding to positive characteristics of the supports. The result is shown in Figure 5.2(a), where the set $\mathcal{N}$ is represented by a solid line. Figure 5.2(b) shows graphs of the real and imaginary parts of the uncontrollable modes $\sigma(y) \pm i\omega(y)$. The maximal error $\|\alpha_b(y) - \gamma_b(y) \circ \alpha(\mathbf{p}(y))\|$ along the curve $\mathcal{N}$ is about $4 \cdot 10^{-7}$, which is less than the accuracy of the ordinary differential equation solver (the calculations were carried out in MATLAB using the standard ode45 solver).

Using the computed data, it can be shown that one mode of free vibrations of the system with the parameter vector $\mathbf{p}(y) = (c_2(y), f_2(y), \xi(y))$ has a node at the distance $\xi(y)l$ from the center of the platform; i.e., this mode represents rotation of the platform around a point. The force F applied at this point has no influence on the rotational mode, which leads to uncontrollability of the system. From Figure 5.2(a) we see that uncontrollability occurs when one of the supports has smaller stiffness and damping coefficients, and the force is applied at the side of a softer support. The obtained results are useful for the design of the system to avoid uncontrollability effects.

6. Singularities of the uncontrollability set. In this section we consider points of the uncontrollability set corresponding to matrix pairs whose types are different from $\mathbf{J}_\sigma$ and $\mathbf{J}_{\sigma\pm i\omega}$. By Theorem 3.1, these points belong to a boundary of the regular part of $\mathcal{N}$, represented by matrix pairs of $\mathbf{J}_\sigma$ and $\mathbf{J}_{\sigma\pm i\omega}$ types, and determine singularities (nonsmooth points) of the uncontrollability set.

In order to understand the role of singular points in the structure of the uncontrollability set, let us consider a specific case when the Jordan part of the Brunovsky

canonical form α_b of a pair $\alpha(\mathbf{p})$, $\mathbf{p} \in \mathcal{N}$, is a 2×2 Jordan block

$$\mathbf{J}_{\sigma^2} = \begin{pmatrix} \sigma & 1 \\ 0 & \sigma \end{pmatrix} \tag{6.1}$$

with a double real generalized eigenvalue σ. In the generic case, points $\mathbf{p} \in \mathcal{N}$ corresponding to matrix pairs of this type form a smooth surface of codimension $2m+1$ in the parameter space [6]. If the number of parameters is less than $2m+1$, then matrix pairs of $\mathbf{J}_{\sigma^2}$ type do not appear in generic families $\alpha(\mathbf{p})$.

In the case under consideration, a versal deformation of the pair α_b has the form (3.5), where [6]

$$\begin{gathered} \mathbf{X}^c_{21} = (\mathbf{L}^c_1(q_1, q_2), \dots, \mathbf{L}^c_r(q_{2r-1}, q_{2r})), \\ \mathbf{Y}^c_{22} = \begin{pmatrix} q_{2r+1} & \cdots & q_{2m-1} \\ q_{2r+2} & \cdots & q_{2m} \end{pmatrix}, \quad \mathbf{X}^c_{22} = \begin{pmatrix} q_{2m+2} & 0 \\ q_{2m+1} & q_{2m+2} \end{pmatrix}, \end{gathered} \tag{6.2}$$

and $\mathbf{L}^c_i(q_{2i-1}, q_{2i})$ is a $2 \times k_i$ matrix of the form

$$\mathbf{L}^c_i(q_{2i-1}, q_{2i}) = \begin{pmatrix} q_{2i-1} & 0 & \cdots & 0 \\ q_{2i} & 0 & \cdots & 0 \end{pmatrix}; \tag{6.3}$$

the blocks $\mathbf{Y}^c_{11}$ and $\mathbf{Y}^c_{12}$ depend on $q_{2m+3}, \dots, q_\ell$. Using controllability condition (2.2), we find that the uncontrollability set of the versal deformation in the neighborhood of $\mathbf{q} = 0$ is determined by the equations

$$q^2_{2i-1} q_{2m+1} - q^2_{2i} = 0, \quad i = 1, \dots, m. \tag{6.4}$$

Every equation in (6.4) determines in the space $(q_{2i-1}, q_{2i}, q_{2m+1})$ a surface shown in Figure 3.1 and discussed in Example 3.1. Hence, the regular part of the uncontrollability set consists of one smooth surface of $\mathbf{J}_{\sigma \pm i\omega}$ type and codimension $2m$, determined by the equations

$$q_i = 0, \quad i = 1, \dots, 2m, \quad q_{2m+1} < 0, \tag{6.5}$$

and smooth surfaces of $\mathbf{J}_\sigma$ type determined by the equations

$$q^2_{2i-1} q_{2m+1} - q^2_{2i} = 0, \quad q_{2i-1} \neq 0, \quad i = 1, \dots, m, \quad q_{2m+1} \geq 0. \tag{6.6}$$

There are 2^m separate surfaces of $\mathbf{J}_\sigma$ type corresponding to different combinations of signs of the parameters q_{2i-1}, $i = 1, \dots, m$, in (6.6). The singular part of $\mathcal{N}$ is a boundary of the regular part. It consists of several smooth surfaces, which are parts of the set (6.4) with the additional condition

$$q_{2j-1} = q_{2j} = 0, \quad q_{2m+1} \geq 0 \tag{6.7}$$

for some $j \in \{1, \dots, m\}$.

The structure of the uncontrollability set for a generic family $\alpha(\mathbf{p})$ in the neighborhood of a point $\mathbf{p}_0 \in \mathcal{N}$ of $\mathbf{J}_{\sigma^2}$ type is the same as for the versal deformation. These sets are related by a smooth change of parameters $\mathbf{q} = \mathbf{q}(\mathbf{p})$. Analogously to the method of Theorem 4.1, we can use formulae of Theorem 2.1 to calculate the gradients ∇q_i of the functions $q_i(\mathbf{p})$ at the singular point $\mathbf{p}_0$. Then expressions (6.4)–(6.7), where $q_i(\mathbf{p})$ is substituted by its linear approximation $(\nabla q_i, \mathbf{p} - \mathbf{p}_0)$, provide first-order approximations of the regular and singular parts of $\mathcal{N}$.

Singular points lead to a more rich and complicated structure of the uncontrollability set. This affects the behavior of the underlying dynamical system and causes numerical difficulties in the analysis of $\mathcal{N}$. The information on the local form of $\mathcal{N}$ at its regular or singular point is useful for the analysis and construction of the uncontrollability set. In particular, this information allows choosing the locally optimal change of design parameters in order to get a controllable system.

7. Conclusion. In this paper, fundamental properties of the uncontrollability set for a multi-input linear dynamical system dependent on parameters are investigated. It is shown that the uncontrollability set has a regular part, which consists of smooth surfaces corresponding to one real uncontrollable mode or a complex conjugate pair of uncontrollable modes. Explicit formulae for local quantitative analysis of the uncontrollability set and perturbation of the uncontrollable modes are derived and used for numerical construction of the uncontrollability set in the parameter space.

A constructive method for qualitative and quantitative analysis of the uncontrollability set based on the versal deformation theory is developed. The idea of regularization of the parameter space by transformation to a versal deformation, proposed in the paper, provides a powerful tool of multiparameter perturbation theory for control systems.

Using the duality theorem [3, 13], all the results of this paper can be applied to the analysis of an unobservability set for a multioutput linear dynamical system dependent on parameters.

Appendix. Let us consider the linear algebraic equation with respect to $\xi \in T_e\mathcal{G}$

$$df_\alpha(\xi) = \alpha', \quad \xi \in \bigl(\operatorname{Ker} df_\alpha\bigr)^\perp, \tag{7.1}$$

assuming that a solution exists, i.e., $\alpha' \in \operatorname{Im} df_\alpha$. We denote by $\operatorname{vec}(\mathbf{A})$ a column vector, which is an ordered stack of columns of $\mathbf{A}$ from left to right (its dimension is equal to the number of elements of $\mathbf{A}$). Analogously, we introduce the vectorization of the matrix pairs $\alpha = (\mathbf{A}, \mathbf{B})$, $\alpha' = (\mathbf{A}', \mathbf{B}')$, and matrix triple $\xi = (\mathbf{U}, \mathbf{V}, \mathbf{W})$ as follows:

$$\operatorname{vec}(\alpha) = \begin{pmatrix} \operatorname{vec}(\mathbf{A}) \\ \operatorname{vec}(\mathbf{B}) \end{pmatrix}, \ \operatorname{vec}(\alpha') = \begin{pmatrix} \operatorname{vec}(\mathbf{A}') \\ \operatorname{vec}(\mathbf{B}') \end{pmatrix}, \ \operatorname{vec}(\xi) = \begin{pmatrix} \operatorname{vec}(\mathbf{U}) \\ \operatorname{vec}(\mathbf{V}) \\ \operatorname{vec}(\mathbf{W}) \end{pmatrix}. \tag{7.2}$$

Then (7.1) for the mapping df_α defined in (2.12) can be written in the form

$$\mathbf{G}_\alpha \operatorname{vec}(\xi) = \operatorname{vec}(\alpha'), \quad \operatorname{vec}(\xi) \in \bigl(\operatorname{null} \mathbf{G}_\alpha\bigr)^\perp, \tag{7.3}$$

where $\mathbf{G}_\alpha$ is an $(n^2 + nm) \times (n^2 + m^2 + nm)$ real matrix of the form

$$\mathbf{G}_\alpha = \begin{pmatrix} \mathbf{I}_n \otimes \mathbf{A} - \mathbf{A}^T \otimes \mathbf{I}_n & 0 & \mathbf{I}_n \otimes \mathbf{B} \\ -\mathbf{B}^T \otimes \mathbf{I}_n & \mathbf{I}_m \otimes \mathbf{B} & 0 \end{pmatrix}, \tag{7.4}$$

where $\mathbf{I}_n \otimes \mathbf{A}$ denotes the Kronecker product of matrices. The vector $\operatorname{vec}(\xi)$ satisfying the condition $\operatorname{vec}(\xi) \in \bigl(\operatorname{null} \mathbf{G}_\alpha\bigr)^\perp$ can be expressed as follows:

$$\operatorname{vec}(\xi) = \mathbf{G}_\alpha^T \mathbf{y}, \tag{7.5}$$

where $\mathbf{y}$ is a column vector of dimension $n^2 + nm$. Substituting (7.5) into (7.3), we find

$$\mathbf{G}_\alpha \mathbf{G}_\alpha^T \mathbf{y} = \mathrm{vec}(\alpha'). \tag{7.6}$$

The linear mapping df_α considered in this paper has a nontrivial null-space. Hence, the matrix $\mathbf{G}_\alpha \mathbf{G}_\alpha^T$ is singular. Recall that $\{\alpha_1^n, \dots, \alpha_\ell^n\}$ is a basis of $\mathrm{Ker}\, df_\alpha^*$. Then $\{\mathrm{vec}(\alpha_1^n), \dots, \mathrm{vec}(\alpha_\ell^n)\}$ is a basis of the null-space of the symmetric matrix $\mathbf{G}_\alpha \mathbf{G}_\alpha^T$. Using the method described in [15], we construct the equation

$$\left(\mathbf{G}_\alpha \mathbf{G}_\alpha^T + \sum_{i=1}^{\ell} \mathrm{vec}(\alpha_i^n) \big(\mathrm{vec}(\alpha_i^n)\big)^T \right) \mathbf{y} = \mathrm{vec}(\alpha'), \tag{7.7}$$

where the matrix in the left-hand side is nonsingular. Solution $\mathbf{y}$ of (7.7) can be found numerically using the standard codes. The obtained vector $\mathbf{y}$ is a particular solution of (7.6), which determines the unique solution (7.5) of (7.1).

For a matrix pair $\alpha = \alpha_b$, where α_b is the Brunovsky canonical form (5.5) considered in section 5, we have $\ell = 4$, and the pairs $\alpha_1^n q_1 + \dots + \alpha_4^n q_4$ are given by expressions (4.16), (4.21), (4.22), where $r = 1$, $k_1 = n - 2$, $\mathbf{X}_{11}^n = 0$, $\mathbf{Y}_{11}^n = 0$, and $\mathbf{Y}_{12}^n = 0$.

OPTIMAL HARVESTING OF A JUMP DIFFUSION POPULATION AND THE EFFECT OF JUMP UNCERTAINTY*

NILS CHR. FRAMSTAD†

Abstract. The problem of irreversibly harvesting from a general one-dimensional (Wiener–Poisson) jump diffusion population model is studied. For a wide class of stochastic models, the optimal strategy has a downwards local time reflection at a trigger level x^*, which is typically known to be larger than in the corresponding deterministic problem if the uncertainty is Brownian. This paper shows that the presence of zero-mean jump uncertainty may or may not have the opposite effect on x^*. The property of uncertainty increasing x^* is related to the applicability of a comparison theorem.

Key words. optimal harvesting, singular stochastic control, reflected jump diffusion model, behavior towards risk

AMS subject classifications. 92D25, 91B32, 93E20, 49K45, 60G51, 60H10, 60J75, 60K37

DOI. 10.1137/S0363012902385910

1. Introduction.

The problem of optimally harvesting a population has been widely studied. The canonical example is asking how to get the most out of a logistic growth model. This paper is strongly inspired by two papers studying stochastic versions of the logistic growth models. Lungu and Øksendal [10] assume the process to follow the Itô (nonanticipative) stochastic differential equation

$$\mathrm{d}X_t = X_t(1 - X_t/K) \cdot (\beta_0 \,\mathrm{d}t + \sigma_{\mathrm{a}} \,\mathrm{d}B_t) - \mathrm{d}H_t, \tag{1.1a}$$

where, throughout this paper, H_t is the *cumulative harvested amount* up to and including time t. This is maybe the most straightforward generalization to a stochastic model, merely adding (a constant factor σ_{a} times) white noise to the (constant, positive) growth term β_0; here, B is standard Brownian motion and the positive constant K is the carrying capacity of the environment. In this model, volatility is largest when growth rate is. An alternative model, studied by, e.g., Alvarez and Shepp [3] and later by Myhre [11], generalizes the logistic model by adding a noise term where *relative* uncertainty is constant:

$$\mathrm{d}X_t = \beta_0 X_t(1 - X_t/K) \,\mathrm{d}t + \sigma_{\mathrm{b}} X_t \,\mathrm{d}B_t - X_{t^-} \cdot \mathrm{d}N_t - \mathrm{d}H_t \,. \tag{1.1b}$$

In their model there is also an implicit killing time, independent of everything else, where the population or the opportunity to harvest it disappears once and for all; the Poisson process N_t in (1.1b) makes this term explicit. Alvarez [2] has also analyzed a class of models described by

$$\mathrm{d}X_t = X_t\beta(X_t) \,\mathrm{d}t + \sigma_{\mathrm{c}}(X_t) \,\mathrm{d}B_t - \mathrm{d}H_t \,. \tag{1.1c}$$

All the aforementioned works are, as this paper, concerned with the problem of maximizing expected discounted total harvest. They find that the optimal strategy is a local time downwards reflection at a trigger level x^*, which turns out to be

*Received by the editors January 11, 2002; accepted for publication (in revised form) March 9, 2003; published electronically October 2, 2003. †Skogvollveien 40, NO-0580 Oslo, Norway (ncf@math.uio.no).

greater than in the corresponding deterministic case obtained by replacing σ by 0. Alvarez's paper [2], being the most general treatment of the above, concludes that "*the sign of the relationship between stochasticity and the optimal policy is unambiguously negative.*" A main object of this paper is to show that Alvarez's conclusions rely crucially upon modeling uncertainty with Brownian motion; it will turn out that if the Gaussian noise is replaced by another (infinitely divisible) zero-mean probability law, then the trigger level x^* may be lower than in the corresponding deterministic case. A careful note is appropriate: it is obvious that an *uncompensated* jump term (with nonzero mean) may lower x^*—like the simple "catastrophe intensity" in the model (1.1b) above, where the jump to zero intensity has the same effect as an increased discounting rate. We emphasize that we will instead be introducing a pure jump *martingale* to the model. Pure jump martingales may be regarded as a modeling alternative to the Brownian motion, at least if the jumps are small, and we shall see that the phenomena might have qualitatively different implications.

In the above cited works, the optimal strategy is described completely by the single value x^* at which one reflects the process downwards. However, if growth at zero does not exceed the interest rate, it may be that a profit maximizer will deplete a low population; that in particular goes with models with depensation, also called Allee effect, namely negative (expected) growth rate at sufficiently small populations due to, for example, the difficulty of finding a mate. If a population is doomed to decline until extinction, an economic agent will then harvest it right away. Optimality of immediate depletion also occurs in stochastic models: a case is treated by Alvarez in [1], where it is shown that the optimal strategy is described by two trigger values: downwards reflection at some x^*, and immediate total depletion whenever X falls below some $x_* < x^*$. Lande, Engen, and Sæther [9] have found by numerical methods that introducing a Gaussian noise may *increase* the optimal x_* in such a model. Therefore, even in the Brownian motion case, there are cases where the presence of uncertainty may lead to earlier total depletion of the population. We shall see why the arguments leading to our conclusions concerning the upper trigger level x^* do not apply to the lower trigger value x_* given that the latter exists (is strictly positive).

2. The model. Assume to be given a filtered probability space $(\Omega, \mathfrak{S}, \{\mathcal{F}_t\}_{t\geq t_0}, \mathsf{P})$ satisfying the usual conditions. The population is assumed to be an adapted process X following a stochastic differential equation given in (2.1) below. X will be driven by a standard Brownian motion B and by a centered integer-valued random measure governing jumps. It will be convenient to allow for state-dependent jump intensity, as well as the usual representation with Poisson random jumps, so let us give both forms. In the latter, $\tilde{N}$ is a centered Poisson random measure with Lévy measure λ, while in the former setting, we denote the centered random measure by $\tilde{M}$ while the jump intensity is q. Thus, if population at time t^- is at level x, then the intensity of a jump by a factor belonging to a Borel set Z is $q(x, Z)$, with $q(x, \{0\}) = 0$. Consider now two different representations for the dynamics:

$$\mathrm{d}X_t = X_{t^-} \cdot \Big(\beta(X_t)\,\mathrm{d}t + \sigma(X_t)\,\mathrm{d}B_t + \int z\,\tilde{M}(\mathrm{d}t, \mathrm{d}z)\Big) - \mathrm{d}H_t \tag{2.1a}$$

$$= X_{t^-} \cdot \Big(\beta(X_t)\,\mathrm{d}t + \sigma(X_t)\,\mathrm{d}B_t + \int \eta(X_{t^-}, z)\,\tilde{N}(\mathrm{d}t, \mathrm{d}z)\Big) - \mathrm{d}H_t, \tag{2.1b}$$

$$\text{both whenever } X_{t^-} > 0\text{; elsewhere, assume } \mathrm{d}X = 0. \tag{2.1c}$$

H_t is the total amount harvested up to and including time t, subject to our choice under the following restrictions.

DEFINITION 2.1. *Let* $\mathsf{P}^{t_0,x}$ *be the probability law of the time-space process* (t, X) *starting at* $(t_0, X_{t_0}) = (t_0, x)$ *with* $x \geq 0$*, and define* the class $\mathcal{H}$ of admissible controls *to be the* $\mathcal{F}_t$*-predictable, left-continuous nondecreasing stochastic processes* H *such that* $\mathsf{P}^{t_0,x}$*-a.s. we have* $H_{t_0} = 0$ *and* $X_t \geq 0$ *for all* $t \geq t_0$.

In particular, we will have to stop harvesting (i.e., $\mathrm{d}H = 0$) from the moment X hits zero. We emphasize that this can happen both by itself, with no harvesting, or by depleting the population by choosing $H_{t^+} = H_t + X_t$. We note that there always exists an admissible strategy, namely immediate depletion. As we do not allow negative values for X, we shall assume that for all x,

$$q(x, (-\infty, -1)) = 0 \leq 1 + \eta(x, \cdot) \quad \lambda\text{-almost everywhere.} \tag{2.2}$$

It will be useful to decompose q into mutually singular measures $\bar{q}, \check{q}, \hat{q}$ as follows:

$$\bar{q}(\cdot, \mathrm{d}z) := q(\cdot, \mathrm{d}z) \cdot \chi_{\{-1\}}(z) \qquad \text{(annihilation)}, \tag{2.3a}$$

$$\check{q}(\cdot, \mathrm{d}z) := q(\cdot, \mathrm{d}z) \cdot \chi_{(-1,0)}(z) \qquad \text{(other negative jumps)}, \tag{2.3b}$$

$$\hat{q}(\cdot, \mathrm{d}z) := q(\cdot, \mathrm{d}z) \cdot \chi_{(0,\infty)}(z) \qquad \text{(positive jumps)}, \tag{2.3c}$$

and, by abuse of notation, to identify the former with the function $\bar{q}(x) := q(x, \{-1\})$.

Existence and uniqueness will now be granted by familiar assumptions (i.e., sublinear growth and Lipschitz conditions on $x\beta$, $x\sigma$, $x\eta$; see, e.g., [4], [8], or [12] for more information about stochastic differential equations with jumps); we shall instead make the appropriate regularity assumptions ad hoc.

Assumption 2.2. The coefficients β, σ^2, and q are assumed to be one-sided continuous at each point, and admit existence and uniqueness of a weak solution to (2.1). We assume that $x\beta$ is locally upper bounded, and that q satisfies (2.2) and $\int z \wedge z^2 \, q(x, \mathrm{d}z) < \infty$ for all x.

DEFINITION 2.3. *Let* $\mathsf{E} = \mathsf{E}^{t_0,x}$ *be expectation w.r.t.* $\mathsf{P}^{t_0,x}$*,* $x \geq 0$*. Assume that* $\delta > 0$ *is a constant discount rate and that one wants to maximize* total discounted expected harvest *defined as*

$$J^H := \mathsf{E}\left[\int_{[t_0,\infty)} \mathrm{e}^{-\delta t} \, \mathrm{d}H_t\right] \tag{2.4}$$

and, if it exists, find an optimal strategy $H^* \in \mathcal{H}$ *such that*

$$J^{H^*} = \sup_{H \in \mathcal{H}} J^H =: \Phi(t_0, x) =: \mathrm{e}^{-\delta t_0} \Psi(x). \tag{2.5}$$

We note that by the Markov property, Ψ will indeed be a function of x only, not depending on t_0. Therefore, we can and will without loss of generality assume

$$t_0 = 0. \tag{2.6}$$

We also note that we need not really assume global existence of solution, but should the process possibly explode to infinity—which is very unrealistic from a biological point of view—we would be able to harvest an arbitrarily high amount in finite time. The same consideration lies behind the assumed local upper boundedness on $x\beta$; were it not, then one could in the deterministic case gain arbitrarily high discounted harvest by keeping the population at a level where $x\beta$ were sufficiently high. Clearly, there are stochastic cases with the same property: take $\sigma = 0$ and $q(\cdot, [-1, \infty))$ locally bounded in x, and consider only what happens before first negative jump.

3. Sufficient conditions and properties of the value function. Because it is always admissible to harvest any given amount not exceeding the present population, we have $\Psi(x) \geq \Psi(y)+x-y$ whenever $x \geq y \geq 0$, with equality if it is optimal to harvest at least $(x-y)$. Thus $\Psi'(x) \geq 1$ whenever it exists, with equality on intervals where harvesting is optimal. In the cases treated by the works [2], [3], [10], and [11] they find a unique threshold x^* such that $\Psi' > 1$ iff $x < x^*$; hence the *continuation region* D is of the form $D = [0, x^*)$. In the case of depensation, or if growth rate at zero is small, one may also want to deplete the population at small rates, and D may become an interval bounded away from zero, as found in [1]. Heuristically it is reasonable that D is at worst a countable union of intervals, and we shall restrict ourselves to this case. On D, we shall characterize Ψ by the Hamilton–Jacobi–Bellman (HJB) equation. Define

$$\mathsf{Q}\psi(x) := \int \big(\psi(x+zx) - \psi(x) - zx\psi'(x)\big)\, q(x, \mathrm{d}z) \tag{3.1a}$$

and

$$\mathsf{A}\psi(x) := -\delta\psi(x) + x\beta(x)\psi'(x) + \tfrac{1}{2}x^2\sigma^2(x)\psi''(x) + \mathsf{Q}\psi(x). \tag{3.1b}$$

For functions $\psi \in \mathsf{C}^2$ vanishing at 0 and with sublinear growth (cf. Theorem 3.3), $(\mathsf{A}+\delta)$ coincides with the generator of the process X when $\mathrm{d}H = 0$. It turns out—see Proposition 3.5 and Remark 3.6—that everywhere twice continuous differentiability frequently is too strong of a requirement: A function ψ is called *stochastically* C^2 in the sense of [5] if the Dynkin formula

$$\mathsf{E}[\mathrm{e}^{-\delta\tau}\psi(X_\tau)] = \psi(x) + \mathsf{E}\left[\int_0^\tau \mathsf{A}\psi(X_t)\,\mathrm{d}t\right]$$

holds for any bounded stopping time τ if there is no harvesting on $[0, \tau)$. It is possible to formulate conditions for (super)optimality in terms of viscosity solutions to the HJB quasi-variational inequality

$$\max\{\mathsf{A}\psi,\ 1-\psi'\} = 0$$

—see, e.g., [7, proof of Theorem 3] for a similar case. However, in section 5 below, we shall use the second derivative (see Proposition 3.5 for regularity at the reflection threshold). We therefore state a verification theorem which is tailored to the case we want to study.

THEOREM 3.1 (sufficient conditions). *Suppose we can find a* $\psi : [0,\infty) \mapsto [0,\infty)$ *which is stochastically* C^2 *and such that for all* $x > 0$,

$$\max\{\mathsf{A}\psi(x^-),\ 1-\psi'(x^-)\} \leq 0. \tag{3.2}$$

Then

$$\psi \geq \Psi. \tag{3.3}$$

For optimality, define the nonintervention region D *as*

$$D := \{x \geq 0;\ \psi'(x) > 1\}$$

and assume that D is a union of disjoint intervals $(\check{x}^{(k)}, \hat{x}^{(k)})$ and point 0. Suppose in addition that (3.2) holds with equality, $\psi \in \mathsf{C}^2((0,\infty) \setminus \cup_k\{\check{x}^{(k)}\})$, and $\psi(0) = 0$. Define the control $\hat{H}$ by

$$\hat{H}_{t^+} = \sum_k L_t^{\hat{x}^{(k)}} + \sum_{s\in[0,t]} \inf\{h \geq 0; X_s - h \in D\}, \tag{3.4}$$

where L^y is the local time of X at y. Suppose that using this $\hat{H}$ we have a sequence of stopping times τ_n such that

$$\mathsf{E}[\mathrm{e}^{-\delta\tau_n}\psi(X_{\tau_n^+})] \to 0. \tag{3.5}$$

Then $\psi = \Psi$ and $H^* := \hat{H}$ is optimal.

Proof. Using an arbitrary control H and expanding $\mathsf{E}[\mathrm{e}^{-\delta\tau}\psi(X_\tau)]$ using the Itô formula, we have

$$\psi(x) \geq \mathsf{E}\left[\int_{[0,\tau)} \mathrm{e}^{-\delta t}\,\mathrm{d}H_t\right] + \mathsf{E}[\mathrm{e}^{-\delta\tau}\psi(X_\tau)] \tag{3.6}$$

for all bounded stopping times τ, and superoptimality follows from the nonnegativity of ψ. To prove optimality we use H^*. This strategy involves action only on the at most countable points $\{\hat{x}^{(k)}\}$, $\{\check{x}^{(k)}\}$. At the former, we have reflection at a point where $\psi' = 1$, and ψ is C^2. At the latter, when X hits $\check{x}^{(k)}$ it is immediately harvested down to $\hat{x}^{(k-1)}$ (note that $\psi' = 1$ on $(\hat{x}^{(k-1)}, \check{x}^{(k)})$), so we may apply the Itô formula piecewise and disregard the possible discontinuity in $\mathsf{A}\psi$. In conclusion, equality in (3.2) implies equality in (3.6), and condition (3.5) grants that $\psi = \Psi$. □

Remark 3.2. The assumption (3.5) is ad hoc, and though it trivially holds if D is bounded, one may want an alternative condition. Note that if we have $\beta \leq \delta$ for all large enough x, then $\Psi(x) \leq x + F$, where $F := \sup(x(\beta/\delta - 1))$ is finite by the assumed local boundedness of $x\beta$. This can be verified by (3.2) but does not depend on the Markovian nature of the problem. In this case, it is no restriction to impose $\psi \leq x + F$ for our candidate ψ to be checked for optimality. This bound, together with a slightly stronger assumption on β, namely the condition that there exists some $\epsilon \in (0, \delta)$ such that $\beta < \delta - \epsilon$ for large enough x, will imply (3.5). Since $F\mathrm{e}^{-\delta T} \to 0$, it suffices to check that $\mathrm{e}^{-\delta T}\mathsf{E}[X_T]$ tends to zero. By Itô's formula,

$$\mathsf{E}[X_T] \leq x + \int_0^T \mathsf{E}[X_t\beta(X_t)]\,\mathrm{d}t \leq x + \int_0^T \big(\delta F + (\delta - \epsilon)\mathsf{E}[X_t]\big)\,\mathrm{d}t := Y_T \geq 0.$$

By a Gronwall argument, it easily follows that

$$\mathrm{e}^{-\delta T}\mathsf{E}[X_T] \leq \mathrm{e}^{-\delta T}Y_T \leq \mathrm{e}^{-\epsilon T}\left(x + \frac{\delta F}{\delta - \epsilon}\right) \xrightarrow[T\to\infty]{} 0.$$

Let us introduce the notation

$$x^* := \sup D, \qquad x_* := \inf D \setminus \{0\} \tag{3.7}$$

and also agree to say that some $x = \hat{x}$ if it is optimal to reflect downwards at x; i.e., $y \in D$ for all sufficiently large $y < x$ but no sufficiently small $y > x$. Similarly, we write $x = \check{x}$ if $y \in D$ for all sufficiently small $y > x$ but for no sufficiently large $y < x$. We then have some properties of the optimal harvesting problem.

THEOREM 3.3.

(a) *If there is an $\epsilon > 0$ such that $\beta - \delta > \epsilon$ everywhere, then $\Psi(x) = \infty$ for all $x > 0$.*

(b) *If $\Psi(x) = x$, then on $(0, x)$ we have $\beta(y) \le \delta$.*

(c) *Assume either both $x = x^*$ and $\Psi'(x^{*-}) = 1$, or both Ψ concave and $x < x^*$. Then $\beta(x^-) \ge \delta$ with equality iff Ψ linear on $[0, x]$.*

Proof.

(a) Consider the (admissible) strategy of harvesting a constant fraction $h \in (0, \epsilon]$ of the population, i.e., $\mathrm{d}H_t = hX_t \mathrm{d}t$. Expanding $\mathrm{e}^{-\delta t} X_t$ using the Itô formula and assuming $X_0 = x > 0$, we get

$$\begin{aligned} J^H &= h \int_0^\infty \mathsf{E}[\mathrm{e}^{-\delta t} X_t] \, \mathrm{d}t \\ &= h \int_0^\infty \int_0^t \left(x + \mathrm{e}^{-\delta s} \mathsf{E}[(\beta(X_s) - \delta - h) X_s] \right) \mathrm{d}s \, \mathrm{d}t \\ &\ge hx \int_0^\infty \int_0^t 1 \, \mathrm{d}s \, \mathrm{d}t = \infty, \end{aligned}$$

since $h \le \epsilon$ implies $\beta(x) - \delta - h \ge 0$ by assumption.

(b) For $y \in (0, x)$, we must have $\Psi(y) = y$ and

$$0 \ge \mathsf{A}\Psi(y) = -\delta y + y\beta(y) + \mathsf{Q}\Psi(y) \ge -\delta y + y\beta(y)$$

since $\Psi(y + zy) \ge y + zy$ always. So $0 \ge -\delta y + y\beta(y)$.

(c) Consider $\Psi(x + zx) - \Psi(x) - zx\Psi'(x)$. It is easy to see that it is negative if Ψ is concave, which also applies at x^{*-} if $z \ge 0$. On the other hand, for $z < 0$ we have

$$\Psi(x + zx) \le \Psi(x) - zx = \Psi(x) - zx\Psi'(x^{*-})$$

by assumption. So the hypothesis implies that $-\delta\Psi(x) + x\beta(x^-)\Psi'(x^-)$ is nonnegative. In the concave case, we know that $x\Psi'(x^-) \le \Psi(x)$ which proves the claim. At $x = x^{*-}$, it follows by $\Psi'(x^{*-}) = 1$ and $\Psi(x) \ge x$. □

Remark 3.4. Note that we cannot allow $\epsilon = 0$ in part (a) above. A counterexample is given: Let $\theta \in (0, 1)$ and $A > 0$, and assume $\beta = \frac{x + Ax^\theta}{x + \theta Ax^\theta} \delta$ and for simplicity $\sigma = 0 = q$. Then it is easy to show that no optimal strategy exists, as waiting is always better, and that $\psi(x) = x + Ax^\theta$ is superoptimal. However, in a real world population model it is hardly a restriction to assume that $\beta < \delta$ when x is large enough—and property (c) above then upper bounds x^*. Property (b) shows that if $\delta < \beta(0^+)$, it is never optimal to harvest the population to extinction. This is a well-known feature from the deterministic and Brownian motion settings and is also proven under more general concave or linear Hindy–Huang preferences in [6]. This is not the same as saying that the optimal harvesting strategy will not indirectly lead to extinction; let, for example, $y > 0$ be a trap of the process if uncontrolled, while for $x < y$ the annihilation intensity $\bar{q}$ is positive. Then if we harvest any amount, the population could become extinct in finite time (typically even a.s.).

Even if the viscosity solution concept enables us to consider also nonsmooth candidates for value function, smoothness is certainly a valuable property; indeed, we should expect the value function to be smooth (if finite) also at points $x = \hat{x}$ at which reflection is optimal.

PROPOSITION 3.5 (regularity at $\hat{x}$). *Assume that* $\mathsf{A}\Psi(\hat{x}^-) = 0$ *(in the classical sense), that* $\Psi'(x^{*-})$ *exists and is* 1, *and that* β *and* $x \mapsto q$ *are continuous at* $\hat{x}$. *If* $\lim_{x \nearrow \hat{x}} \sigma^2(x) = 0$, *then assume that* $\beta(\hat{x}) > 0$ *(which holds if* $\hat{x} = x^*$ *or if* $\hat{q}(\hat{x}, \cdot) = 0$*), and furthermore that* $\sigma^2(\hat{x}^-)\Psi'''(\hat{x}^-) = 0$ *and that the coefficients are differentiable at* $\hat{x}$. *Then* Ψ *is* C^2 *at* $\hat{x}$.

Proof. For any sequence $x_n \nearrow \hat{x}$, we have

$$0 \geq \mathsf{A}\Psi(\hat{x}^+) = \lim \left(\mathsf{A}\Psi(x_n) - \tfrac{1}{2}x_n^2\sigma^2(x_n)\Psi''(x_n)\right) \geq 0, \tag{3.8}$$

since Ψ' is decreasing at $\hat{x}$. Therefore, $\mathsf{A}\Psi$ is continuous at $\hat{x}$, and we must have Ψ'' continuous at $\hat{x}$ unless possibly if $\sigma^2(\hat{x}^-) = 0$. In that case, we first note that with $\hat{x} = x^*$ or $\hat{q}(\hat{x}, \cdot) = 0$, then $\mathsf{A}\Psi(\hat{x})$ will be strictly negative unless $\hat{x}\beta(\hat{x})\Psi'(\hat{x}) > 0$. Now $x \mapsto \mathsf{A}\Psi$ is decreasing at $\hat{x}$, while its left-hand derivative is zero. For $x < \hat{x}$,

$$\begin{aligned} 0 &= ((x\beta)' - \delta)\Psi' + (x\beta + \tfrac{1}{2}(x^2\sigma^2)')\Psi'' + \tfrac{1}{2}x^2\sigma^2\Psi''' + \tfrac{\mathrm{d}}{\mathrm{d}x}\mathsf{Q}\Psi(x) \\ &\geq \left[((x\beta)' - \delta)\Psi' + \tfrac{\mathrm{d}}{\mathrm{d}x}\mathsf{Q}\Psi(x)\right]_{x=\hat{x}}. \end{aligned}$$

Since $\hat{x}$ is a minimum for $x^2\sigma^2$, then $0 \leq \hat{x}\beta(\hat{x})\Psi''(\hat{x}^-)$. □

Remark 3.6. While Proposition 3.5 gives good reason to expect Ψ to be C^2 at points where it is optimal to reflect downwards, there is no reason to expect that the value function behaves equally nice at $\check{x}$: there, the value function is convex, which invalidates the positivity inequality in (3.8), and so we cannot expect $\mathsf{A}\Psi$ to be continuous at $\hat{x}$. Furthermore, at that point we will perform a proper impulse, not a reflection, which makes the problem akin to optimal stopping—indeed, the problem of optimizing w.r.t. x_* is a proper optimal stopping problem; those problems are known to frequently exhibit exact once continuous differentiability of the value function, and it is not difficult to construct examples where the value function cannot be C^2. Briefly, continuous second derivative would imply that $\beta^{-1}(\delta)$ determines indifference on whether or not to deplete the population, but it is easy to see that waiting for a sufficiently small time τ and then keeping the population constant from then on yields a higher performance in the deterministic case. The expected nonsmoothness at $\check{x}$ is the reason for the ad hoc formulation of Theorem 3.1 above. The nonsmoothness also helps to explain why the introduction of uncertainty may increase both x^* (as we will see in section 5 below) and x_* (as found in [9]) and thus, informally, postpone population at high levels but hasten it at low levels.

4. Finding an optimal solution: The concave case. This section concerns the search for a function satisfying the sufficient conditions of Theorem 3.1. We shall restrict ourselves to the case where

$$D = [0, x^*). \tag{4.1}$$

Consider, informally, the continuous case; then it is natural to proceed by finding a function f that vanishes at 0, solves the HJB equation $\mathsf{A}f = 0$, and has some inflection point $\tilde{x}$ for which $f'(\tilde{x}) > 0$. We then construct a candidate ψ by

$$\psi(x) = \frac{f(\min(\tilde{x}, x))}{f'(\tilde{x})} + \max\{0, x - \tilde{x}\}. \tag{4.2}$$

Then ψ will be C^2 and satisfy $(1 - \psi') \cdot (\mathsf{A}\psi) = 0$. We want both factors nonpositive, and if f is concave on $(0, \tilde{x})$, then we have $\psi' \geq 1$ and it suffices to check that $\mathsf{A}\psi \leq 0$

for $x \geq \tilde{x}$. Concavity is the reason for assuming the form (4.1)—if that does not hold, we will have $\psi' = 1$ on disjoint intervals. We also note that by Theorem 3.3 (b), we can hope for concavity if

$$\beta(x) > \delta \quad \text{for all small enough } x > 0. \tag{4.3}$$

Because of (4.1), the above approach will work just as well in the case with negative jumps, as we can then safely paste at high levels—we must, however, exclude positive jumps through part of the analysis.

So we proceed to show that there is a quite wide class of cases where we can find an f which vanishes at 0, is concave at 0, and solves the HJB equation. It turns out that if coefficients are real analytic (at least near 0), then we may, as in [10], adapt the Frobenius theory (at least near 0) if $\hat{q} = 0$. So assume that within some positive convergence radius, the coefficients may be represented as

$$\beta(x) = \sum_{j=0}^{\infty} \beta_j x^j, \quad \sigma^2(x) = \sum_{j=0}^{\infty} \zeta_j x^j, \quad \text{and} \quad q(x, \mathrm{d}z) = \sum_{j=0}^{\infty} q_j(\mathrm{d}z) x^j. \tag{4.4}$$

Now try to insert a nonzero function of the form $f(x) = x^\theta \sum_{i=0}^{\infty} a_i x^i$ into the HJB equation to get

$$\begin{aligned} 0 = \sum_{i=0}^{\infty} \Bigg(-\delta + \sum_{j=0}^{\infty} \Bigg[& \theta(\beta_j + \tfrac{1}{2}(\theta - 1)\zeta_j) \\ & + \int \left((1+z)^{\theta+i} - 1 - (\theta + i)z \right) q_j(\mathrm{d}z) \\ & + i(\beta_j + \theta\zeta_j) + \tfrac{1}{2} i(i-1)\zeta_j \Bigg] x^j \Bigg) a_i x^i. \end{aligned} \tag{4.5}$$

If $\beta_0 > \delta$, the constant term determines $\theta \in (0, 1)$:

$$0 = -\delta + \theta\beta_0 + \tfrac{1}{2}\theta(\theta - 1)\zeta_0 + \int \Big((1+z)^\theta - 1 - \theta z \Big) q_0(\mathrm{d}z). \tag{4.6}$$

Choosing $a_0 > 0$, we then have $f'(0^+) = +\infty = -f''(0^+)$ and thus f increasing and concave at zero. Assuming (4.3) the only remaining case is $\beta_0 = \delta$; rather than choosing $\theta = 1$ from (4.6), we equivalently pick $\theta = a_0 = 0$. It turns out that all solutions must then have $a_1 \neq 0$, and the index of the next nonzero coefficient a_{i_1} will be determined by

$$i_1 - 1 = j_1 := \min\{j \geq 1; \beta_j \neq 0\}. \tag{4.7}$$

To see this, first note that $\beta_{j_1} > 0$ by (4.3), while $\beta_0 = \delta$. Matching the i_1th coefficients we get

$$a_{i_1} \Big((i_1 - 1)(\delta + \tfrac{1}{2} i_1 \zeta_0) + \int \left((1+z)^{i_1} - 1 - i_1 z \right) q_0(\mathrm{d}z) \Big) = -a_1 \beta_{i_1 - 1}, \tag{4.8}$$

which shows both that $a_1 \neq 0$ and that i_1 is determined by (4.7), and that $a_{i_1} < 0$ and thus f concave at zero: it is easy to see that the integrand is nonnegative, and

so is $\zeta_0 = \sigma^2(0)$, while $\delta > 0$. So if the right-hand side were zero, then so would a_{i_1} and f. We have proved the following proposition.

PROPOSITION 4.1. *Assume* (4.3) *and that on some interval* $(0, R) \neq \varnothing$ *the coefficients are real analytic with* $\hat{q} = 0$. *Then on* $(0, R)$, *the HJB equation* $\mathsf{A}f = 0$ *has a solution* f *which vanishes at* 0, *increases at* 0, *and is concave at* 0.

Remark 4.2. The reader who might feel uncomfortable with the real analyticity of the measure-valued function $x \mapsto q$, may verify that a similar condition may be imposed equally well on the usual Lévy representation, which yields

$$\int \Big((1 + \eta(x,z))^{\theta+i} - 1 - (\theta + i)\eta(x,z) \Big) \lambda(\mathrm{d}z). \tag{4.9}$$

If $x \mapsto \eta$ is real analytic for each z, then for each i the integrand is analytic, being a composition of analytic functions (we may separately treat the z-values which yield $\eta = -1$). So the expression in (4.9) is analytic in x also, and we may proceed as above.

At this point, we do not know whether this concave f will have any inflection point $\tilde{x}$, or if $f'(\tilde{x}) > 0$, which is essential for the construction (4.2). This is addressed in Proposition 4.3, which is written to suit a ψ constructed by (4.2) but for the sake of generality has a slightly ad hoc formulation which does not exclude cases with positive jumps.

PROPOSITION 4.3. *Assume* (4.3). *Let* ψ *be nonlinear and concave, and assume it vanishes at* 0 *and increases at* 0. *Assume that there exists some* $\tilde{x} \in (0, \infty]$ *such that* ψ *is affine for* $x \geq \tilde{x}$, C^1 *at* $\tilde{x}$ *and solves the HJB equation* $\mathsf{A}\psi = 0$ *for* $x < \tilde{x}$. *Then* $\beta > \delta$ *on* $(0, \tilde{x})$ *and also at* $\tilde{x}^-$ *iff finite. Furthermore,* $\psi' > 0$ *everywhere and* $\mathsf{A}\psi \leq 0$ *whenever* $\beta \leq \delta$.

Proof. Concavity implies $-\delta\psi(x) \leq -\delta x(\psi'(x) + \psi(0))$ (with equality iff ψ linear on $(0, x)$), and also that $\mathsf{Q}\psi(x) \leq 0$. We therefore have

$$\mathsf{A}\psi(x) \leq x(\beta(x) - \delta)\psi'(x) + \frac{1}{2}x^2\sigma^2(x)\psi''(x) + \mathsf{Q}\psi(x) \leq x(\beta(x) - \delta)\psi'(x) \tag{4.10}$$

for all $x \in (0, \tilde{x})$. In fact, the right-hand side is strictly positive; if not, we would have $\psi(x) = kx$ on $(0, x)$, with $k > 0$ because ψ is assumed to be increasing at zero. But for sufficiently small $x > 0$ we have $\beta > \delta$ by (4.3). With the right-hand side strictly positive, ψ' cannot hit zero, and by continuity whenever $\mathsf{A}\psi$ is defined it is strictly positive, and so $\beta > \delta$. This holds for all $x \in (0, \tilde{x})$ and at $\tilde{x}^-$ if finite, in which case $\psi'(y) = \psi'(\tilde{x}) > 0$ for all $y \geq \tilde{x}$ as well. So $\psi' > 0$ everywhere. It now follows from (4.10) that $\beta \leq \delta$ implies $\mathsf{A}\psi \leq 0$. □

As long as Proposition 4.3 applies, we can by scaling with a constant assume $\psi'(\tilde{x}) = 1$, and the problem is solved if we can show that $\mathsf{A}\psi \leq 0$ on $(\tilde{x}, \bar{x})$, where $\bar{x} \leq \infty$ is defined as

$$\bar{x} := \sup\{x \geq \tilde{x};\ \beta(x) > \delta\}. \tag{4.11}$$

Note that the potentially troublesome interval $(\tilde{x}, \bar{x})$ is nonempty if β is continuous at $\tilde{x}$ and $\tilde{x} < \infty$.

Before we give the main result of this section, let us point out a few useful properties of the function $Q(x)$ defined for a fixed ψ as

$$Q(x) := \mathsf{Q}\psi(x). \tag{4.12a}$$

If $\psi \in \mathsf{C}^2$, we have

$$Q(x) = \int \int_{x+zx}^{x} \int_{y}^{x} \psi''(w)\,\mathrm{d}w\,\mathrm{d}y\,q(x,\mathrm{d}z). \tag{4.12b}$$

Assuming sufficient regularity, the first two derivatives of Q are then

$$\begin{aligned} Q'(x) &= \int \int_{x+zx}^{x} \int_{y}^{x} \psi''(w)\,\mathrm{d}w\,\mathrm{d}y\,q'(x,\mathrm{d}z) \\ &\quad + \int \Big((1+z)\big(\psi'(x+zx)-\psi'(x)\big) - zx\psi''(x)\Big)\,q(x,\mathrm{d}z) \end{aligned} \tag{4.12c}$$

and

$$\begin{aligned} Q''(x) &= \int \int_{x+zx}^{x} \int_{y}^{x} \psi''(w)\,\mathrm{d}w\,\mathrm{d}y\,q''(x,\mathrm{d}z) \\ &\quad + 2\int \Big((1+z)\big(\psi'(x+zx)-\psi'(x)\big) - zx\psi''(x)\Big)\,q'(x,\mathrm{d}z) \\ &\quad + \int \Big((1+z)\big((1+z)\psi''(x+zx)-\psi''(x)\big) - z(x\psi''(x))'\Big)\,q(x,\mathrm{d}z), \end{aligned} \tag{4.12d}$$

where $q'(x,\mathrm{d}z) := (\partial/\partial x)q(x,\mathrm{d}z)$ and $q''(x,\mathrm{d}z) := (\partial/\partial x)^2 q(x,\mathrm{d}z)$ are signed measures. We then have the following theorem.

THEOREM 4.4. *Assume that $\psi''(\tilde{x}) = 0$, with $0 < \tilde{x} < \infty$.*

(a) Optimality, $x(\beta-\delta)+Q$ eventually nonincreasing: *If Proposition* 4.3 *applies and*

$$\tilde{x}(\beta(\tilde{x})-\delta) + Q(\tilde{x}) \geq x(\beta(x)-\delta) + Q(x) \quad \forall x \geq \tilde{x}, \tag{4.13}$$

then we have $\Psi = \psi$ and the optimal continuation region is $D = [0,x^*) = [0,\tilde{x})$.

(b) Optimality, $x(\beta-\delta)+Q$ eventually concave: *If Proposition* 4.3 *applies and the coefficients are continuous at $\tilde{x}$, and $x\beta+Q$ is concave on $[\tilde{x},\bar{x}]$, then $\mathsf{A}\psi \leq 0$ and thus $\Psi = \psi$ and the optimal continuation region is $D = [0,x^*) = [0,\tilde{x})$. Note that if at some point $y \geq \tilde{x}$ we have $x \mapsto \check{q}$ nonincreasing ($\Rightarrow Q$ nondecreasing!) and convex and $\bar{q}$ is convex, then Q is concave at y.*

(c) Optimality w.r.t. a possibly modified problem: *Assume that Proposition* 4.3 *applies and that ψ is not C^∞ at $\tilde{x}$. Let the nth derivative $\psi^{(n)}$ be discontinuous at $\tilde{x}$ and assume in addition that we either have $\sigma(\tilde{x}) \neq 0$ and C^{n-2} coefficients, or $\beta(\tilde{x}) - \int z\,q(\tilde{x},\mathrm{d}z)$ exists and is > 0 and C^{n-1} coefficients. Then $\mathsf{A}\psi \leq 0$ for all small enough $x \geq \tilde{x}$. Therefore, if $\hat{q} = 0$, then we can construct a* new *problem with value function ψ and optimal continuation region $[0,\tilde{x})$ by leaving the coefficients unchanged on some right-open interval containing $[0,\tilde{x}]$ and changing β from there on.*

Proof.

(a) Since $\mathsf{A}\psi(\tilde{x}) = \psi''(\tilde{x}) = 0$, then for $x \geq \tilde{x}$,

$$\begin{aligned} \mathsf{A}\psi(x) &= \mathsf{A}\psi(x) - \mathsf{A}\psi(\tilde{x}) \\ &= -\delta\psi(x) + \delta\psi(\tilde{x}) + x\beta(x) - \tilde{x}\beta(\tilde{x}) + \mathsf{Q}\psi(x) - \mathsf{Q}\psi(\tilde{x}) \\ &= x(\beta(x)-\delta) - \tilde{x}(\beta(\tilde{x})-\delta) + \mathsf{Q}\psi(x) - \mathsf{Q}\psi(\tilde{x}). \end{aligned} \tag{4.14}$$

(b) Consider

$$\frac{\mathrm{d}}{\mathrm{d}x}\mathsf{A}\psi(x) = (x(\beta-\delta))'\psi'(x) + \frac{\mathrm{d}}{\mathrm{d}x}\mathsf{Q}\psi(x) + \left(x\beta + \frac{1}{2}(x^2\sigma^2)'\right)\psi''(x) + \frac{1}{2}x^2\sigma^2\psi'''(x). \tag{4.15}$$

By the nonnegativity of the latter term at $\tilde{x}^-$, we know that $\mathsf{A}\psi$ has nonpositive derivative at $\tilde{x}$. Relaxing differentiability, we still have $\mathsf{A}\psi$ nonincreasing at $\tilde{x}$. Fix $x \in (\tilde{x}, \bar{x})$. Since $\psi' = 1$ around x, the derivative of (4.15) reduces to $(x\beta + Q)''$. For the last claim, consider (4.12d): Q'' reduces to

$$\int\int_{x+zx}^{x}\int_{y}^{x} \psi''(w)\,\mathrm{d}w\,\mathrm{d}y\,(\check{q}''(x,\mathrm{d}z) + \bar{q}''(x,\mathrm{d}z)) + 2\int (1+z)\big(\psi'(x+zx)-1\big)\,\check{q}'(x,\mathrm{d}z), \tag{4.16}$$

which is nonpositive if $\check{q}''$ and $\bar{q}''$ are nonnegative and $\check{q}'$ is nonpositive, since $\psi' \geq 1$ and decreasing.

(c) To prove the last assertion, let n be the smallest number such that the nth derivative $\psi^{(n)}$ is discontinuous at $\tilde{x}$. Then necessarily n is odd and $\psi^{(n)}(\tilde{x}^-) > 0 = \psi^{(n)}(\tilde{x}^+)$. If $\sigma(\tilde{x}) \neq 0$, differentiate $n-2$ times to get

$$\Big(\frac{\mathrm{d}}{\mathrm{d}x}\Big)^{n-2}\mathsf{A}\psi(\tilde{x}^+) - \Big(\frac{\mathrm{d}}{\mathrm{d}x}\Big)^{n-2}\mathsf{A}\psi(\tilde{x}^-) = -\frac{1}{2}\tilde{x}^2\sigma^2(\tilde{x})\cdot\psi^{(n)}(\tilde{x}^-), \tag{4.17a}$$

which is < 0 by assumption. If $\sigma(\tilde{x}) = 0$, differentiate instead $n-1$ times to get

$$\Big(\frac{\mathrm{d}}{\mathrm{d}x}\Big)^{n-1}\mathsf{A}\psi(\tilde{x}^+) - \Big(\frac{\mathrm{d}}{\mathrm{d}x}\Big)^{n-1}\mathsf{A}\psi(\tilde{x}^-) = -\tilde{x}\left(\beta(\tilde{x}) - \int z\,q(x,\mathrm{d}z)\right)\cdot\psi^{(n)}(\tilde{x}^-), \tag{4.17b}$$

which is < 0 by assumption. Finally, if $\hat{q} = 0$, then we can change β at x without affecting the quasi-variational inequality at values to the left of x. □

Note that if we remove the assumption $\tilde{x} < \infty$, we can conclude only that ψ is superoptimal; cf. Remark 3.4.

COROLLARY 4.5. *Assume that Proposition* 4.1 *applies and that f'' has a (finite) zero. Let $\tilde{x}$ be the leftmost, and define ψ by* (4.2). *Then Theorem* 4.4(c) applies.

Proof. By (4.10) we have that $f'(\tilde{x}) > 0$, so ψ is also concave. Now analytic functions are determined by their derivatives, so while the coefficients are C^∞ at x^*, ψ is not, unless identically equal to x, which is impossible by (4.3). □

5. The effect of uncertainty. Having found (under suitable conditions) the value function in section 4, we shall throughout this section assume some regularity.

Assumption 5.1. It is optimal to reflect the process downwards at $\hat{x}$. The value function Ψ is C^2 at $\hat{x}$.

We know from Proposition 3.5 and section 4 that this ad hoc assumption does cover a wide range of control problems, just as obtained in [2] in the nonjump case.

For a given stochastic problem denote by x_0^* the x^* obtained in the corresponding deterministic problems, i.e., the one that arises when the uncertainty terms σ and q

are replaced by zero (recall x^* defined by (3.7)). In the continuous cases studied in [3] and [10] they find that $x^* \geq x_0^*$ (equal to $\operatorname{argmax} x(\beta - \delta)$); Myhre [11] improves the bound to $x^* \geq x_0^* + \sigma_{\mathrm{b}}/\beta_0$ for the latter case (1.1b). The relation $x^* \geq x_0^*$ may have the interpretation of one being more careful under uncertainty. It turns out that jump uncertainty may violate this property (at least apparently; see the closing remarks for an interpretation). However, it holds if the jump intensity is nonincreasing in x, which leads us to the well-known comparison theorem. Consider for a moment the Lévy representation (2.1b). To extend the comparison theorem of the continuous case, it is sufficient that state after jump is nondecreasing as a function of the prejump state for almost every jump index z, i.e., that $x(1+\eta)$ is nondecreasing. This is also almost necessary—comparison fails if X is expected to spend positive time where $x(1+\eta)$ is strictly decreasing. Now in terms of the Lévy representation, we have

$$Q'(x) = \int \big((\Psi'(x + x\eta(x,z)) - \Psi'(x)) \cdot (x + x\eta)' - x\eta\Psi''(x)\big)\, \lambda(\mathrm{d}z). \tag{5.1}$$

At $\hat{x}$, Ψ' attains its minimum value and $\Psi'' = 0$. Therefore, comparison—locally at $\hat{x}$—is sufficient to grant $Q'(\hat{x}) \geq 0$, a property which turns out to be critical for the behavior towards risk.

PROPOSITION 5.2. *Assume $\Psi'''(\hat{x}^-)$ exists and assume (for simplicity, admits generalizations) coefficients differentiable at $\hat{x}$. If $Q'(\hat{x}) \geq 0$ (resp., > 0), then*

$$0 \geq \ \textit{(resp., >)}\ (x(\beta - \delta))'|_{x=\hat{x}}.$$

Hence for $x\beta$ concave, $\hat{x}$ is no smaller than (resp., strictly greater than) in the deterministic case. If, on the other hand, $\sigma(\hat{x}) = 0$ and $Q'(\hat{x}) \leq 0$ (resp., < 0), then $(x(\beta - \delta))'|_{x=\hat{x}} \geq 0$ (resp., > 0); hence for $x\beta$ concave, $\hat{x}$ is no larger than (resp., strictly smaller than) in the deterministic case. Furthermore, x^* is unaffected by $\hat{q}$ as long as $\sigma(x^*) = 0$.

Proof. Differentiate the equation $\mathsf{A}\Psi = 0$ and insert $\hat{x}^-$:

$$-\big(x(\beta - \delta)\big)'|_{x=\hat{x}} = \frac{1}{2}\hat{x}^2\sigma^2(\hat{x})\Psi'''(\hat{x}^-) + Q'(\hat{x}) \geq Q'(\hat{x}) \tag{5.2}$$

with equality if $\sigma(\hat{x}) = 0$; in that case, Ψ''' vanishes from (5.2), which is therefore not affected by $\hat{q}$—to see this, do the construction (4.12c) with $\hat{q}$ instead of q to see that the integrands become zero. □

Proposition 5.2 combined with Theorem 4.4(c) now yields a main point of this paper.

META-THEOREM 5.3 (behavior towards risk). *There is a wide class of problems for which the optimal solution is to reflect downwards at the same or a lower level than the corresponding deterministic problem, contrary to the case covered in* [2].

While this may appear a bit counterintuitive at first glance, it certainly makes sense: jump intensity decreasing in x may lead to one keeping the population at a higher level to reduce the probability of "disasters," i.e., negative jumps; on the other hand, the presence of the jump terms may lead us to harvest and reduce X before the jumps do. This is, however, a priori not a valid argument, since jumps are compensated. The case with only annihilation risk is illustrative, but it will be convenient (and no more complicated, as $\hat{q}$ does not affect $Q'(x^*)$) to include positive jumps if $\hat{x} = x^*$ in the following theorem.

THEOREM 5.4. *Assume $\hat{q} = 0$ or $\hat{x} = x^*$, and furthermore $\breve{q} = \sigma = 0$ and continuous and piecewise differentiable coefficients. Then $\hat{x}$ is a stationary point of*

$x(\beta-\delta)/(\delta+\bar{q})$. Furthermore, $x(\beta-\delta)$ is (strictly) increasing (resp., decreasing) at $\hat{x}$ iff $\bar{q}$ is. In particular, if $x(\beta-\delta)/\delta$ and $x(\beta-\delta)/(\delta+\bar{q})$ have unique maximum points $\hat{x}_0$, $\hat{x}$, respectively, their respective control problems have optimal continuation regions $D_0=[0,x_0^*)=[0,\hat{x}_0)$ and $D=[0,x^*)=[0,\hat{x})$ and $x^*\le x_0^*$ ($<x_0^*$) iff $\bar{q}$ is (strictly) increasing at x^*.

Proof. The HJB equation $\mathsf{A}\Psi=0$ is now

$$0=-(\delta+\bar{q})\Psi(x)+x(\beta+\bar{q})\Psi'(x)+Q(x). \tag{5.3a}$$

Inserting $x=\hat{x}$, then by our assumptions we have

$$0=-(\delta+\bar{q}(\hat{x}))\Psi(\hat{x})+\hat{x}(\beta(\hat{x})+\bar{q}(\hat{x})). \tag{5.3b}$$

Differentiate (5.3a), evaluate at $\hat{x}$, and insert for $\Psi(\hat{x})$ from (5.3b). Then we get that $\hat{x}$ must be a stationary point for $x(\beta-\delta)/(\delta+\bar{q})$, i.e., where

$$\frac{(x(\beta-\delta))'}{x(\beta-\delta)}=\frac{\bar{q}'}{(\delta+\bar{q})} \tag{5.4}$$

since $\beta(\hat{x})>\delta$ (if not, (5.3a) would yield $\Psi(\hat{x})\le\hat{x}$). □

It is known that Brownian uncertainty has the effect of reducing the optimal *value* (or leaving it unchanged)—see [2, Theorem 6]. We see from the above calculation that this property is not necessarily connected to the postponed harvesting associated with the Brownian uncertainty, as the introduction of a $\bar{q}$ not affecting x^* will reduce $\Psi(x^*)=x^*(1+(\beta(x^*)-\delta)/(\delta+\bar{q}(x^*)))$. But in Theorem 5.4, positive jumps do not affect the value function for $x\ge x^*$; nevertheless we have the following theorem.

THEOREM 5.5 (compensated positive jumps' effect on optimal value). *Assume that Theorem 5.4 applies and $\hat{q}$ is nonzero for all sufficiently large $x<x^*$. Then $\hat{q}$ reduces the optimal value for all sufficiently large $x<x_0^*$.*

Proof. By Theorem 5.4, we know that x^* and $\Psi(x^*)$ are not affected. Now since Ψ' is decreasing to 1, we have that Ψ is concave on (y,∞) for all sufficiently large $y<x^*$. Fix such a y; since $\beta(x^*)>0$, we can and will assume $\beta>0$ on (y,x^*). Let $\hat{\Psi}$ be the value function with $\hat{q}$ as assumed, and let $\hat{\Psi}_0$ be the value function with $\hat{q}$ replaced by the zero measure; then we have $\mathsf{Q}\hat{\Psi}<0=\mathsf{Q}\hat{\Psi}_0$ on (y,x^*), and by the HJB equation we have

$$-\delta\hat{\Psi}_0+x\beta\hat{\Psi}_0'=0<-\delta\hat{\Psi}+x\beta\hat{\Psi}'.$$

Let $\Delta:=\hat{\Psi}-\hat{\Psi}_0$; then we have $\Delta(x^*)=0$ and

$$\delta\Delta<x\beta\Delta' \quad \text{on } (y,x^*). \tag{5.5}$$

Assume for contradiction that $\Delta(x)\ge 0$ for some $x\in(y,x^*)$; then $\Delta'(x)>0$, and so Δ becomes positive and thus by (5.5) continues to increase and will ultimately violate $\Delta(x^*)=0$. We conclude that $\Delta<0$, i.e., $\hat{\Psi}<\hat{\Psi}_0$, on (y,x^*). □

We end our analysis with an example illustrating Theorem 5.4.

Example 5.6. If $x\beta$ is concave and $\bar{q}$ is convex, we can solve the problem completely if $x(\beta-\delta)$ is increasing at 0 and has some stationary point, and that $\beta(0)>\delta$ and $\beta'(0^+)$ and $\bar{q}(0^+)$ are both finite. Then it is easy to verify that $x(\beta-\delta)/(\delta+\bar{q})$ also is increasing at 0 and has some stationary point; let x^* be the smallest one. Then for $x\le x^*$,

$$\psi(x)=x^*\cdot\frac{\beta(x^*)+\bar{q}(x^*)}{\delta+\bar{q}(x^*)}\exp\left\{\int_{x^*}^{x}\frac{\delta+\bar{q}(y)}{y(\beta(y)+\bar{q}(y))}\,dy\right\}. \tag{5.6}$$

It is easy to verify that the HJB equation holds, that $\psi'' \le 0$, and hence that $\psi' \ge \psi'(x^*) = 1$ and that Theorem 4.4 (b) applies. By (5.4), we can merely check sign $\bar{q}'(x^*)$ to find whether the optimal trigger is higher than in the deterministic case or not. As a special case, consider the logistic growth model

$$\beta(x) = \beta_0(1 - x/K) \tag{5.7}$$

(with $\beta_0 > \delta$) modified with a compensated annihilation term with intensity $\bar{q}(x)$ of the form $(q_0 + q_1 x)^+$ (convex); assume $\sigma = \hat{q} = \check{q} = 0$. Then $x_0^* = (\beta_0 - \delta)K/2\beta_0$. Assume that $\bar{q}(x^*) > 0$; one may verify that

$$x^* = \frac{\delta + q_0}{q_1}\left(-1 + \sqrt{1 + 2x_0^* \frac{q_1}{\delta + q_0}}\right). \tag{5.8}$$

We see that x^* is strictly decreasing in $(\delta + q_0)/q_1$; therefore, increasing both q_0 and q_1 simultaneously gives no information on whether x^* increases or decreases. We may also find the value function: For $x < x^*$,

$$\ln \Psi(x) = \begin{cases} \frac{\delta+q_0}{\beta_0+q_0} \ln x + \left(\frac{Kq_1}{Kq_1-\beta_0} - \frac{\delta+q_0}{\beta_0+q_0}\right) \ln(\beta_0 + q_0 + (q_1 - \frac{\beta_0}{K})x) \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{if } q_1 \ne \frac{\beta_0}{K}, \text{ and} \\ \frac{1}{\beta_0+q_0}\left((\delta + q_0)\ln x + \frac{\beta_0}{K}x\right) \qquad \text{if } q_1 = \frac{\beta_0}{K}. \end{cases} \tag{5.9}$$

We omit the details.

6. Closing remarks. We have seen that even in this simple model, the optimal strategy may adapt qualitatively differently to the introduction of a jump martingale compared to the introduction of Brownian noise to the model. The result suggests that one should be careful about how one models uncertainty. We have also seen that the property of increasing trigger value $\hat{x}$ is related not solely to the Brownian motion assumption but to the applicability of a comparison theorem. Comparison means, roughly speaking, that by saving rather than harvesting, we do not risk losing more than what we save, while a general jump term may cost us more if we allow the population to grow to a state where the jumps are "worse." We therefore interpret Proposition 5.2 as *a tradeoff between noise level on one hand, and on the other hand exposure to risk of falling to a lower level.* Speaking heuristically, the assertion that "risk leads to higher trigger level" is now modified by adding "as long as it does not become risky to increase the trigger level"—a reservation which is redundant under continuity or comparison.

From [2], we know that if we consider problems indexed by the Brownian volatility, as $\{\ell\sigma\}_{\ell \ge 0}$, then under suitable assumptions we have x^* monotonically increasing in ℓ. We have now established that introducing a pure jump Markov martingale to a deterministic model may either reduce or increase the optimal trigger x^*, and one may want to ask, If we introduce jump intensities $\{\ell q\}_{\ell \ge 0}$, for what q is x^* monotone with respect to ℓ? And, ultimately, for what $\{(\ell\sigma, \ell q)\}$ is x^* monotone in ℓ? These are topics for future research.

MARKOWITZ'S MEAN-VARIANCE PORTFOLIO SELECTION WITH REGIME SWITCHING: A CONTINUOUS-TIME MODEL*

XUN YU ZHOU† AND G. YIN‡

Abstract. A continuous-time version of the Markowitz mean-variance portfolio selection model is proposed and analyzed for a market consisting of one bank account and multiple stocks. The market parameters, including the bank interest rate and the appreciation and volatility rates of the stocks, depend on the market mode that switches among a finite number of states. The random regime switching is assumed to be independent of the underlying Brownian motion. This essentially renders the underlying market *incomplete*. A Markov chain modulated diffusion formulation is employed to model the problem. Using techniques of stochastic linear-quadratic control, mean-variance efficient portfolios and efficient frontiers are derived explicitly in *closed forms*, based on solutions of two systems of linear ordinary differential equations. Related issues such as a minimum-variance portfolio and a mutual fund theorem are also addressed. All the results are markedly different from those for the case when there is no regime switching. An interesting observation is, however, that if the interest rate is deterministic, then the results exhibit (rather unexpected) similarity to their no-regime-switching counterparts, even if the stock appreciation and volatility rates are Markov-modulated.

Key words. continuous time, regime switching, Markov chain, mean-variance, portfolio selection, efficient frontier, linear-quadratic control

1. Introduction.

Recently there has been an increasing interest in financial market models whose key parameters, such as the bank interest rate, stocks appreciation rates, and volatility rates, are modulated by some Markov processes. This is motivated by the need of more realistic models that better reflect random market environment. A factor that dominates the movement of a stock is the trend of the market. To reflect the market trend, it is necessary to allow the key parameters to respond to the general market movements. One such formulation is the regime switching model, where the market parameters depend on the market mode that switches among a finite number of states. The market mode could reflect the state of the underlying economy, the general mood of investors in the market, and other economic factors. For example, the market can be roughly divided as "bullish" and "bearish," while the market parameters can be quite different in the two modes. One could certainly introduce more intermediate states between the two extremes. A regime switching model can be formulated mathematically as a stochastic differential equation (SDE) whose coefficients are modulated by a continuous-time Markov chain. Such models have been mainly employed in the literature to deal with options; see Barone-Adesi and Whaley [1], Di Masi, Kabanov, and Runggaldier [6], Guo [10], Buffington and

Elliott [3], and Yao, Zhang, and Zhou [26]. In addition, recently Zhang [30] studied an optimal stock selling rule for a Markov-modulated Black–Scholes model (see also [27] for a stochastic optimization approach).

In this paper, we develop a continuous-time version of the Nobel prize winning mean-variance portfolio selection model with regime switching and attempt to derive closed-form solutions for efficient portfolios and efficient frontier. The mean-variance model was originally proposed by Markowitz [20, 21] for portfolio construction in a single period. One of the salient features of his model is as follows: It enables an investor to seek the highest return after specifying his/her acceptable risk level that is quantified by the variance of the return. The mean-variance approach has become the foundation of modern finance theory and has inspired numerous extensions and applications. One natural extension is to investigate *dynamic* mean-variance models. Along this line, multiperiod mean-variance portfolio selection was studied in, for example, Samuelson [23], Hakansson [11], and Pliska [22] among others. On the other hand, continuous-time mean-variance hedging problems were attacked by Duffie and Richardson [7] and Schweizer [24], where optimal dynamic strategies were derived, based on the projection theorem, to hedge contingent claims in incomplete markets. In [7], the result was derived under the assumption that all the coefficients (interest rate, volatility rate, etc.) are deterministic, time-invariant constants. The model considered in [24] is mathematically general; however, the solution is based on an abstract martingale measure and is thus not easily decipherable.

It should be noted that the research works on dynamic portfolio selections have been dominated by those of maximizing expected utility functions of the terminal wealth. In the utility model, besides the difficulty in eliciting utility functions from the investors, tradeoff between the risk and return is implicit, making an investment decision much less intuitive. In this sense, Markowitz's mean-variance approach has not been fully utilized in the utility approach.

Using the recently developed stochastic linear-quadratic (LQ) control framework [4, 5, 29], Zhou and Li [31] studied the mean-variance problem for a continuous-time model from another angel. By embedding the original (not readily solvable) problem into a tractable auxiliary problem, following a similar embedding technique introduced in Li and Ng [19] for the multiperiod model, it was shown that this auxiliary problem in fact is a stochastic optimal LQ problem and can be solved explicitly by LQ theory. Such an approach establishes a natural connection of the portfolio selection problems and standard stochastic control models. The theory of stochastic control is rich, and many mathematical machineries are available; see Fleming and Soner [9] and Yong and Zhou [29], which provides an opportunity for treating more complicated situations. For example, a portfolio selection problem with random coefficients was solved in [16] using LQ theory and backward SDEs, a problem with short sell prohibition was studied in [15] via LQ and viscosity solution theories, and a mean-variance hedging problem was treated in [12] within the LQ framework.

In this work, we focus on a continuous-time mean-variance model modulated by a Markov chain representing the regime switching. The random switching of the market modes is assumed to be independent of the Brownian motion in defining the stock prices. Therefore, the underlying market is essentially incomplete, as the regime switching constitutes an additional dimension of uncertainty that cannot be perfectly hedged by any combination of the stocks and the bank account. We formulate the problem as a Markov-modulated stochastic LQ control model with a terminal

constraint representing the expected payoff of the investor. The feasibility due to the constraint is first addressed under a very mild condition. Then, using Lagrange multiplier techniques, the problem is converted to an unconstrained problem. We proceed with the solution of the unconstrained problem based on two systems of ordinary differential equations (ODEs). This leads to the analytic expressions of the efficient portfolios in a feedback form as well as the efficient frontier. In addition, the minimum variance is explicitly derived. In fact, one needs only to solve two systems of linear ODEs in order to completely determine the efficient portfolios/frontier of the underlying mean-variance problem. It is interesting, though rather expected, that the efficient frontier is no longer a straight line in the mean-standard deviation diagram. However, if the interest rate is independent of the Markov chain, then the efficient frontier becomes a straight line again, and the one-fund theorem is preserved, even if the appreciation and volatility rates of the stocks are random (i.e., Markov-modulated).

It should be noted that in our model the wealth process is allowed to take negative values, representing the bankruptcy situation. This is due to our definition of admissible portfolios. (A portfolio is defined to be a vector consisting of the dollar values of different stocks.) In most of the literature, a portfolio contains the *fractions* of wealth in stocks, which *automatically* ensures the positivity of the wealth process (see Remark 1). In our model, requiring a nonnegative wealth process imposes an *additional state constraint*, which is a very difficult problem from the stochastic control point of view. We are not able to treat such a case in this paper and will defer it to later consideration. We remark that portfolio selection problems with constraints on wealth have been studied by many researchers, mostly in the realm of utility optimization. In particular, Korn and Trautmann considered in [14], for the first time, a mean-variance problem with nonnegative terminal constraint and without regime switching; see also Korn [13, Chapter 4]. The basic idea presented in these references is to reduce the problem to one finding an optimal attainable terminal wealth, the latter being a quadratic optimization problem. Then the efficient portfolio is the one that duplicates the optimal attainable terminal wealth.

The rest of the paper is arranged as follows. Section 2 begins with the precise problem formulation. Section 3 is concerned with the feasibility issue of the underlying model. Section 4 proceeds with the solution of the unconstrained optimization problem. The efficient frontier is obtained in section 5. Section 6 specializes in the case when the interest rate is independent of the modulating Markov chain. Finally, concluding remarks are made in the last section.

2. Problem formulation. Throughout the paper, let $(\Omega, \mathcal{F}, P)$ be a fixed complete probability space on which are defined a standard d-dimensional Brownian motion $W(t) \equiv (W_1(t), \dots, W_d(t))'$ and a continuous-time stationary Markov chain $\alpha(t)$ taking value in a finite state space $\mathcal{M} = \{1, 2, \dots, l\}$ such that $W(t)$ and $\alpha(t)$ are independent of each other. The Markov chain has a generator $Q = (q_{ij})_{l\times l}$ and stationary transition probabilities

$$p_{ij}(t) = P(\alpha(t) = j | \alpha(0) = i), \quad t \geq 0, \quad i, j = 1, 2, \dots, l. \tag{2.1}$$

Define $\mathcal{F}_t = \sigma\{W(s), \alpha(s) : 0 \leq s \leq t\}$. We denote by $L^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ the set of all $\mathbb{R}^m$-valued, measurable stochastic processes $f(t)$ adapted to $\{\mathcal{F}_t\}_{t\geq 0}$, such that $E\int_0^T |f(t)|^2 dt < +\infty$. We will also use the following notation.

Notation.

M':	the transpose of any vector or matrix M;
m_j:	the jth component of any vector M;
$\|M\|$:	$= \sqrt{\sum_{i,j} m_{ij}^2}$ for any matrix vector $M = (m_{ij})$ or $= \sqrt{\sum_j m_j^2}$ for any vector $M = (m_j)$;
$\mathrm{tr}(M)$:	the trace of a square matrix M;
$C([0,T];X)$:	the Banach space of X-valued continuous functions on $[0,T]$ endowed with the maximum norm $\|\cdot\|$ for a given Hilbert space X;
$C^2([0,T]\times\mathbb{R}^n)$:	the space of all twice continuously differentiable functions on $[0,T]\times\mathbb{R}^n$;
$L^2(0,T;X)$:	the Hilbert space of X-valued integrable functions on $[0,T]$ endowed with the norm $(\int_0^T \| f(t) \|_X^2 \, dt)^{\frac{1}{2}}$ for a given Hilbert space X.

Consider a market in which $d+1$ assets are traded continuously. One of the assets is a bank account whose price $P_0(t)$ is subject to the stochastic ODE

$$\begin{cases} dP_0(t) = r(t,\alpha(t))P_0(t)dt, \quad t \in [0,T], \\ P_0(0) = p_0 > 0, \end{cases} \tag{2.2}$$

where $r(t,i) \geq 0,\ i = 1,2,\ldots,l$, are given as the interest rate processes corresponding to different market modes. The other d assets are stocks whose price processes $P_m(t)$, $m = 1,2,\ldots,d$, satisfy the system of SDEs

$$\begin{cases} dP_m(t) = P_m(t)\left\{ b_m(t,\alpha(t))dt + \sum_{n=1}^{d} \sigma_{mn}(t,\alpha(t))dW_n(t) \right\}, \quad t \in [0,T], \\ P_m(0) = p_m > 0, \end{cases} \tag{2.3}$$

where for each $i = 1,2,\ldots,l$, $b_m(t,i)$ is the appreciation rate process and $\sigma_m(t,i) := (\sigma_{m1}(t,i),\ldots,\sigma_{md}(t,i))$ is the volatility or the dispersion rate process of the mth stock, corresponding to $\alpha(t) = i$.

Define the volatility matrix

$$\sigma(t,i) := \begin{pmatrix} \sigma_1(t,i) \\ \vdots \\ \sigma_d(t,i) \end{pmatrix} \equiv (\sigma_{mn}(t,i))_{d\times d} \quad \text{for each } i = 1,\ldots,l. \tag{2.4}$$

We assume throughout this paper that the nondegeneracy condition

$$\sigma(t,i)\sigma(t,i)' \geq \delta I \quad \forall t \in [0,T] \ \text{ and } \ i = 1,2,\ldots,l \tag{2.5}$$

is satisfied for some $\delta > 0$. We also assume that all the functions $r(t,i), b_m(t,i), \sigma_{mn}(t,i)$ are measurable and uniformly bounded in t.

Suppose that the initial market mode $\alpha(0) = i_0$. Consider an agent with an initial wealth $x_0 > 0$. These initial conditions are fixed throughout the paper. Denote by $x(t)$ the total wealth of the agent at time $t \geq 0$. Assuming that the trading of

shares takes place continuously and that transaction cost and consumptions are not considered, then one has (see, e.g., [29, p. 57])

$$\begin{cases} dx(t) &= \left\{ r(t,\alpha(t))x(t) + \sum_{m=1}^{d} \big[b_m(t,\alpha(t)) - r(t,\alpha(t))\big] u_m(t) \right\} dt \\ &\quad + \sum_{n=1}^{d}\sum_{m=1}^{d} \sigma_{mn}(t,\alpha(t)) u_m(t) dW_n(t), \\ x(0) &= x_0 > 0, \quad \alpha(0) = i_0, \end{cases} \tag{2.6}$$

where $u_m(t)$ is the total market value of the agent's wealth in the mth asset, $m = 0, 1, \ldots, d$, at time t. We call $u(\cdot) = (u_1(\cdot), \ldots, u_d(\cdot))'$ a *portfolio* of the agent. Note that once $u(\cdot)$ is determined, $u_0(\cdot)$, the asset in the bank account is completely specified since $u_0(t) = x(t) - \sum_{i=1}^{d} u_i(t)$. Thus, in our analysis to follow, only $u(\cdot)$ is considered.

Setting

$$B(t,i) := (b_1(t,i) - r(t,i), \ldots, b_d(t,i) - r(t,i)), \ i = 1, 2, \ldots, l, \tag{2.7}$$

we can rewrite the wealth equation (2.6) as

$$\begin{cases} dx(t) = [r(t,\alpha(t))x(t) + B(t,\alpha(t))u(t)]dt + u(t)'\sigma(t,\alpha(t))dW(t), \\ x(0) = x_0, \quad \alpha(0) = i_0. \end{cases} \tag{2.8}$$

Definition 2.1. *A portfolio $u(\cdot)$ is said to be admissible if $u(\cdot) \in L^2_{\mathcal{F}}(0,T;\mathbb{R}^d)$ and the SDE* (2.8) *has a unique solution $x(\cdot)$ corresponding to $u(\cdot)$. In this case, we refer to $(x(\cdot), u(\cdot))$ as an* admissible (wealth, portfolio) pair.

Remark 1. Most works in the literature define a portfolio, say, $\pi(\cdot)$, as the fractions of wealth allocated to different stocks. That is,

$$\pi(t) = \frac{u(t)}{x(t)}, \quad t \in [0,T]. \tag{2.9}$$

With this definition, (2.8) can be rewritten as

$$\begin{cases} dx(t) = x(t)[r(t,\alpha(t)) + B(t,\alpha(t))\pi(t)]dt + x(t)\pi(t)'\sigma(t,\alpha(t))dW(t), \\ x(0) = x_0, \quad \alpha(0) = i_0. \end{cases} \tag{2.10}$$

It is well known that this equation has a solution that can be expressed explicitly as an exponential of certain process, which therefore must be *automatically* positive if the initial wealth x_0 is positive. The reason for this guaranteed positivity of wealth is because the very definition of the portfolio, (2.9), has implicitly assumed that $x(t) \neq 0$; hence $x = 0$ becomes a natural barrier of the wealth process. It is our view, however, that a wealth process with possible zero or negative values is theoretically and practically sensible at least for some circumstances. Hence the nonnegativity of the wealth is better imposed as an *additional constraint*, rather than as a built-in feature, of the model. In our formulation, a portfolio is well defined even if the wealth is zero or negative, and the nonnegativity of the wealth, if so required, would be a constraint.

The agent's objective is to find an admissible portfolio $u(\cdot)$, among all the admissible portfolios whose expected terminal wealth is $Ex(T) = z$ for some given $z \in \mathbb{R}^1$, so that the risk measured by the variance of the terminal wealth

$$\text{Var } x(T) \equiv E[x(T) - Ex(T)]^2 = E[x(T) - z]^2 \tag{2.11}$$

is minimized. Finding such a portfolio $u(\cdot)$ is referred to as the *mean-variance portfolio selection problem.* Specifically, we have the following formulation.

DEFINITION 2.2. *The mean-variance portfolio selection is a constrained stochastic optimization problem, parameterized by* $z \in \mathbb{R}^1$*:*

$$\left\{ \begin{array}{ll} \textit{minimize} & J_{\mathrm{MV}}(x_0, i_0, u(\cdot)) := E[x(T) - z]^2, \\ \textit{subject to} & \left\{ \begin{array}{l} Ex(T) = z, \\ (x(\cdot), u(\cdot)) \quad \textit{admissible.} \end{array} \right. \end{array} \right. \tag{2.12}$$

Moreover, the problem is called feasible *if there is at least one portfolio satisfying all the constraints. The problem is called* finite *if it is feasible and the infimum of* $J_{\mathrm{MV}}(x_0, i_0, u(\cdot))$ *is finite. Finally, an optimal portfolio to the above problem, if it ever exists, is called an* efficient portfolio *corresponding to* z*, and the corresponding* $(\mathrm{Var}\ x(T), z) \in \mathbb{R}^2$ *and* $(\sigma_{x(T)}, z) \in \mathbb{R}^2$ *are interchangeably called an* efficient point*, where* $\sigma_{x(T)}$ *denotes the standard deviation of* $x(T)$*. The set of all the efficient points is called the* efficient frontier*.*

Remark 2. While in the above definition, an efficient portfolio is broadly defined for any given $z \in \mathbb{R}^1$; in the subsequent context we will see that it is practically sensible only for z greater than or equal to certain value. Also, the shape of the efficient frontier depends on whether it is plotted in the mean-variance plane or mean-standard deviation plane. In what follows, we will specify which one we are referring to only when ambiguity might arise.

Remark 3. The mean-variance portfolio selection problem may be defined in some different, albeit equivalent, ways. For example, in [31] the problem is formulated as a multiobjective optimization problem. It should be noted that the model in this paper is a faithful replication in form of the original Markowitz single-period model.

3. Feasibility. Since the problem (2.12) involves a terminal constraint $Ex(T) = z$, in this section, we derive conditions under which the problem is at least feasible. First, the following generalized Itô lemma [2] for Markov-modulated processes is useful.

LEMMA 3.1. *Given an* n*-dimensional process* $x(\cdot)$ *satisfying*

$$dx(t) = b(t, x(t), \alpha(t))dt + \sigma(t, x(t), \alpha(t))dW(t)$$

and a number of functions $\varphi(\cdot, \cdot, i) \in C^2([0, T] \times \mathbb{R}^n)$*,* $i = 1, 2, \ldots, l$*, we have*

$$d\varphi(t, x(t), \alpha(t)) = \Gamma\varphi(t, x(t), \alpha(t))dt + \varphi_x(t, x(t), \alpha(t))'\sigma(t, x(t), \alpha(t))dW(t),$$

where

$$\begin{aligned} \Gamma\varphi(t, x, i) := \quad & \varphi_t(t, x, i) + \varphi_x(t, x, i)'b(t, x, i) \\ & + \frac{1}{2}\mathrm{tr}[\sigma(t, x, i)'\varphi_{xx}(t, x, i)\sigma(t, x, i)] + \sum_{j=1}^{l} q_{ij}\varphi(t, x, j). \end{aligned}$$

Consider a portfolio $u^0(t) \equiv 0$, corresponding to the one that puts all the money in the bank account. The associated wealth process $x^0(\cdot)$ satisfies

$$\left\{ \begin{array}{l} dx^0(t) = r(t, \alpha(t))x^0(t)dt, \\ x^0(0) = x_0, \quad \alpha(0) = i_0, \end{array} \right. \tag{3.1}$$

with its expected terminal wealth

$$z^0 := Ex^0(T) = Ee^{\int_0^T r(s, \alpha(s))ds}x_0. \tag{3.2}$$

LEMMA 3.2. *Let $\psi(\cdot,i)$, $i=1,2,\dots,l$, be the solutions to the following system of linear ODEs:*

$$\begin{cases} \dot{\psi}(t,i) = -r(t,i)\psi(t,i) - \sum_{j=1}^{l} q_{ij}\psi(t,j), \\ \psi(T,i) = 1, \qquad i=1,2,\dots,l. \end{cases} \tag{3.3}$$

Then the mean-variance problem (2.12) *is feasible for every $z \in \mathbb{R}^1$ if and only if*

$$\gamma := E\int_0^T |\psi(t,\alpha(t))B(t,\alpha(t))|^2 dt > 0. \tag{3.4}$$

Proof. To prove the "if" part, construct a family of admissible portfolios $u^\beta(\cdot) = \beta u(\cdot)$ for $\beta \in \mathbb{R}^1$, where

$$u(t) = B(t,\alpha(t))'\psi(t,\alpha(t)). \tag{3.5}$$

Let $x^\beta(\cdot)$ be the wealth process corresponding to $u^\beta(\cdot)$. By linearity of the wealth equation, we have $x^\beta(t) = x^0(t) + \beta y(t)$, where $x^0(\cdot)$ satisfies (3.1) and $y(\cdot)$ is the solution to the following equation:

$$\begin{cases} dy(t) = [r(t,\alpha(t))y(t) + B(t,\alpha(t))u(t)]dt + u(t)'\sigma(t,\alpha(t))dW(t), \\ y(0) = 0, \quad \alpha(0) = i_0. \end{cases} \tag{3.6}$$

Therefore, problem (2.12) is feasible for every $z \in \mathbb{R}^1$ if there exists $\beta \in \mathbb{R}^1$ such that $z = Ex^\beta(T) \equiv Ex^0(T) + \beta Ey(T)$. Equivalently, (2.12) is feasible for every $z \in \mathbb{R}^1$ if $Ey(T) \neq 0$. However, applying the generalized Itô formula (Lemma 3.1) to $\varphi(t,x,i) = \psi(t,i)x$, we have

$$\begin{aligned} & d[\psi(t,\alpha(t))y(t)] \\ &= \Bigg\{ \psi(t,\alpha(t))[r(t,\alpha(t))y(t) + B(t,\alpha(t))u(t)]dt - r(t,\alpha(t))\psi(t,\alpha(t))y(t) \\ &\qquad - \sum_{j=1}^{l} q_{\alpha(t)j}\psi(t,j)y(t) \Bigg\} dt + \sum_{j=1}^{l} q_{\alpha(t)j}\psi(t,j)y(t)dt + \{\cdots\}dW(t) \\ &= \psi(t,\alpha(t))B(t,\alpha(t))u(t)dt + \{\cdots\}dW(t). \end{aligned}$$

Integrating from 0 to T, taking expectation, and using (3.5), we obtain

$$Ey(T) = E\int_0^T \psi(t,\alpha(t))B(t,\alpha(t))u(t)dt = E\int_0^T |\psi(t,\alpha(t))B(t,\alpha(t))|^2 dt. \tag{3.7}$$

Consequently, $Ey(T) \neq 0$ if (3.4) holds.

Conversely, suppose that problem (2.12) is feasible for every $z \in \mathbb{R}^1$. Then for each $z \in \mathbb{R}^1$, there is an admissible portfolio $u(\cdot)$ so that $Ex(T) = z$. However, we can always decompose $x(t) = x^0(t) + y(t)$, where $y(\cdot)$ satisfies (3.6). This leads to $Ex^0(T) + Ey(T) = z$. However, $Ex^0(T) \equiv z_0$ is independent of $u(\cdot)$; thus it is necessary that there is a $u(\cdot)$ with $Ey(T) \neq 0$. It follows then from (3.7) that (3.4) is valid. ∎

THEOREM 3.3. *The mean-variance problem* (2.12) *is feasible for every* $z \in \mathbb{R}^1$ *if and only if*

$$E\int_0^T |B(t,\alpha(t))|^2 dt > 0. \tag{3.8}$$

Proof. By virtue of Lemma 3.2, it suffices to prove that $\psi(t,i) > 0$ for all $t \in [0,T]$, $i = 1,2,\dots,l$. To this end, note that (3.3) can be rewritten as

$$\begin{cases} \dot{\psi}(t,i) = [-r(t,i) - q_{ii}]\,\psi(t,i) - \displaystyle\sum_{j\neq i}^{l} q_{ij}\psi(t,j), \\ \psi(T,i) = 1, \quad i = 1,2,\dots,l. \end{cases} \tag{3.9}$$

Treating this as a system of terminal-valued ODEs, a variation-of-constant formula yields

(3.10)

$$\psi(t,i) = e^{-\int_t^T [-r(s,i)-q_{ii}]ds} + \int_t^T e^{-\int_t^s [-r(\tau,i)-q_{ii}]d\tau} \sum_{j\neq i}^{l} q_{ij}\psi(s,j)ds,\ i = 1,2,\dots,l.$$

Construct a sequence $\{\psi^{(k)}(\cdot,i)\}$ (known as the Picard sequence) as follows:

$$\begin{aligned} &\psi^{(0)}(t,i) = 1,\ t \in [0,T],\ i = 1,2,\dots,l, \\ &\psi^{(k+1)}(t,i) = e^{-\int_t^T [-r(s,i)-q_{ii}]ds} + \int_t^T e^{-\int_t^s [-r(\tau,i)-q_{ii}]d\tau} \sum_{j\neq i}^{l} q_{ij}\psi^{(k)}(s,j)ds,\ t \in [0,T], \\ &\qquad\qquad i = 1,2,\dots,l,\ k = 0,1,\dots. \end{aligned}$$

Noting that $q_{ij} \geq 0$ for all $j \neq i$, we have

$$\psi^{(k)}(t,i) \geq e^{-\int_t^T [-r(s,i)-q_{ii}]ds} > 0,\ k = 0,1,\dots.$$

On the other hand, it is well known that $\psi(t,i)$ is the limit of the Picard sequence $\{\psi^{(k)}(t,i)\}$ as $k \to \infty$. Thus $\psi(t,i) > 0$. This proves the desired result. □

COROLLARY 3.4. *If* (3.8) *holds, then for any* $z \in \mathbb{R}^1$, *an admissible portfolio that satisfies* $Ex(T) = z$ *is given by*

$$u(t) = \frac{z - z^0}{\gamma} B(t,\alpha(t))'\psi(t,\alpha(t)), \tag{3.11}$$

where z^0 *and* γ *are given by* (3.2) *and* (3.4), *respectively.*

Proof. This is immediate from the proof of the "if" part of Lemma 3.2. □

COROLLARY 3.5. *If* $E\int_0^T |B(t,\alpha(t))|^2 dt = 0$, *then any admissible portfolio* $u(\cdot)$ *results in* $Ex(T) = z^0$.

Proof. This is seen from the proof of the "only if" part of Lemma 3.2. □

Remark 4. The condition (3.8) is very mild. For example, (3.8) holds as long as there is one stock whose appreciation-rate process is different from the interest-rate process at any market mode, which is obviously a practically reasonable assumption. On the other hand, if (3.8) fails, then Corollary 3.5 implies that the mean-variance problem (2.12) is feasible only if $z = z^0$. This is a pathological and trivial case that

does not warrant further consideration. Therefore, from this point on we shall assume that (3.8) holds or, equivalently, that the mean-variance problem (2.12) is feasible for any z.

Having addressed the issue of feasibility, we proceed with the study of optimality. The mean-variance problem (2.12) under consideration is a dynamic optimization problem with a constraint $Ex(T) = z$. To handle this constraint, we apply the Lagrange multiplier technique. Define

$$\begin{aligned} J(x_0, i_0, u(\cdot), \lambda) :=& \quad E\big\{|x(T) - z|^2 + 2\lambda[x(T) - z]\big\} \\ =& \quad E[x(T) + \lambda - z]^2 - \lambda^2, \qquad \lambda \in \mathbb{R}^1. \end{aligned} \tag{3.12}$$

Our first goal is to solve the following unconstrained problem parameterized by the Lagrange multiplier λ:

$$\begin{cases} \text{minimize} & J(x_0, i_0, u(\cdot), \lambda) = E\big[x(T) + \lambda - z\big]^2 - \lambda^2 \\ \text{subject to} & (x(\cdot), u(\cdot)) \ \text{ admissible.} \end{cases} \tag{3.13}$$

This turns out to be a Markov-modulated stochastic LQ optimal control problem, which will be solved in the next section.

4. Solution to the unconstrained problem. In this section we solve the unconstrained problem (3.13). First define

$$\rho(t,i) := B(t,i)[\sigma(t,i)\sigma(t,i)']^{-1}B(t,i)', \ i = 1, 2, \ldots, l. \tag{4.1}$$

Consider the following two systems of ODEs:

$$\begin{cases} \dot{P}(t,i) = [\rho(t,i) - 2r(t,i)]\, P(t,i) - \displaystyle\sum_{j=1}^{l} q_{ij} P(t,j), \\ P(T,i) = 1, \quad i = 1, 2, \ldots, l, \end{cases} \tag{4.2}$$

and

$$\begin{cases} \dot{H}(t,i) = r(t,i)H(t,i) - \dfrac{1}{P(t,i)} \displaystyle\sum_{j=1}^{l} q_{ij} P(t,j)[H(t,j) - H(t,i)], \\ H(T,i) = 1, \quad i = 1, 2, \ldots, l. \end{cases} \tag{4.3}$$

The existence and uniqueness of solutions to the above two systems of equations are evident as both are linear with uniformly bounded coefficients.

PROPOSITION 4.1. *The solutions of* (4.2) *and* (4.3) *must satisfy* $P(t,i) > 0$ *and* $0 < H(t,i) \le 1$ *for all* $t \in [0,T]$, $i = 1, 2, \ldots, l$. *Moreover, if for a fixed* i, $r(t,i) > 0$ *a.e.* $t \in [0,T]$, *then* $H(t,i) < 1$ *for all* $t \in [0,T)$.

Proof. The assertion $P(t,i) > 0$ can be proved in exactly the same way as that of $\psi(t,i) > 0$; see the proof of Theorem 3.3. Having proved the positivity of $P(t,i)$, one can then show $H(t,i) > 0$ using the same argument because now $P(t,j)/P(t,i) > 0$.

To prove that $H(t,i) \le 1$, first note that the system of ODEs

$$\begin{cases} \dfrac{d}{dt}\widetilde{H}(t,i) = -\dfrac{1}{P(t,i)} \displaystyle\sum_{j=1}^{l} q_{ij} P(t,j)[\widetilde{H}(t,j) - \widetilde{H}(t,i)], \\ \widetilde{H}(T,i) = 1, \quad i = 1, 2, \ldots, l, \end{cases} \tag{4.4}$$

has the only solutions $\widetilde{H}(t,i) \equiv 1$, $i = 1, 2, \ldots, l$, due to the uniqueness of solutions. Set

$$\widehat{H}(t,i) := \widetilde{H}(t,i) - H(t,i) \equiv 1 - H(t,i),$$

which solves the following equations:

(4.5)
$$\begin{cases} \dfrac{d}{dt}\widehat{H}(t,i) &= r(t,i)\widehat{H}(t,i) - r(t,i) - \dfrac{1}{P(t,i)}\displaystyle\sum_{j=1}^{l} q_{ij}P(t,j)[\widehat{H}(t,j) - \widehat{H}(t,i)] \\ &= \left[r(t,i) + \displaystyle\sum_{j\neq i} q_{ij}\right]\widehat{H}(t,i) - r(t,i) - \dfrac{1}{P(t,i)}\displaystyle\sum_{j\neq i} q_{ij}P(t,j)\widehat{H}(t,j), \\ \widehat{H}(T,i) &= 0, \quad i = 1, 2, \ldots, l. \end{cases}$$

A variation-of-constant formula leads to

$$\widehat{H}(t,i) = \int_t^T e^{-\int_t^s [r(\tau,i) + \sum_{j\neq i} q_{ij}]d\tau} \left[r(s,i) + \frac{1}{P(s,i)}\sum_{j\neq i} q_{ij}P(s,j)\widehat{H}(s,j)\right]. \tag{4.6}$$

A similar trick using the construction of Picard's sequence yields that $\widehat{H}(t,i) \geq 0$. In addition, $\widehat{H}(t,i) > 0$ for all $t \in [0,T)$ if $r(t,i) > 0$ a.e. $t \in [0,T]$. The desired result then follows from the fact that $\widehat{H}(t,i) = 1 - H(t,i)$. □

Remark 5. Equation (4.2) is a Riccati-type equation that arises naturally in studying the stochastic LQ control problem (3.13), whereas (4.3) is used to handle the nonhomogeneous terms involved in (3.13); see the proof of Theorem 4.2 below. On the other hand, $H(t,i)$ has a financial interpretation: for fixed (t,i), $H(t,i)$ is a *deterministic* quantity representing the *risk-adjusted discount factor* at time t when the market mode is i (note that the interest rate itself is random); see also Remark 11 in what follows.

THEOREM 4.2. *Problem* (3.13) *has an optimal feedback control*

$$u^*(t,x,i) = -[\sigma(t,i)\sigma(t,i)']^{-1}B(t,i)'[x + (\lambda - z)H(t,i)]. \tag{4.7}$$

Moreover, the corresponding optimal value is

$$\begin{aligned} &\inf_{u(\cdot)\text{admissible}} J(x_0, i_0, u(\cdot), \lambda) \\ &\quad = [P(0,i_0)H(0,i_0)^2 + \theta - 1](\lambda - z)^2 \\ &\qquad +2[P(0,i_0)H(0,i_0)x_0 - z](\lambda - z) + P(0,i_0)x_0^2 - z^2, \end{aligned} \tag{4.8}$$

where

$$\begin{aligned} \theta &:= E\int_0^T \sum_{j=1}^{l} q_{\alpha(t)j}P(t,j)[H(t,j) - H(t,\alpha(t))]^2 dt \\ &= \sum_{i=1}^{l}\sum_{j=1}^{l}\int_0^T P(t,j)p_{i_0 i}(t)q_{ij}[H(t,j) - H(t,i)]^2 dt \geq 0, \end{aligned} \tag{4.9}$$

with the transition probabilities $p_{i_0 i}(t)$ *given by* (2.1).

Proof. Let $u(\cdot)$ be any admissible control and $x(\cdot)$ be the corresponding state trajectory of (2.8). Applying the generalized Itô formula (Lemma 3.1) to

$$\varphi(t,x,i) = P(t,i)[x+(\lambda-z)H(t,i)]^2,$$

we obtain

(4.10)

$$\begin{aligned}
&d\Big\{P(t,\alpha(t))[x(t)+(\lambda-z)H(t,\alpha(t))]^2\Big\}\\
&\quad= P(t,\alpha(t))\Big\{u(t)'[\sigma(t,\alpha(t))\sigma(t,\alpha(t))']u(t)+2u(t)'B(t,\alpha(t))'[x(t)+(\lambda-z)H(t,\alpha(t))]\\
&\qquad+2r(t,\alpha(t))[x(t)+(\lambda-z)H(t,\alpha(t))]^2\Big\}dt\\
&\qquad-2(\lambda-z)[x(t)+(\lambda-z)H(t,\alpha(t))]\sum_{j=1}^{l}q_{\alpha(t)j}P(t,j)[H(t,j)-H(t,\alpha(t))]dt\\
&\qquad+[\rho(t,\alpha(t))-2r(t,\alpha(t))]P(t,\alpha(t))[x(t)+(\lambda-z)H(t,\alpha(t))]^2dt\\
&\qquad-\sum_{j=1}^{l}q_{\alpha(t)j}P(t,j)[x(t)+(\lambda-z)H(t,\alpha(t))]^2dt\\
&\qquad+\sum_{j=1}^{l}q_{\alpha(t)j}P(t,j)[x(t)+(\lambda-z)H(t,j)]^2dt+\{\cdots\}dW(t)\\
&\quad= P(t,\alpha(t))\Big\{u(t)'[\sigma(t,\alpha(t))\sigma(t,\alpha(t))']u(t)+2u(t)'B(t,\alpha(t))'[x(t)+(\lambda-z)H(t,\alpha(t))]\\
&\qquad+\rho(t,\alpha(t))[x(t)+(\lambda-z)H(t,\alpha(t))]^2\Big\}dt\\
&\qquad+(\lambda-z)^2\sum_{j=1}^{l}q_{\alpha(t)j}P(t,j)[H(t,j)-H(t,\alpha(t))]^2dt+\{\cdots\}dW(t)\\
&\quad= P(t,\alpha(t))[u(t)-u^*(t,x(t),\alpha(t))]'[\sigma(t,\alpha(t))\sigma(t,\alpha(t))'][u(t)-u^*(t,x(t),\alpha(t))]dt\\
&\qquad+(\lambda-z)^2\sum_{j=1}^{l}q_{\alpha(t)j}P(t,j)[H(t,j)-H(t,\alpha(t))]^2dt+\{\cdots\}dW(t),
\end{aligned}$$

where $u^*(t,x,i)$ is defined as the right-hand side of (4.7). Integrating the above from 0 to T and taking expectations, we obtain

$$\begin{aligned}
&E[x(T)+\lambda-z]^2\\
&\quad= P(0,i_0)[x_0+(\lambda-z)H(0,i_0)]^2+\theta(\lambda-z)^2\\
&\qquad+E\int_0^T P(t,\alpha(t))[u(t)-u^*(t,x(t),\alpha(t))]'[\sigma(t,\alpha(t))\sigma(t,\alpha(t))']\\
&\qquad\quad\times[u(t)-u^*(t,x(t),\alpha(t))]dt.
\end{aligned}\tag{4.11}$$

Consequently,

$$\begin{aligned}
&J(x_0,i_0,u(\cdot),\lambda)\\
&\quad= E[x(T)+\lambda-z]^2-\lambda^2\\
&\quad= [P(0,i_0)H(0,i_0)^2+\theta-1](\lambda-z)^2+2[P(0,i_0)H(0,i_0)x_0-z](\lambda-z)\\
&\qquad+P(0,i_0)x_0^2-z^2\\
&\qquad+E\int_0^T P(t,\alpha(t))[u(t)-u^*(t,x(t),\alpha(t))]'[\sigma(t,\alpha(t))\sigma(t,\alpha(t))']\\
&\qquad\qquad\cdot[u(t)-u^*(t,x(t),\alpha(t))]dt.
\end{aligned}\tag{4.12}$$

Since $P(t,\alpha(t)) > 0$ by Proposition 3.1, it follows immediately that the optimal feedback control is given by (4.7) and the optimal value is given by (4.8), provided that the corresponding equation (2.8) under the feedback control (4.7) has a solution. However, under (4.7), the system (2.8) is a nonhomogeneous linear SDE with coefficients modulated by $\alpha(t)$. Since all the coefficients of this linear equation are uniformly bounded and $\alpha(t)$ is independent of $W(t)$, the existence and uniqueness of the solution to the equation are straightforward based on a standard successive approximation scheme.

Finally, since

$$\theta = \sum_{i \neq j} \int_0^T P(t,j) p_{i_0 i}(t) q_{ij} [H(t,j) - H(t,i)]^2 dt$$

and $q_{ij} \geq 0$ for all $i \neq j$, we must have $\theta \geq 0$. This completes the proof. □

5. Efficient frontier. In this section we proceed to derive the efficient frontier for the original mean-variance problem (2.12).

THEOREM 5.1 (efficient portfolios and efficient frontier). *Assume that* (3.8) *holds. Then we have*

$$P(0,i_0)H(0,i_0)^2 + \theta - 1 < 0. \tag{5.1}$$

Moreover, the efficient portfolio corresponding to z, as a function of the time t, the wealth level x, and the market mode i, is

$$u^*(t,x,i) = -[\sigma(t,i)\sigma(t,i)']^{-1} B(t,i)'[x + (\lambda^* - z)H(t,i)], \tag{5.2}$$

where

$$\lambda^* - z = \frac{z - P(0,i_0)H(0,i_0)x_0}{P(0,i_0)H(0,i_0)^2 + \theta - 1}. \tag{5.3}$$

Furthermore, the optimal value of Var $x(T)$*, among all the wealth processes $x(\cdot)$ satisfying $Ex(T) = z$, is*

$$\begin{aligned} &\text{Var } x^*(T) \\ &\quad = \frac{P(0,i_0)H(0,i_0)^2 + \theta}{1 - \theta - P(0,i_0)H(0,i_0)^2} \left[z - \frac{P(0,i_0)H(0,i_0)}{P(0,i_0)H(0,i_0)^2 + \theta} x_0 \right]^2 \\ &\qquad + \frac{P(0,i_0)\theta}{P(0,i_0)H(0,i_0)^2 + \theta} x_0^2. \end{aligned} \tag{5.4}$$

Proof. By assumption (3.8) and Theorem 3.3, the mean-variance problem (2.12) is feasible for any $z \in \mathbb{R}^1$. Moreover, using exactly the same approach as in the proof of Theorem 4.2, one can show that problem (2.12) *without* the constraint $Ex(T) = z$ must have a finite optimal value; hence so does the problem (2.12). Therefore, (2.12) is finite for any $z \in \mathbb{R}^1$. Since $J_{\text{MV}}(x_0, i_0, \pi(\cdot))$ is strictly convex in $u(\cdot)$ and the constraint function $Ex(T) - z$ is affine in $u(\cdot)$, we can apply the well-known duality theorem (see, e.g., [17, p. 224, Theorem 1][1]) to conclude that for any $z \in \mathbb{R}^1$, the

[1]To be precise, one should apply [17, p. 236, Problem 7] together with the proof of [17, p. 224, Theorem 1] in our case, as there is an *equality* constraint, $Ex(T) = z$, in (2.12). To be able to use the result there, one needs to check a condition posed in [17, p. 236, Problem 7]; namely, 0 is an interior point of the set $\mathcal{T} := \{Ex(T) - z | x(\cdot)$ is the wealth process of an admissible portfolio $u(\cdot)\}$. In the present case this condition is implied by Theorem 3.3, which essentially yields that $\mathcal{T} = \mathbb{R}^1$.

optimal value of (2.12) is

$$J^*_{\mathrm{MV}}(x_0,i_0)=\sup_{\lambda\in\mathbb{R}^1}\ \inf_{u(\cdot)\ \text{admissible}} J(x_0,i_0,u(\cdot),\lambda)>-\infty. \tag{5.5}$$

By Theorem 4.2, $\inf_{u(\cdot)\ \text{admissible}} J(x_0,i_0,u(\cdot),\lambda)$ is a quadratic function (4.8) in $\lambda-z$. It follows from the finiteness of the supremum value of this quadratic function (see (5.5)) that

$$P(0,i_0)H(0,i_0)^2+\theta-1\le 0.$$

Now, if

$$P(0,i_0)H(0,i_0)^2+\theta-1=0,$$

then again by Theorem 4.2 and (5.5) we must have

$$P(0,i_0)H(0,i_0)x_0-z=0$$

for every $z\in\mathbb{R}^1$, which is a contradiction. This proves (5.1). On the other hand, in view of (5.5), we maximize the quadratic function (4.8) over $\lambda-z$ and conclude that the maximizer is given by (5.3), whereas the maximum value is given by the right-hand side of (5.4). Finally, the optimal control (5.2) is obtained by (4.7) with $\lambda=\lambda^*$. □

The efficient frontier (5.4) reveals explicitly the tradeoff between the mean (return) and variance (risk) at the terminal. Quite contrary to the case without Markovian jumps [31], the efficient frontier in the present case is no longer a perfect square (or, equivalently, the efficient frontier in the mean-standard deviation diagram is no longer a straight line). As a consequence, one is not able to achieve a risk-free investment. This, certainly, is expected since now the interest rate process is modulated by the Markov chain, and the interest rate risk cannot be perfectly hedged by any portfolio consisting of the bank account and stocks (as with the case studied in [16]) because the Markov chain is independent of the Brownian motion.

Nevertheless, the expression (5.4) does disclose the *minimum variance*, namely, the minimum possible terminal variance achievable by an admissible portfolio, along with the portfolio that attains this minimum variance.

THEOREM 5.2 (minimum variance). *The minimum terminal variance is*

$$\mathrm{Var}\ x^*_{\min}(T)=\frac{P(0,i_0)\theta}{P(0,i_0)H(0,i_0)^2+\theta}x_0^2\ge 0 \tag{5.6}$$

with the corresponding expected terminal wealth

$$z_{\min}:=\frac{P(0,i_0)H(0,i_0)}{P(0,i_0)H(0,i_0)^2+\theta}x_0 \tag{5.7}$$

and the corresponding Lagrange multiplier $\lambda^*_{\min}=0$. *Moreover, the portfolio that achieves the above minimum variance, as a function of the time* t, *the wealth level* x, *and the market mode* i, *is*

$$u^*_{\min}(t,x,i)=-[\sigma(t,i)\sigma(t,i)']^{-1}B(t,i)'[x-z_{\min}H(t,i)]. \tag{5.8}$$

Proof. The conclusions regarding (5.6) and (5.7) are evident in view of the efficient frontier (5.4). The assertion $\lambda^*_{\min}=0$ can be verified via (5.3) and (5.7). Finally, (5.8) follows from (5.2). □

Remark 6. As a consequence of the above theorem, the parameter z can be restricted to $z \geq z_{\min}$ when one defines the efficient frontier for the mean-variance problem (2.12).

THEOREM 5.3 (mutual fund theorem). *Suppose an efficient portfolio $u_1^*(\cdot)$ is given by* (5.2) *corresponding to $z = z_1 > z_{\min}$. Then a portfolio $u^*(\cdot)$ is efficient if and only if there is a $\mu \geq 0$ such that*

$$u^*(t) = (1-\mu)u^*_{\min}(t) + \mu u_1^*(t), \quad t \in [0,T], \tag{5.9}$$

where $u^*_{\min}(\cdot)$ is the minimum variance portfolio defined in Theorem 5.2.

Proof. We first prove the "if" part. Since both $u^*_{\min}(\cdot)$ and $u_1^*(\cdot)$ are efficient, by the explicit expression of any efficient portfolio given by (5.2), $u^*(t) = (1-\mu)u_0^*(\cdot) + \mu u_1^*(t)$ must be in the form of (5.2) corresponding to $z = (1-\mu)z_{\min} + \mu z_1$ (also noting that $x^*(\cdot)$ is linear in $u^*(\cdot)$). Hence $u^*(\cdot)$ must be efficient.

Conversely, suppose $u^*(\cdot)$ is efficient corresponding to a certain $z \geq z_{\min}$. Write $z = (1-\mu)z_{\min} + \mu z_1$ with some $\mu \geq 0$. Multiplying

$$u^*_{\min}(t) = -[\sigma(t,\alpha(t))\sigma(t,\alpha(t))']^{-1}B(t,\alpha(t))'[x^*_{\min}(t) - z_{\min}H(t,\alpha(t))]$$

by $(1-\mu)$, multiplying

$$u_1^*(t) = -[\sigma(t,\alpha(t))\sigma(t,\alpha(t))']^{-1}B(t,\alpha(t))'[x_1^*(t) + (\lambda_1^* - z_1)H(t,\alpha(t))]$$

by μ, and summing them up, we obtain that $(1-\mu)u^*_{\min}(t) + \mu u_1^*(t)$ is represented by (5.2) with $x^*(t) = (1-\mu)x^*_{\min}(t) + \mu x_1^*(t)$ and $z = (1-\mu)z_{\min} + \mu z_1$. This leads to (5.9). □

Remark 7. The above mutual fund theorem implies that any investor needs only to invest in the minimum variance portfolio and another prespecified efficient portfolio in order to achieve the efficiency. Note that in the case where all the market parameters are deterministic [31], the corresponding mutual fund theorem becomes the *one-fund theorem*, which yields that any efficient portfolio is a combination of the bank account and a given efficient risky portfolio (known as the *tangent fund*). This is equivalent to the fact that the fractions of wealth among the stocks are the same among all efficient portfolios. However, in the present Markov-modulated case, this feature is no longer available.

6. A special case: Interest rate unaffected by the Markov chain. In this section we consider a special case where the interest-rate process does not respond to the change in the market mode, namely, $r(t,i) = r(t)$ for any $i = 1,2,\ldots,l$, whereas the appreciation-rate and volatility-rate processes still do. This stems from the situations where substantial changes in the interest-rate process are much less frequent than those in the other processes. For example, the interest rate may typically change on a bimonthly, or even less often, basis, whereas the stock market mode may switch on a weekly, or more frequent, basis. It turns out that the results obtained in the previous sections can be substantially simplified in this case.

The key to the simplification is that when $r(t,i) = r(t)$, the only solutions to (4.3) are

$$H(t,i) = e^{-\int_t^T r(s)ds} \quad \forall i = 1,2,\ldots,l \tag{6.1}$$

due to the uniqueness of solutions to (4.3). It follows then from (4.9) that

$$\theta = 0. \tag{6.2}$$

As a result, Theorem 5.1 reduces to the following result.

THEOREM 6.1. *Assume that* (3.8) *holds and that* $r(t,i) = r(t)$ *for all* $i = 1,2,\ldots,l$. *Then we must have*

$$P(0,i_0) < e^{2\int_0^T r(s)ds}. \tag{6.3}$$

Moreover, the efficient portfolio corresponding to z, *as a function of the time* t, *the wealth level* x, *and the market mode* i, *is*

$$u^*(t,x,i) = -[\sigma(t,i)\sigma(t,i)']^{-1}B(t,i)'[x + (\lambda^* - z)e^{-\int_t^T r(s)ds}], \tag{6.4}$$

where

$$\lambda^* - z = \frac{z - P(0,i_0)e^{-\int_0^T r(s)ds}x_0}{P(0,i_0)e^{-2\int_0^T r(s)ds} - 1}. \tag{6.5}$$

Furthermore, the optimal value of $\operatorname{Var} x(T)$, *among all the wealth processes* $x(\cdot)$ *satisfying* $Ex(T) = z$, *is*

$$\operatorname{Var} x^*(T) = \frac{P(0,i_0)e^{-2\int_0^T r(s)ds}}{1 - P(0,i_0)e^{-2\int_0^T r(s)ds}}\left[z - e^{\int_0^T r(s)ds}x_0\right]^2. \tag{6.6}$$

Proof. This is straightforward by Theorem 5.1, together with (6.1) and (6.2). □

Remark 8. Note that in this case the efficient frontier involves a perfect square, even if the market parameters of the stocks are all random. The *capital market line* (see, e.g., [18]) in the mean-standard deviation diagram is

$$Ex^*(T) = e^{\int_0^T r(t)dt}x_0 + \sqrt{\frac{1 - P(0,i_0)e^{-2\int_0^T r(s)ds}}{P(0,i_0)e^{-2\int_0^T r(s)ds}}}\sigma_{x^*(T)}. \tag{6.7}$$

Therefore, the price of risk is given by

$$p = \sqrt{\frac{1 - P(0,i_0)e^{-2\int_0^T r(s)ds}}{P(0,i_0)e^{-2\int_0^T r(s)ds}}},$$

which depends only on the initial market mode i_0.

Remark 9. Clearly the minimum terminal variance in this case is zero, corresponding to putting all the money in the bank account. Moreover, $z_{\min} = e^{\int_0^T r(t)dt}x_0$. Consequently, the mutual fund theorem (Theorem 5.3) specifies that any efficient portfolio is a combination of the bank account and a given efficient portfolio. In other words, the one-fund theorem is valid in this case. In particular, the proportions of the stocks in all the efficient portfolios are the same under a particular market mode, irrespective of the wealth level and risk preference of the investors. This, in turn, will lead to the so-called market portfolio and *capital asset pricing model* (CAPM); see [18].

Remark 10. If we further assume that all the appreciation-rate and volatility-rate processes are independent of the market mode i, then $P(t,i) = e^{-\int_0^T[\rho(s)-2r(s)]ds}$ for each $i = 1,2,\ldots,l$ are the only solutions to (4.2). In this case, all the results reduce to those of [31].

Remark 11. We see from (6.1) that the functions $H(t,i)$, which are keys in our main results Theorems 5.1–5.3, are nothing else than a generalization of the discount factor between the present time to the terminal time under different market modes. Note that Proposition 4.1 stipulates that if the interest rate $r(t,i) > 0$ for a mode i, then the corresponding $H(t,i) < 1$, representing a genuine discount.

7. Concluding remarks. We have developed mean-variance optimal portfolio selection for a market with regime switching. The formulation allows the market to have random switching among a finite number of possible configurations that are modulated by a continuous-time Markov chain. Such a setup takes into consideration the discrete changes in a regime across which the behavior of the corresponding market could be markedly different. Our main effort has been devoted to obtaining efficient portfolios and an efficient frontier. It is interesting to note that for the Markov-modulated model, the efficient frontier is no longer a perfect square, except in the case when the interest rate is independent of the Markov chain.

There are several interesting problems that deserve further investigation. One is a model with nonnegativity constraints on the terminal wealth. As discussed earlier, this would render a stochastic LQ control problem with a sample-wise state constraint, which is a very challenging problem. Another problem is one with transaction costs. Although with the rapidly growing use of on-line trading, transaction costs nowadays represent a very small, if not at all negligible, portion of the total transacted values, the problem with transaction costs is theoretically interesting as it leads to a singular stochastic control problem whose solution would normally exhibit very different behavior than its no-transaction counterpart. In particular, with transaction costs optimal strategies would no longer be continuously trading strategies as opposed to the no-transaction case. In some sense, one motivation of introducing the transaction costs is to limit the changes in the optimal strategy. Indeed, Soner and Touzi [25] considered a market, in the absence of transaction costs, with the so-called gamma constraints in order to restrict the unbounded variation of the portfolios under consideration. Yet another problem is to remove the assumption that the Markov chain is independent of the underlying Brownian motion. Note that the mean-variance portfolio selection with the Brownian motion adapted random market coefficients has been completely solved in [16]. The model of this paper represents another "extreme" where the random coefficients are entirely independent of the Brownian motion. A more general model where the randomness in the coefficients is neither adapted to nor independent of the Brownian motion may be tackled by decomposing the problem into the two extremes that have been solved. On the other hand, the Markov chain describing the regime switching is assumed to be *completely* observable in this paper. A more realistic and theoretically interesting model is that the Markov chain is "hidden" and only partially observable through the stock prices. In this case, one needs to first perform filtering in order to estimate the state of the current regime before making efficient investment strategies. In [8], Elliott, Malcolm, and Tsoi developed schemes to estimate the appreciation rate, the volatility, and the generator of the underlying Markov chain. Estimates of the generator were also obtained via the stochastic approximation method in [28]. These estimation techniques may be used in conjunction with the portfolio selection approach presented in this work. Finally, a corresponding discrete-time model will be useful in the actual computing. In addition, to take into consideration that the Markov chain may have a large state space, an interesting problem is to reduce complexity via a singular perturbation approach.

Acknowledgments. We thank the editors and three reviewers for their helpful comments and suggestions on an earlier version of the paper.

THE OPTIMAL TIME CONTROL OF A PHASE-FIELD SYSTEM*

LIJUAN WANG† AND GENGSHENG WANG†

Abstract. In this paper, we prove the existence of the optimal time control of a phase-field system by using the Carleman inequality, and we establish the maximum principle for the optimal time control problem governed by the phase-field system.

Key words. optimal time control, phase-field system, Carleman inequality, maximum principle

1. Introduction.

We shall consider the controlled phase-field system

$$
\begin{cases}
u_t(x,t) + lh_t(x,t) - k\triangle u(x,t) = m(x)w(x,t) + f_1(x) \\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{in } Q_\infty = \Omega\times(0,\infty), \\
h_t(x,t) - a\triangle h(x,t) - b(h(x,t) - h^3(x,t)) - cu(x,t) \\
\qquad\qquad\qquad\qquad\qquad = m(x)v(x,t) + f_2(x) \quad \text{in } Q_\infty, \\
u(x,0) = u_0(x), \quad h(x,0) = h_0(x) \quad \text{in } \Omega, \\
u(x,t) = \overline{u}(x), \quad h(x,t) = \overline{h}(x) \qquad \text{on } \textstyle\sum_\infty = \partial\Omega\times(0,\infty),
\end{cases} \tag{1.1}
$$

where Ω is an open, bounded, and smooth set in R^n (of class C^2, for instance), $n = 1, 2, 3$, m is the characteristic function of an open subset ω of Ω, a, b, c, l, k are positive constants, u is the reduced temperature, h is the phase function defining the liquid or the solid phase, and $u_0(x), h_0(x), \overline{u}(x), \overline{v}(x), f_1$, and f_2 are given functions. Throughout this paper we shall denote $L^2(\Omega)$ by H with the usual norm denoted by $|\cdot|_2$, and we denote $H_0^1(\Omega)$ by V with the usual norm denoted by $\|\cdot\|_1$. We set $H^{2,1}(Q) = \{y \in L^2(0,T;H^2(\Omega)); y_t \in L^2(Q)\}$, where $Q = \Omega\times(0,T)$, and $H^1(0,T;H) = \{y \in L^2(0,T;H); y_t \in L^2(0,T;H)\}$. By identifying H with its own dual, we have $V \subset H \subset V^*$. $\langle\cdot,\cdot\rangle$ denotes the scalar product of H and the paring between V and V^*.

We assume that

(H_1) $u_0 \in H^1(\Omega)$, $h_0 \in H^2(\Omega)$, f_1 and $f_2 \in H$.

It is well known that (cf. [17]) under assumption (H_1), for each $T > 0$ and $w, v \in L^2(Q)$, where $Q = \Omega\times(0,T)$, system (1.1) has a unique solution $(u^{w,v}, h^{w,v}) \in H^{2,1}(Q)\times H^{2,1}(Q)$. For simplicity, we denote it by (u,h) if there is no ambiguity.

Throughout this paper, we let $(u_e, h_e) \in H^2(\Omega)\times H^2(\Omega)$ be a steady-state (equilibrium) solution to system (1.1), i.e.,

$$
\begin{cases}
-k\triangle u_e(x) = f_1(x) & \text{in } \Omega, \\
-a\triangle h_e(x) - b(h_e(x) - h_e^3(x)) - cu_e(x) = f_2(x) & \text{in } \Omega, \\
u_e(x) = \overline{u}(x), \qquad h_e(x) = \overline{h}(x) & \text{on } \partial\Omega.
\end{cases} \tag{1.2}
$$

†Mathematics Department and The Center for Optimal Control and Discrete Mathematics, Huazhong Normal University, Wuhan 430079, People's Republic of China (hepeijie@public.wh.hb.cn, wanggs@ ccnu.edu.cn).

Let $\rho > 0$ and $U_\rho = \{(w(x,t), v(x,t)) \in (L^\infty(0,\infty;H))^2 : |w(t)|_2, |v(t)|_2 \le \rho \text{ a.e. } t > 0\}$. U_ρ will be considered as the control set. We shall study the following optimal time control problem:

(P) $\inf\{ T : u^{w,v}(T) = u_e, h^{w,v}(T) = h_e, (w,v) \in U_\rho \}$.

We call $T^* \equiv \inf\{ T : u^{w,v}(T) = u_e, h^{w,v}(T) = h_e, (w,v) \in U_\rho \}$ the minimal time. A pair of controls $(w^*, v^*) \in U_\rho$ such that $u^*(T^*) = u_e$ and $h^*(T^*) = h_e$, where (u^*, h^*) is the solution of (1.1) corresponding to (w^*, v^*), is called a pair of optimal time controls, and (u^*, h^*) is called a pair of optimal time states. A pair of controls $(w,v) \in U_\rho$ is called admissible if there exists a $T > 0$ such that $u^{w,v}(T) = u_e$ and $h^{w,v}(T) = h_e$.

Phase-field system (1.1) models the phase transition of a large class of physical processes including the melting and solidification. The Stefan problem as well as other classical mathematical models of phase transition are limiting cases of system (1.1) (cf. [4], [6], and [17]). Physically, steady-state means that the system does not exchange energy and material with surroundings and every part of the system does not exchange energy and material with each other. When interface between solid and liquid does not move unless the system is perturbed, we say that the system (1.1) reaches its steady-state. Problem (P) is to ask a pair of controls such that the corresponding temperature and phase, which start from given temperature u_0 and phase h_0, reach the temperature u_e and phase h_e of steady-state, respectively, in the shortest time.

In this paper we study the existence of a pair of optimal time controls for problem (P) and the maximum principle of problem (P). As we know, in order to get the existence of a pair of optimal time controls, one needs to obtain the existence of a pair of admissible controls. In general, one proves the existence of an admissible control of optimal time control problem governed by parabolic systems by considering the feedback controller and the corresponding closed loop system (cf. [2], [3], and [16]). However, this method is not applicable to the phase-field system since it is quite difficult to analyze the corresponding closed loop system. The novelty of this paper is that it uses the Carleman inequality to show the existence of a pair of admissible controls. The Carleman inequality has been widely used to obtain local controllability or null controllability of parabolic differential systems, including the Navier–Stokes equation, the Boussinesq system, and the phase-field system (cf. [11], [5], and [20]). However, it seems that no one used such an inequality to obtain the existence of admissible control for an optimal time control problem governed by parabolic differential systems. We believe that the Carleman inequality will be greatly helpful to get the existence of admissible control for optimal time control problems governed by parabolic systems, since in the problem of controllability of parabolic systems, we are asked to find a control so that the corresponding trajectory of the system reaches a given state in a fixed time T, while in the problem of existence of admissible control for an optimal time control problem governed by a parabolic system, we are asked to find a control (in a bounded set in most cases) such that the corresponding trajectory of the system reaches a given state in some time T. The differences between them are that first the arriving time is fixed in the controllability problem, while it is not fixed in the optimal time control problem, and second, the controls in the controllability problem may not be in any bounded set, while the control set is bounded (in most cases) in the optimal time control problem. For other works concerning approximate and null controllability of linear and nonlinear parabolic systems, we refer the readers to [18], [13], [19], [15], [7], [14], [8], [9], [21],

[22], [12], [23], and [10]. These works give us effective ways to deal with different kinds of controllability problems governed by parabolic equations and systems. We believe that the method provided in this work can be widely used to obtain existence of admissible control for the optimal time control problem governed by parabolic systems.

It should be noted that in this paper, in order to obtain the existence of a pair of admissible controls, we put controls in both equations of the phase-field system (1.1), because the technique developed in this paper to obtain the existence of the admissible controls is based on the local controllability of the system. If we put a control only in the first equation of the system (1.1), then one needs the local null controllability to the following linearized system:

$$\begin{cases} y_t(x,t) - a\triangle y(x,t) + \xi(x,t)y(x,t) - cz(x,t) = 0 & \text{in } Q = \Omega \times (0,T), \\ z_t(x,t) - k\triangle z(x,t) + la\triangle y(x,t) - l\xi(x,t)y(x,t) + lcz(x,t) = m(x)w(x,t) & \text{in } Q, \\ y(x,0) = y^0(x), \quad z(x,0) = z^0(x) & \text{in } \Omega, \\ y(x,t) = z(x,t) = 0 & \text{on } \sum = \partial\Omega \times (0,T), \end{cases}$$

where $a, c, k, l, m(x)$ are given in (1.1), $\xi(x,t) \in L^\infty(Q), y^0(x) \in V$, and $z^0(x) \in V$. However, such local null controllability depends on the observability for the corresponding linear backward system, i.e.,

$$|p(0)|_2^2 + |q(0)|_2^2 \le C \int_{Q^\omega} q^2(x,t)\, dx\, dt$$

for all solutions (p,q) satisfying

$$\begin{cases} p_t(x,t) + (a\triangle - \xi(x,t))p(x,t) - (la\triangle - l\xi(x,t))q(x,t) = 0 & \text{in } Q, \\ q_t(x,t) + (k\triangle - lc)q(x,t) + cp(x,t) = 0 & \text{in } Q, \\ p(x,t) = q(x,t) = 0 & \text{on } \sum. \end{cases}$$

To the best of our knowledge, whether such observability holds is still an open problem. So we put two controls in both equations. However, we must mention that this is not completely natural, although it is needed for the theoretical analysis in this paper.

This paper is organized as follows. In section 2 we show the existence of a pair of optimal time controls, and in section 3 we obtain the maximum principle for problem (P).

2. Existence of optimal time control. In this section we shall prove the existence of a pair of optimal time controls if the initial datum (u_0, h_0) is close to (u_e, h_e). First, we apply the infinite dimensional Kakutani fixed point theorem to prove the existence of a pair of admissible controls. Then we show the existence of a pair of optimal time controls.

The main results obtained in this section are presented as follows.

THEOREM 2.1. *Let $T > 0$ be given and $(u_0(x), h_0(x)) \in H^1(\Omega) \times H^2(\Omega)$ be such that*

$$0 < \|u_e - u_0\|_1^2 + \|h_e - h_0\|_{H^2(\Omega)}^2 \le \min\{\rho^2, 1\} e^{-c_0(1+T+\frac{1}{T})}, \tag{2.1}$$

where c_0 is a positive constant independent of T. Then there exists a pair of controls $(w^*, v^*) \in (H^1(0,T;H))^2 \cap U_\rho$ such that the corresponding solution $(u^{w^*,v^*}, h^{w^*,v^*}) \in H^{2,1}(Q) \times (H^{2,1}(Q) \cap L^\infty(0,T;H^2(\Omega)))$ to (1.1), here $Q = \Omega \times (0,T)$, satisfies

$$u^{w^*,v^*}(T) = u_e \quad \text{and} \quad h^{w^*,v^*}(T) = h_e.$$

Theorem 2.1 amounts to saying that system (1.1) is locally exactly controllable with controls in bounded set U_ρ.

COROLLARY 2.2. *Let* $(u_0(x), h_0(x)) \in H^1(\Omega) \times H^2(\Omega)$ *be such that*

$$0 < \|u_e - u_0\|_1^2 + \|h_e - h_0\|_{H^2(\Omega)}^2 \le \min\{\rho^2, 1\} e^{-3c_0}, \tag{2.2}$$

where c_0 *is the constant in Theorem* 2.1. *Then there exists a pair of controls* $(w^*, v^*) \in (H^1(0,1;H))^2 \cap U_\rho$ *such that the corresponding solution* $(u^{w^*,v^*}, h^{w^*,v^*}) \in H^{2,1}(Q_1) \times (H^{2,1}(Q_1) \cap L^\infty(0,1;H^2(\Omega)))$ *to* (1.1), *where* $Q_1 = \Omega \times (0,1)$, *satisfies* $u^{w^*,v^*}(1) = u_e$, $h^{w^*,v^*}(1) = h_e$.

THEOREM 2.3. *Let* $(u_0(x), h_0(x)) \in H^1(\Omega) \times H^2(\Omega)$ *satisfy* (2.2). *Then there exists at least one pair of optimal time controls for problem (P).*

In order to prove the above theorems, we need the following preliminary results.

LEMMA 2.4. *Let* $\omega_0 \subset \Omega$ *be an arbitrary but fixed open subset such that* $\overline{\omega}_0 \subset \omega$. *Then there exists a function* $\widetilde{\psi} \in C^2(\overline{\Omega})$ *such that* $\widetilde{\psi} > 0$ *for all* $x \in \Omega$, $\widetilde{\psi} = 0$ *on* $\partial\Omega$, *and* $|\nabla \widetilde{\psi}(x)| > 0$ *in* $\overline{\Omega} \backslash \omega_0$.

The proof of Lemma 2.4 can be found in [11]. We omit it here.

LEMMA 2.5. *Let* $\omega_0 \subset \Omega$ *be an arbitrary but fixed open subset such that* $\overline{\omega}_0 \subset \omega$. *Then there exists a function* $\psi \in C^2(\overline{\Omega})$ *such that* $\psi > 1$ *for all* $x \in \Omega$, $\psi = 1$ *on* $\partial\Omega$, $|\nabla\psi(x)| > 0$ *in* $\overline{\Omega} \backslash \omega_0$, *and* $\|\psi\| \le \frac{10}{9}$, *where* $\|\psi\|$ *denotes* $\|\psi\|_{C(\overline{\Omega})}$.

Proof. Let $\psi = \frac{\widetilde{\psi}}{n_0} + 1$, where $\widetilde{\psi}$ is the function defined in Lemma 2.4 and n_0 is a positive integer such that $\| \widetilde{\psi} \| \le \frac{1}{9} n_0$. Then ψ is exactly what we desire. This completes the proof. □

Let ψ be given by Lemma 2.5, and set

$$\varphi(x,t) = \frac{e^{\lambda\psi}}{t(T-t)}, \qquad \alpha(x,t) = \frac{e^{\lambda\psi} - e^{\frac{9}{5}\lambda\|\psi\|}}{t(T-t)}.$$

From now on, we shall omit all x, t in the functions of x and t if there is no ambiguity.

Next we shall give the proof of the Carleman inequality for the linear backward heat equation, which is presented below for the sake of completeness and easy reference (see also [10] and [11]).

LEMMA 2.6. *There exist constants* $\lambda_0 \ge 1$ *and* $s_0 \ge 1$ *such that for* $\lambda \ge \lambda_0$ *and* $s \ge s_0(T + T^2)$, *we have*

$$\begin{aligned} &\int_Q [(s\varphi)^{-1}(p_t^2 + |\triangle p|^2) + s\varphi|\nabla p|^2 + s^3\varphi^3 p^2] e^{2s\alpha}\, dx\, dt \\ &\le C\lambda^4 \int_{Q^\omega} s^3\varphi^3 p^2 e^{2s\alpha}\, dx\, dt + C\lambda \int_Q g^2 e^{2s\alpha}\, dx\, dt \end{aligned}$$

for all solutions p *to the linear backward equation*

$$\begin{cases} p_t + b_0 \triangle p = g & \text{in } Q = \Omega \times (0,T), \\ p = 0 & \text{on } \sum = \partial\Omega \times (0,T), \end{cases} \tag{2.3}$$

where b_0 *is a positive constant,* $Q^\omega = \omega \times (0,T)$, *and* C *denotes a positive constant independent of* T, p, λ, *and* s.

Proof. Let $z = pe^{s\alpha}$; it follows that

$$\begin{cases} z_t + b_0 \triangle z + (b_0 s^2\lambda^2\varphi^2|\nabla\psi|^2 - b_0 s\lambda^2\varphi|\nabla\psi|^2)z - 2b_0 s\lambda\varphi\nabla\psi\cdot\nabla z \\ \qquad\qquad - (b_0 s\lambda\varphi\triangle\psi + s\alpha_t)z = ge^{s\alpha} & \text{in } Q, \\ z(x,0) = z(x,T) = 0 & \text{in } \Omega, \\ z = 0 & \text{on } \sum. \end{cases}$$

We set

$$\begin{cases} X(t)z = -2b_0(s\lambda\varphi\nabla\psi\cdot\nabla z + s\lambda^2\varphi|\nabla\psi|^2 z), \\ B(t)z = -b_0\triangle z - b_0 s\lambda^2\varphi|\nabla\psi|^2 z - b_0 s^2\lambda^2\varphi^2|\nabla\psi|^2 z + (b_0 s\lambda\varphi\triangle\psi + s\alpha_t)z; \end{cases}$$

it is easy to show that

$$z_t + X(t)z - B(t)z = ge^{s\alpha} \qquad \text{in } Q. \tag{2.4}$$

First we shall show that as $\lambda \geq \lambda_1$ and $s \geq s_1(T+T^2)$, where $\lambda_1 \geq 1$ and $s_1 \geq 1$ are constants independent of T,

$$\begin{aligned} &\int_Q s^3\lambda^4\varphi^3|\nabla\psi|^4 z^2\,dx\,dt + \int_Q s\lambda^2\varphi|\nabla\psi|^2|\nabla z|^2\,dx\,dt \\ &\leq C\left(\int_Q s^3\lambda^3\varphi^3 z^2\,dx\,dt + \int_Q s\lambda\varphi|\nabla z|^2\,dx\,dt + \int_Q g^2 e^{2s\alpha}\,dx\,dt\right). \end{aligned} \tag{2.5}$$

To this end, we set

$$Y = -\int_Q X(t)z\cdot B(t)z\,dx\,dt.$$

By the same arguments as those in [10] and [11], we may derive the following three inequalities:

$$\begin{aligned} &-2b_0\int_Q (s\lambda\varphi\nabla\psi\cdot\nabla z + s\lambda^2\varphi|\nabla\psi|^2 z)\cdot b_0\triangle z\,dx\,dt \\ &\geq \frac{1}{2}s\lambda^2 b_0^2\int_Q \varphi|\nabla\psi|^2|\nabla z|^2\,dx\,dt - C\int_Q s\lambda^4\varphi z^2\,dx\,dt - C\int_Q s\lambda\varphi|\nabla z|^2\,dx\,dt, \end{aligned} \tag{2.6}$$

$$\begin{aligned} &-2b_0\int_Q s\lambda\varphi(\nabla\psi\cdot\nabla z)\cdot b_0(s^2\lambda^2\varphi^2|\nabla\psi|^2 + s\lambda^2\varphi|\nabla\psi|^2)z\,dx\,dt \\ &\geq -C\int_Q s^3\lambda^3\varphi^3 z^2\,dx\,dt + 3s^3\lambda^4 b_0^2\int_Q \varphi^3|\nabla\psi|^4 z^2\,dx\,dt - C\int_Q s^2\lambda^3\varphi^2 z^2\,dx\,dt, \end{aligned} \tag{2.7}$$

and

$$\begin{aligned} &-2b_0\int_Q s\lambda\varphi\nabla\psi\cdot\nabla z(-b_0 s\lambda\varphi\triangle\psi\cdot z - s\alpha_t z)\,dx\,dt \\ &\geq -C\int_Q s^3\lambda^3\varphi^3 z^2\,dx\,dt - C\int_Q s\lambda\varphi|\nabla z|^2\,dx\,dt \\ &\quad -b_0\int_Q s^2\lambda z^2[\lambda\varphi|\nabla\psi|^2\alpha_t + \varphi\triangle\psi\alpha_t + \lambda\varphi\varphi_t|\nabla\psi|^2]\,dx\,dt, \end{aligned} \tag{2.8}$$

where $\lambda \geq 1$. Here and throughout the proof of Lemma 2.6, C denotes several positive constants independent of T.

On the other hand, we have

$$\varphi_t = (2t-T)\varphi^2 e^{-\lambda\psi}, \qquad \alpha_t = \frac{e^{\lambda\psi} - e^{\frac{9}{5}\lambda\|\psi\|}}{e^{2\lambda\psi}}(2t-T)\varphi^2.$$

The latter combined with Lemma 2.5 indicates that

$$|\varphi_t| \leq CT\varphi^2 \quad \text{and} \quad |\alpha_t| \leq CT\varphi^2,$$

which together with (2.8) yield that

$$\begin{aligned}&-2b_0\int_Q s\lambda\varphi\nabla\psi\cdot\nabla z(-b_0 s\lambda\varphi\triangle\psi\cdot z - s\alpha_t z)\,dx\,dt\\&\geq -C\int_Q s^3\lambda^3\varphi^3 z^2\,dx\,dt - C\int_Q s\lambda\varphi|\nabla z|^2\,dx\,dt - C\int_Q s^2\lambda^2 T\varphi^3 z^2\,dx\,dt,\end{aligned}$$

where $\lambda\geq 1$. It follows from (2.6), (2.7), and the latter that

$$\begin{aligned}Y\geq&\int_Q b_0^2 s^3\lambda^4\varphi^3|\nabla\psi|^4 z^2\,dx\,dt+\frac{1}{2}\int_Q b_0^2 s\lambda^2\varphi|\nabla\psi|^2|\nabla z|^2\,dx\,dt\\&-C\int_Q(s\lambda^4\varphi+s^2\lambda^4\varphi^2+s^2\lambda^2 T\varphi^3+s^3\lambda^3\varphi^3)z^2\,dx\,dt\\&-C\int_Q s\lambda\varphi|\nabla z|^2\,dx\,dt\end{aligned}\tag{2.9}$$

as $\lambda\geq 1$.

By (2.4) and the same arguments as above, we deduce that

$$\begin{aligned}2Y&\leq 2\int_Q z_t\cdot B(t)z\,dx\,dt+\int_Q g^2e^{2s\alpha}\,dx\,dt\\&\leq C\int_Q(s\lambda^2 T\varphi^2+s^2\lambda^2\varphi^3 T+s\varphi^2+sT^2\varphi^3)z^2\,dx\,dt+\int_Q g^2e^{2s\alpha}\,dx\,dt\end{aligned}$$

as $\lambda\geq 1$. The latter combined with (2.9) implies that

$$\begin{aligned}&\int_Q s^3\lambda^4\varphi^3|\nabla\psi|^4 z^2\,dx\,dt+\int_Q s\lambda^2\varphi|\nabla\psi|^2|\nabla z|^2\,dx\,dt\\&\leq\int_Q(s\lambda^4\varphi+s^2\lambda^4\varphi^2+s\varphi^2+s\lambda^2 T\varphi^2+s^2\lambda^2 T\varphi^3+s^3\lambda^3\varphi^3+sT^2\varphi^3)z^2\,dx\,dt\\&\quad+C\int_Q s\lambda\varphi|\nabla z|^2+C\int_Q g^2e^{2s\alpha}\,dx\,dt,\end{aligned}$$

from which we obtain (2.5) as desired.

Next we claim that as $\lambda\geq\lambda_2$ and $s\geq s_2(T+T^2)$, where $\lambda_2\geq\lambda_1$ and $s_2\geq s_1$ are constants independent of T,

$$\begin{aligned}&\int_Q s^3\lambda^3\varphi^3 p^2e^{2s\alpha}\,dx\,dt+\int_Q s\lambda\varphi|\nabla p|^2e^{2s\alpha}\,dx\,dt\\&\leq C\int_{Q^\omega} s^3\lambda^3\varphi^3 p^2e^{2s\alpha}\,dx\,dt+C\int_Q g^2e^{2s\alpha}\,dx\,dt.\end{aligned}\tag{2.10}$$

To this end, we observe from Lemma 2.5 and (2.5) that

$$\begin{aligned}&\int_{Q\setminus Q^{\omega_0}} s^3\lambda^4\varphi^3 z^2\,dx\,dt+\int_{Q\setminus Q^{\omega_0}} s\lambda^{\frac{7}{6}}\varphi|\nabla z|^2\,dx\,dt\\&\leq C\int_{Q^{\omega_0}}(s^3\lambda^3\varphi^3 z^2+s\lambda\varphi|\nabla z|^2)\,dx\,dt+C\int_Q g^2e^{2s\alpha}\,dx\,dt,\end{aligned}$$

where $\lambda \geq \lambda_3, s \geq s_3(T+T^2)$, $\lambda_3 \geq \lambda_1$, and $s_3 \geq s_1$ are constants independent of T. Substituting $z = pe^{s\alpha}$ into the latter inequality, after some calculation, we infer that

$$\begin{aligned} &\int_{Q\setminus Q^{\omega_0}} s^3\lambda^3\varphi^3 p^2 e^{2s\alpha}\,dx\,dt + \int_{Q\setminus Q^{\omega_0}} s\lambda\varphi|\nabla p|^2 e^{2s\alpha}\,dx\,dt \\ &\leq C\int_{Q^{\omega_0}} (s^3\lambda^3\varphi^3 p^2 + s\lambda\varphi|\nabla p|^2)e^{2s\alpha}\,dx\,dt + C\int_Q g^2 e^{2s\alpha}\,dx\,dt, \end{aligned} \tag{2.11}$$

where $\lambda \geq \lambda_4, s \geq s_4(T+T^2)$, $\lambda_4 \geq \lambda_3$, and $s_4 \geq s_3$ are constants independent of T. Taking $\chi \in C_0^\infty(\Omega)$ such that $\chi = 1$ in $\overline{\omega}_0$ and $\chi = 0$ in $\Omega\setminus\omega$, then multiplying (2.3) by $\chi\varphi p e^{2s\alpha}$ and integrating it over Q, we deduce

$$\begin{aligned} &-b_0\int_Q \chi\varphi|\nabla p|^2 e^{2s\alpha}\,dx\,dt + \frac{b_0}{2}\int_Q p^2\triangle(\chi\varphi e^{2s\alpha})\,dx\,dt - \frac{1}{2}\int_Q p^2\chi(\varphi e^{2s\alpha})_t\,dx\,dt \\ &= \int_Q g\chi\varphi p e^{2s\alpha}\,dx\,dt, \end{aligned}$$

which implies

$$\int_{Q^{\omega_0}} s\lambda\varphi|\nabla p|^2 e^{2s\alpha}\,dx\,dt \leq C\int_{Q^\omega} s^3\lambda^3\varphi^3 p^2 e^{2s\alpha}\,dx\,dt + C\int_Q g^2 e^{2s\alpha}\,dx\,dt.$$

Substituting the latter into (2.11), we deduce (2.10) as desired.

To finish the proof of Lemma 2.6, we multiply (2.3) by $(s\varphi)^{-1}p_t e^{2s\alpha}$ and then integrate it over Q to get

$$\int_Q (s\varphi)^{-1}p_t^2 e^{2s\alpha}\,dx\,dt \leq C\int_Q (s\varphi)^{-1}g^2 e^{2s\alpha}\,dx\,dt + C\int_Q s\lambda^2\varphi|\nabla p|^2 e^{2s\alpha}\,dx\,dt,$$

which together with (2.3) and (2.10) completes the proof. □

LEMMA 2.7. *The following estimate holds:*

$$\|f\|_{C([0,T])} \leq C\left(\frac{1}{T}+1\right)\|f\|_{W^{1,1}(0,T)} \qquad \forall\, f \in W^{1,1}(0,T),$$

where $C > 0$ is a constant independent of T and f.

Proof. It is well known that (cf. [1])

$$\|g\|_{C([0,1])} \leq C\|g\|_{W^{1,1}(0,1)} \qquad \forall\, g \in W^{1,1}(0,1).$$

Here and throughout the proof of Lemma 2.7, C denotes several positive constants independent of T from which we deduce that

$$\begin{aligned} &\|f\|_{C([0,T])} = \|f(Tx)\|_{C([0,1])} \leq C\|f(Tx)\|_{W^{1,1}(0,1)} \\ &\leq C\left\|f\left(\frac{T}{2}y\right)\right\|_{W^{1,1}(0,2)} \leq C\left(\frac{1}{T}+1\right)\|f\|_{W^{1,1}(0,T)}. \end{aligned}$$

This completes the proof. □

Next we prove Theorem 2.1.

Proof of Theorem 2.1. Let $h = y + h_e$ and $u = z + u_e$. We are led to prove the local null controllability of the system

$$
\left\{
\begin{array}{ll}
y_t - a\triangle y + a_1 y + b_1 y^2 + by^3 - cz = m(x)v(x,t) & \text{in } Q = \Omega \times (0,T),\\
z_t - k\triangle z + la\triangle y + a_2 y + b_2 y^2 - lby^3 + lcz & \\
\qquad = m(x)(w(x,t) - lv(x,t)) & \text{in } Q,\\
y(x,0) = h_0(x) - h_e(x) \equiv y^0(x) & \text{in } \Omega,\\
z(x,0) = u_0(x) - u_e(x) \equiv z^0(x) & \text{in } \Omega,\\
y(x,t) = z(x,t) = 0 & \text{on } \sum = \partial\Omega \times (0,T),
\end{array}
\right. \tag{2.12}
$$

where $a_1 = 3bh_e^2 - b, b_1 = 3bh_e, a_2 = lb - 3lbh_e^2$, and $b_2 = -3lbh_e$.

We shall use Kakutani's fixed point theorem to prove it. To this end, we set

$$
K = \{\xi(x,t) \in L^\infty(Q) : |\xi(x,t)| \le M \quad \text{a.e. } (x,t) \in Q\}, \tag{2.13}
$$

where $M = \|a_1\|_{L^\infty(\Omega)} + C_0\|b_1\|_{L^\infty(\Omega)} + bC_0^2$ and C_0 is the best constant such that inequality $\|y\|_{L^\infty(\Omega)} \le C_0\|y\|_{H^2(\Omega)}$ holds for all $y \in H^2(\Omega)$. We fix $\xi \in K$ and consider the solution $(y^{w,v}, z^{w,v}) \in (H^{2,1}(Q) \cap V)^2$ to the following linear system:

$$
\left\{
\begin{array}{ll}
y_t - a\triangle y + \xi y - cz = m(x)v(x,t) & \text{in } Q = \Omega \times (0,T),\\
z_t - k\triangle z + la\triangle y - l\xi y + lcz = m(x)(w(x,t) - lv(x,t)) & \text{in } Q,\\
y(x,0) = y^0(x), \qquad z(x,0) = z^0(x) & \text{in } \Omega,\\
y(x,t) = z(x,t) = 0 & \text{on } \sum = \partial\Omega \times (0,T).
\end{array}
\right. \tag{2.14}
$$

LEMMA 2.8. *For all $\xi \in K$, there exist $(w,v) \in (H^1(0,T;H))^2, (y,z) \in (H^{2,1}(Q) \cap V)^2$ satisfying* (2.14) *and such that*

$$
y(x,T) = z(x,T) = 0, \tag{2.15}
$$

$$
\|w\|^2_{H^1(0,T;H)} + \|v\|^2_{H^1(0,T;H)} \le e^{c_0^{(1)}(1+T+\frac{1}{T})}(|y^0|_2^2 + |z^0|_2^2), \tag{2.16}
$$

where $c_0^{(1)} > 0$ is a constant independent of T, ξ, y^0, and z^0.

Proof. We set $\overline{v}(x,t) = w(x,t) - lv(x,t)$. For $\varepsilon > 0$, consider the following optimal control problem:

$$
\begin{aligned}
&\text{Min}\left\{\frac{1}{2}\int_Q e^{-\frac{3}{2}s\alpha}(v^2 + \overline{v}^2)\,dx\,dt + \frac{1}{2\varepsilon}\int_\Omega (y^2(x,T) + z^2(x,T))\,dx\right\}\\
&\quad \text{subject to (2.14).}
\end{aligned} \tag{2.17}
$$

Let $((y_\varepsilon, z_\varepsilon), (v_\varepsilon, \overline{v}_\varepsilon))$ be an optimal pair for problem (2.17). (The existence follows in a standard way; see, for instance, [2].) By the maximum principle, we have that

$$
v_\varepsilon = mp_\varepsilon e^{\frac{3}{2}s\alpha}, \qquad \overline{v}_\varepsilon = mq_\varepsilon e^{\frac{3}{2}s\alpha} \quad \text{a.e. in } Q, \tag{2.18}
$$

where $(p_\varepsilon, q_\varepsilon)$ is the solution to the dual backward system

$$
\left\{
\begin{array}{ll}
(p_\varepsilon)_t + (a\triangle - \xi)p_\varepsilon - (la\triangle - l\xi)q_\varepsilon = 0 & \text{in } Q,\\
(q_\varepsilon)_t + (k\triangle - lc)q_\varepsilon + cp_\varepsilon = 0 & \text{in } Q,\\
p_\varepsilon(T) = -\frac{1}{\varepsilon}y_\varepsilon(T), \qquad q_\varepsilon(T) = -\frac{1}{\varepsilon}z_\varepsilon(T) & \text{in } \Omega,\\
p_\varepsilon(x,t) = q_\varepsilon(x,t) = 0 & \text{on } \sum.
\end{array}
\right. \tag{2.19}
$$

Taking (2.14), (2.18), and (2.19) into account, we obtain

$$\begin{aligned}(2.20)\qquad &\frac{1}{\varepsilon}\int_\Omega (y_\varepsilon^2(T)+z_\varepsilon^2(T))\,dx+\int_{Q^\omega}(p_\varepsilon^2+q_\varepsilon^2)e^{\frac{3}{2}s\alpha}\,dx\,dt\\ &\le |y^0|_2|p_\varepsilon(0)|_2+|z^0|_2|q_\varepsilon(0)|_2.\end{aligned}$$

Now we claim that as $\lambda\ge\lambda_1$ and $s\ge s_1(T+T^2)$, the following inequality holds:

$$\begin{aligned}(2.21)\qquad &\int_Q[(s\varphi)^{-1}(|(p_\varepsilon)_t|^2+|(q_\varepsilon)_t|^2+|\triangle p_\varepsilon|^2+|\triangle q_\varepsilon|^2)+s\varphi(|\nabla p_\varepsilon|^2+|\nabla q_\varepsilon|^2)\\ &\quad+s^3\varphi^3(p_\varepsilon^2+q_\varepsilon^2)]e^{2s\alpha}\,dx\,dt\le\int_{Q^\omega}(p_\varepsilon^2+q_\varepsilon^2)e^{\frac{3}{2}s\alpha}\,dx\,dt,\end{aligned}$$

where $\lambda_1\ge\lambda_0$ and $s_1\ge s_0$ are constants independent of T, and λ_0 and s_0 are the constants arising in Lemma 2.6.

To this end, we apply Lemma 2.6 to $(2.19)_1$ and $(2.19)_2$ (the first and the second equations of (2.19)), respectively, to obtain

$$\begin{aligned}(2.22)\qquad &\int_Q[(s\varphi)^{-1}(|(p_\varepsilon)_t|^2+|\triangle p_\varepsilon|^2)+s\varphi|\nabla p_\varepsilon|^2+s^3\varphi^3p_\varepsilon^2]e^{2s\alpha}\,dx\,dt\\ &\le C\lambda^4\int_{Q^\omega}s^3\varphi^3p_\varepsilon^2e^{2s\alpha}\,dx\,dt+C\lambda\int_Q q_\varepsilon^2e^{2s\alpha}\,dx\,dt+C\lambda\int_Q|\triangle q_\varepsilon|^2e^{2s\alpha}\,dx\,dt,\end{aligned}$$

$$\begin{aligned}(2.23)\qquad &\int_Q[(s\varphi)^{-1}(|(q_\varepsilon)_t|^2+|\triangle q_\varepsilon|^2)+s\varphi|\nabla q_\varepsilon|^2+s^3\varphi^3q_\varepsilon^2]e^{2s\alpha}\,dx\,dt\\ &\le C\lambda^4\int_{Q^\omega}s^3\varphi^3q_\varepsilon^2e^{2s\alpha}\,dx\,dt+C\lambda\int_Q p_\varepsilon^2e^{2s\alpha}\,dx\,dt,\end{aligned}$$

where $\lambda\ge\lambda_2$, $s\ge s_2(T+T^2)$, $\lambda_2\ge\lambda_0$, and $s_2\ge s_0$ are constants independent of T. Here and throughout the proof of Lemma 2.8, $C>0$ denotes several positive constants independent of T.

On the other hand, we have

$$\begin{cases}(t(T-t)p_\varepsilon)_t+(a\triangle-\xi)(t(T-t)p_\varepsilon)=t(T-t)(la\triangle-l\xi)q_\varepsilon\\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad+(T-2t)p_\varepsilon\quad\text{in }\ Q,\\ t(T-t)p_\varepsilon=0\qquad\text{on }\ \textstyle\sum.\end{cases}$$

By applying (2.10) to the latter system, it follows that

$$\begin{aligned}&\int_Q s^3\lambda^3\varphi e^{2\lambda\psi}p_\varepsilon^2e^{2s\alpha}\,dx\,dt+\int_Q s\lambda\varphi^{-1}e^{2\lambda\psi}|\nabla p_\varepsilon|^2e^{2s\alpha}\,dx\,dt\\ &\le C\int_{Q^\omega}s^3\lambda^3\varphi e^{2\lambda\psi}p_\varepsilon^2e^{2s\alpha}\,dx\,dt\\ &\quad+CsT^2e^{\lambda\|\psi\|}\int_Q[(s\varphi)^{-1}|\triangle q_\varepsilon|^2+s^3\varphi^3q_\varepsilon^2]e^{2s\alpha}\,dx\,dt,\end{aligned}$$

where $\lambda\ge\lambda_3$, $s\ge s_3(T+T^2)$, $\lambda_3\ge\lambda_2$, and $s_3\ge s_2$ are constants independent of T. Together with (2.23), the latter implies that

$$\begin{aligned}(2.24)\qquad &\int_Q s^3\lambda^3\varphi e^{2\lambda\psi}p_\varepsilon^2e^{2s\alpha}\,dx\,dt+\int_Q s\lambda\varphi^{-1}e^{2\lambda\psi}|\nabla p_\varepsilon|^2e^{2s\alpha}\,dx\,dt\\ &\le C\int_{Q^\omega}s^3\lambda^3\varphi e^{2\lambda\psi}p_\varepsilon^2e^{2s\alpha}\,dx\,dt+Cs^4T^2e^{\lambda\|\psi\|}\lambda^4\int_{Q^\omega}q_\varepsilon^2\varphi^3e^{2s\alpha}\,dx\,dt\end{aligned}$$

and

$$\begin{aligned}&\int_Q [(s\varphi)^{-1}(|(q_\varepsilon)_t|^2 + |\triangle q_\varepsilon|^2) + s\varphi|\nabla q_\varepsilon|^2 + s^3\varphi^3 q_\varepsilon^2]e^{2s\alpha}\,dx\,dt\\ &\le C\int_{Q^\omega} s^3\lambda^4\varphi^3 q_\varepsilon^2 e^{2s\alpha}\,dx\,dt + CT^2\int_{Q^\omega}\varphi p_\varepsilon^2 e^{2s\alpha}\,dx\,dt.\end{aligned} \tag{2.25}$$

Now (2.21) follows from (2.22) and (2.25) immediately.

Next we shall show that

$$\|v_\varepsilon\|^2_{H^1(0,T;H)} + \|\overline{v}_\varepsilon\|^2_{H^1(0,T;H)} \le e^{\frac{Cse^{\frac{9}{5}\lambda\|\psi\|}}{T^2}}(|y^0|_2^2 + |z^0|_2^2), \tag{2.26}$$

where $\lambda \ge \lambda_4$, $s \ge s_4(T + T^2 + T^3)$, $\lambda_4 \ge \lambda_1$, and $s_4 \ge s_1$ are constants independent of T.

Multiplying $(2.19)_1$ and $(2.19)_2$ by δp_ε and q_ε, respectively, where $\delta > 0$ is suitably chosen, and then integrating them on $\Omega \times (\tau, t)$, after some elementary calculation, we may obtain that

$$\begin{aligned}&|p_\varepsilon(\tau)|_2^2 + |q_\varepsilon(\tau)|_2^2 + \int_\tau^t (|\nabla p_\varepsilon|_2^2 + |\nabla q_\varepsilon|_2^2)\,ds\\ &\le C(|p_\varepsilon(t)|_2^2 + |q_\varepsilon(t)|_2^2) + C\int_\tau^t (|p_\varepsilon|_2^2 + |q_\varepsilon|_2^2)\,ds,\end{aligned}$$

where $0 \le \tau \le t \le T$. The latter combined with Gronwall's inequality indicates that

$$|p_\varepsilon(0)|_2^2 + |q_\varepsilon(0)|_2^2 \le C(|p_\varepsilon(t)|_2^2 + |q_\varepsilon(t)|_2^2)e^{CT} \qquad \forall\, 0 \le t \le T.$$

Integrating the latter on $(\frac{T}{4}, \frac{3}{4}T)$, we get that

$$\begin{aligned}&|p_\varepsilon(0)|_2^2 + |q_\varepsilon(0)|_2^2\\ &\le \frac{Ce^{CT}}{T}\int_{\frac{T}{4}}^{\frac{3}{4}T}\int_\Omega (p_\varepsilon^2 + q_\varepsilon^2)\,dx\,dt\\ &= \frac{Ce^{CT}}{T}\int_{\frac{T}{4}}^{\frac{3}{4}T}\int_\Omega s^{-3}\varphi^{-3}e^{-2s\alpha}s^3\varphi^3(p_\varepsilon^2 + q_\varepsilon^2)e^{2s\alpha}\,dx\,dt\\ &\le \frac{1}{2}e^{\frac{32s}{T^2}e^{\frac{9}{5}\lambda\|\psi\|}}\int_Q s^3\varphi^3(p_\varepsilon^2 + q_\varepsilon^2)e^{2s\alpha}\,dx\,dt,\end{aligned}$$

where $\lambda \ge \lambda_5$, $s \ge s_5(T + T^2 + T^3)$, $\lambda_5 \ge \lambda_1$, and $s_5 \ge s_1$ are constants independent of T. This together with (2.21) yields that

$$|p_\varepsilon(0)|_2^2 + |q_\varepsilon(0)|_2^2 \le \frac{1}{2}e^{\frac{32s}{T^2}e^{\frac{9}{5}\lambda\|\psi\|}}\int_{Q^\omega}(p_\varepsilon^2 + q_\varepsilon^2)e^{\frac{3}{2}s\alpha}\,dx\,dt.$$

The latter together with (2.20) shows that

$$\begin{aligned}&\frac{1}{\varepsilon}\int_\Omega (y_\varepsilon^2(T) + z_\varepsilon^2(T))\,dx + \int_{Q^\omega}(p_\varepsilon^2 + q_\varepsilon^2)e^{\frac{3}{2}s\alpha}\,dx\,dt\\ &\le e^{\frac{32s}{T^2}e^{\frac{9}{5}\lambda\|\psi\|}}(|y^0|_2^2 + |z^0|_2^2),\end{aligned} \tag{2.27}$$

which, combined with (2.18), indicates that

$$\int_Q (v_\varepsilon^2 + \overline{v}_\varepsilon^2)\,dx\,dt + \frac{1}{\varepsilon}\int_\Omega (y_\varepsilon^2(T) + z_\varepsilon^2(T))\,dx \le e^{\frac{32s}{T^2}e^{\frac{9}{5}\lambda\|\psi\|}}(|y^0|_2^2 + |z^0|_2^2). \tag{2.28}$$

Thus (2.26) follows immediately from (2.18), (2.21), (2.27), and (2.28).

Now we claim that

$$\begin{aligned}(2.29)\qquad &\|y_\varepsilon(t)\|_1^2+\|z_\varepsilon(t)\|_1^2+\|y_\varepsilon\|_{H^{2,1}(Q)}^2+\|z_\varepsilon\|_{H^{2,1}(Q)}^2\\ &\le e^{\frac{Cse^{\frac{9}{5}\lambda\|\psi\|}}{T^2}}(\|y^0\|_1^2+\|z^0\|_1^2),\end{aligned}$$

where $\lambda\ge\lambda_6$, $s\ge s_6(T+T^2+T^3)$, $\lambda_6\ge\lambda_4$, and $s_6\ge s_4$ are constants independent of T.

Multiplying $(2.14)_1$ and $(2.14)_2$ by y_ε and δz_ε in $L^2(\Omega)$, respectively, where $\delta>0$ is suitably chosen, and then integrating them over $(0,t)$, after some calculation involving Gronwall's inequality and (2.26), we obtain

$$(2.30)\qquad |y_\varepsilon(t)|_2^2+|z_\varepsilon(t)|_2^2+\int_0^T(|\nabla y_\varepsilon|_2^2+|\nabla z_\varepsilon|_2^2)\,ds\le e^{\frac{Cse^{\frac{9}{5}\lambda\|\psi\|}}{T^2}}(|y^0|_2^2+|z^0|_2^2).$$

Multiplying $(2.14)_1$ and $(2.14)_2$ by $-\triangle y_\varepsilon$ and $-\triangle z_\varepsilon$ in H, respectively, and then integrating them over $(0,t)$, after some elementary calculation, we deduce that

$$|\nabla y_\varepsilon(t)|_2^2+a\int_0^t|\triangle y_\varepsilon|_2^2\,ds\le|\nabla y^0|_2^2+C\int_0^t(|v_\varepsilon|_2^2+|y_\varepsilon|_2^2+|z_\varepsilon|_2^2)\,ds$$

and

$$|\nabla z_\varepsilon(t)|_2^2+k\int_0^t|\triangle z_\varepsilon|_2^2\,ds\le|\nabla z^0|_2^2+C\int_0^t(|\triangle y_\varepsilon|_2^2+|\overline{v}_\varepsilon|_2^2+|y_\varepsilon|_2^2+|z_\varepsilon|_2^2)\,ds,$$

which together with (2.14), (2.26), and (2.30) imply (2.29) as desired.

By (2.26) and (2.29) and by Arzela–Ascoli theorem and the Aubin compactness theorem, there exist subsequences of $\{y_\varepsilon\},\{z_\varepsilon\},\{w_\varepsilon\}$, and $\{v_\varepsilon\}$, still denoted in the same way, such that

$$\begin{aligned}&y_\varepsilon\to y\ \text{ and }\ z_\varepsilon\to z\quad \text{weakly in } H^1(0,T;H)\cap L^2(0,T;H^2(\Omega)),\\ &\qquad\qquad\qquad\quad \text{strongly in } L^2(0,T;V)\cap C([0,T];H),\\ &w_\varepsilon\to w,\qquad v_\varepsilon\to v\quad \text{weakly in } H^1(0,T;H),\end{aligned}$$

and

$$\|w_\varepsilon\|_{H^1(0,T;H)}^2+\|v_\varepsilon\|_{H^1(0,T;H)}^2\le e^{a_0s_4e^{\frac{9}{5}\lambda_4\|\psi\|}(1+T+\frac{1}{T})}(|y^0|_2^2+|z^0|_2^2),$$

where $a_0>0$ is a constant independent of T. If we set $c_0^{(1)}=a_0s_4e^{\frac{9}{5}\lambda_4\|\psi\|}$, then the latter together with (2.28) implies (2.15) and (2.16). By passing to the limit for $\varepsilon\to0$ in (2.14), we conclude that (y,z) and (w,v) satisfy (2.14). This completes the proof of Lemma 2.8. □

Proof of Theorem 2.1 (continued). We set $K_T=\{\xi(x,t)\in L^\infty(0,T;H^2(\Omega)\cap V)\cap H^1(0,T;V):\ \mu(\xi)\le1\}$, where $\mu(\xi)=\sqrt{\|\xi\|_{H^1(0,T;V)}^2+\|\xi\|_{L^\infty(0,T;H^2(\Omega))}^2}$.

Define the multivalued map $\Psi:K_T\longrightarrow L^2(Q)$ by

$$\begin{aligned}\Psi(\xi)=\{y^{w,v}\in L^2(0,T;H^2(\Omega)\cap V)\cap H^1(0,T;H):\ &y^{w,v}(T)=z^{w,v}(T)=0,\\ &\|w\|_{H^1(0,T;H)}^2+\|v\|_{H^1(0,T;H)}^2\le e^{c_0^{(1)}(1+T+\frac{1}{T})}(|y^0|_2^2+|z^0|_2^2)\},\end{aligned}$$

where $c_0^{(1)} > 0$ is the constant arising in Lemma 2.8 and $(y^{w,v}, z^{w,v})$ is the solution to the following equation:

$$
(2.31)\begin{cases} y_t - a\triangle y + (a_1 + b_1\xi + b\xi^2)y - cz = m(x)v(x,t) \ \text{ in } \ Q = \Omega \times (0,T), \\ z_t - k\triangle z + la\triangle y + (a_2 + b_2\xi - lb\xi^2)y + lcz \\ \qquad\qquad = m(x)(w(x,t) - lv(x,t)) \quad \text{in } \ Q, \\ y(x,0) = y^0(x), \qquad z(x,0) = z^0(x) \quad \text{in } \ \Omega, \\ y(x,t) = z(x,t) = 0 \quad \text{on } \ \sum = \partial\Omega \times (0,T). \end{cases}
$$

Then by Lemma 2.8, we have that

$$
\Psi(\xi) \neq \emptyset. \tag{2.32}
$$

Moreover, one can easily check that

$$
\begin{aligned} &K_T \text{ is a convex set in } \ L^2(Q) \text{ and} \\ &\qquad \Psi(\xi) \text{ is a convex set in } \ L^2(Q) \text{ for each } \ \xi \in K_T. \end{aligned} \tag{2.33}
$$

Next we shall show that

$$
K_T \text{ is a compact subset in } \ L^2(Q). \tag{2.34}
$$

Indeed, for any sequence $\{\xi_n\} \subset K_T$, by the definition of K_T, we have

$$
\|\xi_n\|^2_{H^1(0,T;V)} + \|\xi_n\|^2_{L^\infty(0,T;H^2(\Omega))} \leq 1. \tag{2.35}
$$

Thus there exists a subsequence of $\{\xi_n\}$, still denoted by itself, such that

$$
\begin{aligned} &\xi_n \to \xi \text{ weak star in } \ L^\infty(0,T;H^2(\Omega)), \\ &\qquad \text{weakly in } \ H^1(0,T;V) \text{ and strongly in } \ L^2(Q). \end{aligned} \tag{2.36}
$$

It follows from (2.35) and (2.36) that

$$
\|\xi\|^2_{H^1(0,T;V)} + \|\xi\|^2_{L^\infty(0,T;H^2(\Omega))} \leq 1,
$$

which implies $\xi \in K_T$, and (2.34) follows.

Next we prove that Ψ is upper-semicontinuous in $L^2(Q)$; i.e., if $\xi_n \in K_T$ is such that $\xi_n \to \widetilde{\xi}$ strongly in $L^2(Q)$ and $y_n \equiv y^{w_n,v_n} \in \Psi(\xi_n)$ is strongly convergent to $\widetilde{y}$ in $L^2(Q)$, then $\widetilde{y} \in \Psi(\widetilde{\xi})$.

To this end, we observe first that

$$
\|\xi_n\|^2_{H^1(0,T;V)} + \|\xi_n\|^2_{L^\infty(0,T;H^2(\Omega))} \leq 1.
$$

However, $\xi_n \to \widetilde{\xi}$ strongly in $L^2(Q)$; thus there exists a subsequence of $\{\xi_n\}$, still denoted by itself, such that

$$
\begin{aligned} &\xi_n \to \widetilde{\xi} \ \text{ weak star in } \ L^\infty(0,T;H^2(\Omega)), \\ &\qquad \text{weakly in } \ H^1(0,T;V) \text{ and strongly in } \ L^2(Q), \end{aligned} \tag{2.37}
$$

and hence

$$
\widetilde{\xi} \in K_T. \tag{2.38}
$$

Because

$$\|w_n\|^2_{H^1(0,T;H)} + \|v_n\|^2_{H^1(0,T;H)} \le e^{c_0^{(1)}(1+T+\frac{1}{T})}(|y^0|_2^2 + |z^0|_2^2), \tag{2.39}$$

by the same arguments as those in the proof of Lemma 2.8, we deduce that

$$\|y_n(t)\|_1^2 + \|z_n(t)\|_1^2 + \|y_n\|^2_{H^{2,1}(Q)} + \|z_n\|^2_{H^{2,1}(Q)} \le e^{Cc_0^{(1)}(1+T+\frac{1}{T})}(\|y^0\|_1^2 + \|z^0\|_1^2).$$

This together with (2.39) indicates that there exist subsequences of $\{y_n\}, \{z_n\}, \{w_n\}$, and $\{v_n\}$, still denoted in the same way, such that

$$\begin{array}{ll} y_n \to y, \ \ z_n \to z & \text{weakly in } \ L^2(0,T;H^2(\Omega)) \cap W^{1,2}(0,T;H), \\ & \text{strongly in } \ L^2(0,T;V) \cap C([0,T];H), \\ w_n \to \widetilde{w}, \ \ v_n \to \widetilde{v} & \text{weakly in } \ H^1(0,T;H). \end{array} \tag{2.40}$$

This implies

$$\widetilde{y} = y \quad \text{a.e. in } \ Q.$$

Passing to the limit $n \to \infty$ in (2.31) and using (2.37)–(2.40), we obtain

$$\| \widetilde{w} \|^2_{H^1(0,T;H)} + \| \widetilde{v} \|^2_{H^1(0,T;H)} \le e^{c_0^{(1)}(1+T+\frac{1}{T})}(|y^0|_2^2 + |z^0|_2^2)$$

and $\widetilde{y} \equiv y^{\widetilde{w},\widetilde{v}} \in \Psi(\widetilde{\xi})$ as desired.

To finish the proof of Theorem 2.1, we fix $\xi \in K_T$, then take $y \in \Psi(\xi)$ and multiply (scalarly in H) $(2.31)_1$ by $-\triangle y'$(here $y' = y_t$), and integrate it over $(0,t)$. After some calculation, we deduce that

$$\begin{aligned} |\triangle y(t)|_2^2 + \int_0^t |\nabla y'(s)|_2^2 \, ds \le C(\|y^0\|^2_{H^2(\Omega)} + |v(t)|_2^2 + |v(0)|_2^2 + |\nabla y(t)|_2^2) \\ + C\int_0^t (|\nabla y|_2^2 + |\nabla z|_2^2 + |\triangle y|_2^2 + |v_s|_2^2) \, ds. \end{aligned} \tag{2.41}$$

Since $y \in \Psi(\xi)$, we have that

$$\|w\|^2_{H^1(0,T;H)} + \|v\|^2_{H^1(0,T;H)} \le e^{c_0^{(1)}(1+T+\frac{1}{T})}(|y^0|_2^2 + |z^0|_2^2). \tag{2.42}$$

By the same arguments as those in Lemma 2.8, we obtain that

$$\begin{aligned} &\|y(t)\|_1^2 + \|z(t)\|_1^2 + \|y\|^2_{H^{2,1}(Q)} + \|z\|^2_{H^{2,1}(Q)} \\ &\le e^{Cc_0^{(1)}(1+T+\frac{1}{T})}(\|y^0\|_1^2 + \|z^0\|_1^2). \end{aligned} \tag{2.43}$$

Here and throughout the proof of Theorem 2.1, C denotes several positive constants independent of T. Now it follows from Lemma 2.7 and (2.41)–(2.43) that

$$\|y(t)\|^2_{L^\infty(0,T;H^2(\Omega))} + \|y\|^2_{H^1(0,T;V)} \le e^{\widetilde{a_0}c_0^{(1)}(1+T+\frac{1}{T})}(\|y^0\|^2_{H^2(\Omega)} + \|z^0\|_1^2) \tag{2.44}$$

and

$$\|w\|^2_{L^\infty(0,T;H)} + \|v\|^2_{L^\infty(0,T;H)} \le e^{\widetilde{a_0}c_0^{(1)}(1+T+\frac{1}{T})}(|y^0|_2^2 + |z^0|_2^2), \tag{2.45}$$

where $\widetilde{a_0} > 0$ is a constant independent of T.

Let $c_0 = \widetilde{a_0}\ c_0^{(1)}$. Then for $0 < \|y^0\|^2_{H^2(\Omega)} + \|z^0\|^2_1 \le \min\{\rho^2, 1\} e^{-c_0(1+T+\frac{1}{T})}$, we have

$$\|w\|^2_{L^\infty(0,T;H)} + \|v\|^2_{L^\infty(0,T;H)} \le \rho^2 \tag{2.46}$$

and

$$\mu(y) = \sqrt{\|y\|^2_{H^1(0,T;V)} + \|y\|^2_{L^\infty(0,T;H^2(\Omega))}} \le 1.$$

Hence

$$\Psi(K_T) \subset K_T.$$

By (2.32), (2.33), (2.34), and the upper-semicontinuity of Ψ, we may use the infinite dimensional Kakutani fixed point theorem to obtain that there exists $y^* \in \Psi(y^*)$ or, equivalently, that there exist $y^* \in L^\infty(0,T;H^2(\Omega)\cap V)\cap H^1(0,T;V)$ and $(w^*, v^*) \in (H^1(0,T;H))^2$, which satisfy system (2.12) and $y^*(T) = z^*(T) = 0$. Moreover, w^* and v^* satisfy estimate (2.46). This completes the proof of Theorem 2.1. □

Proof of Corollary 2.2. It is clear that $f(T) \equiv e^{-c_0(1+T+\frac{1}{T})}$ attains its supremum on $(0, +\infty)$ at $T = 1$. For $(u_0(x), h_0(x)) \in H^1(\Omega) \times H^2(\Omega)$ satisfying condition (2.2), by taking $T = 1$ in Theorem 2.1, Corollary 2.2 follows immediately. This completes the proof of Corollary 2.2. □

Now we are in the position to prove Theorem 2.3.

Proof of Theorem 2.3. We observe first that problem (P) is equivalent to the problem

$$(P') \quad \inf\{T : y^{w,v}(T) = z^{w,v}(T) = 0, \quad (w,v) \in U_\rho\} \equiv \inf Q_T,$$

where $(y^{w,v}, z^{w,v})$ is the solution of the following system:

$$\begin{cases} y_t - a\triangle y + a_1 y + b_1 y^2 + by^3 - cz \\ \qquad\qquad = m(x)v(x,t) \quad \text{in } Q_\infty = \Omega \times (0,\infty), \\ z_t - k\triangle z + la\triangle y + a_2 y + b_2 y^2 - lby^3 + lcz \\ \qquad\qquad = m(x)(w(x,t) - lv(x,t)) \quad \text{in } Q_\infty, \\ y(x,0) = h_0(x) - h_e(x) \equiv y^0(x) \quad \text{in } \Omega, \\ z(x,0) = u_0(x) - u_e(x) \equiv z^0(x) \quad \text{in } \Omega, \\ y(x,t) = z(x,t) = 0 \quad \text{on } \sum_\infty = \partial\Omega \times (0,\infty). \end{cases} \tag{2.47}$$

By Corollary 2.2, it is clear that under the assumptions of Theorem 2.3, the set Q_T is not empty. Let $T^* = \inf Q_T$; then it is clear that $0 \le T^* < \infty$ and there exist a nonincreasing sequence $\{T_m\}$ and a sequence $\{(w_m, v_m)\} \subset U_\rho$ such that $T_m \to T^*, y^{w_m,v_m}(T_m) = z^{w_m,v_m}(T_m) = 0$. Moreover, $(y^{w_m,v_m}, z^{w_m,v_m})$ is the solution to (2.47), where $v = v_m, w = w_m$.

We let $y_m \equiv y^{w_m,v_m}$ and $z_m \equiv z^{w_m,v_m}$; it is clear that

$$\begin{cases} (y_m)_t - a\triangle y_m + a_1 y_m + b_1 y_m^2 + by_m^3 \\ \qquad\qquad - cz_m = m(x)v_m \quad \text{in } Q = \Omega \times (0,T), \\ (z_m)_t - k\triangle z_m + la\triangle y_m + a_2 y_m + b_2 y_m^2 - lby_m^3 \\ \qquad\qquad + lcz_m = m(x)(w_m - lv_m) \quad \text{in } Q, \\ y_m(x,0) = y^0(x), \quad z_m(x,0) = z^0(x) \quad \text{in } \Omega, \\ y_m(x,t) = z_m(x,t) = 0 \quad \text{on } \sum = \partial\Omega \times (0,T), \end{cases} \tag{2.48}$$

where $T > T_1$ is an arbitrary but fixed constant.

Multiplying $(2.48)_1$ and $(2.48)_2$ by y_m and z_m in $L^2(\Omega)$ and integrating them over $(0,t)$, respectively, after some calculation, we obtain

$$\begin{aligned} &|y_m(t)|_2^2 + \int_0^t |\nabla y_m(s)|_2^2\,ds + \int_0^t \|y_m(s)\|_{L^4(\Omega)}^4\,ds \\ &\le C\left(|y^0|_2^2 + \int_0^t |z_m(s)|_2^2\,ds + 1\right) \end{aligned} \tag{2.49}$$

and

$$\begin{aligned} &|z_m(t)|_2^2 + \int_0^t |\nabla z_m(s)|_2^2\,ds \\ &\le C(|y^0|_2^2 + |z^0|_2^2 + 1) + C\int_0^t \int_\Omega y_m^6\,dx\,ds + C\int_0^t |z_m(s)|_2^2\,ds. \end{aligned} \tag{2.50}$$

Multiplying $(2.48)_1$ by $4y_m^3$ in $L^2(\Omega)$, integrating it over $(0,t)$, and using (2.49), we get

$$\begin{aligned} &\|y_m(t)\|_{L^4(\Omega)}^4 + 12a\int_0^t \int_\Omega y_m^2 |\nabla y_m|^2\,dx\,ds + 2b\int_0^t \int_\Omega y_m^6\,dx\,ds \\ &\le C(\|y^0\|_{L^4(\Omega)}^4 + |y^0|_2^2 + 1) + C\int_0^t |z_m(s)|_2^2\,ds, \end{aligned} \tag{2.51}$$

which, combined with (2.50), implies that

$$\begin{aligned} &|z_m(t)|_2^2 + \int_0^T |\nabla z_m(s)|_2^2\,ds \\ &\le C(|y^0|_2^2 + |z^0|_2^2 + \|y^0\|_{L^4(\Omega)}^4 + 1) \quad \forall\, t \in [0,T]. \end{aligned} \tag{2.52}$$

It follows from (2.49), (2.51), and (2.52) that

$$\begin{aligned} &\|y_m(t)\|_{L^4(\Omega)}^4 + |y_m(t)|_2^2 + \int_0^T |\nabla y_m(t)|_2^2\,dt \\ &+ \int_0^T \int_\Omega y_m^2 |\nabla y_m|^2\,dx\,dt + \int_0^T \|y_m\|_{L^6(\Omega)}^6\,dt \\ &\le C(|y^0|_2^2 + |z^0|_2^2 + \|y^0\|_{L^4(\Omega)}^4 + 1). \end{aligned} \tag{2.53}$$

Multiplying $(2.48)_1$ by $-\triangle y_m$ in $L^2(\Omega)$ and integrating it over $(0,t)$, by $(2.48)_1$, (2.52), and (2.53), after some elementary calculation, we get

$$\begin{aligned} &\|y_m(t)\|_1^2 + \|y_m\|_{H^{2,1}(Q)}^2 \\ &\le C(\|y^0\|_1^2 + |z^0|_2^2 + \|y^0\|_{L^4(\Omega)}^4 + 1) \quad \forall\, t \in [0,T]. \end{aligned} \tag{2.54}$$

Similarly, we deduce that

$$\begin{aligned} &\|z_m(t)\|_1^2 + \|z_m\|_{H^{2,1}(Q)}^2 \\ &\le C(\|y^0\|_1^2 + \|z^0\|_1^2 + \|y^0\|_{L^4(\Omega)}^4 + 1) \quad \forall\, t \in [0,T]. \end{aligned} \tag{2.55}$$

By (2.54) and (2.55), we conclude that there exist subsequences of $\{y_m\}$ and $\{z_m\}$, still denoted in the same way, such that

$$\begin{aligned} &y_m \to y \ \text{ and } \ z_m \to z \quad \text{weakly in } \ W^{1,2}([0,T];H) \cap L^2(0,T;H^2(\Omega)), \\ &\qquad\qquad\qquad\quad \text{strongly in } \ L^2(0,T;V) \cap C([0,T];H). \end{aligned} \tag{2.56}$$

Since $(w_m, v_m) \in U_\rho$, there exist subsequences of $\{w_m\}$ and $\{v_m\}$, still denoted by themselves, such that

$$w_m \to w \ \text{ and } \ v_m \to v \text{ weakly in } \ L^2(0,T;H).$$

Moreover, $(w,v) \in U_\rho$. By passing to the limit for $m \to \infty$ in (2.48), we conclude that $(y^{w,v}, z^{w,v})$ and (w,v) satisfy (2.47).

On the other hand, it follows from (2.56) that

$$\begin{aligned} |y(T^*;w,v)|_2 &\le |y(T^*;w,v) - y_m(T^*)|_2 + |y_m(T^*) - y_m(T_m)|_2 \\ &\le |y(T^*;w,v) - y_m(T^*)|_2 + C(T_m - T^*)^{\frac{1}{2}} \to 0, \end{aligned}$$

which implies that $y(T^*;w,v) = 0$. Similarly, we may obtain that $z(T^*;w,v) = 0$ from which we see that $T^* \neq 0$. Otherwise, we should have $y^0(x) = z^0(x) = 0$, which contradicts assumption (2.2). Hence problem (P') has at least one solution. This completes the proof. □

3. Maximum principle. In this section, we shall derive the maximum principle for optimal time control problem (P) (or, equivalently, (P')) in the case that $\omega \equiv \Omega$ and $al^2 - 4k \le 0$ in system (1.1). In what follows, we denote by *sgnq* the signum function of q.

We state first the maximum principle for the case that $n = 1, 2$ as follows.

THEOREM 3.1. *Let (w^*, v^*) be a pair of optimal time controls for system* (1.1) *and (u^*, h^*) be the pair of corresponding optimal states. Then there exists $(p,q) \in (C([0,T^*];H) \cap L^2(0,T^*;V) \cap W^{1,2}([0,T^*];V^*))^2$ such that*

$$\text{(3.1)} \quad \begin{cases} p_t + a\triangle p - la\triangle q - [a_1 + 2b_1(h^* - h_e) \\ \qquad\qquad +3b(h^* - h_e)^2](p - lq) = 0 \quad a.e.\ \ t \in (0,T^*), \\ q_t + k\triangle q - lcq + cp = 0 \quad a.e.\ \ t \in (0,T^*), \end{cases}$$

$$\text{(3.2)} \quad \begin{cases} w^*(t) = \rho sgnq(t) & a.e.\ \ t \in (0,T^*), \\ v^*(t) = \rho sgn(p(t) - lq(t)) & a.e.\ \ t \in (0,T^*), \end{cases}$$

$$\text{(3.3)} \quad \begin{aligned} &-\langle (A+B)(h^*(t) - h_e, u^*(t) - u_e), (p(t), q(t))\rangle \\ &\qquad +\rho(|q(t)|_2 + |p(t) - lq(t)|_2) = 1 \quad a.e.\ \ t \in (0,T^*). \end{aligned}$$

Here T^* is the minimal time, $A(y,z) = (-a\triangle y, la\triangle y - k\triangle z), B(y,z) = (a_1 y + b_1 y^2 + by^3 - cz, a_2 y + b_2 y^2 - lby^3 + lcz)$, and a_1, a_2, b_1, b_2 are given in (2.12).

For the case that $n = 3$, in order to obtain the maximum principle, we need further assumptions. To this end we shall introduce a constant η_0 and a function a_0. By Sobolev's imbedding theorem and the Poincaré inequality, we have that

$$\|y\|_{L^6(\Omega)} \le C_1 |\nabla y|_2 \quad \forall\, y \in V,$$

where $C_1 > 0$ is the best constant such that the above inequality holds. Now we define η_0 and $a_0(b,c,\rho,l)$ as follows:

$$\eta_0 = \frac{[b^2 C_1^2 (C_1^2 + 6\|h_e\| \cdot |\Omega|^{\frac{1}{6}})^2 + 4b\rho]^{\frac{1}{2}} - bC_1(C_1^2 + 6\|h_e\| \cdot |\Omega|^{\frac{1}{6}})}{4bC_1},$$

$$\begin{aligned} &a_0(b,c,\rho,l) \\ &= \exp\left\{e^{10(b\|h_e\|^2 + b + c + 1)}(l + l\|h_e\|^2 + \frac{l}{b} + 1)(\rho^2 + 4) + 4\rho^2 l^2 + 2l|\Omega|^{\frac{1}{3}} C_1^4\right\} \\ &\quad + 8b|\Omega|^{\frac{1}{3}} C_1^4, \end{aligned}$$

where here and throughout section 3, $\|h_e\|$ and $|\Omega|$ denote $\|h_e\|_{L^\infty(\Omega)}$ and the volume of Ω, respectively.

Now we present the maximum principle for the case that $n = 3$.

THEOREM 3.2. *Let (w^*, v^*) be a pair of optimal time controls for system (1.1) and (u^*, h^*) be the pair of corresponding optimal states. If h_0 satisfies $|\nabla(h_0 - h_e)|_2^2 \le \eta_0$ and (2.2), $a \ge \eta_0^{-1} a_0(b, c, \rho, l)$, then there exists $(p, q) \in (C([0, T^*]; H) \cap L^2(0, T^*; V) \cap W^{1,2}([0, T^*]; V^*))^2$ such that (3.1)–(3.3) hold.*

In order to prove Theorems 3.1 and 3.2, we approximate the optimal time control problem (P) by a free optimal time control problem defined later. To this end, we first construct the penalty functional $L_\varepsilon : R^+ \times L^\infty(0, \infty; H) \times L^\infty(0, \infty; H) \longrightarrow R^+$ as follows, which is based on the penalty functionals defined in [2] and [3] after some modification.

$$\begin{aligned} L_\varepsilon(T, w, v) = T &+ \int_0^T \left[g(w) + g(v) + \frac{\varepsilon}{2}(|w(t)|_2^2 + |v(t)|_2^2) \right] dt \\ &+ \frac{1}{2\varepsilon}(|y(T)|_2^2 + |z(T)|_2^2) \\ &+ \frac{1}{2} \int_0^T \left[\left| \int_0^t (w(s) - w^*(s))\, ds \right|_2^2 + \left| \int_0^t (v(s) - v^*(s))\, ds \right|_2^2 \right] dt, \end{aligned} \tag{3.4}$$

where (y, z) is the solution of the system

$$\begin{cases} y_t - a\triangle y + a_1 y + b_1 y^2 + by^3 - cz = v(x,t) \quad \text{in } \Omega \times (0, \infty), \\ z_t - k\triangle z + la\triangle y + a_2 y \\ \qquad\qquad + b_2 y^2 - lby^3 + lcz = w(x,t) - lv(x,t) \quad \text{in } \Omega \times (0, \infty), \\ y(x, 0) = y^0(x), \qquad z(x, 0) = z^0(x) \quad \text{in } \Omega, \\ y(x, t) = z(x, t) = 0 \quad \text{on } \partial\Omega \times (0, \infty) \end{cases} \tag{3.5}$$

and $g : H \longrightarrow \overline{R} = (-\infty, +\infty]$ is defined by

$$g(u) = \begin{cases} 0 & \text{if } |u|_2 \le \rho, \\ +\infty & \text{otherwise.} \end{cases} \tag{3.6}$$

Here a_1, a_2, b_1, and b_2 are given in (2.12).

We consider the approximating optimal control problem as follows:

(P^ε) Minimize $L_\varepsilon(T, w, v)$ over all $(T, w, v) \in R^+ \times L^\infty(0, \infty; H) \times L^\infty(0, \infty; H)$.

First, we show the existence of the optimal solutions for problem (P^ε) for each $\varepsilon > 0$.

LEMMA 3.3. *For each $\varepsilon > 0$, problem (P^ε) has at least one optimal solution.*

Proof. Let $\varepsilon > 0$ be fixed. It is clear that $\inf L_\varepsilon(T, w, v) > -\infty$.

Let $d = \inf\{L_\varepsilon(T, w, v) : (T, w, v) \in R^+ \times L^\infty(0, \infty; H) \times L^\infty(0, \infty; H)\}$ and $\{(T_n, w_n, v_n)\}$ be a minimizing sequence such that

$$d \le L_\varepsilon(T_n, w_n, v_n) \le d + \frac{1}{n}. \tag{3.7}$$

We set

$$\overline{w}_n(s) = \begin{cases} w_n(s) & \text{if } s \in [0, T_n], \\ w^*(s) & \text{otherwise} \end{cases} \tag{3.8}$$

and

$$\overline{v}_n(s) = \begin{cases} v_n(s) & \text{if } s \in [0, T_n], \\ v^*(s) & \text{otherwise.} \end{cases} \tag{3.9}$$

Let (y_n, z_n) and $(\overline{y}_n, \overline{z}_n)$ be the solutions of system (3.5) corresponding to (w_n, v_n) and $(\overline{w}_n, \overline{v}_n)$, respectively. It is clear that $(\overline{y}_n(s), \overline{z}_n(s)) = (y_n(s), z_n(s))$ for $s \in [0, T_n]$. This together with (3.4) and (3.7)–(3.9) implies that

$$d \le L_\varepsilon(T_n, \overline{w}_n, \overline{v}_n) = L_\varepsilon(T_n, w_n, v_n) \le d + \frac{1}{n}, \tag{3.10}$$

which, combined with (3.8) and (3.9), implies that

$$\limsup_{n\to\infty} T_n \le d \ \text{ and } \ (\overline{w}_n, \overline{v}_n) \in U_\rho.$$

So there exists a subsequence of $\{n\}$, still denoted by itself, such that

$$T_n \to T_0, \ \ \overline{w}_n \to \overline{w}, \ \text{ and } \ \overline{v}_n \to \overline{v} \text{ weak star in } \ L^\infty(0, \infty; H), \tag{3.11}$$

where $(\overline{w}, \overline{v}) \in U_\rho$. By the same arguments as those in the proof of Theorem 2.3 (see (2.54) and (2.55)), we get

$$\begin{aligned} &\overline{y}_n \to \overline{y} \text{ and } \ \overline{z}_n \to \overline{z} \\ &\qquad \text{weakly in } \ H^1([0, T_0+1]; H) \cap L^2(0, T_0+1; H^2(\Omega)), \\ &\qquad \text{strongly in } \ L^2(0, T_0+1; V) \cap C([0, T_0+1]; H), \end{aligned} \tag{3.12}$$

where $(\overline{y}, \overline{z})$ is the solution of (3.5) corresponding to $(\overline{w}, \overline{v})$. These together with (3.10), (3.11), and the weakly lower semicontinuity of the convex integrand indicate that

$$\begin{aligned} &T_0 + \int_0^{T_0} \left[g(\overline{w}) + g(\overline{v}) + \frac{\varepsilon}{2}(|\overline{w}(t)|_2^2 + |\overline{v}(t)|_2^2) \right] dt + \frac{1}{2\varepsilon}(|\overline{y}(T_0)|_2^2 + |\overline{z}(T_0)|_2^2) \\ &+ \frac{1}{2} \int_0^{T_0} \left[\left| \int_0^t (\overline{w}(s) - w^*(s))\, ds \right|_2^2 + \left| \int_0^t (\overline{v}(s) - v^*(s))\, ds \right|_2^2 \right] dt = d. \end{aligned} \tag{3.13}$$

Hence $L_\varepsilon(T_0, \overline{w}, \overline{v}) = d$, which completes the proof of Lemma 3.3. □

LEMMA 3.4. *Let $(T_\varepsilon, w_\varepsilon, v_\varepsilon)$ be optimal for problem (P^ε). Then for $\varepsilon \to 0$, we have*

$$T_\varepsilon \to T^*, \ \ \lim_{\varepsilon\to 0} \int_0^{T_\varepsilon} \left[\left| \int_0^t (w_\varepsilon - w^*)\, ds \right|_2^2 + \left| \int_0^t (v_\varepsilon - v^*)\, ds \right|_2^2 \right] dt = 0$$

and for all $T < T^*$,

$$w_\varepsilon \to w^* \ \text{ and } \ v_\varepsilon \to v^* \ \text{ weak star in } \ L^\infty(0, T; H),$$

$$\begin{aligned} &y_\varepsilon \to y^* \ \text{ and } \ z_\varepsilon \to z^* \\ &\qquad \text{weakly in } \ H^1([0, T]; H) \cap L^2(0, T; H^2(\Omega)), \\ &\qquad \text{strongly in } \ L^2(0, T; V) \cap C([0, T]; H), \end{aligned}$$

where $(y_\varepsilon, z_\varepsilon)$ is the solution of (3.5) *corresponding to $(w_\varepsilon, v_\varepsilon)$.*

Proof. Let

$$\overline{w}_\varepsilon(s) = \begin{cases} w_\varepsilon(s) & \text{if } s \in [0, T_\varepsilon], \\ w^*(s) & \text{otherwise,} \end{cases} \tag{3.14}$$

$$\overline{v}_\varepsilon(s) = \begin{cases} v_\varepsilon(s) & \text{if } s \in [0, T_\varepsilon], \\ v^*(s) & \text{otherwise,} \end{cases} \tag{3.15}$$

and $(\overline{y}_\varepsilon(s), \overline{z}_\varepsilon(s))$ be the solution of (3.5) corresponding to $(\overline{w}_\varepsilon(s), \overline{v}_\varepsilon(s))$. It is clear that $(\overline{y}_\varepsilon(s), \overline{z}_\varepsilon(s)) = (y_\varepsilon(s), z_\varepsilon(s))$ for $s \in [0, T_\varepsilon]$.

By optimality of $(T_\varepsilon, w_\varepsilon, v_\varepsilon)$, we have

$$L_\varepsilon(T_\varepsilon, \overline{w}_\varepsilon, \overline{v}_\varepsilon) = L_\varepsilon(T_\varepsilon, w_\varepsilon, v_\varepsilon) \le L_\varepsilon(T^*, w^*, v^*), \tag{3.16}$$

which, combined with (3.14) and (3.15), yields that

$$(\overline{w}_\varepsilon, \overline{v}_\varepsilon) \in U_\rho, \qquad \limsup_{\varepsilon \to 0} T_\varepsilon \le T^*, \tag{3.17}$$

and

$$\overline{y}_\varepsilon(T_\varepsilon) \to 0, \quad \overline{z}_\varepsilon(T_\varepsilon) \to 0 \text{ strongly in } H. \tag{3.18}$$

Thus, on a subsequence of $\{\varepsilon\}$, still denoted by itself, we have

$$T_\varepsilon \to T_0, \quad \overline{w}_\varepsilon \to \overline{w}, \text{ and } \overline{v}_\varepsilon \to \overline{v} \text{ weak star in } L^\infty(0, \infty; H), \tag{3.19}$$

where $(\overline{w}, \overline{v}) \in U_\rho$. By the same arguments as those in the proof of Theorem 2.3 (see (2.54) and (2.55)), we get

$$\begin{aligned} &\overline{y}_\varepsilon \to \overline{y} \text{ and } \overline{z}_\varepsilon \to \overline{z} \\ &\qquad \text{weakly in } H^1([0, T_0 + 1]; H) \cap L^2(0, T_0 + 1; H^2(\Omega)), \\ &\qquad \text{strongly in } L^2(0, T_0 + 1; V) \cap C([0, T_0 + 1]; H), \end{aligned} \tag{3.20}$$

where $(\overline{y}, \overline{z})$ is the solution of (3.5) corresponding to $(\overline{w}, \overline{v})$. These together with (3.14), (3.15), (3.18), and (3.19) indicate that for all $T < T_0$,

$$w_\varepsilon \to \overline{w} \text{ and } v_\varepsilon \to \overline{v} \text{ weak star in } L^\infty(0, T; H), \tag{3.21}$$

$$\begin{aligned} &y_\varepsilon \to \overline{y} \text{ and } z_\varepsilon \to \overline{z} \\ &\qquad \text{weakly in } H^1([0, T]; H) \cap L^2(0, T; H^2(\Omega) \cap V), \\ &\qquad \text{strongly in } L^2(0, T; V) \cap C([0, T]; H), \end{aligned} \tag{3.22}$$

$$\overline{y}(T_0) = 0, \qquad \overline{z}(T_0) = 0.$$

Hence $(\overline{w}, \overline{v})$ is admissible.

By (3.16), (3.17), (3.19), (3.21), (3.22), and the weakly lower semicontinuity of the convex integrand, we get that $T_0 = T^*, (\overline{w}(s), \overline{v}(s)) = (w^*(s), v^*(s))$, and $(\overline{y}(s), \overline{z}(s)) = (y^*(s), z^*(s))$ for a.e. $s < T^*$.

This completes the proof of Lemma 3.4. □

LEMMA 3.5. *Let $(T_\varepsilon, w_\varepsilon, v_\varepsilon)$ be optimal for problem (P^ε). Then there exists $(p_\varepsilon, q_\varepsilon) \in (H^1([0,T_\varepsilon];H) \cap C([0,T_\varepsilon];V))^2$ such that*

$$
\begin{cases}
p_\varepsilon' + a\triangle p_\varepsilon - la\triangle q_\varepsilon \\
\qquad -(a_1 + 2b_1 y_\varepsilon + 3by_\varepsilon^2)(p_\varepsilon - lq_\varepsilon) = 0 & \text{a.e. } t \in (0,T_\varepsilon), \\
q_\varepsilon' + k\triangle q_\varepsilon - lcq_\varepsilon + cp_\varepsilon = 0 & \text{a.e. } t \in (0,T_\varepsilon), \\
p_\varepsilon(T_\varepsilon) = -\frac{1}{\varepsilon} y_\varepsilon(T_\varepsilon) & \text{in } \Omega, \\
q_\varepsilon(T_\varepsilon) = -\frac{1}{\varepsilon} z_\varepsilon(T_\varepsilon) & \text{in } \Omega,
\end{cases} \tag{3.23}
$$

$$
q_\varepsilon(t) \in \partial g(w_\varepsilon(t)) + \varepsilon w_\varepsilon(t) + \int_t^{T_\varepsilon} ds \int_0^s (w_\varepsilon - w^*)\, d\tau \quad \forall\, t \in (0,T_\varepsilon), \tag{3.24}
$$

$$
\begin{aligned}
&p_\varepsilon(t) - lq_\varepsilon(t) \\
&\in \partial g(v_\varepsilon(t)) + \varepsilon v_\varepsilon(t) + \int_t^{T_\varepsilon} ds \int_0^s (v_\varepsilon - v^*)\, d\tau \quad \forall\, t \in (0,T_\varepsilon),
\end{aligned} \tag{3.25}
$$

$$
\begin{aligned}
1 \le{}& \frac{\varepsilon}{2}(|w_\varepsilon(T_\varepsilon)|_2^2 + |v_\varepsilon(T_\varepsilon)|_2^2) + \rho|p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon) - \varepsilon v_\varepsilon(T_\varepsilon)|_2 \\
&+\rho|q_\varepsilon(T_\varepsilon) - \varepsilon w_\varepsilon(T_\varepsilon)|_2 - \langle (A+B)(y_\varepsilon(T_\varepsilon), z_\varepsilon(T_\varepsilon)), (p_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon))\rangle \\
&\le 1 + \frac{1}{2}\left[\left| \int_0^{T_\varepsilon} (w_\varepsilon - w^*)\, ds \right|_2^2 + \left| \int_0^{T_\varepsilon} (v_\varepsilon - v^*)\, ds \right|_2^2 \right],
\end{aligned} \tag{3.26}
$$

where $\partial g(u) = \{w \in H, \langle w, u - v\rangle \ge 0$ for all $v \in H,\ |v|_2 \le \rho\}$.

Proof. Since $(T_\varepsilon, w_\varepsilon, v_\varepsilon)$ is optimal for problem (P^ε), we have

$$
L_\varepsilon(T_\varepsilon, w_\varepsilon, v_\varepsilon) \le L_\varepsilon(T_\varepsilon, w_\varepsilon + \lambda w, v_\varepsilon + \lambda v)
$$

for all $(w,v) \in (L^\infty(0,\infty;H))^2$ and $\lambda > 0$, which yields

$$
\begin{aligned}
&\int_0^{T_\varepsilon} [g'(w_\varepsilon; w) + g'(v_\varepsilon; v) + \varepsilon(\langle w_\varepsilon, w\rangle + \langle v_\varepsilon, v\rangle)]\, dt \\
&+\frac{1}{\varepsilon}(\langle \varphi_\varepsilon(T_\varepsilon), y_\varepsilon(T_\varepsilon)\rangle + \langle \psi_\varepsilon(T_\varepsilon), z_\varepsilon(T_\varepsilon)\rangle) \\
&+ \int_0^{T_\varepsilon} \left[\left\langle \int_0^t (w_\varepsilon - w^*)\, ds, \int_0^t w\, ds \right\rangle + \left\langle \int_0^t (v_\varepsilon - v^*)\, ds, \int_0^t v\, ds \right\rangle \right] dt \ge 0,
\end{aligned} \tag{3.27}
$$

where g' is the directional derivative of g, and $(\varphi_\varepsilon, \psi_\varepsilon) \in (H^1([0,T_\varepsilon];H) \cap L^2(0,T_\varepsilon; H^2(\Omega) \cap V))^2$ is the solution to the variational system of (3.5) at $(y_\varepsilon, z_\varepsilon)$, i.e.,

$$
\begin{cases}
\varphi_\varepsilon' - a\triangle\varphi_\varepsilon + (a_1 + 2b_1 y_\varepsilon + 3by_\varepsilon^2)\varphi_\varepsilon - c\psi_\varepsilon = v & \text{in } \Omega \times (0,T_\varepsilon), \\
\psi_\varepsilon' - k\triangle\psi_\varepsilon + la\triangle\varphi_\varepsilon \\
\qquad +(a_2 + 2b_2 y_\varepsilon - 3lby_\varepsilon^2)\varphi_\varepsilon + lc\psi_\varepsilon = w - lv & \text{in } \Omega \times (0,T_\varepsilon), \\
\varphi_\varepsilon = \psi_\varepsilon = 0 & \text{on } \partial\Omega \times (0,T_\varepsilon), \\
\varphi_\varepsilon(x,0) = \psi_\varepsilon(x,0) = 0 & \text{in } \Omega.
\end{cases} \tag{3.28}
$$

Let $(p_\varepsilon, q_\varepsilon) \in (H^1([0,T_\varepsilon];H) \cap L^2(0,T_\varepsilon; H^2(\Omega) \cap V))^2$ be the solution to (3.23). (The existence of the solution to (3.23) follows the same arguments as in [17].)

Multiplying $(3.28)_1$ (the first equation of (3.28)) by p_ε scalarly in H, then integrating it over $(0, T_\varepsilon)$, and using $(3.23)_1$ (the first equation of (3.23)), we obtain

$$\begin{aligned}&\langle \varphi_\varepsilon(T_\varepsilon), p_\varepsilon(T_\varepsilon)\rangle\\ &= \int_0^{T_\varepsilon} \langle \varphi_\varepsilon, la\triangle q_\varepsilon + (a_2 + 2b_2 y_\varepsilon - 3lby_\varepsilon^2) q_\varepsilon\rangle\, dt\\ &\quad + \int_0^{T_\varepsilon} \langle v, p_\varepsilon\rangle\, dt + \int_0^{T_\varepsilon} \langle c\psi_\varepsilon, p_\varepsilon\rangle\, dt.\end{aligned} \tag{3.29}$$

Similarly, we have

$$\begin{aligned}&\langle \psi_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon)\rangle\\ &= -\int_0^{T_\varepsilon} \langle \varphi_\varepsilon, la\triangle q_\varepsilon + (a_2 + 2b_2 y_\varepsilon - 3lby_\varepsilon^2) q_\varepsilon\rangle\, dt\\ &\quad + \int_0^{T_\varepsilon} \langle w - lv, q_\varepsilon\rangle\, dt - \int_0^{T_\varepsilon} \langle c\psi_\varepsilon, p_\varepsilon\rangle\, dt,\end{aligned}$$

which, combined with (3.27) and (3.29), indicates that

$$\begin{aligned}&\int_0^{T_\varepsilon} [g'(w_\varepsilon; w) + g'(v_\varepsilon; v) + \varepsilon(\langle w_\varepsilon, w\rangle + \langle v_\varepsilon, v\rangle)]\, dt\\ &- \int_0^{T_\varepsilon} \langle v, p_\varepsilon - lq_\varepsilon\rangle\, dt - \int_0^{T_\varepsilon} \langle w, q_\varepsilon\rangle\, dt\\ &+ \int_0^{T_\varepsilon} \left[\left\langle \int_0^t (w_\varepsilon - w^*)\, ds, \int_0^t w\, ds\right\rangle + \left\langle \int_0^t (v_\varepsilon - v^*)\, ds, \int_0^t v\, ds\right\rangle\right] dt \ge 0.\end{aligned} \tag{3.30}$$

Letting $v = 0$ in (3.30), we get

$$\begin{aligned}&\int_0^{T_\varepsilon} [g'(w_\varepsilon; w) + \varepsilon\langle w_\varepsilon, w\rangle]\, dt - \int_0^{T_\varepsilon} \langle w, q_\varepsilon\rangle\, dt\\ &+ \int_0^{T_\varepsilon} \left\langle w(t), \int_t^{T_\varepsilon} ds \int_0^s (w_\varepsilon - w^*)\, d\tau\right\rangle dt \ge 0 \quad \forall\, w \in L^\infty(0, \infty; H).\end{aligned} \tag{3.31}$$

Letting $w = 0$ in (3.30), we deduce that

$$\begin{aligned}&\int_0^{T_\varepsilon} [g'(v_\varepsilon; v) + \varepsilon\langle v_\varepsilon, v\rangle]\, dt + \int_0^{T_\varepsilon} \langle lq_\varepsilon - p_\varepsilon, v\rangle\, dt\\ &+ \int_0^{T_\varepsilon} \left\langle v(t), \int_t^{T_\varepsilon} ds \int_0^s (v_\varepsilon - v^*)\, d\tau\right\rangle dt \ge 0 \quad \forall\, v \in L^\infty(0, \infty; H).\end{aligned}$$

This together with (3.31) shows (3.24) and (3.25).

It remains to prove (3.26). We note first that

$$L_\varepsilon(T_\varepsilon, w_\varepsilon, v_\varepsilon) \le L_\varepsilon(T_\varepsilon - \lambda, w_\varepsilon, v_\varepsilon) \quad \forall\, \lambda \in (0, T_\varepsilon),$$

which indicates that

$$\begin{aligned}&\frac{\varepsilon}{2}\int_0^{T_\varepsilon} (|w_\varepsilon(t)|_2^2 + |v_\varepsilon(t)|_2^2)\, dt + \frac{1}{2\varepsilon}(|y_\varepsilon(T_\varepsilon)|_2^2 + |z_\varepsilon(T_\varepsilon)|_2^2)\\ &\le -\lambda + \frac{\varepsilon}{2}\int_0^{T_\varepsilon - \lambda} (|w_\varepsilon(t)|_2^2 + |v_\varepsilon(t)|_2^2)\, dt\\ &\quad + \frac{1}{2\varepsilon}(|y_\varepsilon(T_\varepsilon - \lambda)|_2^2 + |z_\varepsilon(T_\varepsilon - \lambda)|_2^2).\end{aligned} \tag{3.32}$$

On the other hand, since $(\varepsilon I + \partial g)^{-1}$ is Lipschitz continuous on H, it follows from (3.24) and (3.25) that $w_\varepsilon, v_\varepsilon$ is Hölder continuous on $[0, T_\varepsilon]$. Then it follows from (3.5) that $(y'_\varepsilon, z'_\varepsilon) \in (C([0, T_\varepsilon]; H))^2$ (cf. [17]). Thus by (3.32), we get that

$$\frac{\varepsilon}{2}(|w_\varepsilon(T_\varepsilon)|_2^2 + |v_\varepsilon(T_\varepsilon)|_2^2) - \langle y'_\varepsilon(T_\varepsilon), p_\varepsilon(T_\varepsilon)\rangle - \langle z'_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon)\rangle \le -1. \tag{3.33}$$

Let

$$w_\varepsilon^\lambda(s) = \begin{cases} w_\varepsilon(T_\varepsilon) & \text{if } \ s \in (T_\varepsilon, T_\varepsilon + \lambda), \\ w_\varepsilon(s) & \text{otherwise} \end{cases}$$

and

$$v_\varepsilon^\lambda(s) = \begin{cases} v_\varepsilon(T_\varepsilon) & \text{if } \ s \in (T_\varepsilon, T_\varepsilon + \lambda), \\ v_\varepsilon(s) & \text{otherwise.} \end{cases}$$

By the optimality of $(T_\varepsilon, w_\varepsilon, v_\varepsilon)$, we get

$$L_\varepsilon(T_\varepsilon, w_\varepsilon, v_\varepsilon) \le L_\varepsilon(T_\varepsilon + \lambda, w_\varepsilon^\lambda, v_\varepsilon^\lambda) \quad \forall\, \lambda > 0,$$

which indicates that

$$\begin{aligned} &\frac{\varepsilon}{2}(|w_\varepsilon(T_\varepsilon)|_2^2 + |v_\varepsilon(T_\varepsilon)|_2^2) - \langle y'_\varepsilon(T_\varepsilon), p_\varepsilon(T_\varepsilon)\rangle - \langle z'_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon)\rangle \\ &\ge -1 - \frac{1}{2}\left[\left|\int_0^{T_\varepsilon}(w_\varepsilon - w^*)\,ds\right|_2^2 + \left|\int_0^{T_\varepsilon}(v_\varepsilon - v^*)\,ds\right|_2^2\right]. \end{aligned} \tag{3.34}$$

It follows from (3.24) and (3.25) that

$$\rho|q_\varepsilon(T_\varepsilon) - \varepsilon w_\varepsilon(T_\varepsilon)|_2 = \langle w_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon) - \varepsilon w_\varepsilon(T_\varepsilon)\rangle$$

and

$$\rho|p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon) - \varepsilon v_\varepsilon(T_\varepsilon)|_2 = \langle v_\varepsilon(T_\varepsilon), p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon) - \varepsilon v_\varepsilon(T_\varepsilon)\rangle,$$

which, combined with (3.5), (3.33), and (3.34), imply (3.26) as desired. This completes the proof of Lemma 3.5. □

Now we turn to the proof of Theorem 3.1.

Proof of Theorem 3.1. By (3.26) and the condition $al^2 - 4k \le 0$, we deduce that

$$\begin{aligned}
&\tfrac{\varepsilon}{2}(|w_\varepsilon(T_\varepsilon)|_2^2 + |v_\varepsilon(T_\varepsilon)|_2^2) \\
&\quad +\rho|q_\varepsilon(T_\varepsilon) - \varepsilon w_\varepsilon(T_\varepsilon)|_2 + \rho|p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon) - \varepsilon v_\varepsilon(T_\varepsilon)|_2 \\
&\le 1 + \tfrac{1}{2}[|\textstyle\int_0^{T_\varepsilon}(w_\varepsilon - w^*)\,ds|_2^2 + |\int_0^{T_\varepsilon}(v_\varepsilon - v^*)\,ds|_2^2] + \langle a_1 y_\varepsilon(T_\varepsilon) - cz_\varepsilon(T_\varepsilon), \\
&\quad p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle + \langle by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon), p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle \\
&\quad - \tfrac{a|\nabla y_\varepsilon(T_\varepsilon)|_2^2 - la\int_\Omega \nabla y_\varepsilon(T_\varepsilon)\cdot\nabla z_\varepsilon(T_\varepsilon)\,dx + k|\nabla z_\varepsilon(T_\varepsilon)|_2^2}{\varepsilon} \\
&\le 1 + \tfrac{1}{2}[|\textstyle\int_0^{T_\varepsilon}(w_\varepsilon - w^*)\,ds|_2^2 + |\int_0^{T_\varepsilon}(v_\varepsilon - v^*)\,ds|_2^2] + \langle a_1 y_\varepsilon(T_\varepsilon) - cz_\varepsilon(T_\varepsilon), \\
&\quad p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle + \langle by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon), p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle \\
&\quad - \tfrac{a|\nabla y_\varepsilon(T_\varepsilon)|_2^2 - la|\nabla y_\varepsilon(T_\varepsilon)|_2|\nabla z_\varepsilon(T_\varepsilon)|_2 + k|\nabla z_\varepsilon(T_\varepsilon)|_2^2}{\varepsilon} \\
&= 1 + \tfrac{1}{2}[|\textstyle\int_0^{T_\varepsilon}(w_\varepsilon - w^*)\,ds|_2^2 + |\int_0^{T_\varepsilon}(v_\varepsilon - v^*)\,ds|_2^2] + \langle a_1 y_\varepsilon(T_\varepsilon) - cz_\varepsilon(T_\varepsilon), \\
&\quad p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle + \langle by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon), p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle \\
&\quad - \tfrac{a(|\nabla y_\varepsilon(T_\varepsilon)|_2 - 2^{-1}l|\nabla z_\varepsilon(T_\varepsilon)|_2)^2 + 4^{-1}(4k - al^2)|\nabla z_\varepsilon(T_\varepsilon)|_2^2}{\varepsilon} \\
&\le 1 + \tfrac{1}{2}[|\textstyle\int_0^{T_\varepsilon}(w_\varepsilon - w^*)\,ds|_2^2 + |\int_0^{T_\varepsilon}(v_\varepsilon - v^*)\,ds|_2^2] + \langle a_1 y_\varepsilon(T_\varepsilon) - cz_\varepsilon(T_\varepsilon), \\
&\quad p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle + \langle by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon), p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle \\
&\quad + \tfrac{al^2 - 4k}{4\varepsilon}|\nabla z_\varepsilon(T_\varepsilon)|_2^2 \\
&\le 1 + \tfrac{1}{2}[|\textstyle\int_0^{T_\varepsilon}(w_\varepsilon - w^*)\,ds|_2^2 + |\int_0^{T_\varepsilon}(v_\varepsilon - v^*)\,ds|_2^2] + \langle a_1 y_\varepsilon(T_\varepsilon) - cz_\varepsilon(T_\varepsilon), \\
&\quad p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle + \langle by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon), p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)\rangle.
\end{aligned} \tag{3.35}$$

Now we claim that

$$\frac{\varepsilon}{2}(|w_\varepsilon(T_\varepsilon)|_2^2 + |v_\varepsilon(T_\varepsilon)|_2^2) + |p_\varepsilon(T_\varepsilon)|_2 + |q_\varepsilon(T_\varepsilon)|_2 \le C. \tag{3.36}$$

Indeed, by the same way as in the proof of Lemma 3.4, we derive that

$$\left|\int_0^{T_\varepsilon} (w_\varepsilon - w^*)\,ds\right|_2^2 + \left|\int_0^{T_\varepsilon} (v_\varepsilon - v^*)\,ds\right|_2^2 \to 0 \ \text{ as } \ \varepsilon \to 0, \tag{3.37}$$

and as $n = 1, 2$,

$$y_\varepsilon(T_\varepsilon) \to 0, \ \ z_\varepsilon(T_\varepsilon) \to 0 \ \text{ weakly in } \ V \ \text{ and strongly in } \ L^6(\Omega).$$

These together with (3.35) yield (3.36).

Multiplying $(3.23)_2$ by q_ε scalarly in H and integrating it over (t, T_ε), after some elementary calculation, we obtain that

$$|q_\varepsilon(t)|_2^2 + \int_t^{T_\varepsilon} |\nabla q_\varepsilon(s)|_2^2\,ds \le C + C\int_t^{T_\varepsilon} |p_\varepsilon(s)|_2^2\,ds \quad \forall\, t \in [0, T_\varepsilon]. \tag{3.38}$$

Similarly, we deduce that

$$|p_\varepsilon(t)|_2^2 + \int_t^{T_\varepsilon} |\nabla p_\varepsilon(s)|_2^2\,ds \le C + C\int_t^{T_\varepsilon} (|p_\varepsilon(s)|_2^2 + |q_\varepsilon(s)|_2^2)\,ds \quad \forall\, t \in [0, T_\varepsilon],$$

which, combined with (3.38), implies that

$$|p_\varepsilon(t)|_2^2 + |q_\varepsilon(t)|_2^2 + \int_0^{T_\varepsilon} |\nabla p_\varepsilon(s)|_2^2\,ds + \int_0^{T_\varepsilon} |\nabla q_\varepsilon(s)|_2^2\,ds \le C \quad \forall\, t \in [0, T_\varepsilon].$$

In particular, the latter implies that $\{p'_\varepsilon\}$ and $\{q'_\varepsilon\}$ are bounded in $L^2(0, T_\varepsilon; V^*)$. Therefore, there exists $(p, q) \in (L^2(0, T^*; V) \cap W^{1,2}([0, T^*]; V^*))^2 \subset (C([0, T^*]; H))^2$ such that on a subsequence of $\{\varepsilon\}$, still denoted by itself, we have that for all $T < T^*$,

$$\begin{aligned} &p_\varepsilon \to p, \ \ q_\varepsilon \to q \ \text{ strongly in } \ L^2(0, T; H), \ \text{ weakly in } \ L^2(0, T; V), \\ &\qquad p'_\varepsilon \to p' \ \text{ and } \ q'_\varepsilon \to q' \ \text{ weakly in } \ L^2(0, T; V^*). \end{aligned} \tag{3.39}$$

Hence, by passing to the limit for $\varepsilon \to 0$ in (3.23)–(3.25), we obtain (3.1) and (3.2) as desired.

