MAXIMUM PRINCIPLE OF OPTIMAL CONTROL FOR DEGENERATE QUASI-LINEAR ELLIPTIC EQUATIONS*

HONGWEI LOU†

Abstract. Optimal control problems governed by degenerate quasi-linear partial differential equations of elliptic type are considered. The optimal control systems considered may lack Cesari-type conditions, and therefore the corresponding approximate optimal control problem may have no solution. To yield the maximum principle of optimal pairs, relaxed controls are used to overcome the difficulties occurring when considering approximate problems. The relaxed controls used are defined by finite additive measures so that the case of the control set being noncompact can be treated.

Key words. optimal control, degenerate quasi-linear equation, necessary condition, finite additive measure, relaxed control

1. Introduction.

Let $\Omega \subset \mathbb{R}^n$ be a bounded domain. Consider the degenerate elliptic partial differential equation,

$$\begin{cases} -\operatorname{div}(\varphi(x,|\nabla y|)\frac{\nabla y}{|\nabla y|}) = f(x,y(x),u(x)) & \text{in } \Omega, \\ y|_{\partial\Omega} = 0, \end{cases} \tag{1.1}$$

and the cost functional

$$J(u(\cdot)) = \int_\Omega f^0(x,y(x),u(x))dx.$$

We assume the following:

(S1) Let $1 < p < +\infty$, $\Omega \subset \mathbb{R}^n$ be a bounded domain with $C^{1,1}$ boundary $\partial\Omega$, U be a separable metric space, and $\mathcal{U}_{ad} \equiv \{v : \Omega \to U | v \text{ is measurable}\}$.

(S2) Let $\varphi \in C(\bar{\Omega}\times[0,+\infty)) \bigcap C^1(\bar{\Omega}\times(0,+\infty))$ satisfy $\varphi(x,0) = 0$ for all $x \in \Omega$. Moreover, there exist $\Lambda > \lambda > 0$ such that for almost all $x \in \Omega$,

$$\lambda s^{p-2} \le \varphi_s(x,s) \le \Lambda s^{p-2} \qquad \forall s \in (0,+\infty), \tag{1.2}$$

$$\sum_{i=1}^n |\varphi_{x_i}(x,s)| \le \Lambda s^{p-1} \qquad \forall s \in (0,+\infty). \tag{1.3}$$

(S3) The function $f : \Omega \times \mathbb{R} \times U \to \mathbb{R}$ has the following properties: $f(\cdot,y,u)$ is measurable in Ω, $f(x,\cdot,u)$ is in $C^1(\mathbb{R})$. $f_y(x,\cdot,\cdot)$ and $f(x,\cdot,\cdot)$ are continuous in $\mathbb{R}\times U$. Moreover,

$$f_y(x,y,u) \le 0 \qquad \forall (x,y,u) \in \Omega \times \mathbb{R} \times U, \tag{1.4}$$

and for any $R > 0$, there exists a constant $M_R > 0$ such that

$$|f(x,y,u)| + |f_y(x,y,u)| \le M_R \qquad \forall (x,u) \in \Omega \times U,\ |y| \le R. \tag{1.5}$$

(S4) The function $f^0 : \Omega \times \mathbb{R} \times U \to \mathbb{R}$ satisfies (S3) except for (1.4).

In our assumptions, U is not necessarily compact, which enables us to treat unbounded controls. The separability of U is used in applying the Filippov lemma and getting maximum conditions from that in integral form.

Our optimal control problem is as follows.

Problem (C). Find a $\bar{u}(\cdot) \in \mathcal{U}_{ad}$ such that

$$J(\bar{u}(\cdot)) = \inf_{u(\cdot)\in\mathcal{U}_{ad}} J(u(\cdot)).$$

The purpose of this paper is to give a Pontryagin maximum principle of an optimal control $\bar{u}(\cdot)$ to Problem (C).

Similar problems were considered by Casas and Fernández [2], [3] (see also [4]).

Because of the degeneracy of (1.1), to get necessary conditions of optimal controls, usually, one needs to consider approximate problems. In our case, no Cesari condition is assumed. Thus, the first difficulty we meet is that even if Problem (C) has an optimal control, the corresponding approximate optimal control problem may have no solution. On the other hand, when the approximate problems have optimal solutions, difficulties still occur in yielding maximum principle for Problem (C) from that for approximate problems. In [2], because of the speciality of the problem treated there, the first difficulty does not occur. Moreover, by using the convexity, the authors of [2] got strong convergence of optimal controls for approximate problems, obtaining the final results. To overcome the difficulties we just mentioned, we will consider relaxed controls. But another difficulty occurs when relaxed control is introduced. To ensure a sequence of relaxed controls having a subsequence converging weakly to a relaxed control, usually, we need to suppose that the control set U is compact (see [11], [21], and [25]). In this paper, we follow the track of Fattorini, who considered finite additive relaxed control in [9]. Such "relaxed controls" are different from those considered in [11], [21], and [25]. Using this new concept of "relaxed control," one is able to treat the case of U being a noncompact set.

Our main theorems are as follows.

THEOREM 1.1. *Suppose that* (S1)–(S4) *hold,* $1 < p < 2$. *Let* $(\bar{y}(\cdot), \bar{u}(\cdot)) \in W_0^{1,p}(\Omega) \times \mathcal{U}_{ad}$ *be an optimal state-control pair to Problem* (C). *Then, there exists a* $\bar{\psi}(\cdot) \in W_0^{1,2}(\Omega)$ *such that*

$$-\operatorname{div}\left\{\left[\frac{\varphi(x,|\nabla\bar{y}|)}{|\nabla\bar{y}|}\left(I-\frac{\nabla\bar{y}(\nabla\bar{y})^T}{|\nabla\bar{y}|^2}\right)+\varphi_s(x,|\nabla\bar{y}|)\frac{\nabla\bar{y}(\nabla\bar{y})^T}{|\nabla\bar{y}|^2}\right]\nabla\bar{\psi}\right\} \tag{1.6}$$

$$= f_y(x,\bar{y},\bar{u}(x))\bar{\psi} - f_y^0(x,\bar{y},\bar{u}(x)) \qquad \text{in } \{\nabla\bar{y}\neq 0\},$$

$$\nabla\bar{\psi}(x) = 0, \qquad a.e.\ x \in \{\nabla\bar{y} = 0\}, \tag{1.7}$$

and for almost all $x \in \Omega$,

$$H(x,\bar{y}(x),\bar{u}(x),\bar{\psi}(x)) = \max_{v\in U} H(x,\bar{y}(x),v,\bar{\psi}(x)), \tag{1.8}$$

where I *denotes the* $n \times n$ *identity matrix and*

$$H(x,y,v,\psi) = f(x,y,v)\psi - f^0(x,y,v) \tag{1.9}$$
$$\forall\ (x,y,v,\psi) \in \Omega \times \mathbb{R} \times U \times \mathbb{R}.$$

THEOREM 1.2. *Suppose that* (S1)–(S4) *hold,* $2 < p < +\infty$. *Moreover, suppose that there exists a constant* $\theta_0 > 0$ *such that*

$$f_y(x, y, u) \le -\theta_0 \qquad \forall\, (x, y, u) \in \Omega \times \mathbb{R} \times U. \tag{1.10}$$

Let $(\bar{y}(\cdot), \bar{u}(\cdot)) \in W_0^{1,p}(\Omega) \times \mathcal{U}_{ad}$ *be an optimal pair to Problem* (C). *Then, there exists a* $\bar{\psi}(\cdot) \in W_{loc}^{1,2}(\Omega)$ *satisfying* (1.6) *such that, for almost all* $x \in \{\nabla \bar{y} \neq 0\}$, (1.8) *holds, where* $W_{loc}^{1,2}(\Omega)$ *denotes the set of functions belonging to* $W^{1,2}(\Omega_0)$ *for any* $\Omega_0 \subset\subset \Omega$.

Because of the degeneracy of the state equation (1.1), usually, the conditions of the adjoint state $\bar{\psi}(\cdot)$ that we have given in Theorems 1.1 and 1.2 are not enough to determine it. Thus, in general, we can hardly determine the optimal controls from these necessary conditions (see also the similar theorems established in [2], [3]). Nevertheless, we can really use such conditions to find some important information about the optimal control. In [15], similar results were used to estimate the optimal controls, getting the regularities of optimal pairs.

In the case that $n = 1$ and $1 < p < 2$, our necessary conditions can be written in the form of equations of first order. Thus, in this case we are able to avoid using singular sets and we are sure that it keeps much important information of the optimal control.

THEOREM 1.3. *Suppose that* (S1)–(S4) *hold,* $1 < p < 2$, $\Omega = (a, b)$ *for some* $-\infty < a < b < +\infty$. *Let* $(\bar{y}(\cdot), \bar{u}(\cdot)) \in W_0^{1,p}(a, b) \times \mathcal{U}_{ad}$ *be an optimal pair to Problem* (C). *Then, there exist a* $\bar{\Psi}(\cdot) \in W^{1,+\infty}(a, b)$ *and a* $\bar{\psi}(\cdot) \in W_0^{1,2}(a, b) \bigcap W^{1,+\infty}(a, b)$ *such that*

$$\begin{cases} \bar{\Psi}'(x) = f_y(x, \bar{y}, \bar{u})\bar{\psi} - f_y^0(x, \bar{y}, \bar{u}), & a < x < b, \\ \bar{\psi}'(x) = -\dfrac{1}{\varphi_s(x, |\bar{y}'(x)|)}\bar{\Psi}(x), & a < x < b, \\ \bar{\psi}(a) = \bar{\psi}(b) = 0, \end{cases} \tag{1.11}$$

and for almost all $x \in (a, b)$

$$H(x, \bar{y}(x), \bar{u}(x), \bar{\psi}(x)) = \max_{v \in U} H(x, \bar{y}(x), v, \bar{\psi}(x)). \tag{1.12}$$

2. Classical control and relaxed control. In this section, we recall the concept of relaxed control and the relation between classical controls and relaxed controls. The concept of relaxed control can be traced back to the work of Young and McShane [27], [28], [29], [18], [19], [20] and their generalized curves (see also [22], [30]). Due to the development of measure theory and theory of generalized functions, McShane [21], Warga [25], and Gamkrelidze [11] gave the concept a new expression called "relaxed control" that is easier to understand than its archetype. In [9], to treat the case of the control set U being noncompact, Fattorini gave a new definition of relaxed control based on finite additive measures on U.

Now, let us recall some basic notions. Let Φ be a family of subsets of U. Φ is called a field of U if it contains the empty set $\emptyset$, the complement of each of its members, and the union of its two elements. Let $\mathcal{F}$ be the field generated by the closed sets of U, that is, $\mathcal{F}$ is the smallest field containing all closed subsets of U. A set function μ defined on $\mathcal{F}$ is called a finitely additive measure on U if $\mu(\emptyset) = 0$ and $\mu(A \bigcup B) = \mu(A) + \mu(B)$ for disjoint $A, B \in \mathcal{F}$ (see [8, p. 96]), where $\mu(A)$ can be a real number, $-\infty$ or $+\infty$. The total variation $|\mu|$ is defined by

$$|\mu|(A) \equiv \sup \sum_{j=1}^{m} |\mu(A_j)|,$$

where the supremum is taken over all finite sequences $\{A_j\}$ of disjoint sets in $\mathcal{F}$ with $A_j \subseteq A$. If

$$\|\mu\| \equiv |\mu|(U) < +\infty,$$

then μ is said to be of bounded variation. A finitely additive measure is called regular if for any $A \in \mathcal{F}$ and $\varepsilon > 0$, there exists two sets $B, D \in \mathcal{F}$ such that $\mathrm{cl}(B) \subseteq A \subseteq \mathrm{int}(D)$ (here $\mathrm{cl}(B)$ and $\mathrm{int}(D)$ denote the closure of B and the interior of D, respectively), and $|\mu|(E) < \varepsilon$ for any set $E \in \mathcal{F}$ with $E \subseteq D \setminus B$. Let $\mathcal{M}(U)$ be the space of all regular bounded finitely additive measures on U (μ is bounded if $\sup_{A\in\mathcal{F}} |\mu(A)| < +\infty$, or equivalently $\|\mu\| < +\infty$). Then $\mathcal{M}(U)$ is a Banach space under norm $\|\cdot\|$. Let $C(U)$ be the space of all continuous bounded functions defined on U with its supremum norm $\|\cdot\|_{C(U)}$. Then we have (see [8, Theorem IV.6.2]) the following lemma.

LEMMA 2.1. *The dual space $C(U)^*$ of $C(U)$ is isometrically isomorphic to $\mathcal{M}(U)$. An element $\mu \in \mathcal{M}(U)$ acts on elements $g(\cdot) \in C(U)$ in the form*

$$\langle \mu, g \rangle \equiv \int_U g(v)\mu(dv). \tag{2.1}$$

For an integration theory based on finitely additive measure, see [8, III.2]. An important difference between an integral based on finitely additive measures and that based on countably additive measures is that for a finitely additive measure μ and an μ-integrable nonnegative function $g(\cdot)$ on U,

$$\int_U g(v)\ \mu(dv) = 0$$

does not means $g = 0$, μ a.e. U.

Let $L^\infty(\Omega; \mathcal{M}(U))_w$ be the space of all $\mathcal{M}(U)$-valued $C(U)$-weakly measurable functions which are bounded almost everywhere. That is, $\sigma(\cdot) \in L^\infty(\Omega; \mathcal{M}(U))_w$ if

$$\sigma(x) \in \mathcal{M}(U) \qquad \forall\ x \in \Omega,$$

$$x \mapsto \langle \sigma(x), g \rangle \qquad \text{is measurable} \qquad \forall\ g \in C(U),$$

and there exists a constant $C > 0$ such that for almost all $x \in \Omega$,

$$\Big|\langle \sigma(x), g \rangle\Big| \le C\|g\|_{C(U)} \qquad \forall\ g \in C(U).$$

An element $\mu \in \mathcal{M}(U)$ is said to be a probability measure on U if μ is nonnegative and $\mu(U) = 1$. Let $\mathcal{M}^1_+(U)$ be the set of all probability measures on U, and let $\mathcal{R}(\Omega; U)$ be the set of all $\mathcal{M}^1_+(U)$-valued $C(U)$-weakly measurable functions in Ω, that is, $\sigma(\cdot) \in \mathcal{R}$ if

$$\sigma(x) \in \mathcal{M}^1_+(U) \qquad \forall\ x \in \Omega,$$

and

$$x \mapsto \int_U g(v)\ \sigma(x)(dv) \qquad \text{is measurable} \qquad \forall\ g \in C(U).$$

Any member of $\mathcal{R}(\Omega; U)$ will be called a relaxed control. Respectively, an element of $\mathcal{U}_{ad}$ is called a classical control.

By Lemma 2.1 and a discussion similar to that in the proof of Theorems 2.1 and 2.3 in [9] (see also [6] and [7]), we can get the following.

LEMMA 2.2. *The dual space $L^1(\Omega; C(U))^*$ of $L^1(\Omega; C(U))$ is isometrically isomorphic to $L^\infty(\Omega; \mathcal{M}(U))_w$.*

Thus, $\mathcal{R}(\Omega; U) \subset L^\infty(\Omega; \mathcal{M}(U))_w$ can be looked at as a subset of $L^1(\Omega; C(U))^*$ by setting

$$\langle \sigma, h\rangle \equiv \int_\Omega dx \int_U h(x,v)\, \sigma(x)(dv) \qquad \forall\, h \in L^1(\Omega, C(U)),\ \sigma \in \mathcal{R}(\Omega; U).$$

Moreover, using the Banach–Alaoglu theorem, we have the following.

LEMMA 2.3. *Suppose $\Omega \subset \mathbb{R}^n$ is a bounded domain and U is a metric space. Then for any sequence $\sigma_k(\cdot) \in \mathcal{R}(\Omega; U)$, there exists a $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$ such that for any $h \in L^1(\Omega; C(U))$, there exists a subsequence $\sigma_{k_j}(\cdot)$ of $\sigma_k(\cdot)$ satisfying*

$$\langle \sigma_{k_j}, h\rangle = \int_\Omega dx \int_U h(x,v)\sigma_{k_j}(x)(dv) \to \langle \sigma, h\rangle.$$

For convenience, in this paper, the above property will be denoted as

$$\sigma_k(\cdot) \xrightarrow{\mathcal{N}} \sigma(\cdot) \qquad \text{in } \mathcal{R}(\Omega; U).$$

We note that in Lemma 2.3, the choice of the subsequence $\sigma_{k_j}(\cdot)$ is dependent of h. On the other hand, when U is compact, $L^1(\Omega; C(U))$ is separable. Consequently, $\sigma_{k_j}(\cdot)$ can be chosen independently of h in this case (see [11, Chapter 8] or [25, Chapter 4]). The following lemma shows that relaxed control can be approximated by classical control.

LEMMA 2.4. *Let* (S1)–(S4) *hold, and let $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$. Then for every finite set $\{h_i\} \subset L^\infty(\Omega; C(U))$, $i = 1, \dots, N$, and any $\delta > 0$, there exist $u_1(\cdot), \dots, u_{N+1}(\cdot) \in \mathcal{U}_{ad}$ and nonnegative measurable functions $\alpha_1(\cdot), \dots, \alpha_{N+1}(\cdot)$ such that*

$$\sum_{i=1}^{N+1} \alpha_i(\cdot) = 1, \tag{2.2}$$

and for any $k = 1, \dots, N$,

$$\left\| \int_U h_k(\cdot, v)\sigma(\cdot)(dv) - \sum_{i=1}^{N+1} \alpha_i(\cdot) h_k(\cdot, u_i(\cdot)) \right\|_{L^\infty(\Omega)} \le \delta. \tag{2.3}$$

Moreover, there exists $\{u^l(\cdot)\} \subset \mathcal{U}_{ad}$ such that for any $k = 1, \dots, N$ and $h^0(\cdot) \in C(\bar\Omega)$,

$$\int_\Omega h^0(x) h_k(x, u^l(x))\, dx \to \int_\Omega dx \int_U h^0(x) h_k(x,v)\sigma(x)(dv) \quad \text{as } l \to +\infty. \tag{2.4}$$

Proof. For any $x \in \Omega$, we set

$$\tilde h_i(x) = \int_U h_i(x,v)\sigma(x)(dv), \qquad i = 1, \dots, N,$$

and

$$\mathcal{E}(x) = \{(h_1(x,v), \dots, h_N(x,v)) | v \in U\}.$$

Then $\mathcal{E}(x)$ is bounded. Moreover, it is easy to see that

$$(\tilde{h}_1(x), \dots, \tilde{h}_N(x)) \in \bar{co}\, \mathcal{E}(x),$$

since $\sum_{i=1}^N a_i \tilde{h}_i(x) + c \le 0$ for any $(a_1, \dots, a_N, c) \in \mathbb{R}^{N+1}$ such that

$$\sum_{i=1}^N a_i z_i + c \le 0 \qquad \forall\, (z_1, \dots, z_N) \in \mathcal{E}(x),$$

where $\bar{co}(A)$ denotes the closed convex hull of set $A \subset \mathbb{R}^N$. Therefore, by the Carathéodory theorem (see [25, p. 139], for example), for any $x \in \Omega$, we have $\hat{\alpha}_i(x) \ge 0$ and $z^i = (z_{i1}, \dots, z_{iN}) \in \bar{co}\, \mathcal{E}(x)$ $(i = 1, \dots, N+1)$ such that

$$\sum_{i=1}^{N+1} \hat{\alpha}_i(x) = 1,$$

and

$$(\tilde{h}_1(x), \dots, \tilde{h}_N(x)) = \sum_{i=1}^{N+1} \hat{\alpha}_i(x) z^i.$$

Consequently, there exist $\hat{u}_i(x) \in U$ $(i = 1, \dots, N+1)$ such that

$$\left| \tilde{h}_k(x) - \sum_{i=1}^{N+1} \hat{\alpha}_i(x) h_k(x, \hat{u}_i(x) \right| \le \delta, \qquad k = 1, \dots, N.$$

Let

$$X = \left\{ (\alpha_1, \dots, \alpha_{N+1}) \in \mathbb{R}^{N+1} | \alpha_i \ge 0, 1 \le i \le N+1, \sum_{k=1}^{N+1} \alpha_k = 1 \right\}.$$

Consider the multifunction $\Gamma : \Omega \to 2^{X \times U^{N+1}}$ defined by

$$\Gamma(x) = \Bigg\{ (\alpha_1, \dots, \alpha_{N+1}, v_1, \dots, v_{N+1}) \in X \times U^{N+1} | \\ |\tilde{h}_k(x) - \sum_{i=1}^{N+1} \alpha_i h_k(x, v_i)| \le \delta, k = 1, \dots, N \Bigg\}.$$

Then $\Gamma(\cdot)$ is measurable and takes nonempty closed set values. By Theorem 2.23 in [13, Chapter 3] (see also [10]), we have measurable functions $\alpha_i(\cdot) : \Omega \to [0, 1]$ and $u_i(\cdot) \in \mathcal{U}_{ad}$ $(i = 1, \dots, N+1)$ such that

$$\sum_{i=1}^{N+1} \alpha_i(x) = 1,$$

and

$$\left| \tilde{h}_k(x) - \sum_{i=1}^{N+1} \alpha_i(x) h_k(x, u_i(x)) \right| \le \delta, \qquad k = 1, \dots, N. \tag{2.5}$$

That is, (2.3) holds.

Now, we turn to prove (2.4). By (2.3), it suffices to prove that there exists a sequence $u^l(\cdot) \in \mathcal{U}_{ad}$ such that for any $h(\cdot,\cdot) \in L^1(\Omega; C(U))$,

$$\lim_{l\to+\infty} \int_\Omega h(x, u^l(x))\, dx = \int_\Omega \sum_{i=1}^{N+1} \alpha_i(x) h(x, \hat{u}_i(x))\, dx. \tag{2.6}$$

We will prove that $u^l(\cdot)$ can be chosen as

$$u^l(x) = \hat{u}_i(x), \qquad x \in \Omega_i^l,\ i = 1, \dots, N+1,$$

where

$$\begin{aligned} &\Omega_i^l \text{ is measurable}, \qquad i = 1, \dots, N+1, \\ &\Omega_i^l \bigcap \Omega_j^l = \emptyset \qquad \text{if } i \neq j, \end{aligned}$$

and

$$\bigcup_{i=1}^{N+1} \Omega_i^l = \Omega.$$

That is, we want to prove that

$$\lim_{l\to+\infty} \sum_{i=1}^{N+1} \int_{\Omega_i^l} h(x, \hat{u}_i(x))\, dx = \int_\Omega \sum_{i=1}^{N+1} \alpha_i(x) h(x, \hat{u}_i(x))\, dx. \tag{2.7}$$

To prove this, it is enough to prove that for any $g_i(\cdot) \in C(\bar{\Omega})$ $(i = 1, \dots, N+1)$,

$$\sum_{i=1}^{N+1} \int_{\Omega_i^l} g_i(x)\, dx \to \int_\Omega \sum_{i=1}^{N+1} g_i(x)\alpha_i(x)\, dx. \tag{2.8}$$

Now, we construct the sets Ω_i^l.

For each $l \geq 1$, we have $\Omega = \sum_{j=1}^{N_l} Q_j^l$, where

$$\begin{aligned} &Q_j^l \text{ is measurable}, \qquad j = 1, 2, \dots, N_l,\ l = 1, 2, 3, \dots, \\ &Q_j^l \bigcap Q_m^l = \emptyset \qquad \text{if } j \neq m, \end{aligned}$$

and

$$0 < diam\,(Q_j^l) \leq \frac{1}{l}, \qquad j = 1, 2, \dots, N_l,\ l = 1, 2, 3, \dots.$$

Furthermore, we can decompose Q_j^l as

$$Q_j^l = Q_{1,j}^l \bigcup \cdots \bigcup Q_{N+1,j}^l,$$

with $Q_{i,j}^l$ being measurable,

$$Q_{i,j}^l \bigcap Q_{m,j}^l = \emptyset \qquad \text{if } i \neq m,$$

and

$$|Q_{i,j}^l| = \int_{Q_j^l} \alpha_i(x)\, dx.$$

Let $\Omega_i^l = \bigcup_{j=1}^{N_l} Q_{i,j}^l$. Then, for any $g_i(\cdot) \in C(\bar{\Omega})$ $(i = 1, \dots, N+1)$, we get (2.8) from the following:

$$\begin{aligned}
&\int_\Omega \sum_{i=1}^{N+1} g_i(x)\alpha_i(x)\, dx = \sum_{i=1}^{N+1}\sum_{j=1}^{N_l} \int_{Q_j^l} g_i(x)\alpha_i(x)\, dx \\
&= \sum_{i=1}^{N+1}\sum_{j=1}^{N_l} g_i(x_{l,j}) \int_{Q_j^l} \alpha_i(x)\, dx + O\left(\omega\left(\frac{1}{l}\right)\right) \qquad \text{(where } x_{l,j} \in Q_j^l\text{)} \\
&= \sum_{i=1}^{N+1}\sum_{j=1}^{N_l} g_i(x_{l,j})|Q_{i,j}^l| + O\left(\omega\left(\frac{1}{l}\right)\right) = \sum_{i=1}^{N+1}\sum_{j=1}^{N_l} \int_{Q_{i,j}^l} g_i(x)\, dx + O\left(\omega\left(\frac{1}{l}\right)\right) \\
&= \sum_{i=1}^{N+1} \int_{\Omega_i^l} g_i(x)\, dx + O\left(\omega\left(\frac{1}{l}\right)\right),
\end{aligned}$$

where

$$\omega(r) \equiv \max_{|x-\tilde{x}|\le r} \sum_i |g_i(x) - g_i(\tilde{x})| \to 0 \qquad \text{as } r \to 0^+.$$

Consequently, we get (2.8). By this, we can obtain (2.4) easily and complete the proof. □

The relaxed problem corresponding to Problem (C) is the following.

Problem (R). Find a $\bar{\sigma}(\cdot) \in \mathcal{R}(\Omega; U)$ such that

$$J(\bar{\sigma}(\cdot)) = \inf_{\sigma(\cdot)\in\mathcal{R}(\Omega;U)} J(\sigma(\cdot)),$$

where

$$J(\sigma(\cdot)) = \int_\Omega dx \int_U f^0(x, y(x), v)\sigma(x)(dv), \tag{2.9}$$

and $y(\cdot) \equiv y(\cdot; \sigma(\cdot))$ is the solution of the following equation:

$$\begin{cases} -\operatorname{div}\left(\varphi(x, |\nabla y|)\dfrac{\nabla y}{|\nabla y|}\right) = \displaystyle\int_U f(x, y(x), v)\sigma(x)(dv) \quad \text{in } \Omega, \\ y|_{\partial\Omega} = 0. \end{cases} \tag{2.10}$$

It is easy to verify that the maps $(x, y, \sigma) \to \int_U f(x, y, v)\sigma(dv)$ and $(x, y, \sigma) \to \int_U f^0(x, y, v)\sigma(dv)$ have the analogous (S3) and (S4) properties. Moreover, by identifying $u(\cdot) \in \mathcal{U}_{ad}$ with Dirac measure-valued function $\delta_{u(\cdot)} \in \mathcal{R}(\Omega; U)$, $\mathcal{U}_{ad}$ can be looked upon as a subset of $\mathcal{R}(\Omega; U)$. On the other hand, if for some $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$, $\sigma(x) = \delta_{u(x)}$ for almost all $x \in \Omega$, then $u(\cdot)$ must be measurable, that is, $u(\cdot) \in \mathcal{U}_{ad}$. It is easy to see that $J(\delta_{u(\cdot)}), y(\cdot; \delta_{u(\cdot)})$ defined by (1.2), (1.1) are equal to $J(u(\cdot)), y(\cdot; u(\cdot))$ defined by (2.9), (2.10), respectively. Therefore, the notation $J(\sigma(\cdot))$ would not cause any confusion. If an optimal relaxed control $\bar{\sigma}(\cdot)$ corresponding to

Problem (R) has the form $\delta_{\bar{u}(\cdot)}$, then $\bar{u}(\cdot)$ must be an optimal classical control corresponding to Problem (C). This idea can be used to get the existence theorem of an optimal classical control (see [16], [17] for such results in semilinear cases).

When using relaxed control to get the Pontryagin maximum principle for an optimal classical control, one needs to prove that

$$\inf_{u(\cdot)\in\mathcal{U}_{ad}} J(u(\cdot)) = \inf_{\sigma(\cdot)\in\mathcal{R}(\Omega;U)} J(\sigma(\cdot)). \tag{2.11}$$

In the next section, we will prove the above relationship and give some basic properties of states.

3. Approximation lemma. In this section, we want to prove (2.11). First, let us state a lemma which shows that (2.10) (as well as (1.2)) is well posed for any $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$.

LEMMA 3.1. *Let* (S1)–(S3) *hold. Then for any* $\varepsilon \in [0,1]$, $\sigma(\cdot) \in \mathcal{R}(\Omega;U)$, *there exists a unique weak solution* $y_\varepsilon(\cdot) \equiv y_\varepsilon(\cdot;\sigma(\cdot)) \in W_0^{1,p}(\Omega)\bigcap L^\infty(\Omega)$ *of the following equation:*

$$\begin{cases} -\operatorname{div}\left(\varphi(x,\sqrt{\varepsilon^2+|\nabla y_\varepsilon|^2})\dfrac{\nabla y_\varepsilon}{\sqrt{\varepsilon^2+|\nabla y_\varepsilon|^2}}\right) \\ \qquad = \displaystyle\int_U f(x,y_\varepsilon(x),v)\sigma(x)(dv) \quad \text{in } \Omega, \\ y_\varepsilon|_{\partial\Omega} = 0. \end{cases} \tag{3.1}$$

Moreover, there exists a constant $C>0$, *independent of* $\varepsilon \in [0,1]$ *and* $\sigma(\cdot) \in \mathcal{R}(\Omega;U)$, *such that*

$$\|y\|_{L^\infty(\Omega)} \le C. \tag{3.2}$$

Hereafter, $y_\varepsilon(\cdot;\sigma(\cdot))$ denotes the solution of (3.1) corresponding to $\sigma(\cdot)$. The existence of a solution in the above lemma can be proved by the Schauder fixed point theorem, while (3.2) can be obtained by the De Giorgi–Moser estimate. We omit the proofs since it is similar to that of Theorem 6.11 in [13, p. 78].

The following lemma is a special case of Theorem 1 in [14], which shows the regularity of solutions to quasi-linear equations.

LEMMA 3.2. *Let* (S1)–(S2) *hold,* $\varepsilon \in [0,1]$ *and* $v(\cdot) \in L^\infty(\Omega)$. *Suppose that* $y_\varepsilon(\cdot) \in W_0^{1,p}(\Omega)$ *is the solution of the following equation:*

$$\begin{cases} -\operatorname{div}\left(\varphi(x,\sqrt{\varepsilon^2+|\nabla y_\varepsilon|^2}\,)\frac{\nabla y_\varepsilon}{\sqrt{\varepsilon^2+|\nabla y_\varepsilon|^2}}\right) = v \qquad \text{in } \Omega, \\ y_\varepsilon|_{\partial\Omega} = 0. \end{cases} \tag{3.3}$$

Then there exists a constant $C>0$ *and* $\alpha \in (0,1)$ *dependent only on* $p, \lambda, \Lambda, \Omega$ *and the upper bound of* $\|v\|_{L^\infty(\Omega)}$, *independent of* $\varepsilon \in [0,1]$, *such that* $y_\varepsilon(\cdot) \in C^{1,\alpha}(\bar{\Omega})$ *and*

$$\|y_\varepsilon\|_{C^{1,\alpha}(\bar{\Omega})} \le C. \tag{3.4}$$

By Lemma 3.1, for any $\sigma(\cdot) \in \mathcal{R}(\Omega;U)$, the corresponding solution $y_\varepsilon(\cdot;\sigma(\cdot))$ to (3.1) is bounded uniformly in $L^\infty(\Omega)$. Thus, by (S3), for any $\sigma(\cdot) \in \mathcal{R}(\Omega;U)$, the right-hand term in (3.1) is bounded uniformly in $L^\infty(\Omega)$. Then, using Lemma 3.2, we get the following proposition.

PROPOSITION 3.3. *Let* (S1)–(S3) *hold. Then there exists a constant* $C > 0$ *and* $\alpha \in (0,1)$*, independent of* $\varepsilon \in [0,1]$ *and* $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$*, such that*

$$\|y_\varepsilon(\cdot;\sigma(\cdot))\|_{C^{1,\alpha}(\bar\Omega)} \leq C. \tag{3.5}$$

LEMMA 3.4. *Let* $1 < p < +\infty$*,* $\psi(\cdot) \in C[0,+\infty) \bigcap C^1(0,+\infty)$ *satisfy* $\psi(0) = 0$*. Moreover, there exist* $\Lambda > \lambda > 0$ *such that*

$$\lambda s^{p-2} \leq \psi'(s) \leq \Lambda s^{p-2} \qquad \forall\ s \in (0,+\infty). \tag{3.6}$$

Then, there exists a constant $C = C(p,\lambda,\Lambda) > 0$ *such that for any* $a, b \in \mathbb{R}^m$*,*

$$\left(\psi(|a|)\frac{a}{|a|} - \psi(|b|)\frac{b}{|b|}\right)\cdot(a-b) \geq \begin{cases} C|a-b|^p & \text{if } p \geq 2, \\ C\frac{|a-b|^2}{(|a|+|b|)^{2-p}} & \text{if } 1 < p < 2. \end{cases} \tag{3.7}$$

The above lemma can be obtained with the same argument to that of Lemma 1 in [24] by taking $a_j(x,\eta) = \psi(|\eta|)\frac{\eta_j}{|\eta|}$ and $\kappa = 0$. (This last fact implies that the inequality holds without the term 1, in the case $1 < p < 2$.)

Now, we give the main result of this section.

LEMMA 3.5. *Let* (S1)–(S4) *hold. Then for any* $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$*, there exists* $\{u_k(\cdot)\} \subset \mathcal{U}_{ad}$ *such that*

$$J(u_k(\cdot)) \to J(\sigma(\cdot)) \qquad \text{as } k \to +\infty. \tag{3.8}$$

Consequently, (2.11) *holds.*

Proof. Denote $y(\cdot) = y(\cdot;\sigma(\cdot))$ and

$$(h_1(x,v), h_2(x,v)) = (f(x,y(x),v), f^0(x,y(x),v)).$$

Then $h_i \in L^\infty(\Omega; C(U))$ by Lemma 3.1 and (S3)–(S4). Thus, by Lemma 2.4, there exists $\{u_k(\cdot)\} \subset \mathcal{U}_{ad}$ such that

$$\lim_{k\to+\infty}\int_\Omega h^0(x) f(x,y(x),u_k(x))\,dx = \int_\Omega dx \int_U h^0(x) f(x,y(x),v)\sigma(x)(dv) \qquad \forall\ h^0(\cdot) \in C(\bar\Omega) \tag{3.9}$$

and

$$\lim_{k\to+\infty}\int_\Omega f^0(x,y(x),u_k(x))\,dx = \int_\Omega dx \int_U f^0(x,y(x),v)\sigma(x)(dv). \tag{3.10}$$

Then it follows from $y(\cdot) = y(\cdot;\sigma(\cdot))$ that

$$\begin{cases} -\operatorname{div}\left(\varphi(x,|\nabla y|)\dfrac{\nabla y}{|\nabla y|}\right) = f(x,y(x),u_k(x)) + r_k(x) & \text{in } \Omega, \\ y|_{\partial\Omega} = 0, \end{cases} \tag{3.11}$$

where

$$\lim_{k\to+\infty}\int_\Omega h^0(x) r_k(x)\,dx = 0 \qquad \forall\ h^0(\cdot) \in C(\bar\Omega). \tag{3.12}$$

Let $y_k(\cdot) = y(\cdot; u_k(\cdot))$, i.e.,

$$\begin{cases} -\operatorname{div}\left(\varphi(x, |\nabla y_k|)\dfrac{\nabla y_k}{|\nabla y_k|}\right) = f(x, y_k(x), u_k(x)) & \text{in } \Omega, \\ y_k|_{\partial\Omega} = 0. \end{cases} \tag{3.13}$$

By Proposition 3.3, $y_k(\cdot)$ is uniformly bounded in $C^{1+\alpha}(\bar{\Omega})$. Thus, at least in the sense of a subsequence, we can suppose that

$$y_k(\cdot) \to \tilde{y}(\cdot) \qquad \text{uniformly in } \ C^1(\bar{\Omega}).$$

Thus, by (3.11) and noting that

$$|f(x, y(x), u_k(x))| \le C,$$

we have

$$\begin{aligned} &\int_\Omega r_k(x)(y_k(x) - \tilde{y}(x))\, dx \\ &= \int_\Omega \varphi(x, |\nabla y|)\frac{\nabla y}{|\nabla y|} \cdot \nabla(y_k - \tilde{y})\, dx - \int_\Omega (y_k - \tilde{y}) f(x, y(x), u_k(x))\, dx \\ &\to 0 \qquad \text{as } k \to +\infty. \end{aligned}$$

Thus, by (3.11)–(3.13) and (1.4), we get

$$\begin{aligned} &\int_\Omega \left(\varphi(x, |\nabla y|)\frac{\nabla y}{|\nabla y|} - \varphi(x, |\nabla y_k|)\frac{\nabla y_k}{|\nabla y_k|}\right) \cdot \nabla(y - y_k)\, dx \\ &\le \int_\Omega r_k(x)(y(x) - y_k(x))\, dx \\ &\le \int_\Omega r_k(x)(y(x) - \tilde{y}(x))\, dx + \int_\Omega r_k(x)(\tilde{y}(x) - y_k(x))\, dx \\ &\to 0 \qquad \text{as } k \to +\infty. \end{aligned}$$

Then by Lemma 3.4, we get that

$$\tilde{y}(x) = y(x), \qquad \text{a.e. } \Omega.$$

Therefore,

$$y_k(\cdot) \to y(\cdot) \qquad \text{uniformly in } \ C^1(\bar{\Omega}),$$

not only in the sense of a subsequence. Finally, by (3.10),

$$\begin{aligned} J(u_k(\cdot)) &= \int_\Omega f^0(x, y_k(x), u_k(x))\, dx \\ &= \int_\Omega \Big(f^0(x, y_k(x), u_k(x)) - f^0(x, y(x), u_k(x))\Big)\, dx \\ &\quad + \int_\Omega f^0(x, y(x), u_k(x))\, dx \\ &\to J(\sigma(\cdot)), \end{aligned}$$

since

$$|f^0(x, y_k(x), u_k(x)) - f^0(x, y(x), u_k(x))| \le C|y_k(x) - y(x)|,$$

for some constant $C > 0$. Thus, we get the proof. ∎

4. Maximum principle for optimal pair to approximate problem. We will yield the maximum principle for Problem (C) from that for corresponding approximate problems in the next section. In this section, we consider the corresponding (relaxed) approximate problems.

Let $\bar{u}(\cdot) \in \mathcal{U}_{ad}$ be an optimal control to Problem (C), and let $\bar{y}(\cdot) \in W_0^{1,p}(\Omega)$ be the optimal state corresponding to $\bar{u}(\cdot)$. For $\varepsilon > 0$, $\tau \in (0,1)$, consider (3.1) and

$$J_{\tau,\varepsilon}(\sigma(\cdot)) = \int_\Omega dx \int_U f^{0,\tau}(x, y_\varepsilon(x), v)\, \sigma(x)(dv), \tag{4.1}$$

where $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$, $y_\varepsilon(\cdot) = y_\varepsilon(\cdot; \sigma(\cdot))$,

$$f^{0,\tau}(x,y,v) = f^0(x,y,v) + \frac{\tau\rho(v, \bar{u}(x))}{1+\rho(v,\bar{u}(x))} \qquad \forall\, (x,y,v) \in \Omega \times \mathbb{R} \times U, \tag{4.2}$$

and $\rho(v,w)$ denotes the distance between $v, w \in U$. We want to find the necessary condition of a $\bar{\sigma}_{\tau,\varepsilon}(\cdot) \in \mathcal{R}(\Omega; U)$ satisfying

$$J_{\tau,\varepsilon}(\bar{\sigma}_{\tau,\varepsilon}(\cdot)) = \inf_{\sigma(\cdot)\in\mathcal{R}(\Omega;U)} J_{\tau,\varepsilon}(\sigma(\cdot)). \tag{4.3}$$

First, we give the following lemma, which shows the existence of such $\bar{\sigma}_{\tau,\varepsilon}(\cdot)$'s and the relation between $\bar{\sigma}_{\tau,\varepsilon}(\cdot)$ and $\bar{u}(\cdot)$.

LEMMA 4.1. *Suppose that* (S1)–(S4) *holds. Then for any* $\tau, \varepsilon \in (0,1)$, *there exists a* $\bar{\sigma}_{\tau,\varepsilon}(\cdot) \in \mathcal{R}(\Omega; U)$ *satisfying* (4.3). *Moreover* (*as* $\varepsilon \to 0^+$),

$$\bar{\sigma}_{\tau,\varepsilon}(\cdot) \xrightarrow{\mathcal{N}} \delta_{\bar{u}(\cdot)} \qquad \text{in } \mathcal{R}(\Omega; U).$$

Proof. By Proposition 3.3, there exist positive constants $C > 0$ and $\alpha \in (0,1)$, independent of $\varepsilon \in (0,1)$, such that for any $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$,

$$\|y_\varepsilon(\cdot; \sigma(\cdot))\|_{C^{1,\alpha}(\bar{\Omega})} \le C. \tag{4.4}$$

Thus, it follows from (S4) that

$$\inf_{\sigma(\cdot)\in\mathcal{R}(\Omega;U)} J_{\tau,\varepsilon}(\sigma(\cdot)) > -\infty.$$

Let $\sigma_{\tau,\varepsilon,k}(\cdot) \in \mathcal{R}(\Omega; U)$ satisfy

$$\lim_{k\to+\infty} J_{\tau,\varepsilon}(\sigma_{\tau,\varepsilon,k}(\cdot)) = \inf_{\sigma(\cdot)\in\mathcal{R}(\Omega;U)} J_{\tau,\varepsilon}(\sigma(\cdot)).$$

Let $y_{\tau,\varepsilon,k}(\cdot) = y_\varepsilon(\cdot; \sigma_{\tau,\varepsilon,k}(\cdot))$. Then by (4.4), we can suppose that

$$y_{\tau,\varepsilon,k}(\cdot) \to \bar{y}_{\tau,\varepsilon}(\cdot) \qquad \text{uniformly in } \ C^1(\bar{\Omega}),$$

without losing generality. By Lemma 2.3, there exist $\bar{\sigma}_{\tau,\varepsilon}(\cdot) \in \mathcal{R}(\Omega; U)$ such that (as $k \to +\infty$),

$$\sigma_{\tau,\varepsilon,k}(\cdot) \xrightarrow{\mathcal{N}} \bar{\sigma}_{\tau,\varepsilon}(\cdot) \qquad \text{in } \mathcal{R}(\Omega; U).$$

Consequently, it follows from Lebesgue's dominated convergence theorem that for any $\psi(\cdot) \in C_0^\infty(\Omega)$,

$$\begin{aligned}
&\lim_{k\to+\infty} \int_\Omega \varphi\left(x, \sqrt{\varepsilon^2 + |\nabla y_{\tau,\varepsilon,k}|^2}\right) \frac{\nabla y_{\tau,\varepsilon,k}}{\sqrt{\varepsilon^2 + |\nabla y_{\tau,\varepsilon,k}|^2}} \cdot \nabla\psi \, dx \\
&\quad = \int_\Omega \varphi\left(x, \sqrt{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}\right) \frac{\nabla \bar{y}_{\tau,\varepsilon}}{\sqrt{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}} \cdot \nabla\psi \, dx.
\end{aligned}$$

Moreover, there exists a subsequence $\sigma_{\tau,\varepsilon,k_j}(\cdot)$ (which may be different for different $\psi(\cdot)$) of $\sigma_{\tau,\varepsilon,k}(\cdot)$ such that

$$\begin{aligned}\lim_{k\to+\infty}\int_\Omega dx\int_U \psi(x)f(x,y_{\tau,\varepsilon,k_j}(x),v)\,\sigma_{\tau,\varepsilon,k_j}(x)(dv)\\ =\int_\Omega dx\int_U \psi(x)f(x,\bar y_{\tau,\varepsilon}(x),v)\,\bar\sigma_{\tau,\varepsilon}(x)(dv).\end{aligned}\tag{4.5}$$

This means that $\bar y_{\tau,\varepsilon}(\cdot)=y_\varepsilon(\cdot;\bar\sigma_{\tau,\varepsilon}(\cdot))$. Consequently, as (4.5), we can get

$$\lim_{k\to+\infty} J_{\tau,\varepsilon}(\sigma_{\tau,\varepsilon,k}(\cdot))=J_{\tau,\varepsilon}(\bar\sigma_{\tau,\varepsilon}(\cdot)).$$

That is, $\bar\sigma_{\tau,\varepsilon}(\cdot)$ satisfies (4.3).

Now, we turn to see the relation between $\bar\sigma_{\tau,\varepsilon}(\cdot)$ and $\bar u(\cdot)$. Let

$$J_\tau(\sigma(\cdot))=J(\sigma(\cdot))+\int_\Omega dx\int_U\frac{\tau\rho(v,\bar u(x))}{1+\rho(v,\bar u(x))}\,\sigma(x)(dv).\tag{4.6}$$

By a similar discussion to that above, we can get a $\bar\sigma_\tau(\cdot)\in\mathcal{R}(\Omega;U)$ such that (as $\varepsilon\to0^+$)

$$\bar\sigma_{\tau,\varepsilon}(\cdot)\xrightarrow{\mathcal{N}}\bar\sigma_\tau(\cdot)\qquad\text{in }\mathcal{R}(\Omega;U)\tag{4.7}$$

and

$$J_\tau(\bar\sigma_\tau(\cdot))=\inf_{\sigma(\cdot)\in\mathcal{R}(\Omega;U)}J_\tau(\sigma(\cdot)).$$

Thus,

$$J_\tau(\bar\sigma_\tau(\cdot))\le J_\tau(\delta_{\bar u(\cdot)})=J(\delta_{\bar u(\cdot)}).$$

On the other hand, by Lemma 3.5,

$$J(\delta_{\bar u(\cdot)})\le J(\bar\sigma_\tau(\cdot)).$$

Combining the above two inequalities, we have

$$\int_\Omega dx\int_U\frac{\tau\rho(v,\bar u(x))}{1+\rho(v,\bar u(x))}\,\bar\sigma_\tau(x)(dv)=0.$$

Therefore,

$$\int_U\frac{\rho(v,\bar u(x))}{1+\rho(v,\bar u(x))}\,\bar\sigma_\tau(x)(dv)=0,\qquad\text{a.e. }x\in\Omega.$$

By Lemma 4.2, which we will prove later, we have

$$\bar\sigma_\tau(x)=\delta_{\bar u(x)},\qquad\text{a.e. }x\in\Omega.$$

Thus, it follows from (4.7) that (as $\varepsilon\to0^+$)

$$\bar\sigma_{\tau,\varepsilon}(\cdot)\xrightarrow{\mathcal{N}}\delta_{\bar u(\cdot)}.$$

The proof is completed. □

LEMMA 4.2. *Suppose that* $\mu \in \mathcal{M}_+^1(U)$ *and*

$$\int_U \frac{\rho(v,w)}{1+\rho(v,w)}\,\mu(dv) = 0, \tag{4.8}$$

for some $w \in U$. *Then* $\mu = \delta_w$.

Proof. If μ is an infinitive additive probability measure, then it is natural to get $\mu = \delta_w$ from (4.8). Yet, generally, for a nonnegative finite additive measure μ and a nonnegative function $h(\cdot)$ on U, one cannot get $h = 0$, μ a.e. U, from $\int_U h(v)\,\mu(dv) = 0$ (see [8]).

To prove the lemma, we need to prove that

$$\mu\{v \in U | \rho(v,w) > 0\} = 0.$$

By (4.8), for all $\alpha > 0$,

$$\mu\left\{v \in U | \frac{\rho(v,w)}{1+\rho(v,w)} \geq \frac{\alpha}{1+\alpha}\right\} = 0.$$

That is,

$$\mu\{v \in U | \rho(v,w) \geq \alpha\} = 0 \qquad \forall\, \alpha > 0.$$

Let $A = \{v \in U | \rho(v,w) > 0\}$, $A_\alpha = \{v \in U | 0 < \rho(v,w) < \alpha\}$ $(\alpha > 0)$. Then, A, A_α are open. Consequently, $A, A_\alpha \in \mathcal{F}$, and

$$\mu(A) = \mu(A_\alpha) \qquad \forall\, \alpha > 0.$$

Noting that μ is regular for all $\delta > 0$, there exists $B, D \in \mathcal{F}$ such that

$$\mathrm{cl}(B) \subseteq A \subseteq \mathrm{int}(D), \quad \mu(D \setminus B) < \delta.$$

Since $w \notin A$, $w \notin \mathrm{cl}(B)$. Therefore there exists a $\beta > 0$ such that

$$\{v \in U | \rho(v,w) < \beta\} \cap \mathrm{cl}(B) = \emptyset.$$

On the other hand, $A \subseteq \mathrm{int}(D) \subseteq D$. Thus,

$$(D \setminus B) \supseteq (A \setminus B) \supseteq A_\beta.$$

Therefore,

$$\delta > \mu(D \setminus B) = \mu((D \setminus B) \setminus A_\beta) + \mu(A_\beta) \geq \mu(A_\beta) = \mu(A).$$

Consequently, $\mu(A) = 0$. We get the proof. □

Now, we give the necessary condition of optimal pair $(\bar{y}_{\tau,\varepsilon}(\cdot), \bar{\sigma}_{\tau,\varepsilon}(\cdot))$ in the following lemma.

LEMMA 4.3. *Let* $\tau, \varepsilon \in (0,1)$. *Suppose that* (S1)–(S4) *hold,* $\bar{\sigma}_{\tau,\varepsilon}(\cdot) \in \mathcal{R}(\Omega; U)$ *satisfies* (4.3), $\bar{y}_{\tau,\varepsilon}(\cdot) = y_\varepsilon(\cdot; \bar{\sigma}_{\tau,\varepsilon}(\cdot))$. *Then there exists a* $\bar{\psi}_{\tau,\varepsilon}(\cdot) \in W_0^{1,2}(\Omega)$ *such that*

$$\left\{\begin{array}{l} -\mathrm{div}\left\{\left[\dfrac{\varphi(x, \sqrt{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}\,)}{\sqrt{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}}\left(I - \dfrac{\nabla \bar{y}_{\tau,\varepsilon}(\nabla \bar{y}_{\tau,\varepsilon})^T}{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}\right)\right.\right. \\ \qquad\qquad \left.\left. + \varphi_s\left(x, \sqrt{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}\,\right)\,\dfrac{\nabla \bar{y}_{\tau,\varepsilon}(\nabla \bar{y}_{\tau,\varepsilon})^T}{\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2}\right]\nabla \bar{\psi}_{\tau,\varepsilon}\right\} \\ \qquad = \displaystyle\int_U \left[f_y(x, \bar{y}_{\tau,\varepsilon}, v)\bar{\psi}_{\tau,\varepsilon} - f_y^0(x, \bar{y}_{\tau,\varepsilon}, v)\right]\,\bar{\sigma}_{\tau,\varepsilon}(x)(dv) \text{ in } \Omega, \\ \bar{\psi}_{\tau,\varepsilon}|_{\partial\Omega} = 0, \end{array}\right. \tag{4.9}$$

and

$$\int_\Omega dx \int_U \left[f(x, \bar{y}_{\tau,\varepsilon}(x), v)\bar{\psi}_{\tau,\varepsilon}(x) - f^0(x, \bar{y}_{\tau,\varepsilon}(x), v) - \frac{\tau\rho(v, \bar{u}(x))}{1+\rho(v, \bar{u}(x))} \right] (\sigma(x) - \bar{\sigma}_{\tau,\varepsilon}(x))(dv) \le 0 \qquad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega; U). \tag{4.10}$$

Proof. The proof of the above lemma is quite standard, relatively easy, and similar to the proof of Theorem 3.1 in [3]. It can be got quite directly from

$$0 \le J_{\tau,\varepsilon}(\bar{\sigma}_{\tau,\varepsilon}(\cdot) + \delta(\sigma(\cdot) - \bar{\sigma}_{\tau,\varepsilon}(\cdot))) - J_{\tau,\varepsilon}(\bar{\sigma}_{\tau,\varepsilon}(\cdot)) \qquad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega; U),\ \delta \in (0,1).$$

We give a sketch of the proof. Let $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$, $\sigma^\delta_{\tau,\varepsilon}(\cdot) = \bar{\sigma}_{\tau,\varepsilon}(\cdot) + \delta(\sigma(\cdot) - \bar{\sigma}_{\tau,\varepsilon}(\cdot))$. Then $\sigma^\delta_{\tau,\varepsilon}(\cdot) \in \mathcal{R}(\Omega; U)$, and we have

$$0 \le J_{\tau,\varepsilon}(\sigma^\delta_{\tau,\varepsilon}(\cdot)) - J_{\tau,\varepsilon}(\bar{\sigma}(\cdot)) \qquad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega; U),\ \delta \in (0,1).$$

Let $y^\delta_{\tau,\varepsilon}(\cdot) = y_\varepsilon(\cdot; \sigma^\delta_{\tau,\varepsilon}(\cdot))$. Denoting

$$\eta^{\delta,t}_{\tau,\varepsilon}(\cdot) = \nabla \bar{y}_{\tau,\varepsilon}(\cdot) + t(\nabla y^\delta_{\tau,\varepsilon}(\cdot) - \nabla \bar{y}_{\tau,\varepsilon}(\cdot)), \qquad t \in [0,1],$$

$$A^\delta_{\tau,\varepsilon} = \int_0^1 \left[\frac{\varphi\Big(x, \sqrt{\varepsilon^2 + |\eta^{\delta,t}_{\tau,\varepsilon}|^2}\Big)}{\sqrt{\varepsilon^2 + |\eta^{\delta,t}_{\tau,\varepsilon}|^2}} \left(I - \frac{\eta^{\delta,t}_{\tau,\varepsilon} \left(\eta^{\delta,t}_{\tau,\varepsilon}\right)^T}{\varepsilon^2 + |\eta^{\delta,t}_{\tau,\varepsilon}|^2} \right) + \varphi_s\left(x, \sqrt{\varepsilon^2 + |\eta^{\delta,t}_{\tau,\varepsilon}|^2}\right) \frac{\eta^{\delta,t}_{\tau,\varepsilon} \left(\eta^{\delta,t}_{\tau,\varepsilon}\right)^T}{\varepsilon^2 + |\eta^{\delta,t}_{\tau,\varepsilon}|^2} \right] dt,$$

$$b^\delta_{\tau,\varepsilon} = \int_U \left[\int_0^1 f_y(x, \bar{y}_{\tau,\varepsilon} + t(y^\delta_{\tau,\varepsilon} - \bar{y}_{\tau,\varepsilon}), v)\, dt \right] \bar{\sigma}_{\tau,\varepsilon}(x)(dv),$$

$$c^\delta_{\tau,\varepsilon} = \int_U f(x, y^\delta_{\tau,\varepsilon}, v)\, (\sigma(x) - \bar{\sigma}_{\tau,\varepsilon}(x))(dv),$$

and

$$Y^\delta_{\tau,\varepsilon} = \frac{y^\delta_{\tau,\varepsilon} - \bar{y}_{\tau,\varepsilon}}{\delta},$$

we have

$$\begin{cases} -\operatorname{div}(A^\delta_{\tau,\varepsilon}\, \nabla Y^\delta_{\tau,\varepsilon}) = b^\delta_{\tau,\varepsilon} Y^\delta_{\tau,\varepsilon} + c^\delta_{\tau,\varepsilon}, & \text{in } \Omega, \\ Y^\delta_{\tau,\varepsilon}\big|_{\partial\Omega} = 0. \end{cases} \tag{4.11}$$

On the other hand, by Proposition 3.3,

$$\|y^\delta_{\tau,\varepsilon}(\cdot)\|_{C^{1,\alpha}(\bar{\Omega})}, \|\bar{y}_{\tau,\varepsilon}(\cdot)\|_{C^{1,\alpha}(\bar{\Omega})} \le C \tag{4.12}$$

for some $C > 0$ independent of $\delta \in (0,1)$. Consequently

$$\|\eta^{\delta,t}_{\tau,\varepsilon}\|_{C^\alpha(\bar\Omega)} \le C \qquad \forall\, t \in [0,1].$$

Therefore, for some $\beta > 0$

$$\|A^\delta_{\tau,\varepsilon}\|_{C^\beta(\bar\Omega;\mathbb{R}^{n\times n})} \le C, \tag{4.13}$$

and by (S3)

$$\|b^\delta_{\tau,\varepsilon}\|_{L^\infty(\Omega)} \le C,$$

$$\|c^\delta_{\tau,\varepsilon}\|_{L^\infty(\Omega)} \le C.$$

Then it follows easily from (4.11) and (S2) that

$$\|Y^\delta_{\tau,\varepsilon}\|_{W^{1,2}_0(\Omega)} \le C_\varepsilon$$

for some positive constant C_ε, independent of δ. Thus (as $\delta \to 0^+$),

$$y^\delta_{\tau,\varepsilon} = \bar y_{\tau,\varepsilon} + \delta Y^\delta_{\tau,\varepsilon} \to \bar y_{\tau,\varepsilon} \qquad \text{strongly in } W^{1,2}_0(\Omega). \tag{4.14}$$

Combining (4.14) with (4.12), we get that

$$y^\delta_{\tau,\varepsilon} \to \bar y_{\tau,\varepsilon} \qquad \text{uniformly in } C^1(\bar\Omega).$$

Therefore, at least in the sense of a subsequence,

$$\begin{aligned} A^\delta_{\tau,\varepsilon} \to A_{\tau,\varepsilon} \equiv{}& \frac{\varphi(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,)}{\sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}} \left(I - \frac{\nabla \bar y_{\tau,\varepsilon} \left(\nabla \bar y_{\tau,\varepsilon}\right)^T}{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2} \right) \\ &+ \varphi_s \left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\, \right) \frac{\nabla \bar y_{\tau,\varepsilon} \left(\nabla \bar y_{\tau,\varepsilon}\right)^T}{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2} \\ &\text{uniformly in } C(\bar\Omega; \mathbb{R}^{n\times n}), \end{aligned}$$

$$\begin{aligned} b^\delta_{\tau,\varepsilon} \to b_{\tau,\varepsilon} \equiv{}& \int_U f_y(x, \bar y_{\tau,\varepsilon}, v) \bar\sigma_{\tau,\varepsilon}(x)(dv) \\ &\text{strongly in } L^2(\Omega), \\ c^\delta_{\tau,\varepsilon} \to c_{\tau,\varepsilon} \equiv{}& \int_U f(x, \bar y_{\tau,\varepsilon}, v)\, (\sigma(x) - \bar\sigma_{\tau,\varepsilon}(x))(dv) \\ &\text{strongly in } L^2(\Omega). \end{aligned}$$

Consequently,

$$Y^\delta_{\tau,\varepsilon}(\cdot) \to Y(\cdot) \qquad \text{strongly in } W^{1,2}_0(\Omega), \tag{4.15}$$

with $Y(\cdot)$ being the solution of the following equation:

$$\begin{cases} -\operatorname{div}\left(A_{\tau,\varepsilon} \nabla Y\right) = b_{\tau,\varepsilon} Y + c_{\tau,\varepsilon} & \text{in } \Omega, \\ Y|_{\partial\Omega} = 0. \end{cases} \tag{4.16}$$

Since $Y(\cdot) \in W_0^{1,2}(\Omega)$ is the unique solution of (4.16), we really get that (4.15) holds not only in the sense of a subsequence, though the convergence of a subsequence is enough in application. Now, it follows from the following inequality,

$$\begin{aligned}
0 &\le \frac{1}{\delta}\left(J_{\tau,\varepsilon}(\sigma^{\delta}_{\tau,\varepsilon}(\cdot)) - J_{\tau,\varepsilon}(\bar\sigma_{\tau,\varepsilon}(\cdot))\right)\\
&= \int_\Omega \left\{ Y^{\delta}_{\tau,\varepsilon} \int_U \left[\int_0^1 f^0_y(x, \bar y_{\tau,\varepsilon} + t(y^{\delta}_{\tau,\varepsilon} - \bar y_{\tau,\varepsilon}), v)\, dt\right] \bar\sigma_{\tau,\varepsilon}(x)(dv)\right\} dx\\
&\qquad + \int_\Omega dx \int_U f^{0,\tau}(x, y^{\delta}_{\tau,\varepsilon}, v)\, (\sigma(x) - \bar\sigma_{\tau,\varepsilon}(x))(dv),
\end{aligned}$$

that

$$\begin{aligned}
0 \le \int_\Omega \Big\{ Y(x) \int_U f^0_y(x, \bar y_{\tau,\varepsilon}(x), v)\, \bar\sigma_{\tau,\varepsilon}(x)(dv)\\
+ \int_U f^{0,\tau}(x, \bar y_{\tau,\varepsilon}(x), v)\, (\sigma(x) - \bar\sigma_{\tau,\varepsilon}(x))(dv)\Big\}\, dx.
\end{aligned} \tag{4.17}$$

Let $\bar\psi_{\tau,\varepsilon}(\cdot) \in W_0^{1,2}(\Omega)$ satisfy (4.9). We get (4.10) from (4.17). □

5. Proofs of the main theorems. Now, we will give the proofs of Theorems 1.1–1.3. Let $\bar y_{\tau,\varepsilon}(\cdot), \bar\sigma_{\tau,\varepsilon}(\cdot)$, and $\bar\psi_{\tau,\varepsilon}(\cdot)$ be given in Lemma 4.3.

Proof of Theorem 1.1. By (S2), we have

$$\varphi(x,s) \ge \frac{\lambda}{p-1} s^{p-1} \qquad \forall\, (x,s) \in \bar\Omega \times (0, +\infty).$$

For $x \in \Omega$, $\tau, \varepsilon \in (0,1)$, if

$$h_{\tau,\varepsilon}(x) \equiv \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\, \varphi_s\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) - \varphi\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) \ge 0,$$

then

$$\begin{aligned}
&\varphi\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) \frac{|\nabla \bar\psi_{\tau,\varepsilon}|^2}{\sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}} + h_{\tau,\varepsilon}(x) \frac{(\nabla \bar\psi_{\tau,\varepsilon})^T \nabla \bar y_{\tau,\varepsilon} \nabla \bar y^T_{\tau,\varepsilon} \nabla \bar\psi_{\tau,\varepsilon}}{(\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2)^{\frac{3}{2}}}\\
&\ge \varphi\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) \frac{|\nabla \bar\psi_{\tau,\varepsilon}|^2}{\sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}} \ge \frac{\lambda}{p-1} (\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2)^{\frac{p-2}{2}} |\nabla \bar\psi_{\tau,\varepsilon}|^2.
\end{aligned}$$

Otherwise,

$$\begin{aligned}
&\varphi\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) \frac{|\nabla \bar\psi_{\tau,\varepsilon}|^2}{\sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}} + h_{\tau,\varepsilon}(x) \frac{(\nabla \bar\psi_{\tau,\varepsilon})^T \nabla \bar y_{\tau,\varepsilon} \nabla \bar y^T_{\tau,\varepsilon} \nabla \bar\psi_{\tau,\varepsilon}}{(\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2)^{\frac{3}{2}}}\\
&\ge \varphi_s\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) |\nabla \bar\psi_{\tau,\varepsilon}|^2 \ge \lambda (\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2)^{\frac{p-2}{2}} |\nabla \bar\psi_{\tau,\varepsilon}|^2.
\end{aligned}$$

Thus, there exists a constant λ_0 (independent of $\tau, \varepsilon \in (0,1)$, $x \in \bar\Omega$) such that

$$\begin{aligned}
&\varphi\left(x, \sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}\,\right) \frac{|\nabla \bar\psi_{\tau,\varepsilon}|^2}{\sqrt{\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2}} + h_{\tau,\varepsilon}(x) \frac{(\nabla \bar\psi_{\tau,\varepsilon})^T \nabla \bar y_{\tau,\varepsilon} \nabla \bar y^T_{\tau,\varepsilon} \nabla \bar\psi_{\tau,\varepsilon}}{(\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2)^{\frac{3}{2}}}\\
&\ge \lambda_0 (\varepsilon^2 + |\nabla \bar y_{\tau,\varepsilon}|^2)^{\frac{p-2}{2}} |\nabla \bar\psi_{\tau,\varepsilon}|^2.
\end{aligned} \tag{5.1}$$

Thus, it follows from (4.9), Proposition 3.3, and (S3)–(S4) that

$$
\begin{aligned}
(5.2)\qquad & \lambda_0 \int_\Omega (\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2)^{\frac{p-2}{2}} |\nabla \bar{\psi}_{\tau,\varepsilon}|^2 \, dx \\
&\le \int_\Omega dx \int_U \left[f_y(x, \bar{y}_{\tau,\varepsilon}, v) \bar{\psi}^2_{\tau,\varepsilon} - f^0_y(x, \bar{y}_{\tau,\varepsilon}, v) \bar{\psi}_{\tau,\varepsilon} \right] \bar{\sigma}(x)(dv) \\
&\le - \int_\Omega dx \int_U f^0_y(x, \bar{y}_{\tau,\varepsilon}, v) \bar{\psi}_{\tau,\varepsilon} \, \bar{\sigma}(x)(dv) \\
&\le C \int_\Omega |\bar{\psi}_{\tau,\varepsilon}(x)| \, dx.
\end{aligned}
$$

Since $1 < p < 2$, we get

$$
\begin{aligned}
&\lambda_0 \int_\Omega |\nabla \bar{\psi}_{\tau,\varepsilon}|^2 \, dx \\
&\quad \le \lambda_0 \| \varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2 \|^{\frac{2-p}{2}}_{L^\infty(\Omega)} \int_\Omega (\varepsilon^2 + |\nabla \bar{y}_{\tau,\varepsilon}|^2)^{\frac{p-2}{2}} |\nabla \bar{\psi}_{\tau,\varepsilon}|^2 \, dx \\
&\quad \le C \int_\Omega |\bar{\psi}_{\tau,\varepsilon}(x)| \, dx.
\end{aligned}
$$

Consequently,

$$
\|\bar{\psi}_{\tau,\varepsilon}\|_{W^{1,2}_0(\Omega)} \le C. \tag{5.3}
$$

Thus (see [1] and [26]), we can suppose that (at least in the sense of subsequence), as $\varepsilon \to 0^+$,

$$
\bar{\psi}_{\tau,\varepsilon}(\cdot) \to \bar{\psi}_\tau(\cdot) \qquad \text{weakly in } \ W^{1,2}_0(\Omega), \text{ strongly in } \ L^2(\Omega). \tag{5.4}
$$

Moreover,

$$
\|\bar{\psi}_\tau\|_{W^{1,2}_0(\Omega)} \le C. \tag{5.5}
$$

On the other hand, by Proposition 3.3, we can suppose that, as $\varepsilon \to 0^+$,

$$
\bar{y}_{\tau,\varepsilon}(\cdot) \to \tilde{y}_\tau(\cdot) \qquad \text{uniformly in } C^1(\bar{\Omega}). \tag{5.6}
$$

By Lemma 4.1,

$$
\bar{\sigma}_{\tau,\varepsilon}(\cdot) \xrightarrow{\mathcal{N}} \delta_{\bar{u}(\cdot)} \qquad \text{in } \mathcal{R}(\Omega; U). \tag{5.7}
$$

Then, it is easy to see that $\tilde{y}_\tau(\cdot) = \bar{y}(\cdot)$. Denoting

$$
H^\tau(x, y, v, \psi) = f(x, y, v)\psi - f^{0,\tau}(x, y, v) \qquad \forall\, (x, y, v, \psi) \in \mathbb{R}^n \times \mathbb{R} \times U \times \mathbb{R}^n,
$$

by (4.10), for any $\sigma(\cdot) \in \mathcal{R}(\Omega; U)$, we have

(5.8)

$$
\begin{aligned}
0 &\ge \int_\Omega dx \int_U H^\tau(x, \bar{y}_{\tau,\varepsilon}(x), v, \bar{\psi}_{\tau,\varepsilon}(x))(\sigma(x) - \bar{\sigma}_{\tau,\varepsilon}(x))(dv) \\
&= \int_\Omega dx \int_U \Big(H^\tau(x, \bar{y}_{\tau,\varepsilon}(x), v, \bar{\psi}_{\tau,\varepsilon}(x)) - H^\tau(x, \bar{y}(x), v, \bar{\psi}_{\tau,\varepsilon}(x)) \Big)(\sigma(x) - \bar{\sigma}_{\tau,\varepsilon}(x))(dv) \\
&\quad + \int_\Omega dx \int_U \Big(H^\tau(x, \bar{y}(x), v, \bar{\psi}_{\tau,\varepsilon}(x)) - H^\tau(x, \bar{y}(x), v, \bar{\psi}_\tau(x)) \Big)(\sigma(x) - \bar{\sigma}_{\tau,\varepsilon}(x))(dv) \\
&\quad + \int_\Omega dx \int_U H^\tau(x, \bar{y}(x), v, \bar{\psi}_\tau(x))(\sigma(x) - \bar{\sigma}_{\tau,\varepsilon}(x))(dv) \\
&\equiv I_1 + I_2 + I_3.
\end{aligned}
$$

By (5.3), (5.6), and (S3)–(S4), we have (as $\varepsilon \to 0^+$)

$$
\begin{aligned}
(5.9)\qquad |I_1| &\le C \int_\Omega dx \int_U \|\bar{y}_{\tau,\varepsilon}(x) - \bar{y}\|_{C(\bar{\Omega})}(|\bar{\psi}_{\tau,\varepsilon}(x)| + 1)(\sigma(x) + \bar{\sigma}_{\tau,\varepsilon}(x))(dv) \\
&= 2C\|\bar{y}_{\tau,\varepsilon}(x) - \bar{y}\|_{C(\bar{\Omega})} \int_\Omega (|\bar{\psi}_{\tau,\varepsilon}(x)| + 1)\, dx \to 0.
\end{aligned}
$$

Similarly,

$$
(5.10)\qquad \lim_{\varepsilon \to 0^+} I_2 = 0.
$$

On the other hand, by (5.7), we have (choosing a subsequence if necessary)

$$
(5.11)\qquad I_3 \to \int_\Omega dx \int_U H^\tau(x, \bar{y}(x), v, \bar{\psi}_\tau(x))(\sigma(x) - \bar{\sigma}_\tau(x))(dv).
$$

Combining (5.8)–(5.11), we get

$$
\begin{aligned}
(5.12)\qquad &\int_\Omega dx \int_U \left[f(x, \bar{y}(x), v)\bar{\psi}_\tau(x) - f^{0,\tau}(x, \bar{y}(x), v)\right](\sigma(x) - \delta_{\bar{u}(x)})(dv) \\
&\le 0 \qquad\qquad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega; U).
\end{aligned}
$$

By (5.5), we can suppose that (at least in the sense of a subsequence), as $\tau \to 0^+$,

$$
(5.13)\qquad \bar{\psi}_\tau(\cdot) \to \bar{\psi}(\cdot) \qquad \text{weakly in } W_0^{1,2}(\Omega), \text{ strongly in } L^2(\Omega).
$$

Then we have

$$
\begin{aligned}
&\int_\Omega dx \int_U H(x, \bar{y}(x), v, \bar{\psi}(x))\, (\sigma(x) - \delta_{\bar{u}(x)})(dv) \\
&= \int_\Omega dx \int_U \left[f(x, \bar{y}(x), v)\bar{\psi}(x) - f^0(x, \bar{y}(x), v)\right](\sigma(x) - \delta_{\bar{u}(x)})(dv) \\
&= \lim_{\tau \to 0^+} \int_\Omega dx \int_U \left[f(x, \bar{y}(x), v)\bar{\psi}_\tau(x) - f^{0,\tau}(x, \bar{y}(x), v)\right](\sigma(x) - \delta_{\bar{u}(x)})(dv) \\
&\le 0 \qquad\qquad \forall\, \sigma(\cdot) \in \mathcal{R}(\Omega; U).
\end{aligned}
$$

In particular, for any $v(\cdot) \in \mathcal{U}_{ad}$,

$$
(5.14)\qquad \int_\Omega \left[H(x, \bar{y}(x), v(x), \bar{\psi}(x)) - H(x, \bar{y}(x), \bar{u}(x), \bar{\psi}(x))\right]\, dx \le 0.
$$

Then it is easily to get that for any $v \in U$,

$$
H(x, \bar{y}(x), v, \bar{\psi}(x)) \le H(x, \bar{y}(x), \bar{u}(x), \bar{\psi}(x)), \qquad \text{a.e. } x \in \Omega.
$$

Since U is separable and $H(x, \bar{y}(x), \cdot, \bar{\psi}(x))$ is continuous in U, we get (1.8).

On the other hand, by (4.9), (5.4), (5.6), (5.13), and $\tilde{y}_\tau(\cdot) = \bar{y}(\cdot)$, we have

$$
\begin{aligned}
&\int_\Omega \left\{ \left[\frac{\varphi(x, |\nabla \bar{y}|\,)}{|\nabla \bar{y}|} \left(I - \frac{\nabla \bar{y}(\nabla \bar{y})^T}{|\nabla \bar{y}|^2} \right) + \varphi_s(x, |\nabla \bar{y}|\,) \frac{\nabla \bar{y}(\nabla \bar{y})^T}{|\nabla \bar{y}|^2} \right] \nabla \bar{\psi} \right\} \cdot \nabla \xi\, dx \\
&\quad = \int_\Omega [f_y(x, \bar{y}, \bar{u}(x))\bar{\psi} - f_y^0(x, \bar{y}, \bar{u}(x))]\xi(x)\, dx \qquad \forall\, \xi(\cdot) \in C_c^\infty(\{\nabla \bar{y} \ne 0\}),
\end{aligned}
$$

where $C_c^\infty(\{\nabla\bar{y}\neq 0\})$ is the set of $C^\infty(\{\nabla\bar{y}\neq 0\})$ functions having compact support in $\{\nabla\bar{y}\neq 0\}$. That is, (1.6) holds. By (5.6), for any $\gamma>0$, there exists an $\varepsilon_\tau\in(0,1)$ such that

$$|\nabla\bar{y}_{\tau,\varepsilon}(x)|\leq\gamma\qquad\forall\, x\in\{\nabla\bar{y}=0\},\ \varepsilon\in(0,\varepsilon_\tau).$$

Thus, by (5.2)–(5.3), we get

$$\frac{\lambda_0}{(\varepsilon^2+\gamma^2)^{\frac{2-p}{2}}}\int_{\{\nabla\bar{y}=0\}}|\nabla\bar{\psi}_{\tau,\varepsilon}|^2\,dx\leq C\qquad\forall\,\varepsilon\in(0,\varepsilon_\tau).$$

Therefore

$$\int_{\{\nabla\bar{y}=0\}}|\nabla\bar{\psi}_\tau|^2\,dx\leq\frac{C\gamma^{2-p}}{\lambda_0}.$$

Consequently,

$$\int_{\{\nabla\bar{y}=0\}}|\nabla\bar{\psi}_\tau|^2\,dx=0,$$

$$\int_{\{\nabla\bar{y}=0\}}|\nabla\bar{\psi}|^2\,dx=0,$$

and we get (1.7). □

Proof of Theorem 1.2. Similarly, in this case, we have (5.2) and (5.6). By (1.10) and the first inequality in (5.2), we have

$$\begin{aligned}\theta_0\int_\Omega&\bar{\psi}^2_{\tau,\varepsilon}(x)\,dx\\&\leq-\int_\Omega dx\int_U f_y(x,\bar{y}_{\tau,\varepsilon},v)\bar{\psi}^2_{\tau,\varepsilon}(x)\bar{\sigma}(x)(dv)\\&\leq-\int_\Omega dx\int_U f^0_y(x,\bar{y}_{\tau,\varepsilon},v)\bar{\psi}_{\tau,\varepsilon}\,\bar{\sigma}(x)(dv)\\&\leq C\int_\Omega|\bar{\psi}_{\tau,\varepsilon}(x)|\,dx.\end{aligned}$$

Thus,

$$\int_\Omega\bar{\psi}^2_{\tau,\varepsilon}(x)\,dx\leq C.\tag{5.15}$$

Then, by (5.2), (5.6), and (5.15), we get that for any $\Omega_0\subset\subset\{\nabla\bar{y}\neq 0\}$, there exists a constant $C(\Omega_0)>0$, independent of $\tau,\varepsilon\in(0,1)$, such that

$$\|\bar{\psi}_{\tau,\varepsilon}\|_{W^{1,2}(\Omega_0)}\leq C(\Omega_0)\qquad\forall\,\varepsilon\in(0,1).\tag{5.16}$$

Thus, we have $\bar{\psi}_\tau(\cdot),\bar{\psi}(\cdot)\in W^{1,2}_{loc}(\{\nabla\bar{y}\neq 0\})$ such that

$$\bar{\psi}_{\tau,\varepsilon}(\cdot)\to\bar{\psi}_\tau(\cdot)\qquad\text{weakly in }\ W^{1,2}(\Omega_0)\ \forall\,\Omega_0\subset\subset\{\nabla\bar{y}\neq 0\},$$

as $\varepsilon\to 0^+$, and

$$\bar{\psi}_\tau(\cdot)\to\bar{\psi}(\cdot)\qquad\text{weakly in }\ W^{1,2}_{loc}(\Omega_0)\ \forall\,\Omega_0\subset\subset\{\nabla\bar{y}\neq 0\},$$

as $\tau \to 0^+$. Then, we get (1.6). Moreover, similar to (5.14), it follows that for any $v(\cdot) \in \mathcal{U}_{ad}$,

$$\int_{\Omega_0} \left[H(x, \bar{y}(x), v(x), \bar{\psi}(x)) - H(x, \bar{y}(x), \bar{u}(x), \bar{\psi}(x))\right] \, dx \le 0. \tag{5.17}$$

And consequently, (1.8) holds for almost all $x \in \{\nabla \bar{y} \neq 0\}$. □

Proof of Theorem 1.3. In the case that $n = 1$ and $1 < p < 2$, (4.9) becomes

$$\begin{cases} -\left[\left(\dfrac{\varepsilon^2 \varphi\left(x, \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right)}{(\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2)^{\frac{3}{2}}} + \dfrac{|\bar{y}'_{\tau,\varepsilon}|^2 \varphi_s\left(x, \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right)}{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right) \bar{\psi}'_{\tau,\varepsilon}\right]' \\ \qquad = \displaystyle\int_U \left[f_y(x, \bar{y}_{\tau,\varepsilon}, v)\bar{\psi}_{\tau,\varepsilon} - f^0_y(x, \bar{y}_{\tau,\varepsilon}, v)\right] \, \bar{\sigma}_{\tau,\varepsilon}(x)(dv) \text{ in } (a,b), \\ \bar{\psi}_{\tau,\varepsilon}(a) = \bar{\psi}_{\tau,\varepsilon}(b) = 0. \end{cases}$$

Let

$$\bar{\Psi}_{\tau,\varepsilon} = -\left(\frac{\varepsilon^2 \varphi\left(x, \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right)}{(\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2)^{\frac{3}{2}}} + \frac{|\bar{y}'_{\tau,\varepsilon}|^2 \varphi_s\left(x, \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right)}{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right) \bar{\psi}'_{\tau,\varepsilon}.$$

Then

$$\begin{cases} \bar{\Psi}'_{\tau,\varepsilon}(x) = \displaystyle\int_U \left[f_y(x, \bar{y}_{\tau,\varepsilon}, v)\bar{\psi}_{\tau,\varepsilon} - f^0_y(x, \bar{y}_{\tau,\varepsilon}, v)\right] \, \bar{\sigma}_{\tau,\varepsilon}(x)(dv), & a < x < b, \\ \bar{\psi}'_{\tau,\varepsilon}(x) = h_{\tau,\varepsilon}(x) \, \bar{\Psi}_{\tau,\varepsilon}(x), & a < x < b, \\ \bar{\psi}_{\tau,\varepsilon}(a) = \bar{\psi}_{\tau,\varepsilon}(b) = 0, \end{cases} \tag{5.18}$$

where

$$h_{\tau,\varepsilon} = -\frac{(\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2)^{\frac{3}{2}}}{\varepsilon^2 \varphi\left(x, \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right) + |\bar{y}'_{\tau,\varepsilon}|^2 \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2} \varphi_s\left(x, \sqrt{\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2}\right)}.$$

By (5.3), we have

$$\|\bar{\psi}_{\tau,\varepsilon}\|_{C[a,b]} \le C,$$

and $\bar{\psi}'_{\tau,\varepsilon}(\cdot) \in L^2(a,b)$. By (S2),

$$|\bar{\Psi}_{\tau,\varepsilon}(x)| \le C\varepsilon^{p-2} |\bar{\psi}'_{\tau,\varepsilon}(x)| \qquad \forall \, x \in (a,b).$$

Thus, $\bar{\Psi}_{\tau,\varepsilon}(\cdot) \in L^2(a,b)$. Then, by (5.18), we have $\bar{\Psi}_{\tau,\varepsilon}(\cdot) \in W^{1,2}(a,b) \hookrightarrow C[a,b]$. Since $h_{\tau,\varepsilon}(\cdot) \in C(a,b)$, the second equation in (5.18) shows that $\bar{\psi}_{\tau,\varepsilon}(\cdot) \in C^1(a,b)$. Thus, since $\bar{\psi}_{\tau,\varepsilon}(a) = \bar{\psi}_{\tau,\varepsilon}(b) = 0$, there exists a $c_{\tau,\varepsilon} \in (a,b)$ such that $\bar{\psi}'_{\tau,\varepsilon}(c_{\tau,\varepsilon}) = 0$. Therefore, $\bar{\Psi}_{\tau,\varepsilon}(c_{\tau,\varepsilon}) = 0$. Consequently, noting that

$$|h_{\tau,\varepsilon}(x)| \le C \, \left(\varepsilon^2 + |\bar{y}'_{\tau,\varepsilon}|^2\right)^{\frac{2-p}{2}},$$

we get easily from (5.18) that

$$\|\bar{\Psi}_{\tau,\varepsilon}(\cdot)\|_{W^{1,\infty}(a,b)} \le C$$

and

$$\|\bar{\psi}_{\tau,\varepsilon}(\cdot)\|_{W^{1,\infty}(a,b)} \leq C.$$

Thus, at least in the sense of a subsequence, we have $\bar{\Psi}_\tau(\cdot)$, $\bar{\Psi}(\cdot) \in W^{1,q}(a,b)$, $\bar{\psi}_\tau(\cdot)$, $\bar{\psi}(\cdot) \in W_0^{1,q}(a,b)$ (for all $1 < q < +\infty$) such that

$$\begin{aligned} \bar{\Psi}_{\tau,\varepsilon}(\cdot) &\to \bar{\Psi}_\tau(\cdot) \qquad \text{weakly in } \ W^{1,q}(a,b), \\ \bar{\psi}_{\tau,\varepsilon}(\cdot) &\to \bar{\psi}_\tau(\cdot) \qquad \text{weakly in } \ W_0^{1,q}(a,b), \end{aligned}$$

as $\varepsilon \to 0^+$, and

$$\begin{aligned} \bar{\Psi}_\tau(\cdot) &\to \bar{\Psi}(\cdot) \qquad \text{weakly in } \ W^{1,q}(a,b), \\ \bar{\psi}_\tau(\cdot) &\to \bar{\psi}(\cdot) \qquad \text{weakly in } \ W_0^{1,q}(a,b), \end{aligned}$$

as $\tau \to 0^+$. Then, (1.11) follows easily from (5.18) and it follows from (1.11) that $\bar{\Psi}(\cdot)$, $\bar{\psi}(\cdot) \in W^{1,\infty}(a,b)$. Finally, (1.12) is just (1.8). We get the proof. □

A NEW APPROACH OF STABILIZATION OF NONDISSIPATIVE DISTRIBUTED SYSTEMS*

AISSA GUESMIA†

Abstract. In this paper we propose a new approach to prove the nonlinear (internal or boundary) stabilization of certain nondissipative distributed systems (the usual energy is not decreasing). This approach leads to decay estimates (known in the dissipative case) when the integral inequalities method due to Komornik [*Exact Controllability and Stabilization. The Multiplier Method*, Masson, Paris, John Wiley, Chichester, UK, 1994] cannot be applied due to the lack of dissipativity.

First we study the stability of a semilinear wave equation with a nonlinear damping based on the equation

$$u'' - \Delta u + h(\nabla u) + f(u) + g(u') = 0.$$

We consider the general case with a function h satisfying a smallness condition, and we obtain uniform decay of strong and weak solutions under weak growth assumptions on the feedback function and without any control of the sign of the derivative of the energy related with the above equation.

In the second part we consider the case $h(\nabla u) = -\nabla\phi \cdot \nabla u$ with $\phi \in W^{1,\infty}(\Omega)$. We prove some precise decay estimates (exponential or polynomial) of equivalent energy without any restriction on ϕ.

The same results will be proved in the case of boundary feedback.

Finally, we comment on some applications of our approach to certain nondissipative distributed systems.

Some results of this paper were announced without proof in [A. Guesmia, *C. R. Acad. Sci. Paris Sér.* I *Math.*, 332 (2001), pp. 633–636].

1. Introduction.

Consider the semilinear wave equation with a nonlinear internal dissipative term,

$$\text{(P)} \qquad \begin{cases} u'' - \Delta u + h(\nabla u) + f(u) + g(u') = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega, \end{cases}$$

and the nonlinear boundary feedback,

$$\text{(P}') \qquad \begin{cases} u'' - \Delta u + h(\nabla u) + f(u) = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = 0 & \text{on} \quad \Gamma_0 \times \mathbb{R}^+, \\ \partial_\nu u + g(u') = 0 & \text{on} \quad \Gamma_1 \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^n$ $(n \in \mathbb{N}^*)$ is an open bounded domain with smooth boundary Γ and $f, g : \mathbb{R} \to \mathbb{R}$ and $h : \mathbb{R}^n \to \mathbb{R}$ are continuous nonlinear functions satisfying some

general properties (see Assumptions 2.1–2.5 below). In (P′), ν represents the outward unit normal to $\Gamma = \Gamma_0 \cup \Gamma_1$, where Γ_0 and Γ_1 are closed and disjoint. In this paper Δ and ∇ stand, respectively, for the Laplacian and the gradian with respect to the spatial variables, $'$ denotes the derivative with respect to time t, and $\mathbb{R}^+ = [0, \infty[$.

The main goal of this paper is to show that strong and weak solutions to problems (P) and (P′) decay to zero when $t \to \infty$ and give some precise decay properties.

When $h \equiv 0$ the bibliography of works in this direction is truly long. We can cite, for instance, the works of Nakao [18, 21, 22], Kawashima, Nakao, and Ono [11], Nakao and Narazaki [19], Nakao and Ono [20], Haraux and Zuazua [10], Pucci and Serrin [23], and Zuazua [27], among others.

In [21], Nakao considered the following initial boundary value problem:

$$\text{(P1)} \qquad \begin{cases} u'' - \Delta u + \rho(u') + f(u) = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega, \end{cases}$$

where $\rho(v) = |v|^\beta v$, $\beta > -1$, $f(u) = bu|u|^\alpha$, α, $b > 0$ (in this paper $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}$ and $\mathbb{R}^n$), and Ω is a bounded domain of $\mathbb{R}^n$ $(n \geq 1)$, with a smooth boundary $\Gamma := \partial\Omega$. He showed that (P1) has a unique global weak solution if $0 \leq \alpha \leq 2/(n-2)$, $n \geq 3$, and a global unique strong solution if $\alpha > 2/(n-2)$, $n \geq 3$ (of course if $n = 1$ or 2, then there is no restriction on α). In addition to global existence the issue of the decay rate was addressed. In both cases, it has been shown that the energy of the solution decays algebraically if $\beta > 0$ and it decays exponentially if $\beta = 0$. This improves an earlier result obtained by the author in [22], where he studied the problem in an abstract setting and established a theorem concerning the decay of the solution energy only for the case $\alpha \leq 2/(n-2)$, $n \geq 3$. Later on, in a joint work with Ono [20], this result has been extended to the Cauchy problem for the equation

$$u'' - \Delta u + \lambda^2(x)u + \rho(u') + f(u) = 0, \qquad (x,t) \in \mathbb{R}^n \times \mathbb{R}^+,$$

where $\rho(u')$ behaves like $|u'|^\beta u'$ and $f(u)$ behaves like $-bu|u|^\alpha$. In this case the authors required that the initial data be small enough in $H^1 \times L^2$ norm and of compact support.

Pucci and Serrin [23] discussed the stability of the problem

$$\text{(P2)} \qquad \begin{cases} u'' - \Delta u + Q(x,t,u,u') + f(x,u) = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega \end{cases}$$

and proved that the energy of the solution is a Liapunov function. Although they did not discuss the issue of the decay rate, they did show that in general the energy goes to zero as t approaches infinity. They also considered an important special case of (P2), which occurs when $Q(x,t,u,u') = a(t)t^\alpha u'$ and $f(x,u) = V(x)u$, and showed that the behavior of the solutions depends crucially on the parameter α. If $|\alpha| \leq 1$, then the rest field is asymptotically stable. On the other hand, when $\alpha < -1$ or $\alpha > 1$ there are solutions that do not approach zero or approach nonzero functions $\phi(x)$ as $t \to \infty$.

Messaoudi [16] discussed an initial boundary value problem related to the equation

$$u'' - \Delta u + a(1 + |u'|^{m-2})u' + bu|u|^{p-2} = 0 \quad \text{in} \quad \Omega \times \mathbb{R}^+,$$

where a, $b > 0$, $m \geq 2$, $p > 2$, and proved that the energy of the solution decays exponentially. The proof of this result is based on a direct method used in [3] and [5].

Concerning the boundary feedback case, problem (P′) with $h \equiv 0$ has attracted considerable attention in the literature and, in recent years, important progress has been obtained in this context. New techniques were developed which allow us to stabilize a system through its boundary or control it from an initial to a final state (controllability). There is a large body of literature regarding boundary stabilization with linear feedback; we refer the reader to the following works: Lagnese [13], Russell [24], Triggiani [25], and You [26]. Now when the boundary feedback is nonlinear we can cite the works of Zuazua [28], Lasiecka and Tataru [14], Komornik [12], and Guesmia [5], among others. For such cases, the main purpose is to obtain the same stabilization results when a boundary feedback of the form

$$\partial_\nu u + a(x)u + b(x)g(u') = 0 \quad \text{on} \quad \Gamma_1 \times \mathbb{R}^+$$

is applied on a part Γ_1 of the boundary Γ of Ω which satisfies certain geometric conditions and a, b, and g are given functions, whereas no feedback is applied on the other part of the boundary, i.e.,

$$u = 0 \quad \text{on} \quad (\Gamma \setminus \Gamma_1) \times \mathbb{R}^+.$$

However, when $h \not\equiv 0$ very little is known in the literature; more general and recent results in this direction were obtained in [2]. In this paper the authors established well-posedness of the following large class of hyperbolic equations:

$$K(x,t)u'' - \Delta u + F(x,t,u,u',\nabla u) = f(x)$$

with boundary conditions and initial data as in (P′), where K, F, and f are given functions satisfying some hypotheses.

However, to obtain exponential stability of solutions using classical multipliers and integral inequalities, they assumed some additional hypotheses on F which require, in particular, that F is global Lipschitz with respect to its last variable, where the Lipschitz constant is a function on t and converges exponentially to 0 at ∞. This is a strong hypothesis which is not satisfied if, for example, the function F does not depend on time t, as in our case.

Hyperbolic-parabolic equations are interesting from the point of view of not only the general theory of PDEs but also to applications in mechanics. For instance, the transonic Karman equation

$$u'u'' - \Delta u = 0$$

models flows of compressible gas in the transonic region where the velocity of gas varies from subsonic values to supersonic ones (see [2] and the references therein).

We note that stability of problems with the nonlinear term $h(\nabla u)$ requires careful treatment because we have any information neither about the influence of the integral $\int_\Omega h(\nabla u)u'\,dx$ on the norm

$$\|(u,u')\|^2_{H_0^1(\Omega)\times L^2(\Omega)} = \int_\Omega \left(|u'(x,t)|^2 + |\nabla u(x,t)|^2\right) dx$$

nor about the sign of its derivative; that is, the energy E defined by (2.7) is not necessary decreasing (see identities (3.2) and (5.1)). Decrease of energy plays a crucial

role in studying the asymptotic stability of the solution, as it was considered in the prior literature, in particular, in the works cited above.

We also observe that our problem deals with nonlinearity, which involves the gradient combined with a nonlinear feedback. This situation was not previously considered and leads to new difficulties. In order to overcome these difficulties and obtain energy decay estimates, we give a new and direct approach based on a combination of some ideas given by Guesmia in [3, 4] and the multiplier technique.

In the case where h is linear we introduce a nonincreasing equivalent energy (see (2.14)) and then, by the use of appropriate multipliers and a well-known lemma due to Haraux–Komornik (see [12, Theorem 9.1]), the exponential and polynomial decay estimates are proved. In the case where h is nonlinear, the introduction of a such equivalent energy seems to be not possible. In this case, the main ingredient for proving the exponential stability is to obtain a generalized integral inequalities of the form

$$(*) \quad \begin{cases} \int_S^T E(t)dt \le a_1(E(S)+E(T)) + a_2(E(S)-E(T)) & \forall 0 \le S \le T < \infty, \\ E'(t) \le a_3 E(t) & \forall t \ge 0, \end{cases}$$

where a_i, $i = 1, 2, 3$, are nonnegative constants and where E stands for the classical energy (2.7). Then we show that if, in addition, $2a_1a_3 < 1$ or $a_1 \le a_2$, E must converge exponentially to 0 at ∞.

Notice that a positive function satisfying $(*)$ does not necessarily converge to 0 at ∞; if $a_1a_3 \ge 1 + a_2a_3$, then the function $E(t) = e^{a_3 t}$ satisfies $(*)$. As an open question, it would be interesting to know what happens if $a_1a_3 \in [\frac{1}{2}, 1 + a_2a_3[$ and $a_1 > a_2$.

The integral result $(*)$ gives a generalization to the Haraux–Komornik lemma, which concerns nonincreasing functions (that is, $a_3 = 0$).

The rest of this paper is organized as follows. In section 2 we establish assumptions and state our main results. In section 3 we obtain the uniform stability of (P). In section 4 we consider the case $h(\nabla u) = -\nabla\phi \cdot \nabla u$, where $\phi \in W^{1,\infty}(\Omega)$ and $\cdot$ denotes the scalar product in $\mathbb{R}^n$, and we prove some decay estimates of equivalent energy of (P). In sections 5 and 6 we prove the same results for (P′). Finally, in the last section we give some applications of our approach to Petrovsky, coupled, and elasticity systems.

2. Assumptions and main results. We begin this section stating the general hypotheses.

Assumption 2.1 (assumptions on f). $f : \mathbb{R} \to \mathbb{R}$ is a C^1 function such that $f(0) = 0$ and, deriving from a potential F, that is

$$F(s) = \int_0^s f(\sigma)\, d\sigma \qquad \forall s \in \mathbb{R},$$

$$F(s) \ge -as^2 \qquad \forall s \in \mathbb{R}, \tag{2.1}$$

with $0 \le a < \frac{1}{2c_0}$, where c_0 is the smallest positive constant (depending only on Ω) such that (Poincaré's inequality)

$$\int_\Omega |v|^2 dx \le c_0 \int_\Omega |\nabla v|^2 dx \qquad \forall v \in H_0^1(\Omega). \tag{2.2}$$

Also, there exists $b > 0$ such that

$$2bF(s) \le sf(s) \qquad \forall s \in \mathbb{R}. \tag{2.3}$$

Assumption 2.2 (assumptions on g). $g : \mathbb{R} \to \mathbb{R}$ is a C^1 function, nondecreasing, $g(0) = 0$, such that

$$g(s)s > 0 \qquad \forall s \neq 0. \tag{2.4}$$

Also, there exist two positive constants c_1 and c_2 such that

$$c_1|s| \leq |g(s)| \leq c_2|s| \qquad \forall s \in \mathbb{R}. \tag{2.5}$$

Assumption 2.3 (assumptions on h). $h : \mathbb{R}^n \to \mathbb{R}$ is a C^1 function such that ∇h is bounded and there exists $\beta > 0$ such that

$$|h(\zeta)| \leq \beta|\zeta| \qquad \forall \zeta \in \mathbb{R}^n. \tag{2.6}$$

We define the energy of the solution of (P) by the formula

$$E(t) = \int_\Omega \left(\left|u'\right|^2 + \left|\nabla u\right|^2 + 2F(u) \right) dx, \qquad t \in \mathbb{R}^+. \tag{2.7}$$

Remarks. 1. If the function f is increasing and $f(0) = 0$, then (2.1) and (2.3) are satisfied with $a = 0$ and $b = \frac{1}{2}$.

2. Condition (2.1) assures the following inequality:

$$\|(u, u')\|^2_{H_0^1(\Omega)\times L^2(\Omega)} \leq kE(t) \qquad \forall t \in \mathbb{R}^+, \tag{2.8}$$

where $k = \frac{1}{1-2ac_0} > 0$. Indeed, (2.1) and (2.2) imply that

$$\begin{aligned} E(t) &\geq \int_\Omega \left(\left|u'\right|^2 + \left|\nabla u\right|^2 - 2a\left|u\right|^2 \right) dx \\ &\geq \int_\Omega \left(\left|u'\right|^2 + (1 - 2ac_0)\left|\nabla u\right|^2 \right) dx \\ &\geq (1 - 2ac_0) \int_\Omega \left(\left|u'\right|^2 + \left|\nabla u\right|^2 \right) dx = (1 - 2ac_0)\|(u, u')\|^2_{H_0^1(\Omega)\times L^2(\Omega)}, \end{aligned}$$

which gives (2.8).

3. Under Assumptions 2.1, 2.2, 2.3 and using analogous considerations like the ones used in [2] (we omit the details), we can use Galerkin's method (semigroup theory is not suitable to treat degenerate problems) and prove that problem (P) possesses a unique strong solution, $u :]0, \infty[\to \mathbb{R}$, such that

$$u \in L^\infty(]0, \infty[; H_0^1(\Omega) \cap H^2(\Omega)), \qquad u' \in L^\infty(]0, \infty[; H_0^1(\Omega)), \tag{2.9}$$

and

$$u'' \in L^\infty(]0, \infty[; L^2(\Omega)).$$

Moreover, supposing that $\{u_0, u_1\}$ is in $H_0^1(\Omega) \times L^2(\Omega)$ and using density arguments, we can show that (P) has a unique weak solution $u : \Omega\times]0, \infty[\to \mathbb{R}$ in the space

$$C(]0, \infty]; H_0^1(\Omega)) \cap C^1(]0, \infty[; L^2(\Omega)). \tag{2.10}$$

Now we are in position to state our first main result.

THEOREM 2.1. *Assume that Assumptions* 2.1, 2.2, 2.3 *hold such that* $b < 1$ *and* β *satisfies the following smallness hypotheses:*

$$\frac{\beta}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}+\sqrt{c_0}\right)+\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}\le 1-b,$$

$$\beta<\frac{b}{k^2\sqrt{c_0}},\quad \text{or}\quad \frac{k\sqrt{c_0}}{2}\le\frac{1}{c_1}+\frac{1}{2}\sqrt{\frac{c_0c_2}{\sqrt{2}\beta}}.$$

Then the energy determined by the strong solution u *decays exponentially. That is, to say for some positive constants* c,ω, *one has*

$$E(t)\le cE(0)e^{-\omega t}\qquad \forall t\in\mathbb{R}^+. \tag{2.11}$$

Furthermore, (2.11) *holds for the weak solution* u.

Remark. If F is positive (for example, $sf(s)\ge 0$ for all $s\in\mathbb{R}$), then β and b can be taken such that $b>0$ and

$$\frac{\beta}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}+(1+2k^2)\sqrt{c_0}\right)+\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}<1,\qquad \beta<\frac{b}{k^2\sqrt{c_0}}$$

or

$$\frac{\beta}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}+\sqrt{c_0}\right)+\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}<1,\qquad \frac{k\sqrt{c_0}}{2}\le\frac{1}{c_1}+\frac{1}{2}\sqrt{\frac{c_0c_2}{\sqrt{2}\beta}}.$$

We consider now the case $h(\nabla u)=-\nabla\phi\cdot\nabla u$, where $\phi\in W^{1,\infty}(\Omega)$ and g satisfies a hypothesis weaker than (2.5).

Assumption 2.4 (assumptions on g). $g:\mathbb{R}\to\mathbb{R}$ is a C^1 function, nondecreasing, $g(0)=0$, such that (2.4) holds and there exist four constants r, $p\ge 1$ and c_1, $c_2>0$ such that

$$c_1\min\{|s|,|s|^r\}\le|g(s)|\le c_2\max\{|s|^{\frac{1}{r}},|s|^p\}\qquad\forall s\in\mathbb{R}, \tag{2.12}$$

$$(n-2)p\le n+2. \tag{2.13}$$

We have the following stabilization result.

THEOREM 2.2. *Let* u *be a solution of* (P) *in the class* (2.10). *Under Assumptions* 2.1 *and* 2.4, *there exist two positive constants* ω, c *such that the equivalent energy of* (P), *defined by*

$$E(t)=\int_\Omega e^{\phi(x)}\left(|u'|^2+|\nabla u|^2+2F(u)\right)dx,\qquad t\in\mathbb{R}^+, \tag{2.14}$$

satisfies (2.11) *if* $r=1$, *and*

$$E(t)\le c(1+t)^{\frac{-2}{r-1}}\qquad\forall t\in\mathbb{R}^+ \tag{2.15}$$

if $r>1$.

Remarks. 1. If we take $g(s) = \alpha s$ for all $s \in \mathbb{R}$ with $\alpha > 0$ (that is, $r = p = 1$), then we find the results obtained in [15]. On the other hand, the case of $g(s) = \alpha(1 + |s|^{m-2})s$ for all $s \in \mathbb{R}$ with $m > 2$ (that is, $p = m - 1$ and $r = 1$) gives the results obtained in [16].

2. In Theorem 2.1 we can weaken assumption (2.6) by taking β as the Lipschitz constant of only the nonlinear part of h; that is, we assume that there exists $\bar{\zeta} \in \mathbb{R}^n$ such that

$$|h(\zeta) + \bar{\zeta} \cdot \zeta| \leq \beta|\zeta| \qquad \forall \zeta \in \mathbb{R}^n.$$

To prove this we have only to consider the equivalent energy defined by (2.14) where $\phi(x) = \bar{\zeta} \cdot x$.

3. It is possible to weaken the growth assumption (2.12) as was done for the study of elasticity systems in [3, 7] and the Petrovsky system in [6]. In order to simplify we shall only consider in this paper the case of assumption (2.12).

Now we are concerned by the stability of (P′). In order to obtain the estimates (2.11) and (2.15), the following assumptions are made on Γ and f. Let x^0 be a fixed point in $\mathbb{R}^n$. Then put

$$m = m(x) = x - x^0, \qquad R = \max_{x \in \bar{\Omega}} |m(x)|$$

and partition the boundary Γ into two nonempty sets:

$$\Gamma_0 = \{x \in \Gamma : \ m(x) \cdot \nu(x) \leq 0\}, \qquad \Gamma_1 = \{x \in \Gamma : \ m(x) \cdot \nu(x) \geq \delta > 0\}.$$

Examples. Concerning the existence of such a partition of Γ, we can take Ω as follows:

1. If $n = 1$, then Ω is a bounded open interval, say $\Omega =]x_1, x_2[\subset \mathbb{R}$, and our geometric hypotheses are satisfied in each of the following two cases:

(i) $\Gamma_0 = \{x_1\}$, $\Gamma_1 = \{x_2\}$, and $x^0 \leq x_1$,

(ii) $\Gamma_0 = \{x_2\}$, $\Gamma_1 = \{x_1\}$, and $x^0 \geq x_2$.

2. If $n \geq 2$ and $\Omega = \Omega_1 \setminus \bar{\Omega}_0$, where Ω_1 and Ω_0 are two open domains with boundary Γ_1, and Γ_0, respectively, $\bar{\Omega}_0 \subset \Omega_1$, and Ω_1 and Ω_0 are star-shaped with respect to some point $x^0 \in \Omega_0$ (a domain Ω is called star-shaped with respect to x^0 if $m \cdot \nu > 0$ on $\partial\Omega$), then our geometric hypotheses are satisfied.

3. If $n \geq 2$ and Ω is not of the form mentioned in the preceding example, then in general there is no point x^0 satisfying simultaneously the geometric hypotheses assumed on Γ_1 and Γ_0. By applying an approximational method, one could considerably weaken these geometric hypotheses, at least in dimensions $n = 2$, 3, by adapting an analogous argument given by Komornik–Zuazua for the wave equation (see [12] and the references therein).

Assumption 2.5 (assumptions on f). $f : \mathbb{R} \to \mathbb{R}$ is a C^1 function such that (2.3) and

$$F(s) \geq 0 \qquad \forall s \in \mathbb{R}. \tag{2.16}$$

The well-posedness of the problem (P′) can be established by standard Galerkin's method (see [15]); we do not discuss this point here. We use the notations

$$V = \{v \in H^1(\Omega) : \ v = 0 \ \text{ on } \ \Gamma_0\} \quad \text{and} \quad W = H^2(\Omega) \cap V;$$

we have the following:

1. For all $(u_0, u_1) \in W \times V$ such that $\partial_\nu u_0 + g(u_1) = 0$ on Γ_1, problem (P′) has a unique strong solution, $u :]0, \infty[\to \mathbb{R}$, such that

$$u \in L^\infty(]0, \infty[; W), \quad u' \in L^\infty(]0, \infty[; V), \text{ and } u'' \in L^\infty(]0, \infty[; L^2(\Omega)).$$

2. If $\{u_0, u_1\}$ is in $V \times L^2(\Omega)$, then (using density arguments) the solution is weak: $u : \Omega \times]0, \infty[\to \mathbb{R}$ in the space

$$C(]0, \infty]; V) \cap C^1(]0, \infty[; L^2(\Omega)). \tag{2.17}$$

THEOREM 2.3. *Let u be a solution of* (P′) *in the class* (2.17). *Assume, moreover, that Assumptions* 2.2, 2.3, 2.5 *hold with β small enough and $b > 1$ or f is linear. Then the energy of u, defined by* (2.7), *decays exponentially to zero in the sense of* (2.11).

We consider now the case $h(\nabla u) = -\nabla\phi \cdot \nabla u$, where $\phi \in W^{1,\infty}(\Omega)$.

We have the following stabilization result for (P′).

THEOREM 2.4. *Let u be a solution of* (P′) *in the class* (2.17). *Under Assumptions* 2.5, 2.4 *with $p = 1$, $R\|\nabla\phi\|_\infty < \min\{2, n\}$, and $b > \frac{n+R\|\nabla\phi\|_\infty}{n-R\|\nabla\phi\|_\infty}$ or f is linear and $\|\nabla\phi\|_\infty$ is small enough, where $\|\nabla\phi\|_\infty = \max_{x\in\bar{\Omega}} |\nabla\phi(x)|$, the results of Theorem* 2.2 *hold true.*

Remarks. 1. As an example of a function f satisfying Assumption 2.5, we can take $f(s) = \gamma s\,|s|^{q-1}$ with $\gamma \geq 0$ and $q \geq 1$. Condition (2.3) is satisfied for all $b \leq \frac{q+1}{2}$.

2. We have many possibilities to take the function g such that condtions (2.12) and (2.13) are satisfied, for example, $g(s) = \gamma|s|^{r-1}s$ if $|s| \leq 1$, and $g(s) = \gamma s$ if $|s| \geq 1$, where $\gamma > 0$.

3. Thanks to (2.16), the function F is positive, and then the usual energy (2.7) satisfies

$$\int_\Omega \left(\left|u'\right|^2 + \left|\nabla u\right|^2 \right) dx \leq E(t). \tag{2.18}$$

The quantity $(\int_\Omega \left|\nabla u\right|^2 dx)^{\frac{1}{2}}$ defines a norm on V equivalent to the usual norm induced by $H^1(\Omega)$; consequently, V is a Hilbert space with this norm.

4. If h is nonlinear and $r > 1$, we do not know if the energy of (P) and (P′) decays polynomially to zero.

5. In the case of uniform stability (Theorem 2.1 and Theorem 2.3), our proof allows us to obtain explicit constants c and ω in (2.11).

6. Theorem 2.1, Theorem 2.3, and Theorem 2.4 probably remain valid without the smallness conditions assumed on β, but we could not prove them.

3. Uniform decay: Proof of Theorem 2.1. To justify all the computations that follow, we assume first that the solution is strong, and by a standard density argument we deduce the result for weak solutions.

We are going to prove that the energy defined by (2.7) satisfies the estimate

$$E(S + T_0) \leq dE(S) \qquad \forall S \in \mathbb{R}^+ \tag{3.1}$$

with $0 < d < 1$ and $T_0 > 0$. (This will be fixed later in the course of the proof.) Using (3.1), inequality (3.9) below gives (2.11).

We start this section by giving an explicit formula for the derivative of the energy. A simple computation shows that

$$E'(t) = -2\int_\Omega u' g(u')\,dx - 2\int_\Omega u' h\left(\nabla u\right)\,dx. \tag{3.2}$$

Multiplying the first equation in (P) by u and integrating the obtained result over $\Omega \times [S,T]$, we obtain

$$\begin{aligned} 0 &= \int_S^T \int_\Omega u\left(u'' - \Delta u + h(\nabla u) + f(u) + g(u')\right) dx\,dt \\ &= \left[\int_\Omega u u' dx\right]_S^T + \int_S^T \int_\Omega \left(-\left|u'\right|^2 + \left|\nabla u\right|^2 + u f(u)\right) dx\,dt \\ &\quad + \int_S^T \int_\Omega u g(u')\,dx dt + \int_S^T \int_\Omega u h\left(\nabla u\right) dx\,dt. \end{aligned} \tag{3.3}$$

Hence, from (3.3), making use of the Cauchy–Schwarz inequality and taking assumption (2.6) and property (2.2) into account, we infer

$$\begin{aligned} &\int_S^T \int_\Omega \left(\left|u'\right|^2 + \left|\nabla u\right|^2 + u f(u)\right) dx\,dt \\ &\leq -\left[\int_\Omega u u' dx\right]_S^T + \int_S^T \int_\Omega \left(2\left|u'\right|^2 - u g(u')\right) dx\,dt \\ &\quad + \frac{\beta}{2\sqrt{c_0}} \int_S^T \int_\Omega \left|u\right|^2 dx\,dt + \frac{\sqrt{c_0}}{2\beta} \int_S^T \int_\Omega \left|h\left(\nabla u\right)\right|^2 dx\,dt \\ &\leq -\left[\int_\Omega u u' dx\right]_S^T + \int_S^T \int_\Omega \left(2\left|u'\right|^2 - u g(u')\right) dx\,dt \\ &\quad + \frac{\beta\sqrt{c_0}}{2} \int_S^T \int_\Omega \left|\nabla u\right|^2 dx\,dt + \frac{\beta\sqrt{c_0}}{2} \int_S^T \int_\Omega \left|\nabla u\right|^2 dx\,dt. \end{aligned}$$

Then, taking assumption (2.3) into account, from this inequality we deduce

$$\begin{aligned} &\int_S^T \int_\Omega \left(\left|u'\right|^2 + (1 - \beta\sqrt{c_0})\left|\nabla u\right|^2 + 2bF(u)\right) dx\,dt \\ &\leq -\left[\int_\Omega u u' dx\right]_S^T + \int_S^T \int_\Omega \left(2\left|u'\right|^2 - u g(u')\right) dx\,dt. \end{aligned} \tag{3.4}$$

Using (2.2), (2.8), and the Cauchy–Schwarz inequality, we can easily get

$$\begin{aligned} \left|\int_\Omega u u' dx\right| &\leq \frac{1}{2}\int_\Omega \left(\sqrt{c_0}\left|u'\right|^2 + \frac{1}{\sqrt{c_0}}\left|u\right|^2\right) dx \\ &\leq \frac{\sqrt{c_0}}{2}\int_\Omega \left(\left|u'\right|^2 + \left|\nabla u\right|^2\right) dx \leq \frac{k\sqrt{c_0}}{2} E(t); \end{aligned}$$

then

$$-\left[\int_\Omega uu'dx\right]_S^T \le \frac{k\sqrt{c_0}}{2}\left(E(S)+E(T)\right).$$

Next, we insert this inequality into (3.4); it follows that

$$\int_S^T\int_\Omega \left(|u'|^2+(1-\beta\sqrt{c_0})\,|\nabla u|^2+2bF(u)\right)dx\,dt \tag{3.5}$$

$$\le \frac{k\sqrt{c_0}}{2}\left(E(S)+E(T)\right)+\int_S^T\int_\Omega\left(2\,|u'|^2-ug(u')\right)dx\,dt.$$

Next, we want to majorize the last term in the right-hand side of (3.5).

Estimate for $\int_S^T\int_\Omega \left(2|u'|^2-ug(u')\right)dx\,dt$. Using (3.2) and the Cauchy–Schwarz inequality and taking the assumptions (2.4), (2.5), and (2.6) into account, it holds that

$$2\int_S^T\int_\Omega |u'|^2dx\,dt \le \frac{2}{c_1}\int_S^T\int_\Omega u'g(u')dx\,dt$$

$$=\frac{1}{c_1}\int_S^T\left(-E'(t)-2\int_\Omega u'h(\nabla u)dx\right)dt$$

$$\le \frac{1}{c_1}\left(E(S)-E(T)\right)+\frac{1}{c_1}\int_S^T\int_\Omega\left(\epsilon|u'|^2+\frac{\beta^2}{\epsilon}|\nabla u|^2\right)dx\,dt;$$

we choose $\epsilon>0$ such that $\frac{\beta^2}{\epsilon c_1}=\frac{\epsilon}{c_1}-\beta\sqrt{c_0}$, that is, $\epsilon=\frac{\beta}{2}(\sqrt{{c_1}^2c_0+4}+c_1\sqrt{c_0})$; then we deduce

$$2\int_S^T\int_\Omega |u'|^2dx\,dt \le \frac{1}{c_1}\left(E(S)-E(T)\right) \tag{3.6}$$

$$+\beta\int_S^T\int_\Omega\left(\frac{1}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}+\sqrt{c_0}\right)|u'|^2+\frac{1}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}-\sqrt{c_0}\right)|\nabla u|^2\right)dx\,dt.$$

Similary we have

$$-\int_S^T\int_\Omega ug(u')dx\,dt \le \frac{1}{2}\int_S^T\int_\Omega\left(\frac{1}{\epsilon}g^2(u')+\epsilon|u|^2\right)dx\,dt$$

$$\le \frac{1}{2}\int_S^T\int_\Omega\left(\frac{c_2}{\epsilon}u'g(u')+\epsilon c_0|\nabla u|^2\right)dx\,dt$$

$$=\frac{c_2}{2\epsilon}\int_S^T\left(-\frac{1}{2}E'(t)-\int_\Omega u'h(\nabla u)dx\right)dt+\frac{\epsilon c_0}{2}\int_S^T\int_\Omega|\nabla u|^2dx\,dt$$

$$\leq \frac{c_2}{4\epsilon}\left(E(S)-E(T)\right)+\frac{\epsilon c_0}{2}\int_S^T\int_\Omega |\nabla u|^2 dx\,dt$$

$$+\frac{c_2}{2\epsilon}\int_S^T\int_\Omega\left(\frac{\epsilon'\beta^2}{2}|\nabla u|^2+\frac{1}{2\epsilon'}|u'|^2\right)dx\,dt;$$

we choose $\epsilon=\beta\sqrt{\frac{c_2\epsilon'}{2c_0}}$ and $\epsilon'=\frac{1}{\sqrt{2}\beta}$. It follows that

$$-\int_S^T\int_\Omega ug(u')dx\,dt\leq\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}\int_S^T\int_\Omega\left(|u'|^2+|\nabla u|^2\right)dx\,dt + \frac{1}{2}\sqrt{\frac{c_0c_2}{\sqrt{2}\beta}}\left(E(S)-E(T)\right). \tag{3.7}$$

Combining (3.5), (3.6), and (3.7), we conclude that

$$\begin{aligned}&\left(1-\frac{\beta}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}+\sqrt{c_0}\right)-\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}\right)\int_S^T\int_\Omega\left(|u'|^2+|\nabla u|^2\right)dx\,dt\\&+b\int_S^T\int_\Omega 2F(u)dx\,dt\\&\leq\left(\frac{k\sqrt{c_0}}{2}+\frac{1}{c_1}+\frac{1}{2}\frac{\sqrt{c_0c_2}}{\sqrt{2}\beta}\right)E(S)+\left(\frac{k\sqrt{c_0}}{2}-\frac{1}{c_1}-\frac{1}{2}\frac{\sqrt{c_0c_2}}{\sqrt{2}\beta}\right)E(T).\end{aligned} \tag{3.8}$$

Hence, if we take β small enough so that $\frac{\beta}{2}(\sqrt{c_0+(\frac{2}{c_1})^2}+\sqrt{c_0})+\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}\leq 1-b$ as it is assumed in Theorem 2.1, then, from (3.8) and making use of definition (2.7) of energy, we arrive at

$$\int_S^T E(t)dt \tag{3.9}$$

$$\leq\frac{k\sqrt{c_0}}{2b}\left(E(S)+E(T)\right)+\frac{1}{b}\left(\frac{1}{c_1}+\frac{1}{2}\sqrt{\frac{c_0c_2}{\sqrt{2}\beta}}\right)\left(E(S)-E(T)\right).$$

If F is positive, then we assume that $\frac{\beta}{2}(\sqrt{c_0+(\frac{2}{c_1})^2}+\sqrt{c_0})+\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}<1$ and we obtain (3.9) with b replaced by

$$\bar{b}=\min\left\{b,1-\frac{\beta}{2}\left(\sqrt{c_0+\left(\frac{2}{c_1}\right)^2}+\sqrt{c_0}\right)-\sqrt{\frac{c_0c_2\beta}{2\sqrt{2}}}\right\}.$$

Now we return to equality (3.2). Using (2.4), (2.6), (2.8), and the Cauchy–Schwarz inequality, we infer

$$E'(t)\leq -2\int_\Omega u'h(\nabla u)dx\leq\int_\Omega\left(\beta|u'|^2+\frac{1}{\beta}|h(\nabla u)|^2\right)dx$$

$$\leq \beta \int_\Omega \left(|u'|^2 + |\nabla u|^2\right) dx \leq \beta k E(t);$$

then

$$E'(t) \leq \beta k E(t). \tag{3.10}$$

We may assume in the rest of this section that $E(t) > 0$ for all $t \geq 0$. Otherwise if $E(t_0) = 0$ for some $t_0 \geq 0$, then from (2.8) we have $u(t_0, x) = u'(t_0, x) = 0$ in Ω; hence $v(t, x) := u(t + t_0, x)$ solves (P) with $(0, 0)$ as initial data. By the uniqueness of solution we conclude that $v = v' = 0$; hence $E(t) = 0$ for all $t \geq t_0$ and then we have nothing to prove.

Now by Gronwall's lemma, we conclude from (3.10) that

$$E(t) \leq e^{\beta k(t-\tau)} E(\tau) \qquad \forall\, 0 \leq \tau \leq t < \infty. \tag{3.11}$$

On the other hand, (3.10) implies that

$$E(t) \geq \frac{1}{\beta k} \frac{\partial}{\partial t} \left((1 - e^{-\beta k(t-\tau)}) E(t) \right) \qquad \forall\, 0 \leq \tau \leq t < \infty. \tag{3.12}$$

Now we distinguish two cases (corresponding to the hypothesis assumed on β in Theorem 2.1).

Case 1. $\beta < \frac{b}{k^2 \sqrt{c_0}}$. We fix

$$T_0 > \frac{-1}{\beta k} \ln \left(1 - \frac{\beta k^2 \sqrt{c_0}}{b} \right). \tag{3.13}$$

From (3.12) with $\tau = S$ we have

$$\int_S^{S+T_0} E(t) dt \geq \frac{1}{\beta k} (1 - e^{-\beta k T_0}) E(S + T_0).$$

Combining this inequality and (3.9) with $T = S + T_0$, we arrive at

$$\left(\frac{1}{\beta k} (1 - e^{-\beta k T_0}) + \frac{1}{b} \left(\frac{1}{c_1} + \frac{1}{2} \sqrt{\frac{c_0 c_2}{\sqrt{2}\beta}} \right) - \frac{k\sqrt{c_0}}{2b} \right) E(S + T_0)$$

$$\leq \left(\frac{k\sqrt{c_0}}{2b} + \frac{1}{b} \left(\frac{1}{c_1} + \frac{1}{2} \sqrt{\frac{c_0 c_2}{\sqrt{2}\beta}} \right) \right) E(S).$$

Thanks to our choice (3.13) of T_0, we have

$$\frac{1}{\beta k} (1 - e^{-\beta k T_0}) > \frac{k\sqrt{c_0}}{b};$$

then we obtain (3.1) with

$$d = \frac{\frac{1}{b} \left(\frac{1}{c_1} + \frac{1}{2} \sqrt{\frac{c_0 c_2}{\sqrt{2}\beta}} \right) + \frac{k\sqrt{c_0}}{2b}}{\frac{1}{\beta k} (1 - e^{-\beta k T_0}) + \frac{1}{b} \left(\frac{1}{c_1} + \frac{1}{2} \sqrt{\frac{c_0 c_2}{\sqrt{2}\beta}} \right) - \frac{k\sqrt{c_0}}{2b}} \in]0, 1[.$$

We note that if a nonnegative function $E:\mathbb{R}^+\to\mathbb{R}^+$ satisfies the estimate (3.1), then it also satisfies (2.11). Indeed, let $t\in\mathbb{R}^+$; then $t=mT_0+t_0$ with $0\le t_0<T_0$ and $m\in\mathbb{N}$. From (3.1) and taking (3.11) with $t=t_0$ and $\tau=0$ into account, it holds that

$$E(t)\le dE((m-1)T_0+t_0)\le\cdots\le d^mE(t_0)$$

$$\le d^{\frac{1}{T_0}(t-t_0)}e^{\beta kt_0}E(0)\le\frac{e^{\beta kT_0}}{d}E(0)e^{\frac{\ln d}{T_0}t};$$

then we deduce (2.11), where $c=\frac{e^{\beta kT_0}}{d}$ and $\omega=-\frac{\ln d}{T_0}$.

Case 2. $\frac{k\sqrt{c_0}}{2}\le\frac{1}{c_1}+\frac{1}{2}\sqrt{\frac{c_0c_2}{\sqrt{2}\beta}}$. Inequality (3.9) implies that

$$\int_S^T E(t)dt\le a_0E(S)\qquad\forall 0\le S\le T<\infty,$$

where $a_0=\frac{k\sqrt{c_0}}{2b}+\frac{1}{b}(\frac{1}{c_1}+\frac{1}{2}\sqrt{\frac{c_0c_2}{\sqrt{2}\beta}})$. Let T go to ∞; we deduce

$$\int_S^\infty E(t)dt\le a_0E(S)\qquad\forall S\ge 0. \tag{3.14}$$

Introduce the function

$$\psi(S)=\int_S^\infty E(t)dt,\qquad S\ge 0.$$

It is positive and nonincreasing. Differentiating and using (3.14), we find that

$$\psi'(S)\le-\frac{1}{a_0}\psi(S),$$

hence $(\ln(\psi(S)))'\le-\frac{1}{a_0}$. Integrating in $[0,S]$ and using (3.14) again, we obtain that

$$\psi(S)\le a_0E(0)e^{-\frac{1}{a_0}S}\qquad\forall S\ge 0. \tag{3.15}$$

On the other hand, E being nonnegative and satisfying (3.12) (with $\tau=S$), $\psi(S)$ may be estimated as follows: let $T_0>0$,

$$\psi(S)\ge\int_S^{S+T_0}E(t)dt\ge\int_S^{S+T_0}\frac{1}{\beta k}\frac{\partial}{\partial t}\left((1-e^{-\beta k(t-S)})E(t)\right)dt$$

$$=\frac{1-e^{-\beta kT_0}}{\beta k}E(S+T_0).$$

Therefore, taking $t=S+T_0$ and choosing $T_0=\frac{1}{\beta k}\ln(1+\beta ka_0)$ (for which the quantity $\frac{e^{T_0/a_0}}{1-e^{-\beta kT_0}}$ reachs its minimum), hence we deduce from (3.15) the estimate

$$E(t)\le(1+\beta ka_0)^{1+\frac{1}{\beta ka_0}}E(0)e^{-\frac{1}{a_0}t}\qquad\forall t\ge T_0. \tag{3.16}$$

This inequality holds, in fact, also for $t\in[0,T_0]$. Indeed, by (3.11) with $\tau=0$, we have

$$E(t)\le e^{\beta kt}E(0)\le e^{(\beta k+\frac{1}{a_0})T_0}E(0)e^{-\frac{1}{a_0}t}=(1+\beta ka_0)^{1+\frac{1}{\beta ka_0}}E(0)e^{-\frac{1}{a_0}t}.$$

Then (3.16) holds true for all $t\ge 0$ and hence the inequality (2.11) follows with $c=(1+\beta ka_0)^{1+\frac{1}{\beta ka_0}}$ and $\omega=\frac{1}{a_0}$.

This concludes the proof of Theorem 2.1.

4. Energy decay estimates: Proof of Theorem 2.2. For the proof of Theorem 2.2 which concerns the stability of (P) in the particular case $h(\nabla u) = -\nabla\phi \cdot \nabla u$, with $\phi \in W^{1,\infty}(\Omega)$, we are going to prove that the equivalent energy E defined by (2.14) satisfies, for any $0 \le S < \infty$,

$$\int_S^\infty E^{\frac{r+1}{2}}(t)dt \le cE(S). \tag{4.1}$$

Here and in what follows we shall denote by c diverse positive constants, by ϵ diverse positive constants small enough, and by c_ϵ diverse positive constants depending on ϵ. (All these constants do not depend on S.) The inequality (4.1) gives (2.11) and (2.15) (see [12, Theorem 9.1]).

Using the first equation of (P) and the boundary condition, we can easily prove that the equivalent energy E satisfies

$$E'(t) = -2\int_\Omega e^{\phi(x)}u'g(u')dx, \qquad t \in \mathbb{R}^+. \tag{4.2}$$

Assumption (2.4) implies that the equivalent energy is nonincreasing. Given $0 \le S \le T < \infty$ arbitrarily, integrate (4.2) between S and T to get

$$\int_S^T \int_\Omega e^{\phi(x)}u'g(u')dx = \frac{1}{2}\left(E(S) - E(T)\right). \tag{4.3}$$

We multiply the first equation of (P) by $E^{\frac{r-1}{2}}(t)e^{\phi(x)}u$ and integrate over $\Omega\times[S,T]$ to get

$$\int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left(\left|u'\right|^2 + \left|\nabla u\right|^2 + uf(u)\right)dxdt \tag{4.4}$$

$$= \int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left(2\left|u'\right|^2 - ug(u')\right)dxdt$$

$$+ \frac{r-1}{2}\int_S^T \int_\Omega E^{\frac{r-3}{2}}(t)E'(t)e^{\phi(x)}uu'dxdt - \left[\int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)}uu'dxdt\right]_S^T.$$

The last two terms of (4.4) can be easily majorized by $cE^{\frac{r+1}{2}}(S)$ (see [3] and [5]). We follow now the proof given in [5]. We note $q = p + 1$,

$$\Omega^+ = \{x \in \Omega : \left|u'\right| > 1\}, \quad \text{and} \quad \Omega^- = \Omega \setminus \Omega^+.$$

We exploit the Cauchy–Schwarz, Hölder, and Young inequalities and the Sobolev imbedding $H_0^1(\Omega) \subset L^q(\Omega)$ to get

$$-\int_S^T \int_{\Omega^+} E^{\frac{r-1}{2}}(t)e^{\phi(x)}ug(u')dxdt$$

$$\le \int_S^T E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left(\int_{\Omega^+}\left|u\right|^q dx\right)^{\frac{1}{q}}\left(\int_{\Omega^+}\left|g(u')\right|^{1+\frac{1}{p}}dx\right)^{\frac{p}{p+1}}dt$$

$$\leq \int_S^T E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left(\epsilon\int_{\Omega^+}\left|u\right|^q dx + c_\epsilon\int_{\Omega^+}\left|g(u')\right|^{1+\frac{1}{p}}dx\right)dt$$

$$\leq \epsilon\int_S^T E^{\frac{r+q-1}{2}}(t)dt + c_\epsilon E^{\frac{r-1}{2}}(S)\int_S^T\int_{\Omega^+} e^{\phi(x)}u'g(u')dxdt$$

$$\leq \epsilon\int_S^T E^{\frac{r+1}{2}}(t)dt + c_\epsilon\left(E^{\frac{r+1}{2}}(S) - E^{\frac{r+1}{2}}(T)\right).$$

On the other hand, using the growth assumption (2.12) and Poincaré's inequality, we have

$$-\int_S^T\int_{\Omega^-} E^{\frac{r-1}{2}}(t)e^{\phi(x)}ug(u')dxdt$$

$$\leq \int_S^T E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left(\epsilon\int_{\Omega^-}\left|u\right|^2 dx + c_\epsilon\int_{\Omega^-} g^2(u')dx\right)dt$$

$$\leq \epsilon\int_S^T E^{\frac{r-1}{2}}(t)\int_{\Omega^-} e^{\phi(x)}\left|\nabla u\right|^2 dxdt + c_\epsilon\int_S^T\int_{\Omega^-} E^{\frac{r-1}{2}}(t)\left(e^{\phi(x)}u'g(u')\right)^{\frac{2}{r+1}}dxdt$$

$$\leq \epsilon\int_S^T E^{\frac{r+1}{2}}(t)dt + c_\epsilon\left(E(S) - E(T)\right).$$

Taking the sum of the last two inequalities and substituting it into the right-hand side of (4.4), using (2.3), and choosing $\epsilon \in]0, b[$, we obtain that

$$\int_S^T E^{\frac{r+1}{2}}(t)dt \leq c\left(E^{\frac{r+1}{2}}(S) + E(S)\right) + c\int_S^T\int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left|u'\right|^2 dxdt. \tag{4.5}$$

Using another time (2.12) and (4.3), we have

$$\int_S^T\int_{\Omega^+} E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left|u'\right|^2 dxdt \leq cE^{\frac{r-1}{2}}(S)\int_S^T\int_{\Omega^+} e^{\phi(x)}u'g(u')dxdt$$

$$\leq c\left(E^{\frac{r+1}{2}}(S) - E^{\frac{r+1}{2}}(T)\right).$$

In the same way, using Young's inequality, we get

$$\int_S^T\int_{\Omega^-} E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left|u'\right|^2 dxdt \leq c\int_S^T\int_{\Omega^-} E^{\frac{r-1}{2}}(t)\left(e^{\phi(x)}u'g(u')\right)^{\frac{2}{r+1}}dxdt$$

$$\leq \epsilon\int_S^T E^{\frac{r+1}{2}}(t)dt + c_\epsilon\int_S^T\int_{\Omega^-} e^{\phi(x)}u'g(u')dxdt$$

$$\leq \epsilon\int_S^T E^{\frac{r+1}{2}}(t)dt + c_\epsilon\left(E(S) - E(T)\right).$$

Substituting the sum of these two estimates into the right-hand side of (4.5), choosing ϵ small enough, and letting T go to ∞, we obtain

$$\int_S^\infty E^{\frac{r+1}{2}}(t)dt \leq c\left(1 + E^{\frac{r-1}{2}}(0)\right)E(S) \leq cE(S);$$

then (4.1) follows, which gives (2.11) and (2.15) and finishes the proof of Theorem 2.2.

5. Uniform decay: Proof of Theorem 2.3. In this section we prove the exponential decay of energy (2.7) for strong solutions of (P′), and by a density argument we obtain the same results for weak solutions.

The proof is similar to the one given in section 3.

Using the first equation in (P′) and the boundary conditions, we can easily prove that

$$E'(t) = -2\int_{\Gamma_1} u' g(u')\, d\Gamma - 2\int_\Omega u' h(\nabla u)\, dx. \tag{5.1}$$

Using Assumptions 2.2, 2.3, and 2.5, from (5.1) it holds that (see section 3)

$$E'(t) \le -2\int_\Omega u' h(\nabla u)\, dx \le \beta \int_\Omega \Big(|u'|^2 + |\nabla u|^2\Big)\, dx \le \beta E(t);$$

then E satisfies (3.11) and (3.12) with $k = 1$ (see (2.18)). Following the proof given in section 3, it is sufficient to prove that, for all $0 \le S \le T < \infty$,

$$\int_S^T E(t)dt \le \bar{a}(E(S) + E(T)) + \hat{a}(E(S) - E(T)) \tag{5.2}$$

with $\bar{a}$, $\hat{a} > 0$ and $2\beta\bar{a} < 1$ or $\bar{a} \le \hat{a}$. Then the proof can be completed as in section 3.

To prove (5.2), let $\epsilon_0 \in]0, 1[$ (will be chosen later in the course of the proof); we multiply the first equation in (P′) by

$$2m \cdot \nabla u + (n - \epsilon_0)u,$$

integrating the obtained result over $\Omega \times [S, T]$ and using the boundary conditions. We are going to estimate the terms of the result formula. We have

$$I_1 := \int_S^T \int_\Omega u''\Big(2m \cdot \nabla u + (n - \epsilon_0)u\Big)dxdt$$

$$= \Big[\int_\Omega u'\Big(2m \cdot \nabla u + (n - \epsilon_0)u\Big)dx\Big]_S^T - \int_S^T \int_\Omega \Big(m \cdot \nabla (u')^2 + (n - \epsilon_0)\,|u'|^2\Big)dxdt$$

$$= \epsilon_0 \int_S^T \int_\Omega |u'|^2\, dxdt - \int_S^T \int_{\Gamma_1} (m \cdot \nu)\,|u'|^2\, d\Gamma dt$$

$$+ \Big[\int_\Omega u'\Big(2m \cdot \nabla u + (n - \epsilon_0)u\Big)dx\Big]_S^T.$$

We estimate the last term in this inequality; we have

$$\int_\Omega \Big(2m \cdot \nabla u + (n - \epsilon_0)u\Big)^2 dx - \int_\Omega (2m \cdot \nabla u)^2 dx$$

$$= \int_\Omega \Big((n - \epsilon_0)^2\,|u|^2 + 2(n - \epsilon_0)m \cdot \nabla (u)^2\Big)\, dx$$

$$= \int_\Omega \Big((n-\epsilon_0)^2 |u|^2 - 2(n-\epsilon_0) n |u|^2 \Big) dx + 2(n-\epsilon_0) \int_{\Gamma_1} (m\cdot\nu) |u|^2 d\Gamma$$

$$= (\epsilon_0+n)(\epsilon_0-n) \int_\Omega |u|^2 dx + 2(n-\epsilon_0) \int_{\Gamma_1} (m\cdot\nu) |u|^2 d\Gamma$$

$$\leq 2(n-\epsilon_0) R \int_{\Gamma_1} |u|^2 d\Gamma;$$

then

$$\int_\Omega \Big(2m\cdot\nabla u + (n-\epsilon_0)u \Big)^2 dx \leq \int_\Omega (2m\cdot\nabla u)^2 dx + 2(n-\epsilon_0) R \int_{\Gamma_1} |u|^2 d\Gamma. \tag{5.3}$$

Since, for all $\epsilon > 0$,

$$\Big| \int_\Omega \Big(2m\cdot\nabla u + (n-\epsilon_0)u \Big) u' dx \Big|$$

$$\leq \frac{\epsilon}{2} \int_\Omega |u'|^2 dx + \frac{1}{2\epsilon} \Big(\int_\Omega (2m\cdot\nabla u)^2 dx + 2(n-\epsilon_0) R \int_{\Gamma_1} |u|^2 d\Gamma \Big)$$

$$\leq \int_\Omega \left(\frac{\epsilon}{2} |u'|^2 + \frac{2R^2}{\epsilon} |\nabla u|^2 dx \right) + \frac{R}{\epsilon} (n-\epsilon_0) \bar{c} \int_\Omega |\nabla u|^2 dx,$$

where $\bar{c}$ is the positive constant satisfying (Poincaré's inequality)

$$\int_{\Gamma_1} |v|^2 d\Gamma \leq \bar{c} \int_\Omega |\nabla v|^2 dx \qquad \forall v \in V.$$

Choosing $\epsilon = 2\sqrt{R(R + \frac{\bar{c}}{2}(n-\epsilon_0))}$, we obtain

$$\Big| \int_\Omega \Big(2m\cdot\nabla u + (n-\epsilon_0)u \Big) u' dx \Big| \leq \sqrt{R\Big(R + \frac{\bar{c}}{2}(n-\epsilon_0) \Big)} E(t) := a_1 E(t).$$

Then we deduce

$$I_1 \geq -a_1 (E(S) + E(T)) - R \int_S^T \int_{\Gamma_1} |u'|^2 d\Gamma dt + \epsilon_0 \int_S^T \int_\Omega |u'|^2 dx dt. \tag{5.4}$$

On the other hand, taking the generalized Green formula and recalling the identity

$$2\nabla u \cdot \nabla (m\cdot\nabla u) = 2|\nabla u|^2 + m\cdot\nabla(|\nabla u|^2)$$

(note also that on Γ_0 we have $\nabla u = \partial_\nu u \nu$), we infer

$$I_2 := \int_S^T \int_\Omega (-\Delta u) \Big(2m\cdot\nabla u + (n-\epsilon_0)u \Big) dx dt$$

$$= (2-\epsilon_0) \int_S^T \int_\Omega |\nabla u|^2 dx dt - \int_S^T \int_{\Gamma_0} (m\cdot\nu) |\nabla u|^2 d\Gamma dt$$

$$+ \int_S^T \int_{\Gamma_1} \Big((m\cdot\nu) |\nabla u|^2 - (n-\epsilon_0) u \partial_\nu u - 2(m\cdot\nabla u)\partial_\nu u \Big) d\Gamma dt.$$

Using the definition of Γ_0 and Γ_1, we deduce

$$I_2 \geq (2-\epsilon_0)\int_S^T\int_\Omega |\nabla u|^2\,dxdt$$

$$+\int_S^T\int_{\Gamma_1}\Big(\delta\,|\nabla u|^2-(n-\epsilon_0)u\partial_\nu u-\delta\,|\nabla u|^2-\frac{R^2}{\delta}(\partial_\nu u)^2\Big)d\Gamma dt;$$

then

$$I_2 \geq (2-\epsilon_0)\int_S^T\int_\Omega |\nabla u|^2\,dxdt-\int_S^T\int_{\Gamma_1}\Big((n-\epsilon_0)u\partial_\nu u+\frac{R^2}{\delta}(\partial_\nu u)^2\Big)d\Gamma dt. \tag{5.5}$$

Similarly, using (2.6), (5.3), and the Cauchy–Schwarz inequality, we have

$$I_3 := \int_S^T\int_\Omega h(\nabla u)\Big(2m\cdot\nabla u+(n-\epsilon_0)u\Big)dxdt$$

$$\geq -\frac{R}{\beta}\int_S^T\int_\Omega h^2(\nabla u)dxdt-\frac{\beta}{4R}\int_S^T\Big(4R^2\int_\Omega |\nabla u|^2\,dx+2(n-\epsilon_0)R\int_{\Gamma_1}|u|^2\,d\Gamma\Big)dt;$$

we conclude that

$$I_3 \geq -2\beta R\int_S^T\int_\Omega |\nabla u|^2\,dxdt-\frac{\beta}{2}(n-\epsilon_0)\int_S^T\int_{\Gamma_1}|u|^2\,d\Gamma dt. \tag{5.6}$$

Using (2.3) and the fact that F is nonnegative and $F(0)=0$, we obtain

$$\begin{aligned} I_4 &:= \int_S^T\int_\Omega f(u)\Big(2m\cdot\nabla u+(n-\epsilon_0)u\Big)dxdt\\ &\geq (n-\epsilon_0)b\int_S^T\int_\Omega 2F(u)dxdt+\int_S^T\int_\Omega 2m\cdot\nabla(F(u))dxdt\\ &\geq ((n-\epsilon_0)b-n)\int_S^T\int_\Omega 2F(u)dxdt+\int_S^T\int_{\Gamma_1}2(m\cdot\nu)F(u)d\Gamma dt; \end{aligned}$$

then we deduce

$$I_4 \geq ((n-\epsilon_0)b-n)\int_S^T\int_\Omega 2F(u)dxdt. \tag{5.7}$$

Now we distinguish two cases.

Case 3. If $b>1$, then assuming that $\beta R<1$ and choosing $\epsilon_0=\min\{1-\beta R,\frac{b-1}{b+1}n\}$, we deduce that $\min\{\epsilon_0,2-\epsilon_0-2\beta R,(n-\epsilon_0)b-n\}=\epsilon_0$. Combining (5.4)–(5.7), taking the fact that $I_1+I_2+I_3+I_4=0$ in account, we obtain

$$\epsilon_0\int_S^T\int_\Omega\Big(|u'|^2+|\nabla u|^2+2F(u)\Big)dxdt\leq a_1(E(S)+E(T))$$

$$+\int_S^T\int_{\Gamma_1}\left(R\left|u'\right|^2+\frac{\beta}{2}(n-\epsilon_0)\left|u\right|^2+(n-\epsilon_0)u\partial_\nu u+\frac{R^2}{\delta}(\partial_\nu u)^2\right)d\Gamma dt.$$

Case 4. If f is linear, $f(s)=\alpha s$ for some positive constant α, then $b=1$ and we conclude from (5.7) that

$$\begin{aligned}I_4&\geq-\epsilon_0\int_S^T\int_\Omega 2F(u)dxdt=\epsilon_0\int_S^T\int_\Omega 2F(u)dxdt-2\epsilon_0\int_S^T\int_\Omega 2F(u)dxdt\\&=\epsilon_0\int_S^T\int_\Omega 2F(u)dxdt-2\epsilon_0\alpha\int_S^T\int_\Omega\left|u\right|^2dxdt\\&\geq\epsilon_0\int_S^T\int_\Omega 2F(u)dxdt-2\epsilon_0\alpha\hat{c}\int_S^T\int_\Omega\left|\nabla u\right|^2dxdt,\end{aligned}$$

where $\hat{c}$ is the smallest imbedding positive constant satisfying

$$\int_\Omega\left|v\right|^2dx\leq\hat{c}\int_\Omega\left|\nabla v\right|^2dx\qquad\forall v\in V. \tag{5.8}$$

Assuming that $\beta R<1$ and choosing $\epsilon_0=\frac{1-\beta R}{1+\alpha\hat{c}}$, then $\min\{\epsilon_0,2-\epsilon_0-2\beta R-2\epsilon_0\alpha\hat{c}\}=\epsilon_0$ and the same inequality obtained in Case 3 holds true.

We now use the boundary condition on Γ_1; we have in both previous cases

$$\epsilon_0\int_S^T E(t)dt\leq a_1(E(S)+E(T)) \tag{5.9}$$

$$+\int_S^T\int_{\Gamma_1}\left(R\left|u'\right|^2+\frac{R^2}{\delta}g^2(u')+\frac{\beta}{2}(n-\epsilon_0)\left|u\right|^2-(n-\epsilon_0)ug(u')\right)d\Gamma dt.$$

Using (5.1), the Cauchy–Schwarz inequality and taking the assumptions (2.4), (2.5), and (2.6) into account, it holds that

$$\int_S^T\int_{\Gamma_1}\left(R|u'|^2+\frac{R^2}{\delta}g^2(u')\right)dx\,dt\leq\left(\frac{R}{c_1}+\frac{R^2}{\delta}c_2\right)\int_S^T\int_{\Gamma_1}u'g(u')dx\,dt$$

$$=\frac{1}{2}\left(\frac{R}{c_1}+\frac{R^2}{\delta}c_2\right)\int_S^T\left(-E'(t)-2\int_\Omega u'h(\nabla u)dx\right)dt$$

$$\leq\frac{1}{2}\left(\frac{R}{c_1}+\frac{R^2}{\delta}c_2\right)(E(S)-E(T))+\frac{1}{2}\left(\frac{R}{c_1}+\frac{R^2}{\delta}c_2\right)\beta\int_S^T\int_\Omega\left(|u'|^2+|\nabla u|^2\right)dx\,dt;$$

we note $a_2:=\frac{1}{2}(\frac{R}{c_1}+\frac{R^2}{\delta}c_2)$ and deduce

$$\int_S^T\int_{\Gamma_1}\left(R|u'|^2+\frac{R^2}{\delta}g^2(u')\right)dx\,dt\leq a_2\left(E(S)-E(T)\right)+\beta a_2\int_S^T E(t)dt. \tag{5.10}$$

Similarly, we have

$$
\begin{aligned}
&(n-\epsilon_0)\int_S^T\int_{\Gamma_1}\left(\frac{\beta}{2}|u|^2-ug(u')\right)dx\,dt\\
&\le\frac{1}{2}(n-\epsilon_0)\int_S^T\int_{\Gamma_1}\left(\frac{1}{\epsilon}g^2(u')+(\beta+\epsilon)|u|^2\right)dx\,dt\\
&\le\frac{1}{2}(n-\epsilon_0)\int_S^T\int_{\Gamma_1}\left(\frac{c_2}{\epsilon}u'g(u')+(\beta+\epsilon)|u|^2\right)dx\,dt\\
&=\frac{c_2}{2\epsilon}(n-\epsilon_0)\int_S^T\left(-\frac{1}{2}E'(t)-\int_\Omega u'h(\nabla u)dx\right)dt\\
&\quad+\frac{1}{2}(\beta+\epsilon)(n-\epsilon_0)\bar{c}\int_S^T\int_\Omega|\nabla u|^2dx\,dt\\
&\le\frac{c_2}{4\epsilon}(n-\epsilon_0)(E(S)-E(T))+\frac{1}{2}(\beta+\epsilon)(n-\epsilon_0)\bar{c}\int_S^T\int_\Omega|\nabla u|^2dx\,dt\\
&\quad+\frac{c_2}{2\epsilon}(n-\epsilon_0)\int_S^T\int_\Omega\left(\frac{\epsilon'\beta^2}{2}|\nabla u|^2+\frac{1}{2\epsilon'}|u'|^2\right)dx\,dt,
\end{aligned}
$$

we choose $\epsilon=\beta\sqrt{\frac{c_2\epsilon'}{2\bar{c}}}$, $\epsilon'=\frac{1}{\beta\sqrt{2}}$, and we note $a_3:=\frac{1}{2}(n-\epsilon_0)\sqrt{\frac{\bar{c}c_2}{\sqrt{2}\beta}}$, $a_4:=(n-\epsilon_0)(\frac{\beta\bar{c}}{2}+\sqrt{\frac{\bar{c}c_2\beta}{2\sqrt{2}}})$. It follows that

$$
\begin{aligned}
&(n-\epsilon_0)\int_S^T\int_{\Gamma_1}\left(\frac{\beta}{2}|u'|^2-ug(u')\right)dx\,dt\\
&\le a_4\int_S^T E(t)dt+a_3\left(E(S)-E(T)\right).
\end{aligned}
\tag{5.11}
$$

Combining (5.9), (5.10), and (5.11), we have

$$
\begin{aligned}
&(\epsilon_0-\beta a_2-a_4)\int_S^T E(t)dt\\
&\le a_1\left(E(S)+E(T)\right)+(a_2+a_3)\left(E(S)-E(T)\right).
\end{aligned}
\tag{5.12}
$$

If β is small enough so that $2\beta a_1<a_5:=\epsilon_0-\beta a_2-a_4$, that is,

$$
\beta(2a_1+a_2)+a_4<\epsilon_0=\begin{cases}\min\{1-\beta R,\frac{b-1}{b+1}n\} & \text{if } b>1,\\ \frac{1-\beta R}{1+\alpha\hat{c}} & \text{if } f \text{ is linear}\end{cases}
$$

(note that $\beta(2a_1+a_2)+a_4$ goes to 0 when β goes to 0), we conclude (5.2) with $\bar{a}=\frac{a_1}{a_5}$ and $\hat{a}=\frac{a_2+a_3}{a_5}$. We fix then $T_0>\frac{-1}{\beta}\ln(1-2\beta\bar{a})$. Using (3.12) with $\tau=S$, we have

$$
\int_S^{S+T_0}E(t)dt\ge\frac{1}{\beta}(1-e^{-\beta T_0})E(S+T_0).
$$

We insert this inequality into (5.2) with $T = S + T_0$ and obtain

$$\left(\frac{1}{\beta}(1 - e^{-\beta T_0}) + \hat{a} - \bar{a}\right) E(S + T_0) \leq (\hat{a} + \bar{a}) E(S).$$

Thanks to the hypothesis on T_0, we have $\frac{1}{\beta}(1 - e^{-\beta T_0}) > 2\bar{a}$, which implies (3.1) with $d = \frac{\hat{a}+\bar{a}}{\frac{1}{\beta}(1-e^{-\beta T_0})+\hat{a}-\bar{a}}$.

If $\beta a_2 + a_4 < \epsilon_0$ and $a_1 \leq a_2 + a_3$ (that is, $\sqrt{R(R + \frac{\bar{c}}{2}(n - \epsilon_0))} \leq \frac{1}{2}(\frac{R}{c_1} + \frac{R^2}{\delta} c_2) + \frac{1}{2}(n - \epsilon_0)\sqrt{\frac{\bar{c} c_2}{\sqrt{2}\beta}}$), we conclude from (5.12) that (3.14) follows with $a_0 = \frac{a_1+a_2+a_3}{a_5}$.

Then in both cases the proof of Theorem 2.3 can be completed as in section 3.

6. Decay estimates: Proof of Theorem 2.4. To prove Theorem 2.4, which concerns the stability of (P′) in the particular case $h(\nabla u) = -\nabla\phi \cdot \nabla u$, with $\phi \in W^{1,\infty}(\Omega)$, it is sufficient to prove that the equivalent energy E defined by (2.14) satisfies (4.1) (see section 4).

In this section, we shall denote by c diverse positive constants, by ϵ diverse positive constants small enough (which can be changed from a line to another), and by c_ϵ diverse positive constants depending on ϵ.

A simple computation shows that

$$E'(t) = -2 \int_{\Gamma_1} e^{\phi(x)} u' g(u') dx, \qquad t \in \mathbb{R}^+. \tag{6.1}$$

Assumption (2.4) implies that the equivalent energy is nonincreasing.

We fix $\epsilon_0 > 0$ and we multiply the first equation in (P′) by

$$E^{\frac{r-1}{2}}(t) e^{\phi(x)} \Big(2m \cdot \nabla u + (n - \epsilon_0) u\Big),$$

integrating the obtained result over $\Omega \times [S, T]$ and using the boundary conditions. We have

$$\begin{aligned}
I_1 &:= \int_S^T \int_\Omega E^{\frac{r-1}{2}}(t) e^{\phi(x)} u'' \Big(2m \cdot \nabla u + (n - \epsilon_0) u\Big) dx dt \\
&= \left[\int_\Omega E^{\frac{r-1}{2}}(t) e^{\phi(x)} u' \Big(2m \cdot \nabla u + (n - \epsilon_0) u\Big) dx\right]_S^T \\
&\quad - \frac{r-1}{2} \int_S^T \int_{\Gamma_1} E^{\frac{r-3}{2}}(t) E'(t) e^{\phi(x)} \Big(2m \cdot \nabla u + (n - \epsilon_0) u\Big) dx dt \\
&\quad - \int_S^T \int_\Omega E^{\frac{r-1}{2}}(t) e^{\phi(x)} \int_\Omega \Big(m \cdot \nabla (u')^2 + (n - \epsilon_0) |u'|^2\Big) dx dt \\
&= \int_S^T \int_\Omega E^{\frac{r-1}{2}}(t) e^{\phi(x)} (\epsilon_0 + m \cdot \nabla\phi) |u'|^2 dx dt - \int_S^T \int_{\Gamma_1} E^{\frac{r-1}{2}}(t) e^{\phi(x)} (m \cdot \nu) |u'|^2 d\Gamma dt \\
&\quad + \Big[\int_\Omega E^{\frac{r-1}{2}}(t) e^{\phi(x)} u' \Big(2m \cdot \nabla u + (n - \epsilon_0) u\Big) dx\Big]_S^T \\
&\quad - \frac{r-1}{2} \int_S^T \int_{\Gamma_1} E^{\frac{r-3}{2}}(t) E'(t) e^{\phi(x)} \Big(2m \cdot \nabla u + (n - \epsilon_0) u\Big) dx dt.
\end{aligned}$$

The last two terms of this equality can be easily majorized by $cE^{\frac{r+1}{2}}(S)$; then we deduce

$$I_1 \geq -cE^{\frac{r+1}{2}}(S) - R\int_S^T \int_{\Gamma_1} E^{\frac{r-1}{2}}(t)e^{\phi(x)} |u'|^2 \, d\Gamma dt \tag{6.2}$$

$$+(\epsilon_0 - R\|\nabla\phi\|_\infty)\int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)} |u'|^2 \, dxdt.$$

On the other hand, taking the generalized Green formula (see section 5), we infer

$$I_2 := \int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)}(-\Delta u - \nabla\phi\cdot\nabla u)\Big(2m\cdot\nabla u + (n-\epsilon_0)u\Big)dxdt$$

$$= (2-\epsilon_0)\int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)} |\nabla u|^2 \, dxdt - \int_S^T \int_{\Gamma_0} E^{\frac{r-1}{2}}(t)e^{\phi(x)}(m\cdot\nu) |\nabla u|^2 \, d\Gamma dt$$

$$+\int_S^T \int_{\Gamma_1} E^{\frac{r-1}{2}}(t)e^{\phi(x)}\Big((m\cdot\nu) |\nabla u|^2 - (n-\epsilon_0)u\partial_\nu u - 2(m\cdot\nabla u)\partial_\nu u\Big)d\Gamma dt.$$

Using the definition of Γ_0 and Γ_1, we deduce

$$I_2 \geq (2-\epsilon_0)\int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)} |\nabla u|^2 \, dxdt \tag{6.3}$$

$$-\int_S^T \int_{\Gamma_1} E^{\frac{r-1}{2}}(t)e^{\phi(x)}\left((n-\epsilon_0)u\partial_\nu u + \frac{R^2}{\delta}(\partial_\nu u)^2\right)d\Gamma dt.$$

Using (2.3) and the fact that F is nonnegative, we obtain

$$I_3 := \int_S^T \int_\Omega E^{\frac{r-1}{2}}(t)e^{\phi(x)} f(u)\Big(2m\cdot\nabla u + (n-\epsilon_0)u\Big)dxdt$$

$$\geq (n-\epsilon_0)b\int_S^T \int_\Omega 2E^{\frac{r-1}{2}}(t)e^{\phi(x)}F(u)dxdt + \int_S^T \int_\Omega 2E^{\frac{r-1}{2}}(t)e^{\phi(x)}m\cdot\nabla(F(u))dxdt$$

$$\geq \int_S^T \int_\Omega ((n-\epsilon_0)b - n - m\cdot\nabla\phi)2E^{\frac{r-1}{2}}(t)e^{\phi(x)}F(u)dxdt$$

$$+\int_S^T \int_{\Gamma_1} 2E^{\frac{r-1}{2}}(t)e^{\phi(x)}(m\cdot\nu)F(u)d\Gamma dt;$$

then we conclude that

$$I_3 \geq ((n-\epsilon_0)b - n - R\|\nabla\phi\|_\infty)\int_S^T \int_\Omega 2F(u)dxdt. \tag{6.4}$$

Thanks to the assumptions in Theorem 2.4, we have the following.

Case 5. If $R\|\nabla\phi\|_\infty < \min\{2,n\}$ and $b > \frac{n+R\|\nabla\phi\|_\infty}{n-R\|\nabla\phi\|_\infty}$, we can choose $\epsilon_0 \in]R\|\nabla\phi\|_\infty, \min\{2, n-\frac{n+R\|\nabla\phi\|_\infty}{b}\}[$ and then

$$\min\{\epsilon_0 - R\|\nabla\phi\|_\infty, 2-\epsilon_0, (n-\epsilon_0)b - n - R\|\nabla\phi\|_\infty\} > 0.$$

Case 6. If f is linear, $f(s) = \alpha s$ for some positive constant α, then $b = 1$ and we conclude from (6.4) that

$$\begin{aligned} I_3 &\geq (-\epsilon_0 - R\|\nabla\phi\|_\infty)\int_S^T\int_\Omega 2F(u)dxdt \\ &= (\epsilon_0 - R\|\nabla\phi\|_\infty)\int_S^T\int_\Omega 2F(u)dxdt - 2\epsilon_0\int_S^T\int_\Omega 2F(u)dxdt \\ &= (\epsilon_0 - R\|\nabla\phi\|_\infty)\int_S^T\int_\Omega 2F(u)dxdt - 2\epsilon_0\alpha\int_S^T\int_\Omega |u|^2\,dxdt \\ &\geq (\epsilon_0 - R\|\nabla\phi\|_\infty)\int_S^T\int_\Omega 2F(u)dxdt - 2\epsilon_0\alpha\hat{c}\int_S^T\int_\Omega |\nabla u|^2\,dxdt, \end{aligned}$$

where $\hat{c}$ is the positive constant defined by (5.8). Then, assuming that $R\|\nabla\phi\|_\infty < \frac{2}{1+2\alpha\hat{c}}$ and taking $\epsilon_0 \in]R\|\nabla\phi\|_\infty, \frac{2}{1+2\alpha\hat{c}}[$, the quantity $\min\{\epsilon_0 - R\|\nabla\phi\|_\infty, 2-(1+2\alpha\hat{c})\epsilon_0\}$ is positive.

Combining (6.2)–(6.4), taking the fact that $I_1 + I_2 + I_3 = 0$ into account, and using the boundary condition on Γ_1, we obtain in both previous cases

$$\begin{aligned} (6.5)\quad \int_S^T\int_\Omega E^{\frac{r+1}{2}}(t)dt &\leq cE^{\frac{r+1}{2}}(S) \\ &\quad + c\int_S^T\int_{\Gamma_1} E^{\frac{r-1}{2}}(t)e^{\phi(x)}\Big(|u'|^2 + g^2(u') + |ug(u')|\Big)d\Gamma dt. \end{aligned}$$

We now estimate the last term of (6.5). We exploit the Cauchy–Schwarz inequality and the Sobolev imbedding $V \subset L^2(\Gamma_1)$ to get

$$\int_{\Gamma_1}|ug(u')|d\Gamma \leq \epsilon\int_{\Gamma_1}|u|^2d\Gamma + c_\epsilon\int_{\Gamma_1}g^2(u')d\Gamma \leq \epsilon E(t) + c_\epsilon\int_{\Gamma_1}g^2(u')d\Gamma.$$

Substituting this inequality into the right-hand side of (6.5) and choosing $\epsilon > 0$ small enough, we obtain that

$$\begin{aligned} (6.6)\qquad \int_S^T\int_\Omega E^{\frac{r+1}{2}}(t)dt &\leq cE^{\frac{r+1}{2}}(S) \\ &\quad + c\int_S^T\int_{\Gamma_1} E^{\frac{r-1}{2}}(t)e^{\phi(x)}\Big(|u'|^2 + g^2(u')\Big)d\Gamma dt. \end{aligned}$$

We follow now the proof given in section 4. We note

$$\Gamma^+ = \{x \in \Gamma_1 : \big|u'\big| > 1\} \quad \text{and} \quad \Gamma^- = \Gamma_1 \setminus \Gamma^+.$$

By (2.12) and (6.1) we have

$$\int_S^T \int_{\Gamma^+} E^{\frac{r-1}{2}}(t) e^{\phi(x)} \Big(\big|u'\big|^2 + g^2(u') \Big) dxdt \le cE^{\frac{r-1}{2}}(S) \int_S^T \int_{\Gamma^+} e^{\phi(x)} u' g(u') dxdt$$
$$\le c \left(E^{\frac{r+1}{2}}(S) - E^{\frac{r+1}{2}}(T) \right).$$

In the same way (using Young's inequality), we get

$$\int_S^T \int_{\Gamma^-} E^{\frac{r-1}{2}}(t) e^{\phi(x)} \Big(\big|u'\big|^2 + g^2(u') \Big) dxdt \le c \int_S^T \int_{\Gamma^-} E^{\frac{r-1}{2}}(t) \Big(e^{\phi(x)} u' g(u') \Big)^{\frac{2}{r+1}} dxdt$$
$$\le \epsilon \int_S^T E^{\frac{r+1}{2}}(t) dt + c_\epsilon \int_S^T \int_{\Gamma^-} e^{\phi(x)} u' g(u') dxdt$$
$$\le \epsilon \int_S^T E^{\frac{r+1}{2}}(t) dt + c_\epsilon \left(E(S) - E(T) \right).$$

Substituting the sum of these two estimates into the right-hand side of (6.6), choosing ϵ small enough, and letting T go to ∞, we obtain (4.1). This finishes the proof of Theorem 2.4.

Remark. Using the method developed above, the same results can be easily obtained if we replace the first equation in (P) by

$$u'' - \Delta u + q_1(x) h(\nabla u) + q_2(x) f(u) + q_3(x) g(u') = 0 \quad \text{in} \quad \Omega \times \mathbb{R}^+,$$

and the first equation and the boundary condition on Γ_1 in (P′) by

$$\begin{cases} u'' - \Delta u + q_1(x) h(\nabla u) + q_2(x) f(u) = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ \partial_\nu u + q_4(x) u + q_3(x) g(u') = 0 & \text{on} \quad \Gamma_1 \times \mathbb{R}^+, \end{cases}$$

where $q_i : \Omega \to \mathbb{R}$ are bounded functions such that $q_2(x) \ge 0$, $q_4(x) \ge 0$, $q_3(x) \ge a_0 > 0$. If $q_4(x) \ge b_0 > 0$, we may take $\Gamma_0 = \emptyset$.

We define the equivalent energy of (P) and (P′), respectively, by

$$E(t) = \int_\Omega e^{\varphi(x)} \left(\big|u'\big|^2 + \big|\nabla u\big|^2 + 2q_2(x) F(u) \right) dx, \tag{6.7}$$

$$E(t) = \int_\Omega e^{\varphi(x)} \left(\big|u'\big|^2 + \big|\nabla u\big|^2 + 2q_2(x) F(u) \right) dx + \int_{\Gamma_1} e^{\varphi(x)} \big|u\big|^2 d\Gamma \tag{6.8}$$

if $h(\nabla u) = -\nabla\phi \cdot \nabla u$ with $\phi \in W^{1,\infty}(\Omega)$, where $\varphi \in W^{1,\infty}(\Omega)$ satisfying $\nabla\varphi = q_1(x)\nabla\phi$.

In the general case, we assume that $\beta \|q_1\|_\infty$ is small enough as in Theorem 2.1 and Theorem 2.3, where β, c_1, and c_2 are replaced by $\beta\|q_1\|_\infty$, $a_0 c_1$, and $c_2 \|q_3\|_\infty$, respectively, and we define the energy of (P) and (P′), respectively, by (6.7) and (6.8) with $\varphi \equiv 0$. In order to get ride of the lower-order term, which is $\int_{\Gamma_1} \big|u\big|^2 d\Gamma$, we use the solution of an auxiliary elliptic problem as an additional multiplier (see [4, Lemma 4.2]).

7. Some applications of our method. In [6], we considered the following Petrovsky system:

$$\begin{cases} u'' + \Delta^2 u + q(x)u + g(u') = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = \partial_\nu u = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega, \end{cases} \tag{7.1}$$

where Ω is a bounded domain in $\mathbb{R}^n$ $(n \geq 1)$ with a smooth boundary Γ and ν is the outward unit normal vector to Γ. For g continuous, increasing, satisfying $g(0) = 0$, and $q : \Omega \to \mathbb{R}^+$ a bounded function, we proved a global existence and a regularity result. We also established, under suitable growth conditions on g, decay results for weak, as well as strong, solutions. Precisely, we showed that the solution decays exponentially if g behaves like a linear function, whereas the decay is of a polynomial order otherwise. Similar results to the above system, coupled with a semilinear wave equation, have been established by Guesmia in [5]. In [17], Messaoudi studied the problem

$$\begin{cases} u'' + \Delta^2 u + au'\big|u'\big|^{m-2} - bu\big|u\big|^{p-2} = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = \partial_\nu u = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega, \end{cases}$$

where a, $b > 0$ and p, $m > 2$. This is a similar problem to (7.1), which contains a nonlinear source term competing with the damping factor. He established an existence result and showed that the solution continues to exist globally if $m \geq p$; however, it blows up in finite time if $m < p$. In this paper no result of stability was announced.

In [7], we obtained some stabilization results of the following elasticity system:

$$\begin{cases} u_i'' - \sigma_{ij,j} + g_i(u_i') = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u_i = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u_i(x,0) = u_i^0(x) \quad \text{and} \quad u_i'(x,0) = u_i^1(x) & \text{in} \quad \Omega, \\ i = 1, \dots, n, \end{cases} \tag{7.2}$$

where the unknown $u = (u_1, \dots, u_n) : \Omega \to \mathbb{R}^n$. Here, $\sigma_{ij,j} = \sum_{j=1}^{j=n} \frac{\partial \sigma_{ij}}{\partial x_j}$, $\sigma_{ij} = \sum_{k,l=1}^{k,l=n} a_{ijkl}\varepsilon_{ij}$, $\varepsilon_{ij} = \frac{1}{2}(u_{i,j} + u_{j,i})$, $u_{i,j} = \frac{\partial u_i}{\partial x_j}$, $u_{j,i} = \frac{\partial u_j}{\partial x_i}$, and $a_{ijkl} \in W^{1,\infty}(\Omega)$. We proved some decay estimates which are crucially dependent on the behavior of the damping g_i at the origin and infinity. In [8], we extended these results to the case of localized dissipations; that is, the damping is effective only in a neighborhood of a suitable subset of the boundary.

In [4], we considered the problem of exact controllability and boundary stabilization of elasticity systems with coefficients a_{ijkl} depending also on time t. The stabilization results obtained in [4] were generalized in [3] to the nonlinear feedback case. The results obtained in [3] and [4] improve and generalize some ones obtained earlier by Alabau and Komornik [1] in the case where g_i is linear and $a_{ijkl} = \text{const}$.

The decrease of energy plays a crucial role in studying the asymptotic stability of the systems cited above. The situation of nondissipative systems (that is, the energy is not decreasing) was not previously considered.

Using the method developed in previous sections, we can extend Theorems 2.1–2.4 to the following more general nondissipative problems.

7.1. Petrovsky system.

$$\begin{cases} u'' + \Delta^2 u + q_1(x)h(\Delta u) + q_2(x)f(u) + q_3(x)g(u') = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u = \partial_\nu u = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u(x,0) = u_0(x) \quad \text{and} \quad u'(x,0) = u_1(x) & \text{in} \quad \Omega, \end{cases}$$

where h, f, $g : \mathbb{R} \to \mathbb{R}$ are three given functions satisfying Assumptions 2.1–2.5 and q_i are three given functions defined as in the remark above. Here $c_0 > 0$ is the smallest imbedding positive constant (depending only on Ω) satisfying

$$\int_\Omega \big|v\big|^2 dx \le c_0 \int_\Omega \big|\Delta v\big|^2 dx \qquad \forall v \in H_0^2(\Omega).$$

The energy and the equivalent energy are, respectively, defined by

$$E(t) = \int_\Omega \Big(\big|u'\big|^2 + \big|\Delta u\big|^2 + 2q_2(x)F(u) \Big) dx, \qquad t \in \mathbb{R}^+,$$

in the general case, and

$$E(t) = \int_\Omega e^{\varphi(x)} \Big(\big|u'\big|^2 + \big|\Delta u\big|^2 + 2q_2(x)F(u) \Big) dx, \qquad t \in \mathbb{R}^+$$

if $h(\Delta u) = -\phi(x)\Delta u$, with $\phi \in L^\infty(\Omega)$, where $\varphi \in W^{2,\infty}(\Omega)$ satisfying $\Delta\varphi = q_1(x)\phi(x)$.

7.2. Coupled system. We consider the nonlinear coupled wave equation and Petrovsky system:

$$\begin{cases} u_1'' + \Delta^2 u_1 + q_1(x)h_1(\Delta u_1) + q_2(x)f_1(u_1) \\ \qquad\qquad + q_3(x)g_1(u_1') + a_1(x)u_2 = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u_2'' - \Delta u_1 + l_1(x)h_2(\nabla u_2) + l_2(x)f_2(u_2) \\ \qquad\qquad + l_3(x)g_2(u_2') + a_2(x)u_1 = 0 & \text{in} \quad \Omega \times \mathbb{R}^+, \\ u_2 = u_1 = \partial_\nu u_1 = 0 & \text{on} \quad \Gamma \times \mathbb{R}^+, \\ u_i(x,0) = u_i^0(x) \quad \text{and} \quad u_i'(x,0) = u_i^1(x), \ i = 1,2 & \text{in} \quad \Omega, \end{cases}$$

where a_1, a_2 are two bounded functions with norms small enough (see [5]) and the l_i, h_i, f_i, and g_i are given functions defined as q_i, h, f, and g, respectively.

If $h_1(\Delta u_1) = -\phi_1(x)\Delta u_1$ and $h_2(\nabla u_2) = -\nabla\phi_2 \cdot \nabla u_2$ with $\phi_1 \in L^\infty(\Omega)$ and $\phi_2 \in W^{1,\infty}(\Omega)$, then we assume that $a_1(x)e^{\varphi_1(x)} = a_2(x)e^{\varphi_2(x)}$, where $\varphi_1 \in W^{2,\infty}(\Omega)$ and $\varphi_2 \in W^{1,\infty}(\Omega)$ satisfying $\Delta\varphi_1 = q_1(x)\phi_1(x)$ and $\nabla\varphi_2 = l_1(x)\nabla\phi_2$; we define the equivalent energy by

$$E(t) = \int_\Omega e^{\varphi_1(x)} \Big(\big|u_1'\big|^2 + \big|\Delta u_1\big|^2 + 2q_2(x)F_1(u_1) \Big) dx \tag{7.3}$$

$$+ \int_\Omega e^{\varphi_2(x)} \Big(\big|u_2'\big|^2 + \big|\nabla u_2\big|^2 + 2l_2(x)F_2(u_2) \Big) dx + 2\int_\Omega e^{\varphi_1(x)} a_1(x)u_1u_2 dx,$$

which is nonincreasing,

$$E'(t) = -2\int_\Omega \Big(e^{\varphi_1(x)} q_3(x)u_1'g_1(u_1') + e^{\varphi_2(x)} l_3(x)u_2'g_2(u_2') \Big) \le 0.$$

In the general case, we assume that $a_1(x) = a_2(x)$ and we define the energy by (7.3) with $\varphi_1 \equiv \varphi_2 \equiv 0$.

7.3. Elasticity systems. We are interested in the precise decay property of the solution for elasticity systems:

$$
\begin{cases}
u_i'' - \sigma_{ij,j} + q_{1,i}(x)h_i(\sigma_{i1},\dots,\sigma_{in}) \\
\qquad\qquad + q_{2,i}(x)f_i(u_i) + q_{3,i}(x)g_i(u_i') = 0 & \text{in} \quad \Omega\times\mathbb{R}^+, \\
u_i = 0 & \text{on} \quad \Gamma\times\mathbb{R}^+, \\
u_i(x,0) = u_i^0(x) \quad \text{and} \quad u_i'(x,0) = u_i^1(x) & \text{in} \quad \Omega, \\
i = 1,\dots,n,
\end{cases} \tag{7.4}
$$

with the same notations as before. Here for $i = 1,\dots,n$, h_i, f_i, and g_i satisfy the same hypothesis as h, f, and g in section 2, respectively, and $q_{1,i}$, $q_{2,i}$, and $q_{3,i}$ are defined as q_1, q_2, and q_3 in section 7.1, respectively.

We define the equivalent energy of (7.4) by the formula

$$
E(t) = \int_\Omega \sum_{i=1}^{i=n} e^{\varphi_i(x)} \left(\left|u_i'\right|^2 + \sum_{j=1}^{j=n} \sigma_{ij}\varepsilon_{ij} + 2q_{2,i}(x)F_i(u_i) \right) dx,
$$

where $\varphi_i \equiv 0$ if h_i is nonlinear, and if h_i is linear, $h_i(\zeta) = -\nabla\phi_i\cdot\zeta$ for all $\zeta\in\mathbb{R}^n$ with $\phi_i \in W^{1,\infty}(\Omega)$, then we take $\varphi_i \in W^{1,\infty}(\Omega)$ such that $\nabla\varphi_i = q_{1,i}(x)\nabla\phi_i$. In the case where all the functions h_i are linear, our system is dissipative:

$$
E'(t) = -2\int_\Omega \sum_{i=1}^{i=n} e^{\varphi_i(x)} q_{3,i}(x)u_i' g_i(u_i')dx \le 0.
$$

We obtain the results of Theorem 2.1 and Theorem 2.2.

Under some geometric condition as in [3], the results of Theorem 2.3 and Theorem 2.4 can be easily proved in the case of boundary feedback; that is, we consider the homogenous Dirichlet condition on Γ_0, and we consider the following one on Γ_1 (see [3]):

$$
\sum_{j=1}^{j=n} \sigma_{ij}\nu_j + q_{4,i}(x)u_i + q_{3,i}(x)g_i(u_i') = 0.
$$

Remark. The method developed in this paper is direct and very flexible; it can be applied to various nondissipative problems (elasticity, thermoelasticity, Kirchoff, von Karman, coupled systems, ...) with an internal or a boundary feedback, and it can generalize the decay estimates (known in the dissipative case) to the nondissipative one.

Open questions. The main restrictive assumptions under which the stability results are valid are the smallness conditions on β (defined by (2.6)) assumed in Theorems 2.1, 2.3, and 2.4. In the case of nonlinear function h, these assumptions are required to obtain the inequalities $(*)$ (given in the introduction). In Theorem 2.4 (stability of (P') with $h(\nabla u) = -\nabla\phi\cdot\nabla u$), the smallness assumption on β is required to absorb some terms caused by the use of the second multiplier $m\cdot\nabla u$. It would be interesting to know if the stability estimates still hold true under weaker assumption on β, using more sophisticated tools, for example, general multipliers. And if it is not the case, it would be interesting to know if other weaker stability estimates can be obtained.

Another important aspect of the case of nonlinear function h is assumption (2.5) imposed on the damping g. It would be interesting to prove the same polynomial

stability (obtained in the case of linear function h) under the weaker assumption (2.12). With this perspective, it would be interesting to look at what we can conclude at ∞ on a positive function satisfying the following inequalities more general than $(*)$:

$$\begin{cases} \int_S^T E^{a_0}(t)dt \le a_1(E(S)+E(T)) + a_2(E(S)-E(T)) & \forall 0 \le S \le T < \infty, \\ E'(t) \le a_3 E(t) & \forall t \ge 0, \end{cases}$$

where a_i, $i = 0, 1, 2, 3$, are nonnegative constants.

It would also be very interesting (particularly from the point of view of applications) to explore a more general class of hyperbolic equations based on the equation

$$K(x,t)u'' - Au + F(x,t,u,u',\nabla u) = 0,$$

where K and F are given functions and $Au = \sum_{i,j=1}^{n} \partial_{x_i}(a_{ij}(x,t)\partial_{x_j}u)$ is a second-order elliptic differential operator with smooth coefficients a_{ij}.

Acknowledgments. The author is very grateful to the referees and the associate editor for their valuable comments and suggestions.

GENERAL LINEAR QUADRATIC OPTIMAL STOCHASTIC CONTROL PROBLEMS WITH RANDOM COEFFICIENTS: LINEAR STOCHASTIC HAMILTON SYSTEMS AND BACKWARD STOCHASTIC RICCATI EQUATIONS*

SHANJIAN TANG†

Abstract. Consider the minimization of the following quadratic cost functional:

$$J(u) := E\langle Mx_T, x_T\rangle + E\int_0^T (\langle Q_s x_s, x_s\rangle + \langle N_s u_s, u_s\rangle)\, ds,$$

where x is the solution of the following linear stochastic control system:

$$\begin{aligned} dx_t =& (A_t x_t + B_t u_t)\, dt + \sum_{i=1}^{d} (C_t^i x_t + D_t^i u_t)\, dW_t^i, \\ x_0 =& h \in \mathbb{R}^n, \qquad u_t \in \mathbb{R}^m; \end{aligned}$$

u is a square integrable adapted process. The problem is conventionally called the stochastic LQ (the abbreviation of "linear quadratic") problem. We are concerned with the following general case: the coefficients A, B, C^i, D^i, Q, N, and M are allowed to be adapted processes or random matrices. We prove the existence and uniqueness result for the associated Riccati equation, which in our general case is a backward stochastic differential equation with the generator (the drift term) being *highly nonlinear* in the two unknown variables. This solves Bismut and Peng's long-standing open problem (for the case of a Brownian filtration), which was initially proposed by the French mathematician J. M. Bismut [in *Séminaire de Probabilités* XII, Lecture Notes in Math. 649, C. Dellacherie, P. A. Meyer, and M. Weil, eds., Springer-Verlag, Berlin, 1978, pp. 180–264]. We also provide a rigorous derivation of the Riccati equation from the stochastic Hamilton system. This completes the interrelationship between the Riccati equation and the stochastic Hamilton system as two different but equivalent tools for the stochastic LQ problem.

There are two key points in our arguments. The first one is to connect the *existence* of the solution of the Riccati equation to the *homomorphism* of the stochastic flows derived from the optimally controlled system. Actually, we establish their equivalence. As a consequence, we can construct solutions to a sequence of suitably modified Riccati equations in terms of the associated stochastic Hamilton systems (and the optimal controls). The second key point is to establish a new type of a priori estimate for solutions of Riccati equations, with which we show that the sequence of constructed solutions has a limit which is a solution to the original Riccati equation.

Key words. linear quadratic optimal stochastic control, random coefficients, Riccati equation, backward stochastic differential equations, stochastic Hamilton flows, homomorphism of stochastic flows, optimality conditions

1. Formulation of the problem and basic assumptions.

Consider the following so-called linear quadratic (LQ in short form) optimal stochastic control problem: minimize over $u \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ the following quadratic cost functional:

$$J(u; 0, h) := E\langle Mx_T, x_T\rangle + E\int_0^T (\langle Q_s x_s, x_s\rangle + \langle N_s u_s, u_s\rangle)\, ds, \tag{1.1}$$

This research was supported by a Research Fellowship from the Alexander von Humboldt Foundation and by the National Natural Science Foundation of China under project 79790130.

http://www.siam.org/journals/sicon/42-1/38755.html

†Department of Mathematics, Fudan University, Shanghai 200433, China (sjtangk@online.sh.cn).

where x is the solution of the following linear stochastic control system:

$$\begin{cases} dx_t = (A_t x_t + B_t u_t)\,dt + \sum_{i=1}^{d} (C_t^i x_t + D_t^i u_t)\,dW_t^i, \\ x_0 = h \in \mathbb{R}^n. \end{cases} \tag{1.2}$$

Here, $\{W_t := (W_t^1, \dots, W_t^d)', 0 \le t \le T\}$ is a d-dimensional standard Brownian motion defined on some probability space $(\Omega, \mathcal{F}, P)$. Denote by $\{\mathcal{F}_t, 0 \le t \le T\}$ the augmented natural filtration of the standard Brownian motion W. The control u belongs to the Banach space $\mathcal{L}^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$, which consists of all $\mathbb{R}^m$-valued square integrable $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted processes.

Throughout this paper, we make the following three assumptions on the coefficients of the above problem.

(A1) Assume that the matrix processes $A : [0, T] \times \Omega \to \mathbb{R}^{n\times n}$, $B : [0, T] \times \Omega \to \mathbb{R}^{n\times m}$; $C^i : [0, T] \times \Omega \to \mathbb{R}^{n\times n}$, $D^i : [0, T] \times \Omega \to \mathbb{R}^{n\times m}$, $i = 1, \dots, d$; $Q : [0, T] \times \Omega \to \mathbb{R}^{n\times n}$, $N : [0, T] \times \Omega \to \mathbb{R}^{m\times m}$ and the random matrix $M : \Omega \to \mathbb{R}^{n\times n}$ are uniformly bounded and $\{\mathcal{F}_t, 0 \le t \le T\}$-adapted or $\mathcal{F}_T$-measurable.

(A2) Assume that the state weighting matrix process Q and the control weighting matrix process N are almost surely and almost everywhere (abbreviated hereafter as a.s.a.e.) symmetric and nonnegative. Also assume that the terminal state weighting random matrix M is almost surely (hereafter abbreviated as a.s.) symmetric and nonnegative.

(A3) Assume that the control weighting matrix process N is uniformly positive.

In this paper, we shall demonstrate how to use (the optimal control processes of the stochastic LQ problem and) the solutions of the stochastic Hamilton system to construct a solution of the Riccati equation (see (3.1) in section 3), which in general is a highly nonlinear backward stochastic differential equation (BSDE in short form). We connect the existence of a solution of the Riccati equation to the homomorphism of the stochastic flows derived from the optimally controlled system and identify their equivalence. In this way, on one hand, we complete the interrelationship—partially existing in the literature—between the stochastic Hamilton system and the Riccati equation (see section 3). On the other hand, we solve the long-standing open problem which was initially proposed in 1978 by J. M. Bismut [4] (see section 4).

The rest of our paper is organized as follows. Section 2 describes the stochastic Hamilton system theory associated with the above LQ problem—most of which has been known in the literature. Section 3 recalls known connections of the Riccati equation to the stochastic LQ problem and to the associated stochastic Hamilton system. Section 4 reviews some previous results concerning the Riccati equation, which are known to the author. Section 5 sketches the main ideas and the main results of this paper. The next three sections (6–8) are devoted to the detailed proofs of the main results. Finally, in section 9, we give some concluding comments.

2. The stochastic Hamilton system. Let τ be a $\{\mathcal{F}_t, 0 \le t \le T\}$-stopping time such that $0 \le \tau \le T$. Consider the initial-data-parameterized stochastic LQ problem: minimize over $u \in \mathcal{L}^2_{\mathcal{F}}(0, T; \mathbb{R}^m)$ the quadratic cost functional

$$J(u; \tau, h) := E\langle M x_T^{\tau,h;u}, x_T^{\tau,h;u}\rangle + E\int_\tau^T (\langle Q_s x_s^{\tau,h;u}, x_s^{\tau,h;u}\rangle + \langle N_s u_s, u_s\rangle)\,ds, \tag{2.1}$$

where $x^{\tau,h;u}$ is the solution of the following linear stochastic control system:

$$\begin{cases} dx_t = (A_t x_t + B_t u_t)\,dt + \sum_{i=1}^{d} (C_t^i x_t + D_t^i u_t)\,dW_t^i, & \tau \le t \le T, \\ x_\tau = h \in L^2(\Omega, \mathcal{F}_\tau, P; \mathbb{R}^n). \end{cases} \tag{2.2}$$

Assumptions (A1), (A2), and (A3) imply that the above stochastic LQ problem has a unique optimal control. See Bismut [4] for the proof of this result. A further step is to characterize the optimal control.

THEOREM 2.1. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Then, a necessary and sufficient condition for* u *to be an optimal control of the parameterized stochastic LQ problem is*

$$N_t u_t + B_t' y_t + \sum_{i=1}^{d} (D_t^i)' z_t^i = 0, \quad \tau \le t \le T, \quad a.s. \tag{2.3}$$

Here (y, z) (*called the adjoint processes with* $z := (z^1, \dots, z^d)$) *is the* (*unique*) *solution* (*see Pardoux and Peng* [16]) *of the BSDE* (*conventionally called the adjoint equation*):

$$\begin{cases} -dy_t = \left[A_t' y_t + \sum_{i=1}^{d} (C_t^i)' z_t^i + Q_t x_t^{\tau,h;u} \right] dt - \sum_{i=1}^{d} z_t^i\,dW_t^i, & \tau \le t \le T, \\ y_T = M x_T^{\tau,h;u}. \end{cases} \tag{2.4}$$

The proof is simple. In fact, the necessary part results from some simple variational calculus and some dual representation considerations. This part is conventionally called the stochastic maximum principle (see Bensoussan [2], Peng [20], and Tang and Li [22], for example). The sufficient part stems from the convexity of the cost functional $J(\cdot; \tau, h)$. All the details of the proof of Theorem 2.1 can be given similar to the work in Bismut [3, 4].

From (2.3), we get the optimal control

$$u_t = -N_t^{-1} \left[B_t' y_t + \sum_{i=1}^{d} (D_t^i)' z_t^i \right], \qquad \tau \le t \le T. \tag{2.5}$$

The so-called *stochastic Hamilton system* is given by

$$\begin{cases} dx_t = (A_t x_t + B_t u_t)\,dt + \sum_{i=1}^{d} (C_t^i x_t + D_t^i u_t)\,dW_t^i, & \tau \le t \le T, \\ u_t := -N_t^{-1} \left[B_t' y_t + \sum_{i=1}^{d} (D_t^i)' z_t^i \right], & \tau \le t \le T, \\ -dy_t = \left[A_t' y_t + \sum_{i=1}^{d} (C_t^i)' z_t^i + Q_t x_t \right] dt - \sum_{i=1}^{d} z_t^i\,dW_t^i, & \tau \le t \le T, \\ x_\tau = h \in L^2(\Omega, \mathcal{F}_\tau, P; \mathbb{R}^n), \quad y_T = M x_T, \quad z_t := (z_t^1, \dots, z_t^d). \end{cases} \tag{2.6}$$

It is a system of forward-backward stochastic differential equations (FBSDEs in short form). The solution consists of a triple (x, y, z).

THEOREM 2.2. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Then, for each fixed pair* (τ, h) *with* $\tau \in [0,T]$ *a.s. and* $h \in L^2(\Omega, \mathcal{F}_s, P; \mathbb{R}^n)$, *the stochastic Hamilton system* (2.6) *has a unique adapted solution, which is a triple of stochastic processes parameterized by the initial data* (τ, h), *denoted by*

$$\{(\phi_{\tau,t}(h), \psi_{\tau,t}(h), \mu_{\tau,t}(h)); \tau \le t \le T, h \in L^2(\Omega, \mathcal{F}_\tau, P; \mathbb{R}^n)\}.$$

Moreover, we have for some deterministic positive constant β,

$$E \max_{\tau \le t \le T} |\phi_{\tau,t}(h)|^2 + E \max_{\tau \le t \le T} |\psi_{\tau,t}(h)|^2 + E \int_\tau^T |\mu_{\tau,t}(h)|^2 \, dt \le \beta E|h|^2. \tag{2.7}$$

LEMMA 2.1. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. If*

$$\{(\phi_{\tau,t}(h), \psi_{\tau,t}(h), \mu_{\tau,t}(h)); \tau \le t \le T, h \in L^2(\Omega, \mathcal{F}_\tau, P; \mathbb{R}^n)\}$$

is a solution to (2.6), *then for any* $\{\mathcal{F}_t, 0 \le t \le T\}$*-stopping time* $\gamma \in [\tau, T]$,

$$\begin{aligned} &\langle \psi_{\tau,\gamma}(h), \phi_{\tau,\gamma}(h) \rangle \\ &= E^{\mathcal{F}_\gamma} \left\{ \int_\gamma^T (\langle Q_r \phi_{\tau,r}(h), \phi_{\tau,r}(h) \rangle + \langle N_r u_r, u_r \rangle) \, dr + \langle M \phi_{\tau,T}(h), \phi_{\tau,T}(h) \rangle \right\}, \end{aligned} \tag{2.8}$$

where u *is the optimal control given by* (2.5).

Proof of Lemma 2.1. Using Itô's formula to compute the term $\langle \psi_{\tau,r}(h), \phi_{\tau,r}(h) \rangle$ and then taking the conditional expectation, we get the desired result. □

Proof of Theorem 2.2. Assumptions (A1), (A2), and (A3) imply the existence of an optimal control u. From Theorem 2.1, u should satisfy (2.5), and then (x, y, z) is a solution. The existence part is proved. The uniqueness assertion is obvious once (2.7) is true. Therefore, it remains to prove that (2.7) holds.

From Lemma 2.1, we have

$$\begin{aligned} &E \int_\tau^T \langle Q_r \phi_{\tau,r}(h), \phi_{\tau,r}(h) \rangle \, dr + E \langle M \phi_{\tau,T}(h), \phi_{\tau,T}(h) \rangle \le E \left(|\psi_{\tau,\tau}(h)| \cdot |h| \right), \\ &E \int_\tau^T \langle N_r u_r, u_r \rangle \, dr \le E \left(|\psi_{\tau,\tau}(h)| \cdot |h| \right). \end{aligned} \tag{2.9}$$

While we have (2.6), it follows from a classical a priori estimate for BSDEs (see El Karoui, Peng, and Quenez [6]) that

$$\begin{aligned} &E \max_{\tau \le t \le T} |\psi_{\tau,t}(h)|^2 + E \int_\tau^T |\mu_{\tau,t}(h)|^2 \, dt \\ &\le \beta E \int_\tau^T |Q_r \phi_{\tau,r}(h)|^2 \, dr + \beta E |M \phi_{\tau,T}(h)|^2 \\ &\le \beta E \int_\tau^T \langle Q_r \phi_{\tau,r}(h), \phi_{\tau,r}(h) \rangle \, dr + \beta E \langle M \phi_{\tau,T}(h), \phi_{\tau,T}(h) \rangle. \end{aligned}$$

Here and in the following, β stands for a universal deterministic positive constant, possibly changing from lines to lines. Therefore, we have from (2.9)

$$E \max_{\tau \le t \le T} |\psi_{\tau,t}(h)|^2 + E \int_\tau^T |\mu_{\tau,t}(h)|^2 \, dt \le \beta E \left(|\psi_{\tau,\tau}(h)| \cdot |h| \right). \tag{2.10}$$

In particular,

$$E|\psi_{\tau,\tau}(h)|^2 \le \beta E(|\psi_{\tau,\tau}(h)|\cdot|h|) \le \beta(E|\psi_{\tau,\tau}(h)|^2 E|h|^2)^{1/2},$$

which implies

$$E|\psi_{\tau,\tau}(h)|^2 \le \beta E|h|^2. \tag{2.11}$$

On the other hand, we derive from the forward stochastic differential equation in (2.6) the following estimate:

$$E\max_{\tau\le t\le T}|\phi_{\tau,t}(h)|^2 \le \beta\Big\{E|h|^2 + E\int_\tau^T |u_t|^2\,dt\Big\}.$$

From (2.9) and assumption (A3), we have

$$E\max_{\tau\le t\le T}|\phi_{\tau,t}(h)|^2 \le \beta\Big\{E|h|^2 + E\int_\tau^T \langle N_t u_t, u_t\rangle\,dt\Big\} \le \beta\Big\{E|h|^2 + E(|\psi_{\tau,\tau}(h)|\cdot|h|)\Big\}. \tag{2.12}$$

Combining (2.10), (2.11), and (2.12), it is easy to see that (2.7) holds. The proof is complete. □

An indirect proof of Theorem 2.2 can also be given similar to the proof in Bismut [4]. The above uniqueness proof is a direct one, which is an adaptation of relevant arguments of Peng and Wu [21].

In the above, the solution of the LQ problem is reduced in an equivalent way to the solution of the associated stochastic Hamilton system (2.6). However, the stochastic Hamilton system (2.6) is a system of fully coupled FBSDEs, which is not a satisfactory characterization to the optimal control. Some efforts have been made by Bismut [3, 4] to decouple the FBSDEs, along the lines of Lions [15, Chapter III, section 4]. In the following, we summarize his relevant results and refine his partial arguments in the more general case of random initial times.

Let e_i denote the unit vector of $\mathbb{R}^n$ whose ith component is one. Define, for $\tau \le t \le T$,

$$\begin{aligned} X_{\tau,t} &:= (\phi_{\tau,t}(e_1),\dots,\phi_{\tau,t}(e_n)),\\ Y_{\tau,t} &:= (\psi_{\tau,t}(e_1),\dots,\psi_{\tau,t}(e_n)),\\ Z_{\tau,t} &:= (\mu_{\tau,t}(e_1),\dots,\mu_{\tau,t}(e_n)). \end{aligned} \tag{2.13}$$

Then,

$$E\max_{\tau\le t\le T}|X_{\tau,t}|^2 + E\max_{\tau\le t\le T}|Y_{\tau,t}|^2 + E\int_\tau^T |Z_{\tau,t}|^2\,dt < \infty.$$

Since $Y_{\tau,t}$ is almost surely continuous in $t\in[\tau,T]$, the meaning of $Y_{\tau,\tau}$ is clear, and set $P_\tau := Y_{\tau,\tau}$. Note that it is not clear whether the matrix-valued process $\{P_t, 0\le t\le T\}$ is continuous.

THEOREM 2.3. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Then, we have, for any* $h\in L^2(\Omega,\mathcal{F}_\tau,P;\mathbb{R}^n)$ *and any* $\{\mathcal{F}_t, 0\le t\le T\}$*-stopping time* $\gamma\in[\tau,T]$,

$$\phi_{\tau,\gamma}(h) = X_{\tau,\gamma}h, \quad \psi_{\tau,\gamma}(h) = Y_{\tau,\gamma}h, \quad \mu_{\tau,\gamma}(h) = Z_{\tau,\gamma}h. \tag{2.14}$$

In particular,

$$\psi_{\tau,\tau}(h) = Y_{\tau,\tau}h = P_\tau h, \qquad h \in L^2(\Omega, \mathcal{F}_\tau, P; \mathbb{R}^n), \tag{2.15}$$

and therefore, for every stopping $\tau \le T$,

$$\psi_{0,\tau}(h) = Y_{\tau,\tau}\phi_{0,\tau}(h) = P_\tau \phi_{0,\tau}(h). \tag{2.16}$$

Remark 2.1. From the first equality of (2.14), it follows that for $s \le t$, the random linear transformation $\phi_{s,t}(\cdot)$ is a.s. a homomorphism if and only if the transformation matrix $X_{s,t}$ *a.s.* has an inverse.

Proof. We can use Itô's formula to verify that $\{(X_{\tau,t}h, Y_{\tau,t}h, Z_{\tau,t}h), \tau \le t \le T\}$ satisfies (2.6). By the uniqueness assertion of Theorem 2.2, we get (2.14). Letting $\gamma = \tau$ in the second equality of (2.14), we get (2.15). Finally, since $\psi_{0,\tau}(h) = \psi_{\tau,\tau}(\phi_{0,\tau}(h))$, then (2.16) follows from (2.15). The proof is complete. □

We have the following feedback representation of the adjoint process $\{y_t, 0 \le t \le T\}$.

THEOREM 2.4. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Let* (x, y, z) *be the solution of* (2.6) *as* $\tau = 0$. *Then for any stopping time* $\gamma \le T$, *we have*

$$y_\gamma = P_\gamma x_\gamma, \quad a.s. \tag{2.17}$$

Moreover, we have

$$\begin{aligned} P_\gamma &= E^{\mathcal{F}_\gamma}\left\{\int_\gamma^T (\langle Q_s X_{\gamma,s}, X_{\gamma,s}\rangle + \langle N_s U_{\gamma,s}, U_{\gamma,s}\rangle)\, ds + \langle M X_{\gamma,T}, X_{\gamma,T}\rangle\right\}, \\ P_T &= M, \end{aligned} \tag{2.18}$$

and P_γ *is symmetric, nonnegative, and uniformly bounded. Here,*

$$U_{\gamma,s} = -N_s^{-1}\left[B_s' Y_{\gamma,s} + \sum_{i=1}^d D_s^i Z_{\gamma,s}^i\right], \qquad \gamma \le s \le T. \tag{2.19}$$

Proof of Theorem 2.4. We have $x_\gamma = \phi_{0,\gamma}(h)$ and $y_\gamma = \psi_{0,\gamma}(h)$. Then (2.17) is identical to (2.16). The rest assertions of Theorem 2.4 can be proved in a way similar to the proof of Proposition II.4 of Bismut [4, p. 211]. □

3. The Riccati equation: Known connections to the LQ problem and the Hamilton system. In view of deterministic LQ theory, it is natural to connect the stochastic LQ problem with the Riccati equation. In fact, the Riccati equation results from decoupling the stochastic Hamilton system. However, the way how to go from the stochastic Hamilton system to the Riccati equation has not yet been—to the best of the author's knowledge—established in a rigorous manner. In the literature, a formal approach to derive the associated Riccati equation from the stochastic Hamilton system a priori assumes that there is a semimartingale K of the form

$$K_t = K_0 + \int_0^t K_1(s)\, ds + \int_0^t \sum_{i=1}^d L_s^i\, dW_s^i$$

such that

$$y_t = K_t x_t.$$

Then, use Itô's formula to compute $K_t x_t$, compare with y_t, and identify the integrands of the Lebesgue integral and Itô's integral, respectively. As a consequence, the following Riccati equation can be derived:

$$\begin{cases} dK_t = -G(A_t, B_t, C_t, D_t; Q_t, N_t; K_t, L_t)\,dt + \sum_{i=1}^{d} L_t^i\,dW_t^i, \\ K_T = M, \qquad L_t := (L_t^1, \dots, L_t^d), \end{cases} \tag{3.1}$$

where for any $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times m}$, $C = (C^1, \dots, C^d) \in (\mathbb{R}^{n\times n})^d$, $D = (D^1, \dots, D^d) \in (\mathbb{R}^{n\times m})^d$; $Q \in \mathbb{R}^{n\times n}$(being nonnegative), $N \in \mathbb{R}^{m\times m}$(being uniformly positive), $K \in \mathbb{R}^{n\times n}$, $L = (L^1, \dots, L^d) \in (\mathbb{R}^{n\times n})^d$ with K being symmetric and nonnegative and L^i $(i = 1, \dots, d)$ being symmetric, we have defined

$$\begin{aligned} G_1(B, C, D, N; K, L) := & -\left[KB + \sum_{i=1}^{d}(C^i)'KD^i + \sum_{i=1}^{d} L^i D^i\right]\left[N + \sum_{i=1}^{d}(D^i)'KD^i\right]^{-1} \\ & \times \left[KB + \sum_{i=1}^{d}(C^i)'KD^i + \sum_{i=1}^{d} L^i D^i\right]', \\ G(A, B, C, D; Q, N; K, L) := & A'K + KA + Q + \sum_{i=1}^{d}(C^i)'KC^i + \sum_{i=1}^{d}[(C^i)'L^i + L^i C^i] \\ & + G_1(B, C, D, N; K, L). \end{aligned} \tag{3.2}$$

It is a BSDE with the generator $G(A_t, B_t, C_t, D_t; Q_t, N_t; K, L)$ being nonlinear in K and L. For the full details on the above-mentioned formal derivation, we refer to Bismut [3, 4]. The above backward stochastic Riccati differential equation (3.1) will be hereafter abbreviated as BSRDE (3.1). Note that the semimartingale property of K is assumed rather than being proved.

DEFINITION 3.1. *A solution of BSRDE* (3.1) *is defined as a pair* (K, L) *of adapted matrix processes such that*

(i) $\int_0^T |L_s|^2\,ds < \infty$, *a.s.*;

(ii) $N + \sum_{i=1}^{d}(D^i)'KD^i$ *is a.s.a.e. positive; moreover,*

$$\int_0^T |G(A_s, B_s, C_s, D_s; Q_s, N_s; K_s, L_s)|\,ds < \infty, \ \text{a.s.};$$

and

(iii) $K_t = M + \int_t^T G(A_s, B_s, C_s, D_s; Q_s, N_s; K_s, L_s)\,ds - \int_t^T \sum_{i=1}^{d} L_s^i\,dW_s^i$ *for all* $t \in [0, T]$.

In the literature, we have the following rigorous connections of the Riccati equation to the stochastic Hamilton system and to the stochastic LQ problem.

THEOREM 3.1. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Let* τ *be a* $\{\mathcal{F}_t, 0 \le t \le T\}$*-stopping time such that* $0 \le \tau \le T$, *and let* (x, y, z, u) *be the solution of* (2.6) *with* u *being the optimal control. Assume that* (K, L) *is a solution to BSRDE* (3.1) *such that* K *is nonnegative and uniformly bounded and* L *is square integrable. Then, we have, for* $t \in [\tau, T]$,

$$\begin{aligned} & y_t = K_t x_t, \\ & z_t^i = L_t^i x_t + K_t(C_t^i x_t + D_t^i u_t), \qquad i = 1, 2, \dots, d, \\ & z_t := (z_t^1, \cdots, z_t^d), \qquad L_t := (L_t^1, \dots, L_t^d). \end{aligned} \tag{3.3}$$

Proof of Theorem 3.1. Use Itô's formula to compute $K_t x_t$ and compare it with y_t. The identification of the integrands of Lebesgue integrals and Itô's integrals yields the desired connections (3.3). □

THEOREM 3.2. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied.* τ *is a* $\{\mathcal{F}_t, 0 \le t \le T\}$*-stopping time such that* $0 \le \tau \le T$. *Let* u *be the optimal control of the parameterized stochastic LQ problem and* x *be the solution of* (2.2). *Assume that* (K, L) *is a solution to BSRDE* (3.1) *such that* K *is nonnegative and uniformly bounded and* $L := (L^1, \dots, L^d)$ *is square integrable. Then, the optimal control* u *has the following closed form: for* $t \in [\tau, T]$,

$$u_t = -\left[N_t + \sum_{i=1}^{d} (D_t^i)' K_t D_t^i\right]^{-1} \left[K_t B_t + \sum_{i=1}^{d} (C_t^i)' K_t D_t^i + \sum_{i=1}^{d} L_t^i D_t^i\right]' x_t. \tag{3.4}$$

Moreover, for every $h \in L^2(\Omega, \mathcal{F}_\tau, P; \mathbb{R}^n)$, *we have*

$$\begin{aligned} E\langle K_\tau h, h\rangle = \inf_{u \in \mathcal{L}^2_{\mathcal{F}}(0,T;\mathbb{R}^m)} E\Big\{ & \langle M\phi_{\tau,T}(h), \phi_{\tau,T}(h)\rangle \\ & + \int_\tau^T \left(\langle Q_r \phi_{\tau,r}(h), \phi_{\tau,r}(h)\rangle + \langle N_r u_r, u_r\rangle\right) dr \Big\}, \end{aligned} \tag{3.5}$$

where $\phi_{t,\cdot}$ *is the state process starting from* h *at time* t *under the control process* u.

Remark 3.1. Formula (3.4) provides a characterization of the optimal control in terms of the solution of BSRDE (3.1). BSRDE (3.1) is not a coupled equation, and this characterization is preferred to (2.3).

Remark 3.2. Putting (3.4) into the second equality of (3.3), we have

$$\begin{aligned} z_t^i = {} & (L_t^i + K_t C_t^i) x_t \\ & - K_t D_t^i \left[N_t + \sum_{i=1}^{d} (D_t^i)' K_t D_t^i\right]^{-1} \left[K_t B_t + \sum_{i=1}^{d} (C_t^i)' K_t D_t^i + \sum_{i=1}^{d} L_t^i D_t^i\right]' x_t, \\ & i = 1, \dots, d, \quad t \in [\tau, T]. \end{aligned} \tag{3.6}$$

Proof of Theorem 3.2. Putting (3.3) into (2.3), we get (3.4). Combining Lemma 2.1, the first relation in (3.3), and Theorem 2.1, we get (3.5). The proof is complete. □

Obviously, the above mathematically rigorous relationship between Riccati equation (3.1) and the stochastic Hamilton system (2.6) is *not complete*. There is *a gap* here. In this paper, we close this gap by providing a rigorous argument to derive Riccati equation (3.1) from the stochastic Hamilton system (see sections 5–8 below). In this way, we show the existence of a solution to Riccati equation (3.1)—which solves Bismut and Peng's long-standing open problem (for the case of a Brownian filtration) initially proposed in 1978 by J. M. Bismut [4] (see section 4 below for more information).

4. Previous results on the Riccati equation and some comments. The connection of the stochastic LQ problem to BSRDE (3.1) indicated in Theorem 3.2 directs the study of the former to the study of the latter. And some crucial results and useful methods have been developed for the latter.

When the coefficients A, B, C^i, D^i, Q, N, M are all deterministic, then $L^1 = \cdots = L^d = 0$ and BSRDE (3.1) is reduced to the following nonlinear matrix ordinary

differential equation:

$$\begin{cases} \dfrac{d}{dt}K_t = -G(A_t, B_t, C_t, D_t; Q_t, N_t; K_t, 0), & 0 \le t < T, \\ K_T = M, \end{cases} \tag{4.1}$$

which was essentially solved by Wonham [23] by applying Bellman's principle of quasi linearization (see Bellman [1]) and a monotone convergence result of symmetric matrices.

The attention to the randomness of the coefficients A, B, C, D, Q, N, M is dated back at least to Bismut [3, 4]. Bismut [3, 4] studied the case of random coefficients, but he could solve only some special simple cases at that time. Let the integer $0 \le d_0 \le d$, and denote by $\{\mathcal{G}_t, 0 \le t \le T\}$ the P-augmented natural filtration generated by the $(d - d_0)$-dimensional Brownian motion $(W^{d_0+1}, \dots, W^d)$. Bismut [3, 4] assumed that the randomness of the coefficients only comes from the smaller filtration $\{\mathcal{G}_t, 0 \le t \le T\}$, which leads to $L^1 = \cdots = L^{d_0} = 0$. He further assumed in the paper [3] that

$$C^{d_0+1} = \cdots = C^d = 0, \qquad D^{d_0+1} = \cdots = D^d = 0, \tag{4.2}$$

under which the generator G does not involve L at all. In the work [4], Bismut assumed only that

$$D^{d_0+1} = \cdots = D^d = 0, \tag{4.3}$$

under which the generator G depends on the second unknown variable L only in a linear way. Moreover, his method consists of constructing a contraction mapping and then using a fixed point theorem.

Later, Peng [18] gave a nice treatment on the proof of existence and uniqueness for BSRDE (4.5) by using Bellman's principle of quasi linearization and a monotone convergence result of symmetric matrices—a generalization of Wonham's approach to the random situation.

The solution of the general BSRDE (3.1), whose generator is allowed to contain a quadratic term of L, turns out to become a long-standing problem. As early as 1978, Bismut [4] commented on page 220 that "Nous ne pourrons pas démontrer l'existence de solution pour l'équation (2.49) dans le cas général." (We could not prove the existence of solution for equation (2.49) for the general case.) On page 238, he pointed out that the essential difficulty for the solution of the general BSRDE (3.1) lies in the integrand of the martingale term which appears in the generator in a quadratic way. Since then, the stochastic LQ problem seemed to have been silent until Peng [18]. Two decades later in 1998, Peng [19] formally included the above problem in his list of open problems on BSDEs.

Taking this opportunity, the author would like to acknowledge that as early as 1993, Professor S. Peng has introduced the open case of the general adapted possibly nonzero D in his private communication with the author.

To overcome the difficult feature of the quadratic growth in the martingale term of the generator G, Kobylanski [8] and Lepeltier and San Martin [13, 14] have developed a quite useful technique. Unfortunately, this technique is essentially of one-dimensional nature, and is difficult to be adapted to the underlying matrix-valued BSRDEs.

Recently, Kohlmann and Tang have made some progress towards solving the above open problem. See [9, 10, 11, 12] and the references therein. However, it is still very far from the complete solution.

In what follows, we shall give a complete solution with a new constructive method —which is totally different from the previous methods.

5. Main ideas and results of the paper. The traditional formal derivation of the Riccati equation (3.1) uses the following a priori hypothesis: assume that P in the adjoint-primal processes relation (see section 3)

$$y_t = P_t x_t, \qquad 0 \le t \le T,$$

or in the associated value function formula (see Peng [18, p. 299, eq. (5.4)])

$$V(t,x) := \langle P_t x, x\rangle, \qquad (t,x) \in [0,T] \times \mathbb{R}^n,$$

is a semimartingale. Note that P_t will be shown to be the first component K_t of the solution (K,L) of BSRDE (3.1).

The hypothesis has not yet been proved to be true, to the author's best knowledge. Therefore, the relevant arguments existing in the literature are formal, rather than being rigorous.

In this paper, we provide a rigorous derivation of Riccati equation (3.1) from the stochastic Hamilton system (2.6). We construct a solution of Riccati equation (3.1), using a basis of fundamental solutions of the stochastic Hamilton system (2.6).

Our *new observation* is the *connection* of the *existence* issue for BSRDE (3.1) to the *homomorphism* of the stochastic flows $\{\phi_{0,\cdot}(h), h \in \mathbb{R}^n\}$: if the stochastic flows $\{\phi_{0,\cdot}(h), h \in \mathbb{R}^n\}$ are a.s. homomorphism at each time t, i.e., if they a.s. have an inverse at each time t, then we can produce a BSDE from the first equality of (3.3), which turns out to be exactly BSRDE (3.1). Theorem 5.2 below states their equivalence.

The above-stated connection points out a promising new approach to the study of BSRDE (3.1). However, it is not directly known whether the stochastic flows $\{\phi_{0,\cdot}(h), h \in \mathbb{R}^n\}$ are a.s. homomorphism at each time t. This difficulty is overcome by considering the *first degenerate time* τ of the associated flows transformation (see the precise definition below), which is a stopping time.

The *first degenerate time* τ of the associated flows transformation will be shown to be a.s. $+\infty$, i.e., the stochastic flows $\{\phi_{0,\cdot}(h), h \in \mathbb{R}^n\}$ are a.s. homomorphism at each time $t \in [0,T]$. To prove this fact, we need to study the regularity of the approaching quantities $L(k)$ (see the definitions below) near the degenerate time τ, and then the following a priori estimate is needed.

THEOREM 5.1. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Let* (K,L) *be a solution of BSRDE* (3.1) *with* K *being a.s.a.e. nonnegative and uniformly bounded. Then, there is a deterministic constant* β_0 *such that the following estimate holds:*

$$E\left(\int_0^T |L_s|^2\, ds\right)^p \le \beta_0, \qquad \forall p \ge 1. \tag{5.1}$$

Here, β_0 *depends only on* p, *the uniform upper bound of* K *and all the coefficients, and the uniformly lower bound of (positive) eigenvalues of* $\{N_t, 0 \le t \le T\}$.

In Theorem 5.1, K is assumed to be uniformly bounded. This distinguishes Theorem 5.1 from the known a priori estimates for BSDEs given by Pardoux and Peng [17] and El Karoui, Peng, and Quenez [6]. Note that the operator P_t which connects the adjoint process y_t and the primal state x_t "should" be the first component K_t of the solution (K,L) of BSRDE (3.1). In sections 2 and 3, through a flows analysis on the associated stochastic Hamilton system, we have obtained rich information on P_t: nonnegativity and uniform boundedness. However, we could say almost nothing about L: the difficulty lies in the fact that $L := (L^1, \dots, L^d)$ and $z := (z^1, \dots, z^d)$

in the second equality (3.3) or (3.6) is in general known only to be square integrable over time rather than continuous, which creates a difficulty in explaining the second equality of (3.3) or (3.6) at a time. Fortunately, Theorem 5.1 permits us to draw a useful property of L from those known properties on P obtained in sections 2 and 3.

Before going further, it is necessary to introduce the following notation.

Let $u(e_1), \dots, u(e_n)$ denote the optimal controls corresponding to the initial states $e_1, \dots, e_n$, respectively, at the initial time 0. Define

$$\begin{aligned} &U := (u(e_1), \dots, u(e_n)), \qquad X := (\phi_{0,\cdot}(e_1), \dots, \phi_{0,\cdot}(e_n)), \\ &Z^i := (\mu^i_{0,\cdot}(e_1), \dots, \mu^i_{0,\cdot}(e_n)), \qquad Y := (\psi_{0,\cdot}(e_1), \dots, \psi_{0,\cdot}(e_n)). \end{aligned} \tag{5.2}$$

Then, it is straightforward that X solves the matrix-valued stochastic differential equation (SDE in short form):

$$\begin{cases} dX_t = (A_t X_t + B_t U_t)\, dt + \displaystyle\sum_{i=1}^{d} (C^i_t X_t + D^i_t U_t)\, dW^i_t, \\ X_0 = I_{n\times n}, \text{the unit matrix of dimension } n \times n, \end{cases} \tag{5.3}$$

and the pair (Y, Z) of adapted processes solves the matrix-valued BSDE:

$$\begin{cases} -dY_t = \Big[A'_t Y_t + Q_t X_t + \displaystyle\sum_{i=1}^{d} (C^i_t)' Z^i_t \Big]\, dt - \sum_{i=1}^{d} Z^i_t\, dW^i_t, \\ Y_T = MX_T, \qquad Z_t := (Z^1_t, \dots, Z^d_t). \end{cases} \tag{5.4}$$

Moreover, it follows from Theorem 2.1 that the triple (U, Y, Z) of processes satisfies the following:

$$N_t U_t + B'_t Y_t + \sum_{i=1}^{d} (D^i_t)' Z^i_t = 0 \quad a.s.a.e.\ t \in [0, T]. \tag{5.5}$$

The following theorem states the *equivalence* between the *existence* of a solution to BSRDE (3.1) and the *homomorphism* of the stochastic flows $\{\phi_{0,\cdot}(h), h \in \mathbb{R}^n\}$.

THEOREM 5.2. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Let* (X, Y, Z, U) *be defined by* (5.2). *Then, the existence of a solution to BSRDE* (3.1) *is equivalent to the homomorphism of the stochastic flows* $\{\phi_{0,\cdot}(h), h \in \mathbb{R}^n\}$, *i.e., to the fact that* X_t *a.s. has an inverse at each* $t \in [0, T]$. *More precisely, we have the following two assertions:*

(i) *If BSRDE has a solution* (K, L) *with* K *being a uniformly bounded nonnegative matrix valued process, then* X_t *a.s. has an inverse at each* $t \in [0, T]$.

(ii) *Conversely, if* X_t *a.s. has an inverse at each* $t \in [0, T]$, *then* (K, L) *defined by*

$$\begin{aligned} &K_t := Y_t X_t^{-1}, \\ &L^i_t := Z^i_t X_t^{-1} - Y_t X_t^{-1}(C^i_t + D^i_t U_t X_t^{-1}), \qquad i = 1, \dots, d, \\ &L_t := (L^1_t, \dots, L^d_t), \qquad 0 \le t \le T, \end{aligned} \tag{5.6}$$

solves BSRDE (3.1). *Moreover,* K *is nonnegative and uniformly bounded, and* L *is square integrable.*

Remark 5.1. By virtue of (5.5), we have

$$U_t = -N_t^{-1}\left[B_t' Y_t + \sum_{i=1}^{d}(D_t^i)' Z_t^i\right], \qquad t \in [0,T].$$

Therefore, L_t constructed in Theorem 5.2(ii) is expressible only in terms of the solutions (X, Y, Z) of stochastic Hamilton system (2.6).

If X_t a.s. has an inverse at each $t \in [0,T]$, then it follows from the above theorem that BSRDE (3.1) has a solution, and the uniqueness is easily derived from Theorem 3.2 (see (3.5)). This shows that BSRDE (3.1) has a unique solution. Unfortunately, as already pointed out in the beginning of this section, it is not obvious that X_t a.s. has an inverse at *every* $t \in [0,T]$. This seems to discourage us from going on. However, there are also the following two encouraging facts:

(i) X a.s. has an inverse on the subinterval $[0,\tau]$ when $\tau > 0$ is sufficiently small.

(ii) The a priori known uniform boundedness of the above-constructed $P = \{Y_t X_t^{-1}, 0 \le t \le T\}$ helps to improve the *regularity* of the constructed L (see Theorem 5.1). This property can be studied through their BSRDE (see (6.2) in section 6 below) using the classical techniques from the theory of BSDEs.

In the following, we develop the above two points. For this purpose, define

$$\tau := \inf\{t \in [0,T] : \det(X_t) \le 0\}. \tag{5.7}$$

Here and in the following, we use the convention that $\inf \emptyset = +\infty$. Since $X_0 = I_{n\times n}$, $\det(X_0) = 1$, and since X is a continuous process, we have $\tau > 0$, a.s. Define

$$\tau_k := \inf\left\{t \in [0,T] : \det(X_t) \le \frac{1}{k+1}\right\}, \qquad k = 1, \dots. \tag{5.8}$$

We have

$$\tau_k \uparrow \tau, \qquad \text{as } k \uparrow +\infty, \tag{5.9}$$

and

$$\det(X_{t\wedge\tau_k}) \ge \frac{1}{k+1} > 0 \qquad \forall t \in [0,T] \tag{5.10}$$

for each positive integer k, i.e., $X_{t\wedge\tau_k}$ a.s. has an inverse at every $t \in [0,T]$.

THEOREM 5.3. *Let assumptions* (A1), (A2), *and* (A3) *be satisfied. Then, we have*

$$\tau = +\infty, \qquad a.s.$$

Therefore, X_t a.s. has an inverse for each $t \in [0,T]$, and BSRDE (3.1) *has a unique adapted solution (K, L) with $K := \{Y_t X_t^{-1}, 0 \le t \le T\}$ being nonnegative and uniformly bounded and $L := \{\{Z_t^i X_t^{-1} - Y_t X_t^{-1}(C_t^i + D_t^i U_t X_t^{-1})\}_{i=1}^d, 0 \le t \le T\}$ being square integrable.*

6. A priori estimate for the Riccati equation: The proof of Theorem 5.1. This section is devoted to the proof of Theorem 5.1.

Define, for $k = 1, 2, \dots,$

$$\sigma_k := T \wedge \inf\left\{t \in [0,T] : \int_0^t |L_s|^2\, ds > k\right\}. \tag{6.1}$$

Note the convention $\inf \emptyset = +\infty$. Then, σ_k is a stopping time for each positive integer k. Moreover, as $k \to \infty$, we have $\sigma_k \uparrow T$, a.s.

$\{(K_{t\wedge\sigma_k}, \chi_{[0,\sigma_k]}L(t)), 0 \le t \le T\}$ satisfies the following:

$$\begin{aligned} dK_{t\wedge\sigma_k} = &-\chi_{[0,\sigma_k]}(t)\Big[A_t'K_t + K_tA_t + \sum_{i=1}^{d}(C_t^i)'K_tC_t^i + Q_t + \sum_{i=1}^{d}[(C_t^i)'L_t^i + L_t^iC_t^i] \\ &+ G_1(B_t, C_t, D_t, N_t; K_t, L_t)\Big]\,dt + \sum_{i=1}^{d}\chi_{[0,\sigma_k]}(t)L_t^i\,dW_t^i, \qquad 0 \le t < T, \end{aligned} \tag{6.2}$$

where G_1 is defined by (3.2).

Using Itô's formula, we get

$$\begin{aligned} d|K_{t\wedge\sigma_k}|^2 = &-\chi_{[0,\sigma_k]}(t)\Big[4\,\mathrm{tr}\,\left(K_t^2A_t\right) + \sum_{i=1}^{d}2\,\mathrm{tr}\,\left(K_t(C_t^i)'K_tC_t^i\right) + 2\,\mathrm{tr}\,\left(K_tQ_t\right) \\ &+ \sum_{i=1}^{d}4\,\mathrm{tr}\,\left(K_tL_t^iC_t^i\right) + 2\,\mathrm{tr}\,\left[K_tG_1(B_t, C_t, D_t, N_t; K_t, L_t)\right] - |L_t|^2\Big]\,dt \\ &+ \sum_{i=1}^{d}2\chi_{[0,\sigma_k]}(t)\,\mathrm{tr}\,\left(K_tL_t^i\right)\,dW_t^i, \qquad 0 \le t < T. \end{aligned} \tag{6.3}$$

We observe that since

$$G_1(B_t, C_t, D_t, N_t; K_t, L_t) \le 0, \qquad K_t \ge 0, \tag{6.4}$$

we have

$$\mathrm{tr}\,\left[K_tG_1(B_t, C_t, D_t; K_t, L_t)\right] = \mathrm{tr}\,\left[K_t^{\frac{1}{2}}G_1(B_t, C_t, D_t; K_t, L_t)K_t^{\frac{1}{2}}\right] \le 0. \tag{6.5}$$

Hence, from (6.3), it follows

$$\begin{aligned} &\int_0^T \chi_{[0,\sigma_k]}(s)|L_s|^2\,ds \\ &= |K_{T\wedge\sigma_k}|^2 - |K_0|^2 + \int_0^T 2\chi_{[0,\sigma_k]}(s)\,\mathrm{tr}\,\left[K_sG_1(B_s, C_s, D_s; K_s, L_s)\right]\,ds \\ &\quad + \int_0^T \chi_{[0,\sigma_k]}(s)\Big[4\,\mathrm{tr}\,\left(K_s^2A_s\right) + \sum_{i=1}^{d}2\,\mathrm{tr}\,\left(K_s(C_s^i)'K_sC_s^i\right) + 2\,\mathrm{tr}\,\left(K_sQ_s\right) \\ &\quad + \sum_{i=1}^{d}4\,\mathrm{tr}\,\left(K_sL_s^iC_s^i\right)\Big]\,ds - \int_0^T 2\chi_{[0,\sigma_k]}(s)\sum_{i=1}^{d}\mathrm{tr}\,\left(K_sL_s^i\right)\,dW_s^i \\ &\le \int_0^T \chi_{[0,\sigma_k]}(s)\Big[4\,\mathrm{tr}\,\left(K_s^2A_s\right) + \sum_{i=1}^{d}2\,\mathrm{tr}\,\left(K_s(C_s^i)'K_sC_s^i\right) + 2\,\mathrm{tr}\,\left(K_sQ_s\right) \\ &\quad + \sum_{i=1}^{d}4\,\mathrm{tr}\,\left(K_sL_s^iC_s^i\right)\Big]\,ds + |K_{T\wedge\sigma_k}|^2 - \int_0^T 2\chi_{[0,\sigma_k]}(s)\sum_{i=1}^{d}\mathrm{tr}\,\left(K_sL_s^i\right)\,dW_s^i. \end{aligned} \tag{6.6}$$

Therefore (using assumption (A1) and the uniform boundedness of K),

$$\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^p \le \beta\left[1+\left(\int_0^T \chi_{[0,\sigma_k]}|L|\,ds\right)^p + \left|\int_0^T 2\chi_{[0,\sigma_k]}\sum_{i=1}^d \operatorname{tr}(KL^i)\,dW_s^i\right|^p\right]. \tag{6.7}$$

We have from the Burkholder–Davis–Gundy inequality the following:

$$E\left|\int_0^T \sum_{i=1}^d 2\chi_{[0,\sigma_k]}\operatorname{tr}\left(KL^i\right)\,dW_s^i\right|^p \le \beta E\left|\int_0^T \chi_{[0,\sigma_k]}|K|^2|L|^2\,ds\right|^{p/2}, \tag{6.8}$$

while from the Cauchy–Schwarz inequality, we have

$$E\left(\int_0^T \chi_{[0,\sigma_k]}|L|\,ds\right)^p \le T^{p/2}E\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^{p/2}. \tag{6.9}$$

Finally, in view of (6.8) and (6.9), we get from (6.7)

$$E\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^p \le \beta+\beta E\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^{p/2},$$

which by the elementary inequality $2ab \le a^2+b^2$ implies the following:

$$E\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^p \le \beta, \qquad k=1,2,\ldots.$$

Using Fatou's lemma, we have

$$\begin{aligned} E\left(\int_0^T |L|^2\,ds\right)^p &= E\lim_{k\to+\infty}\left(\int_0^{\sigma_k}|L|^2\,ds\right)^p = E\lim_{k\to+\infty}\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^p \\ &\le \varliminf_{k\to+\infty} E\left(\int_0^T \chi_{[0,\sigma_k]}|L|^2\,ds\right)^p \le \beta, \qquad k=1,2,\ldots, \end{aligned}$$

which completes the proof. □

7. Equivalence between the existence of the solution to the Riccati equation and the homomorphism of the stochastic flows: The proof of Theorem 5.2. This section is devoted to the proof of Theorem 5.2—the equivalence between the existence of a solution to BSRDE (3.1) and the homomorphism of the stochastic flows $\{\phi_{0,\cdot}(h), h\in\mathbb{R}^n\}$.

For the reader's convenience, we begin with the following lemma, which is an immediate adaptation of Gal'chuk [7, basic theorem on pp. 756–757] to the underlying semimartingale

$$\{(\overbrace{1,\ldots,1}^{d})'t+W_t, 0\le t\le T\}.$$

LEMMA 7.1. *Assume that the vector functions* $f : \Omega \times [0,T] \times \mathbb{R}^n \to \mathbb{R}^n$ *and* $g : \Omega \times [0,T] \times \mathbb{R}^n \to \mathbb{R}^{n\times d}$ *satisfy the following two conditions:*

(i) *For each* $x \in \mathbb{R}^n$, $f(\cdot,x)$ *and* $g(\cdot,x)$ *are* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted processes. Moreover,*

$$\int_0^T |f(t,0)|\,dt < \infty, \qquad \int_0^T |g(t,0)|^2\,dt < \infty, \quad a.s.$$

(ii) *There exist two positive functions* α_1 *and* α_2 *such that they are* $\{\mathcal{F}_t, 0 \le t \le T\}$*-adapted. Moreover,*

$$\int_0^T \alpha_1(t)\,dt < \infty, \qquad \int_0^T |\alpha_2(t)|^2\,dt < \infty, \quad a.s.$$

For any $x, y \in \mathbb{R}^n$,

$$|f(t,x) - f(t,y)| \le \alpha_1(t)|x-y|,$$
$$|g(t,x) - g(t,y)| \le \alpha_2(t)|x-y|.$$

Then, the SDE

$$dx_t = f(t,x_t)\,dt + g(t,x_t)\,dW_t,\ 0 < t \le T; \qquad x(0) = h$$

has a unique strong solution.

The proof of Theorem 5.2 is divided into two parts.

Proof of (i). If BSRDE has a solution $\{(P_t, L_t), 0 \le t \le T\}$, then it follows from Theorem 3.1 that X solves the following matrix-valued SDE:

$$\begin{cases} dX_t = \widehat{A}_t X_t\,dt + \sum_{i=1}^d \widehat{C}_t^i X_t\,dW_t^i, \\ X_0 = I_{n\times n}, \end{cases} \tag{7.1}$$

where $\widehat{A}$ and $\widehat{C}^i$ $(i = 1,\dots,d)$ are defined as follows:

$$\begin{aligned} \widehat{A}_t &:= A_t - B_t\Big[N_t + \sum_{i=1}^d (D_t^i)' P_t D_t^i\Big]^{-1}\Big[P_t B_t + \sum_{i=1}^d (C_t^i)' P_t D_t^i + \sum_{i=1}^d L_t^i D_t^i\Big]', \\ \widehat{C}_t^i &:= C_t^i - D_t^i\Big[N_t + \sum_{i=1}^d (D_t^i)' P_t D_t^i\Big]^{-1}\Big[P_t B_t + \sum_{i=1}^d (C_t^i)' P_t D_t^i + \sum_{i=1}^d L_t^i D_t^i\Big]'. \end{aligned} \tag{7.2}$$

In view of assumption (A1) and Definition 3.1, the coefficients of the above optimal closed system $\widehat{A}$ and $\widehat{C}_i$ $(i = 1,\dots,d)$ satisfy the following conditions:

$$\int_0^T |\widehat{A}_s|^2\,ds < \infty, \qquad \int_0^T |\widehat{C}_s^i|^2\,ds < \infty, \quad i = 1,\dots,d, \quad \text{a.s.}$$

It follows from Lemma 7.1 that the linear matrix-valued SDE

$$\begin{cases} d\mathcal{X}_t = -\mathcal{X}_t\Big(\widehat{A}_t - \sum_{i=1}^d (\widehat{C}_t^i)^2\Big)\,dt - \mathcal{X}_t \sum_{i=1}^d \widehat{C}_t^i\,dW_t^i, \\ \mathcal{X}_0 = I_{n\times n} \end{cases} \tag{7.3}$$

has a unique strong solution on $[0,T]$. Using Itô's formula, we can verify that $X\mathcal{X}$ solves the following SDE:

$$\begin{cases} dV_t = \Big(\widehat{A}_t V_t - V_t\widehat{A}_t + V_t\sum_{i=1}^d(\widehat{C}_t^i)^2 - \sum_{i=1}^d \widehat{C}_t^i V_t \widehat{C}_t^i\Big)\,dt + \sum_{i=1}^d(\widehat{C}_t^i V_t - V_t\widehat{C}_t^i)\,dW_t^i, \\ V_0 = I_{n\times n}. \end{cases} \tag{7.4}$$

Obviously, the constant matrix process $I_{n\times n}$ is its solution. Since this equation has a unique solution (by virtue of Lemma 7.1), we have $X_t\mathcal{X}_t = I_{n\times n}$ a.s. Therefore, X_t a.s. has an inverse at each $t\in[0,T]$. □

Proof of (ii). Applying Itô's formula to compute X_t^{-1}, we have from (5.3) the following:

$$\begin{aligned} dX_t^{-1} =& -X_t^{-1}(dX_t)X_t^{-1} + \sum_{i=1}^d X_t^{-1}(C_t^iX_t + D_t^iU_t)X_t^{-1}(C_t^iX_t + D_t^iU_t)X_t^{-1}\,dt \\ =& -X_t^{-1}\Big[A_t + B_tU_tX_t^{-1} - \sum_{i=1}^d(C_t^i + D_t^iU_tX_t^{-1})(C_t^i + D_t^iU_tX_t^{-1})\Big]\,dt \\ & - \sum_{i=1}^d X_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})\,dW_t^i. \end{aligned} \tag{7.5}$$

Then, we have (in view of (5.4))

$$\begin{aligned} d(Y_tX_t^{-1}) =& -\sum_{i=1}^d Z_t^iX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})\,dt + Y_t\,d(X_t^{-1}) + (dY_t)X_t^{-1} \\ =& -\sum_{i=1}^d Y_tX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})\,dW_t^i - \sum_{i=1}^d Z_t^iX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})\,dt \\ & - Y_tX_t^{-1}\Big[A_t + B_tU_tX_t^{-1} - \sum_{i=1}^d(C_t^i + D_t^iU_tX_t^{-1})(C_t^i + D_t^iU_tX_t^{-1})\Big]\,dt \\ & - \Big[A_t'Y_tX_t^{-1} + Q_t + \sum_{i=1}^d(C_t^i)'Z_t^iX_t^{-1}\Big]\,dt + \sum_{i=1}^d Z_t^iX_t^{-1}\,dW_t^i \\ =& -\sum_{i=1}^d[Z_t^iX_t^{-1} - Y_tX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})](C_t^i + D_t^iU_tX_t^{-1})\,dt \\ & - \Big[A_t'Y_tX_t^{-1} + Q_t + \sum_{i=1}^d(C_t^i)'Z_t^iX_t^{-1}\Big]\,dt - Y_tX_t^{-1}(A_t + B_tU_tX_t^{-1})\,dt \\ & + \sum_{i=1}^d[Z_t^iX_t^{-1} - Y_tX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})]\,dW_t^i. \end{aligned} \tag{7.6}$$

Recall that

$$L_t^i := Z_t^iX_t^{-1} - Y_tX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1}), \qquad i = 1,\dots,d. \tag{7.7}$$

Since X^{-1} is a.s. bounded on $[0,T]$, we have

$$\int_0^T |L_s|^2\,ds < \infty, \quad \text{a.s.}$$

However, it is not clear now that

$$E\int_0^T |L_s|^2\,ds < \infty.$$

From (7.7), it follows that

$$Z_t^i X_t^{-1} = L_t^i + Y_t X_t^{-1}(C_t^i + D_t^i U_t X_t^{-1}). \tag{7.8}$$

On the one hand, putting (7.8) into (7.6), we get

$$\begin{aligned} d(Y_tX_t^{-1}) =& -\left\{A_t'Y_tX_t^{-1} + Q_t + \sum_{i=1}^d (C_t^i)'[L_t^i + Y_tX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})]\right\}dt \\ & - Y_tX_t^{-1}(A_t + B_tU_tX_t^{-1})\,dt - \sum_{i=1}^d L_t^i(C_t^i + D_t^iU_tX_t^{-1})\,dt + \sum_{i=1}^d L_t^i\,dW_t^i \\ =& -\left\{A_t'Y_tX_t^{-1} + Y_tX_t^{-1}A_t + Q_t \right. \\ & \left. + \sum_{i=1}^d (C_t^i)'Y_tX_t^{-1}C_t^i + \sum_{i=1}^d [(C_t^i)'L_t^i + L_t^iC_t^i]\right\}dt \\ & - \left[Y_tX_t^{-1}B_t + \sum_{i=1}^d (C_t^i)'Y_tX_t^{-1}D_t^i + \sum_{i=1}^d L_t^iD_t^i\right]U_tX_t^{-1}\,dt + \sum_{i=1}^d L_t^i\,dW_t^i. \end{aligned} \tag{7.9}$$

On the other hand, in view of (5.5) and (7.8), we have

$$N_tU_tX_t^{-1} + B_t'Y_tX_t^{-1} + \sum_{i=1}^d (D_t^i)'[L_t^i + Y_tX_t^{-1}(C_t^i + D_t^iU_tX_t^{-1})] = 0; \tag{7.10}$$

that is,

$$\left(N_t + \sum_{i=1}^d (D_t^i)'Y_tX_t^{-1}D_t^i\right)U_tX_t^{-1} + B_t'Y_tX_t^{-1} + \sum_{i=1}^d (D_t^i)'Y_tX_t^{-1}C_t^i + \sum_{i=1}^d (D_t^i)'L_t^i = 0. \tag{7.11}$$

At this stage, we apply Theorem 2.4 and get

$$K_t = Y_tX_t^{-1} = P_t, \quad \text{a.s.} \tag{7.12}$$

From Theorem 2.4, it also follows that K is nonnegative and is uniformly bounded.

Putting (7.12) into (7.7) and (7.11), we have

$$L_t^i = Z_t^iX_t^{-1} - K_t(C_t^i + D_t^iU_tX_t^{-1}), \qquad i = 1,\dots,d, \tag{7.13}$$

and

$$(7.14)\quad \left(N_t+\sum_{i=1}^{d}(D_t^i)'K_tD_t^i\right)U_tX_t^{-1}+B_t'K_t+\sum_{i=1}^{d}(D_t^i)'K_tC_t^i+\sum_{i=1}^{d}(D_t^i)'L_t^i=0.$$

The last equality implies (noting K_t is symmetric and nonnegative) that

$$(7.15)\quad U_tX_t^{-1}=-\left(N_t+\sum_{i=1}^{d}(D_t^i)'K_tD^i\right)^{-1}\left[B_t'K_t+\sum_{i=1}^{d}(D_t^i)'K_tC_t^i+\sum_{i=1}^{d}(D_t^i)'L_t^i\right].$$

Putting (7.12) and (7.15) into (7.9), we see that (K,L) solves BSRDE (3.1). Moreover, we can apply Theorem 5.1 here and derive that L is square integrable. The proof is complete.

8. Existence and uniqueness of the solution to the BSRDE: The proof of Theorem 5.3. This section is devoted to the proof of Theorem 5.3.

The uniqueness easily follows from formula (3.5) in Theorem 3.2. In fact, (3.5) implies immediately the uniqueness of the first component of the adapted solution of BSRDE (3.1). Then, the uniqueness of the second component is proved by a direct application of Itô's formula to the difference of the two BSRDEs with the consideration that the first components are the same.

The following is concentrated on the proof of the existence part, by actually constructing a solution using the stochastic Hamilton system.

It is convenient to introduce the following notation:

$$(8.1)\quad \begin{aligned}&P_t:=Y_tX_t^{-1},\\ &L_t^i:=Z_t^iX_t^{-1}-P_t(C_t^i+D_t^iU_tX_t^{-1}),\qquad i=1,\dots,d,\\ &L_t:=(L_t^1,\cdots,L_t^d).\end{aligned}$$

Note that the two notations P_t and L_t are well defined only when X_t has an inverse. At the moment, we know that P and L are a.s. well defined on $[0,\tau)$. Please keep in mind that in what follows, P_t and L_t are assumed to be zero whenever they are not well defined in the context.

From (8.1), we see that both P_t and L_t might a.s. have a singularity at $t=\tau$.

The proof of the existence part consists of three steps. In the first step, we describe the counterparts of section 7 when the mathematical objects (processes, SDEs, BSDEs, BSRDE,...) are stopped or truncated by the sequence of stopping times $\{\tau_k\}_{k=1}^{\infty}$. In the second step, we perform a limit analysis to some concerned integrals and processes by giving five lemmas. In this step, Theorem 5.1 plays a crucial rule. Finally, in the third step, we pass to the limit in the sequence of stopped/truncated BSRDEs, based on the previous analysis at the limit.

Step 1. Define for $0\le t\le T$,

$$(8.2)\quad \begin{aligned}X_t^k:=&X_{t\wedge\tau_k},\qquad Y_t^k:=Y_{t\wedge\tau_k},\\ Z_t(k):=&\chi_{[0,\tau_k]}(t)Z_t,\qquad U_t^k:=\chi_{[0,\tau_k]}(t)U_t\end{aligned}$$

and

$$(8.3)\quad \begin{aligned}&A_t(k):=\chi_{[0,\tau_k]}(t)A_t,\qquad B_t(k):=\chi_{[0,\tau_k]}(t)B_t,\\ &C_t^i(k):=\chi_{[0,\tau_k]}(t)C_t^i,\qquad D_t^i(k):=\chi_{[0,\tau_k]}(t)D_t^i,\quad i=1,\dots,d,\\ &C_t(k):=(C_t^1(k),\dots,C_t^d(k)),\qquad D_t(k):=(D_t^1(k),\dots,D_t^d(k)),\\ &Q_t(k):=\chi_{[0,\tau_k]}(t)Q_t.\end{aligned}$$

Then, X^k a.s. has an inverse at each $t \in [0,T]$. Therefore, we can define, similar to section 7,

$$\begin{aligned} &P_t^k := Y_t^k (X_t^k)^{-1} = Y_{t\wedge\tau_k}(X_{t\wedge\tau_k})^{-1} = P_{t\wedge\tau_k}, \\ &L_t^i(k) := Z_t^i(k)(X_t^k)^{-1} - P_t^k[C_t^i(k) + D_t^i(k)U_t^k(X_t^k)^{-1}], \qquad i = 1,\dots,d, \\ &L_t(k) := (L_t^1(k),\dots,L_t^d(k)). \end{aligned} \tag{8.4}$$

From Theorem 2.4, it follows that P^k is uniformly bounded and $P_t^k \geq 0$.