It remains to prove (3.3). By (3.5) and (3.23), it follows that

$$\begin{aligned} &\frac{d}{dt}\langle (A + B)(y_\varepsilon(t), z_\varepsilon(t)), (p_\varepsilon(t), q_\varepsilon(t))\rangle \\ &= \langle (v_\varepsilon(t), w_\varepsilon(t) - l v_\varepsilon(t)), (p'_\varepsilon(t), q'_\varepsilon(t))\rangle \quad \text{a.e. } \ t \in (0, T_\varepsilon). \end{aligned} \tag{3.40}$$

Set

$$U_\varepsilon(t) = \int_t^{T_\varepsilon} ds \int_0^s (w_\varepsilon(\tau) - w^*(\tau))\,d\tau \quad \forall\, t \in [0, T_\varepsilon],$$

$$\overline{U}_\varepsilon(t) = \int_t^{T_\varepsilon} ds \int_0^s (v_\varepsilon(\tau) - v^*(\tau))\,d\tau \quad \forall\, t \in [0, T_\varepsilon],$$

and then (3.24) and (3.25) can be rewritten as

$$\begin{cases} w_\varepsilon(t) = (\varepsilon + \partial g)^{-1}(q_\varepsilon(t) - U_\varepsilon(t)), & \text{a.e. } t \in (0, T_\varepsilon), \\ v_\varepsilon(t) = (\varepsilon + \partial g)^{-1}(p_\varepsilon(t) - lq_\varepsilon(t) - \overline{U}_\varepsilon(t)), & \text{a.e. } t \in (0, T_\varepsilon), \end{cases}$$

and therefore it follows from (3.40) that

$$\begin{aligned} &\frac{d}{dt}(\langle (A+B)(y_\varepsilon(t), z_\varepsilon(t)), (p_\varepsilon(t), q_\varepsilon(t))\rangle \\ &\quad -g_\varepsilon^*(q_\varepsilon(t) - U_\varepsilon(t)) - g_\varepsilon^*(p_\varepsilon(t) - lq_\varepsilon(t) - \overline{U}_\varepsilon(t))) \\ &= \langle (w_\varepsilon(t), v_\varepsilon(t)), (U_\varepsilon'(t), \overline{U}_\varepsilon'(t))\rangle \quad \text{a.e. } t \in (0, T_\varepsilon), \end{aligned}$$

where $g_\varepsilon^*(p) = \sup\{(p,u) - \frac{\varepsilon}{2}|u|_2^2 : \ |u|_2 \le \rho\}$, which implies

$$\begin{aligned} &\langle (A+B)(y_\varepsilon(T_\varepsilon), z_\varepsilon(T_\varepsilon)), (p_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon))\rangle - g_\varepsilon^*(q_\varepsilon(T_\varepsilon)) - g_\varepsilon^*(p_\varepsilon(T_\varepsilon) - lq_\varepsilon(T_\varepsilon)) \\ &= \langle (A+B)(y_\varepsilon(t), z_\varepsilon(t)), (p_\varepsilon(t), q_\varepsilon(t))\rangle \\ &\quad -g_\varepsilon^*(q_\varepsilon(t) - U_\varepsilon(t)) - g_\varepsilon^*(p_\varepsilon(t) - lq_\varepsilon(t) - \overline{U}_\varepsilon(t)) \\ &\quad + \int_t^{T_\varepsilon} \langle (w_\varepsilon(s), v_\varepsilon(s)), (U_\varepsilon'(s), \overline{U}_\varepsilon'(s))\rangle \, ds \quad \forall\, t \in [0, T_\varepsilon). \end{aligned}$$

This together with (3.26), Lemma 3.4, and (3.37) shows that

$$\begin{aligned} &\langle (A+B)(y_\varepsilon(t), z_\varepsilon(t)), (p_\varepsilon(t), q_\varepsilon(t))\rangle \\ &\to \rho|q(t)|_2 + \rho|p(t) - lq(t)|_2 - 1 \quad \text{as } \ \varepsilon \to 0 \ \forall\, t \in (0, T^*). \end{aligned} \tag{3.41}$$

On the other hand, by Lemma 3.4 and (3.39), we see that

$$\begin{aligned} &\langle (A+B)(y_\varepsilon(t), z_\varepsilon(t)), (p_\varepsilon(t), q_\varepsilon(t))\rangle \\ &\to \langle (A+B)(y^*(t), z^*(t)), (p(t), q(t))\rangle \quad \text{a.e. in } \ (0, T^*). \end{aligned}$$

Then by (3.41), we get (3.3) as desired.

This completes the proof of Theorem 3.1. □

Finally, we prove Theorem 3.2.

Proof of Theorem 3.2. We only need to prove that (3.36) holds. The rest of the proof is the same as the proof of Theorem 3.1.

Indeed, by the same arguments as those in the proof of Theorem 2.3, we obtain

$$|\nabla y_\varepsilon(t)|_2^2 \le |\nabla y^0|_2^2 + \frac{a_0(b,c,\rho,l)}{a},$$

which yields that

$$\begin{aligned} &|by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon)|_2 \\ &\le b|y_\varepsilon^3(T_\varepsilon)|_2 + 3b\|h_e\| \cdot |y_\varepsilon^2(T_\varepsilon)|_2 \\ &\le b\|y_\varepsilon(T_\varepsilon)\|_{L^6(\Omega)}^3 + 3b\|h_e\| \cdot |\Omega|^{\frac{1}{6}} \cdot \|y_\varepsilon(T_\varepsilon)\|_{L^6(\Omega)}^2 \\ &\le bC_1^2 |\nabla y_\varepsilon(T_\varepsilon)|_2^2 (C_1 |\nabla y_\varepsilon(T_\varepsilon)|_2 + 3\|h_e\| \cdot |\Omega|^{\frac{1}{6}}) \\ &\le bC_1^2 \left[C_1 \left(|\nabla y^0|_2^2 + \frac{a_0(b,c,\rho,l)}{a} \right)^{\frac{1}{2}} + 3\|h_e\| \cdot |\Omega|^{\frac{1}{6}} \right] \left(|\nabla y^0|_2^2 + \frac{a_0(b,c,\rho,l)}{a} \right). \end{aligned}$$

So for $|\nabla y_0|_2^2 \le \eta_0$ and $a \ge \eta_0^{-1} a_0(b, c, \rho, l)$, one may derive that

$$\begin{aligned} &|by_\varepsilon^3(T_\varepsilon) + 3bh_e y_\varepsilon^2(T_\varepsilon)|_2 \\ &\le bC_1^2[(2\eta_0)^{\frac{1}{2}} C_1 + 3\|h_e\| \cdot |\Omega|^{\frac{1}{6}}]2\eta_0 \\ &\le bC_1^2[2\eta_0 + C_1^2 + 6\|h_e\| \cdot |\Omega|^{\frac{1}{6}}]\eta_0 \\ &= 2bC_1^2\eta_0^2 + bC_1^2(C_1^2 + 6\|h_e\| \cdot |\Omega|^{\frac{1}{6}})\eta_0 \\ &\le \frac{\rho}{2}. \end{aligned} \tag{3.42}$$

On the other hand, it follows from Lemma 3.4 that

$$y_\varepsilon(T_\varepsilon) \to 0, \quad z_\varepsilon(T_\varepsilon) \to 0 \ \text{ weakly in } \ V \ \text{ and strongly in } \ H,$$

which, combined with (3.35), (3.37), and (3.42), imply (3.36). This completes the proof of Theorem 3.2. □

Remark. It should be noted that in order to obtain the maximum principle for problem (P), we put controls on the whole domain Ω and in both equations of the system (1.1) in section 3. This is because, in general, one approximates an optimal time control problem by a free optimal time control problem in order to derive the maximum principle (see, for instance, [2] and [16]). Thus one needs to estimate the values of the adjoint states at T_ε. However, such an estimate seems to depend on the values of the controls on the whole domain Ω. More precisely, for the phase-field system, in order to get the boundness of $\{(p_\varepsilon(T_\varepsilon), q_\varepsilon(T_\varepsilon))\}$ in $L^2(\Omega) \times L^2(\Omega)$, one needs to have both controls in two equations, which are defined on Ω.

Acknowledgment. The authors thank the referee for his (or her) careful reading of this paper and valuable suggestions.

ON THE GENERICITY OF THE OBSERVABILITY OF UNCONTROLLED DISCRETE NONLINEAR SYSTEMS*

J.-C. VIVALDA†

Abstract. In this paper, it is proven that, generically, a nonlinear discrete system given on a compact manifold X is observable.

Key words. observability, discrete-time systems, transversality

AMS subject classifications. 57R40, 93B07, 93B27, 93C55

DOI. 10.1137/S0363012902403997

1. Introduction. This paper deals with the question of genericity of observability for discrete-time nonlinear system such that

$$\left\{\begin{array}{rcl} x_{k+1} & = & f(x_k), \\ y_k & = & h(x_k), \\ x_k \in X, & & y_k \in \mathbb{R}, \end{array}\right. \tag{1}$$

where X is a C^∞ connected n-dimensional manifold, f is a diffeomorphism, and $h : X \to \mathbb{R}$ is a C^∞ mapping.

There are many notions of observability; among them the weaker is the following. We will say that (1) is observable if, given two initial conditions x_0 and $\bar{x}_0$, there exists $k \in \mathbb{N}^*$ such that $h(x_k) \neq h(\bar{x}_k)$. Our main result is about the stronger notion of strong observability defined below.

DEFINITION 1. *Denoting by f^s, $f \circ \cdots \circ f$ s times, we say that system* (1) *is strongly observable if the map*

$$\begin{array}{rccl} \Theta_{f,h} : & X & \longrightarrow & \mathbb{R}^{2n+1}, \\ & x & \longmapsto & (h(x), h \circ f(x), \ldots, h \circ f^{2n}(x)) \end{array}$$

is an embedding.

We will prove that the set of pairs $(f, h) \in \mathrm{Diff}(X) \times C^\infty(X, \mathbb{R})$ such that system (1) is strongly observable is residual (for the C^∞ topology).

On this subject, we have to mention an important work from Gauthier and Kupka; in [4] the authors (together with Hammouri) proved the genericity of the observability for uncontrolled continuous-time systems; in [5] the same result is established for controlled continuous-time systems.

We want to compare this work with works on the same subject in the scientific literature: we begin with a paper written by Aeyels [2]. In this article, the author considers an uncontrolled system given on a compact manifold X such as

$$\left\{\begin{array}{l} \dot{x} = f(x), \\ y = h(x) \end{array}\right. \tag{2}$$

*Received by the editors March 13, 2002; accepted for publication (in revised form) April 20, 2003; published electronically October 28, 2003. Research for this work was supported by Inria-Lorraine (CONGE project) and UMR CNRS 7122.

†Inria-Lorraine, ISGMP Bât. A, Université de Metz, Ile du Saulcy, 57045 Metz Cedex 01, France (vivalda@loria.fr).

and works with the discretized vector field f. He introduces the notion of P-observability.

DEFINITION 2 (Aeyels). *A time $T > 0$ being given, P is a finite subset of $[0, T]$. System (2) is said to be P-observable iff for each $(x, y) \in X^2$, $x \neq y$, there exists a $t_i \in P$ such that $h \circ \Phi_{t_i}(x) \neq h \circ \Phi_{t_i}(y)$, where Φ denotes the flow of f.*

Two results are proved in this paper.

THEOREM 1 (Aeyels). *There exists an open and dense set of vector fields such that, a vector field f in this set being fixed, the subset of functions h belonging to $C^r(X, \mathbb{R})$ such that the system (f, h) is P-observable is open and dense in $C^r(X, \mathbb{R})$. This is true for almost any finite subset P of $(2 \dim X + 1)$ points in $[0, T]$.*

The second theorem is the dual of this: the same result is stated with h fixed. The tools used to prove these results are also the tools of transversality theory. Our result is a little bit more general because we work with a diffeomorphism f which does not necessarily derive from the flow of a vector field. Moreover, the result we prove is about a stronger notion of observability. Notice, however, that in a concluding remark of the above-mentioned paper, the author mentions that it is possible to extend the result to an embedding context. The proof is not explicitly written but can be made along the same lines.

In [8], the author proves exactly the same result as the one of this paper; nevertheless, its proof is, in our opinion, oversimplified and does not seem to use the same tools as the ones used in this article. We have to mention also the paper [7], where a proof of this result is given; the proof is based on the tools of transversality theory and is similar to the one supplied here.

All the works mentioned in this introduction make extensive use of the tools of the transversality theory; as explained hereafter, we will use the same tools to prove our result.

2. Preliminaries. In this section we recall some theorems from differential topology which will be intensively used in the proof of the main result of this paper. For details on the C^∞ Whitney topology, the reader is referred to the book "Stable Mappings and their Singularities" (see [6]).

If X and Y are two smooth manifolds, $J^k(X, Y)$ will denote, as usual, the set of k-jets from X to Y, $\alpha : J^k(X, Y) \to X$ is the source map, and $\beta : J^k(X, Y) \to Y$ is the target map. If f is in $C^\infty(X, Y)$—the space of smooth maps from X to Y—$j^k f$ denotes the k-jet of f. Recall that the set $C^\infty(X, Y)$ endowed with the Whitney topology is a Baire space, and so every residual set of $C^\infty(X, Y)$ (i.e., every countable intersection of open dense subsets) is dense.

The notion of transversality is of paramount importance for our purpose, and we recall below its definition.

DEFINITION 3. *Let f be a smooth mapping between two smooth manifolds X and Y, W a submanifold of Y, and x a point in X. We will say that f intersects W* transversely *at x if either*

(i) $f(x) \notin W$ *or*

(ii) $f(x) \in W$ *and* $T_{f(x)}Y = T_{f(x)}W + df_x(T_xX)$,

T_xX denoting the tangent space to X at x and df_x the Jacobian of f at x. We will say that f intersects W transversely if it intersects W transversely at x for all x in W. We will use the symbol $\pitchfork$ to denote the transversality.

The following theorem states a result of genericity (see [6]).

THEOREM 2 (Thom transversality theorem). *Let X and Y be smooth manifolds*

and W a submanifold of $J^k(X,Y)$. Let

$$T_W = \{f \in C^\infty(X,Y) \mid j^k f \pitchfork W\}.$$

Then T_W is a residual subset of $C^\infty(X,Y)$ in the C^∞ topology. Moreover, if W is closed, then T_W is open.

The following result generalizes the above theorem to multijet spaces. We first define the set $X^{(s)} = \{\,(x_1,\dots,x_s) \in X^s \;\; x_i \neq x_j \text{ for } 1 \leq i < j \leq s\,\}$ and the mapping

$$\begin{aligned} \alpha^s : \big(J^k(X,Y)\big)^s &\longrightarrow X^s, \\ (\sigma_1,\dots,\sigma_s) &\longmapsto \big(\alpha(\sigma_1),\dots,\alpha(\sigma_s)\big), \end{aligned}$$

and we let $J^k_s(X,Y) = (\alpha^s)^{-1}(X^{(s)})$, $J^k_s(X,Y)$ being a submanifold of $\Big(J^k(X,Y)\Big)^s$.

For $f \in C^\infty(X,Y)$, we can define

$$\begin{aligned} j^k_s f : \qquad X^{(s)} \qquad &\longrightarrow J^k_s(X,Y), \\ (x_1,\dots,x_s) \quad &\longmapsto \big(j^k f(x_1),\dots,j^k f(x_s)\big). \end{aligned}$$

THEOREM 3 (multijet transversality theorem). *Let W be a submanifold of $J^k_s(X,Y)$, and let*

$$T_W = \{f \in C^\infty(X,Y) \mid j^k_s f \pitchfork W\}.$$

Then T_W is a residual subset of $C^\infty(X,Y)$ in the C^∞ topology. Moreover, if W is compact, then T_W is open.

We will use also a transversality theorem due to Abraham and Robbin (see [1]). Let $\mathcal{A}, X$, and Y be C^r manifolds, $C^r(X,Y)$ the set of C^r maps from X to Y, and $p : \mathcal{A} \to C^r(X,Y)$ a map.

For $a \in \mathcal{A}$, we write ρ_a, the C^r map

$$\begin{aligned} \rho_a : X &\longrightarrow Y, \\ x &\longmapsto \rho_a(x) = \rho(a)(x), \end{aligned}$$

and we say that ρ is a C^r representation if the evaluation map

$$\begin{aligned} \mathrm{ev}_\rho : \mathcal{A} \times X &\longrightarrow Y, \\ (a,x) &\longmapsto \rho_a(x) = \rho(a)(x) \end{aligned}$$

is a C^r map from $\mathcal{A} \times X$ to Y.

THEOREM 4 (Abraham transversal density theorem). *Let $\mathcal{A}, X, Y$ be C^r manifolds, $\rho : \mathcal{A} \to C^r(X,Y)$ a C^r representation, $W \subset Y$ a submanifold (not necessarily closed), and $\mathrm{ev}_\rho : \mathcal{A} \times X \to Y$ the evaluation map. Define $\mathcal{A}_W \subset \mathcal{A}$ by*

$$\mathcal{A}_W = \{a \in \mathcal{A} \mid \rho_a \pitchfork W\}.$$

Assume that

(i) *X has a finite dimension n and W has a finite codimension q in Y;*
(ii) *$\mathcal{A}$ and X are second countable;*
(iii) *$r > \max(0, n-q)$;*
(iv) *$\mathrm{ev}_\rho \pitchfork W$.*

Then $\mathcal{A}_W$ is residual in $\mathcal{A}$.

Notice that manifold $\mathcal{A}$ is not necessarily finite dimensional; it may be a Banach space or an open subset of a Banach space.

Finally, we will need the following theorem that can also be found in [1].

THEOREM 5 (openness of transversal intersection). *Let $\mathcal{A}$, X, and Y be C^r manifolds with X finite dimensional, $W \subset Y$ a closed C^r submanifold, K a compact subset of X, and $\rho : \mathcal{A} \to C^r(X, Y)$ a C^r representation. Then the subset $\mathcal{A}_{KW} \subset \mathcal{A}$ defined by*

$$\mathcal{A}_{KW} = \{a \in \mathcal{A} \mid \rho_a \pitchfork_x \ W \text{ for } x \in K\}$$

is open.

3. Main result. In what follows in this paper, X will denote a compact manifold and $\mathrm{Diff}(X)$ will denote the set of diffeomorphisms on X. There are many notions of observability; among them the weaker is the following. We will say that (1) is observable if, given two initial conditions x_0 and $\bar{x}_0$, there exists $k \in \mathbb{N}^*$ such that $h(x_k) \neq h(\bar{x}_k)$. Our main result is about the stronger notion of strong observability defined below.

DEFINITION 4. *Denoting by f^s, $f \circ \cdots \circ f$ s times, we say that system* (1) *is strongly observable if the map*

$$\begin{aligned} \Theta_{f,h} : \ X &\longrightarrow \mathbb{R}^{2n+1}, \\ x &\longmapsto (h(x), h \circ f(x), \ldots, h \circ f^{2n}(x)) \end{aligned}$$

is an embedding.

We state the following theorem about the discrete system of type (1).

THEOREM 6. *The set of pair $(f, h) \in \mathrm{Diff}(X) \times \mathscr{C}^\infty(X, \mathbb{R})$ such that system* (1) *is strongly observable is residual.*

The proof of this theorem will be given through Lemmas 1–6. In Lemmas 1–3, we prove that the set $\mathscr{C}_{2n}(X)$ of diffeomorphisms whose periodic points with period $\leq 2n$ and which are cocyclic at each periodic point is open dense. In Lemmas 4–7, we prove that a diffeomorphism $f \in \mathscr{C}_{2n}(X)$ being given, the set of maps $h \in C^\infty(X, \mathbb{R})$ such that $\Theta_{f,h}$ is an immersion at each s-periodic point of f and is injective when restricted to the set of periodic points of f is dense. In Lemmas 5–6, we conclude that the set of pairs (f, h) such that $\Theta_{f,h}$ is an embedding is dense in $\mathrm{Diff}(X) \times C^\infty(X, \mathbb{R})$.

3.1. Periodic points. Let f be a diffeomorphism of X; the point $x \in X$ is said to be a periodic point of f with period s (we will also say s-periodic point of f) if $f^s(x) = x$ and $f^p(x) \neq x$ whenever $0 < p < s$. We will say that the s-tuple $(x_1, \ldots, x_s)$ is a cycle of length s (or an s-cycle) for f if $x_{i+1} = f(x_i)$ for $i = 1, \ldots, s-1$ and $f(x_s) = x_1$; this is equivalent to saying that x_i is an s'-periodic point of f (with s' a divisor of s). Let $\Gamma_s(f)$ denote the set of all periodic points of f with period $\leq s$.

LEMMA 1. *For every $r \in \mathbb{N}^*$, there exists an open dense set $\mathscr{P}_r(X)$ of diffeomorphisms of X such that if $f \in \mathscr{P}_r(X)$, $\Gamma_r(f)$ is finite.*

Proof. Let us denote by Ω_r the set of roots of unity with order no greater than r ($\omega \in \Omega_r \Leftrightarrow \omega^e = 1$ with $1 \leq e \leq r$) and by $\mathscr{P}_r(X)$ the set of diffeomorphisms f such that if x is a s-periodic point of f with $s \leq r$, none of the eigenvalues of df_x^s belongs to Ω_r.

First we claim that if f belongs to $\mathscr{P}_r$, $\Gamma_r(f)$ is finite. Indeed, we notice first that the limit of a sequence of periodic points is also a periodic point, so $\Gamma_r(f)$ is closed.

Then we will see that every periodic point in $\Gamma_r(f)$ is isolated (among the points of this set). Suppose on the contrary that $x_0 \in \Gamma_r(f)$ is not isolated; then there exists a sequence $(x_n)_{n\geq 1}$ of points in $\Gamma_r(f)$ whose limit is x_0; we can suppose that all the x_n are periodic with the same period $s \leq r$, and so we have $f^s(x_0) = x_0$, which proves that x_0 is an s'-periodic point of f (with s' a divisor of s). In other words, x_0 is a nonisolated fixed point for f^s, but it is well known that if x_0 is a nonisolated fixed point of a mapping g, dg_x admits the number 1 as an eigenvalue. We deduce that 1 is an eigenvalue of $df^s_{x_0}$, which implies that $df^{s'}_{x_0}$ has an eigenvalue in Ω_r, but this is in contradiction with the definition of $\mathscr{P}_r$.

Density of $\mathscr{P}_r$. We will prove now that $\mathscr{P}_r$ is open dense. For the density part of the lemma, it suffices to prove that the set of $f \in \mathrm{Diff}(X)$ such that df^s_x has no eigenvalue in Ω_r if x is an s-periodic point of f is residual. Manifold X being second countable and metrizable, there exists a countable family $\mathscr{F}$ of open subsets whose union is equal to X and which satisfies

$$\forall (x,y) \in X^2, x \neq y \Rightarrow \exists (p,q) \in \mathbb{N}^2 \mid x \in U_p, y \in U_q, U_p \cap U_q = \emptyset.$$

We will assume that a coordinate function Φ_p is associated with each U_p.

Let $s \leq r$ and $\mathscr{A}_s$ be the set of s-tuples $(M_1, \dots, M_s)$ of matrices of $\mathcal{M}_n(\mathbb{R})$ such that the product $M_1 \cdots M_s$ has at least one eigenvalue in Ω_r; clearly, $\mathscr{A}_s$ is an algebraic set and thus, from Whitney's theorem (see [9]), a finite union of smooth submanifolds of $(\mathcal{M}_n(\mathbb{R}))^s : \mathscr{A}_s = W_1 \cup \cdots \cup W_N$. Let $(U_1, \Phi_1), \dots, (U_s, \Phi_s)$ be charts of X with $U_i \in \mathscr{F}$ and $U_i \cap U_j = \emptyset$ if $i \neq j$. We consider the chart $(\mathscr{J}, \gamma)$ of $J^1_s(X,X)$, where $\mathscr{J} = J^1(U_1,U_2) \times \cdots \times J^1(U_{s-1},U_s) \times J^1(U_s,U_1)$ and γ is the mapping from $\mathscr{J}$ to

$$\mathscr{U} = \Phi_1(U_1) \times \Phi_2(U_2) \times \cdots \times \Phi_{s-1}(U_{s-1}) \times \Phi_s(U_s) \times \Phi_s(U_s) \times \Phi_1(U_1) \times (\mathcal{M}_n(\mathbb{R}))^s$$

defined by

$$\begin{aligned}\gamma(\sigma_1, \dots, \sigma_s) = \Big(&\phi_1\big(\alpha(\sigma_1)\big), \phi_2\big(\beta(\sigma_1)\big), \dots, \phi_s\big(\alpha(\sigma_s)\big), \phi_1\big(\beta(\sigma_s)\big),\\ &d\big(\phi_2 \circ f_1 \circ \phi_1^{-1}\big)_{\phi_1(\alpha(\sigma_1))}, \dots, d\big(\phi_1 \circ f_s \circ \phi_s^{-1}\big)_{\phi_s(\alpha(\sigma_s))}\Big),\end{aligned}$$

the f_i's representing the σ_i's. Let W_i be one of the submanifolds appearing in the decomposition of the algebraic manifold $\mathcal{A}$ described above. We denote by $(x_1, x_2', x_2, x_3', \dots, x_{s-1}, x_s', x_s, x_1', M_1^s)$ an element of $\gamma(\mathcal{J})$, and we consider $V_i \subset \gamma(\mathcal{J})$ defined by the relations

$$\begin{cases} x_i = x_i' \text{ for } i = 1, \dots, s, \\ M_1^s \in W_i. \end{cases}$$

V_i is a submanifold of $\gamma(\mathcal{J})$ of codimension $\operatorname{codim} V_i = sn + d_i$ ($d_i = \operatorname{codim} W_i$). Thus, $\tilde{V}_i = \gamma^{-1}(V_i)$ is a submanifold of $J^1_s(X,X)$ with the same codimension as V_i.

For $f \in \mathrm{Diff}(X)$, to say that the mapping $j^1_s f : X^{(s)} \to J^1_s(X,X)$ is transverse to $\tilde{V}_i$ means that $j^1_s f(x) \notin \tilde{V}_i$ for all x because the codimension of $\tilde{V}_i$ is equal to $sn + d_i$ and is greater than sn, the dimension of $X^{(s)}$.

Let us consider the countable set $\{\mathcal{J}_1, \mathcal{J}_2, \dots\}$ of charts of $J^1_s(X,X)$ defined from the s-tuples $(U_1, \dots, U_s)$ as above. To each chart $\mathcal{J}_k$ are associated N manifolds $\tilde{V}_i^k$ $(i = 1, \dots, N)$; thanks to the multijet transversality theorem, we can assert that the set of $\mathscr{R}^k$ of diffeomorphisms f such that the mapping $j^1_s f : X^{(s)} \to J^1_s(X,X)$ is

transverse to $\tilde{V}_i^k$ is residual, so the set $\mathscr{R}^k$ of f such that the mapping $j_s^1 f : X^s \to J_s^1(X,X)$ is transverse to each submanifold $\tilde{V}_i^k$ $(i = 1, \dots, N)$ is residual as a finite intersection of residual sets, and $\mathscr{R} = \bigcap_{k\geq 1} \mathscr{R}^k$ is also residual.

Now, let f be an element of $\mathscr{R}$ and suppose that x is a periodic point of order $s \leq r$ for f. If we put

$$\begin{cases} x_1 = x, \\ x_2 = f(x), \\ \vdots \\ x_s = f^{s-1}(x). \end{cases}$$

Then $x_i \neq x_j$ for $i \neq j$ and $f(x_s) = x_1$.

From the definition of $\mathscr{F}$, it is possible to find charts $(U_1, \phi_1), \dots, (U_s, \phi_s)$ such that $U_i \in \mathscr{F}$, $U_i \cap U_j = \emptyset$ if $i \neq j$ and $x_i \in U_i$ for $i = 1, \dots, s$.

To say that the map $j_s^1 f$ is transverse to $\tilde{V}_i$ at the point $(x_1, \dots, x_s)$ means that $j_s^1 f(x_1, \dots, x_s)$ does not belong to $\tilde{V}_i$. From the definition of $\tilde{V}_i$, this means that $\gamma\big(j_s^1 f(x_1, \dots, x_s)\big) \notin V_i$; therefore $\big(d\big(\phi_2 \circ f \circ \phi_1^{-1}\big)_{\phi_1(x_1)}, \dots d\big(\phi_1 \circ f \circ \phi_s^{-1}\big)_{\phi_s(x_s)}\big) \notin W_i$ (for $i = 1, \dots; N$), which implies that the s-tuple of matrices

$$\Big(d\big(\phi_2 \circ f \circ \phi_1^{-1}\big)_{\phi_1(x_1)}, \dots d\big(\phi_1 \circ f \circ \phi_s^{-1}\big)_{\phi_s(x_s)}\Big)$$

does not belong to $\mathscr{A}_s$, and so none of the eigenvalues of df_x^s is in Ω_r if x is an s-periodic point of f.

Openness of $\mathscr{P}_r$. Let f_0 be in $\mathscr{P}_r$; the s-periodic points of f_0 are isolated $(s \leq r)$ and X is compact, so $\Gamma_r(f_0)$ is finite. By definition of the topology of $\mathrm{C}^\infty(X,X)$ and since X is compact, we have

$$\forall \varepsilon > 0, \exists\, U_\varepsilon \mid g \in U_\varepsilon \Rightarrow d(f(x), g(x)) < \varepsilon \ \forall x \in X,$$

where U_ε is an open neighborhood of f in $C^\infty(X,X)$ and d is a distance compatible with the topology of X. For $s \leq r$, the number of s-cycles of f is finite; we will denote them by

$$\begin{array}{cccc} x_{11}, & x_{12}, & \dots, & x_{1s}, \\ x_{21}, & x_{22}, & \dots, & x_{2s}, \\ & & \vdots & \\ x_{N1}, & x_{N2}, & \dots, & x_{Ns}. \end{array}$$

We choose $\rho > 0$ such that $B(x_{ij}, \rho) \cap B(x_{i'j'}, \rho) = \emptyset$ if $x_{ij} \neq x_{i'j'}$ ($B(x_{ij}, \rho)$ denotes the open ball of center x_{ij} and radius ρ); to each $B(x_{ij}, \rho)$ we associate a chart ϕ_{ij}.

We set

$$\begin{aligned} B_i =& \Big(B(x_{i1}, \rho) \times \dots \times B(x_{is}, \rho)\Big) \cup \Big(B(x_{i2}, \rho) \times \dots \times B(x_{is}, \rho) \times B(x_{i1}, \rho)\Big), \\ & \cup \dots \cup \Big(B(x_{is}, \rho) \times B(x_{i1}, \rho) \times \dots \times B(x_{is-1}, \rho)\Big), \\ K =& X^s \setminus \bigcup_{i=1}^{N} B_i, \\ \beta =& \inf_{(x_1, \dots, x_s) \in K} \{d(f(x_1), x_2) + \dots + d(f(x_{s-1}), x_s) + d(f(x_s), x_1\}. \end{aligned}$$

We have $\beta \neq 0$. Indeed, if $\beta = 0$, then by continuity of f and since K is compact, there exists $(x_1, \dots, x_s) \in K$ satisfying $f(x_1) = x_2, \dots, f(x_s) = x_1$, which means that $(x_1, \dots, x_s)$ is an s-cycle for f which is impossible because all the s-cycles belong to $\bigcup_{i=1}^{N} B_i$.

Let $\varepsilon > 0$ be such that $s\varepsilon < \beta$, let $g \in U_\varepsilon$ and x_1 be a periodic point of g of order s, and put $x_2 = g(x_1), \dots, x_s = g(x_{s-1})$; we have $g(x_s) = x_1$.

If $(x_1, \dots, x_s) \notin \bigcup_{i=1}^{N} B_i$, then $d(f(x_1), x_2) + \cdots + d(f(x_{s-1}), x_s) + d(f(x_s), x_1) \geq \beta$. Since $x_i = g(x_{i-1})$, this implies $\beta \leq d(f(x_1), g(x_1)) + \cdots + d(f(x_{s-1}), g(x_{s-1})) + d(f(x_s), g(x_s)) < s\epsilon < \beta$, which is a contradiction.

We conclude that all the periodic points of g are in the balls $B(x_{ij}, \rho)$. Now if ρ and ε are chosen small enough, it is clear that none of the eigenvalues of $dg^s x_1$ is contained in Ω_r.

Remark 1. If f is in $\mathscr{P}_r$, X being compact, the set of periodic points of f of order $\leq r$ is finite.

3.2. Cocyclic diffeomorphisms.

DEFINITION 5. *Let $f \in \mathrm{Diff}(X)$, and let x be a periodic point of order $s \leq n-1$ of f; we will say that f is* cocyclic *at x if it is possible to find s covectors $h_1, \dots, h_s$ ($h_i \in \left(T_{f^{i-1}(x)}X\right)^*$) such that the covectors*

$$h_1,\ h_2 \cdot df_x, \dots, h_s \cdot df_x^{s-1}, \dots,\ h_1 \cdot df_x^{sq}, \dots, h_{r+1} \cdot df_x^{sq+r}$$

are linearly independent ($n - 1 = sq + r$ with $0 \leq r < s$).

We will denote by $\mathscr{C}_r(X)$ the subset of $\mathscr{P}_r(X)$ constituted by the diffeomorphisms which are cocyclic at all their s-periodic points for all $s \leq r$.

LEMMA 2. *The set $\mathscr{C}_r(X)$ is residual.*

Proof. Let $s \leq r$, in $(M_n(\mathbb{R}))^s$, we consider the set $\mathscr{M}$ of s-tuples $(A_1, A_2, \dots, A_s)$ for which there exist s covectors $C_1, C_2, \dots, C_s$ such that the n covectors

$$\begin{array}{ccccccc}
C_1, & C_2A_1, & C_3A_2A_1, & \dots, & \dots, & C_sA_{s-1}\dots A_1, \\
C_1\tilde{A}, & C_2A_1\tilde{A}, & C_3A_2A_1\tilde{A}, & \dots, & \dots, & C_sA_{s-1}\dots A_1\tilde{A}, \\
 & & \vdots & & & \\
C_1\tilde{A}^{q-1}, & C_2A_1\tilde{A}^{q-1}, & C_3A_2A_1\tilde{A}^{q-1}, & \dots, & \dots, & C_sA_{s-1}\dots A_1\tilde{A}^{q-1}, \\
C_1\tilde{A}^{q}, & C_2A_1\tilde{A}^{q}, & C_3A_2A_1\tilde{A}^{q}, & \dots, & C_rA_{r-1}\dots A_1\tilde{A}^{q} &
\end{array}$$

are linearly independent ($n = sq + r$ with $0 \leq r < s$, and we put $\tilde{A} = A_s \cdots A_1$).

We notice that the set $\mathcal{A} = (M_n(\mathbb{R}))^s \setminus \mathscr{M}$ is algebraic, and so it is a finite union of smooth submanifolds of $(M_n(\mathbb{R}))^s$. Now the proof uses exactly the same arguments as in the proof of the previous lemma. The codimension of each submanifold W_i is at least equal to 1 since the complement of $\mathcal{A}$ is an open nonempty subset of $(M_n(\mathbb{R}))^s$. □

LEMMA 3. *The set $\mathscr{C}_r(X)$ is open.*

Proof. The proof is analogous to the one of Lemma 1. From this last lemma, we know that all the periodic points of order $\leq r$ of f are isolated, so the same is true for all the s-cycles of f; these s-cycles will be denoted by

$$\begin{array}{cccc}
x_{11}, & x_{12}, & \dots, & x_{1s}, \\
x_{21}, & x_{22}, & \dots, & x_{2s}, \\
 & & \vdots & \\
x_{N1}, & x_{N2}, & \dots, & x_{Ns}.
\end{array}$$

If diffeomorphism g is closed enough to f, all the periodic points of g (of order $\leq s$) will be closed to the periodic points of f, and the differentials of g at a periodic point will be closed to the differential of f at some periodic point x_{ij}, from which we can deduce that $g \in \mathscr{C}_r$ as soon as g is closed enough to f. □

3.3. Genericity of the injectivity.

LEMMA 4. *For a given finite set $E = \{x_1^0, \dots, x_p^0\}$ of points of X, the set $\mathscr{H}(E)$ of mappings $h \in C^\infty(X, \mathbb{R})$ satisfying $h(x_i^0) \neq h(x_j^0)$ for all $i \neq j$ is open and dense in $C^\infty(X, \mathbb{R})$.*

Proof. Once again we will use the multijet transversality theorem with

$$J_p^0(X, \mathbb{R}) = \{(x_1, r_1, \dots, x_p, r_p) \in (X \times \mathbb{R})^p \ : \ x_i \neq x_j \text{ if } i \neq j\}.$$

For a pair $(i, j) \in \{1, \dots, p\}$ with $i \neq j$ let

$$W_{ij} = \{(x_1, r_1, \dots, x_p, r_p) \in J_p^0(X, \mathbb{R}) \mid x_1 = x_1^0, \dots, x_p = x_p^0, r_i = r_j\}.$$

W_{ij} is a closed submanifold of $J_p^0(X, \mathbb{R})$ with codimension $np + 1$. Since this codimension is greater than $\dim X^{(p)}$, to say that the mapping $j_p^0 h$

$$\begin{array}{rccc} j_p^0 h : & X^{(p)} & \longrightarrow & J_p^0(X, \mathbb{R}), \\ & (x_1, \dots, x_p) & \longmapsto & \big(x_1, h(x_1), \dots, x_p, h(x_p)\big) \end{array}$$

is transverse to W_{ij} means that $j_p^0 h(x_1, \dots, x_p) \notin W_{ij}$ for all $(x_1, \dots, x_p)$, which is equivalent to saying that $h(x_i^0) \neq h(x_j^0)$. So the set $\mathscr{H}(E)$ of mappings $h \in C^\infty(X, \mathbb{R})$ such that $h(x_i^0) \neq h(x_j^0)$ for every pair (i, j) such that $1 \leq i < j \leq p$ is residual. Now, it is easy to see that if h is in $\mathscr{H}(E)$, the same is true for every mapping $\bar{h}$ closed enough to h, which proves that $\mathscr{H}(E)$ is open. □

LEMMA 5. *Let f be an element of $\mathscr{C}_{2n}(X)$, and recall that $\Gamma_{2n}(f)$ denotes the set of periodic points of f of order $\leq 2n$. The set $\mathscr{B}(f)$ defined by*

$$\mathscr{B}(f) = \{\, h \in C^\infty(X, \mathbb{R}) \mid \big(h(x), \dots, h \circ f^{2n}(x)\big) \neq \big(h(x_0), \dots, h \circ f^{2n}(x_0)\big) \\ \forall (x, x_0) \in \big(X \setminus \Gamma_{2n}(f)\big) \times \Gamma_{2n}(f) \,\}$$

is open dense.

Proof. We begin by proving the density part of this lemma; to this end, we need the Abraham's theorem (Theorem 4) that we recalled in the introduction.

In this proof, we consider that $C^\infty(X, \mathbb{R})$ is included in $C^r(X, \mathbb{R})$ endowed with the C^r topology (which is a Banach space); it is sufficient to prove the lemma for every (large enough) finite r to get the C^∞ result.

For each period $s = 1, 2, \dots, 2n$, we consider the C^r representation

$$\rho^s : C^\infty(X, \mathbb{R}) \to C^r(X, \mathbb{R}^{n+1})$$

defined by

$$\rho^s(h)(x) = \big(h(x) - h \circ f^s(x), h \circ f(x) - h \circ f^{s+1}(x), \dots, h \circ f^n(x) - h \circ f^{n+s}(x)\big).$$

The set $\tilde{X} = X \setminus \Gamma_{2n}(f)$ is a manifold as an open subset of X. We take $W = \{0\} \subset \mathbb{R}^{n+1}$, and we will show that ev_{ρ^s} is transverse to W.

$$\begin{array}{rcl} \mathrm{ev}_{\rho^s} : C^\infty(X,\mathbb{R}) \times \tilde{X} & \longrightarrow & \mathbb{R}^{n+1}, \\ (h,x) & \longmapsto & (h(x) - h\circ f^s(x), \dots, h\circ f^n(x) - h\circ f^{n+s}(x)). \end{array}$$

The differential of ev_{ρ^s} at (h_0, x_0) is given by

$$d\ \mathrm{ev}_{\rho^s}\,|_{(h_0,x_0)}.(h,\xi) = (\psi_0, \psi_1, \dots, \psi_n),$$

where $\psi_i = h\circ f^i(x_0) + d(h_0\circ f^i)_{x_0}\cdot\xi - h\circ f^{i+s}(x_0) - d(h\circ f^{i+s})_{x_0}\cdot\xi$.

This differential is surjective; indeed, let $u = (u_0, u_1, \dots, u_n) \in \mathbb{R}^{n+1}$; we will show that there exists a map $h : X \to \mathbb{R}$ such that $d\,\mathrm{ev}_{\rho^s}\,|_{(h_0,x_0)}.(h,0) = u$.

To this end, it is enough to show that there exists h satisfying the following system:

$$\left\{\begin{array}{rcl} h(x_0) - h\circ f^s(x_0) & = & u_0, \\ h\circ f(x_0) - h\circ f^{s+1}(x_0) & = & u_1, \\ & \vdots & \\ h\circ f^n(x_0) - h\circ f^{n+s}(x_0) & = & u_n. \end{array}\right. \tag{3}$$

Put $x_i = f^i(x_0)$; if $s \le n$, the points $x_0, x_1, \dots, x_{n+s}$ are all distinct because $x_0 \in \tilde{X} = X \setminus \Gamma_{2n}(f)$ so that either x_0 is not a periodic point or it is a periodic point with order $> 2n$. Obviously, the system

$$\left\{\begin{array}{rcl} y_0 - y_s & = & u_0, \\ y_1 - y_{s+1} & = & u_1, \\ & \vdots & \\ y_n - y_{n+s} & = & u_n \end{array}\right. \tag{4}$$

of $n+1$ equations and $n+s+1$ unknown $y_0, \dots, y_{n+s}$ has always at least one solution. If $\bar{y}_0, \dots, \bar{y}_{n+s}$ is a solution of (4), then it is always possible to find a map h such that $h(x_i) = \bar{y}_i$, and then h is a solution of (3).

If $s > n$, we consider the two lists

$$l_1 = \{x_0, \dots, x_n, x_{n+1}, \dots, x_{2n}\} \text{ and } l_2 = \{x_{2n+1}, \dots, x_{n+s}\}.$$

The elements of l_2 are all distinct because the equality $x_{2n+i} = x_{2n+j}$ with $1 \le i < j \le s-n$ implies $x_{j-i} = x_0$, which in turn implies that x_0 is a periodic point of period $\le j - i \le n-1$.

If $l_1 \cap l_2 = \emptyset$, we can conclude as above, so assume that $l_1 \cap l_2 \neq \emptyset$; then there exists $0 \le i \le 2n$ and $1 \le j \le s-n$ such that $x_i = x_{2n+j}$, which implies $x_{2n+j-i} = x_0$, and so x_0 is periodic with a period dividing $2n+j-i$. Notice also that $j-i$ must be positive since $x_0 \notin \Gamma_{2n}(f)$, and let $r_0 = \min\{r \mid x_{2n+r} = x_0\}$ $(0 < r_0 \le s-n)$. Now the points $x_0, \dots, x_{2n}, \dots, x_{2n+r_0-1}$ are all distinct, while the other ones satisfy

$$\left\{\begin{array}{rcl} x_{2n+r_0} & = & x_0, \\ & \vdots & \\ x_{n+s} & = & x_{s-n-r_0}. \end{array}\right.$$

Consider now the following system:

$$\left\{\begin{array}{rcl} y_0 - y_s & = & u_0, \\ & \vdots & \\ y_{2n+r_0-s-1} - y_{2n+r_0-1} & = & u_{2n+r_0-s-1}, \\ y_{2n+r_0-s} - y_0 & = & u_{2n+r_0-s-1}, \\ & \vdots & \\ y_n - y_{s-n-r_0} & = & u_n. \end{array}\right.$$

The rank of the matrix of this linear system ($n+1$ equations, $3n+r_0-s+1$ unknowns) is equal to $n+1$, so this system has at least one solution. If $\bar{y}_0, \ldots, \bar{y}_n, \bar{y}_s, \ldots, \bar{y}_{2n+r_0-1}$ is a solution, then in order to satisfy (3), it is sufficient to choose h such that $h(x_i) = \bar{y}_i$ for $0 \leq i \leq n$ and $s \leq i \leq 2n + r_0 - 1$.

So, in every case, there exists a map h such that (3) holds which proves that the evaluation map ev_{ρ_s} is transverse to $W = \{0\}$. So the set $\mathscr{B}^s(f) \subset C^\infty(X, \mathbb{R})$ such that $(\rho^s)_h$ is transverse to W is residual. To say that the map $(\rho^s)_h$ is transverse to $W = \{0\}$ means that $\rho^s(h)(x) \notin W$ because $\operatorname{codim} W = n + 1 > \dim X$. Let $\mathscr{B}(f) = \bigcap_{s=1}^{2n} \mathscr{B}^s(f)$, $\mathscr{B}(f)$ is residual, and, by construction, if $h \in \mathscr{B}(f)$, then for all $(x, x_0) \in (X \setminus \Gamma_{2n}(f) \times \Gamma_{2n}(f)$ one has

$$(h(x), h \circ f(x), \ldots, h \circ f^{2n}(x)) \neq (h(x_0), \ldots, h \circ f^{2n}(x_0))$$

because there exist $s \leq 2n$ such that $h \circ f^i(x_0) - h \circ f^{i+s}(x_0) = 0$ for all $0 \leq i \leq n$.

The remaining part of the proof is devoted to demonstrating the openness of $\mathscr{B}(f)$; to this end, we need Theorem 5 of openness of transversal intersection.

Let $h_0 \in \mathscr{B}(f)$, for every $\bar{x} \in \Gamma_{2n}(f)$, the covectors $(dh_{0\bar{x}}, d(h_0 \circ f)_{\bar{x}}, \ldots, d(h_0 \circ f^{n-1})_{\bar{x}})$ being linearly independent. This ensures the existence of a positive number $r(\bar{x}, h_0)$ such that the map

$$\theta_{h_0} : x \longmapsto (h_0(x), h_0 \circ f(x), \ldots, h_0 \circ f^{n-1}(x))$$

is a diffeomorphism from $B(\bar{x}, r(\bar{x}, h_0))$ to its image by θ_{h_0}. Then there exists an open set $\theta(h_0, \bar{x}) \subset C^\infty(X, \mathbb{R})$ such that, for all h in this set, the map

$$\theta_h : x \longmapsto (h(x), h \circ f(x), \ldots, h \circ f^{n-1}(x))$$

is a diffeomorphism from $B(\bar{x}, \frac{r(\bar{x}, h_0)}{2})$ to its image.

Furthermore, $s(\bar{x})$ denoting the period of $\bar{x}$, by continuity, there exists $r'(\bar{x}, h_0)$ $(0 < r' < r/2)$ such that $f^s(x) \in B(\bar{x}, r/2)$ for all $x \in B(\bar{x}, r')$; also we can choose $r(\bar{x}, h_0)$ so small that $B(\bar{x}, r(\bar{x}, h_0)) \cap B(\bar{y}, r(\bar{y}, h_0)) = \emptyset$ whenever $\bar{x}, \bar{y} \in \Gamma_{2n}(f)$ and $\bar{x} \neq \bar{y}$.

Now, in order to apply the above theorem, we consider the compact set

$$K = X \setminus \bigcup_{\bar{x} \in \Gamma_{2n}(f)} B(\bar{x}, r'(\bar{x}, h_0))$$

and the representation ρ^s defined in the first part of this proof. We set $C_K^s = \{\, h \in C^\infty(X, \mathbb{R}) \mid \rho_h^s \pitchfork_x \{0\} \text{for all } x \in K \,\}$; thanks to the above-mentioned theorem, we can assert that C_K^s is open and the set

$$\mathscr{U}_{h_0} = \left(\bigcap_{s=1}^{2n} C_K^s \right) \cap \left(\bigcap_{\bar{x} \in \Gamma_{2n}(f)} \theta(h_0, \bar{x}) \right)$$

is open and contains h_0.

We will now show that $\mathscr{U}_{h_0}$ is included in $\mathscr{B}(f)$; to this end, it suffices to show that the equality

$$(h(x) - h \circ f^s(x), \dots, f \circ f^n(x) - h \circ f^{n+s}(x)) = (0, \dots, 0) \tag{5}$$

implies, if $h_0 \in \mathscr{U}_{h_0}$, that $x \in \Gamma_{2n}(f)$. So let $x \in X$ and $h \in \mathscr{U}_{h_0}$:

(i) if $x \in K$, then by construction of $\mathscr{U}_{h_0}$, x cannot satisfy the above equality (notice that $\rho_h^s \pitchfork_x \{0\}$ means $\rho_h^s(x) \neq 0$);

(ii) if $x \notin K$, then $x \in B(\bar{x}, r'(\bar{x}, h_0))$ for some $\bar{x} \in \Gamma_{2n}(f)$, which implies that $f^s(x) \in B(\bar{x}, r(\bar{x}, h_0)/2)$. Now the map θ_h is a diffeomorphism from $B(\bar{x}, r/2)$ to its image, so equality (5) is equivalent to $\theta_h(x) = \theta_h(f^s(x))$, which leads to $x = f^s(x)$. This implies that x is a periodic point for f and thus $x = \bar{x} \in \Gamma_{2n}(f)$ because x is the unique periodic point of f which belongs to $B(\bar{x}, r_{\bar{x}})$. □

LEMMA 6. *Let $f \in \mathscr{C}_{2n}(X)$ be a given diffeomorphism. Then the set of mappings $h \in C^\infty(X, \mathbb{R})$ for which the map $\Theta_{f,h}$ is injective is residual.*

Proof. We define the set $\tilde{X}^{(2)} = \{(x_1, x_2) \in (X \setminus \Gamma_{2n}(f))^2 \mid x_1 \neq x_2\}$, and we consider the map $\rho : C^\infty(X, \mathbb{R}) \to C^r\big(\tilde{X}^{(2)}, \mathbb{R}^{2n+1}\big)$ defined by

$$\rho(h)(x_1, x_2) = \big(h(x_1) - h(x_2), h \circ f(x_1) - h \circ f(x_2), \dots, h \circ f^{2n}(x_1) - h \circ f^{2n}(x_2)\big)$$

and the evaluation map

$$\begin{array}{rccl} \mathrm{ev}_\rho & : & C^\infty(X, \mathbb{R}) \times \tilde{X}^{(2)} & \longrightarrow & \mathbb{R}^{2n+1}, \\ & & (h, x) & \longmapsto & \Big(h(x_1) - h(x_2), h \circ f(x_1) - h \circ f(x_2), \dots, \\ & & & & \dots, h \circ f^{2n}(x_1) - h \circ f^{2n}(x_2)\Big). \end{array}$$

Using the same reasoning as in the proof of density of $\mathscr{B}(f)$ (Lemma 5), we can prove that the linear tangent map of ev_ρ, computed at any point of $C^\infty(X, \mathbb{R}) \times \tilde{X}^{(2)}$, is surjective. This implies that ev_ρ is a submersion on $C^\infty(X, \mathbb{R}) \times \tilde{X}^{(2)}$. Hence ev_ρ is transverse to $\{(0, \dots, 0)\} \subset \mathbb{R}^{2n+1}$. From Theorem 4, we deduce that the set of h for which $\rho(h)(x_1, x_2) \neq 0$ for all $(x_1, x_2) \in \tilde{X}^{(2)} \times \tilde{X}^{(2)}$ is residual. On the other hand, if $(x_1, x_2) \in (X \setminus \Gamma_{2n}(f)) \times \Gamma_{2n}(f)$, then $\Theta_{f,h}(x_1) \neq \Theta_{f,h}(x_2)$ for $h \in \mathscr{B}(f)$, which is open and dense (Lemma 5). Finally, if $(x_1, x_2) \in \Gamma_{2n}(f) \times \Gamma_{2n}(f)$, then $\Theta_{f,h}(x_1) \neq \Theta_{f,h}(x_2)$ for $h \in \mathscr{H}(\Gamma_{2n}(f))$, which is open and dense. This allows us to conclude that the set of h for which $\Theta_{f,h}$ is injective is residual. □

3.4. Mapping $\Theta_{f,h}$ is generically an immersion.

LEMMA 7. *Let $f \in \mathscr{C}(X)$ be a given mapping; then the set of mappings $h \in C^\infty(X, \mathbb{R})$, for which the covectors*

$$dh_x, d(h \circ f)_x, \dots, d(h \circ f^{n-1})_x$$

are linearly independent for every periodic point of f, is open and dense in $C^\infty(X, \mathbb{R})$.

Proof. Let $f \in C^\infty(X, X)$ be a mapping with a finite number of periodic points of order $\leq r$, and let x be a periodic point of order $s \leq r$. It is sufficient to show the density of mapping $h \in \mathrm{C}^\infty(X, \mathbb{R})$ that satisfies

$$dh_x, d(h \circ f)_x, \dots, d(h \circ f^{n-1})_x \text{ are linearly independent.}$$

To show this, we can adapt the proof of Lemmas 2 and 3 by noticing that for given matrices $A_1, \dots, A_s$, the set of covectors $C_1, C_2, \dots, C_s$ such that the n covectors

$$\begin{array}{ccccccc}
C_1, & C_2A_1, & C_3A_2A_1, & \dots, & \dots, & C_sA_{s-1}\dots A_1, \\
C_1\tilde{A}, & C_2A_1\tilde{A}, & C_3A_2A_1\tilde{A}, & \dots, & \dots, & C_sA_{s-1}\dots A_1\tilde{A}, \\
 & & \vdots & & & \\
C_1\tilde{A}^{q-1}, & C_2A_1\tilde{A}^{q-1}, & C_3A_2A_1\tilde{A}^{q-1}, & \dots, & \dots, & C_sA_{s-1}\dots A_1\tilde{A}^{q-1}, \\
C_1\tilde{A}^{q}, & C_2A_1\tilde{A}^{q}, & C_3A_2A_1\tilde{A}^{q}, & \dots, & C_rA_{r-1}\dots A_1\tilde{A}^{q} &
\end{array}$$

are linearly dependent is an algebraic subset of $((\mathbb{R}^n)^*)^s$.

The proof of the openness is analogous to the proof of Lemma 4. □

For a given $f \in \mathcal{C}_r(X)$, we denote by $\mathscr{A}_r(f)$ the subset of $\mathrm{C}^\infty(X,\mathbb{R})$ verifying the conclusion of the above lemma.

LEMMA 8. *Let E be an n-dimensional vector space, and, for $k > n$, let $V(E,k)$ denote the set of k-tuples $(v_1,\dots,v_k) \in E^k$ such that* $\operatorname{rank}(v_1,\dots,v_k) < n$. *We claim that $V(E,k)$ is a finite union of smooth submanifolds of E^k, say, $W_1,\dots,W_l$; moreover, if* $\dim W_i = \max(\dim W_1,\dots,\dim W_l)$, *then* $\operatorname{codim} W_i = k - n + 1$.

Proof. An element $(v_1,\dots,v_k)$ of E^k can be identified with the matrix of $M_{n\times k}(\mathbb{R})$ whose columns are the v_i. Therefore, to prove the lemma it is sufficient to prove that the set of matrices with rank $< n$ is a finite union of smooth submanifolds of $M_{n\times k}(\mathbb{R})$. The proof of this result (as well as the computation of the least codimension) can be found in [6, pp. 60–61]. □

LEMMA 9. *For a given $f \in \mathscr{C}_r(X)$, the set of mappings $h \in C^\infty(X,\mathbb{R})$ such that the map*

$$\begin{array}{rcl}
\Theta_{f,h} : X & \longrightarrow & \mathbb{R}^{2n+1}, \\
x & \longmapsto & \big(h(x), h\circ f(x),\dots,h\circ f^{2n}(x)\big)
\end{array}$$

is an immersion is residual.

Proof. The map $\pi : T^*X \to X$ denoting the canonical projection, we consider the following set:

$$(T^*X)^{\otimes k} = \{\, (p_1,\dots,p_k) \in (T^*X)^k \;\mid \pi(p_1) = \pi(p_2) = \dots = \pi(p_k) \,\}.$$

Using the same notations as in Lemma 8, we set $\mathcal{V}(k,T^*X) = \bigcup_{x\in X} V(k,T^*_xX)$. Thanks to this lemma we know that $\mathcal{V}(k,T^*X)$ is a union of submanifolds of $(T^*X)^{\otimes k}$, the codimension of the highest dimensional submanifold being $k-n+1$.

Let $f \in \mathscr{C}_{2n}(X)$ and $\tilde{X} = X \setminus \Gamma_{2n}(f)$, and consider the map

$$\rho \;:\; \mathscr{A}_{2n}(f) \to \mathrm{C}^r\left(\tilde{X}, (T^*X)^{\otimes 2n+1}\right)$$

defined by $\rho(h)(x) = \big(dh_x, d(h\circ f)_x,\dots,d(h\circ f^{2n})_x\big)$. We will show that the evaluation map ev_ρ defined by

$$\begin{array}{rcl}
ev_\rho \;:\; \mathscr{A}(f)\times\tilde{X} & \longrightarrow & (T^*X)^{\otimes 2n+1}, \\
(h,x) & \longmapsto & \big(dh_x, d(h\circ f)_x,\dots,d(h\circ f^{2n})_x\big)
\end{array}$$

is transverse to $\mathcal{V}(2n+1,T^*X)$ (i.e., transverse to every submanifold of the union $\mathcal{V}(k,T^*X)$). To prove this, it is sufficient to show that ev_ρ is a submersion at every point $(h,x) \in \mathscr{A}_{2n}(f)\times\tilde{X}$. For a given $\bar{x} \in \tilde{X}$ the map

$$\begin{array}{rcl}
\mathrm{ev}_{\rho\bar{x}} \;:\; \mathscr{A}_{2n}(f) & \longrightarrow & (T^*X)^{\otimes 2n+1}, \\
h & \longmapsto & \big(dh_{\bar{x}}, d(h\circ f)_{\bar{x}},\dots,d(h\circ f^{2n})_{\bar{x}}\big)
\end{array} \tag{6}$$

is linear, so its expression at $\bar{h}$ coincides with the one of its linear tangent map at $\bar{h}$. This tangent map is surjective; indeed, $\bar{x} \notin \Gamma_{2n}(f)$, so $f^i(\bar{x}) \neq f^j(\bar{x})$ for all $i, j \in \{0, 1, \dots, 2n\}$ $(i \neq j)$. Therefore, for a given $(p_0, \dots, p_{2n}) \in (T^*_{\bar{x}}X)^{\otimes 2n+1}$, it is possible to find $h \in \mathscr{A}_{2n}(f)$ in such a way that $d(h \circ f^i)_{\bar{x}} = dh_{f^i(\bar{x})} \circ df^i(\bar{x}) = p_i$. We showed that the map $ev_{\rho\bar{x}}$ defined by (6) is a submersion at every $h \in \mathscr{A}_{2n}(f)$; this implies that ev_ρ is a submersion at every point $(h, x) \in \mathscr{A}_{2n}(f) \times \tilde{X}$ and thus ev_ρ is transverse to $\mathcal{V}(2n+1, T^*X)$. Thanks to Theorem 4, we can conclude that the set of h such that ρ_h is transverse to $\mathcal{V}(2n+1, T^*X)$ is residual. Here, transversality means nonintersection for the codimension of the highest dimensional submanifold contained in $\mathcal{V}(2n+1, T^*X)$ is $2n+1-n+1 = n+2 > \dim \tilde{X}$. Therefore, $\rho_h \pitchfork \mathcal{V}(2n+1, T^*X)$ implies $\operatorname{rank}\left(dh_x, d(h \circ f)_x, \dots, d(h \circ f^{2n})_x\right) = n$ for all $x \in \tilde{X}$ and thus the set of h such that $\Theta_{f,h}$ is an immersion on $\tilde{X}$ is residual. On the other hand, the set of h such that $\Theta_{f,h}$ is an immersion at each point of $\Gamma_{2n}(f)$ is $\mathscr{A}_{2n}(f)$, which is open and dense (Lemma 7). Hence the set of $h \in \mathrm{C}^r(X, \mathbb{R})$ such that $\Theta_{f,h}$ is an immersion on $X = \tilde{X} \cup \Gamma_{2n}(f)$ is residual in $C^r(X, \mathbb{R})$. The result being true for all $r \in \mathbb{R}$ it is still true for $r = \infty$. □

3.5. Proof of Theorem 6. A diffeomorphism $f \in \mathscr{C}_{2n}(f)$ being given, we saw that the set of maps h such that $\Theta_{f,h}$ is an injective immersion (and so an embedding) is dense in $C^\infty(X, \mathbb{R})$. Now the set $\mathscr{C}_{2n}(f)$ is dense in $\mathrm{Diff}(X)$, so we can conclude that the set of pairs $(f, h) \in \mathrm{Diff}(X) \times C^\infty(X, \mathbb{R})$ such that $\Theta_{f,h}$ is an embedding is dense.

4. Counterexample. In this section, we provide a counterexample to speculations that the observability could be generic even if map f is not a diffeomorphism. We will show that, even if the number of observations is equal to the dimension of manifold X, the property of observability is not generic. This counterexample is very similar to the one given in [3] for a slightly different purpose; in fact, it is based on the same idea: we will choose f and h such that (f, h) is an immersion with normal crossings; for such an immersion, a slight perturbation does not eliminate the crossings.

As compact manifold X, we take the n-dimensional torus $\mathbb{T}^n = (S^1)^n$, and we will produce a pair $(h, f) \in C^\infty(X, \mathbb{R}^n) \times C^\infty(X, X)$ such that there exists an open neighborhood $\mathscr{O}$ of (h, f) such that all pairs $(\bar{h}, \bar{f}) \in \mathscr{O}$ are not observable.

We take

$$\begin{aligned} h : \quad \mathbb{T}^n &\longrightarrow \mathbb{R}^n, \\ (e^{i\theta_1}, \dots, e^{i\theta_n}) &\longrightarrow (\sin\theta_1, \dots, \sin\theta_n) \end{aligned}$$

and

$$\begin{aligned} f : \quad \mathbb{T}^n &\longrightarrow \mathbb{T}^n, \\ (e^{i\theta_1}, \dots, e^{i\theta_n}) &\longrightarrow (e^{2i\theta_1}, e^{i(\theta_1+\theta_2)}, \dots, e^{i(\theta_{n-1}+\theta_n)}). \end{aligned}$$

In order to prove our claim, it suffices to prove that the mapping (h, f) is not one-to-one but is stable. As a matter of fact, (f, h) stable implies that the mapping $(\bar{f}, \bar{h})$ is equivalent to (f, h) if it belongs to some neighborhood of (f, h) (see [6]); so there exist $\varphi \in \mathrm{Diff}(X)$ and $\psi \in \mathrm{Diff}(X \times \mathbb{R}^n)$ such that $(\bar{f}, \bar{h}) = \psi \circ (f, h) \circ \varphi$, which implies that $(\bar{f}, \bar{h})$ is not one-to-one as (f, h). Obviously the fact that $(\bar{f}, \bar{h})$ is not one-to-one implies nonobservability: there exist $x_0 \neq x_1$ in X such that $\bar{h}(x_0) = \bar{h}(x_1)$ and $\bar{f}(x_0) = \bar{f}(x_1)$ and points x_0 and x_1 are indistinguishable.

We investigate now the injectivity of f, taking two points $x_0 = (e^{i\theta_1}, \dots, e^{i\theta_n})$ and $x_0' = (e^{i\theta_1'}, \dots, e^{i\theta_n'})$ in $\mathbb{T}^n$; they will have the same image under mapping (f, h) iff

$$\begin{cases} \theta_1' &= \theta_1 + k_1\pi, \\ \theta_2' &= \theta_2 + \theta_1 - \theta_1' + 2k_2\pi, \\ &\vdots \\ \theta_n' &= \theta_n + \theta_{n-1} - \theta_{n-1}' + 2k_n\pi, \\ \sin\theta_1' &= \sin\theta_1, \\ &\vdots \\ \sin\theta_n' &= \sin\theta_n, \end{cases}$$

which is equivalent to $\theta_i' = \theta_i$ or $\theta_i = \varepsilon_i\pi$ and $\theta_i' = (1-\varepsilon_i)\pi$ $(i = 1, \dots, n,\ \varepsilon_i \in \{0, 1\})$. This proves that (f, h) is not one-to-one. In order to prove that (f, h) is stable, it suffices to show that (f, h) is an immersion with normal crossings (see [6]). We recall that a mapping g between two manifolds X and Y is called *immersion with normal crossings* iff

(i) it is an immersion;

(ii) letting $g^{(s)} : X^{(s)} \to Y^s$, the restriction of g^s to $X^{(s)}$ and denoting by ΔY^s the subset of Y^s: $\Delta Y^s = \{(y, \dots, y) \mid y \in Y\}$, we ask that $g^{(s)} \pitchfork \Delta Y^s$ for every $s > 1$.

Notice that for our mapping, we have to check the second point of this definition only for $s = 2$ since it is impossible to have $(f, h)(x_1) = \cdots = (f, h)(x_p)$ for more than two points. Now, the computations to prove that (f, h) verifies the two preceding points are tedious but do not present any kind of difficulty, and so they are not reproduced here.

THE TOPOLOGICAL ASYMPTOTIC FOR THE HELMHOLTZ EQUATION*

BESSEM SAMET†, SAMUEL AMSTUTZ†, AND MOHAMED MASMOUDI†

Abstract. The aim of the topological sensitivity analysis is to obtain an asymptotic expansion of a functional with respect to the creation of a small hole in the domain. In this paper such an expansion is obtained for the Helmholtz equation with a Dirichlet condition on the boundary of a circular hole. Some applications of this work to waveguide optimization are presented.

Key words. topological optimization, shape optimization, topological gradient, topological asymptotic, Helmholtz equation, waveguides, adjoint equation

1. Introduction. Classical shape optimization methods are based on the perturbation of the boundary of the initial shape. The initial and the final shapes have the same topology. The aim of topological optimization is to find an optimal shape without any a priori assumption about the topology of the structure. Many important contributions in this field are concerned with structural mechanics and, in particular, the minimization of the compliance (external work) subject to a volume constraint. In view of the fact that the optimal structure generally has a large number of small holes, most authors [3, 5, 15] have considered composite material optimization. Using the homogenization theory, Allaire and Kohn [3] exhibit a class of laminated materials with an explicit expression for the optimal material at any point of the structure. The range of application of this approach is quite restricted. For this reason, global optimization techniques like genetic algorithms and simulated annealing are used in order to solve more general problems [26]. Unfortunately, these methods are very slow.

The topological gradient has been introduced by Schumacher [27] to minimize a cost function $j(\Omega) = J(\Omega, u_\Omega)$, where u_Ω is the solution to a PDE defined in the domain Ω. The idea is to create a spherical hole $B(x, \varepsilon)$ of radius ε around a point x in Ω. Generally, an asymptotic expansion of the function j can be obtained in the following form:

$$j(\Omega \setminus \overline{B(x,\varepsilon)}) - j(\Omega) = f(\varepsilon)g(x) + o(f(\varepsilon)). \tag{1.1}$$

The function $f(\varepsilon)$ is positive and tends to zero with ε. We call this expansion the topological asymptotic. To minimize the criterion, we have to create holes where g is negative. The optimality condition $g \geq 0$ in Ω is exactly what Buttazzo and Dal Maso [6] have obtained for the Laplace equation, using a relaxed formulation. The topological gradient $g(x)$ has been computed by Schumacher [27] in the case of compliance minimization with Neumann condition on the boundary of the hole. In the same context, Sokolowski [25] gave some mathematical justifications in the

plane stress case and generalized it to various cost functions. A topological sensitivity framework using an adaptation of the adjoint method and a truncation technique has been introduced in [16] in the case of an homogeneous Dirichlet condition imposed on the boundary of a circular hole. The fundamental property of the adjoint technique is to provide the variation of a function with respect to a parameter by using a solution u_Ω and an adjoint state p_Ω which do not depend on the chosen parameter. From the numerical viewpoint, only two systems have to be solved for obtaining $g(x)$ for all $x \in \Omega$. This observation leads to very efficient numerical algorithms. In [10, 11, 12], the topological sensitivity has been obtained in the contexts of linear elasticity, the Poisson equation, and the Stokes problem with general shape functions and arbitrary shaped holes. These publications are concerned with PDE operators whose symbols are homogeneous polynomials.

In this paper, we are interested in the differential operator

$$P = \sum_{i=1}^{2} \frac{\partial^2}{\partial {x_i}^2} + k^2,$$

whose symbol is not homogenous. First, an adaptation of the adjoint method to the topological context is proposed in section 2 for the operator P. Next, a waveguide problem, the truncation method, and the explicit expression of the topological asymptotic are presented in section 3. Finally, an optimization algorithm and some applications of the topological gradient to waveguide optimization are given in section 4. This work was done in collaboration with Alcatel Space Industries.

2. A generalized adjoint method. In this section, the adjoint method is adapted to topological optimization. Let $\mathcal{V}$ be a fixed complex Hilbert space. For $\varepsilon \geq 0$, let $a_\varepsilon(.,.)$ be a sesquilinear and continuous form on $\mathcal{V}$ and l_ε be a semilinear and continuous form on $\mathcal{V}$. We consider the following assumptions.

Hypothesis 1. There exists a sesquilinear and continuous form δ_a, a semilinear and continuous form δ_l, and a real function $f(\varepsilon) > 0$ defined on ${\mathbb{R}^*}_+$ such that

$$\lim_{\varepsilon \to 0} f(\varepsilon) = 0, \tag{2.1}$$

$$\|a_\varepsilon - a_0 - f(\varepsilon)\delta_a\|_{\mathcal{L}_2(\mathcal{V})} = o(f(\varepsilon)), \tag{2.2}$$

$$\|l_\varepsilon - l_0 - f(\varepsilon)\delta_l\|_{\mathcal{L}(\mathcal{V})} = o(f(\varepsilon)), \tag{2.3}$$

where $\mathcal{L}(\mathcal{V})$ (respectively, $\mathcal{L}_2(\mathcal{V})$) denotes the space of continuous and semilinear (respectively, sesquilinear) forms on $\mathcal{V}$.

Hypothesis 2. There exists a constant $\alpha > 0$ such that

$$\inf_{u \neq 0} \sup_{v \neq 0} \frac{|a_0(u,v)|}{\|u\|_{\mathcal{V}} \|v\|_{\mathcal{V}}} \geq \alpha.$$

We say that a_0 satisfies the inf-sup condition.

According to (2.2), there exists a constant $\beta > 0$ (independent of ε) such that

$$\inf_{u \neq 0} \sup_{v \neq 0} \frac{|a_\varepsilon(u,v)|}{\|u\|_{\mathcal{V}} \|v\|_{\mathcal{V}}} \geq \beta \quad \forall \varepsilon \geq 0.$$

For $\varepsilon \geq 0$, we suppose that the following problem has one solution: find $u_\varepsilon \in \mathcal{V}$ such that

$$a_\varepsilon(u_\varepsilon, v) = l_\varepsilon(v) \qquad \forall v \in \mathcal{V}. \tag{2.4}$$

According to Hypothesis 2, this solution is unique. We have the following lemma.

LEMMA 2.1. *If Hypotheses* 1 *and* 2 *are satisfied, then*

$$\|u_\varepsilon - u_0\|_{\mathcal{V}} = O(f(\varepsilon)).$$

Proof. It follows from Hypothesis 2 that there exists $v_\varepsilon \in \mathcal{V}, v_\varepsilon \neq 0$, such that

$$\beta\|u_\varepsilon - u_0\|_{\mathcal{V}}\|v_\varepsilon\|_{\mathcal{V}} \leq |a_\varepsilon(u_\varepsilon - u_0, v_\varepsilon)|,$$

which implies

$$\begin{aligned}
&\beta\|u_\varepsilon - u_0\|_{\mathcal{V}}\|v_\varepsilon\|_{\mathcal{V}}\\
&\leq |a_\varepsilon(u_0, v_\varepsilon) - l_\varepsilon(v_\varepsilon)|\\
&= |a_\varepsilon(u_0, v_\varepsilon) - (l_\varepsilon - l_0 - f(\varepsilon)\delta_l)(v_\varepsilon) - l_0(v_\varepsilon) - f(\varepsilon)\delta_l(v_\varepsilon)|\\
&= |(a_\varepsilon(u_0, v_\varepsilon) - a_0(u_0, v_\varepsilon)) - (l_\varepsilon - l_0 - f(\varepsilon)\delta_l)(v_\varepsilon) - f(\varepsilon)\delta_l(v_\varepsilon)|\\
&\leq |a_\varepsilon(u_0, v_\varepsilon) - a_0(u_0, v_\varepsilon) - f(\varepsilon)\delta_a(u_0, v_\varepsilon)| + |l_\varepsilon(v_\varepsilon) - l_0(v_\varepsilon) - f(\varepsilon)\delta_l(v_\varepsilon)|\\
&\quad + f(\varepsilon)(|\delta_a(u_0, v_\varepsilon)| + |\delta_l(v_\varepsilon)|).
\end{aligned}$$

Using Hypothesis 1, we obtain

$$\beta\|u_\varepsilon - u_0\|_{\mathcal{V}}\|v_\varepsilon\|_{\mathcal{V}} \leq \left(o(f(\varepsilon)) + f(\varepsilon)(\|\delta_a\|_{\mathcal{L}_2(\mathcal{V})}\|u_0\|_{\mathcal{V}} + \|\delta_l\|_{\mathcal{L}(\mathcal{V})})\right)\|v_\varepsilon\|_{\mathcal{V}}. \qquad \square$$

Consider now a cost function $j(\varepsilon) = J(u_\varepsilon)$, where the functional J satisfies

$$J(u + h) = J(u) + \Re(L_u(h)) + o(\|h\|_{\mathcal{V}}) \qquad \forall u, h \in \mathcal{V}. \tag{2.5}$$

Here, L_u is a linear and continuous form on $\mathcal{V}$. We suppose that the following problem has a unique solution p_0, called the adjoint state: find $p_0 \in \mathcal{V}$ such that

$$a_0(v, p_0) = -L_{u_0}(v) \qquad \forall v \in \mathcal{V}. \tag{2.6}$$

For $\varepsilon \geq 0$, we define the Lagrangian operator $\mathcal{L}_\varepsilon$ by

$$\mathcal{L}_\varepsilon(u, v) = J(u) + a_\varepsilon(u, v) - l_\varepsilon(v) \qquad \forall u, v \in \mathcal{V}.$$

The next theorem gives the asymptotic expansion of $j(\varepsilon)$.

THEOREM 2.2. *If Hypotheses* 1 *and* 2 *are satisfied, then*

$$j(\varepsilon) - j(0) = f(\varepsilon)\Re(\delta_{\mathcal{L}}(u_0, p_0)) + o(f(\varepsilon)), \tag{2.7}$$

where u_0 is the solution to (2.4) *with $\varepsilon = 0$, p_0 is the adjoint state solution to problem* (2.6)*, and*

$$\delta_{\mathcal{L}}(u, v) = \delta_a(u, v) - \delta_l(v) \quad \forall u, v \in \mathcal{V}.$$

Proof. We have that

$$j(\varepsilon) = \mathcal{L}_\varepsilon(u_\varepsilon, v) \qquad \forall \varepsilon \geq 0, \quad \forall v \in \mathcal{V}.$$

Next, choosing $v = p_0$, we obtain

$$\begin{aligned}
j(\varepsilon) - j(0) &= \mathcal{L}_\varepsilon(u_\varepsilon, p_0) - \mathcal{L}_0(u_0, p_0)\\
&= J(u_\varepsilon) - J(u_0) + a_\varepsilon(u_\varepsilon, p_0) - a_0(u_0, p_0) + l_0(p_0) - l_\varepsilon(p_0)\\
&= J(u_\varepsilon) - J(u_0) + \Re(a_\varepsilon(u_\varepsilon, p_0) - a_0(u_0, p_0)) - \Re(l_\varepsilon(p_0) - l_0(p_0))\\
&= J(u_\varepsilon) - J(u_0) + \Re(a_\varepsilon(u_\varepsilon, p_0) - a_0(u_\varepsilon, p_0) + a_0(u_\varepsilon - u_0, p_0))\\
&\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)).
\end{aligned}$$

Using (2.5), we have that

$$J(u_\varepsilon) - J(u_0) = \Re(L_{u_0}(u_\varepsilon - u_0)) + o(\|u_\varepsilon - u_0\|_{\mathcal{V}}).$$

Hence,

$$\begin{aligned} &j(\varepsilon) - j(0) \\ &= \Re(a_\varepsilon(u_\varepsilon, p_0) - a_0(u_\varepsilon, p_0)) + \Re(a_0(u_\varepsilon - u_0, p_0) + L_{u_0}(u_\varepsilon - u_0)) + o(\|u_\varepsilon - u_0\|_{\mathcal{V}}) \\ &\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

Using that p_0 is the adjoint solution, we obtain

$$\begin{aligned} j(\varepsilon) - j(0) &= \Re(a_\varepsilon(u_\varepsilon, p_0) - a_0(u_\varepsilon, p_0)) + o(\|u_\varepsilon - u_0\|_{\mathcal{V}}) \\ &\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)) \\ &= \Re((a_\varepsilon - a_0)(u_0, p_0)) + \Re((a_\varepsilon - a_0)(u_\varepsilon - u_0, p_0)) + o(\|u_\varepsilon - u_0\|_{\mathcal{V}}) \\ &\quad -\Re(l_\varepsilon(p_0) - l_0(p_0) - f(\varepsilon)\delta_l(p_0)) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

It follows from Hypothesis 1 that

$$\begin{aligned} j(\varepsilon) - j(0) = f(\varepsilon)\Re(\delta_a(u_0, p_0)) + o(f(\varepsilon)) + f(\varepsilon)\Re(\delta_a(u_\varepsilon - u_0, p_0)) + o(f(\varepsilon))\|u_\varepsilon - u_0\|_{\mathcal{V}} \\ + o(\|u_\varepsilon - u_0\|_{\mathcal{V}}) - f(\varepsilon)\Re(\delta_l(p_0)). \end{aligned}$$

Finally, from Lemma 2.1 and the hypothesis $\lim_{\varepsilon\to 0} f(\varepsilon) = 0$, we have

$$j(\varepsilon) = j(0) + f(\varepsilon)\Re(\delta_a(u_0, p_0) - \delta_l(p_0)) + o(f(\varepsilon)),$$

since δ_a is continuous by assumption. ∎

3. A waveguide problem. In this section, we study a problem of a waveguide as a component of a spatial antenna feeding system. Because the waveguide $\mathcal{O}$ has a uniform thickness, $\mathcal{O} = \Omega\times]a, b[$, $\Omega \subset \mathbb{R}^2$, and the electric field has a vertical polarization (normal to Ω), the three-dimensional problem can be reduced to a two-dimensional problem in Ω, called the H-plane model. We assume that Ω is a domain of $\mathbb{R}^2$ with a regular boundary $\Gamma = \Gamma_0 \cup \Gamma_1 \cup \cdots \cup \Gamma_N$, $N \in \mathbb{N}^*$. We denote by u_Ω the normal component to Ω of the electric field. It is a solution to the Helmholtz problem:

$$\left\{ \begin{array}{lll} \Delta u_\Omega + k^2 u_\Omega & = 0 & \text{in } \Omega, \\ u_\Omega & = 0 & \text{on } \Gamma_0, \\ \partial_n u_\Omega - iku_\Omega & = h_j & \text{on } \Gamma_j, j = 1, 2, \ldots, N, \end{array} \right. \tag{3.1}$$

where $\partial_n u_\Omega$ is the normal derivative of u_Ω, $k \in \{k \in \mathbb{C}^*/\Im(k) \geq 0\}$, and $h_j \in H_{00}^{\frac{1}{2}}(\Gamma_j)'$ for all $j \in \{1, 2, \ldots, N\}$. The first boundary condition means that Γ_0 is a perfect metallic surface. When $h_j = 0$, the last equation is an approximate absorbing boundary condition (the normal incident plane waves are completely absorbed). When $h_j \neq 0$, it is a transmission condition. We prove in section 5.1 that problem (3.1) has one and only one solution in the Hilbert space

$$\mathcal{V}_\Omega = \{u \in H^1(\Omega), u = 0 \text{ on } \Gamma_0\}. \tag{3.2}$$

Here and in the following, all the Sobolev spaces involve complex-valued functions.

For a given $x \in \Omega$, let us consider the perforated open set $\Omega_\varepsilon = \Omega\backslash\overline{B(x, \varepsilon)}$, where x is a point of Ω and $B(x, \varepsilon)$ is the ball of center x and of radius ε (see Figure 1). We

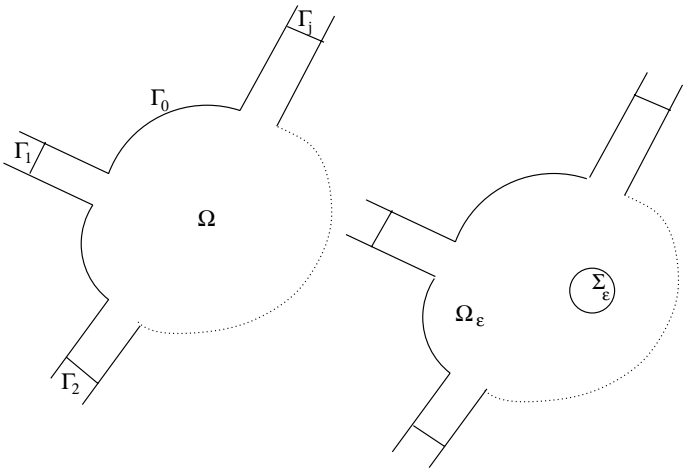

FIG. 1. *The initial domain and the same domain after the perforation.*

assume that $\varepsilon > 0$ is small enough, and we denote $\Sigma_\varepsilon = \partial B(x,\varepsilon)$. Our aim is to get the sensitivity analysis of u_{Ω_ε}, being the unique solution (see section 5.1) to

$$\left\{\begin{array}{lll} \Delta u_{\Omega_\varepsilon} + k^2 u_{\Omega_\varepsilon} & = 0 & \text{in } \Omega_\varepsilon, \\ u_{\Omega_\varepsilon} & = 0 & \text{on } \Gamma_0, \\ u_{\Omega_\varepsilon} & = 0 & \text{on } \Sigma_\varepsilon, \\ \partial_n u_{\Omega_\varepsilon} - iku_{\Omega_\varepsilon} & = h_j & \text{on } \Gamma_j, j = 1,2,\ldots,N, \end{array}\right. \tag{3.3}$$

with respect to ε at $\varepsilon = 0$. The solution of problem (3.3) is defined on the variable open set Ω_ε; thus it belongs to a functional space which depends on ε. Hence, if we want to derive the asymptotic expansion of a function of the form

$$j(\varepsilon) = J(u_{\Omega_\varepsilon}), \tag{3.4}$$

we cannot apply directly the tools of section 2, which require a fixed functional space. In classical shape optimization, this requirement can be satisfied with the help of a domain parameterization technique [13, 20, 17]. This technique involves a fixed domain and a bi-Lipshitz map between this domain and the modified one. In the topology optimization context, such a map does not exist between Ω and Ω_ε. However, a functional space independent of ε can be constructed by using a domain truncation technique.

3.1. The domain truncation. Let $R > \varepsilon$ be such that the ball $B(x,R)$ is included in Ω. The boundary of $B(x,R)$ is denoted by Σ_R. The truncated domain $\Omega\backslash\overline{B(x,R)}$ is denoted by Ω_R, and D_ε denotes the corona $B(x,R)\backslash\overline{B(x,\varepsilon)}$ (see Figure 2).

For a $\Psi \in H^{\frac{1}{2}}(\Sigma_R)$, we consider u_Ψ^ε the solution to the problem

$$\left\{\begin{array}{lll} \Delta u_\Psi^\varepsilon + k^2 u_\Psi^\varepsilon & = 0 & \text{in } D_\varepsilon, \\ u_\Psi^\varepsilon & = \Psi & \text{on}\Sigma_R, \\ u_\Psi^\varepsilon & = 0 & \text{on } \Sigma_\varepsilon \end{array}\right. \tag{3.5}$$

and the *Dirichlet-to-Neumann* operator

$$\begin{array}{rccc} T^\varepsilon : & H^{1/2}(\Sigma_R) & \longrightarrow & H^{-1/2}(\Sigma_R), \\ & \Psi & \longmapsto & T^\varepsilon\Psi = \nabla u_\Psi^\varepsilon . n_{|\Sigma_R}, \end{array}$$

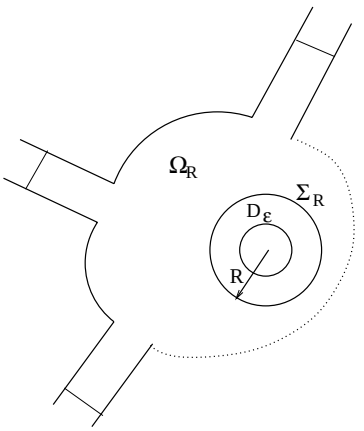

FIG. 2. *The truncated domain.*

where $n_{|\Sigma_R}$ denotes the outward normal to the boundary Σ_R. Using the Poincaré inequality, we obtain that, for $\varepsilon < R < (\sqrt{2}|k|)^{-1}$, problem (3.5) is coercive. Hence it has one and only one solution.

We consider the truncated problem: find u_ε such that

$$\left\{\begin{array}{lll} \Delta u_\varepsilon + k^2 u_\varepsilon & = 0 & \text{in } \Omega_R, \\ u_\varepsilon & = 0 & \text{on } \Gamma_0, \\ \partial_n u_\varepsilon + T^\varepsilon u_\varepsilon & = 0 & \text{on } \Sigma_R, \\ \partial_n u_\varepsilon - iku_\varepsilon & = h_j & \text{on } \Gamma_j, j = 1, 2, \ldots, N. \end{array}\right. \tag{3.6}$$

The variational formulation associated to problem (3.6) is the following: find $u_\varepsilon \in \mathcal{V}_R$ such that

$$a_\varepsilon(u_\varepsilon, v) = l(v) \qquad \forall v \in \mathcal{V}_R, \tag{3.7}$$

where the functional space $\mathcal{V}_R$, the sesquilinear form a_ε, and the semilinear form l are defined by

$$\mathcal{V}_R = \{u \in H^1(\Omega_R), u = 0 \text{ on } \Gamma_0\}, \tag{3.8}$$

$$a_\varepsilon(u, v) = \int_{\Omega_R} \nabla u.\overline{\nabla v}\, dx - k^2 \int_{\Omega_R} u\overline{v}\, dx + \int_{\Sigma_R} (T^\varepsilon u)\overline{v}\, d\gamma(x) \tag{3.9}$$

$$-ik \sum_{j=1}^{N} \int_{\Gamma_j} u\overline{v}\, d\gamma(x), \tag{3.10}$$

$$l(v) = \sum_{j=1}^{N} \int_{\Gamma_j} h_j \overline{v}\, d\gamma(x). \tag{3.11}$$

Here, $\nabla u.\overline{\nabla v} = \sum_{i=1}^{2} \frac{\partial u}{\partial x_i} \frac{\partial \overline{v}}{\partial x_i}$ and $d\gamma(x)$ is the Lebesgue measure on the boundary. The following result is standard in PDE theory.

PROPOSITION 3.1. *Problem* (3.6) *has one and only one solution in* $\mathcal{V}_R$ *which is the restriction to* Ω_R *of the solution to* (3.3).

Proof. Existence: Applying the definition of T^ε, we prove that the restriction to Ω_R of the solution to (3.3) is a solution to (3.6).

Uniqueness: Any solution u to problem (3.6) can be extended in Ω_ε to the solution to problem (3.3): we use the solution u^ε_Ψ to (3.5) with $\Psi = u_{|\Sigma_R}$. ∎

We have now at our disposal the fixed Hilbert space $\mathcal{V}_R$ required by section 2. We assume that the function J is defined in a neighbor part of Γ. Then we have

$$j(\varepsilon) = J(u_{\Omega_\varepsilon}) = J(u_\varepsilon) \qquad \forall \varepsilon \geq 0. \tag{3.12}$$

3.2. Variation of the sesquilinear form. The variation of the sesquilinear form $a_\varepsilon - a_0$ reads

$$a_\varepsilon(u,v) - a_0(u,v) = \int_{\Sigma_R} \left((T^\varepsilon - T^0)u\right) \overline{v}\, d\gamma(x). \tag{3.13}$$

Hence, the problem reduces to the computation of $(T^\varepsilon - T^0)\Psi$ for $\Psi = u_{|\Sigma_R}$.
We have the following proposition.

PROPOSITION 3.2. *The solution u^ε_Ψ to problem* (3.5) *and the operator T^ε are given by the explicit expressions:*

$$u^\varepsilon_\psi(r,\theta) = \sum_{n\in\mathbb{Z}} \frac{J_n(kr)Y_n(k\varepsilon) - J_n(k\varepsilon)Y_n(kr)}{J_n(kR)Y_n(k\varepsilon) - Y_n(kR)J_n(k\varepsilon)} \psi_n e^{in\theta}$$

and

$$T^\varepsilon\psi = k \sum_{n\in\mathbb{Z}} \frac{J_n'(kR)Y_n(k\varepsilon) - J_n(k\varepsilon)Y_n'(kR)}{J_n(kR)Y_n(k\varepsilon) - Y_n(kR)J_n(k\varepsilon)} \psi_n e^{in\theta}, \tag{3.14}$$

where (r,θ) are the polar coordinates in $\mathbb{R}^2$, (Ψ_n) are the Fourier coefficients of Ψ, and (J_n) and (Y_n) are, respectively, the Bessel functions of the first and the second kind.

Proof. We have in polar coordinates

$$u^\varepsilon_\psi(r,\theta) = \sum_{n\in\mathbb{Z}} c_n(r) e^{in\theta},$$

where $c_n(r)$ satisfies the differential equation:

$$\frac{d^2c_n}{dr^2} + \frac{1}{r}\frac{dc_n}{dr} + \left(k^2 - \frac{n^2}{r^2}\right) c_n(r) = 0 \qquad \forall n \in \mathbb{Z},$$

and thus c_n is a linear combination of J_n and Y_n Bessel functions:

$$c_n(r) = a_n J_n(kr) + b_n Y_n(kr) \quad \forall n \in \mathbb{Z}.$$

Using the boundary conditions, we obtain

$$a_n = \frac{Y_n(k\varepsilon)}{J_n(kR)Y_n(k\varepsilon) - Y_n(kR)J_n(k\varepsilon)}\psi_n, \quad b_n = \frac{-J_n(k\varepsilon)}{J_n(kR)Y_n(k\varepsilon) - Y_n(kR)J_n(k\varepsilon)}\psi_n. \qquad ∎$$

In particular, for $\varepsilon = 0$ we have the following proposition.

PROPOSITION 3.3. *The solution u^0_Ψ and the operator T^0 are given by the explicit expressions*

$$u^0_\psi(r,\theta) = \sum_{n\in\mathbb{Z}} \frac{J_n(kr)}{J_n(kR)} \psi_n e^{in\theta}$$

and

$$T^0\psi = k\sum_{n\in\mathbb{Z}} \frac{J_n'(kR)}{J_n(kR)}\psi_n e^{in\theta}, \tag{3.15}$$

where u_ψ^0 *is the solution to* (3.5) *for* $\varepsilon = 0$.

For $\Psi \in H^s(\Sigma_R)$, let

$$\|\psi\|_{s,\Sigma_R}^2 = \sum_{n\in\mathbb{Z}} |\psi_n|^2(1+|n|)^{2s} \tag{3.16}$$

be the norm of Ψ in this space. The so defined norm is equivalent to the usual norm of $H^s(\Sigma_R)$. We introduce the operator:

$$\begin{array}{rccc} \delta_T: & H^{1/2}(\Sigma_R) & \longrightarrow & H^{-1/2}(\Sigma_R), \\ & \Psi & \longmapsto & \delta_T\Psi = \frac{1}{RJ_0^2(kR)}\Psi_0. \end{array}$$

We have the following lemma.

LEMMA 3.4. *We have that*

$$\left\| T^\varepsilon - T^0 - \frac{-1}{\log(\varepsilon)}\delta_T \right\|_{\mathcal{L}(H^{1/2}(\Sigma_R);H^{-1/2}(\Sigma_R))} = o\left(\frac{-1}{\log(\varepsilon)}\right).$$

Proof. Let $\Psi \in H^{\frac{1}{2}}(\Sigma_R)$. Using the series (3.14) and (3.15), we obtain

$$\begin{aligned}(T^\varepsilon - T^0)\psi &= k\sum_{n\in\mathbb{Z}} \frac{J_n'(kR)Y_n(k\varepsilon) - J_n(k\varepsilon)Y_n'(kR)}{J_n(kR)Y_n(k\varepsilon) - Y_n(kR)J_n(k\varepsilon)}\psi_n e^{in\theta} - k\sum_{n\in\mathbb{Z}} \frac{J_n'(kR)}{J_n(kR)}\psi_n e^{in\theta} \\ &= k\sum_{n\in\mathbb{Z}^*} \frac{J_n'(kR)Y_n(k\varepsilon) - J_n(k\varepsilon)Y_n'(kR)}{J_n(kR)Y_n(k\varepsilon) - Y_n(kR)J_n(k\varepsilon)}\psi_n e^{in\theta} - k\sum_{n\in\mathbb{Z}^*} \frac{J_n'(kR)}{J_n(kR)}\psi_n e^{in\theta} \\ &\quad -k\frac{Y_0'(kR)J_0(kR) - Y_0(kR)J_0'(kR)}{J_0^2(kR)} \frac{J_0(k\varepsilon)J_0(kR)}{J_0(kR)Y_0(k\varepsilon) - Y_0(kR)J_0(k\varepsilon)}\psi_0.\end{aligned}$$

We have that [1]

$$\begin{aligned}\frac{Y_0'(kR)J_0(kR) - Y_0(kR)J_0'(kR)}{J_0^2(kR)} &= \frac{W\{J_0(kR), Y_0(kR)\}}{J_0^2(kR)} \\ &= \frac{2}{\pi kR}\frac{1}{J_0^2(kR)},\end{aligned}$$

where W is the Wronskian. Then

$$\begin{aligned}(T^\varepsilon - T^0)\psi &= k\sum_{n\in\mathbb{Z}^*} \frac{J_n(k\varepsilon)Y_n(kR)}{Y_n(k\varepsilon)J_n(kR) - Y_n(kR)J_n(k\varepsilon)}\left(\frac{J_n'(kR)}{J_n(kR)} - \frac{Y_n'(kR)}{Y_n(kR)}\right)\psi_n e^{in\theta} \\ &\quad - \frac{2}{\pi}\frac{J_0(k\varepsilon)J_0(kR)}{J_0(kR)Y_0(k\varepsilon) - Y_0(kR)J_0(k\varepsilon)}\frac{1}{RJ_0^2(kR)}\psi_0. \end{aligned} \tag{3.17}$$

We have the following formula [1]:

$$Y_0(k\varepsilon) = \frac{2}{\pi}\left(\log\left(\frac{k\varepsilon}{2}\right) + \gamma\right)J_0(k\varepsilon) + \varepsilon\alpha(\varepsilon), \tag{3.18}$$

where γ denotes Euler's constant and $\alpha(\varepsilon) \to 0$ when $\varepsilon \to 0$. We insert (3.18) into (3.17):

$$(T^\varepsilon - T^0)\psi = \varepsilon R_\varepsilon \Psi + \frac{-1}{\log(\varepsilon)} \left(1 + \frac{M}{\log(\varepsilon)} + \varepsilon\theta(\varepsilon)\right)^{-1} \delta_T \Psi,$$

where M is a constant independent of ε, $\theta(\varepsilon) \to 0$ when $\varepsilon \to 0$ and

$$R_\varepsilon \psi = \sum_{n\in\mathbb{Z}^*} \frac{k}{\varepsilon} \frac{J_n(k\varepsilon)Y_n(kR)}{Y_n(k\varepsilon)J_n(kR) - Y_n(kR)J_n(k\varepsilon)} \left(\frac{J_n'(kR)}{J_n(kR)} - \frac{Y_n'(kR)}{Y_n(kR)}\right) \psi_n e^{in\theta}.$$

Then

$$\left(T^\varepsilon - T^0 - \frac{-1}{\log(\varepsilon)}\delta_T\right)\psi = \varepsilon R_\varepsilon \psi + O(1)\left(\frac{-1}{\log(\varepsilon)}\right)^2 \frac{1}{RJ_0^2(kR)}\psi_0.$$

Using (3.16), we have

$$\| R_\varepsilon \psi \|^2_{-\frac{1}{2};\Sigma_R} = \sum_{n\in\mathbb{Z}^*} \frac{|k|^2}{\varepsilon^2} \left|\frac{J_n(k\varepsilon)Y_n(kR)}{Y_n(k\varepsilon)J_n(kR) - Y_n(kR)J_n(k\varepsilon)}\right|^2 \cdot \left|\frac{J_n'(kR)}{J_n(kR)(1+|n|)} - \frac{Y_n'(kR)}{Y_n(kR)(1+|n|)}\right|^2 (1+|n|)|\psi_n|^2.$$

Let us prove that there exists a constant $c > 0$ (independent of Ψ and ε) such that for all $0 < \varepsilon < \varepsilon_0 < R$,

$$\|R_\varepsilon \psi\|_{-\frac{1}{2};\Sigma_R} \leq c \| \psi\|_{\frac{1}{2};\Sigma_R}.$$

We have [1]

$$\frac{1}{1+|n|}\frac{J_n'(kR)}{J_n(kR)} = -\frac{1}{1+|n|}\frac{J_{n+1}(kR)}{J_n(kR)} + \frac{n}{1+|n|}\frac{1}{kR}$$

and for $n \to \infty$

$$J_n(z) \sim (2\pi n)^{-\frac{1}{2}} \left(\frac{ez}{2n}\right)^n.$$

Then

$$\lim_{n\to\infty} \frac{1}{1+|n|}\frac{J_{n+1}(kR)}{J_n(kR)} = 0$$

and

$$\left|\frac{1}{1+|n|}\frac{J_n'(kR)}{J_n(kR)}\right| \leq c \quad \forall n \in \mathbb{Z}^*.$$

Here and in what follows, c is a positive constant independent of the data (e.g., of ε and n). Similarly, we have

$$\left|\frac{1}{1+|n|}\frac{Y_n'(kR)}{Y_n(kR)}\right| \leq c \quad \forall n \in \mathbb{Z}^*.$$

Hence,

$$\left|\frac{J_n'(kR)}{J_n(kR)(1+|n|)} - \frac{Y_n'(kR)}{Y_n(kR)(1+|n|)}\right| \leq c \quad \forall n \in \mathbb{Z}^*.$$

We denote

$$f_n(\varepsilon) = \frac{1}{\varepsilon}\left|\frac{J_n(k\varepsilon)Y_n(kR)}{Y_n(k\varepsilon)J_n(kR) - Y_n(kR)J_n(k\varepsilon)}\right|.$$

We have also

$$f_n(\varepsilon) = \left|\frac{\varepsilon J_n(kR)Y_n(k\varepsilon)}{J_n(k\varepsilon)Y_n(kR)} - \varepsilon\right|^{-1}.$$

We show in section 5.3 that there exist n_0 and ε_0 such that

$$\left|\varepsilon\frac{J_n(kR)}{J_n(k\varepsilon)}\right| \geq c\left(\frac{R}{\varepsilon}\right)^{n-1} \qquad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0 \tag{3.19}$$

and

$$\left|\frac{Y_n(k\varepsilon)}{Y_n(kR)}\right| \geq c\left(\frac{R}{\varepsilon}\right)^{n} \qquad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0. \tag{3.20}$$

Using (3.19) and (3.20), we obtain

$$\left|\frac{\varepsilon Y_n(k\varepsilon)J_n(kR)}{J_n(k\varepsilon)Y_n(kR)}\right| \geq c \qquad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0$$

and

$$f_n(\varepsilon) \leq c \qquad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0.$$

For $p \in \{1, 2, \ldots, n_0 - 1\}$, we have $f_p(\varepsilon) \to 0$ when $\varepsilon \to 0$. Then

$$f_n(\varepsilon) \leq c \quad \forall n \in \mathbb{Z}^*, \quad \forall \varepsilon < \varepsilon_0.$$

Hence

$$\|R_\varepsilon \psi\|_{-\frac{1}{2},\Sigma_R} \leq c \parallel \psi \parallel_{\frac{1}{2};\Sigma_R} \quad \forall \psi \in H^{\frac{1}{2}}(\Sigma_R).$$

This completes the proof. □

From this lemma we obtain the following proposition.

PROPOSITION 3.5. *Let δ_a be the sesquilinear and continuous form defined on $\mathcal{V}_R$ by*

$$\delta_a(u,v) = \frac{u^{mean}}{J_0(kR)}\frac{\overline{v^{mean}}}{J_0(kR)},$$

where u^{mean} and v^{mean} denote, respectively, the mean values of u and v on Σ_R. We have

$$\left|a_\varepsilon(u,p) - a_0(u,p) - \frac{-2\pi}{\log(\varepsilon)}\delta_a(u,p)\right| = o\left(\frac{-1}{\log(\varepsilon)}\right)\|u\|_{\mathcal{V}_R}\|p\|_{\mathcal{V}_R} \qquad \forall u,p \in \mathcal{V}_R.$$

3.3. The asymptotic expansion. We prove in section 5.2 that the sesquilinear form a_0 satisfies Hypothesis 2 (inf-sup condition).
The adjoint problem is the following: find $p_\Omega \in \mathcal{V}_\Omega$ such that

$$\int_\Omega (\nabla v.\overline{\nabla p_\Omega} - k^2 v\overline{p_\Omega})\,dx - ik\sum_{j=1}^{N}\int_{\Gamma_j} v\overline{p_\Omega}\,d\gamma(x) = -L_{u_\Omega}(v) \quad \forall v \in \mathcal{V}_\Omega. \tag{3.21}$$

This problem has one and only one solution (see section 5.1). If $L_{u_\Omega} \in H_{00}^{\frac{1}{2}}(\Gamma_m)'$, $m \in \{1, 2, \ldots, N\}$, the strong formulation of problem (3.21) is

$$\begin{cases} \Delta p_\Omega + \overline{k}^2 p_\Omega &= 0 & \text{in } \Omega, \\ p_\Omega &= 0 & \text{on } \Gamma_0, \\ \partial_n p_\Omega + i\overline{k} p_\Omega &= -L_{u_\Omega} & \text{on } \Gamma_m, \\ \partial_n p_\Omega + i\overline{k} p_\Omega &= 0 & \text{on } \Gamma_j, j \in \{1, 2, \ldots, N\}\backslash\{m\}. \end{cases} \tag{3.22}$$

Hence, all the assumptions of section 2 are satisfied and we can apply the adjoint method. Then we have the following theorem.

THEOREM 3.6. *The function j has the following asymptotic expansion:*

$$j(\varepsilon) - j(0) = \frac{-2\pi}{\log(\varepsilon)}\Re(u_\Omega(x)\overline{p_\Omega}(x)) + o\left(\frac{-1}{\log(\varepsilon)}\right).$$

Proof. Using Theorem 2.2, we obtain

$$j(\varepsilon) - j(0) = \frac{-2\pi}{\log(\varepsilon)}\Re(\delta_a(u_0, p_0)) + o\left(\frac{-1}{\log(\varepsilon)}\right),$$

where u_0 is the solution to (3.7) for $\varepsilon = 0$ and p_0 is the solution to the adjoint problem

$$a_0(v, p_0) = -L_{u_0}(v) \qquad \forall v \in \mathcal{V}_R. \tag{3.23}$$

As observed in Proposition 3.1, u_0 is the restriction to Ω_R of u_Ω. Let us prove that the same property holds for p_0 and p_Ω. For $v \in \mathcal{V}_\Omega$, we denote by p_R and v_R the restriction of p_Ω and v to Ω_R. On the one hand, we have

(3.24)

$$\begin{aligned} &\int_\Omega (\nabla v.\overline{\nabla p_\Omega} - k^2 v\overline{p_\Omega})\,dx - ik\sum_{j=1}^{N}\int_{\Gamma_j} v\overline{p_\Omega}\,d\gamma(x) \\ &= \int_{\Omega_R} (\nabla v_R.\overline{\nabla p_R} - k^2 v_R\overline{p_R})\,dx - ik\sum_{j=1}^{N}\int_{\Gamma_j} v_R\overline{p_R}\,d\gamma(x) + \int_{D_0} (\nabla v.\overline{\nabla p_\Omega} - k^2 v\overline{p_\Omega})\,dx \\ &= \int_{\Omega_R} (\nabla v_R.\overline{\nabla p_R} - k^2 v_R\overline{p_R})\,dx - ik\sum_{j=1}^{N}\int_{\Gamma_j} v_R\overline{p_R}\,d\gamma(x) + \int_{\Sigma_R} (T^0 v_R)\overline{p_R}\,d\gamma(x) \\ &= a_0(v_R, p_R). \end{aligned}$$

On the other hand, due to the fact that J is defined in a neighbor part of Γ, we have that $J(u) = J(u_R)$ for all $u \in \mathcal{V}_\Omega$. Hence

$$L_{u_\Omega}(v) = L_{u_0}(v_R). \tag{3.25}$$

Then, gathering (3.24), (3.21), and (3.25), we obtain

$$a_0(v_R, p_R) = -L_{u_0}(v_R) \qquad \forall v_R \in \mathcal{V}_R,$$

which proves that p_R is the solution to (3.23). Then p_0 is the restriction to Ω_R of p_Ω. It remains to prove that $\delta_a(u_{\Omega|\Omega_R}, p_{\Omega|\Omega_R}) = u_\Omega(x).p_\Omega(x)$. Using that u_Ω is the solution to the Helmholtz equation in the ball $B(x, R)$, we obtain

$$u_\Omega(x) = \frac{u_{\Omega|\Sigma_R}^{mean}}{J_0(kR)}.$$

Similarly, we have

$$\overline{p}_\Omega(x) = \frac{\overline{p_{\Omega|\Sigma_R}^{mean}}}{J_0(kR)}.$$

Hence

$$\begin{aligned}\delta_a(u_0, p_0) &= \delta_a(u_{\Omega|\Omega_R}, p_{\Omega|\Omega_R}) \\ &= u_\Omega(x)\overline{p_\Omega(x)}.\end{aligned}$$

This completes the proof. ∎

Then the topological gradient is

$$g = \Re(u_\Omega \overline{p_\Omega}).$$

4. Numerical results.

4.1. T-shaped waveguide. We use the topological gradient to design an H-plane T-shaped waveguide. The geometric constraints are shown in Figure 3(a). The input Γ_1 is excited by the TE10 mode (see the second boundary condition of (4.1)): the excitation is given by

$$u_e(y) = \cos\left(\frac{\pi y}{d}\right) \quad \forall y \in \Gamma_1.$$

We follow the two ideas [22]:

- the initial guess is the free space;
- instead of minimizing the reflected energy, we maximize the transmitted energy on Γ_2 and Γ_3.

At the beginning, only the input and output channels have metallic boundaries. In order to use the finite element method, the design domain is delimited by a fictitious boundary Γ_4 on which an absorbing condition is imposed (see Figure 3(b)). The problem is modelized as follows:

$$\left\{\begin{array}{lll} \Delta u + k^2 u = 0 & & \text{in } \Omega, \\ u = 0 & & \text{on } \Gamma_0, \\ \partial_n u - ik'u = \partial_n u_e - ik'u_e & & \text{on } \Gamma_1, \\ \partial_n u - ik'u = 0 & & \text{on } \Gamma_2, \Gamma_3, \\ \partial_n u - iku = 0 & & \text{on } \Gamma_4, \end{array}\right. \tag{4.1}$$

where $k^2 = k'^2 + \frac{\pi^2}{d^2}$, d being the length of Γ_1. The perfect conduction on the metallic boundary leads to the first boundary condition $u = 0$ on Γ_0. The third

boundary condition prevents reflections on Γ_2, Γ_3. The last equation is an approximate absorbing boundary condition. Here and in the following, we take $k = 10$.

The cost function to maximize is

$$J(u) = |S_{12}(u)|^2 + |S_{13}(u)|^2,$$

where $S_{1j}(u)$ is given by

$$S_{1j}(u) = \int_{\Gamma_j} u_{|\Gamma_j} \cos\left(\frac{\pi x}{d}\right)\, dx, \quad j \in \{2, 3\}.$$

The adjoint state is the solution to

$$\left\{\begin{array}{lll} \Delta\bar{p} + k^2\bar{p} &= 0 & \text{in } \Omega, \\ \bar{p} &= 0 & \text{on } \Gamma_0, \\ \partial_n\bar{p} - ik'\bar{p} &= 0 & \text{on } \Gamma_1, \\ \partial_n\bar{p} - ik'\bar{p} &= -2\overline{S_{12}(u)}\cos\left(\frac{\pi x}{d}\right) & \text{on } \Gamma_2, \\ \partial_n\bar{p} - ik'\bar{p} &= -2\overline{S_{13}(u)}\cos\left(\frac{\pi x}{d}\right) & \text{on } \Gamma_3, \\ \partial_n\bar{p} - ik\bar{p} &= 0 & \text{on } \Gamma_4. \end{array}\right. \tag{4.2}$$

Then the topological gradient is $g = \Re(u\bar{p})$ (see Figure 4(b)). We are interested in the relative loss of energy

$$P(u) = \frac{E_e - (E_2 + E_3)(u)}{E_e},$$

where E_e is the entering energy and $E_j(u)$ is the outgoing energy through Γ_j, $j \in \{2, 3\}$.

We present here the topological optimization procedure. The underlying idea is the following: in the ℓth step of the process, if $\overline{x}$ is such that the topological gradient is higher than a certain value t_ℓ, we insert at this point a Dirichlet node (metal). The constant t_ℓ is chosen by the user, which allows him to take into account other constraints, for example the feasibility. The process is stopped when the topological gradient is everywhere negative in the design domain or when the shape suits the designer. The algorithm is as follows.

- Initialization: choose the initial domain Ω_0, and set $\ell = 0$. The domain Ω_0 is meshed and it is identified with the set of the nodes: $\Omega_0 = \{x_k, k \in \{1, 2, \ldots, n\}\}$. The grid is fixed during the process.
- Repeat:
  1. compute u_ℓ, p_ℓ the direct and adjoint solutions in the domain Ω_ℓ,
  2. compute the topological gradient $g_\ell = \Re(u_\ell\overline{p_\ell})$,
  3. set $\Omega_{\ell+1} = \Omega_\ell \backslash \{x_k, g_\ell(x_k) \geq t_{\ell+1}\}$,
  4. $\ell \leftarrow \ell + 1$.

Figure 4 shows the isovalues of $|u|$ and the topological gradient for the initial geometry. In this case, 94.4% of the energy is lost. After two iterations, the loss is reduced to 2.02% (see Figure 5) and the topological gradient is everywhere negative. The last step consists of smoothing the boundary of the domain by inserting some metal where $|u|$ is close to zero. The loss of energy of this waveguide is equal to 1.5% (see Figure 6). The convergence history is given by Figure 7.

4.2. L-shaped waveguide. Here, we use the topological gradient like a decision help system to build a junction between two rectangular waveguides. The initial

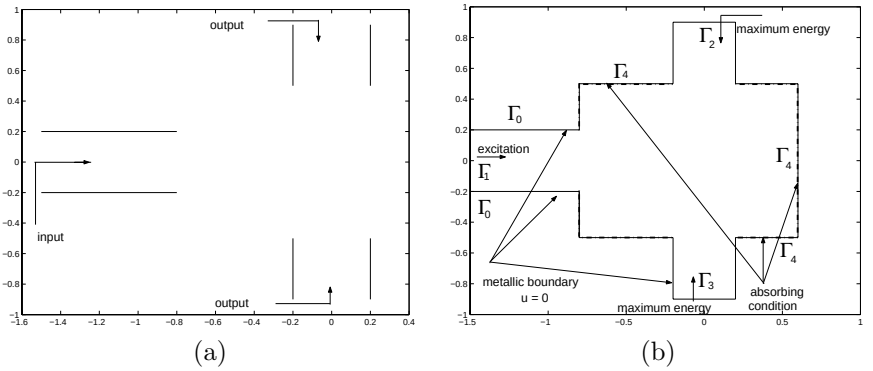

FIG. 3. *The initial geometry* (a) *and the design domain* (b).

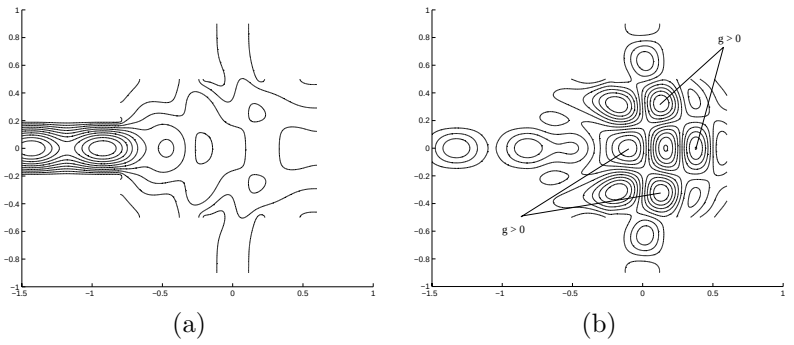

FIG. 4. *Modulus of the electric field* (a) *and topological gradient* (b).

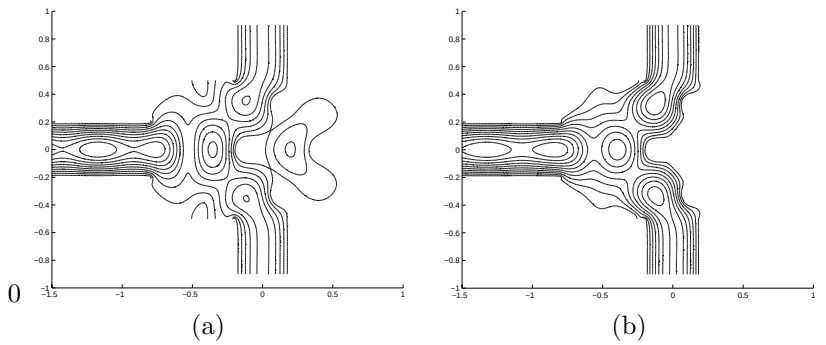

FIG. 5. *Modulus of the electric fields obtained after a first iteration* (a) *and after two iterations* (b).

geometry and the design domain are given by Figure 8. The cost function to maximize is

$$J(u) = |S_{12}(u)|^2.$$

Figure 9(a) shows the isovalues of $|u|$ for the initial geometry. In this case, 95.43% of the energy is lost. We observe that the topological gradient is high on a quarter

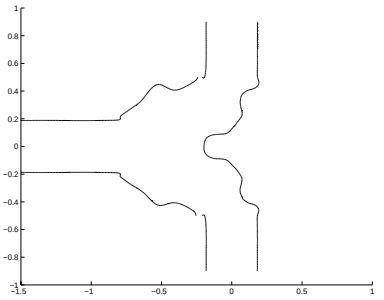

FIG. 6. *Final geometry.*

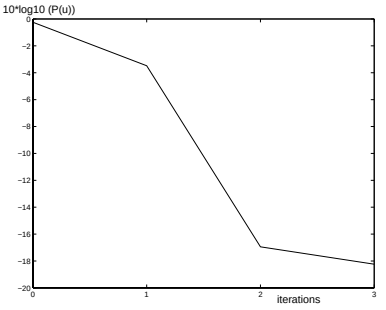

FIG. 7. *Convergence history.*

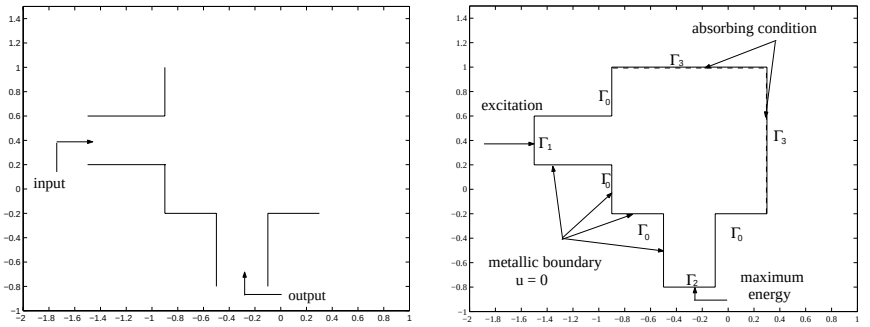

(a) (b)

FIG. 8. *The initial geometry* (a) *and the design domain* (b).

of circle where we decide to put metal (see Figure 9(b)). The loss of energy of the obtained waveguide is now equal to 0.34% (see Figure 10).

4.3. U-shaped waveguide. Here, the initial guess is a metallic cavity. The geometry of the waveguide is shown in Figure 11. The cost function to maximize is

$$J(u) = |S_{12}(u)|^2.$$

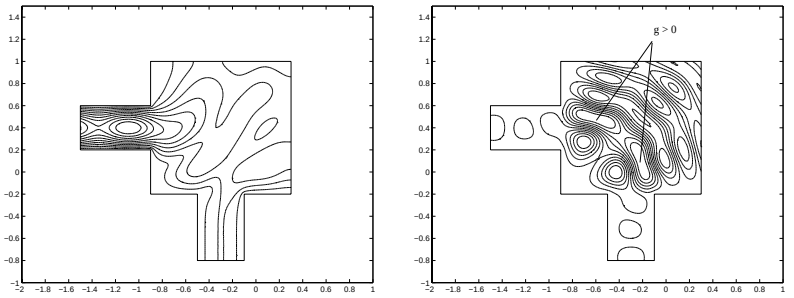

FIG. 9. *Modulus of the electric field* (a) *and topological gradient* (b).

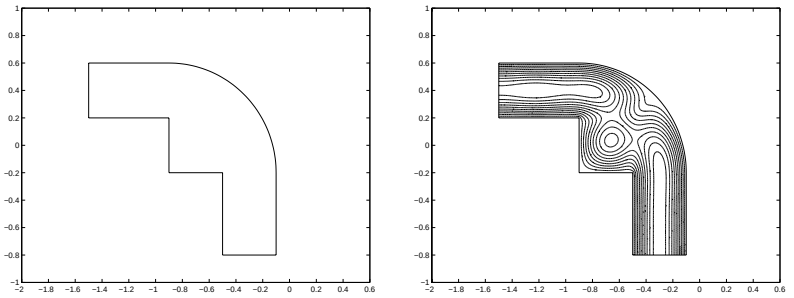

FIG. 10. *Final geometry* (a) *and modulus of the electric field* (b).

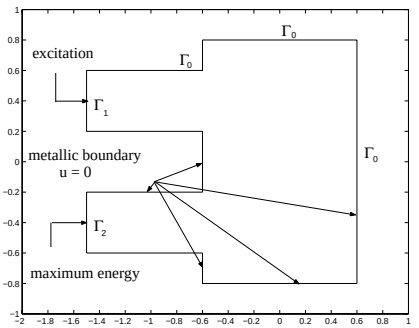

FIG. 11. *Geometry of the initial guide.*

Figure 12(a) shows the isovalues of $|u|$ for the initial geometry. In this case, 88.45% of the energy is reflected. There are three local maximas of the topological gradient (see Figure 12(b)). At each local maxima, we introduce a pointwise Dirichlet condition (a metallic plot). The new energy distribution is shown in Figure 13(a). The loss of energy is now equal to 39.19%. A new analysis is performed: after the introduction of another metallic plot, we obtain the design of Figure 13(b). The objective is fulfilled; the loss of energy is equal to 0.7%. For feasibility reasons, we decide not to insert additional plots.

5. Appendix.

5.1. Existence and uniqueness of the solution. Here we establish the existence and uniqueness of the solution to problem (3.1). Replacing Ω with Ω_ε, the argumentation would be the same for problem (3.3). Without any loss of generality, we suppose here that $N = 1$. The variational form of problem (3.1) is the following: find $u \in \mathcal{V}_\Omega$ satisfying

$$a(u, v) = l(v) \quad \forall v \in \mathcal{V}_\Omega, \tag{5.1}$$

where the functional space $\mathcal{V}_\Omega$, the sesquilinear form a, and the semilinear form l are defined by

$$\begin{aligned} \mathcal{V}_\Omega &= \{v \in H^1(\Omega), v = 0 \text{ on } \Gamma_0\}, \\ a(u, v) &= \int_\Omega (\nabla u . \overline{\nabla v} - k^2 u \overline{v})\, dx - ik \int_{\Gamma_1} u \overline{v}\, d\gamma(x), \\ l(v) &= \int_{\Gamma_1} g \overline{v}\, d\gamma(x). \end{aligned}$$

We split a in the following form:

$$a(u, v) = b(u, v) + c(u, v), \tag{5.2}$$

where b and c are defined by

$$b(u,v) = \int_\Omega (\nabla u.\overline{\nabla v} + u\overline{v})\, dx, \tag{5.3}$$

$$c(u,v) = -(1+k^2)\int_\Omega u\overline{v}\, dx - ik\int_{\Gamma_1} u\overline{v}\, d\gamma(x). \tag{5.4}$$

We recall the following result which is a consequence of the Lax–Milgram theorem.

LEMMA 5.1. *For all $f \in \mathcal{V}'_\Omega$, there exists a unique $u_f \in \mathcal{V}_\Omega$ such that*

$$b(u_f, v) = \langle f, v\rangle_{\mathcal{V}'_\Omega, \mathcal{V}_\Omega}.$$

The operator $f \mapsto u_f$ is continuous from $\mathcal{V}'_\Omega$ to $\mathcal{V}_\Omega$.

We define

$$\begin{array}{rccc} \mathcal{C}: & \mathcal{V}_\Omega & \longrightarrow & \mathcal{V}_\Omega, \\ & u & \longmapsto & \mathcal{C}u \end{array}$$

such that

$$b(\mathcal{C}u, v) + c(u,v) = 0 \quad \forall v \in \mathcal{V}_\Omega. \tag{5.5}$$

We have the following lemma.

LEMMA 5.2. *The operator $\mathcal{C}$ is compact.*

Proof. By Lemma 5.1, it suffices to prove that the operator

$$u \longmapsto c(u,.)$$

from $\mathcal{V}_\Omega$ to $\mathcal{V}'_\Omega$ is compact. Let (u_i) be a sequence bounded in $\mathcal{V}_\Omega$. The imbeddings $\mathcal{V}_\Omega \to L^2(\Omega)$ and $H^{\frac{1}{2}}_{00}(\Gamma_1) \to L^2(\Gamma_1)$ are compact; then there exists a subsequence always denoted by (u_i) such that

$$u_i \to w_1 \text{ in } L^2(\Omega)$$

and

$$\gamma_0 u_i \to w_2 \text{ in } L^2(\Gamma_1).$$

Then

$$c(u_i,.) \to l^{w_2}_{w_1} \text{ in } \mathcal{V}'_\Omega,$$

where $l^{w_2}_{w_1}$ is defined by

$$\left\langle l^{w_2}_{w_1}, v\right\rangle_{\mathcal{V}'_\Omega, \mathcal{V}_\Omega} = -(1+k^2)\int_\Omega w_1\overline{v}\, dx - ik\int_{\Gamma_1} w_2\overline{v}\, d\gamma(x) \quad \forall v \in \mathcal{V}_\Omega.$$

Hence the operator $\mathcal{C}$ is compact. ∎

Using (5.5), problem (5.1) can be written as follows: find $u \in \mathcal{V}_\Omega$ such that

$$b((I-\mathcal{C})u, v) = l(v) \quad \forall v \in \mathcal{V}_\Omega. \tag{5.6}$$

We have the following lemma.

LEMMA 5.3. *For $k \in \{k \in \mathbb{C}^*/\Im(k) \geq 0\}$, the following problem has no nontrivial solution: find $u \in \mathcal{V}_\Omega$ such that*

$$a(u,v) = 0 \quad \forall v \in \mathcal{V}_\Omega. \tag{5.7}$$

Proof. Let u be a solution to problem (5.7). For $v = u$, we have

$$a(u,u) = 0.$$

Then

$$\int_\Omega |\nabla u|^2\, dx - k^2 \int_\Omega |u|^2\, dx - ik \int_{\Gamma_1} |u|^2\, d\gamma(x) = 0. \tag{5.8}$$

By writing $k = k_1 + ik_2$, where $(k_1, k_2) \in \mathbb{R}^2$ and using (5.8), we obtain

$$\int_\Omega |\nabla u|^2\, dx - (k_1^2 - k_2^2) \int_\Omega |u|^2\, dx + k_2 \int_{\Gamma_1} |u|^2\, d\gamma(x) = 0 \tag{5.9}$$

and

$$k_1 \int_{\Gamma_1} |u|^2\, d\gamma(x) + 2k_1 k_2 \int_\Omega |u|^2\, dx = 0. \tag{5.10}$$

Two cases can arise:

- First case: $k_2 > 0$. If $k_1 = 0$, using (5.9) we obtain

$$\int_\Omega |\nabla u|^2\, dx + k_2^2 \int_\Omega |u|^2\, dx + k_2 \int_{\Gamma_1} |u|^2\, d\gamma(x) = 0.$$

  Then $u = 0$ in Ω. If $k_1 \neq 0$, using (5.10) we obtain

$$\int_{\Gamma_1} |u|^2\, d\gamma(x) + 2k_2 \int_\Omega |u|^2\, dx = 0.$$

  Then $u = 0$ in Ω.
- Second case: $k_2 = 0$ and $k_1 \neq 0$. Using (5.10), we obtain

$$u = 0 \quad \text{on } \Gamma_1.$$

  Let $\tilde{\Omega}$ be a regular domain containing Ω and so that $\Gamma_0 \subset \partial\tilde{\Omega}$. Extending u by zero in $\tilde{\Omega} \setminus \Omega$, we obtain a function $\tilde{u}$ that satisfies

$$\Delta\tilde{u} + k^2\tilde{u} = 0 \quad \text{in } \mathcal{D}'(\tilde{\Omega}).$$

  This extension is analytic; it is equal to zero in an open subset of a connected domain; thus $\tilde{u} = 0$ in $\tilde{\Omega}$.

This completes the proof. ∎

By Lemmas 5.2 and 5.3, and by using the Fredholm alternative, we obtain the following result.

THEOREM 5.4. *For $k \in \{k \in \mathbb{C}^*/\Im(k) \geq 0\}$, problem* (5.1) *has one and only one solution.*

5.2. The inf-sup condition. Our aim is to prove that the sesquilinear form a_0 defined by (3.9) for $\varepsilon = 0$ satisfies the inf-sup condition (see Hypothesis 2). We have the following lemma.

LEMMA 5.5. *The sesquilinear form a defined in* (5.1) *satisfies the* inf-sup *condition.*

Proof. Let u $\in \mathcal{V}_\Omega$. We set $v = (I - \mathcal{C})u$, where $\mathcal{C}$ is the operator defined by (5.5). According to (5.5), we have

$$\begin{aligned} a(u,v) &= b(v,v) \\ &= \|(I-\mathcal{C})u\|_{\mathcal{V}_\Omega}\|v\|_{\mathcal{V}_\Omega} \\ &\geq \alpha\|u\|_{\mathcal{V}_\Omega}\|v\|_{\mathcal{V}_\Omega}, \end{aligned}$$

where $\alpha = \|(I-\mathcal{C})^{-1}\|^{-1}_{\mathcal{L}(\mathcal{V}_\Omega,\mathcal{V}_\Omega)}$. Thus the sesquilinear form a satisfies the inf-sup condition. ∎

We have the following result.

PROPOSITION 5.6. *The sesquilinear form a_0 satisfies the* inf-sup *condition.*

Proof. We have

$$a_0(u,v) = \int_{\Omega_R} (\nabla u.\overline{\nabla v} - k^2 u\overline{v})\, dx + \int_{\Sigma_R} (T^0 u)\overline{v}\, d\gamma(x) - ik\int_{\Gamma_1} u\overline{v}\, d\gamma(x) \quad \forall u, v \in \mathcal{V}_R.$$

For all $u \in \mathcal{V}_R$ we set

$$\tilde{u} = \begin{cases} u \text{ in } \Omega_R, \\ u^0_\psi \text{ in } B(x,R), \end{cases}$$

where $\psi = u_{|\Sigma_R}$ and u^0_ψ is the solution to

$$\begin{cases} \Delta u^0_\psi + k^2 u^0_\psi = 0 & \text{in } B(x,R), \\ u^0_\psi = \psi & \text{on } \Sigma_R. \end{cases}$$

It can easily be proved that

$$a_0(u, v_{|\Omega_R}) = a(\tilde{u}, v) \quad \forall u \in \mathcal{V}_R, \quad \forall v \in \mathcal{V}_\Omega.$$

According to Lemma 5.5, there exists $v \in \mathcal{V}_\Omega, v \neq 0$, such that

$$\begin{aligned} a_0(u, v_{|\Omega_R}) = a(\tilde{u}, v) &\geq \alpha\|\tilde{u}\|_{\mathcal{V}_\Omega}\|v\|_{\mathcal{V}_\Omega} \\ &\geq \alpha\|u\|_{\mathcal{V}_R}\|v_{|\Omega_R}\|_{\mathcal{V}_R}. \end{aligned}$$

This completes the proof. ∎

5.3. Some useful inequalities. We have the following proposition.

PROPOSITION 5.7. *There exists $c > 0$ such that*

$$\left|\varepsilon\frac{J_n(kR)}{J_n(k\varepsilon)}\right| \geq c\left(\frac{R}{\varepsilon}\right)^{n-1} \quad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0.$$

Proof. The Bessel function $J_n(z)$ is defined by

$$J_n(z) = \left(\frac{1}{2}z\right)^n \sum_{p=0}^{+\infty} \frac{(-\frac{1}{4}z^2)^p}{p!\Gamma(n+p+1)}.$$

Then we have

$$\begin{aligned}
\varepsilon \frac{J_n(kR)}{J_n(k\varepsilon)} &= \varepsilon \left(\frac{R}{\varepsilon}\right)^n \frac{\displaystyle\sum_{p=0}^{+\infty} \frac{(-\frac{1}{4}k^2R^2)^p}{p!\Gamma(n+p+1)}}{\displaystyle\sum_{p=0}^{+\infty} \frac{(-\frac{1}{4}k^2\varepsilon^2)^p}{p!\Gamma(n+p+1)}} \\
&= \varepsilon \left(\frac{R}{\varepsilon}\right)^n \frac{(\Gamma(n+1))^{-1} + \displaystyle\sum_{p=1}^{+\infty} \frac{(-\frac{1}{4}k^2R^2)^p}{p!\Gamma(n+p+1)}}{(\Gamma(n+1))^{-1} + \displaystyle\sum_{p=1}^{+\infty} \frac{(-\frac{1}{4}k^2\varepsilon^2)^p}{p!\Gamma(n+p+1)}} \\
&= \varepsilon \left(\frac{R}{\varepsilon}\right)^n \frac{1 + \displaystyle\sum_{p=1}^{+\infty} \frac{n!}{p!(n+p)!} \left(-\frac{1}{4}k^2R^2\right)^p}{1 + \displaystyle\sum_{p=1}^{+\infty} \frac{n!}{p!(n+p)!} \left(-\frac{1}{4}k^2\varepsilon^2\right)^p} \\
&= \left(\frac{R}{\varepsilon}\right)^{n-1} u_n(\varepsilon),
\end{aligned}$$

where $u_n(\varepsilon)$ is defined by

$$u_n(\varepsilon) = \frac{R + \displaystyle\sum_{p=1}^{+\infty} \frac{Rn!}{p!(n+p)!} \left(-\frac{1}{4}k^2R^2\right)^p}{1 + \displaystyle\sum_{p=1}^{+\infty} \frac{n!}{p!(n+p)!} \left(-\frac{1}{4}k^2\varepsilon^2\right)^p}.$$

It is easy to see that the series which intervene in the expression of $u_n(\varepsilon)$ converge normally with respect to (n, ε). Hence, we have

$$\lim_{(n,\varepsilon)\to(\infty,0)} u_n(\varepsilon) = R.$$

Using the limit definition, there exists $c > 0$ such that

$$|u_n(\varepsilon)| \geq c \quad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0.$$

This completes the proof. □

By the same techniques we obtain the following result.

PROPOSITION 5.8. *There exists $c > 0$ such that*

$$\left|\frac{Y_n(k\varepsilon)}{Y_n(kR)}\right| \geq c \left(\frac{R}{\varepsilon}\right)^n \qquad \forall n \geq n_0, \quad \forall \varepsilon < \varepsilon_0.$$

PARTIAL HEDGING UNDER TRANSACTION COSTS*

KENJI KAMIZONO†

Abstract. In this paper, we consider the problem of minimizing expected shortfall for a contingent claim in a continuous-time, multiasset financial market in the presence of proportional transaction costs. By generalizing the convex duality technique of Cvitanić [*SIAM J. Control. Optim.*, 38 (2000), pp. 1050–1066] to the case of multivariate contingent claim, we establish the existence of an optimal trading strategy and describe it in terms of an appropriate dual optimization problem.

Key words. hedging, expected shortfall, transaction costs

1. Introduction. In a standard, complete financial market, every contingent claim can be replicated through some admissible portfolio, and the minimum initial capital required for replication defines the hedging price of the contingent claim. Although there is no such unique hedging price in the presence of proportional transaction costs, an investor who is to cover a contingent claim at the terminal time can still eliminate the entire risk of shortfall by putting up a sufficient amount of initial capital, the least amount of which is called the *upper hedging price*. The upper hedging price is thus the price required by the most conservative investor. It has been pointed out, however, that the superreplication of a contingent claim often requires a large amount of initial capital. For example, in the case of simple European call-options, except for the transaction cost at initial time, the upper hedging price is just the initial stock price, which is a trivial upper bound on the value of the option; and the optimal strategy for hedging a call-option is the so-called *buy-and-hold* strategy; see, for example, [5], [13], and [2].

With such a situation in mind, we consider the problem of *minimization of expected shortfall*, the idea of which goes back to [4], [6], and [3]. We generalize the results of these works to the general case of financial markets with several risky assets under proportional transaction costs. The prototype and some results in the superreplicating problem of such markets can be found in [9]. The paper [7] recently considered similar problems by directly tackling the primal problem. We take an alternative approach via convex duality.[1] An advantage of the recourse to an appropriate dual problem is that we can solve the problem with minimum use of the martingale theory. In fact, we do not need the semimartingality of the asset price process. All we need, in fact, is the $K(S(T))$-Fatou closedness of the set $\mathscr{C}_{x,y}$ in Definition 2.4 below. A sufficient condition for $\mathscr{C}_{x,y}$ to be $K(S(T))$-Fatou closed is that the asset price process S is a continuous semimartingale for which there exists an equivalent martingale measure. However, our result still holds true even for nonsemimartingale price processes if the set $\mathscr{C}_{x,y}$ is $K(S(T))$-Fatou closed.

This paper is organized as follows. In section 2, we set up our financial market

[1] In the review process of this paper, the results of [7] were generalized for nonsemimartingale price processes; see [8].

model with proportional transaction costs. The model is essentially the same as [9], except that we exclude bartering between the risky assets. The dissertation [11] dealt with the general case with bartering allowed but with an additional restriction on the contingent claim. In section 3, we present our main result and proofs. There, we generalize the convex duality techniques of [3] to the case of vector-valued contingent claims.

2. The model. Throughout this paper, we fix a filtered probability space $(\Omega, \mathscr{F}, \{\mathscr{F}(t)\}_{t\in[0,T]}, \mathbb{P})$ satisfying the usual conditions. Our financial market consists of one risk-free asset with price normalized to be one and d risky assets with price given by a $(0,\infty)^d$-valued, measurable, adapted process $S \triangleq \{(S_1(t),\dots,S_d(t))\}_{t\in[0,T]}$. By changing the physical unit of the assets, if necessary, we assume $S(0) = \mathbf{1}$, where $\mathbf{1}$ denotes the vector in $\mathbb{R}^d$ with each component equal to 1. We do not make any additional assumptions on the process S such as semimartingality or the existence of an equivalent martingale measure.

We regard the risk-free asset as money and assume that an investor must purchase risky assets through money; that is, bartering between two risky assets is impossible. Furthermore, purchase (respectively, sale) of the ith risky asset is subject to a proportional transaction cost of rate λ_i (respectively, μ_i); an investor is allowed to buy (respectively, sell) the ith asset at time t for price $(1+\lambda_i)S_i(t)$ (respectively, $(1-\mu_i)S_i(t)$). The numbers $\lambda_i > 0$ and $0 < \mu_i < 1$ are assumed to be constant throughout the investment period.

A *trading strategy* is simply an $\mathbb{R}^d$-valued adapted process $A \triangleq \{A_i(t)\}_{t\in[0,T]}$ such that each component A_i has right-continuous paths of bounded variation with the property

$$\int_{[0,T]} S_i(t)d|A_i|(t) < \infty \quad \text{a.s.},$$

where $|A_i| \triangleq \{|A_i|(t)\}_{t\in[0,T]}$ denotes the total variation process of A_i. We set $A(0-) \triangleq 0$. As is well known, we have a decomposition $A_i = A_i^{\oplus} - A_i^{\ominus}$ into the positive variation $A^{\oplus}$ and the negative variation $A^{\ominus}$. These processes are right-continuous, nondecreasing adapted processes. The random variable $A_i^{\oplus}(t)$ (respectively, $A_i^{\ominus}(t)$) signifies the cumulative number-of-shares of the ith asset, purchased (respectively, sold) up to time t. Given a trading strategy A, we define the *portfolio-holdings process* to be the process $(X^A, A) \triangleq \{(X^A(t), A(t))\}_{t\in[0,T]}$ with $X^A(t)$ given by

$$X^A(t) \triangleq \sum_{i=1}^{d} \int_{[0,t]} S_i(u)\{(1-\mu_i)dA_i^{\ominus}(u) - (1+\lambda_i)dA_i^{\oplus}(u)\}. \tag{2.1}$$

The random variable $X^A(t)$ signifies the amount of money held at time t by an investor who has chosen a trading strategy A with no initial-holdings.

Our formulation on transaction costs is essentially the same as [9] with the additional assumption that

$$(1+\lambda^{i1})(1+\lambda^{1j}) < (1+\lambda^{ij}) \quad \forall i \neq j \tag{2.2}$$

in their notation. Under this assumption, it is more efficient to use money as the medium of exchange than to barter, and inefficient strategies involving bartering will be excluded by optimality. Notice also that since the price process S need not be a semimartingale, there is no stochastic differential equation for the portfolio-holdings

process $(X^A, S_1A_1, \ldots, S_dA_d)$ in terms of amount. In this paper, therefore, we always express portfolio-holdings in terms of the number-of-shares.

DEFINITION 2.1 (the solvency region). *For each $s \in (0,\infty)^d$, we define the* solvency region $K(s)$ *to be the set of vectors $(x,y) \in \mathbb{R} \times \mathbb{R}^d$ such that*

$$\ell(s,x,y) \triangleq x + \sum_{i=1}^{d} s_i\{(1-\mu_i)y_i^+ - (1+\lambda^i)y_i^-\} \geq 0. \tag{2.3}$$

We also define the positive polar $K^*(s)$ *of the set $K(s)$ by*

$$K^*(s) \triangleq \{(\xi,\eta) \in \mathbb{R} \times \mathbb{R}^d \mid \xi x + \eta \cdot y \geq 0 \quad \forall (x,y) \in K(s)\}. \tag{2.4}$$

It is easy to see that the sets $K(s)$ and $K^*(s)$ are convex polyhedral cones in $\mathbb{R} \times \mathbb{R}^d$ such that $K^*(s) \subseteq \mathbb{R}_+ \times \mathbb{R}^d_+ \subseteq K(s)$. The economic significance of the solvency region $K(s)$ is the following. If an investor with a portfolio-holdings vector $(x,y) \in \mathbb{R} \times \mathbb{R}^d$ liquidates his portfolio-holdings when the price vector of the risky assets is s, then after this liquidation has taken place the amount of money which he will be holding is equal to $\ell(s,x,y)$. Therefore, the portfolio-holdings vector (x,y) belongs to the solvency region $K(s)$ if and only if the value of the portfolio-holdings vector (x,y) is "nonnegative." We call the function $\ell : (0,\infty)^d \times \mathbb{R} \times \mathbb{R}^d \to \mathbb{R}$ the *liquidation function.*

At this point, we remark that as portfolio-holdings vectors are expressed in terms of number-of-shares, our notations such as $K(S(T))$ and $K^*(S(T))$ correspond to $\hat{K}$ and $\hat{K^*}$ of [9] via what they called the "hat" operator; by applying the hat operator, one can divide primal (respectively, multiply dual) random vectors by the diagonal matrix with diagonal elements $1, S_1(T), \ldots, S_d(T)$. Thus, except for easy line-by-line modifications, we may use their results, for example Theorem 2.6.

Given a set-valued random variable $\omega \to E(\omega)$, where $E(\omega)$ is a Borel set of some Euclidean space for each ω, we denote by $\mathbb{L}^0(E)$ the set of all $\mathscr{F}(T)$-measurable random variables ξ such that $\xi(\omega) \in E(\omega)$ almost surely. The following notion of the "boundedness from below" of a random vector was given by [9].

DEFINITION 2.2. *Given a random vector $\theta \in \mathbb{L}^0((0,\infty)^d)$, a random vector $(G,H) \in \mathbb{L}^0(\mathbb{R}) \times \mathbb{L}^0(\mathbb{R}^d)$ is said to be* $K(\theta)$-bounded from below *if there exists a constant $\kappa \geq 0$ such that*

$$(G,H) + \kappa(1,\mathbf{1}) \in \mathbb{L}^0(K(\theta)). \tag{2.5}$$

We denote by $\mathbb{L}^0_{b,\theta}$ the set of all random vectors $(G,H) \in \mathbb{L}^0(\mathbb{R}) \times \mathbb{L}^0(\mathbb{R}^d)$ that are $K(\theta)$-bounded from below.

In this paper, we do not make any restriction on the trading strategy except for a mild boundedness-from-below condition. In particular, the portfolio-holdings vector $(X^A(t), A(t))$ may go out of the solvency region $K(S(t))$. The dissertation [11] discussed the case where the *nonbankruptcy* condition "$(X^A(t), A(t)) \in K(S(t))$ $\forall t \in [0,T]$" is imposed.

DEFINITION 2.3. *A trading strategy A is said to be* admissible *if the random vector $(X^A(t), A(t))$ is $K(S(t))$-bounded from below uniformly in t, in the sense that there exists a constant $\kappa \geq 0$ with the property*

$$(X^A(t), A(t)) + \kappa(1,\mathbf{1}) \in K(S(t)) \quad a.s. \tag{2.6}$$

for every $t \in [0,T]$. We denote by $\mathscr{A}$ the set of all admissible trading strategies.

A *contingent claim* is simply a random vector $(G,H)\in\mathbb{L}^0_{b,S(T)}$. Here the random variable G (respectively, H_i) denotes the amount of money (respectively, the number-of-shares of the ith risky asset) that the claim holder receives at time T. Similarly, an *initial-holdings vector* is simply a vector $(x,y)\in\mathbb{R}\times\mathbb{R}^d$, where x denotes the initial amount of money held and y_i the initial number-of-shares of the ith risky asset held.

DEFINITION 2.4. *Let (x,y) be an initial-holdings vector. A contingent claim (G,H) is said to be* hedgeable *with (x,y) if there exists an admissible trading strategy A such that*

$$(x+X^A(T)-G,\,y+A(T)-H)\in\mathbb{L}^0(K(S(T))). \tag{2.7}$$

We denote by $\mathscr{C}_{x,y}$ the set of all contingent claims that are hedgeable with (x,y).

It is easy to see that the set $\mathscr{C}_{x,y}$ is convex and $K(S(T))$-solid in $\mathbb{L}^0_{b,S(T)}$; that is, we have $\big(\mathscr{C}_{x,y}-\mathbb{L}^0(K(S(T)))\big)\cap\mathbb{L}^0_{b,S(T)}\subseteq\mathscr{C}_{x,y}$. We make the following assumption about the set $\mathscr{C}_{x,y}$.

Assumption 2.5. The set $\mathscr{C}_{x,y}$ is $K(S(T))$-Fatou closed; that is, if $\{(G^n,H^n)\}_{n\in\mathbb{N}}$ is a sequence in $\mathscr{C}_{x,y}$ such that $(G^n,H^n)+\kappa(1,\mathbf{1})\in\mathbb{L}^0(K(S(T)))\ \forall n\in\mathbb{N}$ and if $(G^n,H^n)\to(G,H)\in\mathbb{L}^0_{b,S(T)}$ $(n\to\infty)$ almost surely, then we have $(G,H)\in\mathscr{C}_{x,y}$.

Note that since $\mathscr{C}_{x,y}=(x,y)+\mathscr{C}_{0,0}$, $K(S(T))$-Fatou closedness of $\mathscr{C}_{\bar{x},\bar{y}}$ for some $(\bar{x},\bar{y})$ implies that of $\mathscr{C}_{x,y}$ $\forall(x,y)$. The following theorem of [9] gives a sufficient condition for $\mathscr{C}_{x,y}$ to be $K(S(T))$-Fatou closed; see also Lemma 3.5 of [10] for a more general result.

THEOREM 2.6 (Kabanov–Last [9]). *If the asset price process S is a continuous semimartingale and if there exists an equivalent martingale measure for S, then the set $\mathscr{C}_{x,y}$ is $K(S(T))$-Fatou closed.*

Let $(x,y)\in(0,\infty)\times(0,\infty)^d$ be a "positive" initial-holdings vector. For such (x,y), we consider the set $\mathscr{D}_{x,y}$, given by

$$\mathscr{D}_{x,y}\triangleq\Big\{(\Gamma,\Phi)\in\mathbb{L}^0(K^*(S(T)))\;\Big|\;\mathbb{E}[\Gamma G+\Phi\cdot H]\le 1\quad\forall(G,H)\in\mathscr{C}_{x,y}\cap\mathbb{L}^0(K(S(T)))\Big\}. \tag{2.8}$$

It is easy to see that the set $\mathscr{D}_{x,y}$ is convex, bounded in $\mathbb{L}^1(\mathbb{R})\times\mathbb{L}^1(\mathbb{R}^d)$, and closed in almost-sure convergence. Furthermore, if the set $\mathscr{C}_{x,y}$ is $K(S(T))$-Fatou closed, then by using the results of [9], especially Theorem 4.1, we can prove the next lemma, for which we leave the proof to the readers. Again, we should keep in mind that our model is related to that of [9] via (2.2) and the so-called hat operator. Note also that the key Lemma 3.1 of [9] does not involve the stochastic integral with respect to S and thus is still valid without semimartingality of S.

LEMMA 2.7. *Let Assumption* 2.5 *hold, and let $(x,y)\in(0,\infty)\times(0,\infty)^d$. If $(G,H)\in\mathbb{L}^0_{b,S(T)}$ satisfies*

$$\mathbb{E}[\Gamma G+\Phi\cdot H]\le 1\quad\forall(\Gamma,\Phi)\in\mathscr{D}_{x,y}, \tag{2.9}$$

then $(G,H)\in\mathscr{C}_{x,y}$.

3. The partial hedging problem. We fix a contingent claim $(G,H)\in\mathbb{L}_{b,S(T)}$ and consider a financial institute which will issue this contingent claim (G,H). The financial institute, which is thus going to face a random obligation (G,H) at time T, may allocate some initial-holdings vector $(x,y)\in\mathbb{R}\times\mathbb{R}^d$ and wants to minimize

the expected shortfall at time T. Here, the shortfall is defined to be the amount of additional money that is necessary for the financial institute to pay the full amount of the obligation. In other words, if the financial institute chooses a trading strategy A, the shortfall will be

$$\ell\big(S(T), x + X^A(T) - G, y + A(T) - H\big)^-.$$

The optimal value of the expected-shortfall minimization problem is then given by

$$V_{x,y} \triangleq \inf_{A\in\mathscr{A}} \mathbb{E}\Big[\ell\big(S(T), x + X^A(T) - G, y + A(T) - H\big)^-\Big]. \tag{3.1}$$

As a matter of fact, the following lemma implies that minimizing the expected shortfall is equivalent to minimizing the expected value of a weighted sum of the shortfall in each asset.

LEMMA 3.1. *The optimal value $V_{x,y}$ given by* (3.1) *can also be written as*

$$V_{x,y} = \inf_{A\in\mathscr{A}} \mathbb{E}\Big[\big(G - x - X^A(T)\big)^+ + \sum_{i=1}^d (1+\lambda_i) S_i(T)\big(H_i - y_i - A_i(T)\big)^+\Big]. \tag{3.2}$$

Proof. Denote the right-hand side of (3.1) (respectively, (3.2)) by $V^1_{x,y}$ (respectively, $V^2_{x,y}$). Then, by comparing the random variables inside the expectations, we may easily see that $V^1_{x,y} \le V^2_{x,y}$. To see the reverse, for given $A \in \mathscr{A}$, let

$$\rho \triangleq \min\Big\{k \ge 1 \;\Big|\; x - X^A(T-) - G + \sum_{i=1}^d S_i(T)(1-\mu_i)\big(y_i + A_i(T-) - H_i\big)^+ < \sum_{i=1}^k S_i(T)(1+\lambda_i)\big(y_i + A_i(T-) - H_i\big)^-\Big\}$$

on the set $B \triangleq \{\omega \in \Omega \mid \ell\big(S(T), x + X^A(T-) - G, y + A(T-) - H\big) < 0\}$, and define the process $\tilde{A}(\cdot)$ by setting $\tilde{A}(t) \triangleq A(t)$ for $t \in [0, T)$,

$$\tilde{A}_i(T) \triangleq \begin{cases} H_i - y_i & \text{if } 1 \le i \le \rho - 1, \\ A_\rho(T-) + \frac{1}{(1+\lambda_\rho)S_\rho(T)}\Big\{x + X^A(T-) - G \\ \quad + \sum_{j=1}^d S_j(T)(1-\mu_j)\big(y_j + A_j(T-) - H_j\big)^+ \\ \quad - \sum_{j=1}^{\rho-1} S_j(T)(1+\lambda_j)\big(y_j + A_j(T-) - H_j\big)^-\Big\} & \text{if } i = \rho, \\ A_i(T-) - \big(y_i + A_i(T-) - H_i\big)^+ & \text{otherwise,} \end{cases}$$

on B and $\tilde{A}_i(T) \triangleq H_i - y_i$ for $i = 1, \dots, d$ on B^c. Then it is easy to check that $\tilde{A} \in \mathscr{A}$ and

$$\big(G - x - X^{\tilde{A}}(T)\big)^+ + \sum_{i=1}^d S_i(T)(1+\lambda_i)\big(H_i - y_i - \tilde{A}_i(T)\big)^+ = \ell\big(S(T), x + X^A(T-) - G, y + A(T-) - H\big)^-.$$

Since we easily see that the right-hand side is dominated by $\ell\big(S(T), x + X^A(T) - G, y + A(T) - H\big)^-$, we obtain $V^2_{x,y} \le V^1_{x,y}$. This completes the proof. ∎

In what follows, we shall work on the optimization problem (3.2), which is equivalent to (3.1) by Lemma 3.1 above. For the contingent claim $(G,H)\in\mathbb{L}_{b,S(T)}$ in consideration, we make the following assumptions.

Assumption 3.2. The contingent claim $(G,H)\in\mathbb{L}_{b,S(T)}$ satisfies

$$\mathbb{E}\Big[|G|+\sum_{i=1}^{d}S_i(T)|H_i|\Big]<\infty \quad \text{and} \tag{3.3a}$$

$$\sup_{(\Gamma,\Phi)\in\mathscr{D}_{1,\mathbf{1}}}\mathbb{E}[\Gamma G+\Phi\cdot H]<\infty. \tag{3.3b}$$

It is easy to see that

$$V_{x,y}=\inf_{(\xi,\eta)\in\mathscr{C}_{x,y}}\mathbb{E}\Big[(G-\xi)^+ +\sum_{i=1}^{d}(1+\lambda_i)S_i(T)(H_i-\eta_i)^+\Big], \tag{3.4}$$

which is finite by (3.3a) since $(x,y)\in\mathscr{C}_{x,y}$. We can also see that if there exists $(\hat{\xi},\hat{\eta})\in\mathscr{C}_{x,y}$ that attains the infimum in (3.4), then any trading strategy $A\in\mathscr{A}$ satisfying $(X^A(T)-\hat{\xi},A(T)-\hat{\eta})\in\mathbb{L}^0(K(S(T)))$, which will exist, will be optimal for the original optimization problem (3.2).

In what follows, we fix some "positive" initial-holdings vector $(x,y)\in(0,\infty)\times(0,\infty)^d$. Notice, however, that we do not lose generality by this positivity restriction since we may always translate the contingent claim (G,H) by $(x-1,y-\mathbf{1})$. In particular, the conditions in Assumption 3.2 are not affected by this translation. Notice also that from (3.3b) and the $\mathbb{L}^1$-boundedness of the set $\mathscr{D}_{x,y}$, we have

$$\alpha_{x,y}(G,H)\triangleq\sup_{(\Gamma,\Phi)\in\mathscr{D}_{x,y}}\mathbb{E}[\Gamma G+\Phi\cdot H]<\infty. \tag{3.5}$$

We now define the *optimal value function* $V_{x,y}(\cdot)$ by

$$V_{x,y}(\alpha)\triangleq V_{\alpha x,\alpha y},\quad 0<\alpha<\alpha_{x,y}(G,H). \tag{3.6}$$

Noting that $\mathscr{C}_{\alpha x,\alpha y}=\alpha\mathscr{C}_{x,y}$, we see

(3.7)

$$V_{x,y}(\alpha)=\inf_{(\xi,\eta)\in\mathscr{C}_{x,y}}\mathbb{E}\Big[(G-\alpha\xi)^+ +\sum_{i=1}^{d}(1+\lambda_i)S_i(T)(H_i-\alpha\eta_i)^+\Big]\quad\forall 0<\alpha<\alpha_{x,y}(G,H).$$

We adopt the convex-duality approach to solve the optimization problem (3.7). As a conjugate of the objective function, we consider the function $\tilde{R}(\cdot,\cdot;\omega)\colon\mathbb{R}\times\mathbb{R}^d\to$

$[-\infty,\infty)$ given by

(3.8)
$$\begin{aligned}
&\tilde{R}(z,w;\omega)\\
&\triangleq \inf_{(u,v)\in\mathbb{R}\times\mathbb{R}^d}\Big[\big(G(\omega)-u\big)^+ + \sum_{i=1}^d (1+\lambda_i)S_i(T,\omega)\big(H_i(\omega)-v_i\big)^+ + zu + w\cdot v\Big]\\
&= \inf_{u\in\mathbb{R}}\Big[\big(G(\omega)-u\big)^+ + zu\Big]\\
&\qquad + \sum_{i=1}^d (1+\lambda_i)S_i(T,\omega)\inf_{v_i\in\mathbb{R}}\left[\big(H_i(\omega)-v_i\big)^+ + \frac{w_i}{(1+\lambda_i)S_i(T,\omega)}v_i\right]\\
&= \left\{\begin{array}{ll} zG(\omega)+w\cdot H(\omega) & \text{if } 0\le z\le 1 \text{ and } 0\le w_i\le (1+\lambda_i)S_i(T,\omega)\\ & \forall i=1,\dots d,\\ -\infty & \text{otherwise}\end{array}\right\}.
\end{aligned}$$

Here, the infimum in the second line are attained at

$$\begin{array}{ll} u\in[G(\omega),\infty) & \text{if}\quad z=0,\\ u=G(\omega) & \text{if}\quad 0<z<1,\\ u\in(-\infty,G(\omega)] & \text{if}\quad z=1\end{array}\tag{3.9}$$

and

$$\begin{array}{ll} v_i\in[H_i(\omega),\infty) & \text{if}\quad w_i=0,\\ v_i=H_i(\omega) & \text{if}\quad 0<w_i<(1+\lambda_i)S_i(T),\\ v_i\in(-\infty,H_i(\omega)] & \text{if}\quad w_i=(1+\lambda_i)S_i(T),\end{array}\tag{3.10}$$

respectively.

Now, alongside the space $\mathscr{C}_{x,y}(\alpha)\triangleq\alpha\mathscr{C}_{x,y}$, where $\alpha>0$, we shall define the space $\mathscr{D}_{x,y}(\beta)\triangleq\beta\mathscr{D}_{x,y}$ for each $\beta>0$. Then, for given $(\xi,\eta)\in\mathbb{L}^0_{b,S(T)}$, we have $(\xi,\eta)\in\mathscr{C}_{x,y}(\alpha)$ and

(3.11)
$$\begin{aligned}
\mathbb{E}\Big[\big(G-\xi\big)^+ + \sum_{i=1}^d (1+\lambda_i)S_i(T)\big(H_i-\eta_i\big)^+\Big] &\ge \mathbb{E}[\tilde{R}(\beta\Gamma,\beta\Phi)] - \beta\mathbb{E}[\Gamma\xi+\Phi\cdot\eta]\\
&\ge \mathbb{E}[\tilde{R}(\beta\Gamma,\beta\Phi)] - \beta\alpha,
\end{aligned}$$

provided that

$$\mathbb{E}[\xi\Gamma+\eta\cdot\Phi]\le\alpha\quad\forall(\Gamma,\Phi)\in\mathscr{D}_{x,y}.\tag{3.12}$$

Moreover, the inequalities in (3.11) hold as an equality if and only if we have

$$\begin{aligned}
&0\le\beta\Gamma\le 1,\\
&0\le\beta\Phi_i\le(1+\lambda_i)S_i(T)\quad\forall i=1,\dots,d,
\end{aligned}\tag{3.13a}$$

$$\begin{aligned}
&\xi = G1_{\{0<\beta\Gamma<1\}} + U1_{\{\beta\Gamma=0 \text{ or } \beta\Gamma=1\}},\\
&\eta_i = H_i1_{\{0<\beta\Phi_i<(1+\lambda_i)S_i(T)\}} + V_i1_{\{\beta\Phi_i=0 \text{ or } \beta\Phi_i=(1+\lambda_i)S_i(T)\}}\quad\forall i=1,\dots,d
\end{aligned}\tag{3.13b}$$

almost surely, and

$$\mathbb{E}[\Gamma\xi + \Phi\cdot\eta] = \alpha, \tag{3.13c}$$

where U and V_i are any random variables satisfying

$$\begin{array}{c} \left\{ \begin{array}{lll} U \geq G & \text{on} & \{\beta\Gamma = 0\}, \\ U \leq G & \text{on} & \{\beta\Gamma = 1\}, \end{array} \right\} \quad \text{and} \\ \left\{ \begin{array}{lll} V_i \geq H_i & \text{on} & \{\beta\Phi_i = 0\}, \\ V_i \leq H_i & \text{on} & \{\beta\Phi_i = (1+\lambda_i)S_i(T)\} \end{array} \right\} \quad \forall i = 1,\dots,d \end{array} \tag{3.13d}$$

almost surely. For each $\beta > 0$, the dual optimization problem is given by

$$\tilde{V}_{x,y}(\beta) \triangleq \sup_{(\Gamma,\Phi)\in\mathscr{D}_{x,y}} \mathbb{E}[\tilde{R}(\beta\Gamma, \beta\Phi)]. \tag{3.14}$$

Our main theorem is the following.

MAIN THEOREM. *Let $(G,H) \in \mathbb{L}^0_{b,S(T)}$ be a contingent claim satisfying the conditions in Assumption* 3.2*, and let $(x,y) \in (0,\infty)\times(0,\infty)^d$ be a positive initial-holdings vector. Then we have the following:*

(i) *For each $\beta > 0$, there exists a random vector $(\hat{\Gamma},\hat{\Phi}) \equiv (\hat{\Gamma}(\beta),\hat{\Phi}(\beta)) \in \mathscr{D}_{x,y}$ that attains the supremum in* (3.14)*. Such $(\hat{\Gamma},\hat{\Phi})$ necessarily satisfies* (3.13a) *as well.*

(ii) *For each $0 < \alpha < \alpha_{x,y}(G,H)$, there exists a number $\hat{\beta} > 0$ that attains the supremum*

$$\sup_{\beta>0}\Big[\tilde{V}_{x,y}(\beta) - \beta\alpha\Big]. \tag{3.15}$$

(iii) *The functions $V_{x,y}(\cdot)$ and $\tilde{V}_{x,y}(\cdot)$ are conjugate of each other; that is, we have*

$$\begin{aligned} V_{x,y}(\alpha) &= \sup_{\beta>0}\Big[\tilde{V}_{x,y}(\beta) - \beta\alpha\Big] \quad \forall 0 < \alpha < \alpha_{x,y}(G,H), \\ \tilde{V}_{x,y}(\beta) &= \inf_{0<\alpha<\alpha_{x,y}(G,H)}\Big[V_{x,y}(\alpha) + \alpha\beta\Big] \quad \forall \beta > 0. \end{aligned} \tag{3.16}$$

(iv) *For each $0 < \alpha < \alpha_{x,y}(G,H)$, there exists a random vector $(U,V) \in \mathbb{L}^0(\mathbb{R})\times\mathbb{L}^0(\mathbb{R}^d)$ satisfying* (3.13d) *almost surely such that the random vector $(\hat{\xi},\hat{\eta})$ given by the right-hand side of* (3.13b) *with $\beta \equiv \hat{\beta}$ and $(\Gamma,\Phi) \equiv (\hat{\Gamma},\hat{\Phi})$ satisfies* (3.13c) *as well and thereby attains the infimum in* (3.7)*.*

4. Proof of main theorem. We shall give our proof of the main theorem in the form of a series of lemmas. The results in this section are generalization of those of [3] to the case of a vector-valued contingent claim.

LEMMA 4.1. *For each $\beta > 0$ there exists a random vector $(\hat{\Gamma},\hat{\Phi}) \equiv (\hat{\Gamma}(\beta),\hat{\Phi}(\beta)) \in \mathscr{D}_{x,y}$ that attains the supremum in* (3.14)*. Moreover, such $(\hat{\Gamma},\hat{\Phi})$ necessarily satisfies* (3.13a) *as well.*

Proof. First of all, note that since $(0,0) \in \mathscr{D}_{x,y}$, we have $\tilde{V}_{x,y}(\beta) \geq \mathbb{E}[\tilde{R}(0,0)] = 0 > -\infty$. This, in particular, gives the second assertion of the lemma. Also, from (3.5) and the last equality of (3.8), we see $\tilde{V}_{x,y}(\beta) \leq \beta\alpha_{x,y}(G,H) < \infty$.

To see the existence of a maximizer $(\hat{\Gamma},\hat{\Phi})$, take a sequence $\{(\Gamma^n,\Phi^n)\}_{n=1}^{\infty} \subseteq \mathscr{D}_{x,y}$ such that $\lim_{n\to\infty} \uparrow \mathbb{E}[\tilde{R}(\beta\Gamma^n,\beta\Phi^n)] = \tilde{V}_{x,y}(\beta)$. Then, from the L^1-boundedness of

the set $\mathscr{D}_{x,y}$ and Komlós's theorem, we may take a subsequence $\{(\Gamma^{n_k}, \Phi^{n_k})\}_{k=1}^{\infty}$ of $\{(\Gamma^n, \Phi^n)\}_{n=1}^{\infty}$ such that the sequence $\{(\Theta^k, \Psi^k)\}_{k=1}^{\infty}$ defined by

$$(\Theta^k, \Psi^k) \triangleq \frac{1}{k}\sum_{i=1}^{k}(\Gamma^{n_i}, \Phi^{n_i}), \quad k \geq 1,$$

converges, almost surely, to some random vector $(\hat{\Gamma}, \hat{\Phi}) \in \mathbb{L}^0(\mathbb{R}_+) \times \mathbb{L}^0(\mathbb{R}_+^d)$; see, for example, [12]. By the convexity and closedness in almost-sure convergence of $\mathscr{D}_{x,y}$, we have $(\Theta^k, \Psi^k) \in \mathscr{D}_{x,y}$, $\forall k \in \mathbb{N}$, and $(\hat{\Gamma}, \hat{\Phi}) \in \mathscr{D}_{x,y}$. Then the concavity of the functional $(\Gamma, \Phi) \mapsto \mathbb{E}[\tilde{R}(\beta\Gamma, \beta\Phi)]$ implies

$$\tilde{V}_{x,y}(\beta) \geq \mathbb{E}[\tilde{R}(\beta\Theta^k, \beta\Psi^k)] \geq \frac{1}{k}\sum_{i=1}^{k}\mathbb{E}[\tilde{R}(\beta\Gamma^{n_i}, \beta\Phi^{n_i})] \quad \forall k \in \mathbb{N}. \tag{4.1}$$

Let $k \to \infty$. Then, being the Cesàro average of the set of numbers $\{\mathbb{E}[\tilde{R}(\beta\Gamma^{n_i}, \beta\Phi^{n_i})]\}_{i=1}^{k}$, the right-hand side of (4.1) converges to $\tilde{V}_{x,y}(\beta)$, which implies that $\lim_{k\to\infty}\mathbb{E}[\tilde{R}(\beta\Theta^k, \beta\Psi^k)] = \tilde{V}_{x,y}(\beta)$.

Finally, from the inequalities (3.3a) and (3.13a) and from the last equality of (3.8), we see $|\tilde{R}(\beta\Gamma^k, \beta\Phi^k)| \leq C|G + S(T)\cdot H|$ for large $k \in \mathbb{N}$ with some suitable constant $C > 0$, and then, from the dominated convergence theorem, $\mathbb{E}[\tilde{R}(\beta\hat{\Gamma}, \beta\hat{\Phi})] = \lim_{k\to\infty}\mathbb{E}[\tilde{R}(\beta\Theta^k, \beta\Psi^k)]$. Therefore, $\tilde{V}_{x,y}(\beta) = \mathbb{E}[\tilde{R}(\beta\hat{\Gamma}, \beta\hat{\Phi})]$. □

For each $\alpha \in (0, \alpha_{x,y}(G,H))$, put

$$\psi_{x,y}(\beta;\alpha) \triangleq \tilde{V}_{x,y}(\beta) - \beta\alpha, \quad \beta > 0. \tag{4.2}$$

LEMMA 4.2. *Let $\alpha \in (0, \alpha_{x,y}(G,H))$. Then the function $\psi_{x,y}(\cdot;\alpha)$, defined by (4.2), is continuous and concave on $(0,\infty)$ and satisfies*

$$\lim_{\beta\to 0}\frac{\psi_{x,y}(\beta;\alpha)}{\beta} = \alpha_{x,y}(G,H) - \alpha > 0, \tag{4.3}$$

as well as

$$\lim_{\beta\to\infty}\frac{\psi_{x,y}(\beta;\alpha)}{\beta} = -\alpha. \tag{4.4}$$

Proof. The concavity of $\psi_{x,y}(\cdot\,;\alpha)$ follows from that of the function $\tilde{R}(\cdot,\cdot)$ and from the fact $k\beta_1\mathscr{D}_{x,y} + (1-k)\beta_2\mathscr{D}_{x,y} \subseteq (k\beta_1 + (1-k)\beta_2)\mathscr{D}_{x,y}$ $\forall 0 \leq k \leq 1$ and $\forall \beta_1, \beta_2 > 0$.

To prove the continuity of $\psi_{x,y}(\cdot\,;\alpha)$, it suffices to prove that $\lim_{\beta\downarrow 0}\tilde{V}_{x,y}(\beta) = 0$. To prove this equation, notice that since $(\hat{\Gamma}, \hat{\Phi})$ satisfies (3.13a), we have $\tilde{V}_{x,y}(\beta) \geq 0$ $\forall \beta > 0$. This, together with the fact that $\tilde{V}_{x,y}(\beta) \leq \beta\alpha_{x,y}(G,H)$ and $\alpha_{x,y}(G,H) < \infty$, gives $\lim_{\beta\downarrow 0}\tilde{V}_{x,y}(\beta) = 0$.

Next, we prove (4.3). Since

$$\frac{\tilde{V}_{x,y}(\beta)}{\beta} = \sup_{(\Gamma,\Phi)\in\mathscr{D}_{x,y}}\mathbb{E}\Big[\frac{\tilde{R}(\beta\Gamma,\beta\Phi)}{\beta}\Big] \leq \sup_{(\Gamma,\Phi)\in\mathscr{D}_{x,y}}\mathbb{E}[\Gamma G + \Phi\cdot H] = \alpha_{x,y}(G,H),$$

we have

$$\overline{\lim_{\beta\downarrow 0}}\frac{\psi_{x,y}(\beta;\alpha)}{\beta} = \overline{\lim_{\beta\downarrow 0}}\frac{\tilde{V}_{x,y}(\beta)}{\beta} - \alpha \leq \alpha_{x,y}(G,H) - \alpha. \tag{4.5}$$

To show the reverse inequality for the limit inferior, we take, for each $\varepsilon > 0$, a random vector $(\Gamma^\varepsilon, \Phi^\varepsilon) \in \mathscr{D}_{x,y}$ such that

$$\mathbb{E}[\Gamma^\varepsilon G + \Phi^\varepsilon \cdot H] > \sup_{(\Gamma,\Phi)\in\mathscr{D}_{x,y}} \mathbb{E}[\Gamma G + \Phi \cdot H] - \varepsilon = \alpha_{x,y}(G,H) - \varepsilon.$$

Then, for each $\beta > 0$, we have

$$\begin{aligned}\frac{\psi_{x,y}(\beta;\alpha)}{\beta} &= \sup_{(\Gamma,\Phi)\in\mathscr{D}_{x,y}} \mathbb{E}\Big[\Gamma G 1_{\{\beta\Gamma\le 1\}} + \sum_{i=1}^d \Phi_i H_i 1_{\{\beta\Phi_i \le (1+\lambda_i)S_i(T)\}}\Big] - \alpha \\ &\ge \mathbb{E}\Big[\Gamma^\varepsilon G 1_{\{\beta\Gamma^\varepsilon\le 1\}} + \sum_{i=1}^d \Phi_i^\varepsilon H_i 1_{\{\beta\Phi_i^\varepsilon \le (1+\lambda_i)S_i(T)\}}\Big] - \alpha.\end{aligned}$$

Letting $\beta \downarrow 0$, we obtain from Fatou's lemma

$$\varliminf_{\beta\downarrow 0} \frac{\psi_{x,y}(\beta;\alpha)}{\beta} \ge \mathbb{E}[\Gamma^\varepsilon G + \Phi^\varepsilon \cdot H] - \alpha > \alpha_{x,y}(G,H) - \varepsilon - \alpha.$$

Since $\varepsilon > 0$ is arbitrary, we conclude that

$$\varliminf_{\beta\downarrow 0} \frac{\psi_{x,y}(\beta;\alpha)}{\beta} \ge \alpha_{x,y}(G,H) - \alpha. \tag{4.6}$$

In conjunction with (4.5), the inequality (4.6) now gives (4.3).

It remains to prove (4.4). Since $V_{x,y}(\alpha) \ge \psi_{x,y}(\beta;\alpha)$ and $\tilde{V}_{x,y}(\beta) \ge 0$, we have

$$\frac{V_{x,y}(\alpha)}{\beta} \ge \frac{\psi_{x,y}(\beta;\alpha)}{\beta} = \frac{\tilde{V}_{x,y}(\beta)}{\beta} - \alpha \ge -\alpha.$$

Then, since $0 \le V_{x,y}(\alpha) \le C\mathbb{E}|G + S(T)\cdot H| < \infty$ with some suitable constant $C > 0$, we may let $\beta \to \infty$ to obtain

$$0 \ge \varlimsup_{\beta\to\infty} \frac{\tilde{V}_{x,y}(\beta)}{\beta} - \alpha \ge -\alpha.$$

By letting $\alpha \downarrow 0$, we obtain

$$\lim_{\beta\to\infty} \frac{\tilde{V}_{x,y}(\beta)}{\beta} = 0.$$

It follows that

$$\lim_{\beta\to\infty} \frac{\psi_{x,y}(\beta;\alpha)}{\beta} = \lim_{\beta\to\infty} \frac{\tilde{V}_{x,y}(\beta)}{\beta} - \alpha = -\alpha.$$

This completes the proof of the lemma. □

LEMMA 4.3. *The function $\psi_{x,y}(\cdot\,;\alpha)$ attains its supremum at some $0 < \hat{\beta} < \infty$.*

Proof. Suppose that $\sup_{0<\beta<\infty} \psi_{x,y}(\beta;\alpha) = \lim_{\beta\uparrow\infty} \psi_{x,y}(\beta;\alpha) > \psi_{x,y}(\beta;\alpha)\ \forall 0 < \beta < \infty$. Then there exists a sequence $\{\beta_n\}_{n=1}^\infty \subseteq (0,\infty)$ such that $\beta_n \uparrow \infty$ and the sequence $\{\psi_{x,y}(\beta_n;\alpha)\}_{n=1}^\infty$ is increasing. However, in view of the previous lemma, in particular (4.4), this is impossible. Therefore, either the function $\psi_{x,y}(\cdot\,;\alpha)$ attains the supremum at some $\hat{\beta} > 0$, or else we have $\psi_{x,y}(\beta;\alpha) \le \psi_{x,y}(0;\alpha) = 0\ \forall \beta > 0$.

Suppose the latter is true. Then $\psi_{x,y}(\beta;\alpha)/\beta \le 0\ \forall \beta > 0$. But this is again impossible because of (4.3). Therefore the function $\psi_{x,y}(\cdot\,;\alpha)$ must attain its supremum at some $0 < \hat{\beta} < \infty$. □

We now proceed to prove the main theorem. First, (i) and (ii) have already been proved in Lemmas 4.1 and 4.3, respectively. From (3.11), we have

$$V_{x,y}(\alpha) \ge \sup_{\beta>0}\Big[\tilde{V}_{x,y}(\beta) - \beta\alpha\Big] \quad \forall 0 < \alpha < \alpha_{x,y}(G,H). \tag{4.7}$$

Once we have established (iv), the reverse inequality of (4.7) follows as well, which yields by duality the second equality of (3.16). It therefore remains to prove (iv).

We begin with defining the space $\mathbb{L}$ by

$$\mathbb{L} \triangleq \mathbb{R} \times \mathbb{L}^1(\mathbb{R}) \times \mathbb{L}^1(\mathbb{R}^d) \tag{4.8}$$

equipped with the norm

$$\|(\beta,K,L)\| \triangleq |\beta| + \mathbb{E}[|K| + |L|], \quad (\beta,K,L) \in \mathbb{L}. \tag{4.9}$$

Define also the subset $\mathscr{G}$ by

$$\mathscr{G} \triangleq \{(\beta,K,L) \in \mathbb{L} \mid \beta \ge 0,\ (K,L) \in \beta\mathscr{D}_{x,y}\}. \tag{4.10}$$

We see easily that $\mathscr{G}$ is a convex cone of $\mathbb{L}$. The set $\mathscr{G}$ is also closed in the norm topology of $\mathbb{L}$. To see this, let $\{(\beta^n,\beta^n\Gamma^n,\beta^n\Phi^n)\}_{n=1}^{\infty}$ be any sequence in $\mathscr{G}$ that converges to some $(\beta,K,L) \in \mathbb{L}$. Then we have $\lim_{n\to\infty}\beta^n = \beta$, $\lim_{n\to\infty}\mathbb{E}|\beta^n\Gamma^n - K| = 0$, and $\lim_{n\to\infty}\mathbb{E}|\beta^n\Phi^n - L| = 0$. If $\beta = 0$, then $\lim_{n\to\infty}\mathbb{E}|\beta^n\Gamma^n| = \lim_{n\to\infty}\beta^n\mathbb{E}|\Gamma^n| = 0$ because of the $\mathbb{L}^1$-boundedness of $\mathscr{D}_{x,y}$, and we are done. If $\beta \neq 0$, then we have

$$\begin{aligned}
\mathbb{E}\left|\Gamma^n - \frac{K}{\beta}\right| &\le \frac{1}{\beta}\Big(\mathbb{E}|\beta\Gamma^n - \beta^n\Gamma^n| + \mathbb{E}|\beta^n\Gamma^n - K|\Big) \\
&= \frac{1}{\beta}\Big(|\beta - \beta^n|\mathbb{E}|\Gamma^n| + \mathbb{E}|\beta^n\Gamma^n - K|\Big) \\
&\to 0 \quad \text{as} \quad z \to \infty,
\end{aligned}$$

again by the $\mathbb{L}^1$-boundedness of $\mathscr{D}_{x,y}$. Similarly, we can show that $\lim_{n\to\infty}\mathbb{E}|\Phi^n - L/\beta| = 0$. Take a subsequence $\{(\Gamma^{n_k},\Phi^{n_k})\}_{k=1}^{\infty}$ of $\{(\Gamma^n,\Phi^n)\}_{n=1}^{\infty}$ such that $(\Gamma^{n_k},\Phi^{n_k}) \to (K/\beta, L/\beta)$ as $k \to \infty$ almost surely. Then Fatou's lemma gives

$$\mathbb{E}\Big[\frac{K}{\beta}\xi + \frac{L}{\beta}\cdot\eta\Big] \le \varliminf_{k\to\infty}\mathbb{E}[\Gamma^{n_k}\xi + \Phi^{n_k}\cdot\eta] \le 1 \quad \forall(\xi,\eta) \in \mathscr{C}_{x,y} \cap (\mathbb{L}^0(\mathbb{R}_+) \times \mathbb{L}^0(\mathbb{R}^d_+)),$$

which implies that $(K/\beta, L/\beta) \in \mathscr{D}_{x,y}$ and hence that $(\beta,K,L) \in \mathscr{G}$.

On the space $\mathbb{L}$, we consider the functional $\tilde{J}$ given by

$$\tilde{J}(\beta,K,L) \triangleq -\mathbb{E}[\tilde{R}(K,L)] + \beta\alpha, \quad (\beta,K,L) \in \mathbb{L}, \tag{4.11}$$

where $0 < \alpha < \alpha_{x,y}(G,H)$ is a fixed constant. Then it is easy to see that the functional $\tilde{J}$ is convex and proper. From (3.3a) and the dominated convergence theorem, we can easily see that $\tilde{J}$ is lower semicontinuous under the norm topology of $\mathbb{L}$. Furthermore, from Lemmas 4.1 and 4.3, we know that $\tilde{J}$ attains the infimum over $\mathscr{G}$ at $(\hat{\beta},\hat{\beta}\hat{\Gamma},\hat{\beta}\hat{\Phi})$, which belongs to $\mathscr{G} \setminus \{(0,0,0)\}$. Therefore, from standard results on

convex optimization (for example, Corollary 4.6.3 of [1]), it follows that there exists a pair $(\hat{\gamma}, \hat{Y}, \hat{Z})$ in the dual space $\mathbb{L}^* = \mathbb{R} \times \mathbb{L}^\infty(\mathbb{R}) \times \mathbb{L}^\infty(\mathbb{R}^d)$ that satisfies

$$-(\hat{\gamma}, \hat{Y}, \hat{Z}) \in \partial \tilde{J}(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi}) \tag{4.12}$$

and

$$(\hat{\gamma}, \hat{Y}, \hat{Z}) \in N(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi}), \tag{4.13}$$

where $\partial \tilde{J}(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi})$ and $N(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi})$ are the subdifferential of $\tilde{J}$ and the normal cone of $\mathscr{G}$ at $(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi})$, respectively. These sets are given by

$$\begin{aligned} \partial \tilde{J}(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi}) \triangleq \Big\{ (\gamma, Y, Z) \in \mathbb{L}^* \;\Big|\; & \tilde{J}(\beta, K, L) \geq \tilde{J}(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi}) + (\beta - \hat{\beta})\gamma \\ & + \mathbb{E}[(K - \hat{\beta}\hat{\Gamma})Y] + \mathbb{E}[(L - \hat{\beta}\hat{\Phi}) \cdot Z] \quad \forall (\beta, K, L) \in \mathbb{L} \Big\} \end{aligned} \tag{4.14}$$

and

$$\begin{aligned} N(\hat{\beta}, \hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi}) \triangleq \Big\{ (\gamma, Y, Z) \in \mathbb{L}^* \;\Big|\; & (\beta - \hat{\beta})\gamma + \mathbb{E}[(\beta\Gamma - \hat{\beta}\hat{\Gamma})Y] \\ & + \mathbb{E}[(\beta\Phi - \hat{\beta}\hat{\Phi}) \cdot Z] \leq 0 \quad \forall (\beta, \beta\Gamma, \beta\Phi) \in \mathscr{G} \Big\}; \end{aligned} \tag{4.15}$$

see, for example, Propositions 4.4.4 and 4.3.3 of [1]. By definition, (4.12) and (4.13) are equivalent to

$$\begin{aligned} -\mathbb{E}[\tilde{R}(K, L)] + \beta\alpha \geq & -\mathbb{E}[\tilde{R}(\hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi})] + \hat{\beta}\alpha - (\beta - \hat{\beta})\hat{\gamma} \\ & - \mathbb{E}[(K - \hat{\beta}\hat{\Gamma})\hat{Y}] - \mathbb{E}[(L - \hat{\beta}\hat{\Phi}) \cdot \hat{Z}] \quad \forall (\beta, K, L) \in \mathbb{L} \end{aligned} \tag{4.16}$$

and

$$(\beta - \hat{\beta})\hat{\gamma} + \mathbb{E}[(\beta\Gamma - \hat{\beta}\hat{\Gamma})\hat{Y}] + \mathbb{E}[(\beta\Phi - \hat{\beta}\hat{\Phi}) \cdot \hat{Z}] \leq 0 \quad \forall (\beta, \beta\Gamma, \beta\Phi) \in \mathscr{G}, \tag{4.17}$$

respectively. We claim that this $(\hat{Y}, \hat{Z})$ satisfies

$$\mathbb{E}[\hat{\Gamma}\hat{Y} + \hat{\Phi}\hat{Z}] = \alpha, \tag{4.18a}$$

$$\mathbb{E}[\Gamma\hat{Y} + \Phi\hat{Z}] \leq \alpha \quad \forall (\Gamma, \Phi) \in \mathscr{D}_{x,y} \tag{4.18b}$$

and can be written as the right-hand side (3.13b) with $\beta \equiv \hat{\beta}$, $(\Gamma, \Phi) \equiv (\hat{\Gamma}, \hat{\Phi})$, and with some $(U, V) \in \mathbb{L}^0(\mathbb{R}) \times \mathbb{L}^0(\mathbb{R}^d)$ satisfying (3.13d); once these claims are established, we may conclude that $(\hat{Y}, \hat{Z})$ serves as an optimal solution to (3.7); the $K(S(T))$-boundedness from below of $(\hat{Y}, \hat{Z})$ is trivial because $(\hat{Y}, \hat{Z}) \in \mathbb{L}^\infty(\mathbb{R}) \times \mathbb{L}^\infty(\mathbb{R}^d)$.

First, by taking $(\beta, K, L) = (\beta, 0, 0)$ in (4.16), we see

$$\infty > \mathbb{E}[\tilde{R}(\hat{\beta}\hat{\Gamma}, \hat{\beta}\hat{\Phi})] - \hat{\beta}\mathbb{E}[\hat{\Gamma}\hat{Y} + \hat{\Phi} \cdot \hat{Z}] \geq -(\beta - \hat{\beta})(\alpha + \hat{\gamma}) \quad \forall \beta \in \mathbb{R},$$

which implies $\hat{\gamma} = -\alpha$; otherwise, we could make the middle-hand side arbitrarily large by letting $\beta \to \pm\infty$.

To prove (4.18a) and (4.18b), note first that since $\hat{\gamma} = -\alpha$, letting $\beta \downarrow 0$ in the inequality (4.17) and then dividing by $\hat{\beta} > 0$ yield

$$\mathbb{E}[\hat{\Gamma}\hat{Y} + \hat{\Phi}\hat{Z}] \geq \alpha.$$

The reverse inequality also follows from the inequality (4.17) with $\hat{\gamma} = -\alpha$ and $(\beta, \beta\Gamma, \beta\Phi) = (\hat{\beta} + \varepsilon, (\hat{\beta} + \varepsilon)\hat{\Gamma}, (\hat{\beta} + \varepsilon)\hat{\Phi})$ for some $\varepsilon > 0$. This establishes (4.18a). Finally, letting $\beta = \hat{\beta}$ in (4.17) and then using (4.18a), we obtain (4.18b).

It remains to show that $(\hat{Y}, \hat{Z})$ can be written as the right-hand side (3.13b) with $\beta \equiv \hat{\beta}$, $(\Gamma, \Phi) \equiv (\hat{\Gamma}, \hat{\Phi})$, and with some $(U, V) \in \mathbb{L}^0(\mathbb{R}) \times \mathbb{L}^0(\mathbb{R}^d)$ satisfying (3.13d). For this end, we define a random vector $(A, B) \in \mathbb{L}^0(\mathbb{R}) \times \mathbb{L}^0(\mathbb{R}^d)$ by

$$\hat{Y} = G1_{\{0<\hat{\beta}\hat{\Gamma}<1\}} + A, \tag{4.19a}$$

$$\hat{Z}_i = H_i 1_{\{0<\hat{\beta}\hat{\Phi}_i<(1+\lambda_i)S_i(T)\}} + B_i, \quad i = 1, \dots, d. \tag{4.19b}$$

Then, for every $(K, L) \in \mathbb{L}^1(\mathbb{R}) \times \mathbb{L}^1(\mathbb{R}^d)$ satisfying

$$0 \le K \le 1 \quad \text{and} \quad 0 \le L_i \le (1 + \lambda_i)S_i(T) \quad \forall i = 1, \dots, d \quad \text{a.s.}, \tag{4.20}$$

the inequality (4.16) with $\hat{\gamma} = -\alpha$ gives

$$\begin{aligned} \mathbb{E}\Big[(K - \hat{\beta}\hat{\Gamma})(A - G1_{\{\hat{\beta}\hat{\Gamma}=1, \text{ or } \hat{\beta}\hat{\Gamma}=0\}}) \\ + \sum_{i=1}^{d} (B_i - H_i 1_{\{\hat{\beta}\hat{\Phi}_i=(1+\lambda_i)S_i(T) \text{ or } \hat{\beta}\hat{\Phi}_i=0\}})(L_i - \hat{\beta}\hat{\Phi}_i)\Big] \ge 0. \end{aligned} \tag{4.21}$$

Taking $L_i = \hat{\beta}\hat{\Phi}_i$ for $i = 1, \dots, d$ in (4.21), we obtain

$$\mathbb{E}\Big[(K - \hat{\beta}\hat{\Gamma})(A - G1_{\{\hat{\beta}\hat{\Gamma}=1 \text{ or } \hat{\beta}\hat{\Gamma}=0\}})\Big] \ge 0. \tag{4.22}$$

Suppose $\mathbb{P}\big(0 < \hat{\beta}\hat{\Gamma} < 1 \text{ and } A > 0\big) > 0$. Then, with $K = 1_{\{\hat{\beta}\hat{\Gamma}=1\}} + \hat{\beta}\hat{\Gamma}1_{\{\hat{\beta}\hat{\Gamma}<1 \text{ and } A\le 0\}}$, we would obtain from (4.22)

$$\mathbb{E}[-\hat{\beta}\hat{\Gamma}A1_{\{0<\hat{\beta}\hat{\Gamma}<1 \text{ and } A>0\}}] \ge 0,$$

which would be impossible because the integrand would be nonpositive almost surely and strictly negative with positive probability. Therefore, it must be that

$$A \le 0 \quad \text{on} \quad \{0 < \hat{\beta}\hat{\Gamma} < 1\}.$$

Similarly, supposing $\mathbb{P}\big(0 < \hat{\beta}\hat{\Gamma} < 1 \text{ and } A < 0\big) > 0$, we can derive a contradiction by taking $K = \hat{\beta}\hat{\Gamma} - (1 - \hat{\beta}\hat{\Gamma})1_{\{0<\hat{\beta}\hat{\Gamma}<1 \text{ and } A<0\}}$. Therefore,

$$A = 0 \quad \text{on} \quad \{0 < \hat{\beta}\hat{\Gamma} < 1\}. \tag{4.23}$$

In conjunction with (4.23), the inequality (4.22) implies

$$\mathbb{E}\Big[(K - 1)(A - G)1_{\{\hat{\beta}\hat{\Gamma}=1\}}\Big] + \mathbb{E}\Big[K(A - G)1_{\{\hat{\beta}\hat{\Gamma}=0\}}\Big] \ge 0. \tag{4.24}$$

Now, suppose $\mathbb{P}(A > G \text{ and } \hat{\beta}\hat{\Gamma} = 1) > 0$. Then there would exist $\delta > 0$ such that

$$\mathbb{E}\Big[(A - G)1_{\{A>G \text{ and } \hat{\beta}\hat{\Gamma}=1\}}\Big] > \delta,$$

and with $K = 1_{\{A\le G \text{ and } \hat{\beta}\hat{\Gamma}=1\}}$ it would follow from (4.24) that

$$\mathbb{E}\Big[-(A - G)1_{\{A>G \text{ and } \hat{\beta}\hat{\Gamma}=1\}}\Big] \ge 0,$$

a contradiction. Therefore,

$$A \leq G \quad \text{on} \quad \{\hat{\beta}\hat{\Gamma} = 1\}. \tag{4.25}$$

Finally, suppose $\mathbb{P}\big(A < G \text{ and } \hat{\beta}\hat{\Gamma} = 0\big) > 0$. Then there would exist $\delta > 0$ such that

$$\mathbb{E}\Big[(A - G)1_{\{A<G \text{ and } \hat{\beta}\hat{\Gamma}=0\}}\Big] < -\delta,$$

and with $K = 1_{\{A<G \text{ and } \hat{\beta}\hat{\Gamma}=0\}} + 1_{\{\hat{\beta}\hat{\Gamma}=1\}}$ it would follow from (4.24) that

$$\mathbb{E}\Big[(A - G)1_{\{A<G \text{ and } \hat{\beta}\hat{\Gamma}=0\}}\Big] \geq 0,$$

a contradiction. Therefore,

$$A \geq G \quad \text{on} \quad \{\hat{\beta}\hat{\Gamma} = 0\}. \tag{4.26}$$

The inequalities (4.23), (4.25), and (4.26) now imply that $\hat{Y}$ can be written as the right-hand side of the first equation of (3.13b).

Similarly, for each fixed $i = 1, \ldots, d$, we can show, by taking $K = 0$, and $L_j = 0$ for $j \neq i$ in (4.21), that $\hat{Z}_i$ can be written as the right-hand side of the second equation of (3.13b). This completes the proof.

Acknowledgment. This work is developed from part of my Ph.D. dissertation at Columbia University. I would like to express my deep gratitude to my adviser, Professor Ioannis Karatzas, for his guidance throughout my years at Columbia University.

STUDY OF THE OPTIMAL HARVESTING CONTROL AND THE OPTIMALITY SYSTEM FOR AN ELLIPTIC PROBLEM*

M. DELGADO†, J. A. MONTERO‡, AND A. SUÁREZ†

Abstract. An optimal harvesting problem with a concave nonquadratic cost functional and a diffusive degenerate elliptic logistic state equation type is investigated. Under certain assumptions, we prove the existence and uniqueness of an optimal control. A characterization of the optimal control via the optimality system is also derived, which leads to approximating the optimal control.

Key words. degenerate logistic equation, singular eigenvalue problems, optimal control, optimality system

1. Introduction. In this work we consider the optimal harvesting control of a species whose state is governed by the degenerate elliptic logistic equation; i.e.,

$$\begin{cases} -\Delta u = (a-f)u^{\alpha} - bu^{\beta} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a bounded and regular domain of $\mathbb{R}^N$, $N \geq 1$. Here a, f, and b are bounded functions. In particular, a is strictly positive, b is nonnegative and nontrivial, $a - f$ can change sign, and α and β satisfy

$$0 < \alpha < 1, \qquad \alpha < \beta. \tag{1.2}$$

The solutions of (1.1) can be regarded as the steady states solutions of the corresponding time-dependent model. In such a case, $u(x)$ stands for the population density and Ω for the inhabiting area. Since the population is subject to homogeneous Dirichlet boundary conditions, we are assuming that the environment surrounding Ω is lethal. In such a model, the positive function $b(x)$ describes the introspecific pressure of the species and $a(x)$ represents the growth rate of the species. The function $f(x)$ will be considered nonnegative and denotes the distribution of control harvesting of the species by reducing the growth rate. Equation (1.1), under the change of variables $w^m = u$, is a particular case of

$$\begin{cases} -\Delta w^m = (a-f)w - bw^2 & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.3}$$

This model was introduced in population dynamics by Gurtin and MacCamy in [11] for describing the dynamics of biological populations whose mobility depends upon their

density. In this context, $m > 1$ (nonlinear slow diffusion) means that the diffusion is slower than in the linear case $m = 1$, giving rise to more realistic biological results; see [11].

One of the main differences between the degenerate case ($m > 1$) and the nondegenerate one ($m = 1$) is that in the first case the strong maximum principle does not hold in general. So, unlike the nondegenerate case, three kinds of solutions appear: the trivial solution, the strictly positive solutions (the species can survive in the whole domain), and the nonnegative and nontrivial solutions, which are zero in a region of Ω. This region is called *dead core*.

Equation (1.1) has been studied previously for $b = 0$ in [1] and [2] and for b strictly positive in [8] and [19] and references therein. However, very little is known in the case that b can vanish in some region. In our knowledge, this problem has been analyzed only in [9] in the particular case $a - f$ equals a constant. We generalize these results and prove that there exists a maximal nonnegative solution of (1.1), which will be denoted by u_f. Moreover, when f is such that the function $a - f$ is positive, we show that (1.1) possesses a unique positive solution which is linearly asymptotically stable.

After studying in detail the state equation, our main goal is to analyze the optimal control criteria, that is, maximize the payoff functional

$$J(f) := \int_\Omega (\lambda u_f h(f) - k(f)), \tag{1.4}$$

where h and k are regular functions, and $\lambda > 0$ will be considered as a parameter. Here, J represents the difference between economic revenue measured by $\int_\Omega \lambda u_f h(f)$ and the control cost measured by $\int_\Omega k(f)$. The parameter λ describes the quotient between the price of the species and the cost of the control. This functional includes the special case (quadratic functional)

$$h(t) = t \qquad \text{and} \qquad k(t) = t^2,$$

which seems to have been introduced in population dynamics in [17] (see also [6], [15], and references therein).

We say that $f \in L^\infty_+(\Omega)$ is an optimal control if

$$J(f) = \sup_{g \in L^\infty_+(\Omega)} J(g).$$

This control problem is a generalization of the one studied in detail in [6], [17], and [18], where $\alpha = 1$, $\beta = 2$, $h(t) = t$, and $k(t) = t^2$.

In [7], the authors analyzed the case $0 < \alpha < 1 \le \beta$, b strictly positive, and the cost functional (1.4) under more restrictive monotony assumptions on functions h, k. There, the controls are restricted to the set

$$\mathcal{D} := \{f \in L^\infty_+(\Omega) : f \le a \quad \text{a.e. in } \Omega\}.$$

If $f \in \mathcal{D}$, then the maximal solution of (1.1) is strictly positive. In such a case, the existence and uniqueness of optimal control in $\mathcal{D}$ for λ sufficiently small are proved.

In this work, we assume only (1.2), b nonnegative and nontrivial, and our control space is $L^\infty_+(\Omega)$. So, u_f can have dead cores depending on the control $f \in L^\infty_+(\Omega)$ chosen. In this framework, we show that there exists an optimal control in $L^\infty_+(\Omega)$ for any $\lambda > 0$. When λ is smaller than a determined bound, we can express the optimal

control in terms of u_f and, if λ is small enough, then the optimal control is unique. In such a case, our assumptions imply that if f is an optimal control, then the dead core for u_f is empty. See [20], where a related problem is studied and where the dead core is allowed to exist.

In order to obtain the uniqueness result, we will use two different ways. First, we follow an argument described in [6] proving that the map $f \mapsto J(f)$ is Fréchet differentiable and strictly concave. The Fréchet derivability of the map $f \mapsto J(f)$ is rather more difficult than in the case $m = 1$, because it involves both linear elliptic and eigenvalue problems with potentials which blow up in a neighborhood of $\partial\Omega$. These difficulties have been solved by using results of singular eigenvalue problems from [4]; see also [12]. Second, we express the unique optimal control in terms of the solution of the optimality system, and we give an alternative proof of the uniqueness for the optimal control via the optimality system. This is an interesting point in the optimal control problems, because it allows us to approximate the optimal control by a constructive scheme which provides us with a sequence of functions converging to some special solutions of the optimality system. The uniqueness of solution of the optimality system was not considered in [17], but it was studied in [6] in the particular case $m = 1$ and the quadratic functional. Here, we present an alternative and shorter proof of the uniqueness, which can be applied to the case studied in [6]. Again, the second alternative presents another technical difficulty that must be overcome: the optimality system is a reaction-diffusion system with a singular reaction term. We present the subsupersolution method for these kinds of systems which provides us with an iterative method to approach the solution of the nonlinear system; see [5], [12] for the case of one equation.

An outline of this work is as follows: in section 2 we introduce some notations and collect some results concerning the existence and uniqueness of the principal eigenvalue and the corresponding solution for linear elliptic problems with unbounded potentials. In section 3 we study (1.1). We show the existence of a maximal nonnegative solution and, under stronger restrictions on the coefficients, the existence and uniqueness of a positive solution of (1.1). In section 4 we prove the existence of optimal control for functional J and show that for λ sufficiently small the functional J is Fréchet differentiable and strictly concave. Then, we deduce easily the uniqueness of optimal control. In the last section we characterize the optimal control. This characterization provides us with the optimality system. Finally, we prove the uniqueness of the positive solution of the optimality system and an iterative scheme based on alternating monotone sequences to approach its solution. As is remarked in recent related works (see [16], [17, Remark 4.1]), it is interesting to give conditions to guarantee the convergence of the method to the solution of the optimal control problem.

2. Preliminaries and notations. Let Ω be a bounded domain in $\mathbb{R}^N$ with a smooth boundary $\partial\Omega$. For any $f \in L^\infty(\Omega)$ we denote

$$f_M := \operatorname{ess\,sup} f, \qquad f_L := \operatorname{ess\,inf} f,$$

and define the sets

$$L^\infty_+(\Omega) := \{f \in L^\infty(\Omega) : f_L \geq 0\} \quad L^\infty_-(\Omega) := \{f \in L^\infty(\Omega) : f_M \leq 0\}.$$

Moreover, we denote $C^1_0(\overline{\Omega}) = \{u \in C^1(\overline{\Omega}) : u = 0 \quad \text{on } \partial\Omega\}$ and by P_+ its nonnegative cone, whose interior is

$$\operatorname{int}(P_+) := \{u \in C^1_0(\overline{\Omega}) : \ u > 0 \quad \text{in } \Omega,\ \partial u/\partial n < 0 \quad \text{on } \partial\Omega\},$$

where n is the outward unit normal at $\partial\Omega$.

In this section we primarily consider the singular eigenvalue problem

$$\begin{cases} -\Delta u + M(x)u = \sigma u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.1}$$

where

$$M \in L^\infty_{loc}(\Omega) \quad \text{verifying} \quad M(x)d_\Omega(x) \in L^\infty(\Omega), \tag{HM}$$

and $d_\Omega(x) := dist(x, \partial\Omega)$.

The following result, whose proof can be found in [13], shows that (2.1) is well defined in $H^1_0(\Omega)$.

LEMMA 2.1. *Let $\varphi \in W^{1,q}_0(\Omega)$ for some $1 < q < \infty$. Then there exists a constant $C > 0$ such that*

$$\left\| \frac{\varphi}{d_\Omega} \right\|_q \leq C \|\varphi\|_{W^{1,q}(\Omega)}.$$

Although (2.1) is not included in the singular eigenvalue problem studied in [4], we can do some minor changes to the proofs of Theorem 3.4 and Lemma 3.5 in [4] to conclude the existence and uniqueness of the principal eigenvalue of (2.1) and its associated eigenfunction. In the following result, we collect these results and some properties of the principal eigenvalue; see [7].

THEOREM 2.2. *Assume that M satisfies* (HM). *Then there exists a unique principal eigenvalue (i.e., a real eigenvalue with an associated positive eigenfunction $\varphi_1(-\Delta + M)$). We denote it by $\sigma_1(-\Delta + M)$. Moreover, $\varphi_1(-\Delta + M) \in W^{2,p}(\Omega)$ for all $p > 1$, and so $\varphi_1(-\Delta + M) \in \text{int}(P_+)$. Furthermore, we have the following:*

1. *Assume that M_i, $i = 1, 2$, satisfy* (HM) *and $M_1 \leq M_2$. Then*

$$\sigma_1(-\Delta + M_1) \leq \sigma_1(-\Delta + M_2).$$

2. *Assume that M_n, M, $n \in \mathbb{N}$, satisfy* (HM) *with*

$$\int_\Omega M_n \varphi^2 \to \int_\Omega M\varphi^2 \quad \text{as } n \to \infty \text{ and for all } \varphi \in H^1_0(\Omega). \tag{2.2}$$

Then,

$$\sigma_1(-\Delta + M_n) \to \sigma_1(-\Delta + M) \quad \text{as } n \to \infty.$$

In the particular case $M \equiv 0$, we denote $\sigma_1 := \sigma_1(-\Delta)$ and $\varphi_1 = \varphi_1(-\Delta)$ normalized such that $\|\varphi_1\|_\infty = 1$.

When M verifies (HM), the following strong maximum principle is satisfied.

LEMMA 2.3. *Let $u \in W^{2,p}(\Omega) \cap C^1(\overline{\Omega})$, $p > 1$, be such that $u \geq 0$ in Ω, $u \neq 0$, and*

$$(-\Delta + M)u \geq 0 \quad \text{a.e. in } \Omega, \qquad u \geq 0 \quad \text{on } \partial\Omega.$$

Then $u(x) > 0$ for all $x \in \Omega$ and $(\partial u/\partial n)(x_0) < 0$ for all $x_0 \in \partial\Omega$, where $u(x_0) = 0$.

Proof. Assume there exists $x_0 \in \Omega$ such that $u(x_0) = 0$. By hypothesis, we can take $x_1 \in \Omega$, where $u(x_1) > 0$ and a subdomain regular $\Omega_1 \subset \Omega$ such that $x_0, x_1 \in \Omega_1$. But $M \in L^\infty(\Omega_1)$, and so the strong maximum principle leads us to a contradiction.

On the other hand, applying Lemma 3.6 in [4] with $\rho(s) = s^{-1}$, we get that $(\partial u/\partial n)(x_0) < 0$ for all $x_0 \in \partial\Omega$ such that $u(x_0) = 0$. □

The following technical result will help us to prove the positivity of the principal eigenvalue.

PROPOSITION 2.4. *Assume that M satisfies* (HM) *and that there exists $\varphi \in W^{2,p}_{loc}(\Omega) \cap C^0_0(\overline{\Omega})$, $p > N$ such that $\varphi > 0$ in Ω and for all subdomain $\Omega' \subset \overline{\Omega}' \subset \Omega$ it holds $(-\Delta + M)\varphi := F$ with $F_L > 0$ in Ω'. Then, $\sigma_1(-\Delta + M) > 0$.*

Proof. From the Krein–Rutman theorem, it is well known that if $-\Delta + M$ satisfies the strong maximum principle in Ω, then $\sigma_1(-\Delta + M) > 0$. Let $v \in W^{2,p}(\Omega) \cap C^1(\overline{\Omega})$ be such that $v \neq 0$, and

$$(-\Delta + M)v \geq 0 \quad \text{in a.e. } \Omega, \qquad v \geq 0 \quad \text{on } \partial\Omega.$$

We have to prove that $v > 0$ in Ω and $\partial v/\partial n(x) < 0$ for all $x \in \partial\Omega$ such that $v(x) = 0$. For each $\epsilon > 0$ and $K > 0$, we define

$$w := v + \epsilon + \epsilon K\varphi \in C^0(\overline{\Omega}).$$

And so, for any $\epsilon > 0$, there exists $\gamma(\epsilon) > 0$ such that $w > 0$ in $\Omega_\epsilon := \{x \in \Omega : d_\Omega(x) < \gamma(\epsilon)\}$. Moreover,

$$(-\Delta + M)w \geq \epsilon(M + KF) > 0 \quad \text{a.e. in } \Omega\backslash\overline{\Omega}_\epsilon \tag{2.3}$$

for K sufficiently large. Moreover, since φ is a strict supersolution in $\Omega\backslash\overline{\Omega}_\epsilon$, we can apply Corollary 2.4 in [3] and obtain that $w > 0$ in $\Omega\backslash\overline{\Omega}_\epsilon$. Thus, we get that $w > 0$ in $\Omega\backslash\overline{\Omega}_\epsilon$. Hence, $w > 0$ in Ω for all $\epsilon > 0$, and we obtain that $v \geq 0$ in Ω. Now, it suffices to apply Lemma 2.3. □

Given M verifying (HM) and $f \in L^\infty(\Omega)$ we consider the problem

$$\begin{cases} -\Delta u + M(x)u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.4}$$

Observe that by Lemma 2.1, (2.4) is well defined in $H^1_0(\Omega)$. The following result (whose proof can be found in [7]) shows that (2.4) possesses a unique solution in $C^1_0(\overline{\Omega})$; it provides a useful estimate and properties of the solution.

THEOREM 2.5. *Assume that M satisfies* (HM) *and $\sigma_1(-\Delta + M) > 0$. Then, there exists a unique solution $u \in C^{1,\kappa}(\overline{\Omega})$ for some $\kappa \in (0,1)$ of* (2.4). *Moreover, there exists a constant $K > 0$ (independent of f) such that*

$$\|u\|_{C^{1,\kappa}(\overline{\Omega})} \leq K\|f\|_\infty. \tag{2.5}$$

Furthermore, the following properties hold:

1. *Consider $f_i \in L^\infty(\Omega)$, $i = 1, 2$, with $f_1 \leq f_2$, and let u_i, $i = 1, 2$, be the respective solutions of* (2.4). *Then, $u_1 \leq u_2$.*
2. *Assume that M_i, $i = 1, 2$, satisfy* (HM), *$\sigma_1(-\Delta + M_1) > 0$, and $M_1 \leq M_2$. Let u_i, $i = 1, 2$, be the respective solutions of* (2.4) *with $f \in L^\infty_+(\Omega)$. Then, $u_2 \leq u_1$.*

Note: Similar results to the previous ones have been obtained in [12] when $M \in C^1(\Omega)$, $Md^\gamma_\Omega \in L^\infty(\Omega)$ for $\gamma \in (0, 2)$, and the operator is not necessarily self-adjoint.

3. The state equation. Consider the equation

$$\begin{cases} -\Delta u = (a-f)u^\alpha - bu^\beta & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.1}$$

and assume that

$$\begin{gathered} 0<\alpha<1, \quad \alpha<\beta, \quad a,b\in L^\infty_+(\Omega)\backslash\{0\}, \quad f\in L^\infty(\Omega), \\ a_L>0,\ (a-f)_M>0. \end{gathered} \tag{H1}$$

Observe that if $(a-f)_M \le 0$, then, by the maximum principle, (3.1) does not possess a nonnegative and nontrivial solution. This justifies the hypothesis $(a-f)_M > 0$.

In order to study (3.1), we consider the porous medium equation

$$\begin{cases} -\Delta w = \mu w^\alpha & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.2}$$

where $\mu \in \mathbb{R}$. The following lemma holds.

LEMMA 3.1. *Assume $0<\alpha<1$. The porous medium equation* (3.2) *has a nontrivial and nonnegative solution if and only if $\mu>0$. If $\mu>0$, there exists a unique solution, denoted w_μ, which is strictly positive and $w_\mu \in C^{2,\alpha}(\overline{\Omega})$. Moreover, it verifies*

$$\epsilon_0\varphi_1 \le w_\mu \le K_0 e \quad \text{in } \Omega, \tag{3.3}$$

where e is the unique positive solution of

$$-\Delta e = 1 \quad \text{in } \Omega, \qquad e=0 \quad \text{on } \partial\Omega,$$

and $\epsilon_0^{1-\alpha} = \mu/\sigma_1$, $K_0^{1-\alpha} = \mu\|e\|_\infty^\alpha$.

The results of the existence and uniqueness of a positive solution of (3.2) are well known; see [1], for instance. Estimate (3.3) can be obtained easily by the subsupersolution method.

The following result shows that (3.1) has a maximal nonnegative solution.

THEOREM 3.2. *Assume* (H1). *There exists a unique maximal nonnegative solution u_f of* (3.1). *Moreover, by elliptic regularity $u_f \in W^{2,p}(\Omega)$, for all $p>1$, and so $u_f \in C^{1,\kappa}(\overline{\Omega})$, with $0<\kappa\le 1-N/p$. Furthermore, we have the following a priori bound:*

$$\|u_f\|_\infty \le ((a-f)_M\|e\|_\infty)^{1/(1-\alpha)}. \tag{3.4}$$

Finally, the map $f \mapsto u_f$ is nonincreasing.

Proof. Let u be a weak solution of (3.1); then by (H1) and elliptic regularity it follows that $u \in C_0^1(\overline{\Omega})$. So, there exists $K>0$ sufficiently large such that

$$u \le Ke \qquad \text{in } \Omega,$$

and the pair (u, Ke) is a subsupersolution of (3.2) with $\mu = (a-f)_M$. By the uniqueness of positive solution of (3.2) it follows that

$$u \le w_{(a-f)_M}.$$

The existence of positive a priori bounds and that $u \equiv 0$ is a solution of (3.1) imply the existence of a nonnegative maximal solution of (3.1). By (3.3) we get the bound (3.4).

Let $f_1, f_2 \in L^\infty(\Omega)$ be such that $f_1 \leq f_2$. It is clear that the pair (u_{f_2}, Ke) is a subsupersolution of (3.1) for $f = f_1$ for $K > 0$ sufficiently large. So, there exists a solution u such that $u_{f_2} \leq u \leq Ke$. The maximality of u_{f_1} completes the proof. □

Note: From (3.4) we get, for each maximal nonnegative solution of (3.1), a uniform upper bound, i.e.,

$$u_f \leq ((a-f)_M \|e\|_\infty)^{1/(1-\alpha)} \leq (a_M \|e\|_\infty)^{1/(1-\alpha)} := \mathcal{K}, \tag{3.5}$$

for any $f \in L^\infty_+(\Omega)$.

Observe that u_f would be eventually the trivial solution. The following result shows that this cannot occur in a subset of $L^\infty(\Omega)$. We define

$$\mathcal{C} := \{f \in L^\infty(\Omega) : (a-f)_L > 0\}.$$

In the following result we prove the existence and uniqueness of positive solution of (3.1) when $f \in \mathcal{C}$.

PROPOSITION 3.3. *Assume* (H1), *and let* $f \in \mathcal{C}$. *Then, there exists a unique nontrivial and nonnegative solution,* u_f, *of* (3.1). *Moreover,* u_f *is strictly positive; in fact,*

$$\epsilon_f \varphi_1 \leq u_f \quad \text{in } \Omega, \tag{3.6}$$

where ϵ_f *satisfies*

$$\epsilon_f^{1-\alpha} \sigma_1 + \epsilon_f^{\beta-\alpha} b_M = (a-f)_L. \tag{3.7}$$

Moreover, u_f *is linearly asymptotically stable, i.e.,*

$$\sigma_1(-\Delta + M_f) > 0, \tag{3.8}$$

where

$$M_f := -\alpha(a-f)u_f^{\alpha-1} + \beta b u_f^{\beta-1}. \tag{3.9}$$

Furthermore, the map $f \in \mathcal{C} \mapsto u_f$ *is continuous.*

Note: Observe that by (H1), (3.7) possesses a unique positive solution.

Proof. For the existence of solution, it is not hard to show that $(\epsilon_f \varphi_1, w_{(a-f)_M})$ is a subsupersolution of (3.1) for $\epsilon_f > 0$ defined in (3.7).

Observe that by the strong maximum principle for $f \in \mathcal{C}$, any nontrivial and nonnegative solution u of (3.1) is strictly positive; this means that $u \in int(P_+)$.

The uniqueness of positive solution follows as in Theorem 1 of [9] and the continuity of the map $f \mapsto u_f$ as in Theorem 3.3 of [7].

It remains to prove (3.8). First observe that M_f satisfies (HM). Indeed, by (3.6), there exists a positive constant C (independent of f) such that

$$C\epsilon_f d_\Omega \leq u_f \quad \text{in } \Omega. \tag{3.10}$$

Thus, since $\alpha < 1$, we have that

$$\begin{aligned} |M_f| d_\Omega &= |u_f^{\alpha-1} d_\Omega| - \alpha(a-f) + \beta b u_f^{\beta-\alpha}| \\ &\leq |C^{\alpha-1}\epsilon_f^{\alpha-1} d_\Omega^{\alpha-1} d_\Omega| - \alpha(a-f) + \beta b u_f^{\beta-\alpha}| \leq K \end{aligned}$$

for some $K > 0$. Therefore, M_f satisfies (HM), and $\sigma_1(-\Delta + M_f)$ is well defined. Observe that $u_f^\alpha \in W^{2,p}_{loc}(\Omega) \cap C^0_0(\overline{\Omega})$ for all $p > 1$, and it satisfies

$$(-\Delta + M_f)(u_f^\alpha) = \alpha(1-\alpha)u_f^{\alpha-2}|\nabla u_f|^2 + (\beta-\alpha) b u_f^{\alpha+\beta-1} > 0 \quad \text{in } \Omega,$$

and thus we can apply Proposition 2.4 and conclude that $\sigma_1(-\Delta + M_f) > 0$. □

4. Existence and uniqueness of optimal control. For $\lambda > 0$ we consider the functional $J : L^\infty_+(\Omega) \mapsto \mathbb{R}$,

$$J(g) := \int_\Omega (\lambda h(g) u_g - k(g)),$$

where $h \in C^1(\mathbb{R}^+;\mathbb{R}^+)$, $k \in C^2(\mathbb{R}^+;\mathbb{R}^+)$; $h(s) = 0$ if and only if $s = 0$, and $k(s) = 0$ if and only if $s = 0$. Function h is concave, and k is a strictly convex function satisfying $k''(s) \geq k_0 > 0$ for some k_0. Note that h', k' are Lipschitz continuous functions on a bounded set. We assume

$$\text{(H2)} \qquad \lim_{t\to 0} \frac{k(t)}{h(t)} = 0, \qquad \lim_{t\to+\infty} \frac{k(t)}{h(t)} = +\infty.$$

Observe that the particular case $h(t) = t$ and $k(t) = t^2$, studied in [6], [15], [17], and [18], is in the setting of our functional. Also, we remove some hypotheses of monotonous type involving functions k and h considered in [7]. The idea will be to show that the integrand of functional $J(f)$ must be positive if f is an optimal control.

In the first part of this section we want to prove the existence of the optimal control under hypothesis (H2). First, we prove that the optimal controls are bounded.

LEMMA 4.1. *Assume* (H2). *If $f \in L^\infty_+(\Omega)$ is an optimal control, then*

$$\lambda u_f(x) h(f(x)) \geq k(f(x)) \text{ a.e. in } \Omega. \tag{4.1}$$

Moreover, if $f \in L^\infty_+(\Omega)$ is an optimal control, then

$$0 \leq f \leq T_\lambda,$$

where

$$T_\lambda := \sup\left\{ t \in \mathbb{R}^+ : \frac{k(t)}{h(t)} = \lambda \mathcal{K} \right\},$$

and $\mathcal{K}$ is the uniform bound defined in (3.5).

Note: By the hypotheses imposed on h and k and (H2), it follows that $T_\lambda > 0$ and that $T_\lambda \to 0$ as $\lambda \downarrow 0$.

Proof. Suppose that $f \in L^\infty_+(\Omega)$ is an optimal control and (4.1) is not true. Then, there exists $\Omega_1 \subset \Omega$ with $|\Omega_1| > 0$ (positive measure) such that

$$\lambda u_f(x) h(f(x)) < k(f(x)) \quad \forall x \in \Omega_1. \tag{4.2}$$

Now, by defining a new control $\overline{f}$ as

$$\overline{f}(x) = \begin{cases} f(x) & \text{if } x \in \Omega \setminus \Omega_1, \\ 0 & \text{if } x \in \Omega_1, \end{cases}$$

and taking into account that $u_{\overline{f}} \geq u_f$ in Ω, we obtain

$$\begin{aligned} J(f) = & \int_{\Omega_1} \lambda u_f(x) h(f(x)) - k(f(x)) + \int_{\Omega\setminus\Omega_1} \lambda u_f(x) h(f(x)) - k(f(x)) \\ < & \int_{\Omega\setminus\Omega_1} \lambda u_f(x) h(f(x)) - k(f(x)) \leq \int_{\Omega\setminus\Omega_1} \lambda u_{\overline{f}}(x) h(f(x)) - k(f(x)) \\ = & \int_{\Omega\setminus\Omega_1} \lambda u_{\overline{f}}(x) h(\overline{f}(x)) - k(\overline{f}(x)) = J(\overline{f}). \end{aligned}$$

But f is an optimal control. So, previous inequality shows that (4.2) is absurd. It also shows that $f \leq T_\lambda$ follows from the definition of T_λ, Theorem 3.2, and (4.1). □

THEOREM 4.2. *Assume* (H2). *There exists an optimal control; i.e.,* $f \in L^\infty_+(\Omega)$ *such that*

$$J(f) = \sup_{g \in L^\infty_+(\Omega)} J(g).$$

Moreover, the benefit is positive, i.e., $\sup_{g \in L^\infty_+(\Omega)} J(g) > 0$.

Proof. By (3.5) and Lemma 4.1, it follows that

$$s := \sup_{g \in L^\infty_+(\Omega)} J(g) < +\infty,$$

and so there exists a maximizing sequence $f_n \in L^\infty_+(\Omega)$. By similar reasoning to that used in the previous lemma, we can suppose that $0 \leq f_n \leq T_\lambda$. Then, there exists a subsequence, relabelled by f_n, such that

$$f_n \rightharpoonup f \in [0, T_\lambda] \quad \text{in } L^2(\Omega).$$

By (3.5), we can prove that

$$u_{f_n} \to u_* \quad \text{in } H^1_0(\Omega), \tag{4.3}$$

where u_* is a positive solution of (3.1) (possibly not the maximal positive solution). In any case, we have $u_f \geq u_*$.

Now, taking into account the concavity of the functions h and $-k$, it follows that

$$J(f) \geq \limsup \int_\Omega \lambda h(f_n) u_{f_n} - k(f_n) = s,$$

and so we have the existence of an optimal control.

The optimal benefit is positive by following an argument like that used in [7]. In fact, it is clear, from the asymptotic properties of the functions h and k, that $J(\epsilon) > 0$ by taking $\epsilon \in \mathbb{R}^+$ small enough. □

Now, we are going to prove that, for λ sufficiently small, there exists a unique optimal control. For that we will use the argument described in section 6 in [6]. In summary, by Lemma 4.1 we know that the optimal controls belong to a convex, $[0, T_\lambda]$. Moreover, we will show that J is Fréchet continuously differentiable and strictly concave in $[0, T_\lambda]$. Hence, the uniqueness of optimal control is a direct consequence. The first step is the following result, which provides us with the Gâteaux derivative of the map $f \in \mathcal{C} \mapsto u_f \in \text{int}(P_+)$. Its proof is similar to Lemma 3.5 in [7], and so we omit it.

LEMMA 4.3. *Let* $f \in \mathcal{C}$, $g \in L^\infty(\Omega)$, *and* $\epsilon \simeq 0$ *be such that* $f + \epsilon g \in \mathcal{C}$. *Then,*

$$\frac{u_{f+\epsilon g} - u_f}{\epsilon} \rightharpoonup \xi_{f,g} \quad \text{in } H^1_0(\Omega) \text{ as } \epsilon \to 0,$$

where $\xi_{f,g}$ *is the unique solution of*

$$\begin{cases} -\Delta \xi + M_f(x)\xi = -g u_f^\alpha & \text{in } \Omega, \\ \xi = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.4}$$

Observe that (4.4) has a unique solution because $\sigma_1(-\Delta + M_f) > 0$ (see (3.8)) and Theorem 2.5.

Now, we can prove the following proposition (see Proposition 4.4 in [7]).

PROPOSITION 4.4. *Let $J : \mathcal{C} \subset L^\infty(\Omega) \mapsto \mathbb{R}$ be. Then J is Fréchet continuously differentiable and*

$$J'(f)(g) = \int_\Omega (\lambda h'(f)u_f - \lambda u_f^\alpha P_f - k'(f))g \quad \forall f \in \mathcal{C}\ \forall g \in L^\infty(\Omega), \tag{4.5}$$

where for any $f \in \mathcal{C}$, $P_f \in C_0^1(\overline{\Omega})$ is the unique solution of

$$\begin{cases} -\Delta P_f + M_f(x)P_f = h(f) & \text{in } \Omega, \\ P_f = 0 & \text{on } \partial\Omega, \end{cases} \tag{4.6}$$

and M_f is defined in (3.9).

Note: Since M_f satisfies (HM) and by (3.8), it follows from Theorem 2.5 that the existence and uniqueness of $P_f \in C_0^1(\overline{\Omega})$.

Observe that by the note following Lemma 4.1, there exists $\lambda_0 > 0$ such that

$$a_L > T_\lambda \quad \text{for } \lambda < \lambda_0. \tag{4.7}$$

Following the argument of Theorem 3.1 in [17] (using now (4.7) and Proposition 4.4) we obtain the following corollary.

COROLLARY 4.5. *Assume* (H2). *Let $f \in L^\infty_+(\Omega)$ be an optimal control. Then for $\lambda < \lambda_0$,*

$$k'(f) = \lambda(h'(f)u_f - u_f^\alpha P_f)^+.$$

In order to prove that J is strictly concave in $[0, T_\lambda]$, we will show that maps involved in J' are Lipschitz continuous. This result was proven in [7] when $\beta \geq 1$. Since the Lipschitz character of the maps involved is crucial in this work (see, for example, the proof of Lemma 5.4), we present a complete proof of this result for the reader's convenience.

THEOREM 4.6. *Assume* (H2). *There exists $\Lambda > 0$ such that for $0 < \lambda < \Lambda$ the maps*

$$f \in [0, T_\lambda] \mapsto u_f,\ P_f,\ u_f^\alpha P_f \in L^\infty(\Omega),$$

are Lipschitz continuous, with the Lipschitz constants independent of λ.

Proof. Let $f, g \in [0, T_\lambda]$ be; by the monotony of the map $f \mapsto u_f$, it follows that $u_{T_\lambda} \leq u_f, u_g \leq u_0$. Moreover, for $\lambda < \lambda_0$ (defined in (4.7)), $u_{T_\lambda} > 0$, and so

$$0 < u_{T_\lambda} \leq u_f, u_g \leq u_0$$

for $\lambda < \lambda_0$. Hereafter, we take $\lambda < \lambda_0$. By the mean value theorem,

$$\begin{aligned} &u_f^\alpha - u_g^\alpha = \alpha\theta^{\alpha-1}(f,g)(u_f - u_g), \quad u_f^\beta - u_g^\beta = \beta\eta^{\beta-1}(f,g)(u_f - u_g) \quad \text{with} \\ &0 < u_{T_\lambda} \leq \min\{u_f, u_g\} \leq \theta(f,g), \eta(f,g) \leq \max\{u_f, u_g\} \leq u_0. \end{aligned} \tag{4.8}$$

Let $w := u_f - u_g$ be. Then, w satisfies

$$\begin{cases} (-\Delta + N(f,g))w = (g - f)u_g^\alpha & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega, \end{cases}$$

where

$$N(f,g) := -\alpha(a-f)\theta^{\alpha-1}(f,g) + \beta b\eta^{\beta-1}(f,g).$$

Using $f \geq 0$ and (4.8), it follows that

$$N(f,g) \geq -\alpha a\theta^{\alpha-1}(f,g) + \beta b\eta^{\beta-1}(f,g) \geq m_\lambda,$$

where

$$m_\lambda := \begin{cases} -\alpha a u_{T_\lambda}^{\alpha-1} + b\beta u_{T_\lambda}^{\beta-1} & \text{if } \beta \geq 1, \\ -\alpha a u_{T_\lambda}^{\alpha-1} + b\beta u_0^{\beta-1} & \text{if } \beta < 1. \end{cases} \tag{4.9}$$

It is not hard to show that m_λ satisfies (HM). Moreover, we claim that as $\lambda \downarrow 0$,

$$\int_\Omega m_\lambda \varphi^2 \to \int_\Omega (-\alpha a u_0^{\alpha-1} + b\beta u_0^{\beta-1})\varphi^2 \quad \forall \varphi \in H_0^1(\Omega). \tag{4.10}$$

Indeed, for $\varphi \in H_0^1(\Omega)$ and using (3.10) we have

$$\int_\Omega (u_{T_\lambda}^{\alpha-1} - u_0^{\alpha-1})\varphi^2 = \int_\Omega (u_{T_\lambda}^{\alpha} - u_{T_\lambda} u_0^{\alpha-1})\frac{\varphi}{u_{T_\lambda}}\varphi \leq C\epsilon_{T_\lambda}^{-1} \|u_{T_\lambda}^{\alpha} - u_{T_\lambda} u_0^{\alpha-1}\|_\infty \int_\Omega \frac{\varphi}{d_\Omega}\varphi,$$

where ϵ_{T_λ} is defined in (3.7). By the continuity of the map $f \mapsto u_f$, Lemma 2.1, and the fact that ϵ_{T_λ} does not tend to 0 as $\lambda \downarrow 0$, we obtain that

$$\int_\Omega (u_{T_\lambda}^{\alpha-1} - u_0^{\alpha-1})\varphi^2 \to 0 \qquad \text{as } \lambda \downarrow 0.$$

Reasoning similarly with the other terms, (4.10) is proved. So, by Theorem 2.2 we obtain that

$$\sigma_1(-\Delta + N(f,g)) \geq \sigma_1(-\Delta + m_\lambda) \to \sigma_1(-\Delta - \alpha a u_0^{\alpha-1} + b\beta u_0^{\beta-1}) > 0 \tag{4.11}$$

as $\lambda \downarrow 0$. This last inequality follows by (3.8) because $f \equiv 0 \in \mathcal{C}$. Hence, using the monotony of the map $\lambda \mapsto T_\lambda$, there exists $\lambda_1 > 0$ such that

$$N(f,g) \geq m_\lambda \geq m_{\lambda_1} \tag{4.12}$$

and

$$\sigma_1(-\Delta + N(f,g)) \geq \sigma_1(-\Delta + m_{\lambda_1} > 0 \quad \text{for } \lambda < \lambda_1. \tag{4.13}$$

So, by (4.12) we get

$$(-\Delta + m_{\lambda_1})w \leq (g-f)u_g^\alpha,$$

and hence, using (4.13), Theorem 2.5, and (3.5), it follows that

$$\|u_f - u_g\|_\infty = \|w\|_\infty \leq \|w\|_{C^1(\overline{\Omega})} \leq C\|f-g\|_\infty. \tag{4.14}$$

This shows that the map $f \mapsto u_f$ is Lipschitz.

Now, take $f \in [0, T_\lambda]$. Using the monotony of the map $f \mapsto u_f$, we have that

$$M_f \geq m_{\lambda_1}. \tag{4.15}$$

Thus, by Theorem 2.5 we obtain that

$$P_f \le \mathcal{P} \quad \text{in } \Omega, \tag{4.16}$$

where $\mathcal{P} \in C_0^1(\overline{\Omega})$ is the unique solution of

$$\begin{cases} -\Delta u + m_{\lambda_1} u &= T \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \end{cases}$$

and $T := \max_{r\in[0,T_{\lambda_1}]} h(r)$.

We will prove now that the map $f \mapsto P_f$ is Lipschitz. Let $f, g \in [0, T_\lambda]$ and $z := P_f - P_g$ be. Then z satisfies

$$-\Delta z + M_f z = T(f,g) \quad \text{in } \Omega, \qquad z = 0 \quad \text{on } \partial\Omega,$$

where

$$T(f,g) = h(f) - h(g) + P_g[\alpha(a-f)(u_f^{\alpha-1} - u_g^{\alpha-1}) - \beta b(u_f^{\beta-1} - u_g^{\beta-1})] + \alpha(g-f)P_g u_g^{\alpha-1}.$$

Applying again the mean value theorem, we get

$$\begin{gathered} u_f^{\alpha-1} - u_g^{\alpha-1} = (\alpha-1)\xi^{\alpha-2}(f,g)(u_f - u_g), \\ u_f^{\beta-1} - u_g^{\beta-1} = (\beta-1)\eta^{\beta-2}(f,g)(u_f - u_g), \\ 0 < u_{T_\lambda} \le \min\{u_f, u_g\} \le \xi(f,g), \eta(f,g) \le \max\{u_f, u_g\} \le u_0. \end{gathered} \tag{4.17}$$

Hence,

$$T(f,g) = h(f) - h(g) + P_g[\alpha(\alpha-1)(a-f)\xi^{\alpha-2} - \beta(\beta-1)b\eta^{\beta-2}](u_f - u_g) + \alpha(g-f)P_g u_g^{\alpha-1}.$$

By a similar argument to the one used in the proof of (4.14), we obtain

$$\|P_f - P_g\|_\infty = \|z\|_\infty \le C\|T(f,g)\|_\infty. \tag{4.18}$$

Since $\mathcal{P} \in C_0^1(\overline{\Omega})$, it follows that

$$|\mathcal{P}(x)| \le d_\Omega(x)\|\mathcal{P}\|_{C^1(\overline{\Omega})}. \tag{4.19}$$

So, using (3.10), (4.16), and (4.19), we obtain

$$\begin{aligned} \|(f-g)P_g u_g^{\alpha-1}\|_\infty &\le C\|f-g\|_\infty \|P_g u_{T_\lambda}^{\alpha-1}\|_\infty \le C\|f-g\|_\infty \|\mathcal{P} d_\Omega^{\alpha-1}\|_\infty \\ &\le C\|f-g\|_\infty \|d_\Omega^\alpha\|_\infty \|\mathcal{P}\|_{C^1(\overline{\Omega})} \le C\|f-g\|_\infty, \end{aligned}$$

with C independent of f and g.
On the other hand, since $u_f - u_g \in C_0^1(\overline{\Omega})$ and using (4.14), (4.16), (4.17), and (4.19),

$$\begin{aligned} \|(a-f)P_g\xi^{\alpha-2}(u_f - u_g)\|_\infty &\le C\|\mathcal{P}\xi^{\alpha-2}(u_f - u_g)\|_\infty \\ &\le C\|\mathcal{P}\|_{C^1(\overline{\Omega})}\|d_\Omega^\alpha\|_\infty \|u_f - u_g\|_{C^1(\overline{\Omega})} \le C\|f-g\|_\infty \end{aligned}$$

with C independent of f and g.

Analogously it can be treated the term $P_g\eta^{\beta-2}(u_f - u_g)$. Then, since h is Lipschitz in $[0, T_\lambda]$ and by (4.18), it follows that the map $f \mapsto P_f$ is Lipschitz.

Let $f, g \in [0, T_\lambda]$ be. By (4.8), we have

$$\|(u_f^\alpha - u_g^\alpha)P_f\|_\infty = \|\alpha\xi^{\alpha-1}P_f(u_f - u_g)\|_\infty \le C\|\mathcal{P}\|_{C^1(\overline{\Omega})}\|f-g\|_\infty \le C\|f-g\|_\infty,$$

and so

$$\|u_f^\alpha P_f - u_g^\alpha P_g\|_\infty \le \|(u_f^\alpha - u_g^\alpha)P_f\|_\infty + \|u_g^\alpha(P_f - P_g)\|_\infty \le C\|f-g\|_\infty.$$

This completes the proof. □

We can conclude the main result about uniqueness of optimal control of this section with the following theorem.

THEOREM 4.7. *Assume* (H2). *Then, there exists* $\Lambda_0 > 0$ *such that if* $\lambda < \Lambda_0$, *there exists a unique optimal control.*

5. The optimality system and the approximation to the optimal control. In this section, we deduce the optimality system in the special cases $h(t) = t$ and $k(t) = t^2$, which satisfy clearly (H2). The optimality system will be used to demonstrate the uniqueness of the optimal control in a different way and provides an iterative method to approach it. In this case, we know that

$$T_\lambda = \lambda\mathcal{K} \quad \text{and} \quad \lambda_0 = \frac{a_L}{\mathcal{K}},$$

where $\mathcal{K}$ is defined in (3.5). Moreover, by Corollary 4.5, for $\lambda < \lambda_0$, if f is an optimal control, then

$$f = \frac{\lambda}{2} u_f (1 - u_f^{\alpha-1} P_f)^+. \tag{5.1}$$

Let ψ be the unique positive solution of

$$\begin{cases} -\Delta\psi + m_{\lambda_1}\psi = \mathcal{K} & \text{in } \Omega, \\ \psi = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.2}$$

where m_{λ_1} is defined in (4.9) and satisfies (4.12) and (4.13). So, if f is an optimal control it follows by Lemma 4.1 that $f \in [0, \lambda\mathcal{K}]$. On the other hand, by (4.15) and Theorem 2.5, we get that

$$P_f \le \lambda\psi \qquad \text{for } \lambda \le \lambda_1. \tag{5.3}$$

As a consequence of (5.3) we obtain the following proposition (see Proposition 5.2 and Corollary 5.3 in [7]).

PROPOSITION 5.1. *Assume* (H1). *There exists a constant* $\Lambda_1 > 0$ *such that if* $\lambda \le \Lambda_1$, *then*

$$P_f \le u_f^{1-\alpha}. \tag{5.4}$$

So, if f *is an optimal control, we have that*

$$f = \frac{\lambda}{2} u_f (1 - u_f^{\alpha-1} P_f). \tag{5.5}$$

As a consequence, any optimal control f *may be expressed as in* (5.5), *where the pair* $(u_f, P_f) := (u, P)$ *satisfies*

$$\begin{cases} -\Delta u = u^\alpha(a - \frac{\lambda}{2}u + \frac{\lambda}{2}u^\alpha P - bu^{\beta-\alpha}) \text{ in } \Omega, \\ -\Delta P + (-\alpha a u^{\alpha-1} + \beta b u^{\beta-1})P = \frac{\lambda}{2}(u - u^\alpha P(1+\alpha) + \alpha u^{2\alpha-1}P^2) \text{ in } \Omega, \\ u = P = 0 \text{ on } \partial\Omega, \end{cases} \tag{5.6}$$

and $u > 0$.

The former result says that, when λ is small enough, if f is an optimal control, then (u_f, P_f) is a solution of (5.6). We are going to prove now that, for a range of λ, there exists a unique positive solution of (5.6) verifying $u^{1-\alpha} \geq P$, and so the unique optimal control will be

$$f = \frac{\lambda}{2}(u - u^\alpha P).$$

THEOREM 5.2 (uniqueness of optimal control). *Assume* (H1). *There exists* $\Lambda_2 > 0$ *such that for* $\lambda \leq \Lambda_2$, (5.6) *possesses a unique positive solution* (u, P) *satisfying* $u^{1-\alpha} \geq P$.

Proof. We define the following map:

$$\mathcal{T} : I := [0, \lambda\mathcal{K}] \subset L^\infty_+(\Omega) \mapsto L^\infty_+(\Omega), \qquad f \mapsto \mathcal{T}(f) = \frac{\lambda}{2}(u_f - u_f^\alpha P_f).$$

By Theorem 4.6, for $\lambda < \Lambda$, $\mathcal{T}$ is a Lipschitz continuous function with Lipschitz constant of type $\lambda\mathcal{L}/2$, where $\mathcal{L}$ is the corresponding one for the function $f \mapsto u_f - u_f^\alpha P_f$. So, we can choose $\Lambda_2 := \min\{\Lambda, \frac{2}{\mathcal{L}}\}$ such that for $\lambda \leq \Lambda_2$, $\mathcal{T}$ is a contractive function.

Assume that there exist two positive solutions (u_i, P_i), $i = 1, 2$, of (5.6) with $u_i^{1-\alpha} \geq P_i$. We define

$$f_i = \frac{\lambda}{2}(u_i - u_i^\alpha P_i) \in I, \quad i = 1, 2.$$

Hence, by (5.6) and Proposition 3.3 we have that

$$u_i = u_{f_i}, \qquad P_i = P_{f_i}, \quad \Rightarrow \mathcal{T}(f_i) = f_i, \quad i = 1, 2.$$

Since $\mathcal{T}$ is contractive, it follows that $f_1 = f_2$, and again by Proposition 3.3 we have that $u_{f_1} = u_{f_2}$; hence $u_1 = u_2$, and so $P_1 = P_2$. This completes the proof. □

Now, we use the optimal control characterization obtained by formula (5.5) to give an iterative procedure to approach it. The idea is to be near the solution of the optimality system by sub- and supersolutions (see other papers related with similar problems [6], [14], [15], [17]). The interest here, besides the degeneration of the second equation of the optimality system, is that we prove the convergence of the method by a different argument than that used in the mentioned references. We start this part with some notation. We define, for simplicity, the following functions:

$$B(x, u, p) = \left[a(x) - \frac{\lambda}{2}(u - u^\alpha p)\right] u^\alpha - b(x)u^\beta \text{ for } x \in \Omega,$$

and, taking into account the monotony properties of the second equation of optimality system (5.6), we define

$$D(x, u, p) = \begin{cases} \frac{\lambda}{2}u - \beta p b(x) u^{\beta-1} & \text{if } \beta < 1,\ 2\alpha - 1 < 0, \\ \frac{\lambda}{2}u - \beta p b(x) u^{\beta-1} + \frac{\lambda}{2}\alpha u^{2\alpha-1}p^2 & \text{if } \beta < 1,\ 2\alpha - 1 \geq 0, \\ \frac{\lambda}{2}u & \text{if } \beta \geq 1,\ 2\alpha - 1 < 0, \\ \frac{\lambda}{2}u + \frac{\lambda}{2}\alpha u^{2\alpha-1}p^2 & \text{if } \beta \geq 1,\ 2\alpha - 1 \geq 0 \end{cases}$$

and

$$C(x,u,p)=\begin{cases} p(\alpha a(x)u^{\alpha-1}-\frac{\lambda}{2}u^{\alpha}(\alpha+1))+\frac{\lambda}{2}\alpha u^{2\alpha-1}p^2 & \text{if } \beta<1,\ 2\alpha-1<0,\\ p(\alpha a(x)u^{\alpha-1}-\frac{\lambda}{2}u^{\alpha}(\alpha+1)) & \text{if } \beta<1,\ 2\alpha-1\geq 0,\\ p(\alpha a(x)u^{\alpha-1}-\beta b(x)u^{\beta-1} & \\ -\frac{\lambda}{2}u^{\alpha}(\alpha+1))+\frac{\lambda}{2}\alpha u^{2\alpha-1}p^2 & \text{if } \beta\geq 1,\ 2\alpha-1<0,\\ p(\alpha a(x)u^{\alpha-1}-\beta b(x)u^{\beta-1}-\frac{\lambda}{2}u^{\alpha}(\alpha+1)) & \text{if } \beta\geq 1,\ 2\alpha-1\geq 0. \end{cases}$$

We are interested in the solutions, (u,p), of optimality system (5.6) that satisfy $u_{\lambda\mathcal{K}}\leq u\leq u_0$ and $0\leq p\leq\lambda\psi$ (recall (5.3)). Consequently, we can reduce the study for solutions that satisfy $(u,p)\in[u_{\lambda\mathcal{K}},u_0]\times[0,\lambda\psi]$. Therefore, there exist a constant $K>0$ and a function $M_1(x), x\in\Omega$, satisfying hypothesis (HM) such that

$$\begin{array}{ll} B(x,u,p)+Ku^{\alpha} & (\nearrow u,\nearrow p)\,,\\ C(x,u,p)+M_1(x)p & (\searrow u,\nearrow p)\,,\\ D(x,u,p)+M_1(x)p & (\nearrow u,\nearrow p)\,; \end{array}$$

i.e., $B(x,u,p)+Ku^{\alpha}$ is increasing in u for fixed $x\in\Omega$ and $0\leq p\leq\lambda\psi$ and increasing in p for fixed $x\in\Omega$ and $u_{\lambda\mathcal{K}}\leq u\leq u_0$. The other terms are interpreted analogously.

Definition 5.3 (subsupersolutions). *The functions $u_1,p_1,u^1,p^1\in L^{\infty}(\Omega)\cap H^1(\Omega)$ are said to be a system of subsupersolutions for optimality system* (5.6) *if they verify*

$$\begin{cases} u_1(x)\leq u^1(x),\quad p_1(x)\leq p^1(x) & \text{a.e. in } \Omega,\\ p_1\leq 0\leq p^1 & \text{on } \partial\Omega, \end{cases} \tag{5.7}$$

and there exists a positive constant k such that

$$0<kd_{\Omega}(x)\leq u_1(x)\leq u^1(x)\quad \text{a.e. in } \Omega \tag{5.8}$$

and, for any $\phi\in H_0^1(\Omega)$, $\phi\geq 0$,

$$\int_{\Omega}\nabla u^1\cdot\nabla\phi\geq\int_{\Omega}B(x,u^1,p^1)\phi,\qquad \int_{\Omega}\nabla u_1\cdot\nabla\phi\leq\int_{\Omega}B(x,u_1,p_1)\phi,$$

$$\int_{\Omega}\nabla p^1\cdot\nabla\phi\geq\int_{\Omega}C(x,u_1,p^1)\phi+\int_{\Omega}D(x,u^1,p^1)\phi,$$

$$\int_{\Omega}\nabla p_1\cdot\nabla\phi\leq\int_{\Omega}C(x,u^1,p_1)\phi+\int_{\Omega}D(x,u_1,p_1)\phi.$$

Recall that a function $v\in H^1(\Omega)$ is said to be less than or equal to $w\in H^1(\Omega)$ on $\partial\Omega$ when $(v-w)^+=\max\{0,v-w\}\in H_0^1(\Omega)$.

It is not difficult to prove that, under the hypothesis of Theorem 5.2, there exists a $\Lambda_3>0$ such that if $\lambda\leq\Lambda_3$, then the functions

$$u_1=u_{\lambda\mathcal{K}},\quad p_1\equiv 0,\quad u^1=u_0,\quad p^1=\lambda\psi, \tag{5.9}$$

are a system of subsupersolutions for the optimality system (5.6) in the sense of Definition 5.3. We show only the case $p^1=\lambda\psi$ when $\beta\geq 1$, $2\alpha-1\geq 0$. The other cases are similar. It is not hard to show that $p^1=\lambda\psi$ is a supersolution if

$$\lambda(\mathcal{K}-m_{\lambda_1}\psi)\geq\lambda\psi\left[\alpha a u_{\lambda\mathcal{K}}^{\alpha-1}-\beta b u_{\lambda\mathcal{K}}^{\beta-1}-\frac{\lambda}{2}u_{\lambda\mathcal{K}}^{\alpha}(\alpha+1)\right]+\frac{\lambda}{2}u_0+\frac{\lambda}{2}\alpha u_0^{2\alpha-1}(\lambda\psi)^2$$

or, equivalently,

$$\mathcal{K} \geq \psi \left[m_{\lambda_1} + \alpha a u_{\lambda\mathcal{K}}^{\alpha-1} - \beta b u_{\lambda\mathcal{K}}^{\beta-1} \right] - \frac{\lambda}{2} u_{\lambda\mathcal{K}}^{\alpha}(\alpha+1)\psi + \frac{1}{2}u_0 + \frac{\alpha}{2}\lambda^2 u_0^{2\alpha-1}\psi^2.$$

Recalling the definition of m_{λ_1}, for $\lambda \leq \lambda_1$ we have that $m_{\lambda_1} + \alpha a u_{\lambda\mathcal{K}}^{\alpha-1} - \beta b u_{\lambda\mathcal{K}}^{\beta-1} \leq 0$, and by (3.5) $u_0 \leq \mathcal{K}$; it is enough to take λ small to obtain that p^1 is a supersolution.

Now, we define by induction, for $n \geq 2$, the sequences $\{u_n\}$, $\{u^n\}$, $\{p_n\}$, $\{p^n\} \in H_0^1(\Omega)$ as

$$-\Delta u_n + K(u_n)^\alpha = B(x, u_{n-1}, p_{n-1}) + K(u_{n-1})^\alpha \quad \text{in } \Omega, \tag{5.10}$$

$$-\Delta u^n + K(u^n)^\alpha = B(x, u^{n-1}, p^{n-1}) + K(u^{n-1})^\alpha \quad \text{in } \Omega, \tag{5.11}$$

$$-\Delta p_n + M_1(x)p_n = C(x, u^n, p_{n-1}) + D(x, u_n, p_{n-1}) + M_1(x)p_{n-1} \quad \text{in } \Omega, \tag{5.12}$$

$$-\Delta p^n + M_1(x)p^n = C(x, u_n, p^{n-1}) + D(x, u^n, p^{n-1}) + M_1(x)p^{n-1} \quad \text{in } \Omega. \tag{5.13}$$

Observe that sequences $\{u_n\}$, $\{u^n\}$, are well defined because the map $u \mapsto Ku^\alpha$ is continuous and strictly increasing and such that $B(x,u,p) + Ku^\alpha$ is also increasing in u when the other variables are fixed. (See more details in [5], [10].)

On the other hand, fixed u_1, u^1 and, thanks to (5.8), the problems (5.12) and (5.13) are in the setting of (2.4), and so by Theorem 2.5 it follows the existence and uniqueness of p_2 and p^2 and such that $p_2 \leq p^2$ and so on. We note that for (5.10)–(5.11) and (5.12)–(5.13), the subsupersolutions method works (cf. [12]). The standard method gives us the following order relation:

$$u_1 \leq u_2 \leq \cdots \leq u_n \leq u^n \leq u^{n-1} \leq \cdots \leq u^1,$$
$$p_1 \leq p_2 \leq \cdots \leq p_n \leq p^n \leq p^{n-1} \leq \cdots \leq p^1$$

and

$$u_n \nearrow u,\ u^n \searrow v,\ p_n \nearrow p,\ p^n \searrow q$$

(pointwise), where u, v, p, q belong to $C^{1,\delta}(\Omega)$, for any $\delta \in (0,1)$, and satisfy the system

$$\begin{cases} -\Delta u = B(x,u,p) & \text{in } \Omega, \\ -\Delta v = B(x,v,q) & \text{in } \Omega, \\ -\Delta p = C(x,v,p) + D(x,u,p) & \text{in } \Omega, \\ -\Delta q = C(x,u,q) + D(x,v,q) & \text{in } \Omega, \\ u = v = p = q = 0 & \text{on } \partial\Omega \end{cases} \tag{5.14}$$

and

$$\begin{aligned} u_1 = u_{\lambda\mathcal{K}} \leq u,\ v \leq u^1 = u_0 \quad &\text{in } \Omega \\ p_1 = 0 \leq p,\ q \leq p^1 = \lambda\psi \leq u_{\lambda\mathcal{K}}^{1-\alpha} \quad &\text{in } \Omega. \end{aligned} \tag{5.15}$$

Clearly, if (u,p) is the solution of optimality system (5.6), then (u,u,p,p) is a solution of (5.14). So, to complete the iterative approximation and the convergence of the sequences $\{u_n\}$, $\{u^n\}$, $\{p_n\}$, $\{p^n\}$ to the unique solution, (u,p), of the optimality system, it is sufficient to prove the uniqueness of the solution for system (5.14), under conditions (5.15). To do it, we need the following technical lemma.

LEMMA 5.4. *Assume* (H1). *Then*

$$\forall f,\ g \in [0, \lambda\mathcal{K}] \subset L_+^\infty(\Omega),$$

it is possible to define the function $P_{f,g}$ as the unique positive solution of the problem

$$\begin{cases} -\Delta P = C(x,u_f,P) + D(x,u_g,P) & \text{in } \Omega, \\ P = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.16}$$

satisfying

$$0 \le P_{f,g} \le \lambda\psi, \tag{5.17}$$

provided that the parameter λ is small enough and the function ψ is defined in (5.2). *Moreover, the map defined before, $(f,g) \in [0,\lambda\mathcal{K}] \times [0,\lambda\mathcal{K}] \mapsto P_{f,g} \in L^\infty(\Omega)$, is Lipschitz continuous.*

An analogous result is obtained interchanging u_f and u_g in (5.16).

Proof. We consider the case $\beta \ge 1$, $2\alpha - 1 \ge 0$. The other cases have similar proofs. Observe that, in this case, (5.16) is

$$\begin{cases} -\Delta P + \left[-\alpha a u_f^{\alpha-1} + \beta b u_f^{\beta-1} + \frac{\lambda}{2} u_f^\alpha (1+\alpha) \right] P = \frac{\lambda}{2} u_g + \frac{\lambda}{2} \alpha u_g^{2\alpha-1} P^2 \text{ in } \Omega, \\ P = 0 \quad \text{on } \partial\Omega. \end{cases} \tag{5.18}$$

Taking into account Theorem 2.5, condition (5.17), and the definition of the function ψ, we can use the subsupersolution method with $p_* \equiv 0$ as subsolution and $p^* \equiv \lambda\psi$ as supersolution, provided $\lambda > 0$ small. Thus, the existence of positive solution of (5.18) is proved. The uniqueness of a contradiction argument follows. Suppose that P, Q are two solutions under above requirements; then $P - Q$ satisfies

$$(-\Delta + M_1(x))(P - Q) = 0,$$

where

$$M_1 = -\alpha a u_f^{\alpha-1} + \beta b u_f^{\beta-1} + \frac{\lambda}{2} u_f^\alpha (1+\alpha) - \frac{\lambda}{2} \alpha u_g^{2\alpha-1} (P+Q).$$

Observe that M_1 satisfies (HM). Now, using that $P, Q \le \lambda\psi$, we obtain that

$$M_1 \ge -\alpha a u_{T_\lambda}^{\alpha-1} + \beta b u_{T_\lambda}^{\beta-1} + \frac{\lambda}{2} u_{T_\lambda}^\alpha (1+\alpha) - \lambda^2 \alpha u_0^{2\alpha-1} \psi,$$

and so we can prove the existence of a function N satisfying (HM) and $\lambda_0 > 0$ such that for $\lambda \le \lambda_0$

$$M_1 \ge N \qquad \text{in } \Omega \text{ and} \qquad \sigma_1(-\Delta + N) > 0. \tag{5.19}$$

Hence, the previous equation has the unique solution $(P - Q) \equiv 0$.

To show the Lipschitzian character of the map $(f,g) \mapsto P_{f,g}$, let $P_{f,g}$ be the solution of problem (5.18) satisfying (5.17). Denote $\overline{q} = P_{\overline{f},\overline{g}}$ and $q = P_{f,g}$. Then, some calculus gives

$$\begin{aligned} &(-\Delta + M(x))(q - \overline{q}) = R_{f,\overline{f},g,\overline{g}} := \alpha a q (u_f^{\alpha-1} - u_{\overline{f}}^{\alpha-1}) \\ &-\beta b q (u_f^{\beta-1} - u_{\overline{f}}^{\beta-1}) - \tfrac{\lambda}{2}(\alpha+1) q (u_f^\alpha - u_{\overline{f}}^\alpha) + \tfrac{\lambda}{2}(u_g - u_{\overline{g}}) + \tfrac{\lambda}{2} \alpha q^2 (u_g^{2\alpha-1} - u_{\overline{g}}^{2\alpha-1}), \end{aligned}$$

where

$$M = -\alpha a u_{\overline{f}}^{\alpha-1} + \beta b u_{\overline{f}}^{\beta-1} + \frac{\lambda}{2}(\alpha+1)u_{\overline{f}}^{\alpha} - \frac{\lambda}{2}\alpha(q+\overline{q})u_{\overline{g}}^{2\alpha-1}.$$

As in the proof of (5.19), we can prove the existence of a function N satisfying (HM) such that for $M \geq N$ in Ω and $\sigma_1(-\Delta + N) > 0$ for small λ. Thus, by Theorem 2.5 we get that

$$\|q - \overline{q}\|_\infty = ||P_{f,g} - P_{\overline{f},\overline{g}}||_\infty \leq \|P_{f,g} - P_{\overline{f},\overline{g}}\|_{C^1(\overline{\Omega})} \leq C\|R_{f,\overline{f},g,\overline{g}}\|_\infty.$$

Now, using a similar argument to the one used in the proof of Theorem 4.6 to obtain a bound of $\|T(f,g)\|_\infty$, we have

$$\left\|\alpha a q(u_f^{\alpha-1} - u_{\overline{f}}^{\alpha-1}) + \beta b q(u_f^{\beta-1} - u_{\overline{f}}^{\beta-1}) + \tfrac{\lambda}{2}(\alpha+1)q\left(u_f^{\alpha} - u_{\overline{f}}^{\alpha}\right)\right\|_\infty \leq C\|f - \overline{f}\|_\infty,$$
$$\left\|\tfrac{\lambda}{2}(u_g - u_{\overline{g}}) + \tfrac{\lambda}{2}\alpha q^2\left(u_g^{2\alpha-1} - u_{\overline{g}}^{2\alpha-1}\right)\right\|_\infty \leq C\|g - \overline{g}\|_\infty,$$

and so $\|R_{f,\overline{f},g,\overline{g}}\|_\infty \leq C\left\{\|f - \overline{f}\|_\infty + \|g - \overline{g}\|_\infty\right\}$. Finally, we have

$$\|P_{f,g} - P_{\overline{f},\overline{g}}\|_\infty \leq C\left\{\|f - \overline{f}\|_\infty + \|g - \overline{g}\|_\infty\right\} \tag{5.20}$$

for a convenient positive constant C. □

THEOREM 5.5. *Assume* (H1). *There exists a positive constant* Λ_4 *such that if* $\lambda \leq \Lambda_4$, *then the system* (5.14)–(5.15) *has a unique solution.*

Proof. The main idea is simple. We will use the Lipschitzian character of the solutions of system (5.14)–(5.15) with respect to the controls and an argument similar to the one used in Theorem 5.2.

Suppose (u_i, v_i, p_i, q_i), for $i = 1, 2$, are two solutions of system (5.14)–(5.15). We define, for $i = 1, 2$,

$$f_i = \frac{\lambda}{2}[u_i - u_i^{\alpha} p_i], \qquad g_i = \frac{\lambda}{2}[v_i - v_i^{\alpha} q_i]. \tag{5.21}$$

Now, taking into account the previous notation, we have for $i = 1, 2$,

$$u_i = u_{f_i}, \quad v_i = u_{g_i}, \quad p_i = P_{g_i,f_i}, \quad q_i = P_{f_i,g_i}$$

and

$$f_i = \frac{\lambda}{2}[u_{f_i} - u_{f_i}^{\alpha} P_{g_i,f_i}], \qquad g_i = \frac{\lambda}{2}[u_{g_i} - u_{g_i}^{\alpha} P_{f_i,g_i}].$$

We know (recall Theorem 4.6 and Lemma 5.4) that the operator $T : [0, \lambda\mathcal{K}] \times [0, \lambda\mathcal{K}] \to L^\infty(\Omega) \times L^\infty(\Omega)$, defined as

$$T(f,g) = \left(\frac{\lambda}{2}[u_f - u_f^{\alpha} P_{g,f}], \frac{\lambda}{2}[u_g - u_g^{\alpha} P_{f,g}]\right),$$

is Lipschitz continuous, with constant $\lambda C/2$, where $C > 0$ is the Lipschitz constant of map $(f,g) \mapsto \left(u_f - u_f^{\alpha} P_{f,g}, u_g - u_g^{\alpha} P_{g,f}\right)$ and verifies $T(f_i, g_i) = (f_i, g_i)$. Therefore, by taking $\lambda < \min\{\Lambda_1, \frac{2}{C}\}$, T is a contraction and consequently has an unique fixed point. So, $(f_1, g_1) = (f_2, g_2)$. Then, we have $u_1 = u_2$, $v_1 = v_2$, and finally $p_1 = p_2$ and $q_1 = q_2$. □

CONDITIONAL MOMENT GENERATING FUNCTIONS FOR INTEGRALS AND STOCHASTIC INTEGRALS*

C. D. CHARALAMBOUS†, R. J. ELLIOTT‡, AND V. KRISHNAMURTHY§

Abstract. In this paper we present two methods for computing filtered estimates for moments of integrals and stochastic integrals of continuous-time nonlinear systems. The first method utilizes recursive stochastic partial differential equations. The second method utilizes conditional moment generating functions. An application of these methods leads to the discovery of new classes of finite-dimensional filters. For the case of Gaussian systems the recursive computations involve integrations with respect to Gaussian densities, while the moment generating functions involve differentiations of parameter dependent ordinary stochastic differential equations. These filters can be used in Volterra or Wiener chaos expansions and the expectation-maximization algorithm. The latter yields maximum-likelihood estimates for identifying parameters in state space models.

Key words. moment generating functions, finite-dimensional, filters, recursions, expectation-maximization

1. Introduction.

Conditional expectations of functionals of systems state processes given noisy observations require, in general, infinite-dimensional computations. To determine whether such conditional expectations are finite-dimensional, it is of interest to derive representations of the conditional distribution.

This paper discusses the following problem. We are given noisy observations $\{y_s; 0 \le s \le t\}$ of the system state process $\{x_s; 0 \le s \le t\}$, and we wish to derive filtered estimates for moments of integrals and stochastic integrals. The underlying mathematical system model can be diverse; for example, it includes continuous-time processes, discrete-time processes, jump point processes, or a combination of these processes. In this paper we focus our attention on continuous-time processes.

Here, our system state process $\{x_s; 0 \le s \le t\}$ and observation process $\{y_s; 0 \le s \le t\}$ are solutions of the Itô stochastic differential equations

$$dx_t = f(t, x_t)dt + \sigma(t, x_t)dw_t, \qquad x(0) \in \mathbb{R}^n, \tag{1.1}$$

$$dy_t = h(t, x_t)dt + \alpha_t dw_t + N_t^{1/2} db_t, \qquad y(0) = 0 \in \mathbb{R}^n, \tag{1.2}$$

in which $\{w_s; 0 \le s \le t\}$ and $\{b_s; 0 \le s \le t\}$, are, respectively, m-dimensional and d-dimensional, independent standard Wiener processes; $x(0)$ is a random variable

independent of the Wiener processes. The precise assumptions on the coefficients of our model are stated in section 2.

We are interested in conditional expectations (filtered estimates) of moments of integrals and stochastic integrals

$$L_{0,t}^{\kappa,1} = \left(\int_0^t f^1(s, x_s) ds \right)^\kappa, \quad L_{0,t}^{\kappa,2} = \left(\int_0^t f^2(s, x_s) dw_s \right)^\kappa, \quad L_{0,t}^{\kappa,3} = \left(\int_0^t f^3(s, x_s) db_s \right)^\kappa, \quad \kappa \geq 1, \tag{1.3}$$

for Borel measurable functions $f^1 : [0,T] \times \mathbb{R}^n \to \mathbb{R}$, $f^2 : [0,T] \times \mathbb{R}^n \to (\mathbb{R}^m)'$, $f^3 : [0,T] \times \mathbb{R}^n \to (\mathbb{R}^d)'$, which are continuous in t. Aside from their mathematical value, these estimates are important, for example, in least-squares estimation/filtering, Volterra series expansions of nonlinear realization theory [1], Wiener chaos expansions (of nonlinear filtering) [2], and maximum likelihood estimation through the expectation-maximization (EM) algorithm [3]. For the case $\kappa = 1$, these estimates are important in estimating parameters, a problem which arises in many disciplines, such as signal processing, communications, and control systems.

The first method, Theorem 3.1, utilizes a system of stochastic partial differential equations (SPDEs) that enable us to compute the above estimates recursively. The second method, Theorem 4.5, utilizes conditional moment generating functions for $L_{0,t}^{1,j}, j = 1,2,3$. That is, for a test function $\Phi : \mathbb{R}^n \to \mathbb{R}$, we use measure-valued conditional moment generating functions

$$\widetilde{\beta}_t^{\theta,j}(\Phi) = \widetilde{\mathrm{E}}[\Phi(x_t) \exp\left(\theta L_{0,t}^{1,j}\right) | \mathcal{F}_{0,t}^y], \qquad j = 1,2,3, \qquad \theta = i\omega, \quad i = \sqrt{-1}. \tag{1.4}$$

Therefore, when the unnormalized versions of $\widetilde{\beta}_t^{\theta,j}(\Phi)$ have densities $\beta^{\theta,j}(x,t), j = 1,2,3$, the latter satisfy linear SPDEs. The computation of filtered estimates of moments (1.3) are obtained by simply differentiating the conditional densities with respect to the parameter θ.

For the case of Gaussian system models (i.e., $dx_t = Fx_t dt + Gw_t$, $dy_t = Hx_t dt + N^{\frac{1}{2}} b_t$), we derive filtered estimates for

$$L_{0,t}^{1,1} = \int_0^t x_s' Q x_s ds \quad L_{0,t}^{1,2} = \int_0^t x_s' R dw_s, \quad L_{0,t}^{1,3} = \int_0^t x_s' S db_s. \tag{1.5}$$

Each filtered estimate is propagated by four statistics. Two of these are the conditional mean and error covariances of x_t given $\{y_s; 0 \leq s \leq t\}$ (Kalman filter), while the remaining two are modified versions of the Kalman filter; the latter are driven by the conditional mean and error covariance of the Kalman filter.

In the past, the computation of these filtered estimates was confined to integrals $L_{0,t}^{1,1}$, which are obtained using smoothing operations (e.g., [4]), and certain Lie algebraic techniques applied to Volterra expansions (e.g., [1]). However, for analogous discrete-time systems the filtering estimates in (1.5) are obtained using smoothing operations (e.g., [5]). Recently, conditional expectations for the items in (1.5) were obtained using filtering operations in [6]; the estimates were propagated by five statistics. The techniques in [6], which are different from ours, are only applicable to Gaussian systems, and they are confined to $\kappa = 1$.

2. The Duncan–Mortensen–Zakai (DMZ) equation.

Notation 2.1.

1. "$\prime$" denotes transposition of a matrix;
2. I_k denotes $k \times k$ identity matrices;
3. $(\cdot)_i$ denotes the ith component of a vector and $(\cdot)_{i,j}$ denotes the ijth component of a matrix;
4. $\mathcal{L}(V_1; V_2)$ denotes the space of linear transformations of a vector space V_1 into a vector space V_2;
5. $C^{p,q}_{x,t}(\mathbb{R}^n \times [0,T]) = \{\Phi : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n; \Phi(\cdot,t)$ is "p" times continuously differentiable in "x," and $\Phi(x,\cdot)$ is "q" times continuously differentiable in "t"$\}$;
6. $D_x = [\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \dots, \frac{\partial}{\partial x_n}]', \quad D^2_x = \begin{bmatrix} \frac{\partial^2}{\partial x_1^2}, & \cdots, & \frac{\partial^2}{\partial x_1 \partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial^2}{\partial x_n \partial x_1}, & \cdots, & \frac{\partial^2}{\partial x_n^2} \end{bmatrix}$;
7. $\Phi : \mathbb{R}^n \to \mathbb{R}$ denotes an arbitrary test function which is $C^2_x(\mathbb{R}^n)$ and has compact support;
8. $\mathrm{E}, \widetilde{\mathrm{E}}$ denote expectations with respect to measures $P, \widetilde{P}$, respectively;
9. $N_t \doteq N_t^{\frac{1}{2}} N_t^{\frac{1}{2}\prime}$.

Assumption 2.2.

1. $f : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n, \sigma : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n, h : [0,T] \times \mathbb{R}^n \to \mathbb{R}^d, T > 0$, are bounded Borel measurable functions;
2. $N : [0,T] \to \mathcal{L}(\mathbb{R}^d; \mathbb{R}^d), \alpha : [0,T] \to \mathcal{L}(\mathbb{R}^n; \mathbb{R}^d), N, \alpha$ are bounded Borel measurable functions, and $\exists \beta_1 > 0, \beta_2 > 0$ such that $N_t \geq \beta_1 I_d \ \forall t \in [0,T]$, $a(t,x) \doteq \sigma(t,x)\sigma(t,x)' \geq \beta_2 I_n \ \forall (t,x) \in [0,T] \times \mathbb{R}^n$;
3. σ is continuous in x, uniformly on compact subsets of $[0,T] \times \mathbb{R}^n$, $\frac{\partial}{\partial x_i}\sigma_{i,j}$ is a bounded measurable function of $(t,x) \in [0,T] \times \mathbb{R}^n$, $1 \leq i,j \leq n$;
4. $|f(t,x) - f(t,z)| + \|\sigma(t,x) - \sigma(t,z)\| \leq k|x - z|$;
5. $x(0)$ has distribution $\Pi_0(dx) = p_0(x)dx$, where $p_0(\cdot) \in L^2(\mathbb{R}^n)$.

The above assumptions, with the exception of statement 4, are assumed to hold throughout the manuscript.

Next, we start with a reference probability measure which is important in deriving certain conditional densities for the filtering problem discussed earlier. Let $(\Omega, \mathcal{F}, P)$ be a reference probability with complete filtration $\{\mathcal{F}_{0,t}; t \in [0,T]\}$, on which we have the following:

(a) $w : [0,T] \times \Omega \to \mathbb{R}^n, b : [0,T] \times \Omega \to \mathbb{R}^d$, which are $\{\mathcal{F}_{0,t}; t \in [0,T]\}$ adapted independent Wiener processes;

(b) $x(0) : \Omega \to \mathbb{R}^n$, an $\mathcal{F}_{0,0}$-measurable random variable, which is independent of $\{w_t, b_t; t \in [0,T]\}$;

(c) processes $\{x_t; t \in [0,T]\}, \{y_t; t \in [0,T]\}$, which (in view of Assumption 2.2) are unique and continuous solutions of the stochastic differential equations

$$dx_t = f(t,x_t)dt - \sigma(t,x_t)\alpha_t' C_t^{-1} h(t,x_t)dt + \sigma(t,x_t)dw_t, \qquad x(0) \in \mathbb{R}^n, \tag{2.1}$$

$$dy_t = \alpha_t dw_t + N_t^{1/2} db_t, \qquad y(0) = 0 \in \mathbb{R}^n, \tag{2.2}$$

where

$$C_t \doteq \alpha_t \alpha_t' + N_t. \tag{2.3}$$

Consider the P-martingale

$$m_t = \int_0^t h'(s,x_s) C_s^{-1} dy_s, \tag{2.4}$$

and introduce the exponential martingale

$$\varepsilon(m_t) = \exp\left(m_t - \frac{1}{2}\langle m, m\rangle_t\right) = \Lambda_{0,t}, \tag{2.5}$$

where $\langle m, m\rangle_t = \int_0^t |C_s^{-1/2} h(s, x_s)|^2 ds$ is the quadratic variation of $\{m_t; t \in [0,T]\}$. By Assumption 2.2, we have $\mathrm{E}[\Lambda_{0,t}] = 1 \forall t \in [0,T]$ (see [7]). Consequently, we define a measure $\widetilde{P}$ through the Radon–Nikodým derivative

$$\Lambda_{0,T} \doteq \mathrm{E}\left[\frac{d\widetilde{P}}{dP}|\mathcal{F}_{0,T}\right] = \varepsilon(m_T). \tag{2.6}$$

Since $\widetilde{P}(\Omega) = \int_\Omega \Lambda_{0,t}(\omega) dP(\omega) = 1 \ \forall t \in [0,T]$, the Girsanov theorem (see [7]) states that $\widetilde{P}$ is a probability measure on $(\Omega, \mathcal{A})$ and that

$$\begin{aligned} \begin{bmatrix} \overline{w}_t \\ \overline{b}_t \end{bmatrix} &= \begin{bmatrix} w_t \\ b_t \end{bmatrix} - \begin{bmatrix} \langle w, m\rangle_t \\ \langle b, m\rangle_t \end{bmatrix} \\ &= \begin{bmatrix} w_t \\ b_t \end{bmatrix} - \begin{bmatrix} \int_0^t \alpha_s' C_s^{-1} h(s, x_s) ds \\ \int_0^t N_s^{1/2,\prime} C_s^{-1} h(s, x_s) ds \end{bmatrix} \end{aligned} \tag{2.7}$$

are independent Wiener processes on $(\Omega, \mathcal{F}, \widetilde{P}; \mathcal{F}_{0,t})$. Substituting (2.7) into (2.1), (2.2), on the new probability space $(\Omega, \mathcal{F}, \widetilde{P}; \mathcal{F}_{0,t})$ we have constructed (weak) solutions $\{x_t; t \in [0,T]\}, \{y_t; t \in [0,T]\}$ of the stochastic equations

$$dx_t = f(t, x_t)dt + \sigma(t, x_t) d\overline{w}_t, \qquad x(0) \in \mathbb{R}^n, \tag{2.8}$$

$$dy_t = h(t, x_t)dt + \alpha_t d\overline{w}_t + N_t^{1/2} d\overline{b}_t, \qquad y(0) = 0 \in \mathbb{R}^d. \tag{2.9}$$

Since $\{\overline{w}_t; t \in [0,T]\}$ and $\{\overline{b}_t; t \in [0,T]\}$ are versions of Wiener processes (which are independent), (2.8), (2.9) constitute our original system model (simply by letting $\overline{w} \to w, \overline{b} \to b$). Note that we may remove the Lipschitz condition Assumption 2.2, statement 4, and employ the martingale approach to construct weak solutions.

Notation 2.3.

1. $\{\mathcal{F}_{0,t}^y; t \in [0,T]\}$ denotes the complete filtration generated by the observations σ-algebra $\sigma\{y_\tau; 0 \le \tau \le t\}$, $\{\mathcal{F}_{0,t}^w; t \in [0,T]\}$ denotes that of $\sigma\{w_\tau; 0 \le \tau \le t\}$, and $\mathcal{F}^{x(0)} = \sigma\{x(0)\}$;
2. The measure-valued process $q_t(\Phi) = \mathrm{E}[\Phi(x_t)\Lambda_{0,t}|\mathcal{F}_{0,t}^y]$ is well defined.

The problem of least-squares filtering is concerned with estimating the conditional mean of x_t given the past and present measurements, i.e., $\mathcal{F}_{0,t}^y$. Thus, the least-squares filtering can be cast in terms of computing conditional expectations $\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y]$.

Lemma 2.4.

1. *A version of Bayes's formula yields*

$$\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y] = \frac{\mathrm{E}[\Phi(x_t)\frac{d\widetilde{P}}{dP}|\mathcal{F}_{0,t}^y]}{\mathrm{E}[\frac{d\widetilde{P}}{dP}|\mathcal{F}_{0,t}^y]} = \frac{q_t(\Phi)}{q_t(1)}. \tag{2.10}$$

2. *If the measure-valued process $q_t(\Phi)$ has an $\mathcal{F}_{0,t}^y$-measurable density function $q : \mathbb{R}^n \times [0,T] \times \Omega \to \mathbb{R}$, then*

$$\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y] = \frac{\int_{\mathbb{R}^n} \Phi(z) q(z,t) dz}{\int_{\mathbb{R}^n} q(z,t) dz}. \tag{2.11}$$

Proof. 1. A version of Bayes' rule yields the equality in (2.10).

2. The proof follows from the existence of the density $q(\cdot)$. □

The existence of the density $q(x,t)$ will follow from the existence and uniqueness of solutions of SPDEs [8, 9, 10], as it will be shown shortly.

We now derive an evolution equation for $q(\cdot)$. Note that $\{\Lambda_{0,t}; t \in [0,T]\}$ is a solution of the stochastic differential equation

$$\Lambda_{0,t} = 1 + \int_0^t \Lambda_{0,s} h'(s,x_s) C_s^{-1} dy_s. \tag{2.12}$$

THEOREM 2.5. *The unnormalized density of the conditional distribution* $\widetilde{P}(x_t \in A|\mathcal{F}_{0,t}^y), A \in \mathcal{B}(\mathbb{R}^n)$ *is* $q(\cdot)$ *and satisfies the SPDE*

$$dq(z,t) = A(t)^* q(z,t)dt + B(t)^* q(z,t)dy_t, \qquad (z,t) \in (0,T] \times \mathbb{R}^n, \tag{2.13}$$

$$q(z,0) = p_0(z), \qquad z \in \mathbb{R}^n, \tag{2.14}$$

where

$$A(t)^*\Phi(x) = \frac{1}{2}\sum_{i,j=1}^n \left(\frac{\partial^2}{\partial x_i \partial x_j} \left((\sigma(t,x)\sigma'(t,x))_{i,j} \Phi(x) \right) \right) - \sum_{i=1}^n \frac{\partial}{\partial x_i}\big(f_i(t,x)\Phi(x)\big), \tag{2.15}$$

$$B_k(t)^*\Phi(x) = \sum_{i=1}^d \left(C_t^{-1}\right)_{i,k} h_i(t,x)\Phi(x) - \sum_{i=1}^n \frac{\partial}{\partial x_i}\left(\left(\sigma(t,x)\alpha_t' C_t^{-1}\right)_{i,k}\Phi(x)\right). \tag{2.16}$$

Proof. Recall that under $P, \{x_t, y_t; t \in [0,T]\}$ are solutions of (2.1), (2.2). Define

$$D_t \doteq I_m - \alpha_t' C_t^{-1} \alpha_t, \tag{2.17}$$

and introduce

$$\widetilde{y}_t = \int_0^t C_s^{-1/2} dy_s, \qquad \widetilde{w}_t = \int_0^t D_s^{-1/2}(dw_s - \alpha_s' C_s^{-1} dy_s). \tag{2.18}$$

Substituting into (2.1) we have

$$\begin{aligned} dx_t = {} & \big(f(t,x_t) - \sigma(t,x_t)\alpha_t' C_t^{-1} h(t,x_t)\big)dt + \sigma(t,x_t) D_t^{1/2} d\widetilde{w}_t \\ & + \sigma(t,x_t)\alpha_t' C_t^{-1/2} d\widetilde{y}_t, \qquad x(0) \in \mathbb{R}^n. \end{aligned} \tag{2.19}$$

Moreover, $\{\widetilde{y}_t; t \in [0,T]\}$ and $\{\widetilde{w}_t; t \in [0,T]\}$ are independent standard Wiener processes, and $\mathcal{F}_{0,t}^y = \widetilde{\mathcal{F}}_{0,t}^y$; that is, no information is gained or lost. By (2.12), (2.18) we deduce

$$\Lambda_{0,t} = 1 + \int_0^t \Lambda_{0,s} h'(s,x_s) C_s^{-1/2} d\widetilde{y}_s. \tag{2.20}$$

By the Itô product rule

$$\begin{aligned} \Phi(x_t)\Lambda_{0,t} = {} & \Phi(x(0)) + \int_0^t \Phi(x_s) d\Lambda_{0,s} + \int_0^t d\Phi(x_s)\Lambda_{0,s} \\ & + \int_0^t d\langle \Phi(x), \Lambda \rangle_s. \end{aligned} \tag{2.21}$$

Since

$$\begin{aligned}\Phi(x_t) &= \Phi(x(0)) + \frac{1}{2}\int_0^t \mathrm{Tr}\big(\sigma(s,x_s)D_s'\sigma'(s,x_s)D_x^2\Phi(x_s)\big)ds \\ &\quad + \frac{1}{2}\mathrm{Tr}\big(\sigma(s,x_s)\alpha_s'C_s^{-1}\alpha_s\sigma'(s,x_s)D_x^2\Phi(x_s)\big)ds \\ &\quad + \int_0^t D_x'\Phi(x_s)\big(f(s,x_s) - \sigma(s,x_s)\alpha_s'C_s^{-1}h(s,x_s)\big)ds \\ &\quad + \int_0^t D_x'\Phi(x_s)\sigma(s,x_s)D_s^{1/2}d\widetilde{w}_s + \int_0^t D_x'\Phi(x_s)\sigma(s,x_s)\alpha_s'C_s^{-1/2}d\widetilde{y}_s, \\ \langle\Phi(x),\Lambda\rangle_t &= \int_0^t \Lambda_{0,s}D_x'\Phi(x_s)\sigma(s,x_s)\alpha_s'C_s^{-1}h(s,x_s)ds,\end{aligned}$$

substituting into (2.21) we have

$$\begin{aligned}\Phi(x_t)\Lambda_{0,t} &= \Phi(x(0)) + \frac{1}{2}\int_0^t \Lambda_{0,s}\mathrm{Tr}\big(\sigma(s,x_s)D_s\sigma'(s,x_s)D_x^2\Phi(x_s)\big)ds \\ &\quad + \frac{1}{2}\int_0^t \Lambda_{0,s}\mathrm{Tr}\big(\sigma(s,x_s)\alpha_s'C_s^{-1}\alpha_s\sigma'(s,x_s)D_x^2\Phi(x_s)\big)ds \\ &\quad + \int_0^t \Lambda_{0,s}D_x'\Phi(x_s)\big(f(s,x_s) - \sigma(s,x_s)\alpha_s'C_s^{-1}h(s,x_s)\big)ds \\ &\quad + \int_0^t \Lambda_{0,s}D_x'\Phi(x_s)\sigma(s,x_s)D_s^{1/2}d\widetilde{w}_s + \int_0^t \Lambda_{0,s}\Phi(x_s)h'(s,x_s)C_s^{-1/2}d\widetilde{y}_s \\ &\quad + \int_0^t \Lambda_{0,s}D_x'\Phi(x_s)\sigma(s,x_s)\alpha_s'C_s^{1/2}d\widetilde{y}_s \\ &\quad + \int_0^t \Lambda_{0,s}D_x'\Phi(x_s)\sigma(s,x_s)\alpha_s'C_s^{-1}h(s,x_s)ds.\end{aligned} \tag{2.22}$$

Conditioning each side of (2.22) on $\mathcal{F}_{0,t}^y$ and then using the mutual independence of $x(0), \{\widetilde{w}_t; t \in [0,T]\}, \{\widetilde{y}_t; t \in [0,T]\}$ (see [11]) and a version of Fubinis theorem [7, 12], we conclude that

$$q_t(\Phi) = q_0(\Phi) + \int_0^t q_s(A(s)\Phi(x))ds + \int_0^t q_s(B(s)\Phi(x))C_s^{-1/2}d\widetilde{y}_s. \tag{2.23}$$

Integrating each term by parts and then substituting $\widetilde{y}_t = \int_0^t C_s^{-1/2}dy_s$ we obtain (2.13), (2.14). □

Next, we employ certain results of variational methods of partial differential equations to show existence and uniqueness of solutions to (2.13) and (2.14).

Introduce the space $H(\mathbb{R}^n) = L^2(\mathbb{R})$ and the Sobolev space $H^1(\mathbb{R}^n)$ defined by

$$H^1(\mathbb{R}^n) = \left\{u \in L^2(\mathbb{R}^n),\ \frac{\partial}{\partial x_i}u \in L^2(\mathbb{R}^n), 1 \le i \le n\right\}.$$

Furnish $H(\mathbb{R}^n), H^1(\mathbb{R}^n)$ with the norm topologies

$$\|u\|_H = \int_{\mathbb{R}^n} |u|^2 dx,\ u \in H(\mathbb{R}^n),$$

$$\|u\|_{H^1} = \left\{\int_{\mathbb{R}^n} |u|^2 dx + \sum_{i=1}^n \int \left|\frac{\partial}{\partial x_i}u\right|^2 dx\right\}^{1/2},\ u \in H^1(\mathbb{R}^n).$$

$H(\mathbb{R}^n)$ and $H^1(\mathbb{R}^n)$ are Hilbert spaces with scalar products defined by

$$(\phi,\psi)_H = \int_{\mathbb{R}^n} \phi\psi dx,\ \phi,\psi \in H(\mathbb{R}^n),$$
$$(\phi,\psi)_{H^1} = \int_{\mathbb{R}^n} \phi\psi dx + \sum_{i=1}^n \int \frac{\partial\phi}{\partial x_i}\frac{\partial\psi}{\partial x_i}dx = (\phi,\psi)_{L^2(\mathbb{R}^n)} + \sum_{i=1}^n \left(\frac{\partial\phi}{\partial x_i}, \frac{\partial\psi}{\partial x_i}\right)_{L^2(\mathbb{R}^n)},\ \phi,\psi \in H^1(\mathbb{R}^n).$$

Let $H^{-1}(\mathbb{R}^n)$ denote the dual of $H^1(\mathbb{R}^n)$ (the space of continuous linear functionals on $H^1(\mathbb{R}^n)$). The norm of elements of $H^{-1}(\mathbb{R}^n)$ is denoted by $\|\cdot\|_*$, and the duality between $H^1(\mathbb{R}^n)$ and $H^{-1}(\mathbb{R}^n)$ is denoted by $\langle\cdot,\cdot\rangle$.

Let

$$B(\cdot)^*u = \begin{bmatrix} B_1(\cdot)^*u \\ \vdots \\ B_d(\cdot)^*u \end{bmatrix},\ u \in H^1(\mathbb{R}^n),$$

and write the adjoint operators of $A(\cdot)^*$ and $B(\cdot)^*$ as

$$\langle u, A(t)^*v\rangle = \langle\ A(t)u, v\rangle = -\frac{1}{2}\sum_{i,j=1}^n \left(a_{i,j}(t,\cdot)\frac{\partial}{\partial x_i}u, \frac{\partial}{\partial x_j}v\right)_{L^2(\mathbb{R}^n)} + \sum_{i=1}^n \left(\tilde{f}_i(t,\cdot)\frac{\partial}{\partial x_i}u, v\right)_{L^2(\mathbb{R}^n)}, \qquad u,v \in H^1(\mathbb{R}^n),$$

where

$$\tilde{f}_i(t,x) = f_i(t,x) - \frac{1}{2}\sum_{j=1}^n \frac{\partial}{\partial x_j}a_{i,j}(t,x)$$

$$\langle u, B(t)^*v\rangle = \langle\ B(t)u, v\rangle = \sum_{i,k=1}^d ((C_t^{-1})_{i,k}h_i(t,\cdot)u, v)_{L^2(\mathbb{R}^n)} + \sum_{k=1}^d\sum_{i=1}^n \left((\sigma(t,\cdot)\alpha_t'C_t^{-1})_{i,k}\frac{\partial}{\partial x_i}u, v\right)_{L^2(\mathbb{R}^n)}, \qquad u,v \in H^1(\mathbb{R}^n).$$

In view of Assumption 2.2, statements 1, 2, 3, and 5, it can be shown that

$$\begin{aligned} &A(\cdot), A(\cdot)^* \in L^\infty((0,T);\mathcal{L}(H^1(\mathbb{R}^n);H^{-1}(\mathbb{R}^n))),\\ &B(\cdot), B(\cdot)^* \in L^\infty((0,T);\mathcal{L}(H^1(\mathbb{R}^n);(L^2(\mathbb{R}^n))^d)). \end{aligned} \tag{2.24}$$

Moreover, $A(t) \in \mathcal{L}(H^1(\mathbb{R}^n);H^{-1}(\mathbb{R}^n))$, $B(t) \in \mathcal{L}(H^1(\mathbb{R}^n);(L^2(\mathbb{R}^n))^d$ satisfy the following coercivity condition. There exist $\lambda_1,\lambda_2 > 0$ such that

$$-2\langle A(t)u,u\rangle + \lambda_1\|u\|^2_{L^2(\mathbb{R}^n)} \geq \lambda_2\|u\|^2_{H^1(\mathbb{R}^n)} + \|Bu\|^2_{(L^2(\mathbb{R}^n))^d}\ \forall u \in H^1(\mathbb{R}^n),\ \forall t \in [0,T]. \tag{2.25}$$

Define the space

$$L_y^2((0,T);H^1) \doteq \{u \in L^2(\Omega,\mathcal{F},P;\ L^2((0,T);H^1);\ a.e.\ on\ [0,T],\ u(t) \in L^2(\Omega,\mathcal{F}_{0,t}^y,P;H^1)\}.$$

LEMMA 2.6. *There exists one and only one solution* $q(\cdot)$ *of* (2.13), (2.14) *in the space*

$$q(\cdot) \in L_y^2((0,T);H^1) \cap L^2(\Omega,\mathcal{F},P;C((0,T);H)).$$

Proof. Assumption 2.2 statements 1, 2, 3, and 5 imply the coercivity condition (2.25), which is then employed to show existence and uniqueness of solutions to (2.13), (2.14) (see [8, 9, 10]). □

The next tool employed in subsequent sections is the concept of fundamental solutions to stochastic differential equations.

DEFINITION 2.7. *A fundamental solution of* (2.13), (2.14) *is an* $\mathcal{F}_{0,t}^y$*-measurable function* $q(z,t;x,s)$, *with* $(z,x) \in \mathbb{R}^n \times \mathbb{R}^n, 0 \le s < t \le T$, *such that the following hold:*

1. $q(\cdot,\cdot;x,s)$ *is a solution of*

(2.26)
$$dq(z,t;x,s) = A(t)^* q(z,t;x,s)dt + B(t)^* q(z,t;x,s)dy_t, \quad 0 < s < t \le T,$$

(2.27)
$$\lim_{t \downarrow s} q(z,t;x,s) = \delta(z-x).$$

2. *For fixed* $(s,x) \in (0,t) \times \mathbb{R}^n$, $q(\cdot,t;x,s) \in C_z^2(\mathbb{R}^n)$.
3. *For* $\varphi : \mathbb{R}^n \to \mathbb{R}$, *which is continuous with compact support,*

$$\lim_{t \downarrow s} \int_{-\infty}^{\infty} q(z,t;x,s)\varphi(x)dx = \varphi(z). \tag{2.28}$$

That is, $\lim_{t \downarrow s} q(z,t;x,s) = \delta(z-x)$ *is a Dirac delta function.*

Unfortunately, Assumption 2.2 is too weak to imply that $q(\cdot,t;x,s) \in C_z^2(\mathbb{R}^n)$. However, if there is no correlation between the state noise and the observation noise (e.g., $\alpha_t = 0\ \forall t \in [0,T]$), and we impose additional smoothness and continuity conditions on (f,σ,h), then by considering the pathwise version of (2.13), (2.14), it can be shown that for each $y \in C([0,T];\mathbb{R}^d)$ there exists a unique solution, which is a fundamental solution [13]. For the correlated case, we have the following result which is found in [9, 10] (see also [14] for alternative conditions).

THEOREM 2.8. *Suppose the coefficient of* A *and* B_k, $k = 1,\dots,d$ *have bounded partial derivatives in* x *of any order. Then*

1. $\{q(z,t;x,s); 0 \le s < t \le T\}$, $(z,x) \in \mathbb{R}^n \times \mathbb{R}^n$, *is a unique fundamental solution of the unnormalized condition density equation* (2.13), (2.14), *and* $q(\cdot,t;x,s) \in C_b^\infty(\mathbb{R}^n)$, $P-a.s. \forall t \in (s,T]$.

2. *A version of the conditional distribution* $\widetilde{P}(x_t \in A|\mathcal{F}_{0,t}^y), A \in \mathcal{B}(\mathbb{R}^n)$, *is*

$$\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y] = \frac{q_t(\Phi)}{q_t(1)} = \frac{\int_{\mathbb{R}^n \times \mathbb{R}^n} \Phi(z)q(z,t;x,0)p_0(x)dxdz}{\int_{\mathbb{R}^n \times \mathbb{R}^n} q(z,t;x,0)p_0(x)dxdz}. \tag{2.29}$$

Proof. 1. This is shown in [10, pp. 227–228].
2. Let $q(z,t;x,s)$ be a solution of (2.26), (2.27); set $\widetilde{q}(z,t) = \int_{\mathbb{R}^n} q(z,t;x,0)p_0(x)dx$. Then

$$\begin{aligned} d\widetilde{q}(z,t) &= \int_{\mathbb{R}^n} dq(z,t;x,0)p_0(x)dx \\ &= \int_{\mathbb{R}^n} A(t)^* q(z,t;x,0)p_0(x)dxdt + \int_{\mathbb{R}^n} B(t)^* q(z,t;x,0)p_0 dx dy_t \\ &= A(t)^*\widetilde{q}(z,t)dt + B(t)^*\widetilde{q}(z,t)dy_t. \end{aligned}$$

This shows that $\widetilde{q}(z,t)$ satisfies (2.13) for $(z,t) \in \mathbb{R}^n \times (0,T]$. Since $\lim_{t\downarrow 0} \widetilde{q}(z,t) = \lim_{t\downarrow 0} \int_{\mathbb{R}^n} q(z,t;x,0)p_0(x)dx = p_0(z)$, we also have (2.14). By Lemma 2.4 we establish (2.29). □

DEFINITION 2.9. *Let $f^1 : [0,T] \times \mathbb{R}^n \to \mathbb{R}, f^2 : [0,T] \times \mathbb{R}^n \to (\mathbb{R}^n)', f^3 : [0,T] \times \mathbb{R}^n \to (\mathbb{R}^d)'$ be Borel measurable and bounded functions.*

1. *The integrals*

$$\begin{aligned} L^{\kappa,1}_{0,t} &= \left(\int_0^t f^1(s,x_s)ds\right)^\kappa, \quad L^{\kappa,2}_{0,t} = \left(\int_0^t f^2(s,x_s)dw_s\right)^\kappa, \\ L^{\kappa,3}_{0,t} &= \left(\int_0^t f^3(s,x_s)db_s\right)^\kappa, \qquad \kappa \geq 1, \end{aligned} \tag{2.30}$$

are well defined.

2. *The measure-valued processes*

$$M^{\kappa,j}_t(\Phi) = \mathrm{E}[\Phi(x_t)\Lambda_{0,t}L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}], \qquad \kappa \geq 0, \quad j = 1,2,3, \tag{2.31}$$

are well defined.

We are interested in filtered estimates of κth moments ($\kappa \geq 1$) of integrals and stochastic integrals. That is, we wish to derive expressions for $\widetilde{\mathrm{E}}[L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}]$. An application of Bayes's theorem yields

$$\widetilde{\mathrm{E}}[L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}] = \frac{\mathrm{E}[\Lambda_{0,t}L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}]}{\mathrm{E}[\Lambda_{0,t}|\mathcal{F}^y_{0,t}]}, \qquad \kappa \geq 1, \quad j = 1,2,3. \tag{2.32}$$

3. Recursive equations. Here we prove that the filtered estimates (2.32) can be expressed in terms of the fundamental solution of the DMZ equation; namely, $q(z,t;x,s), 0 \leq s < t \leq T$, which satisfies (2.13), (2.14). This enables us to conclude that if $q(z,t;x,s)$ is a finite-dimensional statistic, then these filtered estimates can be described in terms of solutions of a finite-number of stochastic differential equations.

THEOREM 3.1. *Suppose $M^{\kappa,j}_t(\cdot)$ have $\mathcal{F}^y_{0,t}$-measurable density functions $M^{\kappa,j} : \mathbb{R}^n \times [0,T] \times \Omega \to \mathbb{R}, j = 1,2,3$.*

Then

$$M^{\kappa,j}(x,t)dx = \mathrm{E}[I_{x_t \in dx}\Lambda_{0,t}L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}], \qquad \kappa \geq 1, \quad j = 1,2,3, \tag{3.1}$$

satisfy the following recursive system of SPDEs:

$$
\begin{aligned}
dM^{\kappa,1}(x,t) &= A(t)^* M^{\kappa,1}(x,t)dt + B(t)^* M^{\kappa,1}(x,t)dy_t \\
&\quad + \kappa f^1(t,x) M^{k-1,1}(x,t)dt, \qquad \kappa \geq 1, \quad (t,x) \,\epsilon\, (0,T] \times \mathbb{R}^n, \qquad (3.2)\\
dM^{\kappa,2}(x,t) &= A(t)^* M^{\kappa,2}(x,t)dt + B(t)^* M^{\kappa,2}(x,t)dy_t \\
&\quad + \frac{1}{2}\kappa(\kappa-1)|f^{2,\prime}(t,x)|^2 M^{\kappa-2,2}(x,t)dt \\
&\quad - \kappa \sum_{i=1}^{n} \frac{\partial}{\partial x_i}\left(M^{\kappa-1,2}(x,t)\left(\sigma(t,x) f^{2,\prime}(x,t)\right)_i\right) dt \\
&\quad + \kappa f^2(t,x) M^{\kappa-1,2}(x,t)\alpha_t' C_t^{-1} dy_t, \qquad \kappa \geq 1, \quad (t,x) \,\epsilon\, (0,T] \times \mathbb{R}^n, \qquad (3.3)\\
dM^{\kappa,3}(x,t) &= A(t)^* M^{\kappa,3}(x,t)dt + B(t)^* M^{\kappa,3}(x,t)dy_t \\
&\quad + \frac{1}{2}\kappa(k-1)|C^{1/2} N^{-1/2} f^{3,\prime}(t,x)|^2 M^{\kappa-2,3}(x,t)dt \\
&\quad + \kappa f^3(t,x) M^{\kappa-1,3}(x,t) N^{1/2} C^{-1} dy_t, \qquad \kappa \geq 1, \quad (t,x) \,\epsilon\, (0,T] \times \mathbb{R}^n, \qquad (3.4)
\end{aligned}
$$

where the convention $M^{p,j}(x,t) = 0$ *for* $p < 0$ *is used. The initial conditions are*

$$M^{\kappa,j}(x,0) = 0, \qquad \kappa \geq 1, \quad j = 1,2,3, \tag{3.5}$$

and for $\kappa = 0$

$$M^{0,j}(x,t) = q(x,t), \qquad j = 1,2,3. \tag{3.6}$$

Proof. We shall use induction. Consider (3.2). Now, the case $\kappa = 1$ is easily verified, so it is omitted. Suppose (3.2) holds for $\kappa \to k-1$. We shall show that it also holds for κ. To this end, consider $\Phi(x_t)\Lambda_{0,t} L_{0,t}^{\kappa,1}$, where $\{x_t; t \,\epsilon\, [0,T]\}$ and $\{\Lambda_{0,t}; t \,\epsilon\, [0,T]\}$ are solutions of (2.19), (2.20), respectively. By the Itô product rule

$$L_{0,t}^{\kappa,1} = \kappa \int_0^t L_{0,s}^{\kappa-1,1} f^1(s,x_s)ds, \qquad \kappa \geq 1. \tag{3.7}$$

Employing the Itô product rule once again, we have

$$
\begin{aligned}
\Phi(x_t)\Lambda_{0,t} L_{0,t}^{\kappa,1} &= \int_0^t \Phi(x_s) d(\Lambda_{0,s} L_s^{\kappa,1}) + \int_0^t d\Phi(x_s)\Lambda_{0,s} L_{0,s}^{\kappa,1} \\
&\quad + \int_0^t \langle \Phi(x), \Lambda L^{\kappa,1}\rangle_s. \qquad (3.8)
\end{aligned}
$$

Now, from (3.7), (2.20) we compute

$$
\begin{aligned}
\Lambda_{0,t} L_{0,t}^{\kappa,1} &= \int_0^t \Lambda_{0,s} dL_{0,s}^{\kappa,1} + \int_0^t L_{0,s}^{\kappa,1} d\Lambda_{0,s} + \int_0^t d\langle \Lambda, L^{\kappa,1}\rangle_t \\
&= \kappa \int_0^t f^1(s,x_s)\Lambda_{0,s} L_{0,s}^{\kappa-1,1} ds + \int_0^t \Lambda_{0,s} L_{0,s}^{\kappa,1} h'(s,x_s) C_s^{-1/2} d\widetilde{y}_s. \qquad (3.9)
\end{aligned}
$$

Substituting (3.9) into (3.8) and then proceeding as in the derivation of Theorem

2.5, we obtain

$$\begin{aligned}\Phi(x_s)\Lambda_{0,t}L^{\kappa,1}_{0,t} &= \frac{1}{2}\int_0^t \Lambda_{0,s}L^{\kappa,1}_{0,s}\mathrm{Tr}\left(\sigma(s,x_s)\sigma'(s,x_s)D^2_x\Phi(x_s)\right)ds \\ &+ \int_0^t \Lambda_{0,s}L^{\kappa,1}_{0,s}D'_x\Phi(x_s)\sigma(s,x_s)D^{1/2}_s d\widetilde{w}_s \\ &+ \int_0^t \Lambda_{0,s}L^{\kappa,1}_{0,s}\Phi(x_s)h'(s,x_s)C^{-1/2}_s d\widetilde{y}_s \\ &+ \int_0^t \Lambda_{0,s}L^{\kappa,1}_{0,s}D'_x\Phi(x_s)\sigma(s,x_s)\alpha'_sC^{1/2}_s d\widetilde{y}_s + \kappa\int_0^t \Lambda_{0,s}L^{\kappa-1,1}_{0,s}f^1(s,x_s)ds. \end{aligned} \tag{3.10}$$

Conditioning each side of (3.10) on $\mathcal{F}^y_{0,t}$ using (3.1), and then integrating by parts, we deduce (3.2). When $\kappa = 0, j = 1$, we have $M^{0,1}(x,t)dx = \mathrm{E}[I_{x_t\epsilon dx}\Lambda_{0,t}|\mathcal{F}^y_{0,t}]$, and thus $M^{0,1}(x,t)$ satisfies the DMZ equation.

The derivation (3.3) is done similarly; therefore we shall outline only the important steps. Under measure P,

$$L^{\kappa,2}_{0,t} = \left[\int_0^t f^2(s,x_s)(dw_s - \alpha'_sC^{-1}_s h(s,x_s)ds)\right]^\kappa. \tag{3.11}$$

Substituting $w_t = \int_0^t D^{1/2}_s d\widetilde{w}_s + \int_0^t \alpha'_sC^{-1/2}_s d\widetilde{y}_s$ into (3.11),

$$L^{\kappa,2}_{0,t} = \left[\int_0^t f^2(s,x_s)(D^{1/2}_s d\widetilde{w}_s + \alpha'_sC^{-1/2}_s d\widetilde{y}_s - \alpha'_sC^{-1}_s h(s,x_s)ds)\right]^\kappa. \tag{3.12}$$

By the Itô product rule

$$\begin{aligned} L^{\kappa,2}_{0,t} &= \kappa\int_0^t L^{k-1,2}_{0,s}f^2(s,x_s)(D^{1/2}_s d\widetilde{w}_s + \alpha'_sC^{-1/2}_s d\widetilde{y}_s - \alpha'_sC^{-1}_s h(s,x_s)ds) \\ &+ \frac{1}{2}\kappa(k-1)\int_0^t L^{k-2,2}_{0,s}f^2(s,x_s)D^{1/2}_s D^{1/2,\prime}_s f^{2,\prime}(s,x_s)ds \\ &+ \frac{1}{2}\kappa(k-1)\int_0^t L^{k-2,2}_{0,s}f^2(s,x_s)\alpha'_sC^{-1}_s\alpha_s f^{2,\prime}(s,x_s)ds. \end{aligned} \tag{3.13}$$

Employing the Itô product rule to $\Phi(x_t)\Lambda_{0,t}L^{\kappa,2}_{0,t}$, as in (3.9), (3.10), and then invoking $M^{\kappa,2}(z,t)dx = \mathrm{E}[I_{x_t\epsilon dx}\Lambda_{0,t}L^{\kappa,2}_{0,t}|\mathcal{F}^y_{0,t}]$, after some algebra we derive (3.3), and (3.5) for $j = 2, \kappa \geq 2$. The special case $\kappa = 1, 2$ is done similarly. Also, to derive (3.4), we start with

$$L^{\kappa,3}_{0,t} = \left[\int_0^t f^3(s,x_s)\left(db_s - N^{1/2}_s C^{-1}_s h(s,x_s)ds\right)\right]^\kappa, \tag{3.14}$$

which is defined under measure P, and then we follow the above procedure to obtain (3.4), and (3.5), for $j = 3$. □

Next, we establish existence and uniqueness of the moment processes $M^{\kappa,j}(\cdot), \kappa \geq 1, j = 1, 2, 3$, using the variational methods of SPDEs, similar to Theorem 3.1.

Clearly, (3.2)–(3.4) with their corresponding boundary conditions (3.5), (3.6) are

of the general form

$$M(x,t) = \int_0^t A(s)^* M(x,s)ds + \int_0^t B(s)^* M(x,s)dy_s + \int_0^t \psi(s)ds + \int_0^t \phi(s)dy_s + \int_0^t \eta(s)ds, \tag{3.15}$$

where $\eta(t) \in L_y^2((0,T);H^1), \psi(t) \in L_y^2((0,T);H^{-1}), \phi(t) \in L_y^2((0,T);(L^2(\mathbb{R}^n))^d)$. For example, the fourth right side term of (3.3) belongs to $L_y^2((0,T);(L^2(\mathbb{R}^n))^d)$. Therefore, for finite κ, an application of variational methods of SPDEs (see [8, 9, 10]) implies there exists one and only one solution to (3.15) in the space $M(\cdot) \in L_y^2((0,T);H^1) \cap L_y^2(\Omega,\mathcal{F},P;C((0,T);H))$. Consequently, the moment processes of Theorem 3.1 have unique solutions as well.

Notice that the filtered estimates for $L_{0,t}^{\kappa,j}, \kappa \geq 1, j = 1,2,3$, can be computed from

$$\widetilde{\mathrm{E}}[L_{0,t}^{\kappa,j}|\mathcal{F}_{0,t}^y] = \frac{\int_{\mathbb{R}^n} M^{\kappa,j}(z,t)dz}{\int_{\mathbb{R}^n} q(z,t)dz}, \quad \kappa \geq 1, \quad j = 1,2,3. \tag{3.16}$$

Clearly, if the fundamental solution of the DMZ equation $q(t,t;x,s)$ is finite-dimensional, then according to Lemma 3.2, (3.16) can be computed explicitly in terms of finite numbers of statistics.

LEMMA 3.2. *Suppose the coefficients of $A, B_k,\ k = 1,\ldots,d$, and $f^j,\ 1 \leq j \leq 3$, have bounded partial derivatives in x of any order. Then $M_t^{\kappa,j}(\cdot)$ have $\mathcal{F}_{0,t}^y$-measurable density functions given by*

$$M^{\kappa,1}(z,t) = \kappa \int_0^t \int_{\mathbb{R}^n} f^1(s,x) M^{\kappa-1,1}(x,s) q(z,t;x,s)dxds, \qquad \kappa \geq 1, \tag{3.17}$$

$$\begin{aligned} M^{\kappa,2}(z,t) &= \frac{1}{2}\kappa(\kappa-1)\int_0^t \int_{\mathbb{R}^n} |f^2(s,x)|^2 M^{k-2,2}(x,s) q(z,t;x,s)dxds \\ &\quad - \kappa \int_0^t \int_{\mathbb{R}^n} \sum_{i=1}^n \frac{\partial}{\partial x_i}\left(M^{k-1,2}(x,s)\left(\sigma(s,x)f^{2,\prime}(s,x)\right)_i\right) q(z,t;x,s)dxds \\ &\quad + \kappa \int_0^t \int_{\mathbb{R}^n} f^2(s,x) M^{k-1,2}(x,s)\alpha_s' C_s^{-1} q(z,t;x,s)dxdy_s, \qquad \kappa \geq 1, \end{aligned} \tag{3.18}$$

$$\begin{aligned} M^{\kappa,3}(z,t) &= \frac{1}{2}\kappa(k-1)\int_0^t \int_{\mathbb{R}^n} |C_s^{1/2} N_s^{-1/2} f^3(s,x)|^2 M^{k-2,3}(x,s) q(z,t;x,s)dxds \\ &\quad + \kappa \int_0^t \int_{\mathbb{R}^n} f^3(s,x) M^{k-1,3}(x,s) N^{1/2} C_s^{-1} q(z,t;x,s) C_s^{-1} dxdy_s, \qquad \kappa \geq 1, \end{aligned} \tag{3.19}$$

with the convention $M^{p,j}(x,t) = 0$ for $p < 0$, $j = 1,2,3$.

Proof. Theorem 2.8 establishes the existence and uniqueness of a fundamental solution to the DMZ equation. Let $\widehat{M}^{\kappa,1}(z,t)$ denote the right side of (3.17). For $\kappa = 1$, we have

$$\widehat{M}^{1,1}(z,t) = \int_0^t \int_{\mathbb{R}^n} f^1(x,s) q(x,s) q(z,t;x,s)dxds,$$

because $M^{0,1}(\cdot,\cdot) = q(\cdot,\cdot)$. Then

$$\begin{aligned} d\widehat{M}^{1,1}(z,t) &= f^1(t,z)q(z,t)dt + \int_0^t \int_{\mathbb{R}^n} f^1(s,x)q(x,s)dq(z,t;x,s)dxds \\ &= f^1(t,z)q(z,t)dt + A(t)^* \int_0^t \int_{\mathbb{R}^n} f^1(s,x)q(x,s)q(z,t;x,s)dxdsdt \\ &+ B(t)^* \int_0^t \int_{\mathbb{R}^n} f^1(s,x)q(x,s)q(z,t)dxdsdy_t \\ &= A(t)^*\widehat{M}^{1,1}(z,t)dt + B(t)^*\widehat{M}^{1,1}(z,t)dy_t + f^1(t,z)q(z,t)dt. \end{aligned}$$

Thus, $\widehat{M}^{1,1}(\cdot,\cdot)$ satisfies (3.2); for $t = 0, \widehat{M}^{1,1}(z,0)$, and so (3.17) holds for $\kappa = 1$. Let

$$\widehat{M}^{\kappa,1}(z,t) = \kappa \int_0^t \int_{\mathbb{R}^n} f^1(s,x)\widehat{M}^{k-1,1}(x,s)q(z,t;x,s)dxds \tag{3.20}$$

and assume it satisfies (3.2) for $(t,z)\ \epsilon\ (0,T]\times\mathbb{R}^n$, and (3.5) for $t = 0$. We shall show that

$$\widehat{M}^{k+1,1}(z,t) = (k+1) \int_0^t \int_{\mathbb{R}^n} f^1(s,x)\widehat{M}^{k,1}(x,s)q(z,t;x,s)dxds \tag{3.21}$$

satisfies (3.2), with $k \to k+1$, for $(t,z)\ \epsilon\ (0,T]\times\mathbb{R}^n$. Clearly, $\widehat{M}^{k+1,1}(z,0) = 0$, so (3.5) holds (with $j = 1$). Now,

$$\begin{aligned} d\widehat{M}^{k+1,1}(z,t) &= (k+1)f^1(t,z)\widehat{M}^{k,1}(z,t)dt \\ &\quad + (k+1)\int_0^t \int_{\mathbb{R}^n} f^1(s,x)\widehat{M}^{k,1}(x,s)dq(z,t;x,s)dxds \\ &= (k+1)f^1(t,z)\widehat{M}^{k,1}(z,t)dt \\ &+ (k+1)A^*(t)\int_0^t \int_{\mathbb{R}^n} f^1(s,x)\widehat{M}^{k,1}(x,s)q(z,t;x,s)dxds \\ &+ (k+1)B(t)^*\int_0^t \int_{\mathbb{R}^n} f^1(s,x)\widehat{M}^{k,1}(x,s)q(z,t;x,s)dxdy_s \\ &= (k+1)f^1(t,z)\widehat{M}^{k,1}(z,t)dt + A^*(t)\widehat{M}^{k+1,1}(z,t)dt + B(t)^*\widehat{M}^{k+1,1}(z,t)dy_t. \end{aligned}$$

Hence (3.17) satisfies (3.2), (3.5) with $k \to k+1$. Similarly, one may use induction to verify the representations (3.18), (3.19). □

Next, we introduce an example to demonstrate the computations described in (3.17).

3.1. Specific application. Consider the system

$$\begin{aligned} dx_t &= Fx_t dt + Gdw_t, \qquad x(0)\ \epsilon\ \mathbb{R}^n, \\ dy_t &= Hx_t + N^{\frac{1}{2}}db_t, \qquad y(0) = 0\ \epsilon\ \mathbb{R}^d. \end{aligned}$$

The random variable $x(0)$ is Gaussian. Although the above linear system does not satisfy Assumption 2.2, statements 1, 2, 3, and 5, the fundamental solution of the DMZ equation exists, and it is given by

$$q(z,t;x,s) = \frac{1}{(2\pi)^{n/2}|P_{s,t}|^{1/2}} \exp\left(-\frac{1}{2}|P_{s,t}^{-1/2}(z - r_{s,t}(x))|^2\right) \times \Lambda_{s,t}(x), \tag{3.22}$$

$$dr_{s,t}(x) = \big(F - P_{s,t}H'N^{-1}H\big)r_{s,t}(x)dt + P_{s,t}H'N^{-1}dy_t, \quad r_{s,s}(x) = x, \tag{3.23}$$

$$\dot{P}_{s,t} = FP_{s,t} + P_{s,t}F' - P_{s,t}H'N^{-1}HP_{s,t} + GG', \quad P_{s,s} = 0, \tag{3.24}$$

$$\Lambda_{s,t}(x) = \exp\left(\int_s^t (Hr_{s,\tau})'N^{-1}dy_\tau - \frac{1}{2}\int_s^t |N_\tau^{-\frac{1}{2}}Hr_{s,\tau}(x)|^2 d\tau\right). \tag{3.25}$$

Let

$$r_{s,t}(x) = \Phi_{s,t}x + \beta_{s,t},$$

where

$$\dot{\Phi}_{s,t} = \big(F - P_{s,t}H'N^{-1}H\big)\Phi_{s,t}, \quad \Phi_{s,s} = I_n,$$

$$d\beta_{s,t} = \big(F - P_{s,t}H'N^{-1}H\big)\beta_{s,t}dt + P_{s,t}H'N^{-1}dy_t, \quad \beta_{s,s} = 0.$$

Then

$$\Lambda_{s,t}(x) = \gamma_{s,t}\exp\left(x'\rho_{s,t} - \frac{1}{2}x'S_{s,t}x\right),$$

where

$$\gamma_{s,t} = \exp\left(\int_s^t \beta'_{s,\tau}H'N^{-1}dy_\tau - \frac{1}{2}\int_s^t |N^{-1/2}H\beta_{s,\tau}|^2 d\tau\right),$$

$$S_{s,t} = \int_s^t \Phi'_{s,\tau}H'N^{-1}H\Phi_{s,\tau}d\tau,$$

$$\rho_{s,t} = \int_s^t \Phi'_{s,\tau}H'N^{-1}\big(dy_\tau - H\beta_{s,\tau}d\tau\big).$$

Moreover, the unnormalized conditional density of x_s given $\mathcal{F}_{0,s}^y$ is

$$q(x,s) = \frac{1}{(2\pi)^{n/2}|\Sigma_{0,s}|^{1/2}}\exp\left(-\frac{1}{2}|\Sigma_{0,s}^{-1/2}(x - \widehat{x}_{0,s})|^2\right) \times \widehat{\Lambda}_{0,s},$$

where $\widehat{x}_{0,s}$ is a solution of (3.23) with $\widehat{x}_{0,0} = \xi$, $\Sigma_{0,s}$ is a solution of (3.24) with $\Sigma_{0,0} = \Sigma_0$, and $\widehat{\Lambda}_{0,s}$ is given by (3.25) with $r \to \widehat{x}, P \to \Sigma$. Notice that

$$\int_{\mathbb{R}^n} q(x,s)q(z,t;x,s)dx = \frac{1}{(2\pi)^{n/2}|P_{s,t}|^{1/2}} \times \frac{1}{(2\pi)^{n/2}|\Sigma_{0,s}|^{1/2}} \times \widehat{\Lambda}_{0,s} \times \gamma_{s,t}$$
$$\times \int_{\mathbb{R}^n} \exp\left(-\frac{1}{2}|P_{s,t}^{-1/2}\big(z - \Phi_{s,t}x - \beta_{s,t}\big)|^2 - \frac{1}{2}|\Sigma_{0,s}^{-1/2}\big(x - \widehat{x}_{0,s}\big)|^2 + x'\rho_{s,t} - \frac{1}{2}x'S_{s,t}x\right)dx.$$

Therefore, the integral with respect to x is computed by completing the squares. Consequently, we deduce that $\tilde{E}\big[\int_0^t f(x_s)ds|\mathcal{F}_{0,t}^y\big]$ is finite-dimensional computable for large classes of functions $f(x)$ such as $f(x) = x^p, p \geq 1$, p an integer.

4. Conditional moment generating functions. Next we introduce moment generating functions for computing the conditional moments of integrals and stochastic integrals (2.32).

DEFINITION 4.1. *Let* $\theta = i\omega, i = \sqrt{-1}$.

1. *The measure-valued conditional moment generating functions of the stochastic processes* $\{L_{0,t}^{1,j}; t \in [0,T]\}, j = 1,2,3,$ *given by*

$$\widetilde{\beta}_t^{\theta,j}(\Phi) = \widetilde{\mathrm{E}}[\Phi(x_t) \exp\left(\theta L_{0,t}^{1,j}\right) | \mathcal{F}_{0,t}^y], \qquad j = 1,2,3, \tag{4.1}$$

are well defined.

2. *The measure-valued unnormalized conditional moment generating functions of the stochastic processes* $\{L_{0,t}^{1,j}; t \in [0,T]\}, j = 1,2,3,$ *given by*

$$\beta_t^{\theta,j}(\Phi) = \mathrm{E}[\Phi(x_t)\Lambda_{0,t} \exp\left(\theta L_{0,t}^{1,j}\right) | \mathcal{F}_{0,t}^y], \qquad j = 1,2,3, \tag{4.2}$$

are well defined.

LEMMA 4.2. *Suppose* $\beta_t^{\theta,j}(\cdot)$ *have* $\mathcal{F}_{0,t}^y$*-measurable density function* $\beta^{\theta,j} : \mathbb{R}^n \times [0,T] \times \Omega \to \mathbb{R}, j = 1,2,3.$

1. *Then*

$$\widetilde{\mathrm{E}}[\Phi(x_t) \exp\left(\theta L_{0,t}^{1,j}\right) | \mathcal{F}_{0,t}^y] = \frac{\beta_t^{\theta,j}(\Phi)}{q_t(1)} = \frac{\int_{\mathbb{R}^n} \Phi(z)\beta^{\theta,j}(z,t)dz}{\int_{\mathbb{R}^n} q(z,t)dz}, \qquad j = 1,2,3. \tag{4.3}$$

2. *The conditional characteristic functions of the stochastic processes* $\{L_{0,t}^{1,j}; t \in [0,T]\}, j = 1,2,3,$ *are given by*

$$\widetilde{\mathrm{E}}\left[\exp\left(i\omega L_{0,t}^{1,j}\right) | \mathcal{F}_{0,t}^y\right] = \frac{\beta_t^{i\omega,j}(1)}{q_t(1)} = \frac{\int_{\mathbb{R}^n} \beta^{i\omega,j}(z,t)dz}{\int_{\mathbb{R}^n} q(z,t)dz}, \quad j = 1,2,3. \tag{4.4}$$

Proof. The proof is similar to Lemma 2.4. □

THEOREM 4.3. *Suppose* $\beta_t^{\theta,j}(\cdot)$ *have* $\mathcal{F}_{0,t}^y$*-measurable density functions* $\beta^{\theta,j}(\cdot), j = 1,2,3.$

The densities of the measure-valued unnormalized conditional moment generating functions, namely,

$$\beta^{\theta,j}(x,t)dx = \mathrm{E}\left[I_{x_t \in dx}\Lambda_{0,t} \exp\left(\theta L_{0,t}^{1,j}\right) | \mathcal{F}_{0,t}^y\right], \qquad j = 1,2,3, \tag{4.5}$$

satisfy the following system of SPDEs:

$$\begin{aligned} d\beta^{\theta,1}(x,t) &= A(t)^*\beta^{\theta,1}(x,t)dt + B(t)^*\beta^{\theta,1}(x,t)dy_t \\ &\quad + \theta f^1(t,x)\beta^{\theta,1}(x,t)dt, \qquad (t,x) \in (0,T] \times \mathbb{R}^n, \end{aligned} \tag{4.6}$$

$$\begin{aligned} d\beta^{\theta,2}(x,t) &= A(t)^*\beta^{\theta,2}(x,t)dt + B(t)^*\beta^{\theta,2}(x,t)dy_t \\ &\quad + \frac{\theta^2}{2}|f^{2,\prime}(t,x)|^2\beta^{\theta,2}(x,t)dt - \theta\sum_{i=1}^n \frac{\partial}{\partial x_i}\left(\left(\sigma(t,x)f^{2,\prime}(x,t)\right)_i \beta^{\theta,2}(x,t)\right)dt \end{aligned}$$

$$+ \theta f^2(t,x)\beta^{\theta,2}(x,t)\alpha_t' C_t^{-1} dy_t, \qquad (t,x) \in (0,T] \times \mathbb{R}^n, \tag{4.7}$$

$$\begin{aligned} d\beta^{\theta,3}(x,t) &= A(t)^* \beta^{\theta,3}(x,t)dt + B(t)^* \beta^{\theta,3}(x,t)dy_t \\ &\quad + \frac{\theta^2}{2} |C^{1/2} N^{-1/2} f^{3,\prime}(t,x)|^2 \beta^{\theta,3}(x,t)dt \\ &\quad + \theta f^3(t,x)\beta^{\theta,3}(x,t) N^{1/2} C^{-1} dy_t, \qquad (t,x) \in (0,T] \times \mathbb{R}^n. \end{aligned} \tag{4.8}$$

The initial conditions are

$$\beta^{\theta,j}(x,0) = p_0(x), \qquad x \in \mathbb{R}^n, \qquad j = 1,2,3. \tag{4.9}$$

Proof. First, absorb $\exp\left(\theta L_{0,t}^{1,j}\right)$ in the exponential term $\Lambda_{0,t}$ by setting

$$\widehat{\Lambda}_{0,t}^j = \Lambda_{0,t} \exp\left(\theta L_{0,t}^{1,j}\right).$$

Second, apply the Itô product rule as in Theorem 3.1. This derivation is along the lines of information state equations in [13]. □

Equations (4.6), (4.7), (4.8) with their respective boundary conditions (4.9) are of the general form

$$M^\theta(x,t) = p_0(x) + \int_0^t A^\theta(s)^* M(x,s)ds + \int_0^t B^\theta(s)^* M(x,s)dy_s, \tag{4.10}$$

where the operators $A^\theta(t)^*, B^\theta(t)^*$ and their adjoints $A^\theta(t), B^\theta(t)$ depend on θ. Moreover, for sufficiently small $\theta \in \mathbb{R}$, these operators are bounded linear operators as described in (2.24), and there exist $\lambda_1^\theta, \lambda_2^\theta$, which depend on $\theta \in \mathbb{R}$ such that they satisfy the coercivity condition (2.25). Consequently, similar to Lemma 2.6, there exists one and only one solution of (4.6)–(4.9) in the space $\beta^{\theta,j}(\cdot) \in L_y^2((0,T);H^1) \cap L^2(\Omega,\mathcal{F},P;C((0,T);H))$.

LEMMA 4.4. *For $j = 1,2,3$,*

$$E\left[\Phi(x_t)\Lambda_{0,t}\exp\left(\theta L_{0,t}^{1,j}\right)|\mathcal{F}_{0,t}^y\right] = E\left[\Phi(x_t)\Lambda_{0,t}|\mathcal{F}_{0,t}^y\right] + \sum_{\kappa=1}^{\infty} \frac{\theta^\kappa}{\kappa!} E\left[\Phi(x_t)\Lambda_{0,t} L_{0,t}^{\kappa,j}|\mathcal{F}_{0,t}^y\right], \tag{4.11}$$

where the infinite series converges in $L^1(\Omega,\mathcal{F}_{0,t}^y,P)$. Moreover,

$$\beta_t^{\theta,j}(\Phi) = q_t(\Phi) + \sum_{\kappa=1}^{\infty} \frac{\theta^\kappa}{\kappa!} M_t^{\kappa,j}(\Phi), \qquad j = 1,2,3. \tag{4.12}$$

Proof. We shall invoke the following estimate found in [15, p. 353]:

$$\left| e^{\theta x} - \sum_{k=0}^{n} \frac{(\theta x)^k}{k!} \right| \le \min\left\{ \frac{|\theta x|^{n+1}}{(n+1)!}, \frac{2|\theta x|^n}{n!} \right\}, \ \theta \in \mathbb{R}, \ x \in \mathbb{R}.$$

The first right side term is an estimate for $|\theta x|$ small and the second for $|\theta x|$ large. Using the above estimate

$$\begin{aligned}
&\mathrm{E}\Big\{\Big|\mathrm{E}[\Phi(x_t)\Lambda_{0,t}\exp(\theta L^{1,j}_{0,t})|\mathcal{F}^y_{0,t}] - \sum_{k=0}^{n}\frac{\theta^k}{k!}\mathrm{E}[\Phi(x_t)\Lambda_{0,t}L^{k,j}_{0,t}|\mathcal{F}^y_{0,t}]\Big|\Big\}\\
&\le \mathrm{E}\Big\{|\Phi(x_t)|\Lambda_{0,t}\left(\left|\exp(\theta L^{1,j}_{0,t}) - \sum_{k=0}^{n}\frac{\theta^k}{k!}L^{k,j}_{0,t}\right|\right)\Big\}\\
&\le \mathrm{E}\Big\{|\Phi(x_t)|\Lambda_{0,t}\min\left\{\frac{|\theta|^{n+1}L^{n+1,j}_{0,t}}{(n+1)!}, \frac{2|\theta|^n L^{n,j}_{0,t}}{n!}\right\}\Big\}
\end{aligned}$$

(4.13)

$$\le \Big(\mathrm{E}\Big\{|\Phi(x_t)|^2\Lambda^2_{0,t}\Big\}\Big)^{1/2}\left(\mathrm{E}\min\left\{\left(\frac{|\theta|^{n+1}L^{n+1,j}_{0,t}}{(n+1)!}\right)^2, \left(\frac{2|\theta|^n L^{n,j}_{0,t}}{n!}\right)^2\right\}\right)^{1/2}.$$

The first right side term of (4.13) is bounded for any $(t,x)\,\epsilon\,[0,T]\times\mathbb{R}^n$, and the second is bounded because $f^j(t,x),\ j=1,2,3$, are bounded for any $(t,x)\,\epsilon\,[0,T]\times\mathbb{R}^n$.

Moreover, $\lim_{n\to\infty}\left(\frac{\theta^n}{n!}\right)^2\mathrm{E}L^{2n,j}_{0,t}=0$, and therefore in the limit, as $n\to\infty$, the right side of (4.13) converges to zero. Consequently, the following expansion must hold:

$$\mathrm{E}[\Phi(x_t)\Lambda_{0,t}\exp(\theta L^{1,j}_{0,t})|\mathcal{F}^y_{0,t}] = \sum_{k=0}^{\infty}\frac{\theta^k}{k!}\mathrm{E}[\Phi(x_t)\Lambda_{0,t}L^{k,j}_{0,t}|\mathcal{F}^y_{0,t}],$$

which is equivalent to (4.11) and, by Definition 2.9, to (4.12). □

At this stage, we may formally differentiate both sides of (4.12) with respect to θ, and then take the limit as $\theta\to 0$, to obtain relations between $\lim_{\theta\to 0}\frac{d^\kappa}{d\theta^\kappa}\beta^{\theta,j}_t(\Phi)$ and $M^{\kappa,j}_t(\Phi), j=1,2,3$. These results are presented next.

THEOREM 4.5. *We have the following:*

1. $\widetilde{\beta}^{i\omega,j}(1), \beta^{i\omega,j}(1), j=1,2,3$ *have* κ *continuous derivatives with respect to* ω, *w.p.*1.
2.

$$\lim_{\theta\to 0}\frac{d^\kappa}{d\theta^\kappa}\widetilde{\beta}^{\theta,j}_t(\Phi) = \lim_{\theta\to 0}\frac{d^\kappa}{d\theta^\kappa}\frac{\beta^{\theta,j}_t(\Phi)}{q_t(1)} = \widetilde{\mathrm{E}}[\Phi(x_t)L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}] \quad w.p.1, \tag{4.14}$$
$$\theta = i\omega, \quad \kappa\ge 0, \quad j=1,2,3.$$

3.

$$\lim_{\theta\to 0}\frac{d^\kappa}{d\theta^\kappa}\widetilde{\beta}^{\theta,j}_t(1) = \lim_{\theta\to 0}\frac{d^\kappa}{d\theta^\kappa}\frac{\beta^{\theta,j}_t(1)}{q_t(1)} = \widetilde{\mathrm{E}}[L^{\kappa,j}_{0,t}|\mathcal{F}^y_{0,t}] \quad w.p.1, \tag{4.15}$$
$$\theta = i\omega, \quad \kappa\ge 0, \quad j=1,2,3.$$

Proof. Recall that

$$\widetilde{\beta}^{i\omega,j}_t(\Phi) = \widetilde{\mathrm{E}}\big[\Phi(x_t)\exp\big(i\omega L^{1,j}_{0,t}\big)|\mathcal{F}^y_{0,t}\big] = \frac{E\big[\Lambda_{0,t}\exp\big(i\omega L^{1,j}_{0,t}\big)|\mathcal{F}^y_{0,t}\big]}{q_t(1)}.$$

Here $q_t(1)$ is independent of θ. The numerator $\mathrm{E}[\Phi(x_t)\Lambda_{0,t}\exp(i\omega L^{1,j}_{0,t})|\mathcal{F}^y_{0,t}]$ admits the power series expansion of Lemma 4.4, which implies 1, 2, 3. □

4.1. Specific application. Consider the system

$$dx_t = Fx_t dt + Gdw_t, \qquad x(0) \in \mathbb{R}^n,$$
$$dy_t = Hx_t + N^{\frac{1}{2}} db_t, \qquad y(0) = 0,$$
$$f^1(t,x) = \frac{1}{2}x'Qx, \quad f^2(t,x) = x'R, \quad f^3(t,x) = x'S, \qquad Q = Q'.$$

We assume $x(0)$ is a Gaussian random variable.

Suppose F, H are random matrices which we wish to identify or estimate. In [6] an algorithm is presented for estimating these matrices. This involves filtered estimates of the processes $\int_0^t f^1(s,x_s)ds$, $\int_0^t f^2(s,x_s)dw_s, \int_0^t f^3(s,x_s)db_s$. Here we apply Theorem 4.5 to obtain these estimates.

A solution of (2.13), (2.14) is

$$q(x,t) = \frac{1}{(2\pi)^{n/2}|P_t^0|^{1/2}} \exp\left(-\frac{1}{2}|P_t^{0,-1/2}\left(x - \widehat{x}_t^0\right)|^2\right) \times \widehat{\Lambda}_{0,t}^0, \tag{4.16}$$

where $\widehat{x}^0(\cdot), P^0(\cdot), \widehat{\Lambda}^0(\cdot)$ are given by

$$d\widehat{x}_t^0 = F\widehat{x}_t^0 dt + P_t^0 H' N^{-1}\left(dy_t - H\widehat{x}_t^0 dt\right), \qquad \widehat{x}^0(0) = \xi, \tag{4.17}$$

$$\dot{P}_t^0 = FP_t^0 + P_t^\theta F' - P_t^0 H' N^{-1} H P_t^0 + GG', \qquad P^0(0) = P_0, \tag{4.18}$$

$$\widehat{\Lambda}_{0,t}^0 = \exp\left(\int_0^t \left(H\widehat{x}_s^0\right)' N^{-1} dy_s - \frac{1}{2}\int_0^t \left(H\widehat{x}_s^0\right)' N^{-1} H\widehat{x}_s^0 ds\right). \tag{4.19}$$

These computations are easily verified by substitution into the DMZ equation. Recall also that $q(x,t) = M^{0,j}(x,t), j = 1,2,3$.

1. *Computation of* $\widehat{L}_{0,t}^{1,1} = \widetilde{\mathrm{E}}[\frac{1}{2}\int_0^t x_s' Q x_s ds | \mathcal{F}_{0,t}^y]$:

A solution of (4.6), (4.9) is (see, for example, [11, 13])

$$\beta^{\theta,1}(x,t) = \frac{1}{(2\pi)^{n/2}|P_t^\theta|^{1/2}} \exp\left(-\frac{1}{2}|P_t^{\theta,-1/2}\left(x - \widehat{x}_t^\theta\right)|^2\right) \times \widehat{\Lambda}_{0,t}^\theta \times \exp\left(\frac{\theta}{2}\int_0^t \mathrm{Tr}(P_s^\theta Q)ds\right), \tag{4.20}$$

where

$$d\widehat{x}_t^\theta = \left(F + \theta P_t^\theta Q\right)\widehat{x}_t^\theta dt + P_t^\theta H' N^{-1}\left(dy_t - H\widehat{x}_t^\theta dt\right), \qquad \widehat{x}(0) = \xi, \tag{4.21}$$

$$\dot{P}_t^\theta = FP_t^\theta + P_t^\theta F' - P_t^\theta\left(H' N^{-1} H - \theta Q\right) P_t^\theta + GG', \qquad P^\theta(0) = P_0, \tag{4.22}$$

$$\widehat{\Lambda}_{0,t}^\theta = \exp\left(\int_0^t \left(H\widehat{x}_s^\theta\right)' N^{-1} dy_s - \frac{1}{2}\int_0^t \left(H\widehat{x}_s^\theta\right)' N^{-1} H\widehat{x}_s^\theta ds\right). \tag{4.23}$$

In fact, we can show that $\lim_{\theta\to 0} P_t^\theta = P_t^0$, uniformly on compact subsets of $[0,T]$, and $\lim_{\theta\to 0}\widehat{x}_t^\theta = \widehat{x}_t^0$ a.s.

According to Theorem 4.5 we need

$$\frac{d}{d\theta}\frac{\beta_t^{\theta,1}(1)}{\widehat{\Lambda}_{0,t}^0} = \frac{d}{d\theta}\left[\widehat{\Lambda}_{0,t}^\theta\left(\widehat{\Lambda}_{0,t}^0\right)^{-1}\exp\left(\frac{\theta}{2}\int_0^t \mathrm{Tr}(P_s^\theta Q)\right)\right]. \tag{4.24}$$

Let

$$r_t^\theta = \frac{d}{d\theta}\widehat{x}_t^\theta, \qquad \Sigma_t^\theta = \frac{d}{d\theta}P_t^\theta.$$

Then from the differentiability of parameter dependent solutions of stochastic differential equations we know that

$$
\begin{aligned}
r_t^\theta &= \int_0^t \left(F + \theta P_s^\theta Q - P_s^\theta H' N^{-1} H r_t^\theta\right) r_s^\theta ds \\
&\quad + \int_0^t \theta \Sigma_s^\theta Q \widehat{x}_s^\theta ds + \int_0^t \Sigma_s^\theta H' N^{-1} \left(dy_s - H\widehat{x}_s^\theta ds\right) + \int_0^t P_s^\theta Q \widehat{x}_s^\theta ds, \qquad (4.25)\\
\Sigma_t^\theta &= \int_0^t F\Sigma_s^\theta ds + \int_0^t \Sigma_s^\theta F' ds - \int_0^t \Sigma_s^\theta \left(H' N^{-1} H - \theta Q\right) P_s^\theta ds \\
&\quad - \int_0^t P_s^\theta \left(H' N^{-1} H - \theta Q\right) \Sigma_s^\theta ds + \int_0^t P_s^\theta Q P_s^\theta ds \qquad (4.26)
\end{aligned}
$$

are well defined. Similarly as before we have $\lim_{\theta\to 0} r_t^\theta = r_t^0$ (a.s.), $\lim_{\theta\to 0} \Sigma_t^\theta = \Sigma_t^0$, where

$$
\begin{aligned}
r_t^0 &= \int_0^t P_s^0 Q \widehat{x}_s^0 ds + \int_0^t \Sigma_s^0 H' N^{-1} \left(dy_s - H\widehat{x}_s^0 ds\right) \\
&\quad + \int_0^t \left(F - P_s^0 H' N^{-1} H\right) r_s^0 ds, \qquad (4.27)
\end{aligned}
$$

(4.28)

$$
\Sigma_t^0 = \int_0^t \left(F - P^0 H' N^{-1} H\right) \Sigma_s^0 ds + \int_0^t \Sigma_s^0 \left(F - P^0 H' N^{-1} H\right)' ds + \int_0^t P_s^0 Q P_s^0 ds.
$$

Consequently,

$$
\begin{aligned}
&\lim_{\theta\to 0} \frac{d}{d\theta} \left\{ \widehat{\Lambda}_{0,t}^\theta \left(\widehat{\Lambda}_{0,t}^0\right)^{-1} \exp\left(\frac{\theta}{2} \int_0^t \mathrm{Tr}(P_s^\theta Q) ds\right)\right\} \\
&= \lim_{\theta\to 0} \left\{ \left(\int_0^t (Hr_s^\theta)' N^{-1} dy_s - \int_0^t (Hr_s^\theta)' N^{-1} H\widehat{x}_s^\theta ds + \frac{1}{2} \int_0^t \mathrm{Tr}\left(P_s^\theta Q + \theta \Sigma_s^\theta Q\right) ds \right) \right. \\
&\left. \times \widehat{\Lambda}_{0,t}^\theta \left(\widehat{\Lambda}_{0,t}^0\right)^{-1} \exp\left(\frac{\theta}{2} \int_0^t \mathrm{Tr}(P_s^\theta Q) ds\right)\right\} \\
&= \frac{1}{2} \int_0^t \mathrm{Tr}\left(P_s^0 Q\right) ds + \int_0^t \left(Hr_s^0\right)' N^{-1} \left(dy_s - H\widehat{x}_s^0\right) ds. \qquad (4.29)
\end{aligned}
$$

Finally, $\widehat{L}_{0,t}^{1,1} = \widetilde{\mathrm{E}}[\frac{1}{2}\int_0^t x_s' Q x_s ds | \mathcal{F}_{0,t}^y]$ is a solution of the stochastic equation

$$
d\widehat{L}_{0,t}^{1,1} = \frac{1}{2} \mathrm{Tr}\left(P_t^0 Q\right) dt + \left(Hr_t^0\right)' N^{-1} \left(dy_t - H\widehat{x}_t^0 ds\right), \qquad \widehat{L}_{0,t}^{1,1} = 0. \qquad (4.30)
$$

2. *Computation of* $\widehat{L}_{0,t}^{1,2} = \widetilde{\mathrm{E}}[\int_0^t x_s' R dw_s | \mathcal{F}_{0,t}^y]$:
A solution of (4.7), (4.9) is (see [11])

$$
\begin{aligned}
\beta^{\theta,2}(x,t) &= \frac{1}{(2\pi)^{n/2} |P_t^\theta|^{1/2}} \exp\left(-\frac{1}{2} |P_t^{\theta,-1/2} \left(x - \widehat{x}_t^\theta\right)|^2\right) \\
&\quad \times \widehat{\Lambda}_{0,t}^\theta \times \exp\left(\frac{\theta^2}{2} \int_0^t \mathrm{Tr}(P_s^\theta R R') ds\right), \qquad (4.31)
\end{aligned}
$$

where

(4.32)
$$d\widehat{x}_t^\theta = \left(F + \theta^2 P_t^\theta RR' + \theta GR'\right)\widehat{x}_t^\theta dt + P_t^\theta H' N^{-1}\left(dy_t - H\widehat{x}_t^\theta dt\right), \qquad \widehat{x}(0) = \xi,$$

(4.33)
$$\dot{P}_t^\theta = \left(F + \theta GR'\right)P_t^\theta + P_t^\theta\left(F + \theta RG'\right)' - P_t^\theta\left(H'N^{-1}H - \theta^2 RR'\right)P_t^\theta + GG',$$
$$P^\theta(0) = P_0,$$

(4.34)
$$\widehat{\Lambda}_{0,t}^\theta = \exp\left(\int_0^t \left(H\widehat{x}_s^\theta\right)' N^{-1} dy_s - \frac{1}{2}\int_0^t \left(H\widehat{x}_s^\theta\right)' N^{-1} H\widehat{x}_s^\theta ds\right).$$

By Theorem 4.5 we need

$$\frac{d}{d\theta}\frac{\beta_t^{\theta,2}(1)}{\widehat{\Lambda}_{0,t}^0} = \frac{d}{d\theta}\left[\widehat{\Lambda}_{0,t}^\theta\left(\widehat{\Lambda}_{0,t}^0\right)^{-1}\exp\left(\frac{\theta^2}{2}\int_0^t \mathrm{Tr}(P_s^\theta RR')\right)\right]. \tag{4.35}$$

Computing $\lim_{\theta\to 0} r_t^\theta = \lim_{\theta\to 0}\frac{d}{d\theta}\widehat{x}_t^\theta = r_t^0, \lim_{\theta\to 0}\Sigma_t^\theta = \lim_{\theta\to 0}\frac{d}{d\theta}P_t^\theta = P_t^0$, similarly as before, we have

$$\begin{aligned} r_t^0 &= \int_0^t GR'\widehat{x}_s^0 ds + \int_0^t \Sigma_s^0 H' N^{-1}\left(dy_s - H\widehat{x}_s^0 ds\right) \\ &\quad + \int_0^t \left(F - P_s^0 H' N^{-1} H\right) r_s^0 ds, \end{aligned} \tag{4.36}$$

$$\begin{aligned} \Sigma_t^0 &= \int_0^t \left(F - P^0 H' N^{-1} H\right)\Sigma_s^0 ds + \int_0^t \Sigma_s^0\left(F - P^0 H' N^{-1} H\right)' ds \\ &\quad + \int_0^t GR' P_s^0 ds + \int_0^t P_s^0 RG' ds. \end{aligned} \tag{4.37}$$

Hence

$$\begin{aligned} &\lim_{\theta\to 0}\frac{d}{d\theta}\left\{\widehat{\Lambda}_{0,t}^\theta\left(\widehat{\Lambda}_{0,t}^0\right)^{-1}\exp\left(\frac{\theta^2}{2}\int_0^t Tr(P_s^\theta RR')ds\right)\right\} \\ &= \int_0^t \left(Hr_s^0\right)' N^{-1}\left(dy_s - H\widehat{x}_s^0\right) ds. \end{aligned} \tag{4.38}$$

Finally, $\widehat{L}_{0,t}^{1,2} = \widetilde{\mathrm{E}}[\int_0^t x_s' R dw_s | \mathcal{F}_{0,t}^y]$ is a solution of the stochastic equation

$$d\widehat{L}_{0,t}^{1,2} = \left(Hr_t^0\right)' N^{-1}\left(dy_t - H\widehat{x}_t^0 ds\right), \qquad \widehat{L}_{0,t}^{1,2} = 0. \tag{4.39}$$

3. *Computation of* $\widehat{L}_{0,t}^{1,3} = \widetilde{\mathrm{E}}[\int_0^t x_s' S db_s | \mathcal{F}_{0,t}^y]$:
A solution of (4.7), (4.9) is (see [11])

$$\begin{aligned} \beta^{\theta,3}(x,t) &= \frac{1}{(2\pi)^{n/2}|P_t^\theta|^{1/2}}\exp\left(-\frac{1}{2}|P_t^{\theta,-1/2}\left(x - \widehat{x}_t^\theta\right)|^2\right) \\ &\quad \times \widehat{\Lambda}_{0,t}^\theta \times \exp\left(\frac{\theta^2}{2}\int_0^t \mathrm{Tr}(P_s^\theta SS')ds\right), \end{aligned} \tag{4.40}$$

where

$$d\widehat{x}_t^\theta = \left(F + \theta^2 P_t^\theta SS'\right)\widehat{x}_t^\theta dt + P_t^\theta H^{\theta,\prime} N^{-1}\left(dy_t - H^\theta \widehat{x}_t^\theta dt\right), \qquad \widehat{x}(0) = \xi, \tag{4.41}$$

$$\dot{P}_t^\theta = FP_t^\theta + P_t^\theta F' - P_t^\theta\left(H^{\theta,\prime} N^{-1} H^\theta - \theta^2 SS'\right) P_t^\theta + GG', \qquad P^\theta(0) = P_0, \tag{4.42}$$

$$\widehat{\Lambda}_{0,t}^\theta = \exp\left(\int_0^t \left(H^\theta \widehat{x}_s^\theta\right)' N^{-1} dy_s - \frac{1}{2}\int_0^t \left(H^\theta \widehat{x}_s^\theta\right)' N^{-1} H^\theta \widehat{x}_s^\theta ds\right), \tag{4.43}$$

$$H^\theta = H + \theta N^{-1/2,\prime} S'. \tag{4.44}$$

From Theorem 4.5 we need

$$\frac{d}{d\theta}\frac{\beta_t^{\theta,3}(1)}{\widehat{\Lambda}_{0,t}^0} = \frac{d}{d\theta}\left[\widehat{\Lambda}_{0,t}^\theta\left(\widehat{\Lambda}_{0,t}^0\right)^{-1}\exp\left(\frac{\theta^2}{2}\int_0^t \mathrm{Tr}(P_s^\theta SS')\right)ds\right]. \tag{4.45}$$

This can be done as in the previous cases.

Finally, $\widehat{L}_{0,t}^{1,3} = \widetilde{\mathrm{E}}[\int_0^t x_s' S db_s | \mathcal{F}_{0,t}^y]$ is a solution of the stochastic equation

$$\begin{aligned} d\widehat{L}_{0,t}^{1,3} &= \left(Hr_t^0\right)' N^{-1}\left(dy_t - H\widehat{x}_t^0 dt\right) + \left(N^{-\frac{1}{2}} S'\widehat{x}_t^0\right)' N^{-1}\left(dy_t - N^{-\frac{1}{2},\prime} S'\widehat{x}_t^0 dt\right), \\ \widehat{L}_{0,t}^{1,3} &= 0, \end{aligned} \tag{4.46}$$

where

$$\begin{aligned} r_t^0 &= \int_0^t \left(\Sigma_s^0 H' N^{-1} + P_s^0 (SN^{-1/2})' N^{-1}\right)\left(dy_s - H\widehat{x}_s^0 ds\right) \\ &\quad + \int_0^t P_s^0 H' N^{-1}\left(dy_s - (SN^{-1/2})'\widehat{x}_s^0 ds\right) + \int_0^t \left(F - P_s^0 H' N^{-1}\right) r_s^0 ds, \end{aligned} \tag{4.47}$$

$$\begin{aligned} \Sigma_t^0 &= \int_0^t \left(F - P^0 H' N^{-1} H\right)\Sigma_s^0 ds + \int_0^t \Sigma_s^0\left(F - P^0 H' N^{-1} H\right)' ds \\ &\quad - \int_0^t P_s^0\left((SN^{-1/2}) N^{-1} H + (N^{-1}H)'(SN^{-1/2})'\right) P_s^0 ds. \end{aligned} \tag{4.48}$$

□

Remark 4.6. The above methodology can be generalized to joint conditional moment generating functions of $L_{0,t}^{1,j}, L_{0,t}^{1,\ell}, 1 \le j, \ell \le 3$.

5. Applications to nonlinear filtering problems. Both methods introduced in section 3 can be used in Wiener chaos expansions of nonlinear filtering [2] problems.

Consider the nonlinear filtering problem

$$dx_t = f(t, x_t)dt + \sigma(t, x_t)dw_t, \qquad x(0) \in \mathbb{R}^n, \tag{5.1}$$

$$dy_t = h(t, x_t)dt + N_t^{1/2} db_t, \qquad y(0) = 0 \in \mathbb{R}^d. \tag{5.2}$$

Here $\{x_t; t \in [0,T]\}$ and $\{y_t; t \in [0,T]\}$ are the state and observation processes, respectively. Throughout, we assume Assumption 2.2 holds. Similar to section 2, under the reference probability space $(\Omega, \mathcal{A}, P, \mathcal{F}_{0,t})$, processes $\{x_t; t \in [0,T]\}$, $\{y_t; t \in [0,T]\}$, are independent; the former is a solution of (5.1), while the latter is a solution of

$$dy_t = N_t^{1/2} db_t, \qquad y(0) = 0 \in \mathbb{R}^d. \tag{5.3}$$

The Radon–Nikodým derivative is

$$\Lambda_{0,T} \doteq \left[\frac{d\widetilde{P}}{dP}|\mathcal{F}_{0,T}\right] = \exp\left(m_t - \frac{1}{2}\langle m,m\rangle_t\right), \tag{5.4}$$

where $m_t = \int_0^t h'(s,x_s)N_s^{-1}dy_s$. Thus, $\{\Lambda_{0,t}; t \in [0,T]\}$ is a solution of the stochastic differential equation

$$\Lambda_{0,t} = 1 + \int_0^t \Lambda_{0,s}h'(s,x_s)N_s^{-1}dy_s. \tag{5.5}$$

Moreover, if the measured-valued processes $q_t(\Phi) = E[\Phi(x_t)\Lambda_{0,t}|\mathcal{F}_{0,t}^y]$ have a density $q(x,t)$, then

$$dq(z,t) = A(t)^*q(z,t)dt + h'(t,z)q(z,t)N_t^{-1}dy_t, \qquad (z,t) \in [0,T]\times\mathbb{R}^n, \tag{5.6}$$

$$q(z,0) = p_0(z), \qquad z \in \mathbb{R}^n. \tag{5.7}$$

In what follows, we employ some of the recursive systems derived in section 3 to obtain representations for certain asymptotic expansions of $\mathrm{E}[\Phi(x_t)|\mathcal{F}_{0,t}^y]$.

Definition 5.1. *Suppose* $\mathrm{E}[\int_0^T |N_s^{-1/2}h(s,x_s)|^2ds]^p < \infty$. *Then the multiple stochastic integrals*

$$I_t^p[h] = \int_0^t\int_0^{s_1}\cdots\int_0^{s_{p-1}} h'(s_p,x_{s_p})N_{s_p}^{-1}dy_{s_p}h'(s_{p-1},x_{s_{p-1}})N_{s_{p-1}}^{-1}dy_{s_{p-1}} \cdots h'(s_1,x_{s_1})N_{s_1}^{-1}dy_{s_1}, \tag{5.8}$$

$$I_t^{[p]}[h] = \int_0^t\int_0^{s_1}\cdots\int_0^{s_p} \Lambda_{s_{p+1}}h'(s_{p+1},x_{s_{p+1}})N_{s_{p+1}}^{-1}dy_{s_{p+1}}h'(s_p,x_{s_p})N_{s_p}^{-1}dy_{s_p} \cdots h'(s_1,x_{s_1})N_{s_1}^{-1}dy_{s_1} \tag{5.9}$$

are well defined.

Consider the exponential martingale $\{\Lambda_{0,t}; t \in [0,T]\}$. Iterating (5.5) we have

$$\begin{aligned}
\Lambda_{0,t} &= 1 + \int_0^t \Lambda_{0,s}h'(s,x_s)N_s^{-1}dy_s \\
&= 1 + \int_0^t h'(s,x_s)N_s^{-1}dy_s + \int_0^t\int_0^{s_1} \Lambda_{0,s_2}h'(s_2,x_{s_2})N_{s_2}^{-1}dy_{s_2}h'(s_1,x_{s_1})N_{s_1}^{-1}dy_{s_1} \\
&+ \vdots \\
&= 1 + \int_0^t h'(s,x_s)N_s^{-1}dy_s + \int_0^t\int_0^{s_1} \Lambda_{0,s_2}h'(s_2,x_{s_2})N_{s_2}^{-1}dy_{s_2}h'(s_1,x_{s_1})N_{s_1}^{-1}dy_{s_1} \\
&\quad + \cdots + \int_0^t\int_0^{s_1}\cdots\int_0^{s_{p-1}} h'(s_p,x_{s_p})N_{s_p}^{-1}dy_{s_p}h'(s_{p-1},x_{s_{p-1}})N_{s_{p-1}}^{-1}dy_{s_{p-1}}
\end{aligned}$$

$$\cdots h'(s_1,x_{s_1})N_{s_1}^{-1}dy_{s_1} + I_t^{[p]}[h]. \tag{5.10}$$

If we now assume $\mathrm{E}[\Phi^2(x_t)\int_0^T |N_s^{-1}h(s,x_s)|^2ds]^p < \infty$ (which is satisfied by As-

sumption 2.2) and then substitute (5.10) into $q_t^0(\Phi) = \mathrm{E}[\Lambda_{0,t}\Phi(x_t)|\mathcal{F}_{0,t}^y]$ we have

$$\begin{aligned} q_t(\Phi) &= \mathrm{E}[\Lambda_{0,t}\Phi(x_t)|\mathcal{F}_{0,t}^y] = \mathrm{E}[\Phi(x_t)|\mathcal{F}_{0,t}^y] \\ &\quad + \sum_{k=1}^{p} \mathrm{E}\,[\,\Phi(x_t)\int_0^t\int_0^{s_1}\cdots\int_0^{s_{k-1}} h'(s_k,x_{s_k})N_{s_k}^{-1}dy_{s_k}\cdots h'(s_1,x_{s_1})N_{s_1}^{-1}dy_{s_1}|\mathcal{F}_{0,t}^y\,] \\ &\quad + \mathrm{E}\left[\Phi(x_t)I_t^{[p]}[h]|\mathcal{F}_{0,t}^y\right]. \end{aligned} \tag{5.11}$$

Note that under measure P, the processes $\{x_t; t \in [0,T]\}$ and $\{y_t; t \in [0,T]\}$ are independent; therefore $\mathrm{E}[\Phi(x_t)|\mathcal{F}_{0,t}^y] = \mathrm{E}[\Phi(x_t)]$. In addition, the increments $dy_{s_1}, dy_{s_2}, \ldots, dy_{s_k}$ are measurable with respect to $\mathcal{F}_{0,t}^y$; in the scalar case, $d=1$, the second right side term of (5.11) becomes

$$\sum_{k=1}^{p}\int_0^t\int_0^{s_1}\cdots\int_0^{s_{k-1}} \mathrm{E}[\Phi(x_t)h(s_k,x_{s_k})N_{s_k}\cdots h(s_1,x_{s_1})N_{s_1}]dy_{s_k}\cdots dy_{s_1}.$$

Formally, letting $p=\infty$ in (5.11) we derive the full expansion, which is made rigorous in the next theorem.

THEOREM 5.2.

1. *Suppose* $\mathrm{E}[\int_0^t |N_s^{-1/2}h(s,x_s)|^2ds]^p < \infty$ *and* $\mathrm{E}[\Phi(x_t)^2\int_0^t |N_s^{-1/2}h(s,x_s)|^2ds]^p < \infty$. *Then*

$$\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y] = \frac{q_t(\Phi)}{q_t(1)} \tag{5.12}$$
$$= \frac{\mathrm{E}[\Phi(x_t)] + \sum_{k=1}^p \mathrm{E}[\Phi(x_t)I_t^k[h]|\mathcal{F}_{0,t}^y] + \mathrm{E}[\Phi(x_t)I_t^{[p]}[h]|\mathcal{F}_{0,t}^y]}{1 + \sum_{k=1}^p \mathrm{E}[I_t^p[h]|\mathcal{F}_{0,t}^y] + \mathrm{E}[I_t^{[p]}[h]|\mathcal{F}_{0,t}^y]}.$$

2. *Suppose* $\mathrm{E}[\exp\int_0^t |N_s^{-1/2}h(s,x_s)|^2ds] < \infty$ *and*

$$\mathrm{E}[\Phi(x_t)\exp\int_0^t |N_s^{-1/2}h(s,x_s)|^2ds] < \infty.$$

Then

$$\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y] = \frac{q_t(\Phi)}{q_t(1)} = \frac{\mathrm{E}[\Phi(x_t)] + \sum_{k=1}^\infty \mathrm{E}[\Phi(x_t)I_t^k[h]|\mathcal{F}_{0,t}^y]}{1 + \sum_{k=1}^\infty \mathrm{E}[I_t^k[h]|\mathcal{F}_{0,t}^y]} \tag{5.13}$$

and the infinite series of (5.13) *converges in* $L^1(\Omega,\mathcal{F}_{0,t}^y,P)$.

Proof. See [2]. □

5.1. Recursive equations.

DEFINITION 5.3. *Suppose* $\mathrm{E}[\Phi^2(x_t)\int_0^t |N_s^{-1/2}h(s,x_s)|^2]^p < \infty$.

The measure-valued processes

$$M_t^0(\Phi) \doteq \mathrm{E}[\Phi(x_t)] = \int_{\mathbb{R}^n}\Phi(z)p(z,t;x,0)dx, \tag{5.14}$$

$$M_t^k(\Phi) \doteq \mathrm{E}[\Phi(x_t)I_t^k[h]|\mathcal{F}_{0,t}^y], \qquad k \geq 1, \tag{5.15}$$

are well defined.

THEOREM 5.4. *Suppose* $M_t^k(\cdot), k \geq 0$, *have density functions* $M^k(z,t)$.

1. *The density of the distribution* $\widetilde{P}(x_t \in A), A \in \mathcal{B}(\mathbb{R}^n)$, *satisfies the Kolmogorov equation*

$$dp(z,t) = A(t)^* p(z,t)dt, \quad (z,t) \in \mathbb{R}^n \times (0,T]; \qquad \lim_{t\to 0} p(z,t) = p_0(z). \tag{5.16}$$

2. *The densities of* $M_t^k(\cdot), k \geq 1$ *satisfy the following recursive system of SPDEs:*

$$dM^k(z,t) = A(t)^* M^k(z,t)dt + h^*(t,z)M^{k-1}(z,t)N_t^{-1}dy_t, \qquad (z,t) \in \mathbb{R}^n \times [0,T], \tag{5.17}$$

$$M^k(z,0) = 0, \quad z \in \mathbb{R}^n. \tag{5.18}$$

Proof. The distribution of $\{x_t; t \in [0,T]\}$ is the same under measure $\widetilde{P}$ and P. Hence, the density $p(\cdot,\cdot)$ satisfies (5.16).

Now, for $k = 1$ consider

$$I_t^1[h] = \int_0^t h'(s,x_s)N_s^{-1}dy_s. \tag{5.19}$$

By the Itô product rule

$$\begin{aligned}\Phi(x_t)I_t^1[h] = &\int_0^t A(s)^*\Phi(x_s)I_s^1[h]ds \\ &+ \int_0^t D_x'\Phi(x_s)I_s^1[h]\sigma(s,x_s)dw_s \\ &+ \int_0^t \Phi(x_s)h'(s,x_s)N_s^{-1}dy_s.\end{aligned} \tag{5.20}$$

Conditioning both sides of (5.20) on $\mathcal{F}_{0,t}^y$, and then using the independence of $\{w_t; t \in [0,T]\}$ and $\{y_t; t \in [0,T]\}$ (and a version of Fubini's theorem [12]), we have

$$\begin{aligned}M_t^1(\Phi) = &\int_0^t \int_{\mathbb{R}^n} A(s)\Phi(z)M^1(z,s)dzds \\ &+ \int_0^t \int_{\mathbb{R}^n} \Phi(z)h'(s,z)M^0(z,s)N_s^{-1}dzdy_s.\end{aligned} \tag{5.21}$$

Hence (5.17), (5.18) hold for $k = 1$.

Now, for $k = \ell$ consider

$$I_t^\ell[h] = \int_0^t \int_0^{s_1} \cdots \int_0^{s_{\ell-1}} h'(s_\ell, x_{s_\ell})N_{s_\ell}^{-1}dy_{s_\ell} \cdots h'(s,x_{s_1})N_{s_1}^{-1}dy_{s_1}. \tag{5.22}$$

Then

$$dI_t^\ell[h] = I_t^{\ell-1}[h]h'(t,x_t)N_t^{-1}dy_t.$$

By the Itô product rule

$$\begin{aligned}\Phi(x_t)I_t^\ell[h] = &\int_0^t A(s)\Phi(x_s)I_s^\ell[h]ds \\ &+ \int_0^t D_x'\Phi(x_s)I_s^\ell[h]\sigma(s,x_s)dw_s + \int_0^t \Phi(x_s)h'(s,x_s)I_s^{\ell-1}[h]N_s^{-1}dy_s.\end{aligned} \tag{5.23}$$

Similarly as before, conditioning both sides of (5.2) on $\mathcal{F}_{0,t}^y$ we have

$$M_t^\ell(\Phi) = \int_0^t \int_{\mathbb{R}^n} A(s)\Phi(z)M^\ell(z,t)dzds + \int_0^t \int_{\mathbb{R}^n} \Phi(z)h'(s,z)M^{\ell-1}(z,s)N_s^{-1}dzdy_s. \tag{5.24}$$

Hence, (5.17), (5.18) holds for any $k \geq 1$. □

COROLLARY 5.5. *Let* $\{p(z,t;x,s); 0 \leq s < t \leq T\}, (z,x) \in \mathbb{R}^n \times \mathbb{R}^n$ *be the fundamental solution of the density equation* (5.16)*:*

$$dp(z,t;x,s) = A(t)^* p(z,t;x,s)dt, \quad (z,t) \in \mathbb{R}^n \times (0,T]; \quad \lim_{t\to s} P(z,t;x,s) = \delta(z-x). \tag{5.25}$$

Then the solutions of (5.16)–(5.18) *are represented by*

$$M^k(z,t) = \int_0^t \int_{\mathbb{R}^n} h'(s,x)N_s^{-1}M^{k-1}(x,s)p(z,t;x,s)dxdy_s, \qquad k \geq 1, \tag{5.26}$$

$$M^0(z,t) = \int_{\mathbb{R}^n} p(z,t;x,0)p_0(x)dx. \tag{5.27}$$

Proof. Follow the procedures of Theorem 2.5. □

Remark 5.6. Because of the linearity of (5.16), (5.18), any finite expansion of both numerator and denominator of (5.13), say,

$$q_t^\ell(\Phi) = \mathrm{E}[\Phi(x_t)] + \sum_{k=1}^{\ell} \mathrm{E}[\Phi(x_t)I_t^k[h]|\mathcal{F}_{0,t}^y], \qquad \ell \geq 1, \tag{5.28}$$

is a solution of the SPDE

$$dq_t^\ell(\Phi) = q_t^\ell(A(t)\Phi)dt + \sum_{k=1}^{\ell} M_t^{k-1}(h'(t,z)\Phi)N_t^{-1}dy_t. \tag{5.29}$$

From Theorem 5.2, we know that in order to approximate $\widetilde{\mathrm{E}}[\Phi(x_t)|\mathcal{F}_{0,t}^y]$ through a finite series we need to compute $M_t^k(\Phi), 0, \leq k \leq p$. The latter can be computed from the joint-moment generating function of the random processes $\{\int_0^t h'(s,x_s)N^{-1}dy_s; t \in [0,T]\}$ and $\{\int_0^t |h'(s,x_s)|^2 ds; t \in [0,T]\}$.

6. Conclusion. This paper presents two methods for computing conditional moments of integrals and stochastic integrals for general diffusion processes. The first method employs recursive SPDEs; the second method employs conditional moment generating functions. An application of the first method results in new finite-dimensional filters. An application of the second method to the EM algorithm results in a significant reduction in the sufficient statistics required in the computation of the parameters.

APPROXIMATE CONTROLLABILITY OF SEMILINEAR DETERMINISTIC AND STOCHASTIC EVOLUTION EQUATIONS IN ABSTRACT SPACES*

NAZIM I. MAHMUDOV†

Abstract. Various sufficient conditions for approximate controllability of linear evolution systems in abstract spaces have been obtained, but approximate controllability of semilinear control systems usually requires some complicated and limited assumptions. In this paper, we show the approximate controllability of the abstract semilinear deterministic and stochastic control systems under the natural assumption that the associated linear control system is approximately controllable. The results are obtained using new properties of symmetric operators (which are proved in this paper), compact semigroups, the Schauder fixed point theorem, and/or the contraction mapping principle.

Key words. symmetric operators, controllability, the Schauder fixed point theorem, the contraction mapping principle, semilinear evolution equations, stochastic evolution equations

1. Introduction.

Consider a deterministic or stochastic control system on the finite time interval $I = [0, T]$ with $T > 0$. Let $x(T; x_0, u)$ be its (random or not) state value at time T corresponding to the control $u(\cdot)$ taken from the set of admissible controls U_{ad} and the initial value x_0. Suppose that Z is the state space. Introduce the set

$$R(T; x_0, u) = \{x(T; x_0, u) : u(\cdot) \in U_{ad}\}. \tag{1.1}$$

DEFINITION 1.1. *A control system is said to be approximately controllable on I if $\overline{R(T; x_0, u)} = Z$.*

Controllability of the deterministic systems in finite dimensional spaces has been extensively studied (see [3], [21], and references therein). Several authors (see [1], [2], [3], [7], [8], [9], [14], [15], [16], [17], [18], [19], [20], [21], [22], [26], [28], [33], [34], [35], [36]) studied the concept for systems represented by evolution equations in infinite dimensional spaces. Most of the controllability results for nonlinear infinite dimensional control systems concern the so-called semilinear control systems which consist of a linear and a nonlinear part. Moreover, it should be emphasized that for infinite dimensional systems several concepts of controllability are analyzed.

In section 3, we consider the semilinear evolution system of the form

$$\begin{aligned} &\dot{x}(t) = Ax(t) + Bu(t) + f(t, x(t), u(t)), \quad t \in I = [0, T], \\ &x(0) = x_0, \end{aligned} \tag{1.2}$$

where $f : I \times X \times U \to X$ is a nonlinear operator, X is a separable reflexive Banach space, U is a Hilbert space, A is a linear operator on X, and B is a linear bounded operator from U to X.

†Department of Mathematics, Eastern Mediterranean University, Gazimagusa, Mersin 10, Turkey (nazim.mahmudov@emu.edu.tr).

A mild solution $x(\cdot)$ of the semilinear evolution system we are considering is defined as a solution of the following integral equation:

$$x(t;x_0,u)=x(t)=S(t)x_0+\int_0^t S(t-s)\left[Bu(s)+f(s,x(s),u(s)\right]ds. \tag{1.3}$$

Any element of $L_2(I,U)$ is called a control. Any solution $x(\cdot;x_0,u)$ of (1.3) is referred to as a state trajectory of the evolution system corresponding to the initial state x_0 and the control $u(\cdot)$.

There have been many papers on the approximate controllability of the semilinear system (1.2) under different conditions; see [21], [36], and references therein.

Yamamoto and Park in [33] considered control systems described by an abstract parabolic differential equation with uniformly bounded nonlinear term and finite dimensional input operator. Naito in [26] investigated the approximate controllability of semilinear control systems under a range condition of the control action operator and an inequality condition on the system parameters. Seidman in [28] considered the reachable set of the abstract equation in a Banach space. Assuming invariance of the reachable set under affine perturbations, "already a fairly strong controllability hypothesis," various conditions are proved under which nonlinear perturbations also leave the reachable set invariant. Li and Yong in [34] studied the same problem assuming the approximate controllability of the associated linear system under arbitrary perturbation in $L_\infty(I,L(X))$.

In modeling physical processes in bounded domains by controlled PDEs, two types of controls, boundary and internal, are typically used. The boundary controls act upon the system from the outside, while the internal controls act in the interior of the system's space domain. Each of these controls can be both distributed, depending on x and t, and lumped, depending on t only. In the beginning of the 1990's, Fabre, Puel, and Zuazua in [14] proved the global approximate controllability for the second order semilinear parabolic equations with nonlinear term $f(t,x,y)$ of sublinear growth in the variable y at infinity. Later, Imanuvilov [19] proved the global exact controllability for the same equation. This result was improved by Fernandez-Cara [17]. On the other hand, for the case of the nonlinear term including ∇y, the approximate controllability was established only recently by Fernandez and Zuazua [16] and Zuazua [36]. The method of these works involves unique continuation and fixed point techniques combined with a variational approach. The lumped controls were studied by Khapalov [20]. The method used in this paper is quite different from the classical fixed point or implicit function arguments.

On the other hand, the approximate controllability for various class of evolution stochastic differential equations was studied by Dubov and Mordukhovich [12], Bashirov and Mahmudov [6], Mahmudov [24], Barbu and Tessitore [4], and Sirbu and Tessitore [30]. To the best knowledge of the author, the controllability of semilinear stochastic evolution systems has not been studied yet.

In this paper, our purpose is to show approximate controllability of the deterministic and stochastic systems under basic assumptions on the system operators. In particular, we assume the approximate controllability of the associated linear system. To prove the main results we develop a constructive approach for approximate controllability for semilinear evolution (deterministic or stochastic) equations. The method is similar to Tikhonov regularization and is based on the new characterization of a symmetric positive operator in terms of strong (weak) convergence of a sequence of (resolvent) operators.

The paper is organized as follows. In section 2, we present some definitions and prove two theorems about the symmetric operators. In particular, Theorem 2.3 gives a characterization of a symmetric positive operator in terms of strong (weak) convergence of a sequence of operators. These results are used in sections 3 and 4 to obtain approximate controllability for the semilinear deterministic and stochastic evolution equations. In section 3, using some constructive control function, we transfer the controllability problem for semilinear systems into a fixed point problem for an appropriate nonlinear operator in a function space. Using the Schauder fixed point theorem, we guarantee the existence of a fixed point of this operator and study an approximate controllability of the system (1.2). In section 4, we study the approximate controllability of the semilinear stochastic evolution systems with uniformly bounded nonlinear term of Lipschitz type. Finally, in section 5, we discuss two examples.

Remark 1.2. Several comments are in order:

1. The result from section 3 can be applied to both distributed and lumped controls.
2. The result obtained in section 3 in some sense extends those in Khapalov [20] that provide the approximate controllability for the one dimensional heat equation to the space
$$W = \left\{ \phi : \phi(\theta) = \sum_{k=1}^{\infty} \alpha_k e_k(\theta), \ \sum_{k=1}^{\infty} \alpha_k c_k^2 < \infty \right\},$$
endowed with the norm $\|\phi\|^2 = \sum_{k=1}^{\infty} \alpha_k c_k^2$, where $\{c_k\}$ is a nonincreasing sequence of specifically defined positive number if $f(x)$ is globally Lipschitz and sublinear.
3. The result of section 4 is new.
4. Combining the methods of this paper with those developed in Lasiecka and Triggiani [22], one may expect the results of this paper to hold for a class of problem with unbounded control operator B.
5. Combining the methods in Zuazua [36] and the techniques of this paper, one may expect finite and approximate controllability of the deterministic and stochastic evolution systems considered here.
6. The analogue of the results obtained in this paper may be proved for exact null controllability.

2. Positive operators. Let Z be a separable reflexive Banach space, and let Z^* stand for its dual space with respect to the continuous pairing $\langle \cdot, \cdot \rangle$. We may assume, without loss of generality, that Z and Z^* are smooth and strictly convex, by virtue of the renorming theorem (see, for example, [5], [34]). In particular, this implies that the duality mapping J of Z into Z^* given by the relations
$$\|J(z)\| = \|z\|, \ \langle J(z), z \rangle = \|z\|^2 \text{ for all } z \in Z$$
is bijective, demicontinuous (i.e., continuous from Z with a strong topology into Z^* with weak topology), and strictly monotonic. Moreover, $J^{-1} : Z^* \to Z$ is also duality mapping.

An operator $\Gamma : Z^* \to Z$ is symmetric if
$$\langle z_1^*, \Gamma z_2^* \rangle = \langle z_2^*, \Gamma z_1^* \rangle$$
for all $z_1^*, z_2^* \in Z^*$. It is easy to see that Γ is linear and continuous (see [32]). Γ is nonnegative if $\langle z^*, \Gamma z^* \rangle \geq 0$ for all $z^* \in Z^*$.

First, we recall the following result about the structure of a class of nonnegative symmetric operators (see [32]).

LEMMA 2.1. *Let Γ be a nonnegative symmetric operator. Then there exists a Hilbert space H and an operator $A \in \mathcal{L}(Z^*, H)$ such that $A^*A = \Gamma$ and $A(Z^*)$ is dense in H. Furthermore, $A^*(H) \subset X$ and $\overline{\Gamma(Z^*)} = \overline{A^*(H)}$.*

Proof. Set $M = \{z^* \in Z^* \mid \langle z^*, \Gamma z^* \rangle = 0\}$. It is obvious that M is closed subspace of Z^*. Let us define the following inner product in a quotient space Z^*/M:

$$(z_1^* + M, z_2^* + M) = \langle z_1^*, \Gamma z_2^* \rangle .$$

It is clear that this inner product is well defined. Let H denote a completion of the obtained pre-Hilbert space. Let A be a natural embedding Z^* to H. We have

$$\|Az^*\|_H^2 = (z^* + M, z^* + M) = \langle z^*, \Gamma z^* \rangle \leq \|\Gamma\| \, \|z^*\|^2 \quad \text{for all } z^* \in Z^*.$$

So A is a continuous operator and $\|A\| \leq \sqrt{\|\Gamma\|}$ and

$$\langle z_1^*, \Gamma z_2^* \rangle = (z_1^* + M, z_2^* + M) = (Az_1^*, Az_2^*) = \langle z_1^*, A^*Az_2^* \rangle .$$

From here $\Gamma = A^*A$. Now let us show that $A^*(H) \subset \overline{\Gamma(Z^*)}$. Indeed, $A^*(A(Z^*)) = \Gamma(Z^*) \subset Z$ and $A^*(H) = A^*(\overline{A(Z^*)})$, and consequently $A^*(H) \subset \overline{\Gamma(Z^*)} \subset Z$. ∎

LEMMA 2.2. *For every $h \in Z$ and $\alpha > 0$ the equation*

$$\alpha z_\alpha + \Gamma J(z_\alpha) = \alpha h \tag{2.1}$$

has a unique solution $z_\alpha = z_\alpha(h) = \alpha \left(\alpha I + \Gamma_0^T J\right)^{-1}(h)$ and

$$\|z_\alpha(h)\| = \|J(z_\alpha(h))\| \leq \|h\| . \tag{2.2}$$

Proof. First, let us consider the following equation in Z^*:

$$\alpha J^{-1}(z^*) + \Gamma z^* = \alpha h. \tag{2.3}$$

Set

$$\mathcal{A}(z^*) = \alpha J^{-1}(z^*) + \Gamma z^* - \alpha h.$$

The operator $\mathcal{A}$ maps Z^* into Z and has the following properties:

1. $\mathcal{A}$ is demicontinuous since J^{-1} is demicontinuous and Γ is linear continuous (so demicontinuous).

2. $\mathcal{A}$ is strictly monotone, i.e., $\langle z_1^* - z_2^*, \mathcal{A}(z_1^*) - \mathcal{A}(z_2^*) \rangle > 0$ for all $z_1^* \neq z_2^*$ in Z^* since J^{-1} is strictly monotonic.

3. There is a $\rho > 0$ such that

$$\langle z^*, \mathcal{A}(z^*) \rangle > 0 \text{ for all } z^* \in Z^* \text{ such that } \|z^*\| > \rho.$$

Indeed, from the inequality

$$\begin{aligned} \langle z^*, \mathcal{A}(z^*) \rangle &= \left\langle z^*, \alpha J^{-1}(z^*) + \Gamma z^* - \alpha h \right\rangle \\ &\geq \alpha(\|z^*\|^2 - \langle z^*, h \rangle) \geq \alpha(\|z^*\|^2 - \|z^*\| \, \|h\|) \\ &= \alpha \left(\|z^*\| - \|h\|\right) \|z^*\| , \end{aligned}$$

property 3 follows.

By the Minty–Browder theorem (see [29, Theorem 2.2]), there exists a unique solution $z^* \in Z^*$ of $\mathcal{A}(z^*) = 0$. Thus (2.3) has a unique solution z^* in Z^*. Then $z_\alpha = J^{-1}(z^*)$ is a unique solution of (2.1). Solving this equation for z_α, we get

$$z_\alpha = \alpha \left(\alpha I + \Gamma_0^T J\right)^{-1}(h).$$

To prove (2.2), let $z_\alpha = z_\alpha(h)$ be the solution of (2.1). Then

$$\begin{aligned} \alpha \langle J(z_\alpha), z_\alpha \rangle + \langle J(z_\alpha), \Gamma J(z_\alpha) \rangle &= \alpha \langle J(z_\alpha), h \rangle, \\ \alpha \|z_\alpha\|^2 + \langle J(z_\alpha), \Gamma J(z_\alpha) \rangle &= \alpha \langle J(z_\alpha), h \rangle, \\ \alpha \|z_\alpha\|^2 \le \alpha \langle J(z_\alpha), h \rangle &\le \alpha \|z_\alpha\| \|h\|, \\ \|z_\alpha\| = \|J(z_\alpha)\| &\le \|h\|. \end{aligned} \tag{2.4}$$

The lemma is proved. □

THEOREM 2.3. *Let Γ be a symmetric operator. Then the following three conditions are equivalent:*

(i) *Γ is positive; that is, $\langle z^*, \Gamma z^* \rangle > 0$ for all nonzero $z^* \in Z^*$.*

(ii) *For all $h \in Z$, $J(z_\alpha(h))$ converges to the zero as $\alpha \to 0^+$ in the weak topology, where $z_\alpha(h) = \alpha(\alpha I + \Gamma J)^{-1}(h)$ is a solution of (2.1).*

(iii) *For all $h \in Z$, $z_\alpha(h) = \alpha(\alpha I + \Gamma J)^{-1}(h)$ converges to the zero as $\alpha \to 0^+$ in the strong topology.*

Proof. (i) $\Rightarrow$ (ii): Suppose that Γ is positive. From (2.2) it follows that we can extract a subsequence (still denoted by z_α) which is weakly convergent; i.e., there exists $\overline{z}^* \in Z^*$ such that

$$\langle J(z_\alpha), z \rangle \to \langle \overline{z}^*, z \rangle \text{ as } \alpha \to 0^+$$

for all $z \in Z$, and since J is bijective there exists $\overline{z} \in Z$ such that

$$\langle J(z_\alpha), z \rangle \to \langle J(\overline{z}), z \rangle \text{ as } \alpha \to 0^+.$$

Then from (2.1) we have

$$\alpha \langle J(\overline{z}), z_\alpha \rangle + \langle J(\overline{z}), \Gamma J(z_\alpha) \rangle = \alpha \langle J(\overline{z}), h \rangle.$$

Taking the limit in the latter equality, we obtain

$$\langle J(\overline{z}), \Gamma J(\overline{z}) \rangle = 0,$$

and, consequently, $J(\overline{z}) = 0$ by positivity of Γ. In fact, we proved that the limit of every weakly convergent subsequence is zero. Thus the sequence $\{J(z_\alpha)\}$ itself converges weakly to zero.

(ii) $\Rightarrow$ (iii): Assume that $J(z_\alpha) \rightharpoonup 0$ as $\alpha \to 0^+$. Then, dividing (2.4) by α and taking the limit, we obtain

$$\lim_{\alpha \to 0^+} \|z_\alpha\|^2 = \lim_{\alpha \to 0^+} \|J(z_\alpha)\|^2 \le \lim_{\alpha \to 0^+} \langle J(z_\alpha), h \rangle = 0.$$

(iii) $\Rightarrow$ (i): Now, assume that for all $h \in Z$, $\lim_{\alpha \to 0^+} \|z_\alpha(h)\| = 0$, but there exists $z^* \neq 0$ such that $\langle z^*, \Gamma z^* \rangle = 0$. Then by Lemma 2.1

$$\langle z^*, \Gamma z^* \rangle = \langle z^*, A^* A z^* \rangle = \|A z^*\|^2 = 0,$$

which implies that $Az^* = 0$ and, consequently, $\Gamma z^* = A^* A z^* = 0$.

On the other hand, as $J : Z \to Z^*$ is bijective, there exists a unique nonzero $z \in Z$ such that $J(z) = z^*$. Then for $h = z$

$$\alpha z + \Gamma J(z) = \alpha h,$$

since $\Gamma J(z) = \Gamma z^* = 0$. Thus $\lim_{\alpha \to 0^+} z_\alpha(h) = h \neq 0$, which leads to a contradiction. □

Remark 2.4. The analogue of this theorem in Hilbert spaces is proved in [23].

THEOREM 2.5. *Let $\Gamma : Z^* \to Z$ be a positive symmetric operator, and let $h : Z \to Z$ be a nonlinear operator. Assume z_α is a solution of the equation*

$$\alpha z_\alpha + \Gamma J(z_\alpha) = \alpha h(z_\alpha) \tag{2.5}$$

and

$$\left\| h(z_\alpha) - \overline{h} \right\| \to 0 \text{ as } \alpha \to 0^+.$$

Then there exists a subsequence of the sequence $\{z_\alpha\}$ converging strongly to zero as $\alpha \to 0^+$.

Proof. From (2.2) and strong convergence of the sequence $\{h(z_\alpha)\}$, it is easy to see that there exists $C > 0$ such that for all $\alpha > 0$

$$\|z_\alpha\| = \|J(z_\alpha)\| \leq \|h(z_\alpha)\| \leq C.$$

Then we can extract a subsequence, still denoted by z_α, such that

$$J(z_\alpha) \rightharpoonup J(\overline{z}_0) \quad \text{as} \quad \alpha \to 0^+$$

for some $\overline{z}_0 \in Z$. Applying $J(\overline{z}_0)$ to (2.5) and taking the limit, we obtain

$$\begin{aligned} \alpha \langle J(\overline{z}_0), z_\alpha \rangle + \langle J(\overline{z}_0), \Gamma J(z_\alpha) \rangle &= \alpha \langle J(\overline{z}_0), h(z_\alpha) \rangle, \\ \lim_{\alpha \to 0^+} \langle J(\overline{z}_0), \Gamma J(z_\alpha) \rangle &= \langle J(\overline{z}_0), \Gamma J(\overline{z}_0) \rangle = 0, \\ J(\overline{z}_0) &= 0. \end{aligned}$$

So, $J(z_\alpha) \rightharpoonup 0$ as $\alpha \to 0^+$. Now applying $J(z_\alpha)$ to (2.5), dividing through by α, and taking the limit, we obtain

$$\begin{aligned} \|z_\alpha\|^2 + \frac{1}{\alpha} \langle J(z_\alpha), \Gamma J(z_\alpha) \rangle &= \langle J(z_\alpha), h(z_\alpha) \rangle, \\ \lim_{\alpha \to 0^+} \|z_\alpha\|^2 &\leq \lim_{\alpha \to 0^+} \langle J(z_\alpha), h(z_\alpha) \rangle \\ &\leq \lim_{\alpha \to 0^+} \left\langle J(z_\alpha), h(z_\alpha) - \overline{h} \right\rangle + \lim_{\alpha \to 0^+} \left\langle J(z_\alpha), \overline{h} \right\rangle = 0. \end{aligned}$$

The proof is complete. □

3. Deterministic systems. We start this section with the following assumptions.

(A1) X is a separable reflexive Banach space, and U is a separable Hilbert space.

(A2) $A : D(A) \subset X \to X$ generates a compact semigroup $S(t), t > 0$, on X.

(A3) The function $f : I \times X \times U \to X$ is continuous, and there exist functions $\lambda_i(\cdot) \in L_1(I, R^+)$ and $\phi_i(\cdot) \in L_1(X \times U, R^+)$, $i = 1, 2, \ldots, q$, such that

$$\|f(t,x,u)\| \le \sum_{i=1}^{q} \lambda_i(t)\,\phi_i(x,u) \quad \text{for all } (t,x,u) \in I \times X \times U.$$

Next, for convenience, let us introduce the following notation:

$$K = \max\{\|S(t)\| : 0 \le t \le T\}, \quad M = \|B\|, \quad \|\lambda_i\| = \int_0^T \lambda_i(s)\,ds,$$
$$k = \max\{1, MK, MKT\},$$
$$a_i = 3kMK^2\|\lambda_i\|, \quad b_i = 3K\|\lambda_i\|, \quad c_i = \max\{a_i, b_i\},$$
$$d_1 = 3kMK(\|x_T\| + K\|x_0\|), \quad d_2 = 3K\|x_0\|, \quad d = \max\{d_1, d_2\}.$$

(A4) For all $\alpha > 0$, $\limsup_{r\to\infty}(r - \sum_{i=1}^{q} \frac{c_i}{\alpha} \sup\{\phi_i(x,u) : \|(x,u)\| \le r\}) = \infty$.

(AB) For every $h \in X$, $z_\alpha(h) = \alpha\left(\alpha I + \Gamma_0^T J\right)^{-1}(h)$ converges to zero as $\alpha \to 0^+$ in strong topology, where

$$L_0^T u := \int_0^T S(T-s)\,Bu(s)\,ds,$$
$$\Gamma_0^T := \int_0^T S(T-s)\,BB^*S^*(T-s)\,ds = L_0^T\left(L_0^T\right)^*,$$

and $z_\alpha(h)$ is a solution of the equation

$$\alpha z_\alpha + \Gamma_0^T J(z_\alpha) = \alpha h.$$

Remark 3.1. By Theorem 2.3, (AB) holds if and only if $\|\left(L_0^T\right)^* z\| > 0$ for all nonzero $z \in X$. In other words, (AB) holds if and only if the corresponding linear system is approximately controllable.

In section 4, it will be shown that the system (1.2) is approximately controllable if for all $\alpha > 0$ there exists a continuous function $(x,u)(\cdot) \in C(I, X \times U)$ such that

$$\begin{cases} u(t) = B^*S^*(T-t)\,J(\left(\alpha I + \Gamma_0^T J\right)^{-1} p(x(\cdot), u(\cdot))), \\ x(t) = S(t)\,x_0 + \int_0^t S(t-s)\,[Bu(s) + f(s, x(s), u(s))]\,ds, \end{cases} \tag{3.1}$$

where

$$p(x(\cdot), u(\cdot)) = x_T - S(T)\,x_0 - \int_0^T S(T-s)\,f(s, x(s), u(s))\,ds.$$

Having noticed this fact, our goal in this section is to find conditions for solvability of (3.1).

For all $\alpha > 0$, define the operator $\mathcal{P}_\alpha$ on $C(I, X \times U)$ as

$$\mathcal{P}_\alpha(x,u) = (z,v), \tag{3.2}$$

where

$$v(t)\,(=v_\alpha(t)) = B^*S^*(T-t)\,J\left((\alpha I+\Gamma_0^T J)^{-1}p(x(\cdot),u(\cdot))\right), \tag{3.3}$$

$$z(t)\,(=z_\alpha(t)) = S(t)\,x_0+\int_0^t S(t-s)\,(Bv_\alpha(s)+f(s,x(s),u(s)))\,ds, \tag{3.4}$$

$$p(x(\cdot),u(\cdot)) = x_T - S(T)\,x_0-\int_0^T S(T-s)\,f(s,x(s),u(s))\,ds.$$

It will be shown that for all $\alpha>0$ the operator $\mathcal{P}_\alpha$ from $C(I,X\times U)$ into itself has a fixed point.

On Banach space $C(I,X\times U)$ introduce a set

$$Y_r := \{(x,u)(\cdot)\in C(I,X\times U)\mid x(0)=x_0,\ \|(x,u)(\cdot)\|\le r\},$$

where r is the positive constant.

THEOREM 3.2. *Assume assumptions* (A1)–(A4) *are satisfied. Then for all* $0<\alpha\le 1$ *the system* (3.1) *has a solution; that is, the operator* $\mathcal{P}_\alpha$ *has a fixed point.*

Proof. The proof of the theorem is long and technical. We split it into two steps.

Step 1. For arbitrary $\alpha>0$ there is a positive constant $r(\alpha)$ such that $\mathcal{P}_\alpha : Y_{r(\alpha)}\to Y_{r(\alpha)}$.

Let

$$\psi_i(r)=\sup\{\phi_i(x,u):\|(x,u)\|\le r\}.$$

By the assumption (A4), for all $\alpha>0$ there exists $r(\alpha)>0$ such that

$$\frac{d}{\alpha}+\sum_{i=1}^q\frac{c_i}{\alpha}\psi_i(r(\alpha))\le r(\alpha).$$

If $(x,u)(\cdot)\in Y_{r(\alpha)}$, from (3.3) and (3.4) we have

$$\begin{aligned}\|v(t)\| &\le \frac{1}{\alpha}MK\left(\|x_T\|+K\|x_0\|+K\int_0^T\sum_{i=1}^q\lambda_i(s)\,\phi_i(x(s),u(s))\,ds\right)\\ &= \frac{1}{\alpha}MK(\|x_T\|+K\|x_0\|)+\frac{1}{\alpha}MK^2\sum_{i=1}^q\|\lambda_i\|\,\psi_i(r(\alpha))\\ &\le \frac{d}{3k\alpha}+\frac{1}{3k}\sum_{i=1}^q\frac{c_i}{\alpha}\psi_i(r(\alpha)) = \frac{1}{3k}\left(\frac{d}{\alpha}+\sum_{i=1}^q\frac{c_i}{\alpha}\psi_i(r(\alpha))\right)\le\frac{r(\alpha)}{3k},\end{aligned}$$

$$\begin{aligned}\|z(t)\| &\le \frac{d}{3}+KMT\|v\|+K\int_0^t\sum_{i=1}^q\lambda_i(s)\,\phi_i(x(s),u(s))\,ds\\ &\le \frac{d}{3}+k\|v\|+\frac{1}{3}\sum_{i=1}^q c_i\psi_i(r(\alpha))\\ &\le \frac{1}{3}\left[d+\sum_{i=1}^q c_i\psi_i(r(\alpha))\right]+k\|v\|\\ &\le \frac{\alpha r(\alpha)}{3}+\frac{r(\alpha)}{3}\le\frac{2r(\alpha)}{3}.\end{aligned}$$

So

$$\|(\mathcal{P}_\alpha(x,u))(t)\| = \|z(t)\| + \|v(t)\| \le r(\alpha).$$

Hence $\mathcal{P}_\alpha$ maps $Y_{r(\alpha)}$ into itself.

Step 2. For all $\alpha > 0$ the operator $\mathcal{P}_\alpha$ maps $Y_{r(\alpha)}$ into a relatively compact subset of $Y_{r(\alpha)}$, and $\mathcal{P}_\alpha$ has a fixed point.

According to the infinite dimensional version of the Ascoli–Arzela theorem, we have to show that

(i) for arbitrary $t \in I$ the set

$$V(t) = \left\{(\mathcal{P}_\alpha(x,u))(t) \mid (x(\cdot), u(\cdot)) \in Y_{r(\alpha)}\right\}$$

is relatively compact;

(ii) for arbitrary $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\|(\mathcal{P}_\alpha(x,u))(t_1) - (\mathcal{P}_\alpha(x,u))(t_2)\| < \varepsilon$$

if $\|x\| \le r$, $|t_1 - t_2| \le \delta$, $t_1, t_2 \in I$.

Let us prove (i). In fact, the case where $t = 0$ is trivial since $V(0) = \{x_0\}$. So let t, $0 < t \le T$, be a fixed real number, and let η be a given real number satisfying $0 < \eta < t$. Define

$$(\mathcal{P}_\alpha^\eta(x,u))(t) = \left[S(\eta) z(t-\eta), B^* S^*(T-t) J\left((\alpha I + \Gamma_0^T J)^{-1} \mathcal{P}(x(\cdot), u(\cdot))\right)\right].$$

Since $S(\eta)$ is compact and $z(t-\eta)$ and $\mathcal{P}(x(\cdot), u(\cdot))$ are bounded on $Y_{r(\alpha)}$, the set

$$V_\eta(t) = \left\{(\mathcal{P}_\alpha^\eta(x,u))(t) \mid (x,u)(\cdot) \in Y_{r(\alpha)}\right\}$$

is a relatively compact set in $X \times U$; that is, we can find a finite set $\{y_i,\ 1 \le i \le m\}$ in $X \times U$ such that

$$V_\eta(t) \subset \bigcup_{i=1}^m N(y_i, \varepsilon/2),$$

where $N(y_i, \varepsilon/2)$ is an open ball in $X \times U$ with the center at y_i of radius $\varepsilon/2$. On the other hand,

$$\|(\mathcal{P}_\alpha(x,u))(t) - (\mathcal{P}_\alpha^\eta(x,u))(t)\| = \left\| \int_{t-\eta}^t S(t-s)\left[Bu(s) + f(s, x(s), u(s))\right] ds \right\|$$

$$\le \frac{1}{\alpha} K^2 M^2 \left(\|x_T\| + K\|x_0\| + K \int_0^T \sum_{i=1}^q \lambda_i(s)\, \psi_i(r(\alpha))\, ds \right) \eta$$

$$+ K \sum_{i=1}^q \int_{t-\eta}^t \lambda_i(s)\, ds \psi_i(r(\alpha)) \le \frac{\varepsilon}{2}.$$

Consequently,

$$V(t) \subset \bigcup_{i=1}^m N(y_i, \varepsilon).$$

Hence, for each $t \in [0,T]$, $V(t)$ is relatively compact in $X \times U$.

Next, we show (ii). We have to show that $V = \left\{ (\mathcal{P}_\alpha (x,u))(\cdot) \mid (x,u)(\cdot) \in Y_{r(\alpha)} \right\}$ is equicontinuous on $[0,T]$. In fact, for $0 < t_1 < t_2 \le T$, we have

$$\begin{aligned}
\|v(t_1) - v(t_2)\| &\le \|B^* S^*(T-t_1) - B^* S^*(T-t_2)\| \\
&\quad \times \frac{1}{\alpha} \left[\|x_T\| + K\|x_0\| + K \int_0^T \sum_{i=1}^q \lambda_i(s)\, \phi_i(x(s), u(s))\, ds \right] \\
&\le \|B^* S^*(T-t_1) - B^* S^*(T-t_2)\| \\
&\quad \times \frac{1}{\alpha} \left[\|x_T\| + K\|x_0\| + K \sum_{i=1}^q \|\lambda_i\|\, \psi_i(r(\alpha)) \right],
\end{aligned}$$

$$\begin{aligned}
\|z(t_1) - z(t_2)\| &\le \|S(t_1) - S(t_2)\|\, \|x_0\| + KM \int_{t_1}^{t_2} \|v(s)\|\, ds \\
&\quad + M \int_0^{t_1} \|S(t_2 - s) - S(t_1 - s)\|\, \|v(s)\|\, ds \\
&\quad + K \int_{t_1}^{t_2} \sum_{i=1}^q \lambda_i(s)\, \phi_i(x(s), u(s))\, ds \\
&\quad + \int_0^{t_1} \|S(t_2 - s) - S(t_1 - s)\| \sum_{i=1}^q \lambda_i(s)\, \phi_i(x(s), u(s))\, ds \qquad (3.5) \\
&\le \|S(t_1) - S(t_2)\|\, \|x_0\| + KM \int_{t_1}^{t_2} \|v(s)\|\, ds \\
&\quad + M \int_0^{t_1} \|S(t_2 - s) - S(t_1 - s)\|\, \|v(s)\|\, ds \\
&\quad + K \sum_{i=1}^q \int_{t_1}^{t_2} \lambda_i(s)\, ds \psi_i(r(\alpha)) \\
&\quad + \sum_{i=1}^q \int_0^{t_1} \|S(t_2 - s) - S(t_1 - s)\|\, \lambda_i(s)\, ds \psi_i(r(\alpha)) \\
&= I_1 + I_2 + I_3 + I_4 + I_5.
\end{aligned}$$

Moreover, for all $(x(\cdot), u(\cdot)) \in Y_{r(\alpha)}$,

$$\begin{aligned}
\|v\| &\le \frac{1}{\alpha} MK \left(\|x_T\| + K\|x_0\| + K \int_0^T \sum_{i=1}^q \lambda_i(s)\, \phi_i(x(s), u(s))\, ds \right) \\
&\le \frac{1}{\alpha} MK \left(\|x_T\| + K\|x_0\| + K \sum_{i=1}^q \|\lambda_i\|\, \psi_i(r(\alpha)) \right).
\end{aligned}$$

Thus the right-hand side of (3.5) does not depend on particular choices of $(x,u)(\cdot)$. It is clear that $I_2 \to 0$ and $I_4 \to 0$ as $t_1 - t_2 \to 0$. Since the semigroup $S(\cdot)$ is compact, $\|S(t_2 - s) - S(t_1 - s)\| \to 0$ as $t_1 - t_2 \to 0$ for arbitrary t, s such that $t - s > 0$. Then $I_1 \to 0$, and by Lebesgue's dominated convergence theorem $I_3 \to 0$ and $I_5 \to 0$ as $t_1 - t_2 \to 0$. So, we obtain the equicontinuity of V. Thus $\mathcal{P}_\alpha \left[Y_{r(\alpha)} \right]$ is equicontinuous and also bounded. By the Ascoli–Arzela theorem, $\mathcal{P}_\alpha \left[Y_{r(\alpha)} \right]$ is

relatively compact in $C(I, X \times U)$. On the other hand, it is easy to see that for all $\alpha > 0, \mathcal{P}_\alpha$ is continuous on $C(I, X \times U)$. Hence, for all $\alpha > 0, \mathcal{P}_\alpha$ is a compact continuous operator on $C(I, X \times U)$. From the Schauder fixed point theorem, $\mathcal{P}_\alpha$ has a fixed point. □

Consider the following linear system with $f(\cdot) \in L_1(I, X)$:

$$z(t; x_0, u) = S(t) x_0 + \int_0^t S(t-s) [Bu(s) + f(s)] ds. \tag{3.6}$$

LEMMA 3.3. *If*

$$p = x_T - S(T) x_0 - \int_0^T S(T-s) f(s) ds$$

and if $u_\alpha(\cdot) \in L_2(I, U)$ *is a control defined by*

$$u_\alpha(t) = B^* S^*(T-t) J \left(\left(\alpha I + \Gamma_0^T J \right)^{-1} p \right), \tag{3.7}$$

then

$$z(T; x_0, u_\alpha) - x_T = -\alpha \left(\alpha I + \Gamma_0^T J \right)^{-1} p \tag{3.8}$$

and

$$\begin{aligned} z(t; x_0, u_\alpha) &= S(t) x_0 + \int_0^t S(t-s) f(s) ds \\ &\quad + \Gamma_0^t S^*(T-t) J \left(\left(\alpha I + \Gamma_0^T J \right)^{-1} p \right), \end{aligned} \tag{3.9}$$

where $x_T \in X$ *and* $\alpha > 0$ *is a parameter.*

Proof. Inserting (3.7) in (3.6), we have

$$\begin{aligned} z(t; x_0, u_\alpha) &= S(t) x_0 + \int_0^t S(t-s) f(s) ds + \int_0^t S(t-s) B u_\alpha(s) ds \\ &= S(t) x_0 + \int_0^t S(t-s) f(s) ds \\ &\quad + \int_0^t S(t-s) B B^* S^*(T-s) J \left(\left(\alpha I + \Gamma_0^T J \right)^{-1} p \right) ds \\ &= S(t) x_0 + \int_0^t S(t-s) f(s) ds \\ &\quad + \Gamma_0^t S^*(T-t) J \left(\left(\alpha I + \Gamma_0^T J \right)^{-1} p \right). \end{aligned}$$

Writing the latter equation for $t = T$ and solving the obtained one for $z(T; x_0, u_\alpha) - x_T$, we obtain (3.8):

$$\begin{aligned} z(T) &= S(T) x_0 + \int_0^T S(T-s) f(s) ds + \Gamma_0^T J \left(\left(\alpha I + \Gamma_0^T J \right)^{-1} p \right) \\ z(T) - x_T &= S(T) x_0 + \int_0^T S(T-s) f(s) ds - x_T \\ &\quad + \left(-\alpha I + \alpha I + \Gamma_0^T J \right) \left(\alpha I + \Gamma_0^T J \right)^{-1} p \\ &= S(T) x_0 + \int_0^T S(T-s) f(s) ds - x_T \end{aligned}$$

$$
\begin{aligned}
&-\alpha\left(\alpha I+\Gamma_0^T J\right)^{-1} p+\left(\alpha I+\Gamma_0^T J\right)\left(\alpha I+\Gamma_0^T J\right)^{-1} p \\
&=-\alpha\left(\alpha+\Gamma_0^T J\right)^{-1} p.
\end{aligned}
$$

The lemma is proved. □

THEOREM 3.4. *Under the conditions* (A1), (A2), (AB)*, and the following:*

(AF) *The function $f: I\times X\times U\to X$ is continuous and uniformly bounded; i.e., there exists $L>0$ such that*

$$\|f(t,x,u)\|\le L \quad \text{for all } (t,x,u)\in I\times X\times U,$$

the system (1.2) *is approximately controllable.*

Proof. It is obvious that the conditions (A3) and (A4) follow from (AF).

Let $\left(x_\alpha^*,u_\alpha^*\right)(\cdot)$ be a fixed point of $\mathcal{P}_\alpha$ in $Y_{r(\alpha)}$. Then $x_\alpha^*(\cdot)$ is a mild solution of (1.2) on $[0,T]$ under the control

$$u_\alpha^*(t)=B^*S^*(T-t)J\left(\left(\alpha I+\Gamma_0^T J\right)^{-1} p\left(x_\alpha^*(\cdot),u_\alpha^*(\cdot)\right)\right)$$

and satisfies the following equality:

$$x_\alpha^*(T)=x_T-\alpha\left(\alpha I+\Gamma_0^T J\right)^{-1} p\left(x_\alpha^*(\cdot),u_\alpha^*(\cdot)\right).$$

In other words, by Lemma 2.2, $z_\alpha=x_\alpha^*(T)-x_T$ is a solution of the equation

$$\alpha z_\alpha+\Gamma_0^T J(z_\alpha)=\alpha h_\alpha$$

with

$$h_\alpha=-p\left(x_\alpha^*(\cdot),u_\alpha^*(\cdot)\right)=S(T)x_0+\int_0^T S(T-s)f\left(s,x_\alpha^*(s),u_\alpha^*(s)\right)ds-x_T.$$

By (AF)

$$\int_0^T\left\|f\left(s,x_\alpha^*(s),u_\alpha^*(s)\right)\right\|^2 ds\le L^2T,$$

and, consequently, the sequence $\left\{f\left(\cdot,x_\alpha^*(\cdot),u_\alpha^*(\cdot)\right)\right\}$ is bounded and belongs to $L_2(I,X)$. Then there is a subsequence still denoted by $\left\{f\left(\cdot,x_\alpha^*(\cdot),u_\alpha^*(\cdot)\right)\right\}$ that weakly converges to, say, $f(\cdot)$ in $L_2(I,X)$. Then by Corollary 3.3 from [34], we obtain

$$
\begin{aligned}
\|h_\alpha-h\| &=\left\|\int_0^T S(T-s)\left[f\left(s,x_\alpha^*(s),u_\alpha^*(s)\right)-f(s)\right]ds\right\| \\
&\le \sup_{0\le t\le T}\left\|\int_0^t S(t-s)\left[f\left(s,x_\alpha^*(s),u_\alpha^*(s)\right)-f(s)\right]ds\right\|\to 0,
\end{aligned}
$$

where

$$h=S(T)x_0+\int_0^T S(T-s)f(s)\,ds-x_T$$

as $\alpha\to 0^+$ because of the compactness of an operator $g(\cdot)\to\int_0^{\cdot} S(\cdot-s)g(s)\,ds: L_2(I,X)\to C(I,X)$. Then by Theorem 2.5

$$\left\|x_\alpha^*(T)-x_T\right\|=\|z_\alpha\|\to 0$$

as $\alpha\to 0^+$. This gives the approximate controllability. The theorem is proved. □

4. Stochastic systems. In this section, we examine the approximate controllability of the following stochastic semilinear control system in a Hilbert space X:

$$\begin{aligned} dx(t) &= [Ax(t) + Bu(t) + f(t, x(t), u(t))]dt + g(t, x(t), u(t))dw(t), \\ x(0) &= x_0, \quad t \in I = [0, T]. \end{aligned} \tag{4.1}$$

Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t \uparrow \subset \mathcal{F}, t \geq 0\}, P)$ denote a complete probability space equipped with a family of nondecreasing subsigma algebras. Let $\mathbf{E}\{\cdot\}$ denote the integration with respect to the measure P. All random processes considered in the paper will be assumed to be strongly $\mathcal{F}_t$-progressively measurable processes unless stated otherwise. Let E be a separable Hilbert space, and let $\{w(t), t \geq 0\}$ be a Wiener process with values in E with covariance operator Q, where Q is a positive nuclear operator in E. We assume that there exist a complete orthonormal system $\{e_k\}$ in E, a bounded sequence of nonnegative real numbers λ_k such that $Qe_k = \lambda_k e_k$, $k = 1, 2, \ldots$, and a sequence $\{\beta_k\}$ of independent Brownian motions such that

$$\langle w(t), e\rangle = \sum_{k=1}^{\infty} \sqrt{\lambda_k}\, \langle e_k, e\rangle\, \beta_k(t), \ e \in E, \ t \geq 0.$$

Further, we assume that $\mathcal{F}_t$ is generated by $\{w(s) : 0 \leq s \leq t\}$. Let $L_2^0 := L_2(Q^{1/2}E, X)$ be the space of all Hilbert–Schmidt operators from $Q^{1/2}E$ to X. The space L_2^0 is a separable Hilbert space, equipped with the norm $\|\Psi\|_Q^2 = tr[\Psi Q \Psi^*]$. We use $L_p(\mathcal{F}, X)$, $1 \leq p \leq \infty$, to denote the Banach space of strongly $\mathcal{F}$-measurable, X-valued random variables satisfying $\mathbf{E}\|x\|_X^2 < \infty$. Since for each $t \geq 0$ the subsigma algebras $\mathcal{F}_t$ are complete, $L_p(\mathcal{F}_t, X)$ are closed subspaces of $L_p(\mathcal{F}, X)$, and hence they are also Banach spaces. Similarly, $L_p^{\mathcal{F}}(I, X)$ will denote the Banach space of $\mathcal{F}_t$-progressively measurable random processes defined on I, taking values from X satisfying $\mathbf{E}\int_I \|x(t)\|_X^2\, dt < \infty$. $C(I, L_2(\Omega, \mathcal{F}, P, X))$ is the Banach space of continuous maps from $I = [0, T]$ into $L_2(\Omega, \mathcal{F}, P, X)$ satisfying the condition $\sup_{t\in I} \mathbf{E}\|x(t)\|^2 < \infty$. $\mathcal{H}_2$ is the closed subspace of $C(I, L_2(\Omega, \mathcal{F}, P, X))$ consisting of measurable and $\mathcal{F}_t$-adapted processes $x(t)$. Then $\mathcal{H}_2$ is a Banach space with the norm topology given by $\|x\|_{\mathcal{H}_2} = (\sup_{t\in I} \mathbf{E}\|x(t)\|^2)^{1/2}$. Further notation will be introduced as required.

Concerning the operators A, B, f, and g, we assume the following hypotheses:

(H1) The operator A generates a compact semigroup $S(\cdot)$.

(H2) The functions $f : I \times X \times U \to X$ and $g : I \times X \times U \to L_2^0$ are continuous, and there exists a constant $L > 0$ such that

$$\begin{aligned} \|f(t, x, u) - f(t, y, u)\| + \|g(t, x, u) - g(t, y, u)\|_Q &\leq L\|x - y\|, \\ \|f(t, x)\| + \|g(t, x)\|_Q &\leq L \ \text{ for all } t \in I, \ x, y \in X. \end{aligned}$$

(H3) For every $0 \leq r < T$, the operator $\alpha\left(\alpha I + \Gamma_r^T\right)^{-1}$ converges to zero as $\alpha \to 0^+$ in the strong operator topology; that is, the linear deterministic system that corresponds to (4.1) is approximately controllable on every $[r, T]$, $0 \leq r < T$ (or on every $[0, t]$, $0 < t \leq T$).

It is clear that under these conditions the system (4.1) admits a mild solution $x(\cdot) \in \mathcal{H}_2$ for any $x_0 \in X$, $u(\cdot) \in L_2^{\mathcal{F}}(I, U)$; see Da Prato and Zabczyk [11].

For any $\alpha > 0$ define the operator

$$\mathcal{P}_\alpha(y, v) = (z, w),$$

where

$$
\begin{aligned}
z(t) &= S(t)x_0 + \int_0^t S(t-r)Bw(r)\,dr + \int_0^t S(t-r)f(r,y(r),v(r))\,dr \\
&\quad + \int_0^t S(t-r)\sigma(r,y(r),v(r))\,dw(r), \\
w(t) &= B^*S^*(T-t)\left[\left(\alpha+\Gamma_0^T\right)^{-1}(\mathbf{E}h - S(T)x_0) + \int_0^t \left(\alpha+\Gamma_r^T\right)^{-1}\varphi(r)\,dw(r)\right] \\
&\quad - B^*S^*(T-t)\int_0^t \left(\alpha+\Gamma_r^T\right)^{-1} S(T-r)f(r,y(r),v(r))\,dr \\
&\quad - B^*S^*(T-t)\int_0^t \left(\alpha+\Gamma_r^T\right)^{-1} S(T-r)\sigma(r,y(r),v(r))\,dw(r),
\end{aligned}
$$

and $\varphi(\cdot) \in L_2^{\mathcal{F}}\left(I, L_2^0\right)$ from the representation $h = \mathbf{E}h + \int_0^T \varphi(s)\,dw(s)$ of $h \in L_2(\mathcal{F}_T, X)$; see [24].

It will be shown that the system (4.1) is approximately controllable if for all $\alpha > 0$ there exists a fixed point of the operator $\mathcal{P}_\alpha$. To show that $\mathcal{P}_\alpha$ has a fixed point, we employ the contraction mapping principle in $\mathcal{H}_2$.

THEOREM 4.1. *For all $\alpha > 0$ the operator $\mathcal{P}_\alpha$ has a unique fixed point in $\mathcal{H}_2$.*

Proof. It is obvious that $\mathcal{P}_\alpha$ maps $\mathcal{H}_2$ into itself. Show that for every $\alpha > 0$ there exists $n > 0$ such that $\mathcal{P}_\alpha^n$ is a contraction mapping. To do this, let $\mathcal{P}_\alpha(y_1, v_1) = (z_1, w_1)$ and $\mathcal{P}_\alpha(y_2, v_2) = (z_2, w_2)$. Then for each $\alpha > 0$ there exists $L(\alpha)$ such that

$$
\mathbf{E}\left\|(z_1,w_1)(t) - (z_2,w_2)(t)\right\|^2 \le tL(\alpha)\left\|(y_1,v_1) - (y_2,v_2)\right\|_{\mathcal{H}_2}^2.
$$

Evidently

$$
\mathbf{E}\left\|\mathcal{P}_\alpha^2(y_1,v_1)(t) - \mathcal{P}_\alpha^2(y_2,v_2)(t)\right\|^2 \le \frac{t^2}{2!}L^2(\alpha)\left\|(y_1,v_1) - (y_2,v_2)\right\|_{\mathcal{H}_2}^2.
$$

By mathematical induction,

$$
\begin{aligned}
&\mathbf{E}\left\|\mathcal{P}_\alpha^n(y_1,v_1)(t) - \mathcal{P}_\alpha^n(y_2,v_2)(t)\right\|^2 \\
&\le L(\alpha)\int_0^t E\left\|\mathcal{P}_\alpha^{n-1}(y_1,v_1)(s) - \mathcal{P}_\alpha^{n-1}(y_2,v_2)(s)\right\|^2 ds \\
&\le \frac{t^n}{n!}L^n(\alpha)\left\|(y_1,v_1) - (y_2,v_2)\right\|_{\mathcal{H}_2}^2.
\end{aligned}
$$

Thus

$$
\sup_{t\in[0,T]} \mathbf{E}\left\|\mathcal{P}_\alpha^n(y_1,v_1)(t) - \mathcal{P}_\alpha^n(y_2,v_2)(t)\right\|^2 \le \frac{(L(\alpha)t)^n}{n!}\left\|(y_1,v_1) - (y_2,v_2)\right\|_{\mathcal{H}_2}^2.
$$

For any fixed $\alpha > 0$ there exists n such that $\frac{(L(\alpha)t)^n}{n!} < 1$. This results that $\mathcal{P}_\alpha^n$ is a contraction mapping for sufficiently large n. Then by the contraction mapping principle the operator $\mathcal{P}_\alpha$ has a unique fixed point in $\mathcal{H}_2$. The theorem is proved. □

THEOREM 4.2. *Assume hypotheses $(H1), (H2)$, and $(H3)$ are satisfied. Then the system (4.1) is approximately controllable.*

Proof. Let $(x_\alpha^*, u_\alpha^*)(\cdot)$ be a fixed point of $\mathcal{P}_\alpha$ in $\mathcal{H}_2$. Using the Fubini theorem, one can show that any fixed point of $\mathcal{P}_\alpha$ satisfies

$$\begin{aligned} x_\alpha^*(T) &= h - \alpha\left(\alpha I + \Gamma_0^T\right)^{-1}(\mathbf{E}h - S(T)x_0) - \int_0^T \alpha\left(\alpha I + \Gamma_r^T\right)^{-1}\varphi(r)\,dw(r) \\ &\quad + \int_0^T \alpha\left(\alpha I + \Gamma_r^T\right)^{-1} S(T-r) f(r, x_\alpha^*(r), u_\alpha^*(r))dr \\ &\quad + \int_0^T \alpha\left(\alpha I + \Gamma_r^T\right)^{-1} S(T-r)\sigma(r, x_\alpha^*(r), u_\alpha^*(r))dw(r). \end{aligned} \tag{4.2}$$

By (H2)

$$\|f(s, x_\alpha^*(s), u_\alpha^*(s))\|^2 + \|g(s, x_\alpha^*(s), u_\alpha^*(s))\|_Q^2 \le L$$

in $I \times \Omega$. Then there is a subsequence, still denoted by $\{f(s, x_\alpha^*(s)), g(s, x_\alpha^*(s))\}$, weakly converging to, say, $(f(s,\omega), g(s,\omega))$ in $X \times L_2^0$. The compactness of $S(t), t > 0$, implies that

$$\begin{aligned} &S(T-s) f(s, x_\alpha^*(s), u_\alpha^*(s)) \to S(T-s) f(s), \\ &S(T-s) g(s, x_\alpha^*(s), u_\alpha^*(s)) \to S(T-s) g(s) \text{ in } I \times \Omega. \end{aligned}$$

On the other hand,

$$\|S(T-s) f(s, x_\alpha^*(s), u_\alpha^*(s))\|^2 + \|S(T-s) g(s, x_\alpha^*(s), u_\alpha^*(s))\|_Q^2 \le K^2 L \text{ in } I \times \Omega.$$

Thus by the Lebesgue dominated convergence theorem

$$\begin{aligned} &\mathbf{E}\int_0^T \|S(T-s)[f(s, x_\alpha^*(s), u_\alpha^*(s)) - f(s)]\|^2 ds \\ &+\mathbf{E}\int_0^T \|S(T-s)[g(s, x_\alpha^*(s), u_\alpha^*(s)) - g(s)]\|^2 ds \to 0 \text{ as } \alpha \to 0^+. \end{aligned}$$

Then having in mind $\left\|\alpha R(\alpha, \Gamma_r^T)\right\|^2 \le 1$ and $\alpha R(\alpha, \Gamma_r^T) \to 0$ in strong operator topology for all $0 \le r < T$, from (4.2) we obtain

$$\begin{aligned} \sqrt{\mathbf{E}\|x_\alpha^*(T) - h\|^2} &\le \left\|\alpha R(\alpha, \Gamma_0^T)(\mathbf{E}h - S(T)x_0)\right\| + \sqrt{\mathbf{E}\int_0^T \|\alpha R(\alpha, \Gamma_r^T)\|^2 \|\varphi(r)\|^2 dr} \\ &+ \sqrt{T\mathbf{E}\int_0^T \|\alpha R(\alpha, \Gamma_r^T)\|^2 \|S(T-r)[f(s, x_\alpha^*(r), u_\alpha^*(r)) - f(r)]\|^2 dr} \\ &+ \sqrt{\mathbf{E}\int_0^T \|\alpha R(\alpha, \Gamma_r^T)\|^2 \|S(T-r)[g(r, x_\alpha^*(r), u_\alpha^*(r)) - g(r)]\|^2 dr} \\ &\to 0 \end{aligned}$$

as $\alpha \to 0^+$. This gives the approximate controllability. The theorem is proved. ∎

5. Applications.

Example 1. Consider a control system governed by the semilinear heat equation

$$\begin{aligned} dx(t,\theta) &= [x_{\theta\theta}(t,\theta) + Bu(t,\theta) + f(t,x(t,\theta))] + dw(t), \\ x(t,0) &= x(t,\pi) = 0, \quad 0 \le t \le T, \ \ 0 < \theta < \pi. \end{aligned} \tag{5.1}$$

Let $X = L_2[0,\pi]$, and let $A : X \to X$ be an operator defined by

$$Az = z''$$

with domain

$$D(A) = \{z \in X \mid z, z' \ \text{ are absolutely continuous } \ z'' \in X, \ z(0) = z(\pi) = 0\}.$$

Then

$$Az = \sum_{n=1}^{\infty} \left(-n^2\right)(z, e_n)\, e_n(\theta), \quad z \in D(A),$$

where $e_n(\theta) = \sqrt{2/\pi}\sin n\theta$, $0 \le x \le \pi$, $n = 1, 2, \ldots$. It is known that A generates an analytic semigroup $S(t), t > 0$, in X and is given by

$$S(t)z = \sum_{n=1}^{\infty} e^{-n^2 t}(z, e_n)\, e_n(\theta), \quad z \in X.$$

Now define an infinite dimensional space

$$U = \left\{ u = \sum_{n=2}^{\infty} u_n e_n(\theta) \,\middle|\, \sum_{n=2}^{\infty} u_n^2 < \infty \right\}$$

with a norm defined by $\|u\| = \left(\sum_{n=2}^{\infty} u_n^2\right)^{1/2}$ and a linear continuous mapping B from U to X as follows:

$$Bu = 2u_2 e_1(\theta) + \sum_{n=2}^{\infty} u_n e_n(\theta).$$

It is obvious that for $u(t,\theta,\omega) = \sum_{n=2}^{\infty} u_n(t,\omega)\, e_n(\theta) \in L_2^{\mathcal{F}}(I,U)$,

$$Bu(t) = 2u_2(t)\, e_1(\theta) + \sum_{n=2}^{\infty} u_n(t)\, e_n(\theta) \in L_2^{\mathcal{F}}(I,X).$$

Moreover,

$$B^* v = (2v_1 + v_2)\, e_2(\theta) + \sum_{n=3}^{\infty} v_n e_n(\theta),$$

$$B^* S^*(t)x = \left(2x_1 e^{-t} + x_2 e^{-4t}\right) e_2(\theta) + \sum_{n=3}^{\infty} x_n e^{-n^2 t} e_n(\theta)$$

for $v = \sum_{n=1}^{\infty} v_n e_n(\theta)$ and $x = \sum_{n=1}^{\infty} x_n e_n(\theta)$. Let

$$\|B^* S^*(t)x\| = 0, \ \ t \in [0,T];$$

it follows that

$$\left\|2x_1e^{-t}+x_2e^{-4t}\right\|^2+\sum_{n=3}^{\infty}\|x_ne^{-n^2t}\|^2=0,\quad t\in[0,T],$$
$$\Rightarrow x_n=0,\quad n=1,2,\cdots\Rightarrow x=0.$$

Thus the deterministic linear system corresponding to (5.1) is approximately controllable on $[0,T]$ for every T, and by Theorem 4.2, the system (5.1) is approximately controllable on $[0,T]$ provided that f satisfies the assumptions (H2).

Example 2. We consider the following homogeneous Dirichlet problem for the semilinear one dimensional heat equation. Let $X=L_2[0,\pi]$, $U=L_2[0,T]$, and $A=d^2/d\theta^2$ with

$$D(A)=\{y\in X\mid y,dy/d\theta \text{ are absolutely continuous and } d^2y/d\theta^2\in X \text{ and } y(0)=y(\pi)=0\}.$$

Put $e_n(\theta)=(2/\pi)^{1/2}\sin n\theta$, $0\le\theta\le\pi$, $n=1,2,\dots$; then $\{e_n(\theta),\ n=1,2,\dots\}$ is an orthogonal basis for X and e_n is the eigenfunction corresponding to the eigenvalue $\lambda_n=n^2$ of the operator A, $n=1,2,\dots$.

Consider a control system governed by the semilinear heat equation

$$\begin{aligned}\frac{\partial x(t,\theta)}{\partial t}&=\frac{\partial^2x(t,\theta)}{\partial\theta^2}+f(x(t,\theta))+\chi_{(l_1,l_2)}(\theta)\,u(t),\\ z(t,0)&=z(t,\pi)=0,\quad 0\le t\le T,\\ z(0,\theta)&=z_0(\theta),\qquad 0\le\theta\le\pi,\end{aligned}\tag{5.2}$$

where $\chi_{(l_1,l_2)}(\theta)$ is the characteristic function of a given subinterval $(l_1,l_2)\subset(0,\pi)$. Now we can define the bounded linear operator $B:R\to L_2(0,\pi)$ by $(Bu)(t)=\chi_{(l_1,l_2)}(\theta)\,u(t)$, and the nonlinear operator f on X is assumed to satisfy (AF).

In [20], Khapalov showed that if $f(z)$ is globally Lipschitz and sublinear, the above control system is approximately controllable in

$$W=\left\{\phi:\phi(\theta)=\sum_{k=1}^{\infty}\alpha_ke_k(\theta),\ \sum_{k=1}^{\infty}\alpha_kc_k^2<\infty\right\},$$

endowed with the norm $\|\phi\|^2=\sum_{k=1}^{\infty}\alpha_kc_k^2$, where $\{c_k\}$ is a nonincreasing sequence of specifically defined positive numbers. Note that $L_2[0,\pi]$ is continuously embedded into W.

If $l_1\pm l_2$ is an irrational number, then the linear system corresponding to (5.2) is approximately controllable, and by Theorem 3.4, the system (5.2) is approximately controllable.

Acknowledgments. The author is grateful to the two anonymous referees and the corresponding editor for suggestions which led to the improvement of the paper and for pointing out [8] and to Professor Agamirza Bashirov of the Eastern Mediterranean University for fruitful discussions.

VERIFICATION THEOREMS FOR HAMILTON–JACOBI–BELLMAN EQUATIONS*

MAURO GARAVELLO†

Abstract. We study an optimal control problem in Bolza form, and we consider the value function associated to this problem. We prove two verification theorems which ensure that, if a function W satisfies some suitable weak continuity assumptions and a Hamilton–Jacobi–Bellman inequality outside a countably $\mathcal{H}^n$-rectifiable set, then it is lower than or equal to the value function. These results can be used for optimal synthesis approach.

Key words. verification theorem, optimal control, HJB equation, value function, viscosity solution

1. Introduction.

In this paper we consider a control system of the type

$$\dot{x} = f(t, x, u), \qquad u \in U, \tag{1.1}$$

where $x \in \mathbb{R}^n$ is the state, $U \subset \mathbb{R}^q$ is the control space, and f is the controlled dynamic. Given a target $S \subset \mathbb{R}^n$, a running cost $L(t, x, u)$, a final cost $\psi(t, x)$, and an initial condition (t_0, x_0), we consider the optimal control problem in Bolza form consisting in minimizing the integral of L summed with the value of ψ at final points for trajectories that start at x_0 at time t_0 and reach the target S. We define in the usual way the value function $V(t_0, x_0)$ to be the infimum of the problem with initial condition (t_0, x_0). It is well known that, under special conditions on the data of the problem, V satisfies the dynamic programming principle. This is the key point in order to prove that V is a viscosity solution of the Hamilton–Jacobi–Bellman (HJB) equation; see [2]. In general, it may happen that V is not the unique viscosity solution for this equation. With some more requirements on the Hamiltonian and on the regularity of the value function, V becomes the unique viscosity solution to the HJB equation; see [2].

Therefore, given a function W with suitable properties, it is possible to determine if W coincides with the value function, checking if it is a viscosity solution to the HJB equation. This type of theorem, called a verification theorem, is useful, for example, when a candidate value function is produced by means of the construction of a synthesis [19]. It is then natural to ask for minimal conditions under which a function W coincides with the value function. If we know that W was obtained via a synthesis, then the inequality $W \geq V$ is granted by construction, and thus we make this assumption. Then, for W to coincide with the value function, we prove it is sufficient that, outside a rectifiable set of codimension one, W is differentiable and it satisfies an HJB inequality in the classical sense. Moreover, we make use of only some weak continuity assumptions, already used in [19] to prove optimality of a regular extremal synthesis; see Theorems 5.2 and 6.1 for details. A first result in this direction can be found in [12], where the HJB inequality is asked outside a locally

finite collection of regular manifolds of positive codimension (under more restrictive continuity assumptions). Notice that, for an optimal control problem, if the value function is also semiconcave, it is differentiable outside a countably $\mathcal{H}^n$-rectifiable set; see [1, 9, 21].

We start considering the main assumptions for the problem and present two technical lemmas, one of which deals with the cardinality of the intersections between admissible trajectories and a countably $\mathcal{H}^n$-rectifiable set, while the other gives some conditions to ensure the monotonicity of a real valued function. Also, we state, without proofs, two propositions dealing with the properties of the solution to (1.1) and, in particular, dealing with existence, uniqueness, and continuous dependence on data.

Then, in section 3, we recall briefly the synthesis approach and various results available in the literature for comparison. Some examples of regular optimal synthesis, to which our main results are applicable, are given.

The first case we treat is the problem of finite time. We define a value function as the infimum, over all admissible trajectories reaching the target in finite time. The main result of this part is Theorem 5.2, which permits to verify if the function W is lower than or equal to the value function.

Next, we consider the infinite time problem. In this case the value function (6.1) is defined as the infimum of the cost functional over all admissible trajectories reaching the target in infinite time. The main result of this section is Theorem 6.1, which gives sufficient conditions on the function W to ensure the inequality $W \leq V$, where V is the value function. In this case, for a technical reason, we consider a suitable neighborhood S_1 of the target S, and we suppose that the final cost ψ is defined on S_1 in order to give sense to the limit in the definition of the value function (6.1). As a corollary of Theorems 5.2 and 6.1, we can treat a mixed case (see also [18]), considering at the same time the trajectories reaching the target both in finite time and in infinite time.

A key ingredient for Theorems 5.2 and 6.1 is the positiveness of the Lagrangian L, in order to prevent some bad phenomena such as the permanence of the system for an arbitrary interval of times in a region where L is negative making the value function equal to $-\infty$, as we see in Example 4. More precisely, it is not necessary to suppose L positive in the whole space, but some relaxed assumptions can be made, as we see in Remark 4.

This paper ends with an appendix, where we give the definition of a noncontinuous viscosity solution as in [2] and we state Theorem A.7, which ensures that, under suitable assumptions, the value functions (2.4) and (6.1) are viscosity solutions to the HJB equation.

2. Preliminaries. We consider a control system

$$\dot{x}(t) = f(t, x(t), u(t)), \quad (t, x) \in \Omega, \quad u(t) \in U, \tag{2.1}$$

where the following hold:

(A-1) Ω is an open and connected subset of $\mathbb{R} \times \mathbb{R}^n$.

(A-2) U is a nonempty subset of $\mathbb{R}^q$ for some $q \geq 1$, $q \in \mathbb{N}$.

(A-3) $\mathcal{U} = L^p(\mathbb{R}; U)$ with $1 \leq p < +\infty$ is the set of admissible controls.

(A-4) $f : \Omega \times U \to \mathbb{R}^n$ is measurable in t, continuous in (x, u), differentiable in x, and, for each $u \in U$, $D_x f(\cdot, \cdot, u)$, bounded on compact sets. Moreover, there exists $\varphi_1 : \mathbb{R} \to \mathbb{R}^+$ integrable, and for every K, compact subset of Ω, there exist a modulus

of continuity ω_K and a constant $L_K > 0$ such that, if $(t,x) \in K$ and $(t,y) \in K$, then for all u

$$\begin{cases} |f(t,x,u) - f(t,y,u)| \le \omega_K(|x-y|), \\ (f(t,x,u) - f(t,y,u)) \cdot (x-y) \le L_K |x-y|^2, \\ |f(t,x,u)| \le L_K(\varphi_1(t) + |u|^p). \end{cases} \tag{2.2}$$

We consider a function $L : \Omega \times U \to \mathbb{R}$ and assume the following:

(A-5) L is measurable in t and continuous in (x,u). Moreover, there exist $\varphi_2 : \mathbb{R} \to \mathbb{R}^+$ integrable and, for every $R \ge 0$, $C_R \ge 0$ such that

$$|L(t,x,u)| \le C_R(\varphi_2(t) + |u|^p), \quad |(t,x)| \le R. \tag{2.3}$$

In this paper we indicate with $x(\cdot\,; u, t_0, x_0)$ the solution to (2.1) such that $x(t_0;u,t_0,x_0) = x_0$. Define the value function

$$V(t_0,x_0) := \inf_{\substack{u \in \mathcal{U} \\ (T,x(T;u,t_0,x_0)) \in S}} \left\{ \int_{t_0}^{T} L(s, x(s;u,t_0,x_0), u(s)) ds + \psi(T, x(T;u,t_0,x_0)) \right\}, \tag{2.4}$$

where S, the target, is a closed subset of $\mathbb{R} \times \mathbb{R}^n$ contained in Ω, and $\psi : S \to \mathbb{R}$ is the final cost. We recall the following definition.

DEFINITION 2.1. *A subset A of Ω is a* countably $\mathcal{H}^n$-rectifiable set *if there exist A_1 and A_2 such that $A = A_1 \cup A_2$, A_1 is a finite or countable union of connected $\mathcal{C}^1$ submanifolds of positive codimension, and $\mathcal{H}^n(A_2) = 0$, where $\mathcal{H}^k$ is the k-dimensional Hausdorff measure.*

3. Examples of syntheses. In the next sections, we give sufficient conditions for a candidate value function W to coincide with V. Besides some regularity conditions, we require an HJB inequality outside a countably $\mathcal{H}^n$-rectifiable set. This regularity is shared by every function W obtained from a regular synthesis; thus it can be used to prove the optimality of the synthesis itself. In this section, we give various examples to which Theorem 5.2 is applicable. First, we need some definitions.

DEFINITION 3.1. *A synthesis Γ is a collection $\{(x_{(\bar t,\bar y)}(\cdot), u_{(\bar t,\bar y)})\}_{(\bar t,\bar y)\in\Omega}$ such that $x_{(\bar t,\bar y)}(\cdot) = x(\cdot; u_{(\bar t,\bar y)}, \bar t, \bar y) : [\bar t, \tau(\bar t,\bar y)] \to \mathbb{R}^n$, $u_{(\bar t,\bar y)} \in \mathcal{U}$, for every $(\bar t,\bar y) \in \Omega$, $x_{(\bar t,\bar y)}(\tau(\bar t,\bar y)) \in S$, and for every $t \in [\bar t, \tau(\bar t,\bar y)]$*

$$u_{(t,x_{(\bar t,\bar y)}(t))}(s) = u_{(\bar t,\bar y)}(s+t) \quad a.e.$$

and

$$x_{(t,x_{(\bar t,\bar y)}(t))}(\cdot) = x_{(\bar t,\bar y)}(\cdot + t).$$

DEFINITION 3.2. *A synthesis Γ is optimal if every $u_{(\bar t,\bar y)}$ is an optimal control.*

There is a standard method in geometric control theory to construct an optimal synthesis; see [4]. This consists of four steps: (1) using the Pontryagin maximum principle and other geometric tools to study the properties of optimal trajectories, (2) determining a finite dimensional family $\mathcal{F}$ of extremal trajectories sufficient for optimality, i.e., such that for each initial data $(\bar t,\bar y) \in \Omega$ there exists an element of $\mathcal{F}$ solving the corresponding optimal control problem, (3) constructing a synthesis formed by extremal trajectories, and (4) proving its optimality. In many cases, for autonomous systems, it happens that the extremal synthesis is associated to a feedback

$u : \mathbb{R}^n \to U$ that is smooth on each stratum of a stratification; see [19] for details. Roughly speaking, a stratification is a locally finite collection of disjoint regular submanifolds of various dimensions that is a partition and such that the boundary of each manifold is a union of manifolds of higher codimensions. In this case, the synthesis is called regular in the sense of Boltyanskii–Brunovský; see [3, 8, 19].

Step (4) of the geometric control approach can thus be obtained in essentially two ways: either by using the regularity of the synthesis (see [19]) or by proving that the candidate value function W associated to the synthesis coincides with V. The latter is exploited in [12] for a continuous W, defined on a subset of $\mathbb{R}^n$, that is differentiable and satisfies the HJB equation outside a locally finite union of smooth submanifolds of positive codimension. Then the optimality is granted for initial points for which all admissible trajectories remain in the domain of W. A mild generalization is obtained in [5], where trajectories can exit the domain of W, but the boundary of the domain of W is a level set of W itself. Another approach is one of nonsmooth analysis, using the various verification theorems that can be proved; see, for example, [20].

Our main results (see Theorems 5.2 and 6.1) generalize previous results in the following way:

1. As in [5], we assume that W can be defined on a subset and the boundary of its domain is a level curve of W.

2. We ask W to be differentiable and satisfy the HJB equation only outside a countably $\mathcal{H}^n$-rectifiable set.

3. W is only lower semicontinuous (satisfying other weak continuity assumptions).

A direct comparison with results of nonsmooth analysis is difficult. However, we point out that the value function fails in general to be locally Lipschitz continuous (see Example 1) for regular synthesis. In case of locally Lipschitz regularity, our result is a consequence of those obtained by nonsmooth analysis methods; see, for example, [10, 20].

We now give some examples to illustrate the applicability of our results. A whole class of examples can be found in [6, 17]. The first example shows a typical regular synthesis with a not locally Lipschitz continuous value function. In the second, the value function is not continuous, and it is differentiable only outside a countably $\mathcal{H}^n$-rectifiable set. The last example shows the well-known Fuller phenomenon. In this case, optimal trajectories have an infinite number of switchings, and the methods of Boltyanskii–Brunovský do not work (while the method developed in [19] does work in the case of the Fuller phenomenon).

Example 1. Let $x \in \mathbb{R}$ and $u \in [-1, 1]$. Consider the control system

$$\ddot{x} + x = u$$

and the problem of reaching the origin in minimum time. If we define $x_1 = x$ and $x_2 = \dot{x}$, we obtain the following first-order system:

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = -x_1 + u. \end{cases} \tag{3.1}$$

Every optimal trajectory is a bang-bang trajectory, i.e., formed by arcs corresponding to control $+1$ or -1. The synthesis is illustrated in Figure 3.1. There are some "switching curves":

(i) all semicircles of radius 1 contained in $\{(x_1, x_2) : x_2 \le 0\}$ and centered at $(2n + 1, 0)$, with $n \in \mathbb{N} \setminus \{0\}$;

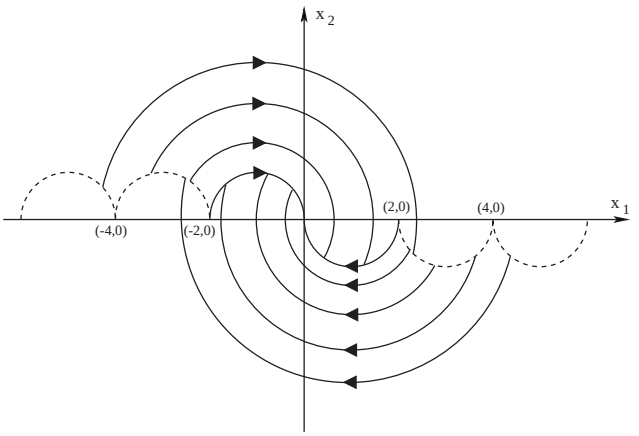

FIG. 3.1. *Synthesis of system* (3.1).

(ii) all semicircles of radius 1 contained in $\{(x_1, x_2) : x_2 \geq 0\}$ and centered at $(-2n-1, 0)$, with $n \in \mathbb{N} \setminus \{0\}$.

Optimal trajectories switch along these curves, i.e., change control from $+1$ to -1 or vice versa. Let $\gamma^{\pm}$ be the trajectory that switches at points $(\pm 2, 0)$ (defined, say, on $[-\infty, 0]$). Then the value function is not locally Lipschitz continuous at any point of supp $(\gamma^{\pm})$, but it satisfies all the hypotheses of Theorem 5.2.

Example 2. Let $\Omega = \mathbb{R}^2$, $f \equiv 0$, and $L \equiv 1$. Consider the target

$$S = \{(t, x) : x \neq 0, t = \sin(1/x)\} \cup \{x = 0, -1 \leq t \leq 1\} \cup \{t \geq 1\}$$

and the final cost ψ constantly equal to 0. The value function for this problem is given by

$$V(t,x) = \begin{cases} \sin(1/x) - t & \text{if} \quad x \neq 0, t \leq \sin(1/x), \\ 1 - t & \text{if} \quad x \neq 0, \sin(1/x) < t < 1, \\ 0 & \text{if} \quad t \geq 1, \\ -1 - t & \text{if} \quad x = 0, t \leq -1, \\ 0 & \text{if} \quad x = 0, -1 < t < 1. \end{cases}$$

This function satisfies all the hypotheses of Theorem 5.2, and clearly it is not continuous. Moreover, it is differentiable outside a countably $\mathcal{H}^n$-rectifiable set A, which is not a locally finite union of regular manifolds.

Example 3 (Fuller phenomenon). Let us consider the system

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = u, \end{cases}$$

with $|u| \leq 1$, $\Omega = \mathbb{R} \times \mathbb{R}^2$, $S = \mathbb{R} \times \{0\}$, $\psi \equiv 0$, and $L(t, x_1, x_2, u) = x_1^2$. This problem is well known in the literature; see, for example, [22]. Every optimal trajectory is composed by an infinite number of bang-bang arcs, while the time for reaching the origin of $\mathbb{R}^2$ is finite. There are two switching curves ζ^+ and ζ^- which separate $\mathbb{R}^2$ into two regions Z^+ and Z^-, where the optimal trajectory uses, respectively, the controls $u = +1$ and $u = -1$; see Figure 3.2. The value function of this problem satisfies all the hypotheses of Theorem 5.2.

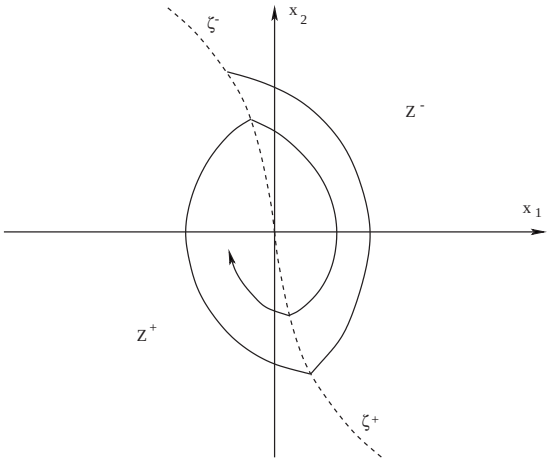

FIG. 3.2. *Synthesis of Fuller phenomenon.*

4. Some useful results. We start by recalling without proofs some classical results about ODEs.

PROPOSITION 4.1 (local existence and uniqueness). *Assume* (A-1)–(A-4). *With fixed* $u \in \mathcal{U}$ *and* $(t_0, x_0) \in \Omega$, *there exist* $\delta > 0$ *and a unique absolutely continuous function* $x(\cdot; u, t_0, x_0) : [t_0, t_0 + \delta] \to \mathbb{R}^n$ *solution to* (2.1).

PROPOSITION 4.2 (continuous dependence on data). *Assume* (A-1)–(A-4). *Let* $(t_0, x_0) \in \Omega$, $(t_0, x_n) \in \Omega$ *for every* $n \in \mathbb{N}$ *and* $u \in \mathcal{U}$, $u_n \in \mathcal{U}$ *for every* $n \in \mathbb{N}$. *Let us suppose that there exists a time* $T > t_0$ *such that* $x(\cdot; u, t_0, x_0)$ *and* $x(\cdot; u_n, t_0, x_n)$ *are defined in* $[t_0, T]$. *If* $x_n \to x_0$ *and* $u_n \to u$ *in the strong topology of* $L^p([t_0, T]; U)$ *as* $n \to +\infty$, *then* $x(\cdot; u_n, t_0, x_n) \to x(\cdot; u, t_0, x_0)$ *uniformly in* $[t_0, T]$ *as* $n \to +\infty$.

Now, we present two technical lemmas used to prove the theorems of the next sections.

LEMMA 4.3. *Fix an element* $\omega \in U$, $t' < t''$ *and* $x \in \mathbb{R}^n$ *with* $(t'', x) \in \Omega$. *Assume that there exists* $\mathcal{W}$, *an open neighborhood of* x *in* $\mathbb{R}^n$, *such that* $\zeta^y(\cdot)$, *the solution to* $\dot{\zeta}^y(t) = f(t, \zeta^y(t), \omega)$ *with* $\zeta^y(t'') = y$, *is defined on* $[t', t'']$ *for any* $y \in \mathcal{W}$ *and* $(t, \zeta^y(t)) \in \Omega$ *for all* $t \in [t', t'']$. *Let* A *be a countable* $\mathcal{H}^n$*-rectifiable set. Then for a.e.* $y \in \mathcal{W}$ *the set* $B^y := \{t \in [t', t''] : (t, \zeta^y(t)) \in A\}$ *is finite or countable.*

This lemma is a slight generalization of a result proved in Theorem 2.14 of [19], since here we consider the trajectory coupled with time.

Proof. We can write $A = A_1 \cup A_2$, where $A_1 = \cup_j M_j$ and $\{M_j\}_{j \in J}$ is a finite or countable family of connected submanifolds of $\mathbb{R}^{n+1}$ of codimension $d_j > 0$, and $\mathcal{H}^n(A_2) = 0$. After replacing each M_j by a finite or countable family of open submanifolds of M_j, we may assume that the M_j are embedded. Define $\widetilde{\mathcal{W}} :=]t', t''[\times \mathcal{W}$, and let Φ be the map $\widetilde{\mathcal{W}} \ni (t, y) \mapsto (t, \zeta^y(t)) \in \Omega$. The Jacobian of Φ is

$$\mathbf{J}\Phi = \left(\begin{array}{c|c} 1 & 0 \cdots\cdots 0 \\ \hline \mathbf{b} & \mathbf{V}^{\zeta}(t; t', \mathbf{Id}) \end{array}\right), \tag{4.1}$$

where $\mathbf{b}$ is the column vector $f(t, \zeta^y(t), \omega)$ and $\mathbf{V}^\zeta(t; t', \mathbf{Id})$ is the fundamental matrix solution to the linear system

$$\dot{v}(t) = -D_x f(t, \zeta^y(-t + t' + t''), w) \cdot v(t) \tag{4.2}$$

such that $\mathbf{V}^\zeta(t'; t', \mathbf{Id}) = \mathbf{Id}$. So the determinant of $\mathbf{J}\Phi$ is equal to the determinant of $\mathbf{V}^\zeta(t; t', \mathbf{Id})$, which is equal to $\exp \int_{t'}^t \operatorname{tr}(-D_x f(s, \zeta^y(-s+t'+t''), \omega))ds$, by Liouville's theorem (see [14]). In particular, $\det(\mathbf{J}\Phi)$ is strictly positive for any $t \in [t', t'']$. Moreover, by (A-4) $\operatorname{tr}(-D_x f)$ is bounded on compact sets and then there exist $c > 0$, $C > 0$ such that $0 < c \leq \det(\mathbf{J}\Phi) \leq C$.

So Φ is a Lipschitz diffeomorphism. In particular, we have $\mathcal{H}^n(\Phi^{-1}(A_2)) = 0$. Now for each j consider $\widetilde{M}_j := \Phi^{-1}(M_j)$. It is an embedded submanifold of codimension $d_j > 0$. Let $\Pi : \widetilde{\mathcal{W}} \to \mathcal{W}$ be the canonical projection. Consider the set S_j consisting of the points $s \in \widetilde{M}_j$ such that $\Pi|_{\widetilde{M}_j}$ is not regular. Thus, by Sard's theorem, $\mathcal{L}^n(\Pi(S_j)) = 0$. Moreover, $\mathcal{H}^n(\Pi(\Phi^{-1}(A_2))) = 0$. So the set $\mathcal{B} := \Pi(\Phi^{-1}(A_2)) \cup (\bigcup_j \Pi(S_j))$ has Lebesgue measure 0 in $\mathbb{R}^n$.

Let $y \in \mathcal{W} \setminus \mathcal{B}$. Then $(t, \zeta^y(t)) \notin A_2$ if $t' < t < t''$. To obtain the thesis, it is sufficient to show that, for each j, the set $E_j = \{t \in]t', t''[: (t, \zeta^y(t)) \in M_j\}$ is at most countable. Fix j and suppose $t \in E_j$. $\widetilde{M}_j$ has codimension $d_j > 0$, so the dimension ν_j of $\widetilde{M}_j$ is less than or equal to n. Since $y \notin \mathcal{B}$, the map $d\Pi(t, y) : T_{(t,y)}\widetilde{M}_j \to \mathbb{R}^n$ is onto; thus $\nu_j = n$ and $d\Pi(t, y)$ is injective. Obviously $d\Pi(t, y)(\frac{\partial}{\partial t}) = 0$, so $\frac{\partial}{\partial t} \notin T_{(t,y)}\widetilde{M}_j$ and, consequently, $(\tilde{t}, y) \notin \widetilde{M}_j$ if $0 < |\tilde{t} - t| \leq \varepsilon$ for $\varepsilon > 0$ sufficiently small. Therefore, t is an isolated point of E_j, and so the lemma is proved. □

LEMMA 4.4. *Let g be a real valued function on a compact interval $[a, b]$. Assume that there exists a finite or countable subset E of $[a, b]$ with the following properties:*

(i) $\liminf_{h \downarrow 0} \frac{g(x+h)-g(x)}{h} \geq 0$ *for all* $x \in [a, b[\setminus E$,
(ii) $\liminf_{h \downarrow 0} g(x + h) \geq g(x)$ *for all* $x \in [a, b[$,
(iii) $\liminf_{h \downarrow 0} g(x - h) \leq g(x)$ *for all* $x \in]a, b]$.

Then $g(b) \geq g(a)$.

For a proof of this, lemma, see [19, Lemma B.1].

5. Problem with finite time. We indicate with ∂Q the topological boundary of an arbitrary $Q \subseteq \mathbb{R} \times \mathbb{R}^n$. Before stating the theorem, we need the following definition.

DEFINITION 5.1. *Suppose that we have a time-varying Lipschitz-continuous vector field X on $\mathbb{R}^n$ and $W : \Omega \to \mathbb{R} \cup \{\pm\infty\}$. We say that W has the* no downward jumps *(NDJ) property along X if for any $[a, b] \ni t \mapsto \gamma(t)$, solution to $\dot{\gamma}(t) = X(t, \gamma(t))$ such that $(t, \gamma(t)) \in \Omega$ for all $t \in [a, b]$, we have $\liminf_{h \downarrow 0} W(t - h, \gamma(t - h)) \leq W(t, \gamma(t))$ whenever $t \in]a, b]$.*

THEOREM 5.2. *Suppose* (A-1)–(A-5) *hold. Let $Q \subseteq \Omega$ be an open subset containing S. Let $W : \overline{Q} \to \mathbb{R}$ be a lower semicontinuous function such that the following hold:*

(i) *W has the NDJ property along every time-varying vector field of the type $f(t, x, u)$ with $u \in U$ fixed and for each t*

$$\text{ess–liminf}_{y \to x} W(t, y) \leq W(t, x).$$

(ii) $W \le \psi$ *on* S.
(iii) *At every point* $(t,x) \in \partial Q$ *one has*

$$W(t,x) = \sup_{(s,y)\in Q} W(s,y).$$

(iv) *There exists a countably* $\mathcal{H}^n$*-rectifiable set* $A \subseteq \Omega$ *such that* W *is differentiable on* $Q \setminus A$ *and satisfies*

$$W_s(s,y) + \inf_{\omega\in U} \{W_y(s,y)\cdot f(s,y,\omega) + L(s,y,\omega)\} \ge 0 \quad \text{on } Q\setminus A.$$

(v) $L \ge 0$.
Then $W \le V$ *on* Q. *If* $Q = \Omega$, *we can drop hypotheses* (iii) *and* (v).