From (5.3), it follows that X^k is the solution of the matrix-valued SDE:

$$\begin{cases} dX_t^k = [A_t(k)X_t^k + B_t(k)U_t^k]\,dt + \sum_{i=1}^d [C_t^i(k)X_t^k + D_t^i(k)U_t^k]\,dW_t^i, \\ X_0^k = I_{n\times n}. \end{cases} \tag{8.5}$$

From (5.4), it follows that the pair $(Y^k, Z(k))$ of processes is the solution of the matrix-valued BSDE:

$$\begin{cases} -dY_t^k = \left[A_t(k)'Y_t^k + Q_t(k)X_t^k + \sum_{i=1}^d C_t^i(k)'Z_t^i(k)\right]dt - \sum_{i=1}^d Z_t^i(k)\,dW_t^i, \\ Y_T^k = P_T^k X_T^k, \qquad Z_t(k) := (Z_t^1(k),\dots,Z_t^d(k)). \end{cases} \tag{8.6}$$

Moreover, from (5.5) we have

$$N_t U_t^k + B_t(k)'Y_t^k + \sum_{i=1}^d D_t^i(k)'Z_t^i(k) = 0. \tag{8.7}$$

Note that the terminal condition of BSDE (8.6) comes from the first relations in (8.4).

Proceeding identically as in the previous section, we can show that the pair $(P^k, L(k))$ of processes satisfies the following BSRDE:

$$\begin{cases} dP_t^k = -\Big\{A_t(k)'P_t^k + P_t^k A_t(k) + Q_t(k) + \sum_{i=1}^d C_t^i(k)'P_t^k C_t^i(k) \\ \qquad\qquad + \sum_{i=1}^d [C_t^i(k)'L_t^i(k) + L_t^i(k)C_t^i(k)]\Big\}\,dt \\ \qquad\qquad - G_1(B_t(k), C_t(k), D_t(k), N_t; P_t^k, L_t(k))\,dt + \sum_{i=1}^d L_t^i(k)\,dW_t^i, \quad 0 \leq t \leq T, \\ L_t(k) := (L_t^1(k),\dots,L_t^d(k)). \end{cases} \tag{8.8}$$

Step 2. We have the following five lemmas.

LEMMA 8.1. *Under the assumptions of Theorem* 5.3 *and the above notation, we have*

$$E\int_0^T |\chi_{[0,\tau)}(t)L_t|^2\,dt < \infty.$$

Before starting the proof, let us remark that according to the convention given at the beginning of this section, we have defined in the above

$$\chi_{[0,\tau)}(t)L_t = 0 \quad \text{as } t \geq \tau.$$

Similar other terms will also appear in the following expositions, and we will not repeat this kind of statement.

Proof of Lemma 8.1. From Theorem 2.4, it follows that P^k is uniformly bounded with respect to (t, ω, k) and is nonnegative. Then it follows from Theorem 5.1 that

$$E\int_0^T |L_t(k)|^2\,dt \leq \beta, \tag{8.9}$$

where β is a positive constant independent of k. Since $\tau_k \uparrow \tau$ a.s., we have

$$|L_t(k)|^2 = \chi_{[0,\tau_k]}(t)|L_t|^2 \to \chi_{[0,\tau)}(t)|L_t|^2, \quad \text{a.s.a.e.}$$

Using Fatou's lemma, we further obtain

$$E\int_0^T |\chi_{[0,\tau)}(t)L_t|^2\,dt \leq \varliminf_{k\to\infty} E\int_0^T |L_t(k)|^2\,dt \leq \beta. \tag{8.10}$$

This completes the proof. □

LEMMA 8.2. *Under the assumptions of Theorem* 5.3 *and the above notation, we have*

$$\lim_{k\to\infty}\int_0^T \sum_{i=1}^d L_t^i(k)\,dW_t^i = \int_0^T \sum_{i=1}^d \chi_{[0,\tau)}(t)L_t^i\,dW_t^i, \quad \textit{a.s.} \tag{8.11}$$

Proof of Lemma 8.2. It suffices to prove that the quadratic variation of the difference of the two stochastic integrals a.s. converges to zero, i.e., to show

$$\lim_{k\to\infty}\int_0^T |L_t(k) - \chi_{[0,\tau)}(t)L_t|^2\,dt = 0, \quad \text{a.s.}$$

Since $\tau_k \uparrow \tau$ a.s., we have

$$L_t(k) - \chi_{[0,\tau)}(t)L_t = -\chi_{[\tau_k,\tau)}(t)L_t \to 0, \quad \text{a.s.a.e.}$$

While

$$|L_t(k) - \chi_{[0,\tau)}(t)L_t|^2 = |\chi_{[\tau_k,\tau)}(t)L_t|^2 \leq |\chi_{[0,\tau)}(t)L_t|^2,$$

the last term of which is by Lemma 8.1 a.s. square integrable on $[0,T]$, i.e.,

$$\int_0^T |\chi_{[0,\tau)}(t)L_t|^2\,dt < \infty, \quad \text{a.s.}$$

The desired result then follows from Lebesgue's dominated convergence theorem. □

LEMMA 8.3. *Under the assumptions of Theorem* 5.3 *and the above notation, we have*

$$\begin{aligned}&\lim_{k\to\infty}\int_0^T G(A_t(k), B_t(k), C_t(k), D_t(k); Q_t(k), N_t; P_t^k, L_t(k))\,dt\\ &= \int_0^T \chi_{[0,\tau)}(t)G(A_t, B_t, C_t, D_t; Q_t, N_t; P_t, L_t)\,dt, \quad \textit{a.s.}\end{aligned} \tag{8.12}$$

Proof of Lemma 8.3. Note that

$$\begin{aligned}&\int_0^T G(A_t(k),B_t(k),C_t(k),D_t(k);Q_t(k),N_t;P_t^k,L_t(k))\,dt\\&=\int_0^{T\wedge\tau_k}\chi_{[0,\tau)}(t)G(A_t,B_t,C_t,D_t;Q_t,N_t;P_t,L_t)\,dt.\end{aligned}\tag{8.13}$$

Since P is uniformly bounded and $\chi_{[0,\tau)}L$ is square integrable with respect to (t,ω), the underlying integrand is integrable on $[0,T]\times\Omega$. Hence the desired result then follows.

Note that $P_0^k=Y_0$ for $k=1,2,\ldots$. From Lemmas 8.2 and 8.3, Theorem 2.4, and BSRDE (8.8), the following statement is immediate.

LEMMA 8.4. *Under the assumptions of Theorem* 5.3 *and the above notation,* P_T^k *a.s. converges. The limit* P_T^∞ *is uniformly bounded. Moreover,*

$$Y_{T\wedge\tau}=P_T^\infty X_{T\wedge\tau}.\tag{8.14}$$

We can write

$$\begin{aligned}P_t^k&=Y_0-\int_0^{t\wedge\tau_k}\chi_{[0,\tau)}(s)G(A_s,B_s,C_s,D_s;Q_s,N_s;P_s,L_s)\,ds\\&\quad+\int_0^{t\wedge\tau_k}\chi_{[0,\tau)}(s)\sum_{i=1}^d L_s^i\,dW_s^i.\end{aligned}\tag{8.15}$$

Proceeding identically as before, we can show the following lemma.

LEMMA 8.5. *Under the assumptions of Theorem* 5.3 *and the above notation,* P_t^k *strongly converges to* P_t^∞*, which is defined as follows:*

$$\begin{aligned}P_t^\infty&:=Y_0-\int_0^{t\wedge\tau}\chi_{[0,\tau)}(s)G(A_s,B_s,C_s,D_s;Q_s,N_s;P_s,L_s)\,ds\\&\quad+\int_0^{t\wedge\tau}\chi_{[0,\tau)}(s)\sum_{i=1}^d L_s^i\,dW_s^i\\&=Y_0-\int_0^t\chi_{[0,\tau)}(s)G(A_s,B_s,C_s,D_s;Q_s,N_s;P_s,L_s)\,ds\\&\quad+\int_0^t\chi_{[0,\tau)}(s)\sum_{i=1}^d L_s^i\,dW_s^i.\end{aligned}\tag{8.16}$$

Step 3. We can pass to the limit in BSRDE (8.8). This shows that $(P^\infty,\chi_{[0,\tau)}L)$ satisfies the following BSRDE:

$$\begin{cases}d\widetilde{P}_t=-\Big\{A_t(\infty)'\widetilde{P}_t+\widetilde{P}_tA_t(\infty)+Q_t(\infty)+\sum_{i=1}^d C_t^i(\infty)'\widetilde{P}_tC_t^i(\infty)\\\qquad+\sum_{i=1}^d[C_t^i(\infty)'\widetilde{L}_t^i+\widetilde{L}_t^iC_t^i(\infty)]+G_1(B_t(\infty),C_t(\infty),D_t(\infty),N_t;\widetilde{P}_t,\widetilde{L}_t)\Big\}\,dt\\\qquad+\sum_{i=1}^d\widetilde{L}_t^i\,dW_t^i,\qquad 0\le t\le T,\\\widetilde{P}_T=P_T^\infty,\qquad \widetilde{L}_t:=(\widetilde{L}_t^1,\ldots,\widetilde{L}_t^d).\end{cases}\tag{8.17}$$

Here,

$$\begin{aligned}
&A_t(\infty) := \chi_{[0,\tau]}(t)A_t, \qquad B_t(\infty) := \chi_{[0,\tau]}(t)B_t,\\
&C_t^i(\infty) := \chi_{[0,\tau]}(t)C_t^i, \qquad D_t^i(\infty) := \chi_{[0,\tau]}(t)D_t^i, \quad i = 1, \dots, d,\\
&C_t(\infty) := (C_t^1(\infty), \dots, C_t^d(\infty)), \qquad D_t(\infty) := (D_t^1(\infty), \dots, D_t^d(\infty)),\\
&Q_t(\infty) := \chi_{[0,\tau]}(t)Q_t, \qquad U_t(\infty) := \chi_{[0,\tau]}(t)U_t.
\end{aligned} \tag{8.18}$$

Note that $\{(X_{t\wedge\tau}, Y_{t\wedge\tau}, \chi_{[0,\tau)}(t)Z_t), 0 \le t \le T\}$ satisfies the following:

$$\begin{cases}
d\widetilde{X}_t = [A_t(\infty)\widetilde{X}_t + B_t(\infty)U_t(\infty)]\,dt + \sum_{i=1}^{d}[C_t^i(\infty)\widetilde{X}_t + D_t^i(\infty)U_t(\infty)]\,dW_t^i,\\
-d\widetilde{Y}_t = \left[A_t(\infty)'\widetilde{Y}_t + Q_t(\infty)\widetilde{X}_t + \sum_{i=1}^{d} C_t^i(\infty)'\widetilde{Z}_t^i\right]dt - \sum_{i=1}^{d}\widetilde{Z}_t^i\,dW_t^i,\\
\widetilde{X}_0 = I_{n\times n}, \qquad \widetilde{Y}_T = P_T^\infty \widetilde{X}_T,\\
0 = N_tU_t(\infty) + B_t(\infty)'\widetilde{Y}_t + \sum_{i=1}^{d} D_t^i(\infty)'\widetilde{Z}_t^i.
\end{cases} \tag{8.19}$$

It follows from Theorem 5.2(i) that $X_{T\wedge\tau}$ a.s. has an inverse. On the other hand, by definition of stopping time τ and the trajectory-continuity of process X, we see that $X_{T\wedge\tau}$ is degenerate on $\{\tau < \infty\}$. Therefore, to avoid a contradiction, it is necessary that

$$P(\{\tau < \infty\}) = 0.$$

Therefore, X a.s. has an inverse at each $t \in [0,T]$, $P^\infty = YX^{-1}$, $\chi_{[0,\tau)}L = L$, and BSRDE (8.17) coincides with BSRDE (3.1). The proof is complete. □

9. Concluding comments. The results of this paper can be adapted to the singular case (N is allowed to be only nonnegative) but with suitable additional conditions such as the following:

(A4) Assume that the matrix process $\sum_{i=1}^{d}(D^i)'D^i$ and the terminal state weighting random matrix M are uniformly positive.

This subject will be detailed elsewhere.

The singular case has received much recent interests because of its appearance in financial mean-variance problems. More generally, N can also be possibly negative—this is the so-called indefinite case. On these features, the interested reader is referred to Chen and Yong [5], Kohlmann and Tang [9, 12], Yong and Zhou [24], and the references therein.

Finally, the quadratic optimal control problem of linear stochastic evolution system with random coefficients can also be discussed. The details will be presented elsewhere.

Acknowledgments. The author would like to thank Prof. Michael Kohlmann for his help and relevant discussions as well as his hospitality during the author's stay in Konstanz. This work was reported in April 2001 at the School of Mathematics and System Science, University of Shandong, Jinan 250100. The author is grateful to Prof. Peng for his kind invitation and helpful comments. Last but not least, the author would like to thank the associate editor and the two referees for their helpful comments.

STABILIZATION OF LPV SYSTEMS: STATE FEEDBACK, STATE ESTIMATION, AND DUALITY*

FRANCO BLANCHINI† AND STEFANO MIANI‡

Abstract. In this paper we consider the problem of stabilizing linear parameter varying (LPV) systems by means of gain scheduling control. This technique amounts to designing a controller which is able to update its parameters on-line according to the variations of the plant parameters. We first consider the state feedback case and show a design procedure based on the construction of a Lyapunov function for discrete-time LPV systems in which the parameter variations are affine and occur in the state matrix only. This procedure produces a nonlinear static controller. We show that, different from the robust stabilization case, we can always derive a linear controller, that is, nonlinear controllers cannot outperform linear ones for the gain scheduling problem. Then we show that this procedure has a dual version which leads to the construction of a linear gain scheduling observer. The two procedures may be combined to derive an observer-based linear gain scheduling compensator.

Key words. LPV systems, gain scheduling, nonquadratic Lyapunov functions, robust stabilization

1. Introduction.

The control of linear parameter varying (LPV) systems is a problem which is encountered in several applications in the industrial world. In many cases the parameter variations cannot be measured on-line and in this case the robust control approach is appropriate. The problem is different in the case in which the parameters can be measured on-line. In this case the compensator may take advantage of this knowledge and improve its performance [5].

The gain scheduling approach is classical and is often used in industrial applications. However, only quite recently these techniques, which have been heuristically applied, became a subject of mathematical investigation. In [29], [30] a rigorous stability analysis of some general gain-scheduled schemes is provided. A pole placement-like technique for gain scheduling synthesis is proposed in [28]. In [17] it is considered the problem of designing a nonlinear controller whose linearizations in several operating points match the linear controllers designed for these points. A linear matrix inequality (LMI) technique for the gain scheduled control design is proposed in [27]. A μ-analysis approach is proposed in [16]. A more recent technique based on a set-theoretic approach is presented in [31] for discrete-time LPV systems with bounded variations. The reader is referred to [26] for a tutorial exposition.

Although the knowledge of the plant parameters is an advantage for the compensator, an interesting exception has been investigated in the literature which concerns the state feedback case. Indeed, for the class of control-affine nonlinear continuous-time systems in which the term associated with the control is certain [22] or the so-called convex processes [10], the knowledge of the parameter is not an advantage

for the compensator as far as it concerns its stabilization capability. As a particular case, gain scheduling design for state feedback LPV systems can be handled without restriction as a robust design, with the remarkable advantage that no parameter measurement is needed.

In the discrete-time case this property does not hold. As we will see, there are trivial examples of LPV discrete-time systems that can be stabilized via gain scheduling controllers, but no stabilizing controllers which ignore the parameters exist. This fact motivated us to derive a procedure to design a gain scheduling control in which the exploitation of the parameter measurement is allowed. In particular, we consider a procedure for the robust stabilization case [7], [12], which is in principle unsuitable for the gain scheduling design, and we show that it still helps if applied to a proper subsystem evidenced by a suitable transformation.

Furthermore, we show that in the discrete-time gain scheduling case nonlinear compensators cannot outperform linear ones. This is in contrast to the robust stabilization case in which nonlinear controllers can outperform linear ones [11] (see also [21] for further implications). Thus limiting the attention to linear compensators is not a restriction for gain scheduling state feedback stabilization. (This result holds for continuous-time systems as well [10].)

Then we consider the dual problem of designing a gain scheduling state observer based only on the knowledge of the current output and parameter measurements of the type considered in [20], [25], [32]. We show that necessary and sufficient conditions for the existence of such a linear observer are the dual of those for the existence of a gain scheduling state feedback compensator (linear or not). We show how this kind of duality does not hold for the robust state estimation problem, i.e., when the parameters are not available to the observer, and by means of a simple example we show that the class of linear gain scheduling observers proposed does not parameterize the class of gain scheduling observers.

Finally we show that the two procedures for state feedback stabilization and state detection can be combined together to solve the problem of stabilization by means of a linear observer-based compensator.

2. Problem statement and basic results. In this paper we consider LPV systems of the form

$$\begin{aligned} x(k+1) &= A(w(k))x(k) + Bu(k), \\ y(k) &= Cx(k), \end{aligned} \tag{1}$$

where $x(k) \in \mathbb{R}^n$ is the state, $u(k) \in \mathbb{R}^q$ is the control input, $y(k) \in \mathbb{R}^p$ is the control output, and $w(k)$ is a time-varying parameter. We assume that the state matrix $A(w(k))$ is constrained to belong to the matrix polytope

$$A(w(k)) = \sum_{h=1}^{m} A^{(h)} w_h(k), \tag{2}$$

where, for every k,

$$w(k) \in \mathcal{W} = \left\{ w = [w_1, \ldots, w_m]^T : w_h \geq 0, h = 1, \ldots, m, \sum_{h=1}^{m} w_h = 1 \right\}, \tag{3}$$

and $A^{(h)}$, $h = 1, 2, \ldots, m$, are assigned constant $n \times n$ matrices. A function $w(\cdot) : \mathbb{N}_o \to \mathbb{R}^m$ will be said *admissible* if $\mathrm{im}(w) \subseteq \mathcal{W}$.

In the following we will work under the assumption below.

Assumption 2.1. Matrices B and C have full column and row rank, respectively.

The basic problem considered in this paper is the stabilization of system (1) by means of a state observer and an estimated state feedback compensator which are scheduled on the parameter $w(k)$.

DEFINITION 2.1. *The system* (1) *is gain scheduling state feedback (GSSF) stabilizable if there exists a (possibly dynamic) continuous state feedback compensator whose equations are a function of the time-varying parameter* $w(k)$*,*

$$\begin{aligned} z(k+1) &= F(z(k), x(k), w(k)), \\ u(k) &= G(z(k), x(k), w(k)), \end{aligned} \tag{4}$$

such that the resulting closed-loop system is globally uniformly asymptotically stable for every admissible function $w(\cdot)$*.*

The next definition is essentially the dual.

DEFINITION 2.2. *The system* (1) *is gain scheduling detectable (GSD) if there exists a (possibly dynamic) system whose equations are a function of the time–varying parameter* $w(k)$*,*

$$\begin{aligned} z(k+1) &= F(z(k), y(k), u(k), w(k)), \\ \hat{x}(k) &= G(z(k), y(k), u(k), w(k)), \end{aligned} \tag{5}$$

and such that for all $x(0)$*,* $z(0)$*,* $w(\cdot)$ *the condition* $e(k) \doteq \hat{x}(k) - x(k) \to 0$ *as* $k \to \infty$ *is assured for every admissible function* $w(\cdot)$*.*

With obvious meaning, we will say that (1) is *robustly stabilizable* (RS) and *robustly detectable* (RD) if (4) and (5) do not depend on the parameter w. Furthermore, we will distinguish the case in which $F(\cdot)$ and $G(\cdot)$ in (4) and (5), for fixed $w(k) \in \mathcal{W}$, are linear with respect to $x(k)$ and $z(k)$ (respectively, $y(k)$, $u(k)$, and $z(k)$).

2.1. Robust stabilization and state detection. One of the main points of the paper is to show that there is no apparent duality between the problem of robust detection and robust state feedback stabilization while, in turn, a kind of duality relationship exists between the gain scheduling stabilization and detection problems.

Let us consider the following system:

$$\begin{aligned} x(k+1) &= A(w(k))x(k) + Bu(k), \\ y(k) &= x(k); \end{aligned} \tag{6}$$

let us define its dual as follows:

$$\begin{aligned} x(k+1) &= A^T(w(k))x(k) + u(k), \\ y(k) &= B^T x(k). \end{aligned} \tag{7}$$

As is well known, if A is a constant matrix, we have a duality relation which says that (6) is stabilizable if and only if (7) is detectable. In our case such a relation does not exist as long as the parameter w is unknown, as can be shown by the next counterexample. Consider the system

$$\begin{bmatrix} x_1(k+1) \\ x_2(k+1) \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ 1+w(k) & 0 \end{bmatrix} \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix},$$
$$y(k) = x_2(k)$$

with $|w(k)| \le \bar{w}$. Such a system is such that there is no observer which can estimate asymptotically $x_1(k)$ ignoring $w(k)$. Indeed, in the second state equation $x_1(k)$ enters

in the term $\xi \doteq (1+w(k))x_1(k)$. Although $\xi(k) = x_2(k+1)$ can be determined with one step delay, it is impossible to estimate $x_1(k)$ from $\xi(k)$, if $\bar{w} > 0$, up to the fact it belongs to the uncertainty interval $\xi/(1+\bar{w}) \le x_1 \le \xi/(1-\bar{w})$, whose size grows arbitrarily if $x_1(0) \neq 0$. Conversely, its dual system

$$\begin{bmatrix} x_1(k+1) \\ x_2(k+1) \end{bmatrix} = \begin{bmatrix} 2 & 1+w(k) \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(k)$$

with the control $u(k) = -4x_1(k) - 2x_2(k)$ is stable provided that $\bar{w}$ is sufficiently small. Thus, roughly, robust stabilizability does not imply the robust detectability of the dual.

It can be easily shown that robust detectability does not imply the robust stabilizability of the dual as well. To this aim it is sufficient to consider the following simple example with $A(w(k)) = w(k)$, $B = 1$, and $C = 1$ (say the system and its dual coincide):

$$x(k+1) = w(k)x(k) + u(k), \tag{8}$$

$$y(k) = x(k) \tag{9}$$

with $|w(k)| \le 2$, which cannot be robustly stabilized by any state feedback, but is obviously detectable. Note in passing that the last example shows that robust state feedback stabilization and the gain scheduling state feedback stabilization are different problems for discrete-time systems. Indeed, the system can be gain scheduling stabilized (e.g., by $u(k) = -w(k)x(k)$), but not robustly stabilized. This fact was pointed out in [10] and will motivate the results of the next section in which we will present a procedure for the GSSF stabilization by means of the procedures already available for robust control synthesis [7], [12].

2.2. Some definitions and preliminary results. In this section we recall some basic results concerning the stability of LPV systems. We denote by C-set a convex and compact set containing the origin as an interior point. We say that a set $\mathcal{P}$ is 0-symmetric if $x \in \mathcal{P}$ implies $-x \in \mathcal{P}$. We denote by $\text{int}\{\mathcal{P}\}$ the interior of $\mathcal{P}$ and for any real $\lambda > 0$; we denote by $\lambda\mathcal{P}$ the scaled set $\lambda\mathcal{P} = \{x : \frac{x}{\lambda} \in \mathcal{P}\}$. Given $x \in \mathbb{R}^n$ the one norm and the infinity norm are defined as

$$\|x\|_1 = \sum_{i=1}^{n} |x_i|, \qquad \|x\|_\infty = \max_i |x_i|,$$

respectively. The corresponding induced norms for matrices are

$$\|H\|_1 = \sup_{x\neq 0} \frac{\|Hx\|_1}{\|x\|_1} = \sup_j \sum_{i=1}^{n} |H_{ij}|, \qquad \|H\|_\infty = \sup_{x\neq 0} \frac{\|Hx\|_\infty}{\|x\|_\infty} = \sup_i \sum_{j=1}^{n} |H_{ij}|.$$

As it is known, the two norms above are dual in $\mathbb{R}^n$ [19].

Definition 2.3 (see [18]). *The set $\mathcal{P} \in \mathbb{R}^n$ obtained as the convex hull of finitely many vectors*

$$\mathcal{P} = conv\{x_1, \dots, x_r\} = \left\{ x : x = \sum_{i=1}^{r} \alpha_i x_i, \sum_{i=1}^{r} \alpha_i = 1,\ \alpha_i \ge 0, x_i \in \mathbb{R}^n, i = 1, \dots, r \right\}$$

is called a (convex) polytope. We will denote by $vert\{\mathcal{P}\}$ the minimal set of vectors $\{x_1, \dots, x_l\}$, $l \le r$, such that $conv\{x_1, \dots, x_l\} = conv\{x_1, \dots, x_r\}$. A vector $x \in vert\{\mathcal{P}\}$ is called a vertex of $\mathcal{P}$.

DEFINITION 2.4 (see [18]). *A set $\mathcal{P} \in \mathbb{R}^n$ is polyhedral if it is the intersection of a finite number of closed half-spaces:*

$$\mathcal{P} = \{x : f_i x \leq g_i,\ f_i^T \in \mathbb{R}^n,\ \ g_i \in \mathbb{R},\ i = 1, \dots, s\}. \tag{10}$$

If we restrict our attention to polyhedral 0-symmetric C-sets, the following proposition holds.

PROPOSITION 2.5. *Any 0-symmetric polyhedral C-set $\mathcal{P} \in \mathbb{R}^n$ is a polytope and can be represented in the form*

$$\mathcal{P} = \{x :\ \|Fx\|_\infty \leq 1\}, \tag{11}$$

where $F \in \mathbb{R}^{s \times n}$ is a full column rank matrix, or in the dual form

$$\mathcal{P} = \{x = X\alpha,\ \ \alpha \in \mathbb{R}^l,\ \|\alpha\|_1 \leq 1\}, \tag{12}$$

where $X \in \mathbb{R}^{n \times l}$ is a full row rank matrix.

Proof. The proof that a bounded polyhedral set is a polytope can be found in [18, Theorem 20.9]. As far as the representation (11), by Definition 2.4, in view of the 0-symmetry of $\mathcal{P}$, $\mathcal{P}$ can be represented by inequalities of the form

$$|f_i x| \leq g_i,\ \ g_i \geq 0,\ \ \text{for } i = 1, \dots, s. \tag{13}$$

Now since $\mathcal{P}$ is a C-set, $0 \in \text{int}\{\mathcal{P}\}$, thus $g_i > 0$ for every i. Dividing each of the (13) by g_i we get $|F_i x| \leq 1$, $i = 1, \dots, s$, with $F_i = \frac{f_i}{g_i}$, which is equivalent to (11). To conclude, if F were not full column rank, then for every arbitrarily large $k > 0$ there would exist x, $\|x\| > k$, such that $Fx = 0$, say $x \in \mathcal{P}$ and $\|x\| > k$, in contrast with the boundedness of $\mathcal{P}$.

Now note that, if $\mathcal{P}$ is 0-symmetric, the vertices of $\mathcal{P}$ can be stacked columnwise into a matrix $X_{symm} = [x_1, \dots x_l, -x_1, \dots, -x_l] = [X, -X] \subset \mathbb{R}^{n \times 2*l}$. Then the corresponding convex hull is formed by all the vectors

$$x = \sum_{i=1}^{l} \beta_i x_i - \gamma_i x_i = \sum_{i=1}^{l} (\beta_i - \gamma_i) x_i \tag{14}$$

with $\beta_i,\ \gamma_i \geq 0$, and $\sum_{i=1}^{l} (\beta_i + \gamma_i) = 1$. The vector α whose components are $\alpha_i = \beta_i - \gamma_i$ is such that $\|\alpha\|_1 \leq 1$, which leads to (12). The argument can be reversed. If x is as in (12), then define $\beta_i = \max\{\alpha_i, 0\}$ and $\gamma_i = \min\{\alpha_i, 0\}$; we get expression (14), with $\sum_{i=1}^{l} (\beta_i + \gamma_i) \leq 1$. This means that x is in the convex hull of the columns of X_{symm}. □

We will say that a function $\Psi(x) :\ \mathbb{R}^n \to \mathbb{R}^+$ is *polyhedral* if it is the Minkowski functional of a polyhedral 0-symmetric C-set $\mathcal{P}$. Such a function can be represented either by means of the "plane" representation (11),

$$\Psi(x) = \|Fx\|_\infty, \tag{15}$$

or by means of the dual "vertex" representation

$$\Psi(x) = \inf\{\|p\|_1,\ \ \text{s.t.}\ \ x = Xp\}. \tag{16}$$

In this paper we consider polyhedral functions as candidate Lyapunov functions for asserting the stability of the closed-loop system, according to the next definitions.

DEFINITION 2.6. *The polyhedral function $\Psi(x)$ is a Lyapunov function for the dynamic system $x(k+1) = f(x(k), w(k))$, $w(k) \in \mathcal{W}$, if for every admissible function $w(\cdot)$ the following condition holds:*

$$\Psi(x(k+1)) \leq \lambda \Psi(x(k)),$$

for some nonnegative $\lambda < 1$ and every solution $x(k)$.

DEFINITION 2.7. *A dynamic system $x(k+1) = f(x(k), w(k))$, $w(k) \in \mathcal{W}$, is robustly stable if it is globally uniformly asymptotically stable for every admissible function $w(\cdot)$.*

The main point in considering polyhedral functions is that they are described by a finite number of parameters and have been shown to be nonconservative for proving the robust stability for the class of systems considered here, say a system in the considered class is robustly stable if and only if it admits a polyhedral Lyapunov function. (Note that the same property does not hold for quadratic Lyapunov functions.) More precisely we have the following lemmas.

LEMMA 2.8 (see [12]). *The system*

$$x(k+1) = A(w(k))x(k), \tag{17}$$

where $A(w)$ is as in (2), is robustly stable if and only if there exists an integer $l \geq n$ and a full row rank matrix $X \in \mathbb{R}^{n \times l}$ and m matrices $P^{(h)} \in \mathbb{R}^{l \times l}$ such that, for every $h = 1, \ldots, m$, $\|P^{(h)}\|_1 \leq \lambda < 1$ and

$$A^{(h)} X = X P^{(h)}.$$

LEMMA 2.9 (see [2], [3], [4], [5]). *The system (17), where $A(w)$ is as in (2), is robustly stable if and only if there exists an integer $s \geq n$ and a full column rank matrix $F \in \mathbb{R}^{s \times n}$ and m matrices $H^{(h)} \in \mathbb{R}^{s \times s}$ such that, for every $h = 1, \ldots, m$, $\|H^{(h)}\|_\infty \leq \lambda < 1$ and*

$$F A^{(h)} = H^{(h)} F.$$

The coefficient λ above turns out to be the same index of the speed of convergence of Definition 2.6. Lemma 2.9 rephrases the results in [2], [3], [4], [5], and the proof follows immediately by the fact that if the system is stable, then it admits a polyhedral Lyapunov function (see also [14], [23], [24]). Note that the matrices F and X in the above lemmas have the meaning of (15) and (16), namely, they characterize a polyhedral function. Note also that the two lemmas are dual in the sense that by transposing all the matrices Lemma 2.8 reduces to Lemma 2.9 for the dual system

$$x(k+1) = A^T(w(k))x(k)$$

and vice versa. This also means that (17) is robustly stable if and only if the dual system is robustly stable.

3. Solution of the gain scheduling state feedback stabilization problem. In this section we consider the problem of determining a state feedback control of the gain scheduling type for the system (1). To this aim we introduce the following important definition of exponential stabilizability.

DEFINITION 3.1. *We say that the system (1) is* exponentially *GSSF stabilizable if it is GSSF stabilizable and there exists two constants $0 \leq \lambda < 1$ and $C \geq 0$ such that*

$$\|x_{cl}(k)\| \leq C \lambda^k \|x_{cl}(0)\|,$$

where x_{cl} is the overall closed-loop system state. The constant λ is referred to as the speed of convergence.

We will see that any stabilizable system of the considered class can indeed be exponentially stabilized.

3.1. Problem solvability. To solve our problem we consider the class of polyhedral functions as candidate Lyapunov functions. The next theorem motivates this choice by showing that the existence of one such Lyapunov function is not only sufficient for the gain scheduling stabilizability of system (1), but it is also necessary as well.

THEOREM 3.2. *The following statements are equivalent:*

(i) *System* (1) *is GSSF stabilizable.*

(ii) *System* (1) *is exponentially GSSF stabilizable.*

(iii) *There exists a static control law $u(k) = \Phi(x(k), w(k))$ and a polyhedral function* (16) *which is a Lyapunov function for system* (1).

(iv) *There exist a full row rank matrix $X \in \mathbb{R}^{n\times l}$, m matrices $P^{(h)} \in \mathbb{R}^{l\times l}$ and $U^{(h)} \in \mathbb{R}^{q\times l}$, such that for every $h = 1, \dots, m$*

$$A^{(h)}X + BU^{(h)} = XP^{(h)}, \quad \textit{with} \ \ \|P^{(h)}\|_1 < 1. \tag{18}$$

Proof. We skip the obvious implications (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i) and relegate to the appendix the proof that (i) implies (iv).

(iv) $\Rightarrow$ (iii) Assume that (18) holds and let

$$\lambda = \max_{h=1,\dots,m} \|P^{(h)}\|_1 < 1. \tag{19}$$

Consider the function (16) associated with X:

$$\Psi(x) = \inf\{\|p\|_1, \ \ \text{s.t.} \ \ x = Xp\}.$$

Since the infimum is actually a minimum, for every x there exists $\hat{p}$ such that $x = X\hat{p}$ and $\|\hat{p}\|_1 = \Psi(x)$. Let

$$u(x, w) = \sum_{h=1}^{m} \ w_h \ \ U^{(h)}\hat{p}. \tag{20}$$

For all possible $w = [w_1, \dots, w_m]^T \in \mathcal{W}$ we have that

$$\begin{aligned} A(w)x + Bu &= \sum_{h=1}^{m} \ w_h \ A^{(h)}x + \sum_{h=1}^{m} \ w_h \ BU^{(h)}\hat{p} = \sum_{h=1}^{m} \ w_h \ [A^{(h)}X + BU^{(h)}]\hat{p} \\ &= \sum_{h=1}^{m} \ w_h \ XP^{(h)}\hat{p} = X\sum_{h=1}^{m} \ w_h \ P^{(h)}\hat{p} = X\hat{p}'(w). \end{aligned}$$

The vector $\hat{p}'(w) = \sum_{h=1}^{m} \ w_h P^{(h)}\hat{p}$ is a convex combination of the vectors $P^{(h)}\hat{p}$ whose norms are such that $\|P^{(h)}\hat{p}\|_1 \le \lambda\|\hat{p}\|_1$; thus $\|\hat{p}'(w)\|_1 \le \lambda\|\hat{p}\|_1$. This means that for all $w \in \mathcal{W}$

$$\Psi(A(w)x + Bu) = \inf\{\|p\|_1, \ \ \text{s.t.} \ \ [A(w)x + Bu] = Xp\} \le \lambda\|\hat{p}\|_1,$$

and then

$$\Psi(A(w)x + Bu) \le \lambda\Psi(x).$$

Therefore Ψ is a Lyapunov function for the closed-loop system. □

The previous theorem states that (18) is crucial, since the existence of a solution in terms of X, $P^{(h)}$, and $U^{(h)}$ is necessary and sufficient for the GSSF stabilization problem to be solvable. The next theorem states that as long as the parameter w is known to the controller, we can always implement a linear controller for the system, namely, GSSF stabilizability implies GSSF stabilizability by means of a linear controller. This result extends that in [10] to the discrete-time case. To introduce the theorem we augment (18) as follows:

$$\begin{bmatrix} A^{(h)} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} X \\ Z \end{bmatrix} + \begin{bmatrix} B & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} U^{(h)} \\ V^{(h)} \end{bmatrix} = \begin{bmatrix} X \\ Z \end{bmatrix} P^{(h)} \tag{21}$$

(we remind the reader that $\|P^{(h)}\|_1 < 1$), where Z is an arbitrary matrix such that $\left[\begin{smallmatrix} X \\ Z \end{smallmatrix}\right]$ is square invertible, and $V^{(h)} \doteq ZP^{(h)}$. We are now able to state the following theorem, which states that gain scheduling stabilizability is equivalent to gain scheduling stabilizability via linear control.

THEOREM 3.3. *If system* (1) *is GSSF stabilizable, then it is GSSF stabilizable* via linear control. *A stabilizing control is given by*

$$\begin{aligned} u(k) &= K(w)x(k) + H(w)z(k), \\ z(k+1) &= G(w)x(k) + F(w)z(k), \end{aligned} \tag{22}$$

where

$$\begin{bmatrix} K(w) & H(w) \\ G(w) & F(w) \end{bmatrix} = \sum_{h=1}^{m} \begin{bmatrix} K^{(h)} & H^{(h)} \\ G^{(h)} & F^{(h)} \end{bmatrix} w_h \tag{23}$$

with

$$\begin{bmatrix} K^{(h)} & H^{(h)} \\ G^{(h)} & F^{(h)} \end{bmatrix} = \begin{bmatrix} U^{(h)} \\ V^{(h)} \end{bmatrix} \begin{bmatrix} X \\ Z \end{bmatrix}^{-1}. \tag{24}$$

Proof. Given system (1) with the control (22)–(24), the closed-loop system is

$$\begin{bmatrix} x(k+1) \\ z(k+1) \end{bmatrix} = A_{aug}(w) \begin{bmatrix} x(k) \\ z(k) \end{bmatrix}, \tag{25}$$

where

$$\begin{aligned} A_{aug}(w) &= \begin{bmatrix} A(w) + BK(w) & BH(w) \\ G(w) & F(w) \end{bmatrix} \\ &= \begin{bmatrix} \sum_{h=1}^m A^{(h)} w_h + B \sum_{h=1}^m K^{(h)} w_h & B \sum_{h=1}^m H^{(h)} w_h \\ \sum_{h=1}^m G^{(h)} w_h & \sum_{h=1}^m F^{(h)} w_h \end{bmatrix} \qquad (26) \\ &= \sum_{h=1}^{m} w_h \begin{bmatrix} A^{(h)} + BK^{(h)} & BH^{(h)} \\ G^{(h)} & F^{(h)} \end{bmatrix}, \text{ with } \sum_{h=1}^{m} w_h = 1, \quad w_h \geq 0. \qquad (27) \end{aligned}$$

By construction we have that

$$\begin{bmatrix} A^{(h)} + BK^{(h)} & BH^{(h)} \\ G^{(h)} & F^{(h)} \end{bmatrix} \begin{bmatrix} X \\ Z \end{bmatrix} = \begin{bmatrix} X \\ Z \end{bmatrix} P^{(h)}; \tag{28}$$

therefore, according to Lemma 2.8, the system in (25) is robustly stable and the proof is completed. □

3.2. Computation of the Lyapunov function. The results above are nonconstructive as long as we cannot provide algorithms to compute the matrices X, $P^{(h)}$, and $U^{(h)}$ in (18). As observed in [9], such types of equations are not convenient to solve the problem, since they are bilinear as long as X and $P^{(h)}$ are both unknown. Note also that the same problem holds in the robust stabilization case, where we have to cope with the same equation with the difference that [9], [12] the matrices $U^{(h)}$ are all equal according to the following proposition.

PROPOSITION 3.4 (see [7], [12], [13], [15]). *The system*

$$x(k+1) = A(w(k))x(k) + B(w(k))u(k), \tag{29}$$

where $A(w(k))$ *is as in* (2) *and*

$$B(w(k)) = \sum_{h=1}^{m} B^{(h)} w_h(k) \tag{30}$$

and $B^{(h)} \in \mathbb{R}^{n\times q}$, $h = 1, 2, \ldots, m$, *are assigned constant matrices, is robustly state feedback stabilizable if and only if there exists a full row rank matrix* $X \in \mathbb{R}^{n\times l}$, m *matrices* $P^{(h)}$, *and a* single *matrix* $U \in \mathbb{R}^{q\times l}$ *such that, for every* $h = 1, \ldots, m$,

$$A^{(h)}X + B^{(h)}U = XP^{(h)}, \quad \textit{with} \ \ \|P^{(h)}\|_1 < 1. \tag{31}$$

In [7], [12] an iterative procedure is proposed to compute X, $P^{(h)}$, and U. Clearly this procedure might be applied in a conservative way to our problem since if a system is robustly stabilizable, then it is also GSSF stabilizable. However, for discrete-time systems this is a conservative way of proceeding since, as we have seen, the knowledge of w can be an advantage for the compensator. The next result will allow us to exploit the existing procedures for the solution of the robust stabilization problem for GSSF stabilizability.

In view of Assumption 2.1, we consider the system in the following form:

$$\hat{A}(w) = \begin{bmatrix} \hat{A}_{11}(w) & \hat{A}_{12}(w) \\ \hat{A}_{21}(w) & \hat{A}_{22}(w) \end{bmatrix} = \sum_{h=1}^{m} w_i \begin{bmatrix} \hat{A}_{11}^{(h)} & \hat{A}_{12}^{(h)} \\ \hat{A}_{21}^{(h)} & \hat{A}_{22}^{(h)} \end{bmatrix} \tag{32}$$

and

$$\hat{B} = \begin{bmatrix} 0 \\ I \end{bmatrix}. \tag{33}$$

It is immediately seen that this form is achieved by applying to all the generating matrices $A^{(h)}$ the linear transformation

$$T = \begin{bmatrix} \tilde{B} & B \end{bmatrix}, \tag{34}$$

where $\tilde{B}$ is any matrix such that T is invertible, so that $\hat{A}^{(h)} = T^{-1}A^{(h)}T$ and $\hat{B} = T^{-1}B$.

The system is thus in the form

$$\hat{x}_1(k+1) = \hat{A}_{11}(w)\hat{x}_1(k) + \hat{A}_{12}(w)\hat{x}_2(k), \tag{35}$$

$$\hat{x}_2(k+1) = \hat{A}_{21}(w)\hat{x}_1(k) + \hat{A}_{22}(w)\hat{x}_2(k) + u(k). \tag{36}$$

By means of this form, we can recast the GSSF stabilization problem in a robust stabilization problem for the pair $(\hat{A}_{11}(w(k)), \hat{A}_{12}(w(k)))$ according to the following theorem.

THEOREM 3.5. *System* (1) *is GSSF stabilizable if and only if the system*

$$\hat{x}_1(k+1) = \hat{A}_{11}(w)\hat{x}_1(k) + \hat{A}_{12}(w)\hat{x}_2(k) \tag{37}$$

(where $\hat{x}_2$ now has to be thought of as an input signal) is robustly stabilizable.

Proof. If. Assume that (37) is robustly stabilizable. Then by Proposition 3.4 there exist a full row rank matrix $\hat{X}_1$, a matrix $\hat{X}_2$, and m matrices $\|P_1^{(h)}\|_1 < 1$ such that, for every $h = 1, \ldots, m$,

$$\hat{A}_{11}^{(h)}\hat{X}_1 + \hat{A}_{12}^{(h)}\hat{X}_2 = \hat{X}_1 P_1^{(h)}. \tag{38}$$

Now define the elements $U^{(h)}$ as the matrices that match the equalities

$$\hat{A}_{21}^{(h)}\hat{X}_1 + \hat{A}_{22}^{(h)}\hat{X}_2 + U^{(h)} = \hat{X}_2 P_1^{(h)}.$$

Combining the two equations we get

$$\begin{bmatrix} \hat{A}_{11}^{(h)} & \hat{A}_{12}^{(h)} \\ \hat{A}_{21}^{(h)} & \hat{A}_{22}^{(h)} \end{bmatrix} \begin{bmatrix} \hat{X}_1 \\ \hat{X}_2 \end{bmatrix} + \begin{bmatrix} 0 \\ I \end{bmatrix} U^{(h)} = \begin{bmatrix} \hat{X}_1 \\ \hat{X}_2 \end{bmatrix} P_1^{(h)}. \tag{39}$$

Assume now, for the moment being, that the matrix

$$\hat{X} \doteq \begin{bmatrix} \hat{X}_1 \\ \hat{X}_2 \end{bmatrix} \tag{40}$$

has full row rank. Then, by Theorem 3.2, (39) implies that the system (1) is GSSF stabilizable. If the matrix $\hat{X}$ in (40) has not full row rank, then we can augment the equation as follows:

$$\begin{aligned} \begin{bmatrix} \hat{A}_{11}^{(h)} & \hat{A}_{12}^{(h)} \\ \hat{A}_{21}^{(h)} & \hat{A}_{22}^{(h)} \end{bmatrix} \begin{bmatrix} \hat{X}_1 & 0 \\ \hat{X}_2 & \epsilon I \end{bmatrix} + \begin{bmatrix} 0 \\ I \end{bmatrix} \begin{bmatrix} U^{(h)} & \epsilon\tilde{U}^{(h)} \end{bmatrix} \\ = \begin{bmatrix} \hat{X}_1 & 0 \\ \hat{X}_2 & \epsilon I \end{bmatrix} \begin{bmatrix} P^{(h)} & \epsilon R^{(h)} \\ 0 & 0 \end{bmatrix}, \end{aligned} \tag{41}$$

where $R^{(h)}$, $h = 1, \ldots, m$, are matrices such that[1] $\hat{X}_1 R^{(h)} = \hat{A}_{12}^{(h)}$, $\tilde{U}^{(h)} \doteq \hat{X}_2 R^{(h)} - \hat{A}_{22}^{(h)}$, and $\epsilon > 0$. The matrix

$$\hat{X}_{aug} = \begin{bmatrix} \hat{X}_1 & 0 \\ \hat{X}_2 & \epsilon I \end{bmatrix}$$

now has full row rank and the matrices

$$P_{aug}^{(h)} = \begin{bmatrix} P^{(h)} & \epsilon R^{(h)} \\ 0 & 0 \end{bmatrix}$$

have 1-norm $\|P_{aug}^{(h)}\|_1 = \|P^{(h)}\|_1$, provided that ϵ is sufficiently small. Then (41) implies that (1) is GSSF stabilizable.

[1] We remind the reader that $\hat{X}_1$ has full row rank.

Only if. If (1) is GSSF stabilizable, then, by implication of (i)→ (iv) of Theorem 3.2, there exists a full row rank matrix X, m matrices $P^{(h)}$ and $U^{(h)}$ satisfying (18). By choosing the transformation matrix T as in (34), we get (39) with the matrix in (40) of full row rank. By selecting the first block, we get (38), with $\hat{X}_1$ of full row rank. In view of Proposition 3.4, this in turn implies that (37) is RS. □

Thus the algorithm to solve the gain scheduling stabilization problem turns out to be the following procedure.

PROCEDURE 3.1.

1. *Given the matrices $A^{(h)}$ and B, take $\tilde{B}$ such that $T = [\tilde{B}\ B]$ is invertible and compute the form* (35)–(36) *by means of the state transformation $T = [\tilde{B}\ B]$.*
2. *Compute the matrices $\hat{X}_1$ and $\hat{X}_2$ in* (38) *by computing a polyhedral Lyapunov function for the robust stabilization of the subsystem* (37) *and let $\hat{X}$ be defined as in* (40). *(In the event that $\hat{X}$ is not full row rank, apply the augmentation as in* (41).*)*
3. *Apply the reverse transformation to* (39) *and let $X \doteq T\hat{X}$ to achieve*
$$A^{(h)}X + BU^{(h)} = XP^{(h)}.$$
4. *Compute the linear dynamic control as in* (22)–(23).

4. Solution of the gain scheduling state estimation problem. In the previous section we have considered the problem of designing a state feedback gain scheduling compensator. Among the results, we have seen that if a system is gain scheduling stabilizable, then it is gain scheduling stabilizable via linear state feedback control. Now we cope with the dual problem of designing a linear state observer for the system

$$\begin{aligned} x(k+1) &= A(w(k))x(k) + v(k), \\ y(k) &= Cx(k). \end{aligned} \tag{42}$$

The candidate linear observer we consider is of the form

$$\begin{aligned} z(k+1) &= P(w(k))z(k) - L(w(k))y(k) + T_1(w(k))v(k), \\ \hat{x}(k) &= Q(w(k))z(k) + R(w(k))y(k), \end{aligned} \tag{43}$$

with $z(k) \in \mathbb{R}^s$.

DEFINITION 4.1. *The system* (43) *is a linear gain scheduled asymptotic observer for system* (42) *if it has the following properties:*

(i) Convergence. *For all $w(k)$, $v(k)$, and $x(0)$ and $z(0)$ we have $\hat{x}(k) - x(k) \to 0$ as $k \to \infty$.*

(ii) Initialization. *If $x(0) = 0$, $z(0) = 0$, then $\hat{x}(k) = x(k)$ for all $w(k) \in \mathcal{W}$ and $v(k)$.*

(iii) Internal stability. *If $x(k) \to 0$ as $k \to \infty$, then $z(k) \to 0$.*

It is known that, for a given *constant* $\bar{w}$, the system (43) represents the most general form of a linear observer [25]. Furthermore, for a given constant $\bar{w}$, for (43) to be an observer the following necessary and sufficient conditions must hold:

$$P(\bar{w})T_1(\bar{w}) - T_1(\bar{w})A(\bar{w}) = L(\bar{w})C, \tag{44}$$

$$Q(\bar{w})T_1(\bar{w}) + R(\bar{w})C = I, \tag{45}$$

and $P(\bar{w})$ is a stable matrix (i.e., its eigenvalues are inside the open unit disk).

The main problem now is to see what happens when $w(k)$ is time-varying as in our case. The next lemma leads to a simplification of the structure of (43), namely, that there is no restriction in considering observers of the form

$$\begin{aligned} z(k+1) &= P(w(k))z(k) - L(w(k))y(k) + T_1 v(k), \\ \hat{x}(k) &= Q(w(k))z(k) + R(w(k))y(k), \end{aligned} \tag{46}$$

with T_1 *constant and of full column rank.*

LEMMA 4.2. *Assume that there exists an observer of the form* (43). *Then there exists an observer with the same structure where the matrix* $T_1(w) = T_1$ *is constant and of full column rank.*

Proof. See the appendix. ∎

Define now the error variable $r(k)$ as

$$r(k) = z(k) - T_1 x(k), \tag{47}$$

whose associated error equation, derived from (44)–(46), is

$$\begin{array}{rcl} r(k+1) & = & P(w(k))r(k), \\ e(k) \doteq \hat{x}(k) - x(k) & = & Q(w(k))r(k). \end{array} \tag{48}$$

The previous equation leads us immediately to the following basic result.

LEMMA 4.3. *The system* (46), *with* T_1 *of full column rank, is an observer for* (42) *only if the time-varying system*

$$r(k+1) = P(w(k))r(k)$$

is robustly stable and T_1 *is such that, for all* $w \in \mathcal{W}$,

$$\begin{array}{rcl} P(w)T_1 - T_1 A(w) & = & L(w)C, \\ Q(w)T_1 + R(w)C & = & I. \end{array} \tag{49}$$

The proof of the above Lemma is immediate and thus it is omitted. We are in the position now to prove the main result of this section.

THEOREM 4.4. *The following statements are equivalent.*

(i) *There exists a linear gain scheduled observer for* (42) *of the form* (46) *with* T_1 *full column rank.*

(ii) *There exist a full column rank matrix* F, m *matrices* $H^{(h)}$, *and* m *matrices* $Y^{(h)}$ *such that, for every* $h = 1, \ldots, m$, *the dual equation of* (18) *holds:*

$$FA^{(h)} + Y^{(h)}C = H^{(h)}F, \quad \textit{with} \quad \|H^{(h)}\|_\infty < 1, \tag{50}$$

(iii) *The dual system*

$$x(k+1) = A^T(w(k))x(k) + C^T u(k)$$

is gain scheduling stabilizable.

Proof. (ii) $\Longleftrightarrow$ (iii) The equivalence comes from the duality between (50) and (18). Indeed, if (18) is satisfied, we achieve (50) by transposition by setting $F = X^T$, $Y^{(h)} = {U^{(h)}}^T$, $H^{(h)} = {P^{(h)}}^T$. Note that $\|H^{(h)}\|_\infty = \|P^{(h)}\|_1$, being the ∞-norm equal to the 1-norm of the transpose.

(ii) $\Rightarrow$ (i) Consider the dynamic observer (46) with

$$P(w(k)) = \sum_{h=1}^{m} w_h(k) H^{(h)}, \tag{51}$$

$$L(w(k)) = \sum_{h=1}^{m} w_h(k) Y^{(h)}, \tag{52}$$

$$T_1 = F, \tag{53}$$

$$Q(w(k)) = F^\dagger, \tag{54}$$

$$R(w(k)) = 0, \tag{55}$$

where $F^\dagger$ is any left inverse of F (which exists since F is full column rank). With the usual change of variable $r(k) = z(k) - Fx(k)$ the overall system dynamics (system + observer) becomes

$$r(k+1) = \sum_{h=1}^{m} w_h(k) H^{(h)} r(k), \tag{56}$$

$$e(k) = \hat{x}(k) - x(k) = F^\dagger r(k), \tag{57}$$

which is stable since $\| \sum_{h=1}^{m} w_h H^{(h)} \|_\infty < 1$ and satisfies the requirements in Definition 4.1.

(i) $\Rightarrow$ (ii) The first equation in (48) represents a stable system. A stable system always admits a polyhedral Lyapunov function. In particular, by Lemma 2.9 there exist m matrices $H^{(h)}$ such that $\|H^{(h)}\|_\infty \le \lambda < 1$ and a full column rank matrix $\hat{T}$ such that

$$\hat{T} P^{(h)} = H^{(h)} \hat{T}, \tag{58}$$

with $P^{(h)} = P(w^{(h)})$, where $w^{(h)}$ are the vertices of the polytope $\mathcal{W}$, namely,

$$w^{(h)} = [0 \ \dots 0 \ 1 \ 0 \dots 0]^T.$$

Define in a similar way $L^{(h)} = L(w^{(h)})$ to get

$$P^{(h)} T_1 - T_1 A^{(h)} = L^{(h)} C.$$

Then by multiplying by $\hat{T}$ on the left we get, in view of (58),

$$H^{(h)} \underbrace{\hat{T} T_1}_{F} = \underbrace{\hat{T} T_1}_{F} A^{(h)} + \underbrace{\hat{T} L^{(h)}}_{Y^{(h)}} C. \tag{59}$$

Note that $F = \hat{T} T_1$ is of full column rank since both $\hat{T}$ and T_1 are such; thus the last equation is exactly (50). □

The previous result is constructive, since, by duality, we can always apply the procedure to design a GSSF stabilizer to the dual system $(A^T(w), C^T)$ to design the observer.

It is important to remark that the proposed class of observers does not parameterize the whole class of observers as in Definition 2.2. For instance, it can be shown that the system

$$\begin{bmatrix} x_1(k+1) \\ x_2(k+1) \end{bmatrix} = \begin{bmatrix} w(k) & 0 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix},$$

$$y(k) = \begin{bmatrix} 0 & 1 \end{bmatrix} \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix}$$

with $|w(k)| \le 2$ is *not* gain scheduling observable by means of an observer of the form (43) though the following *nonlinear* system,

$$\begin{aligned} z(k+1) &= w(k), \\ \hat{x}_1(k) &= z(k) y(k), \\ \hat{x}_2(k) &= y(k), \end{aligned}$$

is an observer. The trouble is that, in general, computing this kind of nonlinear observer can be very hard. It could be done by means of the observability matrix $\mathcal{O}(k)$ associated with the last n steps (obtaining expressions which are very involved) or by means of standard Kalman filtering [1], [25]. Unfortunately, for our problem, these solutions have the following problem: one has to impose some *detectability conditions* [1] *for all possible sequences* $w(k) \in \mathcal{W}$. To the best of the authors' knowledge, this problem has not been solved and seems to be very difficult.

To recap, we report the following table which shows the relations between the GSSF stabilization (via linear control), = GSSF(L), and the gain scheduling estimation (via linear observer), = GSE(L):

$$\begin{array}{ccc} \text{GSSF} & \Longleftrightarrow & \text{GSSFL} \\ & & \Uparrow \\ & & \text{dual conditions.} \\ & & \Downarrow \\ \text{GSE} & \Longleftarrow & \text{GSEL} \end{array}$$

5. A separation principle for design. We briefly describe a way to stabilize system (1) by means of a linear observer and a gain scheduling estimated state feedback. The next theorem is a simple consequence of the results of the previous sections. It shows that one can always synthesize a stabilizing compensator by separately designing an observer and a state feedback control if the system is GSSF stabilizable and GSD via linear observer.

THEOREM 5.1. *Assume that* $(A(w), B)$ *is GSSF stabilizable and* $(C, A(w))$ *is GSD via linear observer. Then the dynamic controller (we dropped the time-dependence in* $w(k)$ *for clarity)*

$$\begin{array}{rcl} z_c(k+1) &=& G(w)\hat{x}(k) + F(w)z_c(k), \\ z_o(k+1) &=& P(w)z_o(k) - L(w)y(k) + T_1 B u(k), \\ \hat{x}(k) &=& Q(w)z_o(k) + R(w)y(k), \\ u(k) &=& K(w)\hat{x}(k) + H(w)z_c(k), \end{array} \tag{60}$$

where the matrices in the above equations are as in (22)–(24) *in Theorem* 3.3 *and* (51)–(55) *in Theorem* 4.4*, asymptotically stabilizes the plant.*

Proof. By combining (60) with the system dynamics, setting $r(k) = z_o(k) - T_1 x(k)$, and recalling (48), after some algebra the closed-loop system can be written as

$$\begin{bmatrix} x(k+1) \\ z_c(k+1) \\ r(k+1) \end{bmatrix} = \begin{bmatrix} A(w) + BK(w) & BH(w) & BK(w)Q(w) \\ G(w) & F(w) & G(w)Q(w) \\ 0 & 0 & P(w) \end{bmatrix} \begin{bmatrix} x(k) \\ z_c(k) \\ r(k) \end{bmatrix}.$$

The block triangular structure implies closed-loop stability if the blocks on the diagonal are stable. The latter stability condition can be always guaranteed according to the results of sections 3 and 4. Indeed, the first block $(= A_{aug}(w))$ satisfies (28), while the second $(= P(w))$ given by (51) can be taken stable because of the assumed linear detectability. □

6. Example. As an example we consider the discrete-time system described by the vertex matrices

$$A^{(1)} = \begin{bmatrix} 1 & .25 & 0 \\ .25 & 1 & -.2 \\ 0 & 0 & -.16 \end{bmatrix}, \qquad A^{(2)} = \begin{bmatrix} 1 & .25 & 0 \\ .25 & 1 & -.05 \\ 0 & 0 & .16 \end{bmatrix},$$

$$A^{(3)} = \begin{bmatrix} 1 & .32 & 0 \\ .32 & 1 & -.05 \\ 0 & 0 & -.16 \end{bmatrix}, \qquad A^{(4)} = \begin{bmatrix} 1 & .32 & 0 \\ .32 & 1 & -.2 \\ 0 & 0 & .16 \end{bmatrix}$$

and

$$B = \begin{bmatrix} 0 \\ 0 \\ .3 \end{bmatrix}, \qquad C = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix}.$$

As far as the gain scheduling stabilization problem is concerned, we applied Procedure 3.1 with $\lambda_c = .96$, which led to the matrices

$$X = \begin{bmatrix} 1 & 1 & .0017 \\ -1 & -.3666 & 1 \\ 0 & 4.17 & 9.75 \end{bmatrix},$$

$$P^{(1)} = \begin{bmatrix} .75 & .908 & .253 \\ 0 & 0 & 0 \\ 0 & -.042 & -.698 \end{bmatrix}, \qquad P^{(2)} = \begin{bmatrix} .75 & 0 & 0 \\ 0 & .908 & .251 \\ 0 & .008 & .605 \end{bmatrix},$$

$$P^{(3)} = \begin{bmatrix} .68 & 0 & 0 \\ 0 & .883 & .321 \\ 0 & .068 & .63 \end{bmatrix}, \qquad P^{(4)} = \begin{bmatrix} .68 & .880 & .323 \\ 0 & .003 & 0 \\ 0 & 0 & -.628 \end{bmatrix},$$

and

$$U^{(1)} = \begin{bmatrix} 0 & .8587 & -17.4958 \end{bmatrix}, \qquad U^{(2)} = \begin{bmatrix} 0 & 10.6599 & 17.9611 \end{bmatrix},$$
$$U^{(3)} = \begin{bmatrix} 0 & 16.7125 & 30.1538 \end{bmatrix}, \qquad U^{(4)} = \begin{bmatrix} 0 & -2.1828 & -25.6258 \end{bmatrix}.$$

Since X is square, the compensator (22)–(23) reduces to a static compensator with $K^{(h)} = U^{(h)} X^{-1}$:

$$\begin{bmatrix} K^{(1)} \\ K^{(2)} \\ K^{(3)} \\ K^{(4)} \end{bmatrix} = \begin{bmatrix} 40.6617 & 40.6617 & -5.9683 \\ 14.5357 & 14.5357 & 0.3486 \\ 18.6315 & 18.6315 & 1.1778 \\ 42.7795 & 42.7795 & -7.0191 \end{bmatrix}.$$

As far as the state estimation is concerned, we determined the matrices of the estimator by determining a gain scheduling controller for the dual system with convergence speed $\lambda_o = .3$. The matrices derived for the observer were

$$F = \begin{bmatrix} 0 & 0 & 1.0000 \\ -3.2400 & .9334 & -.0666 \\ -3.2800 & .9248 & .0752 \end{bmatrix},$$

$$H^{(1)} = \begin{bmatrix} -.1600 & 0 & 0 \\ -.1672 & .1322 & 0 \\ -.1895 & .1123 & 0 \end{bmatrix}, \qquad H^{(2)} = \begin{bmatrix} .1600 & 0 & 0 \\ -.0485 & .1322 & 0 \\ -.0267 & .1123 & 0 \end{bmatrix},$$

$$H^{(3)} = \begin{bmatrix} -.1600 & 0 & 0 \\ -.0276 & 0 & -.1118 \\ -.0481 & 0 & -.1349 \end{bmatrix}, \qquad H^{(4)} = \begin{bmatrix} .1600 & 0 & 0 \\ -.1889 & 0 & -.1118 \\ -.1628 & 0 & -.1349 \end{bmatrix},$$

and

$$\begin{bmatrix} Y^{(1)} & Y^{(2)} & Y^{(3)} & Y^{(4)} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 2.5783 & 2.5783 & 3.3080 & 3.3080 \\ 2.6850 & 2.6850 & 3.4267 & 3.4267 \end{bmatrix}.$$

The resulting gain scheduling output feedback controller is hence given by

$$\begin{aligned} z_o(k+1) &= \left(\sum_{i=1}^{4} H^{(i)} w_i(k)\right) z_o(k) - \left(\sum_{i=1}^{4} Y^{(i)} w_i(k)\right) y(k) + FBu(k), \\ \hat{x}(k) &= F^{\dagger} z_o(k), \\ u(k) &= \left(\sum_{i=1}^{4} K^{(i)} w_i(k)\right) \hat{x}(k). \end{aligned}$$

The overall behavior was simulated with a random $w(\cdot)$ starting from the initial condition $x(1) = \begin{bmatrix} 1 & -2 & 1 \end{bmatrix}^T$. Figures 1 and 2 depict the state and error time evolution during the first 12 time-steps.

We let the reader note that, though at first surprising, the peak of x_3 is essentially due to the fact that x_3 is the "virtual" input for the uncertain subsystem associated with the first two components and the magnitude of the elements $(3, 2)$ in $A(w)$ can be very small.

7. Concluding discussions. In this paper we focused our attention on the stabilization of linear parameter varying (LPV) discrete-time systems. We showed by very simple examples that the robust stabilization and the gain scheduling stabilization problems, different from the continuous-time case, are rather different problems. We also showed the existence of a duality relation between the gain scheduling control and the gain scheduling linear observation problem for LPV. Finally, a separation principle to derive linear output feedback stabilizing controllers was derived.

Among the limits of the paper we remind the reader that the matrices C and B are assumed constant. If we assume that $B = \sum_{i=1}^{m} w_h \, B^{(h)}$, we have trouble with (18) since its natural extension $A^{(h)}X + B^{(h)}U^{(h)} = XP^{(h)}$, with $\|P^{(h)}\|_1 < 1$, does not even ensure stabilizability of the system. Therefore future research directions in this area are the investigation of discrete-time gain scheduling observers when the matrices B and C are also time-dependent, discrete-time robust observers, and the properties of continuous-time gain scheduling observers. In particular, as far as it concerns the continuous time case, the construction procedures proposed in this paper can be immediately used to produce continuous-time compensators by means of the Euler approximating system (see [8])

$$x(k+1) = [I + \tau A(w)]x(t) + \tau Bu$$

obtained from the continuous-time model $\dot{x} = A(w)x + Bu$. Thus the design procedure proposed in [10] for GSSF design can be complemented by the state observer design procedure proposed here.

However, some theoretical questions remain open. For instance, in [10] it is shown that, in the continuous-time case, there is no advantage for the compensator in the

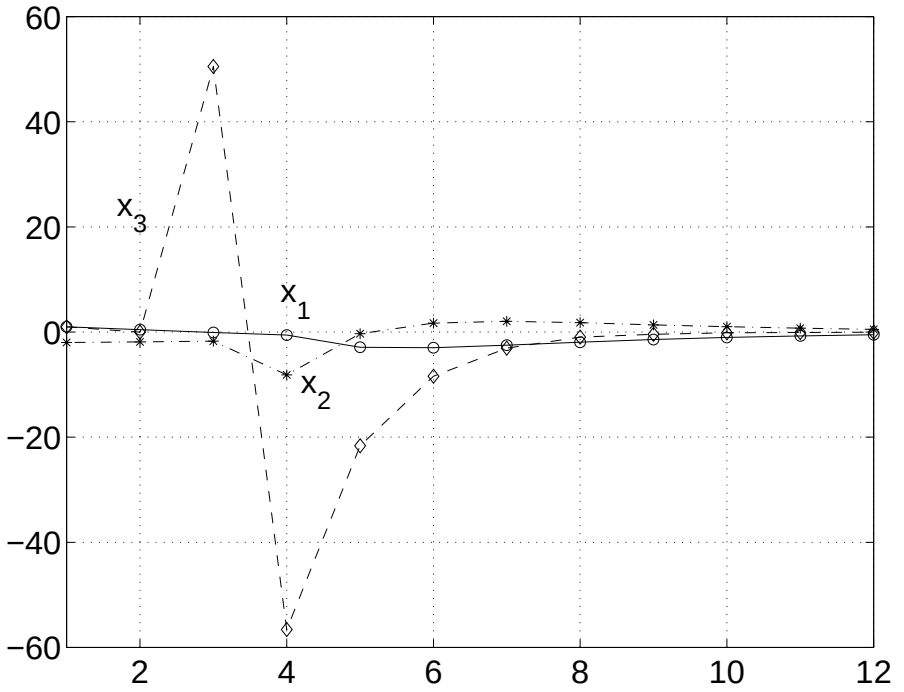

FIG. 1. *System state evolution.*

knowledge of $w(t)$ if $x(t)$ is available to the controller. It is not clear if or under which conditions this property holds in the output feedback case. Also we have shown, by means of a simple counterexample, that in the discrete-time case there can exist gain scheduling nonlinear observers for systems which do not admit linear gain scheduling observers. It is not obvious how to generate these examples in the continuous-time case (if it is possible at all). We think that these questions may be interesting subjects of investigation.

Appendix A. Proof of (i) $\Rightarrow$ (iv) in Theorem 3.2. Before starting with the proof, we present its main idea. If there exists a continuous stabilizing control, it is obviously stabilizing if we consider only the extremal sequences $w(k)$ with values in the vertices of $\mathcal{W}$, namely, if we assume $w(k) \in vert\{\mathcal{W}\}$ for every $k \geq 0$. If we take as initial conditions the vertices of a polytope including the origin as an interior point, and we consider the convex hull of all possible trajectories of the state (associated with extremal sequences) emanated by these vertices, we achieve a new polytope in the augmented state space. The key point is that this polytope as well as its projection on the plant state space are controlled-invariant, namely, they can be rendered positively invariant by a suitable controller (which is not necessarily the one whose existence is assumed). From such a region we can obtain a symmetric one by considering the convex hull of the union of it and its opposite. By introducing a perturbation parameter, we prove the existence of a solution for the considered equation.

Proof. Assume that there exists a continuous gain scheduling state feedback compensator of the form (4) and let $\mathcal{P}_0$ be an arbitrary polytope in the $x - z$ space

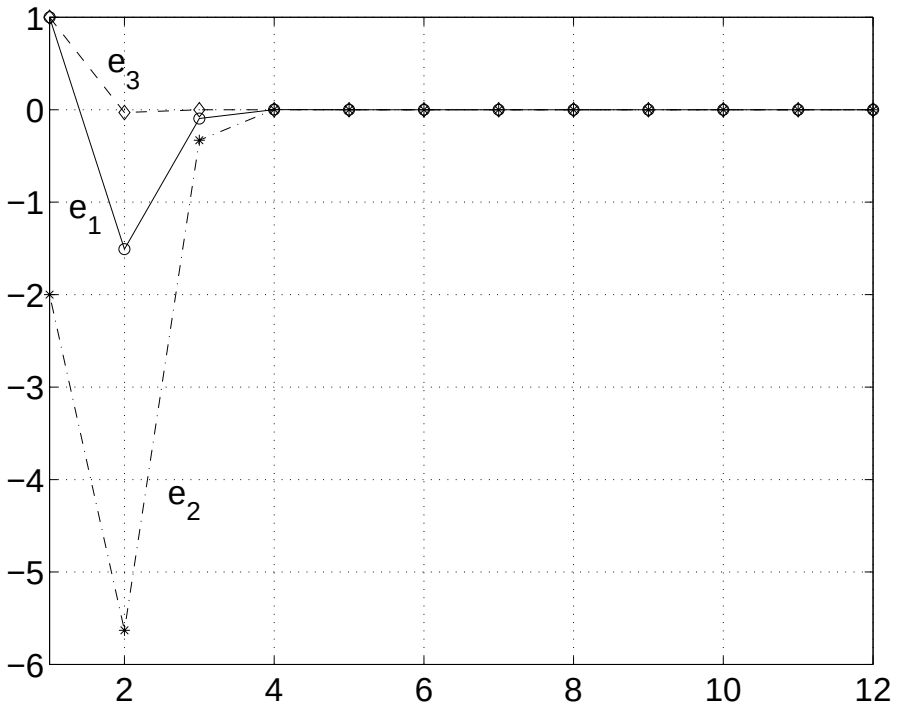

FIG. 2. *System error evolution.*

including the origin in its interior. The closed-loop system is

$$\begin{array}{rcl} x(k+1) & = & \lambda^{-1}[A(w(k))x(k) + Bu(k)], \\ z(k+1) & = & \lambda^{-1}[F(z(k), x(k), w(k))], \\ u(k) & = & G(z(k), x(k), w(k)), \end{array} \tag{61}$$

where λ, currently set to $\lambda = 1$, is a fictitious parameter whose significance will be soon explained. Let

$$Reach(\mathcal{P}_0, \lambda, k)$$

be the *discrete* set formed by all the possible states of the system (61) which can be reached in k steps, for all possible initial conditions taken on the vertices of $\mathcal{P}_0$, namely, $[x(0)^T \;\; z(0)^T]^T \in vert\{\mathcal{P}_0\}$, and when we have restricted

$$w(k) \in vert\{\mathcal{W}\}.$$

In view of the assumed stability there exists $\bar{k}$ such that

$$Reach(\mathcal{P}_0, 1, \bar{k}) \subset \text{int}\{\mathcal{P}_0\}.$$

Now, by continuity, there exists $0 \leq \lambda < 1$ such that

$$Reach(\mathcal{P}_0, \lambda, \bar{k}) \subset \text{int}\{\mathcal{P}_0\}.$$

Denote by $\mathcal{P}$ the polytope which is the convex hull of all the extremal trajectories

$$\mathcal{P} \doteq conv\left\{\bigcup_{k=0}^{\bar{k}} Reach(\mathcal{P}_0, \lambda, k)\right\}.$$

By construction for every vertex $\left[\begin{array}{cc} x^T & z^T \end{array}\right]^T$ of $\mathcal{P}$ and every vertex w of $\mathcal{W}$, there exists $u = G(z, x, w)$ such that

$$\left[\begin{array}{c} \lambda^{-1}[A(w)x + Bu] \\ \lambda^{-1}F(z, x, w) \end{array}\right] \in \mathcal{P} \Longrightarrow \left[\begin{array}{c} x' \\ z' \end{array}\right] = \left[\begin{array}{c} A(w)x + Bu \\ F(z, x, w) \end{array}\right] \in \lambda\mathcal{P}. \tag{62}$$

If we denote by $\mathcal{X}$ the projection of $\mathcal{P}$ on the plant state space (thus $\lambda\mathcal{X}$ is projection of $\lambda\mathcal{P}$), then, since the vertices of $\mathcal{X}$ are the projections of some of the vertices of $\mathcal{P}$, for each vertex x of $\mathcal{X}$ and $w \in vert\{\mathcal{W}\}$ there exist u such that

$$A(w)x + Bu \in \lambda\mathcal{X}, \tag{63}$$

being one such u of the control $u = G(z, x, w)$ associated with the vertex $[x^T\ z^T]^T$, whose projection is x. If we consider the opposite set, $-\mathcal{X}$, we obtain the opposite relation

$$A(w)(-x) + B(-u) \in \lambda(-\mathcal{X}).$$

Therefore, if we consider the 0-*symmetric* polytope $\tilde{\mathcal{X}} \doteq conv\{-\mathcal{X} \bigcup \mathcal{X}\}$ (whose vertices $vert\{\tilde{X}\} = \{x_1, \ldots, x_l, -x_1, \ldots, -x_l\}$ form a subset of $vert\{\mathcal{X}\} \bigcup vert\{-\mathcal{X}\}$ and can be stacked columnwise into the matrix $[X, -X] = [x_1, \ldots, x_l, -x_1, \ldots, -x_l]$), we have that, for each $w^{(h)} \in vert\{\mathcal{W}\}$,

$$A^{(h)}x_j + Bu_j^{(h)} \in \lambda\tilde{\mathcal{X}}, \qquad j = 1, \ldots, l.$$

Denoting by $\Psi(\cdot)$ the Minkowski functional of $\tilde{\mathcal{X}}$, this in turn means that $\Psi(A^{(h)}x_j + Bu_j^{(h)}) \leq \lambda$. In view of (16), this can be written as

$$A^{(h)}x_j + Bu_j^{(h)} = Xp_j^{(h)},$$

where $\|p_j^{(h)}\|_1 \leq \lambda$. Grouping together these equations, with $U^{(h)} = [u_1^{(h)} \ldots u_l^{(h)}]$ and $P^{(h)} = [p_1^{(h)} \ldots p_l^{(h)}]$, we get

$$A^{(h)}X + BU^{(h)} = XP^{(h)},$$

which concludes the proof. □

Appendix B. Proof of Lemma 4.2. To prove the lemma we recall the notion of invariant subspace for a family of matrices.

DEFINITION B.1. *Given a family of matrices $P(w)$, $w \in \mathcal{W}$, we say that a subspace $\mathcal{S}$ of $\mathbb{R}^n$ is $P(w)$-invariant if $x \in \mathcal{S}$ implies $P(w)x \in \mathcal{S}$ for all $w \in \mathcal{W}$. Furthermore we call the kernel of $P(w)$ the set of all vectors r such that $P(w)r = 0$ for all $w \in \mathcal{W}$.*

We first show that if an observer of the form (43) exists, there is an "equivalent" one satisfying the following assumption.

Assumption B.1. There are no $P(w)$-invariant subspaces included in the kernel of $Q(w)$.

Note that for known P and Q this is just an observability assumption. In our case this assumption means that

$$z(k+1) = P(w(k))z(k), \tag{64}$$

$$p(k) = Q(w(k))z(k) \tag{65}$$

cannot be reduced by the transformation $[S\ \tilde{S}]$, where S is a basis of $\mathcal{S}$, the invariant subspace, and $\tilde{S}$ is a complement matrix to the form

$$\hat{P}(w(k)) = \begin{bmatrix} \hat{P}_{11}(w(k)) & \hat{P}_{12}(w(k)) \\ 0 & \hat{P}_{22}(w(k)) \end{bmatrix}, \qquad \hat{Q}(w(k)) = \begin{bmatrix} 0 & \hat{Q}_2(w(k)) \end{bmatrix}.$$

Now, if the decomposition above can be achieved, then we can eliminate the "nonobservable" part of the system and consider an observer of the form (43) with $P(w(k)) = \hat{P}_{22}(w(k))$ and $Q(w(k)) = \hat{Q}_2(w(k))$ that fulfills the assumption. With this we are ready to show that, under such an assumption, T_1 must be constant.

Proof. Consider the variable $r(k) = z(k) - T_1(w(k))x(k)$. With simple computations, if we replace $r(k)$ in (43) in view of (44) which, as we have seen, must hold for each $w \in \mathcal{W}$, we get the following equation:

$$\begin{array}{rcl} r(k+1) & = & P(w(k))r(k) + [T_1(w(k)) - T_1(w(k+1))]x(k+1), \\ \hat{x}(k) - x(k) & = & Q(w(k))r(k). \end{array} \tag{66}$$

We show that $[T_1(w(k+1)) - T_1(w(k))] = 0$ for all $w(k), w(k+1) \in \mathcal{W}$. By contradiction assume that there exists w_0 and w_1 such that $T_1(w_0) \neq T_1(w_1)$. Let $x(0) = 0$, $z(0) = 0$ (thus $r(0) = 0$). From (ii) in Definition 4.1 we should have

$$\hat{x}(k) - x(k) = 0 \qquad \text{for all} \quad k > 0. \tag{67}$$

Assume that $w(0) = w_0$ and $w(1) = w_1$ and take x such that $(T_1(w_0) - T_1(w_1))x = r_1 \neq 0$. Then if we take $v(0) = x$, we get $x(1) = x$ and $r(1) = r_1$. Note that $v(k)$ can always be such that $x(k) = 0$, $k \geq 2$, and we assume that this is the case. Thus we consider system (66) with zero input. Consider the set of all vectors that can be reached from r_1, namely, the set

$$\mathit{Reach}(r_1) = \{x(k) = A(w(k))A(w(k-1)) \dots A(w(1))r_1 \quad \text{for some } k \geq 1\},$$

and let $\mathcal{S}$ be the smallest subspace that includes $\mathit{Reach}(r_1)$. $\mathcal{S}$ is necessarily $A(w)$-invariant because it admits as a basis a finite set of vectors $r_i \in \mathit{Reach}(r_1)$. From (67) for all vectors $r \in \mathit{Reach}(r_1)$ we must have $Q(w)r = 0$ for all $w \in \mathcal{W}$; then $Q(w)r = 0$ for all $r \in \mathcal{S}$ in contradiction with the assumption.

The final step is to show that if there exists an observer, with constant T_1, then there exists one with T_1 full column rank. This is trivial. It is sufficient to fictitiously augment (46) as

$$\begin{array}{rcll} z(k+1) & = & P(w(k))z(k) - L(w(k))y(k) & + T_1 v(k), \\ \tilde{z}(k+1) & = & & + \tilde{T}_1 v(k), \\ \hat{x}(k) & = & Q(w(k))z(k) + R(w(k))y(k), & \end{array}$$

with $\left[\begin{smallmatrix} T_1 \\ \tilde{T}_1 \end{smallmatrix}\right]$ full column rank. ∎

OPTIMIZATION-BASED STABILIZATION OF SAMPLED-DATA NONLINEAR SYSTEMS VIA THEIR APPROXIMATE DISCRETE-TIME MODELS*

LARS GRÜNE† AND DRAGAN NEŠIĆ‡

Abstract. We present results on numerical regulator design for sampled-data nonlinear plants via their approximate discrete-time plant models. The regulator design is based on an approximate discrete-time plant model and is carried out either via an infinite horizon optimization problem or via a finite horizon with terminal cost optimization problem. In both cases, we discuss situations when the sampling period T and the integration period h used in obtaining the approximate discrete-time plant model are the same or they are independent of each other. We show that, using this approach, practical and/or semiglobal stability of the exact discrete-time model is achieved under appropriate conditions.

Key words. controller design, asymptotic controllability, stabilization, numerical methods, optimal control

1. Introduction.

Stabilization of controlled systems is one of the central topics in control theory that has lead to a wealth of different stabilization techniques. An important set of stabilization methods is based on optimization techniques, such as receding horizon control (RHC) or model predictive control (MPC) (see [15, 8] and references therein). In optimization-based stabilization methods, one can compute control signals either on-line, like in MPC algorithms, or off-line, like in [9, 10, 14]. In either case, it is common to implement the controller using a computer with A/D and D/A converters (sampler and zero-order hold), which leads to the investigation of sampled-data nonlinear systems.

One of the main issues in sampled-data nonlinear control is the fact that the control designer usually cannot compute the exact discrete-time model of the plant and has to use an approximate discrete-time model when designing a stabilizing controller. The approximate model is obtained by numerically integrating the continuous-time plant dynamics over one sampling interval while keeping the control constant (if a zero-order hold is used). However, it is typically assumed in the optimization-based stabilization literature that the exact discrete-time plant model is available for controller design (see, for instance, [6, 15, 14, 13, 12, 1]). Hence there are gaps in the literature between the developed theory that is based on exact discrete-time models and the actual implementation of algorithms that invariably make use of approximate discrete-time models to compute control actions (see Example 1 in [3], section V in [6], and section IV in [14]). It is the purpose of this paper to present a careful investigation of the effects that numerical errors in approximating the model may have on the stabilization of the exact discrete-time model.

While it may seem that any controller that stabilizes a sufficiently "good" approximate model would always stabilize the exact model for sufficiently small values of integration and/or sampling period, this issue is much more subtle than it may appear at a first glance. Indeed, a number of counterexamples illustrating different mechanisms that cause instability of exact models when controlled by controllers that stabilize approximate models have been presented in [16, 19]. Moreover, results in [16, 19] present a set of general sufficient conditions on the continuous-time plant model, the approximate discrete-time plant model, and the designed controller that guarantee that controllers that stabilize the approximate model would also stabilize the exact model for a sufficiently small sampling and/or integration period. Moreover, backstepping results in [18] show that controller design within the framework proposed in [16] may lead to considerable performance improvement as opposed to controller design based on the continuous-time plant model that is followed by discretization of the controller (emulation design).

Results in [16, 19] present a framework for controller design via approximate discrete-time models, but they do not explain how the actual controller design can be carried out within this framework. It is the purpose of this paper to investigate several situations in which the optimization-based stabilization is done within the framework of [16, 19]. In particular, we consider the following problem:

> Suppose we are given a family of approximate discrete-time plant models
>
> $$x(k+1) = F^a_{T,h}(x(k), u(k))$$
>
> that are parameterized with the sampling period T and a modeling parameter h, which is typically the integration period of the underlying integration scheme. Given a family of cost functions $J_{T,h}$, suppose that a family of controllers
>
> $$u(k) = u^{a,*}_{T,h}(x(k))$$
>
> minimizes the given family of costs and is stabilizing for the family of approximate models. When would the same family of controllers stabilize the family of exact models
>
> $$x(k+1) = F^e_{T,h}(x(k), u(k))$$
>
> for sufficiently small values of the modeling parameter h?

We present conditions that guarantee that the family of controllers $u^{a,*}_{T,h}$ stabilizes in an appropriate sense the family of exact models for sufficiently small values of the modeling parameter. Two important situations are considered:

(i) $J_{T,h}$ is an infinite horizon cost function;
(ii) $J_{T,h}$ is a finite horizon cost function with a terminal cost.

In either case, we discuss two important subcases:

(i) T and h are independent of each other. This case is important when the sampling period T is fixed and the family of approximate models is generated via a numerical integration method with adjustable integration step h. This case usually produces better results, but the numerical computations required are more intensive (see, for instance, [14, 6]).
(ii) $T = h$ and T can be arbitrarily adjusted. This case is often used in the literature. The main motivation for using this approach is a reduced computational

burden in obtaining the approximate model, but it will be shown below that this method requires much stronger conditions than the first method (see [3]).

While our results do not cover all possible costs $J_{T,h}$ of interest, the presented proofs can be adapted to cover many other important situations. Moreover, the results we present are important in cases when the approximation of the plant model comes from a completely different mechanism than numerical integration of the plant dynamics. For example, the modeling parameter h may capture the size of the cells used in the space discretization that is usually needed in numerical calculation of the controller via optimization techniques, such as dynamic programming (see [14]). The modeling parameter h can be, in general, a vector capturing several different approximation mechanisms in obtaining the plant model, and our results can be extended to cover this important case.

The paper is organized as follows. In section 2, we present several motivating examples. Preliminaries are presented in section 3. Several results from [16, 19] that we use to prove our main results are presented in section 4. Infinite horizon and finite horizon optimization-based stabilization problems are considered, respectively, in sections 5 and 6. Conclusions are presented in the last section, and some auxiliary lemmas are stated and proved in the appendix.

2. Motivation. In this section, we present two examples for which a family of optimal control laws is designed to stabilize the family of approximate models, but the exact discrete-time model is destabilized for sufficiently fast sampling by the same family of controllers. These examples strongly motivate the results of our paper.

Example 2.1. We consider the sampled-data control of the triple integrator (this example was taken from [19])

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = x_3, \quad \dot{x}_3 = u.$$

While the exact discrete-time model of this system can be computed, we base our control algorithm on the family of Euler approximate discrete-time models in order to illustrate possible pitfalls in optimal control design based on approximate discrete-time models. The family of Euler approximate discrete-time models is

$$\begin{aligned} x_1(k+1) &= x_1(k) + Tx_2(k), \\ x_2(k+1) &= x_2(k) + Tx_3(k), \\ x_3(k+1) &= x_3(k) + Tu(k). \end{aligned} \tag{2.1}$$

Denote $x_i := x_i(0), i = 1, 2, 3$, $x := (x_1\ x_2\ x_3)^T$, and $\bar{u} := \{u(0), u(1), u(2), \ldots\}$. A minimum time dead beat controller for the Euler discrete-time model is designed to minimize the cost

$$\begin{aligned} J_T(x, \bar{u}) = x^T(3)x(3) &= (x_1 + 3Tx_2 + 3T^2x_3 + T^3u(0))^2 \\ &\quad + (x_2 + 3Tx_3 + 2T^2u(0) + T^2u(1))^2 + (x_3 + Tu(0) + Tu(1) + Tu(2))^2, \end{aligned}$$

and we obtain the optimal controller

$$u_T^*(x) = \left(-\frac{x_1}{T^3} \ -\frac{3x_2}{T^2} \ -\frac{3x_3}{T} \right). \tag{2.2}$$

The closed loop system (2.1)–(2.2) has all poles equal to zero for all $T > 0$, and hence this discrete-time Euler-based closed loop system is asymptotically stable for

all $T > 0$. On the other hand, the closed loop system consisting of the exact discrete-time model of the triple integrator and the optimal controller (2.2) has a pole at ≈ -2.644 for all $T > 0$. Hence, the optimal controller for the approximate model destabilizes the exact model for any sampling period.

Example 2.2. Consider the scalar linear system

$$\dot{x} = x + u, \tag{2.3}$$

whose exact discrete-time model is

$$x(k+1) = e^T x(k) + (e^T - 1)u(k). \tag{2.4}$$

We use the Euler model

$$x(k+1) = (1+T)x(k) + Tu(k) = F_T x(k) + G_T u(k) \tag{2.5}$$

for controller design. Consider the cost

$$J_T(x, \bar{u}) = \sum_{k=0}^{\infty} (Q_T x^2(k) + R_T u^2(k)), \tag{2.6}$$

where $Q_T = T$ and $R_T = T^3(1-T)^3$. Obviously, the instantaneous cost $Q_T x^2 + R_T u^2$ is a positive definite function of x, u for all $T \in (0, 1)$. Using [2, pp. 53–54], we can obtain the family of optimal controllers for (2.5) as

$$u_T^*(x) = \frac{G_T F_T S_T}{G_T^2 S_T + R_T}\, x, \tag{2.7}$$

where S_T is the solution of the following Ricatti equation:

$$S_T = F_T^2 \left(S_T - \frac{S_T^2 G_T^2}{G_T^2 S_T + R_T} \right) + Q_T. \tag{2.8}$$

Using the computer algebra system MAPLE, we computed the family of optimal control laws to be

$$u_T^*(x) = \left(-1 - \frac{5}{2} T^2 + O(T^3) \right) x,$$

which, for sufficiently small T, yields the stable approximate closed loop

$$x(k+1) = \left(1 - \frac{5}{2} T^3 + O(T^4) \right) x(k).$$

However, the same family of controllers yields the unstable exact closed loop

$$x(k+1) = \left(1 + \frac{1}{2} T^2 + O(T^3) \right) x(k)$$

for all sufficiently small T. Again, the family of optimal controllers for the family of approximate models is destabilizing for the family of exact models for all sufficiently small sampling periods T.

Remark 2.3. Note that the optimal controller gain in the first example is not uniformly bounded in T, and, in particular, as $T \to 0$, we have for any $x \neq 0$

that $|u_T(x)| \to \infty$. It may appear that this is the only reason why instability of the exact model occurs. However, in the second example, we have that the optimal controller gain is bounded uniformly in T, and yet instability occurs. Additional similar examples that do not use optimal control laws can be found in [19].

In both examples above, we can say that the used cost $J_T(x, \bar{u})$ is ill parameterized with T, and this causes instability of the exact closed loop. In what follows, we present conditions for well-parameterized costs that avoid problems presented in the examples.

Remark 2.4. The interpretation of the above results is as follows. One cannot first find a sufficiently "good" approximate plant model with a sufficiently small sampling and/or integration period and then assume that the optimal controller for the approximate model with respect to any given cost would stabilize the exact model. Indeed, because of the fact that we are considering parameterized systems and costs, the examples illustrate that, given an arbitrarily small sampling period (and hence an arbitrarily "good" plant model), there exists a cost function for which the controller that is optimal for the approximate model would destabilize the exact model. Hence a careful investigation of stability is needed to avoid situations presented in the examples.

3. Preliminaries. $\mathbb{R}$ and $\mathbb{N}$ denote, respectively, the sets of real and natural numbers. We also denote $\mathbb{N}_0 := \{0\} \cup \mathbb{N}$. In the Euclidean space $\mathbb{R}^n$, $\|\cdot\|$ denotes the usual Euclidean norm, and B_r and $\overline{B}_r$ denote, respectively, the open and closed ball with radius r around the origin. A continuous function $\gamma : \mathbb{R}_0^+ \to \mathbb{R}_0^+$ is of class $\mathcal{K}$ if it is strictly increasing with $\gamma(0) = 0$; it is of class $\mathcal{K}_\infty$ if it is of class $\mathcal{K}$ and unbounded. A continuous function $\beta : \mathbb{R}_0^+ \times \mathbb{R}_0^+ \to \mathbb{R}_0^+$ is of class $\mathcal{KL}$ if it is of class $\mathcal{K}$ in the first argument and strictly decreasing to 0 in the second.

Consider a continuous-time plant given by

$$\dot{x} = f(x, u), \tag{3.1}$$

where $x \in \mathbb{R}^n$ and $u \in U \subseteq \mathbb{R}^m$ with $0 \in U$. The plant is to be controlled via a computer that is connected to the plant via a sampler and a zero-order hold. We assume that f is locally Lipschitz, which guarantees that the solutions of (3.1) exist locally in time. Let $\phi(t, x_0, u)$ denote the solution trajectory for time t, initial value x_0, and constant control function $u \in U$. Suppose that, for a given T, x, u, the solution $\phi(t, x, u)$, exists for all $t \in [0, T]$. Then we can introduce the exact discrete-time model of the system

$$x_{k+1} = F_T^e(x(k), u(k)), \tag{3.2}$$

where $F_T^e(x, u) := \phi(T, x, u)$. Note that the trajectories of (3.1) may have finite escape time, in which case $F_T^e(x, u)$ might not be defined for all $x \in \mathbb{R}^n$, $u \in U$. However, since f is assumed to be locally Lipschitz, we have that for each $\Delta > 0$ there exists $T_\Delta^* > 0$ such that $F_T^e(x, u)$ exists for all $x \in \overline{B}_\Delta$, $u \in \overline{B}_\Delta$, and $T \in (0, T_\Delta^*]$. The set of all control sequences is denoted by $\mathcal{U}$; members of $\mathcal{U}$ will be denoted by $\overline{u} = (u(k))_{k \in \mathbb{N}_0}$.

We note that, since f is typically nonlinear, F_T^e in (3.2) is not known in most cases. Hence, if we want to carry out controller design for the sampled-data plant (3.1) via its discrete-time model, we need to use instead an approximate discrete-time model

$$x_{k+1} = F_{T,h}^a(x(k), u(k)), \tag{3.3}$$

where $T \in (0, T^*]$ is the sampling rate with some upper bound $T^* > 0$ and $h \in (0, T]$

is a parameter for the accuracy of the approximate model, e.g., the integration step for some underlying numerical one-step approximation.

Remark 3.1. The map $F^a_{T,h}$ defining the approximate model is typically interpreted as a numerical approximation of F^e_T using some suitable numerical scheme. For instance, $F^a_{T,h}$ might be constructed using multiple steps of a one-step Runge–Kutta scheme Φ_{h_i} with integration step sizes h_i, $i = 1, \dots, m$, satisfying $h_i \le h$ and $\sum_{i=1}^m h_i = T$; i.e.,

$$x_\circ = x, \;\; x_{i+1} = \Phi_{h_i}(x_i, u), \;\; F^a_{T,h}(x, u) = x_m.$$

Note that, for constant control functions u, system (3.1) is an autonomous ODE, and hence all numerical schemes for autonomous ODEs are applicable; see, e.g., [11], [23], or [24] for a description of suitable numerical methods. In the simplest case, Φ_{h_i} could be chosen as the Euler method $\Phi_{h_i}(x, u) = x + hf(x, u)$. Note that, for any T, h, the numerical scheme $F^a_{T,h}(x, u)$ will normally exist for all x, u because the computation of $F^a_{T,h}$ is usually based on finitely many evaluations of f only.

Given a family of cost functions $J_{T,h}(x, \overline{u})$, we will design a family of optimal control laws for the approximate model

$$u(k) = u^{a,*}_{T,h}(x(k)) \tag{3.4}$$

and investigate when they stabilize the family of exact models (3.2) for all small h.

In general, it is useful to consider exact models that are also parameterized by a modeling parameter (for motivation, see [19])

$$x_{k+1} = F^e_{T,h}(x(k), u(k)). \tag{3.5}$$

In this case, however, h is not interpreted as a numerical integration step. We write $F_{T,h}$ if we refer to a general discrete-time parameterized system

$$x_{k+1} = F_{T,h}(x(k), u(k)); \tag{3.6}$$

in particular, $F_{T,h}$ may stand for both $F^e_{T,h}$ and $F^a_{T,h}$. The special case $T = h$ has received much attention in the literature, and, in this case, we will write F_T instead of $F_{T,T}$. Given $\overline{u}$ and $x_\circ$, the trajectories of the systems (3.5) and (3.3) are denoted, respectively, by $\phi^e_{T,h}(k, x_\circ, \overline{u})$ and $\phi^a_{T,h}(k, x_\circ, \overline{u})$. Again, if we refer to a generic system (3.6), we use the notation $\phi_{T,h}(k, x_\circ, \overline{u})$, and, if $T = h$, we write ϕ_T instead of $\phi_{T,T}$.

Assumption 3.2. We assume that both $F^e_{T,h}$ and $F^a_{T,h}$ are continuous in u and satisfy a local Lipschitz condition of the following type: for each $\Delta > 0$, there exist $T > 0$, $L > 0$, and $h^* > 0$, such that

$$\|F_{T,h}(x, u) \; - \; F_{T,h}(y, u)\| \le e^{LT}\|x - y\| \tag{3.7}$$

holds for all $u \in \overline{B}_\Delta$, all $h \in (0, h^*]$, and all x, $y \in \overline{B}_\Delta$.

For the exact model, this property is easily verified using Gronwall's lemma (if $F^e_{T,h}$ is well defined), while, for the approximate model, it depends on the properties of the numerical scheme in use. For Runge–Kutta schemes, e.g., it is verified by induction using the property $\|\Phi_{h_i}(x, u) - \Phi_{h_i}(y, u)\| \le (1 + Lh_i)\|x - y\|$ (cf. [24]) and the inequality $1 + Lh_i \le e^{Lh_i}$.

4. Definitions and background results. In [16, 19], sufficient conditions based on the Lyapunov second method were presented that guarantee that the family of controllers that stabilizes (3.3) would also stabilize (3.5) for sufficiently small h. Here the control laws under consideration do not need to come from optimal control problems; however, they will still be parameterized by the parameters T and h. The results in this section will be used in the rest of this paper. In order to state these results, we need several definitions.

DEFINITION 4.1. *Let strictly positive real numbers (T, Δ_1, Δ_2) be given. If there exists $h^* > 0$ such that*

$$\sup_{\{x \in B_{\Delta_1} \ , \ h \in (0,h^*]\}} |u_{T,h}(x)| \leq \Delta_2, \tag{4.1}$$

then we say that the family of controllers (3.4) *is (T, Δ_1, Δ_2)-uniformly bounded. Moreover, if $T = h$ and if, for any strictly positive Δ_1, there exist strictly positive (Δ_2, h^*) so that* (4.1) *holds, then we say that the family of controllers* (3.4) *is semiglobally uniformly bounded.*

The following "consistency" property is central in our developments, and it is an appropriate adaptation and generalization of a consistency property used in the numerical analysis literature (see [24]).

DEFINITION 4.2. *Let a triple of strictly positive numbers (T, Δ_1, Δ_2) be given, and suppose that there exist $\gamma \in \mathcal{K}$ and $h^* > 0$ such that*

$$(x,u) \in B_{\Delta_1} \times B_{\Delta_2}, h \in (0,h^*] \implies \|F^a_{T,h}(x,u) - F^e_{T,h}(x,u)\| \leq T\gamma(h). \tag{4.2}$$

Then we say that the family $F^a_{T,h}$ is (T, Δ_1, Δ_2)-consistent with $F^e_{T,h}$. Moreover, if $T = h$ and if, for any pair of strictly positive numbers (Δ_1, Δ_2), there exist $\gamma \in \mathcal{K}$ and $h^* > 0$ such that (4.2) *holds, then we say that $F^a_{T,h}$ is semiglobally consistent with $F^e_{T,h}$.*

Sufficient checkable conditions for consistency properties can be found in [16, 19].

DEFINITION 4.3. *Let a pair of strictly positive real numbers (T, D), a family of functions $V_{T,h} : \mathbb{R}^n \to \mathbb{R}_{\geq 0}$, functions $\sigma_1, \sigma_2 \in \mathcal{K}_\infty$, and a positive definite function $\sigma_3 : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ be given. Suppose, for any pair of strictly positive real numbers (δ_1, δ_2) with $\delta_2 < D$, that there exist $h^* > 0$ and $c > 0$ such that, for all $x \in B_D$, $h \in (0, h^*]$, we have*

$$\sigma_1(\|x\|) \leq V_{T,h}(x) \leq \sigma_2(\|x\|), \tag{4.3}$$

$$V_{T,h}(F^a_{T,h}(x, u_{T,h}(x))) - V_{T,h}(x) \leq -T\sigma_3(\|x\|) + T\delta_1, \tag{4.4}$$

and, for all $x_1, x_2 \in B_D - B_{\delta_2}$, with $\|x_1 - x_2\| \leq c$, we have

$$|V_{T,h}(x_1) - V_{T,h}(x_2)| \leq \delta_1. \tag{4.5}$$

Then we say that the family (3.6), (3.4) *is (T, D)-practically stable with a continuous Lyapunov function. Moreover, if $T = h$ and, for any triple of strictly positive real numbers (D, δ_1, δ_2) with $\delta_2 < D$, there exist $h^* > 0$ and $L > 0$ such that, for all $x, x_1, x_2 \in B_D$, $h \in (0, h^*]$, we have that* (4.3), (4.4), *and*

$$|V_T(x_1) - V_T(x_2)| \leq L\|x_1 - x_2\| \tag{4.6}$$

hold, then we say that the family (3.6), (3.4) *is semiglobally stable with a Lipschitz Lyapunov function.*

The following two theorems from [16, 19] play a central role in our developments.

THEOREM 4.4. *Suppose that there exist a triple of strictly positive numbers* (T, D, M) *such that the following hold:*

(i) *The family of closed loop systems* $(F^a_{T,h}, u^a_{T,h})$ *is* (T, D)*-practically stable with a continuous Lyapunov function.*
(ii) *The family of controllers* $u^a_{T,h}$ *is* (T, D, M)*-uniformly bounded.*
(iii) *The family* $F^a_{T,h}$ *is* (T, D, M)*-consistent with* $F^e_{T,h}$.

Then there exist $\beta \in \mathcal{KL}$, $D_1 \in (0, D)$, *and, for any* $\delta > 0$, *there exists* $h^* > 0$ *such that, for all* $x_\circ \in B_{D_1}$ *and* $h \in (0, h^*]$, *the solutions of the family* $(F^e_{T,h}, u^a_{T,h})$ *satisfy*

$$\|\phi^e_{T,h}(k, x_\circ)\| \le \beta(\|x_\circ\|, kT) + \delta \qquad \forall k \in \mathbb{N}_0. \tag{4.7}$$

THEOREM 4.5. *Suppose that* $T = h$ *and the following conditions hold:*

(i) *The family of closed loop systems* (F^a_T, u^a_T) *is semiglobally stable with a Lipschitz Lyapunov function.*
(ii) *The family of controllers* u^a_T *is semiglobally uniformly bounded.*
(iii) *The family* F^a_T *is semiglobally consistent with* F^e_T.

Then there exists $\beta \in \mathcal{KL}$ *such that, for any* $D_1 > 0$ *and* $\delta > 0$, *there exists* $T^* > 0$ *such that, for all* $x_\circ \in B_{D_1}$ *and* $T \in (0, T^*]$ *the solutions of the family* (F^e_T, u^a_T) *satisfy*

$$\|\phi^e_T(k, x_\circ)\| \le \beta(\|x_\circ\|, kT) + \delta \qquad \forall k \in \mathbb{N}_0. \tag{4.8}$$

Remark 4.6. Theorems 4.4 and 4.5 provide general conditions on the controller, approximate model, and continuous-time plant that guarantee that the controllers that are designed via the approximate model would also stabilize the exact model for sufficient values of the small modeling parameter. In what follows, we investigate the conditions under which control laws that are optimal in some sense for the approximate model satisfy all conditions of Theorems 4.4 and 4.5.

All conditions of Theorems 4.4 and 4.5 are checkable in principle since they do not require the knowledge of the exact discrete-time model. Indeed, the consistency can be checked using the properties of the approximate model (3.3) and the continuous-time plant model (3.1), and it holds for most reasonable numerical integration schemes such as consistent Runge–Kutta methods. Classical numerical texts [11, 23, 24] present a range of consistent numerical schemes that can be used within our framework. Boundedness of the control law is relatively easy to check. Finally, the Lyapunov conditions are hard to check in general, but there is a range of important situations where this is possible to do, as illustrated in [17, 18, 7] and references therein. The present paper presents another class of problems where the Lyapunov conditions can be verified.

5. Infinite horizon problems. In the first part of this section, we assume that $T \ne h$ and h can be assigned arbitrarily and independently of T, which is arbitrary but fixed. In the second part, we consider the case when $T = h$ and T can be assigned arbitrarily.

5.1. Stabilization with a fixed sampling rate T. We consider the optimal control problem

$$\min_{\overline{u} \in \mathcal{U}} \sum_{k=0}^{\infty} T l_h(\phi_{T,h}(k, x, \overline{u}), u(k)), \tag{5.1}$$

where the running cost l_h satisfies the following assumption.

Assumption 5.1. The following hold:

(i) l_h is continuous with respect to x and u, uniformly in small h.

(ii) There exist $h^* > 0$ and two class $\mathcal{K}_\infty$ functions ρ_1 and ρ_2 such that the inequality

$$\rho_1(\|x\| + \|u\|) \le l_h(x,u) \le \rho_2(\|x\| + \|u\|) \tag{5.2}$$

holds for all x, u, and $h \in (0, h^*]$.

(iii) For each $\Delta > 0$, there exist $N > 0$ and $h^* > 0$ such that

$$|l_h(x,u) - l_h(y,u)| \le N\|x - y\|$$

for all $h \in (0, h^*]$, $x, y \in \mathbb{R}^n$, and all $u \in U$ with $\|x\|, \|y\|, \|u\| \le \Delta$.

Note that the sum in (5.1) may diverge; hence it may take the value ∞. We make the convention that this sum takes the value ∞ if the trajectory $\phi_{T,h}(\cdot, x, \overline{u})$ does not exist for some $k \in \mathbb{N}_0$.

We denote the optimal cost functions related to the exact and the approximate system by

$$W^e_{T,h}(x) := \min_{\overline{u}\in\mathcal{U}} \sum_{k=0}^{\infty} Tl_h(\phi^e_{T,h}(k, x, \overline{u}), u(k)),$$

$$W^a_{T,h}(x) := \min_{\overline{u}\in\mathcal{U}} \sum_{k=0}^{\infty} Tl_h(\phi^a_{T,h}(k, x, \overline{u}), u(k)),$$

again using $W_{T,h}(x)$ if we want to refer to a general system and W_T if $T = h$. Note that $W_{T,h}(x) = \infty$ is possible, so we will have to formulate conditions such that $W_{T,h}$ is finite at least for compact subsets of the state space.

It is clear that not every plant would allow for a meaningful solution of the optimal control problem (5.1). However, if the plant model satisfies the following asymptotic controllability assumption, we will prove in Theorem 5.4 that a solution to (5.1) exists under certain assumptions.

DEFINITION 5.2. *Let $T > 0$, $\beta \in \mathcal{KL}$, and $\Delta > 0$ be given. The family of systems* (3.6) *is called (T, Δ, β)-asymptotically controllable to the origin with vanishing controls if there exists $h^* > 0$ such that, for all $h \in (0, h^*]$ and each $x \in \overline{B}_\Delta$, there exists $\overline{u} \in \mathcal{U}$ such that*

$$\|\phi_{T,h}(k, x, \overline{u})\| + \|u(k)\| \le \beta(\|x\|, Tk), \qquad k \in \mathbb{N}_0.$$

Asymptotic controllability has been introduced in [21], and we have adapted the definition from [14] to be applicable to families of discrete-time systems. Note that this definition, in particular, requires $\|u(k)\| \le \beta(\|x\|, Tk)$. This assumption is mainly needed in order to simplify some of the following arguments and could be relaxed in various ways, e.g., to $\|u(k)\| \le \delta + \beta(\|x\|, Tk)$ for some $\delta > 0$, provided that Assumption 5.1 (ii) is suitably adjusted also. The following result is used in what follows.

PROPOSITION 5.3 (see [22]). *Given an arbitrary $\beta \in \mathcal{KL}$, there exist two functions $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ such that the following holds:*

$$\beta(s,t) \le \alpha_2\left(\alpha_1(s)e^{-t}\right) \qquad \forall s, t \ge 0. \tag{5.3}$$

Note that, using Proposition 5.3, there is no loss of generality if we assume that $\beta(s,t)$ in Definition 5.2 is replaced by $\alpha_2(\alpha_1(s)e^{-t})$. The following theorem shows conditions under which the optimal feedback law for the approximate model exists and can be used to stabilize the exact closed loop system.

THEOREM 5.4. *Let strictly positive real numbers (Δ, T) and functions $\beta \in \mathcal{KL}$ and $l_h(\cdot,\cdot)$ satisfying Assumption 5.1 be given. Let β generate $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ using Proposition 5.3, and let l_h generate $\rho_1, \rho_2 \in \mathcal{K}_\infty$ via (5.2). Suppose the following:*

(i) *The family of approximate models $F^a_{T,h}$ satisfies Assumption 3.2.*

(ii) *The family of approximate models $F^a_{T,h}$ is (T, Δ, β)-asymptotically controllable to the origin with vanishing controls.*

(iii) *There exists $C > 0$ such that*

$$\int_0^1 \frac{\rho_2 \circ \alpha_2(s)}{s} ds \le C. \tag{5.4}$$

Then, for the family of systems $F^a_{T,h}$, there exists a solution to the family of optimal control problems

$$\min_{\overline{u} \in \mathcal{U}} \sum_{k=0}^{\infty} T l_h(\phi^a_{T,h}(k, x, \overline{u}), u(k))$$

of the form

$$u(k) = u^{a,*}_{T,h}(x(k)) \tag{5.5}$$

and numbers $D \in (0, \Delta)$, $M > 0$ such that the following hold:

(i') *The family of controllers $u^{a,*}_{T,h}$ is (T, D, M)-uniformly bounded.*

(ii') *The family $(F^a_{T,h}, u^{a,*}_{T,h})$ is (T, D)-practically stable with continuous Lyapunov function.*

Suppose, moreover, that the following additional condition holds:

(iii') *The family of approximate models $F^a_{T,h}$ is (T, D, M)-consistent with $F^e_{T,h}$.*

Then, there exists $D_1 \in (0, D)$ and $\beta_1 \in \mathcal{KL}$, and, for any $\delta > 0$, there exists $h^* > 0$ such that, for all $x_\circ \in B_{D_1}$ and all $h \in (0, h^*]$, the solutions of the family $(F^e_{T,h}, u^{a,*}_{T,h})$ satisfy

$$\|\phi^e_{T,h}(k, x_\circ)\| \le \beta_1(\|x_\circ\|, kT) + \delta \qquad \forall k \in \mathbb{N}_0.$$

Proof. Let all the conditions of Theorem 5.4 be satisfied. We will prove that conditions (i), (ii), and (iii) imply conditions (i') and (ii'). Then the last statement follows immediately from (i'), (ii'), and (iii') via Theorem 4.4.

(i)+(ii)+(iii) $\Rightarrow$ (ii'). We use the optimal value of the cost $W^a_{T,h}(x)$ as the Lyapunov function for the approximate closed loop system, which is standard in optimization literature. We now show that $W^a_{T,h}$ satisfies (4.3), (4.4), and (4.5) of Definition 4.3.

It is immediate from (5.2) that, for any x and $h \in (0, h^*]$, we have

$$\sigma_1(\|x\|) := T\rho_1(\|x\|) \le W^a_{T,h}(x). \tag{5.6}$$

Let $x \in \overline{B}_\Delta$ and $h \in (0, h^*]$. Using the definition of the cost, the bound (5.2), and condition (ii), we obtain for $\overline{u}$ from Definition 5.2:

$$\begin{aligned}
W^a_{T,h}(x) &\le \sum_{k=0}^{\infty} T l_h(\phi^a_{T,h}(k,x,\overline{u}),u(k)) \\
&\le \sum_{k=0}^{\infty} T\rho_2(\|\phi^a_{T,h}(k,x,\overline{u})\| + \|u(k)\|) \\
&\le \sum_{k=0}^{\infty} T\rho_2(\beta(\|x\|,kT)) \\
&\le \sum_{k=0}^{\infty} T\rho_2(\alpha_2(e^{-kT}\alpha_1(\|x\|))) \\
&= T\rho_2\circ\alpha_2\circ\alpha_1(\|x\|) + \sum_{k=1}^{\infty} T\rho_2(\alpha_2(e^{-kT}\alpha_1(\|x\|))) \\
&\le T\rho_2(\alpha_2(\alpha_1(\|x\|))) + \int_0^{\infty} \rho_2(\alpha_2(e^{-t}\alpha_1(\|x\|)))dt.
\end{aligned}$$

It was shown in [4, Proof of Theorem 1] that, under condition (iii), the integral term in the last inequality can be bounded by $\tilde{\sigma}(\|x\|)$ for some $\tilde{\sigma} \in \mathcal{K}_\infty$. Hence, if we define $\sigma_2(r) := T\rho_2(\alpha_2(\alpha_1(r))) + \tilde{\sigma}(r)$, we can write, for all $x \in \overline{B}_\Delta$ and $h \in (0, h^*]$, that

$$W^a_{T,h}(x) \le \sigma_2(\|x\|). \tag{5.7}$$

Hence (5.6) and (5.7) show that (4.3) holds.

Let an arbitrary $\delta_1 > 0$ be given. We show now that, for the given (Δ, δ_1), there exist $D \in (0, \Delta]$, $c > 0$, and $h^* > 0$ such that the implication

$$x \in \overline{B}_D, \|x-y\| \le c, h \in (0,h^*] \Rightarrow \ |W^a_{T,h}(x) - W^a_{T,h}(y)| \le \delta_1 \tag{5.8}$$

holds, which proves that (4.5) is satisfied.[1]

For the rest of the proof, we use lemmas that are presented and proved in the appendix. Let $\rho_1, \rho_2 \in \mathcal{K}_\infty$, and $h^*_1 > 0$ come from Assumption 5.1. Define the following numbers:

$$\begin{aligned}
S &:= \sigma_1(\Delta) + \delta_1/4, \\
\widetilde{\Delta} &:= \rho_1^{-1}(S/T), \\
\alpha &= \sigma_2^{-1}\left(\frac{\delta_1}{8}\right).
\end{aligned}$$

Let $(S, \alpha/2)$ generate via Lemma A.2 the number $\tau > 0$. Let $\widetilde{\Delta}$ generate via (3.7) the numbers $N > 0$ and $h^*_2 > 0$. Let $(\tilde{\Delta}, \tau, T)$ and $\delta := \min\{\alpha/2, \frac{\delta_1}{2N\tau}\}$ generate via Lemma A.4 the numbers $c > 0$ and $h^*_3 > 0$. Let $h^* := \min\{h^*_1, h^*_2, h^*_3\}$. Let $D := \sigma_2^{-1} \circ \sigma_1(\Delta)$.

In all calculations below, we consider arbitrary $x \in \overline{B}_D$, $h \in (0, h^*]$, and $\|x-y\| \le c$. Let $\overline{u}$ be a control sequence such that

$$\sum_{k=0}^{\infty} l_h(\phi^a_{T,h}(k,x,\overline{u}),u(k)) \le W^a_{T,h}(x) + \delta_1/4,$$

[1] Note that this is a stronger condition than what is needed in Definition 4.3 since we have $\delta_2 = 0$.

which implies from $\|x\| \le D$ and the definition of S that $\sum_{k=0}^{\infty} l_h(\phi_{T,h}(k,x,\overline{u}),u(k)) \le S$. From Lemma A.1 and the definition of $\widetilde{\Delta}$, we have

$$\|\phi^a_{T,h}(k,x,\overline{u})\| + \|u(k)\| \le \widetilde{\Delta} \qquad \forall k \in \mathbb{N}_0.$$

From the definition of α and (5.7), we have $W^a_{T,h}(x) \le \delta_1/8$ for all $x \in \overline{B}_\alpha$. From our choice of τ, it follows from Lemma A.2 that, for some $j \in \mathbb{N}_0$ with $Tj \le \tau$, we have $\|\phi^a_{T,h}(j,x,u)\| \le \alpha/2$. Moreover, from Lemma A.4 and our choice of δ, it follows that $\|\phi^a_{T,h}(j,x,\overline{u}) - \phi^a_{T,h}(j,y,\overline{u})\| \le \delta \le \alpha/2$ and, consequently, $\|\phi^a_{T,h}(j,y,\overline{u})\| \le \alpha$, which implies from the choice of α that

$$W^a_{T,h}(\phi^a_{T,h}(j,y,\overline{u})) \le \delta_1/8\ .$$

Abbreviating $\tilde{y} = \phi^a_{T,h}(j,y,\overline{u})$, we can choose a control sequence $\overline{u}^*$ satisfying

$$\sum_{k=0}^{\infty} l_h(\phi^a_{T,h}(k,\tilde{y},\overline{u}^*),u^*(k)) \le W^a_{T,h}(\tilde{y}) + \delta_1/8 \le \delta_1/4.$$

Replacing $u(k)$, $k = j, j+1, \ldots$, by u^*_{k-j}, we thus obtain

$$\begin{aligned} W^a_{T,h}(y) &\le \sum_{k=0}^{j-1} T l_h(\phi^a_{T,h}(k,y,\overline{u}),u(k)) + \sum_{k=j}^{\infty} T l_h(\phi^a_{T,h}(k,y,\overline{u}),u(k)) \\ &= \sum_{k=0}^{j-1} T l_h(\phi^a_{T,h}(k,y,\overline{u}),u(k)) + \sum_{k=0}^{\infty} T l_h(\phi^a_{T,h}(k,\tilde{y},\overline{u}^*),u^*(k)) \\ &\le \sum_{k=0}^{j-1} T l_h(\phi^a_{T,h}(k,y,\overline{u}),u(k)) + \delta_1/4. \end{aligned} \tag{5.9}$$

Again, using Lemma A.4, the Lipschitz property of l_h, the fact that $jT \le \tau$, and our choice of δ, we can conclude that

$$\sum_{k=0}^{j-1} T(l_h(\phi^a_{T,h}(k,y,\overline{u}),u(k)) - l_h(\phi^a_{T,h}(k,x,\overline{u}),u(k))) \le N\tau\delta \le \delta_1/2. \tag{5.10}$$

The definition of $W^a_{T,h}$, the choice of $\overline{u}$, and the positive definiteness of l_h imply

$$W^a_{T,h}(x) \ge \sum_{k=0}^{j-1} T l_h(\phi^a_{T,h}(k,x,\overline{u})) - \delta_1/4. \tag{5.11}$$

We now combine (5.9), (5.10), and (5.11):

$$\begin{aligned} W^a_{T,h}(y) - W^a_{T,h}(x) &\le \sum_{k=0}^{j-1} T l_h(\phi^a_{T,h}(k,y,\overline{u}),u(k)) \\ &\qquad - \sum_{k=0}^{j-1} T l_h(\phi^a_{T,h}(k,x,\overline{u}),u(k)) + \delta_1/4 + \delta_1/4 \\ &\le \delta_1/2 + \delta_1/4 + \delta_1/4 = \delta_1. \end{aligned}$$

Since the corresponding estimate for $W_T^a(x) - W_T^a(y)$ follows by symmetry, this completes the proof of (4.5).

Finally, with the given (Δ, δ_1), we show that (4.4) is satisfied. For any fixed T and h, standard optimal control arguments show that $W_{T,h}^a$ satisfies the dynamic programming equation

$$W_{T,h}^a(x) = \inf_{u \in U} \{Tl_h(x,u) + W_{T,h}^a(F_{T,h}^a(x,u))\}.$$

Since $F_{T,h}^a$ and l_h are continuous in u, $W_{T,h}^a$ is continuous in x, and l_h is positive definite, the "inf" is actually a "min," and we can define the desired $u_{T,h}^{a,*}(x)$ by choosing it such that

$$Tl_h(x, u_{T,h}^{a,*}(x)) + W_{T,h}^a(F_{T,h}^a(x, u_{T,h}^{a,*}(x))) = \min_{u \in U}\{Tl_h(x,u) + W_{T,h}^a(F_{T,h}^a(x,u))\}.$$

Combining the given bounds above and using (5.2), we obtain

$$\begin{aligned} W_{T,h}^a(F_{T,h}^a(x, u_{T,h}^{a,*}(x))) - W_{T,h}^a(x) &= -Tl_h(x, u_{T,h}^{a,*}(x)) \\ &\le -T\rho_1(\|x\|) \\ &\le -T\rho_1(\|x\|) + T\delta_1, \end{aligned}$$

which proves (4.4) and completes the proof of (ii').

(i)+(ii)+(iii) $\Rightarrow$ (i'). Since, for all $x \in \overline{B}_D$, we have $Tl_h(x, u_{T,h}^{a,*}(x)) \le W_{T,h}^a(x)$ and since (5.2) holds, we can write that

$$\begin{aligned} \|u_{T,h}^{a,*}(x)\| &\le \rho_1^{-1}(l_h(x, u_{T,h}^{a,*}(x))) \\ &\le \rho_1^{-1}\left(\frac{1}{T} W_{T,h}^a(x)\right) \\ &\le \rho_1^{-1}\left(\frac{1}{T}\sigma_2(\|x\|)\right) \\ &\le \rho_1^{-1}\left(\frac{\sigma_2(D)}{T}\right) =: M, \end{aligned} \tag{5.12}$$

which proves that (i') holds. □

Remark 5.5. The conditions in Theorem 5.4 are relatively hard to verify. We have already commented on condition (i) after Assumption 3.2. The asymptotic controllability (condition (ii)) is a necessary condition for any stabilization problem, and most well-designed control systems will satisfy this condition. Finally, the condition (iii) suggests that, if the system is asymptotically controllable with a certain α_2, then we can always adjust the cost $l_h(x,u)$ so that $\rho_2(s) \le \alpha_2^{-1}(Cs)$ for some $C > 0$. Hence, by reducing ρ_2 sufficiently, we can always make condition (iii) hold for any asymptotically controllable system. Since we are interested only in stabilization, the procedure for computing a stabilizing controller for asymptotically controllable systems may be as follows: start with a certain pair of $l_h(x,u), \rho_2$, and attempt the numerical optimization. If the optimal solution has been obtained, use this optimal controller. If the optimal solution was not obtained, introduce new $\tilde{\rho}$ such that $\tilde{\rho}(s) < \rho(s)$ for all $s > 0$ and a new $\tilde{l}_h(x,u)$, and repeat the procedure.

Remark 5.6. It is often the case that, instead of the optimal controller, one can only compute a certain suboptimal controller with a corresponding value function. Our results still apply in this case if the suboptimal controller and the resulting value

function satisfy the first two conditions of Theorems 4.4 or 4.5 and the approximate model satisfies the third condition in these theorems. Hence, under these conditions, the suboptimal controller for the approximate model will still be stabilizing the exact model in an appropriate sense. Due to space reasons, we did not pursue this issue in more detail.

Remark 5.7. Note that if T can be adjusted arbitrarily and independent of h, and, moreover, if for any arbitrary $\Delta > 0$ there exists T so that the system is (T, Δ, β)-asymptotically controllable with vanishing controls, and if all other conditions of Theorem 5.4 hold, then all conclusions of Theorem 5.4 hold. Hence, for T varying and independent of h, we can modify the statement of Theorem 5.4 to obtain a result on semiglobal practical stabilization. However, if $T = h$, we need much stronger conditions to achieve semiglobal practical stabilization, which is discussed in more detail in the next subsection.

Remark 5.8. Neither of the examples of section 2 satisfies Assumption 5.1, and that is the reason why the controllers $u_T^{a,*}$ do not stabilize the family of exact models F_T^e.

Remark 5.9. It is possible under mild conditions to obtain $\mathcal{KL}$ stability bounds for the solutions of the sampled-data system from the $\mathcal{KL}$ stability bounds for the exact discrete-time model and bounds on the intersample behavior, as illustrated in [20].

5.2. Stabilization with varying sampling rate $T = h$. The case in which $T = h$ is sometimes considered in the literature (see Example 1 in [3]), and we discuss it next. For instance, some authors use the Euler approximate model

$$x(k+1) = F_T^a(x(k), u(k)) = x(k) + Tf(x(k), u(k))$$

in MPC of a continuous-time plant $\dot{x} = f(x, u)$. While this approach is very attractive because of the reduced computational effort in obtaining the approximate discrete-time model F_T^a, we show below that it may have serious limitations.

Note that for $T = h$ we need to use Theorem 4.5, which requires (among other things) the following:

C1. a lower bound on the optimal value function that is uniform in small T; cf. Theorem 5.12 (iv);

C2. boundedness of the optimal controller $u_T^{a,*}$ on compact sets uniform in small T; cf. Theorem 5.12 (iii');

C3. W_T^a locally Lipschitz and uniformly in small T; cf. Theorem 5.12 (v).

It is well known from optimal control theory that, even for fixed $T > 0$, one cannot expect W_T^a to be locally Lipschitz in general, and hence condition C3 usually does not hold. Moreover, note that the inequalities (5.6) and (5.12) seem to suggest that, in general, for any fixed x, we may have that $W_T^a(x) \to 0$ and $\|u_T^{a,*}(x)\| \to \infty$ as $T \to 0$, which violates conditions C1 and C2. The next example shows that this can indeed happen when $T = h$.

Example 5.10. Consider the scalar system

$$\dot{x} = u^3$$

with $u \in U = \mathbb{R}$ and the running cost $l(x, u) = \|x\|^2 + \|u\|^2$. The corresponding exact discrete-time model is given by

$$x(k+1) = x(k) + Tu^3(k) =: F_T(x(k), u(k)),$$

so the control sequence $\overline{u}$ induced by the state feedback law

$$u_T^*(x) = -(x/T)^{1/3}$$

yields

$$\sum_{k=0}^{\infty} Tl(\phi_T(k, x(0), \overline{u}), u(k)) = T(\|x(0)\|^2 + (x(0)/T)^{2/3}) = T\|x(0)\|^2 + T^{1/3}\|x(0)\|^{2/3}.$$

Consequently, we obtain

$$W_T(x(0)) \le T\|x(0)\|^2 + T^{1/3}\|x(0)\|^{2/3}.$$

Setting $W_T(x(0)) = T\|x(0)\|^2 + T^{1/3}\|x(0)\|^{2/3}$, one sees that the equality

$$l(x, u_T^*(x)) + W_T(F_T(x, u_T^*(x))) = \inf_{u\in U}\{l(x,u) + W_T(F_T(x,u))\}$$

holds. (One verifies that, for all x, T, the term on the right-hand side has only two local minima located at $u = 0$ and $u = u_T^*(x)$, and the latter yields a smaller value.) Hence the feedback law $u_T^*(x)$ is optimal for this problem.

Note that, for any fixed $x \neq 0$, we have $T \to 0 \implies W_T(x) \to 0$ and $\|u_T^*(x)\| \to \infty$.

While, in the example discussed above, $u_T^*(x)$ still asymptotically stabilizes the exact model (due to the fact that, for this simple system, the exact discrete-time model and its Euler approximation coincide), in general, this phenomenon poses a serious problem, and $u_T^{a,*}$ may, in general, destabilize the family F_T^e. Several examples illustrating this phenomenon can be found in [19].

As a result of the above discussion, it is obvious that one can either search for conditions on f, F_T^a, and l_T to guarantee that C1, C2, and C3 hold or simply assume that they hold. While it is apparent that the first approach poses interesting and relevant questions, we did not pursue it in this paper. Using the second approach, we can state Theorem 5.4. Before we state the theorem, we need to slightly modify the definition of asymptotic controllability as follows.

DEFINITION 5.11. *Let $\beta \in \mathcal{KL}$ be given. The family of systems $x(k+1) = F_T(x(k), u(k))$ is called semiglobally asymptotically controllable to the origin with vanishing controls if, for each $\Delta > 0$, there exists $T^* > 0$ such that, for all $T \in (0, T^*]$ and each $x \in \overline{B}_\Delta$, there exists $\overline{u} \in \mathcal{U}$ such that*

$$\|\phi_T(k, x, \overline{u})\| + \|u(k)\| \le \beta(\|x\|, Tk).$$

THEOREM 5.12. *Let $T = h$. Let $\beta \in \mathcal{KL}$ and $l_T(\cdot,\cdot)$ satisfying Assumption 5.1 be given. Let β generate $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$ using Proposition 5.3, and let l_T generate $\rho_1, \rho_2 \in \mathcal{K}_\infty$ via (5.2). Suppose the following:*

(i) *The family of approximate models F_T^a satisfies the following: for any $\Delta > 0$, there exist $N > 0$ and $T^* > 0$ such that, for all $T \in (0, T^*]$ and $x \in \overline{B}_\Delta$, we have*

$$\|F_T^a(x,u) - F_T^a(y,u)\| \le e^{NT}\|x - y\|.$$

(ii) *The family of approximate models F_T^a is semiglobally asymptotically controllable to the origin with vanishing controls.*

(iii) *There exists $C > 0$ such that condition* (5.4) *holds.*

(iv) *Condition* C1 *holds; i.e., there exist $\sigma_1 \in \mathcal{K}_\infty$ and $T^* > 0$ such that, for all x and $T \in (0, T^*]$, we have*

$$\sigma_1(\|x\|) \le W_T^a(x).$$

(v) *Condition* C3 *holds; that is, for any $\Delta > 0$, there exist $T^* > 0$ and $L > 0$ such that*

$$|W_T^a(x) - W_T^a(y)| \le L\|x - y\|$$

for all $x, y \in \overline{B}_\Delta$, $T \in (0, T^*]$.

Then, for the family of systems F_T^a, there exists a solution to the family of optimal control problems

$$\min_{\overline{u} \in \mathcal{U}} \sum_{k=0}^{\infty} Tl_T(\phi_T^a(k, x, \overline{u}), u(k))$$

of the form

$$u(k) = u_T^{a,*}(x(k)) \tag{5.13}$$

such that the following holds:

(i') *The family $(F_T^a, u_T^{a,*})$ is semiglobally practically stable with a Lipschitz Lyapunov function.*

Suppose, moreover, that the following additional conditions hold:

(ii') *The family of approximate models F_T^a is semiglobally consistent with F_T^e.*

(iii') *Condition* C2 *holds; i.e., for any $\Delta > 0$, there exist $T^* > 0$ and $M > 0$ such that, for all $\|x\| \le \Delta$, $T \in (0, T^*)$,*

$$\|u_T^{a,*}(x)\| \le M.$$

Then there exists $\beta_1 \in \mathcal{KL}$ such that, for any strictly positive (D_1, δ), there exists $T^* > 0$ such that, for all $x_\circ \in B_{D_1}$ and all $T \in (0, T^*]$, the solutions of the family $(F_T^e, u_T^{a,*})$ satisfy

$$\|\phi_T^e(k, x_\circ)\| \le \beta_1(\|x_\circ\|, kT) + \delta \qquad \forall k \in \mathbb{N}_0.$$

Proof. We provide only a sketch of the proof since it is very similar to the proof of Theorem 5.4. The only thing to prove is that (i)–(v) imply (i') since the rest of the proof follows immediately from Theorem 4.5.

Note that the condition (v) implies (4.6) and the condition (iv) implies the lower bound in (4.3). The upper bound in (4.3) is established in the same way as that in the proof of Theorem 5.4. The inequality (4.4) is established in the same way as in the proof of Theorem 5.4, which completes the proof. ∎

6. Finite horizon with terminal cost problems. In practice, the optimal control problem under consideration will often not be solved over an infinite time horizon but by using a suitable terminal cost. There are various ways to introduce a terminal cost (see, e.g., [5, sections III.3 and IV.3]), and we believe that our approach can be adjusted in order to cope with most of them. In order to illustrate this procedure, we consider the special type of terminal cost introduced by Kreisselmeier and Birkhölzer in [14].

We consider a family of continuous and positive definite functions $\overline{W}_{T,h} : \mathbb{R}^n \to \mathbb{R}_0^+$ for $T \in (0, T^*]$ and $h \in (0, T]$ and define the following family of finite horizon optimal control problems with terminal costs:

$$W^a_{T,h}(x) := \inf_{\overline{u}\in\mathcal{U},\, k'\in\mathbb{N}_0} \left\{ \sum_{k=0}^{k'-1} Tl_h(\phi^a_{T,h}(k, x, \overline{u}), u(k)) + \overline{W}_{T,h}(\phi^a_{T,h}(k', x, \overline{u})) \right\}. \tag{6.1}$$

Using our continuity assumptions on $F^a_{T,h}$ and l_h in u, it is easily seen that there always exists a feedback law $u^{a,*}_{T,h} : \mathbb{R}^n \to U$ satisfying

$$Tl_h(x, u^{a,*}_{T,h}(x)) + W^a_{T,h}(F^a_{T,h}(x, u^{a,*}_{T,h}(x))) = \min_{u\in U}\{Tl_h(x, u) + W^a_{T,h}(F^a_{T,h}(x, u))\}. \tag{6.2}$$

Moreover, observe that, using (6.2), the dynamic programming equation for $W^a_{T,h}(x)$ reads

$$W^a_{T,h}(x) = \min\{Tl_h(x, u^{a,*}_{T,h}(x)) + W^a_{T,h}(F^a_{T,h}(x, u^{a,*}_{T,h}(x))),\ \overline{W}_{T,h}(x)\}. \tag{6.3}$$

6.1. Stabilization with fixed sampling rate T. In this section, we consider T as an arbitrary but fixed positive sampling rate. In order to derive a stabilization result, we need the following assumption on $\overline{W}_{T,h}$.

Assumption 6.1. The following hold:

(i) $\overline{W}_{T,h}$ is continuous, uniformly in small h.

(ii) There exist $h^* > 0$ and two class $\mathcal{K}_\infty$ functions γ_1 and γ_2 such that the inequality

$$\gamma_1(\|x\|) \le \overline{W}_{T,h}(x) \le \gamma_2(\|x\|) \tag{6.4}$$

holds for all x and $h \in (0, h^*]$.

THEOREM 6.2. *Let strictly positive real numbers (Δ, T) and the family of functions $\overline{W}_{T,h}(\cdot)$ satisfying Assumption* 6.1 *and the family of functions $l_h(\cdot,\cdot)$ satisfying Assumption* 5.1 *be given.*

Suppose the following:

(i) *The family of approximate models $F^a_{T,h}$ satisfies Assumption* 3.2.

(ii) *For any $d > 0$, there exists $h^* > 0$ such that, for all $h \in (0, h^*]$, there exists a solution to the optimization problem* (6.1) *that satisfies*

$$W^a_{T,h}(x) < \overline{W}_{T,h}(x) \qquad \forall x \in B_\Delta - B_d,\ h \in (0, h^*]. \tag{6.5}$$

Then there exists $M > 0$ such that $u^{a,*}_{T,h}(\cdot)$ from (6.2) *satisfies the following properties for $D = \Delta$:*

(i') *The family of controllers $u^{a,*}_{T,h}$ is (T, D, M)-uniformly bounded.*

(ii') *The family $(F^a_{T,h}, u^{a,*}_{T,h})$ is (T, D)-practically stable with a continuous Lyapunov function.*

Suppose, moreover, that the following additional condition holds:

(iii') *The family of approximate models $F^a_{T,h}$ is (T, D, M)-consistent with $F^e_{T,h}$.*

Then there exists $D_1 \in (0, D)$ and $\beta_1 \in \mathcal{KL}$, and, for any $\delta > 0$, there exists $h^* > 0$ such that, for all $x_\circ \in \overline{B}_{D_1}$ and all $h \in (0, h^*]$, the solutions of the family $(F^e_{T,h}, u^{a,*}_{T,h})$ satisfy

$$\|\phi^e_{T,h}(k, x_\circ)\| \le \beta_1(\|x_\circ\|, kT) + \delta \qquad \forall k \in \mathbb{N}_0.$$

Proof. Similar to the proof of Theorem 5.4, the main task is to prove that conditions (i), (ii), and (iii) imply conditions (i') and (ii'). Then, again, the last statement follows immediately from (i'), (ii'), and (iii') via Theorem 4.4.

(i)+(ii)+(iii) $\Rightarrow$ (ii'). We use the optimal value function $W^a_{T,h}(x)$ as a Lyapunov function candidate and verify the conditions (4.3), (4.4), and (4.5) of Definition 4.3 for the family $(F^a_{T,h}, u^{a,*}_{T,h})$.

Let Assumption 6.1 generate $h_1^* > 0$ and $\gamma_1, \gamma_2 \in \mathcal{K}_\infty$. Let Assumption 5.1 generate $h_2^* > 0$ and $\rho_1, \rho_2 \in \mathcal{K}_\infty$. Let (T, Δ) come from conditions of the theorem. Define $D := \Delta$, and let δ_1 be an arbitrarily strictly positive real number.[2] Let d be such that

$$T\rho_2(d) + \gamma_2(e^{LT}d) \le T\delta_1.$$

Let (D, d) generate $h_3^* > 0$ using condition (ii) of the theorem. Let $h^* := \min\{h_1^*, h_2^*, h_3^*\}$. In the rest of the proof, we consider arbitrary $x \in \overline{B}_D$ and $h \in (0, h^*]$.

First, we prove that (4.3) holds. Using the definition of $W^a_{T,h}$, we obtain the inequality

$$W^a_{T,h}(x) \le \overline{W}_{T,h}(x) \ \le \gamma_2(\|x\|) =: \sigma_2(\|x\|).$$

For the lower bound, observe from (6.3) that we have either

$$W^a_{T,h}(x) = \overline{W}_{T,h}(x) \ge \gamma_1(\|x\|)$$

or

$$W^a_{T,h}(x) \ge T l_h(x, u^{a,*}_{T,h}(x)) \ge T\rho_1(\|x\|),$$

and hence

$$W^a_{T,h}(x) \ge \min\{\gamma_1(\|x\|), T\rho_1(\|x\|)\} =: \sigma_1(\|x\|),$$

which completes the proof of (4.3).

Next we show (4.4) for the family $(F^a_{T,h}, u^{a,*}_{T,h})$. From our choice of x and h, for any $x \in B_D - B_d$, we obtain that the "min" in (6.3) is attained in the first term; hence

$$W^a_{T,h}(F^a_{T,h}(x, u^{a,*}_{T,h}(x))) - W^a_{T,h}(x) = -T l_h(x, u^{a,*}_{T,h}(x)). \tag{6.6}$$

For $x \in B_d$, observe that inequality (3.7) and $F^a_{T,h}(0,0) = 0$ imply $\|F^a_{T,h}(x,0)\| \le e^{LT}\|x\|$. Hence from (6.2) we obtain

$$\begin{aligned} T l_h(x, u^{a,*}_{T,h}(x)) + W^a_{T,h}(F^a_{T,h}(x, u^{a,*}_{T,h}(x))) &\le T l_h(x,0) + W^a_{T,h}(F^a_{T,h}(x,0)) \\ &\le T\rho_2(\|x\|) + \gamma_2(e^{LT}\|x\|) \\ &\le T\rho_2(d) + \gamma_2(e^{LT}d) \\ &\le T\delta_1 \ . \end{aligned} \tag{6.7}$$

Since $W^a_{T,h}(x) \ge 0$, this implies

$$W^a_{T,h}(F^a_{T,h}(x, u^{a,*}_{T,h}(x))) - W^a_{T,h}(x) \le -T l_h(x, u^{a,*}_{T,h}(x)) + T\delta_1. \tag{6.8}$$

[2] Like in the previous section, we prove that all conditions of Definition 4.3 hold with $\delta_2 = 0$.

Then, for $x \in B_D$, either (6.6) or (6.8) holds, which implies

$$\begin{aligned} W^a_{T,h}(F^a_{T,h}(x, u^{a,*}_{T,h}(x))) - W^a_{T,h}(x) &\le -Tl_h(x, u^{a,*}_{T,h}(x)) + T\delta_1 \\ &\le -T\rho_1(\|x\|) + T\delta_1 \\ &=: -T\sigma_3(\|x\|) + T\delta_1; \end{aligned}$$

i.e., the desired estimate (4.4) holds.

In order to show the continuity property (4.5), first observe that, by the continuity condition on $\overline{W}_{T,h}$ from Assumption 6.1, for any given $\tilde{\delta} > 0$, we find $\tilde{c} > 0$ such that, for all $x, y \in B_D$ with $\|x - y\| \le \tilde{c}$, we obtain

$$|\overline{W}^a_{T,h}(x) - \overline{W}^a_{T,h}(y)| \le \tilde{\delta}. \tag{6.9}$$

Consider the (arbitrary) $\delta_1 > 0$, which has been chosen above. Then, for any $x \in B_D$, we find a control sequence $\overline{u}$ and a value $\overline{k} \in \mathbb{N}_0$ such that

$$W^a_{T,h}(x) + \delta_1/4 \ge \sum_{k=0}^{\overline{k}-1} Tl_h(\phi^a_{T,h}(k, x, \overline{u}), u(k)) + \overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, x, \overline{u})).$$

Proceeding similarly as in the proof of Theorem 5.4, we find a constant $c > 0$ and, from Lemma A.2, a time $\tau > 0$ such that either $\overline{k} - 1 \le \tau/T$ or, for any $y \in B_D$ with $\|x - y\| \le c$, the inequality

$$W^a_{T,h}(\phi^a_{T,h}(j, y, \overline{u})) \le \delta_1/8$$

holds for some $j \in \mathbb{N}_0$ with $j \le \tau/T$. If $\overline{k} - 1 > \tau/T$ holds, we can exactly follow the proof of Theorem 5.4 to obtain that the implication

$$\|x - y\| \le c \;\Rightarrow\; W^a_{T,h}(y) - W^a_{T,h}(x) \le \delta_1$$

holds. Otherwise, i.e., when $\overline{k} - 1 \le \tau/T$, using the values defined in the proof of Theorem 5.4, for any $y \in B_D$ with $\|x - y\| \le c$, we obtain

$$\begin{aligned} W^a_{T,h}(y) - W^a_{T,h}(x) \le &\sum_{k=0}^{\overline{k}-1} Tl_h(\phi^a_{T,h}(k, y, \overline{u}), u(k)) + \overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, y, \overline{u})) \\ &- \sum_{k=0}^{\overline{k}-1} Tl_h(\phi^a_{T,h}(k, x, \overline{u}), u(k)) - \overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, x, \overline{u})) + \delta_1/4 \\ &\le \delta_1/2 + \delta_1/4 + \overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, y, \overline{u})) - \overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, x, \overline{u})). \end{aligned}$$

Setting $\tilde{\delta}$ from (6.9) equal to $\delta_1/4$, we find $\tilde{c}$ such that

$$\overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, y, \overline{u})) - \overline{W}_{T,h}(\phi^a_{T,h}(\overline{k}, x, \overline{u})) \le \delta_1/4$$

if $\|\phi^a_{T,h}(\overline{k}, x, \overline{u}) - \phi^a_{T,h}(\overline{k}, y, \overline{u})\| \le \tilde{c}$. Using that $\overline{k} - 1 \le \tau/T$ and that the control sequence $u^{a,*}_{T,h}$ is bounded by Lemma A.1, by reducing $c > 0$, if necessary, Lemma A.4 guarantees that $\|x - y\| \le c$ implies $\|\phi^a_{T,h}(\overline{k}, x, \overline{u}) - \phi^a_{T,h}(\overline{k}, y, \overline{u})\| \le \tilde{c}$. Thus, also in the case in which $\overline{k} - 1 \le \tau/T$, we obtain the implication

$$\|x - y\| \le c \;\Rightarrow\; W^a_{T,h}(y) - W^a_{T,h}(x) \le \delta_1.$$

Since the same estimate for $W^a_{T,h}(x) - W^a_{T,h}(y)$ follows by symmetry, this proves (4.5) and thus the proof of (ii').

(i)+(ii)+(iii) $\Rightarrow$ (i'). For $x \in B_D - B_d$, this follows exactly as in the proof of Theorem 5.4, and we have that (5.12) holds. For $x \in B_d$, from inequality (6.7), we obtain

$$T\rho_1(\|u^{a,*}_{T,h}(x)\|) \le Tl_h(x, u^{a,*}_{T,h}(x)) \le T\rho_2(d) + \gamma_2(e^{LT}d),$$

implying that, for all $x \in B_D$ and $h \in (0, h^*]$, we have

$$\|u^{a,*}_{T,h}(x)\| \le \max\left\{\rho_1^{-1}\left(\frac{\sigma_2(D)}{T}\right), \rho_1^{-1}\left(\rho_2(d) + \frac{\gamma_2(e^{LT}d)}{T}\right)\right\} =: M,$$

which completes the proof. □

Remark 6.3. The results of Theorem 6.2 provide a rigorous framework for optimization-based stabilization via a finite horizon with terminal cost problem. The same optimization problem was considered in [14] under the assumption that the exact discrete-time plant model is known. In the same reference in section IV, an inverted pendulum example was successfully stabilized using this method, where the discrete-time model of the plant was obtained by integrating the continuous-time dynamics over one sampling interval. Strictly, the theoretical results of [14] do not directly apply to the example considered since an approximate (instead of exact) discrete-time model was used for the example. Hence our Theorem 6.2 provides a rigorous proof that justifies the use of the approximate discrete-time model for the inverted pendulum example in [14].

6.2. Stabilization with varying sampling rate $T = h$. We now state conditions that guarantee that optimization-based stabilization of sampled-data systems via their approximate discrete-time models with $T = h$ can be successfully carried out. Consider the following version of Assumption 6.1 for $T = h$.

Assumption 6.4. There exists $T^* > 0$ such that the following hold:

(i) $\overline{W}_T$ is continuous, uniformly in $T \in (0, T^*]$.

(ii) There exist two class $\mathcal{K}_\infty$ functions γ_1 and γ_2 such that the inequality

$$\gamma_1(\|x\|) \le \overline{W}_T(x) \le \gamma_2(\|x\|) \tag{6.10}$$

holds for all x and $T \in (0, T^*]$.

THEOREM 6.5. *Let functions $\overline{W}_T(\cdot)$ satisfying Assumption* 6.4 *and $l_T(\cdot,\cdot)$ satisfying Assumption* 5.1 *be given.*

Suppose the following:

(i) *The family of approximate models F^a_T satisfies Assumption* 3.2 *and satisfies that, for each $\Delta > 0$, there exist $\gamma \in \mathcal{K}$ and $T^* > 0$ such that the inequality*

$$\|F_T(x, 0) - x\| \le T\gamma(\|x\|)$$

holds for all $\|x\| \le \Delta$ and all $T \in (0, T^*]$.

(ii) *For any pair of positive real values (D, d), there exists $T^* > 0$ such that, for all $T \in (0, T^*]$, there exists a solution to the optimization problem* (6.1) *that satisfies*

$$W^a_T(x) < \overline{W}_T(x) \qquad \forall x \in B_D - B_d,\ T \in (0, T^*]. \tag{6.11}$$

(iii) *For any $\Delta > 0$, there exist $L > 0$ and $T^* > 0$ such that*

$$|W_T^a(x) - W_T^a(y)| \le L\|x - y\|$$

for all $x, y \in B_\Delta$, $T \in (0, T^*]$.

(iv) *There exist $\sigma_1 \in \mathcal{K}_\infty$ and $T^* > 0$ such that, for all x and $T \in (0, T^*]$, we have*

$$\sigma_1(\|x\|) \le W_T^a(x).$$

Then we have the following:

(i') *The family $(F_T^a, u_T^{a,*})$ is semiglobally stable with a Lipschitz Lyapunov function.*

Suppose, moreover, that the following additional conditions hold:

(ii') *The family of approximate models F_T^a is semiglobally consistent with F_T^e.*

(iii') *The family of controllers $u_T^{a,*}$ is semiglobally uniformly bounded.*

Then there exists $\beta_1 \in \mathcal{KL}$ such that, for any strictly positive (D_1, δ), there exists $T^* > 0$ such that, for all $x_\circ \in \overline{B}_{D_1}$ and all $T \in (0, T^*]$, the solutions of the family $(F_T^e, u_T^{a,*})$ satisfy

$$\|\phi_T^e(k, x_\circ)\| \le \beta_1(\|x_\circ\|, kT) + \delta \qquad \forall k \in \mathbb{N}_0.$$

Proof. It suffices to prove that (i)–(iv) imply (i') because then the statement follows from (i'), (ii'), and (iii') by applying Theorem 4.5.

Since the condition (iii) implies (4.6), for proving (i'), we have only to show (4.3) and (4.4).

Let (D, δ_1) be given.[3] Let $\overline{W}_T$ generate via Assumption 6.4 the functions $\gamma_1, \gamma_2 \in \mathcal{K}_\infty$ and $T_1^* > 0$. Let l_T generate via Assumption 5.1 the functions $\rho_1, \rho_2 \in \mathcal{K}_\infty$ and $T_2^* > 0$. Let the condition (iv) generate σ_1 and $T_3^* > 0$. Let $\Delta = D$ generate via the condition (i) the function $\gamma \in \mathcal{K}$ and $T_4^* > 0$. Let $\Delta_1 = D + \gamma(D)$ generate $L > 0$ and $T_5^* > 0$ via the condition (iii). Let $d > 0$ be such that

$$\rho_2(d) + L\gamma(d) \le \delta_1.$$

Let (D, d) generate $T_6^* > 0$ via the condition (ii). Let $T^* = \min\{1, T_1^*, T_2^*, T_3^*, T_4^*, T_5^*, T_6^*\}$. Consider arbitrary $T \in (0, T^*]$ and $x \in \overline{B}_D$.

In order to prove (4.3), observe that the lower bound follows from the condition (iv), while the upper bound follows immediately from the inequality $W_T^a(x) \le \overline{W}_T(x)$ and Assumption 6.4. Recall from (6.3) that the dynamic programming equation for $W_T^a(x)$ reads

$$W_T^a(x) = \min\{Tl_T(x, u_T^{a,*}(x)) + W_T^a(F_T^a(x, u_T^{a,*}(x))),\ \overline{W}_T(x)\}.$$

For all $T \in (0, T^*]$ and all $x \in \overline{B}_D - \overline{B}_d$, we obtain that the "min" is attained in the first term; hence

$$W_T^a(F_T^a(x, u_T^{a,*}(x))) - W_T^a(x) = -Tl_T(x, u_T^{a,*}(x)). \tag{6.12}$$

[3] We will again prove (4.4) with $\delta_2 = 0$.

For $x \in \overline{B}_d$, recall Assumption (i), which yields $\|F^a_{T,h}(x,0) - x\| \le T\gamma(\|x\|)$. Hence from (6.2) we obtain

$$\begin{aligned} Tl_T(x, u_T^{a,*}(x)) + W_T^a(F_T^a(x, u_T^{a,*}(x))) - W_T^a(x) &\le Tl_T(x,0) + W_T^a(F_T^a(x,0)) - W_T^a(x) \\ &\le T\rho_2(\|x\|) + LT\gamma(\|x\|) \\ &\le T(\rho_2(d) + L\gamma(d)) \ \le \ T\delta_1. \end{aligned} \tag{6.13}$$

Hence, for $x \in \overline{B}_D$, either (6.12) or (6.13) holds, which implies

$$W_T^a(F_T^a(x, u_T^{a,*}(x))) - W_T^a(x) \le -Tl_T(x, u_T^{a,*}(x)) + T\delta_1 \le -T\rho_1(\|x\|) + T\delta_1,$$

i.e., the desired estimate (4.4) with $\alpha_3(r) := \rho_1(r)$. □

7. Conclusion and outlook. Results on optimization-based stabilization of sampled-data systems via approximate discrete-time plant models are presented. Infinite horizon and finite horizon with terminal cost optimization problems were considered. In both cases, it was shown under reasonable assumptions that, when integration period h is independent of the sampling period T, then one can use an approximate discrete-time plant model in the controller design to achieve stability of the exact discrete-time plant model. On the other hand, if $T = h$, then optimization-based stabilization of sampled-data systems via approximate discrete-time models requires much stronger assumptions to produce a stabilizing controller for the exact discrete-time plant model. Several examples are presented to illustrate the most common problems with this approach.

Apart from the optimal control problem we have considered in this paper, one of the most important optimal control techniques is RHC, which is often used in MPC schemes; cf. the references in the introduction. Due to the special structure of RHC and MPC techniques, our results in this paper are not directly applicable. We do, however, think that analysis techniques similar to those we have used here can be applied also to these kinds of controllers. Future research will include the derivation of rigorous results in this direction.

Appendix.

LEMMA A.1. *Let l_h satisfy* (5.2) *with some $\rho_1, \rho_2 \in \mathcal{K}_\infty$, and $h^* > 0$. Then, for any strictly positive (S,T), $h \in (0, h^*]$, and $x \in \mathbb{R}^n, \overline{u} \in \mathcal{U}, \overline{k} \in \mathbb{N}_0$ satisfying*

$$\sum_{k=0}^{\overline{k}} Tl_h(\phi^a_{T,h}(k,x,\overline{u}), u(k)) \le S, \tag{A.1}$$

we have

$$\|\phi^a_{T,h}(k,x,\overline{u})\| + \|u(k)\| \le \rho_1^{-1}(S/T) \qquad \forall k \in \mathbb{N}_0,\ k \le \overline{k}.$$

Proof. Let (A.1) hold, and assume the existence of $k \in \mathbb{N}_0$ with

$$\|\phi^a_{T,h}(k,x,\overline{u})\| + \|u(k)\| > \rho_1^{-1}(S/T).$$

This implies, using (5.2), that

$$Tl_h(\phi^a_{T,h}(k,x,\overline{u}), u(k)) \ge T\rho_1(\|\phi^a_{T,h}(k,x,\overline{u})\| + \|u(k)\|) > S,$$

which contradicts (A.1). □

LEMMA A.2. *Let l_h satisfy (5.2) with some $\rho_1, \rho_2 \in \mathcal{K}_\infty$, and $h^* > 0$. Then, for any pair of strictly positive numbers (C, ε), there exists $\tau = \tau(C, \varepsilon) > 0$ such that, for any $x \in \mathbb{R}^n, \overline{u} \in \mathcal{U}$, any $T > 0$ and $h \in (0, h^*]$, and any $\overline{k} \in \mathbb{N}$ with $\overline{k}T > \tau$ satisfying*

$$\sum_{k=0}^{\overline{k}} T l_h(\phi_{T,h}(k, x, \overline{u}), u(k)) < C, \tag{A.2}$$

there exists $j \in \mathbb{N}_0$ with $j \le \tau/T$ such that $\|\phi^a_{T,h}(j, x, \overline{u})\| + \|u_j\| \le \varepsilon$.

Proof. We define $\tau := C/\rho_1(\varepsilon)$. Now assume $\|\phi^a_{T,h}(j, x, \overline{u})\| + \|u_j\| \ge \varepsilon$ for all $j \in \mathbb{N}_0$ with $j \le \tau/T$. Denoting by $[\tau/T]$ the integer part of τ/T and using (5.2), we can conclude that

$$\begin{aligned}\sum_{k=0}^{\overline{k}} T l_h(\phi^a_{T,h}(k, x, \overline{u}), u(k)) &\ge \sum_{k=0}^{[\tau/T]} T l_h(\phi^a_{T,h}(k, x, \overline{u}), u(k)) \ge [\tau/T + 1] T \rho_1(\varepsilon) \\ &\ge \tau \rho_1(\varepsilon) \ge C,\end{aligned}$$

which contradicts (A.2). ∎

The following lemma is a consequence of the consistency property. Similar results can be found in numerical analysis literature (see, for example [24, Theorems 6.2.1 and 6.2.2]), and the proof is provided below for completeness.

LEMMA A.3. *Let a 4-tuple of strictly positive numbers $(\Delta_1, \Delta_2, T, \tau)$ be given, and let $F^a_{T,h}$ be (T, Δ_1, Δ_2)-consistent with $F^e_{T,h}$. Let Assumption 3.2 hold. Consider any $x \in \mathbb{R}^n, \overline{u} \in \mathcal{U}$ satisfying*

$$kT \in [0, \tau] \Longrightarrow \|\phi^a_{T,h}(k, x, \overline{u})\| \le \Delta_1 \text{ and } \|u(k)\| \le \Delta_2. \tag{A.3}$$

Then, for any $\delta > 0$, there exist strictly positive numbers $h^* = h^*(\Delta_1, \Delta_2, \delta, T) > 0$ and $L = L(\Delta_1, \Delta_2, \delta)$ and $\gamma \in \mathcal{K}$ such that, if $h \in (0, h^*]$, then $kT \in [0, \tau]$ implies that

$$\|\phi^e_{T,h}(k, x, \overline{u})\| \le \Delta_1 + \delta \tag{A.4}$$

and

$$\|\phi^a_{T,h}(k, x, \overline{u}) - \phi^e_{T,h}(k, x, \overline{u})\| \le T\gamma(h) \frac{e^{L(\tau+T)} - 1}{LT}. \tag{A.5}$$

Moreover, an analogous estimate holds if we exchange the roles of $\phi^a_{T,h}$ and $\phi^e_{T,h}$.

Proof. Let all conditions of the lemma hold. Let $L > 0$ be the Lipschitz constant from (3.7) on the set $\overline{B}_{\max\{\Delta_1+\delta, \Delta_2\}}$, and let $\gamma \in \mathcal{K}$ come from the consistency property for the same set. Define

$$h^* = \gamma^{-1}\left(\frac{\delta L}{e^{L(\tau+T)} - 1}\right).$$

Consider now arbitrary $x, \overline{u}$ satisfying (A.3), and let $h \in (0, h^*]$. We abbreviate $x(k)^a = \phi^a_{T,h}(k, x, \overline{u})$, $x(k)^e = \phi^e_T(k, x, \overline{u})$ and show the assertion by induction. For $k = 0$, there is nothing to show. Pick $k \ge 1$ such that $kT \in [0, \tau]$, and assume for the purpose of induction that for the step $k - 1$ the following holds:

$$\|\phi^a_{T,h}(k-1, x, \overline{u}) - \phi^e_T(k-1, x, \overline{u})\| \le \gamma(h) T \sum_{i=0}^{k-1} e^{LTi} \;\le\; \delta. \tag{A.6}$$

We can conclude using Assumption 3.2 and consistency that

$$\begin{aligned}
&\|x(k)^a - x(k)^e\| \\
&= \|F^a_{T,h}(x^a_{k-1}, u_{k-1}) - F^e_{T,h}(x^e_{k-1}, u_{k-1})\| \\
&\leq \|F^a_{T,h}(x^a_{k-1}, u_{k-1}) - F^e_{T,h}(x^a_{k-1}, u_{k-1})\| + \|F^e_{T,h}(x^a_{k-1}, u_{k-1}) - F^e_{T,h}(x^e_{k-1}, u_{k-1})\| \\
&\leq \gamma(h)T + e^{LT}\gamma(h)T\sum_{i=0}^{k-1} e^{LTi} \\
&\leq \gamma(h)T + \gamma(h)T\sum_{i=1}^{k} e^{LTi} \\
&\leq \gamma(h)T\sum_{i=0}^{k} e^{LTi} \ ,
\end{aligned}$$

which shows that (A.6) holds for the step k. Finally, since $T\sum_{i=0}^{k} e^{LTi} \leq \frac{e^{LT(k+1)}-1}{L}$ and because of our choice of h^*, it follows that, for all $h \in (0, h^*]$ and all $kT \in [0, \tau]$, we have

$$\begin{aligned}
\|x(k)^a - x(k)^e\| &\leq T\gamma(h)\frac{e^{L(\tau+T)} - 1}{LT} \\
&\leq \delta,
\end{aligned}$$

which proves that (A.5) holds. Finally, since $x^a_k \in \overline{B}_{\Delta_1}$ for all $kT \in [0, \tau]$ and (A.7) holds, this implies that (A.4) is satisfied, which completes the proof. □

LEMMA A.4. *Let an arbitrary triple of strictly positive numbers (Δ, τ, T) be given. Let $k_0 \in \mathbb{N}$ be such that $k_0 T \in [0, \tau]$. Let Assumption 3.2 hold for the family $F_{T,h}$. Then, for each $\delta > 0$, there exist $c > 0$, $L > 0$, and $h^* > 0$ such that, for each $h \in (0, h^*]$, each two points $x, y \in \mathbb{R}^n$ with $\|x - y\| \leq c$, and each $\overline{u} \in \mathcal{U}$ satisfying*

$$\|\phi_{T,h}(k, x, \overline{u})\| + \|u(k)\| \leq \Delta \quad \forall k = 0, 1, \ldots, k_0,$$

the inequalities

$$\|\phi_{T,h}(k, y, \overline{u})\| \leq \Delta + \delta$$

and

$$\|\phi_{T,h}(k, x, \overline{u}) - \phi_{T,h}(k, y, \overline{u})\| \leq \|x - y\| e^{LTk} \leq \delta$$

hold for all $k = 0, 1, \ldots, k_0$.

Proof. The proof follows with arguments similar to those in the proof of Lemma A.3. □

INDEFINITE STOCHASTIC RICCATI EQUATIONS*

YING HU† AND XUN YU ZHOU‡

Abstract. This paper is concerned with stochastic Riccati equations (SREs), which are a class of matrix-valued, nonlinear backward stochastic differential equations (BSDEs). The SREs under consideration are, in general, indefinite, in the sense that certain parameter matrices are indefinite. This kind of equations arises from the stochastic linear-quadratic (LQ) optimal control problem with random coefficients and indefinite state and control weighting costs, the latter having profound implications in both theory and applications. While the solvability of the SREs is the key to solving the indefinite stochastic LQ control, it remains, in general, an extremely difficult, open problem. This paper attempts to solve the problem of existence and uniqueness of solutions to the indefinite SREs for a number of special, yet important, cases.

Key words. stochastic Riccati equation, backward stochastic differential equation, stochastic linear-quadratic optimal control

1. Introduction.

In this paper, we study the following matrix-valued equation, called a stochastic Riccati equation (SRE), on a finite time horizon $[0,T]$ (the time variable t is suppressed):

(1.1)
$$\begin{cases} dP = -\Big\{P\,A + A'\,P + \sum_{j=1}^{k}(\Lambda_j\,C_j + C_j'\,\Lambda_j + C_j'\,P\,C_j) + Q \\ \qquad\quad - \Big[P\,B + \sum_{j=1}^{k}(C_j'P + \Lambda_j)\,D_j\Big]\,K^{-1}\,\Big[B'P + \sum_{j=1}^{k} D_j'\,(PC_j + \Lambda_j)\Big]\Big\}\,dt \\ \qquad\quad + \sum_{j=1}^{k}\Lambda_j\,dW^j, \qquad t \in [0,\,T], \\ P(T) = H, \\ K = R + \sum_{j=1}^{k} D_j'\,P\,D_j \;>\; 0. \end{cases}$$

Note that the last (matrix) positive definiteness constraint is *part* of the equation that must be satisfied by any solution. Thus, strictly speaking, this is an equation with mixed equality/inequality constraints. The first two constraints constitute what is known as a nonlinear backward stochastic differential equation (BSDE). The unknown of the SRE is the matrix-valued stochastic process $(P(t), \Lambda_1(t), \ldots, \Lambda_k(t))$ adapted to the filtration $\mathcal{F}_t$ that is generated by the underlying Brownian motion $W(t) = (W^1(t), \ldots, W^k(t))$. The coefficients of this equation, $A(t), B(t), C_j(t), D_j(t), Q(t)$, and $R(t)$, are matrix-valued $\mathcal{F}_t$-adapted stochastic processes, and H is an $\mathcal{F}_T$-measurable random matrix.

The SRE (1.1) relates intimately to the following optimal linear-quadratic (LQ) control problem with *random* coefficients:

Minimize the quadratic cost functional

$$J(x_0, u(\cdot)) = E\Big\{ \int_0^T \Big(x(t)'Q(t)x(t) + u(t)'R(t)u(t) \Big)\, dt + x(T)'Hx(T) \Big\}, \tag{1.2}$$

subject to the stochastic linear system dynamics

$$\begin{cases} dx(t) = [A(t)\, x(t) + B(t)\, u(t)\,]\, dt \\ \qquad\qquad + \sum_{j=1}^{k} [C_j(t)\, x(t) + D_j(t)\, u(t)]\, dW^j(t), \qquad t \in [0,\ T], \\ x(0) = x_0. \end{cases} \tag{1.3}$$

In general, if the SRE (1.1) admits a solution, then the LQ problem (1.2)–(1.3) is solvable, and an optimal control can be represented explicitly in terms of the solution to (1.1) (see section 3 for details). Bismut [5] was the first to study the stochastic LQ problem with random coefficients and the associated SRE. Using a fixed-point argument, he proved the existence and uniqueness of solutions to the SRE under the assumptions (among others) that the random coefficients are independent of the Brownian motion and that R is uniformly positive definite and Q and H are positive semidefinite. The definiteness assumption is particularly crucial in proving the result, though the assumption per se seems rather natural because it had been taken for granted in the stochastic LQ literature [3, 4], which was presumably inherited from its deterministic counterpart [2]. Note, however, the SRE investigated by Bismut is not really a BSDE in the sense of Pardoux and Peng [16] since the coefficients are independent of, rather than adapted to, the driving Brownian motion. Later, Peng [17] studied the SRE (1.1) as a nonlinear BSDE, but again under the definiteness condition, i.e., $R > 0$, $Q \geq 0$, $H \geq 0$, in addition to a strong assumption that $D = 0$.

Recently, it was found by Chen, Li, and Zhou [6] that a stochastic LQ problem where R is possibly *indefinite* may still be solvable as long as the corresponding SRE (1.1) is solvable. This finding has triggered an extensive research on the so-called *indefinite* LQ control problem [9, 1, 7, 8, 18]. The problem not only stands out on its own as an interesting theoretical problem, but also has promising applications in practical areas, especially in finance. In the mean-variance portfolio selection [20, 14], or hedging [13], problems, for example, the matrix R is inherently zero, which is a special indefinite case. Moreover, a pollution control model where R is *negative* definite is formulated in [6].

The indefinite stochastic LQ problem leads to an *indefinite* SRE, adding new twists and greater difficulty to the study of the backward SRE, an already hard problem in terms of the existence of its solutions. To make it more precise, in the definite case, i.e., $R > 0$, $Q \geq 0$, $H \geq 0$, the third inequality constraint normally becomes redundant which can therefore be eliminated from consideration. In the indefinite case, though, this constraint becomes a hard one that must be taken care of. In [6], a special case when all the coefficients are deterministic (so the equation reduces to an ordinary differential equation) and $C = 0$ is solved. However, even that case is nontrivial due to the indefiniteness of R. Most of the subsequent research has centered around solving the indefinite SRE, analytically or computationally, with deterministic coefficients [9, 1, 13, 18]. For the case with random coefficients a very special indefinite SRE was solved in [14] where P is scalar-valued, $C_j = Q = 0$, R is a zero matrix, and $H = 1$. This special SRE arises from a mean-variance portfolio selection problem for a market with random parameters. The existence of a solution to this special SRE is proved in [14] using an ad hoc approach. On the other hand,

local solvability (i.e., existence of solution in a small neighborhood of the terminal time) of the general SRE (1.1) is established in [7, 8]. Note, however, that the local solvability is not very useful in view of the LQ control application because the time horizon in a control problem is typically given a priori.

The *global* existence of the general, indefinite SRE (1.1) on the entire time interval $[0, T]$ remains an extremely challenging, if not at all insurmountable, open problem due to the following reasons. First of all, it is a highly nonlinear BSDE, especially in view of the matrix inverse term $(R+D'PD)^{-1}$, for which the normal Lipschitz/linear growth conditions for solvability [16, 15, 19] are not valid. Second, the indefiniteness of R makes possible the singularity of the term $R + D'PD$ when one tries to use the typical approximation scheme to construct a solution. Third, the final constraint in (1.1) must be satisfied by any solution. This is a feature not typically dealt with in the BSDE literature. Finally, (1.1) is a *matrix* equation. Hence certain terms do not commute which adds substantial difficulty to the analysis.

This paper represents the *first* systematic attempt to tackle the indefinite SRE (1.1), where Q, R, and H are all allowed to be indefinite. While the results of this paper are still far away from being a complete solution to the solvability of (1.1) in its greatest generality, we are able to identify some special cases where a global solution is available.

It should be mentioned that, after finishing this work, we have received the preprints [11, 12] by Kohlmann and Tang. In these, Peng's result for definite SRE [17] is improved to the case where R is possibly singular, i.e., $R \geq 0$, $Q \geq 0$, $H \geq 0$, albeit with various other assumptions. The main approach of [11, 12] is an approximation scheme, which does not apply to the indefinite case due to the possible singularity mentioned above.

The remainder of this paper is organized as follows: In section 2, we give preliminaries including two known results needed in the subsequent study. In section 3 we recall the origin of the SRE, namely, the stochastic LQ optimal control problem, via which we also address the uniqueness of solutions to SRE. Sections 4 and 5 are devoted to the study of one-dimensional SREs and higher-dimensional SREs, respectively. Finally, section 6 concludes the paper.

2. Preliminaries. We assume throughout that $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, P)$ is a given complete, filtered probability space and that $W(\cdot)$ is a k-dimensional standard Brownian motion on this space with $W(0) = 0$. In addition, we assume that $\mathcal{F}_t$ is the augmentation of $\sigma\{W(s) \,|\, 0 \leq s \leq t\}$ by all the P-null sets of $\mathcal{F}$.

Throughout this paper, we denote by $\mathbb{R}^{m\times n}$ the set of $m \times n$ real matrices, and by $\mathbb{S}^n$ the set of symmetric $n \times n$ real matrices. If $M = (m_{ij}) \in \mathbb{R}^{m\times n}$, we denote its norm by $||M|| = \sqrt{\sum_{i,j} m_{ij}^2}$. If $M \in \mathbb{S}^n$ is positive (positive semi)definite, we write $M > (\geq)\ 0$. Suppose $\eta : \Omega \to \mathbb{R}^n$ is an $\mathcal{F}_T$-random variable. We write $\eta \in L^2_{\mathcal{F}_T}(\Omega; \mathbb{R}^n)$ if η is square integrable (i.e., $E|\eta|^2 < \infty$), and $\eta \in L^\infty_{\mathcal{F}_T}(\Omega; \mathbb{R}^n)$ if η is uniformly bounded. Consider now the case when $f : [0, T] \times \Omega \to \mathbb{R}^n$ is an $\{\mathcal{F}_t\}_{t\geq 0}$ adapted process. If $f(\cdot)$ is square integrable (i.e., $E\int_0^T |f(t)|^2\, dt < \infty$) we shall write $f(\cdot) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^n)$; if $f(\cdot)$ is uniformly bounded (i.e., ess $\sup_{(t,\omega)\in[0,T]\times\Omega} |f(t)| < \infty$), then $f(\cdot) \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^n)$. If $f(\cdot)$ has (P-a.s.) continuous sample paths and $E \sup_{t\in[0,T]} |f(t)|^2 < \infty$, we write $f(\cdot) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}^n))$. These definitions generalize in the obvious way to the case when $f(\cdot)$ is $\mathbb{R}^{n\times m}$- or $\mathbb{S}^n$-valued. Finally, we say that $N \in L^2_{\mathcal{F}}(0, T; \mathbb{S}^n)$ is positive (positive semi)definite, which is sometimes denoted simply by $N > (\geq)\ 0$, if $N(t, \omega) > (\geq)\ 0$ for a.e. $t \in [0, T]$ and P-a.s. ω, and

we say that N is uniformly positive definite if $N \geq \delta I$ for a.e. $t \in [0, T]$ and P-a.s. ω with some given $\delta > 0$.

DEFINITION 2.1. *A stochastic process* $(P, \Lambda_1, \ldots, \Lambda_k) \in L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{S}^n)) \times \big(L^2_{\mathcal{F}}(0, T; \mathbb{S}^n)\big)^k$ *is called a solution to the SRE* (1.1) *if it satisfies the first equation of* (1.1) *in the Itô sense as well as the second (the terminal condition) and third (the positive definiteness) constraints of* (1.1). *A solution* $(P, \Lambda_1, \ldots, \Lambda_k)$ *of* (1.1) *is called bounded if* $P \in L^\infty_{\mathcal{F}}(0, T; \mathbb{S}^n)$, *and is called positive (positive semi)definite if* $P > (\geq)\, 0$.

Throughout this paper, we impose the following assumptions on the parameters of the SRE (1.1).

Assumption.

(A1)

$$\begin{cases} A,\, C_j \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^{n\times n}), & j = 1, 2, \ldots, k, \\ B,\, D_j \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^{n\times m}), & j = 1, 2, \ldots, k, \\ Q \in L^\infty_{\mathcal{F}}(0, T; \mathbb{S}^n), \\ R \in L^\infty_{\mathcal{F}}(0, T; \mathbb{S}^m), \\ H \in L^\infty_{\mathcal{F}_T}(\Omega; \mathbb{S}^n). \end{cases}$$

In particular, we do not assume that $Q \geq 0$, $R > 0$, or $H \geq 0$. In addition, A, B, C_j, D_j, Q, R, H are random. Later, we shall impose other specific assumptions for various special cases considered in this paper.

Next, we collect two known results needed in our subsequent study of indefinite SREs. The first result, due to Kobylanski [10], concerns the existence of solution and comparison theorem for one-dimensional BSDEs with quadratic growth.

Let $\alpha_0, \beta_0, b \in \mathbb{R}$, and $c : [0, +\infty) \to [0, +\infty)$ be a continuous increasing function. We say that the coefficient F satisfies condition (H1) with α_0, β_0, b, c, if F is continuous, and for all $(t, y, z, \omega) \in [0, +\infty) \times \mathbb{R} \times \mathbb{R}^k \times \Omega$,

$$F(t, y, z, \omega) = a_0(t, y, z, \omega)y + F_0(t, y, z, \omega),$$

where $a_0(\cdot, y, z, \cdot)$ and $F_0(\cdot, y, z, \cdot)$ are $\{\mathcal{F}_t\}_{t\geq 0}$ adapted processes for fixed $(y, z) \in \mathbb{R} \times \mathbb{R}^k$, and

$$\beta_0 \leq a_0(t, y, z, \omega) \leq \alpha_0, \qquad P\text{-a.s. } \omega,$$

$$|F_0(t, y, z, \omega)| \leq b + c(|y|)||z||^2, \qquad P\text{-a.s. } \omega.$$

LEMMA 2.1. *Let* (F, ξ) *be a set of parameters of the following BSDE:*

$$Y(t) = \xi + \int_t^T F(s, Y(s), Z(s))ds - \int_t^T Z(s)dW(s), \qquad 0 \leq t \leq T. \tag{2.1}$$

Suppose that the coefficient F *satisfies* (H1) *with* α_0, β_0, b, c, *and* $\xi \in L^\infty_{\mathcal{F}_T}(\Omega)$. *Then,*

(i) *the BSDE* (2.1) *has at least one solution* $(Y, Z) \in [L^\infty_{\mathcal{F}}(0, T; \mathbb{R}) \cap L^2_{\mathcal{F}}(\Omega; C(0, T; \mathbb{R}))] \times L^2_{\mathcal{F}}(0, T; \mathbb{R}^k)$;

(ii) *there exists a maximal solution* (Y^*, Z^*) *of* (2.1) *in the following sense: For any set of parameters* (G, η), *where* G *satisfies* (H1) *with* α_0, β_0, b, c, *if*

$$F \geq G \text{ and } \xi \geq \eta,$$

then for any solution (Y_G, Z_G) *of the BSDE* (2.1) *with the parameters* (G, η), *one must have*

$$Y^* \geq Y_G.$$

The second result, due to Peng [17, Theorem 5.1], is about the unique solvability of the SRE (1.1) in the definite case (i.e., $Q \geq 0$, $H \geq 0$, $R > 0$), where $D = 0$ is additionally assumed.

LEMMA 2.2. *The following SRE with $Q \geq 0$, $H \geq 0$, $R > 0$,*

$$\begin{cases} dP = -\Big\{P\,A + A'\,P + \sum_{j=1}^{k}(\Lambda_j\,C_j + C_j'\,\Lambda_j + C_j'\,P\,C_j) + Q - P\,BR^{-1}\,B'P\Big\}\,dt \\ \qquad\quad + \sum_{j=1}^{k}\Lambda_j\,dW^j, \qquad t \in [0,\,T], \\ P(T) = H, \end{cases}$$

admits a unique bounded positive semidefinite solution (P, Λ).

3. Stochastic LQ control and uniqueness of solutions to SRE. In this section we recall the connection between the SRE (1.1) and the stochastic LQ control problem. A general result of the uniqueness of solutions to SRE will also be addressed via LQ control.

We first recall the formulation of the stochastic LQ control [6]. Let $(\Omega,\,\mathcal{F},\,\{\mathcal{F}_t\}_{t\geq 0},\,P)$ be a complete filtered probability space on which a k-dimensional standard Brownian motion $W(\cdot)$ is defined such that $\{\mathcal{F}_t\}_{t\geq 0}$ is the natural filtration of $W(t)$ augmented by all the P-null sets of $\mathcal{F}$. For any given $(s,\xi) \in [0,T)\times L^2_{\mathcal{F}_s}(\Omega;\mathbb{R}^n)$, consider the following linear SDE on $[s,T]$:

$$\begin{cases} dx(t) = [A(t)\,x(t) + B(t)\,u(t)\,]\,dt \\ \qquad\quad + \sum_{j=1}^{k}[C_j(t)\,x(t) + D_j(t)\,u(t)]\,dW^j(t), \qquad t \in [s,\,T], \\ x(s) = \xi, \end{cases} \tag{3.1}$$

where A, B, C_j, and D_j are the same parameters as appearing in the SRE (1.1). The class of *admissible controls* is the set $\mathcal{U} = L^2_{\mathcal{F}}(0,\,T;\,\mathbb{R}^m)$. If $u(\cdot) \in \mathcal{U}$ and $x(\cdot)$ is the associated solution of (3.1), then we refer to $(x(\cdot),\,u(\cdot))$ as an *admissible pair*.

Suppose that the cost functional is given by

$$J(s,\xi;u(\cdot)) = E\left\{\int_0^T \Big(x(t)'Q(t)x(t) + u(t)'R(t)u(t)\Big)\,dt + x(T)'Hx(T)\Big|\mathcal{F}_s\right\}. \tag{3.2}$$

Again, Q, R, and H are the same as given in (1.1). To summarize, the *stochastic LQ control problem* associated with (3.1)–(3.2) is as follows:

$$\begin{cases} \min J(s,\xi;u(\cdot)) \\ \text{subject to } (x(\cdot),\,u(\cdot)) \text{ admissible for (3.1).} \end{cases} \tag{3.3}$$

The problem (3.3) is said to be *solvable* if for any $(s,\xi) \in [0,T)\times L^2_{\mathcal{F}_s}(\Omega;\mathbb{R}^n)$ there exists a control $u^*(\cdot) \in \mathcal{U}$ such that

$$-\infty < J(s,\xi;u^*(\cdot)) \leq J(s,\xi;u(\cdot)), \qquad P\text{-a.s. } \omega \quad \forall\, u(\cdot) \in \mathcal{U}.$$

In this case, the control $u^*(\cdot)$ is referred to as an *optimal control*.

Suppose $(P, \Lambda_1, \dots, \Lambda_k)$ is a solution to (1.1). We introduce the following (forward) SDE (the argument t is suppressed):

(3.4)
$$\begin{cases} dx = \Big[A - BK^{-1}(B'P + \sum_{j=1}^k D_j'(P\,C_j + \Lambda_j))\Big]x\,dt \\ \qquad\quad + \sum_{j=1}^k \Big[C_j - D_jK^{-1}(B'P + \sum_{j=1}^k D_j'(P\,C_j + \Lambda_j))\Big]x\,dW^j, \quad t \in [s,\,T], \\ x(s) = \xi. \end{cases}$$

LEMMA 3.1. *Assume that* (A1) *holds. Suppose that the BSDE* (1.1) *has a solution* $(P,\,\Lambda) \in L^\infty_{\mathcal{F}}(0,\,T;\mathbb{R}^{n\times n}) \times L^2_{\mathcal{F}}(0,\,T;\mathbb{R}^{n\times n})^k$, *where* $\Lambda = (\Lambda_1, \dots, \Lambda_k)$, *and the SDE* (3.4) *has a solution* $x(\cdot) \in L^2_{\mathcal{F}}(\Omega;\,C(0,\,T;\,\mathbb{R}^n))$. *Then the stochastic LQ problem* (3.3) *is solvable. A (unique) optimal feedback control is*

$$u^*(t) = -K(t)^{-1}\left[\left(B(t)'P(t) + \sum_{j=1}^k D_j(t)'(P(t)\,C_j(t) + \Lambda_j(t))\right)\,x(t)\right], \tag{3.5}$$

where $K(t) = R(t) + \sum_{j=1}^k D_j(t)'\,P(t)\,D_j(t)$, *and the associated optimal cost is*

$$\inf_{u(\cdot)\in\mathcal{U}} J(s,\xi;u(\cdot)) = \xi'\,P(s)\,\xi, \quad P\text{-a.s. } \omega. \tag{3.6}$$

Proof. This result has been proved in [6, Theorem 3.1] along with [6, Remark 3.1]. The only minor difference is that in [6] the initial state ξ is deterministic, but the argument there works for the case when ξ is $\mathcal{F}_s$-measurable, since ξ is almost surely deterministic under the the probability measure $P(\cdot|\mathcal{F}_s)$. □

THEOREM 3.2. *Assume that* (A1) *holds. If* (1.1) *has two solutions* (P^i, Λ^i), $i = 1, 2$, *such that the corresponding SDE* (3.4) *has solutions* $x_i(\cdot) \in L^2_{\mathcal{F}}(\Omega;\,C(0,\,T;\,\mathbb{R}^n))$, $i = 1, 2$, *then* $(P^1(s), \Lambda^1(s)) = (P^2(s), \Lambda^2(s))$, *P-a.s.* ω, *a.e.* $s \in [0, T]$.

Proof. By Lemma 3.1, $\xi' P^1(s)\xi = \xi' P^2(s)\xi$, for all $(s, \xi) \in [0, T) \times L^2_{\mathcal{F}_s}(\Omega;\mathbb{R}^n)$. Therefore $P^1(s) = P^2(s)$, P-a.s. ω, for all $s \in [0, T]$. Now applying Itô's formula to $|P^1(s) - P^2(s)|^2$ and using their respective equations, we get

$$\begin{aligned} 0 \equiv d|P^1(s) - P^2(s)|^2 &= 2(P^1(s) - P^2(s))d(P^1(s) - P^2(s)) + |\Lambda^1(s) - \Lambda^2(s)|^2 ds \\ &= |\Lambda^1(s) - \Lambda^2(s)|^2 ds. \end{aligned}$$

Hence $\Lambda^1(s) = \Lambda^2(s)$, P-a.s. ω, a.e. $s \in [0, T]$. □

Remark 3.1. Theorem 3.2 essentially gives the uniqueness to the SRE (1.1) among such solutions that (3.4) admits solutions. As stipulated in [6, Remark 3.1] the solvability of (3.4) depends on some moment estimates of its coefficients and may be available in some special cases.

4. Existence: The case when $n = 1$. In this section, we consider the case when $n = 1$ (therefore the unknown P of the SRE (1.1) is a scalar). However, it is still allowed that $m > 1$, $k > 1$. Note that this situation is typically encountered in many financial problems, where the state variable is the wealth, which is scalar-valued; see, e.g., [20, 13, 14].

When $n = 1$, (1.1) reduces to

$$\begin{cases} dP = -\Big\{(2A + \sum_{j=1}^k C_j^2)P + 2\sum_{j=1}^k C_j\Lambda_j + Q \\ \qquad\qquad - \Big[(B + \sum_{j=1}^k C_jD_j)P + \sum_{j=1}^k D_j\Lambda_j\Big]K^{-1} \\ \qquad\qquad \times \Big[(B' + \sum_{j=1}^k C_jD_j')P + \sum_{j=1}^k D_j'\Lambda_j\Big]\Big\}dt \\ \qquad + \sum_{j=1}^k \Lambda_j dW^j, \qquad t \in [0,\, T], \\ P(T) = H, \\ K = R + P\sum_{j=1}^k D_j'D_j > 0. \end{cases} \tag{4.1}$$

Let us set

$$\alpha = 2A + \sum_{j=1}^k C_j^2, \qquad \beta \equiv (\beta_1, \beta_2, \dots, \beta_k)' = (2C_1, 2C_2, \dots, 2C_k)',$$
$$\Gamma = B + \sum_{j=1}^k C_jD_j, \quad D = (D_1', D_2', \dots, D_k')', \quad \Lambda = (\Lambda_1, \Lambda_2, \dots, \Lambda_k).$$

Then, the above equation can be rewritten as

$$\begin{cases} dP = -\Big\{\alpha P + \Lambda\beta + Q - (\Gamma P + \Lambda D)(R + PD'D)^{-1}(\Gamma P + \Lambda D)'\Big\}dt \\ \qquad + \Lambda dW, \qquad t \in [0, T], \\ P(T) = H, \\ R + PD'D > 0. \end{cases} \tag{4.2}$$

4.1. Standard case. The standard case (i.e., $H \geq 0$, $R > 0$, $Q \geq 0$) can be treated as an application of Lemma 2.1. In fact, we are going to study this case for a generalized version of (4.2), which in turn will be useful for the case when R is possibly indefinite (see section 4.3 below). To be specific, we add a parameter Δ, which is an m-dimensional-row-vector-valued, essentially bounded $\mathcal{F}_t$-adapted process, in (4.2):

$$\begin{cases} dP = -\Big\{\alpha P + \Lambda\beta + Q \\ \qquad - (\Gamma P + \Lambda D + \Delta)(R + PD'D)^{-1}(\Gamma P + \Lambda D + \Delta)'\Big\}dt \\ \qquad + \Lambda dW, \qquad t \in [0, T], \\ P(T) = H, \\ R + PD'D > 0. \end{cases} \tag{4.3}$$

THEOREM 4.1. *Assume that $H \geq 0$, $R > 0$, $D'D > 0$, $Q - \Delta R^{-1}\Delta' \geq 0$, $R^{-1} \in L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{m\times m})$, and $(D'D)^{-1} \in L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{m\times m})$. Then* (4.3) *admits a bounded nonnegative solution. In particular, the Riccati equation* (4.2) *admits a bounded nonnegative solution if $H \geq 0$, $R > 0$, $D'D > 0$, $Q \geq 0$, $R^{-1} \in L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{m\times m})$, and $(D'D)^{-1} \in L^\infty_{\mathcal{F}}(0,\, T; \mathbb{R}^{m\times m})$.*

Proof. Let us consider the following equation:

$$\begin{cases} dP = -F(t, P, \Lambda)dt + \Lambda dW, \qquad t \in [0, T], \\ P(T) = H, \end{cases} \tag{4.4}$$

where

$$\begin{aligned} &F(t, P, \Lambda) \\ &\quad = \alpha(t)P + \Lambda\beta(t) + Q(t) \\ &\qquad - (\Gamma(t)P^+ + \Lambda D(t) + \Delta(t))(R + P^+D'D)^{-1}(\Gamma(t)P^+ + \Lambda D(t) + \Delta(t))'. \end{aligned}$$

In the above, $P^+ = \max(P, 0)$. Noting the following inequalities (by virtue of the assumptions that $R > 0$ and $D'D > 0$),

$$||(R + P^+D'D)^{-1}|| \le ||R^{-1}||, \qquad ||(R + P^+D'D)^{-1}|| \le \frac{||(D'D)^{-1}||}{|P^+|} \ \text{(for } P \neq 0),$$

we can easily check that (4.4) satisfies the assumption of Lemma 2.1. Hence it admits a bounded maximal solution (P, Λ). Moreover, we have (t is suppressed)

$$\begin{aligned} F(t, P, \Lambda) = {} & \alpha P + \Lambda\beta + Q - 2\Delta(R + P^+D'D)^{-1}(\Gamma P^+ + \Lambda D)' \\ & + \Delta[R^{-1} - (R + P^+D'D)^{-1}]\Delta' \\ & - (\Gamma P^+ + \Lambda D)(R + P^+D'D)^{-1}(\Gamma P^+ + \Lambda D)' \\ & + Q - \Delta R^{-1}\Delta'. \end{aligned}$$

On the other hand, the following BSDE

$$\begin{cases} dP = -\Big\{\alpha P + \Lambda\beta - 2\Delta(R + P^+D'D)^{-1}(\Gamma P^+ + \Lambda D)' \\ \qquad + \Delta[R^{-1} - (R + P^+D'D)^{-1}]\Delta' \\ \qquad - (\Gamma P^+ + \Lambda D)(R + P^+D'D\ )^{-1}(\Gamma P^+ + \Lambda D)'\Big\}dt \\ \qquad + \Lambda dW, t \in [0, T], \\ P(T) = 0 \end{cases}$$

satisfies the assumption of Lemma 2.1 and admits a bounded solution $(0, 0)$. Applying Lemma 2.1(ii) to (4.4), we deduce that $P \ge 0$. Hence, P is also a bounded nonnegative solution of (4.3). The assertion regarding the original equation (4.2) is straightforward. □

4.2. Case when $R = 0$. The case when $R = 0$ is studied in [14] under the additional assumptions that $C = 0$ (i.e., $\beta = 0$) and $Q = 0$, which arises naturally in a mean-variance portfolio selection problem. Now we discuss this case without those additional assumptions.

When $R = 0$, (4.2) specializes to

$$\begin{cases} dP = -\Big\{\alpha P + \Lambda\beta + Q - \frac{1}{P}(\Gamma P + \Lambda D)(D'D)^{-1}(\Gamma P + \Lambda D)'\Big\}dt \\ \qquad + \Lambda dW, \qquad t \in [0, T], \\ P(T) = H, \\ P > 0. \end{cases} \tag{4.5}$$

The key idea is that if (4.5) has a bounded solution, then, assuming that $H > 0$, $H^{-1} \in L^\infty(\Omega, \mathcal{F}_T, P; \mathbb{R})$, and $D'D > 0$, $(D'D)^{-1} \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^{m\times m})$, the process $(Y, Z) = (\frac{1}{P}, -\frac{\Lambda}{P^2})$ should satisfy the following equation (by virtue of the Itô formula):

$$\begin{cases} dY = -\Big\{[\Gamma(D'D)^{-1}\Gamma' - \alpha]Y + Z[\beta - 2D(D'D)^{-1}\Gamma] \\ \qquad\qquad - QY^2 - \frac{Z[D(D'D)^{-1}D' - I]Z'}{Y}\Big\}dt \\ \qquad + ZdW, \qquad t \in [0, T], \\ Y(T) = \frac{1}{H}. \end{cases} \tag{4.6}$$

THEOREM 4.2. *Suppose that $H > 0$, $H^{-1} \in L^\infty(\Omega, \mathcal{F}_T, P; \mathbb{R})$, $Q \ge 0$, $m = k$, and that $D'D > 0$, $(D'D)^{-1} \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}^{m\times m})$. Then (4.5) admits a unique bounded, uniformly positive solution.*

Proof. Since $m = k$ and D is invertible, the last term of the drift coefficient of (4.6) vanishes. Thus (4.6) is a type of SRE (1.1) for which Lemma 2.2 applies. So it has a unique bounded nonnegative solution. Rewrite this equation as

$$\begin{cases} dY = -\Big\{[\Gamma(D'D)^{-1}\Gamma' - \alpha - QY]Y + Z[\beta - 2D(D'D)^{-1}\Gamma]\Big\}dt \\ \qquad\quad + ZdW, \qquad t \in [0,T], \\ Y(T) = \frac{1}{H}. \end{cases} \tag{4.7}$$

Put

$$\tilde{\alpha} = \Gamma(D'D)^{-1}\Gamma' - \alpha - QY, \quad \tilde{\beta} = \beta - 2D(D'D)^{-1}, \quad \tilde{W}_t = W_t - \int_0^t \tilde{\beta}(s)ds.$$

Then from the well-known Girsanov theorem, $\tilde{W}$ is a Brownian motion under a certain probability measure $\tilde{P}$. The above equation now becomes

$$\begin{cases} dY = -\tilde{\alpha}Y dt + Z d\tilde{W}, \qquad t \in [0,T], \\ Y(T) = \frac{1}{H}. \end{cases}$$

Hence,

$$Y(t) = \tilde{E}\left(\frac{1}{H} e^{\int_t^T \tilde{\alpha}_s ds} | \mathcal{F}_t\right) \geq \frac{1}{||H||_\infty} e^{-||\tilde{\alpha}||_\infty (T-t)} \geq \frac{1}{||H||_\infty} e^{-||\tilde{\alpha}||_\infty T} > 0.$$

Thus we can set

$$(P, \Lambda) = \left(\frac{1}{Y}, -\frac{Z}{Y^2}\right).$$

Applying Itô's formula, we deduce easily that (P, Λ) is a bounded solution of (4.5) with P uniformly positive. Finally, the uniqueness follows from that of (4.7). □

Remark 4.1. Under the assumption that $D'D$ is invertible, it is necessary that $m \leq k$ ($m = \text{rank}(D'D) \leq \text{rank } D \leq k$). When $m < k$, it means that, in the context of the stochastic control that leads to the SRE (1.1), the number of the independent controllable directions is less than that of the independent random sources. In the special case of a stochastic market, $m < k$ implies that the number of the stocks available for selection is less than that of the independent random sources that constitute the market or, in other words, the market is incomplete. Hence, assuming $m = k$ (and $D'D$ is invertible) really stipulates that we are in the realm of the complete market in the context of the finance problem. On the other hand, when $m < k$, then (4.6) suggests that one should handle the last term of its drift coefficient (in particular, the matrix-valued process $I - D(D'D)^{-1}D'$, which is only positive semidefinite with possible zero eigenvalues).

Remark 4.2. In [11], results similar to Theorems 4.1 and 4.2 are derived using approximation techniques which are quite involved. Here we provide completely different yet much simpler proofs. It should be emphasized, however, that our ultimate objective is to prove the existence for some indefinite SREs, for which Theorems 4.1 and 4.2 will be utilized. See the next subsection for details.

4.3. Case when R is indefinite. The case with an indefinite R is more complicated. Unfortunately we are able to only treat the case when $m = k = 1$. In this

case, (4.2) further simplifies to

$$\begin{cases} dP = -\Big\{\alpha P + \Lambda\beta + Q - \frac{(\Gamma P+\Lambda D)^2}{R+D^2P}\Big\}dt + \Lambda dW, \qquad t \in [0,T], \\ P(T) = H, \\ R + D^2P > 0, \end{cases} \tag{4.8}$$

where

$$\alpha = 2A + C^2, \qquad \beta = 2C, \qquad \Gamma = B + CD.$$

In this subsection we give two sets of sufficient conditions that guarantee the solvability of the Riccati equation (4.8).

THEOREM 4.3. *Assume that* $\Gamma = 0$, $D \neq 0$, $Q - \frac{\alpha R}{D^2} \geq 0$, $\frac{R}{D^2} + H > 0$, *and* $(\frac{R}{D^2} + H)^{-1} \in L^\infty(\Omega, \mathcal{F}_T, P; \mathbb{R})$. *Moreover, assume that* $\frac{R}{D^2}$ *is constant. Then the Riccati equation* (4.4) *admits a unique bounded solution.*

Proof. Let us consider the following BSDE:

$$\begin{cases} dY = -\Big\{ -\alpha Y + \beta Z - (Q - \frac{\alpha R}{D^2})Y^2\Big\}dt + ZdW, \qquad t \in [0,T], \\ Y(T) = \frac{D^2}{R+HD^2}. \end{cases}$$

As in the proof of Theorem 4.2, this equation has a unique bounded solution by virtue of the assumptions. Moreover, we can prove in the same manner that there exists a constant $\delta > 0$ such that $Y \geq \delta$. Now, we set

$$(P, \Lambda) = \left(\frac{1}{Y} - \frac{R}{D^2}, -\frac{Z}{Y^2}\right).$$

Applying Itô's formula and noting that $\frac{R}{D^2}$ is constant, we deduce easily that (P, Λ) is a solution of (4.4), which is bounded. The uniqueness comes from the inverse procedure. □

Remark 4.3. From the above result we can see that the SRE may admit a solution even when *both* Q and R are negative. (In the context of the stochastic LQ control, this amounts to saying that an LQ control may be solvable even when both the running state and control costs are negative.) To see this, take an example where all the assumptions of Theorem 4.3 are satisfied. Moreover, let $\alpha = 2A + C^2 > 0$. Then we see that the critical condition $Q - \frac{\alpha R}{D^2} \geq 0$ may be satisfied even when both Q and R are negative (but then H must be positive and large enough).

In the above result it is assumed that $\Gamma \equiv B + CD = 0$, which is rather strict. The next theorem replaces this condition by others.

THEOREM 4.4. *Assume that there exists a constant* $\epsilon > 0$ *such that*

$$|D| > 0, \;\; H + \frac{R}{D^2} \geq \epsilon, \quad Q + \alpha\left(\epsilon - \frac{R}{D^2}\right) - \frac{\Gamma^2(\epsilon - \frac{R}{D^2})^2}{D^2\epsilon} \geq 0. \tag{4.9}$$

Moreover, assume that $\frac{R}{D^2}$ *is constant, and* $D^{-1} \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R})$. *Then there exists a bounded solution for the Riccati equation* (4.8).

Proof. Consider the following Riccati equation:

$$\begin{cases} dY = -\Big\{\alpha Y + \beta Z + Q + \alpha(\epsilon - \frac{R}{D^2}) - \frac{[\Gamma Y + \Lambda D + \Gamma(\epsilon - \frac{R}{D^2})]^2}{D^2\epsilon + D^2 Y}\Big\}dt \\ \qquad\quad + ZdW, \qquad t \in [0,T], \\ Y(T) = H + \frac{R}{D^2} - \epsilon. \end{cases}$$

This equation is of the same type as (4.3) with $\Delta = \Gamma(\epsilon - \frac{R}{D^2})$. The assumption of Theorem 4.1 is satisfied due to (4.9). Thus by Theorem 4.1 the above equation admits a bounded nonnegative solution $(Y, Z) \in L^\infty_{\mathcal{F}}(0, T; \mathbb{R}) \times L^2_{\mathcal{F}}(0, T; \mathbb{R})$.

We set

$$(P, \Lambda) = \left(Y + \epsilon - \frac{R}{D^2}, Z \right).$$

It is straightforward to verify that (P, Λ) is a bounded solution of the Riccati equation (4.4). Moreover, since $\frac{R}{D^2}$ is a constant, the solution $P = Y + \epsilon - \frac{R}{D^2}$ is bounded. □

Remark 4.4. Condition (4.9) gives the overall requirement for the coefficients of the SRE in order for it to admit a solution. The positiveness/nonnegativeness of *individual* coefficients is no longer required.

Example 4.1. Let us take an example to illustrate Theorem 4.4. Take $H \equiv 1$, $D \equiv 1$, and R being negative with $1 + R \geq \epsilon$. In this case, the conditions (4.9) specialize to

$$Q + (\epsilon - R) \left(\alpha - \Gamma^2 + \frac{R\Gamma^2}{\epsilon} \right) \geq 0. \tag{4.10}$$

Now if $\alpha \equiv 2A + C^2 \leq \Gamma^2 \equiv (B + C)^2$, then Q has to be positive in order for the above inequality holds. However, if $\alpha > \Gamma^2$, then Q can also be negative while still satisfying (4.10). Indeed, as long as $\alpha > \frac{\Gamma^2}{\epsilon}$ one can show that $(\epsilon - R)(\alpha - \Gamma^2 + \frac{R\Gamma^2}{\epsilon}) > 0$. Hence there is some room for Q to be negative.

5. Existence: The case when $n > 1$. In this section, we will investigate the case when the unknown P is a matrix. For technical reasons, we assume that $k = 1$ and $m = n$. Note that even in the standard case (i.e., $Q \geq 0$, $H \geq 0$, $R > 0$), the solvability of the Riccati equation remains generally unsolved. In this section we shall study two cases where $R = 0$ and R is indefinite, respectively.

5.1. Case when $R = 0$. In this subsection, we treat the case when $R = 0$. We need to assume in addition that $C = 0$.

First we have the following technical lemma.

LEMMA 5.1. *We have the following assertions.*

(i) *If X is a square matrix, then $X + X' + 2||X||I \geq 0$.*

(ii) *If X is a positive definite matrix, then $X^{-1} - ||X||^{-1} I \geq 0$.*

Proof. (i) For any column vector x of appropriate size, we have by the Cauchy–Schwarz inequality

$$-(x'Xx + x'X'x) \leq |x'Xx| + |x'X'x| \leq 2||x||^2||X||,$$

or equivalently

$$x'(X + X' + 2||X||I)x \geq 0 \qquad \forall x.$$

This proves the claim.

(ii) For any column vector x of appropriate size, again by the Cauchy–Schwarz inequality

$$(X^{-\frac{1}{2}}x)'X(X^{-\frac{1}{2}}x) \leq ||X||||X^{-\frac{1}{2}}x||^2 = ||X||(x'X^{-1}x),$$

or equivalently

$$x'(X^{-1} - ||X||^{-1}I)x \geq 0 \qquad \forall x.$$

This proves the claim. □

THEOREM 5.2. *Suppose that $Q \geq 0$, $H > 0$, $H^{-1} \in L^{\infty}_{\mathcal{F}_T}(\Omega; \mathbb{S}^n)$, D is nonsingular, and $D^{-1} \in L^{\infty}_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n})$. Then the Riccati equation* (5.1) *admits a unique bounded, uniformly positive definite solution.*

Proof. Let us first assume that $D \equiv I$. Then the Riccati equation becomes

(5.1)
$$\begin{cases} dP = -\Big\{PA + A'P + Q - (PB + \Lambda)P^{-1}(B'P + \Lambda)\Big\}dt + \Lambda dW, \quad t \in [0,T], \\ P(T) = H, \\ P > 0. \end{cases}$$

Consider the following BSDE:

$$\begin{cases} dY = -\Big\{ - AY - YA' - BZ - ZB' + BYB' - YQY\Big\}dt + ZdW, \quad t \in [0,T], \\ Y(T) = H^{-1}. \end{cases}$$

This equation admits a unique bounded positive semidefinite solution according to Lemma 2.2. Rewrite the equation as

$$\begin{cases} dY = -\Big\{Y\tilde{A} + \tilde{A}'Y + \tilde{C}'Y\tilde{C} + Z\tilde{C} + \tilde{C}'Z\Big\}dt + ZdW, \qquad t \in [0,T], \\ Y(T) = H^{-1}, \end{cases} \tag{5.2}$$

where $\tilde{A} = -A' - \frac{1}{2}QY$ and $\tilde{C} = -B'$.

We need to prove that $Y > 0$. To this end, introduce

$$\bar{Y} = ||H||_{\infty}^{-1} e^{-2(T-t)||\tilde{A}||_{\infty}} I, \qquad \bar{Z} = 0,$$

where

$$||\tilde{A}||_{\infty} = \operatorname{esssup}_{(t,\omega)} ||\tilde{A}(t,\omega)||, \qquad ||H||_{\infty} = \operatorname{esssup}_{\omega} ||H(\omega)||.$$

Then $(\bar{Y}, \bar{Z})$ is a bounded solution of the following BSDE:

$$\begin{cases} d\bar{Y} = -\Big\{ - 2||\tilde{A}||_{\infty}\bar{Y} + \bar{Z}\tilde{C} + \tilde{C}'\bar{Z}\Big\}dt + \bar{Z}dW, \qquad t \in [0,T], \\ \bar{Y}(T) = ||H||_{\infty}^{-1} I. \end{cases}$$

Now we put

$$\hat{Y} = Y - \bar{Y}, \quad \hat{Z} = Z - \bar{Z}.$$

Then $(\hat{Y}, \hat{Z})$ satisfies the following BSDE:

$$\begin{cases} d\hat{Y} = -\Big\{\hat{Y}\tilde{A} + \tilde{A}'\hat{Y} + \hat{Z}\tilde{C} + \tilde{C}'\hat{Z} + \tilde{C}'\bar{Y}\tilde{C} \\ \qquad\qquad + \bar{Y}(\tilde{A} + \tilde{A}' + 2||\tilde{A}||_{\infty} I)\Big\}dt + \hat{Z}dW, \qquad t \in [0,T], \\ \hat{Y}(T) = H^{-1} - ||H||_{\infty}^{-1} I. \end{cases}$$

By Lemma 5.1, we have

$$\tilde{A}(t,\omega)+\tilde{A}'(t,\omega)+2||\tilde{A}||_\infty I\geq 0 \qquad \forall(t,\omega)$$

and

$$H(\omega)^{-1}-||H||_\infty^{-1}I\geq 0 \qquad \forall\omega.$$

It follows then from Lemma 2.2 that

$$\hat{Y}\geq 0,$$

namely,

$$Y\geq \bar{Y}>0.$$

Now set

$$(P,\Lambda)=(Y^{-1},-Y^{-1}ZY^{-1}).$$

It is easy to check, via the Itô formula, that (P,Λ) is a bounded, uniformly positive definite solution of (5.1). Again, the uniqueness follows from the inverse procedure.

Now, for a general nonsingular D, the Riccati equation can be rewritten as

$$\begin{cases} dP=-\Big\{PA+A'P+Q-(PBD^{-1}+\Lambda)P^{-1}((D^{-1})'B'P+\Lambda)\Big\}dt \\ \qquad\quad +\Lambda dW, \qquad t\in[0,T], \\ P(T)=H, \\ P>0. \end{cases}$$

This is in the same form of (5.1). The proof is completed. □

5.2. Case when $B=0$, $C=0$. In this subsection we study another special case when $B=0$, $C=0$. We also need to assume that R is a constant matrix. However, R is allowed to be *indefinite*.

THEOREM 5.3. *Assume that $Q-RA-A'R\geq 0$, $R+H>0$, $(R+H)^{-1}\in L^\infty(\Omega,\mathcal{F}_T,P;\mathbb{S}^n)$, D is nonsingular, and $D^{-1}\in L^\infty_{\mathcal{F}}(0,T;\mathbb{R}^{n\times n})$. Then the Riccati equation* (5.3) *admits a unique bounded solution.*

Proof. First let us take $D=I$. Then the Riccati equation under consideration is

$$\begin{cases} dP=-\Big\{PA+A'P+Q-\Lambda(R+P)^{-1}\Lambda\Big\}dt+\Lambda dW, \qquad t\in[0,T], \\ P(T)=H, \\ R+P>0. \end{cases} \tag{5.3}$$

Consider the following BSDE:

$$\begin{cases} dY=-\Big\{-AY-YA'-Y(Q-RA-A'R)Y\Big\}dt+ZdW, \qquad t\in[0,T], \\ Y(T)=(R+H)^{-1}. \end{cases} \tag{5.4}$$

By Lemma 2.2, this equation admits a unique bounded solution $(Y,Z)\in L^\infty_{\mathcal{F}}(0,T;\mathbb{S}^n)\times L^2_{\mathcal{F}}(0,T;\mathbb{S}^n)$. As in the proof of the preceding theorem, there exists a

constant $c > 0$, such that $Y \geq cI$. Hence we may set $(P, \Lambda) = (Y^{-1} - R, -Y^{-1}ZY^{-1})$. It is easy to verify via the Itô formula that (P, Λ) is a bounded solution of (5.3). On the other hand, the uniqueness comes from the inverse procedure.

Now for a general nonsingular D, the Riccati equation can be rewritten as

$$\begin{cases} dP = -\Big\{PA + A'P + Q - \Lambda((D^{-1})'RD^{-1} + P)^{-1}\Lambda\Big\}dt + \Lambda dW, \qquad t \in [0, T], \\ P(T) = H, \\ (D^{-1})'RD^{-1} + P > 0. \end{cases}$$

This is in the same form of (5.3), which completes the proof. □

Remark 5.1. In [12] the unique solvability of a *definite* SRE is proved under the assumptions (among others) that $B = C = 0$ and R is uniformly positive definite.

6. Concluding remarks. In this paper we have investigated the stochastic Riccati equation (1.1) with random coefficients where the matrix-valued stochastic processes Q, R, and H are possibly indefinite. The existence of its solution is a prerequisite for solving the corresponding indefinite stochastic linear-quadratic control problem, which in turn has important applications in many applied areas especially in finance. Here we have identified several special cases where the existence is proved. The general global existence remains an extremely challenging open problem.

Acknowledgment. We thank the two anonymous referees for their careful reading of an earlier version of the paper and for their helpful comments.

SUFFICIENT SECOND-ORDER OPTIMALITY CONDITIONS FOR A PARABOLIC OPTIMAL CONTROL PROBLEM WITH POINTWISE CONTROL-STATE CONSTRAINTS*

A. RÖSCH† AND F. TRÖLTZSCH†

Abstract. An optimal control problem for a semilinear parabolic equation is investigated, where pointwise constraints are given on the control and the state. The state constraints are of mixed (bottleneck) type, where associated Lagrange multipliers can be assumed to be bounded and measurable functions. Based on this property, a second-order sufficient optimality condition is established that considers strongly active constraints.

Key words. optimal control, heat equation, parabolic differential equation, sufficient second-order optimality condition, pointwise mixed control-state constraints, bottleneck constraints

1. Introduction.

In this paper we consider the optimal control problem to minimize

(1.1)
$$F(y,u) = \int_\Omega \omega(x, y(T,x))\, dx + \int_\Sigma \sigma(t,x,y(t,x),u(t,x))\, d\Gamma dt + \int_Q q(t,x,y(t,x))\, dxdt$$

subject to the state equations

$$\begin{aligned} y_t + Ay &= 0 && \text{in } Q = (0,T)\times\Omega, \\ \partial_n y &= b(t,x,y,u) && \text{in } \Sigma = (0,T)\times\Gamma, \\ y(0,x) &= y_o(x) && \text{in } \Omega \end{aligned} \tag{1.2}$$

and subject to the mixed control-state constraints

$$0 \le u(t,x) \le c(t,x) + \gamma(t,x)y(t,x) \quad \text{for } (t,x)\in\Sigma. \tag{1.3}$$

The main task of our paper is to establish second-order sufficient optimality conditions that are close to the associated necessary ones. For control-constrained problems, this issue was discussed quite completely in literature for semilinear elliptic and parabolic equations. We mention Bonnans [3], Casas, Tröltzsch, and Unger [5], Goldberg and Tröltzsch [8], and Heinkenschloss and Tröltzsch [9].

The main difficulty in our problem is the presence of the pointwise control-state constraint $u(t,x) \le c(t,x) + \gamma(t,x)y(t,x)$ in (1.3). If pointwise state constraints are given, then the theory of sufficient second-order conditions is faced with specific difficulties that are still far from being solved. In particular, these problems arise for pointwise state constraints of the type $y(t,x) \le c$. Here, the difficulties are caused by the low regularity of Lagrange multipliers associated with the pointwise state

constraints. The multipliers are Borel measures. We refer to Casas, Tröltzsch, and Unger [6] and Raymond and Tröltzsch [12].

In our problem (1.1)–(1.3), the situation is slightly simpler, since the constraint (1.3) is a *mixed* control-state constraint of bottleneck type. In this case, the Lagrange multipliers are more regular, and they can be assumed to be functions of $L^\infty(\Sigma)$; see Bergounioux and Tröltzsch [2] or Arada and Raymond [1].

Higher regularity of the multipliers is the main advantage enabling us to establish second-order conditions. Moreover, the second-order conditions should require minimum assumptions, i.e., they should be as close as possible to associated necessary conditions. Often, this task is accomplished by considering strongly active sets (see [7] for control-constrained optimal control of ordinary differential equations). Here, we extend this technique to our case of mixed constraints. Our analysis will show that this is by far not an easy problem. It indicates again that pointwise state constraints of more general type will give rise to even more difficult techniques. Our paper extends the results of [15], where second-order conditions were derived for a weakly singular integral state equation. This problem covered the one-dimensional parabolic case.

The paper is organized as follows: In section 2 we formulate first- and second-order optimality conditions and state the main result. Section 3 contains several auxiliary results. The proof that our second-order conditions are sufficient for local optimality is presented in section 4.

In the paper we use the following notations: By $b'(t,x,y,u)$ and $b''(t,x,y,u)$ we denote the gradient and the Hessian matrix of b with respect to (y,u):

$$b'(t,x,y,u) = \begin{pmatrix} b_y(t,x,y,u) \\ b_u(t,x,y,u) \end{pmatrix}, \quad b''(t,x,y,u) = \begin{pmatrix} b_{yy}(t,x,y,u) & b_{yu}(t,x,y,u) \\ b_{yy}(t,x,y,u) & b_{uu}(t,x,y,u) \end{pmatrix}.$$

Here, the notations $b_y(t,x,y,u) = D_y b(t,x,y,u)$ and $b_{yy}(t,x,y,u) = D_{yy} b(t,x,y,u)$ are used. The norms $|b'|$, $|b''|$ are defined by adding the absolute values of all entries of b' and b'', respectively. By ∂_n we denote the outward normal derivative at Γ.

The following assumptions are required:

(A1) The function $b : \Sigma \times \mathbb{R}^2 \to \mathbb{R}$, $b = b(t,x,y,u)$, satisfies the following Carathéodory condition: b is of class C^2 with respect to (y,u). Moreover, for all $(y,u) \in \mathbb{R}^2$, it is measurable with respect to (t,x).

For all $M > 0$, there are a constant $C_M > 0$ and a continuous, monotone increasing function $\eta \in C(\mathbb{R}^+ \cup \{0\})$ with $\eta(0) = 0$ such that:

$$|b(t,x,0,0)| + |b'(t,x,0,0)| + |b''(t,x,0,0)| \le C_M,$$
$$|b''(t,x,y_1,u_1) - b''(t,x,y_2,u_2)| \le \eta(|y_1 - y_2| + |u_1 - u_2|)$$

for almost all (t,x) and all $|y|, |u|, |y_1|, |y_2|, |u_1|, |u_2| \le M$. The same conditions are imposed for $\sigma = \sigma(t,x,y,u)$.

In addition, we suppose on $\Sigma \times \mathbb{R}^2$ that

$$b_u(t,x,y,u) \ge 0, \quad b_y(t,x,y,u) \le 0, \quad |b(t,x,y_1,u) - b(t,x,y_2,u)| \le L|y_1 - y_2|$$

holds for all $|y|, |u| \le M$ and $y_1, y_2 \in \mathbb{R}$. Notice that b is supposed to be globally Lipschitz with respect to y. The constant L does not depend on M.

(A2) The function $\omega : \Omega \times \mathbb{R} \to \mathbb{R}$, $\omega = \omega(x,y)$, is of class C^2 with respect to y. Furthermore, ω is measurable with respect to x for all $y \in \mathbb{R}$. We assume $\omega(\cdot,0) \in L^\infty(\Omega)$, $\omega_y(\cdot,0) \in L^\infty(\Omega)$, $\omega_{yy}(\cdot,0) \in L^\infty(\Omega)$, and

$$|\omega_{yy}(x,y_1) - \omega_{yy}(x,y_2)| \le \eta(|y_1 - y_2|)$$

for almost all $x \in \Omega$ and all $|y_1| \le M$, $|y_2| \le M$.

The function $q = q(t,x,y)$ is assumed to satisfy the assumptions on ω, where Q is substituted for Ω and (t,x) is substituted for x.

(A3) We assume that $c, \gamma \in C(\bar\Sigma)$ and $c(t,x) > 0$, $\gamma(t,x) \geq 0$ for all $(t,x) \in \bar\Sigma$. In addition, we require $y_0 \in C(\bar\Omega)$, $y_0(x) \geq 0$ for all $x \in \Omega$.

(A4) The domain $\Omega \subset \mathbb{R}^m$ has a boundary Γ of class C^2. The elliptic operator A is defined by

$$Ay(x) = -\sum_{i,j=1}^{m} D_i(a_{ij}(x)D_j y(x)),$$

where $a_{ij} \in C^{1,\nu}$ satisfy, for some positive m_0, the condition of ellipticity

$$\sum_{i,j=1}^{m} a_{ij}(x)\xi_i\xi_j \geq m_0|\xi|^2.$$

Other estimates of b, ω, σ, q and their first derivatives can be derived from (A1), (A2) by the mean value theorem. For convenience, in (A1) we assume a global Lipschitz continuity for b with respect to y. This is not really a strong assumption. The maximum principle of the parabolic equation ensures a priori bounds on the solution of the parabolic equation. Therefore, the Lipschitz continuity with respect to y is only needed on a bounded set that is predetermined by the given data.

2. First- and second-order optimality conditions. First, we introduce the spaces $V = H^1(\Omega)$ and $W(0,T) = \{v \in L^2(0,T;V) : v_t \in L^2(0,T;V^*)\}$. Since $W(0,T)$ is not embedded in the space $C(\bar Q)$, which is needed to differentiate the superposition operators associated with the nonlinear functions ω, σ, q, and b, we fix $\alpha > \frac{m}{2} + 1$, $s > m + 1$ and introduce the state space

$$Y = \{y \in W(0,T) | y_t + Ay \in L^\alpha(Q), \partial_n y \in L^s(\Sigma), y(0) \in C(\bar\Omega)\}$$

endowed with the norm

$$\|y\|_Y = \|y\|_{W(0,T)} + \|y_t + Ay\|_{L^\alpha(Q)} + \|\partial_n y\|_{L^s(\Sigma)} + \|y(0)\|_{C(\bar\Omega)}.$$

Due to the choice of α and s, the embedding of Y into $C(\bar Q)$ is continuous [4], [13].

We denote by $a = a[y,v] : V \times V \to \mathbb{R}$ the bilinear form associated with A:

$$a[y,v] = \int_\Omega \sum_{i,j=1}^{m} a_{ij}(x)D_j y(x)D_i v(x)\, dx.$$

A function $y \in Y$ is said to be a (weak) solution of (1.2) if y satisfies the initial value problem

$$\begin{aligned} \frac{d}{dt}(y(t),v)_{L^2(\Omega)} + a[y(t),v] &= (b(t,\cdot,y(t),u(t)),v)_{L^2(\Gamma)}, \\ y(0,\cdot) &= y_0 \end{aligned} \tag{2.1}$$

for almost all t and all $v \in V$.

LEMMA 2.1. *For each $u \in L^\infty(\Sigma)$, (1.2) admits a unique solution $y \in Y$.*

For the proof we refer to [11] and [13]. In these papers, the authors use a weak solution approach. It is also possible to get a similar result by semigroup techniques; see, for instance, [14].

By Lemma 2.1, a solution mapping $G : L^\infty(\Sigma) \to C(\bar{Q})$ is defined that assigns to $u \in L^\infty(\Sigma)$ the solution y of (1.2). The boundary values of y are of particular importance for us. Thus we define the mapping $S : L^\infty(\Sigma) \to C(\bar{\Sigma})$ with $S = \tau G$ that assigns to u the boundary values of y. It is known from literature that G and S are twice continuously Fréchet-differentiable. Nevertheless, for our further results it is useful to briefly sketch the proof. Let $(\bar{y}, \bar{u}) \in Y \times L^\infty(\Sigma)$ be a fixed reference pair. Later, this couple will stand for a local minimum of (1.1)–(1.3). Below we use the abbreviations $\bar{b}_u = b_u(t, x, \bar{u}(t, x), \bar{y}(t, x))$, $\bar{b}_y = b_y(t, x, \bar{u}(t, x), \bar{y}(t, x))$ with $\bar{y} = S(\bar{u})$. In the same way $\bar{b}_{yy}$, $\bar{b}_{uu}$, $\bar{\sigma}_y$, etc. are defined.

LEMMA 2.2. *The nonlinear mapping $S : L^\infty(\Sigma) \to C(\bar{Q})$ is of class C^1. Its Fréchet derivative $S'(\bar{u})$ at $\bar{u}$ in direction u is given by $S'(\bar{u})u = w|_\Sigma$, where w is the solution of the initial-boundary value problem*

$$\begin{aligned} w_t + Aw &= 0 && \text{in } Q, \\ \partial_n w - \bar{b}_y\, w &= \bar{b}_u\, u && \text{in } \Sigma, \\ w(0, x) &= 0 && \text{in } \Omega. \end{aligned} \tag{2.2}$$

Proof. Let w be the solution of (2.2) with $u = \tilde{u} - \bar{u}$ and set

$$z := \tilde{y} - \bar{y} - w = S(\tilde{u}) - S(\bar{u}) - w. \tag{2.3}$$

Next, we perform a Taylor expansion for $b(t, x, \tilde{u}(t, x), \tilde{y}(t, x))$:

$$\begin{aligned} b(t, x, \tilde{u}(t, x), \tilde{y}(t, x)) &= b(t, x, \bar{u}(t, x), \bar{y}(t, x)) + \bar{b}_u(\tilde{u}(t, x) - \bar{u}(t, x)) \\ &\quad + \bar{b}_y(\tilde{y}(t, x) - \bar{y}(t, x)) + r(t, x). \end{aligned} \tag{2.4}$$

The remainder term $r = r(t, x)$ depends on the point $\bar{u}$ and on the direction h. It is known that

$$\frac{\|r(\bar{u}, h)\|_{L^\infty(\Sigma)}}{\|h\|_{L^\infty(\Sigma)}} \to 0 \quad \text{as } \|h\|_{L^\infty(\Sigma)} \to 0. \tag{2.5}$$

One can easily verify that z solves the initial-boundary value problem

$$\begin{aligned} z_t + Az &= 0 && \text{in } Q, \\ \partial_n z - \bar{b}_y\, z &= r && \text{in } \Sigma, \\ z(0, x) &= 0 && \text{in } \Omega. \end{aligned} \tag{2.6}$$

The estimate (2.5) of the remainder r implies a similar property for z,

$$\frac{\|z(\bar{u}, h)\|_{C(\bar{Q})}}{\|h\|_{L^\infty(\Sigma)}} \to 0 \quad \text{as } \|h\|_{L^\infty(\Sigma)} \to 0, \tag{2.7}$$

and the differentiability of S is readily seen from $S(\tilde{u}) = S(\bar{u}) + w + z(\bar{u}, h)$. ∎

It is possible to extend the operator $S'(\bar{u})$ to a linear continuous operator in $\mathcal{L}(L^2(\Sigma))$. From now on, we consider $S'(\bar{u})$ in this way. The known property

$$\frac{\|r(\bar{u}, h)\|_{L^2(\Sigma)}}{\|h\|_{L^2(\Sigma)}} \to 0 \quad \text{as } \|h\|_{L^\infty(\Sigma)} \to 0$$

(see Maurer [10]) implies a similar property for $z|_\Sigma$:

$$\frac{\|z|_\Sigma(\bar{u}, h)\|_{L^2(\Sigma)}}{\|h\|_{L^2(\Sigma)}} \to 0 \quad \text{as } \|h\|_{L^\infty(\Sigma)} \to 0.$$

Next, we introduce the L^2-adjoint operator $S'(\bar{u})^* \in \mathcal{L}(L^2(\Sigma))$. This operator is given by $S'(\bar{u})^*\mu = \varphi|_\Sigma$, where φ is the solution of the well-posed parabolic backward problem

$$\begin{aligned} -\varphi_t + A^*\varphi &= 0 && \text{in } Q, \\ \partial_n\varphi - \bar{b}_y\ \varphi &= \bar{b}_u\ \mu && \text{in } \Sigma, \\ \varphi(T,x) &= 0 && \text{in } \Omega, \end{aligned} \tag{2.8}$$

where A^* is the formal adjoint operator to A. In all that follows let $(\bar{y},\bar{u})$ be a locally optimal reference solution of (1.1)–(1.3). Let us set up the associated first-order necessary optimality conditions in form of a Karush–Kuhn–Tucker-type theorem.

To this aim, we introduce the Lagrange functional $L : Y \times L^\infty(\Sigma) \times Y \times L^\infty(\Sigma)^2 \to \mathbb{R}$,

$$\begin{aligned} L(y,u,p,\mu_1,\mu_2) = F(y,u) &- \int_Q (y_t + Ay)p\ dxdt - \int_\Sigma (\partial_n y - b)p\ d\Gamma dt \\ &- \int_\Sigma \mu_1 u\ d\Gamma dt + \int_\Sigma (u - c - \gamma y)\mu_2\ d\Gamma dt, \end{aligned}$$

where $d\Gamma$ denotes the Lebesgue surface measure induced on Γ with respect to x.

Let us now comment on this choice for L. The heat equation (1.2) is considered in Y, while the inequality constraints (1.3) are posed in $L^\infty(\Sigma)$. Knowing the general Karush–Kuhn–Tucker theory in Banach spaces, one expects associated Lagrange multipliers $p \in Y^*$ and $\mu_i \in (L^\infty(\Sigma))^*$, together with a related quite complicated Lagrange functional. In contrast to this, special techniques for optimal control problems of bottleneck type have shown that, under natural assumptions, the Lagrange multipliers can be expressed by regular functions, i.e., $p \in W(0,T)\cap C(\bar{Q})$ and $\mu_i \in L^\infty(\Sigma)$; see Bergounioux and Tröltzsch [2] and Arada and Raymond [1]. This well-known advantage of bottleneck-type problems is our key idea to establish special second-order sufficient optimality conditions, which are hardly to be expected for $\mu_i \in (L^\infty(\Sigma))^*$. The existence of such regular multipliers can be shown under a Slater-type condition and the assumption $\gamma(t,x) \geq 0$. Here, the nonnegativity of γ plays a crucial role.

Therefore we are justified to *assume* that an adjoint state $\bar{p} \in W(0,T)\cap C(\bar{Q})$ and Lagrange multipliers $\bar{\mu}_i \in L^\infty(\Sigma)$ exist such that $(\bar{y},\bar{u},\bar{p},\bar{\mu}_1,\bar{\mu}_2)$ satisfies the following first-order necessary optimality system (FON):

$$\text{(FON)} \quad \begin{cases} D_y L(\bar{y},\bar{u},\bar{p},\bar{\mu}_1,\bar{\mu}_2) &= 0, \\ D_u L(\bar{y},\bar{u},\bar{p},\bar{\mu}_1,\bar{\mu}_2) &= 0, \\ \text{and for almost all } (t,x) \in \Sigma & \\ \bar{\mu}_1(t,x) &\geq 0, \\ \bar{\mu}_2(t,x) &\geq 0, \\ \bar{u}(t,x)\bar{\mu}_1(t,x) &= 0, \\ (\bar{u}(t,x) - c(t,x) - \gamma(t,x)\bar{y}(t,x))\bar{\mu}_2(t,x) &= 0. \end{cases}$$

The last two conditions of (FON) are the well-known *complementary slackness conditions*. They imply $\bar{\mu}_1(t,x) > 0 \ \Rightarrow \bar{u}(t,x) = 0$ and $\bar{\mu}_2(t,x) > 0 \ \Rightarrow \bar{u}(t,x) = c(t,x) + \gamma(t,x)\bar{y}(t,x)$. Let us express these optimality conditions also in terms of

partial differential equations. As it is well known, the first equation of (FON) is represented by the adjoint equation

$$\begin{aligned} -\bar{p}_t + A^*\bar{p} &= q_y(t,x,\bar{y}) && \text{in } Q,\\ \partial_n\bar{p} - b_y(t,x,\bar{y},\bar{u})\bar{p} &= \sigma_y(t,x,\bar{y},\bar{u}) - \gamma\bar{\mu}_2 && \text{in } \Sigma,\\ \bar{p}(T,x) &= \omega_y(x,\bar{y}(T,x)) && \text{in } \Omega. \end{aligned} \tag{2.9}$$

The second equation of (FON) is equivalent to

$$\sigma_u(t,x,\bar{y},\bar{u}) + b_u(t,x,\bar{y},\bar{u})\bar{p} - \bar{\mu}_1 + \bar{\mu}_2 = 0. \tag{2.10}$$

Next, we discuss a sufficient second-order optimality condition (SSC). For this purpose, we define *strongly active sets* and the associated *critical subspace*. Assume that $(\bar{y},\bar{u},\bar{p},\bar{\mu}_1,\bar{\mu}_2)$ fulfills (FON).

DEFINITION 2.3. *Let $\delta_1,\delta_2 > 0$ be real numbers and $\bar{\mu}_1,\bar{\mu}_2 \in L^\infty(\Sigma)$ be the Lagrange multipliers introduced in* (FON). *The sets*

$$A_1(\delta_1) := \{(t,x) \in \Sigma : \bar{\mu}_1(t,x) \geq \delta_1\}, \tag{2.11}$$

$$A_2(\delta_2) := \{(t,x) \in \Sigma : \bar{\mu}_2(t,x) - (S'(\bar{u})^*\gamma\bar{\mu}_2)(t,x) \geq \delta_2\} \tag{2.12}$$

are called strongly active sets.

All further arguments hold true for an arbitrary choice of δ_1 and δ_2. Later, these numbers will be chosen such that a second-order sufficient optimality condition is satisfied.

On $A_1(\delta_1)$ we have $\bar{\mu}_1 > 0$; hence the complementary slackness conditions yield $\bar{u}(t,x) = 0$. On $A_2(\delta_2)$, it holds $\bar{\mu}_2 > \delta_2 + S'(\bar{u})^*\gamma\bar{\mu}_2 \geq \delta_2 > 0$, hence the complementary slackness conditions give $\bar{u}(t,x) = c(t,x) + \gamma(t,x)\bar{y}(t,x)$. Notice that $A_1(\delta_1) \cap A_2(\delta_2) = \emptyset$, because $\bar{y} \geq 0$ and

$$c(t,x) + \gamma(t,x)\bar{y}(t,x) \geq c(t,x) > 0$$

holds true. Therefore we cannot have $\bar{u} = 0$ and $\bar{u} = c + \gamma\bar{y}$ at the same time.

DEFINITION 2.4. *We say that $(y,u) \in C(\bar{Q}) \times L^\infty(\Sigma)$ belongs to the critical subspace if*

$$u = 0 \qquad \text{on } A_1, \tag{2.13}$$

$$u = \gamma y|_\Sigma \qquad \text{on } A_2 \tag{2.14}$$

and

$$\begin{aligned} y_t + Ay &= 0 && \text{in } Q,\\ \partial_n y - \bar{b}_y\, y &= \bar{b}_u\, u && \text{in } \Sigma,\\ y(0,x) &= 0 && \text{in } \Omega. \end{aligned} \tag{2.15}$$

Notice that (2.15) implies $y|_\Sigma = S'(\bar{u})u$. In (2.12), the expression $S'(\bar{u})^*\gamma\bar{\mu}_2$ can be evaluated by solving the backward problem

$$\begin{aligned} -\kappa_t + A^*\kappa &= 0 && \text{in } Q,\\ \partial_n\kappa - \bar{b}_y\, \kappa &= \bar{b}_u\, \gamma\,\bar{\mu}_2 && \text{in } \Sigma,\\ \kappa(T,x) &= 0 && \text{in } \Omega. \end{aligned} \tag{2.16}$$

The boundary values of κ deliver the desired expression, $\kappa|_\Sigma = S'(\bar u)^*\gamma\bar\mu_2$. Knowing κ, it is easy to determine the strongly active set A_2.

Before we formulate the second-order sufficient optimality condition, we mention for convenience the explicit expression of $L''_{(u,y)}(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)[h_y,h_u]^2$:

$$\begin{aligned} L''_{(u,y)}(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)[h_y,h_u]^2 &= \int_\Omega \bar\omega_{yy}h_y^2\,dx + \int_Q \bar q_{yy}h_y^2\,dxdt \\ &\quad + \int_\Sigma (\bar\sigma_{yy}h_y^2 + 2\bar\sigma_{yu}h_yh_u + \bar\sigma_{uu}h_u^2)\,d\Gamma dt \\ &\quad + \int_\Sigma (\bar b_{yy}h_y^2 + 2\bar b_{yu}h_yh_u + \bar b_{uu}h_u^2)\bar p\,d\Gamma dt. \end{aligned} \tag{2.17}$$

Here, h_y, h_u denote arbitrary increments of y and u, respectively. Now we state the main result of our paper, the second-order sufficient condition.

(SSC). There exist positive numbers δ, δ_1, δ_2 such that the coercivity condition

$$L''_{(u,y)}(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)[h_y,h_u]^2 \ge \delta\|h_u\|^2_{L^2(\Sigma)} \tag{2.18}$$

holds true for all (h_y,h_u) belonging to the critical subspace defined upon δ_1, δ_2.

THEOREM 2.5 (second-order sufficiency). *Assume that $(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)$ fulfills the first-order optimality system* (FON). *If the second-order condition* (SSC) *is satisfied, then there exist $\delta_s>0$ and $\varepsilon>0$ such that the quadratic growth condition*

$$F(y,u) - F(\bar y,\bar u) \ge \delta_s\|u-\bar u\|^2_{L^2(\Sigma)} \tag{2.19}$$

holds for all admissible pairs (y,u) with $\|u-\bar u\|_{L^\infty(\Sigma)}<\varepsilon$. Therefore, $\bar u$ is a locally optimal control in the norm of $L^\infty(\Sigma)$.

The proof is contained in section 4.

3. Auxiliary results.

LEMMA 3.1. *Let $\beta\in L^\infty(\Sigma)$ and $f\in L^2(\Sigma)$ be given and let v be the solution of the initial boundary value problem*

$$\begin{aligned} v_t + Av &= 0 && \text{in } Q,\\ \partial_n v + \beta v &= f && \text{in } \Sigma,\\ v(0,x) &= 0 && \text{in } \Omega. \end{aligned}$$

If $f\ge 0$ holds a.e. on Σ, then also $v\ge 0$ holds true a.e. on Σ.

For a proof of this *comparison principle* we refer to Raymond and Zidani [13].

DEFINITION 3.2. *A continuous linear operator A in $\mathcal{L}(L^2(\Sigma))$ is said to be nonnegative if $u\ge 0$ a.e. on Σ implies $Au\ge 0$ a.e. on Σ. In this case, we write $A\ge 0$.*

LEMMA 3.3 (comparison principle). *Under the assumptions* (A1)–(A4), *the nonnegativity properties*

$$S'(\bar u) \ge 0, \tag{3.1}$$

$$(I-\gamma S'(\bar u))^{-1} \ge 0 \tag{3.2}$$

hold true.

Proof. The operator $S'(\bar u): u\mapsto w_\Sigma$, is defined upon (2.2). In (A1) we have assumed $b_u\ge 0$. Hence Lemma 3.1, applied with $\beta=-\bar b_y$, $f=\bar b_u u$, yields that $u\ge 0$ implies $w|_\Sigma\ge 0$ and (3.1) is proved.

To prove (3.2), we apply Lemma 3.1 to the system

$$\begin{aligned} v_t + Av &= 0 && \text{in } Q, \\ \partial_n v - (\bar{b}_y + \gamma \bar{b}_u)v &= \bar{b}_u u && \text{in } \Sigma, \\ v(0,x) &= 0 && \text{in } \Omega. \end{aligned} \tag{3.3}$$

Invoking Lemma 3.1 again, the implication $u \geq 0 \Rightarrow v|_\Sigma \geq 0$ holds. A comparison of (3.3) with (2.2) shows that

$$S'(\bar{u})(\gamma v + u) = v$$

holds. Setting $z = \gamma v + u$, we get $z = \gamma S'(\bar{u})(\gamma v + u) + u = \gamma S'(\bar{u})z + u$, hence $z = (I - \gamma S'(\bar{u}))^{-1}u$. Thanks to the implication $u \geq 0 \Rightarrow v|_\Sigma \geq 0$, (A3), and $z = \gamma v + u$, we obtain $u \geq 0 \Rightarrow z \geq 0$. This proves (3.2). □

COROLLARY 3.4. *The property* (3.1) *extends to the adjoint operator* $S'(\bar{u})^*$,

$$S'(\bar{u})^* \geq 0. \tag{3.4}$$

In what follows, we repeatedly need controls u defined as follows: Let M_1, M_2 be disjoint measurable subsets of Σ such that $M_1 \cup M_2 = \Sigma$, and let $f \in L^\infty(\Sigma)$ be given. Then we would like to define u by

$$u(t,x) = \begin{cases} f(t,x) & \text{on } M_1, \\ f(t,x) + \gamma(t,x)(S'(\bar{u})u)(t,x) & \text{on } M_2. \end{cases} \tag{3.5}$$

The next lemma shows that this setting is correct.

LEMMA 3.5. *For all disjoint measurable subsets* M_1, M_2 *of* Σ *with* $M_1 \cup M_2 = \Sigma$ *and all* $f \in L^\infty(\Sigma)$, *there is exactly one function* $u \in L^\infty(\Sigma)$ *that satisfies condition* (3.5). *In addition, the implication*

$$f \geq 0 \quad \Rightarrow \quad u \geq 0 \tag{3.6}$$

holds true. Moreover, the estimates

$$\|u\|_{L^\infty(\Sigma)} \leq c_1 \|f\|_{L^\infty(\Sigma)}, \tag{3.7}$$

$$\|u\|_{L^2(\Sigma)} \leq c_2 \|f\|_{L^2(\Sigma)} \tag{3.8}$$

hold with certain constants c_1, c_2 *that do not depend on* M_1, M_2, *and* f.

Proof. Suppose that $u \in L^\infty(\Sigma)$ satisfies (3.5). Put $v := S'(\bar{u})u$. Then v satisfies the heat equation with homogeneous initial data and the boundary condition

$$\partial_n v - \bar{b}_y v = \begin{cases} \bar{b}_u f & \text{on } M_1, \\ \bar{b}_u(f + \gamma v) & \text{on } M_2; \end{cases} \tag{3.9}$$

that is,

$$\partial_n v - (\bar{b}_y v + \chi_{M_2} \bar{b}_u \gamma)v = \bar{b}_u f \quad \text{on } \Sigma. \tag{3.10}$$

This solution v is unique. Therefore, if u satisfies (3.5), then $v = S'(\bar{u})u$ is unique; hence u is unique, because of

$$u = \begin{cases} f & \text{on } M_1, \\ f + \gamma v & \text{on } M_2. \end{cases} \tag{3.11}$$

On the other hand, starting from M_1, M_2, and f, the solution v of the heat equation with homogeneous initial data and boundary condition (3.10) is defined, and the function u given by (3.11) satisfies (3.5), since, by definition of v, $u = S'(\bar u)v$.

Finally, by Lemma 3.1 applied to (3.10) with $f := \bar b_u f$, the relation $f \ge 0$ implies $v \ge 0$, hence also $u \ge 0$. The estimates (3.7) and (3.8) follow immediately from those for v and (3.11). □

To prove the main result, we later have to compare the reference pair $(\bar y, \bar u)$ with another admissible pair (y,u), where $y = S(u)$. Then we have to estimate the difference

$$y - \bar y = S(u) - S(\bar u) = S'(\bar u)(u - \bar u) + r_1(\bar u, u - \bar u),$$

where r_1 stands for the associated first-order remainder term. In the following, we denote for short the remainder $r_1(\bar u, u - \bar u)$ and the derivative $S'(\bar u)$ by r_1 and S', respectively, if there is no risk of notational confusion.

Before continuing our analysis of second-order sufficiency, we briefly discuss the main difficulties and our main ideas to resolve them. We start with the case of pure control constraints, which is covered by our setting for $\gamma(t,x) \equiv 0$. Then the constraints are simple box constraints,

$$0 \le u(t,x) \le c(t,x).$$

On A_1, we have $\bar u(t,x) \equiv 0$, hence $u - \bar u \ge 0$ on A_1, while $\bar u(t,x) = c(t,x)$ holds on A_2; thus $u - \bar u \le 0$ on A_2. The associated terms in the Lagrange functional can be estimated as

$$\begin{aligned}\int_{A_1} \bar\mu_1(u - \bar u)\, d\Gamma dt - \int_{A_2} \bar\mu_2(u - \bar u)\, d\Gamma dt &\ge \int_{A_1} \delta_1(u - \bar u)\, d\Gamma dt + \int_{A_2} \delta_2(u - \bar u)\, d\Gamma dt \\ &= \delta_1 \|u - \bar u\|_{L^1(A_1)} + \delta_2 \|u - \bar u\|_{L^1(A_2)}.\end{aligned}$$

In the proof of the sufficiency theorem the L^1-norms on the right-hand side will compensate for the lack of coercivity, since (2.18) does not help on $A_1 \cup A_2$.

Now we return to the given mixed control-state constraints

$$0 \le u(t,x) \le c(t,x) + \gamma(t,x)\, y(t,x).$$

To simplify our explanation, assume for a while that the control-state mapping is linear. This holds for $y_0 = 0$ functions b being linear with respect to y and u. Then $S' = S$; hence

$$0 \le u \le c + \gamma S' u \tag{3.12}$$

holds for any admissible control u. On A_1, we have again $0 = \bar u \le u$, hence $u - \bar u \ge 0$ on A_1. However, in contrast to the case of pure control constraints, the relation $u \le \bar u$ cannot be expected on A_2 now. If $u > \bar u$ holds somewhere on $\Sigma \setminus A_2$, then $S'u > S'\bar u$ can hold on A_2. Then the right-hand side of (3.12) is greater than $c + \gamma S'\bar u$ and $u > \bar u$ can happen.