Proof. Suppose by contradiction that there exists $(t_0,x_0)\in Q$ such that $W(t_0,x_0) > V(t_0,x_0)$. In particular, $V(t_0,x_0) < +\infty$. First, let us consider the case $V(t_0,x_0) > -\infty$. So we can find $\varepsilon > 0$, $\delta > 0$ such that

$$V(t_0,x_0) \le W(t_0,x_0) - 2\varepsilon \tag{5.1}$$

and, by the lower semicontinuity of W,

$$|x - x_0| < \delta \quad \Rightarrow \quad W(t_0,x) > V(t_0,x_0) + \varepsilon. \tag{5.2}$$

We can find $u^* \in \mathcal{U}$ such that $x^*(\cdot) := x(\cdot; u^*, t_0, x_0)$ satisfies $(T, x^*(T)) \in S$ and

$$\int_{t_0}^{T} L(s,x^*(s),u^*(s))ds + \psi(T,x^*(T)) \le V(t_0,x_0) + \frac{\varepsilon}{2}. \tag{5.3}$$

Moreover, for every $l \in \mathbb{N}$ there exists $u_l \in \mathcal{U}$ such that $\|u_l - u^*\|_{L^p([t_0,T])} \le \frac{1}{l}$, and u_l is piecewise constant and left continuous. By [7, Theorem IV.9], there exist a subsequence of $(u_l)_l$, denoted again by $(u_l)_l$, and a function $h \in L^p([t_0,T])$ such that $|u_l| \le h$ a.e. and u_l converges to u^* a.e. as $l \to +\infty$. Hence, if we denote by $x_l(\cdot)$ the trajectory $x(\cdot; u_l, T, x^*(T))$, for l sufficiently big we have (see Proposition 4.2)

$$|x_l(t) - x^*(t)| < \frac{\delta}{2} \qquad \forall t \in [t_0,T] \tag{5.4}$$

and

$$\left| \int_{t_0}^{T} [L(s,x_l(s),u_l(s)) - L(s,x^*(s),u^*(s))]ds \right| \le \frac{\varepsilon}{2}. \tag{5.5}$$

Fix l such that (5.4) and (5.5) hold and an interval $]t',t'']$ such that $u_l(t) \equiv \omega$ on $]t',t'']$. Suppose that $(t,x_l(t)) \in Q$ for all $t \in [t',t'']$. Let $\zeta^y(t)$ be the trajectory associated to the constant control ω such that $\zeta^y(t'') = y$. By the fact that $d(\partial Q, \{(t,x_l(t)) : t \in [t',t'']\}) > 0$, we can find an open neighborhood $\mathcal{W}$ of $x_l(t'')$ in $\mathbb{R}^n$ such that $(t'',y) \in Q$ for all $y \in \mathcal{W}$ and $\{(t,\zeta^y(t)) : t \in [t',t'']\} \subseteq Q$ for all $y \in \mathcal{W}$. By Lemma 4.3, we have that for a.e. $y \in \mathcal{W}$ the set $B^y := \{t \in [t',t''] : (t,\zeta^y(t)) \in A\}$ is at most countable.

Therefore, since for every fixed t ess–liminf$_{y\to x}W(t,y) \le W(t,x)$, then for every $\delta_j \to 0$, $\delta_j > 0$ there exists a sequence $(y_j^l)_j \in \mathbb{N}$ such that $y_j^l \to x_l(t'')$, $W(t'', y_j^l) \le W(t'', x_l(t'')) + \delta_j$, and $B^{y_j^l}$ is at most countable. Consider the following function defined on $[t', t'']$:

$$\varphi_j^l(t) := W(t, \zeta^{y_j^l}(t)) + \int_{t'}^{t} L(s, \zeta^{y_j^l}(s), \omega)ds.$$

By the choice of y_j^l and the hypotheses (iv), φ_j^l is differentiable a.e. with a nonnegative derivative. By the lower semicontinuity of W and the NDJ condition, it follows that φ_j^l verifies the hypotheses of Lemma 4.4 and so $\varphi_j^l(t') \le \varphi_j^l(t'')$. Thus

$$W(t', \zeta^{y_j^l}(t')) \le W(t'', \zeta^{y_j^l}(t'')) + \int_{t'}^{t''} L(s, \zeta^{y_j^l}(s), \omega)ds. \tag{5.6}$$

Now, using the fact that $\zeta^{y_j^l}(t'') = y_j^l$, we obtain

$$\begin{aligned} W(t', \zeta^{y_j^l}(t')) &\le W(t'', y_j^l) + \int_{t'}^{t''} L(s, \zeta^{y_j^l}(s), \omega)ds \\ &\le W(t'', x_l(t'')) + \delta_j + \int_{t'}^{t''} L(s, \zeta^{y_j^l}(s), \omega)ds. \end{aligned} \tag{5.7}$$

By Proposition 4.2, $\zeta^{y_j^l}(\cdot) \to x_l(\cdot)$ as $j \to +\infty$, and so by the Lebesgue theorem and the lower semicontinuity of W, passing to the limit as $j \to +\infty$, we obtain

$$W(t', x_l(t')) \le W(t'', x_l(t'')) + \int_{t'}^{t''} L(s, x_l(s), \omega)ds. \tag{5.8}$$

First consider the case $\{(t, x_l(t)) : t \in [t_0, T]\} \subseteq Q$. Summing (5.8) over each interval on which u_l is constant, we have

$$W(t_0, x_l(t_0)) \le W(T, x_l(T)) + \int_{t_0}^{T} L(s, x_l(s), u_l(s))ds. \tag{5.9}$$

Now, $x_l(T) = x^*(T)$ by definition, and so, using (5.2)–(5.5) and (ii),

$$\begin{aligned} W(t_0, x_l(t_0)) &\le W(T, x^*(T)) + \int_{t_0}^{T} L(s, x_l(s), u_l(s))ds \\ &\le \psi(T, x^*(T)) + \int_{t_0}^{T} L(s, x_l(s), u_l(s))ds \\ &\le V(t_0, x_0) + \frac{\varepsilon}{2} - \int_{t_0}^{T} L(s, x^*(s), u^*(s))ds \\ &\quad + \int_{t_0}^{T} L(s, x_l(s), u_l(s))ds \\ &\le V(t_0, x_0) + \varepsilon < W(t_0, x_l(t_0)). \end{aligned}$$

This is a contradiction.

Suppose now $\{(t, x_l(t)) : t \in [t_0, T]\} \not\subseteq Q$. Define

$$\hat{\tau} := \inf \{t \leq T : (s, x_l(s)) \in Q \quad \forall s \in [t, T]\}. \tag{5.10}$$

In particular, $(\hat{\tau}, x_l(\hat{\tau})) \in \partial Q$. Using the same argument to pass from (5.8) to (5.9), we obtain that for every $\tau > \hat{\tau}$

$$W(\tau, x_l(\tau)) \leq W(T, x^*(T)) + \int_\tau^T L(s, x_l(s), u_l(s))ds, \tag{5.11}$$

and so, using (ii) and (5.3),

$$\begin{aligned} W(\tau, x_l(\tau)) &\leq \psi(T, x^*(T)) + \int_\tau^T L(s, x_l(s), u_l(s))ds \\ &\leq V(t_0, x_0) + \frac{\varepsilon}{2} - \int_{t_0}^T L(s, x^*(s), u^*(s))ds \\ &\quad + \int_\tau^T L(s, x_l(s), u_l(s))ds. \end{aligned} \tag{5.12}$$

Using (5.1), (5.5), and (v), we obtain for all $\tau > \hat{\tau}$

$$W(\tau, x_l(\tau)) \leq V(t_0, x_0) + \varepsilon \leq W(t_0, x_0) - \varepsilon. \tag{5.13}$$

Passing to the liminf as $\tau \to \hat{\tau}$ and using the lower semicontinuity of W, we conclude

$$W(\hat{\tau}, x_l(\hat{\tau})) \leq W(t_0, x_0) - \varepsilon, \tag{5.14}$$

and so by (iii)

$$W(t_0, x_0) \leq \sup_{(t,x)\in Q} W(t, x) \leq W(t_0, x_0) - \varepsilon, \tag{5.15}$$

which is a contradiction.

Now, we have to treat the case $V(t_0, x_0) = -\infty$. Since $W(t_0, x_0) > -\infty$ and W is lower semicontinuous, we may find two constants $M > 1$ and $\delta > 0$ such that

$$W(t_0, x) > -M$$

for every x so that $|x - x_0| < \delta$. Moreover, we can find $u^* \in \mathcal{U}$ such that $x^*(\cdot) := x(\cdot; u^*, t_0, x_0)$ satisfies $(T, x^*(T)) \in S$ and

$$\int_{t_0}^T L(s, x^*(s), u^*(s))ds + \psi(T, x^*(T)) \leq -2M.$$

With the same arguments in the first part of the proof, we may find a control $u_l \in \mathcal{U}$ piecewise constant and left continuous such that, if we denote by $x_l(\cdot)$ the trajectory $x(\cdot; u_l, T, x^*(T))$,

$$|x_l(t) - x^*(t)| < \frac{\delta}{2} \quad \forall t \in [t_0, T]$$

and

$$\left| \int_{t_0}^{T} [L(s, x_l(s), u_l(s)) - L(s, x^*(s), u^*(s))] ds \right| \leq 1.$$

Repeating the same calculations as before, we obtain that

$$\begin{aligned} -M &\leq W(T, x^*(T)) + \int_{t_0}^{T} L(s, x_l(s), u_l(s)) ds \\ &\leq \psi(T, x^*(T)) + \int_{t_0}^{T} L(s, x^*(s), u^*(s)) ds + 1 \\ &\leq -2M + 1, \end{aligned}$$

which gives $M \leq 1$, a contradiction.

This concludes the proof of the theorem. □

COROLLARY 5.3. *Let us suppose that W satisfies all the hypotheses of the previous theorem. If, moreover, $W \geq V$, then $W = V$.*

Remark 1. If W is produced by a synthesis procedure, the inequality $W \geq V$ always holds, and so if W satisfies all the hypotheses of Theorem 5.2, then W coincides with the value function.

Using the same techniques as those of the previous theorem, we can prove a corollary for value functions generated by approximated syntheses and give a bound of the error thus produced.

COROLLARY 5.4. *Suppose* (A-1)–(A-5) *hold. Let $Q \subseteq \Omega$ be an open subset containing S. Let $W : \overline{Q} \to \mathbb{R}$ be a lower semicontinuous function verifying the NDJ property along every time-varying vector field of the type $f(t, x, u)$ with $u \in U$ fixed. Moreover, we assume that, for each t,* ess–$\liminf_{y \to x} W(t, y) \leq W(t, x)$ *and that there exist $\varepsilon > 0$ and $g \in L^1(\mathbb{R})$, $g \geq 0$, such that the following hold:*

(i) *$W \leq \psi + \varepsilon$ on S.*

(ii) *At every point $(t, x) \in \partial Q$ one has*

$$W(t, x) = \sup_{(s,y) \in Q} W(s, y).$$

(iii) *There exists a countably $\mathcal{H}^n$-rectifiable set $A \subseteq \Omega$ such that W is differentiable on $Q \setminus A$ and satisfies*

$$W_s(s, y) + \inf_{\omega \in U} \{W_y(s, y) \cdot f(s, y, \omega) + L(s, y, \omega)\} \geq -\varepsilon g(s) \quad \text{on } Q \setminus A.$$

(iv) *$L \geq -\varepsilon g$.*

Then $W \leq V + \varepsilon(1 + \|g\|_1)$ on Q.

Proof. Note that $L(t, x, u) + \varepsilon g(t) \geq 0$, and so

$$\begin{aligned} W(t_0, x_0) &\leq \inf_{\substack{u \in \mathcal{U} \\ (T, x(T; u, t_0, x_0)) \in S}} \left\{ \int_{t_0}^{T} L(s, x(s; u, t_0, x_0), u(s)) ds + \psi(T, x(T; u, t_0, x_0)) \right\} \\ &\leq V(t_0, x_0) + \varepsilon(1 + \|g\|_{L^1}). \end{aligned}$$ □

Remark 2. Notice that the value function of an optimal control problem has the NDJ property along every possible direction as a consequence of the dynamic

programming principle. Indeed, for every $(t,y) \in \Omega \setminus S$ and for every admissible control $u \in \mathcal{U}$ (in particular, for every control $\omega\chi_I$, where $\omega \in U$ and I is a bounded interval), the function

$$h \mapsto \int_t^{t+h} L(s, x(s;u,t,y), u(s))ds + V(t+h, x(t+h;u,t,y))$$

is nondecreasing for $h \in [0,\delta]$ and δ small enough.

Instead, the hypothesis

$$\text{ess–liminf}_{y\to x} W(t,y) \le W(t,x)$$

for each t fixed says that for every $\varepsilon > 0$ there exists a subset $V \subseteq \{y \in \mathbb{R}^n : |y-x| \le \varepsilon\}$ of strictly positive Lebesgue measure such that

$$\inf_{y\in V} W(t,y) \le W(t,x).$$

So, if we consider a set $V_1 \subseteq \mathbb{R}^n$ of zero Lebesgue measure with x as a cluster point, the set $V \setminus V_1$ has a strictly positive Lebesgue measure. In the proof of Theorem 5.2, this fact is used to avoid the points y for which B^y is not countable. Moreover, this hypothesis, coupled with the lower semicontinuity of W, gives the following:

- For each t,

$$W(t,x) = \liminf_{y\to x} W(t,y) = \text{ess–liminf}_{y\to x} W(t,y).$$

Remark 3. Hypothesis (iii) of Theorem 5.2 says that, in the case $Q \neq \Omega$, the boundary of Q must be a level set of the function W. We can relax the same hypothesis in the following way:

- At every point $(t,x) \in \partial Q$ one has

$$\liminf_{\substack{\tau\to t, y\to x \\ (\tau,y)\in Q}} W(\tau,y) \ge \sup_{(s,y)\in Q} W(s,y).$$

Thus the conclusion of the theorem remains valid. Moreover, if we define with $R(t,x)$ the set of points reachable with an admissible control from (t,x), the previous condition can be replaced by

$$\inf_{(s,y)\in R(t,x)\cap\partial Q} W(s,y) \ge W(t,x),$$

and the conclusion still holds.

The hypothesis of the positiveness of L is almost optimal as the next example shows. However, the Lagrangian L may be negative on some region if trajectories cannot stay for too long in such a region, and one can relax the assumption (v) as shown in Remark 4.

Example 4. Consider the system $\dot{x} = u$, $U = [-1,1]$ and $\mathcal{U} = L^1(\mathbb{R};U)$, $\Omega = \mathbb{R}^2$, $S = \mathbb{R} \times \{0\}$, $Q = \mathbb{R}\times]-1,1[$ with the Lagrangian $L(t,x,u) = u^2 + x^4 - 6x^3 + 7x^2$ (see Figure 5.1) and $\psi \equiv 0$ on S. Since the Lagrangian is negative in a region where the system can stay for an arbitrary interval of times, clearly the value function for this problem is equal to $-\infty$. If $W \equiv C$ on $\overline{Q}$ with C a negative constant, then W verifies all the hypotheses of the Theorem 5.2 but (v). In fact (i), (ii), and (iii) are obvious, while (iv) holds because L is positive on Q and W is differentiable on Q. So

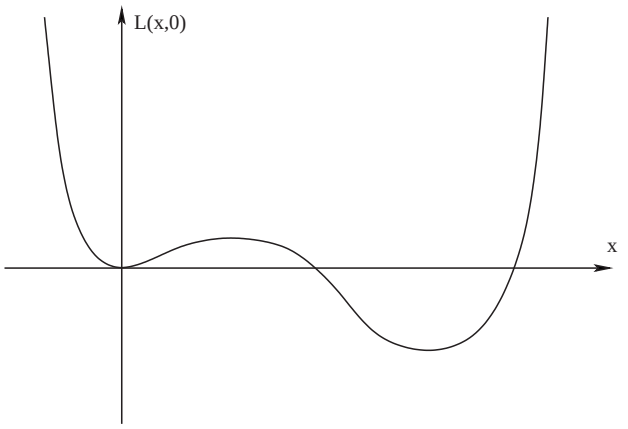

FIG. 5.1. $L(x,0)$ *of Example* 4.

there exist infinitely many functions W defined on $\overline{Q}$ verifying all the hypotheses of Theorem 5.2 except (v), which are not lower than or equal to the value function V.

Remark 4. If one wants to eliminate hypothesis (v) from the previous theorem, one may assume one of the following conditions:

(a) Fix $\varepsilon > 0$ and $(\bar{t},\bar{x}) \in Q$. We call $x_\varepsilon : [\bar{t},T] \to \mathbb{R}^n$ an ε–quasi-optimal trajectory (ε–q.o.t.) for $(\bar{t},\bar{x})$ if

(a.1) $\exists\, u_\varepsilon \in \mathcal{U}$ such that $\dot{x}_\varepsilon(s) = f(s, x_\varepsilon(s), u_\varepsilon(s))$ for a.e. $s \in [\bar{t},T]$,

(a.2) $x_\varepsilon(\bar{t}) = \bar{x}$,

(a.3) $(T, x_\varepsilon(T)) \in S$,

(a.4) $V(\bar{t},\bar{x}) + \varepsilon \geq \int_{\bar{t}}^{T} L(s, x_\varepsilon(s), u_\varepsilon(s))ds + \psi(T, x_\varepsilon(T))$.

Now define Q_1 as the set of points $(\bar{t},\bar{x}) \in Q$ such that, for every $\varepsilon > 0$, there exists x_ε, an ε–q.o.t. for $(\bar{t},\bar{x})$, satisfying $(s, x_\varepsilon(s)) \in Q$ for any $s \in [\bar{t},T]$. What we need is that $L \geq 0$ in $\Omega \backslash Q_1$. In fact, under this assumption, we may suppose that $(s, x(s)) \in \Omega \backslash Q_1$ for every $s \in [t_0, \hat{\tau}[$, where x is the trajectory defined in the proof of Theorem 5.2 and the time $\hat{\tau}$ is defined in (5.10). So the integral $\int_{t_0}^{\hat{\tau}} L(s, x(s), u(s))ds$ is positive. Otherwise, we can assume $Q_1 = Q$.

(b) We can also use a hypothesis similar to one given in [15, 16]. For any $(\bar{t},\bar{x}) \in \Omega$ and $u \in \mathcal{U}$, let $x_{\bar{t},\bar{x}}(\cdot;u) := x(\cdot;u,\bar{t},\bar{x})$ be the solution to (2.1) associated to the control u. Consider the set P consisting of those points $(\bar{t},\bar{x})$ of Q such that

$$\int_{\bar{t}}^{T} L(s, x_{\bar{t},\bar{x}}(s;u), u(s))ds \geq 0 \qquad \forall T > t, \quad \forall u \in \mathcal{U}.$$

We have to suppose that, if $(\bar{t},\bar{x}) \in Q \setminus [P \cup S]$, there exist a bounded and open set B, $(\bar{t},\bar{x}) \in B \subseteq Q$, $B \cap S = \emptyset$, so that $\partial B \subseteq Q$, and a positive number M strictly less than

$$\inf_{u\in\mathcal{U}} \left\{ T > 0 : d((\bar{t}+T, x_{\bar{t},\bar{x}}(\bar{t}+T;u)), \partial B) \leq d((\bar{t},\bar{x}), \partial B)/2 \right\}$$

such that, for all $u \in \mathcal{U}$, $(M+\bar{t}, x_{\bar{t},\bar{x}}(M+\bar{t};u)) \in Q \cap P$ and

$$\int_{\bar{t}}^{\bar{t}+M} L(s, x_{\bar{t},\bar{x}}(s), u(s))ds \geq 0,$$

and this allows us to conclude the proof of Theorem 5.2 without using $L \geq 0$ on the whole space.

Example 5. Consider the system $\dot{x} = u$, $U = [-1, 1]$, $\mathcal{U} = L^1(\mathbb{R}; U)$, $\Omega = \mathbb{R}^+ \times \mathbb{R}$, $S = \mathbb{R}^+ \times \{0\}$, $Q = \mathbb{R}^+ \times]-1, 1[$, $\psi = 0$ on S and the Lagrangian defined by

$$L(t,x,u) := \begin{cases} u^2 + x^2 & \text{if} \quad x \leq 1, \\ (u^2+1)(2-x) + (x-1)(u^2 + Ct) & \text{if} \quad 1 < x < 2, \\ u^2 + x^2 - 6x + 8 + Ct & \text{if} \quad x \geq 2. \end{cases}$$

It is clear that this Lagrangian, for C sufficiently big, satisfies the conditions (a) and (b) of the previous remark, even if it is not positive outside Q.

Remark 5. We can relax hypotheses (iii) and (v) with the following:

(iii') the boundary ∂Q is a level set of W;

(v') $L \geq 0$ on $\Omega \setminus Q$.

With these hypotheses, we can obtain an inequality of type (5.8) for each interval where the couple time-trajectory is in Q, and then, using (iii'), (v'), the lower semicontinuity of W, and the NDJ property, we can obtain (5.9).

6. Problem with infinite time. In this section we consider the control system (2.1) and assume that (A-1)–(A-5) hold with $0 \leq C_R \leq C$ for some $C > 0$ and every $R > 0$. Moreover, we suppose that the target S is a closed subset of $\mathbb{R} \times \mathbb{R}^n$ which satisfies the following structural property:

$(*)$ For any $T > 0$, there exists $(t, x) \in S$ with $t \geq T$.

Let S_1 be an open neighborhood of S contained in Ω. Assume that the final cost ψ is defined on S_1 and, if $d((t, x(t; u, t_0, x_0)), S) \to 0$ as $t \to +\infty$, then the trajectory $x(\cdot; u, t_0, x_0)$ is definitively in S_1; that is,

$(**)$ $\exists\, T > t$ such that $(s, x(s; u, t_0, x_0)) \in S_1$ for all $s \geq T$.

Define the value function

(6.1)
$$V(t_0, x_0) := \inf_{\substack{u \in \mathcal{U} \\ d((t,x(t;u,t_0,x_0)),S) \to 0 \\ \text{as } t \to +\infty}} \left\{ \int_{t_0}^{+\infty} L(s, x(s; u, t_0, x_0), u(s)) ds + \limsup_{t \to +\infty} \psi(t, x(t; u, t_0, x_0)) \right\}.$$

In other words, we consider only the trajectories that approach the target S in infinite time. Notice that this condition does not imply that $(T, x(T)) \notin S$ for any $T \geq t_0$.

Remark 6. The introduction of an open neighborhood of the target S is due to a technical reason and precisely to the fact that it is necessary to compare the candidate value function to the final cost near the target. Notice that in the following theorem the set Q must contain S_1. For example we consider $\Omega = \mathbb{R}^+ \times \mathbb{R}$, $S = \mathbb{R}^+ \times \{0\}$, $Q = \{(t, x) : t > 0, x < 1/t\}$, and $S_1 = \{(t, x) : t > 0, x < 3/t\}$. If $(t, 2/t)$ with $t > 0$ is a trajectory, then it is definitely in S_1, but it is never in Q.

THEOREM 6.1. *Let $Q \subseteq \Omega$ be an open subset containing S_1. Let $W : \overline{Q} \to \mathbb{R}$ be a lower semicontinuous function such that the following hold:*

(i) *W has the NDJ property along every time-varying vector field of the type $f(t, x, u)$ with $u \in U$ fixed, and for each t,*

$$\text{ess–liminf}_{y \to x} W(t, y) \leq W(t, x).$$

(ii) *$W \leq \psi$ on S_1.*

(iii) *At every point* $(t,x)\in\partial Q$ *one has*

$$W(t,x)=\sup_{(s,y)\in Q} W(s,y).$$

(iv) *There exists a countable* $\mathcal{H}^n$*-rectifiable set* $A\subseteq\Omega$ *such that* W *is differentiable in* $Q\setminus A$ *and satisfies*

$$W_s(s,y)+\inf_{\omega\in U}\{W_y(s,y)\cdot f(s,y,\omega)+L(s,y,\omega)\}\geq 0 \quad \textit{in } Q\setminus A.$$

(v) $L\geq 0$.

Then $W\leq V$ *on* Q. *If* $Q=\Omega$, *we can drop hypotheses* (iii) *and* (v).

Proof. Suppose by contradiction that there exists $(t_0,x_0)\in Q$ such that $W(t_0,x_0)>V(t_0,x_0)$. In particular, $V(t_0,x_0)<+\infty$. First, let us consider the case $V(t_0,x_0)>-\infty$. As in the first part of the proof of Theorem 5.2, we can find $\varepsilon>0$ and $\delta>0$ such that the following hold:

$$V(t_0,x_0)\leq W(t_0,x_0)-2\varepsilon, \tag{6.2}$$

$$|x-x_0|<\delta \quad\Rightarrow\quad W(t_0,x)>V(t_0,x_0)+\frac{3\varepsilon}{2}\ . \tag{6.3}$$

We can choose $u^*\in\mathcal{U}$, with the property that the trajectory $(t,x^*(t))$ approaches the target when $t\to+\infty$, such that

$$\int_{t_0}^{+\infty} L(s,x^*(s),u^*(s))ds+\limsup_{t\to+\infty}\psi(t,x^*(t))\leq V(t_0,x_0)+\frac{\varepsilon}{2}\ , \tag{6.4}$$

where $x^*(\cdot)$ is the trajectory corresponding to the control u^* such that $x^*(t_0)=x_0$.

Consider, now, a strictly increasing sequence of times $T_j>t_0$ converging to $+\infty$. We may suppose that $(t,x^*(t))\in Q$ for every $t\geq T_1$. Fix $j\in\mathbb{N}$. For every $l\in\mathbb{N}$, there exists $u_j^l\in\mathcal{U}$ piecewise constant and left continuous such that $\|u_j^l-u^*\|_{L^p([t_0,T_j])}\leq\frac{1}{l}$. So, by [7, Theorem IV.9], we can extract a subsequence of $(u_j^l)_l$, denoted again with $(u_j^l)_l$, and we can find a function $h_j\in L^p([t_0,T_j])$ such that $|u_j^l|\leq h_j$ a.e. for every $l\in\mathbb{N}$ and $u_j^l\to u^*$ for a.e. $t\in[t_0,T_j]$ as $l\to+\infty$. Thus, denoting with $x_j^l(\cdot)$ the trajectory $x(\cdot;u_j^l,T_j,x^*(T_j))$, for l sufficiently big we have (see Proposition 4.2)

$$\left|x_j^l(t)-x^*(t)\right|\leq\frac{\delta}{2}\qquad\forall t\in[t_0,T_j] \tag{6.5}$$

and then

$$\left|\int_{t_0}^{T_j}\left[L(s,x_j^l(s),u_j^l(s))-L(s,x^*(s),u^*(s))\right]ds\right|\leq\frac{\varepsilon}{2}. \tag{6.6}$$

Now, fix $l\in\mathbb{N}$ such that (6.5) and (6.6) hold. First, let us suppose that $\{(t,x_j^l(t)):t\in[t_0,T_j]\}\subseteq Q$. So, using Lemma 4.3, Lemma 4.4, the same arguments as in the proof of Theorem 5.2, and (6.6), we conclude

$$\begin{aligned}W(t_0,x_j^l(t_0))&\leq W(T_j,x_j^l(T_j))+\int_{t_0}^{T_j}L(s,x_j^l(s),u_j^l(s))ds\\&\leq W(T_j,x^*(T_j))+\int_{t_0}^{T_j}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}.\end{aligned}$$

Using (6.3) and (6.5), we have

$$V(t_0,x_0)+\frac{3\varepsilon}{2}<W(T_j,x^*(T_j))+\int_{t_0}^{T_j}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}. \tag{6.7}$$

Now consider the other case and precisely $\{(t,x_j^l(t)):t\in[t_0,T_j]\}\not\subseteq Q$. Define

$$\tau_j^l:=\inf\left\{t\geq t_0:(s,x_j^l(s))\in Q\ \ \forall s\in[t,T_j]\right\}. \tag{6.8}$$

Given $\tau_j^l<t<T_j$,

$$W(t,x_j^l(t))\leq W(T_j,x_j^l(T_j))+\int_t^{T_j}L(s,x_j^l(s),u_j^l(s))ds. \tag{6.9}$$

Considering the fact that $(t,x_j^l(t))\to(\tau_j^l,x_j^l(\tau_j^l))$ as $t\to\tau_j^l$, $(\tau_j^l,x_j^l(\tau_j^l))\in\partial Q$ and (iii), we obtain

$$W(t_0,x_0)\leq W(T_j,x^*(T_j))+\int_{\tau_j^l}^{T_j}L(s,x_j^l(s),u_j^l(s))ds. \tag{6.10}$$

We can now use the hypothesis (v), (6.3), and (6.6) in order to have

$$\begin{aligned}V(t_0,x_0)+\frac{3\varepsilon}{2}&<W(t_0,x_0)\\ &\leq W(T_j,x^*(T_j))+\int_{t_0}^{T_j}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}.\end{aligned} \tag{6.11}$$

In all cases we have that, for every $j\in\mathbb{N}$,

$$V(t_0,x_0)+\frac{3\varepsilon}{2}<W(T_j,x^*(T_j))+\int_{t_0}^{T_j}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}. \tag{6.12}$$

So, applying the limsup as $j\to+\infty$, we get

$$\begin{aligned}V(t_0,x_0)+\frac{3\varepsilon}{2}&\leq\limsup_{j\to+\infty}W(T_j,x^*(T_j))+\int_{t_0}^{+\infty}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}\\ &\leq\limsup_{t\to+\infty}W(t,x^*(t))+\int_{t_0}^{+\infty}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}.\end{aligned}$$

For t sufficiently big, $(t,x^*(t))\in S_1$, and so, using (ii) and (6.4),

$$\begin{aligned}V(t_0,x_0)+\frac{3\varepsilon}{2}&\leq\limsup_{t\to+\infty}\psi(t,x^*(t))+\int_{t_0}^{+\infty}L(s,x^*(s),u^*(s))ds+\frac{\varepsilon}{2}\\ &\leq V(t_0,x_0)+\varepsilon,\end{aligned}$$

which implies

$$V(t_0,x_0)\leq V(t_0,x_0)-\frac{\varepsilon}{2},$$

which is a contradiction.

It remains the case that $V(t_0, x_0) = -\infty$. Since $W(t_0, x_0) > -\infty$ and W is lower semicontinuous, we may find two constants $M > 1$ and $\delta > 0$ such that

$$W(t_0, x) > -M$$

for every x so that $|x - x_0| < \delta$. Moreover, we can find $u^* \in \mathcal{U}$ such that $x^*(\cdot) := x(\cdot; u^*, t_0, x_0)$ approaches the target when $t \to +\infty$ and

$$\int_{t_0}^{+\infty} L(s, x^*(s), u^*(s))ds + \limsup_{t\to+\infty} \psi(t, x^*(t)) \le -2M.$$

Consider a strictly increasing sequence of times $T_j > t_0$ converging to $+\infty$ and repeat the previous arguments in order to find a control $u_j^l \in \mathcal{U}$ piecewise constant, left continuous, and such that, if $x_j^l(\cdot) := x(\cdot; u_j^l, T_j, x^*(T_j))$,

$$\left|x_j^l(t) - x^*(t)\right| \le \frac{\delta}{2} \quad \forall t \in [t_0, T_j]$$

and

$$\left|\int_{t_0}^{T_j} [L(s, x_j^l(s), u_j^l(s)) - L(s, x^*(s), u^*(s))]ds\right| \le 1.$$

Proceeding as before, we obtain that

$$\begin{aligned} -M &\le W(T_j, x^*(T_j)) + \int_{t_0}^{T_j} L(s, x_j^l(s), u_j^l(s))ds \\ &\le W(T_j, x^*(T_j)) + \int_{t_0}^{T_j} L(s, x^*(s), u^*(s))ds + 1 \end{aligned}$$

for every $j \in \mathbb{N}$. Passing to the limit, we have

$$\begin{aligned} -M &\le \limsup_{j\to+\infty} W(T_j, x^*(T_j)) + \int_{t_0}^{+\infty} L(s, x^*(s), u^*(s))ds + 1 \\ &\le \limsup_{t\to+\infty} W(t, x^*(t)) + \int_{t_0}^{+\infty} L(s, x^*(s), u^*(s))ds + 1 \\ &\le \limsup_{t\to+\infty} \psi(t, x^*(t)) + \int_{t_0}^{+\infty} L(s, x^*(s), u^*(s))ds + 1 \\ &\le -2M + 1, \end{aligned}$$

which gives $M \le 1$, a contradiction.

So the theorem is proved. □

COROLLARY 6.2. *Let W satisfy all the hypotheses of the previous theorem and, moreover, $W \ge V$, where V is defined in* (6.1). *Then W coincides with the value function.*

Remark 7. In Theorem 6.1 the condition (ii) can be relaxed in the following way:

$$\limsup_{t\to+\infty} W(t, x(t)) \le \limsup_{t\to+\infty} \psi(t, x(t))$$

for every $x(\cdot)$ solution to (2.1) such that $d((t, x(t)), S) \to 0$ as $t \to +\infty$.

So, if one wants to minimize a Lagrangian cost without final cost, the condition becomes

$$\limsup_{t\to+\infty} W(t,x(t)) \le 0$$

for every $x(\cdot)$ with the above property.

Remark 8. If we assume that there exists $\eta > 0$ such that $S + B(0,\eta) \subseteq S_1$, where $B(0,\eta)$ is the ball in $\mathbb{R}^{n+1}$ centered in 0 with radius η, then hypothesis $(**)$ obviously holds. In fact, suppose $d((t,x(t;u,t_0,x_0)),S) \to 0$ as $t \to +\infty$. Then there exists $T > 0$ such that $d((s,x(s;u,t_0,x_0)),S) < \frac{\eta}{2}$ for all $s \ge T$. So we can choose an element $(t(s),y(s)) \in S$ in order to have $d((s,x(s;u,t_0,x_0)),(t(s),y(s))) < \frac{\eta}{2}$ for all $s \ge T$. So the points $(s,x(s;u,t_0,x_0)) \in S + B(0,\eta) \subseteq S_1$ for every $s \ge T$.

Remark 9. We obtain a generalization of Theorems 5.2 and 6.1 considering the same problem (2.1) with assumptions (A-1)–(A-4), but we accept at the same time all the trajectories that hit the target in finite time or that tend to the target in infinite time. Obviously an analogous theorem to Theorems 5.2 and 6.1 holds.

Remark 10. Also, in this case we can substitute hypothesis (iii) of Theorem 6.1 in an analogous way as in Remark 3. Moreover, we can eliminate hypothesis (v) of Theorem 6.1 in the same way as in Remark 4.

Appendix. Viscosity solutions and value functions. This appendix is intended to recall the notion of viscosity sub- and supersolution and to state some known properties of the value function. Proofs are analogous to those of [2].

Let Ω_1 be an open subset of $\mathbb{R}\times\mathbb{R}^n$. We need the following definitions.

DEFINITION A.1. *Let $f : A \to \overline{\mathbb{R}}$ be a function where A is an open subset of $\mathbb{R}^l$ for some $l \in \mathbb{N}\setminus\{0\}$. The lower semicontinuous envelope f_* and the upper semicontinuous envelope f^* of f are defined by*

$$f_*(x) := \lim_{r\to 0^+} \inf\{f(y) : y \in A, |y-x| \le r\},$$
$$f^*(x) := \lim_{r\to 0^+} \sup\{f(y) : y \in A, |y-x| \le r\}.$$

PROPOSITION A.2. *The lower semicontinuous (resp., upper semicontinuous) envelope of a function f is a lower semicontinuous (resp., upper semicontinuous) function. More precisely, it is the greatest (resp., least) lower semicontinuous (resp., upper semicontinuous) function less than or equal to (resp., greater than or equal to) f. Moreover, f is continuous if and only if $f_* = f^*$.*

DEFINITION A.3. *We say that a lower semicontinuous function $V : \Omega_1 \to \overline{\mathbb{R}}$ is a viscosity supersolution to $F(t,x,D_tV,D_xV) = 0$ in Ω_1 if, for any $\varphi \in \mathcal{C}^1(\Omega_1)$ and for any $(t_0,x_0) \in \Omega_1$ point of local minimum for $V-\varphi$, one has*

$$F^*(t_0,x_0,D_t\varphi(t_0,x_0),D_x\varphi(t_0,x_0)) \ge 0.$$

DEFINITION A.4. *We say that an upper semicontinuous function $V : \Omega_1 \to \overline{\mathbb{R}}$ is a viscosity subsolution to $F(t,x,D_tV,D_xV) = 0$ in Ω_1 if, for any $\varphi \in \mathcal{C}^1(\Omega_1)$ and for any $(t_0,x_0) \in \Omega_1$ point of local maximum for $V-\varphi$, one has*

$$F_*(t_0,x_0,D_t\varphi(t_0,x_0),D_x\varphi(t_0,x_0)) \le 0.$$

DEFINITION A.5. *We say that a function $V : \Omega_1 \to \overline{\mathbb{R}}$ is a viscosity solution to $F(t,x,D_tV,D_xV) = 0$ in Ω_1 if V_* is a viscosity supersolution and V^* is a viscosity subsolution to the equation.*

Remark 11. Note that the notion of viscosity solution is not bilateral in the sense that the sets of viscosity solutions to $F = 0$ and $-F = 0$ in general are different.

Let us consider the following hypotheses:

(H-1) The functions f and L are continuous in all the variables.

(H-2) U is a bounded set.

We have the following.

PROPOSITION A.6. *Let us assume* (A-1)–(A-5) *and* (H-1)–(H-2). *Then the value function V defined in* (2.4) *satisfies the dynamic programming principle, that is,*

$$V(t_0,x_0) = \inf_{\substack{u\in\mathcal{U}\\(T,x(T;u,t_0,x_0))\in S}} \left\{ \int_{t_0}^{T_1} L(s,x(s;u,t_0,x_0),u(s))ds + V(T_1,x(T_1;u,t_0,x_0)) \right\}$$

for every $(t_0,x_0) \in \Omega \setminus S$ and for every T_1 less than the minimum time to reach the target.

An analogous proposition holds for the value function V defined in (6.1).

Let us now state without proof the result that ensures that the value function is a viscosity solution to an HJB equation.

THEOREM A.7. *Let us assume* (A-1)–(A-5) *and* (H-1)–(H-2). *Then the value functions* (2.4) *and* (6.1) *are viscosity solutions of*

$$-V_s(t,x) - \inf_{\omega\in U} \{f(t,x,\omega)\cdot V_y(t,x) + L(t,x,\omega)\} = 0 \quad \text{in } \Omega \setminus S.$$

Acknowledgments. The author wishes to thank Professor B. Piccoli for having proposed to him the study of this problem and for his useful advice, and the referees for their suggestions for improvement.

BOUNDARY STABILIZATION FOR A HYBRID SYSTEM OF VISCOELASTICITY*

QIONG ZHANG† AND FALUN HUANG‡

Abstract. In this paper, we study the boundary feedback stabilization of a hybrid system that is composed of a viscoelastic thin plate with one part of its edge clamped and the remaining free part attached to a viscoelastic rigid body. By adopting the frequency domain method, we prove that the boundary feedback controls together with the dissipation induced by the memory effect are strong enough to secure the result of the exponential stability of energy. We also reach the result of the exponential stability of the hybrid system on the domain with corners without any extra hypotheses on the regularity of solutions.

Key words. hybrid system, viscoelasticity, C_0 contraction semigroup, exponential stability, nonsmooth domain

1. Introduction.

In recent years, much attention has been paid to the topic of control and stabilization of hybrid (or coupled) systems, in which the dynamics of systems are related to possible rigid bodies (see, e.g., [14, 23, 26, 28, 29, 31, 32, 33] and references therein). However, little attention was paid to the hybrid systems of special materials. In this paper, we consider a linear hybrid model that is composed of a viscoelastic thin plate clamped on one part of its boundary and along the other free part rimmed with a viscoelastic flange that has mass and bending moment inertia. Mathematically speaking, the vibration u of the plate is described by a viscoelastic plate equation with two dynamical viscoelastic boundary conditions:

$$
\begin{cases}
u''(t) + \Delta^2 u(t) + \displaystyle\int_0^\infty D'(s)\Delta^2 u(t-s)ds = 0 & \text{in } \Omega,\\
u(t) = \partial_\nu u(t) = 0 & \text{on } \Gamma_0,\\
J\partial_\nu u''(t) + B_1 u(t) + \displaystyle\int_0^\infty D'(s)B_1 u(t-s)ds = -\partial_\nu u'(t) & \text{on } \Gamma_1,\\
\rho u''(t) - B_2 u(t) - \displaystyle\int_0^\infty D'(s)B_2 u(t-s)ds = -u'(t) & \text{on } \Gamma_1,\\
u(0) = u_0,\ u'(0) = u_1 & \text{in } \Omega,\\
u(-s) = \theta(s), \quad 0 < s < \infty & \text{in } \Omega,
\end{cases}
\tag{1.1}
$$

where B_1, B_2 denote the boundary operators associated with the plate equation:

$$B_1 u = \Delta u + (1-\mu)\left(2\nu_1\nu_2 \frac{\partial^2 u}{\partial x_1 \partial x_2} - \nu_1^2 \frac{\partial^2 u}{\partial x_2^2} - \nu_2^2 \frac{\partial^2 u}{\partial x_1^2}\right),$$

$$B_2 u = \partial_\nu \Delta u + (1-\mu)\partial_\tau \left[\left(\nu_1^2 - \nu_2^2\right) \frac{\partial^2 u}{\partial x_1 \partial x_2} + \nu_1\nu_2 \left(\frac{\partial^2 u}{\partial x_2^2} - \frac{\partial^2 u}{\partial x_1^2}\right)\right].$$

$\nu = (\nu_1, \nu_2)$ is the unit outer normal vector and $\tau = (-\nu_2, \nu_1)$ is the unit tangent vector. $\Omega \subset R^2$ is a bounded open domain with smooth or nonsmooth boundary $\Gamma = \Gamma_0 \bigcup \Gamma_1$. $0 < \mu < \frac{1}{2}$ is the Poisson ratio of elasticity, $\rho > 0$ is the linear boundary density, and $J > 0$ is the bending moment of inertia per unit length of the boundary. $D(\cdot)$ denotes the relaxation function. θ is the specified "history," and u_0, u_1 are initial data. $-\partial_\nu u'(t)$ and $-u'(t)$ are the boundary feedback controls applied on the free boundary part Γ_1.

As far as the wave equation with viscoelastic damping is considered, Dafermos first proved that the energy of the system tends to zero asymptotically under the Dirichlet boundary conditions [6, 7]. Day [8] obtained an explicit rate at which the energy decays to zero. Desch and Miller [9, 10] and Hannsgen and Wheeler [15] provided the results on the exponential stability. Fabiano and Lazzari [11] investigated the three-dimensional viscoelastic system and obtained the result on the exponential stability. In [25] (or [27]), the authors introduced an abstract frame to study the viscoelastic system and obtained a spectrum determined growth rate property. Lagnese [18] proved the exponential stability of the viscoelastic Kirchhoff plate. In this paper, we will show that the feedback controls $-\partial_\nu u'(t)$ and $-u'(t)$(noncompact) just applied on the rimmed part of the boundary of the plate are sufficient to provide the uniformly exponential energy decay of the viscoelastic model on smooth and nonsmooth domains.

A common way to prove the exponential stability for the mechanical systems was given by Huang in [16] (or lately, Weiss in [34]). If $T(t)$ is a bounded C_0 semigroup with generator A, and if the resolvent of A is bounded on the imaginary axis, then $T(t)$ is exponentially stable. Such a frequency domain method was used in [32], where an explicit representation of the resolvent operator is needed, as well as in [4], where it is combined with the energy multiplier technique [17, 18] and where the "geometric conditions" are necessary. In this paper, we adopt the indirect contradiction argument of the frequency domain method to avoid the requirement for any explicit knowledge of the resolvent of A. Moreover, due to the dissipation induced by the memory effect, our approach enables us to get the desired exponential stability of the system (1.1) on smooth or nonsmooth domains even if dispensing all geometric restrictions that are routinely imposed when the multiplier technique is adopted.

In the special case of domain with corners, one of the major differences between this and the case of smooth domain in studying the stabilization problem is that additional energy terms are contributed by the twisting moment at corner points, and, consequently, extra feedback controls are required to treat the "corner effects" [3, 4]. Another difference is that the solutions lose regularity because of the presence of corners [2, 13]. Then neither the energy multipliers technique, which needs the high regularity of solutions, nor the microlocal analysis method [1, 20], which could be used only on the domain with sufficiently smooth boundary, can be applied in this situation. We introduce several proper spaces and operators to skip this difficulty, and the result of exponential stability of system (1.1) on the nonsmooth domain could be achieved through the frequency domain method.

In the next section, we introduce the viscoelastic hybrid system on the domain with sufficiently smooth boundary and prove the well-posedness through the classical semigroup theory. In section 3, we derive the uniformly exponential decay of energy of system (1.1) on the domain with sufficiently smooth boundary. In section 4, domain with corners is considered. By introducing proper pointwise constraints on the corner points, we get the well-posedness and the exponential stability of the system.

2. The well-posedness. In this section, we deal with the system (1.1) described above when the boundary of domain Ω is sufficiently smooth. Assume Γ is C^2-smooth and its partition satisfies $\overline{\Gamma}_0 \bigcap \overline{\Gamma}_1 = \emptyset$, the clamped part Γ_0 is not empty and has positive boundary measure, and the rimmed part Γ_1 is relatively open in Γ. Let the relaxation function $D(\cdot)$ satisfy the following basic conditions:

(H1) $D(t) \in C^2[0,\infty)$.

(H2) $D(t) > 0$, $D'(t) < 0$, $D''(t) \geq 0$.

(H3) $D_\infty > 0$.

Condition (H2) means that the memory is strictly decreasing, the rate of the loss of the memory is increasing, and $D_\infty \doteq D(\infty)$, $D'_\infty \doteq D'(\infty)$ exist, $D_\infty \geq 0$, $D'_\infty = 0$. (H3) implies that the material is viscoelastic solid. We shall suppose that $D(0) = 1$ without affecting the result.

We rewrite system (1.1) as follows:

$$
\begin{cases}
u''(t) + D_\infty \Delta^2 u(t) + \displaystyle\int_0^\infty D'(s)\Delta^2 w(t,s)ds = 0 & \text{in } \Omega,\\
w(t,s) = u(t-s) - u(t), \quad 0 < s < \infty, & \text{in } \Omega,\\
u(t) = \partial_\nu u(t) = 0 & \text{on } \Gamma_0,\\
J\partial_\nu u''(t) + D_\infty B_1 u(t) + \displaystyle\int_0^\infty D'(s)B_1 w(t,s)ds = -\partial_\nu u'(t) & \text{on } \Gamma_1,\\
\rho u''(t) - D_\infty B_2 u(t) - \displaystyle\int_0^\infty D'(s)B_2 w(t,s)ds = -u'(t) & \text{on } \Gamma_1,\\
u(0) = u_0,\ u'(0) = u_1 & \text{in } \Omega,\\
w(0,s) = \theta(s) - u_0, \quad 0 < s < \infty, & \text{in } \Omega.
\end{cases} \tag{2.1}
$$

Define the associated energy of (2.1) as

$$
\begin{aligned}
E(t) \doteq \frac{1}{2}\Bigg[& D_\infty a(u(t)) + \int_\Omega |u'(t)|^2 dx + \int_0^\infty |D'(s)| a(u(t-s)\\
& - u(t))ds + \int_{\Gamma_1} (J|\partial_\nu u'(t)|^2 + \rho|u'(t)|^2)d\Gamma\Bigg],
\end{aligned} \tag{2.2}
$$

where $a(u) = a(u,u)$, and $a(u,v)$ is the following sesquilinear form:

$$
\begin{aligned}
a(u,v) = \int_\Omega \Bigg[& \frac{\partial^2 u}{\partial x_1^2}\overline{\frac{\partial^2 v}{\partial x_1^2}} + \frac{\partial^2 u}{\partial x_2^2}\overline{\frac{\partial^2 v}{\partial x_2^2}} + \mu\left(\frac{\partial^2 u}{\partial x_1^2}\overline{\frac{\partial^2 v}{\partial x_2^2}} + \frac{\partial^2 u}{\partial x_2^2}\overline{\frac{\partial^2 v}{\partial x_1^2}}\right)\\
& + 2(1-\mu)\frac{\partial^2 u}{\partial x_1 \partial x_2}\overline{\frac{\partial^2 v}{\partial x_1 \partial x_2}}\Bigg] dx.
\end{aligned}
$$

A straightforward calculation gives that

$$\frac{d}{dt}E(t) = -\frac{1}{2}\int_0^\infty D''(s)a(u(t-s)-u(t))ds - \int_{\Gamma_1}(|u'(t)|^2 + |\partial_\nu u'(t)|^2)d\Gamma \le 0.$$

Therefore, the energy of the system (2.1) decreases on $[0,\infty)$.

We at first formulate system (2.1) as a first-order evolution equation on a certain Hilbert space. Set

$$V^m = \{u \in H^m(\Omega) \ : \ u|_{\Gamma_0} = \partial_\nu u|_{\Gamma_0} = 0\}, \quad m \ge 2 \text{ is an integer.}$$

When $m = 2$, we define the equivalent norm on V^2 as

$$\|u\|_{V^2} = [D_\infty a(u)]^{\frac{1}{2}}.$$

It is clear that $a(u,v)$ is well-posed on V^2 since Γ_0 is nonempty and has positive boundary measure. Let the "history space" $L^2([0,\infty),|D'|,V^2)$ consist of V^2-valued functions $w(\cdot)$ on $[0,\infty)$ for which

$$\|w(\cdot)\|_{L^2([0,\infty),|D'|,V^2)} = \left[\int_0^\infty |D'(s)|a(w(s))ds\right]^{\frac{1}{2}} < \infty.$$

Set the Hilbert space

$$H = V^2 \times L^2(\Omega) \times L^2([0,\infty),|D'|,V^2) \times L^2_J(\Gamma_1) \times L^2_\rho(\Gamma_1)$$

with the energy norm

$$\begin{aligned}\|(u,v,w(\cdot),\xi,\eta)\|_H = [&\|u\|^2_{V^2} + \|v\|^2_{L^2(\Omega)} + \|w(\cdot)\|^2_{L^2([0,\infty),|D'|,V^2)} \\ &+ \|\xi\|^2_{L^2_J(\Gamma_1)} + \|\eta\|^2_{L^2_\rho(\Gamma_1)}]^{\frac{1}{2}},\end{aligned}$$

where $\|\xi\|^2_{L^2_J(\Gamma_1)} = J\int_{\Gamma_1}|\xi|^2 d\Gamma$, and $\|\eta\|^2_{L^2_\rho(\Gamma_1)} = \rho\int_{\Gamma_1}|\eta|^2 d\Gamma$.

For further analysis, the following integration-by-parts formula is needed:

$$\int_\Omega \Delta^2 u\bar{v}dx = a(u,v) + \int_{\Gamma_1} B_2 u\bar{v}d\Gamma - \int_{\Gamma_1} B_1 u\overline{\partial_\nu v}d\Gamma \quad \forall u \in W,\ v \in V^2, \tag{2.3}$$

where

$$W = \{u \in V^2 \ : \ \Delta^2 u \in L^2(\Omega), B_1 u, B_2 u \in L^2(\Gamma_1)\}.$$

Now we define an unbounded linear operator A on H as

$$\begin{aligned}D(A) = \{&z = (u,v,w(\cdot),\xi,\eta) \in H \ : \ D_\infty u + Lw(\cdot) \in W, v \in V^2, \\ &w(\cdot) \in C^1([0,\infty),|D'|,V^2), w(0) = 0, \xi = \partial_\nu v|_{\Gamma_1}, \eta = v|_{\Gamma_1}\}, \\ A(u,v,w(\cdot),\xi,\eta) = \Big(&v, -D_\infty\Delta^2 u - \Delta^2 Lw(\cdot), -\frac{\partial}{\partial s}w(\cdot) - v, -\frac{1}{J}(D_\infty B_1 u \\ &+ B_1 Lw(\cdot) + \xi), \frac{1}{\rho}(D_\infty B_2 u + B_2 Lw(\cdot) - \eta)\Big),\end{aligned}$$

where

$$C^1([0,\infty),|D'|,V^2)=\left\{w(\cdot)\in L^2([0,\infty),|D'|,V^2):\ \frac{\partial}{\partial s}w(\cdot)\in L^2([0,\infty),|D'|,V^2)\right\},$$

and the operator L is

$$L:\ L^2([0,\infty),|D'|,V^m)\to V^m,\quad Lw(\cdot)=\int_0^\infty D'(s)w(s)ds.$$

Let $z(t)=(u(t),u'(t),u(t-s)-u(t),\partial_\nu u'(t)|_{\Gamma_1},u'(t)|_{\Gamma_1})$. Then the system (2.1) can be formulated as

$$z'(t)=Az(t),\qquad z(0)=z_0\in H. \tag{2.4}$$

THEOREM 2.1. *Assume that the relaxation function $D(\cdot)$ satisfies* (H1), (H2), *and* (H3). *Then the operator A generates a C_0 contraction semigroup e^{tA} on H.*

Proof. For $z=(u,v,w(\cdot),\xi,\eta)\in D(A)$, we have

$$\begin{aligned}&\Re e(Az,z)_H\\ &=\ -\frac{1}{2}\int_0^\infty D''(s)a(w(s))ds-\int_{\Gamma_1}(|\partial_\nu v|^2+|v|^2)d\Gamma\le 0.\end{aligned} \tag{2.5}$$

Thus, A is dissipative. On the other hand, for any $f=(f_1,f_2,f_3(\cdot),f_4,f_5)\in H$, solve the equation

$$(I-A)z=f,\quad z=(u,v,w(\cdot),\xi,\eta)\in D(A). \tag{2.6}$$

This implies

$$\begin{cases}u-v=f_1,\\ v+D_\infty\Delta^2u+\Delta^2Lw(\cdot)=f_2,\\ \dfrac{\partial}{\partial s}w(s)+v+w(s)=f_3(s),\\ (J+1)\xi+D_\infty B_1u+B_1Lw(\cdot)=Jf_4,\\ (\rho+1)\eta-D_\infty B_2u-B_2Lw(\cdot)=\rho f_5.\end{cases}$$

Eliminating v and using $\xi=\partial_\nu v|\Gamma_1$, $\eta=v|\Gamma_1$, we obtain

$$u+D_\infty\Delta^2u+\Delta^2Lw(\cdot)=f_1+f_2, \tag{2.7}$$

$$w(s)=-(1-e^{-s})(u-f_1)+\int_0^s e^{\sigma-s}f_3(\sigma)d\sigma, \tag{2.8}$$

$$(J+1)\partial_\nu u+D_\infty B_1u+B_1Lw(\cdot)=Jf_4+(J+1)\partial_\nu f_1, \tag{2.9}$$

$$(\rho+1)u-D_\infty B_2u-B_2Lw(\cdot)=\rho f_5+(\rho+1)f_1. \tag{2.10}$$

It follows from (2.8) that

$$Lw(\cdot)=\int_0^\infty D'(s)w(s)ds=X(u-f_1)+Y,$$

where

$$X=\int_0^\infty D'(s)(e^{-s}-1)ds=-D_\infty+\int_0^\infty D(s)e^{-s}ds$$

and

$$Y = \int_0^\infty \int_0^s D'(s) e^{\sigma - s} f_3(\sigma) d\sigma ds.$$

Using the formula (2.3), we deduce that (2.7) and (2.9)–(2.10) are equivalent to the following equality:

$$\begin{aligned} &\int_\Omega u\overline{\phi} dx + (D_\infty + X)a(u,\phi) + (J+1)\int_{\Gamma_1} \partial_\nu u \overline{\partial_\nu \phi} d\Gamma \\ &+ (\rho+1)\int_{\Gamma_1} u\overline{\phi} d\Gamma = \int_\Omega (f_1 + f_2)\overline{\phi} dx + a(Xf_1 - Y, \phi) \\ &+ \int_{\Gamma_1} [(Jf_4 + (J+1)\partial_\nu f_1)\overline{\partial_\nu \phi} + (\rho f_5 + (\rho+1)f_1)\overline{\phi}] d\Gamma \quad \forall \phi \in V^2. \end{aligned} \tag{2.11}$$

Due to the Lax–Milgram theorem, (2.11) admits a unique solution $u \in V^2$ for any given $f \in H$. Therefore, it follows from (2.7)–(2.10) that the range of $I - A$ is H. By Theorem 4.6 in [30], we have $\overline{D(A)} = H$. The generation of C_0 contraction semigroup now follows from the Lumer–Phillips theorem. □

Now the following well-posedness result is obvious.

COROLLARY 2.2. *Suppose that the relaxation function $D(\cdot)$ satisfies hypotheses* (H1), (H2), *and* (H3). *Then we have the following:*

(i) *For any initial value $z_0 \in H$, system* (2.1) *has a unique mild solution satisfying*

$$z(t) = (u(t), u'(t), u(t-s) - u(t), \partial_\nu u'(t)|_{\Gamma_1}, u'(t)|_{\Gamma_1}) \in C([0,\infty), H).$$

Moreover,

$$\|z(t)\|_H \le \|z_0\|_H \quad \forall t \ge 0.$$

(ii) *For any initial value $z_0 \in D(A)$, system* (2.1) *has a unique classical solution satisfying*

$$z(t) \in C^1([0,\infty), H) \bigcap C([0,\infty), D(A)).$$

3. Exponential stability. We first recall Huang's frequency domain theorem [16].

LEMMA 3.1. *Let e^{tA} be a C_0 semigroup in Hilbert space H, and there exists a position constant number M such that $\|e^{tA}\| \le M (t \ge 0)$. Then e^{tA} is exponentially stable if and only if $\{\lambda \in C : \Re e\lambda = 0\} \subset \rho(A)$ and $\sup\{\|(\lambda - A)^{-1}\|_H : \Re e\lambda = 0\} < \infty$.*

We will use the following properties of the relaxation function.

LEMMA 3.2. *Assume that the function $D(\cdot)$ satisfies* (H1)–(H3). *Then for any $\epsilon > 0$, there exists a constant $\delta > 0$ such that*

$$\inf_{\{\beta \in R\,:\,|\beta| \ge \epsilon > 0\}} \int_0^\infty |D'(s)||e^{-i\beta s} - 1|^2 ds \ge \delta. \tag{3.1}$$

Proof. Through direct computation, we have

$$\begin{aligned}\Pi(\beta) &\doteq \int_0^\infty |D'(s)||e^{-i\beta s}-1|^2 ds \\ &= 2\int_0^\infty |D'(s)|(1-\cos\beta s)ds \\ &= 2\int_0^\infty |D'(s)|ds - \int_0^\infty |D'(s)|(e^{-i\beta s}+e^{i\beta s})ds.\end{aligned} \tag{3.2}$$

Applying the Riemann–Lebesgue lemma [12] yields that there exists $\kappa > \epsilon$ such that

$$\left|\int_0^\infty |D'(s)|(e^{-i\beta s}+e^{i\beta s})ds\right| \le \int_0^\infty |D'(s)|ds, \quad |\beta| > \kappa.$$

Therefore,

$$\Pi(\beta) \ge \int_0^\infty |D'(s)|ds, \quad |\beta| > \kappa. \tag{3.3}$$

Furthermore, notice that Π is a positive continuous function on compact subset $\{\beta \in R : \epsilon \le |\beta| \le \kappa\}$. Thus there exists $\delta_0 > 0$ such that

$$\Pi(\beta) \ge \delta_0, \quad \epsilon \le |\beta| \le \kappa. \tag{3.4}$$

Set $\delta \doteq \min\{\delta_0, \int_0^\infty |D'(s)|ds\}$. We deduce from (3.3) and (3.4) that

$$\Pi(\beta) \ge \delta > 0, \quad \epsilon \le |\beta| \le \infty. \qquad \square$$

Now we turn to our main result in this section. A further assumption about the relaxation function is set.

(H4) There exists a constant $k > 0$ such that $D''(s) + kD'(s) \ge 0$ for all $s \ge 0$.

THEOREM 3.3. *Let the relaxation function $D(\cdot)$ satisfy hypotheses* (H1)–(H4). *Then*

$$0 \in \rho(A).$$

Proof. For any $f = (f_1, f_2, f_3(\cdot), f_4, f_5)$, we consider the equation

$$Az = f, \quad z = (u, v, w(\cdot), \xi, \eta),$$

which implies

$$v = f_1, \tag{3.5}$$

$$D_\infty \Delta^2 u + \Delta^2 L w(\cdot) = -f_2, \tag{3.6}$$

$$\frac{\partial}{\partial s} w(s) + v = -f_3(s), \tag{3.7}$$

$$D_\infty B_1 u + B_1 L w(\cdot) + \xi = -J f_4, \tag{3.8}$$

$$D_\infty B_2 u + B_2 L w(\cdot) - \eta = \rho f_5. \tag{3.9}$$

It follows from (3.5) that

$$\xi = \partial_\nu v|_{\Gamma_1} = \partial_\nu f_1|_{\Gamma_1}, \qquad \eta = v|_{\Gamma_1} = f_1|_{\Gamma_1}. \tag{3.10}$$

Furthermore, we can deduce from (3.5) and (3.7) that

$$w(s) = -\int_0^s f_3(\sigma)d\sigma - s f_1. \tag{3.11}$$

It is clear that $\frac{\partial}{\partial s}w(\cdot) \in L^2([0,\infty), |D'|, V^2)$. And from assumption (H4), we have $-D'(s) \le -D'(0)e^{-ks}$ for all $s \ge 0$. Thus $w(\cdot) \in L^2([0,\infty), |D'|, V^2)$ by (3.11). Finally, we have from (3.6), (3.8) and (3.9) that $D_\infty u + Lw(\cdot) \in W$, and for all $\phi \in V$,

$$\begin{aligned} & D_\infty a(u,\phi) \\ = & -\int_\Omega f_2\overline{\phi}dx + a\left(L\left(\int_0^s f_3(\sigma)d\sigma + sf_1\right),\phi\right) \\ & -\int_{\Gamma_1}(Jf_4\overline{\partial_\nu\phi} + \rho f_5\overline{\phi})d\Gamma - \int_{\Gamma_1}(\partial_\nu f_1\overline{\partial_\nu\phi} + f_1\overline{\phi})d\Gamma. \end{aligned} \tag{3.12}$$

Applying the Lax–Milgram theorem yields that there exists a unique $u \in V^2$ satisfying (3.12) for all fixed $f \in H$. Combining (3.10)–(3.11), we obtain that $Az = f$ admits a unique solution $z \in D(A)$ for all $f \in H$. Thus A^{-1} exists and is bounded by the closed graph theorem. □

THEOREM 3.4. *Suppose the boundary* Γ *is* C^2*-smooth and the relaxation function* $D(\cdot)$ *satisfies* (H1)–(H4). *Then*

(i) $\{i\omega : \omega \in R\} \subset \rho(A)$;

(ii) e^{tA} *is an exponentially stable* C_0 *semigroup; i.e., there exist two positive constants* M *and* ϖ *such that*

$$E(t) \le Me^{-\varpi t} \quad \forall t \ge 0.$$

Proof. From Lemma 3.1 and Theorem 3.3, we will prove (i) and (ii) at the same time if we can verify the following condition: there exists $r > 0$ such that

$$\inf\{\|(i\omega - A)z\|_H : z \in D(A), \|z\|_H = 1, \omega \in R\} \ge r. \tag{3.13}$$

Suppose (3.13) is not true. By the continuity of the resolvent and the resonance theorem, there exist a sequence $\omega_n \in R$ and a sequence of vectors $z_n = (u_n, v_n, w_n(\cdot), \xi_n, \eta_n) \in D(A)$ $(n = 1, 2, \ldots)$ such that

$$\|z_n\|_H = 1, \quad n = 1, 2, \ldots, \tag{3.14}$$

$$\lim_{n\to\infty} \|(i\omega_n - A)z_n\|_H = 0. \tag{3.15}$$

Moreover, it follows from (3.15) that $\lim_{n\to\infty} \Re e(Az_n, z_n)_H = 0$. Consequently,

$$\lim_{n\to\infty}\int_{\Gamma_1}|\partial_\nu v_n|^2 d\Gamma = 0, \qquad \lim_{n\to\infty}\int_{\Gamma_1}|v_n|^2 d\Gamma = 0, \tag{3.16}$$

and

$$\lim_{n\to\infty}\int_0^\infty D''(s)a(w_n(s))ds = 0. \tag{3.17}$$

By the assumption (H4), we can get from (3.17) that

$$\begin{aligned} \lim_{n\to\infty}\|w_n(\cdot)\|^2_{L^2([0,\infty),|D'|,V^2)} &= -\lim_{n\to\infty}\int_0^\infty D'(s)a(w_n(s))ds \\ &\le \frac{1}{k}\lim_{n\to\infty}\int_0^\infty D''(s)a(w_n(s))ds = 0. \end{aligned} \tag{3.18}$$

Furthermore, in view of (3.15), we have

$$g_n \doteq i\omega_n u_n - v_n \longrightarrow 0 \qquad \text{in } V^2, \tag{3.19}$$

$$h_n(s) \doteq i\omega_n w_n(s) + \frac{\partial}{\partial s} w_n(s) + v_n \longrightarrow 0 \qquad \text{in } L^2([0,\infty), |D'|, V^2). \tag{3.20}$$

Substituting (3.19) into (3.20) yields

$$\frac{\partial}{\partial s} w_n(s) + i\omega_n w_n(s) - h_n(s) + i\omega_n u_n - g_n \longrightarrow 0 \qquad \text{in} \quad L^2([0,\infty), |D'|, V^2).$$

Through direct computation, we obtain

$$w_n(s) = (e^{-i\omega_n s} - 1)\left(u_n - \frac{1}{i\omega_n} g_n\right) + \int_0^s e^{-i\omega_n(s-\tau)} h_n(\tau) d\tau \text{ in } \quad L^2([0,\infty), |D'|, V^2).$$

Thus,

$$\begin{aligned} &\left(\int_0^\infty |D'(s)||e^{-i\omega_n s} - 1|^2 ds\right) a(u_n) \\ \leq\ & \|w_n(\cdot)\|^2_{L^2([0,\infty),|D'|,V^2)} + \frac{1}{|\omega_n|^2}\left(\int_0^\infty |D'(s)||e^{-i\omega_n s} - 1|^2 ds\right) a(g_n) \\ &+ \left\| \int_0^{\cdot} e^{-i\omega_n(\cdot - \tau)} h_n(\tau) d\tau \right\|^2_{L^2([0,\infty),|D'|,V^2)}. \end{aligned} \tag{3.21}$$

By Lemma 3.2 and (3.18), we can deduce from (3.21) that

$$\lim_{n\to\infty} a(u_n) = 0. \tag{3.22}$$

On the other hand, substituting (3.16) and (3.18) into (3.14) yields

$$D_\infty a(u_n) + \int_\Omega |v_n|^2 dx \longrightarrow 1. \tag{3.23}$$

Assume that $\varrho \doteq \lim_{n\to\infty} \int_\Omega |v_n|^2 dx$, $\varrho \neq 0$. Then $\lim_{n\to\infty} D_\infty a(u_n) = 1 - \varrho$. Taking the inner product of (3.19) with v_n in $L^2(\Omega)$, we get

$$\lim_{n\to\infty} \int_\Omega |v_n|^2 dx = -\lim_{n\to\infty} i\omega_n \int_\Omega v_n \overline{u_n} dx. \tag{3.24}$$

Also, we take the inner product of (3.19) with v_n in $L^2(\Gamma_1)$ to get

$$\lim_{n\to\infty} \int_{\Gamma_1} |v_n|^2 d\Gamma = -\lim_{n\to\infty} i\omega_n \int_{\Gamma_1} v_n \overline{u_n} d\Gamma.$$

Using (3.16) yields

$$\lim_{n\to\infty} i\omega_n \int_{\Gamma_1} v_n \overline{u_n} d\Gamma = 0. \tag{3.25}$$

Similarly,

$$\lim_{n\to\infty} i\omega_n \int_{\Gamma_1} \partial_\nu v_n \overline{\partial_\nu u_n} d\Gamma = 0. \tag{3.26}$$

Furthermore, it follows from (3.15) that

$$\begin{aligned} &i\omega_n v_n + D_\infty \Delta^2 u_n + \Delta^2 L w_n(\cdot) \longrightarrow 0 && \text{in } L^2(\Omega),\\ &(i\omega_n J + 1)\partial_\nu v_n + D_\infty B_1 u_n + B_1 L w_n(\cdot) \longrightarrow 0 && \text{in } L^2(\Gamma_1),\\ &(i\omega_n \rho + 1) v_n - D_\infty B_2 u_n - B_2 L w_n(\cdot) \longrightarrow 0 && \text{in } L^2(\Gamma_1). \end{aligned} \tag{3.27}$$

Consequently,

$$\begin{aligned} &i\omega_n \int_\Omega v_n \overline{u_n} dx + D_\infty a(u_n) + a(L w_n(\cdot), u_n)\\ &+ \int_{\Gamma_1} [i\omega_n (J\partial_\nu v_n \overline{\partial_\nu u_n} + \rho v_n \overline{u_n}) + (\partial_\nu v_n \overline{\partial_\nu u_n} + v_n \overline{u_n})] d\Gamma \longrightarrow 0. \end{aligned} \tag{3.28}$$

Substituting (3.16), (3.17) and (3.24)–(3.26) into (3.28), we obtain

$$\lim_{n\to\infty} D_\infty a(u_n) = \lim_{n\to\infty} \int_\Omega |v_n|^2 dx - \lim_{n\to\infty} a(L w_n(\cdot), u_n). \tag{3.29}$$

From the Hölder inequality, we have [18]

$$\begin{aligned} &\left| \int_\Omega L(\partial_{ij} w(s)) \overline{L(\partial_{kl} w(s))} dx \right|\\ = &\left| \int_\Omega \int_0^\infty D'(s) \partial_{ij} w(s) ds \overline{\int_0^\infty D'(s) \partial_{kl} w(s) ds} dx \right|\\ \le &\int_\Omega \left| \int_0^\infty D'(s) \partial_{ij} w(s) ds \right| \left| \int_0^\infty D'(s) \partial_{kl} w(s) ds \right| dx\\ \le &\int_0^\infty |D'(s)| ds \int_\Omega \left(\int_0^\infty |D'(s)| |\partial_{ij} w(s)|^2 ds \right)^{\frac{1}{2}} \left(\int_0^\infty |D'(s)| |\partial_{kl} w(s)|^2 ds \right)^{\frac{1}{2}} dx\\ \le &\frac{1}{2}(1 - D_\infty) \left(\int_\Omega \int_0^\infty |D'(s)| |\partial_{ij} w(s)|^2 ds dx + \int_\Omega \int_0^\infty |D'(s)| |\partial_{kl} w(s)|^2 ds dx \right), \end{aligned}$$

where $\partial_{ij} = \frac{\partial^2}{\partial x_i \partial x_j}, i, j, k, l = 1, 2.$
Thus there exists a constant $C > 0$ such that

$$a(Lw(\cdot)) \le C \|w(\cdot)\|^2_{L^2([0,\infty), |D'|, V^2)}. \tag{3.30}$$

From (3.29), (3.30) and (3.18), we can assert that

$$\lim_{n\to\infty} a(u_n) = \frac{\varrho}{D_\infty} = \frac{1}{2D_\infty} \neq 0.$$

This is in contradiction to (3.22). The proof is completed. □

4. Stabilization on nonsmooth domain. When the viscoelastic plate is posed on a domain with corners, the analysis of well-posedness and stabilization for system (1.1) is somehow different from that in sections 2 and 3 and therefore must be further discussed. Mathematically, the basic difference of the four-order elliptic boundary problem between the domain without corners and the domain with corners is the integration-by-parts formula. Since the corners are present, the extra energy terms

appear. In order to take the corner effects into account, the integration-by-parts formula needs to be amended. Hence the additional feedback control is also needed to keep the dissipation of the system. On the other hand, it is well known that the solutions of the elliptic boundary problems on the nonsmooth domain lose the regularity (see, e.g., [2, 13]). Therefore, we can apply neither the energy multiplier technique [17, 18] that requires high regularity, $u \in H^{\frac{7}{2}+\epsilon}(\Omega)$ $(0 < \epsilon \leq \frac{1}{2})$, nor the method of microlocal analysis [1, 20] that demands the boundary is C^∞-smooth. Here, we introduce several proper spaces and operators. With the help of the frequency domain method, we get around the technical difficulties due to the emergence of corners and reach the desired exponential stability result without any extra assumptions on the regularity of solutions.

Before the analysis, we formulate the condition about the domain with corners.

(H5) Ω is a bounded open connected convex domain in R^2. Its boundary $\partial\Omega$ is C^2-smooth everywhere except at finite corner points $P \doteq \{P_i : i = 1, 2, \ldots, l\}$. $\partial\Omega$ is the union of two connected subsets, Γ_0 and Γ_1, where Γ_0 is not empty and has positive boundary measure, Γ_1 is relatively open in Γ, and Γ_0 and Γ_1 either are disjoint or share two common end points which are corner points.

LEMMA 4.1 (see [3]). *Let Ω satisfy* (H5). *Let $\partial\Omega$ be parameterized in a counterclockwise sense. Then, for sufficiently smooth functions u and v and for the sesquilinear form $a(\cdot,\cdot)$ in section* 2, *we have*

$$\begin{aligned}\int_\Omega \Delta^2 u\overline{v}dx = a(u,v) + \int_{\Gamma_1} (B_2 u\overline{v} - B_1 u\overline{\partial_\nu v})d\Gamma \\ + \sum_{i=1}^{l} [M_t(u)(P_i)]\overline{v(P_i)},\end{aligned} \tag{4.1}$$

where B_1 and B_2 are given as in section 1,

$$[M_t(u)(P_i)] = M(u)(P_i^+) - M(u)(P_i^-)$$

is the jump of $M_t(u)$ across P_i in the direction of increasing arc length, and

$$M(u) = (1-\mu)\left[(\nu_1^2 - \nu_2^2)\frac{\partial^2 u}{\partial x_1 \partial x_2} + \nu_1\nu_2\left(\frac{\partial^2 u}{\partial x_2^2} - \frac{\partial^2 u}{\partial x_1^2}\right)\right]$$

is the twisting moment.

Comparing (2.3) with (4.1), we notice that the sum in (4.1) denotes the work done by l corner forces $[M_t(u)(P_i)](i = 1, 2, \ldots, l)$, acting through l corner displacements $v(P_i)$ [3, 4].

For sufficiently smooth function $u(t)$, we can naturally derive the following boundary feedback law:

$$\begin{cases} u(t) = \partial_\nu u(t) = 0 & \text{on } \Gamma_0, \\ J\partial_\nu u''(t) + B_1 u(t) + \displaystyle\int_0^\infty D'(s)B_1 u(t-s)ds = -\partial_\nu u'(t) & \text{on } \Gamma_1/P, \\ \rho u''(t) - B_2 u(t) - \displaystyle\int_0^\infty D'(s)B_2 u(t-s)ds = -u'(t) & \text{on } \Gamma_1/P \end{cases} \tag{4.2}$$

and

$$[M_t(u)(t,P_i)] + \int_0^\infty D'(s)[M_t(u)(t-s,P_i)]ds = u'(t,P_i) \quad \text{for } P_i \in \Gamma/\overline{\Gamma}_0. \tag{4.3}$$

Then a straight computation gives that for sufficiently smooth functions u and u', the energy of the system on the domain with corners, still defined by (2.2), is nonincreasing:

$$\begin{aligned}\frac{d}{dt}E(t) = -\frac{1}{2}\int_0^\infty D''(s)a(u(t-s)-u(t))ds - \int_{\Gamma_1}(|u'(t)|^2 \\ +|\partial_\nu u'(t)|^2)d\Gamma - \sum_{P_i\in\Gamma/\overline{\Gamma}_0}|u'(t,P_i)|^2 \le 0.\end{aligned} \tag{4.4}$$

Remark 4.2. More precisely, for sufficiently smooth functions u and u', we can deduce the following boundary conditions at corner points [4]:

$$[M_t(u)(t,P_i)] + \int_0^\infty D'(s)[M_t(u)(t-s,P_i)]ds = \begin{cases} u'(t,P_i) & \text{for } P_i\in\Gamma/\overline{\Gamma}_0, \\ 0 & \text{for } P_i\in\overline{\Gamma}_0. \end{cases}$$

Remark 4.3. Boundary conditions (4.2) and (4.3) require that u and u' are sufficiently smooth. In fact, in order for the pointwise limits of the twisting moments $M_t(u)(P_i^+)$, $M_t(u)(P_i^-)$ and the pointwise values $u'(P_i)$ to exist ($i=1,2,\dots,l$), the sufficient conditions are

$$\begin{cases} u\in C^{2,\alpha_1}(\Gamma), \quad 0<\alpha_1<1, \\ u'\in C^{0,\alpha_2}(\Gamma), \quad 0<\alpha_2<1. \end{cases}$$

If $u\in V^{\frac{7}{2}+\varepsilon}$, $0<\varepsilon\le\frac{1}{2}$, and $u'\in V^2$, there would be no problem in (4.2) and (4.3) from the imbedding theorem on the domain with Lipschitz boundary [13]. However, since the boundary Γ contains corners, the classical regularity results for elliptic boundary problems may no longer be valid [2, 13].

We are now in a position to determine the C_0 semigroup and its infinitesimal generator corresponding to the following system:

$$\begin{cases} u''+D_\infty\Delta^2 u+\displaystyle\int_0^\infty D'(s)\Delta^2 w(s)ds=0 & \text{in } \Omega, \\ w(t,s)=u(t-s)-u(t), \quad 0<s<\infty, & \text{in } \Omega, \\ u=\partial_\nu u=0 & \text{on } \Gamma_0, \\ J\partial_\nu u''+D_\infty B_1 u+\displaystyle\int_0^\infty D'(s)B_1 w(s)ds=-\partial_\nu u' & \text{on } \Gamma_1/P, \\ \rho u''-D_\infty B_2 u-\displaystyle\int_0^\infty D'(s)B_2 w(s)ds=-u' & \text{on } \Gamma_1/P, \\ D_\infty[M_t(u)(P_i)]+\displaystyle\int_0^\infty D'(s)[M_t(w)(s,P_i)]ds=u'(P_i) & \text{for } P_i\in\Gamma/\overline{\Gamma}_0, \\ u(0)=u_0, \quad u'(0)=u_1 & \text{in } \Omega, \\ w(0,s)=\theta(s)-u_0, \quad 0<s<\infty, & \text{in } \Omega. \end{cases} \tag{4.5}$$

To overcome the difficulties due to the loss of the regularity of solution for system (4.5), we introduce several proper spaces and operators. First, we define two

sesquilinear forms:

$$c(u,\hat{u}) = \int_\Omega u\overline{\hat{u}}dx + J\int_{\Gamma_1} \partial_\nu u\overline{\partial_\nu \hat{u}}d\Gamma + \rho\int_{\Gamma_1} u\overline{\hat{u}}d\Gamma \quad \forall u,\hat{u}\in V^2;$$

$$b(u,\hat{u}) = \int_{\Gamma_1} \partial_\nu u\overline{\hat{u}}d\Gamma + \int_{\Gamma_1} u\overline{\hat{u}}d\Gamma + \sum_{i=1}^{l} u(P_i)\overline{\hat{u}(P_i)} \quad \forall u,\hat{u}\in V^2.$$

The completion of the space V^2 normed by $c^{\frac{1}{2}}(\cdot,\cdot)$ is denoted by $\mathcal{H}$. Furthermore, we set

$$\hat{\mathcal{H}} = L^2(\Omega)\times L^2_J(\Gamma_1)\times L^2_\rho(\Gamma_1),$$
$$\|(u_1,u_2,u_3)\|_{\hat{\mathcal{H}}} = [\|u_1\|^2_{V^2} + \|u_2\|^2_{L^2_J(\Gamma_1)} + \|u_3\|^2_{L^2_\rho(\Gamma_1)}]^{\frac{1}{2}}.$$

Then we know from [24] that $\mathcal{H}$ is isomorphic and isometric to $\hat{\mathcal{H}}$.

Remark 4.4. In fact, define the operator J as $Ju = (u, \partial_\nu u|_{\Gamma_1}, u|_{\Gamma_1})$. Then J is the isometrical isomorphism of $\mathcal{H}$ onto $\hat{\mathcal{H}}$.

Let $(V^2)^*$ be the dual of V^2 pivotal to $\mathcal{H}$. It is clear that $V^2 \hookrightarrow \mathcal{H} = \mathcal{H}^* \hookrightarrow (V^2)^*$, where "$\hookrightarrow$" denotes the continuous dense injection. We define the operators as[1]

$$\mathcal{C}: \mathcal{H}\to\mathcal{H}^*, \qquad \langle \mathcal{C}u,\hat{u}\rangle_{\mathcal{H}\times\mathcal{H}} = c(u,\hat{u}) \quad \forall u,\hat{u}\in\mathcal{H};$$
$$\mathcal{A}: V^2\to(V^2)^*, \quad \langle \mathcal{A}u,\hat{u}\rangle_{(V^2)^*\times V^2} = (u,\hat{u})_{V^2} = D_\infty a(u,\hat{u}) \quad \forall u,\hat{u}\in V^2;$$
$$\mathcal{B}: V^2\to(V^2)^*, \quad \langle \mathcal{B}u,\hat{u}\rangle_{(V^2)^*\times V^2} = b(u,\hat{u}) \quad \forall u,\hat{u}\in V^2.$$

It is clear that $\mathcal{C}$ is the isomorphism of $\mathcal{H}$ and $\mathcal{A}$ is the isomorphism of V^2 onto $(V^2)^*$. $\mathcal{B}$ is a symmetric nonnegative operator.

Then we write (4.5) as follows:

$$\mathcal{C}u''(t) + \mathcal{A}u(t) + \frac{1}{D_\infty}\mathcal{A}L(u(t-\cdot)-u(t)) + \mathcal{B}u'(t) = 0 \qquad \text{in } (V^2)^*. \tag{4.6}$$

Let us set the Hilbert space

$$H_c = V^2\times\mathcal{H}\times L^2([0,\infty),|D'|,V^2)$$
$$= V^2\times\hat{\mathcal{H}}\times L^2([0,\infty),|D'|,V^2)$$

with the energy norm

$$\|(u,v,w(\cdot))\|_{H_c} = [\|u\|^2_{V^2} + \|v\|^2_{\mathcal{H}} + \|w(\cdot)\|^2_{L^2([0,\infty),|D'|,V^2)}]^{\frac{1}{2}}$$
$$= [\|u\|^2_{V^2} + \|v\|^2_{L^2(\Omega)} + \|w(\cdot)\|^2_{L^2([0,\infty),|D'|,V^2)}$$
$$+ \|\partial_\nu v\|^2_{L^2_J(\Gamma_1)} + \|v\|^2_{L^2_\rho(\Gamma_1)}]^{\frac{1}{2}}.$$

Set $(\mathcal{A}_w w)(s) = \mathcal{A}(w(s))$. Then $\mathcal{A}_w$ is the isomorphism of $L^2([0,\infty),|D'|,V^2)$ onto $(L^2([0,\infty),|D'|,V^2))^* = L^2([0,\infty),|D'|,(V^2)^*)$. Note that H_c^*, the dual of H_c,

[1] Here we denote the value of u^* at u by $\langle u^*,u\rangle$.

is $(V^2)^* \times \mathcal{H} \times L^2([0,\infty), |D'|, (V^2)^*)$. Now we define two operators as

$$C = \begin{pmatrix} \mathcal{A} & 0 & 0 \\ 0 & \mathcal{C} & 0 \\ 0 & 0 & \mathcal{A}_w \end{pmatrix} \text{ is the isomorphism of } H_c \text{ onto } H_c^*;$$

$$A_c = \begin{pmatrix} 0 & \mathcal{A} & 0 \\ -\mathcal{A} & -\mathcal{B} & -\dfrac{1}{D_\infty}\mathcal{A}L \\ 0 & -\mathcal{A}_w & -\mathcal{A}_w \dfrac{\partial}{\partial s} \end{pmatrix} : D(A_c) \to H_c^*,$$

$$D(A_c) = \Big\{ u, v, w(\cdot)) \in H_c \,:\, v \in V^2, \mathcal{A}u + \mathcal{B}v + \frac{1}{D_\infty}\mathcal{A}Lw(\cdot) \in \mathcal{H},$$
$$w(0) = 0, w(\cdot) \in C^1([0,\infty), |D'|, V^2) \Big\}.$$

It is obvious that $C^{-1}A_c : D(A_c) \to H_c$. Assume $z(t) \doteq (u(t), u'(t), u(t-s) - u(t))$. Then we can formulate (4.5) as

$$z'(t) = C^{-1}A_c z(t), \qquad z(0) = z_0 \in H_c. \tag{4.7}$$

The existence of the unique solution of system (4.5) on the nonsmooth domain is guaranteed by the following theorem.

THEOREM 4.5. *Let the domain Ω and the relaxation function $D(\cdot)$ satisfy* (H5) *and* (H1)–(H3)*, respectively. Then the unbounded operator $C^{-1}A_c$ generates a C_0 contraction semigroup $e^{tC^{-1}A_c}$ on H_c.*

Proof. For $z = (u, v, w(\cdot)) \in D(A_c)$, we have that

$$\begin{aligned} \Re e(C^{-1}A_c z, z)_{H_c} &= (v,u)_{V^2} - c\left(\mathcal{C}^{-1}\mathcal{A}u + \mathcal{C}^{-1}\mathcal{B}v + \frac{1}{D_\infty}\mathcal{C}^{-1}\mathcal{A}Lw(\cdot), v\right) \\ &\quad - \left(v + \frac{\partial}{\partial s}w(\cdot), w(\cdot)\right)_{L^2([0,\infty),|D'|,V^2)} \\ &= -b(v,v) - \int_0^\infty |D'(s)| a\left(\frac{\partial}{\partial s}w(s), w(s)\right) ds \\ &= -\frac{1}{2}\int_0^\infty D''(s)a(w(s))ds - \int_{\Gamma_1}(|\partial_\nu v|^2 + |v|^2)d\Gamma \\ &\quad - \sum_{P_i \in \Gamma/\overline{\Gamma}_0} |v(P_i)|^2 \le 0. \end{aligned} \tag{4.8}$$

Thus $C^{-1}A_c$ is dissipative. To prove the range of $I - C^{-1}A_c$ is H_c, we let $f = (f_1, f_2, f_3(\cdot)) \in H_c$ and consider the resolvent equation $(I - C^{-1}A_c)z = f$, $z = (u, v, w(\cdot)) \in D(C^{-1}A_c)$. It is equivalent to

$$\begin{cases} u - v = f_1 \in V^2, \\ v + \mathcal{C}^{-1}\mathcal{A}u + \mathcal{C}^{-1}\mathcal{B}v + \dfrac{1}{D_\infty}\mathcal{C}^{-1}\mathcal{A}Lw(\cdot) = f_2 \in \mathcal{H}, \\ w(\cdot) + v + \dfrac{\partial}{\partial s}w(\cdot) = f_3(\cdot) \in L^2([0,\infty), |D'|, V^2). \end{cases}$$

Therefore,

$$v = u - f_1 \in V^2, \tag{4.9}$$

$$u + \mathcal{C}^{-1}\mathcal{A}u + \mathcal{C}^{-1}\mathcal{B}u + \frac{1}{D_\infty}\mathcal{C}^{-1}\mathcal{A}Lw(\cdot) = f_1 + \mathcal{C}^{-1}\mathcal{B}f_1 + f_2 \in \mathcal{H}, \tag{4.10}$$

$$w(s) = -(1 - e^{-s})(u - f_1) + \int_0^s e^{\sigma - s} f_3(\sigma)d\sigma \in L^2([0,\infty), |D'|, V^2). \tag{4.11}$$

From (4.10), we have

$$\begin{aligned} & c(u,\phi) + D_\infty a(u,\phi) + b(u,\phi) + a(Lw(\cdot),\phi) \\ = \;& c(f_1 + f_2, \phi) + b(f_1,\phi) \quad \forall \phi \in V^2. \end{aligned} \tag{4.12}$$

By the same argument as that in Theorem 2.1, we know that (4.11) and (4.12) admit a unique solution $u \in V^2$ for any $f \in H_c$. Combining this with (4.9) and (4.11), we get that the range of $I - C^{-1}A_c$ is H_c. Thus $C^{-1}A_c$ is m-dissipative. □

By an approach similar to that employed in Theorem 3.3, we can get the following result.

THEOREM 4.6. *Suppose that the relaxation function $D(\cdot)$ satisfies hypotheses* (H1)–(H4) *and the domain Ω satisfies* (H5). *Then we have*

$$0 \in \rho(C^{-1}A_c).$$

THEOREM 4.7. *Suppose the relaxation function $D(\cdot)$ satisfies* (H1)–(H4) *and the nonsmooth domain Ω satisfies* (H5). *Then there exist positive constants M_c and ϖ_c such that the energy $E(t)$ of the system* (4.5), *still defined by* (2.2), *satisfies*

$$E(t) \le M_c e^{-\varpi_c t} \qquad \forall t \ge 0.$$

Proof. From Lemma 3.1, we need only to show

$$\sup\{\|(i\omega - C^{-1}A_c)^{-1}\|_{H_c} \;:\; \omega \in R\} < \infty.$$

If it fails, there are a sequence $\omega_n \in R$ and a sequence of vectors $z_n = (u_n, v_n, w_n(\cdot)) \in D(A_c)$ such that

$$\|z_n\|_{H_c} = 1, \quad n = 1, 2, \ldots, \tag{4.13}$$

$$\lim_{n\to\infty} \|(i\omega_n - C^{-1}A_c)z_n\|_{H_c} = 0. \tag{4.14}$$

It follows from (4.14) that $\lim_{n\to\infty} \Re e(C^{-1}A_c z_n, z_n)_{H_c} = 0$. Thus

$$\lim_{n\to\infty} \int_0^\infty D''(s)a(w_n(s))ds = 0, \tag{4.15}$$

$$\lim_{n\to\infty} \int_{\Gamma_1} |\partial_\nu v_n|^2 d\Gamma = \lim_{n\to\infty} \int_{\Gamma_1} |v_n|^2 d\Gamma = 0, \tag{4.16}$$

$$\lim_{n\to\infty} v_n(P_i) = 0, \quad i = 1, \ldots, l. \tag{4.17}$$

From the hypothesis (H4), (4.15) yields

$$\lim_{n\to\infty} \|w_n(\cdot)\|_{L^2([0,\infty),|D'|,V^2)} = 0. \tag{4.18}$$

Moreover, by (4.14),

$$i\omega_n u_n - v_n \longrightarrow 0 \quad \text{in } V^2; \tag{4.19}$$

$$i\omega_n v_n + \mathcal{C}^{-1}\mathcal{A}u_n + \mathcal{C}^{-1}\mathcal{B}v_n + \frac{1}{D_\infty}\mathcal{C}^{-1}\mathcal{A}Lw_n(\cdot) \longrightarrow 0 \quad \text{in } \mathcal{H}; \tag{4.20}$$

$$i\omega_n w_n(\cdot) + v_n + \frac{\partial}{\partial s}w_n(\cdot) \longrightarrow 0 \quad \text{in } L^2([0,\infty), |D'|, V^2). \tag{4.21}$$

Using the same argument as that in Theorem 3.4, we can obtain from (4.18) and (4.21) that

$$\lim_{n\to\infty} a(u_n) = 0. \tag{4.22}$$

On the other hand, under the assumption $\varrho \doteq \lim_{n\to\infty}\int_\Omega |v_n|^2 dx$, we can deduce from (4.13), (4.16) and (4.18) that $\lim_{n\to\infty} D_\infty a(u_n) = 1 - \lim_{n\to\infty}\int_\Omega |v_n|^2 dx = 1 - \varrho$. As in the proof of Theorem 3.4, it follows from (4.19) that

$$\lim_{n\to\infty} -i\omega_n \int_\Omega v_n\overline{u_n}dx = \lim_{n\to\infty}\int_\Omega |v_n|^2 dx = \varrho \tag{4.23}$$

and

$$\lim_{n\to\infty} i\omega_n \int_{\Gamma_1} \partial_\nu v_n \overline{\partial_\nu u_n} d\Gamma = \lim_{n\to\infty} i\omega_n \int_{\Gamma_1} v_n\overline{u_n}d\Gamma = 0. \tag{4.24}$$

Moreover, (4.20) yields

$$\begin{aligned} 0 \longleftarrow\ & i\omega_n c(v_n, u_n) + c\left(\mathcal{C}^{-1}\mathcal{A}u_n + \mathcal{C}^{-1}\mathcal{B}v_n + \frac{1}{D_\infty}\mathcal{C}^{-1}\mathcal{A}Lw_n(\cdot), u_n\right) \\ =\ & i\omega_n\left[\int_\Omega v_n\overline{u_n}dx + \int_{\Gamma_1}(J\partial_\nu v_n\overline{u_n} + \rho v_n\overline{u_n})d\Gamma\right] + D_\infty a(u_n) \\ & + b(v_n, u_n) + a(Lw_n(\cdot), u_n). \end{aligned} \tag{4.25}$$

Notice that $|u(P_j)| \le C_j$ ($C_j > 0$ are constants, $j = 1, 2, \ldots$) since $u \in C^{0,\alpha}(\Gamma_1)$, $0 < \alpha < 1$. Therefore, substituting (4.16)–(4.18), (4.23) and (4.24) into (4.25), we obtain

$$\lim_{n\to\infty} D_\infty a(u_n) = \varrho.$$

Therefore, $\varrho = \frac{1}{2}$. This is in contradiction to (4.22). □

CONTROLLABILITY TO THE TRAJECTORIES OF PHASE-FIELD MODELS BY ONE CONTROL FORCE*

F. AMMAR KHODJA†, A. BENABDALLAH†, C. DUPAIX†, AND I. KOSTIN†

Abstract. In this article, we study the controllability to the trajectories of 2×2 nonlinear parabolic systems for control forces acting on a single equation of the system. This result, which in particular applies to Caginalp's phase-field model, actually extends those obtained for the semilinear heat equations. The proof relies on Kakutani's fixed point theorem and makes use of an observability estimate for the associated linearized system.

Key words. nonlinear parabolic systems, controllability

1. Introduction.

The aim of this article is the study of controllability for phase-field models when the control force acts on a single equation of the system. The models that we consider here are generalizations of Caginalp's phase-field model [9] (see also [8]) in its enthalpy formulation. For given time $T > 0$ and bounded domain $\Omega \subset \mathbb{R}^N$ $(1 \leq N < 6)$ with smooth boundary $\partial\Omega$, it reads as follows:

$$\begin{cases} \phi_t = \Delta\phi - h(\phi) + u, & \\ u_t = D\Delta u - \Delta\phi \ + f & \text{in } (0,T) \times \Omega = Q_T, \\ \phi = u = 0 & \text{on } (0,T) \times \partial\Omega = \Sigma_T, \\ \phi(0) = \phi_0,\ u(0) = u_0 & \text{in } \Omega, \end{cases} \tag{1}$$

where $D > 0$ is a constant and $h : \mathbb{R} \to \mathbb{R}$ is a C^1 function (locally Lipschitz continuous is actually sufficient). We assume that $f = \chi_\omega g$, where $g \in L^2(Q_T)$ and χ_ω is the characteristic function of a nonempty open and fixed set $\omega \Subset \Omega$ (namely $\overline{\omega} \subset \Omega$). The unknown functions ϕ and u can, respectively, be interpreted as a phase parameter and an enthalpy.

As we will see below, a part of the results here obtained depend on the behavior of the function h near $\pm\infty$. However, this hypothesis on h is not a restriction from the phase transition point of view. In fact, besides some monotonicity property of h, the main requirement for the phase-field models is that at least for $|s| \leq 1$, $h(s) = c_1 H'(s) - c_2 s$, where c_1, c_2 are positive constants and H is a symmetric double-well potential having two local minima at $s = \pm 1$. Although this model is known to be inconsistent with the second law of thermodynamics, it has been proved to be quite useful since many other models of the phase transition phenomena can be derived from Caginalp's model by taking suitable limits with respect to the parameters of the system (i.e., D, c_1, and c_2).

In this work we are interested in the controllability of such systems and we recall, therefore, that system (1) is said to be *controllable to the trajectories at time T if for any initial data (ϕ_0, u_0) there exists a control f such that the corresponding solution*

(ϕ, u) of (1) *is defined on* $[0, T]$ *and satisfies*

$$(\phi(T,.), u(T,.)) = (\phi^*(T,.), u^*(T,.)) \text{ a.e. in } \Omega, \tag{2}$$

where (ϕ^*, u^*) *is any bounded solution of* (1) *defined on* $[0, T]$ *associated with the data* ϕ_0^*, u_0^*, *and* f^*.

System (1) *is locally controllable to the trajectories at time* T *if there exists a constant* $r > 0$ *such that for any initial data* (ϕ_0, u_0) *satisfying* $\|\phi_0 - \phi_0^*\| + \|u_0 - u_0^*\| < r$ *the solution* (ϕ, u) *of system* (1) *satisfies* (2).

The functional spaces will be precised in the forthcoming sections.

Considering $(\phi - \phi^*, u - u^*)$ as a new unknown, the problem is reduced to drive the solution at time T to the state $(0, 0)$. Therefore, referring to the linear case, this kind of controllability is often called *null-controllability*. Notice that in the finite dimensional case and for linear problems, null, exact, and approximate controllability are equivalent (see, for instance, [21]).

The originality of our approach is to control 2×2 nonlinear systems by *acting (locally in space) on a single equation* of it. From this point of view and to our knowledge, our results are the first ones in this direction. Controlling a system with a minimum number of forces, or by forces satisfying an algebraic or a differential (or any other type) relation, is a common problem in the control theory (see, for instance, [19, Chapter V, p. 322] for other types of systems). Other approaches deal with dynamic controls which, roughly speaking, means that the control itself obeys a dynamic (see [1] and the references therein). From this last point of view, the variable u of system (1) can be seen as a dynamic control with respect to the variable ϕ.

Null-controllability of linear and semilinear heat equations has been extensively studied in recent years. The main ingredients, therefore, are global estimates of Carleman type for linear parabolic equations with an additional fixed point argument for the nonlinear case. The appropriate version of the Carleman estimates was established, in their most general form, by Imanuvilov [17] and Fursikov and Imanuvilov [16] (see also Lebeau and Robbiano [20] for the linear heat equation). These estimates were first used to prove the controllability to the trajectories of semilinear heat equations with globally Lipschitz continuous nonlinearities (see [16]) and then to extend this property to superlinear heat equations (see, for instance, [12], [5], [14]). In contrast with this collection of results, few works deal with the controllability of linear or nonlinear parabolic systems. In [10] De Teresa considers a semilinear heat equation coupled with an adjoint problem. The specific form of the system allows the proof of controllability to the trajectories in the case of globally Lipschitz continuous nonlinearities. However, in the case of system (1) such a proof does not work since the two equations are coupled in a very different way. Recently, Anita and Barbu [3] have considered a 2×2 reaction-diffusion system with a bilinear nonlinearity. They proved the local controllability to the stationary solutions of the system by two control forces acting on both equations of the system. Their result seems to be the first one dealing with the controllability to the trajectories for semilinear parabolic systems. More recently, Barbu [6] has considered the phase-field model (1) with a cubic nonlinearity and in an (equivalent) temperature formulation. He has proved the local controllability to the stationary solutions by *two control* forces localized on the same subdomain. At this stage let us point out that *the one control force result* cannot be obtained as a simple generalization of Barbu's result. It relies on the construction (using a multiplier technique) of a suitable functional Λ with suitable weights (see Lemma 3.4 and (34)). This is one of the crucial points of the proof of our results. It

also appears to be useful for the study of the null-controllability by a single force of abstract general linear "parabolic" systems of two equations [2]. Besides the sufficient conditions of controllability, in [2] we also construct a counterexample showing that if the coupling operators are "too compact," null-controllability fails to hold.

The sketch of the proof of our results is by now well known and was adopted for a scalar semilinear parabolic equation by several authors (see [16], [12], [5], [14]). The idea is to prove an observability estimate for the "linearized" system and then to use a fixed point theorem. The main difficulty is to prove the observability estimate for the "linearized" system corresponding to *the control by a single force*. To achieve this goal we first establish a global Carleman-type estimate for a linear parabolic system. This implies the controllability by two forces. In a second step we obtain an observability estimate which implies the controllability of the linear system by a single force. The fixed point method we use makes it necessary to construct a sufficiently regular control which induces by parabolic regularity a solution in a suitable space (here $L^\infty(Q_T)$). This explains the need for a "refined" observability estimate (see Lemma 3.4).

The paper is organized as follows. In the second section, by admitting an essential lemma (see Lemma 2.3), we state and prove the main result of this article (Theorem 2.1). We prove this lemma in the fourth section, after having shown in the third section the crucial observability estimate for a linear adjoint problem (see Lemma 3.4).

We conclude this section with the following two remarks.

1. Since the diffusion coefficient D in (1) changes only the constants in the proofs, we assume for simplicity that $D = 1$. However, the dependence of these constants on D (and on c_1 and c_2 for Caginalp's model) is explicit and may be of interest from the point of view of the theory of phase transitions.

2. Also for the sake of simplicity, we consider only the homogeneous Dirichlet boundary conditions. However, all the results seem to still be valid for the homogeneous Neumann boundary conditions.

2. The main result. To simplify, we will work with a function h satisfying

$$h \in C^1(R), \quad h(0) = 0. \tag{3}$$

With this assumption, system (1) admits $(0, 0)$ as a global solution associated with null initial data and control.

Let $1 \le N < 6$ and $\frac{N+2}{2} < q_N < 2\frac{N+2}{N-2}$ if $N \ge 3$, and $q_N \in (2, +\infty)$ if $N = 1, 2$ (even if the physical case reduces to $N = 1, 2, 3$). We use the following notation:

$$W_q^{2,1}(Q_T) = \{\zeta \in L^q(Q_T);\ D_t^r D_x^s \zeta \in L^q(Q_T); 2r + s \le 2\},$$

and $W^{m,p}(\Omega)$ is the standard Sobolev space. With the assumption on q_N, we have the following embeddings [18]:

$$W_{q_N}^{2,1}(Q_T) \hookrightarrow L^\infty(Q_T), \quad W^{2(1-\frac{1}{q_N}),q_N}(\Omega) \hookrightarrow L^\infty(\Omega). \tag{4}$$

Our main result is the following theorem.

THEOREM 2.1. *Assume that h satisfies* (3). *Let $T > 0$, $1 \le N < 6$, and let (ϕ^*, u^*) be a globally defined and bounded solution of* (1) *associated with the data $\phi_0^*, u_0^* \in L^2(\Omega)$ and $g^* \in L^2(Q_T)$.*

(i) Controllability to the trajectories. *If h satisfies*

$$\lim_{|s|\to+\infty} \frac{h(s)}{|s|\ \ln^{3/2}(1 + |s|)} = 0, \tag{5}$$

then $\forall \phi_0, u_0 \in L^2(\Omega)$ *with* $\phi_0 - \phi^*, u_0 - u_0^* \in H_0^1(\Omega) \cap W^{2(1-\frac{1}{q_N}),q_N}(\Omega)$, *one can find* $g \in L^2(Q_T)$ *with* $g - g^* \in L^{q_N}(Q_T)$ *such that there exists* (ϕ_g, u_g) *solution of* (1) *with* $\phi_g - \phi^*, u_g - u^* \in W_{q_N}^{2,1}(Q_T)$ *and satisfying*

$$(\phi_g - \phi^*)(T) = 0, \ \ (u_g - u^*)(T) = 0.$$

(ii) Local controllability to the trajectories. *There is* $\rho > 0$ *such that if* $\phi_0 - \phi^*, u_0 - u_0^* \in H_0^1(\Omega) \cap W^{2(1-\frac{1}{q_N}),q_N}(\Omega)$ *with* $\|(\phi_0 - \phi^*, u_0 - u_0^*)\|_{L^\infty(\Omega)} \leq \rho$, *one can find* $g - g^* \in L^{q_N}(Q_T)$ *such that there exists* (ϕ_g, u_g) *solution of* (1) *with* $\phi_g - \phi^*, u_g - u^* \in W_{q_N}^{2,1}(Q_T)$ *and satisfying*

$$(\phi_g - \phi^*)(T) = 0, \ \ (u_g - u^*)(T) = 0.$$

Remark 2.2. This result implies the one of Barbu [6, Theorem 1, p. 364].

Proof of Theorem 2.1. For the sake of simplicity, we assume that $\phi_0^* = u_0^* = 0$ and $g^* = 0$ so that $(\phi^*, u^*) = (0, 0)$, and we introduce the function:

$$\nu(s) = \begin{cases} \frac{h(s)}{s} & \text{if } s \neq 0, \\ h'(0) & \text{if } s = 0. \end{cases}$$

For $R > 0$, we set

$$K_R = \left\{ z \in L^\infty(Q_T); \ \|z\|_{L^\infty(Q_T)} \leq R \right\},$$

and let $z \in K_R$.

Consider the "linearized" version of (1) with $a = -\nu(z)$:

$$\begin{cases} \psi_t = \Delta\psi + a\psi + v & \text{in } Q_T, \\ v_t = \Delta v - \Delta\psi + \chi_\omega g & \text{in } Q_T, \\ \psi = v = 0 & \text{on } \Sigma_T, \\ \psi(0,.) = \psi_0, \, v(0,.) = v_0 & \text{in } \Omega. \end{cases} \tag{6}$$

Note that if $(\phi^*, u^*) \neq (0, 0)$, it suffices to consider the function

$$\widetilde{\nu} \ : \ Q_T \times \mathbb{R} \to \mathbb{R},$$
$$\widetilde{\nu}(t, x, s) = \begin{cases} \frac{h(s+\phi^*) - h(\phi^*)}{s} & \text{if } s \neq 0, \\ h'(\phi^*) & \text{if } s = 0 \end{cases}$$

and to study (6) with $a(t, x) = -\widetilde{\nu}(t, x, z)$. The crucial point is the following result.

LEMMA 2.3. *Let* $X_0 = (\psi_0, v_0) \in (H_0^1(\Omega) \cap W^{2(1-\frac{1}{q_N}),q_N}(\Omega))^2$. *For any* $T > 0$, *there exists* $g \in L^{q_N}(Q_T)$ *such that the associated solution* ψ_g, v_g *of* (6) *is in* $L^2(0, T; H_0^1(\Omega)) \cap W_{q_N}^{2,1}(Q_T)$ *and, moreover,*

$$(\psi_g, v_g)(T) = 0 \ \ \textit{a.e. } \Omega, \tag{7}$$

$$\|\chi_\omega g\|^2_{L^{q_N}(Q_T)} \leq C_T \ \|X_0\|^2_{L^2(\Omega)}, \tag{8}$$

with

$$C_T = \exp\left(C \left(1 + \frac{1}{T} + (1 + \|a\|_\infty) T + \|a\|_\infty^{2/3} \right) \right).$$

The next sections are devoted to the proof of this lemma. With this result in hand, let us continue the proof of Theorem 2.1.

For each $z \in K_R$, we apply Lemma 2.3 and consider the set $F(z) \subset L^2(Q_T)$ of the first components ψ_g of all the solutions $\psi_g, v_g \in L^2(0,T;H_0^1(\Omega)) \cap W^{2,1}_{q_N}(Q_T)$ associated with any control $g \in L^{q_N}(Q_T)$ such that $(\psi_g, v_g)(T) = 0$ a.e. sΩ and $\|\chi_\omega g\|^2_{L^{q_N}(Q_T)} \leq C_T \|X_0\|^2_{L^2(\Omega)}$. The set is a nonempty closed convex subset of $L^2(Q_T)$.

Let us prove that for $R > 0$ sufficiently large we have $F(K_R) \subset K_R$. To do this, we first show that

$$\|\psi_g\|^2_{L^\infty(Q_T)} \leq \|(\psi_g, v_g)\|^2_{L^\infty(Q_T)} \leq C_T \|X_0\|^2_{L^\infty(\Omega)}. \tag{9}$$

Indeed, using the fundamental matrix $\Gamma = (\Gamma_{ij})_{1\leq i,j\leq 2}$ associated with the parabolic operator

$$L_0 = \begin{pmatrix} \partial_t - \Delta & 0 \\ \Delta & \partial_t - \Delta \end{pmatrix}$$

(see [18, p. 620]), with homogeneous Dirichlet boundary conditions, we can write down the solution of (6) with the notation $X_g = (\psi_g, v_g)$

$$\begin{aligned} X_g(t,x) = &\int_\Omega \Gamma(t,0,x,y) X_0(y)\, dy \\ &+ \int_0^t \int_\Omega \Gamma(t,\tau,x,y)\, (a\psi_g + v_g, \chi_\omega g)\, (\tau,y) dy\, d\tau. \end{aligned}$$

The entries Γ_{ij} of Γ satisfy for $1 \leq i,j \leq 2$

$$\begin{gathered} \left|D_t^k D_x^s \Gamma_{ij}\right| \leq C(t-\tau)^{-\frac{N+2k+s}{2}} \exp\left(-C\frac{|x-y|^2}{t-\tau}\right), \\ x, y \in \Omega,\ 0 < \tau < t < T, \quad 2s + k = 0, 1, 2 \end{gathered} \tag{10}$$

(notice that in this special situation, $\Gamma_{12} = 0$). The positive constant C depends only on Ω and $1 \leq i,j \leq 2$. We will assume, without loss of generality, that it is the same constant. Set

$$\Gamma_0(t,x) = t^{-\frac{N}{2}} \exp\left(-C\frac{|x|^2}{t}\right), \quad (t,x) \in (0,\infty) \times \mathbb{R}^N.$$

We know by [18, Theorem 10.4] that $X_g \in W^{2,1}_{q_N}(Q_T)$ and the embeddings (4) allow us to write

$$\begin{aligned} \|X_g(t)\|_{L^\infty(\Omega)} \leq C \Bigg(&\|\Gamma_0(t,.) * |X_0|\|_{L^\infty(\Omega)} + \left\|\Gamma_0 \underset{t,x}{*} \chi_\omega\, |g|\right\|_{L^\infty(\Omega)} \\ &+ (1 + \|a\|_\infty) \left\|\Gamma_0 \underset{t,x}{*} |X_g|\right\|_{L^\infty(\Omega)} \Bigg), \end{aligned} \tag{11}$$

where $(f \underset{t,x}{*} g)(t,x) = \int_0^t d\tau \int_\Omega f(t-\tau, x-y) dy$. Now, we first have

$$\begin{aligned} \|\Gamma_0(t,.) * |X_0|\|_{L^\infty(\Omega)} &\leq \|\Gamma_0(t,.)\|_{L^1(\Omega)} \|X_0\|_{L^\infty(\Omega)} \\ &\leq C \|X_0\|_{L^\infty(\Omega)}, \end{aligned}$$

since for any $t>0$, $\|\Gamma_0(t,.)\|_{L^1(\Omega)} \leq C$ (a constant depending only on the dimension N) and, in the same way,

$$\left\| \Gamma_0 \underset{t,x}{*} |X_g| \right\|_{L^\infty(\Omega)} \leq C \int_0^t \|X_g(\tau)\|_{L^\infty(\Omega)} \, d\tau.$$

From Young's inequality (see [7]), we get with $\frac{1}{p}+\frac{1}{q_N}=1$ and the condition on q_N:

$$\begin{aligned} \left\| \Gamma_0 \underset{t,x}{*} \chi_\omega |g| \right\|_{L^\infty(\Omega)} &\leq \left\| \Gamma_0 \underset{t,x}{*} \chi_\omega |g| \right\|_{L^\infty(Q_t)} \\ &\leq \|\Gamma_0\|_{L^p(Q_t)} \|\chi_\omega g\|_{L^{q_N}(Q_t)} \\ &\leq C T^{-\frac{N+2}{2q_N}+1} \|\chi_\omega g\|_{L^{q_N}(Q_T)}. \end{aligned}$$

These three last inequalities transform (11) into

$$\begin{aligned} \|X_g(t)\|_{L^\infty(\Omega)} \leq C \Bigg(& \|X_0\|_{L^\infty(\Omega)} + T^{-\frac{N+2}{2q_N}+1} \|\chi_\omega g\|_{L^{q_N}(Q_T)} \\ & + \left(1+\|a\|_{L^\infty(Q_T)}\right) \int_0^t \|X_g(\tau)\|_{L^\infty(\Omega)} \, d\tau \Bigg), \end{aligned}$$

and from Gronwall's inequality we get

$$\|X_g\|_{L^\infty(Q_T)} \leq C e^{C\left(1+\|a\|_{L^\infty(Q_T)}\right)T} \left(\|X_0\|_{L^\infty(\Omega)} + T^{-\frac{N+2}{2q_N}+1} \|\chi_\omega g\|_{L^{q_N}(Q_T)} \right), \tag{12}$$

and (9) follows from (12) and Lemma 2.3.

Now, from (5) it follows that for any $\eta>0$ there exists $C_\eta = C_\eta(h) > 0$ such that

$$|\nu(s)|^{2/3} \leq C_\eta + \eta \ln(1+|s|) \ \forall s \in \mathbb{R} \tag{13}$$

and

$$\begin{aligned} \|\psi_g\|^2_{L^\infty(Q_T)} &\leq \exp\left(C \left(1 + \frac{1}{T} + (1+\|\nu(z)\|_{L^\infty(Q_T)})T + \|\nu(z)\|^{2/3}_{L^\infty(Q_T)} \right) \right) \|X_0\|^2_{L^\infty(\Omega)} \\ &\leq \exp\Bigg(C \Bigg(1 + \frac{1}{T} + (1+[C_\eta + \eta \ln(1+R)]^{3/2})T \\ &\quad + C_\eta + \eta \ln(1+R) \Bigg) \Bigg) \|X_0\|^2_{L^\infty(\Omega)}. \end{aligned}$$

Choosing $T := T(R,\eta) = [C_\eta + \eta \ln(1+R)]^{-1}$, we get for R sufficiently large

$$\begin{aligned} \|\psi_g\|^2_{L^\infty(Q_T)} &\leq \exp\left(C \left(1 + C_\eta + \eta \ln(1+R) \right) \right) \|X_0\|^2_{L^\infty(\Omega)} \\ &\leq (1+R)^{\eta C} \exp\left(C \left(1 + C_\eta \right) \right) \|X_0\|^2_{L^\infty(\Omega)}. \end{aligned}$$

Choosing $\eta = \frac{1}{2C}$ yields

$$\|\psi_g\|^2_{L^\infty(Q_T)} \leq C(1+R)^{1/2} \|X_0\|^2_{L^\infty(\Omega)},$$

and clearly this will imply, for R sufficiently large, that

$$\|\psi_g\|^2_{L^\infty(Q_T)} \leq R.$$

It follows that $F(K_R) \subset K_R$. Parabolic regularity implies that $F(K_R)$ is relatively compact in $L^2(Q_T)$ and exactly as in [5], and F is semicontinuous using again [18, Theorem 10.4]. Applying the Kakutani fixed point theorem (see, for instance, [4]) in the space $L^2(Q_T)$, we deduce that there is at least one $z \in L^\infty(Q_T)$ such that $z \in F(z)$. Therefore, there is at least one pair (ψ_g, v_g) satisfying the first claim of Theorem 2.1. Actually, we have proved this first claim for any $T = T(R,\eta)$, but, clearly, this implies the same result for any $T > T(R,\eta)$: in this case, we choose a control defined on $(0, T(R,\eta))$ which gives a solution satisfying (7) at $T = T(R,\eta)$ and extend it by 0 to the whole interval $(0,T)$.

The second claim of Theorem 2.1 is obtained starting from (9) and choosing X_0 so that $C_T \|X_0\|^2_{L^\infty(\Omega)} \le R$. This ends the proof of Theorem 2.1. ∎

3. Observability estimate. The main result of this section is the proof of the observability estimate (32) in Lemma 3.4 which allows us to build controls satisfying estimate (8) of Lemma 2.3.

Following [15], let us introduce some notation. Let $\omega' \Subset \omega$ be a subdomain of ω and let β be a $C^2(\overline{\Omega})$ function such that

$$\min\left\{|\nabla\beta(x)|\,,\ x \in \overline{\Omega\backslash\omega'}\right\} > 0 \quad \text{and} \quad \frac{\partial\beta}{\partial n} \le 0 \ \text{ on } \partial\Omega, \tag{14}$$

where n denotes the outward unit normal to $\partial\Omega$. Moreover, we can always assume that β satisfies

$$\min\left\{\beta(x),\ x \in \overline{\Omega}\right\} \ge \max\left(\frac{3}{4}\|\beta\|_{L^\infty(\Omega)}, \ln(3)\right). \tag{15}$$

Finally, we introduce the following functions with parameters $\lambda > 0$ and $\tau > 0$:

$$\rho(t,x) := \frac{e^{\lambda\beta(x)}}{t(T-t)}, \qquad (t,x) \in Q_T, \tag{16}$$

$$\alpha(t,x) := \tau\frac{e^{\frac{4}{3}\lambda\|\beta\|_{L^\infty(\Omega)}} - e^{\lambda\beta(x)}}{t(T-t)}, \qquad (t,x) \in Q_T. \tag{17}$$

Then the following result holds (Carleman estimate).

THEOREM 3.1 (see [15, Theorem 7.1, p. 288]). *There exist $\lambda_0 > 0$, $\tau_0 > 0$ and a positive constant C such that $\forall\lambda \ge \lambda_0$, $\forall\tau \ge \tau_0$, and $\forall s \ge -3$ the inequality*

$$\int_{Q_T}\left(\frac{1}{\lambda}|z_t|^2 + \left|D_x^2 z\right|^2 + \lambda\tau^2\rho^2|\nabla z|^2 + \lambda^4\tau^4\rho^4 z^2\right)\rho^{2s-1}e^{-2\alpha}dxdt$$

$$\le C\left(\tau\int_{Q_T}|z_t \pm \Delta z|^2\rho^{2s}e^{-2\alpha}dxdt + \lambda^4\tau^4\int_0^T\int_{\omega'} z^2\rho^{2s+3}e^{-2\alpha}dxdt\right) \tag{18}$$

holds for any function z satisfying an homogeneous Dirichlet condition and such that the right-hand side of (18) *is finite. Moreover, the constants C and λ_0 depend only on Ω and ω'. The constant τ_0 is of the form*

$$\tau_0 = c_0(\Omega,\omega')(T + T^2).$$

The explicit dependence in time of the constants is not given in [15]. We refer to [13], where the above formula for τ_0 is obtained.

In what follows, the symbol C will stand for various constants independent of T and a.

The adjoint problem associated with (6) is

$$\begin{cases} \varphi_t = \Delta\varphi + a\ \varphi - \Delta w & \text{in } (0,T)\times\Omega = Q_T, \\ w_t = \Delta w + \varphi & \text{in } Q_T, \\ \varphi = w = 0 & \text{on } (0,T)\times\partial\Omega = \Sigma_T, \\ \varphi(0) = \varphi_0,\ w(0) = w_0, & \text{in } \Omega. \end{cases} \tag{19}$$

Let us introduce the following notation: For given λ and τ as in Theorem 3.1, we set $\delta = \tau\rho$ and consider the functional:

$$I(s,z) = \int_{Q_T} \left(\frac{1}{\lambda} |z_t|^2 + |\Delta z|^2 + \lambda\delta^2 |\nabla z|^2 + \lambda^4\delta^4 z^2 \right) \delta^{2s-1} e^{-2\alpha} dxdt. \tag{20}$$

LEMMA 3.2. *Let $\lambda_0 > 1$, $\tau_1 = C(T + (1 + \|a\|^{2/3}_{L^\infty(Q_T)})T^2)$, C being the constant given in Theorem* 3.1. *Then $\forall\lambda \geq \lambda_0$, $\forall\tau \geq \tau_1$, and $\forall s \geq -3/2$, the solution (φ, w) of* (19) *satisfies the estimate:*

$$I\left(s - \frac{3}{2}, \varphi\right) + I(s,w) \leq C(1+\lambda^4) \int_0^T \int_{\omega'} \left(\varphi^2\delta^{2s} + w^2\delta^{2s+3}\right) e^{-2\alpha} dxdt. \tag{21}$$

As a consequence, we get

$$I(-3,\varphi) + I\left(-\frac{3}{2}, w\right) \leq C(1+\lambda^4) \int_0^T \int_{\omega'} \left(\varphi^2 + w^2\right) e^{-2\alpha} dxdt. \tag{22}$$

Remark 3.3. The estimate (22) is sufficient to prove controllability by two forces as in Barbu [6].

Proof. Applying Theorem 3.1 to the first equation of problem (6) and multipyling (18) by τ^{2s-1}, we obtain

$$\begin{aligned} I(s,\varphi) \leq C \Bigg(& \int_{Q_T} \left(|\Delta w|^2 + |a\varphi|^2 \right) \delta^{2s} e^{-2\alpha}\, dx\, dt \\ & + \lambda^4 \int_0^T \int_{\omega'} \varphi^2 \delta^{2s+3} e^{-2\alpha}\, dx\, dt \Bigg). \end{aligned} \tag{23}$$

Theorem 3.1 applied to the second equation of (6) yields

$$\begin{aligned} \int_{Q_T} |\Delta w|^2 \delta^{2s} e^{-2\alpha} dxdt \leq\ & I(s+\frac{1}{2}, w) \\ & \leq C \Bigg(\int_{Q_T} \varphi^2 \delta^{2s+1} e^{-2\alpha} dxdt \\ & \quad + \lambda^4 \int_0^T \int_{\omega'} w^2 \delta^{2s+4} e^{-2\alpha} dxdt \Bigg). \end{aligned}$$

Inserting the latter estimate in (23), we get

$$\begin{aligned} I(s,\varphi) \leq C \Bigg(& \int_{Q_T} \left(\varphi^2\delta^{2s+1} + |a\varphi|^2 \delta^{2s} \right) e^{-2\alpha} dxdt \\ & + \lambda^4 \int_0^T \int_{\omega'} \left(\varphi^2\delta^{2s+3} + w^2\delta^{2s+4}\right) e^{-2\alpha} dxdt \Bigg). \end{aligned} \tag{24}$$

Observe that

$$\begin{aligned}&\int_{Q_T}\left(\delta^{2s+1}\varphi^2+\delta^{2s}\left|a\varphi\right|^2\right)e^{-2\alpha}dxdt\\&\leq\int_{Q_T}\left(\delta^{2s+1}\varphi^2+\left\|a\right\|^2_{L^\infty(Q_T)}\,\delta^{2s}\left|\varphi\right|^2\right)e^{-2\alpha}dxdt.\end{aligned}\tag{25}$$

Thus, we get

$$\begin{aligned}I(s,\varphi)\leq C\Bigg(&\int_{Q_T}\left(\delta^{2s+1}\varphi^2+\left\|a\right\|^2_{L^\infty(Q_T)}\,\delta^{2s}\left|\varphi\right|^2\right)e^{-2\alpha}dxdt\\&+\lambda^4\int_0^T\int_{\omega'}\left(\varphi^2\delta^{2s+3}+w^2\delta^{2s+4}\right)e^{-2\alpha}dxdt\Bigg).\end{aligned}\tag{26}$$

In order to get rid of the first integral at the right-hand side of inequality (26), we transfer it to the left to obtain

$$\begin{aligned}&\frac{1}{2}\int_{Q_T}\lambda^4\tau^4\rho^{2s+3}\left|\varphi\right|^2e^{-2\alpha}dxdt\\&-C\tau\int_{Q_T}\left(\tau\rho+\left\|a\right\|^2_{L^\infty(Q_T)}\right)\rho^{2s}\left|\varphi\right|^2e^{-2\alpha}dxdt\\&=\int_{Q_T}\left(\frac{1}{2}\lambda^4\tau^3\rho^3-C\tau\rho-C\left\|a\right\|^2_{L^\infty(Q_T)}\right)\tau\rho^{2s}\left|\varphi\right|^2e^{-2\alpha}dxdt\\&\geq\int_{Q_T}\left(\frac{1}{4}\lambda^4\tau^3\rho^3-C\left\|a\right\|^2_{L^\infty(Q_T)}\right)\tau\rho^{2s}\left|\varphi\right|^2e^{-2\alpha}dxdt,\end{aligned}\tag{27}$$

provided (see (16)) $\tau\geq C\dfrac{T^2}{\lambda^2}$.

Now notice that

$$\frac{1}{4}\lambda^4\tau^3\rho^3-C\left\|a\right\|^2_{L^\infty(Q_T)}\geq 2^4\frac{\lambda^4}{T^6}\tau^3-C\left\|a\right\|^2_{L^\infty(Q_T)}\geq 0,$$

provided

$$\begin{aligned}\tau&\geq C\frac{T^2}{(2\lambda)^{4/3}}\left\|a\right\|^{2/3}_{L^\infty(Q_T)}\\&\geq CT^2\left\|a\right\|^{2/3}_{L^\infty(Q_T)}.\end{aligned}\tag{28}$$

Taking into account these computations, (26) becomes

$$I(s,\varphi)\leq C\lambda^4\int_0^T\int_{\omega'}\left(\varphi^2\delta^{2s+3}+w^2\delta^{2s+4}\right)e^{-2\alpha}dxdt,\tag{29}$$

provided $\tau\geq\tau_1$.

Similarly, for the second equation of problem (6), we obtain for $s\geq -3/2$ and using (29)

$$
\begin{aligned}
I(s,w) &\leq C\left(\int_{Q_T}\varphi^2\delta^{2s}e^{-2\alpha}dxdt+\lambda^4\int_0^T\int_{\omega'}w^2\delta^{2s+3}e^{-2\alpha}dxdt\right)\\
&\leq C\left(\frac{1}{\lambda^4}I\left(s-\frac{3}{2},\varphi\right)+\lambda^4\int_0^T\int_{\omega'}w^2\delta^{2s+3}e^{-2\alpha}dxdt\right)\\
&\leq C\int_0^T\int_{\omega'}\left(\varphi^2\delta^{2s}+w^2\delta^{2s+1}+\lambda^4w^2\delta^{2s+3}\right)e^{-2\alpha}dxdt\\
&\leq C\int_0^T\int_{\omega'}\left(\varphi^2\delta^{2s}+\lambda^4w^2\delta^{2s+3}\right)e^{-2\alpha}dxdt, \qquad (30)
\end{aligned}
$$

the last inequality being obtained by noting that $\delta \geq 1$ for τ sufficiently large.

Adding up inequalities (29) and (30), we get (21).

The consequence (22) follows from $\delta \geq 1$ for τ sufficiently large and by taking $s=-\frac{3}{2}$ □

We are now ready to state our crucial lemma.

LEMMA 3.4. *Under the assumptions of Lemma* 3.2, $\forall r \in [0,2)$ *there exists a constant* $C=C_r$ *such that*

$$
\int_0^T\int_{\omega'}\left(\varphi^2+w^2\right)\ e^{-2\alpha}\,dx\,dt \leq C\left(\ 1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_{\omega}\ e^{-r\alpha}w^2\,dx\,dt. \qquad (31)
$$

As an immediate consequence, it follows that

$$
I(-3,\varphi)+I\left(-\frac{3}{2},w\right) \leq C\left(\ 1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_{\omega}\ e^{-r\alpha}w^2\,dx\,dt. \qquad (32)
$$

Remark 3.5. We will see later that it is important to be able to choose $r>1$. Notice that r cannot be equal to 2: this is the "cost" of the control by a single force.

Proof. The main idea is to estimate $\int_0^T\int_{\omega'}\varphi^2\ e^{-2\alpha}\,dx\,dt$ by $\int_0^T\int_{\omega}\ e^{-r\alpha}w^2\,dx\,dt$ for some $r\in[0,2)$ using the second equation of (19). To do this, we first localize the system in space, multiply the second equation by $-\beta_0 e^{-2\alpha}\eta\varphi$, and manage the "bad" terms appearing (see $\Lambda(t)$ in (34) and our paper [2] for the construction of this function in an abstract setting).

Let $\xi\in C^\infty(R^n)$ be a truncation function satisfying

$$
\begin{cases}
\xi(x)=1 & \forall x\in\omega',\\
0<\xi(x)\leq 1 & \forall x\in\omega'',\\
\xi(x)=0 & \forall x\in\mathbb{R}^n\backslash\omega'',
\end{cases} \qquad (33)
$$

where $\omega' \Subset \omega'' \Subset \omega \Subset \Omega$. We introduce the function $\eta:=\xi^6$. For real numbers $\beta_0,\beta_1,p,q>0$, which will be chosen below, set

$$
\Lambda(t)=\int_\Omega\left(e^{-p\alpha}\eta^{4/3}\varphi^2-\beta_0e^{-2\alpha}\eta\varphi w+\beta_1e^{-q\alpha}\eta^{2/3}w^2\right)dx. \qquad (34)
$$

Differentiating Λ with respect to t and replacing φ_t and w_t by their expressions given

by (19) we obtain

$$
\begin{aligned}
\Lambda' &= \int_\Omega \left(-pe^{-p\alpha}\eta^{4/3}\varphi^2 + 2\beta_0 e^{-2\alpha}\eta\varphi w - \beta_1 q\, e^{-q\alpha}\eta^{2/3}w^2\right)\alpha_t\, dx \\
&\quad + \int_\Omega 2e^{-p\alpha}\eta^{4/3}\varphi(\Delta\varphi + a\varphi - \Delta w)\, dx \\
&\quad -\beta_0 \int_\Omega e^{-2\alpha}\eta\left[\varphi(\Delta w + \varphi) + w(\Delta\varphi + a\varphi - \Delta w)\right] dx \\
&\quad + \int_\Omega 2\beta_1\, e^{-q\alpha}\eta^{2/3} w(\Delta w + \varphi) dx.
\end{aligned} \tag{35}
$$

We have $\Lambda(0) = \Lambda(T) = 0$, and therefore the integration of (35) over $(0,T)$ yields

$$
\begin{aligned}
\beta_0 \int_{Q_T} e^{-2\alpha}\eta\varphi^2 dx &= \int_{Q_T} \Big\{ \left(-p\alpha_t + 2a\right) e^{-p\alpha}\eta^{4/3}\varphi^2 - \beta_1\, q\alpha_t\, e^{-q\alpha}\eta^{2/3}w^2 \\
&\qquad + \left(\beta_0\ (2\alpha_t - a)\, e^{-2\alpha}\eta + 2\beta_1\, e^{-q\alpha}\eta^{2/3}\right)\varphi\, w\Big\}\, dx\, dt \\
&\quad +2\int_{Q_T} e^{-p\alpha}\eta^{4/3}\,\varphi\,\Delta\varphi\, dx\, dt \\
&\quad -\int_{Q_T}\left(2e^{-p\alpha}\eta^{4/3} + \beta_0 e^{-2\alpha}\eta\right)\varphi\,\Delta w\, dx\, dt \\
&\quad -\int_{Q_T} \beta_0\, e^{-2\alpha}\eta\, w\,\Delta\varphi\, dx dt \\
&\quad +\int_{Q_T}\left(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}\right) w\,\Delta w\, dx\, dt \\
&= J_1 + J_2 + J_3 + J_4 + J_5.
\end{aligned} \tag{36}
$$

Now we estimate each of the five terms $J_1, \dots, J_5$.

For J_1, one has

$$
\begin{aligned}
J_1 &= \int_{Q_T} \left\{\left(-p\alpha_t + 2a\right) e^{-p\alpha}\eta^{4/3}\varphi^2 - \beta_1\, q\alpha_t\, e^{-q\alpha}\eta^{2/3}w^2\right. \\
&\qquad \left. + \left(\beta_0\ (2\alpha_t - a)\, e^{-2\alpha}\eta + 2\beta_1\, e^{-q\alpha}\eta^{2/3}\right)\varphi\, w\right\}\, dx\, dt.
\end{aligned}
$$

In order to estimate $\beta_0\ (2\alpha_t - a)\, e^{-2\alpha}\eta\,\varphi\, w$ in terms of $e^{-2\alpha}\eta\varphi^2$, we need to bound $(2\alpha_t - a)^2\, e^{-2\alpha}\eta^{2/3}w^2$. So, since $\alpha_t \notin L^\infty(Q_T)$, we introduce $r \in [0,2)$ and write $e^{-2\alpha} = e^{-(2-r)\alpha}e^{-r\alpha}$. Assuming that

$$
p > 2,\ q > 1 + \frac{r}{2}, \tag{37}
$$

we get, with $\beta_1 \geq 1$,

$$
\begin{aligned}
J_1 &\leq \left(\frac{1}{2} + \left\|\left(-p\alpha_t + 2a\right) e^{-(p-2)\alpha}\eta^{1/3}\right\|_{L^\infty(Q_T)}\right)\int_{Q_T} e^{-2\alpha}\eta\varphi^2\, dx\, dt \\
&\quad + \left\{\frac{1}{2}\left\|\beta_0\ (2\alpha_t - a)\, e^{-(1-\frac{r}{2})\alpha}\eta^{1/3} + 2\beta_1\, e^{-(q-1-\frac{r}{2})\alpha}\right\|^2_{L^\infty(Q_T)}\right. \\
&\quad \left. + \beta_1 q\left\|\alpha_t\, e^{-(q-r)\alpha}\eta^{1/3}\right\|_{L^\infty(Q_T)}\right\}\int_{Q_T}\eta^{1/3}e^{-r\alpha}w^2 dx\, dt. \\
&\leq C\left[\left(1 + \left\|\alpha_t e^{-(p-2)\alpha}\right\|_{L^\infty(Q_T)} + \|a\|^2_{L^\infty(Q_T)}\right)\int_{Q_T} e^{-2\alpha}\eta\varphi^2\, dx\, dt\right.
\end{aligned}
$$

$$+\left(\left(\|a\|^2_{L^\infty(Q_T)}+\left\|\alpha_t\, e^{-(1-\frac{r}{2})\alpha}\right\|_{L^\infty(Q_T)}\right)\beta_0^2 + \left(1+\left\|\alpha_t\, e^{-(q-r)\alpha}\right\|_{L^\infty(Q_T)}\right)\beta_1^2\right)\int_{Q_T}\eta^{1/3}e^{-r\alpha}w^2dxdt\Bigg],$$

where $C=C(p,q,\|\eta\|_{L^\infty(\Omega)})$. Now, assuming that $\tau\geq\tau_1$ and $\beta_1\geq 1$, one obtains

$$J_1\leq C\left[\left(1+\frac{\tau}{T^3}+\|a\|^2_{L^\infty(Q_T)}\right)\int_{Q_T}e^{-2\alpha}\eta\varphi^2dxdt + \left(1+\|a\|^2_{L^\infty(Q_T)}+\frac{\tau^2}{T^6}\right)\left(\beta_1^2+\beta_0^2\right)\int_{Q_T}\eta^{1/3}e^{-r\alpha}w^2dxdt\right]. \tag{38}$$

Concerning J_2,

$$\begin{aligned}J_2&=2\int_{Q_T}e^{-p\alpha}\eta^{4/3}\,\varphi\,\Delta\varphi\,dx\,dt\\&=-2\int_{Q_T}e^{-p\alpha}\eta^{4/3}\,|\nabla\varphi|^2\,dx\,dt-2\int_{Q_T}\varphi\,\nabla\varphi.\nabla\left(e^{-p\alpha}\eta^{4/3}\right)\,dx\,dt\\&=-2\int_{Q_T}e^{-p\alpha}\eta^{4/3}\,|\nabla\varphi|^2\,dx\,dt+\int_{Q_T}\varphi^2.\Delta\left(e^{-p\alpha}\eta^{4/3}\right)\,dx\,dt\\&=-2\int_{Q_T}e^{-p\alpha}\eta^{4/3}\,|\nabla\varphi|^2\,dx\,dt\\&\quad+\int_{Q_T}\left(e^{-2\alpha}\eta\varphi^2\right).e^{2\alpha}\eta^{-1}\Delta\left(e^{-p\alpha}\eta^{4/3}\right)\,dx\,dt.\end{aligned}$$

We have

$$\Delta\left(e^{-p\alpha}\eta^l\right)=e^{-p\alpha}\left[\left(p^2\,|\nabla\alpha|^2-p\Delta\alpha\right)\eta^l+l\left(\Delta\eta-2p\nabla\alpha.\nabla\eta\right)\eta^{l-1}+p(p-1)\,|\nabla\eta|^2\,\eta^{l-2}\right].$$

So

$$\begin{aligned}e^{2\alpha}\eta^{-1}\Delta\left(e^{-p\alpha}\eta^{4/3}\right)=e^{-(p-2)\alpha}\Big[&\left(p^2\,|\nabla\alpha|^2-p\Delta\alpha\right)\eta^{1/3}\\&+\frac{4}{3}\left(\Delta\eta-2p\nabla\alpha.\nabla\eta\right)\eta^{-2/3}\\&+p(p-1)\,|\nabla\eta|^2\,\eta^{-5/3}\Big].\end{aligned}$$

Note that

$$\frac{\nabla\eta}{\eta^{5/6}}=6\nabla\xi\in L^\infty(\Omega),\quad \frac{\nabla\eta}{\eta^{2/3}}=6\xi\nabla\xi\in L^\infty(\Omega),$$
$$\frac{\Delta\eta}{\eta^{2/3}}=30\,|\nabla\xi|^2+6\xi\Delta\xi\in L^\infty(\Omega).$$

It follows from this last computation and $p>2$ that

$$\left\|e^{2\alpha}\eta^{-1}\Delta\left(e^{-p\alpha}\eta^{4/3}\right)\right\|_{L^\infty(Q_T)}\leq C\left(1+\frac{\tau^2}{T^4}\right),$$

where $C = C(p, \|\eta\|_{L^\infty(\Omega)})$. Coming back to J_2, we get

$$J_2 \leq -2\int_{Q_T} e^{-p\alpha}\eta^{4/3}\ |\nabla\varphi|^2\ dx\,dt + C\left(1+\frac{\tau^2}{T^4}\right)\int_{Q_T} e^{-2\alpha}\eta\varphi^2\ dx\,dt. \tag{39}$$

We now estimate $J_3 + J_4$. We have

$$\begin{aligned}
J_3 + J_4 &= -\int_{Q_T} \beta_0 e^{-2\alpha}\eta\left(\varphi\,\Delta w + w\,\Delta\varphi\right)\ dx\,dt - \int_{Q_T} 2e^{-p\alpha}\eta^{4/3}\varphi\,\Delta w dxdt \\
&= -\int_{Q_T} \beta_0 e^{-2\alpha}\eta\left(\Delta\left(\varphi\, w\right) - 2\nabla\varphi.\nabla w\right)\ dx\,dt \\
&\quad + \int_{Q_T} 2e^{-p\alpha}\eta^{4/3}\nabla\varphi\,.\nabla w dxdt \\
&\quad + \int_{Q_T} 2\varphi\nabla(e^{-p\alpha}\eta^{4/3}).\nabla w\,dxdt \\
&= -\beta_0\int_{Q_T} \Delta\left(e^{-2\alpha}\eta\right)\varphi\, w\,dx\,dt \\
&\quad +2\int_{Q_T}\left(\beta_0 e^{-2\alpha}\eta + e^{-p\alpha}\eta^{4/3}\right)\nabla\varphi\,.\nabla w dxdt \\
&\quad + \int_{Q_T} 2\varphi\nabla(e^{-p\alpha}\eta^{4/3}).\nabla w\,dxdt.
\end{aligned}$$

Proceeding as previously, thanks to the assumption $r < 2$, we first get

$$\begin{aligned}
\left|\beta_0\int_{Q_T}\Delta\left(e^{-2\alpha}\eta\right)\varphi\, w\,dx\,dt\right| \leq C\Bigg(&\int_{Q_T} e^{-2\alpha}\eta\varphi^2\ dx\,dt \\
&+ \beta_0^2\left(1+\frac{\tau^4}{T^8}\right)\int_{Q_T}\eta^{1/3}e^{-r\alpha}w^2 dxdt\Bigg).
\end{aligned}$$

In the same way, with $p > 2$ and $\eta^{-1/6}\nabla\eta \in L^\infty(\Omega)$,

$$\begin{aligned}
\left|\int_{Q_T} 2\varphi\nabla(e^{-p\alpha}\eta^{4/3}).\nabla w\,dxdt\right| \leq C\Bigg(&\int_{Q_T} e^{-2\alpha}\eta\varphi^2\ dx\,dt \\
&+\left(1+\frac{\tau^2}{T^4}\right)\int_{Q_T}\eta^{2/3}e^{-2(p-1)\alpha}\left|\nabla w\right|^2 dxdt\Bigg).
\end{aligned}$$

It appears that

$$\begin{aligned}
J_3 + J_4 \leq C\Bigg(&\int_{Q_T} e^{-2\alpha}\eta\varphi^2\ dx\,dt + \beta_0^2\left(1+\frac{\tau^4}{T^8}\right)\int_{Q_T}\eta^{1/3}e^{-r\alpha}w^2 dxdt \\
&+\left(1+\frac{\tau^2}{T^4}\right)\int_{Q_T}\eta^{2/3}e^{-2(p-1)\alpha}\left|\nabla w\right|^2 dxdt\Bigg) \\
&+2\int_{Q_T}\left(\beta_0 e^{-2\alpha}\eta + e^{-p\alpha}\eta^{4/3}\right)\nabla\varphi\,.\nabla w dxdt.
\end{aligned} \tag{40}$$

Finally, we estimate J_5.

$$J_5 = \int_{Q_T}\left(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}\right)\, w\,\Delta w\,dx\,dt$$

$$= -\int_{Q_T} \left(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}\right) |\nabla w\,|^2\, dx\, dt$$
$$+\frac{1}{2}\int_{Q_T} \Delta\left(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}\right) w^{\,2} dx\, dt.$$

Again, in the same way, we get using the condition $q > r$ and the definition of η:

$$\frac{1}{2}\left|\int_{Q_T} \Delta\left(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}\right) w^{\,2} dx\, dt\right| \leq C\beta_1\left(1+\frac{\tau^2}{T^4}\right)\int_{Q_T} \eta^{1/3} e^{-r\alpha} w^2 dx dt.$$

Thus

$$J_5 \leq -\int_{Q_T} \left(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}\right) |\nabla w\,|^2\, dx\, dt$$
$$+C\beta_1\left(1+\frac{\tau^2}{T^4}\right)\int_{Q_T} \eta^{1/3} e^{-r\alpha} w^2 dx dt. \tag{41}$$

Fix $\beta_0 = 2C(1+\frac{\tau^2}{T^4} + \|a\|^2_{L^\infty(Q_T)})$. Then from (38), (39), (40), and (41), we get with $\tau \geq \tau_0$, conditions (37) and $\beta_1 \geq 1$:

$$\int_{Q_T} e^{-2\alpha}\eta\varphi^2 dx \leq 2C\left(1+\|a\|^2_{L^\infty(Q_T)} + \frac{\tau^4}{T^8}\right)\frac{\left(\beta_1^2+\beta_0^2\right)}{\beta_0}\int_{Q_T} \eta^{1/3} e^{-r\alpha} w^2 dx dt$$
$$-\frac{4}{\beta_0}\int_{Q_T} e^{-p\alpha}\eta^{4/3}\, |\nabla\varphi|^2\, dx\, dt$$
$$-\frac{2}{\beta_0}\int_{Q_T} \Big(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}$$
$$-C\left(1+\frac{\tau^2}{T^4}\right)\eta^{2/3} e^{-2(p-1)\alpha}\Big) |\nabla w|^2\, dx dt$$
$$+\frac{4}{\beta_0}\int_{Q_T} \left(\beta_0 e^{-2\alpha}\eta + e^{-p\alpha}\eta^{4/3}\right)\nabla\varphi\,.\nabla w\, dx dt.$$

Consider the three last terms in the right-hand side of the previous inequality. Assume moreover that

$$\frac{1}{2}q + 1 < p < 4 - q. \tag{42}$$

For β_1 sufficiently large, we have

$$\left(\beta_0 e^{-2\alpha}\eta + e^{-p\alpha}\eta^{4/3}\right)^2 \leq 2e^{-p\alpha}\eta^{4/3}\Big(\beta_0\, e^{-2\alpha}\eta + 2\beta_1 e^{-q\alpha}\eta^{2/3}$$
$$-C\left(1+\frac{\tau^2}{T^4}\right)\eta^{2/3} e^{-2(p-1)\alpha}\Big) \text{ on } Q_T.$$

Here is the proof. Indeed, it is sufficient to prove

$$\frac{1}{4}\left(\beta_0 e^{-(2-\frac{p+q}{2})\alpha} + e^{-\frac{p-q}{2}\alpha}\eta^{1/3}\right)^2 + \frac{1}{2}C\left(1+\frac{\tau^2}{T^4}\right) e^{-(2p-q-2)\alpha} \leq \beta_1 \text{ on } Q_T.$$

Taking into account (42), this last estimate is true if, for instance,

$$\beta_1 \geq C\left(\left(\beta_0\ +1\right)^2 + 1 + \frac{\tau^2}{T^4}\right)$$

with a large constant $C = C(\Omega, \omega, \omega', \eta)$. To summarize, we have

$$\int_{Q_T} e^{-2\alpha}\eta\varphi^2 dxdt \le C\frac{\left(1+\|a\|^2_{L^\infty(Q_T)}+\frac{\tau^4}{T^8}\right)\left(\beta_1^2+\beta_0^2\right)}{\beta_0}\int_{Q_T}\eta^{1/3}e^{-r\alpha}w^2dxdt,$$

and all the computations are valid with the following conditions:

$$\begin{aligned} &r<2,\ p>2,\ q>1+\frac{r}{2},\ \frac{1}{2}q+1<p<4-q,\\ &\beta_0 = 2C\left(1+\frac{\tau^2}{T^4}+\|a\|^2_{L^\infty(Q_T)}\right),\\ &\beta_1 \ge C\left(\left(\beta_0\ +1\right)^2+1+\frac{\tau^2}{T^4}\right),\\ &\tau\ge\tau_1. \end{aligned} \tag{43}$$

It is clear that there is a nonempty set of (p, q, r) verifying (43): for instance, $(2+\frac{1}{16}, 2-\frac{1}{8}, \frac{3}{2})$ satisfies this condition. With maybe a modified constant C, we get the following final estimate:

$$\int_{Q_{T,\omega'}} e^{-2\alpha}\varphi^2 dxdt \le C\left(\ 1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_{Q_{T,\omega}} e^{-r\alpha}w^2dxdt,$$

where $Q_{T,\omega} = (0,T)\times\omega$. This final estimate ends the proof of the lemma. ∎

4. Proof of Lemma 2.3. For $r\in(1,2)$ and $\varepsilon>0$, we define

$$J_\varepsilon(g) = \frac{1}{2}\int_{Q_T} e^{r\alpha}g^2dxdt+\frac{1}{2\varepsilon}\left\|(\psi,v)(T)\right\|^2_{L^2(\Omega)},$$

where $g\in L^2(Q_T)$ and (ψ, v) is the associated solution of (6). Introduce also the dual functional (see [11]):

$$J^*_\varepsilon(Y_0) = \frac{1}{2}\int_0^T\int_\omega e^{-r\alpha}w^2dxdt+\frac{\varepsilon}{2}\left\|Y_0\right\|^2_{L^2(\Omega)}+\int_\Omega Y(0).X_0dx,$$

where $X_0 = (\psi_0, v_0)\in H^1_0(\Omega)\times H^1_0(\Omega)$ is the fixed initial data of (6) and $Y = (\varphi, w)$ is the solution of the backward linear system with initial data $Y_0 = (\varphi_0, w_0)\in L^2(\Omega)\times L^2(\Omega)$

$$\begin{cases} -\varphi_t = \Delta\varphi + a\ \varphi - \Delta w & \text{in } (0,T)\times\Omega = Q_T,\\ -w_t = \Delta w+\varphi & \text{in } Q_T,\\ \varphi = w = 0 & \text{on } (0,T)\times\partial\Omega = \Sigma_T,\\ \varphi(T)=\varphi_0,\ w(T)=w_0, & \text{in } \Omega. \end{cases} \tag{44}$$

It is easy to prove that the minimization problems $\min_g J_\varepsilon(g)$ and $\min_{Y_0} J^*_\varepsilon(Y_0)$ have both exactly one solution $(g_\varepsilon, Y_{0\varepsilon})$ and, moreover, by the maximum principle (or see, for instance, [11])

$$g_\varepsilon = \chi_\omega e^{-r\alpha}w_\varepsilon \text{ on } Q_T;\ \ Y_{0\varepsilon} = -\frac{1}{\varepsilon}(\psi_\varepsilon, v_\varepsilon)(T) \text{ on } \Omega, \tag{45}$$

where $(\psi_\varepsilon, v_\varepsilon)$ (resp., $(\varphi_\varepsilon, w_\varepsilon)$) is the solution of (6) (resp., (44)) associated with g_ε (resp., $Y_{0\varepsilon}$). Since $J^*_\varepsilon(Y_{0\varepsilon}) \leq 0$, we get

(46)
$$\frac{1}{2}\int_0^T \int_\omega e^{-r\alpha} w_\varepsilon^2 dxdt + \frac{1}{2\varepsilon} \|(\psi_\varepsilon, v_\varepsilon)(T)\|^2_{L^2(\Omega)} \leq \|(\varphi_\varepsilon, w_\varepsilon)(0)\|_{L^2(\Omega)} \cdot \|X_0\|_{L^2(\Omega)}.$$

To obtain a uniform estimate, we will need the following result.

LEMMA 4.1. *For $r \in (0,2)$, any solution pair of* (44) *satisfies the estimate*

$$\|(\varphi, w)(0)\|^2_{L^2(\Omega)} \leq C_T \int_0^T \int_\omega e^{-r\alpha} w^2 dxdt, \tag{47}$$

with

$$C_T = \exp\left(C\left(1 + \frac{1}{T} + (1 + \|a\|_{L^\infty(Q_T)})T + \|a\|^{2/3}_{L^\infty(Q_T)}\right)\right).$$

We will prove this lemma at the end of this section. From (47) and (47), we get $\forall \varepsilon > 0$

$$\frac{1}{2}\int_0^T \int_\omega e^{-r\alpha} w_\varepsilon^2 dxdt + \frac{1}{2\varepsilon} \|(\psi_\varepsilon, v_\varepsilon)(T)\|^2_{L^2(\Omega)} \leq C_T \|X_0\|^2_{L^2(\Omega)}. \tag{48}$$

We obtain from this last estimate a control in $L^2(Q_T)$; however, as it appeared clearly in the proof of Theorem 2.1, it is not sufficient. So we will prove that our control is in $L^{q_N}(Q_T)$.

We introduce $\zeta_\varepsilon = e^{-r\alpha} w_\varepsilon$. It satisfies by (44)

$$\begin{cases} (\zeta_\varepsilon)_t + \Delta\zeta_\varepsilon = f_\varepsilon & \text{in } (0,T)\times\Omega = Q_T, \\ \zeta_\varepsilon = 0 & \text{on } (0,T)\times\partial\Omega = \Sigma_T, \\ \zeta_\varepsilon(T) = 0 & \text{in } \Omega, \end{cases}$$

with

$$f_\varepsilon = -2r\nabla\alpha.\left(e^{-r\alpha}\nabla w_\varepsilon\right) + \left(\Delta\left(e^{-r\alpha}\right) - \left(e^{-r\alpha}\right)_t\right) w_\varepsilon - e^{-r\alpha}\varphi_\varepsilon.$$

By parabolic regularity, we have

$$\|\zeta_\varepsilon\|_{W_2^{2,1}(Q_T)} \leq C \|f_\varepsilon\|_{L^2(Q_T)}. \tag{49}$$

On the other hand, setting

$$I_1 = \int_{Q_T} e^{-2r\alpha}\varphi_\varepsilon^2 \, dx\, dt$$

we have, using (32) in Lemma 3.4,

$$\begin{aligned} I_1 &= \int_{Q_T} \left(\delta^3 e^{-2(r-1)\alpha}\right)\left(\delta^{-3} e^{-2\alpha}\varphi_\varepsilon^2\right) dx\, dt \\ &\leq \left\|\delta^3 e^{-2(r-1)\alpha}\right\|_{L^\infty(Q_T)} \int_{Q_T} \delta^{-3} e^{-2\alpha}\varphi_\varepsilon^2 \, dx\, dt \\ &\leq C\left\|\delta^3 e^{-2(r-1)\alpha}\right\|_{L^\infty(Q_T)} \left(1 + \frac{\tau^8}{T^{14}} + \|a\|^6_{L^\infty(Q_T)}\right) \int_0^T \int_\omega e^{-r\alpha} w_\varepsilon^2 dxdt \\ &\leq C\left(1 + \frac{\tau^8}{T^{14}} + \|a\|^6_{L^\infty(Q_T)}\right) \int_0^T \int_\omega e^{-r\alpha} w_\varepsilon^2 dxdt. \end{aligned}$$

Notice that $\left\|\delta^3 e^{-2(r-1)\alpha}\right\|_{L^\infty(Q_T)}$ is finite since we have assumed $r>1$ and the same remark holds in what follows. In the same way, setting

$$I_2 = \int_{Q_T} \left|\nabla\alpha.\left(e^{-r\,\alpha}\nabla w_\varepsilon\right)\right|^2 dx\,dt,$$

$$\begin{aligned} I_2 &\le \int_{Q_T} \left(|\nabla\alpha|^2\,\delta^2 e^{-2(r-1)\alpha}\right)\left(\delta^{-2}e^{-2\alpha}\,|\nabla w_\varepsilon|^2\right) dx\,dt \\ &\le \left\||\nabla\alpha|^2\,\delta^2 e^{-2(r-1)\alpha}\right\|_{L^\infty(Q_T)} C\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt \\ &\le C\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt, \end{aligned}$$

and, if

$$I_3 = \int_{Q_T} \left|\left(\Delta\left(e^{-r\,\alpha}\right)-\left(e^{-r\,\alpha}\right)_t\right)\,w_\varepsilon\right|^2 dx\,dt,$$

$$\begin{aligned} I_3 &= \int_{Q_T}\left|-r\Delta\alpha+r^2\,|\nabla\alpha|^2+r\alpha_t\right|^2 e^{-2r\alpha}w_\varepsilon^2 dx\,dt \\ &= \int_{Q_T}\left(\left|-r\Delta\alpha+r^2\,|\nabla\alpha|^2+r\alpha_t\right|^2 e^{-2(r-1)\alpha}\right)\left(e^{-2\alpha}w_\varepsilon^2\right)dx\,dt \\ &\le C\left\|\left|-r\Delta\alpha+r^2\,|\nabla\alpha|^2+r\alpha_t\right|^2 e^{-2(r-1)\alpha}\right\|_{L^\infty(Q_T)} \\ &\quad\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt \\ &\le C\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt. \end{aligned}$$

It follows from these three last inequalities and (49) that

$$\|\zeta_\varepsilon\|^2_{W_2^{2,1}(Q_T)} \le C\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt.$$

Now, by the embedding $W_2^{2,1}(Q_T)\hookrightarrow L^{q_N}(Q_T)$ (see, for instance, [18, Lemma 3.2, p. 80])

$$\|\zeta_\varepsilon\|^2_{L^{q_N}(Q_T)} \le C\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt.$$

Going back to our control, we get, using (48),

$$\begin{aligned} \|g_\varepsilon\|^2_{L^{q_N}(Q_T)} &= \|\chi_\omega\zeta_\varepsilon\|^2_{L^{q_N}(Q_T)} \\ &\le C\left(1+\frac{\tau^8}{T^{14}}+\|a\|^6_{L^\infty(Q_T)}\right)\int_0^T\int_\omega e^{-r\alpha}w_\varepsilon^2 dxdt \\ &\le C_T\ \|X_0\|^2_{L^2(\Omega)}. \end{aligned} \tag{50}$$

From (50) and [18, Theorem 10.4, p. 621], it follows, at least for a subsequence, that for $\varepsilon \to 0$

$$\begin{aligned} g_\varepsilon &\rightharpoonup g && \text{weakly in } L^{q_N}(Q_T), \\ (\psi_\varepsilon, v_\varepsilon) &\rightharpoonup (\psi, v) && \text{weakly in } L^2(0,T;H_0^1(\Omega)) \cap W^{2,1}_{q_N}(Q_T), \end{aligned}$$

and $((\psi, v), g)$ satisfy (6) with $(\psi, v)(T) = 0$ and

$$\|\chi_\omega g\|^2_{L^{q_N}(Q_T)} \leq C_T \ \|X_0\|^2_{L^2(\Omega)}. \qquad \square$$

To complete the proof, it remains to show Lemma 4.1.

Proof of Lemma 4.1. According to Lemma 3.4

$$\int_{T/4}^{3T/4} \int_\Omega \left(\delta^{-3} |\varphi|^2 + |w|^2\right) e^{-2\alpha} dx dt \leq C \left(1 + \frac{\tau^8}{T^{14}} + \|a\|^6_{L^\infty(Q_T)}\right) \int_0^T \int_\omega e^{-r\alpha} w^2 \, dx \, dt, \tag{51}$$

provided $\tau \geq \tau_1$. Let us estimate $\delta^{-3} e^{-2\alpha}$ from below on $(T/4, 3T/4) \times \Omega$:

$$\begin{aligned} \delta^{-3}(t,x) e^{-2\alpha(t,x)} &= \tau^{-3} t^3 (T-t)^3 e^{-3\lambda\beta(x)} \exp\left(-2\tau \frac{e^{\frac{4}{3}\lambda\|\beta\|_{L^\infty(\Omega)}} - e^{\lambda\beta(x)}}{t(T-t)}\right) \\ &\geq \tau^{-3} e^{-3\lambda\|\beta\|_{L^\infty(\Omega)}} t^3 (T-t)^3 \exp\left(-2\tau \frac{e^{\frac{4}{3}\lambda\|\beta\|_{L^\infty(\Omega)}} - e^{\lambda \ln 3}}{t(T-t)}\right) \\ &\geq C\tau^{-3} T^6 \exp\left(-\frac{C\tau}{T^2}\right) \\ &\geq C\tau^{-3} \exp\left(-\frac{C\tau}{T^2}\right). \end{aligned}$$

Inserting this inequality into (51), we get

$$\begin{aligned} &\int_{T/4}^{3T/4} \int_\Omega \left(|\varphi|^2 + |w|^2\right) dx \, dt \\ &\leq C\tau^3 \exp\left(\frac{C\tau}{T^2}\right) \left(1 + \frac{\tau^8}{T^{14}} + \|a\|^6_{L^\infty(Q_T)}\right) \int_0^T \int_\omega e^{-r\alpha} w^2 \, dx \, dt. \end{aligned} \tag{52}$$

If (φ, w) satisfies (44), then for $m = \|a\|_{L^\infty(Q_T)} + \frac{1}{2}$ we have

$$\begin{aligned} &\frac{d}{dt}\left(e^{-2m(T-t)}\left(|\varphi(t)|_2^2 + |w(t)|_2^2\right)\right) \\ &= 2me^{-2m(T-t)}\left(|\varphi(t)|_2^2 + |w(t)|_2^2\right) + 2e^{-2m(T-t)}\left(\int_\Omega (ww_t + \varphi\varphi_t)(t)dx\right), \end{aligned} \tag{53}$$

or, together with the Cauchy–Schwarz and Young inequalities,

$$\begin{aligned} &\frac{d}{dt}\left(e^{-2m(T-t)}\left(\|\varphi(t)\|^2_{L^2(\Omega)} + \|w(t)\|^2_{L^2(\Omega)}\right)\right) \\ &\geq 2e^{-2m(T-t)}\left\{\left(m - \frac{1}{2}\right)\|w(t)\|^2_{L^2(\Omega)} + \left(m - \|a\|_{L^\infty(Q_T)} - \frac{1}{2}\right)\|\varphi(t)\|^2_{L^2(\Omega)}\right\} \geq 0. \end{aligned} \tag{54}$$

The integration of (54) over $[T/4, 3T/4]$ yields

$$\frac{T}{2}e^{-2mT}\left(\|\varphi(0)\|^2_{L^2(\Omega)}+\|w(0)\|^2_{L^2(\Omega)}\right)\le\int_{\frac{T}{4}}^{\frac{3T}{4}}\int_\Omega e^{-2m(T-t)}\left(\varphi^2+w^2\right)dx\,dt$$
$$\le e^{-m\frac{T}{2}}\int_{\frac{T}{4}}^{\frac{3T}{4}}\int_\Omega\left(\varphi^2+w^2\right)dx\,dt.$$

Using (52) and setting $\tau=C(T+(1+\|a\|^{2/3}_{L^\infty(Q_T)})T^2)$ with C sufficiently large, we finally arrive at

$$\|\varphi(0)\|^2_{L^2(\Omega)}+\|w(0)\|^2_{L^2(\Omega)}$$
$$\le\frac{2}{T}e^{m\frac{3T}{2}}\int_{\frac{T}{4}}^{\frac{3T}{4}}\int_\Omega\left(\varphi^2+w^2\right)dxdt$$
$$\le\exp\left(C\left(1+\frac{1}{T}+(1+\|a\|_{L^\infty(Q_T)})T+\|a\|^{2/3}_{L^\infty(Q_T)}\right)\right)\int_0^T\int_\omega e^{-r\alpha}w^2dxdt,$$

which is the desired estimate. □

RICCATI EQUATIONS FOR STABLE WELL-POSED LINEAR SYSTEMS: THE GENERIC CASE*

RUTH F. CURTAIN†

Abstract. Under the generic assumption that zero is in the resolvent set of the generator, we show that the optimal control problem for a stable well-posed linear system is equivalent to a control problem for its reciprocal system which has bounded generating operators. Consequently, the operator X that defines the optimal cost satisfies a Riccati equation with bounded operators. Previous results needed various regularity assumptions to obtain X as a solution to a Riccati equation resembling that in the finite-dimensional theory.

Key words. Riccati equations, well-posed linear systems, weakly regular linear systems, Popov function, spectral factorizations, optimal control

AMS subject classifications. 49N10, 93B05, 93C25

DOI. 10.1137/S0363012901399362

1. Introduction.

A key to solving a number of problems in systems and control is the existence of a solution to a Riccati equation which is closely related to a spectral factorization problem and to a linear quadratic optimal control problem. More concretely, consider the finite-dimensional linear system

$$\dot{x}(t) = Ax(t) + Bu(t),\ x(0) = x_0,\ \ y(t) = Cx(t) \tag{1.1}$$

and the cost functional

$$J(x_0, u) = \int_0^\infty \left\langle \begin{bmatrix} Q & N^* \\ N & R \end{bmatrix} \begin{bmatrix} y(t) \\ u(t) \end{bmatrix}, \begin{bmatrix} y(t) \\ u(t) \end{bmatrix} \right\rangle \mathrm{d}t, \tag{1.2}$$

where A, B, C, R, N, Q are matrices of appropriate dimensions, and $R = R^* > 0, Q = Q^*$.

The *optimal control problem* is to find the input function $u^{opt} \in \mathbf{L}_2(0, \infty; \mathbb{C}^m)$ that minimizes $J(x_0, u)$, where x, y are given by (1.1), and to compute this minimum. The corresponding *Popov function* is given by

$$\Pi(i\omega) = R + N\mathbf{G}(i\omega) + \mathbf{G}(i\omega)^* N^* + \mathbf{G}(i\omega)^* Q \mathbf{G}(i\omega), \tag{1.3}$$

where $\mathbf{G}(i\omega) = C(i\omega I - A)^{-1}B$ and $\omega \in \mathbb{R}$.

We consider the case corresponding to a coercive Popov function: $\Pi(i\omega) \geq \epsilon I$ for some $\epsilon > 0$ and all $\omega \in \mathbb{R}$. Then it is known that the control problem has a minimum given by

$$J(x_0, u^{opt}) = \langle Xx_0, x_0 \rangle, \tag{1.4}$$

where X is the minimal self-adjoint matrix solution of the associated *Riccati equation*

$$XA + A^*X + C^*QC = (XB + C^*N^*)R^{-1}(B^*X + NC). \tag{1.5}$$

Moreover, $u^{opt}(t) = -R^{-1}(B^*X + NC)x(t) \in \mathbf{L}_2(0,\infty;\mathbb{C}^m)$ (the closed-loop system need not be stable). For each matrix solution X of (1.5) we obtain a spectral factorization of Π:

$$\Pi(i\omega) = \mathbf{\Xi}(i\omega)^*\mathbf{\Xi}(i\omega), \tag{1.6}$$

$$\mathbf{\Xi}(s) = W[I + R^{-1}(B^*X + NC)(sI - A)^{-1}B], \tag{1.7}$$

where $W^*W = R$. If we choose W to be invertible, then $\mathbf{\Xi}$ has the inverse

$$[I - R^{-1}(B^*X + NC)(sI - A + BR^{-1}(B^*X + NC))^{-1}B]W^{-1}.$$

Both $\mathbf{\Xi}$ and its inverse are in $\mathbf{H}_\infty$.

In this paper, we investigate some extensions of the above theory to the class of infinite-dimensional systems known as *stable well-posed linear systems*. This is a large class of systems, including many systems described by partial differential equations with boundary control and point observations, as well as by delay equations with delayed observations and control action (see Weiss [18], [17], [16], [19], [20]).

Staffans [11] and Weiss and Weiss [22] solved the optimal control problem (1.1)–(1.2) for the subclass of stable weakly regular linear systems using a spectral factorization approach under the coercivity assumption $\Pi(i\omega) \geq \varepsilon I$ for some $\varepsilon > 0$ and almost all $\omega \in \mathbb{R}$. In [14], [12] Staffans solved the problem for the unstable well-posed class, and a complete theory of more general optimal control problems and Riccati equations can be found in Mikkola [9]. The solution for the stable case is obtained in terms of a spectral factorization like (1.6). In its full generality the theory becomes very technical. Although it is possible to give nice conditions for the existence of a solution to the optimal control problem, and the minimum cost has the form (1.4), it is not always possible to obtain a Riccati equation like (1.5). In Weiss and Weiss [22], as well as the weak regularity assumption, they need to assume that the spectral factor $\mathbf{\Xi}$ in (1.6) is regular. In general, this is hard to check, but the following sufficient conditions are known:

1. B is less than maximally unbounded ($\alpha(B) < \frac{1}{2}$ in (2.18)) in Weiss and Curtain [21] .
2. B is infinite-time admissible, $\mathcal{Y}$ is finite-dimensional, and C is bounded in Weiss and Weiss [22].
3. The input-output map is a convolution with an operator-valued L_1-function plus a constant feedthrough and delays (see Staffans [13] and Mikkola [9]).

Even if the spectral factor is regular, the general Riccati equation may have a different factor to R in (1.5) which is rather disconcerting and impossible to compute in general. One sufficient condition for R to be in (1.5) is condition 2 above. While examples are given in [22] and Weiss and Zwart [23] which show that these anomalies can actually occur, it is curious that they have never appeared in the alternative partial differential equation approach to Riccati equations (see Lasiecka and Triggiani [7]).

In this paper, we consider the optimal control problem for a stable well-posed linear system and we attempt to clarify the technicalities under the extra assumption that zero is in the resolvent set of the infinitesimal generator of the weakly regular linear system. This ensures the existence of its *reciprocal system* $A^{-1}, A^{-1}B, -CA^{-1}$, $\mathbf{G}(0)$, where A, B, C are the generating operators of the original well-posed linear system and $\mathbf{G}$ is its transfer function. Note that the generating operators of the reciprocal system are all bounded! Interesting connections between well-posed systems and their reciprocal systems are established in section 3. In particular, they have the

same controllability and observability gramians. The concept of reciprocal systems can be traced back to Livsic in his book [8]. As reported in [3], although this concept has been implicitly used, for example, in studying controllability, it has taken a long while for the reciprocal system approach to be used as a tool for finding solutions to Riccati equations for infinite-dimensional systems. Earlier results include Callier and Grabowski [1], [2]), where they assume scalar control and observation operators, exponential stability of A, and strong stability of its inverse, and Curtain [4], where the control operator is assumed to be bounded. Our results show that none of these strong assumptions is necessary. In section 2 we give the relevant background on well-posed and weakly regular linear systems, and in section 4 we first introduce the optimal control problem for a stable well-posed system and review the known results from [22] and [11]. Under the generic assumption $0 \in \rho(A)$, we show that the optimal control problem for the well-posed system is equivalent to one for the reciprocal system. The minimum cost is given by (1.4), where X is the minimal solution of the following reciprocal Riccati equation with bounded operators:

$$\begin{aligned} &A^{-*}X + XA^{-1} + A^{-*}C^*QCA^{-1} \\ &= (B^*A^{-*}X - N_-CA^{-1})^*R_-^{-1}(B^*A^{-*}X - N_-CA^{-1}), \end{aligned}$$

where $N_- = N + G_0^*Q$, $R_- = R + NG_0 + G_0^*N^* + G_0^*QG_0$, and $G_0 = \mathbf{G}(0)$. Moreover, the spectral factor $\mathbf{\Xi}$ is given by $\mathbf{\Xi}(s) = D_-^\xi + C_-^\xi(\frac{1}{s}I - A^{-1})^{-1}A^{-1}$. This represents a complete solution to the problem without making any regularity assumptions, and it is our main new contribution. However, it is instructive to compare our solution with those in the existing literature. In particular, we give new necessary and sufficient conditions for $\mathbf{\Xi}$ to be (weakly) regular; namely, Σ is (weakly) regular and the following limit exists in the (weak) strong topology:

$$\lim_{\lambda\to\infty} B^*A^{-*}X\lambda(\lambda I - A)^{-1}B.$$

If, in addition, $B^*_{\Lambda_w}X(\lambda I - A)^{-1}B$ has the weak limit $V \in \mathcal{L}(\mathcal{U})$ as $\lambda \to \infty$, then $(D^\xi)^*D^\xi = R + V$. This formula was previously obtained in [14]. We also obtain a new result: if the degree of unboundedness of B is $< \frac{1}{2}$ (B is less than maximally unbounded), then $\mathbf{\Xi}$ is uniformly regular with an invertible feedthrough operator and X also satisfies the Riccati equation (4.12) given in [22].

Finally, we remark that the term "generic" is not misplaced. Analogous results may be obtained by replacing the assumption that $0 \in \rho(A)$ by the assumption that $i\omega \in \rho(A)$ for some real ω. In this case, the relevant reciprocal system is $\Sigma(A_\omega^{-1}, A_\omega^{-1}B, -CA_\omega^{-1}, \mathbf{G}(i\omega))$. While there are generators (e.g., the shift operator) that do not satisfy the above condition, most do.

2. Preliminaries. Since our results are based on the theory of *well-posed linear systems* and *weakly regular linear systems*, we review the relevant theory from Weiss [16], [17], [18], [19], [20], Weiss and Curtain [21] and Weiss and Weiss [22]. We begin with some notation.

DEFINITION 2.1. *Let $\mathcal{Z}_1, \mathcal{Z}_2$ be Hilbert spaces, $\mathcal{B}$ a Banach space, and $\Omega \subset \mathbb{R}$.*

- $\mathbf{L}_2(\Omega, \mathcal{Z}_1)$ *is the space of Lebesgue-measurable, square integrable, $\mathcal{Z}_1$-valued functions on Ω.*
- $\mathbf{L}_2^{loc}(0,\infty;\mathcal{Z}_1)$ *is the space of Lebesgue-measurable functions from $[0,\infty)$ to $\mathcal{Z}_1$, which are square integrable on $[0,\tau]$ for every $\tau > 0$, with the topology determined by the seminorms $\|\cdot\|_{\mathbf{L}_2[0,\tau]}$.*

- $\mathbf{H}_2(\mathcal{Z}_1)$ *is the space of holomorphic* $\mathcal{Z}_1$*-valued functions on the open right half-plane* $\mathbb{C}^+$ *which are uniformly square integrable on vertical lines.*
- $\mathbf{H}_\infty(\mathcal{B})$ *is the space of bounded, holomorphic,* $\mathcal{B}$*-valued functions on* $\mathbb{C}^+$*.*
- $\mathbf{L}_\infty(\mathcal{L}(\mathcal{Z}_1,\mathcal{Z}_2))$ *is the space of essentially bounded, weakly measurable,* $\mathcal{L}(\mathcal{Z}_1, \mathcal{Z}_2)$*-valued functions on the imaginary axis.*

Scalar-valued function spaces will be denoted $\mathbf{H}_2, \mathbf{H}_\infty, \mathbf{L}_\infty$, etc. For simplicity, we suppose that all Hilbert spaces are separable. Let $\mathcal{W}$ be any such Hilbert space. We denote the right shift by τ on $\mathbf{L}_2^{loc}(0,\infty;\mathcal{W})$ by $\mathbf{S}_\tau$, i.e.,

$$(\mathbf{S}_\tau w)(t) = \begin{cases} 0, & 0 \le t < \tau, \\ w(t-\tau), & t \ge \tau. \end{cases}$$

An operator $\mathbb{F}$ on $\mathbf{L}_2^{loc}(0,\infty;\mathcal{W})$ is called *shift-invariant* if $\mathbb{F}\,\mathbf{S}_\tau = \mathbf{S}_\tau\mathbb{F}$ for all $\tau > 0$. $\mathbf{P}_\tau$ denotes the projection of $\mathbf{L}_2^{loc}(0,\infty;\mathcal{W})$ into $\mathbf{L}_2(0,\infty;\mathcal{W})$ by truncation, defined for $w \in \mathbf{L}_2^{loc}(0,\infty;\mathcal{W})$ by

$$(\mathbf{P}_\tau w)(t) = \begin{cases} w(t), & 0 \le t < \tau, \\ 0, & t \ge \tau. \end{cases}$$

For $w_1, w_2 \in \mathbf{L}_2^{loc}(0,\infty;\mathcal{W})$ and $\tau \ge 0$, the τ*-concatenation* of w_1 and w_2, denoted $w_1 \underset{\tau}{\diamond} w_2$, is defined by

$$\left(w_1 \underset{\tau}{\diamond} w_2\right)(t) = \mathbf{P}_\tau w_1 + \mathbf{S}_\tau w_2.$$

We now define well-posed linear systems on Hilbert spaces.

DEFINITION 2.2. *Let* $\mathcal{U}, \mathcal{X}, \mathcal{Y}$ *be given Hilbert spaces. A* well-posed linear system *on* $\mathcal{U}$*,* $\mathcal{X}$*, and* $\mathcal{Y}$ *is a quadruple* $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$*, where*

(i) $\mathbb{T} = (\mathbb{T}_t)_{t\ge 0}$ *is a strongly continuous semigroup of bounded linear operators on* $\mathcal{X}$*;*

(ii) $\Phi = (\Phi_t)_{t\ge 0}$ *is a family of bounded linear operators from* $\mathbf{L}_2(0,\infty;\mathcal{U})$ *to* $\mathcal{X}$ *such that*

$$\Phi_{\tau+t}\left(u \underset{\tau}{\diamond} v\right) = \mathbb{T}_t\Phi_\tau u + \Phi_t v$$

for any $u, v \in \mathbf{L}_2(0,\infty;\mathcal{U})$ *and any* $\tau, t \ge 0$*;*

(iii) Ψ *is a continuous linear operator from* $\mathcal{X}$ *to* $\mathbf{L}_2^{loc}(0,\infty;\mathcal{Y})$ *such that for any* $x \in \mathcal{X}$ *and* $\tau > 0$*,*

$$\Psi x = \Psi x \underset{\tau}{\diamond} \Psi\mathbb{T}_\tau x;$$

(iv) $\mathbb{F}$ *is a continuous linear operator from* $\mathbf{L}_2(0,\infty;\mathcal{U})$ *to* $\mathbf{L}_2^{loc}(0,\infty;\mathcal{Y})$ *such that for any* $u, v \in \mathbf{L}_2(0,\infty;\mathcal{U})$*,*

$$\mathbb{F}\left(u \underset{\tau}{\diamond} v\right) = \mathbb{F}u \underset{\tau}{\diamond} (\Psi\Phi_\tau u + \mathbb{F}v).$$

$\mathcal{U}$ *is the* input space*,* $\mathcal{X}$ *is the* state-space*, and* $\mathcal{Y}$ *is the* output space*.*

If A is the generator of the strongly continuous semigroup $\mathbb{T}$ on $\mathcal{X}$, we denote by $\mathcal{X}_1$ the space $\mathcal{D}(A)$ with the norm $\|z\|_1 = \|(\beta I - A)z\|$, where $\beta \in \rho(A)$, and $\mathcal{X}_{-1}$ is the completion of $\mathcal{X}$ with respect to the norm $\|z\|_1 = \|(\beta I - A)^{-1}z\|$. The choice of β is unimportant, since different choices produce equivalent norms. Consequences of

the definition are the existence of certain operators A, B, C. Assumption (i) implies the existence of the infinitesimal generator $A \in \mathcal{L}(\mathcal{X}_1, \mathcal{X})$ of $\mathbb{T}$. Assumptions (i) and (ii) above imply the existence of a unique $B \in \mathcal{L}(\mathcal{U}, \mathcal{X}_{-1})$, called the *control operator* of Σ, such that for all $t \geq 0$,

$$\Phi_t u = \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma)\, \mathrm{d}\sigma. \tag{2.1}$$

The fact that $\Phi_t u \in \mathcal{X}$ means that B is an *admissible control operator* for $\mathbb{T}$ (i.e., $\Phi_t \in \mathcal{L}(\mathbf{L}_2(0,t;\mathcal{U}), \mathcal{X})$). From (2.1) we see that $\Phi_t u$ depends only on $\mathbf{P}_t u$, and so Φ_t has a natural extension to $\mathbf{L}_2^{loc}(0,\infty;\mathcal{U})$. B is called *infinite-time admissible* for $\mathbb{T}$ if for all $u \in \mathcal{L}(\mathbf{L}_2(0,\infty;\mathcal{U}))$,

$$\sup_{0\leq t<\infty} \left\| \int_0^t \mathbb{T}_\sigma B u(\sigma)\, \mathrm{d}\sigma \right\|_{\mathcal{X}} < \infty. \tag{2.2}$$

In this case, we can define the *extended input map* $\tilde{\Phi} \in \mathcal{L}(\mathbf{L}_2(0,\infty;\mathcal{U}), \mathcal{X})$ by

$$\tilde{\Phi} v = \lim_{T\to\infty} \int_0^T \mathbb{T}_\sigma B v(\sigma)\, \mathrm{d}\sigma. \tag{2.3}$$

If $x_0 \in \mathcal{X}$ is the initial state of Σ and $u \in \mathbf{L}_2^{loc}(0,\infty;\mathcal{U})$ is its input function, then the *state trajectory* of Σ, $x : [0,\infty) \to \mathcal{X}$ is defined by

$$x(t) = \mathbb{T}_t x_0 + \Phi_t u \tag{2.4}$$

for all $t \geq 0$. The function x is continuous in $\mathcal{X}$ and it satisfies the differential equation

$$\dot{x}(t) = Ax(t) + Bu(t) \tag{2.5}$$

in the strong sense in $\mathcal{X}_{-1}$. The function x is the unique solution of (2.5) satisfying the initial condition $x(0) = x_0$. If u has the Laplace transform $\hat{u}$ and $x_0 = 0$, then x has the Laplace transform $\hat{x}(s) = (sI - A)^{-1} B\hat{u}(s)$ for all s with $\mathrm{Re}(s)$ sufficiently large. The operator Ψ in Definition 2.2 is called the *extended output map* of Σ. More generally, any operator Ψ which satisfies assumption (iii) in Definition 2.2 is called an *extended output map* for $\mathbb{T}$. For every such Ψ there exists a unique $C \in \mathcal{L}(\mathcal{X}_1, \mathcal{Y})$ called the *observation operator* of Ψ, such that

$$(\Psi x_0)(t) = C\mathbb{T}_t x_0 \tag{2.6}$$

for every $x_0 \in \mathcal{X}_1$ and every $t \geq 0$. This C determines Ψ, since $\mathcal{X}_1$ is dense in $\mathcal{X}$. The function $y_0 = \Psi x_0$ has a Laplace transform $\hat{y}_0$, and we have $\hat{y}_0(s) = C(sI - A)^{-1} x_0$ for all $x_0 \in \mathcal{X}$ and for $\mathrm{Re}(s)$ sufficiently large. If Ψ is *bounded*, i.e., $\Psi \in \mathcal{L}(\mathcal{X}, \mathbf{L}_2(0,\infty;\mathcal{Y}))$, then we say that C is *infinite-time admissible*.

In Grabowski [5] it is shown that C is infinite-time admissible if and only if the following Lyapunov equation has a self-adjoint nonnegative solution $L \in \mathcal{L}(X)$ for all $z, x \in D(A)$:

$$\langle Az, Lx\rangle + \langle z, LAx\rangle = -\langle Cz, Cx\rangle. \tag{2.7}$$

The *observability gramian* $L_C = \Psi^*\Psi$ is the minimal solution of (2.7) (see Hansen and Weiss [6], where the dual controllability gramian is treated).

The Λ-*extension* of C is defined by

$$C_\Lambda z = \lim_{\lambda \to +\infty} C\lambda(\lambda I - A)^{-1} z. \tag{2.8}$$

The domain $\mathcal{D}(C_\Lambda)$ consists of those $z \in \mathcal{X}$ for which the above limit exists (λ is real). If we replace C by C_Λ in (2.6), then it holds for all $x_0 \in \mathcal{X}$ and almost every $t \geq 0$. The operator C_{Λ_w}, the *weak* Λ-*extension* of C, is defined by

$$C_{\Lambda_w} z = \text{weak} \lim_{\lambda \to +\infty} C\lambda(\lambda I - A)^{-1} z. \tag{2.9}$$

The domain of C_{Λ_w} consists of those $z \in \mathcal{X}$ for which the above limit exists. C_{Λ_w} is an extension of C_Λ and they are equal if $\mathcal{Y}$ is finite-dimensional. Note that for all $x_0 \in \mathcal{X}$ and almost all $t \geq 0$,

$$(\Psi x_0)(t) = C_{\Lambda_w} \mathbb{T}_t x_0 = C_\Lambda \mathbb{T}_t x_0. \tag{2.10}$$

The operator $\mathbb{F}$ in Definition 2.1 is called the *extended input-output map* of Σ. $\mathbb{F}$ is shift-invariant, which implies that $\mathbb{F}$ is *causal*:

$$\mathbf{P}_\tau \mathbb{F} = \mathbf{P}_\tau \mathbb{F} \mathbf{P}_\tau \quad \text{for all} \quad \tau \geq 0. \tag{2.11}$$

Using (2.11), we can extend $\mathbb{F}$ continuously to $\mathbf{L}_2^{loc}(0, \infty; \mathcal{U})$. If $\mathbb{T}_t$ is exponentially stable, then $\mathbb{F} \in \mathcal{L}(\mathbf{L}_2(0, \infty; \mathcal{U}), \mathbf{L}_2(0, \infty; \mathcal{Y}))$ and B and C are infinite-time admissible. We can represent $\mathbb{F}$ via the *transfer function* $\mathbf{G}$ of Σ, which is a bounded analytic $\mathcal{L}(\mathcal{U}, \mathcal{Y})$-valued function on some right half-plane in $\mathbb{C}$. We do not distinguish between two transfer functions defined on different right half-planes if one is a restriction of the other. The connection between $\mathbb{F}$ and $\mathbf{G}$ is as follows: if $u \in \mathbf{L}_2(0, \infty; \mathcal{U})$, then $y = \mathbb{F}u$ has a Laplace transform $\hat{y}$ and, for $\text{Re}(s)$ sufficiently large,

$$\hat{y}(s) = \mathbf{G}(s)\hat{u}(s), \tag{2.12}$$

and $\mathbb{F} \in \mathcal{L}(\mathbf{L}_2(0, \infty; \mathcal{U}), \mathbf{L}_2(0, \infty; \mathcal{Y}))$ if and only if $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(\mathcal{U}, \mathcal{Y}))$. For s, β in some right half-plane, the relationship with the generating operators is given by

$$\begin{aligned} \mathbf{G}(s) - \mathbf{G}(\beta) &= C[(sI - A)^{-1} - (\beta I - A)^{-1}]B \\ &= (\beta - s)C(sI - A)^{-1}(\beta I - A)^{-1}B. \end{aligned} \tag{2.13}$$

In fact, a necessary and sufficient condition for A, B, C to generate a well-posed system is that B and C are admissible for $T(\cdot)$ and the right-hand side of (2.13) be uniformly bounded on some right half-plane for one $\beta \in \rho(A)$. The formula (2.13) can be extended to all s, β in the resolvent set of A, and it is used as the definition of the transfer function on page 10 in Staffans and Weiss [15]. If $\rho(A)$ is connected, this agrees with the analytic continuation to $\rho(A)$, but otherwise these two extensions may differ. To avoid confusion we call this extension the *characteristic function* and denote it by $\mathfrak{G}$. Under our assumptions in section 4, the two concepts are consistent.

LEMMA 2.3. *Suppose that the well-posed linear system Σ has the generating operators A, B, C and the transfer function $\mathbf{G}$. If C is an infinite-time admissible observation operator, then $\mathbf{G}$ has an analytic extension on $\mathbb{C}_0^+$ and $\mathbf{G} = \mathfrak{G}$ in $\rho(A) \cap \mathbb{C}_0^+$.*

Proof. Now $\Psi \in \mathcal{L}(\mathcal{X}, \mathbf{L}_2(0, \infty; \mathcal{Y}))$ and so its Laplace transform is such that $\hat{\Psi}x \in \mathbf{H}_2(\mathcal{Y})$ for $x \in \mathcal{X}$ and from (2.10) $\hat{\Psi}(s)x = C(sI - A)^{-1}x$ for s in some right

half-plane. For $x \in D(A)$ we also have $\hat{\Psi}(s)(sI - A)x = Cx$, and since both sides are analytic on $\mathbb{C}_0^+$, this extends to $s \in \mathbb{C}_0^+$. So we obtain

$$\hat{\Psi}(s)x = C(sI - A)^{-1}x \quad \text{for} \quad s \in D(A) \cap \mathbb{C}_0^+, \tag{2.14}$$

and since $D(A)$ is dense in $\mathcal{X}$, this extends to $x \in \mathcal{X}$. Now we fix a number $\beta \in \rho(A)$ in some right half-plane and rewrite (2.13) as follows:

$$\mathbf{G}(s) - \mathbf{G}(\beta) = (\beta - s)\hat{\Psi}(s)(\beta I - A)^{-1}B. \tag{2.15}$$

This shows that $\mathbf{G}$ has an extension to an analytic function on $\mathbb{C}_0^+$. Similarly, for $z \in \mathbb{C}_0^+$, we have

$$\mathbf{G}(z) - \mathbf{G}(\beta) = (\beta - z)\hat{\Psi}(z)(\beta I - A)^{-1}B, \tag{2.16}$$

and subtracting (2.16) from (2.15) gives

$$\begin{aligned}\mathbf{G}(s) - \mathbf{G}(z) &= \beta[\hat{\Psi}(s) - \hat{\Psi}(z)](\beta I - A)^{-1}B - [s\hat{\Psi}(s) - z\hat{\Psi}(z)](\beta I - A)^{-1}B \\ &= (z - s)\hat{\Psi}(s)(zI - A)^{-1}B \quad \text{for} \quad s, z \in \rho(A) \cap \mathbb{C}_0^+ \\ &= (z - s)C(sI - A)^{-1}(zI - A)^{-1}B, s, z \in \rho(A) \cap \mathbb{C}_0^+,\end{aligned}$$

where we have used (2.14). Thus for $s, z \in D(A) \cap \mathbb{C}_0^+$, we obtain

$$\mathbf{G}(s) - \mathbf{G}(z) = \mathfrak{G}(s) - \mathfrak{G}(z). \qquad \square$$

Clearly, the above lemma has a dual version with B an infinite-time admissible control operator.

If $\mathbf{G}$ is a bounded, analytic, $\mathcal{L}(\mathcal{U}, \mathcal{Y})$-valued function defined on some right half-plane in $\mathbb{C}$, then a *realization* of $\mathbf{G}$ is a well-posed linear system Σ whose transfer function is $\mathbf{G}$.

In order to obtain nice state-space formulas we need to assume a regularity condition.

DEFINITION 2.4. *The system Σ (or its transfer function $\mathbf{G}$) is called* weakly regular *if the following limit exists in $\mathcal{Y}$ for all $v \in \mathcal{U}$:*

$$\textit{weak} \lim_{\lambda \to +\infty} \mathbf{G}(\lambda)v = Dv. \tag{2.17}$$

Note that λ in the above is real. Σ (or $\mathbf{G}$) is called *regular* if the limit (2.17) exists in the norm topology of $\mathcal{Y}$ and uniformly regular if the limit exists in the operator norm topology. The operator $D \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$ is called the *feedthrough operator* of Σ (or of $\mathbf{G}$). A sufficient condition for weak regularity of a well-posed linear system is that $C_{\Lambda_w}(\beta I - A)^{-1}B$ exists for some β in the resolvent set of A. If $\mathcal{Y}$ is finite-dimensional, then weak regularity equals regularity, and if B is bounded, Σ is uniformly regular. Other conditions for regularity can be expressed in terms of the degree of unboundedness of B or of C. If B is an admissible control operator for $\mathbb{T}$, its *degree of unboundedness*, denoted $\alpha(B)$, is the infimum of those $\alpha \geq 0$ for which there exist positive constants δ, ω such that

$$\|(\lambda I - A)^{-1}B\|_{\mathcal{L}(\mathcal{U},\mathcal{X})} \leq \frac{\delta}{\lambda^{1-\alpha}} \quad \text{for all } \lambda \in (\omega, \infty). \tag{2.18}$$

It is known that $\alpha(B) \leq \frac{1}{2}$, and if B is bounded, then $\alpha(B) = 0$. The *degree of unboundedness of an admissible observation operator* C is the degree of unboundedness of the admissible control operator C^* for $\mathbb{T}^*$. We reformulate the recent result from Proposition 4.2 in [21].

LEMMA 2.5. *Let B and C be admissible control and observation operators for $T(\cdot)$. If either B or C has a degree of unboundedness less than $\frac{1}{2}$, then A, B, C are the generating operators of a uniformly regular system.*

One advantage of considering (weakly) regular linear systems is that the formulas for $\mathbf{G}$ and $\mathbb{F}$ are the same as the finite-dimensional ones with C_{Λ_w} replacing C (for well-posed systems they are rather complicated).

THEOREM 2.6. *If Σ is weakly regular, then the following hold:*

(i) $\mathbf{G}(s) = C_{\Lambda_w}(sI - A)^{-1}B + D$ *for sufficiently large* Re s.

(ii) $\mathbb{F} : \mathbf{L}_2^{loc}(0, \infty; \mathcal{U}) \to \mathbf{L}_2^{loc}(0, \infty; \mathcal{Y})$ *is given by*

$$(\mathbb{F}u)(t) = C_{\Lambda_w} \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma)\, \mathrm{d}\sigma + Du(t)$$

for almost all $t \geq 0$.

(iii) *If x is the state trajectory of Σ corresponding to the initial state $x_0 \in \mathcal{X}$ and the input function $u \in \mathbf{L}_2^{loc}(0, \infty; \mathcal{U})$, then $x(t)$ given by (2.4) satisfies $x(t) \in \mathcal{D}(C_{\Lambda_w})$ for almost every $t \geq 0$, and the output function of Σ, $y = \Psi x_0 + \mathbb{F}u$ satisfies*

$$y(t) = C_{\Lambda_w} x(t) + Du(t) \quad \textit{for almost all } t \geq 0.$$

If Σ is regular, then C_Λ may replace C_{Λ_w} in the above. A, B, C, D are called the generating operators *of Σ.*

In this paper the operator $B^*_{\Lambda_w}$ occurs frequently, where

$$B^*_{\Lambda_w} z = \text{weak} \lim_{\lambda \to \infty} B^* \lambda (\lambda I - A^*)^{-1} z, \tag{2.19}$$

and its domain consists of all $z \in \mathcal{X}$ for which the weak limit makes sense.

The following proposition about inverses of regular linear systems follows from results in sections 4 and 7 in [19] by considering unity feedback of $I - \mathbf{G}$.

PROPOSITION 2.7. *Let Σ be a regular linear system with generating operators A, B, C, D and transfer function $\mathbf{G}$. Then D is invertible if and only if $\mathbf{G}^{-1}$ is regular. In this case $\mathbf{G}^{-1}$ is the transfer function of the regular linear system Σ^{inv} with generating operators $A^{inv}, B^{inv}, C^{inv}, D^{inv}$ given by*

$$\begin{aligned} A^{inv}x &= (A - BD^{-1}C_\Lambda)x \quad \textit{for all } x \in D(A^{inv}), \\ D(A^{inv}) &= \{x \in D(C_\Lambda) \mid (A - BD^{-1}C_\Lambda)x \in \mathcal{X}\}, \\ C^{inv}x &= -D^{-1}C_\Lambda x \quad \textit{for all } x \in \mathcal{D}(A^{inv}), \\ B^{inv} &= BD^{-1}, D^{inv} = D^{-1}. \end{aligned}$$

Under the assumptions of this proposition, we call Σ^{inv} the inverse of Σ.

3. Reciprocal systems. In this section we consider a well-posed linear system Σ with the generating operators A, B, C, transfer function $\mathbf{G}$, and characteristic function $\mathfrak{G}$, and we assume that $0 \in \rho(A)$. Using the definition of the transfer function from (2.13), it is clear that for all $s \in \rho(A)$

$$\begin{aligned} \mathfrak{G}(s) - \mathfrak{G}(0) &= C[(sI - A)^{-1} + A^{-1}]B \\ &= -CA^{-1}\left(\frac{1}{s}I - A^{-1}\right)^{-1} A^{-1}B. \end{aligned} \tag{3.1}$$

Note that $A^{-1}, A^{-1}B, CA^{-1}$ are all bounded operators, and so they generate a regular linear system with feedthrough operator zero, and (3.1) holds for all $s \in \rho(A)$. This motivates the following definition.

DEFINITION 3.1. *Let* $\mathbf{G}$ *be the transfer function of a well-posed linear system* Σ *with generating operators* A, B, C *with* $0 \in \rho(A)$. *We call the regular linear system* Σ_- *with generating operators* $A^{-1}, A^{-1}B, -CA^{-1}, \mathfrak{G}(0)$ *the* reciprocal system corresponding to Σ. *We denote its transfer function and characteristic functions by* $\mathbf{G}_-$ *and* $\mathfrak{G}_-$, *respectively.*

In the next lemma we prove some interesting connections between well-posed linear systems and their reciprocal systems.

LEMMA 3.2. *Under the assumptions of Definition* 3.1 *and denoting the group with generator* A^{-1} *by* $\mathbb{T}_-$, *the following hold:*

1. $\mathfrak{G}_-(\frac{1}{s}) = \mathfrak{G}(s)$ *for all* $s \in \rho(A)$.
2. C *is an infinite-time admissible observation operator for* $\mathbb{T}$ *if and only if* CA^{-1} *is an infinite-time admissible operator for* $\mathbb{T}_-$. *In this case, their observability gramians are equal and are the minimal solutions of their respective Lyapunov equations.*
3. B *is an infinite-time admissible control operator for* $\mathbb{T}$ *if and only if* $A^{-1}B$ *is an infinite-time admissible control operator for* $\mathbb{T}_-$. *In this case, their controllability gramians are equal and are the minimal solutions of their respective Lyapunov equations.*
4. *If* C *is an infinite-time admissible observation operator for* $\mathbb{T}$, *then* $\mathbf{G}(s) = \mathbf{G}_-(\frac{1}{s})$ *for* $s \in \mathbb{C}_0^+$. *Moreover,* $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(\mathcal{U}, \mathcal{Y}))$ *if and only if* $\mathbf{G}_- \in \mathbf{H}_\infty(\mathcal{L}(\mathcal{U}, \mathcal{Y}))$.

Proof.

1. This follows from (3.1).
2. From Grabowski [5] we know that C is an infinite-time admissible operator for $\mathbb{T}$ if and only if Lyapunov equation (2.7) has a self-adjoint nonnegative solution $L \in \mathcal{L}(\mathcal{X})$. An analogous statement holds for CA^{-1} and the following Lyapunov equation with values in $\mathcal{X}$:

$$A^{-*}L_C + L_C A^{-1} = -A^{-*}C^*CA^{-1}. \tag{3.2}$$

   It is clear that L solves (2.7) if and only if it solves (3.2). Moreover, if C is infinite-time admissible, the observability gramian of Σ is $\Psi^*\Psi$, and it is the minimal solution of (2.7). An analogous statement holds for the reciprocal system and this proves the claim.
3. This is a dual statement to the infinite-time observability (see Hansen and Weiss [6]).
4. Now, from part 2, both C and CA^{-1} are infinite-time admissible, and so from Lemma 2.3 we have

$$\mathbf{G}(s) = \mathfrak{G}(s) \quad \text{for} \quad s \in \rho(A) \cap \mathbb{C}_0^+ \quad \text{and}$$

$$\mathbf{G}_-(s) = \mathfrak{G}_-(s) \quad \text{for} \quad s \in \rho(A^{-1}) \cap \mathbb{C}_0^+.$$

   This together with (3.1) gives

$$\mathbf{G}(s) = \mathbf{G}_-\left(\frac{1}{s}\right) \quad \text{for} \quad s \in \rho(A) \cap \mathbb{C}_0^+.$$

However, from Lemma 2.3 both $\mathbf{G}$ and $\mathbf{G}_-$ are analytic on $\mathbb{C}_0^+$, and so the above equality holds on $\mathbb{C}_0^+$. □

We now relate the reciprocals of inverses of regular systems.

THEOREM 3.3. *Suppose that Σ is a regular linear system with the generating operators A, B, C, D and $0 \in \rho(A)$. Let Σ_- denote its reciprocal system with transfer function $\mathbf{G}_-$. If D is invertible, then the inverse system Σ^{inv} of Σ is regular. Moreover, Σ_-^{inv}, the inverse system of Σ_-, is the reciprocal system of Σ^{inv}.*

Proof. By Proposition 2.7, if D is invertible, then Σ^{inv} is a regular linear system with generating operators $A^{inv}, C^{inv} = -D^{-1}C_\Lambda, B^{inv} = BD^{-1}, D^{inv} = D^{-1}$, where

$$\begin{aligned} A^{inv}x &= (A - BD^{-1}C_\Lambda)x \quad \text{for all} \quad x \in \mathcal{D}(A^{inv}),\\ \mathcal{D}(A^{inv}) &= \{x \in \mathcal{D}(C_\Lambda)\,|(A - BD^{-1}C_\Lambda)x \in \mathcal{X}\}. \end{aligned}$$

By the same proposition, the inverse of the reciprocal system Σ_-^{inv} has the generating operators

$$\begin{aligned} A_-^{inv} = A^{-1} + A^{-1}BD_-^{-1}CA^{-1}, B_-^{inv} = A^{-1}BD_-^{-1},\\ C_-^{inv} = D_-^{-1}CA^{-1}, D_-^{inv} = D_-^{-1}, \end{aligned} \tag{3.3}$$

where $D_- = \mathfrak{G}(0)$. To show that the reciprocal system of Σ^{inv} is well defined, we first show that A^{inv} has the bounded inverse A_-^{inv}. Consider for all $x \in \mathcal{X}$

$$\begin{aligned} A^{inv}A_-^{inv}x &= (A - BD^{-1}C_\Lambda)(A^{-1} + A^{-1}BD_-^{-1}CA^{-1})x\\ &= (I + BD_-^{-1}CA^{-1} - BD^{-1}C_\Lambda A^{-1})x\\ &\quad -(BD^{-1}C_\Lambda A^{-1}BD_-^{-1}CA^{-1})x\\ &= x + BD^{-1}(D - D_- - C_\Lambda A^{-1}B)D_-^{-1}CA^{-1}x\\ &= x, \end{aligned}$$

where in the second line the terms are well defined in $\mathcal{X}_{-1}$. Next consider for $x \in \mathcal{D}(A^{inv}) \subset \mathcal{D}(C_\Lambda)$

$$\begin{aligned} A_-^{inv}A^{inv}x &= (A^{-1} + A^{-1}BD_-^{-1}CA^{-1})(A - BD^{-1}C)x\\ &= x - A^{-1}BD^{-1}C_\Lambda x + A^{-1}BD_-^{-1}C_\Lambda x\\ &\quad -A^{-1}BD_-^{-1}C_\Lambda A^{-1}BD^{-1}C_\Lambda x\\ &= x + A^{-1}BD_-^{-1}(-D_- + D - C_\Lambda A^{-1}B)D^{-1}C_\Lambda x\\ &= x. \end{aligned}$$

So the reciprocal system of Σ^{inv} is well defined and it has the generating operators $(A^{inv})^{-1}, (A^{inv})^{-1}B^{inv}, -C^{inv}(A^{inv})^{-1}, D^{inv} - C^{inv}(A^{inv})^{-1}B^{inv}$. We show that these are precisely the generating operators of Σ_-^{inv}. We consider the control operator

$$\begin{aligned} (A^{inv})^{-1}B^{inv} &= (A^{inv})^{-1}BD^{-1} = A_-^{inv}BD^{-1}\\ &= (A^{-1} + A^{-1}BD_-^{-1}C_\Lambda A^{-1})BD^{-1}\\ &= A^{-1}BD_-^{-1}(D_- + C_\Lambda A^{-1}B)D^{-1}\\ &= A^{-1}BD_-^{-1}. \end{aligned}$$

The observation operator is

$$\begin{aligned} C^{inv}(A^{inv})^{-1} &= -D^{-1}C_\Lambda(A^{inv})^{-1} = -D^{-1}C_\Lambda(A^{-1} + A^{-1}BD_-^{-1}CA^{-1})\\ &= -D^{-1}(D_- + C_\Lambda A^{-1}B)D_-^{-1}CA^{-1}\\ &= -D_-^{-1}CA^{-1}. \end{aligned}$$

Finally, the feedthrough term is

$$\begin{aligned} D^{inv} - C^{inv}(A^{inv})^{-1}B^{inv} &= D^{-1} + D^{-1}C_\Lambda[A^{-1} + A^{-1}BD_-^{-1}C_\Lambda A^{-1}]BD^{-1} \\ &= D^{-1}[D + C_\Lambda A^{-1}B + C_\Lambda A^{-1}BD_-^{-1}C_\Lambda A^{-1}B]D^{-1} \\ &= D^{-1}[D + C_\Lambda A^{-1}BD_-^{-1}(D_- + C_\Lambda A^{-1}B)]D^{-1} \\ &= D^{-1}[D + C_\Lambda A^{-1}BD_-^{-1}D]D^{-1} \\ &= D_-^{-1}. \qquad \square \end{aligned}$$

4. The linear quadratic optimal control problem. In this section, we consider the well-posed linear system $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$ on the Hilbert spaces $\mathcal{U}, \mathcal{X}, \mathcal{Y}$, and we denote its generating operators by A, B, C and its transfer function by $\mathbf{G}$. We suppose that Σ satisfies the following assumptions:

(a) $\mathbb{F} \in \mathcal{L}(\mathbf{L}_2(0,\infty;\mathcal{U}), \mathbf{L}_2(0,\infty;\mathcal{Y}))$.
(b) $\Psi \in \mathcal{L}(\mathcal{X}, \mathbf{L}_2(0,\infty;\mathcal{Y}))$.
(c) $\mathcal{U}$ is a separable Hilbert space.
(d) $0 \in \rho(A)$.

Assumption (b) implies that $\hat{\Psi}x \in \mathbf{H}_2(\mathcal{Y})$ for all $x \in \mathcal{X}$, and so we have $\mathbf{G} = \mathfrak{G}$ for $s \in \rho(A) \cap \mathbb{C}_0^+$ (see Lemma 2.3). In particular, with assumption (d) we obtain $\mathbf{G}(0) = \mathfrak{G}(0)$. Consequently, we do not have to distinguish between the transfer function and the characteristic function in what follows. Assumption (b) is equivalent to $\mathbf{G} \in \mathbf{H}_\infty(\mathcal{L}(\mathcal{U},\mathcal{Y}))$. Assumption (c) is made because we choose to quote results from Weiss and Weiss [22] and they use a frequency domain approach. However, it is possible to prove all the results without (c) using a time domain approach similar to that in Mikkola [9]. Let us consider the following cost functional associated with Σ:

$$J(x_0,u) = \int_0^\infty \left\langle \begin{bmatrix} Q & N^* \\ N & R \end{bmatrix} \begin{bmatrix} y(t) \\ u(t) \end{bmatrix}, \begin{bmatrix} y(t) \\ u(t) \end{bmatrix} \right\rangle_{\mathcal{Y}\times\mathcal{U}} dt, \tag{4.1}$$

where $R = R^* \in \mathcal{L}(\mathcal{U}), Q = Q^* \in \mathcal{L}(\mathcal{Y})$, and $N \in \mathcal{L}(\mathcal{Y},\mathcal{U})$. Note that no positivity assumptions are made on R or on Q. For each initial state $x_0 \in \mathcal{X}$, u and y are related as in Theorem 2.6. The *optimal control problem* is to find the input function $u^{opt} \in \mathbf{L}_2(0,\infty;\mathcal{U})$ that minimizes $J(x_0,u)$. We denote this the optimal control problem by (Σ, J). We substitute $y = \Psi x_0 + \mathbb{F}u$ into (4.1) to obtain

$$J(x_0,u) = \left\langle \begin{bmatrix} \Psi^*Q\Psi & \Psi^*(Q\mathbb{F} + N^*) \\ (\mathbb{F}^*Q + N)\Psi & \mathcal{R} \end{bmatrix} \begin{bmatrix} x_0 \\ u \end{bmatrix}, \begin{bmatrix} x_0 \\ u \end{bmatrix} \right\rangle, \tag{4.2}$$

where the scalar product is from $\mathcal{X} \times \mathbf{L}_2(0,\infty;\mathcal{U})$ and

$$\mathcal{R} = R + N\mathbb{F} + \mathbb{F}^*N^* + \mathbb{F}^*Q\mathbb{F}. \tag{4.3}$$

Under our assumptions (a), (b), we see that $J(x_0,u)$ is finite for all $x_0 \in \mathcal{X}$ and $u \in \mathbf{L}_2(0,\infty;\mathcal{U})$. $\mathcal{R}$ is a Toeplitz operator whose symbol is the *Popov function* associated with the above control problem.

DEFINITION 4.1. *The* Popov function $\Pi : i\mathbb{R} \to \mathcal{L}(\mathcal{U})$ *associated with the well-posed linear system* Σ *and the cost function* J *in* (4.1) *is defined for almost every* $\omega \in \mathbb{R}$ *by*

$$\Pi(i\omega) = R + N\mathbf{G}(i\omega) + \mathbf{G}(i\omega)^*N^* + \mathbf{G}(i\omega)^*Q\mathbf{G}(i\omega), \tag{4.4}$$

where $\mathbf{G}$ *is the transfer function of* Σ.

We remark that a sufficient condition for the Popov function Π to be well defined is that $\mathbb{F}$ be a bounded operator from $\mathbf{L}_2(0,\infty;\mathcal{U})$ to $\mathbf{L}_2(0,\infty;\mathcal{Y})$. For in this case, $\mathbf{G}\in\mathbf{H}_\infty(\mathcal{L}(\mathcal{U},\mathcal{Y}))$ and it has an extension to $s=i\omega$ in the sense that $\lim_{\sigma\to 0}\mathbf{G}(\sigma+i\omega)u$ exists for all $u\in\mathcal{U}$, for almost all $\omega\in\mathbb{R}$ (see Theorem 4.5 in Rosenblum and Rovnyak [10]). Moreover, $\Pi\in\mathbf{L}_\infty(\mathcal{L}(\mathcal{U}))$.

We summarize the main results from Weiss and Weiss [22] for the well-posed case (or see Staffans [11]).

THEOREM 4.2. *Let $\Sigma=(\mathbb{T},\Phi,\Psi,\mathbb{F})$ be a well-posed linear system satisfying assumptions* (a), (b), (c)*, and consider the associated cost function J from* (4.1)*. If the corresponding Popov function Π from* (4.4) *is coercive, i.e., there exists $\epsilon>0$ such that $\Pi(i\omega)\geq\epsilon I$ for almost all $\omega\in\mathbb{R}$, then it has a spectral factorization*

$$\Pi(i\omega)=\mathbf{\Xi}(i\omega)^*\mathbf{\Xi}(i\omega) \tag{4.5}$$

for almost all $\omega\in\mathbb{R}$. $\mathbf{\Xi}$ and its inverse are in $\mathbf{H}_\infty(\mathcal{L}(\mathcal{U},\mathcal{Y}))$ and it has the well-posed realization $\Sigma^\xi=(\mathbb{T},\Phi,\Psi^\xi,\mathbb{F}^\xi)$, where Ψ^ξ is an extended output map for $\mathbb{T}$ defined by

$$\Psi^\xi=(\mathbb{F}^\xi)^{-*}(\mathbb{F}^*Q+N)\Psi. \tag{4.6}$$

The optimal control is $u^{opt}=-\mathcal{R}^{-1}(\mathbb{F}^*Q+N)\Psi x_0$ and the optimal cost has the form

$$J(x_0,u^{opt})=\langle Xx_0,x_0\rangle, \tag{4.7}$$

where $X=X^*\in\mathcal{L}(\mathcal{X})$ is defined by

$$X=\Psi^*Q\Psi-\Psi^*(Q\mathbb{F}+N^*)\mathcal{R}^{-1}(\mathbb{F}^*Q+N)\Psi \tag{4.8}$$

$$=\Psi^*Q\Psi-(\Psi^\xi)^*\Psi^\xi. \tag{4.9}$$

Proof. All results are stated explicitly in Weiss and Weiss [22] with the exception of (4.9). This follows from the two equations (11.5) and (12.3) in [22], namely,

$$\mathcal{R}=(\mathbb{F}^\xi)^*\mathbb{F}^\xi \quad\text{and}\quad (\mathbb{F}^\xi)^*\Psi^\xi=(\mathbb{F}^*Q+N)\Psi. \qquad \square$$

In order to obtain Riccati equations resembling the usual ones (1.5) it is necessary to assume that Σ is weakly regular. The main results for this case from [22] are as follows.

THEOREM 4.3. *Let $\Sigma=(\mathbb{T},\Phi,\Psi,\mathbb{F})$ be a weakly regular linear system satisfying assumptions* (a), (b), (c) *and with feedthrough operator zero. If the Popov function is coercive and its spectral factor $\mathbf{\Xi}$ is regular with an invertible feedthrough operator D^ξ, then it has the generating operators A,B,C^ξ,D^ξ, where*

$$C^\xi=D^\xi((D^\xi)^*D^\xi)^{-1}(B^*_{\Lambda_w}X+NC), \tag{4.10}$$

where X maps $D(A)$ into $D(B^*_{\Lambda_w})$ and

$$\mathbf{\Xi}(s)=D^\xi+C^\xi_\Lambda(sI-A)^{-1}B. \tag{4.11}$$

Moreover, X satisfies the Riccati equation

$$A^*X+XA+C^*QC=(B^*_{\Lambda_w}X+NC)^*((D^\xi)^*D^\xi)^{-1}(B^*_{\Lambda_w}X+NC), \tag{4.12}$$

where all terms have values in $\mathcal{L}(\mathcal{X}_1,\mathcal{X}_{-1})$, and the optimal control is given by $u^{opt}(t)=-(D^{\xi^*}D^\xi)^{-1}(B^*_{\Lambda_w}X+NC)_\Lambda x^{opt}(t)$.

Note that even if Σ is regular, the spectral factor need not be. Moreover, even if the spectral factor is regular, $(D^{\xi})^* D^{\xi} = R$ need not hold as in the finite-dimensional theory; D_{ξ} is defined as the feedthrough operator of the spectral factor. While there are known sufficient conditions for these to hold (see the introduction), it is not as nice a theory as we had hoped for.

So far we have not used assumption (d). This is now invoked to show that for the general well-posed system the operator X defined by (4.8) is always the solution of a certain Riccati equation. Regularity is not needed. To achieve this we introduce the reciprocal system of Σ: $\Sigma_- = (\mathbb{T}_-, \Phi_-, \Psi_-, \mathbb{F}_-)$ with the generating operators $A^{-1}, A^{-1}B, -CA^{-1}, \mathbf{G}(0) = G_0$ and a cost functional J_- of the form (4.1) with $(\mathbb{T}, \Phi, \Psi, \mathbb{F})$ replaced by $(\mathbb{T}_-, \Phi_-, \Psi_-, \mathbb{F}_- - G_0)$ and R, N replaced by N_-, R_- given by

$$N_- = N + G_0^* Q; \quad R_- = R + NG_0 + G_0^* N^* + G_0^* Q G_0. \tag{4.13}$$

Note that this is an algebraic device to reduce a control problem for the reciprocal system Σ_-, which has nonzero feedthrough, to an equivalent control problem for a system with zero feedthrough. (This is the formulation of the control problem in Theorems 4.2 and 4.3.) We denote this optimal control problem by (Σ_-, J_-), and we call it the *reciprocal optimal control problem associated with the optimal control problem* (Σ, J). The following result justifies this notation.

THEOREM 4.4. *Let Σ be a well-posed linear system that satisfies assumptions* (a)–(d). *Then the minimum cost of the control problem (Σ, J) equals the minimum cost of the reciprocal control problem (Σ_-, J_-).*

Proof. The cost functionals can be expressed as

$$\begin{aligned} J(x,u) = {} & \langle \Psi^* Q \Psi x, x\rangle + \langle \mathcal{R} u, u\rangle_2 \\ & + \langle (\mathbb{F}^* Q + N)\Psi x, u\rangle_2 + \langle u, (\mathbb{F}^* Q + N)\Psi x\rangle_2, \end{aligned} \tag{4.14}$$

where $\langle \cdot, \cdot \rangle$ denotes the scalar product in $\mathcal{X}$ (or subsequently $\mathcal{U}$ or $\mathcal{Y}$) and $\langle \cdot, \cdot \rangle_2$ denotes the scalar product in $\mathbf{L}_2(0, \infty; \mathcal{U})$ (or $\mathbf{L}_2(0, \infty; \mathcal{Y})$).

$$\begin{aligned} J_-(x,v) = {} & \langle \Psi_-^* Q \Psi_- x, x\rangle + \langle \mathcal{R}_- v, v\rangle_2 \\ & + \langle (\mathbb{F}_-^* Q + N)\Psi_- x, v\rangle_2 + \langle v, (\mathbb{F}_-^* Q + N)\Psi_- x\rangle_2, \end{aligned} \tag{4.15}$$

where

$$\mathcal{R}_- = R_- + N_- \mathbb{F}_- + \mathbb{F}_-^* N_-^* + \mathbb{F}_-^* Q \mathbb{F}_-, \tag{4.16}$$

R_-, N_- are defined by (4.13), and we have used

$$(\mathbb{F}_-^* - G_0)Q + N_- = \mathbb{F}_-^* Q + N.$$

The Popov function for the reciprocal control problem is given by

$$\begin{aligned} \Pi_-(i\omega) &= R_- + N_-(\mathbf{G}_-(i\omega) - G_0) + (\mathbf{G}_-(i\omega) - G_0)^* N_-^* \\ &\quad + (\mathbf{G}_-(i\omega) - G_0)^* Q (\mathbf{G}_-(i\omega) - G_0) \\ &= R + N\mathbf{G}_-(i\omega) + \mathbf{G}_-(i\omega)^* N^* + \mathbf{G}_-(i\omega)^* Q \mathbf{G}_-(i\omega). \end{aligned} \tag{4.17}$$

Thus, using Lemma 3.2, we see that

$$\Pi_-\left(\frac{1}{i\omega}\right) = \Pi(i\omega) \quad \text{for almost all } \omega \in \mathbb{R}. \tag{4.18}$$

Next we make use of a useful operator $\mathcal{H}$ on $\mathbf{H}_2(\mathcal{U})$ (or $\mathbf{H}_2(\mathcal{Y})$)

$$(\mathcal{H}f)(s) = \frac{1}{s} f\left(\frac{1}{s}\right) \quad \text{for} \quad f \in \mathbf{H}_2(\mathcal{U}). \tag{4.19}$$

It is readily verified that it is one-to-one, has a bounded inverse, and, in particular, has the properties

$$\langle \mathcal{H}f, g\rangle_{\mathbf{H}_2} = \langle f, \mathcal{H}g\rangle_{\mathbf{H}_2}, \ \langle \mathcal{H}f, \mathcal{H}g\rangle_{\mathbf{H}_2} = \langle f, g\rangle_{\mathbf{H}_2} \tag{4.20}$$

for f, g $\in \mathbf{H}_2(\mathcal{U})$, where $\langle \cdot, \cdot \rangle_{\mathbf{H}_2}$ is the scalar product in $\mathbf{H}_2(\mathcal{U})$ (or $\mathbf{H}_2(\mathcal{Y})$). We show that

$$\widehat{\Psi_- x} = \mathcal{H}(\widehat{\Psi x}), \tag{4.21}$$

where $\hat{u}$ denotes the Laplace transform of u. Now for $x \in D(A)$ we have

$$\begin{aligned} \text{right-hand side (RHS) of (4.21)} &= \mathcal{H}(C(sI - A)^{-1}x) \\ &= \frac{1}{s} C\left(\frac{1}{s} I - A\right)^{-1} x \\ &= -CA^{-1}(sI - A^{-1})^{-1}x \\ &= \text{left-hand side (LHS) of (4.21)}, \end{aligned}$$

and as in Lemma 2.3 this extends to $\mathcal{X}$. Next we prove

$$\Psi^* Q \Psi = \Psi_-^* Q \Psi_- \tag{4.22}$$

by considering the following expression for $x, y \in \mathcal{X}$:

$$\begin{aligned} \langle \Psi^* Q \Psi x, y\rangle &= \frac{1}{2\pi} \langle Q\widehat{\Psi x}, \widehat{\Psi y}\rangle_{\mathbf{H}_2} \\ &= \frac{1}{2\pi} \langle \mathcal{H} Q \widehat{\Psi x}, \mathcal{H}\widehat{\Psi y}\rangle_{\mathbf{H}_2} \\ &= \frac{1}{2\pi} \langle Q\widehat{\Psi_- x}, \widehat{\Psi_- y}\rangle_{\mathbf{H}_2} \quad \text{by (4.21)} \\ &= \langle \Psi_- y, Q \Psi_- x\rangle_2. \end{aligned}$$

This holds for all $x, y \in \mathcal{X}$, and so (4.22) holds. We now define the input v in (4.15) via $\hat{v} = \mathcal{H}\hat{u}$. From (4.19) $v \in \mathbf{L}_2(0, \infty; \mathcal{U})$ if and only if $u \in \mathbf{L}_2(0, \infty; \mathcal{U})$. With this definition we show that for all $u \in \mathbf{L}_2(0, \infty; \mathcal{U})$

$$\langle N\Psi x, u\rangle_2 = \langle N\Psi_- x, v\rangle_2. \tag{4.23}$$

$$\begin{aligned} \text{LHS of (4.23)} &= \frac{1}{2\pi} \langle \widehat{\Psi x}, N^* \hat{u}\rangle_{\mathbf{H}_2} \\ &= \frac{1}{2\pi} \langle \mathcal{H}\widehat{\Psi x}, N^* \mathcal{H}\hat{u}\rangle_{\mathbf{H}_2} \quad \text{from (4.20)} \\ &= \frac{1}{2\pi} \langle \widehat{\Psi_- x}, N^* \hat{v}\rangle_{\mathbf{H}_2} \quad \text{from (4.21)} \\ &= \text{RHS of (4.23)}. \end{aligned}$$

Next for all $u \in \mathbf{L}_2(0,\infty;\mathcal{U}), x \in \mathcal{X}$ we verify

$$\langle \mathbb{F}^* Q \Psi x, u\rangle_2 \;=\; \langle \mathbb{F}_-^* Q \Psi_- x, v\rangle_2. \tag{4.24}$$

$$\begin{aligned}
\text{LHS of (4.24)} &= \langle \Psi x, Q\mathbb{F}u\rangle_2 \\
&= \frac{1}{2\pi}\langle \widehat{\Psi x}, Q\widehat{\mathbb{F}u}\rangle_{\mathbf{H}_2} \\
&= \frac{1}{2\pi}\langle \mathcal{H}(\widehat{\Psi x}), Q\mathcal{H}(\mathbf{G}\hat{u})\rangle_{\mathbf{H}_2} \quad \text{by (4.20)} \\
&= \frac{1}{2\pi}\langle \widehat{\Psi_- x}, Q\mathbf{G}_-\hat{v}\rangle_{\mathbf{H}_2} \quad \text{by (4.21) and Lemma 3.2} \\
&= \langle \Psi_- x, Q\mathbb{F}_- v\rangle_2 \\
&= \text{RHS of (4.24)}.
\end{aligned}$$

Next for all $u \in \mathbf{L}_2(0,\infty;\mathcal{U})$ we show that

$$\langle \mathcal{R}u, u\rangle_2 \;=\; \langle \mathcal{R}_- v, v\rangle_2. \tag{4.25}$$

$$\begin{aligned}
\text{LHS of (4.25)} &= \frac{1}{2\pi}\langle \Pi\hat{u}, \hat{u}\rangle_{\mathbf{H}_2} \\
&= \frac{1}{2\pi}\langle \mathcal{H}(\Pi\hat{u}), \mathcal{H}(\hat{u})\rangle_{\mathbf{H}_2} \quad \text{by (4.20)} \\
&= \frac{1}{2\pi}\langle \Pi_-\hat{v}, \hat{v}\rangle_{\mathbf{H}_2} \quad \text{from (4.18)} \\
&= \text{RHS of (4.25)}.
\end{aligned}$$

Finally, combining (4.22), (4.21), (4.23), and (4.25), we conclude that

$$J(x,u) = J_-(x,v) \quad \text{for all } \; u \in \mathbf{L}_2(0,\infty;\mathcal{U}), x \in \mathcal{X},$$

which completes the proof. □

Now the reciprocal system certainly satisfies all the assumptions of Theorem 4.3, and this leads to our main result.

THEOREM 4.5. *Suppose that* Σ *is a well-posed linear system satisfying the conditions* (a)–(d). *If its Popov function* Π *associated with the optimal control problem* (Σ, J) *is coercive, then the reciprocal optimal control problem* (Σ_-, J_-) *has the minimum cost*

$$J_-(x_0, v^{opt}) = \langle x_0, X_- x_0\rangle, \tag{4.26}$$

where X_- *is given by*

$$X_- = \Psi_-^* Q \Psi_- - \Psi_-^*(Q\mathbb{F}_- + N_-^*)\mathcal{R}_-^{-1}(\mathbb{F}_-^* Q + N_-)\Psi_-,$$

where $\mathcal{R}_-$ *is given by* (4.16) *and* R_-, N_- *by* (4.13). X_- *is a solution of the Riccati equation*

$$A^{-*}X + XA^{-1} + A^{-*}C^*QCA^{-1} \tag{4.27}$$

$$= (B^*A^{-*}X - N_-CA^{-1})^* R_-^{-1}(B^*A^{-*}X - N_-CA^{-1}), \tag{4.28}$$

and the optimal control $v^{opt} \in \mathbf{L}_2(0,\infty;\mathcal{U})$ *is given by* $v^{opt}(t) = -R_-^{-1}(B^*A^{-*}X - N_-CA^{-1})x_-^{opt}(t)$.

The Popov function defined by (4.17) *has a spectral factor given by*

$$\mathbf{\Xi}_-(s) = D_-^\xi + C_-^\xi(sI - A^{-1})^{-1}A^{-1}B, \tag{4.29}$$

where D_-^ξ *is any invertible solution of* $R_- = (D_-^\xi)^*D_-^\xi$ *and* C_-^ξ *is infinite-time admissible and is defined by*

$$C_-^\xi = D_-^\xi R_-^{-1}(B^*A^{-*}X - N_-CA^{-1}). \tag{4.30}$$

The optimal cost for the control problem (Σ, J) *equals that of the reciprocal optimal control problem* (Σ_-, J_-), *and their optimal controls are related by* $\hat{u}^{opt} = \mathcal{H}\hat{v}^{opt}$.

Moreover, the realization $\Sigma_-^\xi = (\mathbb{T}_-, \Phi_-, \Psi_-^\xi, \mathbb{F}_-^\xi)$ *of* $\mathbf{\Xi}_-$ *is the reciprocal system of* $\Sigma^\xi = (\mathbb{T}, \Phi, \Psi^\xi, \mathbb{F}^\xi)$, *and the observation operator for* $\mathbf{\Xi}_-$ *is given by*

$$-C^\xi A^{-1} = C_-^\xi = D_-^\xi R_-^{-1}(B^*A^{-*}X - N_-CA^{-1}). \tag{4.31}$$

Proof. Note first from Lemma 3.2 that Σ_- satisfies conditions (a), (b), (c) if and only if Σ does. Now (4.18) shows that $\Pi_- \geq \epsilon I$ if and only if $\Pi \geq \epsilon I$. So Π_- has a spectral factorization and the spectral factor is necessarily regular by Lemma 2.5 and Theorem 4.2. In fact, it is regular in the uniform topology and the feedthrough operator D_-^ξ is invertible. We apply Theorem 4.3 to (Σ_-, J_-) to conclude that the reciprocal control problem has the solution as stated.

From Theorem 4.4 we know that the optimal cost is the same as for the original control problem (Σ, J) and the optimal control for the original system u^{opt} is defined in terms of v^{opt} via $\hat{u}^{opt} = \mathcal{H}\hat{v}^{opt}$ (see (4.19)). Since the spectral factorizations are unique up to left multiplication by a unitary $U \in \mathcal{L}(\mathcal{U})$, using (4.18), we can assume without loss of generality that

$$\mathbf{\Xi}(s) = \mathbf{\Xi}_-\left(\frac{1}{s}\right) \quad \text{for all} \quad s \in \mathbb{C}_0^+. \tag{4.32}$$

Theorems 4.3 and 4.2 show that $\Sigma^\xi = (\mathbb{T}, \Phi, \Psi^\xi, \mathbb{F}^\xi)$ and $\Sigma_-^\xi = (\mathbb{T}_-, \Phi_-, \Psi_-^\xi, \mathbb{F}_-^\xi)$. So to show that Σ_-^ξ is the reciprocal system of Σ^ξ, we need only to establish (4.31). It is clear from the proof of Theorem 4.4, particularly (4.21), that (4.31) holds if and only if for all $x \in \mathcal{X}$

$$\mathcal{H}\widehat{\Psi^\xi}x = \widehat{\Psi_-^\xi}x, \tag{4.33}$$

where $\mathcal{H}$ is defined by (4.19). We recall from (4.6) in Theorem 4.2 the formulas for the extended output maps of the spectral factor systems Σ^ξ and Σ_-^ξ, respectively:

$$\Psi^\xi = (\mathbb{F}^\xi)^{-*}(\mathbb{F}^*Q + N)\Psi, \tag{4.34}$$

$$\Psi_-^\xi = (\mathbb{F}_-^\xi)^{-*}(\mathbb{F}_-^*Q + N)\Psi_-. \tag{4.35}$$

Let $u \in \mathbf{L}_2(0,\infty;\mathcal{U})$, and define $v \in \mathbf{L}_2(0,\infty;\mathcal{U})$ by $\hat{v} = \mathcal{H}\hat{u}$. Now (4.34) holds if and only if for all $x \in \mathcal{X}$ and all $u \in \mathbf{L}_2(0,\infty;\mathcal{U})$ there holds

$$\langle \mathbb{F}^\xi u, \Psi^\xi x\rangle_2 = \langle \mathbb{F}u, Q\Psi x\rangle_2 + \langle u, N\Psi x\rangle_2.$$

As in the proof of Theorem 4.4, using Laplace transforms and the properties of the $\mathcal{H}$ operator, we obtain equivalent expressions for the left- and right-hand sides of the above expression:

$$\begin{aligned}
\text{LHS} &= \frac{1}{2\pi}\langle\widehat{\mathbb{F}^{\xi}u}, \widehat{\Psi^{\xi}x}\rangle_{\mathbf{H}_2} \\
&= \frac{1}{2\pi}\langle\Xi\hat{u}, \widehat{\Psi^{\xi}x}\rangle_{\mathbf{H}_2} \\
&= \frac{1}{2\pi}\langle\mathcal{H}(\boldsymbol{\Xi}\hat{u}), \mathcal{H}\widehat{\Psi^{\xi}x}\rangle_{\mathbf{H}_2} \quad \text{by (4.20)} \\
&= \frac{1}{2\pi}\langle\boldsymbol{\Xi}_{-}\hat{v}, \mathcal{H}\widehat{\Psi^{\xi}x}\rangle_{\mathbf{H}_2} \quad \text{by (4.19) and Lemma 3.2}
\end{aligned}$$

and

$$\begin{aligned}
\text{RHS} &= \langle\mathbb{F}u, Q\Psi x\rangle_2 + \langle u, N\Psi x\rangle_2 \\
&= \frac{1}{2\pi}\langle\widehat{\mathbb{F}u}, Q\widehat{\Psi x}\rangle_{\mathbf{H}_2} + \frac{1}{2\pi}\langle\hat{u}, N\widehat{\Psi x}\rangle_{\mathbf{H}_2} \\
&= \frac{1}{2\pi}\langle\mathbf{G}\hat{u}, Q\widehat{\Psi x}\rangle_{\mathbf{H}_2} + \frac{1}{2\pi}\langle\hat{u}, N\widehat{\Psi x}\rangle_{\mathbf{H}_2} \\
&= \frac{1}{2\pi}\langle\mathcal{H}\mathbf{G}\hat{u}, Q\mathcal{H}\widehat{\Psi x}\rangle_{\mathbf{H}_2} + \frac{1}{2\pi}\langle\mathcal{H}\hat{u}, N\mathcal{H}\widehat{\Psi x}\rangle_{\mathbf{H}_2} \quad \text{by (4.20)} \\
&= \frac{1}{2\pi}\langle\mathbf{G}_{-}\hat{v}, Q\widehat{\Psi_{-}x}\rangle_{\mathbf{H}_2} + \frac{1}{2\pi}\langle\hat{v}, N\widehat{\Psi_{-}x}\rangle_{\mathbf{H}_2} \quad \text{by (4.19) and Lemma 3.2} \\
&= \langle\mathbb{F}_{-}v, Q\Psi_{-}x\rangle_2 + \langle v, N\Psi_{-}x\rangle_2 \\
&= \langle v, (\mathbb{F}_{-}^{*}Q + N)\Psi_{-}x\rangle_2 \\
&= \langle\mathbb{F}_{-}^{\xi}v, \Psi_{-}^{\xi}x\rangle_2 \quad \text{by (4.35)} \\
&= \frac{1}{2\pi}\langle\boldsymbol{\Xi}_{-}\hat{v}, \widehat{\psi_{-}^{\xi}x}\rangle_{\mathbf{H}_2}.
\end{aligned}$$

Equating the last expressions of the left- and right-hand sides, we obtain

$$\langle\boldsymbol{\Xi}_{-}\hat{v}, \mathcal{H}(\widehat{\Psi^{\xi}x}) - \widehat{\Psi_{-}^{\xi}x}\rangle_{\mathbf{H}_2} = 0.$$

Since this holds for all $v \in \mathbf{L}_2(\mathcal{U})$ and all $x \in \mathcal{X}$ and $\boldsymbol{\Xi}_{-}$ is boundedly invertible over $\mathbf{H}_\infty(\mathcal{U})$, we have established (4.33). ∎

So under minimal conditions we have shown that the X in (4.8) is always a solution of the reciprocal Riccati equation (4.27) with bounded operators, and we have the following explicit formula for the spectral factor $\boldsymbol{\Xi}$ in the right half-plane given by

$$\boldsymbol{\Xi}(s) = D_{-}^{\xi} + C_{-}^{\xi}\left(\frac{1}{s}I - A^{-1}\right)^{-1}A^{-1}B, \tag{4.36}$$

without making any regularity assumptions. This represents a complete solution to the problem, but it is interesting to compare our solution with those in the existing literature. We recall from Theorem 4.2 that under the assumptions that $\boldsymbol{\Xi}$ is regular and its feedthrough operator is invertible, C^{ξ} satisfies (4.10) and X satisfies (4.12), whereas we have obtained a different formula (4.31) for C^{ξ} and a different Riccati equation (4.27) for X.

Next we give new explicit necessary and sufficient conditions for the spectral factor $\mathbf{\Xi}$ to be (weakly) regular.

LEMMA 4.6. *Suppose that Σ is a weakly regular linear system satisfying the conditions* (a)–(d) *and that its Popov function Π associated with the optimal control problem (Σ, J) is coercive.*

1. *The spectral factor $\mathbf{\Xi}$ is weakly regular if and only if the following limit exists in the weak topology for all $u \in \mathcal{U}$:*

$$Pu = \text{weak} \lim_{\mu \to 0} B^* A^{-*} X(\mu I - A^{-1})^{-1} A^{-1} Bu \tag{4.37}$$

$$= -\text{weak} \lim_{\lambda \to \infty} B^* A^{-*} X \lambda (\lambda I - A)^{-1} Bu. \tag{4.38}$$

In this case, the feedthrough operator of $\mathbf{\Xi}$ is given by

$$D^\xi = D^\xi_- R_-^{-1}(R_- + P + N_-(D - G(0))), \tag{4.39}$$

$$X(sI - A)^{-1}B : \mathcal{U} \to \mathcal{D}(B^*_{\Lambda_w}) \quad \text{for } s \in \rho(A),$$

$$P^* = -B^*_{\Lambda_w} X A^{-1} B, \tag{4.40}$$

and

$$X : \quad \mathcal{D}(A) \to \mathcal{D}(B^*_{\Lambda_w}). \tag{4.41}$$

2. *If Σ is regular, the limit P exists in the strong topology, and D^ξ is invertible, then Σ^ξ has the generating operators*

$$A, B, D^\xi((D^\xi)^* D^\xi)^{-1}(B^*_{\Lambda_w} X + NC), D^\xi. \tag{4.42}$$

In addition, Σ^{inv}_-, the inverse system of Σ^ξ_-, is the reciprocal system of Σ^{inv}, the inverse system of Σ^ξ; in particular, their semigroup generators are related by $A^{inv}_- = (A^{inv})^{-1}$, where

$$A^{inv} = A - B((D^\xi)^* D^\xi)^{-1}(B^*_{\Lambda_w} X + NC),$$
$$A^{inv}_- = A^{-1} - A^{-1} B R_-^{-1}(B^* A^{-*} X - N_- C A^{-1}).$$

Proof. 1. From (4.36) and (4.30) we have

$$\begin{aligned} &\mathbf{\Xi}(s) \\ &= D^\xi_- R_-^{-1} \left[R_- + (B^* A^{-*} X - N_- C A^{-1}) \left(\frac{1}{s} I - A^{-1} \right)^{-1} \right] A^{-1} B \\ &= D^\xi_- R_-^{-1} \left[R_- - (B^* A^{-*} X - N_- C A^{-1}) s (sI - A)^{-1} \right] B \\ &= D^\xi_- R_-^{-1} [R_- - B^* A^{-*} X s (sI - A)^{-1} B \\ &\quad + N_-(\mathbf{G}(s) - \mathbf{G}(0))], \end{aligned} \tag{4.43, 4.44}$$

where we have used (2.13) with $\beta = 0$. Since $\mathbf{G}$ is weakly regular, $\mathbf{\Xi}$ will be weakly regular if and only if (4.38) holds.

2. (4.39) follows by taking the weak limit in (4.36) as $s \to \infty$ and using (4.13).

3. To prove (4.40) consider for $u, v \in \mathcal{U}$

$$\begin{aligned} -\langle v, Pu \rangle &= \lim_{\lambda \to \infty} \langle v, B^* A^{-*} X \lambda (\lambda I - A)^{-1} Bu \rangle \\ &= \lim_{\lambda \to \infty} \langle B^* \lambda (\lambda I - A^*)^{-1} X A^{-1} Bv, u \rangle. \end{aligned}$$

This together with (2.19) shows that $XA^{-1}B : \mathcal{U} \to \mathcal{D}(B^*_{\Lambda_w})$ and $P^* = -B^*_{\Lambda_w} XA^{-1}B$. The resolvent identity completes the proof of (4.40).

4. To prove (4.41) we use the expression (4.9) for X and show that $(\Psi^\xi)^*\Psi^\xi$ and $\Psi^* Q \Psi$ map $\mathcal{D}(A)$ into $\mathcal{D}(B^*_{\Lambda_w})$. Now Σ^ξ is weakly regular, $\boldsymbol{\Xi} \in \mathbf{H}_\infty(\mathcal{L}(\mathcal{U}))$, and Ψ^ξ is an extended output map, so Theorem 11.1 in [22] applied to $\Psi^{new} = (\mathbb{F}^\xi)^*\Psi^\xi$ shows that $(\Psi^\xi)^*\Psi^\xi$ maps $\mathcal{D}(A)$ into $\mathcal{D}(B^*_{\Lambda_w})$. The proof for $\Psi^* Q \Psi$ is similar.

5. The statements about regularity follow as in 1. Since $\boldsymbol{\Xi}$ is regular and D^ξ is invertible, Theorem 4.3 now applies to obtain the formulas (4.42). An application of Theorem 3.3 completes the proof. □

We have the following corollary.

COROLLARY 4.7. *Under the assumptions of Theorem* 4.5 *the operators* A, B, $B^*A^{-*}XA, 0$ *are the generating operators of a well-posed linear system* Σ^1. *If* Σ *is (weakly) regular, then* Σ^1 *is (weakly) regular if and only if* Σ^ξ *is. In this case, the transfer function is* $\boldsymbol{\Xi}^1(s) = (B^*A^{-*}X)_{\Lambda_w}(sI - A)^{-1}B$. *If the degree of unboundedness of* B *is* $< \frac{1}{2}$, *then* Σ, Σ^ξ, *and* Σ^1 *are uniformly regular.*

Proof. Since CA^{-1} and C^ξ_- in (4.30) are infinite-time admissible observation operators for $T_-(\cdot)$, so is $B^*A^{-*}X$. So from Lemma 3.2 we see that $B^*A^{-*}XA$ is an infinite-time admissible observation operator for $T(\cdot)$. From (4.44) and (2.13) with $\beta = 0$ for Σ^1 we obtain

$$\boldsymbol{\Xi}(s) = D^\xi_- R_-^{-1}(R_- - (\boldsymbol{\Xi}^1(s) - \boldsymbol{\Xi}^1(0)) + N_-(\mathbf{G}(s) - \mathbf{G}(0))),$$

which shows that Σ^1 is well-posed, since Σ^ξ and Σ are well-posed. Moreover, if Σ is (weakly) regular, Σ^1 will be (weakly) regular if and only if Σ^ξ is. If the degree of unboundedness of B is $\le \frac{1}{2}$, the statement on uniform regularity follows from Lemma 2.5. □

We remark that the existence of the weak limit P is equivalent to the condition $XA^{-1}B : \mathcal{U} \to \mathcal{D}(B^*_{\Lambda_w})$. This was obtained earlier in [14] as well as formulas for $(D^\xi)^* D^\xi$. We derive similar ones in the next lemma.

LEMMA 4.8. *Suppose that* Σ *is a weakly regular linear system satisfying the conditions* (a)–(d) *and that its Popov function* Π *associated with the optimal control problem* (Σ, J) *is coercive.*

1. *If the limit* P *in* (4.38) *exists, then so does the limit*

$$V = \textit{weak} \lim_{\lambda \to \infty} B^*_{\Lambda_w} X(\lambda I - A)^{-1}B \tag{4.45}$$

and

$$(D^\xi)^* D^\xi = R + V. \tag{4.46}$$

2. *If* Σ *is regular, the limit* P *in* (4.38) *exists in the strong topology, and* D^ξ *is invertible, then the limit* V *exists in the strong topology and satisfies*

$$V = (B^*_{\Lambda_w} X)_\Lambda A^{-1}B - B^*_{\Lambda_w} XA^{-1}B.$$

Proof. 1. The implication (4.40) $\Longrightarrow$ (4.45) has been shown in Lemma 9.11.5 (e) of [9]. To prove (4.46) we denote

$$\begin{aligned} E(\lambda, \mu) &= \langle \mu(\mu I - A)^{-1}Bv, A^{-*}X\lambda(\lambda I - A)^{-1}Bu \rangle \\ &= \langle \mu(\mu I - A)^{-1}A^{-1}Bv, X\lambda(\lambda I - A)^{-1}Bu \rangle \end{aligned}$$

and calculate the following expressions:

$$\begin{aligned}\lim_{\lambda\to\infty}\lim_{\mu\to\infty} E(\lambda,\mu) &= \lim_{\lambda\to\infty}\langle A^{-1}Bv, X\lambda(\lambda I-A)^{-1}Bu\rangle\\ &= -\langle v, Pu\rangle;\end{aligned}$$

$$\begin{aligned}&\lim_{\mu\to\infty}\lim_{\lambda\to\infty} E(\lambda,\mu)\\ &= \lim_{\mu\to\infty}\lim_{\lambda\to\infty}\langle B^*\lambda(\lambda I-A^*)^{-1}X\mu(\mu I-A)^{-1}A^{-1}Bv,u\rangle\\ &= \lim_{\mu\to\infty}\langle B^*_{\Lambda_w}XA^{-1}\mu(\mu I-A)^{-1}Bv,u\rangle \text{ by (2.19) and (4.41)}\\ &= \langle (V-P^*)v,u\rangle \text{ by (4.45).}\end{aligned}$$

Similarly, if we denote

$$F(\lambda,\mu)=\langle \mu(\mu I-A)^{-1}Bv, XA^{-1}\lambda(\lambda I-A)^{-1}Bu\rangle,$$

using (4.41) and (4.40), we obtain

$$\begin{aligned}\lim_{\lambda\to\infty}\lim_{\mu\to\infty} F(\lambda,\mu) &= \lim_{\lambda\to\infty}\langle v, B^*_{\Lambda_w}XA^{-1}\lambda(\lambda I-A)^{-1}Bu\rangle \text{ by (4.41)}\\ &= \langle v,(V-P^*)u\rangle \quad \text{by (4.45),}\end{aligned}$$

$$\begin{aligned}\lim_{\mu\to\infty}\lim_{\lambda\to\infty} F(\lambda,\mu) &= \lim_{\mu\to\infty}\langle v, B^*\mu(\mu I-A^*)^{-1}XA^{-1}Bu\rangle\\ &= \langle v, B^*_{\Lambda_w}XA^{-1}Bu\rangle \text{ by (2.19) and (4.40)}\\ &= -\langle Pv,u\rangle \text{ by (4.40).}\end{aligned}$$

Further, denoting

$$Q(\lambda,\mu)=\langle \mu(\mu I-A)^{-1}Bv, A^{-*}C^*QCA^{-1}\lambda(\lambda I-A)^{-1}Bu\rangle,$$

using (2.19), $G_0=-C_\Lambda A^{-1}B$, and the regularity of Σ, we obtain

$$\lim_{\mu\to\infty}\lim_{\lambda\to\infty} Q(\lambda,\mu)=\lim_{\lambda\to\infty}\lim_{\mu\to\infty} Q(\lambda,\mu)=\langle G_0v, QG_0u\rangle.$$

Finally, denoting

$$R(\lambda,\mu)=\langle \mu(\mu I-A)^{-1}Bv, (C^\xi_-)^*C^\xi_-\lambda(\lambda I-A)^{-1}Bu\rangle,$$

using (4.31), (4.38), and the regularity of Σ, we obtain

$$\begin{aligned}\lim_{\mu\to\infty}\lim_{\lambda\to\infty} R(\lambda,\mu) &= \lim_{\lambda\to\infty}\lim_{\mu\to\infty} R(\lambda,\mu)\\ &= \langle (P-N_-G_0)v, R_-^{-1}(P-N_-G_0)u\rangle.\end{aligned}$$

Next we deduce a useful identity from (4.27) by applying the following operation for arbitrary $u,v\in\mathcal{U}$:

$$\langle \mu(\mu I-A)^{-1}Bv, (4.27)\ \lambda(\lambda I-A)^{-1}Bu\rangle,$$

which yields

$$E(\lambda,\mu)+F(\lambda,\mu)+Q(\lambda,\mu)=R(\lambda,\mu). \tag{4.47}$$

Using our calculations above for the limits as λ and $\mu \to \infty$ and denoting $M = P - N_- G_0$, we obtain

$$-P - P^* + V + G_0^* Q G_0 = M^* R_-^{-1} M. \tag{4.48}$$

Finally, using (4.39), we calculate

$$\begin{aligned}(D^\xi)^* D^\xi &= R_- + M^* + M + M^* R_-^{-1} M \\ &= R_- + P^* - G_0^* N_-^* + P - N_- G_0 - P - P^* + V \\ &\quad + G_0^* Q G_0 \qquad \text{from (4.48)} \\ &= R_- - G_0^* Q G_0 - G_0^* N^* - N G_0 + V \\ &= R + V \quad \text{by (4.13)}.\end{aligned}$$

2. From part 2 of Lemma 4.6, Σ^ξ is regular with generating operators given by (4.42). So $A, B, B_{\Lambda_w}^* X, 0$ are the generating operators of a regular linear system Σ_2 with transfer function $\mathbf{G}_2$. From (2.13) we have

$$\begin{aligned}\mathbf{G}_2(\lambda) - \mathbf{G}_2(0) &= \lambda B_{\Lambda_w}^* X (\lambda I - A)^{-1} A^{-1} B \\ &= B_{\Lambda_w}^* X A^{-1} B + B_{\Lambda_w}^* X (\lambda I - A)^{-1} B,\end{aligned}$$

where we have used (4.40). Now the claim in (2) follows, since $\mathbf{G}_2$ is regular, and $\mathbf{G}_2(0) = -(B_{\Lambda_w}^* X)_\Lambda A^{-1} B$.

Note that $V = 0$ if and only if

$$\lim_{\lambda \to \infty} \lim_{\mu \to \infty} F(\lambda, \mu) = \lim_{\mu \to \infty} \lim_{\lambda \to \infty} F(\lambda, \mu)$$

or a similar statement for $E(\lambda, \mu)$ holds. □

Of course it is difficult to check whether the limit P exists and whether D^ξ is invertible. D^ξ is always left invertible, and so if $\mathcal{U}$ is finite-dimensional, it will be invertible, and X satisfies the Riccati equation (4.12) (as already remarked in [22]). However, if the degree of unboundedness of B is $< \frac{1}{2}$, then from Lemma 2.5 we can conclude that $\mathbf{\Xi}$ will be uniformly regular and D^ξ will be invertible even for infinite-dimensional $\mathcal{U}$ (see [22, Proposition 12.3]).

COROLLARY 4.9. *Suppose that B and C are infinite-time admissible operators for $T(\cdot)$ and the degree of unboundedness of B is $< \frac{1}{2}$. Then $A, B, C, 0$ are the generating operators of a uniformly regular linear system Σ. Suppose that Σ satisfies the conditions* (a)–(c) *and its Popov function Π associated with the optimal control problem (Σ, J) is coercive. Then $\mathbf{\Xi}$ is uniformly regular, D^ξ is invertible, and X from* (4.7) *satisfies the Riccati equation* (4.12) *with $(D^\xi)^* D^\xi = R$.*

Acknowledgment. I would like to thank Kalle Mikkola for his useful comments on comparisons of my approach with the existing literature.

A SEMIMARTINGALE BACKWARD EQUATION AND THE VARIANCE-OPTIMAL MARTINGALE MEASURE UNDER GENERAL INFORMATION FLOW*

MICHAEL MANIA† AND REVAZ TEVZADZE‡

Abstract. We consider a financial market model, where the dynamics of asset prices are given by an R^d-valued continuous semimartingale and the information flow is right-continuous. Using the dynamic programming approach we express the variance-optimal martingale measure in terms of the value process of a suitable optimization problem and show that this value process uniquely solves the corresponding semimartingale backward equation. We consider two extreme cases when this equation admits an explicit solution. In particular, we give necessary and sufficient conditions in order that the variance-optimal martingale measure coincides with the minimal martingale measure as well as with the martingale measure appearing in the second extreme case.

Key words. backward semimartingale equation, variance-optimal martingale measure, incomplete markets, contingent claim pricing

1. Introduction.

Let $X = (X_t, t \in [0,T])$ be an R^d-valued semimartingale defined on a filtered probability space $(\Omega, \mathcal{F}, F = (F_t, t \in [0,T]), P)$, and let η be an F_T-measurable random variable. The components of X_t are interpreted as discounted prices of d risky assets in a financial market and η is a contingent claim. Denote by $\mathcal{M}^e$ the set of martingale measures of X, i.e., probability measures Q that are equivalent to P such that X is a local martingale under Q. Let $(Z_t(Q), t \in [0,T])$ be the density process of Q with respect to P.

It is well known that the prices of contingent claims can usually be computed as expectations under a suitable martingale measure. The choice of the pricing (martingale) measure depends on the context, e.g., on the criterion relative to which the quality of the hedging strategy is measured. It was shown by Schweizer [23] that if the quadratic criterion to measure the hedging error is used, then the variance minimizing hedging price c of the claim η is equal to $E^*\eta$, where the expectation is calculated with respect to the variance-optimal martingale measure. The variance-optimal martingale measure also plays a crucial role in determining the optimal mean-variance hedging strategy (see Pham, Rheinländer, and Schweizer [19], Delbaen et al. [7], Gouriéroux, Laurent, and Pham [11], and Rheinländer [20]).

The variance-optimal martingale measure is defined by the property that its density with respect to P has minimal L^2 norm among all signed martingale measures (see Schweizer [23] for a precise definition of the last term).

In general, the variance-optimal martingale measure is not a positive measure. Therefore, in some situations the price of a nonnegative contingent claim $E^*\eta$ calcu-

lated by the variance-optimal martingale measure is negative, and a signed measure Q^* is not always attractive for the characterization of the price system. However, if

(i) the discounted asset price process X is continuous and

(ii) the set $\mathcal{M}_2^e = \{Q \in \mathcal{M}^e : E(Z_T^Q)^2 < \infty\}$ is not empty,

then, as was shown by Delbaen and Schachermayer [5], the variance-optimal martingale measure Q^* is positive and equivalent to P and may be used as a pricing measure. Therefore, assuming (i) and (ii), we may define the variance-optimal martingale measure as a solution of the optimization problem

$$EZ_T^2(Q) \to \inf_{Q \in \mathcal{M}_2^e}, \tag{1.1}$$

and we shall focus our attention on the study of the structure of the optimal martingale measure, using the dynamic programming approach. The dynamic programming method to determine the variance-optimal martingale measure was used by Laurent and Pham [14] for a multidimensional diffusion model with Brownian filtration. They characterize the variance-optimal martingale measure in terms of the value function associated to the problem (1.1), and they gave explicit expressions for this value function under special conditions on the model coefficients.

Our aim is to give a construction of the variance-optimal martingale measure when the dynamics of the discounted asset price process is governed by a continuous semimartingale and the information flow is right-continuous, rejecting the condition of continuity of the filtration imposed in our previous paper [17]. We obtain a description of the variance-optimal martingale measure in terms of a value process corresponding to the problem (1.1) and show that this value function uniquely solves the corresponding semimartingale Bellman equation. Such a type of backward equations was introduced by Chitashvili [3] (see also [4], [16]) as a stochastic version of the Bellman equation for an optimal control problem. We consider two extreme cases, including two specific cases studied by Pham, Rheinländer, and Schweizer [19], Laurent and Pham [14], and Biagini, Guasoni, and Pratelli [2], when this equation admits an explicit solution. In particular, we give necessary and sufficient conditions when the variance-optimal martingale measure coincides with the minimal martingale measure as well as with the martingale measure appearing in the second extreme case.

2. Basic assumptions, definitions, and some auxiliary facts. Let $(\Omega, \mathcal{F}, F = (F_t, t \in [0,T]), P)$ be a filtered probability space satisfying the usual conditions of right-continuity and completeness, where $T < \infty$ is a fixed time horizon and $\mathcal{F} = F_T$.

1. *The space BMO and exponential martingales.* We recall some definitions and known results on the relation of BMO and exponential martingales used in what follows.

DEFINITION 1. *A uniformly integrable martingale $M = (M_t, t \in [0,T])$ belongs to the class BMO_2 if there is a constant $C > 0$ such that*

$$E((M_T - M_{\tau-})^2 | F_\tau) \le C, \quad P\text{-a.s.}$$

for every stopping time τ. The smallest constant with this property (or $+\infty$ if it does not exist) is called the BMO_2 norm of M and is denoted by $||M||_{BMO_2}$.

Remark. If $M \in \mathcal{M}^2_{\text{loc}}$, then $M \in BMO_2$ if and only if M is of bounded jumps and for a constant C

$$E(\langle M \rangle_T - \langle M \rangle_\tau | F_\tau) \le C, \quad P\text{-a.s.}$$

for every stopping time τ (see Dellacherie and Meyer [6]).

Denote by $\mathcal{E}(X)$ the Doléans exponential of a semimartingale X, which is the unique solution of the linear SDE

$$Z_t = 1 + \int_0^t Z_{s-} dX_s. \tag{2.1}$$

Moreover, any solution of this equation coincides with $\mathcal{E}(X)$ on the set $\{(\omega, t) : \mathcal{E}_t(X) \neq 0\}$. Therefore, any strictly positive martingale Z with $Z_0 = 1$ is represented as a Doléans exponential $\mathcal{E}(X)$, with $X = \frac{1}{Z_-} \cdot Z$. We use the notation $\psi \cdot X$ for the stochastic integral with respect to the semimartingale X.

PROPOSITION 1 (Kazamaki [13]). *If M is a right-continuous BMO_2-martingale satisfying*

$$\Delta M \geq -1 + h$$

for some $h > 0$, then $\mathcal{E}(M)$ is a uniformly integrable martingale.

Let Z be a positive process that satisfies condition (J): There exists a constant C such that

$$\frac{1}{C} Z_- < Z < C Z_-.$$

DEFINITION 2. *A strictly positive adapted process Z satisfies the reverse Hölder inequality $R_p(P)$, where $1 < p < \infty$, if there exists a constant C such that*

$$E\left(\left(\frac{Z_T}{Z_\tau} \right)^p \middle/ F_\tau \right) \leq C, \quad P\text{-a.s.}$$

for every stopping time τ.

The following assertion relates BMO and the reverse Hölder condition.

PROPOSITION 2 (Doléans-Dade and Meyer [8]). *Let M be a local martingale and $\mathcal{E}(M)$ its Doléans exponential. The following assertions are equivalent:*

(i) *M belongs to the class BMO_2 and $\Delta M \geq -1 + h$ for some $h > 0$.*

(ii) *$\mathcal{E}(M)$ is a uniformly integrable martingale satisfying condition* (J) *and the reverse Hölder inequality $R_p(P)$ for some $p > 1$.*

2. *Martingale measures.* Let the discounted asset price process X admit a decomposition

$$X_t = X_0 + \Lambda_t + M_t, \quad \Lambda \in \mathcal{A}_{\mathrm{loc}}, M \in \mathcal{M}^2_{\mathrm{loc}}. \tag{2.2}$$

X satisfies the structure condition if there is a predictable R^d-valued process λ such that

$$X_t = X_0 + \int_0^t d\langle M \rangle_s \lambda_s + M_t, \quad P\text{-a.s. for all } t \in [0, T], \text{ and} \tag{2.3}$$

$$K_t = \langle \lambda \cdot M \rangle_t < \infty, \quad P\text{-a.s. for all } t \in [0, T].$$

The process K is called the mean-variance tradeoff process of X (see Schweizer [22]).

Denote by $\mathcal{M}^e$ the set of measures Q equivalent to P on F such that X is a local martingale under Q. Let Z_t^Q be the density process of Q with respect to the basic measure P which can be expressed as a Doléans exponential $Z_t^Q = \mathcal{E}_t(M^Q)$ of a local

martingale M^Q. Here and in what follows we identify the measure Q with Z^Q or with M^Q.

If the local martingale $\hat{Z}_t = \mathcal{E}_t(-\lambda \cdot M)$ is a true martingale, $d\hat{P}/dP = \hat{Z}_T$ defines an equivalent probability measure called the minimal martingale measure for X.

Throughout the paper we assume that the following conditions are satisfied.

(A) The discounted asset price process X is a continuous R^d-valued semimartingale.

(B) The minimal martingale measure exists and $E\mathcal{E}_T^2(-\lambda \cdot M) < \infty$.

We shall often use the following stronger condition.

(B*) The minimal martingale measure exists and satisfies the reverse Hölder condition $R_2(P)$.

Remark 1. (A) and (B) imply that the semimartingale X satisfies the structure condition; hence X admits the decomposition (2.3), where M is a continuous local martingale.

Remark 2. Since for any $Q \in \mathcal{M}_2^e$ the density process Z^Q is a strictly positive square integrable martingale, the process $M^Q = \frac{1}{Z_-^Q} \cdot Z^Q$ belongs to $\mathcal{M}_{\text{loc}}^2$; hence the square bracket $\langle M^Q \rangle$ exists for any $Q \in \mathcal{M}_2^e$.

Since X is assumed to be continuous, any element Q of $\mathcal{M}^e$ is given by the density Z_t^Q of the form

$$\mathcal{E}_t(-\lambda \cdot M + N), \tag{2.4}$$

where N is a local martingale strongly orthogonal to M.

Denote by $\mathcal{M}_2^e$ the subset of $\mathcal{M}^e$ with square integrable densities, i.e.,

$$\mathcal{M}_2^e = \left\{ Q \sim P : \frac{dQ}{dP} \in L^2(P), X \text{ is a } Q\text{-local martingale} \right\}.$$

Denote by $\mathcal{N}(X)$ the class of local martingales N strongly orthogonal to M such that the process $(\mathcal{E}_t(-\lambda \cdot M + N), t \in [0,T])$ is a martingale under P.

Let $\mathcal{N}_2(X)$ be the subclass of $\mathcal{N}(X)$ of local martingales N such that the process $(\mathcal{E}_t(-\lambda \cdot M + N), t \in [0,T])$ is a strictly positive square integrable martingale under P. Then

$$\mathcal{M}_2^e = \left\{ Q \sim P : \frac{dQ}{dP} = \mathcal{E}_T(-\lambda \cdot M + N), N \in \mathcal{N}_2(X) \right\}. \tag{2.5}$$

3. *The optimality principle.* Consider the value process V_t,

$$V_t = \operatorname*{ess\,inf}_{Q \in \mathcal{M}_2^e} E(\mathcal{E}_{tT}^2(M^Q)/F_t) = \operatorname*{ess\,inf}_{N \in \mathcal{N}_2(X)} E(\mathcal{E}_{tT}^2(-\lambda \cdot M + N)/F_t), \tag{2.6}$$

where

$$\mathcal{E}_{\tau T}(M^Q) = \frac{\mathcal{E}_T(M^Q)}{\mathcal{E}_\tau(M^Q)} = \mathcal{E}_T(M^Q - M^Q_{\cdot \wedge \tau})$$

for any $Q \in \mathcal{M}^e$ and any stopping time τ. We shall use also the notation

$$\langle M \rangle_{tT} = \langle M \rangle_T - \langle M \rangle_t$$

for the square bracket of the martingale M.

The following assertion is proved in a standard manner (see, e.g., [9],[10]).

PROPOSITION 3. (a) *There exists a right-continuous with left limits (RCLL) semimartingale still denoted by* V_t *such that for each* $t \in [0,T]$

$$V_t = \operatorname*{ess\,inf}_{Q \in \mathcal{M}_2^e} E(\mathcal{E}_{tT}^2(M^Q)/F_t).$$

V_t *is the largest RCLL process equal to* 1 *at time* T *such that* $V_t\mathcal{E}_t^2(M^Q)$ *is a submartingale for every* $Q \in \mathcal{M}_2^e$.

(b) *The following properties are equivalent:*

(i) Q^* *is variance-optimal, i.e.,* $V_0 = \inf_{Q \in \mathcal{M}_2^e} E\mathcal{E}_T^2(M^Q) = E\mathcal{E}_T^2(M^{Q^*})$.

(ii) Q^* *is variance-optimal for all conditional criteria; i.e., for all* $t \in [0,T]$

$$V_t = E(\mathcal{E}_{tT}^2(M^{Q^*})/F_t) \quad a.s.$$

(iii) $V_t\mathcal{E}_t^2(M^{Q^*})$ *is a P-martingale.*

We recall that any local martingale m admits a decomposition (see, e.g., Jacod [12] or Liptser and Shiryayev [15])

$$m = m^c + m^d = m^c + m^{dq} + m^{dp}, \tag{2.7}$$

where

- m^c is a continuous local martingale,
- m^{dq} is compensated sum of totally inaccessible jumps of m (m^{dq} is quasi-left-continuous),
- m^{dp} is compensated sum of predictable jumps of m, and
- $m^d = m^{dq} + m^{dp}$ is orthogonal to any continuous martingale and is called the purely discontinuous part of m.

Let Y be a special semimartingale with the decomposition

$$Y_t = Y_0 + B_t + L_t, \quad B \in \mathcal{A}_{\mathrm{loc}} \cap \mathcal{P}, L \in \mathcal{M}_{\mathrm{loc}}, \tag{2.8}$$

and let

$$L_t = \int_0^t \psi_s dM_s + \bar{L}_s, \quad \langle \bar{L}, M \rangle = 0, \tag{2.9}$$

be the Galtchouk–Kunita–Watanabe (GKW) decomposition of L with respect to the martingale M, and $\mathcal{P}$ is the class of predictable processes.

Equations (2.7)–(2.9) imply that any special semimartingale Y admits a decomposition

$$Y_t = Y_0 + B_t + \int_0^t \psi_s dM_s + \bar{L}_t^c + \bar{L}_t^d, \quad \langle \bar{L}^c, M \rangle = 0. \tag{2.10}$$

Note that, since M is continuous, we have that

$$L_t^c = \int_0^t \psi_s dM_s + \bar{L}_t^c, \quad \bar{L}_t^d = L_t^d, \quad \Delta\bar{L}_t = \Delta L_t. \tag{2.11}$$

Finally, we recall that the process X is said to belong to the class D if the random variables $X_\tau I_{(\tau \le T)}$ for all stopping times τ are uniformly integrable.

3. Backward semimartingale equation for the value process. Let us consider the optimization problem

$$E\mathcal{E}_T^2(M^Q) \to \inf_{Q\in\mathcal{M}_2^e}. \tag{3.1}$$

Conditions (A) and (B) imply that the value process of problem (3.1) defined by (2.6) is a special semimartingale with respect to the measure P, since the process $V_t\mathcal{E}_t^2(-\lambda\cdot M)$ is a P-submartingale and the process $\mathcal{E}_t^{-2}(\lambda\cdot M)$ is locally bounded. Let

$$V_t = m_t + A_t,\ \ m\in M_{\mathrm{loc}},\ \ A\in\mathcal{A}_{\mathrm{loc}}, \tag{3.2}$$

be the canonical decomposition of V, and let

$$m_t = \int_0^t \varphi_s dM_s + \bar{m}_s,\quad \langle\bar{m}, M\rangle = 0, \tag{3.3}$$

be the GKW decomposition of m with respect to M.

We say that the process B strongly dominates the process A and write $A\prec B$ if the difference $B-A\in\mathcal{A}^+_{\mathrm{loc}}$, i.e., is a locally integrable increasing process.

Let $(A^Q, Q\in\mathcal{Q})$ be a family of processes of finite variations, zero at time zero. Denote by $\operatorname{ess\,inf}_{Q\in\mathcal{Q}}(A^Q)$ the largest process of finite variation, zero at time zero, which is strongly dominated by the process $(A_t^Q, t\in[0,T])$ for every $Q\in\mathcal{Q}$; i.e., this is an "ess inf" of the family $(A^Q, Q\in\mathcal{Q})$ with respect to the strong order $\prec$.

Throughout the paper the symbols "ess inf" are used in the sense of the strong order.

Denote by $\tilde{A}$ the compensator (or the dual predictable projection) of A.

THEOREM 1. *Let conditions* (A) *and* (B) *be satisfied. Then, the value process V is a solution of the semimartingale backward equation*

$$Y_t = Y_0 - \operatorname*{ess\,inf}_{Q\in\mathcal{M}_2^e}\ \Big[\int_0^t Y_s d\langle M^{Q,c}\rangle_s + 2\langle M^{Q,c}, L^c\rangle_t$$

$$+\sum_{s\le t}(Y_s\widetilde{(\Delta M_s^Q)^2} + 2\Delta L_s\Delta M_s^Q)\Big] + L_t \tag{3.4}$$

with the boundary condition

$$Y_T = 1. \tag{3.5}$$

Proof. Let us first show that the process $[V, 2M^Q + [M^Q]]$ or, equivalently, the process $\sum_{s\le t}(2\Delta V_s\Delta M_s^Q + \Delta V_s(\Delta M_s^Q)^2)$ is P-locally integrable for any $Q\in\mathcal{M}_2^e$. By the Itô formula

$$\mathcal{E}_t^2(M^Q) = 1 + \int_0^t \mathcal{E}_{s-}^2(M^Q) d(2M_s^Q + [M^Q]_s), \tag{3.6}$$

and hence $2M_t^Q + [M^Q]_t = \int_0^t \mathcal{E}_{s-}^{-2}(M^Q)d\mathcal{E}_s^2(M^Q)$. Therefore, since $\mathcal{E}_{t-}^{-2}(M^Q)$ is locally bounded, it is sufficient to show that the process $[V, \mathcal{E}^2(M^Q)]_t$ is locally integrable. However, this is clearly true since V_t, as mentioned above, is a special semimartingale and $\mathcal{E}_t^2(M^Q)V_t$ is a submartingale and thus also a special semimartingale.

Thus the process

$$[V, 2M^Q + [M^Q]]_t = 2\langle m, M^{Q,c}\rangle_t + \sum_{s\le t}(2\Delta V_s \Delta M_s^Q + \Delta V_s(\Delta M_s^Q)^2) \tag{3.7}$$

is locally P-integrable for any $Q \in \mathcal{M}_2^e$; hence there exists the dual predictable projection of this process, and since $\sum_{s\le t}\Delta A_s \Delta M_s^Q$ is a local martingale, we have that

$$[V, 2\widetilde{M^Q + [M^Q]}]_t = 2\langle m, M^{Q,c}\rangle_t + \sum_{s\le t}(2\Delta m_s \Delta \widetilde{M_s^Q} + \Delta V_s(\Delta M_s^Q)^2). \tag{3.8}$$

Using (2.1), (3.6), the decomposition of V, and the Itô formula for $\mathcal{E}_t^2(M^Q)V_t$, we have

$$\mathcal{E}_t^2(M^Q)V_t = V_0 + \int_0^t \mathcal{E}_{s-}^2(M^Q)dV_s + \int_0^t V_{s-}\mathcal{E}_{s-}^2(M^Q)d(2M_s^Q + [M^Q]_s)$$

$$+ \int_0^t \mathcal{E}_{s-}^2(M^Q)d[V, 2M^Q + [M^Q]]_s = V_0 + \int_0^t \mathcal{E}_{s-}^2(M^Q)d(m_s + 2(V_- \cdot M^Q)_s)$$

$$+ \int_0^t \mathcal{E}_{s-}^2(M^Q)d\big(A_s + (V_- \cdot [M^Q])_s + 2[M^Q, V]_s] + [V, [M^Q]]_s\big). \tag{3.9}$$

Since the processes

$$[M^Q]_t - \langle M^{Q,c}\rangle_t - \sum_{s\le t}\widetilde{(\Delta M_s^Q)^2}$$

and

$$[V, 2M^Q + [M^Q]]_t - 2\langle m^c, M^{Q,c}\rangle_t - \sum_{s\le t}(\Delta V_s \widetilde{(\Delta M_s^Q)^2} + 2\Delta m_s \Delta M_s^Q)$$

are local martingales and $V_t\mathcal{E}_t^2(M^Q)$ is a submartingale, from (3.9) and from the uniqueness of the canonical decomposition of submartingales we obtain that

$$\int_0^t \mathcal{E}_{u-}^2(M^Q)d\Bigg[A_u + 2\langle m^c, M^{Q,c}\rangle_u + \int_0^t V_{s-}d\langle M^{Q,c}\rangle_s$$

$$+ \sum_{s\le t}(V_s \widetilde{(\Delta M_s^Q)^2} + 2\Delta m_s \Delta M_s^Q)\Bigg]$$

is an integrable increasing process. Therefore, since $\mathcal{E}_{t-}(M^Q)$ is strictly positive, we obtain that

$$A_t + 2\langle m^c, M^{Q,c}\rangle_t + \int_0^t V_{s-}d\langle M^{Q,c}\rangle_s \tag{3.10}$$

$$+ \sum_{s\le t}(V_s \widetilde{(\Delta M_s^Q)^2} + 2\Delta m_s \Delta M_s^Q) \in \mathcal{A}_{\mathrm{loc}}^+$$

for every $Q \in \mathcal{M}_2^e$. According to Delbaen and Schachermayer [5], there exists an optimal martingale measure Q^* which is equivalent to P. Therefore, by the optimality principle (Proposition 3) $V_t\mathcal{E}_t^2(M^{Q^*})$ is a P-martingale, and using the same arguments (as above) we have that

$$A_t + 2\langle m^c, M^{Q^*,c}\rangle_t + \int_0^t V_{s-} d\langle M^{Q^*,c}\rangle_s \tag{3.11}$$

$$+\sum_{s\le t}(V_s(\Delta M_s^{Q^*})\widetilde{^2} + 2\Delta m_s \Delta M_s^{Q^*}) = 0.$$

Hence relations (3.10) and (3.11) imply that

$$A_t = -\operatorname*{ess\,inf}_{Q\in\mathcal{M}_2^e}\Big[2\langle m^c, M^{Q,c}\rangle_t + \int_0^t V_{s-} d\langle M^{Q,c}\rangle_s \tag{3.12}$$

$$+\sum_{s\le t}(V_s(\Delta M_s^{Q})\widetilde{^2} + 2\Delta m_s \Delta M_s^{Q})\Big]$$

and V satisfies (3.4). □

COROLLARY 1. *Suppose that there exists $\hat{Q} \in \mathcal{M}_2^e$ with continuous density process $Z^{\hat{Q}}$. Then a.s. for all $t \in [0,T]$*

$$\Delta L_t \le \Delta Y_t$$

for any solution Y of (3.4)*, where L is the martingale part of Y.*

Proof. Since Y solves (3.4) we have for any $Q \in \mathcal{M}_2^e$ that

$$B_t + 2\langle L^c, M^{Q,c}\rangle_t + \int_0^t Y_{s-} d\langle M^{Q,c}\rangle_s \tag{3.13}$$

$$+\sum_{s\le t}(Y_s(\Delta M_s^{Q})\widetilde{^2} + 2\Delta L_s \Delta M_s^{Q}) \in \mathcal{A}_{\mathrm{loc}}^+.$$

Taking $Q = \hat{Q}$ (3.13) implies that $\Delta B_t \ge 0$ a.s. for all $t \in [0,T]$; hence $\Delta Y_t = \Delta B_t + \Delta L_t \ge \Delta L_t$. □

Remark. If there exists an equivalent local martingale measure $\tilde{Q}$ which satisfies the reverse Hölder inequality $R_2(P)$, then the variance-optimal martingale measure satisfies the reverse Hölder inequality $R_2(P)$ since for any stopping time τ

$$E(\mathcal{E}_{\tau,T}^2(M^{Q^*})/F_\tau) = \operatorname*{ess\,inf}_{Q\in\mathcal{M}_2^e} E(\mathcal{E}_{\tau,T}^2(M^{Q})/F_\tau) \le E(\mathcal{E}_{\tau,T}^2(M^{\tilde{Q}})/F_\tau) \le C.$$

LEMMA 1. *Assume that there is an equivalent local martingale measure $Q \in \mathcal{M}_2^e$ such that the associated local martingale M^Q belongs to BMO_2; then the martingale part L of any bounded solution Y of* (3.4) *belongs to the class BMO_2.*

Proof. Since $|Y_t| \le C$, we have that $|\Delta Y_t| \le 2C$ and $|\Delta L_t| \le 2C$ (see, e.g., Proposition 2.14 from Jacod [12]). Therefore, $[Y] \in \mathcal{A}_{\mathrm{loc}}^+$, $L \in \mathcal{M}_{\mathrm{loc}}^2$, and without loss

of generality we may assume that $[Y]$ is integrable and $L \in \mathcal{M}^2$; otherwise one can use the localization arguments.

By the Itô formula

$$Y_t^2 = Y_0^2 + 2\int_0^t Y_{s-}dY_s + [Y]_t, \tag{3.14}$$

and from the boundary condition $Y_T = 1$ we have

$$[Y]_T - [Y]_\tau + 2\int_\tau^T Y_{s-}d(B_s + L_s) = 1 - Y_\tau^2 \le 1 \tag{3.15}$$

for any stopping time τ.

Since Y satisfies (3.4), relation (3.13) implies that

$$B_t + \int_0^t \widetilde{Y_s d[M^Q]_s} + 2\langle M^Q, L\rangle_t \in \mathcal{A}^+_{\mathrm{loc}}. \tag{3.16}$$

On the other hand, $C[M^Q]_t - \int_0^t Y_s d[M^Q]_s \in \mathcal{A}^+_{\mathrm{loc}}$ by boundedness of Y, and hence

$$C\langle M^Q\rangle_t - \int_0^t \widetilde{Y_s d[M^Q]_s} \in \mathcal{A}^+_{\mathrm{loc}}. \tag{3.17}$$

Therefore,

$$B_t + C\langle M^Q\rangle_t + 2\langle M^Q, L\rangle_t \tag{3.18}$$

is also a locally integrable increasing process and (3.15) implies that

$$[Y]_T - [Y]_\tau + 2\int_\tau^T Y_{s-}dL_s - 2C\int_\tau^T Y_{s-}d\langle M^Q\rangle_s \tag{3.19}$$

$$- 4\int_\tau^T Y_{s-}d\langle M^Q, L\rangle_s \le 1.$$

Taking conditional expectations in (3.19), having inequality $Y_{t-} \le C$ in mind, we have

$$E([Y]_T - [Y]_\tau|F_\tau) \le 1 + 2C^2E(\langle M^Q\rangle_T - \langle M^Q\rangle_\tau/F_\tau)$$

$$+ 4CE\left(\int_\tau^T |d\langle M^Q, L\rangle_s|/F_\tau\right). \tag{3.20}$$

Since $E(\langle L\rangle_T - \langle L\rangle_\tau|F_\tau) \le E([Y]_T - [Y]_\tau|F_\tau)$, (3.20) and the Kunita–Watanabe inequality imply that

$$E(\langle L\rangle_T - \langle L\rangle_\tau/F_\tau) \le 1 + 2C^2E(\langle M^Q\rangle_T - \langle M^Q\rangle_\tau/F_\tau)$$

$$+ 4CE^{1/2}(\langle M^Q\rangle_T - \langle M^Q\rangle_\tau/F_\tau)E^{1/2}(\langle L\rangle_T - \langle L\rangle_\tau/F_\tau).$$

Since $M^Q \in BMO_2$, we obtain that

$$E(\langle L\rangle_T - \langle L\rangle_\tau / F_\tau) \le c_1 + c_2 E^{1/2}(\langle L\rangle_T - \langle L\rangle_\tau / F_\tau)$$

for some positive constants c_1 and c_2 which do not depend on τ. It follows from the latter inequality that $E(\langle L\rangle_T - \langle L\rangle_\tau / F_\tau)$ is bounded for every stopping time τ by one and the same constant. This implies $L \in BMO_2$, since L is of bounded jumps. □

COROLLARY 2. *Suppose that there exists a martingale measure Q, with continuous density process Z^Q, which satisfies the reverse Hölder inequality $R_2(P)$. Then the martingale part m of the value process belongs to the class BMO_2.*

Proof. The reverse Hölder condition implies that the value process is bounded (see the remark after Theorem 1) and that $M^Q \in BMO_2$ (Proposition 2). Thus it follows from Theorem 1 that the value process is a bounded solution of (3.4); hence $m \in BMO_2$ by Lemma 1. □

Let C be the predictable support of the set $]0,\infty[\cup\{\Delta m \ne 0\}$, and let $(\tau_n, n \ge 1)$ be a sequence of predictable stopping times such that $C = \cup[\tau_n]$.

Let us consider the martingale

$$M_t^{Q^*} = -\int_0^t \lambda_s dM_s + N_t^*, \tag{3.21}$$

where

$$N_t^* = -\int_0^t \frac{1}{V_{s-}} d\bar{m}_s^c - \int_0^t \frac{1}{V_s} d\bar{m}_s^{dq} \tag{3.22}$$

$$+ \sum_{\tau_n \le t} \frac{E(\frac{\Delta\bar{m}_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-}) - \Delta\bar{m}_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}{V_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}.$$

Since $\bar{m}^{dq}$ is quasi-left-continuous and $V \ge 1$ (by Jensen's inequality), the stochastic integral $\frac{1}{V}\cdot\bar{m}^{dq}$ is well defined by the Chou–Lepingle lemma (see, e.g., Jacod [12]) as a unique purely discontinuous local martingale I such that

$$\Delta I_t = \frac{1}{V_t}\Delta\bar{m}_t^{dq}.$$

Using the equality $\Delta\bar{m} = \Delta m = \Delta V - \Delta A$ and that A_τ is $F_{\tau-}$-measurable, it is easy to see that the equality

$$\frac{E(\frac{\Delta\bar{m}_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-}) - \Delta\bar{m}_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}{V_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n})} = -1 + \frac{1}{V_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})} \tag{3.23}$$

holds.

Later we shall show that the measure Q^* defined by $dQ^* = \mathcal{E}_T(M^{Q^*})dP$ is variance-optimal. Let us show that Q^* is an equivalent martingale measure of X.

LEMMA 2. *Let conditions* (A) *and* (B*) *be satisfied. Then Q^* defined by* (3.21)–(3.22) *is an equivalent martingale measure of X.*

Proof. Let us first show that

$$\Delta M_t^{Q^*} \ge -1 + \frac{1}{C}. \tag{3.24}$$

It is evident that the moments of jumps of martingales M^{Q^*} and m coincide. If a moment of jump σ of M^{Q^*} is totally inaccessible, then from (3.22) we have that

$$\Delta M_\sigma^{Q^*} = -\frac{1}{V_\sigma}\Delta \bar{m}_\sigma^{dq} = -\frac{1}{V_\sigma}\Delta m_\sigma \geq -\frac{1}{V_\sigma}\Delta V_\sigma$$

$$= -1 + \frac{V_{\sigma-}}{V_\sigma} \geq -1 + \frac{1}{C}. \tag{3.25}$$

Here we used Corollary 1 of Theorem 1 and the inequality $1 \leq V_t \leq C$ valid for all $t \in [0, T]$.

If τ is a predictable moment of jump of m, then equalities (3.22), (3.23) and inequality $1 \leq V_t \leq C$ imply that

$$\Delta M_\tau^{Q^*} = -1 + \frac{1}{V_\tau E(\frac{1}{V_\tau}/F_{\tau-})} \geq -1 + \frac{1}{C}. \tag{3.26}$$

Therefore, (3.24) holds.

Let us show now that $M^{Q^*} \in BMO_2$. For this it is sufficient to show that each martingale entering (3.22) is in BMO_2.

$\lambda \cdot M \in BMO_2$ by Condition (B*) and Proposition 2.

The martingales $\frac{1}{V} \cdot \bar{m}^c$ and $\frac{1}{V} \cdot \bar{m}^{dq}$ belong to BMO_2 since $V \geq 1$,

$$\langle \bar{m}^c \rangle_T - \langle \bar{m}^c \rangle_\tau + \langle \bar{m}^{dq} \rangle_T - \langle \bar{m}^{dq} \rangle_\tau \leq \langle m \rangle_T - \langle m \rangle_\tau,$$

and $m \in BMO_2$ by Corollary 2.

It is easy to see that the last term of (3.22) is a martingale from the class BMO_2, since it is of bounded jumps and (denoting this martingale by l)

$$E(\langle l \rangle_{\tau T} | F_\tau) = E\left[\sum_{\tau \leq \tau_n \leq T} E\left(\left(\frac{E(\frac{\Delta m_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-}) - \Delta m_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}{V_{\tau_n} E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}\right)^2 |F_{\tau_n-}\right)|F_\tau\right]$$

$$\leq 2cE(\langle m \rangle_{\tau T}|F_\tau).$$

Thus $M^{Q^*} \in BMO_2$, which together with (3.24) implies that $\mathcal{E}_t(M^{Q^*})$ is a true martingale (Proposition 1). Besides it follows from (3.24) that $\mathcal{E}_T(M^{Q^*}) > 0$ so that $Q^* \in \mathcal{M}^e$. □

LEMMA 3. *Suppose that there exists $Q \in M^e$ satisfying the reverse Hölder condition $R_2(P)$. Then for any predictable stopping time τ*

$$\operatorname*{ess\,inf}_{N \in \mathcal{M}^2 : E(\Delta N_\tau | F_{\tau-}) = 0} E\left[\left(\sqrt{V_\tau}\Delta N_\tau + \frac{1}{\sqrt{V_\tau}}\Delta m_\tau\right)^2 |F_{\tau-}\right] = \frac{E^2(\frac{\Delta m_\tau}{V_\tau}|F_{\tau-})}{E(\frac{1}{V_\tau}|F_{\tau-})}, \tag{3.27}$$

and the infimum is attained for N^* with

$$\Delta N_\tau^* = \frac{E(\frac{\Delta m_\tau}{V_\tau}|F_{\tau-}) - \Delta m_\tau E(\frac{1}{V_\tau}|F_{\tau-})}{V_\tau E(\frac{1}{V_\tau}|F_{\tau-})}. \tag{3.28}$$

Proof. The $R_2(P)$ condition implies that V is bounded above and that $m \in BMO_2$. Therefore, conditional expectations in (3.27) and (3.28) exist. Using the

Cauchy–Schwarz inequality for any N with $E(\Delta N_\tau|F_{\tau-})=0$, we have

$$\begin{aligned}
&E\left(\frac{1}{V_\tau}|F_{\tau-}\right)E\left[\left(\sqrt{V_\tau}\Delta N_\tau+\frac{1}{\sqrt{V_\tau}}\Delta m_\tau\right)^2|F_{\tau-}\right]\\
&\quad\geq E^2\left[\frac{1}{\sqrt{V_\tau}}\left(\sqrt{V_\tau}\Delta N_\tau+\frac{1}{\sqrt{V_\tau}}\Delta m_\tau\right)|F_{\tau-}\right]\\
&\quad=E^2\left(\frac{\Delta m_\tau}{V_\tau}|F_{\tau-}\right).
\end{aligned}$$

On the other hand, it is easy to verify that

$$E\left[\left(\sqrt{V_\tau}\Delta N^*_\tau+\frac{1}{\sqrt{V_\tau}}\Delta m_\tau\right)^2|F_{\tau-}\right]=\frac{E^2(\frac{\Delta m_\tau}{V_\tau}|F_{\tau-})}{E(\frac{1}{V_\tau}|F_{\tau-})},$$

which proves the assertion of the lemma. □

LEMMA 4. *Let conditions* (A) *and* (B*) *be satisfied. Then*

$$\begin{aligned}
&\operatorname*{ess\,inf}_{N\in\mathcal{N}_2(X)}\left[\int_0^t V_{s-}d\langle N^c\rangle_s+2\langle\bar m^c,N\rangle_t+\sum_{s\leq t}(V_s\widetilde{(\Delta N_s)^2}+2\Delta\bar m_s\Delta N_s)\right]\\
&\quad=-\int_0^t\frac{1}{V_{s-}}d\langle\bar m^c\rangle_s-\sum_{s\leq t}\widetilde{\frac{1}{V_s}(\Delta\bar m_s)^2}+\sum_{\tau_n\leq t}\frac{E^2(\frac{\Delta\bar m_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-})}{E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}.
\end{aligned}\tag{3.29}$$

Proof. Let us write (3.29) in the form

$$\operatorname*{ess\,inf}_{N\in\mathcal{N}_2(X)}A_t(N)=\bar A_t\tag{3.30}$$

with evident notation. Let us first show that

$$A_t(N)-\bar A_t\in\mathcal{A}^+_{\mathrm{loc}}.\tag{3.31}$$

We have

$$\begin{aligned}
A_t(N)-\bar A_t&=\left\langle\int\sqrt{V}_s dN^c_s+\int\frac{1}{\sqrt{V}_s}d\bar m^c_s\right\rangle_t\\
&\quad+\sum_{s\leq t}\left(\widetilde{\frac{1}{\sqrt{V}_s}\Delta\bar m_s}+\sqrt{V}_s\Delta N_s\right)^2-\sum_{\tau_n\leq t}\frac{E^2(\frac{\Delta\bar m_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-})}{E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}\\
&=\left\langle\int\sqrt{V}_s dN^c_s+\int\frac{1}{\sqrt{V}_s}d\bar m^c_s\right\rangle_t+\sum_{\sigma_n\leq t}\left(\widetilde{\frac{1}{\sqrt{V}_{\sigma_n}}\Delta\bar m_{\sigma_n}}+\sqrt{V}_{\sigma_n}\Delta N_{\sigma_n}\right)^2\\
&\quad+\sum_{\tau_n\leq t}E\left[\left(\frac{1}{\sqrt{V_{\tau_n}}}\Delta\bar m_{\tau_n}+\sqrt{V}_{\tau_n}\Delta N_{\tau_n}\right)^2|F_{\tau_n-}\right]-\sum_{\tau_n\leq t}\frac{E^2(\frac{\Delta\bar m_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-})}{E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}\\
&=A^1_t+A^2_t+A^3_t-A^4_t.
\end{aligned}\tag{3.32}$$

Here we used Proposition 1.49 of Jacod [12], and we recall that τ_n, σ_n are sequences of predictable and totally inaccessible stopping times, respectively, exhausting the jumps of m and that $\Delta m = \Delta \bar{m}$.

Lemma 3 implies that $A^3_t - A^4_t$ is an increasing process. It is evident that A^1 and A^2 also are increasing processes. Therefore, (3.31) holds. Let us show that

$$\bar{A}_t - \operatorname*{ess\,inf}_{N \in \mathcal{N}_2(X)} A_t(N) \in \mathcal{A}^+_{\mathrm{loc}}. \tag{3.33}$$

Define a sequence of stopping times $(s_n,\ \ n \geq 1)$ by

$$s_k = \inf\{t : \mathcal{E}_t(N^*) \geq k\},$$

where N^* is given by (3.22). Let $N^k_t = N^*_{t \wedge s_k}$.

Since N^* is of bounded jumps, it is evident that $\mathcal{E}_t(N^k) = \mathcal{E}_{t \wedge s_k}(N^*) \leq \text{const}$, $\mathcal{E}_t(-\lambda \cdot M + N^k)$ is a square integrable martingale with $\Delta N^k > -1$ (by Lemma 2), and N^k belongs to the class $N_2(X)$. Therefore, for every $k \geq 1$ we have that

$$A_t(N^k) - \operatorname*{ess\,inf}_{N \in \mathcal{N}_2(X)} A_t(N) \in \mathcal{A}^+_{\mathrm{loc}} \tag{3.34}$$

by definition of ess inf with respect to the strong order $\prec$.

It is easy to see that

$$A_t(N^k) = -\int_0^{t \wedge s_k} \frac{1}{V_{s-}} d\langle \bar{m}^c \rangle_s - \sum_{s \leq t \wedge s_k} \widetilde{\frac{1}{V_s}} (\Delta \bar{m}_s)^2 + \sum_{\tau_n \leq t \wedge s_k} \frac{E^2(\frac{\Delta \bar{m}_{\tau_n}}{V_{\tau_n}} | F_{\tau_n -})}{E(\frac{1}{V_{\tau_n}} | F_{\tau_n -})}$$

and $A_t(N^k) \to \bar{A}_t$ a.s. for every t as $k \to \infty$. Therefore, (3.33) follows from (3.34). It is evident that relations (3.31) and (3.33) imply the assertion of this lemma. □

Now we shall prove the main statement of the paper. Recall that any special semimartingale Y can be expressed in the form

$$Y_t = Y_0 + B_t + \int_0^t \psi_s dM_s + \bar{L}_t,$$

where $\bar{L}$ is a local martingale orthogonal to M.

THEOREM 2. *Let conditions* (A) *and* (B*) *be satisfied. Then the value process V is a unique solution of the semimartingale backward equation*

$$Y_t = Y_0 - \int_0^t Y_{s-} d\langle \lambda \cdot M \rangle_s + 2\langle \lambda \cdot M, \psi \cdot M \rangle_t \tag{3.35}$$

$$- \sum_{\tau_n \leq t} \frac{E^2(\frac{\Delta \bar{L}_{\tau_n}}{Y_{\tau_n}} | F_{\tau_n -})}{E(\frac{1}{Y_{\tau_n}} | F_{\tau_n -})} + \int_0^t \widetilde{\frac{1}{Y_s}} d[\bar{L}]_s + \int_0^t \psi_s dM_s + \bar{L}_t, \ \ Y_T = 1$$

in the class of semimartingales Y satisfying the two-sided inequality

$$c \leq Y_t \leq C \ \ \textit{for all} \ \ t \in [0,T] \ \ \textit{a.s.} \tag{3.36}$$

for some constants $0 < c \leq C$.

Moreover, the martingale measure Q^* is variance-optimal if and only if it is given by $dQ^* = \mathcal{E}_T(M^{Q^*})dP$, where

$$M_t^{Q^*} = -\int_0^t \lambda_s dM_s - \int_0^t \frac{1}{V_s} d(\bar{m}_s^c + \bar{m}_s^{dq}) + \sum_{\tau_n \le t} \left(-1 + \frac{1}{V_{\tau_n} E(\frac{1}{\Delta V_{\tau_n}} | F_{\tau_n -})} \right) \tag{3.37}$$

and $(\tau_n,\ n \ge 1)$ is a sequence of stopping times exhausting the predictable moments of jumps for V.

Proof. It follows from Lemma 4 that

$$-\operatorname*{ess\,inf}_{N \in \mathcal{N}_2^e} \left[\int_0^t V_{s-} d\langle M^{Q,c} \rangle_s + 2\langle M^{Q,c}, m \rangle_t + \sum_{s \le t} (V_s (\Delta M_s^Q)^{\widetilde{2}} + 2\Delta \bar{m}_s \Delta M_s^Q) \right]$$

$$= -\int_0^t V_{s-} d\langle \lambda \cdot M \rangle_s + 2\langle \lambda \cdot M, \varphi \cdot M \rangle_t + \int_0^t \widetilde{\frac{1}{V_s}} d[\bar{m}_s]$$

$$- \sum_{\tau_n \le t} \frac{E^2(\frac{\Delta \bar{m}_{\tau_n}}{V_{\tau_n}} | F_{\tau_n -})}{E(\frac{1}{V_{\tau_n}} | F_{\tau_n -})}. \tag{3.38}$$

Therefore, according to Theorem 1, the value process satisfies (3.35).

Let us show that the optimal martingale measure is of the form (3.37). Let the martingale measure Q^0 be optimal. By the optimality principle $V_t \mathcal{E}_t^2(M^{Q^0})$ is martingale. Since V solves (3.4), this implies that

$$\operatorname*{ess\,inf}_{Q \in \mathcal{M}_2^e} \left[\int_0^t V_{s-} d\langle M^{Q,c} \rangle_t + 2\langle M^{Q,c}, \bar{m}^c \rangle_t + \sum_{s \le t} (V_s (\Delta M_s^Q)^{\widetilde{2}} + \Delta m_s \Delta M_s^Q) \right]$$

$$= \int_0^t V_{s-} d\langle M^{Q^0,c} \rangle_t + 2\langle M^{Q^0,c}, \bar{m}^c \rangle_t$$

$$+ \sum_{s \le t} (V_s (\Delta M_s^{Q^0})^{\widetilde{2}} + 2\Delta m_s \Delta M_s^{Q^0}). \tag{3.39}$$

Since M^{Q^0} is represented in the form $-\lambda \cdot M + N^0$ for some $N^0 \in \mathcal{N}_2(X)$, it follows from (3.38) and (3.39) that

$$-\int_0^t \widetilde{\frac{1}{V_s}} d[\bar{m}]_s + \sum_{\tau_n \le t} \frac{E^2(\frac{\Delta \bar{m}_{\tau_n}}{V_{\tau_n}} | F_{\tau_n -})}{E(\frac{1}{V_{\tau_n}} | F_{\tau_n -})}$$

$$= \int_0^t V_{s-} d\langle N^{0,c} \rangle_s + 2\langle N^{0,c}, \bar{m}^c \rangle_t + \sum_{s \le t} (V_s (\Delta N_s^0)^{\widetilde{2}} + 2\Delta \bar{m}_s \Delta N_s^0),$$

and hence

$$\left\langle \sqrt{V}\cdot N^{0,c}+\frac{1}{\sqrt{V}}\cdot\bar{m}^{c}\right\rangle_t+\sum_{s\le t}\left(\sqrt{V_s}\Delta\widetilde{N_s^{0,dq}}+\frac{1}{\sqrt{V_s}}\Delta\bar{m}_s\right)^2$$
$$+\sum_{s\le t}\left(\sqrt{V_s}\Delta\widetilde{N_s^{0,dp}}+\frac{1}{\sqrt{V_s}}\Delta\bar{m}_s\right)^2$$
$$-\sum_{\tau_n\le t}\frac{E^2(\frac{\Delta\bar{m}_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-})}{E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}=0.$$

This equality implies that the process N^0 may have the jumps at the moments of jumps of $\bar{m}$ only. Therefore,

$$\sum_{s\le t}\left(\sqrt{V_s}\Delta\widetilde{N_s^{0,dp}}+\frac{1}{\sqrt{V_s}}\Delta\bar{m}_s^{dp}\right)^2=\sum_{\tau_n\le t}E\left[\left(\Delta N^0_{\tau_n}+\frac{1}{V_{\tau_n}}\Delta\bar{m}_{\tau_n}\right)^2|F_{\tau_n-}\right],$$

and from Lemma 3 we obtain that

$$N^{0,c}=-\frac{1}{V}\cdot\bar{m}^{c},\quad N^{0,dq}=-\frac{1}{V}\cdot\bar{m}^{dq},$$

and

$$\Delta N^0_{\tau_n}=\frac{E(\frac{\Delta\bar{m}_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-})-\Delta\bar{m}_{\tau_n}E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}{V_{\tau_n}E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}.$$

Thus the processes M^{Q^*} (defined by (3.37)) and M^{Q^0} are indistinguishable. Therefore, $Q^*\in\mathcal{M}_2^e$ and the variance-optimal martingale measure is unique and admits representation (3.37).

Uniqueness. Let Y be a solution of (3.35) satisfying (3.36). Since Y solves (3.35) using the Itô formula for $\mathcal{E}_t^2(M^Q)Y_t$, we obtain that for every $Q\in\mathcal{M}_2^e$ the process $Y_t\mathcal{E}_t^2(M^Q)$ is a local submartingale under P. Since Y is positive and bounded, $Y_t\mathcal{E}_t^2(M^Q)$ is a submartingale of class D, and it follows from the boundary condition that for every $Q\in\mathcal{M}_2^e$

$$Y_t\mathcal{E}_t^2(M^Q)\le E(Y_T\mathcal{E}_T^2(M^Q)|F_t)\le E(\mathcal{E}_T^2(M^Q)|F_t).$$

Hence $Y_t\le E(\mathcal{E}_{tT}^2(M^Q)|F_t)$ for all $Q\in\mathcal{M}_2^e$ and

$$Y_t\le Q\in M_2^e\,\text{ess inf}E(\mathcal{E}_{tT}^2(M^Q)|F_t)=V_t. \tag{3.40}$$

Let us prove the converse inequality.

Similarly to (3.38), one can show that

$$B_t=-\int_0^t Y_{s-}d\langle\lambda\cdot M\rangle_s+2\langle\lambda\cdot M,\psi\cdot M\rangle_t \tag{3.41}$$

$$-\sum_{\tau_n\le t}\frac{E^2(\frac{\Delta\bar{L}_{\tau_n}}{V_{\tau_n}}|F_{\tau_n-})}{E(\frac{1}{V_{\tau_n}}|F_{\tau_n-})}+\int_0^t\widetilde{\frac{1}{Y_s}d[\bar{L}]_s}.$$

Consider the martingale

$$M_t^{Q^0} = -\int_0^t \lambda_s dM_s - \int_0^t \frac{1}{V_s} d(\bar{L}_s^c + \bar{L}_s^{dq}) + \sum_{\tau_n \le t} \left(-1 + \frac{1}{Y_{\tau_n} E(\frac{1}{Y_{\tau_n}} | F_{\tau_n -})} \right), \tag{3.42}$$

which belongs to BMO_2 by Lemmas 1 and 2.

Using again the Itô formula, (3.41), and (3.42), one can show that the process $Y_t \mathcal{E}_t^2(M^{Q^0})$ is a local martingale. Since any positive local martingale is a supermartingale, we have that

$$Y_t \mathcal{E}_t^2(M^Q) \ge E(Y_T \mathcal{E}_T^2(M^{Q^0}) | F_t),$$

which gives that

$$E\mathcal{E}_T^2(M^{Q^0}) \le Y_0 < \infty. \tag{3.43}$$

Since $\Delta M^{Q^0} \ge -1 + \frac{c}{C}$ and $M^{Q^0} \in BMO_2$, the process $(\mathcal{E}_t(M^{Q^0}), t \in [0,T])$ is a uniformly integrable martingale and (3.43) implies that this martingale is square-integrable. Thus $Q^0 \in \mathcal{M}_2^e$, and $Y_t \mathcal{E}_t^2(M^{Q^0})$ is a martingale of the class D, since Y is bounded. Now the martingale property and the boundary condition imply that

$$Y_t = E(\mathcal{E}_{tT}^2(-\lambda \cdot M + N^0) | F_t).$$

Therefore, (3.40) and the latter equality imply that $Y_t = V_t$ for all $t \in [0,T]$; hence V is the unique solution of (3.35).

The same arguments show that the measure $dQ^* = \mathcal{E}_T(M^{Q^*}) dP$, where M^{Q^*} is given by (3.37), belongs to the class $\mathcal{M}_2^e$ and $V_t \mathcal{E}_t^2(M^{Q^*})$ is a martingale; hence Q^* is variance-optimal by the optimality principle. □

Remark 1. Since

$$\int_0^t \widetilde{\frac{1}{Y_s}} d[\bar{L}]_s = \sum_{\tau_n \le t} E\left(\frac{(\Delta \bar{L}_{\tau_n})^2}{Y_{\tau_n}} | F_{\tau_n -} \right) + \int_0^t \frac{1}{Y_{s-}} d\langle \bar{L}^{dq} \rangle_s + \int_0^t \frac{1}{Y_{s-}} d\langle \bar{L}^c \rangle_s,$$

one can write (3.35) in the following equivalent form:

$$\begin{aligned} Y_t = Y_0 - \int_0^t Y_{s-} d\langle \lambda \cdot M \rangle_s + 2\langle \lambda \cdot M, \psi \cdot M \rangle_t + \int_0^t \frac{1}{Y_{s-}} d\langle \bar{L}^c \rangle_s \\ + \int_0^t \frac{1}{Y_{s-}} d\langle \bar{L}^{dq} \rangle_s + \sum_{\tau_n \le t} \left[E\left(\frac{(\Delta \bar{L}_{\tau_n})^2}{Y_{\tau_n}} | F_{\tau_n -} \right) - \frac{E^2(\frac{\Delta \bar{L}_{\tau_n}}{Y_{\tau_n}} | F_{\tau_n -})}{E(\frac{1}{Y_{\tau_n}} | F_{\tau_n -})} \right] \\ + \int_0^t \psi_s dM_s + \bar{L}_t. \end{aligned} \tag{3.44}$$

Remark 2. Theorem 2 can also be formulated in the following form: The triple $(V, \varphi, \bar{m})$ is a unique solution of (3.35) (or (3.44)) in the class of processes $(Y, \psi, \bar{L})$ such that $0 < c \le Y \le C$, $\psi \cdot M \in BMO_2$, $\bar{L} \in BMO_2$.

COROLLARY 3. *The martingale measure Q^* is variance-optimal if and only if*

$$Z_T^* = c + \int_0^T h_s dX_s \tag{3.45}$$

for a constant c and an X-integrable process h such that the process $\int_0^t h_s dX_s$ is a Q-martingale for any $Q \in \mathcal{M}_2^e$. Moreover, $c = V_0$ and the integrand h can be expressed as

$$h_t = V_0 \mathcal{E}_{t-}\left(\left(\frac{\varphi}{V} - \lambda\right) \cdot X\right)\left(\frac{\varphi_t}{V_t} - \lambda_t\right), \tag{3.46}$$

where φ is defined by (3.3).

Proof. The first statement is proved in [5]. Let us show the validity of representation (3.46). Let Q^* be an optimal martingale measure. By Theorem 2, Q^* admits representation (3.37). It follows from the Itô formula for $V_t \mathcal{E}_t(M^{Q^*})$, using expressions (3.38) and (3.37), that

$$V_t \mathcal{E}_t(M^{Q^*}) = V_0 + \int_0^t V_{s-} \mathcal{E}_{s-}(M^{Q^*}) \left(\frac{\varphi_s}{V_s} - \lambda_s\right) dX_s. \tag{3.47}$$

Therefore, from (2.1)

$$\begin{aligned} V_t \mathcal{E}_t(M^{Q^*}) &= V_0 \mathcal{E}_t\left(\left(\frac{\varphi}{V} - \lambda\right) \cdot X\right) \\ &= V_0 \left(1 + \int_0^t \mathcal{E}_{s-}\left(\left(\frac{\varphi}{V} - \lambda\right) \cdot X\right)\left(\frac{\varphi_s}{V_s} - \lambda_s\right) dX_s\right), \end{aligned} \tag{3.48}$$

and using the boundary condition, we obtain representation (3.45) with h expressed by (3.46). Besides, it follows from (3.48) and from the optimality principle that $V_0 + \int_0^t h_s dX_s$ is a Q^*-martingale.

It follows from (3.45), (3.48) that

$$\int_0^t h_s dX_s \geq -V_0.$$

The latter inequality implies (see Ansel and Stricker [1]) that the process $\int_0^t h_s dX_s$ is a Q-local martingale; hence it is also a supermartingale for any $Q \in \mathcal{M}_2^e$.

On the other hand, since Q^* is optimal, by Lemma 1 of Schweizer [23] $E^Q \mathcal{E}_T(M^{Q^*}) =$ const for any $Q \in \mathcal{M}_2^e$ which implies that $E^Q \mathcal{E}_T(M^{Q^*}) = V_0$, and from (3.48) we have

$$E^Q \int_0^T h_s dX_s = E^Q \mathcal{E}_T(M^{Q^*}) - V_0 = 0.$$

Hence $\int_0^t h_s dX_s$ is a martingale for all $Q \in \mathcal{M}_2^e$. □

4. Some particular cases. In this section we consider the martingale analogues of two specific extreme cases, already studied by Pham, Rheinländer, and Schweizer [19], Laurent and Pham [14], and Biagini, Guasoni, and Pratelli [2], when the semimartingale backward equation (3.4) admits an explicit solution. Besides, we give necessary and sufficient conditions in order that the variance-optimal martingale measure coincides with the minimal martingale measure as well as with the martingale measure appearing in the second extreme case.

Let $X_t(2) = M_t + 2\int_0^t d < M >_s \lambda_s$. Condition (B) implies that the process $(\mathcal{E}_t(-2\lambda \cdot M), t \in [0,T])$ is a martingale, and one can define a probability measure

$Q(2)$ by $dQ(2) = \mathcal{E}_T(-2\lambda \cdot M)dP$. Note that the process $X(2)$ is a local martingale under $Q(2)$, by Girsanov's theorem.

PROPOSITION 4. *Let conditions* (A) *and* (B*) *be satisfied. Then the variance-optimal martingale measure coincides with the minimal martingale measure if and only if*

$$e^{\langle \lambda \cdot M \rangle_T} = c + \int_0^T h_s dX_s(2) \tag{4.1}$$

for a constant c *and an* $X(2)$*-integrable* h *such that the process* $(\int_0^t h_s dX_s(2),\ t \in [0,T])$ *is a martingale under* $Q(2)$.

Moreover, in this case (3.35) *admits an explicit solution*

$$V_t = E(\mathcal{E}^2_{tT}(-\lambda \cdot M)|F_t) = E^{Q(2)}(e^{\langle \lambda \cdot M \rangle_{tT}}|F_t)$$

with the martingale part

$$\int_0^t e^{-\langle \lambda \cdot M \rangle_s} h_s dM_s.$$

Proof. Let (4.1) be satisfied. Consider the process

$$Y_t = E(\mathcal{E}^2_{tT}(-\lambda \cdot M)|F_t) = E(\mathcal{E}_{tT}(-2\lambda \cdot M)e^{\langle \lambda \cdot M \rangle_{tT}}|F_t).$$

It is evident that $1 \le Y \le C$. Using (4.1), we have that $Y_t = e^{-\langle \lambda \cdot M \rangle_t} \bar{M}_t$, where $\bar{M}_t = c + \int_0^t h_s dX_s(2)$. By the Itô formula we obtain that

$$Y_t = Y_0 - \int_0^t e^{-\langle \lambda \cdot M \rangle_s} \bar{M}_s d\langle \lambda \cdot M \rangle_s + \int_0^t e^{-\langle \lambda \cdot M \rangle_s} h_s dX_s(2),$$

and Y satisfies the equation

$$Y_t = Y_0 - \int_0^t Y_s d\langle \lambda \cdot M \rangle_s + 2\int_0^t e^{-\langle \lambda \cdot M \rangle_s} d\langle h \cdot M, \lambda \cdot M \rangle_s + \int_0^t e^{-\langle \lambda \cdot M \rangle_s} h_s dM_s.$$

Thus Y is a bounded solution of (3.35) with $\psi_s = h_s e^{-<\lambda \cdot M>_s}$, $s \in [0,T]$, and $\bar{L} = 0$. Therefore, Theorem 2 implies that $Y = V$, which means that the minimal martingale measure Q^{min} is variance-optimal.

Assume that Q^{min} is variance-optimal. Then by Theorem 2 the process N^* defined by (3.22) is indistinguishable from 0. Since the martingales from (3.22) are orthogonal to each other, we have that $\bar{m}^c = 0$, $\bar{m}^{dq} = 0$, and for any predictable stopping time τ

$$\frac{E(\frac{\Delta \bar{m}_\tau}{V_\tau}|F_{\tau-}) - \Delta \bar{m}_\tau E(\frac{1}{V_\tau}|F_{\tau-})}{V_\tau E(\frac{1}{V_\tau}|F_{\tau-})} = 0.$$

The latter equality implies that $\Delta \bar{m}_\tau$ is $F_{\tau-}$-measurable, and hence $\Delta \bar{m}_\tau = E(\Delta \bar{m}_\tau|F_{\tau-}) = 0$ for any predictable moment τ, and we obtain that $\bar{m} = 0$. Therefore, the value process satisfies

$$V_t = V_0 - \int_0^t V_s d\langle \lambda \cdot M \rangle_s + \int_0^t \varphi_s dX_s(2).$$

Solving this equation with respect to V and using the boundary condition $V_T = 1$, we have that

$$e^{\langle \lambda \cdot M \rangle_T} = V_0 \mathcal{E}_T\left(\frac{\varphi}{V} \cdot X(2)\right) = V_0 + V_0 \int_0^T \mathcal{E}_s\left(\frac{\varphi}{V} \cdot X(2)\right) \frac{\varphi_s}{V_s} dX_s(2).$$

Since $\lambda \cdot M \in BMO_2$ and $V \geq 1$, it follows from Lemma 1 and Proposition 7 of Doléans-Dade and Meyer [8] that $\frac{\varphi}{V} \cdot X(2)$ belongs to the class $BMO_2(Q(2))$ and hence the process $\int_0^t \mathcal{E}_s(\frac{\varphi}{V} \cdot X(2))\frac{\varphi_s}{V_s} dX_s(2)$ is a $Q(2)$-martingale. □

PROPOSITION 5. *Let conditions* (A) *and* (B*) *be satisfied. Then the variance-optimal martingale measure is of the form*

$$\mathcal{E}_T(M^{Q^*}) = c\mathcal{E}_T(-\lambda \cdot X) \tag{4.2}$$

if and only if

$$e^{-\langle \lambda \cdot M \rangle_T} = \hat{c} + \hat{m}_T \tag{4.3}$$

for a constant $\hat{c}$ and a martingale $\hat{m}$ orthogonal to M.

Under (4.3), (3.35) *admits an explicit solution*

$$V_t = \frac{1}{E(\exp\{- < \lambda \cdot M >_{tT}\}/F_t)}.$$

Proof. Assume that the variance-optimal martingale measure is of the form (4.2). By Theorem 2 the optimal density is of the form $\mathcal{E}_T(-\lambda \cdot M + N^*)$, where N^* admits representation (3.22). Therefore, (4.2) implies that

$$\mathcal{E}_T(-\lambda \cdot M + N^*) = c\mathcal{E}_T(-\lambda \cdot X)$$

and

$$\mathcal{E}_T(N^*) = c\frac{\mathcal{E}_T(-\lambda \cdot X)}{\mathcal{E}_T(-\lambda \cdot M)} = ce^{-\langle \lambda \cdot M \rangle_T}.$$

Thus

$$e^{-\langle \lambda \cdot M \rangle_T} = \frac{1}{c} + \frac{1}{c}\int_0^T \mathcal{E}_{s-}(N^*) dN_s^*,$$

and, according to Lemma 2, $N^* \in BMO_2$, $\Delta N^* \geq -1 + h$, and hence the process $\hat{m}_t = \frac{1}{c}\int_0^t \mathcal{E}_{s-}(N^*) dN_s^*$ is a true martingale.

Conversely, let (4.3) be satisfied. By Theorem 2 the optimal density is of the form

$$Z_T^{Q^*} = \mathcal{E}_T(-\lambda \cdot M + N^*), \tag{4.4}$$

where N^* is defined by (3.37). On the other hand, Corollary 3 implies (see (3.46) and (3.48)) that the optimal density can be expressed in the alternate form

$$Z_T^{Q^*} = c\mathcal{E}_T((\bar{\varphi} - \lambda) \cdot X), \tag{4.5}$$

where $\bar{\varphi} = \frac{\varphi}{V}$ and φ is defined by (3.3).

Using equality

$$\mathcal{E}_T((\bar{\varphi} - \lambda) \cdot X) = \mathcal{E}_T(-\lambda \cdot M)\mathcal{E}_T(\bar{\varphi} \cdot X(2)) \exp\{-\langle \lambda \cdot M \rangle_T\},$$

from (4.3) and (4.5) we have

$$Z_T^{Q^*} = c\mathcal{E}_T(-\lambda \cdot M)\mathcal{E}_T(\bar{\varphi} \cdot X(2))(\hat{c} + \hat{m}_T). \tag{4.6}$$

Therefore, from (4.4) and (4.6) we obtain the equality

$$\mathcal{E}_T(N^*) = c\mathcal{E}_T(\bar{\varphi}\cdot X(2))(\hat{c}+\hat{m}_T). \tag{4.7}$$

Lemma 1, inequality (3.24), and the two-sided inequality $1 \le V \le C$ imply that N^* and $\bar{\varphi}\cdot M$ belong to BMO_2. Therefore, by Proposition 7 of Doléans-Dade and Meyer [8], $\bar{\varphi}\cdot X(2) \in BMO_2(Q(2))$, and since N^* is orthogonal to M, it is also in $BMO_2(Q(2))$. Hence the corresponding Doléans exponentials are uniformly integrable martingales by Proposition 1. From condition (4.3) we have that

$$\hat{c}+\hat{m}_t = E(\exp\{- < \lambda\cdot M >_T\}|F_t);$$

hence $\hat{m}$ is a bounded $Q(2)$-martingale, and since it is orthogonal to M the process $(\mathcal{E}_t(\bar{\varphi}\cdot X(2))(\hat{c}+\hat{m}_t), t\in[0,T])$ is a uniformly integrable martingale. Therefore, taking conditional expectations in (4.7) with respect to the measure $Q(2)$, we obtain that this equality holds for any $t\in[0,T]$, i.e.,

$$\mathcal{E}_t(N^*) = c\mathcal{E}_t(\bar{\varphi}\cdot X(2))(\hat{c}+\hat{m}_t). \tag{4.8}$$

Let $N_t^0 = \int_0^t \frac{1}{\hat{c}+\hat{m}_{s-}} d\hat{m}_s$. Then $1+\frac{1}{\hat{c}}\hat{m}_t = \mathcal{E}_t(N^0)$, and, using the Yor formula from (4.8), we obtain that

$$\mathcal{E}_t(N^*) = c\hat{c}\mathcal{E}_t(\bar{\varphi}\cdot X(2)+N^0) \tag{4.9}$$

for each $t\in[0,T]$. However, this implies that $c=\hat{c}^{-1}$ and

$$N_t^* = \int_0^t \bar{\varphi}_s dM_s + 2\langle\bar{\varphi}\cdot M, \lambda\cdot M\rangle_t + N_t^0,$$

and since the martingales N^* and N^0 are orthogonal to M and $\langle\bar{\varphi}\cdot M,\lambda\cdot M\rangle$ is of bounded variation, we obtain that the stochastic integral $\bar{\varphi}\cdot X(2)$ is indistinguishable from zero. Hence $\bar{\varphi}=0$ a.e. with respect to the Doléans measure of $\langle M\rangle$, which implies that $\bar{\varphi}\cdot X(2)$ is also the zero process. Therefore, from (4.5) (or (3.46)) we obtain that the density of the variance-optimal martingale measure admits the form (4.2).

Finally, the last equality implies that $N^*=N^0$, and one can write the optimal density in the following alternate form:

$$\mathcal{E}_t(M^{Q^*}) = \mathcal{E}_t\left(-\lambda\cdot M + \int_0^{\cdot}\frac{1}{\hat{c}+\hat{m}_{s-}}d\hat{m}_s\right) = \mathcal{E}_t(-\lambda\cdot M)\left(1+\frac{\hat{m}_t}{\hat{c}}\right).$$

Therefore, the value process is equal to

$$V_t = \frac{E(\mathcal{E}_{tT}^2(-\lambda\cdot M)(c+\hat{m}_T)^2/F_t)}{(c+\hat{m}_t)^2}.$$

Using (4.3) and the fact that $\hat{m}$ is a martingale under $Q(2)$, we obtain that

$$\frac{E(\mathcal{E}_{tT}^2(-\lambda\cdot M)(c+\hat{m}_T)^2/F_t)}{(c+\hat{m}_t)^2} = \frac{e^{-\langle\lambda\cdot M\rangle_t}E^{Q(2)}(c+\hat{m}_T/F_t)}{(c+\hat{m}_t)^2} = \frac{e^{-\langle\lambda\cdot M\rangle_t}}{(c+\hat{m}_t)}$$

$$= \frac{1}{E(\exp\{- < \lambda\cdot M >_{tT}\}/F_t)},$$

and the last term satisfies equation (3.35), since it coincides with the value process. □

Similar results were obtained in Mania, Santacroce, and Tevzadze [18] and Santacroce [21] for the minimal entropy and p-optimal martingale measures, respectively, under condition of continuity of the filtration.

Example. Let W be a standard Brownian motion defined on a complete probability space (Ω, F, F, P) with filtration. Let π be a standard Poisson process with intensity α, independent from W, defined on the same space. Assume that $F = (F_t, t \in [0,T])$ coincides with the P-augmented filtration generated by W and π.

Assume that there are two assets, a stock and a bond, traded on the market. For simplicity the bond price is supposed to be 1 at all times and the stock price dynamics is given by

$$dX_t = X_t(\mu_t dt + \sigma_t dW_t), \quad t \in [0,T]. \tag{4.10}$$

The market coefficients, the process μ of stock appreciation rate and the volatility σ, are progressively measurable with respect to F. We also require that for any $t \in [0,T]$ the volatility is nonsingular almost surely.

Straightforward calculations yield that in this case $\lambda = \mu X^{-1}\sigma^{-2}$,

$$\int_0^t \lambda_s dM_s = \int_0^t \theta_s dW_s, \qquad \langle \lambda \cdot M \rangle_t = \int_0^t \theta_s^2 ds$$

is the mean variance tradeoff, and $\theta = \sigma^{-1}\mu$ is the market price of risk.

By the Itô representation theorem, any locally square integrable martingale L adapted to the filtration F admits an integral representation

$$L_t = \int_0^t \psi_s dW_s + \int_0^t \bar{\psi}_s d(\pi_s - \alpha s) \tag{4.11}$$

for some F-predictable processes $(\psi, \bar{\psi})$ such that $\int_0^T \psi_t^2 dt + \int_0^T \bar{\psi}_t^2 dt < \infty$ a.s.

As before, we denote by $\mathcal{M}^e$ the set of equivalent martingale measures of X. From (2.4) and (4.11) the density of any martingale measure is expressed as

$$Z_t^\nu = \mathcal{E}_t\left(-\int_0^\cdot \theta_s dW_s + \int_0^\cdot \nu_s d(\pi_s - \alpha s)\right), \quad t \in [0,T], \tag{4.12}$$

for some F-predictable process ν such that $\int_0^T \nu_t^2 dt < \infty$. Let

$$\mathcal{K}_2(\sigma) = \{\nu : EZ_T^\nu = 1, E(Z_T^\nu)^2 < \infty\}.$$

Then the subclass $\mathcal{M}_2^e$ of equivalent martingale measures is given by

$$\mathcal{M}_2^e = \{P^\nu : dP^\nu/dP = Z_T^\nu, \nu \in \mathcal{K}_2(\sigma)\} \tag{4.13}$$

and condition (B) is equivalent to $\nu = 0 \in \mathcal{K}_2(\sigma)$.

For simplicity we assume the following.

(C) The mean-variance tradeoff is bounded; i.e., $\int_0^T ||\theta_s||^2 ds \le C$ a.s. for some $C > 0$.

Note that condition (C) implies that the minimal martingale measure exists and satisfies the reverse Hölder $R_2(P)$ inequality, since for any stopping time τ

$$E(\mathcal{E}^2_{\tau T}(-\lambda\cdot M)/F_\tau) = E(\mathcal{E}_{\tau T}(-2\lambda\cdot M)e^{\langle\lambda\cdot M\rangle_{\tau T}}|F_\tau) \le e^C. \tag{4.14}$$

Therefore, conditions (A) and (B*) are satisfied and it follows from Theorem 2 that the martingale measure Q^* is variance-optimal if and only if it is given by

$$M_t^{Q^*} = -\int_0^t \theta_s dW_s - \int_0^t \frac{1}{V_s}\bar{\varphi}_s d(\pi_s - \alpha s), \tag{4.15}$$

where the triple $(V,\varphi,\bar{\varphi})$ uniquely solves the backward stochastic differential equation (BSDE)

$$V_t = V_0 - \int_0^t \left(V_s\theta_s^2 - 2\theta_s\varphi_s - \frac{\alpha}{V_s}\bar{\varphi}_s^2\right) ds \tag{4.16}$$

$$+ \int_0^t \varphi_s dW_s + \int_0^t \bar{\varphi}_s d(\pi_s - \alpha s), \quad V_T = 1,$$

in the class of semimartingales satisfying (3.36).

Now we consider the abovementioned extreme cases for this example.

Case 1 (an "almost complete" model). If the market price of risk is adapted to the filtration F^W generated by the Brownian motion W, i.e., $\theta = \theta(t,W), t\in[0,T])$, then it follows from Example 1 of Pham, Rheinländer, and Schweizer [19] that the variance-optimal martingale measure coincides with the minimal martingale measure.

Let $X(2)$ be the process satisfying

$$dX_t(2) = X_t(2)(2\mu_t dt + \sigma_t dW_t), \quad t\in[0,T], \tag{4.17}$$

and denote by $Q(2)$ the measure defined by $dQ(2) = \mathcal{E}_T(-2\theta\cdot W)dP$. Under $Q(2)$ the process $X(2)$ satisfies the SDE

$$dX_t(2) = X_t(2)\sigma_t dW_t(2), \quad t\in[0,T],$$

where

$$W_t(2) = 2\int_0^t \theta(s,W)ds + W_t$$

is the Brownian motion with respect to the measure $Q(2)$ by Girsanov's theorem.

If (as in Example 1 of Pham, Rheinländer, and Schweizer [19]) the market price of risk θ is F^W-adapted, then by the representation property of W (and thus of $W(2)$ due to the Bayes rule) the random variable $e^{\int_0^T\theta_s^2 ds}$ admits an integral representation

$$e^{\int_0^T\theta_s^2 ds} = c + \int_0^T \gamma_s dW_s(2) \tag{4.18}$$

for some F^W-predictable γ with $\int_0^T\gamma_t^2 dt < \infty$. Note that if (4.18) is satisfied by some F-predictable γ, then the market price of risk θ need not be F^W-adapted, but condition (4.1) is satisfied (with $h = \gamma/\sigma$) and according to Proposition 4

the variance-optimal martingale measure coincides with the minimal martingale measure.

Case 2. Assume that the market price of risk is adapted to the filtration F^π generated by the Poisson process π, i.e.,

$$\theta = (\theta(t,\pi), t \in [0,T]).$$

Since θ is F^π-adapted, by the integral representation theorem there exists an F^π-adapted process g such that

$$\exp\left\{-\frac{1}{2}\int_0^T \theta_s^2 ds\right\} = c + \int_0^T g_s d(\pi_s - \alpha s).$$

Therefore, condition (4.3) is satisfied, and Proposition 5 implies that the variance-optimal martingale measure is of the form (4.2). Moreover, condition (4.3) is satisfied if g is F-predictable, and such a representation is also necessary for the variance-optimal martingale measure to admit the form (4.2).

Acknowledgment. We would like to thank the referees for valuable remarks and suggestions which led to many improvements in the paper.

LIPSCHITZ CONTINUITY OF OPTIMAL CONTROLS FOR STATE CONSTRAINED PROBLEMS*

GRANT N. GALBRAITH† AND RICHARD B. VINTER‡

Abstract. This paper provides new conditions under which optimal controls are Lipschitz continuous for dynamic optimization problems with functional inequality constraints, a control constraint expressed in terms of a general closed convex set and a coercive cost function. It is shown that the linear independence condition on active state constraints, present in the earlier literature, can be replaced by a less restrictive, positive linear independence condition that requires linear independence merely with respect to nonnegative weighting parameters. Smoothness conditions on the data, imposed in earlier work, are also relaxed. The new conditions for Lipschitz continuity of optimal controls are obtained by a detailed analysis of the implications of first order optimality conditions in the form of a nonsmooth maximum principle.

Key words. optimal control, Lipschitz controls, normal necessary conditions

1. Introduction.

Consider the following optimal control problem with functional inequality state constraints, distinguishing features of which are that the controlled differential equation (the dynamic constraint) is linear in the control variable and that an integral term is included in the cost function:

$$(\mathcal{P})\quad \begin{cases} \text{Minimize } l(x(S),x(T)) + \int_S^T L(t,x(t),u(t))\,dt \\ \text{over } x \in W^{1,1}([S,T],\mathbb{R}^n) \text{ and measurable } u:[S,T]\to\mathbb{R}^m \\ \text{satisfying} \\ \dot{x}(t) = f(t,x(t)) + G(t,x(t))u(t) \quad \text{for a.e. } t\in[S,T], \\ h_j(t,x(t)) \le 0 \quad \text{for all } t\in[S,T],\ j=1,\dots,r, \\ u(t)\in U \quad \text{for a.e. } t\in[S,T], \\ (x(S),x(T))\in C, \end{cases} \tag{1.1}$$

with data an interval $[S,T]$, functions $L:[S,T]\times\mathbb{R}^n\times\mathbb{R}^m\to\mathbb{R}$, $f:[S,T]\times\mathbb{R}\to\mathbb{R}^n$, $G:[S,T]\times\mathbb{R}^n\to\mathbb{R}^{n\times m}$, $h_j:\mathbb{R}\times\mathbb{R}^n\to\mathbb{R}$ for $j=1,\dots,r$, and closed sets $U\subset\mathbb{R}^m$ and $C\subset\mathbb{R}^n\times\mathbb{R}^n$.

(Here, $W^{1,1}([S,T],\mathbb{R}^n)$, abbreviated as $W^{1,1}$, is the space of absolutely continuous $\mathbb{R}^n$-valued functions on $[S,T]$.)

A control function is a measurable function $u:[S,T]\to\mathbb{R}^m$ such that $u(t)\in U$ for a.e. $t\in[S,T]$. A process (x,u) comprises a control function u and a $W^{1,1}$ function x satisfying the constraints of $(\mathcal{P})$. We say the process $(\bar{x},\bar{u})$ is a minimizer if it achieves the minimum. In this case, $\bar{u}$ and $\bar{x}$ are referred to as an optimal control and an optimal state trajectory (corresponding to $\bar{u}$), respectively.

This paper focuses on conditions on the data for the above control problem that guarantee Lipschitz continuity of the optimal control $\bar{u}$. The issue of minimizer regularity is important for several reasons. One is its relevance to computations; prior

knowledge of minimizer regularity influences the choice of discretization procedures since, typically, higher order schemes can achieve improved rates of convergence only when minimizers are sufficiently regular [6]. It also affects the selection of sample period in digital implementation of control strategies. It is further relevant to physical modeling, where a variational formulation of the underlying dynamics must be matched to observed phenomena, including regularity [1].

A key advance in the quest for conditions ensuring Lipschitz continuity of optimal controls in the presence of both state and control functional inequality constraints was provided in Hager's 1979 paper [7]. Here, Lipschitz continuity was established under hypotheses that, in the special case when no control constraints are imposed, include the following:

(i) The data is of class C^2, the cost integrand is jointly convex in both the (x, u) variables and uniformly coercive in the u variable, and the dynamics are affine with respect to the (x, u) variables.

(ii) There exists a process (x, u) such that u is continuous and x and u lie in the interiors of, respectively, the state and control constraint sets for each time ("interiority"), and $C = C_0 \times \mathbb{R}^n$ for some $C_0 \subset \mathbb{R}^n$(no right endpoint constraint).

(iii) There exists $\gamma > 0$ such that, for each $t \in [S, T]$,

$$\left| G^T(t, \bar{x}(t)) \sum_j \alpha_j \nabla_x h_j(t, \bar{x}(t)) \right| \geq \gamma \left(\sum_j |\alpha_j|^2 \right)^{\frac{1}{2}},$$

where $\nabla_x h_j$ is interpreted as a column vector and the summations are taken over values of the index j for which the state constraint is active ("linear independence of active state constraints").

Lipschitz continuity of optimal controls under these hypotheses was established in [7] by consideration of the implications of the maximum principle for optimal control problems with an affine state equation, a convex cost, and convex functional inequality constraints.

Malanowski [8] refined Hager's analysis to establish Lipschitz continuity of optimal controls under less restrictive conditions that allow dynamics nonlinear with respect to the state variable and a cost integrand which is possibly nonconvex with respect to the state variable. Alternative proofs and additional regularity properties of optimal controls under certain circumstances ("piecewise analyticity") were later proved by Dontchev and Hager [3] and Dontchev and Kolmanovsky [4].

This paper establishes Lipschitz continuity of optimal controls under hypotheses that are less restrictive that those invoked hitherto in a number of respects. The most significant improvement is that the linear independence hypothesis (iii) of Hager, present in different forms in [3], [8], is replaced by a less demanding *positive* linear independence hypothesis on the state constraints (hypothesis (H4) below). We also allow a general convex constraint on the control variable ("$u(t) \in U$ for some closed convex set U") in place of the collection of functional inequality constraints in previous work, and we relax differentiability hypotheses on the data in a number of respects.

The positive linear independence hypothesis that we employ has previously arisen in connection with conditions for normality of multiplier sets in nonlinear programming; specifically it provides a dual formulation of the Mangasarian–Fromowitz constraint qualification (see [9]). However, consideration of positive linear independence, in the context of optimal control regularity analysis, appears to be new.

The conditions for Lipschitz continuity of optimal controls are obtained with the help of a more detailed analysis of the implications of the maximum principle (now in a nonsmooth manifestation) than has previously been undertaken. A key step (Lemma 4.6) is to consider the properties of trajectory subarcs with the property that all state constraints active at some intermediate time are active also at the endtimes; the significance of such subarcs for regularity investigations was earlier emphasized by Hager [7, Thm. 2.1]. The analysis greatly simplifies if the control constraints are absent, the cost is quadratic in the u variable, and there is only one state constraint. (See [12, Ch. 11].)

We highlight also the role of the Legendre–Fenchel transform in our analysis. This provides an important explicit representation of the optimal control (see (4.1) below) in terms of the costate variables and state constraint multipliers.

Research efforts following Hager's 1979 paper were directed, in part, toward assembling a set of hypotheses ensuring regularity of minimizers, uniqueness of multipliers, and smooth dependence on parameters and constructing a framework for numerical solution techniques involving "dual" concepts. The present paper is of narrower focus, concentrating exclusively on conditions for regularity of optimal controls. If this alone is our goal, then the linear independence hypotheses of the earlier literature can be relaxed to positive linear independence. Note, however, that, under this positive linear independence hypothesis, the state constraint multipliers may fail to be unique.

Finally, we give some notation. $|\,.\,|$ denotes the Euclidean norm. The closed unit ball in Euclidean space is written B. $C^{\oplus}(S,T)$ denotes the space of nonnegative Borel measures on the Borel subsets of $[S,T]$. For a given subset $A \subset \mathbb{R}^k$, Ψ_A denotes the indicator function

$$\Psi_A(y) = \begin{cases} 0 & \text{if} \quad y \in A, \\ +\infty & \text{otherwise.} \end{cases}$$

We make use of two standard constructs from nonsmooth analysis (see, for example, [11] for full details), the normal cone and the subgradient, defined as follows.

DEFINITION 1.1. *Take a closed set $C \subset \mathbb{R}^n$ and a point $\bar{x} \in C$. We say that $y \in \mathbb{R}^n$ is a normal to C at $\bar{x}$ if there exist $y_i \to y$ and $x_i \to \bar{x}$ (in C) such that for all i,*

$$\langle y_i, x - x_i \rangle \le o(|x - x_i|)$$

for all $x \in C$. The normal cone to C at $\bar{x}$, written $N_C(\bar{x})$, is the set of all normals to C at $\bar{x}$. (It is also referred to as the limiting normal cone*.)*

Given a lower semicontinuous (lsc) function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$, we denote by $\partial f(\bar{x})$ the subgradient of f at $\bar{x}$ (also known as the limiting subgradient*), defined as*

$$\partial f(\bar{x}) := \{y : (y, -1) \in N_{\operatorname{epi} f}(\bar{x}, f(\bar{x}))\},$$

in which epi f *denotes the set* $\{(x,\alpha) \in \mathbb{R}^n \times \mathbb{R} : \alpha \ge f(x)\}$.

2. The maximum principle and normality. Denote by $\mathcal{H} : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R} \to \mathbb{R}$ the unmaximized Hamiltonian

$$\mathcal{H}(t,x,p,u,\lambda) = \langle p, f(t,x) + G(t,x)u \rangle - \lambda L(t,x,u). \tag{2.1}$$

Let $(\bar{x}, \bar{u})$ be a minimizing process. Under mild hypotheses and, in particular, under hypotheses (H1)–(H3) of section 3, necessary conditions of optimality, known as the

(state constrained) maximum principle [12], provide the following information about $(\bar{x}, \bar{u})$.

There exist "multipliers" $p \in W^{1,1}([S,T]; \mathbb{R}^n)$, $\mu_j \in C^{\oplus}(S,T)$ for $j = 1, \ldots, r$, and $\lambda \geq 0$ such that, writing

$$q(t) \;=\; p(t) + \sum_{j=1}^{r} \int_{[S,t)} \nabla_x h_j(s, \bar{x}(s)) \mu_j(ds), \tag{2.2}$$

we have

$$(p, \mu, \lambda) \;\neq\; (0,0,0), \tag{2.3}$$

$$-\dot{p}(t) \;\in\; \operatorname{con} \partial_x \mathcal{H}(\, t,\, \bar{x}(t),\, q(t^-),\, \bar{u}(t),\, \lambda\,) \text{ a.e. } t \in [S,T], \tag{2.4}$$

$$\begin{aligned} \mathcal{H}(\, t,\, \bar{x}(t),\, q(t^-),\, \bar{u}(t),\, \lambda\,) \;&=\; \max_{u \in U} \mathcal{H}(\, t,\, \bar{x}(t),\, q(t^-),\, u,\, \lambda\,) \\ &\text{a.e. } t \in [S,T], \end{aligned} \tag{2.5}$$

$$\operatorname{supp}\{\mu_j\} \;\subset\; \{t \;:\; h_j(t, \bar{x}(t)) = 0\} \quad \textit{for } j = 1, \ldots, r, \tag{2.6}$$

$$\begin{aligned} &\left(p(S), - \left[p(T) + \sum_{j=1}^{r} \int_{[S,T]} \nabla_x h_j(t, \bar{x}(t)) \mu_j(dt) \right] \right) \\ &\qquad \in \lambda \partial l(\bar{x}(S), \bar{x}(T)) + N_C(\bar{x}(S), \bar{x}(T)). \end{aligned} \tag{2.7}$$

A process for which these conditions are satisfied is said to be an *extremal*.

The methodology behind the ensuing analysis is to deduce regularity properties of optimal controls from the conditions of the maximum principle. It is inevitable then that some kind of hypothesis on the data for problem $(\mathcal{P})$ is imposed, ensuring that the maximum principle supplies useful information about the minimizer $(\bar{x}, \bar{u})$. This hypothesis is *normality*. If it is possible to satisfy the conditions of the maximum principle with a set of multipliers $(p, \mu_1, \ldots, \mu_r, \lambda)$ in which $\lambda = 0$, the maximum principle makes no reference to the cost function and degenerates into a relationship between the constraints. "Normality" means that this kind of degeneracy is excluded.

DEFINITION 2.1. *A process $(\bar{x}, \bar{u})$ is said to be a normal extremal if there exist $p \in W^{1,1}([S,T]; \mathbb{R}^n)$ and $\mu_j \in C^{\oplus}(S,T)$, $j = 1, \ldots, r$, such that the relationships (2.2)–(2.7) are satisfied with $\lambda = 1$.*

We address the question of when minimizers are normal extremals in section 5.

3. Conditions for Lipschitz continuity of normal extremals. We shall invoke the following hypotheses; reference is made here to the process $(\bar{x}, \bar{u})$ of interest. In the hypotheses, $\Omega \subset [S,T] \times \mathbb{R}^n$ is some "tube" about $\bar{x}$. That is,

$$\Omega \;=\; \{(t,x) \in [S,T] \times \mathbb{R}^n \;:\; |x - \bar{x}(t)| \leq \bar{\varepsilon}\}$$

(for some given $\bar{\varepsilon} > 0$). We denote by $\mathcal{J}(t, \bar{x})$ the collection of active state constraints at time t; that is,

$$\mathcal{J}(t, \bar{x}) \;=\; \{j \;:\; h_j(t, \bar{x}(t)) = 0\}.$$

(H1) *G, l, and f are locally Lipschitz continuous functions.*

(H2) *For $j = 1, \dots, r$, h_j is of class $\mathcal{C}^{1+}$ on Ω; i.e., h_j is continuously differentiable with locally Lipschitz continuous gradient.*

(H3) *U is a closed convex set. For each $(t, x) \in \Omega$, $L(t, x, .)$ is finite-valued, convex, and continuously differentiable. $L(t, x, .)$ is uniformly coercive in the sense that there exists a monotone function $\theta : [0, \infty) \to \mathbb{R}$, such that $\theta(s)/s \to \infty$ as $s \to \infty$ and*

$$L(t, x, v) \ > \theta(|v|) \quad \textit{for all } (t, x) \in \Omega \textit{ and } v \in U.$$

Both L and $\nabla_u L$ are locally Lipschitz continuous. $L(t, x, .)$ is strictly convex in the following uniform sense: for each $M > 0$ there is a constant $k_M > 0$, such that, for any $(t, x) \in \Omega$ and $u_1, u_2 \in M\mathbb{B}$, we have

$$\langle y_2 - y_1, u_2 - u_1 \rangle \geq k_M |u_2 - u_1|^2, \tag{3.1}$$

where $y_2 = \nabla_u L(t, x, u_2)$ and $y_1 = \nabla_u L(t, x, u_1)$.

(H4) *For every $t \in [S, T]$ and every set of nonnegative numbers $\{\alpha_j\}_{j \in \mathcal{J}(t, \bar{x})}$, not all zero, we have*

$$\sum_{j \in \mathcal{J}(t, \bar{x})} \alpha_j G^T(t, \bar{x}(t)) \nabla_x h_j(t, \bar{x}(t)) \notin \textit{span}\, N_U(\bar{u}(t)).$$

(For a subset $D \subset \mathbb{R}^k$, span D denotes the intersection of all linear subspaces of $\mathbb{R}^k$ that contain D.)

The stage is now set for statement of conditions for Lipschitz continuity of optimal controls.

THEOREM 3.1. *Let $(\bar{x}, \bar{u})$ be a normal extremal. Assume* (H1)–(H4). *Then $\bar{u}$ is Lipschitz continuous.*

Comments.

(a) Of course interest focuses primarily on cases when optimal processes are normal extremals, for then Theorem 3.1 gives conditions for Lipschitz continuity of optimal controls. We discuss conditions for normality in section 5. Note, however, that as far as applications to Hamiltonian mechanics are concerned, normal extremals (and related issues of regularity) are of direct interest, since the action principle interprets motions as normal extremals, which may fail to be minimizers of the action functional.

(b) The key difference between the hypotheses of Theorem 3.1 and those formerly invoked for regularity of optimal controls concerns the "nondegeneracy" of the state constraints. The linear independence hypothesis of [7] (condition (iii) of section 1) has been replaced by the positive linear independence hypothesis (H4). (H4) is a less restrictive hypothesis in which nonzero linear combinations of active state constraint function gradients are required to be nonzero *only for linear combinations with nonnegative weights.* A simple case when (iii) is always violated, but (H4) is possibly satisfied, is when there are two state constraint functions such that, at some time t' when they are both active, we have $\nabla_x h_1(t', \bar{x}(t')) = \alpha \nabla_x h_2(t', \bar{x}(t'))$ for some $\alpha > 0$. Another case is when the number of active state constraints exceeds the dimension of

the state space; here the gradients of the state constraint functions cannot be linearly independent, but they will be positively linear independent if the gradients are, in some sense, "unidirectional."

(c) Suppose that the cost integrand L can be decomposed as

$$L(t,x,u) = L_1(t,x) + L_2(t,x,u)\,.$$

Then the analysis of this paper, almost without change, allows us to deduce Lipschitz continuity of optimal controls when L_2 satisfies (H3) and L_1 satisfies the following condition: $L_1(t,x)$ is locally bounded, measurable in t for each x, and locally Lipschitz continuous in x uniformly in t. We draw attention to this refinement, since the optimal control problems with quadratic cost integrand

$$L(t,x,u) = x^T Q(t)x + u^T R(t)u$$

are of widespread interest. Our analysis establishes Lipschitz continuity of optimal controls for such problems when $Q(.)$ is merely measurable and essentially bounded. ($R(.)$ is required to be Lipschitz continuous and such that $R(t)$ is positive definite for all t.)

4. Proof of Theorem 3.1. Define the extended-real-valued function $L_0 : [S,T]\times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}\cup\{+\infty\}$

$$L_0(t,x,u) \;=\; L(t,x,u) + \Psi_U(u),$$

in which Ψ_U is the indicator function of the set U. Note that, since

$$\max_{u\in U}\mathcal{H}(t,\bar{x}(t),q(t^-),1) \;=\; \langle q(t^-), f(t,\bar{x}(t))\rangle + \max_{u\in\mathbb{R}^m}\{\langle q(t^-), G(t,\bar{x}(t))u\rangle - L_0(t,\bar{x}(t),u)\}\,,$$

we have from the "maximization of the Hamilitonian" condition (2.5) that

$$\begin{aligned}&\langle G^T(t,\bar{x}(t))q(t^-),\bar{u}(t)\rangle - L(t,\bar{x}(t),\bar{u}(t))\\ &\quad= \max_{u\in\mathbb{R}^m}\{\langle G^T(t,\bar{x}(t))q(t^-),u\rangle - L_0(t,\bar{x}(t),u)\} \quad \text{a.e. } t\in[S,T].\end{aligned}$$

By the rules governing subdifferentials of convex functions, this last condition implies that

$$\bar{u}(t) \;=\; \partial_y L_0^*(t,\bar{x}(t),G^T(t,\bar{x}(t))q(t^-)) \quad \text{a.e. } t\in[S,T]. \tag{4.1}$$

Here, $L_0^*(t,x,.):\mathbb{R}^m\to\mathbb{R}\cup\{+\infty\}$ is the Fenchel dual function of $L_0(t,x,.)$ for each (t,x).

The representation (4.1) of the optimal control in terms of the Fenchel dual function L_0^* has a crucial role in the following analysis. We pause to investigate some of its properties.

LEMMA 4.1.

(i) *For each $(t,x,y)\in\Omega\times\mathbb{R}^m$, $\partial_y L_0^*(t,x,y)$ is single-valued and continuously differentiable. (Write it henceforth $\nabla_y L_0^*(t,x,y)$.)*

(ii) *$(t,x,y)\to\nabla_y L_0^*(t,x,y)$ is locally Lipschitz continuous.*

Proof. Take any $(t,x)\in\Omega$ and $y\in\mathbb{R}^m$. The nonemptiness of $\partial_y L_0^*(t,x,y)$ follows from the representation of the subdifferential

$$\partial_y L_0^*(t,x,y) \;=\; \left\{u \;:\; u\cdot y - L_0(t,x,u) = \max_{v\in\mathbb{R}^m}\{v\cdot y - L_0(t,x,v)\}\right\}$$

and the coercivity of L (see hypothesis (H3)), which ensures existence of a maximizing v. Take any compact neighborhood $\mathcal{N}$ of (t,x) and a number $N>0$. Representation (4.1) and hypothesis (H3) also ensure the existence of $M>0$ such that

$$u' \in \partial_y L_0^*(t',x',y') \quad \text{and} \quad (t'x') \in \Omega,\ y' \in y + NB$$

imply

$$|u'| \ \leq \ M\,. \tag{4.2}$$

Let k_1 be a Lipschitz constant for L on $\mathcal{N} \times MB$. Choose arbitrary $(t',x') \in \mathcal{N}$ and $y' \in y + NB$. Choose also

$$u \in \partial_y L_0^*(t,x,y) \quad \text{and} \quad u' \in \partial_y L_0^*(t',x',y')\,.$$

By a fundamental property of "convex" subdifferentials,

$$y \in \partial_u L_0(t,x,u) \quad \text{and} \quad y' \in \partial_u L_0(t,x',u')\,.$$

However, since $\nabla_u L(t,x,.)$ is continuously differentiable,

$$\partial_u L_0(t,x,u) \ = \ \nabla_u L(t,x,u) + N_U(u)\,.$$

It follows that

$$y = \nabla_u L(t,x,u) + e, \quad y' = \nabla_u L(t',x',u') + e'$$

for some $e \in N_U(u)$ and $e' \in N_U(u')$. In consequence of the local Lipschitz continuity of $\nabla_u L$ and (4.2), there exists $k_1>0$, independent of the choice of t',x',y',u', such that

$$|\nabla_u L(t,x,u') - \nabla_u L(t',x',u')| \ \leq \ k_1 |(t',x') - (t,x)|\,.$$

Let $\tilde{y} = \nabla_u L(t,x,u') + e'$. Then

$$|y' - \tilde{y}| \ \leq \ k_1 |(t',x') - (t,x)|\,. \tag{4.3}$$

We have

$$\begin{aligned} |\tilde{y} - y||u' - u| \ \geq \ \langle \tilde{y} - y, u' - u\rangle &= \langle \nabla_u L(t,x,u') - \nabla_u L(t,x,u), u' - u\rangle \\ &\quad + \langle e', u' - u\rangle \ + \ \langle e, u - u'\rangle\,. \end{aligned}$$

However, there exists $k_2 > 0$ (independent of our choice of $((t',x'),y')$ in $\mathcal{N} \times (y + NB)$) such that

$$\langle \nabla_u L(t,x,u') - \nabla_u L(t,x,u), u' - u\rangle \ \geq \ k_2 |u' - u|^2\,.$$

Also, by the definition of the "convex" normal cone

$$\langle e', u' - u\rangle \geq 0 \quad \text{and} \quad \langle e, u - u'\rangle \geq 0\,.$$

It follows that

$$|u' - u| \ \leq \ k_2^{-1} |\tilde{y} - y|\,.$$

By (4.3) and the triangle inequality

$$\begin{aligned}|u'-u| &\le k_2^{-1}(|y'-y|+|y'-\tilde{y}|)\\ &\le k_2^{-1}(|y'-y|+k_1|(t',x')-(t,x)|)\\ &\le \max\{1,k_1\}k_2^{-1}\sqrt{2}|(t',x',y')-(t,x,y)|\,.\end{aligned}$$

This inequality implies that $\partial_y L_0^*(t,x,y)$ is single-valued. Since a convex function with a single-valued subdifferential is continuously differentiable, $\partial_y L_0^*(t,x,.)$ is continuously differentiable. The above inequality also implies that $(t,x,y)\to\partial_y L_0^*(t,x,y)$ is locally Lipschitz continuous.

LEMMA 4.2. *There exist $\bar{k}>0$ and $\varepsilon>0$ such that, for any $t\in[S,T]$, $y\in\mathbb{R}^m$, and $\{\alpha_j\}_{j=1}^r$ such that*

(4.4)
$\alpha_j\ge 0$ *for each j and $\alpha_j=0$ if $h_j(t',\bar{x}(t'))<0$ for all $t'\in(t-\varepsilon,t+\varepsilon)\cap[S,T]$,*

we have

$$\langle v,\nabla_y L_0^*(t,\bar{x}(t),y+v)-\nabla_y L_0^*(t,\bar{x}(t),y)\rangle \;\ge\; \bar{k}\left|\sum_j\alpha_j\right|^2,$$

where

$$v \;=\; G^T(t,\bar{x})\sum_j\alpha_j\nabla_x h_j(t,\bar{x}(t))\,.$$

Proof. To simplify notation, we shall write $\nabla_y L_0^*(t,x,y+v)$ as $\nabla_y L_0^*(y+v)$ and suppress the argument (t,x) in expressions involving $G(t,x)$, etc.

Take any $\{\alpha_j\}$ such that $\alpha_j\ge 0$ for each j. Write

$$u'=\nabla_y L_0^*(y+v)\quad\text{and}\quad u=\nabla_y L_0^*(y),$$

where v is as in the lemma. Then

$$y+v\in\partial_u L_0(u')\quad\text{and}\quad y\in\partial_u L_0(u)\,.$$

Since L is continuously differentiable (with respect to the control variable),

$$y+v=\nabla_u L(u')+e'\quad\text{and}\quad y=\nabla_u L(u)+e \tag{4.5}$$

for some $e'\in N_U(u')$ and $e\in N_U(u)$.

By the strong convexity hypothesis (H3), there exists $k_1>0$, independent of our choice of t, y and $\{\alpha_j\}$, such that

$$\langle\nabla_u L(u')-\nabla_u L(u),u'-u\rangle \;\ge\; k_1|\nabla_u L(u')-\nabla_u L(u)|^2\,.$$

From (4.5)

$$\langle v,u'-u\rangle+\langle e',u-u'\rangle+\langle e,u'-v\rangle \;\ge\; k_1\left|\sum_j\alpha_j G^T\nabla_x h_j-e'+e\right|^2.$$

By properties of the (convex) normal cone

$$\langle e', (u - u')\rangle \le 0 \quad \text{and} \quad \langle e, (u' - u)\rangle \le 0\,.$$

Further, it can be deduced from the constraint qualification (H4) that there exist k_2 and $\varepsilon > 0$, independent of our choice of (t, x, y), e', e and $\{\alpha_j\}$ satisfying (4.4), such that

$$\left|\sum_j \alpha_j G^T \nabla_x h_j + e' - e\right| \;\ge\; k_2 \left|\sum_j \alpha_j\right|\,.$$

Assembling these inequalities, we conclude that

$$\langle v, u' - u\rangle \;\ge\; \bar{k}\left|\sum_j \alpha_j\right|^2\,,$$

where $\bar{k} = k_1 k_2^2$. This is what the lemma asserts.

The following lemma, stated without proof, is a direct consequence of Lemma 4.1, the representation of $\bar{u}$ given by (4.1), the fact that $q(.)$ is a function of bounded variation, and the maximum principle conditions.

LEMMA 4.3. *We can choose $\bar{u}$ (from the equivalence class of a.e. equal functions) to have left and right limits at all points in (S, T) and one sided limits at the endpoints. (This version of) $\bar{u}$ is a bounded function. The functions $\bar{x}$ and p are Lipschitz continuous.*

Next we establish that μ has no atoms at interior points, and we list some related properties.

LEMMA 4.4. *μ has no atoms in (S, T). Consequently, $q(.)$ is continuous on (S, T) and has one sided limits at its endpoints. $\bar{u}$ is continuous on $[S, T]$ (strictly speaking, has a continuous version). For each $t \in (S, T)$ and $j \in \mathcal{J}(t, \bar{x})$, we have*

$$\nabla_t h_j(t, \bar{x}(t)) + \langle \nabla_x h_j(t, \bar{x}(t)), f(t, \bar{x}(t)) + G(t, \bar{x}(t))\bar{u}(t)\rangle \;=\; 0\,. \tag{4.6}$$

Proof. Take any $t \in (S, T)$. Choose $j \in \{1, 2, \ldots, r\}$. If $j \notin \mathcal{J}(t, \bar{x})$, then $\mu_j(\{t\}) = 0$, by the complementary slackness condition (2.6). If, on the other hand, $j \in \mathcal{J}(t, \bar{x}(t))$, then $h_j(t, \bar{x}(t)) = 0$. It follows that

$$\delta^{-1}(h_j(t + \delta, \bar{x}(t + \delta)) - h_j(t, \bar{x}(t))) \;\le\; 0$$

and

$$\delta^{-1}(h_j(t, \bar{x}(t)) - h_j(t - \delta, \bar{x}(t - \delta))) \;\ge\; 0$$

for δ sufficiently small. Passing to the limit as $\delta \downarrow 0$ and recalling that $\bar{u}$ has left and right limits, we obtain

$$\nabla_t h_j + \langle \nabla_x h_j, f + G\bar{u}(t^+)\rangle \;\le\; 0 \tag{4.7}$$

and

$$\nabla_t h_j + \langle \nabla_x h_j, f + G\bar{u}(t^-)\rangle \;\ge\; 0\,. \tag{4.8}$$

(Here, h_j, f, etc. are evaluated at $(t, \bar{x}(t))$.)

We deduce from these inequalities that

$$\langle \nabla_x h_j, G(\bar{u}(t^+) - \bar{u}(t^-)) \rangle \leq 0 .$$

Noting (4.1) and appropriately weighting and summing this inequality over all j's in $\mathcal{J}(t, \bar{x})$ give

$$\left\langle \sum_{j \in \mathcal{J}(t,\bar{x})} \mu_j(\{t\}) G^T \nabla_x h_j, \nabla_y L_0^*(G^T q(t^+)) - \nabla_y L_0^*(G^T q(t^-)) \right\rangle \leq 0 .$$

By Lemma 4.2, however, there exists $k_1 > 0$ such that

$$\left\langle \sum_{j \in \mathcal{J}(t,\bar{x})} \mu_j(\{t\}) G^T \nabla_x h_j, \nabla_y L_0^*(G^T q(t^+)) - \nabla_y L_0^*(G^T q(t^-)) \right\rangle \geq k_1 \left| \sum_j \mu_j(\{t\}) \right|^2 .$$

It follows that $\sum_j \mu_j(\{t\}) = 0$. We have shown that μ has no atoms in (S, T).

We conclude from the definition of $q(.)$ that $q(.)$ is continuous on (S, T) and has one sided limits at the endpoints. The same is true then of $\bar{u}$, in view of Lemma 4.1. By redefining $\bar{u}$ to take at its endpoint values one sided limits, we can arrange that $\bar{u}$ is continuous. Finally, we observe that (4.6) follows from (4.7) and (4.8).

In view of the preceding lemma, we can unambiguously write $\int_{[s,t]} \mu_j(d\sigma)$ as $\int_s^t \mu_j(d\sigma)$ for any $[s, t] \subset [S, T]$.

The next objective is to find a constant K such that, for any interval $[s, t] \subset [S, T]$, we have $\int_s^t \mu_j(d\sigma) \leq K|t - s|$.

The following lemma establishes such a bound in the special case when $[s, t]$ has the following property: all state constraints that are active at *some* point in the interior of $[s, t]$ are also active at *both* endpoints. To investigate this special case, it is helpful to introduce some additional notation:

$$\mathcal{A}_{[s,t]} := \{j \in \{1, \ldots, r\} : h_j(\tau, \bar{x}(\tau)) = 0 \text{ for some } \tau \in (s, t)\} .$$

(The right side will be recognized as "the set of indices corresponding to state constraints that are active at some point in (s, t).")

LEMMA 4.5. *There exists $K > 0$ such that, given any interval $[s, t] \subset (S, T)$ with the property*

$$h_j(s, \bar{x}(s)) = h_j(t, \bar{x}(t)) = 0 \quad \textit{for all } j \in \mathcal{A}_{[s,t]} ,$$

we have

$$\sum_j \int_s^t \mu_j(d\sigma) \leq K|t - s| \quad \textit{for all } j \in \mathcal{A}_{[s,t]}.$$

Proof. Suppose the assertions of the lemma are false. Then there exist $K_i \uparrow \infty$ and intervals $[s_i, t_i] \subset (S, T)$, $i = 1, 2, \ldots$, such that

$$h_j(s_i, \bar{x}(s_i)) = h_j(t_i, \bar{x}(t_i)) = 0 \quad \text{for all } j \in \mathcal{A}_{[s_i,t_i]} \tag{4.9}$$

and

$$\sum_j \int_{s_i}^{t_i} \mu_j(d\sigma) \;\geq\; K_i|t_i - s_i| \quad \text{for all } i\,. \tag{4.10}$$

By extracting a subsequence, we can arrange that there is a fixed index set $\mathcal{A}$ such that $\mathcal{A} = \mathcal{A}_{[s_i,t_i]}$ for all i. Notice that (4.10) implies that $|t_i - s_i| \to 0$ as $i \to \infty$. Since

$$\sum_j \int_{s_i}^{t_i} \mu_j(d\sigma) \;=\; \sum_j \int_{s_i}^{\frac{s_i+t_i}{2}} \mu_j(d\sigma) + \sum_j \int_{\frac{s_i+t_i}{2}}^{t_i} \mu_j(d\sigma)\,,$$

we can arrange, by extraction of a further subsequence, that either of the two cases (a) or (b) occur:

(a) $\sum_j \int_{s_i}^{\frac{s_i+t_i}{2}} \mu_j(d\sigma) \geq \frac{K_i}{2}|t_i - s_i|$ for all i;

(b) $\sum_j \int_{\frac{s_i+t_i}{2}}^{t_i} \mu_j(d\sigma) \geq \frac{K_i}{2}|t_i - s_i|$ for all i.

Let us first assume that (a) is true. For each i define

$$P_i \;=\; \int_{s_i}^{t_i} \sum_j \left(h_j(t_i, \bar{x}(t_i)) - h_j(s, \bar{x}(s))\right) \mu_j(ds)\,.$$

Note, however, that, for each $j \in \mathcal{A}$,

$$\text{supp}\{\mu_j\} \;\subset\; \{s \;:\; h_j(s, \bar{x}(s)) = 0\} \quad \text{and} \quad h_j(t_i, \bar{x}(t_i)) = 0\,.$$

It follows that

$$P_i = 0\,.$$

Writing

$$h_j(t_i, \bar{x}(t_i)) - h_j(s, \bar{x}(s)) \;=\; \int_s^{t_i} \left(\nabla_t h_j + \langle \nabla_x h_j, (f + G(\bar{u}))\rangle\right) dt$$

and carrying out an integration by parts give

$$P_i \;=\; \int_{s_i}^{t_i} \sum_j \int_{s_i}^{t} \mu_j(d\sigma) \left(\nabla_t h_j + \langle \nabla_x h_j, (f + G(\bar{u}(t)))\rangle\right) dt\,.$$

(Here and below, $\nabla_t h_j$, $\nabla_x h_j$, f, and G are evaluated at $(t, \bar{x}(t))$.) However,

$$P_i \;=\; a_i + b_i,$$

where

$$a_i = \int_{s_i}^{t_i} \sum_j \int_{s_i}^{t} \mu_j(ds) \left[\nabla_t h_j + \langle \nabla_x h_j, (f + Gu_i(t))\rangle\right] dt\,,$$

$$b_i = \int_{s_i}^{t_i} \sum_j \int_{s_i}^{t} \mu_j(ds) \langle \nabla_x h_j, G(\bar{u}(t) - u_i(t))\rangle dt\,.$$

In these formulae,

$$u_i \;=\; \nabla_y L_0^* \left(t, \bar{x}(t), G^T \left[p(t) + \int_{[S,t]} \sum_j \nabla_x h_j(s, \bar{x}(s)) \mu_j(ds) \right.\right.$$
$$\left.\left. - \sum_j \nabla_x h_j(t, \bar{x}(t)) \int_{s_i}^t \mu_j(ds) \right] \right) dt\,.$$

Taking note of (4.6) and the local Lipschitz continuity of f, $\nabla_t h_j$, and $\nabla_x h_j$, we deduce from Lemmas 4.1 and 4.3 that there exists $k_1 > 0$ (independent of i) such that, for each j and $t \in [s_i, t_i]$,

$$|\nabla_t h + \langle \nabla_x h_j, (f + G u_i(t)) \rangle| \;\le\; k_1 \left(1 + \sum_j \int_{s_i}^{t_i} \mu_j(ds) \right) (t - s_i).$$

We conclude that

$$a_i \;\ge\; -\frac{k_1}{2} \left(\sum_j \int_{s_i}^{t_i} \mu_j(ds) \right) \left(1 + \sum_j \int_{s_i}^{t_i} \mu_j(ds) \right) (t_i - s_i)^2\,.$$

On the other hand, Lemma 4.2 tells us that there exists $k_2 > 0$, independent of i, such that

$$b_i \ge k_2 \int_{s_i}^{t_i} \left| \sum_j \int_{s_i}^t \mu_j(ds) \right|^2 dt$$
$$\ge k_2 \left| \sum_j \int_{s_i}^{\frac{s_i + t_i}{2}} \mu_j(ds) \right|^2 \left(\frac{t_i - s_i}{2} \right).$$

Bearing in mind that

$$\sum_j \int_{s_i}^{\frac{s_i + t_i}{2}} \mu_j(ds) \;\ge\; \frac{1}{2} \sum_j \int_{s_i}^{t_i} \mu_j(ds) \;\ge\; \frac{1}{2} K_i |t_i - s_i|\,,$$

we deduce that

$$a_i + b_i \;\ge\; -\frac{k_1}{2} K_i |t_i - s_i|^3 (1 + K_i |t_i - s_i|) \;+\; \frac{k_2}{8} K_i^2 (t_i - s_i)^3\,.$$

However, the expression on the right is positive for i sufficiently large. This is not possible since $P_i = a_i + b_i = 0$ for all i. The case (b) is treated in analogous fashion by considering the equation $Q_i = 0$, where

$$Q_i \;=\; \sum_j \int_{s_i}^{t_i} \sum_j \left(h_j(s, \bar{x}(s)) - h_j(s_i, \bar{x}(s_i)) \right) \mu_j(ds)\,.$$

Now define

$$\mathcal{N}_{[s,t]} \;:=\; \text{cardinality}(\mathcal{A}_{[s,t]})\,.$$

For $\bar{r} \in \{0, \dots, r\}$ denote by $(H_{\bar{r}})$ the following condition.

$(H_{\bar{r}})$ There exists $K_{\bar{r}} \geq 0$ with the following property: given any subinterval $[s,t] \subset [S,T]$ such that $\mathcal{N}_{[s,t]} \leq \bar{r}$, we have

$$\sum_j \int_{[s,t]} \mu_j(d\sigma) \ \leq \ K_{\bar{r}}|t-s|.$$

LEMMA 4.6. *Condition $(H_{\bar{r}})$ is satisfied for $\bar{r} = r$.*

Proof. $(H_{\bar{r}})$ is satisfied with $\bar{r} = 0$ since, in this case, $\mu_j = 0$ for all $j \in \{1, \dots, r\}$. Fix $\bar{r} \in \{0, \dots, r-1\}$, and assume that

$$(H_{\bar{r}}) \text{ is true.}$$

We shall show that $(H_{\bar{r}+1})$ is true. The assertions of the lemma then follow by induction.

Take any $[s,t] \subset [S,T]$ such that $\mathcal{N}_{[s,t]} \leq \bar{r}+1$.We must find $K_{\bar{r}+1}$ (independent of $[s,t]$) such that

$$\sum_j \int_{[s,t]} \mu_j(d\sigma) \ \leq \ K_{\bar{r}+1}|t-s| \,. \tag{4.11}$$

We can assume that $\mathcal{N}_{[s,t]} = \bar{r}+1$, for otherwise (4.11) is true with $K_{\bar{r}+1} = K_{\bar{r}}$. Our next goal is to find a point $\bar{s} \in [s,t]$ such that

$$\sum_j \int_{[s,\bar{s}]} \mu_j(d\sigma) \ \leq \ K_{\bar{r}}|\bar{s}-s| \tag{4.12}$$

and either of the following two conditions holds:

(a) $\bar{s} = t$, or

(b) $h_j(\bar{s}, \bar{x}(\bar{s})) = 0$ for all $j \in \mathcal{A}_{[s,t]}$.

If $h_j(s, \bar{x}(s)) = 0$ for all $j \in \mathcal{A}_{[s,t]}$, we can set $\bar{s} = s$, and (4.12) and condition (b) are satisfied. So we can assume that

$$h_j(\bar{s}, \bar{x}(\bar{s})) < 0 \text{ for some } j \in \mathcal{A}_{[s,t]}. \tag{4.13}$$

We now construct an increasing sequence $\{s_i\} \subset (s,t]$ that terminates after N steps, in which case we set $\bar{s} = s_N$, or which is an infinite sequence, in which case we set $\bar{s} = \lim_{i\to\infty} s_i$. In either case, $\bar{s}$ will have the desired properties, as we now confirm.

Define

$$s_1 \ = \ \sup_{\sigma \in (s,t)} \{\sigma \,:\, \mathcal{N}_{[s,\sigma]} \leq \bar{r}\} \,.$$

By condition (4.13), $s_1 > s$. We have

$$\sum_j \int_{[s,s_1]} \mu_j(d\sigma) \ \leq \ K_{\bar{r}}|s_1 - s| \,.$$

If $s_1 = t$, set $\bar{s} = s_1$. Then condition (a) is satisfied, and so is (4.12), by the induction hypothesis. If $s_1 < t$ and

$$h_j(s_1, \bar{x}(s_1)) \ = \ 0 \quad \text{for all } j \in \mathcal{A}_{[s,t]},$$

also set $\bar{s} = s_1$. In this case condition (b) and (4.12) are satisfied. Otherwise, $s_1 < t$ and

$$h_{\bar{j}}(s_1, \bar{x}(s_1)) \ < \ 0 \quad \text{for some } \bar{j} \in \mathcal{A}_{[s,t]}\,.$$

In this case define $s_2 (> s_1)$ to be

$$s_2 \ = \ \sup_{\sigma \in (s_1, t)} \{\sigma \ : \ \mathcal{N}_{[s_1,\sigma]} \leq \bar{r}\}. \tag{4.14}$$

By the induction hypothesis $\sum_j \int_{[s_1,s_2]} \mu_j(ds) \leq \ K_{\bar{r}}|s_2 - s_1|$, from which we conclude that

$$\sum_j \int_{[s,s_2]} \mu_j(d\sigma) \ \leq \sum_j \int_{[s,s_1]} \mu_j(d\sigma) + \sum_j \int_{[s_1,s_2]} \mu_j(ds) \leq \ K_{\bar{r}}|s_2 - s|\,.$$

Observe also that, if $s_2 < t$,

$$\max_{\sigma \in [s_1,s_2]} h_j(\sigma, \bar{x}(\sigma)) \ = \ 0 \quad \text{for all } j \in \mathcal{A}_{[s,t]},$$

for otherwise s_2 cannot provide the supremum in (4.14). If $s_2 = t$, set $\bar{s} = s_2$. In this case (4.12) and condition (a) are satisfied. If $s_2 < t$ and $h_j(s_2, \bar{x}(s_2)) = 0$ for all $j \in \mathcal{A}_{[s,t]}$, set $\bar{s} = s_2$; (4.12) and condition (b) are satisfied.

If neither condition (a) nor (b) are satisfied (when $\bar{s} = s_2$), construct $s_3 \in (s_2, t]$, and so on.

This procedure either provides an element $\bar{s} \in (s, t]$ satisfying (4.12) and either condition (a) or (b) in a finite number of steps or generates an infinite increasing sequence $\{s_i\}$ in $(s, t]$. In the latter case

$$\sum_j \int_{[s,s_i]} \mu_j(d\sigma) \leq \ K_{\bar{r}}|s_i - s| \quad \text{for all } i$$

and

$$\max_{s_i \leq \sigma \leq s_{i+1}} h_j(\sigma, \bar{x}(\sigma)) \ = \ 0 \quad \text{for all } j \in \mathcal{A}_{[s,t]}\,.$$

Let $\bar{s} = \lim_{i \to \infty} s_i$. We have $\bar{s} \in (s, t]$. Furthermore, the preceding relationships ensure that

$$\sum_j \int_{[s,\bar{s}]} \mu_j(d\sigma) \leq \ K_{\bar{r}}|\bar{s} - s| \tag{4.15}$$

and

$$h_j(\bar{s}, \bar{x}(\bar{s})) \ = \ 0 \quad \text{for all } j \in \mathcal{A}_{[s,t]}\,.$$

Similarly, working from the right endpoint of $[s, t]$, we can find $\bar{t} \in [s, t]$ such that

$$\sum_j \int_{[\bar{t},t]} \mu_j(d\sigma) \leq \ K_{\bar{r}}|t - \bar{t}| \tag{4.16}$$

and either

(a′) $\bar{t} = s$ or

(b′) $h_j(\bar{t}, \bar{x}(\bar{t})) = 0$ for all $j \in \mathcal{A}_{[s,t]}$.

If either (a) or (a′) are true, then (4.11) is true with $K_{\bar{r}+1} = K_{\bar{r}}$. If, on the other hand, $\bar{s} < t$ and $s < \bar{t}$, then $\bar{s} \leq \bar{t}$ and

$$h_j(\bar{s}, \bar{x}(\bar{s})) = h_j(\bar{t}, \bar{x}(\bar{t})) \;=\; 0 \quad \text{for all } j \in \mathcal{A}_{[s,t]}.$$

If follows from Lemma 4.5 that, for some $K > 0$ (that does not depend on $[s,t]$),

$$\sum_j \int_{[\bar{s},\bar{t}]} \mu_j(d\sigma) \;\leq\; K|\bar{t} - \bar{s}|\,.$$

However, then, by (4.15) and (4.16),

$$\sum_j \int_{[s,t]} \mu_j(d\sigma) \;=\; \sum_j \int_{[s,\bar{s}]\cup[\bar{s},\bar{t}]\cup[\bar{s},t]} \mu_j(d\sigma) \;\leq\; \tilde{K}|t - s|\,,$$

where $\tilde{K} = \max\{K, K_r\}$. Since $\tilde{K}$ does not depend on $[s,t]$, the lemma is proved.

Completion of the proof of Theorem 3.1 is now straightforward. Since

$$\text{cardinality}(\mathcal{A}_{[S,T]}) \;\leq\; r,$$

we deduce from Lemma 4.6 that there exists $K_r > 0$ such that, for every $[s,t] \subset [S,T]$,

$$\sum_j \int_{[s,t]} \mu_j(d\sigma) \;\leq\; K_r|t - s|\,.$$

Since $p(.)$ is Lipschitz continuous,

$$q(t) \;\left(:= p(t) + \int_{[S,t)} \sum_j \nabla_x h_j(s, \bar{x}(s))\mu_j(ds) \right)$$

is also Lipschitz continuous on (S,T).

It merely remains to conclude from Lemma 4.1 that the version of $\bar{u}$ chosen to coincide with the function $t \to \partial_y L_0^*(t, \bar{x}(t), G^T(t, \bar{x}(t))q(t))$ on the interior of $[S,T]$ and to assume the function's one sided limits at the endpoints, is Lipschitz continuous.

5. Conditions for normality. Theorem 3.1 provides conditions for Lipschitz continuity of optimal controls in circumstances when minimizers are normal extremals. It is of interest then to know when minimizers can be interpreted as normal extremals.

In this section we give two "constraint qualifications" (i.e., conditions on the data relating to the dynamic, pathwise, and endpoint constraints of problem $(\mathcal{P})$) that, when added to (H1)–(H4), ensure normality.

The first involves the (Clarke) generalized Jacobian: take $y \in \mathbb{R}^k$ and a function $\psi : \mathbb{R}^n \to \mathbb{R}^k$ which is Lipschitz continuous on a neighborhood of y. The generalized Jacobian $\text{co}\,\partial\psi(y)$ of ψ at y is defined to be

$$\text{co}\,\partial\psi(y) \;:=\; \text{co}\{\xi \in \mathbb{R}^{k\times n} \;:\; \exists y_i \;\to y\,,\, \xi_i \to \xi,\; \text{and } \xi_i = \nabla\psi(y_i) \text{ for all } i\}$$

(In this definition, $\nabla\psi(y_i)$ refers to the Fréchet derivative. There is no ambiguity of notation, since, in the case $k = 1$, $\text{co}\,\partial\psi(y)$ coincides with the convex hull of the

subdifferential $\partial\psi(y)$ defined in section 1 (see [2]).) $\operatorname{co}\partial_x\psi(y)$ denotes the (partial) generalized Jacobian of a function of several variables including x, with respect to the x variable alone.

Define

$$C_1 := \{x \in \mathbb{R}^n : (\bar{x}(S), x) \in C\}. \tag{5.1}$$

$(\mathrm{CQ})_1$ *For every measurable function* $A(.) : [S,T] \to \mathbb{R}^{n\times n}$ *such that*

$$A(t) \in co\,\partial_x(f(t,x) + G(t,x)\bar{u}(t))|_{x=\bar{x}(t)} \quad a.e.\ t \in [S,T],$$

there exists a measurable function $u : [S,T] \to \mathbb{R}^m$ *such that*

$$\nabla_t h_j(t,\bar{x}(t)) + \langle \nabla_x h_j(t,\bar{x}(t)), y_u(t)\rangle < 0 \quad \text{for all } j \in \mathcal{J}(t,\bar{x}) \text{ and } t \in [S,T] \tag{5.2}$$

and

$$\langle v, y_u(T)\rangle < 0 \quad \text{for all nonzero vectors } v \in N_{C_1}(\bar{x}(T)),$$

where y_u *is the solution to*

$$\dot{y}_u(t) = A(t)y_u(t) + G(t,\bar{x}(t))(u(t) - \bar{u}(t)) \quad a.e.\ t \in [S,T], \tag{5.3}$$

$$y_u(S) = 0. \tag{5.4}$$

$(\mathrm{CQ})_1$ can be regarded as a generalization of the Slater-type "interiority" hypothesis invoked by Hager [7] to allow for nonlinear nonsmooth dynamics.

$(\mathrm{CQ})_1$ falls somewhat short of providing directly verifiable hypotheses for normality, since it involves assessing controllability properties of a time-varying linear system, in the presence of pathwise control and state constraints.

The next constraint qualification places merely pointwise restrictions on the data and is accordingly of a more directly verifiable nature. The application of this alternative constraint qualification is restricted, however, to optimal control problems for which the right endpoint of state trajectories are free. On the other hand, it covers problems for which C takes the form

$$C = \{x_0\} \times \mathbb{R}^n$$

("fixed left endpoint and free right endpoint") and for which

$$h_j(S, x_0) = 0$$

("fixed initial state located in the state constraint set boundary"). This is a case of interest in which $(\mathrm{CQ})_1$ is never satisfied. (Equation (5.2) is violated at $t = 0$.)

$(\mathrm{CQ})_2$ *The endpoint constraint set takes the form* $C = C_0 \times \mathbb{R}^n$ *for some* $C_0 \subset \mathbb{R}^n$. *The functions* h_k, $i = 1,\dots,r$ *are twice continuously differentiable. There exist constants* $\varepsilon, \delta, \gamma > 0$ *and a continuous function* $\nu : [S,T] \times \mathbb{R}^n \to U$ *such that if* $(t,\xi) \in [S,T] \times \mathbb{R}^n$ *is any point satisfying*

$$|\xi - \bar{x}(t)| \le \varepsilon \quad \text{and} \quad h_j(t,\bar{x}(t)) \ge -\delta \quad \text{for some } j,$$

then

$$\nabla_t h_j(t,\xi) + \langle \nabla_x h_j(t,\xi), f(t,\xi) + G(t,\xi)\nu(t,\xi)\rangle < -\gamma.$$

The following proposition provides conditions for optimal controls to be Lipschitz continuous, in which the "$(\bar{x}, \bar{u})$ is a normal extremal" hypothesis of Theorem 3.1 is replaced by either of the above constraint qualifications.

PROPOSITION 5.1. *Let $(\bar{x}, \bar{u})$ be a minimizer for $(\mathcal{P})$. Assume Hypotheses* (H1)–(H4) *are satisfied. Assume also that either* $(\mathrm{CQ})_1$ *or* $(\mathrm{CQ})_2$ *is satisfied. Then $\bar{u}$ is Lipschitz continuous.*

Proof. Take $(\bar{x}, \bar{u})$ to be a minimizer for $(\mathcal{P})$. Then $(\bar{x}, \bar{u})$ is a minimizer also for the related optimal control problem (we label it $(\mathcal{Q})$), in which the endpoint constraint set C is replaced by $\{\bar{x}(S)\} \times C_1$, where C_1 was defined by (5.1).

If $(\mathrm{CQ})_2$ is satisfied (together with (H1)–(H4)), then it is known (see [10]) that the minimizer $(\bar{x}, \bar{u})$ is a normal extremal. The fact that $\bar{u}$ is Lipschitz continuous (after, if required, adjustment on a null-set) now follows from Theorem 3.1, applied to $(\bar{x}, \bar{u})$, regarded as a minimizer for $(\mathcal{Q})$.

Suppose next that condition $(\mathrm{CQ})_1$ (together with (H1)–(H4)) is satisfied. Then the conditions are met under which $(\bar{x}, \bar{u})$, regarded as a minimizer for $(\mathcal{Q})$, satisfies the maximum principle (see, e.g., [12, Chapter 6]). We conclude that there exist $p \in W^{1,1}([S,T]; \mathbb{R}^n)$, $\mu_j \in C^{\oplus}(S,T)$ for $j = 1, \ldots, r$, and $\lambda \geq 0$ such that, writing

$$q(t) = p(t) + \sum_{j=1}^{r} \int_{[S,t)} \nabla_x h_j(s, \bar{x}(s)) \mu_j(ds), \tag{5.5}$$

conditions (2.3), (2.5), and (2.6) are satisfied, and also

$$-\dot{p}(t) = A^T(t) p(t), \tag{5.6}$$

$$-\left(p(T) + \int_{[S,T]} \nabla_x h_j(t, \bar{x}(t)) \mu_j(dt) \right) = \lambda \eta + v \tag{5.7}$$

for some

$$\eta \in \partial_{x_1} l(\bar{x}(S), x_1)|_{x_1 = x(\bar{T})} \quad \text{and} \quad v \in N_{C_1}(\bar{x}(T)) \,.$$

We now show that these conditions can be satisfied only if $\lambda > 0$. Since multipliers can be scaled by an arbitrary positive constant, this will imply that the maximum principle (for $(\bar{x}, \bar{u})$, regarded as a solution to $(\mathcal{Q})$) is satisfied with $\lambda = 1$, i.e., $(\bar{x}, \bar{u})$ is a normal extremal for $(\mathcal{Q})$. The Lipschitz continuity of $\bar{u}$ will then follow from Theorem 3.1.

Suppose, to the contrary, that $\lambda = 0$. Then

$$((\mu_1, \ldots, \mu_r), p) \neq ((0, \ldots, 0), 0) \,.$$

Define

$$a(u(.)) \;:=\; \int_S^T \langle q(t), G(t, \bar{x}(t))(u(t) - \bar{u}(t)) \rangle dt \,.$$

Here, $u(.)$ is the function whose existence is hypothesized in $(\mathrm{CQ})_1$. From (2.5) we deduce that

$$a(u(.)) \;\geq\; 0 \,.$$

However, an analysis along the lines of that in [5] permits us to deduce from (2.5), (2.6), and (5.7) that

(5.8)
$$(0 \leq)\ a(u(.)) \ = \ \int_{[S,T]} \sum_{j=1}^{r} (\nabla_t h_j(t, \bar{x}(t)) + \langle \nabla_x h_j(t, \bar{x}(t)), y_u(t) \rangle) \mu_j(dt) + \langle v, y_u(T) \rangle \, .$$

We know that, since it is assumed that $\lambda = 0$,

$$((\mu_1, \ldots, \mu_r), p) \neq 0 \, .$$

However, if $\mu_j \neq 0$ for some j, the right side of (5.8) is strictly negative, which is a contradiction. So suppose $\mu_j = 0$ for all j. In this case $p \neq 0$. We must have $v \neq 0$ (since otherwise by (5.6), $p \equiv 0$). However, then, once again, we arrive at the contradiction that the right side of (5.8) is strictly negative.

NONTANGENCY-BASED LYAPUNOV TESTS FOR CONVERGENCE AND STABILITY IN SYSTEMS HAVING A CONTINUUM OF EQUILIBRIA*

SANJAY P. BHAT† AND DENNIS S. BERNSTEIN‡

Abstract. This paper focuses on the stability analysis of systems having a continuum of equilibria. Two notions that are of particular relevance to such systems are convergence and semistability. Convergence is the property whereby every solution converges to a limit point that may depend on the initial condition. Semistability is the additional requirement that all solutions converge to limit points that are Lyapunov stable. We give new Lyapunov-function-based results for convergence and semistability of nonlinear systems. These results do not make assumptions of sign definiteness on the Lyapunov function. Instead, our results use a novel condition based on nontangency between the vector field and invariant or negatively invariant subsets of the level or sublevel sets of the Lyapunov function or its derivative and represent extensions of previously known stability results involving semidefinite Lyapunov functions. To illustrate our results we deduce convergence and semistability of the kinetics of the Michaelis–Menten chemical reaction and the closed-loop dynamics of a scalar system under a universal adaptive stabilizing feedback controller.

1. Introduction.

This paper focuses on the stability analysis of systems that have a continuum of equilibria. Examples of such systems include mechanical systems having rigid-body modes and isospectral matrix dynamical systems [15]. Such systems also arise in chemical kinetics, compartmental modeling, and adaptive control. Since every neighborhood of a nonisolated equilibrium contains another equilibrium, a nonisolated equilibrium cannot be asymptotically stable. Thus asymptotic stability is not the appropriate notion of stability for systems having a continuum of equilibria. However, given a system that has a continuum of equilibria, it is still natural to ask if the trajectories converge to limit points and if the limit points are Lyapunov stable. These questions lead us to consider the properties of *convergence* and *semistability*. For linear systems, semistability was originally defined in [9] and applied to matrix second-order systems in [3]. In the present paper, we extend the notion of semistability to nonlinear systems. Preliminary versions of some of the results of this paper appeared in [5, 6].

Convergence is the notion that every trajectory of the system converges to a limit point. The limit point, which is necessarily an equilibrium, depends in general on the initial conditions. In a convergent system, the limit points of trajectories may or may not be Lyapunov stable. Semistability is the additional requirement that trajectories converge to limit points that are Lyapunov stable. More precisely, an equilibrium is semistable if it is Lyapunov stable, and every trajectory starting in a neighborhood

of the equilibrium converges to a (possibly different) Lyapunov stable equilibrium. It can be seen that, for an equilibrium, asymptotic stability implies semistability, while semistability implies Lyapunov stability.

The relationship between Lyapunov stability, semistability, and asymptotic stability can be understood by considering the motion of a particle translating along a fixed direction. Such a particle, when moving under the action of a linear elastic spring, possesses a unique equilibrium, which is Lyapunov stable. In the additional presence of viscous damping, all motions of the particle converge to the unique equilibrium state, which is thus asymptotically stable. On the other hand, a particle moving under the action of viscous damping in the absence of a position-dependent restoring force can remain at rest in any position and thus exhibits a continuum of equilibria, each of which is Lyapunov stable. All motions of such a particle converge to rest, and the equilibrium that the particle converges to is determined by the initial position and velocity of the particle. The motion of the particle is thus convergent, while every equilibrium of the dynamics is semistable.

Besides the damped motion of a particle, there are several applications which involve systems having a continuum of equilibria, and in which semistability is the appropriate notion of stability. For example, we can consider the stability of the lateral dynamics of an aircraft in level trimmed flight. For disturbances affecting the angle between the longitudinal axis and the velocity vector, the vertical tail is designed to influence yaw so as to cause the sideslip angle to converge to zero. However, the heading angle will not generally converge to its predisturbance value. The offset in the final heading angle is an indication of the existence of a continuum of semistable equilibria.

Another application of semistability involves the kinetics of chemical reactions. While periodic or chaotic behavior can occur in chemical reactions [27], it is of interest to determine conditions under which the concentrations of the reacting species converge. In this case, the limiting concentrations are not completely determined by the dynamics but depend upon the initial concentrations as well. The stability of chemical kinetics with respect to a stoichiometric subspace is considered in [11, 12, 28], while [4] applies Lyapunov theory to study the semistability of mass action chemical kinetics.

Chemical reactions are a special case of a more general class of systems known as compartmental systems, which involve mass or energy balance [18]. Compartmental systems arise in biomedical, environmental, economic, power, and thermodynamic applications. Since compartmental systems possess a continuum of equilibria, semistability is the appropriate notion of stability.

In control applications, it is often desirable to design the control system so that the closed-loop system, in the absence of exogenous inputs (commands and disturbances), has an equilibrium that is asymptotically stable. For such designs, semistability is not needed. However, adaptive controllers [17, 22, 23, 24] involve feedback gains that evolve in response to the plant trajectories; that is, the limiting values of the gains depend on the initial condition of the plant states. An adaptive closed-loop system is thus not asymptotically stable, yet convergence and Lyapunov stability of the plant/gain equilibria, that is, semistability, is desirable.

In all of the applications above, it is of interest to determine the convergence and semistability properties of the system. Accordingly, we wish to obtain Lyapunov tests for convergence and semistability.

It is obvious that if a system is convergent, then all of its trajectories converge

to the set of equilibria. However, as the following example shows, the converse is not true.

Example 1.1. Consider the system $\dot{y}(t) = f(y(t))$, where $f : \mathbb{R}^2 \to \mathbb{R}^2$ is the continuous vector field given by

$$\begin{aligned} f(x) = {} & \operatorname{sign}(x_1^2 + x_2^2 - 1)|x_1^2 + x_2^2 - 1|^{\alpha} f_r(x) \\ & + \operatorname{sign}(x_1^2 + x_2^2 - 1)|x_1^2 + x_2^2 - 1|^{\beta} f_\theta(x), \end{aligned} \tag{1}$$

with $\alpha, \beta \geq 1$ and the vector fields f_r and f_θ given by

$$f_r(x) = \begin{bmatrix} -x_1 \\ -x_2 \end{bmatrix}, \ f_\theta(x) = \begin{bmatrix} x_2 \\ -x_1 \end{bmatrix}. \tag{2}$$

The vector fields f_r and f_θ point in the radial and circumferential directions, respectively, and thus the parameters α and β determine the rates at which solutions move in these directions, respectively. This can be seen more clearly by rewriting (1) in terms of polar coordinates $r = \sqrt{x_1^2 + x_2^2}$ and $\theta = \tan^{-1}(x_2/x_1)$ as

$$\dot{r} = -r\operatorname{sign}(r^2 - 1)|r^2 - 1|^{\alpha}, \tag{3}$$

$$\dot{\theta} = -\operatorname{sign}(r^2 - 1)|r^2 - 1|^{\beta}. \tag{4}$$

It can be seen from (3) and (4) that the set of equilibria $f^{-1}(0)$ consists of the origin $x = 0$ and the unit circle $\mathrm{S}^1 = \{x \in \mathbb{R}^2 : x_1^2 + x_2^2 = 1\}$. All solutions of the system starting from nonzero initial conditions $y(0)$ that are not on the unit circle approach the unit circle. Solutions starting outside the unit circle spiral in clockwise toward the unit circle, while solutions starting inside the unit circle spiral out counterclockwise. Consequently, all solutions are bounded, and, for every choice of α and β, all solutions converge to the set of equilibria. However, if $\alpha \geq \beta + 1$, then the system is not convergent. This can be seen by using (3) and (4) to obtain

$$\frac{dr}{d\theta} = r|r^2 - 1|^{\alpha - \beta}. \tag{5}$$

For initial values $r(0) > 1$, solutions of (5) converge to the equilibrium value $r = 1$ for decreasing θ, while, for initial values $r(0) < 1$, solutions converge to $r = 1$ for increasing θ. For $\alpha \geq \beta + 1$, the right-hand side of (5) is locally Lipschitz in r. Consequently, (5) has a unique maximally defined solution given by $r \equiv 1$ for the initial condition $r(0) = 1$ for increasing as well as decreasing θ. Since convergence to the equilibrium value $r = 1$ on a finite θ-interval for increasing (decreasing) θ implies nonuniqueness of solutions for decreasing (increasing) θ for the initial condition $r(0) = 1$, it follows that the solution $r(\cdot)$ of (5) can approach $r = 1$ only as $\theta \to \infty$ if $r(0) < 1$ and as $\theta \to -\infty$ if $r(0) > 1$. This implies that, for $\alpha - \beta \geq 1$, the solutions of (3)–(4) that converge to the unit circle spiral around an infinite number of times, thus ruling out convergence. In subsequent sections, we will use the results of this paper to show convergence and semistability in the case $\alpha \leq \beta$. Figure 1 shows the phase portrait of the system for $\alpha = 2$ and $\beta = 1$, while Figure 2 shows the phase portrait of the system for $\alpha = \beta = 1$.

In the case of Figure 1, where $\alpha = 2$ and $\beta = 1$, it follows from (5) that $\frac{dr}{d\theta} \to 0$ as $r \to 1$ so that all nontrivial trajectories approach the unit circle tangentially. As shown above, the system depicted in Figure 1 is not convergent, and, moreover, every equilibrium on the unit circle is unstable. In contrast, all trajectories in Figure 2,

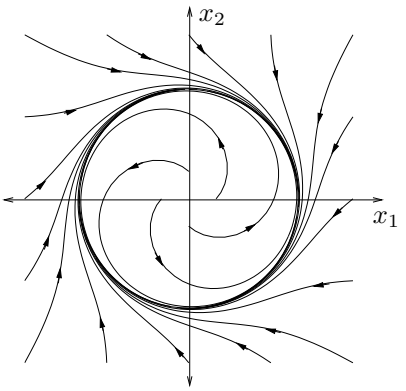

FIG. 1. *Phase portrait of* (3)–(4) *for* $\alpha = 2$, $\beta = 1$.

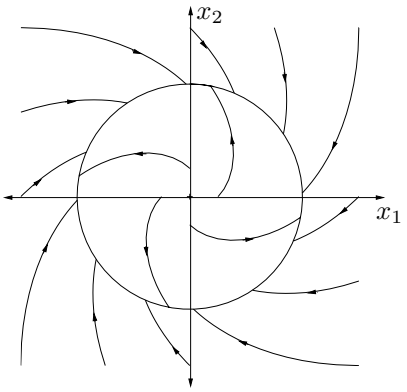

FIG. 2. *Phase portrait of* (3)–(4) *for* $\alpha = \beta = 1$.

where $\alpha = \beta = 1$, approach the unit circle nontangentially, the system is convergent, and all equilibria on the unit circle are semistable. Thus, Figures 1 and 2 suggest that nontangency of trajectories to the set of equilibria is a sufficient condition under which convergence to the set of equilibria implies convergence and semistability.

Intuitively, a vector field is nontangent to a set at a point if the vector field at the point is not contained in the tangent space to the set at that point. We shall apply this intuitive idea to the situation depicted in Figure 2, where the vector field is the vector field describing the dynamics and the set is the set of equilibria of the system. However, this intuitive notion presents two chief difficulties when the set under consideration is the set of singular points of the vector field, that is, the set of equilibria of the system. First, the vector field at an equilibrium is zero, and hence it is always contained in the tangent space to the set of equilibria. To capture the notion of nontangency in such a case, we introduce the *direction cone* of a vector field in section 4. The second difficulty is that, unlike as in Figures 1 and 2, the set of equilibria may not be sufficiently regular to possess a tangent space at the equilibrium point under consideration and may have corners or self-intersections. For example, consider a dynamical system that evolves on the nonnegative orthant and has the boundary of the orthant as its set of equilibria. In this case, the set of equilibria has a corner at the origin. We overcome this difficulty by considering the tangent

cone [2, 26], which extends the notion of a tangent space to a nonsmooth setting. In section 4, we formalize our intuitive notion of nontangency by defining nontangency of a vector field to a set at a point to be the condition that the tangent cone to the set at the point and the direction cone of the vector field at that point have no nonzero vector in common. Section 4 contains examples illustrating direction cones as well as nontangency. We also present a result that is useful in computing the direction cone of a vector field in applications.

We apply our notion of nontangency in section 5, where we show that the solution starting from a point converges if and only if the vector field is nontangent to the positive limit set of the point at some positive limit point. While this result cannot be applied directly in practice, we use it along with well-known properties of positive limit sets to show that, if the vector field is nontangent to the largest invariant subset of the zero-level set of the derivative of a Lyapunov function that is nonincreasing along the solutions, then every bounded solution converges to a limit.

Since the application of the convergence results of section 5 depend on verifying the boundedness of trajectories, we consider the property of boundedness in section 3. We extend well-known results for boundedness involving proper (that is, radially unbounded in the case where the state-space is $\mathbb{R}^n$) Lyapunov functions [21, 30] by introducing the notion of a *weakly proper* function. A function is weakly proper if the connected components of its sublevel sets are compact. We show that the existence of a weakly proper function that is nonincreasing along the trajectories implies that the trajectories are bounded. The usefulness of this result is illustrated in the examples given in section 3.

In section 6, we apply nontangency to Lyapunov stability. Here, prolongations [7, 8] play a role analogous to that played by positive limit sets in section 5. More specifically, we introduce the *restricted prolongation* of a point and show that an equilibrium point is Lyapunov stable if and only if the vector field is nontangent at the equilibrium to its restricted prolongation. The restricted prolongation of a point is a subset of its positive prolongation as defined in [7, 8]. While positive prolongations have been widely used in stability analysis [7], restricted prolongations have invariance properties that are needed for the results that we present. These properties, which are established in section 6, represent one of the key contributions of this paper.

In section 7, we use the results of sections 5 and 6 to obtain novel Lyapunov tests for Lyapunov stability, semistability, and asymptotic stability of nonlinear systems. These results do not make any assumptions about the sign definiteness of the Lyapunov function. Instead, they require only that the Lyapunov function derivative be nonpositive and the equilibrium be a local minimizer of the Lyapunov function on the set of points at which the Lyapunov function derivative is negative. For Lyapunov stability, the weaker assumptions on the Lyapunov function are supplemented by assuming nontangency of the vector field to invariant or negatively invariant subsets of the level set of the Lyapunov function containing the equilibrium and, for semistability, to invariant or negatively invariant subsets of the zero-level set of the Lyapunov function derivative. These results either extend or complement known results for Lyapunov stability and asymptotic stability involving semidefinite Lyapunov functions and Lyapunov function derivatives as given in [1, 16, 20, 21].

As mentioned above, chemical kinetics comprise one of the application areas for semistability theory. Since the kinetic equation for a system of chemical reactions governs concentrations of the reacting species, all solutions of physical interest take values in the nonnegative orthant. For such systems, which evolve on possibly closed

positively invariant subsets of $\mathbb{R}^n$, it is natural to consider relative stability, that is, stability with respect to perturbed initial conditions that belong to the positively invariant subset. Therefore, with applications to nonnegative dynamics in mind, we consider relative stability of dynamical systems that evolve on (not necessarily open) subsets of $\mathbb{R}^n$. Relative stability has been considered previously in [7, 16].

We illustrate the main results by applying them to examples from chemical kinetics and adaptive control. More specifically, we use the nontangency-based Lyapunov results to deduce convergence and semistability of the kinetics of the Michaelis–Menten chemical reaction [11] and the closed-loop dynamics of a scalar system under a universal adaptive stabilizing controller given in [17, 22].

2. Preliminaries. Let $\mathcal{G} \subseteq \mathbb{R}^n$, and let $\|\cdot\|$ denote a norm on $\mathbb{R}^n$. A subset $\mathcal{U}$ of $\mathcal{G}$ is *relatively open* in $\mathcal{G}$ if $\mathcal{U}$ is open in the subspace topology induced on $\mathcal{G}$ by the norm $\|\cdot\|$. Given $\mathcal{K} \subseteq \mathcal{G}$, we let int $\mathcal{K}$ and bd $\mathcal{K}$ denote the interior and boundary, respectively, of $\mathcal{K}$ in the subspace topology on $\mathcal{G}$. Thus int $\mathcal{K}$ is the largest subset of $\mathcal{K}$ that is relatively open in $\mathcal{G}$, while bd $\mathcal{K} = (\overline{\mathcal{K}} \cap \mathcal{G}) \backslash \text{int } \mathcal{K}$, where $\overline{\mathcal{K}}$ denotes the closure of $\mathcal{K}$ in $\mathbb{R}^n$. A set $\mathcal{U} \subseteq \mathcal{G}$ is *relatively bounded* in $\mathcal{G}$ if $\overline{\mathcal{U}}$ is compact and contained in $\mathcal{G}$. A point $x \in \mathbb{R}^n$ is a *subsequential limit* of a sequence $\{x_i\}$ in $\mathbb{R}^n$ if there exists a subsequence of $\{x_i\}$ that converges to x in the norm $\|\cdot\|$. A sequence $\{x_i\}$ in $\mathcal{G}$ is relatively bounded in $\mathcal{G}$ if it is relatively bounded when viewed as a set. Every sequence that is relatively bounded in $\mathcal{G}$ has at least one subsequential limit, and every subsequential limit of the sequence is contained in $\mathcal{G}$. When there is no possibility of confusion, we will use "relatively open (bounded)" instead of "relatively open (bounded) in $\mathcal{G}$." Also, in the case where $\mathcal{G} = \mathbb{R}^n$, we will use "open" and "bounded" instead of "relatively open" and "relatively bounded," respectively.

We recall that a set $\mathcal{K} \subseteq \mathcal{G}$ is *connected* if and only if every pair of relatively open sets $\mathcal{U}_i \subseteq \mathcal{G}$, $i = 1, 2$, satisfying $\mathcal{K} \subseteq \mathcal{U}_1 \cup \mathcal{U}_2$ and $\mathcal{U}_i \cap \mathcal{K} \neq \varnothing$, $i = 1, 2$, has a nonempty intersection. Also, a connected component of the set $\mathcal{K} \subseteq \mathcal{G}$ is a connected subset of $\mathcal{K}$ that is not properly contained in any connected subset of $\mathcal{K}$.

Consider the system of differential equations

$$\dot{y}(t) = f(y(t)), \tag{6}$$

where $f : \mathcal{D} \to \mathbb{R}^n$ is continuous on the open set $\mathcal{D} \subseteq \mathbb{R}^n$. We assume that, for every initial condition $y(0) \in \mathcal{D}$ and every $a > 0$, the differential equation (6) possesses a unique C^1 solution $y : [0, a) \to \mathcal{D}$ on the interval $[0, a)$. Letting $\psi(\cdot, x)$ denote the solution of (6) that exists on $[0, \infty)$ and satisfies the initial condition $y(0) = x$, the above assumptions imply that the map $\psi : [0, \infty) \times \mathcal{D} \to \mathcal{D}$ is continuous [14, Thm. V.2.1], satisfies $\psi(0, x) = x$, and possesses the semigroup property, that is, $\psi(t, \psi(h, x)) = \psi(t + h, x)$ for all $t, h \geq 0$ and $x \in \mathcal{D}$. Given $t \geq 0$, it will often be convenient to denote the map $\psi(t, \cdot) : \mathcal{D} \to \mathcal{D}$ by ψ_t. The *orbit* $\mathcal{O}_x$ of a point $x \in \mathcal{D}$ is the set $\{\psi(t, x) : t \geq 0\}$.

A set $\mathcal{U} \subseteq \mathbb{R}^n$ is *positively invariant* if $\psi_t(\mathcal{U}) \subseteq \mathcal{U}$ for all $t \geq 0$. The set $\mathcal{U}$ is *negatively invariant* if, for every $z \in \mathcal{U}$ and every $t \geq 0$, there exists $x \in \mathcal{U}$ such that $\psi(t, x) = z$ and $\psi(\tau, x) \in \mathcal{U}$ for all $\tau \in [0, t]$. Hence, if $\mathcal{U}$ is negatively invariant, then $\mathcal{U} \subseteq \psi_t(\mathcal{U})$ for all $t \geq 0$, although the converse is not generally true. Finally, the set $\mathcal{U}$ is *invariant* if $\psi_t(\mathcal{U}) = \mathcal{U}$ for all $t \geq 0$. Note that a set is invariant if and only if it is positively as well as negatively invariant. Also, it is easy to show that each connected component of a positively invariant (respectively, negatively invariant, invariant) set is positively invariant (respectively, negatively invariant, invariant).

In the rest of the paper, $\mathcal{G} \subseteq \mathcal{D}$ will denote a positively invariant set so that $\mathcal{O}_x \subseteq \mathcal{G}$ for all $x \in \mathcal{G}$. Except for local compactness, which is invoked in section 4 and subsequent sections, we require no additional hypotheses on $\mathcal{G}$.

An *equilibrium point* of (6) is a point $x \in \mathcal{D}$ satisfying $f(x) = 0$ or, equivalently, $\psi(t, x) = x$ for all $t \geq 0$. We let $\mathcal{E} = f^{-1}(0) \cap \mathcal{G}$, the set of all equilibrium points of (6) in $\mathcal{G}$. An *isolated* equilibrium is an isolated point of $\mathcal{E}$. An equilibrium point $x \in \mathcal{E}$ is *Lyapunov stable* relative to $\mathcal{G}$ if, for every relatively open neighborhood $\mathcal{U}_\varepsilon \subseteq \mathcal{G}$ of x, there exists a relatively open neighborhood $\mathcal{U}_\delta \subseteq \mathcal{G}$ of x such that $\psi_t(\mathcal{U}_\delta) \subseteq \mathcal{U}_\varepsilon$ for all $t \geq 0$. If $x \in \mathcal{E}$ is Lyapunov stable relative to $\mathcal{G}$, then every relatively open neighborhood of x contains a positively invariant, relatively open neighborhood of x [8, section V.1].

The system (6) is *convergent* relative to $\mathcal{G}$ if, for every $x \in \mathcal{G}$, $\lim_{t\to\infty} \psi(t, x)$ exists and is contained in $\mathcal{G}$. It follows from the continuity of ψ and the semigroup property that, if $x \in \mathcal{G}$ is such that $\lim_{t\to\infty} \psi(t, x)$ exists and is contained in $\mathcal{G}$, then, for every $h > 0$, $\psi_h(\lim_{t\to\infty} \psi(t, x)) = \lim_{t\to\infty} \psi(t + h, x) = \lim_{t\to\infty} \psi(t, x)$ so that $\lim_{t\to\infty} \psi(t, x) \in \mathcal{E}$.

An equilibrium point $x \in \mathcal{G}$ is *semistable* relative to $\mathcal{G}$ if there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that, for every $z \in \mathcal{U}$, $\lim_{t\to\infty} \psi(t, z)$ exists, is contained in $\mathcal{G}$, and is Lyapunov stable relative to $\mathcal{G}$. Note that if the equilibrium $x \in \mathcal{G}$ is semistable relative to $\mathcal{G}$, then every equilibrium in some relatively open neighborhood of x is Lyapunov stable relative to $\mathcal{G}$. In particular, every equilibrium that is semistable relative to $\mathcal{G}$ is also Lyapunov stable relative to $\mathcal{G}$.

An equilibrium point $x \in \mathcal{G}$ is *asymptotically stable* relative to $\mathcal{G}$ if x is Lyapunov stable relative to $\mathcal{G}$ and there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that, for every $z \in \mathcal{U}$, $\lim_{t\to\infty} \psi(t, z) = x$. It is easy to see that an equilibrium is asymptotically stable relative to $\mathcal{G}$ if and only if it is an isolated equilibrium and is semistable relative to $\mathcal{G}$.

Given a function $V : \mathcal{G} \to \mathbb{R}$, a point $x \in \mathcal{G}$ is a *local minimizer* of V relative to $\mathcal{K} \subseteq \mathcal{G}$ if there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that $V(x) \leq V(z)$ for all $z \in \mathcal{U} \cap \mathcal{K}$. The point $x \in \mathcal{G}$ is a *global minimizer* of V relative to $\mathcal{G}$ if $V(x) \leq V(z)$ for all $z \in \mathcal{G}$. Local and global maximizers of V are defined similarly.

Given a continuous function $V : \mathcal{G} \to \mathbb{R}$, we define

$$\dot{V}(x) = \lim_{h\to 0^+} \frac{1}{h}[V(\psi(h, x)) - V(x)] \tag{7}$$

for every $x \in \mathbb{R}^n$ such that the limit in (7) exists. It is easy to see that if $x \in \mathcal{E}$ and $V : \mathcal{G} \to \mathbb{R}$, then $\dot{V}(x)$ is defined and equals zero.

Some of the results that we present involve an equilibrium point that is also a local or global maximizer of $\dot{V}$ for some function V. Since $\dot{V}$ is zero at equilibrium points, an equilibrium x is a local maximizer of $\dot{V}$ relative to $\mathcal{G}$ if and only if $\dot{V}$ assumes nonpositive values in some relatively open neighborhood of x. Similarly, an equilibrium x is a global maximizer of $\dot{V}$ relative to $\mathcal{G}$ if and only if $\dot{V}$ assumes nonpositive values in $\mathcal{G}$. We will find it convenient to state the familiar requirements of local and global negative semidefiniteness on $\dot{V}$ in terms of the equilibrium being a local or global maximizer, respectively, of $\dot{V}$.

3. Boundedness of orbits. A function $U : \mathcal{G} \to \mathbb{R}$ is *proper* if $U^{-1}(\mathcal{I})$ is a compact subset of $\mathcal{G}$ for all compact subsets $\mathcal{I}$ of $\mathbb{R}$, and *weakly proper* if, for every $c \in \mathbb{R}$, every connected component of the set $\{x \in \mathcal{G} : U(x) \leq c\} = U^{-1}((-\infty, c])$ is compact. If U is proper and bounded below on $\mathcal{G}$, then U is weakly proper.

We present a Lyapunov test for boundedness of orbits that will be useful in some of the examples we present in this paper. The test involves weakly proper functions.

PROPOSITION 3.1. *Suppose there exists a weakly proper, continuous function $U : \mathcal{G} \to \mathbb{R}$ such that $\dot{U}$ is defined on $\mathcal{G}$ and such that $\dot{U}(x) \leq 0$ for all $x \in \mathcal{G}$. Then, for every $x \in \mathcal{G}$, $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$.*

Proof. Consider $x \in \mathcal{G}$, and let $c = U(x)$. The assumptions on $\dot{U}$ imply that the function $t \mapsto U(\psi(t,x))$ is nonincreasing. Hence $U(\psi(t,x)) \leq c$ for all $t \geq 0$ so that $\psi(t,x) \in \mathcal{K} \stackrel{\text{def}}{=} \{z \in \mathcal{G} : U(z) \leq c\}$ for all $t \geq 0$. Thus $\mathcal{O}_x \subseteq \mathcal{K}$. Since $\mathcal{O}_x$ is connected, it follows that $\mathcal{O}_x$ is contained in a connected component $\mathcal{M}$ of $\mathcal{K}$. By weak properness, $\mathcal{M}$ is compact, and thus $\overline{\mathcal{O}}_x$ is contained in $\mathcal{M}$. Hence $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$. ∎

Proposition 3.1 is an extension of the following well-known sufficient condition for boundedness of orbits. See, for instance, [21, Thm. 4], [30, Thm. 8.7].

COROLLARY 3.1. *Suppose there exists a proper, continuous function $U : \mathcal{G} \to \mathbb{R}$ such that $\dot{U}$ is defined on $\mathcal{G}$ and such that $U(x) \geq 0$ and $\dot{U}(x) \leq 0$ for all $x \in \mathcal{G}$. Then, for every $x \in \mathcal{G}$, $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$.*

Proof. The result follows from Proposition 3.1 by noting that the function U is weakly proper. ∎

Example 3.1. Consider the uncertain linear system

$$\dot{y}(t) = -ay(t) + bu(t), \tag{8}$$

where $a, b \in \mathbb{R}$ and b is nonzero but otherwise unknown. A universal adaptive stabilizing controller for the system (8) is given by [17, 22, 24]

$$u(t) = -k^2(t) \cos k(t) y(t), \tag{9}$$

where the adaptive gain parameter k satisfies the update law

$$\dot{k}(t) = y^2(t). \tag{10}$$

The corresponding closed-loop system on $\mathcal{G} = \mathbb{R}^2$ is described by (10) and

$$\dot{y}(t) = -[a + bk^2(t) \cos(k(t))] y(t). \tag{11}$$

We will use Proposition 3.1 to show that all orbits of the closed-loop system (10)–(11) are bounded.

Consider the function $U : \mathbb{R}^2 \to \mathbb{R}$ given by $U(x) = \frac{1}{2}y^2 + g(k)$, where $x = (y,k)$ and $g : \mathbb{R} \to \mathbb{R}$ is given by $g(k) = ak + b(k^2 - 2) \sin k + 2bk \cos k$. It is easy to verify that, for the closed-loop system, $\dot{U}(x) = 0$ for every $x \in \mathbb{R}^2$. We claim that the function U is weakly proper.

Let $c \in \mathbb{R}$, let $\mathcal{K} = \{x \in \mathbb{R}^2 : U(x) \leq c\}$, and consider $x_0 = (y_0, k_0) \in \mathcal{K}$. Let $\mathcal{M}$ be the connected component of $\mathcal{K}$ containing x_0. By continuity of U, $\mathcal{K}$ is closed. Since $\mathcal{M}$ is a connected component of a closed set, $\mathcal{M}$ is closed.

First suppose $b > 0$, and let $p : \mathbb{R} \to \mathbb{R}$ be given by $p(k) = bk^2 + ak - 2b$. There exists an integer $m > 0$ such that, for $k_1 = -(2m + \frac{3}{2})\pi$ and $k_2 = (2m + \frac{1}{2})\pi$, it follows that $p(k_i) > c$, $i = 1, 2$, and $k_0 \in [k_1, k_2]$. A simple computation shows that $p(k_i) = g(k_i)$, $i = 1, 2$, so that, for every $y \in \mathbb{R}$, the points $x_i = (y, k_i)$, $i = 1, 2$, satisfy $U(x_i) = \frac{1}{2}y^2 + p(k_i) > c$. Letting ρ denote the projection $(y,k) \mapsto k$, it follows that $\rho(\mathcal{M})$ is a connected set that contains $k_0 \in [k_1, k_2]$ but does not contain k_1 and k_2. Hence it follows that $\rho(\mathcal{M}) \subseteq [k_1, k_2]$; that is, $k \in [k_1, k_2]$ for every

$x = (y,k) \in \mathcal{M}$. Denote $l = \min_{k\in[k_1,k_2]} g(k)$. Then, for every $x = (y,k) \in \mathcal{M}$, $\frac{1}{2}y^2 \le c - g(k) \le c - l$. Thus, for every $x = (y,k) \in \mathcal{M}$, $y \in [y_1, y_2]$, where $y_1 = -\sqrt{2(c-l)}$ and $y_2 = \sqrt{2(c-l)}$. Thus the closed set $\mathcal{M}$ is contained in the compact set $[y_1, y_2] \times [k_1, k_2]$ and hence compact. It follows that U is weakly proper in the case where $b > 0$.

Now suppose $b < 0$, and let $p : \mathbb{R} \to \mathbb{R}$ be given by $p(k) = -bk^2 + ak + 2b$. There exists an integer $m > 0$ such that, for $k_1 = -(2m + \frac{1}{2})\pi$ and $k_2 = (2m + \frac{3}{2})\pi$, it follows that $p(k_i) > c$, $i = 1, 2$, and $k_0 \in [k_1, k_2]$. Letting $l = \min_{k\in[k_1,k_2]} g(k)$, $y_1 = -\sqrt{2(c-l)}$, and $y_2 = \sqrt{2(c-l)}$, it can be shown by repeating the arguments given above that the closed set $\mathcal{M}$ is contained in the compact set $[y_1, y_2] \times [k_1, k_2]$ and hence compact. It follows that U is weakly proper in the case where $b < 0$.

Since the function U is weakly proper and $\dot{U} \equiv 0$, it follows from Proposition 3.1 that every orbit of the closed-loop system (10)–(11) is bounded.

4. Direction cones and nontangency. Given a set $\mathcal{K} \subseteq \mathbb{R}^n$, we let co $\mathcal{K}$ denote the union of the convex hulls of the connected components of $\mathcal{K}$ and let coco $\mathcal{K}$ denote the cone generated by co $\mathcal{K}$. Given $\mathcal{K} \subseteq \mathbb{R}^n$ and $x \in \mathbb{R}^n$, we denote $\operatorname{dist}(x, \mathcal{K}) = \inf_{y\in\mathcal{K}} \|x - y\|$. Finally, we let $\mathrm{S}^{n-1} = \{x \in \mathbb{R}^n : \|x\| = 1\}$ denote the unit sphere in $\mathbb{R}^n$.

Given $x \in \mathcal{G}$, the *direction cone* $\mathcal{F}_x$ of f at x relative to $\mathcal{G}$ is the intersection of all sets of the form $\overline{\text{coco}\,(f(\mathcal{U})\backslash\{0\})}$, where $\mathcal{U} \subseteq \mathcal{G}$ is a relatively open neighborhood of x. It is easy to see that if $x \in \mathcal{G}\backslash\text{int}\,\mathcal{E}$, then $\mathcal{F}_x$ is a closed cone containing $f(x)$, while if $x \in \text{int}\,\mathcal{E}$, then $\mathcal{F}_x = \varnothing$.

Let $\mathcal{K} \subseteq \mathbb{R}^n$ and $x \in \mathcal{K}$. A vector $v \in \mathbb{R}^n$ is *tangent* to $\mathcal{K}$ at $x \in \mathcal{K}$ if there exist a sequence $\{x_i\}$ in $\mathcal{K}$ converging to x and a sequence $\{h_i\}$ of positive real numbers converging to 0 such that $\lim_{i\to\infty} \frac{1}{h_i}(x_i - x) = v$. The *tangent cone* to $\mathcal{K}$ at x is the closed cone $T_x\mathcal{K}$ of all vectors tangent to $\mathcal{K}$ at x [2, p. 121], [26, Prop. 6.2]. It is easy to see that $0 \in T_x\mathcal{K}$. Moreover, if x is an isolated point of $\mathcal{K}$, then $T_x\mathcal{K} = \{0\}$. Also, if $\mathcal{K} \subseteq \mathcal{M}$, then, for every $x \in \mathcal{K}$, $T_x\mathcal{K} \subseteq T_x\mathcal{M}$. Finally, if $x \in \mathcal{K}$ and $\mathcal{U} \subseteq \mathbb{R}^n$ is an open neighborhood of x such that $\mathcal{K} \cap \mathcal{U}$ is a differentiable submanifold of $\mathbb{R}^n$, then $T_x\mathcal{K}$ is the usual tangent space to $\mathcal{K}$ at x.

Remark 4.1. Tangent cones are called *contingent cones* in [2]. We have followed the terminology used in [26].

The vector field f is *nontangent* to the set $\mathcal{K} \subseteq \mathcal{G}$ at the point $x \in \mathcal{K}$ relative to $\mathcal{G}$ if $T_x\mathcal{K} \cap \mathcal{F}_x \subseteq \{0\}$.

Remark 4.2. The notion of nontangency introduced here is different from the well-known notion of *transversality* [13]. Transversality between a vector field and a set is possible only at a point in the set where the vector field is not zero and the set is locally a differentiable submanifold of codimension one. On the other hand, nontangency is possible even if the vector field is zero and the set is not a differentiable submanifold of codimension one.

In the rest of the paper, we assume that $\mathcal{G}$ is *locally compact*, that is, every point in $\mathcal{G}$ is contained in a relatively open and relatively bounded set $\mathcal{U} \subseteq \mathcal{G}$. In particular, if $\mathcal{G}$ is either open or closed, then $\mathcal{G}$ is locally compact. Local compactness implies that every relatively open neighborhood of a point $x \in \mathcal{G}$ contains a relatively open neighborhood of x that is also relatively bounded in $\mathcal{G}$ [10, Thm. XI.6.2].

The following proposition is a key result of this paper. The result shows that if the vector field f is nontangent to the set $\mathcal{B}$ of all subsequential limits of sequences of points taken from a sequence of segments of orbits of (6), then the set $\mathcal{B}$ contains exactly one point. This result will be applied to positive limit sets in section 5

and restricted prolongations in section 6 to obtain nontangency-based conditions for convergence and stability.

PROPOSITION 4.1. *Let $x \in \mathcal{G}$, and let $\{x_i\}$ be a sequence in $\mathcal{G}$ converging to x. Let $\mathcal{I}_i \subseteq [0,\infty)$, $i = 1, 2, \ldots$, be intervals containing 0, and let $\mathcal{B} \subseteq \mathcal{G}$ be the set of all subsequential limits contained in $\mathcal{G}$ of sequences of the form $\{\psi(\tau_i, x_i)\}$, where $\tau_i \in \mathcal{I}_i$ for each i. Then $\mathcal{B} = \{x\}$ if and only if f is nontangent to $\mathcal{B}$ at x relative to $\mathcal{G}$.*

Proof. First, we note that $x \in \mathcal{B}$ since $x = \lim_{i\to\infty} \psi(0, x_i)$. Necessity now follows by noting that if $\mathcal{B} = \{x\}$, then $T_x\mathcal{B} = \{0\}$, and hence $T_x\mathcal{B} \cap \mathcal{F}_x \subseteq \{0\}$.

To prove sufficiency, suppose $z_0 \in \mathcal{B}$, $z_0 \neq x$. If the sequence $\{f(x_i)\}$ is eventually zero, then every sequence of the form $\{\psi(\tau_i, x_i)\}$ converges to x, and, consequently, $\mathcal{B}$ is a singleton. Hence we may assume without loss of generality that $f(x_i) \neq 0$ for every i. Let $\{\mathcal{U}_k\}$ be a nested sequence of neighborhoods of x that are relatively bounded and relatively open in $\mathcal{G}$, contained in $\mathcal{U}$, and such that $\overline{\mathcal{U}_{k+1}} \subset \mathcal{U}_k$ and $x_k \in \mathcal{U}_k$ for every $k = 1, 2, \ldots$, $\cap_k \mathcal{U}_k = \{x\}$, and $z_0 \notin \mathcal{U}_1$. Since $z_0 \in \mathcal{B}$, there exists a sequence $\{\tau_i\}$ such that $\tau_i \in \mathcal{I}_i$ for every i, and $\lim_{i\to\infty} \psi(\tau_i, x_i) = z_0 \notin \mathcal{U}_1$. By continuity of ψ, for every k, there exists a sequence $\{h_j^k\}_{j=k}^{\infty}$ in $[0,\infty)$ such that, for every $j \geq k$, $h_j^k \in \mathcal{I}_j$, $h_j^k \leq \tau_j$, $\psi(\tau, x_j) \in \mathcal{U}_k$ for every $\tau \in [0, h_j^k)$, and $\psi(h_j^k, x_j) \in \operatorname{bd} \mathcal{U}_k$. For each k, let $z_k \in \operatorname{bd} \mathcal{U}_k$ be a subsequential limit of the relatively bounded sequence $\{\psi(h_j^k, x_j)\}_{j=k}^{\infty}$. Then, for every k, it follows that $z_k \in \mathcal{B}$, $z_k \neq x$, and $\lim_{k\to\infty} z_k = x$. Now consider a subsequential limit v of the bounded sequence $\{\|z_k - x\|^{-1}(z_k - x)\}$. Clearly, $v \in T_x\mathcal{B}$. Also, $\|v\| = 1$ so that $v \neq 0$. We claim that $v \in \mathcal{F}_x$.

Let $\mathcal{V} \subseteq \mathcal{G}$ be a relatively open neighborhood of x, and consider $\varepsilon > 0$. By construction, there exists k such that $\big\|v - \|z_k - x\|^{-1}(z_k - x)\big\| < \varepsilon/3$. Moreover, since $\cap_i \mathcal{U}_i = \{x\}$, we can assume that $\mathcal{U}_k \subseteq \mathcal{V}$. Since z_k belongs to the boundary of a relatively open neighborhood of x, $\delta \stackrel{\text{def}}{=} \|z_k - x\| > 0$. Since $z_k = \lim_{i\to\infty} \psi(h_i^k, x_i)$ and $x = \lim_{i\to\infty} x_i$, there exists i such that $x_i \in \mathcal{V}$, $\|x - x_i\| < \varepsilon\delta/3$, and $\|z_k - \psi(h_i^k, x_i)\| < \varepsilon\delta/3$. Let $\mathcal{A}$ be the connected component of $f(\mathcal{V})\backslash\{0\}$ containing $f(x_i) \neq 0$. Since f is continuous, it follows that $f(\psi(\tau, x_i)) \in \overline{\mathcal{A}}$ for all $\tau \in [0, h_i^k]$. Therefore, $w \stackrel{\text{def}}{=} \psi(h_i^k, x_i) - x_i = \int_0^{h_i^k} f(\psi(\tau, x_i))d\tau$ is contained in the convex cone generated by $\overline{\mathcal{A}}$ [29, Thm. I.6.13]. Since $\mathcal{A}$ is connected, coco $\mathcal{A}$ is simply the convex cone generated by $\mathcal{A}$. Since $\mathcal{A}$ and $\overline{\mathcal{A}}$ generate the same closed convex cone, we have coco $\overline{\mathcal{A}} \subseteq \overline{\text{coco } \overline{\mathcal{A}}} = \overline{\text{coco } \mathcal{A}} \subseteq \overline{\text{coco } (f(\mathcal{V})\backslash\{0\})}$. Thus $w \in \overline{\text{coco } (f(\mathcal{V})\backslash\{0\})}$. Now,

$$\begin{aligned}\big\|v - \delta^{-1}w\big\| &= \big\|v - \delta^{-1}(z_k - x) - \delta^{-1}(\psi(h_i^k, x_i) - z_k) - \delta^{-1}(x - x_i)\big\| \\ &\leq \big\|v - \|z_k - x\|^{-1}(z_k - x)\big\| + \delta^{-1}\|\psi(h_i^k, x_i) - z_k\| + \delta^{-1}\|x - x_i\| \\ &< \varepsilon.\end{aligned}$$

We conclude that, for every $\varepsilon > 0$, there exists $w \in \overline{\text{coco } (f(\mathcal{V})\backslash\{0\})}$ and $\delta > 0$ such that $\|v - \delta^{-1}w\| < \varepsilon$. It follows that $v \in \overline{\text{coco } (f(\mathcal{V})\backslash\{0\})}$. Since the neighborhood $\mathcal{V}$ was arbitrary, it follows that $v \in \mathcal{F}_x$. Thus, if $\mathcal{B} \neq \{x\}$, then there exists $v \in \mathbb{R}^n$ such that $v \neq 0$ and $v \in T_x\mathcal{B} \cap \mathcal{F}_x$; that is, f is not nontangent to $\mathcal{B}$ at x relative to $\mathcal{G}$. Sufficiency now follows. ∎

Since any application of Proposition 4.1 will involve finding the direction cone, we next give a result that provides a convenient means of determining the direction cone in applications. For this purpose, it will be useful to introduce the limiting direction set of a vector field at a point.

Let $x \in \mathcal{G}\backslash\operatorname{int} \mathcal{E}$. A vector $v \in \mathrm{S}^{n-1}$ is a *limiting direction* of f at x relative to $\mathcal{G}$ if there exists a sequence $\{x_i\}$ in $\mathcal{G}\backslash\mathcal{E}$ such that $\lim_{i\to\infty} x_i = x$ and

$\lim_{i\to\infty} \frac{1}{\|f(x_i)\|} f(x_i) = v$. The *limiting direction set* $\mathcal{L}_x$ of f at x relative to $\mathcal{G}$ is the set of all limiting directions of f at x relative to $\mathcal{G}$. Clearly, $\mathcal{L}_x$ is nonempty, compact, and contained in S^{n-1}. Moreover, for every $\varepsilon > 0$, there exists a relatively open neighborhood $\mathcal{U}_\varepsilon \subseteq \mathcal{G}$ of x such that, for every $z \in \mathcal{U}_\varepsilon \backslash \mathcal{E}$, $\operatorname{dist}(\frac{1}{\|f(z)\|} f(z), \mathcal{L}_x) < \varepsilon$.

Consider $x \in \mathcal{G} \backslash \operatorname{int} \mathcal{E}$, and let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open neighborhood of x. For every sequence $\{x_i\}$ in $\mathcal{G}\backslash\mathcal{E}$ converging to $x \in \mathcal{G}$, the sequence $\{\frac{1}{\|f(x_i)\|} f(x_i)\}$ is eventually in the cone generated by $f(\mathcal{U})\backslash\{0\}$ and hence in coco $(f(\mathcal{U})\backslash\{0\})$ so that every subsequential limit of the sequence $\{\frac{1}{\|f(x_i)\|} f(x_i)\}$ is contained in coco $(f(\mathcal{U})\backslash\{0\})$. Since $\mathcal{U}$ was chosen arbitrarily, it follows that $\mathcal{L}_x \subseteq \mathcal{F}_x$. The following result shows that if no connected component of the limiting direction set contains the origin in its convex hull, then the direction cone is contained in the union of the convex cones generated by the connected components of the limiting direction set. This result provides a convenient means for determining the direction cone in applications.

PROPOSITION 4.2. *Let $x \in \mathcal{G}\backslash\operatorname{int} \mathcal{E}$, and suppose $0 \notin \operatorname{co} \mathcal{L}_x$. Then $\mathcal{F}_x \subseteq \operatorname{coco} \mathcal{L}_x$.*

Proof. See the appendix. ∎

Remark 4.3. A special case where Proposition 4.2 applies is the case where $\mathcal{L}_x \subseteq \mathrm{S}^{n-1}$ is finite. Suppose $x \in \mathcal{G}$ is such that $\mathcal{L}_x$ is finite. Then $\operatorname{co} \mathcal{L}_x = \mathcal{L}_x \subseteq \mathrm{S}^{n-1}$, and thus $0 \notin \operatorname{co} \mathcal{L}_x$. Moreover, $\operatorname{coco} \mathcal{L}_x$ is the union of rays generated by the points of $\mathcal{L}_x$. Proposition 4.2 implies that $\mathcal{F}_x \subseteq \operatorname{coco} \mathcal{L}_x$. However, since $\mathcal{L}_x \subset \mathcal{F}_x$ and since $\mathcal{F}_x$ is a cone, the rays generated by points of $\mathcal{L}_x$ are contained in $\mathcal{F}_x$, that is, $\operatorname{coco} \mathcal{L}_x \subseteq \mathcal{F}_x$. Thus, in the case where the limiting direction set is finite, the direction cone is the union of rays generated by points of the limiting direction set.

The following example shows that, in general, $\mathcal{F}_x \not\subseteq \operatorname{coco} \mathcal{L}_x$.

Example 4.1. Consider the system (6), where $f : \mathbb{R}^3 \to \mathbb{R}^3$ is given by

$$f(x) = -(x_1^2 + x_2^2)^6 \begin{bmatrix} x_1 \\ x_2 \\ 0 \end{bmatrix} + (x_1^2 + x_2^2) \begin{bmatrix} x_2 \\ -x_1 \\ 0 \end{bmatrix} + (x_1^2 + x_2^2)^2 \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}. \tag{12}$$

Letting $\mathcal{G} = \mathbb{R}^3$, the set of equilibria is $\mathcal{E} = \{x \in \mathcal{G} : x_1 = x_2 = 0\}$.

Let $a \in \mathbb{R}$, and consider $x = [0 \ 0 \ a]^{\mathrm{T}} \in \mathcal{E}$. To compute $\mathcal{L}_x$, it will be convenient to introduce the function $r : \mathcal{G} \to \mathbb{R}$ given by $r(z) = \sqrt{z_1^2 + z_2^2}$ and the function $\theta : \mathcal{G}\backslash\mathcal{E} \to [0, 2\pi)$ such that, for every $z \in \mathcal{G}\backslash\mathcal{E}$, $z_1 = r(z)\cos(\theta(z))$ and $z_2 = r(z)\sin(\theta(z))$.

For every $z \in \mathcal{G}$, $\|f(z)\| = (r(z))^3 \sqrt{1 + (r(z))^2 + (r(z))^{20}}$, while, for every $z \in \mathcal{G}\backslash\mathcal{E}$,

$$\frac{1}{\|f(z)\|} f(z) = \frac{1}{\sqrt{1 + (r(z))^2 + (r(z))^{20}}} \begin{bmatrix} -(r(z))^{10}\cos(\theta(z)) + \sin(\theta(z)) \\ -(r(z))^{10}\sin(\theta(z)) - \cos(\theta(z)) \\ r(z) \end{bmatrix}, \tag{13}$$

where $\|\cdot\|$ denotes the Euclidean norm on $\mathbb{R}^3$. Consider a sequence $\{x_i\}$ in $\mathcal{G}\backslash\mathcal{E}$ converging to x. Since $\lim_{i\to\infty} r(x_i) = 0$, it is easy to see from (13) that every subsequential limit of the sequence $\{\|f(x_i)\|^{-1} f(x_i)\}$ is of the form $[\sin\alpha \ -\cos\alpha \ 0]^{\mathrm{T}}$, where $\alpha \in \mathbb{R}$. On the other hand, for every $\alpha \in \mathbb{R}$, the sequence $\{x_i\}$ given by $x_i = \left[\frac{1}{i}\cos\alpha \ \frac{1}{i}\sin\alpha \ a\right]^{\mathrm{T}}$ converges to x while $\lim_{i\to\infty} \|f(x_i)\|^{-1} f(x_i) = [\sin\alpha \ -\cos\alpha \ 0]^{\mathrm{T}}$. Hence we conclude that the limiting direction set of f at x is a circle and is given by $\mathcal{L}_x = \{[\sin\alpha \ -\cos\alpha \ 0]^{\mathrm{T}} : \alpha \in \mathbb{R}\}$. $\mathcal{L}_x$ is connected, and hence it easily follows that $\operatorname{co} \mathcal{L}_x = \{w \in \mathbb{R}^3 : w_1^2 + w_2^2 \le 0, w_3 = 0\}$ and $\operatorname{coco} \mathcal{L}_x = \{w \in \mathbb{R}^3 : w_3 = 0\}$. Note that $0 \in \operatorname{co} \mathcal{L}_x$.

We claim that $\mathcal{F}_x \not\subseteq \operatorname{coco} \mathcal{L}_x$. To see this, consider the vector $w = [0\ 0\ 1]^{\mathrm{T}}$. Clearly, $w \notin \operatorname{coco} \mathcal{L}_x$. We claim that $w \in \mathcal{F}_x$.

Let $\mathcal{U}$ be an open neighborhood of x. Choose $\varepsilon > 0$ such that $\{z \in \mathcal{G} : \|z - x\| \leq \varepsilon\} \subseteq \mathcal{U}$, and consider $z_1 = [\varepsilon\ 0\ a]^{\mathrm{T}}$ and $z_2 = [-\varepsilon\ 0\ a]^{\mathrm{T}}$. Then $z_i \in \mathcal{U}$, $i = 1, 2$. It is easy to verify that $w = \frac{1}{2}\varepsilon^{-4}[f(z_1) + f(z_2)]$. Since $\mathcal{U}\backslash\mathcal{E}$ is connected and f is continuous, $f(\mathcal{U})\backslash\{0\} = f(\mathcal{U}\backslash\mathcal{E})$ is also connected. Therefore, $f(z_i)$, $i = 1, 2$, are contained in the same connected component of $f(\mathcal{U})\backslash\{0\}$. Hence $w \in \operatorname{coco}(f(\mathcal{U})\backslash\{0\})$. Since $\mathcal{U}$ was chosen to be arbitrary, it follows that $w \in \mathcal{F}_x$.

The following example illustrates direction cones, nontangency, and the use of Proposition 4.2.

Example 4.2. Consider the system described in Example 1.1 with $\mathcal{G} = \mathbb{R}^2$, and let $x \in \mathrm{S}^1$. As discussed in Example 1.1, x is an equilibrium point for the system. It is easy to show that

$$\begin{aligned} \mathcal{L}_x &= \{\pm f_\theta(x)\}, && \alpha > \beta, \\ &= \left\{\pm \tfrac{1}{\sqrt{2}}(f_\theta(x) + f_r(x))\right\}, && \alpha = \beta, \\ &= \{\pm f_r(x)\}, && \alpha < \beta, \end{aligned}$$

where f_r and f_θ are given in (2). Thus $\mathcal{L}_x$ is finite, and hence, by Remark 4.3,

$$\begin{aligned} \mathcal{F}_x &= \{k f_\theta(x) : k \in \mathbb{R}\}, && \alpha > \beta, \\ &= \{k(f_\theta(x) + f_r(x)) : k \in \mathbb{R}\}, && \alpha = \beta, \\ &= \{k f_r(x) : k \in \mathbb{R}\}, && \alpha < \beta. \end{aligned} \tag{14}$$

The unit circle S^1 is a differentiable submanifold of $\mathbb{R}^2$. Hence, for every $x \in \mathrm{S}^1$, $T_x\mathrm{S}^1$ is the tangent line to S^1 at x. Since the vector field f_θ points in the circumferential direction at every point, it follows that, for every $x \in \mathrm{S}^1$, $T_x\mathrm{S}^1 = \operatorname{span}\{f_\theta(x)\}$. It now follows from (14) that

$$\begin{aligned} T_x\mathrm{S}^1 \cap \mathcal{F}_x &= T_x\mathrm{S}^1, && \alpha > \beta, \\ &= \{0\}, && \alpha \leq \beta. \end{aligned} \tag{15}$$

Thus, for every $x \in \mathrm{S}^1$, f is nontangent to S^1 at x relative to $\mathcal{G}$ if and only if $\alpha \leq \beta$. It can be observed that Figures 1 and 2 reflect this fact.

5. Positive limit sets, convergence, and nontangency. In this section, we present nontangency-based Lyapunov results for convergence. These results use three key ideas. The first of these, given in Proposition 5.1, is that a solution of (6) converges to a limit if and only if its positive limit set is a singleton set. The second key idea, presented as Proposition 5.2, is to use Proposition 4.1 to show that the positive limit set of a solution of (6) is a singleton set if and only if the vector field f is nontangent to the positive limit set at some point. Since it is not generally possible to find the positive limit set of a solution in practice, it is difficult to check nontangency of the vector field f to the positive limit set in applications. Since nontangency to any outer estimate of the positive limit set implies nontangency to the positive limit set itself, the third key idea is to check nontangency of the vector field f to an outer estimate of the positive limit set that is easier to find in practice. Proposition 5.3 gives outer estimates of the positive limit sets in terms of invariant subsets of the level and sublevel sets of a Lyapunov function and its derivative. Theorem 5.1, the main result of this section, combines the ideas of Propositions 5.1, 5.2, and 5.3 to give

a sufficient condition for convergence that involves a nontangency condition between the vector field f and invariant subsets of the level sets of the derivative of a Lyapunov function.

Given $x \in \mathcal{G}$, the *positive limit set* of x relative to $\mathcal{G}$ is the set $\mathcal{O}_x^\infty$ of points $z \in \mathcal{G}$ such that there exists a divergent sequence $\{t_i\}$ in $[0, \infty)$ satisfying $\lim_{i\to\infty} \psi(t_i, x) = z$. The first part of the following result on positive limit sets is well known in the case $\mathcal{G} = \mathbb{R}^n$. See, for instance, [7, Thm. 5.5, 5.9], [8, p. 24], [19, p. 114], and [21]. The second part depends on the local compactness of $\mathcal{G}$.

PROPOSITION 5.1. *Let $x \in \mathcal{G}$. If $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$, then $\mathcal{O}_x^\infty$ is nonempty, compact, invariant, and connected, and, in addition, $\psi(t, x) \to \mathcal{O}_x^\infty$ as $t \to \infty$; that is, for every relatively open subset $\mathcal{U} \subseteq \mathcal{G}$ that contains $\mathcal{O}_x^\infty$, there exists $T > 0$ such that $\psi(t, x) \in \mathcal{U}$ for all $t > T$. Moreover, $\lim_{t\to\infty} \psi(t, x)$ exists and is contained in $\mathcal{G}$ if and only if $\mathcal{O}_x^\infty$ contains exactly one point.*

Proof. The first part of the result is well known for $\mathcal{G} = \mathbb{R}^n$. The proof is similar in the case where $\mathcal{G} \neq \mathbb{R}^n$ and is left to the reader. In the second part, the necessity is straightforward. To prove sufficiency, suppose that $\mathcal{O}_x^\infty = \{z\}$. Let $\mathcal{U}_\varepsilon \subseteq \mathcal{G}$ be a relatively open neighborhood of z. Since $\mathcal{G}$ is locally compact, there exists a neighborhood $\mathcal{U} \subseteq \mathcal{U}_\varepsilon$ of x that is relatively open and relatively bounded in $\mathcal{G}$. Since $z \in \mathcal{O}_x^\infty$, there exists a divergent sequence $\{t_i\}$ in $[0, \infty)$ such that $\psi(t_i, x) \in \mathcal{U}$ for all i. We claim that there exists $T > 0$ such that $\psi(t, x) \in \mathcal{U}_\varepsilon$ for all $t > T$. If not, then by the continuity of ψ, for every i, there exists $\tau_i > t_i$ such that $\psi(\tau_i, x) \in \operatorname{bd} \mathcal{U}$. In this case, the sequence $\{\psi(\tau_i, x)\}$ is relatively bounded in $\mathcal{G}$ and hence has a subsequential limit $w \in \mathcal{G}$. By construction, $w \in \operatorname{bd} \mathcal{U}$ and hence $w \neq z$. However, by definition, $w \in \mathcal{O}_x^\infty = \{z\}$, which is a contradiction. Hence we conclude that there exists $T > 0$ such that $\psi(t, x) \in \mathcal{U}_\varepsilon$ for all $t > T$. Since $\mathcal{U}_\varepsilon$ was chosen arbitrarily, it follows that $\lim_{t\to\infty} \psi(t, x) = z \in \mathcal{G}$. ∎

The following application of Proposition 4.1 gives a nontangency-based necessary and sufficient condition for a solution of (6) to converge to a limit.

PROPOSITION 5.2. *Let $x \in \mathcal{G}$, and suppose that $\mathcal{O}_x^\infty$ is nonempty. Then $\lim_{t\to\infty} \psi(t, x)$ exists and is contained in $\mathcal{G}$ if and only if there exists $z \in \mathcal{O}_x^\infty$ such that f is nontangent to $\mathcal{O}_x^\infty$ at z relative to $\mathcal{G}$.*

Proof. Consider $z \in \mathcal{O}_x^\infty$. There exists a divergent sequence $\{t_i\}$ in $[0, \infty)$ such that $\lim_{i\to\infty} \psi(t_i, x) = z$. For every i, denote $x_i = \psi(t_i, x)$ so that $\lim_{i\to\infty} x_i = z$. $\mathcal{O}_x^\infty$ is the set of subsequential limits of sequences of the form $\{\psi(h_i, x_i)\}$, where $h_i \in [0, \infty)$ for every i. Letting $\mathcal{I}_i = [0, \infty)$ for every i and $\mathcal{B} = \mathcal{O}_x^\infty$, it follows from Proposition 4.1 that $\mathcal{O}_x^\infty = \{z\}$ if and only if f is nontangent to $\mathcal{O}_x^\infty$ at z. The result now follows from the second part of Proposition 5.1. ∎

Example 5.1. Consider the system described in Example 1.1, and assume that $\alpha \geq \beta + 1$. Let $\mathcal{G} = \mathbb{R}^2$, and consider $x \in \mathcal{G} \backslash \mathrm{S}^1$. As discussed in Example 1.1, $\lim_{t\to\infty} \psi(t, x)$ does not exist. Indeed, $\mathcal{O}_x^\infty = \mathrm{S}^1$. As discussed in Example 4.2, f is not nontangent to $\mathcal{O}_x^\infty = \mathrm{S}^1$ at x, thus illustrating Proposition 5.2.

It should be noted that in order to apply Proposition 5.2 to a solution of (6), the positive limit set of the solution needs to be known. Since it is not generally possible to find the positive limit set of a solution, Proposition 5.2 is not directly useful in applications. However, Lyapunov functions can sometimes be used to obtain sets that contain the positive limit set of a solution. The following proposition gives two such containment results for positive limit sets. The result is a straightforward extension of [8, Thm. VIII.6.1, c)] and [21, Thm. 1]. Hence the proof is left to the reader. We note only that the proof uses the invariance properties of positive limit

sets given in Proposition 5.1.

PROPOSITION 5.3. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$, and $\dot{V}(x) \leq 0$ for all $x \in \mathcal{G}$. Let $x \in \mathcal{G}$ be such that $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$. Let $\mathcal{P}$ and $\mathcal{N}$ denote the largest invariant subsets of the sets $\{z \in \mathcal{G} : V(z) \leq V(x)\}$ and $\dot{V}^{-1}(0)$, respectively. Then $\mathcal{O}_x^\infty \subseteq \mathcal{P} \cap \mathcal{N}$. In addition, if $\dot{V} \equiv 0$, then $\mathcal{O}_x^\infty$ is contained in the largest invariant subset of $V^{-1}(V(x))$.*

In the following example, we illustrate Propositions 5.2 and 5.3 by applying them to the chemical kinetics of the Michaelis–Menten chemical reaction.

Example 5.2. In the Michaelis–Menten chemical reaction, a substrate S is converted into a product P through an intermediate complex C in the presence of an enzyme E. The reaction is depicted as

$$\mathrm{S} + \mathrm{E} \underset{k_2}{\overset{k_1}{\rightleftharpoons}} \mathrm{C} \xrightarrow{k_3} \mathrm{P} + \mathrm{E},$$

where $k_i > 0$, $i = 1, 2, 3$, are chemical rate constants. In this example, we use Propositions 5.2 and 5.3 to show that the concentrations of species S, P, C, and E in this chemical reaction converge to equilibrium values.

Letting $y_1(t), y_2(t), y_3(t)$, and $y_4(t)$ denote the instantaneous nonnegative concentrations of the species S, C, E, and P, respectively, the law of mass action kinetics yields [11]

$$\dot{y}(t) = y_2(t)v_1 + y_1(t)y_3(t)v_2, \tag{16}$$

where $v_1 = \begin{bmatrix} k_2 & -(k_2+k_3) & k_2+k_3 & k_3 \end{bmatrix}^{\mathrm{T}}$ and $v_2 = \begin{bmatrix} -k_1 & k_1 & -k_1 & 0 \end{bmatrix}^{\mathrm{T}}$. Equation (16) is of the form (6), where $f : \mathbb{R}^4 \to \mathbb{R}^4$ is given by $f(x) = x_2v_1 + x_1x_3v_2$.

The nonnegative orthant $\mathcal{G} = \{x \in \mathbb{R}^4 : x_i \geq 0, i = 1, \ldots, 4\}$ is positively invariant under the dynamics (16) [4, 11]. Since the vectors v_1 and v_2 are linearly independent, it is easy to see that the set of equilibrium concentrations in $\mathcal{G}$ is $\mathcal{E} = \mathcal{E}_1 \cup \mathcal{E}_2$, where $\mathcal{E}_1 = \{x \in \mathcal{G} : x_1 = 0, x_2 = 0, x_3 > 0\}$ and $\mathcal{E}_2 = \{x \in \mathcal{G} : x_1 \geq 0, x_2 = 0, x_3 = 0\}$.

We claim that f is nontangent to $\mathcal{E}_1$ at every point in $\mathcal{E}_1$ relative to $\mathcal{G}$. Indeed, the direction cone $\mathcal{F}_x$ of f at every point $x \in \mathcal{G}$ is contained in the span of v_1 and v_2, while every vector that is tangent to $\mathcal{E}_1$ at some point $x \in \mathcal{E}_1$ is contained in the span of the vectors $v_3 = \begin{bmatrix} 0 & 0 & 1 & 0 \end{bmatrix}^{\mathrm{T}}$ and $v_4 = \begin{bmatrix} 0 & 0 & 0 & 1 \end{bmatrix}^{\mathrm{T}}$. Since $\{v_i : i = 1, 2, 3, 4\}$ is a set of linearly independent vectors, it follows that $\mathrm{span}\{v_1, v_2\} \cap \mathrm{span}\{v_3, v_4\} = \{0\}$. Thus $T_x\mathcal{E}_1 \cap \mathcal{F}_x \subseteq \{0\}$ for every $x \in \mathcal{E}_1$.

It is easy to verify that the function $U : \mathcal{G} \to \mathbb{R}$ given by $U(x) = x_1 + 2x_2 + x_3 + x_4$ is proper and satisfies $\dot{U} \equiv 0$. It follows from Corollary 3.1 that every orbit in $\mathcal{G}$ is relatively bounded in $\mathcal{G}$. Hence, by Proposition 5.1, $\mathcal{O}_x^\infty$ is nonempty for every $x \in \mathcal{G}$.