To overcome this difficulty, we represent u in the form $u = u_1 + u_2$, such that $u_1 \le \bar u$ can be shown on A_2 and u_2 stands for the additional margin of freedom that is caused by $u > \bar u$ outside of A_2. Hence we split u in two parts, $u = u_1 + u_2$ on Σ, where

$$\begin{aligned} &u_1 = \bar u, && u_2 = u - \bar u && \text{on } \Sigma \setminus A_2, \\ &u_2 = \gamma(S'u_2 + r_1), && u_1 = u - u_2 && \text{on } A_2. \end{aligned} \tag{3.13}$$

The functions u_1 and u_2 are well defined. To see this, we apply Lemma 3.5, where $M_1 = \Sigma \setminus A_2$ and $M_2 = A_2$. On M_1, u_2 is given by $u - \bar{u}$. On M_2, $u_2 = \gamma r_1 + \gamma S' u_2$; hence

$$u_2 = \begin{cases} f & \text{on } M_1, \\ f + \gamma S' u_2 & \text{on } M_2, \end{cases}$$

where $f = u - \bar{u}$ on M_1, $f = \gamma r_1$ on M_2. Then u_2 is well defined by Lemma 3.5. Note that $S'u_2 = S'(\bar{u})(\chi_{M_1}(u - \bar{u}) + \chi_{M_2} u_2)$. From (3.10) and the properties of the remainder r_1 we easily get

$$\|u_2\|_{L^\infty(\Sigma)} \le c_3 \|u - \bar{u}\|_{L^\infty(\Sigma)}.$$

Therefore, we find

$$\begin{aligned} \|u_1 - \bar{u}\|_{L^\infty(A_2)} &\le \|u - \bar{u}\|_{L^\infty(A_2)} + \|u_2\|_{L^\infty(A_2)} \\ &\le c_4 \|u - \bar{u}\|_{L^\infty(\Sigma)}. \end{aligned} \tag{3.14}$$

LEMMA 3.6. *Assume that $(\bar{y}, \bar{u}, \bar{p}, \bar{\mu}_1, \bar{\mu}_2)$ fulfills the first-order optimality system* (FON) *and take any u satisfying the mixed control-state constraints. Let u be split by $u = u_1 + u_2$ according to formula* (3.13). *Then it holds that*

$$\bar{u} - u_1 \ge 0 \quad \text{a.e. on } \Sigma. \tag{3.15}$$

Proof. Let A_1 and A_2 be the strongly active sets of $\bar{u}$ defined by δ_1 and δ_2. On A_2, the inequality $\bar{\mu}_2 \ge \bar{\mu}_2 - \gamma S'(\bar{u})^* \bar{\mu}_2 \ge \delta_2 > 0$ holds. Therefore, (FON) implies $\bar{u} = c + \gamma \bar{y}$ there. In addition, we know on A_2 that $u - \gamma y \le c = \bar{u} - \gamma \bar{y}$; hence

$$u - \gamma S(u) \le \bar{u} - \gamma S(\bar{u})$$

holds there. In view of this, we find on A_2

$$\begin{aligned} u - \gamma(S(u) - S(\bar{u})) &\le \bar{u}, \\ u - \gamma(S'(\bar{u})(u - \bar{u}) + r_1) &\le \bar{u}, \\ u_1 - \gamma S' u_1 + (u_2 - \gamma(S' u_2 + r_1)) &\le \bar{u} - \gamma S' \bar{u}, \\ u_1 - \gamma S' u_1 &\le \bar{u} - \gamma S' \bar{u}, \\ (I - \gamma S')(u_1 - \bar{u}) &\le 0, \end{aligned} \tag{3.16}$$

where we have inserted the definition of u_2. Outside of A_2, it holds by definition $u_1 = \bar{u}$. We are now again in the situation that was described in Lemma 3.5. Indeed, taking $M_1 := \Sigma \setminus A_2$, $M_2 = A_2$, $f = 0$ on M_1, and $f = (I - \gamma S')(\bar{u} - u_1)$ on M_2, we have $f \ge 0$. Applying (3.6), we obtain

$$\bar{u} - u_1 \ge 0 \quad \text{a.e. on } \Sigma,$$

which is just inequality (3.15). ∎

LEMMA 3.7. *Assume that $(\bar{y}, \bar{u}, \bar{p}, \bar{\mu}_1, \bar{\mu}_2)$ fulfill the first-order optimality system* (FON). *Then the estimates*

$$\int_\Sigma (u - \bar{u}) \bar{\mu}_1 \, d\Gamma dt \ge \frac{\delta_1}{\varepsilon} \|u - \bar{u}\|^2_{L^2(A_1)}, \tag{3.17}$$

$$-\int_\Sigma (u - \bar{u} - \gamma(y - \bar{y})) \bar{\mu}_2 \, d\Gamma dt \ge \frac{\delta_2}{c_4 \varepsilon} \|u_1 - \bar{u}\|^2_{L^2(A_2)} \tag{3.18}$$

are valid for all $\varepsilon > 0$ and all admissible pairs (u, y) satisfying $\|u - \bar{u}\|_{L^\infty(\Sigma)} < \varepsilon$.

Proof. (i) Because of (FON), $\bar\mu_1 > 0$ can only hold if $\bar u = 0$. If $\bar u > 0$, then $\bar\mu_1 = 0$. Moreover, u is admissible, hence $u \ge 0$ and we have almost everywhere

$$(u - \bar u)\bar\mu_1 \ge 0.$$

Therefore we get by (2.11)

$$\int_\Sigma (u - \bar u)\bar\mu_1 \, d\Gamma dt \ge \int_{A_1} (u - \bar u)\bar\mu_1 \, d\Gamma dt \ge \delta_1 \|u - \bar u\|_{L^1(A_1)}.$$

By our assumption, we have $\|u - \bar u\|_{L^\infty(\Sigma)} < \varepsilon$. In particular, this inequality includes $\|u - \bar u\|_{L^\infty(A_1)} < \varepsilon$. Consequently,

$$\int_\Sigma (u - \bar u)\bar\mu_1 \, d\Gamma dt \ge \delta_1 \|u - \bar u\|_{L^1(A_1)} \frac{\|u - \bar u\|_{L^\infty(A_1)}}{\varepsilon} \ge \frac{\delta_1}{\varepsilon} \|u - \bar u\|^2_{L^2(A_1)},$$

and (3.17) is proved.

(ii) Next, we discuss the integral in (3.18). Because of (FON), $\bar\mu_2 > 0$ can only hold for $\bar u - c - \gamma\bar y = 0$. In addition, (y, u) is admissible, hence in particular $u \le c + \gamma y$. Therefore, we obtain almost everywhere

$$-(u - \bar u - \gamma(y - \bar y))\bar\mu_2 \ge 0$$

and

$$-\int_\Sigma (u - \bar u - \gamma(y - \bar y))\bar\mu_2 \, d\Gamma dt \ge -\int_{A_2} (u - \bar u - \gamma(y - \bar y))\bar\mu_2 \, d\Gamma dt.$$

Let us discuss this integral more detailed. Expressing $y - \bar y$ in terms of the controls,

$$\int_{A_2} (u - \bar u - \gamma(y - \bar y))\bar\mu_2 \, d\Gamma dt = \int_{A_2} (u - \bar u - \gamma(S'(\bar u)(u - \bar u) + r_1))\bar\mu_2 \, d\Gamma dt \tag{3.19}$$

is found. The definition of u_1 and u_2 yields on A_2

$$u - \gamma(S'u + r_1) = u_1 + u_2 - \gamma S'u_1 - \gamma S'u_2 - \gamma r_1 = u_1 - \gamma S'u_1.$$

Inserting the last equation in (3.19), we continue by

$$\begin{aligned}
\int_{A_2} (u - \bar u - \gamma(y - \bar y))\bar\mu_2 \, d\Gamma dt &= \int_{A_2} (u_1 - \bar u - \gamma(S'(\bar u)(u_1 - \bar u)))\bar\mu_2 \, d\Gamma dt \\
&= \int_\Sigma (u_1 - \bar u - \gamma(S'(\bar u)(u_1 - \bar u)))\chi_{A_2}\bar\mu_2 \, d\Gamma dt \\
&= \int_\Sigma (u_1 - \bar u)(I - (\gamma S')^*)(\chi_{A_2}\bar\mu_2) \, d\Gamma dt \\
&= \int_{A_2} (u_1 - \bar u)(I - (\gamma S')^*)(\chi_{A_2}\bar\mu_2) \, d\Gamma dt. \qquad (3.20)
\end{aligned}$$

To deduce the last equation, we used $\bar u - u_1 = 0$ outside of A_2. Now we discuss the expression $(I - (\gamma S')^*)(\chi_{A_2}\bar\mu_2)$ in (3.20). On A_2 we have

$$(I - (\gamma S')^*)(\chi_{A_2}\bar\mu_2) = \chi_{A_2}\bar\mu_2 - (\gamma S')^*(\chi_{A_2}\bar\mu_2) = \bar\mu_2 - (\gamma S')^*(\chi_{A_2}\bar\mu_2).$$

Using the nonnegativity of S'^* following from (3.4), together with $\chi_{A_2}\bar\mu_2 \le \bar\mu_2$, we obtain

$$(\gamma S')^*(\chi_{A_2}\bar\mu_2) = (S')^*(\gamma\chi_{A_2}\bar\mu_2) \le (S')^*(\gamma\bar\mu_2) = (\gamma S')^*\bar\mu_2.$$

Combining these results, we continue by

$$(I-(\gamma S')^*)(\chi_{A_2}\bar\mu_2) = \bar\mu_2 - (\gamma S')^*(\chi_{A_2}\bar\mu_2) \ge (I-(\gamma S')^*)\bar\mu_2 \ge \delta_2, \tag{3.21}$$

where the last inequality follows from the definition (2.12) of A_2. Inserting (3.15) and (3.21) in (3.20), we infer

$$\begin{aligned} -\int_{A_2}(u-\bar u-\gamma(y-\bar y))\bar\mu_2\,d\Gamma dt &= -\int_{A_2}(u_1-\bar u)(I-(\gamma S')^*)(\chi_{A_2}\bar\mu_2)\,d\Gamma dt \\ &\ge \delta_2\|\bar u-u_1\|_{L^1(A_2)}. \end{aligned}$$

Invoking again $\|u-\bar u\|_{L^\infty(\Sigma)} < \varepsilon$ and (3.14), we obtain

$$\begin{aligned} -\int_{A_2}(u-\bar u-\gamma(y-\bar y))\bar\mu_2\,d\Gamma dt &\ge \delta_2\|u_1-\bar u\|_{L^1(A_2)}\cdot\frac{\|u-\bar u\|_{L^\infty(A_2)}}{\varepsilon} \\ &\ge \frac{\delta_2}{c_4\varepsilon}\|u_1-\bar u\|^2_{L^2(A_2)}, \end{aligned}$$

implying inequality (3.18). □

If $A_1\cup A_2=\Sigma$, then the critical subspace contains only the zero-function. Then the assumptions of Theorem 2.5 are trivially fulfilled. In this case, (3.17) and (3.18) express the so-called *first-order sufficient optimality conditions*.

4. Second-order sufficient optimality condition. This section includes the proof of the sufficiency Theorem 2.5. We start from an admissible control u in a sufficiently small L^∞-neighborhood of $\bar u$ and have to show that $F(y,u)\ge F(\bar y,\bar u)$. Let us introduce the increments $\delta u := u-\bar u$ and $\delta y := S'(\bar u)\delta u$. We split $\delta u = u_0+u_+$, where

$$\begin{array}{lll} u_0=0, & u_+=\delta u & \text{on } A_1,\\ u_0=\delta u, & u_+=0 & \text{on } \Sigma\setminus(A_1\cup A_2),\\ u_0=\gamma S'(\bar u)u_0, & u_+=\delta u-u_0 & \text{on } A_2. \end{array}$$

Thanks to Lemma 3.5, the definition of u_0 and hence u_+ are correct. We take $M_1=\Sigma\setminus A_2$, $M_2=A_2$, $f:=0$ on $A_1\cup A_2$, $f:=\delta u$ on $\Sigma\setminus(A_1\cup A_2)$. The part u_0 belongs to the critical subspace, while u_+ is the part of δu that accounts for the effects of first-order sufficiency. Furthermore, we define $y_0 := S'u_0$ and $y_+ := S'u_+$. By the linearity of S', we have $\delta y = y_0+y_+$.

Below, we estimate the difference $L(y,u,\bar p,\bar\mu_1,\bar\mu_2)-L(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)$. Let us write for short $L(y,u)-L(\bar y,\bar u)$, since $(\bar p,\bar\mu_1,\bar\mu_2)$ remains fixed in all the following considerations. We also do not explicitly indicate the point $(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)$ where all derivatives are taken, i.e., we write $L_u u$ instead of $(D_uL)(\bar y,\bar u,\bar p,\bar\mu_1,\bar\mu_2)u$.

LEMMA 4.1. *Under the assumptions of Theorem* 2.5,

$$L(y,u)-L(\bar y,\bar u)\ge\frac{\delta}{4}\|u_0\|^2_{L^2(\Sigma)}-\frac{c_s}{2}\|u_+\|^2_{L^2(\Sigma)}+r_2+\tilde r_2 \tag{4.1}$$

holds, where r_2, $\tilde r_2$ are second-order remainder terms with

$$\frac{|r_i|}{\|u-\bar u\|^2_{L^2(\Sigma)}}\to 0 \quad \text{if } \|u-\bar u\|_{L^\infty(\Sigma)}\to 0.$$

Proof. Using a Taylor expansion, in view of (FON) we get

$$\begin{aligned} L(y,u) - L(\bar y,\bar u) &= L_u[u-\bar u] + L_y[y-\bar y] + \frac{1}{2}(L_{uu}[u-\bar u]^2 \\ &\quad + 2L_{uy}[u-\bar u, y-\bar y] + L_{yy}[y-\bar y]^2) + r_2 \\ &= \frac{1}{2}(L_{uu}[u-\bar u]^2 + 2L_{uy}[u-\bar u, y-\bar y] + L_{yy}[y-\bar y]^2) + r_2. \end{aligned} \tag{4.2}$$

The following property of the remainder is known:

$$\frac{|r_2(\bar u,h)|}{\|h\|^2_{L^2(\Sigma)}} \to 0 \quad \text{as } \|h\|_{L^\infty(\Sigma)} \to 0.$$

For the proof we refer to [16]. According to the notation of Lemma 3.5, we get $y-\bar y = \delta y + r_1$. Replacing $y-\bar y$ by δy in (4.2), we cause a small error of second order

$$\begin{aligned} \tilde r_2 := \frac{1}{2}(L_{uu}[u-\bar u]^2 + 2L_{uy}[u-\bar u, y-\bar y] + L_{yy}[y-\bar y]^2) \\ - \frac{1}{2}(L_{uu}[\delta u]^2 + 2L_{uy}[\delta u, \delta y] + L_{yy}[\delta y]^2). \end{aligned}$$

It is easy to show that

$$\frac{|\tilde r_2|}{\|u-\bar u\|^2_{L^2(\Sigma)}} \to 0 \quad \text{as } \|u-\bar u\|_{L^\infty(\Sigma)} \to 0.$$

With these notations, we can express (4.2) in the form

$$L(y,u) - L(\bar y,\bar u) = \frac{1}{2}(L_{uu}[\delta u]^2 + 2L_{uy}[\delta u, \delta y] + L_{yy}[\delta y]^2) + r_2 + \tilde r_2. \tag{4.3}$$

We continue by splitting the Lagrange functional,

$$\begin{aligned} L_{uu}[\delta u]^2 + 2L_{uy}[\delta u, \delta y] + L_{yy}[\delta y]^2 &= L_{uu}[u_0]^2 + 2L_{uy}[u_0, y_0] + L_{yy}[y_0]^2 \\ &\quad + L_{uu}[u_+]^2 + 2L_{uy}[u_+, y_+] + L_{yy}[y_+]^2 \\ &\quad + 2L_{uu}[u_0, u_+] + 2L_{uy}[u_0, y_+] \\ &\quad + 2L_{uy}[u_+, y_0] + 2L_{yy}[y_0, y_+]. \end{aligned}$$

As u_0 belongs to the critical subspace, the second-order condition (SSC) yields

$$L''[u_0,y_0]^2 = L_{uu}[u_0]^2 + 2L_{uy}[u_0,y_0] + L_{yy}[y_0]^2 \ge \delta \|u_0\|^2_{L^2(\Sigma)}.$$

The other terms are easily estimated by $\|y_0\|^2_{L^2(\Sigma)} \le \|S'\|^2 \|u_0\|^2_{L^2(\Sigma)}$, $\|y_+\|^2_{L^2(\Sigma)} \le \|S'\|^2 \|u_+\|^2_{L^2(\Sigma)}$, and by means of Young's inequality,

$$\begin{aligned} |L_{uu}[u_+]^2 + 2L_{uy}[u_+, y_+] + L_{yy}[y_+]^2 \\ + 2L_{uu}[u_0, u_+] + 2L_{uy}[u_0, y_+] \\ + 2L_{uy}[u_+, y_0] + 2L_{yy}[y_0, y_+]| \le \frac{\delta}{2}\|u_0\|^2_{L^2(\Sigma)} + c_s \|u_+\|^2_{L^2(\Sigma)}. \end{aligned}$$

In this setting, c_s is a certain (large) constant. Combining the last two results, we arrive at

$$L_{uu}[\delta u]^2 + 2L_{uy}[\delta u, \delta y] + L_{yy}[\delta y]^2 \ge \frac{\delta}{2}\|u_0\|^2_{L^2(\Sigma)} - c_s \|u_+\|^2_{L^2(\Sigma)}.$$

Returning to (4.3), we end up with

$$L(y,u) - L(\bar{y},\bar{u}) \geq \frac{\delta}{4}\|u_0\|^2_{L^2(\Sigma)} - \frac{c_s}{2}\|u_+\|^2_{L^2(\Sigma)} + r_2 + \tilde{r}_2,$$

which is exactly the assertion. □

In the next lemma, we estimate the term $\|u_+\|^2_{L^2(\Sigma)}$ in (4.1).

LEMMA 4.2. *Under the assumptions of Theorem* 2.5,

$$\left(\frac{c_s}{2} + \frac{\delta}{4}\right)\|u_+\|^2_{L^2(\Sigma)} \leq c_5\|u_1 - \bar{u}\|^2_{L^2(A_2)} + c_6\|r_1\|^2_{L^2(\Sigma)} + c_7\|u - \bar{u}\|^2_{L^2(A_1)} \tag{4.4}$$

holds with certain positive constants c_5, c_6, *and* c_7.

Proof. First, we get on A_1

$$\|u_+\|_{L^2(A_1)} = \|\delta u\|_{L^2(A_1)} = \|u - \bar{u}\|_{L^2(A_1)}. \tag{4.5}$$

On the whole set Σ we have

$$u_+ + u_0 = \delta u = u - \bar{u}.$$

We apply the operator $I - \gamma S'$ to this equation and consider the image only on the set A_2. Using $u_0 = \gamma S' u_0$ on A_2, we find

$$u_+ - \gamma S' u_+ = u - \gamma S' u - (\bar{u} - \gamma S'\bar{u}) \text{ on } A_2.$$

Now, u is again replaced by $u_1 + u_2$ (see (3.13)) to obtain on A_2

$$u_+ - \gamma S' u_+ = u_1 - \gamma S' u_1 + u_2 - \gamma S' u_2 - (\bar{u} - \gamma S'\bar{u}).$$

On A_2, by definition, the equation $u_2 - \gamma S' u_2 = r_1$ is satisfied. Therefore, here we are able to continue by

$$u_+ - \gamma S' u_+ = u_1 - \bar{u} - (\gamma S'(\bar{u})(u_1 - \bar{u})) + r_1 \text{ on } A_2.$$

Due to our definitions, $u_+ = \delta u = u - \bar{u}$ holds on A_1. In addition, u_+ vanishes on $\Sigma \setminus (A_1 \cup A_2)$. Therefore, we find

$$u_+ = \begin{cases} u_1 - \bar{u} + \gamma S'(\bar{u})(u_+ - u_1 + \bar{u}) + r_1 & \text{on } A_2, \\ u - \bar{u} & \text{on } A_1, \\ 0 & \text{on } \Sigma \setminus (A_1 \cup A_2). \end{cases}$$

Again we have a construction that was investigated in Lemma 3.5. Setting $M_2 = A_2$, $M_1 = \Sigma \setminus A_2$, and applying (3.11), we get the inequality

$$\|u_+\|_{L^2(\Sigma)} \leq c_2\|f\|_{L^2(\Sigma)},$$

where f is defined by

$$f = \begin{cases} r_1 + (u_1 - \bar{u}) - \gamma S'(\bar{u})(u_1 - \bar{u}) & \text{on } A_2, \\ u - \bar{u} & \text{on } A_1, \\ 0 & \text{on } \Sigma \setminus (A_1 \cup A_2). \end{cases}$$

Therefore, we obtain

$$\|u_+\|_{L^2(\Sigma)} \leq c_2(\|u - \bar{u}\|_{L^2(A_1)} + c_8\|u_1 - \bar{u}\|_{L^2(\Sigma)} + \|r_1\|_{L^2(A_2)}),$$

where the positive constant c_8 is related to $\|S'\|$. Using $\|u_1-\bar u\|_{L^2(\Sigma)} = \|u_1-\bar u\|_{L^2(A_2)}$,

$$\|u_+\|_{L^2(\Sigma)} \le c_9\|u_1-\bar u\|_{L^2(A_2)} + c_2\|r_1\|_{L^2(A_2)} + c_2\|u-\bar u\|_{L^2(A_1)}$$

is found. Young's inequality yields

$$\|u_+\|^2_{L^2(\Sigma)} \le 3c_9\|u_1-\bar u\|^2_{L^2(A_2)} + 3c_2\|r_1\|^2_{L^2(\Sigma)} + 3c_2\|u-\bar u\|^2_{L^2(A_1)}.$$

A multiplication by $(\frac{c_s}{2}+\frac{\delta}{4})$,

$$\left(\frac{c_s}{2}+\frac{\delta}{4}\right)\|u_+\|^2_{L^2(\Sigma)} \le c_5\|u_1-\bar u\|^2_{L^2(A_2)} + c_6\|r_1\|^2_{L^2(\Sigma)} + c_7\|u-\bar u\|^2_{L^2(A_1)},$$

concludes the proof of the lemma. □

Now we are able to prove our main result, Theorem 2.5.

Proof of Theorem 2.5. Inserting (4.4) in (4.1),

$$\begin{aligned} L(y,u)-L(\bar y,\bar u) \ge{}& \frac{\delta}{4}(\|u_0\|^2_{L^2(\Sigma)} + \|u_+\|^2_{L^2(\Sigma)}) + r_2 + \tilde r_2 \\ &- c_7\|u-\bar u\|^2_{L^2(A_1)} - c_5\|u_1-\bar u\|^2_{L^2(A_2)} - c_6\|r_1\|^2_{L^2(\Sigma)} \end{aligned}$$

is obtained. Next, we return to the objective F,

$$\begin{aligned} L(y,u)-L(\bar y,\bar u) &= F(y,u)-F(\bar y,\bar u) \\ &\quad - \int_Q (y_t+Ay)\bar p\,dxdt - \int_\Sigma (\partial_n y - b)\bar p\,d\Gamma dt \\ &\quad + \int_Q (\bar y_t+A\bar y)\bar p\,dxdt + \int_\Sigma (\partial_n \bar y - \bar b)\bar p\,d\Gamma dt \\ &\quad - \int_\Sigma \bar\mu_1 u\,d\Gamma dt + \int_0^T \bar\mu_1\bar u\,d\Gamma dt \\ &\quad + \int_\Sigma (u-c-\gamma y)\bar\mu_2\,d\Gamma dt \\ &\quad - \int_\Sigma (\bar u - c - \gamma\bar y)\bar\mu_2\,d\Gamma dt \\ &= F(y,u)-F(\bar y,\bar u) \\ &\quad - \int_\Sigma \bar\mu_1(u-\bar u)\,d\Gamma dt \\ &\quad + \int_\Sigma (u-\bar u-\gamma(y-\bar y)\bar\mu_2\,d\Gamma dt. \end{aligned}$$

Using Lemma 3.7, we find

$$\begin{aligned} F(y,u)-F(\bar y,\bar u) \ge{}& \frac{\delta}{4}(\|u_0\|^2_{L^2(\Sigma)} + \|u_+\|^2_{L^2(\Sigma)}) + r_2 + \tilde r_2 \\ &+ \left(\frac{\delta_1}{\varepsilon} - c_7\right)\|u-\bar u\|^2_{L^2(A_1)} + \left(\frac{\delta_2}{c_4\varepsilon} - c_5\right)\|u_1-\bar u\|^2_{L^2(A_2)} \\ &- c_6\|r_1\|^2_{L^2(\Sigma)}. \end{aligned} \tag{4.6}$$

Next, $\|\delta u\|_{L^2(\Sigma)} = \|u_0 + u_+\|^2_{L^2(\Sigma)} \le 2\|u_0\|^2_{L^2(\Sigma)} + 2\|u_+\|^2_{L^2(\Sigma)}$ is applied to continue by

$$\begin{aligned} F(y,u) - F(\bar y,\bar u) \ge{}& \frac{\delta}{8}\|\delta u\|^2_{L^2(\Sigma)} + r_2 + \tilde r_2 \\ &+ \left(\frac{\delta_1}{\varepsilon} - c_7\right)\|u-\bar u\|^2_{L^2(A_1)} + \left(\frac{\delta_2}{c_4\varepsilon} - c_5\right)\|u_1-\bar u\|^2_{L^2(A_2)} \\ &- c_6\|r_1\|^2_{L^2(\Sigma)}. \end{aligned} \tag{4.7}$$

Now take ε sufficiently small such that

$$\frac{\delta_1}{\varepsilon} - c_7 \ge 0 \quad \text{and} \quad \frac{\delta_2}{c_4\varepsilon} - c_5 \ge 0.$$

Then we can omit the associated terms in (4.6),

$$F(y,u) - F(\bar y,\bar u) \ge \frac{\delta}{8}\|\delta u\|^2_{L^2(\Sigma)} + r_2 + \tilde r_2 - c_6\|r_1\|^2_{L^2(\Sigma)}. \tag{4.8}$$

Due to the discussions during the proof, all terms of the right-hand side (except the first one) are small with respect to $\|u-\bar u\|^2_{L^2(\Sigma)}$. Therefore

$$F(y,u) - F(\bar y,\bar u) \ge \frac{\delta}{16}\|u-\bar u\|^2_{L^2(\Sigma)} \tag{4.9}$$

holds if $\|u-\bar u\|_{L^\infty(\Sigma)} < \varepsilon$ and ε is sufficiently small. The quadratic growth condition is proved. We can choose $\delta_s = \delta/16$. □

LOCALLY CONVERGENT NONLINEAR OBSERVERS*

ARTHUR J. KRENER† AND WEI KANG‡

Abstract. We introduce a new method for the design of observers for nonlinear systems using backstepping. The method is applicable to a class of nonlinear systems slighter larger than those treated by Gauthier, Hammouri, and Othman [*IEEE Trans. Automat. Control,* 27 (1992), pp. 875–880]. They presented an observer design method that is globally convergent using high gain. In contrast to theirs, our observer is not high gain, but it is only locally convergent. If the initial estimation error is not too large, then the estimation error goes to zero exponentially. A design algorithm is presented.

Key words. nonlinear estimation, nonlinear observers

1. Introduction. The problem of estimating the state of a dynamical system from partial and possibly noisy measurements has a long history. In its nonlinear state space form, one assumes that the dynamics satisfies a known nonlinear differential equation with unknown initial condition and the measurement is a known nonlinear function of the state

$$\begin{aligned} \dot{x} &= f(x), \\ x(0) &= x^0, \\ y &= h(x). \end{aligned} \tag{1.1}$$

The linear form of the problem is

$$\begin{aligned} \dot{x} &= Ax, \\ x(0) &= x^0, \\ y &= Cx. \end{aligned} \tag{1.2}$$

One is given an estimate $\hat{x}^0$ of x^0 and the observations $y(s),\ 0 \le s \le t$, up to time t. The problem is to generate an estimate $\hat{x}(t)$ of $x(t)$ in real time, as the process evolves. The estimate should converge to the true state as $t \to \infty$. Ideally the estimation process should be robust to noise both in the dynamics and in the observations, to the initial state error, and also to modeling errors in the functions $f,\ h$. Furthermore, the error should converge to zero quickly.

One way of approaching this problem is to assume that the dynamics, the initial condition, and the observations are corrupted by noises with known distributions and then to find the conditional density of the state given the past observations. If the dynamics and observations are linear functions of the state and if the noises and

‡Department of Mathematics, Naval Postgraduate School, Monterey, CA (wkang@math.nps.navy.mil).

the initial condition are independent and Gaussian, then the conditional density is Gaussian and explicitly computable. Wiener [28] solved this problem for stationary Gaussian processes using the method of spectral factorization. Kalman [12], [13] extended this to nonstationary Gaussian processes and reduced the problem to solving an off-line Riccati equation and an on-line linear differential equation driven by the observations.

When the dynamics and/or observations are nonlinear the unnormalized conditional density satisfies the Zakai equation, a parabolic PDE driven by the observations [4]. It is a very difficult task to accurately compute its solution in real time for all but the smallest state dimensions.

The extended Kalman filter [10] is a widely used alternative method for estimating the state of a nonlinear system. It is obtained by linearizing the nonlinear dynamics and the observation along the trajectory of the estimate. It requires that the on-line solution of a Riccati differential equation and a linear differential equation be driven by the observations. The extended Kalman filter is globally defined but it is only a local method. Under certain conditions, the estimate converges to the true state if the initial estimation error is not too large [1], [23].

There are several nonstochastic approaches to state estimation. For linear systems (1.2), Luenberger [19] developed the concept of an observer. This is another linear dynamical system that is driven by the observations in such a way that the error dynamics is asymptotically stable.

Several nonstochastic methods have been proposed for nonlinear estimation. Some of these are surveyed by Misawa and Hedrick [21]. Other methods include linearization [16], [2], [17], H_∞ methods [15], bilinear systems [29], and high gain observers [3], [5], [6], [7], [8], [9], [24], [25], [26], [27].

This paper describes a simple and efficient method for the design of observers for a broad class of nonlinear systems based on backstepping. The backstepping technique has been used extensively to design stabilizing state feedback control laws [18], [20]. The assumptions on the system are that it be smooth and observable in an appropriate sense. The method is applicable to systems whose error dynamics are not necessarily linearizable by a change of coordinates and input/output injection [16], [2], [17]. It is applicable to a slightly larger class of systems than the high gain observer of Gauthier, Hammouri, and Othman [8]. The latter result can be applied to systems that can be globally described in observable form while the backstepping approach requires only a local observable form. Moreover, backstepping is not a high gain design procedure and hence only local convergence is guaranteed. An explicit formula for the observer gain is derived. The gains are functions of the state of the observer. The gains can be derived off-line through an algorithm presented below. The observer is defined on an arbitrarily large compact subset of the state space but is only locally convergent. We shall prove that the estimate converges exponentially to the true state if the state starts in a compact positively invariant set and the initial estimation error is not too large.

The paper is organized as follows. In section 2 the backstepping approach to observer design is illustrated for a scalar output system without inputs in observable form. In section 3 this is generalized to systems in observable form with vector output and no inputs. In section 4, this technique is generalized to systems that locally can be described in observable form. Systems with inputs are discussed in section 5. In section 6, the relative perfomance of the high gain observer and the backstepping observer are discussed. We close with examples in section 7.

2. The backstepping observer. Consider a smooth nonlinear system in observable form:

$$\begin{aligned} y &= x_1, \\ \dot{x}_1 &= x_2, \\ \dot{x}_2 &= x_3, \\ &\vdots \\ \dot{x}_{n-1} &= x_n, \\ \dot{x}_n &= f_n(x). \end{aligned} \tag{2.1}$$

The state x is n dimensional and the output y is one dimensional. There is no input. Later we shall relax these assumptions. By smooth we mean C^r for r sufficiently large.

The backstepping observer will be in the following form:

$$\begin{aligned} \dot{\hat{x}}_1 &= \hat{x}_2 + \psi_1(\hat{x})(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_2 &= \hat{x}_3 + \psi_2(\hat{x})(x_1 - \hat{x}_1), \\ &\vdots \\ \dot{\hat{x}}_{n-1} &= \hat{x}_n + \psi_{n-1}(\hat{x})(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_n &= f_n(\hat{x}) + \psi_n(\hat{x})(x_1 - \hat{x}_1). \end{aligned} \tag{2.2}$$

The error $e = x - \hat{x}$ dynamics is given by

$$\begin{aligned} \dot{e}_1 &= e_2 - \psi_1(\hat{x})e_1, \\ \dot{e}_2 &= e_3 - \psi_2(\hat{x})e_1, \\ &\vdots \\ \dot{e}_{n-1} &= e_n - \psi_{n-1}(\hat{x})e_1, \\ \dot{e}_n &= f_n(x) - f_n(\hat{x}) - \psi_n(\hat{x})e_1. \end{aligned} \tag{2.3}$$

The problem of observer design is to find gains $\psi_i(\hat{x})$, $1 \le i \le n$, so that $e(t) \to 0$ as $t \to \infty$.

Notice that the error dynamics (2.3) is dependent on both e and $\hat{x}$. The combined system, consisting of the system and its observer, can be described in $x, \hat{x}$ coordinates (2.1), (2.2), in $e, \hat{x}$ coordinates (2.2), (2.3), or in x, e coordinates (2.1), (2.3).

Suppose that K is a compact subset of x space, which is positively invariant under (2.1), i.e., if a trajectory starts in K, then it remains in K for all future times. The set $K \times \{e = 0\}$ is a positively invariant set of the combined system (2.1), (2.3). Using a backstepping approach [18], we will construct a local Lyapunov function for the combined system to prove local exponential convergence to this positively invariant set. The observer gains ψ_i will be chosen in the course of this construction.

We employ the following notation: an error term $O(e)^k$ is a function of $\hat{x}, e$ such that on any compact subset L of $\hat{x}$ space there exists a constant $N > 0, \delta > 0$ such that

$$|O(e)^k| \le N|e|^k \tag{2.4}$$

for all $\hat{x} \in L$ and all $|e| < \delta$. We abbreviate $O(e)^1$ as $O(e)$.

We now proceed with the construction of the backstepping observer on a compact, positively invariant set K and show its local convergence.

Define $z_1 = e_1$ and $V_1 = \frac{1}{2}z_1^2$; then

$$\dot{V}_1 = z_1\dot{z}_1 = -c_1 z_1^2 + z_1 z_2 + O(e)^3,$$

where $c_1 > 0$ and z_2 is the linear function of e that satisfies $z_2 = c_1 z_1 + \dot{z}_1 + O(e)^2$.

If $n = 1$, we choose

$$\psi_1(\hat{x}) = c_1 + \frac{df_1}{dx_1}(\hat{x}_1)$$

so that the auxiliary variable $z_2 = 0$ and

$$\dot{V}_1 = z_1\dot{z}_1 = -c_1 z_1^2 + O(e)^3. \tag{2.5}$$

If $n \geq 2$, then z_1, z_2 and e_1, e_2 are linearly related by

$$\begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ b_{2,1} - \psi_1 & 1 \end{bmatrix} \begin{bmatrix} e_1 \\ e_2 \end{bmatrix}, \tag{2.6}$$

where

$$b_{2,1} = c_1. \tag{2.7}$$

Define $V_2 = V_1 + \frac{1}{2}z_2^2$; then

$$\dot{V}_2 = -c_1 z_1^2 - c_2 z_2^2 + z_2 z_3 + O(e)^3,$$

where $c_2 > 0$ and z_3 is the linear function of e that satisfies $z_3 = z_1 + c_2 z_2 + \dot{z}_2 + O(e)^2$. Notice that z_2, z_3 depend on the as yet unspecified observer gains $\psi_1(\hat{x}), \psi_2(\hat{x})$.

If $n = 2$, then we would like to choose the gains so that the auxiliary variable z_3 is 0, for then

$$\dot{V}_2 = -c_1 z_1^2 - c_2 z_2^2 + O(e)^3. \tag{2.8}$$

Now

$$\begin{aligned} z_3 &= z_1 + c_2 z_2 + \dot{z}_2 + O(e)^2 \\ &= (b_{3,1} + f_{2;1} - \psi_2)e_1 + (b_{3,2} + f_{2,2} - \psi_1)e_2, \end{aligned}$$

where

$$f_{n;i} = \frac{\partial f_n}{\partial x_i}(\hat{x}),$$

$$\begin{aligned} b_{3,1} &= 1 + c_2(b_{2,1} - \psi_1) + (b_{2,1} - \psi_1)' - (b_{2,1} - \psi_1)\psi_1, \\ b_{3,2} &= c_1 + c_2. \end{aligned} \tag{2.9}$$

We denote differentiation along the observer dynamics when $e_1 = 0$ by $'$. For an n dimensional observer (2.2), the operation $'$ is defined on functions $\phi(\hat{x})$ by

$$\phi'(\hat{x}) = \sum_{j=1}^{n-1} \frac{\partial \phi}{\partial \hat{x}_j}(\hat{x})\hat{x}_{j+1} + \frac{\partial \phi}{\partial \hat{x}_n}(\hat{x}) f_n(\hat{x}).$$

Notice that $'$ does not involve the gains ψ_i and

$$\phi' = \dot{\phi} + O(e).$$

If $n = 2$, we successively define

$$\psi_1(\hat{x}) = b_{3,2}(\hat{x}) + f_{2;2}(\hat{x}),$$
$$\psi_2(\hat{x}) = b_{3,1}(\hat{x}) + f_{2;1}(\hat{x});$$

then (2.8) holds. Notice that the gains are functions of $\hat{x}$ alone.

If $n \geq 3$, we define z_1, z_2 as before (2.6) and z_3 as a linear function of e so that

$$z_3 = z_1 + c_2 z_2 + \dot{z}_2 + O(e)^2.$$

By a calculation similar to the above, we see that

$$z_3 = (b_{3,1} - \psi_2)e_1 + (b_{3,2} - \psi_1)e_2 + e_3, \tag{2.10}$$

where $b_{3,1},\ b_{3,2}$ are given by (2.9). Define $V_3 = V_2 + \frac{1}{2}z_3^2$; then

$$\dot{V}_3 = -c_1 z_1^2 - c_2 z_2^2 - c_3 z_3^2 + z_3 z_4 + O(e)^3,$$

where $c_3 > 0$ and z_4 is the linear function of e that satisfies $z_4 = z_2 + c_3 z_3 + \dot{z}_3 + O(e)^2$.

If $n = 3$, we would like to choose the observer gains so that the auxiliary variable z_4 is 0. After a straightforward calculation, one finds that

$$\begin{aligned} z_4 = {} & (b_{4,1} + f_{3;1} - \psi_3)e_1 + (b_{4,2} + f_{3;2} - \psi_2)e_2 \\ & + (b_{4,3} + f_{3;3} - \psi_1)e_3, \end{aligned} \tag{2.11}$$

where $b_{4,j} = b_{4,j}(\hat{x})$ are functions only of $\hat{x}$ and $b_{4,j}$ depends only on c, ψ_k for $1 \leq k < 3 - j$ and $b_{r,s}$ for $1 < r < 4,\ 1 \leq r - s \leq 4 - j$:

$$\begin{aligned} b_{4,1} &= b_{2,1} - \psi_1 + c_3(b_{3,1} - \psi_2) + (b_{3,1} - \psi_2)' - (b_{3,1} - \psi_2)\psi_1 - (b_{3,2} - \psi_1)\psi_2, \\ b_{4,2} &= 1 + c_3(b_{3,2} - \psi_1) + (b_{3,2} - \psi_1)' + b_{3,1}, \\ b_{4,3} &= c_3 + b_{3,2}. \end{aligned} \tag{2.12}$$

Hence we can successively solve (2.12) for the desired observer gains,

$$\psi_1 = b_{4,3} + f_{3;3},$$
$$\psi_2 = b_{4,2} + f_{3;2},$$
$$\psi_3 = b_{4,1} + f_{3;1}.$$

Turning to the n dimensional system in observable form, the variables $z_1, \ldots, z_{n+1}$ are defined as follows:

$$\begin{aligned} z_1 &= e_1, \\ z_2 &= c_1 z_1 + \dot{z}_1 + O(e)^2, \\ z_3 &= z_1 + c_2 z_2 + \dot{z}_2 + O(e)^2, \\ &\vdots \\ z_i &= z_{i-2} + c_{i-1} z_{i-1} + \dot{z}_{i-1} + O(e)^2, \\ &\vdots \\ z_{n+1} &= z_{n-1} + c_n z_n + \dot{z}_n + O(e)^2, \end{aligned} \tag{2.13}$$

where $c_i > 0$ and the error terms are chosen so that z is a linear function of e. A straightforward calculation yields

(2.14)
$$\begin{bmatrix} z_1 \\ z_2 \\ \vdots \\ z_n \\ z_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ b_{2,1} - \psi_1 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ b_{n,1} - \psi_{n-1} & b_{n,2} - \psi_{n-2} & \cdots & 1 \\ b_{n+1,1} + f_{n;1} - \psi_n & b_{n+1,2} + f_{n;2} - \psi_{n-1} & \cdots & b_{n+1,n} + f_{n;n} - \psi_1 \end{bmatrix} \begin{bmatrix} e_1 \\ e_2 \\ \vdots \\ e_n \end{bmatrix},$$

where $b_{i,j} = b_{i,j}(\hat{x})$ are functions of $\hat{x}$ given by (2.7), (2.9) and for $4 \le i \le n+1$ and $2 \le j \le i-3$,

$$\begin{aligned} b_{i,1} &= b_{i-2,1} - \psi_{i-3} + c_{i-1}(b_{i-1,1} - \psi_{i-2}) + (b_{i-1,1} - \psi_{i-2})' \\ &\quad - \sum_{j=1}^{i-2} (b_{i-1,j} - \psi_{i-j-1})\psi_j, \end{aligned}$$

$$\begin{aligned} b_{i,j} &= b_{i-2,j} - \psi_{i-j-2} + c_{i-1}(b_{i-1,j} - \psi_{i-j-1}) + (b_{i-1,j} - \psi_{i-j-1})' \\ &\quad + b_{i-1,j-1}, \end{aligned} \tag{2.15}$$

$$b_{i,i-2} = 1 + c_{i-1}(b_{i-1,i-2} - \psi_1) + (b_{i-1,i-2} - \psi_1)' + b_{i-1,i-3},$$

$$b_{i,i-1} = c_{i-1} + b_{i-1,i-2}.$$

In the backstepping observer we choose the observer gains to zero the last row of the matrix in (2.14),

$$\begin{aligned} \psi_1 &= b_{n+1,n} + f_{n;n}, \\ &\vdots \\ \psi_{n-1} &= b_{n+1,2} + f_{n;2}, \\ \psi_n &= b_{n+1,1} + f_{n;1}, \end{aligned} \tag{2.16}$$

so that $z_{n+1} = 0$.

By induction one sees that $b_{i,j}$ depends only on the quantities

$$\begin{aligned} &c_1, \dots, c_{i-1}, \\ &\psi_1, \dots, \psi_{i-j-1}, \\ &b_{r,s}, \quad 1 < r < i, \quad 1 \le r - s < i - j, \end{aligned} \tag{2.17}$$

and so $b_{i,j}$ can be computed down the diagonals of (2.14). We start with the diagonal just below the main one and successively compute $b_{2,1}, b_{3,2}, \dots, b_{n+1,n}$, which yields

$$b_{i,i-1} = c_1 + \cdots + c_{i-1}.$$

Then we define ψ_1 by (2.16). Going down the diagonal two below the main we compute $b_{3,1}, b_{4,2}, \dots, b_{n+1,n-1}$ and then ψ_2, etc.

THEOREM 2.1. *Suppose that K is a compact, positively invariant set for the system* (2.1). *Consider the observer* (2.2) *with backstepping gains* (2.16) *and error dynamics* (2.3). *There exist constants $M > 0$, $\epsilon > 0$, $\gamma > 0$ such that if $x(0) \in K$ and $|e(0)| < \epsilon$, then*

$$|e(t)| < M|e(0)| \exp(-\gamma t).$$

Proof. Define

$$V = \frac{1}{2}\sum_{i=1}^{n} z_i^2; \tag{2.18}$$

then from (2.13)

$$\dot{V} = -\sum_{i=1}^{n} c_i z_i^2 + z_n z_{n+1} + O(e)^3$$

and

$$\dot{V} = -\sum_{i=1}^{n} c_i z_i^2 + O(e)^3. \tag{2.19}$$

Now let U_r be the $r > 0$ neighborhood of K; then its closure $\bar{U}_r$ is a compact subset. Hence there exist constants $N > 0, \epsilon > 0$ such that the error term in (2.19) satisfies

$$|O(e)^3| \leq N|e|^3 \tag{2.20}$$

for all $\hat{x} \in \bar{U}_r, |e| < \epsilon$. Redefine ϵ to be the smaller of r and ϵ.

From (2.14) we know that there exist constants $M_1 > 0, M_2 > 0$ such that for all $\hat{x} \in \bar{U}_r$ and all e, z,

$$M_1|e| \leq |z| \leq M_2|e|. \tag{2.21}$$

Since $c_i > 0$ there exists a constant $\gamma > 0$ such that

$$4\gamma|z|^2 \leq \sum_{i=1}^{n} c_i z_i^2. \tag{2.22}$$

Hence there is an $\epsilon > 0$ sufficiently small so that the error term in (2.19) satisfies

$$|O(e)^3| \leq \frac{1}{2}\sum_{i=1}^{n} c_i z_i^2 \tag{2.23}$$

for all $\hat{x} \in \bar{U}_r$ and all $|e| < \epsilon$. For these $\hat{x}, e$

$$\dot{V} \leq -\frac{1}{2}\sum_{i=1}^{n} c_i z_i^2 \tag{2.24}$$

$$\leq -2\gamma V. \tag{2.25}$$

Consider the set $D = \{(x, e) : x \in K, V(z(e)) < M_1\epsilon/2\}$; this is a neighborhood of $K \times \{0\}$ in x, e space. From (2.21) we see that on D, we have $|e| < \epsilon$, so $\dot{V} < -2\gamma V$, so D is positively invariant, and by Gronwall's inequality

$$V(t) \leq \exp(-2\gamma t)V(0). \tag{2.26}$$

From (2.21) we obtain

$$|e(t)| \leq \frac{M_2}{M_1}\exp(-\gamma t)|e(0)| \qquad \square$$

Remark 1. There are other possible choices of the Lyapunov function (2.18)—this one was chosen to simplify the calculations. The constants c_i appearing in (2.14) can be chosen as functions of $y, \hat{x}$ as long as they are positive and bounded away from zero.

3. Vector output systems in observable form. The above result generalizes immediately to vector output systems with all observability indices the same. These are systems of the form

$$\begin{aligned} y_l &= x_{1,l}, \\ \dot{x}_{1,l} &= x_{2,l}, \\ \dot{x}_{2,l} &= x_{3,l}, \\ &\vdots \\ \dot{x}_{k,l} &= f_{k,l}(x_1, \dots, x_k), \end{aligned} \tag{3.1}$$

where $l = 1, \dots, p$. The output $y = (y_1, \dots, y_p)$ is p dimensional and so is each $x_i = (x_{i,1}, \dots, x_{i,p})$. The state dimension is then $n = pk$ dimensional. The construction of the observer proceeds exactly as before except that the previously scalar quantities $\hat{x}_i, e_i, z_i, \psi_i$ are now p dimensional, z_i^2 is replaced by $|z_i|^2$, $z_i z_j$ is replaced by $z_i \cdot z_j$, and $\psi_i, b_{i,j}, f_{n,j}$ are $p \times p$ dimensional.

More generally we consider systems of the form

$$\begin{aligned} y_l &= x_{1,l}, \\ \dot{x}_{1,l} &= x_{2,l}, \\ \dot{x}_{2,l} &= x_{3,l}, \\ &\vdots \\ \dot{x}_{k_l,l} &= f_{k_l,l}(x_1, \dots, x_{k_l}), \end{aligned} \tag{3.2}$$

where y is p dimensional, x is $n = \sum k_l$ dimensional, and without loss of generality $k_1 \geq k_2 \geq \cdots \geq k_p$. The indices $k_1, \dots, k_p$ are the observability indices of the system [17]. The dual indices are $m_1, \dots, m_{k_1}$, where m_i is the number of k_l's that are greater than or equal to i. The subvectors x_i are defined as $x_i = (x_{i,1}, \dots, x_{i,m_i})$.

The observer is of the form

$$\begin{aligned} \dot{\hat{x}}_{1,l} &= \hat{x}_{2,l} + \psi_{1,l}(\hat{x}_1, \dots, \hat{x}_{k_l})(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_{2,l} &= \hat{x}_{3,l} + \psi_{2,l}(\hat{x}_1, \dots, \hat{x}_{k_l})(x_1 - \hat{x}_1), \\ &\vdots \\ \dot{\hat{x}}_{k_l,l} &= f_{k_l,l}(\hat{x}_1, \dots, \hat{x}_{k_l}) + \psi_{k_l,l}(\hat{x}_1, \dots, \hat{x}_{k_l})(x_1 - \hat{x}_1), \end{aligned} \tag{3.3}$$

where $\psi_{r,l}(\hat{x}_1, \dots, \hat{x}_{k_l})$ is $1 \times p$ dimensional.

The error dynamics is given by

$$\begin{aligned} \dot{e}_{1,l} &= e_{2,l} - \psi_{1,l}(\hat{x}_1, \dots, \hat{x}_{k_l})e_1, \\ \dot{e}_{2,l} &= e_{3,l} - \psi_{2,l}(\hat{x}_1, \dots, \hat{x}_{k_l})e_1, \\ &\vdots \\ \dot{e}_{k_l,l} &= f_{k_l,l}(x_1, \dots, x_{k_l}) - f_{k_l,l}(\hat{x}_1, \dots, \hat{x}_{k_l}) - \psi_{k_l,l}(\hat{x}_1, \dots, \hat{x}_{k_l})e_1. \end{aligned} \tag{3.4}$$

The method is a modification of the previous approach but the notation is cumbersome. The subvector x_j is m_j dimensional and so are the subvectors $\hat{x}_j$ and e_j.

The subvector z_j is m_{j-1} dimensional and is defined by a modification of (2.13),

$$
\begin{aligned}
z_{1,l} &= e_{1,l}, && 1 \le l \le p,\\
z_{2,l} &= c_{1,l}z_{1,l} + \dot{z}_{1,l} + O(e)^2, && 1 \le l \le m_1,\\
z_{3,l} &= z_{1,l} + c_{2,l}z_{2,l} + \dot{z}_{2,l} + O(e)^2, && 1 \le l \le m_2,\\
&\vdots &&\\
z_{r+1,l} &= z_{r-1,l} + c_{r,l}z_{r,l} + \dot{z}_{r,l} + O(e)^2, && 1 \le l \le m_r,\\
&\vdots &&\\
z_{k_1+1,l} &= z_{k_1-1,l} + c_{k_1,l}z_{k_1,l} + \dot{z}_{k_1,l} + O(e)^2, && 1 \le l \le m_{k_1}.
\end{aligned} \tag{3.5}
$$

The auxiliary variables are the extra components of z, namely $z_{k_1+1,1}, \dots, z_{k_p+1,p}$, and the observer gains are determined by setting them to zero. If

$$V = \frac{1}{2}\sum_{l=1}^{p}\sum_{r=1}^{k_l} z_{r,l}^2,$$

then

$$\dot{V} = -\sum_{l=1}^{p}\sum_{r=1}^{k_l} c_{r,l}z_{r,l}^2 + O(e)^3$$

and the argument proceeds as before.

We illustrate with an example. Consider a three dimensional system

$$
\begin{aligned}
y_1 &= x_{1,1},\\
y_2 &= x_{1,2},\\
\dot{x}_{1,1} &= x_{2,1},\\
\dot{x}_{1,2} &= f_{1,2}(x_{1,1}, x_{1,2}),\\
\dot{x}_{2,1} &= f_{2,1}(x_{1,1}, x_{1,2}, x_{2,1}).
\end{aligned} \tag{3.6}
$$

The indices are $k_1 = 2, k_2 = 1$ and the dual indices are $m_1 = 2, m_2 = 1$. The observer is of the form

$$
\begin{aligned}
\dot{\hat{x}}_{1,1} &= \hat{x}_{2,1} + \psi_{1,1,1}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})(x_{1,1} - \hat{x}_{1,1}) + \psi_{1,1,2}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})(x_{1,2} - \hat{x}_{1,2}),\\
\dot{\hat{x}}_{1,2} &= f_{1,2}(\hat{x}_{1,1}, \hat{x}_{1,2}) + \psi_{1,2,1}(\hat{x}_{1,1}, \hat{x}_{1,2})(x_{1,1} - \hat{x}_{1,1}) + \psi_{1,2,2}(\hat{x}_{1,1}, \hat{x}_{1,2})(x_{1,2} - \hat{x}_{1,2}),\\
\dot{\hat{x}}_{2,1} &= f_{2,1}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1}) + \psi_{2,1,1}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})(x_{1,1} - \hat{x}_{1,1})\\
&\quad + \psi_{2,1,2}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})(x_{1,2} - \hat{x}_{1,2}),
\end{aligned} \tag{3.7}
$$

and the error dynamics is

$$
\begin{aligned}
\dot{e}_{1,1} &= e_{2,1} - \psi_{1,1,1}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})e_{1,1} - \psi_{1,1,2}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})e_{1,2},\\
\dot{e}_{1,2} &= f_{1,2}(x_{1,1}, x_{1,2}) - f_{1,2}(\hat{x}_{1,1}, \hat{x}_{1,2}) - \psi_{1,2,1}(\hat{x}_{1,1}, \hat{x}_{1,2})e_{1,1} - \psi_{1,2,2}(\hat{x}_{1,1}, \hat{x}_{1,2})e_{1,2},\\
\dot{e}_{2,1} &= f_{2,1}(x_{1,1}, x_{1,2}, x_{2,1}) - f_{2,1}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})\\
&\quad - \psi_{2,1,1}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})e_{1,1} - \psi_{2,1,2}(\hat{x}_{1,1}, \hat{x}_{1,2}, \hat{x}_{2,1})e_{1,2}.
\end{aligned} \tag{3.8}
$$

From (3.5) we obtain

$$
\begin{aligned}
z_{1,1} &= e_{1,1},\\
z_{1,2} &= e_{1,2},\\
z_{2,1} &= (c_{1,1} - \psi_{1,1,1})e_{1,1} - \psi_{1,1,2}e_{1,2} + e_{2,1},\\
z_{2,2} &= \left(\frac{\partial f_{1,2}}{\partial \hat{x}_{1,1}} - \psi_{1,2,1}\right) e_{1,1} + \left(c_{1,2} + \frac{\partial f_{1,2}}{\partial \hat{x}_{1,2}} - \psi_{1,2,2}\right) e_{1,2},\\
z_{3,1} &= \Bigg(1 + c_{1,1}c_{2,1} - (c_{1,1} + c_{2,1})\psi_{1,1,1} - \psi'_{1,1,1} + \psi^2_{1,1,1}\\
&\quad - \psi_{1,1,2}\left(\frac{\partial f_{1,2}}{\partial \hat{x}_{1,1}} - \psi_{1,2,1}\right) + \frac{\partial f_{2,1}}{\partial \hat{x}_{1,1}} - \psi_{2,1,1}\Bigg)e_{1,1}\\
&\quad + \Bigg(- (c_{1,1+}c_{2,1})\psi_{1,1,2} - \psi'_{1,1,2} + \psi_{1,1,1}\psi_{1,1,2}\\
&\quad - \psi_{1,1,2}\left(\frac{\partial f_{1,2}}{\partial \hat{x}_{1,2}} - \psi_{1,2,2}\right) + \frac{\partial f_{2,1}}{\partial \hat{x}_{1,2}} - \psi_{2,1,2}\Bigg) e_{1,2}\\
&\quad + \left(c_{1,1} + c_{2,1} + \frac{\partial f_{2,1}}{\partial \hat{x}_{2,1}} - \psi_{1,1,1}\right) e_{2,1}.
\end{aligned}
\tag{3.9}
$$

Setting the auxiliary variables $z_{2,2} = z_{3,1} = 0$, we obtain a solution

$$
\begin{aligned}
\psi_{1,2,1} &= \frac{\partial f_{1,2}}{\partial \hat{x}_{1,1}},\\
\psi_{1,2,2} &= c_{1,2} + \frac{\partial f_{1,2}}{\partial \hat{x}_{1,2}},\\
\psi_{2,1,1} &= 1 + c_{1,1}c_{2,1} - (c_{1,1} + c_{2,1})\psi_{1,1,1} - \psi'_{1,1,1} + \psi^2_{1,1,1}\\
&\qquad -\psi_{1,1,2}\left(\frac{\partial f_{1,2}}{\partial \hat{x}_{1,1}} - \psi_{1,2,1}\right) + \frac{\partial f_{2,1}}{\partial \hat{x}_{1,1}},\\
\psi_{2,1,2} &= -(c_{1,1+}c_{2,1})\psi_{1,1,2} - \psi'_{1,1,2} + \psi_{1,1,1}\psi_{1,1,2} + \frac{\partial f_{2,1}}{\partial \hat{x}_{1,2}},\\
\psi_{1,1,1} &= c_{1,1} + c_{2,1} + \frac{\partial f_{2,1}}{\partial \hat{x}_{2,1}},\\
\psi_{1,1,2} &= 0.
\end{aligned}
\tag{3.10}
$$

There are other solutions with $\psi_{1,1,2} \neq 0$.

A computationally simpler approach [22] is to add extra states so as to make all the observability indices the same. We illustrate with the three dimensional system (3.6) above. We imbed it in the four dimensional system

$$
\begin{aligned}
y_1 &= x_{1,1},\\
y_2 &= x_{1,2},\\
\dot{x}_{1,1} &= x_{2,1},\\
\dot{x}_{1,2} &= x_{2,2} + f_{1,2}(x_{1,1}, x_{1,2}),\\
\dot{x}_{2,1} &= f_{2,1}(x_{1,1}, x_{1,2}, x_{2,1}),\\
\dot{x}_{2,2} &= 0.
\end{aligned}
\tag{3.11}
$$

In the new coordinates

$$\begin{aligned}\bar{x}_{1,1} &= x_{1,1},\\ \bar{x}_{1,2} &= x_{1,2},\\ \bar{x}_{2,1} &= x_{2,1},\\ \bar{x}_{2,2} &= x_{2,2} + f_{1,2}(x_{1,1}, x_{1,2}),\end{aligned} \tag{3.12}$$

the system is in observable form

$$\begin{aligned} y_1 &= \bar{x}_{1,1},\\ y_2 &= \bar{x}_{1,2},\\ \dot{\bar{x}}_{1,1} &= \bar{x}_{2,1},\\ \dot{\bar{x}}_{1,2} &= \bar{x}_{2,2},\\ \dot{\bar{x}}_{2,1} &= f_{2,1}(\bar{x}_{1,1}, \bar{x}_{1,2}, \bar{x}_{2,1}),\\ \dot{\bar{x}}_{2,2} &= \frac{\partial f_{1,2}}{\partial \bar{x}_{1,1}}(\bar{x}_{1,1}, \bar{x}_{1,2})\bar{x}_{2,1} + \frac{\partial f_{1,2}}{\partial \bar{x}_{1,2}}(\bar{x}_{1,1}, \bar{x}_{1,2}) f_{1,2}(\bar{x}_{1,1}, \bar{x}_{1,2}).\end{aligned} \tag{3.13}$$

This process can be repeated to make all the observability indices identical. An observer can be constructed for the higher dimensional system and since it is convergent it will yield convergent estimates for the original system.

4. Systems locally in observable form. In this section we construct an observer for a nonlinear system with scalar output of the form

$$\begin{aligned}\dot{\xi} &= f(\xi),\\ y &= h(\xi),\end{aligned} \tag{4.1}$$

where $\xi \in \mathbb{R}^n, y \in \mathbb{R}$.

Following [6] and [8], we say a system is *uniformly observable* if the mapping

$$\xi \mapsto \begin{bmatrix} h(\xi) \\ L_f h(\xi) \\ \vdots \\ L_f^{n-1} h(\xi) \end{bmatrix} \tag{4.2}$$

is a global diffeomorphism, where $L_f^j h(\xi)$ is the j-fold Lie derivative of h by f,

$$\begin{aligned} L_f h(\xi) &= \frac{\partial h}{\partial \xi}(\xi) f(\xi),\\ L_f^j h(\xi) &= \frac{\partial L_f^{j-1} h}{\partial \xi}(\xi) f(\xi).\end{aligned} \tag{4.3}$$

A system can be transformed globally into observable form iff it is uniformly observable. The high gain observer of Gauthier, Hammouri, and Othman [8] requires that the system be uniformly observable while our observer requires only that the system be locally uniformly observable.

A system is *locally uniformly observable* at ξ^0 if the mapping (4.2) is a local diffeomorphism on a neighborhood of ξ^0. A system is *locally uniformly observable* on a set K if it is *locally uniformly observable* at every $\xi^0 \in K$.

If a system is locally uniformly observable at ξ^0, then we can define new local coordinates around ξ^0:

$$x(\xi) = \begin{bmatrix} h(\xi) \\ L_f h(\xi) \\ \vdots \\ L_f^{n-1} h(\xi) \end{bmatrix}. \tag{4.4}$$

In these coordinates the system is in observable form (2.1) with

$$f_n(x) = L_f^n h(\xi(x)). \tag{4.5}$$

LEMMA 4.1. *Suppose that the system* (4.1) *is locally uniformly observable on a compact subset K of ξ space; then there exist an $\epsilon > 0$ and constants $M_1 > 0, M_2 > 0$ such that for all $\xi, \zeta \in K$, $|\xi - \zeta| < \epsilon$*

$$M_1|\xi - \zeta| \leq |x(\xi) - x(\zeta)| \leq M_2|\xi - \zeta|. \tag{4.6}$$

Proof. The map (4.2) is a local diffeomorphism so at any $\zeta \in K$ there exist $\delta(\zeta) > 0, M_1(\zeta) > 0, M_2(\zeta) > 0$ such that

$$M_1(\zeta)|\xi_1 - \xi_2| \leq |x(\xi_1) - x(\xi_2)| \leq M_2(\zeta)|\xi_1 - \xi_2| \tag{4.7}$$

for all $|\xi_i - \zeta| < \delta(\zeta)$. Let $B(\zeta)$ denote the open ball around ζ of radius $\delta(\zeta)/2$. These balls form an open cover of the compact set K so there exists a finite subcover $B(\zeta_1), \ldots, B(\zeta_k)$. Define

$$\begin{aligned} \epsilon &= \frac{1}{2} \min\{\delta(\zeta_1), \ldots, \delta(\zeta_k)\}, \\ M_1 &= \min\{M_1(\zeta_1), \ldots, M_1(\zeta_k)\}, \\ M_2 &= \max\{M_2(\zeta_1), \ldots, M_2(\zeta_k)\}. \end{aligned}$$

If $|\xi_1 - \xi_2| < \epsilon$, then there exists a j such that $|\xi_i - \zeta_j| < \delta(\zeta_j)$ for $i = 1, 2$, so the conclusion follows from (4.7). □

The observer for (4.1) will be of the form

$$\begin{aligned} \dot{\hat{\xi}} &= f(\hat{\xi}) + \phi(\hat{\xi})\,(y - \hat{y})\,, \\ \hat{y} &= h(\hat{\xi}). \end{aligned} \tag{4.8}$$

THEOREM 4.2. *Suppose the system* (4.1) *is locally uniformly observable on a compact positively invariant set K. There exists an observer* (4.8) *and constants $M > 0$, $\epsilon > 0$, $\gamma > 0$ such that if $\xi(0) \in K$ and $|\xi(0) - \hat{\xi}(0)| < \epsilon$, then*

$$|\xi(t) - \hat{\xi}(t)| < M|\xi(0) - \hat{\xi}(0)| \exp(-\gamma t).$$

Proof. Notice that the mapping (4.4) is globally defined on the compact positively invariant set K. It may fail to define global coordinates on K but it is locally one to one and so defines valid local coordinates. In these local coordinates the system is in observable form (2.1) and so we can proceed as in section 2. In the local x coordinates the observer (4.8) takes the form (2.2) and the local error dynamics is given by (2.3). It is important to note that the x variables are globally defined as are $\hat{x}, e$, although

they may be valid coordinates only locally. This allows us to construct the observer in the x variables exactly as before and its local convergence is guaranteed by the above lemma. The observer in the ξ coordinates is given by (4.8), where

$$\phi(\hat{\xi}) = \left[\frac{\partial x}{\partial \xi}(\hat{\xi})\right]^{-1} \psi(x(\hat{\xi})). \tag{4.9}$$

Note that this does not require inverting $x = x(\hat{\xi})$, but it does require inverting the Jacobian matrix $\frac{\partial x}{\partial \xi}(\hat{\xi})$ at each $\hat{\xi}$. □

5. Systems with inputs. In this section we consider systems with inputs

$$\begin{aligned} \dot{\xi} &= f(\xi, u), \\ y &= h(\xi). \end{aligned} \tag{5.1}$$

The state trajectory of a system in observable form (2.1) is completely determined by the output trajectory. The generalization of observable form to a system with inputs is one of the form

$$\begin{aligned} y &= x_1, \\ \dot{x}_1 &= x_2 + g_1(x_1, u), \\ \dot{x}_2 &= x_3 + g_2(x_1, x_2, u), \\ &\vdots \\ \dot{x}_{n-1} &= x_n + g_{n-1}(x_1, \ldots, x_{n-1}, u), \\ \dot{x}_n &= f_n(x) + g_n(x, u). \end{aligned} \tag{5.2}$$

Such a system is said to be *uniformly observable for any input* [9]. Regardless of what input $u = u(t)$ is chosen, the system is observable in the sense that the output and input trajectories uniquely determine the state trajectory,

$$\begin{aligned} x_1 &= y, \\ x_2 &= \dot{x}_1 - g_1(x_1, u), \\ x_3 &= \dot{x}_2 - g_2(x_1, x_2, u), \\ &\vdots \\ x_n &= \dot{x}_{n-1} - g_{n-1}(x_1, \ldots, x_{n-1}, u). \end{aligned}$$

We assume that the state estimate from the observer will be used in a feedback law $u = \kappa(\hat{x})$ to control the system. For a system that is uniformly observable for any input (5.2), the observer will be in the following form:

$$\begin{aligned} \dot{\hat{x}}_1 &= \hat{x}_2 + g_1(\hat{x}_1, \kappa(\hat{x})) + \psi_1(\hat{x})(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_2 &= \hat{x}_3 + g_2(\hat{x}_1, \hat{x}_2, \kappa(\hat{x})) + \psi_2(\hat{x})(x_1 - \hat{x}_1), \\ &\vdots \\ \dot{\hat{x}}_{n-1} &= \hat{x}_n + g_{n-1}(\hat{x}_1, \ldots, \hat{x}_{n-1}, \kappa(\hat{x})) + \psi_{n-1}(\hat{x})(x_1 - \hat{x}_1), \\ \dot{\hat{x}}_n &= f_n(\hat{x}) + g_n(\hat{x}, \kappa(\hat{x})) + \psi_n(\hat{x})(x_1 - \hat{x}_1). \end{aligned} \tag{5.3}$$

The error $e = x - \hat{x}$ dynamics is given by

$$\begin{aligned}
\dot{e}_1 &= e_2 + g_1(x_1, \kappa(\hat{x})) - g_1(\hat{x}_1, \kappa(\hat{x})) - \psi_1(\hat{x})e_1,\\
\dot{e}_2 &= e_3 + g_2(x_1, x_2, \kappa(\hat{x})) - g_2(\hat{x}_1, \hat{x}_2, \kappa(\hat{x})) - \psi_2(\hat{x})e_1,\\
&\vdots\\
\dot{e}_{n-1} &= e_n + g_{n-1}(x_1, \dots, x_{n-1}, \kappa(\hat{x})) - g_{n-1}(\hat{x}_1, \dots, \hat{x}_{n-1}, \kappa(\hat{x})) - \psi_{n-1}(\hat{x})e_1,\\
\dot{e}_n &= f_n(x) - f_n(\hat{x}) + g_n(x, \kappa(\hat{x})) - g_n(\hat{x}, \kappa(\hat{x})) - \psi_n(\hat{x})e_1.
\end{aligned} \tag{5.4}$$

The observer is constructed as before; define variables $z_1, \dots, z_{n+1}$ by (2.13), where the error terms are chosen so that z is a linear function of e, (2.14). The coefficients $b_{i,j}(\hat{x})$ are given by the generalization of (2.7), (2.9), and (2.15),

$$\begin{aligned}
b_{2,1} &= c_1 + g_{1,1},\\
b_{3,1} &= 1 + c_2(b_{2,1} - \psi_1) + (b_{2,1} - \psi_1)' + (b_{2,1} - \psi_1)(g_{1,1} - \psi_1) + g_{2,1},\\
b_{3,2} &= c_2 + b_{2,1} + g_{2,2},
\end{aligned} \tag{5.5}$$

and for $4 \le i \le n+1$ and $2 \le j \le i-3$

$$\begin{aligned}
b_{i,1} &= b_{i-2,1} - \psi_{i-3} + c_{i-1}(b_{i-1,1} - \psi_{i-2}) + (b_{i-1,1} - \psi_{i-2})'\\
&\quad - \sum_{j=1}^{i-2}(b_{i-1,j} - \psi_{i-j-1})(\psi_j - g_{j;1}) + g_{i-1;1},
\end{aligned}$$

$$\begin{aligned}
b_{i,j} &= b_{i-2,j} - \psi_{i-j-2} + c_{i-1}(b_{i-1,j} - \psi_{i-j-1}) + (b_{i-1,j} - \psi_{i-j-1})'\\
&\quad + b_{i-1,j-1} + \sum_{k=j}^{i-2}(b_{i-1,k} - \psi_{i-k-1})g_{k;j} + g_{i-1;j},
\end{aligned}$$

$$\begin{aligned}
b_{i,i-2} &= 1 + c_{i-1}(b_{i-1,i-2} - \psi_1) + (b_{i-1,i-2} - \psi_1)' + b_{i-1,i-3}\\
&\quad + (b_{i-1,i-2} - \psi_1)g_{i-2;i-2} + g_{i-1;i-2},
\end{aligned}$$

$$b_{i,i-1} = c_{i-1} + b_{i-1,i-2} + g_{i-1;i-1}, \tag{5.6}$$

where

$$g_{i;j}(\hat{x}) = \frac{\partial g_i}{\partial x_j}(\hat{x}, \kappa(\hat{x})) \tag{5.7}$$

and the operation $'$ is defined on functions $\phi(\hat{x})$ by

$$\phi'(\hat{x}) = \sum_{j=1}^{n-1} \frac{\partial \phi}{\partial \hat{x}_j}(\hat{x})\left(\hat{x}_{j+1} + g_j(\hat{x}, \kappa(\hat{x}))\right) + \frac{\partial \phi}{\partial \hat{x}_n}\left(f_n(\hat{x}) + g_n(\hat{x}, \kappa(\hat{x}))\right). \tag{5.8}$$

Notice that as before that $'$ does not involve the gains ψ_i and

$$\phi' = \dot{\phi} + O(e).$$

Define

$$V = \frac{1}{2}\sum_{i=1}^{n} z_i^2; \tag{5.9}$$

then from (2.13)

$$\dot{V} = -\sum_{i=1}^{n} c_i z_i^2 + z_n z_{n+1} + O(e)^3. \tag{5.10}$$

We choose the observer gains

$$\begin{aligned} \psi_1 &= b_{n+1,n} + f_{n;n}, \\ &\vdots \\ \psi_{n-1} &= b_{n+1,2} + f_{n;2}, \\ \psi_n &= b_{n+1,1} + f_{n;1} \end{aligned} \tag{5.11}$$

so that $z_{n+1} = 0$ and

$$\dot{V} = -\sum_{i=1}^{n} c_i z_i^2 + O(e)^3. \tag{5.12}$$

A system (5.1) is said to *locally uniformly observable for any input* if around every ξ^0 the transformation (4.2) locally carries it to the form (5.2). For such systems the above algorithm will yield an observer on any compact positively invariant set.

If the system is not locally uniformly observable for any input, then one can still attempt to design the observer by the above algorithm by defining variables $z_1, \dots, z_{n+1}$ by (2.13), where the error terms are chosen so that z is a linear function of e, (2.14). The triangular structure of (2.14) will be lost so there is no guarantee that the transformation from e to z is invertible. If it is, then the algorithm yields a locally convergent observer.

Suppose $U(x)$ is a Lyapunov function for the system (5.1) under full state feedback $u = \kappa(x)$,

$$\dot{U}(x) = \frac{\partial U}{\partial x}(x) f(x, \kappa(x)) \le 0,$$

and suppose that the Lipschitz conditions

$$\begin{aligned} \left| \frac{\partial U}{\partial x}(x) \left(f(x,u) - f(x,\kappa(x)) \right) \right| &\le M \left| u - \kappa(x) \right|, \\ \left| \kappa(x) - \kappa(\hat{x}) \right| &\le M \left| x - \hat{x} \right| \end{aligned}$$

hold for some constant M. If we are able to design an observer using the backstepping technique, then we can choose $c_1 = \cdots = c_n = N$ so that $U(x) + V^{\frac{1}{2}}(e, \hat{x})$ is a Lyapunov function for the combined system. For $|e|$ sufficiently small by (2.21) and (2.23),

$$\begin{aligned} \frac{d}{dt}\left(U + V^{\frac{1}{2}} \right) &= \frac{\partial U}{\partial x}(x) f(x, \kappa(\hat{x})) + \frac{1}{2} V^{-\frac{1}{2}} \dot{V} \\ &= \frac{\partial U}{\partial x}(x) f(x, \kappa(x)) + (M^2 - 2^{-\frac{1}{2}} N M_1) |e| \le 0 \end{aligned}$$

if N is sufficiently large, where M_1 satisfies (2.21). Hence for small initial estimation errors, the output feedback certainty equivalence control inherits the stability of the state feedback control.

6. The high gain observer. In this section, we compare the high gain observer of [8] with high gain, the same observer using low gain, and the backstepping observer. Consider a smooth, scalar output nonlinear system in observable form:

$$\begin{aligned} y &= x_1, \\ \dot{x}_1 &= x_2, \\ \dot{x}_2 &= x_3, \\ &\vdots \\ \dot{x}_{n-1} &= x_n, \\ \dot{x}_n &= f_n(x). \end{aligned} \tag{6.1}$$

The observer proposed in [8] is of the form

$$\begin{aligned} \dot{\hat{x}}_1 &= \hat{x}_2 + L_1(y - \hat{x}_1), \\ \dot{\hat{x}}_2 &= \hat{x}_3 + L_2(y - \hat{x}_1), \\ &\vdots \\ \dot{\hat{x}}_{n-1} &= \hat{x}_n + L_{n-1}(y - \hat{x}_1), \\ \dot{\hat{x}}_n &= f_n(\hat{x}) + L_n(y - \hat{x}_1) \end{aligned} \tag{6.2}$$

with

$$L_i = \begin{pmatrix} n \\ i \end{pmatrix} \theta^i,$$

where θ is a parameter that must be chosen "sufficiently large" to insure global convergence—just how large is never explicitly stated. A mathematical proof of the convergence of the high gain observer with sufficiently high gain has been given in [8] for systems without noise. But because of the high gain even relatively small noise can degrade the performance of the high gain observer.

Suppose the variables and functions are of order one and hence one might choose θ to be an order of magnitude bigger, say $\theta = 10$, so as to be "sufficiently large." If the system is three dimensional, then the largest gain is 1000! If the other variables are of order one, then the right side of the observer dynamics (6.2) is completely dominated by its gain times innovation term. The innovation is $y - \hat{x}_1$. If there is any observation noise, then this is magnified by the gains in the error dynamics. For example, suppose there is observation noise of order $\epsilon = 0.01$ so the signal to noise ratio is 100—not a bad situation. However, the noise in the gain times innovation term of the last state is of order 10 while the state is of order 1. When $\hat{x}_1 \approx x_1$, the signal to noise ratio in the observer dynamics is 0.1—hardly conducive to accurate estimation. Even if there is no observation noise, driving noises can have similar but less dramatic effects.

Many successful applications of the high gain observer have been reported in the literature [8], [6], [7], [9]. In most of these applications, a high gain is not actually used. The method of Gauthier, Hammouri, and Othman [8] is used to design an observer but the gain parameter, θ, is chosen to be relatively small. No attempt is made to determine how large θ must be to guarantee global convergence. It appears that the high gain observer with low gain is actually an excellent local observer and this is why it has been successful in applications. It would nice to have a theoretical explanation for why this is so.

TABLE 6.1
Mean square errors of different observers.

State error	High gain $\theta = 8$	Low gain $\theta = 2$	Backstepping $c_i = 1$
e_1	1.32e-05	3.31e-06	6.27e-07
e_2	6.49e-04	1.22e-05	8.93e-06
e_3	4.18e-03	3.16e-05	1.15e-04

We give a simple example exhibiting this problem. Consider a three dimensional system

$$y = Cx + v, \tag{6.3}$$

$$\dot{x} = Ax + g(x), \tag{6.4}$$

where

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{bmatrix},$$

$$C = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix},$$

$$g(x) = \begin{bmatrix} 0 \\ 0 \\ 7\sin(x_1^2 + x_2^2 + x_3^2) \end{bmatrix}.$$

There is one equilibrium at $x = 0$ which is asymptotically stable as the eigenvalues of A are $\{-1, -2, -3\}$. The nonlinear term g is bounded. The observation noise v is assumed to be small, band limited, Gaussian noise.

The observer with noise is

$$\dot{\hat{x}} = A\hat{x} + g(\hat{x}) + L(x_1 - \hat{x}_1 + v),$$

where the observer gain is

$$L = \begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix} = \begin{bmatrix} 3\theta \\ 3\theta^2 \\ \theta^3 \end{bmatrix}.$$

To estimate how large the gain parameter θ should be, we started the system at $x(0) = (0, 0, 0)$ and the observer at $\hat{x}(0) = (0, 0, 1)$. The noiseless observer did not converge to the true value when $\theta = 7$ but did converge when $\theta = 8$, so we chose the latter value. We simulated three observers with small observation noise starting from the true state $\hat{x}(0) = x(0) = (0, 0, 0)$. We used white Gaussian noise of covariance 1e$-$04, sampled and held for 0.1 second. The first was the observer [8] with a high gain $\theta = 8$, the second was the observer [8] with a relatively low gain $\theta = 2$ and the third was the backstepping observer that is presented above with all the design parameters $c_i = 1$. As can be seen from Table 6.1, the high gain observer performs poorly as compared with the low gain and backstepping observers, which are comparable in performance. Table 6.2 contains the errors of high and low gain observers relative to the backstepping observer.

It should be noted that in the absence of noise there is no assurance that $\theta = 8$ is high enough so that the high gain observer converges globally or even locally. On

TABLE 6.2
Relative errors of different observers.

State error	High gain $\theta = 8$	Low gain $\theta = 2$	Backstepping $c_i = 1$
e_1	21.0	5.3	1
e_2	72.7	1.4	1
e_3	36.2	0.3	1

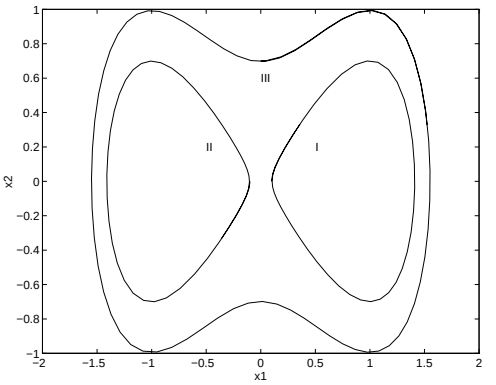

FIG. 1. *The trajectories of Duffing's equation.*

the other hand we have proven that the backstepping observer converges locally for any $c_i > 0$.

One might ask how the example of [8] avoids this high gain difficulty in its the noisy simulations. The answer is very simple: by taking small noise and $\theta = 1,\ n = 2$, it is not really high gain.

7. Examples. The design algorithm described in section 2 has been implemented in MAPLE. This is applied to some examples.

7.1. Duffing's equation. Duffing's equation [11], [14] is

$$\begin{aligned} y &= \xi_1 + \frac{1}{2}\xi_2, \\ \dot{\xi}_1 &= \xi_2, \\ \dot{\xi}_2 &= \xi_1 - \xi_1^3. \end{aligned} \tag{7.1}$$

It is a conservative system with the energy function

$$E(\xi) = \frac{1}{2}\xi_2^2 - \frac{1}{2}\xi_1^2 + \frac{1}{4}\xi_1^4.$$

It has three equilibrium points, $\xi^0 = (0,0)$, $\xi^I = (1,0)$, and $\xi^{II} = (-1,0)$. There are three typical trajectories (see Figure 1): one is around ξ^I (type I), one is around ξ^{II} (type II), and the third one encloses all three equilibria (type III). We define the compact positively invariant region K to be the area enclosed by a trajectory of type III. The system is locally uniformly observable on $\mathbb{R}^2$. The observation function, $h(\xi) = \xi_1 + \frac{1}{2}\xi_2$, was chosen so that the system is not in observable form. The system can be transformed globally into observable form but cannot be transformed into the

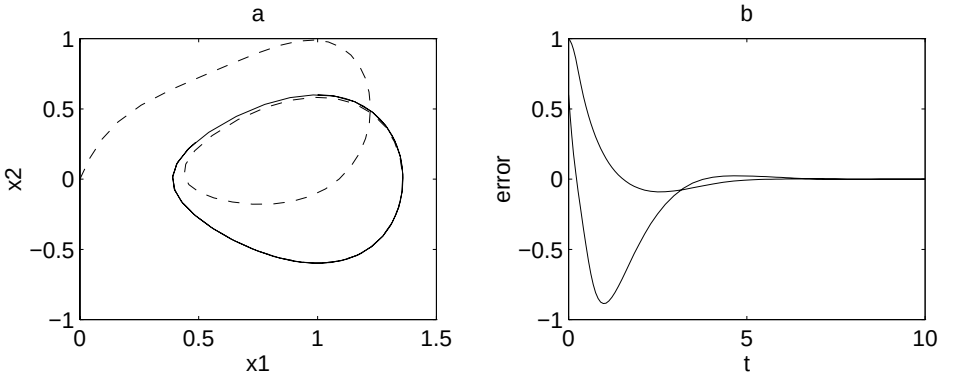

FIG. 2. *Estimation of trajectory of type* I *for Duffing's equation.*

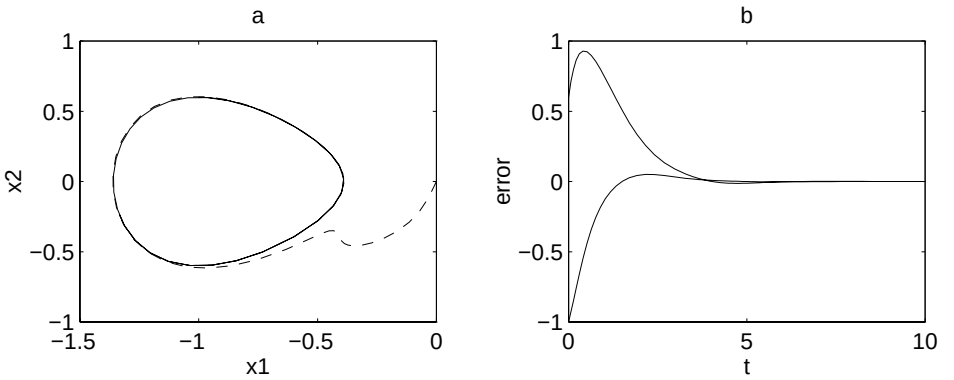

FIG. 3. *Estimation of trajectory of type* II *for Duffing's equation.*

observer form by output injection and change of coordinates [17]. When $c_1 = c_2 = 1$, the observer gain is

$$\phi_1(\hat{\xi}) = -\frac{-2 - 14\,\hat{\xi}_1^2 - 14\,\hat{\xi}_1^4 - 8\,\hat{\xi}_1\hat{\xi}_2 - 8\,\hat{\xi}_1^3\hat{\xi}_2 - 4\,\hat{\xi}_2^2 + 12\,\hat{\xi}_2^2\hat{\xi}_1^2 - 2\,\hat{\xi}_1^6}{3\left(1 + \hat{\xi}_1^2\right)^3},$$

$$\phi_2(\hat{\xi}) = \frac{8 + 8\,\hat{\xi}_1^2 + 8\,\hat{\xi}_1^4 - 4\,\hat{\xi}_1\hat{\xi}_2 + 8\,\hat{\xi}_1^3\hat{\xi}_2 + 8\,\hat{\xi}_1^6 + 12\,\hat{\xi}_1^5\hat{\xi}_2 - 8\,\hat{\xi}_2^2 + 24\,\hat{\xi}_2^2\hat{\xi}_1^2}{3\left(1 + \hat{\xi}_1^2\right)^3}.$$

Three simulations of the system and the backstepping observer are shown in Figures 2, 3, and 4 for trajectory types I, II, and III. Notice that all the simulations use the same observer with the same gain and the same initial estimate but different initial states. The state trajectories are of different types around different equilibrium points.

The solid and dotted curves in Figures 2a, 3a, and 4a are the graphs of the trajectories of the system and the observer. The curves in Figures 2b, 3b, and 4b show the errors $e_1 = \xi_1 - \hat{\xi}_1$ and $e_2 = \xi_2 - \hat{\xi}_2$.

7.2. Homoclinic bifurcation. The backstepping approach can be used to design observers for systems with parameters. Such systems can undergo bifurcations.

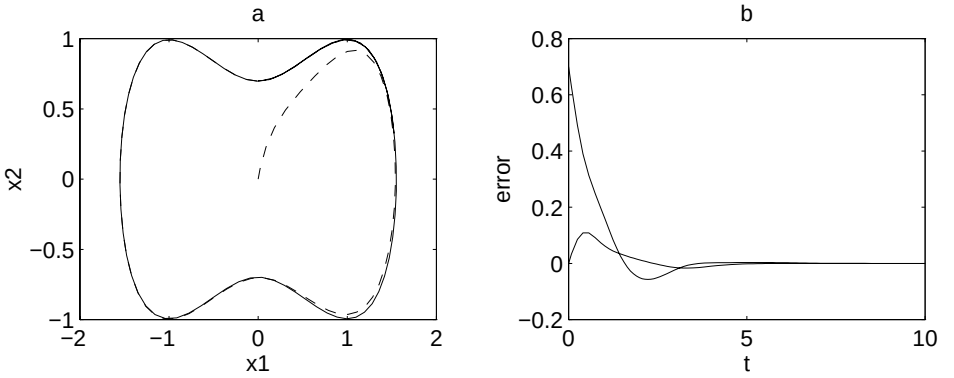

FIG. 4. *Estimation of trajectory of type* III *for Duffing's equation.*

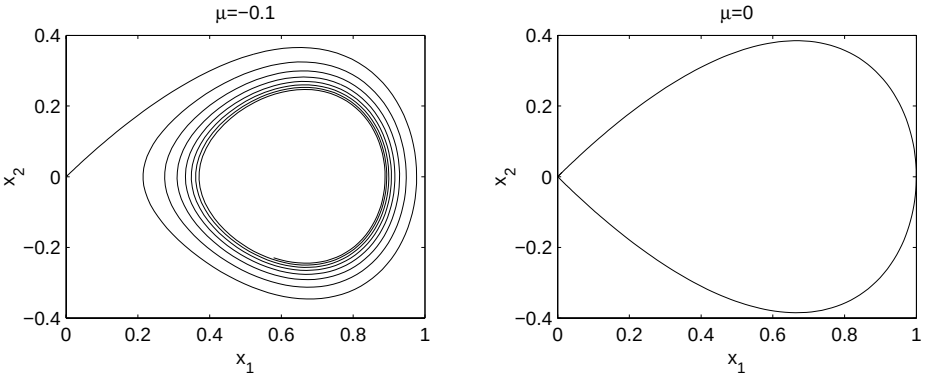

FIG. 5. *The homoclinic bifurcation.*

Consider the following system from [11]:

$$\begin{aligned} y &= \xi_1, \\ \dot{\xi}_1 &= 2\xi_2, \\ \dot{\xi}_2 &= 2\xi_1 - 3\xi_1^2 - \xi_2(\xi_1^3 - \xi_1^2 + \xi_2^2 - \mu). \end{aligned} \tag{7.2}$$

The system depends on a parameter c. For all values of the parameter, there is a saddle at $(0,0)$ with one stable and one unstable direction and an unstable source at $(2/3,0)$. For $-4/27 < \mu < 0$, there is an asymptotically stable periodic orbit around the unstable source. At $\mu = 0$, the periodic orbit becomes a homoclinic orbit consisting of branches of the stable and unstable manifolds of the saddle. For $\mu > 0$, there are no periodic orbits nearby (see Figure 5). For $\mu < 0$ we can find a compact positively invariant set K containing the attracting limit cycle, and for $\mu = 0$ we can take as K the compact set consisting of the homoclinic orbit and it interior. Because of the parameter μ, (7.2) represents a family of systems. However, the computational algorithm for the observer gain is implemented symbolically and μ can be treated as a parameter in the observer. Notice the construction of the observer does not depend on K.

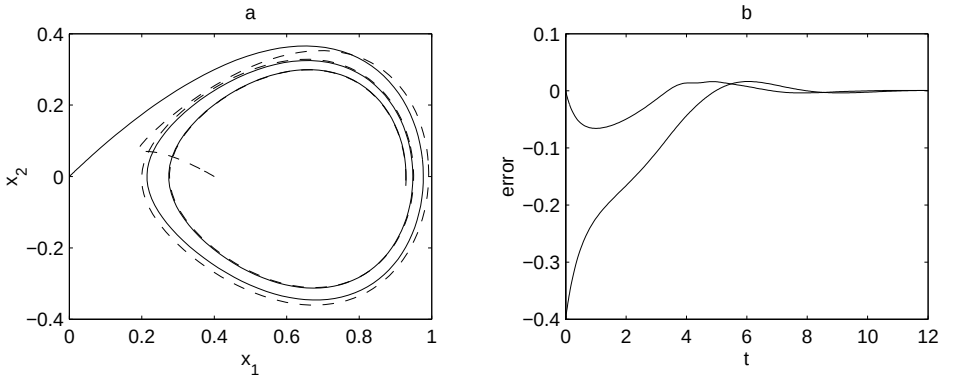

FIG. 6. *Estimation around the periodic solution with* $\mu = -0.1$.

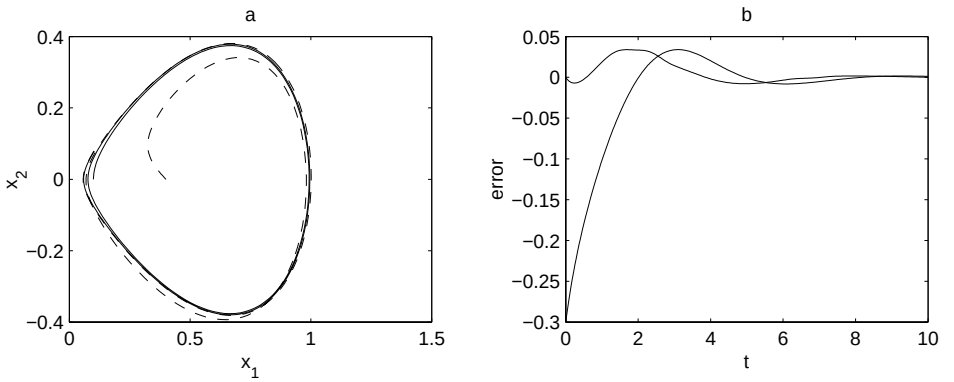

FIG. 7. *Initial state and estimate inside the homoclinic loop with* $\mu = 0$.

If we set $c_1 = c_2 = 1$, the observer gains are

$$\phi_1(\hat{\xi}) = 2 - \hat{\xi}_1^3 + \hat{\xi}_1^2 - 3\,\hat{\xi}_2^2 + \mu,$$
$$\phi_2(\hat{\xi}) = 6\,\hat{\xi}_2\hat{\xi}_1 - 6\,\hat{\xi}_1 + \hat{\xi}_1^2 - \hat{\xi}_1^3 - 3\,\hat{\xi}_2^2 + \mu + \frac{3\,\hat{\xi}_2^4}{2} + \frac{\hat{\xi}_1^6}{2} - \hat{\xi}_1^5 + \frac{\hat{\xi}_1^4}{2} - \hat{\xi}_1^3\mu + \hat{\xi}_1^2\mu + \frac{\mu^2}{2} - 9\,\hat{\xi}_2\hat{\xi}_1^2 + 3.$$

The performance of the observer for $\mu = -0.1$ and $\mu = 0$ are shown in Figures 6, 7, and 8. In Figures 6a, 7a, and 8a the trajectories of (7.2) (solid curves) and the trajectories of the observer (dotted curves) are shown. The estimation error is plotted in Figures 6b, 7b, and 8b. Notice that, in Figure 8, the state starts inside the homoclinic orbit, the estimate starts outside where the system is unstable, and the observer still converges.

8. Conclusion. We have presented a method for designing observers for nonlinear systems based on the backstepping. The method is broadly applicable and the observer error exponentially converges to zero provided the initial error is not too large. It is applicable to a slightly broader class of systems than the high gain observer of Gauthier, Hammouri, and Othman [8] but differs in that the gain is not high and the convergence is only local. The method is easily implemented in a symbolic

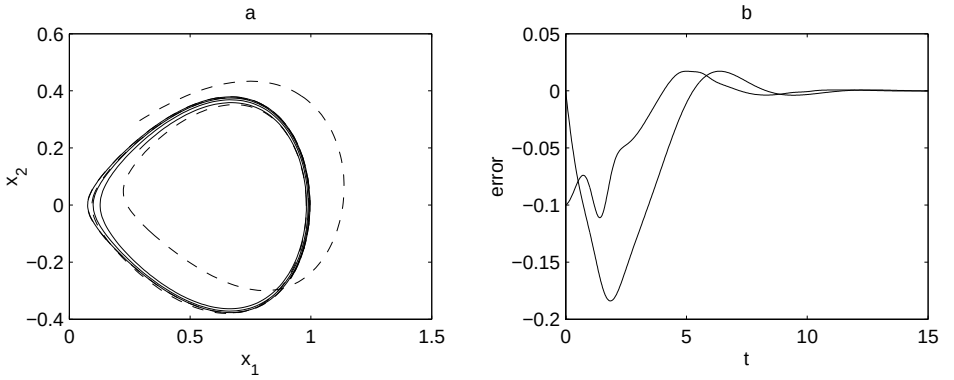

FIG. 8. *Initial state inside the homoclinic loop and initial estimate outside the homoclinic loop with* $\mu = 0$.

computational package such as MAPLE.

SEQUENCING AND ROUTING IN MULTICLASS QUEUEING NETWORKS PART II: WORKLOAD RELAXATIONS*

SEAN P. MEYN†

Abstract. Part II continues the development of policy synthesis techniques for multiclass queueing networks based upon a linear fluid model. The following are shown:

(i) A relaxation of the fluid model based on workload leads to an optimization problem of lower dimension. An analogous workload-relaxation is introduced for the stochastic model. These relaxed control problems admit pointwise optimal solutions in many instances.

(ii) A translation to the original fluid model is *almost optimal*, with vanishing relative error as the network load ρ approaches one. It is pointwise optimal after a short transient period, provided a pointwise optimal solution exists for the relaxed control problem.

(iii) A translation of the optimal policy for the fluid model provides a policy for the stochastic network model that is almost optimal in heavy traffic, over all solutions to the relaxed stochastic model, again with vanishing relative error. The regret is of order $|\log(1-\rho)|$.

Key words. queueing networks, routing, scheduling, optimal control

1. Introduction.

Variability in a queueing system may have significant impact on performance. Kingman's bound implies that in heavy traffic, when the load ρ is close to unity, even small variations in service times or interarrival times can lead to long delays [3]. This is one reason for the much-publicized difficulties in the air-traffic, highway, and power industries, where real-life networks in heavy traffic are experienced each day by pilots, passengers, and home-owners (see, e.g., [45, 5]).

Variability often plays a smaller role in *relative performance* in network models, when comparing two candidate policies for network regulation (although this depends upon the specific network topology and the performance metric under consideration). For this reason, variability often plays a minor role in many aspects of network design and analysis. Stability of a network under a particular policy is determined by first order statistics (mean arrival and service rates and routing probabilities), except in pathological examples [8, 10, 9, 34, 36]. Part I primarily concerns policy synthesis in queueing networks. It is shown that robustly stabilizing policies can be constructed by appropriately translating a policy for the associated linear fluid model, which is defined only by first order statistics (see [36] for a bibliography).

This paper continues the development of part I. We focus primarily on policy synthesis and network optimization because of the intrinsic importance of these issues, and because it is likely that a deeper understanding will lead to improved methods for addressing many other issues in design, such as performance approximation and network planning. Among the issues not addressed in [36, 35] are the following:

(i) *The role of variability in design.* It is known that an understanding of variability is important in the determination of safety stocks to prevent unwanted idleness. Is this the only use of high order statistical information in policy synthesis?

(ii) *Complexity management.* For example, is it possible to construct optimal policies for the fluid model when the network is large?

(iii) *Performance validation.* Will a translation lead to an optimal allocation for the physical network?

Some answers to these questions are provided here.

A series of recent papers in the stochastic network literature show that a combination of "resource pooling" and "state space collapse" occur in heavy traffic, where $\rho \sim 1$ [38, 39, 43, 29, 25, 4]. See also the recent monographs [6, 30]. State space collapse can transform a network with hundreds of buffers into a far simpler model that retains most of the essential information required for the design of efficient policies. All of these prior results are based on a reflected Brownian motion (RBM) model to approximate the network of interest. This approach is not pursued here for several reasons: Technicalities arising in a proof of weak convergence to an RBM model are avoided, and as pointed out in part I, it is not necessary to assume that the network is *balanced* (i.e., loads at all stations are comparable). This allows significantly greater flexibility in modelling. In this paper we also find that the "Brownian motion scaling" may wash away too many details. By avoiding any scaling, relative bounds on performance are obtained that are far stronger than reported previously in any examples.

As in part I, the primary model considered here is the linear fluid model (2.5). One of the main contributions of the present paper is to introduce a *workload-relaxation* of the fluid model that may be viewed as a generalization of state space collapse, as formulated in the aforementioned references. The significant model reduction obtained in a workload-relaxation provides a framework for addressing many aspects of (i)–(iii).

We show in particular that very strong solidarity exists between respective optimal control solutions. Let c denote a norm on the state space of buffer-levels $\mathsf{X} := \mathbb{R}_+^\ell$—in the results below we eventually specialize to piecewise linear functions on X. Suppose that $\boldsymbol{Q}$ is any queue length process evolving on X defined by some admissible policy. Kingman's bound will then give a steady-state bound of the form

$$\mathsf{E}[c(Q(t))] \geq O\Big(\frac{1}{1-\rho}\Big).$$

Suppose that $\boldsymbol{Q}^\circ$ is the process on X obtained through tracking the optimal fluid model trajectories, as described below. Under general geometric conditions (including uniqueness of solutions to the fluid-model optimal-control problem), we show in Theorem 4.3 that $\boldsymbol{Q}^\circ$ *is approximately optimal, with logarithmic regret*: as $\rho \uparrow 1$,

$$\frac{1}{T}\int_0^T c(Q^\circ(t;x))\,dt \leq \frac{1}{T}\int_0^T c(Q(t;x))\,dt + O(\log\big((1-\rho)^{-1}\big)), \quad 0 \leq T \leq \frac{1}{(1-\rho)^3},$$

where $\boldsymbol{Q}$ is any other solution. We also find that no formulation of sample-path optimality is feasible in heavy traffic under complementary geometric conditions. Consequently, extensions of the results reported here require comparison of a mean-performance metric, rather than sample path bounds (see [7] for recent results in this direction).

The remainder of the paper is organized as follows. Section 2 provides a description of a stochastic network model and the linear fluid model. A reduced order model based on "workload-relaxation" is developed in section 3, and optimal policies for the relaxation are constructed.

Section 4 concerns models in heavy traffic, where $\rho \sim 1$. A policy is constructed based on a translation of the optimal solution to the relaxed fluid-model optimal-control problem. It is shown that this translation is almost optimal for the original fluid model, with bounded error as the system load approaches unity. When a reflected Brownian motion limit exists in heavy traffic, then this "state space collapse" coincides with that observed in the aforementioned references. Similar results hold for a general stochastic model: it is shown that this policy is approximately optimal for a stochastic model, with logarithmic regret, over all solutions to a relaxation of the associated stochastic optimal-control problem.

Section 5 contains conclusions and poses various possible extensions.

2. Models and control. As in [36], this paper is based on a stochastic, bursty model, and a linear fluid model that may be interpreted as a scaled version of its bursty counterpart.

2.1. The stochastic model. The network model described here is a version of the stochastic processing network developed in [23, 24]. We denote by $\boldsymbol{Q}$ the stochastic process evolving on $\mathsf{X} = \mathbb{R}_+^\ell$ whose components indicate buffer levels for the stochastic network model. For example, the network shown in Figure 1 is a simple manufacturing model in which $\ell = 16$, and four of these buffers are *virtual*, corresponding to backlog or excess inventory.

For a given initial condition $Q(0;x) = x \in \mathsf{X}$ the dynamics of $\boldsymbol{Q}$ are expressed

$$Q(t;x) = x - S(Z(t;x)) + R(Z(t;x)) + A(t), \qquad t \geq 0. \tag{2.1}$$

The vector-valued stochastic process $\boldsymbol{Z}$ is the *allocation* (or *control*) evolving on $\mathbb{R}_+^{\ell_u}$ for some integer ℓ_u. The ith component $Z_i(t;x)$ gives the cumulative time that the activity i has run up to time t, $1 \leq i \leq \ell_u$. Activities may include a combination of *sequencing* of various jobs at a particular station and *routing* those jobs to other stations once service is completed. Several examples are given in [36].

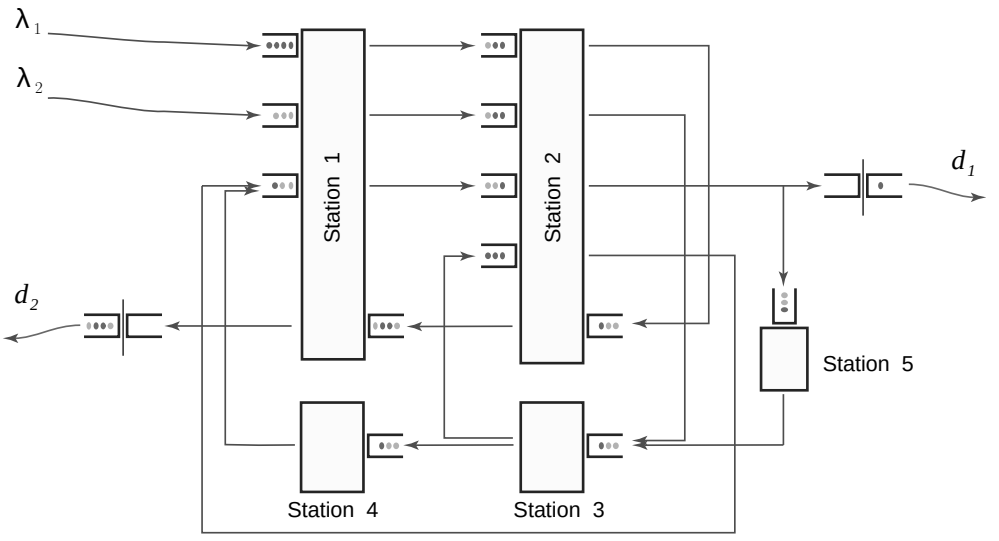

FIG. 1. *A network with many buffers, controlled routing, uncontrolled routing, multiple demands, and virtual buffers.*

The allocation rates are subject to linear constraints

$$Z(t;x) - Z(s;x) \ge \boldsymbol{\theta}\,, \quad C[Z(t;x) - Z(s;x)] \le [t-s]\mathbf{1}\,, \qquad t \ge s \ge 0, \tag{2.2}$$

where the *constituency matrix* C is an $\ell_m \times \ell_u$ matrix with binary entries; $\boldsymbol{\theta}$ is a vector of zeros; and $\mathbf{1}$ is a vector of ones. The *ith resource* $\mathcal{R}_i$ is defined to be the set of activities j such that $C_{ij} = 1$. The constraint (2.2) expresses the condition that resources are shared, and they are limited.

The process $\boldsymbol{A}$ may denote a combination of exogenous arrivals to the network and exogenous demands for materials *from* the network. The function $S(\,\cdot\,)$ represents possibly random service times, and the function $R(\,\cdot\,)$ represents the effects of a combination of possibly uncontrolled, possibly random routing and random service times.

Specific statistical assumptions on $\{\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S}\}$ are given in section 4.2 where the stochastic model is considered in detail. Many of the variables $\{A_i(\,\cdot\,), R_i(\,\cdot\,), S_i(\,\cdot\,)\}$ will be null in general, and they are typically highly correlated.

The average-cost optimization problem is concerned with minimizing the long-run average cost,

$$\Gamma(x) = \limsup_{T\to\infty} \mathsf{E}\Big[\frac{1}{T}\int_0^T c(Q(t;x))\,dt\Big]\,, \tag{2.3}$$

subject to the constraints given above, where $c\colon \mathbb{R}^\ell \to \mathbb{R}_+$ is a convex function that vanishes only at the origin. In section 4.2 we consider generalizations in which $c(\,\cdot\,)$ is also a function of $\boldsymbol{Z}$. In this case the cost function may be chosen to reflect the desire to maximize utilization of some resources, while minimizing utilization of others.

It is clear that an exact optimal solution to (2.3) will not be found except in very special cases.

2.2. The linear fluid model. Assumption S, to be imposed in section 4.2, implies that the law of large numbers holds: For some $\ell \times \ell_u$ matrix B, a vector $\alpha \in \mathbb{R}^\ell_+$, and any $z \in \mathbb{R}^{\ell_u}_+$,

$$Bz = \lim_{T\to\infty} \frac{1}{T}\int_0^T [-S(zt) + R(zt)]\,dt, \qquad \alpha = \lim_{T\to\infty}\frac{1}{T}\int_0^T A(t)\,dt\,. \tag{2.4}$$

This provided motivation in [36] for the fluid analogue of (2.1) given by

$$q(t;x) = x + Bz(t;x) + \alpha t, \qquad t \ge 0.$$

The vector $\zeta(t;x) = \frac{d}{dt} z\,(t;x)$ denotes allocation rates, and $q(t;x)$ is a vector of buffer levels. This is also expressed as the controlled, linear ordinary differential equation

$$\frac{d}{dt} q(t;x) = B\zeta(t;x) + \alpha\,, \quad t \ge 0\,, \qquad q(0;x) = x\,, \tag{2.5}$$

where throughout the paper the symbol "$\frac{d}{dt}$" denotes a *right derivative*.

It is convenient to envision (2.5) as a differential inclusion:

(i) The state $\boldsymbol{q}$ is constrained to evolve in the polyhedron $\mathsf{X} = \mathbb{R}^\ell_+$.

(ii) The allocation rates $\boldsymbol{\zeta}$ evolve in a polyhedron $\mathsf{U} \subseteq \mathbb{R}^{\ell_u}_+$, defined by

$$\mathsf{U} := \{\zeta \in \mathbb{R}^{\ell_u} : \zeta \ge \boldsymbol{\theta}, C\zeta \le \mathbf{1}\}.$$

(iii) The velocity $\frac{d}{dt}q$ is constrained to lie in the polyhedron

$$\mathsf{V} := \{v = B\zeta + \alpha : \zeta \in \mathsf{U}\}.$$

The assumptions below imply that the network can be controlled so that, starting empty, it will remain empty. This means that V contains the origin, or equivalently, there exists at least one solution $\zeta^{\text{ss}} \in \mathsf{U}$ to the equilibrium equation

$$B\zeta^{\text{ss}} = -\alpha.$$

Section 2.3 is concerned with the existence of equilibria and simple formulations of *optimality* for ζ^{ss}.

Two dynamic optimization problems are singled out because of their mathematical and economic interest:

Time-optimal control. For any initial condition $q(0) = x$, find an allocation $\boldsymbol{z}$ that minimizes

$$T(x) = \min\{t : q(t; x) = \boldsymbol{\theta}\}.$$

The minimal draining time is denoted $T^*(x)$, with the convention that the minimum over an empty set is interpreted as infinity.

Total-cost optimal control. For any initial condition $q(0) = x$, find an allocation $\boldsymbol{z}$ that minimizes

$$J(x) = \int_0^T c(q(t; x))\, dt\,. \tag{2.6}$$

We consider primarily the infinite-horizon case in which $T = \infty$, and in this case we let J^* denote the "optimal cost" (i.e., the infimum over all policies).

The fluid model is called *stabilizable* if $T^*(x) < \infty$ for all $x \in \mathsf{X}$. If the model is stabilizable, then there exists a time-optimal allocation that is *linear*. For any $x \in \mathsf{X}$, if $\boldsymbol{z}$ is any time-optimal allocation, then we write

$$\zeta^\circ = \frac{z(T^*(x); x)}{T^*(x)} \in \mathsf{U}. \tag{2.7}$$

The allocation $z^\circ(t; x) = t\zeta^\circ$, $0 \le t \le T^*(x)$, is evidently feasible and time-optimal. This linear policy and stochastic translations are considered in [11], and generalizations are treated in [17, 14].

The infinite-horizon cost criterion is more closely aligned with the average-cost optimization problem. Computing J^* and an optimal allocation z^* can be formulated as an infinite-dimensional linear program when the cost c is piecewise linear [37]. Algorithms are available that solve this control problem for models of moderate complexity [32, 42].

In the remainder of the paper we take c to be piecewise linear, of the form

$$c(x) = \max_{1 \le i \le \ell_c} \langle c^i, x \rangle, \qquad x \in \mathbb{R}^\ell, \tag{2.8}$$

where $\langle \cdot, \cdot \rangle$ denotes the usual inner product on $\mathbb{R}^\ell$. We can approximate any norm on $\mathbb{R}^\ell$ through an appropriate choice of $\{c^i\} \subset \mathbb{R}^\ell$. A lower bound on performance,

at a specific time t, given a specific initial condition $x \in \mathsf{X}$, is found by solving the linear program

$$
\begin{aligned}
&\min \quad \gamma \\
&\text{subject to} \quad \begin{aligned} \gamma &\geq \langle c^i, y \rangle, \quad 1 \leq i \leq \ell_c, \\ y &= x + Bz + \alpha t, \\ Cz &\leq t\mathbf{1}, \\ y, z &\geq \boldsymbol{\theta}\,. \end{aligned}
\end{aligned} \tag{2.9}
$$

We denote the value of this linear program by $\underline{c}^*(t;x)$. A feasible state trajectory $\boldsymbol{q}^*$ starting from x is called *pointwise optimal* if $c(q^*(t;x)) = \underline{c}^*(t;x)$ for every t. A pointwise optimal trajectory is always time-optimal, and it is also *greedy*: The derivative $\frac{d}{dt}c(q(t;x))$ is minimized over all allocation rates at each time t.

It is rare to find a model for which a pointwise optimal solution exists from each initial condition. However, in section 3 general conditions are formulated which ensure that $c(q^*(t;x)) = \underline{c}^*(t;x)$ for all t following a short transient period.

A first step towards optimization is stabilizability: When are T^* and J^* finite-valued? What is the network load?

2.3. Capacity and time-optimal control. If the fluid model is stabilizable, then the origin is an equilibrium for the model, which means that $\boldsymbol{\theta} \in \mathsf{V}$. We let U_{ss} denote the set of all allocation rates that achieve this: $\mathsf{U}_{\text{ss}} = \{\zeta : B\zeta + \alpha = \boldsymbol{\theta}\}$. In the classical *scheduling* problem there is a unique activity associated with each buffer. This implies that the matrix B is square, and stabilizability ensures that B is full-rank. It then follows that U_{ss} contains a unique vector of steady-state allocation rates given by $\zeta^{\text{ss}} := -B^{-1}\alpha$. We then define the *vector load* by

$$
\boldsymbol{\rho} = (\rho_1, \ldots, \rho_\ell)^{\scriptscriptstyle T} = -CB^{-1}\alpha = C\zeta^{\text{ss}}, \tag{2.10}
$$

and the *system load* is the maximum, $\rho = \max_i \rho_i$.

In other models the matrix B may not be square. The set of equilibrium rates U_{ss} may be large, and some may impose a greater "load" on the system than others. The following is taken from [23], following [29, 22]. The network load ρ is defined as the solution to the linear program

$$
\begin{aligned}
&\min \quad \rho \\
&\text{subject to} \quad \begin{aligned} B\zeta + \alpha &= \boldsymbol{\theta}, \\ C\zeta &\leq \rho\mathbf{1}, \\ \zeta &\geq \boldsymbol{\theta}. \end{aligned}
\end{aligned} \tag{2.11}
$$

The idea is that we consider all allocation rates ζ^{ss} that provide an equilibrium and choose among these the one that has minimal overall impact on the system in the sense that $\max_i [C\zeta^{\text{ss}}]_i$ is smallest.

Closely related is the linear program defining the minimal draining time

$$
\begin{aligned}
&\min \quad T \\
&\text{subject to} \quad \begin{aligned} x + Bz + \alpha T &= \boldsymbol{\theta}, \\ Cz &\leq T\mathbf{1}, \\ z &\geq \boldsymbol{\theta}\,, \end{aligned}
\end{aligned} \tag{2.12}
$$

where $x \in \mathbb{R}^\ell$ is given. The value of this linear program is equal to $T^*(x)$.

We let $W^*(x)$ denote the minimum time to drain the fluid model for an arrival-free model where $\alpha = \boldsymbol{\theta}$. The definition of load is thus motivated by considering the fluid model (2.5) without arrivals: on comparing (2.12) and (2.11) it is seen that $\rho = W^*(\alpha)$. Thus, if α units of material arrives at the network in one second, the *system load* is the amount of time required to clear this material, given that no other material arrives.

Alternative representations for the minimal emptying times are found through a representation of the velocity set V. Let V_0 denote the velocity set for the arrival-free model:

$$\mathsf{V}_0 := \{v - \alpha : v \in \mathsf{V}\} = \{B\zeta : \zeta \in \mathsf{U}\}\,. \tag{2.13}$$

THEOREM 2.1. *The sets V_0, V are described by the intersection of half-spaces: There exists a set of vectors $\{\xi^i : 1 \le i \le \ell_v\} \subset \mathbb{R}^{\ell_v}$, for some minimal integer $\ell_v \ge 1$, and binary values $\{b_i : 1 \le i \le \ell_v\} \subset \{0, 1\}$ such that the following hold:*

$$\mathsf{V}_0 = \{v : \langle \xi^i, v\rangle \ge -b_i,\ 1 \le i \le \ell_v\}, \tag{2.14}$$

$$\mathsf{V} = \{v : \langle \xi^i, v\rangle \ge -(b_i - \rho_i),\ 1 \le i \le \ell_v\}\,, \tag{2.15}$$

where in (2.15) *we set $\rho_i = \langle \xi^i, \alpha\rangle$ for $1 \le i \le \ell_v$.*

Proof. The representation V_0 in (2.14) follows from the fact that it is a polyhedral subset of $\mathbb{R}^\ell$ containing the origin. The representation for V then follows from the formula $\mathsf{V} = \{v + \alpha : v \in \mathsf{V}_0\}$ and the definition of $\{\rho_i\}$. ∎

The vector ξ^i is called a *workload vector* if $b_i \neq 0$. We denote by ℓ_r the number of distinct workload vectors.

For a given $\alpha \in \mathbb{R}^\ell_+$ we assume that the vectors $\{\xi^i\}$ are ordered so that $\rho_1 \ge \cdots \ge \rho_{\ell_v}$. Provided the linear program defining ρ is feasible, we see from Theorem 2.2(ii) that, under this ordering, the set of workload vectors is given by $\{\xi^i : 1 \le i \le \ell_r\}$ and that the system load defined in (2.11) is equal to ρ_1.

THEOREM 2.2. *The following hold for the model* (2.5)*, for any given $\alpha \in \mathbb{R}^\ell_+$, $x \in \mathsf{X}$:*

(i) *If $\langle \xi^i, x\rangle > 0$ for some $i > \ell_r$, then $W^*(x) = \infty$. Otherwise, the minimal emptying time for the arrival-free model is finite and given by*

$$W^*(x) = \max_{1 \le i \le \ell_r} \langle \xi^i, x\rangle\,.$$

(ii) *Suppose that the constraint set in the linear program* (2.11) *is nonempty. Then, $\rho_i \le 0$ for $i > \ell_r$, and the system load can be expressed as*

$$\rho = W^*(\alpha) = \max_{1 \le i \le \ell_r} \rho_i\,.$$

(iii) *If $\langle \xi^i, x\rangle > 0$ and $\rho_i \ge 0$ for some $i > \ell_r$, then $T^*(x) = \infty$. Otherwise, provided $\rho < 1$, the minimal emptying time T^* is finite and given by*

$$T^*(x) = \max_{1 \le i \le \ell_v} \frac{\langle \xi^i, x\rangle}{b_i - \rho_i}\,.$$

(iv) *The model is stabilizable if $\rho < 1$, and $\rho_i < 0$ for $i > \ell_r$. The second condition is automatic if the arrival-free model is stabilizable.*

Proof. Part (i) follows from Theorem 2.1: for $x \neq \boldsymbol{\theta}$, provided $W^*(x) < \infty$,

$$\begin{aligned} W^*(x) &= \min(T > 0 : -T^{-1}x \in \mathsf{V}_0) \\ &= \min(T > 0 : \langle \xi^i, -T^{-1}x \rangle \geq b_i,\ 1 \leq i \leq \ell_v) \\ &= \min(T > 0 : \langle \xi^i, x \rangle \leq b_i T,\ 1 \leq i \leq \ell_v). \end{aligned}$$

Recall that $b_i = 0$ for $i > \ell_r$. If for some such i we have $\langle \xi^i, x \rangle > 0$, then we see that the constraint set in the minimization is infeasible, and we conclude that $W^*(x)$ cannot be finite. Conversely, if $\langle \xi^i, x \rangle \leq 0$ for $i > \ell_r$, then the equation above gives the desired representation for W^*. This establishes (i), and (iii) follows similarly using the definition $\rho_i := \langle \xi^i, \alpha \rangle$.

The proof of (ii) follows from (i) and the representation $\rho = W^*(\alpha)$, and result (iv) follows directly from (iii). ∎

The workload vectors may be interpreted as Lagrange multipliers since they define sensitivity of the optimal draining time with respect to the initial condition x. The following results provide further interpretations. For a given $x \in \mathbb{R}^\ell$, consider the dual of the linear program (2.12)

$$\begin{aligned} &\max \quad \langle \xi, x \rangle \\ &\text{subject to} \quad \begin{aligned} B^{\scriptscriptstyle T}\xi + C^{\scriptscriptstyle T}\eta &\geq \boldsymbol{\theta}, \\ -\alpha^{\scriptscriptstyle T}\xi + \mathbf{1}^{\scriptscriptstyle T}\eta &\leq 1, \\ \eta &\geq \boldsymbol{\theta}. \end{aligned} \end{aligned} \tag{2.16}$$

On considering the extreme points of (2.16), we may express the value of this linear program as a piecewise linear function on the domain $\{x \in \mathbb{R}^\ell : T^*(x) < \infty\}$. Applying Theorem 2.2, we see that these correspond to the vectors $\{\xi^i : 1 \leq i \leq \ell_r\}$ used in the representation of the sets V and V_0.

In view of this solidarity we denote by $\{(\xi^i, \eta^i) : 1 \leq i \leq \ell_r\}$ the nonzero extreme points of the constraint set in (2.16) when $\alpha = \boldsymbol{\theta}$. For each i we have $\xi^i \in \mathbb{R}^\ell$, $\eta^i \in \mathbb{R}_+^{\ell_m}$. An interpretation of the vectors $\{\eta^i\}$ is provided in the following proposition.

PROPOSITION 2.3. *Consider the linear program* (2.16) *with* $\alpha = \boldsymbol{\theta}$. *If* (ξ, η) *is an extreme point in the constraint set satisfying* $\xi \neq \boldsymbol{\theta}$, *then* $\eta \in \mathbb{R}_+^{\ell_m}$ *satisfies* $\langle \mathbf{1}, \eta \rangle = 1$. *Consequently, for any* $1 \leq i \leq \ell_r$ *we may interpret the vector* η^i *as a probability distribution on the resources* $\{1, \ldots, \ell_m\}$.

Proof. Suppose that (ξ, η) is any feasible pair with $0 \leq \langle \mathbf{1}, \eta \rangle < 1$, and $\xi \neq \boldsymbol{\theta}$. Then $(\gamma\xi, \gamma\eta)$ is also feasible for any $0 < \gamma < \langle \mathbf{1}, \eta \rangle^{-1}$, which implies that (ξ, η) cannot be an extreme point. ∎

The *workload process* is defined on a fluid scale by

$$w(t; x) = \Xi q(t; x), \qquad t \geq 0, \quad x \in \mathsf{X}, \tag{2.17}$$

where Ξ denotes the $\ell_r \times \ell$ matrix whose ith row is given by ${\xi^i}^{\scriptscriptstyle T}$.

PROPOSITION 2.4. *The following lower bounds hold:*

$$\text{(i)} \qquad \langle \xi^i, B\zeta \rangle \geq -b_i, \qquad \zeta \in \mathsf{U}, \quad 1 \leq i \leq \ell_v;$$

$$\text{(ii)} \qquad \frac{d}{dt} w_i(t; x) \geq -(1 - \rho_i), \qquad t \geq 0, \quad 1 \leq i \leq \ell_r.$$

Proof. For (i), note that $v_0 := B\zeta$ is a generic element of V_0, so the result follows from the representation of V_0 in Theorem 2.1. As for (ii), observe that

$$\frac{d}{dt} w_i = \langle \xi^i, v \rangle \,,$$

where $v := B\zeta + \alpha$ is a generic element of V. This and Theorem 2.1 again imply the result since $b_i = 1$ for $1 \le i \le \ell_r$. ∎

We define the ith set of *pooled-resources* by

$$\mathcal{R}_i^\circ := \{j \le \ell_m : \eta_j^i > 0\}\,, \qquad 1 \le i \le \ell_r\,.$$

Resource j is called a *bottleneck* if $j \in \mathcal{R}_i^\circ$ for some $i \le \ell_r$, and $\rho_i = \rho$. The following result provides motivation for this terminology.

PROPOSITION 2.5. *For any $1 \le i \le \ell_r$, and any $\zeta \in \mathsf{U}$, the following are equivalent:*

(i) $\langle \xi^i, B\zeta\rangle = -1$,

(ii) $(C\zeta)_j = 1$ *for all* $j \in \mathcal{R}_i^\circ$, *and* ζ *satisfies the* complementary slackness *condition*

$$\zeta_j > 0 \Longrightarrow [B^{\scriptscriptstyle T}\xi^i + C^{\scriptscriptstyle T}\eta^i]_j = 0\,.$$

Proof. Suppose that (i) holds. Then we may multiply $\zeta^{\scriptscriptstyle T}$ times the constraint $B^{\scriptscriptstyle T}\xi + C^{\scriptscriptstyle T}\eta \ge \boldsymbol{\theta}$ in (2.16) to obtain the bound

$$-1 + \langle \eta^i, C\zeta\rangle = \langle \xi^i, B\zeta\rangle + \langle \eta^i, C\zeta\rangle = \langle \zeta, [B^{\scriptscriptstyle T}\xi^i + C^{\scriptscriptstyle T}\eta^i]\rangle \ge 0\,,$$

and it follows that $\langle \eta^i, C\zeta\rangle \ge 1$. Since the reverse inequality also holds when $\zeta \in \mathsf{U}$, we must have equality:

$$-1 + \langle \eta^i, C\zeta\rangle = \langle \zeta, [B^{\scriptscriptstyle T}\xi^i + C^{\scriptscriptstyle T}\eta^i]\rangle = 0\,. \tag{2.18}$$

In fact, since η^i is a probability distribution on $\{1, \dots, \ell_u\}$ and $C\zeta \le \mathbf{1}$, the equality (2.18) implies that $(C\zeta)_j = 1$ for all $j \in \mathcal{R}_i^\circ$. The equation (2.18) also implies the complementary slackness condition in (ii) since $[B^{\scriptscriptstyle T}\xi^i + C^{\scriptscriptstyle T}\eta^i] \ge \boldsymbol{\theta}$, and $\zeta \in \mathbb{R}_+^{\ell_m}$.

Conversely, if (ii) holds, then the complementary slackness condition implies the identity, $\langle \xi^i, B\zeta\rangle + \langle \eta^i, C\zeta\rangle = \langle \zeta, [B^{\scriptscriptstyle T}\xi^i + C^{\scriptscriptstyle T}\eta^i]\rangle = 0$. This combined with the assumption in (ii) that $(C\zeta)_j = 1$ whenever $j \in \mathcal{R}_i^\circ$ (equivalently $\langle \eta^i, C\zeta\rangle = 1$) gives (i) immediately. ∎

The workload vectors allow us to define "hot spots" in the network and give some intuition about the structure of good policies. Suppose that at time t the state takes the value $q(t; x) = y$. The ith pooled-resource is a *dynamic bottleneck* at time t if

$$T^*(y) = \langle \xi^i, y\rangle/(1 - \rho_i).$$

An ordinary resource j is called a *dynamic bottleneck* at time t if $j \in \mathcal{R}_i^\circ$ for some $1 \le i \le \ell_r$, and pooled-resource i is a dynamic bottleneck. We say that the ith pooled-resource is *working at capacity* at time t if $\langle \xi^i, B\zeta(t)\rangle = -1$.

The following is then immediate from Proposition 2.4, Proposition 2.5, and Theorem 2.2.

THEOREM 2.6. *Suppose that $\boldsymbol{q}$ is any solution to the fluid-model equations* (2.5) *starting at $x \in \mathsf{X}$.*

(i) *If $\boldsymbol{q}$ is time-optimal (so that $q(t; x) = \boldsymbol{\theta}$ for $t \ge T^*(x)$), then each dynamic-bottleneck pooled-resource is working at capacity for each $t < T^*(x)$.*

(ii) *If each dynamic-bottleneck pooled-resource works at capacity for $t < T^*(x)$, then the state trajectory $\boldsymbol{q}$ is time-optimal.* ∎

3. The relaxed control problem. We introduce here a relaxation of the optimal-control problem (2.6). The main idea is that, for the purposes of control, only a few of the workload vectors impose serious constraints. A much simpler optimal control problem is obtained by relaxing those constraints corresponding to relatively small load.

3.1. Almost-equivalent workload formulation. For arbitrary $1 \le n \le \ell_r$, the *nth relaxation* of (2.5) is defined as follows. As before, the state space X is taken as $\mathbb{R}^{\ell}_{+}$, but the velocity set is given by

$$\widehat{\mathsf{V}} = \left\{ v : \langle \xi^i, v \rangle \ge -(1-\rho_i), 1 \le i \le n \right\}.$$

An application of Theorem 2.1 establishes the inclusion $\mathsf{V} \subset \widehat{\mathsf{V}}$. It is assumed throughout that $\{\xi^i : 1 \le i \le n\}$ are linearly independent vectors.

We denote by $\widehat{q}$ any feasible state trajectory:

$$\widehat{q}(0;x) = x, \quad \widehat{q}(t;x) \in \mathsf{X}, \quad \textit{and} \quad \frac{q(t;x) - q(s;x)}{t-s} \in \widehat{\mathsf{V}}, \qquad 0 \le s < t. \tag{3.1}$$

The nth relaxation may also be described in a form analogous to (2.5):

$$\frac{d}{dt}\widehat{q}(t;x) = B\widehat{\zeta}(t;x) + \alpha\,, \quad t \ge 0\,, \qquad \widehat{q}(0;x) = x\,. \tag{3.2}$$

The allocation rates in (3.2) are subject to the constraints

$$\widehat{\zeta}(t;x) \in \widehat{\mathsf{U}} := \{\zeta \in \mathbb{R}^{\ell_u} : \widehat{C}\zeta \le \mathbf{1}\}\,,$$

where $\widehat{C} := -\widehat{\Xi}B$, and $\widehat{\Xi}$ denotes the $n \times \ell$ matrix

$$\widehat{\Xi} = [\xi^1 \mid \cdots \mid \xi^n]^{\mathrm{T}}. \tag{3.3}$$

The equivalence of the representations (3.1) and (3.2) follows from Propositions 2.4 and 2.5. The matrix $\widehat{C}$ may be viewed as a constituency matrix for the fluid model (3.2).

If $n \ll \ell_r$, then the behavior of this system may be entirely unnatural since so many constraints have been removed. We show in section 4 that this error can be bounded when considering optimal-control solutions for the fluid model. Related results are obtained for the stochastic model in section 4.2. Such solidarity requires that $n \ge 1$ be chosen sufficiently large, but in many examples this is significantly smaller than ℓ_r.

Our goal remains the same: We wish to minimize, over all feasible state trajectories, the infinite-horizon cost

$$\widehat{J}(x) = \int_0^\infty c(\widehat{q}(t;x))\,dt, \qquad x \in \mathsf{X}. \tag{3.4}$$

Procedures for *translation* of an optimal allocation $\widehat{\boldsymbol{z}}^*$ to both the original fluid model and to the stochastic model (2.1) are treated in sections 4.1 and 4.2, respectively.

In analogy with (2.17), the workload process for this model is given by

$$\widehat{w}(t;x) = \widehat{\Xi}\widehat{q}(t;x), \qquad t \ge 0.$$

For all $1 \le i \le n$ we retain the simple constraint

$$\frac{d}{dt}\widehat{w}_i(t;x) \ge -(1-\rho_i)\,, \qquad t \ge 0\,. \tag{3.5}$$

These constraints are *decoupled* under our assumption that the workload vectors are linearly independent. However, the workload process is also constrained to the set

$$\widehat{\mathsf{W}} := \{\widehat{\Xi}x : x \in \mathsf{X}\}\,. \tag{3.6}$$

The set $\widehat{\mathsf{W}} \subseteq \mathbb{R}^n$ is a convex cone since $\mathsf{X} = \mathbb{R}^\ell_+$. In general, $\widehat{\mathsf{W}} \not\subseteq \mathbb{R}^n_+$ since elements of a workload vector $w \in \widehat{\mathsf{W}}$ may have negative entries.

Two states $x,\ y \in \mathsf{X}$ are called *exchangeable* if $\widehat{\Xi}(x-y) = \boldsymbol{\theta}$. Letting $\widehat{T}^*(x,y)$ denote the optimal time to travel from x to y,

$$\widehat{T}^*(x,y) = \Big(\max_{1\le i\le n} \frac{\langle \xi^i, x-y\rangle}{1-\rho_i}\Big)^+,$$

we see that $\widehat{T}^*(x,y) = \widehat{T}^*(y,x) = 0$ when x and y are exchangeable.

If one is interested in optimal control, then of course one will never stay in a state x if there exists an exchangeable state y with lower cost. Hence an optimal trajectory $\widehat{\boldsymbol{q}}^*$ can always be chosen so that it takes values in

$$\widehat{\mathsf{X}} = \big\{x \in \mathsf{X} : c(x) \le c(y) \text{ whenever } \widehat{\Xi}x = \widehat{\Xi}y\big\}.$$

This is an example of *state space collapse* as described in the introduction.

This reasoning leads to the following definitions:

(i) The *effective cost* $\bar{c}\colon \widehat{\mathsf{W}} \to \mathbb{R}_+$ is defined for any $w \in \widehat{\mathsf{W}}$ as the value of the linear program

$$\begin{aligned} &\min \quad \gamma \\ &\text{subject to} \quad \begin{aligned} \gamma &\ge \langle c^i, x\rangle, \quad 1 \le i \le \ell_c, \\ \widehat{\Xi}x &= w, \\ x &\in \mathsf{X}, \end{aligned} \end{aligned} \tag{3.7}$$

where $\{c^i\}$ are the components of the cost function given in (2.8). The effective cost is piecewise linear:

$$\bar{c}(w) = \max_i \langle \bar{c}^i, w\rangle, \qquad w \in \widehat{\mathsf{W}}\,, \tag{3.8}$$

where $\{\bar{c}^i\} \in \mathbb{R}^n$ are the extreme points obtained in the dual of (3.7).

(ii) For any $w \in \widehat{\mathsf{W}}$, the *effective state* $\mathcal{X}^*(w)$ is defined to be the vector $x \in \widehat{\mathsf{X}}$ that minimizes the linear program (3.7):

$$\mathcal{X}^*(w) = \arg\min_{x\in\mathsf{X}} \Big(c(x) : \widehat{\Xi}x = w\Big). \tag{3.9}$$

(iii) For any $x \in \mathsf{X}$, the optimal exchangeable state $\mathcal{P}^*(x) \in \widehat{\mathsf{X}}$ is defined via

$$\mathcal{P}^*(x) = \mathcal{X}^*(\widehat{\Xi}x). \tag{3.10}$$

The function $\mathcal{X}^*$ may not be uniquely defined, but it is chosen to be a continuous map from $\widehat{\mathsf{W}}$ to $\widehat{\mathsf{X}}$. This is always possible by restricting to basic feasible solutions in (3.7) to obtain a piecewise linear function of x.

Let $\widehat{\mathsf{W}}^+ \subset \mathbb{R}^n$ denote the closed, positive cone

$$\widehat{\mathsf{W}}^+ = \{w \in \widehat{\mathsf{W}} : \bar{c}(w) \le \bar{c}(w') \quad \text{whenever } w' \ge w, w' \in \widehat{\mathsf{W}}\}. \tag{3.11}$$

The function $\bar{c}\colon \widehat{\mathsf{W}} \to \mathbb{R}_+$ is called *monotone* if $\widehat{\mathsf{W}}^+ = \widehat{\mathsf{W}}$ and $\widehat{\mathsf{W}} \subseteq \mathbb{R}^n_+$.

Let $\widehat{q}^*(\,\cdot\,;x)$ denote an optimal trajectory for the relaxed control problem with initial condition x, and let $\widehat{w}^*(\,\cdot\,;x)$ denote the corresponding workload process. By optimality we have the equivalence

$$c(\widehat{q}^*(t;x)) = \bar{c}(\widehat{w}^*(t;x)), \qquad t \ge 0.$$

PROPOSITION 3.1. *Suppose that the nth relaxation is stabilizable. Then, the optimal trajectory $\widehat{\boldsymbol{q}}^*$ can be chosen so that for any initial condition $x \in \mathsf{X}$,*

(i) *$c(\widehat{q}^*(t;x))$ is decreasing, convex, and piecewise linear,*

(ii) *both $\widehat{\boldsymbol{q}}^*$ and $\widehat{\boldsymbol{w}}^*$ are piecewise linear and continuous on $(0,\infty)$.*

Proof. The proof of (i) is identical to the result for the original network model (see [36, Proposition 5]).

To see (ii), consider first the workload process. By convexity, $\bar{c}(\widehat{w}^*(t;x))$ can be discontinuous only at $t = 0$. Moreover, we may assume that $\widehat{\boldsymbol{w}}^*$ is linear on each of the open intervals (T_i, T_{i+1}), $1 \le i \le m-1$, where $\{T_i\}$ denotes the times at which $\frac{d}{dt}c(\widehat{q}^*(t;x))$ is discontinuous, with $T_0 = 0$, $T_m = \infty$.

We now show that, without any loss of generality, the trajectory $\widehat{\boldsymbol{w}}^*$ can be taken to be continuous on $(0,\infty)$. Consider the second time-interval $[T_1, T_2]$. We consider the linear path on this interval given by

$$\widehat{w}^\circ(t) = \widehat{w}^*(T_1-;x) + \frac{t-T_1}{T_2-T_1}\Big[\widehat{w}^*(T_2-;x) - \widehat{w}^*(T_1-;x)\Big], \qquad T_1 < t < T_2.$$

The identity $\bar{c}(\widehat{w}^\circ(t)) = \bar{c}(\widehat{w}^*(t;x))$ holds on this interval since $\bar{c}(\widehat{w}^*(T_1-;x)) = \bar{c}(\widehat{w}^*(T_1+;x))$.

The trajectory $\widehat{\boldsymbol{w}}^\circ$ is feasible, and we can thus redefine $\widehat{\boldsymbol{w}}^*$ on $(0,T_2)$ so that it is continuous. This procedure can be continued on each interval to form an optimal solution that is continuous on $(0,\infty)$.

To show that $\widehat{\boldsymbol{q}}^*$ can also be taken as continuous, choose $\widehat{q}^*(t;x) = \mathcal{X}^*(\widehat{w}^*(t;x))$, $t > 0$. ∎

3.2. One-dimensional workload. The workload process for the relaxed control problem frequently admits an identifiable optimal solution, and in many instances this solution is pointwise optimal.

In the one-dimensional case the matrix $\widehat{\Xi}$ is a row vector, $\widehat{\Xi} = \xi^{1\mathsf{T}}$. Provided $\rho = \rho_1 < 1$, the minimal draining time is given by

$$\widehat{T}^*(x) = \frac{\max(0, \langle \xi^1, x\rangle)}{1-\rho_1}, \qquad x \in \mathsf{X}.$$

The following results follow from linearity of $\widehat{T}^*$ and radial homogeneity of the cost function.

PROPOSITION 3.2. *The following hold for the one-dimensional relaxation for any piecewise linear cost function:*

(i) *The velocity set* $\widehat{\mathsf{V}}$ *is the half space*

$$\widehat{\mathsf{V}} = \{v : \langle \xi^1, v\rangle \geq -(1-\rho)\}.$$

(ii) *The effective cost* $\bar{c}$ *and the lifting map* $\mathcal{X}^*$ *are linear functions of* w*, for* $w \geq 0$*. Hence, letting* $x^* = \mathcal{X}^*(1)$*, the following hold for any* $w \geq 0$ *and any* $x \in \mathsf{X}$ *satisfying* $\langle \xi^1, x\rangle \geq 0$*:*

$$\bar{c}(w) = wc(x^*), \quad \mathcal{X}^*(w) = wx^*, \quad \mathcal{P}^*(x) = \langle \xi^1, x\rangle x^* \,.$$

(iii) *For any* $x \in \mathsf{X}$ *satisfying* $\langle \xi^1, x\rangle \geq 0$*, an optimal state trajectory is given by*

$$\widehat{q}^*(t;x) = \mathcal{P}^*(x)\Big(\frac{\widehat{T}^*(x) - t}{\widehat{T}^*(x)}\Big), \qquad 0 < t \leq \widehat{T}^*(x).$$

(iv) *If the initial condition* $x \in \mathsf{X}$ *satisfies* $\langle \xi^1, x\rangle \leq 0$*, then an optimal solution is given by* $\widehat{q}^*(t;x) = \boldsymbol{\theta}$ *for* $t > 0$. ∎

Proposition 3.3 shows that the solution in (iii) is pointwise optimal.

PROPOSITION 3.3. *Consider the relaxed control problem with* $n = 1$*. For* any *monotone, convex cost function* $c\colon \mathsf{X} \to \mathbb{R}_+$ *and any initial condition, there exists a pointwise optimal allocation.*

Proof. Let $x \in \mathsf{X}$ be given. If $\langle \xi^1, x\rangle \leq 0$, then $\widehat{q}^*(t;x) = \boldsymbol{\theta}$ for all $t > 0$. This is a pointwise optimal solution.

The proof is by comparison when $\langle \xi^1, x\rangle > 0$. Let $x^*(t)$ be the solution to the nonlinear program

$$\begin{aligned} \min \quad & c(y) \\ \text{subject to} \quad & y = x + \widehat{v}t, \\ & \langle \xi^1, \widehat{v}\rangle \geq -(1-\rho), \\ & y \geq \boldsymbol{\theta}. \end{aligned}$$

Its value, $\widehat{c}^* = c(x^*(t))$, is a lower bound on $c(\widehat{q}(t;x))$ for any feasible state trajectory $\widehat{\boldsymbol{q}}$ since we are optimizing over all states attainable at time t. Moreover, because $\widehat{\mathsf{V}}$ is a half-space, the state trajectory $\widehat{q}^*(t;x) = x^*(t)$, $t > 0$, is feasible for the relaxed fluid model. ∎

When c is linear, the effective cost has the following specific form:

$$\bar{c}(w) = \Big(\frac{c_{i^*}}{\xi^1_{i^*}}\Big)w = \Big(\min \frac{c_i}{\xi^1_i} : \xi^1_i > 0\Big)w, \qquad w \geq 0\,,$$

and $x^* = (\xi^1_{i^*})^{-1}e^{i^*}$. In this case, Proposition 3.2(ii) may be viewed as a generalization of the $c\mu$-rule [6, 30].

The routing model shown in Figure 2 was used in [29] to illustrate a form of state space collapse for a stochastic model. We assume that the router with service rate μ_3 is fast, so that, in particular, $\mu_3 > \mu_1 + \mu_2$.

The fluid model is given by

$$B = \begin{bmatrix} -\mu_1 & 0 & \mu_3 & 0 \\ 0 & -\mu_2 & 0 & \mu_3 \\ 0 & 0 & -\mu_3 & -\mu_3 \end{bmatrix}, \quad \alpha = \begin{bmatrix} 0 \\ 0 \\ \alpha_3 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix}. \tag{3.12}$$

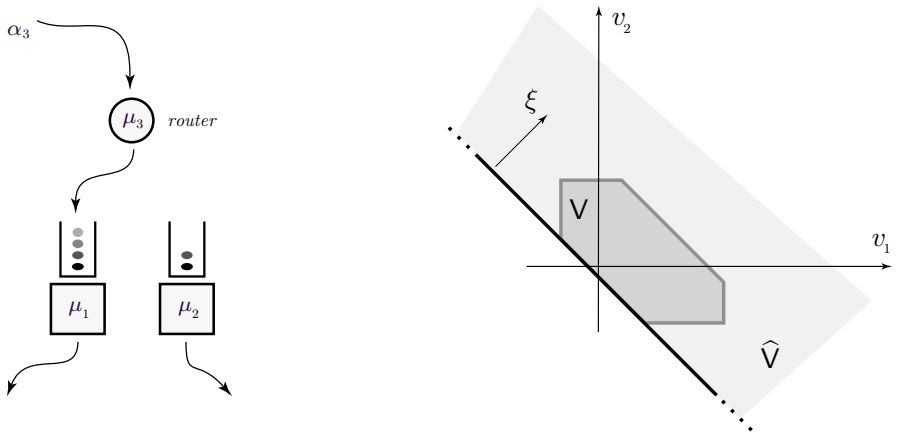

FIG. 2. *On the left is shown a simple routing model. At right is the velocity set* V*, and its one-dimensional relaxation, projected onto* $\{v \in \mathbb{R}^3 : v_3 = 0\}$.

We have four workload vectors,

$$\begin{aligned} \xi^1 &= (\mu_1+\mu_2)^{-1}(1,1,1)^{\scriptscriptstyle T}, & \eta^1 &= (\mu_1+\mu_2)^{-1}(\mu_1,\mu_2,0)^{\scriptscriptstyle T}, \\ \xi^2 &= (m_1,0,0)^{\scriptscriptstyle T}, & \eta^2 &= e^1, \\ \xi^3 &= (0,m_2,0)^{\scriptscriptstyle T}, & \eta^3 &= e^2, \\ \xi^4 &= (0,0,m_3)^{\scriptscriptstyle T}, & \eta^4 &= e^3, \end{aligned}$$

where $m_i = 1/\mu_i$. The vector ξ^1 defines the workload at the two downstream stations, pooled together to form a single resource.

The respective loads are given by $\rho_1 = \alpha_3/(\mu_1+\mu_2)$, $\rho_2 = \rho_3 = 0$, $\rho_4 = \alpha_3/\mu_3$. The system load is $\rho = \max(\rho_1,\rho_4) = \rho_1$ since we have assumed that $\mu_3 > \mu_1+\mu_2$. Using the formula given in Theorem 2.2 we can compute the minimum emptying time from an initial condition $x \in \mathsf{X} = \mathbb{R}^3_+$:

$$T^*(x) = \max\Big(\frac{1}{1-\rho_1}\frac{x_1+x_2+x_3}{\mu_1+\mu_2}, \frac{x_1}{\mu_1}, \frac{x_2}{\mu_2}, \frac{1}{1-\rho_4}\frac{x_3}{\mu_3}\Big).$$

Given the expression for ξ^1 we find that the velocity set for the first workload-relaxation is given by

$$\widehat{\mathsf{V}} = \{v : v_1+v_2+v_3 \ge -(\mu_1+\mu_2-\alpha_3)\}\,.$$

This set is compared to the entire velocity set V in Figure 2. Although both are defined to be a subset of $\mathbb{R}^3$, we can set $q_3 = v_3 \equiv 0$ to obtain the two-dimensional projection shown. We have $\widehat{\mathsf{W}} = \mathbb{R}_+$ in the first workload-relaxation, and if the cost is linear, $c(x) = c^{\scriptscriptstyle T}x$, $x \in \mathsf{X}$, then the effective cost is given by

$$c(w) = c_{i_*}(\mu_1+\mu_2)w\,, \qquad w \in \widehat{\mathsf{W}}\,,$$

where $c_{i_*} = \min(c_1,c_2,c_3)$.

3.3. Dimension two. Under certain conditions on the cost we can again be assured of a pointwise optimal solution even when $\widehat{\mathsf{V}}$ is not a half-space. We illustrate this in the two-dimensional case where

$$\begin{aligned} &\widehat{\Xi} = [\xi^1 \mid \xi^2]^{\scriptscriptstyle T}, \\ &\widehat{\mathsf{V}} = \{v : \langle \xi^i, v\rangle \ge -(1-\rho_i), \quad i = 1,2\}. \end{aligned}$$

The following result holds for any piecewise linear cost function. Recall the definition of the monotone set given in (3.11).

THEOREM 3.4. *Suppose that* $\widehat{\mathsf{W}} \subseteq \mathbb{R}^2_+$.

(i) *When the initial condition satisfies* $\widehat{w}(0) \in \widehat{\mathsf{W}}^+$*, then there exists a pointwise optimal solution.*

(ii) *If the vector* $(1-\rho_1, 1-\rho_2)^T$ *lies in* $\widehat{\mathsf{W}}^+$*, then there is a pointwise optimal solution from* any *initial condition.*

Proof. The proof follows from the rectangular geometry of the set of all states reachable from $\widehat{w}(0) = w$: If w^1 can be reached from w at time t using some allocation, then any $w^2 \in \widehat{\mathsf{W}}$ can also be reached, provided $w_i^2 \geq w_i^1$ for each i. Under the conditions imposed in (i), using the greedy policy we have $\widehat{w}^*(t;x) \in \widehat{\mathsf{W}}^+$ for all $t > 0$, and $\widehat{w}^*(t;x)$ is pointwise minimal within $\widehat{\mathsf{W}}^+$ in the sense that

$$\widehat{w}_i^*(t;x) \leq \widehat{w}_i(t;x), \qquad t \geq 0, \quad i = 1, 2,$$

for any other feasible trajectory $\widehat{\boldsymbol{w}}$ evolving in $\widehat{\mathsf{W}}^+$, starting at $w = \widehat{\Xi}x$. The result (ii) then follows from (i) since $\widehat{w}_i^*(t;x) \in \widehat{\mathsf{W}}^+$ for all $t > 0$ under the assumptions of (ii). ∎

Figure 3 shows the structure of the cost function, the set $\widehat{\mathsf{W}}^+$, and optimal state trajectories for a model that satisfies the assumptions of Theorem 3.4(ii).

Pathwise optimality cannot be expected in general. If the workload dimension is greater than one, and if the cost function c favors starvation of some dynamic bottleneck from some initial condition, then the greedy policy is not time-optimal and hence it cannot be pointwise optimal. Figure 4 illustrates one example with $(1-\rho_1, 1-\rho_2) \notin \widehat{\mathsf{W}}^+$ and $\widehat{w}(0) \notin \widehat{\mathsf{W}}^+$. The initial condition satisfies

$$\frac{d}{dw_2} c\left(\widehat{w}(0)\right) < 0.$$

From this initial condition it is advantageous in the short term to allow $\widehat{w}(0+) \in \partial\widehat{\mathsf{W}}^+$ since $\bar{c}$ is not monotone. This is the greedy, or myopic, policy, which is not time-optimal in this example. The paths shown minimize the infinite-horizon cost given in

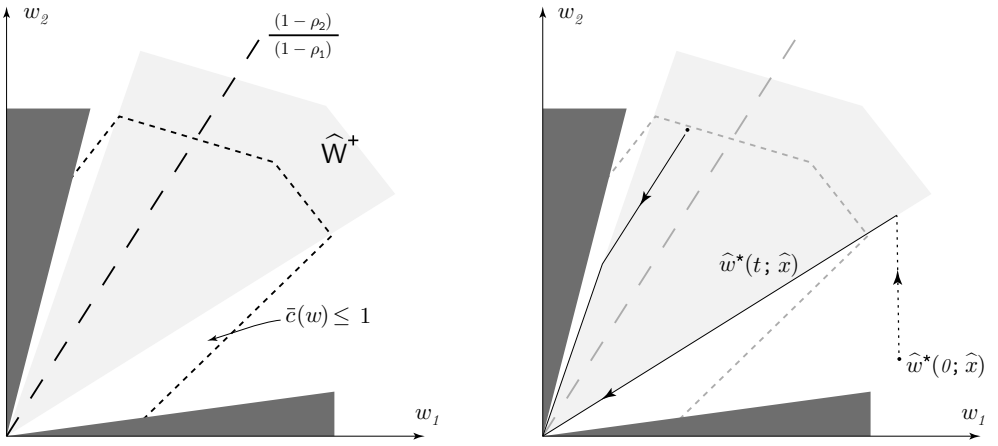

FIG. 3. *The figure at left shows a level set of the cost function* $\bar{c}$ *and the positive cone* $\widehat{\mathsf{W}}^+$ *on which the cost it is monotone. The plot at right shows three optimal state trajectories from varying initial conditions. The darkest region in each figure shows workload vectors* w *that are not feasible.*

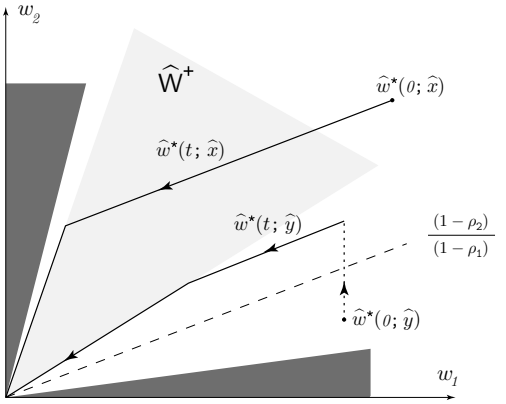

FIG. 4. *Shown are two optimal state trajectories from two different initial conditions. This example is exactly as before, except that ρ_2 is somewhat larger. A trade-off must be made in this case: An overly greedy decision at time 0+ will significantly extend the time to empty the network.*

(3.4), or equivalently $\widehat{J} = \int_0^\infty \bar{c}(\widehat{w}(t;x))\,dt$. An optimal allocation makes a trade-off between reducing the cost at time 0+ and preserving a fast draining time for the model, whenever $\widehat{w}(0) \notin \widehat{\mathsf{W}}^+$.

The three-buffer model shown in Figure 5 is described by the linear fluid model with parameters

$$B = \begin{bmatrix} -\mu_1 & 0 & 0 \\ \mu_1 & -\mu_2 & 0 \\ 0 & \mu_2 & -\mu_3 \end{bmatrix}, \quad \alpha = \begin{bmatrix} \alpha_1 \\ 0 \\ 0 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}. \tag{3.13}$$

The load parameters and workload vectors are given by

$$\begin{aligned} \xi^1 &= (m_1 + m_3, m_3, m_3)^T, & \rho_1 &= \alpha_1(m_1 + m_3), \\ \xi^2 &= (m_2, m_2, 0)^T, & \rho_2 &= \alpha_1 m_2, \end{aligned}$$

where we have used $\boldsymbol{\rho} = \widehat{\Xi}\alpha$, with $\widehat{\Xi}$ given in (3.3) with $n = 2$, and $m_i = \mu_i^{-1}$.

Figure 6 shows the optimal solutions for the first and second workload-relaxations. In this numerical example we have taken $\rho_1 = \rho_2 = 9/10$ and $c = (1, 1, 1)^T$. The two plots are very different since the loads at stations one and two are equal.

In Figure 7 the optimal trajectory minimizing (2.6) is compared to the pointwise optimal solution for the two-dimensional relaxation. The triangular region shows the (apparent) error introduced by relaxing the original network optimization problem. We introduce a procedure in Theorem 4.1 below to translate the solution of the relaxed

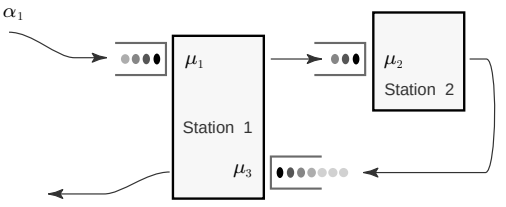

FIG. 5. *A two station scheduling problem*

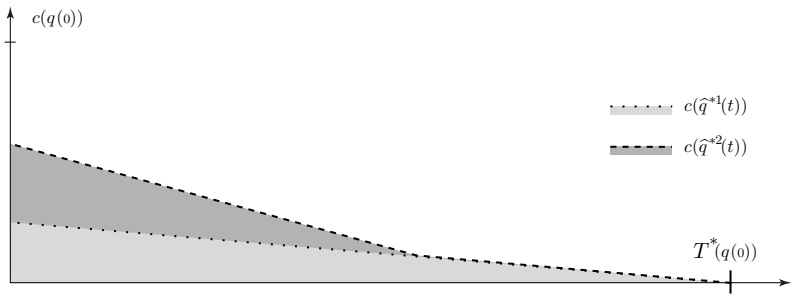

FIG. 6. *Optimal cost-curves for the first and second workload-relaxations.*

problem to the original network model. This yields precisely the optimal policy in this example.

Figure 1 shows a *pull model* in which four of the buffers are virtual. This example is analyzed in [14] under the assumption that the arrivals are *controlled*. An optimal policy will simultaneously determine sequencing and routing rules at each station and release rules for material to the network. Specific service rate values may be found in Chapter 3 of [14]. The cost c is linear, with a weighting of 10 for deficit and unity weighting at the two other virtual buffers and all real buffers.

Although the model is complex, the effective cost for the second workload-relaxation is very simple: as shown in Figure 8, it is defined by five linear functions $\{\bar{c}^i, i = 1, \ldots, 5\}$. Figure 8 shows that the set $\widehat{\mathsf{W}}^+$ contains the ray $\{w \in \mathbb{R}^2_+ : \bar{c}^1 w = \bar{c}^2 w\}$ but not much else, since both $\bar{c}^1$ and $\bar{c}^2$ have negative components. It follows that pointwise optimal trajectories exist for each initial condition only for a very small set of arrival-rate vectors α. (In this example, arrivals are interpreted as *demand* of material from the network.)

3.4. Higher workload dimension. The two-dimensional case is special because one can always find, for each initial w and each time t, a workload vector $\widehat{w}^*(t) \in \widehat{\mathsf{W}}^+$ that is pointwise minimal and reachable from w at time t. This geometry breaks down in three or more dimensions.

Consider first some positive results.

THEOREM 3.5. *Suppose that $\widehat{\mathsf{W}} \subseteq \mathbb{R}^n_+$ for the nth workload-relaxation. The following are then equivalent:*

(i) *A pointwise minimal solution $\widehat{\boldsymbol{w}}^*$ exists for any initial condition $x \in \mathsf{X}$ and any arrival-rate vector α.*

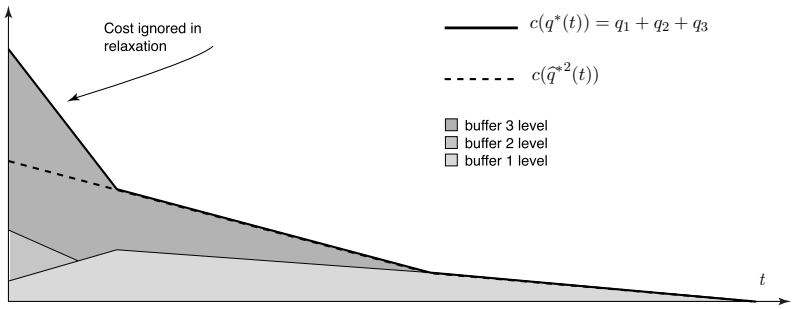

FIG. 7. *The dashed line shows the cost $c(\widehat{q}^*(t;x))$ for the optimized two-dimensional workload-relaxation. The actual optimal policy incurs a higher cost, but this error is bounded in ρ.*

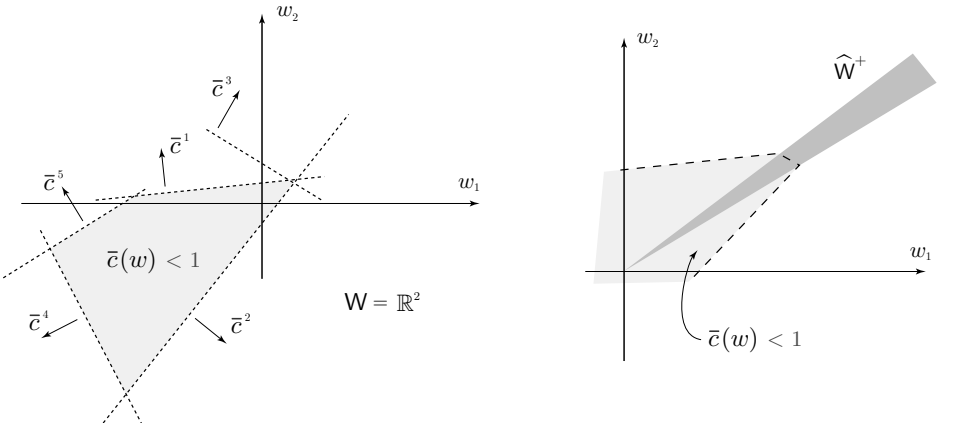

FIG. 8. *On the left is shown a sublevel set of the effective cost for one set of parameters in a two-dimensional relaxation of the network shown in* Figure 1. *The figure at right shows the set* $\widehat{\mathsf{W}}^+$ *together with a close-up of the sublevel set of* $\bar{c}$*, restricted to* $\mathbb{R}^2_+$*. The workload space* $\widehat{\mathsf{W}}$ *is equal to all of* $\mathbb{R}^2$ *in this example.*

(ii) *For each* $w \in \mathbb{R}^n$*, the set*

$$\widehat{\mathsf{W}}_w = \{\widehat{w} : \widehat{w} \in \widehat{\mathsf{W}}, \widehat{w}_i \geq w_i, \quad i = 1, \dots, n\}, \tag{3.14}$$

contains a pointwise minimal element.

If either of these equivalent conditions hold, then a pointwise minimal trajectory may be expressed,

$$\widehat{w}^*(t; x) = [\widehat{\Xi} x - (\mathbf{1} - \boldsymbol{\rho})t]_+, \tag{3.15}$$

where $[w]_+$*,* $w \in \mathbb{R}^n$*, is the projection of* w *onto the set* $\widehat{\mathsf{W}}_w$ *in the standard* ℓ_2 *norm.*

Proof. We first show that the pointwise minimal trajectory is given by (3.15) if (i) holds. Observe that for any t, x the inequality $\widehat{w}^*(t; x) \geq \widehat{\Xi} x - (\mathbf{1} - \boldsymbol{\rho})t$ holds, and $\widehat{w}^*(t; x) \in \widehat{\mathsf{W}}$. Since $\widehat{\boldsymbol{w}}^*$ is minimal, it serves as the projection as claimed.

This implication also shows that (i) $\Rightarrow$ (ii).

Conversely, if (ii) holds, then the trajectory given by $\widehat{w}^\circ(t; x) = [\widehat{\Xi} x - (\mathbf{1} - \boldsymbol{\rho})t]_+$, $t \geq 0$, is obviously pointwise minimal, and it is a piecewise linear function of t for each initial condition x. We show below that the semigroup property holds:

$$\widehat{w}^\circ(t + s; x) = [\widehat{w}^\circ(t; x) - (\mathbf{1} - \boldsymbol{\rho})s]_+, \qquad t, s \geq 0, \quad x \in \mathsf{X}. \tag{3.16}$$

This implies that $\frac{d}{dt}\widehat{w}^\circ(t; x) \geq -(\mathbf{1} - \boldsymbol{\rho})$ for all t, so that this trajectory is feasible for the relaxed fluid model, and hence (i) holds with $\widehat{\boldsymbol{w}}^* = \widehat{\boldsymbol{w}}^\circ$.

To establish (3.16), fix $s, t > 0$, let $T_1 = s + t$, and consider for comparison the trajectory

$$\widehat{w}(T; x) = \widehat{\Xi} x + \frac{T}{T_1}[\widehat{w}^\circ(t + s; x) - \widehat{\Xi} x], \qquad 0 \leq T \leq T_1.$$

This is feasible, and by minimality of $\widehat{w}^\circ(t; x)$ we have $\widehat{w}(t; x) \geq \widehat{w}^\circ(t; x)$. The following bounds then follow:

$$\begin{aligned} \widehat{w}^\circ(t + s; x) = \widehat{w}(T_1; x) &= [\widehat{w}(t; x) + (\widehat{w}(t + s; x) - \widehat{w}(t; x))]_+ \\ &\geq [\widehat{w}(t; x) - (\mathbf{1} - \boldsymbol{\rho})s]_+ \\ &\geq [\widehat{w}^\circ(t; x) - (\mathbf{1} - \boldsymbol{\rho})s]_+. \end{aligned}$$

To obtain an inequality in the reverse direction, note that $\widehat{w}^\circ(t;x) \ge \widehat{\Xi}x - (\mathbf{1}-\boldsymbol{\rho})t$, which implies that

$$\widehat{w}^\circ(t+s;x) := [\widehat{\Xi}x - (\mathbf{1}-\boldsymbol{\rho})(t+s)]_+ \le [\widehat{w}^\circ(t;x) - (\mathbf{1}-\boldsymbol{\rho})s]_+ .$$

We therefore obtain (3.16). □

Under these conditions there is some hope in finding a pointwise optimal solution to the relaxed optimal control problem.

COROLLARY 3.6. *Suppose that*

(i) *the effective cost $\bar{c}$ is monotone and*

(ii) *a pointwise minimal solution $\widehat{\boldsymbol{w}}^*$ exists for the nth workload-relaxation, for any initial condition $x \in \mathsf{X}$.*

Then for any $x \in \mathsf{X}$ there is a pointwise optimal solution for the nth workload-relaxation. □

Assumption (ii) fails in general. Consider the three-station network shown in Figure 9 (see [29, sections 6 and 7] for related examples of RBM networks). The arrival rates α_1, α_6 are equal, and all service rates are equal to unity. For any x, the vector $\widehat{w} = \widehat{\Xi}x \in \mathbb{R}^3$ can be written

$$\widehat{w}_1 = x_1 + x_2 + x_4 + x_6 , \quad \widehat{w}_2 = x_1 + x_3 + x_4 + x_6 , \quad \widehat{w}_3 = x_6 + x_1 + x_3 + x_5 .$$

For example, $\widehat{w}^3 := \widehat{\Xi}e^3 = [0,\ 1,\ 1]^{\mathrm{T}}$, and $\widehat{w}^4 := \widehat{\Xi}e^4 = [1,\ 1,\ 0]^{\mathrm{T}}$. The two states $\{e^3, e^4\}$ are not exchangeable for a three-dimensional relaxation since the workload vectors $\widehat{w}^3, \widehat{w}^4$ are different.

For simplicity consider the arrival-free model where $\alpha_1 = \alpha_6 = 0$ so that $\rho = 0$. The initial condition $x = e^3 + e^4$ has corresponding workload $\widehat{w}(0) = \widehat{\Xi}x = (1,2,1)^{\mathrm{T}}$. From this initial condition it is possible to reach either e^3 or e^4 in exactly one second. Any minimal workload vector $\widehat{w}^*$ must then satisfy $\widehat{w}^*(t;x) \le \widehat{w}^3$ and $\widehat{w}^*(t;x) \le \widehat{w}^4$ at $t = 1$, which implies that $\widehat{w}^*(1;x) \le (0,1,0)^{\mathrm{T}}$.

The only vector in $\widehat{\mathsf{W}}$ satisfying this inequality is $w = (0,0,0)^{\mathrm{T}}$. However, this state is not reachable in one second since the minimal draining time is $W^*(x) = T^*(x) = \max(\widehat{w}_1(0), \widehat{w}_2(0), \widehat{w}_3(0)) = 2$.

We now investigate the structure of pointwise optimal solutions under the conditions of Corollary 3.6.

The ith pooled-resource is said to be *satiated* at state x provided there exists $v \in \widehat{\mathsf{V}}$ satisfying $\langle \xi^i, v\rangle = -(1-\rho_i)$, and $v_i \ge 0$ whenever $x_i = 0$. A resource is said to be satiated if it is a component of a satiated pooled-resource.

Consider any $x \in \mathsf{X}$, and suppose $y \in \mathsf{X}$ with $\langle \xi^k, x\rangle > \langle \xi^k, y\rangle$ for some $1 \le k \le n$. Then the optimal time to travel from x to y is nonzero:

$$\widehat{T}^*(x,y) = \max_{1\le j\le n} \frac{\langle \xi^j, x-y\rangle}{1-\rho_j} > 0 .$$

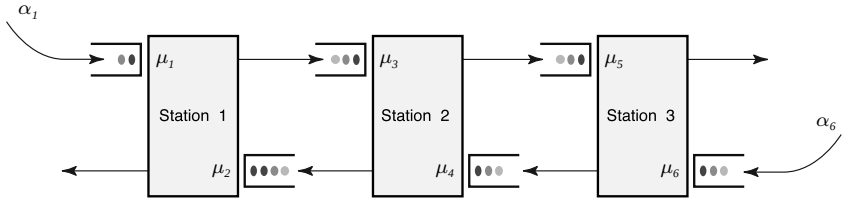

FIG. 9. *A three-station network.*

With $v = (y-x)/\widehat{T}^*(x,y) \in \widehat{\mathsf{V}}$, the trajectory below is both feasible and time-optimal:

$$\widehat{q}(t;x) = x + vt, \qquad 0 \le t \le \widehat{T}^*(x,y)\,.$$

Moreover, simple dynamic programming arguments ensure that

$$\frac{d}{dt}\widehat{T}^*(\widehat{q}(t;x),y) = -1, \qquad 0 < t < \widehat{T}^*(x,y).$$

Hence, whenever i is a maximizer, so that

$$\widehat{T}^*(x,y) = \frac{\langle \xi^i, x-y\rangle}{1-\rho_i},$$

we must have $\langle \xi^i, v\rangle = -(1-\rho_i)$. This implies that pooled-resource i is satiated by x and proves the following.

PROPOSITION 3.7. *Suppose that $\rho < 1$. Then $\widehat{T}^*(x,y) < \infty 0$, $x, y \in \mathsf{X}$, and if $\widehat{T}^*(x,y) > 0$, then*

$$\begin{aligned}\widehat{T}^*(x,y) &= \max\left\{\frac{\langle \xi^j, x-y\rangle}{1-\rho_j} : 1 \le j \le n\right\}\\ &= \max\left\{\frac{\langle \xi^j, x-y\rangle}{1-\rho_j} : j \text{ is satiated by } x\right\}.\end{aligned}$$ □

Satiated resources play a role analogous to dynamic bottlenecks in the construction of a time-optimal trajectory. The following result is the analogue of Theorem 2.6. It is an easy corollary to Proposition 3.7.

THEOREM 3.8. *Suppose that $\rho < 1$, and that the nth relaxation satisfies $\widehat{\mathsf{W}} \subseteq \mathbb{R}^n_+$. Let $\widehat{\boldsymbol{q}}$ be any solution to the nth workload-relaxation, starting at $x \in \mathsf{X}$, and let $\widehat{w}(t;x) = \widehat{\Xi}\widehat{q}(t;x)$, $t \ge 0$. We then have the following:*

(i) *If $\widehat{\boldsymbol{w}}$ is pointwise minimal, then each satiated pooled-resource is working at capacity for each $0 < t < \infty$. That is, if pooled-resource i is satiated at time t, then*

$$\frac{d}{dt}\widehat{w}_i(t) = -(1-\rho_i).$$

(ii) *If each satiated pooled-resource works at capacity for all t, then the resulting workload trajectory $\widehat{\boldsymbol{w}}$ is pointwise minimal.* □

3.5. Variability and continuity. We close this section with some continuity properties for pointwise minimal solutions. Our interest lies in the fluid model with *exogenous disturbance*, defined by

$$\widehat{q}(t;x) = B\widehat{z}(t;x) + \alpha t + d_0(t)\,, \quad t \ge 0\,, \qquad \widehat{q}(0;x) = x\,. \tag{3.17}$$

We assume as in (3.2) that the allocation is subject to the linear constraints

$$\widehat{C}[\widehat{z}(t;x) - \widehat{z}(s;x)] \le [t-s]\mathbf{1}, \qquad 0 \le s \le t\,, \tag{3.18}$$

where $\widehat{C} = -\widehat{\Xi}B$ is defined below (3.2), and we assume throughout that the disturbance $\boldsymbol{d}_0$ is of bounded variation.

Letting $\widehat{w}(t;x) := \widehat{\Xi}\widehat{q}(t;x)$, $d(t) = \widehat{\Xi}d_0(t)$, we obtain the corresponding workload model

$$\widehat{w}(t;x) = \widehat{\Xi}x - (\mathbf{1} - \boldsymbol{\rho})t + \iota(t) + d(t), \qquad t \geq 0, \tag{3.19}$$

where $\iota(t) := t\mathbf{1} - \widehat{C}\widehat{z}(t;x)$, $t \geq 0$. The idleness process $\boldsymbol{\iota}$ is nonnegative with nondecreasing components, and $\widehat{\boldsymbol{w}}$ evolves in $\widehat{\mathsf{W}}$.

Rather than define $\widehat{\boldsymbol{w}}$ through (3.17), for the purposes of optimization we may restrict attention to the simpler model (3.19). Given the current workload-value $\widehat{w} = \widehat{w}^*(t;x)$ we take $\widehat{z}^*(t;x)$ to be any optimizer of the linear program

$$\begin{aligned} &\min \quad \gamma \\ &\text{subject to} \quad \begin{aligned} \gamma &\geq \langle c^i, y\rangle, \quad 1 \leq i \leq \ell_c, \\ y &= x + Bz + \alpha t + d_0(t), \\ \widehat{\Xi}y &= \widehat{w}, \\ y &\in \mathsf{X}. \end{aligned} \end{aligned} \tag{3.20}$$

It follows from the definitions that the optimizer $\widehat{\boldsymbol{z}}^*$ satisfies the constraints given in (3.18).

If $\boldsymbol{d} \equiv \boldsymbol{\theta}$, then (3.19) is the linear workload model considered earlier. In this case, it follows from Theorem 3.5 and Assumption M below that (3.19) admits a pointwise minimal solution for any value of $\boldsymbol{\rho}$. This is generalized to arbitrary disturbances in Theorem 3.10.

Assumption M.

(i) The workload vectors for the nth relaxation are linearly independent and satisfy

$$\xi^i \in \mathbb{R}_+^\ell \text{ for } 1 \leq i \leq n.$$

(ii) For each $w \in \mathbb{R}^n$ the set $\widehat{\mathsf{W}}_w$ defined in (3.14) contains a pointwise minimal element denoted $[w]_+$.

Although the semigroup property (3.16) does not hold in general for a model with disturbances, we always have the lower bound.

LEMMA 3.9. *Under Assumption* M*, if $\widehat{\boldsymbol{w}}$ is a feasible state trajectory for the nth relaxation, then*

$$\widehat{w}(t;x) \geq [\widehat{w}(s;x) - (\mathbf{1} - \boldsymbol{\rho})(t-s) + d(t) - d(s)]_+, \qquad t \geq s \geq 0,\ x \in \mathsf{X}.$$

Proof. The lower bound $\widehat{w}(t;x) \geq (\widehat{w}(s;x) - (\mathbf{1} - \boldsymbol{\rho})(t-s) + d(t) - d(s))$ holds since the idleness process is nondecreasing. Hence the result follows from the definition of the projection, combined with Assumption M, which asserts that the projection can be taken to be pointwise minimal. ∎

Theorem 3.10 establishes existence of minimal solutions and some strong robustness properties. This existence question is closely related to the *generalized Skorokhod problem* [21, 26, 2, 15, 16, 18]. These results will facilitate the treatment of stochastic models in section 4.

THEOREM 3.10. *Under Assumption* M*, for any given disturbance $\boldsymbol{d}$ of bounded variation, the model* (3.19) *admits a solution $\widehat{\boldsymbol{w}}^*$ that is pointwise minimal. For two disturbances $(\boldsymbol{d}^1, \boldsymbol{d}^2)$ the respective minimal solutions $(\widehat{\boldsymbol{w}}^{*1}, \widehat{\boldsymbol{w}}^{*2})$ satisfy the following:*

(i) *Provided $d_0^1(t) \leq d_0^2(t)$, $t \geq 0$,*

$$\widehat{w}^{*2}(t;x) \leq \widehat{w}^{*1}(t;x) + d^2(t) - d^1(t), \qquad t \geq 0,\ x \in \mathsf{X}.$$

(ii) *Suppose that* $d_0^1(t) = d_0^2(t) - \varepsilon_0(t)$, $t \ge 0$, *with* $\varepsilon_0(\cdot)$ *a nonnegative and nondecreasing function from* $\mathbb{R}_+$ *to* $\mathbb{R}_+^\ell$. *Then,*

$$\widehat{w}^{*1}(t;x) \le \widehat{w}^{*2}(t;x), \qquad t \ge 0,\ x \in \mathsf{X}.$$

(iii) *For arbitrary disturbances* $\boldsymbol{d}_0^1$, $\boldsymbol{d}_0^2$,

$$\widehat{w}^{*1}(t;x) \le \widehat{w}^{*2}(t;x) + |\boldsymbol{d}^2 - \boldsymbol{d}^1|_\infty^t - [d^2(t) - d^1(t)], \qquad t \ge 0,\ x \in \mathsf{X},$$

where $(|\boldsymbol{f}|_\infty^t)_i := \sup_{0\le s\le t} |f_i(s)|$ *for any function* $\boldsymbol{f}\colon \mathbb{R}_+ \to \mathbb{R}^n$.

Proof. We first establish the three properties, given that minimal solutions exist.

To prove (i), observe that if the optimal allocation $\widehat{\boldsymbol{z}}^{*1}$ for the first system is applied to the second, then we have for all $t \ge 0$

$$\begin{aligned} \widehat{q}^{*1}(t;x) &= x + B\widehat{z}^{*1}(t) + \alpha t + d_0^1(t), \\ \text{and}\quad \widehat{q}^{2}(t;x) &= x + B\widehat{z}^{*1}(t) + \alpha t + d_0^2(t) \ge \widehat{q}^{*1}(t;x) \ge \boldsymbol{\theta}. \end{aligned} \tag{3.21}$$

Hence $\widehat{\boldsymbol{z}}^{*1}$ is feasible for the second disturbance, and consequently $\widehat{w}^{*2}(t;x) \le \widehat{w}^{2}(t;x)$, with $\widehat{w}^{2}(t;x) := \widehat{\Xi}\widehat{q}^{2}(t;x)$, by the assumed existence of a minimal process $\widehat{\boldsymbol{w}}^{*2}$. Moreover, (3.21) implies that $\widehat{w}^{2}(t;x) = \widehat{w}^{*1}(t;x) + d^2(t) - d^1(t)$, $t \ge 0$, which gives (i).

The proof of (ii) is similar: Define $\varepsilon(t) := \widehat{\Xi}\varepsilon_0(t)$, $t \ge 0$. Under Assumption M and the conditions imposed in (ii), this is nonnegative and nondecreasing. Let $\hat{\imath}^{*i}(t) = \mathbf{1}t - \widehat{C}\widehat{z}^{*i}(t)$, $i = 1, 2$, denote the optimal idleness, and set $\hat{\imath}^{1}(t) = \hat{\imath}^{*2} + \varepsilon(t)$, $t \ge 0$. We have $\frac{d}{dt}\hat{\imath}^{1}(t) \ge \boldsymbol{\theta}$, and we also have under this policy, applied to the first model, $\widehat{w}^{1}(t;x) = \widehat{w}^{*2}(t;x)$. This combined with minimality of $\widehat{\boldsymbol{w}}^{*1}$ proves (ii).

To prove (iii) let $\boldsymbol{d}_0^3$ denote the disturbance $d_0^3(t) = d_0^1(t) + |\boldsymbol{d}_0^2 - \boldsymbol{d}_0^1|_\infty^t$, and let $\widehat{\boldsymbol{w}}^{*3}$ denote the associated minimal solution. We have $d_0^3(t) \ge d_0^2(t)$, and $\varepsilon_0(t) := d_0^3(t) - d_0^1(t)$ is nonnegative and nondecreasing. Consequently, for any $t \ge 0$, $x \in \mathsf{X}$, we have

$$\begin{aligned} \widehat{w}^{*3}(t;x) &\le \widehat{w}^{2*}(t;x) + |\boldsymbol{d}^2 - \boldsymbol{d}^1|_\infty^t + [d^1(t) - d^2(t)] && \text{from (i)}, \\ \widehat{w}^{*1}(t;x) &\le \widehat{w}^{3*}(t;x) && \text{from (ii)}. \end{aligned}$$

Combining these bounds gives (iii).

We now establish existence. Consider first the special case in which all of the disturbances are continuous and piecewise linear. In this case we may construct a pointwise minimal trajectory $\widehat{\boldsymbol{w}}^*$ inductively by adapting the construction used in Theorem 3.5. Set $\widehat{w}^*(0;x) = \widehat{\Xi}x$, and

$$\widehat{w}^*(T_k + t; x) = [\widehat{w}^*(T_k;x) - (\mathbf{1} - \boldsymbol{\rho})t + m_k t]_+, \qquad 0 < t < T_{k+1} - T_k, \quad k \ge 0,$$

where $\{T_i\}$ are the times at which the slope of $\boldsymbol{d}$ changes, and m_k denotes the slope of $\boldsymbol{d}$ on the interval $[T_k, T_{k+1}]$. An application of Theorem 3.5 shows that this is the desired minimal solution on $[T_k, T_{k+1}]$ with initial condition $\widehat{w} = \widehat{w}^*(T_k;x)$, and by induction it follows that $\widehat{\boldsymbol{w}}^*$ is pointwise minimal.

For an arbitrary disturbance $\boldsymbol{d}$ of bounded variation we can construct a sequence of piecewise linear functions $\{\boldsymbol{d}^k\}$ such that $d^k(t) \downarrow d(t)$, $k \to \infty$. We let $\{\widehat{\boldsymbol{w}}^{*k}\}$ denote the respective optimal solutions and set $\widehat{w}^*(t;x) = \lim\inf_{k\to\infty} \widehat{w}^{*k}(t;x)$ for all t, x. Using property (i) for the $\{\widehat{\boldsymbol{w}}^{*k}\}$ we deduce that $\widehat{\boldsymbol{w}}^*$ is the desired pointwise minimal solution. ∎

We see that it is frequently possible to compute a pointwise optimal trajectory $\widehat{\boldsymbol{q}}^*$ for the relaxed control problem, with or without disturbances. What does this

then tell us about the original model of interest? The sharpest results are obtained by examining a model in heavy traffic, with $\rho \sim 1$.

4. Networks in heavy traffic. We consider here a sequence of networks, indexed by an integer $r \geq 1$, for which $\rho^r \uparrow 1$ as $r \to \infty$. It is in this heavily loaded regime that the time-scale separation developed in the previous section is most evident in the (unrelaxed) network model.

We assume that B and C are independent of r. Two arrival-rate vectors α^1, α^∞ are given, and for arbitrary $r \geq 1$ we set

$$\alpha^r := \alpha^\infty - \tfrac{1}{r}(\alpha^\infty - \alpha^1). \tag{4.1}$$

We impose the following assumptions throughout this section.

Assumption H.

(i) The model with arrival-rate vector α^1 is stabilizable. In particular,

$$\rho^1 := W^*(\alpha^1) < 1\,.$$

(ii) The arrival-rate vector α^∞ satisfies $\alpha^1 \leq \alpha^\infty$ and

$$\rho^\infty := W^*(\alpha^\infty) = 1.$$

We let $\mathcal{I}_b = \{i : \langle \xi^i, \alpha^\infty \rangle = 1\}$ denote the index set of bottleneck stations for the model with arrival rate α^∞. By reordering, we can assume, without loss of generality, that $\mathcal{I}_b = \{1, \ldots, \ell_b\}$ for some integer $\ell_b \geq 1$.

The choice of a perturbation in the arrival stream is for the sake of convenience since we can then take a fixed set of workload vectors. If we assume that V_r is a general, convergent sequence of polyhedra, then the theory below remains essentially unchanged.

Throughout this section we consider the nth workload-relaxation with $n = \ell_b$.

4.1. Fluid models. The rth network is defined on a fluid scale by

$$\frac{d}{dt} q(t;x) = B\zeta(t;x) + \alpha^r t, \qquad t \geq 0. \tag{4.2}$$

We let V_r denote the corresponding velocity space so that $\frac{d}{dt} q(t;x) \in \mathsf{V}_r$ for all t, x, r.

The following bound on ρ^r shows that this model is stabilizable for finite $r \geq 1$. The inequality is obtained using convexity of W^*:

$$\begin{aligned} \rho^r = W^*(\alpha^r) &= W^*\left((1 - \tfrac{1}{r})\alpha^\infty + \tfrac{1}{r}\alpha^1\right) \\ &\leq (1 - \tfrac{1}{r})\rho^\infty + \tfrac{1}{r}\rho^1 = 1 - \tfrac{1}{r}(1 - \rho^1) < 1. \end{aligned} \tag{4.3}$$

For finite r we have $\rho_i^r = 1 - r^{-1}\langle \xi^i, \alpha^\infty - \alpha^1 \rangle$, $i \in \mathcal{I}_b$.

Theorem 4.1 shows that little is lost when considering the ℓ_bth relaxation. Let J^*, $\widehat{J}^*$ denote the value functions for the infinite-horizon optimal control problems defined in (2.3), (3.4), respectively. We always have

$$\widehat{J}^*(x) \leq J^*(x), \qquad x \in \mathsf{X}.$$

We obtain a bound in the reverse direction in this section. The analysis is simplest when optimal trajectories are uniquely defined.

Assumption U.

(i) The linear program (3.9) that defines the effective state $\mathcal{X}^*(w)$ has a unique solution for each $w \in \widehat{\mathsf{W}}$.

(ii) For all $r \geq 1$ sufficiently large and each $T > 0$, $x \in \mathsf{X}$, the ℓ_bth workload-relaxation admits a solution $\widehat{\boldsymbol{q}}^{r*}$ that minimizes the total cost (2.6), and this solution is *unique*.

Consider for example the one-dimensional relaxation of the simple routing model shown in Figure 2. Assume that the cost is linear, so that $c(x) = \langle c, x\rangle$, with $c \in \mathbb{R}^3_+$. If $c_3 \geq c_2 > c_1$, then the above conditions hold. The greedy priority policy that prefers routing to buffer 1, whenever buffer 2 is nonempty, is the unique (pointwise) optimal solution.

Note that Assumption U(i) implies (ii) under Assumption M since in this case $\widehat{q}^*(t;x) = \mathcal{X}^*(\widehat{w}^*(t;x))$, and the pointwise minimal solution $\widehat{\boldsymbol{w}}^*$ is always uniquely defined when it exists.

Applying (3.5) and the form of the rate vector given in (4.1), we find that the constraints on the workload relaxation may be expressed as

$$\frac{d}{dt}\widehat{w}_i(t;x) \geq -\tfrac{1}{r}\delta_i, \qquad 1 \leq i \leq \ell_b,\ r \geq 1,\ t > 0\,,$$

where $\delta_i = \langle \xi^i, \alpha^\infty - \alpha^1\rangle$. Letting $\widehat{\boldsymbol{w}}^{1*}, \widehat{J}^{1*}$ denote the optimal trajectory and value function when $r = 1$, it follows that for any $r \geq 1$ the optimal solution is given by

$$\begin{aligned} \widehat{w}_i^*(t;x) &= \widehat{w}_i^{1*}(t/r;x), \qquad 1 \leq i \leq \ell_b,\ t > 0\,, \\ \widehat{J}^*(x) &= r\widehat{J}^{1*}(x), \qquad\qquad x \in \mathsf{X}\,. \end{aligned} \tag{4.4}$$

We define a policy for the unrelaxed model as follows. Applying Proposition 3.1 we are assured of the existence of a piecewise linear, optimal solution to the relaxed control problem, which we denote $[\widehat{q}^*(t;x), \widehat{\zeta}^*(t;x)]$. The allocation rate $\zeta(t;x)$ for the unrelaxed model is defined to be a function of $[\widehat{q}^*(t;x), \widehat{\zeta}^*(t;x), q(t;x)]$ for any initial condition x and any $t \geq 0$. Let $\mathcal{I}_c(x) = \{i : c(x) = \langle c^i, x\rangle\}$, and given the current states $y = q(t;x)$, $y^* = \widehat{q}^*(t;x)$, let $\zeta(t;x)$ be the optimizing value of the variable ζ in the linear program

$$\begin{aligned} &\min \quad \gamma \\ &\text{subject to} \quad \begin{aligned} \gamma &\geq \langle c^i, B\zeta\rangle, \quad i \in \mathcal{I}_c(y), \\ C\zeta &\leq \mathbf{1}, \\ \zeta &\geq \boldsymbol{\theta}, \\ (B\zeta + \alpha^r)_i &\geq 0 \quad \text{if } y_i = 0, \\ \langle \xi^i, (B\zeta + \alpha^r)\rangle &\leq \langle \xi^i, (B\widehat{\zeta}^* + \alpha^r)\rangle, \quad \text{whenever } i \leq \ell_b, \\ &\qquad\qquad\qquad\qquad\quad \text{and } \langle \xi^i, y\rangle = \langle \xi^i, y^*\rangle. \end{aligned} \end{aligned} \tag{4.5}$$

The last constraint ensures that $w_i(t;x) \leq \widehat{w}_i^*(t;x)$ for all $i \leq \ell_b$ and all t.

Assume that $q(t;x)$ is the resulting state trajectory using this policy for all t, and set

$$e^r(t;x) = q(t;x) - \widehat{q}^*(t;x),\ t > 0, \qquad \underline{T}_{r\circ}(x) = \min\{t : e^r(t;x) = \boldsymbol{\theta}\}.$$

The following result provides uniform bounds on $\underline{T}_{r\circ}$ and shows that this first hitting time is in fact a *coupling time*. It is possible to relax the uniqueness assumption in

Theorem 4.1, but one must redefine $\underline{T}_{r\circ}(x)$ as the first hitting time to *some* optimal $\widehat{q}^*(t;x)$. A proof is provided in Appendix A.

THEOREM 4.1. *Under Assumptions* H *and* U, *the following hold for the state trajectory* $\boldsymbol{q}$ *for any initial condition* $x \in \mathsf{X}$*:*

(i) $w(t;x) \le \widehat{w}^*(t;x)$, $t \ge 0$, *where the inequality is interpreted componentwise.*

(ii) *The time* $\underline{T}_{r\circ}$ *is uniformly bounded in* r*: For some* $b_0 < \infty$,

$$\underline{T}_{r\circ}(x) \le b_0 \|e^r(0+;x)\|\,, \qquad x \in \mathsf{X},\ r \ge 1.$$

(iii) $q(t;x) = \widehat{q}^*(t;x)$ *for all* $t \ge \underline{T}_{r\circ}(x)$.

(iv) *There is a constant* b_1 *such that*

$$\begin{aligned} J(x) := \int_0^\infty c(q(t;x)) &\le (1 + b_1/r)\widehat{J}^*(x) \\ &\le (1 + b_1/r)J^*(x)\,, \qquad x \in \mathsf{X},\ r \ge 1. \end{aligned}$$

(v) *Suppose that* $\widehat{\boldsymbol{q}}^*$ *is a pointwise optimal solution. Then*

$$c(q(t;x)) = \underline{c}^*(t;x), \qquad t \ge \underline{T}_{r\circ}(x),$$

where $\underline{c}^*$ *is given in* (2.9). □

4.2. Stochastic models. Although the workload-relaxation is in general a significant distortion of the original model, we have seen in Theorem 4.1 that this is negligible when the model is in heavy traffic. The workload constraints overwhelm all other constraints on the velocity vector field. In this section we establish similar solidarity for the stochastic model.

To obtain any such solidarity we must control modelling error, and we must understand when if ever a user can benefit from statistical information. Consider a $G/G/2$ queue, where the two servers are constrained so that only one can work at any given time-instance. The fluid model is given by the one-dimensional model

$$\frac{d}{dt}q(t;x) = -\mu_1\zeta_1(t;x) - \mu_2\zeta_2(t;x) + \alpha, \tag{4.6}$$

with the linear control constraint $\zeta_1 + \zeta_2 \le 1$. This can be viewed as an idealized two-armed bandit, where α is the rate at which a gambler is paying the casino, and $\mu_i\zeta_i$ is his rate of return on using the ith arm. The casino's reward at time t is a linear function of $q(t)$. If $\mu_1 = \mu_2 > \alpha$, then obviously any nonidling policy is optimal, from the gambler's point of view, for any monotone cost function.

For the stochastic model, however, the particular allocation chosen can have great impact since variability of service rates determines the steady-state queue length. For a priority policy in which server i is used exclusively, we obtain in steady-state an approximation of the form, for $\rho \sim 1$,

$$\mathsf{E}[Q(t)] = \tfrac{1}{2}\frac{\gamma^2}{1-\rho} + O(1).$$

The infinite-horizon optimal policy is precisely the priority policy that chooses the server with the smallest variability parameter γ^2.

This example is special because the optimal fluid policy is *not unique*. Typically, the optimal control problem for the fluid model may be solved uniquely since linear

programs generically have unique solutions. If this is the case, then we have fewer opportunities to successfully gamble.

In Theorem 4.3 we impose uniqueness through Assumption U, and an assumption that B is full-rank with $\ell \geq \ell_u$, so that $\boldsymbol{Z}$ is essentially determined by $\boldsymbol{Q}$. The latter assumption may be relaxed considerably by expanding the state space.

Take, for example, the routing model in which B is the 3×4 matrix given in (3.12). Consider the associated four-dimensional network model $\boldsymbol{Q}^{\mathrm{a}}$ on $\mathsf{X}:=\mathbb{R}^4_+$, in which the fourth component is the total-idleness at buffer 1, given by $Q^{\mathrm{a}}_4(t;x) = t - Z_1(t;x)$, $t \geq 0$. The associated matrix B^{a} is invertible, as seen by the explicit form

$$B^{\mathrm{a}} = \begin{bmatrix} -\mu_1 & 0 & \mu_3 & 0 \\ 0 & -\mu_2 & 0 & \mu_3 \\ 0 & 0 & -\mu_3 & -\mu_3 \\ -1 & 0 & 0 & 0 \end{bmatrix}, \qquad \alpha^{\mathrm{a}} = \begin{bmatrix} 0 \\ 0 \\ \alpha_3 \\ 1 \end{bmatrix}.$$

If the cost function on $\boldsymbol{Q}^{\mathrm{a}}$ is assumed linear, with $c_1 < c_2 < c_3$ and $c_4 > 0$, then Assumption U holds for the four-dimensional model.

For any network model one may augment the state space to include total-idleness, as well as total-allocation values. The cost may be similarly augmented to reflect the desire to maximize utilization of some resources, while minimizing utilization of others. The augmented model will satisfy assumptions (i)–(iii) of Theorem 4.3 for a very general class of network models and cost criteria.

How do we choose the allocation $\boldsymbol{Z}$ to maintain solidarity with an ideal fluid solution $[\widehat{\boldsymbol{q}}^*, \widehat{\boldsymbol{z}}^*]$? There are three issues that must be addressed:

(i) Suppose that for a given state x, a state $x^* \in \mathsf{X}$ is chosen as a target, with $\widehat{\Xi} x^* \in \widehat{\mathsf{W}}^+$. For the fluid model, even if the buffers are empty, an associated resource may be required to work at full capacity. This is not feasible for the discrete model: if a resource finds no work available, then it cannot work. This may be disastrous if the resource is a dynamic bottleneck since any idle time will rule out time-optimality.

(ii) To ensure feasibility we can impose small safety stocks, a well-motivated and standard technique in policy synthesis for manufacturing models [13, 20, 36]. We must ensure that these safety-stock levels can be maintained through a modification of the fluid-allocation without introducing idleness.

(iii) To ensure success we require bounds on the variability of the stochastic processes $(\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S})$ used in the stochastic model.

To simplify the statements of our assumptions we henceforth assume that the stochastic model (2.1) has the following specific form: For each $1 \leq i \leq \ell$ and $t \geq 0$,

$$Q^r_i(t;x) = x - \sum_{j=1}^{\ell_u} S_{ij}(Z_j(t)) + \sum_{j=1}^{\ell_u} R_{ij}(Z_j(t)) + A_i(t(1 - r^{-1}\delta^\alpha_i)),$$

where $\delta^\alpha_i := (\alpha^\infty_i - \alpha^1_i)/\alpha^\infty_i$ for each i, and the arrival-rate vectors α^1, α^∞ satisfy Assumption H. We assume that the stochastic model is consistent with the fluid model, in the sense that (2.4) holds with $\alpha = \alpha^\infty$. In particular, if $\alpha^\infty_i = 0$, then the process $\boldsymbol{A}_i$ is null. Assumption S formalizes our remaining probabilistic assumptions. Under this condition we can devise a policy that tracks any fluid idealization and simultaneously ensures that critical resources do not risk starvation.

Assumption S. For all $1 \leq i \leq \ell$ and $1 \leq k \leq \ell_u$, each of the stochastic processes $\{\boldsymbol{A}_i, \boldsymbol{R}_{ik}, \boldsymbol{S}_{ik},\ t \geq 0\}$ is either null or is an undelayed renewal process whose increment process possesses a moment generating function that is bounded in a neighborhood

of the origin. The stochastic processes $\{\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S}\}$ are adapted to a given filtration $\{\mathcal{H}_t : t \geq 0\}$.

We continue to assume that the allocation process $\boldsymbol{Z}$ satisfies the constraints (2.2), and we assume that any allocation $\boldsymbol{Z}$ is progressively measurable in the sense that

$$\sigma(Q^r(s), Z^r(s) : s \leq t) \subset \mathcal{H}_t, \qquad t \geq 0\,.$$

A relaxed model $[\widehat{\boldsymbol{Q}}, \widehat{\boldsymbol{Z}}]$ is defined in analogy with (3.2), in which the allocation constraint is relaxed to

$$\widehat{C}[\widehat{Z}(t;x) - \widehat{Z}(s;x)] \leq [t-s]\mathbf{1}\,, \qquad \widehat{C} := -\widehat{\Xi}^{\scriptscriptstyle T} B\,. \tag{4.7}$$

This is of course subject to the additional constraint that $\widehat{Q}(t;x)$ evolves in $\mathsf{X} := \mathbb{R}^{\ell}_{+}$. We assume that $\widehat{\boldsymbol{Z}}$ is of bounded variation, but unlike $\boldsymbol{Z}$, it is not subject to any statistical constraints.

For any feasible pair $[\widehat{\boldsymbol{Q}}, \widehat{\boldsymbol{Z}}]$ we define the *pseudodisturbance* $\boldsymbol{d}_0$ through the equation

$$\widehat{Q}(t;x) = x + B\widehat{Z}(t;x) + \alpha^{\scriptscriptstyle T} t + d_0(t)\,, \quad t \geq 0\,, \tag{4.8}$$

and we let $d(t) = \widehat{\Xi} d_0(t)$, $t \geq 0$. The associated workload process may be expressed in terms of $\boldsymbol{d}$ as follows: first define the idleness process by $\widehat{I}(t;x) := t\mathbf{1} - \widehat{C}\widehat{Z}(t;x)$, $t \geq 0$. This is vector-valued, and (4.7) implies that its components are nonnegative and nondecreasing. We then write

$$\widehat{W}(t;x) := \widehat{\Xi}\widehat{Q}(t;x) = -(\mathbf{1} - \boldsymbol{\rho}^r)t + \widehat{I}(t;x) + d(t)\,.$$

We consider below the optimal solution $[\widehat{\boldsymbol{q}}^*, \widehat{\boldsymbol{z}}^*]$ to the ℓ_bth fluid-model relaxation (3.17) with respect to the (random) pseudodisturbance $\boldsymbol{d}_0$. This of course depends upon $\widehat{\boldsymbol{Z}}$. These processes are used for comparison to obtain performance bounds. For example, under the conditions of Theorem 3.10 we obviously have the absolute lower bound, $\widehat{W}(t;x) \geq \widehat{w}^*(t;x) := \widehat{\Xi}\widehat{q}^*(t;x)$, $t \geq 0$. Perhaps surprisingly, the policies considered below almost achieve this lower bound, uniformly for the time-horizons considered.

4.3. Sensitivity and optimality. In the development that follows we construct a trajectory $[\boldsymbol{Q}^{r\circ}, \boldsymbol{Z}^{r\circ}]$ by attempting to mimic the flow of the optimal fluid trajectory. We begin with a list of desirable properties that $[\boldsymbol{Q}^{r\circ}, \boldsymbol{Z}^{r\circ}]$ should satisfy. In Theorem 4.3 we show that these general properties imply a strong form of approximate optimality.

Following this we provide a constructive procedure for policy synthesis to attain these properties. This requires some assumptions on the model that we illustrate first in one dimension in section 4.4 and then for general models in section 4.5.

The following result is central to all of the remaining analysis in this section and is essentially our only motivation for Assumption S. A proof may be found in Appendix B.

If $(\boldsymbol{X}, \boldsymbol{Y}) = \{(X_r, Y_r) : r \geq 1\}$ is a sequence of random variables, we write $\boldsymbol{X} \leq O(\boldsymbol{Y})$ if $X_r \leq b_\bullet Y_r$ for some fixed deterministic constant $b_\bullet$, $t \geq 0$, and we write $\boldsymbol{X} \leq o(\boldsymbol{Y})$ if $\lim_{r\to\infty} X_r/Y_r = 0$ a.s. The constant $b_\bullet$ is assumed fixed throughout.

PROPOSITION 4.2. *Let $\boldsymbol{X}$ be a real-valued i.i.d. process with common mean $m = \mathsf{E}[X_i] > 0$ and moment generating function bounded in a neighborhood of the origin.*

There exists $I_0 > \infty, \delta_0 > 0, B_0 < \infty$ such that for all $0 < \delta \le \delta_0$, we have the following:

(i) *For any $N \ge 1$, writing $S_T := \sum_{i=1}^T X_i$,*

$$\mathsf{P}\Big\{ \inf_{T\ge 1} (S_T - (m-\delta)T) \le -N \Big\} \le B_0 \exp(-I_0 \delta^2 N).$$

(ii) *Let $\boldsymbol{Y}$ be the undelayed renewal process with increment process $\boldsymbol{X}$. There exists $B_1 < \infty$ such that for $k_0 \ge 2$,*

$$\lim_{r\to\infty} \sup_{0\le s\le t\le r^{k_0}} \left(\frac{Y(t) - Y(s) - (t-s)(m^{-1}+\delta)}{\log(r)} \right) \le B_1 k_0 \delta^{-2} \qquad a.s. \qquad \square$$

Throughout this section we let $[\widehat{\boldsymbol{Q}}, \widehat{\boldsymbol{Z}}]$ denote any feasible trajectory for the relaxed stochastic model. It is defined on the same sample space through identical generating processes $(\boldsymbol{A}, \boldsymbol{R}, \boldsymbol{S})$. Our goal is to construct a policy for (2.1) that uniformly outperforms any such feasible trajectory on a time-window of the form $[\underline{T}_{r^\bullet}, T_{r^\bullet}]$, where

$$\underline{T}_{r^\bullet} = b_0[\|x - \mathcal{P}^*(x)\| + \log(r)], \qquad T_{r^\bullet} = r^3, \tag{4.9}$$

with $b_0 < \infty$ sufficiently large.

The following two uniform bounds will be established for the policies constructed below, and for the optimal policy. Property P1 appears to be desirable for any network and any cost function on X. However, Property P2 is desirable only when the effective cost is monotone.

Recall that $\widehat{\boldsymbol{w}}^*$ denotes the minimal solution to the workload relaxation (3.17), where the disturbance $\boldsymbol{d}_0$ is defined in (4.8).

Property P1 *(relative optimization).* For any $x \in \mathsf{X}$, $r \ge 1$,

$$\|\widehat{Q}(t;x) - \mathcal{P}^*(\widehat{Q}(t;x))\| \quad \le \quad O(\log(r)) + o(1), \qquad \underline{T}_{r^\bullet} \le t \le T_{r^\bullet}, \quad \text{a.s.}$$

Property P2 *(relative minimal workload).* For any $x \in \mathsf{X}$, $r \ge 1$,

$$\widehat{W}(t;x) - \widehat{w}^*(t;x) \quad \le \quad O(\log(r)) + o(1), \qquad \underline{T}_{r^\bullet} \le t \le T_{r^\bullet}, \quad \text{a.s.}$$

THEOREM 4.3. *Suppose that $\ell \ge \ell_u$ in* (2.1) *and the following additional assumptions hold:*

(i) *Assumption* M *holds with $n = \ell_b$, and the effective cost $\bar{c}$ for the ℓ_bth workload-relaxation is monotone.*

(ii) *Assumptions* H, S, *and* U *hold, and the matrix B has rank ℓ_u.*

(iii) *The pair $[\boldsymbol{Q}^{r\circ}, \boldsymbol{Z}^{r\circ}]$ satisfies conditons* P1 *and* P2.

Then, as $r \to \infty$,

$$\sup_{[\widehat{Q}^r, \widehat{Z}^r]} \left(\sup_{0\le T\le T_{r^\bullet}} \left(\frac{1}{T} \int_0^T [c(Q^{r\circ}(t;x)) - c(\widehat{Q}^r(t;x))]\, dt \right) \right) \le O(\log(r)) + o(1).$$

Proof. Given the allocation $\boldsymbol{Z}^{r\circ}$, and any other allocation $\widehat{\boldsymbol{Z}}^r$ satisfying (4.7), we can construct respective pseudodisturbances $\boldsymbol{d}_0^{r\circ}$, $\boldsymbol{d}_0^r$ via (4.8).

The proof of Theorem 4.3 is based upon a comparison of the respective optimal solutions to the ℓ_bth fluid-model relaxation (3.17), denoted $[\widehat{\boldsymbol{q}}^{r\circ^*}, \widehat{\boldsymbol{z}}^{r\circ^*}]$ and $[\widehat{\boldsymbol{q}}^{r^*}\, \widehat{\boldsymbol{z}}^{r^*}]$.

This comparison is made possible via the following "coupling property": For any $x \in \mathsf{X}$, and all small $\delta > 0$,

(4.10)
$$\|d_0^{r\circ}(t) - d_0^r(t)\| \le \delta \|Z^{r\circ}(t) - \widehat{Z}^r(t)\| + O(\delta^{-2}\log(r)) + o(1), \quad 0 \le t \le T_{r\bullet}, \text{ a.s.}$$

This bound follows directly from Proposition 4.2 and Assumption S.

Rather than a general allocation, for each r we consider a "near-optimal" solution $[\widehat{\boldsymbol{Q}}^r, \widehat{\boldsymbol{Z}}^r]$ defined as follows. We fix $0 < T_\bullet \le T_{r\bullet}$, and we assume that for any other solution $[\widehat{\boldsymbol{Q}}, \widehat{\boldsymbol{Z}}]$,

$$\frac{1}{T_\bullet}\int_0^{T_\bullet} c(\widehat{Q}^r(t;x))\,dt \le \frac{1}{T_\bullet}\int_0^{T_\bullet} c(\widehat{Q}(t;x))\,dt + O(\log(r)).$$

Recall that in this notation $O(\log(r)) \le b_\bullet \log(r)$ with $b_\bullet$ fixed throughout, so that the above bound is uniform in $\{\widehat{\boldsymbol{Q}}\}$. It is shown in Proposition B.2 in Appendix B that a solution can be chosen so that $[\widehat{\boldsymbol{Q}}^r, \widehat{\boldsymbol{Z}}^r]$ satisfies conditions P1 and P2.

Combining conditions P1 and P2 for $[\widehat{\boldsymbol{Q}}^{r\circ}, \widehat{\boldsymbol{Z}}^{r\circ}]$ and $[\widehat{\boldsymbol{Q}}^r, \widehat{\boldsymbol{Z}}^r]$ gives

$$\begin{aligned} \|Q^{r\circ}(t;x) - \widehat{q}^{r\circ^*}(t;x)\| &\le O(\log(r)) + o(1), \\ \|\widehat{Q}^r(t;x) - \widehat{q}^{r^*}(t;x)\| &\le O(\log(r)) + o(1) \quad \text{a.s.} \end{aligned} \tag{4.11}$$

Theorem 3.10 and Assumption U give

$$\|\widehat{q}^{r\circ^*}(t;x) - \widehat{q}^{r^*}(t;x)\| \le O(\|\boldsymbol{d}_0^{r\circ} - \boldsymbol{d}_0^r\|_\infty^t)\,. \tag{4.12}$$

Combining (4.11), (4.12) with (4.10) and the rank condition on B then gives

$$\begin{aligned} \|Z^{r\circ}(t;x) - \widehat{Z}^r(t;x)\| &\le O(\|Q^{r\circ}(t;x) - \widehat{Q}^r(t;x)\|) + O(\|d_0^{r\circ}(t) - d_0^r(t)\|) \\ &\le O(\|\boldsymbol{d}_0^{r\circ} - \boldsymbol{d}_0^r\|_\infty^t) + O(\log(r)) + o(1) \\ &\le \tfrac{1}{2}\|\boldsymbol{Z}^{r\circ} - \widehat{\boldsymbol{Z}}^r\|_\infty^t + O(\log(r)) + o(1) \\ &\le \tfrac{1}{2}\|\boldsymbol{Z}^{r\circ} - \widehat{\boldsymbol{Z}}^r\|_\infty^{T_\bullet} + O(\log(r)) + o(1) \end{aligned}$$

uniformly for $0 \le t \le T_\bullet$. It follows that $\|\boldsymbol{Z}^{r\circ} - \widehat{\boldsymbol{Z}}^r\|_\infty^{T_\bullet} = O(\log(r))$, and this easily implies the result. ∎

The proof of Theorem 4.3 hinges on uniqueness of $[\widehat{\boldsymbol{q}}^*, \widehat{\boldsymbol{z}}^*]$ for a given disturbance $\boldsymbol{d}$. Without uniqueness one can attempt to search over optimal fluid allocations whose associated translation $\boldsymbol{Z}^{r\circ}$ has minimal cost, as in the "two-armed bandit" (4.6). The monotonicity assumption is also critical and, as we have seen, often fails in complex network models when the workload dimension is taken larger than one. We return to this issue in section 4.5.

How then can we design a policy that satisfies conditions P1 and P2? We present here an approach based on a "discrete-review" structure, following [27, 33, 1]. Let $T_r > 0$, $\bar{x}^r \in \mathsf{X}$ denote, respectively, a planning horizon and safety-stock levels for the rth network. We take the explicit form

$$T_r = K_0 \log(r), \quad \bar{x}_i^r = K_1 \log(r)\bar{x}_i, \qquad r \ge 1,\ 1 \le i \le \ell, \tag{4.13}$$

where K_j, $j = 0, 1$, and $\bar{x}_i$, $i = 0, \dots, \ell$, are strictly positive constants. The ratio $\Delta_0 := K_1/K_0$ determines the likelihood of starvation.

In practice, taking a fixed safety-stock level is neither desirable nor practical—a fixed value $\bar{x}^r$ is chosen for convenience. A more desirable choice may be a "moving target," such as

$$\bar{x}^r = K_1 \log(\|x\| + 1)\bar{x}\,,$$

where x is the current state of the network. It is also not necessary to assume strict positivity of *every* element of $\bar{x}$: it is only necessary to assume that every pooled-resource, for $i \le \ell_r$, can work at capacity at time t if $q(t;x) \ge \bar{x}$. The results below can be extended to cover such generalizations.

We choose the allocation rates exactly as in the fluid-translation (4.5), except that we introduce safety-stock constraints that may be viewed as a shift of the origin. Let $\bar{w}^r = \widehat{\Xi}\bar{x}^r$, $r \ge 1$, and denote by $[w]^r_+$ the projection of w, in the standard ℓ_2 norm, onto the set $\widehat{\mathsf{W}}^r_w := \{\widehat{w} + \bar{w}^r : \widehat{w} \in \widehat{\mathsf{W}},\ \widehat{w} + \bar{w}^r \ge w\}$. This is equal to the pointwise minimal element of this set under Assumption M.

Fix $\delta_0 > 0$, and consider the following linear program:

$$\begin{aligned}
&\min \quad \gamma \\
&\text{subject to} \quad
\begin{aligned}
\gamma &\ge \langle c^i, y\rangle, \qquad 1 \le i \le \ell_c, \\
y &= x + Bz + \alpha^r T_r, \\
y_i &\ge (x_i + \delta_0 \bar{x}^r_i) \wedge \bar{x}^r_i, \qquad 1 \le i \le \ell, \\
\widehat{\Xi} y &\le [\widehat{\Xi} x - (\mathbf{1} - \boldsymbol{\rho})T_r]^r_+, \\
Cz &\le T_r \mathbf{1}, \\
z &\ge \boldsymbol{\theta}.
\end{aligned}
\end{aligned} \tag{4.14}$$

We assumed in Assumption M that the workload vectors satisfy $\{\xi^i : 1 \le i \le \ell_r\} \subset \mathbb{R}^\ell_+$. Under this condition, an application of Lemma A.1 implies that $\delta_0 > 0$ may be chosen sufficiently small so that this linear program is feasible for any $r \ge 1$.

Given a solution z^* to (4.14) we then set $\zeta^{r\circ} := z^*/T_r$, and $Z^{r\circ}(t;x) = t\zeta^{r\circ}$, $0 \le t \le T_r$. In practice, additional constraints on $\boldsymbol{Z}$ will force an approximation, but this will be negligible for large r. This can then be repeated for each interval $[kT_r, (k+1)T_r]$ for $k \ge 0$ to obtain $(Q^{r\circ}(t), Z^{r\circ}(t))$ for $t \ge 0$. On any time-interval $[kT_r, (k+1)T_r]$ the buffers behave like decoupled $G/G/1$ queues.

In addition to feasibility of the linear program (4.14), the definition of $\boldsymbol{Z}^{r\circ}$ requires *feasibility of the resulting state trajectory* so that $Q^{r\circ}(t;x) \in \mathsf{X}$ for all $t \ge 0$. Positivity of $\boldsymbol{Q}$ and approximate optimality follow from the large deviation bound in Proposition 4.2. We demonstrate this, and provide conditions under which P1–P2 also hold in the following two subsections.

4.4. One-dimensional workload. In this case there is a single set of pooled bottleneck-resources to be considered, and we set $\xi = \xi^1$, $\mathcal{R}^\circ = \mathcal{R}^\circ_1$. This case is special since the effective cost is always monotone, and the relaxed control problem admits a simple, pointwise optimal solution (see Proposition 3.2).

Recall that b_0 determines the times $\underline{T}_{r\bullet}$, and $\Delta_0 = K_1/K_0$ (see (4.13)).

THEOREM 4.4. *Suppose that the following assumptions hold:*

(i) *Assumption* M *holds with* $n = \ell_b = 1$.

(ii) *Assumptions* H, S, *and* U *hold.*

Then for all $\Delta_0 > 0$ *sufficiently large, there exists* $b_0 < \infty$ *such that Properties* P1 *and* P2 *hold for the policy defined via the linear program* (4.14).

Proof. In the one-dimensional case, provided $\langle \xi, x\rangle \ge 2\bar{w}^r := 2\langle \xi, \bar{x}^r\rangle$, the linear program (4.14) to obtain $\zeta^{r\circ}$ on $[0, T_r]$ reduces to

$$
\begin{aligned}
&\min \quad \gamma \\
&\text{subject to} \qquad
\begin{aligned}
\gamma &\ge \langle c^i, y\rangle, \qquad 1 \le i \le \ell_c, \\
y &= x + Bz + \alpha^r T_r, \\
y_i &\ge (x_i + \delta_0 \bar{x}_i^r) \wedge \bar{x}_i^r, \qquad 1 \le i \le \ell, \\
Cz &\le T_r \mathbf{1}, \\
z &\ge \boldsymbol{\theta}, \\
\langle \xi, Bz\rangle &= -T_r.
\end{aligned}
\end{aligned} \tag{4.15}
$$

Given a solution z^* to (4.15) we then set $\zeta^{r\circ} := T_r^{-1} z^*$. Let $y^{r\circ}$ denote the associated optimal state, starting from the initial condition x:

$$
y^{r\circ} = x + (B\zeta^{r\circ} + \alpha^r) T_r.
$$

As in the deterministic setting, we consider the error process

$$
E^{r\circ}(t; x) := Q^{r\circ}(t; x) - \mathcal{P}^*(Q^{r\circ}(t; x)). \tag{4.16}
$$

One can show as in Theorem 4.1 that for some fixed $\delta > 0$ independent of r, whenever $\|E^{r\circ}(0)\| = \|x - \mathcal{P}^*(x)\| \ge 2\|\bar{x}^r\|$, and $T^*(x) \ge T^*(\bar{x}^r) + T_r$,

$$
\begin{aligned}
\|y^{r\circ} - \mathcal{P}^*(y^{r\circ})\| &\le \|E^{r\circ}(0)\| - \delta T_r, \\
\mathsf{E}[\|E^{r\circ}((k+1)T_r)\| \mid \mathcal{H}_{kT_r}] &\le \|E^{r\circ}(kT_r)\| - \delta T_r.
\end{aligned} \tag{4.17}
$$

We will show that this implies P1, and that the constraint $\langle \xi, Bz\rangle = -T_r$ in (4.15) implies P2.

For $k \ge 1$ let $G_{r,k}$ denote the union of "good events,"

$$
\begin{aligned}
G_{r,k} = \Big\{ W^{r\circ}(kT_r) \le 2\bar{w}^r \Big\} \\
\bigcup \Big\{ \tfrac{1}{2}\delta_0 \bar{x}^r \le E^{r\circ}(t; x) \le \tfrac{3}{2}\bar{x}^r, \quad kT_r \le t \le (k+1)T_r, \\
\text{and} \quad \langle \xi, B[Z^{r\circ}((k+1)T_r) - Z^{r\circ}(kT_r)]\rangle = -T_r \Big\},
\end{aligned}
$$

and define for any r

$$
G_r = \bigcup_{\underline{T}_{r\bullet} \le k \le T_{r\bullet}/T_r} G_{r,k}.
$$

For sufficiently large b_0 and constants $B_2 < \infty$, $I_2 > 0$, Proposition 4.2 implies the bound $\mathsf{P}\{G_r^c\} \le r^3 B_2 \exp(-I_2 \Delta_0 \log(r))$, $r \ge 1$. For $\Delta_0 \ge 5 I_2^{-1}$ this is bounded by $B_2 r^{-2}$, and it then follows that

$$
\sum_{r=1}^{\infty} \mathsf{P}\{G_r^c\} < \infty.
$$

From the Borel–Cantelli lemma we can conclude that, with probability one, each state-allocation trajectory $[\boldsymbol{Q}^{r\circ}, \boldsymbol{Z}^{r\circ}]$ eventually satisfies G_r for large enough r. It follows that P1 and P2 also hold and that $\boldsymbol{Q}^{r\circ}$ evolves in X for all large r. ∎

4.5. Higher dimensions. For the general workload dimension, even if the fluid model admits a pointwise optimal solution, one cannot hope to obtain the strong sample-path optimality established in Theorem 4.4 for the stochastic model. Consider the workload processes

$$W^r(t;x) = \widehat{\Xi} Q^r(t;x), \qquad W^{r\circ}(t;x) = \widehat{\Xi} Q^{r\circ}(t;x).$$

In heavy traffic, any greedy policy would attempt to drive $W^r(t;x)$ into the set $\widehat{\mathsf{W}}^+$. This is illustrated in Figure 10. Initially, the trajectory $W^{r\circ}$ mimics the behavior of the fluid model. It is probable that a sample path will then drift throughout the region $\widehat{\mathsf{W}}^+$ if $\rho \sim 1$. For the sample path shown, initially $\bar{c}(W^r(t;x))$ is much greater than $\bar{c}(W^{r\circ}(t;x))$, but then the opposite is true following the upward drift of $W_2^{r\circ}$ shown in the figure.

This counterexample depends upon the specific geometry shown. Although a pointwise optimal solution exists for the fluid model, the effective cost $\bar{c}$ is not monotone. Consequently, property P2 is not desirable—the optimal workload trajectory $\widehat{\boldsymbol{w}}^*$ for the fluid model is not pointwise minimal.

Assuming that the effective cost is monotone, the arguments used in the proofs of Theorem 3.10 and Theorem 4.4 may be applied to establish the following consequences.

THEOREM 4.5. *Suppose that the following assumptions hold:*

(i) *Assumption* M *holds with* $n = \ell_b$*, and the effective cost* $\bar{c}$ *for the* ℓ_b*th workload-relaxation is monotone.*

(ii) *Assumptions* H, S, *and* U *hold.*

Then for all $\Delta_0 > 0$ *sufficiently large, there exists* $b_0 < \infty$ *such that Properties* P1 *and* P2 *hold for the policy defined via the linear program* (4.14).

Proof. The proof of condition P1, and positivity of the state trajectory $\boldsymbol{Q}^{r\circ}$, is identical to the proof in the one-dimensional case since (4.17) continues to hold for the associated error process given in (4.16).

To establish condition P2 we first note that the allocation rate $\zeta_k^{r\circ}$ on $[kT_r, (k+1)T_r]$ is designed to be *almost optimal* for a disturbance-free model on $[kT_r, (k+1)T_r]$,

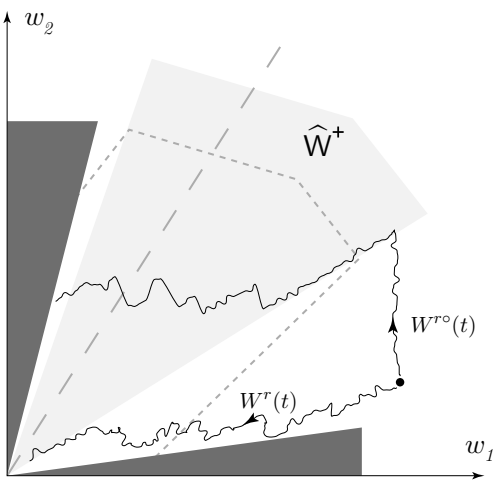

FIG. 10. *The figure shows two trajectories for the stochastic workloads* $W^r(t)$ *and* $W^{r\circ}(t)$*,* $t \geq 0$.

in the sense that

$$W^{r\circ}(kT_r;x) + \widehat{\Xi}[B\zeta_k^{r\circ}T_r + \alpha^r T_r] \le [W^{r\circ}(kT_r;x) - (\mathbf{1}-\boldsymbol{\rho}^r)T_r]_+^r \,. \tag{4.18}$$

Using (4.18) we verify the following restricted form of condition P2 by induction:

$$W^{r\circ}(kT_r;x) \le \widehat{w}^{r\circ^*}(kT_r;x) + 2\bar{w}^r \,, \qquad k \ge 0. \tag{4.19}$$

In fact, this bound combined with Proposition 4.2(ii) implies that P2 holds.

The inequality (4.19) is obvious for $k = 0$. Assuming it is valid for a given $k \ge 1$, denote $D(k+1) := d^{r\circ}((k+1)T_r) - d^{r\circ}(kT_r)$, and consider the following bounds:

$$\begin{aligned}
W^{r\circ}((k+1)T_r;x) &\le \big[W^{r\circ}(kT_r;x) - (\mathbf{1}-\boldsymbol{\rho}^r)T_r\big]_+^r + D(k+1) \\
&\qquad\qquad \text{by (4.18)} \\
&\le \big[\widehat{w}^{r\circ^*}(kT_r;x) + 2\bar{w}^r - (\mathbf{1}-\boldsymbol{\rho}^r)T_r\big]_+^r + D(k+1) \\
&\qquad\qquad \text{by induction} \\
&= \widehat{w}^{r\circ^*}(kT_r;x) + 2\bar{w}^r - (\mathbf{1}-\boldsymbol{\rho}^r)T_r + D(k+1) \\
&\qquad\qquad \text{for } r \text{ sufficiently large} \\
&\le \big[\widehat{w}^{r\circ^*}(kT_r;x) - (\mathbf{1}-\boldsymbol{\rho}^r)T_r + D(k+1)\big]_+ + 2\bar{w}^r \\
&\le \widehat{w}^{r\circ^*}((k+1)T_r;x) + 2\bar{w}^r \\
&\qquad\qquad \text{by Lemma 3.9.}
\end{aligned}$$

The equality in the third line follows since $\bar{w}^r$ is an interior point of $\widehat{\mathsf{W}}$, and $\boldsymbol{\rho}^r \to \mathbf{1}$ as $r \to \infty$. This completes the verification of the induction hypothesis. □

5. Conclusions. The results of this paper lead to practical control solutions for large networks. One must consider an appropriate relaxation for the fluid model, define idealized target states through this idealization, and use safety stocks and some regulation policy to attempt to meet these target values.

Consider for example the network illustrated in Figure 1. For certain parameters a two-dimensional workload-relaxation is justifiable, and a policy that is nearly optimal in heavy traffic can be computed by hand once the effective cost is found. When the cost c is linear and $\mathsf{X} = \mathbb{R}_+^\ell$, the effective cost $\bar{c}(x)$ is the value of the linear program

$$\begin{aligned}
&\min \quad \langle c, x\rangle \\
&\text{subject to} \quad \xi_i^T x = w_i, \quad i = 1,2, \\
&\qquad\qquad\quad x \ge \boldsymbol{\theta}.
\end{aligned} \tag{5.1}$$

It is amazing that optimal policy synthesis can be conceptualized so easily for such a complex model!

In practice, it may be difficult to summarize *every* goal in a single cost function. Optimization may be viewed as a method of generating a family of candidate *good policies*. One can then choose among these or formulate generalizations to satisfy various goals.

A complex network model such as that shown in Figure 1 illustrates the importance of taking a flexible viewpoint in modelling, and in control design. By restricting to a basic feasible solution of (5.1), one may assume that an optimal trajectory $\widehat{q}^*(t;x)$ is null, with the exception of at most two positive components when the cost function c is linear. This is born out in numerical experiments conducted in [14]. After a short

transient period, it is observed that in all but two of the buffers, all of the inventory vanishes in the optimal fluid state trajectory. Similar behavior is commonly seen in the heavy-traffic networks literature (see, e.g., [29, 25, 1]).

In practice, such behavior is rarely feasible because buffers are finite. One can add a state space constraint to both models: for an $\ell_s \times \ell$ *constraint matrix* C_s,

$$C_s Q(t;x) \le \mathbf{1}, \quad Q(t;x) \ge \boldsymbol{\theta}, \qquad t \ge 0. \tag{5.2}$$

The state space is then redefined via $\mathsf{X} = \{x \in \mathbb{R}^\ell : x \ge \boldsymbol{\theta},\ C_s x \le \mathbf{1}\}$, and in this case the set $\widehat{\mathsf{W}}$ given in (3.6) is no longer a simple positive cone. These additional constraints increase the complexity of optimal state trajectories so that work is distributed across a greater number of buffers. Alternatively, if a strictly convex cost function is used, rather than a linear one, then more reasonable optimal trajectories will be obtained.

Another question concerns uncertainty. In telecommunications applications one may know little about the arrival rates to the system, and in a manufacturing application *demand* may be uncertain. One approach is to define a set of *generalized Klimov indices*, as in Proposition 12 of [36]. Alternatively, given prior information regarding arrival rates, one can expand the definition of V. Suppose that A is a polyhedron that defines possible arrival rates. The corresponding worst-case emptying time is given by

$$\overline{T}^*(x) = \max_{\alpha \in \mathsf{A}} \max_{1 \le i \le \ell_r} \frac{\langle \xi^i, x \rangle}{1 - \langle \xi^i, \alpha \rangle}.$$

It is then straightforward to design efficient policies for the fluid model that drain the system before this time without knowledge of the exact value of α. Other approaches have been considered recently in [31, 40, 19].

It has been taken for granted in this paper that activities and buffers far outnumber resources. However, in communication applications, particularly in wireless models, one frequently finds that the set of possible allocation rates is a highly complex convex set (see, e.g., [41, 44]). In particular, it may not be a polyhedron. One interpretation is that in wireless models there are an infinite number of resources through time-division, frequency selection, multiple paths, or choices in coding schemes. Extensions of the methods developed here may be possible provided the rate set V is suitably smooth, and in this case a one-dimensional relaxation is suggested.

There are many questions left unanswered.

(i) Can one formulate a version of Theorem 4.5 when the fluid model admits pointwise optimal solutions, yet the effective cost $\bar{c}$ is not monotone? This question is interesting even in the case of a single bottleneck since sample-path optimality does not hold if ξ^1 has any negative components (see [7]).

(ii) What if a pointwise optimal allocation does not exist for the ℓ_bth workload-relaxation? Can one obtain a near-optimal policy in this case (in the infinite-horizon sense (2.3))?

(iii) The policies described in this paper are based on state-feedback, using a workload-based model. It is expected that RBM models will play a role in the determination of optimality in the mean and in a finer performance analysis.

(iv) Can efficient recursive algorithms, based on workload dimension, be constructed for policy synthesis on a fluid scale?

(v) Where are the sources of highest sensitivity in control design?

(vi) Do the results of this paper lead to improved methods for performance approximation via simulation, or through calculation, by exploiting the simplicity of the network model following state space collapse?

(vii) Finally, extensions of these algorithms have been formulated for sequencing and routing in the face of breakdowns or preventative maintenance. We are eager to see how these methods actually work in practice.

Topics (i)–(v) are considered in what follows [7, 28], but the story is far from complete.

Appendix A. Workload relaxations. The proof of Theorem 4.1 is based on the following lemma, which shows that, relative to the system load, exchangeable states for the ℓ_bth workload-relaxation are almost exchangeable for the original fluid model when r is large.

LEMMA A.1. *Suppose that Assumption* H *holds. There exists $b_0 < \infty$ such that for any $x, y \in \mathsf{X}$, and any $r \geq 1$, the time to reach y from x is uniformly bounded,*

$$T^*(x,y) \leq b_0 \|x - y\| \quad \textit{whenever} \quad \widehat{\Xi}(y - x) \geq \boldsymbol{\theta}.$$

Proof. If $\langle \xi^i, y - x \rangle \geq 0$ for $1 \leq i \leq \ell_b$, then it follows from the definition of T^* that

$$\begin{aligned} T^*(x,y) &= \max_{i \geq 1} \frac{\langle \xi^i, x - y \rangle}{1 - \langle \xi^i, \alpha^r \rangle} \\ &= \max_{i > \ell_b} \frac{\langle \xi^i, x - y \rangle}{1 - \langle \xi^i, \alpha^r \rangle}, \qquad 1 \leq r < \infty. \end{aligned}$$

The right-hand side is bounded in r by construction of α^r and the definition of ℓ_b. It also scales linearly on scaling $(x - y)$. This gives the required bound. ∎

Proof of Theorem 4.1. Fix $0 < t < \underline{T}_{r\circ}(x)$, and define

$$\widehat{v}^{\perp} = -\beta \frac{e^r(t;x)}{\|e^r(t;x)\|}.$$

The constant $\beta > 0$ is chosen so that $\widehat{v}^{\perp}$ is a boundary point of V_r. We have the explicit formula $\beta^{-1} = \frac{T^*(x^1,x^2)}{\|x^2 - x^1\|}$, with $x^1 = q(t;x)$, $x^2 = \widehat{q}^*(t;x)$.

We have already remarked that the constraints ensure that (i) holds so that $w_i(t;x) \leq \widehat{w}_i^*(t;x)$ for all $t \geq 0$, and $1 \leq i \leq \ell_b$. It follows that $\widehat{\Xi}\widehat{v}^{\perp} \geq \boldsymbol{\theta}$, and Lemma A.1 implies directly that $\beta = \beta(r)$ is uniformly bounded from below in r. Applying this and Assumption U(i), we conclude that there is some fixed $\Delta > 0$, independent of $x \in \mathsf{X}$ and $r \geq 1$, such that for all $0 \leq t < \underline{T}_{r\circ}(x)$ and sufficiently small $s > 0$,

$$c(q(t;x) + s\widehat{v}^{\perp}) - c(q(t;x)) \leq -\Delta s. \tag{A.1}$$

Now let

$$v = \widehat{v}^* + \Big(1 - \tfrac{1}{2}\frac{r_0}{r}\Big)\widehat{v}^{\perp}, \tag{A.2}$$

where $\widehat{v}^* = \frac{d}{dt}\widehat{q}^*(t;x)$ and r_0 is a constant. We show that this is in V_r for any $r \geq r_0$ provided r_0 is sufficiently large. For $1 \leq i \leq \ell_b$ we have $\langle \xi^i, \widehat{v}^{\perp} \rangle \geq 0$, and hence for $r \geq r_0$,

$$\langle \xi^i, v \rangle := \langle \xi^i, \widehat{v}^* + (1 - r_0/(2r))\widehat{v}^{\perp} \rangle \geq \langle \xi^i, \widehat{v}^* \rangle \geq -(1 - \rho_i^r).$$

For $i > \ell_b$ we can reason as follows: The identity (4.4) implies that $\|\frac{d}{dt}\widehat{w}^*(t)\| \le K_0/r$ for some $K_0 < \infty$ and all $t > 0$. Since $\mathcal{X}^*$ is continuous, we must have a similar bound for $\widehat{\boldsymbol{q}}^*$, so that $\|\widehat{v}^*\| \le K_1/r$ for some finite K_1. Then, for $i > \ell_b$ and $r \ge r_0$,

$$\begin{aligned}\langle \xi^i, v\rangle &\ge \langle \xi^i, \widehat{v}^*\rangle + \tfrac{1}{2}\frac{r_0}{r}(1-\rho_i^r) - (1-\rho_i^r)\\ &\ge \frac{1}{r}(\tfrac{1}{2}r_0(1-\rho_i^r) - K_1\|\xi^i\|) - (1-\rho_i^r).\end{aligned}$$

Hence, to ensure feasibility of v, it is enough to choose $r_0 > 2K_1\|\xi^i\|(1-\rho_i^\infty)^{-1}$ for all $i > \ell_b$.

Using (A.1), (A.2), and the minimality of $\langle \nabla c, \frac{d}{dt}q\rangle$, we obtain the bound, for any $0 < t < \underline{T}_{r\circ}$, $r \ge r_0$,

$$\frac{d}{dt}(c(q(t;x)) - c(\widehat{q}^*(t;x))) \le -\left(1 - \tfrac{1}{2}\frac{r_0}{r}\right)\Delta \le -\tfrac{1}{2}\Delta.$$

Let $g(t) = c(q(t;x)) - c(\widehat{q}^*(t;x))$, $t \ge 0$. This function is piecewise linear on $(0,\infty)$ and satisfies $g(0+) = c(x) - c(\mathcal{P}^*(x))$, where $\mathcal{P}^*$ is defined in (3.10). The previous bound then gives

$$g(t) \le g(0+) - \tfrac{1}{2}\Delta t, \qquad 0 < t < \underline{T}_{r\circ},$$

and since g is nonnegative, $g(t) = 0$ for $t \ge 2g(0+)/\Delta$. Assumption U(ii) then implies that $q(t;x) = \widehat{q}^*(t;x)$ for such t, and hence

$$\underline{T}_{r\circ}(x) < \frac{2}{\Delta}g(0+) = \frac{2}{\Delta}(c(x) - c(\mathcal{P}^*(x))).$$

This proves (ii) and (iii) since c is a norm, and results (iv) and (v) follow immediately. □

Appendix B. Stochastic models.

Proof of Proposition 4.2. In part (i) we are asking, *When can the graph* (T, S_T) *of the partial sums of* X_i *hit the line* $l(T) = (m-\delta)T - N$ *for some* $T \ge 0$*?* Hence, the bound in (i) follows easily from Cramer's theorem [12].

For (ii) we define, for any $i \ge 1$, the event

$$\mathcal{E}_i := \{Y(S_i + T) - Y(S_i) - m^{-1}T \ge \delta T + N \quad \text{some } T \ge 0\}.$$

Using the fact that $S_i := \sum_{j=1}^i X_j$, $i \ge 1$, is equal to the time of the ith jump of $\boldsymbol{Y}$, we obtain the identity

$$\mathcal{E}_i = \left\{ \sum_{j=i+1}^{(m^{-1}+\delta)T+N} X_j \le T, \quad \text{some } T \ge 0 \right\}.$$

Applying (i) gives a bound of the form $\mathsf{P}(\mathcal{E}_i) \le B_1 \exp(-I_1\delta^2 N)$ for some $B_1 < \infty$, $I_1 > 0$, and all i, N. Consequently, for any $r \ge 1$,

$$\begin{aligned}&\mathsf{P}\left\{\sup_{0\le s\le t\le r^{k_0}}\left(\frac{Y(t)-Y(s)-(t-s)(m^{-1}+\delta)}{N}\right) \ge 1\right\}\\ &\quad\le \mathsf{P}\{S_{r^{k_0+1}} \le r^{k_0}\} + \textstyle\sum_{i=1}^{r^{k_0+1}} \mathsf{P}\{\mathcal{E}_i\}\\ &\quad\le B_1\exp(-I_1\delta_0 r) + r^{k_0+1}B_1\exp(-I_1\delta^2 N).\end{aligned}$$

We now define N via $I_1\delta^2 N = \log(r^{k_0+3})$, so that the right-hand side is bounded by $2B_2 r^{-2}$. This is summable, and hence by the Borel–Cantelli lemma,

$$\limsup_{r\to\infty}\left\{\sup_{0\le s\le t\le r^{k_0}}\left(\frac{Y(t)-Y(s)-(t-s)(m^{-1}+\delta)}{(I_1\delta^2)^{-2}\log(r^{k_0+3})}\right)\right\}\le 1 \quad \text{a.s.} \qquad \square$$

We may now develop properties of the stochastic relaxation used to prove Theorem 4.3. Consider the value function for the relaxed stochastic network for a given $T>0$, $x\in\mathsf{X}$,

$$\widehat{\Gamma}^{r*}(T;x) = \min \frac{1}{T}\int_0^T c(\widehat{Q}(t))\,dt\,,$$

where the minimum is over all allocations $\widehat{\boldsymbol{Z}}$ satisfying the constraints (4.7), subject to the additional constraint that $\widehat{\boldsymbol{Q}}$ evolves in $\mathsf{X}=\mathbb{R}^{\ell}_+$.

Given the value of $\widehat{\boldsymbol{Z}}^*$ at time t, the associated idleness process is given by

$$\widehat{I}^{r*}(t;x) = t\mathbf{1} - \widehat{C}\widehat{Z}^{r*}(t;x), \qquad t\ge 0,\ x\in\mathsf{X}.$$

Conversely, one can determine the optimal allocation given the current value of the idleness. If $\widehat{I}^{r*}(t;x)=\widehat{I}$, then we take $\widehat{Z}^{r*}(t;x)$ to be the minimizer $\widehat{Z}^{r*}$ of the nonlinear optimization problem

$$\begin{aligned} \min c(y) \qquad \text{subject to} \qquad y &= x - S(\widehat{Z}) + R(\widehat{Z}) + A(t),\\ \widehat{C}\widehat{Z} &= \widehat{I},\\ \widehat{Z} &\in \mathbb{R}^{\ell_u},\\ y &\ge \boldsymbol{\theta}. \end{aligned} \tag{B.1}$$

This representation leads to the following conclusion.

PROPOSITION B.1. *Suppose that Assumptions* H *and* S *hold. Then, the optimal solution* $[\widehat{\boldsymbol{Q}}^{r*},\widehat{\boldsymbol{Z}}^{r*}]$ *satisfies condition* P1.

Proof. Fix any $t_0>0$, set $y=\widehat{Q}^{r*}(t_0)$, let $y^*=\mathcal{P}^*(y)$, and set ζ^+ as any solution to $B\zeta^+ = y^*-y$, so that $\widehat{C}\zeta^+=\boldsymbol{\theta}$. Under Assumption U(i) there exists $\kappa>0$ such that $c(y+sB\zeta^+)\le c(y)-s\|\zeta^+\|\kappa$ for $s\le 1$.

Consider the allocation $\widehat{\boldsymbol{Z}}^{*\Delta}$ given by $\widehat{Z}^{*\Delta}(t)=\widehat{Z}^{r*}(t)$ if $t\ne t_0$, and $\widehat{Z}^{r\Delta}(t_0)=\widehat{Z}^{r*}(t_0)+\Delta\zeta^+$. On the remainder of $\mathbb{R}_+$ we again suppose that this allocation is linear on each time-horizon. This is feasible for a range of $\Delta\ge 0$, and by Proposition 4.2 we have

$$c(\widehat{Q}^{r*}(t_0)) \ge c(\widehat{Q}^{r\Delta}(t_0)) - O(s\|\zeta^+\|\kappa) + O(\log(r)).$$

We must therefore have $\|\zeta^+\| = O(\log(r))$, so that P1 holds. $\square$

We may also establish a form of P2.

PROPOSITION B.2. *Suppose that Assumptions* H, M, U, *and* S *hold, where all bounds are with respect to the* ℓ_b*th workload-relaxation. Then for any* $r\ge 1$ *and any* $0<T_\bullet\le T_{r\bullet}$, *there exists a solution* $[\widehat{\boldsymbol{Q}}^{r},\widehat{\boldsymbol{Z}}^{r}]$ *that satisfies conditions* P1 *and* P2, *and*

$$\frac{1}{T_\bullet}\int_0^{T_\bullet} c(\widehat{Q}^{r}(t))\,dt \le \widehat{\Gamma}^{r*}(T_\bullet;x) + O(\log(r))\,. \tag{B.2}$$

Proof. The proof is again by comparison. We approximately retain the convention that $\widehat{\boldsymbol{Z}}^r$ is determined from its idleness process through the following restricted form of (B.1): For a given value $\widehat{I} = \widehat{I}^r(t;x)$ we take $\widehat{Z}^r(t;x)$ to be the minimizer $\widehat{Z}^*$ of

$$\begin{aligned} \min c(y) \qquad \text{subject to} \qquad y &= x - S(\widehat{Z}) + R(\widehat{Z}) + A(t), \\ \widehat{C}\widehat{Z} &= \widehat{I}, \\ \widehat{Z} &\in \mathbb{R}^{\ell_u}, \\ y &\geq \tfrac{1}{2}\bar{x}^r. \end{aligned} \tag{B.3}$$

Under this restriction, one can adapt the proof given in Proposition B.1 to show that $[\widehat{\boldsymbol{Q}}^r, \widehat{\boldsymbol{Z}}^r]$ satisfies Property P1.

We now show how $\widehat{\boldsymbol{I}}^r$ may be constructed so that P2 holds.

For a given $\Delta > 0$, let $\widehat{\boldsymbol{I}}^{r\Delta}$ denote the idleness process defined by $\widehat{I}^{r\Delta}(t;x) = \widehat{I}^{r*}(t;x) + \Delta\bar{w}^r$, $t \geq 0$, where $\bar{w}^r := \widehat{\Xi}\bar{x}^r$. An application of Proposition 4.2 implies that Δ can be chosen so large that the resulting state trajectory satisfies

$$\widehat{W}^{r*}(t;x) + 2\Delta\bar{w}^r + o(1) \geq \widehat{W}^{r\Delta}(t;x) \geq \bar{w}^r - o(1)\,, \quad 0 \leq t \leq T_\bullet\,.$$

This can be chosen independently of $r \geq 1$ and independently of $0 < T_\bullet \leq T_{r\bullet}$. It is obvious that (B.2) holds for the allocations $\{\widehat{\boldsymbol{I}}^{r\Delta}\}$.

We now refine this allocation to form an allocation $\widehat{\boldsymbol{I}}^r$ as follows. We first define this for $t = kT_r$ and then take it to be linear on each interval $[kT_r, (k+1)T_r]$ for each $k \geq 0$.

For $k = 0$ we set $\widehat{I}^r(0;x) := \widehat{I}^{r\Delta}(0;x) = \Delta\bar{w}^r$. For all $k \geq 1$, given that $\widehat{I}^r((k-1)T_r;x)$ has been specified, we define an upperbound $\bar{I} \in \mathbb{R}^{\ell_b}_+$ on the idleness rate on the interval $[(k-1)T_r, kT_r]$. This is given as the solution to

$$\widehat{W}^r((k-1)T_r;x) - (\mathbf{1} - \boldsymbol{\rho}^r)T_r + \bar{I}T_r = \big[\widehat{W}^r((k-1)T_r;x) - (\mathbf{1} - \boldsymbol{\rho}^r)T_r\big]^r_+. \tag{B.4}$$

We then define $\widehat{I}^r(kT_r;x)$ as

$$\widehat{I}^r(kT_r;x) := \min\Big([\widehat{I}^r((k-1)T_r;x) + \bar{I}T_r], \widehat{I}^{r\Delta}(kT_r;x)\Big),$$

where the minimum is interpreted componentwise. One can show that for sufficiently large $r \geq 1$, $\widehat{W}^r(t;x) - \frac{1}{2}\bar{w}^r \in \widehat{\mathsf{W}}$, $t \geq 0$. It follows that $\widehat{\boldsymbol{I}}^r$ defines a feasible allocation $\boldsymbol{Z}^r$, in the sense that the nonlinear program (B.3) is feasible when $\widehat{I} = \widehat{I}^r(t)$. Following familiar arguments we may conclude that the resulting state trajectory $\widehat{\boldsymbol{Q}}^r$ evolves in X for sufficiently large r.

Moreover, (B.4) implies that the resulting workload process satisfies a bound similar to (4.18): We have by construction

$$\widehat{W}^r(kT_r;x) - (\mathbf{1} - \boldsymbol{\rho}^r)T_r + \hat{\imath}^r_k T_r \leq [W^r(kT_r;x) - (\mathbf{1} - \boldsymbol{\rho}^r)T_r]^r_+\,,$$

where $\hat{\imath}^r_k := T_r^{-1}[\widehat{I}^r((k+1)T_r;x) - \widehat{I}^r(kT_r;x)]$ denotes the idleness on the kth interval. The proof of P2 is then identical to the proof of P2 for $\widehat{\boldsymbol{Q}}^{r\circ}$ given in Theorem 4.5.

Finally, since $\widehat{I}^r(kT_r;x) \leq \widehat{I}^{r\Delta}(kT_r;x)$ for all k and $\widehat{\boldsymbol{I}}^{r\Delta}$ satisfies (B.2) by construction, we may establish (B.2) for $\widehat{\boldsymbol{I}}^r$ by an application of Proposition 4.2 as in the proof of Proposition B.1. ∎

Acknowledgments. The author would like to express his thanks to Michael Chen, Michael Harrison, and Shane Henderson for many useful comments on an earlier

draft of this manuscript. The anonymous referee also provided valuable input. Of course, the author takes full responsibility for any remaining errors. Thanks are also due to Maury Bramson, Kavita Ramanan, and Ruth Williams for sharing their unpublished work, and for many fruitful discussions.

NEEDLE VARIATIONS THAT CANNOT BE SUMMED*

ROSA-MARIA BIANCHINI† AND MATTHIAS KAWSKI‡

Abstract. This article analyzes sets of higher order tangent vectors to reachable sets of analytic control systems (affine in the control). Both small-time local *output* controllability and small-time local controllability about a nonstationary reference trajectory are considered. In a series of purposefully constructed examples it is shown that the *cones* generated by *needle variations* may fail to be convex. The examples demonstrate that the usual technical condition that *needle variations* must be *movable* is essential to guarantee desirable convexity properties. Moreover, new doubts are cast on the structural stability of controllability properties, as apparently higher order perturbations can reverse the (lack of) controllability of *lower order* nilpotent approximating systems, thereby providing new insights about the ultimate question of whether controllability is finitely determined.

Key words. nonlinear controllability, optimality, control variations, tangent cones

1. Introduction.

A fundamental dichotomy for a control system with a reference trajectory is whether the trajectory is *optimal* or whether the system is *controllable* about this trajectory. Topologically, this translates into the reference trajectory lying either on the boundary or in the interior of the *funnel of reachable sets*. Derivatives of the *endpoint map* with respect to the controls serve as the main analytic tool: If the derivative has full rank, then the trajectory lies in the interior and the system is *controllable*. Conversely, a necessary condition for *optimality* is that the derivative does not have full rank, which leads to the Pontryagin maximum principle [19] (which is a *first derivative* test). See [23] for the current state of the art unifying nonsmooth with differential geometric approaches.

Since commonly the first derivative does not have full rank (at the reference control), there have been many efforts to obtain higher order conditions for controllability and optimality, with Krener's high order maximal principle [17], Stefani's high order conditions for optimality [20], and Sussmann's general theorem for controllability [22] being a few prominent classical ones. See [23] and the references therein for the current state of the art. As opposed to purely theoretical statements in terms of high order Frechet derivatives, the main interest is in *effectively computable* conditions, leading, e.g., to algebraic rank conditions in terms of iterated Lie brackets of the system vector fields evaluated at a point as, e.g., in [20, 22]. Underlying such conditions are notions of higher order tangent vectors together with open mapping theorems. The higher order tangent vectors are basically high order directional derivatives of the endpoint

map, obtained from *families of control variations* (i.e., curves in the space of admissible controls). Open mapping theorems guarantee that if a *cone of tangent vectors* is the whole tangent space, then the reference trajectory lies in the interior. Of course, depending on the precise technical notion of the tangent object, one needs dedicated open mapping theorems—see, e.g., Lee and Markus [18] for such classical statements. A notable effort in the 1980s by Frankowska employed *nonsmooth analysis* to obtain a general purpose open mapping theorem [9, 10], relying on high order variations of set-valued maps.

The basic trade-off is between narrowly defined tangent objects (with straightforward open mapping theorems) and *large* tangent objects, which may lack nice convexity and approximation properties. Recall that classical calculus of variations primarily employed families of variations that are parameterized by their amplitude. In optimal control theory several alternative approaches have been analyzed. These include both *curves* $s \mapsto u_s(\cdot)$, $s \geq 0$ (with $u_0 = u^*$ the *reference control*) such that $\|u_s - u^*\|_\infty \searrow 0$, curves such that $\|u_s - u^*\|_1 \searrow 0$ as $s \searrow 0$ (compare with [8]), and the so-called *needle variations*: Loosely speaking, these are such that the *variation* u_s agrees with the reference control u^* everywhere except on a (finite number of) interval(s) whose (combined) length goes to zero as $s \searrow 0$. The main attraction of such needle variations is that they are conceptually easy to combine for the purpose of generating convex combinations of tangent vectors, resulting in tangent cones with nice convexity properties. Of course, such schemes hinge on the intervals on which the variations differ from the reference control, eventually (for sufficiently small $s > 0$) becoming disjoint. Alternatively, one might require that every needle variation be *movable*, i.e., one must be able to *move* the variation by a small time-amount and still be able to generate the same tangent vector. Precise technical specification of such conditions can be quite involved.

This article is not overly concerned about specific ways of combining needle variations. The main results are independent of such technical intricacies because we show that certain directions can be generated by the most basic needle variations, while certain other points cannot be reached by any control variations at all. Of course, this implies that one cannot reach those points or generate those tangent vectors by any kind of composition of needle variations either, no matter how these are defined.

For analytic, affine control systems with a *stationary* reference trajectory, no such conditions are needed, and a wealth of necessary and sufficient conditions for controllability and optimality have been found in recent decades; see, e.g., [22]. On the other hand, distinctive features of the existing literature for nonstationary reference trajectories are much more careful and provide more delicate notions of variations, tangent objects, and open mapping theorems; see, e.g., [1, 4, 5, 6, 16, 23]. A major open question has been whether such technical conditions are truly essential, or whether they are merely artifacts of a still imperfect knowledge level (e.g., future work might show that they are automatically satisfied for reasonable classes of systems). This article provides a definitive answer: Loosely speaking, even for the most benign classes of nonlinear systems (polynomial cascades, affine in the control, convex compact control values), the tangent *cones* generated by needle variations can be nonconvex. Moreover, even if their convex hull is the entire space the reference trajectory may lie on the boundary of the reachable sets. Both may happen even for arbitrary small positive times.

This article is organized as follows: After this introduction, we give and review technical definitions of controllability, needle variations, tangent cones, and open map-

ping theorems. The subsequent three sections analyze a sequence of increasingly more delicate examples. First we consider the *output controllability* of a simple polynomial cascade system about an equilibrium (stationary reference trajectory). Most of the innovative constructions and critical inequalities may be found here. The next section slightly modifies the system so that it falls into the class of standard small-time local controllability about a nonstationary reference trajectory. Finally, we add some terms which at first sight appear to be higher order perturbations, but we show that these actually destroy the delicate controllability properties. The final section reflects and speculates on the possible implications of such a lack of robustness of the notion of controllability.

The constructions in the proofs fall into two categories: On one side we provide very explicit constructions of *needle variations* and demonstrate that they generate certain tangent vectors. Similarly, in the absence of applicable open mapping theorems, we explicitly construct controls that steer the system to any given target point. On the other side, we show that certain (regions of) points cannot be reached by any control whatsoever, and thus not by any needle variations either. Such arguments naturally involve delicate arguments with integral inequalities.

2. Control variations and approximating cones. The main thrust of this article is *counterexamples*. Thus for positive controllability results we use constructions that rely on small sets of tools, e.g., very narrow notions of (needle) variations. Such results clearly hold a fortiori if the sets of admissible variations etc. are broadened. Conversely, negative results (lack of convexity or controllability) are usually stated in the form that even for very large sets of controls something is impossible.

The systems under consideration are finite-dimensional, deterministic, analytic systems (possibly including an analytic *output* function) that are affine in the control.

$$\dot{x} = f_0(x) + \sum_{i=1}^{\ell} u_i(t) f_i(x), \qquad x(0) = 0, \qquad y = \varphi(x). \tag{2.1}$$

Here $x \in \mathbb{R}^n$, $f_i\colon \mathbb{R}^n \mapsto \mathrm{T}\mathbb{R}^n$ are analytic vector fields; the controls $u\colon [0,T] \mapsto U \subseteq \mathbb{R}^\ell$ are measurable functions defined on finite intervals and take values in a compact convex set U, usually $U = [-1,1]^\ell$. The output map $\varphi\colon \mathbb{R}^n \mapsto \mathbb{R}^p$ is analytic. In this article the vector fields are actually always of a polynomial cascade form, the controls in all constructions are piecewise constant, and the output map is either the identity or a projection onto a subspace. The solution curves of (2.1) corresponding to a control u, starting from $x(0) = 0$, are denoted by $x(t,u)$ or, when no confusion arises, by $x(t)$. Their images under the output map are denoted $y(t,u) = \varphi(x(t,u))$ or simply $y(t)$. Throughout this article we also conveniently identify the tangent spaces $\mathrm{T}_p\mathbf{R}^n$ with $\mathbf{R}^n$.

The reachable sets $\mathcal{R}(t)$ consist of all points $x(t,u)$ reached in time t by trajectories of (2.1) from $x(0) = 0$ by means of admissible controls (measurable, and with values in U almost everywhere). Given a reference trajectory $x^*(t) = x(t,u^*)$, controllability is defined as follows.

Definition 2.1. *The system* (2.1) *is small-time locally controllable* (STLC) *about* x^* *if* $x^*(t) \in \mathrm{int}\mathcal{R}(t)$ *for all* $t > 0$. *The system* (2.1) *is small-time locally output controllable* (STLOC) *about* $y^* = \varphi(x^*)$ *if* $y^*(t) \in \mathrm{int}(\varphi(\mathcal{R}(t)))$ *for all* $t > 0$.

The latter notion is related to Kaskosz's g-controllability [13] but is not yet standard. In general one needs to distinguish STLOC about a reference output y^* with a fixed initial condition $x(0) = 0$ from a notion that requires only $x(0) \in \varphi^{-1}(y_0)$. In

this article this distinction will not play a role.

Throughout this article we will use the norm $\|x\|_\infty \stackrel{\text{def}}{=} \max_{k=1}^n |x_k|$ for $x \in \mathbb{R}^n$. In particular, the open ball of *radius* $r \geq 0$ about $p \in \mathbb{R}^n$ is $B_p^\infty(r) = \{x \in \mathbb{R}^k : \|x - p\|_\infty < r\}$. Since $\|x\|_\infty \leq \|x\|_2 \leq \sqrt{n}\|x\|_\infty$, this does not change the quality of any statements but allows us to dispense with lots of additional factors of $\sqrt{n}$ throughout our constructions and statements of results.

DEFINITION 2.2. *A one-parameter family of control variations of a reference control* $u^* : [0,T] \mapsto U$ *is a curve* $s \mapsto u_s \in \mathcal{U} = \{u : [0,T] \mapsto U \text{ measurable}\}$ *defined for* $s \in [0, s_0]$ *for some* $s_0 > 0$ *and with* $u_0 = u^*$. *Such a family is called a family of control variations* at zero *if* $u_s(t) = u^*(t)$ *for all* $t \in (s,T]$.

In the latter case it is convenient to identify u_s with its restriction to $[0,s]$. Conversely we generally do not distinguish between a control $u_s : [0,s] \mapsto U$ and its extension to $[0,T]$ defined by setting $u_s(t) = u^*(t)$ if $t \in (s,T]$. Using either kind of curves one may define derivatives to the family of reachable sets. Denote by $\Phi : (t,p) \mapsto \Phi_t(p) = x(t,u^*;p)$ the flow corresponding to the reference control u^*. In all systems analyzed in this article, this flow will be analytic, and hence there are no subtleties about transporting tangent vectors via the tangent maps Φ_{t*} from one tangent space to another. To facilitate comparisons, we move all tangent vectors back to the tangent space at the initial point. In the following definitions let $u^* : [0,T] \mapsto U$ be an admissible control generating a (reference) trajectory $x^* : [0,T] \mapsto \mathbf{R}^n$.

DEFINITION 2.3. *A vector* $v \in \mathbb{R}^n$ *is an* m*th order tangent vector to the family of reachable sets* $\{\mathcal{R}(T)\}_{T \geq 0}$ *at (time) zero, written* $v \in \mathcal{K}_0^m$, *if there exists a family of control variations at zero* $u_s : [0,s] \mapsto U$ *of* u^* *such that*

$$x(s,u_s) = x(s,u^*) + s^m \Phi_{s*}(v) + o(s^m). \tag{2.2}$$

DEFINITION 2.4. *A vector* $v \in \mathbb{R}^p$ *is called an* m*th order tangent vector to the output-reachable sets of the system* (2.1) *with stationary reference trajectory* $x^* \equiv 0$, *written* $v \in \mathcal{K}_\varphi^m$, *if there exists a family of control variations* $u_s : [0,s] \mapsto U$ *such that*

$$\varphi(x(s,u_s)) = \varphi(x(0)) + s^m v + o(s^m). \tag{2.3}$$

Most of the statements in this article involve these approximating sets to the *family* of reachable sets at the initial time. However, in a few places (e.g., system (2.9) and Corollary 5.8) it is convenient for precise statements to use the following notion of tangent vectors to a fixed reachable set (but transported back to the initial time for easy comparisons). In order to allow rudimentary comparisons with the above notions of higher order tangent vectors, the following definition uses the L^1-norm of the differences $(u_s - u^*)$.

DEFINITION 2.5. *A vector* $v \in \mathbb{R}^n$ *is an* m*th order tangent vector to the reachable set* $\mathcal{R}(T)$ *at* $x^*(T)$, *written* $v \in \mathcal{K}_T^m$, *if there exists a family of control variations* $u_s : [0,T] \mapsto U$ *of* u^* *such that*

$$x(T,u_s) = x(T,u^*) + \|u_s - u^*\|_1^m \Phi_{T*}(v) + o(\|u_s - u^*\|_1^m). \tag{2.4}$$

Note, that in all three definitions no regularity whatsoever is assumed or required for the maps $s \mapsto u_s$.

If $\{u_s\}_{s>0}$ is a family of control variations at zero (and thus $u_s(t) = u^*(t)$ for $s < t \leq T$), it is clear that $\|u_s - u^*\|_1^m \leq c^m s^m$, where $c = \max_{w \in U} |w|$ is finite (due to compactness of U). Thus, basically from the definition,

$$\mathcal{K}_0^m \subseteq \mathcal{K}_T^m \quad \text{for all } m \geq 0 \text{ and all } T > 0. \tag{2.5}$$

However, the reverse inequality need not hold as, e.g., $\|u_s - u^*\|_1^m \searrow 0$ might go to zero faster than s^m as $s \searrow 0$. Nonetheless, for typical families of control variations at zero, as constructed in what follows, one often can readily conclude that they generate corresponding tangent vectors of the same order m, lying in $\mathcal{K}_0^m$ and $\mathcal{K}_T^m$. Write $\overline{\mathcal{K}}_T$, $\overline{\mathcal{K}}_0^m$, and $\overline{\mathcal{K}}_\varphi^m$ for the cones $\overline{\mathcal{K}}_0^m = \{\lambda v : v \in \mathcal{K}_0^m,\ \lambda \geq 0\}$ etc. generated by $\mathcal{K}_T$, $\mathcal{K}_0^m$, and $\mathcal{K}_\varphi^m$, respectively, and also refer to the elements of the cones $\overline{\mathcal{K}}^m$ as *tangent vectors.* In the case of a stationary reference trajectory $x^* \equiv x(0)$ together with full-state output $\varphi \equiv \mathrm{id}_{\mathbf{R}^n}$, the definitions of $\mathcal{K}_0^m$ and $\mathcal{K}_\varphi^m$ agree, and they are subsets of adjacent tangent cones and, moreover, have nice convexity and approximation properties [9].

The sets $\overline{\mathcal{K}}_\varphi^m$ of tangent vectors to output-reachable sets in general may have more complicated structures. In particular, they generally are not simply the images of the corresponding sets $\overline{\mathcal{K}}_0^m$ under the tangent map φ_* as illustrated in the basic example

$$\begin{cases} \dot{x}_1 = u, & x(0) = 0, \\ \dot{x}_2 = x_1^2, & |u(\cdot)| \leq 1, \\ \dot{x}_3 = x_1^3, & \varphi(x) = (x_1, x_3) \end{cases} \tag{2.6}$$

with reference control $u^* \equiv 0$. Here $\overline{\mathcal{K}}_0^m = \mathbf{R} \times \{(0,0)\}$ for $m = 1, 2$, and $\overline{\mathcal{K}}_0^m = \mathbf{R} \times [0, \infty) \times \{0\}$ for $m \geq 3$, while $\overline{\mathcal{K}}_\varphi^m = \mathbf{R}^2$ for $m \geq 4$. In particular, $\overline{\mathcal{K}}_\varphi^4 \neq \varphi_* \overline{\mathcal{K}}_0^4$.

A key step to rendering the sets of tangent vectors useful for obtaining optimality results is to establish their convexity. For a wide variety of different settings, results that are similar to the following may be found in, e.g., [4, 5, 6, 8, 9, 10, 14, 18].

PROPOSITION 2.1. *For systems of form* (2.1) *with a stationary reference trajectory the following hold:*

If $\lambda \in [0,1]$ *and* $v \in \mathcal{K}_0^m$, *then* $\lambda v \in \mathcal{K}_0^m$.

If $m \leq m'$, *then* $\mathcal{K}_0^m \subseteq \mathcal{K}_0^{m'}$.

If v_1, $v_2 \in \mathcal{K}_0^m$ *and* $\lambda \in [0,1]$, *then* $\lambda^m v_1 + (1-\lambda)^m v_2 \in \mathcal{K}_0^m$.

THEOREM 2.2 (see [9, 10, 11, 14]). *Suppose* $x^* \equiv 0$ *is the stationary reference trajectory of a system of form* (2.1). *Then for every closed convex cone* K *that is strictly contained in* $\{0\} \cup \mathrm{int}\overline{\mathcal{K}}_0^m$, *there exist* $C > 0$ *and* $T > 0$ *such that*

$$K \cap B_0^\infty(Ct^m) \subseteq \mathcal{R}(t) \text{ for all } 0 \leq t \leq T. \tag{2.7}$$

Moreover, if $\overline{\mathcal{K}}_0^m = \mathbb{R}^n$, *then the system* (2.1) *is STLC about* $x^* = 0$, *and the minimum time function* $V(q) = \min\{t \geq 0 : \exists u \quad \text{such that} \quad x(t,u) = q\}$ *is Hölder continuous of order* $\frac{1}{m}$ *at* $x = 0$.

If the reference trajectory is nonstationary, then the cones $\overline{\mathcal{K}}_0^m$ need not have similarly nice convexity and approximation properties. Thus much work in recent decades has focused on developing more refined notions of tangent objects for that setting. The classical open mapping theorems (compare, e.g., [18, 19]) use topological arguments that rely on continuity of the multiparameter families of control variations that naturally generalize the (single-parameter) curves introduced above. Typically, one might have constructed n curves $s \mapsto u_s^{(i)} \in \mathcal{U}$, which generate the tangent vectors $v^{(i)} \in \mathcal{K}_0^m$, $i = 1, \ldots, n$. The critical next step is to somehow combine these variations in order to show that the convex combinations $(c_1 v_1 + \cdots + c_n v_n)$ with $c_1 + \cdots + c_n = 1$ are mth order tangent vectors, i.e., are contained in $\overline{\mathcal{K}}_0^m$, too. A natural first try is to consider convex combinations of suitable reparameterizations of the original curves

$$s \mapsto u_{s,c_1,\ldots,c_n} = c_1 u^{(1)}_{\alpha_1(c,s)} + c_2 u^{(2)}_{\alpha_2(c,s)} + \cdots + c_n u^{(n)}_{\alpha_n(c,s)} \tag{2.8}$$

and analyze the corresponding curves $s \mapsto x(s, u_{s,c})$ of endpoints for each value c. Variations that lend themselves especially well to generating such convex combinations are needle variations. (Alternatively, compare with, e.g., [8] for variations such that $\|u_s - u^*\|_1 \searrow 0$.) Basically, each such control u_s agrees with u^* on all of $[0,T]$ except on an interval whose length is of order s for $s \searrow 0$. Two such families of variations are easily combined unless the intervals on which they disagree from u^* overlap for all small $s > 0$. In that case, one might be tempted to simply *move* the interval in one of the families. The continuous dependence of solution curves on the data suggests that after such small (or vanishing, as $s \searrow 0$) moves, the combined variations might still generate the desired tangent vectors.

Before giving a technical (broad) definition of needle variations, we discuss a very simple example that illustrates the problem that some (narrowly defined) *needle variations* might *not be able to be moved*:

$$\begin{cases} \dot{x}_0 = 1, & |u(\cdot)| \le 1, \\ \dot{x}_1 = u, & x(0) = 0, \\ \dot{x}_2 = (x_0 - 1)x_1^2, & x^*(t) = (t,0,0,0), \\ \dot{x}_3 = x_1^7, & t \in [0,2] = [0,T]. \end{cases} \tag{2.9}$$

In this case the family of *needle variations* $u_s^{\pm}\colon [0,2] \mapsto [-1,1]$ defined by $u_s^{\pm}(t) = \pm 1$ if $1 - \frac{1}{2}s \le t < 1$, $u_s^{\pm}(t) = \mp 1$ if $1 \le t < 1 + \frac{1}{2}s$, and $u_s^{\pm}(t) = 0$ else, generates the curves $x(2, u_s^{\pm}) = (2,0,0,\pm 2^{-10}s^8) \in \mathcal{R}_0(2)$, and thus $v = (0,0,0,\pm 1) \in \overline{\mathcal{K}}_2^8$ as 8th order tangent vectors at $T = 2$ (note that $\|u_s - u^*\|_1 = s$).

In general, suppose $u_s\colon [0,2] \mapsto [-1,1]$ is any family of control variations that agrees with $u_s(t) = u^*(t) = 0$ for all $t \in [0,T] \setminus I_s$, where $I_s \subseteq [0,T]$ is an interval of any of the forms $[a, a+s]$, $[a-s, a]$, or $[a - \frac{s}{2}, a + \frac{s}{2}]$ for some fixed $a \in [0,2]$. Then $x(T, u_s) = (2,0,0,Cs^8) + o(s^8)$ is only possible if I_s is of the third form, and in addition $a = 1$. This means that the only *single* family of *needle variations* that can generate $v = (0,0,0,\pm 1)$ as tangent vector *"cannot be moved."*

In this simple example it is clear that either v can easily be generated by control variations whose support (technically the support of $(u_s - u^*)$) consists of two disjoint intervals, e.g.,

$$u_s(t) = \begin{cases} 1 & \text{if } \ \pm\frac{1}{2} - \frac{1}{4}s \le t < \pm\frac{1}{2}, \\ -1 & \text{if } \ \pm\frac{1}{2} \le t < \pm\frac{1}{2} + \frac{1}{4}s, \\ 0 & \text{else.} \end{cases} \tag{2.10}$$

This demonstrates that if one considers only control variations that are supported in a single interval shrinking to a point, then it may be possible that certain tangent vectors can be generated *only* at a specific point t_0 that cannot be moved.

The example appears contrived and the notion of needle variation unnecessarily constrained. It is customary to broaden the notion of needle variations to allow the support of $(u_s - u^*)$ to be a finite union of intervals of total length of order s.

DEFINITION 2.6. *A family of control variations $s \mapsto u_s\colon [0,T] \mapsto U$ defined for $s \in [0, s_0]$ with $s_0 > 0$ is a (family of)* needle variations *of the reference control $u^* = u_0$ if there exist a constant $C > 0$ and a finite number of pairs of increasing functions $s \mapsto a_s^{(k)}$ and decreasing functions $s \mapsto b_s^{(k)}$ defining intervals $[a_s^{(k)}, b_s^{(k)}] \subseteq [0,T]$, $k = 1, \dots, N$, such that*

$$\operatorname{supp}(u_s - u^*) \subseteq \bigcup_{k=1}^{N} [a_s^{(k)}, b_s^{(k)}] \ \text{ and } \ \sum_{k=1}^{N} (b_s^{(k)} - a_s^{(k)}) \le Cs \ \text{ for all } s \le s_0. \tag{2.11}$$

Note that a family of variations *at zero* as defined earlier automatically qualifies as a family of needle variations as one may take $N = 1$ and intervals defined by $a_s^{(1)} = 0$ and $b_s^{(1)} = s$. Definition 2.6 also includes other common constructions with $N = 1$ and $[a_s^{(1)}, b_s^{(1)}] = [\alpha, \alpha + s]$ (*right* variations at $t = \alpha$) or $[a_s^{(1)}, b_s^{(1)}] = [\beta - s, \beta]$ (*left* variations at $t = \beta$). The constructions in this article use mainly (right) needle variations at zero, combined with some (left) needle variations at the final time T. But the main claim of *"needle variations that cannot be summed"* holds even if the combinations (or sums) are allowed to lie in a more general class as in Definition 2.6.

3. The main construction. This section analyzes a custom-designed polynomial cascade system (affine in the control) with output, which forms the heart of the promised counterexample in section 5. We demonstrate that the growth rates of its reachable sets are very sensitive to reflections about the origin. More specifically, the approximating cones of tangent vectors are described not only by intersections, but also by unions of half spaces. The basic system with *output* φ is

$$\begin{cases} \dot{x}_1 = u_1, & |u_1(\cdot)| \le 1, \\ \dot{x}_2 = u_2, & |u_2(\cdot)| \le 1, \\ \dot{x}_3 = x_1^2, & x(0) = 0, \\ \dot{x}_4 = x_2^2, & \varphi(x) = (x_1, x_2, x_5, x_6), \\ \dot{x}_5 = x_4 x_1^2 - x_1^7, & \\ \dot{x}_6 = x_3 x_2^2 - x_2^7. & \end{cases} \tag{3.1}$$

Figure 3.1 pictorially summarizes key properties of this system, showing cross-sections of approximating cones of the image $\varphi(\mathcal{R}(t))$ of the reachable set under the output map. The remainder of this section proves technical statements that make this illustration precise.

THEOREM 3.1. *For all $T > 0$ (sufficiently small)*

$$\varphi(R_0(T)) \supseteq B_0^\infty(2^{-18}T^8) \cap \{y \in \mathbb{R}^4 \colon (y_3 \ge 0 \textbf{ or } \ y_4 \ge 0\,) \textbf{ and } y_1 = y_2 = 0\}. \tag{3.2}$$

The proof shows in particular that points of the forms $x = (0, 0, *, *, -2^{-18}s^8, 0)$ and $x = (0, 0, *, *, 0, -2^{-18}s^8)$ can be reached in time s, i.e., by control variations at zero. Thus the tangent vectors $(0, 0, -1, 0), (0, 0, 0, -1) \in \overline{\mathcal{K}}_\varphi^8$ are generated by *needle variations* of the zero reference control.

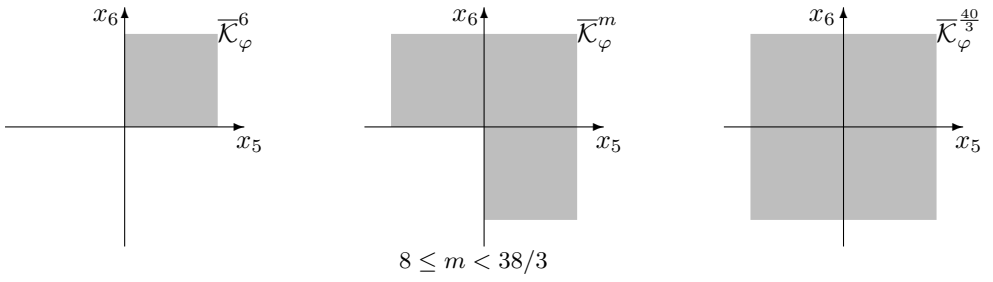

FIG. 3.1. *Cross-sections of approximating cones of tangent vectors for system* (3.1).

Proof. Suppose $T > 0$ and $\eta \in \mathbb{R}^4$ are given, with $\|\eta\|_\infty < 2^{-18}T^8$, $\eta_3 < 0$, and $\eta_4 \geq 0$. (The case of $\eta_4 < 0$ and $\eta_3 \geq 0$ is analogous.) Set $t_1 = (-4\eta_3)^{1/8} > 0$. Define the control $u\colon [0,T] \mapsto [-1,1]^2$ (with $t_2 \geq 0$ to be determined later) by

$$u(t) = \begin{cases} (\ 1,\ \ 0) & \text{if} \quad 0 \leq t \leq t_1, \\ (-1,\ \ 0) & \text{if} \quad t_1 \leq t \leq 2t_1, \\ (\ 0,\ -1) & \text{if} \quad 2t_1 \leq t \leq 2t_1 + t_2, \\ (\ 0,\ \ 1) & \text{if} \quad 2t_1 + t_2 \leq t \leq 2t_1 + 2t_2, \\ (\ 0,\ \ 0) & \text{else.} \end{cases} \tag{3.3}$$

From $u_2(t) = 0$ for $t \leq 2t_1$ it is easily seen that $x(2t_1, u) = (0, 0, \frac{2}{3}(-4\eta_3)^{3/8}, 0, \eta_3, 0)$ and thus $\varphi(x(2t_1, u)) = (0, 0, \eta_3, 0)$. Then $\varphi(x(2t_1 + 2t_2, u)) = (0, 0, \eta_3, \xi(t_2))$, where

$$\xi\colon t_2 \mapsto x_6(2t_1 + 2t_2) = 2\int_0^{t_2} \Big(\tfrac{2}{3}(-4\eta_3)^{3/8}t^2 + t^7\Big)\, dt = \tfrac{4}{9}(-4\eta_3)^{3/8}t_2^3 + \tfrac{1}{4}t_2^8 \tag{3.4}$$

is a strictly increasing function. Thus there exists a unique $0 \leq t_2^* \leq (4\eta_4)^{1/8}$ such that $\xi(t_2^*) = \eta_4$. One easily verifies that the total time satisfies

$$(2t_1 + 2t_2^*) \leq 2(-4\eta_3)^{1/8} + 2(4\eta_4)^{1/8} \leq 4 \cdot \|4\eta\|_\infty^{1/8} = \big(2^{18}\|4\eta\|_\infty\big)^{1/8} < T. \tag{3.5}$$

Points $\eta = (0, 0, \eta_3, \eta_4)$ with $\eta_3 > 0$ and $\eta_4 > 0$ are even easier to reach using again piecewise constant controls, but now both u_1 and u_2 start with value $+1$, followed by -1 and zero. Note that in the directions of this positive quadrant the reachable set grown even faster, of order T^6. ∎

Several stronger statements appear possible, e.g., characterizing the image $\varphi(\mathcal{R}_0(T))$ of the reachable set without the condition $y_1 = y_2 = 0$. However, in what follows we have no need for this, and it is quite cumbersome to find the precise complete boundary of the reachable sets.

One consequence of the next statement is that there does not exist a constant $C > 0$ such that one can reach points $x = (0, 0, *, *, -CT^8, -CT^8)$ in the fourth quadrant for all sufficiently small times $T > 0$ using *any* controls. Thus, a fortiori, one cannot reach such points by any combination of needle variations in time $T > 0$, and $(0, 0, -1, -1) \notin \overline{\mathcal{K}}_\varphi^8$.

THEOREM 3.2. *Suppose* $0 \leq T < 1$, *and* $x_1(T, u) = x_2(T, u) = 0$. *Define* $C = 3^{1/5} \cdot 2^{-35/3} > 0$. *If* $x_5(T, u) < 0$, *then* $x_6(T, u) > -CT^{38/3}$, *and if* $x_6(T, u) < 0$, *then* $x_5(T, u) > -CT^{38/3}$.

The following useful restatements and consequences are immediate corollaries from the theorem (or from its proof given in what follows).

COROLLARY 3.3. *If* $C, m > 0$ *are such that the images of reachable set of system* (3.1) *contain the open balls* $B_0^\infty(CT^m) \subseteq \varphi(\mathcal{R}_0(T))$ *for all* $T > 0$ *(sufficiently small), then* $m \geq \frac{38}{3}$.

COROLLARY 3.4. *For system* (3.1), $(0, 0, a, b) \in \overline{\mathcal{K}}_\varphi^8$ *if and only if* $a \geq 0$ *or* $b \geq 0$.

Proof of Corollary 3.4. The *"if"* part is clear from Theorem (3.1). For the *"only if"* part, suppose $(0, 0, a, b) \in \mathcal{K}_\varphi^8$ for some $a, b \in \mathbb{R}$. By definition of $\mathcal{K}_\varphi$ there exist $0 < s_0 < 1$ and a family of control variations $u_s\colon [0, s] \mapsto [-1, 1]^2$, $0 \leq s \leq s_0$, such that for some $\xi\colon [0, s_0] \mapsto \mathbb{R}^6$ with $\|\xi(s)\|_\infty = o(s^8)$ the endpoints have the form

$$x(s, u_s) = s^8 \cdot (0, 0, *, *, a, b) + \xi(s) \in \mathcal{R}(s). \tag{3.6}$$

Define a new family of control variations $v_{2s}\colon [0,2s] \mapsto [-1,1]^2$, $0 \le 2s \le s_0$, by

$$v_{2s}(t) = \begin{cases} u_s(t) & \text{if } 0 \le t \le s, \\ -\frac{1}{s} \cdot (\xi_1(s), \xi_2(s)) & \text{if } s < t \le 2s. \end{cases} \tag{3.7}$$

Then $x(t, v_{2s}) = x(t, u_s)$ for $0 \le t \le s$, and in particular $x(s, v_{2s}) = x(s, u_s)$. For $t \in [s, 2s]$ in the second half of the domain of v_{2s} the first two components $x_i(t, v_{2s}) = (2s-t)\xi_i(s)$, $i = 1, 2$, remain of size $o(s^8)$. Consequently also $x_3(t, v_{2s})$ and $x_4(t, v_{2s})$ remain of size $o(s^8)$, and the change in the last two components

$$\|x_i(2s, v_{2s}) - x_i(s, v_{2s})\|_\infty = o(s^{24}) \quad \text{for } i = 5, 6 \tag{3.8}$$

is again of higher order. The endpoints are of the form

$$x(2s, v_{2s}) = (0, 0, *, *, s^8 a + o(s^8), s^8 b + o(s^8)), \tag{3.9}$$

and in particular they lie in the plane $x_1 = x_2 = 0$, satisfying the hypotheses of Theorem 3.2. Thus $a \ge 0$ or $b \ge 0$. ∎

COROLLARY 3.5. *For $8 < m < 38/3$ the approximating cones $\overline{\mathcal{K}}^m_\varphi$ of the output-reachable set are not convex.*

To streamline the proof of Theorem 3.2 we first establish two technical lemmata. Consider the following simple system about its equilibrium point $x = 0$:

$$\begin{cases} \dot{x}_1 = u, & |u(\cdot)| \le 1, \\ \dot{x}_2 = c x_1^2 - x_1^7, & x(0) = 0. \end{cases} \tag{3.10}$$

LEMMA 3.6. *If $c \neq 0$, then the system (3.10) is not STLC about $x = 0$. If $T > 2\left(\frac{8}{3}|c|\right)^{\frac{1}{5}}$, then $0 \in \operatorname{int} \mathcal{R}(T)$.*

Proof. W.l.o.g. assume $c > 0$ (else consider the coordinate change $(x_1, x_2) \mapsto (x_1, -x_2)$). The first assertion follows from $x_2(T) = \int_0^T x_1^2(t)(c - x_1^5(t))\, dt \ge 0$ since $|x_1^5(t)| \le t^5 \le T^5 \le c$ if $T \le c^{\frac{1}{5}}$.

Conversely, suppose $T > 2b_0$, where $b_0 = (\frac{8}{3}c)^{\frac{1}{5}}$ is the first positive zero of $t \mapsto \frac{1}{3}ct^3 - \frac{1}{8}t^8$.

Consider the 2-parameter family of controls

$$u_{a,b}(t) = \begin{cases} 0 & \text{if} \quad 0 \le t \le T - 2b_0 - 2b - a, \\ 1 & \text{if} \quad T - 2b_0 - 2b - a < t \le T - b_0 - b - a, \\ -1 & \text{if} \quad T - b_0 - b - a < t \le T. \end{cases} \tag{3.11}$$

Since $T - 2b_0 > 0$, these controls are defined for (a, b) in some neighborhood of $(0, 0)$. (To be precise, they are defined for $-b_0 \le b$, $-b_0 \le a + b$, and $a + 2b \le T - 2b_0$.) It is straightforward to verify that $x(T, u_{0,0}) = 0$ and that the Jacobian (for some polynomial p in two variables)

$$\frac{\partial\, x(T, u_{a,b})}{\partial(a, b)} = \begin{pmatrix} -1 & 0 \\ ca^2 + a^7 & -\frac{20}{9}\left(54c^7\right)^{\frac{1}{5}} + b \cdot p(b, c^{\frac{1}{5}}) \end{pmatrix} \tag{3.12}$$

of the map $(a, b) \mapsto x(T, u_{a,b})$ has full rank at $(a, b) = (0, 0)$ when $(c \neq 0)$. By the inverse mapping theorem, $0 \in \operatorname{int} \mathcal{R}(T)$, and the system (3.6) is STLC. ∎

LEMMA 3.7. *Suppose $f\colon [0, T] \mapsto \mathbb{R}$ is absolutely continuous with $|f'(t)| \le \varepsilon$ a.e. and $f(0) = f(T) = 0$. Then for any even integer $m = 2k \ge 2$*

$$\int_0^T f^m(t)\, dt \ge \tfrac{2}{(m+1)\varepsilon} \|f\|_\infty^{m+1}. \tag{3.13}$$

Proof. Since f is continuous there exists $t_0 \in [0,T]$ such that $f(t_0) = \|f(t)\|_\infty$. W.l.o.g. assume $f(t_0) > 0$. Since $|f'(t)| \le \varepsilon$ a.e., use the lower bound $f(t_0 \pm \tau) \ge f(t_0) - \varepsilon\tau$ for $0 \le \tau \le \tau_0 = f(t_0)/\varepsilon$ to obtain the estimate

(3.14)
$$\int_0^T f^{2k}(t)\,dt \ge \int_{t_0-\tau_0}^{t_0+\tau_0} f^{2k}(t)dt \ge 2\cdot\int_0^{\tau_0} (\varepsilon t)^{2k}\,dt = \frac{2\varepsilon^{2k}\tau_0^{2k+1}}{2k+1} = \frac{2\,\|f\|_\infty^{2k+1}}{(2k+1)\varepsilon}. \qquad \square$$

Proof of Theorem 3.2. Before going into technical details we lay out some heuristic ideas that motivate the strategy.

The presence of the definite terms in system (3.1) suggests using controls u_1 and u_2 with disjoint support. If one first keeps $u_2 \equiv 0$, thus also $x_4 \equiv 0$, and using a simple bang-bang control u_1 one easily reaches a point of the form $(0,0,q_3,0,-q_5,0)$ with $q_3, q_5 > 0$. Next one holds $u_1 \equiv 0$ and, using a suitable control u_2, tries to reach a point $(0,0,q_3,q_4,-q_5,-q_6)$ with all $q_i > 0$. But according to Lemma 3.6 this second step requires that the *available time* is sufficiently large (as determined by q_3). The subsequent estimates quantify this delicate trade-off, with the conclusion that, roughly speaking, if $x_6(T) < 0$, then $|x_5(T)| < CT^{38/3}$ for all T sufficiently small. The proof shows that this is true for all controls, not only for whatever clever combinations of the needle variations are used in the proof of Theorem 3.1. One of the key obstacles to making this heuristics into a general argument is that in such setting of *all possible* controls, there does not exist a clear notion of which of the two directions is obtained first. Thus the first objective is to identify an abstraction of *"which of the directions x_5 and x_6 is generated first."* Since

$$\int_0^T\!\!\left(\int_0^t x_1^2(s)\,ds\right)x_2^2(t)\,dt + \int_0^T\!\! x_1^2(t)\left(\int_0^t x_2^2(s)\,ds\right)dt = \left(\int_0^T\!\! x_1^2(t)\,dt\right)\cdot\left(\int_0^T\!\! x_2^2(t)\,dt\right)$$

and the system is invariant under the index permutation $(x_1,x_2,x_3,x_4,x_5,x_6) \mapsto (x_2,x_1,x_4,x_3,x_6,x_5)$, we may assume w.l.o.g. that

$$\int_0^T\left(\int_0^t x_1^2(s)\,ds\right)x_2^2(t)\,dt \ge \tfrac{1}{2}\left(\int_0^T x_1^2(t)\,dt\right)\left(\int_0^T x_2^2(t)\,dt\right), \tag{3.15}$$

which may be rewritten in the most useful form

$$\int_0^T\left(\int_0^t x_1^2(s)\,ds\right)x_2^2(t)\,dt \ge \tfrac{1}{2}\int_0^T\left(\int_0^T x_1^2(s)\,ds\right)x_2^2(t)\,dt. \tag{3.16}$$

The key advantage of this form is that the weight against which x_2^2 is integrated is now a constant, so that Lemma 3.6 applies. If $x_6(T) \ge 0$, nothing needs to be shown. Thus assume $x_6(T) < 0$. Then

$$0 > x_6(T) = \int_0^T \big(x_3^2(t)x_2^2(t) - x_2^7(t)\big)dt \ge \int_0^T x_2^2(t)\,\left(\tfrac{1}{2}\int_0^T x_1^2(s)\,ds - x_2^5(t)\right)dt \tag{3.17}$$

and thus

$$\xi_2 \stackrel{\text{def}}{=} \max_{0\le t\le T} x_2(t) > \left(\tfrac{1}{2}\int_0^T x_1^2(s)\,ds\right)^{\frac{1}{5}}. \tag{3.18}$$

The term on the right-hand side may be considered a *cost*, or *energy*, that is required to move $x_6(0) = 0$ to $x_6(T) < 0$. The next step is to find a lower bound for this energy in terms of the displacement. Using Lemma 3.7 with $\varepsilon = 1$ and $f = x_1$ gives the crude estimate

$$\int_0^T x_1^2(s)\,ds \geq 2 \cdot \left(\tfrac{1}{3}\right) \cdot \xi_1^3 \stackrel{\text{def}}{=} \tfrac{2}{3} \max_{0\leq t\leq T} x_1(t). \tag{3.19}$$

On the other hand, using Minkowski's inequality (backwards), we get

$$-x_5(T) = \int_0^T (x_1^7(t) - x_4(t)x_1^2(t))dt \leq \int_0^T |x_1^7(t)|dt \leq T \cdot \xi_1^7. \tag{3.20}$$

Combining (3.18), (3.19), and (3.20) yields

$$\xi_2 > \left(\tfrac{1}{2}\int_0^T x_1^2(s)\,ds\right)^{\frac{1}{5}} \geq \left(\tfrac{1}{2}\cdot\tfrac{2}{3}\,\xi_1^3\right)^{\frac{1}{5}} \geq \left(\tfrac{1}{3}\left(\frac{-x_5(T)}{T}\right)^{\frac{3}{7}}\right)^{\frac{1}{5}}. \tag{3.21}$$

Using that $\xi_2 \leq \frac{1}{2}T$ (from $u_2(\cdot)| \leq 1$ together with $x_2(0) = x_2(T) = 0$) implies

$$-x_5(T) \leq 3^{\frac{1}{5}} \cdot \xi_2^{\frac{35}{3}} \cdot T \leq 3^{\frac{1}{5}} \cdot 2^{-\frac{35}{3}} \cdot T^{\frac{38}{3}}. \tag{3.22}$$

Note that, in particular, if $x(T) = (0, 0, *, *, -\rho, -\rho) \in \mathcal{R}_0(T)$ with $\rho > 0$, then $\rho < CT^{38/3}$ (with $C = 3^{1/5} \cdot 2^{-35/3}$). □

THEOREM 3.8. *There exists a constant $C > 0$ such that for all sufficiently small $T > 0$ the image $\varphi(\mathcal{R}(T))$ of the reachable set of system* (3.1) *contains the open ball $B_0^\infty(CT^{40/3})$.*

COROLLARY 3.9. *The system* (3.1) *is STLOC about $y = 0$.*

COROLLARY 3.10. *The approximating cone $\overline{\mathcal{K}}_\varphi^{\frac{40}{3}}$ is the whole tangent space $T_0\mathbb{R}^4$.*

Main elements of the construction. These statements all follow directly from Theorem 4.3 and we refer to its proof for the full technical details. At this point we illustrate the critical elements in the construction showing a slightly weaker result. The general proof given in section 4 requires no major innovation but mainly involves keeping track of many more quantities.

The objective in this construction is to suitably combine the families of control variations

$$u_s^{(1)}(t) = \begin{cases}(+1,0) & \text{if } 0 \leq t < \frac{s}{2},\\ (-1,0) & \text{if } \frac{s}{2} \leq t < s\end{cases} \text{ and } u_s^{(2)}(t) = \begin{cases}(0,+1) & \text{if } 0 \leq t < \frac{s}{2},\\ (0,-1) & \text{if } \frac{s}{2} \leq t < s,\end{cases} \tag{3.23}$$

which steer to points $y(s, u_s^{(1)}) = (0, 0, -2^{-7}s^8, 0)$ and $y(s, u_s^{(2)}) = (0, 0, 0, -2^{-7}s^8)$ on the negative y_3 and y_4 axes to obtain families of control variations that steer to points in the third quadrant $y_3 < 0$ and $y_4 < 0$ in the plane $y_1 = y_2 = 0$. Thus consider the control

$$u(t) = \begin{cases}(+1,0) & \text{if} \quad 0 \leq t < t_1 = c\varepsilon^r,\\ (-1,0) & \text{if} \quad t_1 \leq t < t_2 = 2c\varepsilon^r,\\ (0,+1) & \text{if} \quad t_2 \leq t < t_3 = 2c\varepsilon^r + \varepsilon + \mu\varepsilon^m,\\ (0,-1) & \text{if} \quad t_3 \leq t < T = 2c\varepsilon^r + 2\varepsilon + 2\mu\varepsilon^m,\end{cases} \tag{3.24}$$

with $r, m \geq 1$ and constants c, μ to be determined (first think of $r = 1$ and $\mu = 0$).

Verify that at selected switching times the trajectory passes through

$$
\begin{aligned}
x(t_1) &= (c\varepsilon^r, 0, \tfrac{1}{3}c^3\varepsilon^{3r}, 0, -\tfrac{1}{8}c^8\varepsilon^{8r}, 0),\\
x(t_2) &= (\ 0\ , 0, \tfrac{2}{3}c^3\varepsilon^{3r}, 0, -\tfrac{1}{4}c^8\varepsilon^{8r}, 0),\\
x(t_3) &= (0, \varepsilon+\mu\varepsilon^m, \tfrac{2}{3}c^3\varepsilon^{3r}, \tfrac{1}{3}(\varepsilon+\mu\varepsilon^m)^3, -\tfrac{1}{4}c^8\varepsilon^{8r}\tfrac{2}{9}c^3\varepsilon^{3+3r} - \tfrac{1}{8}\varepsilon^8 + p_{36}\cdot\mu\varepsilon^m),\\
x(T) &= (\ 0\ ,\ 0\ , \tfrac{2}{3}c^3\varepsilon^{3r}, \tfrac{2}{3}(\varepsilon+\mu\varepsilon^m)^3, -\tfrac{1}{4}c^8\varepsilon^{8r}, \tfrac{4}{9}c^3\varepsilon^{3+3r} - \tfrac{1}{4}\varepsilon^8 + p_{46}\cdot\mu\varepsilon^m).
\end{aligned}
\tag{3.25}
$$

Here p_{36} and p_{46} are polynomial expressions in $(c, \varepsilon, \varepsilon^r, \mu\varepsilon^m)$. In particular,

$$
p_{46} = \left(\tfrac{4}{3}c^3\varepsilon^{3r+2} - 2\varepsilon^7\right) + q_{46}\cdot\mu\varepsilon^m, \tag{3.26}
$$

where q_{46} is a polynomial expression in $(c, \varepsilon, \varepsilon^r, \mu\varepsilon^m)$. First consider the case with $\mu = 0$ (no *perturbation*). If $r = 1$, then $x_6(2c\varepsilon^r + 2\varepsilon) > 0$ for all sufficiently small $\varepsilon > 0$. However, (still with $\mu = 0$) if one chooses $r \geq \frac{5}{3}$, then one may obtain $y_4(T) < 0$ for suitable choices of c. Choosing the critical value $r = \frac{5}{3}$ yields equality of the exponents in ε^8 and ε^{3+3r}, and thus by varying the parameter c one reaches the points $y(T) = \varepsilon^{\frac{40}{3}}\ (0, 0, -\frac{1}{4}c^8, \frac{4}{9}c^3 - \frac{1}{4})$ in the third quadrant of the plane $y_1 = y_2 = 0$.

Alternatively, fix the value $c^* = (9/16)^{1/3}$, which yields $y_4(T) = 0$ when $\mu = 0$. To reach a given point $\eta = (0, 0, \eta_3, \eta_4)$ with $\eta_3, \eta_4 < 0$ first choose $\varepsilon = (16/9)^{1/5}\cdot(-4\eta_3)^{3/40}$. Then, using that $p_{46}|_{\mu=0} \neq 0$, the implicit function theorem guarantees that (for $-\eta_4 > 0$ sufficiently small) one can solve $\eta_4 = \mu\varepsilon^m \cdot p_{46}(c, \varepsilon, \varepsilon^r, \mu\varepsilon^m)$ (with $m = \frac{40}{3}$) for $\mu > 0$.

Note that the total time $T = 2\varepsilon + 2c\varepsilon^{\frac{5}{3}} + 2\mu\varepsilon^{\frac{40}{3}} \stackrel{!}{=} s$ is of order ε (for $\varepsilon < 1$), and it is straightforward to reparameterize the controls choosing a constant multiple $s = a\varepsilon$ so that they qualify as a family of control variations at zero. Such linear reparameterization clearly does not affect the exponents such as $\frac{40}{3}$, thus yielding the statements in Theorem 3.8 and its corollaries. The construction of controls steering to any point $\eta \in \mathbb{R}^4$ with η_1, η_2 not necessarily zero requires no major innovation, just much book-keeping, and it is completely analogous to the proof of Theorem 4.3 given below. □

Remark 3.11. Recall that one commonly *linearly* reparameterizes needle variations when constructing convex combinations of tangent vectors as tangent vectors *of the same order*. What is new here is that one must consider nonlinear reparameterizations (here basically replace s by a power s^r with r strictly larger than one). As a consequence one may still obtain the convex combinations of the original tangent vectors here but not as tangent vectors of the same order. (Here the combination of eighth order tangent vectors yields at best tangent vectors of order (40/3) as shown above.) Further, much more severe implications for controllability properties in general are analyzed in section 5.

In summary—using the traditional language of STLC—the analysis of system (3.1) *quantified* the delicate interplay of simultaneous *neutralization* of two *obstructions* to controllability by (what initially might appear to be) *higher order* terms: The terms $\int x_4 x_1^2$ and $\int x_3 x_2^2$, which are always nonnegative, are 6th order in time, whereas the indefinite terms $\int x_2^7$ and $\int x_1^7$ are 8th order in time. The constructions in this section showed that it is indeed possible to reach points $p = (p_1, \ldots, p_6)$ with either $p_5 < 0$ or $p_6 < 0$ from $x(0) = 0$ in a time of order $\|p\|_\infty^{1/8}$, and even points p with both $p_5 < 0$ and $p_6 < 0$, but only in time of order at least $\|p\|_\infty^{3/38}$—as a result we have the nonconvex approximating cones for $8 \leq m < \frac{40}{3}$ sketched in Figure 3.1. The critical value obtained in this section is the exponent $\frac{5}{3} > 1$, which relates the maximal distance the variation can be translated to the *length* of the needle variation.

These phenomena never played a role in the classical study STLC as the *lower order obstructions* $\int x_1^2$ and $\int x_2^2$ cannot be *neutralized*, making any further study of the system in view of STLC irrelevant. Nonetheless, not only does this example demonstrate a noteworthy feature from the point of view of STLOC, but it also serves as the foundation of constructions in the next sections, which basically replace the role of the output map $\varphi\colon x \mapsto (x_1, x_2, x_5, x_6)$ by a nonstationary reference trajectory in order to obtain unexpected controllability properties.

4. A nonstationary reference trajectory. A slight modification of this system with output yields a corresponding result for controllability about (and optimality of) a *nonstationary reference trajectory*. It might well be possible to construct a similar example with fewer controls. We chose this implementation with four controls for its structural simplicity and because it allows one to easily build on the results of the previous section.

$$\begin{cases} \dot{x}_1 = u_1, & |u_1(\cdot)| \le 1, \\ \dot{x}_2 = u_2, & |u_2(\cdot)| \le 1, \\ \dot{x}_3 = x_1^2 + (1 + u_{01}), & |u_{01}(\cdot)| \le 1, \\ \dot{x}_4 = x_2^2 + (1 + u_{02}), & |u_{02}(\cdot)| \le 1, \\ \dot{x}_5 = x_4 x_1^2 - x_1^7, & x(0) = 0, \\ \dot{x}_6 = x_3 x_2^2 - x_2^7, & x^*(t) = (\,0, 0, t, t, 0, 0). \end{cases} \tag{4.1}$$

The key in this construction is that the *lower order* (i.e., apparently dominant) definite components $\int_0^T x_1^2(t)dt$ and $\int_0^T x_2^2(t)dt$ are aligned with the direction of the nonstationary reference trajectory and that the *zero speed* $\|\dot{x}\| = 0$ is on the *boundary* of the set of admissible *velocities* (on the hyperplane $x_1 = x_2 = 0$, which includes the reference trajectory). With the fixed boundary velocity $u_{01} = u_{02} = -1$ the system may be considered a two-input system (with controls (u_1, u_2)) about the *stationary reference trajectory* $x \equiv 0$ (basically system (3.1)). This two-input system is not STLC as obviously the (x_3, x_4)-directions are uncontrollable. (It is impossible to reach points x with $x_3 < 0$ or $x_4 < 0$ from $x = 0$.) But in (4.1) these uncontrollable directions are aligned with (as opposed to transversal to) the nonstationary reference trajectory, and thus controllability involves comparison with $\dot{x}_3 = \dot{x}_4 \equiv 1$ (as opposed to $\dot{x}_3 = \dot{x}_4 \equiv 0$).

With this design in mind, it is natural to combine standard techniques and results about STLC and convexity of approximating cones that apply to systems about an equilibrium point (i.e., first holding $u_{01} = u_{02} = -1$ fixed) with constructions unique to nonstationary reference trajectories. In particular, after having *generated* desired tangent vectors working in the vicinity of the *equilibrium point*, it is straightforward to *catch up* with the prescribed nonstationary reference trajectory by using $u_{01} > 0$ and $u_{02} > 0$; compare Figure 4.1 for a schematic illustration.

THEOREM 4.1. *For* $8 \le m < \frac{38}{3}$ *the approximating cones* $\overline{\mathcal{K}}_0^m$ *of system* (4.1) *are not convex as they have* inward corners *in the sense that*

$$(0, 0, 0, 0, v_5, v_6) \in \overline{\mathcal{K}}_0^m \iff (\, v_5 \ge 0 \ \text{ or } \ v_6 \ge 0\,). \tag{4.2}$$

Proof. First note that if $\xi(\cdot, u)$ and $x(\cdot, u)$ denote the solution curves of systems (3.1) and (4.1), respectively (for the same control), then clearly $x_5(t, u) \ge \xi_5(t, u)$ and $x_6(t, u) \ge \xi_6(t, u)$ for all $t \ge 0$. Thus, it is a direct consequence of Theorem 3.2 that if $m < \frac{38}{3}$, $v_5 < 0$, *and* $v_6 < 0$, then $(0, 0, 0, 0, v_5, v_6) \notin \mathcal{K}_0^m$.

In the other direction, we show that every $v = (0, 0, v_3, v_4, v_5, v_6) \in \mathbb{R}^6$ with $v_5 \ge 0$ or $v_6 \ge 0$ is contained in the cones $\overline{\mathcal{K}}_0^m$ for $m \ge 8$. (More general conclusions

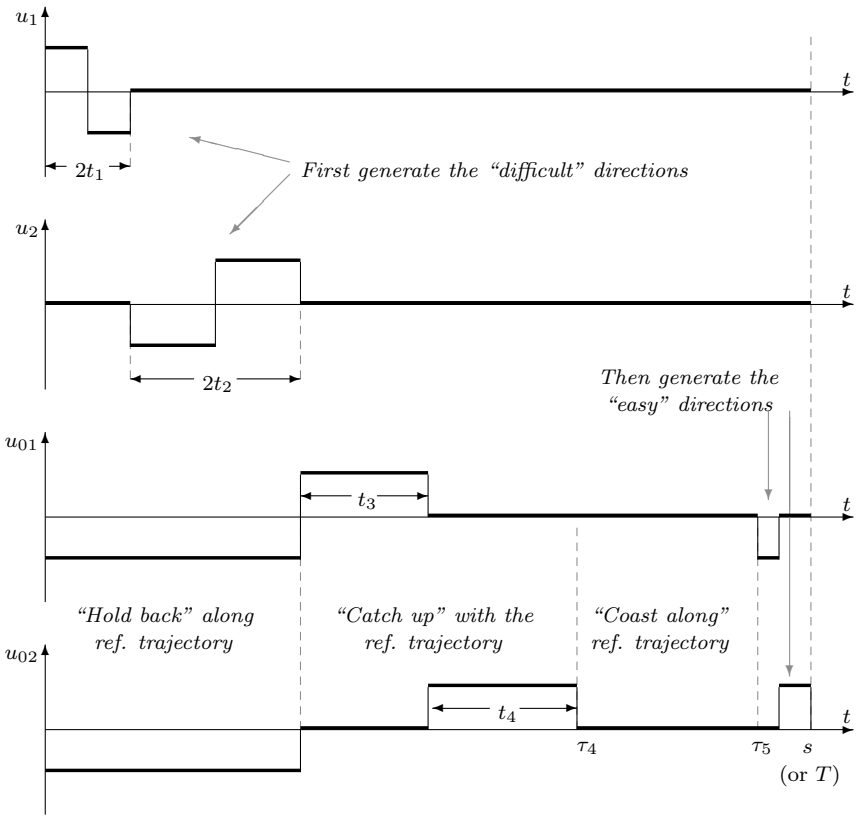

FIG. 4.1. *Schematic design of the needle variations for the proof of Theorem* 4.1.

allowing $v_1, v_2 \neq 0$ may be obtained using Theorem 4.3.) Suppose $0 < s < 1$ is given and $q = (0, 0, q_3, q_4, q_5, q_6) \in R^6$ is such that $\|q\|_\infty < (1/26)^8$ and w.l.o.g. $q_6 \geq 0$. We exhibit a family of control variations at zero, $u_s = u_{s,q}\colon [0, s] \mapsto [-1, 1]^4$, $0 \leq s \leq 1$, such that $x(s, u_s) = x^*(s) + s^8 q$. Write $t_1 = s\,(4|q_5|)^{1/8}$, and let $t_2 \geq 0$ be the unique nonnegative number such that $s^8 q_6 = \frac{2}{9} t_1^3 t_2^3 + \frac{1}{8} t_2^8$. Moreover, let $t_3 = 2t_1 + 2t_2 - \frac{2}{3} t_1^3$, and $t_4 = 2t_1 + 2t_2 - \frac{2}{3} t_2^3$. Write $\tau_4 = 2t_1 + 2t_2 + t_3 + t_4$ and $\tau_5 = s - s^8(|q_3| + |q_4|)$.

It is critical that $\tau_4 \leq \tau_5$. To see this, note that $t_i \leq 2s\|q\|_\infty^{1/8}$ for both $i = 1, 2$. Next $t_i \leq 8s\|q\|_\infty^{1/8}$ for both $i = 3, 4$, and thus $\tau_4 \leq 24s\|q\|_\infty^{1/8}$. On the other hand, $\tau_5 \geq s - 2s\|q\|_\infty^{1/8}$ (since both $s < 1$ and $\|q\|_\infty < 1$). Thus $\tau_5 - \tau_4 \geq s(1 - 26\|q\|_\infty^{1/8}) \geq 0$ follows from the assumption that $\|q\|_\infty < (1/26)^8$. Consequently, the following is a well-defined one-parameter family of control variations of $u^* \equiv (0, 0, 0, 0)$:

$$
u(t) = \begin{cases}
(\operatorname{sign}(q_5), 0, -1, -1) & \text{if} \quad 0 \leq t < t_1, \\
(-\operatorname{sign}(q_5), 0, -1, -1) & \text{if} \quad t_1 \leq t < 2t_1, \\
(0, 1, -1, -1) & \text{if} \quad 2t_1 \leq t < 2t_1 + t_2, \\
(0, -1, -1, -1) & \text{if} \quad 2t_1 + t_2 \leq t < 2t_1 + 2t_2, \\
(0, 0, 1, 0) & \text{if} \quad 2t_1 + 2t_2 \leq t < 2t_1 + 2t_2 + t_3, \\
(0, 0, 0, 1) & \text{if} \quad 2t_1 + 2t_2 + t_3 \leq t < \tau_4, \\
(0, 0, 0, 0) & \text{if} \quad \tau_4 \leq t < \tau_5, \\
(0, 0, \operatorname{sign}(q_3), 0) & \text{if} \quad \tau_5 \leq t < s - s^8|q_4|, \\
(0, 0, 0, \operatorname{sign}(q_4)) & \text{if} \quad s - s^8|q_4| \leq t < s.
\end{cases} \tag{4.3}
$$

Note that as a family of control variations *at zero* this is a family of needle variations. One easily verifies that at selected switching times the trajectory passes through

$$\begin{aligned} x(2t_1) &= (0,0,\tfrac{2}{3}t_1^3,0,s^8q_5,0),\\ x(2t_1+2t_2) &= (0,0,\tfrac{2}{3}t_1^3,\tfrac{2}{3}t_2^3,s^8q_5,s^8q_6),\\ x(\tau_4) &= (0,0,\tau_4,\tau_4,s^8q_5,s^8q_6),\\ x(\tau_5) &= (0,0,\tau_5,\tau_5,s^8q_5,s^8q_6),\\ x(s) &= (0,0,s,s,0,0)+s^8q. \end{aligned} \tag{4.4}$$

The flow Φ corresponding to the control $u^* \equiv 0$ satisfies $\Phi_{-s}(0,0,x_3,x_4,x_5,x_6) = (0,0,x_3-s,x_4-s,x_5,x_6)$, and thus $x(s,u_s) = x(s,u^*)+s^8\Phi_s(0,0,q_3,q_4,q_5,q_6)$. Consequently $(0,0,\lambda q_3,\lambda q_4,\lambda q_5,\lambda q_6) \in \overline{\mathcal{K}}_0^8$ for all $\lambda \geq 0$. □

The proof showed, in particular, that the vectors $(0,0,0,0,-1,0)$ and $(0,0,0,0,0,-1)$ are members of $\overline{\mathcal{K}}_0^8$ that are generated by *needle variations*. In contrast, according to Theorem 3.2, the convex combination $\frac{1}{2}(0,0,0,0,-1,-1)$ cannot at all be generated as an eighth order tangent vector. In particular, it cannot be generated by any (however clever) combination of needle variations. Nonetheless, in analogy to Corollary 3.10, in this particular system, this convex combination can still be generated as an even higher order tangent vector as shown below. First we establish a basic estimate needed later.

LEMMA 4.2. *If $0 < a < M^5$ and $0 < b < M^8$, then the unique positive root t_0 of the scalar function $f(t) = b + at^3 - \frac{1}{8}t^8$ satisfies $t_0 < 2M$.*

Proof. The existence of a unique positive root is elementary. Set $t_{00} = (8a)^{1/5}$, which is the first positive root of $t \mapsto at^3 - \frac{1}{8}t^8$. Since $f''(t) < 0$ for all $t \geq t_{00}$, the linear estimate $0 \overset{!}{=} f(t_0) \leq f(t_{00}) + f'(t_{00})(t_0 - t_{00}) = b - 5 \cdot 8^{2/5}a^{7/5}(t_0 - (8a)^{1/5})$ yields the bound

$$t_{00} \leq t_0 \leq t_{00} + \frac{b}{10 \cdot 2^{1/5}a^{7/5}} = \frac{10 \cdot 2^{4/5}a^{8/5} + b}{10 \cdot 2^{1/5}a^{7/5}}. \tag{4.5}$$

In the case that $b < a^{8/5}$, this immediately yields the desired estimate $t_0 < 2a^{1/5} \leq 2M$. Alternatively, if a is too small, i.e., if $b \geq a^{8/5}$, we find directly that $f(2b^{1/8}) \leq b + b^{5/8}(2b^{1/8})^3 - \frac{1}{8}(2b^{1/8})^8 = -23b < 0$, and hence the first positive zero t_0 of f again satisfies $x_0 \leq 2b^{1/8} < 2M$. □

THEOREM 4.3. *For every $T > 0$ sufficiently small, the reachable set $\mathcal{R}(T)$ of system (4.1) contains the open ball $B^\infty_{x^*(T)}((2^{-5}T)^{40/3})$ centered at $x^*(T)$.*

COROLLARY 4.4. *The system (4.1) is STLC about the reference trajectory $x^*(t) = (0,0,t,t,0,0)$.*

COROLLARY 4.5. *The approximating cone $\overline{\mathcal{K}}_0^{40/3}$ of system (4.1) is the whole tangent space $\overline{\mathcal{K}}_0^{40/3} = T_0\mathbb{R}^6$.*

Proof. Similar to the proof of Theorem 4.1 we explicitly construct for any given time $T > 0$ and any given point q sufficiently close to $x^*(T)$ a control $u = u_q\colon [0,T] \mapsto [-1,1]^4$ which steers the system to q. The main differences to the prior work is that now we need to also consider the case when $q_1 \neq 0$ and $q_2 \neq 0$. Note that since suitable open mapping principles for approximating cones for this setting are not available, we cannot rely on just generating tangent vectors.

Suppose $0 < T < 1$ and $q \in B_0^\infty(2^{-40}T^{40/3})$ are given. We consider only the case that both $q_5 < 0$ and $q_6 < 0$. All other cases can be handled analogously, albeit

with considerably simpler constructions. The basic construction for moving into the *difficult* directions $(0,0,0,0,*,*)$ is the same as in earlier proofs. These are followed by simple control actions that move into the *easy* directions. However, these later moves also have some effect on the difficult directions. Thus we first calculate these side effects and modify the initial controls to *overshoot* the targets in the difficult directions. The required corrections are calculated to cancel the integrals that result from (4.11) (also compare (4.12)).

$$\Delta q_{31} = q_1^2|q_2| = \int_0^{|q_2|} q_1^2\,dt, \qquad \Delta q_3 = \tfrac{1}{3}|q_1|^3 + |q_2|q_1^2 = \Delta q_{31} + \int_0^{|q_1|} (\sigma_1 t)^2 dt, \tag{4.6}$$

$$\Delta q_4 = \tfrac{1}{3}|q_2|^3 = \int_0^{|q_2|} t^2 dt, \tag{4.7}$$

$$\begin{aligned}\Delta q_{51} &= q_1^2|q_2|(T+q_4) - \tfrac{1}{2}q_1^2q_2^2 - \tfrac{1}{4}q_1^2q_2^4 - q_1^7|q_2| \\ &= \int_0^{|q_2|} \left((\tau_8 + q_4 - \Delta q_4 + (t + \tfrac{1}{3}t^3))q_1^2 - q_1^7\right)\,dt,\end{aligned} \tag{4.8}$$

$$\begin{aligned}\Delta q_5 &= \Delta q_{51} + \tfrac{1}{3}|q_1|^3(T+q_4) - \tfrac{1}{3}|q_1|^3|q_2| - \tfrac{1}{9}|q_1|^3|q_2|^3 - \tfrac{1}{12}q_1^4 - \tfrac{1}{8}|q_1|q_1^7 \\ &= \Delta q_{51} + \int_0^{|q_1|} \left((\tau_7 + t + q_4 - \Delta q_4)(\sigma_1 t)^2 + (\sigma_1 t)^7\right)\,dt,\end{aligned} \tag{4.9}$$

$$\begin{aligned}\Delta q_6 &= \tfrac{1}{3}|q_2|^3 T + \tfrac{1}{3}|q_2|^3 q_3 - \tfrac{1}{12}q_1^2q_2^4 - \tfrac{1}{12}q_2^4 - \tfrac{1}{8}|q_2|q_2^7 \\ &= \int_0^{|q_2|} \left((\tau_8 + q_3 - \Delta q_{31} + (q_1^2+1)t)(\sigma_2 t)^2 - (\sigma_2 t)^7\right)\,dt.\end{aligned} \tag{4.10}$$

What really matters in the subsequent construction is the size of these correction terms—clearly they are all of order at least 3 in $\|q\|_\infty$. Next let $t_1 = (-4(q_5 - \Delta q_5))^{\frac{1}{8}}$, $t_2 \geq 0$, be the smallest nonnegative number such that $(q_6 - \Delta q_6) = \frac{2}{9}t_1^3t_2^3 - \frac{1}{8}t_2^8$ (which is unique in the challenging case of $(q_6 - \Delta q_6) < 0$). Let $t_3 = 2t_1 + 2t_2 - \frac{2}{3}t_1^3$ and $t_4 = 2t_1 + 2t_2 - \frac{2}{3}t_2^3$. Write $\tau_3 = 2t_1 + 2t_2 + t_3$, $\tau_4 = 2t_1 + 2t_2 + t_3 + t_4$ and working backwards $\tau_8 = T - |q_2|$, $\tau_7 = \tau_8 - |q_1|$, $\tau_6 = \tau_7 - |q_4 - \Delta q_4|$, $\tau_5 = \tau_6 - |q_3 - \Delta q_3|$. Also use the abbreviations $\sigma_i = \operatorname{sign}(q_i)$ for $i = 1,2$ and $\sigma_i = \operatorname{sign}(q_i - \Delta q_i)$ for $i = 3,4$. Define the control $u = u_{q,T}\colon [0,T] \mapsto [-1,1]^4$ by

$$u(t) = \begin{cases} (1, & 0, & -1, & -1) & \text{if} & 0 \leq t < t_1, \\ (-1, & 0, & -1, & -1) & \text{if} & t_1 \leq t < 2t_1, \\ (0, & 1, & -1, & -1) & \text{if} & 2t_1 \leq t < 2t_1 + t_2, \\ (0, & -1, & -1, & -1) & \text{if} & 2t_1 + t_2 \leq t < 2t_1 + 2t_2, \\ (0, & 0, & 1, & 0) & \text{if} & 2t_1 + 2t_2 \leq t < \tau_3, \\ (0, & 0, & 0, & 1) & \text{if} & \tau_3 \leq t < \tau_4, \\ (0, & 0, & 0, & 0) & \text{if} & \tau_4 \leq t < \tau_5, \\ (0, & 0, & \sigma_3, & 0) & \text{if} & \tau_5 \leq t < \tau_6, \\ (0, & 0, & 0, & \sigma_4) & \text{if} & \tau_6 \leq t < \tau_7, \\ (\sigma_1, & 0, & 0, & 0) & \text{if} & \tau_7 \leq t < \tau_8, \\ (0, & \sigma_2, & 0, & 0) & \text{if} & \tau_8 \leq t < T. \end{cases} \tag{4.11}$$

It is essential to verify that $\tau_4 \le \tau_5$. Start with the crude estimate $|\Delta q_i| \le 2\|q\|_\infty^3 \le 2\|q\|_\infty$ for $i = 1, 2, 5, 6$. Next $t_1 \le 2\|q\|_\infty^{1/8}$. The critical estimate is for t_2—note the sign reversal in the defining equation in this construction compared to the one in the proof of Theorem 4.1: The earlier construction allowed one to estimate $s^8 q_6 = \frac{2}{9}t_1^3 t_2^3 + \frac{1}{8}t_2^8 \overset{!}{\ge} \frac{1}{8}t_2^8$ yielding $t_2 \le (8s^8 q\_6)^{1/8}$. Now in the interesting case $0 \ge (q_6 - \Delta q_6) = \frac{2}{9}t_1^3 t_2^3 - \frac{1}{8}t_2^8$ Lemma 4.2 applies with $a = \frac{2}{9}t_1^3 \le \frac{4}{9}\|q\|_\infty^{3/8}$, $b = (\Delta q_6 - q_6) \le 3\|q\|_\infty$, and $M = \|q\|_\infty^{3/40}$, yielding $t_2 \le 2\|q\|_\infty^{3/40}$. Easily $t_i \le 8\|q\|_\infty^{3/40}$ for $i = 3, 4$, and thus $\tau_4 \le 24\|q\|_\infty^{3/40}$.

On the other hand, $T - \tau_5 \le 4\|q\|_\infty + |\Delta q_5| + |\Delta q_6| \le 8\|q\|_\infty \le 8\|q\|_\infty^{3/40}$. Together with $0 < T < 1$ and $\|q\|_\infty < (2^{-5}T)^{\frac{40}{3}}$ this yields $\tau_5 - \tau_4 \ge T - 32\|q\|_\infty^{3/40} \ge 0$.

Note that $x_1(t) = x_2(t) = 0$ for all $t \in [2t_1 + 2t_2, \tau_7]$. Thus $x_5(\cdot)$ and $x_6(\cdot)$ are constant on this interval. It is straightforward to verify that at selected switching times the trajectory passes through

$$
\begin{aligned}
x(t_1) &= (t_1, 0, \tfrac{1}{3}t_1^3, 0, -\tfrac{1}{8}t_1^8, 0),\\
x(2t_1) &= (0, 0, \tfrac{2}{3}t_1^3, 0, q_5 - \Delta q_5, 0),\\
x(2t_1 + t_2) &= (0, t_2, \tfrac{2}{3}t_1^3, \tfrac{1}{3}t_2^3, q_5 - \Delta q_5, -\tfrac{1}{8}t_2^8 + \tfrac{2}{9}t_1^3 t_2^3),\\
x(2t_1 + 2t_2) &= (0, 0, \tfrac{2}{3}t_1^3, \tfrac{2}{3}t_2^3, q_5 - \Delta q_5, q_6 - \Delta q_6),\\
x(\tau_3) &= (0, 0, \tau_3, t_3 + \tfrac{2}{3}t_2^3, q_5 - \Delta q_5, q_6 - \Delta q_6),\\
x(\tau_4) &= (0, 0, \tau_4, \tau_4, q_5 - \Delta q_5, q_6 - \Delta q_6),\\
x(\tau_5) &= (0, 0, \tau_5, \tau_5, q_5 - \Delta q_5, q_6 - \Delta q_6),\\
x(\tau_6) &= (0, 0, \tau_6 + q_3 - \Delta q_3, \tau_6, q_5 - \Delta q_5, q_6 - \Delta q_6),\\
x(\tau_7) &= (0, 0, \tau_7 + q_3 - \Delta q_3, \tau_7 + q_4 - \Delta q_4, q_5 - \Delta q_5, q_6 - \Delta q_6),\\
x(\tau_8) &= (q_1, 0, \tau_8 + q_3 - \Delta q_{31}, \tau_8 + q_4 - \Delta q_4, q_5 - \Delta q_{51}, q_6 - \Delta q_6),\\
x(T) &= (q_1, q_2, T + q_3, T + q_4, q_5, q_6). \qquad \square
\end{aligned}
\tag{4.12}
$$

Note that the construction above was given for a fixed terminal time T. But it is easily modified to yield families of control variations $u_s\colon [0, s] \mapsto U$ at zero by replacing T by s and q by $s^{40/3}q$. This yields the curve of endpoints $x(s, u_s) = (0, 0, s, s, 0, 0) + s^{40/3}q$ yielding $q \in \overline{\mathcal{K}}_0^{40/3}$.

In summary, this section modified the system (3.1) so that its STLOC properties translate into even less expected properties of STLC about a nonstationary reference trajectory. The key step in the construction is to align the *obstructions* $\int x_1^2$ and $\int x_2^2$ with the reference trajectory and to utilize control values that lie on the boundary of the control set U. As a result, the *difficult* directions (negative in x_5 and negative in x_6) can only be generated by *needle variations* at $t = 0$, which moreover can only be moved by time intervals whose length is a power of the length of the variation that is strictly larger than 1 (here 5/3). The tangent cones again exhibit loss of convexity for $8 \le m < \frac{38}{3}$, as illustrated in Figure 3.1.

5. Delicate structural instability. This section analyzes small modifications of the systems considered in the preceding sections. The main result is that what at first appear to be *"at a higher order"* perturbations can nonetheless destroy the delicate controllability exhibited in the earlier sections. More specifically, we exhibit a polynomial cascade system which has nonconvex approximating cones generated by needle variations and which is not controllable.

Returning to the discussion of the system (4.1), we recall that cones $\overline{\mathcal{K}}_0^8$ are not convex. While the vectors $(0,0,0,0,-1,0) \in \overline{\mathcal{K}}_0^8$ and $(0,0,0,0,0,-1) \in \overline{\mathcal{K}}_0^8$ could be generated by needle variations at zero as 8th order tangent vectors, it was shown that it is impossible to obtain convex combinations of these as tangent vectors of the same order. However, such convex combinations can be generated as even higher order tangent vectors, e.g., $(0,0,0,0,-\frac{1}{2},-\frac{1}{2}) \in \overline{\mathcal{K}}_0^{40/3}$ by fairly delicate constructions. As we illustrate next, such constructions can be rendered impossible through quite innocent-looking perturbations. Similar to section 3, we start again with an affine system with output and a stationary reference trajectory:

$$\text{(5.1)} \qquad \begin{cases} \dot z_1 = u_1, & |u_1(\cdot)| \le 1, \\ \dot z_2 = u_2, & |u_2(\cdot)| \le 1, \\ \dot z_3 = z_1^2, & z(0) = 0, \\ \dot z_4 = z_2^2, & \varphi(z) = (z_1, z_2, z_5, z_6), \\ \dot z_5 = z_4 z_1^2 - z_1^7 + z_1^{10} + z_2^{10}, & \\ \dot z_6 = z_3 z_2^2 - z_2^7 + z_1^{10} + z_2^{10}. & \end{cases}$$

It is clear that the added 10th order terms do not at all affect the construction given in the proof of Theorem 3.2 and Corollary 3.4, and thus it is still true that the 8th order cone is nonconvex.

PROPOSITION 5.1. *For the system* (5.1), $(0,0,a,b) \in \overline{\mathcal{K}}_\varphi^8$ *if and only if* $a \ge 0$ *or* $b \ge 0$.

However, we will show that the perturbations destroy the controllability, and the tangent cones of all orders $m \ge 8$ are not convex.

THEOREM 5.2. *For* $0 \le T < 1$ *the image* $\varphi(\mathcal{R}(T))$ *of the reachable set of system* (5.1) *does not contain any points of the form* $(0,0,\eta_3,\eta_4)$ *with* $\eta_3 < 0$ *and* $\eta_4 < 0$.

COROLLARY 5.3. *The system* (5.1) *is not* STLOC *about* $y = 0$.

COROLLARY 5.4. *For the system* (5.1) *and* $m \ge 8$, *both* $(0,0,-1,0) \in \overline{\mathcal{K}}_\varphi^m$ *and* $(0,0,0,-1) \in \overline{\mathcal{K}}_\varphi^m$ *are generated by needle variations, but if* $\eta_3, \eta_4 < 0$, *then* $(0,0,\eta_3,\eta_4) \notin \overline{\mathcal{K}}_\varphi^m$ *for all* $m > 0$. *In particular, for all* $m > 0$, *the convex combination* $(0,0,-\frac{1}{2},-\frac{1}{2}) \notin \overline{\mathcal{K}}_\varphi^m$.

Proof. We write z and x for the corresponding solutions of the perturbed and unperturbed systems (3.1) and (5.1); i.e., $z_i(t,u) = x_i(t,u)$ for $i = 1,2,3,4$, while for $i = 5,6$

$$\text{(5.2)} \qquad z_i(t,u) = x_i(t,u) + \int_0^t \big(x_1^{10}(\tau,u) + x_2^{10}(\tau,u)\big)\, d\tau \quad \text{for all } \ 0 \le t \le T.$$

W.l.o.g. again assume that (3.15) holds (else permute in the following arguments the indices $(1,2,3,4,5,6) \mapsto (2,1,4,3,6,5)$). If $x_5(T,u) \ge 0$ (or $x_6(T,u) \ge 0$), then also $z_5(T,u) \ge 0$ (or $z_6(T,u) \ge 0$, respectively), and nothing needs to be shown. Thus suppose $x_5(T,u) < 0$ and $x_6(T) < 0$. Then use Lemma 3.7 and the key estimate (3.21) to obtain

$$\text{(5.3)} \qquad \int_0^T x_2^{10}(t)\, dt = \int_0^T |x_2(t)|^{10} dt \ge \tfrac{2}{11}\, \xi_2^{11} \ge \tfrac{2}{11} \left(\left(\frac{-x_5(T)}{T} \right)^{\frac{3}{35}} \right)^{11} \ge |x_5(T)| > 0.$$

If $T < 1$, clearly $|x_5(T)| < 1$. Together with $\frac{33}{35} < 1$ this shows that $z_5(T) = x_5(T) + \int_0^T |x_2(t)|^{10} dt \ge 0$ if $z_6(T) < 0$. ∎

For corresponding results for loss of controllability about a nonstationary reference trajectory, consider the system

$$
\begin{cases}
\dot{z}_1 = u_1, & |u_1(\cdot)| \le 1,\\
\dot{z}_2 = u_2, & |u_2(\cdot)| \le 1,\\
\dot{z}_3 = z_1^2 + (1+u_{01}), & |u_{01}(\cdot)| \le 1,\\
\dot{z}_4 = z_2^2 + (1+u_{02}), & |u_{02}(\cdot)| \le 1,\\
\dot{z}_5 = z_4 z_1^2 - z_1^7 + z_1^{10} + z_2^{10}, & z(0) = 0,\\
\dot{z}_6 = z_3 z_2^2 - z_2^7 + z_1^{10} + z_2^{10}, & z^*(t) = (\,0,0,t,t,0,0).
\end{cases}
\tag{5.4}
$$

By combining the arguments from the previous sections, one readily obtains the following statements. In particular, the 10th order terms in (5.4) do not affect the constructions of the 8th order tangent vectors; compare the proof of Theorem 3.2.

PROPOSITION 5.5. *For the system* (5.4), $(0,0,0,0,a,b) \in \overline{\mathcal{K}}_0^8$ *if and only if* $a \ge 0$ *or* $b \ge 0$.

On the other hand the estimate (5.3) in the proof of Theorem 5.2 applies also to the system with nonstationary reference trajectory.

THEOREM 5.6. *For* $0 \le T < 1$ *the reachable set* $\mathcal{R}(T)$ *of system* (5.4) *does not contain any points of the form* $(0,0,0,0,q_5,q_6)$ *with* $q_5 < 0$ *and* $q_6 < 0$.

COROLLARY 5.7. *The system* (5.4) *is not* STLC *about* $z^*(t) = (0,0,t,t,0,0)$.

The control variations constructed to generate the tangent vectors $(0,0,0,0,-1,0)$ and $(0,0,0,0,0,-1)$ satisfy the requirements of Definition 2.5. Together with Theorem 5.6 this allows us to state the last corollary for both notions of tangent vectors $\mathcal{K}_0^m$ and $\mathcal{K}_T^m$.

COROLLARY 5.8. *For the system* (5.4), $m \ge 8$, $0 \le T < 1$, *none of the cones* $\overline{\mathcal{K}}_T^m$ *is convex. In particular,* $(0,0,0,0,-1,0) \in \overline{\mathcal{K}}_T^m$ *and* $(0,0,0,0,0,-1) \in \overline{\mathcal{K}}_T^m$ *are generated by needle variations at zero, but* $(0,0,0,0,-\frac{1}{2},-\frac{1}{2}) \notin \overline{\mathcal{K}}_T^m$ *for all* $m > 0$ *and* $T \ge 0$.

In summary, this section exploited the lack of convexity of tangent cones of order $8 \le m < \frac{38}{3}$ to *destroy* the controllability properties of systems (3.1) and (4.1) by adding some *perturbations*, which at first view may appear to be of even higher order. While in the systems in the previous sections needle variations could still be combined to generate convex combinations of tangent vectors, albeit at a higher order, these *perturbed* systems make it entirely impossible to obtain convex combinations (at any order) of tangent vectors that are generated by needle variations.

6. Conclusion and further outlook. Summarizing, the analysis of the custom-designed systems in this article has yielded two major insights. The immediate result is a counterexample for a long-standing natural conjecture about needle variations.

- The most general notion of a tangent vector (which works well for stationary reference trajectories) does not necessarily yield convex cones either for nonstationary reference trajectories or for systems with output.
- Narrower notions of tangent vectors that yield convex cones, e.g., by requiring explicitly that needle variations must be *movable* by fixed times, may miss the controllability of some systems. (Recall in section 4 that the systems were controllable, but this cannot be detected with needle variations that require standard *movability*.)
- The common *technical* conditions on *needle variations* are *not* stated only because of *not yet discovered* stronger theorems, but they are essential even for some of the most benign systems. In a nutshell, the *time(s)* at which needle variations are generated must be movable—though not necessarily by a fixed distance, but by a distance of the same order of magnitude as the

duration of the needle variation. Movability by a smaller amount, e.g., some power larger than one, is not sufficient; compare Remark 3.11. Otherwise, one should expect a lack of convexity of the *cones* of tangent vectors and a consequent failure to satisfy the hypotheses for open mapping theorems that are essential for making the cones into meaningful *"approximating cones."*

On a deeper level these examples cast further doubt on the structural stability and robustness of the STLC property. It is well known that simple Taylor approximations do not preserve controllability (see, e.g., [3]). For example, the system $\dot{x}_1 = u$, $\dot{x}_2 = x_1$, $\dot{x}_3 = x_2^2 + x_1^3$ [21] is STLC about $x(0) = 0$ and $|u(\cdot)| \leq 1$, but its quadratic Taylor approximation $\dot{y}_1 = u$, $\dot{y}_2 = y_1$, $\dot{y}_3 = y_2^2$ is not STLC. Instead, many controllability results of the past two decades rely on nilpotent approximating systems [4, 12] which are based on *graded structures*: For a fixed set of local coordinates $(x_1, \ldots, x_n)$ on $\mathbb{R}^n$ and weights $r_1, \ldots, r_n \geq 1$, consider the family of dilations $\Delta: \mathbb{R}^+ \times \mathbb{R}^n \mapsto \mathbb{R}$ defined by $\Delta_s(x) = (s^{r_1}x_1, \ldots, s^{r_n}x_n)$. A function $\varphi: \mathbb{R}^n \mapsto \mathbb{R}^n$ is called homogeneous of order m with respect to Δ if $\varphi \circ \Delta_s = s^m \varphi$. A vector field f is called homogeneous of order k if (considered as a first order partial differential operator) it maps (smooth) homogeneous functions of any order m to homogeneous functions of order $m + k$. To *approximate* the system (2.1) by a *nilpotent* system of the same form, replace each vector field f_i by the *principal part* g_i of the expansion of f_i into a (generally infinite) series of homogeneous vector fields. If all vector fields g_i have negative degrees of homogeneity, then all are polynomial vector fields of *cascade form*, and they generate a *nilpotent* Lie algebra; see the survey [12] for details. Roughly speaking, the fundamental result is that if such *homogeneous* nilpotent approximating system with vector fields g_i is STLC, then the original system is *STLC*; see, e.g., [4, 22]. By varying the construction of the local coordinates and dilation exponents r_i, several major results for STLC follow; see, e.g., [4, 21, 22]. On the other hand, it is known that there exist polynomial systems that are STLC, but for them any such homogeneous nilpotent approximating system is not STLC [15].

Returning to the systems (3.1) and (4.1) discussed in this article which are STLOC and STLC, respectively, these are similar to the system in [15], as any of the standard nilpotent approximation schemes will simply delete the terms x_1^7 and x_2^7 on the right-hand side, yielding homogeneous nilpotent approximating systems that are not STLOC nor STLC. Since the example constructed in [15], one has been searching for more general approximating schemes that would *recognize* the need to preserve terms such as x_1^7 and x_2^7 in the above systems, which are essential for their controllability and which would only truncate *truly higher order* terms that are not essential for controllability. However, the analysis in the preceding section of the systems (5.1) and (5.4) raises new questions as the inclusion of the even higher order terms x_1^{10} and x_2^{10} again causes loss of controllability. One naturally wonders whether it is possible to construct such an infinite chain, which could possibly lead to a negative answer to the long-standing question of whether STLC (of analytic systems) is *finitely determined* [2].

Acknowledgments. The authors thank the anonymous referees and H. Frankowska who made numerous suggestions to help improve the article.

BOUNDARY FEEDBACK STABILIZATION OF SHALLOW SHELLS*

SHUGEN CHAI†, YUXIA GUO‡, AND PENG-FEI YAO§

Abstract. We consider the stabilization of the shallow shell by boundary feedbacks where the model has a middle surface of any shape. First, we put the shallow shell model in a suitable semigroup scheme. The existence, the uniqueness, and the properties of solutions to the shallow shell are then treated by the semigroup approach and the regularity of elliptic boundary value problems. Finally, we establish the uniform energy decay rate for the shallow shell under some checkable geometric conditions on the middle surface.

Key words. shallow shell, regularity, boundary stabilization

1. Introduction.

We are concerned with the stabilization of the shallow shell by boundary feedbacks. This issue has been analyzed a great deal for the wave equation and plates; see Lagnese [8], Lagnese and Lions [9], Lasiecka and Triggiani [10], [11], and many others. For thin shells, we know very little about this problem. A circular cylindrical shell is considered by Chen, Coleman, and Liu [3] and a spherical shell by Lasiecka, Triggiani, and Valente [12], and Triggiani [17]. In the above cases the models are expressed in terms of special coordinates and all the work takes place in those coordinates.

We study the shallow shell model where the tensor of change of curvature is given by the Hessian of the normal displacement; see Ciarlet [4], Mason [13], Niordson [14], or Koiter [7]. The model is written into a coordinate free form by using the global geometry analysis in Yao [20]. This is one of the simplest thin shell models. For other models, for example, the Koiter model where the change of the curvature tensor is much more complicated, the control problems seem to be even more difficult; see Chai and Yao [2].

We shall carry out the control scheme, which is given in Lagnese [8] for the boundary stabilization of thin plates, to study the boundary stabilization of the shallow shell and we obtain the exponential stabilization under very weak geometrical conditions. There are some difficulties we have to overcome.

One of the key problems in getting the uniform energy decay rate is obtaining the regularity of solutions to the shallow shell. By using some ideas in Lagnese [8] and the geometry approach, we address the resulting closed-loop system of the shallow shell after exerting the boundary feedback controls in an appropriate semigroup scheme so that the regularity in the time variable follows from the semigroup theory; see

Pazy [15]. In addition, the regularity we need in the spatial variables is obtained by using the elliptic boundary value theory; see Agmon, Douglis, and Nirenberg [1]. We mention that, for the static problem, the existence, uniqueness, and regularity (i.e., the ellipticity) have been thoroughly treated by Ciarlet [4].

Another problem is that we have to develop some trace estimates for solutions of the closed-loop system which permit certain boundary traces to be expressed in terms of other traces modulo lower-order interior terms. We use Horn [6] to obtain the trace estimates on the tangential component of solutions of the shallow shell and Lasiecka and Triggiani [11] on the bending component. Those results allow us to have the stabilization under very weak geometrical conditions. We mention that trace estimates for the wave equation were developed in Lasiecka and Triggiani [10] to eliminate the geometric constraints.

1.1. Some notation. We introduce some notations in preparation for the shallow shell.

Denote the usual inner product in $\mathbb{R}^3$ by $\langle \cdot, \cdot \rangle$, i.e., the dot product. Let M be a surface in $\mathbb{R}^3$. For simplicity, M is assumed to be smooth. Surface M produces a natural Riemannian manifold of dimension 2 with the induced metric in $\mathbb{R}^3$. We denote this induced metric on surface M by g or by $\langle \cdot, \cdot \rangle$, as is convenient. For each $x \in M$, M_x is the tangential space of M at x. It is assumed that surface M is orientable with the unit normal field N on M. Denote the set of all vector fields on M by $\mathcal{X}(M)$. Denote the set of all k-order tensor fields and the set of all k-forms on M by $T^k(M)$ and $\Lambda^k(M)$, respectively, where k is a nonnegative integer. Then

$$\Lambda^k(M) \subset T^k(M).$$

In particular, $\Lambda^0(M) = T^0(M) = C^\infty(M)$ is the set of all C^∞ functions on M and

$$T^1(M) = T(M) = \Lambda(M) = \mathcal{X}(M),$$

where $\Lambda(M) = \mathcal{X}(M)$ is in the following isomorphism: for $X \in \mathcal{X}(M)$ given, the equation

$$U(Y) = \langle Y, X \rangle \qquad \forall\, Y \in \mathcal{X}(M)$$

determines a unique $U \in \Lambda(M)$.

It is well known that, for each $x \in M$, k-order tensor space T_x^k on M_x is an inner product space defined as follows. Let e_1, e_2 be an orthonormal basis of M_x. For any α, $\beta \in T_x^k$, $x \in M$, the inner product is given by

$$\langle \alpha, \beta \rangle_{T_x^k} = \sum_{i_1,\dots,i_k=1}^{2} \alpha(e_{i_1}, \dots, e_{i_k}) \beta(e_{i_1}, \dots, e_{i_k}) \qquad \text{at } x. \tag{1.1}$$

In particular, for $k = 1$ definition (1.1) becomes

$$g(\alpha, \beta) = \langle \alpha, \beta \rangle_{T_x} = \langle \alpha, \beta \rangle \qquad \forall\, \alpha, \beta \in M_x,$$

that is, the induced inner product of M_x in $\mathbb{R}^3$.

Let Ω be a bounded region of surface M with a regular boundary Γ or without boundary (when Γ is empty). From (1.1), $T^k(\Omega)$ are then inner product spaces in the following sense:

$$(T_1, T_2)_{T^k(\Omega)} = \int_\Omega \langle T_1, T_2 \rangle_{T_x^k}\, dx \qquad \forall\, T_1, T_2 \in T^k(\Omega), \tag{1.2}$$

where dx is the volume element of surface M in its Riemaniann metric g.

The completions of $T^k(\Omega)$ in inner products (1.2) are denoted by $L^2(\Omega, T^k)$. In particular, $L^2(\Omega, \Lambda) = L^2(\Omega, T)$. $L^2(\Omega)$ is the completion of $C^\infty(\Omega)$ in the following inner product:

$$(f, h)_{L^2(\Omega)} = \int_\Omega f(x)h(x)\, dx \qquad \forall\, f,\, h \in C^\infty(\Omega).$$

Let D be the Levi–Civita connection on M in the induced metric g of surface M. For $U \in \mathcal{X}(M)$, DU is the covariant differential of U which is a 2-order covariant tensor field in the following sense:

$$DU(X, Y) = D_Y U(X) = \langle D_Y U,\, X\rangle \qquad \forall\, X,\, Y \in M_x,\, x \in M. \tag{1.3}$$

We also define $D^*U \in T^2(M)$ by

$$D^*U(X, Y) = DU(Y, X) \qquad \forall\, X,\, Y \in M_x,\, x \in M, \tag{1.4}$$

that is, $D^*U \in T^2(M)$ is the transpose of DU. For any $T \in T^2(M)$, the trace of T at $x \in M$ is defined by

$$\mathrm{tr}T = \sum_{i=1}^{2} T(e_i, e_i),$$

where $e_1,\ e_2$ is an orthonormal basis of M_x. It is obvious that $\mathrm{tr}T \in C^\infty(M)$ if $T \in T^2(M)$.

For $T \in T^k(M)$ and $X \in \mathcal{X}(M)$, we define $l_X T \in T^{k-1}(M)$ by

$$l_X T(X_1, \ldots, X_{k-1}) = T(X, X_1, \ldots, X_{k-1}) \qquad \forall\, X_1,\, \ldots,\, X_{k-1} \in \mathcal{X}(M).$$

The Sobolev space $H^k(\Omega)$ is the completion of $C^\infty(\Omega)$ with respect to the norm

$$\|f\|^2_{H^k(\Omega)} = \sum_{i=1}^{k} \|D^i f\|^2_{L^2(\Omega, T^i)} + \|f\|^2_{L^2(\Omega)}, \qquad f \in C^\infty(\Omega), \tag{1.5}$$

where $D^i f$ is the ith covariant differential of f in the induced metric g of M which is an i-order tensor field on Ω, and $\|\cdot\|_{L^2(\Omega, T^i)}$ and $\|\cdot\|_{L^2(\Omega)}$ are the induced norms in inner products (1.1)–(1.2), respectively. For details on Sobolev spaces on Riemannian manifolds, we refer to Hebey [5] or Taylor [16].

Another important Sobolev space for us is $H^k(\Omega, \Lambda)$, defined by

$$H^k(\Omega, \Lambda) = \{\, U \,|\, U \in L^2(\Omega, \Lambda),\ D^i U \in L^2(\Omega, T^{i+1}),\ 1 \le i \le k \,\}$$

with inner product

$$(U, V)_{H^k(\Omega,\Lambda)} = \sum_{i=0}^{k} (D^i U, D^i V)_{L^2(\Omega, T^{i+1})} \qquad \forall\, U,\ V \in H^k(\Omega, \Lambda);$$

for example, see Wu [18]. In particular, $H^0(\Omega, \Lambda) = L^2(\Omega, \Lambda)$.

For $\hat{\Gamma} \subset \Gamma$, set

$$H^1_{\hat{\Gamma}}(\Omega, \Lambda) = \{\, W \,|\, W \in H^1(\Omega, \Lambda),\ W|_{\hat{\Gamma}} = 0 \,\}, \tag{1.6}$$

$$H^2_{\hat{\Gamma}}(\Omega) = \left\{ w \,|\, w \in H^2(\Omega),\ w\Big|_{\hat{\Gamma}} = \frac{\partial w}{\partial n}\Big|_{\hat{\Gamma}} = 0 \right\}. \tag{1.7}$$

In particular, $H^1_0(\Omega, \Lambda) = H^1_\Gamma(\Omega, \Lambda)$ and $H^2_0(\Omega) = H^2_\Gamma(\Omega)$.

1.2. Model. We assume that the middle surface of the shell is a bounded region Ω of surface M in $\mathbb{R}^3$ before the deformation takes place. The shell, a body in $\mathbb{R}^3$, is defined by

$$\mathcal{S} = \{\, p \,|\, p = x + zN(x),\ x \in \Omega,\ -h/2 < z < h/2 \,\},$$

where h is the thickness of the shell, small.

Denote by $\eta(x)$ the displacement vector of point x of the middle surface. We decompose the displacement vector η into a sum

$$\eta(x) = W(x) + w(x)N(x), \qquad x \in \Omega,\ W(x) \in M_x, \tag{1.8}$$

i.e., W and w are components of η on the tangent plane and on the normal of the undeformed middle surface Ω, respectively. The linearized strain tensor and the change of curvature tensor of the middle surface Ω are given by

$$\Upsilon(\eta) = \frac{1}{2}(DW + D^*W) + w\Pi \tag{1.9}$$

and

$$\rho(\eta) = -D^2 w \tag{1.10}$$

in a coordinate free form, respectively, where Π is the second fundamental form of surface M and D^2w the Hessian of w, which are justified for a shallow shell. For (1.9) and (1.10), we refer to Ciarlet [4], Niordson [14], Mason [13], or to Koiter [7].

Remark 1.1. If we express the two tensors (1.9) and (1.10) by a coordinate, they look complicated. Let the middle surface of the shell be given by a coordinate

$$\varphi = (\varphi_1(x_1, x_2),\ \varphi_2(x_1, x_2),\ \varphi_3(x_1, x_2)), \qquad (x_1, x_2) \in \mathbb{R}^2.$$

Set

$$\mathbf{a}_\alpha = \left(\frac{\partial \varphi_1}{\partial x_\alpha},\ \frac{\partial \varphi_2}{\partial x_\alpha},\ \frac{\partial \varphi_3}{\partial x_\alpha}\right), \qquad W = w_1\mathbf{a}_1 + w_2\mathbf{a}_2.$$

Then the tensors (1.9) and (1.10) become

$$\Upsilon_{\alpha\beta} = \frac{1}{2}(w_{\alpha|\beta} + w_{\beta|\alpha}) - b_{\alpha\beta}w,$$

$$\rho_{\alpha\beta} = -w|_{\alpha\beta},$$

where $1 \le \alpha,\ \beta \le 2$, $b_{\alpha\beta} = -\partial_{\mathbf{a}_\alpha} N \cdot \partial_{\mathbf{a}_\beta}$ is the second fundamental form, and

$$w_{\alpha|\beta} = \partial_{\mathbf{a}_\beta} w_\alpha - \Gamma^\lambda_{\alpha\beta} w_\lambda, \qquad w|_{\alpha\beta} = \partial_{\mathbf{a}_\beta}\partial_{\mathbf{a}_\alpha} w - \Gamma^\lambda_{\alpha\beta} w.$$

The shell strain energy associated with a displacement field η of the middle surface Ω can be written as

$$\mathcal{B}_1(\eta, \eta) = \frac{Eh}{1-\mu^2} \int_\Omega B(\eta, \eta)\, dx, \tag{1.11}$$

where

$$B(\eta, \eta) = a(\Upsilon(\eta), \Upsilon(\eta)) + \gamma a(\rho(\eta), \rho(\eta)), \qquad \gamma = h^2/12, \tag{1.12}$$

$$a(T_1, T_1) = (1-\mu)\langle T_1, T_1\rangle_{T_x^2} + \mu(\mathrm{tr}T_1)^2, \qquad T_1 \in T^2(\overline{\Omega}), \tag{1.13}$$

for $x \in \Omega$, where E, μ, respectively, denote Young's modulus and Poisson's coefficient of the material.

Thus, with expression (1.11) we are able to associate the following symmetric bilinear form, directly defined on the middle surface Ω:

$$\mathcal{B}(\eta, \zeta) = \int_\Omega B(\eta, \zeta)\, dx, \tag{1.14}$$

where η is given in (1.8) and

$$\zeta = U + uN, \qquad U(x) \in M_x, \quad x \in \Omega.$$

Denote by H and by k the mean curvature and the Gauss curvature of surface M, respectively. From Yao [20], we have the following Green's formula for the shallow shell.

Formula I. Let the bilinear form $\mathcal{B}(\cdot,\cdot)$ be given in (1.14). For all sufficiently smooth $\eta = (W, w)$ and $\varsigma = (U, u)$, we have

$$\mathcal{B}(\eta, \varsigma) = (\mathcal{A}\eta, \varsigma)_{L^2(\Omega,\Lambda)\times L^2(\Omega)} + \int_\Gamma \partial(\mathcal{A}\eta, \varsigma) d\Gamma, \tag{1.15}$$

where

$$\partial(\mathcal{A}\eta, \varsigma) = v_1(\eta)\langle U, n\rangle + v_2(\eta)\langle U, \tau\rangle + v_3(\eta)\frac{\partial u}{\partial n} + v_4(\eta)u, \tag{1.16}$$

n, τ are the normal and the tangential along curve Γ, respectively,

$$\mathcal{A}\eta = \begin{pmatrix} -\Delta_\mu W - (1-\mu)kW - \mathcal{F}(w) \\ \gamma[\Delta^2 w - (1-\mu)\delta(kdw)] + (H^2 - 2(1-\mu)k)w + \mathcal{G}(W) \end{pmatrix}, \tag{1.17}$$

Δ_μ is of the Hodge-Laplacian type, applied to the 1-form (or equivalently vector fields), defined by

$$\Delta_\mu = -\left(\frac{1-\mu}{2}\delta d + d\delta\right), \tag{1.18}$$

d the exterior differential, δ the formal adjoint of d, Δ the Laplacian on manifold M,

$$\begin{cases} \mathcal{F}(w) &= (1-\mu)l_{dw}\Pi + \mu H dw + w dH, \\ \mathcal{G}(W) &= (1-\mu)\langle DW, \Pi\rangle_{T_x^2} - \mu H \delta W, \end{cases} \tag{1.19}$$

and

$$\begin{cases} v_1(\eta) &= (1-\mu)\Upsilon(\eta)(n,n) + \mu(wH - \delta W), \\ v_2(\eta) &= (1-\mu)\Upsilon(\eta)(n,\tau), \\ v_3(\eta) &= \gamma[\Delta w - (1-\mu)D^2 w(\tau,\tau)], \\ v_4(\eta) &= -\gamma\left\{\dfrac{\partial \Delta w}{\partial n} + (1-\mu)\left[\dfrac{\partial}{\partial \tau}(D^2 w(\tau, n)) + k(x)\dfrac{\partial w}{\partial n}\right]\right\}. \end{cases} \tag{1.20}$$

By the "principle of virtual work" and Formula I, we obtain the following displacement equations for a shallow shell (see Yao [20]) after changing t to t/λ with $\lambda^2 E/(1-\mu^2) = 1$.

Formula II. We assume that there are no external loads on the shell and the shell is clamped along a portion Γ_0 of Γ and free on Γ_1, where $\Gamma_0 \cup \Gamma_1 = \Gamma$ and $\Gamma_0 \cap \Gamma_1 = \emptyset$. Then the displacement vector $\eta = (W, w)$ satisfies the following boundary value problem:

$$\begin{cases} W_{tt} - [\Delta_\mu W + (1-\mu)kW + \mathcal{F}(w)] = 0, \\ w_{tt} - \gamma\Delta w_{tt} + \gamma\left(\Delta^2 w - (1-\mu)\delta(kdw)\right) \\ \qquad\qquad +(H^2 - 2(1-\mu)k)w + \mathcal{G}(W) = 0, \\ \eta(0) = \eta^0, \quad \eta_t(0) = \eta^1, \end{cases} \quad \text{in } Q_\infty, \tag{1.21}$$

$$\begin{cases} W = 0, \\ w = \dfrac{\partial w}{\partial n} = 0, \end{cases} \quad \text{on } \Sigma_{0\infty}, \tag{1.22}$$

$$v_1(\eta) = v_2(\eta) = v_3(\eta) = 0 \quad \text{and} \quad v_4(\eta) + \gamma\frac{\partial w_{tt}}{\partial n} = 0 \quad \text{on } \Sigma_{1\infty}, \tag{1.23}$$

where

$$Q_\infty = \Omega \times (0,\infty), \quad \Sigma_{0\infty} = \Gamma_0 \times (0,\infty), \quad \Sigma_{1\infty} = \Gamma_1 \times (0,\infty). \tag{1.24}$$

Remark 1.2. If the shell is flat, a plate, the equations in (1.21) are uncoupled. The equation on the component w is the same as in Lagnese [8]—a Kirchhoff plate (see Yao [20]).

1.3. Uniform stabilization. We write (1.21) as

$$\eta_{tt} - \gamma(0, \Delta w_{tt}) + \mathcal{A}\eta = 0 \tag{1.25}$$

and define the total energy of shell by

$$E(t) = \frac{1}{2}[\|W_t\|^2_{L^2(\Omega,\Lambda)} + \|w_t\|^2_{L^2(\Omega)} + \gamma\|Dw_t\|^2_{L^2(\Omega,\Lambda)} + \mathcal{B}(\eta,\eta)]. \tag{1.26}$$

By Green's formula (1.15), the equations (1.25), and the boundary conditions (1.22) we obtain

$$\begin{aligned} &\frac{d}{dt}E(t) \\ &= \frac{d}{dt}\left\{\frac{1}{2}[\|W_t\|^2_{L^2(\Omega,\Lambda)} + \|w_t\|^2_{L^2(\Omega)} + \gamma\|Dw_t\|^2_{L^2(\Omega,\Lambda)} + \mathcal{B}(\eta,\eta)]\right\} \\ &= \mathcal{B}(\eta,\eta_t) + \int_\Omega [\langle W_{tt}, W_t\rangle + w_{tt}w_t + \gamma\langle Dw_{tt}, Dw_t\rangle]dx \\ &= \int_\Omega [\langle W_{tt}, W_t\rangle + w_{tt}w_t - \gamma\Delta w_{tt}w_t]dx + (\mathcal{A}\eta, \eta_t)_{L^2(\Omega,\Lambda)\times L^2(\Omega)} \\ &\quad + \int_\Gamma \left[\partial(\mathcal{A}\eta,\eta_t) + \gamma\frac{\partial w_{tt}}{\partial n}w_t\right]d\Gamma \\ &= \int_\Omega \langle \eta_{tt} - \gamma(0,\Delta w_{tt}) + \mathcal{A}\eta, \eta_t\rangle dx + \int_\Gamma \left(\partial(\mathcal{A}\eta,\eta_t) + \gamma\frac{\partial w_{tt}}{\partial n}w_t\right)d\Gamma \\ &= \int_{\Gamma_1} \left\{v_1(\eta)\langle W_t, n\rangle + v_2(\eta)\langle W_t, \tau\rangle + v_3(\eta)\frac{\partial w_t}{\partial n} + \left[v_4(\eta) + \gamma\frac{\partial w_{tt}}{\partial n}\right]w_t\right\}d\Gamma. \end{aligned} \tag{1.27}$$

For simplicity, we set

$$\breve{\zeta} = \left(\langle U, n \rangle, \langle U, \tau \rangle, \frac{\partial u}{\partial n}, \frac{\partial u}{\partial \tau}, u \right) \tag{1.28}$$

for any $\zeta = (U, u)$. In this paper, we shall consider feedback laws to be defined by

$$\begin{cases} v_i(\eta) = \mathcal{J}_i(\eta_t), & i = 1, 2, 3, \\ v_4(\eta) + \gamma \dfrac{\partial w_{tt}}{\partial n} = \mathcal{J}_4(\eta_t), \end{cases} \tag{1.29}$$

where the feedback operators $\mathcal{J}_i$ are given by

$$\begin{cases} \mathcal{J}_i(\zeta) = -\breve{\zeta} F_i^\tau, & i = 1, 2, 3, \\ \mathcal{J}_4(\zeta) = -\breve{\zeta} F_5^\tau + \dfrac{\partial}{\partial \tau}(\breve{\zeta} F_4^\tau), \end{cases} \tag{1.30}$$

$F_i = (f_{i1}, f_{i2}, f_{i3}, f_{i4}, f_{i5})$ for $1 \le i \le 5$, and $\zeta = (U, u)$. In the formula (1.30) the superscript τ denotes a transpose, f_{ij} are real $L^\infty(\Gamma_1)$ functions, and the matrix $F = (F_1^\tau, F_2^\tau, F_3^\tau, F_4^\tau, F_5^\tau)$ satisfies

$$\text{F is symmetric and positive semidefinite on } \Gamma_1. \tag{1.31}$$

If we put the feedback laws of the formulas (1.29) and (1.30) into the formula (1.27), by the assumption (1.31) we obtain

$$\begin{aligned} \frac{d}{dt} E(t) &= \int_{\Gamma_1} \left[-\breve{\eta}_t F \breve{\eta}_t{}^\tau + \frac{\partial w_t}{\partial \tau} F_4 \breve{\eta}_t{}^\tau + w_t \frac{\partial}{\partial \tau} F_4 \breve{\eta}_t{}^\tau \right] d\Gamma \\ &= - \int_{\Gamma_1} \breve{\eta}_t F \breve{\eta}_t{}^\tau d\Gamma \le 0 \end{aligned} \tag{1.32}$$

so that the resulting closed-loop system under the feedback laws of (1.29) and (1.30) is dissipative in the sense that $E(t)$ is nonincreasing.

Remark 1.3. When the tangent component $W = 0$, the feedback laws of (1.29) and (1.30) are what Lagnese [8] presented for the uniform stabilization of the Kirchhoff plate.

We now set up some geometric conditions on the middle surface of the shallow shell which are necessary to get the energy decay.

Assumption (H.1). There is a constant λ_0 such that

$$\lambda_0 \mathcal{B}(\eta, \eta) \ge \|DW\|^2_{L^2(\Omega, T^2)} + \gamma \|D^2 w\|^2_{L^2(\Omega, T^2)} \tag{1.33}$$

for $\eta = (W, w) \in H^1(\Omega, \Lambda) \times H^2(\Omega)$.

Assumption (H.2). There is a vector field $V \in \mathcal{X}(M)$ such that

$$DV(X, X) = b(x)|X|^2, \quad X \in M_x, \quad x \in \overline{\Omega}, \tag{1.34}$$

where b is a function on $\overline{\Omega}$. Set

$$a(x) = \frac{1}{2} \langle DV, \mathcal{E} \rangle_{T^2_x}, \qquad x \in \overline{\Omega},$$

where $\mathcal{E}$ is the volume element of M. Moreover, suppose that b and a meet inequality

$$2\min_{x\in\overline{\Omega}} b(x) > \lambda_0(1+\mu)\max_{x\in\overline{\Omega}}|a(x)|. \tag{1.35}$$

Assumption (H.3). Γ_0 and Γ_1 satisfy the following conditions:

$$\overline{\Gamma}_0 \neq \emptyset, \quad \overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset, \quad \text{and } V(x)\cdot n(x) \leq 0 \quad \text{on } \Gamma_0. \tag{1.36}$$

Assumption (H.4). $F \in C^1(\Gamma_1)$ is a positive definite matrix.

Remark 1.4. The assumptions (H.1)–(H.3) are geometric conditions on the middle surface of the shell, while the assumption (H.4) is on the feedback. For a plate the assumptions (H.1)–(H.2) automatically satisfy, where we set $V = x - x_0$. For the general case, the assumptions (H.1)–(H.2) can be verified by the geometry method; see, for example, Yao [21]. Here the geometric assumption (H.3) is, generally, considered to be much weaker than the following:

$$V(x)\cdot n(x) \leq 0 \quad \text{on} \quad \Gamma_0 \quad \text{and} \quad V(x)\cdot n(x) > 0 \quad \text{on} \quad \Gamma_1,$$

which is used to avoid the complex trace estimates.

We are now in a position to state our main results.

THEOREM 1.1. *Assume that the assumptions* (H.1)–(H.4) *hold. Let the energy* $E(t)$ *be defined by* (1.26) *for the closed-loop system* (1.21), (1.22), *and* (1.29). *Then there are positive constants* K *and* ω *such that*

$$E(t) \leq Ke^{-\omega t}E(0), \qquad t \geq 0, \tag{1.37}$$

for any $\eta^0 \in H^1_{\Gamma_0}(\Omega,\Lambda)\times H^2_{\Gamma_0}(\Omega)$ *and any* $\eta^1 \in L^2(\Omega,\Lambda)\times H^1_{\Gamma_0}(\Omega)$.

2. Existence, uniqueness, and properties of solutions. In this section, we follow the ideas in Lagnese [8] for the Kirchhoff plate to put the shallow shell problem into a semigroup frame. Then the regularity of solutions we need for the stabilization is worked out by Agmon, Douglis, and Nirenberg [1].

2.1. Variational formulation. We shall set

$$\mathcal{W} = H^1_{\Gamma_0}(\Omega,\Lambda)\times H^2_{\Gamma_0}(\Omega), \quad \mathcal{V} = L^2(\Omega,\Lambda)\times H^1_{\Gamma_0}(\Omega), \quad \text{and} \quad \mathcal{L} = L^2(\Omega,\Lambda)\times L^2(\Omega). \tag{2.1}$$

Introduce the forms

$$a_0(\eta,\zeta) = \int_\Omega [\langle \eta,\zeta\rangle + \gamma\langle Dw, Du\rangle]dx \tag{2.2}$$

and

$$a_1(\eta,\zeta) = \int_{\Gamma_1} \breve{\eta} F \breve{\zeta}^\tau d\Gamma \tag{2.3}$$

for $\eta = (W,w)$ and $\zeta = (U,u)$. It follows from Green's formula (1.15) that an appropriate variational formulation of the systems (1.21), (1.22), and (1.29) is as follows: Find a vector field $\eta \in C([0,\infty);\mathcal{W})\cap C^1([0,\infty);\mathcal{V})$ such that

$$\begin{cases} \dfrac{d}{dt}[a_0(\eta_t,\zeta) + a_1(\eta,\zeta)] + \mathcal{B}(\eta,\zeta) = 0 \qquad \forall\, \zeta \in \mathcal{W}, \\ \eta(0) = \eta^0 \in \mathcal{W}, \quad \eta_t(0) = \eta^1 \in \mathcal{V}. \end{cases} \tag{2.4}$$

2.2. Well-posedness of (1.21), (1.22), and (1.29). The bilinear forms $a_0(\cdot,\cdot)$, $a_1(\cdot,\cdot)$, and $\mathcal{B}(\cdot,\cdot)$ are continuous, symmetric, and nonnegative on $\mathcal{V}$ and $\mathcal{W}$, respectively, and if we set

$$a_0(\eta) = a_0(\eta,\eta) \quad \text{and} \quad a_1(\eta) = a_1(\eta,\eta), \tag{2.5}$$

then we have

$$a_0(\eta) \geq \gamma \|\eta\|^2_{L^2(\Omega,\Lambda)\times H^1(\Omega)} \quad \text{and} \quad a_1(\eta) \geq 0. \tag{2.6}$$

The form $a_0(\cdot,\cdot)$ defines a scalar product on $\mathcal{V}$ and so does $\mathcal{B}(\cdot,\cdot)$ on $\mathcal{W}$ because of the ellipticity (1.33). Those scalar products are equivalent to the ones previously introduced in those spaces. We identify $\mathcal{L}$ with its dual $\mathcal{L}'$ so that we have the dense and continuous embeddings

$$\mathcal{W} \subset \mathcal{V} \subset \mathcal{L} \subset \mathcal{V}' \subset \mathcal{W}'. \tag{2.7}$$

Let A_0 (respectively, P) denote the canonical isomorphism of $\mathcal{V}$ (respectively, $\mathcal{W}$) endowed with the scalar product $a_0(\cdot,\cdot)$ (respectively, $\mathcal{B}(\cdot,\cdot)$) onto $\mathcal{V}'$ (respectively, $\mathcal{W}'$). Then

$$a_0(\eta,\zeta) = \langle A_0\eta,\zeta\rangle \qquad \forall \eta, \quad \zeta \in \mathcal{V},$$

$$\mathcal{B}(\eta,\zeta) = \langle P\eta,\zeta\rangle \qquad \forall \eta, \quad \zeta \in \mathcal{W},$$

where $\langle\cdot,\cdot\rangle$ refers to $(\cdot,\cdot)_{L^2(\Omega,\Lambda)\times L^2(\Omega)}$. Furthermore, there is a nonnegative operator $A_1 \in \mathcal{B}(\mathcal{W},\mathcal{W}')$ such that

$$a_1(\eta,\zeta) = \langle A_1\eta,\zeta\rangle \qquad \forall \eta, \quad \zeta \in \mathcal{W}.$$

We write (2.4) as

$$\frac{d}{dt}(A_0\eta_t + A_1\eta) + P\eta = 0 \quad \text{in} \quad \mathcal{W}'. \tag{2.8}$$

Let us formally rewrite (2.4) as the system

$$\begin{pmatrix} P & 0 \\ 0 & A_0 \end{pmatrix} \begin{pmatrix} \eta \\ \eta_t \end{pmatrix}' + \begin{pmatrix} 0 & -P \\ P & A_1 \end{pmatrix} \begin{pmatrix} \eta \\ \eta_t \end{pmatrix} = 0$$

or

$$\mathbb{C}Y' + \mathcal{Q}Y = 0, \qquad t \geq 0, \tag{2.9}$$

where

$$\mathbb{C} = \begin{pmatrix} P & 0 \\ 0 & A_0 \end{pmatrix}, \quad \mathcal{Q} = \begin{pmatrix} 0 & -P \\ P & A_1 \end{pmatrix}, \quad \text{and} \quad Y = \begin{pmatrix} \eta \\ \eta_t \end{pmatrix}.$$

We wish to solve (2.9) in the space $\mathcal{W}\times\mathcal{V}$. In order to make sense of (2.9) in that space it is natural to introduce

$$\mathcal{D}(\mathcal{Q}) = \{(\eta,\zeta) | \eta \in \mathcal{W}, \zeta \in \mathcal{W}, P\eta + A_1\zeta \in \mathcal{V}'\}.$$

Then $\mathcal{Q} : \mathcal{D}(\mathcal{Q}) \to \mathcal{W}' \times \mathcal{V}'$. Since $\mathbb{C}$ is the canonical isomorphism of $\mathcal{W} \times \mathcal{V}$ onto $\mathcal{W}' \times \mathcal{V}'$, we rewrite (2.9) in the form

$$Y' + \mathbb{C}^{-1}\mathcal{Q}Y = 0 \quad \text{in } \mathcal{W} \times \mathcal{V}. \tag{2.10}$$

Solutions of the system (1.21), (1.22), and (1.29) are therefore defined via (2.10).

THEOREM 2.1. *$-\mathbb{C}^{-1}\mathcal{Q}$ is the infinitesimal generator of a C_0-semigroup of contraction on $\mathcal{W} \times \mathcal{V}$.*

Proof. (i) $\mathcal{D}(\mathcal{Q})$ is dense in $\mathcal{W} \times \mathcal{V}$.

By the definition of P and A_1, for $\varsigma = (U, u) \in \mathcal{W}$, we obtain

$$\begin{aligned}
\langle P\eta + A_1\zeta, \varsigma\rangle &= \mathcal{B}(\eta, \varsigma) + a_1(\zeta, \varsigma) \\
&= -\int_\Omega \langle \Delta_\mu W + (1-\mu)kW + \mathcal{F}(w),\ U\rangle dx - \gamma \int_\Omega \langle d\Delta w, du\rangle dx \\
&\quad + \int_\Omega [-(1-\mu)\delta(kdw) + \mathcal{G}(W) + (H^2 - 2(1-\mu)k)w]u dx \\
&\quad + \int_{\Gamma_1} \left[v_1(\eta)\langle U, n\rangle + v_2(\eta)\langle U, \tau\rangle + v_3(\eta)\frac{\partial u}{\partial n}\right] d\Gamma \\
&\quad - (1-\mu)\gamma \int_{\Gamma_1} \left[\frac{\partial}{\partial \tau} D^2 w(n, \tau) + k\frac{\partial w}{\partial n}\right] u\, d\Gamma \\
&\quad - \int_{\Gamma_1} \left[\mathcal{J}_1(\zeta)\langle U, n\rangle + \mathcal{J}_2(\zeta)\langle U, \tau\rangle + \mathcal{J}_3(\zeta)\frac{\partial u}{\partial n} + \mathcal{J}_4(\zeta)u\right] d\Gamma.
\end{aligned} \tag{2.11}$$

The expression on the right-hand side of the formula (2.11) implies the relation

$$\begin{aligned}
\mathcal{D}(\mathcal{Q}) \supset \mathcal{D}_0 = \{\, (\eta, \zeta) \,|\, \eta \in \mathcal{W} \cap H^2(\Omega, \Lambda) \times H^4(\Omega),\ \zeta \in \mathcal{W},\ v_1(\eta) = \mathcal{J}_1(\zeta), \\
v_2(\eta) = \mathcal{J}_2(\zeta),\ \text{and } v_3(\eta) = \mathcal{J}_3(\zeta) \text{ on } \Gamma_1 \,\}.
\end{aligned}$$

Indeed, if $(\eta, \zeta) \in \mathcal{D}_0$, then

$$\begin{aligned}
|\langle P\eta + A_1\zeta, \varsigma\rangle| &\le C(\|W\|_{H^2(\Omega,\Lambda)} + \|w\|_{H^3(\Omega)})(\|U\|_{L^2(\Omega,\Lambda)} + \|u\|_{H^1(\Omega)}) \\
&\quad + C\left\| \mathcal{J}_4(\zeta) + (1-\mu)\gamma \left[\frac{\partial}{\partial \tau} D^2 w(n, \tau) + k\frac{\partial w}{\partial n}\right] \right\|_{H^{-\frac{1}{2}}(\Gamma_1)} \|u\|_{H^{\frac{1}{2}}(\Gamma_1)} \\
&\le C_{\eta,\zeta}\|\varsigma\|_{\mathcal{V}},
\end{aligned}$$

that is,

$$P\eta + A_1\zeta \in \mathcal{V}'.$$

We mention that in the above inequality the following result is used: $\eta \in \mathcal{W} \cap H^2(\Omega, \Lambda) \times H^4(\Omega)$ and $\zeta \in \mathcal{W}$ imply $\mathcal{J}_4(\zeta) + (1-\mu)\gamma[\frac{\partial}{\partial \tau} D^2 w(n, \tau) + k\frac{\partial w}{\partial n}] \in H^{-\frac{1}{2}}(\Gamma_1)$.

$\mathcal{D}(\mathcal{Q})$ is then dense in $\mathcal{W} \times \mathcal{V}$ since $\mathcal{D}_0$ is in $\mathcal{W} \times \mathcal{V}$.

(ii) $-\mathbb{C}^{-1}\mathcal{Q}$ is dissipative. This is shown by

$$\begin{aligned}
\langle \mathbb{C}^{-1}\mathcal{Q}(\eta, \zeta), (\eta, \zeta)\rangle &= \langle (-\zeta, A_0^{-1}(P\eta + A_1\zeta)), (\eta, \zeta)\rangle \\
&= -\mathcal{B}(\zeta, \eta) + \mathcal{B}(\eta, \zeta) + a_1(\zeta, \zeta) \\
&= a_1(\zeta, \zeta) \ge 0
\end{aligned} \tag{2.12}$$

for $(\eta, \zeta) \in \mathcal{D}(\mathcal{Q})$.

(iii) We also have $\text{Range}(\lambda I + \mathbb{C}^{-1}\mathcal{Q}) = \mathcal{W} \times \mathcal{V}$, for $\lambda > 0$, $(\eta, \zeta) \in \mathcal{D}(\mathcal{Q})$. In fact, this is equivalent to

$$\text{Range}(\lambda^2 A_0 + \lambda A_1 + P) = \mathcal{V}'.$$

But, by the Lax–Milgram theorem, it is actually true. □

As a consequence of Theorem 2.1, we have the following result.

THEOREM 2.2. *Assume that* (1.29) *and* (1.31) *hold and*

$$\eta^0 \in \mathcal{W}, \quad \eta^1 \in \mathcal{W}, \quad P\eta^0 + A_1\eta^1 \in \mathcal{V}'. \tag{2.13}$$

Then the problem (2.4) *admits a unique solution with*

$$\eta \in C^1([0,\infty); \mathcal{W}) \cap C^2([0,\infty); \mathcal{V}),$$

$$\eta_{tt} \in C([0,\infty); \mathcal{V}),$$

$$A_0\eta_{tt} + A_1\eta_t + P\eta = 0, \qquad t \geq 0, \tag{2.14}$$

$$\eta(0) = \eta^0, \qquad \eta_t(0) = \eta^1.$$

2.3. Regularity of solutions. In the following, we shall use local coordinate systems to obtain the regularity of variational solutions to the system (1.21), (1.22), and (1.29). Let us consider the system

$$\begin{cases} \eta \in \mathcal{W}, \quad \mathcal{A}\eta \in \mathcal{V}', \\ v_i(\eta) \in H^{\frac{1}{2}}(\Gamma_1), \qquad i = 1,2,3, \\ v_4(\eta) \in H^{-\frac{1}{2}}(\Gamma_1). \end{cases} \tag{2.15}$$

First, we have the following lemma.

LEMMA 2.3. *Let* η *satisfy the problem* (2.15). *Then*

$$\eta \in H^2(\Omega, \Lambda) \times H^3(\Omega) \cap \mathcal{W}. \tag{2.16}$$

Proof. First, we prove that, for any $\varphi \in C^\infty(\overline{\Omega})$, $\varphi\eta$ still satisfies the problem (2.15), so our analysis of η on $\overline{\Omega}$ can be localized.

Note that

$$\mathcal{A}(\varphi\eta) = \varphi\mathcal{A}\eta + [\mathcal{A}, \varphi]\eta, \tag{2.17}$$

where the commutator $[\mathcal{A}, \varphi]$ is a first-order differential operator on the component W and a third-order differential operator on the component w. Then the hypothesis $\mathcal{A}\eta \in \mathcal{V}'$, together with $\eta \in \mathcal{W}$, gives $\mathcal{A}(\varphi\eta) \in \mathcal{V}'$. Similarly, it is easy to check from the formulas in (1.20) that when η satisfies the problem (2.15) all the boundary conditions in the problem (2.15) for $\varphi\eta$ are still true.

So suppose η, satisfying (2.15), is supported on a coordinate chart $(\mathcal{U}, \psi)$ where $(\mathcal{U}, \psi)$ is chosen in such a way that there exists a positive smooth function Θ on $\mathcal{U}$ to meet

$$g = \Theta(dx_1^2 + dx_2^2) \quad \text{on} \quad \mathcal{U}, \tag{2.18}$$

where g is the induced metric of the Riemannian manifold M; see Wu [19]. It is noticeable that the expression in (2.18) does not hold in general when the dimension of the manifold is larger than 2.

In addition, the formulas in (1.19) and the hypothesis $\eta \in \mathcal{W}$ imply

$$\mathcal{F}(w) \in H^1_{\Gamma_0}(\Omega) \quad \text{and} \quad \mathcal{G}(W) \in L^2(\Omega, \Lambda). \tag{2.19}$$

Set

$$W = u_1 \frac{\partial}{\partial x_1} + u_2 \frac{\partial}{\partial x_2}. \tag{2.20}$$

By the relations (2.18)–(2.20) and through a computation, we separate the problem (2.15) into the two following ones:

$$\begin{cases} (u_1, u_2) \in H^1_{\partial O_0}(O), \\ \dfrac{\partial^2 u_1}{\partial x_1^2} + \dfrac{1-\mu}{2}\dfrac{\partial^2 u_1}{\partial x_2^2} + \dfrac{1+\mu}{2}\dfrac{\partial^2 u_2}{\partial x_1 \partial x_2} \in L^2(O), \\ \dfrac{1-\mu}{2}\dfrac{\partial^2 u_2}{\partial x_1^2} + \dfrac{\partial^2 u_2}{\partial x_2^2} + \dfrac{1+\mu}{2}\dfrac{\partial^2 u_1}{\partial x_1 \partial x_2} \in L^2(O), \\ n_1 \dfrac{\partial u_1}{\partial n} + n_2 \dfrac{\partial u_2}{\partial n} - \mu n_2 \dfrac{\partial u_1}{\partial \tau} + \mu n_1 \dfrac{\partial u_2}{\partial \tau} \in H^{\frac{1}{2}}(\partial O_1), \\ -n_2 \dfrac{\partial u_1}{\partial n} + n_1 \dfrac{\partial u_2}{\partial n} + n_1 \dfrac{\partial u_1}{\partial \tau} + n_2 \dfrac{\partial u_2}{\partial \tau} \in H^{\frac{1}{2}}(\partial O_1), \end{cases} \tag{2.21}$$

and

$$\begin{cases} w \in H^2_{\partial O_0}(O), \\ \Delta_0^2 w \in H^{-1}(O), \\ \Delta_0 w - (1-\mu)\Theta \dfrac{\partial^2 w}{\partial \tau^2} \in H^{\frac{1}{2}}(\partial O_1), \\ \dfrac{\partial \Delta_0 w}{\partial n} + (1-\mu)\Theta \left[k \dfrac{\partial w}{\partial n} + \dfrac{\partial^3 w}{\partial \tau^2 \partial n} \right] \in H^{-\frac{1}{2}}(\partial O_1), \end{cases} \tag{2.22}$$

where

$$O = \psi(\mathcal{U} \cap \Omega), \quad \partial O_1 = \psi(\Gamma_1 \cap \mathcal{U}), \quad \partial O_0 = \partial O / \partial O_1,$$

$$n = n_1 \frac{\partial}{\partial x_1} + n_2 \frac{\partial}{\partial x_2}, \quad \tau = -n_2 \frac{\partial}{\partial x_1} + n_1 \frac{\partial}{\partial x_2}, \quad \Delta_0 = \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2}.$$

It is clear that the problem (2.22) is a classical elliptic boundary value problem since $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$ and Γ is smooth enough. We therefore obtain

$$w \in H^3(O) \cap H^2_{\partial O_0}(O).$$

Next, since the determinant of coefficients of $\{\partial u_1/\partial n, \partial u_1/\partial n\}$ in the boundary conditions of the problem (2.21) is $1/\Theta > 0$, the classical theory of Agmon, Douglis, and Nirenberg [1] yields

$$(u_1, u_2) \in \left(H^2(O)\right)^2.$$

Finally, the partition of unity subject to a coordinate cover of $\overline{\Omega}$ completes the proof. □

In order to apply Green's formula to solutions of the system (1.21), (1.22), and (1.29), we have to get more regularity than what is given by Theorem 2.2. To this end, we need to require more regularity of the initial data than what is supposed in (2.13). The requisite assumptions are obtained as follows. We introduce

$$\tilde{A}_0 = A_0|_{\mathcal{W}}, \quad \mathcal{H} = \text{Range}\tilde{A}_0, \tag{2.23}$$

and we assume

$$\eta^0 \in \mathcal{W}, \quad \eta^1 \in \mathcal{W} \cap H^2(\Omega,\Lambda) \times H^3(\Omega), \quad \text{and} \quad A_1\eta^1 + P\eta^0 \in \mathcal{H}. \tag{2.24}$$

From (2.14) we have $A_0\eta_{tt}(0) = -(A_1\eta^1 + P\eta^0) \in \mathcal{H}$ and, therefore,

$$\eta_{tt}(0) = -\tilde{A}_0^{-1}(A_1\eta^1 + P\eta^0) \in \mathcal{W}. \tag{2.25}$$

We further assume

$$v_i(\eta^1) = \mathcal{J}_i(\eta_{tt}(0)), \qquad i = 1,2,3, \quad \text{on} \quad \Gamma_1. \tag{2.26}$$

Then we conclude that

$$A_1\eta_{tt}(0) + P\eta^1 \in \mathcal{V}'. \tag{2.27}$$

Indeed, for $\varsigma = (U,u) \in \mathcal{V}$, from (2.3), (1.31), and (2.26) we have

$$a_1(\eta_{tt}(0),\varsigma) = -\int_{\Gamma_1}\left[v_1(\eta^1)\langle U,n\rangle + v_2(\eta^1)\langle U,\tau\rangle + v_3(\eta^1)\frac{\partial u}{\partial n} + \mathcal{J}_4(\eta_{tt}(0))u\right]d\Gamma \tag{2.28}$$

and, therefore, by Green's formula (1.15),

$$\begin{aligned}
&\langle A_1\eta_{tt}(0) + P\eta^1,\, \varsigma\rangle = a_1(\eta_{tt}(0),\varsigma) + \mathcal{B}(\eta^1,\varsigma)\\
&= -\int_\Omega \langle \Delta_\mu W^1 + (1-\mu)kW^1 + \mathcal{F}(w^1),\ U\rangle\, dx - \gamma\int_\Omega \langle d\Delta w^1,\, du\rangle\, dx\\
&\quad + \int_\Omega \gamma[-(1-\mu)\delta(kdw^1) + (H^2 - 2(1-\mu)k)w^1 + \mathcal{G}(W^1)]u\, dx\\
&\quad - \int_{\Gamma_1}\left\{\mathcal{J}_4(\eta_{tt}(0)) + \gamma(1-\mu)\left[\frac{\partial}{\partial\tau}D^2w^1(n,\tau) + k\frac{\partial w^1}{\partial n}\right]\right\}u\, d\Gamma.
\end{aligned} \tag{2.29}$$

Now the expression (2.29) produces

$$\begin{aligned}
&|\langle A_1\eta_{tt}(0) + P\eta^1,\, \varsigma\rangle|\\
&\le C\left(\|W^1\|_{H^2(\Omega,\Lambda)} + \|w^1\|_{H^3(\Omega)}\right.\\
&\quad \left. + \left\|\mathcal{J}_4(\eta_{tt}(0)) + \gamma(1-\mu)\left[\frac{\partial}{\partial\tau}D^2w^1(n,\tau) + k\frac{\partial w^1}{\partial n}\right]\right\|_{H^{-\frac{1}{2}}(\Gamma_1)}\right)\|\varsigma\|_{\mathcal{V}}.
\end{aligned} \tag{2.30}$$

Consequently, (2.27) holds as claimed.

We have shown that if (2.24) and (2.26) hold, then

$$\eta^1 \in \mathcal{W}, \quad \eta_{tt}(0) \in \mathcal{W}, \quad A_1\eta_{tt}(0) + P\eta^1 \in \mathcal{V}', \tag{2.31}$$

that is, $\{\eta^1, \eta_{tt}(0)\} \in \mathcal{D}(\mathbb{C}^{-1}Q)$. It follows from Theorem 2.2 that η satisfies

$$\eta_t \in C^1([0,\infty); \mathcal{W}) \quad \text{and} \quad \eta_{tt} \in C([0,\infty); \mathcal{W}). \tag{2.32}$$

Then, as a consequence of $A_1\eta_t + P\eta = -A_0\eta_{tt}$ we obtain that η satisfies

$$\begin{cases} \eta \in C^2([0,\infty); \mathcal{W}), \\ \mathcal{A}\eta = -(\eta_{tt} - \gamma(0, \Delta w_{tt})) \in C([0,\infty); L^2(\Omega,\Lambda) \times L^2(\Omega)), \\ v_i(\eta) = \mathcal{J}_i(\eta_t) \in H^{\frac{1}{2}}(\Gamma_1), \qquad i = 1,2, \\ v_3(\eta) = \mathcal{J}_3(\eta_t) \in H^{\frac{3}{2}}(\Gamma_1), \\ v_4(\eta) + \gamma \dfrac{\partial w_{tt}}{\partial n} = \mathcal{J}_4(\eta_t) \in H^{\frac{1}{2}}(\Gamma_1). \end{cases} \tag{2.33}$$

Elliptic theory then yields

$$w \in H^4(\Omega).$$

We now write the above analysis into the following result.

THEOREM 2.4. *Assume that* Γ *is smooth enough,* $\overline{\Gamma}_1 \cap \overline{\Gamma}_0 = \emptyset$*, and conditions* (2.24) *and* (2.26) *hold. Then variational solutions of the system* (1.21), (1.22), *and* (1.29) *satisfy*

$$\eta \in C([0,\infty); H^2(\Omega,\Lambda) \times H^4(\Omega) \cap \mathcal{W}) \cap C^1([0,\infty); H^1(\Omega,\Lambda) \times H^3(\Omega) \cap \mathcal{V}). \tag{2.34}$$

Remark 2.1. If $\eta^0 \in H^3(\Omega,\Lambda) \times H^4(\Omega) \cap \mathcal{W}$ and $\eta^1 \in H^2(\Omega,\Lambda) \times H^3(\Omega) \cap \mathcal{W}$, then conditions (2.24) and (2.26) hold.

3. Proof of Theorem 1.1. We assume that the initial data satisfy the assumptions of Theorem 2.4 and, therefore, the solution $\eta = (W, w)$ of the system (1.21), (1.22), and (1.29) meets the regularity of (2.34).

Let a vector field V be given to satisfy the assumption (H.2). Set

$$\eta_1 = (W, 0), \quad \eta_2 = (0, w), \quad m(\eta) = (D_V W, V(w)),$$

$$L(t) = \|W\|^2_{L^2(\Omega,\Lambda)} + \|w\|^2_{L^2(\Omega)} + \gamma\|w_t\|^2_{L^2(\Omega)} + \|Dw\|^2_{L^2(\Omega,\Lambda)},$$

$$\sigma_0 = \max_{x\in\overline{\Omega}} |V|, \qquad \sigma_1 = \min_{x\in\overline{\Omega}} b(x) - \frac{\lambda_0(1+\mu)}{2} \max_{x\in\overline{\Omega}} |a(x)|,$$

$$Q^T = (0,T) \times \Omega, \quad \Sigma^T = (0,T) \times \Gamma, \quad \Sigma_0^T = (0,T) \times \Gamma_0, \quad \text{and} \quad \Sigma_1^T = (0,T) \times \Gamma_1,$$

where $T > 0$ is given.

LEMMA 3.1. *Let the assumptions* (H.1) *and* (H.2) *hold. If we denote*

$$p(\eta) = \left(b - \frac{\sigma_1}{2}\right)\eta_1 - \frac{b}{2}\eta_2, \tag{3.1}$$

then we have

$$\begin{aligned}\sigma_1 \int_0^T E(t)dt \le \frac{1}{2}\int_{\Sigma_1^T} [|\eta_t|^2 + \gamma|Dw_t|^2 - B(\eta,\eta)]\langle V, n\rangle \, d\Sigma \\ + \frac{1}{2}\int_{\Sigma_0^T} B(\eta,\eta)\langle V, n\rangle \, d\Sigma - \int_0^T a_1(\eta_t,\, m(\eta) + p(\eta))\, dt \\ + C_T\left[E(0) + E(T) + \int_0^T L(t)\, dt\right]. \end{aligned} \tag{3.2}$$

Proof. By the embedding theorem there is $C_T > 0$ such that

$$L(0) \le C_T E(0) \quad \text{and} \quad L(T) \le C_T E(T). \tag{3.3}$$

Then, from (3.3), Theorem 1.1 of Yao [21] gives the following inequality:

$$\sigma_1 \int_0^T E(t)\, dt \le (SB)_1|_{\Sigma^T} + (SB)_2|_{\Sigma^T} + C_T\left[E(0) + E(T) + \int_0^T L(t)\, dt\right], \tag{3.4}$$

where

$$(SB)_1|_{\Sigma^T} = \frac{1}{2}\int_{\Sigma^T} [|\eta_t|^2 + \gamma|Dw_t|^2 - B(\eta,\eta)]\langle V, n\rangle \, d\Sigma, \tag{3.5}$$

$$(SB)_2|_{\Sigma^T} = \int_{\Sigma^T}\left[\partial\left(\mathcal{A}\eta,\, m(\eta) + p(\eta)\right) + \gamma\left(V(w) - \frac{1}{2}bw\right)\frac{\partial w_{tt}}{\partial n}\right] d\Sigma. \tag{3.6}$$

Let us examine the integrals over Σ_0^T in (3.5) and (3.6). By the boundary conditions of (1.22) on Γ_0 we have, from Proposition 2.12(ii) of Yao [21],

$$(SB)_1|_{\Sigma_0^T} = -\frac{1}{2}\int_{\Sigma_0^T} B(\eta,\eta)\langle V, n\rangle \, d\Sigma \quad \text{and} \quad (SB)_2|_{\Sigma_0^T} = \int_{\Sigma_0^T} B(\eta,\eta,)\langle V, n\rangle \, d\Sigma. \tag{3.7}$$

First, we consider the calculation of $(SB)_2|_{\Sigma_1^T}$.

From the formula (1.16) and the feedback law of (1.29) and (1.30) we obtain, for any $\varsigma = (U, u) \in L^2(\Omega, \Lambda) \times H^1(\Omega)$,

$$\begin{aligned}\int_{\Gamma_1}\left[\partial(\mathcal{A}\eta,\, \varsigma) + \gamma u\frac{\partial w_{tt}}{\partial n}\right] d\Gamma &= -a_1(\eta_t,\, \varsigma) + \int_{\Gamma_1}\left[u\frac{\partial}{\partial\tau}(\breve{\eta}_t F_4^\tau) + \breve{\eta}_t F_4^\tau\frac{\partial u}{\partial\tau}\right] d\Gamma \\ &= -a_1(\eta_t,\, \varsigma)\end{aligned} \tag{3.8}$$

since $\overline{\Gamma}_0 \cap \overline{\Gamma}_1 = \emptyset$. By applying the formula (3.8) to the expression (3.6) with $\varsigma = m(\eta) + p(\eta)$, one finds out

$$(SB)_2|_{\Sigma_1^T} = -\int_0^T a_1(\eta_t,\, m(\eta) + p(\eta))\, dt. \tag{3.9}$$

Substituting (3.7) and (3.9) into (3.4) yields the inequality (3.2). □

Next, we consider a trace result which is a consequence of Horn [6]. Let U be a vector field on $\overline{\Omega}$. Set

$$S(U) = \frac{1}{2}(DU + D^*U), \tag{3.10}$$

a two-order tensor on $\overline{\Omega}$.

LEMMA 3.2. *Let $T > 0$ and $1/2 > \epsilon > 0$ be given. Suppose that a vector field U satisfies the problem*

$$\begin{cases} U \in L^2([0,T]; H^{\frac{1}{2}+\epsilon}(\Omega,\Lambda)), \quad U_t \in L^2(\Sigma^T,\Lambda), \\ U_{tt} - \Delta_\mu U \in H^{-\frac{1}{2}}(Q^T,\Lambda), \\ (1-\mu)S(U)(n,n) - \mu\delta U \in L^2(\Sigma^T,\Lambda), \\ S(U)(n,\tau) \in L^2(\Sigma^T,\Lambda). \end{cases} \tag{3.11}$$

Then, for $T/2 > \alpha > 0$, there is $C_{T,\alpha,\epsilon} > 0$ such that

$$\begin{aligned} &\|D_\tau U\|^2_{L^2([\alpha,\,T-\alpha];L^2(\Gamma,\Lambda))} \\ &\le C_{T,\alpha,\epsilon}(\|U_t\|^2_{L^2(\Sigma^T,\Lambda)} + \|(1-\mu)S(U)(n,n) - \mu\delta U\|^2_{L^2(\Sigma^T)} + \|S(U)(n,\tau)\|^2_{L^2(\Sigma^T)}) \\ &\quad + C_{T,\alpha,\epsilon}(\|W_{tt} - \Delta_\mu W\|^2_{H^{-1/2}(Q^T,\Lambda)} + \|U\|^2_{L^2([0,T];H^{1/2+\epsilon}(\Omega,\Lambda))}). \end{aligned} \tag{3.12}$$

Proof. It is easy to check that, if U satisfies the problem (3.11), then, for any $\varphi \in C^\infty(\overline{\Omega})$, φU still does, which means the problem (3.11) can be localized. Suppose that U is supported in a coordinate chart $(\mathcal{U},\phi)$ with the metric g of (2.18). Set

$$U = u_1\frac{\partial}{\partial x_1} + u_2\frac{\partial}{\partial x_2}.$$

On the chart $(\mathcal{U},\phi)$, the problem (3.11) changes into the problem

$$\begin{cases} u_i \in L^2([0,T]; H^{1/2+\epsilon}(O)), \quad u_{it} \in L^2((0,T)\times\partial O), \qquad i = 1,2, \\ u_{1tt} - \left(\dfrac{\partial^2 u_1}{\partial x_1^2} + \dfrac{1-\mu}{2}\dfrac{\partial^2 u_1}{\partial x_2^2} + \dfrac{1+\mu}{2}\dfrac{\partial^2 u_2}{\partial x_1\partial x_2}\right) \in H^{-1/2}((0,T)\times O), \\ u_{2tt} - \left(\dfrac{1-\mu}{2}\dfrac{\partial^2 u_2}{\partial x_1^2} + \dfrac{\partial^2 u_2}{\partial x_2^2} + \dfrac{1+\mu}{2}\dfrac{\partial^2 u_1}{\partial x_1\partial x_2}\right) \in H^{-1/2}((0,T)\times O), \\ f_1, f_2 \in L^2([0,T]\times\partial O), \end{cases} \tag{3.13}$$

where

$$\begin{cases} f_1 = n_1\dfrac{\partial u_1}{\partial n} + n_2\dfrac{\partial u_2}{\partial n} - \mu n_2\dfrac{\partial u_1}{\partial\tau} + \mu n_1\dfrac{\partial u_2}{\partial\tau}, \\ f_2 = -n_2\dfrac{\partial u_1}{\partial n} + n_1\dfrac{\partial u_2}{\partial n} + n_1\dfrac{\partial u_1}{\partial\tau} + n_2\dfrac{\partial u_2}{\partial\tau}, \end{cases} \tag{3.14}$$

$O = \phi(\mathcal{U})$, and $\partial O = \partial\phi(\mathcal{U})$.

Next we want to show that the problem (3.13) is a special case of some three dimensional dynamic elasticity, so Theorem 1.2 of Horn [6] can be applied. To this end, we set

$$u = (u_1, u_2, 0) \quad \text{and} \quad O' = O\times(0,1).$$

If we let the Lamé coefficients λ and μ in Horn [6] be μ and $\frac{1-\mu}{2}$, respectively, we have

$$\sigma_{ij} = \mu(\mathrm{div}u)\delta_{ij} + \frac{1-\mu}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right), \tag{3.15}$$

$$\frac{\partial u_i}{\partial x_3} = 0 \tag{3.16}$$

for any $1 \le i, j \le 3$. By the notation of Horn [6], we have

$$\sigma(u)n' = \begin{pmatrix} n_1 & n_2 & 0 \\ -n_2 & n_1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} f_1 \\ f_2 \\ 0 \end{pmatrix} \tag{3.17}$$

and the problem (3.13) is then equivalent to the three dimensional problem

$$\begin{cases} u \in L^2([0,T];(H^{1/2+\epsilon}(O'))^3), \quad u_t \in (L^2([0,T]\times\partial O'))^3, \\ u_{tt} - \nabla\cdot\sigma(u) \in (H^{-1/2}([0,T]\times O'))^3, \\ \sigma(u)\cdot n' \in (L^2([0,T]\times\partial O'))^3, \end{cases} \tag{3.18}$$

where $n' = (n_1, n_2, 0)$ and $\sigma(u) = (\sigma_{ij})_{3\times 3}$.

Applying Theorem 1.2 of Horn [6] locally and using the partition of unity complete our proof. □

By using the same ideas as in Lemma 3.2 and applying Theorem 2.1 of Lasiecka and Triggiani [11], we get the following lemma.

LEMMA 3.3. *Let $T/2 > \alpha > 0$ and $1/2 > \epsilon > 0$ and $1/2 > s_0$. Suppose that w satisfies the problem*

$$\begin{cases} w_{tt} - \gamma\Delta w_{tt} + \gamma\Delta^2 w \in H^{-s_0}(Q^T), \\ w = \dfrac{\partial w}{\partial n} = 0 \quad on \quad \Sigma_0^T, \\ \Delta w - (1-\mu)D^2 w(\tau,\tau) \in L^2(\Sigma_1^T), \\ \dfrac{\partial \Delta w}{\partial n} + (1-\mu)\left[\dfrac{\partial}{\partial\tau}(D^2 w(\tau,n)) + k(x)\dfrac{\partial w}{\partial n} - \dfrac{\partial w_{tt}}{\partial n}\right] \in H^{-1}(\Sigma_1^T). \end{cases} \tag{3.19}$$

Then there is $C_{\alpha,\epsilon,T}$ such that

$$\begin{aligned} &\|D^2 w\|^2_{L^2([\alpha,T-\alpha];L^2(\Gamma_1,T^2))} \\ &\le C_{\alpha,\epsilon,T}\left\{\|w_{tt} - \gamma\Delta w_{tt} + \gamma\Delta^2 w\|^2_{H^{-s_0}(Q^T)} + \|\Delta w - (1-\mu)D^2 w(\tau,\tau)\|^2_{L^2(\Sigma_1^T)}\right. \\ &\quad + \left\|\frac{\partial\Delta w}{\partial n} + (1-\mu)\left[\frac{\partial}{\partial\tau}(D^2 w(\tau,n)) + k(x)\frac{\partial w}{\partial n} - \frac{\partial w_{tt}}{\partial n}\right]\right\|^2_{H^{-1}(\Sigma_1^T)} + \|Dw_t\|^2_{L^2(\Sigma_1^T,\Lambda)} \\ &\quad \left. + \|w\|^2_{L^2([0,T];H^{3/2+\epsilon}(\Omega))} + \|w_t\|^2_{L^2(\Sigma_1^T)}\right\}. \end{aligned} \tag{3.20}$$

LEMMA 3.4. *Let η be a solution of the system* (1.21), (1.22), *and* (1.29) *with the regularity* (2.34). *Let $T/2 > \alpha > 0$ and $1/2 > \epsilon > 0$ and $1/2 > s_0 > 0$ be given. Then*

$$\int_\alpha^{T-\alpha}\int_{\Gamma_1}(|DW|^2 + |D^2 w|^2)\,d\Sigma \le C_{\alpha,T,s_0,\epsilon}\int_{\Sigma_1^T}(|\eta_t|^2 + |Dw_t|^2)\,d\Sigma + lot(\eta). \tag{3.21}$$

Proof. From the formulas in (1.20), (1.29), and (1.30),

$$\begin{cases} (1-\mu)\Upsilon(\eta)(n,n) + \mu(wH - \delta W) = -\breve{\eta}_t F_1^\tau \quad \text{on} \quad \Gamma_1, \\ (1-\mu)\Upsilon(\eta)(n,\tau) = -\breve{\eta}_t F_2^\tau \quad \text{on} \quad \Gamma_1, \end{cases} \tag{3.22}$$

and we obtain

$$\begin{cases} DW(n,n) = -\mu DW(\tau,\tau) - w[(1-\mu)\Pi(n,n) + \mu H] - \breve{\eta}_t F_1^\tau, \\ DW(\tau,n) = -DW(n,\tau) - 2w\Pi(n,\tau) - \dfrac{2}{1-\mu}\breve{\eta}_t F_2^\tau. \end{cases} \tag{3.23}$$

It follows from (3.23) that

$$\begin{aligned} |DW|^2 &= |D_\tau W|^2 + [DW(n,n)]^2 + [DW(\tau,n)]^2 \\ &\le C(|D_\tau W|^2 + |\eta_t|^2 + |Dw_t|^2 + w^2) \quad \text{on} \quad \Gamma_1. \end{aligned} \tag{3.24}$$

Next, note $\Upsilon(\eta) = S(W) + w\Pi$ and the formulas (3.22) and, after applying the inequality (3.12) with $U = W$, we have

$$\begin{aligned} &\|D_\tau W\|^2_{L^2([\alpha, T-\alpha];L^2(\Gamma,\Lambda))} \\ &\le C_{T,\alpha,\epsilon}(\|W_t\|^2_{L^2(\Sigma^T,\Lambda)} + \|w_t\|^2_{L^2(\Sigma_1^T)} + \|Dw_t\|^2_{L^2(\Sigma^T,\Lambda)}) + lot(\eta), \end{aligned} \tag{3.25}$$

where the following inequality is used:

$$\begin{aligned} \|W_{tt} - \Delta_\mu W\|^2_{H^{-1/2}(Q^T,\Lambda)} &= \|(1-\mu)kW + \mathcal{F}(w)\|^2_{H^{-1/2}(Q^T,\Lambda)} \\ &\le C\|(1-\mu)kW + \mathcal{F}(w)\|^2_{L^2(Q^T,\Lambda)} = lot(\eta). \end{aligned} \tag{3.26}$$

Let us consider the component w. We now prove that there is a constant $C > 0$ such that

$$\|D^2 w\|^2_{H^{-s_0}(Q^T,T^2)} \le C\int_0^T \|w\|^2_{H^{2-s_0}(\Omega)}\,dt \qquad \forall\ w \in H^{-s_0}(Q^T). \tag{3.27}$$

For simplicity, we assume that Ω is a coordinate $\mathcal{U}$ with the coordinate system $x = (x_1, x_2)$. Then $Q^T = (0,T) \times \mathcal{U}$. Denote the Fourier transform variable of (t,x) by (ζ_0, ζ). By definition,

$$H^{-s_0}(Q^T) = (H_0^{s_0}(Q))^*, \quad H_0^{s_0}(Q^T) = \{\, w \,|\, w \in H^{s_0}(\mathbb{R}^3),\ \operatorname{supp} w \subset Q^T \,\}.$$

For $u \in H^{-s_0}(Q^T)$ given, we then have

$$\begin{aligned} \|u\|^2_{H^{-s_0}(Q^T)} &= \|(1+|\zeta_0|^2+|\zeta|^2)^{-s_0/2}\hat{u}\|^2_{L^2(\mathbb{R}^3)} \\ &\le \|(1+|\zeta|^2)^{-s_0/2}\hat{u}\|^2_{L^2(\mathbb{R}^3)} \\ &= \int_{\mathbb{R}^2}(1+|\zeta|^2)^{-s_0}\left(\int_{\mathbb{R}}|\hat{u}|^2 d\zeta_0\right)d\zeta_1\zeta_2 \\ &= \int_{\mathbb{R}^2}(1+|\zeta|^2)^{-s_0}\left(\int_0^T|\hat{u}^x|^2 dt\right)d\zeta_1\zeta_2 \\ &= \int_0^T \|u\|^2_{H^{-s_0}(\Omega)}dt \end{aligned} \tag{3.28}$$

since $\operatorname{supp} u \subset Q^T$, where $\hat{u}^x$ denotes the Fourier transform of u with respect to the variable x. In addition, for $i = 1, 2$,

$$\begin{aligned} \left\|\frac{\partial^2 w}{\partial x_i \partial x_j}\right\|^2_{H^{-s_0}(\Omega)} &= \left\|(1+|\zeta|^2)^{-\frac{s_0}{2}}\frac{\partial^2 \hat{w}}{\partial x_i \partial x_j}\right\|^2 \\ &\le \|(1+|\zeta|^2)^{\frac{2-s_0}{2}}\hat{w}\|^2 = \|w\|^2_{H^{2-s_0}(\Omega)}. \end{aligned} \tag{3.29}$$

The inequality (3.27) follows from the inequalities (3.28) and (3.29). The same argument leads us to the following:

$$\|DW\|^2_{H^{-s_0}(Q^T,T^2)} \le C\int_0^T \|W\|^2_{H^{1-s_0}(\Omega,\Lambda)}\,dt, \tag{3.30}$$

and

$$\left\|\frac{\partial}{\partial\tau}(\breve{\eta}_t F_5^\tau)\right\|^2_{H^{-1}(Q^T)} \le C\|\breve{\eta}_t F_5^\tau\|^2_{L^2(Q^T)}. \tag{3.31}$$

Apply the inequality (3.20), together with the inequalities (3.27), (3.30), and (3.31), to obtain

$$\|D^2 w\|^2_{L^2([\alpha,T-\alpha];L^2(\Gamma_1,T^2))} \le C_{\alpha,\epsilon,T}\int_{\Sigma_1^T}(|\eta_t|^2+|Dw_t|^2)\,d\Sigma + lot(\eta). \tag{3.32}$$

The inequality (3.21) follows from the inequalities (3.24), (3.25), and (3.32). □

Proof of Theorem 1.1. First, we make some estimates for the terms in the right-hand side of the inequality (3.2).

Let s_1, $s_2 > 0$ be such that

$$s_1|\nu|^2 \le \nu F\nu^\tau \le s_2|\nu|^2 \qquad \forall\ \nu\in\mathbb{R}^5. \tag{3.33}$$

Then the definition (2.3) of $a_1(\cdot,\cdot)$ gives, for $\varsigma = (U,u)$,

$$s_1\int_{\Gamma_1}(|\varsigma|^2+|Du|^2)\,d\Gamma \le a_1(\varsigma,\varsigma) \le s_2\int_{\Gamma_1}(|\varsigma|^2+|Du|^2)\,d\Gamma. \tag{3.34}$$

Use of the right-hand side of the inequality (3.34), therefore, yields

$$\begin{aligned}
&|a_1(\eta_t,\, m(\eta)+p(\eta))|\\
&\le [a_1(\eta_t,\eta_t)]^{1/2}[a_1(m(\eta)+p(\eta),\ m(\eta)+p(\eta))]^{1/2}\\
&\le C\int_{\Gamma_1}(|\eta_t|^2+|Dw_t|^2+|m(\eta)+p(\eta)|^2+|D(V(w)-b/2w)|^2)\,d\Gamma\\
&\le C\int_{\Gamma_1}[|\eta_t|^2+|Dw_t|^2+|DW|^2+|W|^2+|D^2w|^2+|Dw|^2+w^2]\,\Gamma\\
&= C\int_{\Gamma_1}(|\eta_t|^2+|Dw_t|^2+|DW|^2+|D^2w|^2)\,d\Gamma + l(\eta).
\end{aligned} \tag{3.35}$$

In addition, we have

$$B(\eta,\eta) \le C(|DW|^2+|D^2w|^2+w^2) \quad \text{on} \quad \Gamma_1 \tag{3.36}$$

and, from the geometrical condition (H.3),

$$\int_{\Sigma_0^T} B(\eta,\eta)\langle V,n\rangle\,d\Sigma \le 0. \tag{3.37}$$

Now we substitute the inequalities (3.35)–(3.37) into the inequality (3.2) to obtain

$$\begin{aligned}
\sigma_1\int_0^T E(t)\,dt \le C\int_{\Sigma_1^T}(|\eta_t|^2+|Dw_t|^2+|DW|^2+|D^2w|^2)\,d\Sigma\\
+ C_T(E(0)+E(T)) + lot(\eta).
\end{aligned} \tag{3.38}$$

Next, change the integral domain Σ_1^T into $[\alpha, T-\alpha]\times\Gamma_1$ in both sides of the inequalities (3.38) and use the inequality (3.21) to give

(3.39)
$$\sigma_1\int_\alpha^{T-\alpha} E(t)\,dt \le C_T\left\{E(\alpha)+E(T-\alpha)+\int_{\Sigma_1^T}(|\eta_t|^2+|Dw_t|^2)\,d\Sigma\right\}+lot(\eta).$$

Note the relation $E'(t)=-a_1(\eta_t,\eta_t)$ and the right-hand side of the inequality (3.34) again, and we find, for any $T>\beta>0$,

$$E(\beta)=E(T)+\int_\beta^T a_1(\eta_t,\eta_t)\,dt \le E(T)+C\int_{\Sigma_1^T}(|\eta_t|^2+|Dw_t|^2)\,d\Sigma. \tag{3.40}$$

Using the inequality (3.40) in the inequality (3.39), we obtain, for $T>0$ suitably large,

$$E(T)\le C_T\int_{\Sigma^T}(|\eta_t|^2+|Dw_t|^2)\,d\Sigma+lot(\eta). \tag{3.41}$$

By the compactness and uniqueness (Proposition 2.13 of Yao [21]) approach, we now have

$$E(T)\le C_T\int_{\Sigma_1^T}(|\eta_t|^2+|Dw_t|^2)\,d\Sigma. \tag{3.42}$$

Finally, using the inequality (3.42) and the left-hand side of the inequality (3.34) leads to

$$E(T)\le C_T\int_0^T a_1(\eta_t,\eta_t)\,dt = C_T(E(0)-E(T)), \tag{3.43}$$

that is,

$$E(T)\le \frac{C_T}{1+C_T}E(0). \tag{3.44}$$

Theorem 1.1 follows from the inequality (3.44). □

Acknowledgments. The authors would like to thank Professors I. Lasiecka and R. Triggiani for picking up two mistakes in the first version of this paper and for some advice.

EXISTENCE OF SOLUTIONS TO DIFFERENTIAL INCLUSIONS AND TO TIME OPTIMAL CONTROL PROBLEMS IN THE AUTONOMOUS CASE*

ARRIGO CELLINA† AND ANTÓNIO ORNELAS‡

Abstract. We prove existence of solutions to upper semicontinuous differential inclusions and to time optimal control problems under conditions that are strictly weaker than the usual assumption of convexity.

Key words. differential inclusions, time optimal control problems

AMS subject classifications. 49J15, 34A34, 34A36

1. Introduction. The condition of convexity with respect to the variable gradient has been of universal use in the calculus of variations, in optimal control, and in differential inclusions to prove the existence of solutions. In fact, convexity is the property required in order to pass to a weak limit along a sequence, be it a minimizing sequence or a sequence of successive approximations, preserving the properties that are needed. This approach, however, because of its generality, need not always provide the best results, since it does not take into account possible additional information such as, for instance, the presence of symmetries in the problem. One is led to think that, by suitably exploiting these symmetries, the convexity condition could be substantially reduced. The purpose of the present paper is to show that, for the simplest of such symmetries, the time invariance in the problem of the existence of solutions to upper semicontinuous differential inclusions, convexity can be replaced by a strictly weaker condition, our almost convexity, below. Moreover, we show that, in the case of autonomous control systems of the form

$$x'(t) = f(x(t), u(t)), \quad u(t) \in U(x(t))$$

for the existence of a time optimal solution, Filippov's classical assumption of convexity of the images of the map $F(x) = f(x, U(x))$ can be replaced by the weaker assumption of almost convexity of the same images. As will be shown, our assumption does not imply that the set of solutions to the differential inclusion is closed in the space of continuous functions with uniform convergence, as happens in the case of the assumption of convexity, but only that the sections of this set of solutions are closed. This property is sufficient to establish the existence of time optimal solutions.

2. Main results. The following is our assumption of almost convexity.

DEFINITION 1. *Let X be a vector space. A set $K \subset X$ is called* almost convex *if for every $\xi \in coK$ there exist λ_1 and λ_2, $0 \le \lambda_1 \le 1 \le \lambda_2$, such that $\lambda_1 \xi \in K, \lambda_2 \xi \in K$.*

Every convex set is almost convex. If a set K is almost convex and $0 \in co(K)$, then $0 \in K$. Typical cases of almost convex sets are $K = \partial C$, with C a convex set not containing the origin, or $K = \{0\} \cup \partial C$, C a convex set containing the origin.

It is our purpose to prove the following theorem.

THEOREM 1. *Let $\Omega \subset R^N$ be open, and let F, from Ω to the nonempty subsets of R^N, be upper semicontinuous with bounded, closed, and almost convex values. Then the Cauchy problem*

$$y'(s) \in F(y(s)), \quad y(0) = x_0 \in \Omega$$

admits a solution defined on some interval $[-\delta, \delta]$, $\delta > 0$. Moreover, for every $\tau \in [-\delta, \delta]$, the attainable set at τ, $A_{x_0}(\tau)$, is closed and coincides with $A^{co}_{x_0}(\tau)$, the attainable set at τ of the convexified problem

$$y'(s) \in coF(y(s)), \quad y(0) = x_0.$$

Remarks. (1) The upper semicontinuous map F, from R to the closed subsets of R, defined by $F(x) = -\text{sign}(x)$ for $x \neq 0$, $F(0) = \{-1, +1\}$, is not almost convex at $x = 0$, and the corresponding Cauchy problem with the condition $y(0) = 0$ admits no local solution.

(2) Under the condition of almost convexity, the attainable sets are closed for every (small) τ, but the set of solutions need not be closed in $C(I)$, unlike in the convex case.

The following corollary to Theorem 1, to be compared with Theorem 1 of Filippov [3], shows that, in the case of autonomous control systems, for the existence of a time optimal solution, Filippov's assumption that the set $f(x, U(x))$ is convex can be replaced by the weaker assumption that the same set is almost convex.

COROLLARY 1. *Let $f(x, u)$ be continuous for $x \in \Omega$ and $u \in U(x)$, and let the set valued map $U(x)$, from Ω to the nonempty compact subsets of R^N, be upper semicontinuous. Moreover, assume that the set*

$$F(x) = f(x, U(x))$$

is almost convex for every $x \in \Omega$. Let x_0 and x_1 be given in Ω, and assume that for some $\tilde{t} \geq 0$, $x_1 \in A_{x_0}(\tilde{t})$. Then the problem of reaching x_1 from x_0 in minimum time admits a solution.

For the proof of Theorem 1 we shall need the following preliminary result.

THEOREM 2. *Let F be upper semicontinuous. Let $x : [a, b] \to R^n$ be a solution to*

$$y'(t) \in co(F(y(t))), \quad y(a) = x_a.$$

Assume that there are two integrable functions $\lambda_1(.), \lambda_2(.)$, from $[a, b]$ to R, satisfying $0 \leq \lambda_1(t) \leq 1 \leq \lambda_2(t)$ and such that, for almost every $t \in [a, b]$, we have $\lambda_1(t)x'(t) \in F(x(t))$ and $\lambda_2(t)x'(t) \in F(x(t))$. Then there exists $t = t(s)$, a nondecreasing absolutely continuous map of the interval $[a, b]$ onto itself, such that the map $\tilde{x}(s) = x(t(s))$ is a solution to

$$y'(s) \in F(y(s)), \quad y(a) = x_a.$$

Moreover, $\tilde{x}(a) = x(a)$ and $\tilde{x}(b) = x(b)$.

Proof. (a) When $x'(t) = 0$, we shall assume, without loss of generality, that $\lambda_2(t) = 1$. Consider the set

$$C = \{t \in I : 0 \in F(x(t))\}.$$

From the continuity of x and the upper semicontinuity of F, we obtain that C is closed. Without loss of generality we shall assume that, for t in C, $\lambda_1(t)x'(t) = 0$.

(b) Let $[\alpha, \beta]$ be an interval, and assume that, on this interval, there exist two functions $\lambda_1(.), \lambda_2(.)$ with the properties stated above. In addition, assume that $\lambda_1(t) > 0$ a.e. We claim that there exist two measurable subsets of $[\alpha, \beta]$, having characteristic functions χ_1 and χ_2 such that $\sum \chi_i = \chi_{[\alpha,\beta]}$, and an absolutely continuous function $s = s(t)$ on $[\alpha, \beta]$, $s(\alpha) - s(\beta) = \alpha - \beta$, such that

$$s'(t) = \chi_1(t)\lambda_1(t) + \chi_2(t)\lambda_2(t).$$

This concludes the proof of this claim. □

Redefine $\lambda_1(t)$ and $\lambda_2(t)$ on a set of measure zero to have both functions positive for every $t \in [\alpha, \beta]$. Set $p(.)$ to be $\frac{1}{2}$ when $\lambda_1(t) = \lambda_2(t) = 1$, to be $\frac{\lambda_2 - 1}{\lambda_2 - \lambda_1}$ otherwise. With this definition we have that $0 \le p(t) \le 1$ and that both equalities

$$1 = p(t) + (1 - p(t))$$

and

$$1 = p(t)\lambda_1(t) + (1 - p(t))\lambda_2(t)$$

hold true. In particular, we have

$$\int_\alpha^\beta 1dt = \int_\alpha^\beta [p(t) + (1 - p(t))]dt = \int_\alpha^\beta \left[\frac{p(t)\lambda_1(t)}{\lambda_1(t)} + \frac{(1 - p(t))\lambda_2(t)}{\lambda_2(t)}\right] dt.$$

We wish to apply Liapunov's theorem on the range of measures, to infer the existence of two measurable subsets having characteristic functions $\chi_1(.), \chi_2(.)$ such that $\sum \chi_i = \chi_{[\alpha,\beta]}$ and with the property that

$$\int_\alpha^\beta 1dt = \int_\alpha^\beta \left[\chi_1(t)\frac{1}{\lambda_1(t)} + \chi_2(t)\frac{1}{\lambda_2(t)}\right] dt.$$

However, it is not obvious that the function $\frac{1}{\lambda_1(t)}$ is integrable, and thus the results of [2] need not be applicable. For this purpose we shall use a device already used in [1]. Consider the sequence of disjoint sets

$$E^n = \left\{ t \in [\alpha, \beta] : n < \frac{1}{\lambda_1(t)} \le n + 1 \right\}.$$

We have that $\cup E^n = [\alpha, \beta]$. Applying Liapunov's theorem to each E^n, we infer the existence of two sequences of measurable subsets E_1^n, E_2^n, having characteristic functions χ_1^n, χ_2^n, such that for every n,

$$\int_{E^n} 1dt = \int_{E^n} \left[\chi_1^n(t)\frac{1}{\lambda_1(t)} + \chi_2^n(t)\frac{1}{\lambda_2(t)}\right] dt.$$

Set $\cup E_1^n = E_1$, $\cup E_2^n = E_2$ and $\chi_1 = \sum \chi_1^n$, $\chi_2 = \sum \chi_2^n$. For each m, the function

$$\sigma^m(t) = \sum_{n=0}^{m} \left[\chi_1^n(t)\frac{1}{\lambda_1(t)} + \chi_2^n(t)\frac{1}{\lambda_2(t)}\right]$$

is positive, and the sequence converges pointwise monotonically to

$$\sigma(t) = \chi_1(t)\frac{1}{\lambda_1(t)} + \chi_2(t)\frac{1}{\lambda_2(t)}.$$

Moreover, the sequence of sets $V^m = (\cup_{n=0}^m E^n)_m$ is monotonically increasing to $[a, b]$, so that $\int_\alpha^\beta 1dt = \lim_m \int_{V^m} 1dt$. Hence

$$\int_\alpha^\beta 1dt = \lim_m \int s^m(t)dt = \int \lim_m s^m(t)dt,$$

so that we obtain

$$\int s(t)dt = \int \left[\chi_1(t)\frac{1}{\lambda_1(t)} + \chi_2(t)\frac{1}{\lambda_2(t)}\right] dt = \int_\alpha^\beta 1dt.$$

Define $s'(t) = \sigma(t)$. Then $\int_\alpha^\beta s'(t)dt = \beta - \alpha$. This proves the claim.

(c) Consider the case in which C is empty. In this case, it cannot be that $\lambda_1(t) = 0$ on a set of positive measure, and the previous point (b) can be applied to the interval $[a, b]$. Set $s(t) = a + \int_a^t s'(\tau)d\tau$. By the previous point (b), s is strictly monotonic increasing and maps $[a, b]$ onto itself. Let $t = t(s)$ be its inverse, so that, in particular, $t(a) = a$: we have that $1 = s'(t(s))t'(s)$. Consider the map $\tilde{x}(s) = x(t(s))$. We have

$$\begin{aligned}
\frac{d}{ds}\tilde{x}(s) &= x'(t(s))t'(s) = x'(t(s))\frac{1}{s'(t(s))} \\
&= x'(t(s))\frac{1}{s'(t(s))}\chi_1(t(s)) + x'(t(s))\frac{1}{s'(t(s))}\chi_2(t(s)) \\
&= x'(t(s))\lambda_1(t(s))\chi_1(t(s)) + x'(t(s))\lambda_2(t(s))\chi_2(t(s)) \\
&\in F(x(t(s)) = F(\tilde{x}(s)).
\end{aligned}$$

Hence the theorem is proved in this case.

(d) From now on we shall assume that C is nonempty. Set $c = \sup C$, so that $c \in C$. The complement of C is open relative to $[a, b]$; it consists of at most countably many nonoverlapping open intervals (a_i, b_i), with the possible exception of one of the form $[a_{i_i}, b_{i_i})$ with $a_{i_i} = a$, and one $(a_{i_f}, b_{i_f}]$ with $a_{i_f} = c$. For each i apply point (b) to the interval (a_i, b_i) to infer the existence of K_1^i and K_2^i, two subsets of (a_i, b_i) with characteristic functions $\chi_1^i(t)$ and $\chi_2^i(t)$ such that $\chi_1^i(t) + \chi_2^i(t) = \chi_{(a_i,b_i)}$ and such that, setting

$$s'(t) = \chi_1^i(t)\frac{1}{\lambda_1(t)} + \chi_2^i(t)\frac{1}{\lambda_2(t)},$$

we obtain

$$\int_{a_i}^{b_i} s'(\tau)d\tau = b_i - a_i.$$

(e) On $[a, c]$ set

$$s'(t) = \frac{1}{\lambda_2(t)}\chi_C(t) + \sum\left(\chi_1^i(t)\frac{1}{\lambda_1(t)} + \chi_2^i(t)\frac{1}{\lambda_2(t)}\right),$$

where the sum is over all intervals contained in $[a, c]$, i.e., with the exception of $(c, b]$. We have that

$$\int_a^c s'(\tau)d\tau = \kappa \leq c - a$$

since $\lambda_2(t) \geq 1$ and $\int_{a_i}^{b_i} s'(\tau)d\tau = b_i - a_i$. Setting $s(t) = a + \int_a^t s'(\tau)d\tau$, we obtain that s is an invertible map from $[a, c]$ to $[a, \kappa]$.

(f) Define $t = t(s)$ from $[a, \kappa]$ to $[a, c]$ to be the inverse of $s(.)$. Extend $t(.)$ as an absolutely continuous map $\tilde{t}(.)$ on $[a, c]$, setting

$$\tilde{t}'(s) = 0$$

for $s \in [\kappa, c]$. We claim that the function $\tilde{x}(s) = x(\tilde{t}(s))$ is a solution to

$$y'(s) \in F(y(s)), \quad y(a) = x_a$$

on the interval $[a, c]$. Moreover, we claim that it satisfies $\tilde{x}(c) = x(c)$.

To prove the claim, notice that, as in (c), we have that for s in $[a, \kappa]$, $\tilde{t}(s) = t(s)$ is invertible and

$$\begin{aligned}\frac{d}{ds}\tilde{x}(s) &= x'(\tilde{t}(s))\frac{1}{s'(\tilde{t}(s))} = x'(t(s))\frac{1}{s'(t(s))} \\ &= x'(\tilde{t}(s))\left[\lambda_2(t(s))\chi_C(t(s)) + \sum\left(\chi_1^i(t(s))\lambda_1(t(s)) + \chi_2^i(t(s))\lambda_2(t(s))\right)\right] \\ &\in F(x(t(s)) = F(\tilde{x}(s)).\end{aligned}$$

In particular, from $t(\kappa) = c$ we obtain $\tilde{x}(\kappa) = x(c)$. On $[\kappa, c]$, $\tilde{x}$ is constant and we have

$$\frac{d}{ds}\tilde{x}(s) = 0 \in F(x(c)) = F(\tilde{x}(\kappa)) = F(\tilde{x}(s)).$$

This proves the claim.

(g) It is left to define the solution on $[c, b]$. On it, $\lambda_1(t) > 0$ and the construction of points (b) and (c) can be repeated to find a solution to

$$y'(s) \in F(y(s)), \quad y(c) = x(c)$$

on $[c, b]$. This completes the proof. □

Proof of Theorem 1. By the upper semicontinuity of F, there exist a ball $B = B[x_a, \rho]$ and a positive real M such that F is bounded by M on $B = B[x_a, \rho]$; set $\delta = \frac{\rho}{M}$ and consider the interval $I = [a - \delta, a + \delta]$. On I a solution x to the Cauchy problem

$$y'(s) \in coF(y(s)), \quad y(a) = x_a$$

exists.

Fix any $\tau \in I$. Since the attainable set at τ, $A_{x_0}(\tau)$, is contained in the attainable set for the solutions to the convexified problem, $A_{x_0}^{co}(\tau)$, it is enough to show that $A_{x_0}^{co}(\tau) \subset A_{x_0}(\tau)$.

By assumption, for every x, $F(x)$ is almost convex; hence for almost every $t \in I$ there exist two nonempty sets $\Lambda_1(t)$ and $\Lambda_2(t)$ such that $\lambda_1 x'(t)) \in F(x(t))$ for

$\lambda_1 \in \Lambda_1(t)$, $\lambda_2 x'(t)) \in F(x(t))$ for $\lambda_2 \in \Lambda_2(t)$, and $0 \leq \lambda_1 \leq 1$, $1 \leq \lambda_2$. Set $Z = \{t : x'(t) = 0\}$: there is no loss of generality in assuming that, for $t \in Z$, $\Lambda_1(t) = \Lambda_2(t) = \{1\}$. We claim that the set valued map $t \to \Lambda_1(t)$ is measurable. Applying Lusin's theorem to x', write $I \setminus Z$ as $(\cup K_i) \cup N$, where the measure of N is 0, each K_i is compact, and the restriction to K_i of x' is continuous on K_i. Then, by the continuity on K_i of x' and of x and the upper semicontinuity of F, it follows that the map Λ_1 has a closed graph on $K_i \times R^N$; since, in addition, its values are closed subsets of $[0, 1]$, it is upper semicontinuous. It follows then that Λ_1 is measurable on I. The proof that $t \to \Lambda_2(t)$ is measurable is similar, with the difference that the values of Λ_2 need not be bounded. In this case, write $I \setminus Z$ as the countable union of the sets $M_n = \{t : \|x'(t)\| \geq 1/n\}$. On each M_n, Λ_2 has an upper bound, since F is bounded, and the same reasoning as in the previous point can be applied.

Hence, by standard arguments, there exist measurable selections $\lambda_1(.)$ and $\lambda_2(.)$ from the maps $\Lambda_1(.)$ and $\Lambda_2(.)$.

Apply Theorem 2 to the interval $[a, \tau]$ or $[\tau, a]$ to prove Theorem 1. □

Proof of Corollary 1. Let $t^* = \inf\{t \in [0, \tilde{t}] : x_1 \in A_{x_0}(t)\}$. Let (t_n) be decreasing to t_* and let x_n be solutions to the differential inclusion

$$x'(t) \in F(x(t))$$

such that $x_n(0) = x_0$ and $x_n(t_n) = x_1$. A subsequence of this sequence converges uniformly to x_*, and it is known that x_* is a solution to

$$x'(t) \in coF(x(t)).$$

Then, $x_*(t_*) \in A^{co}_{x_0}(t_*)$, and by Theorem 1 this set coincides with $A_{x_0}(t_*)$. Hence, x_* is the solution to the minimum time problem, and t_* is the minimum time required. □

THE FRACTIONAL REPRESENTATION APPROACH TO SYNTHESIS PROBLEMS: AN ALGEBRAIC ANALYSIS VIEWPOINT PART I: (WEAKLY) DOUBLY COPRIME FACTORIZATIONS*

A. QUADRAT†

Abstract. In this paper, we show how to reformulate the fractional representation approach to analysis and synthesis problems within an algebraic analysis framework. In terms of modules, we give necessary and sufficient conditions so that a system admits (weakly) left/right/doubly coprime factorizations. Moreover, we explicitly characterize the integral domains A such that every plant—defined by means of a transfer matrix whose entries belong to the quotient field of A—admits (weakly) doubly coprime factorizations. Finally, we show that this algebraic analysis approach allows us to recover, on the one hand, the approach developed in [M. C. Smith, *IEEE Trans. Automat. Control*, 34 (1989), pp. 1005–1007] and, on the other hand, the ones developed in [K. Mori and K. Abe, *SIAM J. Control Optim.*, 39 (2001), pp. 1952–1973; V. R. Sule, *SIAM J. Control Optim.*, 32 (1994), pp. 1675–1695 and 36 (1998), pp. 2194–2195; M. Vidyasagar, H. Schneider, and B. A. Francis, *IEEE Trans. Automat. Control*, 27 (1982), pp. 880–894; M. Introduction. In the seventies, Vidyasagar and others introduced the idea of representing a class of transfer functions as the quotient field of a certain integral domain A of proper and stable transfer functions. Examples of such integral domains A, usually encountered in the literature, are the Banach algebra $H_\infty(\mathbb{C}_+)$ of bounded analytic functions in the open right half-plane $\mathbb{C}_+ = \{s \in \mathbb{C} \,|\, \mathrm{Re}\, s > 0\}$ [8], the algebra $RH_\infty = \mathbb{R}(s) \cap H_\infty(\mathbb{C}_+)$ of proper stable real rational functions [49], and the Wiener algebras $\mathcal{A}$, $\hat{\mathcal{A}}$ [3, 8], and $l_1(\mathbb{Z}_+)$ [49]. In the early eighties, this idea naturally led to the *fractional representation approach to synthesis problems*, principally developed in [3, 9, 48, 49]. The main outcome of this point of view is a reformulation of various questions of feedback stabilization of systems in terms of algebraic properties of some matrices whose entries belong to A (e.g., internal/strong/simultaneous/robust/optimal stabilization, parametrization of all the stabilizing controllers, graph topology, etc.).

Unfortunately, questions seem to remain for some classes of (infinite-dimensional) systems, in particular, the following:

1. Do necessary and sufficient conditions exist for internal stabilizability?
2. Is it possible to characterize all the integral domains A such that every plant—defined by means of a transfer matrix whose entries belong to the quotient field of A—is internally stabilizable?
3. What are the links between internal stabilizability and the existence of a doubly coprime factorization for the transfer matrix?

4. Is it always possible to parametrize all the stabilizing controllers of a stabilizing plant by means of the Youla–Kučera parametrization?

In order to solve certain of these open questions, the authors of [40] tried to revisit the fractional representation approach to stabilization problems of single-input single-output (SISO) systems using a more intrinsic framework than the one used in [3, 9, 48, 49]. A module approach has recently been developed in [44] and continued in [22]. In the same years as that last work, another approach was developed in [30, 31, 32] using the ideas of *algebraic analysis* (see [27, 28, 29] and the references therein). The purpose of this paper is to present this new mathematical framework and to explain how certain of the previous open questions can be solved using this algebraic analysis point of view.

In this paper, we first introduce the concepts of *weakly left/right/doubly coprime factorizations*, give necessary and sufficient conditions in terms of modules so that a transfer matrix admits such factorizations, and characterize all the integral domains A over which every transfer matrix admits weakly doubly coprime factorizations (namely, *coherent Sylvester domains*, e.g., $H_\infty(\mathbb{C}_+)$). Moreover, we also give necessary and sufficient conditions so that a transfer matrix admits left/right/doubly coprime factorizations, and we recover a result of Vidyasagar [49] describing all the integral domains A over which every transfer matrix admits doubly coprime factorizations (namely, *Bézout domains*). In particular, we recover and generalize some standard results of [22, 43, 44, 49]. In the second part of the paper [33], we shall use the same mathematical framework and the previous results to develop necessary and sufficient conditions for *internal stabilizability* [9, 48, 49]. Moreover, we shall characterize all the integral domains A over which every plant—defined by means of a transfer matrix whose entries belong to the quotient field of A—is internally stabilizable (namely, *Prüfer domains*). Hence, the algebraic analysis framework seems to solve the first three questions listed above. We refer the reader to [34] for a general answer to the fourth one. Let us note that all these results use the techniques of module theory and homological algebra, and they seem difficult to obtain using only a matrix approach.

If we want to develop some general algorithms (i.e., valid for a general integral domain A) that check the existence of (weakly) left/right/doubly coprime factorizations and compute them, we then have to overcome the difficulty arising from the fact that most of the integral domains of SISO stable plants are *Banach algebras* (e.g., $H_\infty(\mathbb{C}_+)$, $\mathcal{A}$, $\hat{\mathcal{A}}$, $l_1(\mathbb{Z}_+)$). Indeed, a result proves that *noetherian* Banach algebras are only finite-dimensional [41], and thus, most of the Banach algebras used in systems theory are not noetherian. Therefore, it seems that we cannot use the standard techniques of commutative algebra, module theory, and homological algebra developed for noetherian rings to study general (infinite-dimensional) linear systems. (Some modules may fail to be finitely generated.) We show that the only possibility for coping with this difficulty seems to require that the Banach algebras be *coherent rings*. This result could explain why coherent Sylvester domains, Prüfer and Bézout domains, which play important roles in the fractional representation approach (see above), are all coherent. Using the fact that a system is defined by means of a transfer matrix, we prove that, if A is a coherent domain, then every system defines a *coherent A-module*. Now, the (category of) coherent A-modules over a coherent ring A (is) are invariant under all the elementary algebraic manipulations (e.g., intersection, sum, quotient, tensor product, duality, etc.). Therefore, we can use homological algebra to develop general algorithms which check the existence of (weakly) left/right/doubly coprime factorizations (or internal stabilizability in [33]) of (infinite-dimensional) linear systems defined over a coherent domain A.

Plan. In the first part of this paper (section 1), we describe the framework of the fractional representation approach to analysis and synthesis problems and explain why and how it is possible to use module theory. We recall some definitions of module theory and homological algebra that will be constantly used in the rest of the paper and in [33]. The second part (section 2) is related to factorization problems. We first introduce the concept of *a weakly doubly coprime factorization* and show that it corresponds to the weakest coprimeness for transfer matrices. We give necessary and sufficient conditions so that a transfer matrix admits a weakly left/right/doubly coprime factorization. In the third part (section 3), we introduce the concept of coherent rings and modules. We prove that every transfer matrix, with entries in the quotient field of A, admits a weakly doubly coprime factorization iff A is a *coherent Sylvester domain*. We show that $H_\infty(\mathbb{C}_+)$ is a coherent Sylvester domain. Finally, in the last part (section 4), we give necessary and sufficient conditions so that a transfer matrix admits left/right/doubly coprime factorizations.

Notation. In the course of the text, A denotes a commutative integral domain ($a\,b = 0, a \neq 0 \Rightarrow b = 0$) with a unit, $M_{q\times p}(A)$ (resp., $M_p(A)$) the set of $q \times p$ (resp., $p\times p$) matrices whose entries belong to A, and I_p the identity matrix. If $R \in M_{q\times p}(A)$, then R^T is the transposed matrix. *By convention, every vector with entries in A is a row vector.* The positive integers p, $q \in \mathbb{Z}_+$ will always satisfy $p \geq q$. If M and N are two A-modules, then $M \cong N$ means that M and N are isomorphic as A-modules, $\hom_A(M, N)$ is the A-module of the A-morphisms (i.e., A-linear maps) from M to N, and $M^* = \hom_A(M, A)$. Finally, $(a_1, \ldots, a_n)$ denotes the ideal $A\,a_1 + \cdots + A\,a_n$, and $\triangleq$ means "by definition."

1. The fractional representation approach to synthesis problems.

1.1. Introduction. Following ideas of Zames [51], a class of transfer functions needs to have the structure of a ring if we want to connect two systems in cascade (product) or in parallel (sum). In the fractional representation approach to analysis and synthesis problems, we start with an integral domain A of *SISO stable plants* [3, 8, 9, 48, 49]. Classical examples of integral domains of SISO stable plants are the Banach algebra $H_\infty(\mathbb{C}_+)$ of the bounded analytic functions on the open right half-plane $\mathbb{C}_+ = \{s \in \mathbb{C} \mid \mathrm{Re}\, s > 0\}$ [8], the ring RH_∞ of proper stable real rational functions [49], or the Wiener algebras $\mathcal{A}$, $\hat{\mathcal{A}}$, $l_1(\mathbb{Z}_+)$ [8, 49]. Then, the class of (unstable) SISO plants considered is defined by the field of fractions of A:

$$K = Q(A) = \{n/d \mid 0 \neq d,\, n \in A\}. \tag{1.1}$$

Example 1.1. Let us give some examples.

- Let us consider $A = RH_\infty = \{p = n/d \mid \deg n \leq \deg d,\, d(\underline{s}) = 0 \Rightarrow \mathrm{Re}\,\underline{s} < 0\}$ the integral domain of proper stable real rational functions. The transfer function $p = 1/(s-1)$ (resp., $p = s$) does not belong to A because p has the unstable pole 1 in $\mathbb{C}_+$ (resp., p is not proper) but belongs to $K = Q(A) = \mathbb{R}(s)$ because p can be represented as $p = n/d$ with $n = 1/(s+1) \in A$ and $d = (s-1)/(s+1) \in A$ (resp., $n = s/(s+1) \in A$ and $d = 1/(s+1) \in A$).
- Let us consider the following Wiener algebra [3, 8]:

$$\mathcal{A} = \left\{ f(t) + \sum_{i=0}^{\infty} a_i\, \delta(t - t_i) \mid f \in L_1(\mathbb{R}_+), (a_i)_{i\geq 0} \in l_1(\mathbb{Z}_+),\ 0 = t_0 \leq t_1 \ldots \right\},$$

with the two operations + and the convolution $\star$ and the Dirac distribution δ as the unit. Endowed with the topology defined by the norm

$$\| g \|_{\mathcal{A}} = \| f \|_{L_1(\mathbb{R}_+)} + \| (a_i)_{i\geq 0} \|_{l_1(\mathbb{Z}_+)},$$

$\mathcal{A}$ becomes a *Banach algebra* and an integral domain [3, 8, 48, 49]. The same properties hold for $\hat{\mathcal{A}} = \{\hat{f} \mid f \in \mathcal{A}\}$ ($\hat{\cdot}$ is the Laplace transform) with the norm $\| \hat{f} \|_{\hat{\mathcal{A}}} = \| f \|_{\mathcal{A}}$. For instance, an example of a transfer function which belongs to $K = Q(\mathcal{A})$ is the following:

$$p = e^t\, Y(t) \star \delta(t-1) = (\delta(t) - 2\, e^{-t}\, Y(t))^{-1} \star (e^{-t}\, Y(t) \star \delta(t-1)),$$

where $Y(t)$ denotes the Heaviside distribution (i.e., 1 for $t \geq 0$, and 0 otherwise) and $\delta(t) - 2\, e^{-t}\, Y(t)$, $e^{-t}\, Y(t) \star \delta(t-1) \in \mathcal{A}$. Equivalently, in the frequency domain, the same plant is defined by the following transfer function:

$$p = \frac{e^{-s}}{s-1} = \frac{\left(\frac{e^{-s}}{s+1}\right)}{\left(\frac{s-1}{s+1}\right)} \in Q(\hat{\mathcal{A}}), \qquad \frac{e^{-s}}{s+1},\ \frac{s-1}{s+1} \in \hat{\mathcal{A}}.$$

If $P \in M_{q\times(p-q)}(K)$, then it is always possible to write it as $P = D^{-1}\, N = \tilde{N}\, \tilde{D}^{-1}$, where $D \in M_q(A)$ and $\tilde{D} \in M_{p-q}(A)$ are two invertible matrices and $N \in M_{q\times(p-q)}(A)$, $\tilde{N} \in M_{q\times(p-q)}(A)$, i.e., all the entries of these four matrices are stable. For example, we can use $D = d\, I_q$ and $N = d\, P$, where $0 \neq d \in A$ is the product of the denominators of all the entries of P, and similarly for $\tilde{D} = d\, I_{p-q}$ and $\tilde{N} = P\, d$.

Example 1.2. Let $A = H_\infty(\mathbb{C}_+)$, and let us consider the plant defined by

$$P = \begin{pmatrix} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s-1} \end{pmatrix} \in M_2(K), \qquad K = Q(A). \tag{1.2}$$

Then, P can be written as $P = D^{-1}\, N$ with

$$D = \begin{pmatrix} \frac{s-1}{s+1} & 0 \\ 0 & \frac{s-1}{s+1} \end{pmatrix} \in M_2(A), \qquad N = \begin{pmatrix} \frac{(s-1)\, e^{-s}}{(s+1)^2} & \left(\frac{s-1}{s+1}\right)^2 \\ 0 & \frac{1}{s+1} \end{pmatrix} \in M_2(A). \tag{1.3}$$

Thus, instead of representing a plant by $y = P\, u$ with $P \in M_{q\times(p-q)}(K)$, the fractional representation approach studies the following two systems:

$$(D : -N) \begin{pmatrix} y \\ u \end{pmatrix} = 0, \qquad \begin{pmatrix} y \\ u \end{pmatrix} = \begin{pmatrix} \tilde{N} \\ \tilde{D} \end{pmatrix} z,$$

with $R = (D : -N) \in M_{q\times p}(A)$ and $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. Then, using linear algebra over the ring A, it is possible to study the structural properties of P by looking at the algebraic properties of the matrices R and $\tilde{R}$ (left/right/doubly factorizations). See [3, 8, 9, 48, 49] for more information.

For linear finite-dimensional systems [49], the fractional representation approach gives necessary and sufficient conditions for internal stabilizability, existence of doubly coprime factorizations, or Youla–Kučera parametrizations of all the stabilizing controllers, etc. [49]. The possibility of generalizing these results to linear infinite-dimensional

systems (delay systems, partial differential equations such as the wave/heat/Euler–Bernoulli equations) has naturally been asked from theoretical and practical points of view [3, 8, 9, 48, 49]. In this framework, classes of linear infinite-dimensional systems are generally modelized by means of Banach algebras such as $H_\infty(\mathbb{C}_+)$, $\hat{\mathcal{A}}$, $l_1(\mathbb{Z}_+)$. These rings are algebraically and topologically more complex than the ring RH_∞ used for finite-dimensional systems. Hence, some questions, such as the ones given in the introduction, are still open for some classes of infinite-dimensional systems [8, 48, 49]. As we described it in the introduction, the purpose of this paper is to show that we can solve certain of these problems if we adopt an *algebraic analysis* framework rather than a matricial one. Here, we call "algebraic analysis" a mathematical framework which uses commutative algebra, module theory, and homological algebra combined with functional analysis (Banach algebras). This idea could seem natural if we notice that, in order to understand the structural properties of a plant, defined by the transfer matrix $P \in M_{q\times(p-q)}(K)$, we need to study the matrices $R \in M_{q\times p}(A)$ and $\tilde{R} \in M_{p\times(p-q)}(A)$, whose entries belong to a certain algebra of functions (e.g., a Banach algebra), and linear algebra over a ring is just a part of module theory.

1.2. Definitions. In this section, we give some definitions that we shall need to characterize intrinsically the structural properties of systems.

Let $R \in M_{q\times p}(A)$, and let us define the A-morphism (i.e., an A-linear map) $.R$ by

$$\begin{array}{rccc} .R: & A^q & \longrightarrow & A^p, \\ & (a_1 : \cdots : a_q) & \longrightarrow & (a_1 : \cdots : a_q)R. \end{array}$$

Then, the image $\operatorname{im} .R$ is the A-module generated by the A-linear combinations of the rows of R. This A-module is usually used in control theory [22, 44]. In *algebraic analysis* [27, 28, 29], one usually prefers to use the A-module $M = \operatorname{coker} .R = A^p/A^q R$.

Definition 1.1. *We have the following definitions (see* [1, 2, 39]*):*

- *A* complex *is a sequence of A-modules F_i and A-morphisms d_i, denoted by* $\cdots \longrightarrow F_{i+1} \xrightarrow{d_{i+1}} F_i \xrightarrow{d_i} F_{i-1} \longrightarrow \cdots$, *such that* $d_i \circ d_{i+1} = 0$, *i.e.,*

$$\operatorname{im} d_{i+1} \subseteq \ker d_i.$$

- *The ith* A-module of homology *of a complex is defined by*

$$H(F_i) = \frac{\ker d_i}{\operatorname{im} d_{i+1}}.$$

- *A sequence is said to be* exact *at F_i if $H(F_i) = 0$, i.e.,* $\ker d_i = \operatorname{im} d_{i+1}$, *and* exact *if we have $H(F_i) = 0$ for all i.*

Example 1.3. For instance, the exact sequence $0 \longrightarrow M' \xrightarrow{f} M$ means that f is injective, whereas the exact sequence $M \xrightarrow{g} M'' \longrightarrow 0$ means that g is surjective.

Let π be the A-morphism which associates to every row vector of A^p its class in the quotient A-module $M = A^p/A^q R$. We have the following exact sequence:

$$A^q \xrightarrow{.R} A^p \xrightarrow{\pi} M \longrightarrow 0. \tag{1.4}$$

Let $\{e_1, \ldots, e_p\}$ be the canonical basis of A^p, and $\{f_1, \ldots, f_q\}$ that of A^q. We define

$z_i = \pi(e_i),\ i = 1, \dots, p$. Then, we have for $i = 1, \dots, q$

$$
\begin{aligned}
f_i\, R = (R_{i1} : \cdots : R_{ip}) &= \sum_{j=1}^{p} R_{ij}\ e_j \in A^q\, R \\
\Rightarrow \pi(f_i\, R) &= \sum_{j=1}^{p} R_{ij}\ \pi(e_j) = \sum_{j=1}^{p} R_{ij}\ z_j = 0.
\end{aligned} \tag{1.5}
$$

Hence, M is defined by the equations $R\, z = 0$, where $z = (z_1 : \cdots : z_p)^T$, and their A-linear combinations. Moreover, for all $m \in M$, there exists $(a_1 : \cdots : a_p) \in A^p$ such that

$$
m = \pi((a_1 : \cdots : a_p)) = \pi\left(\sum_{i=1}^{p} a_i\, e_i\right) = \sum_{i=1}^{p} a_i\, \pi(e_i) = \sum_{i=1}^{p} a_i\, z_i.
$$

This means that every element m of M is an A-linear combination of the elements $z_1, \dots, z_p$, and the A-module M is said to be *finitely generated*. In fact, the module is defined by a finite number of equations (q equations) with a finite number of unknowns (p unknowns). In this case, we say that M is *finitely presented*, a fact which is equivalent to the existence of the exact sequence (1.4).

Example 1.4. Let us reconsider Example 1.2. We have $A = H_\infty(\mathbb{C}_+)$, and the matrix $R = (D : -N) \in M_{2\times 4}(A)$ is defined by

$$
R = \begin{pmatrix} \frac{s-1}{s+1} & 0 & -\frac{(s-1)\, e^{-s}}{(s+1)^2} & -\left(\frac{s-1}{s+1}\right)^2 \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{pmatrix}. \tag{1.6}
$$

Then, the A-morphism $.R$ is defined by

$$
\begin{aligned}
A^2 &\longrightarrow A^4, \\
(a_1 : a_2) &\longrightarrow \left(a_1\, \left(\tfrac{s-1}{s+1}\right) :\ a_2\, \left(\tfrac{s-1}{s+1}\right) :\ -a_1\, \left(\tfrac{(s-1)\, e^{-s}}{(s+1)^2}\right) :\ -a_1\, \left(\tfrac{s-1}{s+1}\right)^2 - a_2\, \tfrac{1}{(s+1)}\right).
\end{aligned}
$$

Therefore, the A-module $M = A^4/A^2\, R$ is defined by the equations

$$
\begin{cases} \frac{(s-1)}{(s+1)}\, y_1 - \frac{(s-1)\, e^{-s}}{(s+1)^2}\, u_1 - \left(\frac{s-1}{s+1}\right)^2 u_2 = 0, \\ \frac{(s-1)}{(s+1)}\, y_2 - \frac{1}{(s+1)}\, u_2 = 0 \end{cases}
$$

and their A-linear combinations, where $y_i = \pi(e_i),\ u_i = \pi(e_{i+2}),\ i = 1, 2$.

Definition 1.2. *We have the following definitions (see* [1, 39]*):*

- *An A-module M is* finitely generated *if there exists an A-module of the form $F_0 \cong A^{r_0}$, $r_0 \in \mathbb{Z}_+$, such that we have the following exact sequence:*

$$
F_0 \xrightarrow{d_0} M \longrightarrow 0. \tag{1.7}
$$

- *An A-module M is* finitely presented *if there exist two A-modules $F_i \cong A^{r_i}$, $r_i \in \mathbb{Z}_+$, $i = 0, 1$, such that we have the following exact sequence:*

$$
F_1 \xrightarrow{d_1} F_0 \xrightarrow{d_0} M \longrightarrow 0. \tag{1.8}
$$

One of the main interests of associating an A-module with a matrix $R \in M_{q\times p}(A)$ is that we can use the natural classification of the properties of the module to understand the structural properties of the system $R\,z = 0$. The purpose of the next sections and [33] is to illustrate how some concepts of modules play interesting roles in characterizing the existence of a (weakly) left/right/doubly coprime factorization and internal stabilizability.

DEFINITION 1.3 (see [2, 39]). *If M is a finitely generated A-module, then*

- *M is* free *if $M \cong A^r$ for $r \in \mathbb{Z}_+$.*
- *M is* stably free *if there exist $r, s \in \mathbb{Z}_+$ such that $M \oplus A^s \cong A^r$.*
- *M is* projective *if there exist an A-module N and $r \in \mathbb{Z}_+$ such that*

$$M \oplus N \cong A^r.$$

- *M is* reflexive *if the A-morphism $\epsilon : M \longrightarrow \hom_A(\hom_A(M, A), A)$—defined by $\epsilon(m)(f) = f(m)$ for all $m \in M$, for all $f \in \hom_A(M, A)$—is an isomorphism.*
- *M is* torsion-free *if its* torsion submodule

$$t(M) = \{m \in M \mid \exists\, a \in A \setminus 0 :\ a\,m = 0\}$$

is reduced to 0. $m \in t(M)$ is a torsion element. *We have the exact sequence:*

$$0 \longrightarrow t(M) \longrightarrow M \longrightarrow M/t(M) \longrightarrow 0. \tag{1.9}$$

- *M is a* torsion *A-module if $t(M) = M$.*
- *M is a* flat *A-module if, for every relation $\sum_{i=1}^{q} a_i\, m_i = 0,\ a_i \in A,\ m_i \in M$, there exist $n_i \in M$ and $b_{ij} \in A$ such that*

$$\begin{cases} m_i = \displaystyle\sum_{j=1}^{r} b_{ij}\, n_j, & 1 \le i \le q, \\ \displaystyle\sum_{i=1}^{q} a_i\, b_{ij} = 0, & 1 \le j \le r. \end{cases}$$

PROPOSITION 1.4 (see [1, 2, 39]). *We have the following relations:*

1. *Free $\Rightarrow$ stably free $\Rightarrow$ projective $\Rightarrow$ reflexive $\Rightarrow$ torsion-free.*
2. *Projective $\Rightarrow$ flat $\Rightarrow$ torsion-free.*
3. *A finitely generated flat A-module is projective.*
4. *If A is a Bézout domain—namely, a domain A such that every finitely generated ideal I of A has the form $I = (a)$ for a certain $a \in A$—then every finitely generated torsion-free A-module is free and $M \cong t(M) \oplus M/t(M)$.*

DEFINITION 1.5. *We have the following definitions (see* [6, 20]*):*

- *A is a* Hermite ring *if every finitely generated stably free A-module is free, or, equivalently, if every* unimodular row $(a_1 : \cdots : a_n) \in A^n$ *—namely a row such that there exists $(b_1 : \cdots : b_n)^T$ satisfying $\sum_{i=1}^{n} a_i\, b_i = 1$—can be completed to a* unimodular matrix, *i.e., to a matrix of $GL_n(A)$.*
- *A is a* projective-free ring *if every finitely generated projective A-module is free.*

In particular, a projective-free ring (e.g., a Bézout domain) is a Hermite ring. A difficult result, namely, the Quillen–Suslin theorem [20, 39], proves that the ring of polynomials $k[\chi_1, \ldots, \chi_n]$ in χ_i, with coefficients in a field k, is projective-free.

THEOREM 1.6. *RH_∞ and $k[s]$, where k is a field, are principal ideal domains (namely, a domain such that every ideal I of A is principal, i.e., has the form $I = (a)$ for a certain $a \in A$; see* [49]*). The domain of entire functions with coefficients in $k = \mathbb{R}, \mathbb{C}$,*

$$E(k) = \left\{ f(s) = \sum_{n=0}^{+\infty} a_n \, s^n \mid a_n \in k, \lim_{n \to +\infty} |a_n|^{1/n} = 0 \right\},$$

and $\mathcal{E} = E(\mathbb{R}) \cap \mathbb{R}(s)\,[e^{-s}]$ are Bézout domains (see [18, 21]*). Thus, all these rings are projective-free.*

We introduce the concept of *localization* of modules. In the following sections, we shall show why this concept is interesting for the study of the links between a transfer matrix $y = P\,u$, $P = D^{-1}\,N \in M_{q\times(p-q)}(K)$ and the system $D\,y = N\,u$, where $R = (D : -N) \in M_{q\times p}(A)$.

DEFINITION 1.7 (see [1, 39]). *We have the following definitions:*

- *A* multiplicative set *S of A is a subset of A such that for all $a, b \in S \Rightarrow a\,b \in S$ and $1 \in S$.*
- *Let M be an A-module. We define an equivalence relation $\sim$ on $S \times M$ by $(s, m) \sim (s', m')$ if there exists $t \in S$ such that $t(sm' - s'm = 0)$. The* localization *of the A-module M with respect to S is the $S^{-1}A = \{a/s \mid (s, a) \in S \times A\}$-module*

$$S^{-1}M = (S \times M)/\sim .$$

If we denote by m/s the equivalence class of (s, m) in $S^{-1}M$, then we have

$$S^{-1}M = \{(a/s)\,m \mid (s, a) \in S \times A,\, m \in M\}\,.$$

The localization of a module is just a way to extend the scalars of the A-module M from A to $S^{-1}A$. Moreover, we have the following canonical A-morphism:

$$\begin{array}{rcl} i_S : M & \longrightarrow & S^{-1}M, \\ m & \longrightarrow & m/1, \end{array}$$

from which we obtain $\ker i_S = \{m \in M \mid \exists\, 0 \neq a \in S,\ a\,m = 0\}$.

DEFINITION 1.8. *If $S = A \setminus 0$, then S is a multiplicative set of A, and the* field of fractions *of A is defined by $S^{-1}A = Q(A) = \{a/b \mid 0 \neq b,\, a \in A\}$. We have*

$$\ker\, i_S = t(M) = \{m \in M \mid \exists\, 0 \neq a \in A : a\,m = 0\}. \tag{1.10}$$

In the course of the paper, we shall denote by K the field of fractions $Q(A)$ of A.

Example 1.5. Let us reconsider the A-module $M = A^4/A^2\,R$ defined in Example 1.4. We can check that the element $z = y_1 - \frac{e^{-s}}{(s+1)}\,u_1 - \frac{(s-1)}{(s+1)}\,u_2$ satisfies $\frac{(s-1)}{(s+1)}\,z = 0$, i.e., z is a torsion element of M. (See Example 3.4 for an explicit computation of the torsion elements of M.) If $S = A \setminus 0$, then, in the $K = Q(A)$-module $S^{-1}\,M$, we have

$$\frac{(s-1)}{(s+1)}\left(\frac{z}{1}\right) = \frac{\frac{(s-1)}{(s+1)}\,z}{1} = \frac{0}{1} \Rightarrow \frac{(s+1)}{(s-1)}\,\frac{(s-1)}{(s+1)}\left(\frac{z}{1}\right) = \frac{z}{1} = \frac{0}{1} \Rightarrow i_S(z) = \frac{0}{1}.$$

Moreover, we have the following isomorphism (see [1, 39]):

$$\begin{array}{rcl} S^{-1}M & \cong & S^{-1}A \otimes_A M, \\ (a/b)\,m & \longleftrightarrow & a/b \otimes m, \end{array} \tag{1.11}$$

which shows that the localization corresponds to the *tensor product* $S^{-1}A\otimes_A$.

DEFINITION 1.9 (see [1, 39]). *The* rank *of an A-module is defined by*

$$\operatorname{rank}_A(M) = \dim_K(K \otimes_A M),$$

where $K \otimes_A M$ is a K-vector space and $\dim_K(K \otimes_A M)$ is its dimension over K.

PROPOSITION 1.10 (see [1, 2, 39]). *If S is a multiplicative set of A, then $S^{-1}A$ is a flat A-module, and, for every exact sequence $0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$, we have the following exact sequence:*

$$0 \longrightarrow S^{-1}A \otimes_A M' \longrightarrow S^{-1}A \otimes_A M \longrightarrow S^{-1}A \otimes_A M'' \longrightarrow 0.$$

Moreover, if M', M, and M'' are finitely generated A-modules, then we have

$$\operatorname{rank}_A(M) = \operatorname{rank}_A(M') + \operatorname{rank}_A(M''). \tag{1.12}$$

2. Weakly doubly coprime factorizations. Since the work of Rosenbrock [38] on coprime factorizations of rational matrices, this concept has played an increasing role in analysis and synthesis problems. This technique has been popularized by the book of Vidyasagar [49]. However, contrary to finite-dimensional systems, the transfer matrices of more general systems (delay systems, partial differential equations) do not generally admit doubly coprime factorizations. Intuitively, this comes from the fact that the algebraic properties of rings such as $H_\infty(\mathbb{C}_+)$, $\mathcal{A}$, $\hat{\mathcal{A}}$, and $l_1(\mathbb{Z}_+)$ are more complex than the ones of RH_∞ or $k[s]$ (with k a field), which are used for finite-dimensional systems. In the next section, we shall give a mathematical formulation of the term "more complex." In order to achieve this goal, we shall need to introduce the concept of weakly doubly coprime factorizations of a transfer matrix.

2.1. Weak primeness and torsion-free modules. Let us introduce the concept of a weakly left-prime matrix.

DEFINITION 2.1. *Let A be an integral domain and $K = Q(A)$ its field of fractions. The matrix $R \in M_{q\times p}(A)$ is* weakly left-prime *if it satisfies*

$$K^q R \cap A^p = A^q R,$$

namely, if, for every $\lambda \in A^p$ satisfying $\lambda = \mu R$ for a certain $\mu \in K^q$, there exists $\nu \in A^q$ such that $\lambda = \nu R$. The concept of weak right-primeness *can be defined similarly. Let us notice that R is weakly right-prime iff R^T is weakly left-prime.*

If $R \in M_{q\times p}(A)$ has *full row rank*, namely, if the q rows of R are A-linearly independent, then R is weakly left-prime iff

$$\mu \in K^q, \quad \mu R \in A^p \Rightarrow \mu \in A^q.$$

Example 2.1. Let us consider the full row rank matrix R defined by (1.6). This matrix R is not weakly left-prime because $(\frac{s+1}{s-1} : 0) \notin A^2$ and we have

$$\left(\tfrac{s+1}{s-1} : 0\right) \begin{pmatrix} \frac{s-1}{s+1} & 0 & -\frac{(s-1)\,e^{-s}}{(s+1)^2} & -\left(\frac{s-1}{s+1}\right)^2 \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{pmatrix} = \left(1 : 0 : -\tfrac{e^{-s}}{s+1} : -\tfrac{s-1}{s+1}\right) \in A^4.$$

PROPOSITION 2.2 (see [43]). *If A is* a greatest common divisor domain *(GCDD), namely, every couple of elements of A has a greatest common divisor, then a full row*

rank matrix $R \in M_{q\times p}(A)$ is weakly left-prime iff R is irreducible *(or* minor left-prime [27]*), namely,* 1 *is the greatest common divisor of the $q \times q$ minors of R.*

Let us notice that if A is no longer a GCDD, then the previous result fails to be true [43]. In particular, it is not known whether or not $\mathcal{A}$ or $\hat{\mathcal{A}}$ are GCDD.

LEMMA 2.3. *Let A be an integral domain, $K = Q(A)$ its field of fractions, and $R \in M_{q\times p}(A)$. Then, we have*

$$K^q R \cap A^p = \overline{A^q R},$$

where $\overline{A^q R} = \{\lambda \in A^p \mid \exists\, 0 \neq a \in A : a\lambda \in A^q R\}$ is called the A-closure of the submodule $A^q R$ in A^p *(see* [7]*).*

Proof. Let $\lambda \in K^q R \cap A^p$; then $\lambda \in A^p$, and there exists $\mu \in K^q$ such that $\lambda = \mu R$. Let us write $\mu = d^{-1}\nu$ with $\nu \in A^q$ and $0 \neq d \in A$. Then, we have $d\lambda = \nu R$, i.e., $\lambda \in \overline{A^q R}$. Conversely, let $\lambda \in \overline{A^q R}$; then $\lambda \in A^p$, and there exists $0 \neq d \in A$ such that $d\lambda \in A^q R$. Thus, there exists $\nu \in A^q$ such that $d\lambda = \nu R$; i.e., $\lambda = (d^{-1}\nu) R \in K^q R$, i.e., $\lambda \in K^q R \cap A^p$. □

PROPOSITION 2.4. *Let A be an integral domain, $K = Q(A)$ its field of fractions, $R \in M_{q\times p}(A)$, and $M = A^p/A^q R$. Then, we have*

$$\begin{cases} t(M) = (K^q R \cap A^p)/A^q R, \\ M/t(M) = A^p/(K^q R \cap A^p). \end{cases}$$

Proof. Let us note that we have $A^q R \subseteq K^q R \cap A^p$. Therefore, we have the following commutative exact diagram,

$$\begin{array}{ccccccccc}
 & & 0 & & 0 & & & & \\
 & & \downarrow & & \downarrow & & & & \\
0 & \longrightarrow & A^q R & \longrightarrow & A^p & \longrightarrow & M & \longrightarrow & 0 \\
 & & \downarrow & & \| & & \downarrow & & \\
0 & \longrightarrow & K^q R \cap A^p & \longrightarrow & A^p & \longrightarrow & A^p/(K^q R \cap A^p) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & (K^q R \cap A^p)/A^q R & & 0 & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array}$$

from which we deduce the following exact sequence (snake lemma [2, 39]):

$$0 \longrightarrow (K^q R \cap A^p)/A^q R \longrightarrow M \longrightarrow A^p/(K^q R \cap A^p) \longrightarrow 0. \tag{2.1}$$

Using Lemma 2.3, we obtain

$$(K^q R \cap A^p)/A^q R = \overline{A^q R}/A^q R = \{m \in M \mid \exists\, 0 \neq a \in A : a\, m = 0\} = t(M).$$

Then, we have $A^p/(K^q R \cap A^p) = M/t(M)$ (see (1.9)), which proves the proposition. □

A direct consequence of Proposition 2.4 is the following corollary, which gives a module interpretation of the weak left-primeness.

COROLLARY 2.5. *Let A be an integral domain and $K = Q(A)$ its field of fractions, $R \in M_{q\times p}(A)$, and the A-module $M = A^p/A^q R$. Then, we have the equivalences*

1. *R is weakly left-prime, i.e., $\overline{A^q R} = K^q R \cap A^p = A^q R$;*
2. *M is a torsion-free A-module, i.e., $t(M) = 0$.*

Example 2.2. From Example 2.1, we know that the matrix R defined by (1.6) is not weakly left-prime. By Corollary 2.5, we deduce that the A-module $M = A^4/A^2\,R$ is not torsion-free. A torsion element is obtained by taking the class of the vector $(1:\ 0:\ -\frac{e^{-s}}{s+1}:\ -\frac{s-1}{s+1})$ (see Example 2.1) in M to obtain $z = y_1 - \frac{e^{-s}}{(s+1)}\,u_1 - \frac{(s-1)}{(s+1)}\,u_2$. We recover the torsion element z obtained in Example 1.5. It satisfies $\frac{(s-1)}{(s+1)}\,z = 0$.

Dually, we can prove that $\tilde{R} \in M_{p\times(p-q)}(A)$ is weakly right-prime iff the A-module $A^p/A^{p-q}\,\tilde{R}^T$ is torsion-free.

2.2. Transfer matrices. The following lemma shows that if a transfer matrix $P \in M_{q\times(p-q)}(K)$ is such that $P = D^{-1}\,N$, then the A-module $\overline{A^q\,R}$ depends only on P and not on $R = (D:\ -N) \in M_{q\times p}(A)$.

LEMMA 2.6. *Let A be an integral domain, $K = Q(A)$ its field of fractions, and $P \in M_{q\times(p-q)}(K)$ a transfer matrix. If P can be written as $P = D_1^{-1}\,N_1 = D_2^{-1}\,N_2$, where $R_1 = (D_1:\ -N_1) \in M_{q\times p}(A)$ and $R_2 = (D_2:\ -N_2) \in M_{q\times p}(A)$, then we have*

$$\begin{cases} A^q\,R_1 \subseteq \overline{A^q\,R_2}, \\ \\ A^q\,R_2 \subseteq \overline{A^q\,R_1}, \end{cases} \Rightarrow \overline{A^q\,R_1} = \overline{A^q\,R_2},$$

and thus, $\overline{A^q\,R_i}$ and $M_i/t(M_i) = A^p/\overline{A^q\,R_i}$ depend only on P and not on R_i, where $M_i = A^p/A^q\,R_i$. In particular, if $A^q\,R_1$ (resp., $A^q\,R_2$) is A-closed, then we have $\overline{A^q\,R_2} = A^q\,R_1$ (resp., $\overline{A^q\,R_1} = A^q\,R_2$). The same result holds for $P = \tilde{N}_i\,\tilde{D}_i^{-1}$.

Proof. Clearing the denominators of P, we have $P = d^{-1}\,H = H\,d^{-1}$, where $0 \neq d \in A$, and $H \in M_{q\times(p-q)}(A)$. Let $R = (d\,I_q:\ -H) \in M_{q\times p}(A)$. Then, we have

$$\begin{cases} D_i\,H = d\,N_i, \\ \\ (\det D_i)\,H = (D_i^c\,d)\,N_i, \end{cases} \Rightarrow \begin{cases} D_i\,R = d\,R_i, \\ \\ (\det D_i)\,R = (D_i^c\,d)\,R_i, \end{cases} \quad i = 1, 2,$$

where D_i^c is the cofactors matrix of D_i, i.e., it satisfies $D_i^c\,D_i = (\det D_i)\,I_q$. Let $\lambda \in A^q\,R_i$; then there exists $\mu \in A^q$ such that $\lambda = \mu\,R_i$, and thus,

$$d\,\lambda = \mu\,(d\,R_i) = \mu\,(D_i\,R) = (\mu\,D_i)\,R \Rightarrow \lambda \in \overline{A^q\,R} \Rightarrow A^q\,R_i \subseteq \overline{A^q\,R}.$$

Conversely, let $\lambda \in A^q\,R$; then there exists $\mu \in A^q$ such that $\lambda = \mu\,R$. Thus,

$$(\det\,D_i)\,\lambda = \mu\,((\det\,D_i)\,R) = \mu\,(D_i^c\,d\,R_i) = (\mu\,D_i^c\,d)\,R_i \Rightarrow \lambda \in \overline{A^q\,R_i} \Rightarrow A^q\,R \subseteq \overline{A^q\,R_i}.$$

Using the fact that $X \subseteq Y \Rightarrow \overline{X} \subseteq \overline{Y}$ for two submodules X and Y of a free A-module, we obtain

$$A^q\,R_i \subseteq \overline{A^q\,R} \subseteq \overline{A^q\,R_j} \quad \Rightarrow \quad \overline{A^q R_i} = \overline{A^q R_j}, \qquad i, j = 1, 2.$$

Now, if $A^q\,R_i$ is A-closed, then

$$A^q\,R_i \subseteq \overline{A^q\,R_j} \subseteq \overline{A^q\,R_i} = A^q\,R_i \Rightarrow \overline{A^q\,R_j} = A^q\,R_i. \qquad \square$$

LEMMA 2.7. *If $R \in M_{q\times p}(A)$ has full row rank and F is a free submodule of $\ker.R^T$ of rank $p-q$, then $\overline{F} = \ker.R^T$, where $\overline{F}$ is the A-closure of F in A^p.*

Proof. Let us note $N \triangleq \operatorname{coker}.R^T$. We have the following exact sequence:

$$0 \longleftarrow N \longleftarrow A^q \xleftarrow{.R^T} A^p \longleftarrow \ker.R^T \longleftarrow 0.$$

The A-module N is defined by the A-linear combinations of the equations $R^T z = 0$, where z_i is the class of the ith vector of the canonical basis of A^q in $N = A^q/A^p R^T$ (see (1.5)). Using the fact that R has full row rank, then there exist q equations of $R^T z = 0$ which are A-linearly independent. If we denote by $R_0^T \in M_q(A)$ the full rank matrix corresponding to these q A-linearly independent equations, then we have $R_0^T z = 0$, and thus, by multiplying R_0^T by its cofactors matrix, we obtain $(\det R_0^T)\, z = 0$ with $0 \neq \det R_0^T \in A$. This equation shows that N is a torsion A-module. Now, let us notice that we have $K \otimes_A N = 0$ because N is a torsion A-module: for all $n \in N$, there exists $0 \neq a \in A :\ a\, n = 0$, and thus, $1 \otimes n = (a/a) \otimes n = (1/a) \otimes a\, n = 0$. Using the fact that $K = Q(A)$ is a flat A-module (see Proposition 1.10), we have the following exact sequence:

$$0 = K \otimes_A N \longleftarrow K^q \xleftarrow{.R^T} K^p \longleftarrow K \otimes_A \ker .R^T \longleftarrow 0.$$

Here $K \otimes_A \ker .R^T$ is a subvector space of K^p of dimension $p - q$. As F is a free submodule of $\ker .R^T$ of rank $p-q$, we have $K \otimes_A F = K \otimes_A \ker .R^T \subset K^p$, and thus,

$$\overline{F} = (K \otimes_A F) \cap A^p = (K \otimes_A \ker .R^T) \cap A^p = \overline{\ker .R^T} = \ker .R^T$$

because $\ker .R^T$ is an A-closed submodule of A^p. Indeed, using the fact that A is an integral domain, we obtain

$$\begin{aligned} \lambda \in \overline{\ker .R^T} &\Rightarrow \exists\, 0 \neq a \in A :\ a\, \lambda \in \ker .R^T \Rightarrow a\, (\lambda\, R^T) = 0 \Rightarrow \lambda\, R^T = 0 \\ &\Rightarrow \lambda \in \ker .R^T. \qquad \square \end{aligned}$$

Proposition 2.8. *Let $P \in M_{q\times(p-q)}(K)$ be such that $P = D^{-1} N = \tilde{N}\, \tilde{D}^{-1}$, where $R = (D :\ -N) \in M_{q\times p}(A)$ and $\tilde{R} = (\tilde{N}^T :\ \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. If we define the A-modules $M = A^p/A^q\, R$ and $\tilde{M} = A^p/A^{p-q}\, \tilde{R}^T$, then we have*

$$\begin{cases} \ker .R^T = \overline{A^{p-q}\, \tilde{R}^T}, \\ \ker .\tilde{R} = \overline{A^q\, R}, \end{cases} \qquad \begin{cases} \tilde{M}/t(\tilde{M}) \cong A^p\, R^T, \\ M/t(M) \cong A^p\, \tilde{R}. \end{cases}$$

Proof. Using the fact that $R\, \tilde{R} = 0$, we obtain the following two complexes:

$$\begin{aligned} 0 \longrightarrow \quad & A^q \xrightarrow{.R} A^p \xrightarrow{.\tilde{R}} A^{p-q}, \\ & A^q \xleftarrow{.R^T} A^p \xleftarrow{.\tilde{R}^T} A^{p-q} \longleftarrow 0. \end{aligned}$$

Thus, $A^{p-q}\, \tilde{R}^T$ (resp., $A^q\, R$) is a free submodule of $\ker .R^T$ (resp., $\ker .\tilde{R}$) of rank $p - q$ (resp., q). By Lemma 2.7, Proposition 2.4, and Lemma 2.3, we obtain that

$$\begin{cases} \ker .R^T = \overline{A^{p-q}\, \tilde{R}^T}, \\ \ker .\tilde{R} = \overline{A^q\, R}, \end{cases} \Rightarrow \begin{cases} A^p\, R^T \cong A^p/\ker .R^T = A^p/\overline{A^{p-q}\, \tilde{R}^T} = \tilde{M}/t(\tilde{M}), \\ A^p \tilde{R} \cong A^p/\ker .\tilde{R} = A^p/\overline{A^q\, R} = M/t(M). \qquad \square \end{cases}$$

Let us notice that Proposition 2.8 is close in its spirit to some results obtained in [26] for linear multidimensional systems in the behavioral approach.

From Proposition 2.8 and Lemma 2.6, we obtain that the A-modules $A^p\, \tilde{R}$ and $A^p\, R^T$ depend only, up to an isomorphism, on the transfer matrix P. This result was proved in [22] in a different way (without any references to torsion-free A-modules). Using the fact that the structural properties of P do not depend on the choice of the fractional representation of P, we obtain the following corollary.

COROLLARY 2.9. *Let $P \in M_{q\times(p-q)}(K)$ be such that $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1}$, where $R = (D:\ -N) \in M_{q\times p}(A)$ and $\tilde{R} = (\tilde{N}^T:\ \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. Then, the structural (intrinsic) properties of P depend only on the A-modules $\overline{A^q\,R}$ and $\overline{A^{p-q}\,\tilde{R}^T}$ or, up to an isomorphism, on the A-modules $A^p\,\tilde{R}$ and $A^p\,R^T$.*

2.3. Weakly doubly coprime factorizations. Let us introduce the concepts of weakly left/right/doubly coprime factorizations.

DEFINITION 2.10. *Let A be an integral domain and $K = Q(A)$.*

- *A transfer matrix $P \in M_{q\times(p-q)}(K)$ admits a* weakly left-coprime factorization *if there exists a weakly left-prime matrix $R = (D:\ -N) \in M_{q\times p}(A)$, with $\det D \neq 0$, such that $P = D^{-1}\,N$.*
- *A transfer matrix $P \in M_{q\times(p-q)}(K)$ admits a* weakly right-coprime factorization *if there exists a weakly right-prime matrix $\tilde{R} = (\tilde{N}^T:\ \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$, with $\det\tilde{D} \neq 0$, such that $P = \tilde{N}\,\tilde{D}^{-1}$.*
- *A transfer matrix P admits a* weakly doubly coprime factorization *if P admits weakly left- and right-coprime factorizations $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1}$.*

THEOREM 2.11. *Let A be an integral domain, $K = Q(A)$ its quotient field, $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1} \in M_{q\times(p-q)}(K)$ a transfer matrix, $R = (D:\ -N) \in M_{q\times p}(A)$, and $\tilde{R} = (\tilde{N}^T:\ \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. Then, $P = D^{-1}\,N$ admits a weakly left-coprime factorization (resp., weakly right-coprime factorization) iff $\overline{A^q\,R}$ (resp., $\overline{A^{p-q}\,\tilde{R}^T}$) is a free A-module of rank q (resp., $p-q$).*

Proof. $\Rightarrow$ If P admits a weakly left-coprime factorization, then there exists a weakly left-prime matrix $R' = (D':\ -N') \in M_{q\times p}(A)$, with $\det D' \neq 0$, such that we have $P = D'^{-1}\,N'$. Using Lemma 2.6, we deduce that $\overline{A^q\,R} = A^q\,R'$. Moreover, $A^q\,R' \cong A^q$ because R' has full row rank, and thus, $\overline{A^q\,R} \cong A^q$.

$\Leftarrow$ If $\overline{A^q\,R}$ is a finitely generated free A-module of rank q, then, choosing a basis for $\overline{A^q\,R}$, we obtain a full row rank matrix $R' \in M_{q\times p}(A)$ such that $\overline{A^q\,R} = A^q\,R'$, and thus, R' is weakly left-prime. If R_i is the ith row of R, then $R_i \in \overline{A^q\,R} = A^q\,R'$ because $R_i \in A^q\,R \subseteq \overline{A^q\,R}$. Therefore, there exists $R''_i \in A^q$ such that $R_i = R''_i\,R'$, and then, there exists $R'' \in M_q(A)$ such that $R = R''\,R'$. Using the fact that R has full row rank, we deduce that R'' also has full row rank. Finally, let $R' = (D':\ N')$, where $R' \in M_{q\times p}(A)$; then we have $D = R''\,D'$ and $N = R''\,N'$, and thus, $\det D' \neq 0$. This proves the result because we have $P = D^{-1}\,N = (R''\,D')^{-1}\,(R''\,N') = D'^{-1}\,N'$.

The result for weak right-coprime factorizations can be proved similarly. □

COROLLARY 2.12. *A transfer matrix $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1}$ admits a weakly doubly coprime factorization iff the A-modules $\overline{A^q\,R}$ and $\overline{A^{p-q}\,\tilde{R}^T}$ are two free A-modules of rank, respectively, q and $p-q$.*

Let us notice that, from Corollary 2.9, Corollary 2.5, and the fact that a coprime factorization is an intrinsic property of the transfer matrix, we deduce that weakly left/right/coprime factorizations are the weakest possible coprime factorizations.

3. Coherent rings and modules.

3.1. Introduction. Any mathematical model of a plant is only an approximation of the real system. Thus, the algebra of SISO stable plants needs to be endowed with a norm in order to take into account some errors in the modelization. For technical reasons, we usually prefer to ask this normed algebra to be complete. Therefore, we generally require an algebra of SISO stable systems to be a *Banach algebra* [16, 49] (e.g., $H_\infty(\mathbb{C}_+)$, $\mathcal{A}$, $\hat{\mathcal{A}}$, $l_1(\mathbb{Z}_+)$ [3, 8, 9, 48, 49]).

However, it is known that all *noetherian k-Banach algebras* ($k = \mathbb{R}, \mathbb{C}$)—namely, Banach algebras such that every ideal is finitely generated—are k-finite-dimensional [41]. Hence, for instance, $H_\infty(\mathbb{C}_+)$, $\hat{\mathcal{A}}$, $L_1(\mathbb{R}_+) + \mathbb{R}\,\delta$, $l_1(\mathbb{Z}_+)$ are not noetherian rings, and thus, an ideal I of these algebras A generally does not have the form $I = \sum_{i=1}^{n} A\,a_i$ for a finite set $\{a_1, \ldots, a_n\}$ of elements of A. A direct consequence is that most of the algebraic objects (kernel, image, quotient, sum, intersection, etc.) are generally not finitely generated. Hence, we cannot study the algebraic properties of systems, defined by matrices whose entries belong to Banach algebras, by means of the concepts and techniques developed for noetherian rings (i.e., the main part of commutative algebra).

The concept of a *coherent ring* was first introduced in 1960 by Chase [5], and the definition of a *coherent module* appeared in [1] in 1964 (see [17] for more details). Coherent rings form a general class of rings including noetherian rings, Boolean rings, Bézout domains, semihereditary rings, etc. [17, 39]. This concept is closely related to the one of a *coherent sheaf* introduced by Cartan [4] and Serre [42] in the study of analytic and algebraic geometries.

In this section, we show that one possible way to cope with the fact that most of the integral domains of SISO stable plants are not noetherian is to require that these domains be coherent rings. In particular, for coherent rings, we give algorithms which compute the A-closure $\overline{A^q\,R}$ of an A-module of the form $A^q\,R$ (see Theorem 2.11) and which check whether or not a finitely generated A-module is torsion-free, reflexive, or projective. Finally, we shall characterize explicitly the class of integral domains A such that every transfer matrix, with entries in $K = Q(A)$, admits a weakly doubly coprime factorization.

3.2. Definitions and results.

DEFINITION 3.1 (see [2, 15, 39]). *We have the following definitions:*

- *An A-module M is* coherent *if M is a finitely generated A-module and every finitely generated submodule of M is finitely presented.*
- *A ring A is* coherent *if it is coherent as an A-module.*

Hence, A is a coherent ring iff every finitely generated ideal $I = \sum_{i=1}^{n} A\,a_i$ of A is finitely presented, i.e., the *module of relations* of I (or *syzygy* of I), defined by

$$S(I) = \left\{ r = (r_1 : \cdots : r_n) \in A^n \;\mid\; \sum_{i=1}^{n} r_i\,a_i = 0 \right\}, \tag{3.1}$$

is finitely generated. In terms of equations, A is a coherent ring iff for every $n \in \mathbb{Z}_+$ and $a = (a_1 : \cdots : a_n)^T \in A^n$ there exist $m \in \mathbb{Z}_+$ and $R \in M_{m\times n}(A)$ such that

$$\forall\, r = (r_1 : \cdots : r_n) \in A^n : \quad r\,a = 0 \Leftrightarrow \exists\, b = (b_1 : \cdots : b_m) \in A^m :\; r = b\,R.$$

Example 3.1. Any *noetherian ring*, namely a ring where any ideal I is finitely generated, i.e., has the form $I = \sum_{i=1}^{n} A\,a_i$ for a finite number of $a_i \in A$, is coherent [1, 39]. In particular, RH_∞ and $k[s]$, with k a field, are coherent domains. An example of a coherent ring which is not noetherian is given by the ring $k[\chi_i, i \in \mathbb{N}]$ of polynomials in infinitely many variables χ_i with coefficients in a field k (see [39]).

We give a few definitions which are related to the extension of (1.4) on the left.

DEFINITION 3.2. *We have the following definitions (see* [1, 14, 24, 39]*):*

- *A* projective *(resp.,* free, flat*)* resolution *of an A-module M is an exact sequence of the form*

$$\cdots \xrightarrow{d_3} F_2 \xrightarrow{d_2} F_1 \xrightarrow{d_1} F_0 \longrightarrow M \longrightarrow 0, \tag{3.2}$$

where F_i is a projective (resp., free, flat) A-module and d_i is an A-morphism.

- *A* finite free resolution *of an A-module M is an exact sequence of the form* (3.2)*, where F_i is a* finite free *A-module, i.e., $F_i \cong A^{r_i}$, $r_i \in \mathbb{Z}_+$, for $i \geq 0$.*
- *The* projective *(resp.,* flat*)* dimension $\mathrm{pd}_A(M)$ *(resp.,* $\mathrm{w.dim}_A(M)$*) of an A-module M is the minimum $n \in \mathbb{Z}_+ \cup \{+\infty\}$ such that there exists a projective (resp., flat) resolution of M of length n, i.e., of the form*

$$0 \longrightarrow F_n \xrightarrow{d_n} F_{n-1} \xrightarrow{d_{n-1}} \cdots \xrightarrow{d_2} F_1 \xrightarrow{d_1} F_0 \longrightarrow M \longrightarrow 0.$$

- *The* global dimension *and* weak global dimension *of A are defined by*

$$\mathrm{gl.dim}(A) = \sup\{\mathrm{pd}_A(M) \mid A - \text{module } M\} \in \mathbb{Z}_+ \cup \{+\infty\},$$
$$\mathrm{w.gl.dim}(A) = \sup\{\mathrm{w.dim}_A(M) \mid A - \text{module } M\} \in \mathbb{Z}_+ \cup \{+\infty\}.$$

For a general ring A, we have the inequality $\mathrm{w.gl.dim}(A) \leq \mathrm{gl.dim}(A)$. If A is a noetherian ring, then the equality holds [2, 39].