Now consider the function $V : \mathcal{G} \to \mathbb{R}$ defined by $V(x) = \frac{1}{2}x_2^2 + x_1(x_2 + x_3) - \frac{1}{2}x_3^2$. Then $\dot{V}(x) = -k_3x_2(x_2 + x_3) \leq 0$ for all $x \in \mathcal{G}$. Thus $\dot{V}^{-1}(0) = \{x \in \mathcal{G} : x_2 = 0\}$. If a solution y of the differential equation (16) satisfies $y_2 \equiv 0$, then $\dot{y}_2 \equiv 0$ and hence $y_1y_3 \equiv 0$. It therefore follows that the largest invariant subset of $\dot{V}^{-1}(0)$ is the set $\mathcal{E}$ of equilibrium concentrations. Proposition 5.3 now implies that $\mathcal{O}_x^\infty \subseteq \mathcal{E}$ for every $x \in \mathcal{G}$.

Next, consider the function $W : \mathcal{G} \to \mathbb{R}$ defined by $W(x) = x_2 + x_3$. It is easy to verify that $\dot{W} \equiv 0$. Hence, by Proposition 5.3, for every $x \in \mathcal{G}$, $\mathcal{O}_x^\infty$ is contained in the level set $W^{-1}(W(x))$ of W containing x. Thus it follows that, for every $x \in \mathcal{G}$, $\mathcal{O}_x^\infty \subseteq W^{-1}(W(x)) \cap \mathcal{E}$. Since $W^{-1}(0) = \mathcal{E}_2$, it follows that $W^{-1}(W(x)) \cap \mathcal{E} \subseteq \mathcal{E}_1$ for every $x \in \mathcal{G}$ satisfying $W(x) > 0$. Hence we conclude that, for every $x \in \mathcal{G} \backslash \mathcal{E}_2$, $\mathcal{O}_x^\infty \subseteq \mathcal{E}_1$.

Now consider $x \in \mathcal{E}_2$. Then x is an equilibrium, and concentrations starting from the initial value x clearly converge to the equilibrium value x. Next, consider $x \in \mathcal{G}\backslash\mathcal{E}_2$. Then $\mathcal{O}_x^\infty \subseteq \mathcal{E}_1$ and, for every $z \in \mathcal{O}_x^\infty$, $T_z\mathcal{O}_x^\infty \cap \mathcal{F}_z \subseteq T_z\mathcal{E}_1 \cap \mathcal{F}_z \subseteq \{0\}$. Hence Proposition 5.2 implies that concentrations starting from the initial values x converge to equilibrium values. We conclude that the system described by (16) is convergent relative to $\mathcal{G}$; that is, the concentrations of all species in the Michaelis–Menten reaction converge to equilibrium values.

The following result gives a sufficient condition for a trajectory of (6) to converge to a limit. Unlike Proposition 5.2, the following result is not based on nontangency.

PROPOSITION 5.4. *Let $x \in \mathcal{G}$. If $\mathcal{O}_x^\infty$ contains an equilibrium z that is Lyapunov stable relative to $\mathcal{G}$, then $z = \lim_{t\to\infty} \psi(t,x)$; that is, $\mathcal{O}_x^\infty = \{z\}$.*

Proof. Suppose $z \in \mathcal{O}_x^\infty$ is Lyapunov stable relative to $\mathcal{G}$. Let $\mathcal{U}_\varepsilon \subseteq \mathcal{G}$ be a relatively open neighborhood of z. By Lyapunov stability, there exists a relatively open neighborhood $\mathcal{U}_\delta \subset \mathcal{G}$ of z such that $\psi_t(\mathcal{U}_\delta) \subseteq \mathcal{U}_\varepsilon$ for every $t \geq 0$. Since $z \in \mathcal{O}_x^\infty$, there exists $h \geq 0$ such that $\psi(h,x) \in \mathcal{U}_\delta$. Therefore, $\psi(t+h,x) = \psi_t(\psi(h,x)) \in \psi_t(\mathcal{U}_\delta) \subseteq \mathcal{U}_\varepsilon$ for every $t > 0$. Since $\mathcal{U}_\varepsilon \subseteq \mathcal{G}$ was chosen arbitrarily, it follows that $z = \lim_{t\to\infty} \psi(t,x)$. It immediately follows that $\lim_{i\to\infty} \psi(t_i,x) = z$ for every divergent sequence $\{t_i\}$ and thus $\mathcal{O}_x^\infty = \{z\}$. ∎

Our next result applies Propositions 5.2, 5.3, and 5.4 to obtain a sufficient condition for convergence. The result uses Proposition 5.3 to obtain a set containing all positive limit sets and then uses Propositions 5.2 and 5.4 to show convergence.

THEOREM 5.1. *Suppose $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$ for all $x \in \mathcal{G}$, and assume that there exists a continuous function $V : \mathcal{G} \to \mathbb{R}$ such that $\dot{V}$ is defined on $\mathcal{G}$ and satisfies $\dot{V}(x) \leq 0$ for all $x \in \mathcal{G}$. Let $\mathcal{S} \subseteq \mathcal{E}$ denote the set of equilibria that are Lyapunov stable relative to $\mathcal{G}$, and let $\mathcal{N}_0$ denote the largest invariant subset of $\dot{V}^{-1}(0)$. For every $k = 0,1,2,\ldots$, let $\mathcal{M}_k \subseteq \mathcal{N}_k$ denote the set of points in $\mathcal{N}_k$ where f is not nontangent to $\mathcal{N}_k$ relative to $\mathcal{G}$, and let $\mathcal{N}_{k+1} \subseteq \mathcal{M}_k$ denote the largest invariant subset of $\mathcal{M}_k$. If $\mathcal{M}_k \subseteq \mathcal{S}$ for some k, then the system* (6) *is convergent relative to $\mathcal{G}$.*

Proof. Consider $x \in \mathcal{G}$. Since $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$, Proposition 5.1 implies that $\mathcal{O}_x^\infty$ is nonempty and invariant. To prove the result, we first show that if $\mathcal{O}_x^\infty$ contains more than one element, then $\mathcal{O}_x^\infty \subseteq \mathcal{M}_k\backslash\mathcal{S}$ for every k.

Suppose $\mathcal{O}_x^\infty$ contains more than one element. By Proposition 5.3, it follows that $\mathcal{O}_x^\infty \subseteq \mathcal{N}_0$. Now assume that $\mathcal{O}_x^\infty \subseteq \mathcal{N}_k$ for some $k = 0,1,\ldots$. Since $\mathcal{O}_x^\infty$ contains more than one element, it follows from Proposition 5.2 that, for every $z \in \mathcal{O}_x^\infty$, f is not nontangent to $\mathcal{O}_x^\infty$ at z relative to $\mathcal{G}$, that is, $\{0\} \not\supseteq T_z\mathcal{O}_x^\infty \cap \mathcal{F}_z \subseteq T_z\mathcal{N}_k \cap \mathcal{F}_z$. Since $\mathcal{M}_k = \{z \in \mathcal{N}_k : T_z\mathcal{N}_k \cap \mathcal{F}_z \not\subseteq \{0\}\}$, it follows that $\mathcal{O}_x^\infty \subseteq \mathcal{M}_k$. Since $\mathcal{O}_x^\infty$ is invariant, $\mathcal{O}_x^\infty \subseteq \mathcal{N}_{k+1}$. It follows by induction that $\mathcal{O}_x^\infty \subseteq \mathcal{N}_{k+1} \subseteq \mathcal{M}_k$ for every k. Also, it follows from Proposition 5.4 that $\mathcal{O}_x^\infty \cap \mathcal{S} = \varnothing$. Thus $\mathcal{O}_x^\infty \subseteq \mathcal{M}_k\backslash\mathcal{S}$ for every k.

It follows from the above arguments that if $\mathcal{M}_k\backslash\mathcal{S} = \varnothing$ for some k, then $\mathcal{O}_x^\infty$ contains only one element, and hence, by Proposition 5.1, $\lim_{t\to\infty} \psi(t,x)$ exists and is contained in $\mathcal{G}$. The result now follows. ∎

Example 5.3. In this example, we use Theorem 5.1 to show that the closed-loop adaptive system given by (10) and (11) in Example 3.1 is convergent.

It was shown in Example 3.1 that every orbit of the system (10)–(11) is bounded. Consider the function $V : \mathbb{R}^2 \to \mathbb{R}$ given by $V(x) = e^{-k}$, $x = (y,k) \in \mathbb{R}^2$. For the closed-loop system (10)–(11), it follows that $\dot{V}(x) = -e^{-k}y^2 \leq 0$ for all $x = (y,k) \in \mathbb{R}^2$. Thus $\dot{V}^{-1}(0) = \{(y,k) \in \mathbb{R}^2 : y = 0\} = \mathcal{E}$, the set of equilibria, and the largest invariant subset of $\dot{V}^{-1}(0)$ is $\mathcal{N}_0 = \dot{V}^{-1}(0) = \mathcal{E}$.

To investigate nontangency, let $f : \mathbb{R}^2 \to \mathbb{R}^2$ denote the right-hand side of (10)–(11), and let $\mathcal{Z} = \{(0,k) : a + bk^2 \cos k = 0\}$. We note that $\mathcal{Z} \subseteq \mathcal{E}$. Since $b \neq 0$, the set $\mathcal{Z}$ is nonempty, and every point of $\mathcal{Z}$ is isolated. For every $x = (y,k) \in \mathcal{N}_0 \backslash \mathcal{Z}$ and every sequence $\{x_i\} = \{(y_i, k_i)\}$ in $\mathbb{R}^2 \backslash \mathcal{E}$ converging to x and satisfying $\operatorname{sign}(y_i) = \operatorname{sign}(y_j)$, $i, j = 1, 2, \ldots$, we have

$$\begin{aligned}\lim_{i\to\infty} \frac{1}{\|f(x_i)\|} f(x_i) &= \lim_{i\to\infty} \frac{1}{\sqrt{y_i^2 + (a + bk_i^2 \cos k_i)^2}} \begin{bmatrix} -\operatorname{sign}(y_i)(a + bk_i^2 \cos k_i) \\ |y_i| \end{bmatrix} \\ &= \begin{bmatrix} -\operatorname{sign}(y_1)\operatorname{sign}(a + bk^2 \cos k) \\ 0 \end{bmatrix} \\ &\in \{[\pm 1 \ 0]^{\mathrm{T}}\}.\end{aligned}$$

Thus, for every $x \in \mathcal{N}_0 \backslash \mathcal{Z}$, $\mathcal{L}_x$ is finite. By Remark 4.3, for every $x \in \mathcal{N}_0 \backslash \mathcal{Z}$, $\mathcal{F}_x = \operatorname{coco} \mathcal{L}_x = \{(c, 0) : c \in \mathbb{R}\}$. On the other hand, for every $x \in \mathcal{N}_0$, $T_x \mathcal{N}_0 = \{(0, c) : c \in \mathbb{R}\}$. Hence f is nontangent to $\mathcal{N}_0$ at every point $x \in \mathcal{N}_0 \backslash \mathcal{Z}$.

In order to apply Theorem 5.1, we note that, in the notation of Theorem 5.1, $\mathcal{N}_1 \subseteq \mathcal{M}_0 \subseteq \mathcal{Z}$. If $\mathcal{N}_1$ is empty, then $\mathcal{M}_1 \subseteq \mathcal{N}_1$ is empty. If $\mathcal{N}_1$ is nonempty, $\mathcal{Z}$ consists only of isolated points and hence $T_x \mathcal{N}_1 = \{0\}$ for every $x \in \mathcal{N}_1$. Consequently, f is nontangent to $\mathcal{N}_1$ at every point in $\mathcal{N}_1$ and hence $\mathcal{M}_1$ is empty. In either case, $\mathcal{M}_1 \subseteq \mathcal{S}$ vacuously. It now follows from Theorem 5.1 that the system (10)–(11) is convergent relative to $\mathbb{R}^2$.

The following two results follow easily from Theorem 5.1.

COROLLARY 5.1. *Suppose $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$ for all $x \in \mathcal{G}$, and assume that there exists a continuous function $V : \mathcal{G} \to \mathbb{R}$ such that $\dot{V}$ is defined on $\mathcal{G}$ and satisfies $\dot{V}(x) \leq 0$ for all $x \in \mathcal{G}$. Let $\mathcal{N}$ be the largest invariant subset of $\dot{V}^{-1}(0)$. If f is nontangent to $\mathcal{N}$ at every $z \in \mathcal{N}$ relative to $\mathcal{G}$, then the system* (6) *is convergent relative to $\mathcal{G}$.*

Proof. Suppose f is nontangent to $\mathcal{N}$ at every $z \in \mathcal{N}$ relative to $\mathcal{G}$. In the notation of Theorem 5.1, $\mathcal{N}_0 = \mathcal{N}$, while $\mathcal{M}_0 = \varnothing$. Thus $\mathcal{M}_0 \subseteq \mathcal{S}$ vacuously, and the result follows from Theorem 5.1. ∎

COROLLARY 5.2. *Suppose $\mathcal{O}_x$ is relatively bounded in $\mathcal{G}$ for all $x \in \mathcal{G}$, and assume that there exists a continuous function $V : \mathcal{G} \to \mathbb{R}$ such that $\dot{V}$ is defined on $\mathcal{G}$ and satisfies $\dot{V}(x) \leq 0$ for all $x \in \mathcal{G}$. Let $\mathcal{N}$ be the largest invariant subset of $\dot{V}^{-1}(0)$. If every point in $\mathcal{N}$ is Lyapunov stable relative to $\mathcal{G}$, then the system* (6) *is convergent relative to $\mathcal{G}$.*

Proof. Suppose every point in $\mathcal{N}$ is Lyapunov stable relative to $\mathcal{G}$. Then, in the notation of Theorem 5.1, $\mathcal{M}_0 \subseteq \mathcal{N}_0 = \mathcal{N} = \mathcal{S}$. The result now follows from Theorem 5.1. ∎

In the following example, we illustrate Corollary 5.1 by applying it to the system considered in Example 1.1.

Example 5.4. Consider the system described in Example 1.1. Suppose $\alpha \leq \beta$, and let $\mathcal{G} = \mathbb{R}^2$. Consider the Lyapunov function $V : \mathcal{G} \to \mathbb{R}$ given by $V(x) = \frac{1}{4}(x_1^2 + x_2^2 - 1)^2$. It is easy to compute $\dot{V}(x) = -(x_1^2 + x_2^2)|x_1^2 + x_2^2 - 1|^{1+\alpha}$ so that $\dot{V}(x) \leq 0$ for all $x \in \mathcal{G}$ and $\dot{V}^{-1}(0) = \mathrm{S}^1 \cup \{0\}$. Since every point in $\dot{V}^{-1}(0)$ is an equilibrium, the largest invariant subset of $\dot{V}^{-1}(0)$ is $\mathcal{N} = \dot{V}^{-1}(0)$. We know from Example 4.2 that f is nontangent to $\mathcal{N}$ at every point in S^1 relative to $\mathcal{G}$. Since $\{0\}$ is an isolated point of $\mathcal{N}$, it follows that f is nontangent to $\mathcal{N}$ at 0 relative to $\mathcal{G}$. Thus the hypotheses of Corollary 5.1 are satisfied, and we conclude that the system considered in Example 1.1 is convergent relative to $\mathcal{G} = \mathbb{R}^2$ in the case where $\alpha \leq \beta$.

6. Restricted prolongations, Lyapunov stability, and nontangency. In this section, we develop three key ideas that will be needed for the nontangency-based Lyapunov tests for Lyapunov stability, semistability, and asymptotic stability that we present in the next section. The first of these ideas, given in Proposition 6.2, is that an equilibrium is Lyapunov stable if and only if its restricted prolongation, as defined below, is a singleton set. The second key idea, given in Proposition 6.3, is to use Proposition 4.1 to show that the restricted prolongation of an equilibrium of (6) is a singleton set if and only if the vector field f is nontangent to the restricted prolongation at the equilibrium. Since it is not generally possible to find the restricted prolongation of an equilibrium in practice, nontangency of the vector field f to the restricted prolongation is difficult to verify in applications. Since nontangency to any outer estimate of the restricted prolongation implies nontangency to the restricted prolongation itself, the third key idea is to determine outer estimates of the restricted prolongation that are easier to find in practice. Proposition 6.4 gives outer estimates of restricted prolongations in terms of connected components of invariant and negatively invariant subsets of level and sublevel sets of a Lyapunov function and its derivative. This result depends on the invariance properties of restricted prolongations given in Proposition 6.1.

Given a point $x \in \mathcal{G}$ and a relatively open and relatively bounded neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x, the *restricted prolongation* of x with respect to $\mathcal{U}$ is the set $\mathcal{R}_x^{\mathcal{U}} \subseteq \overline{\mathcal{U}}$ of all subsequential limits of sequences of the form $\{\psi(t_i, x_i)\}$, where $\{t_i\}$ is a sequence in $[0, \infty)$ and $\{x_i\}$ is a sequence in $\mathcal{U}$ converging to x such that the set $\psi([0, t_i] \times \{x_i\})$ is contained in $\overline{\mathcal{U}}$ for every i. It is easy to see that, for every $x \in \mathcal{G}$ and every relatively bounded and open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x, $\mathcal{R}_x^{\mathcal{U}}$ contains x and is thus nonempty. The *restricted prolongation* of x relative to $\mathcal{G}$ is the union $\mathcal{R}_x$ of all sets of the form $\mathcal{R}_x^{\mathcal{U}}$ where $\mathcal{U} \subseteq \mathcal{G}$ is a relatively open and relatively bounded neighborhood of x. It can be shown that $\mathcal{R}_x$ is the set of all subsequential limits of sequences of the form $\{\psi(t_i, x_i)\}$, where $\{t_i\}$ is a sequence in $[0, \infty)$ and $\{x_i\}$ is a sequence in $\mathcal{G}$ converging to x such that the set $\cup_i \psi([0, t_i] \times \{x_i\})$ is relatively bounded in $\mathcal{G}$. The restricted prolongation is a subset of the positive prolongation as defined in [7, 8].

The following result gives invariance properties of restricted prolongations.

PROPOSITION 6.1. *Suppose $x \in \mathcal{G}$, and let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open and relatively bounded neighborhood of x. Then $\mathcal{R}_x^{\mathcal{U}}$ and $\mathcal{R}_x$ are connected. Moreover, if x is an equilibrium, then $\mathcal{R}_x^{\mathcal{U}}$ is negatively invariant and $\mathcal{R}_x$ is invariant.*

Proof. To prove the first part of the proposition, suppose $\mathcal{R}_x^{\mathcal{U}}$ is not connected. Then there exist open and disjoint subsets $\mathcal{V}$ and $\mathcal{W}$ of $\mathbb{R}^n$ such that $\mathcal{R}_x^{\mathcal{U}} \subseteq \mathcal{V} \cup \mathcal{W}$, $\mathcal{R}_x^{\mathcal{U}} \cap \mathcal{V} \neq \varnothing$, and $\mathcal{R}_x^{\mathcal{U}} \cap \mathcal{W} \neq \varnothing$. Since $x \in \mathcal{R}_x^{\mathcal{U}}$, we may assume without loss of generality that $x \in \mathcal{V}$.

Consider $z \in \mathcal{R}_x^{\mathcal{U}} \cap \mathcal{W}$. There exist a sequence $\{x_i\}$ in $\mathcal{G}$ converging to x and a sequence $\{t_i\}$ in $[0, \infty)$ such that $\lim_{i \to \infty} \psi(t_i, x_i) = z$ and $\psi([0, t_i] \times \{x_i\}) \subseteq \overline{\mathcal{U}}$ for every i. Since $\lim_{i \to \infty} \psi(0, x_i) = x$ and $\lim_{i \to \infty} \psi(t_i, x_i) = z$, there exists $k > 0$ such that, for every $i > k$, the connected set $\psi([0, t_i] \times \{x_i\})$ intersects the disjoint, relatively open sets $\mathcal{V}$ and $\mathcal{W}$. We conclude that, for every $i > k$, there exists $\tau_i \in [0, t_i]$ such that $\psi(\tau_i, x_i) \in (\mathcal{V} \cup \mathcal{W})^{\mathrm{c}} = \mathcal{V}^{\mathrm{c}} \cap \mathcal{W}^{\mathrm{c}}$, where $\mathcal{A}^{\mathrm{c}}$ denotes the complement $\mathbb{R}^n \backslash \mathcal{A}$ of the set $\mathcal{A} \subseteq \mathbb{R}^n$. The sequence $\{\psi(\tau_i, x_i)\}$ is relatively bounded in $\mathcal{G}$ and contained in the closed set $\mathcal{V}^{\mathrm{c}} \cap \mathcal{W}^{\mathrm{c}}$. Therefore, the sequence $\{\psi(\tau_i, x_i)\}$ has a subsequential limit in $\mathcal{V}^{\mathrm{c}} \cap \mathcal{W}^{\mathrm{c}}$. However, by definition, every subsequential limit of the sequence $\{\psi(\tau_i, x_i)\}$ is contained in $\mathcal{R}_x^{\mathcal{U}} \subset \mathcal{V} \cup \mathcal{W}$. This contradiction proves that $\mathcal{R}_x^{\mathcal{U}}$ is connected.

It now follows that $\mathcal{R}_x$ is a union of connected sets of the form $\mathcal{R}_x^{\mathcal{U}}$, all of which contain x, and is thus connected [10, Thm. V.1.5].

To prove the second part of the proposition, suppose $x \in \mathcal{G}$ is an equilibrium, and consider $z \in \mathcal{R}_x^{\mathcal{U}}$. There exist a sequence $\{t_i\}$ in $[0, \infty)$ and a sequence $\{x_i\}$ in $\mathcal{G}$ converging to x such that $z = \lim_{i\to\infty} \psi(t_i, x_i)$ and, for every i, $\psi(h, x_i) \in \overline{\mathcal{U}}$ for every $h \in [0, t_i]$.

Now, let $t \geq 0$. If $z = x$, then $\psi(\tau, x) = x = z$ for every $\tau \in [0, t]$. Hence suppose $z \neq x$. If the sequence $\{t_i\}$ has a bounded subsequence, say, $\{t_{i_k}\}$, then we may assume that $\lim_{k\to\infty} t_{i_k} = T$ so that $z = \lim_{k\to\infty} \psi(t_{i_k}, x_{i_k}) = \psi(T, x) = x$. However, this contradicts our assumption that $z \neq x$. Hence we conclude that the sequence $\{t_i\}$ diverges. Therefore, there exists $N > 0$ such that $t_i > t$ for all $i > N$. The sequence $\{\psi(t_{i+N} - t, x_{i+N})\}_{i=1}^{\infty}$ is contained in $\overline{\mathcal{U}}$ and hence relatively bounded in $\mathcal{G}$. Let $y \in \mathcal{G}$ be a subsequential limit point of this sequence. Clearly, $y \in \mathcal{R}_x^{\mathcal{U}}$. Also, by continuity and the semigroup property, $\psi(t, y) = z$, and, for every $\tau \in [0, t]$, $\psi(\tau, y)$ is a subsequential limit of the bounded sequence $\{\psi(t_{i+N} + \tau - t, x_{i+N})\}_{i=1}^{\infty}$ and hence contained in $\mathcal{R}_x^{\mathcal{U}}$. This proves the negative invariance of $\mathcal{R}_x^{\mathcal{U}}$.

From the negative invariance of $\mathcal{R}_x^{\mathcal{U}}$, it follows that $\mathcal{R}_x$ is the union of negatively invariant sets and hence negatively invariant. To prove positive invariance of $\mathcal{R}_x$, let $\tau \geq 0$ and $z \in \mathcal{R}_x$. There exist a sequence $\{t_i\}$ in $[0, \infty)$ and a sequence $\{x_i\}$ in $\mathcal{G}$ converging to x and a compact set $\mathcal{M} \subseteq \mathcal{G}$ such that $z = \lim_{i\to\infty} \psi(t_i, x_i)$ and, for every i and every $h \in [0, t_i]$, $\psi(h, x_i) \in \mathcal{M}$. Now, for every i and every $h \in [0, t_i + \tau]$, $\psi(h, x_i)$ is contained in the compact subset $\psi([0, \tau] \times \mathcal{M})$ of $\mathcal{G}$. Hence a subsequence of the sequence $\{\psi(t_i + \tau, x_i)\}$ converges in $\mathcal{G}$. The limit of this subsequence is $\psi(\tau, z)$ by continuity and the semigroup property and is contained in $\mathcal{R}_x$ by definition. Thus $\psi(\tau, z) \in \mathcal{R}_x$ for every $z \in \mathcal{R}_x$ and $\tau \geq 0$. This proves the positive invariance and hence the invariance of $\mathcal{R}_x$. □

The utility of prolongations in stability analysis stems from the well-known fact that an equilibrium point is Lyapunov stable if and only if the positive prolongation of the equilibrium consists only of the equilibrium point. See, for instance, [7, Prop. 7.3] and [8, Thm. V.1.12]. We prove the same result for restricted prolongations in Proposition 6.2 below. Since, as mentioned above, the restricted prolongation of a point is a subset of the positive prolongation of the point, Proposition 6.2 is a sharper version of the results [7, Prop. 7.3] and [8, Thm. V.1.12]. However, our reason for considering restricted prolongations instead of positive prolongations in this paper is that restricted prolongations are invariant and connected as proved in Proposition 6.1 above. Positive prolongations, on the other hand, may neither be connected nor invariant under our assumptions on the system (6). Since the invariance and connectedness of restricted prolongations play a crucial role in our main results, we introduce restricted prolongations instead of using positive prolongations.

PROPOSITION 6.2. *Suppose $x \in \mathcal{G}$, and let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open and relatively bounded neighborhood of x. Then the following statements are equivalent.*

(i) *The point x is a Lyapunov stable equilibrium relative to $\mathcal{G}$.*
(ii) $\mathcal{R}_x^{\mathcal{U}} = \{x\}$.
(iii) $\mathcal{R}_x = \{x\}$.

Proof. If x is a Lyapunov stable equilibrium relative to $\mathcal{G}$, then the positive prolongation of x, which contains $\mathcal{R}_x$, is $\{x\}$ [7, Prop. 7.3], [8, Th. V.1.12], and hence $\mathcal{R}_x = \{x\}$. Thus (i) implies (iii).

Since $x \in \mathcal{R}_x^{\mathcal{U}}$ and $\mathcal{R}_x^{\mathcal{U}} \subseteq \mathcal{R}_x$, (iii) implies (ii).

To show that (ii) implies (i), suppose x is not a Lyapunov stable equilibrium

relative to $\mathcal{G}$. Then there exist a neighborhood $\mathcal{V} \subseteq \mathcal{U}$ of x that is relatively bounded and relatively open in $\mathcal{G}$, a sequence $\{x_i\}$ in $\mathcal{V}$ converging to x, and a sequence $\{t_i\}$ in $[0, \infty)$ such that $\psi(t_i, x_i) \in \text{bd } \mathcal{V}$ for every i. Without loss of generality, we may assume that the sequence $\{t_i\}$ is chosen such that, for every i, $\psi(h, x_i) \in \mathcal{V}$ for all $h \in [0, t_i)$. Now, every subsequential limit of the relatively bounded sequence $\{\psi(t_i, x_i)\}$ is distinct from x by construction and is contained in $\mathcal{R}_x^{\mathcal{U}}$ by definition. Thus the negation of (i) implies the negation of (ii). Hence it follows that (ii) implies (i). ∎

The following result characterizes Lyapunov stable equilibrium points in terms of nontangency.

PROPOSITION 6.3. *Let $x \in \mathcal{G}$, and let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open and relatively bounded neighborhood of x. Then the following statements are equivalent.*

(i) *The point x is a Lyapunov stable equilibrium relative to $\mathcal{G}$.*
(ii) *The vector field f is nontangent to $\mathcal{R}_x^{\mathcal{U}}$ at x relative to $\mathcal{G}$.*
(iii) *The vector field f is nontangent to $\mathcal{R}_x$ at x relative to $\mathcal{G}$.*

Proof. If x is a Lyapunov stable equilibrium relative to $\mathcal{G}$, then it follows from Proposition 6.2 that $\mathcal{R}_x = \{x\}$ and hence $T_x\mathcal{R}_x = \{0\}$. Thus (i) implies (iii).

Since $\mathcal{R}_x^{\mathcal{U}} \subseteq \mathcal{R}_x$, it follows that $T_x\mathcal{R}_x^{\mathcal{U}} \subseteq T_x\mathcal{R}_x$ and hence (iii) implies (ii).

Now, suppose (ii) holds so that $T_x\mathcal{R}_x^{\mathcal{U}} \cap \mathcal{F}_x \subseteq \{0\}$. Let $z \in \mathcal{R}_x^{\mathcal{U}}$. There exist a sequence $\{x_i\}$ converging to x and a sequence $\{t_i\}$ in $[0, \infty)$ such that $\cup_i \psi([0, t_i] \times \{x_i\}) \subset \overline{\mathcal{U}}$ and $\lim_{i\to\infty} \psi(t_i, x_i) = z$.

First, suppose that the sequence $\{t_i\}$ converges to 0. Then by continuity, $z = \lim_{i\to\infty} \psi(t_i, x_i) = \psi(0, x) = x$. Next, suppose the sequence $\{t_i\}$ does not converge to 0. Then there exists a subsequence $\{t_{i_k}\}$ of the sequence $\{t_i\}$ such that $\inf_k t_{i_k} > 0$. Let $\mathcal{I}_k = [0, t_{i_k}]$ for each k, and let $\mathcal{B} \subseteq \overline{\mathcal{U}}$ denote the set of all subsequential limits of sequences of the form $\{\psi(\tau_k, x_{i_k})\}_{k=1}^{\infty}$, where $\tau_k \in \mathcal{I}_k$ for every k. By construction, $z \in \mathcal{B}$ and $\mathcal{B} \subseteq \mathcal{R}_x^{\mathcal{U}}$. Therefore, $T_x\mathcal{B} \cap \mathcal{F}_x \subseteq T_x\mathcal{R}_x^{\mathcal{U}} \cap \mathcal{F}_x \subseteq \{0\}$; that is, f is nontangent to $\mathcal{B}$ at x relative to $\mathcal{G}$. It now follows from Proposition 4.1 that $\mathcal{B} = \{x\}$. Hence $z = x$. Since $z \in \mathcal{R}_x^{\mathcal{U}}$ was arbitrary, it follows that $\mathcal{R}_x^{\mathcal{U}} = \{x\}$. Proposition 6.2 now implies that (i) holds. ∎

Example 6.1. Consider the system described in Example 1.1, and assume that $\alpha \geq \beta + 1$. Let $\mathcal{G} = \mathbb{R}^2$. As discussed in Example 1.1, every point in S^1 is an unstable equilibrium. From Figure 1, we observe that, for every $z \in \mathrm{S}^1$, $\mathcal{R}_z = \mathrm{S}^1$. Since S^1 consists only of equilibrium points, it follows that $\mathcal{R}_z$ is invariant for every $z \in \mathrm{S}^1$. This illustrates Proposition 6.1. As seen in Example 4.2, the vector field f is not nontangent to S^1 at any $z \in \mathrm{S}^1$, thus illustrating the equivalence of (i) and (iii) in Proposition 6.3.

As mentioned earlier, it is not generally possible to find the restricted prolongation of an equilibrium, and hence Proposition 6.3 cannot be directly used in applications. However, the following proposition shows that Lyapunov functions can be used to obtain sets that contain the restricted prolongation of an equilibrium. The proof uses the properties of invariance and connectedness of restricted prolongations given in Proposition 6.1.

PROPOSITION 6.4. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$. Let $x \in \mathcal{G}$ be an equilibrium, and let $\mathcal{W} \subseteq \mathcal{G}$ be a relatively open neighborhood of x. Let $\mathcal{M}_x$ and $\mathcal{N}_x$ denote the largest connected subsets of $V^{-1}(V(x)) \cap \mathcal{W}$ and $\overline{\dot{V}^{-1}(0)} \cap \mathcal{W}$, respectively, that contain x and are negatively invariant. Let $\mathcal{P}_x$ denote the largest connected subset of $\{z \in \mathcal{G} : V(z) \leq V(x)\}$ that contains x and is invariant. Then the following statements hold.*

(i) *If x is a global maximizer of $\dot{V}$ relative to $\mathcal{G}$, then $\mathcal{R}_x \subseteq \mathcal{P}_x$.*

(ii) *If x is a local maximizer of $\dot{V}$ relative to $\mathcal{G}$ and a local minimizer of V relative to the set $\mathcal{K} \stackrel{\text{def}}{=} \mathcal{G} \backslash \overline{\dot{V}^{-1}(0)}$, then there exists a relatively open and relatively bounded neighborhood $\mathcal{V} \subseteq \mathcal{W}$ of x such that $\mathcal{R}_x^{\mathcal{V}} \subseteq \mathcal{M}_x$.*

(iii) $\mathcal{M}_x \subseteq \mathcal{N}_x$.

Proof. (i) Suppose x is a global maximizer of $\dot{V}$ relative to $\mathcal{G}$ so that $\dot{V}(z) \leq \dot{V}(x) = 0$ for every $z \in \mathcal{G}$. Consider $z \in \mathcal{R}_x$. Let $\{x_i\}$ be a sequence in $\mathcal{G}$ converging to x and $\{t_i\}$ a sequence in $[0, \infty)$ such that $\lim_{i \to \infty} \psi(t_i, x_i) = z$. Since V is continuous and decreasing along the solutions of (6), it follows that $V(z) = \lim_{i \to \infty} V(\psi(t_i, x_i)) \leq \lim_{i \to \infty} V(x_i) = V(x)$. Thus $\mathcal{R}_x$ is contained in the set $\{z \in \mathcal{G} : V(z) \leq V(x)\}$. By Proposition 6.1, $\mathcal{R}_x$ is invariant and connected. Also, $x \in \mathcal{R}_x$. Hence it follows that $\mathcal{R}_x \subseteq \mathcal{P}_x$.

(ii) Let x be a local maximizer of $\dot{V}$ relative to $\mathcal{G}$ and a local minimizer of V relative to the set $\mathcal{K}$. Let $\mathcal{U} \subseteq \mathcal{W}$ be a relatively open neighborhood of x such that $\dot{V}(z) \leq \dot{V}(x) = 0$ for every $z \in \mathcal{U}$ and $V(x) \leq V(w)$ for every $w \in \mathcal{U} \cap \mathcal{K}$. Consider $w \in \mathcal{U} \cap \overline{\mathcal{K}}$. There exists a sequence $\{w_i\}$ in $\mathcal{U} \cap \mathcal{K}$ that converges to w. Then $V(w_i) \geq V(x)$ for every i. It now follows by continuity of V that $V(w) = \lim_{i \to \infty} V(w_i) \geq V(x)$. Next let $\mathcal{V} \subseteq \mathcal{G}$ be a relatively open and relatively bounded neighborhood of x such that $\overline{\mathcal{V}} \subseteq \mathcal{U}$. Then, for every $w \in \overline{\mathcal{V}} \cap \overline{\mathcal{K}}$, $V(w) \geq V(x)$.

Now consider $z \in \mathcal{R}_x^{\mathcal{V}}$. Let $\{x_i\}$ be a sequence in $\mathcal{V}$ converging to x and $\{t_i\}$ a sequence in $[0, \infty)$ such that the sequence $\{\psi(t_i, x_i)\}$ converges to z and, for every i, $\psi(\tau, x_i) \in \overline{\mathcal{V}} \subset \mathcal{U}$ for every $\tau \in [0, t_i]$. Then, $V(z) = \lim_{i \to \infty} V(\psi(t_i, x_i)) \leq \lim_{i \to \infty} V(x_i) = V(x)$. Thus $V(z) \leq V(x)$. We claim that $V(z) = V(x)$. To see this, first suppose $z \in \mathcal{R}_x^{\mathcal{V}} \cap \overline{\mathcal{K}} \subseteq \overline{\mathcal{V}} \cap \overline{\mathcal{K}}$. Then, since $V(w) \geq V(x)$ for every $w \in \overline{\mathcal{V}} \cap \overline{\mathcal{K}}$, it follows that $V(z) = V(x)$. Next assume that $z \in \mathcal{R}_x^{\mathcal{V}} \cap (\mathcal{G} \backslash \overline{\mathcal{K}}) = \mathcal{R}_x^{\mathcal{V}} \cap \operatorname{int} \dot{V}^{-1}(0)$. Since $\mathcal{G} \backslash \overline{\mathcal{K}}$ is relatively open in $\mathcal{G}$ and $z \in \mathcal{G} \backslash \overline{\mathcal{K}}$, there exists $m > 0$ such that $\psi(t_i, x_i) \in \mathcal{G} \backslash \overline{\mathcal{K}}$ for every $i > m$. For each $i > m$, let τ_i denote the smallest number in $[0, t_i]$ such that $\psi(t, x_i) \in \mathcal{G} \backslash \overline{\mathcal{K}}$ for all $t \in (\tau_i, t_i]$. The sequence $\{\tau_i\}_{i=m}^{\infty}$ either has a positive subsequence or is eventually zero.

First consider the case where $\{\tau_i\}_{i=m}^{\infty}$ has a positive subsequence, say, $\{\tau_{i_k}\}_{k=1}^{\infty}$. By the continuity of ψ, it follows that $\psi(\tau_{i_k}, x_{i_k}) \in \overline{\mathcal{K}}$ for every k. Since V is nonincreasing along the solutions of (6) in $\mathcal{U}$, $V(\psi(\tau_{i_k}, x_{i_k})) \leq V(x_{i_k})$ for all k, and hence $\lim_{k \to \infty} V(\psi(\tau_{i_k}, x_{i_k})) \leq \lim_{k \to \infty} V(x_{i_k}) = V(x)$. On the other hand, x is a global minimizer of V on the set $\overline{\mathcal{V}} \cap \overline{\mathcal{K}}$ so that $V(\psi(\tau_{i_k}, x_{i_k})) \geq V(x)$ for all k. Thus $\lim_{k \to \infty} V(\psi(\tau_{i_k}, x_{i_k})) = V(x)$ for all k. Since $\psi(t, x_i) \in \mathcal{G} \backslash \overline{\mathcal{K}} \subseteq \dot{V}^{-1}(0)$ for all $t \in (\tau_i, t_i]$ and every i, it follows that $V(\psi(t_{i_k}, x_{i_k})) = V(\psi(\tau_{i_k}, x_{i_k}))$ for all k. Hence $V(z) = \lim_{k \to \infty} V(\psi(t_{i_k}, x_{i_k})) = \lim_{k \to \infty} V(\psi(\tau_{i_k}, x_{i_k})) = V(x)$.

Finally, consider the case where the sequence $\{\tau_i\}_{i=m}^{\infty}$ is eventually zero. In this case, there exists $K > 0$ such that, for every $i > K$ and every $t \in [0, t_i]$, it follows that $V(\psi(t, x_i)) = V(x_i)$. Hence $V(z) = \lim_{i \to \infty} V(\psi(t_i, x_i)) = \lim_{i \to \infty} V(x_i) = V(x)$.

We have thus shown that if $z \in \mathcal{R}_x^{\mathcal{V}}$, then $V(z) = V(x)$. Therefore, $\mathcal{R}_x^{\mathcal{V}} \subseteq V^{-1}(V(x)) \cap \overline{\mathcal{V}} \subset V^{-1}(V(x)) \cap \mathcal{W}$. By Proposition 6.1, $\mathcal{R}_x^{\mathcal{V}}$ is negatively invariant and connected, and $x \in \mathcal{R}_x^{\mathcal{V}}$. Hence $\mathcal{R}_x^{\mathcal{V}} \subseteq \mathcal{M}_x$.

(iii) Consider $z \in \mathcal{M}_x$, and let $t > 0$. By negative invariance, there exists $w \in \mathcal{M}_x$ such that $\psi(t, w) = z$ and $\psi(\tau, w) \in \mathcal{M}_x \subseteq V^{-1}(V(x))$ for all $\tau \in [0, t]$. Hence $V(\psi(\tau, w)) = V(x)$ for every $\tau \in [0, t]$, and thus $\dot{V}(\psi(\tau, w)) = 0$ for every $\tau \in [0, t)$. Let $\{t_i\}$ be a sequence in $[0, t)$ converging to t. Then, by the continuity of ψ, $\{\psi(t_i, w)\}$ is a sequence in $\dot{V}^{-1}(0)$ that converges to z. It follows that $z \in \overline{\dot{V}^{-1}(0)}$. Thus $\mathcal{M}_x \subseteq \overline{\dot{V}^{-1}(0)}$. Since $\mathcal{M}_x$ is negatively invariant, connected, contains x, and is contained in $\mathcal{W}$, the result follows. ∎

It is interesting to note the parallels between the ideas used in this section and those used in the previous section. The propositions given in section 5 allow us to conclude convergence of a solution of (6) under the assumption of nontangency of the vector field f to an outer estimate of the positive limit set of that solution. The results of this section allow us to conclude the Lyapunov stability of an equilibrium of (6) under the assumption of nontangency of the vector field f to an outer estimate of the restricted prolongation of the equilibrium. The outer estimates of the positive limit set in section 5 and the restricted prolongation in this section are in terms of invariant and negatively invariant subsets of level and sublevel sets of a Lyapunov function and its derivative. Moreover, the results of sections 5 and 6 depend on the invariance properties of the positive limit set and the restricted prolongation, respectively.

7. Stability theorems. In this section, we use the results of the previous two sections to derive Lyapunov results for Lyapunov stability, semistability, and asymptotic stability. The main results are Theorems 7.1 and 7.2. These results do not make any assumptions about the sign definiteness of the Lyapunov function. Instead, these results require only that the Lyapunov function derivative be nonpositive and the equilibrium be a local minimizer of the Lyapunov function on the set of points where the Lyapunov function derivative is negative. The weaker assumptions on the Lyapunov function are supplemented by assuming nontangency of the vector field to the level set of the Lyapunov function containing the equilibrium or to the closure of the zero-level set of the Lyapunov function derivative. In both Theorems 7.1 and 7.2, Propositions 6.4 and 5.3 are used to "trap" the restricted prolongation and the positive limit set, respectively, in the level sets of the Lyapunov function and its derivative. Propositions 6.3 and 5.2 are then used to deduce stability and convergence from nontangency.

THEOREM 7.1. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$. Let $x \in \mathcal{E}$ be a local maximizer of $\dot{V}$ relative to $\mathcal{G}$ and a local minimizer of V relative to the set $\mathcal{K} \stackrel{\text{def}}{=} \mathcal{G} \backslash \overline{\dot{V}^{-1}(0)}$. Let $\mathcal{W} \subseteq \mathcal{G}$ be a relatively open neighborhood of x. For every $z \in \mathcal{E} \cap \mathcal{W}$, let $\mathcal{M}_z$ denote the largest connected subset of $V^{-1}(V(z)) \cap \mathcal{W}$ that is negatively invariant and contains z. Let $\mathcal{N}$ denote the largest negatively invariant subset of $\overline{\dot{V}^{-1}(0)} \cap \mathcal{W}$ and, for every $z \in \mathcal{N}$, let $\mathcal{N}_z$ denote the connected component of $\mathcal{N}$ containing z.*

Then the following statements hold.

(i) *If f is nontangent to $\mathcal{M}_x$ at x relative to $\mathcal{G}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(ii) *If f is nontangent to $\mathcal{N}_x$ at x relative to $\mathcal{G}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(iii) *If there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{W}$ of x such that every equilibrium in $\mathcal{U}$ is a local minimizer of V relative to $\mathcal{K}$ and, for every $z \in \mathcal{N} \cap \mathcal{U}$, f is nontangent to $\mathcal{N}_z$ at z relative to $\mathcal{G}$, then x is semistable relative to $\mathcal{G}$.*

(iv) *If x is an isolated equilibrium, and there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{W}$ of x such that, for every $z \in \mathcal{N} \cap \mathcal{U}$, f is nontangent to $\mathcal{N}_z$ at z relative to $\mathcal{G}$, then x is asymptotically stable relative to $\mathcal{G}$.*

Proof. (i) Suppose $T_x\mathcal{M}_x \cap \mathcal{F}_x \subseteq \{0\}$. By (ii) of Proposition 6.4, there exists a relatively open and bounded neighborhood $\mathcal{V} \subseteq \mathcal{W}$ of x such that $\mathcal{R}_x^{\mathcal{V}} \subseteq \mathcal{M}_x$. Therefore, $T_x\mathcal{R}_x^{\mathcal{V}} \cap \mathcal{F}_x \subseteq T_x\mathcal{M}_x \cap \mathcal{F}_x \subseteq \{0\}$. Hence, by Proposition 6.3, x is a Lyapunov stable equilibrium relative to $\mathcal{G}$.

(ii) Note that since x is an equilibrium, $x \in \dot{V}^{-1}(0)$. Suppose $T_x\mathcal{N}_x \cap \mathcal{F}_x \subseteq \{0\}$.

By (iii) of Proposition 6.4, $\mathcal{M}_x \subseteq \mathcal{N}_x$. Hence $T_x\mathcal{M}_x \cap \mathcal{F}_x \subseteq T_x\mathcal{N}_x \cap \mathcal{F}_x \subseteq \{0\}$. Therefore, by (i), x is a Lyapunov stable equilibrium relative to $\mathcal{G}$.

(iii) Let $\mathcal{U} \subseteq \mathcal{W}$ be a relatively open neighborhood of x such that every equilibrium in $\mathcal{U}$ is a local minimizer of V relative to $\mathcal{K}$ and $T_z\mathcal{N}_z \cap \mathcal{F}_z \subseteq \{0\}$ for every $z \in \mathcal{N} \cap \mathcal{U}$. Since x is a local maximizer of $\dot{V}$ relative to $\mathcal{G}$, we may assume without loss of generality that $\dot{V}(z) \leq \dot{V}(x) = 0$ for every $z \in \mathcal{U}$. It follows that every equilibrium in $\mathcal{U}$ is a local maximizer of $\dot{V}$ relative to $\mathcal{G}$. Since every equilibrium in $\mathcal{U}$ is contained in $\mathcal{N}$, it follows from (ii) that every equilibrium in $\mathcal{U}$ is Lyapunov stable relative to $\mathcal{G}$. In particular, x is Lyapunov stable relative to $\mathcal{G}$. By Lyapunov stability of x and local compactness of $\mathcal{G}$, there exists a positively invariant neighborhood $\mathcal{V} \subset \mathcal{U}$ of x that is relatively open and relatively bounded in $\mathcal{G}$, and such that $\overline{\mathcal{V}} \subset \mathcal{U}$. For every $z \in \mathcal{V}$, $\mathcal{O}_z \subseteq \mathcal{V}$ is relatively bounded in $\mathcal{G}$. Therefore, by Propositions 5.1 and 5.3, $\mathcal{O}_z^\infty \subseteq \overline{\mathcal{V}} \subset \mathcal{W}$ is nonempty and contained in $\overline{\dot{V}^{-1}(0)}$. The invariance of $\mathcal{O}_z^\infty$ implies that $\mathcal{O}_z^\infty$ is contained in the largest invariant subset of $\overline{\dot{V}^{-1}(0)} \cap \mathcal{W}$. Since every invariant set is also negatively invariant, it follows that $\mathcal{O}_z^\infty \subseteq \mathcal{N}$ for every $z \in \mathcal{V}$. Consider $z \in \mathcal{V}$ and $w \in \mathcal{O}_z^\infty$. Since $\mathcal{O}_z^\infty$ is connected and contained in $\mathcal{N}$, it follows that $\mathcal{O}_z^\infty \subseteq \mathcal{N}_w$. Therefore, $T_w\mathcal{O}_z^\infty \cap \mathcal{F}_w \subseteq T_w\mathcal{N}_w \cap \mathcal{F}_w \subseteq \{0\}$. Now Proposition 5.2 implies that $\lim_{t\to\infty} \psi(t, z)$ exists. Since $z \in \mathcal{V}$ was chosen arbitrarily, it follows that every trajectory in $\mathcal{V}$ converges to a limit. The positive invariance of $\mathcal{V}$ implies that the limit of every trajectory in $\mathcal{V}$ is contained in $\overline{\mathcal{V}}$. Since every equilibrium in $\overline{\mathcal{V}} \subset \mathcal{U}$ is Lyapunov stable relative to $\mathcal{G}$, it follows that x is semistable relative to $\mathcal{G}$.

(iv) Suppose x is an isolated equilibrium, and let $\mathcal{U} \subseteq \mathcal{W}$ be a relatively open neighborhood of x such that $T_z\mathcal{N}_z \cap \mathcal{F}_z \subseteq \{0\}$ for every $z \in \mathcal{N} \cap \mathcal{U}$. Without loss of generality, we may assume that x is the only equilibrium in $\mathcal{U}$. Then, it follows from (iii) that x is semistable relative to $\mathcal{G}$. Asymptotic stability now follows by noting that every isolated equilibrium that is semistable relative to $\mathcal{G}$ is asymptotically stable relative to $\mathcal{G}$. ∎

Remark 7.1. Note that Theorem 7.1 does not require $\dot{V}$ to be continuous. However, in the case where $\dot{V}$ is continuous, we have $\overline{\dot{V}^{-1}(0)} = \dot{V}^{-1}(0)$, and the set $\mathcal{K}$ in Theorem 7.1 is the set of points where the Lyapunov derivative is negative. Thus, in the case where $\dot{V}$ is continuous, Theorem 7.1 requires the equilibrium to be a local minimizer of V only relative to the set of points where the Lyapunov function is strictly decreasing along the solutions of (6).

Example 7.1. In this example, we apply Theorem 7.1 to the mass action kinetics (16) of the Michaelis–Menten chemical reaction introduced in Example 5.2.

Recall that the set of equilibrium concentrations of the reaction in the nonnegative orthant $\mathcal{G}$ is $\mathcal{E} = \mathcal{E}_1 \cup \mathcal{E}_2$, where $\mathcal{E}_1 = \{x \in \mathcal{G} : x_1 = 0, x_2 = 0, x_3 > 0\}$ and $\mathcal{E}_2 = \{x \in \mathcal{G} : x_1 \geq 0, x_2 = 0, x_3 = 0\}$. Also recall from Example 5.2 that the right-hand side f of the differential equation (16) is nontangent to $\mathcal{E}_1$ at every point in $\mathcal{E}_1$ relative to $\mathcal{G}$.

We claim that every equilibrium in $\mathcal{E}_1$ is semistable relative to $\mathcal{G}$. To show this, let $\alpha \in (1, 1 + k_3/k_2)$, and consider the function $V : \mathcal{G} \to \mathbb{R}$ defined by $V(x) = \alpha x_1 + x_2$. Then, $V(x) \geq 0$ for every $x \in \mathcal{G}$ and $V^{-1}(0) = \overline{\mathcal{E}_1}$. Thus every point in $\mathcal{E}_1$ is a local minimizer of V relative to $\mathcal{G}$. Since $\dot{V} : \mathcal{G} \to \mathbb{R}$ is given by $\dot{V}(x) = [\alpha k_2 - (k_2 + k_3)]x_2 + k_1(1 - \alpha)x_1x_3$, it follows that $\dot{V}(x) \leq 0$ for every $x \in \mathcal{G}$ and $\dot{V}^{-1}(0) = \overline{\dot{V}^{-1}(0)} = \mathcal{E}$ so that the largest negatively invariant subset of $\overline{\dot{V}^{-1}(0)}$ is $\mathcal{E}$.

Now consider an equilibrium $x \in \mathcal{E}_1$. There exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that $\mathcal{U} \cap \mathcal{E} = \mathcal{U} \cap \mathcal{E}_1$. It now follows that every equilibrium $z \in \mathcal{U} \cap \mathcal{E}$

is a local maximizer of $\dot{V}$ and a local minimizer of V relative to $\mathcal{G}$ and, as shown in Example 5.2, that f is nontangent to $\mathcal{E}$ at every $z \in \mathcal{U} \cap \mathcal{E}$ relative to $\mathcal{G}$. Hence, applying (iii) of Theorem 7.1 with $\mathcal{W} = \mathcal{G}$, it follows that every equilibrium in $\mathcal{E}_1$ is semistable relative to $\mathcal{G}$.

The following corollary of Theorem 7.1 is an extension of Theorems 1 and 2 from [16].

COROLLARY 7.1. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$. Let $x \in \mathcal{E}$ be a local maximizer of $\dot{V}$ relative to $\mathcal{G}$ and a local minimizer of V relative to the set $\mathcal{K} \stackrel{\text{def}}{=} \mathcal{G} \backslash \overline{\dot{V}^{-1}(0)}$. Let $\mathcal{W} \subseteq \mathcal{G}$ be a relatively open neighborhood of x. For every $z \in \mathcal{W}$, let $\mathcal{M}_z$ denote the largest connected subset of $V^{-1}(V(z)) \cap \mathcal{W}$ that is negatively invariant and contains z. Let $\mathcal{N}$ denote the largest negatively invariant subset of $\overline{\dot{V}^{-1}(0)} \cap \mathcal{W}$. Then the following statements hold.*

(i) *If $\mathcal{M}_x = \{x\}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(ii) *If x is an isolated point of $\mathcal{N}$, then x is asymptotically stable relative to $\mathcal{G}$.*

Proof. (i) Suppose $\mathcal{M}_x = \{x\}$. Then Lyapunov stability of x follows from (i) of Theorem 7.1 by noting that $T_x\mathcal{M}_x = \{0\}$.

(ii) Suppose $\{x\}$ is an isolated point of $\mathcal{N}$. Since every equilibrium in $\mathcal{W}$ is contained in $\mathcal{N}$, it follows that x is an isolated equilibrium. Also, the connected component $\mathcal{N}_x$ of $\mathcal{N}$ containing x is $\{x\}$, and hence $T_x\mathcal{N}_x = \{0\}$. The statement (ii) now follows by applying Theorem 7.1, (iv). ∎

Remark 7.2. Theorems 1 and 2 of [16] follow from (i) and (ii) of Corollary 7.1, respectively. However, while Corollary 7.1 requires only that the equilibrium be a local minimizer of the Lyapunov function relative to the set of points at which the Lyapunov function is strictly decreasing, the results of [16] require the equilibrium to be a local minimizer of the Lyapunov function relative to $\mathcal{G}$. Thus Corollary 7.1 is an extension of the main results of [16]. It is shown in [16] that the main result of [1] follows from Theorem 1 in [16]. Since Corollary 7.1 is an extension of the main results of [16], the arguments presented in [16] can be used to show that the main result of [1] follows from Corollary 7.1.

Remark 7.3. It is interesting to note that neither Corollary 7.1 nor the results of [16] can be applied in the case of Example 7.1, because the level sets of V and $\dot{V}$ containing the equilibrium point of interest contain a continuum of equilibria. Consequently, the equilibrium point of interest is not an isolated point of the largest negatively invariant subset of the level sets of V or $\dot{V}$, and the results mentioned above do not apply.

The following corollary of Theorem 7.1 does not require finding negatively invariant subsets of the level sets of the Lyapunov function and its derivative.

COROLLARY 7.2. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$. Let $x \in \dot{V}^{-1}(0)$ be a local maximizer of $\dot{V}$ relative to $\mathcal{G}$ and a local minimizer of V relative to the set $\mathcal{K} \stackrel{\text{def}}{=} \mathcal{G} \backslash \overline{\dot{V}^{-1}(0)}$. Then the following statements hold.*

(i) *If f is nontangent to $V^{-1}(V(x))$ at x relative to $\mathcal{G}$, then x is a Lyapunov stable equilibrium relative to $\mathcal{G}$.*

(ii) *If f is nontangent to $\overline{\dot{V}^{-1}(0)}$ at x relative to $\mathcal{G}$, then x is a Lyapunov stable equilibrium relative to $\mathcal{G}$.*

(iii) *If there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that every equilibrium in $\mathcal{U}$ is a local minimizer of V relative to $\mathcal{K}$ and f is nontangent*

to $\overline{\dot{V}^{-1}(0)}$ *at every point in* $\mathcal{U} \cap \overline{\dot{V}^{-1}(0)}$ *relative to* $\mathcal{G}$*, then* x *is a semistable equilibrium relative to* $\mathcal{G}$*.*

(iv) *If* x *is an isolated point of the set* $\dot{V}^{-1}(0)$*, then* x *is an asymptotically stable equilibrium relative to* $\mathcal{G}$*.*

Proof. Let $\mathcal{V} \subseteq \mathcal{G}$ be a relatively open neighborhood of x such that $\dot{V}(z) \leq \dot{V}(x) = 0$ for every $z \in \mathcal{V}$ and $V(x) \leq V(z)$ for every $z \in \mathcal{K} \cap \mathcal{V}$. There exists $\tau > 0$ such that $\psi(t,x) \in \mathcal{V}$ for all $t \in [0,\tau)$. Therefore, $V(\psi(t,x)) \geq V(x)$ for every $t \in [0,\tau)$. However, since $\dot{V}(\psi(t,x)) \leq 0$ for every $t \in [0,\tau)$, it follows that $V(\psi(t,x)) \leq V(x)$ for every $t \in [0,\tau)$. We conclude that $V(\psi(t,x)) = V(x)$ and $\dot{V}(\psi(t,x)) = 0$ for every $t \in [0,\tau)$. In other words, $\psi(t,x) \in V^{-1}(V(x)) \cap \dot{V}^{-1}(0)$ for every $t \in [0,\tau)$. In particular, $x \in \dot{V}^{-1}(0)$. Also, if $\{t_i\}$ is a sequence in $[0,\tau)$ that converges to zero, then $\{\psi(t_i,x)\}$ is a sequence in $V^{-1}(V(x)) \cap \dot{V}^{-1}(0)$ converging to x such that $\lim_{i\to\infty} \frac{1}{t_i}[\psi(t_i,x) - x] = f(x)$. Thus $f(x) \in T_x\dot{V}^{-1}(0) \cap T_xV^{-1}(V(x))$.

(i) Suppose $T_xV^{-1}(V(x)) \cap \mathcal{F}_x \subseteq \{0\}$. If $\mathcal{F}_x = \varnothing$, then $x \in \operatorname{int} \mathcal{E}$ and $f(x) = 0$. On the other hand, if $\mathcal{F}_x \neq \varnothing$, then $f(x) \in T_xV^{-1}(V(x)) \cap \mathcal{F}_x \subseteq \{0\}$ so that $f(x) = 0$. In either case, it follows that x is an equilibrium. Lyapunov stability of x now follows from (i) of Theorem 7.1 by noting that if $\mathcal{M}_x$ is the largest connected, negatively invariant subset of $V^{-1}(V(x))$ containing x, then $T_x\mathcal{M}_x \cap \mathcal{F}_x \subseteq T_xV^{-1}(V(x)) \cap \mathcal{F}_x \subseteq \{0\}$.

(ii) Suppose $T_x\overline{\dot{V}^{-1}(0)} \cap \mathcal{F}_x \subseteq \{0\}$. Arguing as in the proof of (i), it can be shown that x is an equilibrium. Lyapunov stability of x now follows from (ii) of Theorem 7.1 by noting that if $\mathcal{N}_x$ is the largest connected, negatively invariant subset of $\overline{\dot{V}^{-1}(0)}$ containing x, then $T_x\mathcal{N}_x \cap \mathcal{F}_x \subseteq T_x\overline{\dot{V}^{-1}(0)} \cap \mathcal{F}_x \subseteq \{0\}$.

(iii) Suppose $\mathcal{U} \subseteq \mathcal{G}$ is a relatively open neighborhood of x such that every equilibrium in $\mathcal{U}$ is a local minimizer of V relative to the set $\mathcal{K}$ and $T_z\overline{\dot{V}^{-1}(0)} \cap \mathcal{F}_z \subseteq \{0\}$ for every $z \in \mathcal{U} \cap \overline{\dot{V}^{-1}(0)}$. Arguing as in the proof of (i), it can be shown that x is an equilibrium. The result now follows from (iii) of Theorem 7.1 by noting that, if $\mathcal{N}$ is the largest negatively invariant subset of $\overline{\dot{V}^{-1}(0)}$, then, for every $z \in \mathcal{N} \cap \mathcal{U} \subseteq \overline{\dot{V}^{-1}(0)} \cap \mathcal{U}$, it follows that $T_z\mathcal{N} \cap \mathcal{F}_z \subseteq T_z\overline{\dot{V}^{-1}(0)} \cap \mathcal{F}_z \subseteq \{0\}$.

(iv) Suppose x is an isolated point of $\dot{V}^{-1}(0)$. Then x is also an isolated point of $\overline{\dot{V}^{-1}(0)}$. Since $\psi(t,x) \in \dot{V}^{-1}(0)$ for all $t \in [0,\tau)$, it follows from the continuity of ψ that $\psi(t,x) = x$ for all $t \in [0,\tau)$. In other words, x is an equilibrium. Since every equilibrium is contained in $\dot{V}^{-1}(0)$, it follows that x is an isolated equilibrium. Since x is an isolated point of $\overline{\dot{V}^{-1}(0)}$, it follows that $T_x\overline{\dot{V}^{-1}(0)} = \{0\}$. Hence (iii) implies that x is semistable relative to $\mathcal{G}$. Since an isolated semistable equilibrium is asymptotically stable, (iv) follows. ∎

Example 7.2. Consider the system described in Example 1.1. Suppose $\alpha \leq \beta$, and let $\mathcal{G} = \mathbb{R}^2$. Consider the Lyapunov function $V : \mathcal{G} \to \mathbb{R}$ given by $V(x) = \frac{1}{4}(x_1^2 + x_2^2 - 1)^2$ introduced in Example 5.4, and recall that $\dot{V}(x) = -(x_1^2+x_2^2)|x_1^2+x_2^2-1|^{1+\alpha}$ so that $\dot{V}(x) \leq 0$ for all $x \in \mathcal{G}$ and $\overline{\dot{V}^{-1}(0)} = \mathrm{S}^1 \cup \{0\}$. The set $\mathcal{K} = \mathcal{G}\backslash\overline{\dot{V}^{-1}(0)}$ in Corollary 7.2 is given in this case by $\mathcal{K} = \mathcal{G}\backslash(\mathrm{S}^1 \cup \{0\})$. Hence every point $x \in \mathrm{S}^1$ is a local minimizer of V relative to $\mathcal{K}$. We know from Example 4.2 that f is nontangent to S^1 and hence to $\dot{V}^{-1}(0)$ at every $z \in \mathrm{S}^1$ relative to $\mathcal{G}$. Hence by (iii) of Corollary 7.2, it follows that every $x \in \mathrm{S}^1$ is semistable relative to $\mathcal{G} = \mathbb{R}^2$.

The following theorem gives stability conditions in terms of invariant sets rather than negatively invariant sets as in Theorem 7.1. Also, the first part of the theorem does not require the equilibrium to be a local minimizer of the Lyapunov function.

THEOREM 7.2. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$. For every $z \in \mathcal{G}$, let $\mathcal{P}_z$ denote the largest connected subset of $\{w \in \mathcal{G} : V(w) \leq V(z)\}$ that is invariant and contains z. Let $x \in \mathcal{E}$ be a global maximizer of $\dot{V}$ relative to $\mathcal{G}$. Let $\varepsilon > 0$, and let $\mathcal{Q}$ be the largest invariant subset of the set $\{w \in \mathcal{G} : V(w) < V(x) + \varepsilon\}$. For every $z \in \mathcal{Q}$, let $\mathcal{Q}_z$ denote the connected component of $\mathcal{Q}$ containing z. Then the following statements hold.*

(i) *If f is nontangent to $\mathcal{P}_x$ at x relative to $\mathcal{G}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(ii) *If there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that, for every $z \in \mathcal{U} \cap \mathcal{Q}$, f is nontangent to $\mathcal{Q}_z$ at z relative to $\mathcal{G}$, then x is semistable relative to $\mathcal{G}$.*

(iii) *If x is an isolated point of $\mathcal{Q}$, then x is asymptotically stable relative to $\mathcal{G}$.*

If, in addition, x is a local minimizer of V relative to the set $\mathcal{K} \stackrel{\text{def}}{=} \mathcal{G} \backslash \overline{\dot{V}^{-1}(0)}$, then the following statements hold.

(iv) *If f is nontangent to $\mathcal{P}_x \cap V^{-1}(V(x))$ at x relative to $\mathcal{G}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(v) *If f is nontangent to $\mathcal{P}_x \cap \overline{\dot{V}^{-1}(0)}$ at x relative to $\mathcal{G}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(vi) *If there exists a relatively open neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that every equilibrium in $\mathcal{U}$ is a local minimizer of V relative to the set $\mathcal{K}$ and, for every $z \in \mathcal{U} \cap \mathcal{Q}$, f is nontangent to $\mathcal{Q}_z \cap \overline{\dot{V}^{-1}(0)}$ at z relative to $\mathcal{G}$, then x is semistable relative to $\mathcal{G}$.*

Proof. Note that by (i) of Proposition 6.4, $\mathcal{R}_x \subseteq \mathcal{P}_x$.

(i) Suppose $T_x\mathcal{P}_x \cap \mathcal{F}_x \subseteq \{0\}$. We have $T_x\mathcal{R}_x \cap \mathcal{F}_x \subseteq T_x\mathcal{P}_x \cap \mathcal{F}_x \subseteq \{0\}$. Hence it follows from Proposition 6.3 that x is Lyapunov stable relative to $\mathcal{G}$.

(ii) Let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open neighborhood of x such that $T_z\mathcal{Q}_z \cap \mathcal{F}_z \subseteq \{0\}$ for every $z \in \mathcal{U} \cap \mathcal{Q}$. Since V is continuous, we can assume without loss of generality that $V(z) < V(x) + \varepsilon$ for every $z \in \mathcal{U}$. Then, for every $z \in \mathcal{U}$, $\{w \in \mathcal{G} : V(w) \leq V(z)\} \subseteq \{w \in \mathcal{G} : V(w) < V(x) + \varepsilon\}$. Consequently, $\mathcal{P}_z \subseteq \mathcal{Q}_z$ for every $z \in \mathcal{U}$. In particular, if $z \in \mathcal{U}$ is an equilibrium, then $z \in \mathcal{P}_z \subseteq \mathcal{Q}_z$ so that $T_z\mathcal{P}_z \cap \mathcal{F}_z \subseteq T_z\mathcal{Q}_z \cap \mathcal{F}_z \subseteq \{0\}$. It therefore follows from (i) that every equilibrium in $\mathcal{U}$ is Lyapunov stable relative to $\mathcal{G}$. In particular, x is Lyapunov stable relative to $\mathcal{G}$. By Lyapunov stability of x and local compactness of $\mathcal{G}$, there exists a positively invariant neighborhood $\mathcal{V} \subset \mathcal{U}$ of x that is relatively open and bounded in $\mathcal{G}$ and such that $\overline{\mathcal{V}} \subset \mathcal{U}$. Consider $z \in \mathcal{V}$. Then $\mathcal{O}_z \subseteq \mathcal{V}$ is relatively bounded in $\mathcal{G}$, and hence by Propositions 5.1 and 5.3, $\mathcal{O}_z^\infty \subseteq \overline{\mathcal{V}} \subset \mathcal{U}$ is nonempty, connected, and contained in the largest invariant subset of $\{w \in \mathcal{G} : V(w) \leq V(z)\}$ and hence in $\mathcal{Q}$. Next, let $w \in \mathcal{O}_z^\infty$. Since $\mathcal{O}_z^\infty \subseteq \mathcal{Q}$ is connected, it follows that $\mathcal{O}_z^\infty \subseteq \mathcal{Q}_w$. Now, since $w \in \overline{\mathcal{V}} \cap \mathcal{Q} \subseteq \mathcal{U} \cap \mathcal{Q}$, we have $T_w\mathcal{O}_z^\infty \cap \mathcal{F}_w \subseteq T_w\mathcal{Q}_w \cap \mathcal{F}_w \subseteq \{0\}$. Proposition 5.2 now implies that $\lim_{t\to\infty} \psi(t, z)$ exists and is contained in $\overline{\mathcal{V}} \subseteq \mathcal{G}$. Since $z \in \mathcal{V}$ was chosen arbitrarily, it follows that every trajectory in $\mathcal{V}$ converges to a limit. The positive invariance of $\mathcal{V}$ implies that the limit of every trajectory in $\mathcal{V}$ is contained in $\overline{\mathcal{V}}$. Since every equilibrium in $\overline{\mathcal{V}} \subset \mathcal{U}$ is Lyapunov stable relative to $\mathcal{G}$, it follows that x is semistable relative to $\mathcal{G}$.

(iii) Suppose x is an isolated point of $\mathcal{Q}$, and let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open neighborhood of x such that $\mathcal{U} \cap \mathcal{Q} = \{x\}$. Then $T_x\mathcal{Q} = \{0\}$, and hence every point $z \in \mathcal{U} \cap \mathcal{Q}$ satisfies $T_z\mathcal{Q} \cap \mathcal{F}_z \subseteq \{0\}$. By (ii), x is semistable relative to $\mathcal{G}$. Next, consider the relatively open neighborhood $\mathcal{V} = \{z \in \mathcal{G} : V(z) < V(x) + \varepsilon\}$ of x. Since every equilibrium in $\mathcal{V}$ is contained in $\mathcal{Q}$, we have $(\mathcal{U} \cap \mathcal{V}) \cap \mathcal{E} = \mathcal{U} \cap (\mathcal{V} \cap \mathcal{E}) \subseteq \mathcal{U} \cap \mathcal{Q} = \{x\}$.

Since $\mathcal{U} \cap \mathcal{V}$ is a relatively open neighborhood of x, it follows that x is an isolated equilibrium. The result now follows by noting that an isolated equilibrium that is semistable relative to $\mathcal{G}$ is also asymptotically stable relative to $\mathcal{G}$.

Now, suppose x is a local minimizer of V relative to the set $\mathcal{K} = \mathcal{G} \backslash \overline{\dot{V}^{-1}(0)}$. By (ii) and (iii) of Proposition 6.4, there exists a neighborhood $\mathcal{V}$ of x that is open and bounded relative to $\mathcal{G}$, and such that $\mathcal{R}_x^{\mathcal{V}} \subseteq V^{-1}(V(x)) \cap \overline{\dot{V}^{-1}(0)}$.

(iv) Suppose $T_x(\mathcal{P}_x \cap V^{-1}(V(x))) \cap \mathcal{F}_x \subseteq \{0\}$. Then $T_x \mathcal{R}_x^{\mathcal{V}} \cap \mathcal{F}_x \subseteq T_x(\mathcal{R}_x \cap V^{-1}(V(x))) \cap \mathcal{F}_x \subseteq T_x(\mathcal{P}_x \cap V^{-1}(V(x))) \cap \mathcal{F}_x \subseteq \{0\}$. It now follows from Proposition 6.3 that x is Lyapunov stable relative to $\mathcal{G}$.

(v) Suppose $T_x(\mathcal{P}_x \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_x \subseteq \{0\}$. Then $T_x \mathcal{R}_x^{\mathcal{V}} \cap \mathcal{F}_x \subseteq T_x(\mathcal{R}_x \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_x \subseteq T_x(\mathcal{P}_x \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_x \subseteq \{0\}$. It now follows from Proposition 6.3 that x is Lyapunov stable relative to $\mathcal{G}$.

(vi) Let $\mathcal{U} \subseteq \mathcal{G}$ be a relatively open neighborhood of x such that every equilibrium in $\mathcal{U}$ is a local minimizer of V relative to the set $\mathcal{K}$, and every point z in $\mathcal{U} \cap \mathcal{Q}$ satisfies $T_z(\mathcal{Q}_z \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_z \subseteq \{0\}$. Without loss of generality, we assume that $V(z) < V(x) + \varepsilon$ for every $z \in \mathcal{U}$. Then, for every $z \in \mathcal{U}$, $\mathcal{P}_z \subseteq \mathcal{Q}_z$ and hence $T_z(\mathcal{P}_z \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_z \subseteq T_z(\mathcal{Q}_z \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_z \subseteq \{0\}$. It therefore follows from (v) that every equilibrium in $\mathcal{U}$ is Lyapunov stable relative to $\mathcal{G}$. In particular, x is Lyapunov stable relative to $\mathcal{G}$. By Lyapunov stability of x and local compactness of $\mathcal{G}$, there exists a positively invariant, relatively open, and relatively bounded neighborhood $\mathcal{V} \subset \mathcal{G}$ of x such that $\overline{\mathcal{V}} \subset \mathcal{U}$. Consider $z \in \mathcal{V}$. Then $\mathcal{O}_z \subseteq \mathcal{V}$ is relatively bounded in $\mathcal{G}$, and hence by Propositions 5.1 and 5.3, $\mathcal{O}_z^\infty \subseteq \overline{\mathcal{V}}$ is nonempty, connected, and contained in the largest invariant subset of $\{w \in \mathcal{G} : V(w) \leq V(z)\} \subset \{w \in \mathcal{G} : V(w) < V(x) + \epsilon\}$ and hence in $\mathcal{Q}$. Next, let $w \in \mathcal{O}_z^\infty$. Since $\mathcal{O}_z^\infty \subseteq \mathcal{Q}$ is connected, it follows that $\mathcal{O}_z^\infty \subseteq \mathcal{Q}_w$. By Proposition 5.3, $\mathcal{O}_z^\infty$ is also contained in $\dot{V}^{-1}(0)$. Now, since $w \in \overline{\mathcal{V}} \cap \mathcal{Q} \subseteq \mathcal{U} \cap \mathcal{Q}$, we have $T_w \mathcal{O}_z^\infty \cap \mathcal{F}_w \subseteq T_w(\mathcal{Q}_w \cap \dot{V}^{-1}(0)) \cap \mathcal{F}_w \subseteq T_w(\mathcal{Q}_w \cap \overline{\dot{V}^{-1}(0)}) \cap \mathcal{F}_w \subseteq \{0\}$. Proposition 5.2 now implies that $\lim_{t \to \infty} \psi(t, z)$ exists and is contained in $\mathcal{G}$. Since $z \in \mathcal{V}$ was chosen to be arbitrary, it follows that every trajectory in $\mathcal{V}$ converges to an equilibrium in $\overline{\mathcal{V}} \subset \mathcal{U}$. Semistability of x relative to $\mathcal{G}$ now follows by noting that every equilibrium in $\overline{\mathcal{V}} \subset \mathcal{U}$ is Lyapunov stable relative to $\mathcal{G}$. □

Example 7.3. In this example, we use Theorem 7.2 to show that every equilibrium $(0, k)$ of the adaptive closed-loop system (10)–(11) satisfying $g'(k) = a + bk^2 \cos k > 0$ is semistable, where g' is the derivative of the function $g : k \mapsto ak + b(k^2 - 2) \sin k + 2bk \cos k$ introduced in Example 3.1.

Suppose $k_0 \in \mathbb{R}$ is such that $g'(k_0) > 0$. Since g' is continuous, there exist $\delta > 0$ and $r > 0$ such that $g'(k) > r$ for all $k \in [k_0 - \delta, k_0 + \delta]$. In particular, we note that g is increasing on the interval $[k_0 - \delta, k_0 + \delta]$.

We claim that the equilibrium $(0, k_0)$ of the system (10)–(11) is semistable. To show this, consider the Lyapunov function $V(y, k) = e^{-k}$ introduced in Example 5.3, and let $\varepsilon = V(0, k_0)(e^\delta - 1)$. It is easy to see that the set $\{(y, k) \in \mathbb{R}^2 : V(y, k) \leq V(0, k_0) + \varepsilon\} = \{(y, k) \in \mathbb{R}^2 : k \geq k_0 - \delta\}$. Let $\mathcal{Q}$ denote the largest invariant subset of $\{(y, k) \in \mathbb{R}^2 : k \geq k_0 - \delta\}$. Also, recall from Example 5.3 that $\dot{V}(y, k) = -e^{-k} y^2$ and $\dot{V}^{-1}(0) = \{(0, k) : k \in \mathbb{R}\} = \mathcal{E}$.

Let $U : \mathbb{R}^2 \to \mathbb{R}$ be the function $U(y, k) = \frac{1}{2} y^2 + g(k)$, and recall from Example 3.1 that U is weakly proper and $\dot{U} \equiv 0$. Choose $k_1 \in (k_0, k_0 + \delta)$, and let $c = U(0, k_1) = g(k_1)$. Note that since g is increasing on $[k_0, k_0 + \delta]$, $U(0, k_0) = g(k_0) < g(k_1) = c$. Let $\mathcal{U}$ be the connected component of the set $\{(y, k) \in \mathbb{R}^2 : U(y, k) < c\}$ containing $(0, k_0)$. The set $\mathcal{U}$ is open by continuity and bounded by weak properness of U.

Moreover, letting ρ denote the projection $(y,k) \mapsto k$, the set $\rho(\mathcal{U})$ is a connected set that contains k_0 and does not contain $k_1 > k_0$. Hence we conclude that, for every $(y,k) \in \mathcal{U}$, $k < k_1 < k_0 + \delta$. It follows that every $(y,k) \in \mathcal{U} \cap \mathcal{Q}$ satisfies $k \in [k_0 - \delta, k_0 + \delta]$. Also, since $\mathcal{U}$ is bounded, it follows that there exists $Y \geq 0$ such that every $(y,k) \in \mathcal{U}$ satisfies $|y| \leq Y$.

We claim that $\mathcal{U} \cap \mathcal{Q}$ is contained in $\dot{V}^{-1}(0)$. To see this, consider $(y,k) \in \mathcal{U} \cap \mathcal{Q}$, and let $\tau > 0$. By the invariance of $\mathcal{Q}$, there exists $(y_2,k_2) \in \mathcal{Q}$ such that $(\phi_1(\tau), \phi_2(\tau)) = (y,k)$, where $\phi : \mathbb{R} \to \mathbb{R}^2$ denotes the solution of (10)–(11) satisfying $\phi(0) = (y_2,k_2)$. Since $\dot{U} \equiv 0$, $U(\phi(t)) = U(y,k) < c$ for every $t \in [0,\tau]$. Since, for every $t \in [0,\tau]$, both (y,k) and $\phi(t)$ are contained in the connected subset $\phi([0,\tau])$ of the set $\{(y,k) : U(y,k) < c\}$, it follows that $\phi(t) \in \mathcal{U}$ for every $t \in \mathcal{U}$. Thus $\phi(t) \in \mathcal{U} \cap \mathcal{Q}$ for every $t \in [0,\tau]$. Consequently, $\phi_2(t) \in [k_0 - \delta, k_0 + \delta]$ for all $t \in [0,\tau]$. Next we compute $\frac{d}{dt}(\phi_1(t))^2 = -2g'(\phi_2(t))(\phi_1(t))^2$ so that $y^2 = (\phi_2(\tau))^2 = y_2^2 \exp[-2\int_0^\tau g'(\phi_2(t))dt] \leq Y^2 \exp(-2r\tau)$. Since $\tau > 0$ was chosen arbitrarily, it follows that $y = 0$. Thus $\mathcal{U} \cap \mathcal{Q} \subseteq \dot{V}^{-1}(0)$.

It was shown in Example 5.3 that, for every $(y,k) \in \dot{V}^{-1}(0)$ such that $g'(k) \neq 0$, the vector field f defined by the right-hand side of (10)–(11) is nontangent to $\dot{V}^{-1}(0)$. Hence, for every point $(0,k) \in \mathcal{U} \cap \mathcal{Q}$, $T_z\mathcal{Q} \cap \mathcal{F}_z = T_z(\mathcal{U} \cap \mathcal{Q}) \cap \mathcal{F}_z \subseteq T_z(\dot{V}^{-1}(0)) \cap \mathcal{F}_z \subseteq \{0\}$. Thus f is nontangent to $\mathcal{Q}$ at every point in $\mathcal{U} \cap \mathcal{Q}$. By (ii) of Theorem 7.2, we conclude that the equilibrium $(0,k_0)$ is semistable.

Remark 7.4. It is worthwhile to note that Theorem 7.1 cannot be applied in Example 7.3 using the Lyapunov function V, because none of the equilibria of the closed-loop system (10)–(11) are local minimizers of the function V. In fact, the Lyapunov function V chosen in the example does not have any local minimizers.

Remark 7.5. The convergence of the closed-loop system (10)–(11) is also proved in [17, p. 46]. However, unlike the proof given in [17], our proof of convergence given in Example 5.3 is based on Lyapunov analysis. Moreover, in Example 7.3 we go beyond convergence and identify a class of semistable equilibria for the closed-loop system.

Remark 7.6. Theorems 7.1 and 7.2 involve hypotheses on the Lyapunov function and its derivative that are weaker than sign definiteness or sign semidefiniteness. For instance, in Theorem 7.1 and (iv)–(vi) of Theorem 7.2, the Lyapunov function is required to have a local nonstrict minimum at the equilibrium point only with respect to the set of points where the Lyapunov function derivative is negative, while in (i)–(iii) of Theorem 7.2, the Lyapunov function is not required to have even a local minimum at the equilibrium point of interest. Consequently, Theorems 7.1 and 7.2 can be used to deduce stability of all equilibria in a continuum by considering a single Lyapunov function for all the equilibria. This makes Theorems 7.1 and 7.2 particularly suited for applications to systems having a continuum of equilibria. Examples 7.1 and 7.3 illustrate these observations.

Our final result is the following corollary of Theorem 7.2.

COROLLARY 7.3. *Suppose $V : \mathcal{G} \to \mathbb{R}$ is a continuous function such that $\dot{V}$ is defined on $\mathcal{G}$. Let $x \in \mathcal{E}$ be a global minimizer of V relative to $\mathcal{G}$ and a global maximizer of $\dot{V}$ relative to $\mathcal{G}$. Let $\mathcal{P}$ denote the largest subset of $V^{-1}(V(x))$ that is invariant and connected and contains x. Let $\mathcal{N}$ denote the largest invariant subset of $\overline{\dot{V}^{-1}(0)}$. Then the following statements hold.*

(i) *If $\mathcal{P} = \{x\}$, then x is Lyapunov stable relative to $\mathcal{G}$.*

(ii) *If x is an isolated point of $\mathcal{N}$, then x is asymptotically stable relative to $\mathcal{G}$.*

Proof. (i) Since x is a global minimizer of V relative to $\mathcal{G}$, it follows that $\mathcal{P}$ is also the largest connected subset of the set $\{z \in \mathcal{G} : V(z) \leq V(x)\}$ that is invariant and contains x. If $\mathcal{P} = \{x\}$, then $T_x\mathcal{P} \cap \mathcal{F}_x \subseteq \{0\}$, and hence the result follows from (i) of Theorem 7.2.

(ii) Since $\mathcal{P}$ is an invariant subset of a level set of V, it follows that $\mathcal{P} \subseteq \dot{V}^{-1}(0)$. Thus $\mathcal{P}$ is a connected invariant subset of $\overline{\dot{V}^{-1}(0)}$ containing x, and hence $\mathcal{P} \subseteq \mathcal{N}$. Now suppose x is an isolated point of $\mathcal{N}$. Then $\mathcal{P} = \{x\}$, and hence, by (i), x is Lyapunov stable relative to $\mathcal{G}$. By Lyapunov stability of x and local compactness of $\mathcal{G}$, there exists a relatively open, relatively bounded, and positively invariant neighborhood $\mathcal{U} \subseteq \mathcal{G}$ of x such that $\overline{\mathcal{U}} \cap \mathcal{N} = \{x\}$. For every $z \in \mathcal{U}$, $\mathcal{O}_z \subseteq \mathcal{U}$ is relatively bounded. By Proposition 5.3, for every $z \in \mathcal{U}$, $\mathcal{O}_z^\infty \subseteq \overline{\mathcal{O}_z} \subseteq \overline{\mathcal{U}}$ is contained in $\mathcal{N}$. Since $\overline{\mathcal{U}} \cap \mathcal{N} = \{x\}$, it follows that $\mathcal{O}_z^\infty = \{x\}$ for every $z \in \mathcal{U}$. Asymptotic stability of x now follows. ∎

Remark 7.7. It is interesting to compare (ii) of Corollary 7.3 with the Krasovskii–LaSalle theorem for asymptotic stability [20, Thm. 14.1]. In the result from [20], the Lyapunov function and its derivative are assumed to be locally positive definite and locally negative semidefinite, respectively, at the equilibrium. In other words, the equilibrium is assumed to be a strict local minimizer for the Lyapunov function and a local nonstrict maximizer for the Lyapunov function derivative. On the other hand, Corollary 7.3 assumes the equilibrium to be a global nonstrict minimizer and a global nonstrict maximizer for the Lyapunov function and its derivative, respectively. In other words, Corollary 7.3 assumes the Lyapunov function to be only positive semidefinite globally instead of positive definite locally at the equilibrium. Thus, both (ii) of Corollary 7.3 and Theorem 14.1 of [20] assert asymptotic stability of the equilibrium under two alternative and complementary sets of assumptions.

Remark 7.8. It is also interesting to compare Corollary 7.3 with Corollary 7.1. While Corollary 7.3 requires the equilibrium to be a global minimizer and a global maximizer of V and $\dot{V}$, respectively, Corollary 7.1 requires only that the equilibrium be a local minimizer and a local maximizer, respectively, of V and $\dot{V}$. Thus the hypotheses of Corollary 7.1 on the Lyapunov function and its derivative are weaker than those of Corollary 7.3. However, Corollary 7.1 requires the equilibrium point to be an isolated point of the largest negatively invariant subsets of level sets of V and $\dot{V}$, while Corollary 7.3 requires only that the equilibrium be an isolated point of the largest invariant subsets of level sets of V and $\dot{V}$. Since invariant sets are also negatively invariant, it is clear that the hypotheses of Corollary 7.3 relating to invariant subsets are weaker than the corresponding hypotheses in Corollary 7.1. Thus both corollaries assert Lyapunov and asymptotic stability under alternative and complementary sets of conditions.

8. Conclusions. This paper introduces convergence and semistability as two notions of importance in the study of systems having a continuum of equilibria. The main contribution of this paper has been the introduction of the notion of nontangency and its application in the Lyapunov analysis of systems having a continuum of equilibria. Positive limit sets and restricted prolongations play a key role in the application of nontangency to Lyapunov analysis of convergence and stability, respectively. We introduce restricted prolongations in the paper, establish their invariance properties, and give inclusion results for restricted prolongations in terms of invariant and negatively invariant subsets of the level and sublevel sets of a Lyapunov function and its derivative. Using nontangency, we obtain Lyapunov results for convergence, Lyapunov stability, semistability, and asymptotic stability. The results on Lyapunov

stability and asymptotic stability involve hypotheses on the Lyapunov function and its derivative that are weaker than sign definiteness or semidefiniteness. This makes our results particularly suited for applications to systems having a continuum of equilibria. The weaker hypotheses on the Lyapunov function and its derivative are supplemented by assuming nontangency of the vector field to appropriate subsets of the level and sublevel sets of the Lyapunov function and its derivative. We illustrate the main results by applying them to an example from chemical kinetics and an example from adaptive control.

Appendix. Proof of Proposition 4.2. We present here the proof of Proposition 4.2. First, we recall some definitions related to set convergence [2, 26]. Consider a sequence $\{\mathcal{W}_k\}$ of subsets of $\mathbb{R}^n$. The limit superior of the sequence, denoted $\limsup_{k\to\infty} \mathcal{W}_k$, is the set of all subsequential limits of sequences $\{w_k\}$ in $\mathbb{R}^n$ such that $w_k \in \mathcal{W}_k$ for every k. The limit inferior of the sequence, denoted by $\liminf_{k\to\infty} \mathcal{W}_k$, is the set of limits of convergent sequences $\{w_k\}$ in $\mathbb{R}^n$ such that $w_k \in \mathcal{W}_k$ for every k. The sequence $\{\mathcal{W}_k\}$ *converges* to the set $\mathcal{W} \subseteq \mathbb{R}^n$ if $\mathcal{W} = \liminf_{k\to\infty} \mathcal{W}_k = \limsup_{k\to\infty} \mathcal{W}_k$.

The proof of Proposition 4.2 requires two basic results on set convergence. The first result is that if $\{\mathcal{W}_k\}$ is a sequence of subsets of a bounded subset of $\mathbb{R}^n$, then the sequence $\{\mathcal{W}_k\}$ has a subsequence that converges to a nonempty set. This result follows from Theorem 1.1.7 of [2] and Theorem 4.18 of [26]. The second result is given by the following lemma.

LEMMA A.1. *Suppose $\{\mathcal{W}_k\}$ is a sequence of connected subsets of a bounded set $\mathcal{B} \subset \mathbb{R}^n$ that converges to a set $\mathcal{W} \subseteq \mathbb{R}^n$. Then $\mathcal{W}$ is connected.*

Proof. Suppose $\mathcal{W}$ is not connected. Then there exist two disjoint open sets $\mathcal{U} \subseteq \mathbb{R}^n$ and $\mathcal{V} \subseteq \mathbb{R}^n$ such that $\mathcal{W} \subseteq \mathcal{U} \cup \mathcal{V}$ and $\mathcal{W} \cap \mathcal{U}$ and $\mathcal{W} \cap \mathcal{V}$ are nonempty. Since $\mathcal{W} = \liminf_{k\to\infty} \mathcal{W}_k$, there exist convergent sequences $\{u_k\}$ and $\{v_k\}$ in $\mathbb{R}^n$ such that $\lim_{k\to\infty} u_k \in \mathcal{W} \cap \mathcal{U}$, $\lim_{k\to\infty} v_k \in \mathcal{W} \cap \mathcal{V}$ and, for every k, $u_k, v_k \in \mathcal{W}_k$. Therefore, there exists $K > 0$ such that, for every $k > K$, $\mathcal{W}_k \cap \mathcal{U}$ and $\mathcal{W}_k \cap \mathcal{V}$ are nonempty. Since each $\mathcal{W}_k$ is connected, it follows that, for every $k > K$, there exists $w_k \in \mathcal{W}_k$ such that $w_k \notin \mathcal{U} \cup \mathcal{V}$. The sequence $\{w_k\}_{k=K}^{\infty}$ is contained in $\mathcal{B}$ and hence bounded. Let w be a subsequential limit of the sequence $\{w_k\}_{k=K}^{\infty}$. Since the sequence $\{w_k\}_{k=K}^{\infty}$ is contained in the closed set $\mathbb{R}^n \backslash (\mathcal{U} \cup \mathcal{V})$, it follows that $w \in \mathbb{R}^n \backslash (\mathcal{U} \cup \mathcal{V})$. On the other hand, $w \in \limsup_{k\to\infty} \mathcal{W}_k = \mathcal{W} \subseteq \mathcal{U} \cup \mathcal{V}$, which leads to a contradiction. Hence we conclude that $\mathcal{W}$ is connected. ∎

Proof of Proposition 4.2. Suppose $0 \notin \operatorname{co} \mathcal{L}_x$. For each $k = 1, 2, \ldots$, let $\mathcal{U}_k = \{w \in \mathbb{R}^n : \operatorname{dist}(w, \mathcal{L}_x) < 1/k\}$. For every k, $\mathcal{U}_k$ is an open set containing $\mathcal{L}_x$, $\overline{\mathcal{U}_k}$ is compact, and $\overline{\mathcal{U}_{k+1}} \subset \mathcal{U}_k$. Moreover, $\cap_k \overline{\mathcal{U}_k} = \mathcal{L}_x$.

For every k, there exists a relatively open neighborhood $\mathcal{V}_k \subseteq \mathcal{G}$ of x such that, for every $z \in \mathcal{V}_k \backslash \mathcal{E}$, $\|f(z)\|^{-1} f(z) \in \mathcal{U}_k$. It is easy to show that, for every k, every connected component of $f(\mathcal{V}_k)\backslash\{0\}$ is contained in the cone generated by a connected component of $\mathcal{U}_k$. Hence it follows that, for every k, $\overline{\operatorname{coco}(f(\mathcal{V}_k)\backslash\{0\})} \subseteq \overline{\operatorname{coco} \mathcal{U}_k}$. Consequently, $\mathcal{F}_x \subseteq \cap_{k=1}^{\infty} \overline{\operatorname{coco}\,(f(\mathcal{V}_k)\backslash\{0\})} \subseteq \cap_{k=1}^{\infty} \overline{\operatorname{coco} \mathcal{U}_k}$.

We claim that $\cap_{k=1}^{\infty} \overline{\operatorname{coco} \mathcal{U}_k} \subseteq \operatorname{co} \mathcal{L}_x$. To prove this, choose $v \in \cap_{k=1}^{\infty} \overline{\operatorname{coco} \mathcal{U}_k}$. There exist a sequence $\{\alpha_k\}$ in $(0, \infty)$ and a sequence $\{v_k\}$ in $\mathbb{R}^n$ such that, for every k, $v_k \in \operatorname{co} \mathcal{U}_k$ and

$$\|v - \alpha_k v_k\| < \frac{1}{k}. \tag{17}$$

For each k, let $\mathcal{W}_k$ be a connected component of $\mathcal{U}_k$ such that v_k is contained in the convex hull of $\mathcal{W}_k$. Each $\mathcal{W}_k$ is a subset of the bounded set $\mathcal{U}_1$. Hence there

exists an increasing sequence $\{k_j\}_{j=1}^{\infty}$ of integers such that the subsequence $\{\mathcal{W}_{k_j}\}_{j=1}^{\infty}$ converges. Let $\mathcal{W} = \lim_{j\to\infty} \mathcal{W}_{k_j}$. Then, by Lemma A.1, $\mathcal{W}$ is connected.

Next, consider $w \in \mathcal{W}$. There exists a sequence $\{w_j\}$ such that $w_j \in \mathcal{W}_{k_j} \subseteq \mathcal{U}_{k_j}$ for every j, and $\lim_{j\to\infty} w_j = w$. Since $\{\mathcal{U}_k\}$ is a decreasing sequence of sets, for every k, the sequence $\{w_j\}$ is eventually contained in $\mathcal{U}_k$. Hence $w \in \overline{\mathcal{U}_k}$ for every k; that is, $w \in \cap_k \overline{\mathcal{U}_k} = \mathcal{L}_x$. Since $w \in \mathcal{W}$ was arbitrary, it follows that $\mathcal{W} \subseteq \mathcal{L}_x$. Hence the connected set $\mathcal{W}$ is contained in a connected component of $\mathcal{L}_x$.

By Caratheodory's theorem [25, Thm. 17.1], for every j, there exist vectors $w_j^i \in \mathcal{W}_{k_j}$, $i = 1, \ldots, n$, and scalars $\lambda_j^i \in [0, 1]$, $i = 1, \ldots, n$, such that $\lambda_j^1 + \cdots + \lambda_j^n = 1$ and

$$v_{k_j} = \lambda_j^1 w_j^1 + \cdots + \lambda_j^n w_j^n. \tag{18}$$

For each $i = 1, \ldots, n$, let $\lambda^i \in [0, 1]$ and w^i be subsequential limits of the bounded sequences $\{\lambda_j^i\}_{j=1}^{\infty}$ and $\{w_j^i\}_{j=1}^{\infty}$, respectively. Then, for every i, $w^i \in \mathcal{W}$, while $\lambda^1 + \cdots + \lambda^n = 1$. Let $w = \lambda^1 w^1 + \cdots + \lambda^n w^n$. Then $w \in \operatorname{co} \mathcal{L}_x$, and hence $w \neq 0$.

By (18), there exists an increasing sequence $\{i_m\}_{m=1}^{\infty}$ of integers such that, for every m,

$$\|v_{i_m} - w\| < \frac{1}{m}. \tag{19}$$

For every m, (17) implies that $\alpha_{i_m}\|v_{i_m}\| \leq \|v\| + i_m^{-1}$, while (19) implies that $\|v_{i_m}\| \geq \|w\| - m^{-1}$. It therefore follows that, for every $m > \|w\|^{-1}$, $\alpha_{i_m} \leq (\|v\| + i_m^{-1})(\|w\| - m^{-1})^{-1}$. There exists $M > 0$ such that, for every $m > M$, $i_m^{-1} < \|v\|$ and $m^{-1} < \|w\|/2$. Then, for every $m > M$, $\alpha_{i_m} \leq 4\|v\|/\|w\|$. It follows that the subsequence $\{\alpha_{i_m}\}_{m=1}^{\infty}$ is bounded. Hence, by choosing subsequences appropriately, we may assume that there exists $\alpha \in [0, \infty)$ such that, for every $m > M$, $|\alpha_{i_m} - \alpha| < m^{-1}$. Then, for every $m > M$, $\|v - \alpha w\| \leq \|v - \alpha_{i_m} v_{i_m}\| + \alpha_{i_m}\|v_{i_m} - w\| + |\alpha_{i_m} - \alpha|\|w\| \leq i_m^{-1} + m^{-1}(\alpha_{i_m} + \|w\|)$. Since the subsequence $\{\alpha_{i_m}\}_{m=1}^{\infty}$ is bounded and the sequence $\{i_m\}$ is divergent, m can be chosen to make the right-hand side of the previous inequality arbitrarily small. It follows that $v = \alpha w$ and thus $v \in \operatorname{coco} \mathcal{L}_x$. The result now follows. ∎

LINEAR CONTROL SYSTEMS ON UNBOUNDED TIME INTERVALS AND INVARIANT MEASURES OF ORNSTEIN–UHLENBECK PROCESSES IN HILBERT SPACES*

MARCO FUHRMAN† AND ANNA MARIA PAGANONI†

Abstract. We consider linear control systems in a Hilbert space over an unbounded time interval of the form

$$y'_\alpha(t) = (A - \alpha I)y_\alpha(t) + Bu(t), \qquad t \in (-\infty, T],$$

with bounded control operator B, under appropriate stability assumptions on the operator A. We study how the space of states reachable at time T depends on the parameter $\alpha \geq 0$. We apply the results to study the dependence on α of the Cameron–Martin spaces of the invariant measures of the Ornstein–Uhlenbeck processes X_α defined by the equation driven by the Wiener process W:

$$dX_\alpha(t) = (A - \alpha I)X_\alpha(t)\, dt + B\, dW(t), \qquad t \geq 0.$$

1. Introduction.

The aim of this paper is to study some controllability properties of a linear control system in a Hilbert space H over an unbounded time interval and to apply these results to study the behavior of the Cameron–Martin space of the invariant measure for a class of Ornstein–Uhlenbeck stochastic processes in H under perturbation.

Let us consider a linear control system in H of the form

$$y'(t) = Ay(t) + Bu(t), \qquad t \in (-\infty, T], \tag{1.1}$$

for t varying in a fixed unbounded time interval $(-\infty, T]$, where A is the infinitesimal generator of a strongly continuous semigroup of operators, B is a bounded operator from another Hilbert space U to H, and u is a control, which will always be assumed to belong to the space $L^2(-\infty, T; U)$ of square summable functions from $(-\infty, T]$ to U. The value of T is irrelevant in most of what follows, and we could even replace T by zero; nevertheless, we will keep the present, slightly more general notation. For the moment we assume for simplicity that A is exponentially stable, although this assumption will be relaxed in the following sections. Then the solution of (1.1) can be defined in a standard way for every control u. The initial condition at $-\infty$ is assumed to be zero. One defines in an obvious way the space of states reachable at time T over the interval $(-\infty, T]$, which is denoted by $\mathcal{K}_\infty$. By straightforward extensions of the results on a finite time interval, this space can be characterized as the image of the square root of the operator Q_∞ defined by

$$Q_\infty h = \int_0^\infty e^{tA} B B^* e^{tA^*} h\, dt, \qquad h \in H.$$

Thus $\mathcal{K}_\infty = im\, Q_\infty^{1/2}$. Clearly, this space does not depend on T.

One of the main results of this paper is a precise description of the behavior of the space of reachable states for the class of perturbed control systems

$$y'_\alpha(t) = (A - \alpha I)y_\alpha(t) + Bu(t), \qquad t \in (-\infty, T], \tag{1.2}$$

when the parameter α ranges over $[0, \infty)$.

We note that the system (1.2) can be reduced to system (1.1) by the transformation $y(t) = e^{\alpha t}y_\alpha(t)$. This transformation is sometimes called the "exponential shift." For control systems on a finite time interval this argument shows that the space of reachable states does not depend on α. We note, however, that the exponential shift maps the control u to the function $t \mapsto e^{\alpha t}u(t)$, which does not necessarily belong to the space $L^2(-\infty, T; U)$ of square summable controls, due to the fact that the time interval $(-\infty, T]$ is unbounded. Keeping the space of controls fixed, the problem arises whether the space of reachable sets may change with α. One can also study a related problem, namely, whether a state which is reachable on $(-\infty, T]$ can also be reached over a finite time interval $[T - r, T]$ for some $r > 0$.

In Theorem 4.1 we give an answer to both questions. Somewhat imprecisely, the situation is as follows: denoting by $\mathcal{K}^\alpha_\infty$ the space of reachable states for the perturbed systems (1.2), it is clear that

$$0 \le \alpha \le \beta \qquad \text{implies} \qquad \mathcal{K}^\alpha_\infty \supset \mathcal{K}^\beta_\infty,$$

possibly with equality. It can happen that $\mathcal{K}^\alpha_\infty$ are strictly decreasing for all $\alpha \ge 0$. Or it can happen that $\mathcal{K}^\alpha_\infty$ are strictly decreasing for α less or equal to some critical value α_0, and then they remain unchanged for $\alpha > \alpha_0$; the case $\alpha_0 = 0$ may occur. Another case can also happen, namely, that $\mathcal{K}^\alpha_\infty$ do not depend on α. Finally, the states in $\mathcal{K}^\alpha_\infty$ can be reached in a finite time interval precisely when a small change of α does not change the reachable set. See Theorem 4.1 for precise statements. We also relate the critical value α_0 to the norms of some appropriately defined operators; see Corollary 4.7.

One may ask whether more general perturbations of the original system (1.1) could affect the space $\mathcal{K}_\infty$ of reachable states over $(-\infty, T]$. The results described above show the (perhaps surprising) fact that even the spaces $\mathcal{K}^\alpha_\infty$ are very "sensitive" to perturbations; an arbitrarily small change in the value of α may suffice to change the space $\mathcal{K}^\alpha_\infty$. Therefore, one expects that more general perturbations of the original system (1.1) will have the same effect, unless very stringent conditions are imposed. That is why we do not address this problem here but rather postpone it to future study.

We devote section 5 to giving examples where the various possibilities described above occur and also to studying some important classes of control systems. For example, we show that the spaces $\mathcal{K}^\alpha_\infty$ do not depend on α if the system is finite-dimensional or exactly null controllable.

In connection with all the properties and problems discussed so far, instead of the set of reachable states one may consider the set of approximately reachable states. In strong contrast with the previous results, the space of approximately reachable states for system (1.2) turns out to be independent of α; see section 4.3.

We believe that the previous results have an intrinsic interest, since they address basic structural properties of linear control systems, but our interest in this question arose from some probabilistic motivation, which we now shortly describe.

Let us consider the following stochastic evolution equation of Itô type:

$$\begin{cases} dX(t) = AX(t)\,dt + B\,dW(t), & t \geq 0, \\ X(0) = X_0, \end{cases}$$

where W is a (cylindrical) Wiener process in a filtered probability space $(\Omega, \mathcal{F}, \mathbb{P}, (\mathcal{F}_t))$ and X_0 is a gaussian $\mathcal{F}_0$-measurable random variable with values in H. Assuming the finite trace condition

$$\text{Trace } Q_\infty < \infty,$$

one can show that the equation uniquely defines a gaussian process X and that the centered gaussian measure μ with covariance operator Q_∞ is invariant for the process X. For these facts we refer to [8] and to the discussion in section 6. The process X is called the (nonsymmetric) Ornstein–Uhlenbeck process and has been intensively studied in recent years; see [3, 4, 5, 6, 13, 14].

Associated to the centered gaussian measure μ is the so-called Cameron–Martin space; see, e.g., [1]. It is the subspace of H consisting of all vectors h such that the image measure of μ under the mapping $x \to x + h$, $x \in H$, is absolutely continuous with respect to μ. The corresponding Radon–Nikodym density is then called the logarithmic derivative of μ along h. The Cameron–Martin space plays a basic role in the construction of the Sobolev classes of functions over the measure space (H, μ) (see [1]), in the definition and properties of the associated Dirichlet forms (see [2], [17]), and in the subsequent constructions needed for the analysis of the stochastic process X (see the references on the Ornstein–Uhlenbeck process cited above). It turns out that the Cameron–Martin space of μ coincides with $im\, Q_\infty^{1/2}$ and hence with the space of reachable states $\mathcal{K}_\infty$ for the control system (1.1). So our results can be applied to study how the Cameron–Martin space behaves under perturbation of the Ornstein–Uhlenbeck process. Thus, for $\alpha \geq 0$, we consider the perturbed processes X_α solution of

$$\begin{cases} dX_\alpha(t) = (A - \alpha I)X_\alpha(t)\,dt + B\,dW(t), & t \geq 0, \\ X_\alpha(0) = X_0, \end{cases}$$

and we consider the corresponding gaussian invariant measures μ_α. Since the Cameron–Martin space of μ_α coincides with $\mathcal{K}_\infty^\alpha$, our results give information on the dependence of the Cameron–Martin space of μ_α on α.

The plan of the paper is as follows: Section 2 is devoted to some preliminary technical facts. Section 3 contains the standing assumptions and some preliminary results on control systems on unbounded time intervals. Section 4 contains the main results, Theorem 4.1 and Corollary 4.7, while section 5 is devoted to examples. Finally, in section 6 it is shown how to apply results to the Ornstein–Uhlenbeck process.

2. Some notation and technical tools. Let H and U be separable Hilbert spaces, over the real or complex field, with norm and scalar product denoted by $|\cdot|$, $\langle\cdot\rangle$. We use $\|\cdot\|$ to denote the operator norm. Later we will consider H as the state space of a control system and U as the space of control parameters.

We start by recalling a few facts on Hilbert space valued integrals.

Let I be an interval in the real line and $f : I \to H$ a Borel measurable function. It is well known that f is integrable (in the sense of Bochner) if and only if $\int_I |f(t)|\,dt < \infty$. To allow more generality, in the following we will use the concept of weak integrals,

and so we are going to recall the definition and some of its elementary properties; for more on this subject the reader may consult, e.g., [9]. We say that f is weakly integrable if $\int_I |\langle f(t), h\rangle|\, dt < \infty$ for every $h \in H$ and there exists a (necessarily unique) element of H, denoted $\int_I f(t)\, dt$, such that

$$\left\langle \int_I f(t)\ dt, h \right\rangle = \int_I \langle f(t), h\rangle\ dt, \qquad h \in H.$$

If f is Bochner integrable, then $\int_I f(t)\, dt$ coincides with the Bochner integral. The definition of weak integrability, as stated above, is slightly redundant, as shown by the following well-known lemma that will be useful in what follows; see, for example, [10, 9].

LEMMA 2.1. *If $f : I \to H$ is Borel measurable and $\int_I |\langle f(t), h\rangle|\, dt < \infty$ for every $h \in H$, then f is weakly integrable.*

In the following sections we will systematically use the following lemma, whose proof can be found in [7] or [21].

LEMMA 2.2. *Let H, U, Z be Hilbert spaces, and let $A : U \to H$ and $B : Z \to H$ be bounded linear operators. Then the inclusion between the images*

$$im\ A \subset im\ B$$

holds if and only if there exists $c > 0$ such that

$$|A^* h| \le c|B^* h|, \qquad h \in H.$$

In this case, denoting by B^{-1} the pseudoinverse of B, we have $\|B^{-1}A\| \le c$.

In particular, if we define $Q = BB^*$, then $im\ B = im\ Q^{1/2}$ and, denoting $Q^{-1/2}$ the pseudoinverse of $Q^{1/2}$, we have $\|B^{-1}Q^{1/2}\| = \|Q^{-1/2}B\| = 1$.

3. Assumptions and preliminaries. Throughout the paper the following assumptions are assumed to hold.

HYPOTHESIS 3.1.

(i) *H and U are separable Hilbert spaces.*

(ii) *The operator A is the generator of a strongly continuous semigroup $\{e^{tA},\ t \ge 0\}$ of bounded linear operators in H. B is a bounded linear operator from U to H.*

(iii) *We have*

$$\int_0^\infty |B^* e^{tA^*} x|^2 dt < \infty, \qquad x \in H. \tag{3.1}$$

We remark that the validity of (3.1) does not imply that the operator A is exponentially stable. Condition (3.1) has received a fair amount of attention in some of the recent literature. At least in the case when $U = \mathbb{R}$ (and therefore B^* maps H to $\mathbb{R}$), in several cases condition (3.1) is equivalent to a bound of the form $|B^*(sI - A^*)^{-1}|_{H^*} \le c/\sqrt{\mathrm{Re}\ s}$ for complex s with $\mathrm{Re}\ s > 0$; see, for instance, [15, 20, 16].

Let us consider a control system in H on a finite time interval. We shortly recall some usual definitions and properties, mainly to fix notation. For further details we refer the reader to any treatise on infinite-dimensional control theory, for instance, [7] or [21].

We will consider a control system on a time interval of length $r > 0$, with initial condition $h \in H$, formally:

$$y'(t) = Ay(t) + Bu(t), \quad t \in [T-r, T], \qquad y(T-r) = h. \tag{3.2}$$

Here T is an arbitrary fixed real number; the choice of the time interval $[T-r, T]$ allows us to conform with some notation that will be introduced later, when dealing with the unbounded time interval $(-\infty, T]$.

When referring to (3.2), we take as the space of controls the space $L^2(T-r, T; U)$ of all Borel measurable functions $u : [T-r, T] \to U$ satisfying $\int_{T-r}^{T} |u(t)|^2 dt < \infty$. $L^2(T-r, T; U)$ will be endowed with its usual Hilbert norm. The solution $y : [T-r, T] \to H$ of (3.2), or the trajectory corresponding to a control u, is defined as

$$y(t) = e^{(t-T+r)A}h + \int_{T-r}^{t} e^{(t-s)A}Bu(s)\, ds, \qquad t \in [T-r, T],$$

and the space $\mathcal{K}_r$ of states reachable from zero in time r (in short, the space of reachable states) is defined as the set of all elements $y(T)$, as u spans the space of controls and $h = 0$. The space $\mathcal{K}_r$ therefore coincides with the image of the so-called controllability operator $\mathcal{L}_r : L^2(T-r, T; U) \to H$ defined by

$$\mathcal{L}_r u = \int_{T-r}^{T} e^{(T-s)A}Bu(s)\, ds, \qquad u \in L^2(-\infty, T; U).$$

The gramian operator is defined by

$$Q_r h = \int_0^r e^{tA}BB^* e^{tA^*} h\, dt, \qquad h \in H,$$

and we have $\mathcal{L}_r \mathcal{L}_r^* = Q_r$ and $\mathcal{K}_r = im\, \mathcal{L}_r = im\, Q_r^{1/2}$. Clearly, $\mathcal{K}_s \subset \mathcal{K}_r$ for $0 < s < r$.

In the case of a finite time interval considered so far, the assumption (3.1) is not needed, and all the indicated integrals are Bochner integrals.

Now, for fixed $T \in \mathbb{R}$, we consider the following control system in H on the unbounded time interval $(-\infty, T]$:

$$y'(t) = Ay(t) + Bu(t), \quad t \in (-\infty, T], \qquad y(-\infty) = 0. \tag{3.3}$$

This expression is only formal, but now we proceed to giving rigorous definitions. We define a control as an element of $L^2(-\infty, T; U)$, i.e., a Borel measurable function $u : (-\infty, T] \to U$ satisfying $\int_{-\infty}^{T} |u(t)|^2 dt < \infty$. $L^2(-\infty, T; U)$ will be endowed with its usual Hilbert norm. A trajectory of the control system (3.3), corresponding to the control u, is by definition the function

$$y(t) = \int_{-\infty}^{t} e^{(t-s)A}Bu(s)\, ds, \qquad t \in (-\infty, T]. \tag{3.4}$$

We note that, for every $h \in H$,

$$\begin{aligned}
\int_{-\infty}^{t} |\langle e^{(t-s)A}Bu(s), h\rangle|\, ds &\le \int_{-\infty}^{t} |u(s)|\, |B^* e^{(t-s)A^*} h|\, ds \\
&\le \left(\int_{-\infty}^{t} |u(s)|^2\, ds\right)^{1/2} \left(\int_{-\infty}^{t} |B^* e^{(t-s)A^*} h|^2\, ds\right)^{1/2} \\
&= \left(\int_{-\infty}^{t} |u(s)|^2\, ds\right)^{1/2} \left(\int_{0}^{\infty} |B^* e^{sA^*} h|^2\, ds\right)^{1/2},
\end{aligned}$$

and the right-hand side is finite by the assumption (3.1). It follows that $y(t)$ is well defined as a weak integral by Lemma 2.1.

We define the space of reachable states $\mathcal{K}_\infty$ as the set of all elements $y(T)$, as u spans the space of controls. The space $\mathcal{K}_\infty$ therefore coincides with the image of the operator $\mathcal{L}_\infty : L^2(-\infty, T; U) \to H$ defined as

$$\mathcal{L}_\infty u = \int_{-\infty}^{T} e^{(T-s)A} B u(s)\, ds, \qquad u \in L^2(-\infty, T; U).$$

We may call $\mathcal{L}_\infty$ the extended controllability operator. The adjoint operator $\mathcal{L}_\infty^* : H \to L^2(-\infty, T; U)$ is easily computed: for $h \in H$, $\mathcal{L}_\infty^* h$ is the function

$$\mathcal{L}_\infty^* h(s) = B^* e^{(T-s)A^*} h, \qquad s \in (-\infty, T].$$

In particular, we find

$$\mathcal{L}_\infty \mathcal{L}_\infty^* h = \int_{-\infty}^{T} e^{(T-s)A} B B^* e^{(T-s)A^*} h\, ds = \int_0^\infty e^{tA} B B^* e^{tA^*} h\, ds,$$

which is a well-defined weak integral. So we can define the extended gramian operator

$$Q_\infty h = \int_0^\infty e^{tA} B B^* e^{tA^*} h\, dt, \qquad h \in H,$$

and conclude that

$$\mathcal{L}_\infty \mathcal{L}_\infty^* = Q_\infty,$$

which implies that Q_∞ is a bounded nonnegative self-adjoint operator in H and, by Lemma 2.2, that the space $\mathcal{K}_\infty$ coincides with the image of $Q_\infty^{1/2}$.

The reader may note that these are immediate extensions of the corresponding notions for systems on a finite time interval.

4. Perturbed systems: Main result. In this section Hypothesis 3.1 is still in force. Our main concern will be to investigate the behavior of the space of reachable states when the system (3.3) is perturbed by replacing the operator A with $A - \alpha I$, where $\alpha \geq 0$. Note that (3.1) holds with A replaced by $A - \alpha I$ since $\alpha \geq 0$. We still keep $L^2(-\infty, T; U)$ as the space of controls.

Thus we are considering the family of control systems written formally

$$y_\alpha'(t) = (A - \alpha I) y_\alpha(t) + B u(t), \quad t \in (-\infty, T], \qquad y_\alpha(-\infty) = 0. \tag{4.1}$$

We note that $A - \alpha I$ is the generator of the semigroup $\{e^{-\alpha t} e^{tA},\ t \geq 0\}$. According to the previous definitions, for the perturbed control system (4.1) the space of reachable states $\mathcal{K}_\infty^\alpha$ is defined as the image of the operator $\mathcal{L}_\infty^{(\alpha)} : L^2(-\infty, T; U) \to H$ given by

$$\mathcal{L}_\infty^{(\alpha)} u = \int_{-\infty}^{T} e^{-\alpha(T-s)} e^{(T-s)A} B u(s)\, ds, \qquad u \in L^2(-\infty, T; U).$$

The extended gramian operator for (4.1) is

$$Q_\infty^{(\alpha)} h = \int_0^\infty e^{-2\alpha t} e^{tA} B B^* e^{tA^*} h\, dt, \qquad h \in H, \tag{4.2}$$

and we have $\mathcal{L}_\infty^{(\alpha)}(\mathcal{L}_\infty^{(\alpha)})^* = Q_\infty^{(\alpha)}$ and $\mathcal{K}_\infty^\alpha = im\ \mathcal{L}_\infty^{(\alpha)} = im\ (Q_\infty^{(\alpha)})^{1/2}$ as before. Note that $\mathcal{K}_\infty^0 = \mathcal{K}_\infty$, $\mathcal{L}_\infty^{(0)} = \mathcal{L}_\infty$, $Q_\infty^{(0)} = Q_\infty$. We also note that for $0 \le \alpha < \beta$ the inequality $Q_\infty^{(\beta)} \le Q_\infty^{(\alpha)}$ is obvious, and by Lemma 2.2 this implies $\mathcal{K}_\infty^\beta = im\ (Q_\infty^{(\beta)})^{1/2} \subset im\ (Q_\infty^{(\alpha)})^{1/2} = \mathcal{K}_\infty^\alpha$.

We may also consider the perturbed system on a bounded time interval; formally, for $r > 0$,

$$y'_\alpha(t) = (A - \alpha I)y_\alpha(t) + Bu(t), \quad t \in [T-r, T], \qquad\qquad y_\alpha(T-r) = 0.$$

However, the space of reachable states for this system clearly does not depend on α and is equal to the image of the operators $\mathcal{L}_r$ introduced above, since the exponential shift, described in the introduction, leaves the space $L^2(T-r, T; U)$ unchanged.

So far the following inclusions have been (trivially) verified: for $0 \le \alpha < \beta$ and $0 < s < r$ we have

$$\mathcal{K}_\infty^\alpha \supset \mathcal{K}_\infty^\beta \supset \mathcal{K}_r \supset \mathcal{K}_s.$$

Our main result is the following.

THEOREM 4.1. *Assume Hypothesis* 3.1. *Then one and only one of the following situations occurs.*

(i) *We have*

$$\mathcal{K}_\infty^\alpha = \mathcal{K}_\infty^\beta \qquad \textit{whenever} \qquad 0 \le \alpha < \beta.$$

Moreover, there exists $r > 0$ such that $\mathcal{K}_r = \mathcal{K}_\infty^\alpha$ for every $\alpha \ge 0$.

(ii) *There exists $\alpha_0 \in [0, \infty]$ such that*

$$\mathcal{K}_\infty^{\gamma_1} \supsetneq \mathcal{K}_\infty^{\gamma_2} \supsetneq \mathcal{K}_\infty^{\alpha_0} \supsetneq \mathcal{K}_\infty^{\beta_1} = \mathcal{K}_\infty^{\beta_2}$$

whenever $0 \le \gamma_1 < \gamma_2 < \alpha_0 < \beta_1 < \beta_2$.

Moreover, given $\alpha \ge 0$, there exists $r > 0$ such that $\mathcal{K}_r = \mathcal{K}_\infty^\alpha$ if and only if $\alpha_0 < \infty$ and $\alpha > \alpha_0$.

Remark 4.2. In the extreme cases $\alpha_0 = 0$ and $\alpha_0 = +\infty$, part (ii) of Theorem 4.1 is understood as follows:

(a) If $\alpha_0 = 0$, then $\mathcal{K}_\infty^0 \supsetneq \mathcal{K}_\infty^{\beta_1} = \mathcal{K}_\infty^{\beta_2}$ for $0 < \beta_1 < \beta_2 < \infty$.

(b) If $\alpha_0 = +\infty$, then $\mathcal{K}_\infty^{\gamma_1} \supsetneq \mathcal{K}_\infty^{\gamma_2}$ for $0 \le \gamma_1 < \gamma_2 < \infty$.

We remark that $\mathcal{K}_\infty^\alpha$ is not defined for $\alpha = +\infty$.

We may rephrase the statement of the theorem by saying that there are only two mutually exclusive cases: (1) the reachability spaces $\mathcal{K}_\infty^\alpha$ are all equal for all values of the parameter $\alpha \ge 0$; (2) the reachability spaces $\mathcal{K}_\infty^\alpha$ coincide for α larger than some critical value α_0, but $\mathcal{K}_\infty^\alpha$ are all distinct for $\alpha \in [0, \alpha_0]$ (and strictly larger than $\mathcal{K}_\infty^{\alpha_0}$, $\alpha > \alpha_0$). Moreover, in case 1 the states reachable in an unbounded time interval can also be reached in a finite time interval, independently of the value of α. In case 2 the states in $\mathcal{K}_\infty^\alpha$ can be reached in a finite time interval if and only if $\alpha > \alpha_0$.

In section 5 we will give examples to show that cases (i) and (ii) of Theorem 4.1 may occur and, in case (ii), each of the possibilities $\alpha_0 = 0$, $0 < \alpha_0 < \infty$, $\alpha_0 = \infty$ may occur.

In section 4.1 we collect some preliminary results for the proof of Theorem 4.1; the proof is presented in section 4.2.

4.1. Some auxiliary operators. The proof of Theorem 4.1 is based on some properties of the operators

$$S_0(t) = Q_\infty^{-1/2} e^{tA} Q_\infty^{1/2}, \qquad t \geq 0,$$

that we are going to study in this subsection. These operators have been introduced independently in [11] and [3]. The following result, proved in these papers, shows in particular that $S_0(t)$ are everywhere defined bounded linear operators on H, with norm less or equal to 1. We report the proof for completeness, with some simplifications contained in [12].

PROPOSITION 4.3. *Assume Hypothesis* 3.1. *For every* $t > 0$ *we have*

$$im\,(e^{tA} Q_\infty^{1/2}) \subset im\, Q_\infty^{1/2} \qquad \text{and} \qquad \|Q_\infty^{-1/2} e^{tA} Q_\infty^{1/2}\| \leq 1. \tag{4.3}$$

Moreover, the following conditions are equivalent:

(i) $\|S_0(t)\| < 1$;

(ii) $im\, Q_\infty^{1/2} = im\, Q_t^{1/2}$.

Proof. By Lemma 2.2, in order to prove (4.3), it suffices to show

$$|Q_\infty^{1/2} e^{tA^*} x|^2 \leq |Q_\infty^{1/2} x|^2, \quad x \in H,$$

i.e., $e^{tA} Q_\infty e^{tA^*} \leq Q_\infty$. This follows from the definition of Q_∞, since

$$e^{tA} Q_\infty e^{tA^*} = \int_0^\infty e^{(t+s)A} BB^* e^{(t+s)A^*}\, ds = \int_t^\infty e^{rA} BB^* e^{rA^*}\, dr = Q_\infty - Q_t \leq Q_\infty. \tag{4.4}$$

Equation (4.3) is now proved.

First note that $Q_t \leq Q_\infty$, so by Lemma 2.2 the inclusion $im\, Q_t^{1/2} \subset im\, Q_\infty^{1/2}$ always holds. By Lemma 2.2 again, (i) holds if and only if there exists $\alpha \in (0,1)$ such that

$$|Q_\infty^{1/2} e^{tA^*} x|^2 \leq \alpha |Q_\infty^{1/2} x|^2, \qquad x \in H.$$

Now note that (4.4) implies

$$|Q_\infty^{1/2} e^{tA^*} x|^2 = \langle (Q_\infty - Q_t)x, x\rangle,$$

so (i) holds if and only if

$$\langle (Q_\infty - Q_t)x, x\rangle \leq \alpha \langle Q_\infty x, x\rangle, \qquad x \in H,$$

or

$$\langle Q_\infty x, x\rangle \leq (1-\alpha)^{-1} \langle Q_t x, x\rangle, \qquad x \in H.$$

By Lemma 2.2 this is equivalent to $im\, Q_\infty^{1/2} \subset im\, Q_t^{1/2}$. □

The following proposition is the main step toward the proof of Theorem 4.1.

PROPOSITION 4.4. *Assume Hypothesis* 3.1.

(i) *If there exists* $r > 0$ *such that* $\|S_0(r)\| < 1$, *then for every* $\alpha > 0$ *there exists* $c > 0$ *such that* $cQ_\infty \leq Q_\infty^{(\alpha)}$.

(ii) *If there exist* $c > 0$ *and* $\alpha > 0$ *such that* $cQ_\infty \leq Q_\infty^{(\alpha)}$, *then there exists* $r > 0$ *such that* $\|S_0(r)\| < 1$.

Proof. We first note the identity, for $h \in H$ and $r > 0$,

$$\int_0^r |B^* e^{tA^*} h|^2 dt = |Q_\infty^{1/2} h|^2 - |Q_\infty^{1/2} e^{rA^*} h|^2, \tag{4.5}$$

which follows from the computation

$$\begin{aligned} \int_0^r |B^* e^{tA^*} h|^2 dt &= \int_0^\infty |B^* e^{tA^*} h|^2 dt - \int_r^\infty |B^* e^{tA^*} h|^2 dt \\ &= |Q_\infty^{1/2} h|^2 - \int_0^\infty |B^* e^{tA^*} e^{rA^*} h|^2 dt \\ &= |Q_\infty^{1/2} h|^2 - |Q_\infty^{1/2} e^{rA^*} h|^2. \end{aligned}$$

Let us prove (i). We have

$$\langle Q_\infty^{(\alpha)} h, h \rangle = \int_0^\infty e^{-2\alpha t} |B^* e^{tA^*} h|^2 dt \geq e^{-2\alpha r} \int_0^r |B^* e^{tA^*} h|^2 dt,$$

and using (4.5) we obtain

$$|(Q_\infty^{(\alpha)})^{1/2} h|^2 \geq e^{-2\alpha r} (|Q_\infty^{1/2} h|^2 - |Q_\infty^{1/2} e^{rA^*} h|^2).$$

Since $Q_\infty^{1/2} e^{rA^*} h = S_0(r)^* Q_\infty^{1/2} h$, we arrive at

$$|(Q_\infty^{(\alpha)})^{1/2} h|^2 \geq e^{-2\alpha r} (1 - \|S_0(r)\|^2) |Q_\infty^{1/2} h|^2,$$

and the conclusion follows with $c = e^{-2\alpha r}(1 - \|S_0(r)\|^2)$.

Now we prove (ii). We can assume $c < 1$. We have

$$\begin{aligned} |Q_\infty^{1/2} e^{rA^*} h|^2 &= \int_0^\infty |B^* e^{tA^*} e^{rA^*} h|^2 dt = \int_r^\infty |B^* e^{tA^*} h|^2 dt \geq e^{2r\alpha} \int_r^\infty e^{-2t\alpha} |B^* e^{tA^*} h|^2 dt \\ &= e^{2r\alpha} \int_0^\infty e^{-2t\alpha} |B^* e^{tA^*} h|^2 dt - e^{2r\alpha} \int_0^r e^{-2t\alpha} |B^* e^{tA^*} h|^2 dt \\ &= e^{2r\alpha} |(Q_\infty^{(\alpha)})^{1/2} h|^2 - e^{2r\alpha} \int_0^r e^{-2t\alpha} |B^* e^{tA^*} h|^2 dt \\ &\geq e^{2r\alpha} |(Q_\infty^{(\alpha)})^{1/2} h|^2 - e^{2r\alpha} \int_0^r |B^* e^{tA^*} h|^2 dt. \end{aligned}$$

By assumption we have $|(Q_\infty^{(\alpha)})^{1/2} h|^2 \geq c |Q_\infty^{1/2} h|^2$, and using (4.5) we obtain

$$|Q_\infty^{1/2} e^{rA^*} h|^2 \geq c\, e^{2r\alpha} |Q_\infty^{1/2} h|^2 - e^{2r\alpha} (|Q_\infty^{1/2} h|^2 - |Q_\infty^{1/2} e^{rA^*} h|^2)$$

or

$$|Q_\infty^{1/2} e^{rA^*} h|^2 \leq (1 - c)\, e^{2r\alpha} (e^{2r\alpha} - 1)^{-1} |Q_\infty^{1/2} h|^2.$$

Choosing $r > 0$ so large that $\gamma := (1 - c)\, e^{2r\alpha} (e^{2r\alpha} - 1)^{-1} < 1$, and noting again that $Q_\infty^{1/2} e^{rA^*} h = S_0(r)^* Q_\infty^{1/2} h$, we obtain

$$|S_0(r)^* Q_\infty^{1/2} h|^2 \leq \gamma |Q_\infty^{1/2} h|^2, \qquad h \in H.$$

This proves that $|S_0(r)^* k|^2 \leq \gamma |k|^2$ for $k \in im\, Q_\infty^{1/2}$. Since, however, by its definition, $S_0(r) k = 0$ for k in the kernel of $Q_\infty^{1/2}$, which is the orthogonal subspace to $im\, Q_\infty^{1/2}$,

it follows that $|S_0(r)^*k|^2 \le \gamma|k|^2$ for every $k \in H$, which proves that $\|S_0(r)\|^2 \le \gamma < 1$. □

Replacing A with $A - \alpha I$ in the definition of $S_0(t)$, we get a different family of operators that we will denote $S_0^{(\alpha)}(t)$, namely,

$$S_0^{(\alpha)}(t) = e^{-\alpha t}(Q_\infty^{(\alpha)})^{-1/2} e^{tA}(Q_\infty^{(\alpha)})^{1/2}, \qquad t \ge 0,\ \alpha \ge 0. \tag{4.6}$$

Note that $S_0^{(0)}(t) = S_0(t)$. As an immediate consequence of the properties enjoyed by $S_0(t)$, we obtain the following result.

COROLLARY 4.5. *Assume Hypothesis* 3.1 *and let* $\alpha \ge 0$.

(i) *If there exists* $r > 0$ *such that* $\|S_0^{(\alpha)}(r)\| < 1$, *then for every* $\beta > \alpha$ *there exists* $c > 0$ *such that* $cQ_\infty^{(\alpha)} \le Q_\infty^{(\beta)}$.

(ii) *If there exist* $c > 0$ *and* $\beta > \alpha$ *such that* $cQ_\infty^{(\alpha)} \le Q_\infty^{(\beta)}$, *then there exists* $r > 0$ *such that* $\|S_0^{(\alpha)}(r)\| < 1$.

(iii) *If there exist* $\alpha \ge 0$ *and* $r > 0$ *such that* $\|S_0^{(\alpha)}(r)\| < 1$, *then for every* $\beta > \alpha$ *there exists* $s > 0$ *such that* $\|S_0^{(\beta)}(s)\| < 1$.

Proof. To prove points (i) and (ii) it suffices to apply Proposition 4.4, replacing A and α with $A - \alpha I$ and $\beta - \alpha$, respectively.

To prove point (iii) take $\beta_1 > \beta$. Then by point (i) (with β_1 instead of β) there exists $c > 0$ such that $cQ_\infty^{(\alpha)} \le Q_\infty^{(\beta_1)}$. By point (ii) (with β instead of α) there exists $s > 0$ such that $\|S_0^{(\beta)}(s)\| < 1$. □

LEMMA 4.6. *Assume Hypothesis* 3.1 *and suppose that* $\|S_0^{(\alpha)}(r)\| < 1$ *for some* $\alpha > 0$ *and* $r > 0$. *Then for all* $\gamma \in (0, \alpha)$ *sufficiently close to* α *we have* $\|S_0^{(\gamma)}(r)\| < 1$.

Proof. We claim that if $\gamma \in (0, \alpha)$ is sufficiently close to α, then there exists $c > 0$ such that

$$Q_\infty^{(\gamma)} \le c\, Q_\infty^{(\alpha)}. \tag{4.7}$$

Assume the claim for a moment. Since the opposite inequality $Q_\infty^{(\gamma)} \ge Q_\infty^{(\alpha)}$ is obvious, we conclude by Lemma 2.2 that $im\ (Q_\infty^{(\alpha)})^{1/2} = im\ (Q_\infty^{(\gamma)})^{1/2}$. Since we assume $\|S_0^{(\alpha)}(r)\| < 1$, we can apply Proposition 4.3 (replacing A with $A - \alpha I$) and conclude that $im\ (Q_\infty^{(\alpha)})^{1/2} = im\ (Q_r^{(\alpha)})^{1/2}$. Since the latter space is clearly identical to $im\ (Q_r^{(\gamma)})^{1/2}$, we also have $im\ (Q_r^{(\gamma)})^{1/2} = im\ (Q_\infty^{(\gamma)})^{1/2}$, and applying Proposition 4.3 again (replacing A with $A - \gamma I$) we conclude that $\|S_0^{(\gamma)}(r)\| < 1$, and the lemma is proved.

It remains to prove (4.7). For $0 \le \gamma < \alpha$ and $h \in H$,

$$\langle e^{tA} Q_\infty^{(\alpha)} e^{tA^*} h, h\rangle = \int_0^\infty |B^* e^{(t+s)A^*} h|^2 e^{-2\alpha s} ds = e^{2\alpha t} \int_t^\infty |B^* e^{sA^*} h|^2 e^{-2\alpha s} ds.$$

Integrating by parts, we have, for $T > 0$,

$$\begin{aligned}
&\int_0^T e^{-2\gamma t} \langle e^{tA} Q_\infty^{(\alpha)} e^{tA^*} h, h\rangle\, dt \\
&\quad = \int_0^T e^{2(\alpha-\gamma)t} \int_t^\infty |B^* e^{sA^*} h|^2 e^{-2\alpha s}\, ds\, dt \\
&\quad = \frac{e^{2(\alpha-\gamma)T}}{2(\alpha-\gamma)} \int_T^\infty |B^* e^{sA^*} h|^2 e^{-2\alpha s} ds - \frac{1}{2(\alpha-\gamma)} \langle Q_\infty^{(\alpha)} h, h\rangle \\
&\qquad\qquad + \frac{1}{2(\alpha-\gamma)} \int_0^T e^{-2\gamma t} |B^* e^{tA^*} h|^2 dt.
\end{aligned}$$

Since

$$e^{2(\alpha-\gamma)T}\int_T^\infty |B^*e^{sA^*}h|^2e^{-2\alpha s}ds \le \int_T^\infty |B^*e^{sA^*}h|^2e^{-2\gamma s}ds \to 0$$

as $T\to\infty$, we arrive at the identity

$$2(\alpha-\gamma)\int_0^\infty e^{-2\gamma t}\langle e^{tA}Q_\infty^{(\alpha)}e^{tA^*}h,h\rangle\,dt = \langle Q_\infty^{(\gamma)}h,h\rangle - \langle Q_\infty^{(\alpha)}h,h\rangle.$$

We note that $\langle e^{tA}Q_\infty^{(\alpha)}e^{tA^*}h,h\rangle = e^{2\alpha t}\langle (Q_\infty^{(\alpha)})^{1/2}S_0^{(\alpha)}(t)S_0^{(\alpha)}(t)^*(Q_\infty^{(\alpha)})^{1/2}h,h\rangle$, so if we define

$$Rh = 2(\alpha-\gamma)\int_0^\infty e^{2(\alpha-\gamma)t}S_0^{(\alpha)}(t)S_0^{(\alpha)}(t)^*h\,dt, \qquad h\in H,$$

and we assume for a moment that R is a well-defined bounded linear operator, we conclude that

$$\langle (Q_\infty^{(\alpha)})^{1/2}R(Q_\infty^{(\alpha)})^{1/2}h,h\rangle = \langle Q_\infty^{(\gamma)}h,h\rangle - \langle Q_\infty^{(\alpha)}h,h\rangle,$$

and consequently $Q_\infty^{(\gamma)} \le (1+\|R\|)Q_\infty^{(\alpha)}$, which proves (4.7). To show that R is well defined, we first note that the family $\{S_0^{(\alpha)}(t),\ t\ge 0\}$ is a contraction semigroup, and since we assume that $\|S_0^{(\alpha)}(r)\|<1$ for some $r>0$, it follows easily that there exist $M,\omega>0$ such that $\|S_0^{(\alpha)}(t)\| \le M\,e^{-\omega t}$ for every $t>0$. If $\alpha-\gamma<\omega$, then the integral defining R is convergent (as a Bochner integral). This finishes the proof. □

4.2. Proof of Theorem 4.1. During the proof we repeatedly use the following properties proved above: for $0\le\alpha<\beta$ and $r>0$

$$\mathcal{K}_\infty^\alpha = im\ (Q_\infty^{(\alpha)})^{1/2}, \qquad \mathcal{K}_r = im\ Q_r^{1/2}, \qquad \mathcal{K}_\infty^\alpha \supset \mathcal{K}_\infty^\beta \supset \mathcal{K}_r. \tag{4.8}$$

We consider two mutually exclusive cases (i) and (ii).

Case (i). Suppose that we have $\|S_0(r)\|<1$ for some $r>0$.

By Proposition 4.4 (i) and Lemma 2.2 we have $im\ Q_\infty^{1/2} \subset im\ (Q_\infty^{(\alpha)})^{1/2}$ for all $\alpha\ge 0$ or, equivalently, $\mathcal{K}_\infty \subset \mathcal{K}_\infty^\alpha$ so that in fact $\mathcal{K}_\infty = \mathcal{K}_\infty^\alpha$ for all $\alpha\ge 0$. Applying Proposition 4.3, we also have $\mathcal{K}_\infty = im\ Q_\infty^{1/2} = im\ Q_r^{1/2} = \mathcal{K}_r$.

Case (ii). Suppose $\|S_0(r)\|=1$ for every $r>0$.

We define

$$J = \{\alpha\ge 0\ :\ \|S_0^{(\alpha)}(r)\|=1 \text{ for every } r>0\}, \qquad \alpha_0 = \sup J.$$

Note that the set J contains at least $\alpha=0$, so α_0 is well defined and $0\le\alpha_0\le\infty$. By Corollary 4.5 (iii) only the following cases can occur:

(a) $\alpha_0=0$, $J=\{0\}$;
(b) $0<\alpha_0<\infty$, $J=[0,\alpha_0]$;
(c) $\alpha_0=\infty$, $J=[0,\infty)$.

Note that the case $0<\alpha_0<\infty$, $J=[0,\alpha_0)$ is impossible by Lemma 4.6.

Suppose $0\le\gamma_1<\gamma_2<\alpha_0\le\infty$. Assume by contradiction that $\mathcal{K}_\infty^{\gamma_1} = \mathcal{K}_\infty^{\gamma_2}$ (respectively, that $\alpha_0<\infty$ and $\mathcal{K}_\infty^{\gamma_2} = \mathcal{K}_\infty^{\alpha_0}$). Then by (4.8) and Lemma 2.2 we have $cQ_\infty^{(\gamma_1)} \le Q_\infty^{(\gamma_2)}$ (respectively, $cQ_\infty^{(\gamma_2)} \le Q_\infty^{(\alpha_0)}$) for some $c>0$, and Corollary 4.5 (ii)

implies that there exists $r > 0$ such that $\|S_0^{(\gamma_1)}(r)\| < 1$ (respectively, $\|S_0^{(\gamma_2)}(r)\| < 1$), which contradicts the definition of α_0. Next note that the equality $\mathcal{K}_\infty^{\gamma_2} = \mathcal{K}_r$ (respectively, $\alpha_0 < \infty$ and $\mathcal{K}_\infty^{\alpha_0} = \mathcal{K}_r$) cannot hold for any $r > 0$ since by Proposition 4.3, applied to $A - \gamma_2 I$ instead of A (respectively, applied to $A - \alpha_0 I$ instead of A), it would imply that $\|S_0^{(\gamma_2)}(r)\| < 1$ (respectively, $\|S_0^{(\alpha_0)}(r)\| < 1$), which is impossible.

Now suppose that $0 \le \alpha_0 < \beta_1 < \beta_2 < \infty$. Assume by contradiction that $\mathcal{K}_\infty^{\alpha_0} = \mathcal{K}_\infty^{\beta_1}$. Then by (4.8) and Lemma 2.2 we have $cQ_\infty^{(\alpha_0)} \le Q_\infty^{(\beta_1)}$, and Corollary 4.5 (ii) implies that there exists $r > 0$ such that $\|S_0^{(\alpha_0)}(r)\| < 1$, which is impossible. Next note that by the definition of α_0 there exists $r > 0$ such that $\|S_0^{(\beta_1)}(r)\| < 1$. By Corollary 4.5 (i) and Lemma 2.2 we have $im\ (Q_\infty^{(\beta_1)})^{1/2} \subset im\ (Q_\infty^{(\beta_2)})^{1/2}$ or, equivalently, $\mathcal{K}_\infty^{\beta_1} \subset \mathcal{K}_\infty^{\beta_2}$ so that in fact $\mathcal{K}_\infty^{\beta_1} = \mathcal{K}_\infty^{\beta_2}$. Finally, applying Proposition 4.3 (with $A - \beta_1 I$ instead of A), we also have $\mathcal{K}_\infty^{\beta_1} = im\ (Q_\infty^{(\beta_1)})^{1/2} = im\ Q_r^{1/2} = \mathcal{K}_r$.

Theorem 4.1 is now completely proved. □

This proof also describes a criterion to decide which case in Theorem 4.1 occurs, as well as the value of α_0.

COROLLARY 4.7. *Assume Hypothesis* 3.1. *Let* $Q_\infty^{(\alpha)}$ *and* $S_0^{(\alpha)}$ *be defined by* (4.2) *and* (4.6), *respectively. Case* (ii) *in Theorem* 4.1 *occurs if and only if the set*

$$J = \{\alpha \ge 0 \ :\ \|S_0^{(\alpha)}(r)\| = 1 \text{ for every } r > 0\}$$

is nonempty, and then $\alpha_0 = \sup J \in [0, \infty]$.

4.3. Approximately reachable states. If the concept of reachability used so far is replaced by approximate reachability, then the behavior of the perturbed system (4.1) is completely different. This is a well-known fact, but we prefer to report a direct proof in this short section since it is often used in a rather implicit way and it is not easy to find a reference (see, however, Chapter 9 of [19]).

First, let us consider the control system (3.2) and define $\mathcal{H}_r$, the space of approximately reachable states from zero in time r, as the set of all elements $k \in H$ such that for all $\epsilon > 0$ there exists a control $u \in L^2(T - r, T; U)$ such that $|y(T) - k| < \epsilon$, where y denotes the corresponding trajectory of system (3.2) with $h = 0$.

In an analogous way we define the space $\mathcal{H}_\infty$ as the space of approximately reachable states over the unbounded time interval $(-\infty, T]$ for system (3.3), corresponding to controls $u \in L^2(-\infty, T; U)$.

For the perturbed system

$$y'_\alpha(t) = (A - \alpha I)y_\alpha(t) + Bu(t), \tag{4.9}$$

with $\alpha \ge 0$, the spaces of approximately reachable states will be denoted by $\mathcal{H}_r^\alpha$ and $\mathcal{H}_\infty^\alpha$, respectively, for the case of a bounded time interval and an unbounded one. Clearly, $\mathcal{H}_r^\alpha = \mathcal{H}_r$.

We claim that $\mathcal{H}_\infty^\alpha = \cup_r \mathcal{H}_r$ for all α, so, in particular, $\mathcal{H}_\infty^\alpha$ is independent of α.

To prove the claim, let us take an element $k \in \mathcal{H}_\infty^\alpha$; we want to prove that there exists a suitable r such that $k \in \mathcal{H}_r^\alpha = \mathcal{H}_r$. In fact, by definition of the trajectory of a control system (compare with formula (3.4)) and by assumption (3.1), we have that for all $\epsilon > 0$ there exists $r > 0$ so large that $|y_\alpha(T) - \tilde{y}_\alpha(T)| < \epsilon$, where $\tilde{y}_\alpha$ denotes the trajectory of the system (4.9), starting from zero at time $T - r$, driven by the control $\tilde{u} \in L^2(T - r, T; U)$ which coincides with u on $[T - r, T]$. By triangular inequality we conclude that $k \in \mathcal{H}_r^\alpha$, and the claim is proved.

5. Examples and remarks. The aim of this section is to show that all the situations in the statement of Theorem 4.1 may occur, namely, case (i) or case (ii) with $\alpha_0 = 0$ or $0 < \alpha_0 < \infty$ or $\alpha_0 = \infty$. The value of α_0 is difficult to compute in general, since it is defined in terms of the semigroup $S_0^{(\alpha)}$ (compare with Corollary 4.7) and not in terms of A and B. Nevertheless, in some interesting cases we do have explicit solutions to the problem. We also discuss the relevance of Theorem 4.1 to special classes of systems—for instance, the finite-dimensional systems or the null controllable ones.

5.1. Case (i) of Theorem 4.1.

5.1.1. The finite-dimensional case.

COROLLARY 5.1. *Assume that Hypothesis* 3.1 *holds and that* $\dim H < \infty$. *Then case* (i) *of Theorem* 4.1 *occurs and* $\mathcal{K}_\infty^\alpha = \mathcal{K}_t$ *for every* $t > 0$ *and* $\alpha \geq 0$.

Thus every state reachable in an unbounded time interval (no matter what the value of α is) can be reached in an arbitrarily small time $t > 0$.

Proof. We claim that

$$im\, Q_\infty^{1/2} = im\, Q_t^{1/2}, \qquad t > 0. \tag{5.1}$$

Since $im\, Q_\infty^{1/2} = \mathcal{K}_\infty$, case (i) of Theorem 4.1 occurs, and the reachability spaces $\mathcal{K}_\infty^\alpha$ coincide for all $\alpha \geq 0$ and in fact they coincide with $\mathcal{K}_t$ for every $t > 0$.

To prove the claim we note that if $\dim H < \infty$, then (5.1) is equivalent to $\ker Q_\infty^{1/2} = \ker Q_t^{1/2}$ (ker denotes of course the kernel of an operator). Clearly, $\ker Q_\infty^{1/2} \subset \ker Q_t^{1/2}$. Conversely, if $Q_t^{1/2} h = 0$ for some $h \in H$, then $Q_t h = 0$ and $Q^{1/2} e^{sA} h = 0$ for every $s \in [0, t]$. By analyticity, $Q^{1/2} e^{sA} h = 0$ for every $s \geq 0$. This implies $Q_\infty h = 0$ and consequently $Q_\infty^{1/2} h = 0$. □

5.1.2. Exactly null controllable systems.

COROLLARY 5.2. *Assume that Hypothesis* 3.1 *holds and that there exists* $r > 0$ *such that*

$$im\, e^{rA} \subset im\, Q_r^{1/2}. \tag{5.2}$$

Then case (i) *of Theorem* 4.1 *occurs and in fact* $\mathcal{K}_\infty^\alpha = \mathcal{K}_r$ *for every* $\alpha \geq 0$.

It is well known that (5.2) is equivalent to the exact null controllability property in time r, defined as follows: for every $h \in H$ there exists a control $u \in L^2([T - r, T]; U)$ such that the trajectory of the control system

$$y'(t) = Ay(t) + Bu(t), \quad t \in [T - r, T], \qquad\qquad y(T - r) = h,$$

satisfies $y(T) = 0$ (see, e.g., [7], [21]). The pair (A, B) is then called a null controllable pair (in time r). It is also well known that this property holds if $B = I$ (for every $r > 0$).

Proof. We claim that (5.2) implies

$$im\, Q_\infty^{1/2} = im\, Q_r^{1/2}. \tag{5.3}$$

Then it follows from Proposition 4.3 that $\|S_0(r)\| < 1$ and by Corollary 4.7 we conclude that case (i) in Theorem 4.1 occurs.

The claim is proved in [8, Theorem 11.13], but we nevertheless include the following simpler proof. First note that the inequality $Q_r \leq Q_\infty$ implies that $im\, Q_r^{1/2} \subset$

im $Q_\infty^{1/2}$ by Lemma 2.2. Next note that the inclusion (5.2) implies that the operator $\Gamma_r := Q_r^{-1/2}e^{rA}$ is everywhere defined, and since it is closed, it is also bounded, by the closed graph theorem. From the definition of Q_∞ it is easy to obtain the identity $e^{rA}Q_\infty e^{rA^*} + Q_r = Q_\infty$, and it follows that $Q_r^{1/2}(\Gamma_r Q_\infty \Gamma_r^* + I)Q_r^{1/2} = Q_\infty$, which implies $|Q_\infty^{1/2}x|^2 \le (1 + \|\Gamma_r Q_\infty \Gamma_r^*\|)|Q_r^{1/2}x|^2$, $x \in H$, and so, by Lemma 2.2, *im* $Q_\infty^{1/2} \subset$ *im* $Q_r^{1/2}$, and (5.3) is proved. □

5.1.3. A special case.

COROLLARY 5.3. *Suppose that Hypothesis* 3.1 *holds and that, setting* $Q = BB^*$, *we have*

$$\text{(5.4)} \qquad \textit{im}\ e^{tA}Q^{1/2} \subset \textit{im}\ Q^{1/2} \qquad \textit{and} \qquad \|Q^{-1/2}e^{tA}Q^{1/2}\| \le Me^{-\beta t}, \quad t \ge 0,$$

for some constants $\beta > 0$, $M > 0$. *Then case* (i) *of Theorem* 4.1 *occurs and* $\mathcal{K}_\infty^\alpha = \mathcal{K}_r$ *for every* $\alpha \ge 0$ *and* $r > 0$.

We remark that *im* $B =$ *im* $Q^{1/2}$ by Lemma 2.2. Moreover, the inclusion in (5.4) implies that the linear operators $Q^{-1/2}e^{tA}Q^{1/2}$ are everywhere defined and therefore, being obviously closed, they are also continuous.

We note that all the assumptions of the corollary hold true if B is a bounded linear operator from U to H and A is the infinitesimal generator of an exponentially stable, strongly continuous semigroup of operators that commute with $Q = BB^*$. Thus there are many control systems satisfying these assumptions.

Proof. We define $\widehat{S}(t) = Q^{-1/2}e^{tA}Q^{1/2}$ for $t > 0$, $\widehat{S}(0) = I$. Clearly, $\widehat{S}$ is a semigroup of bounded linear operators on H, satisfying $\|\widehat{S}(t)\| \le Me^{-\beta t}$, $t \ge 0$. We note that for $x \in H$, $y \in$ *im* $Q^{1/2}$,

$$\text{(5.5)} \qquad \langle \widehat{S}(t)x, y\rangle = \langle e^{tA}Q^{1/2}x, Q^{-1/2}y\rangle \to \langle x, y\rangle, \qquad \text{as } t \to 0.$$

Since $\widehat{S}$ is bounded in the operator norm, it follows that (5.5) holds for every $x \in H$ and $y \in \overline{\textit{im}\ Q^{1/2}}$ (the closure of *im* $Q^{1/2}$ in H). Since $\widehat{S}(t)x = Q^{-1/2}e^{tA}Q^{1/2}x$ is orthogonal to $\ker Q^{1/2} = \overline{\textit{im}\ Q^{1/2}}$, (5.5) holds for all $x, y \in H$. Thus, for every $x \in H$, $\widehat{S}(t)x \to x$ weakly in H; it is well known that this implies that $\widehat{S}$ is a strongly continuous semigroup.

Let $\widehat{A}$ denote the infinitesimal generator of $\widehat{S}$. We consider the pair $(\widehat{A}, I)$, and we define the corresponding controllability operators

$$\widehat{Q}_\infty x = \int_0^\infty \widehat{S}(t)\widehat{S}(t)^* x\, dt, \quad \widehat{Q}_r x = \int_0^r \widehat{S}(t)\widehat{S}(t)^* x\, dt, \qquad x \in H,\ r > 0.$$

Since the pair $(\widehat{A}, I)$ is null controllable in time r for every $r > 0$, by the results of the previous paragraph we conclude that there exists a constant $C_r > 0$ such that $|\widehat{Q}_\infty^{1/2}x|^2 \le C_r|\widehat{Q}_r^{1/2}x|^2$. Since $Q^{1/2}\widehat{S}(t) = e^{tA}Q^{1/2}$, it follows that

$$Q^{1/2}\widehat{Q}_\infty Q^{1/2}x = \int_0^\infty Q^{1/2}\widehat{S}(t)\widehat{S}(t)^*Q^{1/2}x\, dt = \int_0^\infty e^{tA}Qe^{tA^*}x\, dt = Q_\infty x, \qquad x \in H,$$

and, similarly, $Q^{1/2}\widehat{Q}_r Q^{1/2} = Q_r$. Therefore,

$$|Q_\infty^{1/2}x|^2 = |\widehat{Q}_\infty^{1/2}Q^{1/2}x|^2 \le C_r|\widehat{Q}_r^{1/2}Q^{1/2}x|^2 = C_r|Q_r^{1/2}x|^2, \qquad x \in H,$$

which implies *im* $Q_\infty^{1/2} \subset$ *im* $Q_r^{1/2}$. Since the opposite inclusion is obvious, we have *im* $Q_\infty^{1/2} =$ *im* $Q_r^{1/2}$ for $r > 0$ and the result follows. □

5.1.4. Exactly reachable systems.

COROLLARY 5.4. *Suppose that Hypothesis* 3.1 *holds and that A is exponentially stable. If $\mathcal{K}_\infty = H$, then case* (i) *of Theorem* 4.1 *occurs and consequently $\mathcal{K}_r = H$ for $r > 0$ sufficiently large.*

Systems satifying the condition $\mathcal{K}_\infty = H$ may be called *exactly reachable on* $(-\infty, T]$. Thus, if A is exponentially stable, exact reachability on $(-\infty, T]$ implies exact reachability on a bounded interval $[T - r, T]$.

Proof. By a standard duality argument one can check that the equality $\mathcal{K}_\infty = H$ is equivalent to the following condition: there exists $\kappa > 0$ such that

$$\int_0^\infty |B^* e^{tA^*} x|^2 \, dt \geq \kappa |x|^2, \qquad x \in H. \tag{5.6}$$

Condition (5.6) is called *exact observability* for the pair (A^*, B^*). Since A is exponentially stable, it follows from Proposition 2.8 in [18] that (5.6) holds if and only if there exist $r > 0$ and $\kappa_r > 0$ such that

$$\int_0^r |B^* e^{tA^*} x|^2 \, dt \geq \kappa_r |x|^2, \qquad x \in H,$$

and this is equivalent to the equality $\mathcal{K}_r = H$, again by duality. □

5.2. Case (ii) of Theorem 4.1 with $\alpha_0 = 0$. The example in this section was invented by Gołdys for a different purpose [14]. Let $H = U$ be a Hilbert space and $\{h_k,\ k \geq 1\}$ an orthonormal basis of H. Define the operators A and B setting

$$Ah_k = -\frac{1}{k}\, h_k, \qquad Bh_k = \frac{1}{k^{3/2}}\, h_k.$$

Note that A and B are commuting bounded self-adjoint operators, and A is nonpositive, but, in contrast to section 5.1.3, A does not have bounded inverse. Hypothesis 3.1 is easy to verify. We have $S_0(t) = e^{tA}$ and $e^{tA} h_k = e^{-t/k} h_k$, $k \geq 1$, so that $\|S_0(t)\| = 1$ for every $t > 0$, whereas $\|S_0^{(\alpha)}(t)\| = e^{-\alpha t} \|S_0(t)\| < 1$ for every $t > 0$. Corollary 4.7 shows that in this example we have $\alpha_0 = 0$.

Remark 5.5. In this example the semigroup (e^{tA}) is not exponentially stable. In Remark 5.6 below we will give another example, where $\alpha_0 = 0$ and (e^{tA}) is exponentially stable.

5.3. Case (ii) of Theorem 4.1 with $0 < \alpha_0 < \infty$. We take $H = U = L^2(\mathbb{R})$. Let the operators e^{tA} be the shift operators

$$e^{tA} f(x) = f(x - t), \qquad t \geq 0,\ x \in \mathbb{R},$$

and let the operator B be multiplication by the function $e^{-|x|}$: $Bf(x) = e^{-|x|} f(x)$, $x \in \mathbb{R}$. Then one finds with simple calculations

$$e^{tA^*} f(x) = f(x + t), \qquad e^{tA} B B^* e^{tA^*} f(x) = e^{-2|x-t|} f(x), \qquad t \geq 0,\ x \in \mathbb{R},$$

so that $Q_\infty^{(\alpha)}$, $\alpha \geq 0$, is the multiplication operator by the function g_α:

$$Q_\infty^{(\alpha)} f(x) = g_\alpha(x) f(x), \qquad g_\alpha(x) = \int_0^\infty e^{-2\alpha t} e^{-2|x-t|} \, dt, \qquad x \in \mathbb{R}.$$

It is immediate to verify (3.1), and so Hypothesis 3.1 holds. Elementary computations show that for $\alpha \neq 1$

$$g_\alpha(x) = \begin{cases} \dfrac{e^{-2x}}{2(\alpha-1)}\left(1 - \dfrac{2}{\alpha+1}\, e^{-2(\alpha-1)x}\right) & \text{for} \quad x > 0, \\ \dfrac{e^{2x}}{2(\alpha+1)} & \text{for} \quad x \leq 0, \end{cases}$$

whereas

$$g_1(x) = \begin{cases} e^{-2x}\left(x + \dfrac{1}{4}\right) & \text{for} \quad x > 0, \\ \dfrac{e^{2x}}{4} & \text{for} \quad x \leq 0. \end{cases}$$

For $0 \leq \alpha < \beta$, the inclusion $\mathcal{K}_\infty^\alpha = im\ (Q_\infty^{(\alpha)})^{1/2} \supset im\ (Q_\infty^{(\beta)})^{1/2} = \mathcal{K}_\infty^\beta$ always holds, so we have equality if and only if $im\ (Q_\infty^{(\alpha)})^{1/2} \subset im\ (Q_\infty^{(\beta)})^{1/2}$. Since, clearly, $(Q_\infty^{(\alpha)})^{1/2}$ is the multiplication operator by the function $g_\alpha^{1/2}$, equality holds if and only if $\sup_{x\in\mathbb{R}} g_\alpha(x)/g_\beta(x) < \infty$. Taking into account the previous formulae, one concludes that this holds if and only if $1 < \alpha < \beta$. Therefore, in this example the spaces $\mathcal{K}_\infty^\alpha$ are all equal for $\alpha > 1$, whereas they are all distinct for $0 \leq \alpha \leq 1$ (and $\mathcal{K}_\infty^1 \supsetneq \mathcal{K}_\infty^\alpha$ if $\alpha > 1$).

The number α_0 in the statement of Theorem 4.1 is equal to 1.

Remark 5.6. Let us change the definition of the operator A by subtracting the identity operator; namely, we define the semigroup (e^{tA}) setting

$$e^{tA} f(x) = e^{-t}\, f(x-t), \qquad t \geq 0,\ x \in \mathbb{R}.$$

Then (e^{tA}) clearly satisfies $\|e^{tA}\| \leq e^{-t}$ and so it is exponentially stable. In this case the value of α_0 is changed to $\alpha_0 = 0$.

5.4. Case (ii) of Theorem 4.1 with $\alpha_0 = \infty$. We start with some preliminary considerations. Inspection of the statement of Theorem 4.1 shows that if case (i) occurs or if case (ii) occurs with $\alpha_0 < \infty$, then there exist $\alpha > 0$ and $r > 0$ such that $\mathcal{K}_\infty^\alpha = \mathcal{K}_r$. Since, as already noted, $\mathcal{K}_r \subset \mathcal{K}_s \subset \mathcal{K}_\infty^\alpha$ for $r < s$, it follows that in these cases the spaces $\mathcal{K}_t$ coincide for all values of t large enough. Therefore, in order to find a situation where $\alpha_0 = \infty$, it suffices to construct an example where $\mathcal{K}_t$ are all distinct for $t > 0$.

The example that follows was communicated to us by Zabczyk.

We take $H = L^2([0,\infty))$ and let the operators e^{tA} be the right shift operators

$$e^{tA} f(x) = \begin{cases} f(x-t), & t \geq 0,\ x \geq t, \\ 0, & t > 0,\ x < t. \end{cases}$$

Next we denote by b the characteristic function of the interval $[0,1]$ (note that $b \in H$); we take $U = \mathbb{R}$ and define the operator B as the rank one operator: $Bv = bv$, $v \in \mathbb{R}$. Since, for every $t > 0$,

$$\mathcal{K}_t = im\ \mathcal{L}_t = \left\{ \int_0^t e^{(t-s)A} b\, u(s)\, ds \ :\ u \in L^2([0,t]) \right\},$$

it can be easily verified that the closure of $\mathcal{K}_t$ in H, denoted $\overline{\mathcal{K}_t}$, is the closure of the linear span of

$$\{e^{rA} b \ :\ r \in [0,t]\}.$$

It follows that elements of $\overline{\mathcal{K}_t}$ have supports contained in the interval $[0, 1+t]$ and, moreover, $\overline{\mathcal{K}_t}$ contains functions which are nonzero in a left neighborhood of t. Therefore, the spaces $\overline{\mathcal{K}_t}$ are distinct for different values of t, and so the spaces $\mathcal{K}_t$, $t > 0$, are also all distinct.

6. Applications to the Ornstein–Uhlenbeck process. As explained in the introduction, one of the motivations for studying the reachability spaces $\mathcal{K}_\infty$ introduced above is their probabilistic interpretation. This is the subject of the present section.

Let us consider the following stochastic equation:

$$\begin{cases} dX(t) = AX(t)\,dt + B\,dW(t), & t \geq 0, \\ X(0) = X_0. \end{cases} \tag{6.1}$$

We assume that H and U are real separable Hilbert spaces, A is the generator of a strongly continuous semigroup $\{e^{tA},\ t \geq 0\}$ of bounded linear operators in H, and B is a bounded linear operator from U to H. We assume that we are also given a probability space $(\Omega, \mathcal{F}, \mathbb{P})$, endowed with a filtration $\{\mathcal{F}_t,\ t \geq 0\}$ satisfying the usual conditions, and a cylindrical $(\mathcal{F}_t)$-Wiener process $\{W(t)\ t \geq 0\}$ defined on Ω with values in U; see, e.g., [8]. X_0 is an $\mathcal{F}_0$-measurable random variable with values in H. We also assume that the gramian operators

$$Q_t h = \int_0^t e^{sA} B B^* e^{sA^*} h\,ds, \qquad h \in H,\ t > 0,$$

introduced above, have finite trace.

Under these assumptions, the solution of (6.1) is defined as the stochastic process with values in H:

$$X(t) = e^{tA} X_0 + \int_0^t e^{(t-s)A} B\,dW(s), \qquad t \geq 0. \tag{6.2}$$

The integral occurring in (6.2) is the Itô stochastic integral and, for every t, it defines a random variable with values in H because of the finite trace condition Trace $Q_t < \infty$. Moreover, if X_0 is gaussian, then the process X is also gaussian. It is called the (nonsymmetric) Ornstein–Uhlenbeck process. For a detailed exposition of these facts, we refer to [8].

A basic problem is to investigate properties of invariant measures for the process X, i.e., Borel probability measures ν on H such that, if X_0 has distribution ν, then also $X(t)$ has distribution ν for every t. Invariant measures are known to exist if and only if

$$\sup_{t>0} \text{Trace } Q_t < \infty. \tag{6.3}$$

In this case, one invariant measure is the gaussian measure μ on H having zero mean and covariance equal to the extended gramian operator Q_∞ introduced above:

$$Q_\infty h = \int_0^\infty e^{sA} B B^* e^{sA^*} h\,ds, \qquad h \in H.$$

Under some additional assumptions, for instance if A is exponentially stable, μ is the unique invariant measure. For the proof of these facts, we still refer the reader to [8].

Remark 6.1. If (6.3) holds, then it is easy to show that condition (3.1) also holds (in particular, Hypothesis 3.1 is satisfied) and the operator Q_∞ has finite trace.

Associated to the centered gaussian measure μ is the so-called Cameron–Martin space (see, e.g., [1]), which coincides with the image of $Q_\infty^{1/2}$ and hence with the space of reachable states $\mathcal{K}_\infty$ introduced in the previous sections.

We address the problem to study the behavior of the Cameron–Martin space under perturbation of the Ornstein–Uhlenbeck process. Thus, for $\alpha \geq 0$, we consider the processes X_α, solution of

$$\begin{cases} dX_\alpha(t) = (A - \alpha I)X_\alpha(t)\, dt + B\, dW(t), & t \geq 0, \\ X_\alpha(0) = X_0, \end{cases} \tag{6.4}$$

and we consider the centered gaussian measures μ_α with covariance operator $Q_\infty^{(\alpha)}$ defined in (4.2). It follows from the previous discussion that μ_α is an invariant measure for X_α (and it is unique if $A-\alpha$ is exponentially stable) and that the Cameron–Martin space of μ_α coincides with $\mathcal{K}_\infty^\alpha$.

The following proposition is the main result of this section. It is a direct consequence of Theorem 4.1.

PROPOSITION 6.2. *Assume Hypothesis* 3.1 *and assume* (6.3). *Let* μ_α, $\alpha \geq 0$, *be the centered gaussian invariant measures introduced above, and let* $\mathcal{K}_\infty^\alpha$ *be their Cameron–Martin spaces. Then all the conclusions of Theorem* 4.1 *hold true.*

Remark 6.3. The occurrence of the various possibilities described in Theorem 4.1 depends on the inequality $\|S_0^{(\alpha)}(t)\| < 1$ for various values of $\alpha \geq 0$ and $t > 0$ or the equivalent one $im\ (Q_\infty^{(\alpha)})^{1/2} = im\ Q_t^{1/2}$ (compare with Proposition 4.3). These conditions play an important role in connection with various regularity properties of the transition semigroup of the Markov process X_α.

For instance, assume that Hypothesis 3.1 and (6.3) are satisfied, take $\alpha = 0$, and assume that $\ker Q_\infty = \{0\}$. (This simplifies some of the statements.) The transition semigroup of the Ornstein–Uhlenbeck process, denoted $\{R_t,\ t \geq 0\}$, can be considered as a strongly continuous contraction semigroup on each space $L^p(H,\mu)$, $p \in [1,\infty)$ (the space of Borel measurable functions $\phi : H \to \mathbb{R}$ such that $\int_H |\phi(x)|^p \mu(dx) < \infty$, endowed with its usual norm). It is proved in [3, Theorem 2] that the stronger property

$$\begin{aligned} \phi \in L^p(H,\mu),\ p \in (1,\infty) \implies & R_t\phi \in L^q(H,\mu) \text{ and} \\ & \|R_t\phi\|_{L^q(H,\mu)} \leq \|\phi\|_{L^p(H,\mu)} \end{aligned} \tag{6.5}$$

for some $q > p$ holds if and only if $im\ Q_\infty^{1/2} = im\ Q_t^{1/2}$. (The value of q depends on t and p.) Property (6.5) is called hypercontractivity (at time $t > 0$). Thus, by Proposition 4.3 and Corollaries 4.5 and 4.7, hypercontractivity holds at some $t > 0$ if and only if case (i) of Theorem 4.1 occurs.

Similar considerations relate the inequalities $\|S_0^{(\alpha)}(t)\| < 1$ (or the equalities $im\ (Q_\infty^{(\alpha)})^{1/2} = im\ Q_t^{1/2}$) to various regularity properties of the transition semigroup R, such as compactness, differentiability, and smoothing properties in appropriate function spaces. For further details, we refer the reader to [3, 4, 5, 6, 11, 13, 14].

Acknowledgments. We wish to thank Professors Luciano Pandolfi, Roberto Triggiani, and Jerzy Zabczyk for useful discussions. We also thank the anonymous referees for indicating improvements in section 5.

SINGULAR PERTURBATIONS IN INFINITE-DIMENSIONAL CONTROL SYSTEMS*

T. D. DONCHEV† AND A. L. DONTCHEV‡

Abstract. In this paper, we consider a singularly perturbed control system involving differential inclusions in Banach spaces with slow and fast solutions. Using the averaging approach, we obtain sufficient conditions for the Hausdorff convergence of the set of slow solutions in the supremum norm. We present applications of the theorem to prove convergence of the fast solutions in terms of invariant measures and convergence of equi-Lipschitz solutions.

Key words. control systems, differential inclusions, singular perturbations, time scales, order reduction, convergence of solutions

1. Introduction. In this paper, we consider a control system described by two differential inclusions—a "slow" one and a "fast" one, the latter indicated by a "small" parameter ε multiplying the derivative. The problem has the following form:

$$\begin{array}{ll} \dot{x}(t) \in F(x, y, u(t)), & x(0) = x^0, \\ \varepsilon \dot{y}(t) \in G(x, y, u(t)), & y(0) = y^0, \end{array} \tag{1}$$

where $F : E_1 \times E_2 \times U \rightrightarrows E_1$ and $G : E_1 \times E_2 \times U \rightrightarrows E_2$ are set-valued mappings, E_1 and E_2 are Banach spaces with uniformly convex duals E_1^* and E_2^*, respectively, U is a compact metric space, and $t \in I := [0, 1]$. Throughout the paper, we assume that for every $(x, y, u) \in E_1 \times E_2 \times U$, the values $F(x, y, u)$ and $G(x, y, u)$ are nonempty, convex, compact subsets of E_1 and E_2, respectively, and that F and G are upper semicontinuous (USC) in $E_1 \times E_2 \times U$ and lower semicontinuous with respect to u in U for fixed $(x, y) \in E := E_1 \times E_2$. The parameter ε is a positive scalar which may become zero, thus changing the system to a differential-algebraic inclusion, a change justifying the name "singular perturbations." A *control* $u(\cdot)$ is defined as a Lebesgue measurable function with values $u(t) \in U$ for almost every (a.e.) $t \in T$. A *solution* of (1) is any absolutely continuous (AC) function $(x(\cdot), y(\cdot))$ for which there exists a control $u(\cdot)$ such that the relations (1) hold for a.e. $t \in I$. For a fixed $\varepsilon > 0$ we denote by $Z(\varepsilon)$ the set of all solutions to (1). The slow x-part of $Z(\varepsilon)$ is denoted by $X(\varepsilon)$, that is, $X(\varepsilon) = \{x \mid (x, y) \in Z(\varepsilon)\}$, and the fast y-part by $Y(\varepsilon)$. In this paper, we study the asymptotic behavior of the family of sets $X(\varepsilon)$ as $\varepsilon \to 0$.

If F and G are single-valued and U consists of a single point (there is no control) and also $E_1 = \mathbb{R}^n, E_2 = \mathbb{R}^m$ are real Euclidean spaces, (1) becomes a system of singularly perturbed differential equations. The grounds for the modern theory of such equations were already laid in the 1940s, centered around the question of the dependence of solutions on the parameter ε. The earliest publication on this subject seems to be due to Levinson [24]; it was apparently a predecessor of the work of

Tikhonov in [25], [26], [27], which evolved in a basic result, now known as Tikhonov's theorem. Assuming that F and G in (1) are continuous functions acting in Euclidean spaces and there is no control, Tikhonov's theorem can be roughly stated in the following way. For a fixed x and $\varepsilon > 0$, let $\varepsilon\dot{y} = G(x, y)$ have a unique solution $y_\varepsilon(x)$ which converges as $\varepsilon \to 0$ to the unique solution $y(x)$ of the algebraic equation $0 = G(x, y)$ obtained for $\varepsilon = 0$, and, moreover, let the solution of the *associate* equation $\dot{y} \in G(x, y)$ on $[0, \infty)$ be asymptotically stable uniformly in x. Then for any solution (x_0, y_0) of the differential-algebraic equation obtained from (1) for $\varepsilon = 0$, there is a solution $(x_\varepsilon, y_\varepsilon)$ of (1) for $\varepsilon > 0$ which converges to (x_0, y_0) uniformly in I for x and on $[\delta, 1]$ for y as $\varepsilon \to 0$, for any δ satisfying $1 > \delta > 0$. One should note that in the original work of Tikhonov, the uniform in x stability of the associate equation was not assumed; the necessity of such a condition and a complete version of Tikhonov's theorem was given by Hoppensteadt [19], [20].

It was first shown in [12] that a formal generalization of Tikhonov's theorem for differential inclusions, in particular for control systems, is false in the sense that the set of values of the solutions at a given "time" t (the reachable set at t) is not convergent, as $\varepsilon \to 0$, to the set of values of the reduced inclusion obtained for $\varepsilon = 0$. This is mainly caused by the possibility for "rapid" switchings of the control function $u(\cdot)$, with frequency which is proportional to the reciprocal to the value of the parameter ε. A variety of effects may occur when set-valued mappings are involved, to which different "Tikhonov-type" theorems correspond. Since the early 1980s, the literature on Tikhonov-type theorems for differential inclusions and control systems has grown rapidly. Major advances has been made by Artstein [1], Gaitsgory [15], [16], Grammel [17], [18], Donchev and Slavov [9], [10], and Veliov [28], [29]. In particular, Veliov [29] found a Tikhonov-type theorem for differential inclusions in finite dimensions from which the classical theorem of Tikhonov follows directly when the inclusion is an equation.

The present paper is, to the authors' knowledge, a first attempt to obtain a Tikhonov-type theorem for control systems described by differential inclusions in infinite-dimensional spaces. The passage from finite to infinite dimensions requires overcoming several not only technical difficulties, most of which are related to the lack of compactness in the state space. Here, we follow the *averaging approach* to singular perturbations which in finite dimensions has been developed by Gaitsgory [15], [16] and Grammel [17], [18]. Specifically, along with the system (1) we consider the associate system

$$\begin{aligned} &x = \text{const}, \\ &\dot{y}(\tau) \in G(x, y(\tau), u(\tau)) \text{ for } \tau > 0, \quad y(0) = y^0, \end{aligned} \tag{2}$$

and define

$$\hat{V}(x, S, y^0) = \operatorname{cl} \bigcup_{v(\cdot)} \left\{ \frac{1}{S} \int_0^S F(x, y(\tau), v(\tau))\, d\tau \mid y(\cdot) \in \tilde{Y}(x, S, y^0, v(\cdot)) \right\}.$$

Here the union is with respect to all controls $v(\cdot)$ defined on the interval $[0, S]$, that is, measurable functions on $[0, S]$ with $v(\tau) \in U$ for a.e. $\tau \in [0, S]$, and $\tilde{Y}(x, S, y^0, v(\cdot))$ is the set of all solutions $y(\cdot)$ of (2) on $[0, S]$ corresponding to the control $v(\cdot)$ and the initial condition y^0. In our main Theorem 1 stated below, we give conditions under which for every $x \in E_1$ the Hausdorff limit $\lim_{S\to\infty} \hat{V}(x, S, y^0)$ exists and is the same for every fixed $y^0 \in E_2$; that is, this limit depends on x only—we denote it by $V(x)$.

Moreover, the set of slow solutions $X(\varepsilon)$ of (1) has a Hausdorff limit for $\varepsilon \to 0$ in the supremum norm on I, and this limit, denoted X_0, coincides with the set of solutions of the differential inclusion

$$\dot{x}(t) \in V(x(t)), \quad x(0) = x^0. \tag{3}$$

Throughout the paper, $\|\cdot\|$ denotes any norm. Let $\mathcal{X}$ be a Banach space with uniformly convex dual $\mathcal{X}^*$. For $x \in \mathcal{X}, y \in \mathcal{X}^*$, $\langle y, x\rangle$ denotes the value of y at x, and the dual mapping is defined as $J(x) := \{y \in \mathcal{X}^* \mid \|y\| = \|x\| \text{ and } \langle y, x\rangle = \|x\|^2\}$. It is known that for the space $\mathcal{X}$ the dual mapping J is single-valued and uniformly continuous on bounded sets. The support function is defined as $\sigma(y, A) := \sup_{x\in A} \langle x, y\rangle$, and the Hausdorff distance between the sets A, B is denoted by $D_H(A, B)$. The closed hull of a set A is denoted by $\operatorname{cl} A$ and the convex closed hull by $\overline{\operatorname{co}}\, A$. Let Γ be a set-valued mapping acting between Banach spaces which is nonempty-, convex-, and compact-valued and continuous and bounded on bounded sets. For positive reals δ and N we define

$$\omega_\Gamma(\delta, N) = \sup\big\{ D_H(\Gamma(z_1), \Gamma(z_2)) \mid \ \|z_1 - z_2\| \le \delta, \max\{\|z_1\|, \|z_2\|\} \le N\big\}.$$

When it is clear from the context what N is, we write simply $\omega_\Gamma(\delta)$. If Γ is uniformly continuous on bounded sets, then ω_Γ is bounded and $\omega_\Gamma(\delta, N) \to 0$ as $\delta \to 0$. Our main result follows.

THEOREM 1. *Assume the following:*

(i) *There exist positive constants A, B, C, μ such that for all (x_1, y_1), $(x_2, y_2) \in E = E_1 \times E_2$, $u \in U$ the following inequalities hold:*

$$\sigma(J(x_1 - x_2), F(x_1, y_1, u)) - \sigma(J(x_1 - x_2), F(x_2, y_2, u)) \le A\|x_1 - x_2\|^2 + B\|y_1 - y_2\|^2;$$

$$\sigma(J(y_1 - y_2), G(x_1, y_1, u)) - \sigma(J(y_1 - y_2), G(x_2, y_2, u)) \le C\|x_1 - x_2\|^2 - \mu\|y_1 - y_2\|^2.$$

(ii) *For any positive reals m and r,*

$$\sup_{\|x\|\le r, u\in U} \int_0^\infty \omega_{F(x,\cdot,u)}(m \exp(-\mu\tau), r)\, d\tau < \infty,$$

where μ is the constant in the second condition in (i).

Then a mapping $V : E_1 \rightrightarrows E_1$ can be constructed as in (3) *such that, if $X(\varepsilon) = \big\{ x(\cdot) \mid (x(\cdot), y(\cdot))$ is a solution of* (1)$\big\}$ *and X_0 is the set of solutions of* (3)*, we have*

$$\lim_{\varepsilon\to 0} D_H(X(\varepsilon), X_0) = 0,$$

where the Hausdorff distance is defined with the supremum norm on I.

Remark 1. The conditions in (i) for F and G are specific forms of a general property called the *relaxed one-sided Lipschitz* (ROSL) condition. Let $\mathcal{X}$ be a Banach space. A set-valued mapping H from $\mathcal{X}$ into bounded subsets of $\mathcal{X}$ is said to be *one-sided Lipschitz* (OSL) when there exists a constant L such that for every $u, v \in \mathcal{X}$

$$\big\langle J(u - v), h_u - h_v\big\rangle \le L\|u - v\|^2 \text{ for every } h_u \in H(u) \text{ and every } h_v \in H(v).$$

The mapping H is said to be ROSL when there exists a constant L such that for every $u, v \in \mathcal{X}$,

$$\sigma(J(u - v), H(u)) - \sigma(J(u - v), H(v)) \le L\|u - v\|^2.$$

Note that in the assumption (i) the ROSL condition for G is with a negative constant with respect to y.

The OSL condition has been used for quite some time as a dissipative condition; see [22]. The ROSL condition was introduced by the first author in [4] under a different name. Examples and applications of this condition can be found in [6], [7], [8], [23]. In particular, the mapping $\tilde{x} \mapsto \overline{\text{co}}\, f(\tilde{x}, U)$, where $f(\tilde{x}, U) = \bigcup_{u \in U} f(\tilde{x}, u)$, is ROSL with a constant L when $f(\cdot, u)$ is ROSL (e.g., Lipschitz continuous) with a constant L for every $u \in U$.

Remark 2. The mapping ω_Γ is a modulus of continuity of the set-valued mapping Γ. The condition (ii) holds, for example, when $F(x, \cdot, u)$ is hölderian; that is, there exist constants $\alpha \in (0, 1)$ and $\beta > 0$ such that $D_H(F(x, y, u), F(x, z, u)) \leq \beta(\|y - z\|^\alpha + \|y - z\|^{1+\alpha})$, as pointed out in [10].

When F and G are single-valued and Lipschitz continuous with respect to (x, y), the Hausdorff continuity of $X(\cdot)$ at $\varepsilon = 0$ was proved in [16] and in [18] under different assumptions. A related result was also proved in [10] for F and G that are ROSL and continuous. Under weaker assumptions, [13] proved the weaker inclusion $\limsup_{\varepsilon \to 0} X(\varepsilon) \subset X(0)$. We refer also to [14], where upper and lower approximations of singularly perturbed systems are comprehensively studied and interesting examples are considered.

All papers cited above deal with finite-dimensional spaces, and important steps in the proofs in these papers use the compactness of the unit ball. In this paper, we go around such arguments and manage to tackle the infinite-dimensional singularly perturbed differential inclusion of the form (1). It may look specific, but actually it covers a lot of territory. In particular, we cover the case of a control system where the control acting on both x and y appears explicitly while the (different) controls acting separately on x and y are inscribed in the set-valued character of the mappings F and G. The partial differential inclusion described in [21, section I.7] can serve as an example of application of our results.

We do not know whether it would be possible to obtain a Tikhonov theorem of the type of Theorem 1 for a general singularly perturbed infinite-dimensional differential inclusion, such as the inclusion (9) in section 5 of this paper.

Our interests in considering infinite-dimensional systems stems from the natural question of whether and how the well-developed theory in finite dimensions can be extended to tackle infinite-dimensional problems. However, our ultimate goal is broader—not only to generalize but also to understand the meaning of the abstract results for specific infinite-dimensional models such as systems described by differential equations with delay or partial differential equations. In this paper, we chose to present applications of our result to other theoretical works in the area, leaving the exploration of applications to, e.g., distributed parameter systems for future research.

In the next section, we present preliminary results that set the stage for a proof of Theorem 1. Section 3 contains this proof. In section 4, we demonstrate an application of Theorem 1 to establish convergence for the fast subsystem in terms of invariant measures, in the sense of Artstein [1]. Section 5 contains another application of Theorem 1 to obtain an infinite-dimensional version of a result of the authors' with I. Slavov [11], regarding the convergence of sequences of both x and y trajectories that are equi-Lipschitz continuous.

2. Preliminaries. A mapping Γ from a topological space $\mathcal{X}$ into a topological space $\mathcal{Y}$ is said to be upper-semicontinuous (USC) at a given $x \in \mathcal{X}$ if for every open $V \supset \Gamma(x)$ there exists a neighborhood $W \ni x$ such that $V \supset \Gamma(y)$ for $y \in W$. If $\Gamma(\cdot)$ is USC at every point of its domain, we call it USC. When $\mathcal{X}$ and $\mathcal{Y}$ are metric spaces and Γ is compact-valued, Γ is USC iff for every $\delta > 0$ there exists $\lambda > 0$ such that

$\Gamma(B(x,\delta)) \subset B(\Gamma(x),\lambda)$ for any $x \in \mathcal{X}$, where $B(A,\delta) = \{x \in \mathcal{X} \mid \operatorname{dist}(x,A) < \delta\}$. A mapping $\Gamma : I \times \mathcal{X} \rightrightarrows \mathcal{Y}$ is said to be almost USC when for any $\varepsilon > 0$ there exists a compact set $I_\varepsilon \subset I$ with Lebesgue measure $\operatorname{meas}(I_\varepsilon) > 1 - \varepsilon$ such that $\Gamma(\cdot,\cdot)$ is USC at every point of $I_\varepsilon \times \mathcal{X}$. We refer to [3] for all the concepts used in the paper but not explicitly defined. We denote the closed unit balls in E_1 and E_2 by $\mathbb{B}_1$ and $\mathbb{B}_2$, respectively, where E_1 and E_2 are the spaces where the basic inclusion (1) is defined.

In the first two lemmas of this section, we assume that the condition (i) in Theorem 1 holds. These lemmas are based on standard arguments; for the first lemma, see, e.g., the proofs of Lemma 3.1 in [9], while for the second, see [5] or [10].

LEMMA 1. *There exist constants M and $N > 0$ such that for every solution $(\tilde{x}_\varepsilon(\cdot), \tilde{y}_\varepsilon(\cdot))$ of the initial value problem*

$$\begin{aligned} \dot{x}(t) &\in \overline{\operatorname{co}}\, F(x + \mathbb{B}_1, y + \mathbb{B}_2, U), \qquad x(0) = x^0, \\ \varepsilon \dot{y}(t) &\in \overline{\operatorname{co}}\, G(x + \mathbb{B}_1, y + \mathbb{B}_2, U), \qquad y(0) = y^0, \end{aligned}$$

and for every $t \in I$ we have

$$\|\tilde{x}_\varepsilon(t)\| + \|\tilde{y}_\varepsilon(t)\| \le M$$

and

$$\|F(\tilde{x}_\varepsilon(t) + \mathbb{B}_1, \tilde{y}_\varepsilon(t) + \mathbb{B}_2, U)\| + \|G(\tilde{x}_\varepsilon(t) + \mathbb{B}_1, \tilde{y}_\varepsilon(t) + \mathbb{B}_2, U)\| \le N.$$

LEMMA 2. *For every $y^1, y^2 \in E_2$, any $x \in E_1$, and any control $u(\cdot)$, if $y_1(\cdot)$ is a solution of the associate system* (2) *with $y(0) = y^1$, then there exists a solution $y_2(\cdot)$ of* (2) *with $y(0) = y^2$ such that*

$$\|y_1(\tau) - y_2(\tau)\| \le \exp(-\mu\tau)\|y^1 - y^2\| \quad \text{for all } \tau > 0,$$

where μ is the constant in condition (i).

In the remaining part of this section, we assume that both conditions (i) and (ii) of Theorem 1 hold with $m = 2M$ and $r = M$, where M is the constant in Lemma 1. The supremum in (ii) is denoted by L_1. The following corollary will be useful later.

COROLLARY 1. *For compact sets $P \subset E_1$ and $Q \subset E_2$, consider the following differential inclusion:*

$$\dot{y}(\tau) \in \overline{\operatorname{co}}\, G(P, y(\tau), U), \quad y(0) \in Q. \tag{4}$$

There exists a compact set $\hat{K} \subset E_2$ such that $y(t) \in \hat{K}$ for every solution $y(\cdot)$ of (4) *and every $t \ge 0$.*

Proof. First, observe that the set-valued mapping $H(x) := \overline{\operatorname{co}}\, G(P, x, U)$ is ROSL with a constant $-\mu$. Consequently, $\sigma(J(x(t) - 0), H(x(t))) - \sigma(J(x(t) - 0), H(0)) \le -\mu|x(t)|^2$. Therefore, for every solution $y(\cdot)$ of (4) we have

$$\langle J(x(t)), \dot{x}(t) \rangle \le -\mu|x(t)|^2 + |x(t)||H(0)|.$$

Using a standard argument, one can show that

$$\frac{d}{dt}|x(t)| \le -\mu|x(t)| + |H(0)|.$$

Let $m = |H(0)|$. Then either $|x(t)| \le m$ or $\frac{d}{dt}|x(t)| < 0$. Hence $|x(t)| \le \max\{|Q|, m\} = \hat{M}$. From Theorem 1 in [5] we know that the solution set of (4) is nonempty

and precompact in $C([0,T],E_2)$ for every $T>0$. Let $K(t)$ be the set of values $y(t)$ at t of all trajectories $y(\cdot)$ of (4) (the reachable set at t). Denote $N(s,t)=\max\{\exp(-s\mu),\exp(-t\mu)\}$. Then $D_H(K(t),K(s))\le 2N(s,t)\hat{M}$, thanks to Lemma 2. Hence the net $\{K(t)\}_{t\ge 0}$ is a Cauchy net. Therefore, there exists a compact set $K=\lim_{t\to\infty}K(t)$. Since the multimap $t\rightrightarrows K(t)$ is continuous, one has that $\hat{K}=K\bigcup(\bigcup_{t\ge 0}K(t))$ is compact. □

LEMMA 3. *Let $y^1,y^2\in M\mathbb{B}_2$, where M is the constant in Lemma 1. For every solution $y_1(\cdot)$ of (2) with $y_1(0)=y^1$ there exists a solution $y_2(\cdot)$ of (2) with $y_2(0)=y^2$ such that*

$$\frac{1}{S}\int_0^S D_H\big(F(x,y_1(\tau),u(\tau)),F(x,y_2(\tau),u(\tau))\big)\,d\tau\le\frac{L_1}{S}.$$

Proof. It is sufficient to observe that

$$\int_0^S D_H\big(F(x,y_1(\tau),u(\tau)),F(x,y_2(\tau),u(\tau))\big)\,d\tau \le\int_0^\infty \omega_{F(x,\cdot,u)}(2M\exp(-\mu\tau),M)\,d\tau.$$ □

LEMMA 4. *For every $S>0$ the map $\hat{V}(\cdot,S):=\cup_{y\in M\mathbb{B}_2}\hat{V}(\cdot,S,y)$ is ROSL with a constant independent of $S>0$.*

Proof. Let x_1,x_2 be given points in E_1. Let $y_1(\cdot)$ be a solution of (2) with x replaced by x_1 and corresponding control $u(\cdot)$. Define the mapping

$$(\tau,v)\mapsto\Gamma(\tau,v)=\{w\in G(x_2,v,u(\tau))\mid\langle J(y_1(\tau)-v),\dot{y}_1(\tau)-w\rangle \le C\|x_1-x_2\|^2-\mu\|y_1(\tau)-v\|\},$$

where C is from condition (i). The mapping $\Gamma(\cdot,\cdot)$ is almost USC with nonempty, convex, and compact values. Therefore, the inclusion $\dot{y}(t)\in\Gamma(t,y)$, $y(0)=y_0$ admits a solution; see, e.g., Theorem 1 in [5]. That is, there exists $y(\cdot)$ such that

$$\langle J(y_1(t)-y(t)),\dot{y}_1(t)-\dot{y}(t)\rangle\le C\|x_1-x_2\|^2-\mu\|y_1(t)-y(t)\|^2.$$

Hence

$$\|y_1(t)-y(t)\|^2\le\exp(-2\mu t)\int_0^t\exp(2\mu\tau)\{2C\|x_1-x_2\|^2\}\,d\tau =\exp(-2\mu t)\left(\frac{C}{\mu}\|x_1-x_2\|^2\right)[\exp(2\mu t)-1]<\frac{C}{\mu}\|x_1-x_2\|^2.$$

Therefore,

$$\sigma\left(J(x_1-x_2),\frac{1}{S}\int_0^S F(x_1,y_1(\tau),u(\tau))\,d\tau\right) -\sigma\left(J(x_1-x_2),\frac{1}{S}\int_0^S F(x_2,y_2(\tau),u(\tau))\,d\tau\right) \le\frac{1}{S}\int_0^S\Big[A\|x_1-x_2\|^2+B\|x_1-x_2\|\|y_1-y_2\|\Big]\,d\tau\le A\|x_1-x_2\|^2+\frac{BC}{\mu}\|x_1-x_2\|^2.$$

Hence $\hat{V}(\cdot,S,M\mathbb{B}_2)$ is ROSL with a constant $A+BC/\mu$. □

PROPOSITION 1. *There exist a mapping $V : E_1 \rightrightarrows E_1$ and a constant L_2 such that for every $x \in M\mathbb{B}_1$, every $y \in M\mathbb{B}_2$, and every sufficiently large S,*

$$D_H(V(x), \overline{\text{co}}\, \hat{V}(x, S, y)) \le \frac{L_2}{S}.$$

Furthermore, $V(\cdot)$ is USC and ROSL, and for any $x \in M\mathbb{B}_1$

$$\lim_{S\to\infty} D_H(V(x), \hat{V}(x, S, y)) = 0 \quad \textit{uniformly in } y \in M\mathbb{B}_2.$$

Proof. The proof is similar to the proof of Proposition 3.2 of Grammel [17] and will be only sketched. Let $x \in M\mathbb{B}_1$. If for a $y' \in M\mathbb{B}_2$ the set $\overline{\text{co}}\, \hat{V}(x, S, y')$ converges in the Hausdorff sense to some $V(x)$, then it also converges for any other $y \in M\mathbb{B}_2$ to *the same* $V(x)$. We fix $y(0) = y' \in M\mathbb{B}_2$, and, by using the argument in the proof of Proposition 3.2 of [17] which also works in infinite dimensions, we obtain the following.

Claim 1. $D_H(\hat{V}(x, (k+h)S, y'), \hat{V}(x, kS, y')) \le 2N/k$, where N is as in Lemma 1.

Indeed, for all k, all $h \in [0, 1)$, and all $S > 0$, we have

$$\hat{V}(x, (k+h)S, y') = \text{cl} \bigcup_{u(\cdot)} \bigcup_{y(\cdot)\in Y(x,S,y',u(\cdot))} \left\{ \frac{1}{(k+h)S} \left(\int_0^{kS} + \int_{kS}^{(k+h)S} \right) F(x, y(\tau), u(\tau))\, d\tau \right\}.$$

Hence

$$\hat{V}(x, (k+h)S, y') \subset \frac{k}{k+h} \hat{V}(x, kS, y') + \frac{h}{k+h} N\mathbb{B}_1 \subset \hat{V}(x, kS, y') + \frac{2Nh}{k+h}\mathbb{B}_1.$$

Analogously,

$$\hat{V}(x, kS, y') \subset \hat{V}(x, (k+h)S, y') + \frac{2Nh}{k+h}\mathbb{B}_1.$$

Claim 2. For all $k = 1, 2, \ldots$ and for all $S > 0$, we have

$$D_H \left(\hat{V}(x, kS, y), \frac{1}{k} \sum_{i=1}^{k} \hat{V}(x, S, y) \right) \le \frac{L_1}{S}.$$

The proof of Claim 2 is by induction and closely follows the proof of an analogous result in Grammel [17]. Since $D_H(\overline{\text{co}}\, A, \overline{\text{co}}\, B) \le D_H(A, B)$, applying the triangle inequality, one obtains

$$D_H\big(\overline{\text{co}}\, \hat{V}(x, (k+h)S, y), \overline{\text{co}}\, \hat{V}(x, S, y)\big) \le \frac{2N}{k} + \frac{L_1}{S} \tag{5}$$

for all $k = 1, 2, \ldots, S > 0$ and $h \in [0, 1]$. Fix $\varepsilon > 0$. Let $S_1 > 4L_1/\varepsilon$ and $k > 4N/\varepsilon$. Then

$$D_H(\overline{\text{co}}\, \hat{V}(x, (k+h)S_1, y'), \overline{\text{co}}\, \hat{V}(x, S_1, y')) \le \frac{\varepsilon}{2}.$$

Consequently, for $\hat{S}$ and $\tilde{S} > kS_1$ one has $D_H(\overline{\text{co}}\, \hat{V}(x, \hat{S}, y'), \overline{\text{co}}\, \hat{V}(x, \tilde{S}, y')) \le \varepsilon$. Thus $\{\overline{\text{co}}\, \hat{V}(x, S, y')\}_{S>0}$ is a Cauchy net, and therefore it has a limit $V(x)$. Due to Lemma 2

the limit does not depend on $y(0) = y' \in M\mathbb{B}_2$. Furthermore, $V(\cdot)$ is ROSL thanks to Lemma 4. The claim that V is USC follows from the USC property of $\hat{V}$. By virtue of (5) we have

$$D_H(V(x), \overline{\text{co}}\, \hat{V}(x, S, y')) \leq \frac{L_2}{S}.$$

To complete the proof, we use the following fact: Given a compact set A in an arbitrary Banach space with unit ball $\mathbb{B}$, for every $\varepsilon > 0$ there exists n_ε such that

$$D_H\left(\overline{\text{co}}\, A, \frac{1}{k}\sum_{i=1}^{k} A\right) < \varepsilon \quad \text{for} \quad k > n_\varepsilon.$$

Indeed, for $\varepsilon > 0$ there exist a finite number of points $a_i \in \overline{\text{co}}\, A, i = 1, \ldots, n_\varepsilon$, such that if A_ε is the set of those points, then $D_H(\overline{\text{co}}\, A, A_\varepsilon) < \delta$. Further, since $\overline{\text{co}}\, A$ is the closure of the set of all finite convex combinations of elements of A, one has that for every $a_i \in A_\varepsilon$ there exists a finite convex combination of points $a^j \in A, j = 1, 2, \ldots, k_i$, such that

$$\left\| a_i - \sum_{j=1}^{k_i} \lambda_j a^j \right\| < \varepsilon.$$

On the other hand, there exists a natural number N such that for every $n > N$ every such λ_j can be approximated with accuracy $1/n$ by a rational number having the form p_j/n, where $\sum_{j=1}^{k_j} p_j/n = 1$. Hence

$$\left\| a_i - \sum_{j=1}^{k_i} \frac{p_j}{n} a^j \right\| \leq \varepsilon + \frac{k_i}{n} q,$$

where $q \in \mathbb{R}_+$ such that $A \subset q\mathbb{B}$. Therefore,

$$D_H\left(\overline{\text{co}}\, A, \frac{1}{n}\sum_{i=1}^{n} A\right) \leq \varepsilon + \frac{k}{n} q,$$

where $k = \max_i\{k_i\}$. From the arguments above it is clear that for a closed set B with $D_H(A, B) < \varepsilon$ there exists $k(\varepsilon)$ such that $D_H(B_n, \overline{\text{co}}\, A) < 2\varepsilon$ for every $n > k(\varepsilon)$, where $B_n = \frac{1}{n}\sum_{i=1}^{n} B$. Thus one obtains that for every $S > 0$ and every $\delta > 0$ there exists n such that

$$D_H\big(\overline{\text{co}}\, \hat{V}(x, S, y'), \hat{V}(x, (k+h)S, y')\big) < \delta \quad \text{for} \quad k > n.$$

Consequently, $\lim_{S\to\infty} D_H(V(x), \hat{V}(x, S, y)) = 0$. The proof is complete. □

We will also use the following (refined) version of Plis's lemma (see Lemma 8.3 of [3] and [28]).

LEMMA 5. *Given a control $u(\cdot)$ and functions $f : I \to I$ and $g : I \to I$, if (x, y) is AC and such that*

$$\dot{x}(t) \in F(x(t) + f(t)\mathbb{B}_1, y(t) + g(t)\mathbb{B}_2, u(t)),$$
$$\varepsilon\dot{y}(t) \in G(x(t) + f(t)\mathbb{B}_1, y(t) + g(t)\mathbb{B}_2, u(t)),$$

then there exist constants K_x and K_y and a solution (w,z) of (1) with

$$\|x(t)-w(t)\| \le \sqrt{r(t)}, \quad \|y(t)-z(t)\| \le \sqrt{s(t)},$$

where

$$\begin{aligned}
&\dot r(t) = Ar + Bs + K_x(f(t)+g(t)+\omega_J(f(t))), \quad r(0) = \|x^0 - w(0)\|^2,\\
&\varepsilon\dot s(t) = Cr - \mu s + K_y(f(t)+g(t)+\omega_J(g(t))), \quad s(0) = \|y^0 - z(0)\|^2.
\end{aligned}$$

Proof. Consider the mappings

$$\begin{aligned}
&(t,w,z,u) \mapsto \tilde F(t,w,z,u) = \mathrm{cl}\{\alpha \in F(w,z,u) \mid \big\langle J(x(t)-w+f(t)), \dot x(t)-\alpha\big\rangle\\
&\qquad \le A\|x(t)-w+f(t)\|^2 + B\|y(t)-z+g(t)\|^2\},\\
&(t,w,z,u) \mapsto \tilde G(t,w,z,u) = \mathrm{cl}\{\beta \in G(w,z,u) \mid \varepsilon\big\langle J(y(t)-z+g(t)), \dot y(t)-\beta\big\rangle\\
&\qquad \le C\|x(t)-w+f(t)\|^2 - \mu\|y(t)-z+g(t)\|^2\}.
\end{aligned}$$

The so-defined $\tilde F$ and $\tilde G$ are almost USC with nonempty, convex, compact values. Furthermore, the system

$$\begin{aligned}
&\dot x(t) \in \tilde F(t,x,y,u), \quad x(0) = w(0),\\
&\varepsilon\dot y(t) \in \tilde G(t,x,y,u), \quad y(0) = z(0),
\end{aligned}$$

has a solution $(w(t), z(t))$ such that

$$\big\langle J(x(t)-w(t)+f(t)), \dot x(t)-\dot w(t)\big\rangle \le A\|x(t)-w(t)+f(t)\|^2 + B\|y(t)-z(t)+g(t)\|^2 := \mathcal{P}$$

and

$$\varepsilon\big\langle J(y(t)-z(t)+g(t)), \dot y(t)-\dot z(t)\big\rangle \le C\|x(t)-w(t)+f(t)\|^2 - \mu\|y(t)-z(t)+g(t)\|^2.$$

Consequently,

$$\begin{aligned}
&\big\langle J(x(t)-w(t)), \dot x(t)-\dot w(t)\big\rangle \le \mathcal{P}\\
&\quad + \|\big\langle J(x(t)-w(t)+f(t)), \dot x(t)-\dot w(t)\big\rangle - \big\langle J(x(t)-w(t)), \dot x(t)-\dot w(t)\big\rangle\|\\
&\quad \le \mathcal{P} + \|\dot x(t)-\dot w(t)\|\|J(x(t)-w(t)) - J(x(t)-w(t)+f(t))\| \le \mathcal{P} + 2N\omega_J(f(t)).
\end{aligned}$$

On the other hand,

$$\begin{aligned}
&\big|\|x(t)-w(t)+f(t)\|^2 - \|x(t)-w(t)\|^2\big|\\
&\quad = \big|\|x(t)-w(t)+f(t)\| - \|x(t)-w(t)\|\big| \cdot \big|\|x(t)-w(t)+f(t)\| + \|x(t)-w(t)\|\big|\\
&\quad \le f(t)(2\|x(t)\| + 2\|w(t)\| + f(t)) \le \|f(t)\|(4M+1).
\end{aligned}$$

Hence

$$\big\langle J(x-w), \dot x-\dot w\big\rangle \le A\|x-w\|^2 + B\|y-z\|^2 + 2N\omega_J(f(t)) + (4M+1)Af(t) + (4M+1)Bg(t)).$$

Analogously

$$\begin{aligned}
\varepsilon\big\langle J(y-z), \dot x-\dot w\big\rangle \le{}& C\|x-w\|^2 - \mu\|y-z\|^2 + 2N\varepsilon\omega_J(g(t))\\
&+ (4M+1)Cf(t) + (4M+1)\|\mu\|g(t)).
\end{aligned}$$

Therefore, $\|x(t)-w(t)\|^2 \le r(t)$, $\|y(t)-z(t)\|^2 \le s(t)$, where r and s are defined in the statement of the lemma. ∎

3. Proof of Theorem 1. We divide the interval $[0, \varepsilon^{-1}]$ on subintervals $[t_i, t_{i+1}]$ with lengths $\varepsilon S_\varepsilon > 0$ such that $\lim_{\varepsilon\to 0} S_\varepsilon = \infty$, $\lim_{\varepsilon\to 0}(\varepsilon S_\varepsilon) = 0$. Let $t_j = j\varepsilon S_\varepsilon$, $\tau_j = jS_\varepsilon$ for $j = 0, 1, \dots, E_\varepsilon$, where E_ε is the largest integer less or equal to $(\varepsilon S_\varepsilon)^{-1}$. We also let $t_{E_\varepsilon+1} = 1$.

Step I. Let $(x_\varepsilon(\cdot), y_\varepsilon(\cdot))$ be a solution of (1) for a control $u_\varepsilon(\cdot)$ and for a sufficiently small ε. We will show that there exists a solution $z(\cdot)$ of (3) the uniform in I distance from which to $x_\varepsilon(\cdot)$ can be made arbitrary small.

Denote $\Delta = \varepsilon S_\varepsilon$ and $x_j = x_\varepsilon(t_j)$. We will apply Proposition 1 for $x_\varepsilon(t_j)$, but first we have to adjust $y_\varepsilon(\cdot)$. Define on $[t_j, t_{j+1}]$ the mapping $(t, v, w) \mapsto P_\varepsilon(t, v, w)$, where

$$P_\varepsilon(t,v,w) = \operatorname{cl}\big\{g \in G(v,w,u_\varepsilon(t)) \mid \big\langle J(y_\varepsilon(t)-w), \varepsilon\dot{y}_\varepsilon(t) - g\big\rangle \\ \le C\|x_\varepsilon(t)-v\|^2 - \mu\|y_\varepsilon(t)-w\|^2\big\}.$$

The mapping P_ε is almost USC with nonempty, convex, and compact values. Let $y_z(\cdot)$ be a solution of the differential inclusion

$$\varepsilon\dot{y}(t) \in P_\varepsilon(t, x_j, y(t)), \quad y(t_j) = y_j := \lim_{t\to t_j} y(t), \text{ and } y_z(0) = y^0.$$

Since $\bar{y}(\tau) = y_z(\varepsilon(\tau + \tau_j))$ is a solution of the associate system (2) with $\bar{y}(0) = y_z(\tau_j)$ on $[0, s_\varepsilon]$, we have

$$\varepsilon\big\langle J(y_\varepsilon(t) - y_z(t)), \dot{y}_\varepsilon(t) - \dot{y}_z(t)\big\rangle \le C\|x_\varepsilon(t) - x_j\|^2 - \mu\|y_\varepsilon(t) - y_z(t)\|^2,$$

that is,

$$\varepsilon\big\langle J(y_\varepsilon(t) - y_z(t)), \dot{y}_\varepsilon(t) - \dot{y}_z(t)\big\rangle \le N^2C\|t - t_j\|^2 - \mu\|y_\varepsilon(t) - y_z(t)\|^2.$$

Thus

$$\varepsilon\frac{d}{dt}\|y_\varepsilon(t) - y_z(t)\|^2 \le r(t),$$

where

$$\varepsilon\dot{r}(t) \le 2CN^2\Delta^2 - 2\mu r(t), \quad r(0) = 0.$$

Furthermore,

$$e^{-2\mu t/\varepsilon}\int_0^t e^{2\mu\tau/\varepsilon} 2CN^2\Delta^2/\varepsilon\, d\tau = \frac{CN^2\Delta^2}{\mu}(1 - e^{-2\mu/\varepsilon}).$$

Hence there exists a constant C_1 such that

$$\|y_z(t) - y_\varepsilon(t)\| \le C_1\Delta.$$

Now we want to approximate $x_\varepsilon(\cdot)$ with a function with a "piecewise" constant derivative. For $t \in [t_j, t_{j+1}]$, $j = 0, 1, \dots, E_\varepsilon$, consider the mapping

$$W_\varepsilon(t) = \operatorname{cl}\big\{w \in F(h_j, y_z(t), u_\varepsilon(t)) \mid \big\langle J(x_\varepsilon(t) - h_j), \dot{x}_\varepsilon(t) - w\big\rangle \\ \le A\|x_\varepsilon(t) - h_j\|^2 + B\|y_\varepsilon(t) - y_z(t)\|^2\big\}.$$

Define $h(t) = h_j + \int_{t_j}^{t} w(\tau)\,d\tau$, where $w(t) \in W_\varepsilon(t)$ is strongly measurable. Since $\|w(\tau)\| \le N$ (Lemma 1), we have

$$\big\langle J(x_\varepsilon(t)-h(t)), \dot{x}_\varepsilon(t)-\dot{h}(t)\big\rangle \le 2N\omega_J(N\Delta)+BC_1\Delta^2+A\big|\|x_\varepsilon(t)-h_j\|^2-\|x_\varepsilon(t)-h(t)\|^2\big|.$$

Thus

$$\frac{d}{dt}\|x_\varepsilon(t)_h(t)\|^2 \le 4N\omega_J(N\Delta) + BC_1\Delta^2 + 4MA\Delta + 2A\|x_\varepsilon(t) - h(t)\|^2.$$

Hence $\|x_\varepsilon(t)-h(t)\| \le C_1\sqrt{\omega_J(N\Delta)+M\Delta}$ for some constant C_2. Since $\lim_{\varepsilon\to 0}\Delta(\varepsilon) = 0$, one has that $\|x_\varepsilon(t) - h(t)\| \le \lambda(t)$, where $\lim_{\varepsilon\to 0}\lambda(\varepsilon) = 0$. Due to Proposition 1, there exists $v_j \in V(x_j)$, $j = 1, 2, \ldots, E_\varepsilon - 1$, with

$$\left\| \frac{1}{S_\varepsilon}\int_{\tau_j}^{\tau_{j+1}} \big(\dot{h}(\tau) - v_j\big)\,d\tau \right\| \le \frac{L_2}{S_\varepsilon}$$

(where L_2 is from Proposition 1). The function $m(t) = m(t_j) + (t - t_j)v_j$ for $t \in [t_j, t_{j+1}]$, $j = 0, 1, \ldots, E_\varepsilon$, and $m(0) = x_0$ satisfies

$$\|h(t) - m(t)\| \le \frac{L_2}{S_\varepsilon} \quad \text{for all } t \in I.$$

Clearly,

$$\|m(t) - x_\varepsilon(t)\| \le \|h(t) - m(t)\| + \|h(t) - x_\varepsilon(t)\| \le 2M\Delta + 2C\lambda(\varepsilon).$$

Furthermore, $\dot{m}(t) \in V(x_j)$ and $\|x_j - x_\varepsilon(t)\| \le N\Delta$. Hence

$$\dot{m}(t) \in V\big(m(t) + \big(2N\Delta + 2M\Delta + 2C\lambda(\varepsilon)\big)\mathbb{B}_1\big).$$

Consequently, there exists $\nu(\varepsilon) > 0$ with $\lim_{\varepsilon\to 0}\nu(\varepsilon) = 0$ such that $\dot{m}(t) \in V(m(t) + \nu(\varepsilon)\mathbb{B}_1)$. Therefore, we can apply Theorem 1 of [5], obtaining that there exists a solution $z(\cdot)$ of (3) such that

$$\|z(t) - m(t)\| \le D_1\sqrt{\nu(\varepsilon)} + \omega_J(C_2\sqrt{\nu(\varepsilon)}).$$

Step II. We will show now that for every solution $z(\cdot)$ of (3) there exists a solution $(x_\varepsilon, y_\varepsilon)$ of (1) such that $\|x_\varepsilon(t) - z(t)\| \to 0$ as $\varepsilon \to 0$. To this end we employ the idea of partition used in Step I.

The solution set X_0 of (3) is compact. Therefore, the set $\mathcal{L} = \bigcup_{t\in I}\{z(t) \mid\ z(\cdot) \in X_0\}$ is compact and hence for every $\lambda > 0$ there exists a finite λ-net $\{\tilde{z}_i\}_{i=1}^{n_\lambda}$ of it. Observe that

$$\mathcal{A} = \bigcup_{i=1}^{n_\lambda}(\tilde{z}_i + \lambda\mathbb{B}_1) \supset \mathcal{L} + \nu\mathbb{B}_1$$

for some $\nu > 0$ because $\mathcal{A}$ is open and $\mathcal{L} \subset \mathcal{A}$ is compact. Furthermore, for every $\delta > 0$ there exists S_δ such that

$$D_H\left(V(\tilde{z}_i), \frac{1}{S}\bigcup_{v(\cdot)}\left\{\int_0^S F(\tilde{z}_i, y(\tau), v(\tau))\,d\tau \mid y \in Y(\tilde{z}_i, S, M\mathbb{B}_2, v(\cdot))\right\}\right) < \delta$$

for every i and every $S > S_\delta$, where the union is with respect to the feasible controls $v(\cdot)$ and

$$Y(x, S, M\mathbb{B}_2, v(\cdot)) := \bigcup_{y^0 \in M\mathbb{B}_2} \tilde{Y}(x, S, y^0, v(\cdot)).$$

If $z(\cdot)$ is a solution of (3), then for $j = 1, 2, \dots, E_\varepsilon$, one has

$$\dot{z}(t) \in V\big(z(t_j) + N\Delta\mathbb{B}_1\big).$$

In order to apply Proposition 1, we find an approximate solution of (3), which is near $z(\cdot)$. Iteratively, we define a function $w(\cdot)$ and then a mapping W of the form

$$\begin{aligned}(t,p) \mapsto W(t,p) = \operatorname{cl}\{v \in V(w(t_j)) \mid \big\langle J(z(t)-p), \dot{z}(t) - v\big\rangle \\ \le (L+1)(\|z(t) + w(t_j)\|^2 + \|J(w(t_j)) - J(w(t))\|^2)\},\end{aligned}$$

where L is the ROSL constant of V. For $j = 0$ we set $w(0) = x^0$. The mapping W is nonempty-, convex-, and compact-valued and almost USC. Therefore, there exists a solution $w(t)$ on $[t_j, t_{j+1}]$ of

$$\dot{w}(t) \in W(t, w), \quad w(t_j) = \lim_{t \to t_j} w(t).$$

Thus

$$\|w(t) - z(t)\| \le \sqrt{r(t)}, \qquad \text{where} \qquad \dot{r}(t) = Lr(t) + \omega_J(N\Delta),\ r(0) = 0.$$

If $0 < \delta < \nu$, we can choose Δ so small that $\|w(t) - z(t)\| < \delta$. Let $z_j = \Delta^{-1} \int_{t_j}^{t_{j+1}} \dot{w}(t)\, dt$. By the definition of $w(\cdot)$ we have $z_j \in V(w(t_j))$. Now we will use Proposition 1 and the change of time scale $\tau = t/\varepsilon$. Due to Proposition 1 there exists $\varepsilon(\delta) > 0$ such that for every $0 < \varepsilon < \varepsilon(\delta)$ there exists a control $u(\cdot)$ on $(\tau_j, \tau_{j+1}]$ which satisfies

$$\operatorname{dist}\left(\tilde{z}_j, \frac{1}{S_\varepsilon}\left\{ \int_{\tau_j}^{\tau_{j+1}} F(w(\tau_j), v(\tau), u(\tau))\, d\tau \mid \ v(\cdot) \in Y(w(\tau_j), S_\varepsilon; M\mathbb{B}_2, u(\cdot)) \right\}\right) < \delta$$

for some $\tilde{z}_j$ with $\|z_j - \tilde{z}_j\| < \delta$. By the definition of $Y(w(\tau_j), S_\varepsilon; M\mathbb{B}_2, u(\cdot))$ there exists an AC function $y_w(\cdot)$ defined as follows: $y_w(0) = y_0$, $\dot{y}_w(\tau) \in G(w(\tau_j), y_w(\tau), u(\tau))$, with the convention $v(\tau_j) = \lim_{t \to \tau_j - 0} v(t)$, on $[\tau_j, \tau_{j+1}] = [jS_\varepsilon, (j+1)S_\varepsilon]$, such that

$$\operatorname{dist}\left(\tilde{z}_j, \frac{1}{S_\varepsilon}\left\{ \int_{\tau_j}^{\tau_{j+1}} F(w(\tau_j), y_w(\tau), u(\tau))\, d\tau \right\}\right) < \delta.$$

Let $\dot{h}(\cdot)$ be a measurable selection of $F(w(t_j), y_w(\cdot), u(\cdot))$ such that

$$\left\| \tilde{z}_j - \frac{1}{\Delta} \int_{t_j}^{t_{j+1}} \dot{h}(t)\, dt \right\| \le \delta.$$

Now we define an approximate solution $h(\cdot)$ of (1) which is near $w(\cdot)$. Let $h(t) = \int_0^t \dot{h}(\tau)\, d\tau + x_0$. Then $\|h(t) - w(t)\| \le 2\delta + N\Delta/2$. Therefore,

$$\dot{h}(t) \in F(h(t) + (2\delta + N\Delta/2)\mathbb{B}_1, y_w(t), u(t)).$$

Let $(x_\varepsilon, y_\varepsilon)$ be a solution of

$$\dot{x}(t) \in \tilde{F}(t, x(t), y(t), u(t)),\ x(0) = x^0,$$
$$\varepsilon\dot{y}(t) \in \tilde{G}(t, x(t), y(t), u(t)),\ y(0) = y_0,$$

where $\tilde{F}$ and $\tilde{G}$ are defined on $[t_j, t_{j+1}]$ for $j = 0, 1, \ldots, E_\varepsilon$ as follows:

$$\tilde{F}(t, \alpha, \beta, u(t)) = \{p \in F(\alpha, \beta, u(t)) \mid \langle J(\alpha - h_1(t)), p - \dot{h}(t)\rangle$$
$$\leq A\|\alpha - h_1(t)\|^2 + B\|\beta - y_w(t)\|^2\},\ \text{where } \|h_1(t) - h(t)\| \leq 2\delta + \frac{N\Delta}{2};$$
$$\tilde{G}(t, \alpha, \beta, u(t)) = \{q \in G(\alpha, \beta, u(t)) \mid \langle J(\beta - y_w(t_j)), q - \varepsilon\dot{y}_w(t)\rangle$$
$$\leq C\|\alpha - w(t)\|^2 - \mu\|\beta - y_w(t)\|^2.$$

The mappings $\tilde{F}, \tilde{G}$ are almost USC with nonempty, convex, compact values. Furthermore,

$$|\langle J(\alpha - h_1(t)), p - \dot{h}(t)\rangle - \langle J(\alpha - h(t)), p - \dot{h}(t)\rangle| \leq \omega_J(\|h_1(t) - h(t)\|)\|p - \dot{h}(t)\|$$
$$\leq 2N\omega_J\left(2\delta + \frac{N\Delta}{2}\right)2N,$$

$$A\big|\|\alpha - h_1(t)\|^2 - \|\alpha - h(t)\|^2\big| \leq A\left(2\delta + \frac{N\Delta}{2}\right)4M$$

and

$$C\big|\|\alpha - w(t_j)\|^2 - \|\alpha - h(t)\|^2\big| \leq C\|h(t) - w(t_j)\|(2\|\alpha\| + \|w(t_j)\| + \|h(t)\|)$$
$$\leq 4CM\left(2\delta + \frac{N\Delta}{2}\right).$$

Due to Lemma 5

$$\|x_\varepsilon - z(t)\|^2 \leq m(t) \quad \text{and} \quad \|y_\varepsilon(t) - y_w(t)\|^2 \leq s(t),$$

where

$$\dot{m}(t) \leq Am + Bs + 4\Delta^2 + C_1\left(\omega_J\left(2\delta + \frac{N\Delta}{2}\right) + 2\delta\right), \quad m(0) = 0,$$
$$\varepsilon\dot{s}(t) \leq Cm - \mu s + 4\Delta^2 + 4CM\left(2\delta + \frac{N\Delta}{2}\right), \quad s(0) = 0.$$

Therefore,

$$\|h(t) - x_\varepsilon(t)\| \leq \kappa\sqrt{\omega_J\left(2\delta + \frac{N\Delta}{2}\right) + \delta}$$

and

$$\|y_w(t) - y_\varepsilon(t)\| \leq \kappa_1\sqrt{\delta},$$

where κ and κ_1 are constants. Applying the triangle inequality

$$\|z(t) - x_\varepsilon(t)\| \leq \|z(t) - w(t)\| + \|w(t) - h(t)\| + \|h(t) - x_\varepsilon(t)\|,$$

we complete the proof. □

As a side result of the proof of Theorem 1, we obtain compactness of the set of values of the trajectories, which we state as the following corollary.

COROLLARY 2. *On the assumptions of Theorem* 1*, there exists a compact set* K *such that every solution* $(x_\varepsilon(\cdot), y_\varepsilon(\cdot))$ *of* (1) *satisfies* $(x_\varepsilon(t), y_\varepsilon(t)) \in K$ *for every* $(\varepsilon, t) \in (0, 1] \times I$.

Proof. It is clear that the reachable set $X_\varepsilon(t)$ of the slow part of (1) at the moment t is compact. Also, the reachable set of (3), $X_0(t) = \lim_{\varepsilon \to 0} X_\varepsilon(t)$, is compact. Moreover, the map $(\varepsilon, t) \to X_\varepsilon(t)$ is continuous. Hence $\mathcal{K} = \mathrm{cl} \cup_{t \in I} \cup_{\varepsilon \in [0,1]} X_\varepsilon(t) \subset E_1$ is a compact set. Due to Corollary 1, there exists a compact set $\hat{K}$ such that $y(t) \in \hat{K}$ for every t and every solution $y(\cdot)$ of (4) with P replaced by $\mathcal{K}$. Therefore, for every solution $(x_\varepsilon(\cdot), y_\varepsilon(\cdot))$ one has that $x_\varepsilon(t) \in \mathcal{K}$ and $y_\varepsilon(t) \in \hat{K}$. Consequently, the set $K = \mathcal{K} \times \hat{K}$ is the one we need. □

4. Convergence of the fast trajectories. Let $f : I \times E_2 \to \mathbb{R}$ be almost continuous and integrably bounded. The set of all such functions becomes a Banach space with the norm

$$\|f\|_2 = \int_I \sup_{\|y\| \le M} |f(t, y)|\, dt.$$

Denote this space by $\tilde{E}$. Every continuous function $y : I \to E_2$ can be considered as an element of $\tilde{E}^*$. The sequence $\{\nu_i\}_{i=1}^\infty \subset \tilde{E}^*$ is said to converge to ν in $\tilde{E}^*$-weak* topology if it converges to ν for every $f(\cdot, \cdot) \in \tilde{E}$.

Consider the elements of $\tilde{E}$ restricted on the compact set $\hat{K} \subset E_2$ in Corollary 1. The Banach space of all such elements is isometrically isomorphic to $L^1(I, C(\hat{K}))^*$. With a measurable function $f : \mathbb{R} \to E_2$ and an interval $[a, b] \subset \mathbb{R}$, we associate the probability measure

$$D(f(\cdot), [a, b], \omega) = \frac{1}{b - a} \mathrm{meas}\{t \in [a, b] \mid f(t) \in \omega\},$$

where $\omega \subset E_2$ is a Borel set and meas is the Lebesgue measure. Consider the differential inclusion

$$\dot{y}(\tau) \in S(y(\tau)), \quad y(t) = y^\tau,\ \tau \in [t, \infty). \tag{6}$$

Denote by $P(E)$ the set of all probability measures on E. For $A \subset E_2$ define $A^\eta = \{x \in E_2 \mid \mathrm{dist}(x, A) \le \eta\}$. If ν_1, ν_2 are probability measures in the Borel σ algebra of E_2, we define the Prochorov's distance as

$$\rho_P(\nu_1, \nu_2) = \inf\{\eta > 0 \mid\ \nu_1(A) \le \nu_2(A^\eta) + \eta;\ \nu_2(A) \le \nu_1(A^\eta) + \eta \text{ for every Borel set } A \subset E_2\}.$$

DEFINITION 1. *A probability measure* ν *is a limit invariant measure of* (6) *if there exists a solution* $y(\cdot)$ *defined on* $[t, \infty)$ *such that* $D(y(\cdot), [t, T_k])$ *converges to* ν *in* $P(E_2)$ *for some sequence* $T_k \to \infty$ *with respect to Prochorov's distance. If* γ *is in the closed convex hull of the limit measures, then it is called an invariant measure of* (6).