Remark 3.1. Using the canonical basis of the free A-module $F_i \cong A^{r_i}$, every finite free resolution of an A-module M has the form

$$\cdots \xrightarrow{.R_2} A^{r_1} \xrightarrow{.R_1} A^{r_0} \longrightarrow M \longrightarrow 0, \tag{3.3}$$

where R_i is an $(r_i \times r_{i-1})$-matrix whose entries belong to A, and $.R_i : A^{r_i} \to A^{r_{i-1}}$ is defined by letting operate a row vector of length r_i on the left of R_i to obtain a row vector of length r_{i-1}. Moreover, M is defined by the system $R_1\, z = 0$, where z_i is the class of e_i in M and $\{e_1, \ldots, e_{r_0}\}$ is the canonical basis of A^{r_0} (see (1.5)).

Definition 3.3. *We have the following definitions (see* [1, 39]*):*

- *A ring A is* semihereditary *if every finitely generated ideal of A is a projective A-module.*
- *A semihereditary integral domain is called a* Prüfer domain.
- *A ring A is a* Bézout domain *if every finitely generated ideal of A is a principal ideal, i.e., generated by a single element of A.*
- *A ring A is* hereditary *if every ideal of A is a projective A-module.*
- *A hereditary integral domain is called a* Dedekind domain.
- *A ring A is a* principal ideal domain *if every ideal of A is generated by a single element of A.*

We shall give in [33] some examples of Prüfer and Dedekind domains, as they will play an important role in internal stabilizability. Coherent rings with small weak global dimensions have been studied and classified largely in algebra [17, 39, 47].

Theorem 3.4 (see [2, 39]). *We have the following results:*

1. *Semihereditary rings and Prüfer domains are coherent rings.*
2. *Hereditary rings and Dedekind domains are noetherian and, thus, coherent rings.*
3. *If A is an integral domain, then* $\mathrm{w.gl.dim}(A) \leq 1 \Leftrightarrow A$ *is a Prüfer domain.*
4. *If A is an integral domain, then* $\mathrm{gl.dim}(A) \leq 1 \Leftrightarrow A$ *is a Dedekind domain.*

We have the following inclusions of rings:

Noetherian rings:	Principal ideal domains	$\subset$	Dedekind domains
$\cap$	$\cap$		$\cap$
Coherent rings:	Bézout domains	$\subset$	Prüfer domains

Example 3.2. The integral domains $E(k)$, $k = \mathbb{R}$, $\mathbb{C}$, and $\mathcal{E} = E(\mathbb{R}) \cap \mathbb{R}(s)[e^{-s}]$, defined in Theorem 1.6, are Bézout domains and, thus, two coherent rings.

PROPOSITION 3.5 (see [15, 47]). *An integral domain with* $\mathrm{gl.dim}(A) \leq 2$ *is coherent.*

General rings with $\mathrm{w.gl.dim}(A) = 2$ are less understood [14, 17, 24, 47].

PROPOSITION 3.6 (see [1, 39]). *If A is a coherent ring, then an A-module M is coherent iff M is a finitely presented A-module.*

DEFINITION 3.7. *We call an* A-system *a system of the form $R\,z = 0$, where z is a set of formal variables and R is a finite matrix whose entries belong to A.*

From Proposition 3.6, we have the following corollary.

COROLLARY 3.8. *If A is a coherent ring, then there is a one-to-one correspondence between coherent A-modules and A-systems.*

Proof. $\Rightarrow$ Let $\sum_{j=1}^{p} R_{ij}\ z_j = 0,\ R_{ij} \in A,\ i = 1, \ldots, q$, be an A-system and $R = (R_{ij}) \in M_{q\times p}(A)$. Let us define the following A-morphism:

$$\begin{array}{rcl} .R = A^q & \longrightarrow & A^p, \\ (a_1 : \cdots : a_q) & \longrightarrow & (a_1 : \cdots : a_q)\, R. \end{array}$$

If we note $M = \mathrm{coker}\, .R = A^p/A^q\, R$, then we have the following exact sequence,

$$A^q \xrightarrow{.R} A^p \xrightarrow{\pi} M \longrightarrow 0, \tag{3.4}$$

and, by Proposition 3.6, M is a coherent A-module because A is a coherent ring.

$\Leftarrow$ Let M be a coherent A-module. Using the fact that A is a coherent ring, by Proposition 3.6, M is a finitely presented A-module, there exists an exact sequence of the form (3.4), and, thus, M is defined by means of a system of equations of the form $R\,z = 0$. □

3.3. Elementary algebraic operations. The next proposition shows that the class (category) of finitely presented A-modules over a coherent ring A, i.e., coherent modules, is invariant under elementary algebraic operations. First, let us notice that any finitely generated submodule of a coherent module is also coherent.

PROPOSITION 3.9 (see [1, 39]). *If two terms in the exact sequence*

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

are coherent A-modules, so is the third one.

COROLLARY 3.10 (see [1, 39]). *Let M, N, $M' \subset M$, $M'' \subset M$ be coherent A-modules, $\phi : M \longrightarrow N$ an A-morphism, I a coherent ideal, and S a multiplicative set of A. Then, we have the following:*

1. *$M/M', M \oplus N, M' \cap M'', M' + M''$ are coherent A-modules.*
2. *$\ker\,\phi$, $\mathrm{im}\,\phi$, $\mathrm{coker}\,\phi$, and $\mathrm{coim}\,\phi$ are coherent A-modules.*
3. *$M \otimes_A N$ and $\hom_A(M, N)$ are coherent A-modules.*
4. *$S^{-1}A$ is a coherent A-module.*
5. *$IM = \{\sum_{i=1}^{n} a_i\, m_i \mid a_i \in I,\ m_i \in I\}$ is a coherent A-module.*
6. *$\mathrm{ann}(M) = \{a \in A \mid a\, M = 0\}$ is a coherent ideal of A.*

COROLLARY 3.11. *Let A be a coherent ring and M a finitely presented A-module. Then there exists a finite free resolution of M of the form* (3.3).

Proof. Using Proposition 3.9, we prove by induction that every finite power A^{r_i} of A is a coherent A-module (take $M = A^n, M' = A^{n-1}, M'' = A$). The kernel of a homomorphism d_i between two coherent A-modules is a coherent A-module and, by Proposition 3.6, is a finitely presented A-module. Then, the module of relations of R_i is finitely presented, and thus, M has a finite free resolution. □

DEFINITION 3.12. *Let M be an A-module with a projective resolution of the form* (3.2) *and N another A-module. Then we have the following definitions:*

- *The defects of exactness of*

$$\cdots \xleftarrow{d_3^\star} \hom_A(F_2,N) \xleftarrow{d_2^\star} \hom_A(F_1,N) \xleftarrow{d_1^\star} \hom_A(F_0,N) \longleftarrow 0, \tag{3.5}$$

where $d_i^\star$ *is defined by* $d_i^\star(f) = f \circ d_i$ *for all* $f \in \hom_A(F_{i-1},N)$, *depend only on* M *and* N *and not on* (3.2) *and are called* $\operatorname{ext}_A^i(M,N)$ *(see* [2, 29, 39]*). In particular, we have*

$$\begin{cases} \operatorname{ext}_A^0(M,N) = \ker d_1^\star = \hom_A(M,N), \\ \operatorname{ext}_A^i(M,N) = \ker d_{i+1}^\star / \operatorname{im} d_i^\star, \ i \geq 1. \end{cases}$$

- *The defects of exactness of*

$$\cdots \xrightarrow{\mathrm{id}_N \otimes d_3} N \otimes_A F_2 \xrightarrow{\mathrm{id}_N \otimes d_2} N \otimes_A F_1 \xrightarrow{\mathrm{id}_N \otimes d_1} N \otimes_A F_0 \longrightarrow 0, \tag{3.6}$$

where $\mathrm{id}_N \otimes d_i$ *is defined by* $(\mathrm{id}_N \otimes d_i)(n \otimes m) = n \otimes d_i(m)$ *for all* $n \in N$, *for all* $m \in F_i$, *depend only on* M *and* N *and not on* (3.2) *and are called* $\operatorname{tor}_i^A(M,N)$ *(see* [2, 29, 39]*). In particular, we have*

$$\begin{cases} \operatorname{tor}_0^A(M,N) = \operatorname{coker}(\mathrm{id}_N \otimes d_1) = N \otimes_A M, \\ \operatorname{tor}_i^A(M,N) = \ker(\mathrm{id}_N \otimes d_i)/\operatorname{im}(\mathrm{id}_N \otimes d_{i+1}), \quad i \geq 1. \end{cases}$$

Remark 3.2. If M has a finite free resolution of the form (3.3), then (3.5) is defined by $\cdots \xleftarrow{R_3.} N^{r_2} \xleftarrow{R_2.} N^{r_1} \xleftarrow{R_1.} N^{r_0} \longleftarrow 0$, where $R_i. : N^{r_{i-1}} \to N^{r_i}$ is defined by letting operate a column vector of length r_{i-1}, whose entries belong to N on the right of R_i, to obtain a column vector of length r_i, whose entries belong to N. We have

$$\operatorname{ext}_A^i(M,N) = \ker_N(R_{i+1}.)/\operatorname{im}_N(R_i.) \qquad \forall\, i \geq 1.$$

Similarly, (3.6) becomes the complex $\cdots \xrightarrow{.R_3} N^{r_2} \xrightarrow{.R_2} N^{r_1} \xrightarrow{.R_1} N^{r_0} \longrightarrow 0$, where $.R_i : N^{r_i} \to N^{r_{i-1}}$ is defined by letting operate a row vector of length r_i, whose entries belong to N on the right of R_i, to obtain a row vector of length r_{i-1}, whose entries belong to N and

$$\operatorname{tor}_i^A(M,N) = \ker_N .R_i / \operatorname{im}_N .R_{i+1} \qquad \forall\, i \geq 1.$$

Proposition 3.13 (see [2, 39]). *We have the following results:*

- $\operatorname{ext}_A^i(M,N) = 0\ \forall\, i \geq 1, \forall\, N\ A-$*module* $\Leftrightarrow M$ *is a projective* A*-module.*
- $\operatorname{tor}_A^i(M,N) = 0\ \forall\, i \geq 1, \forall\, N\ A-$*module* $\Leftrightarrow M$ *is a flat* A*-module.*

Corollary 3.14. *If* A *is a coherent ring, and* M *and* N *are two coherent* A*-modules, then* $\operatorname{ext}_A^i(M,N)$ *and* $\operatorname{tor}_i^A(M,N)$ *are coherent* A*-modules for* $i \geq 0$. *Moreover,* $\operatorname{ext}_A^i(M,A)$ *is a torsion* A*-module for* $i \geq 1$.

Proof. Using the fact that $\operatorname{ext}_A^i(M,N)$ (resp., $\operatorname{tor}_i^A(M,N)$) does not depend on the projective resolution of M, by Proposition 3.6 and Corollary 3.11, we choose a finite free resolution (3.3) for M. By Proposition 3.9, $\hom_A(F_i,N)$ (resp., $N \otimes_A F_i$) is a coherent A-module, and thus, $\ker d_i^\star$ and $\operatorname{im} d_i^\star$ (resp., $\ker(\mathrm{id}_N \otimes d_i)$ and $\operatorname{im}(\mathrm{id}_N \otimes d_i)$) are coherent A-modules. Finally, $\operatorname{ext}_A^i(M,N)$ (resp., $\operatorname{tor}_i^A(M,N)$) is also a coherent A-module for $i \geq 0$ as a quotient of two coherent A-modules. The proof of the fact that $\operatorname{ext}_A^i(M,A)$ is a torsion A-module is the same as that of Lemma 1 in [28]. ∎

DEFINITION 3.15. *Let M be an A-module defined by a finite presentation:*

$$F_1 \xrightarrow{d_1} F_0 \longrightarrow M \longrightarrow 0.$$

We call the transposed module[1] *of M, the A-module $T(M) = \operatorname{coker} d_1^\star$ defined by*

$$0 \longleftarrow T(M) \longleftarrow F_1^\star \xleftarrow{d_1^\star} F_0^\star.$$

Hence, if $M = A^p/A^q\,R$, then the transposed module is $T(M) = A^q/R\,A^p$, where the vectors of A^q and A^p are now column ones (duality). Using the fact that A is commutative, we finally have $T(M) = A^q/A^p\,R^T$, where we use only row vectors.

If A is a coherent ring and M a coherent A-module, i.e., finitely presented A-module, then $T(M)$ is also a coherent A-module because it is finitely presented.

Remark 3.3. We commit a little abuse of notation in denoting the transposed A-module of M by $T(M)$: $\operatorname{coker} d_1^\star$ depends on the particular choice of d_1, i.e., on the particular form of the system of equations chosen to represent the module. However, we have (see [29]):

1. If R has full row rank, then $T(M)$ depends only on M and not on R.
2. If R does not have full rank, i.e., $\ker .R \neq 0$, then $\operatorname{coker} d_1^\star$ depends only on M up to *a projective equivalence* [39], a fact which shows that $\operatorname{ext}_A^i(T(M), N)$ depends only on M and N for $i \geq 1$.

The next theorem shows how to characterize the module properties in terms of the extension and torsion functors.

THEOREM 3.16. *Let A be a coherent ring with* $\operatorname{w.gl.dim}(A) \leq n$, *$M$ a finitely presented A-module, and $T(M)$ its transposed A-module. Then, we have*

1. $t(M) \cong \operatorname{ext}_A^1(T(M), A)$,
2. $t(M) \cong \operatorname{tor}_1^A(K/A, M)$,
3. *M is torsion-free iff* $\operatorname{ext}_A^1(T(M), A) = 0$,
4. *M is reflexive iff* $\operatorname{ext}_A^i(T(M), A) = 0,\ i = 1, 2$,
5. *M is projective iff* $\operatorname{ext}_A^i(T(M), A) = 0,\ i = 1, \ldots, n$.

Proof. The proofs of 1, 3, 4, 5 are the same as those given in [27, 28] for noetherian rings: we just need to change finitely generated modules (resp., noetherian rings) into finitely presented (resp., coherent) ones. See also the proof of Proposition 3.4 of [33]. For a proof of 2, see [39]. □

Using Proposition 2.4, Lemma 2.3, and Theorem 3.16, we obtain an algorithm which computes the closure $\overline{A^q\,R}$ of an A-module of the form $A^q\,R$.

ALGORITHM. Input: A coherent ring A and $R \in M_{q\times p}(A)$. Output: $R' \in M_{r\times p}(A)$ such that $\overline{A^q\,R} = A^r\,R'$.

1. Start with $R \in M_{q\times p}(A)$.
2. Transpose R to obtain $R^T \in M_{p\times q}(A)$.
3. Find a family of generators of $\ker .R^T = \{\lambda \in A^p \mid \lambda\,R^T = 0\}$. If $\{\lambda_1, \ldots, \lambda_m\}$ is a family of generators of $\ker .R^T$, then denote by $R_{-1}^T \in M_{m\times p}(A)$ the matrix whose ith row is λ_i.
4. Transpose R_{-1}^T to obtain $R_{-1} \in M_{p\times m}(A)$.
5. Find a family of generators of $\ker .R_{-1} = \{\eta \in A^p \mid \eta\,R_{-1} = 0\}$. If $\{\eta_1, \ldots, \eta_r\}$ is a family of generators of $\ker .R_{-1}$, then denote by $R' \in M_{r\times p}(A)$ the matrix whose ith row is η_i. We have $\overline{A^q\,R} = A^r\,R'$, $A^p/\overline{A^q R} \cong A^p R_{-1}$.

[1] Do not confuse the notation of the transposed module $T(M)$ of an A-module M with the torsion submodule $t(M)$ of M.

If R' has full row rank, then $\overline{A^q R} = A^r R'$ is a free A-module. (See Example 3.4 for the explicit computations of the A-closure $\overline{A^q R}$ of a certain A-module $A^q R$.) To finish, let us note that we can use the previous algorithm to check whether a transfer matrix admits a weakly left/right/doubly coprime factorization (see Theorem 2.11). Indeed, the previous algorithm allows us to have a precise description of the A-closure of an A-module of the form $A^q R$. However, checking whether such an A-closure is free can be a very difficult algebraic problem (see, e.g., the proof of the Quillen–Suslin theorem in [39]).

3.4. Coherent Sylvester domains.

DEFINITION 3.17 (see [6, 10]). *A projective-free coherent domain with*

$$\text{w.gl.dim}(A) \leq 2$$

is called a coherent Sylvester domain.

Example 3.3. A Bézout domain (e.g., $E(k)$, $\mathcal{E}$ by Theorem 1.6) and thus, a principal ideal domain (e.g., RH_∞ by Theorem 1.6, $k[s]$, with k a field) are coherent Sylvester domains. More generally, $A = B[x]$ is a coherent Sylvester domain iff B is a Bézout domain [11] (e.g., $A = \mathbb{Z}[x]$, $A = k[s][z] = k[s, z]$, with k a field, or $A = B[x]$, where B is the ring of all algebraic integers, i.e., the integral closure of $\mathbb{Z}$ in $\mathbb{C}$; see [39]).

DEFINITION 3.18. *A ring A is* regular *if every finitely generated ideal of A has a finite projective dimension.*

THEOREM 3.19 (see [50]). *A coherent regular domain A is a GCDD—every a and b of A have a greatest common divisor $[a, b]$—iff every finitely generated projective ideal of A is principal.*

COROLLARY 3.20.[2] *A coherent Sylvester domain is a GCDD.*

Proof. A coherent Sylvester domain is a projective-free coherent domain with $\text{w.gl.dim}(A) \leq 2$ and, thus, a regular ring which satisfies that every finitely generated projective ideal is free, i.e., is principal, because A is an integral domain. Then, the result follows directly from Theorem 3.19. □

PROPOSITION 3.21. *If A is a coherent Sylvester domain, then, for every A-module M defined by a finite free resolution,*

$$F_1 \xrightarrow{d_1} F_0 \longrightarrow M \longrightarrow 0,$$

there exist a free A-module F_1' and two A-morphisms $d_1' : F_1' \to F_0$ and $d_1'' : F_1 \to F_1'$ such that $d_1 = d_1' \circ d_1''$ and we have the following exact sequences:

$$0 \longrightarrow F_1' \xrightarrow{d_1'} F_0 \longrightarrow M/t(M) \longrightarrow 0, \tag{3.7}$$

$$0 \longrightarrow \ker d_1 \longrightarrow F_1 \xrightarrow{d_1''} F_1' \longrightarrow t(M) \longrightarrow 0. \tag{3.8}$$

[2] We would like to thank Prof. W. Dicks for pointing out to us that this result is already contained in Lemma 4.1 of [11].

Proof. We have the following commutative exact diagram:

$$\begin{array}{ccccccccc}
 & & 0 & & & & 0 & & \\
 & & \downarrow & & & & \downarrow & & \\
 & & \ker d_1'' & & 0 & & t(M) & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow \ker d_1 \longrightarrow & F_1 & \xrightarrow{d_1} & F_0 & \xrightarrow{\pi} & M & \longrightarrow 0 & \\
 & & \downarrow d_1'' & & \| & & \downarrow \pi' & & \\
0 & \longrightarrow & \ker\,\phi & \longrightarrow & F_0 & \xrightarrow{\phi} & M/t(M) & \longrightarrow 0, & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & \operatorname{coker} d_1'' & & 0 & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array}$$

where $\phi = \pi' \circ \pi$ and $d_1'' : F_1 \to \ker \phi$ is induced by the identity homomorphism from F_0 to F_0 and $\pi' : M \to M/t(M)$. An easy chase in the diagram shows that $\ker d_1'' \cong \ker d_1$ and $\operatorname{coker} d_1'' \cong t(M)$. Now, let us prove that $\ker \phi$ is a finite free A-module. $M/t(M)$ is a coherent A-module over a coherent ring A [15] and, in particular, $M/t(M)$ is a finitely generated A-module. It is well known that $M/t(M)$ can be imbedded into a finitely generated free A-module F_{-1} (see, e.g., [39] or [15]), and we have the following exact sequence:

$$0 \longrightarrow M/t(M) \longrightarrow F_{-1} \longrightarrow F_{-1}/(M/t(M)) \longrightarrow 0.$$

Hence, we have the following exact sequence:

$$0 \longrightarrow \ker \phi \longrightarrow F_0 \xrightarrow{\phi} F_{-1} \longrightarrow F_1/(M/t(M)) \longrightarrow 0.$$

Using the fact that $\text{w.gl.dim}(A) = 2$, we then have $\operatorname{pd}_A(F_1/(M/t(M))) \leq 2$, and thus, $\operatorname{pd}_A(\ker \phi) = 0$ [2, 39], i.e., $\ker \phi$ is a projective A-module, and thus, a free A-module because A is a projective-free ring. $\ker \phi$ is a finitely generated A-module because $\ker \phi$ is a coherent A-module. ($\ker \phi$ is the kernel of an A-morphism between two finite free A-modules.) Thus, $\ker \phi \cong F_1' \cong A^r$, $r \in \mathbb{Z}_+$, which gives (3.7) and (3.8). □

In the next corollary, we reformulate Proposition 3.21 in terms of weakly doubly coprime factorizations. It generalizes to coherent Sylvester domains a result obtained by Smith in [43] for $H_\infty(\mathbb{C}_+)$ (see section 3.5).

COROLLARY 3.22. *If A is a coherent Sylvester domain, then every matrix P, whose entries belong to $K = Q(A)$, admits a weakly doubly coprime factorization.*

Proof. If $P \in M_{q\times(p-q)}(K)$, then we can define $R = (dI_q : -H) \in M_{q\times p}(A)$, where d is the product of the denominators of the entries of P and $H = dP \in M_{q\times(p-q)}(A)$. By Proposition 3.21, there exist a full rank matrix $R'' \in M_q(A)$ and a weakly left-prime full row rank matrix $R' = (D : -N) \in M_{q\times p}(A)$ such that $R = R''R'$. Thus, we have $(dI_q : -H) = R''(D : -N)$ and $\det R'' \neq 0$. Then, we have

$$\begin{cases} dI_q = R''D \\ H = R''N, \end{cases} \Rightarrow \det D \neq 0, \quad \Rightarrow P = (dI_q)^{-1}H = (R''D)^{-1}(R''N) = D^{-1}N.$$

Dually, we have $P = G(dI_{p-q})^{-1}$, and thus, there exists a weakly right-prime matrix $\tilde{R}' = (\tilde{N}^T : \tilde{D}^T)^T$ such that $\tilde{R} = (G^T : (dI_{p-q})^T)^T = (\tilde{N}^T : \tilde{D}^T)^T\tilde{R}''$.

Therefore, $P = G\,(d\,I_{p-q})^{-1} = (\tilde{N}\,\tilde{R}'')\,(\tilde{D}\,\tilde{R}'')^{-1} = \tilde{N}\,\tilde{D}^{-1}$ is a weakly right-coprime factorization. □

To prove the next theorem, we shall need the next proposition due to Dicks.

PROPOSITION 3.23 (based on [12]). *Let A be an integral domain. If, for every finitely generated free A-module F_0 and every finitely generated free A-submodule F_1 of F_0, the A-closure of F_1 in F_0 is a finitely generated free A-module, then A is a coherent Sylvester domain.*

Proof. Let $K = Q(A)$, p, $q \in \mathbb{Z}_+$, $F_0 = A^p$, and R be any matrix belonging to $M_{p\times q}(A)$. We have the exact sequence $A^q \xleftarrow{.R} A^p \longleftarrow \ker .R \longleftarrow 0$. Applying the tensor product $K\otimes_A$ to the previous exact sequence, we obtain the exact sequence (K is a flat A-module) $K^q \xleftarrow{.R} K^p \longleftarrow K\otimes_A \ker .R \longleftarrow 0$. Therefore, $K\otimes_A \ker .R$ is a K-subvector space of K^p, and thus, there exists a finite basis $\{e_1, \ldots, e_m\}$ of $K\otimes_A \ker .R$, where $m = \dim_K(K\otimes_A \ker .R) \leq p$. Let us note $e_i = f_i/d_i$, with $f_i \in A^p$ and $0 \neq d_i \in A$, and let F_1 be the A-submodule of K^p generated by $\{f_1, \ldots, f_m\}$. Then, F_1 is a free A-submodule of $\ker .R$. Thus, $\overline{F_1} \subseteq \overline{\ker .R} = \ker .R$, because $\ker .R$ is an A-closed submodule of A^q. Moreover, for every $\lambda \in \ker .R$, we have $\lambda = \sum_{i=1}^m a_i\,e_i$, with $a_i \in K$, and clearing the denominators of a_i and $e_i = f_i/d_i$, there exists $0 \neq a \in A$ such that $a\,\lambda \in F_1$, i.e., $\lambda \in \overline{F_1}$, and thus $\overline{F_1} = \ker .R \subseteq A^p = F_0$. Then, by hypothesis, $\ker .R$ is a finitely generated free A-module. Using the implication (v) $\Rightarrow$ (i) of Theorem 10 of [10] (namely, the annihilator of every matrix is free $\Rightarrow$ A is a coherent Sylvester domain), we obtain that A is a coherent Sylvester domain. □

The next theorem characterizes the integral domains over which every transfer matrix admits a weakly doubly coprime factorization.

THEOREM 3.24. *We have the following equivalences:*

1. *Every multi-input multi-output (MIMO) plant admits a weakly doubly coprime factorization.*
2. *A is a coherent Sylvester domain.*

Proof. 1 $\Rightarrow$ 2. Let F_0 be any finitely generated free A-module, and suppose that $F_0 = A^p$ for a certain positive integer p. Let F_1 be any finitely generated free A-submodule of F_0, and suppose that F_1 has rank q. Taking a basis for F_1, then there exists a full row rank matrix $R \in M_{q\times p}(A)$ such that we have $F_1 = A^q\,R$. We can always suppose that R can be written as $R = (D :\ -N)$, where D is a full rank matrix. Then, by hypothesis, $P = D^{-1}\,N$ has a weakly doubly coprime factorization, i.e., there exists a weakly left-prime matrix $R' = (D' :\ -N') \in M_{q\times p}(A)$ such that $\det D' \neq 0$ and $P = {D'}^{-1}\,N'$. Then, by Lemma 2.6 and Theorem 2.11, we have $\overline{A^q\,R} = A^q\,R'$ and, using the fact that $A^q\,R'$ is a free A-module of rank q, we obtain that $\overline{F_1} = \overline{A^q\,R}$ is a finite free A-submodule of F_0. From Proposition 3.23, it follows that A is a coherent Sylvester domain.

2 $\Rightarrow$ 1 was already proved in Corollary 3.22. □

3.5. An example: $H_\infty(\mathbb{C}_+)$.

THEOREM 3.25 (see [23, 37]). *If D is a finitely connected domain of $\mathbb{C}$, then $H_\infty(D)$ is a coherent domain. In particular, if we denote the open right half-plane by $\mathbb{C}_+ = \{s \in \mathbb{C} \mid \mathrm{Re}\,s > 0\}$ and the open unit disc by $\mathbb{D} = \{z \in \mathbb{C} \mid |z| < 1\}$, then $H_\infty(\mathbb{C}_+)$ and $H_\infty(\mathbb{D})$ are two coherent integral domains.*

In the rest of this paper, we shall consider only the case $D = \mathbb{D}$ and, by extension, $D = \mathbb{C}_+$. The proof of the coherence of $H_\infty(D)$ is based on the following theorem, which is a weak-* version of the Beurling–Lax theorem [25]. The condition on m is given by point 2 of the *lemma on the local rank* (p. 44) and Remark (p. 45) of [25].

THEOREM 3.26. *Let $R \in M_{q\times p}(H_\infty(D))$, and let us define the $H_\infty(D)$-morphism:*

$$\begin{array}{rccl} R: & H_\infty(D)^p & \longrightarrow & H_\infty(D)^q, \\ & (a_1 : \cdots : a_p)^T & \longrightarrow & R\,(a_1 : \cdots : a_p)^T. \end{array}$$

Then, there exists $R_{-1} \in M_{p\times m}(H_\infty(D))$ such that

$$\ker R = R_{-1}\, H_\infty(D)^m, \tag{3.9}$$

$$(R_{-1}(e^{i\,\theta}))^\star\, R_{-1}(e^{i\,\theta}) = I_m \qquad \text{for almost every } \theta \in [0,\, 2\pi), \tag{3.10}$$

$$m = p - \operatorname{rank} R, \tag{3.11}$$

where $\operatorname{rank} R$ *is the number of $H_\infty(D)$-linearly independent rows of R.*

COROLLARY 3.27. *Let $A = H_\infty(D)$. If M is a finitely presented A-module, then*

$$\operatorname{pd}_A(M) \leq 2.$$

Proof. Let $A = H_\infty(D)$ and $A^q \xrightarrow{.R} A^p \longrightarrow M \longrightarrow 0$ be a finite presentation of M. Using Theorem 3.26, up to a transposition, there exists an $r \times q$-matrix R_1 whose entries belong to A such that we have the following exact sequence:

$$0 \longrightarrow \ker .R_1 \longrightarrow A^r \xrightarrow{.R_1} A^q \xrightarrow{.R} A^p \longrightarrow M \longrightarrow 0. \tag{3.12}$$

From the exactness of (3.12), we obtain (see Definition 1.9 and Proposition 1.10)

$$\operatorname{rank}(\ker .R_1) + \operatorname{rank} M = r + p - q.$$

From the exact sequence $0 \longrightarrow \operatorname{im}.R \longrightarrow A^p \longrightarrow M \longrightarrow 0$, we obtain $\operatorname{rank} M = p - \operatorname{rank} R$. From (3.11), we have $r = q - \operatorname{rank} R$, and thus, $\operatorname{rank}(\ker .R_1) = 0$, i.e., $\ker .R_1$ is a torsion A-module. However, $\ker .R_1$ is a submodule of the free A-module A^q, and thus, $\ker .R_1 = 0$ because a free module is torsion-free. Hence, every finitely presented A-module M has a finite free resolution of length at most 2, i.e., $\operatorname{pd}_A(M) \leq 2$. □

COROLLARY 3.28. *$H_\infty(D)$ has a weak global dimension 2, i.e.,*

$$\operatorname{w.gl.dim}(H_\infty(D)) = 2. \tag{3.13}$$

Proof. Let $A = H_\infty(D)$. Using Corollary 3.27 and the fact that every finitely presented flat module is projective (see 3 of Proposition 1.4), then every finitely presented A-module M has a finite flat resolution of length at most 2, i.e., $\operatorname{w.dim}_A(M) = \operatorname{pd}_A(M) \leq 2$. Moreover, $\operatorname{w.gl.dim}(A)$ is attained by taking the supremum of the weak dimension of finitely presented modules [14, 24], and thus, $\operatorname{w.gl.dim}(A) \leq 2$. In Example 4.3, we shall give a finitely presented torsion-free $H_\infty(\mathbb{C}_+)$-module which is not projective (similar examples can be exhibited for $D = \mathbb{D}$). Thus, we have $\operatorname{w.gl.dim}(A) = 2$. □

The next corollary follows directly from the fact that $\operatorname{w.gl.dim}(H_\infty(D)) = 2$.

COROLLARY 3.29. *$H_\infty(D)$ is a regular ring.*

The following corollary was first proved in [46] for full row rank matrices.

COROLLARY 3.30. *$H_\infty(D)$ is a projective-free integral domain.*

Proof. Let $A = H_\infty(D)$. Every finitely generated projective module is finitely presented [2]. Hence, let us suppose that M is a finitely presented projective A-module defined by a finite free resolution $F_1 \xrightarrow{d_1} F_0 \longrightarrow M \longrightarrow 0$. Then, $T(M)$ is a coherent

A-module and, by Theorem 3.26, $T(M)$ has a finite free resolution of length 2 of the form $0 \longleftarrow T(M) \longleftarrow F_1^\star \xleftarrow{d_1^\star} F_0^\star \xleftarrow{d_2^\star} F_{-1}^\star \longleftarrow 0$. The fact that M is a projective A-module implies that $\mathrm{ext}_A^i(T(M), A) = 0$, $i \geq 1$ (see Theorem 3.16), and thus, $F_1 \xrightarrow{d_1} F_0 \xrightarrow{d_2} F_{-1} \longrightarrow 0$ is an exact sequence; i.e., $M = \mathrm{coker}\, d_1 \cong \mathrm{im}\, d_2 = F_{-1}$ is a free A-module. □

COROLLARY 3.31. *$H_\infty(D)$ is a coherent Sylvester domain and, thus, a GCDD.*

The fact that $H_\infty(D)$ is a GCDD was first proved in [36] (see also [43]).

Corollary 3.28 shows that, for any finitely presented $A = H_\infty(D)$–module M, we have $\mathrm{ext}_A^i(T(M), A) = 0$ for all $i \geq 3$. Hence, by Theorem 3.16, every finitely presented A-module M satisfies only one of the three following possibilities: M has a nontrivial torsion submodule, M is torsion-free but not free, or M is free.

Example 3.4. In Example 2.1, we proved that the factorization $P = D^{-1}\, N$, defined by (1.3), of the transfer matrix (1.2) was not weakly left-coprime. Let us notice that $R = (D : -N)$ was obtained by clearing the denominators of P once all its entries were written as quotients of (stable) elements of $A = H_\infty(\mathbb{C}_+)$. Hence, clearing the denominators of P does not generally lead to weakly doubly coprime factorizations. In general, we need to use the algorithm developed at the end of section 3.3 to compute a weakly doubly coprime factorization of a transfer matrix. Let us compute a weakly left-coprime factorization of the transfer matrix (1.2).

1. Let us reconsider the A-module $M = A^4/A^2\, R$ defined in Example 1.4. The matrix $R \in M_{2\times 4}(A)$ has full row rank, and thus, we have the finite free presentation

$$0 \longrightarrow A^2 \xrightarrow{.R} A^4 \longrightarrow M \longrightarrow 0.$$

2. The transposed A-module $T(M)$ is defined by the exact sequence

$$0 \longleftarrow T(M) \longleftarrow A^2 \xleftarrow{.R^T} A^4 \longleftarrow \ker .R^T \longleftarrow 0.$$

3. Let $\lambda = (\lambda_1 :\ \lambda_2 :\ \lambda_3 :\ \lambda_4)^T \in \ker .R^T$; then we have

$$\begin{cases} \frac{(s-1)}{(s+1)}\, \lambda_1 - \frac{(s-1)\, e^{-s}}{(s+1)^2}\, \lambda_3 - \left(\frac{s-1}{s+1}\right)^2 \lambda_4 = 0, \\ \frac{(s-1)}{(s+1)}\, \lambda_2 - \frac{1}{(s+1)}\, \lambda_4 = 0. \end{cases} \tag{3.14}$$

By Corollary 3.31, A is a GCDD. The greatest common factor of $\frac{s-1}{s+1}$ and $\frac{1}{s+1}$ is 1; thus, from the second equation of (3.14), we have

$$\begin{cases} \lambda_2 = \frac{1}{(s+1)}\, \mu_1, \\ \lambda_4 = \frac{(s-1)}{(s+1)}\, \mu_1, \end{cases} \qquad \mu_1 \in A.$$

Substituting λ_4 in the first equation of (3.14), we obtain

$$\frac{(s-1)}{(s+1)} \left(\lambda_1 - \frac{e^{-s}}{(s+1)}\, \lambda_3 - \left(\frac{s-1}{s+1}\right)^2 \mu_1 \right) = 0 \Rightarrow \lambda_1 = \frac{e^{-s}}{(s+1)}\, \lambda_3 + \left(\frac{s-1}{s+1}\right)^2 \mu_1$$

because A is an integral domain and $\lambda_i, \mu_1 \in A$. Finally, we have

$$\begin{cases} \lambda_1 = \left(\frac{s-1}{s+1}\right)^2 \mu_1 + \frac{e^{-s}}{(s+1)}\, \mu_2, \\ \lambda_2 = \frac{1}{(s+1)}\, \mu_1, \\ \lambda_3 = \mu_2, \\ \lambda_4 = \frac{(s-1)}{(s+1)}\, \mu_1, \end{cases} \Leftrightarrow (\lambda_1 :\ \lambda_2 :\ \lambda_3 :\ \lambda_4) = (\mu_1 :\ \mu_2) \begin{pmatrix} (\frac{s-1}{s+1})^2 & \frac{1}{s+1} & 0 & \frac{s-1}{s+1} \\ \frac{e^{-s}}{s+1} & 0 & 1 & 0 \end{pmatrix}.$$

If we call the matrix in the second member R_{-1}^T, then we have the following exact sequence:

$$0 \longleftarrow T(M) \longleftarrow A^2 \overset{.R^T}{\longleftarrow} A^4 \overset{.R_{-1}^T}{\longleftarrow} A^2 \longleftarrow 0. \tag{3.15}$$

Moreover, if we note $\mu = (\mu_1 : \mu_2)$, then, from $\lambda = \mu\, R_{-1}^T$, we have

$$\left\{ \begin{array}{l} \mu_1 = 2\,\lambda_2 + \lambda_4, \\ \mu_2 = \lambda_3, \end{array} \right. \Rightarrow S_{-1}^T \triangleq \left(\begin{array}{cc} 0 & 0 \\ 2 & 0 \\ 0 & 1 \\ 1 & 0 \end{array} \right) : \; R_{-1}^T\, S_{-1}^T = I_2 \Rightarrow S_{-1}\, R_{-1} = I_2.$$

4. Dualizing (3.15), we obtain the following complex:

$$0 \longrightarrow A^2 \xrightarrow{.R} A^4 \xrightarrow{.R_{-1}} A^2 \longrightarrow 0.$$

Therefore, we have

$$\left\{ \begin{array}{l} \mathrm{ext}_A^1(T(M), A) = \ker .R_{-1}/A^2\, R, \\ \mathrm{ext}_A^2(T(M), A) = A^2/A^4\, R_{-1}. \end{array} \right.$$

From $S_{-1}\, R_{-1} = I_2$, we deduce that for all $\xi \in A^2$, the element $\eta = \xi\, S_{-1} \in A^4$ is such that $\xi = \eta\, R_{-1}$, i.e., $A^4\, R_{-1} = A^2$, and thus, $\mathrm{ext}_A^2(T(M), A) = A^2/A^4\, R_{-1} = 0$.

5. If $\eta = (\eta_1 : \eta_2 : \eta_3 : \eta_4) \in \ker .R_{-1}$, then we have

$$\left\{ \begin{array}{l} \left(\frac{s-1}{s+1}\right)^2 \eta_1 + \frac{1}{(s+1)}\, \eta_2 + \frac{(s-1)}{(s+1)}\, \eta_4 = 0, \\ \frac{e^{-s}}{(s+1)}\, \eta_1 + \eta_3 = 0, \end{array} \right. \Leftrightarrow \left\{ \begin{array}{l} \eta_3 = -\frac{e^{-s}}{(s+1)}\, \eta_1, \\ \frac{(s-1)}{(s+1)} \left(\frac{(s-1)}{(s+1)}\, \eta_1 + \eta_4 \right) = -\frac{1}{(s+1)}\, \eta_2. \end{array} \right. \tag{3.16}$$

Using the fact that the greatest common factor of $\frac{s-1}{s+1}$ and $\frac{1}{s+1}$ is 1, we then have:

$$(3.16) \Leftrightarrow \left\{ \begin{array}{l} \eta_3 = -\frac{e^{-s}}{(s+1)}\, \eta_1, \\ \eta_2 = \frac{(s-1)}{(s+1)}\, \zeta_2,\ \zeta_2 \in A, \\ \frac{(s-1)}{(s+1)}\, \eta_1 + \eta_4 = -\frac{1}{(s+1)}\, \zeta_2, \end{array} \right. \Leftrightarrow \left\{ \begin{array}{l} \eta_1 = \zeta_1,\ \zeta_1 \in A, \\ \eta_2 = \frac{(s-1)}{(s+1)}\, \zeta_2,\ \zeta_2 \in A, \\ \eta_3 = -\frac{e^{-s}}{(s+1)}\, \zeta_1, \\ \eta_4 = -\frac{(s-1)}{(s+1)}\, \zeta_1 - \frac{1}{(s+1)}\, \zeta_2, \end{array} \right. \Leftrightarrow \eta = \zeta\, R',$$

where $\zeta = (\zeta_1 : \zeta_2)$ and the matrix $R' \in M_{2\times 4}(A)$ is defined by

$$R' = \left(\begin{array}{cccc} 1 & 0 & -\frac{e^{-s}}{(s+1)} & -\frac{s-1}{s+1} \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{array} \right). \tag{3.17}$$

Thus, we have $\overline{A^2\, R} = A^2\, R'$, and R' has full row rank. Hence, $\overline{A^2\, R}$ is a free A-module of rank 2, and, by Theorem 2.11, the transfer matrix P defined by (1.2) admits the following weakly left-coprime factorization:

$$P = \left(\begin{array}{cc} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s-1} \end{array} \right) = \left(\begin{array}{cc} 1 & 0 \\ 0 & \frac{s-1}{s+1} \end{array} \right)^{-1} \left(\begin{array}{cc} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s-1} \end{array} \right). \tag{3.18}$$

Moreover, using the fact that R' has full row rank, we have the exact sequence

$$0 \longrightarrow A^2 \xrightarrow{.R'} A^4 \xrightarrow{.R_{-1}} A^2 \longrightarrow 0 \tag{3.19}$$

and

$$\left\{ \begin{array}{l} t(M) \cong \mathrm{ext}^1_A(T(M), A) = A^2\,R'/A^2\,R, \\ M/t(M) = A^4/A^2\,.R' \cong A^4\,R_{-1} = A^2. \end{array} \right.$$

From $t(M) \cong A^2\,R'/A^2\,R$, we obtain that the class of $(1 : \ 0)\,R'$ in $t(M)$ is the torsion element $z_1 = y_1 - \frac{e^{-s}}{(s+1)}\,u_1 - \frac{(s-1)}{(s+1)}\,u_2$, which satisfies $\frac{(s-1)}{(s+1)}\,z_1 = 0$. Similarly, the class z_2 of $(0 : \ 1)\,R'$ in $t(M)$ is the trivial torsion element 0 because we have $z_2 = \frac{(s-1)}{(s+1)}\,y_2 - \frac{1}{(s+1)}\,u_2 = 0$. Thus, M is not a torsion-free A-module and $M/t(M)$ is a free A-module of rank 2. Finally, we have

$$\left(\begin{array}{cccc} \frac{s-1}{s+1} & 0 & -\frac{(s-1)\,e^{-s}}{(s+1)^2} & -\left(\frac{s-1}{s+1}\right)^2 \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{array} \right) = \left(\begin{array}{cc} \frac{s-1}{s+1} & 0 \\ 0 & 1 \end{array} \right) \left(\begin{array}{cccc} 1 & 0 & -\frac{e^{-s}}{(s+1)} & -\frac{s-1}{s+1} \\ 0 & \frac{s-1}{s+1} & 0 & -\frac{1}{s+1} \end{array} \right).$$

Remark 3.4. For the sake of simplicity, we have treated here just a simple example. Simple computations, which do not require the algorithm developed in section 3.3, can easily give the weakly left-prime matrix (3.17) and, thus, the weakly left-coprime factorization (3.18) of (1.2). However, for more general systems (see, e.g., $P = (\frac{e^{-s}}{(s-1)} \ : \ \frac{e^{-s}}{(s-1)^2})^T$ [32, 35]), it becomes more difficult to guess a weakly left-coprime factorization, and thus, we really need the algorithm to obtain weakly left/right/doubly coprime factorizations.

4. Doubly coprime factorizations.

4.1. Left-coprime factorizations and stably free modules. Let us introduce the concept of a splitting exact sequence.

DEFINITION 4.1 (see [2, 39]). *An exact sequence* $0 \longrightarrow M' \xrightarrow{f} M \xrightarrow{g} M'' \longrightarrow 0$ *is a* splitting exact *sequence if one of the following equivalent assertions is satisfied:*

- *there exists an* A*-morphism* $h : M'' \longrightarrow M$ *such that* $g \circ h = \mathrm{id}_{M''}$,
- *there exists an* A*-morphism* $k : M \longrightarrow M'$ *such that* $k \circ f = \mathrm{id}_{M'}$,
- *there exist* $\phi = \binom{k}{g} : M \longrightarrow M' \oplus M''$ *and* $\psi = (f \ : \ h) : M' \oplus M'' \longrightarrow M$ *such that* $\phi \circ \psi = \mathrm{id}_{M' \oplus M''}$ *and* $\psi \circ \phi = \mathrm{id}_M$, *where* $\mathrm{id}_M(m) = m$, *for all* $m \in M$.

PROPOSITION 4.2. *We have the following results:*

1. *(see* [2, 39]*) Let* $R \in M_{q \times p}(A)$ *be a full row rank matrix. Then, the* A*-module* $M = A^p/A^q\,R$ *is stably free iff the exact sequence*

$$0 \longrightarrow A^q \xrightarrow{.R} A^p \longrightarrow M \longrightarrow 0 \tag{4.1}$$

is a splitting exact sequence, i.e., iff there exists $S \in M_{p \times q}(A)$ *such that*

$$R\,S = I_q. \tag{4.2}$$

2. *(see* [19]*) Let* $R \in M_{q \times p}(A)$ *be a full row rank matrix and* $M = A^p/A^q\,R$ *the corresponding* A*-module. Then,* M *is stably-free iff*

$$T(M) = A^q/A^p\,R^T = 0.$$

Example 4.1. Let us consider the full row rank matrix $R' \in M_{2\times 4}(A)$ defined by (3.17) and $A = H_\infty(\mathbb{C}_+)$. By point 1 of Proposition 4.2, R' admits a right-inverse $S' \in M_{4\times 2}(A)$ iff the A-module $M' = A^4/A^2\,R'$ is stably free, i.e., iff the A-module $T(M') = A^2/A^4\,{R'}^T = 0$ by point 2 of Proposition 4.2. The A-module $T(M') = A^2/A^4\,{R'}^T$ is defined by the following equations:

$$\begin{cases} \lambda_1 = 0, \\ \frac{(s-1)}{(s+1)}\,\lambda_2 = 0, \\ -\frac{e^{-s}}{(s+1)}\,\lambda_1 = 0, \\ -\frac{(s-1)}{(s+1)}\,\lambda_1 - \frac{1}{(s+1)}\,\lambda_2 = 0. \end{cases} \tag{4.3}$$

If we put a second member $\mu = (\mu_1 : \mu_2 : \mu_3 : \mu_4)^T$ in (4.3), then we have

$$\begin{cases} \lambda_1 = \mu_1, \\ \lambda_2 = -2\,\frac{(s-1)}{(s+1)}\,\mu_1 + \mu_2 - 2\,\mu_4, \end{cases}$$

which proves that, from (4.3), we can deduce that $\lambda_1 = \lambda_2 = 0$, i.e., $T(M') = 0$ and M' is a stably free A-module. A right-inverse S' of R', i.e., $R'\,S' = I_2$, is defined by

$$S = \begin{pmatrix} 1 & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \\ 0 & 0 \\ 0 & -2 \end{pmatrix} \in M_{4\times 2}(A). \tag{4.4}$$

Let us give the definition of the *fitting ideals* of a finitely presented A-module M.

Definition 4.3 (see [13]). *Let $d : F_1 \longrightarrow F_0$ be an A-morphism between two finite free A-modules F_0 and F_1. If we choose bases for F_0 and F_1 ($F_0 \cong A^p$, $F_1 \cong A^q$), then d is defined by a matrix $R \in M_{q\times p}(A)$.*

- *We denote by $I_i(R)$ the ideal of A defined by*
  - *all the $i \times i$ minors of R if $1 \leq i \leq \min\{p, q, \}$,*
  - *$I_i(R) = 0$ if $i > \min\{p, q\}$,*
  - *$I_i(R) = A$ if $i \leq 0$.*
- *Let us define the A-module $M = \operatorname{coker} d$, i.e., $M = A^p/A^q\,R$. The ith* fitting ideal $\mathrm{Fitt}_i(M)$ *is the ideal of A defined by $I_{p-i}(R)$. $\mathrm{Fitt}_i(M)$ does not depend on the choice of the finite free presentation of M.*
- *We denote by $I(M)$ the first nonzero fitting ideal $\mathrm{Fitt}_i(M)$ of M.*

Proposition 4.4 (see [13]). *Let M be a finitely presented A-module. Then, we have the following:*

- *M is a projective A-module of rank r iff $\mathrm{Fitt}_r(M) = A$ and $\mathrm{Fitt}_{r-1}(M) = 0$.*
- *M is a projective A-module of a certain rank iff $I(M) = A$.*

Example 4.2. Let us reconsider Example 4.1. We have

$$\mathrm{Fitt}_0(M') = \mathrm{Fitt}_1(M') = 0, \qquad \mathrm{Fitt}_2(M') = \left(\frac{s-1}{s+1}, \frac{1}{s+1}, \frac{e^{-s}}{(s+1)^2}, \frac{(s-1)\,e^{-s}}{(s+1)^2}\right).$$

We can check that $1 = \frac{s-1}{s+1} + \frac{2}{s+1} \in \mathrm{Fitt}_2(M')$, and thus, $\mathrm{Fitt}_2(M') = A$; i.e., M' is a projective A-module of rank 2 by Proposition 4.4.

The next proposition characterizes the projective modules over Banach algebras.

PROPOSITION 4.5. *If A is a Banach algebra which is an integral domain without radical, i.e., $\sqrt{A} = \{a \in A \mid \lim_{n\to+\infty} \|a^n\|_A^{1/n} = 0\} = 0$, then a full row rank matrix $R \in M_{q\times p}(A)$ defines a projective A-module $M = A^p/A^q\,R$ iff $\mathrm{rk}(\hat{R}(\chi))$ is a constant function on the* maximal ideal space $X(A)$ *of A (see* [16, 49]*), where $\hat{R}$ denotes the* Gelfand transform *of R (see* [16, 49]*), or, equivalently, iff*

$$\inf_{\chi\in X(A)} \sum_{i\in I} |\hat{R}_i(\chi)| \geq \delta > 0,$$

where $(\hat{R}_i)_{i\in I}$ is the family of the $q \times q$ minors of R.

Proof. Using the fact that the maximal ideal space $X(A)$ of a Banach algebra is a Hausdorff compact set and A has only two idempotent elements 1 and 0, then, by the *Shilov theorem* [16], $X(A)$ is a connected space. By the *Swan theorem* [45], any *vector bundle* over $X(A)$ is in one-to-one correspondence to a projective module over the ring of continuous functions $C(X(A))$ on $X(A)$. The fact that $X(A)$ is a connected space implies that the rank of any vector bundle over $X(A)$ is globally constant. Finally, using the fact that A is without radical, by the Gelfand transform [16], any matrix whose entries belong to A can be seen as a matrix whose entries belong to $C(X(A))$. Hence, we find that M is a projective A-module iff $\mathrm{rk}(\hat{R}(\chi))$ is a constant function on $X(A)$. □

Example 4.3. $H_\infty(\mathbb{C}_+)$ and $\hat{\mathcal{A}}$ are two integral domains which are Banach algebras without radical. We can use Proposition 4.5 to check whether or not an A-module is projective. For $A = H_\infty(\mathbb{C}_+)$, we can use the fact that $\mathbb{C}_+$ is dense in $X(A)$ (by the *Corona theorem*; see [25]) in order to take χ only in $\mathbb{C}_+$ instead of the whole $X(A)$. Similarly, for $A = \hat{\mathcal{A}}$, we can restrict the evaluation of $\inf_{\chi\in X(A)} \sum_{i\in I} |\hat{R}_i(\chi)|$ to $\chi \in \overline{\mathbb{C}_+}$, where $\overline{\mathbb{C}_+} = \{s \in \mathbb{C} \mid \mathrm{Re}\, s \geq 0\}$ (see [3, 8]).

- Let $A = H_\infty(\mathbb{C}_+)$. Let $R = (\frac{s-1}{s+1} : \frac{e^{-s}}{s+1}) \in M_{1\times 2}(A)$ and the A-module $M = A^2/A\,R$. Then, M is a projective A-module (i.e., free because A is a coherent Sylvester domain) because we have

$$\inf_{s\in\mathbb{C}_+} \left(\left| \frac{s-1}{s+1} \right| + \left| \frac{e^{-s}}{s+1} \right| \right) > 0.$$

  We can check that we have the following Bézout identity:

$$\left(\frac{s-1}{s+1}\right) \left(1 + 2\left(\frac{1-e^{-(s-1)}}{s-1}\right)\right) + 2\,e\left(\frac{e^{-s}}{s+1}\right) = 1.$$

- Let $A = H_\infty(\mathbb{C}_+)$. The matrix $R = (\frac{1}{s+1} : e^{-s}) \in M_{1\times 2}(A)$ does not define a projective A-module $M = A^2/A\,R$ because we have

$$\inf_{s\in\mathbb{C}_+} \left(\left| \frac{1}{s+1} \right| + |\, e^{-s}\, | \right) = 0.$$

  Indeed, if $(x_n)_{n\in\mathbb{Z}_+}$ is a sequence of strictly positive real numbers tending to $+\infty$, we check that $\lim_{n\to+\infty} |\frac{1}{x_n+1}| = 0$ and $\lim_{n\to+\infty} |e^{-x_n}| = 0$. However, the greatest common divisor of $\frac{1}{s+1}$ and e^{-s} is 1, and thus, R is a weakly left-prime matrix by Proposition 2.2 and Corollary 3.31; i.e., M is a torsion-free (see Corollary 2.5) but not free A-module.

DEFINITION 4.6. *Let A be an integral domain and $K = Q(A)$ its field of fractions.*

- *A transfer matrix* $P \in M_{q\times(p-q)}(K)$ *admits a* left-coprime factorization *if there exists a matrix* $R = (D : -N) \in M_{q\times p}(A)$, *with* $\det D \neq 0$, *such that* $P = D^{-1}\,N$ *and* R *has a right-inverse* $S = (X^T : Y^T)^T \in M_{p\times q}(A)$, *i.e.,*

$$R\,S = D\,X - N\,Y = I_q.$$

- *A transfer matrix* $P \in M_{q\times(p-q)}(K)$ *admits a* right-coprime factorization *if there exists a matrix* $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$, *with* $\det \tilde{D} \neq 0$, *such that* $P = \tilde{N}\,\tilde{D}^{-1}$ *and* $\tilde{R}$ *has a left-inverse* $\tilde{S} = (-\tilde{Y} : \tilde{X}) \in M_{(p-q)\times p}(A)$, *i.e.,*

$$\tilde{S}\,\tilde{R} = -\tilde{Y}\,\tilde{N} + \tilde{X}\,\tilde{D} = I_{p-q}.$$

PROPOSITION 4.7. *Let* $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1} \in M_{q\times(p-q)}(K)$ *be a transfer matrix, where* $R = (D : -N) \in M_{q\times p}(A)$ *and* $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. *Let us define the* A*-modules* $M = A^p/A^q\,R$ *and* $\tilde{M} = A^p/A^{p-q}\,\tilde{R}^T$. *Then, we have*

1. *P admits a left-coprime factorization iff $\overline{A^q\,R}$ is a free A-module of rank q and $M/t(M) = A^p/\overline{A^q\,R}$ is a stably free A-module.*
2. *P admits a right-coprime factorization iff $\overline{A^{p-q}\,\tilde{R}^T}$ is a free A-module of rank $p-q$ and $\tilde{M}/t(\tilde{M}) = A^p/\overline{A^{p-q}\,\tilde{R}^T}$ is a stably free A-module.*

Proof. 1. $\Rightarrow$ Let us suppose that P admits a left-coprime factorization of the form $P = {D'}^{-1}\,N'$, where the matrix $R' = (D' : -N') \in M_{q\times p}(A)$ has right-inverse $S' = ({X'}^T : {Y'}^T)^T \in M_{p\times q}(A)$. In particular, R' is weakly left-prime and, by Lemma 2.6, we have $\overline{A^q\,R} = A^q\,R'$. Moreover, R' is a full row rank matrix, and thus, $A^q\,R' = \overline{A^q\,R}$ is a free A-module of rank q. We have the exact sequence

$$0 \longrightarrow A^q \xrightarrow{.R'} A^p \longrightarrow M/t(M) = A^p/\overline{A^q\,R} \longrightarrow 0. \tag{4.5}$$

Using the fact that R' has a right-inverse S', we obtain that (4.5) splits, and thus, we have $A^p \cong A^q \oplus M/t(M)$; i.e., $M/t(M)$ is a stably free A-module.

$\Leftarrow$ Let $P = D^{-1}\,N$ be such that $\overline{A^q\,R}$ is a free A-module of rank q and the A-module $M/t(M) = A^p/\overline{A^q\,R}$ is stably free. Using the fact that $\overline{A^q\,R}$ is a free A-module of rank q, there then exists a weakly left-prime matrix $R' = (D' : -N') \in M_{q\times p}(A)$ such that $\overline{A^q\,R} = A^q\,R'$ and $P = {D'}^{-1}\,N'$. Then, we have the exact sequence (4.5), which splits because $M/t(M) = A^p/A^q\,R'$ is a stably free A-module, and thus, there exists $S' = ({X'}^T : {Y'}^T)^T \in M_{p\times q}(A)$ such that $D'\,X' - N'\,Y' = I_q$, i.e., $P = {D'}^{-1}\,N'$ is a left-coprime factorization of P. Part 2 can be proved similarly. □

Example 4.4. In Example 3.4, we proved that $\overline{A^2\,R} = A^2\,R'$, where R (resp., R') is defined by (1.6) (resp., (3.17)), is a free A-module of rank 2. Moreover, in Example 4.1, we proved that $M/t(M) = A^4/A^2\,R'$ is a stably free A-module. Hence, from point 1 of Proposition 4.7, we deduce that (3.18) is a left-coprime factorization of the transfer matrix (1.2). Finally, using S' obtained in Example 4.1, we obtain

$$\begin{cases} P = \begin{pmatrix} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s-1} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & \frac{s-1}{s+1} \end{pmatrix}^{-1} \begin{pmatrix} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s+1} \end{pmatrix}, \\ \begin{pmatrix} 1 & 0 \\ 0 & \frac{s-1}{s+1} \end{pmatrix} \begin{pmatrix} 1 & -2\,\frac{(s-1)}{(s+1)} \\ 0 & 1 \end{pmatrix} - \begin{pmatrix} \frac{e^{-s}}{s+1} & \frac{s-1}{s+1} \\ 0 & \frac{1}{s+1} \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & -2 \end{pmatrix} = I_2. \end{cases}$$

Example 4.5. Let us consider the example defined in [49, p. 349]. Let us consider the integral domain $A = \mathbb{R}[t_0, t_1, t_2]/(t_0^2+t_1^2+t_2^2-1)$ of polynomials on the unit sphere of $\mathbb{R}^3$. Let x_i be the class of t_i in A. We have $A = \mathbb{R}[x_0, x_1, x_2]$ with the relation $x_0^2 + x_1^2 + x_2^2 = 1$. It is shown in [20, p. 32] that A is a *unique factorization domain* (UFD) [39], and thus, A is a GCDD.

Let us consider $P = -(x_1/x_0 : x_2/x_0) \in M_{1\times 2}(K)$ with $K = \mathbb{R}(x_0, x_1, x_2)$. We have $P = -x_0^{-1}\,(x_1 : x_2)$ and, if we define $R = (x_0 : x_1 : x_2) \in A^3$, then we have $R\,R^T = 1$. Thus, $\overline{A\,R} = A\,R$ is a free A-submodule of rank 1, and $M = A^3/A\,R$ is a stably free A-module, which proves that P admits a (normalized) left-coprime factorization. Moreover, we have $P = -(x_1 : x_2)\,(x_0^{-1}\,I_2)$. Let us define the matrix

$$\tilde{R} = \begin{pmatrix} -x_1 & -x_2 \\ x_0 & 0 \\ 0 & x_0 \end{pmatrix} \in M_{3\times 2}(A)$$

and the corresponding A-module $\tilde{M} = A^3/A^2\,\tilde{R}^T$. We easily check that $\mathrm{Fitt}_0(\tilde{M}) = 0$ and $\mathrm{Fitt}_1(\tilde{M}) = (x_0\,x_1, x_0\,x_2, x_0^2)$. Thus, x_0 is a greatest common factor of all the 2×2 minors, which, by Proposition 2.2, proves that $\tilde{R}^T$ is not weakly left-prime, i.e., the A-module $\tilde{M}$, defined by the equations

$$\begin{cases} -x_1\,y_0 + x_0\,y_1 = 0, \\ -x_2\,y_0 + x_0\,y_2 = 0, \end{cases}$$

has a nonzero torsion submodule. We easily check that $z = -x_2\,y_1 + x_1\,y_2$, satisfying $x_0\,z = 0$, defines the torsion submodule of $\tilde{M}$. Therefore, $A^2\,\tilde{R}^T$ is not A-closed, and we have $\tilde{M}/t(\tilde{M}) = A^3/A^3\,\tilde{R'}^T$, where $\tilde{R'}^T$ is defined by

$$\tilde{R'}^T = \begin{pmatrix} -x_1 & x_0 & 0 \\ -x_2 & 0 & x_0 \\ 0 & -x_2 & x_1 \end{pmatrix} \in M_3(A).$$

We have $\mathrm{Fitt}_0(\tilde{M}/t(\tilde{M})) = 0$ and $x_0^2, x_1^2, x_2^2 \in \mathrm{Fitt}_1(\tilde{M}/t(\tilde{M})) \Rightarrow 1 \in \mathrm{Fitt}_1(\tilde{M}/t(\tilde{M}))$, and thus, by Proposition 4.4, $\tilde{M}/t(\tilde{M})$ is a projective A-module of rank 1. However, a projective module of rank 1 over a UFD is free (see [20, 45]), and thus, $\tilde{M}/t(\tilde{M})$ is a free A-module of rank 1: $u = x_0\,y_0 + x_1\,y_1 + x_2\,y_2$ is a basis of $\tilde{M}/t(\tilde{M})$ because we have $y_i = x_i\,u$ for $i = 1, \ldots, 3$. Thus, we obtain that $\tilde{M}/t(\tilde{M}) \cong A^3\,R^T \cong A$. Moreover, by Proposition 2.8, we know that $\ker.R^T = \overline{A^2\,\tilde{R}^T} = A^3\,\tilde{R'}^T$. However, it is well known that $\ker.R^T$ is a stably free but not a free A-module [20, 49]. By Proposition 4.7, P does not admit a right-coprime factorization.

Corollary 4.8. *Let $P = D^{-1}\,N = \tilde{N}\,\tilde{D}^{-1} \in M_{q\times(p-q)}(K)$ be a transfer matrix, where $R = (D : -N) \in M_{q\times p}(A)$ and $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. Let us define the A-modules $M = A^p/A^q\,R$ and $\tilde{M} = A^p/A^{p-q}\,\tilde{R}^T$. Then, we have*

1. *P admits a left-coprime factorization iff $\tilde{M}/t(\tilde{M}) = A^p/\overline{A^{p-q}\,\tilde{R}^T}$ is a free A-module of rank q.*
2. *P admits a right-coprime factorization iff $M/t(M) = A^p/\overline{A^q\,R}$ is a free A-module of rank $p-q$.*

Proof. 1. $\Rightarrow$ Let us suppose that P admits the left-coprime factorization $P = {D'}^{-1}\,N'$, where $R' = (D' : -N') \in M_{q\times p}(A)$ has a right-inverse S'. Then, $\overline{A^q\,R} = A^q\,R'$ is a free A-module of rank q, and thus, $M/t(M) = A^p/A^q\,R'$, i.e., we have the

following exact sequence:

$$0 \longrightarrow A^q \xrightarrow{.R'} A^p \longrightarrow M/t(M) \longrightarrow 0.$$

By Proposition 4.2, this exact sequence splits, and thus, $A^p\, {R'}^T \cong A^q$. Finally, by Proposition 2.8, we now have $\tilde{M}/t(\tilde{M}) \cong A^p {R'}^T \cong A^q$.

$\Leftarrow$ Let us suppose that the A-module $\tilde{M}/t(\tilde{M})$ is a free A-module of rank q. $t(\tilde{M})$ is a torsion A-module, and thus, we have $(t(\tilde{M}))^\star = 0$. Hence, dualizing the exact sequence $0 \longrightarrow t(\tilde{M}) \longrightarrow \tilde{M} \longrightarrow \tilde{M}/t(\tilde{M}) \longrightarrow 0$, we obtain $\tilde{M}^\star \cong (\tilde{M}/t(\tilde{M}))^\star \cong A^q$. By Proposition 2.8, we know that $\tilde{M}^\star \cong \ker .\tilde{R} = \overline{A^q\, R}$, and thus, $\overline{A^q\, R}$ is a free A-module of rank q. Moreover, by Proposition 1.9 of [33], $A^p\, \tilde{R}$ is a projective A-module because so is $\tilde{M}/t(\tilde{M})$. Thus, the exact sequence $0 \longrightarrow \ker .\tilde{R} \longrightarrow A^p \longrightarrow A^p\, \tilde{R} \longrightarrow 0$ splits, and we obtain that $A^p \cong A^p\, \tilde{R} \oplus \ker .\tilde{R}$. However, by Proposition 2.8, $A^p\, \tilde{R} \cong M/t(M)$. Thus, we have $A^p \cong M/t(M) \oplus A^q$; i.e., $M/t(M)$ is a stably-free A-module. Then, by Proposition 4.7, P admits a left-coprime factorization. Point 2 can be proved similarly. □

Example 4.6. Let us reconsider the system defined in Example 4.5. We proved that the A-module $\tilde{M}/t(\tilde{M})$ is a free A-module of rank 1, and thus, by Corollary 4.8, P admits a left-coprime factorization. Moreover, it is known that $M/t(M) = M$ is a stably free but not a free A-module [20, 45], i.e., P does not admit right-coprime factorizations.

4.2. Doubly coprime factorizations and free modules. The following result characterizes generalized Bézout identities in terms of free A-modules.

PROPOSITION 4.9. *Let $M = A^p/A^q\, R$ be an A-module defined by a full row rank matrix $R \in M_{q\times p}(A)$, i.e., by the following finite free resolution:*

$$0 \longrightarrow A^q \xrightarrow{.R} A^p \longrightarrow M \longrightarrow 0. \tag{4.6}$$

Then, M is a free A-module iff there exist three matrices R_{-1}, S_{-1}, and S such that we have the following splitting exact sequence,

$$0 \longrightarrow A^q \underset{\xleftarrow{.S}}{\xrightarrow{.R}} A^p \underset{\xleftarrow{.S_{-1}}}{\xrightarrow{.R_{-1}}} A^{p-q} \longrightarrow 0, \tag{4.7}$$

or equivalently, iff we have the following generalized Bézout identities:

$$\text{(i)}\ \begin{pmatrix} S & R_{-1} \end{pmatrix} \begin{pmatrix} R \\ S_{-1} \end{pmatrix} = I_p,$$

$$\text{(ii)}\ \begin{pmatrix} R \\ S_{-1} \end{pmatrix} \begin{pmatrix} S & R_{-1} \end{pmatrix} = \begin{pmatrix} I_q & 0 \\ 0 & I_{p-q} \end{pmatrix} = I_p.$$

Proof. $\Rightarrow$ The A-module M is free, and thus, there exists a $p \times (p-q)$ matrix R_{-1} with entries in A such that the exact sequence (4.6) has the form

$$0 \longrightarrow A^q \xrightarrow{.R} A^p \xrightarrow{.R_{-1}} A^{p-q} \longrightarrow 0.$$

This exact sequence finishes by the free A-module A^{p-q}, and thus, by Proposition 4.2, it splits; i.e., there exists a $(p-q)\times p$ matrix S_{-1} such that $R_{-1}\, S_{-1} = I_{p-q}$. By the equivalences of Definition 4.1, we have the Bézout identities (i) and (ii).

$\Leftarrow$ If we have the splitting exact sequence (4.7) or, equivalently, the Bézout identities (i) and (ii), then $M \cong A^p R_{-1} = A^{p-q}$, i.e., M is a free A-module of rank $p-q$. □

DEFINITION 4.10. *A transfer matrix $P \in M_{q\times(p-q)}(K)$ admits a* doubly coprime factorization *if there exist $(D : -N) \in M_{q\times p}(A)$, $(\tilde{N}^T : \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$, $(X^T : Y^T)^T \in M_{p\times q}(A)$, and $(-\tilde{Y} : \tilde{X}) \in M_{(p-q)\times p}(A)$ such that*

- $P = D^{-1} N = \tilde{N} \tilde{D}^{-1}$,
- $\begin{pmatrix} D & -N \\ -\tilde{Y} & \tilde{X} \end{pmatrix} \begin{pmatrix} X & \tilde{N} \\ Y & \tilde{D} \end{pmatrix} = I_p$,
- $\begin{pmatrix} X & \tilde{N} \\ Y & \tilde{D} \end{pmatrix} \begin{pmatrix} D & -N \\ -\tilde{Y} & \tilde{X} \end{pmatrix} = I_p$.

THEOREM 4.11. *Let $P = D^{-1} N = \tilde{N} \tilde{D}^{-1}$, $R = (D : -N)$, $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T$, and the A-modules $M = A^p/A^q R$ and $\tilde{M} = A^p/A^{p-q} \tilde{R}^T$. Then, P admits a doubly coprime factorization iff $M/t(M)$ and $\tilde{M}/t(\tilde{M})$ are free A-modules of rank $p-q$ and q.*

Proof. $\Rightarrow$ If P admits a doubly coprime factorization, then P admits left and right-coprime factorizations, and thus, by Proposition 4.8, the A-modules $M/t(M)$ and $\tilde{M}/t(\tilde{M})$ are free A-modules of rank, respectively, $p-q$ and q.

$\Leftarrow$ By Proposition 4.8, there exist a left and a right-coprime factorization of P:

$$P = {D'}^{-1} N' = \tilde{N}' {\tilde{D}'}^{-1}, \qquad \begin{cases} D' X - N' Y = I_q, \\ -\tilde{Y}' \tilde{N}' + \tilde{X}' \tilde{D}' = I_{p-q}. \end{cases}$$

From $P = {D'}^{-1} N' = \tilde{N}' {\tilde{D}'}^{-1}$, we deduce that $(D' : -N') \begin{pmatrix} \tilde{N}' \\ \tilde{D}' \end{pmatrix} = 0$. If we take

$$\begin{cases} X' = X + \tilde{N}' (\tilde{Y}' X - \tilde{X}' Y), \\ Y' = Y + \tilde{D}' (\tilde{Y}' X - \tilde{X}' Y), \end{cases}$$

we can easily check that $P = {D'}^{-1} N' = \tilde{N}' {\tilde{D}'}^{-1}$ is a doubly coprime factorization:

$$\begin{pmatrix} D' & -N' \\ -\tilde{Y}' & \tilde{X}' \end{pmatrix} \begin{pmatrix} X' & \tilde{N}' \\ Y' & \tilde{D}' \end{pmatrix} = I_p, \qquad \begin{pmatrix} X' & \tilde{N}' \\ Y' & \tilde{D}' \end{pmatrix} \begin{pmatrix} D' & -N' \\ -\tilde{Y}' & \tilde{X}' \end{pmatrix} = I_p. \qquad \square$$

Using Proposition 2.8, we obtain the following corollary of Theorem 4.11.

COROLLARY 4.12. *Let $P = D^{-1} N = \tilde{N} \tilde{D}^{-1} \in M_{q\times(p-q)}(A)$ be a transfer matrix, $R = (D : -N) \in M_{q\times p}(A)$, and $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T \in M_{p\times(p-q)}(A)$. Then, P admits a doubly coprime factorization iff the A-modules $A^p \tilde{R}$ and $A^p R^T$ are two free A-modules of rank, respectively, $p-q$ and q.*

This corollary was first proved in [44]. We have the following corollary of Proposition 4.12, which was first obtained in [49].

COROLLARY 4.13. *A SISO plant, defined by $p = n/d$ $(0 \neq d, n \in A)$, admits a coprime factorization iff the ideal $I = (n, d)$ of A is principal.*

Proof. By Proposition 4.12, $p = n/d$ has a coprime factorization iff the A-module $I = A^2 R^T = (d, n)$ is free of rank 1, where $R = (d : -n) \in M_{1\times 2}(A)$. Using the fact that A is an integral domain, I is a free A-module iff I is a principal ideal. □

The next corollary of Proposition 4.7 was first proved in [49].

COROLLARY 4.14. *If A is a Hermite ring, then every transfer matrix P with a left-coprime (resp., right-coprime) factorization admits a doubly coprime factorization.*

Proof. Let $P = D^{-1} N$ be a left-coprime factorization of the transfer matrix P, where $R = (D : -N) \in M_{q\times p}(A)$. By Proposition 4.7, the A-module $M = A^p/A^q R$

is stably free. Using the fact that A is a Hermite ring, then M is free, and the result follows directly from Corollary 4.8, and similarly for right-coprime factorizations. □

Example 4.7. In Example 4.4, we proved that the transfer matrix P defined by (1.2) admits a left-coprime factorization. Using the fact that $A = H_\infty(\mathbb{C}_+)$ is a coherent Sylvester domain and, in particular, a Hermite ring, by Corollary 4.14, we know that P admits a doubly coprime factorization. In fact, we have already done all the computations to obtain a right-coprime factorization of P. Indeed, we proved that (3.19) is an exact sequence, and thus it splits. Hence, using the matrices $R_{-1} = (\tilde{N}^T : \tilde{D}^T)^T \in M_{4\times 2}(A)$ and $S_{-1} = (-\tilde{Y} : \tilde{X}) \in M_{2\times 4}(A)$, defined in Example 3.4, we obtain the following right-coprime factorization of P:

$$\begin{cases} P = \tilde{N}\,\tilde{D}^{-1} = \begin{pmatrix} \left(\frac{s-1}{s+1}\right)^2 & \frac{e^{-s}}{s+1} \\ \frac{1}{s+1} & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ \frac{s-1}{s+1} & 0 \end{pmatrix}^{-1}, \\ -\begin{pmatrix} 0 & -2 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \left(\frac{s-1}{s+1}\right)^2 & \frac{e^{-s}}{s+1} \\ \frac{1}{s+1} & 0 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ \frac{s-1}{s+1} & 0 \end{pmatrix} = I_2. \end{cases}$$

THEOREM 4.15 (see [49]). *The following assertions are equivalent:*

1. *every MIMO plant admits doubly coprime factorizations,*
2. *every SISO plant admits coprime factorizations,*
3. *A is a Bézout domain.*

Proof. $1 \Rightarrow 2$ is trivial. $2 \Rightarrow 3$ is given by Lemma 4.13.

$3 \Rightarrow 1$. If A is a Bézout domain, then every A-module $M = A^p/A^q\,R$, defined by a full row rank matrix $R = (D : -N) \in M_{q\times p}(A)$, is such that $M/t(M)$ is a free A-module. Moreover, a Bézout domain A is a coherent Sylvester domain, and thus, by Proposition 3.21, there exists a full row rank matrix $R' = (D' : -N') \in M_{q\times p}(A)$ such that $M/t(M) = A^p/A^q\,R'$ and $P = D^{-1}\,N = {D'}^{-1}\,N'$. Finally, using Proposition 4.9, we obtain that P admits a doubly coprime factorization. □

Conclusion. We hope we have convinced the reader that the reformulation of the fractional representation approach to analysis problems within the algebraic analysis framework allows us to obtain some new results. These results will be used in the second part of this work [33] to obtain necessary and sufficient conditions for internal stabilizability and to determine the class of rings A over which every plant is internally stabilizable. For the sake of simplicity, we have treated only the case of integral domains, but all the results are still valid for general rings: we need only to slightly change some definitions (e.g., $K = Q(A) = \{a/b \mid a \in A,\ b \in A \setminus Z(A)\}$, where $Z(A)$ is the set of the nonzero divisors of A, $t(M) = \{m \in M \mid \exists\, a \in A \setminus Z(A) : a\,m = 0\}$, etc.).

Acknowledgements. I would like to thank R. Mortini (University of Metz, France) for pointing me toward the references [23, 37]. I had fruitful discussions with W. Dicks (Universitat Autònoma de Barcelona, Spain) after I read in [6] that coherent Sylvester domains were studied in the papers [10, 11]. In [12], he gave me a proof of Proposition 3.23. I would like to thank him for letting me reproduce his proof in this paper. Finally, I am grateful to J. J. Loiseau (IRCCyN, France) and C. Bonnet (INRIA Rocquencourt, France) for their continuous interest in this work, and to those without whom this paper would never have been written, especially to Céline. I would like to thank the University of Leeds for its hospitality and, especially, J. R. Partington and H. G. Dales.

THE FRACTIONAL REPRESENTATION APPROACH TO SYNTHESIS PROBLEMS: AN ALGEBRAIC ANALYSIS VIEWPOINT PART II: INTERNAL STABILIZATION*

A. QUADRAT†

Abstract. In this second part of the paper [A. Quadrat, *SIAM J. Control Optim.*, 40 (2003), pp. 266–299], we show how to reformulate the fractional representation approach to synthesis problems within an algebraic analysis framework. In terms of modules, we give necessary and sufficient conditions for internal stabilizability. Moreover, we characterize all the integral domains A of SISO stable plants such that every MIMO plant—defined by means of a transfer matrix whose entries belong to the quotient field $K = Q(A)$ of A—is internally stabilizable. Finally, we show that this algebraic analysis approach allows us to recover on the one hand the approach developed in [M. C. Smith, *IEEE Trans. Automat. Control*, 34 (1989), pp. 1005–1007] and on the other hand the ones developed in [K. Mori and K. Abe, *SIAM J. Control Optim.*, 39 (2001), pp. 1952–1973; S. Shankar and V. R. Sule, *SIAM J. Control Optim.*, 30 (1992), pp. 11–30; V. R. Sule, *SIAM J. Control Optim.*, 32 (1994), pp. 1675–1695; M. Vidyasagar, H. Schneider, and B. A. Francis, *IEEE Trans. Automat. Control*, 27 (1982), pp. 880–894; M. Vidyasagar, *Control System Synthesis: A Factorization Approach*, MIT Press, Cambridge, MA, 1985].

Key words. fractional representation approach to synthesis problems, internal stabilization, Prüfer domains, Youla–Kučera parametrization of the stabilizing controllers, (weakly) left/right/doubly coprime factorizations, coherent Sylvester domains, $H_\infty(\mathbb{C}_+)$, algebraic analysis, module theory, homological algebra

Introduction. Using the algebraic analysis viewpoint of the fractional representation approach to analysis and synthesis problems [5, 28, 29], developed in the first part of the paper [17], we give necessary and sufficient conditions for *internal stabilizability*. Moreover, using these results, we prove that every multi-input multi-output (MIMO) plant—defined by means of a transfer matrix $P = D^{-1}N = \tilde{N}\tilde{D}^{-1}$, where $R = (D : -N)$ and $\tilde{R} = (\tilde{N}^T : \tilde{D}^T)^T$ are matrices whose entries belong to an integral domain A of single input single output (SISO) stable plants—is internally stabilizable iff A is a *Prüfer domain* [6, 23]. From the fact that the intersection between coherent Sylvester domains (see [17] for more details) and Prüfer domains are just Bézout domains, we also recover the result of Vidyasagar [29]: every MIMO plant admits doubly coprime factorizations iff A is a *Bézout domain*. Hence, if the algebra A is a Prüfer domain but not a Bézout domain, there exist plants which are internally stabilizable but fail to admit doubly coprime factorizations. Therefore, it is not possible to parametrize all their stabilizing controllers by means of the Youla–Kučera parametrization [4, 28]. These results allow us to explain the counterexamples exhibited in [1, 12]. We prove that, over a *projective-free domain* A (e.g., $H_\infty(\mathbb{C}_+)$, RH_∞), every stabilizable system admits doubly coprime factorizations. Finally, we show that the previous results allow us to recover, on the one hand, the results of [25] and, on

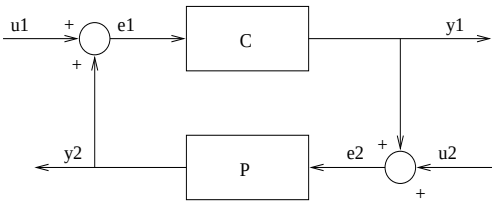

FIG. 1. *Closed-loop.*

the other hand, the ones developed in [12, 13, 24, 26, 27, 28, 29]. We refer to [17] for the development of the algebraic analysis approach used in this second part, as well as for some results that will be continually used in what follows.

Notation. In the course of the text, A denotes a commutative integral domain ($a\,b = 0, a \neq 0 \Rightarrow b = 0$) with a unit, $M_{q\times p}(A)$ (resp., $M_p(A)$), the set of $q \times p$ (resp., $p \times p$) matrices with entries in A and I_p the identity matrix. If $R \in M_{q\times p}(A)$, then R^T is the transposed matrix. *By convention, every vector with entries in A is a row vector.* The positive integers $p, q \in \mathbb{Z}_+$ will always satisfy $p \geq q$. If M and N are two A-modules, then $M \cong N$ means that M and N are isomorphic as A-modules, $\hom_A(M, N)$ is the A-module of the A-morphisms (i.e., A-linear maps) from M to N, and $M^* = \hom_A(M, A)$. Finally, $(a_1, \ldots, a_n)$ denotes the ideal $A\,a_1 + \cdots + A\,a_n$ and $\triangleq$ means "by definition."

1. Closed-loop systems. Let A be an algebra of SISO stable systems which forms an integral domain and let $K = Q(A)$ be its field of fractions. Let us consider the closed-loop formed by a plant $P \in M_{q\times(p-q)}(K)$ and a controller $C \in M_{(p-q)\times q}(K)$ as it is shown in Figure 1. The equations of the closed-loop are

$$\begin{cases} e_1 = u_1 + P\,e_2, \\ e_2 = u_2 + C\,e_1, \\ y_1 = e_2 - u_2, \\ y_2 = e_1 - u_1. \end{cases} \tag{1.1}$$

DEFINITION 1.1 (see [5, 28, 29]). *The plant $P \in M_{q\times(p-q)}(K)$ is* internally stabilizable *if there exists a controller $C \in M_{(p-q)\times q}(K)$ such that all the entries of the following transfer matrix*

$$H(P,C) = \begin{pmatrix} I_q & -P \\ -C & I_{p-q} \end{pmatrix}^{-1} = \begin{pmatrix} (I_q - P\,C)^{-1} & (I_q - P\,C)^{-1}\,P \\ C\,(I_q - P\,C)^{-1} & I_{p-q} + C\,(I_q - P\,C)^{-1}\,P \end{pmatrix} \tag{1.2}$$

are stable, i.e., $H(P,C) \in M_p(A)$.

Let us write P and C in the form $P = {D_p}^{-1}\,N_p$ and $C = {D_c}^{-1}\,N_c$, where $R_p = (D_p : -N_p) \in M_{q\times p}(A)$ and $R_c = (-N_c : D_c) \in M_{(p-q)\times p}(A)$. Thus, we have

$$(1.1) \Leftrightarrow \begin{cases} D_p\,e_1 - N_p\,e_2 - D_p\,u_1 = 0, \\ -N_c\,e_1 + D_c\,e_2 - D_c\,u_2 = 0, \\ y_1 - e_2 + u_2 = 0, \\ y_2 - e_1 + u_1 = 0. \end{cases} \tag{1.3}$$

Let us define the matrices

$$R = \begin{pmatrix} D_p & -N_p & -D_p & 0 \\ -N_c & D_c & 0 & -D_c \end{pmatrix} \in M_{p\times 2p}(A)$$

and

$$R_s = \begin{pmatrix} D_p & -N_p & -D_p & 0 & 0 & 0 \\ -N_c & D_c & 0 & -D_c & 0 & 0 \\ 0 & -I_{p-q} & 0 & I_{p-q} & I_{p-q} & 0 \\ -I_q & 0 & I_q & 0 & 0 & I_q \end{pmatrix} \in M_{2p\times 3p}(A),$$

as well as the following A-modules

$$\begin{cases} M_p = A^p/A^q\,R_p, \\ M_c = A^p/A^{p-q}\,R_c, \\ M = A^{2p}/A^p\,R, \\ M_s = A^{3p}/A^{2p}\,R_s. \end{cases}$$

LEMMA 1.2. *We have $M_s = M \cong M_p \oplus M_c$, and thus*

$$M_s/t(M_s) = M/t(M) \cong M_p/t(M_p) \oplus M_c/t(M_c), \tag{1.4}$$

or equivalently

$$A^{3p}/\overline{A^{2p}\,R_s} = A^{2p}/\overline{A^p\,R} \cong A^p/\overline{A^q\,R_p} \oplus A^p/\overline{A^{p-q}\,R_c},$$

where, for instance, $\overline{A^p\,R}$ is the A-closure of $A^p\,R$ in A^{2p} (see [17] *for more details).*

Proof. We have the following equality:

$$\begin{pmatrix} D_p & -N_p & -D_p & 0 \\ -N_c & D_c & 0 & -D_c \end{pmatrix} \begin{pmatrix} 0 & 0 & I_q & 0 \\ 0 & I_{p-q} & 0 & 0 \\ -I_q & 0 & I_q & 0 \\ 0 & I_{p-q} & 0 & -I_{p-q} \end{pmatrix} = \begin{pmatrix} D_p & -N_p & 0 & 0 \\ 0 & 0 & -N_c & D_c \end{pmatrix}.$$

The second matrix in the left-hand side of the previous equality is unimodular, and thus, invertible. Let us denote this matrix by U. Then, from the previous equality, i.e., $R\,U = R_p \oplus R_c$, we obtain the following commutative exact diagram:

$$\begin{array}{ccccccccc} & & 0 & & & & 0 & & \\ & & \downarrow & & & & \downarrow & & \\ 0 & \longrightarrow & A^p & \xrightarrow{\cdot R} & & & A^{2p} & \xrightarrow{\pi} & M \longrightarrow 0 \\ & & \downarrow \cdot I_p & & & & \downarrow \cdot U & & \\ 0 & \longrightarrow & A^p & \xrightarrow{\cdot (R_p \oplus R_c)} & & & A^{2p} & \xrightarrow{\pi'} & M_p \oplus M_c \longrightarrow 0. \\ & & \downarrow & & & & \downarrow & & \\ & & 0 & & & & 0 & & \end{array}$$

From the previous commutative exact diagram, we deduce that there exists an isomorphism $\phi : M \to M_p \oplus M_c$, defined by $\phi(m) = \pi'(z\,U)$, where $z \in A^{2p}$ is such that $\pi(z) = m$, and thus, $M \cong M_p \oplus M_c$. Moreover, using the equations which define the A-module M_s, we can easily check that $M_s = M$. Finally, using the fact that $M_s = M \cong M_p \oplus M_c$, we obtain $t(M_s) = t(M) \cong t(M_p) \oplus t(M_c)$, and thus, $M/t(M) \cong M_p/t(M_p) \oplus M_c/t(M_c)$. □

2. Internal stabilization: A particular case. We refer the reader to [17] for the definition of a weakly left/right/doubly coprime factorization.

THEOREM 2.1. *Let $P = D_p^{-1} N_p$ and $C = D_c^{-1} N_c$ be two weakly left-coprime factorizations, i.e., $R_p = (D_p : -N_p) \in M_{q\times p}(A)$ and $R_c = (-N_c : D_c) \in M_{(p-q)\times p}(A)$ are weakly left-prime matrices. Then, $P = D_p^{-1} N_p$ is internally stabilized by the controller $C = D_c^{-1} N_c$ iff*

$$\begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} \in M_p(A), \text{ i.e., } \begin{pmatrix} R_p \\ R_c \end{pmatrix} \in GL_p(A). \tag{2.1}$$

The same result also holds for weakly right-coprime factorizations.

Proof. $\Rightarrow$ By hypothesis, R_p and R_c are two weakly left-prime matrices, and thus, by Corollary 2.5 of [17], the A-modules $M_p = A^p/A^q R_p$ and $M_c = A^p/A^{p-q} R_c$ are torsion-free. Thus, $t(M) \cong t(M_p \oplus M_c) \cong t(M_p) \oplus t(M_c) = 0$, i.e., M is a torsion-free A-module. Then, by Corollary 2.5 of [17], R is weakly left-prime. Now, the fact that C internally stabilizes P implies (see Definition 1.1)

$$H(P,C) = \begin{pmatrix} I_q & -P \\ -C & I_{p-q} \end{pmatrix}^{-1} = \begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} \begin{pmatrix} D_p & 0 \\ 0 & D_c \end{pmatrix} \in M_p(A).$$

Therefore, we have

$$\begin{aligned} \begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} R &= \begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} \begin{pmatrix} R_p & -D_p & 0 \\ R_c & 0 & -D_c \end{pmatrix} \\ &= \left(I_p \quad - \begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} \begin{pmatrix} D_p & 0 \\ 0 & D_c \end{pmatrix} \right) \in M_{p\times 2p}(A). \end{aligned}$$

Finally, using the fact that R is a weakly left-prime full row rank matrix, we obtain (2.1) (see [17] for more details).

$\Leftarrow$ We have

$$(2.1) \Rightarrow \begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} \begin{pmatrix} D_p & 0 \\ 0 & D_c \end{pmatrix} = \begin{pmatrix} I_q & -P \\ -C & I_{p-q} \end{pmatrix}^{-1} \in M_p(A),$$

i.e., the controller $C = D_c^{-1} N_c$ internally stabilizes the plant $P = D_p^{-1} N_p$. □

COROLLARY 2.2. *Let $P = D_p^{-1} N_p \in M_{q\times(p-q)}(K)$ be a weakly left-coprime factorization of P. Then, P is internally stabilized by a controller $C \in M_{(p-q)\times q}(K)$ which admits a weakly left-coprime factorization $C = D_c^{-1} N_c$ iff P admits a doubly coprime factorization. The same result also holds for a stabilizable plant P admitting a weakly right-coprime factorization.*

Proof. $\Rightarrow$ Let us suppose that the plant $P = D_p^{-1} N_p$ is internally stabilized by a controller $C = D_c^{-1} N_c$ and R_p and R_c are two weakly left-prime matrices. Then, by Theorem 2.1, we have (2.1). Let us note

$$\begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} = \begin{pmatrix} U_1 & V_1 \\ U_2 & V_2 \end{pmatrix} \in M_p(A).$$

Then, we have the following Bézout identities:

$$\begin{pmatrix} D_p & -N_p \\ -N_c & D_c \end{pmatrix} \begin{pmatrix} U_1 & V_1 \\ U_2 & V_2 \end{pmatrix} = I_p, \qquad \begin{pmatrix} U_1 & V_1 \\ U_2 & V_2 \end{pmatrix} \begin{pmatrix} D_p & -N_p \\ -N_c & D_c \end{pmatrix} = I_p. \tag{2.2}$$

In particular, we have

$$\begin{pmatrix} D_p & -N_p \\ 0 & I_{p-q} \end{pmatrix} \begin{pmatrix} U_1 & V_1 \\ U_2 & V_2 \end{pmatrix} = \begin{pmatrix} I_q & 0 \\ U_2 & V_2 \end{pmatrix} \Rightarrow \det D_p \det \begin{pmatrix} U_1 & V_1 \\ U_2 & V_2 \end{pmatrix} = \det V_2,$$

and, using the fact that the second matrix is unimodular and $\det D_p \neq 0$, we obtain that $\det V_2 \neq 0$. Finally, from (2.2), we deduce

$$\begin{cases} D_p V_1 - N_p V_2 = 0, \\ D_p U_1 - N_p U_2 = I_q, \\ -N_c V_1 + D_c V_2 = I_{p-q}, \end{cases}$$

which shows that $P = D_p^{-1} N_p = V_1 V_2^{-1}$ is a doubly coprime factorization of P.

$\Leftarrow$ If $P = D_p^{-1} N_p = \tilde{N}_p \tilde{D}_p^{-1}$ is a doubly coprime factorization of P, then there exist Bézout identities of the form (2.2). Thus, $R_p = (D_p : -N_p) \in M_{q\times p}(A)$ can be complemented into $(R_p^T : R_c^T)^T \in GL_p(A)$, with $R_c \in M_{(p-q)\times p}(A)$. The complement $R_c = (-N_c : D_c)$ to R_p into a unimodular matrix $(R_p^T : R_c^T)^T$ is not uniquely defined (see Corollary 6.1 on the Youla–Kučera parametrization) and we can choose $D_c \in M_{p-q}(A)$ such that $\det D_c \neq 0$. Finally, R_c admits a right-inverse, i.e., $C = D_c^{-1} N_c$ is in particular a weakly left-coprime factorization. Finally, by Theorem 2.1, $C = D_c^{-1} N_c$ internally stabilizes P. □

The next corollary generalizes a result obtained by Smith for $H_\infty(\mathbb{C}_+)$ [25].

COROLLARY 2.3. *If A is a coherent Sylvester domain (e.g., $A = H_\infty(\mathbb{C}_+)$, RH_∞, Bézout domains), then $P \in M_{q\times(p-q)}(K)$ is internally stabilizable iff P admits a doubly coprime factorization.*

Proof. By Theorem 3.24 of [17], every transfer matrix whose entries belong to $K = Q(A)$ admits a weakly doubly coprime factorization. Then, the result follows directly from Corollary 2.2. □

3. Internal stabilization: The general case. In the previous section, we have obtained some results on internal stabilization in the particular case where the transfer matrices admit weakly left- or right-coprime factorizations. In this section, we give some necessary and sufficient conditions for internal stabilizability without any assumption on the transfer matrices.

LEMMA 3.1. *Let $P = D_p^{-1} N_p \in M_{q\times(p-q)}(K)$ (resp., $C = D_c^{-1} N_c \in M_{(p-q)\times q}(K)$) be a plant (resp., a controller). If C internally stabilizes P, then the A-modules $M_p = A^p/A^q R_p$ and $M_c = A^p/A^{p-q} R_c$, where $R_p = (D_p : -N_p) \in M_{q\times p}(A)$, $R_c = (-N_c : D_c) \in M_{(p-q)\times p}(A)$, satisfy*

$$M_p/t(M_p) \oplus M_c/t(M_c) \cong A^p,$$

i.e., $M_p/t(M_p) = A^p/\overline{A^q R_p}$ and $M_c/t(M_c) = A^p/\overline{A^{p-q} R_c}$ are projective A-modules.

Proof. By hypothesis, P is internally stabilized by C, and thus, we have

$$H(P, C) = \begin{pmatrix} I_q & -P \\ -C & I_{p-q} \end{pmatrix}^{-1} = \begin{pmatrix} R_p \\ R_c \end{pmatrix}^{-1} \begin{pmatrix} D_p & 0 \\ 0 & D_c \end{pmatrix} = N \in M_p(A).$$

Let us define the following A-modules $M = A^{2p}/A^p R$ and $M' = A^{2p}/A^p (I_p : -N)$. By Lemma 2.6 of [17], we have $\overline{A^p R} = A^p (I_p : -N)$ because $A^p (I_p : -N)$ is an A-closed submodule of A^{2p}, and thus, we have

$$M/t(M) = A^{2p}/\overline{A^p R} = A^{2p}/A^p (I_p : -N) = M'.$$

Moreover, it is easy to see that the A-module M' is free of rank p and thus, that we have $M/t(M) \cong A^p$. Finally, using (1.4), we obtain

$$M/t(M) \cong M_p/t(M_p) \oplus M_c/t(M_c) \cong A^p,$$

which shows that $M_p/t(M_p) = A^p/\overline{A^q\, R_p}$ and $M_c/t(M_c) = A^p/\overline{A^{p-q}\, R_c}$ are projective A-modules. □

THEOREM 3.2. *A plant $P = D_p^{-1}\, N_p \in M_{q\times(p-q)}(K)$ is internally stabilizable iff $M_p/t(M_p) = A^p/\overline{A^q\, R_p}$ is a projective A-module, with $R_p = (D_p : -N_p) \in M_{q\times p}(A)$ and $M_p = A^p/A^q\, R_p$.*

Proof. $\Rightarrow$ It was proved in Lemma 3.1.

$\Leftarrow$ Let $M_p/t(M_p)$ be a projective A-module. We have the following commutative exact diagram:

$$\begin{array}{ccccccccc}
 & & & & & & & & 0 \\
 & & & & & & & & \downarrow \\
 & & 0 & & 0 & & t(M_p) & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & A^q & \xrightarrow{.R_p} & A^p & \xrightarrow{\pi} & M_p & \longrightarrow & 0 \\
 & & \downarrow \kappa & & \| & & \downarrow \pi' & & \\
0 & \longrightarrow & \ker\phi & \longrightarrow & A^p & \xrightarrow{\phi} & M_p/t(M_p) & \longrightarrow & 0, \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & \operatorname{coker}\kappa & & 0 & & 0 & & \\
 & & \downarrow & & & & & & \\
 & & 0 & & & & & &
\end{array} \tag{3.1}$$

where $\phi = \pi' \circ \pi$ and $\kappa : A^q \to \ker\phi$ is induced by $\mathrm{id} : A^p \to A^p$ and $\pi' : M_p \to M_p/t(M_p)$. The fact that $M_p/t(M_p)$ is a projective A-module implies that the exact sequence

$$0 \longrightarrow \ker\phi \longrightarrow A^p \xrightarrow{\phi} M_p/t(M_p) \longrightarrow 0 \tag{3.2}$$

splits (see [17]), and thus, $A^p \cong M_p/t(M_p) \oplus \ker\phi$, i.e., $\ker\phi$ is a projective A-module.

The fact that $\ker\phi$ is a projective A-module is equivalent to the existence of a family $\{a_1, \dots, a_m\}$ of elements of A satisfying [3, 23]:

1. The ideal $(a_1, \dots, a_m)$ is equal to A, i.e., $\exists\, x_i \in A : \sum_{i=1}^m x_i\, a_i = 1$.
2. If $S_{a_i} = \{1, a_i, a_i^2, \dots\}$ is the multiplicative set defined by a_i, then $S_{a_i}^{-1} \ker\phi$ is a free $S_{a_i}^{-1} A$-module (see [17]).

By Proposition 1.10 of [17], we obtain the exact sequence of $S_{a_i}^{-1} A$-modules:

$$0 \longrightarrow S_{a_i}^{-1}(\ker\phi) \longrightarrow (S_{a_i}^{-1} A)^p \xrightarrow{S_{a_i}^{-1}\phi} S_{a_i}^{-1}(M_p/t(M_p)) \longrightarrow 0. \tag{3.3}$$

The fact that $t(M_p)$ is a torsion A-module implies that $K \otimes_A t(M_p) = 0$ (see (1.10) of [17]), and thus, $\mathrm{rank}_A(t(M_p)) = \dim_K(K \otimes_A t(M_p)) = 0$ (see [17] for more details). Applying Proposition 1.10 of [17] to the exact sequence

$$0 \longrightarrow t(M_p) \longrightarrow M_p \longrightarrow M_p/t(M_p) \longrightarrow 0,$$

we obtain $\mathrm{rank}_A(M_p/t(M_p)) = \mathrm{rank}_A(M_p) - \mathrm{rank}_A(t(M_p)) = p - q$. Applying again Proposition 1.10 of [17] to the exact sequence (3.2), we obtain

$$\mathrm{rank}_A(\ker\phi) = p - \mathrm{rank}_A(M_p/t(M_p)) = p - (p-q) = q. \tag{3.4}$$

If we note $S_{a_i}^{-1} A = A_i$, then $S_{a_i}^{-1} \ker \phi$ is a free A_i-module of rank q. Taking a basis of $S_{a_i}^{-1} \ker \phi \cong A_i^q$, there exists a matrix $R_i \in M_{q\times p}(A_i)$ such that (3.3) becomes

$$0 \longrightarrow A_i^q \xrightarrow{.R_i} A_i^p \longrightarrow S_{a_i}^{-1}(M_p/t(M_p)) \longrightarrow 0.$$

By hypothesis, $M_p/t(M_p)$ is a projective A-module, and thus, $S_{a_i}^{-1}(M_p/t(M_p))$ is also a projective A_i-module [3, 23]. Hence, using Proposition 4.2 of [17], the previous exact sequence splits, and thus there exists $S_i \in M_{p\times q}(A_i)$ such that

$$R_i\, S_i = I_q. \tag{3.5}$$

Let us note $R_p = (D_p :\ -N_p) \in M_{q\times p}(A)$ and $R_i = (D_i :\ -N_i) \in M_{q\times p}(A_i)$. First, we prove that $P = D_p^{-1}\, N_p = D_i^{-1}\, N_i$. By localization of (3.1) with respect to S_{a_i}, we obtain the commutative exact diagram ($S_{a_i}^{-1} A$ is a flat A-module [17])

$$\begin{array}{ccccccccc}
 & & & & & & & & 0 \\
 & & & & & & & & \downarrow \\
 & & 0 & & 0 & & & & S_{a_i}^{-1} t(M_p) \\
 & & \downarrow & & \downarrow & & & & \downarrow \\
0 & \longrightarrow & A_i^q & \xrightarrow{.R_p} & A_i^p & \longrightarrow & & & S_{a_i}^{-1} M_p & \longrightarrow & 0 \\
 & & \downarrow .R_i'' & & \| & & & & \downarrow & & \\
0 & \longrightarrow & A_i^q & \xrightarrow{.R_i} & A_i^p & \longrightarrow & & & S_{a_i}^{-1}(M_p/t(M_p)) & \longrightarrow & 0, \\
 & & \downarrow & & \downarrow & & & & \downarrow & & \\
 & & A_i^q/A_i^q\, R_i'' & & 0 & & & & 0 & & \\
 & & \downarrow & & & & & & & & \\
 & & 0 & & & & & & & &
\end{array}$$

where $R_i'' \in M_q(A_i)$ corresponds to $S_{a_i}^{-1}\kappa : A_i^q \to S_{a_i}^{-1} \ker \phi \cong A_i^q$. Hence, we have $R_p = R_i''\, R_i$, i.e.,

$$(D_p :\ -N_p) = R_i''\, (D_i :\ -N_i), \tag{3.6}$$

where $R_i'' \in M_q(A_i)$ has full rank and $S_{a_i}^{-1} t(M_p) \cong A_i^q/A_i^q\, R_i''$. Hence, we have

$$P = D_p^{-1}\, N_p = (R_i''\, D_i)^{-1} (R_i''\, N_i) = D_i^{-1}\, N_i.$$

Cleaning the denominators of each R_i and $S_i = (X_i^T :\ Y_i^T)^T$, there exists $\alpha_i \in \mathbb{Z}_+$ such that all the entries of the matrix $a_i^{\alpha_i}\, S_i\, R_i$ are in A. If $\alpha = \max_{1\leq i\leq m} \alpha_i$, then

$$a_i^\alpha\, S_i\, R_i = a_i^\alpha \begin{pmatrix} X_i\, D_i & -X_i\, N_i \\ Y_i\, D_i & -Y_i\, N_i \end{pmatrix} \in M_p(A), \qquad i = 1, \ldots, m. \tag{3.7}$$

Using the fact that $(a_1, \ldots, a_m) = A$, then there exists a family $\{b_1, \ldots, b_m\}$ of elements of A such that $\sum_{i=1}^m b_i\, a_i^\alpha = 1$. Therefore, we have

$$D_p = R_i''\, D_i \Rightarrow D_p = \sum_{i=1}^m b_i\, a_i^\alpha\, D_p = \sum_{i=1}^m b_i\, a_i^\alpha\, R_i''\, D_i, \tag{3.8}$$

$$N_p = R_i''\, N_i \Rightarrow N_p = \sum_{i=1}^m b_i\, a_i^\alpha\, N_p = \sum_{i=1}^m b_i\, a_i^\alpha\, R_i''\, N_i. \tag{3.9}$$

If we define $S = \sum_{i=1}^{m} b_i\, a_i^{\alpha}\, S_i\, D_i$, then we have

$$S = \left(\left(\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i \right)^T : \left(\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, Y_i\, D_i \right)^T \right)^T .$$

We claim that the controller $C \in M_{q\times(p-q)}(K)$, defined by

$$C = \left(\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, Y_i\, D_i \right) \left(\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i \right)^{-1},$$

internally stabilizes the plant P; i.e., we have

$$\begin{pmatrix} I_q & -P \\ -C & I_{p-q} \end{pmatrix}^{-1} = \begin{pmatrix} (I_q - PC)^{-1} & (I_q - PC)^{-1}P \\ C(I_q - PC)^{-1} & I_{p-q} + C(I_q - PC)^{-1}P \end{pmatrix} \in M_p(A).$$

We easily check that

$$\begin{aligned}
&I_q - PC \\
&\quad = I_q - D_p^{-1}\, N_p\, \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, Y_i\, D_i\right) \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1} \\
&\quad = D_p^{-1}[D_p\, \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right) - N_p\, \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, Y_i\, D_i\right)] \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1} \\
&\quad = D_p^{-1}[\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, \left(D_p\, X_i - N_p\, Y_i\right) D_i] \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1} \\
&\quad = D_p^{-1}[\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, R_i''\, \left(D_i\, X_i - N_i\, Y_i\right) D_i] \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1} \quad \text{(by (3.6))} \\
&\quad = D_p^{-1}[\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, R_i''\, D_i] \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1} \quad \text{(by (3.5))} \\
&\quad = D_p^{-1}\, D_p\, \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1} \quad \text{(by (3.8))} \\
&\quad = \left(\textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i\right)^{-1}
\end{aligned}$$

$$\Rightarrow (I_q - PC)^{-1} = \textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, D_i \in M_q(A),$$

$$\Rightarrow C(I_q - PC)^{-1} = \textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, Y_i\, D_i \in M_{(p-q)\times q}(A),$$

$$\Rightarrow (I_q - PC)^{-1}P = \textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, X_i\, N_i \in M_{q\times(p-q)}(A),$$

$$\Rightarrow I_{p-q} + C(I - PC)^{-1}P = I_{p-q} + \textstyle\sum_{i=1}^{m} b_i\, a_i^{\alpha}\, Y_i\, N_i \in M_{p-q}(A). \qquad \square$$

Remark 3.1. Let us note that the proof of Theorem 3.2 seems to be dual to the one given in [13]. The duality between the approach developed in [26], using the A-modules A^p/R^T and $A^p/\tilde{R}^T$, and the one developed here, using the A-modules $A^p/\overline{A^q\, R}$ and $A^p/\overline{A^{p-q}\, \tilde{R}^T}$, will be explained in Proposition 3.4 (see also Proposition 2.8 of [17]). We refer the reader to [20] for another proof of Theorem 3.2 and where it is shown that

$$C' = \left(\sum_{i=1}^{m} b_i a_i^{\alpha} Y_i R_i^{''-1} \right) \left(\sum_{i=1}^{m} b_i a_i^{\alpha} X_i R_i^{''-1} \right)^{-1}$$

is also a stabilizing controller of P.

Example 3.1. Let $A = H_{\infty}(\mathbb{C}_+)$ and let us consider the following transfer matrix:

$$P = \begin{pmatrix} \frac{e^{-s}}{s-1} & a \\ b & \frac{1}{s-1} \end{pmatrix} \in M_2(K), \tag{3.10}$$

where a, $b \in A$. The A-system (see [17]) which corresponds to P is defined by

$$\begin{cases} \frac{(s-1)}{(s+1)}\, y_1 - \frac{e^{-s}}{(s+1)}\, u_1 - a\, \frac{(s-1)}{(s+1)}\, u_2 = 0, \\ \frac{(s-1)}{(s+1)}\, y_2 - b\, \frac{(s-1)}{(s+1)}\, u_1 - \frac{1}{(s+1)}\, u_2 = 0, \end{cases}$$

i.e., $R\, z = 0$, where $z = (y_1 :\ y_2 :\ u_1 :\ u_2)^T$ and R is the matrix defined by

$$R = \begin{pmatrix} \frac{s-1}{s+1} & 0 & -\frac{e^{-s}}{s+1} & -a\, \frac{(s-1)}{(s+1)} \\ 0 & \frac{s-1}{s+1} & -b\, \frac{(s-1)}{(s+1)} & -\frac{1}{s+1} \end{pmatrix} \in M_{2\times 4}(A). \tag{3.11}$$

Let us check whether or not the A-module $M = A^4/A^2\, R$ is projective. We have $\mathrm{Fitt}_0(M) = 0$, $\mathrm{Fitt}_1(M) = 0$, and

$$\mathrm{Fitt}_2(M) = \left(\left(\frac{s-1}{s+1}\right)^2, \frac{(s-1)}{(s+1)^2}, \frac{e^{-s}}{(s+1)^2}, \frac{(s-1)\, e^{-s}}{(s+1)^2} \right).$$

Then, we have

$$\begin{cases} \left(\frac{s-1}{s+1}\right)^2 + 2\, \frac{(s-1)}{(s+1)^2} = \frac{s-1}{s+1} \in \mathrm{Fitt}_2(M), \\ \frac{(s-1)\, e^{-s}}{(s+1)^2} + 2\, \frac{e^{-s}}{(s+1)^2} = \frac{e^{-s}}{s+1} \in \mathrm{Fitt}_2(M). \end{cases}$$

Moreover,

$$\left(\frac{s-1}{s+1}\right) \left(1 + 2\, \left(\frac{1-e^{-(s-1)}}{s-1}\right)\right) + 2\, e\, \left(\frac{e^{-s}}{s+1}\right) = 1 \in \mathrm{Fitt}_2(M) \Rightarrow \mathrm{Fitt}_2(M) = A, \tag{3.12}$$

and thus, by Proposition 4.4 of [17], M is a projective A-module of rank 2. Thus, by Theorem 3.2, P is internally stabilizable. Let us find a controller C using the construction given in the proof of Theorem 3.2. First, let us notice that the fact that $M = A^4/A^2\, R$ is a projective A-module implies that $M/t(M) = M = A^4/A^2\, R$. Second, from (3.12), with the notations of the proof of Theorem 3.2, we have

$$\begin{cases} a_1 = \frac{s-1}{s+1} \in \mathrm{Fitt}_2(M), \\ a_2 = \frac{e^{-s}}{s+1} \in \mathrm{Fitt}_2(M), \\ b_1 = 1 + 2\frac{(1-e^{-(s-1)})}{(s-1)} \in A, \\ b_2 = 2\, e \in A. \end{cases}$$

In $A_{\frac{s-1}{s+1}}$, we have the following right-inverse $S_{\frac{s-1}{s+1}}$ of $R_{\frac{s-1}{s+1}} = R$:

$$\begin{pmatrix} \frac{s-1}{s+1} & 0 & -\frac{e^{-s}}{s+1} & -a\, \frac{(s-1)}{(s+1)} \\ 0 & \frac{s-1}{s+1} & -b\, \frac{(s-1)}{(s+1)} & -\frac{1}{s+1} \end{pmatrix} \begin{pmatrix} \frac{s+1}{s-1} & 0 \\ 0 & \frac{s+1}{s-1} \\ 0 & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

In $A_{\frac{e^{-s}}{s+1}}$, we have the following right-inverse $S_{\frac{e^{-s}}{s+1}}$ of $R_{\frac{e^{-s}}{s+1}} = R$:

$$\begin{pmatrix} \frac{s-1}{s+1} & 0 & -\frac{e^{-s}}{s+1} & -a\, \frac{(s-1)}{(s+1)} \\ 0 & \frac{s-1}{s+1} & -b\, \frac{(s-1)}{(s+1)} & -\frac{1}{s+1} \end{pmatrix} \begin{pmatrix} 0 & -2\, a \\ -b\, \frac{(s+1)}{e^{-s}} & 1 \\ -\frac{(s+1)}{e^{-s}} & 0 \\ 0 & -2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Hence, S is defined by

$$S = \left(\begin{array}{c} \frac{(s-1)}{(s+1)} \left(1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)}\right) \begin{pmatrix} \frac{s+1}{s-1} & 0 \\ 0 & \frac{s+1}{s-1} \\ 0 & 0 \\ 0 & 0 \end{pmatrix} + \frac{e^{-s}}{(s+1)}\, 2\, e \begin{pmatrix} 0 & -2\,a \\ -b\,\frac{(s+1)}{e^{-s}} & 1 \\ -\frac{(s+1)}{e^{-s}} & 0 \\ 0 & -2 \end{pmatrix} \end{array} \right) \frac{(s-1)}{(s+1)}\, I_2$$

$$= \frac{(s-1)}{(s+1)} \begin{pmatrix} 1 + 2\frac{(1-e^{-(s-1)})}{(s-1)} & -4\,a\,\frac{e^{-(s-1)}}{s+1} \\ -2\,e\,b & 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} + 2\,\frac{e^{-(s-1)}}{(s+1)} \\ -2\,e & 0 \\ 0 & -4\,\frac{e^{-(s-1)}}{s+1} \end{pmatrix}.$$

Then, a stabilizing controller C of P is defined by

$$C = \begin{pmatrix} -2\,e & 0 \\ 0 & -4\,\frac{e^{-(s-1)}}{s+1} \end{pmatrix} \begin{pmatrix} 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} & -4\,a\,\frac{e^{-(s-1)}}{(s+1)} \\ -2\,e\,b & 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} + 2\,\frac{e^{-(s-1)}}{(s+1)} \end{pmatrix}^{-1}.$$

Remark 3.2. Dually to Theorem 3.2, $P = \tilde{N}_p\,\tilde{D}_p^{-1} \in M_{q\times(p-q)}(K)$ is internally stabilized by $C = \tilde{X}_c^{-1}\,\tilde{Y}_c \in M_{(p-q)\times q}(K)$ iff $\tilde{M}_p = A^p/A^{p-q}\,\tilde{R}_p{}^T$ is such that $\tilde{M}_p/t(\tilde{M}_p)$ is a projective A-module, with $\tilde{R}_p{}^T = (\tilde{N}_p^T :\ \tilde{D}_p^T)^T \in M_{p\times(p-q)}(A)$. In order to shorten the paper, we let the readers check this result themselves. (We can use the fact that C internally stabilizes P iff C^T internally stabilizes P^T.)

COROLLARY 3.3. *If $P = D_p^{-1}\,N_p \in M_{q\times(p-q)}(K)$ is a weakly left-coprime factorization of P, then P is internally stabilizable iff the A-module $M_p = A^p/A^q\,R_p$ is stably free, i.e., iff $P = D_p^1 N_p$ is a left-coprime factorization of P. Moreover, a stabilizing controller C of P has the form*

$$C = Y_c\,X_c^{-1},$$

where $S = (X_c^T :\ Y_c^T)^T \in M_{p\times q}(A)$ is a right inverse of R_p, i.e., $D_p\,X_c - N_p\,Y_c = I_q$.

Proof. $\Rightarrow$ If $P = D_p^{-1}\,N_p$ is internally stabilizable, then, by Theorem 3.2, the A-module $A^p/\overline{A^q\,R_p}$ is a projective A-module, where $R_p = (D_p :\ -N_p) \in M_{q\times p}(A)$. Using the fact that $P = D_p^{-1}\,N_p$ is a weakly left-coprime factorization of P, then, by Lemma 2.6 and Theorem 2.11 of [17], we have $\overline{A^q\,R_p} = A^q\,R_p$. Thus, the A-module $M_p = A^p/A^q\,R_p$ is projective and, using the fact that M_p is a projective A-module and R_p is a full row rank matrix, the exact sequence $0 \longrightarrow A^q \xrightarrow{.R_p} A^p \longrightarrow M_p \longrightarrow 0$ splits [3, 23]. Thus, we have $M_p \oplus A^q \cong A^p$, i.e., M_p is a stably free A-module.

$\Leftarrow$ Let us suppose that M_p is a stably free A-module. In particular, $M_p = M_p/t(M_p)$ is a stably free A-module, and thus, by Theorem 3.2, P is internally stabilizable.

Moreover, we have the exact sequence $0 \longrightarrow A^q \xrightarrow{.R_p} A^p \longrightarrow M_p \longrightarrow 0$. Using the fact that M_p is a stably free A-module, then this exact sequence splits, i.e., there exists $S = (X_c^T :\ Y_c^T)^T \in M_{p\times q}(A)$ such that $R_p\,S = I_q$. We check that $C = Y_c\,X_c^{-1}$ is a stabilizing controller of $P = D_p^{-1}\,N_p$ by computing (1.2) [29]. (We can also use the construction of the stabilizing controller given in the proof of Theorem 3.2: $\ker\phi = A^q$, $C = (Y_c\,D_p)\,(X_c\,D_p)^{-1} = Y_c \cdot X_c^{-1}$.) ∎

Example 3.2. Let us reconsider the transfer matrix P defined by (3.10). In Example 3.1, we proved that the $A = H_\infty(\mathbb{C}_+)$-module $M = A^4/A^2\,R$, where R is defined by (3.11), is projective. Let us check whether or not the A-module M is stably free. The A-module $T(M) = A^2/A^4\,R^T$ is defined by the following equations:

$$\begin{cases} \frac{(s-1)}{(s+1)}\,\lambda_1 = 0, \\ \frac{(s-1)}{(s+1)}\,\lambda_2 = 0, \\ -\frac{e^{-s}}{(s+1)}\,\lambda_1 - b\,\frac{(s-1)}{(s+1)}\,\lambda_2 = 0, \\ -a\,\frac{(s-1)}{(s+1)}\,\lambda_1 - \frac{1}{(s+1)}\,\lambda_2 = 0. \end{cases} \tag{3.13}$$

If we denote by $\mu = (\mu_1 :\ \mu_2 :\ \mu_3 :\ \mu_4)^T$ the second member of (3.13), we have

$$\begin{cases} \lambda_1 = (1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)})\,\mu_1 - 2\,e\,b\,\mu_2 - 2\,e\,\mu_3, \\ \lambda_2 = -2\,a\,\mu_1 + \mu_2 - 2\,\mu_4, \end{cases}$$

which proves that, from (3.13), we can deduce $\lambda_1 = \lambda_2 = 0$, i.e., $T(M) = 0$, and thus, by 2 of Proposition 4.2 of [17], M is a stably free A-module. Moreover, a right-inverse S of R, i.e., $R\,S = I_2$, is defined by

$$S = \begin{pmatrix} 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} & -2\,a \\ -2\,e\,b & 1 \\ -2\,e & 0 \\ 0 & -2 \end{pmatrix}. \tag{3.14}$$

Thus, a stabilizing controller C of P is defined by

$$C = \begin{pmatrix} -2\,e & 0 \\ 0 & -2 \end{pmatrix} \begin{pmatrix} 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} & -2\,a \\ -2\,e\,b & 1 \end{pmatrix}^{-1}.$$

The next example shows a situation where Corollary 3.3 cannot be used to construct a stabilizing controller for a plant.

Example 3.3. Let us consider the ring $A = \mathbb{R}[t_0, t_1]/(t_0^2 + t_1^2 - 1)$ of polynomials on the unit circle and x_i the class of t_i in A. We have $A = \mathbb{R}[x_0, x_1]$ with the relation $x_0^2 + x_1^2 = 1$. Let $0 \neq a,\, b \in \mathbb{R}$ be such that $a^2 + b^2 = 1$ and let us consider

$$p = (b - x_1)/(x_0 - a) \in K = Q(A). \tag{3.15}$$

It is easy to check that $R = (x_0 - a :\ x_1 - b) \in M_{1\times 2}(A)$ is not weakly left-prime:

$$\left(\tfrac{x_0+a}{x_1-b}\right)\,(x_0 - a :\ x_1 - b) = (-(x_1 + b) :\ x_0 + a) \in A \quad \not\Rightarrow \quad (x_0 + a)/(x_1 - b) \in A.$$

Therefore, by Corollary 2.5 of [17], the A-module $M = A^2/A\,R$ is not torsion-free. We can show that the torsion submodule $t(M)$ of M is generated by

$$z = (x_1 + b)\,y - (x_0 + a)\,u,$$

which satisfies $(x_1 - b)\,z = 0$. In particular, M is not a free A-module, a fact that implies that there do not exist r and s in A such that $(b - x_1)\,s - (x_0 + a)\,r = 1$, i.e.,

p does not admit a coprime factorization. Moreover, we have $M/t(M) = A^2/A^2\,R'$, where R' is defined by

$$R' = \begin{pmatrix} x_0 - a & x_1 - b \\ x_1 + b & -x_0 - a \end{pmatrix} \in M_2(A) \tag{3.16}$$

and we easily check that

$$\begin{cases} \mathrm{Fitt}_0(M/t(M)) = (-x_0^2 + a^2 - x_1^2 + b^2) = 0, \\ \mathrm{Fitt}_1(M/t(M)) = (x_0 - a, x_0 + a, x_1 - b, x_1 + b). \end{cases}$$

Moreover, we have

$$(x_0 + a)/2\,a - (x_0 - a)/2\,a = 1 \in \mathrm{Fitt}_1(M/t(M)) \Rightarrow \mathrm{Fitt}_1(M/t(M)) = A. \tag{3.17}$$

Thus, by Proposition 4.4 of [17], we obtain that $M/t(M)$ is a projective A-module of rank 1 and, then, by Theorem 3.2, p is internally stabilizable. Hence, we are in a situation where Corollary 3.3 cannot be used to determine a stabilizing controller of p because p does not admit any weakly coprime factorization. ($\overline{A\,R} = A^2\,R'$ and $A^2\,R'$ is not a free A-module.)

We show how to construct a stabilizing controller c for p by following the explicit construction given in the proof of Theorem 3.2. Using the fact $M/t(M) = A^2/A^2\,R'$, we obtain that $\ker\phi$ defined by (3.2) satisfies $\ker\phi = A^2\,R'$, where

$$A^2\,R' = \{\lambda_1\,(x_0 - a :\ x_1 - b) + \lambda_2\,(x_1 + b :\ -(x_0 + a)) \mid \lambda_1, \lambda_2 \in A\}.$$

Let $\alpha = (x_0 - a :\ x_1 - b)$ and $\beta = (x_1 + b :\ -(x_0 + a))$. We have the relations

$$\begin{cases} (x_0 + a)\,\alpha + (x_1 - b)\,\beta = 0, \\ (x_1 + b)\,\alpha - (x_0 - a)\,\beta = 0. \end{cases}$$

$A_{x_0+a} \otimes_A \ker\phi$ is a free A_{x_0+a}-module generated by β because we have

$$\alpha = -[(x_1 - b)/(x_0 + a)]\,\beta.$$

Thus, we have $A_{x_0+a} \otimes_A (M/t(M)) = A^2_{x_0+a}/A_{x_0+a}\,(x_1 + b :\ -(x_0 + a))$ and we have

$$\begin{cases} -\frac{(x_1-b)}{(x_0+a)}\ (x_1 + b :\ -(x_0 + a)) = (x_0 - a :\ x_1 - b) \Rightarrow R''_{x_0+a} = -\frac{(x_1-b)}{(x_0+a)}, \\ (x_1 + b :\ -(x_0 + a))\ \begin{pmatrix} 0 \\ \frac{-1}{x_0+a} \end{pmatrix} = 1. \end{cases}$$

$A_{x_0-a} \otimes_A \ker\phi$ is a free A_{x_0-a}-module generated by α because we have

$$\beta = [(x_1 + b)/(x_0 - a)]\,\alpha.$$

Thus, we have $A_{x_0-a} \otimes_A (M/t(M)) = A^2_{x_0-a}/A_{x_0-a}\,(x_0 - a :\ x_1 - b)$, and

$$\begin{cases} (x_0 - a :\ x_1 - b) = (x_0 - a :\ x_1 - b) \Rightarrow R''_{x_0-a} = 1, \\ (x_0 - a :\ x_1 - b)\ \begin{pmatrix} \frac{1}{x_0-a} \\ 0 \end{pmatrix} = 1. \end{cases}$$

Hence, from (3.17), we obtain

$$S = \tfrac{(x_0+a)}{2\,a}\ \begin{pmatrix} 0 \\ \frac{-1}{x_0+a} \end{pmatrix}\ (x_1 + b) - \tfrac{(x_0-a)}{2\,a}\ \begin{pmatrix} \frac{1}{x_0-a} \\ 0 \end{pmatrix}\ (x_0 - a) = -\tfrac{1}{2\,a}\ \begin{pmatrix} x_0 - a \\ x_1 + b \end{pmatrix},$$

and thus, the controller defined by

$$c = \left(-\tfrac{(x_1+b)}{2\,a}\right) / \left(-\tfrac{(x_0-a)}{2\,a}\right) = \tfrac{(x_1+b)}{(x_0-a)}$$

internally stabilizes p. We can easily check that we have

$$\begin{pmatrix} 1 & -p \\ -c & 1 \end{pmatrix}^{-1} = -\frac{1}{2\,a} \begin{pmatrix} x_0-a & -x_1+b \\ x_1+b & x_0-a \end{pmatrix} \in M_2(A).$$

Remark 3.3. Let us notice that Corollary 2.3 also follows from Corollary 3.3: If A satisfies the conditions of Corollary 2.3, then, by Corollary 3.22 of [17], there exists a weakly left-prime matrix $R'_p = (D'_p : -N'_p) \in M_{q\times p}(A)$ such that $P = {D'_p}^{-1} N'_p$. By Corollary 3.3, P is internally stabilizable iff P admits a left-coprime factorization, i.e. the A-module $M'_p = A^p/A^q\,R'_p$ is a stably free A-module (see Proposition 4.7 of [17]). Using the fact that A is a projective-free ring, and thus, a Hermite ring, then M'_p is a free A-module and, by Proposition 4.9 of [17], P is internally stabilizable iff P admits a doubly coprime factorization.

Proposition 3.4. *Let $R \in M_{q\times p}(A)$ and $M = A^p/A^q\,R$ be an A-module. Then, $M/t(M) = A^p/\overline{A^q\,R}$ is a projective A-module iff $A^p\,R^T$ is a projective A-module.*

Proof. $\Rightarrow$ Let $M/t(M)$ be a projective A-module. We have the commutative exact diagram

$$\begin{array}{ccccccccc}
 & & & & 0 & & 0 & & \\
 & & & & \downarrow & & \downarrow & & \\
 & & & & \ker\kappa & & t(M) & & \\
 & & & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \ker.R & \longrightarrow & A^q & \xrightarrow{.R} A^p & \xrightarrow{\pi} & M & \longrightarrow 0 \\
 & & & & \downarrow\kappa & \| & & \downarrow\pi' & \\
 & & 0 & \longrightarrow & \ker\phi & \longrightarrow A^p & \xrightarrow{\phi} & M/t(M) & \longrightarrow 0, \\
 & & & & \downarrow & \downarrow & & \downarrow & \\
 & & & & \operatorname{coker}\kappa & 0 & & 0 & \\
 & & & & \downarrow & & & & \\
 & & & & 0 & & & &
\end{array} \tag{3.18}$$

where $\phi = \pi' \circ \pi$ and $\kappa : A^q \to \ker\phi$ is induced by $\mathrm{id} : A^p \to A^p$ and $\pi' : M \to M/t(M)$. Thus, by the snake lemma [3, 23], we obtain $\ker\kappa \cong \ker.R$ and $\operatorname{coker}\kappa \cong t(M)$. $M/t(M)$ is a projective A-module, and thus, the last horizontal exact sequence splits and $A^p \cong \ker\phi \oplus M/t(M)$. Then, $\ker\phi$ is a finitely generated projective A-module. Therefore, its dual $(\ker\phi)^\star \triangleq \hom_A(\ker\phi, A)$ is also a projective A-module [3, 23]. Dualizing the previous diagram and using the fact that $t(M)^\star \triangleq \hom_A(t(M), A) = 0$, we obtain the following commutative exact diagram:

$$\begin{array}{ccccccccc}
 & & & & 0 & & 0 & & \\
 & & & & \uparrow & & \uparrow & & \\
0 & \longleftarrow & A^p\,R^T & \xleftarrow{.R^T} & A^p & \longleftarrow & M^\star & \longleftarrow 0 & \\
 & & & & \| & & \uparrow & & \\
0 & \longleftarrow & (\ker\phi)^\star & \longleftarrow & A^p & \longleftarrow & (M/t(M))^\star & \longleftarrow 0. & \\
 & & & & \uparrow & & \uparrow & & \\
 & & & & 0 & & 0 & &
\end{array}$$

Hence, we deduce that $A^p\,R^T \cong (\ker\phi)^\star$, and thus, $A^p\,R^T$ is a projective A-module.

$\Rightarrow$ Let $A^p\,R^T$ be a projective A-module. Then, the exact sequence

$$0 \longleftarrow A^p\,R^T \xleftarrow{.R^T} A^p \longleftarrow M^\star \longleftarrow 0$$

splits, and thus, we have $A^p \cong A^p\,R^T \oplus M^\star$, which implies that $M^\star \triangleq \hom_A(M,A)$ is a finitely generated projective A-module, and thus, $M^{\star\star}$ is also a projective A-module [3, 23]. Moreover, using the fact that $M^\star$ is a finitely generated A-module, then $M^\star$ has a finite free resolution [3], and thus, $T(M) = A^q/A^p\,R^T$ has a finite free resolution:

$$0 \longleftarrow T(M) \longleftarrow A^q \xleftarrow{.R^T} A^p \xleftarrow{.R^T_{-1}} A^n \xleftarrow{.R^T_{-2}} A^m \xleftarrow{.R^T_{-3}} \dots .$$

Dualizing this exact sequence, we obtain the following complex:

$$0 \longrightarrow A^q \xrightarrow{.R} A^p \xrightarrow{.R_{-1}} A^n \xrightarrow{.R_{-2}} A^m \xrightarrow{.R_{-3}} \dots .$$

Therefore, we have the following exact sequence (see [3] for more details):

$$0 \longrightarrow \text{ext}^1_A(T(M),A) \longrightarrow M \longrightarrow \ker .R_{-2} \longrightarrow \text{ext}^2_A(T(M),A) \longrightarrow 0.$$

Moreover, we have the exact sequence $0 \longleftarrow M^\star \longleftarrow A^n \xleftarrow{.R^T_{-2}} A^m$, which gives by duality the exact sequence $0 \longrightarrow M^{\star\star} \longrightarrow A^n \xrightarrow{.R_{-2}} A^m$, from which we deduce that $\ker .R_{-2} = M^{\star\star}$. Hence, we obtain the following exact sequence [14]:

$$0 \longrightarrow \text{ext}^1_A(T(M),A) \longrightarrow M \xrightarrow{\epsilon} M^{\star\star} \longrightarrow \text{ext}^2_A(T(M),A) \longrightarrow 0.$$

We have $\text{ext}^2_A(T(M),A) \cong \text{ext}^1_A(A^p\,R^T,A) = 0$ because $A^p\,R^T$ is a projective A-module [3, 23]. Using the fact that M is a finitely presented A-module, we have the following commutative exact diagram (see [14] for more explanations):

$$\begin{array}{ccccccccc}
 & & & & & & & & 0 \\
 & & & & & & & & \downarrow \\
 & & 0 & & 0 & & 0 & & t(M) \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \hom_A(T(M),A) & \longrightarrow & A^q & \xrightarrow{.R} & A^p & \longrightarrow & M & \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
0 & \longrightarrow & \hom_A(T(M),K) & \longrightarrow & K^q & \xrightarrow{.R} & K^p & \longrightarrow & K\otimes_A M & \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
0 & \longrightarrow & \hom_A(T(M),K/A) & \longrightarrow & (K/A)^q & \longrightarrow & (K/A)^p & \longrightarrow & (K/A)\otimes_A M & \longrightarrow 0, \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
 & & \text{ext}^1_A(T(M),A) & & 0 & & 0 & & 0 & \\
 & & \downarrow & & & & & & & \\
 & & \text{ext}^1_A(T(M),K)=0 & & & & & & &
\end{array}$$

where $\text{ext}^1_A(T(M),K) = 0$ because K is an *injective A-module* [3]. Thus, a chase in the diagram shows that $\text{ext}^1_A(T(M),A) \cong t(M)$. Finally, using the fact that $\text{ext}^1_A(T(M),A) \cong t(M)$, we have $M/t(M) \cong M^{\star\star}$. The result follows from the fact that $M^{\star\star}$ is projective, and thus, so is $M/t(M) = A^p/\overline{A^q\,R}$. □

Using Theorem 3.2 and Proposition 3.4, we obtain the following corollary.

COROLLARY 3.5 (see [26]). *The system $P = D^{-1}\,N \in M_{q\times(p-q)}(K)$ is internally stabilizable iff the A-module $A^p\,R^T$ is projective, where $R = (D:\,-N) \in M_{q\times p}(A)$.*

From Corollary 3.5, we deduce the next result. We refer to [20] for more details and a direct proof of this result.

COROLLARY 3.6. *The system $P = D^{-1}\,N \in M_{q\times(p-q)}(K)$ is internally stabilizable iff there exists $S = (X^T : Y^T)^T \in M_{p\times q}(K)$ such that*

1. $S\,R = \begin{pmatrix} X\,D & -X\,N \\ Y\,D & -Y\,N \end{pmatrix} \in M_p(A)$,
2. $R\,S = D\,X - N\,Y = I_q$,

where $R = (D : -N) \in M_{q\times p}(A)$. Then, $C = Y\,X^{-1}$ internally stabilizes P.

PROPOSITION 3.7. *Let $P = (P_1 + P_2) \in M_{q\times(p-q)}(K)$ be a transfer matrix where $P_1 \in M_{q\times(p-q)}(A)$ is the stable part of P and $P_2 \in M_{q\times(p-q)}(K)$ the instable one. Then, we have the following results:*

(1) *P is internally stabilizable iff P_2 is internally stabilizable.*

(2) *If $P_2 = D_2^{-1}\,N_2$ admits a left-coprime factorization and $S_2 = (X_2^T : Y_2^T)^T$ is a right-inverse of $R_2 = (D_2 : -N_2) \in M_{q\times p}(A)$, then a stabilizing controller of P is given by $C = C_2\,(I_q + P_1\,C_2)^{-1}$, where $C_2 = Y_2\,X_2^{-1}$ is a stabilizing controller of P_2. A similar result exists if P_2 admits a right-coprime factorization.*

Proof. (1) Let us suppose that $P_2 = D_2^{-1}\,N_2$ is a fractional representation of P_2 where $R_2 = (D_2 : -N_2) \in M_{q\times p}(A)$. Then, P has the following fractional representation: $P = D_2^{-1}(D_2\,P_1 + N_2)$ with $R = (D_2 : -(D_2\,P_1 + N_2)) \in M_{q\times p}(A)$. Let $M = A^p/A^q\,R$ and $M_2 = A^p/A^q\,R_2$; then we have to prove that the A-module $M/t(M)$ is projective iff $M_2/t(M_2)$ is projective or, equivalently by Proposition 3.4, that the A-module $A^q\,R^T$ is projective iff $A^q\,R_2^T$ is also projective. But, we have trivially $A^q\,R^T = A^q\,R_2^T$.

(2) The A-module $T(M_2) = A^q/A^p\,R_2^T$ is defined by the following equations:

$$\begin{cases} D_2^T\,\lambda = 0, \\ -(N_2^T + P_1^T\,D_2^T)\,\lambda = 0. \end{cases}$$

Putting a second member $\mu = (\mu_1^T : \mu_2^T)^T$ in the previous equations and using the fact that S_2 is a right-inverse of R_2, we obtain $\lambda = (X_2^T + Y_2^T\,P_1^T)\,\mu_1 + Y_2^T\,\mu_2$, i.e., $S = ((X_2 + P_1\,Y_2)^T : Y_2^T)^T$ is a right-inverse of R. Therefore, by Corollary 3.3,

$$\begin{aligned} C &= Y_2\,(X_2 + P_1\,Y_2)^{-1} = Y_2\,((I + P_1\,Y_2\,X_2^{-1})\,X_2)^{-1} \\ &= Y_2\,X_2^{-1}\,(I + P_1\,(Y_2\,X_2^{-1}))^{-1} = C_2\,(I + P_1\,C_2)^{-1} \end{aligned}$$

is a stabilizing controller of P. □

PROPOSITION 3.8. *A system of the form $P \in M_{1\times(p-1)}(K)$ is internally stabilizable iff one of the following assertions is satisfied:*

- *The ideal $I = (a_1, \ldots, a_p)$ is* invertible [22, 23]*, namely we have*

$$I\,(A : I) \triangleq \left\{ \sum_{i=1}^{n} a_i\,b_i \,|\, a_i \in I,\, b_i \in (A : I) \right\} = A, \tag{3.19}$$

  where $(A : I) = \{k \in K = Q(A) \mid (k)\,I \subseteq A\}$ is a fractional ideal of A *and $P = d^{-1}\,N$, $0 \neq d \in A$, $N \in M_{1\times(p-1)}(A)$, $a_1 = d$, and $a_i = N_i$ for $2 \leq i \leq p$.*

- *For $i = 1, \ldots, p$, there exist $x_i \in K = Q(A)$ such that*

$$\begin{cases} \sum_{i=1}^{p} a_i\,x_i = 1, \\ a_i\,x_j \in A, \qquad i, j = 1, \ldots, p. \end{cases} \tag{3.20}$$

Then, the inverse $I^{-1} \triangleq A : I$ *of* I *is defined by* $I^{-1} = (x_1, \ldots, x_p)$ *and*

$$C = -\left(x_2/x_1 : \ldots : x_p/x_1\right)^T \in M_{(p-1)\times 1}(K) \tag{3.21}$$

internally stabilizes P.

Proof. By Theorem 3.2, a plant defined by $P = d^{-1}\,N \in M_{1\times(p-1)}(K)$ is internally stabilizable iff the A-module $M = A^p/A\,R$ is such that the A-module $M/t(M)$ is projective, where $R = (d : -N) = (a_1 : \ldots : a_p) \in M_{1\times p}(A)$. $A^p\,R^T$ is the ideal $I = (a_1, \ldots, a_p)$ of A. Thus, by Proposition 3.4, $M/t(M)$ is a projective A-module iff the ideal $I = (a_1, \ldots, a_p)$ is also a projective A-module. Using the fact that $I \neq 0$, then I is a projective A-module iff I is an invertible ideal, i.e., $I\,(A : I) = A$ [2, 22, 23]. Finally, (3.20) is just (3.19) written in terms of equations (see [23]). □

4. Internal stabilization of SISO plants. The following corollary of Proposition 3.8 gives a characterization of internal stabilization for SISO plants.

COROLLARY 4.1. *A SISO plant, defined by* $p = n/d$ *(*$0 \neq d,\ n \in A$*), is internally stabilizable iff one of the following equivalent assertions is satisfied:*

- *The ideal* $I = (n,\ d)$ *is invertible, i.e., we have*

$$I\,(A : I) = A, \tag{4.1}$$

  where $A : I = \{k \in K = Q(A) \mid k\,n,\ k\,d \in A\}$ *is a fractional ideal of* A.
- *There exist* $x,\ y \in K = Q(A)$ *such that*

$$\begin{cases} d\,x - n\,y = 1, \\ d\,x,\ n\,x,\ d\,y,\ n\,y \in A. \end{cases} \tag{4.2}$$

Then, $I^{-1} = A : I = (x, y)$ *and* $c = y/x$ *internally stabilizes* $p = n/d$.

Remark 4.1. We can also check Corollary 4.1 by computing

$$\begin{pmatrix} 1 & -n/d \\ -y/x & 1 \end{pmatrix}^{-1} = \frac{1}{(d\,x - n\,y)} \begin{pmatrix} d\,x & n\,x \\ d\,y & d\,x \end{pmatrix} \in M_2(A),$$

because $d\,x - n\,y = 1$ and $d\,x,\ n\,x,\ d\,y \in A$. We refer to [16, 19] for more characterizations of stabilization problems of SISO plants in terms of fractional ideals.

Example 4.1. Let us consider the ring $A = \mathbb{R}[t_0, t_1]/(t_0^2 + t_1^2 - 1)$ of polynomials on the unit circle S^1. Let x_i be the class of t_i in $\mathbb{R}_1$ and let us reconsider

$$p = (b - x_1)/(x_0 - a) \in K = Q(A), \quad \text{where } a^2 + b^2 = 1, \quad 0 \neq a, b \in \mathbb{R}.$$

Let us define the ideal $I = (b - x_1,\ x_0 - a)$ of A; then, using the fact that

$$(x_0 - a)\,(x_0 + a) = (b - x_1)\,(b + x_1),$$

we have $A : I = (1, (x_0 + a)/(b - x_1))$ and

$$\left(\tfrac{-1}{2a}\right)\,(x_0 - a) - \left(-\tfrac{x_0+a}{2a(b-x_1)}\right)\,(b - x_1) = 1 \in I\,(A : I) \Rightarrow I\,(A : I) = A.$$

Thus, $c = (x_0+a)/(b-x_1) = (x_1+b)/(x_0-a)$ internally stabilizes $p = (b-x_1)/(x_0-a)$.

Example 4.2. Let us consider $p = (1 + i\sqrt{5})/2$ [1]. Let us define the ideal $I = (2, 1 + i\sqrt{5})$ of $A = \mathbb{Z}[i\sqrt{5}]$. Using the fact that $6 = 2 \times 3 = (1 - i\sqrt{5})(1 + i\sqrt{5})$, we obtain that $A : I = \left(1, (1 - i\sqrt{5})/2\right)$. Moreover, we have

$$(-1)\,2 - \left(-\tfrac{1-i\sqrt{5}}{2}\right)\,(1 + i\sqrt{5}) = 1 \in I\,(A : I) \Rightarrow I\,(A : I) = A,$$

and thus, $c = (1 - i\sqrt{5})/2$ is a stabilizing controller of the plant $p = (1 + i\sqrt{5})/2$.

LEMMA 4.2 (see [15]). *Let $I = (n, d)$ be an ideal of A such that $d \neq 0$; then we have*

$$I\,(A : I) = (d :\ n) + (n :\ d),$$

where $(a :\ b) \triangleq \{c \in A \mid c\,b \in (a)\}$ for all $a,\ b \in A$ [24].

Proof. Let us prove that $(d :\ n) + (n :\ d) \subseteq I\,(A : I)$. Let us choose an element $a \in (d :\ n) = \{b \in A \mid \exists\, k \in A : b\,n = k\,d\}$; then we have

$$\begin{cases} (a/d)\,n = k \in A, \\ (a/d)\,d = a \in A, \end{cases} \Rightarrow (a/d) \in (A : I),\ d \in I \Rightarrow a = d\,(a/d) \in I\,(A : I).$$

Similarly, we prove that $b/n \in (A : I)$, and using the fact that $n \in I$, we obtain that $b = n\,(b/n) \in I\,(A : I)$. Finally, any element $c \in (d :\ n) + (n :\ d)$ can be written as $c = a + b$ with $a \in (d :\ n)$ and $b \in (n :\ d)$, and thus, $c = d\,(a/d) + n\,(b/n) \in I\,(A : I)$, which proves the first inclusion. Second, let us prove that $I\,(A : I) \subseteq (d :\ n) + (n :\ d)$. Any element $c \in I\,(A : I)$ can be written as

$$c = \left(\sum_{i=1}^{l} a_i\,x_i\right) n + \left(\sum_{j=1}^{m} b_j\,x_j\right) d,$$

where $a_i,\ b_j \in A$ and $x_i \in K$ is such that $x_i\,n \in A$ and $x_i\,d \in A$. We have $d\,(\sum_{i=1}^{l} a_i\,x_i\,n) = (\sum_{i=1}^{l} a_i\,x_i\,d)\,n \in (n)$ because $\sum_{i=1}^{l} a_i\,x_i\,d \in A$. In a similar way, we have $n\,(\sum_{j=1}^{m} b_j\,x_j\,d) = (\sum_{j=1}^{m} b_j\,x_j\,n)\,d \in (d)$, and thus, $c \in (d :\ n) + (n :\ d)$, which concludes the proof. □

Using Lemma 4.2, we have the following corollary of Proposition 4.1.

COROLLARY 4.3 (see [24]). *A SISO plant, defined by $p = n/d$ ($0 \neq d,\ n \in A$), is internally stabilizable iff $(d :\ n) + (n :\ d) = A$.*

5. Characterization of the classes of internal stabilizable plants. The following proposition characterizes the integral domains A of SISO stable plants over which every plant is internally stabilizable. We refer to section 3.2 of [17] for the definition of a *Prüfer domain*.

PROPOSITION 5.1 (see [6, 23]). *An integral domain A is a Prüfer domain iff every finitely generated torsion-free A-module M is projective.*

THEOREM 5.2 (see [15]). *We have the equivalences:*

1. *every MIMO plant is internally stabilizable,*
2. *every SISO plant is internally stabilizable,*
3. *A is a Prüfer domain.*

Proof. $1 \Rightarrow 2$ follows from the fact that MIMO plants contain SISO plants.

$2 \Rightarrow 3$ Let us suppose that every SISO system, defined by $p = n/d$, is internally stabilizable. Then, $R = (d :\ -n) \in M_{1\times 2}(A)$ has full row rank. By Theorem 3.2, the A-module $M = A^2/A\,R$ is such that $M/t(M)$ is a projective A-module. But, $A^2\,R^T = (n, d)$ is the ideal of A defined by n and $0 \neq d$. By Proposition 3.4, $M/t(M)$ is a projective A-module iff $I = (n, d)$ is a projective A-module. Hence, every ideal I, generated by two elements n and $0 \neq d$ of A, is a projective A-module, a result which is equivalent to the fact that A is a Prüfer domain (see Lemma 3 of [9]).

$3 \Rightarrow 1$ Let us note $K = Q(A)$ and $P = D^{-1}\,N \in M_{q\times(p-q)}(K)$. Let us define the A-module $M = A^p/A^q\,R$, where $R = (D :\ -N) \in M_{q\times p}(A)$. By hypothesis, A is a

Prüfer domain, and thus, by Proposition 5.1, the torsion-free A-module $M/t(M)$ is projective. Finally, by Theorem 3.2, P is internally stabilizable. □

Example 5.1. We have the following examples of Prüfer domains.

- The domain of entire functions $E(k)$ is a Bézout domain ($k = \mathbb{R}, \mathbb{C}$) [8], and thus, a Prüfer domain [17]. So is $\mathcal{E} = \mathbb{R}(s)[e^{-s}] \cap E(\mathbb{R})$ [11] and RH_∞ [29].
- The integral closure of $\mathbb{Z}$ into a finite extension of $\mathbb{Q}$ is a Dedekind domain, and thus, a Prüfer domain (see section 3.2 of [17] for more details). For instance, the integral closure of $\mathbb{Z}$ in $\mathbb{Q}(i\sqrt{5})$ is the Dedekind domain $\mathbb{Z}[i\sqrt{5}]$.
- If A is a one-dimensional Noetherian domain, K is its field of fractions, and L is a finite algebraic extension field of K, then the integral closure of A in L is a Dedekind domain, and thus, a Prüfer domain. In particular, a nonsingular algebraic surface defines a Dedekind affine domain. For instance, the ring $\mathbb{R}[t_0, t_1]/(t_0^2 + t_1^2 - 1)$ of polynomials on the unit circle is a Dedekind domain.
- If X is an affine irreducible nonsingular real algebraic variety of dimension $m+1$ and Y is any subset of X, then the ring $\mathcal{H}_Y(X)$ of rational functions on X, which are locally bounded on Y (i.e., for all $y \in Y$, there exist a neighborhood $\mathcal{V}(y)$ and a positive real number $M(y)$ such that $|n(x)/d(x)| \leq M(y)$ for all $x \in \mathcal{V}(y) \backslash (d^{-1}(0)y)$, is a Prüfer domain and every finitely generated ideal of $\mathcal{H}_Y(X)$ is generated by $m+1$ elements [10]. More generally, the ring of *meromorphic bounded Nash functions* on a *Nash submanifold* of $\mathbb{R}^m$ is a Prüfer domain [10].
- The integral domain $A = \{P \in \mathbb{Q}[x] \mid P(\mathbb{Z}) \subseteq \mathbb{Z}\}$ of $\mathbb{Z}$-valued polynomials in $\mathbb{Q}[x]$ is a Prüfer domain [6].

6. Youla–Kučera parametrization of the stabilizing controllers. The matrices S and S_{-1} defined in Proposition 4.9 of [17] are defined up to an arbitrary matrix which corresponds to the free parameter in the *Youla–Kučera parametrization* [4, 29].

COROLLARY 6.1. *With the same hypothesis as in Proposition* 4.9 *of* [17]*, we have the following splitting exact sequence:*

$$0 \longrightarrow A^q \underset{\cdot S(Q)}{\overset{\cdot R}{\underset{\longleftarrow}{\longrightarrow}}} A^p \underset{\cdot S_{-1}(Q)}{\overset{\cdot R_{-1}}{\underset{\longleftarrow}{\longrightarrow}}} A^{p-q} \longrightarrow 0, \tag{6.1}$$

with

$$\begin{cases} S_{-1}(Q) = S_{-1} + Q\, R, \\ S(Q) = S - R_{-1}\, Q, \end{cases} \tag{6.2}$$

where R_{-1}, S, *and* S_{-1} *are defined in Proposition* 4.9 *of* [17] *and* $Q \in M_{(p-q)\times q}(A)$. *This is equivalent to the following two Bézout identities:*

(1) $\begin{pmatrix} S(Q) & R_{-1} \end{pmatrix} \begin{pmatrix} R \\ S_{-1}(Q) \end{pmatrix} = I_p$,

(2) $\begin{pmatrix} R \\ S_{-1}(Q) \end{pmatrix} \begin{pmatrix} S(Q) & R_{-1} \end{pmatrix} = \begin{pmatrix} I_q & 0 \\ 0 & I_{p-q} \end{pmatrix} = I_p$.

Proof. We have the following relations which prove the identities (1) and (2):

- $S(Q)\, R + R_{-1}\, S_{-1}(Q) = S\, R + R_{-1}\, S_{-1} = I_p$,
- $R\, S(Q) = R\, S = I_q$,
- $S_{-1}(Q)\, R_{-1} = S_{-1}\, R_{-1} = I_{p-q}$,
- $$\begin{aligned} S_{-1}(Q)\, S(Q) &= S_{-1}\, S - S_{-1}\, R_{-1}\, Q + Q\, R\, S - Q\, R\, R_{-1}\, Q = Q - Q \\ &= 0. \end{aligned}$$ □

COROLLARY 6.2. *Let $P \in M_{q\times(p-q)}(K)$ be a transfer matrix which admits a doubly coprime factorization. Then, all the stabilizing controllers of P are parametrized by means of the Youla–Kučera parametrization*

$$C(Q) = Y(Q)\, X(Q)^{-1} = \tilde{X}(Q)^{-1}\, \tilde{Y}(Q),$$

where $Q \in M_{(p-q)\times q}(A)$ is a free parameter such that $\det X(Q) \neq 0$, $\det \tilde{X}(Q) \neq 0$, and $S_1(Q) = (-\tilde{Y}(Q) : \tilde{X}(Q))$ and $S(Q) = (X(Q)^T : Y(Q)^T)^T$ are defined by (6.2).

Example 6.1. In Example 4.3 of [17], we proved that the $A = H_\infty(\mathbb{C}_+)$-module $M = A^2/A\,R$, with $R = (\frac{s-1}{s+1} : \frac{e^{-s}}{s+1}) \in M_{1\times 2}(A)$, is projective and thus free because A is a coherent Sylvester domain (see Corollary 3.31 of [17]). Few computations lead to the following Bézout identity ($q \in A$):

$$\begin{pmatrix} \frac{s-1}{s+1} & -\frac{e^{-s}}{s+1} \\ 2\,e + \frac{(s-1)}{(s+1)}\,q & 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} - \frac{e^{-s}}{(s+1)}\,q \end{pmatrix} \begin{pmatrix} 1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} - \frac{e^{-s}}{(s+1)}\,q & \frac{e^{-s}}{s+1} \\ -2\,e - \frac{(s-1)}{(s+1)}\,q & \frac{s-1}{s+1} \end{pmatrix} = I_2.$$

Thus, all the stabilizing controllers of $p = e^{-s}/(s-1)$ are parametrized by

$$c(q) = \frac{-(2\,e + \frac{(s-1)}{(s+1)}\,q)}{1 + 2\,\frac{(1-e^{-(s-1)})}{(s-1)} - \frac{e^{-s}}{(s+1)}\,q}, \quad q \in A.$$

THEOREM 6.3. *If A is a projective-free domain, then every internally stabilizable plant, defined by a transfer matrix P with entries in $K = Q(A)$, admits doubly coprime factorizations and all the stabilizing controllers of a stabilizable plant can be parametrized by means of the Youla–Kučera parametrization.*

Proof. Using Theorem 3.2 and the exact sequence (3.2), we obtain that $M_p/t(M_p)$ and $\ker\phi$ are two projective A-modules. Using the fact that A is a projective-free ring, we obtain that $M_p/t(M_p)$ and $\ker\phi$ are two free A-modules. From (3.4), we obtain that $\ker\phi \cong A^q$, and thus, we have the following exact sequence:

$$0 \longrightarrow A^q \xrightarrow{.R'} A^p \longrightarrow M_p/t(M_p) \longrightarrow 0,$$

with $R' \in M_{q\times p}(A)$. Using (3.1), we obtain that there exists a full rank matrix $R'' \in M_q(A)$ such that $R = R''\,R'$, i.e., $(D : -N) = R''\,(D' : -N')$, and thus

$$P = D^{-1}\,N = (R''D')^{-1}\,(R''N') = D'^{-1}\,N'.$$

Therefore, by Proposition 4.9 of [17] and Corollary 6.1, the plant P admits doubly coprime factorizations and all the stabilizing controllers of P are parametrized by the Youla–Kučera parametrization. □

COROLLARY 6.4 (see [25]). *If $A = H_\infty(\mathbb{C}_+)$, then a plant is internally stabilizable iff it admits a doubly coprime factorization.*

Example 6.2. The ring $A = \mathbb{R}[t_0, t_1](t_0^2 + t_1^2 - 1)$ (resp., $A = \mathbb{Z}[i\sqrt{5}]$) is a Dedekind domain which is not a principal ideal domain: The ideal $I = (x_0 - a,\, -x_1 + b)$ (resp., $I = (2,\, 1 + i\,\sqrt{5})$) is not a principal ideal [22]. By Corollary 4.13 of [17], it is not possible to parametrize all the stabilizing controllers of $p = (b - x_1)/(x_0 - a)$ (resp., $p = (1 + i\,\sqrt{5})/2$) by means of the Youla–Kučera parametrization.

It is possible to obtain a parametrization of all the stabilizing controllers which generalizes the Youla–Kučera parametrization for a stabilizable plant which does not admit doubly coprime factorizations. We refer the reader to [19, 20] for more details.

PROPOSITION 6.5. *The intersection between the sets of coherent Sylvester domains and Prüfer domains is exactly the set of Bézout domains.*

Proof. $\Rightarrow$ If A is a Prüfer domain, then every ideal $I = (d,\, n)$, generated by two elements $0 \neq d$ and n of A, is invertible [9]. Using the fact that A is also a coherent Sylvester domain, and thus, a greatest common divisor domain (see Corollary 3.20 of [17]), then $I^{-1} = (1,\, 1/[d,\, n])$, where $[d,\, n]$ denotes the greatest common divisor of d and n, and thus, we have

$$I\, I^{-1} = (d/[d,\, n],\, n/[d,\, n]) = A \Rightarrow \exists\, x,\, y \in A :\; d\, x + n\, y = [d,\, n],$$

which proves that I is a principal ideal of A, and thus, A is a Bézout domain.

$\Leftarrow$ By definition, a Bézout domain is a Prüfer and a coherent Sylvester domain. □

Conclusion. We hope we have convinced the reader that the algebraic analysis framework developed in this paper allows us to generalize some results on internal stabilization and to obtain new ones. Due to a lack of space, it was not possible to develop here the strong and the simultaneous stabilization problems [29]. We refer the reader to [16, 18] for a description of a canonical form, based on the concept of *stable range*, that certain stabilizing controllers possess. This canonical form allows us to show that, over a ring A of SISO stable plants of stable range 1 (e.g., $A = H_\infty(\mathbb{C}_+)$), every plant which admits a doubly coprime factorization is strongly stabilizable (i.e., stabilized by means of a stable controller). We also refer the reader to [19, 20] for other results on synthesis problems using fractional ideal and lattice approaches. In particular, a new parametrization of the stabilizing controllers for plants which do not admit doubly coprime factorizations is obtained. Moreover, in this paper the concept of *class group* $C(A)$ and the group $K_0(A)$ of nontrivial isomorphism classes of projective A-modules [22] are introduced. The computations of these groups allow us to check whether or not every internally stabilizable plant admits a doubly coprime factorization (e.g., $\mathcal{C}(\mathbb{R}[t_0, t_1]/(t_0^2 + t_1^2 - 1)) \cong \mathbb{Z}/2\,\mathbb{Z} \neq 0$ and $\mathcal{C}(\mathbb{Z}[i\sqrt{5}]) \cong \mathbb{Z}/2\,\mathbb{Z} \neq 0$ [22] showing that there exist internal stabilizable plants which do not admit a doubly coprime factorization). Finally, in [21], from the algebraic analysis point of view, we show how to recover the operator-theoretic approach developed in [7] (graphs, domains, unbounded operators, etc.) and to obtain new results.

Acknowledgments. I would like to thank H. Lombardi (University of Franche-Comté, France) for discussions on Prüfer domains and for making his paper, "Platitude, localisation et anneaux de Prüfer: une approche constructive," Publications Mathématiques de Besançon, Théorie des nombres, 2002, available to me. INCLUSION PRINCIPLE FOR LINEAR TIME-VARYING SYSTEMS*

SRDJAN S. STANKOVIĆ† AND DRAGOSLAV D. ŠILJAK‡

Abstract. The main objective of this paper is to consider time-varying linear systems within the framework of the inclusion principle. Starting from general definitions, conditions are derived for a dynamic system to include a dynamic system of smaller dimension. Particular attention is paid to restriction and aggregation, the most important special cases of inclusion. It is proved, using geometric arguments within the general time-varying context, that any inclusion relationship on a given time-interval can be decomposed into a sequence of restriction-aggregation pairs. Connections between inclusion and zero-state equivalence are discussed. The paper also presents a formulation of the contractibility (expandability) conditions for time-varying state-feedback controllers.

Key words. time-varying linear dynamic systems, inclusion principle, restriction, aggregation, composition, zero-state equivalence, controller contractibility

1. Introduction.

In modeling of large dynamic systems, it is desirable to end up with a model which is small enough to be manageable and yet one that represents salient features of the original system. A mathematical framework for comparing dynamic systems of different dimensions has been offered by the *inclusion principle*. The interesting part of motions of the original large-scale system is reproduced by the smaller one; that is, the solution space (and, perhaps, performance indices) of the smaller system are *included* in the solution space (and indices) of the original large system.

Alternatively, a system may be expanded into a larger space in order for overlapping systems, which share common parts, to become disjoint. The expansion-contraction process in control engineering is attractive because we can use well-established design methods for decentralized control of disjoint subsystems in the expanded space and, subsequently, contract the design for implementation in the original space.

The expansion-contraction process, which served as a foundation for the inclusion principle, was introduced in [28] within the concept of reliable control involving overlapping multiple controller systems. A formal definition of the principle was presented in [17, 18] using the fundamental geometric arguments [37]. At present, there are generalizations and applications of the inclusion principle in a wide variety of theoretical and practical situations involving model-reduction, time-delay, discrete-time, nonlinear, and large dynamic systems. (For a survey of these areas, see [29, 30].) More recent developments present new results concerning optimal control [13], parallel computations [27, 7], inclusion of dynamic controllers and observers [12, 32, 35], stochastic inclusion [21, 33], expert systems [9], hybrid systems [15], and choice of complementary matrices in dynamic inclusions [3, 4]. Recent applications of the prin-

ciple are in a wide variety of decentralized control problems in mechanical systems [2], electric power systems [33], platoons of vehicles [34], and large segmented telescope [22].

Almost all of the existing results within the inclusion principle paradigm are concerned with the time-invariant dynamic systems. Exceptions are the papers [17] and [10], where the problem of time-varying inclusion was constrained to the time-invariant expansion-contraction framework, without the full generality that can be provided by a natural use of time-varying transformations.

In this paper a general treatment of the inclusion principle applied to linear continuous-time time-varying dynamic systems is presented. Starting from a formulation of the inclusion principle for time-varying systems, necessary and sufficient inclusion conditions are given in terms of the functions characterizing systems under time-varying input/state/output expansion-contraction relationships. A set of conditions, involving time-varying matrices of the basic state models, is derived and compared to the time-invariant case.

We focus our attention on the input/state/output restrictions and aggregations for time-varying systems. Fundamental properties of a variety of the proposed restriction-aggregation types are made evident through a specific state-space realization of the expanded system. A special emphasis is on the *composition* property. It is proved that any input/state/output inclusion on a given time-interval can be decomposed into a sequence of time-varying input/state/output aggregation and input/state/output restriction pairs. The proof of the theorem provides an insight into some fundamental aspects of the inclusion of time-varying systems.

Connections between the zero-state equivalence of time-varying systems and the inclusion principle are also discussed. The results presented in [18] are extended to the time-varying case, demonstrating that the inclusion of dynamic time-varying systems can be regarded as an extension of the equivalent transformation that does not require preservation of dimensionality.

A definition of state-feedback contractibility (expandability) is also presented. Diverse restriction-aggregation types are considered, together with the conditions ensuring inclusion of the resulting closed-loop systems. Examples, related to both expansion and contraction of the state feedback, indicate some possible applications of the inclusion concept for time-varying systems.

2. Inclusion principle for time-varying systems. Consider a pair of linear time-varying dynamic systems

$$\mathbf{S}\colon \quad \dot{x}(t) = A(t)x(t) + B(t)u(t) \quad (x(t_0) = x_0), \qquad y(t) = C(t)x(t), \tag{1}$$

$$\tilde{\mathbf{S}}\colon \quad \dot{\tilde{x}}(t) = \tilde{A}(t)\tilde{x}(t) + \tilde{B}(t)\tilde{u}(t) \quad (\tilde{x}(t_0) = \tilde{x}_0), \qquad \tilde{y}(t) = \tilde{C}(t)\tilde{x}(t), \tag{2}$$

where $x \in \mathcal{X}$, $u \in \mathcal{U}$, and $y \in \mathcal{Y}$ are n-, m-, and l-vectors and $\tilde{x} \in \tilde{\mathcal{X}}$, $\tilde{u} \in \tilde{\mathcal{U}}$, and $\tilde{y} \in \tilde{\mathcal{Y}}$ are $\tilde{n}$-, $\tilde{m}$-, and $\tilde{l}$-vectors, respectively, satisfying $n \le \tilde{n}$, $m \le \tilde{m}$, and $l \le \tilde{l}$. For $t \ge t_0$, the input functions $u_{[t_0,t]}\colon [t_0, t] \to \mathcal{U}$ and $\tilde{u}_{[t_0,t]}\colon [t_0, t] \to \tilde{\mathcal{U}}$ belong to the sets of piecewise continuous functions $\mathcal{U}_f$ and $\tilde{\mathcal{U}}_f$, respectively. The elements of the matrices in $\mathbf{S} = (A(t), B(t), C(t))$ and $\tilde{\mathbf{S}} = (\tilde{A}(t), \tilde{B}(t), \tilde{C}(t))$ are assumed to be piecewise continuous functions of t. Denote by $x(t; t_0, x_0, u_{[t_0,t]})$ and $\tilde{x}(t; t_0, \tilde{x}_0, \tilde{u}_{[t_0,t]})$ the unique solutions of (1) and (2) for the initial time t_0, initial states x_0 and $\tilde{x}_0$, and fixed control functions $u_{[t_0,t]} \in \mathcal{U}_f$ and $\tilde{u}_{[t_0,t]} \in \tilde{\mathcal{U}}_f$, respectively.

It is assumed further that the inputs, states, and outputs of $\mathbf{S}$ and $\tilde{\mathbf{S}}$ are related by linear *time-varying expansion-contraction transformations* defined by the monomor-

phisms $V(t)$: $\mathcal{X} \to \tilde{\mathcal{X}}$, $R(t)$: $\mathcal{U} \to \tilde{\mathcal{U}}$, and $T(t)$: $\mathcal{Y} \to \tilde{\mathcal{Y}}$ and the epimorphisms $U(t)$: $\tilde{\mathcal{X}} \to \mathcal{X}$, $Q(t)$: $\tilde{\mathcal{U}} \to \mathcal{U}$, and $S(t)$: $\tilde{\mathcal{Y}} \to \mathcal{Y}$ so that $\tilde{x}(t) = V(t)x(t)$ or $x(t) = U(t)\tilde{x}(t)$, $\tilde{u}(t) = R(t)u(t)$ or $u(t) = Q(t)\tilde{u}(t)$, and $\tilde{y}(t) = T(t)y(t)$ or $y(t) = S(t)\tilde{y}(t)$. We also assume that $U(t) = V(t)^L$, $Q(t) = R(t)^L$, and $S(t) = T(t)^L$, where the superscript L denotes the left inverse, and that the elements of $U(t), V(t), Q(t), R(t), S(t)$, and $T(t)$ are piecewise continuous functions of t.

DEFINITION 2.1. *The system* $\tilde{\mathbf{S}}$ *includes the system* $\mathbf{S}$ *on* $[t_a, t_b]$*, that is,* $\mathbf{S} \subset \tilde{\mathbf{S}}$ ($\tilde{\mathbf{S}}$ *is an expansion of* $\mathbf{S}$ *and, vice versa,* $\mathbf{S}$ *is a contraction of* $\tilde{\mathbf{S}}$)*, if there exists a quadruplet of full rank matrices* $(U(t), V(t), R(t), S(t))$ *such that, for any* $t_0 \in [t_a, t_b]$ *and any* $x_0 \in \mathcal{X}$ *and* $u_{[t_0,t]} \in \mathcal{U}_f$*, the choice* $\tilde{x}_0 = V(t_0)x_0$ *and* $\tilde{u}(t) = R(t)u(t)$ *implies* $x(t; t_0, x_0, u_{[t_0,t]}) = U(t)\tilde{x}(t; t_0, \tilde{x}_0, \tilde{u}_{[t_0,t]})$ *and* $y[x(t)] = S(t)\tilde{y}[\tilde{x}(t)]$ *for all* $t \in [t_0, t_b]$*,* $t \geq t_0$*.*

In order to obtain compact formulations, we shall introduce two ordered pairs of variables, composed of the independent variables in the above expansion-contraction relationships between the variables in $\mathbf{S}$ and $\tilde{\mathbf{S}}$. The first pair, P_1, corresponds to the pairs of variables $(x_0, \tilde{x}_0)$ and $(u, \tilde{u})$ that can be chosen exogenously, irrespective of the system dynamics, while the second, P_2, corresponds to the pairs $(x, \tilde{x})$ and $(y, \tilde{y})$, reflecting the system behavior. For example, $P_1 = \{x_0, \tilde{u}\}$ stands for $\tilde{x}_0 = V(t_0)x_0$ and $u(t) = Q(t)\tilde{u}(t)$, $P_1 = \{\tilde{x}_0, u\}$ for $x_0 = U(t_0)\tilde{x}_0$ and $\tilde{u}(t) = R(t)u(t)$, $P_2 = \{\tilde{x}, y\}$ for $x(t) = U(t)\tilde{x}(t)$ and $\tilde{y}(t) = T(t)y(t)$, etc. Using the pairs P_1 and P_2, we introduce the form $P_1 \Rightarrow P_2$ as a shorthand notation for different types of inclusion in the sense of Definition 2.1. In such a way, $P_1 \Rightarrow P_2$, where, for example, $P_1 = \{x_0, u\}$ and $P_2 = \{\tilde{x}, y\}$, written also directly as $\{x_0, u\} \Rightarrow \{\tilde{x}, y\}$, will be given the following meaning: conditions $\tilde{x}_0 = V(t_0)x_0$ and $\tilde{u}(t) = R(t)u(t)$ imply that, for any $x_0 \in \mathcal{X}$ and any $u_{[t_0,t]} \in \mathcal{U}_f$, $\tilde{x}(t; t_0, \tilde{x}_0, \tilde{u}_{[t_0,t]}) = V(t)x(t; t_0, x_0, u_{[t_0,t]})$ and $y[x(t)] = S(t)\tilde{y}[\tilde{x}(t)]$, $t \geq t_0$. Definition 2.1 can now be reformulated as follows.

DEFINITION 2.2. $\mathbf{S} \subset \tilde{\mathbf{S}}$ *on* $[t_a, t_b]$ *if* $\exists (U(t), V(t), R(t), S(t))$ $\{x_0, u\} \Rightarrow \{\tilde{x}, \tilde{y}\}$ *for all* $t_0, t \in [t_a, t_b]$*.*

Definitions 2.1 and 2.2 provide a generalization of the approach presented in [17], where only time-invariant state contractions-expansions for time-varying systems have been considered.

Denote by $\Phi(t, \tau)$ and $\tilde{\Phi}(t, \tau)$ the transition matrices of $\mathbf{S}$ and $\tilde{\mathbf{S}}$, respectively, and by $\psi(t) = \Phi(t, 0)$ and $\tilde{\psi}(t) = \tilde{\Phi}(t, 0)$ the corresponding Wronskians [23]. Introduce also $\nu(t) = \tilde{\psi}(t)^{-1}V(t)\psi(t)$, $\mu(t) = \psi(t)^{-1}U(t)\tilde{\psi}(t)$, $b(t) = \psi(t)^{-1}B(t)$, $\tilde{b}(t) = \tilde{\psi}(t)^{-1}\tilde{B}(t)$, $c(t) = C(t)\psi(t)$, and $\tilde{c}(t) = \tilde{C}(t)\tilde{\psi}(t)$; obviously, maps $\nu(t)$ and $\mu(t)$ are monic and epic, respectively [23, 25].

Inclusion conditions expressed in terms of the properties of $\mathbf{S}$ and $\tilde{\mathbf{S}}$ can be formulated as follows.

THEOREM 2.3. $\mathbf{S} \subset \tilde{\mathbf{S}}$ *on* $[t_a, t_b]$ *iff for all* $t_0, t, \tau \in [t_a, t_b], t_0 \leq \tau \leq t$*,*

$$\begin{aligned} &\mu(t)\nu(t_0) = I, \quad b(\tau) = \mu(t)\tilde{b}(\tau)R(\tau), \quad c(t) = S(t)\tilde{c}(t)\nu(t_0), \\ &c(t)b(\tau) = S(t)\tilde{c}(t)\tilde{b}(\tau)R(\tau). \end{aligned} \tag{3}$$

Proof. According to Definition 2.1, condition $x(t) = U(t)\tilde{x}(t)$ is equivalent to

$$\begin{aligned} &\Phi(t, t_0)x_0 + \int_{t_0}^{t} \Phi(t, \tau)B(\tau)u(\tau)d\tau \\ &\qquad = U(t)\tilde{\Phi}(t, t_0)V(t_0)x_0 + U(t)\int_{t_0}^{t} \tilde{\Phi}(t, \tau)\tilde{B}(\tau)R(\tau)u(\tau)d\tau, \end{aligned} \tag{4}$$

whence $\Phi(t,t_0) = U(t)\tilde{\Phi}(t,t_0)V(t_0)$ or $\mu(t)\nu(t_0) = I$, and

$$\Phi(t,\tau)B(\tau) = U(t)\tilde{\Phi}(t,\tau)\tilde{B}(\tau)R(\tau) \quad \Leftrightarrow \quad b(\tau) = \mu(t)\tilde{b}(\tau)R(\tau). \tag{5}$$

The remaining relations in (3) are obtained in a similar way. Hence we have the result. □

Example 2.4. The purpose of this simple example is to illustrate a wide area of diverse relationships between two linear dynamic systems which can be described by using time-varying expansions-contractions.

Let, for all $t, t_0 \in [t_a, t_b]$, $t \geq t_0$,

$$\mathbf{S}: \quad \dot{x} = (\sin t)x + 2u \quad (x(t_0) = x_0), \qquad y = x; \tag{6}$$

that is, in terms of (1), $A(t) = \sin t$, $B(t) = 2$, and $C(t) = 1$. Let $V(t)^T = [1 \ \ \frac{1}{2}\sin t]$. It is easy to verify that

$$\tilde{A}(t)V(t) - V(t)\sin t = \dot{V}(t), \tag{7}$$

where

$$\tilde{A}(t) = \begin{bmatrix} 0 & 2 \\ \frac{1}{2}\cos t & \sin t \end{bmatrix}.$$

Let $\psi(t)$ and $\tilde{\psi}(t)$ denote Wronskians of the homogeneous differential equations $\dot{x} = (\sin t)x$ and $\dot{\tilde{x}} = \tilde{A}(t)\tilde{x}$, $\tilde{x}^T = (\tilde{x}_1, \tilde{x}_2)$. After multiplying (7) by $\tilde{\psi}(t)^{-1}$ from the left and by $\psi(t)$ from the right, one obtains (according to the definition of $\nu(t)$) that $\dot{\nu}(t) = 0$ or $\nu(t) = \nu(t_a)$ for all $t \in [t_a, t_b]$. If $\mu(t)$ is any left inverse of $\nu(t)$, which obviously exists for all $\nu(t)$, one obtains $\mu(t)\nu(t_a) = 1$, that is, the first relation in (3). Notice that the corresponding state map $U(t)$ can always be found from $U(t) = \psi(t)\mu(t)\tilde{\psi}(t)^{-1}$, according to the definition of $\mu(t)$.

Similarly, if for all $\tau \in [t_a, t_b]$

$$\tilde{B}(\tau) = \begin{bmatrix} 2 \\ \sin\tau \end{bmatrix} = V(\tau)B(\tau) = 2V(\tau),$$

after multiplying both sides by $\tilde{\psi}(t)\tilde{\psi}(\tau)^{-1}$ $(t \geq \tau)$ and noticing that the condition $\nu(t) = \nu(\tau)$ is equivalent to $V(t)\psi(t)\psi(\tau)^{-1} = \tilde{\psi}(t)\tilde{\psi}(\tau)^{-1}$, one gets that $\nu(t)b(\tau) = \tilde{b}(\tau)$, which implies $b(\tau) = \mu(t)\tilde{b}(\tau)$, the second relation in (3) (assuming that $R(t) = 1$).

The third and fourth relations in (3) are verifiable analogously if one assumes that $S(t) = 1$ and

$$C(t) = 1 = [1 \ \ 0]V(t) = \tilde{C}(t)V(t).$$

Consequently, the system

$$\tilde{\mathbf{S}}: \quad \dot{\tilde{x}} = \begin{bmatrix} 0 & 2 \\ \frac{1}{2}\cos t & \sin t \end{bmatrix}\tilde{x} + \begin{bmatrix} 2 \\ \sin t \end{bmatrix}u \quad (\tilde{x}(t_0) = \tilde{x}_0), \qquad y = [1 \ \ 0]\tilde{x} \tag{8}$$

includes $\mathbf{S}$ given by (6) in the sense of Theorem 2.3.

Notice that (7) does not have a time-invariant solution for $V(t)$ (satisfying $\dot{V}(t) = 0$).

The definitions of the matrix functions $\nu(t)$, $\mu(t)$, $b(t)$, $\tilde{b}(t)$, $c(t)$, and $\tilde{c}(t)$ involve the transition matrices of both $\mathbf{S}$ and $\tilde{\mathbf{S}}$, implying problems in direct applications of the general inclusion conditions (3) in practice, especially when one has to design one of the systems under the inclusion relation when the other one is given. The need for simpler and more tractable formulations arises within both model-reduction and model-expansion frameworks. One of the principal aims of all further elaborations in this paper is to obtain inclusion conditions in the form suitable for practical applications. However, in the general time-varying case it is hardly possible to express the inclusion conditions through direct and simple relations between the system matrices of $\mathbf{S}$ and $\tilde{\mathbf{S}}$. For example, using the Peano–Baker series (e.g., [25]), one obtains for $\mu(t)\nu(\tau) = I$ the following general formulation:

$$\begin{aligned} &I + \int_\tau^t A(\sigma_1)d\sigma_1 + \int_\tau^t A(\sigma_1)\int_\tau^{\sigma_1} A(\sigma_2)d\sigma_2 d\sigma_1 + \cdots \\ &\quad = U(t)\left(I + \int_\tau^t \tilde{A}(\sigma_1)d\sigma_1 + \int_\tau^t \tilde{A}(\sigma_1)\int_\tau^{\sigma_1} \tilde{A}(\sigma_2)d\sigma_2 d\sigma_1 + \cdots\right)V(\tau). \end{aligned} \tag{9}$$

Assuming that, in addition, the commutativity condition holds for both $A(t)$ and $\tilde{A}(t)$, that is, $A(t)\int_\tau^t A(\sigma)d\sigma = \int_\tau^t A(\sigma)d\sigma A(t)$ and $\tilde{A}(t)\int_\tau^t \tilde{A}(\sigma)d\sigma = \int_\tau^t \tilde{A}(\sigma)d\sigma\tilde{A}(t)$ (for all t, τ), (9) gives only

$$\begin{aligned} e^{\int_\tau^t A(\sigma)d\sigma} &= \sum_{k=0}^{\infty}\frac{1}{k!}\left[\int_\tau^t A(\sigma)d\sigma\right]^k = U(t)e^{\int_\tau^t \tilde{A}(\sigma)d\sigma}V(\tau) \\ &= \sum_{k=0}^{\infty}\frac{1}{k!}U(t)\left[\int_\tau^t \tilde{A}(\sigma)d\sigma\right]^k V(\tau). \end{aligned} \tag{10}$$

More compact formulations can be obtained in two important particular cases.

Time-invariant systems. For time-invariant systems and time-invariant expansion-contraction maps, the known conditions for state inclusion $A^i = U\tilde{A}^i V$, $i = 0, 1, \ldots, \tilde{n} - 1$, follow from either (9) or (10) after replacing $\Phi(t, \tau)$ and $\tilde{\Phi}(t, \tau)$ by $e^{A(t-\tau)}$ and $e^{\tilde{A}(t-\tau)}$, respectively, and applying the Cayley–Hamilton theorem [18, 16, 29, 35].

Periodic systems. When both $A(t)$ and $\tilde{A}(t)$ are T-periodic, i.e., $A(t+T) = A(t)$ and $\tilde{A}(t+T) = \tilde{A}(t)$, the Floquet decomposition gives $\Phi(t, \tau) = \Pi(t)e^{\Gamma(t-\tau)}\Pi(\tau)^{-1}$ and $\tilde{\Phi}(t, \tau) = \tilde{\Pi}(t)e^{\tilde{\Gamma}(t-\tau)}\tilde{\Pi}(\tau)^{-1}$, where $\Pi(t)$ and $\tilde{\Pi}(t)$ are nonsingular T-periodic matrices, while Γ and $\tilde{\Gamma}$ are constant matrices defined by $e^{\Gamma T} = \Phi(T, 0)$ and $e^{\tilde{\Gamma}T} = \tilde{\Phi}(T, 0)$, respectively; see, for example, [24, 25]. Assume that the time-invariant parts of these decompositions satisfy the inclusion conditions in the sense that $\Gamma^i = U_0\tilde{\Gamma}^i V_0$, $i = 0, 1, \ldots$, where U_0 and V_0 are time-invariant full rank matrices satisfying $U_0V_0 = I$. Then

$$\Phi(t, \tau) = \Pi(t)U_0\tilde{\Pi}(t)^{-1}\tilde{\Phi}(t, \tau)\tilde{\Pi}(\tau)V_0\Pi(\tau)^{-1}. \tag{11}$$

Thus $U(t) = \Pi(t)U_0\tilde{\Pi}(t)^{-1}$ and $V(t) = \tilde{\Pi}(t)V_0\Pi(t)^{-1}$ are now T-periodic full rank matrices satisfying $U(t)V(t) = I$, and the inclusion conditions from Theorem 2.3 hold for $\mathbf{S}$ and $\tilde{\mathbf{S}}$.

A set of interesting and useful relations between the matrices in $\mathbf{S}$ and $\tilde{\mathbf{S}}$, enabling comparisons with the time-invariant case, can be derived from the general inclusion

relations (3). Assuming that the indicated derivatives exist and are continuous, define the following sequences of matrix functions for $\mathbf{S}$ and $\tilde{\mathbf{S}}$, respectively:

$$F_i(t;F_0(t)) = -A(t)F_{i-1}(t;F_0(t)) + \dot{F}_{i-1}(t;F_0(t)) \tag{12}$$

and

$$\tilde{F}_i(t;\tilde{F}_0(t)) = -\tilde{A}(t)\tilde{F}_{i-1}(t;\tilde{F}_0(t)) + \dot{\tilde{F}}_{i-1}(t;\tilde{F}_0(t)), \tag{13}$$

$i = 1, 2, \ldots$, where $F_0(t) = F_0(t;F_0(t))$ and $\tilde{F}_0(t) = \tilde{F}_0(t;\tilde{F}_0(t))$.

COROLLARY 2.5. *Assume that* $\mathbf{S} \subset \tilde{\mathbf{S}}$ *and that the matrices in* (1) *and* (2), *together with the expansion-contraction matrices, are continuously differentiable a sufficient number of times. Then, for* $i = 0, 1, 2, \ldots$,

$$\begin{gathered} F_i(t;I) = U(t)\tilde{F}_i(t;V(t)), \qquad F_i(t;B(t)) = U(t)\tilde{F}_i(t;\tilde{B}(t)R(t)), \\ C(t)F_i(t;I) = S(t)\tilde{C}(t)\tilde{F}_i(t;V(t)), \qquad C(t)F_i(t;B(t)) = S(t)\tilde{C}(t)\tilde{F}_i(t;\tilde{B}(t)R(t)). \end{gathered} \tag{14}$$

Proof. The first relation in (14) follows from $\Phi(t,\tau) = U(t)\tilde{\Phi}(t,\tau)V(\tau)$ after differentiating both sides i times with respect to τ and calculating the obtained derivatives at $\tau = t$. Namely, we have $\frac{\partial^i}{\partial\tau^i}\Phi(t,\tau)\,|_{\tau=t} = U(t)\frac{\partial^i}{\partial\tau^i}\tilde{\Phi}(t,\tau)V(\tau)|_{\tau=t}$, whence

$$F_i(t;I) = \frac{\partial^i}{\partial\tau^i}\Phi(t,\tau)\,|_{\tau=t}, \qquad \tilde{F}_i(t;V(t)) = \frac{\partial^i}{\partial\tau^i}\tilde{\Phi}(t,\tau)V(\tau)\,|_{\tau=t},$$

having in mind that $\frac{\partial}{\partial\tau}\Phi(t,\tau) = -\Phi(t,\tau)A(\tau)$ and $\frac{\partial}{\partial\tau}\tilde{\Phi}(t,\tau) = -\tilde{\Phi}(t,\tau)\tilde{A}(\tau)$. The remaining relations in (14) are obtained analogously. □

For $i = 0$, the first relation in (14) gives $U(t)V(t) = I$; for $i = 1$ and $i = 2$, it provides

$$\begin{gathered} A(t) = U(t)[\tilde{A}(t)V(t) - \dot{V}(t)], \\ A(t)^2 - \dot{A}(t) = U(t)[\tilde{A}(t)^2 - \dot{\tilde{A}}(t)]V(t) + U(t)[\ddot{V}(t) - 2\tilde{A}(t)\dot{V}(t)]. \end{gathered} \tag{15}$$

The remaining relations in (14) give for $i = 0$ and $i = 1$

$$\begin{gathered} B(t) = U(t)\tilde{B}(t)R(t), \\ A(t)B(t) - \dot{B}(t) = U(t)[\tilde{A}(t)\tilde{B}(t) - \dot{\tilde{B}}(t)]R(t) - U(t)\tilde{B}(t)\dot{R}(t), \end{gathered} \tag{16}$$

$$\begin{gathered} C(t) = S(t)\tilde{C}(t)V(t), \qquad C(t)A(t) = S(t)\tilde{C}(t)[\tilde{A}(t)V(t) - \dot{V}(t)], \\ C(t)B(t) = S(t)\tilde{C}(t)\tilde{B}(t)R(t), \end{gathered} \tag{17}$$

$$C(t)[A(t)B(t) - \dot{B}(t)] = S(t)\tilde{C}(t)[\tilde{A}(t)\tilde{B}(t) - \dot{\tilde{B}}(t)]R(t) - S(t)\tilde{C}(t)\tilde{B}(t)\dot{R}(t). \tag{18}$$

In the case of time-invariant expansions-contractions, we have

$$\begin{gathered} A(t) = U\tilde{A}(t)V, \qquad A(t)^2 = U\tilde{A}(t)^2V, \qquad B(t) = U\tilde{B}(t)R, \\ A(t)B(t) = U\tilde{A}(t)\tilde{B}(t)R, \quad C(t) = S\tilde{C}(t)V, \quad C(t)A(t) = S\tilde{C}(t)\tilde{A}(t)V, \\ C(t)B(t) = S\tilde{C}(t)\tilde{B}(t)R, \quad C(t)A(t)B(t) = S\tilde{C}(t)\tilde{A}(t)\tilde{B}(t)R. \end{gathered} \tag{19}$$

If, in addition, the systems themselves are time-invariant, one obtains

$$A^i = U\tilde{A}^iV, \quad A^iB = U\tilde{A}^i\tilde{B}R, \quad CA^i = S\tilde{C}\tilde{A}^iV, \\ CA^iB = S\tilde{C}\tilde{A}^i\tilde{B}R, \quad i = 0, 1, \dots, \tilde{n} - 1, \tag{20}$$

the known set of necessary and sufficient inclusion conditions (e.g., [16, 35]).

Notice that (14) gives for $i = 0$ the basic conditions $U(t)V(t) = I$, $B(t) = U(t)\tilde{B}(t)R(t)$, $C(t) = S(t)\tilde{C}(t)V(t)$, and $C(t)B(t) = S(t)\tilde{C}(t)\tilde{B}(t)R(t)$ appearing in all the cases discussed above (compare with (19) and (20)). Notice also the form of these conditions, recalling the form of (3).

3. Restrictions and aggregations. Restriction and aggregation represent the most important special cases of inclusion in the time-invariant case [16, 18, 29]. The situation is the same in the time-varying case. We give here general definitions, covering a variety of input/output expansion-contraction combinations, which represent a generalization to the time-varying case of the definitions proposed in [33, 35].

DEFINITION 3.1. $\mathbf{S}$ *is a restriction of* $\tilde{\mathbf{S}}$ *on* $[t_a, t_b]$ *if one of the following conditions is satisfied for all* $t_0, t \in [t_a, t_b]$, $t_0 \le t$*:*

$R(a)$: $\exists (V(t), R(t), T(t))\ \{x_0, u\} \Rightarrow \{x, y\}$, $R(b)$: $\exists (V(t), R(t), S(t))\ \{x_0, u\} \Rightarrow \{x, \tilde{y}\}$,
$R(c)$: $\exists (V(t), Q(t), T(t))\ \{x_0, \tilde{u}\} \Rightarrow \{x, y\}$, $R(d)$: $\exists (V(t), Q(t), S(t))\ \{x_0, \tilde{u}\} \Rightarrow \{x, \tilde{y}\}$.

Consequently, we shall distinguish four restriction types: restriction (a), denoted as $\mathbf{S} \overset{R(a)}{\subset} \tilde{\mathbf{S}}$ or $R(a)$, restriction (b), denoted as $\mathbf{S} \overset{R(b)}{\subset} \tilde{\mathbf{S}}$ or $R(b)$, etc.

In the time-invariant case, the state restriction (not including input and output contractions-expansions) has been presented in [18], restriction (a) in [16], and restriction (c) in [14] under the name of *extension*. In [33, 32, 35], a general treatment has been presented. The state restriction for time-varying systems is formulated in [17] under the assumption that the expansions-contractions are time-invariant.

DEFINITION 3.2. $\mathbf{S}$ *is an aggregation of* $\tilde{\mathbf{S}}$ *on* $[t_a, t_b]$ *if one of the following conditions is satisfied for all* $t_0, t \in [t_a, t_b], t_0 \le t$*:*

$A(a)$: $\exists (U(t), Q(t), S(t))\ \{\tilde{x}_0, \tilde{u}\} \Rightarrow \{\tilde{x}, \tilde{y}\}$, $A(b)$: $\exists (U(t), R(t), S(t))\ \{\tilde{x}_0, u\} \Rightarrow \{\tilde{x}, \tilde{y}\}$,
$A(c)$: $\exists (U(t), Q(t), T(t))\ \{\tilde{x}_0, \tilde{u}\} \Rightarrow \{\tilde{x}, y\}$, $A(d)$: $\exists (U(t), R(t), T(t))\ \{\tilde{x}_0, u\} \Rightarrow \{\tilde{x}, y\}$.

We have four aggregation types: aggregation (a), denoted as $\mathbf{S} \overset{A(a)}{\subset} \tilde{\mathbf{S}}$ or $A(a)$, etc.

In the time-invariant case, the state aggregation and aggregation (a) have been described in [1, 16, 18, 29]; a general treatment is presented in [33, 32, 35]. In the case of time-varying systems, the state aggregation has been formulated in [17], assuming that the expansions-contractions are time-invariant.

Let us represent, in general, the matrices in $\tilde{\mathbf{S}}$ as

$$\tilde{A}(t) = V(t)A(t)U(t) + M(t), \quad \tilde{B}(t) = V(t)B(t)Q(t) + N(t), \\ \tilde{C}(t) = T(t)C(t)U(t) + L(t),$$

where $M(t)$, $N(t)$, and $L(t)$ are complementary matrices. The following theorems present the restriction and aggregation conditions expressed in terms of the properties of $\mathbf{S}$ and $\tilde{\mathbf{S}}$.

THEOREM 3.3.

$$\begin{aligned}
&\mathbf{S} \overset{R(a)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\nu(t) = \nu(t_0)) \wedge (\nu(t)b(\tau) = \tilde{b}(\tau)R(\tau)) \wedge (T(t)c(t) = \tilde{c}(t)\nu(t_0)),\\
&\mathbf{S} \overset{R(b)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\nu(t) = \nu(t_0)) \wedge (\nu(t)b(\tau) = \tilde{b}(\tau)R(\tau)) \wedge (c(t) = S(t)\tilde{c}(t)\nu(t_0)),\\
&\mathbf{S} \overset{R(c)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\nu(t) = \nu(t_0)) \wedge (\nu(t)b(\tau)Q(\tau) = \tilde{b}(\tau)) \wedge (T(t)c(t) = \tilde{c}(t)\nu(t_0)),\\
&\mathbf{S} \overset{R(d)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\nu(t) = \nu(t_0)) \wedge (\nu(t)b(\tau)Q(\tau) = \tilde{b}(\tau)) \wedge (c(t) = S(t)\tilde{c}(t)\nu(t_0))\\
&(\forall t_0, \tau, t \in [t_a, t_b], t_0 \le \tau \le t).
\end{aligned}$$

Proof. According to Definition 3.1, for all the restriction types, $V(t)\Phi(t,t_0) = \tilde{\Phi}(t,t_0)V(t_0)$ or $\nu(t) = \nu(t_0)$. The remaining conditions follow directly from the corresponding definitions. □

THEOREM 3.4. *Assume that $V(t)$ is continuously differentiable. Then*

$$\begin{aligned}
&\mathbf{S} \overset{R(a)}{\subset} \tilde{\mathbf{S}} \ \textit{if} \ \ (M(t)V(t) = \dot{V}(t)) \wedge (N(t)R(t) = 0) \wedge (L(t)V(t) = 0),\\
&\mathbf{S} \overset{R(b)}{\subset} \tilde{\mathbf{S}} \ \textit{if} \ \ (M(t)V(t) = \dot{V}(t)) \wedge (N(t)R(t) = 0) \wedge (S(t)L(t)V(t) = 0),\\
&\mathbf{S} \overset{R(c)}{\subset} \tilde{\mathbf{S}} \ \textit{if} \ \ (M(t)V(t) = \dot{V}(t)) \wedge (N(t) = 0) \wedge (L(t)V(t) = 0),\\
&\mathbf{S} \overset{R(d)}{\subset} \tilde{\mathbf{S}} \ \textit{if} \ \ (M(t)V(t) = \dot{V}(t)) \wedge (N(t) = 0) \wedge (S(t)L(t)V(t) = 0)\\
&(\forall t \in [t_a, t_b]).
\end{aligned}$$

Proof. As $\nu(t) = \nu(t_0)$, according to Definition 3.1, we have $\dot{\nu}(t) = 0$ for all $t \in [t_a, t_b]$, or

$$-\tilde{\psi}(t)^{-1}\tilde{A}(t)V(t)\psi(t) + \tilde{\psi}(t)^{-1}\dot{V}(t)\psi(t) + \tilde{\psi}(t)^{-1}V(t)A(t)\psi(t) = 0, \tag{21}$$

giving $\tilde{A}(t)V(t) - V(t)A(t) = \dot{V}(t)$ or $M(t)V(t) = \dot{V}(t)$. For $R(a)$ we have $\tilde{\Phi}(t,\tau)\tilde{B}(\tau)$ $R(\tau) = V(t)\Phi(t,\tau)B(\tau)$ so that $\tilde{\Phi}(t,\tau)\ N(\tau)\ R(\tau) = 0 \Leftrightarrow N(t)\ R(t) = 0$ and $T(t)$ $C(t)\ \Phi(t,t_0) = S(t)\ \tilde{C}(t)\ \tilde{\Phi}(t,t_0)\ V(t_0)$, giving $L(t)\ V(t)\ \Phi(t,\tau) = 0 \Leftrightarrow L(t)\ V(t) = 0$. The remaining relations, characterizing $R(b)$, $R(c)$, and $R(d)$, can be derived analogously. □

We remark that systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$ in Example 2.4 satisfy, in fact, restriction conditions with the triplet of expansion-contraction matrices ($V(t) = [1 \ \ \frac{1}{2}\sin t], R(t) = 1, T(t) = 1$).

THEOREM 3.5.

$$\begin{aligned}
&\mathbf{S} \overset{A(a)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\mu(t) = \mu(t_0)) \wedge (b(\tau)Q(\tau) = \mu(t)\tilde{b}(\tau)) \wedge (c(t)\mu(t_0) = S(t)\tilde{c}(t)),\\
&\mathbf{S} \overset{A(b)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\mu(t) = \mu(t_0)) \wedge (b(\tau) = \mu(t)\tilde{b}(\tau)R(\tau)) \wedge (c(t)\mu(t_0) = S(t)\tilde{c}(t)),\\
&\mathbf{S} \overset{A(c)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\mu(t) = \mu(t_0)) \wedge (b(\tau)Q(\tau) = \mu(t)\tilde{b}(\tau)) \wedge (T(t)c(t)\mu(t_0) = \tilde{c}(t)),\\
&\mathbf{S} \overset{A(d)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (\mu(t) = \mu(t_0)) \wedge (b(\tau) = \mu(t)\tilde{b}(\tau)R(\tau)) \wedge (T(t)c(t)\mu(t_0) = \tilde{c}(t))\\
&(\forall t_0, \tau, t \in [t_a, t_b], t_0 \le \tau \le t).
\end{aligned}$$

Proof. The condition common for all the aggregation types is $U(t)\tilde{\Phi}(t,t_0) = \Phi(t,t_0)U(t_0) \Leftrightarrow \mu(t) = \mu(t_0)$. The remaining conditions are obtained similarly to those in Theorem 3.3. □

THEOREM 3.6. *Assume that $U(t)$ is continuously differentiable. Then*

$$\begin{aligned}
&\mathbf{S} \overset{A(a)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (U(t)M(t) = -\dot{U}(t)) \wedge (U(t)N(t) = 0) \wedge (S(t)L(t) = 0),\\
&\mathbf{S} \overset{A(b)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (U(t)M(t) = -\dot{U}(t)) \wedge (U(t)N(t)R(t) = 0) \wedge (S(t)L(t) = 0),\\
&\mathbf{S} \overset{A(c)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (U(t)M(t) = -\dot{U}(t)) \wedge (U(t)N(t) = 0) \wedge (L(t) = 0),\\
&\mathbf{S} \overset{A(d)}{\subset} \tilde{\mathbf{S}} \ \textit{iff} \ \ (U(t)M(t) = -\dot{U}(t)) \wedge (U(t)N(t)R(t) = 0) \wedge (L(t) = 0)\\
&(\forall t \in [t_a, t_b]).
\end{aligned}$$

Proof. Condition $\dot{\mu}(t) = 0$, resulting from Definition 3.2, is equivalent to $A(t)U(t) - U(t)\tilde{A}(t) = \dot{U}(t)$ and $U(t)M(t) = -\dot{U}(t)$. The remaining conditions can be derived as in Theorem 3.4. □

It is easy to verify that the conditions for all the types of restriction and aggregation satisfy the general inclusion conditions from Theorem 2.3. For example, conditions $\nu(t) = \nu(t_0)$ and $\mu(t) = \mu(t_0)$ imply that there exist a left inverse $\mu(t) = \nu(t)^L$ and a right inverse $\nu(t_0) = \mu(t_0)^R$, respectively, so that $\mu(t)\nu(t_0) = I$.

The known conditions for the time-invariant case (e.g., [29, 35]) can be easily derived. In [17], the state restriction and aggregation conditions are discussed in the case of time-varying parameters and constant expansion-contraction maps; then we have, for restriction $M(t)V = 0$ and $N(t) = 0$ and for aggregation $UM(t) = 0$ and $UN(t) = 0$, special cases of Theorems 3.4 and 3.6.

Essential properties of input/state/output restrictions and aggregations can be seen from a specific equivalent representation of $\tilde{\mathbf{S}}$, similarly as in [18]. Define a nonsingular transformation $P(t) = [V(t)\vdots W(t)]$, where $W(t)$ is chosen such that $\mathcal{R}(W(t)) = \mathcal{N}(U(t))$. ($\mathcal{R}(.)$ denotes the range space and $\mathcal{N}(.)$ the null space of the indicated map.) Then there exists $W^*(t)$, the unique left inverse of $W(t)$, satisfying $\mathcal{N}(W^*(t)) = \mathcal{R}(V(t))$, and we have $P(t)^{-1} = \begin{bmatrix} U(t) \\ W^*(t) \end{bmatrix}$. Assuming, in addition, that $P(t)$ is continuously differentiable, the change of basis $x^*(t) = P(t)^{-1}\tilde{x}(t)$ leads to the following equivalent representation of $\tilde{\mathbf{S}}$:

$$\begin{aligned}
\mathbf{S}^*: \ \ \dot{x}^*(t) &= [P(t)^{-1}\tilde{A}(t)P(t) - P(t)^{-1}\dot{P}(t)]x^*(t) + P(t)^{-1}\tilde{B}(t)\tilde{u}(t)\\
&= \begin{bmatrix} A(t) & A_a(t) \\ A_r(t) & A^*(t) \end{bmatrix} x^*(t) + \begin{bmatrix} B_1(t) \\ B_2(t) \end{bmatrix} \tilde{u}(t),\\
\tilde{y}(t) &= P(t)\tilde{C}(t)x^*(t) = [C_1(t) \quad C_2(t)]x^*(t).
\end{aligned} \tag{22}$$

In the case in which $\mathbf{S} \overset{R(.)}{\subset} \tilde{\mathbf{S}}$, we have $A_r(t) = W^*(t)\tilde{A}(t)V(t) - W^*(t)\dot{V}(t) = W^*(t)V(t)A(t) = 0$ (having in mind the assumed properties of $W^*(t)$). Similarly, when $\mathbf{S} \overset{A(.)}{\subset} \tilde{\mathbf{S}}$, $A_a(t) = U(t)\tilde{A}(t)W(t) - U(t)\dot{W}(t) = [-\dot{U}(t) + A(t)U(t)]W(t) - U(t)\dot{W}(t) = 0$ because $U(t)W(t) = 0 \Rightarrow \dot{U}(t)W(t) + U(t)\dot{W}(t) = 0$. In both cases, the block $A(t)$ remains invariant since $U(t)\tilde{A}(t)V(t) - U(t)\dot{V}(t) = A(t)$ for restriction, and $U(t)\tilde{A}(t)V(t) + \dot{U}(t)V(t) = A(t)$ for aggregation (having in mind that $U(t)\dot{V}(t) + \dot{U}(t)V(t) = 0$). Also, in both cases, $A^*(t) = W^*(t)\tilde{A}(t)W(t) - W^*(t)\dot{W}(t)$.

The control and output matrices in $\mathbf{S}^*$ depend on the inclusion type. For $R(a)$ and $R(b)$, we have $B_1(t) = B(t)Q(t) + U(t)N(t)$ and $B_2(t) = W^*(t)N(t)$, and, for $R(c)$ and $R(d)$, $B_1(t) = B(t)Q(t)$ and $B_2(t) = 0$. In the case of $A(a)$ and $A(c)$, $B_1(t) = B(t)Q$ and $B_2(t) = W^*(t)N(t)$, and, in the case of $A(b)$ and $A(d)$, $B_1(t) = B(t)Q(t) + U(t)N(t)$ and $B_2(t) = W^*(t)N(t)$. Also, for $R(a)$ and $R(c)$, $C_1(t) = T(t)C(t)$ and

$C_2(t) = L(t)W(t)$, while, for $R(b)$ and $R(d)$, $C_1(t) = T(t)C(t) + L(t)V(t)$ and $C_2(t) = L(t)W(t)$. For $A(a)$ and $A(b)$, $C_1(t) = T(t)C(t) + L(t)V(t)$ and $C_2(t) = L(t)W(t)$, and, for $A(c)$ and $A(d)$, $C_1(t) = T(t)C(t)$ and $C_2(t) = 0$.

Using geometric arguments from [37, 18, 32, 35], it can be concluded that the principal property of all the restriction types is that the two-argument map $\Phi(t, t_0)$ describes, in fact, the action of the restriction of the map $\tilde{\Phi}(t, t_0)$ to $\mathcal{R}(V(t_0))$ with reduced codomain $\mathcal{R}(V(t))$ ($V(t)$ being considered as the insertion map). In the case of time-invariant expansions-contractions, we have, moreover, that $A(t) = \tilde{A}(t)|\mathcal{R}(V)$; that is, $A(t)$ represents the restriction of $\tilde{A}(t)$ to $\mathcal{R}(V)$ with codomain $\mathcal{R}(V)$ (as in the case of time-invariant systems). Therefore, in the case of time-varying expansions-contractions, the "dynamic" restriction of $\tilde{\mathbf{S}}$ does not correspond, in general, to the "static" restriction of the system matrix $\tilde{A}(t)$ itself. Similarly, in the case of aggregation, $\Phi(t, t_0)$ is obtained by aggregating $\tilde{\Phi}(t, t_0)$, according to [1, 29]. $A(t)$ represents an aggregation of $\tilde{A}(t)$ (the map induced in $\mathcal{R}(U)$ by $\tilde{A}(t)$) only in the case of time-invariant expansion-contraction maps.

However, only $R(a)$ can be considered as a "pure" restriction, having in mind that $N(t)R(t) = 0 \Leftrightarrow \tilde{B}(t)R(t) = V(t)B(t)$ and $L(t)V(t) = 0 \Leftrightarrow \tilde{C}(t)V(t) = T(t)C(t)$; that is, $B(t)$ is the restriction of $\tilde{B}(t)$ to $\mathcal{R}(R(t))$ with the reduced codomain $\mathcal{X}$, and $C(t)$ is the restriction of $\tilde{C}(t)$ to $\mathcal{R}(V(t))$ with the reduced codomain $\mathcal{Y}$. In $R(c)$, for example, we have $N(t) = 0 \Leftrightarrow \tilde{B}(t) = V(t)B(t)Q(t)$, that is, $B(t)$ is the map induced in $\mathcal{R}(Q(t))$ (aggregation of $\tilde{B}(t)$ to $\mathcal{R}(Q(t))$), with the reduced codomain $\mathcal{X}$. Analogous statements hold for aggregation. In the case of $A(a)$, we have $U(t)N(t) = 0 \Leftrightarrow U(t)\tilde{B}(t) = B(t)Q(t)$ and $S(t)L(t) = 0 \Leftrightarrow S(t)\tilde{C}(t) = C(t)U(t)$; that is, $B(t)$ and $C(t)$ represent aggregations of $\tilde{B}(t)$ and $\tilde{C}(t)$. The other aggregation types involve restrictions either in the domain or in the codomain.

The controllability and observability of systems including each other represent an important issue (e.g., [36]). It is easy to see from (22) that, in the case of $R(c)$ and $R(d)$, $\mathbf{S}^*$ (and, therefore, $\tilde{\mathbf{S}}$) is not controllable even when $\mathbf{S}$ is controllable (having in mind that $B_2(t) = 0$). However, in the case of $R(a)$ and $R(b)$, controllability of $\mathbf{S}$ could be preserved in the expanded space of $\tilde{\mathbf{S}}$ by a proper choice of the complementary matrix $N(t)$. Analogously, in the case of $A(c)$ and $A(d)$, $\mathbf{S}^*$ is not observable ($C_2(t) = 0$), while, in the case of $A(a)$ and $A(b)$, observability could be achieved by a proper choice of $L(t)$. This is an interesting aspect introduced by input/output expansions-contractions: compare this with the analysis in [18] related to the state restriction-aggregation, and with the general treatment of the time-invariant case in [32, 35]. There is a recent development [4, 5, 6], which expands the freedom in choosing complementary matrices in time-invariant inclusions, that can be applied to the time-varying case as well. It would be also possible to extend to the time-varying case the results presented in [36] related to the implementation of controllability and observability in systems satisfying restriction or aggregation conditions. As will be seen from the next two sections, the notions of *instantaneous controllability* and *instantaneous observability* (see [25]) play important roles in the characterization of time-varying systems under the inclusion relation.

4. Composition. The fundamental importance of restrictions and aggregations for inclusion relationships in the time-varying case will be emphasized by the following theorem, where we shall prove that any input/state/output inclusion can be considered as a specific composition of one input/state/output restriction and one input/state/output aggregation. This property has been shown for the state inclusion of time-invariant linear systems in [18].

Let

$$\bar{\mathbf{S}}\text{:}\quad \dot{\bar{x}}(t) = \bar{A}(t)\bar{x}(t) + \bar{B}(t)\bar{u}(t) \quad (\bar{x}(t_0) = \bar{x}_0), \qquad \bar{y}(t) = \bar{C}(t)\bar{x}(t), \tag{23}$$

where $\bar{x}(t) \in \bar{\mathcal{X}}$, $\bar{u}(t) \in \bar{\mathcal{U}}$, and $\bar{y}(t) \in \bar{\mathcal{Y}}$ with $n \le d(\bar{\mathcal{X}}) \le \tilde{n}$, $m \le d(\bar{\mathcal{U}}) \le \tilde{m}$, and $l \le d(\bar{\mathcal{Y}}) \le \tilde{l}$. ($d(.)$ denotes the dimension of the indicated space.)

THEOREM 4.1. *Assume that the matrices in both* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$*, as well as the expansion-contraction matrices* $V(t), U(t), R(t), Q(t), T(t)$*, and* $S(t)$ *are continuously differentiable a sufficient number of times* ($\le \tilde{n}$)*. Then* $\mathbf{S} \subset \tilde{\mathbf{S}}$ *on* $[t_a, t_b]$ *iff for each* $t \in [t_a, t_b]$ *there exist both an interval* $[t_s, t_f)$ *containing* t ($[t_s, t_f) \subset [t_a, t_b]$) *and a system* $\bar{\mathbf{S}}$ *defined on the same interval, such that* $\mathbf{S} \overset{A(b)}{\subset} \bar{\mathbf{S}} \overset{R(b)}{\subset} \tilde{\mathbf{S}}$ *on* $[t_s, t_f)$*. (*$t_s = t_f$ *on a set of measure zero.)*

Proof. The sufficiency follows from the basic fact that restrictions and aggregations are special cases of inclusion and that $(\bar{\mathbf{S}} \subset \tilde{\mathbf{S}}) \wedge (\mathbf{S} \subset \bar{\mathbf{S}}) \Rightarrow \mathbf{S} \subset \tilde{\mathbf{S}}$. Namely, it follows from the assumption of the theorem that any $[t_a, t_b]$ can be represented as a union of consecutive nonoverlapping intervals: $\tau_1 = [t_s^1 = t_a, t_f^1)$, $\tau_2 = [t_s^2 = t_f^1, t_f^2), \ldots, \tau_i = [t_s^i, t_f^i), \ldots$, so that $[t_a, t_b] = \bigcup_i \tau_i$. (For finite intervals $[t_a, t_b]$, the last interval reduces to the isolated point t_b.) Take one set $\{\tau_i\}$ covering $[t_a, t_b]$. By assumption, on each τ_i there exists a system $\bar{\mathbf{S}}$ represented by (23) which satisfies $\mathbf{S} \overset{A(b)}{\subset} \bar{\mathbf{S}} \overset{R(b)}{\subset} \tilde{\mathbf{S}}$. Assign quadruplets $(U_i^r(t), V_i^r(t), R_i^r(t), T_i^r(t))$ to $\bar{\mathbf{S}} \subset \tilde{\mathbf{S}}$ and quadruplets $(U_i^a(t), V_i^a(t), R_i^a(t), T_i^a(t))$ to $\mathbf{S} \subset \bar{\mathbf{S}}$ on τ_i, $i = 1, 2, \ldots$. Therefore, the choice $\tilde{x}(t_0^i) = V_i^r(t_0^i)\bar{x}(t_0^i)$ and $\tilde{u}(t) = R_i^r(t)\bar{u}(t)$ implies $\bar{x}(t) = U_i^r(t)\tilde{x}(t; t_0^i, \tilde{x}(t_0^i), \tilde{u}_{[t_0^i, t]})$ and $\bar{y}[\bar{x}(t)] = S_i^r(t)\tilde{y}[\tilde{x}(t)]$, and the choice $\bar{x}(t_0^i) = V_i^a(t_0^i)x(t_0^i)$ and $\bar{u}(t) = R_i^a(t)u(t)$ implies $x(t) = U_i^a(t)\bar{x}(t; t_0^i, \bar{x}(t_0^i), \bar{u}_{[t_0^i, t]})$ and $y[x(t)] = S_i^a(t)\bar{y}[\bar{x}(t)]$ for all $t_0^i, t \in \tau_i = [t_s^i, t_f^i), t_0^i \le t$, $i = 1, 2, \ldots$. Consequently, the choice $\tilde{x}(t_0^i) = V_i^r(t_0^i)V_i^a(t_0^i)x(t_0^i)$ and $\tilde{u}(t) = R_i^r(t)R_i^a(t)u(t)$ implies $x(t; t_0^i, x(t_0^i), u_{[t_0^i, t]}) = U_i^a(t)U_i^r(t)\tilde{x}(t; t_0^i, \tilde{x}(t_0^i), \tilde{u}_{[t_0^i, t]})$ and $y[x(t)] = S_i^a(t)S_i^r(t)\tilde{y}[\tilde{x}(t)]$ for all $t_0^i, t \in \tau_i = [t_s^i, t_f^i), t_0^i \le t$, and, therefore, $\mathbf{S} \subset \tilde{\mathbf{S}}$ on each τ_i, $i = 1, 2, \ldots$. The continuity of both $x(t)$ and $\tilde{x}(t)$, as solutions of (1) and (2), implies that $U_i^a(t_s^i)U_i^r(t_s^i) = U_{i-1}^a(t_f^{i-1})U_{i-1}^r(t_f^{i-1})$, $V_i^r(t_s^i)V_i^a(t_s^i) = V_{i-1}^r(t_f^{i-1})V_{i-1}^a(t_f^{i-1})$, and $S_i^a(t_s^i)S_i^r(t_s^i) = S_{i-1}^a(t_f^{i-1})S_{i-1}^r(t_f^{i-1})$. (The same conclusion holds for isolated points corresponding to $t_s^i = t_f^i$.) Analogously, $R_i^r(t_s^i)R_i^a(t_s^i) = R_{i-1}^r(t_f^{i-1})R_{i-1}^a(t_f^{i-1})$ except for a set of measure zero. Thus $\mathbf{S} \subset \tilde{\mathbf{S}}$ on $[t_a, t_b]$, with the quadruplet $(U(t) = U_i^a(t)U_i^r(t)$, $V(t) = V_i^r(t)V_i^a(t)$, $R(t) = R_i^r(t)R_i^a(t)$, $S(t) = S_i^a(t)S_i^r(t))$.

The necessity will be proven constructively, extending the essential idea presented in [18] to a more complex situation arising in the time-varying case.

Assume that $\mathbf{S} \subset \tilde{\mathbf{S}}$ on $[t_a, t_b]$, with the assigned quadruplet $(U(t), V(t), R(t), S(t))$.

Choose $V^r(t) = [V'(t) \vdots V(t)]$, where $V'(t) = (I - V(t)U(t))\hat{W}(t)$, and $\hat{W}(t)$ is any basis matrix for

$$\hat{\mathcal{W}}(t) = [\mathcal{R}(\langle \tilde{A}(t) | V(t) \rangle) + \mathcal{R}(\langle \tilde{A}(t) | N(t)R(t) \rangle)] \cap \mathcal{R}(V(t))^{\perp},$$

where

$$\langle \tilde{A}(t) | V(t) \rangle = [V(t) \vdots \tilde{F}_1(t; V(t)) \vdots \ldots \vdots \tilde{F}_{\tilde{n}-1}(t; V(t))],$$

$$\langle \tilde{A}(t) | N(t)R(t) \rangle = [N(t)R(t) \vdots \tilde{F}_1(t; N(t)R(t)) \vdots \ldots \vdots \tilde{F}_{\tilde{n}-1}(t; N(t)R(t))]. \tag{24}$$

($(.)^{\perp}$ denotes the annihilator of the indicated map.) Notice that $\tilde{F}_j(t; .)$ for $j \ge \tilde{n}$ represents a linear combination of $\tilde{F}_i(t, .)$, $i = 0, \ldots, \tilde{n} - 1$, so that the matrices

$\langle \tilde{A}(t)|V(t)\rangle$ and $\langle \tilde{A}(t)|N(t)R(t)\rangle$ in (24) have the maximal possible rank. Having in mind that

$$[V^{'}(t)\vdots V(t)] = [\hat{W}(t)\vdots V(t)] \begin{bmatrix} I & 0 \\ -U(t)\hat{W}(t) & I \end{bmatrix}$$

and $U(t)V(t) = I$, we conclude that $V^r(t)$ is monic as well as that $\mathcal{R}(V^r(t)) = \mathcal{R}(\langle \tilde{A}(t)|V(t)\rangle) + \mathcal{R}(\langle \tilde{A}|(N(t)R(t)\rangle)$ and $\mathcal{N}(U(t)) = \mathcal{R}(V^{'}(t))$, implying the existence of the left inverse $V^{'}(t)^L$ such that the choice $U^r(t) = \begin{bmatrix} V^{'}(t)^L \\ U(t) \end{bmatrix}$ implies $U^r(t)V^r(t) = I$. However, the rank of both $\langle \tilde{A}(t)|V(t)\rangle$ and $\langle \tilde{A}(t)|N(t)R(t)\rangle$ is, in general, time-varying, and, consequently, the dimensions of both $V^r(t)$ and $U^r(t)$ are, in general, time-varying. An insight into the properties of these matrices can be obtained by analyzing the symmetric positive semidefinite matrices $\langle \tilde{A}(t)|V(t)\rangle\langle \tilde{A}(t)|V(t)\rangle^T$ and $\langle \tilde{A}(t)|N(t)R(t)\rangle\langle \tilde{A}(t)|N(t)R(t)\rangle^T$. Their elements are, by assumption, continuous functions of time, which implies that their nonnegative real eigenvalues $\lambda_i^v(t)$ and $\lambda_i^{nr}(t)$, $i = 1, \ldots, \tilde{n}$, respectively, are continuous functions of time as well (see, for example, [11]). Consequently, these eigenvalues can be equal to zero either on closed intervals of nonzero length or on a set of time-instants of measure zero. Therefore, $\text{rank}\langle \tilde{A}(t)|V(t)\rangle$ and $\text{rank}\langle \tilde{A}(t)|N(t)R(t)\rangle$ are piecewise continuous functions of time, implying that, for each $t \in [t_a, t_b]$, there exists an interval $[t_s, t_f)$ containing t on which both functions have constant values. (These intervals reduce to single points, that is, $t_s = t_f$, on a set of points of measure zero, corresponding either to simple zeros of the functions $\lambda_i^v(t)$ and $\lambda_i^{nr}(t)$ or to the right end points of the segments of nonzero length, where these functions are equal to zero.) Starting from the differentiability assumption, we shall choose a continuously differentiable $\hat{W}(t)$ for all the continuity points of $\lambda_i^v(t)$ and $\lambda_i^{nr}(t)$ by selecting, for example, the linearly independent columns of $\langle \tilde{A}(t)|V(t)\rangle$ and $\langle \tilde{A}(t)|N(t)R(t)\rangle$.

We shall choose, also, $R^r(t) = [R^{'}(t)\vdots R(t)]$, where $R^{'}(t)$ is any basis matrix for $\bar{\mathcal{U}} \cap \mathcal{U}^{\perp} \subset \mathcal{N}(N(t)) \cap \mathcal{U}^{\perp}$ (if $\mathcal{N}(N(t)) \cap \mathcal{R}(R(t))^{\perp} = \emptyset$, then $R^r(t) = R(t)$), and $T^r(t) = [T^{'}(t)\vdots T(t)]$, where $T^{'}(t)$ is any basis matrix for $\bar{\mathcal{Y}} \subset \mathcal{Y}^{\perp}$. Therefore, there exist left inverses $R^{'}(t)^L$ and $T^{'}(t)^L$ such that the choice $Q^r(t) = \begin{bmatrix} R^{'}(t)^L \\ Q(t) \end{bmatrix}$ and $S^r(t) = \begin{bmatrix} T^{'}(t)^L \\ S(t) \end{bmatrix}$ implies both $Q^r(t)R^r(t) = I$ and $S^r(t)T^r(t) = I$.

Let the matrices in $\bar{\mathbf{S}}$ be

$$\begin{aligned} \bar{A}(t) = U^r(t)\tilde{A}(t)V^r(t) - U^r(t)\dot{V}^r(t), \quad \bar{B}(t) = U^r(t)\tilde{B}(t)R^r(t), \\ \bar{C}(t) = S^r(t)\tilde{C}(t)V^r(t). \end{aligned} \tag{25}$$

From the general expression $\tilde{A}(t) = V^r(t)\bar{A}(t)U^r(t) + M^r(t)$, we obtain

$$\begin{aligned} M^r(t)V^r(t) - \dot{V}^r(t) &= [\tilde{A}(t) - V^r(t)\bar{A}(t)U^r(t)]V^r(t) - \dot{V}^r(t) \\ &= [I - V^r(t)U^r(t)][\tilde{A}(t)V^r(t) - \dot{V}^r(t)] = 0 \end{aligned}$$

after replacing the expression for $\bar{A}(t)$ and using the fact that $\tilde{A}(t)V^r(t) - \dot{V}^r(t) \subset \mathcal{R}(V^r(t))$ by assumption. Note also that

$$\mathcal{R}(\tilde{B}(t)R^r(t)) \subset \mathcal{R}(V(t)) + \mathcal{R}(N(t)R^r(t)) \subset \mathcal{R}(V^r(t)),$$

having in mind that $\tilde{B}(t) = V(t)B(t)Q(t) + N(t)$ and $\mathcal{R}(N(t)R^r(t)) = \mathcal{R}(N(t)R(t))$, according to the definition of $R^r(t)$. From $\tilde{B}(t) = V^r(t)\bar{B}(t)Q^r(t) + N^r(t)$ we conclude, consequently, that

$$N^r(t)R^r(t) = [\tilde{B}(t) - V^r(t)\bar{B}(t)Q^r(t)]R^r(t) = [I - V^r(t)U^r(t)]\tilde{B}(t)R^r(t) = 0.$$

Also, from $\tilde{C}(t) = T^r(t)\bar{C}(t)U^r(t) + L^r(t)$ we obtain

$$S^r(t)L^r(t)V^r(t) = S^r(t)[\tilde{C}(t) - T^r(t)\bar{C}(t)U^r(t)]V^r(t) = 0.$$

Therefore, according to Theorem 3.4, $\bar{\mathbf{S}} \overset{R(b)}{\subset} \tilde{\mathbf{S}}$ on $[t_s, t_f)$ with the quadruplet $(U^r(t), V^r(t), R^r(t), S^r(t))$.

Choose now $V^a(t) = \begin{bmatrix}0\\ I\end{bmatrix}$, $U^a(t) = [0\ I]$, $R^a(t) = \begin{bmatrix}0\\ I\end{bmatrix}$, $Q^a(t) = [0\ I]$, $T^a(t) = \begin{bmatrix}0\\ I\end{bmatrix}$, and $S^a(t) = [0\ I]$. Obviously, $U^a(t)U^r(t) = U(t)$, $V^r(t)V^a(t) = V(t)$, $R^r(t)R^a(t) = R(t)$, and $S^a(t)S^r(t) = S(t)$.

From $\bar{A}(t) = V^a(t)A(t)U^a(t) + M^a(t)$ we obtain

$$\begin{aligned} U^a(t)M^a(t) &= U^a(t)[U^r(t)\tilde{A}(t)V^r(t) - U^r(t)\dot{V}^r(t) - V^a(t)A(t)U^a(t)] \\ &= U(t)\tilde{A}(t)[V^{'}(t)\vdots V(t)] - U(t)[\dot{V}^{'}(t)\vdots\dot{V}(t)] - A(t)[0\vdots I], \end{aligned} \tag{26}$$

having in mind that $\bar{A}(t) = U^r(t)\tilde{A}(t)V^r(t) - U^r(t)\dot{V}^r(t)$ according to (12), since $\bar{\mathbf{S}} \subset \tilde{\mathbf{S}}$.

Consider

$$U(t)F_1(t; V^{'}(t)) = U(t)(-\tilde{A}(t)V^{'}(t) + \dot{V}^{'}(t)), \tag{27}$$

with $V^{'}(t) = (I - V(t)U(t))\hat{W}(t)$; by assumption, $\hat{W}(t) \in \hat{\mathcal{W}}(t)$. Replacing $\hat{W}(t)$ by $\tilde{F}_j(t; V(t))$ in (27), we obtain that

$$\begin{aligned} U(t)\Big\{ &\tilde{A}(t)\tilde{F}_j(t; V(t)) - \dot{\tilde{F}}_j(t; V(t)) - \tilde{A}(t)V(t)U(t)\tilde{F}_j(t; V(t)) \\ &- \frac{d}{dt}[V(t)U(t)\tilde{F}_j(t; V(t))]\Big\} = 0 \end{aligned} \tag{28}$$

for $j = 0, 1, \ldots, \tilde{n} - 1$ since

$$\begin{aligned} &F_{j+1}(t; I) - U(t)[\tilde{A}(t)V(t)F_j(t; I) - \dot{V}(t)F_j(t; I) - V(t)\dot{F}_j(t; I)] \\ &\quad = F_{j+1}(t; I) - A(t)F_j(t; I) - \dot{F}_j(t; I) = 0. \end{aligned}$$

Analogously, we can show that $\mathcal{R}(\tilde{F}_j(t; \tilde{B}(t)R(t))) \subset \mathcal{N}(U(t))$ using the second relation in (3). As $\mathbf{S} \subset \tilde{\mathbf{S}}$ implies $U(t)\tilde{\Phi}(t, \tau)\tilde{B}(\tau) = U(t)\tilde{\Phi}(t, \tau)V(\tau)U(\tau)\tilde{B}(\tau)R(\tau) = \Phi(t, \tau)B(\tau)$, we obtain that

$$\mathcal{R}(\tilde{F}_j(t; V(t)U(t)\tilde{B}(t)R(t))) \subset \mathcal{N}(U(t)),$$

implying $\mathcal{R}(\tilde{F}_j(t; N(t)R(t))) \subset \mathcal{N}(U(t))$. Therefore, according to the definition of $\hat{\mathcal{W}}(t)$, we have $U^a(t)M^a(t) = 0$.

We also have $\bar{B}(t) = V^a(t)B(t)Q^a(t) + N^a(t)$ and

$$U^a(t)N^a(t)R^a(t) = U^a(t)[\bar{B}(t) - V^a(t)B(t)Q^a(t)]R^a(t) = 0,$$

using the relation $U(t)\tilde{B}(t)R(t) = B(t)$ from (16), since $\mathbf{S} \subset \tilde{\mathbf{S}}$ by assumption.

Reasoning similarly, we start from $\tilde{C}(t) = T(t)C(t)U(t) + L(t)$ and the inclusion relations related to $C(t)$ in (14) and obtain $S(t)L(t)\tilde{F}_i(t; V(t)) = 0$ and $S(t)L(t)\tilde{F}_i(t; \tilde{B}(t)R(t)) = 0$. Consequently,

$$\mathcal{N}(S(t)L(t)) \supset \mathcal{R}(\langle\tilde{A}(t)|V(t)\rangle) + \mathcal{R}(\langle\tilde{A}(t)N(t)R(t)\rangle)$$

and $S(t)L(t)V^{'}(t) = 0$, and we get

$$\begin{aligned} S^a(t)L^a(t) &= S^a(t)[\bar{C}(t) - T^a(t)C(t)U^a(t)] \\ &= S(t)(T(t)C(t)U(t) + L(t))[V^{'}(t)\vdots V(t)] - C(t)[0\vdots I] = 0, \end{aligned}$$

having in mind that $\bar{C}(t) = T^a(t)C(t)U^a(t) + L_a(t)$. Therefore, according to Theorem 3.6, $\mathbf{S} \overset{A(b)}{\subset} \bar{\mathbf{S}}$ on $[t_s, t_f)$ with the quadruplet $(U^a(t), V^a(t), R^a(t), S^a(t))$. Hence we have the result. □

The result of the theorem indicates that input/state/output contractions of dynamic time-varying systems may be considered as specific "compositions" of input/state/output restrictions and aggregations, analogously to the time-invariant case [18].

5. Equivalence. The inclusion relation between $\mathbf{S}$ and $\tilde{\mathbf{S}}$ does not imply algebraic equivalence, as in the time-invariant case (see [18]). However, it is possible to compare their external behavior for zero initial states. Let

$$\mathbf{S}_1\colon \dot{x}_1(t) = A_1(t)x_1(t) + B_1(t)u_1(t), \quad (x_1(t_0) = x_{10}), \qquad y_1(t) = C_1(t)x_1(t), \tag{29}$$

$$\mathbf{S}_2\colon \dot{x}_2(t) = A_2(t)x_2(t) + B_2(t)u_2(t), \quad (x_2(t_0) = x_{20}), \qquad y_2(t) = C_2(t)x_2(t), \tag{30}$$

where $x_1(t) \in \mathcal{X}_1$, $u_1(t) \in \mathcal{U}_1$, and $y_1(t) \in \mathcal{Y}_1$ are n_1-, m_1-, and l_1-vectors and $x_2(t) \in \mathcal{X}_2$, $u_2(t) \in \mathcal{U}_2$, and $y_2(t) \in \mathcal{Y}_2$ are n_2-, m_2-, and l_2-vectors, respectively.

DEFINITION 5.1. *We say that* $\mathbf{S}_1$ *and* $\mathbf{S}_2$ *are zero-state RS-equivalent on* $[t_a, t_b]$ *if there exist full rank matrices* $S_1(t)_{l\times l_1}$, $S_2(t)_{l\times l_2}$, $R_1(t)_{m_1\times m}$, *and* $R_2(t)_{m_2\times m}$ $(m \le \min(m_1, m_2)$, $l \le \min(l_1, l_2))$ *such that*

$$S_1(t)H_1(t,\tau)R_1(\tau) = S_2(t)H_2(t,\tau)R_2(\tau) \quad \forall t, \tau \in [t_a, t_b], t \ge \tau, \tag{31}$$

where $H_1(t,\tau)$ *and* $H_2(t,\tau)$ *denote the impulse responses of* $\mathbf{S}_1$ *and* $\mathbf{S}_2$, *respectively.*

We remark that for $S_1(t) = S_2(t) = I$ and $R_1(t) = R_2(t) = I$, systems $\mathbf{S}_1$ and $\mathbf{S}_2$ are zero-state equivalent in the usual sense [20, 25, 23].

THEOREM 5.2. *Systems* $\mathbf{S}$ *and* $\tilde{\mathbf{S}}$ *in* (1), (2) *are zero-state RS-equivalent on* $[t_a, t_b]$ *if* $\mathbf{S} \subset \tilde{\mathbf{S}}$ *on* $[t_a, t_b]$.

Proof. The inclusion relation $c(t)b(\tau) = S(t)\tilde{c}(t)\tilde{b}(\tau)R(\tau)$ from (3) is equivalent to $H(t,\tau) = S(t)\tilde{H}(t,\tau)R(\tau)$, having in mind that $H(t,\tau) = C(t)\Phi(t,\tau)B(\tau)$ and $\tilde{H}(t,\tau) = \tilde{C}(t)\tilde{\Phi}(t,\tau)\tilde{B}(\tau)$, and that $l \le \tilde{l}$ and $m \le \tilde{m}$. □

Thus, for $S_1(t) = S_2(t) = I$ and $R_1(t) = R_2(t) = I$, expansions and contractions are different realizations of a given impulse response. In this sense, as noted in [18] for the time-invariant case, they can be regarded as equivalent transformations not requiring preservation of dimensionality.

THEOREM 5.3. *Two systems* $\mathbf{S}_1$ *and* $\mathbf{S}_2$ *represented by* (29) *and* (30) *are zero-state RS-equivalent on* $[t_a, t_b]$ *if they have a common contraction* $\mathbf{S}$ *on* $[t_a, t_b]$.

Proof. Assume that $\mathbf{S} \subset \mathbf{S}_1$ with quadruplet $(U_1(t), V_1(t), R_1(t), S_1(t))$, and $\mathbf{S} \subset \mathbf{S}_2$ with quadruplet $(U_2(t), V_2(t), R_2(t), S_2(t))$. Then, according to (3),

$$S_1(t)C_1(t)\Phi_1(t,\tau)B_1(\tau)R_1(\tau) = S_2(t)C_2(t)\Phi_2(t,\tau)B_2(\tau)R_2(\tau) = C(t)\Phi(t,\tau)B(\tau), \tag{32}$$

that is, $\mathbf{S}_1$ and $\mathbf{S}_2$ are zero-state *RS*-equivalent, having in mind that $H_1(t,\tau) = C_1(t)\Phi_1(t,\tau)B_1(\tau)$ and $H_2(t,\tau) = C_2(t)\ \Phi_2(t,\tau)\ B_2(\tau)$. □

Conditions of Theorems 5.2 and 5.3 are not sufficient for inclusion. Assume that $\mathbf{S}_1$ with the impulse response $H_1(t,\tau)$ and $\mathbf{S}_2$ with the impulse response $H_2(t,\tau)$ are zero-state RS-equivalent on $[t_a,t_b]$, and that $\mathbf{S}$ represented by (1) is a realization of the impulse response $H(t,\tau) = S_1(t)H_1(t,\tau)R_1(\tau) = S_2(t)H_2(t,\tau)R_2(\tau)$, which is instantaneously controllable, instantaneously observable, and, therefore, minimal (see [19, 20, 25, 23]). Thus rank $\mathcal{I}(t) = n$ and rank $\mathcal{O}(t) = n$ for all $t \in [t_a,t_b]$, where

$$\begin{aligned} \mathcal{I}(t) &= [B(t)\vdots F_1(t;B(t))\vdots \ldots \vdots F_{n-1}(t;B(t))], \\ \mathcal{O}(t) &= [C(t)^T\vdots G_1(t;C(t))^T\vdots \ldots \vdots G_{n-1}(t;C(t))^T]^T, \end{aligned} \tag{33}$$

with $F_i(t;B(t))$ defined by (12) and (13), while $G_0(t;C(t)) = C(t)$ and $G_i(t;C(t)) = G_{i-1}(t;C(t))A(t) + \dot{G}(t;C(t))$, $i = 1,2,\ldots$. Successive differentiation gives

$$\begin{aligned} &\frac{\partial^{i+j}}{\partial t^i \partial \tau^j} C_k(t)\Phi_k(t,\tau)B_k(\tau) = G_i^k(t;C_k(t))\Phi_k(t,\tau)F_j^k(\tau;B_k(\tau)), \\ &\frac{\partial^{i+j}}{\partial t^i \partial \tau^j} C(t)\Phi(t,\tau)B(\tau) = G_i(t;C(t))\Phi(t,\tau)F_j(\tau;B(\tau)) \qquad (k=1,2), \end{aligned} \tag{34}$$

where $F_j^k(t;B_k(t))$ and $G_i^k(t;C_k(t))$ represent the constituent blocks of the controllability and observability matrices $\mathcal{I}_k(t)$ and $\mathcal{O}_k(t)$ of $\mathbf{S}_k$, $k = 1,2$, according to (33). Therefore,

$$\mathcal{O}(t)\Phi(t,\tau)\mathcal{C}(\tau) = S_1(t)\mathcal{O}_1(t)\Phi_1(t,\tau)\mathcal{C}_1(\tau)R_1(\tau) = S_2(t)\mathcal{O}_2(t)\Phi_2(t,\tau)\mathcal{C}_2(\tau)R_2(\tau). \tag{35}$$

Matrices $\mathcal{I}(t)$ and $\mathcal{O}(t)$ have full column and row rank, respectively, for all $t \in [t_a,t_b]$, implying the existence of both the left inverse $\mathcal{O}(t)^L$ and the right inverse $\mathcal{I}(t)^R$. Moreover, it follows from (35) for $\tau = t$ that if $\bar{V}_k(t) = \mathcal{I}_k(t)R_k(t)\mathcal{I}(t)^R$, then $\bar{U}_k(t) = \mathcal{O}(t)^L S_k(t)\mathcal{O}_k(t)$ satisfies $\bar{U}_k(t)\bar{V}_k(t) = I$. Therefore, (35) implies

$$\begin{aligned} \Phi(t,\tau) = \bar{U}_k(t)\Phi_k(t,\tau)\bar{V}_k(\tau), \qquad \Phi(t,\tau)B(\tau) &= \bar{U}_k(t)\Phi_k(t,\tau)B_k(\tau)R_k(\tau), \\ C(t)\Phi(t,\tau) &= S_k(t)C_k(t)\Phi_k(t,\tau)\bar{V}_k(\tau), \\ C(t)\Phi(t,\tau)B(\tau) &= S_k(t)C_k(t)\Phi_k(t,\tau)B_k(\tau)R_k(\tau), \end{aligned} \tag{36}$$

$k = 1,2$. Obviously, according to (3), $\mathbf{S} \subset \mathbf{S}_k$ with the quadruplets $(\bar{U}_k(t), \bar{V}_k(t), R_k(t), S_k(t))$, $k = 1,2$. This conclusion represents an extension to the time-varying case of the result obtained for the time-invariant case in [18].

6. State-feedback contractibility. The problem of inclusion of systems with feedback structure is important because in decentralized control applications it is necessary to carry out feedback control design in the expanded space, contract the obtained control law, and implement it in the original system (see, for example, [14, 29, 31]). Alternatively, a model-reduction scheme can be used to simplify the feedback design; then the obtained control law must be expanded before implementation [26, 8].

Consider the systems $\mathbf{S}$ and $\tilde{\mathbf{S}}$ under the time-varying state feedback defined by

$$\mathbf{C}\text{:}\quad u(t) = K(t)x(t) + r(t), \qquad \tilde{\mathbf{C}}\text{:}\quad \tilde{u}(t) = \tilde{K}(t)\tilde{x}(t) + \tilde{r}(t), \tag{37}$$

where $r(t)$ and $\tilde{r}(t)$ are reference inputs. Define the closed-loop systems by the corresponding triplets of matrices: $\mathbf{S}_f = (A_f(t), B(t), C(t))$ and $\tilde{\mathbf{S}}_f = (\tilde{A}_f(t), \tilde{B}(t), \tilde{C}(t))$, where $A_f(t) = A(t) + B(t)K(t)$ and $\tilde{A}_f(t) = \tilde{A}(t) + \tilde{B}(t)\tilde{K}(t)$. Obviously, $\mathbf{S}_f \subset \tilde{\mathbf{S}}_f$

on $[t_a, t_b]$ iff the conditions of Theorem 2.3 are satisfied, with the transition matrices $\Phi_f(t,\tau)$ and $\tilde{\Phi}_f(t,\tau)$ for $\mathbf{S}_f$ and $\tilde{\mathbf{S}}_f$, respectively. This formulation does not allow, however, getting explicit conditions for $K(t)$ and $\tilde{K}(t)$ to satisfy $\mathbf{S}_f \subset \tilde{\mathbf{S}}_f$, suitable for design purposes. However, sufficient conditions for controller contractibility (expandability) can be formulated starting from the following definition.

DEFINITION 6.1. *Controller $\tilde{\mathbf{C}}$ is contractible to the controller $\mathbf{C}$ (or $\mathbf{C}$ is expandable to $\tilde{\mathbf{C}}$) if the condition $(C1) \vee (C2)$ holds on $[t_a, t_b]$, where*

$$(C1)\colon \exists (U(t), V(t), R(t), S(t))\ \{x_0, u\} \Rightarrow \{\tilde{x}, \tilde{y}\} \wedge (R(t)K(t)x(t) = \tilde{K}(t)\tilde{x}(t)), \tag{38}$$

$$(C2)\colon \exists (U(t), V(t), Q(t), S(t))\ \{x_0, \tilde{u}\} \Rightarrow \{\tilde{x}, \tilde{y}\} \wedge (K(t)x(t) = Q(t)\tilde{K}(t)\tilde{x}(t)). \tag{39}$$

THEOREM 6.2. *$\tilde{\mathbf{C}}$ is contractible to $\mathbf{C}$ on $[t_a, t_b]$ iff the condition $(D0) \wedge [(D1) \vee (D2)]$ holds for all $t_0, \tau, t \in [t_a, t_b]$, $t_0 \le \tau \le t$:*

$$(D0)\colon \quad \mu(t)\nu(t_0) = I, \qquad c(t) = S(t)\tilde{c}(t)\nu(t_0). \tag{40}$$

$$\begin{aligned} (D1)\colon \quad & b(\tau) = \mu(t)\tilde{b}(\tau)R(\tau), \quad c(t)b(\tau) = S(t)\tilde{c}(t)\tilde{b}(\tau)R(\tau), \\ & R(t)K(t)\Phi(t,t_0) = \tilde{K}(t)\tilde{\Phi}(t,t_0)V(t_0), \\ & R(t)K(t)\Phi(t,\tau)B(\tau) = \tilde{K}(t)\tilde{\Phi}(t,\tau)\tilde{B}(\tau)R(\tau). \end{aligned} \tag{41}$$

$$\begin{aligned} (D2)\colon \quad & b(\tau)Q(\tau) = \mu(t)\tilde{b}(\tau), \quad c(t)b(\tau)Q(\tau) = S(t)\tilde{c}(t)\tilde{b}(\tau), \\ & K(t)\Phi(t,t_0) = Q(t)\tilde{K}(t)\tilde{\Phi}(t,t_0)V(t_0), \\ & K(t)\Phi(t,\tau)B(\tau)Q(\tau) = Q(t)\tilde{K}(t)\tilde{\Phi}(t,\tau)\tilde{B}(\tau). \end{aligned} \tag{42}$$

Proof. The proof follows directly from the conditions $(C1)$ and $(C2)$ in Definition 6.1, using the methodology of the proof of Theorem 2.3. In the case of $(C1)$, condition $(D0)$, together with the first two relations in (41), represents the inclusion conditions for $\mathbf{S}$ and $\tilde{\mathbf{S}}$, according to Theorem 2.3, while the remaining conditions in $(D1)$ follow from $R(t)K(t)x(t) = \tilde{K}(t)\tilde{x}(t)$ in (38). Conditions $(D0) \wedge (D2)$ follow from $C(2)$ in a similar way. Hence we have the result. □

It is very important to notice that contractibility in the sense of Definition 6.1 and Theorem 6.2 implies inclusion of the corresponding closed-loop systems. Indeed, condition $(C2)$, for example, ensures that, for any x_0 and $\tilde{u}_{[t_0,t]}$, $x(t; t_0, x_0, u_{[t_0,t]}) = U(t)\tilde{x}(t; t_0, \tilde{x}_0, \tilde{u}_{[t_0,t]})$, where $u_{[t_0,t]}$ is generated by $u(t) = Q(t)\tilde{u}(t)$ for all $t \in [t_0, t]$, and $\tilde{x}_0 = V(t_0)x_0$. Therefore, the input $\tilde{u}(t) = \tilde{K}(t)\tilde{x}(t)$ is just one particular choice satisfying the conditions for $\mathbf{S}_f \subset \tilde{\mathbf{S}}_f$, provided $u(t) = K(t)x(t) = Q(t)\tilde{K}(t)\tilde{x}(t)$. We have a completely analogous situation with $(C1)$. In both cases, $\mathbf{S} \subset \tilde{\mathbf{S}}$, while the additional conditions for $K(t)$ and $\tilde{K}(t)$ can be considered as the regulator output inclusion conditions (if $K(t)$ and $\tilde{K}(t)$ are considered as output matrices and $Q(t)$ and $R(t)$ as the corresponding expansion-contraction maps). Consequently, one of the important implications of contractibility is the preservation of stability. It follows from (3) that, in general,

$$\mathbf{S}_f \subset \tilde{\mathbf{S}}_f \quad \Rightarrow \quad \|\Phi_f(t,t_0)\| \le \|U(t)\|\,\|\tilde{\Phi}_f(t,t_0)\|\,\|V(t_0)\| \tag{43}$$

so that $\|\tilde{\Phi}_f(t,t_0)\| \le \tilde{M} < \infty \Rightarrow \|\Phi_f(t,t_0)\| \le M < \infty$; that is, the stability of $\tilde{\mathbf{S}}_f$ implies the stability of $\mathbf{S}_f$, provided $(\|U(t)\| \le M_u < \infty) \wedge (\|V(t_0)\| \le M_v < \infty)$ for all $t_0, t \in [t_a, t_b], t \ge t_0$.