Remark 3. The above definition is an equivalent form (cf. [2]) of Definition 3.1 of [1].

The following lemma is a consequence of Theorem 1.

LEMMA 6. *Under the conditions of Theorem* 1, *there exists a limit measure* ν *of*

$$\dot{y}(\tau) \in \overline{\text{co}}\, G(x, y(\tau), U), \quad y(0) = y^0 \in \hat{K},\ x \in \mathcal{K}, \tag{7}$$

where $\mathcal{K}$ *is as defined in the proof of Corollary* 1.

The following theorem extends Theorem 4 of [10] and Theorem 7.4 of [1] to infinite dimensions.

THEOREM 2. *Under the conditions of Theorem* 1, *the solution set* $Z(\varepsilon)$ *of* (1) *has a limit denoted by* $Z(0)$ *with respect to* $C(I, E_1) \times [L^1(I, C(\hat{K}))]^*$*-weak* topology. Furthermore, for every* $(x(\cdot), \nu(\cdot)) \in Z(0)$ *one has* $\dot{x} \in V(x)$, $x(0) = x_0$, *and* $\nu(t)$ *is an invariant measure of* (7) *(with* 0 *replaced by* t *and* x *by* $x(t)$*) almost everywhere in* I.

Proof. Let $\varepsilon \to 0$, and let $\{(x_\varepsilon, y_\varepsilon)\}_{\varepsilon>0}$ be a net of solutions of (1). Due to Corollary 1 there exists a compact K with $(x_\varepsilon(t), y_\varepsilon(t)) \in K$. The net $\{x_\varepsilon\}_{\varepsilon>0}$ is bounded and equicontinuous. Furthermore, $\{y_\varepsilon\}_{\varepsilon>0}$ is $[L^1(I, C(\hat{K}))]^*$ bounded; i.e., there exists a point of density (x_0, ν_0) of this sequence. Denote by Z_0 the set of all such points of density for all sequences $\{(x_\varepsilon, y_\varepsilon)\}_{\varepsilon>0}$ of solutions of (1). We will prove that $Z_0 = Z(0)$.

Let $(x, \nu) \in Z_0$; i.e., there exist a sequence $\{\varepsilon_i\}_{i=1}^\infty$ and a corresponding sequence $\{(x_i, y_i)\}_{i=1}^\infty$ of solutions of (1) converging to (x, ν) in the considered topology. It remains to show the existence of $(x_\varepsilon, y_\varepsilon) \in Z(\varepsilon)$ such that $x_\varepsilon \to x$ in $C(I, E_1)$ and $y_\varepsilon \to \nu$ in $[L^1(I, C(K, E_2))]^*$-weak*. To this end consider the following systems (denoted by (SS) for convenience):

$$\begin{aligned}
&\dot{x}(t) \in F(x, y, u),\ x(0) = x^0,\\
&\dot{w}_1(t) \in f_1(t, y(t)),\ w_1(0) = 0,\\
&\cdots\cdots\cdots\cdots\cdots\cdots\\
&\dot{w}_k(t) \in f_k(t, y(t)),\ w_k(0) = 0,\\
&\varepsilon\dot{y}(t) \in G(x, y, u),\ y(0) = y^0.
\end{aligned}$$

Here $\{f_i\}_{i=1}^\infty$ is a dense in $L^1(I, C(\hat{K}))$ sequence of functions that are almost continuous in t and Lipschitz in y. It is not difficult to see that Theorem 1 is valid also for systems of the form given above. Therefore, the slow part $(X(\varepsilon), W^k(\varepsilon))$ of the solution set of (SS) has a limit in $C(I, E_1) \times C(I, \mathbb{R}^k)$ topology. Let

$$\big(\dot{z}, \dot{w}^k\big) \in V^k(z, w^k), \quad z(0) = x_0, \quad W^k(0) = 0 \text{ for } w^k = (w_1, \ldots, w_k)$$

be corresponding to (SS) differential inclusion (1). Fix k, and let $\delta > 0$ be given. By Theorem 1, there exists $\varepsilon_k(\delta)$ such that

$$D_H\big((X(\varepsilon), W^k(\varepsilon)), (X(0), W^k(0))\big) < \delta \quad \text{for } 0 < \varepsilon \le \varepsilon_k(\delta).$$

Choose a sequence $\{\delta_m\}_{m=1}^\infty$ with $\delta_m > \delta_{m+1}$ and $\lim_{m\to\infty} \delta_m = 0$. Then there exists $\varepsilon_m \to 0$ with

$$D_H\big(\big(X(\varepsilon), W^m(\varepsilon)\big), \big(X(0), W^m(0)\big)\big) < \delta_m \text{ for all positive } \varepsilon < \varepsilon_m.$$

Hence, for every $\varepsilon \in [\varepsilon_m, \varepsilon_{m+1})$ there exists $(x_\varepsilon, y_\varepsilon) \in Z(\varepsilon)$ such that

$$\|x_\varepsilon(t) - x(t)\| \le \delta_m \qquad \text{and} \qquad \left\| f_j(\cdot, y(\cdot)) - \int_K f_j(\cdot)\nu(\cdot)(\,dy) \right\|_{L_1} < \delta_m \tag{8}$$

for $j = 1, 2, \dots, m$. Let $\tilde{Z}(\varepsilon)$ be the set of all $(x_\varepsilon, y_\varepsilon) \in Z(\varepsilon)$ satisfying (8) for $\varepsilon \in [\varepsilon_m, \varepsilon_{m+1})$. Then $\tilde{Z}(\varepsilon)$ is nonempty and $C(I, E_1 \times R^m)$ is compact for every $\varepsilon > 0$. For $(x_\varepsilon, y_\varepsilon) \in \tilde{Z}(\varepsilon)$, we have $(x_\varepsilon, y_\varepsilon) \to (x, \nu)$ with respect to the $C(I, E_1)$-strong $\times$ $[L^1(I, C(\hat{K}))]^*$-weak* topology.

In what follows, we follow the proofs of Theorem 7.4 and Corollary 8.3 of [1] to obtain that $\nu(\cdot)$ is an invariant measure. Denote by $\mathcal{M}(x(t))$ the set of all invariant measures of (7) with 0 replaced by t and x by $x(t)$. The last set is nonempty thanks to Lemma 6. From Lemma 5.4 of [1] we know that $\mathcal{M}(\cdot)$ has closed graph. Furthermore, $\mathcal{M}(x(\cdot))$ is measurable (see the proof of Lemma 8.2 of [1]). Let $\tilde{y}_{\varepsilon_j}(\cdot))$ converge to $\nu(\cdot)$ on $0 \le t < t + \Delta \le 1$. From Egorov's theorem we know that for every $\delta > 0$ there exists an open set $E_\delta \subset I$ with $\text{meas}(E_\delta) < \delta$ such that $\Delta(\varepsilon_j) \to 0$ as $j \to \infty$ and $D(\tilde{y}_j(\cdot), [t, t + \Delta_j]) \to \mathcal{M}(x(t))$ uniformly on $t \in I \setminus E_\delta$. Then $\nu(t) \in \mathcal{M}(x(t))$ for a.e. $t \in I$. □

5. Lipschitz continuous solutions. In this section we consider the differential inclusion

$$\begin{pmatrix} \dot{x}(t) \\ \varepsilon \dot{y}(t) \end{pmatrix} \in H(x(t), y(t)), \quad x(0) = x^0, y(0) = y^0, \tag{9}$$

where H is a multivalued mapping from $E := E_1 \times E_2$ into E. Clearly, (9) is more general than (1) in the context of the analysis of this paper. However, the convergence result we are able to obtain below is somewhat weaker than Theorem 1.

For $L > 0$ denote by $Z_L(\varepsilon)$ the set of all $(x_\varepsilon(\cdot), y_\varepsilon(\cdot)) \in Z(\varepsilon)$ that are Lipschitz continuous with a constant L on I for x and on $[\sqrt{\varepsilon}, 1]$ for y. Denote by $H_1(x, y)$ and $H_2(x, y)$ the projections of $H(x, y)$ on E_1 and on E_2, respectively. The following theorem is a generalization of the main result in [11] to infinite-dimensional spaces.

THEOREM 3. *Let the conditions of Theorem* 1 *hold with F and G replaced by H_1 and H_2, respectively. Then there exists a constant $L > 0$ such that $Z_L(\varepsilon) \neq \emptyset$ for every $\varepsilon > 0$, and if $\delta > 0$ is fixed, then $Z_L(\cdot)$ is USC at $\varepsilon = 0$ with respect to $C(I, E_1) \times C([\delta, 1], E_2)$.*

Proof. Fix $\varepsilon > 0$, and let n be a natural number. We set $h = 1/n$. For $k = 1, 2, \dots, n-1$ and a.e. $t \in [kh, (k+1)h]$, we construct successively a solution $(x_\varepsilon^h(\cdot), y_\varepsilon^h(\cdot))$ of (9) such that

$$\varepsilon \frac{d}{dt} \|y_\varepsilon^h(t) - y_\varepsilon^h(t-h)\| \le -\mu \|y_\varepsilon^h(t) - y_\varepsilon^h(t-h)\| + C \|x_\varepsilon^h(t) - x_\varepsilon^h(t-h)\|.$$

If $(x_\varepsilon^h, y_\varepsilon^h)$ is already defined on $[0, kh]$ for $(x_\varepsilon(\cdot), y_\varepsilon(\cdot)) \in Z(\varepsilon)$ and $t \in [kh, (k+1)h]$, then we define

$$\Gamma_\varepsilon^{kh}(t, x, y) = \Big\{ (p, q) \in H(x, y) \mid \varepsilon \Big\langle J(y_\varepsilon^h(t-h) - y), \dot{y}_\varepsilon^h(t-h) - \frac{q}{\varepsilon} \Big\rangle \le -\mu \|y_\varepsilon^h(t-h) - y\|^2 + C \|x_\varepsilon^h(t) - x\|^2 \Big\}.$$

The mapping Γ_ε^{kh} is almost USC with nonempty, convex, and compact values. Therefore, for $t \in [kh, (k+1)h]$ the system

$$\begin{pmatrix} \dot{x}(t) \\ \varepsilon \dot{y}(t) \end{pmatrix} \in \Gamma_\varepsilon^{kh}(t, x(t), y(t)), \quad x(kh) = x_\varepsilon(kh),\ y(kh) = y_\varepsilon(kh)$$

has a solution $(x_\varepsilon(\cdot), y_\varepsilon(\cdot))$. From Lemma 1, $\|x_\varepsilon^h(t+h) - x_\varepsilon^h(t)\| \le Nh$. Furthermore,

$$\varepsilon\big\langle J(y_\varepsilon^h(t) - y_\varepsilon^h(t-h)), \dot{y}_\varepsilon^h(t) - \dot{y}_\varepsilon^h(t-h)\big\rangle \le -\mu\|y_\varepsilon^h(t) - y_\varepsilon^h(t-h)\|^2 + CN^2h^2.$$

Thus

$$\|y_\varepsilon^h(t)-y_\varepsilon^h(t-h)\|^2 \le 2\exp\left(-2\mu\frac{t-h}{\varepsilon}\right)\left[\|y_\varepsilon^h(h)-y_\varepsilon^h(0)\|^2+\int_h^t \exp\left(2\mu\frac{s-h}{\varepsilon}\right)\frac{CN^2h^2}{\varepsilon}ds\right]$$
$$\le C_2h^2\left(1+\frac{1}{\varepsilon}\exp\left(-2\mu\frac{t-h}{\varepsilon}\right)\right)$$

for a constant $C_2 > 0$. Let $h \to 0$. From Theorem 1 of [5] we know that $Z(\varepsilon)$ is compact in the space $C(I, E)$. Hence there exists $(x_\varepsilon(t), y_\varepsilon(t)) = \lim_{h\to 0}(x_\varepsilon^h(t), y_\varepsilon^h(t))$. Also,

$$\|y_\varepsilon(t+\tau) - y_\varepsilon(t)\| \le C_2\left(1 + \frac{1}{\varepsilon}\exp\left(-2\mu\frac{t}{\varepsilon}\right)\right)\tau.$$

Then there exists a constant N_1 such that $\|y_\varepsilon(t+\tau)-y_\varepsilon(t)\| \le N_1\tau$ for $t \in [\sqrt{\varepsilon}, 1-\tau]$. Indeed,

$$\lim_{\varepsilon\to 0}\max_{t\in[\sqrt{\varepsilon},1]}\frac{1}{\varepsilon}\exp\left(-2m\frac{t}{\varepsilon}\right) = 0.$$

Denote $L = \max(N, N_1)$. Let $\{x_\varepsilon(\cdot), y_\varepsilon(\cdot)\}_{\varepsilon>0} \subset Z_L(\varepsilon)$ be the net just defined. It follows from Theorem 1 that there exists a subnet, say, $x_\varepsilon(\cdot)$, converging uniformly on I to $x_0(\cdot)$. Moreover, since $z_\varepsilon(t) = (x_\varepsilon(t), y_\varepsilon(t))$ is in a compact set K (Corollary 2), we obtain that there exists a subnet, say, $(x_\varepsilon(\cdot), y_\varepsilon(\cdot))$, such that $x_\varepsilon(t) \to x_0(t)$ uniformly on I and $y_\varepsilon(t) \to y_0(t)$ uniformly on $[\delta, 1]$ for every $\delta > 0$. Clearly, the limit satisfies

$$\begin{pmatrix}\dot{x}_0(t)\\ 0\end{pmatrix} \in H(x_0(t), y_0(t)) \qquad \text{for a.e. } t \in I, \qquad x_0(0) = x^0,$$

where $y_0(\cdot)$ is Lipschitz continuous with a constant L on the interval I. □

Note that, without the restriction to equi-Lipschitz trajectories, the trajectory map $Z(\cdot)$ may be not USC at $\varepsilon = 0$, even in finite dimensions.

A VARIATIONAL APPROACH TO NONLINEAR ESTIMATION*

SANJOY K. MITTER† AND NIGEL J. NEWTON‡

Abstract. We consider estimation problems, in which the estimand, X, and observation, Y, take values in measurable spaces. Regular conditional versions of the forward and inverse Bayes formula are shown to have dual variational characterizations involving the minimization of *apparent information* and the maximization of *compatible information*. These both have natural information-theoretic interpretations, according to which Bayes' formula and its inverse are optimal information processors. The variational characterization of the forward formula has the same form as that of Gibbs measures in statistical mechanics. The special case in which X and Y are diffusion processes governed by stochastic differential equations is examined in detail. The minimization of apparent information can then be formulated as a stochastic optimal control problem, with cost that is quadratic in both the control and observation fit. The dual problem can be formulated in terms of infinite-dimensional deterministic optimal control. Local versions of the variational characterizations are developed which quantify information *flow* in the estimators. In this context, the information conserving property of Bayesian estimators coincides with the Davis–Varaiya martingale stochastic dynamic programming principle.

Key words. Bayesian inference, information theory, Legendre-type transforms, nonlinear filtering, stochastic optimal control

1. Introduction.

This article investigates a variational formulation of Bayesian estimation with a natural information-theoretic interpretation. The two "directions" of an abstract Bayes formula (likelihood function to posterior distribution and vice-versa) are given variational representations. The forward representation involves the minimization of *apparent information* of probability measures on the space of the estimand. This apparent information is made up of two parts: the information gain of the measure over the prior distribution for the estimand and a *residual* term representing the information value of the observation, complementary to this. The apparent information of probability measures is greater than or equal to the total information in the observation, with equality if and only if the measure is the posterior distribution of the estimand. Thus the (forward) Bayes formula can be thought of as an optimal "information processor" in that it balances input and output information. Suboptimal processors appear to have access to more information than there is in the observation. The variational representation of the inverse Bayes formula involves the maximization

of *compatible information* of likelihood functions on the space of the estimand. This is defined to be the difference between the information in an unspecified observation associated with the likelihood function and that part of this information complementary to the (given) posterior distribution. The compatible information of likelihood functions is less than or equal to the information gain of the posterior distribution over the prior, with equality if and only if the likelihood function is equivalent to that provided by the inverse Bayes formula. Once again, the inverse Bayes formula can be thought of as an optimal processor, balancing input and output information. However, in this case, rather than appearing to have an additional source of information, suboptimal processors lose (or fail to make use of) part of the input information.

In section 2, the estimand, X, and the observation, Y, of the Bayesian problem are supposed to take values in Borel spaces $(\mathbf{X}, \mathcal{X})$ and $(\mathbf{Y}, \mathcal{Y})$, respectively. The starting point is a "regular conditional" version of the Bayes formula. In section 3, the results are specialized to the estimation of diffusion processes with partial observations. In that context, the regular conditional probability distribution can be chosen to be continuous in the observations. It also has the key property of being Markovian. This means that the family of measures over which apparent information is minimized can be restricted to the distributions of the process X when a "finite energy" feedback control is applied through the drift coefficient. Thus, in this case, the minimization of apparent information can be interpreted in terms of a problem in stochastic optimal control. This is explored in section 4.

The dual variational problem for diffusion processes is developed in section 5. One interpretation of it is as a problem in infinite-dimensional deterministic optimal control. The optimal trajectory of the dual problem is a "likelihood filter" for the process X in reversed time, from which the corresponding nonlinear filter can be found. This gives a new interpretation to a connection between an optimal control problem in one time direction and a nonlinear filter in the other which was made for nondegenerate diffusions in [6] via the Hopf transformation and used to give existence and uniqueness results for the unnormalized conditional density equation with unbounded observations. The results of sections 3–5 are established under fairly weak conditions. In particular, they include the case of degenerate diffusions.

In the context of estimators for diffusion processes, there is a "local" version of the variational formulations which characterizes flow rates of information and shows that Bayesian processors are conservative in the sense that they balance input and output flow rates. This is the subject of section 6.

A variational representation of the Fokker–Planck equation for diffusion processes is discussed in [10]. This involves the minimization of the "energy" of drift coefficients over those that give rise to a particular set of marginal densities. There, as here, the modification of the drift coefficient can be interpreted as the application of a *control* term, which re-expresses the variational problem as one in optimal control. The two problems are somewhat different though. In particular, the controls admitted in [10] give rise to mutually singular transition probabilities, which are certainly not permitted in the present context.

A preliminary account of some of the results herein was reported in [11].

2. A variational formulation of Bayesian estimation. Let $(\Omega, \mathcal{F}, P)$ be a probability space, $(\mathbf{X}, \mathcal{X})$ and $(\mathbf{Y}, \mathcal{Y})$ Borel spaces, and $X : \Omega \to \mathbf{X}$ and $Y : \Omega \to \mathbf{Y}$ measurable mappings with distributions P_X, P_Y, and P_{XY} on $\mathcal{X}$, $\mathcal{Y}$, and $\mathcal{X} \times \mathcal{Y}$,

respectively. Suppose that

(H1) there exists a σ-finite (reference) measure, λ_Y, on $\mathcal{Y}$ such that $P_{XY} \ll P_X \otimes \lambda_Y$. (This could be P_Y itself.)

Let $Q : \mathbf{X} \times \mathbf{Y} \to [0, \infty)$ be a version of the associated Radon–Nikodym derivative, and

$$\bar{\mathbf{Y}} = \left\{ y \in \mathbf{Y} : 0 < \int_{\mathbf{X}} Q(x, y) P_X(dx) < \infty \right\}; \tag{2.1}$$

then $\bar{\mathbf{Y}} \in \mathcal{Y}$ and $P_Y(\bar{\mathbf{Y}}) = 1$. Let $H : \mathbf{X} \times \mathbf{Y} \to (-\infty, +\infty]$ be defined by

$$\begin{aligned} H(x, y) &= -\log(Q(x, y)) \qquad \text{if } y \in \bar{\mathbf{Y}}, \\ &\quad 0 \qquad \text{otherwise;} \end{aligned} \tag{2.2}$$

then $P_{X|Y} : \mathcal{X} \times \mathbf{Y} \to [0, 1]$, defined by

$$P_{X|Y}(A, y) = \frac{\int_A \exp(-H(x, y)) P_X(dx)}{\int_{\mathbf{X}} \exp(-H(x, y)) P_X(dx)}, \tag{2.3}$$

is a *regular conditional probability distribution* for X given Y; i.e.,

$P_{X|Y}(\,\cdot\,, y)$ is a probability measure on $\mathcal{X}$ for each y,

$P_{X|Y}(A, \,\cdot\,)$ is $\mathcal{Y}$-measurable for each A, and

$P_{X|Y}(A, Y) = P(X \in A \,|\, Y)$ a.s.

Equations (2.1)–(2.3) constitute an "outcome-by-outcome" abstract Bayes formula, yielding a posterior probability distribution for X for each outcome of Y. Of course, for any y belonging to a set of P_Y-measure zero, $P_{X|Y}(\,\cdot\,, y)$ depends on the choice of version of the Radon–Nikodym derivative Q. However, in particular examples, we can often find a version such that $P_{X|Y}(A, \,\cdot\,)$ is continuous for each $A \in \mathcal{X}$.

Let $\mathcal{P}(\mathcal{X})$ be the set of probability measures on $(\mathbf{X}, \mathcal{X})$ and $\mathcal{H}(\mathbf{X})$ the set of $(-\infty, +\infty]$-valued, measurable functions on the same space. For $\tilde{P}_X, \hat{P}_X \in \mathcal{P}(\mathcal{X})$, and $\tilde{H} \in \mathcal{H}(\mathbf{X})$, we define

$$\begin{aligned} h(\tilde{P}_X \,|\, \hat{P}_X) &= \int_{\mathbf{X}} \log\left(\frac{d\tilde{P}_X}{d\hat{P}_X}\right) d\tilde{P}_X \quad \text{if } \tilde{P}_X \ll \hat{P}_X \text{ and the integral exists,} \\ &\quad +\infty \qquad \text{otherwise;} \end{aligned} \tag{2.4}$$

$$\begin{aligned} i(\tilde{H}) &= -\log\left(\int_{\mathbf{X}} \exp(-\tilde{H}) dP_X\right) \quad \text{if } 0 < \int_{\mathbf{X}} \exp(-\tilde{H}) dP_X < \infty, \\ &\quad -\infty \qquad \text{otherwise;} \end{aligned} \tag{2.5}$$

$$\begin{aligned} \langle \tilde{H}, \tilde{P}_X \rangle &= \int_{\mathbf{X}} \tilde{H} d\tilde{P}_X \qquad \text{if the integral exists,} \\ &\quad +\infty \qquad \text{otherwise.} \end{aligned} \tag{2.6}$$

It is well known that the relative entropy $h(\tilde{P}_X \,|\, \hat{P}_X)$ can be interpreted as the *information gain* of the probability measure $\tilde{P}_X$ over $\hat{P}_X$. In fact, any version of $-\log(d\tilde{P}_X / d\hat{P}_X)$ is a generalization of the Shannon information for X. For almost all x, it is a measure of the "relative degree of surprise" in the outcome $X = x$ for the two distributions $\tilde{P}_X$ and $\hat{P}_X$. Thus $h(\tilde{P}_X \,|\, \hat{P}_X)$ is the average *reduction* in the degree of surprise in this outcome arising from the acceptance of $\tilde{P}_X$ as the distribution for X, rather than $\hat{P}_X$.

If we interpret $\exp(-\tilde{H})$ as a likelihood function for X, associated with some (unspecified) observation, then $\tilde{H}(x)$ is the "residual degree of surprise" in that observation if we already know that $X = x$, and $i(\tilde{H})$ is the "total degree of surprise" in that observation, i.e., the information in the unspecified observation, if all we know about X is its prior P_X. In what follows we shall call $\tilde{H}(X)$ the *X-conditional information* in the unspecified observation and $i(\tilde{H})$ the information in that observation. (Of course, $H(X, y)$ and, respectively, $i(H(\,\cdot\,, y))$ are the X-conditional information and the information in the observation that $Y = y$.)

PROPOSITION 2.1. *Suppose that* (H1) *is satisfied, and H and $P_{X|Y}$ are as defined above. Then for any y such that*

$$-\int_{\mathbf{X}} H(x,y)\exp(-H(x,y))P_X(dx) < \infty, \quad (\textit{where } +\infty\exp(-\infty) = 0), \tag{2.7}$$

$$\text{(i)} \qquad i(H(\,\cdot\,,y)) = \min_{\tilde{P}_X \in \mathcal{P}(\mathcal{X})} \left\{ h(\tilde{P}_X \,|\, P_X) + \langle H(\,\cdot\,,y), \tilde{P}_X \rangle \right\}; \tag{2.8}$$

$$\text{(ii)} \qquad h(P_{X|Y}(\,\cdot\,,y) \,|\, P_X) = \max_{\tilde{H} \in \mathcal{H}(\mathbf{X})} \left\{ i(\tilde{H}) - \langle \tilde{H}, P_{X|Y}(\,\cdot\,,y) \rangle \right\}; \tag{2.9}$$

(iii) *$P_{X|Y}(\,\cdot\,, y)$ is the unique minimizer in* (2.8)*;*
(iv) *if H^* is a maximizer in* (2.9)*, then there exists a real constant K such that*

$$H^*(X) = H(X,y) + K \quad a.s.$$

Proof. If $y \in \bar{\mathbf{Y}}$ and (2.7) holds, then $h(P_{X|Y}(\,\cdot\,,y) \,|\, P_X) < \infty$, $i(H(\,\cdot\,,y)) > -\infty$, and $H(\,\cdot\,,y) \in L_1(P_{X|Y}(\,\cdot\,,y))$. This is also true if $y \notin \bar{\mathbf{Y}}$ since, in that case, $H(\,\cdot\,,y) = 0$ and $P_{X|Y}(\,\cdot\,,y) = P_X$. Thus it is clear that the minimum in (2.8) is less than $+\infty$, and the maximum in (2.9) is greater than $-\infty$.

Suppose that, for $\tilde{P}_X \in \mathcal{P}(\mathcal{X})$, $h(\tilde{P}_X \,|\, P_X) < \infty$ and $H(\,\cdot\,,y) \in L_1(\tilde{P}_X)$. It readily follows that $\tilde{P}_X \ll P_{X|Y}(\,\cdot\,,y)$, so that

$$h(\tilde{P}_X \,|\, P_X) = \int_{\mathbf{X}} \left(\log\left(\frac{d\tilde{P}_X}{dP_{X|Y}}(x,y) \right) + \log\left(\frac{dP_{X|Y}}{dP_X}(x,y) \right) \right) \tilde{P}_X(dx),$$

and

$$h(\tilde{P}_X \,|\, P_X) + \langle H(\,\cdot\,,y), \tilde{P}_X \rangle = i(H(\,\cdot\,,y)) + h(\tilde{P}_X \,|\, P_{X|Y}(\,\cdot\,,y)). \tag{2.10}$$

It is easy to show that, for any $\tilde{P}_X \in \mathcal{P}(\mathcal{X})$, the relative entropy functional $h(\,\cdot\,|\,\tilde{P}_X)$ is nonnegative, evaluates to zero at $\tilde{P}_X$, and is strictly convex on the subset of $\mathcal{P}(\mathcal{X})$ for which it is finite. This establishes parts (i) and (iii).

Suppose now that, for $\tilde{H} \in \mathcal{H}(\mathbf{X})$, $i(\tilde{H}) > -\infty$ and $\tilde{H} \in L_1(P_{X|Y}(\,\cdot\,,y))$. Let $\tilde{P}_X$ be defined by (2.3) with $\tilde{H}$ replacing $H(\,\cdot\,,y)$. It readily follows that $P_{X|Y}(\,\cdot\,,y) \ll \tilde{P}_X$, and so

$$\begin{aligned} i(\tilde{H}) - \tilde{H}(X) &= \log\left(\frac{d\tilde{P}_X}{dP_X}(X) \right) \\ &= \log\left(\frac{dP_{X|Y}}{dP_X}(X,y) \right) - \log\left(\frac{dP_{X|Y}}{d\tilde{P}_X}(X,y) \right). \end{aligned}$$

Thus

$$i(\tilde{H}) - \langle \tilde{H}, P_{X|Y}(\,\cdot\,, y)\rangle = h(P_{X|Y}(\,\cdot\,, y) \,|\, P_X) - h(P_{X|Y}(\,\cdot\,, y) \,|\, \tilde{P}_X). \tag{2.11}$$

Suppose that there is a set $A \in \mathcal{X}$ for which $P_{X|Y}(A, y) = 0$ but $\tilde{P}_X(A) > 0$. Let $\tilde{P}'_X$ be defined by

$$\tilde{P}'_X(B) = \left(\tilde{P}_X(A^C)\right)^{-1} \tilde{P}_X(A^C \cap B) \qquad \text{for all } B \in \mathcal{X}.$$

Then $h(P_{X|Y}(\,\cdot\,, y) \,|\, \tilde{P}'_X) < h(P_{X|Y}(\,\cdot\,, y) \,|\, \tilde{P}_X)$, and so any maximizer in (2.11) must be absolutely continuous with respect to $P_{X|Y}(\,\cdot\,, y)$. It is easy to show that, for any $\tilde{P}_X \in \mathcal{P}(\mathcal{X})$, the relative entropy functional $h(\tilde{P}_X \mid \cdot\,)$ is nonnegative, evaluates to zero at $\tilde{P}_X$, and is strictly convex on the subset of $\mathcal{P}(\mathcal{X})$ consisting of measures that are absolutely continuous with respect to $\tilde{P}_X$. This establishes parts (ii) and (iv). ∎

Remark 1. If the mutual information between X and Y is finite,

$$\int_{\mathbf{X}\times\mathbf{Y}} \log\left(\frac{dP_{XY}}{d(P_X \otimes P_Y)}\right) dP_{XY} < \infty, \tag{2.12}$$

then there exists a version of Q for which (2.7) is satisfied for all y.

Remark 2. Proposition 2.1 is a special case of an energy-entropy duality that plays a major role in statistical physics and in the theory of large deviations. More general results of this nature are widely available in the literature. (See, for example, [5].) Our aim in this section is to provide an information-theoretic interpretation of the result in the Bayesian context. The simple proof we provide here makes use of the special nature of that context.

Parts (i) and (ii) of Proposition 2.1 both concern the processing of information over and above that in the prior P_X. In part (i), the source of additional information is the observation that $Y = y$. The abstract Bayes formula extracts the part of this information pertinent to X, $h(P_{X|Y}(\,\cdot\,, y) \,|\, P_X)$, and leaves the residual information, $\langle H(\,\cdot\,, y), P_{X|Y}(\,\cdot\,, y)\rangle$. One can think of the input information as being held in the likelihood function, $\exp(-H(\,\cdot\,, y))$, and the extracted information as being held in the distribution, $P_{X|Y}(\,\cdot\,, y)$. An arbitrary estimation procedure that postulates $\tilde{P}_X$ as a "postobservation" distribution for X appears to have access to additional information, in that it yields an information gain on X of $h(\tilde{P}_X \,|\, P_X)$, and a residual information of $\langle H(\,\cdot\,, y), \tilde{P}_X\rangle$. The sum of these two terms (the term in brackets on the right-hand side of (2.8)) is strictly greater than the actual information available, $i(H(\,\cdot\,, y))$, unless $\tilde{P}_X = P_{X|Y}(\,\cdot\,, y)$. We shall call it the *apparent information* of the estimator $\tilde{P}_X$. (Implicit in the interpretation of $h(\tilde{P}_X \,|\, P_X)$ as an information gain is the assumption that $\tilde{P}_X$ represents a rational belief about X given the prior and some additional knowledge, such as an observation.)

In part (ii), the source of additional information is the posterior distribution, $P_{X|Y}(\,\cdot\,, y)$. The aim now is to postulate an observation (with likelihood function $\exp(-\tilde{H})$) which would give rise to this distribution. The input information here, $h(P_{X|Y}(\,\cdot\,, y) \,|\, P_X)$, is merged with the residual information of the postulated observation, $\langle \tilde{H}, P_{X|Y}(\,\cdot\,, y)\rangle$, and the result is greater than or equal to the total information in the postulated observation, $i(\tilde{H})$, with equality if and only if the observation is compatible with $P_{X|Y}(\,\cdot\,, y)$ in the sense of part (iv) of the proposition. The term in brackets on the right-hand side of (2.9) can be thought of as that part of the information in the postulated observation compatible with $P_{X|Y}(\,\cdot\,, y)$. We shall call it the

compatible information of the likelihood function $\exp(-\tilde{H})$. Another interpretation is that the input information, $h(P_{X|Y}(\cdot\,, y)\,|\,P_X)$, is processed to produce compatible information resulting in a net loss of information except when the processor is optimal.

Throughout the rest of the paper, the apparent information and compatible information will be denoted by $F(\tilde{P}_X, y)$ and $G(\tilde{H}, y)$, i.e.,

$$F(\tilde{P}_X, y) = h(\tilde{P}_X \,|\, P_X) + \langle H(\cdot\,, y), \tilde{P}_X \rangle, \tag{2.13}$$

$$G(\tilde{H}, y) = i(\tilde{H}) - \langle \tilde{H}, P_{X|Y}(\cdot\,, y) \rangle. \tag{2.14}$$

As (2.10) and (2.11) show, the minimization of F is equivalent to the minimization of the *information excess* of the estimator $\tilde{P}_X$, $h(\tilde{P}_X \,|\, P_{X|Y}(\cdot\,, y))$, and the maximization of G is equivalent to the minimization of the *information deficit* of the likelihood function $\exp(-\tilde{H})$, $h(P_{X|Y}(\cdot\,, y)\,|\,\tilde{P}_X)$. In fact (as was pointed out by an anonymous referee), these interpretations still hold in the absence of (2.7). However, in not identifying the source information or the extracted information, they do not show the information processing aspects of Bayesian estimation in quite the same way as the quantities F and G. Moreover, F and G make clear the compromises involved in Bayesian estimation. Part (i) of the proposition shows how $P_{X|Y}(\cdot\,, y)$ compromises between being close to the prior P_X and fitting with the observation $Y = y$, whereas part (ii) shows how $H(\cdot\,, y)$ (or its equivalents) compromise between holding a lot of information but not too much residual information.

Of course it is possible to give other variational characterizations of $P_{X|Y}(\cdot\,, y)$. For example, one could consider it as the minimizer of the total variation norm of the difference measure $\tilde{P}_X - P_{X|Y}(\cdot\,, y)$. However, such characterizations lack the information-theoretic interpretation discussed above: F and G are natural error measures for suboptimal estimation procedures. The characterization (2.8) could be used as a basis for approximations. For example, we may wish to approximate a posterior distribution by a discrete law on a finite partition of $\mathbf{X}$. The size of the partition may be fixed, but we may be able to choose the law and the details of the partition by means of a finite number of parameters. The characterization (2.8) could form the basis of an optimization with respect to this set of parameters. Similarly, the characterization (2.9) could be used as a basis for the study of modeling errors, in that it shows the information loss arising from the use of an incorrect likelihood function. Since the use of an incorrect prior, P_X^e (with $P_X^e \ll P_X$), with a Bayesian procedure is equivalent to the use of the incorrect likelihood function

$$\exp(-H^e(\cdot\,, y)) = \exp(-H(\cdot\,, y)) \frac{dP_X^e}{dP_X},$$

(2.9), with $\tilde{H} = H^e(\cdot\,, y)$, also shows the information loss arising through the use of an incorrect prior. Furthermore, if there were any uncertainty in the likelihood function or the prior, the resulting information loss could be studied by means of game-theoretic methods.

Proposition 2.1 is an instance of a Legendre-type transform between the relative entropy of probability measures and the logarithm of the exponential moment of real-valued random variables. A similar transform occurs in the characterization of Gibbs measures in statistical mechanics [8]. In that context, $(\mathbf{X}, \mathcal{X})$ is the *configuration space* of a physical system (the Cartesian product of a number, N, of identical spaces), H is a *Hamiltonian* representing the energies of the configurations, and F is the *free energy*

of the probability measure $\tilde{P}_X$ with respect to the reference measure, P_X, and H. A Gibbs measure represents a thermodynamic state of the system in thermodynamic equilibrium. If N is finite, then there is only one Gibbs measure, and it takes the form (2.3). Gibbs theory comes into its full richness only when N is infinite, in which case there may be multiple Gibbs measures, and formulae such as (2.3) are no longer appropriate. However, variational characterizations are. We note that the Bayesian estimator can be seen to compromise between being close to the prior and fitting with the observation in exactly the same way that a thermodynamic system in equilibrium compromises between maximizing entropy and minimizing average energy.

3. Path estimators. The techniques of section 2 are specialized here for the case in which the estimand, X, and observation, Y, are, respectively, continuous $\mathbb{R}^n$- and $\mathbb{R}^d$-valued processes governed by the following Itô integral equations:

$$\begin{aligned} &X_t = X_0 + \int_0^t b(X_s, s)\, ds + \int_0^t \sigma(X_s, s)\, dV_s \quad \text{for } 0 \le t \le T, \\ &X_0 \sim \mu, \end{aligned} \tag{3.1}$$

$$Y_t = \int_0^t g(X_s)\, ds + W_t \quad \text{for } 0 \le t \le T, \tag{3.2}$$

where $X_t, V_t \in \mathbb{R}^n$, μ is a law on $(\mathbb{R}^n, \mathcal{B}^n)$, $Y_t, W_t \in \mathbb{R}^d$, and b, σ, and g are measurable mappings. Under suitable regularity conditions, these equations will be unique in law and have a weak solution $(\Omega, \mathcal{F}, (\mathcal{F}_t), P, (V, W), (X, Y))$, i.e., a filtered probability space supporting an $(n + d)$-dimensional Brownian motion (V, W) and an $(n + d)$-dimensional semimartingale (X, Y) such that (3.1) and (3.2) are satisfied for all t. The abstract spaces $(\mathbf{X}, \mathcal{X})$ and $(\mathbf{Y}, \mathcal{Y})$ of section 2 now become the spaces $(C([0, T]; \mathbb{R}^n), \mathcal{B}_T)$ and $(C([0, T]; \mathbb{R}^d), \mathcal{B}_T)$ of continuous functions, topologized by the uniform norm. We continue to use the notation $(\mathbf{X}, \mathcal{X})$ and $(\mathbf{Y}, \mathcal{Y})$, though, for the sake of brevity.

Let λ_Y be Wiener measure on $(\mathbf{Y}, \mathcal{Y})$. Under suitable conditions on μ, b, σ, and g, we might expect (H1) to be satisfied and the mutual information, $\mathbf{E} \log(dP_{XY}/d(P_X \otimes \lambda_Y)(X, Y))$, to be finite. This will allow us to proceed as in section 2 to construct a function H on $X \times Y$, and a corresponding regular conditional probability, $P_{X|Y}$, such that (2.7) holds for all y. Furthermore, if we can show that $P_{X|Y}(\cdot\,, y) \sim P_X$, then we shall be able to construct a continuous strictly positive martingale M_y on Ω such that

$$M_{y,t} = \mathbf{E}\left(\frac{dP_{X|Y}(\cdot\,, y)}{dP_X}(X) \,\middle|\, \mathcal{F}_t^X \right) \quad \text{for } 0 \le t \le T,$$

where $(\mathcal{F}_t^X)$ is the filtration generated by the process X. It will then follow from the Cameron–Martin–Girsanov theory that

$$M_{y,t} = M_{y,0} \exp\left(\int_0^t U'_{y,s}\, (dX_s - b(X_s, s)\, ds) - \frac{1}{2} \int_0^t |\sigma(X_s, s)' U_{y,s}|^2\, ds \right) \tag{3.3}$$

for some progressively measurable $\mathbb{R}^n$-valued process U_y. $P_{X|Y}(\cdot\,, y)$ will then be the distribution of a *controlled* process, X_y, satisfying an equation like (3.1), but with a different initial law and with a control term, $\sigma\sigma'(X_s, s)U_{y,s}$, entering the drift coefficient. The use of the progressively measurable control $\tilde{U}$ instead of U_y will result in a process $\tilde{X}$ having a distribution whose apparent information relative to

$(P_X, H(\cdot, y))$ is greater than or equal to that of X_y. Thus, at least in part, the variational characterization of section 2 will become a problem in stochastic optimal control.

We might also expect $P_{X|Y}(\cdot, y)$ to be Markov (at least for almost all y), in which case it will be appropriate to restrict admissible controls $\tilde{U}$ to *feedback* controls of the form $u(\tilde{X}_t, t)$. It should also then be possible to define regular conditional *transition* probabilities for $P_{X|Y}$. With this in mind, let $(\chi_t, 0 \le t \le T)$ be the coordinate process on $\mathbf{X}$, and

$$\mathcal{X}_s^t = \sigma(\chi_r, s \le r \le t) \quad \text{for } 0 \le s \le t \le T. \tag{3.4}$$

We should be able to construct regular conditional probabilities

$$P_{X|Y}^{s+} : \mathcal{X}_s^T \times \mathbb{R}^n \times C([s,T]; \mathbb{R}^d) \to [0,1]$$

such that, for all $A \in \mathcal{X}_s^T$,

$$P_{X|Y}(A, y) = \int_{R^n} P_{X|Y}^{s+}(A, z, (y_t - y_s, s \le t \le T))\, P_{X|Y}(\chi_s^{-1}(dz), y). \tag{3.5}$$

These will have variational characterizations in terms of the corresponding regular conditional probabilities for the prior, P_X, and appropriately constructed likelihood functions. This will lead toward a *localized* version of the results of section 2.

In what follows, we develop the above ideas in a rigorous manner. We do this by placing constraints on b and σ such that (3.1) has a *strong* solution and then use the techniques of stochastic flows. This has the advantage that we are able to include problems with degenerate diffusion coefficients, which are important in many areas of application. (In fact our approach also applies to some problems not satisfying a hypoellipticity condition.)

The constraints we place on μ, b, σ, and g also fit well with Clark's *robustness* ideas (see [2]). These lead to an explicit function H and corresponding regular conditional probability, $P_{X|Y}$, that is Markov for every y. They also admit unbounded observation functions g, which are needed in the linear case.

We suppose that μ, b, σ, and g satisfy the following technical conditions:

(H2) there exists an $\epsilon > 0$ such that

$$\int_{\mathbb{R}^n} \exp\left(\epsilon |z|^2\right) \mu(dz) < \infty;$$

(H3) σ is bounded, and b and σ are uniformly Lipschitz continuous on compact sets and differentiable with respect to the components of z, the derivatives being continuous and bounded;

(H4) g has continuous first, second, and third derivatives, and there exist $C < \infty$ and $\alpha < \infty$ such that for all $z \in \mathbb{R}^n$

$$\sum_i \left| \frac{\partial g}{\partial z_i}(z) \right| \le C,$$

$$\sum_{i,j} \left| \frac{\partial^2 g}{\partial z_i \partial z_j}(z) \right| \le C(1 + |z|),$$

$$\text{and} \quad \sum_{i,j,k} \left| \frac{\partial^3 g}{\partial z_i \partial z_j \partial z_k}(z) \right| \le C(1 + |z|^\alpha).$$

It follows from (H3) that (3.1) has a *strong* solution $\Phi : \mathbb{R}^n \times \mathbf{X} \to \mathbf{X}$, so that on the probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t), P, X_0, (V, W))$ supporting an $\mathbb{R}^n$-valued random variable X_0 with distribution μ, and $(n+d)$-dimensional vector Brownian motion (V, W), independent of X_0, $(X_t = \Phi_t(X_0, V), \mathcal{F}_t; 0 \le t \le T)$ is a continuous semimartingale satisfying (3.1). (See, for example, [15].)

It follows from (H2)–(H4) that $\mathbf{E}\int_0^T |g(X_t)|^2\,dt < \infty$, and from this and the independence of X and W it follows by standard results (see, for example, [9]) that (H1) is satisfied when the reference measure λ_Y is the Wiener measure and the Radon–Nikodym derivative takes the form

$$\frac{dP_{XY}}{d(P_X \otimes \lambda_Y)}(X, Y) = \exp\left(\int_0^T g(X_t)'\,dY_t - \frac{1}{2}\int_0^T |g(X_t)|^2\,dt\right). \tag{3.6}$$

In order to develop the representations of Proposition 2.1, we first need a version of this that is well defined for all y. Under (H2)–(H4) the process $(g(X_t), \mathcal{F}_t, 0 \le t \le T)$ is a semimartingale, and so it is possible to "integrate by parts" in (3.6) and define Q as any measurable function such that, for each y,

$$Q(X, y) = \exp\left(y_T' g(X_T) - \int_0^T y_t'\,dg(X_t) - \frac{1}{2}\int_0^T |g(X_t)|^2\,dt\right). \tag{3.7}$$

(See [2] and [3].) It can also be shown (see, for example, [13], [14]) that the resulting regular conditional probability, $P_{X|Y}$, is continuous in y in the sense of the topology associated with the convergence of means of bounded measurable functions, that

$$0 < \mathbf{E}Q(X, y) < \infty \qquad \text{for all } y, \tag{3.8}$$

and that

$$\mathbf{E}Q(X, y)\log(Q(X, y)) \le \mathbf{E}Q(X, y)^2 < \infty. \tag{3.9}$$

Thus the set $\bar{\mathbf{Y}}$ of (2.1) can be taken to be the entire space $\mathbf{Y}$ in this case, and (2.7) is satisfied for all y. Proposition 2.1 can thus be applied for each y, and $H = -\log(Q)$.

We can now split the path estimation problem as suggested by (3.5). For any $z \in \mathbb{R}^n$ and any $0 \le s \le T$, let $(X_t^{z,s}; s \le t \le T)$ be the solution of (3.1) on the interval $s \le t \le T$ with "initial condition" $X_s^{z,s} = z$, and let

$$H_p : [0, T] \times [0, T] \times \mathbb{R}^n \times \mathbf{X} \times \mathbf{Y} \to \mathbb{R}$$

be a measurable function such that

$$\begin{aligned} H_p(s, t, z, X^{z,s}, y) = {} & -y_t' g(X_t^{z,s}) + y_s' g(z) + \int_s^t y_r'\,dg(X_r^{z,s}) \\ & + \frac{1}{2}\int_s^t |g(X_r^{z,s})|^2\,dr \quad \text{for } 0 \le s \le t \le T. \end{aligned} \tag{3.10}$$

The fact that such a function exists follows from the "strong solution" hypothesis (H3), as does the decomposition

$$H(X, y) = H_p(0, s, X_0, X, y) + H_p(s, T, X_s, (X_t, s \le t \le T), y). \tag{3.11}$$

$H_p(s,t,z,\cdot\,,\cdot\,)$ is the equivalent of H for the problem of estimating the path $(X_r^{z,s}, s \le r \le t)$ given the observation $(Y_r^{z,s}, s \le r \le t)$, where

$$Y_t^{z,s} = \int_s^t g(X_r^{z,s})\,dr + W_t - W_s \quad \text{for } s \le t \le T.$$

In particular, $H_p(s,T,z,\cdot\,,\cdot\,)$ is the equivalent of H for the problem of estimating $X^{z,s}$ given $Y^{z,s}$. Let $v(z,s,y)$ be the minimum apparent information for this problem; then, according to Proposition 2.1 (i),

$$v(z,s,y) = -\log\left(\mathbf{E}\exp(-H_p(s,T,z,X^{z,s},y))\right). \tag{3.12}$$

It now follows that, for any $A \in \mathcal{X}_0^s$,

$$P_{X|Y}(A,y) = \frac{\mathbf{E}\mathbf{1}_A(X)\exp\left(-H_p(0,s,X_0,X,y) - v(X_s,s,y)\right)}{\mathbf{E}\exp\left(-H_p(0,s,X_0,X,y) - v(X_s,s,y)\right)}, \tag{3.13}$$

and from Jensen's inequality and (3.9) it follows that $H_p(0,s,\chi_0,\cdot\,,y) + v(\chi_s(\cdot\,),s,y)$ satisfies (2.7) for all s. So, from Proposition 2.1, the path measure $P_{X|Y}$ restricted to $\mathcal{X}_0^s$ is the unique probability measure on $\mathcal{X}_0^s$ that minimizes the apparent information

$$F_s(\tilde{P}_{X,s},y) = h(\tilde{P}_{X,s}\,|\,P_{X,s}) + \langle H_p(0,s,\chi_0,\cdot\,,y)\,,\,\tilde{P}_{X,s}\rangle + \langle v(\chi_s,s,y)\,,\,\tilde{P}_{X,s}\rangle, \tag{3.14}$$

where $P_{X,s}$ is the restriction of P_X to $\mathcal{X}_0^s$. It also easily follows that the minimum apparent information in (3.14) does not depend on s.

These arguments show that the variational form of the path estimation problem (3.1), (3.2) can be interpreted in terms of dynamic programming, with value function v. For each s we can split the problem into two subproblems: the estimation of $X^{z,s}$ for each z (resulting in a minimum apparent information of $v(z,s,y)$), followed by the estimation of $(X_t, 0 \le t \le s)$, where $v(X_s,s,y)$ plays a part in the likelihood function. $v(X_s,s,y)$ summarizes that part of the likelihood function associated with increments of Y after time s. The first subproblem can be interpreted in terms of stochastic optimal control, where the cost is the apparent information of the controlled process. This is developed in the next section.

4. A stochastic control formulation. We consider the first variational subproblem discussed above with $s = 0$. In keeping with the comments above on dynamic programming, it turns out that we need consider only feedback controls. Also, because controls are intended to produce a change in measure of the form (3.3), it is appropriate to let the control enter the drift through the map $z \mapsto az$, where $a = \sigma\sigma'$.

Consider the following controlled equation:

$$\tilde{X}_t = \theta + \int_0^t \Big(b(\tilde{X}_s,s) + a(\tilde{X}_s,s)u(\tilde{X}_s,s)\Big)\,ds + \int_0^t \sigma(\tilde{X}_s,s)\,d\tilde{V}_s, \tag{4.1}$$

where the initial condition, θ, is nonrandom. Let $\mathbf{U}$ be the set of measurable functions $u : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n$ with the following properties:

(U1) u is continuous,

(U2) $\mathbf{E}\Gamma^u = 1$, where

$$\Gamma^u = \exp\left(\int_0^T u'\sigma(X_t^{\theta,0},t)\,dV_t - \frac{1}{2}\int_0^T |\sigma' u(X_t^{\theta,0},t)|^2\,dt\right), \tag{4.2}$$

and $(\Omega,\mathcal{F},P)$, V, and $X^{z,s}$ are as defined in section 3.

LEMMA 4.1. *If b and σ satisfy* (H3) *and $u \in \mathbf{U}$, then* (4.1) *has a weak solution and is unique in law.*

Proof. From (H3) and (U1) it follows that

$$P\left(\int_0^T \left|\sigma' u(X_t^{\theta,0}, t)\right|^2 \, dt < \infty\right) = 1.$$

This, together with (U2) and Girsanov's theorem, shows that V^u, defined by

$$V_t^u = V_t - \int_0^t \sigma' u(X_s^{\theta,0}, s)\, ds, \tag{4.3}$$

is a standard Brownian motion under the probability measure P^u, defined by

$$\frac{dP^u}{dP} = \Gamma^u. \tag{4.4}$$

This shows that $(\Omega, \mathcal{F}, (\mathcal{F}_t), P^u, X^{\theta,0}, V^u)$ is a weak solution of (4.1).

Next, suppose that $(\tilde{\Omega}, \tilde{\mathcal{F}}, (\tilde{\mathcal{F}}_t), \tilde{P}, \tilde{X}, \tilde{V})$ is a weak solution of (4.1), and, for each natural number N, let $\tau_N : \mathbf{X} \to [0, T]$ be defined by

$$\tau_N(x) = \inf\{t \geq 0 : |x_t| \geq N\} \wedge T.$$

Since $\tilde{X}$ is continuous, $\tilde{P}(\tau_N(\tilde{X}) \to T) = 1$. Also, since u satisfies (U1),

$$\tilde{\mathbf{E}} \exp\left(\frac{1}{2}\int_0^{\tau_N(\tilde{X})} \left|\sigma' u(\tilde{X}_s, s)\right|^2 \, ds\right) < \infty,$$

and so, from a standard variation of Novikov's theorem (see, for example, Theorem 6.1 in [9]), it follows that $(M_t, \tilde{\mathcal{F}}_t, 0 \leq t \leq T)$, where

$$M_t = \exp\left(-\int_0^t u'\sigma(\tilde{X}_s, s)\, d\tilde{V}_s - \frac{1}{2}\int_0^t \left|\sigma' u(\tilde{X}_s, s)\right|^2 \, ds\right) \tag{4.5}$$

is a local martingale with respect to the sequence of stopping times $(\tau_N(\tilde{X});\ N = 1, 2, \ldots)$. Let

$$\tilde{V}_t^N = \tilde{V}_t + \int_0^{t\wedge\tau_N(\tilde{X})} \sigma' u(\tilde{X}_s, s)\, ds;$$

then, by Girsanov's theorem, $\tilde{V}^N$ is a standard Brownian motion under the probability measure $\tilde{P}^N$, defined by $d\tilde{P}^N = M_{\tau_N(\tilde{X})} d\tilde{P}$. Let $(\mathcal{X}_t;\ 0 \leq t \leq T)$ be the filtration on $(\mathbf{X}, \mathcal{X})$ generated by the coordinate process (χ_t). Since

$$\tilde{X}_{t\wedge\tau_N(\tilde{X})} = \Phi_{t\wedge\tau_N(\tilde{X})}(\theta, \tilde{V}^N) \qquad \text{for } 0 \leq t \leq T,$$

where Φ is the strong solution to (3.1), the law of $\tilde{X}$ restricted to $\mathcal{X}_{\tau_N}$ is identical to that of $X^{\theta,0}$ under P^u, restricted to the same sigma-field. Finally, for any $A \in \mathcal{X}$,

$$\begin{aligned}\tilde{P}(\tilde{X} \in A, \tau_N(\tilde{X}) = T) &= \tilde{P}(\tilde{X} \in A) - \tilde{P}(\tilde{X} \in A, \tau_N(\tilde{X}) < T)\\ &\to \tilde{P}(\tilde{X} \in A),\end{aligned}$$

and so, since the events on the left-hand side each belong to one of $(\mathcal{X}_{\tau_N};\ N = 1, 2, \ldots)$, the law of $\tilde{X}$ on $\mathcal{X}$ is identical to that of $X^{\theta,0}$ under P^u. □

Let $(\tilde{\Omega}, \tilde{\mathcal{F}}, (\tilde{\mathcal{F}}_t), \tilde{P}, \tilde{X}, \tilde{V})$ be a weak solution of (4.1) for some $u \in \mathbf{U}$. We define the cost for controls in $\mathbf{U}$ as the apparent information of the resulting distribution of $\tilde{X}$, $\tilde{P}_X$. This is measured relative to the prior $P_X^{\theta,0}$ (the distribution of $X^{\theta,0}$) and $H_p(0, T, \theta, \cdot\,, y)$ (as defined in (3.10)).

$$
\begin{aligned}
J(u, \theta, y) &= h(\tilde{P}_X \mid P_X^{\theta,0}) + \langle H_p(0, T, \theta, \cdot\,, y), \tilde{P}_X \rangle \\
&= \frac{1}{2}\tilde{\mathbf{E}} \int_0^T |\sigma' u(\tilde{X}_t, t)|^2 \, dt - y_T' g(\theta) + \frac{1}{2}\tilde{\mathbf{E}} \int_0^T |g(\tilde{X}_t)|^2 \, dt \\
&\quad -\tilde{\mathbf{E}} \int_0^T (y_T - y_t)'(\mathcal{L}g + \mathcal{D}gau)(\tilde{X}_t, t) \, dt \qquad \text{if the integrals exist,} \\
&\quad +\infty \qquad \text{otherwise,}
\end{aligned} \tag{4.6}
$$

where $\mathcal{L}$ is the differential operator associated with X,

$$
\mathcal{L} = \sum_i b_i \frac{\partial}{\partial z_i} + \frac{1}{2} \sum_{i,j} a_{i,j} \frac{\partial^2}{\partial z_i \partial z_j},
$$

and $\mathcal{D}$ is the row-vector jacobian operator, $\mathcal{D} = [\partial/\partial z_1 \ \partial/\partial z_2 \cdots \partial/\partial z_n]$. The cost functional has a more appealing form in the special case that the observation path, y, is everywhere differentiable:

$$
J(u, \theta, y) = \frac{1}{2}\tilde{\mathbf{E}} \int_0^T \left(|\sigma' u(\tilde{X}_t, t)|^2 + |\dot{y}_t - g(\tilde{X}_t)|^2 \right) dt - \frac{1}{2} \int_0^T |\dot{y}_t|^2 \, dt. \tag{4.7}
$$

This involves an "energy" term for the control and a "least-squares" term for the observation path fit. These correspond to the two terms in Bayes' formula representing the degrees of match with the prior distribution and the observation path. The optimal control problem (4.1), (4.7) can be thought of as a type of energy-constrained *tracking* problem. The optimal control, under which the distribution of $\tilde{X}$ is the regular conditional probability distribution $P_{X|Y}(\cdot\,, y)$, is derived in the following theorem.

THEOREM 4.2. *Suppose that b, σ, and g satisfy* (H3) *and* (H4)*, and let the function $u_* : \mathbb{R}^n \times [0, T] \times \mathbf{Y} \to \mathbb{R}^n$ be defined by*

$$
u_* = -(\mathcal{D}v)', \tag{4.8}
$$

where v is as defined in (3.12)*. Then, for each $y \in \mathbf{Y}$, $u_*(\cdot\,, \cdot\,, y)$ belongs to $\mathbf{U}$, and for all $\theta \in \mathbb{R}^n$, $y \in \mathbf{Y}$, and $\tilde{P}_X \in \mathcal{P}(\mathcal{X})$ (not necessarily the distribution of a controlled process),*

$$
J(u_*(\cdot\,, \cdot\,, y), \theta, y) \le h(\tilde{P}_X \mid P_X^{\theta,0}) + \langle H_p(0, T, \theta, \cdot\,, y), \tilde{P}_X \rangle. \tag{4.9}
$$

Proof. The proof is in three parts. The first uses the methods of stochastic flows to establish a stochastic representation formula for u_*, (4.20). The second proves the statement of the theorem for nondegenerate systems with bounded coefficients. Finally, a truncation argument is used to extend this result to the general case. Only the time-homogeneous case (b and σ not dependent on t) is treated in order to avoid excessive notation. The arguments extend in an obvious way to the general case.

Standard moment bounding arguments (see, for example, Theorem 4.6 in [9]) show that for each natural number m there exists a $C_m < \infty$, not depending on z or s, such that

$$\sup_{s\le t\le T} \mathbf{E}|X_t^{z,s}|^{2m} \le C_m\left(1+|z|^{2m}\right) \tag{4.10}$$

$$\text{and} \quad \sup_{s\le t\le T} \mathbf{E}\,\|\Psi_t^{z,s}\|^{2m} \le C_m, \tag{4.11}$$

where $(\Psi_t^{z,s} \in \mathbb{R}^{n\times n}; s \le t \le T)$ is the solution of the equation of first-order variation associated with $X^{z,s}$,

$$\Psi_t^{z,s} = I + \int_s^t \mathcal{D}b(X_r^{z,s})\Psi_r^{z,s}\,dr + \sum_i \int_s^t \mathcal{D}\sigma_i(X_r^{z,s})\Psi_r^{z,s}\,dV_{i,r}. \tag{4.12}$$

Here and in what follows, σ_i is the ith column of σ, and $V_{i,t}$ is the ith component of V_t. For any $z, \tilde z \in \mathbb{R}^n$ and any $0 \le s \le t \le T$

$$X_t^{z,s} - X_t^{\tilde z,s} = (z-\tilde z) + \int_s^t (b(X_r^{z,s}) - b(X_r^{\tilde z,s}))\,dr + \int_s^t (\sigma(X_r^{z,s}) - \sigma(X_r^{\tilde z,s}))\,dV_r,$$

and so for any natural number m there exists a $C_m < \infty$, not depending on s, t, z, or $\tilde z$, such that

$$\begin{aligned}\mathbf{E}\sup_{s\le r\le t}\left|X_r^{z,s} - X_r^{\tilde z,s}\right|^{2m} &\le 3^{2m-1}\Bigg(|z-\tilde z|^{2m} + \mathbf{E}\sup_{s\le r\le t}\left|\int_s^r (b(X_q^{z,s}) - b(X_q^{\tilde z,s}))\,dq\right|^{2m} \\ &\qquad + \mathbf{E}\sup_{s\le r\le t}\left|\int_s^r (\sigma(X_q^{z,s}) - \sigma(X_q^{\tilde z,s}))\,dV_q\right|^{2m}\Bigg) \\ &\le C_m\left(|z-\tilde z|^{2m} + \int_s^t \mathbf{E}\sup_{s\le q\le r}\left|X_q^{z,s} - X_q^{\tilde z,s}\right|^{2m}\,dr\right),\end{aligned}$$

where we have used Doob's submartingale inequality, (4.10), (H3), and standard bounds for the moments of stochastic integrals. It thus follows from the Gronwall lemma that

$$\mathbf{E}\sup_{s\le t\le T}|X_t^{z,s} - X_t^{\tilde z,s}|^{2m} \le C_m\exp(C_m T)|z-\tilde z|^{2m} \qquad \text{for all } (z,\tilde z,s). \tag{4.13}$$

Similarly,

$$\mathbf{E}\sup_{s\le t\le T}|X_t^{z,s}|^{2m} \le C_m(1+|z|^{2m}) \qquad \text{for all } (z,s), \tag{4.14}$$

and so for any $\epsilon > 0$ and any bounded set $A \subset \mathbb{R}^n$ there exists a $C < \infty$ such that

$$P\left(\sup_{s\le t\le T}|X_t^{z,s}| > C\right) < \epsilon/4 \qquad \text{for all } (z,s) \in A\times[0,T].$$

From (H3) and (H4) it follows that $\mathcal{D}(\mathcal{L}g)$ is uniformly continuous on compacts, and so for any $\eta > 0$ there exists a $\delta > 0$ such that if $z, \tilde z \in A$ and $|z-\tilde z| < \delta$,

$$P\left(\sup_{s\le t\le T}\left\|\mathcal{D}(\mathcal{L}g)(X_t^{z,s}) - \mathcal{D}(\mathcal{L}g)(X_t^{\tilde z,s})\right\| > \eta,\ \sup_{s\le t\le T}(|X_t^{z,s}| \vee |X_t^{\tilde z,s}|) \le C\right) < \epsilon/2,$$

so that

$$P\left(\sup_{s\le t\le T}\left\|\mathcal{D}(\mathcal{L}g)(X_t^{z,s})-\mathcal{D}(\mathcal{L}g)(X_t^{\tilde z,s})\right\|>\eta\right)<\epsilon. \tag{4.15}$$

The polynomial growth of $\mathcal{D}(\mathcal{L}g)$ together with (4.14) and the Vallée–Poussin theorem shows that, for any $0<p<\infty$, the family

$$\left\{\sup_{s\le t\le T}\|\mathcal{D}(\mathcal{L}g)(X_t^{z,s})\|^p\,;z\in A,0\le s\le T\right\}$$

is uniformly integrable. This and (4.15) show that for any $0<p<\infty$

$$\mathbf{E}\sup_{s\le t\le T}\left\|\mathcal{D}(\mathcal{L}g)(X_t^{z,s})-\mathcal{D}(\mathcal{L}g)(X_t^{\tilde z,s})\right\|^p=o(|z-\tilde z|^0) \tag{4.16}$$

uniformly on $A\times[0,T]$. Similar arguments show that $\mathcal{D}g(X_t^{z,s})$, $\mathcal{D}b(X_t^{z,s})$, $\mathcal{D}\sigma_i(X_t^{z,s})$, and $\mathcal{D}(\mathcal{D}g\sigma_i)(X_t^{z,s})$ for $i=1,2,\dots,n$ have the same property.

It follows from the mean-value theorem that

$$\begin{aligned}X_t^{z,s}-X_t^{\tilde z,s}&=(z-\tilde z)+\int_s^t\mathcal{D}b\left(\alpha_{0,r}X_r^{z,s}+(1-\alpha_{0,r})X_r^{\tilde z,s}\right)(X_r^{z,s}-X_r^{\tilde z,s})\,dr\\&\quad+\sum_i\int_s^t\mathcal{D}\sigma_i\left(\alpha_{i,r}X_r^{z,s}+(1-\alpha_{i,r})X_r^{\tilde z,s}\right)(X_r^{z,s}-X_r^{\tilde z,s})\,dV_{i,r},\end{aligned}$$

where $0<\alpha_{i,r}<1$ and $\alpha_{i,r}$ is $\mathcal{F}_r$-measurable for each i. The above continuity properties, Hölder's inequality, and techniques similar to those used to prove (4.13) now show that for any $0<p<\infty$

$$\mathbf{E}\sup_{s\le t\le T}\left|X_t^{z,s}-X_t^{\tilde z,s}-\Psi_t^{z,s}(z-\tilde z)\right|^p=o(|z-\tilde z|^p), \tag{4.17}$$

and

$$\mathbf{E}\,|\Theta(z,s,y)-\Theta(\tilde z,s,y)-\xi(z,s,y)\Theta(z,s,y)(z-\tilde z)|^p=o(|z-\tilde z|^p), \tag{4.18}$$

both uniformly on $A\times[0,T]$, where

$$\Theta(z,s,y)=\exp\left(-H_p(s,T,z,X^{z,s},y)\right)$$

and

$$\begin{aligned}\xi(z,s,y)&=(y_T-y_s)'\mathcal{D}g(z)+\sum_i\int_s^T(y_T-y_t)'\mathcal{D}(\mathcal{D}g\sigma_i)(X_t^{z,s})\Psi_t^{z,s}\,dV_{i,t}\\&\quad+\int_s^T(y_T-y_t)'\mathcal{D}(\mathcal{L}g)(X_t^{z,s})\Psi_t^{z,s}\,dt-\int_s^T g'(X_t^{z,s})\mathcal{D}g(X_t^{z,s})\Psi_t^{z,s}\,dt.\end{aligned}$$

Thus $\mathcal{D}\rho=\mathbf{E}\xi\Theta$, where $\rho=\mathbf{E}\Theta$. Now, Jensen's inequality shows that

$$\inf_{z\in A,0\le s\le T}\rho(z,s,y)\ge\inf_{z\in A,0\le s\le T}\exp(\mathbf{E}\log(\Theta(z,s,y)))>0, \tag{4.19}$$

and so

$$u_*(z,s,y)=\frac{\mathbf{E}\xi(z,s,y)\Theta(z,s,y)}{\mathbf{E}\Theta(z,s,y)}. \tag{4.20}$$

We now consider the special case in which y is differentiable with Hölder continuous derivative, b and g are bounded, and there exists an $\epsilon > 0$ such that

$$\tilde{z}' a(z) \tilde{z} \geq \epsilon |\tilde{z}|^2 \qquad \text{for all } z, \tilde{z} \in \mathbb{R}^n. \tag{4.21}$$

In this case ρ is continuously differentiable with respect to s, is twice continuously differentiable with respect to z, and by a standard extension of the Feynman–Kac formula satisfies the following partial differential equation (see, for example, [7]):

$$\frac{\partial \rho}{\partial s} + \mathcal{L}\rho + \left(\dot{y} - \frac{1}{2}g\right)' g\rho = 0 \quad \text{on } \mathbb{R}^n \times (0,T), \quad \rho(\,\cdot\,, T, y) = 1. \tag{4.22}$$

Since $v = -\log(\rho)$, the value function v satisfies

$$\frac{\partial v}{\partial s} + \mathcal{L}v - \frac{1}{2}\mathcal{D}va(\mathcal{D}v)' - \left(\dot{y} - \frac{1}{2}g\right)' g = 0 \quad \text{on } \mathbb{R}^n \times (0,T), \quad v(\,\cdot\,, T, y) = 0. \tag{4.23}$$

Now, because of (4.10), (4.11), and the boundedness of g and $\mathcal{D}g$, $u_*(\,\cdot\,,\,\cdot\,, y)$ is also bounded and, by Novikov's theorem, satisfies (U2). We have thus shown that in this special case $u_*(\,\cdot\,,\,\cdot\,, y) \in \mathbf{U}$. Let V^* and P^* be abbreviations for $V^{u_*(\,\cdot\,,\,\cdot\,,y)}$ and $P^{u_*(\,\cdot\,,\,\cdot\,,y)}$, respectively, where, for $u \in \mathbf{U}$, V^u and P^u are as defined by (4.3) and (4.4). Then Itô's rule and (4.23) show that

$$\begin{aligned} 0 = v(X_T^{\theta,0}, T, y) = v(\theta, 0, y) &+ \int_0^T \left(\left(\dot{y}_t - \frac{1}{2}g\right)' g - \frac{1}{2}|\sigma' u_*|^2 \right) (X_t^{\theta,0}, t, y)\, dt \\ &- \int_0^T (u_*'\sigma)(X_t^{\theta,0}, t, y)\, dV_t^*. \end{aligned}$$

As was pointed out in the proof of Lemma 4.1, $(\Omega, \mathcal{F}, (\mathcal{F}_t), P^*, X^{\theta,0}, V^*)$ is a weak solution of (4.1), and so, since g, $u_*(\,\cdot\,,\,\cdot\,, y)$ and σ are bounded,

$$\begin{aligned} v(\theta, 0, y) &= \mathbf{E}^* \int_0^T \left(\frac{1}{2}|\sigma' u_*| - \left(\dot{y}_t - \frac{1}{2}g\right)' g \right) (X_t^{\theta,0}, t, y)\, dt \\ &= J(u_*(\,\cdot\,,\,\cdot\,, y), \theta, y). \end{aligned}$$

By definition, $v(\theta, 0, y)$ is the minimum apparent information, and so we have established (4.9) in this special case. A consequence of (4.9), and the uniqueness of the measure minimizing apparent information, is that the distribution of $\tilde{X}$ when $u = u_*(\,\cdot\,,\,\cdot\,, y)$ is the regular conditional distribution of $X^{\theta,0}$ given that $Y = y$. Thus, in this special case,

$$\Gamma^{u_*(\,\cdot\,,\,\cdot\,,y)} = \frac{\Theta(\theta, 0, y)}{\rho(\theta, 0, y)} \text{a.s.}$$

Next, suppose that the additional constraints placed on y, b, g, and σ are removed. For any natural number N, let

$$\begin{aligned} b_N(z) &= b(z) \exp(-|z|^2/N), \\ g_N(z) &= g(z) \exp(-|z|^2/N), \\ \sigma_N(z) &= \begin{bmatrix} \sigma & N^{-1} I \end{bmatrix} \qquad (\text{an } n \times 2n \text{ matrix}), \end{aligned}$$

and let y^N be a sequence of differentiable elements of $\mathbf{Y}$ with Hölder continuous derivatives such that $\|y - y^N\| \to 0$. Then b_N and g_N are bounded and σ_N satisfies (4.21), b_N, σ_N, and g_N satisfy (H3) and (H4) uniformly in N, and b_N, σ_N, g_N, $\mathcal{D}b_N$, $\partial\sigma_N/\partial z_i$, and $\mathcal{D}g_N$ converge to b, $[\sigma\, 0]$, g, $\mathcal{D}b$, $[\partial\sigma/\partial z_i\, 0]$, and $\mathcal{D}g$ (respectively) uniformly on compacts. We add the subscript (or superscript) N to X, Ψ, Θ, etc. to indicate that y, b, g, and σ have been replaced by y^N, b_N, g_N, and σ_N in the various definitions and that V has been replaced by the $2n$-dimensional Brownian motion, (V_t, B_t). Now

$$X_t^{z,s} - X_t^{N,z,s} = \int_s^t \left(b_N(X_r^{z,s}) - b_N(X_r^{N,z,s})\right)\, dr + \int_s^t \left(\sigma(X_r^{z,s}) - \sigma(X_r^{N,z,s})\right)\, dV_r + \int_s^t \left(b(X_r^{z,s}) - b_N(X_r^{z,s})\right)\, dr - N^{-1}(B_t - B_s).$$

Arguments similar to those used to prove (4.13), (4.17), and (4.18) show that, for any natural number m and any bounded set $A \subset \mathbb{R}^n$,

$$\mathbf{E} \sup_{s\le t\le T} \left|X_t^{z,s} - X_t^{N,z,s}\right|^{2m} \to 0, \tag{4.24}$$

$$\mathbf{E} \sup_{s\le t\le T} \left\|\Psi_t^{z,s} - \Psi_t^{N,z,s}\right\|^{2m} \to 0,$$

$$\mathbf{E}\left|\Theta(z,s,y) - \Theta_N(z,s,y^N)\right|^{2m} \to 0, \tag{4.25}$$

$$\text{and} \quad \mathbf{E}\left|\xi(z,s,y) - \xi_N(z,s,y^N)\right|^{2m} \to 0,$$

all uniformly on $A \times [0,T]$. This, Hölder's inequality, and (4.19) show that

$$u_{*N}(\cdot\,,\cdot\,,y^N) \to u_*(\cdot\,,\cdot\,,y) \qquad \text{uniformly on } A\times[0,T]. \tag{4.26}$$

Thus $u_*(\cdot\,,\cdot\,,y)$ satisfies (U1). It follows from (4.24) and (4.26) that

$$\sup_{0\le t\le T}\left|u_*(X_t^{\theta,0},t,y) - u_{*N}(X_t^{N,\theta,0},t,y^N)\right| \to 0 \qquad \text{in probability,}$$

so that

$$\Gamma_N^{u_{*N}(\cdot\,,\cdot\,,y^N)} \to \Gamma^{u_*(\cdot\,,\cdot\,,y)} \qquad \text{in probability.} \tag{4.27}$$

It also follows from (4.25) and (4.19) that

$$\Gamma_N^{u_{*N}(\cdot\,,\cdot\,,y^N)} = \frac{\Theta_N(\theta,0,y^N)}{\rho_N(\theta,0,y^N)} \to \frac{\Theta(\theta,0,y)}{\rho(\theta,0,y)} \qquad \text{in probability,} \tag{4.28}$$

and so $u_*(\cdot\,,\cdot\,,y)$ satisfies (U2), and the unique distribution of $\tilde{X}$ under this control coincides with the regular conditional distribution of X given that $Y = y$. This establishes (4.9) in the general case. □

We return now to the path estimator with initial distribution μ. The minimization of apparent information can be expressed in terms of the following controlled process with random initial condition:

$$\begin{aligned} &\tilde{X}_t = \tilde{X}_0 + \int_0^t \left(b(\tilde{X}_s,s) + a(\tilde{X}_s,s)u(\tilde{X}_s,s)\right)\, ds + \int_0^t \sigma(\tilde{X}_s,s)\, d\tilde{V}_s, \\ &\tilde{X}_0 \sim \tilde{\mu}. \end{aligned} \tag{4.29}$$

A simple variant of Lemma 4.1 shows that, if u is continuous and satisfies (U2) for all $\theta \in \mathbb{R}^n$, then this equation is unique in law and has a weak solution for any initial law, $\tilde{\mu}$. Let $\tilde{P}_X$ be the distribution of $\tilde{X}$ corresponding to the pair $(\tilde{\mu}, u)$; it follows from (3.14) and the subsequent discussion that

$$F(\tilde{P}_X, y) = F_0(\tilde{\mu}, y) = h(\tilde{\mu} \,|\, \mu) + \langle J(u, \cdot\,, y), \tilde{\mu} \rangle, \tag{4.30}$$

and this is minimized by the choice $u = u_*(\cdot\,, \cdot\,, y)$ and $\tilde{\mu} = \mu_Y(\cdot\,, y)$, where for $B \in \mathcal{B}^n$

$$\mu_Y(B, y) = P_{X|Y}(\chi_0^{-1}(B), y). \tag{4.31}$$

Thus, for each y, the regular conditional probability distribution $P_{X|Y}(\cdot\,, y)$ is Markovian with "initial" marginal $\mu_Y(\cdot\,, y)$ and differential operator

$$\mathcal{L}_y = \sum_i (b + a u_*(\cdot\,, \cdot\,, y))_i \frac{\partial}{\partial z_i} + \frac{1}{2} \sum_{i,j} a_{i,j} \frac{\partial^2}{\partial z_i \partial z_j}. \tag{4.32}$$

Of course, the nonlinear filter and interpolator for the process X can be found from the marginals of this path space measure.

5. The inverse problem. The variational characterization of the inverse problem (parts (ii) and (iv) of Proposition 2.1) can also be applied to the path estimator. This involves choosing a likelihood function to be compatible with the (given) regular conditional probability distribution, $P_{X|Y}(\cdot\,, y)$. In section 4, we minimized apparent information over probability measures corresponding to weak solutions of (4.29). Here, we maximize compatible information over (negative) log-likelihood functions, $\tilde{H}$, that give rise to posterior distributions of this type.

Let $(\Omega, \mathcal{F}, P)$, μ, V, and X be as defined in section 3. For each probability measure on $\mathbb{R}^n$, $\tilde{\mu}$, with $\tilde{\mu} \ll \mu$, and each continuous u satisfying (U2) for all θ, let $\tilde{H}$ be a measurable function such that

$$\begin{aligned} \tilde{H}(X) &= -\log\left(\frac{d\tilde{P}_X}{dP_X}(X)\right) + K \\ &= -\log\left(\frac{d\tilde{\mu}}{d\mu}(X_0)\right) - \int_0^T u'\sigma(X_t, t)\, dV_t + \frac{1}{2}\int_0^T |\sigma' u(X_t, t)|^2\, dt + K, \end{aligned} \tag{5.1}$$

where $K \in \mathbb{R}$ and $\tilde{P}_X$ is as defined following (4.29). We shall assume that $\mu_Y(\cdot\,, y) \ll \tilde{\mu}$. If this is not so, then, as shown in the proof of Proposition 2.1, we can always choose another $\tilde{\mu}$ resulting in more compatible information, for which it is. The term K in (5.1) is the information in the associated (unspecified) observation.

Integral log-likelihood functions of the form (5.1) can be thought of as being associated with observations that are "distributed in time," in that information from them gradually becomes available as t increases.

The characterization of $P_{X|Y}$ in terms of stochastic control can be used to express the compatible information corresponding to $\tilde{H}$ as follows:

$$\begin{aligned} G(\tilde{H}, y) &= K - \langle \tilde{H}\,, P_{X|Y}(\cdot\,, y) \rangle \\ &= K + h(\mu_Y(\cdot\,, y) \,|\, \mu) - h(\mu_Y(\cdot\,, y) \,|\, \tilde{\mu}) \\ &\qquad + \int_0^T \int_{\mathbb{R}^n} \left(u_* - \frac{1}{2}u\right)' a u(z, t, y) P_{X|Y}(\chi_t^{-1}(dz), y)\, dt. \end{aligned} \tag{5.2}$$

Log-likelihood functions of the form (5.1) could come from many different types of observation. The only constraints placed on u here are that it be continuous and that it satisfy (U2) for all θ. We could further constrain it to take the form

$$u(z,s) = -(\mathcal{D}\tilde{v})'(z,s,\tilde{y}),$$

where

$$\tilde{v}(z,s,\tilde{y}) = -\log \mathbf{E} \exp\left(\int_s^T \left(\dot{\tilde{y}}_t - \frac{1}{2}\tilde{g}(X_t^{z,s}) \right)' \tilde{g}(X_t^{z,s})\, dt \right)$$

for appropriate $\tilde{g}$ and $\tilde{y}$. This would correspond to observations of the "signal-plus-white-noise" variety similar to (3.2) but with "controlled" observation function and path, $\tilde{g}$ and $\tilde{y}$. This would show the effects of errors in the observation function or approximations of the observation path. Under appropriate regularity conditions, $\tilde{v}$ will satisfy the following partial differential equation:

$$-\frac{\partial \tilde{v}}{\partial t} = \mathcal{L}\tilde{v} - \frac{1}{2}\mathcal{D}\tilde{v}a(\mathcal{D}\tilde{v})' - \left(\dot{\tilde{y}}_t - \frac{1}{2}\tilde{g} \right)' \tilde{g}; \quad \tilde{v}(\,\cdot\,, T) = 0. \tag{5.3}$$

Thus one interpretation of the inverse problem involves an infinite-dimensional deterministic optimal control problem in reversed time, with control $(\tilde{g}, \tilde{y})$, and payoff

$$\Pi(\tilde{g},\tilde{y}) = \int_0^T \int_{\mathbb{R}^n} \mathcal{D}\tilde{v}a \left(u_* - \frac{1}{2}(\mathcal{D}\tilde{v})' \right)(z,t,y) P_{X|Y}(\chi_t^{-1}(dz), y)\, dt. \tag{5.4}$$

The optimal trajectory for this dual problem, $v(\,\cdot\,,\,\cdot\,,y)$ is a time-reversed likelihood filter for X given Y, and the measure $\exp(-v(z,s,y))P_X(\chi_s^{-1}(dz))$ is an unnormalized regular conditional probability distribution for X_s given observations $(Y_t - Y_s, s \le t \le T)$, which coincides with that provided by the Zakai equation for the time-reversed problem. This provides an information-theoretic explanation of the connection between nonlinear filtering and stochastic optimal control used in [6] as well as widening its scope. For a somewhat different problem involving optimization over observation functions, see [16].

6. Information flow and localization. The results of section 2 concerning the information conserving properties of Bayesian estimators can be localized in the context of the diffusion problem (3.1), (3.2). Proposition 2.1 can be applied to provide variational characterizations of various conditional probabilities of the path measure $P_{X|Y}$, including transition probabilities, and these can be used to characterize the *flow* of information at a given time and in a given state.

For any initial law $\tilde{\mu} \ll \mu$ and any control u satisfying (U1) and (U2) for all θ, let $(\tilde{\Omega}, \tilde{\mathcal{F}}, (\tilde{\mathcal{F}}_t), \tilde{P}, \tilde{X}, \tilde{V})$ be a weak solution of (4.29), let $\tilde{P}_X$ be the distribution of $\tilde{X}$, and let $P_{X,s}$, $\tilde{P}_{X,s}$, and $P_{X,s|Y}(\,\cdot\,, y)$ be the restrictions of P_X, $\tilde{P}_X$, and $P_{X|Y}(\,\cdot\,, y)$ to $\mathcal{X}_0^s$ (as defined in (3.4)). It follows from the results of section 4 that $P_{X,s|Y}(\,\cdot\,, y)$ coincides with $\tilde{P}_{X,s}$ when $\tilde{\mu} = \mu_Y(\,\cdot\,, y)$ and $u(\,\cdot\,, t) = u_*(\,\cdot\,, t, y)$ for $0 \le t \le s$. As shown in the discussion following (3.13), this is the unique probability measure on $\mathcal{X}_0^s$ minimizing the apparent information (3.14). The sum of the first two terms on the right-hand side of (3.14) is the apparent information of $\tilde{P}_{X,s}$ in the context of estimators of $(X_t, 0 \le t \le s)$ given observations $(Y_t, 0 \le t \le s)$, which we can think of as being the apparent information *up to* time s. The third term on the right-hand side

of (3.14) is the information in the observations $(Y_t - Y_s, s \le t \le T)$, which we can think of as being the information *remaining* in the observations Y at time s. As s increases, the estimator corresponding to $(\tilde{\mu}, u)$ progressively converts observation information into apparent information. If $u = u_*(\cdot\,, \cdot\,, y)$, then this process is conservative, in that $F_s(\tilde{P}_{X,s}, y)$ does not change with s. However, if u is not optimal, then the apparent information can increase faster than the observation information decreases.

We can refine this argument as follows. Let

$$\tilde{I}_s = \log\left(\frac{d\tilde{P}_{X,s}}{dP_{X,s}}(\tilde{X})\right) + H_p(0, s, \tilde{X}_0, \tilde{X}, y) + v(\tilde{X}_s, s, y) \quad \text{for } 0 \le s \le T, \tag{6.1}$$

where H_p is defined in (3.10). Then it follows from (3.11) that, for all $0 \le s \le t \le T$,

$$\begin{aligned}\tilde{I}_t = \tilde{I}_s + \log\left(\frac{d\tilde{P}_{X,t}}{dP_{X,t}} \times \frac{dP_{X,s}}{d\tilde{P}_{X,s}}(\tilde{X})\right) + H_p(s, t, \tilde{X}_s, (\tilde{X}_r, s \le r \le T), y)\\ + v(\tilde{X}_t, t, y) - v(\tilde{X}_s, s, y).\end{aligned} \tag{6.2}$$

Let $\tilde{Q}_X$ and Q_X be, respectively, the distributions of $(X_r^{z,s}, s \le r \le t)$ (as defined in section 3) with and without the application of the control $(u(X_r^{z,s}, r), s \le r \le t)$. The apparent information of $\tilde{Q}_X$ in the context of estimators for $(X_r^{z,s}, s \le r \le t)$ given $Y^{z,s}$ is

$$\begin{aligned}F_{s,t}(z, \tilde{Q}_X, y) &= h(\tilde{Q}_X \,|\, Q_X) + \langle H_p(s, t, z, \cdot\,, y), \tilde{Q}_X\rangle + \langle v(\chi_t, t, y), \tilde{Q}_X\rangle,\\ &= v(z, s, y) + \frac{1}{2}\int_s^t \int_{\mathbb{R}^n} |\sigma'(u - u_*(\tilde{z}, r, y))|^2\, \tilde{Q}_X(\chi_r^{-1}(d\tilde{z}))\, dr,\end{aligned} \tag{6.3}$$

where we have used (2.10). It now follows that

$$\tilde{\mathbf{E}}(\tilde{I}_t \,|\, \tilde{\mathcal{F}}_s) = \tilde{I}_s + \frac{1}{2}\int_s^t \tilde{\mathbf{E}}\left(|\sigma'(u - u_*)(\tilde{X}_r, r, y)|^2 \,\middle|\, \tilde{\mathcal{F}}_s\right) dr.$$

Thus $(\tilde{I}_t, \tilde{\mathcal{F}}_t)$ is a submartingale and a martingale if $u = u_*(\cdot\,, \cdot\,, y)$. This is the Davis–Varaiya [4] characterization of the optimal control for the problem of section 4.

Setting $t = s + \delta s$ in (6.3), we obtain the following local information quantities:

$$h(\tilde{Q}_X | Q_X) = \frac{1}{2}|\sigma' u(z, s)|^2 \delta s + o(\delta s), \tag{6.4}$$

$$\langle H_p(s, s + \delta s, z, \cdot\,, y), \tilde{Q}_X\rangle = -g(z)'\delta y + \frac{1}{2}|g(z)|^2 \delta s + o(\delta s), \tag{6.5}$$

$$\begin{aligned}\langle v(\chi_{s+\delta s}, s + \delta s, y), \tilde{Q}_X\rangle &= v(z, s, y) + g(z)'\delta y\\ &\quad - \left(\left(u - \frac{1}{2}u_*\right)' a u_* + \frac{1}{2}|g|^2\right)(z, s, y)\delta s + o(\delta s).\end{aligned} \tag{6.6}$$

Equation (6.4) shows the local increase in information gain of the distribution of the process (4.29) over P_X, (6.5) shows the local increase in the residual information of the estimator $\tilde{P}_X$, and (6.6) shows the local decrease in the average information remaining in the observation after time s. If y is differentiable at s, then there is a local rate of increase of apparent information of $|\sigma' u(z, s)|^2/2 - (\dot{y}_s - g/2)' g(z)$ and a local rate of

decrease of the remaining observation information of $(u - u_*/2)'au^*(z,s,y) - (\dot{y}_s - g/2)'g(z)$. The former exceeds the latter unless the control is optimal.

The dual problem can also be localized in this way. For u as above, let $\tilde{H}_p$ be a measurable function such that

$$\tilde{H}_p(s,t,z,X^{z,s}) = -\int_s^t u'\sigma(X_r^{z,s},r)\,dV_r + \frac{1}{2}\int_s^t |\sigma' u(X_r^{z,s},r)|^2\,dr + (K_s - K_t), \tag{6.7}$$

where K is differentiable and $K_T = 0$. This can be thought of as being the equivalent of $H_p(s,t,z,X^{z,s},y)$ for an unspecified time-distributed observation such that at time s the remaining information in the observation is K_s. (This corresponds to $\tilde{H}(X)$ of (5.1) with $K = K_0$.) Let Q_X^* be the distribution of $(X_r^{z,s}, s \le r \le t)$ when it is controlled by the optimal control. Taking expectation with respect to Q_X^* in (6.7) and taking the limit as $t \downarrow s$, we obtain a local rate of decrease of compatible information of $(u_* - u/2)'au(z,s,y)$. The local rate of increase of the information gain of $P_{X|Y}(\,\cdot\,,y)$ is, of course, $|\sigma' u_*(z,s,y)|^2/2$. The latter exceeds the former unless u is optimal.

In the global dual problem (5.1), the regular conditional probability $P_{X|Y}(\,\cdot\,,y)$ is the source of information. At time s the information in this source is

$$S_s = h(\tilde{\mu}|\mu) + \frac{1}{2}\int_0^s \int_{\mathbb{R}^n} |\sigma' u_*(z,t,y)|^2 P_{X|Y}(\chi_t^{-1}(dz),y)\,dt.$$

At time T there is no information in the observation and no residual information—all the information is still in the source. As s decreases, information flows out of the source at a rate $\dot{S}_s$; it is merged with residual information and flows into the observation at a rate $\dot{K}_s$. If u is optimal, then the flow is conservative, whereas more generally information is lost.

Let $\mathcal{H}_{z,s}$ be the Hilbert space of n-vectors of reals with inner product

$$\langle \alpha, \beta \rangle_{z,s} = \alpha' a(z,s)\beta.$$

The developments above show that the regular conditional probability $P_{X|Y}(\,\cdot\,,y)$ is locally characterized at the point (z,s) by the diffusion coefficients $a(z,s)$ and $(b(z,s) + a(z,s)\alpha_*)$, where α_* minimizes

$$\frac{1}{2}\|\alpha\|_{z,s}^2 - \langle \alpha, u_*(z,s,y)\rangle_{z,s}, \tag{6.8}$$

whereas the optimal trajectory in the dual problem (5.3) is locally characterized in that its negative gradient at the point (z,s), β_* maximizes

$$\langle \beta, u_*(z,s,y)\rangle_{z,s} - \frac{1}{2}\|\beta\|_{z,s}^2. \tag{6.9}$$

The local balance of the Bayesian path estimator is thus characterized by the Legendre transform pair (6.8), (6.9). Of course, this is the characterization of the optimal control problem of section 4 provided by the stochastic maximum principle, the adjoint process being the gradient of the optimal dual state, $v(\,\cdot\,,\,\cdot\,,y)$, evaluated at $(\tilde{X}_t, t)$.

7. Conclusions. This article has developed dual variational characterizations of Bayesian estimation, in which the "cost" functionals have particular information-theoretic meaning. These characterizations provide a natural framework for the study of modeling and approximation errors in estimators such as nonlinear filters. They also link such issues with a broader theory of "stochastic dissipativeness" (see [1]), on which the ideas and techniques of statistical physics can be brought to bear. We believe that this will have a number of advantages, for example, in the study of the long-term behavior of stochastic systems. For a recent development of this type see [12]. The characterizations also provide a framework for the representation of estimators, in a broader context, as apparent information minimizers and compatible information maximizers. These issues will be explored elsewhere.

Acknowledgments. The authors would like to thank one of the referees and the Associate Editor for their comments and suggestions which have led to substantial improvement in the paper. The second author would like to thank Denis Talay and Francois LeGland for their hospitality during his visits to the INRIA research groups Omega and Sigma2.

NOISE ASSISTED HIGH-GAIN STABILIZATION: ALMOST SURELY OR IN SECOND MEAN*

HANS CRAUEL†, IAKOVOS MATSIKIS‡, AND STUART TOWNLEY‡

Abstract. For a linear control system with multiplicative white noise, we develop (asymptotic) formulas for the dependence of almost sure and second mean exponential growth rates on a high-gain parameter k. We show that if the diffusion matrix is skew-symmetric so that the noise enters in a purely skew-symmetric way, then the function g, where $g(p)/p$ denotes the exponential growth rate of the pth mean, converges to a straight line, uniformly for $p \in [0, 2]$, as $k \to \infty$. We use these formulas to show that the feedback control system in Stratonovich form is high-gain stabilizable even if the zero-dynamics are unstable, provided that the noise is strong enough. This contrasts with the noise free case, where we need the zero-dynamics to be exponentially stable.

We then consider a class of systems where the diffusion matrix is not skew-symmetric and show that the almost sure and pth mean growth rates have different limiting behavior as $k \to \infty$.

Key words. Lyapunov exponents, high-gain feedback, moment exponents, second mean exponents, Furstenberg–Khasminskii formula

1. Introduction.

The dependence of dynamical properties of systems on parameters is central to many problems in control theory and in dynamical systems. For example, consider a linear single-input single-output control system of the form

$$\begin{aligned} \dot{x} &= Ax + Bu, \\ y &= Cx, \end{aligned} \tag{1}$$

where $x \in \mathbf{R}^d$, A is a real $d \times d$-matrix, and $B, C^T \in \mathbf{R}^d$. A basic control design technique is to study the root locus for (1), i.e., the eigenvalues of $A - kBC$ as k varies. The root locus technique is used, for example, to show that if $CB > 0$ and if (A, B, C) is minimum phase, then high-gain feedback control $u = -ky$ is stabilizing in the sense that the eigenvalues of $A - kBC$ are in the left half-plane for all k sufficiently large.

The parametric dependence of dynamical properties for linear stochastic differential equations (LSDEs) has been investigated with great intensity during the last decades. For a survey on approaches which are closest in spirit to the present work, as well as for further references, see Wihstutz [10]. Note also that the bifurcation behavior of a noisy Duffing–van der Pol-oscillator has been studied in Arnold [1, Chapter 9]. Motivated by this, Imkeller and Lederer [7, 8] performed a more detailed study of the dependence on parameters of Lyapunov exponents for a noisy damped harmonic oscillator.

We want to investigate dynamical properties of certain LSDEs obtained by applying proportional feedback. More precisely, we consider a noisy version of (1) with proportional output feedback, i.e.,

$$dx = (A - kBC)x\,dt + \sum_{j=1}^{m} A_j x * dW_j(t). \tag{2}$$

We are interested in the dependence of exponential growth rates for (2) on k and, in particular, on asymptotic formulas, valid for large k. While for deterministic systems this can be derived by studying the dependence of eigenvalues on parameters, for LSDEs the situation is more complicated. Indeed, there are several competing notions of growth rates (for example, in the pth mean or almost surely). Furthermore, the growth rates depend on which notion of solution of (2) is adopted—Itô or Stratonovich.

The paper is organized as follows. In section 2 we recall some basic facts about LSDEs and their exponential growth rates, specifically Lyapunov exponents and moment exponents. In section 3 we consider almost sure growth rates, and we characterize under which conditions (2) can be stabilized almost surely by high-gain feedback. This means that the leading Lyapunov exponent becomes negative for all sufficiently high gain. We restrict ourselves to the simplest possible nontrivial case, which is the case of a 2×2-system. To calculate the almost sure growth rate, i.e., the leading Lyapunov exponent, we use the Furstenberg–Khasminskii formula, which yields a closed, albeit complicated, formula. These results are in the spirit of those obtained by Imkeller and Lederer [7, 8], who obtained explicit formulas for Lyapunov exponents of certain linear two-dimensional systems arising from the linearization of the Duffing–van der Pol-oscillator around zero.

In section 4 we consider the second mean growth rates and characterize under which conditions the system can be stabilized in the second mean by high-gain feedback. Here we use the classical technique of considering the norm induced by a positive definite matrix P (thus defining a Lyapunov function), applying the Itô formula to obtain estimates for the exponential growth of second moments, and then choosing the matrix P in an appropriate way. As a result we obtain that when the noise enters the system in a purely skew-symmetric way, then for high gain the exponential growth rate of the second moment approaches twice the Lyapunov exponent, the almost sure exponential growth rate. When the noise is entering nonskew-symmetrically, however, the growth rates have different limiting behavior as $k \to \infty$. We prove the main result, Theorem 3.2, in an appendix.

2. Notions of growth rates for LSDEs. To introduce the notions of growth rate for (2), consider a general LSDE

$$dx = Ax\,dt + \sum_{j=1}^{m} A_j x * dW_j(t), \tag{3}$$

where A and A_j are $d \times d$-matrices, W_j are independent standard Wiener processes, $1 \le j \le m$, and $*$ stands for an interpretation of (3) either as an Itô or as a Stratonovich equation. Denote by $x(t, x_0)$ the solution of (3) at time t, with initial condition x_0 at time $t = 0$.

There are several nonequivalent notions of exponential growth rates for (3). The

leading *Lyapunov exponent* of (3) is defined as

$$\lambda = \lim_{t\to\infty} \frac{1}{t} \log\Big(\sup_{\|x_0\|=1} \|x(t;x_0)\| \Big) \qquad P\text{-a. s.}, \tag{4}$$

where $\|\cdot\|$ is any norm on $\mathbf{R}^d$. Existence of the almost sure limit and the fact that the limit is constant almost surely follows from the subadditive ergodic theorem of Kingman [9]. The LSDE (3) is said to be *almost surely exponentially stable* if $\lambda < 0$.

The exponential growth rate in the pth mean is $g(p)/p$, where $g(p)$ is given by

$$g(p) = \lim_{t\to\infty} \frac{1}{t} \log E\Big(\sup_{\|x_0\|=1} \|x(t;x_0)\|^p \Big). \tag{5}$$

In (5), E denotes expectation. The function $p \mapsto g(p)$ is a real analytic function and convex, and $g'(0) = \lambda$, provided certain nondegeneracy conditions are satisfied; see Arnold, Oeljeklaus, and Pardoux [5] (and also Arnold, Kliemann, and Oeljeklaus [4] for the case of colored noise). Consequently,

$$\frac{g(p)}{p} \geq \frac{g(q)}{q} \geq g'(0) = \lambda \tag{6}$$

for $p \geq q > 0$. In particular, the growth rate in the pth mean is greater than or equal to the almost sure growth rate for $p > 0$. We are interested in the dependence of the growth rates given by (4) and (5) for the LSDE (2) as we vary the feedback gain k. For example, how does the feedback gain influence the difference between $g(2)$ and 2λ?

As mentioned earlier in the introduction, the dependence of growth rates of LSDEs on parameters has been of interest. One of the earliest results of this type, of relevance here, goes back to Arnold, Crauel, and Wihstutz [2]. Consider a Stratonovich equation of the form

$$dx = Ax\,dt + \sum_{j=1}^{m} u_j B_j x \circ dW_j(t), \tag{7}$$

where B_j, $1 \leq j \leq m$, form a basis for the $d(d-1)/2$-dimensional linear space of skew symmetric $d \times d$-matrices and, as before, the W_j are independent standard Wiener processes. In [2], the following limiting behavior for the leading Lyapunov exponent is obtained:

$$\lambda \to \frac{1}{d} \operatorname{tr} A = \frac{1}{d} \sum_{i=1}^{d} a_{ii} \qquad \text{as} \quad \min u_j \to \infty.$$

This result has been subsequently generalized by Arnold, Eizenberg, and Wihstutz [3] to allow for weaker conditions on the (B_j). One consequence of this result is the surprising observation that we can "stabilize" (7) by high-intensity noise if $\operatorname{tr} A < 0$. So, given a deterministic system $\dot{x} = Ax$ with $\operatorname{tr} A < 0$, it suffices to agitate the system by noise as in (7) and increase the intensity u until almost sure stability is achieved.

While high-intensity noise would seem impractical, this result motivates us to determine if noise can enhance more traditional stabilization by proportional feedback.

Second mean feedback stabilization of a general controlled Itô LSDE

$$\left\{\begin{array}{rcl} dx &=& (Ax + Bu_0)\,dt + \displaystyle\sum_{j=1}^{m}(A_j x + B_j u_j)\,dW_j(t), \\ y &=& Cx \end{array}\right. \tag{8}$$

has been considered by Damm [6]. Here $u_0, \dots, u_m$ are controls, and A, A_j, B, B_j, and C are matrices of suitable dimensions. This problem is quite involved. It turns out that stabilization in the second mean is equivalent to the existence of positive definite solutions to certain generalized linear matrix inequalities. We are not aware of any similar results for almost sure stabilization. Rather than pursuing this general feedback problem, we limit our interest to the parametric dependence of the growth rates λ and $g(p)$ in a set-up less general than (8). We restrict our attention to the 2×2 case of system (2). This is the simplest nontrivial case, and it allows for a neat and clear formulation of the main results. Higher dimensional cases would also be possible, but the technical conditions are considerably more involved, and we currently do not have a complete picture.

3. Almost sure exponential growth rates. As already mentioned, we will investigate the simplest case possible. That is, we investigate the dependence of the almost sure exponential growth rate, i.e., the Lyapunov exponent, on the parameters k and σ for the Stratonovich equation

$$dx = \begin{pmatrix} a-k & b \\ c & d \end{pmatrix} x\,dt + \sigma \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} x \circ dW(t). \tag{9}$$

In (9), $a, b, c, d \in \mathbf{R}$ are fixed parameters. The drift matrix $\left(\begin{smallmatrix} a-k & b \\ c & d \end{smallmatrix}\right)$ in (9) arises via a change of coordinates from (1) in the case $u = -ky$, and $CB > 0$, if the dimension is 2. We show that $\lim_{k\to\infty} \lambda_{k,\sigma} = \frac{1}{2}(2d - \sigma^2)$, so that (9) is high-gain almost surely exponentially stabilizable if and only if $d < \frac{1}{2}\sigma^2$.

Remark 3.1. Without high-gain k, we have from Arnold, Crauel, and Wihstutz [2] that $\lim_{\sigma\to\infty} \lambda = \frac{1}{2}(a+d)$, and so almost sure stability if mixing of the negative trace by the noise is strong enough. With high gain but no noise, high-gain stabilization is possible only if the zero-dynamics are exponentially stable, i.e., if $d < 0$, while the noise term has a stabilizing effect and with high enough gain k the intensity of the noise has to be only strong enough to overcome the influence of possibly "unstable zero-dynamics."

While the results are simply stated, their derivation, as with analogous results obtained by Imkeller and Lederer [7, 8], is quite involved. To proceed we first recall some details about the well-known method for calculating Lyapunov exponents of an LSDE

$$dx = Ax\,dt + \sum_{j=1}^{m} A_j x \circ dW_j(t) \tag{10}$$

via the Furstenberg–Khasminskii formula. Here A, A_j are $d \times d$-matrices, and W_j are independent Wiener processes, $1 \le j \le m$, and the equation is interpreted in the Stratonovich sense.

Projection of (10) from $\mathbf{R}^d \setminus \{0\}$ onto the unit sphere $S^{d-1} = \{v \in \mathbf{R}^d : |v| = 1\}$

by $x \mapsto x/|x| =: s$ gives the (nonlinear) SDE

$$ds = g_A(s)\,dt + \sum_{j=1}^{m} g_{A_j}(s) \circ dW_j(t) \tag{11}$$

on S^{d-1}, where $g_A(s) = As - (s, As)s$. The SDE (11) defines a random dynamical system on S^{d-1}. Associated to every Lyapunov exponent there exists an invariant measure for this random dynamical system, which is supported by the Oseledets space associated with this Lyapunov exponent; for details see Arnold [1, Chapters 3 and 4]. Furthermore, the maximal Lyapunov exponent (almost sure exponential growth rate) is given by

$$\lambda = \int_{S^{d-1}} \left((s, As) + \sum_{j=1}^{m} \left(\frac{1}{2}((A_j + A_j^*)s, A_j s) - (s, A_j s)^2 \right) \right) dp(s), \tag{12}$$

where p is a (suitable) invariant measure for the Markov semigroup induced by (11). Equation (12) is the Furstenberg–Khasminskii formula in the form it takes for a linear system induced by the LSDE (10). In particular, if (11) is sufficiently nondegenerate, then there exists a unique invariant Markov measure p, and this measure has a smooth density with respect to the Lebesgue measure on S^{d-1}, which we denote by p again. Nondegeneracy means that a certain hypoellipticity condition is satisfied, whose precise form is not of interest here. The density p is given as a suitably normalized solution of the associated Fokker–Planck equation. See Arnold [1] or Imkeller and Lederer [7, 8].

In our particular case we have the Stratonovich LSDE

$$dx = \begin{pmatrix} a-k & b \\ c & d \end{pmatrix} x\,dt + \sigma \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} x \circ dW(t),$$

and (11) becomes

$$ds = g_A(s)\,dt + g_B(s) \circ dW(t)$$

with $g_A(s) = As - (s, As)s$,

$$\begin{aligned} (s, As) &= (a-k)s_1^2 + (b+c)s_1 s_2 + d s_2^2, \\ g_A(s) &= \begin{pmatrix} (a-k)s_1 + b s_2 - (a-k)s_1^3 - (b+c)s_1^2 s_2 - d s_2^2 s_1 \\ c s_1 + d s_2 - (a-k)s_1^2 s_2 - (b+c)s_1 s_2^2 - d s_2^3 \end{pmatrix}, \\ g_B(s) &= \sigma \begin{pmatrix} -s_2 \\ s_1 \end{pmatrix}, \end{aligned}$$

and $s = (s_1, s_2)^T$. In polar coordinates $s = (\cos\varphi, \sin\varphi)^T$ with $\varphi \in [-\pi/2, \pi/2]$, this becomes

$$\begin{aligned} d\varphi &= \frac{ds_2}{\cos\varphi} \\ &= \frac{c\cos\varphi + d\sin\varphi - (a-k)\cos^2\varphi\sin\varphi - (b+c)\cos\varphi\sin^2\varphi - d\sin^3\varphi}{\cos\varphi}\,dt \\ &\quad + \sigma\,dW(t) \\ &= \left(c\cos^2\varphi + (d-a+k)\cos\varphi\sin\varphi - b\sin^2\varphi \right) dt + \sigma\,dW(t). \end{aligned}$$

To determine the invariant measure for the associated Markov semigroup we first note that the SDE for the angle φ is elliptic. Consequently, there is a unique invariant measure for the Markov semigroup, and this invariant measure has a C^∞ density $\varphi \mapsto p_{k,\sigma}(\varphi)$, which is a solution of the Fokker–Planck equation. In the present case the Fokker–Planck equation results in the ordinary differential equation

$$-\left(\frac{1}{2}\sigma^2 p\right)'' + \Big(\big(c\cos^2\varphi + (d-a+k)\cos\varphi\sin\varphi - b\sin^2\varphi\big)p\Big)' = 0$$

with periodic boundary conditions on $[-\pi/2, \pi/2)$. This gives

$$p' = \frac{2}{\sigma^2}(c + (d-a+k)\cos\varphi\sin\varphi - (b+c)\sin^2\varphi)p + \gamma,$$

where γ has to be chosen such that p is periodic. Rewriting in 2φ-terms gives

$$\begin{aligned} p' &= \frac{2}{\sigma^2}\left(c + \frac{1}{2}(d-a+k)\sin 2\varphi - \frac{1}{2}(b+c)(1-\cos 2\varphi)\right)p + \gamma \\ &= \frac{1}{\sigma^2}\Big((c-b) + (d-a+k)\sin 2\varphi + (b+c)\cos 2\varphi\Big)p + \gamma. \end{aligned}$$

Using standard trigonometric identities and setting

$$\begin{aligned} R(\varphi,\eta) = \frac{1}{\sigma^2}\Bigg((c-b)(\varphi-\eta) + \frac{1}{2}(d-a+k)(\cos 2\eta - \cos 2\varphi) \\ + \frac{1}{2}(b+c)(\sin 2\varphi - \sin 2\eta)\Bigg), \end{aligned}$$

we obtain that the general, still to be normalized, solution p is given by

$$p(\varphi) = \mathrm{e}^{R(\varphi,-\frac{\pi}{2})}\, p\left(-\frac{\pi}{2}\right) + \gamma\int_{-\pi/2}^{\varphi} \mathrm{e}^{R(\varphi,\eta)}\, d\eta. \tag{13}$$

In (13) γ has to be chosen such that $p(\frac{\pi}{2}) = p(-\frac{\pi}{2})$. For the leading Lyapunov exponent we then obtain

$$\lambda = \int_{-\pi/2}^{\pi/2}\Big((a-k)\cos^2\varphi + (b+c)\cos\varphi\sin\varphi + d\sin^2\varphi\Big)\, p(\varphi)\, d\varphi. \tag{14}$$

Starting from (13) and (14), we obtain the following theorem on the dependence of the Lyapunov exponent on high-gain feedback.

THEOREM 3.2. *The Lyapunov exponent $\lambda = \lambda_{k,\sigma}$ of the Stratonovich LSDE* (9) *satisfies*

$$\lambda_{k,\sigma} = d - \frac{\sigma^2}{2} + O(k^{-1})$$

for k large. In particular,

$$\lim_{k\to\infty} \lambda_{k,\sigma} = d - \frac{\sigma^2}{2}$$

for every a, b, c, d.

The proof is given in the appendix.

Remark 3.3. (i) We used the explicit formula for the leading Lyapunov exponent $\lambda = \lambda_{k,\sigma}$ given by (14), invoking the density $p = p(k)$ given explicitly by (13). Use of such explicit formulas is not possible for higher dimensional LSDEs. For $d > 2$ one might invoke the more systematic approach as described, for example, by Wihstutz [10]. This involves putting $\varepsilon = k^{-\alpha}$ for suitable $\alpha > 0$ and denoting the generator induced by the projected SDE (11) by L_ε to obtain an expansion of $\lambda = \lambda(\varepsilon)$ around $\varepsilon = 0$ by expanding the expression $\lambda(\varepsilon) = \int q_\varepsilon\, p_\varepsilon$ given by (12), where p_ε is determined by $L_\varepsilon p_\varepsilon = 0$ (which is the Fokker–Planck equation). Performing this asymptotic expansion formally for the two-dimensional case considered here yields the limiting behavior $\lambda = \lambda_{k,\sigma} + o(1)$ for k large in a more intuitive manner than the direct approach which we adopt. However, it would seem from the developments in [10] that justification of this more systematic asymptotic expansion approach needs arguments which are at least as complicated as those used in the direct approach.

(ii) Using a slightly modified approach to the one invoked in the proof of Theorem 3.2 gives more information, specifically allowing a further expansion of the Lyapunov exponent λ in k. This gives

$$\lambda_{k,\sigma} = d - \frac{\sigma^2}{2} + \left(bc - \frac{\sigma^4}{4}\right) k^{-1} + O(k^{-2}). \tag{15}$$

Alternatively we obtain the same result by using the formal expansion approach as described above in (i).

4. Exponential growth rates in the second mean. In the calculation of Lyapunov exponents in the previous section we adopted a Stratonovich interpretation. To calculate the exponential growth rate of the second mean, i.e., $g(2)$, it is more suitable to work with an Itô interpretation. So in order to compare results between the two notions of growth rate, we need to transform (9) from Stratonovich to Itô form. A general Stratonovich LSDE

$$dx = Ax\, dt + \sum_{j=1}^{m} A_j x \circ dW_j(t)$$

is equivalent to the Itô LSDE

$$dx = \left(A + \frac{1}{2}\sum_{j=1}^{m} A_j^2\right) x\, dt + \sum_{j=1}^{m} A_j x\, dW_j(t).$$

In our case this transforms (9) to

$$dx = \begin{pmatrix} a - k - \frac{1}{2}\sigma^2 & b \\ c & d - \frac{1}{2}\sigma^2 \end{pmatrix} x\, dt + \sigma \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} x\, dW(t).$$

For an Itô equation

$$dx = A_0 x\, dt + A_1 x\, dW(t),$$

$g(2)$ coincides with the smallest $\eta \in \mathbf{R}$ such that there exists a symmetric positive definite matrix P with

$$A_0^T P + P A_0 + A_1^T P A_1 \leq \eta P. \tag{16}$$

Indeed this follows from (16) by adopting $\|x\| = \langle x, Px\rangle^{1/2}$ as a norm in the definition of $g(2)$ and by using the Itô formula applied to $V(t) = \langle x(t), Px(t)\rangle$.

PROPOSITION 4.1. *The exponential growth rate of the second mean of the Stratonovich LSDE* (9)*, which is* $g(2)/2$ *with* $g(2) = g_{k,\sigma}(2)$ *given by* (5)*, satisfies*

$$g_{k,\sigma}(2) = (2d - \sigma^2) + O(k^{-1}).$$

Hence, for σ *fixed,*

$$\lim_{k\to\infty} g_{k,\sigma}(2) = 2d - \sigma^2$$

for every a, b, c, d.

Proof. From (6) we already know that $g_{k,\sigma}(2) \geq 2\lambda_{k,\sigma}$ for every k, σ; hence Theorem 3.2 yields

$$g_{k,\sigma}(2) \geq (2d - \sigma^2) + O(k^{-1}) \tag{17}$$

for $k \to \infty$. It remains to show that $g_{k,\sigma}(2) \leq (2d - \sigma^2) + O(k^{-1})$, i.e., that there exist η and $P > 0$ such that

$$\begin{bmatrix} a-k-\frac{1}{2}\sigma^2 & c \\ b & d-\frac{1}{2}\sigma^2 \end{bmatrix} P + P \begin{bmatrix} a-k-\frac{1}{2}\sigma^2 & b \\ c & d-\frac{1}{2}\sigma^2 \end{bmatrix} + \sigma^2 \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} P \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} < \eta P \tag{18}$$

and $\eta \leq (2d-\sigma^2)+O(k^{-1})$. Without loss of generality, we choose $P = \left[\begin{smallmatrix} 1 & q \\ q & p \end{smallmatrix}\right]$. Denoting by $Q(P)$ the left-hand side of (18), we obtain

$$Q(P) = \begin{bmatrix} 2a - 2k - (1-p)\sigma^2 + 2cq & (a - k + d - 2\sigma^2)q + b + cp \\ (a - k + d - 2\sigma^2)q + b + cp & 2dp + (1-p)\sigma^2 + 2bq \end{bmatrix}.$$

Choosing $p = p(k) = 1 + \frac{k}{\sigma^2}$, we obtain

$$Q(P) = \begin{bmatrix} 2a - k + 2cq & (a + d - k - 2\sigma^2)q + b + c(1 + \frac{k}{\sigma^2}) \\ (a + d - k - 2\sigma^2)q + b + c(1 + \frac{k}{\sigma^2}) & (2d - \sigma^2 + \frac{\sigma^2}{p} + \frac{2bq}{p})p \end{bmatrix},$$

where we left p unresolved in the lower right entry. Now choose, for k sufficiently large, $q = q(k) = \frac{b+cp}{k+2\sigma^2-a-d}$. For this choice of $P = P(k)$ we obtain

$$\begin{aligned} Q(P) &= \begin{bmatrix} 2a - k + 2cq & 0 \\ 0 & ((2d - \sigma^2) + \frac{\sigma^2}{p} + \frac{2bq}{p})p \end{bmatrix} \\ &\leq \left((2d - \sigma^2) + O(k^{-1})\right) P. \end{aligned} \tag{19}$$

Combining (17) and (19), we conclude that for $k \to \infty$ the second mean exponent $g_{k,\sigma}(2)$ satisfies

$$g_{k,\sigma}(2) = 2d - \sigma^2 + O(k^{-1})$$

as required. ∎

Remark 4.2. Further expansion of the second mean growth rate $g(2)$ in terms of k gives

$$g_{k,\sigma}(2) = 2d - \sigma^2 + \left(2bc + \frac{\sigma^4}{2}\right) k^{-1} + O(k^{-2}) = 2\lambda_{\kappa,\sigma} + \sigma^4 k^{-1} + O(k^{-2}).$$

This shows that the difference between almost sure and second mean exponents disappears asymptotically with order $1k$.

Until now we have assumed that the noise enters in a skew-symmetric way. For the following slightly more general case the arguments carry over in a rather straightforward manner.

THEOREM 4.3. *Consider the Stratonovich LSDE*

$$dx = \begin{pmatrix} a-k & b \\ c & d \end{pmatrix} x\,dt + \begin{pmatrix} \gamma & -\sigma \\ \sigma & \gamma \end{pmatrix} x \circ dW(t) \tag{20}$$

with $\gamma \in \mathbf{R}$. Then the following hold.

(i) *The almost sure exponential growth rate of* (20)*, the Lyapunov exponent $\lambda_{k,\sigma}$, is independent of γ. In particular,*

$$\lambda_{k,\sigma} = d - \frac{\sigma^2}{2} + O(k^{-1}), \qquad \text{and therefore} \quad \lim_{k\to\infty} \lambda_{k,\sigma} = d - \frac{\sigma^2}{2}$$

for every $\gamma \in \mathbf{R}$.

(ii) *The exponential growth rate of the second mean, $g_{k,\sigma,\gamma}(2)/2$, satisfies*

$$g_{k,\sigma,\gamma}(2) = 2d + 2\gamma^2 - \sigma^2 + O(k^{-1})$$

for large k. In particular,

$$\lim_{k\to\infty} g_{k,\sigma,\gamma}(2) = 2d + 2\gamma^2 - \sigma^2.$$

Note. The theorem can be rephrased as $\frac{g(2)}{2} = \lambda + \gamma^2$ asymptotically.

Proof. It is straightforward to see that the leading Lyapunov exponent of (20) is independent of γ. Indeed, since $\gamma\,\mathrm{Id}$ commutes with all matrices, solutions of (20) and (9) can be transformed into each other as follows. If $x(t;x_0)$ is a solution of (9), then $y(t;x_0) = x(t;x_0)\mathrm{e}^{\gamma\sigma W(t)}$ is a solution of (20). Since $\lim W(t)/t = 0$ almost surely for $t \to \infty$, the Lyapunov exponents of (20) are the same as those of (9). Consequently, application of Theorem 3.2 to (20) for $\gamma = 0$ proves (i).

Concerning the exponential growth rate of the second mean, denote by I the identity matrix, and put $J = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. Transforming the Stratonovich SDE $dx = A_0 x\,dt + A_1 x \circ dW(t)$ with $A_1 = \gamma I + \sigma J$ to Itô form gives

$$dx = \left(A_0 + \frac{1}{2}A_1^2\right) x\,dt + \sigma A_1 x\,dW(t),$$

where $A_1^2 = (\gamma^2 - \sigma^2)I + 2\gamma\sigma J$. In order to determine $g(2)$ we have to find the smallest $\eta \in \mathbf{R}$ for which there exists a positive definite P such that

$$\begin{aligned} \left(A_0 + \frac{1}{2}(\gamma^2-\sigma^2)I + \gamma\sigma I\right)^T P + P\left(A_0 + \frac{1}{2}(\gamma^2-\sigma^2)I + \gamma\sigma I\right) \\ + \big(\gamma I + \sigma J\big)^T P\big(\gamma I + \sigma J\big) \le \eta P. \end{aligned} \tag{21}$$

Now the left-hand side of (21) equals

$$\left(A_0 + \left(\gamma^2 - \frac{\sigma^2}{2}\right) I + 2\gamma\sigma J\right)^T P + P\left(A_0 + \left(\gamma^2 - \frac{\sigma^2}{2}\right) I + 2\gamma\sigma J\right) + \sigma^2\, J^T P J,$$

which is simply (18) for the Itô LSDE

$$dx = \left(A_0 + \left(\gamma^2 - \frac{1}{2}\sigma^2\right) I + \gamma\sigma J\right) x\, dt + \sigma J x\, dW(t),$$

corresponding to the Stratonovich equation

$$dx = (A_0 + \gamma^2 I + \gamma\sigma J)x\, dt + \sigma J x \circ dW(t). \tag{22}$$

Since (22) has the same form as (9) and, in particular,

$$A_0 + \gamma^2 I + \gamma\sigma J = \begin{pmatrix} \tilde{a} - k & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix}$$

with $\tilde{d} = d + \gamma^2$, it follows by applying Proposition 4.1 that

$$g(2) = 2d + 2\gamma^2 - \sigma^2 + O(k^{-1})$$

for $k \to \infty$, proving (ii). □

Remark 4.4. For the case of a skew-symmetric diffusion matrix we see from the calculations of λ and $g(2)$ that while

$$g(2) > 2\lambda$$

(the inequality is strict here—see Arnold, Oeljeklaus, and Pardoux [5]), in the limit, for high-gain k tending to infinity,

$$\lim_{k\to\infty} g_{k,\sigma}(2) = 2 \lim_{k\to\infty} \lambda_{k,\sigma} = 2d - \sigma^2.$$

This means that the strictly convex functions $p \mapsto g_{k,\sigma}(p)$ converge with k to infinity to the linear $p \mapsto (d - \frac{1}{2}\sigma^2)p$, uniformly in $p \in [0, 2]$, for every $\sigma > 0$. So the high-gain feedback leads to an asymptotic degeneracy in $p \mapsto g(p)$.

Remark 4.5. A similar degeneracy occurs in the case of the high-intensity noise problem of Arnold, Crauel, and Wihstutz [2]. Recall that for the Stratonovich equation

$$dx = \begin{pmatrix} a & b \\ c & d \end{pmatrix} x\, dt + \sigma \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} x \circ dW(t)$$

we have

$$\lim_{\sigma\to\infty} \lambda = \frac{1}{2}(a + d).$$

Transforming into the equivalent Itô equation

$$dx = \begin{pmatrix} a - \frac{1}{2}\sigma^2 & b \\ c & d - \frac{1}{2}\sigma^2 \end{pmatrix} x\, dt + \sigma \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} x\, dW(t)$$

and invoking the characterization of $g(2)$ given around (16), one obtains

$$\lim_{\sigma\to\infty} g(2) = (a + d).$$

To see this, we again need to find η so that

$$\tilde{Q}(P) := \begin{bmatrix} 2a-(1-p)\sigma^2+2cq & (a+d-\sigma^2)q+b+cp \\ (a+d-\sigma^2)q+b+cp & 2dp+(1-p)\sigma^2+2bq \end{bmatrix} \leq \eta \begin{bmatrix} 1 & q \\ q & p \end{bmatrix}.$$

Put $p = 1 + \frac{d-a}{\sigma^2}$. Then we need

$$\begin{bmatrix} a+d+2cq & (a+d-2\sigma^2)q+b+c(1+\frac{d-a}{\sigma^2}) \\ (a+d-2\sigma^2)q+b+c(1+\frac{d-a}{\sigma^2}) & a+d-d\frac{(a-d)}{\sigma^2}+2bq \end{bmatrix}$$
$$\leq \eta \begin{bmatrix} 1 & q \\ q & p \end{bmatrix}.$$

Choosing

$$q = \frac{b+c(1+(\frac{d-a}{\sigma^2}))}{2\sigma^2-a-d} = O\left(\frac{1}{\sigma^2}\right)$$

for $2\sigma^2 > a+d$ gives

$$\tilde{Q}(P) = \begin{pmatrix} a+d+O(\frac{1}{\sigma^2}) & 0 \\ 0 & a+d+O(\frac{1}{\sigma^2}) \end{pmatrix} \leq \left((a+d)+O\left(\frac{1}{\sigma^2}\right)\right) \begin{pmatrix} 1 & q \\ q & p \end{pmatrix},$$

so that $g_\sigma(2) \leq (a+d)+O(\sigma^{-2})$. Since $g_\sigma(2) \geq 2\lambda_\sigma$ and

$$\lim_{\sigma\to\infty} \lambda_\sigma = (a+d)/2,$$

we conclude that

$$\lim_{\sigma\to\infty} g_\sigma(2) = a+d.$$

Remark 4.6. In the case of a more general diffusion matrix considered in Theorem 4.3, the degeneration described in Remark 4.4 does not occur. In fact, here noise assisted high-gain stabilization may take place with respect to almost sure stability but not with respect to second mean stability. In particular, with a diffusion matrix of the form $\sigma \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ we have convergence of the almost sure exponential growth rate $\lambda_{k,\sigma}$ to $d-\sigma^2/2$ for $k \to \infty$, whereas $g_{k,\sigma}(2)/2$ converges to $d+\sigma^2/2$ for $k \to \infty$.

5. Concluding remarks. We have considered the dependence of growth rates on the feedback gain k for the simplest case of an LSDE arising from proportional feedback applied to a second order relative degree one control system. We have obtained explicit formulas for the Lyapunov exponents and asymptotics of the growth rates valid for large enough k. We have shown, in particular, that in case of a purely skew-symmetric noise the asymptotic dependence on k for k large is the same whether we consider λ, the leading Lyapunov exponent, or whether we consider the growth rate in the pth mean for any $p \in [0,2]$. This contrasts with the situation where for any fixed k we would have that

$$\lambda < \frac{g(p)}{p} < \frac{g(q)}{q}$$

for all $p < q$.

As an application of these asymptotic estimates we see that the Stratonovich equation (9) is high-gain stabilizable (almost surely or in the pth mean, $0 < p \leq 2$) if and only if

$$\sigma^2 > 2d.$$

In particular, for $\sigma \neq 0$ we can allow $d > 0$, i.e., unstable zero-dynamics, whereas if $\sigma = 0$, we need $d < 0$ i.e., the zero-dynamics to be exponentially stable. We see in this simple example that the noise has a *stabilizing effect*.

When the noise enters in a certain nonskew-symmetric way, then the same comments apply to almost sure growth rates, so the noise is still *stabilizing with respect to almost sure stability*. However, the same noise is *destabilizing with respect to stability in the second mean*.

Appendix. In this appendix we give the proof of Theorem 3.2. We first consider a special case.

The case of a symmetric drift matrix. We first treat the case $b = c$. This means that the drift matrix A in (9) is symmetric. Then $\varphi \mapsto R(\varphi, \eta)$ is periodic for every η, and therefore (13) yields that periodicity of p holds if and only if $\gamma = 0$. This gives

$$p(\varphi) = \exp\left[-\frac{1}{2\sigma^2}\Big((d-a+k)(1+\cos 2\varphi) - 2b\sin 2\varphi\Big)\right] p(-\pi/2).$$

In order to make p the density of a probability measure, we have to choose

$$p\left(-\frac{\pi}{2}\right) = \left(\int_{-\pi/2}^{\pi/2} \exp\left[-\frac{1}{2\sigma^2}\Big((d-a+k)(1+\cos 2\varphi) - 2b\sin 2\varphi\Big)\right] d\varphi\right)^{-1}.$$

Note that $p(-\frac{\pi}{2}) > 0$. Having determined the dependence of the invariant density p on k and σ, we now turn to the calculation of the leading Lyapunov exponent as given by (14), which here takes the form

$$\lambda = \int_{-\pi/2}^{\pi/2} \Big((a-k)\cos^2\varphi + 2b\cos\varphi\sin\varphi + d\sin^2\varphi\Big)\, p(\varphi)\, d\varphi. \tag{23}$$

We first ignore the normalizing factor $p(-\frac{\pi}{2})$ and consider

$$I := \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \big((a-k)\cos^2\varphi + 2b\cos\varphi\sin\varphi + d\sin^2\varphi\big) \times \exp\left(-\frac{1}{2\sigma^2}\big((d-a+k)(1+\cos 2\varphi) - 2b\sin 2\varphi\big)\right) d\varphi.$$

Defining $R_k = \sqrt{(k+d-a)^2 + (2b)^2}$ and ψ_k via $\tan\psi_k = \frac{k+d-a}{2b}$ and using the formula

$$s\cos 2\varphi + t\sin 2\varphi = R\sin(2\varphi + \psi)$$

with $R = \sqrt{s^2 + t^2}$ and $\tan\psi = s/t$, we obtain

$$I = \exp\left(\frac{a-k-d}{2\sigma^2}\right) \int_{-\pi/2}^{\pi/2} \Big[(a-k)\cos^2\varphi + 2b\cos\varphi\sin\varphi + d\sin^2\varphi\Big] \times \exp\left(-\frac{1}{2\sigma^2} R_k \sin(2\varphi + \psi_k)\right) d\varphi.$$

Rearranging

$$\begin{aligned}
&(a-k)\cos^2\varphi + 2b\cos\varphi\sin\varphi + d\sin^2\varphi \\
&= (a-k-d)\cos^2\varphi + 2b\cos\varphi\sin\varphi + d \\
&= \frac{a-k-d}{2}(\cos 2\varphi + 1) + b\sin 2\varphi + d \\
&= \frac{1}{2}\Big[(a-k-d)\cos 2\varphi + 2b\sin 2\varphi + a + d - k\Big]
\end{aligned}$$

and using periodicity of sine and cosine together with the identities $\sin(\beta + \pi/2) = \cos\beta$ and $\cos(\beta + \pi/2) = -\sin\beta$, we obtain

$$\begin{aligned}
I &= \frac{1}{2}\exp\Big(\frac{a-k-d}{2\sigma^2}\Big) \\
&\quad \times \int_{-\pi/2}^{\pi/2} \Big[(a-k-d)\cos(2\varphi - \psi_k) + 2b\sin(2\varphi - \psi_k) + a + d - k\Big] \\
&\qquad \times \exp\Big(-\frac{R_k}{2\sigma^2}\sin 2\varphi\Big)\, d\varphi \\
&= \frac{1}{2}\exp\Big(\frac{a-k-d}{2\sigma^2}\Big) \\
&\quad \times \int_{-\pi/2}^{\pi/2} \Big[-(a-k-d)\sin(2\varphi - \psi_k) + 2b\cos(2\varphi - \psi_k) + a + d - k\Big] \\
&\qquad \times \exp\Big(-\frac{R_k}{2\sigma^2}\cos 2\varphi\Big)\, d\varphi \\
&= \frac{1}{2}\exp\Big(\frac{a-k-d}{2\sigma^2}\Big)\exp\Big(\frac{R_k}{2\sigma^2}\Big) \\
&\quad \times \int_{-\pi/2}^{\pi/2} \Big[(k+d-a)\big(\sin 2\varphi\cos\psi_k - \cos 2\varphi\sin\psi_k\big) \\
&\qquad + 2b\big(\cos 2\varphi\cos\psi_k + \sin 2\varphi + \sin 2\varphi\sin\psi_k\big) + a + d - k\Big] \\
&\qquad \times \exp\Big(-\frac{R_k}{\sigma^2}\cos^2\varphi\Big)\, d\varphi.
\end{aligned}$$

Integrating over a symmetric interval around zero, we keep only integrals over even functions. This gives

$$\begin{aligned}
I &= \exp\Big(\frac{a-k-d+R_k}{2\sigma^2}\Big) \\
&\times \int_0^{\pi/2} \Big[(a-d-k)\cos 2\varphi\sin\psi_k + 2b\cos 2\varphi\cos\psi_k + a + d - k\Big] \\
&\qquad \times \exp\Big(-\frac{R_k}{\sigma^2}\cos^2\varphi\Big)\, d\varphi.
\end{aligned}$$

Now $\cos\psi_k = 2b/R_k$ and $\sin\psi_k = (k+d-a)/R_k$, so

$$\begin{aligned} I &= \exp\Big(\frac{a-k-d+R_k}{2\sigma^2}\Big) \\ &\quad\times \int_o^{\pi/2} \left[\frac{4b^2-(k+d-a)^2}{R_k}\cos 2\varphi + a + d - k\right] \exp\Big(-\frac{R_k}{\sigma^2}\cos^2\varphi\Big)\, d\varphi \\ &= \exp\Big(\frac{a-k-d+R_k}{2\sigma^2}\Big) \\ &\quad\times \int_0^{\pi/2} \left[a+d-k+\frac{(k+d-a)^2-4b^2}{R_k} - \frac{(k+d-a)^2-4b^2}{R_k} 2\cos^2\varphi\right] \\ &\qquad\times \exp\Big(-\frac{R_k}{\sigma^2}\cos^2\varphi\Big)\, d\varphi. \end{aligned}$$

From the theory of hypergeometric functions we know that

$$H := \int_0^{\pi/2} \exp\Big(-\frac{R_k}{\sigma^2}\cos^2\varphi\Big)\, d\varphi \;=\; \frac{\pi}{2}\mathcal{H}\left(\left[\frac{1}{2}\right], [1], \frac{R_k}{\sigma^2}\right)$$

and

$$K := \int_0^{\pi/2} \exp\Big(-\frac{R_k}{\sigma^2}\cos^2\varphi\Big)\cos^2\varphi\, d\varphi \;=\; \frac{\pi}{4}\mathcal{H}\left(\left[\frac{3}{2}\right], [2], \frac{R_k}{\sigma^2}\right),$$

where $\mathcal{H}$ denotes hypergeometric functions. This gives

$$\begin{aligned} I &= \exp\Big(\frac{a-k-d+R_k}{2\sigma^2}\Big) \\ &\quad\times \left(\left[a+d-k+\frac{(k+d-a)^2-4b^2}{\sqrt{(k+d-a)^2+4b^2}}\right] H - 2\left[\frac{(k+d-a)^2-4b^2}{\sqrt{(k+d-a)^2+4b^2}}\right] K\right). \end{aligned}$$

Using similar calculations, we obtain for the normalizing factor

$$\begin{aligned} p\left(-\frac{\pi}{2}\right) &= \pi\exp\Big(\frac{a-d-k+R_k}{2\sigma^2}\Big)\mathcal{H}\left(\left[\frac{1}{2}\right], [1], \frac{R_k}{\sigma^2}\right) \\ &= 2\exp\Big(\frac{a-d-k+R_k}{2\sigma^2}\Big) H. \end{aligned}$$

Now

$$\begin{aligned} a+d-k+\frac{(k+d-a)^2-4b^2}{\sqrt{(k+d-a)^2+4b^2}} &= 2d + e_1(k), \\ \frac{(k+d-a)^2-4b^2}{\sqrt{(k+d-a)^2+4b^2}} &= k + e_2(k), \\ H &= \frac{\pi}{2}\Big(\frac{\sigma^2}{R_k}\Big)^{1/2} + e_3(k), \\ K &= \frac{\pi}{4}\Big(\frac{\sigma^2}{R_k}\Big)^{3/2} + e_4(k), \quad \text{and} \\ R_k = \sqrt{(k+d-a)^2+(2b)^2} &= k + e_5(k), \end{aligned}$$

where $|e_1(k)| \le Mk^{-1}$, $|e_2(k)| \le M$, $|e_3(k)| \le Mk^{-3/2}$, $|e_4(k)| \le Mk^{-5/2}$, and $|e_5(k)| \le Mk^{-1/2}$ for a suitable constant M. In the following we will denote constants independent of k by M without always noting when their value changes. This gives

$$I = \pi \left(d - \frac{\sigma^2}{2} \right) \exp\left(\frac{a-d}{2\sigma^2} \right) \frac{\sqrt{\sigma^2}}{k^{1/2}} + e_6(k) \tag{24}$$

and, introducing the notion J for later reference,

$$J := p\left(-\frac{\pi}{2}\right) = \pi \exp\left(\frac{a-d}{2\sigma^2} \right) \frac{\sqrt{\sigma^2}}{k^{1/2}} + e_7(k), \tag{25}$$

where $|e_6(k)| \le Mk^{-3/2}$ and $|e_7(k)| \le Mk^{-3/2}$.

From (23) we obtain

$$\lambda = \lambda_{k,\sigma} = \frac{I}{J} = d - \frac{\sigma^2}{2} + e_8(k)$$

with $|e_8(k)| \le Mk^{-1}$.

This proves the following proposition.

PROPOSITION A.1. *In the case of a symmetric drift matrix, i.e., in the case $b = c$, the leading Lyapunov exponent $\lambda = \lambda_{k,\sigma}$ of the LSDE* (9) *satisfies*

$$\lambda_{k,\sigma} = d - \frac{\sigma^2}{2} + O(k^{-1})$$

for k large. In particular,

$$\lim_{k\to\infty} \lambda_{k,\sigma} = d - \frac{\sigma^2}{2}.$$

The case of a general drift matrix. Having assumed $b = c$ in the drift matrix for the calculations in the previous subsection, we now use these calculations to obtain a result for the case $b \neq c$.

Proof of Theorem 3.2. Having established the result for the case $b = c$ in the previous section, we proceed by showing that the general case is close to the symmetric case for k sufficiently large.

First note that (13), (14), $p(-\frac{\pi}{2}) = p(\frac{\pi}{2})$, and $\int p(\varphi)\, d\varphi = 1$ give $\lambda = I/J$ with

$$I = \int_{-\pi/2}^{\pi/2} q(\varphi) m(\varphi) g(\varphi)\, d\varphi \qquad \text{and} \quad J = \int_{-\pi/2}^{\pi/2} m(\varphi) g(\varphi)\, d\varphi,$$

where

$$\begin{aligned} q(\varphi) &= (a-k)\cos^2\varphi + (b+c)\cos\varphi\sin\varphi + d\sin^2\varphi \\ &= (a-d-k)\cos^2\varphi + (b+c)\cos\varphi\sin\varphi + d, \\ m(\varphi) &= \exp\Big(\frac{1}{2\sigma^2}[(b+c)\sin 2\varphi - (d-a+k)(\cos 2\varphi + 1)] \Big), \\ g(\varphi) &= \exp\left(\frac{c-b}{\sigma^2}\left(\varphi + \frac{\pi}{2}\right)\right) \\ &\quad + \left[1 - \exp\left(\frac{c-b}{\sigma^2}\pi\right)\right] \left[\exp\left(\frac{c-b}{\sigma^2}\left(\varphi - \frac{\pi}{2}\right)\right)\right] f(\varphi) \end{aligned}$$

and f is given by

$$f(\varphi) = \frac{\displaystyle\int_{-\pi/2}^{\varphi} \exp\left(\tfrac{1}{2\sigma^2}\left[-2(c-b)\eta + (d-a+k)\cos 2\eta - (b+c)\sin 2\eta\right]\right)\, d\eta}{\displaystyle\int_{-\pi/2}^{\pi/2} \exp\left(\tfrac{1}{2\sigma^2}\left[-2(c-b)\eta + (d-a+k)\cos 2\eta - (b+c)\sin 2\eta\right]\right)\, d\eta}.$$

In the symmetric case we had $g(\varphi) \equiv 1$ on $[-\pi/2, \pi/2]$. We will show that I and J are close to the corresponding integrals with $g \equiv 1$. While the integrals I and J look at first glance rather intractable, there are several simplifications if k is large. In particular, for k large we have $f(\varphi) \approx 0$ for $-\pi/2 \le \varphi \le -\pi/4$ and $f(\varphi) \approx 1$ for $\pi/4 \le \varphi \le \pi/2$. We will make this more precise below.

First note that $0 \le f \le 1$; hence there exists $M > 0$, independent of k, such that $|g(\varphi)| \le M$ for all φ. Next consider the behavior of $m(\varphi)$ for large k. Here the relevant term is $-(d-a+k)(\cos 2\varphi + 1)$. Note that $\cos 2\varphi + 1 \ge 0$ for all φ. Define intervals I_k and J_k close to $-\pi/2$ and $\pi/2$, respectively, such that $1 + \cos 2\varphi \ge \frac{1}{\sqrt{k}}$ for all $\varphi \notin I_k \cup J_k$ by

$$I_k = \left[-\pi/2, -\cos^{-1}\frac{1}{\sqrt{2\sqrt{k}}}\right] \qquad \text{and} \quad J_k = \left[\cos^{-1}\frac{1}{\sqrt{2\sqrt{k}}}, \pi/2\right].$$

For $\varphi \notin I_k \cup J_k$,

$$-(d-a+k)(1+\cos 2\varphi) \le -\frac{\sqrt{k}}{3}$$

for k large. Noting that, for k large,

$$|q(\varphi)| = |(a-k)\cos^2\varphi + (b+c)\cos\varphi\sin\varphi + d\sin^2\varphi| \le 2k,$$

we obtain

$$\left|\int_{[-\pi/2,\pi/2]\setminus(I_k\cup J_k)} q(\varphi)m(\varphi)g(\varphi)\, d\varphi\right| \le k\, M\, \exp\left(-\frac{\sqrt{k}}{3}\right)$$

for some $M > 0$. Since $k\exp\left(-\frac{\sqrt{k}}{3}\right) \le \exp\left(-\frac{\sqrt{k}}{4}\right)$ for k large, we thus obtain

$$\left|\int_{[-\pi/2,\pi/2]\setminus(I_k\cup J_k)} q(\varphi)m(\varphi)g(\varphi)\, d\varphi\right| \le M\exp\left(-\frac{\sqrt{k}}{4}\right),$$

and so

$$\left|\int_{-\pi/2}^{\pi/2} q(\varphi)m(\varphi)g(\varphi)\, d\varphi - \int_{I_k\cup J_k} q(\varphi)m(\varphi)g(\varphi)\, d\varphi\right| \le M\exp\left(-\frac{\sqrt{k}}{4}\right). \tag{26}$$

By similar arguments one obtains

$$\left|\int_{-\pi/2}^{\pi/2} q(\varphi)m(\varphi)\, d\varphi - \int_{I_k\cup J_k} q(\varphi)m(\varphi)\, d\varphi\right| \le M\exp\left(-\frac{\sqrt{k}}{4}\right). \tag{27}$$

It follows from (26) and (27) that we need only to deal with the difference between I and $\int q(\varphi)m(\varphi)\,d\varphi$ on $I_k \cup J_k$.

Loosely speaking, we have $g(\varphi) \approx 1$ on I_k and

$$g(\varphi) \approx \exp\left[\frac{c-b}{\sigma^2}\pi\right] + \left(1 - \exp\left[\frac{c-b}{\sigma^2}\pi\right]\right) = 1$$

on J_k, both uniformly in k.

To be more precise, consider first $f(\varphi)$ for $\varphi \in I_k$. For $\varphi \in I_k$ and k sufficiently large we have $\cos 2\varphi \le -1/2$, and for $\varphi \in [-\pi/6, \pi/6]$ we have $\cos 2\varphi \ge 1/2$. It follows that, for $\varphi \in I_k$,

$$\begin{aligned} 0 \le f(\varphi) &\le \frac{\int_{I_k} \exp\left(\frac{1}{2\sigma^2}\left[-2(c-b)\eta + (d-a+k)\cos 2\eta - (b+c)\sin 2\eta\right]\right)\,d\eta}{\int_{-\pi/6}^{\pi/6} \exp\left(\frac{1}{2\sigma^2}\left[-2(c-b)\eta + (d-a+k)\cos 2\eta - (b+c)\sin 2\eta\right]\right)\,d\eta} \\ &\le M\exp(-k), \end{aligned}$$

whence

$$\left| g(\varphi) - \exp\Big(\frac{c-b}{\sigma^2}(\varphi + \tfrac{\pi}{2})\Big)\right| \le M\exp(-k).$$

Expanding $\varphi \mapsto \exp\big(\frac{c-b}{\sigma^2}(\varphi + \frac{\pi}{2})\big)$ in Taylor series around $-\pi/2$, we obtain

(28)
$$g(\varphi) = 1 + \frac{c-b}{\sigma^2}(\varphi + \pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi + \pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi + \pi/2)\Big)^3 + e_1(k)$$

with $|e_1(k)| \le Mk^{-1}$ for all $\varphi \in I_k$.

Similarly, for $\varphi \in J_k$ we have

$$\begin{aligned} 1 \ge f(\varphi) &= 1 - \frac{\int_{\varphi}^{\pi/2} \exp\left(\frac{1}{2\sigma^2}\left[-2(c-b)\eta + (d-a+k)\cos 2\eta - (b+c)\sin 2\eta\right]\right)\,d\eta}{\int_{-\pi/2}^{\pi/2} \exp\left(\frac{1}{2\sigma^2}\left[-2(c-b)\eta + (d-a+k)\cos 2\eta - (b+c)\sin 2\eta\right]\right)\,d\eta} \\ &\ge 1 - M\exp(-k), \end{aligned}$$

and expanding the exp-term in $\varphi \mapsto g(\varphi)$ in Taylor series around $\pi/2$ gives

(29)
$$g(\varphi) = 1 + \frac{c-b}{\sigma^2}(\varphi - \pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi - \pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi - \pi/2)\Big)^3 + e_2(k)$$

with $|e_2(k)| \le Mk^{-1}$ for all $\varphi \in J_k$.

Based on these estimates and expansions, we would expect, loosely speaking, that

$$\int_{I_k \cup J_k} q(\varphi)m(\varphi)g(\varphi)\,d\varphi \approx \int_{I_k \cup J_k} q(\varphi)m(\varphi)\,d\varphi.$$

Actually, this is not as simple as it looks. The problem is that the right-hand side is $O(1/\sqrt{k})$, and so we have to be careful with arguments based on any "errors" being small for $k \to \infty$.

We proceed more carefully: On I_k we obtain, invoking (28),

$$\begin{aligned} &q(\varphi)m(\varphi)g(\varphi) \\ &= q(\varphi)m(\varphi) \\ &\quad \times\Big[1 + \frac{c-b}{\sigma^2}(\varphi + \pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi + \pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi - \pi/2)\Big)^3 + e_1(k)\Big]. \end{aligned}$$

So

$$\begin{aligned}
&q(\varphi)m(\varphi)g(\varphi) - q(\varphi)m(\varphi)\\
&= q(\varphi)\exp\Big(\frac{b+c}{2\sigma^2}\sin 2\varphi\Big)\exp\Big(-\frac{k+d-a}{\sigma^2}\cos^2\varphi\Big)\\
&\quad\times\Big[\frac{c-b}{\sigma^2}(\varphi+\pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi+\pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi+\pi/2)\Big)^3 + e_1(k)\Big].
\end{aligned}$$

Similarly, on J_k we obtain from (29)

$$\begin{aligned}
&q(\varphi)m(\varphi)g(\varphi) - q(\varphi)m(\varphi)\\
&= q(\varphi)\exp\Big(\frac{b+c}{2\sigma^2}\sin 2\varphi\Big)\exp\Big(-\frac{k+d-a}{\sigma^2}\cos^2\varphi\Big)\\
&\quad\times\Big[\frac{c-b}{\sigma^2}(\varphi-\pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi-\pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi-\pi/2)\Big)^3 + e_2(k)\Big].
\end{aligned}$$

We consider the contributions of the terms $\big((a-d-k)\cos^2\varphi\big)$ and $\big((b+c)\cos\varphi\sin\varphi + d\big)$ in $q(\varphi)$ separately. The term $\big((a-d-k)\cos^2\varphi\big)$ contributes

$$\begin{aligned}
&\int_{I_k}(a-d-k)\cos^2\varphi\,\exp\Big(\frac{b+c}{2\sigma^2}\sin 2\varphi\Big)\exp\Big(-\frac{k+d-a}{\sigma^2}\cos^2\varphi\Big)\\
&\times\Big[\frac{c-b}{\sigma^2}(\varphi+\pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi+\pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi+\pi/2)\Big)^3 + e_1(k)\Big]\,d\varphi
\end{aligned}$$

to $\int_{I_k}\big(q(\varphi)m(\varphi)g(\varphi) - q(\varphi)m(\varphi)\big)\,d\varphi$. The corresponding contribution from J_k is

$$\begin{aligned}
&\int_{J_k}(a-d-k)\cos^2\varphi\,\exp\Big(\frac{b+c}{2\sigma^2}\sin 2\varphi\Big)\,\exp\Big(-\frac{k+d-a}{\sigma^2}\cos^2\varphi\Big)\\
&\times\Big[\frac{c-b}{\sigma^2}(\varphi-\pi/2) + \frac{1}{2}\Big(\frac{c-b}{\sigma^2}(\varphi-\pi/2)\Big)^2 + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}(\varphi-\pi/2)\Big)^3 + e_2(k)\Big]\,d\varphi.
\end{aligned}$$

Taking Taylor expansions of $\varphi\mapsto\sin 2\varphi$ and $\varphi\mapsto\cos^2\varphi$ around $-\pi/2$ and $\pi/2$, respectively, changing variables, and combining the contributions of the $(a-d-k)\cos^2\varphi$-terms from I_k and J_k, we arrive at an error term of the form

$$\begin{aligned}
&\int_0^{\frac{1}{\sqrt{2\sqrt{k}}}}(a-d-k)\,x^2\,\exp\Big(-\frac{k+d-a}{\sigma^2}x^2\Big)\\
&\times\Big[\Big(\exp\Big(-\frac{b+c}{\sigma^2}x\Big) - \exp\Big(\frac{b+c}{\sigma^2}x\Big)\Big)\Big(\frac{c-b}{\sigma^2}x + \frac{1}{6}\Big(\frac{c-b}{\sigma^2}\Big)^3\Big)\\
&\quad+\frac{1}{2}\Big(\exp\Big(-\frac{b+c}{\sigma^2}x\Big) + \exp\Big(\frac{b+c}{\sigma^2}x\Big)\Big)\Big(\frac{c-b}{\sigma^2}x\Big)^2\Big]\,dx \;+\; e_3(k)
\end{aligned}\tag{30}$$

with $|e_3(k)|\le Mk^{-3/2}$. Here we used that, after the change of variables around $\pi/2$ and around $-\pi/2$, respectively, $\cos^2\varphi$ gives a term of the order $x^2+O(x^4)$. Using integration by parts, one verifies that the error terms $e_1(k)$ and $e_2(k)$ contribute an $O(k^{-3/2})$-term, and the $O(x^4)$-term from $\cos^2\varphi$ contributes an $O(k^{-2})$-term.

Identifying the exponential terms inside the square brackets as $-2\sinh(\frac{b+c}{\sigma^2}x)$ and $\cosh(\frac{b+c}{\sigma^2}x)$ and expanding $\sinh x$ and $\cosh x$, respectively, around $x=0$, (30) becomes

$$Mk\int_0^{\frac{1}{\sqrt{2\sqrt{k}}}}x^4\exp\left(-\frac{k+d-a}{\sigma^2}x^2\right)\,dx + O(k^{-3/2})$$

for k large. Again using integration by parts this can be seen to grow not faster than $Mk^{-3/2}$ for $k \to \infty$ (recall that M is a variable constant).

Using similar calculations in which we again need to combine contributions from I_k and J_k, we can show that the term $\big((b+c)\cos\varphi\sin\varphi+d\big)$ in $q(\varphi)$ contributes to the integral $\int_{I_k\cup J_k}\big(q(\varphi)m(\varphi)g(\varphi) - q(\varphi)m(\varphi)\big)\,d\varphi$ an error term bounded in magnitude by $Mk^{-3/2}$.

Collecting the above estimates, we obtain

$$\Big|\int_{I_k\cup J_k} q(\varphi)m(\varphi)g(\varphi)\,d\varphi - \int_{I_k\cup J_k} q(\varphi)m(\varphi)\,d\varphi\Big| \le Mk^{-3/2} \qquad \text{and}$$
$$\Big|\int_{I_k\cup J_k} m(\varphi)g(\varphi)\,d\varphi - \int_{I_k\cup J_k} m(\varphi)\,d\varphi\Big| \le Mk^{-3/2}$$

for some positive M and k sufficiently large. In view of (26) and (27), this implies

$$\Big|\int_{-\pi/2}^{\pi/2} q(\varphi)m(\varphi)g(\varphi)\,d\varphi - \int_{-\pi/2}^{\pi/2} q(\varphi)m(\varphi)\,d\varphi\Big| \le Mk^{-3/2} \qquad \text{and} \tag{31}$$
$$\Big|\int_{-\pi/2}^{\pi/2} m(\varphi)g(\varphi)\,d\varphi - \int_{-\pi/2}^{\pi/2} m(\varphi)\,d\varphi\Big| \le Mk^{-3/2}. \tag{32}$$

Now put

$$I_{\text{sym}} = \int_{-\pi/2}^{\pi/2} q(\varphi)m(\varphi)\,d\varphi \qquad \text{and} \quad J_{\text{sym}} = \int_{-\pi/2}^{\pi/2} m(\varphi)\,d\varphi;$$

the subscript "sym" refers to the symmetric case treated in (the proof of) Proposition A.1 From (24) and (25) we obtain

$$I_{\text{sym}} = \pi\left(d - \frac{\sigma^2}{2}\right)\exp\left(\frac{a-d}{2\sigma^2}\right)\frac{\sqrt{\sigma^2}}{k^{1/2}} + \eta_1(k),$$
$$J_{\text{sym}} = \pi\exp\left(\frac{a-d}{2\sigma^2}\right)\frac{\sqrt{\sigma^2}}{k^{1/2}} + \eta_2(k)$$

with both $|\eta_j(k)| \le Mk^{-3/2}$, $j = 1, 2$, where we note that the derivation of (24) and (25) goes through without changes if $2b$ is replaced by $b + c$.

Rewriting (31) and (32) with this notation gives

$$I = I_{\text{sym}} + e_4(k) \qquad \text{and} \quad J = J_{\text{sym}} + e_5(k),$$

where $|e_j(k)| \le Mk^{-\frac{3}{2}}$, $j = 4, 5$. So finally, we obtain

$$\lambda_{k,\sigma} = \frac{I}{J} = \frac{I_{\text{sym}} + e_4(k)}{J_{\text{sym}} + e_5(k)} = d - \frac{\sigma^2}{2} + e_6(k),$$

where, due to the $k^{-1/2}$-term in I_{sym} and J_{sym}, respectively, $|e_6(k)| \le Mk^{-1}$. This proves the claim, finishing the proof of Theorem 3.2. □

Acknowledgments. This paper was prepared while Hans Crauel was with the School of Mathematical Sciences of the University of Exeter. Our thanks go to Ludwig Arnold (Bremen) for pointing out the approach sketched in Remark 3.3 and for discussing it with us.

EXPLICIT SOLUTION TO A ROBUST QUEUEING CONTROL PROBLEM*

PAUL DUPUIS†

Abstract. We consider the robust optimal control of a law of large numbers approximation of a stochastic network. The robust control problem is formulated as a differential game, with one player choosing the policies that determine service and routing assignments and the other choosing quantities such as the arrival and service rates, subject to constraints. The cost to be minimized by the first player and maximized by the second is the time until the origin is reached. An explicit formula is given for the value function, and some of its basic properties are studied.

Key words. robust control, queueing network, differential game, explicit solutions

1. Introduction.

This paper considers the problem of robust service and routing control for a network of servers. Consider such a network, and assume that at each station there are a finite number of distinct customer classes, each with its own buffer. In this paper we will work directly with what is sometimes called a "fluid" model for the network [19]. Models of this sort are usually obtained as law of large numbers approximations to more detailed models [6, 17] and are particularly appealing because in many cases related optimization problems admit closed form solutions [23, 24, 12].

Another feature of the networks we consider is model uncertainty, such as uncertainty in the arrival and service rates. To deal with model uncertainty we adapt the differential game formulation of robust control for unconstrained nonlinear systems [15]. Thus we consider a network where there are two players. One player in the game will represent the "true" control (e.g., service assignments and routing decisions). The other player represents the uncertain or poorly modeled aspects of the system (e.g., arrival and service rates). In keeping with existing convention, we will refer to this latter control as "nature." The two players are antagonistic, with the first player attempting to maintain good system performance.

Differential game formulations provide a powerful tool for the design of robust controls [4, 15]. In many situations knowledge of the true system is limited. System parameters (e.g., arrival rates) may drift with time, and statistical properties (e.g., correlations) may also be unstable. There may be aspects of the system that are left unmodeled, either because they cannot be estimated in any reliable way or because they lead to a model that is too complicated to be useful. This is a common occurrence in stochastic networks, where the network to be controlled is often a subnetwork of some larger system, and "full state information" is simply not available to the controller of the subnetwork.

In situations like these the use of a single "nominal" model can be problematic. For example, just as in the case of unconstrained systems one can construct examples where controls that are optimal in some sense for the nominal model perform poorly when the model is perturbed even slightly. A differential game formulation allows one to construct controls that perform uniformly well over a class of perturbations of the nominal model, with each choice of nature's control corresponding to a different perturbation of the design model. It is, of course, this insensitivity to model perturbations that warrants the term "robust" control. Variations of different kinds can be accommodated through the choice of the cost structure, and one can carefully balance the pursuit of optimality with respect to a nominal model against the need to provide good performance for a range of models. Indeed, for many current design problems (see, e.g., [16]) one would like the maximum robustness possible given certain guaranteed bounds on performance. The main result of this paper is the explicit solution to a robust control problem for a network. By explicit what we mean is that the value function can be represented in terms of a finite dimensional optimization problem and that from this value function one can obtain controls with specific robust properties.

In formulating the differential game special attention must be paid to the cost applied to nature's control, since this determines the degree to which model perturbations are allowed. Within the realm of "fluid" models there are at least two types of cost structures that are natural. One is a cost that simply imposes a constraint on the model parameters. We will refer to this as the case of a "hard constraint." An alternative is to make nature pay an increasing cost for perturbations away from the nominal model, and we will refer to this type of cost as corresponding to "soft constraints." Hard constraints turn out to be mathematically simpler for fluid models of networks, even though the reverse seems to be true for unconstrained systems. The present paper will focus on the case of hard constraints. Of particular interest among games with soft constraints are those which arise as the limit of "risk-sensitive" control problems [2]. However, for problems of control, until the origin is reached the running cost in these games is not of one sign, and so there is no longer uniqueness for the corresponding PDE [18] (even within the viscosity solution framework). This makes the analysis much more difficult.

Besides the cost that nature must pay, one must also specify the cost that the true control faces. In this paper the cost we consider is the time to move the state of the system from an arbitrary position to zero (i.e., all queues empty). The true control will try to minimize this time, while the opposing control will attempt to delay it as much as possible. This cost seems to be a natural analogue, in the setting of constrained systems, of the familiar quadratic cost for unconstrained systems. In particular, it leads to controls with optimal robust stability (in addition to optimal robust performance), and it also allows for a fairly explicit closed form solution.

An outline of the paper is as follows. In section 2 we give a precise formulation of the game problem and show through examples how various systems can be put into this framework. Section 3 includes the main result of the paper, which is a finite dimensional max/min representation for the value function of the game introduced in section 2. Qualitative properties of the value function (convexity, differentiability, etc.) are also discussed in section 3. The proof of this representation is given in section 4. The concluding section 5 formally discusses how an optimal true control can be constructed in feedback form. A proof of the existence of value for the games we consider is given in an appendix.

2. Formulation of the control problem. In this section we formulate the robust control problem as a constrained deterministic differential game. As discussed in the introduction, the model we use can be viewed as a law of large numbers approximation to a more detailed stochastic model. This connection will be used for interpretive purposes throughout the section. The state space of the process is $\mathbb{R}_+^N$, and one can interpret each of the components as a queue length associated with a specific customer class.

The formulation of the model involves two collections of N-dimensional vectors. The first are the *directions of constraint*, which we designate by $\{d_i, i = 1, \ldots, N\}$. These vectors are used to define the Skorokhod or reflection map, which properly corrects the dynamics of the model when one or more components of the state are zero (i.e., one or more customer classes are empty). The second collection is designated $\{v_{jk}, j = 1, \ldots, J, k = 1, \ldots, K\}$ and is used to define the dynamics of the system away from the boundary. Nature's control takes values in a compact convex set $\mathcal{A} \subset \mathbb{R}^K$, and the index $j \in \{1, \ldots, J\}$ corresponds to one of the possible "pure" service/routing configurations the true controller can select (illustrative examples will be given below). If nature chooses the control $\alpha \in \mathcal{A}$ and the true control is the pure configuration j, then the quantity $\sum_{k=1}^K \alpha_k v_{jk}$ characterizes the (law of large numbers) evolution of the network when the state of the network is away from $\partial\mathbb{R}_+^N$. More general service/routing policies can be obtained by considering convex combinations of the pure controls, in which case the velocity of the system is given by

$$F(\rho, \alpha) \doteq \sum_{j=1}^{J} \sum_{k=1}^{K} \rho_j \alpha_k v_{jk},$$

where

$$\rho = (\rho_1, \ldots, \rho_J) \in \mathcal{S} \doteq \left\{ x \in \mathbb{R}^J : x_j \geq 0, j = 1, \ldots, J, \sum_{j=1}^{J} x_j = 1 \right\},$$

and ρ_j is the fraction of time allocated to the pure configuration j.

We will assume the following condition on the directions of constraint. The condition is by now classical in the study of approximations to queueing networks and is called the Harrison–Reiman condition in [11]. It was first used in [14]. Although the Harrison–Reiman condition is usually associated with single class networks, it also defines the proper Skorokhod problem for many formulations of controlled multiclass networks as well. Note that the condition is the original Harrison–Reiman condition and not the generalization that is also studied in [11].

CONDITION 2.1. *For each* $i \in \{1, \ldots, N\}$

$$(d_i)_i = 1, \text{ and } (d_i)_j \leq 0 \text{ for } j \neq i.$$

Let D *be the matrix whose* i*th column is* d_i*. Then the spectral radius of* $I - D$ *is less than* 1.

The following simple examples illustrate the role these different quantities play. The ith unit basis vector is denoted by e_i. Some of the most difficult aspects in the control of networks are due to feedback and the interactions between different servers. From this perspective, the first two examples are too simple to be of great interest. Also, it should be noted that the game formulation we consider in this paper allows routing only at the "fringes" of the network and not between nodes.

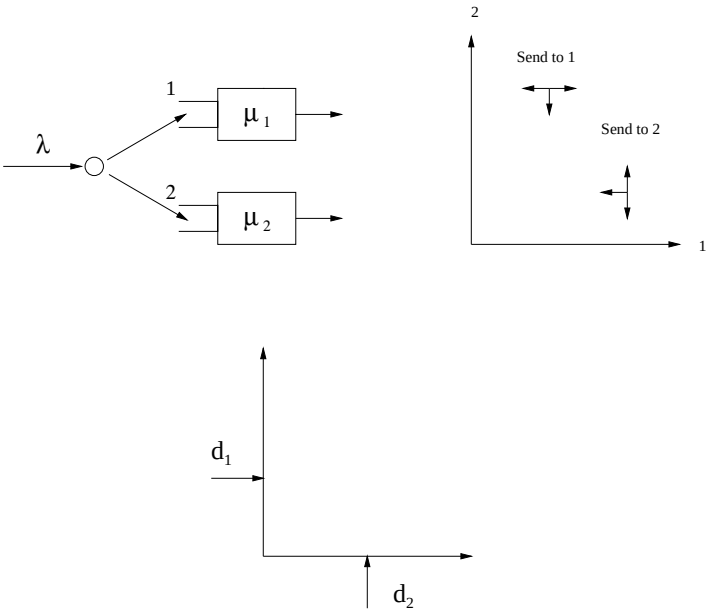

FIG. 1. *Simple routing control.*

Example 1. The first example is a simple routing control problem. The rate of arrivals to the router is $\lambda(t)$, and the service rates of the two servers are $\mu_1(t)$ and $\mu_2(t)$, respectively. The system is illustrated in Figure 1.

This model is put into the framework described above by setting

$$\begin{array}{lll} \alpha_1 = \mu_1, & v_{1,1} = -e_1, & v_{2,1} = -e_1, \\ \alpha_2 = \mu_2, & v_{1,2} = -e_2, & v_{2,2} = -e_2, \\ \alpha_3 = \lambda, & v_{1,3} = e_1, & v_{2,3} = e_2. \end{array}$$

The choice of $\mathcal{A}$ determines the uncertainties and perturbations against which the optimal true control will be robust. For example, if the nominal service and arrival rates are $\bar{\lambda} = 1$ and $\bar{\mu}_i = 1, i = 1, 2$, and if the service rates are well modeled and the arrival rate less so, then one might consider a set of the form

$$\mathcal{A} = [\bar{\mu}_1^L, \bar{\mu}_1^U] \times [\bar{\mu}_2^L, \bar{\mu}_2^U] \times [\bar{\lambda}^L, \bar{\lambda}^U] = [.9, 1.1] \times [.9, 1.1] \times [.5, 1.5].$$

This model is very simple and perhaps too simple to capture any "probabilistic" intuition. For example, there is no constraint on combinations of μ_1 and μ_2. From a probabilistic perspective one might imagine that it is less likely that both of these parameters would equal their minimum value at the same time. The introduction of a constraint to account for this would lead to a set $\mathcal{A}$ with a "curved" boundary.

One might also wish to consider an increasing family of sets $\mathcal{A}(c)$ indexed by $c \in [0, \infty)$ and with $\mathcal{A}(0)$ just the nominal model. The largest c such that a certain robust performance measure can be met (e.g., finiteness of the value function) is an important quantity. In particular, it characterizes the control that is most robust, where the sense of robustness is determined by the shape of $\mathcal{A}$ and the relative uncertainty it assigns to different aspects of the network.

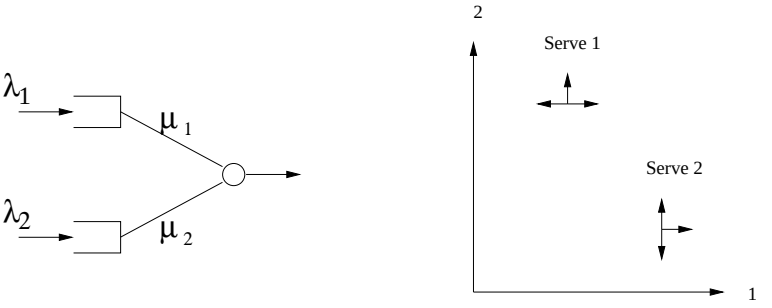

FIG. 2. *Simple service control.*

We return our consideration to the particular example of Figure 1. If a service is attempted at server 1 and the queue is empty, then the proper compensating action is simply to return queue 1 to the level zero. As a consequence, the direction of constraint for the corresponding face is just $d_1 = (1, 0)$. A corresponding remark applies to queue 2.

Example 2. Here we consider a simple service control problem. The system is illustrated in Figure 2.

The Skorokhod problem for this is the same as that for Example 1. This model is put into the standard framework by setting

$$\begin{array}{lll} \alpha_1 = \mu_1, & v_{1,1} = -e_1, & v_{2,1} = 0, \\ \alpha_2 = \mu_2, & v_{1,2} = 0, & v_{2,2} = -e_2, \\ \alpha_3 = \lambda_1, & v_{1,4} = e_1, & v_{2,4} = e_1, \\ \alpha_4 = \lambda_2, & v_{1,4} = e_2, & v_{2,4} = e_2. \end{array}$$

Example 3. This example considers a network of servers, and as a consequence the associated Skorokhod map is more involved. The network is illustrated in Figure 3. Since there are six customer classes, the domain is $\mathbb{R}^6_+$. Suppose the service rate for class i is $\mu_i(t)$ and the arrival rate is $\lambda(t)$.

An example of a pure configuration (labeled, say, j) is to route to class 1 and serve classes 3, 2, and 5. If we let $(\alpha_1, \ldots, \alpha_6, \alpha_7) = (\mu_1, \ldots, \mu_6, \lambda)$, then the vectors v_{jk} for $k = 2, 3, 5, 7$ are

$$v_{j2} = (-e_2 + e_6), v_{j3} = (-e_3 + e_4), v_{j5} = (-e_5 + e_3), v_{j7} = e_1,$$

while $v_{j1} = v_{j4} = v_{j6} = 0$. The velocity of the network under this configuration is $\mu_2 v_{j2} + \mu_3 v_{j3} + \mu_5 v_{j5} + \lambda v_{j7}$.

If a service is attempted for, say, customer class $i = 3$ and the queue is empty, then queue 3 must be returned to zero and in addition queue 4 must be reduced by the same amount. Consequently, the proper direction of constraint for face $i = 3$ is $d_3 = (e_3 - e_4)$. Analogous considerations can be used to identify all other directions of constraint.

Example 4. In some problems there is randomized (uncontrolled) routing. For example, after service a fraction θ_j of the class i customers may become class j customers, and a fraction $\theta_0 = 1 - \sum_{j=1, j\neq i}^{J} \theta_j$ of the customers could leave the system. Let $(d_i)_j = -\theta_j$ if $j \neq i$ and $(d_i)_i = 1$. Then the direction of constraint is d_i on the face $\{x \in \mathbb{R}^N_+ : x_i = 0\}$, and the reason is the same as in the last case: compensating

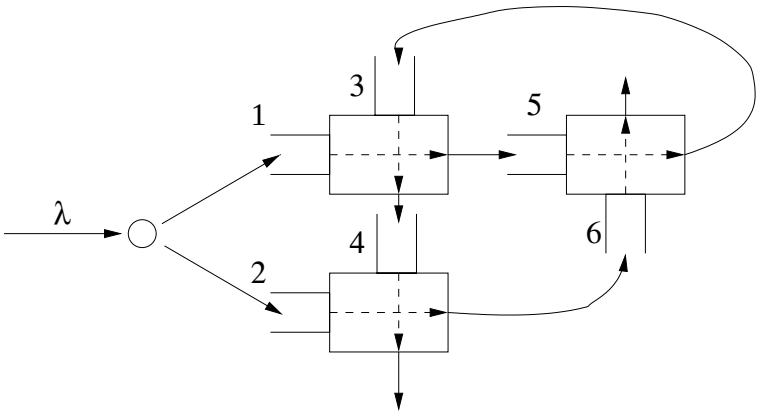

FIG. 3. *Network model.*

for a "fictitious" service of a customer of class i requires a boost to coordinate i and a corresponding decrease in coordinate j with constant of proportionality θ_j [21].

To formulate the robust control problem we must specify the dynamics. Let

$$C_+([0,\infty):\mathbb{R}^N) \doteq \{\psi \in C([0,\infty):\mathbb{R}^N) : \psi(0) \in \mathbb{R}^N_+\},$$

where $C([0,\infty):\mathbb{R}^N)$ is the usual space of continuous functions with the sup norm metric, and suppose that a set of vectors that satisfy Condition 2.1 is given. For each point x on the boundary of $\mathbb{R}^N_+$ let

$$d(x) \doteq \left\{ \sum_{i\in I(x)} a_i d_i : a_i \geq 0, \left\| \sum_{i\in I(x)} a_i d_i \right\| = 1 \right\},$$

where $I(x) \doteq \{i : x_i = 0\}$. The Skorokhod problem assigns to every path $\psi \in C_+([0,\infty):\mathbb{R}^N)$ a path ϕ that starts at $\phi(0) = \psi(0)$ but is constrained to $\mathbb{R}^N_+$ as follows. If ϕ is in the interior of $\mathbb{R}^N_+$, then the evolution of ϕ mimics that of ψ, in that the increments of the two functions are the same until ϕ hits the boundary of $\mathbb{R}^N_+$. When ϕ is on the boundary a constraining "force" is applied to keep ϕ in the domain, and this force can only be applied in one of the directions $d(\phi(t))$ and only for t such that $\phi(t)$ is on the boundary. The precise definition is as follows. For $\eta \in C([0,\infty):\mathbb{R}^N)$ and $t \in [0,\infty)$ we let $|\eta|(t)$ denote the total variation of η on $[0,t]$ with respect to the Euclidean norm on $\mathbb{R}^N$.

DEFINITION 2.1. *Let $\psi \in C_+([0,\infty):\mathbb{R}^N)$ be given. Then (ϕ,η) solves the Skorokhod problem for ψ (with respect to $\mathbb{R}^N_+$ and $d_i, i = 1,\ldots,N$) if $\phi(0) = \psi(0)$, and if for all $t \in [0,\infty)$*

1. $\phi(t) = \psi(t) + \eta(t)$,
2. $\phi(t) \in \mathbb{R}^N_+$,
3. $|\eta|(t) < \infty$,
4. $|\eta|(t) = \int_{[0,t]} 1_{\{\phi(s)\in\partial\mathbb{R}^N_+\}} d|\eta|(s)$,
5. *there exists a Borel measurable function $\gamma : [0,\infty) \to \mathbb{R}^N_+$ such that $d|\eta|$-almost*

everywhere $\gamma(t) \in d(\phi(t))$, *and such that*

$$\eta(t) = \int_{[0,t]} \gamma(s) d|\eta|(s).$$

Note that η changes only when ϕ is on the boundary and only in the directions $d(\phi)$.

Under Condition 2.1 the Skorokhod problem has a solution for all $\psi \in C_+([0,\infty) : \mathbb{R}^N)$. In addition, the mapping $\psi \to \phi$ is Lipschitz continuous [9, 14].

We next define a constrained ODE. As is proved in [9], one can define a projection $\pi : \mathbb{R}^N \to \mathbb{R}^N_+$ that is consistent with the constraint directions $\{d_i, i = 1, \ldots, N\}$, in that $\pi(x) = x$ if $x \in \mathbb{R}^N_+$, and if $x \notin \mathbb{R}^N_+$, then $\pi(x) - x = \alpha r$, where $\alpha \geq 0$, $\pi(x) \in \partial\mathbb{R}^N_+$, and $r \in d(\pi(x))$. Figure 4 illustrates the projection for a two dimensional problem.

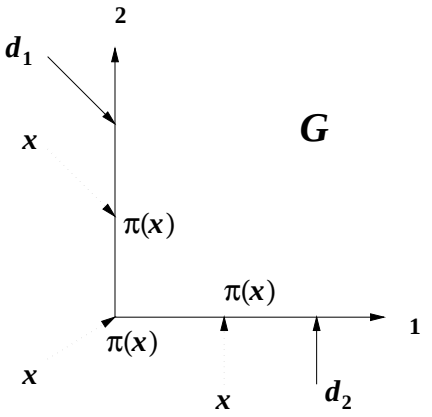

FIG. 4. *The discrete projection.*

With this projection given, we can define for each point $x \in \partial\mathbb{R}^N_+$ and each $v \in \mathbb{R}^N$ the *projected velocity*

$$\pi(x, v) \doteq \lim_{\Delta \downarrow 0} \frac{\pi(x + \Delta v) - \pi(x)}{\Delta}. \tag{1}$$

For details on why this limit is always well defined and further properties of the projected velocity, we refer to [7, section 3 and Lemma 3.8] and [8]. The dynamical model for the game we consider is then given by

$$\dot{\phi}(t) = \pi(\phi(t), F(\rho(t), \alpha(t))), \tag{2}$$

where

$$F(\rho(t), \alpha(t)) = \sum_{j=1}^{J} \sum_{k=1}^{K} \rho_j(t) \alpha_k(t) v_{jk}, \tag{3}$$

and for all $t \in [0,\infty)$ the true control $\rho(t)$ takes values in the set $\mathcal{S}$ and nature's control $\alpha(t)$ takes values in the set $\mathcal{A}$. According to the Skorokhod problem, the velocity $F(\rho, \alpha)$ governs the evolution of the network when all states are positive.

When one or more states are negative, the projection of the velocity provides the proper correction to the dynamics due to nonnegativity constraints.

An absolutely continuous function $\phi : [0,\infty) \to \mathbb{R}^N_+$ is a solution to (2) if the equation is satisfied in an almost everywhere sense in t. By using the regularity properties of the associated Skorokhod map, one can prove that all the standard qualitative properties (existence and uniqueness of solutions, stability with respect to perturbations, etc.) hold [9]. In fact, because of the particularly simple nature of the right-hand side (i.e., $\pi(\phi(t), \beta(t))$ rather than $\pi(\phi(t), b(\phi(t)) + \beta(t))$ for some function b), one can show that ϕ solves (2) if and only if ϕ is the image of $\psi(t) \doteq \int_0^t F(\rho(s), \alpha(s))ds + x$ under the Skorokhod map, in which case all such issues become trivial [9].

The ODE (2) defines the dynamics for the game that we will consider. The cost we consider is the time for the state to reach the origin, which the true control will attempt to minimize and which nature will try to prolong. As usual in differential games, one must deal with the issue of which player has the "information advantage" [13]. In our formulation we will allow the true controller to use "relaxed" controls, and as a consequence the game will have value; i.e., the value function will be the same regardless of who has the information advantage. However, the (upper) value of the game would not be the same if ordinary controls were used. In this sense the game defined as the limit of risk-sensitive control problems is superior, in that the upper value does not depend on whether pure or relaxed controls are used [2].

We use the standard Elliot–Kalton formulation of the game. Define the spaces of (open loop) controls

$$N \doteq \{\rho : [0,\infty) \to \mathcal{S} : \rho \text{ is measurable}\}$$

and

$$M \doteq \{\alpha : [0,\infty) \to \mathcal{A} : \alpha \text{ is measurable}\}.$$

We identify any two controls that are equal almost everywhere. Given $x \in \mathbb{R}^N_+$, the dynamics of the game are given by (2) and (3). Associated with these dynamics is the cost

$$C_x(\rho, \alpha) \doteq \tau_x,$$

where $\tau_x \doteq \inf\{t \geq 0 : \phi(t) = 0\}$. A mapping $\theta : N \to M$ is said to be a *strategy for the maximizing player* if for each $s \geq 0$ and $\rho, \hat{\rho} \in N$

$$\rho(t) = \hat{\rho}(t) \text{ for a.e. } 0 \leq t \leq s$$

implies

$$\theta[\rho](t) = \theta[\hat{\rho}](t) \text{ for a.e. } 0 \leq t \leq s.$$

A *strategy for the minimizing player*, which will be denoted by δ, is defined in an analogous manner. We denote by Θ the set of all maximizing strategies and by Δ the set of all minimizing ones. The *lower value of the game* and the *upper value of the game* are defined by

$$V^-(x) \doteq \inf_{\delta \in \Delta} \sup_{\alpha \in M} C_x(\delta[\alpha], \alpha) \tag{4}$$

and

$$V^+(x) \doteq \sup_{\theta\in\Theta}\inf_{\rho\in N} C_x(\rho,\theta[\rho]), \tag{5}$$

respectively. If $V^-(x) = V^+(x)$, then the game is said to have value.

Let $V : \mathbb{R}^N \to \mathbb{R}$. For points $x \in \mathbb{R}^N$ and directions $w \in \mathbb{R}^N$ for which the limit exists, we let $D_wV(x)$ denote the directional derivative in direction w at x:

$$D_wV(x) \doteq \lim_{a\downarrow 0}\frac{V(x+aw)-V(x)}{a}.$$

We say that V is *radially linear* if $V(ax) = aV(x)$ for all $x \in \mathbb{R}^N$ and $a \in [0,\infty)$.

3. Representation for the value function. For $V^+(x)$ and $V^-(x)$ to be finite we will need some conditions. Define the convex cone

$$\mathcal{C} \doteq \left\{-\sum_{i=1}^N a_i d_i : a_i \geq 0, i = 1,\dots,N\right\},$$

which is the negative of the cone of constraint directions that are allowed at the origin. As observed in [7], this cone can be used to characterize stability conditions for (2).

The following formula gives an explicit representation for the value of the game defined in the last section. The precise statement is given at the end of the section, and the proof is given in section 4. Recall that $F(\rho,\alpha) \doteq \sum_{j=1}^J\sum_{k=1}^K \rho_j\alpha_k v_{jk}$. Then set

$$W(x) \doteq \sup_{\alpha\in\mathcal{A}}\inf_{\rho\in\mathcal{S}}\inf\left\{\sigma : x+\sigma F(\rho,\alpha)\in\mathcal{C}\right\}. \tag{6}$$

We will also make use of

$$W_\alpha(x) \doteq \inf_{\rho\in\mathcal{S}}\inf\left\{\sigma : x+\sigma F(\rho,\alpha)\in\mathcal{C}\right\}. \tag{7}$$

The following condition is necessary and sufficient for $W(x)$ to be finite for all $x \in \mathbb{R}^N$. Let $\mathcal{C}^\circ$ denote the interior of $\mathcal{C}$.

CONDITION 3.1. *For each $\alpha \in \mathcal{A}$ there exists $\rho \in \mathcal{S}$ such that*

$$F(\rho,\alpha) \in \mathcal{C}^\circ.$$

It follows directly from the definition of $W_\alpha(x)$ that under this condition $W_\alpha(x) < \infty$ for all $x \in \mathbb{R}^N$. Since $\mathcal{A}$ is compact, an open covering argument can be used to prove that $W(x) < \infty$ for all $x \in \mathbb{R}^N$.

In order to motivate the representation (6), we first consider (7). In this case there is just "true" control for a fixed set of arrival and service rates. It turns out that W_α equals the minimum time for a control problem that uses the dynamics defined by the Skorokhod problem and stops when the origin is reached. However, from the formula for W_α it is clear that W_α equals the solution to the minimum time problem with the much simpler dynamics $\dot\phi(t) = F(\rho(t),\alpha)$ and the stopping set $\mathcal{C}$. Away from the boundary $\partial\mathbb{R}^N_+$ these two different minimum time problems should satisfy the same Hamilton–Jacobi–Bellman equation. Owing to the constraining dynamics, the first minimum time problem should satisfy a Neumann boundary condition $\langle DW_\alpha(x), d_i\rangle = 0$ for $i \in I(x)$ on $\partial\mathbb{R}^N_+\backslash\{0\}$ (in the viscosity sense). It turns out (under Condition 2.1) that the shape of the stopping set $\mathcal{C}$ in the second minimum

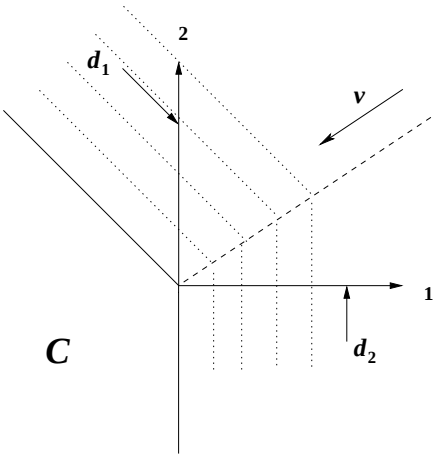

FIG. 5. *Level sets of W_α: Classical boundary conditions.*

time problem produces a function whose gradient satisfies this boundary condition, and so by uniqueness one would expect the two minimum time problems to coincide on $\mathbb{R}^N_+$ [1]. Figure 5 illustrates the situation for a particular two dimensional problem with no control (so that $F(\rho, \alpha) = v$ is a constant). The dotted lines indicate level curves of W_α, and the dashed line indicates the boundary between two regions where the gradient of the value function is constant.

Since the level curves of W_α are parallel to d_i for x near $\{x \in (\mathbb{R}^2_+)\backslash\{0\} : x_i = 0\}$, the gradient is orthogonal to the direction of constraint. Thus the boundary conditions hold, even in a classical sense.

The situation is not always so simple, as indicated by Figure 6. The interpretations of the dotted and dashed lines are the same as in Figure 5. Note that in this case it is only the boundary condition which corresponds to d_1 that holds in the classical sense. Along the boundary that corresponds to d_2 the inner product of the gradient and the direction of constraint is strictly positive. This is due to the fact that on this boundary v points into the interior of $\mathbb{R}^2_+$. One of the important properties of viscosity solutions is that they allow such relaxations of the boundary conditions when they are not physically relevant.

The remarkable fact is that an analogous representation continues to hold even in the game problem, with simply an additional supremization on $\alpha \in \mathcal{A}$. It should be noted that even though the game has value, one cannot permute the $\inf_{\rho\in\mathcal{S}}$ and $\sup_{\alpha\in\mathcal{A}}$ in (6).

In the rest of this section we will prove qualitative properties of W that are needed for the proof that W is the value of the game. W_α turns out to be the value for a control problem, and the identification of W_α as the value function for such problems first appears in [23, 24].

THEOREM 3.1. *Assume that Conditions* 3.1 *and* 2.1 *are satisfied and define $W_\alpha(x)$ for $x \in \mathbb{R}^N$ and $\alpha \in \mathcal{A}$ by* (7)*. The following conclusions hold.*

1. *W_α is finite and radially linear on $\mathbb{R}^N$.*
2. *For each $x \in \mathbb{R}^N$ the infimum in* (7) *is achieved at some probability vector ρ.*
3. *W_α is convex on $\mathbb{R}^N$.*
4. *$W_\alpha(x) > 0$ for $x \in \mathbb{R}^N_+\backslash\{0\}$.*

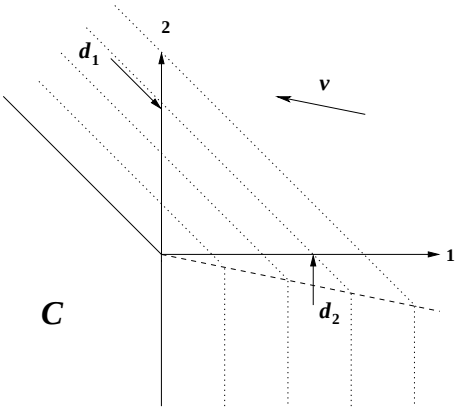

FIG. 6. *Level sets of W_α: Without classical boundary conditions.*

Proof. Under Condition 3.1 it is obvious that the cone $\mathcal{C}$ can be reached from any starting point x, and so $W_\alpha(x) < \infty$, while radially linearity is an immediate consequence of the definition of $W_\alpha(x)$. It follows from the compactness of $\mathcal{S}$ that the infimum is achieved in the definition of $W_\alpha(x)$. Thus the proofs of parts 1 and 2 are complete.

To prove property 3 we first consider points x_1 and x_2 such that $W_\alpha(x_1) = W_\alpha(x_2) \neq 0$. Let c denote the common value, and let ρ^1 and ρ^2 denote minimizing probability vectors in the expression that defines $W_\alpha(x_1)$ and $W_\alpha(x_2)$, respectively. Thus $x_i + cF(\rho^i, \alpha) \in \partial\mathcal{C}$ for $i = 1, 2$. For $s \in [0, 1]$, the convexity of $\mathcal{C}$ implies

$$\begin{aligned} &sx_1 + (1-s)x_2 + scF(\rho^1, \alpha) + (1-s)cF(\rho^2, \alpha) \\ &= (sx_1 + (1-s)x_2) + cF(s\rho^1 + (1-s)\rho^2, \alpha) \in \mathcal{C}. \end{aligned}$$

Since $s\rho^1 + (1-s)\rho^2 \in \mathcal{S}$, it follows that

$$W_\alpha(sx_1 + (1-s)x_2) \leq c = sW_\alpha(x_1) + (1-s)W_\alpha(x_2).$$

We next consider the case of any points x_1 and x_2 such that $W_\alpha(x_1) \neq 0$ and $W_\alpha(x_2) \neq 0$. Let

$$c = sW_\alpha(x_1) + (1-s)W_\alpha(x_2).$$

Since W_α is radially linear,

$$\begin{aligned} &W_\alpha(sx_1 + (1-s)x_2) \\ &= W_\alpha\left(s\frac{W_\alpha(x_1)}{W_\alpha(x_1)}x_1 + (1-s)\frac{W_\alpha(x_2)}{W_\alpha(x_2)}x_2\right) \\ &= W_\alpha\left(\left[\frac{sW_\alpha(x_1)}{c}\frac{x_1}{W_\alpha(x_1)} + \frac{(1-s)W_\alpha(x_2)}{c}\frac{x_2}{W_\alpha(x_2)}\right]c\right) \\ &\leq \frac{sW_\alpha(x_1)}{c}W_\alpha\left(\frac{x_1}{W_\alpha(x_1)}c\right) + \frac{(1-s)W_\alpha(x_2)}{c}W_\alpha\left(\frac{x_2}{W_\alpha(x_2)}c\right) \\ &= sW_\alpha(x_1) + (1-s)W_\alpha(x_2). \end{aligned}$$

The case where $W_\alpha(x_1)$ or $W_\alpha(x_2)$ equals zero is similar and omitted.

Finally we must prove property 4. The Harrison–Reiman condition implies what is called the *completely-$\mathcal{S}$* condition [20, 5], which requires the existence of a vector $v \in \mathbb{R}^N$ satisfying $v_i > 0, i = 1, \ldots, N$, and $\langle v, \gamma \rangle > 0$ for all $\gamma \in d(0)$. Hence if $y \in \mathcal{C} \backslash \{0\}$, then $\langle v, y \rangle < 0$, and so $y \notin \mathbb{R}^N_+$. This shows that

$$\mathcal{C} \cap \mathbb{R}^N_+ = \{0\},$$

and therefore $W_\alpha(x) > 0$ for all $x \in \mathbb{R}^N_+ \backslash \{0\}$. □

THEOREM 3.2. *Assume that Conditions* 3.1 *and* 2.1 *are satisfied and define* $W(x)$ *for* $x \in \mathbb{R}^N$ *by* (6). *The following conclusions hold.*

1. W *is finite and radially linear on* $\mathbb{R}^N$.
2. W *is convex on* $\mathbb{R}^N$.
3. $W(x) > 0$ *for* $x \in \mathbb{R}^N_+ \backslash \{0\}$.

Proof. It follows from Condition 3.1 that for each $x \in \mathbb{R}^N$ $W_\alpha(x)$ is bounded uniformly in $\alpha \in \mathcal{A}$. All the claims then follow from the preceding theorem and $W(x) = \sup_{\alpha \in \mathcal{A}} W_\alpha(x)$. □

Remark. Since W is convex, directional derivatives exist at all points and for all directions.

THEOREM 3.3. *Assume that Conditions* 2.1 *and* 3.1 *are satisfied and define* $W(x), V^-(x)$, *and* $V^+(x)$ *by* (6), (4), *and* (5), *respectively. Then for all* $x \in \mathbb{R}^N_+$

$$W(x) = V^-(x) = V^+(x).$$

4. Proof of the representation. In this section we give the proof of Theorem 3.3. The proof that the differential game has value (i.e., that $V^-(x) = V^+(x)$) is deferred to the appendix. We first prove some preparatory lemmas. Let

$$\rho(x, \alpha) \doteq \{\rho \in \mathcal{S} : x + W_\alpha(x) F(\rho, \alpha) \in \mathcal{C}\}.$$

LEMMA 4.1. *Assume Condition* 3.1. *For each* $x \in \mathbb{R}^N_+$ *and* $\alpha \in \mathcal{A}$ *the set* $\rho(x, \alpha)$ *is nonempty and convex, and moreover the mapping from* $\mathbb{R}^N_+ \times \mathcal{A}$ *to* $\mathcal{S}$ *defined by* $(x, \alpha) \to \rho(x, \alpha)$ *is upper semicontinuous.*

Proof. Fix $x \in \mathbb{R}^N_+$ and $\alpha \in \mathcal{A}$, and let ρ^m come within $1/m$ of the infimum of

$$\inf \{\sigma : x + \sigma F(\rho, \alpha) \in \mathcal{C}\}$$

over $\rho \in \mathcal{S}$. Let σ^m come within $1/m$ of the infimum over σ when $\rho = \rho^m$. By extracting a subsequence, we can assume that $(\rho^m, \sigma^m) \to (\rho^*, W_\alpha(x))$ with $\rho^* \in \mathcal{S}$. We claim that $\rho^* \in \rho(x, \alpha)$. Indeed, we have

$$x + W_\alpha(x) F(\rho^*, \alpha) = \lim_{m \to \infty} (x + \sigma^m F(\rho^m, \alpha)) \in \mathcal{C},$$

which proves that $\rho^* \in \rho(x, \alpha)$ and shows that $\rho(x, \alpha)$ is nonempty. Since $\rho \to F(\rho, \alpha)$ is linear, it follows that $\rho(x, \alpha)$ is also convex.

To prove the upper semicontinuity we first show that $W_\alpha(x)$ is jointly continuous in (x, α). Let $(x^i, \alpha^i) \to (x, \alpha)$ as $i \to \infty$. Under Condition 3.1, for all $\varepsilon > 0$ we can find $\rho \in \mathcal{S}$ such that $x + [W_\alpha(x) + \varepsilon] F(\rho, \alpha) \in \mathcal{C}^\circ$. This implies $\limsup_{i \to \infty} W_{\alpha^i}(x^i) \leq W_\alpha(x) + \varepsilon$, and since $\varepsilon > 0$ is arbitrary $\limsup_{i \to \infty} W_{\alpha^i}(x^i) \leq W_\alpha(x)$. Let $\rho^i \in \rho(x^i, \alpha^i)$. By extracting a subsequence, we can assume that $W_{\alpha^i}(x^i) \to M$ and $\rho^i \to \rho \in \mathcal{S}$. Taking the limit as $i \to \infty$ in

$$x^i + W_{\alpha^i}(x^i) F(\rho^i, \alpha^i) \in \mathcal{C}$$

gives

$$x + MF(\rho, \alpha) \in \mathcal{C},$$

and therefore $\liminf_{i\to\infty} W_{\alpha^i}(x^i) \geq W_\alpha(x)$. We conclude that $W_\alpha(x)$ is jointly continuous in (x, α).

Next let $(x^i, \alpha^i) \to (x, \alpha)$ as $i \to \infty$, and let $\rho^i \in \rho(x^i, \alpha^i)$. We must show that $\rho^i \to \rho^*$ implies $\rho^* \in \rho(x, \alpha)$. Using the continuity of $W_\alpha(x)$,

$$x + W_\alpha(x)F(\rho^*, \alpha) = \lim_{i\to\infty} \left(x^i + W_{\alpha^i}(x^i)F(\rho^i, \alpha^i)\right) \in \mathcal{C}.$$

We conclude that $\rho^* \in \rho(x, \alpha)$, and therefore $(x, \alpha) \to \rho(x, \alpha)$ is upper semicontinuous. □

LEMMA 4.2. *Assume that Conditions* 2.1 *and* 3.1 *are satisfied and define* $W(x)$ *for* $x \in \mathbb{R}^N$ *by* (6). *Consider any point* $x \in \mathbb{R}^N_+ \backslash \{0\}$ *and let* $v \in \mathbb{R}^N$ *be such that* $x + W(x)v \in \mathcal{C}$. *Then*

$$D_v W(x) \leq -1.$$

Proof. Since $x + W(x)v \in \mathcal{C}$, it follows that $W(x + W(x)v) = 0$. The convexity of W then implies that for any $a \in (0, W(x))$

$$\begin{aligned} W(x + av) &\leq \frac{a}{W(x)} W(x + W(x)v) + \left(1 - \frac{a}{W(x)}\right) W(x) \\ &\leq \left(1 - \frac{a}{W(x)}\right) W(x). \end{aligned}$$

It follows that

$$D_v W(x) \doteq \lim_{a\downarrow 0} \frac{W(x + av) - W(x)}{a} \leq -1. \qquad \square$$

Define

$$B(x) \doteq \{v : v = F(\rho, \alpha) \text{ for some } \rho \in \rho(x, \alpha), \alpha \in \mathcal{A}\}.$$

These are the velocities that are optimal (for the true controller) at x for the control problem $W_\alpha(x)$ for some $\alpha \in \mathcal{A}$.

LEMMA 4.3. *Assume that Conditions* 2.1 *and* 3.1 *are satisfied and define* $W(x)$ *for* $x \in \mathbb{R}^N$ *by* (6). *Then for any* $x \in \mathbb{R}^N_+$ *and* $v \in B(x)$ *we have* $x + W(x)v \in \mathcal{C}$.

Proof. Suppose that $v \in B(x)$ corresponds to $\alpha \in \mathcal{A}$. We know that

$$x + W_\alpha(x)v \in \mathcal{C} \text{ and } W_\alpha(x) \leq W(x).$$

If $v \in \mathcal{C}$, then we are done, since $\mathcal{C}$ is a cone with vertex at the origin. Now $x \in \mathbb{R}^N_+$ implies that $v = v_1 + v_2$, where $v_1 \in -\mathbb{R}^N_+$ and $v_2 \in \mathcal{C}$. Thus we need only show $-\mathbb{R}^N_+ \subset \mathcal{C}$. Since $\mathcal{C}$ is a convex cone, to show this it is enough to prove that $-e_i \in \mathcal{C}$ for each $i = 1, \ldots, N$.

Let the vectors $\{d_i^*, i = 1, \ldots, N\}$ be defined by

$$\langle d_i, d_j^* \rangle = \begin{cases} 1, & i = j, \\ 0, & i \neq j. \end{cases}$$

Condition 2.1 implies the vectors $\{d_i, i = 1, \ldots, N\}$ are linearly independent, and so this is well defined. The vectors $\{d_i^*, i = 1, \ldots, N\}$ provide an external representation for $\mathcal{C}$ in that

$$\mathcal{C} = \left\{ y \in \mathbb{R}^N : \langle y, d_i^* \rangle \leq 0, i = 1, \ldots, N \right\}.$$

Thus $-e_i \in \mathcal{C}$ will follow if we show $\langle e_i, d_j^* \rangle \geq 0$ for $j = 1, \ldots, N$. Let D be the matrix whose ith column is d_i. Then D^{-1} is the matrix whose jth row is d_j^*. We can write $D = I - A$, where A is nonnegative. Under Condition 2.1 the spectral radius of A is less than one, and so we can express D^{-1} as $\sum_{\ell=0}^{\infty} A^\ell$. This shows that D^{-1} is nonnegative and completes the proof of the lemma. □

We recall the definition of the projected velocity given in (1) and $I(x) \doteq \{i : x_i = 0\}$ for $x \in \mathbb{R}_+^N$.

LEMMA 4.4. *Assume that Conditions* 2.1 *and* 3.1 *are satisfied and define* $W(x)$ *for* $x \in \mathbb{R}^N$ *by* (6). *Let* $x \in \mathbb{R}_+^N$ *be given. Let* $y \leq x$ *componentwise, and assume* $y \notin \mathcal{C}$ *(so that* $W(y) > 0$*). Let* $v \in B(y)$*, and suppose there exist* $a_i \geq 0, i \in I(x)$*, such that*

$$\left\langle v + \sum_{i \in I(x)} a_i d_i, e_j \right\rangle = 0, \quad j \in I(x). \tag{8}$$

Let $q = v + \sum_{i \in I(x)} a_i d_i$. *Then*

$$D_q W(y) \leq -1.$$

Proof. By Lemma 4.2 it is enough to show that $y + W(y)q \in \mathcal{C}$. According to the last lemma $y + W(y)v \in \mathcal{C}$, and so we can express $(y/W(y)) + v$ as $-\sum_{i=1}^N \bar{a}_i d_i$ for some constants $\bar{a}_i \geq 0, i = 1, \ldots, N$. To prove

$$\begin{aligned} y + W(y)q &= W(y) \left[(y/W(y)) + v + \sum_{i \in I(x)} a_i d_i \right] \\ &= W(y) \left[-\sum_{i=1}^N \bar{a}_i d_i + \sum_{i \in I(x)} a_i d_i \right] \\ &\in \mathcal{C}, \end{aligned}$$

it is therefore enough to show that $\bar{a}_i \geq a_i$ for $i \in I(x)$.

Since $v = -(y/W(y)) - \sum_{i=1}^N \bar{a}_i d_i$, (8) can be rewritten as

$$\left\langle -(y/W(y)) - \sum_{i=1}^N \bar{a}_i d_i + \sum_{i \in I(x)} a_i d_i, e_j \right\rangle = 0$$

for $j \in I(x)$. Let M denote the cardinality of $I(x)$. We recall that $\langle d_j, e_i \rangle \leq 0$ if $i \neq j$ and $y_i \leq x_i \leq 0$ for $i \in I(x)$. As a consequence, we can rewrite this system of M equations as

$$(I - D_M)r = q,$$

where I is the $M \times M$ identity matrix, D_M is nonnegative with spectral radius less than 1, $r_j = a_j - \bar{a}_j$ for $j \in I(x)$, and $q_i = \sum_{j \notin I(x)} \bar{a}_j \langle d_j, e_i \rangle + (y_i/W(y)) \leq 0$ for

each $i \in I(x)$. Since each component of $r = (\sum_{\ell=0}^{\infty} D_M^\ell)q$ is obviously nonpositive, we conclude that $a_i \le \bar{a}_i$ for $i \in I(x)$. □

In the proof of Theorem 3.3 we will need to construct a nearly optimal strategy for the minimizing player to prove that $V^-(x) \le W(x)$. If W were smooth, then such a strategy would be easy to construct. However, since W is only convex, it must be mollified to construct this policy, and this mollification in turn complicates the construction of the optimal control on the boundary. In the lemma that follows we apply the previous lemma to deal with this issue.

LEMMA 4.5. *Assume that Conditions* 2.1 *and* 3.1 *are satisfied and define* $W(x)$ *for* $x \in \mathbb{R}^N$ *by* (6). *Let* $\gamma > 0$ *be given. Then there exists a convex, continuously differentiable, and radially linear function* $W_\gamma : \mathbb{R}^N \to [0, \infty)$ *such that for all* $x \in \mathbb{R}_+^N$, $\alpha \in \mathcal{A}$, *and* $\rho \in \rho(x, \alpha)$,

$$|W_\gamma(x) - W(x)| \le \gamma W(x) \tag{9}$$

and

$$\langle \pi(x, F(\rho, \alpha)), DW_\gamma(x) \rangle \le -(1 - \gamma). \tag{10}$$

Proof. Fix $\gamma > 0$. We begin by noting a relation between directional derivatives and subdifferentials for convex functions. Fix $x \in \mathbb{R}_+^N$, and let $\partial W(x)$ denote the set of subdifferentials of W at x. Then for any $v \in \mathbb{R}^N$ and any $q \in \partial W(x)$, $\langle q, v \rangle \le D_v W(x)$. According to Lemmas 4.1, 4.2, and 4.3, for each $\alpha \in \mathcal{A}$ and $\rho \in \rho(x, \alpha)$ we have $D_{F(\rho,\alpha)} W(x) \le -1$, and therefore for all such α and ρ

$$\langle q, F(\rho, \alpha) \rangle \le -1 \tag{11}$$

for all $q \in \partial W(x)$.

We next mollify the function W. Define the convex set $G \doteq \{x : W(x) \le 1\}$. For $a > 0$ define the translation $G_a \doteq \{y = x + a(1, \ldots, 1) : x \in G\}$, and for $\delta > 0$ consider the δ-fattening $G_a^\delta \doteq \{y : \|y - x\| \le \delta \text{ for some } x \in G_a\}$. Since $0 \in G^\circ$, we can assume without loss that a is small enough that the origin is contained in the interior of G_a^δ. As we will see, the translation is needed to ensure that the fattening does not interfere with the boundary conditions that are required of the mollification. Finally, let

$$W_a^\delta(x) \doteq \inf\{c \ge 0 : x \in \partial(cG_a^\delta)\}.$$

The construction is illustrated in Figure 7.

It is easy to check that W_a^δ is finite and convex. Also, it is well known that G_a^δ has a C^1 boundary for each $\delta > 0$, and thus W_a^δ is continuously differentiable on $\mathbb{R}_+^N \backslash \{0\}$. We first compute the gradient of W_a^δ. Fix any point $x \in \mathbb{R}_+^N \backslash \{0\}$ and let n be the outward normal to G_a^δ at $y \doteq x/W_a^\delta(x)$. Since W_a^δ is radially linear, the gradient of $W_a^\delta(x)$ must be proportional to n, which means there must be a supporting hyperplane of the form $\langle x, rn \rangle$ to W_a^δ at x (here we use the fact that $W_a^\delta(0) = 0$). Thus using the equality $W_a^\delta(x) = \langle x, rn \rangle$, we find that

$$DW_a^\delta(x) = rn = \left(\frac{W_a^\delta(x)}{\langle x, n \rangle} \right) n = \left(\frac{1}{\langle y, n \rangle} \right) n.$$

Let y' be the unique point in G_a that is exactly distance δ from y, and let $z = y - a(1, \ldots, 1)$. Then n is also an outward normal to G at z, and an analogous

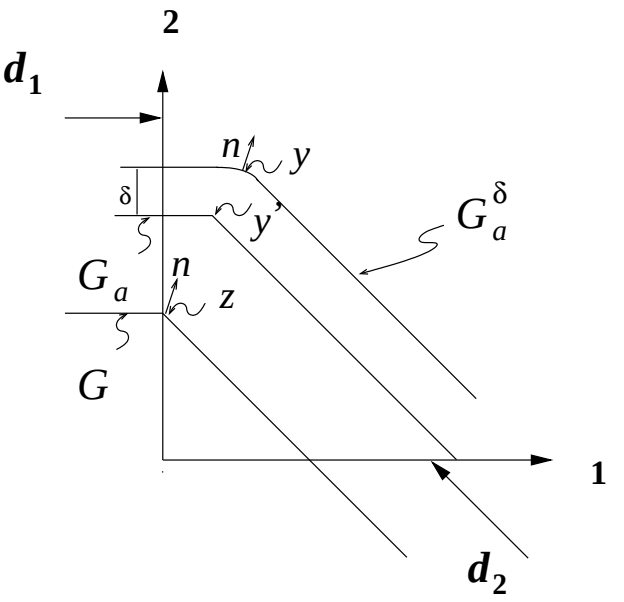

FIG. 7. *Construction of* G_a^δ.

calculation to the one just given shows that for any point of the form bz, $b \in (0, \infty)$, $(1/\langle z, n\rangle)\, n$ is a subdifferential to W at bz. Therefore,

$$DW_a^\delta(x) = \left(\frac{\langle z, n\rangle}{\langle y, n\rangle}\right) q,$$

where q is a subdifferential to W at z. We can make $|y - z|$ as small as desired by choosing $a > 0$ and $\delta > 0$ small. Let $\rho \in \rho(x, \alpha)$.

Since $\langle y, n\rangle$ is uniformly bounded from below away from zero, for all sufficiently small $a > 0$ and $\delta > 0$, (11) implies

$$\langle F(\rho, \alpha), DW_a^\delta(x)\rangle \le -(1 - \gamma).$$

Observe that conditions (8) characterize $\pi(x, F(\rho, \alpha))$. Thus if we knew that $z \le y$ (componentwise), then

$$\langle \pi(x, F(\rho, \alpha)), DW_a^\delta(x)\rangle \le -(1 - \gamma)$$

would also follow from Lemma 4.4. However, $z \le y$ follows easily by fixing $a > 0$ and then choosing $\delta \in (0, a)$. Finally, it is also easy to check that G and G_a^δ can be made arbitrarily close in the Hausdorff topology, which immediately implies

$$|W_a^\delta(x) - W(x)| \le \gamma W(x)$$

when a and δ are small. The lemma now follows by taking $W_\gamma = W_a^\delta$ for suitable $a > 0$ and $\delta > 0$. □

In the proof of Theorem 3.3 we will use a verification argument to show $V^-(x) \le W_\gamma(x)$ plus a small error. The use of feedback controls for the minimizing player would

be problematic. The next lemma will allow the use of piecewise constant controls and thereby simplify the proof. The lemma is an immediate consequence of the continuity of $DW_\gamma(x)$ for $\gamma > 0$ and $x \neq 0$.

LEMMA 4.6. *Assume that Conditions* 2.1 *and* 3.1 *are satisfied and for* $\gamma > 0$ *define* $W_\gamma(x)$ *for* $x \in \mathbb{R}^N$ *by Lemma* 4.5. *Then there is* $\nu > 0$ *such that for all* $z \in \mathbb{R}^N_+$ *with* $\|z\| = 1$, *all* y *with* $\|z - y\| \leq \nu$, *all* $\alpha \in \mathcal{A}$, *and all* $\rho \in \rho(z, \alpha)$,

$$\langle \pi(z, F(\rho, \alpha)), DW_\gamma(y) \rangle \leq -(1 - 2\gamma). \tag{12}$$

Proof of Theorem 3.3. We first prove that $W(x) \leq V^+(x)$. Fix $x \in \mathbb{R}^d_+ \setminus \{0\}$ and $\alpha \in \mathcal{A}$. Let $\rho \in N$ be any open loop control, and let $\tau_x > 0$ be the corresponding first time that the origin is reached by the solution to

$$\dot{\phi}(t) = \pi\left(\phi(t), F(\rho(t), \alpha)\right), \quad \phi(0) = x.$$

If $\tau_x = \infty$, there is nothing to prove, and so we assume $\tau_x < \infty$. Using the definition of the Skorokhod problem, there exist $a_i(t) \geq 0, i = 1, \ldots, N, t \in [0, \tau_x]$, such that

$$\dot{\phi}(t) = F(\rho(t), \alpha) + \sum_{i=1}^{N} a_i(t) d_i$$

for almost every $t \in [0, \tau_x]$. Integrating over $[0, \tau_x]$ and using the definition $\bar{\rho} \doteq \frac{1}{\tau_x} \int_0^{\tau_x} \rho(t) dt$, we find that

$$-x = \tau_x F(\bar{\rho}, \alpha) - \omega$$

for some $\omega \in \mathcal{C}$, and so $x + \tau_x F(\bar{\rho}, \alpha) \in \mathcal{C}$. The definition of $W_\alpha(x)$ then implies $\tau_x \geq W_\alpha(x)$. Since $\theta[\rho](t) = \alpha$ is a legitimate strategy to use in the definition of $V^+(x)$ and $\rho \in N$ is arbitrary, it follows that $V^+(x) \geq W_\alpha(x)$ for all $\alpha \in \mathcal{A}$. Taking the supremum on $\alpha \in \mathcal{A}$ gives $V^+(x) \geq W(x)$.

We next prove $W(x) \geq V^-(x)$. Let $\gamma \in (0, 1/2)$, and let $\nu > 0$ be given according to Lemma 4.6. Fix $x \in \mathbb{R}^d_+ \setminus \{0\}$ and let the open loop control $\alpha \in M$ be given. We recursively construct a strategy $\delta \in \Delta$ as follows. Given a point of the form $x_i \neq 0$ (with $x_0 = x$) and corresponding times τ_i (with $\tau_0 = 0$), we consider the normalized version $z_i = x_i / \|x_i\|$. Let $\rho^*(x, \alpha)$ be any single-valued and measurable selection from $\rho(x, \alpha)$. We define $\delta[\alpha](t)$ for $t \in [\tau_i, \tau_{i+1})$ to be $\rho^*(z_i, \alpha(t))$, where $\tau_{i+1} > \tau_i$ is defined by

$$\inf\{t \geq \tau_i : \|\phi(t)/\|\phi(t)\| - z_i\| \geq \nu\} \wedge \inf\{t \geq \tau_i : \phi(t) = 0\},$$

where

$$\dot{\phi}(t) = \pi(\phi(t), F(\rho^*(z_i, \alpha(t)), \alpha(t))), \quad \phi(\tau_i) = x_i.$$

Since the speed $\|\dot{\phi}(t)\|$ is uniformly bounded from above, it is easy to check that $\inf\{t \geq \tau_i : \|\phi(t)/\|\phi(t)\| - z_i\| \geq \nu\} - \tau_i$ is uniformly bounded away from zero if x_i is in a closed set that does not contain the origin. We will make use of the fact that for any $x \neq 0$ and any v, $\pi(x, v) = \pi(x/\|x\|, v)$. According to Lemma 4.6,

$$\langle DW_\gamma(\phi(t)), \dot{\phi}(t) \rangle = \langle DW_\gamma(\phi(t)), \pi(\phi(t), F(\rho^*(z_i, \alpha(t)), \alpha(t))) \rangle \leq -1 + 2\gamma$$

for almost every t prior to the first time ϕ hits the origin, and therefore for all such times

$$W_\gamma(\phi(t)) - W_\gamma(x) = \int_0^t \langle DW_\gamma(\phi(t)), \dot{\phi}(t)\rangle ds \leq -t(1-2\gamma).$$

We conclude that

$$W_\gamma(\phi(t)) \leq W_\gamma(x) - t(1-2\gamma),$$

and therefore ϕ reaches the origin by time $W_\gamma(x)/(1-2\gamma)$. This implies $V^-(x) \leq W_\gamma(x)/(1-2\gamma)$ and, since $\gamma > 0$ is arbitrary, that $V^-(x) \leq W(x)$.

Thus we have shown that $V^-(x) \leq W(x) \leq V^+(x)$. The proof that $V^-(x) = V^+(x)$ is based on a uniqueness result for the corresponding PDE and is presented in the appendix. This completes the proof of the theorem. □

5. Synthesis of controls. The "true" controls used to prove $W(x) \geq V^-(x)$ in the proof of Theorem 3.3 are not very useful, since they require knowledge of the control that nature applies at all times. In this section we will formally discuss how to construct controls that are optimal (or nearly optimal) and that depend only on the state of the network.

Formally, $W = V^- = V^+$ is the solution to the equation

$$\sup_{\alpha\in\mathcal{A}} \inf_{\rho\in\mathcal{S}} [\langle DW(x), F(\rho,\alpha)\rangle + 1] = 0, \qquad x \in (\mathbb{R}^N_+)^\circ, \tag{13}$$

together with the boundary conditions

$$\langle DW(x), d_i\rangle = 0, \qquad i \in I(x), x \in \partial\mathbb{R}^N_+ \backslash \{0\}, \qquad W(0) = 0. \tag{14}$$

Since F is affine in each variable separately and $\mathcal{A}$ and $\mathcal{S}$ are compact and convex, [22, Corollary 37.6.2] implies that the sup and inf in (13) can be interchanged (i.e., one expects the game to have value).

Since W is not necessarily smooth we cannot expect a classical sense solution to (13)–(14), and so one must consider a weak sense solution, e.g., viscosity solutions. Because W is convex, the set of subdifferentials to W at x (denoted $D^-W(x)$) is never empty. It follows from the characterization of viscosity solutions (see the appendix) that for any $q \in D^-W(x)$ there exists at least one saddle point $(\rho(q), \alpha(q))$ such that

$$\sup_{\alpha\in\mathcal{A}} \langle q, F(\rho(q),\alpha)\rangle \leq -1.$$

Let $R(q)$ denote the set of all points $\rho \in \mathcal{S}$ which have this property. It is easy to check that this set-valued function is upper semicontinuous: $q_n \to q$, $\rho_n \to \rho$, and $\rho_n \in R(q_n)$ implies $\rho \in R(q)$. At each point $x \in \mathbb{R}^N_+$ we define a set of controls $S(x) \subset \mathcal{S}$ by

$$S(x) = \cup_{q\in D^-W(x)} R(q).$$

Note that since $x \to D^-W(x)$ and $q \to R(q)$ are upper semicontinuous, so is the composition $S(x)$, and that the radial linearity of W implies a radial homogeneity of S: $S(ax) = S(x)$ for all $x \in \mathbb{R}^N_+$ and $a \in (0,\infty)$. The set of conjectured controls for x in the interior is then $S(x)$.

However, when on the boundary we must be more careful. As can easily be seen by considering two dimensional examples, there is an important distinction depending on whether the boundary condition holds in a classical sense or not. The following conjectures for the form of the optimal control are based on the analysis of two dimensional examples and have not been verified in any generality. Let us first consider the case of a point x, where $I(x) = i$ for a single value i. In this case the classical sense formulation of the boundary condition is $\langle DW(x), d_i\rangle = 0$. If this condition holds, it means that all optimally controlled trajectories push into the boundary and that any selection from $S(x)$ is optimal. If however $\langle DW(x), d_i\rangle \neq 0$, then even if some elements from $S(x)$ lead to trajectories that push into the boundary, we must restrict ourselves to only those for which the saddle point dynamics do not push strictly into the boundary. If the boundary condition is not valid in the classical sense, then we conjecture that this set is always nonempty. Analogous considerations hold for the points at the intersection of two or more faces. In general, choosing a control for which the saddle point dynamics push into a face is only allowed when the corresponding boundary condition holds in the classical sense.

Appendix. In this appendix we will prove that the game has value, i.e., that $V^+(x) = V^-(x)$ for all $x \in \mathbb{R}^N_+$. A key ingredient is a uniqueness result for the PDE that V^+ and V^- should satisfy. An excellent general reference for the theory of viscosity solutions of first order nonlinear PDEs is the book [3]. The particular results we will need can be found in [1] (see also [10]).

For $q \in \mathbb{R}^N$ define

$$\begin{aligned} H(q) &= \max_{\alpha\in\mathcal{A}} \min_{\rho\in\mathcal{S}} \left[\langle q, F(\rho,\alpha)\rangle + 1\right] \\ &= \min_{\rho\in\mathcal{S}} \max_{\alpha\in\mathcal{A}} \left[\langle q, F(\rho,\alpha)\rangle + 1\right], \end{aligned}$$

where the two expressions on the right-hand side are equal since $F(\rho,\alpha)$ is affine in each variable separately and $\mathcal{S}$ and $\mathcal{A}$ are convex and compact. Consider a Lipschitz continuous function $V : \mathbb{R}^N_+ \to \mathbb{R}$, and for a continuously differentiable function $g : \mathbb{R}^N \to \mathbb{R}$ let y be a local maximum (respectively, minimum) of

$$x \to V(x) - g(x).$$

Then V is called a viscosity subsolution (respectively, viscosity supersolution) to (13) and (14) if

$$H(Dg(y)) \vee \max_{i\in I(y)} \langle Dg(y), d_i\rangle \geq 0, \tag{15}$$

$$\left(H(Dg(y)) \wedge \min_{i\in I(y)} \langle Dg(y), d_i\rangle \leq 0\right), \tag{16}$$

and

$$V(0) \leq 0, \qquad (V(0) \geq 0). \tag{17}$$

We henceforth drop the adjective "viscosity" and note that a function that is both a sub- and supersolution is called a solution.

Recall that $V : \mathbb{R}^N_+ \to \mathbb{R}$ is said to be *radially linear* if $V(ax) = aV(x)$ for all $x \in \mathbb{R}^N_+$ and $a \in [0,\infty)$. According to [1, Theorem 4.3], there is only one function V

satisfying the following conditions: (i) V is a viscosity solution to (15)–(17), (ii) V is Lipschitz continuous and radially linear, and (iii) $V(x) > 0$ for $x \in (\mathbb{R}^N_+)\backslash\{0\}$. Suppose that V^+ and V^- satisfy conditions (ii) and (iii) of the last sentence. Then standard arguments based on dynamic programming can be used to show that (i) holds (see [1, Theorem 3.2] and [3, Chapter VIII]). Thus $V^+ = V^-$ will follow if we can prove that (ii) and (iii) hold for both V^+ and V^-.

Assume for now that V^+ is uniformly bounded on bounded sets. It follows from Theorem 3.3 that $0 \le V^-(x) \le V^+(x) \le \infty$. It is also immediate from the definitions that both $V^+(x)$ and $V^-(x)$ are radially linear and that $V^+(x) \wedge V^-(x) > 0$ for $x \in (\mathbb{R}^N_+)\backslash\{0\}$. Thus if V^+ is uniformly bounded on bounded sets, all that needs to be shown is that V^+ and V^- are Lipschitz continuous. We give the proof for V^+ and note that the proof for V^- is analogous. Let $M \doteq \max_{y:\|y\|=1} V^+(y)$, and assume for now that $M < \infty$. Owing to the radial linearity, $V^+(x) \le M\|x\|$. Fix points $x, y \in \mathbb{R}^N_+$ and $\varepsilon > 0$. Let $K < \infty$ be the Lipschitz constant of the Skorokhod map defined in section 2. We claim that V^+ is Lipschitz continuous with constant MK. The proof adapts a standard argument [3]. Choose $\bar\theta \in \Theta$ such that $V^+(x) \le \inf_{\rho\in N} C_x(\rho, \bar\theta[\rho]) + \varepsilon/2$. Since $\bar\theta$ is suboptimal at y, $V^+(y) \ge \inf_{\rho\in N} C_y(\rho, \bar\theta[\rho])$, and hence there is $\bar\rho$ such that $V^+(y) \ge C_y(\bar\rho, \bar\theta[\bar\rho]) - \varepsilon/2$. Note that also $V^+(x) \le C_x(\bar\rho, \bar\theta[\bar\rho]) + \varepsilon/2$, and hence

$$V^+(x) - V^+(y) \le C_x(\bar\rho, \bar\theta[\bar\rho]) - C_y(\bar\rho, \bar\theta[\bar\rho]) + \varepsilon.$$

If $C_y(\bar\rho, \bar\theta[\bar\rho]) \ge C_x(\bar\rho, \bar\theta[\bar\rho])$ (i.e., it takes longer to reach the origin from y than x), then of course $V^+(x) - V^+(y) \le \varepsilon$. On the other hand, if $C_y(\bar\rho, \bar\theta[\bar\rho]) \le C_x(\bar\rho, \bar\theta[\bar\rho])$, then we can stop the process that was started at x at time $\sigma \doteq C_y(\bar\rho, \bar\theta[\bar\rho])$. If we let $\phi^x(t)$ and $\phi^y(t)$ denote the processes started at the points x and y, then the Lipschitz property of the Skorokhod map implies $\|\phi^x(\sigma) - \phi^y(\sigma)\| \le K\|x - y\|$. Since $\phi^y(\sigma) = 0$, this means that $\|\phi^x(\sigma)\| \le K\|x - y\|$. We can now use dynamic programming to argue that $V^+(x) \le \sigma + V^+(\phi^x(\sigma)) + \varepsilon/2 \le \sigma + MK\|x - y\| + \varepsilon/2$, and thus $V^+(x) - V^+(y) \le MK\|x - y\| + \varepsilon$. Combining the two cases and using that $\varepsilon > 0$ is arbitrary, it follows that $V^+(x) - V^+(y) \le MK\|x - y\|$ for all $x, y \in \mathbb{R}^N_+$.

With the proof that V^+ and V^- are Lipschitz continuous complete, all that remains is to prove that V^+ is uniformly bounded on bounded sets. Under Condition 2.1, it was shown in [9, Lemma 2.1, Theorem 2.1, and p. 60] that there is a compact convex set $B \subset \mathbb{R}^N$ with the following properties:

1. $0 \in B^\circ$,
2. if $z \in \partial B$ and n is an outward normal to B at z, then $|\langle z, e_i\rangle| \le 1$ implies $\langle n, d_i\rangle = 0$,
3. if $z \in \partial B$ and n is an outward normal to B at z, then $\langle z, e_i\rangle\langle n, d_i\rangle \ge 0$.