The methodology of Corollary 2.5 now provides the following corollary.

COROLLARY 6.3. *Assume that* $\tilde{\mathbf{C}}$ *is contractible to* $\mathbf{C}$ *and that all the matrices in* (1) *and* (2), *the expansion-contraction matrices, and matrices* $K(t)$ *and* $\tilde{K}(t)$ *are continuously differentiable a sufficient number of times. Then either*

$$\begin{aligned} R(t)K(t)F_i(t;I) &= \tilde{K}(t)\tilde{F}_i(t;V(t)), \\ R(t)K(t)F_i(t;B(t)) &= \tilde{K}(t)\tilde{F}_i(t;\tilde{B}(t)R(t)) \end{aligned} \tag{44}$$

or

$$\begin{aligned} K(t)F_i(t;I) &= Q(t)\tilde{K}(t)\tilde{F}_i(t;V(t)), \\ K(t)F_i(t;B(t)Q(t)) &= Q(t)\tilde{K}(t)\tilde{F}_i(t;\tilde{B}(t)R(t)). \end{aligned} \tag{45}$$

In the case of restrictions and aggregations the contractibility conditions become the following.

THEOREM 6.4. $\tilde{\mathbf{C}}$ *is contractible to* $\mathbf{C}$ *on* $[t_a, t_b]$ *if one of the following conditions is satisfied for all* $t \in [t_a, t_b]$*:*

$$\begin{aligned} &(R1)\text{:} \quad (\mathbf{S} \overset{R(a)}{\subset} \tilde{\mathbf{S}}) \wedge (R(t)K(t) = \tilde{K}(t)V(t)), \\ &(R2)\text{:} \quad (\mathbf{S} \overset{R(b)}{\subset} \tilde{\mathbf{S}}) \wedge (R(t)K(t) = \tilde{K}(t)V(t)), \\ &(R3)\text{:} \quad (\mathbf{S} \overset{R(c)}{\subset} \tilde{\mathbf{S}}) \wedge (K(t) = Q(t)\tilde{K}(t)V(t)), \\ &(R4)\text{:} \quad (\mathbf{S} \overset{R(d)}{\subset} \tilde{\mathbf{S}}) \wedge (K(t) = Q(t)\tilde{K}(t)V(t)). \end{aligned}$$

THEOREM 6.5. $\tilde{\mathbf{C}}$ *is contractible to* $\mathbf{C}$ *on* $[t_a, t_b]$ *if one of the following conditions is satisfied for all* $t \in [t_a, t_b]$*:*

$$\begin{aligned} &(A1)\text{:} \quad (\mathbf{S} \overset{A(a)}{\subset} \tilde{\mathbf{S}}) \wedge (K(t)U(t) = Q(t)\tilde{K}(t)), \\ &(A2)\text{:} \quad (\mathbf{S} \overset{A(b)}{\subset} \tilde{\mathbf{S}}) \wedge (R(t)K(t)U(t) = \tilde{K}(t)), \\ &(A3)\text{:} \quad (\mathbf{S} \overset{A(c)}{\subset} \tilde{\mathbf{S}}) \wedge (K(t)U(t) = Q(t)\tilde{K}(t)), \\ &(A4)\text{:} \quad (\mathbf{S} \overset{A(d)}{\subset} \tilde{\mathbf{S}}) \wedge (R(t)K(t)U(t) = \tilde{K}(t)). \end{aligned}$$

The inclusion conditions obtained in Theorems 6.4 and 6.5 are completely analogous to the conditions derived in [35] for the time-invariant case and result, essentially, from different combinations of input/output expansions-contractions. It should also be noted that all the conditions from Theorems 6.4 and 6.5 satisfy the contractibility conditions from Theorem 6.2.

Example 6.6. The initial stages of the decentralized overlapping control design in the time-varying case can follow essentially the same lines as in the time-invariant case. Namely, the expansion map, leading to a decomposition of time-varying subsystems, remains, in general, in the same time-invariant form as in [16, 29, 33, 35]. Take, for example, a feedback-linearized time-varying model of a platoon of automotive vehicles, according to [34], in which the ith vehicle is described by

$$\begin{aligned} \dot{d}_i &= v_{i-1} - v_i, \\ \dot{v}_i &= a_i, \\ \dot{a}_i &= -\tau_i(t)^{-1}a_i + \tau_i(t)^{-1}u_i, \end{aligned} \tag{46}$$

where $d_i = x_{i-1} - x_i$ is the distance between two consecutive vehicles, x_{i-1} and x_i being their positions, v_i and a_i are the velocity and acceleration, respectively, u_i is the

input signal chosen to make the closed loop satisfy certain performance criteria, and $\tau_i(t)$ is the time-varying time-constant of the engine (depending, in general, on the velocity) . After forming the state-space model for the platoon with the overall state $X^T = (d_1, v_1, a_1, d_2, v_2, a_2, \ldots, d_N, v_N, a_N)$ and overall input $u^T = (u_1, u_2, \ldots, u_N)$, where N is the number of vehicles, and applying the time-invariant expansions

$$V^T = \begin{bmatrix} I_{3\times3} & 0 & 0 & 0 & 0 & \ldots & 0 \\ 0 & I_{2\times2} & I_{2\times2} & 0 & & & \\ 0 & 0 & 0 & I_{3\times3} & & & \\ & & & & & \ldots & \\ & & & & & & I_{3\times3} \end{bmatrix}$$

and

$$R^T = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & \ldots & 0 \\ 0 & 1 & 1 & 0 & & & \\ 0 & 0 & 0 & 1 & & & \\ & & & & & \ldots & \\ & & & & & & 1 \end{bmatrix},$$

respectively, one obtains the following model in the expanded space:

$$\tilde{\mathbf{S}}: \quad \begin{bmatrix} \dot{\xi}_1 \\ \dot{\xi}_2 \\ \vdots \\ \dot{\xi}_N \end{bmatrix} = \begin{bmatrix} A_1(t) & 0 & \ldots & 0 \\ 0 & A_2(t) & \ldots & \\ & & \ldots & \\ 0 & & & A_N(t) \end{bmatrix} \begin{bmatrix} \xi_1 \\ \xi_2 \\ \vdots \\ \xi_N \end{bmatrix} + \begin{bmatrix} B_1(t) & 0 & \ldots & 0 \\ 0 & B_2(t) & & \\ & & \ldots & \\ 0 & & & B_N(t) \end{bmatrix} \begin{bmatrix} \zeta_1 \\ \zeta_2 \\ \vdots \\ \zeta_N \end{bmatrix}, \tag{47}$$

in which the *overlapping* subsystems are defined by

$$\mathbf{S}_i: \quad \dot{\xi}_i = A_i(t)\xi_i + B_i(t)\zeta_i = \begin{bmatrix} A_i^l(t) & 0 \\ \bar{A}_d & A_i^v(t) \end{bmatrix} \xi_i + \begin{bmatrix} B_i^l(t) & 0 \\ 0 & B_i^v(t) \end{bmatrix} \zeta_i, \tag{48}$$

where $\xi_i^T = (v_{i-1}, a_{i-1}, d_i, v_i, a_i)$ is the state vector of the ith subsystem, $\zeta_i^T = (u_{i-1}, u_i)$ represents its control vector, and

$$A_i^l(t) = \begin{bmatrix} 0 & 1 \\ 0 & \tau_i(t)^{-1} \end{bmatrix}, \quad \bar{A}_d^T = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad B_i^l(t) = \begin{bmatrix} 0 \\ \tau_i(t)^{-1} \end{bmatrix},$$

$$A_i^v(t) = \begin{bmatrix} 0 & -1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -\tau_i(t)^{-1} \end{bmatrix}, \quad B_i^v(t) = \begin{bmatrix} 0 \\ 0 \\ \tau_i(t)^{-1} \end{bmatrix},$$

$i = 1, \ldots, N$. A decentralized time-varying feedback control law can now be designed for the decoupled subsystems. The resulting control law can then be contracted for implementation by using the expansion-contraction matrices as in [16, 18, 29, 34, 35].

Example 6.7. In the case of the reduced order design, time-varying expansions-contractions bring new possibilities; see [26] for the time-invariant case. Consider, for example, the time-varying systems

$$\tilde{\mathbf{S}}: \quad \dot{\tilde{x}} = \begin{bmatrix} 0 & \frac{1}{2}\dot{\alpha}(t) \\ 2 & \alpha(t) \end{bmatrix} \tilde{x} + \begin{bmatrix} 1 \\ 1 \end{bmatrix} u \quad (\tilde{x}(t_0) = \tilde{x}_0), \quad y = \begin{bmatrix} 1 & \frac{1}{2}\alpha(t) \end{bmatrix} \tilde{x}, \tag{49}$$

$$\mathbf{S}: \quad \dot{x} = \alpha(t)x + \left(1 + \frac{1}{2}\alpha(t)\right) u \quad (x(t_0) = x_0), \quad y = x, \tag{50}$$

where $\alpha(t)$ is a continuously differentiable function. It is easy to verify that $\mathbf{S} \overset{A(.)}{\subset} \tilde{\mathbf{S}}$ with the triplet $(U(t) = [1 \ \ \frac{1}{2}\alpha(t)], Q(t) = 1, S(t) = 1)$. Assume that the control design is done in the space of $\mathbf{S}$ and that the resulting feedback gain (possibly optimal in some sense) is $K(t) = k(t)$. Then, according to the above considerations, its expansion to the space of $\tilde{\mathbf{S}}$ should be given by $\tilde{K}(t) = k(t)U(t) = [k(t) \ \ \frac{1}{2}k(t)\alpha(t)]$.

7. Conclusion. This paper presents a unified picture of basic aspects of the inclusion concept applied to dynamic time-varying linear continuous-time systems. Starting from the main definitions, involving time-varying expansions-contractions of inputs, states, and outputs of systems under consideration (previous work has been concerned exclusively with time-invariant expansions-contractions), we expressed inclusion conditions in terms of system characteristics. A set of inclusion conditions has been derived involving time-varying system matrices and their derivatives. Restrictions and aggregations of different types have been introduced, covering different combinations of time-varying input/state/output expansions-contractions. Fundamental aspects of restrictions and aggregations are made evident via a specific equivalent representation of the expanded system model. The main theoretical contribution of the paper is contained in the theorem dealing with the composition property. By that any input/state/output inclusion relation on a given time-interval can be decomposed into a specific sequence of pairs of input/state/output restrictions and input/state/output aggregations. The proof uses geometric arguments in the context of time-variability of system characteristics and expansion-contraction maps. The presentation of basic features of the time-varying inclusion covers the problem of zero-state equivalence. It has been proved, extending the approach in [18] to time-varying systems, that two systems are zero-state equivalent on a given time-interval if they have a common contraction on the same interval. The paper also encompasses the practically important problem of contractibility (expandability) of time-varying state-feedback controllers. An indication is given of how to approach the problems of overlapping decentralized and reduced order control designs.

Further research should explore a direct application of the above-developed methodology to the inclusion of time-varying observers and dynamic controllers in the context of the inclusion of performance indices (generalizing the existing approaches related to time-invariant systems). It would be especially important to clarify main practical aspects of decentralized overlapping and reduced order control design of time-varying systems. Moreover, the proposed methodology of analysis, which was presented in the context of the composition property, indicates possible applications to switching and hybrid dynamical systems.

VARIATIONAL INCLUSIONS UNDER STATE CONSTRAINTS*

MOULKA TAMZALI-LAFOND†

To my son Ander

Abstract. We extend variational equations of ODEs to nonconvex differential inclusions under state constraints. As an application, we provide a direct proof of the maximum principle of the Pontryagin type for an optimal control problem with state constraints.

Key words. differential inclusions, feasible trajectories, maximum principle, state constraints, variational inclusions

Introduction. Let us consider the differential inclusion

$$x'(t) \in F(t, x(t)), \tag{1}$$

where F is a set-valued map from $[0,T] \times \mathbb{R}^n$ into $\mathbb{R}^n$ and $T > 0$ is given.

We denote by $\mathcal{S}_{[0,T]}(x_0)$ the set of solutions to (1) starting at x_0 and defined on the time interval $[0,T]$.

Investigation of optimization problems is often based on linearization techniques. What should we call linearized inclusion?

For a given trajectory $z \in \mathcal{S}_{[0,T]}(x_0)$, it was suggested in Frankowska [10] to consider the inclusion

$$(**) \begin{cases} w'(t) \in F'(z(t), z'(t)) \cdot w(t) \text{ a.e. in } [0,T], \\ w(0) = 0, \end{cases}$$

where F' denotes a derivative of F at $(z(t), z'(t))$ in a sense we specify later.

It was shown that a solution w to (**) is a limit in $W^{1,1}$ of the difference quotients $\frac{x_h - z}{h}$ when $h \to 0^+$ for some $x_h \in \mathcal{S}_{[0,T]}(x_0)$.

This paper is devoted to an extension of this result to a state constraints case formulated as $x(t) \in K$. Namely, we consider the constrained system

$$\begin{cases} x'(t) \in F(t, x(t)), \\ x(0) = x_0 \ \in C_0, \\ x(t) \in K, \end{cases} \tag{2}$$

where C_0 is a given subset of $\mathbb{R}^n$.

The set of all solutions to (2) defined on $[0,T]$ and starting at some x_0 will be denoted by $\mathcal{S}^K_{[0,T]}(x_0)$.

The main theme of this paper is to replace the above differential inclusion by its "linear approximation" along a trajectory $\overline{x} \in \mathcal{S}^K_{[0,T]}(x_0)$ and to prove an extension of variational equations of ODEs to such a constrained multivalued system.

†Centre de recherche Viabilité - Jeux - Contrôle, E.R.S. 2064, Université Paris IX Dauphine, Place du Maréchal de Lattre de Tassigny, 75775 Paris cedex 16, Paris, France (mtamzali-lafond@yahoo.fr).

The linearized system along $\overline{x}$ is defined by

$$\begin{cases} w'(t) \in \ dF(t, \overline{x}(t), \overline{x}'(t)) \cdot w(t) \text{ a.e. in } [0,T], \\ w(0) = w_0, \\ w(t) \ \in \mathcal{C}(t) \quad \forall t \text{ in } [0,T], \end{cases}$$

where dF denotes the derivative of the set-valued map F with respect to x, whose definition is recalled in section 1, and $\mathcal{C}(t)$ is a family of closed cones contained in tangent to K at $\overline{x}(t)$.

In the case in which K has sufficiently smooth boundary, $\mathcal{C}(t)$ are usual tangent cones to K at $\overline{x}(t)$. When the boundary of K is nonsmooth, we have to compensate for it by refinement of cones, requiring them to satisfy some additional properties.

We prove, in the first part, that for every solution $w(\cdot)$ of the linearized system, there exist trajectories $\overline{x}_h(\cdot)$ of the original system satisfying

$$\frac{\overline{x}_h(\cdot) - \overline{x}(\cdot)}{h} \longrightarrow w(\cdot) \text{ as } h \to 0^+,$$

using recent results of Frankowska–Rampazzo [12] and Frankowska–Vinter [14]. In other words, the linearized system plays the same role as the variational equation in ODE theory. For this reason, it is called variational inclusion. We provide different instances of constraints for which variational inclusion holds true.

In the second part, we apply this result to obtain a direct proof of the maximum principle under state constraints.

Consider the following optimal control problem:

$$\text{Minimize } \varphi(x(T)) \text{ over solutions to } \begin{cases} x'(t) \in F(t, x(t)) \text{ a.e. in } [0,T], \\ x(0) = x_0, \\ x(t) \in K \quad \forall t \in [0,T]. \end{cases}$$

Let $\overline{x}(\cdot)$ be a minimizer issued from $\overline{x}_0$.

To prove the first order necessary condition for optimality, we apply Fermat's rule: at the point of minimum, the derivative of the function φ is nonnegative in the direction of $w(T)$, where $w(\cdot)$ is a solution of the linearized system. That means we obtain the following inequality:

$$\langle \nabla \varphi(\overline{x}(T)), w(T) \rangle \geq 0.$$

Naturally, to derive this inequality, we use the first part of the article.

Next, using duality theory, we give a direct proof of the maximum principle. By direct proof we mean arguments based on linearization of the original system (the so-called variational inclusions).

A very simple and direct proof of the maximum principle for unconstrained control problems can be found in Pallu de la Barriere [17]. It is based on the variational equation of the ODE.

Linearization of differential inclusion for unconstrained problems and applications to maximum principle was studied in Frankowska [10].

The necessary condition for differential inclusion problems has been known for many years. Since linearization arguments are not applicable in the constrained case, different authors applied tools based on different arguments. For instance, for target control problems, Pontryagin and al. [18] used fixed point arguments. Clarke and

Loewen [6] and Vinter and Pappas [24] derived necessary conditions associated with the optimal control problem involving state constraints in the form $g(x(t)) \leq 0$ when the function g is Lipschitzian and using the nonsmooth analysis tools of Clarke [5] and the ε-variational principle of Ekeland [7]. We notice that their proofs are based on the reduction of optimal control problems to the Bolza type calculus of variations problems without state constraints.

Recently, Arutyunov and Aseev [3] have obtained nondegenerate necessary conditions in Hamiltonian form when F has convex images and is locally Lipschitz in both variables. We do not assume here that F is Lipschitz with respect to the time and do not study additional assumptions to be imposed to get nondegenerate necessary conditions. However, Case 1 of the proof of Theorem 4.1 yields that conditions are nondegenerate, while Case 2 does not allow this conclusion. Also, in [3] the proof uses Ekeland's principle applied to a family of auxiliary problems and a limiting procedure.

Rampazzo and Vinter [20] derived necessary conditions to a nonconvex problem in terms of normal cones and a limiting subdifferential. Their results are proved by replacing the original problem by a family of Bolza problems and applying Ekeland's principle.

In the present work, the maximum principle is derived to a nonconvex F coming from a control system differentiable with respect to x. It is formulated in the usual Jacobian form (adjoint equations and the maximum condition). Recall that all these different formulations are not equivalent.

In this paper, we shall use a direct proof based on our variational inclusion and duality arguments.

In contrast to the work of previous authors (except [20]), we do not suppose any hypotheses about the convexity of F which are basic for the earlier results.

This paper is organized as follows: in section 1, we recall some notions of set-valued analysis we are dealing with. In section 2, we study variational inclusion in the space of absolutely continuous functions, under inequality constraints or constraints given by a closed smooth set. In section 3, we present an analogous result in the space of continuous functions $C[0,T]$, and in the cases of both smooth and nonsmooth constraints. Section 4 provides an application to Mayer's problem of optimal control.

1. Preliminaries and notation. Denote by

- $C([0,T];\mathbb{R}^n)$ the space of continuous maps x from $[0,T]$ into $\mathbb{R}^n$, with the norm $\| x \|_C = \sup_{t\in[0,T]} \| x(t) \|$,
- $W^{1,1}([0,T];\mathbb{R}^n)$ the space of absolutely continuous functions x from $[0,T]$ into $\mathbb{R}^n$ with the norm $\| x \|_{W^{1,1}[0,T]} = \| x(0) \| + \int_0^T \| x'(t) \| \, dt$, and
- $L^1([0,T];\mathbb{R}^n)$ the space of Lebesgue-integrable functions x from $[0,T]$ into $\mathbb{R}^n$ with the norm $\| x \|_{L^1} = \int_0^T \| x(t) \| \, dt$.

Consider the differential inclusion $x'(t) \in F(t,x(t))$, $x(0) = x_0$.

A function $x \in W^{1,1}([0,T];\mathbb{R}^n)$ is called a solution if it satisfies (1) almost everywhere in $[0,T]$.

We recall that $\mathcal{S}_{[0,T]}(x_0)$ denotes the set of solutions starting at x_0 and defined on $[0,T]$, and $\mathcal{S}^K_{[0,T]}(x_0)$ denotes the set of all $x \in \mathcal{S}_{[0,T]}(x_0)$ verifying the state constraints $x(t) \in K$ for all $t \in [0,T]$.

Consider next the convexified (relaxed) differential inclusion

$$\begin{cases} x'(t) \in \overline{co} F(t,x(t)) \text{ a.e. in } [0,T], \\ x(0) = x_0, \end{cases} \tag{3}$$

and denote the set of its solutions by $\mathcal{S}^{rel}_{[0,T]}(x_0)$.

We recall that $\overline{co}F$ denotes the closed convex hull of F.

We shall denote by $\mathcal{S}^{rel,K}_{[0,T]}(x_0)$ the set of all solutions to (3) such that $x(t) \in K$ for all $t \in [0,T]$.

Throughout the paper, $\mathcal{B}$ will denote the closed unit ball.

Let $\mathrm{dist}(\cdot, K) : \mathbb{R}^n \to R$ be the Euclidean distance function from a set $K \subset \mathbb{R}^n$:

$$\mathrm{dist}(x,K) = \inf\{||x-y|| : y \in K\}.$$

We recall the following definitions.

DEFINITION 1.1. *Let $K \subset \mathbb{R}^n$ and $x \in \overline{K}$ (the closure of K).*

- *Contingent cone to K at x:*

$$T_K(x) = \left\{v \in \mathbb{R}^n : \exists h_i \to 0^+ \ \exists v_i \to v \text{ such that } x + h_i v_i \in K\right\}$$

or, equivalently,

$$T_K(x) = \left\{v \in \mathbb{R}^n : \liminf_{h \to 0^+} \mathrm{dist}\left(v, \frac{K-x}{h}\right) = 0\right\}.$$

- *Intermediate (or adjacent) cone to K at x:*

$$I_K(x) = \left\{v \in \mathbb{R}^n : \forall h_i \to 0^+ \ \exists v_i \to v \text{ such that } x + h_i v_i \in K\right\}$$

or, equivalently,

$$I_K(x) = \left\{v \in \mathbb{R}^n : \lim_{h \to 0^+} \mathrm{dist}\left(v, \frac{K-x}{h}\right) = 0\right\}.$$

- *Clarke's tangent cone to K at x:*

$$C_K(x) = \left\{v \in \mathbb{R}^n : \forall h_i \to 0^+ \ \forall y_i \to x \text{ in } K, \exists v_i \to v \text{ such that } y_i + h_i v_i \in K\right\}$$

or, equivalently,

$$C_K(x) = \left\{v \in \mathbb{R}^n : \lim_{\substack{h \to 0^+ \\ y \to x \text{ in } K}} \mathrm{dist}\left(v, \frac{K-y}{h}\right) = 0\right\}.$$

DEFINITION 1.2. *Consider a set-valued map F, from a finite dimensional space X to a finite dimensional space Y, Lipschitzian around x, and let $(x,y) \in GraphF$. The adjacent derivative of F at (x,y) is the set-valued map $dF(x,y)$ from X into subsets of Y defined by*

$$v \in dF(x,y) \cdot u \Longleftrightarrow \lim_{h \to 0^+} \mathrm{dist}\left(v, \frac{F(x+hu)-y}{h}\right) = 0;$$

see Aubin–Frankowska [2] for properties of set-valued derivatives.

In the next sections, we shall impose the following hypotheses on F.

$H.1$

(i) *For all $(t,x) \in [0,T] \times \mathbb{R}^n$, $F(t,x)$ is a nonempty closed set and $F(\cdot,x)$ is measurable for each $x \in \mathbb{R}^n$.*

(ii) *For some $c > 0$, for all $(t,x) \in [0,T] \times \mathbb{R}^n$, $F(t,x) \subset c(||x|| + 1)\mathcal{B}$.*

(iii) *$\exists\, k_F \in L^1([0,T]; \mathbb{R}_+)$ such that for all $x,\ x' \in \mathbb{R}^n$, and $t \in [0,T]$, $F(t,x) \subset F(t,x') + k_F(t)||x - x'||\,\mathcal{B}$.*

We recall that the celebrated Filippov's Theorem (see [8]) provides an estimate of the distance from an absolutely continuous function y to the set $\mathcal{S}_{[t_0,T]}(x_0)$ under assumptions $H.1$. It also allows us to prove the following Filippov–Wazewski relaxation theorem from [12].

THEOREM 1.3 (relaxation theorem). *Consider a set valued map $F : [t_0, T]\times\mathbb{R}^n \rightsquigarrow \mathbb{R}^n$ satisfying $H.1$, and let y be a solution to the relaxed inclusion* (3). *Then for every $\mu > 0$ there exists a solution $x \in \mathcal{S}_{[t_0,T]}(x_0)$ such that $\|x - y\|_C \leq \mu$.*

2. Variational inclusion in $W^{1,1}([0,T];\mathbb{R}^n)$.

2.1. Inequality constraints. Let $g : \mathbb{R}^n \longrightarrow \mathbb{R}^m$ be a $C^{1,1}$ function. ($C^{1,1}$ denotes the class of C^1 functions with locally Lipschitz continuous gradients).

Set

$$K = \{x \in \mathbb{R}^n \ : \ g(x) \leq 0\}.$$

Fix $\overline{x}_0 \in C_0$ and $\overline{x} \in \mathcal{S}^K_{[0,T]}(\overline{x}_0)$.

We consider the linearized system along $\overline{x}$, which is formulated as the differential inclusion

$$(P) \quad \begin{cases} w'(t) \in dF(t, \overline{x}(t), \overline{x}'(t)) \cdot w(t) \text{ a.e. in } [0,T], \\ w(0) = w_0 \in I_{C_0}(\overline{x}_0), \\ w(t) \in I_K(\overline{x}(t)), \quad \forall t \text{ in } [0,T], \end{cases}$$

where $dF(t, \overline{x}(t), \overline{x}'(t))$ denotes the partial derivative of $F(t,\cdot)$ at $(\overline{x}(t), \overline{x}'(t))$.

We introduce the constraint qualification (of Mangasarian–Fromowitz type)

$$H.2 \left| \begin{array}{l} \textit{For all } R > 0, \textit{ there exists } \alpha > 0 \textit{ such that} \\ \min_{v\in F(t,x)} \nabla g(x) \cdot v < -\alpha \textit{ for } x \in \mathcal{B}(0,R) \cap \partial K \textit{ and a.e. } t \in [0,T], \end{array} \right.$$

where ∂K denotes the boundary of K.

This assumption implies, in particular, that for all t satisfying $g(\overline{x}(t)) = 0$, we have

$$I_K(\overline{x}(t)) = \{v \ : \ \langle \nabla g(\overline{x}(t)), v\rangle \leq 0\} \tag{4}$$

and that $\mathrm{Int}\{x : g(x) \leq 0\} \neq \emptyset$.

Our main theorem is the following.

THEOREM 2.1. *Fix $\overline{x}_0 \in C_0$ and $\overline{x} \in \mathcal{S}^K_{[0,T]}(\overline{x}_0)$. Assume that $H.1$ and $H.2$ are verified, and let $w(\cdot)$ be a solution to (P). Then, for all $h_i \to 0^+$ and every sequence $\{w_i\}$ such that $\lim_{i\to+\infty} w_i = w_0$ and $\overline{x}_0 + h_i w_i \in K$, there exist solutions $\overline{x}_i \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$ such that*

$$\frac{\overline{x}_i(\cdot) - \overline{x}(\cdot)}{h_i} \longrightarrow w(\cdot) \textit{ in } W^{1,1}([0,T];\mathbb{R}^n) \textit{ when } i \to +\infty.$$

Remark. From the proof provided below, it follows that the assumption on g may be weakened. Namely, it is enough to assume that $g \in C^{1,1}$ on a neighborhood of ∂K and g is continuous on $\mathbb{R}^n$.

Proof of Theorem 2.1.

Step 1. We prove first that, for all solutions $w(\cdot)$ of (P), there exists a sequence x_i such that $x_i \in \mathcal{S}_{[0,T]}(\overline{x}_0 + h_i w_i)$ and $\frac{x_i(\cdot)-\overline{x}(\cdot)}{h_i} \longrightarrow w(\cdot)$ in $W^{1,1}$.

To this aim, we mimic the proof from [2, p. 405], by making a few refinements (namely, inequality (8) below) that would allow us to prove our theorem.

Let $w(\cdot)$ be a solution of (P). Let $w_i \to w_0$ when $i \to +\infty$.

By the very definition of the adjacent derivative, for almost all $t \in [0,T]$,

$$\lim_{i\to\infty} \operatorname{dist}\left(w'(t), \frac{F(t,\overline{x}(t)+h_i w(t)) - \overline{x}'(t)}{h_i}\right) = 0. \tag{5}$$

Moreover, since $\overline{x}'(t) \in F(t,\overline{x}(t))$ almost everywhere in [0,T] and by $H.1$, for all sufficiently large i and for almost every $t \in [0,T]$

$$\operatorname{dist}(\overline{x}'(t)+h_i w'(t), F(t,\overline{x}(t)+h_i w(t))) \le h_i(||w'(t)|| + k_F(t)||w(t)||). \tag{6}$$

Set $y_i(t) = h_i w_i + \overline{x}(t) + h_i(w(t) - w_0)$. Then $y_i'(t) = \overline{x}'(t) + h_i w'(t)$, and $y_i(0) = \overline{x}(0) + h_i w_i$.

We want to estimate $\operatorname{dist}(y_i'(t), F(t,y_i(t)))$. Notice that, because of the Lipschitzianity of F,

$$\begin{aligned}&\operatorname{dist}(y_i'(t), F(t,y_i(t))) \le \operatorname{dist}(y_i'(t), F(t,\overline{x}(t)+h_i w(t)))\\ &+k_F(t)h_i||w_i - w_0||.\end{aligned} \tag{7}$$

By (6), it follows that

$$\operatorname{dist}(y_i'(t), F(t,y_i(t))) \le h_i(||w'(t)|| + k_F(t)||w(t)||) + k_F(t)h_i||w_i - w_0||. \tag{8}$$

Then (5), (7), and the Lebesgue dominated convergence theorem yield

$$\int_0^T \operatorname{dist}(y_i'(t), F(t,y_i(t)))dt = \alpha(h_i),$$

$$\text{where } \lim_{h_i\to 0^+} \frac{\alpha(h_i)}{h_i} = 0.$$

Set

$$\begin{cases} \gamma_i(t) = \operatorname{dist}(y_i'(t), F(t,y_i(t))), \\ \eta_i(t) = \int_0^t \gamma_i(s)\exp(\int_s^t k(\nu)d\nu)ds. \end{cases} \tag{9}$$

By Filippov's existence theorem [8] applied to arcs y_i, there exist solutions $x_i \in \mathcal{S}_{[0,T]}(\overline{x}(0)+h_i w_i)$ such that

$$||x_i(t) - y_i(t)|| \le \eta_i(t),$$

$$||x_i'(t) - y_i'(t)|| \le k_F(t)\eta_i(t) + \gamma_i(t) \text{ a.e. in } [0,T].$$

Hence

$$\frac{x_i(\cdot) - y_i(\cdot)}{h_i} \longrightarrow 0 \text{ in } W^{1,1}.$$

Since $\frac{x_i(0)-\overline{x}(0)}{h_i} = w_i \longrightarrow w_0 = w(0)$, this implies that

$$\lim_{i\to+\infty} \frac{x_i(\cdot) - \overline{x}(\cdot)}{h_i} = w(\cdot) \text{ in } W^{1,1} \text{ on } [0,T]. \tag{10}$$

We can easily see that there exists a constant $M \geq 0$ such that

$$||x_i' - \overline{x}' - h_i w'||_{L^1} \leq M \cdot \alpha(h_i)$$

and

$$||x_i(t) - \overline{x}(t) \ - \ h_i w(t)|| \ \leq \ h_i||w_i - w_0|| + M \cdot \alpha(h_i). \tag{11}$$

The constructed solutions $x_i(\cdot)$ do not necessarily remain in K.

Step 2. Let us introduce the following notation:

$$g^+(x) \ = \ \max\left(g(x) \ , \ 0\right).$$

We shall prove the existence of solutions $\overline{x}_i \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$ satisfying for some $L > 0$ and all $i \geq 1$

$$||\overline{x}_i - x_i||_{W^{1,1}([0,T])} \leq \ L \cdot \max_{t\in[0,T]} \ g^+(x_i(t)). \tag{12}$$

We recall the neighboring feasible trajectories theorem from [14].

THEOREM 2.2 (Frankowska–Vinter). *Assume that H.*1 *and H.*2 *are satisfied. Let* $\widehat{x}_0 \in K$. *Then there exists a constant L, which depends on* $|\widehat{x}_0|$, *with the following property: given any solution* $\widehat{x} \ \in \ \mathcal{S}_{[0,T]}(\widehat{x}_0)$, *a solution* $x \ \in \mathcal{S}^K_{[0,T]}(\widehat{x}_0)$ *can be found such that* $||x - \widehat{x}||_{W^{1,1}([0,T])} \leq \ L \cdot \max_{t\in[0,T]} g^+(\widehat{x}(t))$.

We apply this theorem by taking $\widehat{x} = x_i$ and $\widehat{x}_0 = \overline{x}_0 + h_i w_i$. We get then the existence of $\overline{x}_i(\cdot)$ as claimed.

Step 3. Let us show that the quotients $\frac{\overline{x}_i(.) - \overline{x}(.)}{h_i}$ converge to $w(\cdot)$ in $W^{1,1}$ when $h_i \to 0^+$.

Because of (10), it remains to prove that

$$\frac{\overline{x}_i(\cdot) - x_i(\cdot)}{h_i} \longrightarrow 0 \text{ in } W^{1,1}.$$

For all $t \in [0,T]$, we have to estimate $g^+(x_i(t))$.

Fix any $\varepsilon > 0$, and set

$$Q_\varepsilon = \{s \in [0,T] : \langle \nabla g(\overline{x}(s)), w(s)\rangle \ < \varepsilon\}.$$

Let Q^C_ε denote its complement.

Observe that for all $s \in [0,T]$ such that $g(\overline{x}(s)) = 0$, by (4) we have $s \in Q_\varepsilon$.

- *Case* A. If $t \in Q^C_\varepsilon$, since $g(\overline{x}(\cdot))$ is continuous, we deduce, using (4), that there exists $\delta > 0$ such that

$$\forall \ s \in Q^C_\varepsilon \ , \ g(\overline{x}(s)) \leq -\delta < 0.$$

For i large enough, since Q^C_ε is compact and since $x_i \to \overline{x}$ uniformly, we have

$$g(x_i(s)) \leq -\frac{\delta}{2} < 0.$$

Then we obtain in this case

$$\frac{1}{h_i} \sup_{t\in Q^C_\varepsilon} g^+(x_i(t)) = 0.$$

- *Case* B. If $t \in Q_\varepsilon$, we have

$$g(x_i(t)) \;=\; g(\overline{x}(t)) \;+\; \langle \nabla g(\overline{x}(t)) \,,\; x_i(t) - \overline{x}(t) \rangle \;+\; \theta(|x_i(t) - \overline{x}(t)|),$$

where $\frac{\theta(r)}{r} \to 0$ as $r \to 0$:

$$\begin{aligned} g(x_i(t)) \;=\; g(\overline{x}(t)) \;+\; \langle \nabla g(\overline{x}(t)) \,,\; x_i(t) - \overline{x}(t) \;-\; h_i w(t) \rangle \\ + h_i \langle \nabla g(\overline{x}(t)) \,,\; w(t) \rangle \;+\; \theta(|x_i(t) - \overline{x}(t)|). \end{aligned}$$

Then

$$g(x_i(t)) \leq \; \langle \nabla g(\overline{x}(t)) \,,\; x_i(t) - \overline{x}(t) \;-\; h_i w(t) \rangle \;+\; h_i \varepsilon \;+\; \theta(|x_i(t) - \overline{x}(t)|).$$

We set $N = \sup_{t \in [0,T]} ||\nabla g(\overline{x}(t))||$. Then

$$g(x_i(t)) \leq \; N \cdot [h_i ||w_i - w_0|| \;+\; M \cdot \; \alpha(h_i)] \;+\; h_i \varepsilon \;+\; o(h_i) \;\; \forall t \in Q_\varepsilon.$$

Thus

$$\frac{1}{h_i} g^+(x_i(t)) \;\leq\; N \cdot ||w_i - w_0|| \;+\; N \cdot M \; \frac{\alpha(h_i)}{h_i} \;+\; \varepsilon \;+\; \frac{o(h_i)}{h_i}.$$

Since

$$\lim_{h_i \to 0^+} \frac{\alpha(h_i)}{h_i} \;=\; 0, \;\; \lim_{h_i \to 0^+} \frac{o(h_i)}{h_i} \;=\; 0, \text{ and } w_i \to w_0,$$

we obtain in this case

$$\limsup_{h_i \to 0^+} \left(\sup_{t \in Q_\varepsilon} \frac{1}{h_i} g^+(x_i(t)) \right) \leq \varepsilon.$$

From the above two cases (since ε is arbitrary) and (12), we conclude that

$$\lim_{i \to +\infty} \frac{\overline{x}_i(\cdot) - x_i(\cdot)}{h_i} \;=\; 0 \text{ in } W^{1,1} \text{ on } [0,T],$$

which ends the proof. □

2.2. Constraints given by a closed smooth set. In this section, K is a closed set whose boundary is smooth in the sense explained below.

We consider the same variational inclusion (P), where $\overline{x}$, $\overline{x}_0$ have the same meaning as before.

The constraint set verifies the following "smooth boundary" condition.

Let the signed distance $h : \mathbb{R}^n \mapsto \mathbb{R}$ be defined as

$$h(x) = \begin{cases} -\text{dist}(x, \partial K) & \text{if } x \in K, \\ \text{dist}(x, \partial K) & \text{if } x \notin K \end{cases}$$

and be such that the following hold.

H.3

(i) *There exists $\eta > 0$ such that the function h is of class $C^{1,1}$ on a η-neighborhood of ∂K; i.e., it is differentiable with a locally Lipschitz continuous gradient on $\mathcal{B}(\partial K, \eta)$.*

(ii) *There exists $\varepsilon > 0$ such that, for every $x \in \partial K$ and every t, one has $\min_{v \in F(t,x)} \langle\, v, \mathcal{N}(x) \,\rangle \leq -\varepsilon$, where $\mathcal{N}(x)$ denotes the outer normal to K at x.*

Remarks.

(a) Recall that $\mathcal{N}(x) = \nabla h(x)$.

(b) If F is continuous, it is enough to assume that, for all $(t,x) \in [0,T] \times \partial K$, $\min_{v \in F(t,x)} \langle v, \mathcal{N}(x) \rangle < 0$ instead of $H.3$ (ii) to get the same conclusions as below.

We can state the following theorem.

THEOREM 2.3. *Assume that $H.1$ and $H.3$ are verified, and let $\overline{x} \in \mathcal{S}^K_{[0,T]}(\overline{x}_0)$.*

Fix $w_0 \in I_{C_0}(\overline{x}_0)$ and a solution $w(\cdot)$ to (P). Let $h_i \longrightarrow 0^+$ and $w_i \longrightarrow w_0$ be such that $\overline{x}_0 + h_i w_i \in K$.

Then there exist

$$\overline{x}_i \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$$

$$\text{such that } \frac{\overline{x}_i(\cdot) - \overline{x}(\cdot)}{h_i} \longrightarrow w(\cdot) \text{ in } W^{1,1} \text{ on } [0,T].$$

Proof of Theorem 2.3. Define the constraint set as $K = \{x : h(x) \leq 0\}$, and we have the case of the previous subsection, but we have only $h \in C^{1,1}$ on a neighborhood of ∂K.

Observe next that all estimates of the proof of Theorem 2.1 were used only on a neighborhood of $\{x : g(x) = 0\}$. When $x \in \operatorname{Int} K$, we have the case in which $h(x) < 0$, and so again arguments from the proof of Theorem 2.1 do apply.

3. Variational inclusion in $C([0,T];\mathbb{R}^n)$. We consider the solution map $\mathcal{S}_{[0,T]}$ as the set-valued map from $\mathbb{R}^n$ to $C([0,T];\mathbb{R}^n)$.

Fix $\overline{x}_0 \in C_0$, and let $\overline{x} \in \mathcal{S}^K_{[0,T]}(\overline{x}_0)$, $w_0 \in I_{C_0}(\overline{x}_0)$.

Consider the following linearized inclusion:

$$(L^{rel}) \begin{cases} w'(t) \in d\overline{co}F(t, \overline{x}(t), \overline{x}'(t)) \cdot w(t) \text{ a.e. in } [0,T], \\ w(0) = w_0. \end{cases}$$

In this section, we denote by $\overline{\mathcal{S}}^{lin}_{[0,T]}(w_0)$ the closure in $C([0,T];\mathbb{R}^n)$ of all solutions to (L^{rel}).

We suppose that assumptions $H.1$ are verified.

Observe that, if F satisfies $H.1$, then so does the set-valued map $(t,x) \rightsquigarrow \overline{co}F(t,x)$.

In this section, we establish results which are analogous to those proved in the previous section in cases of inequality and smooth and nonsmooth constraints.

3.1. Inequality constraints. Let $g \in C^{1,1}(\mathbb{R}^n, \mathbb{R}^m)$ and $K = \{x : g(x) \leq 0\}$.

THEOREM 3.1. *Let $w \in \overline{\mathcal{S}}^{lin}_{[0,T]}(w_0)$ be such that $w(t) \in I_K(\overline{x}(t))$ for all $t \in [0,T]$. If $H.2$ holds true, then, for all $h_i \to 0^+$ and $w_i \longrightarrow w_0$ satisfying $\overline{x}_0 + h_i w_i \in K$, there exist $\overline{x}_i \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$ such that*

$$\frac{\overline{x}_i(\cdot) - \overline{x}(\cdot)}{h_i} \longrightarrow w(\cdot) \text{ in } C([0,T];\mathbb{R}^n) \text{ when } i \to +\infty.$$

Proof of Theorem 3.1.

Step 1. Let $w(\cdot)$, h_i, w_i be as above. Consider solutions $\overline{w}_j(\cdot)$ to (L^{rel}) converging to $w(\cdot)$ in $C([0,T];\mathbb{R}^n)$.

Applying the same arguments as in step 1 of the proof of Theorem 2.1, and replacing F by $\overline{co}F$, we deduce the existence of $x_{j,i} \in \mathcal{S}^{rel}_{[0,T]}(\overline{x}_0 + h_i w_i)$ such that

$\frac{x_{j,i}(\cdot)-\overline{x}(\cdot)}{h_i}$ converge uniformly to $\overline{w}_j(\cdot)$ and satisfying the following inequality for all t:

$$||x_{j,i}(t) - \overline{x}(t) - h_i\overline{w}_j(t)|| \leq h_i||w_i - w_0|| + M \cdot \alpha_j(h_i) \tag{13}$$

with M independent from i, j and $\lim_{i\to\infty} \frac{\alpha_j(h_i)}{h_i} = 0$.

By the relaxation theorem, Theorem 1.3, we may also assume that $x_{j,i} \in \mathcal{S}_{[0,T]}(\overline{x}_0 + h_i w_i)$.

We apply the Frankowska–Vinter theorem, Theorem 2.2, by taking $\widehat{x} = x_{j,i}$, $\widehat{x}_0 = \overline{x}_0 + h_i w_i$.

We get then the existence of $y_{j,i}(\cdot) \in \mathcal{S}^K_{[0,T]}(x_0 + h_i w_i)$ satisfying for some $L > 0$ and all $i \geq 1$

$$||y_{j,i} - x_{j,i}||_{W^{1,1}([0,T])} \leq \ L \ \cdot \max_{t\in[0,T]} g^+(x_{j,i}(t)).$$

Step 2. Let us show that $\exists L_1 > 0$, $i(j) \geq 1$, and $\varepsilon_j \to 0$ such that, for all $i \geq i(j)$, $\left\| \frac{y_{j,i}(\cdot)-\overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\|_C \leq L_1 \cdot \varepsilon_j$.

We observe that

$$\begin{aligned} &\|y_{j,i}(\cdot) - \overline{x}(\cdot) - h_i\overline{w}_j(\cdot)\|_C \leq L \ \cdot \sup_{t\in[0,T]} g^+(x_{j,i}(t)) \\ &+ \sup_{t\in[0,T]} \|x_{j,i}(t) - \overline{x}(t) - h_i\overline{w}_j(t)\|. \end{aligned} \tag{14}$$

Set for all $r \geq 1$

$$Q_{r,j} = \left\{ s \in [0,T] : \langle \nabla g(\overline{x}(s)) \, , \overline{w}_j(s) \rangle < \frac{1}{r} \right\}.$$

Let $Q^C_{r,j}$ denote its complement.

Since $\overline{w}_j(\cdot) \to w(\cdot)$, $\exists j_0$ such that for all $j \geq j_0$, for all t satisfying $\overline{x}(t) \in \partial K$, we have $t \in Q_{r,j}$.

We mimic step 3 of the proof of Theorem 2.1 by considering two cases.

- *Case* A. If $t \in Q^C_{r,j}$, then $g(\overline{x}(t)) < 0$.
  Then with the same reasoning as step 3 of the proof of Theorem 2.1, for i large enough, we have $g(x_{j,i}(t)) \leq -\frac{\delta}{2} < 0$ and $\frac{1}{h_i} \sup_{t\in Q^C_{r,j}} g^+(x_{j,i}(t)) = 0$.
- *Case* B. If $t \in Q_{r,j}$, we have

  $$\begin{aligned} g(x_{j,i}(t)) \ &= \ g(\overline{x}(t)) \ + \langle \nabla g(\overline{x}(t)) \, , \ x_{j,i}(t) - \overline{x}(t) \ - \ h_i\overline{w}_j(t) \rangle \\ &+ h_i \langle \nabla g(\overline{x}(t)) \, , \ \overline{w}_j(t) \rangle + \theta(|x_{j,i}(t) - \overline{x}(t)|), \end{aligned}$$

  where $\frac{\theta(s)}{s} \to 0$ as $s \to 0$.
  Setting $N = \sup_{t\in[0,T]} ||\nabla g(\overline{x}(t))||$ and using (13), we get, for all $t \in Q_{r,j}$,

  $$g(x_{j,i}(t)) \leq \ N \cdot [h_i||w_i - w_0|| \ + \ M \cdot \ \alpha_j(h_i)] \ + \ h_i \frac{1}{r} \ + \ o_j(h_i).$$

  Thus

  $$\frac{1}{h_i} \sup_{t\in Q_{r,j}} g^+(x_{j,i}(t)) \leq \ N \cdot ||w_i - w_0|| \ + \ N \cdot M \cdot \ \frac{\alpha_j(h_i)}{h_i} \ + \ \frac{1}{r} \ + \ \frac{o_j(h_i)}{h_i}.$$

From the above two cases, and since $\lim_{i\to\infty}\frac{\alpha_j(h_i)}{h_i}=0$, $\lim_{i\to\infty}\frac{o_j(h_i)}{h_i}=0$, and $w_i\to w_0$, and by (14) there exists $L_1\geq 1$ independent from i, j such that for every j we can find $i(j)$ satisfying for all $i\geq i(j)$

$$\left\|\frac{y_{j,i}(\cdot)-\overline{x}(\cdot)}{h_i}-\overline{w}_j(\cdot)\right\|\leq L_1\cdot\frac{3}{r}.$$

Since r is arbitrary, by the diagonalization method we can find sequences $\overline{x}_k\in\{y_{j,i}: i\geq 1,\ j\geq 1\}$ such that $\frac{\overline{x}_k(\cdot)-\overline{x}(\cdot)}{h_k}$ converge to $w(\cdot)$ in $C([0,T];\mathbb{R}^n)$. The proof is complete.

3.2. Smooth constraints. We assume here that the boundary of K is smooth; i.e., assumptions $H.3$ are verified.

THEOREM 3.2. *Let $w\in\overline{\mathcal{S}}^{lin}_{[0,T]}(w_0)$ be such that $w(t)\in I_K(\overline{x}(t))$ for all $t\in[0,T]$. If $H.1$ and $H.3$ hold true, then for all $h_i\to 0^+$ and $w_i\longrightarrow w_0$ satisfying $\overline{x}_0+h_iw_i\in K$, there exist $\overline{x}_i\in\mathcal{S}^K_{[0,T]}(\overline{x}_0+h_iw_i)$ such that $\frac{\overline{x}_i(.)-\overline{x}(.)}{h_i}$ converge to $w(\cdot)$ in $C([0,T];\mathbb{R}^n)$ when $i\to+\infty$.*

Proof of Theorem 3.2. Applying the same arguments as in step 1 of the proof of Theorem 3.1, we deduce the existence of $x_{j,i}(\cdot)\in\mathcal{S}_{[0,T]}(\overline{x}_0+h_iw_i)$ satisfying for all t

$$||x_{j,i}(t)-\overline{x}(t)-h_i\overline{w}_j(t)||\leq h_i||w_i-w_0||+M\cdot\alpha_j(h_i), \tag{15}$$

where $\lim_{i\to\infty}\frac{\alpha_j(h_i)}{h_i}=0$ for all j.

We next estimate $\operatorname{dist}(\overline{x}(t)+h_iw(t),K)$ for all t.

Observe that

$$\operatorname{dist}(\overline{x}(t)+h_iw(t),K)=\begin{cases}0 & \text{if } \overline{x}(t)+h_iw(t)\in K,\\ \operatorname{dist}(\overline{x}(t)+h_iw(t),\partial K) & \text{otherwise.}\end{cases}$$

If i is large enough, $\sup_t(h_i\|w(t)\|)<\eta$.

Let $\varepsilon>0$. Set

$$Q_\varepsilon=\{s\in[0,T]:\langle\nabla h(\overline{x}(s))\,,w(s)\rangle<\varepsilon\},$$

and let Q_ε^C denote its complement.

Observe next that, for all t such that $\overline{x}(t)\in\partial K$, and since $w(t)\in I_K(\overline{x}(t))$, we have $t\in Q_\varepsilon$.

Here again we consider two cases.

- *Case* A. If $t\in Q_\varepsilon^C$, since $\min_{t\in Q_\varepsilon^C}\operatorname{dist}(\overline{x}(t),K^C)>0$, for all i large enough $\min_{t\in Q_\varepsilon^C}\operatorname{dist}(\overline{x}(t)+h_iw(t),K^C)>0$, where K^C denotes the complement of K. So $\sup_{t\in Q_\varepsilon^C}\operatorname{dist}(\overline{x}(t)+h_iw(t),K)=0$.
- *Case* B. If $t\in Q_\varepsilon$, since

  $$h(\overline{x}(t)+h_iw(t))=h(\overline{x}(t))+\langle\nabla h(\overline{x}(t)),h_iw(t)\rangle+o(h_i),$$

  we have for all large i

  $$h(\overline{x}(t)+h_iw(t))\leq 2h_i\varepsilon.$$

From the above two cases, there exists $c>0$ such that for all i large enough

$$\operatorname{dist}(\overline{x}(t)+h_iw(t),K)\leq c\cdot h_i\cdot\varepsilon. \tag{16}$$

Step 1. We prove here that there exist $\overline{y}_{j,i} \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$ satisfying, for some $L \geq 1$, independent from j and i, $i(j) \geq 1$, and $\varepsilon_j \to 0$,

$$\forall i \geq i(j),\ \left\| \frac{\overline{y}_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\| \leq L \cdot \varepsilon_j.$$

Under assumptions $H.1$ and $H.3$, we have the following result (from [12]).

LEMMA 3.3 (Frankowska–Rampazzo). *There exist $L > 0$ and $\tau > 0$ such that for every $(t_0, x_0) \in [0,T] \times K$, and every trajectory $\overline{x}(\cdot) \in \mathcal{S}_{[t_0,t_0+\tau]}(x_0)$, there is a trajectory $x(\cdot) \in \mathcal{S}^K_{[t_0,t_0+\tau]}(x_0)$ such that*

$$||x - \overline{x}||_{C[t_0,t_0+\tau]} \leq L \sup_{t \in [t_0,t_0+\tau]} \operatorname{dist}(\overline{x}(t), K).$$

Let τ and L_1 be as in the above lemma.

- If $\operatorname{Min}(\tau, T) = T$, then we directly apply Lemma 3.3.
  It says that, for $x_{j,i}(\cdot) \in \mathcal{S}_{[0,T]}(\overline{x}_0 + h_i w_i)$, we have the existence of

  $$\overline{y}_{j,i}(\cdot) \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$$

  such that

  $$||\overline{y}_{j,i} - x_{j,i}||_{C[0,T]} \leq L_1 \cdot \sup_{t \in [0,T]} \operatorname{dist}(x_{j,i}(t), K).$$

  Then, using (15),

  $$\begin{aligned} &\left\| \frac{\overline{y}_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\| \leq L_1 \cdot \frac{1}{h_i} \sup_{t \in [0,T]} \operatorname{dist}(x_{j,i}(t), K) \\ &+ \|w_i - w_0\| + M \cdot \frac{\alpha_j(h_i)}{h_i}. \end{aligned} \tag{17}$$

  On the other hand, we have

  $$\begin{aligned} &\operatorname{dist}(x_{j,i}(t), K) \leq h_i ||w_i - w_0|| + M \cdot \alpha_j(h_i) \\ &+ \operatorname{dist}(\overline{x}(t) + h_i w(t), K) + h_i ||\overline{w}_j(t) - w(t)||. \end{aligned} \tag{18}$$

  Then, using (16), (17), (18), and the convergence of $\overline{w}_j$ to w, we deduce the existence of L, $i(j) \geq 1$, and $\varepsilon_j \to 0$ such that, for all $i \geq i(j)$,

  $$\left\| \frac{\overline{y}_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\|_{C([0,\tau])} \leq L \cdot \varepsilon_j. \tag{19}$$

- If $\operatorname{Min}(\tau, T) = \tau < T$, then we apply Lemma 3.3 exactly as above on the time interval $[0, \tau]$ to prove the existence of $y^1_{j,i}(.) \in \mathcal{S}^K_{[0,\tau]}(\overline{x}_0 + h_i w_i)$, L_1, $i(j) \geq 1$, and $\varepsilon_{j,1} \to 0$ as $j \to \infty$ such that, for all $i \geq i(j)$,

  $$\left\| \frac{y^1_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\|_{C([0,\tau])} \leq L_1 \cdot \varepsilon_{j,1}. \tag{20}$$

  Set $z_{j,i}(\tau) = \frac{y^1_{j,i}(\tau) - \overline{x}(\tau)}{h_i}$. Then $y^1_{j,i}(\tau) = \overline{x}(\tau) + h_i z_{j,i}(\tau) \in K$.

We observe that $\|z_{j,i}(\tau) - \overline{w}_j(\tau)\| \leq L_1 \cdot \varepsilon_{j,1}$.
We set $\overline{z}_{j,i}(t) = \overline{x}(t) + h_i(z_{j,i}(\tau) - \overline{w}_j(\tau)) + h_i\overline{w}_j(t)$ for $t \geq \tau$.
Then $\overline{z}'_{j,i}(t) = \overline{x}'(t) + h_i\overline{w}'_j(t)$ and $\overline{z}_{j,i}(\tau) = \overline{x}(\tau) + h_i z_{j,i}(\tau) = y^1_{j,i}(\tau)$.
We observe that, for all $t \geq \tau$,

$$\begin{aligned} &\frac{1}{h_i}\mathrm{dist}(\overline{z}_{j,i}(t), K) \leq ||z_{j,i}(\tau) - \overline{w}_j(\tau)|| + ||\overline{w}_j(t) - w(t)|| \\ &+\frac{1}{h_i}\mathrm{dist}(\overline{x}(t) + h_i w(t), K). \end{aligned} \tag{21}$$

On the other hand, we do have the same inequality as (8) for all $t \geq \tau$:

$$\mathrm{dist}(\overline{z}'_{j,i}(t), \overline{co}F(t, \overline{z}_{j,i}(t))) \leq h_i(||\overline{w}'_j(t)||+k_F(t)||\overline{w}_j(t)||)+h_i k_F(t)||z_{j,i}(\tau)-\overline{w}_j(\tau)||$$

and

$$\frac{1}{h_i}\mathrm{dist}(\overline{z}'_{j,i}(t), \overline{co}F(t, \overline{z}_{j,i}(t))) \leq ||z_{j,i}(\tau) - \overline{w}_j(\tau)|| + o_t(h_i),$$

where $\frac{o_t(h_i)}{h_i} \to 0$ when $i \to \infty$.
This and the Lebesgue dominated convergence theorem yield

$$\int_\tau^T \mathrm{dist}\left(\overline{z}'_{j,i}(t), \overline{co}F(t, \overline{z}_{j,i}(t))\right) dt = \beta_j(h_i),$$

where $\limsup_{i\to\infty} \frac{\beta_j(h_i)}{h_i} \leq C \cdot \varepsilon_{j,1}$ with C independent from j.
Consider next the time interval $[\tau, 2\tau]$. We apply the Filippov's existence theorem [8] on $[\tau, 2\tau]$ to the arcs $\overline{z}_{j,i}$ and the relaxation theorem, Theorem 1.3.
We have then the existence of $l > 0$ independent from i and j and solutions

$$y_{j,i}(\cdot) \in \mathcal{S}_{[\tau,2\tau]}(\overline{x}(\tau) + h_i z_{j,i}(\tau))$$

such that, for all i large enough,

$$\left\| \frac{y_{j,i}(\cdot) - \overline{z}_{j,i}(\cdot)}{h_i} \right\| \leq l \cdot \varepsilon_{j,1} \text{ on } [\tau, 2\tau]. \tag{22}$$

We now apply Lemma 3.3 on $[\tau, 2\tau]$, considering $y_{j,i}(\cdot) \in \mathcal{S}_{[\tau,2\tau]}(\overline{x}(\tau) + h_i z_{j,i}(\tau))$ to obtain the existence of some L and $y^2_{j,i}(\cdot) \in \mathcal{S}^K_{[\tau,2\tau]}(\overline{x}(\tau) + h_i z_{j,i}(\tau))$ such that

$$||y^2_{j,i} - y_{j,i}||_{C([\tau,2\tau]),\mathbb{R}^n)} \leq L \cdot \sup_{t\in[\tau,2\tau]} \mathrm{dist}(y_{j,i}(t), K).$$

However, since

$$\frac{1}{h_i}\sup_{t\in[\tau,2\tau]} \mathrm{dist}(y_{j,i}(t), K) \leq \frac{1}{h_i}\sup_{t\in[\tau,2\tau]} \|y_{j,i}(t)-\overline{z}_{j,i}(t)\|+\frac{1}{h_i}\sup_{t\in[\tau,2\tau]} \mathrm{dist}(\overline{z}_{j,i}(t), K),$$

using (16), (21), and (22), we obtain the existence of L_2, $i(j)$ and $\varepsilon_{j,2} \to 0^+$ such that

$$\left\| \frac{y^2_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\|_{C([\tau,2\tau]} \leq L_2 \cdot \varepsilon_{j,2}. \tag{23}$$

– If $\min(2\tau, T) = T$, then concatenate $y^1_{j,i}(\cdot)$ on $[0,\tau]$ and $y^2_{j,i}(\cdot)$ on $[\tau, 2\tau]$ to get the existence of $\overline{y}_{j,i}$ *on* $[0,T]$ such that

$$\overline{y}_{j,i}(\cdot) \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i).$$

Since $y^1_{j,i}(\tau) = y^2_{j,i}(\tau)$, because of (20) and (23), we get for some L_3 and $\varepsilon_{j,3} \to 0^+$

$$\left\| \frac{\overline{y}_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\|_{C([0,2\tau])} \leq L_3 \cdot \varepsilon_{j,3} \quad \forall\ i \text{ large enough.}$$

– If $\min(2\tau, T) = 2\tau < T$, we proceed inductively. Assume we have already constructed solutions

$$\overline{y}_{j,i}(.) \in \mathcal{S}^K(\overline{x}_0 + h_i w_i) \text{ on } [0, \min(p\tau, T)] \text{ for some } p \geq 1$$

in such a way that

$$\left\| \frac{\overline{y}_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\|_{C([0,\min(p\tau,T)];\mathbb{R}^n)} \leq L_p \cdot \varepsilon_{j,p} \quad \forall \text{ large } i,$$

where L_p does not depend on i, j, and $\varepsilon_{j,p} \to 0$ as $j \to \infty$.
If $\min(p\tau, T) = T$, then the proof is complete.
If not, we use the same reasoning as in step 1 on $[p\tau, \min((p+1)\tau, T)]$ to construct $y^p_{j,i}(.) \in \mathcal{S}^K(\overline{y}_{j,i}(p\tau))$ on $[p\tau, \min((p+1)\tau, T)]$ such that $\left\| \frac{\overline{y}^p_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\| \leq L_{p+1} \cdot \varepsilon_{j,p+1}$, where $\varepsilon_{j,p+1} \to 0^+$ as $j \to \infty$, and we concatenate the two solutions. In this way, we extend the definition of $\overline{y}_{j,i}$ on the whole interval $[0,T]$ in a finite number of steps.

Step 2. We have proved the existence of $\overline{y}_{j,i} \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$, $L > 0$, $i(j)$, and $\varepsilon_j > 0$, satisfying for all $i \geq i(j)$ $\left\| \frac{\overline{y}_{j,i}(\cdot) - \overline{x}(\cdot)}{h_i} - \overline{w}_j(\cdot) \right\| \leq L \cdot \varepsilon_j$ with $\varepsilon_j \to 0^+$. We apply next the diagonalization process to prove the existence of $\overline{x}_i \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$ such that $\frac{\overline{x}_i(\cdot) - \overline{x}(\cdot)}{h_i}$ converge to $w(\cdot)$ in $C([0,T];\mathbb{R}^n)$. The proof is complete. ∎

3.3. Nonsmooth constraints. In this section, we allow the boundary of K to be nonsmooth. We replace hypothesis $H.3$ by the following condition:

$$H.4 \left| \begin{array}{l} \textit{There exists } \eta > 0 \textit{ such that for all } t \in [0,T] \textit{ and } x \in \partial K \\ \exists\ v \in F(t,x) \cap \mathrm{Int}(C_K(x)) \textit{ such that } ||v|| \geq \eta. \end{array} \right.$$

This means that for all $(t,x) \in [0,T] \times \partial K$ there exists at least one velocity $v \in F(t,x)$ pointing strictly in the set K, in the sense that $\exists\ \varepsilon > 0$ such that $y + [0,\varepsilon]\mathcal{B}(v,\varepsilon) \subset K$ for all $y \in \mathcal{B}(x,\varepsilon) \cap K$.

Set for all $t \in [0,T]$

$$\widehat{\mathcal{C}}(t) = \left\{ v \ : \ \lim_{\substack{t' \to t \\ h \to 0^+}} \frac{dist(\overline{x}(t') + hv, K)}{h} = 0 \right\}.$$

Clearly $\widehat{\mathcal{C}}(t) \subset I_K(\overline{x}(t))$.

Set $F(s,x) = F(T,x)$ for all $s \geq T$ and $x \in \mathbb{R}^n$, and assume

$$H_{BV} \left| \begin{array}{l} \textit{There exists } L \geq 0 \textit{ such that for every } d \in [0,T] \\ \textit{and for every Lipschitz map } x(\cdot) \textit{ from } [0,T] \textit{ into } \mathbb{R}^n \\ \int_0^T d_H(F(s,x(s)), F(s+d,x(s)))ds \leq L \cdot d, \end{array} \right.$$

where d_H denotes the Hausdorff distance.

Remark. When $F(\cdot,x)$ is Lipschitz, then the hypothesis H_{BV} is verified.

However, if ∂K is smooth in the sense of subsection 3.2, then, according to [12], this assumption is not needed.

THEOREM 3.4. *Let $w \in \overline{\mathcal{S}}^{lin}_{[0,T]}(w_0)$ be such that $w(t) \in \widehat{\mathcal{C}}(t)$ for all $t \in [0,T]$. If $H.1$, H_{BV}, and $H.4$ hold true, then for all $h_i \to 0^+$ and $w_i \longrightarrow w_0$ satisfying $\overline{x}_0 + h_i w_i \in K$, there exist $\overline{x}_i \in \mathcal{S}^K_{[0,T]}(\overline{x}_0 + h_i w_i)$ such that $\frac{\overline{x}_i(.) - \overline{x}(.)}{h_i}$ converge to $w(\cdot)$ in $C([0,T];\mathbb{R}^n)$ when $i \to +\infty$.*

The proof is very similar to the one of subsection 3.2 above, based on results from [12]. An analogue of Lemma 3.3 can be found in [12] also under assumptions $H.1$, H_{BV}, and $H.4$. The same steps and arguments are applied, and the only difference is the estimation of $\operatorname{dist}(\overline{x}(t) + h_i w(t), K)$.

The assumption $w(t) \in \widehat{\mathcal{C}}(t)$ implies that for all $\varepsilon_1 > 0$ there exist $\delta > 0$ and $i_0 \geq 1$ such that for every $t' \in [0,T] \cap [t-\delta, t+\delta]$ and $i \geq i_0$

$$\operatorname{dist}(\overline{x}(t') + h_i w(t'), K) \leq h_i \, \varepsilon_1. \tag{24}$$

Thus we deduce inequality (16) from (24) by using the compactness of $[0,T]$.

4. A direct proof of the constrained maximum principle. Let K and C_0 be given closed subsets of $\mathbb{R}^n$, and let $\mathcal{Z}$ be a complete separable metric space.

In this section, we study Mayer's problem of optimal control:

Minimize $\varphi(x(T))$ over solutions to

$$\left\{ \begin{array}{l} x'(t) = f(t,x(t),u(t)) \text{ a.e. in } [0,T], \\ u(t) \in U(t), \\ x(0) \in C_0, \\ x(t) \in K \ \forall \, t \in [0,T], \end{array} \right. \tag{25}$$

where the following hold:

- $U : [0,T] \rightsquigarrow \mathcal{Z}$, $U(\cdot)$ is measurable, and $U(t)$ is nonempty and compact.
- $f : [0,T] \times \mathbb{R}^n \times \mathcal{Z} \mapsto \mathbb{R}^n$ is so that $f(t,\cdot,\cdot)$ is continuous, $f(\cdot,x,u)$ is measurable, and $f(t,\cdot,u)$ is differentiable and $k(t)$-Lipschitzian, and for all t, $\sup_{e \in f(t,x,U(t))} ||e|| \leq c(1+||x||)$.
- $\varphi : \mathbb{R}^n \mapsto \mathbb{R}$ is differentiable.

Consider an optimal solution $\overline{x}$, let $\overline{u}$ be a corresponding optimal control, and set $\overline{x}(0) = x_0$. We associate the following linearization along the solution control pair $(\overline{x}, \overline{u})$:

$$(P_a^*) \left\{ \begin{array}{l} w'(t) = \dfrac{\partial f}{\partial x}(t,\overline{x}(t),\overline{u}(t)) \cdot w(t) + v(t), \\ w(0) = w_0 \in K_0, \\ v(t) \in V(t) = T_{\overline{co} f(t,\overline{x}(t),U(t))}(\overline{x}'(t)), \end{array} \right.$$

where K_0 is any closed convex cone contained in $I_{C_0}(x_0)$.

Observe that, for $F(t,x) := f(t,x,U(t))$, we have

$$\frac{\partial f}{\partial x}(t,\overline{x}(t),\overline{u}(t)) \in dF(t,\overline{x}(t),\overline{x}'(t)) \subset d\overline{co}F(t,\overline{x}(t),\overline{x}'(t)),$$

where dF denotes the adjacent derivative with respect to x.

On the other hand, by [2], we have

$$d\overline{co}F(t,\overline{x}(t),\overline{x}'(t)) + T_{\overline{co}f(t,\overline{x}(t),U(t))}(\overline{x}'(t)) \subset d\overline{co}F(t,\overline{x}(t),\overline{x}'(t)).$$

By the last two relations, every solution $w(\cdot)$ to (P_a^*) solves the following differential inclusion:

$$\begin{cases} w'(t) \ \in \ d\overline{co}F(t,\overline{x}(t),\overline{x}'(t)) \cdot w(t), \\ w(0) = w_0 \in K_0. \end{cases}$$

Let $\mathcal{C}(t)$ be closed convex cones satisfying the following assumption:

$H.5$ | *$\mathcal{C}(\cdot) : [0,T] \rightsquigarrow \mathbb{R}^n$ is a lower semicontinuous set-valued map, $\mathcal{C}(t) \subset \widehat{\mathcal{C}}(t)$; there exists a continuous selection $\overline{w}(t) \in \mathcal{C}(t)$ such that for some $\delta > 0$, $B(\overline{w}(t),\delta) \subset \mathcal{C}(t)$ for all t,*

where $\widehat{\mathcal{C}}(t)$ are defined in subsection 3.3.

Remark. If $\mathcal{C}(t) = C_K(\overline{x}(t))$ and Int $C_K(\overline{x}(t)) \neq \emptyset$ for all $t \in [0,T]$, then, using that Int $C_K(\overline{x}(t)) = \{v : \exists \varepsilon > 0$ for all $h \in [0,\varepsilon]$, $y \in \mathcal{B}(\overline{x}(t),\varepsilon) \cap K$ and $z \in \mathcal{B}(v,\varepsilon)$, $y + hz \in K\}$, it is easy to prove that $H.5$ is verified.

We introduce the following notation:

$$Q_1 = \left\{ w \in W^{1,1}([0,T];\mathbb{R}^n) : \ w(\cdot) \text{ solves } (P_a^*) \right\},$$

$$K_2 = \left\{ w \in C([0,T];\mathbb{R}^n) : \ w(t) \in \mathcal{C}(t) \right\}.$$

We notice that K_2 is closed in $C([0,T];\mathbb{R}^n)$ and Int $K_2 \neq \emptyset$.

Let K_1 be the closure in $C([0,T];\mathbb{R}^n)$ of Q_1. We impose the hypothesis $H.2$ in the case of inequality constraints, the hypothesis $H.3$ in the case when the boundary of K is smooth, and $H.4$ together with H_{BV} when the boundary of K is nonsmooth. Now, we can state the maximum principle theorem.

THEOREM 4.1. *If $(\overline{x},\overline{u})$ is optimal, then there exist $\lambda \in \{0,1\}$, a positive Radon measure μ, a measurable function ν, and an absolutely continuous function $p(\cdot)$ not vanishing simultaneously such that*

$$\text{(i)} \quad -p'(t) = \frac{\partial f}{\partial x}(t,\overline{x}(t),\overline{u}(t))^* \cdot \left(p(t) + \int_0^t \nu(s) d\mu(s) \right) \ \text{a.e. on } [0,T],$$

$$\text{(ii)} \quad p(T) + \int_0^T \nu(s) d\mu(s) = \ -\lambda \nabla \varphi(\overline{x}(T)),$$

$$\text{(iii)} \quad p(0) \in K_0^- ,$$

$$\text{(iv)} \quad \nu(t) \in \mathcal{C}(t)^- \ \ \mu \ \textit{a.e. in} \ [0,T],$$

$$\text{(v)} \quad \max_{u \in U(t)} \left\langle p(t) + \int_0^t \nu(s) d\mu(s), f(t, \overline{x}(t), u) \right\rangle$$

$$= \left\langle p(t) + \int_0^t \nu(s) d\mu(s), f(t, \overline{x}(t), \overline{u}(t)) \right\rangle \ \textit{a.e. in} \ [0,T].$$

Remark. If $\mathcal{C}(t) = C_K(\overline{x}(t))$, then $\mathcal{C}(t)^- = N_K(\overline{x}(t))$ (Clarke's normal cone to K at $\overline{x}(t)$).

Proof of Theorem 4.1. We claim the following.

PROPOSITION 4.2. *If $\overline{x}$ is optimal, then, for all $w \in K_1 \cap K_2$,*

$$\langle \nabla \varphi(\overline{x}(T)), w(T) \rangle \geq 0. \tag{26}$$

Indeed, from the previous section, we do have the existence of trajectories $\overline{x}_i$ solving (25) such that $\frac{\overline{x}_i(\cdot) - \overline{x}(\cdot)}{h_i} \longrightarrow w(\cdot)$.

Then

$$\varphi(\overline{x}_i(T)) = \varphi(\overline{x}(T)) + \langle \nabla \varphi(\overline{x}(T)), \overline{x}_i(T) - \overline{x}(T) \rangle + o(h_i).$$

Since $\overline{x}$ is optimal, $\varphi(\overline{x}(T)) \leq \varphi(\overline{x}_i(T))$, and therefore

$$\langle \nabla \varphi(\overline{x}(T)), \overline{x}_i(T) - \overline{x}(T) \rangle + o(h_i) \geq 0.$$

Dividing by h_i and taking the limit when $i \to +\infty$, we obtain the inequality (26).

Define $\gamma : C([0,T]; \mathbb{R}^n) \mapsto \mathbb{R}^n$ by $\gamma(w) = w(T)$. Then the claim (26) is equivalent to, for all $w \in K_1 \cap K_2$,

$$\langle \gamma^* \nabla \varphi(\overline{x}(T)), w \rangle \geq 0, \tag{27}$$

which implies that

$$\gamma^* \nabla \varphi(\overline{x}(T)) \ \in \ (K_1 \cap K_2)^+.$$

We now consider two cases.

Case 1. $0 \in$ Int $(K_2 - K_1)$. Since K_1 and K_2 are nonempty closed convex cones in $C([0,T])$, we infer that

$$(K_1 \cap K_2)^+ = K_1^+ + K_2^+$$

(see, for instance, [4]).

Consequently,

$$\exists \, p_1 \in K_1^+ \ \text{and} \ p_2 \in K_2^+ \ \text{such that} \ \gamma^* \nabla \varphi(\overline{x}(T)) = p_1 + p_2,$$

which yields

$$\langle \gamma^* \nabla \varphi(\overline{x}(T)) - p_2, w \rangle \geq 0 \quad \forall \, w \in K_1,$$

and therefore

$$\langle \nabla\varphi(\overline{x}(T)), w(T)\rangle - \int_0^T w(t)dp_2(t) \geq 0. \tag{28}$$

We need to recall Rockafellar's result; see [21] and [22].

LEMMA 4.3 (Rockafellar). *Let $Q : [0,T] \rightsquigarrow \mathbb{R}^n$ be a lower semicontinuous multifunction such that $Q(t)$ is for every t a nonempty closed convex set. Set $Q = \{w \in C([0,T];\mathbb{R}^n) : w(t) \in Q(t)\}$; then*

$$\begin{aligned} Q^- = \{&\beta \in C([0,T];\mathbb{R}^n)^* \ : \ \exists \text{ a positive measure } \mu \text{ on } [0,T] \text{ and} \\ &\text{a measurable selection } \nu \text{ with } \nu(t) \in Q(t)^- \ \mu \text{ a.e.,} \\ &\text{such that } d\beta(t) = \nu(t)d\mu(t)\}. \end{aligned}$$

Since $-p_2 \in K_2^-$, the above lemma implies that there exist a positive Radon measure μ and a measurable selection ν with $\nu(t) \in \mathcal{C}(t)^-$ such that

$$-dp_2(t) = \nu(t)d\mu(t).$$

Consider next any $w \in Q_1$.

Integrating by parts, we obtain

$$\int_0^T w(t)dp_2(t) = \left\langle w(T), \int_0^T dp_2(t)\right\rangle - \int_0^T w'(t)\left(\int_0^t dp_2(s)\right)dt.$$

Then, replacing this in (28),

$$\left\langle \nabla\varphi(\overline{x}(T)) - \int_0^T dp_2(t), w(T)\right\rangle + \int_0^T w'(t)\left(\int_0^t dp_2(s)\right)dt \geq 0. \tag{29}$$

Let $p(\cdot)$ solve the system

$$\begin{cases} p'(t) = -\dfrac{\partial f}{\partial x}(t,\overline{x}(t),\overline{u}(t))^* \cdot \left(p(t) + \displaystyle\int_0^t \nu(s)d\mu(s)\right), \\ p(T) = -\nabla\varphi(\overline{x}(T)) - \displaystyle\int_0^T \nu(s)d\mu(s). \end{cases} \tag{30}$$

We observe that we have statements (i) and (ii) of Theorem 4.1 with $\lambda = 1$.

Then (29) implies

$$\langle p(T), w(T)\rangle + \int_0^T w'(t)\left(\int_0^t \nu(s)d\mu(s)\right)dt \leq 0. \tag{31}$$

However,

$$\langle p(T), w(T)\rangle = \langle p(0), w(0)\rangle + \int_0^T w'(t)p(t)dt + \int_0^T w(t)p'(t)dt,$$

yielding

$$\begin{aligned} &\langle p(0), w(0)\rangle + \int_0^T w'(t)\left[p(t) + \int_0^t \nu(s)d\mu(s)\right]dt \\ &+ \int_0^T w(t)p'(t)dt \leq 0. \end{aligned} \tag{32}$$

On the other hand, for any integrable selection $v(t) \in V(t)$ and $w(\cdot)$ solving (P_a^*),

$$\begin{aligned}
&\int_0^T w'(t)\left[p(t)+\int_0^t \nu(s)d\mu(s)\right]dt \\
=\ &\int_0^T \left\langle \frac{\partial f}{\partial x}(t,\overline{x}(t),\overline{u}(t))\cdot w(t)+v(t), p(t)+\int_0^t \nu(s)d\mu(s)\right\rangle dt \\
=\ &\int_0^T \left[\left\langle w(t), \frac{\partial f}{\partial x}(t,\overline{x}(t),\overline{u}(t))^*\left(p(t)+\int_0^t \nu(s)d\mu(s)\right)\right\rangle\right. \\
&\left.+\ \left\langle v(t), p(t)+\int_0^t \nu(s)d\mu(s)\right\rangle\right]dt \\
=\ &-\int_0^T w(t)p'(t)dt+\int_0^T \left\langle v(t), p(t)+\int_0^t \nu(s)d\mu(s)\right\rangle dt.
\end{aligned}$$

This and (32) imply

$$\langle w(0), p(0)\rangle + \int_0^T \left\langle v(t), p(t)+\int_0^t \nu(s)d\mu(s)\right\rangle dt \le 0.$$

In particular, taking $v(t) \equiv 0$,

$$\langle w(0), p(0)\rangle \le 0,$$

which means that $p(0) \in K_0^-$.

Taking $w(0) = 0$, we get that, for all integrable selections $v(t) \in V(t)$,

$$\int_0^T \left\langle v(t), p(t)+\int_0^t \nu(s)d\mu(s)\right\rangle dt \le 0,$$

yielding

$$\sup_{v\in V(t)} \left\langle v, p(t)+\int_0^t \nu(s)d\mu(s)\right\rangle \le 0 \text{ a.e.}$$

By [11], for almost every $t \in [0,T]$,

$$\sup_{e\in f(t,\overline{x}(t),U(t))} \left\langle p(t)+\int_0^t \nu(s)d\mu(s), e-\overline{x}'(t)\right\rangle \le 0,$$

implying

$$\begin{aligned}
&\max\nolimits_{u\in U(t)} \left\langle p(t)+\int_0^t \nu(s)d\mu(s), f(t,\overline{x}(t),u)\right\rangle \\
&= \left\langle p(t)+\int_0^t \nu(s)d\mu(s), f(t,\overline{x}(t),\overline{u}(t))\right\rangle \text{ a.e.}
\end{aligned}$$

Case 2. $0 \notin \text{Int}\,(K_2 - K_1)$ or, equivalently, $K_1 \cap (\text{Int}\, K_2) = \emptyset$. Since K_1 and K_2 are closed convex sets in $C([0,T];\mathbb{R}^n)$ and Int $K_2 \neq \emptyset$, they can be separated by a closed hyperplane passing through the origin: i.e., $\exists\, \beta \in (C([0,T];\mathbb{R}^n))^*$, $\beta \neq 0$, such that

$$\langle \beta, a\rangle \le 0 \le \langle \beta, b\rangle \ \forall\, a \in K_2,\ \forall\, b \in K_1. \tag{33}$$

Therefore, $\beta \in K_2^-$. Then, by Lemma 4.3, $\exists$ a positive Radon measure μ and a measurable selection ν with $\nu(t) \in \mathcal{C}(t)^-$ such that $d\beta(t) = \nu(t)d\mu(t)$. On the other hand, (33) implies $\beta \in K_1^+$. Then

$$\forall w \in Q_1\ ,\ \langle \beta, w\rangle \geq 0. \tag{34}$$

However, $\langle \beta, w\rangle = \int_0^T w(t)d\beta(t)$. Integrating by parts, we get

$$\left\langle w(T), \int_0^T d\beta(t)\right\rangle - \int_0^T w'(t)\left(\int_0^t d\beta(s)\right)dt\ \geq 0,$$

and therefore

$$\left\langle w(T), \int_0^T \nu(t)d\mu(t)\right\rangle - \int_0^T w'(t)\left(\int_0^t \nu(s)d\mu(s)\right)dt \geq 0. \tag{35}$$

Let $p(\cdot)$ solve the linear system (30) with the terminal condition $p(T) = -\int_0^T \nu(t)d\mu(t)$.

Thus $p(T) + \int_0^T \nu(t)d\mu(t) = 0$, which is statement (ii) of Theorem 4.1 with $\lambda = 0$. Then, replacing this in (35) and multiplying by -1, we get

$$\langle w(T), p(T)\rangle + \int_0^T w'(t)\left(\int_0^t \nu(s)d\mu(s)\right)dt \leq 0.$$

We have the same inequality as (31). Then statements (iii) and (v) follow in the same way as in Case 1. □

GLOBAL UNIQUENESS TESTS AND PERFORMANCE BOUNDS FOR H^∞ OPTIMA*

J. WILLIAM HELTON† AND MARSHALL A. WHITTLESEY‡

Abstract. Optimization of sup norm–type performance functions over the space of H^∞ functions is central to the subject of H^∞ design, that is, design where stability is the key constraint. Problems with large amounts of plant uncertainty are often highly nonconvex and therefore may have many solutions. In this paper, even for highly nonconvex problems, we give a test one can perform, once a local optimum f^* has been computed, to see if it is a global optimum. The uniqueness phenomena we discovered uses H^∞ properties heavily and are considerably stronger than what occurs in other types of general optimization. Also, even when f^* may not be a global optimum we give a way to use it to bound the best performance possible.

Uniqueness results are valuable for assuring an engineer that a local optimum obtained in a computer run is in fact a true global optimum. This can save a practitioner a lot of time and anguish in that it replaces the usual process of initializing an optimization run many times to see if it always goes to the same local optimum; and even after vast numbers of experiments never being sure.

One of the least intuitive properties of SISO (single input, single output) control is that a (local) optimum for a carefully set up H^∞ problem (cf. Theorem 9.4.1 in [J. W. Helton and O. Merino, *Classical Control Using H^∞ Methods: Theory, Optimization, and Design*, SIAM, Philadelphia, 1998], [J. W. Helton and D. E. Marshall, *Indiana Univ. Math. J.*, 39 (1990), pp. 157–184]) even with large amounts of plant uncertainty is unique. Such problems are quite nonconvex, so the fact is surprising. While the result is false in general for MIMO (multiple input, multiple output) control (cf. [J. W. Helton and O. Merino, *Michigan Math. J.*, 41 (1994), pp. 285–287]), in this note we are describing MIMO situations where uniqueness holds.

The setting in this paper is simultaneous (Pareto) optimization of several competing performances $\Gamma_1, \ldots, \Gamma_\ell$ and we obtain uniqueness results for its solutions.

1. Introduction.

This paper analyzes a problem in which one optimizes performance functions over the space H_N^∞ of bounded analytic vector-valued functions $f = (f_1, \ldots, f_N)$ defined on the unit circle, $\mathbf{T}$, where each coordinate function f_j belongs to $L^\infty(\mathbf{T})$ and extends to be analytic on the entire unit disk. Let $C(\mathbf{T})$ be the space of continuous complex-valued functions on the circle and let $C^1(\mathbf{T})$ be those elements in $C(\mathbf{T})$ with continuous first derivatives.

1.1. Definition of Pareto optimum.

The performance criteria we optimize are described in terms of nonnegative continuous functions Γ defined on $\mathbf{T} \times \mathbf{C}^N$. We are given positive functions $\Gamma_j(e^{i\theta}, z)$, $j = 1, \ldots, \ell$ for $\ell \leq N$ with $e^{i\theta} \in \mathbf{T}$ and

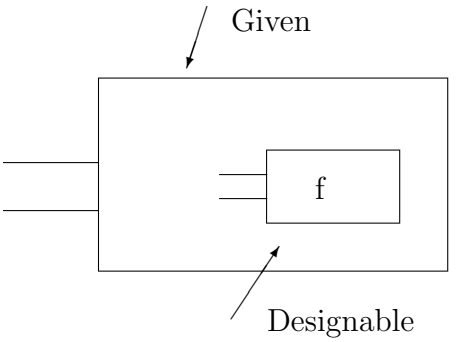

FIG. 1. *For a given plant we want to find the best designable part, represented by* f.

$z \in \mathbf{C}^N$. For function $f \in H_N^\infty$ we define the ℓ performances

$$\gamma_j(f) := \sup_{e^{i\theta} \in \mathbf{T}} \Gamma_j(e^{i\theta}, f(e^{i\theta})), \qquad j = 1, \ldots, \ell.$$

The goals of this paper are best illustrated by the case of two performance functions Γ_1, Γ_2, even though all results hold for ℓ performance functions.

DEFINITION. *A function* $f^* \in H_N^\infty$ *is called a* Pareto optimum *for* Γ_1, Γ_2 *if for each* $f \in H_N^\infty$ *such that* $\gamma_1(f) \le \gamma_1(f^*)$ *and* $\gamma_2(f) \le \gamma_2(f^*)$, *we must have*

$$\gamma_1(f) = \gamma_1(f^*) \quad \textit{and} \quad \gamma_2(f) = \gamma_2(f^*).$$

By the *MultiOPT* problem we shall mean the problem of finding a Pareto optimum. The definition for more Γ_j's is the obvious analogue.

The book of Boyd and Barrat [BB] gives a good discussion of Pareto optimality. The paper [PY95] treats successfully a particular type of frequency domain Pareto optimality, superoptimal H^∞ optimization.

1.2. Engineering motivation. This type of problem is central to frequency domain system design problems where stability is a key constraint. In particular it is important to the area of H^∞-control. The basic physical idea is simple. The following often occurs in a design procedure. We are required to build a system S, but part of the system is given (we are stuck with it) and part of the system is designable (denote its frequency response function by f). Such a system is illustrated in Figure 1. The performance of the system S at frequency ω is a function $\Gamma(\omega, f(i\omega))$ which depends on ω and on our choice of the designable subsystem f. Let us take the convention that large Γ is bad while small Γ is good. Then in a worst case "broadband" design we consider the worst performance over all frequencies

$$\sup_{\omega} \Gamma(\omega, f(i\omega))$$

and try to minimize it over all admissible f. If our main constraint is that the designable subsystem f must be stable, then the design problem becomes the MultiOPT problem with only one Γ, after transforming the right half plane to the unit disk. In this paper we deal with the case where f consists of N designable subsystems $f_1, \ldots, f_N$ and where there are ℓ competing performance criteria $\Gamma_1, \Gamma_2, \ldots, \Gamma_\ell$. Nonconvex performance measures occur in problems with considerable plant uncertainty.

A number of authors, Mayne, Nye, Polak, and Wu [MNPW], Fan, Koninckx, Tits, and Wang [FKTW], Streit [St], Boyd and Barratt [BB], Daleh, Pearson, Balas, Doyle,

Glover, Packard, and Smith [BDGPS], Helton and Merino [HMer98], and Sideris [Si], have theory and computer programs on searching for an optimal f^* with certain kinds of Γ. The main H^∞ optimization problem of quantitative feedback theory (QFT) is essentially the MultiOPT problem. Also integral quadratic constraints (IQCs; see [MR]) address such problems but in a different set of coordinates (behavioral coordinates). Multiple constraints in the frequency domain of a somewhat different flavor are in [KRE96], [PRR97], and [FK93]. There are similar physical problems that they can treat.

1.3. Geometric version of the problem. The MultiOPT problem can be stated geometrically in a way which is physically appealing. The sublevel sets

$$\mathcal{S}^j(\gamma_j) := \{(e^{i\theta}, z) \in \mathbf{T} \times \mathbf{C}^N : \Gamma_j(e^{i\theta}, z) \le \gamma_j\},$$

$$\mathcal{S}^j_\theta(\gamma_j) := \{z \in \mathbf{C}^N : \Gamma_j(e^{i\theta}, z) \le \gamma_j\}$$

of the performance functions Γ_j correspond to values of the frequency response function where the jth performance measure is better (less) than γ_j. For fixed $\vec{\gamma} := (\gamma_1, \ldots, \gamma_\ell)$,

$$\mathcal{S}_\theta(\vec{\gamma}) := \mathcal{S}^1_\theta(\gamma_1) \cap \ldots \cap \mathcal{S}^\ell_\theta(\gamma_\ell) \qquad \forall e^{i\theta} \in \mathbf{T} \tag{1}$$

is the set of values simultaneously yielding peformance level $(\gamma_1, \ldots, \gamma_\ell)$.

Given target sets $\mathcal{S}_\theta(\vec{\gamma})$ in $\mathbf{C}^N$, the suboptimal MultiOPT problem is to find a stable system f whose values $f(e^{i\theta})$ lie in the target sets

$$f(e^{i\theta}) \in \mathcal{S}_\theta(\vec{\gamma}).$$

Standard assumption. Assume that each Γ_j is three times differentiable. Assume that sets $\mathcal{S}_\theta(\vec{\gamma})$ have nonempty interiors for each $\vec{\gamma}$ and are uniformly bounded. Lastly assume that the sets are *uniformly contractible*: there exist mappings $I_t(e^{i\theta}, z)$ from $\mathcal{S}(\vec{\gamma})$ to $\mathcal{S}(\vec{\gamma})$ continuous in t, θ, z such that for each θ, $(e^{i\theta}, z) \mapsto I_t(e^{i\theta}, z)$ is the identity for $t = 0$, the first coordinate of $I_t(e^{i\theta}, z)$ is $e^{i\theta}$, and for each θ, $z \mapsto I_t(e^{i\theta}, z)$ is constant when $t = 1$. Intuitively, uniform contractibility just ensures that each of the domains $\mathcal{S}(\vec{\gamma})$ is arcwise connected (i.e., none have isolated components) and none of them contain holes. Clearly the class of $\mathcal{S}(\vec{\gamma})$ which are uniformly contractible contains the class of $\mathcal{S}(\vec{\gamma})$ whose $\mathcal{S}_\theta(\vec{\gamma})$ are all convex, a class of $\mathcal{S}(\vec{\gamma})$ upon which most uniqueness theory is based. Our assumption is weak and without it most theory and existing algorithms of any existing type appear impossible (unless one is in a situation where the holes do not matter and only one component matters.)[1]

1.4. The gist of the main results. It is common for computer optimization algorithms at the kth step to keep track of both the "primal variables" (in our case f^k) and "dual variables." These are called primal-dual algorithms. We shall see in sections 2 and 4.2 that such an algorithm for MultiOPT which stops in a local

[1]Roughly this means that for all θ, the set $\mathcal{S}_\theta(\vec{\gamma}^*)$ consists only of one piece and has no holes. For such a set to contain holes or to be disconnected, one must be working with a highly nonlinear situation. Under these circumstances, even convergence of one's computer runs to functions f^*, F can be problematic; possibly it would be worth while to reconsider the setup of the original problem.

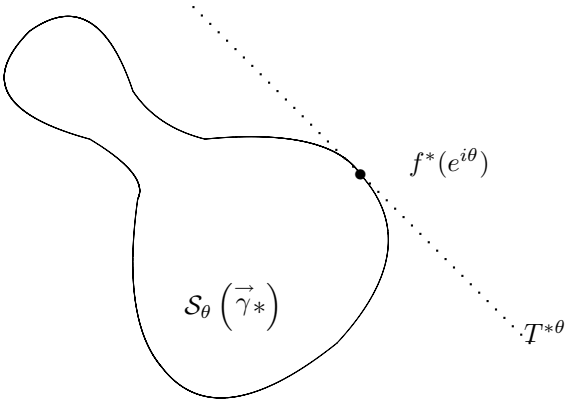

FIG. 2. *Nonconvex but f^* is a unique global optimum.*

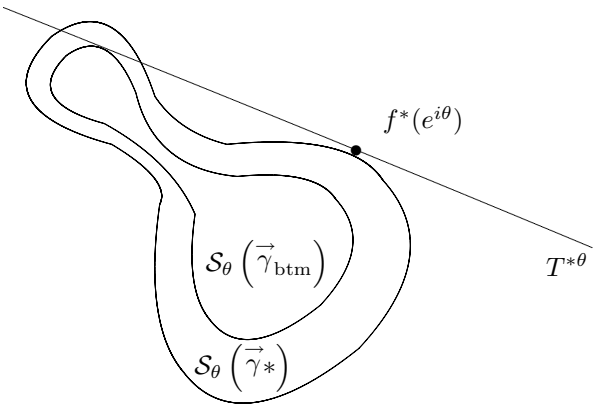

FIG. 3. *Nonconvex but no performance is better than* $\vec{\gamma}^{\rm btm}$.

optimum f^* with performance levels $\vec{\gamma}^* := (\gamma_1(f^*), \ldots, \gamma_\ell(f^*))$ produces information with the simple geometric interpretation that we know the primal local optimum f^* and a[2] tangent plane $T^{*\theta}$ to the boundary $\partial\mathcal{S}_\theta(\vec{\gamma}^*)$ at $f^*(e^{i\theta})$. The tangent plane is a good way to visualize optimal "dual information."

Figure 2 illustrates this situation as well as our uniqueness test when the set $\mathcal{S}_\theta(\vec{\gamma}^*)$ has smooth boundary. Figure 3 illustrates our lower bound for performance. These tests constitute our main results and roughly they say

for each θ, if the tangent plane $T^{*\theta}$ to $\mathcal{S}_\theta(\vec{\gamma}^*)$ at $f^*(e^{i\theta})$

(a) *intersects $\mathcal{S}_\theta(\vec{\gamma}^*)$ at only the point $f^*(e^{i\theta})$, then f^* is the unique global optimum for MultiOPT; see Figure 2;*

(b) *does not intersect $\mathcal{S}_\theta(\vec{\gamma}^{\rm btm})$, then any $f \in H_N^\infty$ has $\vec{\gamma}_j(f) \geq \vec{\gamma}_j^{\rm btm}$ for some $j = 1, 2, \ldots, \ell$. That is, performance can be no better than $\vec{\gamma}^{\rm btm}$; see Figure 3.*

[2]When the set $\mathcal{S}_\theta(\vec{\gamma}^*)$ has smooth boundary (as in problems with a single performance measure Γ^1), the tangent plane $T^{*\theta}$ is unique.

We emphasize that $\mathcal{S}_\theta(\vec{\gamma}^*)$ need not be convex; our conditions are much less stringent. For comparison recall that a closed strictly convex set C with smooth boundary ∂C has the defining property that at each point z_0 on ∂C the tangent plane T_{z_0} to ∂C at z_0 intersects C only at z_0. Thus to check strict convexity one must check this property at *every point* z_0 on ∂C. Our test for uniqueness requires checking this condition at *only one point*, for each θ. This is a surprising property of optimization over spaces of analytic functions.

The tests work in more generality than described here. The sets $\mathcal{S}_\theta(\vec{\gamma}^*)$ can have corners as would be the case with multiperformance problems; see Theorem 4.1. Also, a smaller set than the tangent plane, the *complex tangent plane* suffices in our test; see Theorem 4.2. Section 4.2 gives geometric interpretations of these theorems.

2. Optimality conditions and computation. We begin the detailed description of our global uniqueness test and performance bound by saying precisely what is meant by primal and dual variables.

2.1. Primal-dual optimality conditions. Recall the optimality conditions for MultiOPT. First we introduce the notation

$$\frac{\partial \Gamma}{\partial z} = \begin{pmatrix} \frac{\partial}{\partial z_1}\Gamma_1 & \dots & \frac{\partial}{\partial z_N}\Gamma_1 \\ \dots & \dots & \dots \\ \frac{\partial}{\partial z_1}\Gamma_\ell & \dots & \frac{\partial}{\partial z_N}\Gamma_\ell \end{pmatrix}. \tag{2}$$

THEOREM 2.1 (see [HMer98, Theorem 17.1.1], [HV]). *Assume Γ_j, for $j = 1, \dots, \ell$, satisfies the standard assumption. Suppose that a continuous local optimum f^* does exist with performance values denoted*

$$\gamma_1^*, \dots, \gamma_\ell^*,$$

which makes

$$\frac{\partial \Gamma}{\partial z}(e^{i\theta}, f^*(e^{i\theta}))\frac{\partial \Gamma^T}{\partial z}(e^{i\theta}, f^*(e^{i\theta}))$$

invertible on all $e^{i\theta}$. (This implies $\ell \le N$.) Then there exist functions ψ_j in $L^1(\mathbf{T})$, for $j = 1, \dots, \ell$, which satisfy flatness*,*

$$\psi_j(e^{i\theta})(\gamma_j^* - \Gamma_j(e^{i\theta}, f^*(e^{i\theta}))) = 0 \text{ for } j = 1, \dots, \ell,$$

gradient alignment*,*

$$\psi_1(e^{i\theta})\frac{\partial \Gamma_1}{\partial \bar{z}}(e^{i\theta}, f^*(e^{i\theta})) + \dots + \psi_\ell(e^{i\theta})\frac{\partial \Gamma_\ell}{\partial \bar{z}}(e^{i\theta}, f^*(e^{i\theta})) = e^{-i\theta}\bar{F}(e^{i\theta}), \quad F \in H^2_N, \tag{3}$$

normalization*,*

$$\sum_{j=1}^{\ell} \int_0^{2\pi} \psi_j d\theta = 2\pi,$$

positivity*,*[3]

$$\gamma_j^* - \Gamma_j(e^{i\theta}, f^*(e^{i\theta})) \ge 0 \text{ and } \psi_j \ge 0 \text{ for } j = 1, \dots, \ell.$$

Moreover, it is shown in [HV] *that if f^* is once differentiable, the ψ_j are once differentiable.*

Here A^T denotes the conjugate transpose of A and H^2_N is the set of vector-valued H^2 functions on the circle.

[3]This just reiterates the definition of γ_j^*.

2.2. Computer optimization. It is common for computer optimization algorithms at the kth step to keep track of both the "primal variables" (in our case f^k) and "dual variables" ψ_j^k and consequently F^k. We start with bad guesses $f^0 \in H_N^\infty, \psi_j^0$ and update them in various ways ultimately to approach a solution to the flatness and gradient alignment equations. At optimum a key property is that F is analytic. These are called primal-dual algorithms and are popular. (See [AHO], [VB].) As we shall see in our H^∞ case the dual variable F^k has the interpretation that $e^{-i\theta}\bar{F^k}(e^{i\theta})$ is pointed "normally" to the sets $\mathcal{S}(e^{i\theta})$ at the point $f^k(e^{i\theta})$. Exactly what this means geometrically requires discussion (see section 4.2), but it motivates calling the optimal dual vector function $e^{-i\theta}\bar{F}$ the *conjugate analytic normal* at f^*. The point is that many H^∞ optimization algorithms produce both a primal optimum f^* and a conjugate analytic normal $e^{-i\theta}\bar{F}(e^{i\theta})$ to $\mathcal{S}_\theta(e^{i\theta})$ at $f^*(e^{i\theta})$.

In summary, typical algorithms, c.f. [HMer98], produce a sequence f_k, F_k of approximates to f, F where $f_k \in H_N^\infty \cap C^\infty(\mathbf{T})$. In some algorithms F_k does not belong to H_N^∞, but one can easily compute $\overset{\vee}{F}_k \in H_N^\infty$, which is the best L_N^2 approximate to F_k, and use it as a vague indicator of closeness to optimum f^*, F. In the next section we give a test which removes most of the vagueness from such diagnostics, in that for each $f_k, \overset{\vee}{F}_k$ it gives an absolute lower bound on the best possible performance $\vec{\gamma}^*$. The methods behind proving this lower bound lead to our global uniqueness result.

3. An algorithmic phrasing of our uniqueness test. We now describe our main result in a (high level) algorithmic format. Although a bit redundant it gives a casual reader a description of the method which (except for the most technical hypotheses) is self-contained. The subsequent sections give theorems supplying technical hypotheses and verify that the Algorithm works.

Suppose you have run your favorite numerical algorithm for solving the optimization problem MultiOPT in section 1.1 and that you have obtained a local optimum $f^*, \vec{\gamma}^*$ and the corresponding dual function F.

Before we describe our test, we need a few definitions. For any integer $N > 0$, the N dimensional complex vector space $\mathbf{C}^N$ has the usual inner product $\langle z, w\rangle_C := \sum_j z_j \bar{w}_j =: z \cdot \bar{w}$, but $\mathbf{C}^N$ can be viewed as a $2N$ dimensional real vector space with the inner product $\langle z, w\rangle_R := \operatorname{Re} \sum_j z_j \bar{w}_j =: \operatorname{Re}[z \cdot \bar{w}]$. Define the complex plane which is *complex orthogonal* to the vector $\mathbf{N}$ at location b by

$$\mathbf{N}^{c\perp}(b) := \{z \in \mathbf{C}^N : \bar{\mathbf{N}} \cdot (z - b) = 0\}. \tag{4}$$

This complex orthogonal is a subset of the ordinary *real orthogonal* complement

$$\mathbf{N}^{r\perp}(b) := \{z \in \mathbf{C}^N : \operatorname{Re}[\bar{\mathbf{N}} \cdot (z - b)] = 0\} \tag{5}$$

to $\mathbf{N}$ at b. The b will occasionally be omitted when it is clear from context which point b is intended.

Now we describe our test for global optimality of f^* and, if optimality does not hold, we describe a bound on the best performance.

3.1. The Algorithm. Suppose we are given continuous functions f, F in H_N^∞, where F is never zero on the circle, and the Γ_j satisfy the standard assumption.

1. For each θ, compute[4] a linearly independent set of $N-1$ vectors $\phi^1(e^{i\theta}), \phi^2(e^{i\theta}),$

[4]Given $F(e^{i\theta}) = (F_1(e^{i\theta}), F_2(e^{i\theta}), \dots, F_N(e^{i\theta})) \in \mathbf{C}^N$, there are many ways to compute $\phi^k(e^{i\theta})$ for each θ. One way is to select $\phi^1(e^{i\theta}) = (-F_2(e^{i\theta}), F_1(e^{i\theta}), 0, 0, 0, \dots, 0)$, $\phi^2(e^{i\theta}) = (-F_3(e^{i\theta}), 0, F_1(e^{i\theta}), 0, 0, 0, \dots, 0)$, etc., provided that for that θ, we have $F_1(e^{i\theta}) \neq 0$. The Gram–Schmidt process may be used to obtain an orthogonal set of $\{\phi^k(e^{i\theta})\}_{k=1}^{N-1}$; this may help with numerics.

$\dots, \phi^{N-1}(e^{i\theta})$ satisfying the equation $\phi^k(e^{i\theta}) \cdot F(e^{i\theta}) = 0$ for $k = 1$ to $N-1$. (These $N-1$ vectors form a basis for $\mathbf{N}_\theta^{c\perp}(f(e^{i\theta}))$, where $\mathbf{N}_\theta = e^{-i\theta}\overline{F(e^{i\theta})}$.)

2. For each θ, define $v_\theta^j(w)$ by

$$v_\theta^j(w) := \Gamma_j(e^{i\theta}, f(e^{i\theta}) + w_1\phi^1(e^{i\theta}) + \cdots + w_{N-1}\phi^{N-1}(e^{i\theta})),$$

where $w = (w_1, w_2, \dots, w_{N-1}) \in \mathbf{C}^{N-1}$.

3. For each θ and $j = 1, \dots, \ell$, compute the minimum $\vec{\gamma}_j^{\text{btm}}$ of $v_\theta^j(w)$ for $w \in \mathbf{C}^{N-1}$.

(a) *Global uniqueness of optimum.* If f^* is a local Pareto optimum for MultiOPT with performance $\vec{\gamma}^*$, and F is the corresponding analytic dual, then if for each fixed θ the point $w_0 = 0$ in $\mathbf{C}^{N-1}$ is the unique nondegenerate[5] minimizer for

$$\tilde{\Gamma}(e^{i\theta}, w) := \max\left\{\frac{v_\theta^1(w)}{\gamma_1^*}, \frac{v_\theta^2(w)}{\gamma_2^*}, \dots, \frac{v_\theta^\ell(w)}{\gamma_\ell^*}\right\},$$

then f^* is the only solution to MultiOPT achieving performance level $\vec{\gamma}^*$.

(b) *The multiperformance $\vec{\gamma}^{\text{btm}}$ is a bound on the best performance.* If there exists a $\mathbf{C}^N$-valued continuous[6] function q defined on the circle such that $\operatorname{Re}(e^{i\theta}F(e^{i\theta}) \cdot (q(e^{i\theta}) - f(e^{i\theta}))) < 0$ for all θ and $\Gamma_j(e^{i\theta}, q(e^{i\theta})) \le \vec{\gamma}_j^{\text{btm}}$ for all j and θ,[7] then for any $\tilde{f} \in C(\mathbf{T}) \cap H_N^\infty$, we have $\gamma_j(\tilde{f}) \ge \vec{\gamma}_j^{\text{btm}}$ for at least one $j = 1, \dots, \ell$.

3.2. A tutorial example. Take

$$\Gamma(e^{i\theta}, z_1, z_2) = |(z_1 - e^{-i\theta})(z_1 - ke^{-i\theta})|^2 + |z_2|^2,$$

where $k = e^{\frac{3\pi i}{4}}$. It is easy to see that this is not a convex problem.

One finds that a local optimizer is $f^* := (0, 0)$, giving optimal value equal to $|k|^2 = 1$. We wish to illustrate our global optimality test. Calculate that the partial of Γ with respect to z is

$$\frac{\partial\Gamma}{\partial z}(e^{i\theta}, z) = ((2z_1 - (k+1)e^{-i\theta})\overline{(z_1 - e^{-i\theta})(z_1 - ke^{-i\theta})}, \bar{z_2}),$$

which at $z = (0, 0)$ is

$$\frac{\partial\Gamma}{\partial z}(e^{i\theta}, (0, 0)) = -((k+1)\overline{k}e^{i\theta}, 0).$$

Note this function extends analytically to the disk, which illustrates the gradient alignment condition of local optimality, Theorem 2.1; here $\psi_1 = 1$. There are different ways to implement our global optimality test and we illustrate several of them.

---

[5]Nondegeneracy is a very technical condition which will be defined later in section 4; it involves so fine a distinction that we do not think one would check it in practice.

[6]Note that q does not have to be—in fact, must not be—analytic.

[7]Such a q would exist, for example, if for every j, $\operatorname{Re}(e^{i\theta}F(e^{i\theta}) \cdot (w - f(e^{i\theta}))) < 0$ for all θ and $w \in \mathcal{S}_\theta(\vec{\gamma}^{\text{btm}})$. Here, uniform contractibility of $\mathcal{S}_\theta(\vec{\gamma}^{\text{btm}})$ would guarantee that the continuous function to which those sets may be uniformly contracted would satisfy the conditions that q must satisfy.

The subspace of $\mathbf{C}^N$, which is complex orthogonal to the conjugate of $\frac{\partial \Gamma}{\partial z}(e^{i\theta},(0,0))$, is called the complex tangent plane, and at fixed $e^{i\theta}$ it is

$$\mathbf{N}_\theta^{c\perp}((0,0)) := \{z : z_1 = 0\}.$$

The key issue is whether it intersects

$$\mathcal{S}_\theta(1) = \{z : |(z_1 - e^{-i\theta})(z_1 - ke^{-i\theta})|^2 + |z_2|^2 \le 1\}$$

in more than the one point $(0,0)$. The points in $\mathbf{N}_\theta^{c\perp}((0,0)) \cap \mathcal{S}_\theta(1)$ are

$$\{z : z_1 = 0 \text{ and } |(z_1 - e^{-i\theta})(z_1 - ke^{-i\theta})|^2 + |z_2|^2 \le 1\} = \{z : z_1 = 0 \text{ and } |k|^2 + |z_2|^2 \le 1\}.$$

Since $|k| = 1$ this forces $z_2 = 0$, so $z = (0,0)$. Therefore $(0,0)$ is the unique global optimizer for this MultiOPT problem.

We now give an argument analogous to that just given, but in terms of our Algorithm above. A basis for $\mathbf{N}_\theta^{c\perp}((0,0))$ is $\phi^1(e^{i\theta}) = (0,1)$ for all θ. Then

$$v_\theta^1(w) = \Gamma(e^{i\theta},(0,0) + w(0,1)) = |w|^2.$$

Its minimizer over $w \in \mathbf{C}$ is clearly $(0,0)$ and is unique and nondegenerate.

3.3. Theoretical justification. The lower bound stated in the Algorithm can be rigorously proved under modest assumptions as we now see in Theorem 3.1. See Theorem 3.2 for another bound not requiring the hypothesis concerning q.

THEOREM 3.1. *Suppose the performance functions $\Gamma_1, \ldots, \Gamma_\ell$ satisfy the standard assumption. Suppose that $f, F \in H_N^\infty$ are continuous with F never vanishing. Set $\mathbf{N}_\theta := e^{-i\theta}\bar{F}(e^{i\theta})$. Suppose there exist $\vec{\gamma}_j^{\,\text{btm}}$ such that for every θ and $z \in \mathbf{N}_\theta^{c\perp}(f(e^{i\theta}))$, there exists a $j = 1, 2, \ldots, \ell$ such that*

$$\Gamma_j(e^{i\theta}, z) > \vec{\gamma}_j^{\,\text{btm}} \quad . \tag{6}$$

Suppose that there exists some $\mathbf{C}^N$-valued continuous function $q(e^{i\theta})$ such that $\operatorname{Re}(e^{i\theta}F(e^{i\theta}) \cdot (q(e^{i\theta}) - f(e^{i\theta}))) < 0$ for all θ and $\Gamma_j(e^{i\theta}, q(e^{i\theta})) \le \vec{\gamma}_j^{\,\text{btm}}$ for every $j = 1$ to ℓ. Then there is no $f^{**} \in C(\mathbf{T}) \cap H_N^\infty$ such that $\vec{\gamma}_j\,(f^{**}) \le \vec{\gamma}_j^{\,\text{btm}}$ for $j = 1, 2, \ldots, \ell$.

We soon prove this result which will illustrate the principle behind both 3(a) and 3(b) in the Algorithm.

THEOREM 3.2. *Suppose the performance functions $\Gamma_1, \ldots, \Gamma_\ell$ satisfy the standard assumption. Suppose that $f, F \in H_N^\infty$ are continuous with F never vanishing. Set $\mathbf{N}_\theta := e^{-i\theta}\bar{F}(e^{i\theta})$. Suppose that for every θ and $z \in \mathbf{N}_\theta^{r\perp}(f(e^{i\theta}))$, there exists a $j = 1, 2, \ldots, \ell$ such that*

$$\Gamma_j(e^{i\theta}, z) > \vec{\gamma}_j^{\,\text{btm}} \quad . \tag{7}$$

Then there is no $f^{**} \in C(\mathbf{T}) \cap H_N^\infty$ such that $\vec{\gamma}_j\,(f^{**}) \le \vec{\gamma}_j^{\,\text{btm}}$ for $j = 1, 2, \ldots, \ell$.

COROLLARY 3.3. *If f^* is a local optimum and F is its analytic dual, and if f^*, F are continuous, then f^*, F satisfy the hypotheses of Theorem 3.1 and so its conclusion gives the bound on $\vec{\gamma}_j\,(f^*)$ found in Theorem 3.1.*

Proof of Theorem 3.2. The approach is similar to that which will be used in the proof of the uniqueness theorems in section 5. Consider the transformation of $\mathbf{C}^N$ to $\mathbf{C}$ defined by $\pi_\theta(z) = e^{i\theta}F(e^{i\theta}) \cdot (z - f(e^{i\theta}))$. From assumption (7) we find that $\mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$ does not meet $\mathbf{N}_\theta^{r\perp}$. Thus $\operatorname{Re}\pi_\theta(z)$ is nonzero for all θ and all $z \in \mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$. Thus $\operatorname{Re}\pi_\theta(z)$ has the same sign regardless of the values of θ or $z \in \mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$; by possibly negating F, we may assume that $\pi_\theta(z)$ has strictly negative real part for all $z \in \mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$ and all θ.

Suppose $f^{**} \in H_N^\infty \cap C(\mathbf{T})$ satisfies

$$\Gamma_j(e^{i\theta}, f^{**}(e^{i\theta})) \leq \vec{\gamma}_j^{\,\mathrm{btm}} \tag{8}$$

for every j and θ. The mapping

$$P : \mathbf{T} \to \mathbf{C},$$

$$e^{i\theta} \to \pi_\theta(f^{**}(e^{i\theta}))$$

extends to the analytic function

$$P(s) = sF(s) \cdot (f^{**}(s) - f(s))$$

for s on the closed disk and has a zero at the origin. But since $\pi_\theta(z)$ has strictly negative real part for $z \in \mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$ and all θ, the function P is nonvanishing and has strictly negative real part on the circle. Hence P has strictly negative real part at the origin. This is a contradiction. Thus f^{**} does not exist and the proof is finished. ∎

That P has strictly negative real part on the circle implies that the winding number of P on the circle is zero, while $P(0) = 0$ implies that that winding number is at least 1. This contradiction foreshadows the winding number properties that we shall use in the proof of the Algorithm as stated in Theorem 3.1. The hypothesis involving q could probably be improved.

Proof of Theorem 3.1. Suppose that there exists f^{**} as indicated in the theorem. We construct $\pi_\theta(s)$ and $P(s) = sF(s)(f^{**}(s) - f(s))$ as in the proof of Theorem 3.2. Now assumption (6) and the fact that F is nonzero on the circle imply that for all $\theta, 0 \notin \pi_\theta(\mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}}))$. By continuity of F and f, this implies that for some $\delta > 0$, $\pi_\theta(\mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}}))$ excludes the closed disk of radius δ about 0 in $\mathbf{C}$ for all θ. By uniform contractibility of the $\mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$ there exists a homotopy f_t^{**} from f^{**} to q such that $f_t^{**}(e^{i\theta})$ is contained in $\mathcal{S}_\theta(\vec{\gamma}^{\,\mathrm{btm}})$ for every θ, t. Thus $P_t(e^{i\theta}) := \pi_\theta(f_t^{**}(e^{i\theta}))$ does not vanish for any value of θ nor t, and since it is continuous in t, θ, the winding number $\operatorname{wind}_0(P_t)$ of P_t around 0 is independent of t. Indeed, the winding number of $P(e^{i\theta})$ over the circle is the same as the winding number of $e^{i\theta}F(e^{i\theta}) \cdot (q(e^{i\theta}) - f(e^{i\theta}))$ over the circle, which is zero since we assumed that $\operatorname{Re}(e^{i\theta}F(e^{i\theta}) \cdot (q(e^{i\theta}) - f(e^{i\theta}))) < 0$ for all θ. Now we turn to the completely different property of P, namely $P(0) = 0$, to see that $\operatorname{wind}_0(P) > 0$. This contradicts our finding above that $\operatorname{wind}_0(P) = 0$, and thereby shows that f^{**} cannot exist. ∎

To state rigorous results on uniqueness requires technical definitions and we do this in the next section.

4. Uniqueness theorem. In this section we present the precise theorems which establish the validity of the Algorithm in section 3.

4.1. Uniqueness theorem expressed analytically. First we state a consequence of our main uniqueness theorem, which is easier to understand and carries many of the main ideas.

THEOREM 4.1. *Suppose the performance functions* $\Gamma_1, \dots, \Gamma_\ell$ *satisfy the standard assumption. Suppose the following:*

(1) $f^* \in H_N^\infty(\mathbf{T}) \cap C^1(\mathbf{T})$ *and* $\psi_j \geq 0$ *are functions satisfying the flatness, gradient alignment, normalization, and positivity conditions, as well as the condition that* $\frac{\partial \Gamma}{\partial z} \frac{\partial \Gamma^T}{\partial z}$ *be invertible.*

(2) *Set* $\mathbf{N}_\theta := e^{-i\theta}\bar{F}$. *For each* θ

$$\Gamma(e^{i\theta}, z) := \max\left\{ \frac{\Gamma_1(e^{i\theta}, z)}{\gamma_1^*}, \dots, \frac{\Gamma_\ell(e^{i\theta}, z)}{\gamma_\ell^*} \right\}$$

as a function of z *has a unique minimum for* $z \in \mathbf{N}_\theta^{r\perp}(f^*(e^{i\theta}))$ *occurring at* $z_\theta = f^*(e^{i\theta})$. *Here* $\gamma_j^* := \gamma_j(f^*)$ *denotes the performance level produced by* f^* *with respect to* Γ_j, *for* $j = 1, \dots, \ell$.

Then f^* *is a unique Pareto optimum for MultiOPT at performance level* $\vec{\gamma}$. *Namely, there is no other function* $f \in H_N^\infty \cap C^1$, *with the property* $\gamma_j(f) \leq \gamma_j(f^*)$ *for all* $j = 1, \dots, \ell$.

For the remainder of this work, we shall write $\mathbf{N}_\theta^{r\perp}, \mathbf{N}_\theta^{c\perp}$ to mean $\mathbf{N}_\theta^{r\perp}(f^*(e^{i\theta}))$, $\mathbf{N}_\theta^{c\perp}(f^*(e^{i\theta}))$. A stronger theorem (which is considerably harder to prove) requires minimizing Γ on the set $\mathbf{N}_\theta^{c\perp}$ rather than the set $\mathbf{N}_\theta^{r\perp}$, which is one real dimension bigger than $\mathbf{N}_\theta^{c\perp}$. For SISO systems, that is, $N = 1$, it is this stronger theorem and the observation $\mathbf{N}_\theta^{c\perp} = \{0\}$ which leads to the fact, mentioned in the abstract, that for SISO systems H^∞ optima are unique. Before stating the result we introduce a technical condition.

We say that a real-valued function P on an affine subspace $A \subset \mathbf{C}^N$ has a *nondegenerate* (local) *minimum* at $w_0 \in A$ if P grows at least quadratically near w_0;[8] more precisely, there exists a positive C such that for all w in some neighborhood of w_0 in A, we have

$$|P(w) - P(w_0)| \geq C|w - w_0|^2.$$

THEOREM 4.2. *Suppose the performance functions* $\Gamma_1, \dots, \Gamma_\ell$ *and* f^* *and* F *are as in the set up of Theorem* 4.1 *and satisfy the hypotheses* (1). *Replace hypothesis* (2) *of Theorem* 4.1 *by the following weaker hypotheses:*

(2′a) *Set* $\mathbf{N}_\theta := e^{-i\theta}\bar{F}$. *For each* θ

$$\Gamma(e^{i\theta}, z) := \max\left\{ \frac{\Gamma_1(e^{i\theta}, z)}{\gamma_1^*}, \dots, \frac{\Gamma_\ell(e^{i\theta}, z)}{\gamma_\ell^*} \right\}$$

as a function of z *has a unique minimum for* $z \in \mathbf{N}_\theta^{c\perp}$ *occurring at* $z_\theta = f^*(e^{i\theta})$. *Here* γ_j^* *denotes the performance level produced by* f^* *with respect to* Γ_j, *for* $j = 1, \dots, \ell$.

(2′b) *For every* θ, *the real-valued function* $\Gamma(e^{i\theta}, \cdot)$ *on* $\mathbf{N}_\theta^{c\perp}$ *given in* (2′a) *has a nondegenerate minimum on* $\mathbf{N}_\theta^{c\perp}$ *at* $z = f^*(e^{i\theta})$. *(Note*

[8] For our results we could replace "quadratically" with "polynomially" here; some modification would be required in Lemmas 5.1 and 5.2 to prove this.

that F is never zero on the circle. Condition (2′b) *will be replaced later by condition* (2″b).*)*

Then f^* is a unique Pareto optimum for MultiOPT at performance level $\vec{\gamma}=\vec{\gamma}\,(f^*)$. Namely, there is no other function $f \in H^\infty_N \cap C^1$, with the property $\gamma_j(f) \le \gamma_j(f^*)$ for all $j = 1, \dots, \ell$.

These theorems clearly give a test for determining if a local optimum is the unique global optimum for a MultiOPT problem, which is practical to the extent that computing the minimum of the $\Gamma_j(e^{i\theta}, \cdot)$ over subspace $(e^{-i\theta}\bar{F})^{c\perp}$ or, respectively, over $(e^{-i\theta}\bar{F})^{r\perp}$ is practical. At least this is a $2N-2$ real dimensional problem, respectively, $2N-1$ dimensional problem, as opposed to the infinite dimensional MultiOPT problem.

We emphasize that this condition is much less stringent than a global convexity condition that would be required for uniqueness in most optimization problems (ones not involving stability). This will be explained fully in section 4.3, which describes our results geometrically and compares them to conventional convexity.

4.2. Uniqueness theorem expressed geometrically. All of the results of this paper can be stated geometrically. This way of looking at these optimization problems strongly enhances intuition, and also geometry plays a role in our proofs (see section 5). Critical to a geometric understanding are the sublevel sets

$$\mathcal{S}^j_\theta(\gamma_j) := \{z \in \mathbf{C}^N : \Gamma_j(e^{i\theta}, z) \le \gamma_j\}$$

in $\mathbf{C}^N$ of the performance functions Γ_j. Fix $\vec{\gamma}^* := (\gamma^*_1, \dots, \gamma^*_\ell)$. Let $\partial\mathcal{S}_\theta$ denote the topological boundary of $\mathcal{S}_\theta$. Let $d\partial\mathcal{S}_\theta$ denote

$$d\partial\mathcal{S}_\theta(\gamma^*) := \partial\mathcal{S}^1_\theta(\gamma^*_1) \cap \ldots \cap \partial\mathcal{S}^\ell_\theta(\gamma^*_\ell) \qquad \forall e^{i\theta} \in \mathbf{T}. \tag{9}$$

Of course $d\partial\mathcal{S}_\theta \subset \partial\mathcal{S}_\theta$.

The *flatness hypothesis* corresponds to the geometric statement

$$f^*(e^{i\theta}) \in \partial\mathcal{S}^j_\theta \text{ whenever } \psi_j(e^{i\theta}) \neq 0.$$

Hypothesis (2) of Theorem 4.1 corresponds to the geometric statement

$\mathcal{S}_\theta$ intersects $(e^{-i\theta}\bar{F})^{r\perp}$, a "tangent" plane to $\partial\mathcal{S}_\theta$ at $f^*(e^{i\theta})$, only at $f^*(e^{i\theta})$.

Hypothesis (2′) of Theorem 4.2 corresponds to the geometric statement

$\mathcal{S}_\theta$ intersects $(e^{-i\theta}\bar{F})^{c\perp}$,
a complex tangent plane to $\partial\mathcal{S}_\theta$ at $f^*(e^{i\theta})$,
only at $f^*(e^{i\theta})$ and has second order contact there.

To make these last two statements comprehensible we need some definitions and also we do need to prove the statements. Tangent planes to a smooth surface can be defined as the set of points orthogonal to a normal to the surface; there are two notions of orthogonal, real and complex, which lead to two notions of tangent plane, the ordinary tangent plane and the complex tangent. (See below the discussion on tangents.) We are dealing with surfaces which possibly have corners. Then at a corner there are many normal directions and as a consequence many tangent planes. To get formulas for tangent planes to $\partial\mathcal{S}_\theta$ we need some background.

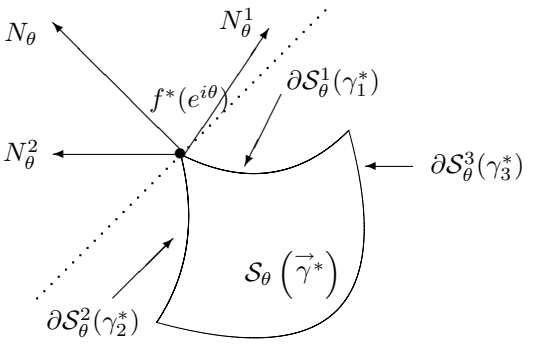

FIG. 4. $\mathbf{N}_\theta^j = \frac{\partial\Gamma_j}{\partial\bar{z}}(e^{i\theta}, f^*(e^{i\theta}))$ *and* $\mathbf{N}_\theta = \psi_1(e^{i\theta})\mathbf{N}_\theta^1 + \psi_2(e^{i\theta})\mathbf{N}_\theta^2 + \psi_3(e^{i\theta})\mathbf{N}_\theta^3$.

Consider a once continuously differentiable function ρ from $\mathbf{C}^N$ to $\mathbf{R}^+$. Let $S = \{z : \rho(z) \le 1\}$ and $\partial S = \{z : \rho(z) = 1\}$ denote its boundary; ρ is called a defining function for ∂S. The surface ∂S is a hypersurface, that is, it has real codimension 1. The gradient $\nabla\rho$ is directed normally to ∂S at z_0, which in complex notation is

$$\nabla\rho(z_0) = \frac{\partial\rho(z_0)}{\partial\bar{z}}.$$

Thus if $z_0 \in \partial\mathcal{S}_\theta^j$, then

$$\frac{\partial\Gamma_j}{\partial\bar{z}}(e^{i\theta}, z_0) \tag{10}$$

is directed normally to $\partial\mathcal{S}_\theta^j$. At a corner of $\mathcal{S}_\theta$ there is a family of normals $\mathcal{N}_\theta$ pointing "out" of $\mathcal{S}_\theta$, which we define to be all vectors of the form

$$\mathcal{N}_\theta := \left\{ \psi_1(e^{i\theta})\frac{\partial\Gamma_1}{\partial\bar{z}}(e^{i\theta}, z_0) + \cdots + \psi_\ell(e^{i\theta})\frac{\partial\Gamma_\ell}{\partial\bar{z}}(e^{i\theta}, z_0) : \text{ for some } \psi_j \ge 0 \right\}. \tag{11}$$

(See Figure 4.) This leads to a formal definition of the *tangent plane* to $\partial\mathcal{S}_\theta$ at $f^*(e^{i\theta})$ as $\mathbf{N}_\theta^{r\perp}$ for some $\mathbf{N}_\theta \in \mathcal{N}_\theta$ and the *complex tangent plane* as $\mathbf{N}_\theta^{c\perp}$ for some $\mathbf{N}_\theta \in \mathcal{N}_\theta$. The *gradient alignment* condition says precisely that

$$e^{-i\theta}\bar{F}(e^{i\theta}) \in \mathcal{N}_\theta.$$

Thus the *gradient alignment* condition amounts to selecting a normal and corresponding tangent planes to $\mathcal{S}_\theta$ at $f^*(e^{i\theta})$. Note the nature of the corner of $\mathcal{S}_\theta$ is determined by which ψ_j are not 0 (called the active ψ_j).

To prove the geometric interpretation of hypotheses (2) and (2′), observe that $\mathcal{S}_\theta(\vec{\gamma}) = \{z : \Gamma(e^{i\theta}, z) \le 1\}$. Thus the hypothesis (2) of Theorem 4.1

$$\Gamma(e^{i\theta}, z) > \min_{\zeta\in T}\Gamma(e^{i\theta}, \zeta) = \Gamma(e^{i\theta}, z_\theta) = 1 \text{ for } z \ne z_\theta \text{ in a set } T$$

says that T touches $\mathcal{S}_\theta(\vec{\gamma})$ only at z_θ where $\Gamma(e^{i\theta}, z_\theta) = 1$. Thus $z_\theta = f^*(e^{i\theta})$ being the location of a unique minimum is equivalent to T touching $\mathcal{S}_\theta(\vec{\gamma})$ only at $f^*(e^{i\theta})$.

The geometrical interpretation of the lower bound presented in section 3 is a variation on what we have just presented which is so straightforward that we will not discuss it in detail.

4.3. Benefits of our uniqueness test and comparisons. The geometric interpretations of this section lead immediately to the statement of our main result given in section 1.4. Recall the striking point is that the test for uniqueness in Theorems 4.2 and 4.1 just requires checking whether a (complex) tangent plane at one point $f^*(e^{i\theta})$ per θ intersects $\mathcal{S}_\theta(\vec{\gamma}^*)$ in other points.

By contrast, convexity requires a test at all points. We now present an analogous "convexity" condition for MultiOPT, a condition which one might try to check a priori; the reader can note how much stronger the hypothesis is than the key condition (2′) presented in Theorem 4.2.

THEOREM 4.3. *Suppose the Γ_j, $j = 1, \dots, \ell$, satisfy the standard assumption. If for every $\theta \in \mathbf{T}$ and every γ_j all complex tangent planes to ∂S_θ touch S_θ in exactly one point and have no more than quadratic order of contact with ∂S_θ,*[9] *then any local optimum is a global optimum.*

Proof. For one smooth Γ this was proved by Vityaev [V] and independently by Whittlesey [W1], [W2]. Multiple Γ_j produce sublevel sets with corners and the slight variation of their proofs required here will be presented in the course of proving Theorem 4.2. Then Theorem 4.3 follows from Theorems 2.1 and 4.2. When "complex tangent plane" is replaced by "tangent plane" thereby producing a stronger assumption in the theorem we have conventional strict convexity; that uniqueness theorem is due to Helton and Howe [HH]. □

4.4. Hypoconvex corners. In this section we are concerned only with uniqueness of optimum and we consider a weaker form of hypothesis (2′) of Theorem 4.2. It is motivated by the fact that often a differentiable local Pareto optimum must be hyperflat; see [HV] for exact hypotheses guaranteeing this. Hyperflatness means that the performance of a particular optimum for every performance Γ_j is flat, i.e., $\Gamma_j(e^{i\theta}, f^*(e^{i\theta}))$ is constant as a function of θ for every $j = 1, 2, \dots, \ell$. The weaker hypothesis is as follows:

(2‴a) Set $\mathbf{N}_\theta := e^{-i\theta}\overline{F}$. The set $\mathbf{N}_\theta^{c\perp}$ intersects $d\partial\mathcal{S}_\theta(\vec{\gamma}^*)$ only at $f^*(e^{i\theta})$ if at all.

(2‴b) There is a homotopy I_t of $d\partial\mathcal{S}_\theta(\vec{\gamma}^*)$ to $f^*(e^{i\theta})$ with $I_t(d\partial\mathcal{S}_\theta(\vec{\gamma}^*))$ lying entirely inside $\mathcal{S}_\theta(\vec{\gamma}^*)$ and missing $\mathbf{N}_\theta^{c\perp}$ for all t, $0 \le t \le 1$.

(2‴c) For every θ, the real-valued function on $\mathbf{N}_\theta^{c\perp}$ given by $z \mapsto \Gamma(e^{i\theta}, z)$ has a nondegenerate minimum on $\mathbf{N}_\theta^{c\perp}$ at $z = f^*(e^{i\theta})$. (Note that this is the same as conditions (2′ b) and (2″ b) of Theorem 4.2.)

THEOREM 4.4. *Assume the hypotheses of Theorem* 4.2 *except replace hypothesis* (2′) *by* (2‴). *Then if f^* and f^{**} are local Pareto optima both with the same performance level $\vec{\gamma}^*$ and if f^{**} is hyperflat, then $f^{**} = f^*$.*

This theorem suggests a class of geometric objects which generalizes the notion of hypoconvexity. We say that $\mathcal{S}_\theta(\vec{\gamma}^*)$ has *hypoconvex corners* provided that at any point p of $d\partial\mathcal{S}_\theta(\vec{\gamma}^*)$ any tangent plane T_p to $d\partial\mathcal{S}_\theta(\vec{\gamma}^*)$ intersects $d\partial\mathcal{S}_\theta(\vec{\gamma}^*)$ only at p and satisfies the order of contact condition (2‴c) at p. Also we require that there be a continuous homotopy I_t satisfying

$$I_t(d\partial\mathcal{S}_\theta(\vec{\gamma}^*)) \subset \mathcal{S}_\theta(\vec{\gamma}^*), \qquad 0 \le t \le 1,$$

[9] This property is called *strict hypoconvexity* and is weaker than strict convexity because complex tangent planes are smaller than tangent planes.

and

$$I_t(d\partial\mathcal{S}_\theta(\vec{\gamma}^{\,*})) \cap T_p = \{p\}.$$

The appeal of having such a geometric condition is as follows. If we have a problem whose sublevel sets $\mathcal{S}_\theta(\vec{\gamma})$ all can be verified to have hypoconvex corners, then clearly no two distinct hyperflat optima f^* and f^{**} can have the same performance levels. Thus if hypoconvexity can be verified in advance, we know (even without any computer runs) that a type of uniqueness must hold.

5. Proofs of Theorem 4.1, Theorem 4.2, and Theorem 4.4. The proof of each theorem begins in the same way and they all follow the pattern laid out in the proofs in section 3. Suppose that $f^* \in H^\infty$, F and performance levels $\gamma_1^*, \ldots, \gamma_\ell^*$ exist meeting hypotheses (1) of Theorem 4.1.

Again consider the transformation

$$\pi_\theta(z) := e^{i\theta}F(e^{i\theta}) \cdot (z - f^*(e^{i\theta})).$$

Transform the sublevel sets $\mathcal{S}_\theta^j(\gamma_j^*)$ with π_θ to obtain sets

$$\tilde{\mathcal{S}}_\theta^j(\gamma_j^*) := \pi_\theta(\mathcal{S}_\theta^j(\gamma_j^*)) \subset \mathbf{C}.$$

This map collapses $\mathcal{S}_\theta^j(\gamma_j^*)$ to $\mathbf{C}$ in a way which makes $\tilde{\mathcal{S}}_\theta^j(\gamma_j^*)$ contain zero.

Suppose f^{**} is an optimizer in $C(\mathbf{T})$ different from f^*. The mapping $P : \mathbf{T} \to \mathbf{C}$ defined by $e^{i\theta} \to \pi_\theta(f^{**}(e^{i\theta}))$ extends to the analytic function

$$P(s) = sF(s) \cdot (f^{**}(s) - f^*(s))$$

for s on the closed disk and has a zero at the origin. P is not identically 0, since the only point $v \in \mathcal{S}_\theta(\vec{\gamma})$ such that $\pi_\theta(v) = 0$ is $f^*(e^{i\theta})$, and for some θ, $f^*(e^{i\theta}) \neq f^{**}(e^{i\theta})$. Thus there is a $\tau > 0$ such that

(P vs. τ) $\quad$ $[0, \tau]$ is in the image of P applied to the unit disk

(by the open mapping theorem applied to P at 0).

5.1. Proof of Theorem 4.1. If $z \in \mathcal{S}_\theta(\vec{\gamma})$, then hypothesis (2) of Theorem 4.1 implies that

$$\operatorname{Re}\pi_\theta(z) \leq 0.$$

To see this, use the geometric interpretation of assumption (2) given in section 4.1, which says

$$\operatorname{Re}\pi_\theta(z) = \operatorname{Re}\left(e^{i\theta}F(e^{i\theta}) \cdot [z - f^*(e^{i\theta})]\right) \neq 0$$

for any $z \in \mathcal{S}_\theta(\vec{\gamma})$ except $z = f^*(e^{i\theta})$. Since $e^{-i\theta}\overline{F}(e^{i\theta})$ is the outward pointing normal we get $\operatorname{Re}\pi_\theta(z) \leq 0$.

Inequality 5.1 implies $\operatorname{Re}P(e^{i\theta}) \leq 0$. Moreover, $P(s)$ is analytic and bounded for s in the unit disk, since f^*, f^{**}, F are. Thus $\operatorname{Re}P(s) \leq 0$ on the unit disk, and in particular $P(s) \neq \tau$ at any $|s| \leq 1$. This contradicts (P vs τ). $\square$

5.2. Proof of Theorem 4.2. In the course of the proof we shall need that fact that condition (2′b.) implies the following condition:

(2″b.) *There exist constants* $C > 0$, $\delta > 0$ *such that for all* θ *and* $z \in \mathcal{S}_\theta(\vec{\gamma})$ *such that* $|z - f^*(e^{i\theta})| < \delta$, *we have* $|F(e^{i\theta}) \cdot (z - f^*(e^{i\theta}))| \geq C|z - f^*(e^{i\theta})|^2$.

We prove this in Lemma 5.1.

Now we must replace the $\operatorname{Re} P \leq 0$ assumption with other weaker structure. This uses the winding number (denoted wind_0) of $(P(e^{i\theta}) - \tau)$ around 0.

The first and greatest difficulty is establishing that it exists. This is accomplished by Lemma 5.2 below, which says we may choose τ small enough that τ is not in $\pi_\theta(\mathcal{S}_\theta(\vec{\gamma}))$ for any θ. Let us assume that this winding number exists and complete the proof.

For perspective note that $\operatorname{Re} P \leq 0$ implies $\operatorname{Re}[P(e^{i\theta}) - \tau] \leq -\tau$, and so $\operatorname{wind}_0[P(e^{i\theta}) - \tau] = 0$. However, even without $\operatorname{Re} P \leq 0$ we can obtain this easily by constructing a homotopy. Recall two functions between which there exists a homotopy not passing through 0 have the same winding number about 0. Begin by constructing a homotopy f_t^{**} of f^{**} to f^* such that every $f_t^{**}(e^{i\theta})$ is contained in $\mathcal{S}_\theta(\vec{\gamma})$. We may do this by using the map I_t from the standard assumption: The maps $I_t(e^{i\theta}, f^*(e^{i\theta}))$ and $I_t(e^{i\theta}, f^{**}(e^{i\theta}))$ construct homotopies of f^* and f^{**} to the same continuous function so the combination is the desired homotopy. Note we do not require the functions f_t^{**} to be analytic, but we merely require them to be continuous. Then the functions P_t

$$e^{i\theta} \mapsto P_t(e^{i\theta}) := \pi_\theta(f_t^{**}(e^{i\theta}))$$

are a homotopy from $P_1 = P$ to $P_0 = 0$. Also,

$$0 = \operatorname{wind}_0(-\tau) = \operatorname{wind}_0(P_0(e^{i\theta}) - \tau) = \operatorname{wind}_0(P(e^{i\theta}) - \tau),$$

since $P_0 = 0$. But from (P vs. τ) the analytic function $P(s) - \tau$ does equal zero for some s in the open disk, so its winding number about 0 is ≥ 1. This is a contradiction, so f^{**} cannot exist. □

LEMMA 5.1. *Condition* (2′b) *implies condition* (2″b).

Proof of Lemma 5.1. Since $z \mapsto \Gamma(e^{i\theta}, z)$ has a nondegenerate minimum on $\mathbf{N}_\theta^{c\perp}$ at $z = f^*(e^{i\theta})$, there exist $\delta(\theta) > 0, C(\theta) > 0$ such that for all $z \in \mathbf{N}_\theta^{c\perp}$ such that $|z - f^*(e^{i\theta})| \leq \delta(\theta)$ we have

$$\Gamma(e^{i\theta}, z) - 1 \geq C(\theta)|z - f^*(e^{i\theta})|^2. \tag{12}$$

By continuity of the functions involved and a compactness argument, we may assume that C and δ are independent of θ. Write $\delta(\theta) = \delta$ and $C(\theta) = C$. Without loss of generality assume that $\delta < 1$. Now suppose that the lemma does not hold; that for each $\epsilon, \gamma > 0$ there exists θ and a $z^1 \in \mathcal{S}_\theta(\vec{\gamma})$ such that $|z^1 - f^*(e^{i\theta})| < \gamma$ but

$$|F(e^{i\theta}) \cdot (z^1 - f^*(e^{i\theta}))| < \epsilon |z^1 - f^*(e^{i\theta})|^2. \tag{13}$$

Let z^2 equal the orthogonal projection of z^1 to $\mathbf{N}_\theta^{c\perp}$. Without loss of generality assume $\gamma < \delta$. Then the distance from z^1 to $\mathbf{N}_\theta^{c\perp}$ is $|z^1 - z^2| = |\frac{F(e^{i\theta})}{|F(e^{i\theta})|} \cdot (z^1 - f^*(e^{i\theta}))| \leq \frac{\epsilon}{|F(e^{i\theta})|}|z^1 - f^*(e^{i\theta})|^2 \leq C_F \epsilon |z^1 - f^*(e^{i\theta})|^2$, where C_F is the reciprocal of the minimum modulus of F on the circle.

Since Γ is uniformly Lipschitz on the set $\{(e^{i\theta}, z) : |z - f^*(e^{i\theta})| \le 1\}$ and $\gamma < \delta < 1$, we find that

$$|z^1 - z^2| \le C_F \epsilon |z^1 - f^*(e^{i\theta})|^2 \tag{14}$$

implies

$$\Gamma(e^{i\theta}, z^2) - 1 \le \Gamma(e^{i\theta}, z^2) - \Gamma(e^{i\theta}, z^1) \le |\Gamma(e^{i\theta}, z^2) - \Gamma(e^{i\theta}, z^1)| \le C_\Gamma C_F \epsilon |z^1 - f^*(e^{i\theta})|^2, \tag{15}$$

where C_Γ depends only on Γ and $|\Gamma(e^{i\theta}, z^2) - \Gamma(e^{i\theta}, z^1)| \le C_\Gamma |z^1 - z^2|$. (Recall $\Gamma(e^{i\theta}, z^1) \le 1$ since $z^1 \in \mathcal{S}_\theta(\vec{\gamma})$.) From (14) and the fact that $|z^1 - f^*(e^{i\theta})| \le \delta < 1$, we obtain $|z^1 - z^2| \le C_F \epsilon |z^1 - f^*(e^{i\theta})|$. Now suppose we choose ϵ so small that $C_F \epsilon < \sqrt{3}/2$. Then the Pythagorean theorem guarantees that $|z^1 - z^2|^2 + |z^2 - f^*(e^{i\theta})|^2 = |z^1 - f^*(e^{i\theta})|^2$, so

$$|z^1 - f^*(e^{i\theta})|^2 \le 4 |z^2 - f^*(e^{i\theta})|^2. \tag{16}$$

Combining (15) and (16),

$$\Gamma(e^{i\theta}, z^2) - 1 \le C_\Gamma C_F 4\epsilon |z^2 - f^*(e^{i\theta})|^2,$$

which contradicts (12) (since $C_\Gamma C_F 4\epsilon$ can be made arbitrarily small), where we recall that $C(\theta) = C$, $z^2 \in \mathbf{N}_\theta^{c\perp}$, and $|z^2 - f^*(e^{i\theta})| \le |z^1 - f^*(e^{i\theta})| < \gamma < \delta$. ∎

Define

$$\tilde{\mathcal{S}}_\theta := \pi_\theta(\mathcal{S}_\theta).$$

We owe the reader the following.

LEMMA 5.2. *The set $\tilde{\mathcal{S}}_\theta$ excludes the set*

$$\mathcal{K} := \left\{ \tilde{z} \in \mathbf{C} : \ \operatorname{Re} \tilde{z} > \frac{1}{2} \sqrt{|\tilde{z}|} \right\} \ \cap \ \{ \tilde{z} \in \mathbf{C} : \ |\tilde{z}| < \varepsilon \},$$

where ε is some positive constant.

The set $\mathcal{K}$ is a "solid cusp" of uniform size (independent of θ) whose interior lies outside of $\tilde{\mathcal{S}}_\theta$ for all θ, and whose singularity touches every $\tilde{\mathcal{S}}_\theta$ at 0.

Proof of Lemma 5.2. The proof splits in two parts. First we show that a $\tilde{z}$ in the image under π_θ of a $z \in \mathcal{S}_\theta$ near $f^*(e^{i\theta})$ lies in the set

$$\left\{ \tilde{z} \in \mathbf{C} : \ \operatorname{Re} \tilde{z} \le \frac{1}{2} \sqrt{|\tilde{z}|} \right\}.$$

In the second part we show that a $\tilde{z}$ in the image of a $z \in \mathcal{S}_\theta$ far from $f^*(e^{i\theta})$ satisfies $|\tilde{z}| \ge \varepsilon$.

CLAIM. *There exists a $\delta > 0$, such that for all*

$$\tilde{z} \in \pi_\theta(\ \mathcal{S}_\theta \cap \{ z \in \mathbf{C}^n \ \ : \ |z - f^*(e^{i\theta})| < \delta \} \ )$$

we have $\operatorname{Re} \tilde{z} \le \frac{1}{2} \sqrt{|\tilde{z}|}$.

Proof of claim. Choose ε so small that for all $e^{i\theta} \in \mathbf{T}$, we have $(\sum_{j=1}^{\ell} \psi_j(e^{i\theta}))\varepsilon / \sqrt{C} < 1/2$, where C comes from assumption (2″b). Choose ε even smaller and then δ so small that assumption (2″b) is satisfied and for $|z - f^*(e^{i\theta})| < \delta$, $z \in \mathcal{S}_\theta$, and $1 \le j \le \ell$,

$$\operatorname{Re} \left(\frac{\partial \Gamma_j}{\partial z}(e^{i\theta}, f^*(e^{i\theta})) \cdot (z - f^*(e^{i\theta})) \right) < \varepsilon |z - f^*(e^{i\theta})|.$$

Then

(17)

$$\mathrm{Re}\,(e^{i\theta}F(e^{i\theta})\cdot(z-f^*(e^{i\theta}))) = \mathrm{Re}\left(\sum_{j=1}^{\ell}\left(\psi_j(e^{i\theta})\frac{\partial\Gamma_j}{\partial z}(e^{i\theta},f^*(e^{i\theta}))\right)\cdot(z-f^*(e^{i\theta}))\right)$$

(18)

$$\leq \left(\sum_{j=1}^{\ell}\psi_j(e^{i\theta})\right)\varepsilon|z-f^*(e^{i\theta})|.$$

By assumption (2″b), $|z-f^*(e^{i\theta})| \leq \frac{1}{\sqrt{C}}\sqrt{|F(e^{i\theta})\cdot(z-f^*(e^{i\theta}))|}$, so

(19) $\mathrm{Re}\,(e^{i\theta}F(e^{i\theta})\cdot(z-f^*(e^{i\theta})))$

(20)

$$\leq \left(\sum_{j=1}^{\ell}\psi_j(e^{i\theta})\right)\frac{\varepsilon}{\sqrt{C}}\sqrt{|e^{i\theta}F(e^{i\theta})\cdot(z-f^*(e^{i\theta}))|}$$

(21)

$$\leq \frac{1}{2}\sqrt{|e^{i\theta}F(e^{i\theta})\cdot(z-f^*(e^{i\theta}))|},$$

i.e.,

$$\mathrm{Re}\,(\pi_\theta(z)) \leq \frac{1}{2}\sqrt{|\pi_\theta(z)|}$$

for all $(s,z)\in\mathcal{S}\cap\{(s,z)\in\mathbf{T}\times\mathbf{C}^n;\ |z-f^*(e^{i\theta})|<\delta\}$. The claim follows.

For the second part of the proof, we consider $\tilde{z}\in\tilde{\mathcal{S}}_\theta$ such that $\tilde{z}=\pi_\theta(z)$ and $|z-f^*(e^{i\theta})|\geq\delta$, where δ is from the first part of the proof. Assumption (2′a) says that $\mathcal{S}_\theta$ misses the complex tangent plane $\mathbf{N}_\theta^{c\perp}$ for all θ (except for $f^*(e^{i\theta})$), so

$$|\pi_\theta(z)|>0$$

for $z\in\mathcal{S}_\theta$ and $z-f^*(e^{i\theta})\neq 0$. By continuity and compactness there exists $\varepsilon>0$ such that if $z\in\mathcal{S}_\theta$ and $|z-f^*(e^{i\theta})|>\delta$ we have

$$|\pi_\theta(z)|>\varepsilon>0$$

uniformly in θ, for some ε and all z,θ, so $|\tilde{z}|>\varepsilon>0$. Combining this with the claim, the proof of the lemma is complete. □

Proof of Theorem 4.4. The proof follows that of Theorem 4.2. The principal difference is the existence of a homotopy f_t^{**} of f^* to f^{**} such that for all θ, $\pi_\theta(f_t^{**}(e^{i\theta}))$ does not belong to the set $\mathcal{K}$. In the proof of Theorem 4.2 the homotopy of the sets $\mathcal{S}$ is the tool that provides us with this fact. Now that we know that the optimum f^* is hyperflat, its graph lies in a smaller set, so the homotopy of the entire $\mathcal{S}$ is not needed; the homotopy of the set where $\Gamma_j=\gamma_j$ for every j (which contains the graph of f^*) will suffice. The only change, then, arises in the second part of the proof of Lemma 5.2, where assumption (2′a) is used. □

COMPUTATION FOR MULTIDIMENSIONAL CAUCHY PROBLEM*

T. WEI†, Y. C. HON‡, AND J. CHENG§

Abstract. This paper devises a computational method for solving a Cauchy problem of Laplace's equation in multidimensional space. By using the Green formula, the Cauchy problem is transformed to a moment problem so that numerical computations using a regularization technique can be achieved. A stability estimation and a suitable choice of regularization parameter for the proposed method are also given. For numerical verification, a numerical example in the three-dimensional case is presented.

Key words. numerical computation, Cauchy problem, ill-posedness, multidimension

1. Introduction.

Let $\Omega \subset \mathcal{R}^{d+1}, d \in \mathcal{N}$, be a simply connected domain with Lipschitz continuous boundary $\partial\Omega$. Assume that Γ is an open part of the boundary $\partial\Omega$. Without loss of generality, Γ is also assumed to be connected. Consider the following multidimensional Cauchy problem of Laplace's equation:

$$\Delta u(x) = 0, \qquad x \in \Omega, \tag{1.1}$$

$$u(x) = f(x), \qquad x \in \Gamma, \tag{1.2}$$

$$\frac{\partial u(x)}{\partial \nu} = g(x), \qquad x \in \Gamma, \tag{1.3}$$

where Δ is the $(d+1)$-dimensional Laplacian operator and ν is the unit outward normal with respect to $\partial\Omega$.

This is the classical Cauchy problem of Laplace's equation which arises from many real applications such as nondestructive testing techniques [1], [5], [6], [10], [12], geophysics [23], and cardiology [13]. The Cauchy problem is known to be highly ill-posed. That is, any small change in the initial data may result in a dramatic change in the solution (see page 16 in [7] and Chapter 2 in [17]). Under an additional a priori boundedness condition, a continuous dependence of the solution on the initial data can be obtained. This is called conditional stability [20]. Other conditional stability for Laplace's equation can be found in [11].

Due to the highly ill-posedness of the problem, numerical computation is very difficult. To the knowledge of the authors, there is still no numerical solution to the Cauchy problem (1.1)–(1.3) in three- or higher-dimensional cases. To obtain a stable numerical solution for these kinds of ill-posed problems, several regularization

methods have been proposed: The quasi-reversibility method [18], [19], the Tikhonov regularization method [3], [23], the boundary element method [15], and discretization [14], [21], [8]. Recently, Cheng et al. [9] and Hon and Wei [16] proposed a new computational method for solving the Cauchy problem for Laplace's equation (1.1)–(1.3) in a two-dimensional case through a transformation of the Cauchy problem to a moment problem whose numerical approximation can be achieved.

This paper further extends the method to solve a multidimensional Cauchy problem for Laplace's equation. The proposed method is similar to the existing boundary element method for solving elliptic equations. From the numerical solution of the moment problem, the boundary values of the solution on $\partial\Omega \setminus \Gamma$ are determined. The interior values of the solution can then be obtained after solving a well-posed mixed boundary value problem for Laplace's equation. A stability estimation and a suitable choice of regularization parameter for the proposed method are also given. For numerical verification, a numerical example is presented at the end of section 6.

2. Methodology. Let v satisfy

$$\Delta v(x) = 0, \qquad x \in \Omega, \tag{2.1}$$

$$\frac{\partial v(x)}{\partial \nu} = 0, \qquad x \in \Gamma_1, \tag{2.2}$$

where $\Gamma_1 = \partial\Omega \setminus \Gamma$.

Using the Green formula, we have

$$\int_\Omega (v\Delta u - u\Delta v)d\sigma = \int_{\partial\Omega} \left(v\frac{\partial u}{\partial \nu} - u\frac{\partial v}{\partial \nu} \right) ds, \tag{2.3}$$

where $d\sigma$ and ds represent the volume and area elements, respectively.

Since u is the solution of (1.1)–(1.3) and v is the solution of (2.1)–(2.2), the identity (2.3) can be rewritten as

$$\int_{\Gamma_1} v\frac{\partial u}{\partial \nu} ds = \int_\Gamma \left(f\frac{\partial v}{\partial \nu} - gv \right) ds. \tag{2.4}$$

Denote

$$\mathcal{H} = \{v \mid v \text{ satisfies (2.1)–(2.2)}\}. \tag{2.5}$$

In our recent work [9], [16], we have the following result.

PROPOSITION 2.1. *If the Cauchy problem* (1.1)–(1.3) *has a solution u such that $\frac{\partial u}{\partial \nu}|_{\Gamma_1} \in L^2(\Gamma_1)$, then $\beta = \frac{\partial u}{\partial \nu}|_{\Gamma_1}$ is the unique solution satisfying the following moment problem:*

$$\int_{\Gamma_1} v\beta ds = \int_\Gamma \left(f\frac{\partial v}{\partial \nu} - gv \right) ds \equiv \mu_v(f, g), \tag{2.6}$$

where $v \in \mathcal{H}$.

Conversely if $\beta \in L^2(\Gamma_1)$ is the solution of (2.6)*, then there exists a unique solution u of the Cauchy problem* (1.1)–(1.3) *such that $\frac{\partial u}{\partial \nu}|_{\Gamma_1} = \beta \in L^2(\Gamma_1)$.*

For numerical computational purposes, we choose $\{v_j\}_{j=0}^\infty \subset \mathcal{H}$ such that

$$\overline{Span\{v_j|_{\Gamma_1}\}_{j=0}^\infty} = L^2(\Gamma_1).$$

The moment problem (2.6) becomes

$$\int_{\Gamma_1} v_j \beta ds = \mu_j, \qquad j = 0, 1, 2, \ldots, \tag{2.7}$$

where $\mu_j = \int_\Gamma (f \frac{\partial v_j}{\partial \nu} - g v_j) ds$ and v_j are functions satisfying (2.1)–(2.2). It is noted here that each μ_j is determined uniquely from f, g, and $v_j \in \mathcal{H}$. In the following sections, it will be shown that the basis functions v_j $(j = 0, 1, 2, \ldots)$ can be suitably chosen to give a stable and satisfactory numerical approximation for the solution of the Cauchy problem.

3. Choices of basis functions in the space $\mathcal{H}$. A constructional method for obtaining a set of basis functions from the space $\mathcal{H}$ is given in the following proposition.

PROPOSITION 3.1. *Given is the following special Cauchy problem for Laplace's equation:*

$$\Delta v(x_1, x_2, \ldots, x_d, x_{d+1}) = 0, \qquad x = (x_1, x_2, \ldots, x_{d+1}) \in \mathcal{R}^{d+1}, \tag{3.1}$$

$$\frac{\partial v}{\partial x_{d+1}}(x_1, \ldots, x_d, 0) = 0, \tag{3.2}$$

$$v(x_1, \ldots, x_d, 0) = x_1^{k_1} x_2^{k_2} \cdots x_d^{k_d}, \tag{3.3}$$

where $k_1, k_2, \ldots, k_d$ are fixed numbers in $\mathcal{N} \cup \{0\}$. There exists a homogeneous polynomial in $\mathcal{R}^{d+1}$ that satisfies (3.1)–(3.3) *of the form*

$$v(x) = x_1^{k_1} x_2^{k_2} \ldots x_d^{k_d} + \sum_{n=2}^{s} P_{s-n}(x_1, x_2, \ldots, x_d) x_{d+1}^n, \tag{3.4}$$

where, for $s = k_1 + k_2 + \cdots + k_d$ and $n = 2, 3, \ldots, s$,

$$P_{s-n} = \begin{cases} 0 & \text{when } n \text{ is odd,} \\ (-1)^{\frac{n}{2}} \frac{1}{n!} \triangle^{\frac{n}{2}} (x_1^{k_1} x_2^{k_2} \cdots x_d^{k_d}) & \text{when } n \text{ is even.} \end{cases} \tag{3.5}$$

Proof. Denote $s = k_1 + k_2 + \cdots + k_d$ to be the order of the polynomial in the right-hand side of (3.3). For the cases in which $s = 0, 1$, it is clear that $v(x) = x_1^{k_1} x_2^{k_2} \cdots x_d^{k_d}$ satisfies (3.1)–(3.3). For the cases in which $s \geq 2$, it is easy to obtain from the boundary conditions (3.2) and (3.3) that the solution $v(x)$ is the following homogeneous polynomial of order s:

$$v(x) = x_1^{k_1} x_2^{k_2} \cdots x_d^{k_d} + \sum_{n=2}^{s} P_{s-n}(x_1, x_2, \ldots, x_d) x_{d+1}^n, \tag{3.6}$$

where $P_m(x_1, x_2, \ldots, x_d)$ is a homogeneous polynomial of $x_1, x_2, \ldots, x_d$ with order $m, m = 0, 1, \ldots, s-2$. Denote $w = x_1^{k_1} x_2^{k_2} \cdots x_d^{k_d}$. We then have

$$\begin{aligned} \Delta v(x) = {} & (\Delta w + 2P_{s-2}) + (0 + 3 \cdot 2 P_{s-3}) x_{d+1} \\ & + \sum_{n=2}^{s-2} (\triangle P_{s-n} + (n+2)(n+1) P_{s-n-2}) x_{d+1}^n. \end{aligned}$$

From (3.1), the homogeneous polynomials $P_m, m = 0, 1, \ldots, s-2$, must satisfy the following recursive formula:

$$\triangle w + 2P_{s-2} = 0, \tag{3.7}$$

$$0 + 3 \cdot 2 P_{s-3} = 0, \tag{3.8}$$

$$\triangle P_{s-n} + (n+2)(n+1) P_{s-n-2} = 0, \quad n = 2, 3, \ldots, s-2, \tag{3.9}$$

for $s \geq 4$. In the case when $s = 2$, only (3.7) is valid. When $s = 3$, only (3.7) and (3.8) are valid. From (3.7)–(3.9), we can deduce that, for $n = 2, 3, \ldots, s$,

$$P_{s-n} = \begin{cases} 0 & \text{when } n \text{ is odd,} \\ (-1)^{\frac{n}{2}} \frac{1}{n!} \triangle^{\frac{n}{2}} w & \text{when } n \text{ is even.} \end{cases} \tag{3.10}$$

Substituting (3.10) into (3.6), we have then constructed a homogeneous polynomial of order s that satisfies the Cauchy problem (3.1)–(3.3). ∎

Henceforth we denote the polynomial solution (3.6) for given $k_1, k_2, \ldots, k_d$ as $v_{k_1 k_2 \cdots k_d}(x)$, $\quad x = (x_1, \ldots, x_{d+1})$. For the three-dimensional case ($d = 2$), several basis functions will be given in section 6.

PROPOSITION 3.2. *For $k_1, k_2, \ldots, k_d \in \mathcal{N} \cup \{0\}$, we have*

$$|v_{k_1, k_2, \ldots, k_d}(x)| \leq (2M)^s, \qquad x \in \bar{\Omega}, \tag{3.11}$$

and

$$\left| \frac{\partial v_{k_1, k_2, \ldots, k_d}(x)}{\partial x_i} \right| \leq (4M)^s, \qquad i = 1, 2, \ldots, d+1, \tag{3.12}$$

where $M = \sup_{x \in \bar{\Omega}} |x|$ and $s = k_1 + k_2 + \cdots + k_d$.

Proof. Since the proof will be similar in the general dimensional cases, we shall give the proof of (3.11) only for the case in which $d = 2$. For $d = 2$, we simply denote $(k_1, k_2) = (i, j)$. By using the formula (3.6) and (3.10) in Proposition 3.1, we get

$$v_{ij}(x) = w - \frac{1}{2!}(\triangle w)x_3^2 + \frac{1}{4!}(\triangle^2 w)x_3^4 + \cdots + (-1)^N \frac{1}{(2N)!}(\triangle^N w)x_3^{2N}, \tag{3.13}$$

where $w = x_1^i x_2^j$ and $N = [\frac{i+j}{2}]$ with $[a]$ denoting the largest integer less or equal to a.

Since

$$\begin{aligned} \triangle^n w &= \left(\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} \right)^n x_1^i x_2^j \\ &= \sum_{r=0}^{n} C_n^r \left(\frac{\partial^2}{\partial x_1^2} \right)^r x_1^i \left(\frac{\partial^2}{\partial x_2^2} \right)^{n-r} x_2^j \\ &= \sum_{r=0}^{n} C_n^r C_i^{2r} C_j^{2n-2r} (2r)!(2n-2r)! x_1^{i-2r} x_2^{j-2(n-r)}, \end{aligned} \tag{3.14}$$

where C_n^r is the usual combinatorial notation, here, $C_n^r = 0$ for $r > n$. Since $C_n^r \leq C_{2n}^{2r}$, we obtain

$$\frac{1}{(2n)!} |\triangle^n w| \leq \sum_{r=0}^{n} C_i^{2r} C_j^{2n-2r} M^{i+j-2n}. \tag{3.15}$$

From (3.13) and (3.15), we then have

$$|v_{ij}| \leq \left(1 + \sum_{n=1}^{N} \sum_{r=0}^{n} C_i^{2r} C_j^{2n-2r} \right) M^{i+j} \tag{3.16}$$

$$\leq 2^i 2^j M^{i+j}. \tag{3.17}$$

A similar proof for (3.12) can be obtained. The proof of the proposition is then complete. □

In the next section, a numerical algorithm with convergence analysis for solving the moment problem is given. The numerical approach will be shown to be both accurate and efficient in section 6.

4. Algorithm for solving the moment problem. Let $\Omega \subset \mathcal{R}_+^{d+1}$ be a bounded and simply connected Lipschitz domain and

$$\Gamma_1 = \partial\Omega \setminus \Gamma = \{\, x \,|\, x_{d+1} = 0,\ 0 \le x_i \le 1,\ \ i = 1, 2, \ldots, d\}, \tag{4.1}$$

where Γ is an open part of the boundary $\partial\Omega$. It is noted here that Γ can be an arbitrary Lipschitz boundary. This makes the proposed method feasible and robust in solving real practical inverse problems arising from the physical world. We choose $v_{k_1 k_2 \cdots k_d}(x)$ as given in Propositions 3.1 and 3.2 for all $k_1, k_2, \ldots, k_d$ in $\mathcal{N} \cup \{0\}$. Since they all satisfy (3.1)–(3.3), we obtain from (2.7) that the Cauchy problem for Laplace's equation (1.1)–(1.3) is equivalent to the following moment problem:

$$\int_{\Gamma_1} x_1^{k_1} \cdots x_d^{k_d} \beta(x_1, \ldots, x_d) dx_1 \cdots dx_d = \mu_{k_1 \cdots k_d} \quad \forall k_1, k_2, \ldots, k_d \in \mathcal{N} \cup \{0\}, \tag{4.2}$$

where $\Gamma_1 = [0, 1]^d$ and

$$\mu_{k_1 \cdots k_d} = \int_\Gamma \left(f \frac{\partial v_{k_1 \cdots k_d}}{\partial \nu} - g v_{k_1 \cdots k_d} \right) ds. \tag{4.3}$$

This moment problem is called the Hausdorff moment problem and has been studied by many researchers (see, e.g., [4], [22], [24], [25]). Particularly, a practical algorithm for the numerical computation of the Hausdorff moment problem in the two-dimensional case can be found in the works of Talenti [22] and Viano [24]. The numerical method for multidimensional Hausdorff moment problems can be found in Ang, Gorenflo, and Trong [2].

Based on the numerical method given by Ang, Gorenflo, and Trong [2], an approximated solution for the moment problem (4.2) can be obtained from the following numerical steps:

Step 1. Calculate the shifted Legendre polynomials and their coefficients:

$$L_m(x) = \sum_{j=0}^{m} C_{mj} x^j, \qquad m = 0, 1, 2, \ldots, \tag{4.4}$$

where

$$C_{mj} = (2m+1)^{\frac{1}{2}} (-1)^j \frac{(m+j)!}{(j!)^2 (m-j)!}, \quad j = 0, 1, \ldots, m. \tag{4.5}$$

Step 2. Calculate the coefficients:

$$\lambda_{k_1 \cdots k_d} = \sum_{p_1=0}^{k_1} \cdots \sum_{p_d=0}^{k_d} C_{k_1 p_1} \cdots C_{k_d p_d} \mu_{p_1 \cdots p_d}. \tag{4.6}$$

Step 3. Calculate the approximated solution:

$$p_N(x_1, \ldots, x_d) = \sum_{k_1, \ldots, k_d = 0}^{k_1 + \cdots + k_d = N} \lambda_{k_1 \cdots k_d} L_{k_1 \cdots k_d}, \tag{4.7}$$

where the orthonormal polynomials $L_{k_1\cdots k_d}$ are defined by

$$L_{k_1\cdots k_d}(x_1,\ldots,x_d) = L_{k_1}(x_1)\cdots L_{k_d}(x_d)$$
$$= \sum_{p_1=0}^{k_1}\cdots\sum_{p_d=0}^{k_d} C_{k_1p_1}\cdots C_{k_dp_d}x_1^{p_1}\cdots x_d^{p_d}.$$

The p_N given in Step 3 then approximates the solution β of the moment problem.

Remark 4.1. The formula given in Step 3 is a little different from the one given in Ang, Gorenflo, and Trong [2].

THEOREM 4.2. *Let $\mu = \{\mu_{k_1\cdots k_d}\}, k_i \in \mathcal{N}\cup\{0\}, i = 1,2,\ldots,d$, be a sequence of real numbers obtained from* (4.3)*, and p_N is given by Step* 3*. Suppose that u is the solution of the Cauchy problem* (1.1)–(1.3)*. Denote $\beta = \frac{\partial u}{\partial \nu}|_{\Gamma_1}$. Then we have*

$$\sum_{k_1,\ldots,k_d=0}^{\infty}\left(\sum_{p_1,\ldots,p_d=0}^{\infty} C_{k_1p_1}\cdots C_{k_dp_d}\mu_{p_1\cdots p_d}\right)^2 \le \infty \tag{4.8}$$

and

$$p_N \to \beta \quad in \quad L^2(\Gamma_1) \quad as \quad n\to\infty, \tag{4.9}$$

where C_{ij} is defined by (4.5) *when $j \le i$ and $C_{ij} = 0$ when $j > i$. Moreover, if β is in $H^1(\Gamma_1)$, then*

$$\|p_N - \beta\| \le \frac{\sqrt{d}}{N+1}(F(\beta))^{\frac{1}{2}}, \qquad N\in\mathcal{N}, \tag{4.10}$$

where $\|\cdot\|$ is the usual $L^2(\Gamma_1)$ norm and

$$F(\beta) = \sum_{i=1}^{d}\int_{\Gamma_1} x_i(1-x_i)\left|\frac{\partial\beta}{\partial x_i}\right|^2 dx_1\cdots dx_d. \tag{4.11}$$

Proof. For simplicity, we give the proof in the case when $d = 2$. For notational convenience, denote $(x_1,x_2) = (x,y)$, $(k_1,k_2) = (i,j)$, $\mu_{k_1k_2} = \mu_{ij}$, $L_{k_1k_2}(x,y) = L_i(x)L_j(y)$, and $\Gamma_1 = [0,1]^2$. From the formula (4.2) and (4.6), we have

$$\int_{\Gamma_1}\beta L_{ij}dxdy = \lambda_{ij}, \qquad i,j = 0,1,\ldots. \tag{4.12}$$

Using the completeness and the orthonormality properties of $\{L_{ij}\}$ in $L^2(\Gamma_1)$, we obtain

$$\beta = \sum_{i,j=0}^{\infty}\lambda_{ij}L_{ij} \tag{4.13}$$

and

$$\|\beta\|^2 = \sum_{i,j=0}^{\infty}|\lambda_{ij}|^2 \le \infty,$$

and hence (4.8) holds. To prove (4.9), we subtract (4.7) from (4.13) to obtain

$$\beta - p_N = \sum_{i+j \geq N+1} \lambda_{ij} L_{ij}. \tag{4.14}$$

Hence

$$\|\beta - p_N\|^2 = \sum_{i+j \geq N+1} |\lambda_{ij}|^2. \tag{4.15}$$

Combining (4.8) and (4.15), we then have (4.9). For (4.10), we rely on the following identity (cf. [2], [22]):

$$\int_0^1 x(1-x)|v'(x)|^2 dx = \sum_{k=0}^{\infty} k(k+1)\alpha_k^2 \qquad \forall v \in H^1(0,1), \tag{4.16}$$

where $\alpha_k = \int_0^1 v(x) L_k(x) dx$. From (4.13) and (4.16), we then have

$$\sum_{i,j=0}^{\infty} i^2 \lambda_{ij}^2 \leq \int_{\Gamma_1} x(1-x) \left| \frac{\partial \beta}{\partial x}(x,y) \right|^2 dxdy \tag{4.17}$$

and

$$\sum_{i,j=0}^{\infty} j^2 \lambda_{ij}^2 \leq \int_{\Gamma_1} y(1-y) \left| \frac{\partial \beta}{\partial y}(x,y) \right|^2 dxdy. \tag{4.18}$$

Adding (4.17) to (4.18), we obtain

$$\sum_{i,j=0}^{\infty} (i^2 + j^2) \lambda_{ij}^2 \leq F(\beta), \tag{4.19}$$

where $F(\beta)$, defined in (4.11), becomes

$$F(\beta) = \int_{\Gamma_1} \left(x(1-x) \left| \frac{\partial \beta}{\partial x}(x,y) \right|^2 + y(1-y) \left| \frac{\partial \beta}{\partial y}(x,y) \right|^2 \right) dxdy. \tag{4.20}$$

Since

$$2(i^2 + j^2) \geq (N+1)^2 \quad \text{for} \quad i + j \geq N+1, \tag{4.21}$$

we finally obtain from (4.15), (4.19), and (4.21) that

$$(N+1)^2 \|p_N - \beta\|^2 \leq 2 \sum_{i+j \geq N+1} (i^2 + j^2) \lambda_{ij}^2 \leq 2F(\beta), \tag{4.22}$$

which then completes the proof. □

5. Stability estimation and choice of regularization parameter. Taking the highly ill-posedness characteristic of the Cauchy problem into consideration, we now assume that the Cauchy data f and g contain some errors.

Let $\widetilde{f}$ and $\widetilde{g}$ be measured data with total error less than ε as

$$\|\widetilde{f} - f\|_{L^2(\Gamma)} + \|\widetilde{g} - g\|_{L^2(\Gamma)} \leq \varepsilon. \tag{5.1}$$

The corresponding moments for $\widetilde{f}$ and $\widetilde{g}$ are

$$\widetilde{\mu}_{k_1\cdots k_d} = \int_\Gamma \left(\widetilde{f} \frac{\partial v_{k_1\cdots k_d}}{\partial \nu} - \widetilde{g} v_{k_1\cdots k_d} \right) ds. \tag{5.2}$$

We have the following error estimate about the moments:

$$\begin{aligned} |\widetilde{\mu}_{k_1\cdots k_d} - \mu_{k_1\cdots k_d}| &\leq \left[\left(\int_\Gamma v_{k_1\cdots k_d}^2 ds \right)^{\frac{1}{2}} + \left(\int_\Gamma \left(\frac{\partial v_{k_1\cdots k_d}}{\partial \nu} \right)^2 ds \right)^{\frac{1}{2}} \right] \varepsilon \\ &= D_{k_1\cdots k_d}\, \varepsilon. \end{aligned} \tag{5.3}$$

Using the choice of $v_{k_1\cdots k_d}$ given in Propositions 3.1 and 3.2, we then have

$$D_{k_1\cdots k_d} \leq 2\sqrt{vol(\Gamma)} A^{k_1+\cdots+k_d} = B A^{k_1+\cdots+k_d}, \tag{5.4}$$

where $A = 4M > 0$ is a constant depending only on Ω.

The approximated solution with noisy data $\widetilde{f}$ and $\widetilde{g}$ is given by

$$\widetilde{p}_N(x_1, \ldots, x_d) = \sum_{k_1,\ldots,k_d=0}^{k_1+\cdots+k_d=N} \widetilde{\lambda}_{k_1\cdots k_d} L_{k_1\cdots k_d}, \tag{5.5}$$

where

$$\widetilde{\lambda}_{k_1\cdots k_d} = \sum_{p_1=0}^{k_1} \cdots \sum_{p_d=0}^{k_d} C_{k_1 p_1} \cdots C_{k_d p_d} \widetilde{\mu}_{p_1\cdots p_d}. \tag{5.6}$$

We can obtain the following stability estimation.

THEOREM 5.1. *Suppose that u is the solution of the Cauchy problem* (1.1)–(1.3). *Denote $\beta = \frac{\partial u}{\partial \nu}|_{\Gamma_1}$. If $\beta \in H^1(\Gamma_1)$, then*

$$\|\beta - \widetilde{p}_N\|_{L^2(\Gamma_1)} \leq \varepsilon B A^N (\sqrt{2\pi})^{-d} (3 + 2\sqrt{2})^{dN+d} + \sqrt{d}(N+1)^{-1} (F(\beta))^{\frac{1}{2}}, \tag{5.7}$$

where $F(\beta)$ is given by (4.11).

Proof. We give a proof only for the case in which $d = 2$. The proof for the general dimension is similar. Since

$$\|\widetilde{p}_N - \beta\| \leq \|p_N - \beta\| + \|p_N - \widetilde{p}_N\|, \tag{5.8}$$

where $\|\cdot\|$ is the usual L^2 norm, from (4.7) and (5.5) we have

$$p_N - \widetilde{p}_N = \sum_{i,j=0}^{i+j=N} \left(\sum_{p=0}^{i} \sum_{q=0}^{j} C_{ip} C_{jq} (\mu_{pq} - \widetilde{\mu}_{pq}) \right) L_i L_j, \tag{5.9}$$

and hence

$$\|p_N - \widetilde{p}_N\|^2 = \sum_{i,j=0}^{i+j=N} \left(\sum_{p=0}^{i} \sum_{q=0}^{j} C_{ip} C_{jq} (\mu_{pq} - \widetilde{\mu}_{pq}) \right)^2. \tag{5.10}$$

From (5.3) and (5.4), we have

$$|\mu_{pq} - \widetilde{\mu}_{pq}| \le \varepsilon B A^{p+q}.$$

Hence we have

$$\begin{aligned} \|p_N - \widetilde{p}_N\|^2 &\le \varepsilon^2 B^2 A^{2N} \sum_{i,j=0}^{i+j=N} \left(\sum_{p=0}^{i} \sum_{q=0}^{j} |C_{ip} C_{jq}| \right)^2 \\ &\le \varepsilon^2 B^2 A^{2N} \left(\sum_{i=0}^{N} \left(\sum_{p=0}^{i} |C_{ip}| \right)^2 \right)^2. \end{aligned} \tag{5.11}$$

We then have (cf. [2, p. 19])

$$\sum_{i=0}^{N} \left(\sum_{p=0}^{i} |C_{ip}| \right)^2 \le (2\pi)^{-1} (3 + 2\sqrt{2})^{2N+2}. \tag{5.12}$$

Substituting this inequality into (5.11), we have

$$\|p_N - \widetilde{p}_N\| \le \varepsilon B (2\pi)^{-1} A^N (3 + 2\sqrt{2})^{2N+2}. \tag{5.13}$$

The proof is then completed by using (4.10), (5.8), and (5.13). □

Theorem 5.1 implies that if $\varepsilon \neq 0$ and N tends to infinity, then the right-hand side of (5.7) will tend to infinity even when ε is very small. This indicates that we have to choose a suitable value for N so that the right-hand side of (5.7) is kept small. This is one kind of regularization technique, with N being the regularization parameter (cf. [2], [3]). The choice of N is given in the following corollary.

COROLLARY 5.2. *Suppose that*

$$f(t) = A^t (3 + 2\sqrt{2})^{td} \tag{5.14}$$

and

$$N(\varepsilon) = [f^{-1}(\varepsilon^{-\frac{1}{2}})] = \left[\frac{\ln(\frac{1}{\varepsilon})}{2 \ln A + 2d \ln(3 + 2\sqrt{2})} \right]. \tag{5.15}$$

If $\beta \in H^1(\Gamma_1)$, we have

$$\|\widetilde{p}_N - \beta\|_{L^2(\Gamma_1)} \le C_1 \varepsilon^{\frac{1}{2}} + C_2 \frac{1}{\ln \frac{1}{\varepsilon}}, \tag{5.16}$$

where

$$C_1 = B \left(\frac{3 + 2\sqrt{2}}{\sqrt{2\pi}} \right)^d \qquad \text{and} \qquad C_2 = 2\sqrt{d} |F(\beta)|^{\frac{1}{2}} (\ln A + d \ln(3 + 2\sqrt{2})).$$

Proof. When $N(\varepsilon)$ is given as in (5.15), the first term of the right-hand side of (5.7) is $C_1\varepsilon^{\frac{1}{2}}$. Since

$$N(\varepsilon)+1 \geq \frac{\ln(\frac{1}{\varepsilon})}{2\ln A + 2d\ln(3+2\sqrt{2})}, \tag{5.17}$$

we have

$$\frac{1}{N(\varepsilon)+1} \leq \frac{2\ln A + 2d\ln(3+2\sqrt{2})}{\ln(\frac{1}{\varepsilon})}. \tag{5.18}$$

Hence (5.16) holds. ∎

Consider the following boundary value problem:

$$\Delta\widetilde{u}_N = 0 \qquad \text{in} \quad \Omega, \tag{5.19}$$

$$\frac{\partial\widetilde{u}_N}{\partial\nu} = \widetilde{p}_N \qquad \text{on} \quad \Gamma_1, \tag{5.20}$$

$$\widetilde{u}_N = \widetilde{f} \qquad \text{on} \quad \Gamma, \tag{5.21}$$

where we suppose that $\widetilde{f} \in H^1(\Omega)$. We also assume that u is the solution of the Cauchy problem (1.1)–(1.3) for which the Cauchy data f in (1.3) is in $H^1(\Omega)$. From the results given in [9], there exists a unique solution for the boundary value problem (5.19)–(5.21) satisfying

$$\|\widetilde{u}_N - u\|_{H^1(\Omega)} \leq C\left(\left\|\widetilde{p}_N - \frac{\partial u}{\partial\nu}\right\|_{L^2(\Gamma_1)} + \|\widetilde{f} - f\|_{H^1(\Omega)}\right), \tag{5.22}$$

where $C>0$ is a constant which depends on Ω and Γ. Therefore, we have the following theorem.

THEOREM 5.3. *Under the assumptions given in Theorem* 5.1 *and the condition*

$$\|\widetilde{f} - f\|_{H^1(\Omega)} + \|\widetilde{g} - g\|_{L^2(\Gamma_1)} \leq \varepsilon, \tag{5.23}$$

there exists a constant $C>0$ which depends on Ω and Γ such that

$$\begin{aligned}\|\widetilde{u}_N - u\|_{L^2(\Omega)} \leq{}& C(\varepsilon + \varepsilon B(\sqrt{2\pi})^{-d}A^N(3+2\sqrt{2})^{dN+d} \\ &+ \sqrt{d}(F(\beta))^{\frac{1}{2}}(N+1)^{-1}).\end{aligned} \tag{5.24}$$

COROLLARY 5.4. *Suppose that*

$$N(\varepsilon) = \left[\frac{\ln(\frac{1}{\varepsilon})}{2\ln A + 2d\ln(3+2\sqrt{2})}\right]. \tag{5.25}$$

There exists a constant $C>0$ which depends on $\|\beta\|_{H^1(\Gamma_1)}$, Ω, and Γ such that

$$\|\widetilde{u}_N(x) - u(x)\|_{L^2(\Omega)} \leq \frac{C}{|\ln\varepsilon|}. \tag{5.26}$$

6. Numerical example. In this section, a numerical example is performed to verify the accuracy and efficiency of the proposed method. Let

$$\Omega = \{(x_1, x_2, x_3) | \quad 0 \le x_i \le 1, \quad i = 1, 2, 3\} \tag{6.1}$$

and

$$\Gamma_1 = \partial\Omega \backslash \Gamma = \{\, x \,|\, 0 \le x_1 \le 1, \quad 0 \le x_2 \le 1, x_3 = 0\}. \tag{6.2}$$

The basis functions are chosen to be

$$\begin{aligned}
v_{00} &= 1, \\
v_{10} &= x_1, \\
v_{01} &= x_2, \\
v_{20} &= x_1^2 - x_3^2, \\
v_{11} &= x_1 x_2, \\
v_{02} &= x_2^2 - x_3^2, \\
v_{30} &= x_1^3 - 3x_1 x_3^2, \\
v_{03} &= x_2^3 - 3x_2 x_3^2, \\
v_{21} &= (x_1^2 - x_3^2) x_2, \\
v_{12} &= (x_2^2 - x_3^2) x_1, \\
v_{22} &= (6x_1^2 x_2^2 - 6x_1^2 x_3^2 - 6x_2^2 x_3^2 + 2x_3^4)/6, \\
v_{40} &= x_1^4 - 6x_1^2 x_3^2 + x_3^4, \\
v_{04} &= x_2^4 - 6x_2^2 x_3^2 + x_3^4, \\
v_{31} &= x_1^3 x_2 - 3x_1 x_2 x_3^2, \\
v_{13} &= x_2^3 x_1 - 3x_1 x_2 x_3^2.
\end{aligned}$$

Example. The exact solution of (1.1)–(1.3) is taken to be

$$u(x_1, x_2, x_3) = \frac{1}{\sqrt{(x_1 - \frac{1}{2})^2 + (x_2 - \frac{1}{2})^2 + (x_3 + 1)^2}}.$$

Following the numerical algorithm given in section 4, we can compute f and g as well as $\mu_{ij} = \int_\Gamma (f \frac{\partial v_{ij}}{\partial \nu} - g v_{ij}) ds$, $i, j = 0, 1, 2, \ldots$. The numerical comparisons between the approximation $p_N = p_N(x_1, x_2)$ as $N = 7$ and the exact $\frac{\partial u}{\partial \nu}$ on Γ_1 is shown in Figures 1a and 1b. As indicated in the surface plots in Figures 1a and 1b, respectively, the p_N approximates the $\frac{\partial u}{\partial \nu}$ very well. The error surface between this approximation and the exact solution is shown in Figure 2.

Finally, we added some noise to the Cauchy data f and g by adding a polynomial of order 4 (error order 10^{-4}) to f and g. The numerical errors surface and line plots for the case when $N = 5$ as shown in Figures 3–4c, respectively, indicate that the proposed method is stable and effective in solving the three-dimensional Cauchy problem for Laplace's equation.

Remark 6.1. For numerical convenience, the given example considers the case in which $\Gamma_1 = \{\, x \,|\, x_{d+1} = 0, 0 \le x_i \le 1, \ i = 1, 2, \ldots, d\}$. With minor modification, the method can readily be applied to more general cases. The only difference is that we have to solve a general moment problem in which the basis functions may not be polynomials.

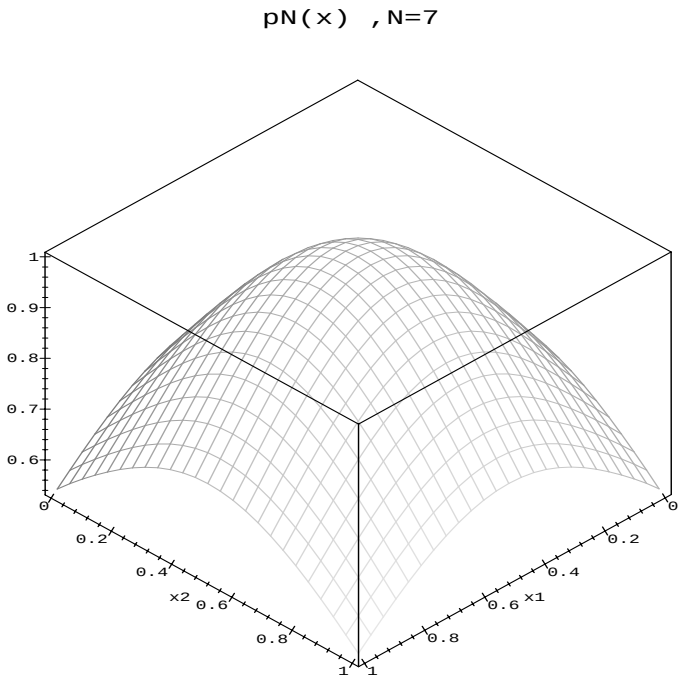

FIG. 1a. *Surface plot of* $p_N(x_1, x_2)$ *for* $N = 7$, $u(x_1, x_2, x_3) = \frac{1}{\sqrt{(x_1-\frac{1}{2})^2+(x_2-\frac{1}{2})^2+(x_3+1)^2}}$.

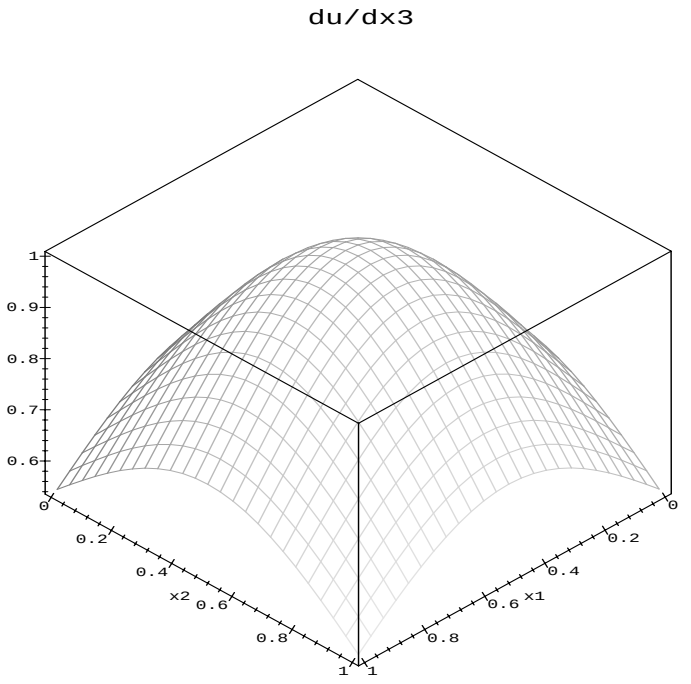

FIG. 1b. *Surface plot of exact* $\beta = \frac{\partial u}{\partial \nu}|_{\Gamma_1}$, $u(x_1, x_2, x_3) = \frac{1}{\sqrt{(x_1-\frac{1}{2})^2+(x_2-\frac{1}{2})^2+(x_3+1)^2}}$.

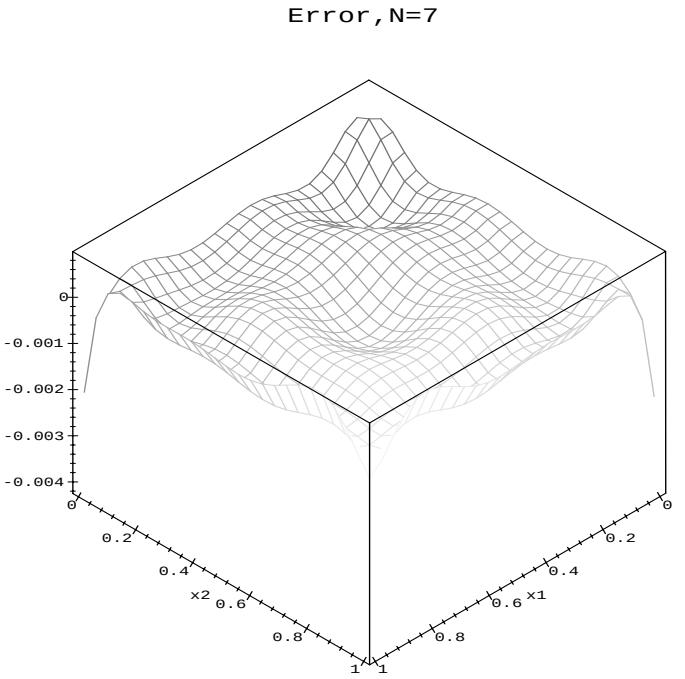

FIG. 2. *Error plot on the difference between* $p_N(x_1, x_2)$ *for* $N = 7$ *and* $\frac{\partial u}{\partial \nu}|_{\Gamma_1}$, $u(x_1, x_2, x_3) = \frac{1}{\sqrt{(x_1-\frac{1}{2})^2+(x_2-\frac{1}{2})^2+(x_3+1)^2}}$.

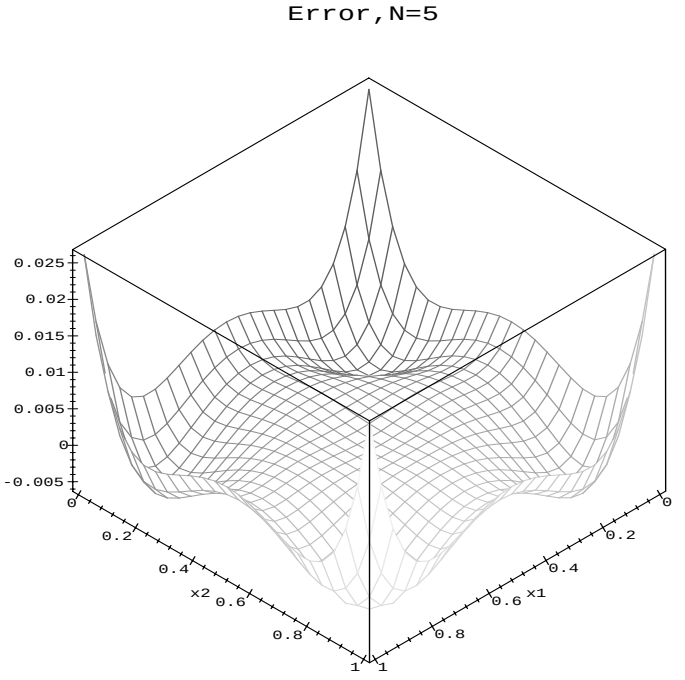

FIG. 3. *Error plot on the difference between* $\widetilde{p}_N(x)$ *for* $N = 5$ *and* $\frac{\partial u}{\partial \nu}|_{\Gamma_1}$ *with noise data* $\widetilde{f}$ *and* $\widetilde{g}$, $\widetilde{f} = f + x_1(1 - x_1)x_2(1 - x_2)10^{-4}$ *on* $x_3 = 1$, $\widetilde{g} = g + x_1(1 - x_1)x_2(1 - x_2)10^{-4}$ *on* $x_3 = 1$.

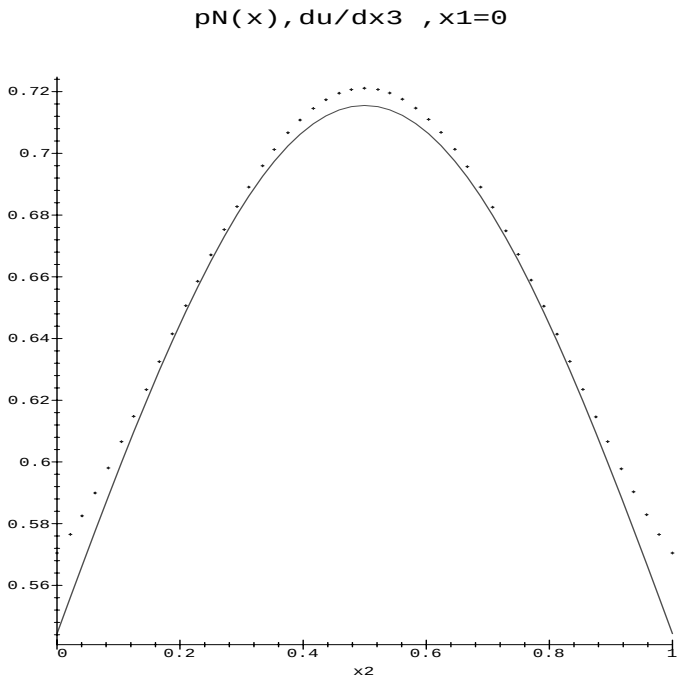

FIG. 4a. *Line plots of* $\frac{\partial u}{\partial \nu}(x_1, x_2)$ *and* $\widetilde{p}_N(x_1, x_2)$ *for* $N = 5$ *and* $x_1 = 0$*; dotted lines: approximated solution; solid lines: exact solution.*

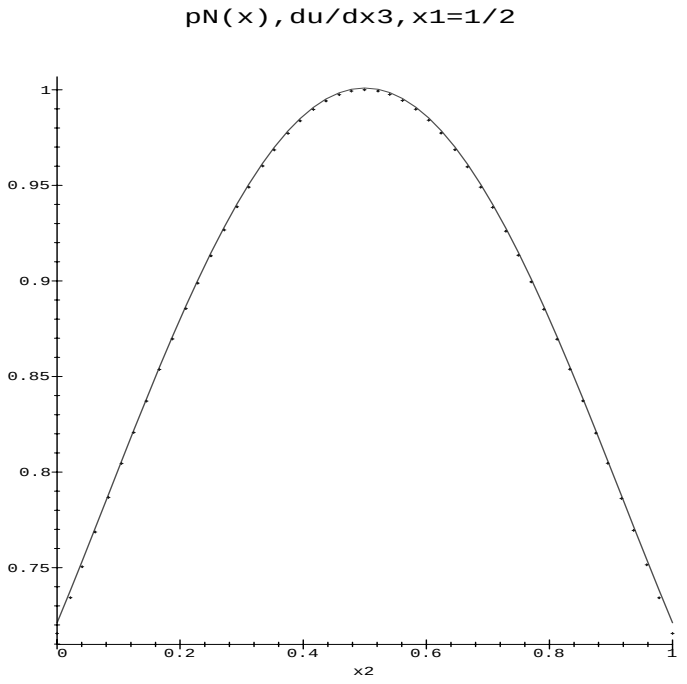

FIG. 4b. *Line plots of* $\frac{\partial u}{\partial \nu}(x_1, x_2)$ *and* $\widetilde{p}_N(x_1, x_2)$ *for* $N = 5$ *and* $x_1 = 1/2$*; dotted lines: approximated solution; solid lines: exact solution.*

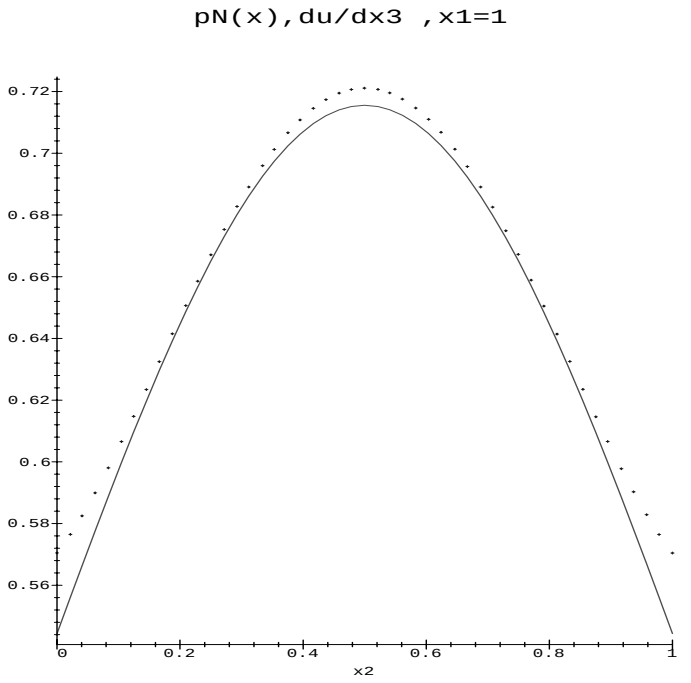

FIG. 4c. *Line plots of* $\frac{\partial u}{\partial \nu}(x_1, x_2)$ *and* $\widetilde{p}_N(x_1, x_2)$ *for* $N = 5$ *and* $x_1 = 1$*; dotted lines: approximated solution; solid lines: exact solution.*

Remark 6.2. The convergence error estimate given in (5.26) is of logarithmical type, which is too weak for efficient numerical simulation. From the theory on ill-posed problems, it is known that, if u is analytic on Γ_1, the estimation can be improved to Hölder type. This can explain the rather good numerical results obtained in section 6.

7. Conclusions. In this paper, a numerical method for solving the multidimensional Cauchy problem for Laplace's equation is proposed. Proofs on the convergence and stability estimation of the method are also given. It is also proven that the regularization parameter for the proposed method can be chosen suitably to give a stable and acceptable approximation to the solution when the Cauchy data have noises. For numerical verification, a numerical example in the three-dimensional case is presented.

Acknowledgment. The authors would like to thank the referees for their careful reading and helpful suggestions on the manuscript.

A PROBLEM OF SEQUENTIAL ENTRY AND EXIT DECISIONS COMBINED WITH DISCRETIONARY STOPPING*

MIHAIL ZERVOS†

Abstract. We consider a stochastic control problem that has emerged in the economics literature as an investment model under uncertainty. This problem combines features of both stochastic impulse control and optimal stopping. The aim is to discover the form of the optimal strategy. It turns out that this has a priori rather unexpected features. The results that we establish are of an explicit nature. We also construct an example whose value function does not possess C^1 regularity.

Key words. stochastic impulse control, optimal switching, optimal stopping, real options

1. Introduction.

Problems that combine features of both stochastic optimal control and optimal stopping have attracted the interest of several researchers. Models of absolutely continuous control of the drift and discretionary stopping have been studied by Krylov [K], Beneš [B], Karatzas and Sudderth [KS], Karatzas and Wang [KW], and Karatzas and Ocone [KO]. Models of combined singular stochastic control where the control effort takes the form of a finite variation process and discretionary stopping have been studied by Davis and Zervos [DZ] and Karatzas, Ocone, Wang, and Zervos [KOWZ]. These two families of problems have been motivated by applications in target tracking, where the controller has to steer a system close to a target and then decide on an engagement time, as well as by applications in finance. The latter ones include the classical consumption/investment problem for a small investor who can decide on the time of their "exit" from the market (see Karatzas and Wang [KW]) as well as the pricing of American contingent claims under constraints or with transaction costs.

In this paper, we consider a problem of stochastic impulse control combined with optimal stopping with a view to discovering the form of the optimal strategy. Note that the impulse control component of the control strategy is not of the standard form because the sizes of the jumps associated with each intervention strategy are not discretionary but are constrained to follow the pattern $\ldots, 1, -1, 1, -1, \ldots$. This simplification makes the problem easier to analyze. However, it is offset by the extra complexity that is introduced by the additional control variable, which is the discretionary stopping.

Problems of this type arise in the context of various applications in which the system dynamics involve discrete actions. For instance, in manufacturing, one needs to choose a machine setup mode over time so as to switch optimally among a finite number of different product types (see Sethi and Zhang [SZ]). The actual motivation of this paper arises from the area of "real options" that has emerged in the economics literature over the past two decades. This area is concerned with the development of new stochastic models that can lead to more accurate pricing of investments in real

assets by taking into account the value of managerial flexibility; the interested reader can consult the books by Dixit and Pindyck [DP] and Trigeorgis [T].

To fix ideas, consider an economic activity that is centered on a project that can operate in two modes, an "open" one and a "closed" one. Whenever the project is in its "open" operating mode, it yields a stream of profits or losses that is a functional of the uncertain prices of input and output commodities. Whenever the project is in its "closed" operating mode, it yields neither profits nor losses. The transition of the project from one of its operating modes to the other one forms a sequence of managerial decisions and is associated with certain fixed costs. The problem is to determine the switching strategy that maximizes the expected present value of all profits and losses resulting from the project. Variants of this problem have been developed in the economics literature as models for the valuation of investments in real assets by Brennan and Schwartz [BS], Dixit [D], and Dixit and Pindyck [DP]. Such a problem has the features of stochastic impulse control, and explicit solutions have been obtained in the mathematics literature by Brekke and Øksendal [BØ1, BØ2], Lumley and Zervos [LZ], and Duckworth and Zervos [DuZ1].

Suppose now that the option of totally abandoning the project at a discretionary time and at a certain fixed cost is added in the set of available managerial decisions. The resulting problem then combines stochastic impulse control with discretionary stopping. In fact, such a model is extensively discussed in Dixit and Pindyck [DP, section 7.2], and is a special case of the one developed by Brennan and Schwartz [BS]. However, these authors make very little progress in actually solving the problem. The purpose of this paper is to solve completely the resulting optimization problem under the assumption that the rate at which the project yields profits or losses is a standard Brownian motion. Such an assumption is probably crude as long as real life applications are concerned. However, it leads to explicit, nontrivial results that unveil the qualitative nature of the optimal strategy.

The results of our analysis take qualitatively different forms, depending on parameter values, and can be summarized informally as follows. Suppose that the switching costs are fixed. If the abandonment cost is very large (see Case I in Theorem 6 and Figure 1), then it is optimal to perpetuate the project by switching it to its "closed" mode as soon as its output cash flow falls below a certain level and by switching it to its "open" mode as soon as its potential output cash flow rises above a certain higher level. If the abandonment cost is very small (see Case III of Theorem 6 and Figure 4), then abandonment is optimal sooner or later. If the project is in its "closed" mode at time 0, then it is switched to its "open" mode as soon as its potential output cash flow exceeds a certain level. Once in it, the project should be kept in its "open" operating mode for as long as its output cash flow is above a given level and should be abandoned as soon as its output cash flow falls below this level. For intermediate values of the abandonment cost, we have an a priori rather unexpected combination of the two cases above (see Case II of Theorem 6 and Figure 3). If the project starts from its "closed" mode, then it is never abandoned, and the situation resembles the case in which the abandonment cost is very large. A similar scenario pertains to the case in which the project is originally "open" and its output cash flow assumes sufficiently high levels. However, if the project is originally "open" and its output cash flow assumes very low values, then it is optimal to abandon the project immediately. The most interesting possibility arises when the project is originally "open" and its output cash flow assumes moderately low values. In this case, it is optimal to keep the project alive and keep on accumulating losses until its output cash flow either

falls below a certain level, in which event the project is totally abandoned, or rises above another certain level, in which event its operation enters the perpetual life-cycle pertaining to the case of a large abandonment cost. As a result, the abandonment time of the project is either finite or infinite, and each of the two possibilities has positive probability.

The paper is organized as follows. Section 2 is concerned with the formulation of the stochastic optimization problem that we address. In section 3, we prove a verification theorem that will play a crucial role in our subsequent analysis. The assumptions of the theorem allow for the possibility that the value function is not C^1, and the proof is developed using Itô–Tanaka's formula and relies on the properties of local times. The explicit solution of the nontrivial case discussed above is developed in section 4. Finally, an example whose value function is not C^1 is presented in section 5.

2. Problem formulation. Let $(\Omega, \mathcal{F}, P)$ be a complete probability space equipped with a filtration $(\mathcal{F}_t)$ satisfying the usual conditions of right continuity and augmentation by P-negligible sets and carrying a standard one-dimensional $(\mathcal{F}_t)$-Brownian motion W. We denote by $\mathcal{Z}$ the family of all adapted, finite variation, càglàd processes Z with values in $\{0,1\}$ and by $\mathcal{S}$ the set of all $(\mathcal{F}_t)$-stopping times.

We consider a stochastic system that can operate in two modes, an "open" one and a "closed" one. The system's mode of operation can be changed at a sequence of $(\mathcal{F}_t)$-stopping times. These transition times constitute a decision strategy that we model by a process $Z \in \mathcal{Z}$. Specifically, given any time t, $Z_t = 1$ if the system is "open" at time t, whereas $Z_t = 0$ if the system is "closed" at time t. The stopping times at which the jumps of Z occur are the intervention times at which the system's operating mode is changed. We denote by $z \in \{0,1\}$ the system's mode at time 0. We also assume that the operation of this system can be permanently abandoned at an $(\mathcal{F}_t)$-stopping time T, which is an additional decision variable. We define the set of all admissible strategies to be

$$\Pi_z = \{(Z,T) \mid \ Z \in \mathcal{Z},\ Z_0 = z,\ T \in \mathcal{S}\}.$$

We assume that the rate at which the system yields payoff, the switching costs associated with the transition of the system from its "closed" mode to its "open" one and vice versa, as well as the permanent abandonment cost are all functions of a state process X which satisfies the one-dimensional SDE

$$dX_t = b(X_t)\,dt + \sigma(X_t)\,dW_t, \qquad X_0 = x \in \mathcal{I}, \tag{1}$$

where $\mathcal{I}$ is a given interval. We assume that the functions $b, \sigma : \mathcal{I} \to \mathbb{R}$ satisfy assumptions such that this SDE has a unique strong solution with values in $\mathcal{I}$ for all $t \geq 0$, P-a.s. In the problem that we solve in section 4, $\mathcal{I} = \mathbb{R}$. However, if, following several of the references mentioned in the introduction, we use X to model commodity prices, we must have $\mathcal{I} =]0, \infty[$.

With each admissible strategy $(Z,T) \in \Pi_z$ we associate the expected payoff

$$\begin{aligned} J_{z,x}(Z,T) = E\Bigg[& \int_0^T R_s\big[H_1(X_s)Z_s + H_0(X_s)(1-Z_s)\big]\,ds \\ & - \sum_{0 \leq s \leq T} 1_{\{s<\infty\}} R_s[G_1(X_s)\,(\Delta Z_s)^+ + G_0(X_s)\,(\Delta Z_s)^-] \\ & - 1_{\{T<\infty\}} R_T F(X_T)\Bigg], \end{aligned} \tag{2}$$

where $\Delta Z_t = Z_{t+} - Z_t$, $(\Delta Z_t)^{\pm} = \max\{\pm\Delta Z_t, 0\}$, and the discounting process R is given by

$$R_t = \exp\left(-\int_0^t r(X_s)\,ds\right) \tag{3}$$

for some positive function $r : \mathcal{I} \to \mathbb{R}$. Here, $H_1(X_t)$ (resp., $H_0(X_t)$) is the rate at which the system yields payoff assuming that, at time t, it is in its "open" (resp., "closed") operating mode. Also, $G_1(X_t)$, $G_0(X_t)$ are the costs associated with switching the investment from its "closed" to its "open" mode, and vice versa, respectively, at time t, whereas $F(X_t)$ is the cost faced if the system is completely abandoned at time t.

The objective is to maximize $J_{z,x}(Z,T)$ over Π_z. Accordingly, we define the value function

$$v(z,x) = \sup_{(Z,T)\in\Pi_z} J_{z,x}(Z,T).$$

We assume that the problem is well posed in the sense that all of the integrals in (2) are well defined for every admissible strategy, and nontrivial in the sense that $v(z,x) < \infty$ for every initial condition (z,x). For the problem to be well posed, we also need to assume that no strategy associated with a finite payoff involves an infinite number of switchings prior to abandonment on a set of positive probability so that every switching strategy can be modelled by a process in $\mathcal{Z}$. A sufficient condition for this assumption to hold is $G_1(x) + G_0(x) > \epsilon > 0$ for all $x \in \mathcal{I}$. From an economics perspective, this assumption is a natural one because it rules out the unrealistic situation in which arbitrarily high profits can be made by rapidly changing the system's operating mode.

All of the assumptions discussed above are of an implicit nature. Further assumptions will appear in the statement of Theorem 1, again in an implicit way. On the other hand, the results of sections 4 and 5 will assume that the problem's data have specific forms.

At this point, it would be of interest to make a comment on a possible generalization of the model considered here. The dynamics of the state process X can be modified to include an additional, regime switching process so that (1) becomes

$$dX_t = b(\theta_t, X_t)\,dt + \sigma(\theta_t, X_t)\,dW_t, \qquad X_0 = x \in \mathcal{I}.$$

The process θ can be taken to be a finite-state Markov chain representing a number of different economic outlooks (e.g., a state of economic growth and a state of recession). Models involving regime switchings have been considered in the literature and include Guo [G], who solves the problem of pricing a Russian option in such a context. A generalization of the model studied here in this direction would multiply the complexity of the problem by the number of states that the process θ can assume, and we leave it as an interesting open problem.

3. A verification theorem. The problem considered in the previous section combines features of both stochastic impulse control and optimal stopping. Therefore, we expect that the value function v should satisfy the Hamilton–Jacobi–Bellman (HJB) equation

$$\begin{aligned} \max\big\{&\mathcal{L}v(z,x) + zH_1(x) + (1-z)H_0(x), \\ &v(1-z,x) - v(z,x) - zG_0(x) - (1-z)G_1(x), \\ &-v(z,x) - F(x)\big\} = 0, \qquad z = 1,0,\ x \in \mathcal{I}, \end{aligned} \tag{4}$$

where the second order elliptic operator $\mathcal{L}$ is defined by

$$\mathcal{L}v(z,x) = \frac{1}{2}\sigma^2(x)v_{xx}(z,x) + b(x)v_x(z,x) - r(x)v(z,x).$$

The ideas behind the origins of this equation are the following. Suppose that, at time 0, the system is in its "open" operating mode, i.e., $z = 1$. The controller's immediate decision consists of choosing between three actions. The first action is to totally terminate the system's operation at the cost of $-F(x)$. Such a possibility gives rise to the inequality

$$v(1,x) \geq -F(x). \tag{5}$$

The second option is to pay the cost of $G_0(x)$ to switch the system to its "closed" operating mode and then continue optimally. This possibility yields the inequality

$$v(1,x) \geq -G_0(x) + v(0,x). \tag{6}$$

The third action is to leave the system in its "open" operating mode for a short time Δt and then continue optimally. This action is associated with the inequality

$$v(1,x) \geq E\left[\int_0^{\Delta t} R_s H_1(X_s)\,ds + R_{\Delta t} v(1, X_{\Delta t})\right].$$

Under the assumption that $v(1,\cdot)$ is sufficiently smooth, we may apply Itô's formula to the last term and then divide by Δt before letting $\Delta t \downarrow 0$ to obtain

$$\begin{aligned}\mathcal{L}v(1,x) + H_1(x) &\equiv \frac{1}{2}\sigma^2(x)v_{xx}(1,x) + b(x)v_x(1,x) - r(x)v(1,x) + H_1(x)\\ &\leq 0.\end{aligned} \tag{7}$$

Now, each of (5)–(7) can hold with strict inequality because the corresponding action may not be optimal. However, we expect that the three actions considered above form a complete repertoire of optimal tactics. Therefore, given any $x \in \mathcal{I}$, we expect that one of (5)–(7) should hold with equality. Combining all of these relationships, we can conclude that the value function $v(1,\cdot)$ should satisfy

$$\max\bigl\{\mathcal{L}v(1,x) + H_1(x),\ v(0,x) - v(1,x) - G_0(x),\ -v(1,x) - F(x)\bigr\} = 0. \tag{8}$$

Using similar reasoning, we can also conclude that the value function $v(0,\cdot)$ associated with the system in its "closed" operating mode (i.e., when $z = 0$) should satisfy

$$\max\bigl\{\mathcal{L}v(0,x) + H_0(x), v(1,x) - v(0,x) - G_1(x),\ -v(0,x) - F(x)\bigr\} = 0. \tag{9}$$

Now, combining (8) and (9), we conclude that the value function v should satisfy (4). Without any further conditions, this equation has, in general, uncountably many solutions.

Example 1. Suppose that $\mathcal{I} = \mathbb{R}$, and, for all $x \in \mathbb{R}$, $b(x) = 0$, $\sigma(x) = \sqrt{2}$, $r(x) = 4$, $H_1(x) = 3e^x + 4$, $H_0(x) = 0$, $G_1(x) = G_0(x) = 1$ and $F(x) = c$ for some constant $c > 0$. It is straightforward to verify that each of the functions defined by

$$w(z,x) = Ae^{2x} + Be^{-2x} + e^x + z, \qquad A, B \geq 0,$$

satisfies (4).

It turns out that the functions $v(1,\cdot)$ and $v(0,\cdot)$ composing the value function of the special case of the control problem that we explicitly solve in section 4 are both C^1 but not C^2. However, it is clear that, as long as the general problem is concerned, we cannot expect such regularity of the value function unless we impose appropriate assumptions on the problem's data. For instance, we cannot in general expect C^1 regularity unless the abandonment cost function F is C^1. An explicitly solvable example illustrating this issue is presented in section 5.

In the next theorem, we consider candidates for the value functions $v(1,\cdot)$ and $v(0,\cdot)$ which are differences of convex functions; for a survey of the results needed here, see Revuz and Yor [RY, Appendix 3]. In particular, we consider solutions of (4) in the following sense.

Definition 1. A function $w : \{0,1\} \times \mathcal{I} \to \mathbb{R}$ satisfies (4) if each of $w(1,\cdot)$, $w(0,\cdot)$ is a difference of two convex functions and (4) is true Lebesgue-a.e., with $\hat{\mathcal{L}}$ in place of $\mathcal{L}$, where the operator $\hat{\mathcal{L}}$ is defined by

$$\hat{\mathcal{L}}w(z,x) = \frac{1}{2}\sigma^2(x)w^{\mathrm{ac}}_{xx}(z,x) + b(x)w^-_x(z,x) - r(x)w(z,x).$$

Here, $w^-_x(z,\cdot)$ is the left-hand derivative of $w(z,\cdot)$. Also,

$$w_{xx}(z,dx) = w^{\mathrm{ac}}_{xx}(z,x)\,dx + w^{\mathrm{s}}_{xx}(z,dx) \tag{10}$$

is the Lebesgue decomposition of the second distributional derivative $w_{xx}(z,dx)$ of $w(z,\cdot)$ to the measure $w^{\mathrm{ac}}_{xx}(z,x)\,dx$, which is absolutely continuous with respect to the Lebesgue measure, and the measure $w^{\mathrm{s}}_{xx}(z,dx)$, which is mutually singular with the Lebesgue measure.

We can now prove conditions which are sufficient for optimality in our problem.

THEOREM 1. *Consider the control problem described in section* 2. *Suppose that* G_1, G_0, F *are continuous functions,* $\sigma^2(x) > 0$ *for all* $x \in \mathcal{I}$, *and, for every admissible strategy* $(Z,T) \in \Pi_z$, *there exists a sequence of times* $t_m \to \infty$ *such that*

$$\lim_{m\to\infty} J_{z,x}(Z, T \wedge t_m) = J_{z,x}(Z,T). \tag{11}$$

Suppose that there exist functions $w(1,\cdot), w(0,\cdot) : \mathcal{I} \to \mathbb{R}$ *which are differences of convex functions such that*

$$-w^{\mathrm{s}}_{xx}(1,dx) \text{ and } -w^{\mathrm{s}}_{xx}(0,dx) \text{ are positive measures} \tag{12}$$

and which satisfy the HJB equation (4) *in the sense of Definition* 1. *Also, suppose that the process* M *defined by*

$$M_t = \int_0^t R_s\sigma(X_s)w^-_x(Z_s,X_s)\,dW_s \tag{13}$$

is a martingale for every switching strategy $Z \in \mathcal{Z}$. *Then, given any initial condition* $(z,x) \in \{0,1\} \times \mathcal{I}$,

(a) $v(z,x) \le w(z,x)$, *and*

(b) *if*

$$\begin{aligned}\operatorname{supp} w^{\mathrm{s}}_{xx}(z,dx) &\subseteq \mathcal{I} \setminus \operatorname{int}\overline{\{x \in \mathcal{I} \mid \ \hat{\mathcal{L}}w(z,x) + zH_1(x) + (1-z)H_0(x) = 0\}} \\ &=: \mathcal{O}_z\end{aligned} \tag{14}$$

and there exists $Z^* \in \mathcal{Z}$ *such that*

$$\hat{\mathcal{L}} w(Z_t^*, X_t) + Z_t^* H_1(X_t) + (1 - Z_t^*) H_0(X_t) = 0 \tag{15}$$

for Lebesgue almost all $t \le T^*$, *P-a.s., and*

$$[w(1, X_t) - w(0, X_t) - G_1(X_t)]\,(\Delta Z_t^*)^+ = 0, \tag{16}$$

$$[w(0, X_t) - w(1, X_t) - G_0(X_t)]\,(\Delta Z_t^*)^- = 0 \tag{17}$$

for all $t \le T^*$, *P-a.s., where*

$$T^* = \inf\{t \ge 0 \mid \ w(Z_t^*, X_t) = -F(X_t)\}, \tag{18}$$

as well as a sequence of times $t_m \to \infty$ *satisfying* (11) *and*

$$\lim_{m\to\infty} E\big[R_{t_m} \big|w(Z^*_{t_m}, X_{t_m})\big|\big] = 0 \quad \textit{and} \quad \lim_{m\to\infty} E\big[R_{t_m} |F(X_{t_m})|\big] = 0, \tag{19}$$

then $v(z, x) = w(z, x)$, *and the optimal strategy is* (Z^*, T^*).

Proof. Fix any $z = 0, 1$. Using Itô–Tanaka's formula (see Revuz and Yor [RY, Theorem VI.1.5]), we obtain

$$\begin{aligned} w(z, X_t) = w(z, x) &+ \int_0^t b(X_s) w_x^-(z, X_s)\, ds + \int_0^t \sigma(X_s) w_x^-(z, X_s)\, dW_s \\ &+ \frac{1}{2} \int_{\mathcal{I}} L_t^a\, w_{xx}(z, da), \end{aligned} \tag{20}$$

where L^a is the local time of the process X at level a. We assume that

$$\text{the mapping } (t, a) \to L_t^a \text{ is continuous in } t \text{ and càdlàg in } a, \tag{21}$$

P-a.s. (see Revuz and Yor [RY, Theorem VI.1.7]). With reference to (10) and the occupation times formula (see Revuz and Yor [RY, Corollary VI.1.6]),

$$\int_{\mathcal{I}} L_t^a w_{xx}^{\mathrm{ac}}(z, a)\, da = \int_0^t \sigma^2(X_s) w_{xx}^{\mathrm{ac}}(z, X_s)\, ds,$$

and so (20) implies

$$\begin{aligned} w(z, X_t) = w(z, x) &+ \int_0^t \left[\frac{1}{2}\sigma^2(X_s) w_{xx}^{\mathrm{ac}}(z, X_s) + b(X_s) w_x^-(z, X_s)\right] ds \\ &+ \int_0^t \sigma(X_s) w_x^-(z, X_s)\, dW_s + A_t^z, \end{aligned}$$

where

$$A_t^z = \frac{1}{2} \int_{\mathcal{I}} L_t^a\, w_{xx}^{\mathrm{s}}(z, da). \tag{22}$$

For future reference, observe that (12) implies

$$-A^z \text{ is a continuous, increasing process} \tag{23}$$

because such a statement is true for local times. Now, using the integration by parts formula for semimartingales, we obtain

$$R_t w(z,X_t) = w(z,x) + \int_0^t R_s \hat{\mathcal{L}} w(z,X_s)\,ds + \int_0^t R_s \sigma(X_s) w_x^-(z,X_s)\,dW_s + \int_0^t R_s\,dA_s^z. \tag{24}$$

We can now prove the two statements of the theorem.

(a) Fix any admissible strategy $(Z,T) \in \Pi_z$, and suppose that the abandonment time T is bounded by a constant. Define the increasing sequence of $(\mathcal{F}_t)$-stopping times (T_n) by

$$T_1 = \inf\{t \geq 0 \mid \ Z_t \neq z\} \quad \text{and} \quad T_{n+1} = \inf\{t > T_n \mid \ Z_t \neq Z_{T_n+}\}, \tag{25}$$

with the usual convention that $\inf \emptyset = \infty$. Note that the assumption that Z is a finite variation process implies that its discontinuities cannot accumulate within any compact subset of $\mathbb{R}_+$, so $T_n \to \infty$, P-a.s. Therefore,

$$\begin{aligned} &R_T w(Z_T,X_T) \\ &\quad = R_T w(Z_T,X_T) 1_{\{T \leq T_1\}} + \sum_{n=1}^{\infty} \Bigg[R_T w(Z_T,X_T) - R_{T_n} w(Z_{T_n+},X_{T_n}) \\ &\qquad + \sum_{j=1}^{n-1} \big[R_{T_{j+1}} w(Z_{T_{j+1}},X_{T_{j+1}}) - R_{T_j} w(Z_{T_j+},X_{T_j}) \big] \\ &\qquad + R_{T_1} w(Z_{T_1},X_{T_1}) + \sum_{j=1}^{n} R_{T_j} \big[w(Z_{T_j+},X_{T_j}) - w(Z_{T_j},X_{T_j}) \big] \Bigg] 1_{\{T_n < T \leq T_{n+1}\}}. \end{aligned} \tag{26}$$

Now, since Z is constant on the stochastic interval $]T_j, T_{j+1}]$ and T is bounded, (24) implies

$$\begin{aligned} \big[R_{T_{j+1}} w(Z_{T_{j+1}},X_{T_{j+1}}) - R_{T_j} w(Z_{T_j+},X_{T_j}) \big] 1_{\{T_{j+1} < T\}} &= \Bigg[\int_{T_j}^{T_{j+1}} R_s \hat{\mathcal{L}} w(Z_s,X_s)\,ds \\ &\quad + M_{T_{j+1}} - M_{T_j} + \int_{T_j}^{T_{j+1}} R_s Z_s\,dA_s^1 + \int_{T_j}^{T_{j+1}} R_s (1-Z_s)\,dA_s^0 \Bigg] 1_{\{T_{j+1} < T\}}, \end{aligned}$$

where M is defined as in (13). Since the terms

$$\begin{aligned} &\big[R_T w(Z_T,X_T) - w(z,x) \big] 1_{\{T \leq T_1\}}, \\ &\big[R_{T_1} w(Z_{T_1},X_{T_1}) - w(z,x) \big] 1_{\{T_1 \leq T\}}, \\ &\big[R_T w(Z_T,X_T) - R_{T_n} w(Z_{T_n+},X_{T_n}) \big] 1_{\{T_n < T \leq T_{n+1}\}} \end{aligned}$$

admit similar expressions, (26) implies

$$\begin{aligned} R_T w(Z_T,X_T) &= w(z,x) + \int_0^T R_s \hat{\mathcal{L}} w(Z_s,X_s)\,ds + M_T \\ &\quad + \sum_{0 \leq s < T} R_s \big[w(Z_{s+},X_s) - w(Z_s,X_s) \big] + \int_0^T R_s Z_s\,dA_s^1 + \int_0^T R_s (1-Z_s)\,dA_s^0. \end{aligned}$$

It follows that

$$\begin{aligned}
&\int_0^T R_s\big[H_1(X_s)Z_s + H_0(X_s)(1-Z_s)\big]\,ds \\
&\qquad - \sum_{0\le s\le T} R_s[G_1(X_s)\,(\Delta Z_s)^+ + G_0(X_s)\,(\Delta Z_s)^-] - R_T F(X_T) \\
&\quad = w(z,x) - R_T\big[w(Z_{T+},X_T) + F(X_T)\big] + M_T \\
&\quad + \int_0^T R_s\big[\hat{\mathcal{L}}w(Z_s,X_s) + H_1(X_s)Z_s + H_0(X_s)(1-Z_s)\big]\,ds \\
&\quad + \sum_{0\le s\le T} R_s\big[w(1,X_s) - w(0,X_s) - G_1(X_s)\big](\Delta Z_s)^+ + \int_0^T R_s Z_s\,dA_s^1 \\
&\quad + \sum_{0\le s\le T} R_s\big[w(0,X_s) - w(1,X_s) - G_0(X_s)\big](\Delta Z_s)^- + \int_0^T R_s(1-Z_s)\,dA_s^0.
\end{aligned} \tag{27}$$

In view of (23) and the fact that w satisfies (4) in the sense of Definition 1, this implies

$$\begin{aligned}
&\int_0^T R_s\big[H_1(X_s)Z_s + H_0(X_s)(1-Z_s)\big]\,ds \\
&\qquad - \sum_{0\le s\le T} R_s[G_1(X_s)\,(\Delta Z_s)^+ + G_0(X_s)\,(\Delta Z_s)^-] - R_T F(X_T) \\
&\qquad \le w(z,x) + M_T.
\end{aligned}$$

Taking expectations and noting that the stochastic integral has expectation 0, we obtain $J_{z,x}(Z,T) \le w(z,x)$.

Now, consider the general case in which the abandonment time T is not necessarily bounded by a constant, and let (t_m) be a sequence satisfying (11). From our analysis above, it follows that $J_{z,x}(Z, T\wedge t_m) \le w(z,x)$ for all m. However, this and (11) imply $J_{z,x}(Z,T) \le w(z,x)$, which establishes this part of the theorem.

(b) Suppose that there exists a strategy (Z^*,T^*) satisfying (15)–(18), let (T_n^*) be the associated sequence of stopping times defined as in (25), and let (t_m) be a sequence satisfying (11) as well as (19). Fix any of the stochastic intervals $]T_n^*\wedge T^*\wedge t_m,\ T_{n+1}^*\wedge T^*\wedge t_m]$, and observe that Z^* is constant on this interval, i.e., $Z_t^* = z$ for some $z\in\{0,1\}$, for all $t\in\,]T_n^*\wedge T^*\wedge t_m,\ T_{n+1}^*\wedge T^*\wedge t_m]$, P-a.s. Since the measure dL_t^a is carried by the set $\{t\ge 0 \mid\ X_t = a\}$, P-a.s., (14) and (15) imply

$$L^a_{T_n^*\wedge T^*\wedge t_m} = L^a_{T_{n+1}^*\wedge T^*\wedge t_m}, \quad P\text{-a.s.}, \quad \forall a\in\mathcal{O}_z.$$

Therefore,

$$L^a_{T_n^*\wedge T^*\wedge t_m} = L^a_{T_{n+1}^*\wedge T^*\wedge t_m} \quad \forall a\in\mathcal{O}_z^d, \tag{28}$$

P-a.s., where $\mathcal{O}_z^d$ is any countable subset of $\mathcal{O}_z$ which is dense in $\mathcal{O}_z$. Now, let $A\in\mathcal{F}$ be such that $P(A)=1$ and (21), (28) are true for all $\omega\in A$. Given any $a\in\mathcal{O}_z\setminus\mathcal{O}_z^d$ and any sequence (a_m) in $\mathcal{O}_z^d$ such that $a_m\downarrow a$, (21) implies

$$L_t^a(\omega) = \lim_{k\to\infty} L_t^{a_k}(\omega) \quad \forall t\ge 0, \quad \forall\omega\in A.$$

However, this and (28) imply

$$L^a_{T_n^*\wedge T^*\wedge t_m}(\omega) = L^a_{T_{n+1}^*\wedge T^*\wedge t_m}(\omega) \quad \forall a\in\mathcal{O}_z, \quad \forall\omega\in A.$$

Combining this with (22), we can see that

$$A^z_{T^*_n\wedge T^*\wedge t_m} = A^z_{T^*_{n+1}\wedge T^*\wedge t_m} \qquad \text{if } Z^*_t = z \text{ for } t \in]T^*_n \wedge T^* \wedge t_m,\, T^*_{n+1} \wedge T^* \wedge t_m].$$

It follows that

$$\int_0^{T^*\wedge t_m} R_s Z^*_s\, dA^1_s = \int_0^{T^*\wedge t_m} R_s(1 - Z^*_s)\, dA^0_s = 0.$$

Therefore, in view of (15)–(18), (27) implies

$$\begin{aligned}
&\int_0^{T^*\wedge t_m} R_s\big[H_1(X_s)Z^*_s + H_0(X_s)(1 - Z^*_s)\big]\, ds \\
&\qquad - \sum_{0\le s\le T^*\wedge t_m} R_s[G_1(X_s)\,(\Delta Z^*_s)^+ + G_0(X_s)\,(\Delta Z^*_s)^-] - R_{T^*\wedge t_m} F(X_{T^*\wedge t_m}) \\
&= w(z,x) - 1_{\{T^*>t_m\}} R_{t_m}\left[w(Z^*_{t_m+}, X_{t_m}) + F(X_{t_m})\right] + M_{T^*\wedge t_m}.
\end{aligned}$$

Taking expectations and letting $m \to \infty$, we obtain $J_{z,x}(Z^*, T^*) = w(z,x)$, by virtue of (11) and (19), and the proof is complete. □

Remark 1. To obtain some further insight into the assumptions of the theorem above, suppose that, given a finite number of points $a^1_1 < a^1_2 < \cdots < a^1_{N^1}$ (resp., $a^0_1 < a^0_2 < \cdots < a^0_{N^0}$), $w(1,\cdot)$ (resp., $w(0,\cdot)$) is twice continuously differentiable at every point $x \in \mathcal{I} \setminus \{a^1_1, \ldots, a^1_{N^1}\}$ (resp., $x \in \mathcal{I} \setminus \{a^0_1, \ldots, a^0_{N^0}\}$). Also, suppose that each of the functions $w^-_x(z,\cdot)$ is locally bounded. In this case, assumptions (12) and (14) are equivalent to

$$w^-_x(z, a^z_{i^z}) \ge w^-_x(z, a^z_{i^z}+) \equiv \lim_{x\downarrow a^z_{i^z}} w^-_x(z,x) \quad \forall i^z = 1, 2, \ldots, N^z \text{ and} \tag{29}$$

$$a^z_1, \ldots, a^z_{N^z} \subseteq \mathcal{I} \setminus \operatorname{int}\overline{\{x \in \mathcal{I} \mid \hat{\mathcal{L}}w(z,x) + zH_1(x) + (1-z)H_0(x) = 0\}}, \tag{30}$$

$z = 0, 1$, respectively. For future reference, we should stress that we cannot dispense with either of these two assumptions. Also, it is worth observing the *asymmetry* presented by (12) or (29): had the optimization problem been a minimization one, we would have to replace (12) by the assumption that $w^{\mathrm{s}}_{xx}(1, dx)$ and $w^{\mathrm{s}}_{xx}(0, dx)$ are positive measures, and we would have to consider the reverse inequalities in (29). With regard to (30), we can conclude that the points where C^1 regularity fails should not belong to the interior of the "continuation" region but can be allowed in the closure of the "switching" or "stopping" regions.

Remark 2. The result proved above can be trivially extended to the case in which the system's operating modes are not just two, namely, "open" and "closed," but are any finite positive integer. On the other hand, the proof cannot be trivially modified to account for the case in which the process X assumes values in a higher dimensional state space because it relies heavily on the use of local times and Itô–Tanaka's formula.

To analyze the problem arising if the state process X is an n-dimensional diffusion under similarly general assumptions, one would have to resort to the use of viscosity solutions of the associated HJB equation (see Fleming and Soner [FS] and Yong and Zhou [YZ]). This project would aim at proving that the value function identifies with the unique viscosity solution of the HJB equation. Furthermore, characterizing the optimal strategy would require a viscosity solution version of the verification Theorem 1 in the spirit of Theorem 5.5.3 in Yong and Zhou [YZ]. Such an analysis lies beyond the scope of this article, and we leave it as an interesting open problem.

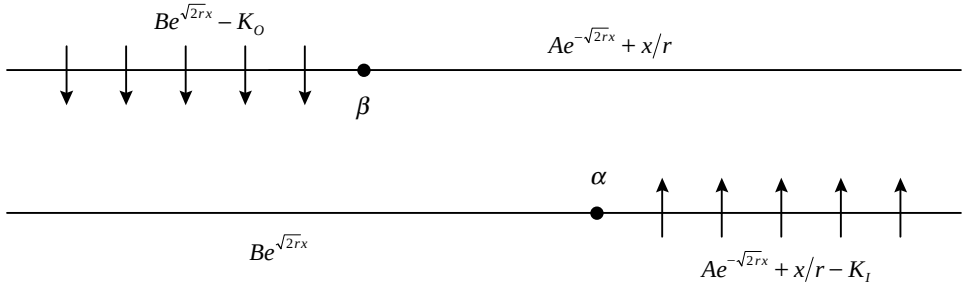

FIG. 1. *The "no-abandonment case."*

4. The explicit solution of a special case. We now solve completely the special case of the general control problem formulated in section 2 that arises if we impose the following assumption.

Assumption 1. $\mathcal{I} = \mathbb{R}$, and $b(x) = 1$, $\sigma(x) = 1$, $r(x) = r$, $H_1(x) = x$, $H_0(x) = 0$, $G_1(x) = K_1$, $G_0(x) = K_0$, and $F(x) = K$ for some constants $r, K_1, K_0, K > 0$, for all $x \in \mathbb{R}$.

In this case, the HJB equation (4) reduces to the following pair of coupled quasi-variational inequalities:

$$\max\left\{\frac{1}{2}v_1''(x) - rv_1(x) + x,\ v_0(x) - v_1(x) - K_0,\ -v_1(x) - K\right\} = 0, \tag{31}$$

$$\max\left\{\frac{1}{2}v_0''(x) - rv_0(x),\ v_1(x) - v_0(x) - K_1,\ -v_0(x) - K\right\} = 0. \tag{32}$$

Here, we write v_1 and v_0 in place of $v(1,\cdot)$ and $v(0,\cdot)$, respectively, to simplify the notation.

To make some headway, we first make some qualitative observations. Since the system yields 0 payoff whenever it operates in its "closed" mode and the abandonment cost K is positive, it follows that abandonment cannot be optimal when the system is in its "closed" mode. As a consequence, abandonment can be part of the optimal strategy only if the system is in its "open" operating mode. Moreover, the system should be in its "open" operating mode if the state process X assumes sufficiently large values and should be in its "closed" operating mode or should be abandoned if the state process X takes sufficiently low values.

Now, a first possibility arises if abandonment is not part of the optimal scenario. In such a case, we should switch the system from its "closed" to its "open" mode whenever the state process X exceeds a level specified by a constant α, and we should switch the system from its "open" to its "closed" mode whenever the state process X falls below a level given by a constant β. Clearly, such a strategy is well defined only if $\beta < \alpha$. It is depicted by Figure 1.

If such a strategy is indeed optimal, the value function should be given by a solution w_1, w_0 of the HJB equations (31)–(32) described as follows. For $x > \beta$, w_1 should satisfy $\frac{1}{2}w_1''(x) - rw_1(x) + x = 0$, namely, $w_1(x) = Ae^{-\sqrt{2r}x} + C_1e^{\sqrt{2r}x} + x/r$ for some constants $A, C_1 \in \mathbb{R}$, whereas, for $x \le \beta$, w_1 should be given by $w_1(x) = w_0(x) - K_0$. On the other hand, if $x < \alpha$, w_0 should satisfy $\frac{1}{2}w_0''(x) - rw_0(x) = 0$, namely $w_0(x) = C_2e^{-\sqrt{2r}x} + Be^{\sqrt{2r}x}$ for some constants $C_2, B \in \mathbb{R}$, whereas, for $x \ge \alpha$, w_0 should be given by $w_0(x) = w_1(x) - K_1$. Now, we must have $C_1 = C_2 = 0$

because, otherwise, the assumptions of Theorem 1 cannot be satisfied. In view of these conditions, w_1, w_0 should be given by

$$w_1(x) = \begin{cases} Be^{\sqrt{2r}x} - K_0 & \text{if } x \leq \beta, \\ Ae^{-\sqrt{2r}x} + x/r & \text{if } x > \beta, \end{cases} \tag{33}$$

$$w_0(x) = \begin{cases} Be^{\sqrt{2r}x} & \text{if } x < \alpha, \\ Ae^{-\sqrt{2r}x} + x/r - K_1 & \text{if } x \geq \alpha, \end{cases} \tag{34}$$

respectively. To specify the parameters A, B, α, β, we postulate that w_1, w_0 are C^1 at the free boundary points β, α, respectively. This requirement gives rise to the system of equations

$$Be^{\sqrt{2r}\alpha} - Ae^{-\sqrt{2r}\alpha} = \frac{\alpha - rK_1}{r}, \tag{35}$$

$$Be^{\sqrt{2r}\alpha} + Ae^{-\sqrt{2r}\alpha} = \frac{1}{r\sqrt{2r}}, \tag{36}$$

$$Be^{\sqrt{2r}\beta} - Ae^{-\sqrt{2r}\beta} = \frac{\beta + rK_0}{r}, \tag{37}$$

$$Be^{\sqrt{2r}\beta} + Ae^{-\sqrt{2r}\beta} = \frac{1}{r\sqrt{2r}.} \tag{38}$$

It is straightforward to verify that these are equivalent to

$$A = -\frac{\beta + rK_0 - 1/\sqrt{2r}}{2r} e^{\sqrt{2r}\beta}, \tag{39}$$

$$B = \frac{\beta + rK_0 + 1/\sqrt{2r}}{2r} e^{-\sqrt{2r}\beta}, \tag{40}$$

$$(\alpha - rK_1 - 1/\sqrt{2r})e^{\sqrt{2r}\alpha} = (\beta + rK_0 - 1/\sqrt{2r})e^{\sqrt{2r}\beta}, \tag{41}$$

$$(\alpha - rK_1 + 1/\sqrt{2r})e^{-\sqrt{2r}\alpha} = (\beta + rK_0 + 1/\sqrt{2r})e^{-\sqrt{2r}\beta}. \tag{42}$$

The next lemma is concerned with the solvability of (41)–(42) and with necessary and sufficient conditions under which the functions w_1, w_0 given above satisfy the HJB equations (31)–(32). To derive the results of Lemma 4 below, we assume here that the constants K_1, K_0 can take negative as well as positive values subject to the condition that $K_1 + K_0 > 0$.

LEMMA 2. *Suppose that $r > 0$ and $K_1, K_0 \in \mathbb{R}$ satisfy $K_1 + K_0 > 0$. There exists a unique pair of points $\alpha = \alpha(r, K_1, K_0)$ and $\beta = \beta(r, K_1, K_0)$ which satisfies* (41)–(42). *Point β is the unique solution of*

$$H(\beta) := \frac{\beta + rK_0 + 1/\sqrt{2r}}{\beta + rK_0 - 1/\sqrt{2r}} \exp(-\sqrt{2r}(2\beta + rK_0 - rK_1)) = -1 \tag{43}$$

and satisfies

$$-rK_0 - \frac{1}{\sqrt{2r}} < \beta < -rK_0, \tag{44}$$

$$-2e^{-2} > \sqrt{2r}(\beta + rK_0 - 1/\sqrt{2r}) \exp(\sqrt{2r}(\beta + rK_0 - 1/\sqrt{2r})) > -e^{-1}, \tag{45}$$

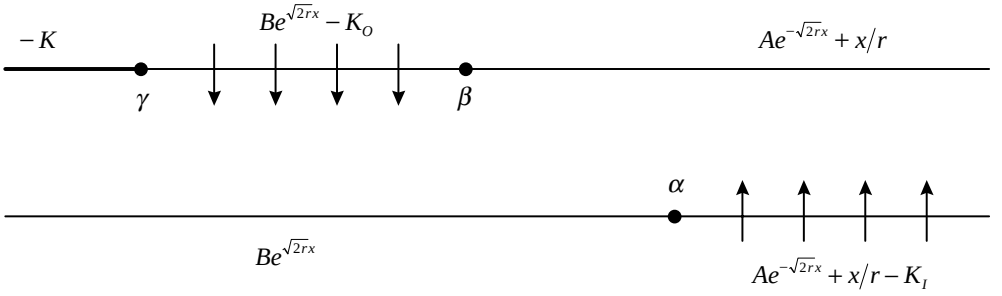

FIG. 2. *An obvious modification of the "no-abandonment case."*

whereas

$$\alpha = -\beta - rK_0 + rK_1 > \beta. \tag{46}$$

The functions w_1, w_0 *defined by* (33)–(34), *where* α *and* β *are as above and* $A, B > 0$ *are given by* (39), (40), *respectively, are convex, nondecreasing,* C^1 *for all* $x \in \mathbb{R}$ *and* C^2 *for all* $x \in \mathbb{R} \setminus \{\beta\}$, $x \in \mathbb{R} \setminus \{\alpha\}$, *respectively, and satisfy*

$$\max\left\{\frac{1}{2}w_1''(x) - rw_1(x) + x,\ w_0(x) - K_0 - w_1(x)\right\} = 0 \tag{47}$$

for all $x \in \mathbb{R} \setminus \{\beta\}$ *and*

$$\max\left\{\frac{1}{2}w_0''(x) - rw_0(x),\ w_1(x) - K_1 - w_0(x),\ -K - w_0(x)\right\} = 0 \tag{48}$$

for all $x \in \mathbb{R} \setminus \{\alpha\}$. *Moreover,* $w_1(x) \geq -K$ *if and only if* $K \geq K_0$.

We collect in the appendix the proofs of those results that are not developed in the text.

If the condition $K \geq K_0$ is not satisfied, we expect that abandonment becomes part of the optimal scenario. Now, assuming that the optimal strategy has a continuous qualitative character, we should expect that, as K_0 rises above K, abandonment should become optimal if the system is "open" and the state process X assumes sufficiently small values. The obvious modification of the strategy studied above is depicted by Figure 2. Such a possibility involves five parameters and three free boundary points, so we cannot impose a C^1 fit at all of the free boundary points.

By an obvious symmetry argument, we can conclude that the value function is C^1 at the points α, β, and C^0 at the point γ. However, by elementary considerations, we can see that the value function is nondecreasing in x. Therefore, if the optimal strategy identifies with the one depicted by Figure 2, we must have $w_1(\gamma-) = 0 < w_1(\gamma+)$, which is unacceptable in light of Remark 1. Alternatively, we can postulate that the value function is C^1 at γ and β (resp., α), and C^0 at α (resp., β). However, such a possibility would impose a discontinuity of the first derivative of the candidate value functions inside the interior of the "continuation" region, which is again contradicting the conclusions of Remark 1. It turns out that a strategy having the form depicted by Figure 2 cannot be optimal. However, the idea that the optimal strategy should possess a character which depends continuously on the problem's data leads us to the conclusion that we should look for a further modification of this strategy. Such

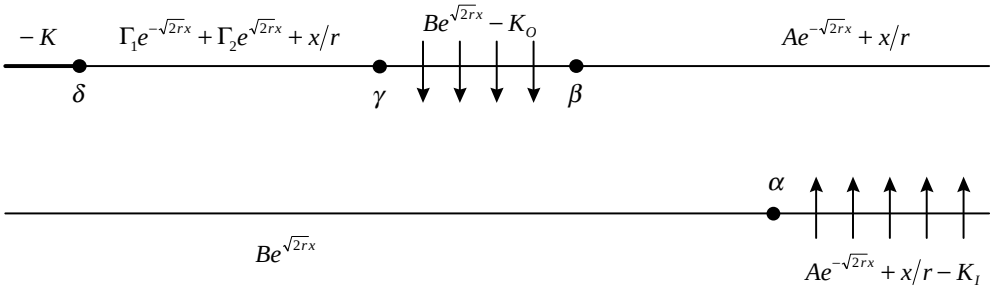

FIG. 3. *The case in which abandonment becomes part of the optimal tactics.*

a modification can be obtained by inserting a "do-not-abandon-or-switch-off" region around γ so that the interface of the "abandonment" and the "switch-off" regions is not just a point but an interval. This strategy is depicted by Figure 3.

If this case is indeed optimal, the value function of the control problem should identify with a solution w_1, w_0 of the HJB equations (31)–(32) described by

$$w_1(x) = \begin{cases} -K & \text{if } x \le \delta, \\ \Gamma_1 e^{-\sqrt{2r}x} + \Gamma_2 e^{\sqrt{2r}x} + x/r & \text{if } \delta < x < \gamma, \\ Be^{\sqrt{2r}x} - K_0 & \text{if } \gamma \le x \le \beta, \\ Ae^{-\sqrt{2r}x} + x/r & \text{if } x > \beta, \end{cases} \tag{49}$$

$$w_0(x) = \begin{cases} Be^{\sqrt{2r}x} & \text{if } x < \alpha, \\ Ae^{-\sqrt{2r}x} + x/r - K_1 & \text{if } x \ge \alpha. \end{cases} \tag{50}$$

The parameters A, B, Γ_1, Γ_2, α, β, γ, δ can then be specified by the requirement that w_1, w_0 are C^1 at the free boundary points α, β, γ, δ. Now, it is a straightforward calculation to verify that this requirement implies that α, β, A, B should satisfy (39)–(42),

$$\Gamma_1 = -\frac{\gamma + rK_0 - 1/\sqrt{2r}}{2r} e^{\sqrt{2r}\gamma}, \tag{51}$$

$$\Gamma_2 = B - \frac{\gamma + rK_0 + 1/\sqrt{2r}}{2r} e^{-\sqrt{2r}\gamma}, \tag{52}$$

and γ, δ should satisfy the system of equations

$$\begin{aligned} F_1(\gamma, \delta) &:= (\delta + rK - 1/\sqrt{2r}) e^{\sqrt{2r}\delta} - (\gamma + rK_0 - 1/\sqrt{2r}) e^{\sqrt{2r}\gamma} \\ &= 0, \end{aligned} \tag{53}$$

$$\begin{aligned} F_2(\gamma, \delta) &:= (\delta + rK + 1/\sqrt{2r}) e^{-\sqrt{2r}\delta} - (\gamma + rK_0 + 1/\sqrt{2r}) e^{-\sqrt{2r}\gamma} + 2rB \\ &= 0. \end{aligned} \tag{54}$$

The next lemma is concerned with the solvability of (53)–(54) as well as with necessary and sufficient conditions under which the functions w_1, w_0 considered above satisfy the HJB equations (31)–(32).

LEMMA 3. *Let $\alpha = \alpha(r, K_1, K_0)$, $\beta = \beta(r, K_1, K_0)$, A, B be as in Lemma 2. The system of equations* (53)–(54) *has a unique solution $\gamma = \gamma(r, K_1, K_0, K)$, $\delta =$*

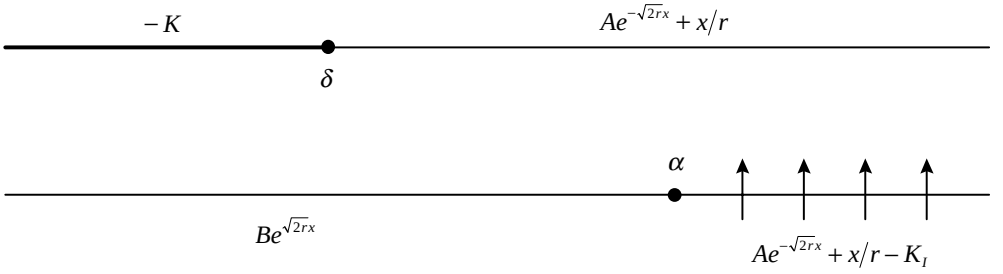

FIG. 4. *The case in which switching the system to its "closed" mode is never optimal.*

$\delta(r, K_1, K_0, K)$ *such that* $\delta < \gamma < \beta$ *if and only if*

$$K_* \vee 0 < K < K_0, \tag{55}$$

where $K_* = K_*(r, K_1, K_0) < K_0$ *is defined by*

$$K_* = -\frac{1}{r\sqrt{2r}} \ln\left(-\frac{\sqrt{2r}}{2}(\beta + rK_0 - 1/\sqrt{2r}) \exp(\sqrt{2r}(\beta + 1/\sqrt{2r}))\right). \tag{56}$$

If $K_* > 0$ *and* $K = K_*$, *then* $\gamma = \beta$, $\delta = -rK - 1/\sqrt{2r}$, $\Gamma_1 = A$, *and* $\Gamma_2 = 0$. *If* (55) *is true, then the functions* w_1, w_0 *defined by* (49), (50), *respectively, where* $\Gamma_1, \Gamma_2 > 0$ *are given by* (51)–(52), *are convex, nondecreasing,* C^1 *for all* $x \in \mathbb{R}$ *and* C^2 *for all* $x \in \mathbb{R} \setminus \{\delta, \gamma, \beta\}$, $x \in \mathbb{R} \setminus \{\alpha\}$, *respectively, and satisfy the HJB equations* (31)–(32).

The optimality of the case considered in the previous lemma depends crucially on the parameter K_*. If $K_* \leq 0$ for every admissible choice of the problem's data, then our solution is complete. However, it turns out that this is not the case in general.

LEMMA 4. *Given any values of the parameters* $r, K_1 > 0$, *the function* $K_*(r, K_1, \cdot)$ *is well defined on* $]-K_1, \infty[$, *is strictly increasing and at least* C^1 *on this interval, and satisfies* $\lim_{K_0 \to \infty} K_*(r, K, K_0) = \infty$ *and* $K_*(r, K, 0) < 0$.

In Lemma 3, we proved that if $K_* > 0$ and $K = K_*$, then $\gamma = \beta$, so the "switch-from-open-to-closed" region disappears, and the optimal strategy is depicted by Figure 4. For $K < K_*$, we can expect that it is not optimal to switch the system from its "open" to its "closed" operating mode at any time, so that the optimal strategy can again be depicted by Figure 4.

If this strategy is indeed optimal, the value function should be given in terms of the functions

$$w_1(x) = \begin{cases} -K & \text{if } x \leq \delta, \\ Ae^{-\sqrt{2r}x} + x/r & \text{if } x > \delta, \end{cases} \tag{57}$$

$$w_0(x) = \begin{cases} Be^{\sqrt{2r}x} & \text{if } x < \alpha, \\ Ae^{-\sqrt{2r}x} + x/r - K_1 & \text{if } x \geq \alpha. \end{cases} \tag{58}$$

Again, we require that w_1, w_0 are C^1 at the free boundary points δ, α, respectively. Straightforward calculations show that C^1 fit at δ yields

$$A = \frac{1}{r\sqrt{2r}} \exp(-\sqrt{2r}(rK + 1/\sqrt{2r})), \tag{59}$$

$$\delta = -rK - \frac{1}{\sqrt{2r}}, \tag{60}$$

whereas C^1 fit at α yields the system of equations

$$Be^{\sqrt{2r}\alpha} - Ae^{-\sqrt{2r}\alpha} = \frac{\alpha - rK_1}{r}, \tag{61}$$

$$Be^{\sqrt{2r}\alpha} + Ae^{-\sqrt{2r}\alpha} = \frac{1}{r\sqrt{2r}}, \tag{62}$$

which is equivalent to

$$B = \frac{\alpha - rK_1 + 1/\sqrt{2r}}{2r} e^{-\sqrt{2r}\alpha}, \tag{63}$$

$$\begin{aligned} G(\alpha) &:= \frac{\sqrt{2r}}{2}(\alpha - rK_1 - 1/\sqrt{2r}) \exp(\sqrt{2r}(\alpha + rK + 1/\sqrt{2r})) \\ &= -1. \end{aligned} \tag{64}$$

The next lemma is concerned with the solvability of (64) and with necessary and sufficient conditions under which this case is optimal.

LEMMA 5. *Equation* (64) *has a unique solution* $\alpha = \alpha(r, K_1, K)$ *such that* $\alpha > -rK - 1/\sqrt{2r}$. *For this value of* α, *and for* $A, B > 0$, *and* $\delta = \delta(r, K)$ *given by* (59), (63), *and* (60), *respectively, the functions* w_1, w_0 *defined by* (57)–(58) *are convex, nondecreasing and* C^1 *for all* $x \in \mathbb{R}$ *and* C^2 *for all* $x \in \mathbb{R} \setminus \{\delta\}$, $\mathbb{R} \setminus \{\alpha\}$, *respectively. Moreover, assuming that* $K_* > 0$, *they satisfy the HJB equations* (31)–(32) *if and only if* $0 < K \leq K_*$.

We can now prove the main result of the section.

THEOREM 6. *Consider the stochastic optimization problem defined in section* 2, *and suppose that its data are as in Assumption* 1. *The value function* v *is* C^1, *convex and nondecreasing in* x, *and is given by* $v(1, \cdot) = w_1$ *and* $v(0, \cdot) = w_0$, *where the following hold:*

(I) *If* $K_0 \leq K$, w_1, w_0 *are given by Lemma* 2 *(see Figure* 1).

(II) *If* $K_* < K < K_0$, *where* $K_* < K_0$ *is given by* (56), w_1, w_0 *are given by Lemma* 3 *(see Figure* 3).

(III) *If* $K_* > 0$ *and* $K \leq K_*$, w_1, w_0 *are given by Lemma* 5 *(see Figure* 4).

In each of the three cases, the optimal strategy can be constructed as in the proof below.

Proof. First, observe that, given any sequence $t_m \to \infty$, (11) and the second limit in (19) are true for all $(Z, T) \in \Pi_z$. Also, in each of the three cases, the functions w_1 and w_0 are convex and nondecreasing.

Now, consider any of the three cases. Since $w_1 \equiv w(1, \cdot)$ and $w_0 \equiv w(0, \cdot)$ are C^1 for all x and C^2 for all x outside a finite set, their second distributional derivatives are measures that are absolutely continuous with respect to the Lebesgue measure. With regard to the notation of Definition 1, this implies that $w^{\mathrm{s}}_{xx}(1, dx) \equiv 0$ and $w^{\mathrm{s}}_{xx}(0, dx) \equiv 0$, and, therefore, (12) as well as (14) are true. Moreover, $w_1 \equiv w(1, \cdot)$ and $w_0 \equiv w(0, \cdot)$ satisfy the HJB equations (31)–(32) in the classical sense, by construction, and, therefore, in the sense of Definition 1.

Since $w(1, \cdot)$ and $w(0, \cdot)$ have bounded first derivatives, the process M defined as in (13) is a square integrable martingale for all $Z \in \mathcal{Z}$. Furthermore, there exist constants C_1 and C_2 such that

$$w(z, x) \leq C_1 + C_2|x| \quad \forall z = 1, 0 \text{ and } x \in \mathbb{R}.$$

It follows that, given any $Z \in \mathcal{Z}$,

$$\lim_{t\to\infty} E\left[e^{-rt}\,|w(Z_t, X_t)|\right] \le \lim_{t\to\infty} E\left[e^{-rt}\,(C_1 + C_2\,|x + W_t|)\right] = 0.$$

However, this shows that (18) is satisfied for all $Z \in \mathcal{Z}$ and, therefore, for the optimal switching process.

The above arguments prove that, in any of the three cases, $w_1 \equiv w(1,\cdot)$ and $w_0 \equiv w(0,\cdot)$ satisfy all of the assumptions related to part (a) of Theorem 1 as well as (14) and (19). As a consequence, to complete the proof, we have to construct a strategy (Z^*, T^*) satisfying (15)–(18).

Now, in Case I, if $z = 1$, then we can see that the strategy (Z^*, T^*), where $T^* = \infty$ and the process $Z^* \in \mathcal{Z}$ is defined by

$$Z_t^* = 1_{\{t=0\}} + \sum_{j=0}^{\infty} 1_{\{T_{2j}^* < t \le T_{2j+1}\}^*}, \tag{65}$$

where $T_0^* = 0$ and the stopping times T_n^*, $n \in \mathbb{N}^*$, are defined recursively by

$$T_{2n+1}^* = \inf\{t \ge T_{2n}^* \mid\ X_t \le \beta\}, \quad n = 0, 1, 2, \ldots, \tag{66}$$

$$T_{2n}^* = \inf\{t \ge T_{2n-1}^* \mid\ X_t \ge \alpha\}, \quad n = 1, 2, \ldots, \tag{67}$$

satisfies (15)–(18). If $z = 0$, we again have $T^* = \infty$, and the optimal switching process Z^* can be constructed in a similar fashion.

In Case II, if $z = 1$ and $x \ge \gamma$ or if $z = 0$, the optimal strategy is the same as in Case I. If $z = 1$ and $x \le \delta$, then the optimal strategy is characterized by $T^* = 0$. If $z = 1$ and $\delta < x < \gamma$, then define

$$T_\delta = \inf\{t \ge 0 \mid\ X_t \le \delta\} \quad \text{and} \quad T_\gamma = \inf\{t \ge 0 \mid\ X_t \ge \gamma\}, \tag{68}$$

and let

$$T^* = T_\delta 1_{\{T_\delta < T_\gamma\}} + \infty 1_{\{T_\delta > T_\gamma\}} \in \mathcal{S}.$$

Also let $T_0^* = 0$, $T_1^* = T_\gamma$, and define T_n^*, $n \ge 2$, as in (67). Then we can see that the strategy (Z^*, T^*) where Z^* is defined as in (65), satisfies (15)–(18).

In Case III, if $z = 1$, then $T^* = T^\delta$, where T_δ is defined as in (68), and Z^*, defined by $Z_t^* = 1$ for all $t \ge 0$, provide the optimal strategy. Finally, if $z = 0$, then $T^* = \inf\{t \ge T_\alpha \mid\ X_t \le \delta\}$, where $T_\alpha = \inf\{t \ge 0 \mid\ X_t \ge \alpha\}$, and Z^* defined by $Z_t^* = 1_{\{T_\alpha < t\}}$, $t \ge 0$, are the optimal strategy, and the proof is complete. □

Remark 3. The rather unexpected qualitative nature of Case II is intimately related to optimal stopping. To understand this claim, consider the case as a perturbation of Case I, where stopping is not part of the optimal strategy. With regard to the heuristic discussion at the beginning of the section, abandonment can be optimal only if the system is "open" and the state process X assumes sufficiently low values. As a result, the optimal strategy should possess the same qualitative nature as in Case I if the system is "closed" or if the system is "open" and the state process X assumes sufficiently large values. Now, as the abandonment cost K falls marginally below the critical value K_0 and abandonment comes into the picture, a continuity argument dictates that the switching boundary points α and β as given by Lemma 2 should be "close" to the optimal ones. However, these points determine completely the function w_0. As a consequence, for sufficiently low values of X, the function w_1

should be "close" to the value function of the purely optimal stopping problem which seeks to maximize

$$E\left[\int_0^\tau e^{-rs}X_s\,ds - e^{-r\tau}\left[K \vee (K_0 - w_0(X_\tau))\right]\right]$$

over all stopping times $\tau \in \mathcal{S}$. In fact, we have proved that w_1 identifies with the value function of this purely optimal stopping problem for appropriate parameter values. Note that the terminal payoff function $-K \vee (K_0 - w_0(\cdot))$ of this problem is not C^1. From these observations, we can conclude that the existence of a "continuation" region such as the interval $]\delta, \gamma[$ in Case II should characterize the optimal strategy in purely optimal stopping problems where the first derivative of the terminal payoff function has appropriate discontinuities.

5. An example in which C^1 regularity of the value function fails. Based on the results established in the previous sections, we can easily construct an example whose value function is not composed by C^1 functions. To this end, consider the problem formulated in section 2, and assume that $\mathcal{I} = \mathbb{R}$, and

$$b(x) = 0, \quad \sigma(x) = 1, \quad r(x) = \frac{1}{2}, \quad H_1(x) = x, \quad H_0(x) = 0,$$
$$G_1(x) = 2, \quad G_0(x) = 10, \quad F(x) = \begin{cases} 5 - e^{x+10} & \text{if } x < -10, \\ 4 & \text{if } x \geq -10 \end{cases}$$

for all $x \in \mathbb{R}$.

With regard to (43) and (56), we calculate

$$\beta\left(\frac{1}{2}, 2, 10\right) = -5.999328399 \quad \text{and} \quad K_*\left(\frac{1}{2}, 2, 10\right) = 9.999328511. \tag{69}$$

Since $K_* > F(x)$, for all $x \in \mathbb{R}$, this example is akin to Case III of Theorem 6. The values of the associated parameters are

$$\delta\left(\frac{1}{2}, 4\right) = -3, \quad \alpha\left(\frac{1}{2}, 2, 4\right) = 1.986338745,$$
$$A = 0.099574137, \quad \text{and} \quad B = 0.272519358.$$

The value function of the example under consideration is given by

$$v(1,x) = \begin{cases} e^{x+10} - 5 & \text{if } x < -10, \\ -4 & \text{if } -10 \leq x < -3, \\ 0.099574137e^{-x} + 2x & \text{if } -3 \leq x, \end{cases}$$
$$v(0,x) = \begin{cases} 0.272519358e^{x} & \text{if } x < 1.9886338745, \\ 0.099574137e^{-x} + 2x - 2 & \text{if } x \geq 1.9886338745. \end{cases}$$

To see this, observe first that the only point where C^1 regularity fails is given by $z = 1$ and $x = -10$. Clearly, (12) and (14) are satisfied (see also Remark 1). Now, with reference to the proofs of Lemma 5 and Theorem 6, all of the assumptions of Theorem 1 will follow if we verify that

$$\frac{1}{2}w_1''(x) - \frac{1}{2}w_1(x) + x \leq 0 \quad \text{for } x < -3,$$
$$w_0(x) - 10 - w_1(x) \leq 0 \quad \text{for } x < -3,$$
$$w_1(x) - 2 - w_0(x) \leq 0 \quad \text{for } x < -3.$$

However, this is a trivial exercise.

Appendix: Proofs of results in section 4.

Proof of Lemma 2. Multiplying (41) and (42) side by side and solving for α, we obtain

$$\alpha = \beta + r(K_1 + K_0) \quad \text{or} \quad \alpha = -\beta - rK_0 + rK_1.$$

Substituting $\beta + r(K_1 + K_0)$ for α in (41) and (42), we obtain

$$(\beta + rK_0 - 1/\sqrt{2r})e^{r\sqrt{2r}(K_1+K_0)} = \beta + rK_0 - 1/\sqrt{2r},$$
$$(\beta + rK_0 + 1/\sqrt{2r})e^{-r\sqrt{2r}(K_1+K_0)} = \beta + rK_0 + 1/\sqrt{2r},$$

respectively. Since $K_1 + K_0 > 0$, there is no β satisfying both of these equations. Therefore, α must be as in (46). Now, (46) and either (41) or (42) yield (43).

Since $H(\beta) > 0$, for all $\beta < -rK_0 - 1/\sqrt{2r}$ and all $\beta > -rK_0 + 1/\sqrt{2r}$, if (43) has a solution, then this has to satisfy $-rK_0 - 1/\sqrt{2r} \le \beta \le -rK_0 + 1/\sqrt{2r}$. Now,

$$H'(\beta) = -2\sqrt{2r}\frac{(\beta + rK_0)^2}{(\beta + rK_0 - 1/\sqrt{2r})^2}\exp(-\sqrt{2r}(2\beta + rK_0 - rK_1)),$$

which implies that H is strictly decreasing in $\mathbb{R} \setminus \{-rK_0, -rK_0 + 1/\sqrt{2r}\}$. Combining this with the facts that $H(-rK_0 - 1/\sqrt{2r}) = 0$ and $H(-rK_0) = -\exp(r\sqrt{2r}(K_1 + K_0)) < -1$, we conclude that (43) has a unique solution which satisfies (44). Observe that the inequality $\beta < -rK_0$ and the expression $\alpha = -\beta - rK_0 + rK_1$ imply trivially that $\beta < \alpha$. Also, (44) implies (45) because the function $x \to xe^x$ is strictly decreasing in $]-\infty, -1[$. Furthermore, (44) along with (39) and (40) imply that $A, B > 0$.

Since $A, B > 0$, the functions w_1, w_0 are convex and nondecreasing. As a consequence, $-K \le w_1$ if and only if $K \ge K_0$, and $-K \le w_0$. Now, to verify that w_1, w_0 satisfy (47) and (48), we have to prove that

$$\frac{1}{2}w_1''(x) - rw_1(x) + x \le 0 \quad \text{for } x < \beta, \tag{70}$$
$$w_1(x) - K_1 - w_0(x) \le 0 \quad \text{for } x \le \beta, \tag{71}$$
$$w_0(x) - K_0 - w_1(x) \le 0 \quad \text{for } \beta \le x \le \alpha, \tag{72}$$
$$w_1(x) - K_1 - w_0(x) \le 0 \quad \text{for } \beta \le x \le \alpha, \tag{73}$$
$$w_0(x) - K_0 - w_1(x) \le 0 \quad \text{for } x \ge \alpha, \tag{74}$$
$$\frac{1}{2}w_0''(x) - rw_0(x) \le 0 \quad \text{for } x > \alpha. \tag{75}$$

Each of (71) and (74) is equivalent to $-K_1 - K_0 \le 0$, which is true. Inequality (70) is trivially implied by $rK_0 + \beta < 0$ (see (44)), whereas (75) is trivially implied by $-\alpha + rK_1 = \beta + rK_0 < 0$.

Now, consider the function g defined by

$$g(x) := Be^{\sqrt{2r}x} - Ae^{-\sqrt{2r}x} - \frac{x}{r} - K_0.$$

Since $g(x) = w_0(x) - K_0 - w_1(x)$ for $x \in [\beta, \alpha]$, (72) and (73) will follow if we prove that

$$-K_1 - K_0 \le g(x) \le 0 \quad \forall x \in [\beta, \alpha]. \tag{76}$$

The function g' is strictly convex because

$$g'''(x) = 2r\sqrt{2r}(Be^{\sqrt{2r}x} + Ae^{-\sqrt{2r}x}) > 0,$$

the inequality being true because $A, B > 0$. As a consequence, $g'(x) < 0$ for all $x \in]\beta, \alpha[$ because $g'(\beta) = g'(\alpha) = 0$ by construction. However, combining this observation with the fact that $g(\beta) = 0$ and $g(\alpha) = -K_0 - K_1$, we conclude that (76) is true. □

Proof of Lemma 3. Fix any $\gamma < -rK_0$, and consider the equation

$$f(\delta) := F_1(\gamma, \delta) = 0. \tag{77}$$

From the calculations

$$\lim_{\delta \to -\infty} f(\delta) = -(\gamma + rK_0 - 1/\sqrt{2r})e^{\sqrt{2r}\gamma} > 0, \tag{78}$$

$$f'(\delta) = \sqrt{2r}(\delta + rK)e^{\sqrt{2r}\delta}, \tag{79}$$

$$f(\gamma) = r(K - K_0)e^{\sqrt{2r}\gamma}, \tag{80}$$

we can see that (77) has a unique solution $\delta < \gamma$ if $K < K_0$. These calculations also imply that (77) does not have a solution $\delta < \gamma$ if $K > K_0$ and $\gamma < -rK$. If $K > K_0$ and $-rK < \gamma$, (77) will have a solution only if f is negative at $\delta = -rK$, where its minimum over $\delta \in]-\infty, \gamma]$ occurs. However,

$$f(-rK) = -(\gamma + rK_0)e^{\sqrt{2r}\gamma} + \frac{1}{\sqrt{2r}}[e^{\sqrt{2r}\gamma} - e^{\sqrt{2r}(-rK)}] > 0,$$

the inequality following because $-rK < \gamma < -rK_0$. From these considerations, we conclude that, given any $\gamma < -rK_0$, (77) has a unique solution $\delta < \gamma$ if and only if $K < K_0$. For the rest of this proof, we assume that this condition is satisfied.

From the above, we can see that, as γ varies, (77) uniquely defines a function $\delta = \delta(\gamma)$ on $]-\infty, -rK_0[$ such that $\delta(\gamma) < \gamma$ for all $\gamma < -rK_0$. Also, by implicit differentiation of (77), we obtain

$$\delta'(\gamma) = \frac{\gamma + rK_0}{\delta(\gamma) + rK} e^{\sqrt{2r}(\gamma - \delta(\gamma))}. \tag{81}$$

Now consider the equation

$$g(\gamma) := F_2(\gamma, \delta(\gamma)) = 0 \quad \text{for } \gamma < \beta. \tag{82}$$

Since

$$g(\gamma) = \sqrt{2r} \int_{\delta(\gamma)}^{\gamma} e^{-\sqrt{2r}s}(s + rK)\, ds + r(K - K_0)e^{-\sqrt{2r}\gamma} + 2rB$$

and $K < K_0$, it follows that

$$\lim_{\gamma \to -\infty} g(\gamma) = -\infty. \tag{83}$$

Also, using (81), we can calculate

$$g'(\gamma) = -2\sqrt{2r}(\gamma + rK_0)e^{-\sqrt{2r}\delta(\gamma)} \sinh[\sqrt{2r}(\gamma - \delta(\gamma))] > 0, \tag{84}$$

whereas, in view of (40),

$$g(\beta) = (\delta(\beta) + rK + 1/\sqrt{2r})e^{-\sqrt{2r}\delta(\beta)}. \tag{85}$$

From (83)–(85), we can see that (82) has a unique solution $\gamma < \beta$ if and only if $\delta(\beta) > -rK - \frac{1}{\sqrt{2r}}$. With regard to the analysis relating to (77), this will be true if and only if $F_1(\beta, -rK - 1/\sqrt{2r}) > 0$, i.e., if and only if

$$-2e^{-2} > \sqrt{2r}(\beta + rK_0 - 1/\sqrt{2r}) \exp(\sqrt{2r}(\beta + rK - 1/\sqrt{2r})). \tag{86}$$

With reference to (45), this is true for $K = K_0$. Furthermore, the right-hand side of this inequality is increasing as K decreases. As a consequence, (86) is true for all $K \in]K_* \vee 0, K_0[$, where $K_* < K_0$ is given by (56).

With regard to the arguments above, if $K_* > 0$ and $K = K_*$, then (86) holds with equality, $\gamma = \beta$, and $\delta = -rK - 1/\sqrt{2r}$. From (39), (51) and (40), (52), it then follows that $\Gamma_1 = A$ and $\Gamma_2 = 0$, respectively.

Since $\gamma < \beta < -rK_0$, (51) implies that $\Gamma_1 > 0$. Furthermore, since

$$\frac{d}{dy}\left[\frac{y + rK_0 + 1/\sqrt{2r}}{2r} e^{-\sqrt{2r}y}\right] = -\frac{1}{\sqrt{2r}}(y + rK_0)e^{-\sqrt{2r}y} > 0 \quad \forall y < -rK_0,$$

it follows that

$$\frac{\beta + rK_0 + 1/\sqrt{2r}}{2r} e^{-\sqrt{2r}\beta} > \frac{\gamma + rK_0 + 1/\sqrt{2r}}{2r} e^{-\sqrt{2r}\gamma}.$$

Therefore, (40) and (52) imply $\Gamma_2 > 0$.

Since $A, B, \Gamma_1, \Gamma_2 > 0$, the functions w_1, w_0 are convex and nondecreasing, so $w_1, w_0 \geq -K$. Also, all of the inequalities associated with the HJB equations (31)–(32) for $x \geq \gamma$ follow from Lemma 2. Therefore, to verify that w_1, w_0 satisfy the HJB equations (31)–(32), it remains to show that

$$\frac{1}{2}w_1''(x) - rw_1(x) + x \leq 0 \quad \text{for } x < \delta, \tag{87}$$

$$w_0(x) - K_0 - w_1(x) \leq 0 \quad \text{for } x \leq \delta, \tag{88}$$

$$w_1(x) - K_1 - w_0(x) \leq 0 \quad \text{for } x \leq \delta, \tag{89}$$

$$w_0(x) - K_0 - w_1(x) \leq 0 \quad \text{for } \delta \leq x \leq \gamma, \tag{90}$$

$$w_1(x) - K_1 - w_0(x) \leq 0 \quad \text{for } \delta \leq x \leq \gamma. \tag{91}$$

The inequalities $\delta + rK < \beta + rK_0 < 0$ trivially imply (87). Also, since $B > 0$, (89) is straightforward, whereas (88) is implied by (90) and the continuity of w_1, w_0.

Now, consider the function g defined by

$$g(x) := -\Gamma_1 e^{-\sqrt{2r}x} + (B - \Gamma_2)e^{\sqrt{2r}x} - \frac{x + rK_0}{r}.$$

Since $g(x) = w_0(x) - K_0 - w_1(x)$, if $x \in [\delta, \gamma]$, (90) and (91) will follow if we show that

$$-K_1 - K_0 \leq g(x) \leq 0 \quad \forall x \in [\delta, \gamma]. \tag{92}$$

By construction,

$$g(\gamma) = g'(\gamma) = 0 \quad \text{and} \quad g''(\gamma) = 2(\gamma + rK_0) < 0. \tag{93}$$

If $B - \Gamma_2 < 0$, then

$$g''(x) = 2r[-\Gamma_1 e^{-\sqrt{2r}x} + (B - \Gamma_2)e^{\sqrt{2r}x}] < 0,$$

so g' is strictly decreasing, which, combined with $g'(\gamma) = 0$, implies $g'(x) > 0$ for all $x < \gamma[$. On the other hand, if $B - \Gamma_2 > 0$, then

$$g'''(x) = 2r\sqrt{2r}[\Gamma_1 e^{-\sqrt{2r}x} + (B - \Gamma_2)e^{\sqrt{2r}x}] > 0,$$

which proves that g' is strictly convex. However, this observation and (93) imply that $g'(x) > 0$ for all $x < \gamma$. Finally, since g is increasing in $[\delta, \gamma]$ and $g(\gamma) = 0$, (92) follows from the observation that

$$g(\delta) = Be^{\sqrt{2r}\delta} - K_0 + K > -K_1 - K_0. \qquad \square$$

Proof of Lemma 4. Suppose that the values of $r, K_1 > 0$ are fixed, and consider the unique solution $\beta = \beta(r, K_1, K_0)$ of (43) as a function of K_0 on $]-K_1, \infty[$. By implicit differentiation of (43), we obtain

$$\frac{\partial \beta}{\partial K_0} + r = \frac{r(\beta + rK_0 + 1/\sqrt{2r})(\beta + rK_0 - 1/\sqrt{2r})}{2(\beta + rK_0)^2}. \tag{94}$$

Now, differentiating (56) with respect to K_0, we obtain

$$\frac{\partial K_*}{\partial K_0} = -\frac{1}{r(\beta + rK_0 - 1/\sqrt{2r})}\left[(\beta + rK_0)\left(\frac{\partial \beta}{\partial K_0} + r\right) - r(\beta + rK_0 - 1/\sqrt{2r})\right].$$

Substituting for $\partial\beta/\partial K_0 + r$ from (94), we obtain

$$\frac{\partial K_*}{\partial K_0} = \frac{\beta + rK_0 - 1/\sqrt{2r}}{2(\beta + rK_0)} > 0,$$

the inequality following because $\beta < -rK_0$. As a consequence, $K_*(r, K_1, \cdot)$ is strictly increasing in $]-K_1, \infty[$.

Now, (45) and (56) imply

$$K_0 > K_* > -\frac{1 - \ln 2}{r\sqrt{2r}} + K_0.$$

However, these inequalities imply $\lim_{K_0 \to \infty} K_*(r, K_1, K_0) = \infty$ and $K_*(r, K_1, 0) < 0$, and the proof is complete. $\square$

Proof of Lemma 5. The fact that (64) has a unique solution $\alpha > -rK - 1/\sqrt{2r}$ follows from the calculations

$$\begin{aligned} G(-rK - 1/\sqrt{2r}) &= -\frac{\sqrt{2r}}{2} r(K + K_1) - 1 < -1, \\ G'(\alpha) &= r(\alpha - rK_1)\exp(\sqrt{2r}(\alpha + rK + 1/\sqrt{2r})), \\ \lim_{\alpha \to \infty} G(\alpha) &= \infty. \end{aligned}$$

Also, this solution satisfies

$$rK_1 < \alpha < rK_1 + 1/\sqrt{2r}, \tag{95}$$

the second inequality holding because $G(rK_1 + 1/\sqrt{2r}) = 0 > -1$.

Now, (63) and (95) imply $B > 0$, whereas $A > 0$ is obvious from (59). Since $A, B > 0$, w_1, w_0 are convex and nondecreasing, $w_1, w_0 \geq -K$. To verify that they satisfy the HJB equations (31)–(32), we have to establish conditions under which

$$\frac{1}{2}w_1''(x) - rw_1(x) + x \leq 0 \quad \text{for } x \leq \delta, \tag{96}$$

$$w_0(x) - K_0 - w_1(x) \leq 0 \quad \text{for } x \leq \delta, \tag{97}$$

$$w_1(x) - K_1 - w_0(x) \leq 0 \quad \text{for } x \leq \delta, \tag{98}$$

$$w_0(x) - K_0 - w_1(x) \leq 0 \quad \text{for } \delta \leq x \leq \alpha, \tag{99}$$

$$w_1(x) - K_1 - w_0(x) \leq 0 \quad \text{for } \delta \leq x \leq \alpha, \tag{100}$$

$$w_0(x) - K_0 - w_1(x) \leq 0 \quad \text{for } x \geq \alpha, \tag{101}$$

$$\frac{1}{2}w_0''(x) - rw_0(x) \leq 0 \quad \text{for } x \geq \alpha. \tag{102}$$

Inequalities (96) and (102) are implied trivially by the fact that $\delta = -rK - 1/\sqrt{2r}$ and the first inequality in (95), respectively. Also, (101) is equivalent to $-K_1 - K_0$, which is true, whereas (98) follows immediately because $B > 0$. In view of the continuity of w_1, w_0 and the fact that $B > 0$, we can also see that (97) is implied by (99).

To study (99), (100), define the function g by

$$g(x) := Be^{\sqrt{2r}x} - Ae^{-\sqrt{2r}x} - \frac{x + rK_0}{r}$$

so that $g(x) = w_0(x) - K_0 - w_1(x)$ if $x \in [\delta, \alpha]$. By construction,

$$g(\alpha) = -K_1 - K_0, \quad g'(\alpha) = 0, \quad g''(\alpha) = 2(\alpha - rK_1) > 0, \tag{103}$$

the inequality following by virtue of (95). Now, since $A, B > 0$,

$$g'''(x) = 2r\left[g'(x) + \frac{1}{r}\right] = 2r\sqrt{2r}[Be^{\sqrt{2r}x} + Ae^{-\sqrt{2r}x}] > 0 \tag{104}$$

imply that g' is strictly convex and $\lim_{x\to-\infty} g'(x) = \infty$. However, these observations and (103) imply that there exists a unique $\hat{x} < \alpha$ such that $g'(\hat{x}) = 0$. Furthermore, $\delta > \hat{x}$ because $g'(\delta) = \sqrt{2r}Be^{\sqrt{2r}\delta} > 0$. From these considerations, we conclude that

$$g'(x) > 0 \quad \forall x \in [\delta, \hat{x}[\qquad \text{and} \qquad g'(x) < 0 \quad \forall x \in]\hat{x}, \alpha[. \tag{105}$$

Now, (100) follows from the fact that

$$-K_1 - K_0 \leq g(x) \quad \forall x \in [\delta, \alpha],$$

which is true in view of (98) and the continuity of w_1, w_0, (103), and (105). On the other hand, (99) will follow if we show that $g(x) \leq 0$ for all $x \in [\delta, \alpha]$. In view of (105), this will be true if and only if $g(\hat{x}) \leq 0$, i.e., if and only if

$$Be^{\sqrt{2r}\hat{x}} - Ae^{-\sqrt{2r}\hat{x}} \leq \frac{\hat{x} + rK_0}{r}. \tag{106}$$

All of the results proved above are true for any positive values of the problem's data r, K_1, K_0, K. Therefore, given any positive value of these parameters, there exists a unique $\Delta \in \mathbb{R}$ such that

$$Be^{\sqrt{2r}\hat{x}} - Ae^{-\sqrt{2r}\hat{x}} = \frac{\hat{x} + r(K_0 + \Delta)}{r}. \tag{107}$$

Clearly, (106) will be true if and only if $\Delta \leq 0$. Now, recall that $\hat{x} \in]\delta, \alpha[$ satisfies $g'(\hat{x}) = 0$, i.e.,

$$Be^{\sqrt{2r}\hat{x}} + Ae^{-\sqrt{2r}\hat{x}} = \frac{1}{r\sqrt{2r}}. \tag{108}$$

With regard to these two equations, we can eliminate B, substitute for A from (59), and solve for K to obtain

$$K = -\frac{1}{r\sqrt{2r}} \ln\left(-\frac{\sqrt{2r}}{2}(\hat{x} + r(K_0 + \Delta) - 1/\sqrt{2r}) \exp(\sqrt{2r}(\hat{x} + 1/\sqrt{2r})) \right). \tag{109}$$

Furthermore, by comparing (61), (62), (107), (108) with (35), (36), (37), (38), respectively, we can see that $\hat{x} = \beta(r, K_1, K_0 + \Delta)$, where β is given by Lemma 2. Therefore, (56) and (109) imply $K = K_*(r, K_1, K_0 + \Delta)$. Since $K_*(r, K_1, \cdot)$ is strictly increasing (see Lemma 4), $\Delta \leq 0$ if and only if $K \leq K_*(r, K_1, K_0)$. However, these arguments establish that (106) is true if and only if $K \leq K_*(r, K_1, K_0)$, and the proof is complete.

Acknowledgments. I am grateful to Kate Duckworth for several discussions on the problem solved in this paper. A preliminary exposition of part of the results obtained here has been presented in Duckworth and Zervos [DuZ2].

STATE CONSTRAINED FEEDBACK STABILIZATION*

F. H. CLARKE† AND R. J. STERN‡

Abstract. A standard finite dimensional nonlinear control system is considered, along with a state constraint set S and a target set Σ. It is proven that open loop S-constrained controllability to Σ implies closed loop S-constrained controllability to the closed δ-neighborhood of Σ, for any specified $\delta > 0$. When the S-constrained minimum time function to Σ satisfies a local continuity condition, conclusions on closed loop S-constrained stabilizability ensue. The (necessarily discontinuous) feedback laws in question are implemented in the sample-and-hold sense and possess a robustness property with respect to state measurement errors. The feedback constructions involve the quadratic infimal convolution of a control Lyapunov function with respect to a certain modification of the original dynamics. The modified dynamics in effect provide for constraint removal, while the convolution operation provides a useful semiconcavity property.

Key words. asymptotic controllability, state constraint, semiconcave control Lyapunov function, constraint removal, feedback, robustness

1. Introduction.

We shall consider a control system of the form

$$\dot{x}(t) = f(x(t), u(t)) \quad \text{a.e.}, \quad u(t) \in U. \tag{1}$$

The state trajectory $x(\cdot)$ evolves in $\mathbb{R}^n$ and control functions $u(\cdot)$ are Lebesgue measurable functions $u : \mathbb{R} \to U$, where $U \subset \mathbb{R}^m$ is a compact control constraint set. We shall assume throughout that the above dynamics satisfy the following standard hypotheses:

(F1) The function $f : \mathbb{R}^n \times U \to \mathbb{R}^n$ is continuous and is locally Lipschitz in the state variable x, uniformly for $u \in U$; that is, for each bounded set $\Gamma \subset \mathbb{R}^n$, there exists $K_\Gamma > 0$ such that

$$\|f(x,u) - f(y,u)\| \le K_\Gamma \|x - y\|,$$

whenever (x,u) and (y,u) are in $\Gamma \times U$.

(F2) The function f possesses linear growth; that is, there exist positive numbers c_1, c_2 such that

$$\|f(x,u)\| \le c_1\|x\| + c_2 \qquad \forall\, (x,u) \in \mathbb{R}^n \times U.$$

(F3) The velocity set

$$f(x,U) := \{f(x,u) : u \in U\}$$

is convex for every $x \in \mathbb{R}^n$.

Under (F1)–(F2), for every initial phase $(\tau, \alpha) \in \mathbb{R} \times \mathbb{R}^n$ and every control function $u(\cdot)$, there exists a unique trajectory $x(t) = x(t; \tau, \alpha, u(\cdot))$ defined for $t \geq \tau$ and satisfying $x(\tau) = \alpha$.

Remark 1.1. Actually, for our purposes, (F2) could be replaced by the somewhat weaker hypothesis that $f(\Gamma, U)$ is bounded for any bounded set $\Gamma \subseteq \mathbb{R}^n$. (See also section 5.3 below with regard to this issue.) Assumption (F3) will be needed below in order to have available a required sequential compactness property of trajectories. On the other hand, in the absence of (F3), the results of this article could be framed in the context of relaxed controls.

A general problem of considerable theoretical as well as applied interest, and one which has received much attention in recent years, is whether *open loop asymptotic controllability* of the origin implies *closed loop stabilization*. We need not give precise definitions of these properties here, but roughly speaking, open loop asymptotic controllability means that for every initial state in $\mathbb{R}^n$, there exists a control function so that the resulting trajectory of (1) is driven asymptotically to the origin and that this property holds in a certain uniform and Lyapunov stable manner. Closed loop stabilizability of the origin involves the existence of a feedback law $k : \mathbb{R}^n \to U$ such that all solutions of the ordinary differential equation

$$\dot{x}(t) = f(x(t), k(x(t))) \tag{2}$$

asymptotically approach the origin, again, in a uniform and Lyapunov stable manner.

A minimal condition for the existence of classical solutions to the ordinary differential equation (2) is that the feedback law $k(\cdot)$ be continuous on $\mathbb{R}^n \backslash \{0\}$. However, as was shown by Sontag and Sussman [36], even when $m = n = 1$, such a feedback law $k(\cdot)$ need not exist. A further negative result in this regard was provided by Brockett [4], who derived a topological condition on the dynamics, which is necessary for the existence of a stabilizing feedback law which is continuous on $\mathbb{R}^n$, and exhibited an example violating this condition, in spite of its global open loop controllability to the origin. In addition, Ryan [32] showed that Brockett's necessary condition persists even when Filippov solutions are considered. The upshot is that in addressing the above problem, due to the fact that continuity of feedback laws cannot be expected, it is advantageous to work with an alternative solution concept for (2), rather than the classical or Filippov ones. On the other hand, if nonautonomous feedbacks of the form $k(t, x)$ are allowed (and they are not, in our problem, which calls for a purely positional feedback law $k(x)$), then continuity is not precluded; see Coron [15] and Coron and Rosier [16].

Clarke et al. [8] obtained an affirmative answer to the above problem in terms of the following "sample-and-hold" solution concept for (2), where $k(\cdot)$ is in general discontinuous. Let an initial state $\alpha \in \mathbb{R}^n$ be specified. Then given a partition

$$\pi = \{t_0, t_1, t_2, \ldots\} \tag{3}$$

of $[0, \infty)$ (where $t_0 = 0$), the associated π-*trajectory* $x(\cdot)$ on $[0, \infty)$ with $x(0) = x(t_0) = \alpha$ is the curve satisfying interval-by-interval dynamics as follows: Set $x_0 = \alpha$. Then on the interval $[t_0, t_1]$, x is the classical solution of the differential equation

$$\dot{x}(t) = f(x(t), k(x_0)), \quad x(t_0) = x_0, \quad t \in (t_0, t_1). \tag{4}$$

We then set $x_1 := x(t_1)$ and restart the system on the next interval as follows:

$$\dot{x}(t) = f(x(t), k(x_1)), \quad x(t_1) = x_1, \quad t \in (t_1, t_2). \tag{5}$$

The process is continued in this manner through each interval. Note that x is the unique solution on $[0,\infty)$ of the differential equation $\dot{x}(t) = f(x(t),u(t))$ satisfying $x(\tau) = \alpha$, with a certain piecewise constant control function u determined by the control feedback $k(x)$. The sample-and-hold solution procedure is sometimes referred to as "closed loop system sampling," and is the same as the "step-by-step" solution concept employed by Krasovskiĭ and Subbotin [23] in differential game theory. We refer the reader to the introduction in Clarke et al. [7] for more detail on the history of the problem, nonsmooth Lyapunov functions, Filippov solutions, and related topics. Other references relevant to the present work are Sontag [35], Clarke et al. [9], [11], Rifford [27], [28], [29], Hermes [19], [20], Kokotovic and Sussman [22], Bacciotti [2], Ancona and Bressan [1], Teel and Praly [37], Kellett and Teel [21], and Prieur [25], [26].

In the present article, we shall address a variant of the problem discussed above, in which a state constraint is imposed; to the best of our knowledge, this is the first such endeavor. Specifically, for a given constraint set $S \subset \mathbb{R}^n$ and target set Σ such that $S \cap \Sigma \neq \emptyset$, we introduce the following definitions.

DEFINITION 1.2. Open loop S-controllability *to* Σ *holds provided that for any initial state* $\alpha \in S$, *there exists a control function* $u(\cdot)$ *and a time* $t(\alpha) \geq 0$ *such that*

$$x(t) = x(t;0,\alpha,u(\cdot)) \in S \qquad \forall\, t \in [0,t(\alpha)] \tag{6}$$

and

$$x(t(\alpha)) \in \Sigma. \tag{7}$$

Note that the controllability property in the preceding definition is not an asymptotic one. On the other hand, if open loop *asymptotic* S-controllability holds for a given target, then obviously open loop S-controllability to the closed γ-neighborhood of Σ holds for every $\gamma > 0$.

DEFINITION 1.3. Closed loop S-controllability *to* Σ *holds provided that there exists a feedback law* $k : \mathbb{R}^n \to U$ *along with reals* $T_1 > 0$ *and* $\beta > 0$ *such that the following holds: If*

$$\operatorname{diam}(\pi) := \max\{t_{i+1} - t_i \,:\, i = 0,1,\ldots\} \leq \beta,$$

then for every $\alpha \in S$, *there exists* $t_1(\alpha) \in [0,T_1]$ *such that the* π*-trajectory associated with the ordinary differential equation*

$$\dot{x}(t) = f(x(t),k(x(t)))$$

and initial condition $x(0) = \alpha$ *satisfies*

$$x(t) \in S \qquad \forall\, t \in [0,t_1(\alpha)] \tag{8}$$

and

$$x(t_1(\alpha)) \in \Sigma. \tag{9}$$

Our first main result (Theorem 4.1) asserts that when certain geometric conditions are imposed upon S, then open loop S-controllability to Σ implies closed loop S-controllability to the closed δ-neighborhood of Σ, for any specified $\delta > 0$. No geometric assumptions are imposed upon the target set Σ, beyond nonemptiness of $S \cap \Sigma$.

DEFINITION 1.4. Closed loop S-stabilizability to Σ *holds provided that closed loop S-controllability to Σ holds, with* (9) *in Definition* 1.3 *fortified to*

$$x(t) \in S \cap \Sigma \qquad \forall\, t \geq t_1(\alpha). \tag{10}$$

In the second main result (Theorem 4.8), we impose a local continuity condition on the S-constrained minimum time function to the target Σ and prove that in the presence of that hypothesis, open loop S-controllability to Σ implies closed loop S-stabilizability to the closed δ-neighborhood of Σ, for any specified $\delta > 0$. Our feedback constructions in these results involve the quadratic infimal convolution of a control Lyapunov function with respect to a certain modification of the original dynamics. The modified dynamics in effect provide for constraint removal, while the convolution operation provides a useful semiconcavity property.

The layout of this article is as follows. In the next section, we will present preliminaries from nonsmooth analysis. Then in section 3, certain required geometric results pertaining to the constraint removal method in Clarke, Rifford, and Stern [12] are recalled. The main results are provided in section 4, while section 5 contains concluding comments, including a robustness property with respect to state measurement error of the feedback laws constructed in section 4.

2. Nonsmooth analysis background. Our general reference on nonsmooth analysis employed in this article is [11]. Other useful references are [9], Clarke [5], [6], Loewen [24], and Vinter [38].

2.1. Notation and definitions. The Euclidean norm is denoted $\|\cdot\|$, and $\langle\, ,\, \rangle$ is the usual inner product. The open unit ball in $\mathbb{R}^n$ is denoted B. For a nonempty set $Z \subset \mathbb{R}^n$, we denote by $\mathrm{co}(Z)$, $\mathrm{cl}(Z)$, $\mathrm{bdry}(Z)$, and $\mathrm{int}(Z)$ the convex hull, closure, boundary, and interior of Z, respectively. We denote the closure of the complement of Z by $\hat{Z} := \mathrm{cl}\{\mathbb{R}^n \backslash Z\}$. Given $\delta > 0$, we denote $Z^\delta := Z + \delta \overline{B}$. The distance of a point u to Z is denoted

$$d_Z(u) := \inf\{\|u - x\| : x \in Z\}.$$

For closed S, the "inf" is replaced with a "min". The set of closest points in Z to a point $x \in \mathbb{R}^n$ is given by

$$\mathrm{proj}_Z(x) := \{z \in Z : d_Z(x) = \|x - z\|\}.$$

This set is nonempty for every x when (the nonempty set) Z is closed.

Let $g : \mathbb{R}^n \to (-\infty, \infty]$ be an extended real valued function which is lower semicontinuous; that is, for each $x \in \mathbb{R}^n$, $g(x) \leq \liminf_{y \to x} g(y)$. A vector $\zeta \in \mathbb{R}^n$ is said to be a *proximal subgradient* (or P-subgradient) of g at a point x such that $g(x) < \infty$ provided that there exists $\sigma > 0$ such that

$$g(y) - g(x) + \sigma \|y - x\|^2 \geq \langle \zeta, y - x \rangle \tag{11}$$

for all y near x; this is known as the *proximal subgradient inequality*. The set of all such vectors ζ is called the P-subdifferential of g at x, denoted $\partial_P g(x)$. One can show that $\partial_P g(x) \neq \emptyset$ for a dense subset of $\mathrm{dom}(g)$, the set of points where g is finite. The limiting, or L-subdifferential, is defined via limits as

$$\partial_L g(x) := \{\lim \zeta_i : \zeta_i \in \partial_P g(x_i), x_i \to x, g(x_i) \to g(x)\},$$

and for g locally Lipschitz, the C-subdifferential is defined as $\partial_C g(x) := \mathrm{co}\{\partial_L g(x)\}$. For such g, one has the inclusions

$$\partial_P g(x) \subset \partial_L g(x) \subset \partial_C g(x) \qquad \forall\, x \in \mathbb{R}^n. \tag{12}$$

2.2. Semiconcavity.

DEFINITION 2.1. *Let $U \subset \mathbb{R}^n$ be open. Then a continuous function $\varphi : U \to \mathbb{R}$ is* semiconcave *on U provided that there exists $c \geq 0$ such that for any $x \in U$*

$$\varphi(x+h) + \varphi(x-h) - 2\varphi(x) \leq c\|h\|^2$$

whenever $\|h\|$ is sufficiently small (depending on x).

Semiconcavity is an important regularity property in the theory of nonlinear partial differential equations and, as first demonstrated by Rifford [28], [29], in Lyapunov theory as well. The following proposition summarizes some useful equivalences involving semiconcavity. It is essentially known, following as it does from facts in Bardi and Capuzzo-Dolcetta [3] and [11].

PROPOSITION 2.2. *For $U \subset \mathbb{R}^n$ open and $\varphi : U \to \mathbb{R}$ locally Lipschitz, the following three properties are equivalent:*

(i) *φ is semiconcave on U.*

(ii) *There exists $c \geq 0$ such that*

$$g(y) := \varphi(y) - c\|y\|^2$$

is locally concave on U; that is, for every $x \in U$, there exists $r_x > 0$ such that $x + r_x B \subset U$ and $g(\cdot)$ is concave on $x + r_x B$.

(iii) *There exists $c \geq 0$ such that given $x \in U$, there exists $r_x > 0$ for which*

$$-\varphi(y) + \varphi(x) + c\|y-x\|^2 \geq \langle \zeta, y - x\rangle \qquad \forall\, \zeta \in \partial_P(-\varphi)(x) \quad \forall\, y \in x + r_x B. \tag{13}$$

Furthermore, if φ is semiconcave on U, then at every $x \in U$ one has

$$\partial_P(-\varphi)(x) = \partial_L(-\varphi)(x) = \partial_C(-\varphi)(x) = -\partial_C\varphi(x). \tag{14}$$

Of particular use to us below will be the following.

COROLLARY 2.3. *Suppose that $U \subset \mathbb{R}^n$ is open and that φ is semiconcave on U. Then for any open convex subset U' of U and any $x, y \in U'$, one has*

$$-\varphi(y) + \varphi(x) + c\|y-x\|^2 \geq \langle \zeta, y - x\rangle \qquad \forall\, \zeta \in \partial_P(-\varphi)(x) \tag{15}$$

and

$$\varphi(y) - \varphi(x) \leq \langle \zeta, y - x\rangle + c\|y-x\|^2 \qquad \forall\, \zeta \in \partial_L\varphi(x), \tag{16}$$

where c is as in (13).

3. State constrained tracking and constraint removal. Our methods will utilize recent results in Clarke, Rifford, and Stern [12] (see also Clarke and Stern [13]), which dealt with the construction of feedback control laws for a general class of state constrained optimal control problems, via a constraint removal method. In that work, extra hypotheses were imposed upon S so as to have available certain geometric properties of *inner approximations* of S, given by

$$S_r := \{x \in S : d_{\hat{S}}(x) \geq r\},$$

for $r \geq 0$; note that $S_0 = S$. Inner approximations were studied in earlier work by Clarke, Ledyaev, and Stern [10], as well as in [12]. Several important properties

verified in [12] regarding inner approximations will also be required in the present article and will be summarized in this section.

The augmented geometric hypotheses on S are now posited. We denote the *lower Hamiltonian* $h : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ by

$$h(x,p) := \min_{u\in U}\langle f(x,u), p\rangle. \tag{17}$$

(S1) S is a compact subset of $\mathbb{R}^n$ which is *wedged* at each $x \in S$; that is, $N_S^C(x)$, the *Clarke normal cone* to S at x, is pointed. This means that $N_S^C(x) \cap \{-N_S^C(x)\} = \{0\}$, or equivalently $\mathrm{int}[T_S^C(x)] \neq \emptyset$ for each $x \in S$, where $T_S^C(x)$ denotes the *Clarke tangent cone* to S at x. (We again refer the reader to [11] for the definitions and properties of these geometric constructs.)

(S2) The following "strict inwardness" condition holds:

$$h(x,\zeta) < 0 \quad \forall\, \zeta \in N_S^C(x)\backslash\{0\} \quad \forall\, x \in \mathrm{bdry}(S). \tag{18}$$

Hypotheses (S1)–(S2) *will be assumed to hold in all that follows.*

Remark 3.1.

(a) Any convex body (i.e., a convex set with nonempty interior) is wedged, but convexity is not required; for example, the closed complement of a convex body is necessarily wedged. Wedgedness of S at $x \in \mathrm{bdry}(S)$ is also referred to in the literature as *epi-Lipschitzness* at x, since the property amounts to S being locally linearly homeomorphic to the epigraph of a Lipschitz function; see Rockafellar [30] and Clarke [5].

(b) The set S is said to be *weakly invariant* provided that for any initial state $\alpha \in S$, there exists a control function $u(\cdot)$ such that

$$x(t) = x(t;0,\alpha,u(\cdot)) \in S \qquad \forall\, t \geq 0.$$

This is equivalent to the proximal condition

$$h(x,\zeta) \leq 0 \quad \forall\, \zeta \in N_S^P(x) \quad \forall\, x \in S; \tag{19}$$

see [11]. Hence conditions (S1)–(S2) are sufficient for weak invariance.

3.1. State constrained trajectory tracking. Required properties of inner approximations are summarized in the following lemma. Part (a) asserts that for small positive r, inner approximations S_r of S are weakly invariant, while parts (b) and (c) provide trajectory tracking properties relative to inner approximations in a uniform manner with respect to r. Among references involving state constrained tracking are the seminal results of Soner [33]; see also Forcellini and Rampazzo [17] and Frankowska and Rampazzo [18]. Part (a) of the lemma is included in Corollary 3.4 of [12], while parts (b) and (c) are provided by the proofs of Theorem 3.10 and Proposition 3.13 of [12], respectively.

LEMMA 3.2. *There exists a constant $r_0 > 0$ satisfying the following three properties:*

(a) *For every $r \in [0, r_0]$, the set S_r is nonempty and weakly invariant.*

(b) *Given $T > 0$, there exists a constant $M(T) > 0$ such that for every $r \in [0, r_0]$, the following holds: Let α_0 and α_1 be initial states in S_r, and let $u_0(\cdot)$ be a control function producing a trajectory which satisfies*

$$x(t;0,\alpha_0,u_0(\cdot)) \in S_r \qquad \forall\, t \in [0,T]. \tag{20}$$

Then there exists a control function $u_1(\cdot)$ which produces a trajectory which satisfies

$$\|x(t;0,\alpha_1,u_1(\cdot)) - x(t;0,\alpha_0,u_0(\cdot))\| \le M(T)\|\alpha_1-\alpha_0\| \qquad \forall\, t\in[0,T] \tag{21}$$

and

$$x(t;0,\alpha_1,u_1(\cdot)) \in S_r \qquad \forall\, t\in[0,T]. \tag{22}$$

(c) *Given $T>0$, there exists a constant $W(T)>0$ such that for any initial state $\alpha\in\operatorname{int}(S)$, if $r\in[0,r_0]$ is such that $\alpha\in S_r$ and $u(\cdot)$ is a control function such that*

$$x(t;0,\alpha,u(\cdot)) \in S \qquad \forall\, t\in[0,T], \tag{23}$$

then there exists a control function $\bar u(\cdot)$ such that

$$\|x(t;0,\alpha,\bar u(\cdot)) - x(t;0,\alpha,u(\cdot))\| \le rW(T) \qquad \forall\, t\in[0,T] \tag{24}$$

and

$$x(t;0,\alpha,\bar u(\cdot)) \in S_r \qquad \forall\, t\in[0,T]. \tag{25}$$

3.2. Modified dynamics and constraint removal. It will be convenient to denote

$$F(x) := f(x,U) = \{f(x,u) : u\in U\}.$$

Let us recall that in view of Filippov's lemma, an absolutely continuous arc $x(\cdot)$ is a trajectory of the differential inclusion

$$\dot x(t) \in F(x(t)) \quad \text{a.e.} \tag{26}$$

on a given time interval if and only if for some control function $u(\cdot)$, $x(\cdot)$ is a trajectory of the original control system (1).

We will require the following lemma, which summarizes certain technical facts from [12].

LEMMA 3.3. *If $r_0>0$ is sufficiently small, then for each $r\in[0,r_0]$, there exists a multifunction F_r with the following properties.*

(a) *$F_r(x)$ is a compact convex subset of $\mathbb{R}^n$ for every $x\in\mathbb{R}^n$. Also,*

$$F_r(x) = F(x) \qquad \forall\, x\in S_r \tag{27}$$

and

$$F_r(x) \subset F(x) \qquad \forall\, x\in S. \tag{28}$$

(b) *There exists $K>0$ (independent of r) such that*

$$F_r(x) \subset F_r(y) + K\|y-x\|B \qquad \forall\, x,y\in\mathbb{R}^n;$$

that is, $F_r(\cdot)$ is globally Lipschitz of rank K.

(c) *For every initial phase* $(\tau, \alpha) \in \mathbb{R} \times \mathbb{R}^n$, *there exists a trajectory* $x(\cdot)$ *satisfying the differential inclusion*

$$\dot{x}(t) \in F_r(x(t)) \quad \text{a.e.} \tag{29}$$

on $[\tau, \infty)$ *such that* $x(\tau) = \alpha$.

(d) *The set* S *is strongly invariant with respect to* F_r; *that is, for every initial state* $\alpha \in S$, *every trajectory* $x(\cdot)$ *of the differential inclusion* (29) *with* $x(0) = \alpha$ *satisfies* $x(t) \in S$ *for all* $t \geq 0$.

(e) *There exists* $\varepsilon_0 > 0$ *such that for any* $\alpha \in S + \varepsilon_0 B$, *there exists a trajectory* $x(\cdot)$ *of* (29) *with* $x(0) = \alpha$ *such that* $x(1) \in S$.

(f) *There exists* $C > 0$ *(independent of* r*) such that the following holds: For any* $\alpha \in S \backslash S_r$, *there exists a trajectory of* $x(\cdot)$ *of* (29) *such that* $x(0) = \alpha$ *and*

$$t(\alpha) := \sup\{t : d_{\hat{S}}(x(t)) \leq r\} \leq Cr. \tag{30}$$

(g) *There exists* $T_2(r) > 0$ *such that if* $\alpha \in S$ *and* $u_\alpha \in U$ *are such that* $f(\alpha, u_\alpha) \in F_r(\alpha)$, *then the (unique) solution* $x_\alpha(\cdot)$ *of the differential equation*

$$\dot{x}(t) = f(x(t), u_\alpha), \tag{31}$$

with $x(0) = \alpha$, *satisfies* $x_\alpha(t) \in S$ *for all* $t \in [0, T_2(r)]$.

According to (a) and (b), the multifunction F_r in the statement is globally Lipschitz and agrees with F on the inner approximation S_r and is contained in $F(x)$ for other points $x \in S$. Part (c) of the lemma follows from the standard existence theory for differential inclusions; observe that the usual "linear growth" condition is implied by the *global* Lipschitz nature of F_r. Note that (d) provides for what we refer to as "constraint removal," in the sense that for any initial state $x(0) \in S$, the state constraint

$$x(t) \in S \qquad \forall\, t \geq 0$$

is *implicit* for the differential inclusion (29). The strong invariance asserted in (d) is a consequence (see [11]) of the fact that the multifunction F_r satisfies

$$F_r(x) \subset \text{int} T_S^C(x) \qquad \forall\, x \in S.$$

(The latter condition is nontrivial just for $x \in \text{bdry}(S)$, since $T_S^C(x) = \mathbb{R}^n$ when x is in the interior of S.) Full details of the construction of F_r satisfying (a)–(d) and (f)–(g) are provided in [12]. We mention that part (e) follows independently from that construction and a result on set attainability in [11].

4. Main results. From this point on, we take $\Sigma \subset \mathbb{R}^n$ to be closed set such that $S \cap \Sigma \neq \emptyset$. Our first main result is the following.

THEOREM 4.1. *Let open loop* S*-controllability to* Σ *hold and let* $\delta > 0$ *be given. Then closed loop* S*-controllability to* Σ^δ *holds.*

We shall require the following lemma.

LEMMA 4.2. *Assume that open loop* S*-controllability to* Σ *holds. Then for any* $\gamma > 0$, *there exists* $T_3 = T_3(\gamma) > 0$ *such that the following hold:*

(a) *For any initial state* $\alpha \in S$, *there exists a control function* $u(\cdot)$ *such that for some* $\bar{t} = \bar{t}(\alpha, \gamma) \in [0, T_3]$ *one has*

$$x(t) = x(t; 0, \alpha, u(\cdot)) \in S \qquad \forall\, t \in [0, \bar{t}\,] \tag{32}$$

and

$$x(\bar{t}) \in \Sigma^{\gamma}. \tag{33}$$

(b) *There exists* $r(\gamma) \in (0, r_0]$ *such that if* $0 \le r \le r(\gamma)$, *then the following holds: For any initial state* $\alpha \in S$ *there exist* $\tilde{t} = \tilde{t}(\alpha, \gamma) \in [0, T_3 + Cr_0]$ *and a trajectory* $x(\cdot)$ *of the differential inclusion* (29) *satisfying* $x(0) = \alpha$ *such that*

$$x(t) \in S \qquad \forall\, t \in [0, \tilde{t}\,] \tag{34}$$

and

$$x(\tilde{t}) \in \Sigma^{2\gamma}. \tag{35}$$

Proof. In order to prove part (a), note that open loop S-controllability to Σ implies that for given $\alpha \in S$, there exists $t(\alpha) \ge 0$ such that for some trajectory $x(\cdot)$ of the control system (1) with $x(0) = \alpha$, one has $x(t) \in S$ for all $t \in [0, t(\alpha)]$ and $x(t(\alpha)) \in \Sigma$. By the S-constrained tracking property (b) of Lemma 3.2, there exists $Q(\alpha) > 0$ such that the following holds: For each

$$\alpha_1 \in N(\alpha) := \{\alpha + Q(\alpha)B\} \cap S,$$

there exists a trajectory $x_1(\cdot)$ of (1) with $x_1(0) = \alpha_1$ such that $x_1(t) \in S$ for all $t \in [0, t(\alpha)]$ and $x_1(t(\alpha)) \in \Sigma^{\gamma}$. In particular, using the notation of Lemma 3.2(b), we can take

$$Q(\alpha) = \frac{\gamma}{M(t(\alpha))}.$$

The family of sets $N(\alpha)$ forms a relatively open cover of S, and since S is compact, we have a finite subcover $\{N(\alpha_i)\}_{i=1}^{k}$. It is readily noted that

$$T_3 = \max\{t(\alpha_i) : 1 \le i \le k\}$$

has the required properties.

As for part (b) of the assertion, consider any initial state $\alpha \in S$, and note that by part (f) of Lemma 3.3, for $r \in [0, r_0]$, there exists a trajectory $x_1(\cdot)$ of differential inclusion (29) emanating from α such that $\alpha_1 := x_1(t_1) \in S_r$ for some $t_1 \in [0, Cr_0]$. Furthermore, by part (d) of that lemma (strong invariance), $x_1(t) \in S$ on the interval $[0, t_1]$. By part (a) of the present lemma, there exists a trajectory $x_2(\cdot)$ of the control system (1) such that $x_2(0) = \alpha_1$ and such that for some $t_2 \in [0, T_3]$ one has $x_2(t) \in S$ for all $t \in [0, t_2]$, and $x_2(t_2) \in \Sigma^{\gamma}$. According to tracking property (c) of Lemma 3.2, if $r \in [0, r(\gamma)]$, where

$$r(\gamma) := \min\left\{r_0, \frac{\gamma}{W(T_3)}\right\},$$

then there also exists a trajectory $x_3(\cdot)$ of the control system (1) such that $x_3(0) = \alpha_1$, $x_3(t) \in S_r$ for all $t \in [0, t_2]$, and $\|x_3(t_2) - x_2(t_2)\| \le \gamma$, implying $x_3(t_2) \in \Sigma^{2\gamma}$. Now note that in view of (27), on the interval $[0, t_2]$, the trajectory $x_3(\cdot)$ is also a trajectory of the differential inclusion (29). The required trajectory $x(\cdot)$ of the assertion is the concatenation of $x_1(\cdot)$ and $x_3(\cdot)$. ∎

Assume that the hypotheses and notations of the preceding lemma are still in effect. For a given $r \in [0, r(\gamma)]$, we introduce the following modification of the multifunction F_r:

$$F_{r,\gamma}(x) := \begin{cases} \operatorname{co}\{F_r(x) \cup \overline{B}\} & \text{if } \|x\| \in \Sigma^{2\gamma}, \\ \operatorname{co}\{F_r(x) \cup \frac{[3\gamma - d_\Sigma(x)]}{\gamma}\overline{B}\} & \text{if } x \notin \Sigma^{2\gamma}, x \in \Sigma^{3\gamma}, \\ F_r(x) & \text{if } x \notin \Sigma^{3\gamma}. \end{cases} \tag{36}$$

By part (b) of the preceding lemma and Lemma 3.3(e), any $\alpha \in S + \varepsilon_0\overline{B}$ is the startpoint of some trajectory of the differential inclusion (29) which reaches the target $\Sigma^{2\gamma}$ at a time not exceeding $T_3 + Cr_0 + 1$. Hence the same is true for the differential inclusion

$$\dot{x}(t) \in F_{r,\gamma}(x(t)) \quad \text{a.e.} \tag{37}$$

This is due to the fact that one has the obvious inclusion

$$F_r(x) \subset F_{r,\gamma}(x) \qquad \forall\, x \in \mathbb{R}^n. \tag{38}$$

Furthermore, since the values of the multifunction $F_{r,\gamma}$ are compact convex subsets of $\mathbb{R}^n$ and since this multifunction is globally Lipschitz, it follows from the standard theory of differential inclusions that the set of trajectories of (37) on any compact time interval, emanating from a given startpoint, is nonempty and sequentially compact in the uniform topology. Hence the minimum time $\tau_{r,\gamma}(\alpha)$ to the target $\Sigma^{2\gamma}$ from any startpoint $\alpha \in S + \varepsilon_0\overline{B}$ is attained; here

$$\tau_{r,\gamma}(\alpha) := \min\{\tilde{t} \geq 0 : x(\tilde{t}) \in \Sigma^{2\gamma}, \dot{x}(t) \in F_{r,\gamma}(x(t)) \text{ a.e.}, x(0) = \alpha\}. \tag{39}$$

Note that in this minimum time problem, there is no state constraint imposed.

We go on to define, for r, γ as above, an extended real valued function $V_{r,\gamma} : \mathbb{R}^n \to (-\infty, \infty]$ as

$$V_{r,\gamma}(\alpha) := \begin{cases} \tau_{r,\gamma}(\alpha) & \text{if } \alpha \in S + \varepsilon_0\overline{B}, \\ \infty & \text{if } \alpha \in \mathbb{R}^n \backslash \{S + \varepsilon_0\overline{B}\}. \end{cases} \tag{40}$$

Important properties of the function $V_{r,\gamma}$ are provided by the following lemma, which follows directly from the more general result—Theorem 3 in [29].

LEMMA 4.3. *Let $\gamma > 0$, assume that the origin is open loop S-controllable to Σ, and assume that $0 < r \leq r(\gamma)$. Then the following properties hold:*

(a) *$V_{r,\gamma}$ is Lipschitz on $S + \varepsilon_0\overline{B}$, where ε_0 is as in Lemma* 3.3(e).

(b) *One has*

$$\min_{v \in F_{r,\gamma}(x)} \langle v, \zeta \rangle \leq -1 \quad \forall\, \zeta \in \partial_P V_{r,\gamma}(x) \quad \forall\, x \in \{S + \varepsilon_0\overline{B}\} \backslash \{\Sigma^{2\gamma}\}. \tag{41}$$

Remark 4.4. Actually, (41) holds in equality form, but it is the stated inequality, which encapsulates *weak decrease* of the "control Lyapunov function" $V_{r,\gamma}$ that is of interest to us; see [11] for a discussion of this property.

For $\lambda > 0$, the *quadratic infimal convolution* of (the lower semicontinuous extended real valued function) $V_{r,\gamma}$ is the function $V^\lambda_{r,\gamma} : \mathbb{R}^n \to \mathbb{R}$ given by

$$V^\lambda_{r,\gamma}(x) := \inf_{y \in \mathbb{R}^n} \{V_{r,\gamma}(y) + \lambda \|y - x\|^2\}. \tag{42}$$

This function, which is clearly dominated by $V_{r,\gamma}$, is locally Lipschitz on $\mathbb{R}^n$. Furthermore, if $x \in \mathbb{R}^n$ is such that $\partial_P V^\lambda_{r,\gamma}(x) \neq \emptyset$, then there exists a point $\bar{y} \in \mathbb{R}^n$ such that the infimum in (42) is uniquely attained at $\bar{y}$ and

$$\partial_P V^\lambda_{r,\gamma}(x) \subset \partial_P V_{r,\gamma}(\bar{y}). \tag{43}$$

It can also be shown that in fact, $\partial_P V^\lambda_{r,\gamma}(x)$ reduces to a singleton, the Fréchet derivative of $V^\lambda_{r,\gamma}$ at x, a fact we will not require. These properties of quadratic infimal convolutions are all verified in [11]. We shall in addition require the following lemma concerning the function $V^\lambda_{r,\gamma}$; the hypotheses of Lemma 4.3 are assumed to still be in effect.

LEMMA 4.5. *There exists $\lambda(\gamma) > 0$ such that if $\lambda > \lambda(\gamma)$, then $V^\lambda_{r,\gamma}$ is semiconcave on the set $S + \frac{\varepsilon_0}{2}B$, and*

$$\min_{v \in F_{r,\gamma}(x)} \langle v, \zeta \rangle \leq -\frac{1}{2} \quad \forall\, \zeta \in \partial_P V^\lambda_{r,\gamma}(x) \quad \forall\, x \in \left\{ S + \frac{\varepsilon_0}{2}B \right\} \setminus \left\{ \Sigma^{3\gamma} \right\}. \tag{44}$$

Proof. One has

$$0 \leq V^\lambda_{r,\gamma}(x) \leq V_{r,\gamma}(x) \leq T_3 + Cr_0 + 1 \quad \forall\, x \in S + \varepsilon_0 \overline{B} \quad \forall\, \lambda > 0.$$

Hence for any $x \in S + \varepsilon_0 \overline{B}$ and any given $\lambda > 0$, there exist points $y \in \mathbb{R}^n$ such that

$$V_{r,\gamma}(y) + \lambda \|y - x\|^2 \leq T_3 + Cr_0 + 2. \tag{45}$$

Then

$$\|y - x\| \leq \sqrt{\frac{T_3 + Cr_0 + 2}{\lambda}} =: w(\gamma, \lambda), \tag{46}$$

and therefore

$$V^\lambda_{r,\gamma}(x) = \min_{y \in x + w(\gamma,\lambda)\overline{B}} \{ V_{r,\gamma}(y) + \lambda \|y - x\|^2 \}, \tag{47}$$

or equivalently

$$-V^\lambda_{r,\gamma}(x) = \max_{y \in x + w(\gamma,\lambda)\overline{B}} \{ -V_{r,\gamma}(y) - \lambda \|y - x\|^2 \}. \tag{48}$$

Now consider $x \in S + \frac{\varepsilon_0}{2}B$, and note that the condition

$$\lambda > \hat{\lambda}(\gamma) := 4\left(\frac{T_3 + Cr_0 + 2}{(\varepsilon_0)^2} \right) \tag{49}$$

implies

$$x + w(\gamma, \lambda)\overline{B} \subset S + \varepsilon_0 B. \tag{50}$$

By Lemma 4.3(a), $V_{r,\gamma}$ is Lipschitz on the ball $x + w(\gamma, \lambda)\overline{B}$, and it follows from (48) that the function $-V^\lambda_{r,\gamma}$ is λ-*lower* C^2 on that ball, in the terminology of Rockafellar, who studied this class of functions in [31]. Furthermore, as was shown in Clarke,

Stern, and Wolenski [14], this property implies that one has the uniform proximal subgradient inequality given by

$$-V^{\lambda}_{r,\gamma}(y) + V^{\lambda}_{r,\gamma}(x) + \lambda\|y-x\|^2 \geq \langle \zeta, y-s\rangle \quad \forall\, \zeta \in \partial_P(-V^{\lambda}_{r,\gamma})(x) \qquad \forall\, y \in x + w(\gamma,\lambda)B. \tag{51}$$

According to Proposition 2.2(iii) (with $c=\lambda$), since (51) holds for every $x \in S + \frac{\varepsilon_0}{2}B$, it follows that the function $V^{\lambda}_{r,\gamma}$ is semiconcave on that set, for every $\lambda > \hat{\lambda}(\gamma)$.

Now let $x \in \{S + \frac{\varepsilon_0}{2}B\}\backslash\{\Sigma^{3\gamma}\}$, and assume that

$$\lambda > \tilde{\lambda}(\gamma) := \max\left\{\hat{\lambda}(\gamma)\ ,\ \frac{T_3 + Cr_0 + 2}{\gamma^2}\right\}. \tag{52}$$

Then

$$x + w(\gamma,\lambda)\overline{B} \subset \{S + \varepsilon_0 B\}\backslash\{\Sigma^{2\gamma}\}, \tag{53}$$

and therefore by (41), for any $y \in x + w(\gamma,\lambda)\overline{B}$ one has

$$\min_{v \in F_{r,\lambda}(y)} \langle v, \zeta\rangle \leq -1 \qquad \forall\, \zeta \in \partial_P V_{r,\lambda}(y). \tag{54}$$

Suppose that $\zeta \in \partial_P V^{\lambda}_{r,\lambda}(x)$. Then by property (43) (in the present context), one has that $\zeta \in \partial_P V_{r,\lambda}(\bar{y})$ for some $\bar{y} \in x + w(\gamma,\lambda)B$. In view of (54), there exists $\bar{v} \in F_{r,\lambda}(\bar{y})$ such that $\langle \bar{v}, \zeta\rangle \leq -1$. Let us denote by $K_{r,\lambda}$ a (global) Lipschitz constant for the multifunction $F_{r,\lambda}$. Then there exists $\hat{v} \in F_{r,\lambda}(x)$ such that $\|\bar{v} - \hat{v}\| \leq K_{r,\lambda} w(\gamma,\lambda)$. Now denote by $K'_{r,\lambda}$ a Lipschitz constant for $V_{r,\lambda}$ on $S + \varepsilon_0\overline{B}$. Then $\|\zeta\| \leq K'_{r,\lambda}$, by a standard fact concerning norm bounds on proximal subgradients of Lipschitz functions. We then obtain

$$\langle \hat{v}, \zeta\rangle \leq \langle \bar{v}, \zeta\rangle + K_{r,\lambda}K'_{r,\lambda} w(\gamma,\lambda). \tag{55}$$

It follows that $\langle \hat{v}, \zeta\rangle \leq -\frac{1}{2}$ provided that

$$\lambda > \bar{\lambda}(\gamma) := \frac{T_3 + Cr_0 + 2}{4(K_{r,\lambda}K'_{r,\lambda})^2}.$$

Upon setting

$$\lambda(\gamma) := \max\{\tilde{\lambda}(\gamma)\ ,\ \bar{\lambda}(\gamma)\},$$

(44) holds and the proof is completed. □

Proof of Theorem 4.1. As in the preceding lemma, let us fix $0 < r \leq r(\gamma)$ and $\lambda > \lambda(\gamma)$, where $\gamma > 0$ has been chosen a priori so that $4\gamma < \delta$.

For ease of notation, from this point on we will denote $V^{\lambda}_{r,\gamma} = V$.

Since

$$F_{r,\gamma}(x) = F_r(x) \qquad \forall\, x \in \mathbb{R}^n\backslash\{\Sigma^{3\gamma}\}, \tag{56}$$

the inequality (44) can be written as

$$\min_{v \in F_r(x)} \langle v, \zeta\rangle \leq -\frac{1}{2} \quad \forall\, \zeta \in \partial_P V(x) \qquad \forall\, x \in \left\{S + \frac{\varepsilon_0}{2}B\right\}\backslash\{\Sigma^{3\gamma}\}. \tag{57}$$

This proximal Hamilton–Jacobi inequality is in turn readily seen to be equivalent to the limiting version

$$\min_{v\in F_r(x)} \langle v,\zeta\rangle \le -\frac{1}{2} \quad \forall\, \zeta \in \partial_L V(x) \qquad \forall\, x \in \left\{S + \frac{\varepsilon_0}{2}B\right\}\backslash\{\Sigma^{3\gamma}\}. \tag{58}$$

A feedback law $k : \mathbb{R}\times\mathbb{R}^n \to U$ is now defined as follows:

- Let $x \in \mathbb{R}^n$.
  - If $x \in S\backslash\{\Sigma^{4\gamma}\}$, arbitrarily choose $\zeta \in \partial_L V(x)$, and then set $k(x) = u \in U$ such that $f(x,u) \in F_r(x)$ and

$$\min_{v\in F_r(x)} \langle v,\zeta\rangle = \langle f(x,u),\zeta\rangle.$$

  - Otherwise take $k(x)$ to be any element of U.

Remark 4.6. It is the L-subdifferential of V that features in the definition of the feedback, and not the P-subdifferential. The advantage of this choice is that $\partial_L V(x) \neq \emptyset$ for every x, whereas the possible emptiness of $\partial_P V(x)$ would be problematic in our ensuing construction. Also observe that in the construction of a π-trajectory associated with the control feedback $k(x)$, the choice of $\zeta \in \partial_L V(x_i)$ does not need to be "remembered" at the next node x_{i+1}, so in the case of an "on-line" procedure, it suffices to calculate an *arbitrary* L-subgradient when a given state is reached.

Given an initial state

$$\alpha \in S\backslash\{\Sigma^{\delta}\} \subset S\backslash\{\Sigma^{4\gamma}\},$$

and a partition

$$\pi = \{t_0 = 0, t_1, t_2, \ldots\}$$

of $[0,\infty)$, let us consider the π-trajectory $x(\cdot)$ associated with the ordinary differential equation $\dot{x}(t) = f(x(t), k(x(t)))$, where the initial node is $x(t_0) = x(0) = x_0 = \alpha$. Our goal is to produce positive numbers β and T_1 such that if $\operatorname{diam}(\pi) \le \beta$, then for every such α, there exists $t_1(\alpha) \in [0, T_1]$ such that

$$x(t) \in S \qquad \forall\, t \in [0, t_1(\alpha)] \tag{59}$$

and

$$x(t_1(\alpha)) \in \Sigma^{4\gamma} \subset \Sigma^{\delta}. \tag{60}$$

Of course, if $\alpha \in S \cap \{\Sigma^{4\gamma}\}$, then we can take $t_1(\alpha) = 0$.

We shall assume that

$$\operatorname{diam}(\pi) \le T_2(r), \tag{61}$$

where $T_2(r)$ is as in Lemma 3.3(g). Then the π-trajectory satisfies

$$x_i \in S\backslash\{\Sigma^{4\gamma}\} \Longrightarrow x(t) \in S \qquad \forall\, t \in [t_i, t_{i+1}], \tag{62}$$

since $F_{r,\gamma}(x_i) = F_r(x_i)$.

By Lemma 4.5, V is semiconcave on $S + \frac{\varepsilon_0}{2}B$, and therefore Corollary 2.3 yields

$$V(y) - V(x) \le \langle \zeta, y - x\rangle + \lambda\|y - x\|^2 \quad \forall\, \zeta \in \partial_L V(x) \quad \forall\, x, y \in U', \tag{63}$$

for every open convex set $U' \subset S + \frac{\varepsilon_0}{2}B$. Let

$$M := \max\{\|f(x,u)\| : x \in S + \varepsilon_0 \overline{B}\ ,\ u \in U\}. \tag{64}$$

In order to be able to apply (63) to the evolving π-trajectory, we will assume (further to (61)) that

$$\operatorname{diam}(\pi) \leq \frac{\min\{\gamma, \frac{\varepsilon_0}{2}\}}{M} =: \rho. \tag{65}$$

This together with (62) yields the implication

$$x_i \in S\backslash\{\Sigma^{4\gamma}\} \Longrightarrow x(t) \in x_i + \rho M B \subset S\backslash\{\Sigma^{3\gamma}\} \qquad \forall\, t \in [t_i, t_{i+1}]. \tag{66}$$

Let us further consider the evolution of the π-trajectory. Pick $\zeta_0 \in \partial_L V(x_0)$. Then by (63) and (66), for $t \in [t_0, t_1]$ one has

$$\begin{aligned} V(x(t)) - V(x_0) &\leq \langle \zeta_0, x(t) - x_0\rangle + \lambda\|x(t) - x_0\|^2 \\ &= \left\langle \zeta_0, \int_{t_0}^{t_1} f(x(s), k(x_0)ds \right\rangle + \lambda\|x(t) - x_0\|^2. \end{aligned}$$

For ease of notation, let us abbreviate $K = K_{r,\lambda}$, which we recall denotes a Lipschitz constant for $V = V_{r,\gamma}$ on $S + \varepsilon_0\overline{B}$. We also denote by $\hat{K} = K_\Gamma$ a Lipschitz constant for f as in (F1), with $\Gamma = S + \varepsilon_0\overline{B}$. Then, bearing (58), (66) in mind, one has

$$V(x_1) - V(x_0) \leq -\frac{1}{2}(t_1 - t_0) + (KM\hat{K} + \lambda M^2)(t_1 - t_0)^2. \tag{67}$$

Now pick $\zeta_1 \in \partial_L V(x_1)$. Upon repeating the above steps on the interval $[t_1, t_2]$ and combining this with (67), we obtain

$$V(x_2) - V(x_0) \leq -\frac{1}{2}(t_2 - t_0) + (KM\hat{K} + \lambda M^2)[(t_1 - t_0)^2 + (t_2 - t_1)^2], \tag{68}$$

which readily yields

$$V(x_2) - V(x_0) \leq \left[-\frac{1}{2} + (KM\hat{K} + \lambda M^2)\operatorname{diam}(\pi)\right](t_2 - t_0). \tag{69}$$

Continuing this process, we arrive at

$$V(x_i) - V(x_0) \leq \left[-\frac{1}{2} + (KM\hat{K} + \lambda M^2)\operatorname{diam}(\pi)\right](t_i - t_0). \tag{70}$$

Let us assume that

$$\operatorname{diam}(\pi) \leq \frac{1}{4(KM\hat{K} + \lambda M^2)} =: \beta_1. \tag{71}$$

Then due to (70),

$$V(x_i) - V(x_0) \leq -\frac{1}{4}(t_i - t_0). \tag{72}$$

It is readily noted that $V = V^{\lambda}_{r,\gamma} \equiv 0$ on $\Sigma^{2\gamma}$. Then since V is continuous on $S + \varepsilon_0 \overline{B}$ and $V \equiv 0$ on S, it follows from (72) that $x(\cdot)$ must enter $\Sigma^{4\gamma}$ at a time not exceeding

$$T_1 := 4 \max\{V(x) : x \in S + \varepsilon_0 \overline{B}\} \leq 4(T_3 + Cr_0 + 1). \tag{73}$$

Upon taking

$$\beta := \min\{T_2(r), \rho, \beta_1\}, \tag{74}$$

the proof of the theorem is completed. □

Remark 4.7. Suppose that in Theorem 4.1, the hypothesis of open loop S-controllability to Σ is strengthened to open loop S-controllability to Σ prior to time T, for some $T > 0$, where this means that in Definition 1.2, one has $0 \leq t(\alpha) \leq T$ for every $\alpha \in S$. Then in the proof of Lemma 4.2, one can take $T_3 = T_3(\gamma) = T$ for every $\gamma > 0$. It follows that the conclusion of Theorem 4.1 can be correspondingly strengthened, to "closed loop S-controllability to Σ^{δ} prior to time $\hat{T} := 4(T + Cr_0 + 1)$, for every $\delta > 0$," meaning that for every $\delta > 0$, there exists a feedback which, in the sample-and-hold sense, steers any $\alpha \in S$ to Σ^{δ} along an S-constrained trajectory, prior to time $\hat{T}$. (An analogous remark could be made regarding the next main result, Theorem 4.8.)

Theorem 4.8, below, provides a strengthening of the conclusion of Theorem 4.1 from S-constrained controllability to S-constrained stabilizability, when an extra assumption is posited. The need for strengthened hypotheses is illustrated by the following example. Consider

$$S = \{x \in \mathbb{R}^2 : 1 \leq \|x\| \leq 2\}, \qquad \Sigma = \{(2, 0)\},$$

where the dynamics are given by the bilinear system (a perturbed harmonic oscillator)

$$\dot{x}(t) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} x(t) + u(t)x(t), \qquad U = [-1, 1].$$

It is easy to check that all the hypotheses of Theorem 4.1 hold, including open loop S-controllability, but closed loop S-stabilization does not hold.

THEOREM 4.8. *Let open loop S-controllability to Σ hold, and let $\delta > 0$ be given. Further assume that there exists $\varepsilon > 0$ such that the S-constrained minimum time function $\tau : S \to \mathbb{R}$ to the target Σ,*

$$\tau(\alpha) := \min\{\tilde{t} \geq 0 : x(\tilde{t}) \in \Sigma,\ \dot{x}(t) \in F(x(t)) \text{ a.e., } x(t) \in S\ \forall\, t \in [0, \tilde{t}],\ x(0) = \alpha\}, \tag{75}$$

is continuous on $S \cap \{\Sigma^{2\varepsilon}\}$. Then closed loop S-stabilizability to Σ^{δ} holds.

In the absence of state constraints, in the case of a point target, the above continuity condition is equivalent to "small time controllability"; see Bardi and Capuzzo-Dolcetta [3]. We also remark that in view of sequential compactness of trajectories of the differential inclusion (26) on any compact time interval, the minimum in (75) is indeed attained, for any $\alpha \in S$.

The proof of Theorem 4.8 is actually a continuation of the proof of Theorem 4.1. There we showed that if $\operatorname{diam}(\pi) \leq \beta$, then for any startpoint $\alpha \in S$, the π-trajectory associated with our feedback $k(\cdot)$ enters $\Sigma^{4\gamma}$ not later than time T_1 and is contained in S until its entry into $\Sigma^{4\gamma}$.

In the present proof, we will specialize (but not violate the definition of) the feedback $k(\cdot)$ from the proof of Theorem 4.1, as follows:

- Let $x \in \mathbb{R}^n$.
  - If $x \in S \backslash \{\Sigma^{4\gamma}\}$, arbitrarily choose $\zeta \in \partial_L V(x)$, and then set $k(x) = u \in U$ such that $f(x,u) \in F_r(x)$ and

$$\min_{v \in F_r(x)} \langle v, \zeta \rangle = \langle f(x,u), \zeta \rangle.$$

  - If $x \in S \cap \{\Sigma^{4\gamma}\}$, choose $k(x) = u \in U$ such that $f(x,u) \in F_r(x)$.
  - Otherwise (i.e., when $x \notin S$), take $k(x)$ to be any element of U.

We shall require the following consequence of S-constrained trajectory tracking.

LEMMA 4.9. *There exists $\hat{r}(\gamma) > 0$ such that if $0 < r < \hat{r}(\gamma)$, the following holds: For any $\alpha \in S \cap \{\Sigma^{\varepsilon}\}$, there exists a trajectory of the differential inclusion* (29) *($\dot{x}(t) \in F_r(x(t))$) such that $x(0) = \alpha$ and $x(\tau(\alpha)) \in \Sigma^{2\gamma}$.*

Proof. Let $\alpha \in S \cap \{\Sigma^{\varepsilon}\}$. In view of Lemma 3.3(f), there exists a trajectory of (29) (necessarily S-constrained by part (d) of that lemma) such that $x(0) = \alpha$ and $x(t') \in S_r$ for some time $t' = t'(\alpha) \in [0, Cr]$. We now denote $\alpha' = x(t')$. If r is small enough, then $\alpha' \in S \cap \{\Sigma^{2\varepsilon}\}$, for any α as above.

Let $u(\cdot)$ be a control function such that

$$x(t; 0, \alpha', u(\cdot)) \in S \qquad \forall\, t \in [0, \tau(\alpha')]$$

and

$$x(\tau(\alpha'); 0, \alpha', u(\cdot)) \in \Sigma.$$

That is, $u(\cdot)$ is optimal in the S-constrained minimum time problem with target Σ and startpoint α'; recall that we are presently assuming open loop S-controllability to Σ. In view of the tracking result given by Lemma 3.2(c), there exists a trajectory $\bar{x}(\cdot)$ of (29) such that $\bar{x}(0) = \alpha'$, $\bar{x}(t) \in S_r$ for all $t \in [0, \tau(\alpha')]$, and

$$\bar{x}(\tau(\alpha')) \in \Sigma + rW(\tilde{T})\overline{B}, \tag{76}$$

where $\tilde{T}$ is an upper bound on (the continuous function) $\tau(\cdot)$ on $S \cap \{\Sigma^{2\varepsilon}\}$. It follows that

$$\tilde{x}(t' + \tau(\alpha')) \in \Sigma + rW(\tilde{T})\overline{B}, \tag{77}$$

where $\tilde{x}(\cdot)$ denotes the concatenation of the trajectories $x(\cdot)$ and $\bar{x}(\cdot)$ of differential inclusion (29); it is therefore a trajectory of (29), and as such remains in S. One has

$$\|\tilde{x}(t' + \tau(\alpha')) - \tilde{x}(\tau(\alpha))\| \leq Mt' + M\|\tau(\alpha') - \tau(\alpha)\|, \tag{78}$$

where M is as in (64), although any norm bound on $F(x) = f(x,U)$ over S will do. Now, $0 < t' < Cr$, $\tau(\cdot)$ is continuous on $S \cap \{\Sigma^{2\varepsilon}\}$ (where both α and α' lie when r is sufficiently small), and $\|\alpha - \alpha'\| \leq MCr$. It then follows from (77) and (78) that $\tilde{x}(\tau(\alpha)) \in \Sigma^{2\gamma}$ if r is sufficiently small, independently of $\alpha \in S$. □

Completing the proof of Theorem 4.8. In view of the definitions of the functions $V_{r,\gamma}$, $V = V^{\lambda}_{r,\gamma}$, and the preceding lemma, one has

$$V(\alpha) \leq V_{r,\gamma}(\alpha) \leq \tau(\alpha) \qquad \forall\, \alpha \in S \cap \{\Sigma^{\varepsilon}\}. \tag{79}$$

Let $\omega : [0, \infty) \to [0, \infty]$ be a modulus of continuity for $\tau(\cdot)$ on $S \cap \{\Sigma^{2\varepsilon}\}$. That is, $\omega(\cdot)$ is continuous, strictly increasing, $\omega(0) = 0$, and

$$|\tau(x) - \tau(y)\| \leq \omega(\|x - y\|) \qquad \forall\, x, y \in S \cap \{\Sigma^{2\varepsilon}\}. \tag{80}$$

It is not hard to show that

$$\tau(x) \le \omega(d_\Sigma(x)) \qquad \forall\, x \in S \cap \{\Sigma^{2\varepsilon}\}. \tag{81}$$

We shall choose

$$0 < \gamma < \min\left\{\frac{2\varepsilon}{5}, \frac{\delta}{5 + 4M\omega(5\gamma)}\right\},$$

$$0 < r < \min\{r(\gamma), \hat{r}(\gamma)\},$$

and we take $\lambda > \lambda(\gamma)$ as well as $\operatorname{diam}(\pi) \le \beta$, where β was defined in (74).

Let us now reconsider the π-trajectory $x(\cdot)$ generated by the feedback $k(\cdot)$, emanating from an arbitrary $\alpha \in S$. We know that $x(\cdot)$ enters $\Sigma^{4\gamma}$ not later than time T_1. Denote by t_{i^*} the first node after the π-trajectory enters $\Sigma^{4\gamma}$. (If $\alpha \in \Sigma^{4\gamma}$, then $i^* = 1$.) Since $M\operatorname{diam}(\pi) \le \gamma$,

$$x(t) \in \Sigma^{5\gamma} \subset S \cap \{\Sigma^{2\varepsilon}\} \qquad \forall\, t \in [t_{i^*}, t_{i^*+1}]. \tag{82}$$

Then (79) and (81) imply

$$V(x(t)) \le \omega(5\gamma) \qquad \forall\, t \in [t_{i^*}, t_{i^*+1}], \tag{83}$$

and in particular one has

$$V(x(t_{i^*+1})) \le \omega(5\gamma). \tag{84}$$

Similarly to the proof of Theorem 4.1, $x(\cdot)$ re-enters $\Sigma^{4\gamma}$ not later than time $t_{i^*+1} + 4\omega(5\gamma)$, and consequently, from time t_{i^*+1} until this re-entry, one has

$$\|x(t) - x(t_{i^*+1}\| \le 4M\omega(5\gamma).$$

Hence, in view of our choice of γ, from time t_{i^*} until re-entry to $\Sigma^{4\gamma}$, the π-trajectory remains in Σ^{δ}. The above arguments show that for any $\alpha \in S$, after the π-trajectory enters $\Sigma^{4\gamma} \subset \Sigma^{\delta}$, it thereafter remains in Σ^{δ}. During its evolution, the π-trajectory never leaves S, since it is a trajectory of (29); recall Lemma 3.3(d). □

5. Concluding remarks.

5.1. Robustness. It transpires that the feedback law in Theorem 4.8 possesses a robustness property with respect to state measurement errors which are small in an appropriate sense and when the partition in the discretization scheme has the additional requirement of being "reasonably uniform," an insight first brought to light in [7].

The perturbed system under study is modeled by

$$\dot{x}(t) = f(x(t), \tilde{k}(x(t) + p(t))), \tag{85}$$

where the function $p(\cdot)$ represents the observational error present in applying the feedback law.

Given a partition π of $[0, \infty]$, the π-trajectory x_π obtained in the model (85) is the curve satisfying the following interval-by-interval dynamics: Upon setting $x_0 = \alpha$, on the interval $[t_0, t_1]$, x_π is the classical solution of

$$\dot{x}_\pi(t) = f(x_\pi(t), \tilde{k}(x_0 + p_0)), \quad x_\pi(t_0) = x_0, \quad t \in (t_0, t_1). \tag{86}$$

We then set $x_1 := x_\pi(t_1)$ and restart the process on the next interval:

$$\dot{x}_\pi(t) = f(x_\pi(t), \tilde{k}(x_1 + p_1)), \quad x_\pi(t_1) = x_1, \quad t \in (t_1, t_2). \tag{87}$$

Here the continuous function $x_\pi(t)$ is the *actual* state of the system at time t, and the values $x_i + p_i$ correspond to the inexact measurements used to generate the piecewise constant control function in the scheme.

We have the following robust version of Theorems 4.1 and 4.8. The result allows for erroneous measurements of the state giving values exterior to S, while the π-trajectory that is generated remains in S.

THEOREM 5.1. *Let $\delta > 0$ be given, and assume that open loop S-controllability to Σ holds. Then there exists a feedback law $\tilde{k} : \mathbb{R}^n \to U$ and positive reals T_1 and β such that the following hold:*

(a) *For every $b \in (0, \beta)$, there exists $E(b) > 0$ with the property that for any partition π of $[0, T]$ having*

$$\frac{b}{2} \leq t_{i+1} - t_i \leq b \qquad \forall\, i = 0, 1, \ldots, \tag{88}$$

the error bounds

$$\|p_i\| < E(\delta) \qquad \forall\, i = 0, 1, \ldots \tag{89}$$

imply that for any initial state $\alpha \in S$, there exists $t_1(\alpha) \in [0, T_1]$ such that the π-trajectory x_π in the model above, with $x_\pi(0) = \alpha$, satisfies

$$x_\pi(t) \in S \qquad \forall\, t \in [0, t_1(\alpha)] \tag{90}$$

and

$$x(t_1(\alpha)) \in \Sigma^\delta. \tag{91}$$

(b) *If the S-constrained small time controllability hypothesis of Theorem* 4.8 *is posited, then the conclusions of part* (a) *can be strengthened by replacing* (91) *with*

$$x_\pi(t) \in S \cap \{\Sigma^\delta\} \qquad \forall\, t \geq t_1(\alpha). \tag{92}$$

For each $x \in \mathbb{R}^n$, choose $s(x) \in \mathrm{proj}_S(x)$. Then the feedback law featuring in the theorem is simply given by

$$\tilde{k}(x) := k(s(x)) \qquad \forall\, x \in \mathbb{R}^n, \tag{93}$$

where $k(\cdot)$ is the feedback law from Theorem 4.8.

The proof of Theorem 5.1 follows from arguments similar to those employed in section 4.2 of [12]. There a finite time optimal control problem was studied, but the technique needed to extend the proofs of Theorems 4.1 and 4.8 to the above robust versions is provided there. The fact that partitions with sufficiently small diameter are required in Theorems 4.1, 4.8, and 5.1 is to be expected, since this is what is needed in order for the decrease property (as manifested by proximal Hamilton–Jacobi inequalities) to come to bear in a sample-and-hold scheme such as ours. On the other hand, as was pointed out in [12], [7], and Sontag [35] (with the latter two references dealing with robust feedback stabilization via a shell-based approach), the near-uniformity of partitions posited in condition (88) precludes a possible "chattering phenomenon" which could otherwise occur in the presence of state measurement errors.

5.2. *S*-restricted dynamics. Suppose that the function f in the dynamics (1) is defined only for state values $x \in S$, where S is the state constraint set in the problem we have studied. In many problems arising in economics and engineering, for example, such a restricted definition is quite reasonable, since the dynamics might not make sense or break down when $x \notin S$. So suppose that $f(x,u)$ is only defined on $S \times U$, while corresponding versions of (F1)–(F3) hold. In this situation, it is possible to now extend f from $S \times U$ to $\mathbb{R}^n \times U$ in a suitable way.

Let f_i denote the ith component function of f, $i = 1, 2, \ldots, n$. For each fixed $u \in U$, define a function $x \to \hat{f}_i(x,u)$ on $\mathbb{R}^n$ as follows:

$$\hat{f}_i(x,u) = \min_{y \in S} \{ f_i(y,u) + K\|y - x\| \}.$$

It is not difficult to show that $x \to \hat{f}_i(x,u)$ agrees with $f_i(x,u)$ on S and is globally Lipschitz of rank K. We extend f componentwise by setting $f_i(x,u) = \hat{f}_i(x,u)$ for every $(x,u) \in \mathbb{R}^n \times U$. The resulting function $f : \mathbb{R}^n \times U \to \mathbb{R}^n$ satisfies (F1)–(F2), but may not satisfy (F3) since the velocity sets $f(x,U)$ need not be convex for $x \notin S$. This poses no difficulty, however, as the tracking results in Lemma 3.2 still hold, as was pointed out in [12].

5.3. The case of unbounded *S*. The main results in this article (as well as [12]) have been stated for the case of compact S. It is worth noting that if compactness of S is relaxed to mere closedness, corresponding versions can be framed. In particular, in the corresponding versions of Definitions 1.2 and 1.3, the open and closed loop controllability properties to target Σ are provided not for any $\alpha \in S$, but for any α in a specified bounded subset of S. In order to show that this is valid, the essential task (and a somewhat routine one) is to obtain appropriately localized versions of the tracking properties in Lemma 3.2 as well as Lemma 3.3 on modified dynamics; we omit these details. Note, however, that in carrying this out, (F2) is required, unlike the weakened version of this condition mentioned in Remark 1.1.

CONSTRAINED AVERAGE COST MARKOV CONTROL PROCESSES IN BOREL SPACES*

ONÉSIMO HERNÁNDEZ-LERMA†, JUAN GONZÁLEZ-HERNÁNDEZ‡, AND RAQUIEL R. LÓPEZ-MARTÍNEZ§

Abstract. This paper considers constrained Markov control processes in Borel spaces, with unbounded costs. The criterion to be minimized is a long-run expected average cost, and the constraints can be imposed on similar average costs, or on average *rewards*, or *discounted* costs or rewards. We give conditions under which the constrained problem (CP) is solvable and equivalent to an equality constrained (EC) linear program. Furthermore, we show that there is no duality gap between EC and the dual program EC* and that in fact the strong duality condition holds. Finally, we introduce an explicit procedure to solve CP in some cases which is illustrated with a detailed example.

Key words. constrained Markov control processes, average cost, discounted cost

1. Introduction.

In this paper, we study constrained Markov control processes (MCPs) in *Borel spaces*, with *unbounded costs*. The criterion to be minimized is a long-run expected *average cost*, and the constraints are imposed on similar average cost functionals. We also consider the cases in which the latter cost functionals are substituted by average *rewards* or by *discounted* costs (or rewards), or even by both average *and* discounted costs. Our results on the *constrained problem* (CP) include the following. First, we give conditions under which CP is *solvable*. Second, by introducing suitable vector spaces of measures and functions, we formulate an "equality constrained" primal linear program EC that is *equivalent* to CP. Third, we consider the dual program EC* and show that there is *no duality gap*, which means EC and EC* both have the same value. Moreover, we show that the *strong duality* condition holds, so both programs are solvable and their optimal values coincide. Finally, we introduce a procedure that can actually solve CP under suitable conditions. This procedure is illustrated with a detailed example.

Constrained MCPs form an important class of stochastic control problems with applications in many areas; see, e.g., [8, 12, 13, 14, 24, 27, 29, 30, 32, 33, 34] as well as the books [1] and [31] and their extensive bibliographies. However, on the other hand, a look at these references shows that virtually all of the related literature is concentrated on constrained MCPs in which the state space is either *countable* or *compact*. This excludes, of course, important control processes for which the state space is as common as $\mathbb{R}^d$, as well as partially observable systems whose solution typically requires transforming the original problem into a control problem on a Borel space of probability measures (p.m.'s) [3, 5, 11, 31, 42]. In fact, as far as we can

tell, for *average cost* constrained MCPs, the only case dealt with in the literature of a problem with an *uncountable*, *noncompact* state space X—actually, $X = \mathbb{R}^q$—is for linear-quadratic (LQ) systems in Chapter 4 of [31]. The techniques for the latter case, however, are very specific of LQ systems, and so, in general, they cannot be extended to non-LQ problems or to general Borel spaces.

As can be seen in the above references, there are several techniques to analyze CP. The easiest and most common is the so-called *direct method* (see [1, 8, 12, 13, 31, 37], for instance, or [17, 18, 21, 22] for the unconstrained case). In this method, the idea is to use occupation measures (which in the average cost case are as in (3.8) below) to transform CP into an equivalent optimization problem, say, CP′, in a suitable space of measures, and then one uses the well-known fact that a lower semicontinuous (l.s.c.) function on a compact topological space attains its minimum value. A second approach is to use (either finite- or infinite-dimensional) *linear programming* (LP) techniques (see, e.g., [1, 27, 31, 37]). To do this , one introduces linear spaces of measures and functions on which CP′ can be expressed as a linear program. In contrast, in the *Lagrange* or *convex-analytic* approach, one rewrites CP′ as a convex program, say, CP″ (see, e.g., [1, 8, 12, 13, 29, 31, 33, 36]). The latter method is closely related to the *Pareto* or *multiobjetive-control* approach because solving CP″ using Lagrange multipliers turns out to be the same as finding a special class of Pareto policies for a certain multiobjective-control problem (see, e.g., [1, 12, 13, 31, 36, 38, 39, 40]). Our paper is concerned with the first two of these approaches, namely, the direct method and the LP formulation, which were developed in, for instance, [17, 18, 21, 22] for *unconstrained* MCPs. Thus our results and techniques can be seen as a natural extension of those in the latter references.

We begin in section 2 by introducing some basic terminology and notation and the CP we are concerned with (see (2.8)) as well as some variants of it (Remark 2.2) that can be studied with our present approach. Also, in Remark 2.2(a), we explain the difference between the "minimum pair" problem we study here and the "ergodic" problem analyzed by other authors. In section 3, we state our first main result, Theorem 3.2, which gives (reasonably mild) conditions under which CP is solvable. A key step in proving Theorem 3.2 is that the analysis of CP can be reduced to consider only *stable policies* (Definition 3.4 and Lemma 3.5). The latter fact is also crucial to introducing, in section 4, an "equality constrained" (EC) linear program (see (4.10), (4.11)), which turns out to be equivalent to CP in the sense that both problems have the same optimal value (see (2.9), (3.10), and (4.12)). Also, in section 4, we introduce the dual program EC* (in (4.14), (4.15)) of EC and show that there is no duality gap for these programs (Theorem 4.4). In addition, a Farkas-like result is presented (Theorem 4.5), which, as any other Farkas-like theorem, gives necessary and sufficient conditions for EC to be consistent. In section 5, we consider the issue of strong duality, and a characterization of optimal solutions to EC and EC* (Theorem 5.2). In particular, we show that a "constrained optimality equation" holds *almost everywhere* (see (5.6)), which of course is the "constrained version" of the well-known average cost optimality equation (ACOE). Finally, in section 6, we introduce a procedure to solve CP, using maximizing sequences for EC* and ACOEs. A detailed example illustrates this procedure. In a work in progress, we use the LP formulation of CP to obtain approximations of it by *finite* linear programs, similar to those developed in [20, 21, 22].

Finally, it is worth mentioning that our results include the so-called multichain case, in which an MCP can have several ergodic classes in addition to a possibly

nonempty set of transient states. This is due to the fact that our assumptions on CP ensure that the corresponding optimization problem can be restricted to *stable* policies—see Definition 3.4 and Lemma 3.5. A multichain system is presented in Example 6.9. To the best of our knowledge, multichain CPs have been studied only by Hordijk and Kallenberg [43] for MCPs with *finite* state and action spaces. (For *unconstrained* multichain MCPs in Borel spaces, see [17].)

2. Constrained MCPs. The material in this introductory section is quite standard—see [1, 3, 8, 10, 11, 12, 13, 15, 16, 17, 18, 22, 24, 25, 26, 27, 28, 29], for instance. For the sake of reference, let us first recall that the usual *unconstrained* (discrete-time, time-homogeneous) Markov control model is of the form

$$(\mathrm{X},\ \mathrm{A},\ \{\mathrm{A}(x)\,|\,x\in\ \mathrm{X}\}, Q, c). \tag{2.1}$$

The spaces X and A are the *state space* and the *control* (or *action*) *set*, respectively. We shall assume that X and A are Borel spaces (that is, Borel subsets of complete and separable metric spaces) endowed with the corresponding Borel σ-algebras $\mathcal{B}(\mathrm{X})$, $\mathcal{B}(A)$. For each state $x\in\mathrm{X}$, the nonempty set $A(x)\in\mathcal{B}(A)$ in (2.1) denotes the set of feasible control actions in x. We suppose that the set

$$\mathbb{K} := \{(x,a)\,|\,x\in\mathrm{X},\ a\in\mathrm{A}(x)\} \tag{2.2}$$

of feasible state-action pairs is a *closed* (hence Borel measurable) subset of $\mathrm{X}\times\mathrm{A}$ and that it contains the graph of a measurable function from X to A. (In other words, the set $\mathbb{F}$ in Definition 2.1(b) below is nonempty.) Moreover, Q (or $Q(B|x,a)$ for $B\in\mathcal{B}(\mathrm{X})$ and $(x,a)\in\mathbb{K}$) stands for the *transition law*, and, finally, $c\colon\mathbb{K}\to\mathbb{R}$ is a measurable function that denotes the *cost-per-stage*.

The *constrained* Markov control model, on the other hand, is of the form

$$(\mathrm{X},\ \mathrm{A},\ \{\mathrm{A}(x)\,|\,x\in\mathrm{X}\}, Q, c, \mathbf{d}, \mathbf{k}), \tag{2.3}$$

where the first five components are as in (2.1), and, furthermore, $\mathbf{d}=(d_1,\dots,d_q)\colon\mathbb{K}\to\mathbb{R}^q$ is a given function and $\mathbf{k}=(k_1,\dots,k_q)$ is a given vector in $\mathbb{R}^q$; these are used to define the CP in (2.7) and (2.8) below. To state the latter, we need the following definitions.

DEFINITION 2.1. (a) *A stochastic kernel φ on* A *given* X *is a function $(x,B)\to\varphi(B|x)$ on $\mathrm{X}\times\mathcal{B}(\mathrm{A})$ such that $\varphi(B|\cdot)$ is a measurable function on* X *for each fixed $B\in\mathcal{B}(\mathrm{A})$, and $\varphi(\cdot|x)$ is a probability measure (p.m.) on $\mathcal{B}(\mathrm{A})$ for each fixed $x\in\mathrm{X}$.*

(b) *Φ stands for the family of stochastic kernels φ on* A *given* X *such that $\varphi(\mathrm{A}(x)|x)=1$ for all $x\in\mathrm{X}$, and $\mathbb{F}$ denotes the set of measurable functions f from* X *to* A *such that $f(x)$ is in $\mathrm{A}(x)$ for all $x\in\mathrm{X}$. (A function f in $\mathbb{F}$ may be identified with the stochastic kernel $\varphi\in\Phi$ such that $\varphi(\cdot\,|x)=\delta_{f(x)}(\cdot)$ is the Dirac measure at $f(x)$ for all $x\in\mathrm{X}$. Thus $\mathbb{F}\subset\Phi$.)*

(c) *Let $H_0:=\mathrm{X}$ and $H_n:=\mathbb{K}^n\times\mathrm{X}$ for $n=1,2,\dots$. A control policy is a sequence $\pi=\{\pi_n\}$ of stochastic kernels π_n on* A *given H_n that satisfy the constraint*

$$\pi_n(\mathrm{A}(x_n)\,|\,h_n)=1 \tag{2.4}$$

for every "history" $h_n=(x_0,a_0,\dots,x_{n-1},a_{n-1},x_n)$ in H_n and $n=0,1,\dots$. The set of all control policies is denoted by Π.

(d) *A control policy $\pi=\{\pi_n\}$ is said to be randomized stationary if there exists a stochastic kernel $\varphi\in\Phi$ such that $\pi_n(\cdot\,|h_n)=\varphi(\cdot\,|x_n)$ for each history $h_n\in H_n$ and*

$n = 0, 1, \ldots$. *The family of randomized stationary policies will be identified with the set* Φ. *Moreover,* π *is called deterministic stationary if there exists an* $f \in \mathbb{F}$ *such that* $\pi_n(\cdot|h_n)$ *is the Dirac measure at* $f(x_n)$ *for all* $h_n \in H_n$ *and* $n = 0, 1, \ldots$. *We shall identify* $\mathbb{F}$ *with the set of deterministic stationary policies.*

Let $\mathbb{P}(\mathrm{X})$ be the class of p.m.'s on $\mathcal{B}(\mathrm{X})$. For each policy $\pi \in \Pi$ and each "initial distribution" $\nu \in \mathbb{P}(\mathrm{X})$, there exist a p.m. P_ν^π and a stochastic process $\{(x_n, a_n), n = 0, 1, \ldots\}$ defined on a canonical measurable space $(\Omega, \mathcal{F})$, where x_n and a_n represent the state and the control variables at time n $(n = 0, 1, \ldots)$. The expectation operator with respect to P_ν^π is denoted by E_ν^π. If ν is concentrated at the initial state $x_0 = x$, then we write P_ν^π and E_ν^π as P_x^π and E_x^π, respectively.

Let c and $\mathbf{d} = (d_1, \ldots, d_q)$ be as in (2.1) and (2.3). For each control policy $\pi \in \Pi$ and initial distribution $\nu \in \mathbb{P}(\mathrm{X})$, consider the long-run expected average costs

$$J_0(\pi, \nu) := \limsup_{n\to\infty} \frac{1}{n} E_\nu^\pi \left[\sum_{t=0}^{n-1} c(x_t, a_t)\right] \tag{2.5}$$

and

$$J_i(\pi, \nu) := \limsup_{n\to\infty} \frac{1}{n} E_\nu^\pi \left[\sum_{t=0}^{n-1} d_i(x_t, a_t)\right] \quad \text{for } i = 1, \ldots, q. \tag{2.6}$$

Furthermore, letting $\mathbf{k} = (k_1, \ldots, k_q)$ be the q-vector in (2.3), define

$$\Delta := \{(\pi, \nu) \in \Pi \times \mathbb{P}(\mathrm{X}) | J_0(\pi, \nu) < \infty \text{ and } J_i(\pi, \nu) \le k_i \ (i = 1, \ldots, q)\}. \tag{2.7}$$

With this notation, we may then define the CP we are concerned with as follows:

$$\begin{aligned} \mathrm{CP}: \quad & \text{Minimize } J_0(\pi, \nu) \\ & \text{subject to } (\pi, \nu) \in \Delta. \end{aligned} \tag{2.8}$$

In the following section, we give conditions under which CP is *solvable*; that is, there exists a pair (π^*, ν^*) in Δ such that

$$J_0(\pi^*, \nu^*) = \inf\{J_0(\pi, \nu) \,|\, (\pi, \nu) \in \Delta\} =: \rho^*. \tag{2.9}$$

In addition, in section 4, we rewrite CP as a linear program on suitable vector spaces, which allows us to obtain further results. First, however, we conclude this section with the following comments.

Remark 2.2. (a) As in [17, 18, 22, 28, 29], we may refer to CP as a (constrained) "minimum pair" problem for an obvious reason: the "decision variables" are the *pairs* (π, ν) in Δ. A different problem, which we might call "ergodic," and which usually requires a different approach (see [1, 29, 31, 33]), is obtained if we *fix the initial distribution* $\nu_0 \in \mathbb{P}(\mathrm{X})$. (In particular, we might take $\nu_0 = \delta_x$ for a given initial state x.) In this case, the CP would be

$$\mathrm{CP}(\nu_0): \quad \text{Minimize } J(\pi, \nu_0) \text{ subject to } \pi \in \Pi \text{ and } (\pi, \nu_0) \in \Delta.$$

In the ergodic CP, one imposes ergodicity (or recurrence) hypotheses that typically ensure a "unichain" behavior, and so, at the outset, we expect the optimal value of CP to be a *constant* independent of the initial state, as for *unconstrained* problems

(see [3, 11, 18, 22], for instance). In this paper, however, we make no such hypotheses. On the contrary, our Assumption 3.1 is designed so that we can transform CP into a "classical optimization" problem on a suitable set of measures (see Lemma 3.5), and the constant optimal value that one would expect in the ergodic problem turns out to be precisely the constant ρ^* in (2.9). To see how one can study CP(ν_0) using our present approach, see Remarks 3.8, 4.6, and 5.3.

(b) *Constrained rewards.* Suppose that the functions d_i in (2.3) are "rewards" rather than costs, and define the long-run *expected average rewards*

$$R_i(\pi,\nu) := \liminf_{n\to\infty} \frac{1}{n} E_\nu^\pi \left[\sum_{t=0}^{n-1} d_i(x_t,a_t)\right] \quad \text{for } i = 1,\dots,q.$$

Then, instead of (2.8), we may consider the CP

$$\text{Minimize } J_0(\pi,\nu) \text{ subject to } R_i(\pi,\nu) \geq k_i, \tag{2.10}$$

and our results in the following sections are valid with the obvious changes. See Remark 3.7(a).

(c) *Constrained discounted cost.* Let $\alpha_1,\dots,\alpha_q$ be "discount factors" in (0,1), and consider the α_i-discounted costs

$$D_i(\pi,\nu) := (1-\alpha_i) E_\nu^\pi \left[\sum_{t=0}^{\infty} \alpha_i^t\, d_i(x_t,a_t)\right] \quad \text{for } i = 1,\dots,q.$$

Then our results are again valid if some or all of the constraints in (2.7) and (2.8) are replaced with

$$D_i(\pi,\nu) \leq k_i \qquad (i = 1,\dots,q), \tag{2.11}$$

and the case of discounted "rewards," as in (2.10), is similar. See Remark 3.7(b).

3. Solvability of CP. The following conditions ensure that CP is solvable (see Theorem 3.2).

Assumption 3.1.

(a) CP is *consistent*; that is, the set Δ in (2.7) is nonempty.

(b) $c(x,a)$ is nonnegative and inf-*compact*, which means that, for each $r \in \mathbb{R}$, the set $\{(x,a) \in \mathbb{K} \mid c(x,a) \leq r\}$ is compact.

(c) $d_i(x,a)$ is nonnegative and l.s.c. for $i = 1,\dots,q$.

(d) The transition law Q is *weakly continuous*; that is (denoting by $C_b(\mathrm{S})$ the space of continuous bounded functions on a topological spaces S), Q is such that $\int_{\mathrm{X}} u(y)Q(dy|\cdot\,)$ belongs to $C_b(\mathbb{K})$ for each function u in $C_b(\mathrm{X})$.

Observe that Assumption 3.1(b) yields, in particular, that c is l.s.c.

On the other hand, parts (b) and (c) can be replaced with the following condition: *all of the cost functions* c, $d_1,\dots,d_q$ *are nonnegative and l.s.c., and (at least) one of them is* inf-*compact.* Moreover, the "nonnegativity" condition on c and d_i may be replaced with "boundedness from below." For further comments on Assumption 3.1, see Remark 3.6.

THEOREM 3.2 (solvability of CP). *Under Assumption* 3.1, *CP is solvable. (See* (2.9)*.)*

Our proof of Theorem 3.2 is based on the "direct method," in which, as was already noted in the introduction, one uses the occupation measures in (3.8) to reduce

CP to an equivalent, "static" optimization problem. The key fact about this approach is that *to solve* CP *we may restrict ourselves to considering "stable" policies.* To state this fact precisely (Lemma 3.5), we shall use the following well-known result.

Remark 3.3 (see, for instance, [7], pp. 88–89 in [11], or p. 89 in [23]). If μ is a p.m. on X×A concentrated on $\mathbb{K}$ (i.e., $\mu(\mathbb{K}^c) = 0$, where $\mathbb{K}^c$ denotes the complement of $\mathbb{K}$), then there exists $\varphi \in \Phi$ such that μ can be "disintegrated" as

$$\mu(\mathrm{B} \times \mathrm{C}) = \int_B \varphi(\mathrm{C}|x)\widehat{\mu}(dx) \quad \forall\ \mathrm{B} \in \mathcal{B}(\mathrm{X}), \mathrm{C} \in \mathcal{B}(\mathrm{A}), \tag{3.1}$$

where $\widehat{\mu}(\mathrm{B}) = \mu(\mathrm{B} \times \mathrm{A})$ for all B in $\mathcal{B}(\mathrm{X})$ is the *marginal* (or projection) of μ on X. Conversely, for each $\varphi \in \Phi$ and $\nu \in \mathbb{P}(\mathrm{X})$, the p.m. μ on X × A defined by

$$\mu(\mathrm{B} \times \mathrm{C}) := \int_B \varphi(\mathrm{C}|x)\nu(dx) \qquad \forall\ \mathrm{B} \in \mathcal{B}(\mathrm{X}), \mathrm{C} \in \mathcal{B}(\mathrm{A}) \tag{3.2}$$

is concentrated on $\mathbb{K}$ (by Definition 2.1(b)), and its marginal on X is $\widehat{\mu} = \nu$. The p.m. μ in (3.1) and (3.2) will be written as $\mu = \widehat{\mu} \cdot \varphi$ and $\mu = \nu \cdot \varphi$, respectively.

For each $\varphi \in \Phi$ and $x \in \mathrm{X}$, we write

$$c(x, \varphi) := \int_A c(x, a)\varphi(da|x) \quad \text{and} \quad Q(\cdot|x, \varphi) := \int_A Q(\cdot|x, a)\varphi(da|x), \tag{3.3}$$

and similarly for $d_i(x, \varphi)$. In particular, for $f \in \mathbb{F}$, (3.3) reduces to

$$c(x, f) := c(x, f(x)) \ \text{ and } \ Q(\cdot\,|x, f) := Q(\cdot\,|x, f(x)). \tag{3.4}$$

(Recall the identification $f(x) \mapsto \varphi(\cdot\,|x) := \delta_{f(x)}(\cdot\,)$ in Definition 2.1(b).)

Definition 3.4 (stable policies). *Let $\mu = \widehat{\mu} \cdot \varphi$ be as in* (3.1). *Then the p.m. μ (or the randomized stationary policy $\varphi \in \Phi$) is said to be* stable *if*

(a) $\langle \mu, c \rangle := \int c(x, a)\mu(d(x, a)) = \int c(x, \varphi)\widehat{\mu}(dx) < \infty$, *and*

(b) *the marginal $\widehat{\mu}$ is an* invariant probability measure *(i.p.m.) for the transition kernel $Q(\cdot\,|\cdot\,, \varphi)$; that is,*

$$\widehat{\mu}(\mathrm{B}) = \int_{\mathrm{X}} Q(\mathrm{B}|x, \varphi)\widehat{\mu}(dx) \qquad \forall\ \mathrm{B} \in \mathcal{B}(\mathrm{X}).$$

We shall denote by $\mathbb{P}(\mathbb{K})$ the family of p.m.'s on X×A concentrated on $\mathbb{K}$, and by $\mathbb{P}_{\mathrm{s}}(\mathbb{K}) \subset \mathbb{P}(\mathbb{K})$ the set defined as

$$\mathbb{P}_{\mathrm{s}}(\mathbb{K}) := \{\mu \in \mathbb{P}(\mathbb{K}) |\, \mu \text{ is stable}\}.$$

By the individual ergodic theorem (see, for instance, p. 388 in [35] or Theorem E.11 in [18]), if $\mu = \widehat{\mu} \cdot \varphi$ is stable, then the long-run expected average cost $J_0(\varphi, \widehat{\mu})$ when using the policy $\varphi \in \Phi$ and the initial distribution is $\widehat{\mu}$ is given by

$$J_0(\varphi, \widehat{\mu}) = \lim_{n \to \infty} \frac{1}{n} E_{\mu}^{\varphi} \left[\sum_{t=0}^{n-1} c(x_t, a_t) \right] = \langle \mu, c \rangle.$$

Thus, for $\mu = \widehat{\mu} \cdot \varphi$ in $\mathbb{P}_{\mathrm{s}}(\mathbb{K})$, we have (using the notation (3.3))

$$J_0(\varphi, \widehat{\mu}) = \langle \mu, c \rangle = \int_{\mathrm{X}} c(x, \varphi)\widehat{\mu}(dx) \tag{3.5}$$

and, similarly,

$$J_i(\varphi,\widehat{\mu}) = \langle \mu, d_i\rangle = \int_{\mathrm{X}} d_i(x,\varphi)\widehat{\mu}(dx) \quad \text{for } i = 1,\dots,q. \tag{3.6}$$

To establish the connection between CP and stable policies, in the right-hand side of (2.5), replace $c(x,a)$ by the indicator function I_Γ of a set Γ in $\mathcal{B}(\mathrm{X}\times\mathrm{A})$. Then we can rewrite (2.5) as

$$J_0(\pi,\nu) = \limsup_{n\to\infty}\langle \mu^\pi_{\nu,n}, c\rangle, \tag{3.7}$$

where $\mu^\pi_{\nu,n}$ denotes the n-stage expected *occupation measure* associated to (π,ν), that is,

$$\mu^\pi_{\nu,n}(\Gamma) := \frac{1}{n}\sum_{t=0}^{n-1} P^\pi_\nu\,[(x_t,a_t)\in\Gamma] \quad \forall \quad \Gamma\in\mathcal{B}(\mathrm{X}\times\mathrm{A}). \tag{3.8}$$

Similarly, (2.6) becomes

$$J_i(\pi,\nu) = \limsup_{n\to\infty}\langle \mu^\pi_{\nu,n}, d_i\rangle \quad \text{for} \quad i = 1,\dots,q. \tag{3.9}$$

Having (3.7)–(3.9), the same proof of Theorem 5.7.9(a) in [18] yields the following.

LEMMA 3.5 (reduction of CP to stable policies). *Under Assumption* 3.1, *for each feasible pair* $(\pi,\nu)\in\Delta$ *for CP, there exists a stable p.m.* $\mu = \widehat{\mu}\cdot\varphi$ *such that*

(a) $(\varphi,\widehat{\mu})$ *is in* Δ, *and*

(b) $J_0(\pi,\nu)\ge J_0(\varphi,\widehat{\mu}) = \langle\mu, c\rangle$.

Hence we can write ρ^* *in* (2.9) *as*

$$\rho^* = \inf\{\langle\mu,c\rangle | \mu\in\Delta_{\mathrm{s}}\}, \tag{3.10}$$

where $\Delta_{\mathrm{s}} := \{\mu\in\mathbb{P}_{\mathrm{s}}(\mathbb{K})|$ *if* $\mu = \widehat{\mu}\cdot\varphi$, *then* $(\varphi,\widehat{\mu})\in\Delta\}$, *and, moreover, there is a p.m.* μ^* *in* Δ_{s} *such that* $\langle\mu^*,c\rangle = \rho^*$.

Lemma 3.5 *yields Theorem* 3.2. Indeed, let $\mu^*\in\Delta_{\mathrm{s}}$ be as in Lemma 3.5, and let us disintegrate it as in (3.1), that is, $\mu^* = \widehat{\mu}^*\cdot\varphi^*$. Then the pair $(\varphi^*,\widehat{\mu}^*)$ is optimal for CP because, by (3.5), (3.6), and (3.10), we have

$$J_0(\varphi^*,\widehat{\mu}^*) = \langle\mu^*,c\rangle = \int_{\mathrm{X}} c(x,\varphi^*)\widehat{\mu}^*(dx) = \rho^* \tag{3.11}$$

and

$$J_i(\varphi^*,\widehat{\mu}^*) = \langle\mu^*,d_i\rangle = \int_{\mathrm{X}} d_i(x,\varphi^*)\widehat{\mu}^*(dx) \le k_i \quad \text{for} \quad i = 1,\dots,q. \tag{3.12}$$

Remark 3.6 (examples). Examples that satisfy Assumption 3.1(b), (d) can be seen, for instance, in [1, 10, 11, 13, 15, 16, 18, 22, 24, 25, 26, 31, 33, 41]. In particular, the examples in [16], [18, Chapter 5], [22, Chapter 10], [26], [31], and [41] include queueing systems, linear systems with quadratic costs, inventories, and a cash-balance model, and they all have in common that the state process $\{x_t\}$ follows a discrete-time equation of the form

$$x_{t+1} = G(x_t,a_t,\xi_t), \quad t = 0,1,\dots,$$

where the ξ_t are independently and identically distributed (i.i.d.) disturbances, independent of the initial state x_0, and $G(x, a, s)$ is a given measurable function. Moreover, G is continuous in (x, a) for each s, and so Assumption 3.1(d) holds. On the other hand, in each case, the cost function $c(x, a)$ satisfies Assumption 3.1(b) or an analogous condition when c is a "reward," as in the cash-balance model in [26]. In the latter reference and also in [16, 22], for instance, $c(x, a)$ is required, in addition, to satisfy a "growth" condition

$$0 \leq \sup_{a \in \mathrm{A}(x)} c(x, a) \leq \mathrm{V}(x) \quad \forall\, x \in \mathrm{X}, \tag{3.13}$$

where $\mathrm{V}(\cdot\,) \geq 1$ is a given measurable function which acts as a "bounding" or "weight" function. Furthermore, conditions are given for the state process $\{x_t\}$ to be a V-*geometrically ergodic* Markov chain for each deterministic stationary policy $f \in \mathbb{F}$. This implies, in particular, that the long-run average cost, say, $J_0(f, \nu)$, is finite for any $f \in \mathbb{F}$ and $\nu \in \mathbb{P}(\mathrm{X})$, and similary for $J_i(f, \nu)$ if the costs $d_i(x, a)$ satisfy (3.13) for $i = 1, \ldots, q$. Thus, as Assumption 3.1(c) is bound to hold in most applications, for all of Assumption 3.1 to be true, we would need only to ensure the existence of $f \in \mathbb{F}$ (say) and $\nu \in \mathbb{P}(\mathrm{X})$ such that $J_i(f, \nu) \leq k_i$ for $i = 1, \ldots, q$. For similar examples (using "bounding" functions) when the state space is a *countable* set, see, for instance, [1, 10, 24].

Remark 3.7. (a) Consider the *constrained rewards* problem (2.10). Then it is easily seen that Theorem 3.2 and Lemma 3.5 are valid for (2.10) if Assumption 3.1(c) is replaced with the following: $d_i(x, a)$ *is upper semicontinuous and bounded above for* $i = 1, \ldots, q$.

(b) *A solution to* CP (see (3.10)) *also solves the problem of minimizing the average cost* $J_0(\pi, \nu)$ *subject to the constrained discounted costs* (2.11). To see this, for each $i = 1, \ldots, q$, consider the *discounted* occupation measures (cf. (3.8))

$$\gamma^{\pi}_{\nu,i}(\Gamma) := (1 - \alpha_i) \sum_{t=0}^{\infty} \alpha_i^t P^{\pi}_{\nu}[(x_t, a_t) \in \Gamma] \quad \forall\, \Gamma \in \mathcal{B}(\mathrm{X} \times \mathrm{A}) \tag{3.14}$$

so that the discounted costs D_i can be expressed as

$$D_i(\pi, \nu) = \langle \gamma^{\pi}_{\nu,i}, d_i \rangle. \tag{3.15}$$

Now let $\mu = \widehat{\mu} \cdot \varphi$ be a *stable* p.m. Then, in particular, by the invariance condition in Definition 3.4(b), we have

$$\widehat{\mu}(\cdot) = \int_{\mathrm{X}} Q^t(\cdot|x, \varphi)\widehat{\mu}(dx) \quad \forall\, t = 0, 1, \ldots. \tag{3.16}$$

Therefore, replacing the pair (π, ν) in (3.14) with $(\varphi, \widehat{\mu})$, we get

$$\gamma^{\varphi}_{\widehat{\mu},i}(\cdot) = \mu(\cdot) \quad \forall\, i = 1, \ldots, q \tag{3.17}$$

because, for any measurable rectangle $\Gamma = \mathrm{B} \times \mathrm{C}$ in $\mathcal{B}(\mathrm{X} \times \mathrm{A})$ and $t = 0, 1, \ldots$, it holds that

$$\begin{aligned} P^{\varphi}_{\mu}(x_t \in \mathrm{B}, a_t \in \mathrm{C}) &= \int_{\mathrm{X}} \int_{\mathrm{B}} \varphi(\mathrm{C}|x) Q^t(dx|y, \varphi)\widehat{\mu}(dy) \\ &= \int_{\mathrm{B}} \varphi(\mathrm{C}|x)\widehat{\mu}(dx) \quad \text{(by (3.16))} \\ &= \mu(\mathrm{B} \times \mathrm{C}) \quad \text{(by (3.1))}. \end{aligned}$$

The latter equality and (3.14) give (3.17). In turn, (3.17) yields that *for any stable p.m.* $\mu = \widehat{\mu} \cdot \varphi$ we can write (3.15) as

$$D_i(\varphi, \widehat{\mu}) = \langle \mu, d_i \rangle \quad \forall\ i = 1, \dots q,$$

and so the discounted costs in (2.11) coincide with the *average costs* in (3.6). Hence, by Lemma 3.5(a), (b), we obtain the desired conclusion.

Finally, observe that the above argument also shows that some of the constraints in CP can include both average *and* discounted costs. This can be relevant for applications in which one has long-run (average) constraints as well as short-term (discounted) constraints.

Remark 3.8. Consider $\mathrm{CP}(\nu_0)$ in Remark 2.2(a), where $\nu_0 \in \mathbb{P}(\mathrm{X})$ is a *fixed* initial distribution. Let us suppose that Assumption 3.1 holds except that part (a) is replaced with

(a′) $\mathrm{CP}(\nu_0)$ *is consistent.*

In addition, we suppose that *there exists* $\varphi \in \Phi$ *such that* $\mu := \nu_0 \cdot \varphi$ *is stable.* Then, from the proof of Lemma 3.5 and Theorem 3.2, it can be seen that these results hold when CP is replaced with $\mathrm{CP}(\nu_0)$. In particular, $\mathrm{CP}(\nu_0)$ is solvable.

4. The LP formulation. General references for this section are Chapter 3 in [2], Chapter 6 in [18], or Chapter 12 in [22]; in fact, we shall follow section 12.3 in [22] closely. Additional related material can be found in [1, 17, 21, 27, 29, 31, 36, 37], for instance. Assumption 3.1 is supposed to hold throughout the following.

As in the unconstrained case, the idea in this section is as follows. In Lemma 3.5, we have reduced CP to the minimization of the *linear map* $\mu \mapsto \langle \mu, c \rangle$ over the subset of p.m.'s μ in Δ_{s}, as in (3.10). Thus, as the objective function is already linear, to transform (3.10) into a *linear program*, the idea is simply to imbed Δ_{s} into a suitable vector space of measures. We next show how this is done.

For each (x, a) in $\mathbb{K}$, define

$$w(x,a) := 1 + c(x,a) \ \text{ and } \ \widehat{w}(x) := \inf_{a \in A(x)} w(x,a) = 1 + \widehat{c}(x), \tag{4.1}$$

where $\widehat{c}(x) := \inf_{a \in A(x)} c(x,a)$ is assumed to be measurable. (To develop the LP formulation, in (4.1), we may in fact take *any measurable function* $w(x,a) \geq c(x,a)$ as long as it is bounded away from zero so that (4.3) is well defined.) Let us now consider the dual pair $(\mathrm{M}(\mathbb{K}), \mathrm{F}(\mathbb{K}))$ of vector spaces defined as follows:

- $\mathrm{M}(\mathbb{K})$ is the vector space of finite signed measures μ on $\mathrm{X} \times \mathrm{A}$, concentrated on $\mathbb{K}$, such that

$$\|\mu\|_w := \int w d|\mu| < \infty, \tag{4.2}$$

  where $|\mu| := \mu^+ + \mu^-$ denotes the total variation of μ (see [4] or [6]).
- $\mathrm{F}(\mathbb{K})$ is the vector space of measurable functions $v : \mathbb{K} \to \mathbb{R}$ such that

$$\|v\|_w := \sup_{(x,a) \in \mathbb{K}} \frac{|v(x,a)|}{w(x,a)} < \infty. \tag{4.3}$$

- The bilinear form $\langle \cdot\,, \cdot \rangle$ on $(\mathrm{M}(\mathbb{K}), \mathrm{F}(\mathbb{K}))$ is

$$\langle \mu, v \rangle := \int_{\mathrm{X} \times \mathrm{A}} v(x,a) \mu(d(x,a)). \tag{4.4}$$

  (See Remark 4.1(b).)

In addition, we consider the dual pair $(\mathrm{M}(\mathrm{X}), \mathrm{F}(\mathrm{X}))$ defined exactly as above, but with X and $\widehat{w}$ in lieu of $\mathrm{X} \times \mathrm{A}$ and w, respectively.

Remark 4.1. (a) By (4.1) and (4.3), it is evident that $c(x,a)$ is in $\mathrm{F}(\mathbb{K})$.

(b) We assume that a function v in $\mathrm{F}(\mathbb{K})$ can be measurably extended to all of $\mathrm{X} \times \mathrm{A}$ in an arbitrary way as long as the integral in (4.4) is finite. For instance, if we define $c(x,a) := +\infty$ for (x,a) in the complement $\mathbb{K}^{\mathrm{c}}$ of $\mathbb{K}$ and make the convention that $0 \cdot (+\infty) = 0$, then (4.4) becomes

$$\langle \mu, c \rangle = \int_{\mathbb{K}} c \, d\mu,$$

which is finite because, by (4.1)–(4.3), $|\langle \mu, c \rangle| \le \int c \, d|\mu| \le \int w \, d|\mu| < \infty$. Also observe that $\langle \mu, 1 \rangle = \mu(\mathrm{X} \times \mathrm{A}) = \mu(\mathbb{K})$.

To rewrite (3.10) as a linear program, we need the following additional assumption.

Assumption 4.2.

(a) d_i is in $F(\mathbb{K})$ for $i = 1, \dots, q$.

(b) $\int_{\mathrm{X}} \widehat{w}(y) Q(dy|\cdot)$ is in $F(\mathbb{K})$, i.e., $\sup_{(x,a)} w(x,a)^{-1} \int \widehat{w}(y) Q(dy|x,a) < \infty$.

Now let $\mathrm{L}_0 : \mathrm{M}(\mathbb{K}) \to \mathrm{M}(\mathrm{X})$ be the linear map $\mu \mapsto \mathrm{L}_0\mu$ defined by

$$\mathrm{L}_0\mu(\mathrm{B}) := \widehat{\mu}(\mathrm{B}) - \int_{\mathrm{X} \times \mathrm{A}} Q(\mathrm{B}|x,a) \mu(d(x,a)) \text{ for } \mathrm{B} \in \mathcal{B}(\mathrm{X}). \tag{4.5}$$

The *adjoint* $\mathrm{L}_0^* : \mathrm{F}(\mathrm{X}) \to \mathrm{F}(\mathbb{K})$ of L_0, which is defined by the relation

$$\langle \mathrm{L}_0\mu, u \rangle = \langle \mu, \mathrm{L}_0^* u \rangle \quad \forall \ \mu \in \mathrm{M}(\mathbb{K}), u \in \mathrm{F}(\mathrm{X}),$$

is given by

$$(\mathrm{L}_0^* u)(x,a) = u(x) - \int_{\mathrm{X}} u(y) Q(dy|x,a) \ \ \forall \ (x,a) \in \mathbb{K}, u \in \mathrm{F}(\mathrm{X}). \tag{4.6}$$

Moreover, by (4.3) and Assumption 4.2(b), L_0^* indeed maps $\mathrm{F}(\mathrm{X})$ into $\mathrm{F}(\mathbb{K})$, which is equivalent to saying that

$$\text{the linear map } \mathrm{L}_0 \colon \mathrm{M}(\mathbb{K}) \to \mathrm{M}(\mathrm{X}) \text{ is weakly continuous,} \tag{4.7}$$

that is, continuous in the weak topologies $\sigma(\mathrm{M}(\mathbb{K}), \mathrm{F}(\mathbb{K})), \sigma(\mathrm{M}(\mathrm{X}), \mathrm{F}(\mathrm{X}))$. With this fact we now have all the ingredients to state (3.10) as a linear program.

First note that (by Definition 3.4, (3.5), and (3.6)), the condition "$\mu \in \Delta_{\mathrm{s}}$" in (3.10) can be written as

$$\mathrm{L}_0\mu = 0, \ \langle \mu, 1 \rangle = \mu(\mathbb{K}) = 1, \ \langle \mu, d_i \rangle \le k_i \ \ (i = 1, \dots, q), \ \mu \in \mathrm{M}_+(\mathbb{K}), \tag{4.8}$$

where $\mathrm{M}_+(\mathbb{K})$ denotes the convex cone of nonnegative measures in $\mathrm{M}(\mathbb{K})$. Moreover, the inequalities $\langle \mu, d_i \rangle \le k_i \ \ (i = 1, \dots, q)$ hold if and only if $\langle \mu, d_i \rangle + \alpha_i = k_i$ for some $\alpha_i \ge 0$. Therefore, letting

$$\mathrm{L} \colon \mathrm{M}(\mathbb{K}) \times \mathbb{R}^q \to \mathrm{M}(\mathrm{X}) \times \mathbb{R} \times \mathbb{R}^q$$

be the linear map given by

$$\mathrm{L}(\mu, \boldsymbol{\alpha}) := (\mathrm{L}_0\mu, \langle \mu, 1 \rangle, \langle \mu, d_1 \rangle + \alpha_1, \dots, \langle \mu, d_q \rangle + \alpha_q) \tag{4.9}$$

for each μ in $\mathrm{M}(\mathbb{K})$ and $\boldsymbol{\alpha} = (\alpha_1, \ldots, \alpha_q)$ in $\mathbb{R}^q$, we can write (4.8) as

$$\mathrm{L}(\mu, \boldsymbol{\alpha}) = (0, 1, \mathbf{k}) \text{ for some } \boldsymbol{\alpha} \in \mathbb{R}^q_+.$$

Thus the nonnegative components α_i of $\boldsymbol{\alpha}$ have an obvious interpretation as "slack variables," and, on the other hand, by (3.10) we see that CP *is equivalent to the* EC *primal linear program*

$$\textbf{EC} \qquad \text{Minimize } \langle \mu, c\rangle = \langle (\mu, \boldsymbol{\alpha}), (c, \mathbf{0})\rangle \tag{4.10}$$

$$\text{subject to } \mathrm{L}(\mu, \boldsymbol{\alpha}) = (0, 1, \mathbf{k}), \quad (\mu, \boldsymbol{\alpha}) \in \mathrm{M}_+(\mathbb{K}) \times \mathbb{R}^q_+. \tag{4.11}$$

Hence, in particular, Theorem 3.2 and Lemma 3.5 yield the following.

COROLLARY 4.3 (solvability of EC). *Under Assumptions* 3.1 *and* 4.2, EC *is solvable.*

In other words, there exists $(\mu^*, \boldsymbol{\alpha}^*)$ that satisfies (4.11), and, in addition, the *value* of EC, namely,

$$\inf(\mathrm{EC}) := \inf\{\langle \mu, c\rangle |\ (4.11) \text{ holds}\},$$

can be written as a "minimum" rather than "infimum," and

$$\langle \mu^*, c\rangle = \langle (\mu^*, \boldsymbol{\alpha}^*), (c, \mathbf{0})\rangle = \min(\mathrm{EC}) = \rho^*. \tag{4.12}$$

To introduce the dual EC^* of EC, let us first note that the adjoint

$$\mathrm{L}^*\colon \mathrm{F}(\mathrm{X}) \times \mathbb{R} \times \mathbb{R}^q \to \mathrm{F}(\mathbb{K}) \times \mathbb{R}^q$$

of L is the linear map

$$\mathrm{L}^*(u, \beta_0, \boldsymbol{\beta}) = \left(\mathrm{L}_0^* u + \beta_0 + \sum_{i=1}^q \beta_i d_i, \boldsymbol{\beta} \right) \tag{4.13}$$

for all $(u, \beta_0, \boldsymbol{\beta})$ in $\mathrm{F}(\mathrm{X}) \times \mathbb{R} \times \mathbb{R}^q$. In particular, by (4.7) and Assumption 4.2(a), L is weakly continuous, and the dual of EC (see (4.10), (4.11)) is

$$\textbf{EC}^* \quad \text{Maximize } \langle (0, 1, \mathbf{k}), (u, \beta_0, \boldsymbol{\beta})\rangle = \beta_0 + \langle \mathbf{k}, \boldsymbol{\beta}\rangle \tag{4.14}$$

$$\text{subject to } \mathrm{L}^*(u, \beta_0, \boldsymbol{\beta}) \le (c, \mathbf{0}),\ (u, \beta_0, \boldsymbol{\beta}) \in \mathrm{F}(\mathrm{X}) \times \mathbb{R} \times \mathbb{R}^q. \tag{4.15}$$

In (4.14), $\langle \mathbf{k}, \boldsymbol{\beta}\rangle$ denotes the usual inner (or scalar) product of q-vectors, i.e.,

$$\langle \mathbf{k}, \boldsymbol{\beta}\rangle = \sum_{i=1}^q k_i \beta_i,$$

whereas the inequality in (4.15) in understood componentwise, i.e., (by (4.13))

$$\mathrm{L}_0^* u + \beta_0 + \sum_{i=1}^q \beta_i d_i \le c \text{ and } \boldsymbol{\beta} \le \mathbf{0}$$

or, more explicitly, by the definition (4.6) of L_0^*,

$$\beta_0 + u(x) \le c(x,a) - \sum_{i=1}^{q} \beta_i d_i(x,a) + \int_{\mathrm{X}} u(y) Q(dy|x,a) \quad \forall\ (x,a) \in \mathbb{K} \tag{4.16}$$

and

$$\beta_i \le 0 \quad \text{for} \quad i = 1, \ldots, q. \tag{4.17}$$

As the cost-per-stage $c(x,a)$ is nonnegative (Assumption 3.1(b)), it is clear that the dual EC* is *consistent.* For instance, the triplet $(u, \beta_0, \boldsymbol{\beta})$=(0,0,$\mathbf{0}$) satisfies (4.15). Therefore, the *weak duality* property yields $\sup(\mathrm{EC}^*) \le \inf(\mathrm{EC})$, where

$$\sup(\mathrm{EC}^*) := \sup\{\langle (0,1,\mathbf{k}), (u, \beta_0,\ \boldsymbol{\beta})\rangle \mid (4.15) \text{ holds}\} \tag{4.18}$$

denotes the value of EC*. Thus, by (4.12), we have

$$\sup(\mathrm{EC}^*) \le \min(\mathrm{EC}),$$

and, in fact, it turns out that the same hypotheses of Corollary 4.3 yield that there is *no duality gap*, that is,

$$\sup(\mathrm{EC}^*) = \min(\mathrm{EC}) \quad (= \rho^*). \tag{4.19}$$

Formally stated, we have the following result, which can be proved as Theorem 12.3.4 in [22] (see also [17] or [37]).

THEOREM 4.4 (absence of duality gap). *If Assumptions* 3.1 *and* 4.2 *are satisfied, then* (4.19) *holds.*

In the next section, we give conditions for the *strong duality* property to be true. This means that the dual EC* is also *solvable*, in which case the value in (4.18) is written as $\max(\mathrm{EC}^*)$, and so (4.19) becomes

$$\max(\mathrm{EC}^*) = \min(\mathrm{EC}) \quad (= \rho^*). \tag{4.20}$$

In the meantime, we conclude this section with a Farkas-like result that gives necessary and sufficient conditions for EC to be consistent—that is, for the existence of a pair $(\mu, \boldsymbol{\alpha})$ that satisfies (4.11).

THEOREM 4.5 (necessary and sufficient conditions for consistency of EC). *Suppose that Assumptions* 3.1(d) *and* 4.2(b) *are satisfied. In addition,*

(i) X *and* $\mathbb{K}$ *are locally compact separable metric spaces, and*

(ii) *for each compact* $\mathrm{K} \subset \mathrm{X}$, *the function* $Q(\mathrm{K}|\cdot\,)$ *vanishes at infinity; that is, for each* $\epsilon > 0$, *there exists a compact set* $\mathrm{K}' = \mathrm{K}'(\epsilon, \mathrm{K}) \in \mathbb{K}$ *such that*

$$Q(\mathrm{K}|x,a) \le \epsilon \quad \forall\ (x,a) \notin \mathrm{K}'.$$

Then the following statements are equivalent:

(a) *There exists a pair* $(\mu, \boldsymbol{\alpha})$ *that satisfies* (4.11).

(b) *If the triplet* $(u, \beta_0, \boldsymbol{\beta})$ *in* $\mathrm{F}(\mathrm{X}) \times \mathbb{R} \times \mathbb{R}^q$ *is such that* $\mathrm{L}^*(u, \beta_0, \boldsymbol{\beta}) \ge (0, \mathbf{0})$, *then*

$$\langle (0,1,\mathbf{k}), (u, \beta_0,\ \boldsymbol{\beta})\rangle = \beta_0 + \langle \mathbf{k}, \boldsymbol{\beta}\rangle \ge 0.$$

The proof of Theorem 4.5 is essentially the same as the proof of Theorem 4.5(a) in [17], which also appears as Theorem 12.3.7 in [22]. In fact, the proof is a straightforward application of a generalized Farkas theorem of Craven and Koliha [9]. (For related Farkas-like theorems, see, for instance, [19].)

Remark 4.6. The results in this section can be expressed for $\mathrm{CP}(\nu_0)$ in Remark 2.2(a) as follows. Let L_0 and L be as in (4.5) and (4.9), and consider the linear maps

$$\mathrm{L}_1 : \mathrm{M}(\mathbb{K}) \to \mathrm{M}(\mathrm{X}) \quad \text{and} \quad \mathrm{T} : \mathrm{M}(\mathbb{K}) \times \mathbb{R}^{\mathrm{q}} \to \mathrm{M}(\mathrm{X})^2 \times \mathbb{R} \times \mathbb{R}^{\mathrm{q}},$$

with $\mathrm{M}(\mathrm{X})^2 := \mathrm{M}(\mathrm{X}) \times \mathrm{M}(\mathrm{X})$, defined by $\mathrm{L}_1\mu := \widehat{\mu}$ and $\mathrm{T}(\mu, \boldsymbol{\alpha}) := (\mathrm{L}_1\mu, \mathrm{L}(\mu, \boldsymbol{\alpha}))$. More explicitly,

$$\mathrm{T}(\mu, \boldsymbol{\alpha}) := (\mathrm{L}_1\mu, \mathrm{L}_0\mu, \langle \mu, 1\rangle, \langle \mu, d_1\rangle + \alpha_1, \ldots, \langle \mu, d_q\rangle + \alpha_q).$$

The adjoint maps $\mathrm{L}_1^* : \mathrm{F}(\mathrm{X}) \to \mathrm{F}(\mathbb{K})$ and $\mathrm{T}^* : \mathrm{F}(\mathrm{X})^2 \times \mathbb{R} \times \mathbb{R}^{\mathrm{q}} \to \mathrm{F}(\mathbb{K}) \times \mathbb{R}^{\mathrm{q}}$ are $(\mathrm{L}_1^* u)(x, a) := u(x)$ and, by (4.13),

$$\mathrm{T}^*(u, v, \beta_0, \boldsymbol{\beta}) := \left(\mathrm{L}_1^* u + \mathrm{L}_0^* v + \beta_0 + \sum_{i=1}^{q} \beta_i d_i, \boldsymbol{\beta} \right).$$

Then the EC linear program corresponding to $\mathrm{CP}(\nu_0)$ is

$$\mathrm{EC}(\nu_0) \quad \text{Minimize} \quad \langle \mu, c\rangle = \langle (\mu, \boldsymbol{\alpha}), (c, \mathbf{0})\rangle$$

$$\text{subject to} \quad \mathrm{T}(\mu, \boldsymbol{\alpha}) = (\nu_0, 0, 1, \mathbf{k}), \quad (\mu, \boldsymbol{\alpha}) \in \mathrm{M}_+(\mathbb{K}) \times \mathbb{R}^{\mathrm{q}}_+. \tag{4.21}$$

(Compare with (4.10), (4.11).) The associated dual program is (cf. (4.14), (4.15))

$$\mathrm{EC}^*(\nu_0) : \quad \text{Maximize } \langle (\nu_0, 0, 1, \mathbf{k}), (u, v, \beta_0, \boldsymbol{\beta})\rangle = \langle \nu_0, u\rangle + \beta_0 + \langle \mathbf{k}, \boldsymbol{\beta}\rangle$$

$$\text{subject to} \quad \mathrm{T}^*(u, v, \beta_0, \boldsymbol{\beta}) \le (c, \mathbf{0}), \quad (u, v, \beta_0, \boldsymbol{\beta}) \in \mathrm{F}(\mathrm{X})^2 \times \mathbb{R} \times \mathbb{R}^{\mathrm{q}}.$$

(a) Suppose that the hypotheses of Remark 3.8 and Assumption 4.2 are satisfied. Then, by Remark 3.8, $\mathrm{EC}(\nu_0)$ is solvable, and, furthermore, there is no duality gap for $\mathrm{EC}(\nu_0)$, i.e., $\sup \mathrm{EC}^*(\nu_0) = \min \mathrm{EC}(\nu_0)$.

(b) Under the hypotheses of Theorem 4.5, the following statements are equivalent:
   (b_1) There exists a pair $(\mu, \boldsymbol{\alpha})$ that satisfies (4.21).
   (b_2) If $(u, v, \beta_0, \boldsymbol{\beta}) \in \mathrm{F}(\mathrm{X})^2 \times \mathbb{R} \times \mathbb{R}^{\mathrm{q}}$ is such that $\mathrm{T}^*(u, v, \beta_0, \boldsymbol{\beta}) \ge (0, \mathbf{0})$, then

$$\langle (\nu_0, 0, 1, \mathbf{k}), (u, v, \beta_0, \boldsymbol{\beta})\rangle = \langle \nu_0, u\rangle + \beta_0 + \langle \mathbf{k}, \boldsymbol{\beta}\rangle \ge 0.$$

5. Strong duality. In view of Theorem 4.4, to prove the strong duality condition (4.20), we need conditions for the dual program EC^* to be *solvable*, that is, for the existence of a triplet $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$ in $\mathrm{F}(\mathrm{X}) \times \mathbb{R} \times \mathbb{R}^q$ that satisfies (4.15) (or (4.16), (4.17)) and attains the supremum in (4.14) (or (4.18)), i.e.,

$$\max(\mathrm{EC}^*) = \beta_o^* + \langle \mathbf{k}, \boldsymbol{\beta}^*\rangle. \tag{5.1}$$

To do this, we first take a *maximizing sequence* for EC*, namely, a sequence of triplets $(u^n, \beta_0^n, \boldsymbol{\beta}^n)$ in $\mathrm{F(X)} \times \mathbb{R} \times \mathbb{R}^q$ that satisfies (4.16) and (4.17), i.e.,

$$\beta_0^n + u^n(x) \le c(x,a) - \sum_{i=1}^{q} \beta_i^n d_i(x,a) + \int_{\mathrm{X}} u^n(y) Q(dy|x,a) \quad \text{and } \boldsymbol{\beta}^n \le \mathbf{0} \tag{5.2}$$

for all $(x,a) \in \mathbb{K}$ and $n = 1, 2, \dots$, and, moreover,

$$\langle (0, 1, \mathbf{k}), (u^n, \beta_0^n, \boldsymbol{\beta}^n) \rangle = \beta_0^n + \langle \mathbf{k}, \boldsymbol{\beta}^n \rangle \uparrow \sup(\mathrm{EC}^*) = \rho^*, \tag{5.3}$$

where the last equality is due to (4.19). The idea now is, of course, to use the maximizing sequence to deduce the existence of an optimal triplet $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$. With this in mind, let us first note that $\beta_0^n + \langle \mathbf{k}, \boldsymbol{\beta}^n \rangle \le \beta_0^n$, which, together with (5.3), yields that

$$\liminf_{n \to \infty} \beta_0^n \ge \rho^* \ge 0.$$

Thus, without loss of generality, we may suppose that the sequence $\{\beta_0^n\}$ is *nonnegative*. We also require the following assumption, which is discussed in the next section together with an example.

Assumption 5.1. There exists a maximizing sequence $\{(u^n, \beta_0^n, \boldsymbol{\beta}^n),\ n = 1, 2, \dots\}$ for EC* such that

(a) the (nonnegative) sequence $\{\beta_0^n\}$ is bounded, and

(b) the sequence $\{u^n\} \subset \mathrm{F(X)}$ is bounded in the $\widehat{w}$-norm (that is, for some constant $\widehat{k}$, $|u^n(x)| \le \widehat{k}\widehat{w}(x)$ for all $x \in \mathrm{X}$ and $n = 1, 2, \dots$).

In Proposition 6.2(a), we show that $\{u^n\}$ can be taken as a *nondecreasing* sequence of *nonnegative* functions. Hence we may replace Assumption 5.1(b) with (6.11).

THEOREM 5.2 (strong duality and the constrained optimality equation). *Suppose that Assumptions* 3.1, 4.2, *and* 5.1 *are satisfied. Then the following hold:*

(a) EC* *is solvable; hence, the strong duality condition* (4.20) *holds.*

(b) *Let* $(\mu^*, \boldsymbol{\alpha}^*)$ and $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$ *be optimal solutions for* EC *and* EC*, *respectively. Disintegrate* μ^* *as in* (3.1), *that is,* $\mu^* = \widehat{\mu}^* \cdot \varphi^*$ *with* φ^* *in* Φ, *and let*

$$c^*(x,a) := c(x,a) - \sum_{i=1}^{q} \beta_i^* d_i(x,a) \quad \textit{for } (x,a) \in \mathbb{K}. \tag{5.4}$$

Then

$$\langle \boldsymbol{\alpha}^*, \boldsymbol{\beta}^* \rangle = 0, \tag{5.5}$$

and, moreover, for $\widehat{\mu}^*$*-almost all (a.a.)* $x \in \mathrm{X}$, *the constrained optimality equation*

$$\beta_0^* + u^*(x) = \inf_{a \in \mathrm{A}(x)} \left[c^*(x,a) + \int_{\mathrm{X}} u^*(y) Q(y|x,a) \right] \tag{5.6}$$

holds, as well as

$$\beta_0^* + u^*(x) = c^*(x, \varphi^*) + \int_{\mathrm{X}} u^*(y) Q(y|x, \varphi^*) \tag{5.7}$$

for $\widehat{\mu}^*$*-a.a.* $x \in \mathrm{X}$. *Hence the following hold:*

(c) *There exists a deterministic stationary policy* $f^* \in \mathbb{F}$ *such that*

$$\beta_0^* + u^*(x) = c^*(x, f^*) + \int_{\mathrm{X}} u^*(y) Q(y|x, f^*) \tag{5.8}$$

for $\widehat{\mu}^*$*-a.a.* $x \in \mathrm{X}$.

(d) *The number* β_0^* *satisfies*

$$\beta_0^* = \langle \mu^*, c^* \rangle = \rho^* - \sum_{i=1}^{q} \beta_i^* \langle \mu^*, d_i \rangle = \rho^* - \langle \mathbf{k}, \boldsymbol{\beta}^* \rangle, \tag{5.9}$$

with $\rho^* = \min(\mathrm{EC}) = \max(\mathrm{EC}^*)$, *as in* (4.20).

We refer to (5.6) as the "constrained optimality equation" because it clearly is the analogue (in the constrained case) of the ACOE for unconstrained MCPs. (See [3, 11, 15, 16, 17, 18, 22, 25, 26].) It should be remarked, though, that (5.6)–(5.8) hold $\widehat{\mu}^*$*-almost everywhere* only. To get the equality for all $x \in \mathrm{X}$ one needs to impose suitable hypotheses, say, as in [29] or [33] (see also the example in the next section). For instance, Example 2.2 in [33] shows a constrained MCP in which every $f \in \mathbb{F}$ induces an irreducible positive recurrent Markov chain, and yet there is no $f \in \mathbb{F}$ that satisfies (5.8) for all $x \in \mathrm{X}$.

Proof of Theorem 5.2. (a) Let $\{(u^n, \beta_0^n, \boldsymbol{\beta}^n), n = 1, 2, \dots\}$ be a maximizing sequence for EC* (that is, as in (5.2) and (5.3)) that satisfies Assumption 5.1. As $\{\beta_0^n\}$ is bounded, it has a convergent subsequence, and, therefore, by (5.3), so does $\{\langle \mathbf{k}, \boldsymbol{\beta}^n \rangle\}$. Hence, as $\langle \mathbf{k}, \boldsymbol{\beta}^n \rangle \le k_i \beta_i^n \le 0$ for all $i = 1, \dots, q$, there exists a subsequence $\{m\}$ of $\{n\}$ such that the limits

$$\beta_i^* := \lim_{m \to \infty} \beta_i^m \text{ for } i = 0, 1, \dots, q \tag{5.10}$$

exist. Now define

$$u^*(x) := \limsup_{m \to \infty} u^m(x) \quad \forall\, x \in \mathrm{X}.$$

By Assumption 5.1(b), $u^*(\cdot)$ is in F(X), and, moreover, by Assumption 4.2(b) and Fatou's lemma,

$$\limsup_{m \to \infty} \int_{\mathrm{X}} u^m(y) Q(dy|x, a) \le \int_{\mathrm{X}} u^*(y) Q(dy|x, a) \quad \forall\, (x, a) \in \mathbb{K}.$$

We can now see that $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$ is an optimal solution for EC*. Indeed, in (5.2), replace n with m, and then take the limit supremum as $m \to \infty$ to get

$$\beta_0^* + u^*(x) \le c(x, a) - \sum_{i=1}^{q} \beta_i^* d_i(x, a) + \int_{\mathrm{X}} u^*(y) Q(dy|x, a) \tag{5.11}$$

for all $(x, a) \in \mathbb{K}$, and

$$\boldsymbol{\beta}^* = (\beta_1^*, \dots, \beta_q^*) \le \mathbf{0}. \tag{5.12}$$

This means that $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$ is feasible for EC* (see (4.15) or (4.16)–(4.17)), and, furthermore, from (5.10) and (5.3), we see that (5.1) holds.

(b) Let $(\mu^*, \boldsymbol{\alpha}^*)$ and $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$ be optimal solutions for EC and EC*, respectively. By the strong duality condition (4.20) and *complementary slackness* (see [2, 18, 22]),

$$\langle (\mu^*, \boldsymbol{\alpha}^*), (c, \mathbf{0}) - \mathrm{L}^*(u^*, \beta_0^*, \boldsymbol{\beta}^*) \rangle = 0.$$

That is, by (4.13) and (5.4),

$$0 \le \langle \mu^*, c^* - \mathrm{L}_0^* u^* - \beta_0^* \rangle = \langle \boldsymbol{\alpha}^*, \boldsymbol{\beta}^* \rangle \le 0, \tag{5.13}$$

where the first and the second inequalities follow from (5.11) and (5.12), respectively. From (5.13) we obtain (5.5) and also that

$$\int [c^*(x,a) - \mathrm{L}_0^* u^*(x,a) - \beta_0^*] \mu^*(d(x,a)) = 0.$$

The remainder of the proof of part (b) as well as the proof of (c) can be done as the proof of Theorem 12.4.2 in [22, pp. 236, 237]. (Similar arguments are used in [37, Theorem 4.6].)

(d) As μ^* is stable (Definition 3.4), its marginal $\widehat{\mu}^*$ on X is an i.p.m. for the transition kernel $Q(\cdot\,|\,\cdot\,, \varphi^*)$. Thus, integrating both sides of (5.7) with respect to μ^*, we get the first equality in (5.9), i.e.,

$$\beta_0^* = \langle \mu^*, c^* \rangle.$$

In turn, the latter equality combined with (5.4) yields

$$\begin{aligned} \beta_0^* &= \langle \mu^*, c \rangle - \sum_{i=1}^{q} \beta_i^* \langle \mu^*, d_i \rangle \\ &= \rho^* - \sum_{i=1}^{q} \beta_i^* \langle \mu^*, d_i \rangle \text{ (by (4.12))}, \end{aligned}$$

which is the second equality in (5.9). Finally, from (4.20) and (5.1),

$$\rho^* = \beta_0^* + \langle \mathbf{k}, \boldsymbol{\beta}^* \rangle,$$

which gives the third equality in equation (5.9). This completes the proof of Theorem 5.2. □

Remark 5.3. Theorem 5.2 holds for the linear programs EC(ν_0) and EC*(ν_0) in Remark 4.6 with the obvious changes. Indeed, in Assumption 5.1, replace $(u^n, \beta_0^n, \boldsymbol{\beta}^n)$ with a maximizing sequence $(v^n, u^n, \beta_0^n, \boldsymbol{\beta}^n) \in \mathrm{F(X)}^2 \times \mathbb{R} \times \mathbb{R}^{\mathrm{q}}$ for EC*(ν_0); both v^n and u^n are supposed to satisfy the boundedness condition in Assumption 5.1(b). Moreover, suppose that the hypotheses in Remark 4.6(a) hold. Then Theorem 5.2(a) is valid for EC*(ν_0) in lieu of EC*. Similarly, parts (b) and (c) hold when $\widehat{\mu}^*$ and $(u^*, \beta_0^*, \boldsymbol{\beta}^*)$ are replaced with ν_0 and $(v^*, u^*, \beta_0^*, \boldsymbol{\beta}^*)$, respectively. Finally, instead of (5.9), we have the following: β_0^* satisfies $\beta_0^* = \langle \mu^*, c^* \rangle$, with c^* as in (5.8) and $\mu^* = \nu_0 \cdot \varphi^*$ for some φ^* in Φ.

6. Computing optimal policies. By (5.6) and (5.9), it is evident that solving CP via the dual linear program EC* is essentially equivalent to solving an ACOE for a certain cost-per-stage function (for instance, as in (5.4)). In this section, we describe a general procedure for solving CP using ACOEs, assuming of course that they are

well defined, and then we present a detailed example to illustrate this approach. We begin by introducing some notation and useful comments.

For each $i = 0, 1, \ldots, q$, let ρ_i be the *unconstrained minimum* of the cost $J_i(\pi, \nu)$ in (2.5), (2.6). That is, for $i = 0, 1, \ldots, q$,

$$\rho_i := \inf\{J_i(\pi, \nu) \,|\, \pi \in \Pi,\ \nu \in \mathbb{P}(\mathrm{X})\}. \tag{6.1}$$

A stationary policy $f_i \in \mathbb{F}$ is said to be *strictly optimal* for J_i $(i = 0, 1, \ldots, q)$ if

$$\rho_i = J_i(f_i, \nu) =: J_i(f_i) \quad \forall\ \nu \in \mathbb{P}(\mathrm{X}). \tag{6.2}$$

Strict optimality typically holds, for instance, for so-called *canonical policies*, which are obtained as "minimizers" of suitable ACOEs—see [3, 11, 15, 18, 22, 26, 31] and (6.13). On the other hand, from (2.7)–(2.9), we can easily deduce the following fact for a strictly optimal policy for J_0 to be optimal for CP.

PROPOSITION 6.1. *Let $f_0 \in \mathbb{F}$ be a stationary policy such that*
(a) *f_0 is strictly optimal for J_0, i.e., $J_0(f_0) = \rho_0$;*
(b) *$J_i(f_0, \nu) = J_i(f_0)$ for all $\nu \in \mathbb{P}(\mathrm{X})$ and $i = 1, \ldots, q$; and*
(c) *$J_i(f_0) \le k_i$ for all $i = 1, \ldots, q$.*
Then f_0 is an optimal policy for CP *in the sense that $J_0(f_0) = \rho^*$.*

Proposition 6.1 is illustrated (with $q = 1$) in Figure 6.1, in which $\Gamma \subset \mathbb{R}^{q+1}$ is the set of all of the cost vectors $\mathbf{J}(\pi, \nu) := (J_0(\pi, \nu), J_1(\pi, \nu), \ldots, J_q(\pi, \nu))$, i.e.,

$$\Gamma := \{\mathbf{J}(\pi, \nu) \mid \pi \in \Pi,\ \nu \in \mathbb{P}(\mathrm{X})\}. \tag{6.3}$$

This set is called the *performance* or *achievable* set of the *multiobjective control problem* with cost vectors $\mathbf{J}(\pi, \nu)$; see [1, 12, 13, 31, 36, 38, 39, 40, 43]. (Actually, some of the components of $\mathbf{J}(\pi, \nu)$ might be $+\infty$, but this is irrelevant in our present case.)

We next proceed to introduce a sequence of feasible triplets for EC*, that is, as in (5.2).

Choose an *arbitrary* q-vector $\boldsymbol{\beta} = (\beta_1, \ldots, \beta_q) \le 0$, and consider the cost-per-stage

$$c^\beta(x, a) := c(x, a) - \sum_{i=1}^{q} \beta_i d_i(x, a) \quad \forall\ (x, a) \in \mathbb{K} \tag{6.4}$$

and the corresponding long-run expected average cost

$$J^\beta(\pi, \nu) := \limsup_{n \to \infty} \frac{1}{n} V_n^\beta(\pi, \nu),$$

where

$$V_n^\beta(\pi, \nu) := E_\nu^\pi \left[\sum_{t=0}^{n-1} c^\beta(x_t, a_t) \right].$$

By (2.5) and (2.6),

$$J^\beta(\pi, \nu) \le J_0(\pi, \nu) - \sum_{i=1}^{q} \beta_i J_i(\pi, \nu). \tag{6.5}$$

Moreover, by Assumption 3.1(b), (c), the cost function c^β is *nonnegative and* inf-*compact*. Therefore, by standard dynamic programming arguments, the optimal n-stage cost

$$v_n^\beta(x) := \inf_{\pi \in \Pi} V_n^\beta(\pi, x) \text{ for } x \in \mathrm{X} \text{ and } n = 1, 2, \ldots,$$

with $v_0^\beta(\cdot) \equiv 0$, satisfies that

$$v_n^\beta(x) = \inf_{a\in \mathrm{A}(x)} \left[c^\beta(x,a) + \int_{\mathrm{X}} v_{n-1}^\beta(y) Q(dy|x,a) \right] \quad \forall\ x \in \mathrm{X}. \tag{6.6}$$

Now, for $n = 1, 2, \ldots$, let

$$\rho_n^\beta := \inf_{x\in \mathrm{X}} [v_n^\beta(x) - v_{n-1}^\beta(x)], \quad m_n^\beta := \rho_n^\beta + m_{n-1}^\beta, \tag{6.7}$$

with $m_0^\beta := 0$, and

$$u_n^\beta(x) := v_n^\beta(x) - m_n^\beta.$$

Then, for all $x \in \mathrm{X}$ and $n = 1, 2, \ldots$, we may rewrite (6.6) as

$$\rho_n^\beta + u_n^\beta(x) = \inf_{a\in \mathrm{A}(x)} \left[c^\beta(x,a) + \int_{\mathrm{X}} u_{n-1}^\beta(y) Q(dy|x,a) \right], \tag{6.8}$$

and we also have the following proposition.

PROPOSITION 6.2.

(a) $\{u_n^\beta(\cdot)\}$ *is a nondecreasing, sequence of nonnegative functions.*

(b) $\{\rho_n^\beta\}$ *is nondecreasing, and*

$$0 \le \rho_n^\beta \le \rho^* - \langle \mathbf{k}, \boldsymbol{\beta} \rangle \quad \forall\ n. \tag{6.9}$$

Proof. Part (a) follows from (6.7). To prove (b), first note that $\rho_n^\beta \ge 0$ because, as c^β is nonnegative, we have $v_n^\beta \ge v_{n-1}^\beta$. Moreover, by (6.6) and using the fact that $\inf u(\cdot) - \inf v(\cdot) \ge \inf[u(\cdot) - v(\cdot)]$ for any two functions $u(\cdot)$ and $v(\cdot)$, with $v(\cdot)$ bounded below, we get

$$v_n^\beta(x) - v_{n-1}^\beta(x) \ge \inf_{a\in \mathrm{A}(x)} \int_{\mathrm{X}} [v_{n-1}^\beta(y) - v_{n-2}^\beta(y)] Q(dy|x,a) \ge \rho_{n-1}^\beta,$$

and so $\{\rho_n^\beta\}$ is nondecreasing. On the other hand, by (6.8) and part (a),

$$\rho_n^\beta + u_n^\beta(x) \le c^\beta(x,a) + \int_{\mathrm{X}} u_n^\beta(y) Q(dy|x,a) \quad \forall\ (x,a) \in \mathbb{K}. \tag{6.10}$$

By Assumption 4.2, together with (6.6) and a straightforward induction argument, the function u_n^β is in $\mathbb{F}(\mathrm{X})$ for each n. Now let $\mu^* \in \Delta_{\mathrm{s}}$ be as in (3.11) and (3.12), and integrate both sides of (6.10) with respect to μ^*. Then (6.4) and the invariance property in Definition 3.4(b) give that

$$\rho_n^\beta \le \rho^* - \sum_{i=1}^q \beta_i \langle \mu^*, d_i \rangle \le \rho^* - \sum_{i=1}^q \beta_i k_i,$$

and (6.9) follows. □

By (6.10), the triplets $(u_n^\beta, \rho_n^\beta, \boldsymbol{\beta})$ satisfy (5.2) for each $n = 1, 2, \ldots$ and $\boldsymbol{\beta} \le \mathbf{0}$. Furthermore, by Proposition 6.2(b), there exists a nonnegative number $\rho^\beta \le \rho^* - \langle \mathbf{k}, \boldsymbol{\beta} \rangle$ such that $\rho_n^\beta \uparrow \rho^\beta$. Now let us suppose that there is a number $\widehat{k} \ge 0$ such that

$$u_n^\beta(\cdot) \le \widehat{k}\widehat{w}(\cdot) \quad \forall\ n. \tag{6.11}$$

Then, by Proposition 6.2(a), there is a nonnegative function u^β in $\mathbb{F}(\mathrm{X})$ such that $u_n^\beta(x) \uparrow u^\beta(x)$ for all $x \in \mathrm{X}$. Therefore, letting $n \to \infty$ in (6.10), monotone convergence yields

$$\rho^\beta + u^\beta(x) \le c^\beta(x,a) + \int_{\mathrm{X}} u^\beta(y) Q(dy|x,a) \quad \forall\ (x,a) \in \mathbb{K},$$

which in turn gives

$$\rho^\beta + u^\beta(x) \le \inf_{a \in \mathrm{A}(x)} \left[c^\beta(x,a) + \int_{\mathrm{X}} u^\beta(y) Q(dy|x,a) \right] \quad \forall\ (x,a) \in \mathrm{X}. \tag{6.12}$$

Summarizing, we have described a general procedure to obtain feasible triplets $(u^\beta, \rho^\beta, \boldsymbol{\beta})$ for EC*. However, to actually solve CP, we need stronger hypotheses, as in the following result. (There are several ways in which one can get the *equality* in (6.12) and the policy f^β in (6.13): see [1, 3, 10, 11, 15, 18, 22, 26, 28, 31, 33, 41].)

THEOREM 6.3. *Suppose Assumptions* 3.1 *and* 4.2 *are satisfied. In addition, there exist a q-vector* $\boldsymbol{\beta} \le \mathbf{0}$ *and a stationary policy* $f^\beta \in \mathbb{F}$ *for which the equality holds in* (6.12), *and* $f^\beta(x) \in \mathrm{A}(x)$ *attains the minimum in* (6.12) *for all* $x \in \mathrm{X}$, *i.e.,*

$$\rho^\beta + u^\beta(x) = c^\beta(x, f^\beta) + \int_{\mathrm{X}} u^\beta(y) Q(dy|x, f^\beta) \quad \forall\ x \in \mathrm{X}. \tag{6.13}$$

Moreover, u^β *is such that*

$$\lim_{n \to \infty} \frac{1}{n} E_x^{f^\beta}[u^\beta(x_n)] = 0, \tag{6.14}$$

and, furthermore,

$$J_i(f^\beta, x) = k_i \quad \forall\ x \in \mathrm{X} \text{ and } i = 1, \ldots, q. \tag{6.15}$$

Then $J_0(f^\beta, \cdot)$ *is a constant, say,* $J_0(f^\beta, x) = J_0(f^\beta)$ *for all* $x \in \mathrm{X}$, *and* f^β *is optimal for* CP *in the sense that* $J_0(f^\beta) = \rho^*$, *and so*

$$\rho^\beta = \rho^* - \langle \mathbf{k}, \boldsymbol{\beta} \rangle.$$

Proof. As in the proof of (6.9),

$$\rho^\beta \le \rho^* - \langle \mathbf{k}, \boldsymbol{\beta} \rangle.$$

On the other hand, iteration of (6.13) and using (6.14) and (6.15) give

$$\rho^\beta = J_0(f^\beta) - \langle \mathbf{k}, \boldsymbol{\beta} \rangle.$$

Hence, as $J_0(f^\beta) \ge \rho^*$, we get

$$\rho^\beta \ge \rho^* - \langle \mathbf{k}, \boldsymbol{\beta} \rangle,$$

and the theorem follows. □

The following LQ example, which is similar to the "stochastic stabilization problem" in [11, 31] and the "mold level control problem" in [41], illustrates the ACOE approach in the previous paragraphs.

Example 6.4. Consider the scalar linear system

$$x_{t+1} = \theta_1 x_t + \theta_2 a_t + \xi_t, \quad t = 0, 1, \ldots, \tag{6.16}$$

with state and control spaces $\mathrm{X} = \mathbb{R}$ and $\mathrm{A}(x) \equiv \mathrm{A} = \mathbb{R}$ for all $x \in \mathrm{X}$, and nonzero coefficients θ_1, θ_2. The random disturbances ξ_t are i.i.d. with

$$E(\xi_0) = 0 \quad \text{and} \quad \sigma^2 := E(\xi_0^2) < \infty$$

and independent of the initial state x_0. The CP we are concerned with is given by (2.5)–(2.8) with $q = 1$, constraint constant $k_1 \geq 0$, and costs

$$c(x, a) := c_1 x^2 + c_2 a^2 \quad \text{and} \quad d_1(x, a) := (x - a)^2, \tag{6.17}$$

where c_1 and c_2 are positive constants. By the "quadratic" nature of the costs, we will consider only initial distributions $\nu \in \mathbb{P}(\mathrm{X})$ with a finite second moment, i.e., $\int x^2 \nu(dx) < \infty$.

Verification of Assumption 3.1. Parts (b), (c), and (d) in Assumption 3.1 trivially hold (concerning (d), see Remark 3.6). To verify (a), observe that the *unconstrained minimum* ρ_1 in (6.1)–(6.2) is given by

$$\rho_1 = J_1(f_1) = 0, \tag{6.18}$$

which is attained by the *strictly optimal* policy $f_1(x) := x$ for all $x \in \mathrm{X}$. Thus $J_1(f_1) \leq k_1$. In fact, for any given constraint constant $k_1 \geq 0$, the stationary policy, say, $f(x) := x + k_1^{\frac{1}{2}}$, satisfies that

$$J_1(f) := J_1(f, x) = k_1 \quad \forall\, x \in \mathrm{X} \text{ (cf. (6.15))}. \tag{6.19}$$

Now let C_0 be the unique positive solution of the quadratic equation

$$(c_2 + \theta_2^2 C)C = c_1 c_2 + (c_2 \theta_1^2 + c_1 \theta_2^2)C, \tag{6.20}$$

and let

$$\widehat{f}_0 := (c_2 + C_0 \theta_2^2)^{-1} C_0 \theta_1 \theta_2.$$

If the constants θ_1, θ_2, and $\widehat{f}_0$ are such that

$$|\theta_1 - \theta_2 \widehat{f}_0| < 1, \tag{6.21}$$

then it is well known that the stationary policy

$$f_0(x) := -\widehat{f}_0 x \quad \forall\, x \in \mathrm{X} \tag{6.22}$$

is *strictly optimal* for J_0 and that the *unconstrained minimum* for J_0 (as in (6.1), (6.2)) is

$$\rho_0 = J_0(f_0) = C_0 \sigma^2; \tag{6.23}$$

see, for instance, [11, 18, 31]. Hence Assumption 3.1(a) holds *at least* when (6.21) is satisfied.

Verification of Assumption 4.2. Let $w(x,a)$ and $\widehat{w}(x)$ be as in (4.1); in our present case, they are given by

$$w(x,a) := 1 + c_1x^2 + c_2a^2 \quad \text{and} \quad \widehat{w}(x) := 1 + c_1x^2. \tag{6.24}$$

As $d_1(x,a) \le 2(x^2+a^2)$, it is clear that part (a) in Assumption 4.2 holds. To verify part (b), note that, by (6.16), for any nonnegative measurable function u on X, we have

$$\int_{\mathrm{X}} u(y)Q(dy|x,a) = E[u(x_{t+1}) \mid x_t = x, a_t = a] = E[u(\theta_1 x + \theta_2 a + \xi_0)].$$

Therefore, *if u is of the form $u(x) = u_1x^2 + u_2$, then* (as $E(\xi_0) = 0$ and $E(\xi_0^2) = \sigma^2$)

$$\int_{\mathrm{X}} u(y)Q(dy|x,a) = u_1(\theta_1 x + \theta_2 a)^2 + u_1\sigma^2 + u_2. \tag{6.25}$$

It follows that Assumption 4.2(b) holds for $\widehat{w}$ in (6.24); that is, for some constant m sufficiently large,

$$\int_{\mathrm{X}} \widehat{w}(y)Q(dy|x,a) \le m \cdot w(x,a) \quad \forall\ (x,a) \in \mathbb{K}.$$

Illustration of Proposition 6.1. First, observe the following lemma.

LEMMA 6.5. *Let $f \in \mathbb{F}$ be a stationary policy given by $f(x) := -\widehat{f}x$ for all $x \in \mathrm{X}$, and let $\widehat{\theta} := \theta_1 - \theta_2\widehat{f}$, where θ_1, θ_2 are the coefficients in* (6.16). *If $|\widehat{\theta}| < 1$, then for all $x \in \mathrm{X}$*

$$J_0(f,x) \equiv J_0(f) = (c_1 + c_2\widehat{f}^2)\sigma^2/(1-\widehat{\theta}^2), \tag{6.26}$$

$$J_1(f,x) \equiv J_1(f) = (1+\widehat{f})^2\sigma^2/(1-\widehat{\theta}^2). \tag{6.27}$$

In particular, for $f_0(x) := -\widehat{f}_0x$ and $f_1(x) := x$ in (6.22) *and* (6.18), *respectively, we have*

$$J_1(f_0) = (1+\widehat{f}_0)^2\sigma^2/(1-\widehat{\theta}_0^{\,2}), \quad \textit{with} \quad \widehat{\theta}_0 := \theta_1 - \theta_2\widehat{f}_0, \tag{6.28}$$

$$J_0(f_1) = (c_1+c_2)\sigma^2/(1-\widehat{\theta}_1^{\,2}), \quad \textit{with} \quad \widehat{\theta}_1 := \theta_1 + \theta_2. \tag{6.29}$$

Proof. Replacing a_t in (6.16) with $a_t := f(x_t) = -\widehat{f}x_t$, we obtain

$$x_t = (\theta_1 - \theta_2\widehat{f})x_{t-1} + \xi_{t-1} = \widehat{\theta}x_{t-1} + \xi_{t-1} \quad \forall\ t = 1,2,\ldots.$$

Hence, for all $t = 1,2,\ldots,$

$$x_t = \widehat{\theta}^t x_0 + \sum_{j=0}^{t-1} \widehat{\theta}^j \xi_{t-1-j},$$

and so

$$E_x^f(x_t^2) = \widehat{\theta}^{2t}x^2 + (\sigma^2(1-\widehat{\theta}^{2t}))/(1-\widehat{\theta}^2).$$

This yields that

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{t=0}^{n-1} E_x^f(x_t^2) = \sigma^2/(1-\widehat{\theta}^2) \quad \forall\, x \in \mathrm{X}. \tag{6.30}$$

Now note that, using $a = f(x) = -\widehat{f}x$ in (6.17), we get

$$c(x,a) = (c_1 + c_2\widehat{f}^2)x^2 \quad \text{and} \quad d_1(x,a) = (1+\widehat{f})^2 x^2 \tag{6.31}$$

for all $x \in \mathrm{X}$. Finally, inserting (6.31) and (6.30) in (2.5), (2.6), we obtain (6.26) and (6.27). □

From (6.28) and Proposition 6.1, we conclude the following (see (6.50) and Figure 6.1).

COROLLARY 6.6. *If the constraint constant k_1 is such that $k_1 \geq J_1(f_0)$, then the policy $f_0 \in \mathbb{F}$ in* (6.22) *is optimal for* CP*, and the optimal value ρ^* of* CP *(see* (2.9)*) is the unconstrained minimum $\rho_0 = C_0\sigma^2$ in* (6.23).

Illustration of (6.4)–(6.8) *and Theorem* 6.3. Consider the cost function $c^\beta(x,a)$ in (6.4) with $q = 1$, $\beta \leq 0$, and $c(x,a)$ and $d_1(x,a)$ as in (6.17), i.e.,

$$c^\beta(x,a) := c_1x^2 + c_2a^2 - \beta(x-a)^2. \tag{6.32}$$

From (6.32), (6.6), and a straightforward induction argument (using (6.25)), we obtain the following.

LEMMA 6.7. *Let $v_0(\beta) = m_0^\beta = 0$. For each $x \in X$ and $n = 1, 2, \ldots$, the stationary policy*

$$f_n^\beta(x) := -f_n(\beta) \cdot x, \tag{6.33}$$

with coefficient

$$f_n(\beta) := (\beta + v_{n-1}(\beta)\theta_1\theta_2)/(c_2 - \beta + v_{n-1}(\beta)\theta_2^2), \tag{6.34}$$

realizes the minimum in (6.6)*, and the "value iteration" function $v_n^\beta(\cdot)$ is given by*

$$v_n^\beta(x) = v_n(\beta)x^2 + m_n^\beta \tag{6.35}$$

with coefficients

$$v_n(\beta) = c_1 + c_2 f_n(\beta)^2 - \beta[1+f_n(\beta)]^2 + v_{n-1}(\beta)[\theta_1 - f_n(\beta)\theta_2]^2, \tag{6.36}$$

$$m_n^\beta := v_{n-1}(\beta)\sigma^2 + m_{n-1}^\beta. \tag{6.37}$$

From (6.34) and (6.36), it follows, in particular, that (6.6) can be expressed as in (6.8) with

$$\rho_n^\beta := v_{n-1}(\beta)\sigma^2 \quad \text{and} \quad u_n^\beta(x) := v_n(\beta)x^2 \quad \forall\, x \in \mathrm{X},\ n = 1, 2, \ldots. \tag{6.38}$$

By Proposition 6.2, we know that

$$\rho_n^\beta \uparrow \rho^\beta \quad \text{and} \quad u_n^\beta(x) \uparrow u^\beta(x) \quad \forall\, x \in \mathrm{X}, \quad \text{as} \quad n \to \infty. \tag{6.39}$$

We now wish to show that the limiting values satisfy (6.13) with *equality*, that is, the ACOE

$$\rho^\beta + u^\beta(x) = \min_{a\in \mathrm{A}(x)} \left[c^\beta(x,a) + \int_X u^\beta(y) Q(dy|x,a) \right] \tag{6.40}$$

holds for all $x \in \mathrm{X}$ (note that we have written "min" rather than "inf"), and, in addition, that u^β is in $\mathbb{F}(\mathrm{X})$. To do this, we will use (6.38) to compute the limits in (6.39) as follows.

Inserting (6.34) in (6.36), a direct calculation shows that we can express $v_n(\beta)$ as a linear-fractional transformation of $v_{n-1}(\beta)$, namely,

$$v_n(\beta) = \frac{P + Q v_{n-1}(\beta)}{R + S v_{n-1}(\beta)}$$

with coefficients

$$P := c_1 c_2 - (c_1 + c_2)\beta, \quad Q := c_1\theta_2^2 + c_2\theta_1^2 - \beta(\theta_1 - \theta_2)^2,$$

$$R := c_2 - \beta, \quad \text{and} \quad S := \theta_2^2.$$

Therefore, standard arguments (see [11] or [18], for instance) show that

$$v_n(\beta) \to v(\beta) \quad \text{as} \quad n \to \infty, \tag{6.41}$$

where $v(\beta)$ is the unique positive solution of the quadratic equation

$$v(\beta) = \frac{P + Q v(\beta)}{R + S v(\beta)}.$$

Therefore, by (6.38) and (6.39), the ACOE (6.40) holds with

$$\rho^\beta = v(\beta)\sigma^2 \quad \text{and} \quad u^\beta(x) = v(\beta)x^2, \tag{6.42}$$

and, moreover, the right-hand side of (6.40) is minimized by the stationary policy

$$f^\beta(x) = -f(\beta)x, \quad \text{with} \quad f(\beta) := [\beta + v(\beta)\theta_1\theta_2]/[c_2 - \beta + v(\beta)\theta_2^2]. \tag{6.43}$$

Observe that this policy can also be obtained from (6.41), letting $n \to \infty$ in (6.34). On the other hand, from the calculations leading to (6.30), we see that (6.14) holds provided that

$$|\theta(\beta)| < 1 \quad \text{with} \quad \theta(\beta) := \theta_1 - \theta_2 f(\beta). \tag{6.44}$$

Summarizing, (6.13) and (6.14) hold for the CP related to (6.16)–(6.17) provided that $\beta \le 0$ satisfies (6.44). Assumming that the latter is true, we can now use Theorem 6.3 to find an optimal policy for CP when the nonnegative constraint constant k_1 is such that $k_1 < J_1(f_0)$; otherwise, we can use Corollary 6.6. With this in mind, observe that (6.26) and (6.27) yield

$$J_0(f^\beta) = [c_1 + c_2 f(\beta)^2]\sigma^2/[1 - \theta(\beta)^2] \tag{6.45}$$

and

$$J_1(f^\beta) = [1 + f(\beta)]^2\sigma^2/[1 - \theta(\beta)^2], \tag{6.46}$$

respectively. Hence Theorem 6.3 yields the following corollary.

COROLLARY 6.8. *Suppose that* $0 \le k_1 < J_1(f_0)$. *If* $\beta \le 0$ *satisfies* (6.44) *and that*

$$J_1(f^\beta) = k_1, \tag{6.47}$$

then the policy $f^\beta \in \mathbb{F}$ *in* (6.43) *is optimal for the* CP *associated to* (6.16)–(6.17), *and the optimal value* ρ^* *of* CP *is given by*

$$\rho^* = J_0(f^\beta) = \rho^\beta + k_1\beta, \tag{6.48}$$

with $J_0(f^\beta)$ *and* ρ^β *as in* (6.45) *and* (6.42), *respectively.*

Observe that, for given values of the coefficients θ_i and c_i in (6.16) and (6.17), one can actually find $\beta \le 0$ that satisfies (6.44) and (6.47).

Graphical interpretation of Corollaries 6.6 *and* 6.8. Let $\Gamma \subset \mathbb{R}^{q+1}$ be as in (6.3), that is, the set of cost vectors

$$\mathbf{J}(\pi,\nu) := (J_0(\pi,\nu), J_1(\pi,\nu), \dots, J_q(\pi,\nu)).$$

It can be shown that Γ is a convex set—see [36, 38], for instance. Given a q-vector $\boldsymbol{\beta} \le \mathbf{0}$, let $\widehat{\boldsymbol{\beta}} := (1, -\boldsymbol{\beta}) \in \mathbb{R}^{q+1}_+$. Then we may write (6.5) as

$$J^\beta(\pi,\nu) \le \langle \widehat{\boldsymbol{\beta}}, \mathbf{J}(\pi,\nu)\rangle. \tag{6.49}$$

If a pair (π^*,ν^*) is a minimum pair for J^β, then the equality holds in (6.49), and (π^*,ν^*) is said to be a $\boldsymbol{\beta}$-*Pareto pair* for the multiobjetive control problem associated to $\mathbf{J}(\pi,\nu)$. The set $\Gamma^* \subset \Gamma$ of all of the cost vectors $\mathbf{J}(\pi^*,\nu^*)$ corresponding to $\boldsymbol{\beta}$-Pareto pairs for $\boldsymbol{\beta} \le \mathbf{0}$ is called the *Pareto set* of the multiobjective problem. In particular, for the problem (6.16), (6.17), the Pareto set Γ^* consists of the vectors

$$\mathbf{j}(\beta) := (J_0(f^\beta), J_1(f^\beta)) \in \mathbb{R}^2 \tag{6.50}$$

with $\beta \le 0$ and $J_i(f^\beta)$ as in (6.45), (6.46); see Figure 6.1. The"extreme points" of Γ^* are the vectors

$$\mathbf{j}_0 := (J_0(f_0), J_1(f_0)) = (\rho_0, J_1(f_0)), \quad \mathbf{j}_1 := (J_0(f_1), J_1(f_1)) = (J_0(f_1), 0); \tag{6.51}$$

see (6.18), (6.23), (6.28), and (6.29). The graphical interpretation of Corollaries 6.6 and 6.8 is now obvious. In particular, in the context of Corollary 6.8, finding an optimal policy f^β for CP amounts to determining $\beta \le 0$ for which the second component of $\mathbf{j}(\beta)$ coincides with the constraint constant k_1, that is, $J_1(f^\beta) = k_1$, as in (6.47).

We conclude the paper with an example of a control system which is "multichain" in the sense that, for each policy π (even if $\pi = f$ is stationary), the average costs in (2.5), (2.6) may vary with the initial distribution ν.

Example 6.9. Consider the following two-dimensional variant of Example 6.4:

$$(x_{t+1}, y_{t+1}) = (\theta_1 x_t + \theta_2 a_t + \theta_3(y_t)\xi_t, y_t) \quad \forall\ t = 0, 1, \dots$$

with state space $\mathrm{X} = \mathbb{R} \times [\lambda, \infty)$, where $\lambda > 0$ is a constant and $\theta_3(y)$ is a nondecreasing, nonnegative, and continuous function on $[\lambda, \infty)$. The constants θ_1, θ_2 and the disturbances ξ_t are as in Example 6.4, except that now the common distribution of the ξ_t is also assumed to be symmetric with respect to the origin. The cost-per-stage functions are similar to those in (6.17):

$$c((x,y),a) := c_1 x^2 + c_2 a^2 + c_3 y^3, \quad d_1((x,y),a) := (x-a)^2, \tag{6.52}$$

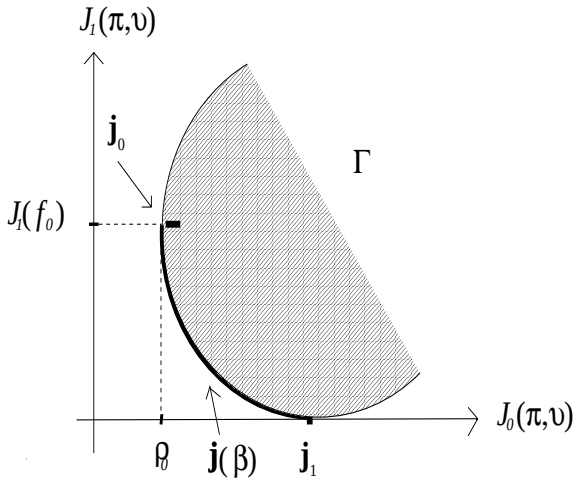

FIG. 6.1. *See* (6.3), (6.50), *and* (6.51).

where c_1, c_2, c_3 are positive constants. Finally, we suppose that (6.21) is satisfied, and so Assumption 3.1 holds.

For each initial state (x_0, y_0) with $y_0 = y \geq \lambda$, let ν_y be an initial distribution concentrated on the set $\{(x, y)|x \in \mathbb{R}\}$. Moreover, let $k_1 \geq 0$ be the constraint constant, and define $f_0 \in \mathbb{F}$ as

$$f_0(x, y) := f_0(x) = -\widehat{f}_0 x \quad \forall\ (x, y) \in \mathrm{X} \quad \text{(see (6.22))}.$$

Then, as in Corollary 6.6, one can see that, if $J_1(f_0, \nu_\lambda) \leq k_1$, then f_0 is optimal for the CP with cost functions in (6.52), and the CP's optimal value is

$$\rho^* = \rho_0 = C_0(\theta_3(\lambda)\sigma)^2 + c_3\lambda^3$$

with C_0 as in (6.23).

A NONLINEAR FILTERING APPROACH TO CHANGEPOINT DETECTION PROBLEMS: DIRECT AND DIFFERENTIAL-GEOMETRIC METHODS*

M. H. VELLEKOOP† AND J. M. C. CLARK‡

Abstract. A benchmark change detection problem is considered which involves the detection of a change of unknown size at an unknown time. Both unknown quantities are modelled by stochastic variables, which allows the problem to be formulated within a Bayesian framework. It turns out that the resulting nonlinear filtering problem is much harder than the well-known detection problem for *known* sizes of the change, and in particular that it can no longer be solved in a recursive manner. An approximating recursive filter is therefore proposed, which is designed using differential-geometric methods in a suitably chosen space of unnormalized probability densities. The new nonlinear filter can be interpreted as an adaptive version of the celebrated Shiryayev–Wonham equation for the detection of a priori known changes, combined with a modified Kalman filter structure to generate estimates of the unknown size of the change. This intuitively appealing interpretation of the nonlinear filter and its excellent performance in simulation studies indicate that it may be of practical use in realistic change detection problems.

Key words. change detection, nonlinear filtering, differential geometry

1. Introduction.

The problem of detecting parameter changes in dynamical systems on the basis of noisy observations has been researched extensively over the last twenty years. Successful applications in many fields have guaranteed a wide interest in the subject and the literature dealing with it is extensive. For good recent surveys of the field and further references, the reader is referred to the papers by Basseville [2], Iserman [13], Lai [21], and Willsky [26], and the book by Basseville and Nikiforov [3]. As is pointed out in [2], the basic method proposed in most of the literature on change detection consists of two steps. First, the problem is transformed into a standard problem by generating certain *residuals*: change indicating signals which are ideally close to zero when no change occurs. Then, in a separate second step, sophisticated statistical methods are developed to solve the resulting detection problem in terms of these residuals. In this paper we will provide a contribution to the second step; the first step will very much depend on the particular application that one wishes to consider, and it is therefore not treated here.

The statistical tools used in the second step usually originate in the field of sequential hypothesis testing, and a wide variety of results concerning their use in change detection problems is now available [21]. Typically these tests compare a certain functional of the observations with a threshold, and an alarm is raised as soon as this threshold is reached. Important examples of such schemes include the celebrated

CUSUM and generalized likelihood ratio (GLR) schemes.

In this paper we want to propose a different approach, in which change detection is considered to be an on-line estimation problem in which a dynamical system possesses certain parameters which may exhibit sudden changes that need to be detected [8]. In our Bayesian formulation of the problem we assume that *both* the time *and* the size of the change are unknown a priori, thus acknowledging the fact that in many practical situations the behavior of the residual after the change is not completely known and detection is thus necessarily linked to estimation. In practical detection problems, one does not only want to know *that* a change has occurred; one also wants to obtain on-line estimates of relevant statistics *after* the change.

We do not consider the problem in which one tries to detect changes off-line, or where one tries to estimate the *time* of the change. GLR methods and maximum likelihood estimators have been defined for such problems; see, for example, the analysis in [20]. In the recent paper [6] results concerning such off-line methods are derived under the asumption that one does not exactly know the correct model after the change (although the assumed model should be "close" to the correct model in a predescribed sense). Those results on the off-line detection problem are in that sense complementary to the methods we will propose here, but since their goal and assumptions differ from ours, we redirect the reader to the reference given above for further information.

In a continuous-time framework, we can define a basic change detection problem concerning a simple jump process, which is equal to zero up to a certain random time τ, then jumps to a random value X, after which it stays constant again. We assume that such a signal can be observed in white noise, and the purpose is to study the conditional distribution of the signal given the σ-algebra generated by all the observations up to the current time t and relevant statistics generated by this conditional distribution. If the value after the change X is known a priori, one can find an explicit stochastic differential equation for the Bayesian a posteriori probability that a change has occurred—the celebrated Shiryayev–Wonham equation [22, 28]. In fact, this statistic can still be calculated recursively if X is known to belong to a finite set of possible values. The problem can then be solved using the theory of hidden Markov models [10].

However, if there exists an infinity of possible jump sizes X, then the problem becomes much harder, since the detection and estimation problem now become closely interrelated. The problem can be addressed using the nonlinear filtering theory for discontinuous stochastic processes, and the optimal nonlinear filter for this case has been derived in [11]. As is often the case in nonlinear filtering problems [7], this filter does not admit a finite-dimensional recursive implementation. However, since the conditional probability distribution of the process based on the noisy observations can be derived explicitly, this may be used as a starting point for approximations which are suboptimal yet can be implemented recursively.

In this paper we will formulate and study such an approximation to the optimal filter for processes containing a jump of unknown size. Our approach extends a powerful statistical projection technique, which was recently introduced by Brigo, Hanzon, and LeGland in order to filter nonlinear diffusions [4, 5, 12], and which is based on differential-geometric methods in statistical information theory [1, 17, 18]. We will show that the resulting filter can be parametrized as a modified Kalman filter which feeds an adaptive version of the Shiryayev–Wonham filter for *known* changes that we mentioned earlier. This interpretation may help to explain its excellent performance when compared to other detection schemes, as will be illustrated in a number of

simulation studies.

The structure of this paper is as follows. In the next section we introduce the stochastic change detection model, and derive the nonlinear filter equations for such models. In sections 3 and 4 we formulate two recursive filtering algorithms, which are based on information-theoretic approximations and approximation of conditional moments, respectively. In section 5 we discuss the relationship between these two filters. In sections 6 and 7 we introduce and analyze a three-dimensional nonlinear filter based on the results derived in earlier sections, and we illustrate the performance of this filter in some simulation studies in section 8. We finish with conclusions and suggestions for further research in the last section.

2. The change detection model and optimal filter equations. Let $(\Omega, \mathcal{F}, P)$ be the complete canonical probability space for Brownian motion, that is, $\Omega = C([0,\infty[)$, the set of all scalar continuous functions on $\mathbb{R}^+$, $\mathcal{F}$ the usual σ-algebra generated by the topology of uniform convergence on compacta, and P the Wiener measure on $\mathcal{F}$. Let $\{\mathcal{F}_t, t \geq 0\}$ be a filtration satisfying the usual conditions, i.e., an increasing family of σ-algebras which is right-continuous and such that $\mathcal{F}_0$ contains all P-null sets. We will use $\mathbb{P}(A)$ as a shorter notation for $P(\{\omega \in \Omega : A(\omega)\})$ in this paper, where $A(\omega)$ is a condition on ω, and we will denote the expectation operator by $\mathbb{E}$, so for a stochastic variable Z we use $\mathbb{E}Z$ to denote $\int_\Omega Z(\omega) dP(\omega)$.

Consider the signal

$$S_t = \begin{cases} 0, & 0 \leq t < \tau, \\ X, & t \geq \tau, \end{cases} \tag{2.1}$$

where $X \in \mathbb{R}$ and $\tau \in \mathbb{R}^+$ are two independent finite random variables on Ω with distribution functions F, G, respectively. We will assume that X and τ have probability densities f and g, so $\mathbb{P}(X \leq x) = F(x) = \int_{-\infty}^{x} f(u)du$ for all $x \in \mathbb{R}$ and $\mathbb{P}(\tau \leq r) = G(r) = \int_0^r g(u)du$ for all $r \in \mathbb{R}^+$. We assume that f and g are both strictly positive on their domains $\mathbb{R}$ and $\mathbb{R}^+$ in this paper, unless we explicitly state otherwise. We will use $E_t = \mathbf{1}_{\{t \geq \tau\}}$ to denote a unit jump process, so $S_t = XE_t$ for all $t \geq 0$.

We will suppose that the signal S_t can be observed in additive white noise. We therefore define a scalar observation process $\{Y_t^\epsilon, t \geq 0\}$ by

$$dY_t^\epsilon \;=\; S_t\, dt \;+\; \epsilon\, dW_t, \qquad\qquad Y_0^\epsilon = 0, \tag{2.2}$$

where $\{(W_t, \mathcal{F}_t), t \geq 0\}$ is a standard Brownian motion process on $(\Omega, \mathcal{F}, P)$, which is independent of both X and τ, and where ϵ is a real positive parameter representing the noise intensity.

Let $\mathcal{S}_t$ be a second filtration which is contained in $\mathcal{F}_t$ and satisfies the usual conditions as well, such that both X and $\mathbf{1}_{\{t \geq \tau\}}$ are $\mathcal{S}_t$-measurable for all $t \geq 0$, i.e., X is $\mathcal{S}_0$-measurable and τ is a stopping time with respect to $\mathcal{S}_t$. The σ-algebra $\mathcal{S}_t$ then represents the *state information* up to time t. Likewise, we define $\mathcal{Y}_t^\epsilon$ as the σ-algebra generated by the observation process up to time t:

$$\mathcal{Y}_t^\epsilon \;\stackrel{\text{def}}{=}\; \sigma(\{Y_s^\epsilon, 0 \leq s \leq t\}) \;\subset\; \mathcal{F}_t.$$

We are interested in the analysis of the conditional laws of the signal S_t, given the observations record up to time t. In particular, we would like to estimate the magnitude of the jump X at time t and the probability that the jump has already occurred before time t:

$$\mathbb{E}[X \mid \mathcal{Y}_t^\epsilon], \qquad \mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon).$$

Since such statistics can be calculated from the conditional distribution of S_t given the observation record $\mathcal{Y}_t^\epsilon$, we will study this conditional law of the signal on a fixed finite time interval $[0, T]$. Our results concerning the postjump time period are therefore conditioned on the set $\{\omega \in \Omega : \tau(\omega) \leq T\}$.

We derive an expression for the conditional distribution of the signal through the Kallianpur–Striebel formula and Girsanov's theorem. One may show that the necessary conditions for these methods to be applicable are indeed satisfied [14] if there exists a $\delta > 0$ such that

$$\mathbb{E}\ \exp[\,\delta X^2\,]\ <\ \infty, \tag{2.3}$$

and we will assume this condition to be satisfied in the rest of the paper. We then find for the conditional distribution of S_t given the observations [14, 27]:

$$\mathbb{P}(S_t \in B \mid \mathcal{Y}_t^\epsilon) = (\rho_t^\epsilon)^{-1} \int_{\mathbb{R}} \int_0^\infty \mathbf{1}_B(x\mathbf{1}_{\{t \geq r\}})\ e^{\frac{Z(x,r,t)}{\epsilon^2}}\, dG(r)dF(x), \tag{2.4}$$

where B is a Borel-measurable set, $\mathbf{1}_B$ is the indicator function for the set B, ρ_t^ϵ is a normalization factor which is equal to the double integral of the right-hand side of this expression for $B = \mathbb{R}$, and

$$\begin{aligned} Z(x,r,t) &= \int_0^t x\,\mathbf{1}_{\{s \geq r\}}\, dY_s^\epsilon\ -\ \frac{1}{2}\int_0^t (x\,\mathbf{1}_{\{s \geq r\}})^2\, ds \\ &= \left[\, x\,(Y_t^\epsilon - Y_r^\epsilon)\ -\ \frac{x^2}{2}\,(t-r)\,\right] \mathbf{1}_{\{r \leq t\}}. \end{aligned}$$

After decomposing the inner integral in (2.4) into the intervals $[0, t[$ and $[t, \infty[$ we find

$$\begin{aligned} &\mathbb{P}(S_t \in B \mid \mathcal{Y}_t^\epsilon) \\ &=\ (\rho_t^\epsilon)^{-1} \int_B \int_0^t\ e^{\frac{Z(x,r,t)}{\epsilon^2}}\, dG(r)dF(x)\ +\ (\rho_t^\epsilon)^{-1}\ (1 - G(t)) \int_B \delta_0(x)\, dx. \end{aligned}$$

Here and in what follows we will allow the slight abuse of notation which represents the Dirac measure with its unit mass in the origin as an integral over a Dirac density $\delta_0(x)$, i.e., $\int_B \delta_0(x)dx = \mathbf{1}_{\{0 \in B\}}$. For $B = \mathbb{R}$ we obtain an expression for the normalization factor:

$$\rho_t^\epsilon = \int_{\mathbb{R}} \int_0^t\ e^{\frac{Z(x,r,t)}{\epsilon^2}}\, dG(r)dF(x)\ +\ (1 - G(t)).$$

We summarize the derived results in the following theorem [11].

THEOREM 2.1. *Under the assumptions mentioned above, the conditional probability density of the signal S_t, given the observations $\{Y_s^\epsilon, 0 \leq s \leq t\}$, is given by*

$$(\rho_t^\epsilon)^{-1}\,[\ (1 - G(t))\,\delta_0(x)\ +\ q_t^\epsilon(x)\ ], \tag{2.5}$$

where

$$q_t^\epsilon(x) = f(x) \int_0^t g(r)\ \exp\left[\frac{x}{\epsilon^2}\,(Y_t^\epsilon - Y_r^\epsilon) - \frac{x^2}{2\epsilon^2}\,(t-r)\right] dr,$$

$$\rho_t^\epsilon = 1 - G(t) + \int_{\mathbb{R}} q_t^\epsilon(x)\,dx.$$

Using Îto's differentiation rule, one may easily check that the density $q_t^\epsilon(x)$ satisfies the following Îto stochastic differential equation,

$$dq_t^\epsilon(x) \;=\; f(x)g(t)\,dt \;+\; \frac{x}{\epsilon^2} q_t^\epsilon(x)\,dY_t^\epsilon\,, \tag{2.6}$$

with initial value $q_0^\epsilon(x) = 0$ for all $x \in \mathbb{R}$. This is the Duncan–Mortensen–Zakai equation of nonlinear filtering for the conditional distribution outside the origin, and it may be derived directly using the infinitesimal generator of the Markov process $\{S_t,\, t \geq 0\}$. The Duncan–Mortensen–Zakai equation suggests that to calculate the optimal filter estimates we have to solve a stochastic partial differential equation online. It can indeed be shown that no finite-dimensional sufficient statistic exists for this problem. Since we need such a finite-dimensional statistic, which can be updated online in a recursive manner for practical implementation, we will propose and analyze finite-dimensional approximations to the infinite-dimensional optimal filter objects in the following sections.

3. Differential-geometric approximations. The first finite-dimensional approximation that we wish to consider uses projection operators in a space of unnormalized probability densities to map the infinite-dimensional optimal filtering objects onto fixed finite-dimensional structures. The appropriate framework for this approximation method is given by the differential-geometrical theory of statistical information and in particular the theory of statistical manifolds. For an excellent introduction to these relatively new fields, the reader is referred to the book by Amari [1] for the general theory and to the papers by Kulhavý [17, 18, 19] for its application to parameter estimation problems. Most important for the approach we wish to take here is the recent application of differential-geometric methods to the filtering problem for nonlinear diffusions [4, 5, 12]. Our analysis forms an extension of the work reported there, and we have therefore tried to keep our notation consistent with these papers whenever possible.

The main idea of our approach will be that we define a finite-dimensional statistical manifold $\mathcal{H}^{1/2}$ in the infinite-dimensional space of unnormalized probability densities. A basis will be derived for the tangent space in every point of this manifold, and we can use these to define a local projection operator which maps the infinitesimal increments generated by the nonlinear filtering equations onto such tangent spaces. The resulting stochastic vector field on $\mathcal{H}^{1/2}$ then defines our nonlinear filter.

In order to use a Hilbert space structure, we will work in the space of square roots of unnormalized probability densities. Let $\mathcal{M}$ be the set of all (not necessarily normalized) finite nonnegative measures κ on $\mathbb{R}$ which are absolutely continuous with respect to Lebesgue measure and have Radon–Nikodym derivatives p which are strictly positive Lebesgue-almost everywhere. Then we have that the function $\sqrt{p}:\ x \mapsto \sqrt{p(x)}$ is an element of $\mathcal{L}^2$, the Hilbert space of Lebesgue-square integrable functions from $\mathbb{R}$ to $\mathbb{R}^+ \setminus \{0\}$. Denote the subspace of $\mathcal{L}^2$ consisting of such square roots of strictly positive densities by $\mathcal{R}$. We define on it a metric $d_{\mathcal{R}}$ induced by the norm

$\|\cdot\|_{\mathcal{L}^2}$, which in turn defines the *Hellinger metric* $d_{\mathcal{M}}$ on the set of measures κ we started with:

$$d_{\mathcal{M}}(\kappa_1,\kappa_2) \;=\; d_{\mathcal{R}}(\sqrt{p_1},\sqrt{p_2}) = \|\sqrt{p_1}-\sqrt{p_2}\|_{\mathcal{L}^2} = \sqrt{\int_{\mathbb{R}} (\,\sqrt{p_1(x)}-\sqrt{p_2(x)}\,)^2\,dx}.$$

To find a recursive approximation for the infinite-dimensional optimal filter, we have to define finite-dimensional structures in the infinite-dimensional space $\mathcal{R}$. We will therefore consider an $m+1$-dimensional manifold N (with $m\in\mathbb{N}$), which as a subset of $\mathcal{R}$ is imbedded in the larger Hilbert space $\mathcal{L}^2$. This means that N is locally homeomorphic to $\mathbb{R}^{m+1}$ and is thus described locally by a *chart*: if $\sqrt{p}\in N$, then there exists an open neighborhood $\mathcal{H}^{1/2}$ of $\sqrt{p}$ in N and a homeomorphism $\varphi:\mathcal{H}^{1/2}\to\Theta$ onto an open and convex subset Θ of $\mathbb{R}^{m+1}$. We will assume that there exists in fact one global and smooth coordinate chart for the entire manifold, so we will consider manifolds $\mathcal{H}^{1/2}$ defined by

$$\mathcal{H}^{1/2} \;=\; \{\sqrt{p(\cdot,\theta)}:\ \theta=(\theta_0,\theta_1,\dots,\theta_m)\in\Theta\} \;=\; \varphi^{-1}(\Theta),$$

where

$$\left\{\frac{\partial\varphi^{-1}(\theta)}{\partial\theta_0},\frac{\partial\varphi^{-1}(\theta)}{\partial\theta_1},\dots,\frac{\partial\varphi^{-1}(\theta)}{\partial\theta_m}\right\}$$

is assumed to be a set of linearly independent vectors in $\mathcal{L}^2$ for all $\theta\in\Theta$. To find the differential-geometric structure of such manifolds $\mathcal{H}^{1/2}$ around a point $\sqrt{p}\in\mathcal{H}^{1/2}$, we consider smooth maps $\alpha:\,]-\nu,\nu[\,\to\mathcal{H}^{1/2}$ ($\nu>0$) such that $\alpha(0)=\sqrt{p}$. The Fréchet derivative of α in zero $D\alpha(0)$, defined by

$$\lim_{t\to0}\frac{\|\alpha(t)-\alpha(0)-D\alpha(0)\cdot t\|_{\mathcal{L}^2}}{t} \;=\; 0,$$

can be interpreted as a tangent vector to the curve α on the manifold $\mathcal{H}^{1/2}$. We therefore define the tangent vector space $\mathcal{T}_{\sqrt{p}}\mathcal{H}^{1/2}$ in $\sqrt{p}$ to $\mathcal{H}^{1/2}$ as the set of *all* possible Fréchet derivatives $D\alpha(0)$ for all such maps α:

$$\mathcal{T}_{\sqrt{p}}\mathcal{H}^{1/2} \;=\; \{\,D\alpha(0):\ \alpha \text{ smooth map }]-\nu,\nu[\,\to\mathcal{H}^{1/2} \text{ with } \alpha(0)=\sqrt{p}\,\}.$$

This is a linear subspace of $\mathcal{L}^2$, which we may calculate more explicitly. Let $\alpha=\varphi^{-1}\circ\bar\alpha$, where $t\to\bar\alpha(t)$ is a smooth map from $]-\nu,\nu[$ to Θ with $\bar\alpha(0)=\theta$ for a fixed $\theta\in\Theta$. Then we may apply the chain rule to $\alpha:t\to\sqrt{p(\cdot,\bar\alpha(t))}$ to find

$$\begin{aligned} D\alpha(0) = D\sqrt{p(\cdot,\bar\alpha(t))}\,\Big|_{t=0} \;&=\; \sum_{k=0}^{m}\frac{\partial\sqrt{p(\cdot,\theta)}}{\partial\theta_k}\,\bar\alpha_k'(0) \\ &= \sum_{k=0}^{m}\frac{1}{2\sqrt{p(\cdot,\theta)}}\,\frac{\partial p(\cdot,\theta)}{\partial\theta_k}\,\bar\alpha_k'(0), \end{aligned}$$

which shows that

$$\mathcal{T}_{\sqrt{p(\cdot,\theta)}}\mathcal{H}^{1/2} \;=\; \operatorname{span}\bigcup_{k=0}^{m}\{B_k(\cdot,\theta)\},\qquad B_k(\cdot,\theta) \;=\; \frac{1}{2\sqrt{p(\cdot,\theta)}}\frac{\partial p(\cdot,\theta)}{\partial\theta_k}. \tag{3.1}$$

The functions $B_k(\cdot,\theta)$ are linearly independent since φ was assumed to be a chart, so they form a basis for the $m+1$-dimensional tangent space in the point $\sqrt{p(\cdot,\theta)}$ on the manifold. The inner products of the basis elements in $\mathcal{L}^2$ generate a matrix function $H(\theta)$:

$$\langle B_i(\cdot,\theta)\,,\, B_j(\cdot,\theta)\rangle_{\mathcal{L}^2} \;=\; \int_{\mathbb{R}} \frac{1}{4p(x,\theta)} \frac{\partial p(x,\theta)}{\partial \theta_i} \frac{\partial p(x,\theta)}{\partial \theta_j}\, dx \;\stackrel{\text{def}}{=}\; \tfrac{1}{4}\, H_{ij}(\theta).$$

In all points of the manifold $\sqrt{p(\cdot,\theta)} \in \mathcal{H}^{1/2}$ where this matrix is invertible, we can define an orthogonal projection operator Π_θ which maps linear subspaces of $\mathcal{L}^2$ containing the finite-dimensional tangent vector space (3.1) onto this tangent vector space, using the formula

$$v \;\stackrel{\Pi_\theta}{\longmapsto}\; \sum_{i=0}^{m} \left[\sum_{j=0}^{m} 4\,[H(\theta)]^{-1}_{ij}\, \langle v,\, B_j(\cdot,\theta)\rangle_{\mathcal{L}^2} \right] B_i(\cdot,\theta). \tag{3.2}$$

In this paper we will use a special class of parametrized families of densities, the finite-dimensional *unnormalized exponential families*. An unnormalized exponential family is given by

$$\mathcal{H}^{1/2} = \{\sqrt{p(\cdot,\theta)},\ \theta \in \Theta\}, \qquad\qquad p(x,\theta) \;=\; f(x)\, \exp\left[\sum_{k=0}^{m} \theta_k c_k(x) \right], \tag{3.3}$$

where m is a strictly positive integer, $\{c_0,\ldots,c_m\}$ is a set of linearly independent scalar functions on $\mathbb{R}$, and f is the probability density of the jump size X, as introduced in the previous section. The parameter vector $\theta = (\theta_0,\theta_1,\ldots,\theta_m)$ is restricted to lie in the parameter set Θ, which is an open nonempty convex subset of $\mathbb{R}^{m+1}$ satisfying

$$\Theta \subseteq \Theta_0 \;\stackrel{\text{def}}{=}\; \left\{ \theta \in \mathbb{R}^{m+1} \,:\, \int_{\mathbb{R}} f(x)\, \exp\left[\sum_{k=0}^{m} \theta_k c_k(x) \right] dx \,<\, \infty \right\}.$$

Throughout this paper we will use the manifold generated by $c_k(x) = x^k$ for $k = 0,1,\ldots,m$, with m an even strictly positive integer, and $\Theta = \{\theta \in \mathbb{R}^{m+1},\, \theta_m < 0\}$. On such manifolds, the differential-geometric structure turns out to be a particularly transparent one. The basis vectors of the tangent space in $\sqrt{p(\cdot,\theta)}$ are given by

$$B_k(x,\theta) \;=\; \frac{1}{2\sqrt{p(x,\theta)}} \frac{\partial p(x,\theta)}{\partial \theta_k} \;=\; \tfrac{1}{2} x^k \sqrt{p(x,\theta)} \tag{3.4}$$

for $k = 0,1,\ldots,m$, and if we define

$$\eta^k(\theta) \;\stackrel{\text{def}}{=}\; \int_{\mathbb{R}} c_k(x) p(x,\theta)\, dx \;=\; \int_{\mathbb{R}} x^k p(x,\theta)\, dx,$$

we find that the earlier defined inner product matrix $H(\theta)$ for the basis elements of the tangent space in a point $\sqrt{p(\cdot,\theta)}$ on the manifold is equal to

$$H_{ij}(\theta) = 4\, \langle B_i(\cdot,\theta), B_j(\cdot,\theta)\rangle_{\mathcal{L}^2} \;=\; \eta^{i+j}(\theta). \tag{3.5}$$

The matrix $H(\theta)$ will be differentiable with respect to θ for all $\theta \in \Theta$ if all finite order moments of the jump size X exist, since

$$\frac{\partial \eta^i}{\partial \theta_j} \;=\; \int_{\mathbb{R}} x^i \,\frac{\partial p(x,\theta)}{\partial \theta_j}\, dx \;=\; \int_{\mathbb{R}} x^{i+j}\, p(x,\theta)\, dx \;=\; \eta^{i+j}(\theta) \;=\; H_{ij}(\theta). \tag{3.6}$$

For $\theta \in \Theta$ the matrix $H(\theta)$ will also be invertible, because if $H(\theta)y = 0$ for some vector $y \in \mathbb{R}^{m+1}$, then

$$\begin{aligned} 0 = \sum_{i=0}^{m}\sum_{j=0}^{m} y_i H_{ij}(\theta) y_j \;&=\; \sum_{i=0}^{m}\sum_{j=0}^{m} \int_{\mathbb{R}} y_i x^{i+j} y_j p(x,\theta)\, dx \\ &= \int_{\mathbb{R}} \left(\sum_{i=0}^{m} y_i\, x^i\right)^2 p(x,\theta)\, dx, \end{aligned}$$

which implies that y is the zero vector in $\mathbb{R}^{m+1}$ since p is strictly positive Lebesgue-almost everywhere. We remark that the matrix $H(\theta)$ coincides with the Fisher information matrix for our class of problems, since we can write it as

$$H_{ij}(\theta) \;=\; \int_{\mathbb{R}} \frac{\partial \ln p(x,\theta)}{\partial \theta_i}\, \frac{\partial \ln p(x,\theta)}{\partial \theta_j}\, p(x,\theta)\, dx.$$

The most important structural property is (3.6). It is exploited repeatedly in [4, 5], and it will play a central role in our analysis as well. A density from the exponential family may be characterized in terms of the θ-coordinate system, or the η-coordinate system, and on Θ the two are related by a diffeomorphism $\eta = \eta(\theta)$, which has the Fisher information matrix H as its Jacobian. In terms of Amari [1], the pair (θ, η) forms a *dual coordinate system*. However, our particular choice for this exponential family is not just motivated by this important property but also by other information theoretic considerations, since it may be shown that it is in fact the class of densities which maximize the *entropy* of a density with respect to Lebesgue measure once its $m+1$ moments $\{\eta_0, \ldots \eta_m\}$ have been specified.

The difference between our problem and the nonlinear filtering problem for diffusions treated in [5] lies mainly in the fact that our state equation does not evolve smoothly (in fact, not even continuously) and that its evolution depends on two stochastic variables (the jump size X and the jump time τ). We have seen in the previous section that the conditional distribution of the signal $\{S_t,\, t \geq 0\}$ consists of a Dirac measure in the origin and a smooth density outside the origin, and for reasons which will become clear later on we do not want to project that part of the conditional distribution which is represented by the Dirac measure. It will therefore be more convenient to apply the projection method to the Duncan–Mortensen–Zakai equation (2.6) for the absolutely continuous part of the density $q_t^\epsilon(x)$ which we defined in Theorem 2.1:

$$dq_t(x) \;=\; f(x)g(t)\, dt \;+\; \frac{x}{\epsilon^2}\, q_t(x)\, dY_t^\epsilon, \tag{3.7}$$

with initial condition $q_0(x) = 0$ for all $x \in \mathbb{R}$. Note that we will suppress the ϵ-dependency of this conditional density in our notation from now on.

Our definition of the exponential family also differs from the manifolds used for diffusion processes in the sense that the densities in our manifold are *not normalized*. In fact the differential-geometric structure takes the form of a cone: all scalar multiples

of a certain density on the manifold also lie on the manifold because of the introduction of the extra parameter θ_0. This is important, since the Duncan–Mortensen–Zakai equation (3.7) provides an unnormalized version of the conditional density outside the origin, and the normalization constant turns out to have a particular significance in our case. Indeed,

$$\mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon) = \mathbb{P}(S_t \neq 0 \mid \mathcal{Y}_t^\epsilon) \;=\; \frac{\int_{\mathbb{R}} q_t(x)\,dx}{\int_{\mathbb{R}} q_t(x)\,dx + 1 - G(t)}, \tag{3.8}$$

so the normalization constant is linked to the probability that a jump has occurred, and estimation of its value using the parameter θ_0 will thus be essential.

Note that alternatively we could have directly defined a projection filter without these modifications, when using projections on measures consisting of convex combinations of the Dirac delta measure and members of the family of exponential distributions

$$\tilde{p}(dx,\theta) = \gamma\,\delta_0(dx) \;+\; (1-\gamma)\frac{f(x)e^{\theta_1 c_1(x)+\cdots+\theta_k c_k(x)}}{\int_{\mathbb{R}} f(u)e^{\theta_1 c_1(u)+\cdots+\theta_k c_k(u)}du}\,dx,$$

where the parameter γ replaces the old parameter θ_0:

$$\gamma = \frac{1-G(t)}{1-G(t)+e^{\theta_0}\int_{\mathbb{R}} f(u)e^{\theta_1 c_1(u)+\cdots+\theta_k c_k(u)}du} \;\in\; [0,1].$$

However, our present formulation involves only measures which are absolutely continuous with respect to Lebesgue measures, and since this allows us to work directly with density functions, it is slightly more convenient.

To simplify the calculations on our statistical manifold we will work with the Stratonovich form of the Duncan–Mortensen–Zakai equation:

$$dq_t(x) \;=\; \left[f(x)g(t) - \frac{x^2}{2\epsilon^2}q_t(x)\right]\,dt \;+\; \frac{x}{\epsilon^2}q_t(x) \circ dY_t^\epsilon,$$

and the differential equation for $\sqrt{q_t} \in \mathcal{L}^2$ thus becomes

$$d\sqrt{q_t(x)} \;=\; \left[\frac{f(x)g(t)}{2\sqrt{q_t(x)}} - \frac{x^2}{4\epsilon^2}\sqrt{q_t(x)}\right]\,dt \;+\; \frac{x}{2\epsilon^2}\sqrt{q_t(x)} \circ dY_t^\epsilon.$$

To simplify notation we rewrite this as

$$d\sqrt{q_t} \;=\; \mathcal{P}_1(\sqrt{q_t})\,dt \;+\; \mathcal{P}_2(\sqrt{q_t}) \circ dY_t^\epsilon,$$

with the nonlinear operators $\mathcal{P}_i$ $(i = 1, 2)$ on $\mathcal{L}^2$ defined in an obvious way. To make sure that these operators do indeed map back into $\mathcal{L}^2$ when we apply them to our approximate densities $p(\cdot,\theta)$, we need the following condition:

For all $\theta \in \Theta$ we have that

$$\text{(A)} \qquad \int_{\mathbb{R}} x^4\,p(x,\theta)\,dx \;<\; \infty \qquad \text{and} \qquad \int_{\mathbb{R}} \frac{f(x)^2}{p(x,\theta)}\,dx \;<\; \infty.$$

The first part of this condition is rather mild, and the second part will be satisfied if the tails of the density f vanish rapidly enough. We will see that both parts of

condition (A) are *not necessary* to formulate our approximate filter, but they are needed if one wants to interpret the filter as the result of a projection in $\mathcal{L}^2$.

The operators $\Pi_\theta \circ \mathcal{P}_i$, with Π_θ as defined in (3.2), now generate a stochastic vector field on the manifold $\mathcal{H}^{1/2}$:

$$d\sqrt{p(\cdot,\theta_t)} = \left[\Pi_{\theta_t} \circ \mathcal{P}_1(\sqrt{p(\cdot,\theta_t)})\right] dt \; + \; \left[\Pi_{\theta_t} \circ \mathcal{P}_2(\sqrt{p(\cdot,\theta_t)})\right] \circ dY_t^\epsilon. \tag{3.9}$$

Note that we will always use the notation q for the real unnormalized conditional density outside the origin, and p for its projection.

Our aim is now to describe the evolution of the density in terms of our parameter vector θ_t, i.e., we want to find a stochastic differential equation for the result of the inverse mapping from the trajectory of projected densities on the manifold $\mathcal{H}^{1/2}$ into our parameter set $\Theta \subseteq \mathbb{R}^{m+1}$. It turns out that we can easily extend the analysis that was carried out in [4] for diffusion processes.

THEOREM 3.1. *Let the conditions of the previous section and condition* (A) *be satisfied. Then the parameter vector θ_t describing the filter* (3.9) *on the manifold generated by the exponential family* (3.3) *with $c_k(x) = x^k$ satisfies the Stratonovich stochastic differential equation*

$$d\theta_t = g(t)\; [H(\theta_t)]^{-1} \begin{pmatrix} 1 \\ \mathbb{E}X \\ \mathbb{E}X^2 \\ \vdots \\ \mathbb{E}X^m \end{pmatrix} dt \; - \; \frac{1}{2\epsilon^2} \begin{pmatrix} 0 \\ 0 \\ 1 \\ \vdots \\ 0 \end{pmatrix} dt \; + \; \frac{1}{\epsilon^2} \begin{pmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix} \circ dY_t^\epsilon, \tag{3.10}$$

with the matrix function H defined as before by

$$H_{ij}(\theta_t) \;=\; \int_{\mathbb{R}} x^{i+j} p(x,\theta_t)\, dx \;=\; \theta_{i+j}.$$

This stochastic differential equation has a unique solution up to the (possibly infinite) almost surely strictly positive exit time $\inf\{t \geq 0 : \theta_t \notin \Theta\}$.

Proof of Theorem 3.1. We deal with the two terms in (3.9) separately. For the first one we find, using (3.2),

$$\begin{aligned}
&\Pi_{\theta_t} \circ \mathcal{P}_1(\sqrt{p(\cdot,\theta_t)}) \\
&= \sum_{i=0}^m \sum_{j=0}^m 4\,[\,H(\theta_t)\,]^{-1}_{ij} \left[\int_{\mathbb{R}} \mathcal{P}_1(\sqrt{p})(x)\, B_j(x,\theta_t)\, dx\right] B_i(\cdot,\theta_t) \\
&= \sum_{i=0}^m \sum_{j=0}^m 4\,[H(\theta_t)]^{-1}_{ij} \left[\int_{\mathbb{R}} \left(\frac{f(x)g(t)}{2\sqrt{p(x,\theta_t)}} - \frac{x^2}{4\epsilon^2}\sqrt{p(x,\theta_t)}\right) \tfrac{1}{2} x^j \sqrt{p(x,\theta_t)}\, dx\right] B_i(\cdot,\theta_t) \\
&= \sum_{i=0}^m \sum_{j=0}^m [H(\theta_t)]^{-1}_{ij} \left[g(t)\mathbb{E}X^j - \frac{\eta_t^{j+2}}{2\epsilon^2}\right] B_i(\cdot,\theta_t).
\end{aligned}$$

Analogously, the second vector field can be shown to satisfy

$$\Pi_{\theta_t} \circ \mathcal{P}_2(\sqrt{p(\cdot,\theta_t)}) \;=\; \sum_{i=0}^m \sum_{j=0}^m [H(\theta_t)]^{-1}_{ij} \left[\frac{\eta_t^{j+1}}{\epsilon^2}\right] B_i(\cdot,\theta_t).$$

But since

$$d\sqrt{p(\cdot,\theta_t)} \;=\; \sum_{i=0}^{m}\left[\frac{1}{2\sqrt{p(\cdot,\theta)}}\,\frac{\partial p(\cdot,\theta)}{\partial\theta_i}\bigg|_{\theta=\theta_t}\circ\, d(\theta_t)_i\right] \;=\; \sum_{i=0}^{m} B_i(\cdot,\theta_t)\circ d(\theta_t)_i,$$

equating the coefficients in front of the basis vectors $B_i(\cdot,\theta_t)$ of the tangent space in $\sqrt{p(\cdot,\theta_t)}$ then gives that

$$\begin{aligned}(d\theta_t)_i &= g(t)\sum_{j=0}^{m}[H(\theta_t)]_{ij}^{-1}\,\mathbb{E}X^j\,dt \;-\; \frac{1}{2\epsilon^2}\sum_{j=0}^{m}[H(\theta_t)]_{ij}^{-1}\,\eta_t^{j+2}\,dt\\ &\quad+\frac{1}{\epsilon^2}\sum_{j=0}^{m}[H(\theta_t)]_{ij}^{-1}\,\eta_t^{j+1}\circ dY_t^{\epsilon}\\ &= g(t)\sum_{j=0}^{m}[H(\theta_t)]_{ij}^{-1}\,\mathbb{E}X^j\,dt \;-\; \frac{1}{2\epsilon^2}\mathbf{1}_{\{i=2\}}\,dt \;+\; \frac{1}{\epsilon^2}\,\mathbf{1}_{\{i=1\}}\circ dY_t^{\epsilon},\end{aligned}$$

because of (3.5). Existence and uniqueness of a solution of this equation up to the almost surely positive exit time $\inf\{t>0:\theta_t\notin\Theta\}$ is guaranteed since we showed before that $[H(\theta)]^{-1}$ exists for all $\theta\in\Theta$ and since $H(\theta)$ is infinitely many times differentiable with respect to θ on this set, its inverse certainly satisfies a local Lipschitz condition. □

Some care must be taken when defining the initial conditions for the stochastic differential equation for θ_t. At time $t=0$ the density outside the origin is equal to $q_0(x)=0$ for all x, which would mean that $\theta_0=-\infty$ and that the other values in the θ-vector can be chosen arbitrarily. We can overcome this problem by looking at the moments vector η instead of θ. We have remarked before that on the domain Θ the θ-vectors and η-vectors are related by a diffeomorphism. If we look at a small time $\delta>0$, we see from the Duncan–Mortensen–Zakai equation (3.7) that $q_\delta(x)$ approximately equals $f(x)g(0)\delta$. By (3.6), we have $H(\theta_t)\circ d\theta_t = d\eta_t$, so rewriting (3.10) in terms of moments gives

$$d\eta_t \;=\; g(t)\begin{pmatrix}1\\ \mathbb{E}X\\ \mathbb{E}X^2\\ \vdots\\ \mathbb{E}X^m\end{pmatrix}dt \;-\; \frac{1}{2\epsilon^2}\,[H(\theta_t)]\begin{pmatrix}0\\0\\1\\\vdots\\0\end{pmatrix}dt \;+\; \frac{1}{\epsilon^2}\,[H(\theta_t)]\begin{pmatrix}0\\1\\0\\\vdots\\0\end{pmatrix}\circ dY_t^{\epsilon},$$

so the moments η_δ at time δ are approximately equal to $g(0)\delta$ times the moments of X, as the expression for q_δ confirms. These moments will then uniquely determine the value of the parameter vector θ_δ, which may then be used as the initial condition for the stochastic differential equation for θ_t. Note that this is the only place where our assumption that $g(0)$ be strictly positive is explicitly needed, and if one is prepared to formulate alternative initial conditions for the approximate filter this assumption can be weakened.