By considering sets of the form $B^\delta \doteq \{y : \|y - x\| \le \delta \text{ for some } x \in B\}$ (with $\delta > 0$), it is easy to verify that without loss we can assume B has a continuously differentiable boundary. Define the function $R : \mathbb{R}^N \to [0, \infty)$ by

$$R(x) \doteq \inf\{c : x \in \partial(cB)\}.$$

From the convexity, properties 1 and 2 listed above, and the smoothness of ∂B, it follows that R is continuously differentiable save at $x = 0$ and that for $x \in \mathbb{R}^N_+\backslash\{0\}$

$$\langle DR(x), d_i\rangle = 0 \text{ if } i \in I(x). \tag{18}$$

Now fix any point $x \in \mathbb{R}^N_+\backslash\{0\}$, and let $z \in \partial B$ satisfy $z = ax$ for some $a \in (0, \infty)$. If n is the corresponding outward normal to B at z, then $DR(x) = bn$ for some

$b \in (0, \infty)$. According to properties 2 and 3 above, $\langle DR(x), d_i \rangle \geq 0$. Let the vectors $d_i^*, i = 1, \ldots, N$, be defined by $\langle d_i, d_j^* \rangle = \delta_{ij}$, where δ_{ij} is 1 if $i = j$ and 0 otherwise. These vectors are well defined, since Condition 2.1 implies the linear independence of $\{d_i, i = 1, \ldots, N\}$. Writing $DR(x) = \sum_{i=1}^N c_i d_i^*$, it follows from $\langle DR(x), d_i \rangle \geq 0$ that $c_i \geq 0$ for $i = 1, \ldots, N$. We now apply Condition 3.1. It follows from this condition that for each $\alpha \in \mathcal{A}$ there are $\rho \in \mathcal{S}$ and $c > 0$ such that

$$\langle DR(x), F(\rho, \alpha) \rangle \leq -c.$$

Since $\mathcal{A}$ is compact, an open covering argument shows the existence of $c > 0$ such that

$$\max_{\alpha \in \mathcal{A}} \min_{\rho \in \mathcal{S}} \langle DR(x), F(\rho, \alpha) \rangle \leq -c. \tag{19}$$

Finally, the radial linearity of R, the continuity of $DR(x)$, and another open covering argument that uses the compactness of $\partial B \cap \mathbb{R}_+^N$ show that $c > 0$ can be selected so that (19) holds for all $x \in \mathbb{R}_+^N \backslash \{0\}$.

Equations (18) and (19) imply that R/c is a (classical) supersolution to (13) and (14). Standard arguments based on dynamic programming can then be used to show that $V^+(x) \leq R(x)/c$. (See, for example, the proof of Theorem 3.3.) This completes the proof that $V^+(x) = V^-(x)$ for all $x \in \mathbb{R}_+^N$.

ZERO-SUM AVERAGE SEMI-MARKOV GAMES: FIXED-POINT SOLUTIONS OF THE SHAPLEY EQUATION*

OSCAR VEGA-AMAYA†

Abstract. This paper deals with zero-sum average semi-Markov games with Borel state and action spaces, unbounded payoffs, and mean holding times. A solution to the Shapley equation is obtained via the Banach fixed-point theorem assuming that the model satisfies a Lyapunov-like condition, a growth hypothesis on the payoff function, and the mean holding times, besides standard continuity and compactness requirements.

Key words. zero-sum semi-Markov games, average payoff criterion, Lyapunov conditions, fixed-point approach

AMS subject classifications. 90D10, 90D20, 93E05

DOI. 10.1137/S0363012902408423

1. Introduction. Several recent papers have used variants of a Lyapunov-like condition to solve an average payoff optimization problem for Markovian systems with unbounded payoff and Borel state and action spaces (see, e.g., [9], [13], [14] for Markov models, [15], [22], [32] for semi-Markov models, [11], [16], [25] for zero-sum Markov games, and [17] for zero-sum semi-Markov games). The key property used in all these papers is that the imposed Lyapunov condition yields the so-called *weighted geometric ergodicity (WGE) property*, which is a generalization of the standard *uniform geometric ergodicity* in Markov chain theory (see [10], [12], and [23] for a detailed discussion of these concepts). Roughly speaking, in these papers the WGE property is combined, explicitly or implicitly, either with the *vanishing discount factor approach* or with some variants of the *policy iteration algorithm* for proving their main results. These facts are the first main differences from the present paper since, in spite of imposing a similar stability condition, we use instead a "fixed-point approach" which does not rely, at least explicitly, on the WGE property.

The fixed-point approach allows us to obtain directly the Shapley equation, which in turn yields the existence of a stationary optimal strategy pair or saddle point—see Theorem 4.7 (a) and (b). In contrast, the approaches followed in [11], [16], [25] first show the existence of a stationary saddle point and then establish the Shapley equation. On the other hand, [22], [21], [15], [17] refer to auxiliary models related to the original one; more precisely, [22] and [21] use the so-called *Schweitzer's data transformation* [29], while the analysis in [15] and [17] relies on certain *perturbed models*.

A second key difference concerns the times between two consecutive decision epochs. In contrast with discrete-time Markov control processes and Markov games, the decision epochs in semi-Markov control processes are random; thus it is necessary to ensure that such processes are *regular*, that is, that they experience only finitely many transitions in each finite time period. This is usually done by means of the Ross condition [28, Prop. 5.1], which assumes that transition times are greater than

some $\gamma > 0$ with a probability of at least $\epsilon > 0$, independently of the state of the system and the control chosen (see Ross [28, Prop. 5.1]). On the other hand, Ross' condition also implies that the mean holding time function is bounded below by a positive constant, which plays a crucial role in the approaches followed in [32], [15], [17], [22] , and [21]; in fact, in the latter four references it is also assumed that the mean holding time function is bounded above by a constant. In the present paper, we do not need either the Ross condition or to assume that the mean holding time function is bounded below by a positive constant as is done in most papers (see, e.g., [2], [5], [26], and their references).

It is important to mention that, as a by-product, the fixed-point approach yields a minimax characterization of a certain solution of the Shapley equation—Theorem 4.7 (c)—which seemingly has not been previously discussed in the literature dealing with zero-sum stochastic games.

We should also mention that the fixed-point approach has been used in several early papers (see, e.g., [7], [12], [19], [27]) but under much stronger ergodicity conditions, which, in particular, exclude the case of unbounded payoffs. The variant of the Lyapunov condition we consider here was recently introduced in [30] for Markov control process and was used in [8] to study minimax problems. In fact, the present paper extends to zero-sum semi-Markov games the results of the two latter references.

For brief surveys of the existing literature on stochastic games with finite or denumerable state space the reader can consult [1], [3], [6], [7], and [20].

The remainder of the paper is organized as follows. The semi-Markov game model and the (ratio) expected average payoff (EAP) criterion are introduced in sections 2 and 3, respectively. The assumptions and main results are stated in section 4. The proofs of all results are given in sections 5 and 6.

2. The game model. Throughout the paper we shall use the following notation. Given a *Borel space* S—that is, a Borel subset of a complete separable metric space—$\mathcal{B}(S)$ denotes the Borel σ-algebra and "measurability" always means measurability with respect to $\mathcal{B}(S)$. The class of all probability measures on S is denoted by $\mathbb{P}(S)$. Given two Borel spaces S and S', a *stochastic kernel* $\varphi(\cdot|\cdot)$ on S given S' is a function such that $\varphi(\cdot|s')$ is in $\mathbb{P}(S)$ for each $s' \in S'$, and $\varphi(B|\cdot)$ is a measurable function on S' for each $B \in \mathcal{B}(S)$. Moreover, $\mathbb{R}_+$ stands for the nonnegative real number subset and $\mathbb{N}$ ($\mathbb{N}_0$, resp.) denotes the positive (nonnegative, resp.) integers subset.

The semi-Markov game model. This paper is concerned with a zero-sum semi-Markov game modeled by

$$(\mathbf{X}, \mathbf{A}, \mathbf{B}, K_A, K_B, Q, F, r),$$

where $\mathbf{X}$ is the *state space*, and the sets $\mathbf{A}$ and $\mathbf{B}$ are the *control spaces* for players 1 and 2, respectively. It is assumed that all these sets are *Borel spaces*. The *constraint sets* K_A and K_B are *Borel* subsets of $\mathbf{X} \times \mathbf{A}$ and $\mathbf{X} \times \mathbf{B}$, respectively. Thus, for each $x \in \mathbf{X}$, the *x-sections*

$$A(x) := \{a \in \mathbf{A} : (x, a) \in K_A\},$$
$$B(x) := \{b \in \mathbf{B} : (x, b) \in K_B\}$$

stand for the sets of *admissible actions or controls* for players 1 and 2, respectively.

Now, let

$$\mathbb{K} := \{(x, a, b) : x \in \mathbf{X}, a \in A(x), b \in B(x)\},$$

which, by [24], is a Borel subset of $\mathbf{X}\times\mathbf{A}\times\mathbf{B}$. The *transition law* $Q(\cdot|\cdot)$ of the system is a stochastic kernel on $\mathbf{X}$ given $\mathbb{K}$. For each $(x,a,b,y)\in\mathbb{K}\times\mathbf{X}$, $F(\cdot|x,a,b,y)$ is a distribution function on $\mathbb{R}_+ := [0,+\infty)$, and $F(t|\cdot)$ is a measurable function on $\mathbb{K}\times\mathbf{X}$ for each $t\in\mathbb{R}_+$. Finally, the payoff r is a measurable function on $\mathbb{K}\times\mathbb{R}_+$.

The game is played over an infinite horizon as follows: at time $t=0$ the game is observed in some state $x_0=x\in\mathbf{X}$ and the players independently choose controls $a_0=a\in A(x_0)$ and $b_0=b\in B(x_0)$. Then, the system remains in state $x_0=x$ for a nonnegative random time δ_1 and player 1 receives the amount $r(x,a,b,\delta_1)$ from player 2. At time δ_1 the system jumps to a new state $x_1=x'\in\mathbf{X}$ according to the probability measure $Q(\cdot|x,a,b)$. The distribution of the random variable δ_1, given that the system has jumped into state x', is $F(\cdot|x,a,b,x')$; that is,

$$F(t|x,a,b,x') = \Pr\left[\delta_1\le t|x_0=x,a_0=a,b_0=b,x_1=x'\right]\quad\forall t\in\mathbb{R}_+.$$

Thus, given that $x_0=x, a_0=a$, and $b_0=b$, the distribution of δ_1 is

$$G(t|x,a,b) := \int_0^{+\infty} F(t|x,a,b,y)Q(dy|x,a,b)\quad\forall t\in\mathbb{R}_+,(x,a,b)\in\mathbb{K},$$

and it is called the *holding time distribution*. Immediately after the transition occurs, the players again choose controls, say, $a_1=a'\in A(x')$ and $b_1=b'\in B(x')$, and the above process is repeated over and over again.

This procedure yields a stochastic processes $\{(x_n,a_n,b_n,\delta_{n+1})\}$, where, for each $n\in\mathbb{N}_0$, x_n is the state of the system, a_n and b_n are the control variables for players 1 and 2, respectively, and δ_{n+1} is the *holding time* at state x_n. The goal of player 1 (player 2, resp.) is to maximize (minimize, resp.) his/her flow rewards (costs, resp.)

$$r(x_0,a_0,b_0,\delta_1), r(x_1,a_1,b_1,\delta_2),\dots$$

over an infinite horizon using an "expected average reward (cost) criterion" defined by (3.1) below.

The functions on $\mathbb{K}$ given as

$$\tau(x,a,b) := \int_0^{+\infty} tG(dt|x,a,b), \tag{2.1}$$

$$R(x,a,b) := \int_0^{+\infty} r(x,a,b,t)G(dt|x,a,b) \tag{2.2}$$

are called the *mean holding time* and the *mean payoff*, respectively.

Strategies. Let $H_0:=\mathbf{X}$ and $H_n := \mathbb{K}\times\mathbb{R}_+\times H_{n-1}$ for $n\in\mathbb{N}$. Then, for each $n\in\mathbb{N}_0$, a generic element of H_n is denoted as

$$h_n := (x_0,a_0,b_0,\delta_1,\dots,x_{n-1},a_{n-1},b_{n-1},\delta_n,x_n),$$

which can be thought of as the history of the game up to the time of the nth transition

$$T_n := T_{n-1}+\delta_n,\quad n\in\mathbf{N}, \tag{2.3}$$

where $T_0:=0$.

Thus a *strategy* for player 1 is a sequence $\pi^1 = \{\pi_n^1\}$ of stochastic kernels π_n^1 on $\mathbf{A}$ given H_n satisfying the constraint

$$\pi_n^1(A(x_n)|h_n) = 1 \quad \forall h_n \in H_n, n \in \mathbb{N}_0.$$

The class of all strategies for player 1 is denoted by Π^1.

For each $x \in \mathbf{X}$, let $\mathbb{A}(x) := \mathbb{P}(A(x))$ and denote by Φ^1 the class of all stochastic kernels φ^1 on $\mathbf{A}$ given $\mathbf{X}$ such that $\varphi^1(\cdot|x) \in \mathbb{A}(x)$ for all $x \in \mathbf{X}$. A policy π^1 is called *stationary* if

$$\pi_n^1(\cdot|h_n) = \varphi^1(\cdot|x_n) \quad \forall h_n \in H_n, n \in \mathbb{N}_0,$$

for some stochastic kernel φ^1 in Φ^1. Following a standard convention, Φ^1 is identified with the class of stationary strategies for player 1. The sets of strategies Π^2 and Φ^2 for player 2 are defined in a similar way but writing $B(x)$ and $\mathbb{B}(x)$ instead of $A(x)$ and $\mathbb{A}(x)$, respectively.

Let $(\Omega, \mathcal{F})$ be the (canonical) measurable space consisting of the sample space $\Omega := (\mathbb{K} \times \mathbb{R}_+)^\infty$ and its product σ-algebra. Thus, for each strategy pair $(\pi^1, \pi^2) \in \Pi^1 \times \Pi^2$ and each "initial state" $x \in \mathbf{X}$, there exists a probability measure $P_x^{\pi^1,\pi^2}$ defined on $(\Omega, \mathcal{F})$ which governs the evolution of the stochastic process $\{(x_n, a_n, b_n, \delta_{n+1})\}$. The expectation operator with respect to the measure probability $P_x^{\pi^1,\pi^2}$ is denoted as $E_x^{\pi^1,\pi^2}$.

Throughout the paper we shall use the following notation: for a measurable function u on $\mathbb{K}$ and a stationary strategy pair $(\varphi^1, \varphi^2) \in \Phi^1 \times \Phi^2$, let

$$u_{\varphi^1,\varphi^2}(x) := \int_{B(x)} \int_{A(x)} u(x,a,b)\varphi^1(da|x)\varphi^2(db|x) \quad \forall x \in \mathbf{X}. \tag{2.4}$$

Thus, in particular, we shall write

$$R_{\varphi^1,\varphi^2}(x) := \int_{B(x)} \int_{A(x)} R(x,a,b)\varphi^1(da|x)\varphi^2(db|x),$$

$$\tau_{\varphi^1,\varphi^2}(x) := \int_{A(x)} \int_{B(x)} \tau(x,a,b)\varphi^1(da|x)\varphi^2(db|x),$$

and, similarly,

$$Q_{\varphi^1,\varphi^2}(\cdot|x) := \int_{B(x)} \int_{A(x)} Q(\cdot|x,a,b)\varphi^1(da|x)\varphi^2(db|x)$$

for all $x \in \mathbf{X}$.

If the players use a stationary strategy pair, say, (φ^1, φ^2), then the state process $\{x_n\}$ is a Markov chain with transition probability $Q_{\varphi^1,\varphi^2}(\cdot|\cdot)$. In this case, the *n-step transition probability* is denoted by $Q^n_{\varphi^1,\varphi^2}(\cdot|\cdot)$ for each $n \in \mathbb{N}_0$, where $Q^0_{\varphi^1,\varphi^2}(\cdot|x)$ is the Dirac measure at $x \in \mathbf{X}$. Thus, for each $u \in B_W(\mathbf{X})$,

$$Q^n_{\varphi^1,\varphi^2}u(x) := \int_{\mathbf{X}} u(y)Q^n_{\varphi^1,\varphi^2}(dy|x) = E_x^{\varphi^1,\varphi^2}u(x_n) \quad \forall x \in \mathbf{X}, n \in \mathbb{N}_0.$$

3. The expected average payoff criterion. The (ratio) *expected average payoff* (EAP) for the strategy pair $(\pi^1, \pi^2) \in \Pi^1 \times \Pi^2$, given the initial state $x_0 = x \in \mathbf{X}$, is defined as

$$J(\pi^1, \pi^2, x) := \liminf_{n\to\infty} \frac{E_x^{\pi^1,\pi^2} \sum_{k=0}^{n-1} r(x_k, a_k, b_k, \delta_{k+1})}{E_x^{\pi^1,\pi^2} T_n}. \tag{3.1}$$

It is easy to verify using properties of conditional expectation that

$$E_x^{\pi^1,\pi^2} \delta_{k+1} = E_x^{\pi^1,\pi^2} \tau(x_k, a_k, b_k)$$

and also that

$$E_x^{\pi^1,\pi^2} r(x_k, a_k, b_k, \delta_{k+1}) = E_x^{\pi^1,\pi^2} R(x_k, a_k, b_k)$$

for all $x \in \mathbf{X}, (\pi^1, \pi^2) \in \Pi^1 \times \Pi^2, k \in \mathbb{N}_0$. Thus (3.1) can be rewritten as

$$J(\pi^1, \pi^2, x) = \liminf_{n\to\infty} \frac{E_x^{\pi^1,\pi^2} \sum_{k=0}^{n-1} R(x_k, a_k, b_k)}{E_x^{\pi^1,\pi^2} \sum_{k=0}^{n-1} \tau(x_k, a_k, b_k)}. \tag{3.2}$$

Now consider the functions on $\mathbf{X}$ defined as

$$L(x) := \sup_{\pi^1\in\Pi^1} \inf_{\pi^2\in\Pi^2} J(\pi^1, \pi^2, x) \quad \text{and} \quad U(x) := \inf_{\pi^2\in\Pi^2} \sup_{\pi^1\in\Pi^1} J(\pi^1, \pi^2, x), \tag{3.3}$$

which are called the *lower value* and the *upper value* of the game, respectively, for the ratio EAP criterion. In general, $L(\cdot) \le U(\cdot)$, but if $L(\cdot) = U(\cdot)$ holds, the common function is called the *value of the game* and is denoted by $V(\cdot)$.

If the game has a value $V(\cdot)$, a strategy $\pi_*^1 \in \Pi^1$ is said to be EAP-*optimal* for player 1 if

$$\inf_{\pi^2\in\Pi^2} J(\pi_*^1, \pi^2, x) = V(x) \quad \forall x \in \mathbf{X}.$$

Similarly, $\pi_*^2 \in \Pi^2$ is said to be EAP-*optimal* for player 2 if

$$\sup_{\pi^1\in\Pi^1} J(\pi^1, \pi_*^2, x) = V(x) \quad \forall x \in \mathbf{X}.$$

If π_*^i is EAP-optimal for player i $(i = 1, 2)$, then (π_*^1, π_*^2) is called an *EAP-optimal pair* or *saddle point*. Note that (π_*^1, π_*^2) is EAP-optimal if and only if

$$J(\pi^1, \pi_*^2, x) \le J(\pi_*^1, \pi_*^2, x) \le J(\pi_*^1, \pi^2, x) \quad \forall x \in \mathbf{X}, (\pi^1, \pi^2) \in \Pi^1 \times \Pi^2.$$

4. Assumptions and main results. Practically all the related literature assumes that the mean holding time τ is bounded below by a positive constant (see, e.g., [2], [5], [15], [17], [19], [20], [22], [26], [29], [32], and their references). In the present paper it is only assumed that the mean holding time is a positive function, which together with Proposition 4.4 (a) below implies that the processes experience finitely many transitions on each finite time period (see [31]).

ASSUMPTION 4.1. $\tau(x, a, b) > 0$ *for all* $(x, a, b) \in \mathbb{K}$.

The second hypothesis imposes a growth condition both in the mean holding time and the mean payoff.

ASSUMPTION 4.2. *There exists a measurable function $W(\cdot)$ on $\mathbf{X}$ bounded below by a constant $\theta > 0$ such that*

$$\max\{\tau(x,a,b), |R(x,a,b)|\} \leq KW(x) \quad \forall (x,a,b) \in \mathbb{K},$$

for a fixed positive constant K.

To state the third set of hypotheses—as well as several of its consequences—some notation is required. For a measurable function $u(\cdot)$ on $\mathbf{X}$, define the *weighted norm with respect to W* (W-norm) as

$$||u||_W := \sup_{x \in \mathbf{X}} \frac{|u(x)|}{W(x)},$$

and denote by $B_W(\mathbf{X})$ the Banach space of all measurable functions with finite W-norm. Moreover, for a measure $\gamma(\cdot)$ on $\mathbf{X}$ let

$$\gamma(u) := \int_{\mathbf{X}} u(x)\gamma(dx),$$

whenever the integral is well defined.

ASSUMPTION 4.3 (Lyapunov condition). *There exist a nontrivial measure $\nu(\cdot)$ on $\mathbf{X}$, a nonnegative measurable function $S(\cdot)$ on $\mathbb{K}$, and a positive constant $\lambda < 1$ such that the following hold:*

(a) $\nu(W) < \infty$;
(b) $Q(B|x,a,b) \geq \nu(B)S(x,a,b)$ *for all* $B \in \mathcal{B}(\mathbf{X}), (x,a,b) \in \mathbb{K}$;
(c) $\int_{\mathbf{X}} W(y)Q(dy|x,a,b) \leq \lambda W(x) + S(x,a,b)\nu(W)$ *for all* $(x,a,b) \in \mathbb{K}$;
(d) $\nu(S_{\varphi^1,\varphi^2}) > 0$ *for all* $(\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2$.

As we mentioned in the introduction, Assumption 4.3 allows us to use a fixed-point approach. More precisely, if we define the kernel

$$\widehat{Q}(\cdot|x,a,b) := Q(\cdot|x,a,b) - \nu(\cdot)S(x,a,b) \quad \forall (x,a,b) \in \mathbb{K}, \tag{4.1}$$

which, under Assumption 4.3, is nonnegative, then Assumption 4.3 (c) can be expressed equivalently as

$$\int_{\mathbf{X}} W(y)\widehat{Q}(dy|x,a,b) \leq \lambda W(x) \quad \forall (x,a,b) \in \mathbb{K}, \tag{4.2}$$

which, roughly speaking, means that $\widehat{Q}(\cdot|\cdot)$ satisfies a certain contraction property. This is precisely the contraction property that we shall exploit to prove our main results (Theorems 4.5 and 4.7 below).

Assumption 4.3 was first used in [30], though it is actually a simplified version of the Lyapunov condition introduced in [9]. Specifically, besides the conditions in Assumption 4.3, [9] assumes the existence of a common irreducibility measure for the transition laws induced by the stationary strategies and also that the inequality in Assumption 4.3 (c) holds uniformly, that is, $\inf_{\varphi^1,\varphi^2} \nu(S_{\varphi^1,\varphi^2}) > 0$. However, as it is shown in [30, Thm. 3.3]—see Proposition 4.4 below—the latter condition is not required and the irreducibility condition is redundant.

As in [9], several other papers have used Lyapunov conditions similar to Assumption 4.3 (see, e.g., [13], [14], [15], [16], [17], [25]). The main difference between the mentioned papers and ours is that they rely on the WGE mentioned in the introduction,

while a fixed-point approach is used herein. For instance, in lieu of Assumption 4.3, papers [15], [16], [17], [25] suppose, roughly speaking, that

$$\int_{\mathbf{X}} W(y)Q(dy|x,a,b) \le \lambda W(x) + b\mathbf{I}_C(x) \quad \forall (x,a,b) \in \mathbb{K}, \tag{4.3}$$

where C is a Borel subset of $\mathbf{X}$, b is a positive constant, and $\lambda \in (0,1)$ and also that

$$Q_{\varphi^1,\varphi^2}(\cdot|x) \ge \delta \mathbf{I}_C(x)\nu_{\varphi^1,\varphi^2}(\cdot) \quad \forall x \in \mathbf{X}, (\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2, \tag{4.4}$$

where each $\nu_{\varphi^1,\varphi^2}(\cdot)$ is a probability measure on $\mathbf{X}$ and δ is a positive constant. A quick glance at the latter conditions shows that they do not lead directly to a contraction property as in (4.2).

On the other hand, recently Küenle and Schurat[1] [18] also used fixed-point arguments under the conditions (4.3)–(4.4). To do this, they first show that these two conditions imply

$$\int_{\mathbf{X}} V(y)Q_{\varphi^1,\varphi^2}(dy|x) \le \lambda' V(x) + \nu_{\varphi^1,\varphi^2}(V)\mathbf{I}_C(x) \quad \forall x \in \mathbf{X}, (\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2,$$

with $V := W + b$ and $\lambda' := (\lambda + b)/(1 + b)$, which combined with (4.3) yields a contraction property as in (4.2). However, instead of taking advantage of this property, Küenle and Schurat use some "contraction" operators which lead to a parametrized family of functional equations depending on two parameters; they then show some continuity and monotonicity properties of the solutions of such equations, which in turn yield a solution of the Shapley equation. In contrast, with our approach, the solutions to the Shapley equation are obtained directly using the Banach fixed-point theorem for some operator closely related to the Shapley equation.

In the next proposition some important consequences of Assumptions 4.2 and 4.3 are stated, which are proved in [30] using fixed-points arguments too.

PROPOSITION 4.4. *Suppose that Assumption* 4.3 *holds. Then, for each stationary strategy pair* $(\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2$*, the following hold:*

(a) *The transition law* $Q_{\varphi^1,\varphi^2}(\cdot|x)$ *is positive Harris recurrent. Thus, in particular, there exists a unique invariant probability measure* $\mu_{\varphi^1,\varphi^2}(\cdot)$*, that is,*

$$\mu_{\varphi^1,\varphi^2}(\cdot) = \int_{\mathbf{X}} Q_{\varphi^1,\varphi^2}(\cdot|x)\mu_{\varphi^1,\varphi^2}(dx).$$

Moreover, ν *is an irreducibility measure for* $Q_{\varphi^1,\varphi^2}(\cdot|\cdot)$.

(b) $\mu_{\varphi^1,\varphi^2}(W)$ *is finite; in fact, it holds the bounds*

$$\theta \le \mu_{\varphi^1,\varphi^2}(W) \le \frac{\nu(W)}{(1-\lambda)\nu(X)}. \tag{4.5}$$

Next observe that, under the Assumptions 4.1–4.3, by Proposition 4.4 the constants

$$\rho(\varphi^1,\varphi^2) := \frac{\mu_{\varphi^1,\varphi^2}(R_{\varphi^1,\varphi^2})}{\mu_{\varphi^1,\varphi^2}(\tau_{\varphi^1,\varphi^2})} \quad \forall (\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2 \tag{4.6}$$

[1]The author thanks one of the referees for bringing his attention to the paper by Küenle and Schurat [18].

are finite. Then, for each $(\varphi^1, \varphi^2) \in \Phi^1 \times \Phi^2$, define on $B_W(\mathbf{X})$ the operator

$$L_{\varphi^1,\varphi^2} u(x) := \overline{R}_{\varphi^1,\varphi^2}(x) + \int_{\mathbf{X}} u(y) Q_{\varphi^1,\varphi^2}(dy|x) \quad \forall x \in \mathbf{X}, \tag{4.7}$$

where

$$\overline{R}_{\varphi^1,\varphi^2}(\cdot) := R_{\varphi^1,\varphi^2}(\cdot) - \rho(\varphi^1, \varphi^2)\tau_{\varphi^1,\varphi^2}(\cdot). \tag{4.8}$$

THEOREM 4.5. *Suppose that Assumptions* 4.1, 4.2, *and* 4.3 *hold. Then for each stationary strategy pair* $(\varphi^1, \varphi^2) \in \Phi^1 \times \Phi^2$, *the following hold:*

(a) *There exists a unique function* $h_{\varphi^1,\varphi^2} \in B_W(\mathbf{X})$, *with* $\nu(h_{\varphi^1,\varphi^2}) = 0$, *that satisfies the (semi-Markov) Poisson equation*

$$\begin{aligned} h_{\varphi^1,\varphi^2}(x) &= L_{\varphi^1,\varphi^2} h_{\varphi^1,\varphi^2}(x) \\ &= \overline{R}_{\varphi^1,\varphi^2}(x) + \int_{\mathbf{X}} h_{\varphi^1,\varphi^2}(y) Q_{\varphi^1,\varphi^2}(dy|x) \quad \forall x \in \mathbf{X}. \end{aligned}$$

(b) *Moreover,* $J(\varphi^1, \varphi^2, \cdot) = \rho(\varphi^1, \varphi^2)$.

Now, we impose some compactness/continuity conditions on the model to ensure the existence of measurable minimizers/maximizers; notice that this can be done in several settings (see, e.g., [10, Thm. 3.5, p. 28] or [8, Lemma 3.5]). Here, for simplicity, we consider the following one.

ASSUMPTION 4.6 (compactness/continuity conditions). *For each* $(x, a, b) \in \mathbb{K}$, *the following hold:*

(a) $A(x)$ *and* $B(x)$ *are nonempty compact subsets.*

(b) $R(x, \cdot, b)$ *is upper semicontinuous on* $A(x)$, *and* $R(x, a, \cdot)$ *is lower semicontinuous on* $B(x)$.

(c) $\tau(x, \cdot, b)$ *and* $\tau(x, a, \cdot)$ *are continuous on* $A(x)$ *and* $B(x)$, *respectively.*

(d) $S(x, \cdot, b)$ *and* $S(x, a, \cdot)$ *are continuous on* $A(x)$ *and* $B(x)$, *respectively.*

(e) *For each bounded measurable function* v *on* $\mathbf{X}$, *the functions*

$$\int_{\mathbf{X}} v(y) Q(dy|x, \cdot, b) \quad \text{and} \quad \int_{\mathbf{X}} v(y) Q(dy|x, a, \cdot)$$

are continuous on $A(x)$ *and* $B(x)$, *respectively.*

(f) *The functions*

$$\int_{\mathbf{X}} W(y) Q(dy|x, \cdot, b) \quad \text{and} \quad \int_{\mathbf{X}} W(y) Q(dy|x, a, \cdot)$$

are continuous on $A(x)$ *and* $B(x)$, *respectively.*

THEOREM 4.7. *Suppose that Assumptions* 4.1, 4.2, 4.3, *and* 4.6 *hold. Then the following hold:*

(a) *There exist a unique function* $h^* \in B_W(\mathbf{X})$ *with* $\nu(h^*) = 0$, *a stationary strategy pair* $(\varphi^1_*, \varphi^2_*) \in \Phi^1 \times \Phi^2$, *and a constant* ρ^* *which satisfy the Shapley*

equation

$$h^*(x) = \min_{\varphi^2 \in \Phi^2} \left\{ R_{\varphi^1_*, \varphi^2}(x) - \rho^* \tau_{\varphi^1_*, \varphi^2}(x) + \int_{\mathbf{X}} h^*(y) Q_{\varphi^1_*, \varphi^2}(dy|x) \right\} \quad \forall x \in \mathbf{X}$$

$$= \max_{\varphi^1 \in \Phi^1} \left\{ R_{\varphi^1, \varphi^2_*}(x) - \rho^* \tau_{\varphi^1, \varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y) Q_{\varphi^1, \varphi^2_*}(dy|x) \right\}$$

$$= R_{\varphi^1_*, \varphi^2_*}(x) - \rho^* \tau_{\varphi^1_*, \varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y) Q_{\varphi^1_*, \varphi^2_*}(dy|x).$$

(b) *The constant ρ^* is the value of the game and $(\varphi^1_*, \varphi^2_*)$ is an EAP-optimal stationary strategy pair. That is, $J(\varphi^1_*, \varphi^2_*, \cdot) = \rho^*$ and*

$$J(\pi^1, \varphi^2_*, \cdot) \le \rho^* \le J(\varphi^1_*, \pi^2, \cdot) \quad \forall (\pi^1, \pi^2) \in \Pi^1 \times \Pi^2.$$

Hence, by Theorem 4.5*,*

$$h^*(\cdot) = h_{\varphi^1_*, \varphi^2_*}(\cdot).$$

(c) *Moreover,*

$$\rho^* = \rho(\varphi^1_*, \varphi^2_*) = \max_{\varphi^1 \in \Phi^1} \min_{\varphi^2 \in \Phi^2} \rho(\varphi^1, \varphi^2) = \min_{\varphi^2 \in \Phi^2} \max_{\varphi^1 \in \Phi^1} \rho(\varphi^1, \varphi^2), \tag{4.9}$$

$$h^*(\cdot) = h_{\varphi^1_*, \varphi^2_*}(\cdot) = \min_{\varphi^2 \in \mathbf{F}^2} h_{\varphi^1_*, \varphi^2}(\cdot) = \max_{\varphi^1 \in \Phi^1} h_{\varphi^1, \varphi^2_*}(\cdot), \tag{4.10}$$

where $\mathbf{F}^i$ stands for the class of all stationary EAP-optimal strategies for player i ($i = 1, 2$).

It is worth mentioning that, to the best of our knowledge, the minimax characterization of the solution $h^*(\cdot)$ of the Shapley equation given in (4.10) has not been discussed in any of the previous papers dealing with zero-sum stochastic games, even for the case of discrete state space.

5. Proof of Theorem 4.5. For the proof of the results in section 4 several preliminary results are needed. The first few are collected in the next lemma.

LEMMA 5.1. *Suppose that Assumptions* 4.1, 4.2*, and* 4.3 *hold. Then the following hold:*

(a) *For each function u in $B_W(\mathbf{X})$,*

$$\lim_{n \to \infty} \frac{1}{n} E_x^{\pi^1, \pi^2} u(x_n) = 0 \quad \forall x \in \mathbf{X}, (\pi^1, \pi^2) \in \Pi^1 \times \Pi^2.$$

(b) *For each stationary strategy pair $(\varphi^1, \varphi^2) \in \Phi^1 \times \Phi^2$, it holds that*

$$\mu_{\varphi^1, \varphi^2}(S_{\varphi^1, \varphi^2}) \ge \frac{(1 - \lambda)\theta}{\nu(W)} > 0.$$

(c) *If in addition Assumptions* 4.1 *and* 4.2 *hold, then*

$$\frac{\mu_{\varphi^1, \varphi^2}(S_{\varphi^1, \varphi^2})}{\mu_{\varphi^1, \varphi^2}(\tau_{\varphi^1, \varphi^2})} \ge \frac{1 - \lambda}{K \nu(W)} > 0.$$

Proof of Lemma 5.1. First note that Assumption 4.3 (b) implies $S(\cdot,\cdot,\cdot) \leq 1/\nu(\mathbf{X})$. Thus Assumption 4.2 and iterations of the inequality in Assumption 4.3 (c) yield

$$\theta \leq E_x^{\pi^1,\pi^2} W(x_n) \leq \lambda^n W(x) + \frac{\nu(W)(1-\lambda^n)}{\nu(\mathbf{X})(1-\lambda)} \quad \forall x \in \mathbf{X}, (\pi^1,\pi^2) \in \Pi^1 \times \Pi^2, n \in \mathbb{N};$$

thus $\lim_{n\to\infty} \frac{1}{n} E_x^{\pi^1,\pi^2} W(x_n) = 0$. Hence the result in part (a) holds for any function $u(\cdot)$ in $B_W(\mathbf{X})$.

Now, from Assumption 4.3 (c), we have

$$\int_{\mathbf{X}} W(y) Q_{\varphi^1,\varphi^2}(dy|x) \leq \lambda W(x) + \nu(W) S_{\varphi^1,\varphi^2}(x) \quad \forall x \in \mathbf{X},$$

for all pairs $(\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2$. Then, integrating both sides of this inequality with respect to the invariant probability measure $\mu_{\varphi^1,\varphi^2}(\cdot)$, we obtain

$$\mu_{\varphi^1,\varphi^2}(W) \leq \lambda \mu_{\varphi^1,\varphi^2}(W) + \nu(W) \mu_{\varphi^1,\varphi^2}(S_{\varphi^1,\varphi^2}),$$

which combined with Assumption 4.2 yields the result in part (b). Finally, part (c) follows directly from Assumption 4.1 and part (b). □

The following lemma concerns the existence of solutions to the Poisson equation which, in addition to being interesting in itself, plays a key role in our development. In fact, its proof exhibits the way we take advantage of the contraction property (4.2).

LEMMA 5.2. *Suppose Assumptions* 4.2 *and* 4.3 *hold and let* $(\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2$ *be fixed but arbitrary. Then, for each function* v *in* $B_W(\mathbf{X})$ *there exists a unique function* h_v *in* $B_W(\mathbf{X})$, *with* $\nu(h_v) = 0$, *which satisfies the Poisson equation*

$$h_v(x) = v(x) - \mu_{\varphi^1,\varphi^2}(v) + \int_{\mathbf{X}} h_v(y) Q_{\varphi^1,\varphi^2}(dy|x) \quad \forall x \in \mathbf{X}. \tag{5.1}$$

Thus, from Lemma 5.1(a),

$$\mu_{\varphi^1,\varphi^2}(v) = \lim_{n\to\infty} \frac{1}{n} E_x^{\varphi^1,\varphi^2} \sum_{k=0}^{n-1} v(x_k) \quad \forall x \in \mathbf{X}. \tag{5.2}$$

Proof of Lemma 5.2. Fix a function $v \in B_W(\mathbf{X})$, and let $\mu(\cdot) := \mu_{\varphi^1,\varphi^2}(\cdot)$, $S(\cdot) := S_{\varphi^1,\varphi^2}(\cdot|\cdot)$, and $Q(\cdot|\cdot) := Q_{\varphi^1,\varphi^2}(\cdot|\cdot)$. Next, define

$$\widehat{T}u(x) = v(x) - \mu(v) + \int_{\mathbf{X}} u(y) \widehat{Q}(dy|x) \quad \forall x \in \mathbf{X}, u \in B_W(\mathbf{X}).$$

By Assumption 4.3 (c), it is clear that $\widehat{T}$ maps $B_W(\mathbf{X})$ into itself. Moreover, for any functions $u, w \in B_W(\mathbf{X})$, it holds that

$$|\widehat{T}u(x) - \widehat{T}w(x)| \leq \int_{\mathbf{X}} |u(y) - w(y)| \, \widehat{Q}(dy|x)$$

$$\leq ||u-w||_W \int_{\mathbf{X}} W(y) \widehat{Q}(dy|x) \leq ||u-w||_W \; \lambda W(x)$$

for all $x \in \mathbf{X}$. Hence

$$||\widehat{T}u - \widehat{T}w||_W \leq \lambda \, ||u - w||_W.$$

That is, $\widehat{T}$ is a contraction operator from $B_W(\mathbf{X})$ into itself with modulus λ. Then, by the Banach fixed-point theorem, there exists a unique function $h_v \in B_W(\mathbf{X})$ that satisfies the equation

$$h_v(x) = v(x) - \mu(v) + \int_{\mathbf{X}} h_v(y)\widehat{Q}(dy|x) \quad \forall x \in \mathbf{X}$$

$$= v(x) - \mu(v) + \int_{\mathbf{X}} h_v(y)Q(dy|x) - \nu(h_v)S(x).$$

Now, an integration with respect to the invariant probability measure $\mu(\cdot)$ in both sides of the last equation yields

$$\nu(h_v)\mu(S) = 0,$$

which, by Lemma 5.1 (b), implies that $\nu(h_v) = 0$. Therefore, h_v satisfies the Poisson equation

$$h_v(x) = v(x) - \mu(v) + \int_{\mathbf{X}} h_v(y)Q(dy|x) \quad \forall x \in \mathbf{X},$$

which proves (5.1).

Finally, the property (5.2) is obtained by iteration of the Poisson equation and using Lemma 5.1 (a). □

Now we proceed to prove Theorem 4.5.

Proof of Theorem 4.5. Let $(\varphi^1, \varphi^2) \in \Phi^1 \times \Phi^2$ be fixed but arbitrary. Thus, since the function

$$v(\cdot) := \overline{R}_{\varphi^1,\varphi^2}(\cdot) = R_{\varphi^1,\varphi^2}(\cdot) - \rho(\varphi^1, \varphi^2)\, \tau_{\varphi^1,\varphi^2}(\cdot)$$

is in $B_W(\mathbf{X})$, by Lemma 5.2 there exists a unique function $h_{\varphi^1,\varphi^2} \in B_W(\mathbf{X})$ with $\nu(h_{\varphi^1,\varphi^2}) = 0$ that satisfies the Poisson equation

$$h_{\varphi^1,\varphi^2}(x) = \overline{R}_{\varphi^1,\varphi^2}(x) + \int_{\mathbf{X}} h_{\varphi^1,\varphi^2}(y)Q_{\varphi^1,\varphi^2}(dy|x) \quad \forall x \in \mathbf{X}.$$

This proves part (a) of the theorem.

Next, to prove part (b), first note that iteration of the last equation yields

$$h_{\varphi^1,\varphi^2}(x) = E_x^{\varphi^1,\varphi^2}\left[\sum_{k=1}^{n-1} R_{\varphi^1,\varphi^2}(x_k) - \rho(\varphi^1, \varphi^2)\sum_{k=1}^{n-1}\tau_{\varphi^1,\varphi^2}(x_k)\right]$$

(5.3)

$$+ \int_{\mathbf{X}} h_{\varphi^1,\varphi^2}(y)Q^n_{\varphi^1,\varphi^2}(dy|x)$$

for all $n \in \mathbb{N}$ and $x \in \mathbf{X}$. Moreover, by Assumptions 4.1 and 4.2, applying Lemma 5.2 with $v(\cdot) := \tau_{\varphi^1,\varphi^2}(\cdot)$, we obtain

$$\mu_{\varphi^1,\varphi^2}(\tau_{\varphi^1,\varphi^2}) = \lim_{n\to\infty} \frac{1}{n} E_x^{\varphi^1,\varphi^2} \sum_{k=1}^{n-1} \tau_{\varphi^1,\varphi^2}(x_k) > 0 \quad \forall x \in \mathbf{X},$$

which combined with (5.3) and Lemma 5.1 (a) implies that

$$\rho(\varphi^1,\varphi^2)=\lim_{n\to\infty}\frac{E_x^{\varphi^1,\varphi^2}\sum_{k=0}^{n-1}R_{\varphi^1,\varphi^2}(x_k)}{E_x^{\varphi^1,\varphi^2}\sum_{k=0}^{n-1}\tau_{\varphi^1,\varphi^2}(x_k)}\quad\forall x\in\mathbf{X}.\qquad\square$$

6. Proof of Theorem 4.7. Define the constants

$$\rho^l:=\sup_{\varphi^1\in\Phi^1}\inf_{\varphi^2\in\Phi^2}\rho(\varphi^1,\varphi^2)\quad\text{and}\quad\rho^u:=\inf_{\varphi^2\in\Phi^2}\sup_{\varphi^1\in\Phi^1}\rho(\varphi^1,\varphi^2).$$

We show in the next lemma that these constants are finite. Observe that this trivially holds if one assumes that the mean holding time function is bounded below by a positive constant.

LEMMA 6.1. *Suppose that Assumptions* 4.1, 4.2, 4.3, *and* 4.6 *hold. Then*

$$|\rho^l|<\infty\quad\textit{and}\quad|\rho^u|<\infty.$$

Proof of Lemma 6.1. Let φ^1 be a fixed but arbitrary stationary strategy for player 1 and consider the Markov (one player) model

$$\mathbf{M}=(\mathbf{X},K_B,\widetilde{Q},\widetilde{\tau}),$$

where $\mathbf{X}$ and K_B are as above, and the transition law and the "one-step cost" function are defined as

$$\widetilde{Q}(\cdot|x,b):=\int_{A(x)}Q(\cdot|x,a,b)\varphi^1(da|x),$$

$$\widetilde{\tau}(x,b):=\int_{A(x)}\tau(x,a,b)\varphi^1(da|x)$$

for all $(x,b)\in K_B$, respectively.

Thus following the notation in (2.4), for all $x\in\mathbf{X}$ and $\varphi^2\in\Phi^2$, define

$$\widetilde{Q}_{\varphi^2}(\cdot|x):=\int_{B(x)}\widetilde{Q}(\cdot|x,b)\varphi^2(db|x),$$

$$\widetilde{\tau}_{\varphi^2}(x):=\int_{B(x)}\widetilde{\tau}(x,b)\varphi^2(db|x).$$

Note that $\widetilde{Q}_{\varphi^2}(\cdot|\cdot)=Q_{\varphi^1,\varphi^2}(\cdot|\cdot)$ and $\widetilde{\tau}_{\varphi^2}(\cdot)=\tau_{\varphi^1,\varphi^2}(\cdot)$ for all $\varphi^2\in\Phi^2$.

The Markov model $\mathbf{M}$ satisfies all the conditions in [30, Thm. 3.6]; hence, in particular, there exists a stationary policy $\varphi^2_+\in\Phi^2$ such that

$$\mu_{\varphi^1,\varphi^2_+}(\tau_{\varphi^1,\varphi^2_+})=\mu_{\varphi^1,\varphi^2_+}(\widetilde{\tau}_{\varphi^2_+})=\inf_{\varphi^2\in\Phi^2}\mu_{\varphi^1,\varphi^2}(\widetilde{\tau}_{\varphi^2}).$$

Then, by Assumption 4.1, it holds that $\mu_{\varphi^1,\varphi^2_+}(\tau_{\varphi^1,\varphi^2_+})>0$. Next observe that

$$|\rho(\varphi^1,\varphi^2)|\le\frac{\mu_{\varphi^1,\varphi^2}(|R_{\varphi^1,\varphi^2}|)}{\mu_{\varphi^1,\varphi^2}(\tau_{\varphi^1,\varphi^2})}\le\frac{\mu_{\varphi^1,\varphi^2}(W)}{\mu_{\varphi^1,\varphi^2_+}(\tau_{\varphi^1,\varphi^2_+})}$$

$$\le\frac{k}{\mu_{\varphi^1,\varphi^2_+}(\tau_{\varphi^1,\varphi^2_+})},$$

where the last inequality follows from (4.5) with $k := \nu(W)[(1-\lambda)\nu(\mathbf{X})]^{-1}$. Hence

$$-\infty < -\frac{k}{\mu_{\varphi^1,\varphi^2_+}(\tau_{\varphi^1,\varphi^2_+})} \leq \inf_{\varphi^2\in\Phi^2} \rho(\varphi^1,\varphi^2) \leq \rho(\varphi^1,\varphi^2) \quad \forall \varphi^1 \in \Phi^1. \tag{6.1}$$

Now fix $\varphi^2 \in \Phi^2$ and proceed as above to get a stationary strategy $\varphi^1_+ \in \Phi$ such that

$$\mu_{\varphi^1_+,\varphi^2}(\tau_{\varphi^1_+,\varphi^2}) = \inf_{\varphi^1\in\Phi^1} \mu_{\varphi^1,\varphi^2}(\tau_{\varphi_1,\varphi^2}) > 0.$$

Then

$$\rho(\varphi^1,\varphi^2) \leq \frac{\mu_{\varphi^1,\varphi^2}(|R_{\varphi^1,\varphi^2}|)}{\mu_{\varphi^1,\varphi^2}(\tau_{\varphi^1,\varphi^2})} \leq \frac{k}{\mu_{\varphi^1_+,\varphi^2}(\tau_{\varphi^1_+,\varphi^2})} < +\infty.$$

Hence

$$\rho(\varphi^1,\varphi^2) \leq \sup_{\varphi^1\in\Phi^1} \rho(\varphi^1,\varphi^2) \leq \frac{k}{\mu_{\varphi^1_+,\varphi^2}(\tau_{\varphi^1_+,\varphi^2})}. \tag{6.2}$$

Therefore, by (6.1)–(6.2),

$$-\infty < \rho^l = \sup_{\varphi^1\in\Phi^1} \inf_{\varphi^2\in\Phi^2} \rho(\varphi^1,\varphi^2) \leq \rho^u = \inf_{\varphi^2\in\Phi^2} \sup_{\varphi^1\in\Phi^1} \rho(\varphi^1,\varphi^2) < +\infty,$$

which proves the desired result. □

For the proof of Theorem 4.7 introduce the following operators: for each $u \in B_W(\mathbf{X})$ define

$$L^l u(x,a,b) := R^l(x,a,b) + \int_{\mathbf{X}} u(y)\widehat{Q}(dy|x,a,b) \quad \forall (x,a,b) \in \mathbb{K}, \tag{6.3}$$

where

$$R^l(x,a,b) := R(x,a,b) - \rho^l \tau(x,a,b) \quad \forall (x,a,b) \in \mathbb{K}. \tag{6.4}$$

Thus, following the notation (2.4), for each strategy pair $(\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2$ define the operators

$$L^l_{\varphi^1,\varphi^2} u(\cdot) := R^l_{\varphi^1,\varphi^2}(\cdot) + \int_{\mathbf{X}} u(y)\widehat{Q}_{\varphi^1,\varphi^2}(dy|\cdot), \tag{6.5}$$

$$L^* u(\cdot) := \sup_{\varphi^1\in\mathbb{A}(x)} \inf_{\varphi^2\in\mathbb{B}(x)} L^l_{\varphi^1,\varphi^2} u(\cdot) \tag{6.6}$$

for each $u \in B_W(\mathbf{X})$.

The results in the next lemma are a combination of the well-known measurable selection theorem [24] and the Fan minimax theorem [4]. The proof is omitted since it is the same as the proof of Lemma 6.5 in [11] and Lemmas 2, 3, and 4 in [25].

LEMMA 6.2. *Suppose that Assumptions* 4.1, 4.2, 4.3, *and* 4.6 *hold and let* u *be a fixed function in* $B_W(\mathbf{X})$. *Then the following hold:*

(a) *For each* $x \in \mathbf{X}$, *the sets* $\mathbb{A}(x)$ *and* $\mathbb{B}(x)$ *are compact with respect to the weak convergence of measures.*

(b) *For each* $x \in \mathbf{X}, (\varphi^1, \varphi^2) \in \Phi^1 \times \Phi^2$, *and* $u \in B_W(\mathbf{X})$, *the mappings*

$$\varphi^1 \to L^l_{\varphi^1,\varphi^2} u(x),$$

$$\varphi^2 \to L^l_{\varphi^1,\varphi^2} u(x)$$

are upper semicontinuous and lower semicontinuous on $\mathbb{A}(x)$ *and* $\mathbb{B}(x)$, *respectively, with respect to the weak convergence of measures.*

(c) *Moreover, there exists a stationary strategy pair* $(\varphi^1_u, \varphi^2_u) \in \Phi^1 \times \Phi^2$ *such that*

$$L^* u(\cdot) = L^l_{\varphi^1_u,\varphi^2_u} u(\cdot)$$

$$= \max_{\varphi^1 \in \Phi^1} L^l_{\varphi^1,\varphi^2_u} u(\cdot) = \min_{\varphi^2 \in \Phi^2} L^l_{\varphi^1_u,\varphi^2} u(\cdot).$$

Hence $L^* u(\cdot)$ *is in* $B_W(\mathbf{X})$.

The proof of Theorem 4.7 follows the same scheme as that of Lemma 5.2, so we first show—in Lemma 6.3 below—that L^* is a contraction operator from $B_W(\mathbf{X})$ into itself with modulus λ; hence, by the Banach fixed-point theorem, there exists a unique function h^* in $B_W(\mathbf{X})$ such that

$$h^*(\cdot) = L^* h^*(\cdot) = \sup_{\varphi^1 \in \mathbb{A}(x)} \inf_{\varphi^2 \in \mathbb{B}(x)} L^l_{\varphi^1,\varphi^2} h^*(\cdot). \tag{6.7}$$

As a second step, in Lemma 6.4, we prove that

$$\rho^* := \rho^l = \rho^u \quad \text{and} \quad \nu(h^*) \le 0.$$

Once the latter is done, we show in Lemma 6.5 that

$$\nu(h^*) = 0.$$

Then (6.7) becomes

$$h^*(x) = \sup_{\varphi^1 \in \mathbb{A}(x)} \inf_{\varphi^2 \in \mathbb{B}(x)} \left[R_{\varphi^1,\varphi^2}(x) - \rho^* \tau_{\varphi^1,\varphi^2}(x) + \int_{\mathbf{X}} h^*(y) Q_{\varphi^1,\varphi^2}(dy|x) \right]$$

for all $x \in \mathbf{X}$. Hence Lemma 6.2 yields a stationary strategy pair $(\varphi^1_*, \varphi^2_*) \in \Phi^1 \times \Phi^2$ satisfying Theorem 4.7 (a).

LEMMA 6.3. *Suppose that the assumptions in Theorem* 4.7 *hold. Then,* L^* *in* (6.6) *is a contraction operator from* $B_W(\mathbf{X})$ *into itself with modulus* λ. *Thus, by the Banach fixed-point theorem and Lemma* 6.2, *there exist a unique function* h^* *in* $B_W(\mathbf{X})$ *and a stationary strategy pair* $(\varphi^1_*, \varphi^2_*) \in \Phi^1 \times \Phi^2$ *such that*

$$h^*(\cdot) = L^* h^*(\cdot) = L^l_{\varphi^1_*,\varphi^2_*} h^*(\cdot) \tag{6.8}$$

$$= \min_{\varphi^2 \in \mathbb{B}(x)} L^l_{\varphi^1_*,\varphi^2} h^*(\cdot) = \max_{\varphi^1 \in \mathbb{A}(x)} L^l_{\varphi^1,\varphi^2_*} h^*(\cdot). \tag{6.9}$$

Proof of Lemma 6.3. By Lemma 6.2 it remains only to prove that L^* is a contraction operator from $B_W(\mathbf{X})$ into itself with modulus λ. To prove this, consider

arbitrary functions u, v in $B_W(\mathbf{X})$ and observe, by Assumption 4.3 (b) and (4.2), that

$$\left|L^l_{\varphi^1,\varphi^2}u(\cdot) - L^l_{\varphi^1,\varphi^2}v(\cdot)\right| \le \|u-v\|_W \int_{\mathbf{X}} W(y)\widehat{Q}_{\varphi^1,\varphi^2}(dy|\cdot)$$

$$\le \|u-v\|_W \lambda W(\cdot)$$

for all $(\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2$. This implies that

$$L^l_{\varphi^1,\varphi^2}u(\cdot) \le L^l_{\varphi^1,\varphi^2}v(\cdot) + \|u-v\|_W \lambda W(\cdot) \quad \forall (\varphi^1,\varphi^2) \in \Phi^1 \times \Phi^2.$$

Thus the latter inequality together with Lemma 6.2 implies

$$\inf_{\varphi^2 \in \mathbb{B}(x)} L^l_{\varphi^1,\varphi^2}u(\cdot) \le \inf_{\varphi^2 \in \mathbb{B}(x)} L^l_{\varphi^1,\varphi^2}v(\cdot) + \|u-v\|_W \lambda W(\cdot) \quad \forall \varphi^1 \in \Phi^1,$$

which, using again Lemma 6.2, yields

$$L^*u(\cdot) \le L^*v(\cdot) + \|u-v\|_W \lambda W(\cdot).$$

Similarly, interchanging the role of u and v, it also holds that

$$L^*v(\cdot) \le L^*u(\cdot) + \|u-v\|_W \lambda W(\cdot).$$

Therefore,

$$\|L^*u - L^*v\|_W \le \lambda \|u-v\|_W .$$

That is, L^* is a contraction operator from $B_W(\mathbf{X})$ into itself with modulus λ. Now, the Banach fixed-point theorem together with Lemma 6.2 ensures the existence of a unique function $h^* \in B_W(\mathbf{X})$ and a stationary strategy pair $(\varphi^1_*, \varphi^2_*) \in \Phi^1 \times \Phi^2$ satisfying (6.8)–(6.9). □

LEMMA 6.4. *Suppose that the assumptions in Theorem* 4.7 *hold and let* h^* *be as in Lemma* 6.3. *Then*

$$\nu(h^*) \le 0 \quad \textit{and} \quad \rho^l = \rho^u.$$

Proof of Lemma 6.4. Let $(\varphi^1_*, \varphi^2_*)$ be as in Lemma 6.3. Then

$$h^*(x) = \min_{\varphi^2 \in \mathbb{B}(x)} \left[R^l_{\varphi^1_*,\varphi^2}(x) + \int_{\mathbf{X}} h^*(y)\widehat{Q}_{\varphi^1_*,\varphi^2}(dy|x) \right] \tag{6.10}$$

$$\le R^l_{\varphi^1_*,\varphi^2}(x) + \int_{\mathbf{X}} h^*(y)\widehat{Q}_{\varphi^1_*,\varphi^2}(dy|x)$$

$$= R^l_{\varphi^1_*,\varphi^2}(x) + \int_{\mathbf{X}} h^*(y)Q_{\varphi^1_*,\varphi^2}(dy|x) - \nu(h^*)S_{\varphi^1_*,\varphi^2}(x)$$

for all $x \in \mathbf{X}, \varphi^2 \in \Phi^2$. Then an integration with respect to the invariant probability measure $\mu_{\varphi^1_*,\varphi^2}$ yields

$$0 \le \mu_{\varphi^1_*,\varphi^2}(R^l_{\varphi^1_*,\varphi^2}) - \nu(h^*)\mu_{\varphi^1_*,\varphi^2}(S_{\varphi^1_*,\varphi^2}) \quad \forall \varphi^2 \in \Phi^2,$$

which implies that

$$\nu(h^*)\mu_{\varphi^1_*,\varphi^2}(S_{\varphi^1_*,\varphi^2}) \le \mu_{\varphi^1_*,\varphi^2}(R_{\varphi^1_*,\varphi^2}) - \rho^l \mu_{\varphi^1_*,\varphi^2}(\tau_{\varphi^1_*,\varphi^2})$$

$$= \mu_{\varphi^1_*,\varphi^2}(\tau_{\varphi^1_*,\varphi^2}) \left[\rho(\varphi^1_*,\varphi^2) - \rho^l\right]$$

for all $\varphi^2 \in \Phi^2$. Now, taking the infimum over Φ^2, we obtain

$$\inf_{\varphi^2\in\mathbb{B}(x)} \left[\frac{\nu(h^*)\mu_{\varphi^1_*,\varphi^2}(S_{\varphi^1_*,\varphi^2})}{\mu_{\varphi^1_*,\varphi^2}(\tau_{\varphi^1_*,\varphi^2})}\right] \le \inf_{\varphi^2\in\mathbb{B}(x)} \rho(\varphi^1_*,\varphi^2) - \rho^l \le 0,$$

which, by Assumption 4.1 and Lemma 5.1 (b), implies that

$$\nu(h^*) \le 0.$$

This inequality combined with (6.9) implies

$$h^*(x) = \max_{\varphi^1\in\mathbb{A}(x)} \left[R^l_{\varphi^1,\varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y)\widehat{Q}_{\varphi^1,\varphi^2_*}(dy|x)\right]$$

$$\ge \max_{\varphi^1\in\mathbb{A}(x)} \left[R^l_{\varphi^1,\varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y)Q_{\varphi^1,\varphi^2_*}(dy|x)\right]$$

$$\ge R^l_{\varphi^1,\varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y)Q_{\varphi^1,\varphi^2_*}(dy|x)$$

for all $x \in \mathbf{X}, \varphi^1 \in \Phi^1$. Now, integrating both sides of the latter inequality with respect to the invariant probability measure $\mu_{\varphi^1,\varphi^2_*}$, we see that

$$0 \ge \mu_{\varphi^1,\varphi^2_*}(R^l_{\varphi^1,\varphi^2_*}) = \mu_{\varphi^1,\varphi^2_*}(R_{\varphi^1,\varphi^2_*}) - \rho^l \mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*}) \quad \forall \varphi^1 \in \Phi^1,$$

which implies that

$$\rho^l \ge \rho(\varphi^1,\varphi^2_*) = \frac{\mu_{\varphi^1,\varphi^2_*}(R_{\varphi^1,\varphi^2_*})}{\mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*})} \quad \forall \varphi^1 \in \Phi^1.$$

Hence

$$\rho^l \ge \sup_{\varphi^1\in\Phi^1} \rho(\varphi^1,\varphi^2_*) \ge \inf_{\varphi^2\in\Phi^2} \sup_{\varphi^1\in\Phi^1} \rho(\varphi^1,\varphi^2) = \rho^u.$$

Therefore, $\rho^l = \rho^u$. □

LEMMA 6.5. *Suppose that the assumptions in Theorem* 4.7 *hold and let* h^* *be as in Lemma* 6.3. *Then*

$$\nu(h^*) = 0.$$

Proof of Lemma 6.5. Let $(\varphi^1_*,\varphi^2_*)$ be as in Lemma 6.3 and put $\rho^* := \rho^l = \rho^u$. By (6.9), we have

$$h^*(x) = \max_{\varphi^1\in\mathbb{A}(x)} \left[R_{\varphi^1,\varphi^2_*}(x) - \rho^*\tau_{\varphi^1,\varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y)\widehat{Q}_{\varphi^1,\varphi^2_*}(dy|x)\right]$$

$$\ge R_{\varphi^1,\varphi^2_*}(x) - \rho^*\tau_{\varphi^1,\varphi^2_*}(x) + \int_{\mathbf{X}} h^*(y)\widehat{Q}_{\varphi^1,\varphi^2_*}(dy|x)$$

for all $x \in \mathbf{X}, \varphi^1 \in \Phi^1$. As above, integrating with respect to the invariant probability measure $\mu_{\varphi^1,\varphi^2_*}$ in both sides of the latter inequality, we obtain

$$\begin{aligned}\nu(h^*)\mu_{\varphi^1,\varphi^2_*}(S_{\varphi^1,\varphi^2_*}) &\geq \mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*})\left[\rho(\varphi^1,\varphi^2_*) - \rho^*\right] \\ &= \mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*})\left[\rho(\varphi^1,\varphi^2_*) - \inf_{\varphi^2\in\Phi^2}\sup_{\varphi^1\in\Phi^1}\rho(\varphi^1,\varphi^2)\right] \\ &\geq \mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*})\left[\rho(\varphi^1,\varphi^2_*) - \sup_{\varphi^1\in\Phi^1}\rho(\varphi^1,\varphi^2_*)\right],\end{aligned}$$

which implies that

$$\frac{\nu(h^*)\mu_{\varphi^1,\varphi^2_*}(S_{\varphi^1,\varphi^2_*})}{\mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*})} \geq \rho(\varphi^1,\varphi^2_*) - \sup_{\varphi^1\in\Phi^1}\rho(\varphi^1,\varphi^2_*) \quad \forall\varphi^1 \in \Phi^1.$$

Then

$$\sup_{\varphi^1\in\Phi^1}\left[\frac{\nu(h^*)\mu_{\varphi^1,\varphi^2_*}(S_{\varphi^1,\varphi^2_*})}{\mu_{\varphi^1,\varphi^2_*}(\tau_{\varphi^1,\varphi^2_*})}\right] \geq 0.$$

This inequality implies that $\nu(h^*) \geq 0$. Hence, by Lemma 6.4, $\nu(h^*) = 0$. □

Finally, we are ready for the proof of Theorem 4.7.

Proof of Theorem 4.7. Let h^* and $(\varphi^1_*, \varphi^2_*)$ be as in Lemma 6.3. First note that the proof of part (a) is given throughout Lemmas 6.3, 6.4, and 6.5. Part (b) follows using standard dynamic programming arguments, while the first statement in part (c) is exactly Lemma 6.4. Thus it remains only to prove the equalities in (4.10). To do this first recall that $\mathbf{F}^i$ denotes the class of all stationary optimal strategies for player i, with $i = 1, 2$, which is nonempty because of part (b). Now, define the following operators on $B_W(\mathbf{X})$:

$$Mu(x) := \max_{\varphi^1\in\mathbb{A}(x)}\left[R_{\varphi^1_*,\varphi^2}(x) - \rho^*\tau_{\varphi^1_*,\varphi^2}(x) + \int_{\mathbf{X}} u(y)\widehat{Q}_{\varphi^1_*,\varphi^2}(dy|x)\right],$$

$$Nu(x) := \min_{\varphi^2\in\mathbb{B}(x)}\left[R_{\varphi^1_*,\varphi^2}(x) - \rho^*\tau_{\varphi^1_*,\varphi^2}(x) + \int_{\mathbf{X}} u(y)\widehat{Q}_{\varphi^1_*,\varphi^2}(dy|x)\right]$$

for all $x \in \mathbf{X}$. Proceeding as above, it is easy to check that M and N are well defined and that they are λ-contraction operators on $B_W(\mathbf{X})$ into itself. In fact, from part (a), h^* is the fixed point for both operators; that is,

$$h^*(\cdot) = Mh^*(\cdot) = Nh^*(\cdot).$$

Next choose an arbitrary strategy φ^1_0 in $\mathbf{F}^1$ and note that

$$\rho^* = \rho(\varphi^1_0, \varphi^2_*).$$

Then, by Theorem 4.5, there exists a unique function $h_{\varphi^1_0,\varphi^2_*}$ in $B_W(\mathbf{X})$, with $\nu(h_{\varphi^1_0,\varphi^2_*}) = 0$, which satisfies

$$h_{\varphi^1_0,\varphi^2_*}(x) = R_{\varphi^1_0,\varphi^2_*}(x) - \rho^*\tau_{\varphi^1_0,\varphi^2_*}(x) + \int_{\mathbf{X}} h_{\varphi^1_0,\varphi^2_*}(y)\widehat{Q}_{\varphi^1_0,\varphi^2_*}(dy|x) \quad \forall x \in \mathbf{X}.$$

Next, observe that

$$h_{\varphi_0^1,\varphi_*^2}(\cdot) \leq Mh_{\varphi_0^1,\varphi_*^2}(\cdot),$$

which implies that

$$h_{\varphi_0^1,\varphi_*^2}(\cdot) \leq M^n h_{\varphi_0^1,\varphi_*^2}(\cdot) \quad \forall n \in \mathbb{N}.$$

Now, since M is a contraction and h^* is its fixed point, we have

$$h_{\varphi_0^1,\varphi_*^2}(\cdot) \leq h^*(\cdot).$$

Hence, since $h^*(\cdot) = h_{\varphi_*^1,\varphi_*^2}(\cdot)$ and the policy φ_0^1 was chosen arbitrarily in $\mathbf{F}^1$, we have

$$\max_{\varphi^1 \in \mathbf{F}^1} h_{\varphi^1,\varphi_*^2}(\cdot) = h^*(\cdot).$$

Similar arguments, but using the operator N instead of M, show that

$$h^*(\cdot) = \min_{\varphi^2 \in \mathbf{F}^2} h_{\varphi_*^1,\varphi^2}(\cdot). \qquad \square$$

Acknowledgments. The author thanks Professor Onésimo Hernández-Lerma for his valuable comments on an early version of this work. He also thanks Professor Heinz-Uwe Küenle who kindly showed him a preliminary version of the paper [18].

A NEW APPROACH TO THE LUR'E PROBLEM IN THE THEORY OF ABSOLUTE STABILITY*

A. A. ZEVIN† AND M. A. PINSKY‡

Abstract. The classical Lur'e problem consists of finding conditions for absolute stability of a linear system with a nonlinear feedback contained within a prescribed sector. Most of the results obtained on this problem are based on the frequency domain or Lyapunov functions methods which are applied to systems with a time-invariant or periodic linear block. This paper develops a new approach providing a sufficient stability criterion for systems with time-variable coefficients, which is expressed in the transfer function of the linear block and the sector margins of the nonlinear block. The systems for which this criterion is precise are found. It is shown that stability of a system with a sign-constant transfer function is guaranteed by stability of the system with a limit linear feedback (so that, for such systems, the famous Aizerman conjecture is true). This, in particular, is the case for systems with a linear block consisting of an arbitrary number of first order time-dependent links. As an example, the stability criterion is applied to a second order system for which the obtained results are contrasted with ones delivered by the Popov criterion.

Key words. absolute stability, Lur'e problem, time-varying systems, exponential stability criteria, Aizerman class

1. Introduction.

We consider a linear system controlled by a nonlinear feedback

$$\begin{aligned} \dot{x} &= A(t)x + b(t)\varphi(\sigma, t), \\ \sigma &= (c, x), \end{aligned} \tag{1.1}$$

where $x \in R^n$, $\sigma \in R^1$; the matrix $A(t)$ and the vector $b(t)$ are bounded and piece-wise continuous; (a, b) means the scalar product of vectors a and b.

It is assumed that the function $\varphi(\sigma, t)$ is contained within a prescribed sector, i.e.,

$$K_1\sigma^2 \le \varphi(\sigma, t)\sigma \le K_2\sigma^2. \tag{1.2}$$

Let $\Phi(K_1, K_2)$ be the set of functions $\varphi(\sigma, t)$ assuming (1.2). System (1.1), (1.2) is called absolutely stable in the class $\Phi(K_1, K_2)$ if for any $\varphi \in \Phi(K_1, K_2)$ and $x(0) \in R^n$, the corresponding solution $x(t) \to 0$ as $t \to \infty$. Finding conditions for absolute stability of system (1.1) in the class $\Phi(K_1, K_2)$ is the classical Lur'e problem [1], which has led to an extensive literature over the last few decades. Most of the known results on the problem are obtained by the frequency domain or Lyapunov functions methods and relate to systems with a time-invariant linear block (e.g., [2, 3, 4, 5, 6, 7, 8, 9]). Periodic systems ($A(t) = A(t + T)$) were considered by Yakubovich [10, 11, 12]; as mentioned in the most recent paper [12], a generalization of frequency domain methods on such systems faces significant complications. Stability analysis of more general nonperiodic systems confronts even more complex problems which, in principle, could

be tackled by the Lyapunov method, but there is no regular technique providing Lyapunov functions for such systems.

A characterization of a class of systems for which asymptotic stability of the corresponding linear system ($\varphi(\sigma) = k\sigma$) for any $k \in [K_1, K_2]$ implies absolute stability of system (1.1) in the class $\Phi(K_1, K_2)$ (the Aizerman problem [13]) is closely related to the absolute stability problem. Bergen and Williams [14] described the closed-loop systems of the third order belonging to this class. Trukhan extended this result on systems with a linear block consisting of up to five stable links (or any number of identical links) of the first order [15]. In [3] Pyatnitsky noted that the question of whether an analogous statement is true for closed-loop systems with arbitrary links of the first order is very interesting; to our knowledge, the answer still remains unknown after more than 30 years. Gil' proved [17] that a time-invariant ($A(t) \equiv A$) system (1.1), (1.2) belongs to the considered class, provided that the transfer function $w(t-s)$ of the linear part is nonnegative for $t \geq s$. Andrusevich showed [18] that if the off-diagonal elements of the matrix $A + \lambda bc'$ is nonnegative for $0 \leq \lambda \leq K$, then the system obeys the Aizerman conjecture (note that it can be shown that under this condition, the transfer function is nonnegative, and this result follows directly from the Gil' theorem).

This paper develops a new approach to stability analysis of system (1.1), (1.2) centered on studying the corresponding Volterra equation (2.4) for function $\sigma(t)$. A sufficient condition for absolute exponential stability of such systems is derived in section 2, Theorem 1. We indicate a class of systems for which this condition is precise (section 3, Theorem 3). We prove (section 3, Theorem 2) that systems with a sign-constant transfer function admit the Aizerman conjecture, which extends the Gil' theorem on time-varying systems. As a result, it is shown that a single-loop system with an arbitrary number of time-varying first order links belongs to the Aizerman class (section 5) yielding a positive answer to the long-standing question mentioned above.

In section 4 we consider stable system (1.1), (1.2) in the presence of an external perturbation. An upper bound for $|\sigma(t)|$ is found (Theorem 4); under a certain additional condition, it is proved that any two solutions $x_1(t)$ and $x_2(t)$ exponentially approach each other as $t \to \infty$ (Theorem 5).

The proposed approach is applied to a second order nonlinear system in section 5. For a time-invariant system, the absolute stability condition is derived in an explicit form and is compared with one implied by the known Popov criterion. It turns out that the developed criterion is superior for larger, and slightly more conservative for smaller, values of dissipation coefficient than the Popov condition.

2. Criterion for absolute exponential stability. Frequently, the class $\Phi(K_1, K_2)$ is reduced to $\Phi(0, K)$ ($K = K_2 - K_1$) by substitution $\varphi_1(\sigma, t) = \varphi(\sigma, t) - K_1\sigma$. In this paper, putting $\varphi_1(\sigma, t) = \varphi(\sigma, t) - K_1\sigma - 0.5K\sigma$ and retaining the previous notation we reduce it to $\Phi(-K/2, K/2)$; i.e., inequality (1.2) becomes

$$-0.5K\sigma^2 \leq \varphi(\sigma, t)\sigma \leq 0.5K\sigma^2. \tag{2.1}$$

Let $W(t, s)$ ($W(s, s) = I$, where I is the unit matrix) be the transition matrix of the linear equation

$$\dot{x} = A(t)x. \tag{2.2}$$

A solution $x(t)$ of (1.1) satisfies the equation

$$x(t) = W(t,0)x(0) + \int_0^t W(t,s)b(s)\varphi(\sigma(s),s)\mathrm{d}s. \tag{2.3}$$

Multiplying (2.3) by $c(t)$, we obtain the integral Volterra equation of the second kind about $\sigma(t)$:

$$\begin{gathered}\sigma(t) = f(t) + \int_0^t w(t,s)\varphi(\sigma(s),s)\mathrm{d}s,\\ f(t) = (c(t), W(t,0)x(0)), \quad w(t,s) = (c(t), W(t,s)b(s)),\end{gathered} \tag{2.4}$$

where $w(t,s)$ is called the transfer function.

Suppose that (2.2) is uniformly exponentially stable; i.e., there exist positive constants C and Δ such that for any solution $x(t)$,

$$\|x(t)\| \le C\exp[-\Delta(t-s)]\,\|x(s)\|, \quad t > s, \tag{2.5}$$

where $\|x\|$ is any norm of x. Note that for an asymptotically stable system with a constant matrix A, the largest real part of the corresponding eigenvalues can be taken as $-\Delta$.

In view of (2.5), system (1.1), (1.2) is absolutely stable in the class $\Phi(K_1, K_2)$ if for any $\varphi \in \Phi(K_1, K_2)$ and $x(0) \in R^n$, the solution of (2.4), $\sigma(t) \to 0$ as $t \to \infty$. Moreover, if there are positive constants N and β such that

$$|\sigma(t)| \le N\exp(-\beta t)\,|\sigma(0)|, \quad t > 0, \tag{2.6}$$

the stability of the system is exponential.

From (2.5) it follows that for some C,

$$\begin{gathered}\|W(t,s)\| \le C\exp[-\Delta(t-s)],\\ |w(t,s)| \le C\exp[-\Delta(t-s)], \quad |f(t)| \le C\exp(-\Delta t).\end{gathered} \tag{2.7}$$

In view of the second inequality (2.7),

$$M = \sup_t \int_0^t |w(t,s)|\mathrm{d}s < \infty. \tag{2.8}$$

Note that in the case of a time-invariant linear block, $w(t,s) = w(t-s)$. Thus, setting $t - s = z$, we get

$$M = \sup_t \int_0^t |w(z)|\mathrm{d}z = \int_0^\infty |w(z)|\mathrm{d}z. \tag{2.9}$$

The following theorem establishes a sufficient condition for absolute exponential stability of the system (1.1), (2.1).

THEOREM 1. *Under conditions* (2.5) *and*

$$KM < 2, \tag{2.10}$$

system (1.1) *is absolutely exponentially stable in the class* $\Phi(-K/2, K/2)$.

Proof. Let us put

$$M(\beta) = \sup_t \int_0^t \exp[\beta(t-s)]\,|w(t,s)|\,\mathrm{d}s. \tag{2.11}$$

As is seen from (2.11) and (2.8), $M(0) = M$. From the second inequality (2.7) it follows that $M(\beta)$ is bounded for $\beta < \Delta$. By (2.10), there exists β_* such that

$$M(\beta)K < 2 \text{ for } \beta \in [0, \beta_*). \tag{2.12}$$

Setting in (2.4)

$$\sigma(t) = \exp(-\beta t)y(t), \tag{2.13}$$

where $\beta \in (0, \beta_*)$, we obtain

$$y(t) = \exp(\beta t)f(t) + \exp(\beta t)\int_0^t w(t,s)\varphi[\exp(-\beta s)y(s), s]\mathrm{d}s. \tag{2.14}$$

Let us show that $|y(t)|$ is bounded for $t \in (0, \infty)$. In fact, otherwise a sequence $t_1, t_2, \ldots$ ($t_i \to \infty$ as $i \to \infty$) can be found such that $|y(t_i)| \geq |y(t)|$ for $t \in [0, t_i]$. Then from (2.1), (2.11), (2.14), and (2.13) one obtains

$$|y(t_i)| \leq \exp(\beta t_i)\,|f(t_i)| + 0.5M(\beta)K\,|y(t_i)|\,. \tag{2.15}$$

Since $\exp(\beta t)\,|f(t)| \to 0$ as $t \to \infty$ ($\beta < \Delta$) and $0.5M(\beta)K < 1$, inequality (2.15) fails for large i, proving that $|y(t)|$ is bounded for $t \in (0, \infty)$, which along with (2.13) proves inequality (2.6) and the theorem. □

Suppose that the nonlinearity bounds are time-dependent, i.e.,

$$-0.5K(t)\sigma^2 \leq \varphi(\sigma, t)\sigma \leq 0.5K(t)\sigma^2,\ K(t) \geq 0. \tag{2.16}$$

We denote the corresponding class $\Phi(-K(t)/2, K(t)/2)$. It is clear from the above proof that Theorem 1 holds true if KM in condition (2.10) is replaced by the value

$$\Phi = \sup_t \int_0^t |K(t)w(t,s)|\mathrm{d}s. \tag{2.17}$$

Note that the definition of absolute stability often assumes that $f(t)$ in (2.4) is any continuous function such that $|f(t)| \to 0$ as $t \to \infty$, which allows extending the admissible class of systems (1.1) to ones with an external perturbation $u(t)$ disappearing at infinity. Let λ be the Lyapunov exponent of the function $f(t)$, i.e.,

$$\lambda = \lim_{t\to\infty} \sup \frac{1}{t} \log |f(t)|\,.$$

Since $|f(t)| \to 0$ as $t \to \infty$, then $\lambda \leq 0$; to consider exponential stability, we assume $\lambda < 0$. Setting in the previous proof $\beta \in (0, -\lambda)$, we find that Theorem 1 holds true.

3. On the Aizerman problem. As is known (see, e.g., [5, 9]), the famous Aizerman conjecture that stability of system (1.1) with $\varphi(\sigma) = k\sigma$ for any $k \in [0, K]$ implies absolute stability in the class $\Phi(0, K)$ is, in general, false. So the Aizerman problem is to find the systems (1.1) for which such an assertion is actually true.

Suppose that the transfer function is sign-constant, i.e.,

$$w(t,s) \geq 0 \text{ or } w(t,s) \leq 0 \text{ for } t \geq s \geq 0. \tag{3.1}$$

Using the above stability definition, we assume that $f(t)$ in (2.4) is a continuous function such that $|f(t)| \to 0$ as $t \to \infty$ (functions with the Lyapunov exponent $\lambda = 0$ are also admitted; here nonexponential absolute stability is meant).

THEOREM 2. *System* (1.1), (2.1), (2.5), (3.1) *is absolutely stable in the class* $\Phi(-K/2, K/2)$ *if it is stable for* $\varphi = 0.5K\sigma$ $(w(t,s) \geq 0)$ *or for* $\varphi = -0.5K\sigma$ $(w(t,s) \leq 0)$.

Proof. Let $w(t,s) \geq 0$; suppose that for $\varphi = 0.5K\sigma$, the system is absolutely stable. Then for the solution of the equation

$$\sigma(t) = |f(t)| + 0.5\int_0^t Kw(t,s)\sigma(s)\mathrm{d}s, \tag{3.2}$$

$\sigma_1(t) \to 0$ as $t \to \infty$. Without loss of generality we assume that if $f(t) > 0$ for some $(0, t_0)$, then $\sigma_1(t) > 0$ for all $t > 0$ and the solution of (2.4), and $\sigma(t) > 0$ for $t \in (0, t_0)$. Since $\varphi(\sigma) \leq 0.5K\sigma$, then $\sigma_1(t) \geq \sigma(t) > 0$ for $t \in (0, t_0)$; this inequality holds for as long as $\sigma(t) > 0$. Let us show that $\sigma_1(t) \geq |\sigma(t)|$ for $t > 0$. Otherwise, $\sigma_1(t) \geq |\sigma(t)|$ for $t \in (0, t_1)$, and $\sigma_1(t_1) = -\sigma(t_1)$ for some t_1. Putting in (3.2) $\sigma = \sigma_1(t)$ and adding (2.4) and (3.2) for $t = t_1$, we obtain

$$0 = |f(t_1)| + f(t_1) + \int_0^{t_1} w(t,s)[0.5K\sigma_1(s) + \varphi(\sigma(s,s))]\mathrm{d}s. \tag{3.3}$$

Clearly, the integrand in (3.3) is nonnegative, so the right-hand side is positive. The obtained contradiction shows that $\sigma_1(t) \geq |\sigma(t)|$ for $t > 0$, and, therefore, $\sigma(t) \to 0$ as $t \to \infty$. In the case of $w(t,s) \leq 0$ for $t \geq s \geq 0$, the proof is quite analogous. ∎

Theorem 2 yields that for systems with a sign-constant transfer function, the Aizerman conjecture is true in the class $\Phi(-K/2, K/2)$; moreover, it is sufficient to check stability for $k = K/2$ or $k = -K/2$ only. As is clear from the proof, for the general class $\Phi(K_1, K_2)$, the theorem is true if the sign of the transfer function is identical to that of K_*, where K_* is the largest in modulus value of K_1, K_2. Then stability for $\varphi(\sigma) = K_*\sigma$ guarantees stability of the system in the class $\Phi(K_1, K_2)$ and even in the class $\Phi(-|K_*|, |K_*|)$. In particular, for the class $\Phi(0, K)$, the Aizerman conjecture is true if the transfer function is nonnegative (then it is also true for the class $\Phi(-K, K)$). This result significantly generalizes the Gil' theorem obtained for time-invariant systems only [17] (note that the technique of [17] is not extendible on time-varying systems).

Clearly, in the case of time-variable bounds, one has to replace K by $K(t)$ in Theorem 2.

Let K_+ correspond to the limit value of the sector angle in the class $\Phi(-K/2, K/2)$ so that the system is stable for $K < K_+$ and unstable for $K = K_+$. The following theorem gives an explicit expression for this value.

Suppose that the function $m(t) = \int_0^t |w(t,s)|\mathrm{d}s$ increases monotonically; then

$$M = \lim m(t) \text{ as } t \to \infty. \tag{3.4}$$

THEOREM 3. *If, in addition to the conditions of Theorem* 2, *condition* (3.4) *holds, then* $K_+ = 2/M$.

Proof. For $K < 2/M$, the stability follows from Theorem 1; let us show that for $K = 2/M$, the system is unstable.

Consider the equation

$$\begin{aligned} \dot{x} &= A(t)x + kb(t)\sigma + \delta(t), \\ \sigma &= (c, x). \end{aligned} \tag{3.5}$$

Setting in (3.5) $k = 0$, choose $x(0)$ and $\delta(t)$ so that for the corresponding solution $x_0(t)$,

$$\sigma_0(t) = (c, x_0(t)) = \sum_{i=1}^{n} c_i x_{0i}(t) = 1 - m(t)/M. \tag{3.6}$$

To this end, one can put $x_{0k}(t) \equiv \sigma_0(t)/c_k$ ($c_k \neq 0$) and $x_{0i}(t) \equiv 0$, $i = 1, \ldots, n; i \neq k$; then $\delta(t) = \dot{x}_0(t) - A(t)x_0(t)$. By (3.4) and (3.6), $\sigma_0(t) \to 0$, and, therefore,

$$\delta(t) \to 0 \text{ as } t \to \infty. \tag{3.7}$$

Suppose that (3.5) with $k = 1/M$ is exponentially stable. Then, in view of (3.7), for any solution

$$x(t) \to 0 \text{ as } t \to \infty. \tag{3.8}$$

Let $x(t)$ be the solution with $x(0) = x_0(0)$; then the corresponding function $\sigma(t)$ satisfies the equation

$$\sigma(t) = \sigma_0(t) + M^{-1} \int_0^t w(t, s)\sigma(s)\mathrm{d}s. \tag{3.9}$$

By a direct substitution we check that for the solution of (3.9), $\sigma(t) = (c, x(t)) \equiv 1$, which is impossible in view of (3.8). The contradiction obtained shows that for $K = 2/M$, (1.1) is not exponentially stable. □

Thus, for systems considered in Theorem 3, stability condition (2.10) is precise.

4. Systems with external perturbations. Consider now system (1.1), (2.1) in the presence of an external perturbation, i.e.,

$$\dot{x} = A(t)x + b\varphi(\sigma, t) + u(t). \tag{4.1}$$

We assume that if $u(t)$ is bounded on $(0, \infty)$, then so is the solution $f(t)$ of the corresponding linear system ($\varphi(\sigma, t) \equiv 0$). The following theorem gives an upper bound for $|\sigma(t)|$.

Let us put $\sigma^*(T) = \max_t |\sigma(t)|$ and $f^*(T) = \max_t |f(t)|$ for $t \in [0, T]$.

THEOREM 4. *Under condition* (2.10),

$$\sigma^*(T) \leq \frac{f^*(T)}{1 - 0.5KM}. \tag{4.2}$$

Proof. Really, let $\sigma(t^*) = \sigma^*(T)$ for $t^* \in [0, T]$. From (2.4) and (2.1) one gets

$$|\sigma(t^*)| = \sigma^*(T) \leq |f(t^*)| + 0.5KM\,|\sigma(t^*)| \leq f^*(T) + 0.5KM\sigma^*(T), \tag{4.3}$$

which implies required inequality (4.2). □

Let, in particular, $\sup_t |f(t)| \leq f^*$ for $t \in [0, \infty)$; then

$$\sup_t |\sigma(t)| \leq \frac{f^*}{1 - 0.5KM}. \tag{4.4}$$

Suppose that the function $\varphi(\sigma, t)$ satisfies the inequality

$$-\frac{K}{2} \le \frac{\varphi(\sigma_1, t) - \varphi(\sigma_2, t)}{\sigma_1 - \sigma_2} \le \frac{K}{2}. \tag{4.5}$$

As is known [19] for a time-invariant system (1.1), the Popov criterion, along with a condition analogous to (4.5), guarantees convergence of any two solutions $x_1(t)$ and $x_2(t)$ of (4.1) for $t \to \infty$. The following theorem establishes the solution convergence for a general time-variable case.

THEOREM 5. *There are positive constants C and β such that for any solutions $x_1(t)$ and $x_2(t)$ of system* (4.1), (2.1), (2.10), (4.5),

$$\|x_1(t) - x_2(t)\| \le C \exp[-\beta(t - t_0)] \, \|x_1(t_0) - x_2(t_0)\| . \tag{4.6}$$

Proof. The difference $y(t) = x_1(t) - x_2(t)$ satisfies the equation

$$\begin{aligned} &\dot{y} = A(t)y + b[\varphi(\sigma_1, t) - \varphi(\sigma_2, t)], \\ &\sigma_i = (c, x_i), \ i = 1, 2. \end{aligned} \tag{4.7}$$

Setting $\sigma = \sigma_1 - \sigma_2$ and $\phi(\sigma_1, \sigma_2, t) = \varphi(\sigma_1, t) - \varphi(\sigma_2, t)$, from (4.5) we find

$$-0.5K\sigma^2 \le \phi(\sigma_1, \sigma_2, t)\sigma \le 0.5K\sigma^2. \tag{4.8}$$

By Theorem 1, for system (4.7), (4.8), $\sigma(t)$ exponentially tends to zero, which guarantees an exponential decay of $y(t)$. □

5. Discussion. According to Theorem 2, a system with a sign-constant transfer function $w(t, s)$ satisfies the Aizerman conjecture in the class $\Phi(-K/2, K/2)$. Let us apply the obtained criteria to a single-loop system consisting of n links. Suppose that the individual transfer function $w_i(t, s)$ of each link is sign-constant. Since the output of such a link to sign-constant input is also sign-constant, the transfer function of the combined system $w(t, s)$ satisfies inequality (3.1), so the system satisfies Theorem 2.

Let, in particular, the links be of the first order; i.e., they are described by the equations

$$\dot{x}_i + a_i(t)x_i = 0, \ i = 1, \dots, n. \tag{5.1}$$

The functions $a_i(t)$ are not supposed to be necessarily positive, so some links may be unstable. For the individual transfer function of a link,

$$w_i(t, s) = \exp\left[-\int_s^t a_i(s)\mathrm{d}s\right] > 0 \quad \text{for } t > s, \tag{5.2}$$

so the transfer function $w(t, s)$ of the circuit is also positive. Therefore, for stability of the corresponding closed-loop system in the class $\Phi(-K/2, K/2)$, it is sufficient that the system be stable for $\varphi = 0.5K\sigma$ (as was mentioned earlier, the known results of this kind embrace, in contrast, only circuits with up to five stable time-invariant links [14], [15]).

Theorem 4 yields an upper bound for the value $|\sigma(t)|$ in the presence of an external perturbation. Theorem 5 provides exponential convergence of different solutions of a perturbed system. In contrast, the known results of this kind are mainly derived using the Popov approach developed only for time-invariant systems [19].

Note that for a time-variable matrix $A(t)$, finding the constant M requires, in general, numerical integration of the equation $\dot{x} = A(t)x$ to calculate the transfer

function $w(t,s)$. It is simplified by the fact that, as is seen from the second inequality (2.7), $w(t,s)$ exponentially tends to zero as $t-s$ increases.

In the case of a T-periodic matrix $A(t)$, the transition matrix satisfies the relations

$$W(t,s)=W(t,0)W^{-1}(s,0),\quad W(t+kT,0)=W(t,0)W(T,0)^k,$$

so it is sufficient to find $W(t,s)$ only for $0\le s\le t\le T$.

If A is time-invariant, an explicit formula for the function $w(t,s)=w(t-s)$ can be derived using A eigenvalues and eigenvectors.

Now we apply the developed approach to a second order system

$$\begin{aligned}&\dot x_1=x_2,\\ &\dot x_2=-a(t)x_1-2h(t)x_2+\varphi(x,t),\\ &-0,5K(t)x^2\le\varphi(x,t)x\le 0,5K(t)x^2.\end{aligned}\tag{5.3}$$

The corresponding transfer function $w(t,s)$ is a solution of the equation

$$\ddot x+2h(t)\dot x+a(t)x=0,\tag{5.4}$$

satisfying the conditions $w(t,t)=0$ and $\dot w(t,t)=1$.

Theorem 1 implies that for absolute exponential stability of system (5.3), it is sufficient that

$$\Phi=\sup_t\int_0^t|K(t)w(t,s)|\mathrm{d}s<2.\tag{5.5}$$

In fact, $w(t,s)>0$ for small $t-s>0$. If this inequality holds for all $t>s$, then, by Theorem 2, stability of (5.4) is provided by stability of the linear system with $\varphi=0.5K(t)x$. In this case (5.4) is nonoscillatory; i.e., any solution $x(t)$ has no more than one zero for $t\in[0,\infty)$. Note that there are numerous criteria ensuring this property directly through $h(t)$ and $a(t)$, e.g., [20]:

$$a(t)-h^2(t)-\dot h(t)\le 0.\tag{5.6}$$

If system (5.3) and bounds for the nonlinear term are time-invariant ($h(t)\equiv h,\ a(t)\equiv a,\ K(t)\equiv K$), then stability condition (5.5) can be explicitly expressed in these constants. Really, let $a>h^2$; then

$$w(t,s)=w(t-s)=\frac{\exp[-h(t-s)]}{\omega}\sin\omega(t-s),$$

where $\omega=\sqrt{a-h^2}$. Integrating (2.9), we obtain

$$M=\frac{1}{\omega^2}\left[1+2\sum_{k=1}^{\infty}\exp(k\beta)\right]=\frac{1+\exp\beta}{\omega^2(1-\exp\beta)},\quad \beta=-\frac{\pi h}{\omega}.\tag{5.7}$$

Thus, the system is absolutely stable if

$$K<K_0=2/M.\tag{5.8}$$

If $a\le h^2$, inequality (5.6) is true, so (5.4) is nonoscillatory and $w(t,s)>0$. Thus, in this case for exponential stability in the class $\Phi(-K/2,K/2)$, it is necessary and sufficient that the system with $\varphi(x)=0.5Kx$ be stable. Evidently, the last is true if $K<2a$ (one can directly check that for $K=2a$, system (5.3) admits the solution $x_1(t)=\text{const}$, $x_2(t)=0$, and thus is not absolutely stable).

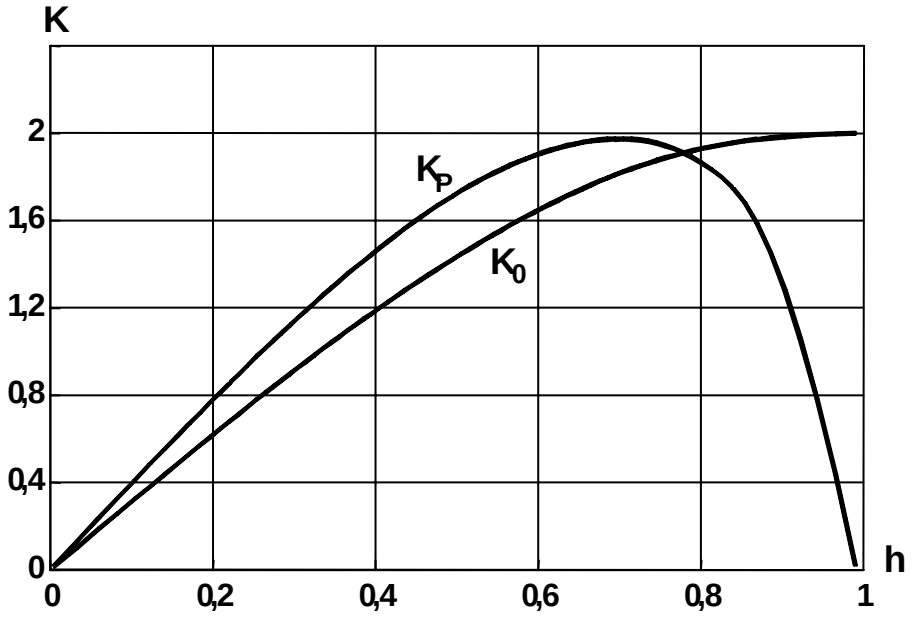

FIG. 1.

The corresponding time-invariant problem could be approached using known methods. For example, for the system

$$\begin{aligned} &\dot{x}_1 = x_2, \\ &\dot{x}_2 = -bx_1 - 2hx_2 - f(x,t), \\ &0 \le f(x,t)x \le Kx^2, \end{aligned} \tag{5.9}$$

the Popov criterion [16] guarantees absolute stability if for all $\omega \in [0, \infty)$,

$$\frac{1}{K} > \frac{\omega^2 - b}{(\omega^2 - b)^2 + 4\omega^2 h^2}. \tag{5.10}$$

The right-hand side of this inequality reaches its maximal value if $\omega^2 = b + 2h\sqrt{b}$, so condition (5.10) holds if

$$K < K_P = 4h\sqrt{b} + 4h^2.$$

Plugging in (5.9), $b = a - K/2$, $f(x,t) = \varphi(x,t) + 0.5Kx$, we reduce it to (5.3). Thus, by the Popov criterion, it is sufficient for absolute stability of system (5.3) that

$$K < K_P = 2h\sqrt{a - h^2}. \tag{5.11}$$

For $a = 1$, the limit values $K_0(h)$ and $K_P(h)$ are obtained using the developed and Popov criteria, and the obtained bounds (formulas (5.8) and (5.11)) are contrasted in Figure 1.

It is clear that for the considered system, the Popov condition is slightly less conservative for relatively small h, while for larger h, and especially close to 1, the presented approach is superior. In fact, for $h \to 1$, $K_0(h)$ approaches the precise bound $K_0(1) = 2$. Let us remind the reader that the described approach is equally applied to a wide class of time-varying systems where known techniques fail.

ADDENDUM TO "GENERIC SIMPLICITY OF THE SPECTRUM AND STABILIZATION FOR A PLATE EQUATION"*

JAIME H. ORTEGA† AND ENRIQUE ZUAZUA‡

Abstract. In this addendum we clarify a technical point of the article [J. H. Ortega and E. Zuazua, *SIAM J. Control. Optim.*, 39 (2001), pp. 1585–1614], devoted to studying the multiplicity of the eigenvalues of the plate equation and some applications to the stabilization.

Key words. plate equation, stabilization, spectral theory, shape differentiation

AMS subject classifications. 35P05, 35J40, 93D15

DOI. 10.1137/S0363012902414032

In this addendum we clarify a technical point of the article [5], devoted to studying the multiplicity of the eigenvalues of the plate equation,

$$\text{(P)} \qquad \begin{cases} \triangle^2 y &= \lambda y & \text{in } \Omega, \\ y &= 0 & \text{on } \partial\Omega, \\ \dfrac{\partial y}{\partial n} &= 0 & \text{on } \partial\Omega, \end{cases}$$

where $\Omega \subseteq \mathbb{R}^d$ is a bounded domain with boundary of class C^4.

Problem (P) admits a sequence of positive eigenvalues

$$0 < \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_n \leq \cdots \longrightarrow \infty,$$

with finite multiplicity. The eigenfunctions $\{y_n\}_n \subset H_0^2(\Omega)$ of (P) can be chosen to form an orthonormal basis of $H_0^2(\Omega)$.

It is well known that, for some domains (some annular domains, for instance, [2]) the spectrum is not simple. In [5] we proved that, generically with respect to the domain, the spectrum is simple. The object of this addendum is to clarify a technical point of the proof.

To do that we recall the precise statement of the main result in [5, Theorem 1.1, p. 1586].

Given a bounded domain Ω of class C^4 of $\mathbb{R}^d$ and a deformation $u \in W^{5,\infty}(\Omega; \mathbb{R}^d)$, we introduce the following deformed domain:

$$\Omega + u = \left\{ z \in \mathbb{R}^d : z = x + u(x), x \in \Omega \right\}.$$

We then consider the plate equation in the deformed domain $\Omega + u$:

$$\text{(P}_\text{u}\text{)} \qquad \begin{cases} \triangle^2 y &= \lambda y & \text{in } \Omega + u, \\ y &= 0 & \text{on } \partial(\Omega + u), \\ \dfrac{\partial y}{\partial n} &= 0 & \text{on } \partial(\Omega + u). \end{cases}$$

The main result in [5] reads as follows.

THEOREM 1. *Let Ω be a bounded domain of $\mathbb{R}^d$ of class C^4. Let Γ_0 be an open nonempty subset of $\partial\Omega$.*

Then the set

$$A=\left\{u\in W^{5,\infty}(\Omega,\mathbb{R}^d) : u=0 \text{ on } \partial\Omega\setminus\Gamma_0 \text{ and the spectrum of } (\mathrm{P_u}) \text{ is simple}\right\}$$

is residual in

$$W_0=\left\{u\in W^{5,\infty}(\Omega,\mathbb{R}^d) : u=0 \text{ on } \partial\Omega\setminus\Gamma_0\right\}.$$

In other words, it is a countable intersection of dense open sets on W_0.

Theorem 1 guarantees the generic simplicity of the spectrum of the plate system with respect to perturbations of the domain Ω. Moreover, the theorem indicates that this property may be achieved by means of deformations that leave invariant most of the boundary of the domain Ω. The additional assumption $u\in W^{5,\infty}\left(\Omega;\mathbb{R}^d\right)$ is necessary for technical reasons. It guarantees the C^4 regularity of the perturbed domain.

In order to prove Theorem 1, in [5] we used classical tools on shape differentiation that we describe briefly. We denote by $\lambda(u)$ and $y(u)$ the eigenvalues and eigenfunctions of $(\mathrm{P_u})$. We perform the change of variables

$$Y(u)=y(u)\circ(I+u).$$

The following problem is equivalent to $(\mathrm{P_u})$: *to find $\lambda(u)\in\mathbb{R}$ and $Y(u)$ such that*

$$\left\{\begin{array}{ll} D_j^2(u)\left(Jac\,(I+u)\,D_i^2(u)\,Y(u)\right) & =\lambda(u)\,Y(u)\,Jac\,(I+u) \qquad \text{in } \Omega,\\ Y(u) & \in H_0^2(\Omega), \end{array}\right. \tag{1}$$

with

$$D_i(u)\,g=\left(\frac{\partial f}{\partial z_i}\right)\circ(I+u)=\sum_j M_{ij}(u)\,\frac{\partial g}{\partial x_j}$$

for $g=f\circ(I+u)$. Here and in what follows $M(u)=(M_{ij}(u))_{i,j=1}^d$ is defined by

$$M(u)=[M_{i,j}(u)]={}^t\left[\frac{\partial}{\partial x_j}(I+u)_i\right]^{-1}=\left[\frac{\partial}{\partial x_i}(I+u)_j\right]^{-1}.$$

In Theorem 3.5 (p. 1599) of [5] we claim that there exist h analytic families of eigenvalues and eigenfunctions of (1) (or, equivalently, $(\mathrm{P_u})$) with respect to the deformation $u\in W^{5,\infty}(\Omega;\mathbb{R}^d)$ of the domain. However, in general, this is not true. But this fact is not really needed in the proof of Theorem 1 above. Indeed, analyticity does hold with respect to scalar perturbations, and this suffices to develop the proof of the generic simplicity result in [5].

Consequently, the statement on the generic simplicity of the spectrum of Theorem 1 above holds. But in the proof given in [5] one has to replace Theorem 3.2 and Proposition 3.3 of [5] by Theorem 2 and Proposition 1 below.

More precisely, Theorem 3.2 in [5] should read as follows.

THEOREM 2. *Let E be a Hilbert space with inner product $\langle\cdot,\cdot\rangle$, and let Λ be a Banach space. Let $P : D(P)\subset E\to E$ be a self-adjoint operator densely defined*

in E. Assume that λ is an eigenvalue of multiplicity h of P, and let $\phi_1, \dots, \phi_h$ be the orthonormal eigenfunctions associated to λ. Moreover, assume that there exists a bounded linear operator $Q : E \to E$ such that $Q\Pi_N = 0$ and $Q(P+\lambda) = I - \Pi_N$, Π_N being the orthogonal projection in $N = \operatorname{Ker}(P+\lambda)$.

Let $R(u)$ be an analytic self-adjoint map in $B(E,F)$ for every u in a neighborhood of $u = 0$ in Λ such that $R(0) = 0$ and $P(u) = P + R(u)$.

Then there exist h continuous functions defined in a neighborhood of $u = 0$ in Λ with values in $\mathbb{R}$, $u \to \lambda_i(u)$, and h continuous functions $u \to \phi_i(u)$, with values in E, $i = 1, \dots, h$, defined in a neighborhood of $u = 0$ in Λ such that

1. $\lambda_j(0) = \lambda, \qquad j = 1, \dots, h.$
2. *For all u small enough, $(\lambda_j(u), \phi_j(u))$ is a solution of the eigenvalue problem $P(u)\phi_j(u) = \lambda_j(u)\phi_j(u)$.*
3. *For all u small enough the set $\{\phi_1(u), \dots, \phi_h(u)\}$ is orthonormal in E.*
4. *For each interval $I \subset \mathbb{R}$ such that $\overline{I}$ contains only the eigenvalue λ of P, there exists a neighborhood U of $u = 0$ such that there are exactly h eigenvalues (counting the multiplicity) $\lambda_1(u), \dots, \lambda_h(u)$ of $P(u)$ contained on I.*
5. *Moreover, for each u in a neighborhood U of $u = 0$ in Λ, the map $t \to (\lambda_j(tu), \phi_j(tu))$ is analytic in a neighborhood of $t = 0$.*

On the other hand, Proposition 3.3 in [5] should read as follows.

PROPOSITION 1. *Under the hypotheses of Theorem 2, if λ is an eigenvalue of multiplicity h of P and $\phi_1, \dots, \phi_h$ are orthonormal eigenfunctions associated to λ, then there exists at least a function $u \longrightarrow (\lambda(u), \phi(u)) \in \mathbb{R} \times E$ which is continuous in a neighborhood of $u = 0$ in Λ such that*

1. $\lambda(0) = \lambda$,
2. *$\phi(u)$ is an eigenfunction of $P(u)$ associated to the eigenvalue $\lambda(u)$.*
3. *Moreover, for each u in a neighborhood U of $u = 0$ in Λ, the map $t \to (\lambda(tu), \phi(tu))$ is analytic in a neighborhood of $t = 0$.*

Remark 1. In Theorem 3.2 and Proposition 3.3 (pp. 1593–1594) of [5], we claimed that the families of eigenvalues and eigenfunctions are analytic in a neighborhood of $u = 0$ in a Banach space Λ. But this statement is not correct. Indeed, in the case of nonscalar perturbations, there are well-known counterexamples (we refer, for instance, to [2]). This lack of analyticity is due to the fact that the perturbation parameter belongs to a multidimensional Banach space. In the case of scalar perturbations the analyticity result does hold ([4, Theorem 3.9, p. 392] and [7, Theorem 1, pp. 57–58]).

Remark 2. The proof of the results above is almost the same as in [5]. But, strictly speaking, that proof yields only continuity of the eigenvalues and eigenfunctions. This is due to the fact that when the problem is reduced to analyze a family of polynomials [5, equation (3.20), p. 1596]

$$p_u(\alpha) = \alpha^h + \sum_{k=0}^{h-1} a_k(u)\alpha^k,$$

with the coefficients depending regularly on u, and such that all its h zeros (counting multiplicity) are real, we can conclude that the branches of zeros of the polynomial depend continuously on u.

In fact, one may prove that the largest zero of p_u define a continuous function in a neighborhood $\mathcal{W}$ of $u = 0$ in Λ. One can then proceed by induction.

Indeed, let $\alpha_h(u)$ be the largest zero of p_u and consider a sequence $\{u_n\}_n \subset \mathcal{W}$, such that $u_n \longrightarrow u_0 \in \mathcal{W}$, and $|\alpha_h(u_n) - \alpha_h(u_0)| \geq \varepsilon > 0$ for all $n \in \mathbb{N}$.

Note that, since the coefficients are continuous in $\mathcal{W}$, they are bounded in $\mathcal{W}$. Therefore there exists $R > 0$ such that for all $u \in \mathcal{W}$

$$|p_u(\alpha)| > 1 \quad \text{if } |\alpha| > R.$$

This implies that the zeros of p_u belong to the interval $(-R, R)$, and therefore the sequence $\{\alpha_h(u_n)\}_n$ is bounded in $\mathbb{R}$. Thus, there exists a subsequence that, to simplify the notation, we will write as $\{\alpha_h(u_n)\}_n$, converging to a real value β. Thus we have that

$$0 = p_{u_n}(\alpha_h(u_n)) = \alpha_h^h(u_n) + \sum_{k=0}^{h-1} a_k(u_n)\alpha_h^k(u_n) \longrightarrow \beta^h + \sum_{k=0}^{h-1} a_k(u_0)\beta^k.$$

That is, β is a zero of p_{u_0}. Moreover, since

$$p_{u_n}(\alpha) > 0 \quad \text{and} \quad p'_{u_n}(\alpha) \geq 0 \quad \forall \alpha > \alpha_m(u_n),$$

we have that

$$p_{u_0}(\alpha) > 0 \quad \text{and} \quad p'_{u_0}(\alpha) \geq 0 \quad \forall \alpha > \beta,$$

which implies that $\beta = \alpha_h(u_0)$. This is in contradiction with our assumption and proves that the largest zero defines a continuous function.

We can then write

$$p_u(\alpha) = \alpha^h + \sum_{k=0}^{h-1} a_k(u)\alpha^k = (\alpha - \alpha_h(u)) \left(\alpha^{h-1} + \sum_{k=0}^{h-2} b_k(u)\alpha^k \right),$$

where the coefficients $b_j(u)$ are defined by

$$b_{h-2}(u) = \alpha_h(u) + a_{h-1}(u) \quad \text{and} \quad b_{k-1}(u) = b_k(u)\alpha_h(u) + a_j(u), \quad k = 1, \ldots, h-2,$$

which are continuous functions, and we may proceed by induction.

Moreover, using classical results (see [4, p. 117] and [7, p. 37]), we can obtain the analyticity of the eigenvalues with respect to perturbations of the form $u = tv$, v being fixed and $t \in \mathbb{R}$ being scalar.

These results may be applied to the map

$$P : W^{5,\infty}(\Omega, \mathbb{R}^d) \longrightarrow \mathcal{L}\left(H_0^2(\Omega); H^{-2}(\Omega)\right)$$

such that

$$P(u)\phi = \frac{1}{Jac\,(I+u)} D_j^2(u) \left(Jac\,(I+u)\, D_i^2(u)\, \phi \right). \tag{2}$$

Theorem 3.5 in [5] should reads as follows.

THEOREM 3. *Let $\Omega \subset \mathbb{R}^d$ be an open bounded domain of class C^4. Let λ be an eigenvalue of multiplicity h of the plate system* ($\mathrm{P_u}$) *for $u = 0$ with associated eigenfunctions $y_1, \ldots, y_h$.*

Then there exist h continuous functions with values in $\mathbb{R}$, $u \to \lambda_i(u)$, and h continuous functions $u \to y_i(u)$, with values in $H^4(\Omega+u) \cap H_0^2(\Omega+u)$, $i = 1, \ldots, h$, defined in a neighborhood of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$ such that

1. $\lambda_j(0) = \lambda, \qquad j = 1, \ldots, h.$

2. *For all u small enough, $(\lambda_j(u), y_j(u))$ is a solution of the plate system defined in the new domain $\Omega + u$.*
3. *For all u small enough the set $\{y(u), \dots, y(u)\}$ is orthonormal in $L^2(\Omega+u)$.*
4. *For each interval $I \subset \mathbb{R}$ such that $\overline{I}$ contains only the eigenvalue λ of* (P), *there exists a neighborhood U of $u = 0$ such that there are exactly h eigenvalues (counting the multiplicity) $\lambda_1(u), \dots, \lambda_h(u)$ of* ($\mathrm{P_u}$) *contained on I.*
5. *For each u in a neighborhood U of $u = 0$ in $W^{5,\infty}(\Omega, \mathbb{R}^d)$, the map $t \to (\lambda_j(tu), \phi_j(tu))$ is analytic in a neighborhood of $t = 0$.*

In the proof of Theorem 1 in [5], we also use the definitions of local derivative and the total derivative:

Let

$$\begin{array}{rccl} v: & W^{k,\infty}\left(\Omega, \mathbb{R}^d\right) & \to & W^{m,r}(\Omega + u), \\ & u & \to & v(u) \end{array}$$

be a function of the perturbation parameter u. Then if $k \geq m$, the *first local variation* can be defined as

$$v'(\Omega; u) = \lim_{t \to 0^+} \frac{v(tu)|_\omega - v(0)|_\omega}{t} \quad \text{in } \omega, \tag{3}$$

where $\omega \subset\subset \Omega$ and $v(tu)|_\omega$, $v(0)|_\omega$ are the restrictions of the functions $v(tu), v(0)$ to ω.

We define the *first order total variation* as

$$\dot{v}(\Omega; u) = \lim_{t \to 0^+} \frac{v(tu) \circ (I + tu) - v(0)}{t} \quad \text{in } \Omega. \tag{4}$$

It is important to observe that the total variation $\dot{v}(\Omega; u)$ is a function defined in the whole Ω while the local variation is a function defined "locally" in subsets $\omega \subset\subset \Omega$.

Moreover, we have that

$$v'(u) = \dot{v}(u) - u \cdot \nabla v(0).$$

We refer, for instance, to [6] or [8] for more details on this issue.

For each $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$, in a neighborhood of $u = 0$, we define the maps

$$t \to \lambda_j(tu), \qquad t \to \phi_j(tu),$$

where $\lambda_j(tu)$ and $\phi_j(tu)$ are eigenvalues and eigenfunctions of the Stokes system in the domain $\Omega + tu = \{x + tu(x) : x \in \Omega\}$.

According to Theorem 2 and Proposition 1, these functions are analytic in an interval $[0, T_u]$ (although analyticity cannot be guaranteed with respect to $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$).

Using the continuity of the eigenvalues with respect to $u \in W^{5,\infty}(\Omega, \mathbb{R}^d)$ and the analyticity with respect to the scalar perturbation, the proof of Theorem 1.1 in [5] applies without further changes.

NUMERICAL APPROXIMATIONS FOR STOCHASTIC DIFFERENTIAL GAMES: THE ERGODIC CASE*

HAROLD J. KUSHNER†

Abstract. The Markov chain approximation method is a widely used, relatively easy to use, and efficient family of methods for the bulk of stochastic control problems in continuous time for reflected-jump-diffusion-type models. It has been shown to converge under broad conditions, and there are good algorithms for solving the numerical problems if the dimension is not too high. We consider a class of stochastic differential games with a reflected diffusion system model and ergodic cost criterion and where the controls for the two players are separated in the dynamics and cost function. It is shown that the value of the game exists and that the numerical method converges to this value as the discretization parameter goes to zero. The actual numerical method solves a stochastic game for a finite state Markov chain and ergodic cost criterion. The essential conditions are nondegeneracy and that a weak local consistency condition hold "almost everywhere" for the numerical approximations, just as for the control problem.

Key words. stochastic differential games, numerical methods, Markov chain approximations

1. Introduction.

The Markov chain approximation method of [18, 19, 22] is a widely used method for the numerical solution of virtually all of the standard forms of stochastic control problems with reflected-jump-diffusion models. It is robust and can be shown to converge under very broad conditions. Extensions to approximations for two-person differential games with discounted, finite time, stopping time, and pursuit-evasion games were given in [21] for reflected diffusion models where the controls for the two players are separated in the dynamics and cost rate functions. In this paper, the basic ideas will be extended to two-player stochastic dynamic games with the same systems model but where the cost function is ergodic. Such ergodic and "separated" models occur, for example, in risk-sensitive and robust control [2, 3, 7, 15]. In fact, the game formulation of risk sensitive control problems for queues in heavy traffic was our original motivation. See [15, section 7] for a formulation of risk sensitive control in terms of a stochastic differential game for a diffusion that fits our form once "numerical boundaries" are added, provided that the covariance does not depend on the control. While Markov chain approximation algorithms have been adapted to such problems, there were no proofs of convergence.

When the robust control is for controlled queues in heavy traffic, then the state is confined to some convex polyhedron by boundary reflection [20]. In many other applications, the state of the physical problem is confined to a bounded set. One example is the heavy traffic limit of controlled queueing networks with finite buffers [1, 20] or robust control of such systems as in [2, 3], where the set is a hyperectangle. Then robust control would lead to a game problem with a hyperrectangular state space. If the system state is not a priori confined to a bounded set, then for numerical purposes

it is commonly necessary to bound the state space artificially by adding a reflecting boundary and then experimenting with the bounds. Our systems model is confined to a state space G that is a convex polyhedron, and it is confined by a "reflection" on the boundary. More generally, the boundaries could be determined by a set of smooth curved surfaces as in [22], but we restrict attention to the polyhedral case, since that is the most common and it avoids minor details which can be distracting.

There are many results for various forms of the game problem, e.g., [4, 5, 6, 24, 28, 29]. However, there seems to be nothing available concerned with the ergodic problem for the reflected diffusion model. We will use purely probabilistic methods of proof. Such methods have the advantage of providing intuition concerning numerical approximations, they cover many of the problem formulations to date, and they converge under quite general conditions. The essential conditions are *weak-sense* existence and uniqueness of the solution to the controlled equations, "almost everywhere" continuity of the dynamical and cost rate terms, and a natural "local consistency" condition: The local consistency and continuity need hold only almost everywhere with respect to the measure of the basic model; hence discontinuities in the dynamics and cost function can be treated under appropriate conditions (see, in particular, the treatment of discontinuities and complex variational problems with singularities and Theorems 4.6 and 7.1 in [22]). Furthermore, the numerical approximations are represented as processes which are close to the original, which gives additional intuitive and practical meaning to the method.

Subsection 2.1 defines the basic systems model. First, the uncontrolled model is introduced. Then the control is added via the Girsanov transformation [17]. The dynamical model is the reflected stochastic differential equation (2.4), also called the *Skorohod problem* [12, 20, 22]. The conditions on the boundary of the state space are (A2.1)–(A2.2). Condition (A2.1) covers the great majority of cases of current interest, including those that arise from queueing and communications networks. The condition is obvious when the state space is a hyperrectangle with reflection directions being the interior normals. The strategies of the players are as follows. Player 1 wishes to minimize and player 2 wishes to maximize. For the infsup problem (the upper value), at the start of the game (i.e., at $t = 0$) player 1 selects a control. This can be either a pure (and time independent) feedback control or a relaxed feedback control (see subsection 2.1 for the definition). The selected feedback control will be used at all $t \geq 0$. Then player 2 selects its strategy. This can either be a relaxed feedback control or it can have the form of a classical relaxed control. Whatever it is, once selected, it cannot be changed.

The situation is analogous if player 2 selects first. Since the controls for the player who chooses first are time independent feedback and these are selected and fixed at the start of the game, and only the player choosing last can use time dependent controls, complications due to the notions of strategy in the time dependent case (e.g., concerning the definition of the value either via a limit of a discrete time game, or via the Elliott–Kalton definition) do not arise. In this sense the paper is simpler than [21]. On the other hand, the treatment of the ergodic cost criterion adds substantial new complications. Subsection 2.3 establishes the existence of the controls yielding the upper and lower values, using approximation methods from [20].

Suppose that, if feedback controls are used, then the asymptotic mean cost per unit time (for either the control or the game problem) does not depend on the initial state value. Then it is reasonable (and is the usual practice) to restrict the controls to being feedback. It is shown that the game has a value with this restriction. For

technical reasons, we allow player 2 to use arbitrary controls (not necessarily feedback). But, if player 1 uses a feedback control, then it is shown that player 2 cannot improve its cost by using a nonfeedback control, so the value is still determined within the space of feedback controls. We do not know whether it is possible for player 1 to achieve a better value by using some nonfeedback control strategy. But any approach that leads to a well posed Isaacs equation will yield feedback controls.

The methods to be used for the ergodic cost function are quite different than those used in [21]. They share the foundation in the theory of weak convergence [9, 13]; however, they depend heavily on the approximations to the ergodic cost control problem as developed in [20, Chapter 4]. The development depends on "continuity" properties of the invariant measures and ergodic costs in the control in an appropriate sense, and on the fact that we lose little in the costs if the controls are "smoothed." Similar results for the pure control problem are in [20], and the development of the paper has been structured to take advantage of the results in [20, 22], wherever possible. To facilitate the development, subsection 2.2 summarizes the results from [20] which will be needed here, with an occasional change of notation to suit that used here.

The Markov chain approximation numerical method is discussed in subsection 3.1. The methods for getting the approximating chain and cost function are the same as in [22] for the pure control problem, since it is the process for arbitrary controls that is approximated. The natural *local consistency condition* is stated. The proof of convergence of the numerical method is in subsection 3.2 and depends on the fact that the original game has a value. The numerical approximations are games for Markov chains. They might or might not have a value, depending on the form of the approximation. However, it is seen that the upper and lower values converge to the value of the original game as the approximation parameter goes to its limit. Finally, the proof that the original game has a value is given in section 4.

2. The dynamical model and background results.

2.1. Assumptions and the dynamical model. Assumptions. The first assumptions define the state space G.

A2.1. *The state space G is the intersection of a finite number of closed half spaces in Euclidean r-space $\mathbb{R}^r$ and is the closure of its interior (i.e., it is a closed convex polyhedron with an interior and planar sides). Let ∂G_i, $i = 1, \ldots,$ denote the faces of G, and n_i the interior normal to ∂G_i. Interior to ∂G_i, the reflection direction is denoted by the unit vector d_i, and $\langle d_i, n_i \rangle > 0$ for each i. The possible reflection directions at points on the intersections of the ∂G_i are in the convex hull of the directions on the adjoining faces. Let $d(x)$ denote the set of reflection directions at the point $x \in \partial G$, whether it is a singleton or not. No more than r constraints are active at any boundary point.*

A2.2. *For each $x \in \partial G$, define the index set $I(x) = \{i : x \in \partial G_i\}$. Suppose that $x \in \partial G$ lies in the intersection of more than one boundary; that is, $I(x)$ has the form $I(x) = \{i_1, \ldots, i_k\}$ for some $k > 1$. Let $N(x)$ denote the convex hull of the interior normals $n_{i_1}, \ldots, n_{i_k}$ to $\partial G_{i_1}, \ldots, \partial G_{i_k}$, resp., at x. Then there is some vector $v \in N(x)$ such that $\gamma' v > 0$ for all $\gamma \in d(x)$.*

There is a neighborhood $N(\partial G)$ and an extension of $d(\cdot)$ to $\overline{N(\partial G)}$ that is upper semicontinuous in the following sense: For each $\epsilon > 0$, there is $\rho > 0$ that goes to zero as $\epsilon \to 0$ and such that if $x \in N(\partial G) - \partial G$ and distance$(x, \partial G) \leq \rho$, then $d(x)$ is in the convex hull of the directions $\{d(v); v \in \partial G,$ distance$(x, v) \leq \epsilon\}$.

A2.3. *The $U_i, i = 1, 2$, are compact sets in some Euclidean space. The $(r \times r)$ matrix-valued function $\sigma(\cdot)$ on G is Hölder continuous, with $\sigma^{-1}(x)$ bounded, and the*

$\mathbb{R}^r$-valued functions $b_i(\cdot)$ on $G \times U_i$ are continuous.

Let $\alpha = (\alpha_1, \alpha_2), \alpha_1 \in U_1, \alpha_2 \in U_2$, denote the canonical control value, with α_i the canonical value for player i. The uncontrolled model is the solution to the Skorohod problem

$$dx(t) = \sigma(x(t))dw(t) + dz(t),\ x(t) \in G. \tag{2.1}$$

The controlled system will be defined via the Girsanov transformation, starting with (2.1). This transformation will add the control or "drift" term $b_1(x(t), \alpha_1)dt + b_2(x(t), \alpha_2)dt$.

The Skorokhod problem is a standard model for a reflected diffusion process. For a detailed discussion of the Skorohod problem and the assumptions (A2.1) and (A2.2), see [20, Chapter 3]. See also the brief comment below (A2.4). By a solution to (2.1) we mean the following. Let Ω denote the path space of $(x(\cdot), z(\cdot), w(\cdot))$, let $\{\mathcal{F}_t, t < \infty)\}$ denote the filtration on the space, and write $|z|(t)$ for the total variation of $z(\cdot)$ on $[0, t]$. Let $x(0) \in G, z(0) = 0$. The $x(\cdot)$ and $z(\cdot)$ are $\mathbb{R}^r$-valued, continuous and $\mathcal{F}_t$-adapted, and $w(\cdot)$ is an $\mathcal{F}_t$-standard $\mathbb{R}^r$-valued Wiener process. The $z(\cdot)$ is the reflection process and satisfies the following conditions: $|z|(t) < \infty$ with probability one (w.p.1) for all t, and there is a measurable function $\gamma(\cdot)$ with $\gamma(t) \in d(x(t))$ w.p.1 such that $z(t) = \int_0^t \gamma(s)d|z|(s)$.

Let Ω_T denote the restriction of Ω to functions defined on $[0, T]$. Define $\mathcal{F} = \lim_t \mathcal{F}_t$ and let P_x denote the measure when the initial condition is $x(0) = x$, with E_x the associated expectation. Let $P_{x,T}(\cdot)$ denote the probability measure, when we confine our interest to paths on the finite interval $[0, T]$.

We will also need the following condition.

A2.4. *There is a unique weak sense solution to* (2.1) *for each initial condition.*

Comments on (A2.1) and (A2.2). One can always construct the extension in (A2.2). Under (A2.1)–(A2.3), the choice of the reflection direction on the corners and edges of G has no effect on the process (w.p.1), since no matter what the choice of direction or of the controls, it spends zero "local time" at such points [20, Theorem 3.6, Chapter 4]. To see that (A2.1) is natural in application note the following. If the state space is being bounded for purely numerical reasons, then the reflections are introduced only to give a compact set G, which should be large enough so that the effects on the solution in the region of main interest are small. A common choice is a hyperrectangle with normal reflection directions, in which case the right side of (2.1) is zero. Next, consider a queueing network model in the heavy traffic limit [16, 20, 27] where the state space is the nonnegative orthant, and the probability that an output of the ith processor goes to the jth processor is q_{ij}. If the spectral radius of the routing matrix $Q = \{q_{ij}; i, j\}$ is less than unity, then all customers will eventually leave the system. The model is a special case of (2.4) with $z(t) = [I - Q']y(t)$, where $y_i(\cdot)$ is nondecreasing, continuous, and can increase only at t, where $x_i(t) = 0$. The condition (A2.1) implies (see [12, 20]), the so-called "completely-S" condition [16, 20, 26], which is used to ensure that $z(\cdot)$ has bounded variation w.p.1.

Classes of controls. A: Relaxed controls $r_i(\cdot)$. Suppose that for some filtration $\{\mathcal{F}_t, t < \infty\}$ and standard vector-valued $\mathcal{F}_t$-Wiener process $w(\cdot)$, each $r_i(\cdot), i = 1, 2$, is a measure on the Borel sets of $U_i \times [0, \infty)$ such that $r_i(U_i \times [0, t]) = t$ and $r_i(A \times [0, t])$ is $\mathcal{F}_t$-measurable for each Borel set $A \subset U_i$. Then $r_i(\cdot)$ is said to be an *admissible relaxed control* for player i, with respect to $w(\cdot)$. If the Wiener process and filtration have been given or are obvious or unimportant, then we simply say that $r_i(\cdot)$ is an admissible relaxed control for player i [14, 20, 22]. For Borel sets $A \subset U_i$,

we will write $r_i(A \times [0,t]) = r_i(A,t)$.

For almost all (ω,t) and each Borel $A \subset U_i$, one can define the derivative[1]

$$r_{i,t}(A,t) = \lim_{\delta \to 0} \frac{r_i(A,t) - r_i(A,t-\delta)}{\delta}.$$

Without loss of generality, we can suppose that the limit exists for each (ω,t). Then for all (ω,t), $r_{i,t}(\cdot,t)$ is a probability measure on the Borel sets of U_i and for any bounded Borel set B in $U_i \times [0,\infty)$,

$$r_i(B) = \int_0^\infty \int_{U_i} I_{\{(\alpha_i,t)\in B\}} r_{i,t}(d\alpha_i,t)dt.$$

An ordinary control $u_i(\cdot)$ can be represented in terms of the relaxed control $r_i(\cdot)$, defined by its derivative $r_{i,t}(A,t) = I_A(u_i(t))$, where $I_A(u_i)$ is unity if $u_i \in A$ and is zero otherwise. The weak topology [22] will be used on the space of admissible relaxed controls. Relaxed controls are commonly used in control theory to prove existence theorems, since any sequence of relaxed controls has a convergent subsequence.

Classes of controls. B: Relaxed feedback control $m_i(\cdot)$ [10, 20]. Suppose that $m_i(x,\cdot), i = 1,2$, is a probability measure on the Borel sets of U_i for each $x \in G$ and that $m_i(\cdot,A)$ is Borel measurable for each Borel set $A \subset U_i$. Then we say that $m_i(\cdot)$ is a relaxed feedback control. Define $U = U_1 \times U_2$. For relaxed feedback controls $m_i(\cdot)$, define the product measure $m(\cdot)$ by $m(x,d\alpha) = m_1(x,d\alpha_1)m_2(x,d\alpha_2)$. Then $m(\cdot)$ is also a relaxed feedback control but with control value space U. Unless explicitly noted otherwise, the symbol $m(\cdot)$ will always denote such a product form for some relaxed feedback controls $m_i(\cdot), i = 1,2$. If $x(\cdot)$ is a solution to (2.4), and $m(\cdot)$ a relaxed feedback control, then $m(\cdot)$ can be represented by a relaxed control $r(\cdot)$ with derivative having the product form $r_t(d\alpha,t) = r_{1,t}(d\alpha_1,t)r_{2,t}(d\alpha_2,t) = m(x(t),d\alpha)$.

The control for the player that chooses its control first will always be a relaxed feedback control, but the control for the player who chooses its control last might be either a relaxed feedback control or a relaxed control which is not representable in relaxed feedback form.

Defining the controlled dynamical system via the Girsanov transformation: Relaxed feedback controls. The controlled model will be defined via the Girsanov transformation [17]. Some of the well-known details will be described, since the equations will be needed for the approximations. This will be done first for the relaxed feedback controls. Let $m_i(\cdot), i = 1,2$, be relaxed feedback controls, and define the product $m(x,d\alpha) = m_1(x,d\alpha_1)m_2(x,d\alpha_2)$. Define

$$b_{i,m_i}(x) = \int_{U_i} b_i(x,\alpha_i)m_i(x,d\alpha_i), \quad b(x,\alpha) = b_1(x,\alpha_1) + b_2(x,\alpha_2),$$

and set $b_m(x) = \int_U b(x,\alpha)m(x,d\alpha) = b_{1,m_1}(x) + b_{2,m_2}(x)$. The $b(x,\alpha)$ will be the canonical drift term for the SDE and $b_m(x)$ the drift term when the control $m(\cdot)$ is used. For $T > 0$ and relaxed feedback control $m(\cdot)$, define

$$\zeta(T,m) = \int_0^T \left[\sigma^{-1}(x(s))b_m(x(s))\right]' dw(s) - \frac{1}{2}\int_0^T \left|\sigma^{-1}(x(s))b_m(x(s))\right|^2 ds,$$

and set

$$R(T,m) = e^{\zeta(T,m)}.$$

[1] In [20, 22], the derivative at t is written simply as $r_{i,t}(A)$.

For each $(x, T, m(\cdot))$, define the measure $P^m_{x,T}$ on $(\Omega_T, \mathcal{F}_T)$ via the Radon–Nikodym derivative $R(T, m)$:

$$dP^m_{x,T} = R(T, m)dP_{x,T}. \tag{2.2}$$

For each $(x, m(\cdot))$, the family $P^m_{x,T}$ of measures, indexed by T, is consistent and can be extended uniquely to a measure P^m_x on $(\Omega, \mathcal{F})$ that is consistent with the $P^m_{x,T}$. When there is no control (i.e., where the system is (2.1)), we omit the superscript m. The process $w_m(\cdot)$ defined by

$$dw_m(t) = dw(t) - \left[\sigma^{-1}(x(s))b_m(x(s))\right] dt \tag{2.3}$$

is an $\mathcal{F}_t$-standard Wiener process on $(\Omega, P^m_x, \mathcal{F})$ [17]. Now, rewrite the uncontrolled model (2.1) as

$$dx(t) = b_m(x(t))dt + \sigma(x(t))dw_m(t) + dz(t). \tag{2.4}$$

Under the measures $\{P^m_x, x \in G\}$, (2.4) is a Markov process, and we use $P^m(x, t, \cdot)$ for its transition function. Use $P(x, t, \cdot)$ for the transition function of the uncontrolled process (2.1). Strictly speaking, the process $w_m(\cdot)$ should be indexed also by the initial condition $x = x(0)$, but we omit it for notational simplicity.

The controlled dynamical system with relaxed controls. Let $r_i(\cdot)$ be a relaxed control for player i, with derivative $r_{i,t}(\cdot, t)$, and define $b_{i,r_i}(x, t) = \int_{U_i} b_i(x, \alpha)r_{i,t}(d\alpha_i, t)$. We will also have occasion to use relaxed (and not necessarily relaxed feedback) controls for one of the players. For specificity at this point, suppose that a relaxed control is used for player 1 and a relaxed feedback control is used for player 2. Write $b_{r_1,m_2}(x, t) = b_{1,r_1}(x, t) + b_{2,m_2}(x)$. Define $\xi(T, r_1, m_2)$ as $\xi(T, m)$ was defined but with $b_{r_1,m_2}(x(t), t)$ replacing $b_m(x(t))$. Using $\xi(T, r_1, m_2)$ in lieu of $\xi(T, m)$, define $P^{r_1,m_2}_{x,T}$, P^{r_1,m_2}_x, and $w_{r_1,m_2}(\cdot)$, analogously, and write the controlled equation with drift $b_{r_1,m_2}(x, t)$ as

$$dx(t) = b_{1,r_1}(x(t), t)dt + b_{2,m_2}(x)dt + \sigma(x(t))dw_{r_1,m_2}(t) + dz(t). \tag{2.5}$$

The measures P^{r_1,m_2}_x are used with (2.5). The development is analogous if player 1 uses the relaxed feedback control and if player 2 uses the relaxed control.

Representation of the reflection process $z(\cdot)$. Recall that d_i is the reflection direction on the interior of the ith face of G. For either the model (2.4) or (2.5), the process $z(\cdot)$ can be represented in terms of processes which increase only on the individual faces of G. In particular, we can write

$$z(t) = \sum_i y_i(t)d_i, \tag{2.6}$$

where the process $y_i(\cdot)$ is nondecreasing, right continuous, increases only at t, where $x(t)$ is on the ith face of G, and satisfies $y_i(0) = 0$. Under (A2.1), (A2.2), and (A2.4), the representation (2.6) is unique, and the contribution when $x(t)$ is on an edge or corner of G is zero, with probability one [20, Theorem 3.6, Chapter 4]. Let M_ϵ denote an ϵ-neighborhood of the boundary set where more than one constraint is active. Then the same theorem implies that, for $t > 0$, $\sup_{x,m} E^m_x |y(t)| I_{\{x(t) \in M_\epsilon\}} \to 0$ as $\epsilon \to 0$.

The representation (2.6) is useful since the individual $y_i(\cdot)$ often have the interpretation as "overflows" or "underflows," as, for example, in heavy traffic modeling of queueing or communications networks. There is often a cost associated with such overflows or underflows, with each component having its own weight.

2.2. Background results and the cost function. The development depends heavily on approximation, continuity, and limit results from [20, Chapter 4] for the control problem. The results carry over to the game problem, since they are concerned with arbitrary relaxed feedback and relaxed controls. To facilitate our development, several key results from [20] will be stated in the notation of this paper.

Illustration of the use of the Girsanov transformation: Mutual absolute continuity of the transition functions. The following theorem is [20, Theorem 3.1, Chapter 4]. We will outline the proof by copying some of the details from the reference, since similar "Girsanov transformation" methods underlie many of the results, there are some slight differences worth noting, and it gives a feeling for the approach. Unless otherwise noted, "almost all" refers to Lebesgue measure. The symbol $\Rightarrow$ denotes weak convergence.

THEOREM 2.1. *Assume* (A2.1)–(A2.4). *Let* $m^n(y,\cdot) \Rightarrow m(y,\cdot)$ *for almost all* $y \in G$ *as* $n \to \infty$, *where* $m(\cdot)$ *and* $m^n(\cdot)$ *are relaxed feedback controls. Then for any* $0 < t_0 < t_1 < \infty$ *and bounded and measurable real-valued function* $f(\cdot)$, *as* $n \to \infty$,

$$\int f(y)P^{m^n}(x,t,dy) \to \int f(y)P^m(x,t,dy) \tag{2.7}$$

uniformly for $(x,t) \in G \times [t_0,t_1]$. *For any* $t > 0$, $P^m(x,t,\cdot)$ *is absolutely continuous with respect to Lebesgue measure uniformly in* $m(\cdot)$ *and in* $(x,t) \in G \times [t_0,t_1]$. *For each relaxed feedback control* $m(\cdot)$, *the process defined by* (2.4) *is a strong Feller process, and it has a unique weak-sense solution for each initial condition* x.

Proof. We concentrate on the uniformity in x of the convergence (2.7). First note that, by the weak convergence and the product form of $m^n(\cdot)$, the limit $m(\cdot)$ can always be represented in the product form $m(x,d\alpha) = m_1(x,d\alpha_1)m_2(x,d\alpha_2)$ for some relaxed feedback controls $m_i(\cdot), i = 1,2$, for almost all x. The expression (2.7) can be written equivalently as

$$E_x f(x(t))R(t,m^n) - E_x f(x(t))R(t,m) \to 0 \ \text{ as } n \to \infty. \tag{2.8}$$

For notational simplicity, let $\sigma(x) = I$, the identity. We will use the following inequalities:

$$\left|e^a - e^b\right| \le |a-b| \left|e^a + e^b\right|, \tag{2.9a}$$

$$\begin{aligned} E_x \left| \int_0^t b'_m(x(s))dw(s) - \int_0^t b'_{m^n}(x(s))dw(s) \right|^2, \\ \le E_x \int_0^t \left|b_m(x(s)) - b_{m^n}(x(s))\right|^2 ds. \end{aligned} \tag{2.9b}$$

By the continuity and boundedness of $b(\cdot)$ and the weak convergence of the $m^n(y,\cdot)$ for almost all $y \in G$, we have, as $n \to \infty$,

$$b_{m^n}(y) = \int_U b(y,\alpha)m^n(y,d\alpha) \to b_m(y) = \int_U b(y,\alpha)m(y,d\alpha)$$

for almost all y. Define

$$\tilde{b}_n(y) = \left|b_m(y) - b_{m^n}(y)\right|^2.$$

Let $t \in [t_0, t_1]$, where $0 < t_0 < t_1 < \infty$. By Egoroff's theorem [11, Theorem 12, p. 149], for each $\epsilon > 0$, there is a measurable set A_ϵ with $l(A_\epsilon) \leq \epsilon$ such that $\tilde{b}_n(y) \to 0$ uniformly in $y \notin A_\epsilon$. Furthermore, $P(x,t,\cdot)$ is absolutely continuous with respect to Lebesgue measure for each x and $t > 0$ (and uniformly in $(x,t) \in G \times [t_0, t_1]$ for any $0 < t_0 < t_1 < \infty$). These facts imply that, as $n \to \infty$,

$$\int_0^t E_x \tilde{b}_n(x(s))ds \to 0$$

uniformly in $x \in G$. The last expression, together with the inequalities (2.9), implies (2.8) uniformly in $x \in G$. □

Additional background results. We will also need the results of Theorems 2.2–2.8, most of which are either taken from [20] or are minor adaptations of such results. Where an elaboration on a proof in [20] would be useful, additional comments will be made. Although the reference does not deal with games, the fact that the product $m(x, d\alpha) = m_1(x, d\alpha_1)m_2(x, d\alpha_2)$ is a relaxed feedback control allows the results to be carried over.

THEOREM 2.2 (from [20, Theorems 3.1–3.3, Chapter 4]). *Assume* (A2.1)–(A2.4). *The process $x(\cdot)$ defined by* (2.4) *has a unique invariant measure $\mu_m(\cdot)$ for each relaxed feedback control of the product form $m(x, d\alpha) = m_1(x, d\alpha_1)m_2(x, d\alpha_2)$. Furthermore, the transition function $P^m(x,t,\cdot)$ and Lebesgue measure are mutually absolutely continuous uniformly in all such $m(\cdot), x \in G$, and $t \in [t_0, t_1]$ for any $0 < t_0 < t_1 < \infty$.*

A smoothed control. Extend the definition of the relaxed feedback control $m_i(y, \cdot)$ so that it is defined as a relaxed feedback control for all $y \in \mathbb{R}^r$. For example, let it be concentrated on some fixed number in U for $y \notin G$. For small $\epsilon > 0$ and $x \in G$, define the smoothed control

$$m_{i,\epsilon}(x, \cdot) = \frac{1}{(2\pi\epsilon)^{r/2}} \int_{\mathbb{R}^r} e^{-|y-x|^2/2\epsilon} m_i(y, \cdot)dy, \quad x \in G.$$

Define $m_\epsilon(x, d\alpha) = m_{1,\epsilon}(x, d\alpha_1)m_{2,\epsilon}(x, d\alpha_2)$.

THEOREM 2.3 (this is [20, Theorem 3.4, Chapter 4]). *Assume* (A2.1)–(A2.4). *$m_\epsilon(\cdot)$ is a relaxed feedback control and $m_\epsilon(x, \cdot) \Rightarrow m(x, \cdot) = m_1(x, \cdot)m_2(x, \cdot)$ for almost all $x \in G$ as $\epsilon \to \infty$. The function $b_{m_\epsilon}(\cdot)$ is continuous for each ϵ, and, as $\epsilon \to 0$, $b_{m_\epsilon}(x) \to b_m(x)$ almost everywhere in G.*

THEOREM 2.4 (from [20, Theorem 4.2, Chapter 4]). *Assume* (A2.1)–(A2.4). *Then $\mu_m(\cdot)$ is continuous in the control in that if $m^n(x, \cdot) \Rightarrow m(x, \cdot)$ for almost all $x \in G$, as $n \to \infty$, then the associated invariant measures converge strongly in that for each Borel set $A \subset G$, as $n \to 0$,*

$$\mu_{m^n}(A) \to \mu_m(A).$$

The cost function. We will need the following assumption.

A2.5. *The real-valued functions $k_i(\cdot)$ on $G \times U_i, i = 1, 2$, are continuous. Also, c is a vector with nonnegative components.*

Define $k(x, \alpha) = k_1(x, \alpha_1) + k_2(x, \alpha_2)$. For a relaxed feedback control $m(x, d\alpha) = m_1(x, d\alpha_1)m_2(x, d\alpha_2)$, define $k_m(x) = \int_U k(x, \alpha)m(x, d\alpha)$ and

$$\gamma_T(x, m) = \frac{1}{T} E_x^m \int_0^T k_m(x(s))ds + \frac{1}{T} E_x^m c'y(T).$$

The $y_i(t)$, defined in (2.6), represents the total overflow or underflow from face i on $[0, t]$. Thus the cost has two parts: the average running cost per unit time and the average weighted overflow or underflow per unit time.

For relaxed feedback controls, the cost function of interest in this paper is

$$\gamma(m) = \lim_T \gamma_T(x, m). \tag{2.10}$$

Under our assumptions, $\gamma(m)$ will not depend on the initial condition (see Theorem 2.5). We will sometimes abuse terminology and write $\gamma(m) = \gamma(m_1, m_2)$.

It is convenient to use the same symbols γ_T and γ for the total mean cost on $[0, T]$ divided by T and its limit, resp., in other cases. We will abuse terminology and continue to use these symbols, with the arguments indicating the variables on which the quantities depend. In particular, if the initial condition x does not appear as an argument of a function, then the function does not depend on it. If player i uses a relaxed control $r_i(\cdot)$, then define

$$k_{r_i}(x, t) = \int_{U_i} k_i(x, \alpha_i) r_{i,t}(d\alpha_i, t).$$

If player 1 selects its control first and uses a relaxed feedback control and player 2 selects its control last and uses a relaxed control, then define (the use of lim inf is just a convention)

$$\gamma_T(x, m_1, r_2) = \frac{1}{T} E_x^{m_1, r_2} \int_0^T \left[k_{1,m_1}(x(s)) + k_{2,r_2}(x(s), s)\right] ds + \frac{1}{T} E_x^{m_1, r_2} c' y(T),$$

$$\gamma(x, m_1, r_2) = \liminf_T \gamma_T(x, m_1, r_2).$$

If player 2 selects its control first and uses a relaxed feedback control and player 1 uses a relaxed control, define (the use of lim sup is just a convention)

$$\gamma(x, r_1, m_2) = \limsup_T \gamma_T(x, r_1, m_2).$$

Representation of the cost in terms of a stationary system. Let $m(\cdot)$ be a relaxed feedback control. The system (2.4) starts with an arbitrary initial condition that does not necessarily have the stationary distribution. It turns out that the limit (2.10) is the same as if the initial condition were distributed as $\mu_m(\cdot)$. This is the assertion of the next theorem.

THEOREM 2.5 (this is [20, Theorem 4.1, Chapter 4]). *Assume* (A2.1)–(A2.5). *Let $m(\cdot)$ be a relaxed feedback control. Then the $E_x^m y_i(1)$ are continuous functions of x and*

$$\gamma(m) = \int k_m(x) \mu_m(dx) + \int E_x^m \left[c' y(1)\right] \mu_m(dx).$$

2.3. Existence of optimal controls for the upper and lower values. Define the upper and lower values, resp., for the game (fb denotes relaxed feedback, and rel denotes relaxed controls):

$$\bar{\gamma}^+ = \inf_{\text{relaxed fb } m_1} \sup_{\text{rel } r_2} \gamma(m_1, r_2), \tag{2.11a}$$

$$\bar{\gamma}^- = \sup_{\text{relaxed fb } m_2} \inf_{\text{rel } r_1} \gamma(r_1, m_2). \tag{2.11b}$$

It is shown below that the use of relaxed controls for the player selecting last offers no advantage over feedback controls. In section 4 it is shown that the game has a value in that $\bar{\gamma}^+ = \bar{\gamma}^- = \bar{\gamma}$. Then the numerical procedure converges to $\bar{\gamma}$ as the discretization level goes to zero (see section 3).

The definition (2.11a) is interpreted to mean that player 2 supposes that player 1 has selected a relaxed feedback control for itself, which will be fixed throughout the game (i.e., player 1 selects first). Given this presumed choice of player 1, player 2 can select any relaxed or relaxed feedback control and will choose so as to maximize. This maximizing control will exist and will actually be of the relaxed feedback control form (implied by Theorem 2.8). It will depend on the presumed choice of player 1. Given this relationship, player 1 will select a minimizing control. By Theorem 2.8, it will exist and be of the relaxed feedback form. The interpretation of (2.11b) is analogous.

THEOREM 2.6 (this is [20, Theorem 4.3, Chapter 4], adapted to the notation of the present case). *Assume* (A2.1)–(A2.5). *For a sequence* $\{m^n(\cdot)\}$ *of relaxed feedback controls, let* $m^n(x,\cdot)$ *converge weakly to* $m(x,\cdot)$ *for almost all* $x \in G$ *as* $n \to \infty$. *Then, as* $n \to \infty$, $\gamma(m^n) \to \gamma(m)$.

For fixed $m_1(\cdot)$, *maximize over* $m_2(\cdot)$, *and let* $\{m_2^n(\cdot)\}$ *be a maximizing sequence. Consider measures over the Borel sets of* $G \times U$ *which are defined by*

$$m^n(x, d\alpha)dx = m_1(x, d\alpha_1)m_2^n(x, d\alpha_2)dx \tag{2.12}$$

and take a weakly convergent subsequence. The limit can be factored into the form

$$m_1(x, d\alpha_1)\tilde{m}_2(x, d\alpha_2)dx, \tag{2.13}$$

where $\tilde{m}_2(\cdot)$ *is a relaxed feedback control for player* 2. *Since* $\tilde{m}_2(\cdot)$ *depends on* $m_1(\cdot)$, *write it as* $\tilde{m}_2(\cdot) = \overline{m}_2(\cdot; m_1)$. *Then, given* $m_1(\cdot)$, *the relaxed feedback control* $\overline{m}_2(\cdot; m_1)$ *is maximizing for player* 2 *in that*

$$\sup_{m_2} \gamma(m_1, m_2) = \gamma(m_1, \overline{m}_2(m_1)).$$

The analogous result holds in the other direction, where player 2 *chooses first.*

Remark on the proof. First, note that owing to the product form any weak sense limit of the sequence defined in (2.12) must be of the form (2.13), where $\tilde{m}_1(\cdot)$ is a relaxed feedback control. The reference [20, Theorem 4.3, Chapter 4] is concerned with a minimization problem. Changing minimization to maximization and adapting the notation to our case where there are two controls and one is fixed, it shows that the limit $m_1(x, d\alpha_1)\tilde{m}_2(x, d\alpha_2)$ is maximizing, which is the assertion of the second paragraph of the theorem. □

Relaxed controls for the player who chooses last. Suppose that with $m_1(\cdot)$ fixed, player 2 is allowed to use relaxed controls and not simply relaxed feedback controls. The following theorem says that the maximization over this larger class will not yield a better result for player 2. The analogue of the result for player 2 choosing first also holds.

THEOREM 2.7 (this is [20, Theorem 6.1, Chapter 4], adapted to the notation of the present case). *Assume* (A2.1)–(A2.5), *fix* $m_1(\cdot)$, *and let* $\overline{m}_2(\cdot; m_1)$ *be an optimal relaxed feedback control and* $r_2(\cdot)$ *an arbitrary relaxed control for player* 2. *Then for each* $x \in G$,

$$\gamma(x, m_1, r_2) \le \gamma(m_1, \overline{m}_2(m_1)).$$

THEOREM 2.8. *Assume* (A2.1)–(A2.5). *Let player* 1 *go first. Then it has an optimal control, denoted by* $\overline{m}_1^+(\cdot)$. *The analogous result holds if player* 2 *chooses first, and its optimal control is denoted by* $\overline{m}_2^-(\cdot)$.

Remark on the proof. The proof is essentially a consequence of [20, Theorem 4.3, Chapter 4], just as Theorem 2.6 was. Let player 1 go first and let $\{m_1^n(\cdot)\}$ be a minimizing sequence of relaxed feedback controls. By Theorem 2.6, if player 1 uses $m_1^n(\cdot)$, then player 2 would use the (maximizing) relaxed feedback control $\overline{m}_2(\cdot; m_1^n)$. Following the method of the reference that was used to prove Theorem 2.6, take a weakly convergent subsequence of the sequence of measures on the Borel sets of $G \times U$ that is defined by $m_1^n(x, d\alpha_1)\overline{m}_2(x, d\alpha_2; m_1^n)dx$ and denote the limit by $\overline{m}_1^+(x, d\alpha_1)\tilde{m}_2(x, d\alpha_2)dx$. Any weak sense limit must have this form, where the $\overline{m}_1^+(\cdot)$ and $\tilde{m}_2(\cdot)$ are relaxed feedback controls. For notational simplicity, let n index the weakly convergent subsequence. Then we must have $m_1^n(x, \cdot) \Rightarrow \overline{m}_1^+(x, \cdot)$ and $\overline{m}_2(x, \cdot; m_1^n) \Rightarrow \tilde{m}_2(x, \cdot)$ for almost all $x \in G$.

We need to show that $\overline{m}_1^+(\cdot)$ is optimal for player 1 if it chooses first and that it can be supposed that $\tilde{m}_2(\cdot) = \overline{m}_2(\cdot; \overline{m}_1^+)$. Since $\{m_1^n(\cdot)\}$ is minimizing for player 1 when it chooses first, $\gamma(m_1^n, \overline{m}_2(m_1^n)) \to \bar{\gamma}^+$. Suppose that $\bar{\gamma}^+ < \sup_{m_2} \gamma(\overline{m}_1^+, m_2)$. Then there is $\hat{m}_2(\cdot)$ such that $\bar{\gamma}^+ < \gamma(\overline{m}_1^+, \hat{m}_2)$. Now, let player 2 use $\hat{m}_2(\cdot)$ instead of $\overline{m}_2(\cdot; m_1^n)$ for large n. Since the sequence defined by $m_1^n(x, d\alpha_1)\hat{m}_2(x, d\alpha_2)dx$ converges weakly to the measure defined by $\overline{m}_1^+(x, d\alpha_1)\hat{m}_2(x, d\alpha_2)dx$, Theorem 2.6 implies that $\gamma(m_1^n, \hat{m}_2) \to \gamma(\overline{m}_1^+, \hat{m}_2) > \bar{\gamma}^+$. This contradicts the fact that $\{m_1^n(\cdot)\}$ is minimizing, since it implies that there is $\epsilon > 0$ such that $\gamma(m_1^n, \hat{m}_2) \geq \bar{\gamma}^+ + \epsilon$ for large n. Thus $\overline{m}_1^+(\cdot)$ is optimal for player 1 if it chooses first. Since $\bar{\gamma}^+ = \gamma(\overline{m}_1^+, \tilde{m}_2)$, without loss of generality we can suppose that $\tilde{m}_2(\cdot) = \overline{m}_2(\cdot; \overline{m}_1^+)$. □

Remark on smooth nearly optimal controls. In section 4 we will need the fact that the optimal relaxed feedback controls for either player can be smoothed with little loss. In particular, suppose that player 1 chooses first, let $\epsilon > 0$, and replace $\overline{m}_1^+(\cdot)$ by the smoothed $\overline{m}_{1,\epsilon}^+(\cdot)$ as defined above Theorem 2.3. It is true that

$$\lim_{\epsilon \to 0} \sup_{m_2} \gamma(\overline{m}_{1,\epsilon}^+, m_2) = \bar{\gamma}^+. \tag{2.14}$$

To prove (2.14), suppose that it does not hold in that there is $\delta > 0$ such that

$$\lim_{\epsilon \to 0} \sup_{m_2} \gamma(\overline{m}_{1,\epsilon}^+, m_2) \geq \bar{\gamma}^+ + \delta. \tag{2.15}$$

Then there are $m_{2,\epsilon}(\cdot)$ such that $\gamma(\overline{m}_{1,\epsilon}^+, m_{2,\epsilon}) \geq \bar{\gamma}^+ + \delta/2$ for all small $\epsilon > 0$. Let ϵ index a weakly convergent subsequence of $\overline{m}_{1,\epsilon}^+(x, d\alpha_1)m_{2,\epsilon}(x, d\alpha_2)dx$. The limit can be written as $\overline{m}_1^+(x, d\alpha_1)\tilde{m}_2(x, d\alpha_2)dx$ for some relaxed feedback control $\tilde{m}_2(\cdot)$. By Theorem 2.6, as $\epsilon \to 0$, $\gamma(\overline{m}_{1,\epsilon}^+, m_{2,\epsilon}) \to \gamma(\overline{m}_1^+, \tilde{m}_2) \geq \bar{\gamma}^+ + \delta/2$, a contradiction to the optimality of $\overline{m}_1^+(\cdot)$ for player 1 if it chooses first. Obviously, there is an analogue if player 2 chooses first.

3. Convergence of the numerical procedure.

3.1. The Markov chain approximation method. The numerical method to be employed is the Markov chain approximation method of [18, 19, 22]. The approximating processes are the same. But the numerical problem to be solved is an ergodic cost problem for a Markov chain. The method approximates the system process (2.4) by a discrete parameter finite state controlled Markov chain that is "locally consistent" with (2.4). The cost function is also approximated, and the

game problem is then solved. Some basic facts from [22] concerning the procedure will now be stated. Let h denote the approximation parameter. Many methods for getting suitable approximating chains are in the references (e.g., see [22, Chapter 5]). The approximating chain and local consistency conditions are the same for the game problems of this paper. In the present case, where $\sigma(x)\sigma'(x)$ is uniformly positive definite, for each small fixed value of h the constructed chains can be selected to be ergodic for each control [22, Chapter 7]), and this will be assumed to be the case. In fact, the chains can be chosen such that for each small h, the rate of convergence of the transition functions to the invariant measure (as time goes to infinity) will be uniform in the control. See [22, Chapter 7] for a discussion of the setup and convergence for the pure control problem.

To construct the approximation, one first defines S_h, a discretization of $\mathbb{R}^r$. For example, S_h might be a regular h-grid. The precise requirements are quite weak, and it is only the points in G and their immediate neighbors that are of interest. The state space for the chain is divided into two parts. The first part is $G_h = G \cap S_h$, on which the chain approximates the diffusion part of (2.4). If the chain tries to leave G_h, then it is returned immediately, consistently with the local reflection direction. Thus, define ∂G_h^+ to be the set of points not in G_h to which the chain might move in one step from some point in G_h. The set ∂G_h^+ is an approximation to the reflecting boundary. The use of ∂G_h^+ simplifies the analysis and allows us to get a reflection process $z^h(\cdot)$ (resp., $y^h(\cdot)$) that is analogous to $z(\cdot)$ (resp., to $y(\cdot)$).

Local consistency on G_h. Let $u_n^h = (u_{1,n}^h, u_{2,n}^h)$ denote the controls used at step n for the approximating chain ξ_n^h. Let $E_{x,n}^{h,\alpha}$ (resp., $\mathrm{Cov}_{x,n}^{h,\alpha}$) denote the expectation (resp., the covariance), given all of the data to step n, when $\xi_n^h = x, u_n^h = \alpha$. Then the chain satisfies the following consistency condition. There is $\Delta t^h(x,\alpha) = \Delta t^h$ (it does not depend on (x,α) for $x \in G$) such that $\Delta t^h \to 0$ as $h \to 0$ and

$$\begin{aligned} E_{x,n}^{h,\alpha}\left[\xi_{n+1}^h - x\right] &= b(x,\alpha)\Delta t^h + o(\Delta t^h), \\ \mathrm{Cov}_{x,n}^{h,\alpha}\left[\xi_{n+1}^h - x\right] &= a(x)\Delta t^h + o(\Delta t^h),\ a(x) = \sigma(x)\sigma'(x), \\ \|\xi_{n+1}^h - \xi_n^h\| &\le K_1 h \end{aligned} \tag{3.1}$$

for some real K_1. The $o(\Delta t^h)$ terms are uniform in (x,α). Let $P^h(x,y|\alpha_1,\alpha_2) = P^h(x,y|\alpha)$ denote the one-step transition probabilities. With the methods in [22], Δt^h is obtained automatically as a by-product of getting the $P^h(x,y|\alpha)$, and it is used as an interpolation interval. More generally, Δt^h can depend on x,α. But for theoretical purposes for the ergodic cost problem, the problem is rescaled to get constant intervals. See the discussion in [22, Chapter 7]. By (3.1), in G the conditional mean first two moments of $\xi_{n+1}^h - \xi_n^h$ are close to those of the differences of the solution to (2.4).

The first two lines of (3.1) give the conditional moments for any fixed control values $\alpha = (\alpha_1, \alpha_2)$. Suppose that the control for player $i = 1, 2$ is chosen at random, depending only on the current state (i.e., it is randomized feedback). Let $m_i^h(x, d\alpha_i)$ denote the associated probability, conditioned on the past and on the current state value x, and define $m^h(x, d\alpha) = m_1^h(x, d\alpha_1)m_2^h(x, d\alpha_2)$. Then the transition probability is

$$\int_U P^h(x,y|\alpha_1,\alpha_2)m_1^h(x,d\alpha_1)m_2^h(x,d\alpha_2).$$

The first two lines of (3.1) are now replaced by

$$\begin{aligned} E^{h,m^h}_{x,n}\left[\xi^h_{n+1}-x\right] &= b_{m^h}(x)\Delta t^h + o(\Delta t^h), \\ \mathrm{Cov}^{h,m^h}_{x,n}\left[\xi^h_{n+1}-x\right] &= a(x)\Delta t^h + o(\Delta t^h),\ a(x)=\sigma(x)\sigma'(x). \end{aligned} \tag{3.2}$$

Thus, the forms are the same as if relaxed feedback controls were used. Although the actual sample paths would differ, the transition probabilities are the same for the randomized and the relaxed feedback forms.

Local consistency on ∂G^+_h. From points in ∂G^+_h, the transitions of the chain are such that they move to G_h, with the conditional mean direction being a reflection direction at x. By (A2.2), it is always possible to construct such transitions. More precisely,

$$\lim_{h\to 0}\sup_{x\in\partial G^+_h}\mathrm{distance}(x,G_h)=0, \tag{3.3}$$

and there are $\theta_1>0$ and $\theta_2(h)\to 0$ as $h\to 0$ such that for all $x\in\partial G^+_h$,

$$\begin{aligned} E^{h,\alpha}_{x,n}\left[\xi^h_{n+1}-x\right] &\in \{a\gamma:\ \gamma\in d(x), \theta_2(h)\ge a\ge\theta_1 h\}, \\ \Delta t^h(x,\alpha) &= 0 \ \text{ for } x\in\partial G^+_h. \end{aligned} \tag{3.4}$$

The last line of (3.4) says that the reflection from states on ∂G^+_h is instantaneous. Without loss of generality, we can suppose that the transition probabilities are continuous in the control variables for each x (see [22, Chapter 5] for typical methods of construction).

Continuous time interpolation. Only the discrete time chain ξ^h_n is needed for the numerical computations. But, for the proofs of convergence, this chain must be interpolated into a continuous time process which approximates $x(\cdot)$. The interpolation intervals are suggested by the $\Delta t^h(\cdot)$ in (3.1) and (3.4). We will use a Markovian interpolation, called $\psi^h(\cdot)$. Recall that the intervals between jumps of a continuous time Markov chain on a finite state space are (conditionally, given the current state value) exponentially distributed. In our interpolation, the (conditional) mean values will just be the interpolation intervals. This interpolation is used for analytical purposes only. Let $\{\Delta\tau^h_n, n<\infty\}$ be conditionally mutually independent and "exponential" random variables in that

$$P^{h,\alpha}_{x,n}\left\{\Delta\tau^h_n\ge t\right\}=e^{-t/\Delta t^h(x,\alpha)}.$$

Note that $\Delta\tau^h_n=0$ if ξ^h_n is on the reflecting boundary ∂G^+_h. Define $\tau^h_0=0$, and for $n>0$, set $\tau^h_n=\sum_{i=0}^{n-1}\Delta\tau^h_i$. The τ^h_n will be the jump times of $\psi^h(\cdot)$. Let E^h_i denote the expectation conditioned on the data to step i. Now define $\psi^h(\cdot)$ and the interpolated reflection processes by

$$\psi^h(t)=x(0)+\sum_{\tau^h_{i+1}\le t}[\xi^h_{i+1}-\xi^h_i],$$

$$Z^h(t)=\sum_{\tau^h_{i+1}\le t}[\xi^h_{i+1}-\xi^h_i]I_{\{\xi^h_i\in\partial G^+_h\}},$$

$$z^h(t) = \sum_{\tau^h_{i+1} \le t} E^h_i[\xi^h_{i+1} - \xi^h_i] I_{\{\xi^h_i \in \partial G^+_h\}}.$$

Define the continuous time interpolations $u^h_i(\cdot)$ of the controls analogously. Let $r^h_i(\cdot)$ denote the relaxed control representation of $u^h_i(\cdot)$. The process $\psi^h(\cdot)$ is a continuous time Markov chain. When the state is x and control pair is α, the jump rate out of $x \in G_h$ is $1/\Delta t^h(x,\alpha)$. So the conditional mean interpolation interval is $\Delta t^h(x,\alpha)$; i.e., $E^{h,\alpha}_{x,n}[\tau^h_{n+1} - \tau^h_n] = \Delta t^h(x,\alpha)$.

Define $\tilde{z}^h(\cdot)$ by $Z^h(t) = z^h(t) + \tilde{z}^h(t)$. This representation splits the effects of the reflection into two parts. The first is composed of the "conditional mean" parts $E^h_i[\xi^h_{i+1} - \xi^h_i] I_{\{\xi^h_i \in \partial G^+_h\}}$, and the second is composed of the perturbations about these conditional means [22, section 5.7.3]. Both components can change only at t, where $\psi^h(t)$ can leave G_h. Suppose that at some time t, $Z^h(t) - Z^h(t-) \neq 0$, with $\psi^h(t-) = x \in G_h$. Then by (3.4), $z^h(t) - z^h(t-)$ points in a direction in $d(N_h(x))$, where $N_h(x)$ is a neighborhood with radius that goes to zero as $h \to 0$. The process $\tilde{z}^h(\cdot)$ is the "error" due to the centering of the increments of the reflection term about their conditional means and has bounded (uniformly in x, h) second moments, and it converges to zero, as will be seen in Theorem 3.1. It is convenient to represent $z^h(\cdot)$ in a form analogous to (2.6). By (A2.1), (A2.2), and the local consistency condition (3.4), we can write (modulo an asymptotically negligible term)

$$z^h(t) = \sum_i d_i y^h_i(t),$$

where $y^h_i(0) = 0$, and $y^h_i(\cdot)$ is nondecreasing and can increase only when $\psi^h(t)$ is arbitrarily close (as $h \to 0$) to the ith face of ∂G.

A representation for $\psi^h(\cdot)$. The process $\psi^h(\cdot)$ has a representation which resembles (2.4) and is useful in the convergence proofs. Let $\xi^h_0 = x$. By [22, Sections 5.7.3 and 10.4.1], we can write

$$\begin{aligned} \psi^h(t) = x \; &+ \int_0^t b(\psi^h(s), u^h(s)) ds \\ &+ \int_0^t \sigma(\psi^h(s)) dw^h(s) + Z^h(s) + \epsilon^h(s), \end{aligned} \tag{3.5}$$

where $\psi^h(t) \in G$. The process $\epsilon^h(\cdot)$ is due to the $o(\cdot)$ terms in (3.1) and is asymptotically unimportant in that, for any T, $\lim_h \sup_{x,u^h} \sup_{s \le T} E^{h,u^h}_x |\epsilon^h(s)|^2 = 0$. The process $w^h(\cdot)$ is a martingale with respect to the filtration induced by $(\psi^h(\cdot), u^h(\cdot), w^h(\cdot))$ and converges weakly to a standard (vector-valued) Wiener process. The $w^h(t)$ is obtained from $\{\psi^h(s), s \le t\}$. All of the processes in (3.5) are constant on the intervals $[\tau^h_n, \tau^h_{n+1})$.

Let $|z^h|(T)$ denote the variation of the process $z^h(\cdot)$ on the time interval $[0,T]$. Then we have the following theorem from [22]. Recall that $z^h(0) = 0$.

THEOREM 3.1 (Theorem 11.1.3 and equation (5.7.5) [22]). *Assume* (A2.1), (A2.2), *the local consistency conditions, and let $b(\cdot)$ and $\sigma(\cdot)$ be bounded and measurable. Then for any $T < \infty$, there are $K_2 < \infty$ and δ_h, where $\delta_h \to 0$ as $h \to 0$, and which do not depend on the controls or initial condition, such that*

$$E\left|z^h\right|^2(T) \le K_2, \tag{3.6}$$

$$E \sup_{s \le T} \left|\tilde{z}^h(s)\right|^2 = \delta_h E \left|z^h\right|(T). \tag{3.7}$$

Owing to the fact that the reflection directions at any corner or edge are linearly independent, the inequalities hold for $y^h(\cdot)$ replacing $z^h(\cdot)$.

The cost function and upper and lower values for the discrete game. Relaxed feedback controls, when applied to the Markov chain, are equivalent to randomized controls. Let $u^h(\cdot) = (u_1^h(\cdot), u_2^h(\cdot))$ be feedback controls for the approximating chain. Then the cost is

$$\begin{gathered}\gamma_T^h(x, u^h) = \gamma_T^h(x, u_1^h, u_2^h) = \frac{1}{T} E_x^{h,u^h} \int_0^T k_{u^h}(\psi^h(s))ds + E_x^{h,u^h} \frac{c' y^h(T)}{T}, \\ \gamma^h(u^h) = \lim_T \gamma_T^h(x, u^h).\end{gathered} \tag{3.8}$$

Now suppose that $m^h(\cdot)$ represents a randomized control (as discussed above (3.2)). Then the cost function can be written as

$$\begin{gathered}\gamma_T^h(x, m^h) = \gamma_T^h(x, m_1^h, m_2^h) = \frac{1}{T} E_x^{h,m^h} \int_0^T k_{m^h}(\psi^h(s))ds + E_x^{h,m^h} \frac{c' y^h(T)}{T}, \\ \gamma^h(m^h) = \lim_T \gamma_T^h(x, m^h).\end{gathered} \tag{3.9}$$

With the relaxed feedback control representation of an ordinary feedback control, (3.8) is a special case of (3.9). Also, we can always take the controls in (3.9) to be randomized feedback.

Suppose that player 1 chooses its control first and uses the relaxed feedback (or randomized feedback) control $m_1^h(\cdot)$. Then player 2 has a maximization problem for a finite state Markov chain. The approximating chain is ergodic for any feedback control, whether randomized or not. Then, since the transition probabilities and cost rates are continuous in the control of the second player, the optimal control of the second player exists and is a pure feedback control (not randomized) [8, volume 2], [25]. The cost does not depend on the initial condition. The analogous situation holds if player 2 chooses its control first. These facts will be used in the next theorem. We use $m_i^h(\cdot)$ to denote either a randomized feedback, relaxed feedback, or the relaxed feedback representation of an ordinary feedback control. Define the upper and lower values, resp.:

$$\bar{\gamma}^{+,h} = \inf_{m_1^h} \sup_{m_2^h} \gamma^h(m_1^h, m_2^h),$$

$$\bar{\gamma}^{-,h} = \sup_{m_2^h} \inf_{m_1^h} \gamma^h(m_1^h, m_2^h).$$

Under our hypotheses, the upper and lower values might be different, although Theorem 3.2 says that they converge to the same value asymptotically. If the dynamics are separated in the sense that $P^h(x, y|\alpha)$ can be written as a function of (x, y, α_1) plus a function of (x, y, α_2), then $\bar{\gamma}^{+,h} = \bar{\gamma}^{-,h}$. (The proof is similar to that giving the analogous result in section 4, except that the state space is discrete here.) One can choose the transition probability so that it is separated, if desired.

3.2. Convergence of the numerical procedure.

THEOREM 3.2. *Assume* (A2.1)–(A2.5) *and suppose that* [2]

$$\bar{\gamma}^+ = \bar{\gamma}^- = \bar{\gamma}. \tag{3.10}$$

Then

$$\bar{\gamma}^- \le \liminf_h \bar{\gamma}^{-,h} \le \limsup_h \bar{\gamma}^{+,h} \le \bar{\gamma}^+. \tag{3.11}$$

Hence

$$\lim_h \bar{\gamma}^{+,h} = \lim_h \bar{\gamma}^{-,h} = \bar{\gamma}, \tag{3.12}$$

and both the upper and lower values for the numerical approximation converge to the value for the original game.

Proof. Let player 1 choose its control first and let $\epsilon > 0$. Let $\overline{m}^+_{\epsilon,1}(\cdot)$ be an ϵ-smoothing of the optimal control $\overline{m}^+_1(\cdot)$ for player 1, when it chooses first, as discussed at the end of section 2. That discussion implies that, given $\delta > 0$, there is $\epsilon > 0$ such that $\overline{m}^+_{1,\epsilon}(\cdot)$ is δ-optimal for player 1 for the original problem. Now, let player 1 use $\overline{m}^+_{1,\epsilon}(\cdot)$ on the approximating chain, either as a randomized feedback or a relaxed feedback control. Given that player 1 chooses first and uses $\overline{m}^+_{1,\epsilon}(\cdot)$, we have a simple control problem for player 2. As noted above, the optimal control for player 2 exists and is pure feedback, and we denote it by $\tilde{u}^h_2(\cdot)$, with relaxed feedback control representation $\tilde{m}^h_2(\cdot)$.

By the definition of the upper value,

$$\bar{\gamma}^{+,h} \le \sup_{u^h_2} \gamma^h(\overline{m}^+_{1,\epsilon}, u^h_2) = \sup_{m^h_2} \gamma^h(\overline{m}^+_{1,\epsilon}, m^h_2) = \gamma^h(\overline{m}^+_{1,\epsilon}, \tilde{u}^h_2), \tag{3.13}$$

where $u^h_2(\cdot)$ denotes an arbitrary ordinary feedback control, and $m^h_2(\cdot)$ an arbitrary randomized feedback control. The maximum value $\gamma^h(\overline{m}^+_{1,\epsilon}, \tilde{u}^h_2)$ of the control problem for player 2 with player 1's control fixed at $\overline{m}^+_{1,\epsilon}(\cdot)$ does not depend on the initial condition. Hence, without loss of generality, the corresponding continuous time interpolation $\psi^h(\cdot)$ can be considered to be stationary. Then, using the continuity in (x, α_2) of $\int_{U_1} b(x,\alpha)\overline{m}^+_{1,\epsilon}(x, d\alpha_1)$ and of $\int_{U_1} k(x,\alpha)\overline{m}^+_{1,\epsilon}(x, d\alpha_1)$ (and replacing the minimization problem by a maximization problem) yields [22, Theorem 3.1, Chapter 11] that there is a relaxed control $\tilde{r}_2(\cdot)$ for the original problem such that[3]

$$\limsup_h \bar{\gamma}^{+,h} \le \limsup_h \gamma^h(\overline{m}^+_{1,\epsilon}, \tilde{u}^h_2) = \gamma(\overline{m}^+_{1,\epsilon}, \tilde{r}_2) \le \bar{\gamma}^+ + \delta. \tag{3.14}$$

The last inequality of (3.14) follows from Theorem 2.7 and the δ-optimality of $\overline{m}^+_{1,\epsilon}(\cdot)$ in the class of relaxed feedback controls for player 1 if it chooses first.

Now, let player 2 choose first. Then there is an analogous result with analogous notation: In particular, given $\delta > 0$, there is an $\epsilon > 0$ and an ϵ-smoothing $\overline{m}^-_{2,\epsilon}(\cdot)$ of the optimal control and a relaxed control $\tilde{r}_1(\cdot)$ for the original problem (2.4) such that

$$\liminf_h \bar{\gamma}^{-,h} \ge \liminf_h \gamma^h(\tilde{u}^h_1, \overline{m}^-_{2,\epsilon}) = \gamma(\tilde{r}_2, \overline{m}^-_{2,\epsilon}) \ge \bar{\gamma}^- - \delta. \tag{3.15}$$

Hence, since δ is arbitrary, (3.11) holds. This, with (3.10), yields the theorem. □

[2] Equation (3.10) will be proved in the next section.

[3] In [22, Theorem 3.1, Chapter 11], the symbol $m(\cdot)$ is used for a relaxed control and not a relaxed feedback control. That reference does not use relaxed feedback controls.

4. Existence of the value of the game. An approach to the proof. The existence of the value, namely (3.10), will be proved in this section. Before proceeding with the proof, we will motivate what will be needed by outlining a tentative approach. The outline is purely formal. But, later, it will be seen that the method can be carried out.

Suppose for the moment that the game for the numerical approximation has a value in that $\bar{\gamma}^{+,h} = \bar{\gamma}^{-,h}$, and let there be controls $\overline{m}_1^h(\cdot), \overline{m}_2^h(\cdot)$ for the numerical method (written in relaxed feedback form) which ttain the value, no matter who chooses first; i.e., $\overline{m}_i^h(\cdot)$ is optimal for player i whether it chooses its control first or last. Thus,

$$\bar{\gamma}^{+,h} = \bar{\gamma}^{-,h} = \bar{\gamma}^h = \gamma^h(\overline{m}_1^h, \overline{m}_2^h). \tag{4.1}$$

Suppose also that there are relaxed feedback controls $\tilde{m}_i(\cdot)$ such that, for some subsequence of $h \to 0$,

$$\overline{m}_1^h(x, d\alpha_1)\overline{m}_2^h(x, d\alpha_2)dx \Rightarrow \tilde{m}_1(x, d\alpha_1)\tilde{m}_2(x, d\alpha_2)dx. \tag{4.2}$$

Finally, suppose that for any sequence (indexed by $h \to 0$) of relaxed feedback controls $\{m_i^h(\cdot)\}, i = 1, 2$, for which $m_1^h(x, d\alpha_1)m_2^h(x, d\alpha_2)dx$ converges weakly to, say, $m_1(x, d\alpha_1)m_2(x, d\alpha_2)dx$, we have the convergence of the costs

$$\gamma^h(m_1^h, m_2^h) \to \gamma(m_1, m_2). \tag{4.3}$$

Then by (3.11) it follows that

$$\bar{\gamma}^- \leq \gamma(\tilde{m}_1, \tilde{m}_2) \leq \bar{\gamma}^+.$$

We claim that, under the above hypotheses, the limit control $\tilde{m}_i(\cdot)$ is optimal for player i if it chooses first. To prove this claim one can proceed as follows. Suppose that $\tilde{m}_1(\cdot)$ is not optimal for player 1 if it chooses first, in that $\sup_{m_2} \gamma(\tilde{m}_1, m_2) > \bar{\gamma}^+$. Then there are $\delta > 0$ and $\hat{m}_2(\cdot)$ such that $\gamma(\tilde{m}_1, \hat{m}_2) \geq \bar{\gamma}^+ + 2\delta$. Following the approach in Theorem 3.2, for $\epsilon > 0$ let $\hat{m}_{2,\epsilon}(\cdot)$ be an ϵ-smoothing of $\hat{m}_2(\cdot)$. Then, for small $\epsilon > 0$, $\gamma(\tilde{m}_1, \hat{m}_{2,\epsilon}) \geq \bar{\gamma}^+ + \delta$. Then apply $\hat{m}_{2,\epsilon}(\cdot)$ to the approximating controlled process $\psi^h(\cdot)$ to get a contradiction to the optimality of $(\overline{m}_1^h(\cdot), \overline{m}_2^h(\cdot))$ for small h. Such a contradiction implies that $\sup_{m_2} \gamma(\tilde{m}_1, m_2) \leq \bar{\gamma}^+$. But, the strict inequality $<$ is impossible due to the definition of the upper value. Hence $\sup_{m_2} \gamma(\tilde{m}_1, m_2) = \bar{\gamma}^+$, as desired.

To get the desired contradiction to the optimality of $(\overline{m}_1^h(\cdot), \overline{m}_2^h(\cdot))$ for small h, let h index a weakly convergence subsequence of the measures defined in the left side of (4.2). The limit must be of the form on the right side of (4.2) for some $\tilde{m}_i(\cdot)$, $i = 1, 2$, where $\overline{m}_i^h(x, \cdot) \Rightarrow \tilde{m}_i(x, \cdot)$ for almost all $x \in G, i = 1, 2$. Apply the control pair $(\overline{m}_1^h(\cdot), \hat{m}_{2,\epsilon}(\cdot))$ to $\psi^h(\cdot)$. Then (along the chosen subsequence of h)

$$\overline{m}_1^h(x, d\alpha_1)\hat{m}_{2,\epsilon}(x, d\alpha_2)dx \Rightarrow \tilde{m}_1(x, d\alpha_1)\hat{m}_{2,\epsilon}(x, d\alpha_2)dx.$$

Since (4.3) implies that $\gamma^h(\overline{m}_1^h, \hat{m}_{2,\epsilon}) \to \gamma(\tilde{m}_1, \hat{m}_{2,\epsilon})$, for small enough ϵ and h, we must have $\gamma^h(\overline{m}_1^h, \hat{m}_{2,\epsilon}) \geq \bar{\gamma}^{+,h} + \delta/2$, which is a contradiction to the optimality of $\overline{m}_1^h(\cdot)$. We can now conclude that

$$\sup_{m_2} \gamma(\tilde{m}_1, m_2) = \bar{\gamma}^+ = \gamma(\tilde{m}_1, \tilde{m}_2). \tag{4.4}$$

Thus, if player 1 chooses its control first and uses its optimal control $\tilde{m}_1(\cdot)$, then $\tilde{m}_2(\cdot)$ is optimal for player 2. By repeating the procedure with the order of the players reversed, we can finally conclude that, if (4.1)–(4.3) hold (at least for some subsequence of h), then (3.10) holds.

The approach outlined above for proving (3.10) is attractive. But it *cannot* work for the class of processes $\psi^h(\cdot)$ which are used for the actual Markov chain approximation numerical method in section 3, since for each h, the state space is only some finite set. Hence, the controls are not defined for all $x \in G$, and the transition function is not mutually absolutely continuous with respect to Lebesgue measure. However, in this section we are concerned only with proving (3.10), and not with the numerical procedure. Thus, we can use the approach which was outlined above for an appropriately chosen alternative approximating process for which (3.11) also holds. A discrete time process will be constructed for which (3.11) and (4.1)–(4.3) hold. This process is to be used solely to prove (3.10). It is not suitable for numerical solution. For future use, note that if the $\overline{m}_i^h(\cdot), i = 1, 2$, are relaxed feedback controls for each h and the $\overline{m}_i^h(x, \cdot)$ are defined for almost all x, then there is always a subsequence and relaxed feedback controls $\tilde{m}_i(\cdot), i = 1, 2$, for which (4.2) holds.

An alternative approximating process. To get the approximating process, time will be discretized but not space. Let $\Delta > 0$ denote the time discretization interval. We need to construct a process whose n-step transition functions $P^\Delta(x, n\Delta, \cdot|\alpha)$ have densities that are mutually absolutely continuous with respect to Lebesgue measure uniformly in (Δ, control, $t_0 \le n\Delta \le t_1$) for any $0 < t_0 < t_1 < \infty$.

Consider the following procedure. Start with the process (2.4) but with the controls held constant on the intervals $[l\Delta, l\Delta + \Delta)$, $l = 0, 1, \ldots$. The discrete approximation will be the samples at times $l\Delta, l = 0, 1, \ldots$. The controls are chosen at $t = 0$, with one of the players selected to choose first, just as for the original game. Let $u_i^\Delta(\cdot), i = 1, 2$, denote the controls if they are in pure feedback (not relaxed or randomized) form. In relaxed control notation write the controls as $m_i^\Delta(\cdot), i = 1, 2$. These controls are used henceforth, whenever control is applied. The chosen controls are applied at random as follows. At each time, only one of the players will use its control. At each time $l\Delta$, $l = 0, 1, \ldots$, flip a fair coin. With probability 1/2, player 1 will use its control during the interval $[l\Delta, l\Delta + \Delta)$ and player 2 will not. Otherwise, player 2 will use its control, and player 1 will not. The values of the controls during the interval will depend on the state at its start. The optimal controls will be feedback. Define $x^\Delta(t) = x(l\Delta)$ on $[l\Delta, l\Delta + \Delta)$. For pure (not randomized or relaxed) feedback controls $u_i^\Delta(\cdot), i = 1, 2$, the system can be written as

$$dx = b^\Delta(x, u^\Delta(x^\Delta))dt + \sigma(x)dw + dz, \tag{4.5a}$$

where the value of $b^\Delta(\cdot)$ is determined by the coin tossing randomization procedure at the times $l\Delta, l = 0, 1 \ldots$. In particular, at $t \in [l\Delta, l\Delta + \Delta)$, $b^\Delta(x, u^\Delta(x^\Delta))$ is defined by $2b_i(x(t), u_i^\Delta(x^\Delta(t)))$, for either $i = 1$ or $i = 2$ according to the random choice made at $l\Delta$. If the controls $u_i^\Delta(x)$ are replaced by relaxed feedback controls $m_i^\Delta(x, \cdot)$, then write the model as

$$dx = b^\Delta(x, m^\Delta(x^\Delta))dt + \sigma(x)dw + dz, \tag{4.5b}$$

where at $t \in [l\Delta, l\Delta+\Delta)$, $b^\Delta(x, m^\Delta(x^\Delta))$ is $2\int_{U_i} b_i(x(t), \alpha_i)m_i^\Delta(x(l\Delta), d\alpha_i)$, for either $i = 1$ or $i = 2$ according to the random choice made at $l\Delta$. Following the Girsanov transformation based usage in (2.4), the Wiener process $w(\cdot)$ should be indexed by the controls $u^\Delta(\cdot)$ or $m^\Delta(\cdot)$, but we omit it for notational simplicity. In the rest of

this section, we consider $m^\Delta(\cdot) = (m_1^\Delta(\cdot), m_2^\Delta(\cdot))$ to be a vector and not a product measure.

Let $E^{\Delta,i,\alpha_i}_{x(l\Delta)}$ denote the expectation of functionals on $[l\Delta, l\Delta+\Delta)$ when player i acts on that interval and uses control action α_i. Let $P_i^\Delta(x,\cdot|\alpha_i)$ denote the measure of $x(\Delta)$, given that the initial condition is x, player i acts and uses control action α_i. The conditional mean increment in the total cost function on the time interval $[l\Delta, l\Delta+\Delta)$ is, for $u_i^\Delta(x(l\Delta)) = \alpha_i, i = 1,2$,

$$C^\Delta(x(l\Delta),\alpha) = \frac{1}{2}\sum_{i=1,2} E^{\Delta,i,\alpha_i}_{x(l\Delta)}\left[\int_{l\Delta}^{l\Delta+\Delta} 2k_i(x(s),\alpha_i))ds + c'\left(y(l\Delta+\Delta) - y(l\Delta)\right)\right]. \tag{4.6}$$

Note that $C^\Delta(x,\alpha)$ is the sum of two terms, one depending on (x,α_1) and the other on (x,α_2). The weak sense uniqueness of the solution to (2.4) for any control and initial condition implies the following result. Define $C^\Delta(x, m^\Delta(x))$ analogously, and we will sometimes write it as $C^\Delta(x, m_1^\Delta(x), m_2^\Delta(x))$.

THEOREM 4.1. *Assume* (A2.1)–(A2.5). *Then for each* $\Delta > 0$, $C^\Delta(\cdot)$ *is continuous, and the measures* $P_i^\Delta(\cdot)$ *are weakly continuous in that for any bounded and continuous real-valued function* $f(\cdot)$, $\int f(y)P_i^\Delta(x,dy|\alpha)$ *and* $C^\Delta(x,\alpha)$ *are continuous in* (x,α).

The reason for choosing the acting controls at random at each time $l\Delta, l = 0,1,\ldots,$ is that the randomization "separates" the cost rates and dynamics in the controls for the two players. By separation, we mean that both the cost function and transition function are the sum of two terms, one depending on (x,α_1) and the other on (x,α_2). This separation is important since it gives the "Isaacs condition" which is needed to assure the existence of a value for the game for the discrete time process, as seen in Theorem 4.2. Proceeding formally at this point, let $\mu^\Delta_{m^\Delta}(\cdot)$ denote the invariant measure under the control $m^\Delta(\cdot)$. Define the stationary cost increment

$$\lambda^\Delta(m^\Delta) = \int_G \mu^\Delta_{m^\Delta}(dx)\left[\int_U C(x,\alpha)m_1^\Delta(x,d\alpha_1)m_2^\Delta(x,d\alpha_2)\right].$$

Note that, due to the scaling, $\lambda^\Delta(m^\Delta)$ is an average over an interval of length Δ: hence $\lambda^\Delta(m^\Delta) = \Delta\gamma^\Delta(m^\Delta)$. Suppose for the moment that there is an optimal control $\overline{m}_i^\Delta(\cdot), i = 1,2$, for each $\Delta > 0$, and define $\overline{\lambda}^\Delta = \lambda^\Delta(\overline{m}^\Delta)$. The "separation" is easily seen from the formal Isaacs equation for the value of the discrete time problem, namely,

$$\overline{\lambda}^\Delta + \overline{g}^\Delta(x) = \inf_{\alpha_1}\sup_{\alpha_2}\left[\frac{1}{2}\int \overline{g}^\Delta(x+y)P_1^\Delta(x,dy|\alpha_1) + \frac{1}{2}\int \overline{g}^\Delta(x+y)P_2^\Delta(x,dy|\alpha_2) + C^\Delta(x,\alpha)\right], \tag{4.7}$$

where $\overline{g}^\Delta(\cdot)$ is the relative value or potential function.

THEOREM 4.2. *Assume* (A2.1)–(A2.5). *Then* (3.10) *holds.*

Proof. We will work with the approximating process $x(l\Delta), l = 0,1,\ldots,$ just described, where $x(\cdot)$ is defined by (4.5) with the piecewise constant control, and verify the conditions imposed in the formal discussion at the beginning of the section. Results from [20] will be exploited whenever possible. The result (3.11) holds (with Δ replacing h) for the same reasons that it holds for the numerical approximating process

of the last section. For any sequence of relaxed feedback controls $m_i^\Delta(\cdot), i = 1, 2$, there is a subsequence (indexed by $\Delta \to 0$) and relaxed feedback controls $\tilde{m}_i^\Delta(\cdot), i = 1, 2$, such that

$$m_1^\Delta(x, d\alpha_1)m_2^\Delta(x, d\alpha_2)dx \Rightarrow \tilde{m}_1(x, d\alpha_1)\tilde{m}_2(x, d\alpha_2)dx.$$

One needs to show the analogue of (4.3), namely (along the same subsequence, indexed by Δ)

$$\gamma^\Delta(m^\Delta) \to \gamma(\tilde{m}). \tag{4.8}$$

The process $\{x(l\Delta)\}$ based on (4.5) inherits the crucial properties of (2.4), as developed in [20, Chapter 4] and summarized in subsection 2.2. In particular, for each positive Δ and n the n-step transition probability $P^\Delta(x, n\Delta, \cdot|m^\Delta)$ is mutually absolutely continuous with respect to Lebesgue measure uniformly in the control and in $x \in G$, $n\Delta \in [t_0, t_1]$, for any $0 < t_0 < t_1 < \infty$, and it is a strong Feller process. The invariant measures are mutually absolutely continuous with respect to Lebesgue measure, again uniformly in the control. Then the proof of (4.8) is very similar to the corresponding proof for (2.4) given in [20, Theorem 4.3, Chapter 4], and the details are omitted. There are relaxed feedback controls $\overline{m}_i^{\Delta,+}(\cdot), i = 1, 2$, which are optimal if player 1 chooses its control first (i.e., for the upper value), and $\overline{m}_i^{\Delta,-}(\cdot), i = 1, 2$, which are optimal if player 2 chooses its control first (i.e., for the lower value).

We will concentrate on showing the analogue of (4.1), namely,

$$\bar{\gamma}^{+,\Delta} = \bar{\gamma}^{-,\Delta}. \tag{4.9}$$

By the (uniform in the controls) mutual absolute continuity (with respect to Lebesgue measure) of the one-step transition probabilities for each $\Delta > 0$, the process satisfies a Doeblin condition uniformly in the control. Hence it is uniformly ergodic (uniformly in the control) [23, Theorems 16.2.1 and 16.2.3]. In particular it follows that there are constants K_Δ and ρ_Δ, with $\rho_\Delta < 1$ such that

$$\sup_{x,m^\Delta} \left| E_x^{\Delta,m^\Delta} \int_U C(x(n\Delta), \alpha)m^\Delta(x(n\Delta), d\alpha) - \lambda^\Delta(m^\Delta) \right| \le K_\Delta \left[\rho_\Delta\right]^n,$$

where $\lambda^\Delta(m^\Delta)$ is defined above (4.7).

Define the relative value function

$$g^\Delta(x, m^\Delta) = \sum_{l=0}^{\infty} \left[E_x^{\Delta,m^\Delta} C(x(l\Delta), m^\Delta(x(n\Delta)) - \lambda^\Delta(m^\Delta) \right].$$

The summands converge to zero exponentially, uniformly in $(x, m^\Delta(\cdot))$. Also, by the strong Feller property the summands (for $l > 0$) are continuous. Define $g^{\Delta,+}(x) = g^\Delta(x, \overline{m}^{\Delta,+})$ and $g^{\Delta,-}(x) = g^\Delta(x, \overline{m}^{\Delta,-})$. Then a direct evaluation yields

$$\bar{\lambda}^{\Delta,+} + g^{\Delta,+}(x) = E_x^{\Delta,\overline{m}^{\Delta,+}} \left[g^{\Delta,+}(x(\Delta)) + C^\Delta(x, \overline{m}^{\Delta,+}(x)) \right]. \tag{4.10}$$

Next we show that under $\overline{m}_1^{\Delta,+}(\cdot)$ for player 1 (and for almost all x)

$$\bar{\lambda}^{\Delta,+} + g^{\Delta,+}(x) = \sup_{\alpha_2} \left[E_x^{\Delta,\overline{m}_1^{\Delta,+},\alpha_2} g^{\Delta,+}(x(\Delta)) + C^\Delta(x, \overline{m}_1^{\Delta,+}(x), \alpha_2) \right]. \tag{4.11}$$

By (4.10), (4.11) holds for almost all x with the equality replaced by the inequality $\leq$. The function in brackets in (4.11) is continuous in α_2 uniformly in $x \in G$. Suppose that (4.11) does not hold on a set $A \subset G$ of Lebesgue measure $l(A) > 0$. Let $\tilde{m}_2^\Delta(\cdot)$ denote the (relaxed feedback control representation of the) maximizing control in (4.11). Then

$$\bar{\lambda}^{\Delta,+} + g^{\Delta,+}(x) \leq \left[E_x^{\Delta,\overline{m}_1^{\Delta,+},\tilde{m}_2^\Delta} g^{\Delta,+}(x(\Delta)) + C^\Delta(x, \overline{m}_1^{\Delta,+}(x), \tilde{m}_2^\Delta(x)) \right], \tag{4.12}$$

with strict inequality for $x \in A$. Now, integrate both sides of (4.12) with respect to the invariant measure $\mu^\Delta_{\{\overline{m}_1^{\Delta,+},\tilde{m}_2^\Delta\}}(\cdot)$ corresponding to the control $(\overline{m}_1^\Delta(\cdot), \tilde{m}_2^\Delta(\cdot))$ and note that

$$\int g^{\Delta,+}(x)\mu^\Delta_{\{\overline{m}_1^{\Delta,+},\tilde{m}_2^\Delta\}}(dx) = \int \left[E_x^{\Delta,\overline{m}_1^{\Delta,+},\tilde{m}_2^\Delta} g^{\Delta,+}(x(\Delta)) \right] \mu^\Delta_{\{\overline{m}_1^{\Delta,+},\tilde{m}_2^\Delta\}}(dx). \tag{4.13}$$

Also, by definition,

$$\lambda^\Delta(\overline{m}_1^{\Delta,+}, \tilde{m}_2^\Delta) = \int C^\Delta(x, \overline{m}_1^{\Delta,+}(x), \tilde{m}_2^\Delta(x))\mu^\Delta_{\{\overline{m}_1^{\Delta,+},\tilde{m}_2^\Delta\}}(dx).$$

Then, canceling the terms in (4.13) from the integrated inequality and using the fact that the invariant measure is mutually absolutely continuous with respect to Lebesgue measure yields $\bar{\lambda}^{\Delta,+} < \lambda^\Delta(\overline{m}_1^{\Delta,+}, \tilde{m}_2^\Delta)$, which contradicts the optimality of $\overline{m}_2^{\Delta,+}(\cdot)$ for player 2 if player 1 selects its control first. Thus, (4.11) holds.

Next, given that (4.11) holds, let us show that for almost all x

$$\bar{\lambda}^{\Delta,+} + g^{\Delta,+}(x) = \inf_{\alpha_1} \sup_{\alpha_2} E_x^{\Delta,\alpha_1,\alpha_2} \left[g^{\Delta,+}(x(\Delta)) + C^\Delta(x, \alpha_1, \alpha_2) \right]. \tag{4.14}$$

By (4.11), this last equation holds if $\overline{m}_1^{\Delta,+}(\cdot)$ replaces α_1 and the inf is dropped. Suppose that (4.14) is false. Then there are $A \in G$ with $l(A) > 0$ and $\epsilon > 0$ such that for $x \in A$ the equality is replaced by the inequality $\geq$ plus ϵ, with the inequality $\geq$ holding for almost all other $x \in G$. More particularly, let $\hat{m}_1^{\Delta,+}(\cdot)$ denote the minimizing control for player 1 in (4.14). Then we have, for almost all x and any $m_2^\Delta(\cdot)$,

$$\bar{\lambda}^{\Delta,+} + g^{\Delta,+}(x) \geq E_x^{\Delta,\hat{m}_1^\Delta,m_2^\Delta} \left[g^{\Delta,+}(x(\Delta)) + C^\Delta(x, \hat{m}_1^\Delta(x), m_2^\Delta(x)) \right] + \epsilon I_{\{x\in A\}}. \tag{4.15}$$

Now, repeating the procedure used to prove (4.11), integrate both sides of (4.15) with respect to the invariant measure associated with $(\hat{m}_1^\Delta(\cdot), m_2^\Delta(\cdot))$, use the fact that the invariant measure is mutually absolutely continuous with respect to Lebesgue measure, uniformly in the controls, and cancel the terms which are analogous to those in (4.13) to get that

$$\bar{\lambda}^{\Delta,+} > \sup_{m_2^\Delta} \lambda^\Delta(\hat{m}_1^\Delta, m_2^\Delta).$$

This implies that $\overline{m}_1^{\Delta,+}(\cdot)$ is not optimal for player 1 if it selects its control first, a contradiction. Thus, (4.14) holds. The analogous procedure can be carried out for the lower value where player 2 selects its control first.

Now the fact that the dynamics and cost rate are separated in the control implies that $\inf_{\alpha_1}\sup_{\alpha_2} = \sup_{\alpha_2}\inf_{\alpha_1}$ in (4.14). Thus, (4.14) holds with the order of the sup

and inf inverted. By working with (4.14) with the sup and inf inverted and following an argument similar to that used to prove (4.14), one can show that $\bar{\lambda}^{\Delta,+} = \bar{\lambda}^{\Delta,-}$ and that $\overline{m}_i^{\Delta}(\cdot)$ is optimal for player i whether it selects first or last. The rest of the details are left to the reader. □

WEAK CONVERSE LYAPUNOV THEOREMS AND CONTROL-LYAPUNOV FUNCTIONS*

CHRISTOPHER M. KELLETT† AND ANDREW R. TEEL‡

Abstract. Given a *weakly uniformly globally asymptotically stable* closed (not necessarily compact) set $\mathcal{A}$ for a differential inclusion that is defined on $\mathbb{R}^n$, is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, and satisfies other basic conditions, we construct a weak Lyapunov function that is locally Lipschitz on $\mathbb{R}^n$. Using this result, we show that uniform global asymptotic controllability to a closed (not necessarily compact) set for a locally Lipschitz nonlinear control system implies the existence of a locally Lipschitz control-Lyapunov function, and from this control-Lyapunov function we construct a feedback that is robust to measurement noise.

Key words. converse Lyapunov theorem, weak set stability, differential inclusions, control-Lyapunov function, asymptotic controllability

1. Introduction.

Herein we consider the related questions of the existence of a weak Lyapunov function for differential inclusions, and the existence of a control-Lyapunov function for controlled differential equations, under the assumption of weak asymptotic stability (respectively, asymptotic controllability) of (to) a closed, not necessarily compact, set $\mathcal{A}$.

The converse question in Lyapunov theory has received a great deal of attention. In the case of the differential inclusion

$$\dot{x} \in F(x),\ x \in \mathbb{R}^n, \tag{1.1}$$

we ask the following question: Given the weak (or strong) asymptotic stability of an attractor $\mathcal{A}$, does there exist a positive definite, proper function $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ satisfying a specific decrease condition along at least one trajectory (respectively, all trajectories)?

Numerous results on the existence of smooth, strong Lyapunov functions for *strong asymptotic stability* have been established, that is, when *all* solutions of (1.1) satisfy stability and uniform attractivity properties with respect to the set $\mathcal{A}$. Among these results is the pioneering work of Kurzweil [17] and Wilson [31] with recent results by Lin, Sontag, and Wang [18], Clarke, Ledyaev, and Stern [7], and Teel and Praly [30]. A more complete summary of these results can be found in Teel and Praly [30].

All of the above references for strong asymptotic stability generate *smooth* Lyapunov functions. Lower semicontinuous Lyapunov functions for weak stability (not

asymptotic) were given by Roxin [21, Theorem 9.5] for arbitrary closed sets $\mathcal{A}$ and by Deimling [10, Proposition 14.2] for $\mathcal{A} = \{0\}$. Clarke, Ledyaev, and Stern [7, Remark 1.5 and Theorem 6.1] noted that the existence of a continuously differentiable Lyapunov function for weak asymptotic stability of $\mathcal{A} = \{0\}$ implies the existence of a smooth Lyapunov function. However, they further demonstrated that the set-valued map $F(\cdot)$ must satisfy a nongeneric covering condition to admit a continuously differentiable weak Lyapunov function. Since we would like to consider inclusions which do not satisfy this covering condition, we require a decrease condition for nondifferentiable functions. We will make use of the Dini subderivate.

DEFINITION 1. *The Dini subderivate of a function $V : \mathbb{R}^n \to \mathbb{R}$ at a point $x \in \mathbb{R}^n$ in the direction $v \in \mathbb{R}^n$ is defined as*

$$DV(x; v) := \liminf_{w \to v, \varepsilon \to 0^+} \frac{V(x + \varepsilon w) - V(x)}{\varepsilon} .$$

For a locally Lipschitz function $V : \mathcal{O} \to \mathbb{R}$ ($\mathcal{O}$ open) at $x \in \mathcal{O}$ in the direction $v \in \mathbb{R}^n$ this simplifies to (see [8, p. 136])

$$DV(x; v) = \liminf_{\varepsilon \to 0^+} \frac{V(x + \varepsilon v) - V(x)}{\varepsilon} .$$

Therefore, in order to consider a more general class of inclusions (i.e., the class that includes inclusions which do not satisfy the previously mentioned covering condition), we search for a locally Lipschitz function $V(\cdot)$ and specify the decrease condition as

$$\min_{w \in F(x)} DV(x; w) \leq -V(x) \ \forall x \in \mathbb{R}^n.$$

Under appropriate conditions on the map $F : \mathbb{R}^n \to$ subsets of $\mathbb{R}^n$, the existence of a locally Lipschitz weak Lyapunov function for (possibly) noncompact attractors is asserted in Theorem 2.1. This result first appeared in Kellett and Teel [14]. We note that, while their results were stated for controlled differential equations, Clarke et al. [5] and Rifford [20] used differential inclusions as an intermediary. Implicitly, Clarke et al. [5] constructed a weak Lyapunov function, locally Lipschitz on compact sets disjoint from the origin, given, essentially, weak asymptotic stability of the origin. Rifford [20] then combined these functions in a clever way to obtain a weak Lyapunov function that is locally Lipschitz on $\mathbb{R}^n$, given weak asymptotic stability to the origin.

Now consider the controlled differential equation

$$\dot{x} = f(x, u), \ x \in \mathbb{R}^n, \ u \in \mathcal{U} , \tag{1.2}$$

where $\mathcal{U}$ is the set of all possible controls, and, rather than a weak Lyapunov function, we are interested in a control-Lyapunov function. An early result related to the existence of control-Lyapunov functions came from Roxin [22]. Results on the existence of control-Lyapunov functions, given asymptotic controllability to the origin, came from Sontag [24] (cf. Sontag and Sussman [29]), Clarke et al. [6], Sontag [28], and Clarke et al. [5]. In [20], Rifford generated a locally Lipschitz control-Lyapunov function, given asymptotic controllability to the origin, answering a longstanding question on the existence of same. A continuous control-Lyapunov function was generated by Albertini and Sontag [1] under the assumption of asymptotic controllability to a closed (not necessarily compact) set.

It is well known that continuously differentiable control-Lyapunov functions fail to exist for generic systems; i.e., systems which fail to satisfy Brockett's covering condition (see Brockett [4] or Ryan [23] for a definition). Again, we would like to consider a broader class of systems, including those that do not satisfy Brockett's condition. Toward this end, we examine the differential inclusion obtained by allowing the controls to range over the admissable control set; i.e.,

$$F(x) := \{z \in \mathbb{R}^n : z = f(x,u), u \in \mathcal{U}\} \ .$$

Intuitively, then, weak asymptotic stability of $\mathcal{A}$ for the differential inclusion thus defined is equivalent to the asymptotic controllability of the differential equation to $\mathcal{A}$. That is, the trajectory of $\dot{x} \in F(x)$ which does not wander too far from and is attracted to the set $\mathcal{A}$ is generated by a particular control selection. The notion of controllability used herein will be made precise in section 3. Following the arguments presented for inclusions, the corresponding decrease condition of the control-Lyapunov function then becomes

$$\min_{w \in f(x,\mathcal{U})} DV(x;w) \leq -V(x) \ \forall x \in \mathbb{R}^n \ .$$

That is, there exists a control selection such that the direction of the vector field defining the system causes the Dini subderivate of $V(\cdot)$ to decrease. Note that this is an intuitive discussion and we have avoided concerning ourselves with specifics such as a necessary "small-control property," precise regularity conditions on $f(\cdot,\cdot)$, and other technical details. These specifics are addressed in the following sections.

Remark 1. The above decrease condition involving the Dini subderivate was also used in Clarke et al. [5], [6]. In both references, use is also made of an equivalent formulation in terms of the proximal subgradient; i.e.,

$$\min_{u \in \mathcal{U}} \langle f(x,u), \zeta \rangle \leq -V(x) \ \forall x \in \mathbb{R}^n \ \forall \zeta \in \partial_P V(x) \ . \qquad \square$$

The significance of this novel result stems from the important role that control-Lyapunov functions have played in the development of stabilizing state feedbacks over the years. As examples, we refer the reader to Artstein [2], Sontag [25], Freeman and Kokotović [12], and Krstić, Kanellakopoulos, and Kokotović [16] for the case of continuously differentiable control-Lyapunov functions and to Clarke et al. [6], Sontag [28], and Clarke et al. [5] for locally Lipschitz control-Lyapunov functions. Similar to the latter articles, in section 4 we present the design of a (discontinuous) stabilizing state feedback that is robust to small additive disturbances and measurement noise using our derived control-Lyapunov function.

Our approach is to convert the control system into a differential inclusion (which is the approach also taken in Clarke et al. [5] and Rifford [20]) and then use the result on the existence of a Lyapunov function for the differential inclusion to get the promised control-Lyapunov function. The novelty of the current control-Lyapunov function is that the result is derived for closed (possibly noncompact) attractors. The proof technique is also novel in that it follows directly from a comparison function formulation of the controllability or stability property. This result first appeared in Kellett and Teel [15].

Our paper is organized as follows. Section 2 contains the precise statement of our weak converse Lyapunov theorem for differential inclusions with the associated proof in section 5. Section 3 contains our control-Lyapunov function result. A stabilizing

feedback construction for use with locally Lipschitz control-Lyapunov functions, such as the one presented in section 3, is given in section 4, with a robustness result for this feedback given in section 4.4. Section 6 contains necessary technical proofs.

2. A weak converse Lyapunov theorem. Having given some insight for the results which follow, we begin to make these ideas more precise. In what follows we let $|\cdot|$ denote the Euclidean norm on $\mathbb{R}^n$; i.e., $|x| = \sqrt{\langle x, x\rangle}$. For a closed set $\mathcal{A} \subset \mathbb{R}^n$ we write the distance from a point $x \in \mathbb{R}^n$ to the set $\mathcal{A}$ as $|x|_{\mathcal{A}} := \inf_{a\in\mathcal{A}} |x - a|$. We let $\overline{\mathcal{B}}_n(x, r)$ denote the closed ball in $\mathbb{R}^n$ of radius r centered at x; i.e., $\overline{\mathcal{B}}_n(x, r) := \{\xi \in \mathbb{R}^n : |\xi - x| \le r\}$. We define $\overline{\mathcal{B}}_n := \overline{\mathcal{B}}_n(0, 1)$, where 0 denotes the origin in $\mathbb{R}^n$. Recall that a function $\alpha : \mathbb{R}_{\ge 0} \to \mathbb{R}_{\ge 0}$ belongs to class-$\mathcal{K}_\infty$ ($\alpha \in \mathcal{K}_\infty$) if it is continuous, zero at zero, strictly increasing, and unbounded. A function $\beta : \mathbb{R}_{\ge 0} \times \mathbb{R}_{\ge 0} \to \mathbb{R}_{\ge 0}$ belongs to class-$\mathcal{KL}$ if, for each $t \ge 0$, $\beta(\cdot, t)$ is nondecreasing and $\lim_{s\to 0^+} \beta(s, t) = 0$, and, for each $s \ge 0$, $\beta(s, \cdot)$ is nonincreasing and $\lim_{t\to\infty} \beta(s, t) = 0$.

A function $x : [0, T] \to \mathbb{R}^n$ ($T > 0$) is said to be a *solution* of the differential inclusion $\dot{x} \in F(x)$ if it is absolutely continuous and satisfies, for almost all $t \in [0, T]$, $\dot{x}(t) \in F(x(t))$. A function $x : [0, T) \to \mathbb{R}^n$ ($0 < T \le +\infty$) is said to be a *maximal solution* of the differential inclusion if it does not have an extension which is a solution belonging to $\mathbb{R}^n$; i.e., either $T = \infty$ or there does not exist a solution $y : [0, T_+] \to \mathbb{R}^n$ with $T_+ > T$ such that $y(t) = x(t)$ for all $t \in [0, T)$. We use $\phi(\cdot, x)$ to denote a solution of $\dot{x} \in F(x)$ starting at x. We denote by $\mathcal{S}[0, T](x)$, or $\mathcal{S}[0, T)(x)$, the set of maximal solutions starting at x that are defined on the time interval $[0, T]$, or $[0, T)$.

The following basic conditions guarantee existence of solutions for differential inclusions.

DEFINITION 2. *The set-valued map $F(\cdot)$ is said to satisfy the* basic conditions on $\mathbb{R}^n$ *if, for each $x \in \mathbb{R}^n$, $F(x)$ is nonempty, compact, and convex and if $F(\cdot)$ is upper semicontinuous on $\mathbb{R}^n$; i.e., for each $x \in \mathbb{R}^n$ and $\varepsilon > 0$ there exists $\delta > 0$ such that, for all $\xi \in \mathbb{R}^n$ satisfying $|x - \xi| < \delta$, we have $F(\xi) \subseteq F(x) + \varepsilon\mathcal{B}_n$.*

Previous results which obtained lower semicontinuous Lyapunov functions (see [21], [10]) assumed the set-valued $F(\cdot)$ was merely upper semicontinuous. Our stronger result (i.e., existence of a locally Lipschitz Lyapunov function) will require a correspondingly stronger regularity property.

DEFINITION 3. *A set-valued map $F : \mathbb{R}^n \to$ subsets of $\mathbb{R}^n$ is* locally Lipschitz on $\mathcal{O} \subseteq \mathbb{R}^n$ *if for all $x \in \mathcal{O}$ there exists a neighborhood $\mathcal{U} \subseteq \mathcal{O}$ of x and $L > 0$ such that $x_1, x_2 \in \mathcal{U}$ implies $F(x_1) \subseteq F(x_2) + L|x_1 - x_2|\overline{\mathcal{B}}_n$. We say that this property is* uniform in distance to the closed set $\mathcal{A}$ *if for any $\ell > 0$ the above neighborhood can be defined as $\mathcal{U} := \{x \in \mathbb{R}^n : |x|_{\mathcal{A}} \le \ell\}$.*

DEFINITION 4. *Analogous to our terminology for set-valued maps, we say that a function $g : \mathbb{R}^n \to \mathbb{R}^n$ is locally Lipschitz, uniformly in distance to the closed set $\mathcal{A}$, if for any $\ell > 0$ and a closed set $\mathcal{U} := \{x \in \mathbb{R}^n : |x|_{\mathcal{A}} \le \ell\}$ there exists $L > 0$ such that for every $x_1, x_2 \in \mathcal{U}$ we have $|g(x_1) - g(x_2)| \le L|x_1 - x_2|$.*

Our stability condition is phrased in the language of comparison functions (as is our controllability condition in the next section). This presents a simple and concise way to summarize both uniform boundedness and attractivity.

DEFINITION 5. *For the differential inclusion $\dot{x} \in F(x)$, the closed set $\mathcal{A} \subset \mathbb{R}^n$ is said to be* weakly uniformly globally asymptotically stable (weakly UGAS) *if there exists $\beta \in \mathcal{KL}$ such that, for each $x \in \mathbb{R}^n$, there exists a solution $\phi \in \mathcal{S}[0, \infty)(x)$ satisfying $|\phi(t, x)|_{\mathcal{A}} \le \beta(|x|_{\mathcal{A}}, t)$ for all $t \ge 0$.*

We will make an assumption that follows [1, Definition 1.5]. This rules out finite time trajectory escape unobservable through distance to the set $\mathcal{A}$. Or, intuitively, it prevents the trajectory escaping to infinity in a direction parallel to the set $\mathcal{A}$.

Assumption 1. For each $r > 0$ there exists $M_r > 0$ such that $|x|_{\mathcal{A}} \leq r$ implies $\sup_{w \in F(x)} |w| \leq M_r$.

We are now in a position to assert the existence of a locally Lipschitz weak Lyapunov function.

THEOREM 2.1. *Suppose $F(\cdot)$ satisfies the basic conditions on $\mathbb{R}^n$, is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, satisfies Assumption* 1*, and, for $\dot{x} \in F(x)$, the closed set $\mathcal{A}$ is weakly UGAS. Then there exists a (weak Lyapunov) function $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ that is locally Lipschitz on $\mathbb{R}^n$ and $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that for all $x \in \mathbb{R}^n$*

$$\alpha_1(|x|_{\mathcal{A}}) \leq V(x) \leq \alpha_2(|x|_{\mathcal{A}}) \quad \text{and} \tag{2.1}$$

$$\min_{w \in F(x)} DV(x; w) \leq -V(x) \ . \tag{2.2}$$

Furthermore, if $F(\cdot)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$, uniformly in distance to the set $\mathcal{A}$, then there exists a locally Lipschitz weak Lyapunov function for $\dot{x} \in F(x)$ with respect to $\mathcal{A}$ where the local Lipschitz property is uniform in distance to the set $\mathcal{A}$.

The theorem is proved in section 5.

Remark 2. The use of the minimum is justified here, and throughout the paper, in place of an infimum by virtue of the fact that the set over which the infimum is taken is compact and the function is continuous; i.e., $DV(x; \cdot)$ is locally Lipschitz for all $x \in \mathbb{R}^n$ when $V(\cdot)$ is locally Lipschitz (see [8, Exercise 3.4.1a]). ∎

3. A control-Lyapunov function. In this section we state our result that uniform asymptotic controllability to a set implies the existence of a locally Lipschitz control-Lyapunov function. In what follows, we take $\mathcal{U}$ to be a locally compact metric space with a unique zero element, "0," and, by abuse of notation, $|u| := d(u, 0)$. We define the closed unit ball in the metric space $\mathcal{U}$ as $\overline{\mathcal{B}}_{\mathcal{U}} := \{\xi \in \mathcal{U} : d(\xi, 0) \leq 1\}$.

DEFINITION 6. *Let $\mathcal{A} \subset \mathbb{R}^n$ be a closed, nonempty set, and let $\sigma : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ be nondecreasing. We say that* (1.2) *is* uniformly globally asymptotically controllable (UGAC) to $\mathcal{A}$ with $\mathcal{U} \cap \sigma$ controls *if there exists a function $\beta \in \mathcal{KL}$ such that for each $x \in \mathbb{R}^n$ there exist a measurable, essentially bounded function $u : [0, \infty) \to \mathcal{U}$ and a solution $\phi(\cdot, x, u)$ of $\dot{x} = f(x, u(t))$ satisfying*

$$\begin{aligned} |\phi(t, x, u)|_{\mathcal{A}} &\leq \beta(|x|_{\mathcal{A}}, t), \\ |u(t)| &\leq \sigma(|\phi(t, x, u)|_{\mathcal{A}}) \quad \text{for almost all } t \geq 0. \end{aligned} \tag{3.1}$$

Remark 3. We note that $\mathcal{U} \cap \sigma$ is an abuse of notation. It is shorthand for allowing controls from $\mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}} = \{u \in \mathcal{U} : |u| \leq \sigma(|x|_{\mathcal{A}})\}$ for each $x \in \mathbb{R}^n$. ∎

Note that the usual definition of UGAC (such as in [24, Definition 2.2] or [27]) limits the control based on the size of the initial condition of the state, whereas for UGAC with $\mathcal{U} \cap \sigma$ controls we limit the control through the size of the trajectory. The following lemma is proved in [13, section 5.3.6].

LEMMA 3.1. *The system* (1.2) *is UGAC to $\mathcal{A}$ with $\mathcal{U} \cap \sigma$ controls if and only if there exist $\beta_c \in \mathcal{KL}$ and $\sigma_c : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ nondecreasing such that for each $x \in \mathbb{R}^n$ there exist a measurable, essentially bounded function $u : [0, \infty) \to \mathcal{U}$ and a maximal solution $\phi(t, x, u(t))$ of* (1.2) *such that $\|u\|_\infty \leq \sigma_c(|x|_{\mathcal{A}})$ and $|\phi(t, x, u(t))|_{\mathcal{A}} \leq \beta_c(|x|_{\mathcal{A}}, t)$.*

DEFINITION 7. *Let $\sigma : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ be nondecreasing. We say a locally Lipschitz function $V : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$ is a* control-Lyapunov function with $\mathcal{U} \cap \sigma$ controls *for the*

system (1.2) *if there exist* $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ *such that* $\alpha_1(|x|_{\mathcal{A}}) \leq V(x) \leq \alpha_2(|x|_{\mathcal{A}})$, *and* $V(\cdot)$ *satisfies the weak infinitesimal decrease property*

$$\min_{w \in \overline{\text{co}} f(x, \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}})} DV(x; w) \leq -V(x) \ \forall x \in \mathbb{R}^n \ .$$

Our result will require the following technical assumption which parallels Assumption 1 and which is essentially [1, Definition 1.5]. Again, this rules out finite time escape of trajectories which is not observable through distance to the set $\mathcal{A}$.

Assumption 2. For all $r_1, r_2 \in \mathbb{R}_{>0}$, there exists $M_{r_1,r_2} > 0$ such that

$$\sup_{\{|x|_{\mathcal{A}} \leq r_1, |u| \leq \sigma(r_2)\}} |f(x,u)| \leq M_{r_1,r_2}.$$

With all the necessary definitions in hand, we state the following theorem.

THEOREM 3.2. *Suppose* (1.2) *satisfies Assumption* 2 *and is UGAC to the set* $\mathcal{A}$ *with* $\mathcal{U} \cap \sigma$ *controls. Furthermore, assume that the set-valued map*

$$F(x) := \overline{\text{co}} f\left(x, \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}}\right)$$

satisfies the basic conditions on $\mathbb{R}^n$ *and is locally Lipschitz on* $\mathbb{R}^n \backslash \mathcal{A}$. *Then there exists a locally Lipschitz control-Lyapunov function with* $\mathcal{U} \cap \sigma$ *controls for* (1.2).

Furthermore, if $F(\cdot)$ *is locally Lipschitz on* $\mathbb{R}^n \backslash \mathcal{A}$, *uniformly in distance to the set* $\mathcal{A}$, *then there exists a locally Lipschitz control-Lyapunov function with* $\mathcal{U} \cap \sigma$ *controls which is locally Lipschitz, uniformly in distance to the set* $\mathcal{A}$.

Remark 4. Two examples of regularity conditions on $f(\cdot, \cdot)$ which would give rise to a locally Lipschitz $F(\cdot)$ are as follows.

1. Let $c > 0$ be constant (possibly $+\infty$) and $\sigma(\cdot) \equiv c$. Furthermore, let $f(x, \cdot)$ be measurable for each $x \in \mathbb{R}^n$ and $f(\cdot, u)$ be locally Lipschitz uniformly in $u \in \mathcal{U} \cap c\overline{\mathcal{B}}_{\mathcal{U}}$. Then $F(\cdot)$ is locally Lipschitz.
2. Consider $\mathcal{U} = \mathbb{R}^m$, and let $\sigma(\cdot)$ be locally Lipschitz (and nondecreasing) and $f(\cdot, \cdot)$ be locally Lipschitz. Then $F(\cdot)$ is locally Lipschitz.

Note that we have not assumed that the set-valued map $f\left(x, \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}}\right)$ is convex. However, if $f\left(x, \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}}\right)$ is Lipschitz, then $\overline{\text{co}} f\left(x, \mathcal{U} \cap \sigma(|x|_{\mathcal{A}})\overline{\mathcal{B}}_{\mathcal{U}}\right)$ is also Lipschitz (see [3, section 1.1, Proposition 6]).

These examples extend easily to the case of generating a set-valued map $F(\cdot)$ which is locally Lipschitz, uniformly in distance to the set $\mathcal{A}$. This is done by requiring the corresponding Lipschitz property on f to be uniform in distance to the set $\mathcal{A}$. □

The proof follows by noting that the set $\mathcal{A}$ will be weakly UGAS for the set-valued map $F(\cdot)$, allowing the application of Theorem 2.1. See [15] and [13] for details.

4. Control construction. By making use of the control-Lyapunov function of Theorem 3.2, we can construct a (discontinuous) time-invariant feedback stabilizer that, when implemented with a sample-and-hold strategy, guarantees semiglobal practical asymptotic stability of the set $\mathcal{A}$ and robustness to small additive disturbances and measurement noise. By sample and hold we mean that the system state is "sampled," a control action is computed, and then it is implemented (or "held") for a fixed holding period. The procedure is then repeated.

Results of this type were presented by Clarke et al. [6] and Sontag [28] for the case where $\mathcal{A}$ is compact, and a construction is given by Clarke et al. [5] that applies to the case of noncompact sets $\mathcal{A}$. Our construction resembles the constructions used

in both of these references. In comparison to the construction in [5], we use proximal aiming to a point that minimizes the control-Lyapunov function in a ball around the current point rather than proximal aiming to a sublevel set of the control-Lyapunov function. This permits a very concise statement of the control synthesis algorithm.

The following assumptions, under which we construct our feedback law, all follow directly from Theorem 3.2. However, these assumptions are somewhat weaker as they simplify the exposition. Specifically, as we use a sample-and-hold strategy to implement our feedback control, we are concerned with only the semiglobal practical qualities of the control-Lyapunov function.

4.1. Assumptions. For $V : \mathbb{R}^n \to \mathbb{R}$ and $\ell_1, \ell_2 \in \{-\infty\} \bigcup \mathbb{R}$ such that $\ell_1 < \ell_2$, we define $\mathcal{V}(\ell_1, \ell_2) := \{x \in \mathbb{R}^n : \ell_1 \leq V(x) \leq \ell_2\}$. We denote $\mathcal{V}(-\infty, \ell_2)$ by $\mathcal{V}(\ell_2)$. Suppose $\sigma(\cdot)$ is nondecreasing and we are given $\ell_1 < \ell_2$, $\varepsilon_2 > 0$, $\varepsilon_3 > 0$, $\varepsilon_4 > 0$, $c > 0$, $L_V > 0$, $L_f > 0$, $\widetilde{M} > 0$ such that

1. for $x_1, x_2 \in \mathcal{V}(\ell_1, \ell_2 + \varepsilon_2) + \varepsilon_3 \overline{\mathcal{B}}_n$ and $u \in \mathcal{U} \cap \sigma(\max\{|x_1|_{\mathcal{A}}, |x_2|_{\mathcal{A}}\} + \varepsilon_4)\overline{\mathcal{B}}_{\mathcal{U}}$
   (a) $|V(x_1) - V(x_2)| \leq L_V |x_1 - x_2|$,