Equation (3.10) for the evolution of θ_t has a remarkably simple structure. In particular, since it has a constant diffusion coefficient, the Stratonovich and Îto forms of the stochastic differential equation coincide, and every Euler scheme to find numerical approximations to its solution will coincide with a Milstein scheme, guaranteeing strong convergence of order one [16]. Moreover, it is quite easy to

give a clear interpretation of the stochastic differential equation. Since q_t approximates the conditional density of S_t outside the origin, i.e., the conditional density of X, we can interpret the stochastic differential equation for θ_t as the sum of two separate vector fields. The first one keeps the conditional density of X close to the prior density of X: since $d\eta_t = H(\theta_t) \circ d\theta_t$, the solution of $d\theta_t = g(t)\ [H(\theta_t)]^{-1}\,[1 \quad \mathbb{E}X \quad \dots \quad \mathbb{E}X^m\,]^T\,dt$ would simply be $G(t) = \mathbb{P}(t < \tau)$ times that density on the manifold which has the same first m moments as X. The second vector field $d\theta_t = \ -\frac{1}{2\epsilon^2}\,[0\ 0\ 1\ \dots\ 0]^T\,dt\ +\ \frac{1}{\epsilon^2}\,[0\ 1\ 0\ \dots\ 0]^T \circ dY_t^\epsilon$ describes the evolution of the Kalman filter for a Gaussian distributed random variable X observed in white noise of intensity ϵ^2. Before the jump, $Y_t^\epsilon = \epsilon W_t$ and the influence of the stochastic increment dY_t^ϵ will be small, while after the jump it will become significant due to the nonzero drift in Y_t^ϵ.

The fact that the diffusion coefficient vector in the stochastic differential equation for θ_t is a constant vector is a consequence of our choice of the basis functions $\{c_0(x), \dots, c_m(x)\}$ which generate the exponential family. The diffusion coefficient vector will always be constant if the function j in the observation equation $dY_t^\epsilon = j(S_t)\,dt + \epsilon\,dW_t$ (in our case simply $j(x) = x$) and its square (in our case $j(x)^2 = x^2$) are both in the linear space spanned by the functions $\{c_0(x), \dots, c_m(x)\}$. A proof is given in [4] for nonlinear filtering problems where the signal S_t is a diffusion instead of a jump process, and this result carries over directly to our case.

4. Statistical approximations. In the previous section, the conditional probability distribution of our original signal process $\{S_t,\, t \geq 0\}$ was approximated by a member of a finite-dimensional family of distributions. Another possible approximation to the optimal filter can be found by applying the Kushner–Stratonovich equation of nonlinear filtering. This equation describes the evolution of conditional statistics in time by means of a stochastic differential equation driven by the observation process $\{Y_t^\epsilon, t \geq 0\}$. We will use it to find such stochastic differential equations for the evolution of the moments of our conditional density and then use these equations to define another approximate filter. To do so, we first state the Kushner–Stratonovich equation (for the special case where the state noise and observation noise are independent) and then derive a stochastic differential equation for the process $\{S_t,\, t \geq 0\}$ which makes it possible to apply it to our particular filtering problem.

Let $\{V_t,\, t \in [0,T]\}$ be a scalar stochastic process such that V_0 is $\mathcal{S}_0$-measurable, with $\mathbb{E}|V_0| < \infty$ and

$$dV_t = D_t\,dt\ +\ dM_t, \tag{4.1}$$

$$dY_t^\epsilon = S_t\,dt\ +\ \epsilon\,dW_t. \tag{4.2}$$

We assume that (see section 2 for the definition of the state filtration $\mathcal{S}_t$)

- $\{M_t,\, t \geq 0\}$ is a right-continuous square integrable $\mathcal{S}_t$-martingale with left-hand limits, which is independent of the Wiener process $\{W_t,\, t \geq 0\}$,
- $\{D_t,\, t \geq 0\}$ is an $\mathcal{S}_t$-adapted process with $\mathbb{E}\int_0^T D_u^2\,du < \infty$, and
- $\{V_t,\, t \geq 0\}$ is such that $\mathbb{E}\int_0^T (S_u V_u)^2\,du\ <\ \infty$.

We will use the notation $\widehat{\alpha}_t = \mathbb{E}\,[\alpha_t \mid \mathcal{Y}_t^\epsilon]$ for the conditional expectation of stochastic processes $\{\alpha_t,\, t \geq 0\}$ with respect to the observations σ-algebra $\mathcal{Y}_t^\epsilon$. The Kushner–Stratonovich equation then states that for $t \in [0,T]$ we have [14, 27]

$$d\,\widehat{V}_t = \widehat{D}_t\,dt\ +\ \frac{1}{\epsilon^2}\left(\widehat{S_t V_t} - \widehat{S}_t\,\widehat{V}_t\right)\,d\nu_t^\epsilon, \tag{4.3}$$

with initial condition $\widehat{V}_0 = \mathbb{E}V_0$. The process

$$\nu_t^\epsilon \;=\; Y_t^\epsilon - \int_0^t \widehat{S}_u \, du \tag{4.4}$$

is called the *innovation process*, and under the conditions stated it is a Brownian motion with respect to the observations filtration $\{\mathcal{Y}_t^\epsilon,\, t \geq 0\}$.

In order to be able to apply the Kushner–Stratonovich equation to our problem, we will now derive a description for the signal $\{S_t,\, t \geq 0\}$ of the form (4.1). Let $E_t = \mathbf{1}_{\{t \geq \tau\}}$ denote, as before, the right-continuous $\mathcal{S}_t$-measurable process which jumps from zero to one at time τ. The probability that the jump occurs in the time interval $[t, t+dt]$ given that it has not occurred before time t equals $\lambda(t)dt + o(dt)$, where $\lambda(t)$ is the *hazard rate* at time t, defined by

$$\lambda(t) \;=\; \frac{g(t)}{1 - G(t)}.$$

Define the process M_t as E_t minus the integral of this hazard rate up to time $t \wedge \tau$ (where we introduce the usual notation $a \wedge b$ for the minimum of a and b):

$$M_t \;=\; E_t - K_t, \qquad\qquad K_t \;=\; \int_0^{t\wedge\tau} \lambda(s)\, ds \;=\; -\ln(1 - G(t \wedge \tau)).$$

Tedious but straightforward calculations show that M_t is an $\mathcal{S}_t$-martingale (for details, see, for example, [9]). But since

$$t \wedge \tau \;=\; \int_0^t (1 - E_u)\, du,$$

we have that

$$M_t \;=\; E_t \;+\; \ln[\, 1 - G(\, \textstyle\int_0^t (1 - E_u) du \,)\,],$$

and we thus find the following representation for E_t:

$$\begin{aligned} dE_t &= \lambda(t \wedge \tau)\,(1 - E_t)\, dt \;+\; dM_t \\ &= \lambda(t)\,(1 - E_t)\, dt \;+\; dM_t, \end{aligned} \tag{4.5}$$

where we have used the fact that $\lambda(t \wedge \tau)(1 - E_t) = \lambda(t)(1 - E_t)$, since if $t \wedge \tau = \tau$, then $1 - E_t = 0$. Our original process may now be represented as $S_t = XE_t$ so it satisfies

$$dS_t \;=\; \lambda(t)\,(X - S_t)\, dt \;+\; X\, dM_t, \tag{4.6}$$

and in fact for arbitrary $k \in \mathbb{N} \setminus \{0\}$

$$d(S_t)^k \;=\; \lambda(t)\,(X^k - (S_t)^k)\, dt \;+\; X^k\, dM_t. \tag{4.7}$$

We can now apply the Kushner–Stratonovich equation to this representation of our signal process, but we first prove a lemma that will be used to simplify the equations which it generates.

LEMMA 4.1. *For all $t \in [0, T]$ and $k \in \mathbb{N} \setminus \{0\}$ we have that, almost surely,*

$$\mathbb{E}\,[X^k - (S_t)^k \mid \mathcal{Y}_t^\epsilon] \;=\; (1 - \widehat{E}_t)\, \mathbb{E}X^k. \tag{4.8}$$

Proof of Lemma 4.1. Let B be any set in $\mathcal{Y}_t^\epsilon$. Then by definition

$$\begin{aligned}\int_B \mathbb{E}\,[X^k - (S_t)^k \mid \mathcal{Y}_t^\epsilon](\omega)\,dP(\omega) &= \int_B (\,X^k(\omega) - (S_t)^k(\omega)\,)\,dP(\omega)\\ &= \int_B X^k(\omega)\,\mathbf{1}_{\{t<\tau(\omega)\}}\,dP(\omega)\\ &= \int_{B\cap\{\omega:t<\tau(\omega)\}} X^k(\omega)\,dP(\omega).\end{aligned}$$

But we have that the σ-algebra generated by sets of the form $B\cap\{\omega : t < \tau(\omega)\}$ (with $B \in \mathcal{Y}_t^\epsilon$) is independent of sets in the σ-algebra generated by X^k, since $Y_t^\epsilon = \epsilon W_t$ on $\{\omega : t < \tau(\omega)\}$ and the process $\{W_t,\, t \geq 0\}$ is independent of X, so

$$\begin{aligned}\int_{B\cap\{\omega:t<\tau(\omega)\}} X^k(\omega)\,dP(\omega) &= \int_{B\cap\{\omega:t<\tau(\omega)\}} \mathbb{E}X^k\,dP(\omega)\\ &= \big(\mathbb{E}X^k\big)\int_B \mathbf{1}_{\{t<\tau(\omega)\}}\,dP(\omega)\\ &= \big(\mathbb{E}X^k\big)\int_B \mathbb{E}\,[1-\mathbf{1}_{\{t\geq\tau\}} \mid \mathcal{Y}_t^\epsilon](\omega)\,dP(\omega)\\ &= \big(\mathbb{E}X^k\big)\int_B (1-\widehat{E}_t(\omega))\,dP(\omega),\end{aligned}$$

and we may now conclude that (4.8) holds by the almost sure uniqueness property of conditional expectations. □

THEOREM 4.2. *Let the random variables X and τ and the stochastic processes $\{S_t,\, t \geq 0\}$ and $\{Y_t^\epsilon,\, t \geq 0\}$ be defined as in section* 2, *and let X and τ satisfy all conditions mentioned in that section. Then the optimal filter estimate $\widehat{S}_t = \mathbb{E}\,[S_t \mid \mathcal{Y}_t^\epsilon]$ and higher order moments for $t \in [0,T]$ are generated by the following Îto stochastic differential equations ($k \in \mathbb{N}\setminus\{0\}$):*

$$d\widehat{E}_t = \lambda(t)(1-\widehat{E}_t)\,dt \;+\; \frac{1}{\epsilon^2}\widehat{S}_t(1-\widehat{E}_t)\,d\nu_t^\epsilon, \tag{4.9}$$

$$\begin{aligned}d\,\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon] &= \lambda(t)\,\mathbb{E}X^k(1-\widehat{E}_t)\,dt\\ &\quad+\frac{1}{\epsilon^2}\Big(\,\mathbb{E}\,[(S_t)^{k+1} \mid \mathcal{Y}_t^\epsilon] - \widehat{S}_t\,\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]\Big)\,d\nu_t^\epsilon,\end{aligned} \tag{4.10}$$

with initial conditions $\widehat{E}_0 = \mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]_{t=0} = 0$ for all $k \in \mathbb{N}\setminus\{0\}$, and where the innovation process $\{\nu_t^\epsilon,\, t \in [0,T]\}$ is defined by (4.4).

Proof of Theorem 4.2. The conditions for application of the Kushner–Stratonovich equation are obviously satisfied for the process E_t since

$$\mathbb{E}\int_0^T [\lambda(u)(1-E_u)]^2 du \;\leq\; \int_0^T \lambda(u)^2 du < \infty$$

(note that $\lambda(t)$ is finite for all $t \geq 0$ and continuous since we assumed that $g(t)$ is continuous and $G(t) < 1$ for all $t \geq 0$) and $\mathbb{E}\int_0^T |E_u S_u| du < T\cdot\mathbb{E}|X| < \infty$. Here and in the rest of the proof we use the fact that all finite order moments of X exist because of condition (2.3), which implies that $\mathbb{E}|X|^k < \infty$ for all $k \geq 0$.

Since $\{W_t,\, t \geq 0\}$ was assumed to be independent of X and τ, it is independent of $\{M_t,\, t \geq 0\}$. The Kushner–Stratonovich equation applied to (4.5) thus results in

$$\begin{aligned} d\widehat{E}_t &= \lambda(t)(1-\widehat{E}_t)\,dt \;+\; \frac{1}{\epsilon^2}(\,\widehat{S_tE_t} - \widehat{S}_t\widehat{E}_t\,)\,d\nu_t^\epsilon \\ &= \lambda(t)(1-\widehat{E}_t)\,dt \;+\; \frac{1}{\epsilon^2}\widehat{S}_t(1-\widehat{E}_t)\,d\nu_t^\epsilon, \end{aligned} \tag{4.11}$$

where we have used the fact that $S_tE_t = S_t$. The initial condition is $\widehat{E}_0 = \mathbb{E}(E_0) = 0$. To find the conditional moments $\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]$ for $k \in \mathbb{N} \setminus \{0\}$, we use (4.7). Since X is $\mathcal{S}_t$-measurable and independent of τ, and $\mathbb{E}|X|^{2k} < \infty$, the process $\{X^kM_t,\, t \geq 0\}$ is again a square integrable $\mathcal{S}_t$-martingale which is independent of $\{W_t,\, t \geq 0\}$. The two other conditions for the Kushner–Stratonovich formula are satisfied as well, since

$$\mathbb{E}\int_0^T (X^k - (S_u)^k)^2\lambda(u)^2 du \leq \mathbb{E}|X|^{2k}\int_0^T \lambda(u)^2 du \;<\; \infty,$$

$$\mathbb{E}\int_0^T |(S_u)^k S_u| du \leq T\cdot\mathbb{E}|X|^{k+1} \;<\; \infty.$$

We therefore have that for $k \in \mathbb{N} \setminus \{0\}$

$$\begin{aligned} d\,\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon] &= \lambda(t)\,\mathbb{E}\,[X^k - (S_t)^k \mid \mathcal{Y}_t^\epsilon]\,dt \\ &\quad + \frac{1}{\epsilon^2}\Big(\,\mathbb{E}\,[(S_t)^{k+1} \mid \mathcal{Y}_t^\epsilon] - \widehat{S}_t\,\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]\Big)\,d\nu_t^\epsilon, \end{aligned} \tag{4.12}$$

with initial condition $\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]_{t=0} = \mathbb{E}[(S_t)^k]_{t=0} = 0$.

Using the result of Lemma 4.1, we see that (4.12) can be simplified to

$$\begin{aligned} d\,\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon] &= \lambda(t)\,\mathbb{E}X^k(1-\widehat{E}_t)\,dt \\ &\quad + \frac{1}{\epsilon^2}\Big(\,\mathbb{E}\,[(S_t)^{k+1} \mid \mathcal{Y}_t^\epsilon] - \widehat{S}_t\,\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]\Big)\,d\nu_t^\epsilon. \end{aligned} \tag{4.13}$$

This proves Theorem 4.2. □

Note that $\mathbb{E}\,[(S_t)^k \mid \mathcal{Y}_t^\epsilon]$, the conditional moment of order k, depends on the conditional moment of order $k+1$, $\mathbb{E}\,[(S_t)^{k+1} \mid \mathcal{Y}_t^\epsilon]$, so (4.9)–(4.10) do not form a closed set of equations. If we want to use these equations to define a finite-dimensional approximation to the optimal filter, we need to use an appropriate closure formula to approximate higher order moments in terms of lower order moments. One possible closure formula, which was proposed in [11], assumes the third order central moment to be zero at all times, i.e., $\mathbb{E}\,[(S_t - \widehat{S}_t)^3 \mid \mathcal{Y}_t^\epsilon] = 0$ for all $t \in [0,T]$.

This closing of the infinite set of moment equations that has now been generated, by expressing higher order moments in terms of lower order moments, means that we restrict our densities to belong to a specific family of distributions. As was pointed out earlier in [4], the *a priori assumption* that the conditional density will belong to this family at every time instant is often incorrect. But it was shown in the same paper that a sound mathematical basis can be given for this so-called *assumed density principle* in some cases which involve the filtering of nonlinear diffusions, by showing that the resulting filter is equivalent to a *projection* in probability density space, like the one we described in the preceding section. In the next section we will show that this idea can be applied to our change detection problem as well, and that we can gain considerable insight into the nature of such problems in doing so.

5. The assumed density principle. To formulate our differential-geometric approximate filter of section 3 in terms of the conditional moments it generates, we define, bearing in mind the interpretation of the normalization constant given in (3.8), the following statistics (where $\approx$ means approximates):

$$
\begin{aligned}
\check{E}_t &= \frac{\int_{\mathbb{R}} p(x,\theta_t)dx}{\int_{\mathbb{R}} p(x,\theta_t)dx + 1 - G(t)} &&\approx \mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon),\\
\check{X}_t &= \frac{\int_{\mathbb{R}} xp(x,\theta_t)dx}{\int_{\mathbb{R}} p(x,\theta_t)dx} &&\approx \mathbb{E}[X \mid \mathcal{Y}_t^\epsilon], \qquad (5.1)\\
\check{S}_t^n &= \frac{\int_{\mathbb{R}} x^n\, p(x,\theta_t)dx}{\int_{\mathbb{R}} p(x,\theta_t)dx + 1 - G(t)} &&\approx \mathbb{E}[(S_t)^n \mid \mathcal{Y}_t^\epsilon],
\end{aligned}
$$

with $n \in \mathbb{N}$, so $\check{S}_t^0 = E_t$ and $\check{S}_t^1 = \check{S}_t$.

We remark that this implies that $\check{S}_t = \check{X}_t\check{E}_t$, i.e., the conditional estimate of the signal $\check{S}_t$ naturally splits into two statistics $\check{E}_t$ and $\check{X}_t$, which approximate the conditional probability of a jump having occurred and the best estimate of the jump size, respectively. We have shown in (4.8) that the optimal filter estimates satisfy, for $\widehat{X}_t = \mathbb{E}\,[X \mid \mathcal{Y}_t^\epsilon] \neq 0$,

$$
\widehat{S}_t = \widehat{X}_t \left(1 - (1 - \widehat{E}_t)\frac{\mathbb{E}X}{\widehat{X}_t}\right),
$$

so the *optimal* filter estimates will in general *not* satisfy the equation $\widehat{S}_t = \widehat{X}_t\widehat{E}_t$.

However, this does not imply that the estimate $\check{S}_t$ which is generated by the differential-geometric approximation is different from the filter estimate $\widehat{S}_t$ generated by closing the Kushner–Stratonovich equations, as we did in the previous section. We now show that they are in fact the same if we use (4.9) and (4.10) to calculate the first $m+1$ moments and then close the equations *in an appropriate way*, by choosing $\check{S}_t^{m+1}$ appropriately.

THEOREM 5.1. *Let the conditions of Theorem* 3.1 *be satisfied, and let the process* $\{\theta_t,\, t \geq 0\}$ *be defined as in* (3.10). *Define* $\check{E}_t$, $\check{S}_t$, *and* $\check{S}_t^n$ *as in* (5.1) *for* $n = 0 \ldots m{+}1$. *Then* $\check{E}_t = \check{S}_t^0$, $\check{S}_t = \check{S}_t^1$, *and* $\check{S}_t^n$ $(n = 2 \ldots m)$ *satisfy*

$$
d\check{S}_t^n = \lambda(t)\,(1 - \check{E}_t)\,\mathbb{E}X^n\,dt \;+\; \frac{1}{\epsilon^2}\,(\,\check{S}_t^{n+1} - \check{S}_t\,\check{S}_t^n\,)\,(\,dY_t^\epsilon - \check{S}_t\,dt\,),
$$

with initial conditions $\check{S}_0^n = 0$ *for all* $n = 0 \ldots m$.

Proof of Theorem 5.1. To find the stochastic differential equations for the $\check{S}_t^n$ $(n = 0 \ldots m)$ we must first find the equations for the approximated conditional moments η_t^k $(k = 0 \ldots m)$, but this is relatively simple since (3.6) implies that

$$
d\eta_t^k \;=\; [\,\eta_t^k \;\; \eta_t^{k+1} \;\; \cdots \;\; \eta_t^{k+m}\,] \circ d\theta_t,
$$

and the result of Theorem 3.1 then gives

$$
d\eta_t^k \;=\; g(t)\,\mathbb{E}X^k\,dt \;-\; \frac{\eta_t^{k+2}}{2\epsilon^2}\,dt \;+\; \frac{\eta_t^{k+1}}{\epsilon^2} \circ dY_t^\epsilon. \qquad (5.2)
$$

Using the Îto form of (5.2),

$$
d\eta_t^k \;=\; g(t)\,\mathbb{E}X^k\,dt \;+\; \frac{\eta_t^{k+1}}{\epsilon^2}\,dY_t^\epsilon,
$$

we find by Îto's differentiation rule that for all $k = 0 \dots m$,

$$\begin{aligned}
d\check{S}_t^k &= \frac{d\eta_t^k}{\eta_t^0 + 1 - G(t)} - \frac{\eta_t^k\, d(\eta_t^0 + 1 - G(t))}{(\eta_t^0 + 1 - G(t))^2} - \frac{d\eta_t^k\, d(\eta_t^0 + 1 - G(t))}{(\eta_t^0 + 1 - G(t))^2} \\
&\quad + \frac{\eta_t^k\, d(\eta_t^0 + 1 - G(t)) d(\eta_t^0 + 1 - G(t))}{(\eta_t^0 + 1 - G(t))^3} \\
&= \frac{\mathbb{E}X^k g(t)dt + \eta_t^{k+1} dY_t^\epsilon/\epsilon^2}{\eta_t^0 + 1 - G(t)} - \frac{\eta_t^k\, \eta_t^1 dY_t^\epsilon/\epsilon^2}{(\eta_t^0 + 1 - G(t))^2} - \frac{\eta_t^{k+1}\eta_t^1 dt/\epsilon^2}{(\eta_t^0 + 1 - G(t))^2} \\
&\quad + \frac{\eta_t^k\, (\eta_t^1)^2 dt/\epsilon^2}{(\eta_t^0 + 1 - G(t))^3} \\
&= \frac{g(t)}{1 - G(t)} \left(1 - \frac{\eta_t^0}{\eta_t^0 + 1 - G(t)}\right) \mathbb{E}X^k\, dt \\
&\quad + \frac{1}{\epsilon^2} \left(\frac{\eta_t^{k+1}}{\eta_t^0 + 1 - G(t)} - \frac{\eta_t^k \eta_t^1}{(\eta_t^0 + 1 - G(t))^2} \right) \left(dY_t^\epsilon - \frac{\eta_t^1}{\eta_t^0 + 1 - G(t)}\, dt \right) \\
&= \lambda(t)(1 - \check{E}_t)\, \mathbb{E}X^k\, dt \;+\; \frac{1}{\epsilon^2} \left(\check{S}_t^{k+1} - \check{S}_t\, \check{S}_t^k \right) \left(dY_t^\epsilon - \check{S}_t\, dt \right),
\end{aligned}$$

which proves the theorem. □

These equations are precisely the same as the ones we derived for the filter of the previous section, (4.9) and (4.10), if we replace $\mathbb{E}\,[S_t^k \mid \mathcal{Y}_t^\epsilon]$ by $\check{S}_t^k$. It thus follows that if we close these equations by choosing $\check{S}_t^{m+1}$ appropriately, then the two filters generate the same estimates almost surely. However, some care must be taken in finding the appropriate closure formula. For example, in the Gaussian case ($m = 2$), we must *not* choose the third central moment to be equal to zero, as we proposed in the end of section 4. Since $p(x, \theta_t) / \int_{\mathbb{R}} p(x, \theta_t) dx$ is assumed to be Gaussian, and since a Gaussian variable A satisfies $\mathbb{E}A^3 = [\mathbb{E}A] \cdot [3\mathbb{E}A^2 - 2(\mathbb{E}A)^2]$, we have

(5.3)
$$\frac{\eta_t^3}{\eta_t^0} = \frac{\eta_t^1}{\eta_t^0} \left(3\frac{\eta_t^2}{\eta_t^0} - 2\left(\frac{\eta_t^1}{\eta_t^0}\right)^2 \right) \qquad \Rightarrow \qquad \frac{\check{S}_t^3}{\check{E}_t} = \frac{\check{S}_t}{\check{E}_t} \left(3\frac{\check{S}_t^2}{\check{E}_t} - 2\left(\frac{\check{S}_t}{\check{E}_t}\right)^2 \right).$$

Only when this more complicated closure formula for $\mathbb{E}\,[(S_t)^3 \mid \mathcal{Y}_t^\epsilon]$ in terms of the lower order moments $\mathbb{E}\,[(S_t)^2 \mid \mathcal{Y}_t^\epsilon]$, $\mathbb{E}\,[S_t \mid \mathcal{Y}_t^\epsilon]$, and $\mathbb{E}\,[E_t \mid \mathcal{Y}_t^\epsilon]$ is used will the estimates generated by the Kushner–Stratonovich equation be the same, almost surely, as those generated by our differential-geometric approximation.

6. A three-dimensional filter. Although the filter derived in section 3 using differential-geometric methods is thus equivalent to the filter derived in section 4 *when the correct closure formula is used*, there are certain advantages of the first parametrization. We already mentioned the fact that better schemes can be used to calculate numerical approximations of (3.10). Another advantage is the much more intuitive structure of the filter. If we define the a priori moments of the jump size X as $P^n = \mathbb{E}(X - \mathbb{E}X)^n$, and the approximate filter estimates

$$\check{P}_t^n = \frac{\int_{\mathbb{R}} (x - \check{X}_t)^n p(x, \theta_t) dx}{\int_{\mathbb{R}} p(x, \theta_t) dx} \qquad \approx \qquad \mathbb{E}[(X - \mathbb{E}\,[X \mid \mathcal{Y}_t^\epsilon])^n \mid \mathcal{Y}_t^\epsilon],$$

then one may show by a tedious but straightforward exercise in Stratonovich calculus [23] that for $n = 2 \dots m$,

$$d\check{E}_t = \lambda(t)(1-\check{E}_t)\,dt \;+\; \check{E}_t(1-\check{E}_t)\frac{\check{X}_t}{\epsilon^2}\,(\,dY_t^\epsilon - \check{S}_t\,dt\,), \tag{6.1}$$

$$d\check{X}_t = \lambda(t)\frac{1-\check{E}_t}{\check{E}_t}\,(\mathbb{E}X - \check{X}_t)\,dt \;+\; \frac{\check{P}_t^2}{\epsilon^2}\,(\,dY_t^\epsilon - \check{X}_t\,dt\,), \tag{6.2}$$

$$\begin{aligned} d\check{P}_t^n = \lambda(t)\frac{1-\check{E}_t}{\check{E}_t}\Bigg[& P^n - \check{P}_t^n \;+\; n(P^{n-1} - \check{P}_t^{n-1})\,(\mathbb{E}X - \check{X}_t) \\ & + \sum_{k=0}^{n-2}\binom{n}{k} P^k(\mathbb{E}X - \check{X}_t)^{n-k}\Bigg]\,dt \\ - \frac{n\,\check{P}_t^2}{\epsilon^2}\,\big[\,\check{P}_t^n - \tfrac{1}{2}(n-1)\,\check{P}_t^2\check{P}_t^{n-2}\,\big]\,dt & \\ + \frac{1}{\epsilon^2}\,[\,\check{P}_t^{n+1} - n\check{P}_t^2\check{P}_t^{n-1}\,]\,(dY_t^\epsilon - \check{X}_t\,dt). & \end{aligned}$$

These stochastic differential equations can be interpreted as the sum of vector fields which drive the conditional density to the a priori density of X (and these dominate before the jump when $\check{E}_t$ will be close to zero), vector fields which resemble those of the Kalman filter for a constant signal (which dominate after the jump when $\check{E}_t$ will be close to one), and some extra terms which make sure we do not leave the manifold that we project upon.

Note that the terms involving the innovation process in the equations for $\widehat{P}_t^n$ ($n = 2 \dots m$) will all be zero if and only if the central moments satisfy the equation $\widehat{P}_t^{n+1} = n\widehat{P}_t^2\widehat{P}_t^{n-1}$ for $n = 0 \dots m$. Since we have that $\widehat{P}_t^0 = 1$ and $\widehat{P}_t^1 = 0$ for all $t \geq 0$, this will be the case if for all $n \in \mathbb{N}$,

$$\widehat{P}_t^{2n} \;=\; (\widehat{P}_t^2)^n \cdot 2^{-n}\,\frac{(2n)!}{n!}, \qquad \widehat{P}_t^{2n+1} \;=\; 0,$$

i.e., the first $m+1$ central moments should be the same as those of a Gaussian distribution. This suggests that the equations will become even simpler if both X and our manifold are Gaussian, which is exactly the exponential family we get if we take $m = 2$ and the parameter set $\Theta = \{(\theta_0, \theta_1, \theta_2) : \theta_2 < 0\}$. In the rest of this section we will analyze the detection and estimation scheme when such a manifold of unnormalized Gaussian densities is used.

If we substitute the relation $\check{S}_t = \check{X}_t\check{E}_t$ into the stochastic differential equation for $\check{E}_t$ given by (6.1), we see the close connection with the celebrated Shiryayev–Wonham detector for *known* jump sizes. As we remarked in section 2, if we assume that the jump size X is known a priori, say $X = a$, then the conditional probability that the jump has occurred $\pi_t = \mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon)$ is finite-dimensionally computable. In fact, it follows the Shiryayev–Wonham equation [22, 28] that

$$d\pi_t \;=\; \lambda(t)(1-\pi_t)\,dt \;+\; \pi_t(1-\pi_t)\frac{a}{\epsilon^2}(dY_t^\epsilon - a\pi_t\,dt), \qquad \pi_0 \;=\; 0. \tag{6.3}$$

Our estimate of the probability that a jump has occurred satisfies a modified version of this Shiryayev–Wonham equation, where a *known* jump size $X = a$ in the equation is replaced by a time-varying *estimated* jump size $\check{X}_t$. For $m = 2$ our differential-geometric approximation thus becomes a mixture of modified Kalman filter equations and this *adaptive* Shiryayev–Wonham equation:

$$
\begin{aligned}
\check{S}_t &= \check{E}_t\,\check{X}_t, \\
d\check{E}_t &= \lambda(t)(1-\check{E}_t)\,dt \;+\; \check{E}_t(1-\check{E}_t)\frac{\check{X}_t}{\epsilon^2}\,(\,dY_t^{\epsilon} - \check{X}_t\check{E}_t\,dt\,), \\
d\check{X}_t &= \lambda(t)\frac{1-\check{E}_t}{\check{E}_t}\,(\mathbb{E}X - \check{X}_t)\,dt \;+\; \frac{\check{P}_t^2}{\epsilon^2}\,(\,dY_t^{\epsilon} - \check{X}_t\,dt\,), \\
d\check{P}_t^2 &= \lambda(t)\frac{1-\check{E}_t}{\check{E}_t}\,[\,(\mathbb{E}X - \check{X}_t)^2 \;+\; \mathrm{Var}\;X \;-\; \check{P}_t^2\,]\,dt \;-\; \frac{(\check{P}_t^2)^2}{\epsilon^2}\,dt,
\end{aligned}
$$

with $\check{E}_0 = 0$, $\check{P}_0^2 = \mathrm{Var}\;X$, and $\check{X}_0 = \mathbb{E}X$.

In Figure 1, a block diagram of the filter is given, which highlights the decomposition of the problem in a detection and an estimation part, which communicate through the jump size estimate $\check{X}_t$ and the conditional probability ratio $(1-\check{E}_t)/\check{E}_t$. We remark that the original optimal detection and estimation problem as we formulated it cannot be solved recursively because we want to perform detection and estimation *simultaneously*. If the estimation problem would be trivial (i.e., if we would know the jump size X immediately after the jump), the detection problem could be solved recursively, since we can then use a Shiryayev–Wonham filter tuned at $a = X$. If the detection problem would be trivial (i.e., we would know immediately after time τ that a jump has occurred), then the estimation problem could be solved recursively, since we could simply start a Kalman filter at time τ.

In our combined problem, however, we must make sure that the Kalman filter does not start filtering too early, since it would then filter the zero signal for some time while its conditional variance $\check{P}_t^2$ would decrease, making its reaction too slow when the jump does indeed occur. The likelihood ratio term in the equation for $\check{P}_t^2$, which

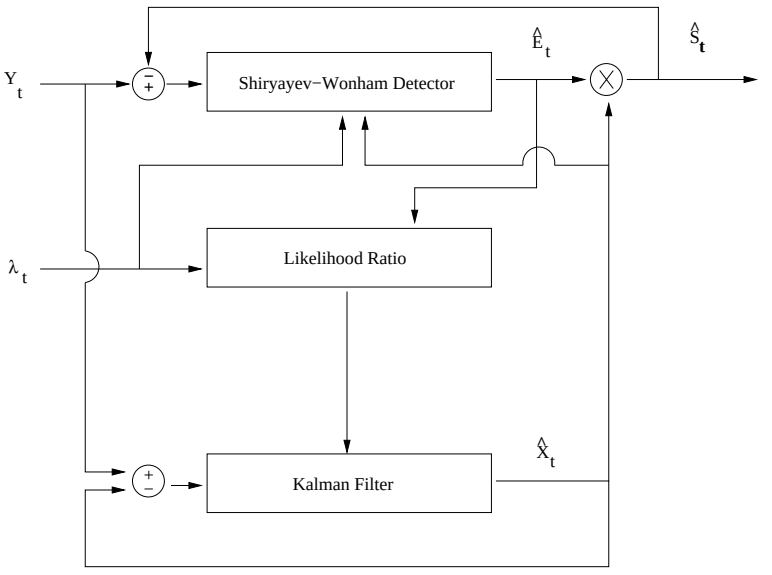

FIG. 1. *Structure of the three-dimensional approximating filter.*

pulls the conditional variance $\check{P}_t^2$ back to the variance of X as long as $\check{E}_t$ is small, prevents this from happening. After the jump has occurred, a good estimate of X should quickly become available, and the stochastic differential equation for $\check{E}_t$ will then resemble the Shiryayev–Wonham equation. We therefore expect the estimate for the conditional probability that a change has occurred to converge to one quite quickly after that. We will see in the simulation studies of section 8 that this will indeed be the case. But first we must make sure that the three-dimensional filter that we have just defined has a finite, nonexploding global solution for all $t \geq 0$. This will be the subject of the next section.

7. Existence and uniqueness of filter estimates. When we derived the equations for our new nonlinear filter in section 3, we defined it only up to the exit time $\inf\{t \geq 0 : \theta_t \notin \Theta\}$. In this section we will show that for the three-dimensional filter that we defined in the preceding section, this exit time will be equal to infinity almost surely under rather mild conditions. This means that a unique, well-defined, finite, nonexploding solution for the stochastic differential equations exists for *all* $t \geq 0$, a fact which has not yet been proven for the diffusion case [4].

The filter equations suggest that it will be convenient to work with the scaled likelihood ratio process defined by

$$\check{Z}_t^\epsilon \;=\; \epsilon^2 \cdot \check{Z}_t \;=\; \epsilon^2 \cdot \lambda(t) \frac{1 - \check{E}_t}{\check{E}_t}.$$

We remark that, strictly speaking, $\check{Z}_t$ is not defined at $t = 0$ since $\check{E}_0 = 0$ but as we remarked before, it can be defined after an arbitrarily small time step, in the same way as we suggested in the discussion after the proof of Theorem 3.1. A simple application of Îto's differentiation rule shows that we may rewrite the filter equations in the following form:

$$d\check{Z}_t^\epsilon = \check{Z}_t^\epsilon \left[-\check{Z}_t^\epsilon \;+\; \epsilon^2 \frac{g'(t)}{g(t)} \;+\; \check{X}_t(\check{X}_t - S_t) \right] \frac{dt}{\epsilon^2} \;-\; \check{Z}_t^\epsilon \check{X}_t \frac{dW_t}{\epsilon}, \tag{7.1}$$

$$d\check{X}_t = [\, \check{Z}_t^\epsilon (\mathbb{E}X - \check{X}_t) \;+\; \check{P}_t^2 (S_t - \check{X}_t) \,] \frac{dt}{\epsilon^2} \;+\; \check{P}_t^2 \frac{dW_t}{\epsilon}, \tag{7.2}$$

$$d\check{P}_t^2 = [\, \check{Z}_t^\epsilon \,(\, (\mathbb{E}X - \check{X}_t)^2 \;+\; \mathrm{Var}\; X \;-\; \check{P}_t^2 \,) \;-\; (\check{P}_t^2)^2 \,] \frac{dt}{\epsilon^2}. \tag{7.3}$$

This shows that the natural time scale is of order ϵ^2.

Using this representation of the filter, we can now prove that the filter equations will indeed have a solution. To do so we shall use the following result.

THEOREM 7.1. *Consider the* $m + 1$*-dimensional stochastic differential system defined by*

$$D_t = D_{t_0} \;+\; \int_{t_0}^t b(s, D_s)\, ds \;+\; \int_{t_0}^t \sigma(s, D_s)\, dW_s, \tag{7.4}$$

with $\{W_t,\, t \geq t_0\}$ *a standard Wiener process. Denote the generator of this process by*

$$L \;=\; \tfrac{\partial}{\partial t} + \sum_i b_i \tfrac{\partial}{\partial x_i} + \tfrac{1}{2} \sum_{i,j} \sigma_i \sigma_j \tfrac{\partial^2}{\partial x_i \partial x_j},$$

and suppose the following:

1. *D_{t_0} is independent of $\{W_t, t \geq t_0\}$.*
2. *Both b and σ are functions $\mathbb{R} \times \mathbb{R}^{m+1} \to \mathbb{R}^{m+1}$ such that for all $R > t_0$ and every x, y in the compact set $\mathcal{U}_R \stackrel{\text{def}}{=} \{d : \|d\| \leq R\}$ and all $t_0 \leq s \leq R$, there exists a constant M_R such that*

$$\begin{aligned} \|b(s,x) - b(s,y)\| \ + \ \|\sigma(s,x) - \sigma(s,y)\| &\leq M_R \|x - y\|, \\ \|b(s,x)\| \ + \ \|\sigma(s,x)\| &\leq M_R (1 + \|x\|). \end{aligned}$$

3. *There exists a nonnegative function $V(t,d) : \mathbb{R} \times \mathbb{R}^{m+1} \to \mathbb{R}^+$, twice differentiable with respect to d, such that*

$$\liminf_{R \to \infty} \inf_{\|d\| > R} V(t,d) \ = \ \infty,$$

which satisfies the linear inequality $LV(t,d) \leq c\,V(t,d)$ for some $c > 0$, for all d outside a compact set $\mathcal{G} \subseteq \mathbb{R}^{m+1}$ and all $t \geq t_0$.

Then there exists a solution to (7.4) for every $t \geq t_0$ (i.e., the solution does not explode in finite time). This solution is unique up to equivalence, and an almost surely continuous stochastic process.

A proof of this theorem can be found in [15]; we just remark that the first two conditions guarantee that the solution is well defined up to the stopping times

$$t_R \ = \ \inf\{t \geq t_0 : \ \|D_t\| \geq R\},$$

while the last condition guarantees that

$$\mathbb{P}\Big(\lim_{R \to \infty} t_R = \infty \Big) \ = \ 1,$$

which means we can extend the solution to all times $t \geq t_0$. We now use this theorem to conclude that (7.1)–(7.3) have a unique nonexploding solution.

THEOREM 7.2. *If the function g is differentiable on its entire domain $\mathbb{R}^+$ and satisfies*

$$\sup_{t \geq 0} \ \frac{g'(t)}{g(t)} \ \stackrel{\text{def}}{=} \ \breve{g} \ < \ \infty,$$

and the stochastic variable X is bounded, i.e., $|X| \leq \bar{X}$ almost surely for some constant $\bar{X} > 0$, then (7.1)–(7.3) have an almost surely continuous solution for all $t \geq 0$, which is unique up to equivalence.

We remark that the condition that X is bounded means that one of the conditions for the derivation of these equations as a *projection* is violated, since the density f is no longer strictly positive Lebesgue-almost everywhere in this case. Although the equations will have a well-defined solution, they can strictly speaking no longer be interpreted as a projection in $\mathcal{L}^2$.

Proof of Theorem 7.2. The first part of the conditions in Theorem 7.1 is trivially satisfied, and so is the second part, since all terms may be linearly bounded in the state variables on a compact domain $\mathcal{U}_R$. We have therefore proven the result if we show that the function

$$V(\check{X}_t, \check{P}_t^2, \check{Z}_t^\epsilon) \ = \ (\check{X}_t)^2 \ + \ \check{P}_t^2 \ + \ \tfrac{1}{2}\check{Z}_t^\epsilon \ + \ (\check{Z}_t^\epsilon)^{-\frac{1}{2}} \tag{7.5}$$

satisfies the third condition. We remark that we have included the term $(\check{Z}_t^\epsilon)^{-\frac{1}{2}}$ to show that $\check{Z}_t^\epsilon$ cannot become zero in finite time and that $\check{Z}_t^\epsilon$ will thus stay strictly positive for all times $t \geq 0$ if its initial value is chosen to be strictly positive, as we suggested in the discussion after the proof of Theorem 3.1. Since the differential equation for $\check{P}_t^2$ shows that $\check{P}_t^2$ will stay strictly positive as well, this will then imply that $V(\check{X}_t, \check{P}_t^2, \check{Z}_t^\epsilon)$ is strictly positive for all $t \geq 0$. Using (7.1)–(7.3), we find that

$$\begin{aligned}
LV &= \tfrac{2\check{X}_t}{\epsilon^2} \cdot [\, \check{Z}_t(\mathbb{E}X - \check{X}_t) \;+\; \check{P}_t^2(S_t - \check{X}_t)\,] \;+\; \tfrac{(\check{P}_t^2)^2}{\epsilon^2} \;+\; \tfrac{\check{Z}_t^\epsilon}{\epsilon^2}[\,(\mathbb{E}X - \check{X}_t)^2 + \text{Var}\; X - \check{P}_t^2\,] \\
&\quad - \tfrac{(\check{P}_t^2)^2}{\epsilon^2} \;+\; \tfrac{\check{Z}_t^\epsilon}{2\epsilon^2}\,[\,-\check{Z}_t^\epsilon + \epsilon^2\tfrac{g'(t)}{g(t)} + \check{X}_t(\check{X}_t - S_t)\,] \\
&\quad - \tfrac{1}{2}(\check{Z}_t^\epsilon)^{-\frac{3}{2}} \cdot \tfrac{\check{Z}_t^\epsilon}{\epsilon^2}\,[\,-\check{Z}_t^\epsilon + \epsilon^2\tfrac{g'(t)}{g(t)} + \check{X}_t(\check{X}_t - S_t)\,] \;+\; \tfrac{1}{2}\cdot\tfrac{3}{4}(\check{Z}_t^\epsilon)^{-\frac{5}{2}} \cdot \tfrac{(\check{Z}_t^\epsilon \check{X}_t)^2}{\epsilon^2} \\
&= \tfrac{\check{Z}_t^\epsilon}{\epsilon^2}\,[\,(\mathbb{E}X)^2 - \tfrac{1}{4}(\check{X}_t)^2 + \text{Var}\; X - \check{P}_t^2 - \tfrac{1}{2}\check{Z}_t^\epsilon + \tfrac{1}{2}\epsilon^2\tfrac{g'(t)}{g(t)} - \tfrac{1}{2}\check{X}_t S_t - \tfrac{1}{4}(\check{X}_t)^2\,] \\
&\quad - 2\tfrac{\check{P}_t^2}{\epsilon^2}\check{X}_t(\check{X}_t - S_t) \;-\; \tfrac{1}{2}\tfrac{(\check{Z}_t^\epsilon)^{-\frac{1}{2}}}{\epsilon^2}\,[\,-\check{Z}_t^\epsilon + \epsilon^2\tfrac{g'(t)}{g(t)} + \tfrac{1}{4}(\check{X}_t)^2 - \check{X}_t S_t\,] \\
&\leq \tfrac{\check{Z}_t^\epsilon}{\epsilon^2}\,[\,(\mathbb{E}X)^2 + \text{Var}\; X + \tfrac{1}{2}\epsilon^2\check{g} - \tfrac{1}{4}\,\big[\,(\check{X}_t)^2 + \check{P}_t^2 + \tfrac{1}{2}\check{Z}_t^\epsilon\big] - \tfrac{1}{2}\check{X}_t S_t - \tfrac{1}{4}(\check{X}_t)^2\,] \\
&\quad - 2\tfrac{\check{P}_t^2}{\epsilon^2}\check{X}_t(\check{X}_t - S_t) \;+\; \tfrac{(\check{Z}_t^\epsilon)^{\frac{1}{2}}}{2\epsilon^2} \;+\; \tfrac{(\check{Z}_t^\epsilon)^{-\frac{1}{2}}}{\epsilon^2}\,[\,\tfrac{1}{2}\epsilon^2\,|\check{g}| - \tfrac{1}{8}(\check{X}_t)^2 + \tfrac{1}{2}\check{X}_t S_t\,].
\end{aligned}$$

We have that $(\check{Z}_t^\epsilon)^{\frac{1}{2}} \leq \check{Z}_t^\epsilon + (\check{Z}_t^\epsilon)^{-\frac{1}{2}}$ and we use the inequality $by - ay^2 \leq \frac{b^2}{4a}$ (all $y \in \mathbb{R}$) to find that

$$\begin{aligned}
-\tfrac{1}{2}\check{X}_t S_t - \tfrac{1}{4}(\check{X}_t)^2 \leq \tfrac{1}{4}(S_t)^2 \;&<\; \tfrac{1}{4}\bar{X}^2, \\
-2\check{X}_t(\check{X}_t - S_t) \leq \tfrac{1}{2}(S_t)^2 \;&<\; \tfrac{1}{2}\bar{X}^2, \\
-\tfrac{1}{8}(\check{X}_t)^2 + \tfrac{1}{2}\check{X}_t S_t \leq \tfrac{1}{2}(S_t)^2 \;&<\; \tfrac{1}{2}\bar{X}^2,
\end{aligned}$$

and therefore

$$\begin{aligned}
LV \leq \frac{\check{Z}_t^\epsilon}{\epsilon^2}\,&\left[\,(\mathbb{E}X)^2 + \text{Var}\; X + \frac{1}{2}\epsilon^2\check{g} - \frac{1}{4}\,\left[\,(\check{X}_t)^2 + \check{P}_t^2 + \frac{1}{2}\check{Z}_t^\epsilon\right] + \frac{1}{4}\bar{X}^2\,\right] \\
&+ \frac{\check{P}_t^2\,\bar{X}^2}{2\epsilon^2} \;+\; \frac{1}{2\epsilon^2}(\,\check{Z}_t^\epsilon + (\check{Z}_t^\epsilon)^{-\frac{1}{2}}\,) \;+\; \frac{(\check{Z}_t^\epsilon)^{-\frac{1}{2}}}{2\epsilon^2}\,[\,\epsilon^2\,|\check{g}| + \bar{X}^2\,],
\end{aligned}$$

so we can take, for example, $c = \frac{1}{2\epsilon^2}(2 + \bar{X}^2 + \epsilon^2|\check{g}|)$ in the last condition of Theorem 7.1, and

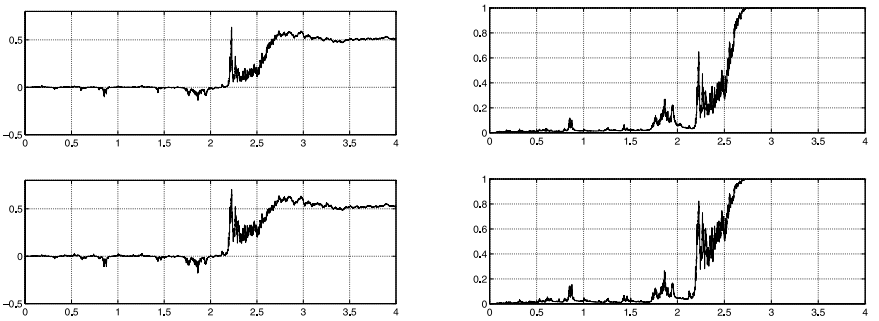
$$\mathcal{G} \;=\; \{\,(x,p,z) :\; x^2 + p + \tfrac{1}{2}z \;\leq\; 4(\mathbb{E}X)^2 + 4\,\text{Var}\; X + 2\epsilon^2\check{g} + \bar{X}^2\,\}.$$

All conditions of Theorem 7.1 are satisfied, and the filter equations have a unique, nonexploding solution. □

We have thus proven that the algorithm that we derived will be well behaved for all times $t \geq 0$ almost surely, and we can now analyze it in simulation studies in the next section.

8. Simulation results. In this section we will investigate the performance of the approximating filters that we defined in previous sections, by means of simulation studies.

Experiment 1. For the first simulation study we took τ to be an exponentially distributed stochastic variable with mean 15.0, and the jump size X normally distributed with zero mean and unit variance. We let the actual jump take place at



(a) Estimate of $\mathbb{E}[S_t \mid \mathcal{Y}_t^\epsilon]$ (b) Estimate of $\mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon)$

FIG. 2. *Comparison between optimal and approximate filter, using* (3.10).

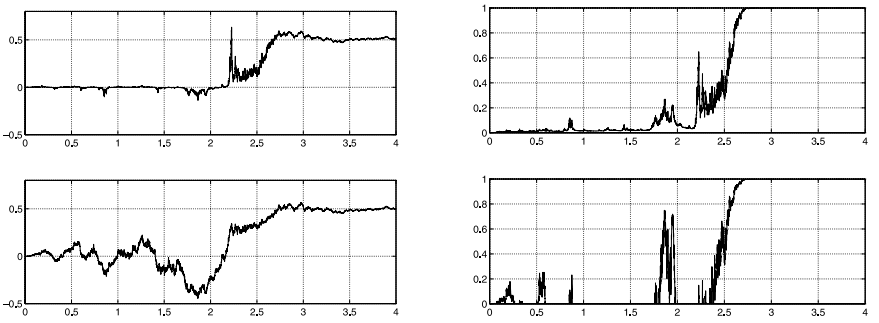
FIG. 3. *Comparison between optimal and approximate filter, using moments.*

$\tau = 2.0$, and the jump size was taken to be $X = 0.5$ exactly. The noise parameter ϵ was taken 0.10. All filters estimates were calculated on a time interval $t \in [0.0, 4.0]$, using an Euler scheme with step size $4.0 \cdot 10^{-5}$.

We first simulated the differential-geometric approximation as formulated in the previous section, i.e., we took the dimension of the filter $m + 1 = 3$, which means we project upon a manifold of Gaussian densities. In Figures 2 and 3 the results are shown for two different implementations of our filter. The top graphs show the real conditional estimate of the signal $\mathbb{E}[S_t \mid \mathcal{Y}_t^\epsilon]$ and the conditional probability that a jump has occurred $\mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon)$. These were obtained by solving the Duncan–Mortensen–Zakai equation on a grid which divided the interval $[-3.0, 3.0]$ for possible values of X in 1500 equidistant points. In Figure 2 the filter was implemented by (3.10), the stochastic differential equation for the parameter vector θ_t, while in Figure 3 the direct equations for the moments which we derived in the previous section were used. There are some small differences between the two, which should be attributed to inaccuracies in the calculation of $[H(\theta_t)]^{-1}$ in (3.10) and in the numerical method we use.



(a) Estimate of $\mathbb{E}[S_t \mid \mathcal{Y}_t^\epsilon]$.

(b) Estimate of $\mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon)$.

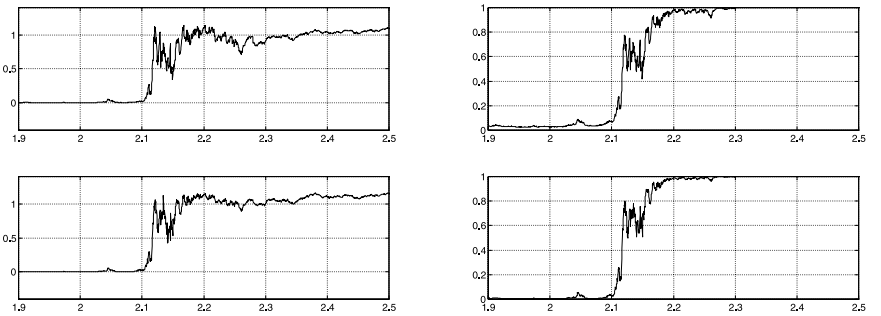
FIG. 4. *Comparison between optimal filter and filter of section* 4.

However, in both cases the filter estimates show an excellent behavior both before and after the change point. Both implementations slightly overestimate the conditional probability of a jump having occurred, but only after the jump. Around $t = 2.6$ the approximate and the exact conditional signal estimate are already indistinguishable. More importantly, the small delay in detection of the optimal filter (seen to be approximately 0.10 here) is the same for the approximate filter. For an extensive analysis of such detection delays in the optimal filter and its suboptimal approximations, the reader is referred to [11] and [23].

For comparison, Figure 4 shows a simulation of the same model setup for the approximating filter which we derived in section 4, where conditional moments are generated by using the Kushner–Stratonovich equation and the assumption that the third order central conditional moment is equal to zero. We showed in (5.3) that this filter, which was proposed in [11], is not equivalent to our filter and its behavior is seen to be a lot worse. Although it will estimate both the signal and the conditional probability correctly in the long run, its behavior before the change is totally unacceptable. Indeed, the conditional probability is negative most of the time, and the estimates of the signal before the change are not close to the true value zero at all.

Experiment 2. To show that the excellent results for our differential-geometric approximation are not just a consequence of X being Gaussian, we performed a second set of simulations in which X was taken to be uniformly distributed on $[0, 2]$. The jump time was given the same distribution as in the first set of experiments, and the actual jump time was again taken to be $\tau = 2.0$. The jump size was taken equal to $X = 1.0$, and $\epsilon = 0.10$.

Figure 5 shows the estimates generated by our approximate filter, implemented by (3.10). The detection delay of 0.10 is almost exactly the same as for the optimal filter, and good filter estimates are produced almost directly after that. Apparently the algorithm works quite well for a jump size X with a uniform distribution, even though this distribution cannot be approximated very well on the exponential manifold that we project upon. In practice this is not important, since after the jump the behavior in the center of the state space can be shown to be asymptotically Gaussian in a large deviations sense. We again refer to [11] and [23] where an exact statement of this result is given, which helps to explain the good performance of our filter.



(a) Estimate of $\mathbb{E}\left[S_t \mid \mathcal{Y}_t^\epsilon\right]$ (b) Estimate of $\mathbb{P}(t \geq \tau \mid \mathcal{Y}_t^\epsilon)$

FIG. 5. *Comparison between optimal and approximate filter.*

9. Conclusions. In this paper, we have argued that nonlinear filtering theory can be used to characterize and approximate relevant conditional statistics in those change detection problems where the size of the change is not known a priori. We have shown that a simple three-dimensional nonlinear filter can be defined which has a global and unique solution under mild conditions, and which performs well in simulation studies. Apart from an interpretation in terms of information geometry and in terms of an assumed density principle, we may view the equations for this filter as an adaptive version of the Shiryayev–Wonham equation, fed by estimates from a modified Kalman filter.

Some interesting problems are still open at the moment. These include, for example, the design of adaptive change detectors for discrete time problems, the design of detectors for more complicated signal changes such as the changing slope process [25]

$$R_t = \begin{cases} 0, & 0 \leq t < \tau, \\ X(t-\tau), & t \geq \tau, \end{cases}$$

and the derivation of further theoretical properties of the filters that we defined in this paper. We hope to address these problems in future research.

A FORMULA FOR THE DERIVATIVE WITH RESPECT TO DOMAIN VARIATIONS IN NAVIER–STOKES FLOW BASED ON AN EMBEDDING DOMAIN METHOD*

THOMAS SLAWIG†

Abstract. Fréchet differentiability and a formula for the derivative with respect to domain variation of a general class of cost functionals under the constraint of the two-dimensional stationary incompressible Navier–Stokes equations are shown. An embedding domain technique provides an equivalent formulation of the problem on a fixed domain and leads to a simple and computationally cheap line integral formula for the derivative of the cost functional with respect to domain variation. Existence of a solution to the corresponding domain optimization problems is proved. A numerical example shows the effectivity of the derivative formula.

Key words. domain optimization, Navier–Stokes equations, embedding domain technique

1. Introduction.

In this paper we present an explicit formula for the Fréchet derivative of a certain class of cost functionals with respect to variations in the shape of the domain under the constraint of the stationary, two-dimensional, incompressible Navier–Stokes equations. The derivative takes the form of a one-dimensional integral and thus is computationally cheap. It is based on the adjoint equation technique and on an embedding domain method, which allows it to formulate the state equations given on a complicated shaped domain in an equivalent way on a simple-shaped domain, e.g., a square. Moreover this method significantly reduces the rediscretization and re-assembling effort of the finite-dimensional system of the state equations on complicated-shaped and varying domains that occur during an iterative domain optimization process.

Embedding (or "fictitious") domain techniques have been widely applied in the treatment of PDEs. For Navier–Stokes equations on complicated-shaped domains, they were studied by, e.g., Glowinski, Pan, and Periaux [1]. Our Lagrange multiplier approach is similar to Glowinski's. Haslinger et al. used a slightly different one by introducing a distributed Lagrange multiplier and applied it on domain optimization problems; see, e.g., [2]. Domain optimization for the Navier–Stokes equations were studied, for example, by Pironneau [3], who computed the shape of body with minimum drag. Gunzburger and Kim [4] showed existence of an optimal shape for a minimum drag problem in a channel flow. Bello et al. [5] proved differentiability of the drag with respect to domain variations in Navier–Stokes flow.

The emphasis of this work is not to prove differentiability but to obtain a fast and effective numerical algorithm to solve domain optimization problems by iterative, gradient-based methods.

The same technique was used by Kunisch and Peichl [6] to obtain a derivative formula for the scalar Poisson problem. This paper extends a former work by Slawig [7] for the Stokes equations to the full nonlinear Navier–Stokes equations.

The outline of the paper is the following: in the next two sections we define the geometric model configuration and summarize the needed results for the stationary Navier–Stokes equations. Then the considered class of domain optimization problems and the embedding domain technique are presented. Later on we show the continuous dependence of the solution of the Navier–Stokes equations with respect to the variation of the domain. The presentation of the explicit formula for the Fréchet derivative is followed by a brief presentation of the numerical solution techniques for the state and adjoint equations and optimization problems. At the end we show an inverse problem as a numerical example.

2. The geometric model configuration. Our model geometry is determined by two requirements for the derivative formula and the embedding domain method:

(a) We need sufficient regularity of the solutions to the state and adjoint equations, i.e., H^2 and H^1 for velocity and pressure, respectively. Classical results (see the next section) require either a smooth (C^2) or a polygonal boundary with convex corners. As can be deduced from [9], a combination of both is sufficient also.

(b) In the embedding domain method we treat the problem on a fixed domain $\hat{\Omega}$ which satisfies $\Omega_\gamma \subset \hat{\Omega}$ for all admissible domains $\Omega_\gamma := \Omega(\gamma) \subset \mathbb{R}^2$, where γ is a parameter describing the shape of Ω_γ. To ensure existence of a solution to the state and adjoint equations on the "fictitious" part $\Omega_\gamma^c := \hat{\Omega} \setminus \bar{\Omega}_\gamma$ (see Figure 1 and section 5) we have to guarantee that Ω_γ^c is Lipschitz.

To ensure that a variable polygonal boundary retains its convex corners is rather technical. Thus we choose the following model configuration, which of course may be generalized according to the two points above. As in [7] the boundary $\partial\Omega_\gamma$ shall consist of the following:

- A fixed part Γ, which is the union of the two lateral sides and the top side of the unit square, i.e., the three segments $[(0,0),(0,1)], [(0,1),(1,1)], [(1,1),(1,0)]$. Thus Γ is a polygon with convex angles.
- A variable part Γ_γ, which is the graph of a function $\gamma : [0,1] \to [0,1)$ with $\gamma(0) = \gamma(1) = 0$; compare Figure 1, left. To guarantee that Ω_γ^c is Lipschitz we assume that γ is linear in neighborhoods of the two end points $(0,0)$ and $(1,0)$. Working in Sobolev spaces we choose $\gamma \in H^3(I)$ with $I := (0,1)$, which by classical embedding theorems ensures $\gamma \in C^2(I)$. To show existence

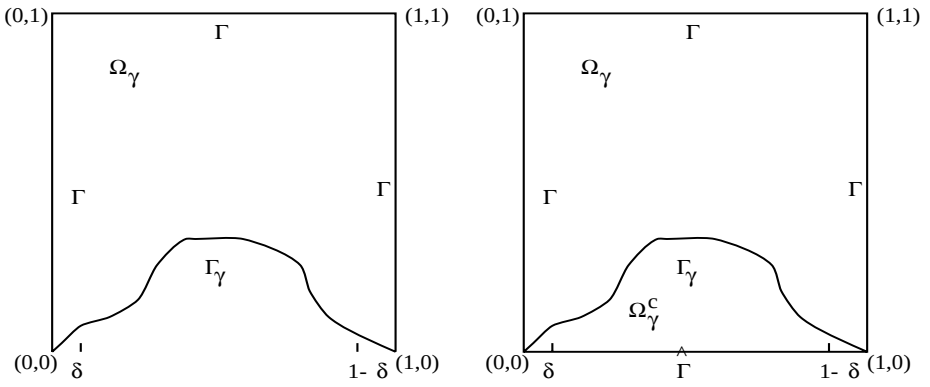

FIG. 1. *The domain Ω_γ in original version (left) and embedded into $\hat{\Omega}$ (right).*

of a solution of the considered domain optimization problems we assume boundedness in $H^3(I)$. The set of admissible functions γ is chosen as

$$\begin{aligned}(2.1)\quad \mathcal{S} := \{\gamma \in H^3(I) : \|\gamma\|_{H^3(I)} \le c_0, \gamma(0) = \gamma(1) = 0,\\ c_1 \le \gamma|_{(\delta,1-\delta)} \le c_2, \gamma'|_{(0,\delta)} = c_3, \gamma'|_{(1-\delta,1)} = c_4\},\end{aligned}$$

where $c_1, c_2 \in (0,1), \delta \in (0, \frac{1}{2}), c_0, c_3 \in \mathbb{R}^+, c_4 \in \mathbb{R}^-$ are fixed. The fact that we choose constant slopes c_3, c_4 here is just for simplicity.

Throughout this paper all considered functions γ shall be in $\mathcal{S}$ except where noted.

3. The Navier–Stokes equations. The stationary incompressible Navier–Stokes equations on a domain $\Omega_\gamma \subset \mathbb{R}^2$ in variational formulation read as follows: find the pair of velocity vector and pressure $(\mathbf{u}_\gamma, p_\gamma) \in H^1(\Omega_\gamma)^2 \times L^2(\Omega_\gamma)$ such that

$$\begin{aligned}\nu(\nabla \mathbf{u}_\gamma, \nabla \mathbf{v})_{\Omega_\gamma} + (\mathbf{u}_\gamma \cdot \nabla \mathbf{u}_\gamma, \mathbf{v})_{\Omega_\gamma} - (p_\gamma, \operatorname{div} \mathbf{v})_{\Omega_\gamma} &= (\mathbf{f}_\gamma, \mathbf{v})_{\Omega_\gamma} && \text{for all } \mathbf{v} \in H_0^1(\Omega_\gamma)^2,\\ (\operatorname{div} \mathbf{u}_\gamma, q)_{\Omega_\gamma} &= 0 && \text{for all } q \in L_0^2(\Omega_\gamma),\\ \mathbf{u}_\gamma &= \Phi && \text{on } \Gamma,\\ \mathbf{u}_\gamma &= \mathbf{0} && \text{on } \Gamma_\gamma,\end{aligned} \tag{3.1}$$

with $L_0^2(\Omega_\gamma) := \{q \in L^2(\Omega_\gamma) : \int_{\Omega_\gamma} q\,dx = 0\}$. The parameter $\nu > 0$ represents the inverse of the Reynolds number. For scalar-valued functions $(\cdot,\cdot)_{\Omega_\gamma}$ denotes the $L^2(\Omega_\gamma)$ inner product; for vector-valued functions we define $(\mathbf{u}, \mathbf{v})_{\Omega_\gamma} := \sum_{i=1}^2 (u_i, v_i)_{\Omega_\gamma}$ and $(\nabla \mathbf{u}, \nabla \mathbf{v})_{\Omega_\gamma} := \sum_{i,j=1}^2 (\frac{\partial u_i}{\partial x_j}, \frac{\partial v_i}{\partial x_j})_{\Omega_\gamma}$. By $|\mathbf{v}|_{H^1(\Omega_\gamma)^2} := (\nabla \mathbf{v}, \nabla \mathbf{v})_{\Omega_\gamma}^{1/2}$ we denote the H^1 seminorm. The nonlinearity is defined by the operator $(\mathbf{u} \cdot \nabla) := \sum_{j=1}^2 u_j \frac{\partial}{\partial x_j}$.

To obtain the needed regularity of the solution we assume $\mathbf{f}_\gamma \in L^2(\Omega_\gamma)^2$; to prove the formula for the derivative in section 7 we will need $\mathbf{f}_\gamma \in L^p(\Omega_\gamma)^2$ with $p > 2$. The Dirichlet boundary conditions indicate that the variable boundary part Γ_γ is a wall with no-slip conditions, whereas the fixed part Γ may be either a wall (if $\Phi = \mathbf{0}$) or a region with prescribed in or outflow velocity. The function Φ shall be in the space

$$H(\Gamma) := \left\{\Phi \in L^2(\Gamma)^2 : \text{there is } \bar{\mathbf{u}}_\gamma \in H^2(\Omega_\gamma)^2 : \operatorname{div} \bar{\mathbf{u}}_\gamma = 0 \text{ in } \Omega_\gamma, \bar{\mathbf{u}}_\gamma|_{\Gamma_\gamma} = \mathbf{0}, \bar{\mathbf{u}}_\gamma|_\Gamma = \Phi\right\}.$$

By our geometric definitions this space is independent of γ. As a consequence Φ satisfies $\int_\Gamma \Phi \cdot \mathbf{n}\,ds = 0$, where $\mathbf{n}$ is the normal vector on Γ.

Existence and uniqueness of the pressure (viewed as Lagrange multiplier corresponding to the constraint of zero divergence) rely on the surjectivity of the weak divergence operator as mapping from $H_0^1(\Omega_\gamma)^2$ onto $L_0^2(\Omega_\gamma)$; see [8, Lemma I.4.1].

LEMMA 3.1. *For every velocity vector* $\mathbf{u}_\gamma \in H^1(\Omega_\gamma)^2$ *solving* (3.1) *the corresponding pressure* p_γ *is unique in* $L^2(\Omega_\gamma)/\mathbb{R}$.

Proof. See [8, Theorem IV.1.4, Corollary I.2.4]. □

The additive constant in the pressure regarded as a function in $L^2(\Omega_\gamma)$ now can be chosen such that $p_\gamma \in L_0^2(\Omega_\gamma)$. This space is often used since—endowed with the L^2 norm—it can be identified isomorphically with $L^2(\Omega_\gamma)/\mathbb{R}$.

Uniqueness of the velocity component of a solution to (3.1) depends on a property of the nonlinear term.

LEMMA 3.2. *Let* $\Omega \subset \mathbb{R}^n, n \le 4$, *be bounded. Then*

$$(\mathbf{u} \cdot \nabla \mathbf{v}, \mathbf{w})_\Omega \le k|\mathbf{u}|_{H^1(\Omega)^2}|\mathbf{v}|_{H^1(\Omega)^2}|\mathbf{w}|_{H^1(\Omega)^2} \quad \textit{for all } \mathbf{u}, \mathbf{w} \in H_0^1(\Omega)^2, \mathbf{v} \in H^1(\Omega)^2,$$

where the constant $k = \frac{1}{2}|\Omega|^{1/2}$ *depends only on* Ω *(*$|\Omega|$ *denotes the measure of* Ω*).*

Proof. See [13, Lemma VIII.1.1]. □

This leads to the following result.

THEOREM 3.3. *Problem* (3.1) *has a unique solution* $(\mathbf{u}_\gamma, p_\gamma) \in H^1(\Omega_\gamma)^2 \times L^2(\Omega_\gamma)/\mathbb{R}$ *if* $\nu > \nu_1 := |\mathbf{u}_\gamma|_{H^1(\Omega_\gamma)^2}/k_\gamma$ *for* $k_\gamma = \frac{1}{2}|\Omega_\gamma|^{1/2}$. *In the case* $\mathbf{f}_\gamma = \mathbf{0}$ *and* $\Phi = \mathbf{0}$, *uniqueness is given without any restriction on* ν.

Proof. See [13, Theorem VIII.2.1]; the result is also valid with weaker assumptions on $\mathbf{f}_\gamma$ and Φ. □

Regularity results for the Navier–Stokes equations are based on those for the Stokes equations by treating the nonlinearity as an additional inhomogeneity and using embedding and function space interpolation theorems; see, e.g., [9, Theorem pp. 403–404] and [10, Prop. II.1.1, Remarks II.1.4, II.1.6]. This implies that the geometric requirements for the regularity and uniform boundedness of the solution (with respect to γ) are the same as for the Stokes equations; see [7, Theorem 3.1].

THEOREM 3.4. *Every solution of* (3.1) *satisfies* $(\mathbf{u}_\gamma, p_\gamma) \in H^2(\Omega_\gamma)^2 \times H^1(\Omega_\gamma)$. *Moreover there exists* $C > 0$ *independent of* $\gamma, \mathbf{f}_\gamma$, *and* Φ *such that*

$$\|\mathbf{u}_\gamma\|_{H^2(\Omega_\gamma)^2} + \|p_\gamma\|_{H^1(\Omega_\gamma)} \le C \left(\|\mathbf{f}_\gamma\|_{L^2(\Omega_\gamma)^2} + \|\Phi\|_{L^\infty(\Gamma)^2} \right).$$

Using this result a lower bound $\nu_0(\gamma, \Phi, \mathbf{f}_\gamma)$ for the constant $\nu_1 = \nu_1(\mathbf{u}_\gamma)$ defined in Theorem 3.3 can be given. Thus uniqueness of the velocity is given if $\nu > \nu_0$, where ν_0 depends on γ, Φ, and $\mathbf{f}_\gamma$. See also [8, Theorem IV.2.4].

4. A class of domain optimization problems. We consider domain optimization problems of the form

$$\min_{\gamma \in \mathcal{S}} \mathcal{J}(\gamma) \;:=\; \min_{\gamma \in \mathcal{S}} \frac{1}{2} \|\mathcal{A}(\mathbf{u}_\gamma) - \mathbf{u}_d\|^2_{L^2(\Omega_C)^k} \quad \text{subject to} \quad \mathbf{u}_\gamma \text{ solves (3.1)} \tag{4.1}$$

with $\mathcal{A} \in \mathcal{L}(H^1(\Omega_\gamma)^2, L^2(\Omega_C)^2), \mathbf{u}_d \in L^2(\Omega_C)^2$ or $\mathcal{A} \in \mathcal{L}(H^1(\Omega_\gamma)^2, L^2(\Omega_C)^{2\times 2}), \mathbf{u}_d \in L^2(\Omega_C)^{2\times 2}$, where $L^2(\Omega_C)^{2\times 2}$ denotes the space of (2×2) matrix-valued functions. The set $\Omega_C \subset \Omega_\gamma$ is assumed to satisfy $\operatorname{dist}(\Gamma_\gamma, \Omega_C) > 0$ for all $\gamma \in \mathcal{S}$. The dependence of $\mathcal{J}$ on γ is implicit due to the fact that $\mathcal{J}$ depends on $\mathbf{u}_\gamma$, which itself depends on γ. The above definition of the cost functional includes typical choices such as the *tracking type* functional

$$\mathcal{J}(\gamma) := \frac{1}{2} \|\mathbf{u}_\gamma - \mathbf{u}_d\|^2_{L^2(\Omega_C)^2}$$

or the *minimum drag problem*; compare Pironneau [3], Gunzburger and Kim [4]:

$$\mathcal{J}(\gamma) := \frac{\nu}{2} \|\nabla \mathbf{u}_\gamma + (\nabla \mathbf{u}_\gamma)^T\|^2_{L^2(\Omega_C)^{2\times 2}} \;:=\; \frac{\nu}{2} (\nabla \mathbf{u}_\gamma + (\nabla \mathbf{u}_\gamma)^T, \nabla \mathbf{u}_\gamma + (\nabla \mathbf{u}_\gamma)^T)_{\Omega_C}.$$

A regularization term penalizing the L^2- or H^1-norm of γ may be added to the cost functional. We skip it in our theoretical investigations since its differentiability is obtained in a straightforward way.

5. The embedding domain method. To solve the domain optimization problem (4.1) by a gradient-based iterative scheme it is necessary to discretize the domain, assemble the system matrices and nonlinear operators, and solve the outgoing nonlinear system in each iteration step. To reduce this effort an equivalent formulation of the Navier–Stokes equations (3.1) on a fixed domain is used: a so-called *fictitious domain* $\hat{\Omega}$ is introduced. It is chosen in such a way that all admissible domains can be embedded in it, i.e., $\Omega_\gamma \subset \hat{\Omega}$ for all $\gamma \in \mathcal{S}$. Furthermore, the fixed boundary part

Γ shall remain a part of $\partial\hat{\Omega}$ whereas Γ_γ is replaced by a partition called $\hat{\Gamma}$, which now is also fixed. Thus $\partial\hat{\Omega} = \bar{\Gamma} \cup \bar{\hat{\Gamma}}$; compare Figure 1 (right). The "fictitious" part of $\hat{\Omega}$ is denoted by $\Omega_\gamma^c := \hat{\Omega} \setminus \bar{\Omega}_\gamma$.

Now we introduce an equivalent formulation of (3.1) on $\hat{\Omega}$. The boundary condition on Γ_γ in the Navier–Stokes equations now becomes a constraint on an inner line of the fictitious domain $\hat{\Omega}$ and is treated similarly to the constraint of zero divergence in (3.1). Analogously to the pressure, which can be regarded as a Lagrange multiplier corresponding to this constraint, an additional multiplier g_γ corresponding to the former boundary condition $\mathbf{u}_\gamma = \mathbf{0}$ on Γ_γ is introduced.

The resulting *fictitious domain formulation of the Navier–Stokes equations* reads as follows: find $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma, g_\gamma) \in H^1(\hat{\Omega})^2 \times L_0^2(\hat{\Omega}) \times H_\gamma^*$ such that

$$
\begin{aligned}
\left.\begin{aligned} \nu(\nabla\hat{\mathbf{u}}_\gamma, \nabla\hat{\mathbf{v}})_{\hat{\Omega}} + (\hat{\mathbf{u}}_\gamma \cdot \nabla\hat{\mathbf{u}}_\gamma, \hat{\mathbf{v}})_{\hat{\Omega}} \\ -(\hat{p}_\gamma, \operatorname{div}\hat{\mathbf{v}})_{\hat{\Omega}} - \langle g_\gamma, \tau_\gamma\hat{\mathbf{v}}\rangle_{H_\gamma^*, H_\gamma} \end{aligned}\right\} &= (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}})_{\hat{\Omega}} \qquad \text{for all } \hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2, \\
(\operatorname{div}\hat{\mathbf{u}}_\gamma, \hat{q})_{\hat{\Omega}} &= 0 \qquad \text{for all } \hat{q} \in L_0^2(\hat{\Omega}), \\
\hat{\mathbf{u}}_\gamma &= \mathbf{0} \qquad \text{on } \Gamma_\gamma, \\
\hat{\mathbf{u}}_\gamma &= \tilde{\Phi} \qquad \text{on } \partial\hat{\Omega}.
\end{aligned} \tag{5.1}
$$

Here τ_γ is the inner trace operator $\hat{\mathbf{v}} \mapsto \hat{\mathbf{v}}|_{\Gamma_\gamma}$, which is linear and continuous from $H^1(\hat{\Omega})^2$ into $H^{1/2}(\Gamma_\gamma)^2$ and from $H_0^1(\hat{\Omega})^2$ onto

$$
H_\gamma := H_{00}^{1/2}(\Gamma_\gamma)^2 = \big\{\mathbf{h} \in H^{1/2}(\Gamma_\gamma)^2 : \text{there is } \tilde{\mathbf{h}} \in H^{1/2}(\partial\Omega_\gamma)^2 : \tilde{\mathbf{h}}|_{\Gamma_\gamma} = \mathbf{h}, \tilde{\mathbf{h}}|_\Gamma = \mathbf{0}\big\};
$$

compare with [11, VII, section 2.1, Remark 1]. To guarantee equivalence between (3.1) and (5.1)—in a sense that is necessary for the derivative formula—inhomogeneity and boundary values have to be extended *by zero* onto the fictitious part of the domain and its boundary, respectively. Moreover the regularity of Theorem 3.4 is needed. In domain optimization problems such as (3.1) it makes sense to assume that the inhomogeneity does not explicitly depend on the shape of the domain but is given by a function $\mathbf{f}$ defined on a domain containing all admissible Ω_γ, let us say $\hat{\Omega}$. Summarizing, we thus assume that

$$
\tilde{\mathbf{f}}_\gamma := \left\{ \begin{array}{lll} \mathbf{f}_\gamma := \mathbf{f}|_{\Omega_\gamma} & \text{in } \Omega_\gamma \\ \mathbf{0} & \text{in } \Omega_\gamma^c \end{array} \right\} \quad \text{and} \quad \tilde{\Phi} := \left\{ \begin{array}{ll} \Phi & \text{on } \Gamma \\ \mathbf{0} & \text{on } \Gamma_\gamma \end{array} \right\}, \tag{5.2}
$$

where $\mathbf{f} \in L^2(\hat{\Omega})^2$. As a consequence $\tilde{\mathbf{f}}_\gamma \in L^2(\hat{\Omega})^2$ and $\tilde{\Phi} \in H^{3/2}(\partial\hat{\Omega})^2$, $\int_{\partial\hat{\Omega}} \tilde{\Phi}\cdot\mathbf{n}\, ds = 0$.

To obtain uniqueness of the Lagrange multipliers $\hat{p}_\gamma, g_\gamma$ we introduce the space

$$
L_*^2(\hat{\Omega}) := \big\{\hat{q} \in L_0^2(\hat{\Omega}) : \hat{q}|_\Sigma = 0\big\} \quad \text{for } \Sigma := \{(x,y) \in \hat{\Omega} : 0 < x < \delta, 0 < y < c_3 x\}
$$

with δ, c_3 defined in (2.1). We have $\Sigma \subset \Omega_\gamma^c$ and $|\Sigma| > 0$ for all $\gamma \in \mathcal{S}$. Thus if $\hat{p} \in L_*^2(\hat{\Omega})$ satisfies $\hat{p}|_{\Omega_\gamma^c} = 0$ in $L^2(\Omega_\gamma^c)/\mathbb{R}$, then $\hat{p}|_{\Omega_\gamma^c} = 0$ even in $L^2(\Omega_\gamma^c)$. We use this fact to show the equivalence of the fictitious domain formulation and (3.1).

THEOREM 5.1. *Let $\mathbf{n}_\gamma$ denote the outer (with respect to Ω_γ) normal vector on Γ_γ. Then $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma, g_\gamma) \in H^1(\hat{\Omega})^2 \times L_*^2(\hat{\Omega}) \times H_\gamma^*$ is a solution to* (5.1) *if and only if*

(a) $(\mathbf{u}_\gamma, p_\gamma) := (\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega_\gamma} \in H^1(\Omega_\gamma)^2 \times L_0^2(\Omega_\gamma)$ *is a solution to* (3.1),

(b) $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega_\gamma^c} = (\mathbf{0}, 0)$ *in* $H^1(\Omega_\gamma^c)^2 \times L^2(\Omega_\gamma^c)$, *and*

$$
\langle g_\gamma, \mathbf{h}\rangle_{H_\gamma^*, H_\gamma} = \left(\nu\frac{\partial\mathbf{u}_\gamma}{\partial\mathbf{n}_\gamma} - p_\gamma\mathbf{n}_\gamma, \mathbf{h}\right)_{\Gamma_\gamma} \qquad \textit{for all } \mathbf{h} \in H_\gamma. \tag{5.3}
$$

Proof. (a) Clearly $\mathbf{u}_\gamma := \hat{\mathbf{u}}_\gamma|_{\Omega_\gamma}$ satisfies the boundary conditions in (3.1). We take any $(\mathbf{v}, q) \in H_0^1(\Omega_\gamma)^2 \times L_0^2(\Omega_\gamma)$ and denote by $(\tilde{\mathbf{v}}, \tilde{q})$ its extension by zero onto $\hat{\Omega}$, which clearly is in $H_0^1(\hat{\Omega})^2 \times L_0^2(\hat{\Omega})$. Testing (5.1) with this pair we obtain that $(\mathbf{u}_\gamma, p_\gamma) \in H^1(\Omega_\gamma)^2 \times L^2(\Omega_\gamma)$ with $p_\gamma := \hat{p}_\gamma|_{\Omega_\gamma}$ is a solution to (3.1).

Taking the extensions by zero of any $(\mathbf{v}, q) \in H_0^1(\Omega_\gamma^c)^2 \times L_0^2(\Omega_\gamma^c)$ and proceeding in the same way (5.1) implies that $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega_\gamma^c} \in H^1(\Omega_\gamma^c)^2 \times L^2(\Omega_\gamma^c)$ is a solution to the homogeneous Navier–Stokes equations on Ω_γ^c with homogeneous boundary conditions. By Theorem 3.3 we have uniqueness and $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega_\gamma^c} = (\mathbf{0}, 0)$ in $H^1(\Omega_\gamma^c)^2 \times L^2(\Omega_\gamma^c)/\mathbb{R}$. Here it is required that also Ω_γ^c is Lipschitz which is guaranteed by (2.1). Now $\hat{p}_\gamma \in L_*^2(\hat{\Omega})$ implies $\hat{p}_\gamma|_{\Omega_\gamma^c} = 0$ and $p_\gamma \in L_0^2(\Omega_\gamma)$. Thus the first equation of (5.1) reads as

$$\left.\begin{array}{l} \nu(\nabla \mathbf{u}_\gamma, \nabla \hat{\mathbf{v}})_{\Omega_\gamma} + (\mathbf{u}_\gamma \cdot \nabla \mathbf{u}_\gamma, \hat{\mathbf{v}})_{\Omega_\gamma} \\ -(p_\gamma, \operatorname{div} \hat{\mathbf{v}})_{\Omega_\gamma} - \langle g_\gamma, \tau_\gamma \hat{\mathbf{v}} \rangle_{H_\gamma^*, H_\gamma} \end{array}\right\} = (\mathbf{f}_\gamma, \hat{\mathbf{v}})_{\Omega_\gamma} \quad \text{for all } \hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2. \tag{5.4}$$

Applying Green's formula (see [8, Lemma I.1.4 and eq. I.(2.17)]) on Ω_γ we get

$$\nu(\nabla \mathbf{u}_\gamma, \nabla \hat{\mathbf{v}})_{\Omega_\gamma} - (p_\gamma, \operatorname{div} \hat{\mathbf{v}})_{\Omega_\gamma} = (-\nu \triangle \mathbf{u}_\gamma + \nabla p_\gamma, \hat{\mathbf{v}})_{\Omega_\gamma} + \left(\nu \frac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} - p_\gamma \mathbf{n}_\gamma, \hat{\mathbf{v}} \right)_{\Gamma_\gamma}$$

for all $\hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2$ and thus

$$\left.\begin{array}{l} (-\nu \triangle \mathbf{u}_\gamma + \mathbf{u}_\gamma \cdot \nabla \mathbf{u}_\gamma + \nabla p_\gamma - \mathbf{f}_\gamma, \hat{\mathbf{v}})_{\Omega_\gamma} \\ + \left(\nu \dfrac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} - p_\gamma \mathbf{n}_\gamma, \hat{\mathbf{v}} \right)_{\Gamma_\gamma} - \langle g_\gamma, \tau_\gamma \hat{\mathbf{v}} \rangle_{H_\gamma^*, H_\gamma} \end{array}\right\} = 0 \quad \text{for all } \hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2. \tag{5.5}$$

Testing this equation with the extension of $\mathbf{v} \in H_0^1(\Omega_\gamma)^2$ by zero onto $\hat{\Omega}$ we get

$$(-\nu \triangle \mathbf{u}_\gamma + \mathbf{u}_\gamma \cdot \nabla \mathbf{u}_\gamma + \nabla p_\gamma - \mathbf{f}_\gamma, \mathbf{v})_{\Omega_\gamma} = 0 \quad \text{for all } \mathbf{v} \in H_0^1(\Omega_\gamma)^2,$$

which means $-\nu \triangle \mathbf{u}_\gamma + \mathbf{u}_\gamma \cdot \nabla \mathbf{u}_\gamma + \nabla p_\gamma = \mathbf{f}_\gamma$ in $H^{-1}(\Omega_\gamma)^2$ and by regularity even in $L^2(\Omega_\gamma)^2$. Now we test (5.5) with any $\hat{\mathbf{v}} \in H_0^1(\hat{\Omega})^2$. Thus $\tau_\gamma \hat{\mathbf{v}} \in H_\gamma$ and by the surjectivity of τ_γ we obtain (5.3).

(b) Obviously $\hat{\mathbf{u}}_\gamma$ satisfies the boundary conditions and the second equation in (3.1). Since $(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)|_{\Omega_\gamma^c} := (\mathbf{0}, 0)$, the first equation in (5.1) is equivalent to (5.4) and, again with Green's formula on Ω_γ, to (5.5). Now (3.1) implies

$$-\nu \triangle \mathbf{u}_\gamma + \mathbf{u}_\gamma \cdot \nabla \mathbf{u}_\gamma + \nabla p_\gamma - \mathbf{f}_\gamma = \mathbf{0} \quad \text{in } L^2(\Omega_\gamma)^2,$$

which together with (5.3) gives (5.5). Obviously $p_\gamma \in L_0^2(\Omega_\gamma)$ implies $\hat{p}_\gamma \in L_*^2(\hat{\Omega})$. Equation (5.3) defines $g_\gamma \in H_\gamma^*$ since

$$\begin{aligned} \left(\nu \frac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} - p_\gamma \mathbf{n}_\gamma, \mathbf{h} \right)_{\Gamma_\gamma} &\le \left(\nu \left\| \frac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} \right\|_{L^2(\Gamma_\gamma)^2} + \|p_\gamma \mathbf{n}_\gamma\|_{L^2(\Gamma_\gamma)} \right) \|\mathbf{h}\|_{L^2(\Gamma_\gamma)^2} \\ &\le C \left(\nu |\mathbf{u}_\gamma|_{H^1(\Omega_\gamma)^2} + \|p_\gamma\|_{L^2(\Gamma_\gamma)} \right) \|\mathbf{h}\|_{H^{1/2}(\Gamma_\gamma)^2}. \end{aligned}$$

□

Remark 5.2. Formula (5.3) is due to the assumptions (5.2) and $\hat{p}_\gamma \in L_*^2(\hat{\Omega})$ (as a correction to [12] where $\hat{p}_\gamma \in L_0^2(\hat{\Omega})$ was used). Without (5.2) the Lagrange multiplier g_γ equals the jump of the right-hand side of $\nu \frac{\partial \mathbf{u}_\gamma}{\partial \mathbf{n}_\gamma} - p_\gamma \mathbf{n}_\gamma$ along Γ_γ; see [1].

We state two direct consequences of the result above and Lemma 3.1 and Theorem 3.3, respectively.

COROLLARY 5.3. *For every solution component* $\hat{\mathbf{u}}_\gamma$ *in* (5.1) *the corresponding pair* $(\hat{p}_\gamma, g_\gamma)$ *is unique in* $L^2_*(\hat{\Omega}) \times H^*_\gamma$.

COROLLARY 5.4. *The families* $\{(\hat{\mathbf{u}}_\gamma, \hat{p}_\gamma)\}_{\gamma\in\mathcal{S}}$ *and* $\{\|g_\gamma\|_{H^*_\gamma}\}_{\gamma\in\mathcal{S}}$ *are uniformly bounded in* $H^1(\hat{\Omega})^2 \times L^2(\hat{\Omega})$ *and* $\mathbb{R}$, *respectively. By* (5.3) *the functional* g_γ *can be extended onto* $L^2(\Gamma_\gamma)^2$. *The family* $\{\|g_\gamma\|_{L^2(\Gamma_\gamma)^2}\}_{\gamma\in\mathcal{S}}$ *is bounded.*

6. Continuous dependence of the solution on the shape of the domain. As a direct consequence of (5.2) the following equation holds for $\gamma, \bar{\gamma} \in \mathcal{S}$ and $I_+ := \{x \in I : \bar{\gamma}(x) \geq \gamma(x)\}, I_- := \{x \in I : \bar{\gamma}(x) < \gamma(x)\}$:

$$\tilde{\mathbf{f}}_{\bar{\gamma}}(x,y) - \tilde{\mathbf{f}}_\gamma(x,y) = \begin{cases} \mathbf{f}(x,y), & x \in I_+, \gamma(x) \leq y \leq \bar{\gamma}(x), \\ -\mathbf{f}(x,y), & x \in I_-, \bar{\gamma}(x) \leq y \leq \gamma(x), \\ \mathbf{0} & \text{otherwise.} \end{cases} \tag{6.1}$$

To show continuity of solutions to (5.1) with respect to γ we need the following results.

LEMMA 6.1. *Let* $\hat{\mathbf{u}}_\gamma, \hat{\mathbf{u}}_{\bar{\gamma}}$ *denote components of solutions to* (5.1). *Then*

$$(\tilde{\mathbf{f}}_{\bar{\gamma}} - \tilde{\mathbf{f}}_\gamma, \hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma)_{\hat{\Omega}} \leq \sqrt{2}\,\|\mathbf{f}\|_{L^2(\hat{\Omega})^2} |\hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma|_{H^1(\hat{\Omega})^2} \|\bar{\gamma} - \gamma\|_{L^\infty(I)}.$$

Proof. Using (6.1) we obtain for $\hat{\mathbf{u}} := \hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma$

$$(\tilde{\mathbf{f}}_{\bar{\gamma}} - \tilde{\mathbf{f}}_\gamma, \hat{\mathbf{u}})_{\hat{\Omega}} = \int_{I_+} \int_\gamma^{\bar{\gamma}} \mathbf{f}(x,y) \cdot \hat{\mathbf{u}}(x,y)\, dydx - \int_{I_-} \int_{\bar{\gamma}}^{\gamma} \mathbf{f}(x,y) \cdot \hat{\mathbf{u}}(x,y)\, dydx =: A - B.$$

We get with $\hat{\mathbf{u}}(x,\gamma(x)) = \mathbf{0}$ a.e. in I_+

$$\begin{aligned} |A| &\leq \int_{I_+} \int_\gamma^{\bar{\gamma}} |\mathbf{f}(x,y) \cdot [\hat{\mathbf{u}}(x,y) - \hat{\mathbf{u}}(x,\gamma)]|\, dydx \\ &\leq \|\mathbf{f}\|_{L^2(\hat{\Omega})^2} \left(\int_{I_+} \int_\gamma^{\bar{\gamma}} \left\| \int_\gamma^y \frac{\partial \hat{\mathbf{u}}}{\partial y}(x,\xi)\, d\xi \right\|_2^2 dydx \right)^{1/2} \\ &\leq \|\mathbf{f}\|_{L^2(\hat{\Omega})^2} \left(\int_{I_+} \int_\gamma^{\bar{\gamma}} |y-\gamma| \int_\gamma^y \left\| \frac{\partial \hat{\mathbf{u}}}{\partial y}(x,\xi) \right\|_2^2 d\xi dydx \right)^{1/2} \\ &\leq \|\mathbf{f}\|_{L^2(\hat{\Omega})^2} \left(\int_{I_+} \int_\gamma^{\bar{\gamma}} |y-\gamma| \int_\gamma^{\bar{\gamma}} \left\| \frac{\partial \hat{\mathbf{u}}}{\partial y}(x,\xi) \right\|_2^2 d\xi dydx \right)^{1/2} \\ &\leq \frac{1}{\sqrt{2}} \|\mathbf{f}\|_{L^2(\hat{\Omega})^2} |\hat{\mathbf{u}}|_{H^1(\hat{\Omega})^2} \|\bar{\gamma} - \gamma\|_{L^\infty(I)}. \end{aligned}$$

Note that $\frac{\partial \hat{\mathbf{u}}}{\partial y} = -\frac{\partial \hat{\mathbf{u}}_\gamma}{\partial y}$ on $I_+ \times (\gamma, \bar{\gamma})$, which by Theorem 3.4 is an H^1 function. Thus the innermost integral exists. The integral B is estimated in a similar way using $\hat{\mathbf{u}}(x, \bar{\gamma}(x)) = \mathbf{0}$ a.e. in I_-. □

LEMMA 6.2. *Let* $\hat{\mathbf{u}}_\gamma, g_\gamma, \hat{\mathbf{u}}_{\bar{\gamma}}$ *be components of solutions to* (5.1) *for* $\gamma, \bar{\gamma}$, *respectively. Then there exists* L *independent of* $\gamma, \bar{\gamma}$ *with*

$$|\langle g_\gamma, \tau_\gamma(\hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma)\rangle_{H^*_\gamma, H_\gamma}| \leq L |\hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma|_{H^1(\hat{\Omega})^2} \|\bar{\gamma} - \gamma\|_{L^\infty(I)}.$$

Proof. Since $\tau_\gamma \hat{\mathbf{u}}_\gamma, \tau_\gamma \hat{\mathbf{u}}_{\bar{\gamma}} \in H_\gamma$, we have for $\hat{\mathbf{u}} := \hat{\mathbf{u}}_{\bar{\gamma}} - \hat{\mathbf{u}}_\gamma$ that

$$|\langle g_\gamma, \tau_\gamma \hat{\mathbf{u}}\rangle_{H^*_\gamma, H_\gamma}| = |(g_\gamma, \tau_\gamma \hat{\mathbf{u}})_{\Gamma_\gamma}| \;\leq\; \|g_\gamma\|_{L^2(\Gamma_\gamma)^2} \|\tau_\gamma \hat{\mathbf{u}}\|_{L^2(\Gamma_\gamma)^2}.$$

The first term on the right-hand side is bounded independently of γ by Corollary 5.4. For the last term we use $\hat{\mathbf{u}}(x,\bar\gamma(x)) = \mathbf{0}$ a.e. in I_- and $\hat{\mathbf{u}}(x,\gamma(x)) = \mathbf{0}$ a.e. in I_+:

$$\begin{aligned}\|\tau_\gamma\hat{\mathbf{u}}\|^2_{L^2(\Gamma_\gamma)^2} &= \int_{I_-} \|\hat{\mathbf{u}}(x,\bar\gamma(x)) - \hat{\mathbf{u}}(x,\gamma(x))\|_2^2 \sqrt{1+\gamma'(x)^2}\,dx \\ &= \int_{I_-} \left\| \int_\gamma^{\bar\gamma} \frac{\partial\hat{\mathbf{u}}}{\partial y}(x,\xi)\,d\xi \right\|_2^2 \sqrt{1+\gamma'(x)^2}\,dx \\ &\le \|\bar\gamma-\gamma\|^2_{L^\infty(I)} |\hat{\mathbf{u}}|^2_{H^1(\hat\Omega)^2} (1+\|\gamma\|^2_{W^{1,\infty}(I)}).\end{aligned}$$

Because $\mathcal{S}$ is bounded in $H^3(I) \hookrightarrow W^{1,\infty}(I)$ the lemma is proved. ∎

The following property of the nonlinear term is a generalization of [8, Lem. IV.2.2].

LEMMA 6.3. *Let $\Omega \subset \mathbb{R}^n$, $\mathbf{u},\mathbf{v},\mathbf{w} \in H^1(\Omega)^n$ with $\operatorname{div}\mathbf{w} = 0$ in Ω. Then*

$$(\mathbf{w}\cdot\nabla\mathbf{u},\mathbf{v})_\Omega = -(\mathbf{w}\cdot\nabla\mathbf{v},\mathbf{u})_\Omega + (\mathbf{w}\cdot\mathbf{n},\mathbf{u}\cdot\mathbf{v})_{\partial\Omega},$$

where $\mathbf{n}$ denotes the outer normal vector on $\partial\Omega$.

Proof. Since $(\mathbf{w}\cdot\nabla\mathbf{u})\cdot\mathbf{u} = \frac12\mathbf{w}\cdot\nabla(\mathbf{u}\cdot\mathbf{u})$ Green's formula and $\operatorname{div}\mathbf{w} = 0$ give

$$(\mathbf{w}\cdot\nabla\mathbf{u},\mathbf{u})_\Omega = \tfrac12\left[-(\operatorname{div}\mathbf{w},\mathbf{u}\cdot\mathbf{u})_\Omega + (\mathbf{w}\cdot\mathbf{n},\mathbf{u}\cdot\mathbf{u})_{\partial\Omega}\right] = \tfrac12(\mathbf{w}\cdot\mathbf{n},\mathbf{u}\cdot\mathbf{u})_{\partial\Omega}$$

and thus $(\mathbf{w}\cdot\nabla(\mathbf{u}-\mathbf{v}),\mathbf{u}-\mathbf{v})_\Omega = \frac12(\mathbf{w}\cdot\mathbf{n},\mathbf{u}\cdot\mathbf{u}-2\mathbf{u}\cdot\mathbf{v}+\mathbf{v}\cdot\mathbf{v})_{\partial\Omega}$. On the other hand

$$\begin{aligned}(\mathbf{w}\cdot\nabla(\mathbf{u}-\mathbf{v}),\mathbf{u}-\mathbf{v})_\Omega &= (\mathbf{w}\cdot\nabla\mathbf{u},\mathbf{u})_\Omega + (\mathbf{w}\cdot\nabla\mathbf{v},\mathbf{v})_\Omega - (\mathbf{w}\cdot\nabla\mathbf{u},\mathbf{v})_\Omega - (\mathbf{w}\cdot\nabla\mathbf{v},\mathbf{u})_\Omega \\ &= \tfrac12(\mathbf{w}\cdot\mathbf{n},\mathbf{u}\cdot\mathbf{u}+\mathbf{v}\cdot\mathbf{v})_{\partial\Omega} - (\mathbf{w}\cdot\nabla\mathbf{u},\mathbf{v})_\Omega - (\mathbf{w}\cdot\nabla\mathbf{v},\mathbf{u})_\Omega.\end{aligned}$$

Taking the difference of both equations the claim follows. ∎

Assuming the sufficient condition on ν for uniqueness of the velocity in (3.1) we now can show Lipschitz continuity.

THEOREM 6.4. *Let $\nu > \nu_1$ be as in Theorem 3.3. Then the velocity part of the solution to (5.1) is Lipschitz continuous with respect to γ, i.e., there exists L independent of $\gamma,\bar\gamma$ with*

$$|\hat{\mathbf{u}}_{\bar\gamma} - \hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2} \le L\|\bar\gamma-\gamma\|_{L^\infty(I)} \qquad \text{for all } \bar\gamma,\gamma \in \mathcal{S}.$$

Proof. For $\hat{\mathbf{u}} := \hat{\mathbf{u}}_{\bar\gamma} - \hat{\mathbf{u}}_\gamma \in H^1_0(\hat\Omega)^2$ we have using Lemma 6.3

$$(\hat{\mathbf{u}}_{\bar\gamma}\cdot\nabla\hat{\mathbf{u}}_{\bar\gamma} - \hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat{\mathbf{u}})_{\hat\Omega} = (\hat{\mathbf{u}}_{\bar\gamma}\cdot\nabla\hat{\mathbf{u}},\hat{\mathbf{u}})_{\hat\Omega} + (\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat{\mathbf{u}})_{\hat\Omega} = (\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat{\mathbf{u}})_{\hat\Omega}.$$

Testing the first equation of (5.1), once for γ and another time for $\bar\gamma$, with $\hat{\mathbf{u}}$ and subtracting both equations thus leads to

$$\nu|\hat{\mathbf{u}}|^2_{H^1(\hat\Omega)^2} = (\tilde{\mathbf{f}}_{\bar\gamma} - \tilde{\mathbf{f}}_\gamma,\hat{\mathbf{u}})_{\hat\Omega} + \langle g_{\bar\gamma},\tau_{\bar\gamma}\hat{\mathbf{u}}\rangle_{H^*_{\bar\gamma},H_{\bar\gamma}} - \langle g_\gamma,\tau_\gamma\hat{\mathbf{u}}\rangle_{H^*_\gamma,H_\gamma} - (\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat{\mathbf{u}})_{\hat\Omega}.$$

Lemmas 3.2, 6.1, and 6.2 give the estimate

$$\nu|\hat{\mathbf{u}}|^2_{H^1(\hat\Omega)^2} \le L\|\bar\gamma-\gamma\|_{L^\infty(I)}|\hat{\mathbf{u}}|_{H^1(\hat\Omega)^2} + k_\gamma|\hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2}|\hat{\mathbf{u}}|^2_{H^1(\hat\Omega)^2}$$

with L independent of $\gamma,\bar\gamma$ and k_γ as in Theorem 3.3. This implies

$$\left(\nu - k_\gamma|\hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2}\right)|\hat{\mathbf{u}}|_{H^1(\hat\Omega)^2} \le L\|\bar\gamma-\gamma\|_{L^\infty(I)}$$

and thus Lipschitz continuity if $(\nu - k_\gamma |\hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2}) > 0$, which together with $|\hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2} = |\mathbf{u}_\gamma|_{H^1(\Omega_\gamma)^2}$ exactly is $\nu > \nu_1$ as in Theorem 3.3. ∎

To show continuity of the pressure and the Lagrange multipliers g_γ with respect to γ we introduce the isomorphism

$$\begin{aligned} \mathcal{I}_\gamma &: L^2(\Gamma_\gamma)^2 \to L^2(I)^2, \\ \mathcal{I}_\gamma \mathbf{h}(x) &:= \mathbf{h}(x, \gamma(x)), \qquad \mathbf{h} \in L^2(\Gamma_\gamma)^2, x \in I, \end{aligned}$$

which is also an isomorphism between $H^{1/2}(\Gamma_\gamma)^2$ and $H^{1/2}(I)^2$ and between H_γ and

$$H_I := H_{00}^{1/2}(I)^2 := \left\{ g \in H^{1/2}(I)^2 : \int_I \frac{\|g(x)\|_2^2}{x(1-x)}\, dx < \infty \right\};$$

see [12, Theorem 2.4]. For the latter case the adjoint of $\mathcal{I}_\gamma^{-1}$ is defined as

$$\begin{aligned} \left(\mathcal{I}_\gamma^{-1}\right)^* &: H_\gamma^* \to H_I^*, \\ \langle \left(\mathcal{I}_\gamma^{-1}\right)^* g, \mathbf{h} \rangle_{H_I{}^*, H_I} &:= \langle g, \mathcal{I}_\gamma^{-1} \mathbf{h} \rangle_{H_\gamma^*, H_\gamma}, \qquad g \in H_\gamma^*, \mathbf{h} \in H_I. \end{aligned}$$

We need a result concerning convergence of the transformed trace operators.

LEMMA 6.5. *If $\gamma_n \to \gamma$ in $W^{1,\infty}(I)$, then $\mathcal{I}_{\gamma_n} \tau_{\gamma_n} \to \mathcal{I}_\gamma \tau_\gamma$ as linear operators from $\{\hat{\mathbf{v}} \in H^1(\hat\Omega)^2 : \hat{\mathbf{v}}|_{\hat\Gamma} = \mathbf{0}\}$ into H_I.*

Proof. See [12, Lemma 2.11]. ∎

Now we can show continuity of the pair $(\hat p_\gamma, g_\gamma)$ in (5.1).

THEOREM 6.6. *Let $\gamma_n \to \gamma$ in $W^{1,\infty}(I)$ and $\nu > \nu_1$ as in Theorem* 3.3. *Then the corresponding components of solutions to* (5.1) *satisfy*

$$\begin{aligned} \hat p_{\gamma_n} &\to \hat p_\gamma && \text{in } L^2_*(\hat\Omega), \\ \left(\mathcal{I}_{\gamma_n}^{-1}\right)^* g_{\gamma_n} &\overset{*}{\rightharpoonup} \left(\mathcal{I}_\gamma^{-1}\right)^* g_\gamma && \text{in } \left(L^2(I)^2\right)^*. \end{aligned}$$

Proof. By Corollary 5.4, $\hat p_{\gamma_n} \rightharpoonup \hat p \in L^2(\hat\Omega)$ for a subsequence. With the strong convergence of the velocities (Theorem 6.4) the first equation of (5.1) gives

$$\begin{aligned} \langle g_{\gamma_n}, \tau_{\gamma_n} \hat{\mathbf{v}} \rangle_{H_{\gamma_n}^*, H_{\gamma_n}} &= \nu(\nabla \hat{\mathbf{u}}_{\gamma_n}, \nabla \hat{\mathbf{v}})_{\hat\Omega} + (\hat{\mathbf{u}}_{\gamma_n} \cdot \nabla \hat{\mathbf{u}}_{\gamma_n}, \hat{\mathbf{v}})_{\hat\Omega} - (\hat p_{\gamma_n}, \operatorname{div} \hat{\mathbf{v}})_{\hat\Omega} - (\tilde{\mathbf{f}}_{\gamma_n}, \hat{\mathbf{v}})_{\hat\Omega} \\ &\to \nu(\nabla \hat{\mathbf{u}}, \nabla \hat{\mathbf{v}})_{\hat\Omega} + (\hat{\mathbf{u}} \cdot \nabla \hat{\mathbf{u}}, \hat{\mathbf{v}})_{\hat\Omega} - (\hat p, \operatorname{div} \hat{\mathbf{v}})_{\hat\Omega} - (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}})_{\hat\Omega} \end{aligned}$$

for all $\hat{\mathbf{v}} \in H_0^1(\hat\Omega)^2$. Taking any $\mathbf{h} \in H_I$ there exists $\hat{\mathbf{v}} \in H_0^1(\hat\Omega)^2$ such that $\tau_\gamma \hat{\mathbf{v}} = \mathcal{I}_\gamma^{-1} \mathbf{h}$. We define $G \in H_I^*$ as

$$G : \mathbf{h} \mapsto \nu(\nabla \hat{\mathbf{u}}, \nabla \hat{\mathbf{v}})_{\hat\Omega} + (\hat{\mathbf{u}} \cdot \nabla \hat{\mathbf{u}}, \hat{\mathbf{v}})_{\hat\Omega} - (\hat p, \operatorname{div} \hat{\mathbf{v}})_{\hat\Omega} - (\tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}})_{\hat\Omega},$$

and $g := \mathcal{I}_\gamma^* G \in H_\gamma^*$. Thus $(\hat{\mathbf{u}}_\gamma, \hat p, g)$ solves (5.1) and due to the uniqueness this implies weak convergence for the whole sequence and $(\hat p, g) = (\hat p_\gamma, g_\gamma)$. Since H_I is dense in $L^2(I)^2$ the second claim follows; see, e.g., [8, Corollary I.2.5, eq. I.(2.14)].

Since the divergence operator is an isomorphism (see, e.g., [8, Corollary I.2.4]), for every n there exists a *unique* function $\hat{\mathbf{v}}_n \in V^\perp \subset H_0^1(\hat\Omega)^2$ such that

$$\operatorname{div} \hat{\mathbf{v}}_n = \hat p_{\gamma_n} - \hat p_\gamma \text{ in } \hat\Omega, \quad \|\mathbf{v}_n\|_{H^1(\hat\Omega)^2} \le c(\hat\Omega) \|\hat p_{\gamma_n} - \hat p_\gamma\|_{L^2(\hat\Omega)} \le C(\hat\Omega),$$

where $V := \{\mathbf{v} \in H_0^1(\hat\Omega)^2 : \operatorname{div} \mathbf{v} = 0 \text{ in } \hat\Omega\}$ and the last inequality holds due to the boundedness of $\{\hat p_\gamma\}_{\gamma \in \mathcal{S}}$ in $L^2(\hat\Omega)$. Testing (5.1) with this function gives

$$\begin{aligned} \|\hat p_{\gamma_n} - \hat p_\gamma\|_{L^2(\hat\Omega)}^2 &= \nu\big(\nabla(\hat{\mathbf{u}}_{\gamma_n} - \hat{\mathbf{u}}_\gamma), \nabla \hat{\mathbf{v}}_n\big)_{\hat\Omega} + (\hat{\mathbf{u}}_{\gamma_n} \cdot \nabla \hat{\mathbf{u}}_{\gamma_n} - \hat{\mathbf{u}}_\gamma \cdot \nabla \hat{\mathbf{u}}_\gamma, \hat{\mathbf{v}}_n)_{\hat\Omega} \\ &\quad - (\tilde{\mathbf{f}}_{\gamma_n} - \tilde{\mathbf{f}}_\gamma, \hat{\mathbf{v}}_n)_{\hat\Omega} - \langle g_{\gamma_n}, \tau_{\gamma_n} \hat{\mathbf{v}}_n \rangle_{H_{\gamma_n}^*, H_{\gamma_n}} + \langle g_\gamma, \tau_\gamma \hat{\mathbf{v}}_n \rangle_{H_\gamma^*, H_\gamma}. \end{aligned}$$

The first term on the right tends to zero because of the Lipschitz continuity of $\{\hat{\mathbf{u}}_\gamma\}_{\gamma\in\mathcal{S}}$ and the boundedness of $\{\hat{\mathbf{v}}_n\}$; the third one tends to zero because of $\|\tilde{\mathbf{f}}_{\gamma_n}-\tilde{\mathbf{f}}_\gamma\|_{L^2(\hat\Omega)^2}\to 0$ due to (5.2). The second term can be estimated using $\hat{\mathbf{u}}_n := \hat{\mathbf{u}}_{\gamma_n}-\hat{\mathbf{u}}_\gamma$ and Lemma 3.2:

$$\begin{aligned}(\hat{\mathbf{u}}_{\gamma_n}\cdot\nabla\hat{\mathbf{u}}_{\gamma_n}-\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat{\mathbf{v}}_n)_{\hat\Omega} &= (\hat{\mathbf{u}}_{\gamma_n}\cdot\nabla\hat{\mathbf{u}}_n,\hat{\mathbf{v}}_n)_{\hat\Omega}+(\hat{\mathbf{u}}_n\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat{\mathbf{v}}_n)_{\hat\Omega}\\ &\le k\big(|\hat{\mathbf{u}}_{\gamma_n}|_{H^1(\hat\Omega)^2}+|\hat{\mathbf{u}}_\gamma|_{H^1(\hat\Omega)^2}\big)|\hat{\mathbf{u}}_n|_{H^1(\hat\Omega)^2}|\hat{\mathbf{v}}_n|_{H^1(\hat\Omega)^2}\end{aligned}$$

and thus tends to zero for the same reasons. The remaining terms we write as

$$\begin{aligned}\langle g_\gamma,\tau_\gamma\hat{\mathbf{v}}_n\rangle_{H^*_\gamma,H_\gamma}-\langle g_{\gamma_n},\tau_{\gamma_n}\hat{\mathbf{v}}_n\rangle_{H^*_{\gamma_n},H_{\gamma_n}} &= \langle\big(\mathcal{I}_\gamma^{-1}\big)^*g_\gamma-\big(\mathcal{I}_{\gamma_n}^{-1}\big)^*g_{\gamma_n},\mathcal{I}_\gamma\tau_\gamma\hat{\mathbf{v}}_n\rangle_{H_I^*,H_I}\\ &\quad+\langle\big(\mathcal{I}_{\gamma_n}^{-1}\big)^*g_{\gamma_n},(\mathcal{I}_\gamma\tau_\gamma-\mathcal{I}_{\gamma_n}\tau_{\gamma_n})\hat{\mathbf{v}}_n\rangle_{H_I^*,H_I}.\end{aligned}$$

Boundedness of $\{\hat{\mathbf{v}}_n\}$ together with its uniqueness now implies $\hat{\mathbf{v}}_n\rightharpoonup\mathbf{0}$ weakly in $H^1_0(\hat\Omega)^2$, and thus $\tau_\gamma\hat{\mathbf{v}}_n\to\mathbf{0}$ in $L^2(\Gamma_\gamma)^2$ and $\mathcal{I}_\gamma\tau_{\gamma_n}\hat{\mathbf{v}}_n\to\mathbf{0}$ in $L^2(I)^2$. Since $\big(\mathcal{I}_{\gamma_n}^{-1}\big)^*g_{\gamma_n}\overset{*}{\rightharpoonup}\big(\mathcal{I}_\gamma^{-1}\big)^*g_\gamma$ in $\big(L^2(I)^2\big)^*$, the first term on the right tends to zero. The second one does so because $\{\big(\mathcal{I}_\gamma^{-1}\big)^*g_\gamma\}_{\gamma\in\mathcal{S}}$ and $\{\hat{\mathbf{v}}_n\}$ are bounded and $\mathcal{I}_{\gamma_n}\tau_{\gamma_n}\to\mathcal{I}_\gamma\tau_\gamma$ strongly due to Lemma 6.5. Thus $\hat p_{\gamma_n}\to\hat p_\gamma$ in $L^2(\hat\Omega)$ and since $L^2_*(\hat\Omega)$ is closed also in this space. ∎

As a consequence the boundedness of $\mathcal{S}$ in $H^3(I)$ now guarantees existence of a solution to the domain optimization problem.

COROLLARY 6.7. *Problem* (4.1) *has at least one solution* $\gamma\in\mathcal{S}$.

Proof. Choose a minimizing sequence and use the compactness of $H^3(I)\hookrightarrow C^2(\bar I)$. ∎

7. Fréchet differentiability and derivative formula. To show differentiability we make use of the adjoint equation of the Navier–Stokes system (3.1). Its derivation is standard and we thus refer to [7, section 7] or [14, section 3.2]: Find $(\lambda_\gamma,\mu_\gamma)\in H^1_0(\Omega_\gamma)^2\times L^2(\Omega_\gamma)$ such that

$$\begin{aligned}\left.\begin{aligned}\nu(\nabla\lambda_\gamma,\nabla\mathbf{v})_{\Omega_\gamma}-(\mu_\gamma,\operatorname{div}\mathbf{v})_{\Omega_\gamma}\\ +(\lambda_\gamma,\mathbf{u}_\gamma\cdot\nabla\mathbf{v}+\mathbf{v}\cdot\nabla\mathbf{u}_\gamma)_{\Omega_\gamma}\end{aligned}\right\} &= -D_u\mathcal{J}(\gamma)\mathbf{v} && \text{for all } \mathbf{v}\in H^1_0(\Omega_\gamma)^2,\\ (\operatorname{div}\lambda_\gamma,q)_{\Omega_\gamma} &= 0 && \text{for all } q\in L^2_0(\Omega_\gamma).\end{aligned}\tag{7.1}$$

Here $\mathbf{u}_\gamma$ is the velocity component of a solution to (3.1), and $D_u\mathcal{J}(\gamma)\mathbf{v}$ denotes the derivative of $\mathcal{J}$ with respect to $\mathbf{u}$ in direction $\mathbf{v}$. Note that the linearized nonlinear term can be rewritten using Green's formula as, e.g., in [14]. As in section 5 we derive a fictitious domain formulation: Find $(\hat\lambda_\gamma,\hat\mu_\gamma,\chi_\gamma)\in H^1_0(\hat\Omega)^2\times L^2(\hat\Omega)\times H^*_\gamma$ such that

$$\begin{aligned}\left.\begin{aligned}\nu(\nabla\hat\lambda_\gamma,\nabla\hat{\mathbf{v}})_{\hat\Omega}+(\hat\lambda_\gamma,\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{v}}+\hat{\mathbf{v}}\cdot\nabla\hat{\mathbf{u}}_\gamma)_{\hat\Omega}\\ -(\hat\mu_\gamma,\operatorname{div}\hat{\mathbf{v}})_{\hat\Omega}-\langle\chi_\gamma,\tau_\gamma\hat{\mathbf{v}}_\gamma\rangle_{H^*_\gamma,H_\gamma}\end{aligned}\right\} &= -D_u\mathcal{J}(\gamma)\hat{\mathbf{v}} && \text{for all } \hat{\mathbf{v}}\in H^1_0(\hat\Omega)^2,\\ (\operatorname{div}\hat\lambda,\hat q)_{\hat\Omega} &= 0 && \text{for all } \hat q\in L^2_0(\hat\Omega),\\ \hat\lambda_\gamma &= \mathbf{0} && \text{on } \Gamma_\gamma.\end{aligned}\tag{7.2}$$

Some main results for the above two systems are summarized in the following.

THEOREM 7.1. *Problem* (7.1) *has a solution* $(\lambda_\gamma,\mu_\gamma)\in[H^2(\Omega_\gamma)^2\cap H^1_0(\Omega_\gamma)^2]\times[H^1(\Omega_\gamma)\cap L^2_0(\Omega_\gamma)]$ *satisfying*

$$\|\lambda_\gamma\|_{H^2(\Omega_\gamma)^2}+\|\mu_\gamma\|_{H^1(\Omega_\gamma)}\le C\|\mathbf{u}_\gamma\|_{L^2(\Omega_\gamma)^2}$$

for some $C>0$ *independent of* γ. *For every* λ_γ *the corresponding* μ_γ *is unique. If* $\nu>\nu_1$ *as in Theorem* 3.3, *also* λ_γ *is unique. Moreover* $(\hat\lambda_\gamma,\hat\mu_\gamma,\chi_\gamma)\in H^1_0(\hat\Omega)^2\times L^2_*(\hat\Omega)\times H^*_\gamma$ *is a solution to* (7.2) *if and only if*

- $(\lambda_\gamma, \mu_\gamma) := (\hat\lambda_\gamma, \hat\mu_\gamma)|_{\Omega_\gamma}$ *is a solution to* (7.1),
- $(\hat\lambda_\gamma, \hat\mu_\gamma)|_{\Omega_\gamma^c} = (\mathbf{0}, 0)$,
- $\langle \chi_\gamma, \mathbf{h}\rangle_{H_\gamma^*, H_\gamma} = (\nu \frac{\partial \lambda_\gamma}{\partial \mathbf{n}_\gamma} - \mu_\gamma \mathbf{n}_\gamma, \mathbf{h})_{\Gamma_\gamma}$ *for all* $\mathbf{h} \in H_\gamma$.

The functional χ_γ *can be extended onto* $L^2(\Gamma_\gamma)^2$. *The families* $\{(\hat\lambda_\gamma, \hat\mu_\gamma)\}_{\gamma\in\mathcal{S}}$ *and* $\{\|\chi_\gamma\|_{H_\gamma^*}\}_{\gamma\in\mathcal{S}}, \{\|\chi_\gamma\|_{L^2(\Gamma_\gamma)^2}\}_{\gamma\in\mathcal{S}}$ *are bounded in* $H_0^1(\hat\Omega)^2 \times L_0^2(\hat\Omega)$ *and* $\mathbb{R}$, *respectively.*

Proof. Existence is shown in [14, Theorem 3.1]; uniqueness follows from continuity and ellipticity of the bilinear form

$$a(\lambda, \mathbf{v}) := \nu(\nabla\lambda, \nabla\mathbf{v})_{\Omega_\gamma} + (\lambda, \mathbf{u}_\gamma \cdot \nabla\mathbf{v} + \mathbf{v}\cdot\nabla\mathbf{u}_\gamma)_{\Omega_\gamma}.$$

Continuity is obvious; for the ellipticity we use Lemmas 3.2 and 6.3 to estimate

$$a(\lambda,\lambda) = \nu|\lambda|^2_{H^1(\Omega_\gamma)^2} - (\lambda\cdot\nabla\lambda, \mathbf{u}_\gamma)_{\Omega_\gamma} \;\geq\; \left(\nu - k_\gamma|\mathbf{u}_\gamma|_{H^1(\Omega_\gamma)^2}\right)|\lambda|^2_{H^1(\Omega_\gamma)^2}$$

and obtain ellipticity under the same condition as for the uniqueness of $\mathbf{u}_\gamma$. For the regularity of the solution of (7.1) see [14, Thm. 3.2]. The generalization for the combination of smooth and convex boundary and the uniform regularity with respect to γ can be obtained as for the (Navier–)Stokes equations; see Theorem 3.4. Equivalence of (7.1) and (7.2) is proved analogously to Theorem 5.1, and the uniform boundedness of the solution is a direct consequence. ∎

For the differentiability of $\mathcal{J}$ with respect to variations in γ we consider $\gamma \in \operatorname{int}\mathcal{S}$, the interior of $\mathcal{S}$, and define the set of admissible directions as

$$\mathcal{S}' := \left\{\bar\gamma \in H^3(I) : \bar\gamma|_{[0,\delta]\cup[1-\delta,1]} = 0\right\}.$$

For every $\gamma \in \operatorname{int}\mathcal{S}$, $\bar\gamma \in \mathcal{S}'$ there exists $t_0 > 0$ such that $\gamma + t\bar\gamma \in \operatorname{int}\mathcal{S}$ for all $t \in [0, t_0)$. Thus we can properly define a directional derivative. We now define $I_+ := \{x \in I : \bar\gamma(x) \geq 0\}, I_- := \{x \in I : \bar\gamma(x) < 0\}$ and state three results needed to prove the derivative formula. The first one is a relaxation of [7, Lemma 7.2].

LEMMA 7.2. *Let* $\hat\lambda_\gamma$ *denote a solution to* (7.2) *and* $\mathbf{f} \in L^p(\hat\Omega)^2$, $p \in (2, \infty]$. *Then there exists* $c = c(\gamma, p)$ *such that for* $\alpha = 2(p-1)/p > 1$ *we have*

$$(\tilde{\mathbf{f}}_{\gamma+t\bar\gamma} - \tilde{\mathbf{f}}_\gamma, \hat\lambda_\gamma)_{\hat\Omega} \leq c\,\|\mathbf{f}\|_{L^p(\hat\Omega)^2}|\lambda_\gamma|_{H^2(\Omega_\gamma)^2}\left(t\|\bar\gamma\|_{L^\infty(I)}\right)^\alpha.$$

Proof. Using (6.1) we obtain, similarly to the proof of Lemma 6.1 for I_+ defined there and $1/p + 1/q = 1$,

$$\begin{aligned}
(\tilde{\mathbf{f}}_{\gamma+t\bar\gamma} - \tilde{\mathbf{f}}_\gamma, \hat\lambda_\gamma)_{\hat\Omega} &\leq \int_{I_+}\int_\gamma^{\gamma+t\bar\gamma} |\mathbf{f}(x,y)\cdot[\lambda_\gamma(x,y) - \lambda_\gamma(x,\gamma)]|\,dydx \\
&\leq \|\mathbf{f}\|_{L^p(\hat\Omega)^2}\left(\int_{I_+}\int_\gamma^{\gamma+t\bar\gamma}\left\|\int_\gamma^y \frac{\partial\lambda_\gamma}{\partial y}(x,\xi)\,d\xi\right\|_2^q dydx\right)^{1/q} \\
&\leq \|\mathbf{f}\|_{L^p(\hat\Omega)^2}\left(\int_{I_+}\int_\gamma^{\gamma+t\bar\gamma}|y-\gamma|\int_\gamma^{\gamma+t\bar\gamma}\left\|\frac{\partial\lambda_\gamma}{\partial y}(x,\xi)\right\|_2^q d\xi dydx\right)^{1/q} \\
&\leq 2^{-1/q}\|\mathbf{f}\|_{L^p(\hat\Omega)^2}|\lambda_\gamma|_{W^{1,q}(\hat\Omega)^2}\left(t\|\bar\gamma\|_{L^\infty(I)}\right)^{2/q}.
\end{aligned}$$

Because of the continuous embedding $H^2(\Omega_\gamma) \hookrightarrow W^{1,q}(\Omega_\gamma)$ the claim follows. ∎

The following two results were already proved in [7, Lemmas 7.3 and 7.4].

LEMMA 7.3. *Let $\hat{\mathbf{u}}_{\gamma+t\bar\gamma}$ and χ_γ be components of solutions to* (5.1) *and* (7.2)*, respectively. Then*

$$\lim_{t\to 0}\frac{1}{t}\langle \chi_\gamma, \tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\rangle_{H^*_\gamma,H_\gamma} = -\int_{I_+}\chi_\gamma(x,\gamma)\cdot\mathbf{u}_{\gamma,y}(x,\gamma)\bar\gamma\sqrt{1+\gamma'^2}\,dx.$$

The integral exists because $\mathcal{S}'\subset L^\infty(I)$, $\chi_\gamma\in L^2(\Gamma_\gamma)^2$, and $\tau_\gamma\mathbf{u}_{\gamma,y}=\mathbf{u}_{\gamma,y}(x,\gamma)$ and also its restriction on the set $\Gamma_\gamma^+:=\{(x,\gamma(x)):x\in I_+\}\subset\Gamma_\gamma$ are L^2 functions since $\mathbf{u}_\gamma\in H^2(\Omega_\gamma)^2$. The same arguments hold for the integral in the next lemma.

LEMMA 7.4. *Let $g_{\gamma+t\bar\gamma}$ and $\hat\lambda_\gamma$ be components of solutions to* (5.1) *and* (7.2)*, respectively. Then*

$$\lim_{t\to 0}\frac{1}{t}\langle g_{\gamma+t\bar\gamma}, \tau_{\gamma+t\bar\gamma}\hat\lambda_\gamma\rangle_{H^*_{\gamma+t\bar\gamma},H_{\gamma+t\bar\gamma}} = \int_{I_-} g_\gamma(x,\gamma)\cdot\lambda_{\gamma,y}(x,\gamma)\bar\gamma\sqrt{1+\gamma'^2}\,dx.$$

Now differentiability of the cost functional with respect to γ and a formula for the derivative are shown under the restriction on ν given in Theorem 3.3 and a slightly stronger assumption on the inhomogeneity (due to Lemma 7.2).

THEOREM 7.5. *Let $\gamma\in\operatorname{int}\mathcal{S}$,* (5.2) *hold for $\mathbf{f}\in L^p(\hat\Omega)^2$, $p>2$, and $\nu>\nu_1$ as in Theorem* 3.3*. Then $\mathcal{J}$ is Fréchet differentiable and the derivative in γ in direction $\bar\gamma\in\mathcal{S}'$ satisfies*

$$D_\gamma\mathcal{J}(\gamma)\bar\gamma = \frac{1}{\nu}\int_I\big[g_\gamma\big(x,\gamma(x)\big)\cdot\chi_\gamma\big(x,\gamma(x)\big) - p_\gamma\big(x,\gamma(x)\big)\mu_\gamma\big(x,\gamma(x)\big)\big]\,\bar\gamma(x)\,dx. \tag{7.3}$$

Proof. Denoting $\hat{\mathbf{u}}:=\hat{\mathbf{u}}_{\gamma+t\bar\gamma}-\hat{\mathbf{u}}_\gamma\in H_0^1(\hat\Omega)^2$ we have

$$\mathcal{J}(\gamma+t\bar\gamma)-\mathcal{J}(\gamma)=\frac{1}{2}\|\mathcal{A}\hat{\mathbf{u}}\|^2_{L^2(\Omega_C)^k}+D_u\mathcal{J}(\gamma)\hat{\mathbf{u}}$$

and by the Lipschitz continuity of $\hat{\mathbf{u}}_\gamma$ with respect to γ (Theorem 6.4)

$$\lim_{t\to 0}\frac{1}{t}\left(\mathcal{J}(\gamma+t\bar\gamma)-\mathcal{J}(\gamma)\right)=\lim_{t\to 0}\frac{1}{t}D_u\mathcal{J}(\gamma)\hat{\mathbf{u}}.$$

Testing the first equation in (7.2) with $\hat{\mathbf{u}}$ gives, using $\tau_\gamma\hat{\mathbf{u}}_\gamma=\mathbf{0}$ and the fact that $\hat{\mathbf{u}}_{\gamma+t\bar\gamma}$ and $\hat{\mathbf{u}}_\gamma$ are weakly divergence free,

$$D_u\mathcal{J}(\gamma)\hat{\mathbf{u}}=-\nu(\nabla\hat\lambda_\gamma,\nabla\hat{\mathbf{u}})_{\hat\Omega}-(\hat\lambda_\gamma,\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}+\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma)_{\hat\Omega}+\langle\chi_\gamma,\tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\rangle_{H^*_\gamma,H_\gamma}.$$

Because of

$$\begin{aligned}-\big[\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}+\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma\big] &= -\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_{\gamma+t\bar\gamma}+\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_\gamma-\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma\\ &= \hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_{\gamma+t\bar\gamma}-\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\cdot\nabla\hat{\mathbf{u}}_{\gamma+t\bar\gamma}+\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_\gamma-\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}_\gamma\\ &= \hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}-\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\cdot\nabla\hat{\mathbf{u}}_{\gamma+t\bar\gamma}+\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_\gamma,\end{aligned}$$

we obtain

$$\begin{aligned}D_u\mathcal{J}(\gamma)\hat{\mathbf{u}} = &-\big[\nu(\nabla\hat{\mathbf{u}}_{\gamma+t\bar\gamma},\nabla\hat\lambda_\gamma)+(\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\cdot\nabla\hat{\mathbf{u}}_{\gamma+t\bar\gamma},\hat\lambda_\gamma)_{\hat\Omega}\big]+(\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}},\hat\lambda_\gamma)_{\hat\Omega}\\ &+\big[\nu(\nabla\hat{\mathbf{u}}_\gamma,\nabla\hat\lambda_\gamma)_{\hat\Omega}+(\hat{\mathbf{u}}_\gamma\cdot\nabla\hat{\mathbf{u}}_\gamma,\hat\lambda_\gamma)_{\hat\Omega}\big]+\langle\chi_\gamma,\tau_\gamma\hat{\mathbf{u}}_{\gamma+t\bar\gamma}\rangle_{H^*_\gamma,H_\gamma}.\end{aligned}$$

The two terms in parentheses can be expressed using the first equation in (5.1) for γ and $\gamma + t\bar{\gamma}$, respectively, with the adjoint variable $\hat{\lambda}_\gamma \in H_0^1(\hat{\Omega})^2$ as a test function. Thus

$$D_u\mathcal{J}(\gamma)\hat{\mathbf{u}} = (\tilde{\mathbf{f}}_\gamma - \tilde{\mathbf{f}}_{\gamma+t\bar{\gamma}}, \hat{\lambda}_\gamma)_{\hat{\Omega}} - \langle g_{\gamma+t\bar{\gamma}}, \tau_{\gamma+t\bar{\gamma}}\hat{\lambda}_\gamma\rangle_{H^*_{\gamma+t\bar{\gamma}},H_{\gamma+t\bar{\gamma}}} + \langle \chi_\gamma, \tau_\gamma \hat{\mathbf{u}}_{\gamma+t\bar{\gamma}}\rangle_{H^*_\gamma,H_\gamma} + (\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}, \hat{\lambda}_\gamma)_{\hat{\Omega}}.$$

Divided by t the first term on the right tends to zero because of Lemma 7.2, the last one because of Lemma 3.2 and the Lipschitz continuity of the velocities:

$$(\hat{\mathbf{u}}\cdot\nabla\hat{\mathbf{u}}, \hat{\lambda}_\gamma)_{\hat{\Omega}} \le k|\hat{\mathbf{u}}|^2_{H^1(\hat{\Omega})^2}|\hat{\lambda}_\gamma|_{H^1(\hat{\Omega})^2} \;\le\; kt^2\|\bar{\gamma}\|^2_{L^\infty(I)}|\hat{\lambda}_\gamma|_{H^1(\hat{\Omega})^2}$$

with k independent of $\gamma, \bar{\gamma}$. Using Lemmas 7.3 and 7.4 the remaining terms give (7.3) as directional derivative. To show that it is actually a Fréchet derivative we proceed exactly as in the proof of the same result for the Stokes case in [7, Theorem 7.5]. □

Note that the formula for the derivative does not include any normal derivatives of state or adjoint variables along the boundary.

8. Numerical methods. To validate the derivative formula (7.3) a numerical example is presented in the next section. To ensure the needed regularity of the boundary partition Γ_γ, i.e., to guarantee that $\gamma \in H^3(I)$, we considered boundaries Γ_γ which were generated by a cubic spline function γ. This function was generated as a linear combination of B-splines on an equidistant grid in the interval $(0, 1)$. The end points $(0, 0)$ and $(1, 0)$ and the slopes at these points were fixed. This conforms with our definition (2.1) for the admissible functions γ; specifically, the regularity and the convexity of the boundary part Γ_γ at the left and right end of the interval $(0, 1)$ is guaranteed. By these conditions the first and last two coefficients of the spline were determined. The values of the remaining ones were used as control parameters. One coefficient c_i in the B-spline representation contributes to the y-value of the generated spline at the point x_i with the weight $\frac{2c_i}{3}$ and to the y-value at the two neighbors x_{i-1} and x_{i+1} with the weight $\frac{c_i}{6}$.

The B-spline representation has the advantages that for nonnegative control parameters the y-values of the points of the generated curve are always nonnegative, too. This is crucial to obtain a feasible boundary $\Gamma_\gamma \subset \hat{\Omega} = (0, 1)^2$. Additional upper bounds on γ were realized as linear inequality constraints of the control parameters, i.e., the B-spline coefficients.

We used the SQP implementation in MATLAB's optimization toolbox version 2, namely the routine `fmincon` (see [15]). It allows the user to provide gradient information which we obtained by evaluating (7.3) for the splines corresponding to independent variations in each control parameter.

We also want to emphasize that the restriction on the parameter ν that we had made to obtain formula (7.3), see Theorems 7.5 and 3.3, namely

$$\nu > \frac{|\mathbf{u}_\gamma|_{H^1(\Omega_\gamma)^2}}{k_\gamma},$$

is restrictive. In our geometric configuration we have $k_\gamma = \frac{1}{2}|\Omega_\gamma|^{1/2} < \frac{1}{2}$ and thus $\nu > 2|\mathbf{u}_\gamma|_{H^1(\Omega_\gamma)^2}$ is required. The standard estimates for dependence of the solution on the inhomogeneity and boundary values then give

$$\nu > 2C\left(\|\mathbf{f}\|_{H^{-1}(\hat{\Omega})^2} + \|\Phi\|_{H^{1/2}(\Gamma)^2}\right),$$

where the constant C depends on the domain only. This makes clear that formula (7.3) is only appropriate for high values of ν, i.e., low Reynolds numbers.

In each step of a gradient-based iterative optimization process (as, e.g., SQP) usually one gradient and several function evaluations for different control variables γ are necessary. Each gradient evaluation requires one solution of both systems (5.1) and (7.2); a function evaluation implies the solution of (5.1).

The velocity and pressure variables and their adjoint counterparts in (5.1) and (7.2) are discretized by stabilized linear finite elements (see [16]), whereas the Lagrange multipliers g_γ and χ_γ are by piecewise constant elements. To satisfy the inf-sup condition for the latter we use a coarser discretization for the Lagrange multipliers as suggested in [17]. This means that the support of a constant basis function for g_γ and χ_γ is at least twice as long as the minimal length of the triangle edges in the discretization of $\hat{\Omega}$. It turned out that this was sufficient to avoid oscillations of the Lagrange multipliers.

The nonlinear system (5.1) was solved by the semi-implicit algorithm given in [8, eq. IV(2.25)] (here in continuous form):

(i) Choose $\hat{\mathbf{w}}$ with $\operatorname{div} \hat{\mathbf{w}} = 0$.

(ii) Compute $(\hat{\mathbf{u}}, \hat{p}, g)$ from

$$\left\{ \begin{array}{rcl} -\nu \triangle \hat{\mathbf{u}} + \hat{\mathbf{w}} \cdot \nabla \hat{\mathbf{u}} + \nabla \hat{p} - \tau_\gamma^* g & = & \tilde{\mathbf{f}}, \\ \operatorname{div} \hat{\mathbf{u}} & = & 0. \end{array} \right.$$

(iii) If "convergence," stop, else set $\hat{\mathbf{w}} := \hat{\mathbf{u}}$ and go back to (ii).

The discrete system to be solved in step (ii) then reads as

$$\begin{pmatrix} \nu A + N(W_\gamma) & B^T & D_\gamma^T \\ B - Q(W_\gamma) & C & 0 \\ D_\gamma & 0 & 0 \end{pmatrix} \begin{pmatrix} U_\gamma \\ P_\gamma \\ G_\gamma \end{pmatrix} = \begin{pmatrix} F_\gamma \\ H \\ 0 \end{pmatrix}, \tag{8.1}$$

where the matrices C, Q and the vector H appear due to the stabilization. The matrix N represents the discretized and linearized convective term and W_γ the discretized last iterate $\hat{\mathbf{w}}$ in (ii). Solving the Navier–Stokes system requires several solutions of (8.1), depending on the necessary number of iterations of the semi-implicit algorithm, in our case at most 8. For (7.2) one linear system of the same structure as (8.1) with different matrices N, Q and a changed right-hand side has to be solved.

Since (8.1) has to be solved quite often for different control parameters γ it is important to note that only the entities with subscript γ change when the control parameter is modified. All other matrices can be assembled in advance and kept fixed. Here D_γ represents a one-dimensional trace operator and thus is very sparse. The inhomogeneity F_γ has to be modified since for the validity of the derivative formula it has to be set to zero in the fictitious part Ω_γ^c. This adjustment requires the integration of the basis functions on triangle partitions whenever Γ_γ intersects the interior of a triangle. To simplify this quadrature the use of linear basis functions, which can be integrated exactly by low-order Gaussian rules, is preferable.

A technical part is to find the intersection points between the two-dimensional grid for U_γ, P_γ and the one-dimensional grid along Γ_γ for G_γ (and for their adjoint counterparts). Here the decisive idea is to exploit the neighborhood information of the triangulation already used to assemble the finite element matrices. This avoids a time-consuming search over all triangles that would be even worse in three space dimensions. After the intersection points are found, the mass matrix D_γ and the

inhomogeneity F_γ can be easily computed by interpolation of the values of the piecewise linear or constant finite element basis functions. Over all, the numerical effort of this assembling and modification is negligible compared to the one needed for the solution of the state and adjoint equations.

In contrast to Stokes problems (see [7]) the discrete systems now change in every iteration of the optimization since the system matrix depends on the last iterate W_γ. Thus one advantage, namely the possibility of one factorization of the system matrix in the beginning of the optimization loop that was possible for the Stokes case (see [7, section 8]), is lost. It can be retained, e.g., by using a projected *cg* algorithm that solves (3.1) by a sequence of Stokes problems; see [18].

Once the discrete counterparts of $p_\gamma, g_\gamma, \mu_\gamma, \chi_\gamma$ are computed, the evaluation of the derivative via (7.3) requires only the evaluation of a one-dimensional integral. This can be done exactly by appropriate numerical quadrature formulas and thus no additional discretization error is introduced by the derivative evaluation. Normal derivatives of state and adjoint velocity along the boundary usually occurring here are implicitly included in g_γ, χ_γ. This fact is due to the embedding domain technique by which these two Lagrange multipliers were introduced.

9. Numerical example. We present an inverse problem for a driven cavity flow. The computational domain is the unit square. On one edge a constant tangential velocity is prescribed, the other edges are regarded as walls with homogeneous Dirichlet boundary conditions for the velocity. The function Φ representing the boundary values was smoothed at the corners. The inhomogeneity $\mathbf{f}$ was set to zero and the parameter $\nu = 1$. In both examples the bottom edge of the cavity was variable between the fix points $(0,0)$ and $(1,0)$. As initial curves for the optimization, we used a straight line as bottom edge. Lower box constraints for the control parameters to ensure $\gamma \geq 0$ and a linear inequality constraint to guarantee $\Gamma_\gamma \cap \Omega_C = \emptyset$ were used. No regularizations were necessary. State and adjoint equations were solved on a triangular grid with 1089 velocity nodes.

9.1. Inverse problem for the driven cavity. Here the function $\Phi = (\Phi_1, \Phi_2) = (1,0)$ was used at the top edge of the cavity. We considered a tracking type cost functional with $\Omega_C := (0,1) \times (0.5,1)$ and the desired state $\mathbf{u}_d := \mathbf{u}_{\gamma_d}$, where γ_d was a cubic spline interpolating the points $(0,0), (0.5,0.4), (1,0)$.

We performed two optimization runs with 5 and 9 control parameters. In Tables 1 and 2 the convergence behavior is documented. It can be seen that the optimization reduces the cost functional rather fast up to one percent. Further reduction affords more iterations, specifically a very low stopping criterion for the accuracy in the control parameters and function value. The convergence for the higher number of controls was faster (concerning the number of iterations). Even if the changes in the controls are in the range of 10^{-4} and are hardly visible, further optimization steps lead to a better value of the cost and to a curve close to the one used to compute the desired state.

Figure 2 shows the boundary curves of the desired state and the two optimized ones. In Figure 3 we depicted the velocity vectors and pressure distribution for the desired state, the initial, and the two obtained optimized curves.

ON THE LOCAL STRUCTURE OF OPTIMAL TRAJECTORIES IN R^3*

ANDREI A. AGRACHEV† AND MARIO SIGALOTTI‡

Abstract. We analyze the structure of a control function $u(t)$ corresponding to an optimal trajectory for the system $\dot{q} = f(q) + u\,g(q)$ in a three-dimensional manifold, near a point where some nondegeneracy conditions are satisfied. The kind of optimality which is studied includes time-optimality. The control turns out to be the concatenation of some bang and some singular arcs. Studying the index of the second variation of the switching times, the number of such arcs is bounded by four.

1. Introduction.

Consider the time-optimal control problem

$$\dot{q} = f(q) + u\,g(q), \qquad u \in [-1, 1], \tag{1}$$

on a three-dimensional manifold M^3, where f and g are two smooth vector fields on M^3 and the admissible controls are all measurable functions $u : t \mapsto u(t) \in [-1, 1]$. The kind of results we are interested in are local regularity properties for the control function corresponding to optimal trajectories. Namely, we fix $q_0 \in M^3$ and we study whether *locally at* q_0 the control function corresponding to a time-optimal trajectory is piecewise smooth, meaning by this that there exist a neighborhood U of q_0 and a time $T > 0$ such that any control function corresponding to a time-optimal trajectory of the system (1) contained in U and defined on a time-interval of length less than or equal to T is piecewise smooth. We are interested in giving an upper bound to the number of smooth pieces, called *arcs*, and in describing the possible concatenations. (For instance, we want to know how many arcs are bang, i.e., such that the control restricted to them is the constant function $+1$ or -1.)

As is well known (see [19]), any irregularity of the optimal control is possible; that is, for any measurable control function $u(\cdot)$; there exists a control system of type (1) such that the trajectory corresponding to $u(\cdot)$ is time-optimal. The correct question is, What kind of behavior can we expect for time-optimal trajectories of a generic system?

A major motivation for the study of this topic is the following: to give a priori restrictions on the local structure of optimal trajectories is a crucial step in the direction of the description of the local optimal synthesis (see, for instance, [22]). The problem is known to be deep: Fuller [7] first proposed a polynomial system of the kind studied here such that the switching time moments of the optimal control form a convergent sequence. (We call *chattering* a control of this kind.) Since then it has been an important issue to understand whether this phenomenon is structurally stable (i.e., cannot

be eliminated by a small perturbation of the system) or not. In big enough dimensions it most likely is stable: stable chattering extremals were constructed in [10, 23], though the optimality of these extremals is not proved.

The language in which the genericness of the system will be expressed, in order to concretely tackle the problem, is the one of "nonresonance conditions" on the configuration of iterated Lie brackets between f and g evaluated at the fixed point q_0. This is natural since the family of Lie bracket relations form a set of differential invariants of the pair of vector fields (f, g), which is complete for analytic systems (see [16, section 4]).

The first step in this direction is to study the structure of the trajectories near the point where some prescribed triples of iterated Lie brackets are linearly independent. If a local regularity property is proved under such conditions, by standard transversality considerations it follows that for a generic pair of vector fields (f, g), for a generic point $q_0 \in M^3$, the regularity property holds locally at q_0. The first result of this kind for a three-dimensional manifold appeared in [18] and asserts that if each of the tensor fields $f \wedge g \wedge [f, g]$, $g \wedge [f, g] \wedge [f + g, [f, g]]$, and $g \wedge [f, g] \wedge [f - g, [f, g]]$ does not vanish at q_0, then locally at q_0 any time-optimal bang-bang trajectory has at most two switchings.

A satisfactory understanding of the three-dimensional problem would be for us to individuate a regularity property, which holds locally at every point of M^3 for a generic pair of vector fields (f, g), in analogy with what has already been done for two-dimensional manifolds by Sussmann (see [17, 20] and also [11]). By Thom's transversality theorem we know that this reduces to the study of all Lie bracket configurations with up to three nontrivial independent relations of linear dependency between its elements. Up to now, in addition to the cited result by Sussmann, there have been similar upper bounds proved in other situations: by Bressan [6] in the case of trajectories steering to an equilibrium point for f under some extra nondependency conditions; by Schättler [12] for bang-bang trajectories for a generic pair (f, g), locally at all points in which $f \wedge g \wedge [f, g] \neq 0$. (For trajectories which are not a priori bang-bang Schättler [13] requires that some extra nondependency conditions hold at the point.) In [3] the following complementary result is stated, which generalizes the one in [6]: if $g \wedge [f, g] \wedge [f \pm g, [f, g]](q_0) \neq 0$, then locally at q_0 a bang-bang time-optimal trajectory has no more than two switches. Part of the present paper is devoted to giving a detailed proof of that statement. The same result had also been proved by Krener and Schättler [9] and Sussmann [21] by different methods.

Unfortunately, the cases studied in the literature do not cover all Lie bracket configurations with up to one dependency relation. In the present paper we give the first result concerning all such configurations: we furnish a common finite local bound on the number of arcs, which is valid not only for bang-bang trajectories, but also for all trajectories with no a priori restriction on the control. We also discuss in which sense the bound is sharp. The main results are contained in Theorem 3 in section 3 and in Lemma 2 in subsection 4.3 and can be summarized as follows, in terms of generic properties for (f, g) and of properties holding at points of M^3, in the local sense introduced above.

THEOREM 1. *Let $V_2^4(M^3)$ be the space of all pairs of $\mathcal{C}^4$ vector fields on M^3, endowed with the Whitney topology. For any element (f, g) from an open everywhere dense subset of $V_2^4(M^3)$ there exist $W_1 \subset W_2 \subset M^3$, where W_1 and W_2 are, respectively, a one-dimensional and a two-dimensional stratified set in M^3, such that*

- *for any point q_0 in $M^3 \setminus W_2$, locally at q_0, any time-optimal trajectory of the system (1) is a finite concatenation of at most three between bang and singular arcs;*

- *for any point q_0, in $W_2 \setminus W_1$, locally at q_0, any time-optimal trajectory of the system* (1) *is a finite concatenation of at most four between bang and singular arcs.*

PROPOSITION 1. *For any (f, g) from an open subset of $V_2^4(M^3)$ there exists a two-dimensional submanifold $U_2 \subset M^3$ such that for any $q_0 \in U_2$ and any $T > 0$ there exists a trajectory passing through q_0 of time-length less than T which is locally (in the $\mathcal{C}^0$ topology) time-optimal and is the concatenation of four bang arcs (of positive length).*

As we mentioned, it is the possible occurrence of the chattering phenomenon that makes the problem deep and hard to study. Our paper is one more step in the demarcation of the nonchattering territory, at least in dimension three. It is not excluded that structurally stable chattering phenomena occur, but it is given a stronger a priori bound to their "dimension."

Another problem is whether the Fuller phenomenon is the worst possible stable behavior. Proposition 2 in section 6 gives a partial answer to this question, stating that under some very weak conditions (which hold everywhere for a generic pair (f, g) in any dimension) an optimal control with values in $\{-1, 1\}$ either has a finite number of switches or is such that its restriction to a subinterval is chattering. This means that any possible bad behavior is built up, in some sense, by chattering modes. If we prove, in particular, that in a certain region chattering does not occur, then a time-optimal trajectory passing through the region (and whose control function takes value in $\{-1, 1\}$) must be bang-bang.

2. A second order optimality condition. Let M be a smooth manifold and f, g two smooth vector fields on M. It is natural and costless to assume throughout this section that the dimension of M is equal to $n \in \mathbf{N}$, with no further restriction on n, since the second order condition we are going to state is independent on the dimension.

A *trajectory* of the system

$$\dot{q} = f(q) + u\, g(q), \qquad u \in [-1, 1], \tag{2}$$

is an absolutely continuous curve $t \mapsto q(t) \in M$ for which there exists a measurable *control function* $t \mapsto u(t) \in [-1, 1]$ such that (2) is verified for almost every t in the domain of $q(\cdot)$. For all $T > 0$ and $q_0 \in M$ we define the *attainable set* from q_0 at time T:

$$A(T, q_0) = \{q(T) \mid q : [0, T] \to M \text{ is a trajectory of (2) such that } q(0) = q_0\}.$$

Let $q : [0, T] \to M$ be a trajectory of (2) and u the corresponding control function. By the Pontryagin maximum principle we know that if $q(T)$ belongs to $\partial A(T, q(0))$, then $q(\cdot)$ is *extremal*; that is, there exist $c \in \mathbf{R}$ and an absolutely continuous covector trajectory $p : [0, T] \to T^*M$ such that $p(t) \in T^*_{q(t)}M \setminus \{0\}$ for every $t \in [0, T]$, which verifies for almost every t the equation

$$\dot{p}(t) = -p(t)(Df(x(t)) + u(t)Dg(x(t))) \tag{3}$$

and the relation

$$\langle p(t), (f + u(t)g)(q(t))\rangle = \min_{v \in [-1,1]} \langle p(t), (f + vg)(q(t))\rangle \equiv c. \tag{4}$$

We say that $q : [0, T] \to M$ is *bang-bang* if the control function u takes values in $\{-1, 1\}$ and there exists a finite number of *switching times* $0 < t_1 < t_2 < \cdots < t_{k-1} < t_k < T$, splitting $[0, T]$ in intervals on which u is alternately the constant $+1$ and -1. In general we say that a piece of trajectory defined on a time subinterval is a bang arc if the corresponding control is constantly equal to $+1$ or -1 (we speak, respectively, of a $+$ arc or a $-$ arc), whereas it is a singular arc if it is not a bang arc and the corresponding control is smooth. We will describe the structure of a trajectory by the standard agreement that, for instance, a $+-$S trajectory is a concatenation of a $+$, a $-$, and a singular arc.

Since we are interested in local results it is justified and convenient for us to assume that all the vector fields involved are complete. Given a complete smooth vector field h on M and a time $t \in \mathbf{R}$, we can associate the flow of h at a time t, which we will denote by $e^{th} : q \mapsto e^{th}(q)$. Both the vector field h and the diffeomorphism e^{th} have a natural interpretation as operators on $\mathcal{C}^\infty(M)$: given a smooth function a on M and a point $q \in M$, $ha(q)$ is defined as the derivative of a in the direction $h(q)$ at the point q, whereas

$$(e^{th}a)(q) = a(e^{th}(q)).$$

Given two smooth vector fields h_1 and h_2, it is always possible to define their commutator (Lie bracket) according to the formula

$$((\mathrm{ad}h_1)h_2)a = [h_1, h_2]a = h_1(h_2a) - h_2(h_1a).$$

In operator terms the action $e_*^{-th_1}$ of the diffeomorphism e^{-th_1} on the vector fields has the form

$$e_*^{-th_1}h_2 = e^{th_1} \circ h_2 \circ e^{-th_1}.$$

The formula

$$\frac{\mathrm{d}}{\mathrm{d}t} e^{th_1} \circ h_2 \circ e^{-th_1}(q) = [h_1, e^{th_1} \circ h_2 \circ e^{-th_1}](q)$$

justifies the notation

$$e^{t\mathrm{ad}h_1}h_2 = e^{th_1} \circ h_2 \circ e^{-th_1}.$$

Notice that, for every t and h, the following relation holds:

$$e^{t\mathrm{ad}h}h = h. \tag{5}$$

Remark. In the case of vector fields which are not smooth but just $\mathcal{C}^k$, the above definitions extend to the case where they are still licit; in particular, if h is $\mathcal{C}^k$, then $e^{t\mathrm{ad}h}$ is a well-defined transformation of $\mathcal{C}^k$ vector fields while $k + 1$ iterated Lie brackets between $\mathcal{C}^k$ vector fields are well-defined $\mathcal{C}^0$ vector fields.

In order to formulate the second order optimality condition it is useful to remark the following fact: Let $q(\cdot)$ be an extremal trajectory of (2) and $p(\cdot)$ an associated covector trajectory. Fix a vector field h and two time instants t and τ in the same bang interval of $q(\cdot)$ on which the control is equal to ν. By (3) we have

$$\langle p(t), h(q(t))\rangle = \langle p(\tau), e^{(t-\tau)\mathrm{ad}(f+\nu g)}h(q(t))\rangle. \tag{6}$$

THEOREM 2. *Let $q : [0,T] \to M$, $T > 0$, be a bang-bang trajectory of (2) and let $u(t)$ be the corresponding control function with k switching times $0 < \tau_1 < \tau_2 < \cdots < \tau_k < T$. Denote by ν the value of u in $(0,\tau_1)$. Let $q(\cdot)$ be extremal and $p(\cdot)$ a corresponding covector trajectory. Assume that $p(\cdot)$ is uniquely defined (up to multiplication by a positive scalar) by (3) and (4). Let $p_0 = p(0)$ and*

$$\begin{aligned} h_0 &= f + \nu g, \\ h_i &= e^{\tau_1 \mathrm{ad}(f+\nu g)} \circ e^{(\tau_2-\tau_1)\mathrm{ad}(f-\nu g)} \circ e^{(\tau_3-\tau_2)\mathrm{ad}(f+\nu g)} \circ \cdots \\ &\quad \circ e^{(\tau_i-\tau_{i-1})\mathrm{ad}(f-(-1)^i \nu g)}(f + (-1)^i \nu g), \qquad i = 1, \ldots, k. \end{aligned}$$

Take the quadratic form

$$Q(\alpha) = \sum_{0 \le i < j \le k} \alpha_i \alpha_j \langle p_0, [h_i, h_j](q(0)) \rangle \tag{7}$$

defined on the space

$$\left\{ \alpha = (\alpha_0, \ldots, \alpha_k) \in \mathbf{R}^{k+1} \;\middle|\; \sum_{i=0}^{k} \alpha_i = 0,\ \sum_{i=0}^{k} \alpha_i h_i(q(0)) = 0 \right\}. \tag{8}$$

If Q is not nonnegative definite, then $q(T) \in \mathrm{int} A(T, q(0))$. Moreover, for every system (f', g') which is close enough to (f, g) in the $\mathcal{C}^1$ topology, the point $q(T)$ is in the interior of the corresponding attainable set $A_{(f',g')}(T, q(0))$.

Remark. The sign condition on Q is usually rephrased in terms of the *index* of Q; that is, the dimension of the maximal subspace on which Q is negative definite. The quadratic form Q is not nonnegative definite if and only if its index is strictly positive.

Remark. Stated as above, the theorem seems to acknowledge a special role for the tangent space $T_{q(0)}M$. If we fix a time t in $[0,T]$, however, an equivalent version of the theorem can be easily set in $T_{q(t)}M$. Let m be such that $\tau_{m-1} \le t < \tau_m$ (with the agreement that $\tau_0 = 0$ and $\tau_{k+1} = T$). Define

$$h_i^t = e^{-(t-\tau_{m-1})\mathrm{ad}(f-(-1)^m \nu g)} \circ \cdots \circ e^{-(\tau_2-\tau_1)\mathrm{ad}(f-\nu g)} \circ e^{-\tau_1 \mathrm{ad}(f+\nu g)} h_i$$

for every $i = 0, \ldots, k$. The equivalent formulation of the theorem follows: the space defined by (8) is unaltered if we replace $h_i(q(0))$ by $h_i^t(q(t))$, and the quadratic form

$$Q^t(\alpha) = \sum_{0 \le i < j \le k} \alpha_i \alpha_j \langle p(t), [h_i^t, h_j^t](q(t)) \rangle$$

is actually independent of t, as follows from an iterated use of (6). We will find useful, in order to simplify the computations, to apply the theorem choosing t between the switching times of the trajectory.

This theorem, in a much more general setting, has been proved in [3]. We will give here just a brief sketch of the proof. Let $q_0 = q(0)$ and let $F : w(\cdot) \mapsto F(w)$ be the endpoint mapping at time T for the system

$$\begin{cases} \dot{x} = f(x) + w g(x), \\ x(0) = q_0, \end{cases}$$

which is defined in an L^1 neighborhood of the reference control $u(\cdot)$. Take

$$G(v) = e^{-\tau_1(f+\nu g)} \circ e^{(\tau_1-\tau_2)(f-\nu g)} \circ \cdots \circ e^{(\tau_k - T)(f+(-1)^k \nu g)} F(u + v),$$

which is just F, simply pulled back by the flow generated by the control u, in order to have $G(0) = q_0$. Our aim is to prove that G is locally open at 0 and, moreover, that this property is stable with respect to $\mathcal{C}^1$ perturbations of our system. Let

$$h(t) = e^{\tau_1 \mathrm{ad}(f+\nu g)} \circ e^{(\tau_2-\tau_1)\mathrm{ad}(f-\nu g)} \circ e^{(\tau_3-\tau_2)\mathrm{ad}(f+\nu g)} \circ \dots \\ \circ e^{(t-\tau_{i-1})\mathrm{ad}(f-(-1)^i \nu g)}(f + (-1)^i \nu g)$$

for all $t \in [\tau_{i-1}, \tau_i]$ and all $i = 1, \dots, k+1$. The extremality condition (4) implies that $\langle p_0, h(t)(q_0)\rangle = c$ for all $t \in [0, T]$, as we immediately deduce from (6). The uniqueness of $p(\cdot)$ means, moreover, that the closed convex cone generated by $\{h(t)(q_0) \mid t \in [0, T]\}$ is an half-space of $T_{q_0}M$, which we denote by H.

For any $\alpha = (\alpha_0, \dots, \alpha_k) \in \mathbf{R}^{k+1}$ with $\sum_{i=0}^k \alpha_i = 0$ and for $s > 0$ small enough, we can define $w_s^\alpha(\cdot)$ as the bang-bang control with switching times

$$0 < \tau_1 + s\alpha_0 < \tau_2 + s(\alpha_0 + \alpha_1) < \dots < \tau_k + s\sum_{i=0}^{k-1} \alpha_i < T.$$

Let $v_s^\alpha = u - w_s^\alpha$. We have that

$$\frac{\mathrm{d}}{\mathrm{d}s} G(v_s^\alpha)\Big|_{s=0+} = \sum_{i=0}^k \alpha_i h_i(q_0)$$

and

$$\frac{\mathrm{d}^2}{\mathrm{d}s^2} G(v_s^\alpha)\Big|_{s=0+} = \sum_{i=0}^k \sum_{j=i+1}^k \alpha_i \alpha_j [h_i, h_j](q_0).$$

The positiveness of Q can thus be read as follows: the elements of the space defined by (8) correspond to the variations of the switching times which preserve the total time T and which produce a zero first order variation in the endpoint. Assume that a variation α exists such that $Q(\alpha)$ is negative. Then the convex cone generated by

$$v_0 = \frac{\mathrm{d}^2}{\mathrm{d}s^2} G(v_s^\alpha)\Big|_{s=0+}$$

and H is the whole $T_{q_0}M$. Fix $t_1, \dots, t_n \in]0, T[\setminus\{\tau_1, \dots, \tau_k\}$ such that the convex cone generated by v_0 and

$$v_i = h(t_i)(q_0), \qquad i = 1, \dots, n,$$

is equal to $T_{q_0}M$. Define the admissible control

$$w_{(s_0,s_1,\dots,s_n)}(t) = \begin{cases} -u(t) & \text{if } t \in \cup_{i=1}^n [t_i, t_i + s_i], \\ w_{s_0}^\alpha(t) & \text{otherwise} \end{cases}$$

for $s_0, s_1, \dots, s_n > 0$ small enough and let $v_{(s_0,s_1,\dots,s_n)} = u - w_{(s_0,s_1,\dots,s_n)}$. Fix $a_0, a_1, \dots, a_n > 0$ and remark that

$$\frac{\mathrm{d}}{\mathrm{d}\varepsilon} G(v_{(a_0\varepsilon, a_1\varepsilon^2/2, \dots, a_n\varepsilon^2/2)})\Big|_{\varepsilon=0+} = 0$$

and

$$\frac{\mathrm{d}^2}{\mathrm{d}\varepsilon^2} G(v_{(a_0\varepsilon, a_1\varepsilon^2/2, \ldots, a_n\varepsilon^2/2)})\Big|_{\varepsilon=0+} = \sum_{i=0}^{n} a_i v_i.$$

Now a standard application of the Brower fixed point theorem implies that for any continuous mapping $\mathcal{C}^0$ close to $(s_0, s_1, \ldots, s_n) \mapsto G(v_{(\sqrt{s_0}, s_1, \ldots, s_n)})$, the image of any neighborhood of 0 in $[0, +\infty)^{n+1}$ contains a neighborhood of q_0 in M. This concludes the sketch of the proof of Theorem 2.

The theorem above naturally suggests the following definition, which makes sense for any smooth control system.

DEFINITION. *We say that a trajectory $q : [0, T] \to M$ of $\dot{q} = f(q, u)$, where f is $\mathcal{C}^1$ with respect to both the state q and the control u, is essential if $q(T)$ belongs to the interior of the attainable set from $q(0)$ at time T for any $\mathcal{C}^1$-close system. Vice versa, we call quasi-optimal a trajectory which is not essential.*

Remark. Given an essential trajectory $q : [0, T] \to M$, if we consider time-rescaled systems (which, up to some technical use of cut-off functions, can be seen as $\mathcal{C}^1$-close to the original one, if the scaling factor is close to 1), we get that $q(T) \in A(t, q(0))$ for t close to T. In particular, $q(\cdot)$ is neither the fastest trajectory connecting $q(0)$ to $q(T)$ (i.e., it is not time-optimal) nor the slowest. Theorem 2, giving necessary conditions for quasi-optimality, furnishes a unified approach for a wide range of phenomena, including time-optimality.

Remark. A property that quasi-optimality shares with time-optimality (and, in general, with any optimality defined by an integral cost) is the fact that the time-reversed of a quasi-optimal trajectory is quasi-optimal for the time-reversed system. Indeed, if $q : [0, T] \to M$ is essential for the control system $\dot{q} = f(q, u)$, then there exist $\delta > 0$ and a neighborhood U of $q(0)$ such that for any f' δ-close to f and for any $q \in U$, $q(T)$ belongs to the attainable set from q at time T of the system $\dot{q} = f'(q, u)$, as we can derive by a reparameterization argument similar to the one above. Thus $q(0)$ belongs to the interior of the attainable set from $q(T)$ at time T for any system δ-close to $\dot{q} = -f(q, u)$.

3. Statement of the results and some general considerations. In this section we explicitly furnish a partition of all Lie bracket configurations with zero or one relation of linear dependency between its elements and we state the corresponding bound on the number of switches that we will prove in the next sections. For the sake of conciseness we set

$$X_{\pm} = [f \pm g, [f, g]],$$
$$X_{\pm\mp} = [f \pm g, [f \mp g, [f, g]]],$$

and, in general, if w is a word with letters in $\{+, -\}$, we set $X_{\pm w} = [f \pm g, X_w]$. The two classes of Lie bracket configurations we will consider are characterized as follows:

Case 0.
$g \wedge [f, g] \wedge X_+ \neq 0,$
$g \wedge [f, g] \wedge X_- \neq 0.$

Case 1.
$g \wedge [f, g] \wedge X_+ = 0,$
$g \wedge [f, g] \wedge X_{++} \neq 0,$
$g \wedge [f, g] \wedge X_- \neq 0.$

Every set of equalities and inequalities has to be interpreted as evaluated at q_0. We say that a Lie bracket configuration is of type 0 or 1 to mean that it satisfies the

conditions of, respectively, Case 0 or 1. This partition is complete since, if in (1) we substitute g by $-g$, we obtain exactly the same system (due to the symmetry of the control set), but the roles of $+$ and $-$ are transposed.

DEFINITION. *Given a point q_0 of type 0 (respectively, 1), we say that a neighborhood U of q_0 is adapted if it is precompact and the relations in inequality form characterizing Case 0 (respectively, Case 1) hold throughout $\overline{U}$.*

Our main result is the following.

THEOREM 3. *Let q_0 be a point of M^3 whose Lie bracket configuration is of type 0 or 1 and fix an adapted neighborhood U of q_0. Then there exists a time $T > 0$ for which a quasi-optimal trajectory of the system (1) contained in U and of time-length less than or equal to T is a finite concatenation of bang and singular arcs. In particular, for T small enough, if we are in the conditions of Case 0, a quasi-optimal trajectory is a concatenation of at most three bang arcs or of a bang, a singular, and a bang arc; if we are in the conditions of Case 1, a quasi-optimal trajectory is a concatenation of at most four bang arcs or of two bang, a singular, and a bang arc and the only possible maximal concatenations including singular arcs are of the type $-+S\pm$ or $\pm S+-$.*

Given an extremal trajectory $q(\cdot)$ and an associated covector trajectory $p(\cdot)$ we can define the so-called *switching function*

$$\varphi(t) = \langle p(t), g(q(t))\rangle.$$

The minimality condition (4) in the Pontryagin maximum principle implies that φ assumes the value zero at the switching times of $q(\cdot)$. From Lemma 1 in [1] we know that, given a smooth vector field X, for almost every t in the domain of $q(\cdot)$, we have

$$\frac{d}{dt}\langle p(t), X(q(t))\rangle = \langle p(t), [f + u(t)g, X](q(t))\rangle. \tag{9}$$

In particular, for almost every t we have

$$\dot\varphi(t) = \langle p(t), [f, g](q(t))\rangle.$$

This equality holds, moreover, for every t since φ is absolutely continuous and $t \mapsto \langle p(t), [f, g](q(t))\rangle$ is (absolutely) continuous. Therefore φ is a $\mathcal{C}^1$ function, its derivative is absolutely continuous, and

$$\ddot\varphi(t) = \langle p(t), [f + u(t)g, [f, g]](q(t))\rangle$$

almost everywhere. We stress that these considerations on the switching function do not depend on the dimension of the manifold. A technical consequence, which we will state in dimension three, is the following.

LEMMA 1. *Let X_i, $i = 1, 2, 3$, be three smooth vector fields on M^3. Let U be a precompact subset of M^3 such that $X_1 \wedge X_2 \wedge X_3 \neq 0$ in $\overline{U}$. Then there exists $T > 0$ such that for each interval I of time-length less than or equal to T, for each extremal trajectory $q : I \to U$ and for each corresponding covector trajectory $p(\cdot)$, if both $x_1(\cdot)$ and $x_2(\cdot)$ have at least one zero in I, then the sign of $x_3(\cdot)$ is constant on I, where $x_i(t) := \langle p(t), X_i(q(t))\rangle$, $i = 1, 2, 3$.*

Proof. Define an Euclidean structure on the cotangent bundle T^*U as follows: for every $q \in U$ and every $p \in T^*_q(M^3)$, let

$$\|p\|^2 = \langle p, X_1(q)\rangle^2 + \langle p, X_2(q)\rangle^2 + \langle p, X_3(q)\rangle^2.$$

From the Gronwall inequality applied to (3), it follows that, fixed $0 < c < 1 < C$, there exists $T > 0$ such that, for every $q(\cdot)$ and $p(\cdot)$ as in the hypothesis of the lemma, with $p(\cdot)$ normalized in such a way that $\|p(t_0)\| = 1$ at the middle point of I, we have $c \leq \|p(t)\| \leq C$ for every $t \in I$. From the expressions of $\dot{x}_i$ given in (9) we easily deduce that there exists a constant K independent of T such that

$$|x_i(t)| \leq TCK\,, \qquad i = 1, 2\,,$$

for every $t \in I$. Thus

$$|x_3(t)|^2 = \|p(t)\|^2 - |x_1(t)|^2 - |x_2(t)|^2 \geq c^2 - 2T^2C^2K^2\,.$$

Taking a small enough T the lemma is proved. □

4. The bang-bang case. In this section we aim to prove Theorem 3 for trajectories which are already known to be bang-bang. Fix a point $q_0 \in M^3$ of type 0 or 1 and an adapted neighborhood U of q_0. Let $q(\cdot)$ be an extremal $-+-+$ trajectory in U with consecutive switching times $0, t_1, t_1+t_2$. This means that $q : [-\eta, t_1+t_2+\eta] \to U$ for some $\eta > 0$ and that u takes value $+1$ on $(0, t_1) \cup (t_1 + t_2, t_1 + t_2 + \eta)$ and -1 on $(-\eta, 0) \cup (t_1, t_1 + t_2)$. We will always assume that $t_1 + t_2 < T$, where T is independent of the trajectory.

Since a switching time is a zero of φ, we have

$$0 = \langle p_0, g(\bar{q})\rangle, \tag{10}$$

$$0 = \langle p_0, e^{t_1 \mathrm{ad}(f+g)} g(\bar{q})\rangle, \tag{11}$$

$$0 = \langle p_0, e^{t_1 \mathrm{ad}(f+g)} e^{t_2 \mathrm{ad}(f-g)} g(\bar{q})\rangle, \tag{12}$$

where $p_0 = p(0)$ and $\bar{q} = q(0)$. We show in the following the uniqueness of the covector p_0, at least if T is small enough. This will allow us to apply Theorem 2 and to formulate necessary conditions for the quasi-optimality of the studied trajectory in terms of the index of

$$Q(\alpha) = \sum_{0 \leq i < j \leq 3} \alpha_i \alpha_j \langle p_0, [h_i, h_j](\bar{q})\rangle,$$

defined for all $\alpha = (\alpha_0, \alpha_1, \alpha_2, \alpha_3) \in \mathbf{R}^4$ such that

$$\sum_{i=0}^{3} \alpha_i h_i(\bar{q}) = 0, \tag{13}$$

$$\sum_{i=0}^{3} \alpha_i = 0, \tag{14}$$

where

$$\begin{aligned} h_0 &= f - g, \\ h_1 &= f + g, \\ h_2 &= e^{t_1 \mathrm{ad}(f+g)}(f - g), \\ h_3 &= e^{t_1 \mathrm{ad}(f+g)} e^{t_2 \mathrm{ad}(f-g)}(f + g). \end{aligned}$$

Remark that the extremality condition (4) implies that $\langle p_0, h_i(\bar{q})\rangle = c$ for $i = 0, \ldots, 3$. For the sake of conciseness we write

$$\sigma_{ij} = \langle p_0, [h_i, h_j](\bar{q})\rangle. \tag{15}$$

Since we want to apply the second order condition to all trajectories of the bang-bang type described above which are contained in U, we will consider Q as a family of quadratic forms parameterized also by the point $\bar{q}$.

Choose a triple $\xi_1,\ \xi_2,\ \xi_3$ of 1-forms on M^3 such that their restriction to U is a dual (moving) basis to $g,\ [f,g],\ -X_-$ (that is, $\langle \xi_i(q), g(q)\rangle = \delta_{1i},\ q \in U,\ i = 1,2,3$, and so on). Equality (10) implies that p_0 is a linear combination of $\xi_2(\bar{q})$ and $\xi_3(\bar{q})$. Moreover, the case in which p_0 is proportional to $\xi_2(\bar{q})$ can be excluded choosing T small enough, as we can easily deduce from (11). Since $p(\cdot)$ is defined up to multiplication by a positive scalar we may normalize:

$$p_0 = \pm(\varepsilon\xi_2(\bar{q}) + \xi_3(\bar{q})). \tag{16}$$

For every word w with letters in $\{+,-\}$, we set

$$\lambda_w = \langle \xi_3, X_w\rangle.$$

Let us stress that these are functions defined on U and that, by definition, $\lambda_- \equiv -1$. Remark, moreover, that, due to our choice of U, λ_+ is separated from zero in Case 0, while the same is true for λ_{++} in Case 1.

In the following we will evaluate the asymptotics of various quantities as the time-length of the trajectory goes to 0. To do it we will consider functions of t and q defined on $(0,T)\times U$ and we will say that $\chi(t,q)$ is of order r with respect to t (we will write $\chi(t,q) = O(t^r)$) if it is actually of order r uniformly in U as t goes to 0.

From (11) we have

$$0 = t_1\langle \varepsilon\xi_2(\bar{q}) + \xi_3(\bar{q}), [f,g](\bar{q})\rangle + \langle \varepsilon\xi_2(\bar{q}) + \xi_3(\bar{q}), O(t_1^2)\rangle = \varepsilon(t_1 + O(t_1^2)) + O(t_1^2),$$

and thus for T small enough we can think at ε as a function of t_1 and $\bar{q}$. Remark, moreover, that, as a function on $(0,T)\times U$, ε is of order 1 with respect to t_1.

Take T, the bound on the length of the trajectory, small enough to apply Lemma 1 to the triple of vector fields g, $[f,g]$, and X_-. Let us check that $q(\cdot)$ actually fits the hypothesis of the lemma: the roles of x_1 and x_2 are played here by φ and $\dot{\varphi}$ and φ takes the value zero at all switching times, while between two switching times $\dot{\varphi}$ must have at least one zero, corresponding to a maximum or a minimum of the switching function. The conclusion that we derive from the lemma is that $\langle p(t), X_-(q(t))\rangle$ has constant sign. This sign has to be equal to -1, since the function under consideration is the second derivative of φ in the interval (t_1, t_1+t_2). Since $\langle \varepsilon\xi_2(\bar{q}) + \xi_3(\bar{q}), X_-(\bar{q})\rangle$ depends continuously on ε, it is clear that, possibly for a further smaller T, we can solve the sign uncertainty in (16) and write

$$p_0 = \varepsilon(t_1, \bar{q})\xi_2(\bar{q}) + \xi_3(\bar{q}).$$

This proves the stated uniqueness of p_0. Remark that

$$\varepsilon = \langle p_0, [f,g](\bar{q})\rangle = \dot{\varphi}(0) \le 0, \tag{17}$$

since φ is nonpositive in a right neighborhood of 0.

Remark. It turns out that the subspace of $\mathbf{R}^4$ defined by (13) and (14) is one-dimensional. Equivalently, let us show that

$$V = \left\{ \sum_{i=0}^{3} \alpha_i h_i(\bar{q}) \;\middle|\; \sum_{i=0}^{3} \alpha_i = 0,\ (\alpha_0,\alpha_1,\alpha_2,\alpha_3) \in \mathbf{R}^4 \right\}$$

is two-dimensional. Let $\lambda \in T^*_{\bar{q}} M^3$ such that $\langle \lambda, V \rangle = 0$. In particular,

$$\langle \lambda, h_i(\bar{q}) - h_{i-1}(\bar{q}) \rangle = 0$$

for $i = 1, 2, 3$, and then λ verifies the relations (10), (11), and (12), as can be derived from (5). Thus λ is proportional to p_0, which means that the orthogonal space to V is one-dimensional and the remark is proved. Moreover, the space of admissible α is given by the solutions of the system

$$(18) \quad \begin{cases} \alpha_0 + \alpha_1 + \alpha_2 + \alpha_3 = 0, \\ -\alpha_0 + \alpha_1 + \langle \xi_1(\bar{q}), (h_2 - f)(\bar{q}) \rangle \alpha_2 + \langle \xi_1(\bar{q}), (h_3 - f)(\bar{q}) \rangle \alpha_3 = 0, \\ \langle \xi_2(\bar{q}), (h_2 - f)(\bar{q}) \rangle \alpha_2 + \langle \xi_2(\bar{q}), (h_3 - f)(\bar{q}) \rangle \alpha_3 = 0. \end{cases}$$

4.1. Case 0. Let q_0 be of type 0. From (11) and recalling that $\varepsilon = O(t_1)$, we have

$$0 = t_1 \langle p_0, [f, g](\bar{q}) \rangle + \frac{t_1^2}{2} \langle p_0, X_+(\bar{q}) \rangle + O(t_1^3) = \varepsilon t_1 + \frac{t_1^2}{2} \lambda_+ + O(t_1^3).$$

Thus

$$(19) \qquad \varepsilon = -t_1 \frac{\lambda_+}{2} + O(t_1^2).$$

Similarly, from (12) we get

$$t_2 = 2(\varepsilon + t_1 \lambda_+) + O(t_2^2) = \lambda_+ t_1 + O(t_1^2).$$

In particular, t_2 is of the same order as t_1 and we have

$$\begin{aligned} h_2 &= f - g - 2t_1 [f, g] + O(t_1^2), \\ h_3 &= f + g + 2t_2 [f, g] + O(t_1^2), \end{aligned}$$

and so

$$\begin{aligned} \sigma_{01} &= 2\varepsilon, \\ \sigma_{02} &= 2t_1 + O(t_1^2), \\ \sigma_{12} &= -2\varepsilon - 2t_1 \lambda_+ + O(t_1^2), \\ \sigma_{03} &= 2\varepsilon - 2t_2 + O(t_1^2), \\ \sigma_{13} &= 2t_2 \lambda_+ + O(t_1^2), \\ \sigma_{23} &= 2\varepsilon - 2t_2 + 2t_1 \lambda_+ + O(t_1^2). \end{aligned}$$

The system (18) has the following form:

$$\begin{cases} \alpha_0 + \alpha_1 + \alpha_2 + \alpha_3 = 0, \\ -\alpha_0 + \alpha_1 - (1 + O(t_1^2))\alpha_2 + (1 + O(t_1^2))\alpha_3 = 0, \\ - (2t_1 + O(t_1^2))\alpha_2 + (2t_2 + O(t_1^2))\alpha_3 = 0, \end{cases}$$

from which we obtain

$$\begin{cases} \alpha_0 = -(\frac{t_2}{t_1} + O(t_1))\alpha_3, \\ \alpha_1 = -(1 + O(t_1^2))\alpha_3, \\ \alpha_2 = (\frac{t_2}{t_1} + O(t_1))\alpha_3. \end{cases}$$

Finally, after some calculations,

$$Q = Q(\alpha_3) = \left(-2t_1\lambda_+^2 + O(t_1^2)\right)\alpha_3^2.$$

Recalling that λ_+ is separated from zero we have that Q is negative definite (for small T), and so $q(\cdot)$ is essential.

This completes the proof that in the hypothesis of Case 0 locally at q_0 a bang-bang quasi-optimal trajectory has no more than two switches. We remark that the choice we made between the order of $+$ and $-$ arcs is irrelevant since the hypotheses we were starting from are symmetric in the two signs.

4.2. Case 1. Let now q_0 be of type 1. We will find it useful to introduce the following notation: given a function χ of t and q defined on $(0,T)\times U$ we write $\chi(t,q) = \Omega(t)$ if $\chi(t,q) = \lambda_+(q)O(1) + O(t)$. We also set $\pi_\star = \langle p_0, X_\star\rangle$, $\star = +, -, \dots$.

From (11) we have

$$\begin{aligned} 0 &= t_1\varepsilon + \frac{t_1^2}{2}\pi_+ + \frac{t_1^3}{6}\pi_{++} + O(t_1^4) \\ &= t_1\left(\varepsilon(1+O(t_1)) + t_1\frac{\lambda_+}{2} + t_1^2\frac{\lambda_{++}}{6} + O(t_1^3)\right). \end{aligned}$$

Thus

$$\varepsilon = -t_1\frac{\lambda_+}{2} - t_1^2\frac{\lambda_{++}}{6} + \lambda_+O(t_1^2) + O(t_1^3) = -t_1\frac{\lambda_+}{2} - t_1^2\frac{\lambda_{++}}{6} + t_1^2\Omega(t_1).$$

From (12) we get similarly

$$t_2 = t_1\lambda_+ + \frac{2}{3}\lambda_{++}t_1^2 + \lambda_+O(t_1^2) + O(t_1^3) = t_1\lambda_+ + \frac{2}{3}\lambda_{++}t_1^2 + t_1^2\Omega(t_1).$$

Remark that, in our notation, $t_2, \varepsilon = t_1\Omega(t_1)$. We have

$$\begin{aligned} h_2 &= f - g - 2t_1[f,g] - t_1^2X_+ + O(t_1^3), \\ h_3 &= f + g + 2t_2[f,g] + 2t_1t_2X_+ + t_1t_2\Omega(t_1), \end{aligned}$$

and so

$$\begin{aligned} \sigma_{01} &= 2\varepsilon, \\ \sigma_{02} &= -2t_1\pi_- + O(t_1^2), \\ \sigma_{12} &= -2\varepsilon - 2t_1\pi_+ - t_1^2\pi_{++} + O(t_1^3), \\ \sigma_{03} &= 2\varepsilon + 2t_2\pi_- + t_2O(t_1), \\ \sigma_{13} &= 2t_2\pi_+ + 2t_1t_2\pi_{++} + t_1t_2\Omega(t_1), \\ \sigma_{23} &= 2\varepsilon + 2t_2\pi_- + 2t_1\pi_+ + t_1^2\pi_{++} + t_1^2\Omega(t_1). \end{aligned}$$

The space of admissible α is determined by the system (18), which has the form

$$\begin{cases} \alpha_0 & +\alpha_1 & +\alpha_2 & & +\alpha_3 & = & 0, \\ -\alpha_0 & +\alpha_1 & -(1+O(t_1^2))\alpha_2 & & +(1+t_2O(t_1))\alpha_3 & = & 0, \\ & & -(2t_1+O(t_1^2))\alpha_2 & & +(2t_2+t_2O(t_1))\alpha_3 & = & 0, \end{cases}$$

from which we obtain

$$\begin{cases} \alpha_0 &= -(\frac{t_2}{t_1} + t_2O(1))\alpha_3, \\ \alpha_1 &= -(1+t_2O(t_1))\alpha_3, \\ \alpha_2 &= (\frac{t_2}{t_1} + t_2O(1))\alpha_3. \end{cases} \tag{20}$$

Thus,

$$\begin{aligned} Q(\alpha_3) = \Bigg[& 2\varepsilon\frac{t_2}{t_1} + 2t_1\pi_-\frac{t_2^2}{t_1^2} + (2\varepsilon + 2t_1\pi_+ + t_1^2\pi_{++})\frac{t_2}{t_1} - (2\varepsilon + 2t_2\pi_-)\frac{t_2}{t_1} \\ & - (2t_2\pi_+ + 2t_1t_2\pi_{++}) + (2\varepsilon + 2t_2\pi_- + 2t_1\pi_+ + t_1^2\pi_{++})\frac{t_2}{t_1} \\ & + t_1t_2\Omega(t_1)\Bigg]\alpha_3^2 \\ = & \left[2\frac{t_2}{t_1}(2\varepsilon + t_1\lambda_+ + t_2\lambda_-) + t_1t_2\Omega(t_1)\right]\alpha_3^2 \\ = & -2t_2(\lambda_+ + t_1\lambda_{++} + t_1\Omega(t_1))\alpha_3^2. \end{aligned}$$

If Q is nonnegative definite, then, since $\varepsilon \le 0$, the following system of inequalities is satisfied:

$$\begin{cases} \lambda_+ + t_1\lambda_{++} & + & t_1\Omega(t_1) & \le & 0, \\ -t_1(\lambda_+ + t_1\frac{\lambda_{++}}{3}) & + & t_1^2\Omega(t_1) & \le & 0, \end{cases}$$

and so

$$\begin{cases} \lambda_+(1 + O(t_1)) & + & t_1\lambda_{++}(1 + O(t_1)) & \le & 0, \\ -\lambda_+(1 + O(t_1)) & - & t_1\lambda_{++}\left(\frac{1}{3} + O(t_1)\right) & \le & 0, \end{cases}$$

from which we deduce

$$\frac{2}{3}t_1\lambda_{++} + O(t_1^2) \le 0.$$

Since λ_{++} is uniformly bounded away from 0 on U, a necessary condition for Q to be nonnegative definite (and even more so a necessary condition for $q(\cdot)$ to be quasi-optimal) is that $\lambda_{++} < 0$. In particular, (recall that $\lambda_- = -1$) if

$$(\operatorname{sign} g \wedge [f,g] \wedge X_-(q_0))(\operatorname{sign} g \wedge [f,g] \wedge X_{++}(q_0)) < 0$$

(that is, if the orientation of the two triples of vectors does not coincide), then a $-+-+$ trajectory of small enough length contained in U is not quasi-optimal. If the above signs coincide, then they are different for the same system with reversed time, that is, where f and g are substituted, respectively, by $-f$ and $-g$. Since the time reversed of a quasi-optimal trajectory of the old system is quasi-optimal for the new one, we have that a $+-+-$ trajectory of the initial system of small enough length contained in U is not quasi-optimal.

We conclude that a short enough quasi-optimal bang-bang trajectory lying in U has no more than three switches, in both Cases 0 and 1. In particular, we have proved that a quasi-optimal trajectory in U has no chattering control.

4.3. Sharpness of the result. The bound given in Case 0 is clearly sharp, as we can realize by a purely dimensional reasoning. To investigate whether the extra switch that we add in Case 1 is needed or not, we refer to the sufficiency condition for optimality proved in [4, Theorem 2.6]: the same reasoning applied to the present case implies that if the quadratic form Q is positive definite, then the corresponding

trajectory $q : [0,T] \to M^3$ is locally time-optimal, in the $\mathcal{C}^0$ sense; that is, there exists a neighborhood U of the graph $\{(t,q(t)) \mid t \in [0,T]\}$ in $[0,T] \times M^3$ such that $q(\cdot)$ is time-optimal between all the admissible trajectories whose graph is contained in U. Our aim is to use this result to show that the bound we gave is sharp in the following sense.

LEMMA 2. *Let $\mathbf{J}^4_{q_0}$ be the space of 4-jets at q_0 of pairs of smooth vector fields on M^3 and let $C_1 \subset \mathbf{J}^4_{q_0}$ be the set of all $J^4_{q_0}(f,g)$ such that (f,g) is of type 1 at q_0. Then there exists an open nonempty subset A_1 of C_1 such that if the 4-jet of (f,g) belongs to A_1, then for any $T > 0$ there exists a trajectory with three switches, passing through q_0 and of time length smaller than T, which is locally time-optimal in the $\mathcal{C}^0$ sense.*

Assume that q_0 is a point of type 1. Let $q(\cdot)$ be a $+-+-$ extremal trajectory with switching times $0, t_1, t_1+t_2$ and such that $q(0) = q_0$. In this subsection we will write $O(t^\gamma)$, $\gamma > 0$, simply to denote functions of $t \in (0,T)$ which are of order t^γ as t goes to 0 (the first switching point is now fixed). The equations for the switching times are

$$0 = \langle p_0, g(q_0)\rangle, \tag{21}$$

$$0 = \langle p_0, e^{t_1 \mathrm{ad}(f-g)} g(q_0)\rangle, \tag{22}$$

$$0 = \langle p_0, e^{t_1 \mathrm{ad}(f-g)} e^{t_2 \mathrm{ad}(f+g)} g(q_0)\rangle. \tag{23}$$

In terms of $\xi_1,\ \xi_2,\ \xi_3$, defined as before, we have

$$p_0 = \varepsilon \xi_2(q_0) + \xi_3(q_0),$$

with $\varepsilon \geq 0$. Remark that now

$$\begin{aligned} h_0 &= f+g, \\ h_1 &= f-g, \\ h_2 &= e^{t_1 \mathrm{ad}(f-g)}(f+g), \\ h_3 &= e^{t_1 \mathrm{ad}(f-g)} e^{t_2 \mathrm{ad}(f+g)}(f-g). \end{aligned}$$

We follow the same procedure as in the previous subsections: we use (22) and (23) to establish the asymptotics of ε and t_2; from (13) and (14) we find the relations among the α_i and we compute Q. The calculations are here more lengthy since the first two computable orders of Q—order $t_1^{3/2}$ and order t_1^2—both annihilate.

In detail, from (22) and (23) we have

$$\varepsilon = \frac{t_1}{2} - \frac{t_1^2}{6}\lambda_{--} + O(t_1^3) \tag{24}$$

and

$$t_2^2 = \frac{3}{\lambda_{++}} t_1 + O(t_1^{3/2}).$$

We can now compute

$$\begin{aligned} h_2 &= f + g + 2t_1[f,g] + t_1^2 X_- + O(t_1^3), \\ h_3 &= f - g - 2t_2[f,g] - t_2^2 X_+ - 2t_1 t_2 X_- - \frac{t_2^3}{3} X_{++} + O(t_1^2), \end{aligned}$$

and

$$\begin{aligned}
\sigma_{01} &= -2\varepsilon,\\
\sigma_{02} &= -2t_1 + t_1^2\pi_{+-} + O(t_1^3),\\
\sigma_{12} &= 2\varepsilon - 2t_1 + t_1^2\pi_{--} + O(t_1^3),\\
\sigma_{03} &= -2\varepsilon - 2t_2\pi_{+} - t_2^2\pi_{++} - 2t_1t_2\pi_{+-} - \frac{t_2^3}{3}\pi_{+++} + O(t_1^2),\\
\sigma_{13} &= 2t_2 - t_2^2\pi_{-+} - 2t_1t_2\pi_{--} - \frac{t_2^3}{3}\pi_{-++} + O(t_1^2),\\
\sigma_{23} &= \sigma_{03} - \sigma_{12} + 2\varepsilon - 2t_1t_2^2\pi_{\times} + O(t_1^{5/2}),
\end{aligned}$$

where

$$\pi_{\times} = \langle p_0, [[f,g], X_+](q_0)\rangle.$$

The space on which Q is defined turns out to be described by

$$\begin{aligned}
\alpha_0 &= -(1 + O(t_1^{3/2}))\alpha_2,\\
\alpha_1 &= \left(-\frac{t_1}{t_2} + t_1\frac{\delta_+}{2} + \frac{t_1t_2}{2}\left(\frac{\delta_{++}}{3} - \frac{\delta_+^2}{2} - \gamma_+\right) + O(t_1^2)\right)\alpha_2,\\
\alpha_3 &= \left(\frac{t_1}{t_2} - t_1\frac{\delta_+}{2} - \frac{t_1t_2}{2}\left(\frac{\delta_{++}}{3} - \frac{\delta_+^2}{2}\right) + O(t_1^2)\right)\alpha_2,
\end{aligned}$$

where

$$\begin{aligned}
\gamma_+ &= \langle \xi_1(q_0), X_+(q_0)\rangle\,,\\
\delta_\star &= \langle \xi_2(q_0), X_\star(q_0)\rangle\,, \qquad \star = +, ++\,.
\end{aligned}$$

Finally, we get

$$\begin{aligned}
Q = Q(\alpha_2) = \Bigg[t_1^2t_2\Bigg(&\frac{\lambda_{-++} + \delta_{++}}{3} - \delta_+^2 - \lambda_{-+}\delta_+ - \gamma_+\\
&- 2\lambda_{\times} + \frac{2}{9}\lambda_{++}\lambda_{--}\Bigg) + O(t_1^3)\Bigg]\alpha_2^2.
\end{aligned}$$

To conclude the proof of Lemma 2 it suffices to exhibit a system on $\mathbf{R}^3$ for which at the point $q_0 = 0$ the Lie bracket configuration is of type 1 and the following sign conditions hold: $\lambda_{++} > 0$ and

$$\frac{\lambda_{-++} + \delta_{++}}{3} - \delta_+^2 - \lambda_{-+}\delta_+ - \gamma_+ - 2\lambda_{\times} + \frac{2}{9}\lambda_{++}\lambda_{--} > 0.$$

This is the case, for instance, of the control system:

$$f(x,y,z) = \begin{bmatrix} 0\\ -x\\ -\frac{x^2}{4} - \frac{x^3}{4} + \frac{y}{2} + y^2 - z\end{bmatrix}, \qquad g(x,y,z) = \begin{bmatrix}1\\0\\0\end{bmatrix},$$

for which we get $\lambda_{++} = 2$ and

$$Q = Q(\alpha_2) = \left(\frac{17}{6}t_1^2t_2 + O(t_1^3)\right)\alpha_2^2.$$

It happens that not only the bang-bang part of Theorem 3 is sharp but also the one involving singular arcs. The results in [15] imply, indeed, that the presence of short time-optimal concatenations of two bang, one singular, and one bang arc is structurally stable in Case 1. We stress [5] that in this case the optimality is proved to be not only local, but also global.

5. Allowing singular arcs. Let $q_0 \in M^3$ be a point of type 0 or 1 and U an adapted neighborhood of q_0. Consider a quasi-optimal trajectory $q : (T_1, T_2) \to U$ with no preliminary restriction on the structure of its corresponding control function u. Let $p : (T_1, T_2) \to T^*M^3$ be an associated covector trajectory.

It is known from Proposition 1 in [1] that, after possibly a modification on a set of measure zero, u is $\mathcal{C}^\infty$ on a open dense subset O of (T_1, T_2). Assume that O is maximal (also with respect to further modifications of u on sets of measure zero). An *arc* is a piece of trajectory corresponding to a connected component of O; it is *bang* if u takes value in $\{-1, 1\}$ on it, otherwise it is *singular*. We will use the word arc also to refer to the connected component of O itself. Remark that on an arc also φ is $\mathcal{C}^\infty$ and all its derivatives can be computed iterating (9). We say that two distinct arcs (τ_1, τ_2) and (t_1, t_2) are *concatenated* if $\tau_2 = t_1$ or $\tau_1 = t_2$. Let $\Sigma = \partial O$. We say that two distinct points of Σ are *subsequent* if the open interval which they identify does not intersect Σ (that is, by density of O, if it is an arc).

In what follows we always assume that $T_2 - T_1 < T$, for $T > 0$, which will be considered as small as needed. In particular, we will assume T to be small enough to deduce from Lemma 1 the following property: if both φ and $\dot\varphi$ have at least one zero in (T_1, T_2), then $\psi_+(\cdot)$ and $\psi_-(\cdot)$ in Case 0 ($\psi_-(\cdot)$ and $\psi_{++}(\cdot)$ in Case 1) do not change sign on (T_1, T_2), where

$$\psi_\star(t) = \langle p(t), X_\star(q(t))\rangle.$$

Remark that if, for instance, $q(\cdot)$ has a bang arc compactly contained in (T_1, T_2), then both φ and $\dot\varphi$ have, indeed, at least one zero in (T_1, T_2).

We start from the situation in which there is no bang arc. If this is the case, then the switching function is identically equal to zero: to prove it, by density of O, we just need to show that if I is a singular arc, then $\varphi|_I \equiv 0$. This is indeed the case: assume that I is singular and that $\varphi|_I$ is not identically equal to zero. Then

$$J = \mathrm{int}\{\tau \in I | \varphi(\tau) = 0\}$$

is a proper nonempty subset of I. Let t be in the boundary of J and in the interior of I. By continuity we obtain that both $|u(t)| = 1$ and $\varphi^{(n)}(t) = 0$ for every $n \geq 0$. As remarked, however, $\varphi^{(n)}(t)$ can be computed iterating (9). It follows, from the nondegeneracy conditions of both Cases 0 and 1, that $p(t)$ is equal to 0, which is impossible.

Thus, if there is no bang arc, φ is identically equal to zero on (T_1, T_2). We want to deduce that the trajectory is made of a single singular arc, by proving that if $\varphi \equiv 0$ on an open interval I, then u is smooth on I. Indeed, both $\dot\varphi$ and its further derivatives are also identically equal to zero on I and so $p(t)$ is orthogonal to both $g(q(t))$ and $[f, g](q(t))$ and, for almost all $t \in I$,

$$\langle p(t), [f, [f, g]](q(t))\rangle + u(t)\langle p(t), [g, [f, g]](q(t))\rangle = 0\,. \tag{25}$$

We remark that in both Cases 0 and 1

$$\mathrm{span}\{g(q), [f, g](q), [f, [f, g]](q), [g, [f, g]](q)\} = T_qM^3$$

for every $q \in U$. Thus $\langle p(t), [g,[f,g]](q(t))\rangle \neq 0$ for every t for which (25) holds, otherwise $p(t) \neq 0$ would annihilate $T_{q(t)}M^3$. If $\langle p(\bar t), [g,[f,g]](q(\bar t))\rangle = 0$ for some $\bar t \in I$, however, we would have that near $\bar t$ the function $t \mapsto \langle p(t), [f,[f,g]](q(t))\rangle$ is bounded away from zero and consequently $|u(t)| > 1$ for some t at which (25) holds. Thus, for every $t \in I$, $\langle p(t), [g,[f,g]](q(t))\rangle \neq 0$ and

$$u(t) = -\frac{\langle p(t), [f,[f,g]](q(t))\rangle}{\langle p(t), [g,[f,g]](q(t))\rangle}. \tag{26}$$

Substituting the last expression in the Hamiltonian, we find that $p|_I$ is a solution of the smooth (autonomous) Hamiltonian system generated by the Hamiltonian

$$h(p) = \langle p, f\rangle - \frac{\langle p, [f,[f,g]]\rangle}{\langle p, [g,[f,g]]\rangle}\langle p, g\rangle,$$

and, in particular, it is smooth. According to (26), the same is true for $u|_I$.

If no bang arc $(\tau_1, \tau_2) \subset\subset (T_1, T_2)$ exists, then, by the same reasoning, the trajectory is a concatenation of at most a bang, a singular, and a bang arc. Let now $(\tau_1, \tau_2) \subset\subset (T_1, T_2)$ be a bang arc. We can associate with it the smaller point t_2 of Σ which satisfies the following conditions: $t_2 \geq \tau_2$, t_2 is the upper bound of a bang arc, and t_2 is not the lower bound of any bang arc. (This is possible since the results of the previous section exclude the existence of an infinite sequence of subsequent bang arcs.) Analogously we can define $t_1 \leq \tau_1$. If the trajectory is not bang-bang, then either $t_1 \neq T_1$ or $t_2 \neq T_2$. Assume that $t_2 \neq T_2$. Then $p(t_2)$ is orthogonal to both $g(q(t_2))$ and $[f,g](q(t_2))$. Indeed, by definition of t_2 in each of its (right) neighborhoods lies the interior point of a singular arc or an entire bang arc, on which $\varphi(t)$ necessarily assumes a zero and a maximum or minimum. By continuity we deduce the stated orthogonality. Denote by I the arc having t_2 as upper bound and by ν be the control corresponding to such arc. Since $\varphi(t_2) = \dot\varphi(t_2) = 0$ and I is compactly contained in (T_1, T_2), it is clear that $\psi_\nu(\cdot)$, the second derivative of $\varphi(\cdot)$ along I, must have a zero in I. Due to our assumptions on T we can exclude that $\nu = -1$, since $\psi_-(\cdot)$ has constant sign along the trajectory in both Cases 0 and 1. For the same reason, the Lie bracket configuration at q_0 cannot be of type 0, and we can restrict our attention to Case 1: therefore $\psi_{++}(\cdot)$ has constant sign along (T_1, T_2) and, since $\psi_{++}(\cdot) = \varphi^{(3)}(\cdot)$ on I, such sign must be -1 (think of the restrictions on the changes of concavity of φ on I). Analogous considerations could be carried out in t_1 in the case $t_1 \neq T_1$, leading up to the opposite sign of ψ_{++}. Thus $t_1 = T_1$. For the same reason there cannot be any bang arc compactly contained in the interval (t_2, T_2). Thus (t_2, T_2) is a singular arc itself or the union of a singular and a bang arc. Up to now we proved that a short enough quasi-optimal trajectory lying in U is the concatenation of at most four bang arcs, a singular arc, and a bang arc. Actually, if the considered trajectory contains a singular arc, an extra quasi-optimality condition is fulfilled: the generalized Legendre condition. (See [8] for a formulation and [2] for a complete mathematical proof.) In the present situation this condition states that $\psi_-(\cdot)$ is positive along the singular arc and so along the entire trajectory. Thus we exclude that a trajectory has both a singular and a compactly contained bang arc corresponding to control -1. Finally the two "maximal" non–bang-bang concatenations are $-{+}\mathrm{S}\pm$ and $\pm\mathrm{S}{+}-$.

6. A result of infinite codimension. This last section presents a result which applies in a more general setting the techniques we used in the above proof. In particular, the result holds in any finite dimension.

PROPOSITION 2. *Take a finite-dimensional manifold M and two smooth vector fields f and g on M. Let X_+, $X_-, \dots$ be defined as usual. We will also write $X_{(m+)}$ for $X_{+\dots+}$, where $+$ is repeated m times. (and $X_{(m-)}$ for the natural counterpart). Assume that the system*

$$\dot{q} = f(q) + u\, g(q), \qquad |u| \le 1\,, \tag{27}$$

is such that for each $q_0 \in M$ and for $\star = +, -$, we have

$$T_{q_0} M = \operatorname{span}\{g(q_0), [f,g](q_0), X_\star(q_0), \dots, X_{(m\star)}(q_0), \dots\} \stackrel{\text{def}}{=} V_\star(q_0)\,.$$

Let $q : (T_1, T_2) \to M$ be an extremal trajectory of the system above such that the corresponding control function u verifies $|u| = 1$ on an open dense subset of (T_1, T_2) and let Σ be the set of discontinuities of u (not avoidable by changing u on a set of measure zero). Then either Σ is discrete or it contains a sequence of infinitely many subsequent isolated points.

Proof. Let O be the maximal open dense subset of (T_1, T_2) on which u, after modification on a set of measure zero, is smooth. Clearly u is constant on any arc, i.e., any connected component of O.

Assume by contradiction that Σ neither is discrete nor contains an infinite sequence of subsequent isolated points. With each (bang) arc (τ_1, τ_2) we can associate the smaller point of Σ which is larger than or equal to τ_2 and which is not isolated, unless there exists a finite sequence of subsequent isolated points including τ_2 and T_2. Denote by A the set of all points which can be associated as described with some arc. By our assumptions A is nonempty and preperfect, i.e., each point of A is a density point for A. We give a partition $A = A_+ \cup A_-$ by defining $A_\star$, $\star = +, -$, as the set of points a of A for which the control u on a left neighborhood of a has constant sign $\star 1$. We have that there exists $\star \in \{+, -\}$ and there exists a subset B of $A_\star$ which is nonempty and preperfect. (Indeed, if $a \in A_+$ is not a density point for A_+, then there exists a neighborhood U of a such that $(U \setminus \{a\}) \cap A$ is a preperfect nonempty subset of A_- and thus either A_+ is nonempty and preperfect or A_- has a preperfect nonempty subset.)

Let $p(\cdot)$ be a covector trajectory associated with $q(\cdot)$. To complete the argument we want to prove that at each point $\tau \in B$ the covector $p(\tau)$ annihilates $V_\star(q(\tau))$. It is clear that $\varphi(\tau) = \langle p(\tau), g(q(\tau))\rangle = 0$ for each $\tau \in \Sigma$. Since on the interval between two subsequent points of Σ there is at least one zero of $\varphi'(\cdot) = \langle p(\cdot), [f,g](q(\cdot))\rangle$, we have that, by continuity, $\langle p(\tau), [f,g](q(\tau))\rangle = 0$ for each $\tau \in A$. Reasoning similarly and using the preperfectness of B we prove by induction on m that $\langle p(\tau), X_{(m\star)}(q(\tau))\rangle = 0$ for each $\tau \in B$. □

Proposition 2 is an improvement of Proposition 2 in [1], where it was proved, under the same hypothesis, that Σ cannot be a perfect set, that is, a closed preperfect set. To express it consistently with Proposition 2, this older result says that either Σ is empty or it contains an isolated point.

AN ERGODIC CONTROL PROBLEM FOR CONSTRAINED DIFFUSION PROCESSES: EXISTENCE OF OPTIMAL MARKOV CONTROL*

AMARJIT BUDHIRAJA†

Abstract. An ergodic control problem for a class of constrained diffusion processes is considered. The goal is the almost sure minimization of long term cost per unit time. The main result of the paper is that there exists an optimal Markov control for the considered problem. It is shown that under the assumption of regularity of the Skorohod map and the assumption that the drift vector field takes values in a certain cone of stability, the class of controlled diffusion processes considered have strong, uniform in control, stability properties. The role of the boundary is critical in obtaining the stability and ergodic control results for the class of controlled constrained diffusion processes considered in this work since the domains are unbounded and the corresponding unconstrained diffusions are typically transient. These stability properties are key in obtaining appropriate tightness estimates. Once these estimates are available the remaining work lies in identifying weak limits of a certain family of occupation measures. In this regard an extension to the Echeverria–Weiss–Kurtz characterization of invariant measures of Markov processes, to the case of constrained-controlled processes considered in this paper, is proved. This characterization result is also crucially used in proving the compactness of the family of invariant measures of Markov processes corresponding to all possible Markov controls.

Key words. ergodic control, optimal Markov control, controlled reflected diffusions, constrained processes, control of queuing networks, patchwork martingale problem, controlled martingale problem, Echeverria's criterion

1. Introduction.

Constrained diffusion processes arise in a natural fashion in the heavy traffic analysis of queuing networks coming from problems in computer, communications, and manufacturing systems. The problem of control of such queuing systems is of great current interest (cf. [31, 20, 23, 19, 32]). Except for a few special cases, the control problem for queuing networks is quite difficult to analyze directly and thus one tries to find more tractable approximations. In that respect, diffusion approximations obtained via appropriate scaling limits become very attractive since in the limit many fine details are eliminated and usually the only parameters remaining are the means, the variances of the various processes, and the mean routing structure. Because of the simple structure, the limit problem is considerably easier to solve. Once the optimal solution to the control problem for the constrained diffusions is obtained, one can then approximate the properties and suggest good policies for the actual physical system. Thus the study of constrained controlled diffusion processes is one of the central objectives in the optimal control of queuing networks.

In this work we consider a control problem for a class of diffusion processes which are constrained to lie in a polyhedral cone G with a vertex at origin. The domain $G \subset \mathbb{R}^k$ is given as an intersection of N half spaces G_i, $i = 1, \ldots, N$. Associated with each G_i are two vectors: the first vector, denoted as n_i, represents the inward normal to G_i while the second, denoted as d_i, gives the "direction of constraint." Roughly speaking, the constrained version of a given unrestricted trajectory in $\mathbb{R}^k$

is obtained by pushing back the trajectory, whenever it is about to exit the domain, in a prespecified direction of constraint using the minimal force required to keep the trajectory within the domain. Precise definitions will be given in section 2. The constraining mechanism is described via the Skorohod map, denoted as $\Gamma(\cdot)$, which takes an unrestricted trajectory $\psi(\cdot)$ and maps it to a trajectory $\phi(\cdot) \doteq \Gamma(\psi)(\cdot)$ such that $\phi(t) \in G$ for all $t \in (0, \infty)$. Under appropriate conditions on $(d_i, n_i)_{i=1}^N$ it follows from the results in [13] that the Skorohod map is well defined and it enjoys a rather strong regularity property (see Theorem 2.3).

The controlled constrained diffusion process that we consider in this paper are obtained as a solution to the equation

$$X(t) = \Gamma\left(X(0) + \int_0^{\cdot} b(X(s), u(s))ds + \int_0^{\cdot} \sigma(X(s))dW(s)\right)(t), \quad t \in [0, \infty), \tag{1.1}$$

where $W(\cdot)$ is a standard Wiener process, $b : G \times U \to \mathbb{R}^k$, $\sigma : G \to \mathbb{R}^{k\times k}$ are suitable coefficients, U is a given control set, and $u(\cdot)$ is a U valued "admissible" control process. The control problem that we study is concerned with the ergodic cost criterion:

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T k(X(s), u(s))ds, \tag{1.2}$$

where the limit above is taken a.s. and $k : G \times U \to \mathbb{R}$ is a suitable map. The two key objectives of the controller are, first, to choose a control in a nonanticipative fashion, which minimizes the cost in (1.2) and, second, to obtain a control which is "easy" to implement. With regard to the second goal, one of the most desirable features of a good control is that the control depends only on the current value of the state and not on the whole history of the state and/or the control process. In other words, we are seeking controls $u(\cdot)$ such that there exists some measurable map $v : G \to U$ satisfying $u(t) = v(X(t))$, a.s. for all $t \in [0, \infty)$. Under such a control the solution to (1.1) becomes a Markov process and for this reason the map $v(\cdot)$ is referred to as a "Markov control." The objective of this work is to show that, under appropriate conditions on the model (cf. Conditions 2.2, 2.4, 2.5, 3.1) there is a Markov control which minimizes the cost in (1.2). The ergodic control problem for unconstrained diffusions is one of the classical problems in stochastic control. The problem has been studied extensively in [39, 30, 7, 6, 40, 22, 28]. The approach taken in the present paper has been inspired by the techniques and results in [7]. For ergodic control results on constrained jump-diffusion processes in bounded domains and *expected* long term cost per unit time criterion, we refer the reader to [4, 34, 31]. For the case of constrained diffusions in unbounded domains, we are not aware of any results which give the existence of optimal Markov control under the ergodic cost criterion considered in this paper.

As is classical in an ergodic control problem of the above form (cf. [6, 40, 31, 28]) the problem of existence of optimal Markov controls under the cost criterion in (1.2) is closely related to certain stability properties of the solutions to (1.1). In a recent work [2], which dealt with uncontrolled constrained diffusions, various stability properties of the solution to (1.1) with $b(x, u) \equiv \beta(x)$, where $\beta : \mathbb{R}^k \to \mathbb{R}^k$ is an appropriate drift vector, were obtained. In particular it was shown that if for all $x \in G$, $\beta(x)$ lies in a certain cone $\mathcal{C}$ (see (3.1)) and its distance from the boundary of the cone is uniformly bounded below by a positive constant, then the constrained diffusion is positive recurrent and has a unique invariant measure. The above results identify an

important, nontrivial class of ergodic constrained diffusions in unbounded domains, in the sense that the corresponding unconstrained version of these processes would typically be transient. To see this one needs only to consider the case where $b(x,u) \equiv b$, where b is some fixed vector in $\mathcal{C}^0$. For this latter case ($b(x,u) \equiv b$), the cone, in fact, provides a necessary and sufficient condition for positive recurrence of constrained diffusions, i.e., if $b \notin \mathcal{C}$, then the corresponding constrained diffusion is transient [9]. In the context of the constant drift case, this necessary and sufficient condition for positive recurrence, for constrained diffusions which correspond to single class networks, was first proved in [21].

The estimates used in the study of the stability properties of the uncontrolled form of (1.1) can be used for the controlled problem studied in this paper as well. Using these estimates, we will obtain rather strong (uniform in control) stability properties for the processes obtained as solutions to (1.1) (see section 6). These stability results are then used in various tightness arguments in this paper. As another consequence of results in [2] we have that under any Markov control $v(\cdot)$, under the assumption that the drift vector field $b(\cdot,\cdot)$ takes values in the set $\mathcal{C}(\delta)$ (see (3.2)) for some $\delta > 0$, the solution to (1.1) is positive recurrent and has a unique invariant measure, denoted as η_v. We abbreviate this statement by saying that "all Markov controls are stable." The above condition on the drift will be the "blanket stability" assumption made in most of the results in this work. In the classical theory of ergodic control (cf. [6]), there are generally two kinds of problems studied. The first is the so-called stable case, where a blanket stability condition on the model is assumed. The study of this case is the main goal of this paper. The second case does not assume stability conditions on the model but instead makes certain restrictive conditions on the cost function k which penalize unstable behavior of the controlled process. This is referred to as the "near monotone case" in [6]. The proof of the existence of a Markov control in the near monotone case, under our setup, is essentially the same as that for the classical model considered in [6]. We briefly sketch the argument in the appendix.

Using the "blanket stability" condition and an ergodic theorem of Khasminskii [24] it will follow that under a Markov control $v(\cdot)$ the limit in (1.2) is a.s. equal to

$$\int_G k(x, v(x))\eta_v(dx). \tag{1.3}$$

The next key step in the program is to show that for any admissible control $u(\cdot)$ the limit in (1.2) can be expressed in the form (1.3) for some measurable $v : G \to U$ which may depend on ω (the parameter of randomness), the control $u(\cdot)$, and other data. This is done in Proposition 7.3. As an immediate consequence of this step it follows that

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T k(X(s), u(s))ds \geq \inf_v \int_G k(x, v(x))\eta_v(dx), \tag{1.4}$$

a.s., where the infimum on the right side above is taken over all measurable maps $v : G \to U$. In order to prove the above step we need a characterization result for the invariant measures of solutions of (1.1) (with $u(\cdot) = v(X(\cdot))$ for some measurable $v(\cdot)$). The characterization results for invariant measures of solutions to martingale problems are classical (cf. [17, 5, 28]). For the class of constrained processes (see (2.2))

considered in this work, one has via an application of Ito's formula that for all $f \in C_0^\infty(G)$

$$f(X(t)) - \int_0^t \int_S (Lf)(X(s),\alpha)u(s)(d\alpha)ds - \sum_{i=1}^N \int_0^t (D_i f)(Z(s))dY_i(s)$$

is a martingale, where L is as in (5.1). Since the local time processes $\{Y_i(\cdot)\}$ are typically not absolutely continuous, this leads us to the study of controlled, *singular*, martingale problems which do not fall in the purview of the results in the above listed references. In section 5, we use the ideas of patchwork and constrained martingale problems introduced by Kurtz [26, 27] to prove a characterization result for invariant measures, suitable for our purposes. It was pointed out by the referee that Theorem 5.7 is a special case of a recently appeared result in [29].

As a final step we need to show that the infimum on the right side of (1.4) is attained for some Markov control $v : G \to U$. This step (Proposition 7.2), combined with the ergodic theorem in [24] yields our main theorem: Theorem 3.4. The fact that the infimum is attained is a consequence of the fact that the family $\{\eta_v : v \text{ is a Markov control}\}$ is compact. The proof of the compactness of this family once more uses the characterization result for the invariant measures studied in section 5 and various tightness estimates, which follow from the stability properties of our controlled diffusions. This is done in Lemma 7.1. Observe that since (1.4) holds a.s., we can replace the left side of the expression by

$$\text{ess inf} \limsup_{T\to\infty} \frac{1}{T} \int_0^T k(X(s),u(s))ds.$$

Thus our main result (Theorem (3.4)) says that there is a Markov control for which the cost, for almost every realization, is no worse than that for the (essentially) best possible realization corresponding to any other control.

In this paper we do not address the problem of construction of the optimal Markov control or the approximation of optimal control for physical queuing systems using the optimal Markov control for the limit diffusion. These questions will be addressed in a future work. One of the important tools in the study of the control problem is the existence and uniqueness of the HJB equation for the value function. However, neither is known for the ergodic control problem studied in this paper and its treatment will be undertaken in a future work.

The paper is organized as follows. In section 2 we present the basic definitions and properties of the Skorohod map. Section 3 introduces the ergodic cost problem that interests us in this work. We give our key condition on the drift vector which assures us that all Markov controls are stable. Finally in this section we state our main result: Theorem 3.4. Section 4 is an assortment of some background results used in the proof of our main theorem. In section 5 we present our extension of the Echeverria–Weiss–Kurtz criterion for the invariant measures, which is a special case of a recently published result by Kurtz and Stockbridge [29]. Section 6 is devoted to obtaining stability properties of our constrained diffusions. This section crucially uses some estimates derived in [2] (cf. Lemma 6.1). As a consequence of these results we prove strong, uniform in control, tightness properties of the solutions of (1.1). Finally, in section 7 we present the proof of Theorem 3.4. In section 8 we comment on the possibility of characterizing the value of the ergodic control problem via a suitable HJB equation.

2. Skorohod map and controlled constrained diffusions. Let $G \subset \mathbb{R}^k$ be a polyhedral cone in $\mathbb{R}^k$ with the vertex at the origin given as the intersection of half spaces G_i, $i = 1, \ldots, N$. Each half space G_i is associated with a unit vector n_i via the relation $G_i = \{x \in \mathbb{R}^k : \langle x, n_i \rangle \geq 0\}$, where $\langle \cdot, \cdot \rangle$ denotes the usual inner product in $\mathbb{R}^k$. Denote the boundary of a set $B \subset \mathbb{R}^k$ by ∂B. We will denote the set $\{x \in \partial G : \langle x, n_i \rangle = 0\}$ by F_i. For $x \in \partial G$, define the set, $n(x)$, of inward normals to G at x by $n(x) \doteq \{r : |r| = 1, \quad \langle r, x - y \rangle \leq 0 \ \ \forall y \in G\}$. With each face F_i we associate a unit vector d_i such that $\langle d_i, n_i \rangle > 0$. This vector defines the *direction of constraint* associated with the face F_i. For $x \in \partial G$ define $d(x) \doteq \{d \in \mathbb{R}^k : d = \sum_{i \in \mathrm{In}(x)} \alpha_i d_i; \alpha_i \geq 0; \ \ ||d|| = 1\}$, where $\mathrm{In}(x) \doteq \{i \in \{1, 2, \ldots, N\} : \langle x, n_i \rangle = 0\}$. We will denote the collection of all subsets of $\{1, \ldots, N\}$ by Λ. Also for $\lambda \in \Lambda$ we will define $F_\lambda \doteq \cap_{i \in \lambda} F_i$. As a convention we will take $F_\emptyset$ as G.

Let $D([0, \infty) : \mathbb{R}^k)$ denote the set of functions mapping $[0, \infty)$ to $\mathbb{R}^k$ that are right continuous and have limits from the left. We endow $D([0, \infty) : \mathbb{R}^k)$ with the usual Skorohod topology. Let $D_G([0, \infty) : \mathbb{R}^k) \doteq \{\psi \in D([0, \infty) : \mathbb{R}^k) : \psi(0) \in G\}$. For $\eta \in D([0, \infty) : \mathbb{R}^k)$ let $|\eta|(T)$ denote the total variation of η on $[0, T]$ with respect to the Euclidean norm on $\mathbb{R}^k$.

Definition 2.1. *Let $\psi \in D_G([0, \infty) : \mathbb{R}^k)$ be given. Then $(\phi, \eta) \in D([0, \infty) : \mathbb{R}^k) \times D([0, \infty) : \mathbb{R}^k)$ solves the Skorohod problem (SP) for ψ with respect to G and d if and only if $\phi(0) = \psi(0)$, and for all $t \in [0, \infty)$ (1) $\phi(t) = \psi(t) + \eta(t)$; (2) $\phi(t) \in G$; (3) $|\eta|(t) < \infty$; (4) $|\eta|(t) = \int_{[0,t]} I_{\{\phi(s) \in \partial G\}} d|\eta|(s)$; (5) there exists (Borel) measurable $\gamma : [0, \infty) \to \mathbb{R}^k$ such that $\gamma(t) \in d(\phi(t))$ ($d|\eta|$-almost everywhere) and $\eta(t) = \int_{[0,t]} \gamma(s) d|\eta|(s)$.*

On the domain $D \subset D_G([0, \infty) : \mathbb{R}^k)$, on which there is a unique solution to the SP, we define the Skorohod map (SM) Γ as $\Gamma(\psi) \doteq \phi$, if $(\phi, \psi - \phi)$ is the unique solution of the SP posed by ψ. We will make the following assumptions on the data defining the SP above.

Condition 2.2. (a) *There exists a compact, convex set $B \in \mathbb{R}^k$ with $0 \in B^0$, such that if $v(z)$ denotes the set of inward normals to B at $z \in \partial B$, then for $i = 1, 2, \ldots, N$, $z \in \partial B$ and $|\langle z, n_i \rangle| < 1$ implies that $\langle v, d_i \rangle = 0$ for all $v \in v(z)$.* (b) *There exists a map $\pi : \mathbb{R}^k \to G$ such that if $y \in G$, then $\pi(y) = y$, and if $y \notin G$, then $\pi(y) \in \partial G$, and $y - \pi(y) = \alpha\gamma$ for some $\alpha \leq 0$ and $\gamma \in d(\pi(y))$.* (c) *For every $x \in \partial G$, there is $n \in n(x)$ such that $\langle d, n \rangle > 0$ for all $d \in d(x)$.*

The above assumptions can be verified for a rich class of problems arising from queuing networks. For example, in the seminal work [18], it was shown that the above properties hold for SPs associated with open, single class queuing networks (cf. [15]). Other classes of network examples for which the above properties hold are in [13, 15, 16, 35, 36]. Condition (c) above is equivalent to the assumption that the $N \times N$ matrix with the (i, j)th entry $\langle d_i, n_j \rangle$ is completely-S (cf. [37, 13]).

The following result is taken from [13].

Theorem 2.3 (see [13]). *Under Condition 2.2 the SM is well defined on all of $D_G([0, \infty) : \mathbb{R}^k)$, i.e., $D = D_G([0, \infty) : \mathbb{R}^k)$ and the SM is Lipschitz continuous in the following sense. There exists a $K < \infty$ such that for all $\phi_1, \phi_2 \in D_G([0, \infty) : \mathbb{R}^k)$*

$$\sup_{0 \leq t < \infty} |\Gamma(\phi_1)(t) - \Gamma(\phi_2)(t)| < K \sup_{0 \leq t < \infty} |\phi_1(t) - \phi_2(t)|. \tag{2.1}$$

In rest of the paper Condition 2.2 will always be taken to hold. We will also assume without loss of generality that $K \geq 1$.

We now introduce the controlled constrained diffusion processes that will be studied in this paper. Throughout this paper we will assume the relaxed control frame-

work, i.e., there is a compact metric space S such that the control set is $U \doteq \mathcal{P}(S)$ (the space of all probability measures on S endowed with the weak convergence topology). All topological spaces in this paper will be endowed with their natural Borel σ-field. For a topological space $\mathcal{K}$, we will denote its Borel σ-field by $\mathcal{B}(\mathcal{K})$. The space of all real, continuous, and bounded functions defined on $\mathcal{K}$ will be denoted as $C_b(\mathcal{K})$ and the space of all probability measures on $(\mathcal{K}, \mathcal{B}(\mathcal{K}))$ by $\mathcal{P}(\mathcal{K})$. The space $\mathcal{P}(\mathcal{K})$ will be endowed with the weak convergence topology. For $A \in \mathcal{B}(\mathcal{K})$, $\mathcal{I}_A(\cdot)$ will denote the indicator function of the set A. Also, we will denote by $C_b^2(G)$ and $C_0^\infty(G)$ the space of real valued, bounded, and twice continuously differentiable functions on G and the space of real valued, infinitely differentiable, vanishing at infinity, functions on G, respectively. By a filtered probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$ we will mean a probability space $(\Omega, \mathcal{F}, P)$ endowed by a filtration $(\mathcal{F}_t)_{t\geq 0}$ satisfying the usual hypothesis. A pair of stochastic processes $(u(\cdot), W(\cdot))$ defined on some filtered probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$ is said to be an admissible pair if $W(\cdot)$ is an $\mathcal{F}_t$ standard Wiener process and $u(\cdot)$ is a U valued, measurable, $\{\mathcal{F}_t\}$ adapted process.

We will consider controlled constrained diffusion processes of the form defined in (1.1), where for $(x,u) \in G \times U$, $b(x,u) \doteq \int_S \bar{b}(x,\alpha)u(d\alpha)$ and the coefficients $\sigma : G \to \mathbb{R}^{k\times k}$ and $\bar{b} : G \times S \to \mathbb{R}^k$ are maps satisfying the following conditions.

CONDITION 2.4. *There exists $r \in (0,\infty)$ such that*

(i) *$\bar{b}$ is a continuous map and for all $x, y \in G$ and $\alpha \in S$*

$$||\bar{b}(x,\alpha) - \bar{b}(y,\alpha)|| + ||\sigma(x) - \sigma(y)|| \leq r||x-y||;$$

(ii) *for all $x \in G$ and $\alpha \in S$*

$$||\bar{b}(x,\alpha)|| + ||\sigma(x)|| \leq r.$$

We will also assume the following nondegeneracy assumption on σ.

CONDITION 2.5. *There exists $c_0 \in (0,\infty)$ such that for all $x \in G$ and $\alpha \in \mathbb{R}^k$ $\alpha'(\sigma(x)\sigma'(x))\alpha \geq c_0\alpha'\alpha$.*

In the rest of the paper, in addition to Condition 2.2, Conditions 2.4 and 2.5 will also be assumed to hold. The following result on the unique strong solution for (1.1) follows on using the Lipschitz property of the SM and the usual fixed point arguments.

THEOREM 2.6. *Let $(u(\cdot), W(\cdot))$ be an admissible pair on some filtered probability space $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$. Then there exists an $\{\mathcal{F}_t\}$ adapted process $X(\cdot)$ with continuous sample paths satisfying* (1.1) *for all t a.s. Furthermore, if $X_1(\cdot)$ and $X_2(\cdot)$ are two such processes, then*

$$P(X_1(t) = X_2(t);\ \ \forall t \in (0,\infty)) = 1.$$

Remark 2.7. If $X(\cdot)$ solves (1.1), then (cf. Theorem 3.5.1 in [31]) there exist continuous, increasing $\mathcal{F}_t$ adapted processes $\{Y_i(\cdot); 1 \leq i \leq N\}$ such that

$$X(t) = X(0) + \int_0^t b(X(s), u(s))ds + \int_0^t \sigma(X(s))dW(s) + \sum_{i=1}^N d_i Y_i(t) \tag{2.2}$$

for all t, a.s. Furthermore, $Y_i(0) = 0$ and for all $t > 0$ $\int_0^t \mathcal{I}_{F_i}(X(s))dY_i(s) = Y_i(t)$, a.s., $i = 1, \ldots, N$.

From the point of view of applications it is important to consider Markov controls, namely the case where $u(\cdot) = v(X(\cdot))$ for some measurable map $v : G \to U$. However,

in such a case (1.1) may not admit a strong solution. Thus we need to work with a weak solution of (1.1).

DEFINITION 2.8. *Let $v : G \to U$ be a measurable map. We say that the equation*

$$X(t) = \Gamma\left(X(0) + \int_0^{\cdot} b(X(s), v(X(s)))ds + \int_0^{\cdot} \sigma(X(s))dW(s)\right)(t), \quad X(0) \sim \mu, \tag{2.3}$$

admits a weak solution if there exists a filtered probability space $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\})$ on which is given a $\{\mathcal{F}_t\}$ Wiener process $W(\cdot)$ and an $\mathcal{F}_t$ adapted process $X(\cdot)$ with continuous paths such that $X(0)$ has the probability law μ and for all t the equality in (2.3) *holds a.s. We say that* (2.3) *admits a unique weak solution if whenever there are two sets of such spaces and processes denoted as $(\Omega^i, \mathcal{F}^i, P^i, \mathcal{F}^i_t)$, $(W^i(\cdot), X^i(\cdot))$, $i = 1, 2$, then the probability law of $X^1(\cdot)$ is same as that of $X^2(\cdot)$.*

With an abuse of terminology we will also call the map v above a "Markov control." Under the standing assumptions of this paper we have the following result. For the proof of this result we refer the reader to Theorem 4.2.2 of [31]. Although the proof there is for the case where G is a compact set, exactly the same arguments hold for the case of unbounded state space. The key idea in the proof, as in the case of unconstrained diffusions, is to use Condition 2.5 and Girsanov's theorem to get rid of the drift and then use the strong Feller property of the new process and estimates on the Radon–Nikodym derivative to conclude the strong Feller property of the original process.

THEOREM 2.9. *There is a unique weak solution for* (2.3). *Denoting the law of the solution process $X(\cdot)$, when $X(0) = x$ a.s., by P^v_x we have that $\{P^v_x\}_{x\in G}$ is a strongly Feller–Markov family. Furthermore, the transition probability law $P(t, x, dy)$ of this Markov process is mutually absolutely continuous with respect to the Lebesgue measure on G in the following uniform sense. Given $\delta > 0$ and $0 < t_0 < t_1 < \infty$ there exists an $\epsilon > 0$ such that for all $A \in \mathcal{B}(G)$ with $\lambda(A) \le \epsilon$, where λ denotes the Lebesgue measure on G, $P(t, x, A) \le \delta$, $x \in G$, $t \in [t_0, t_1]$. Finally for any $\epsilon > 0$, $0 < t_0 < t_1 < \infty$, and compact set $K_0 \subset G$ there is a $\delta > 0$ such that for all $x \in K_0$, $t \in [t_0, t_1]$, and $A \in \mathcal{B}(G)$ with $\lambda(A \cap K_0) \ge \epsilon$ we have that $P(t, x, A) \ge \delta$.*

3. The ergodic cost problem. In this work we are interested in a control problem with an ergodic cost criterion. Namely, we are interested in minimizing, over the class of all admissible controls, the cost defined in (1.2), where $X(\cdot)$ is given as a solution of (1.1) on some filtered probability space with an admissible pair $(u(\cdot), W(\cdot))$, the limit above is taken a.s. on the corresponding probability space, and $k : G \times U \to \mathbb{R}$ is a map defined as follows. For $(x, u) \in G \times U$, $k(x, u) \doteq \int_S \overline{k}(x, \alpha)u(d\alpha)$, where $\overline{k}$ is in $C_b(G \times S)$.

We will call a Markov control v a stable Markov control (SMC) if the corresponding controlled Markov process $\{P^v_x\}_{x\in G}$ is positive recurrent and has a unique invariant measure. We are interested in obtaining conditions under which there is an optimal SMC for the cost criterion (1.2). The following stability assumption on the underlying model will be assumed throughout this paper.

Define

$$\mathcal{C} \doteq \left\{ -\sum_{i=1}^{N} \alpha_i d_i : \alpha_i \ge 0;\ i \in \{1, \dots, N\} \right\}. \tag{3.1}$$

The cone $\mathcal{C}$ was used to characterize stability of a certain class of constrained diffusion processes in [9, 2].

Let $\delta \in (0, \infty)$ be fixed. Define the set

$$\mathcal{C}(\delta) \doteq \{v \in \mathcal{C} : \text{dist}(v, \partial C) \geq \delta\}. \tag{3.2}$$

Our next assumption, which also will be assumed throughout this paper, on the diffusion model stipulates the permissible drifts in the underlying diffusion.

CONDITION 3.1. *There exists a* $\delta \in (0, \infty)$ *such that for all* $(x, u) \in G \times U$, $b(x, u) \in \mathcal{C}(\delta)$.

Under the assumptions made above the results of [2] show that all Markov controls are SMC; more precisely, we have the following.

THEOREM 3.2. *The Markov family* $\{P_x^v\}_{x \in G}$ *of Theorem* 2.9 *is positive recurrent and admits a unique invariant measure, denoted as* η_v.

Remark 3.3. In [2] the proof of positive recurrence assumes that the drift coefficient in the constrained diffusion process satisfies a Lipschitz condition; however, as is pointed out in Remark 4.6 of that paper, the same proof continues to hold with the assumptions on the coefficients made in this paper.

Now we are able to state the main result of this paper.

THEOREM 3.4. *There exists a Markov control* $\overline{v}(\cdot)$ *such that if for some* $\mu \in \mathcal{P}(G)$ $\overline{X}(\cdot)$ *is the corresponding process solving* (2.3) *on some filtered probability space, with the probability law of* $\overline{X}(0)$ *being* μ, *then*

$$\limsup_{T \to \infty} \frac{1}{T} \int_0^T k(\overline{X}(s), \overline{v}(X(s)))ds = \inf \operatorname{ess\,inf} \limsup_{T \to \infty} \frac{1}{T} \int_0^T k(X(s), u(s))ds, \tag{3.3}$$

a.s., where the outside infimum on the right side above is taken over all controlled processes $X(\cdot)$ *with an arbitrary initial distribution and solving* (1.1) *over some filtered probability space with some admissible pair* $(W(\cdot), u(\cdot))$.

Remark 3.5. The referee has pointed out that the boundedness on the cost function can be relaxed to bounded below, and using Choquet's theorem and results in [1] one can show the existence of a regular (nonrelaxed) Markov control which is optimal.

The proof of the above theorem will be given in section 7.

4. Some background results. In this section we collect some background results which will be used in the proof of Theorem 3.4. We begin with an ergodic theorem of Khasminskii [24] which is applicable to the Markov family $\{P_x^v\}$ considered in this paper because of Theorem 2.9. As a consequence of this result the limiting time averages on the left side of (3.3) can be replaced with expectations with respect to the measure $\eta_{\overline{v}}$.

LEMMA 4.1 (see Khasminskii [24, Theorem 3.1]). *For a given* $\mu \in \mathcal{P}(G)$ *and a Markov control* v *let* $\overline{X}(\cdot)$ *be the process on some filtered probability space solving* (2.3) *with the distribution of* $\overline{X}(0)$ *being* μ. *Then for all* η_v *integrable functions* g *on* G, $\frac{1}{T}\int_0^T g(X(s))ds$ *converges a.s. to* $\int_G g(x)\eta_v(dx)$.

The following lemma has been proved in [12]; however, the domain G there is different from our problem. Thus for the sake of completeness we sketch the proof in the appendix. This lemma will be used several times in this paper in controlling the reflection term $Y(\cdot)$ in our constrained diffusion processes.

LEMMA 4.2. *There exists a* $g \in C_b^2(G)$ *such that*

$$\langle \nabla g(x), d_i \rangle \geq 1 \qquad \forall x \in F_i, \quad i \in \{1, \ldots, N\}. \tag{4.1}$$

The following lemma essentially says that in considering admissible controls, we can without loss of generality restrict ourselves to controls that are adapted with respect to the filtration generated by $(X(\cdot), Y(\cdot))$. The proof is similar to Theorem 1.2.2 (p. 18) of [6] and is therefore omitted.

LEMMA 4.3. *Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ be a filtered probability space on which is given an admissible pair $(u(\cdot), W(\cdot))$. Let $X(\cdot)$ be a solution to* (1.1) *with the corresponding boundary processes $\{Y_i(\cdot)\}_{i=1}^N$. Then there exists a enlargement $(\overline{\Omega}, \overline{\mathcal{F}}, \{\overline{\mathcal{F}}_t\}, \overline{P})$ of the above probability space on which is given a $\{\overline{\mathcal{F}}_t\}$ Wiener process $\tilde{W}(\cdot)$ and $\mathcal{P}(S)$ valued measurable stochastic process $\tilde{u}(\cdot)$ such that for a.e. $t \in [0,\infty)$, $\tilde{u}(t)$ is $\mathcal{F}_t^{X,Y}$ measurable, where $\mathcal{F}_t^{X,Y}$ denotes the P completion of $\sigma\{X(s); \{Y_i(s)\}_{i=1}^N; 0 \le s \le t\}$, and $X(\cdot)$ solves*

$$X(t) = X(0) + \int_0^t b(X(s), \tilde{u}(s))ds + \int_0^t \sigma(X(s))d\tilde{W}(s) + \sum_{i=1}^N d_i Y_i(t).$$

The following lemma will be used in some conditioning arguments in the proofs of Lemma 6.4 and Proposition 7.3. The proof is similar to Theorem 1.1.6 (p. 13) of [6]. Thus the proof is omitted. For a Polish space $\mathcal{K}$, denote by $C([0,\infty) : \mathcal{K})$ the space of continuous functions from $[0,\infty)$ to $\mathcal{K}$, endowed with the topology of uniform convergence on compacts.

LEMMA 4.4. *Let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ be a filtered probability space. Let $(u(\cdot), W(\cdot))$ be an admissible pair on this probability space. Let $X(\cdot)$ be given as a solution of* (1.1) *and let τ be an a.s. finite $\{\mathcal{F}_t\}$ stopping time. Denote the conditional distribution of $X(\tau + \cdot)$ given $\mathcal{F}_\tau$ by $\pi(\omega)(\cdot)$, i.e., for $A \in \mathcal{B}(C([0,\infty) : G))$ and a.e. ω $P\left(X(\tau + \cdot) \in A \mid \mathcal{F}_\tau\right)(\omega) = \pi(\omega)(A)$. Then, for a.e. ω, $\pi(\omega)$ equals the probability law of $\overline{X}_\omega(\cdot)$, where $\overline{X}_\omega(\cdot)$ solves an equation of the form* (1.1) *with $(u(\cdot), W(\cdot))$ replaced by some other admissible pair, $(\overline{u}_\omega(\cdot), \overline{W}_\omega(\cdot))$, given on some filtered probability space $(\Omega^\omega, \mathcal{F}^\omega, \{\mathcal{F}_t^\omega\}, P^\omega)$ and $\overline{X}_\omega(0) = X(\tau(\omega))$.*

5. Characterization of the invariant measure. One of the key ingredients of the proof of Theorem 3.4 is an extension of Echeverria–Weiss characterization of invariant measures (cf. [17, 42]) to the class of constrained controlled Markov processes considered in this paper. The proof of this characterization uses a clever idea presented in the proof of a similar characterization result for constrained (uncontrolled) Markov processes in Kurtz [27]. It also uses ideas from [28]. We begin with the following definitions. For $f \in C_b^2(G)$ let $Lf : G \times U \to \mathbb{R}$ be defined as:

$$(Lf)(x,u) \doteq \frac{1}{2}\sum_{i,j=1}^k a_{i,j}(x)\frac{\partial^2 f}{\partial x_i \partial x_j}(x) + \sum_{i=1}^k b_i(x,u)\frac{\partial f}{\partial x_i}(x), \quad (x,u) \in G \times U, \tag{5.1}$$

where $a_{ij}(x) \doteq \sigma(x)\sigma^T(x)$. With an abuse of notation we will write for $\alpha \in S$, $(Lf)(x, \delta_{\{\alpha\}})$, merely as $(Lf)(x,\alpha)$, where $\delta_{\{\alpha\}}$ denotes the probability measure concentrated at the point α. Thus with this notation, for $(x,u) \in G \times U$, $(Lf)(x,u) = \int_S (Lf)(x,\alpha)u(d\alpha)$. For $i = 1, 2, \ldots, N$ and $f \in C_b^2(G)$ let $D_i f : G \to \mathbb{R}$ be defined as $(D_i f)(x) \doteq \langle d_i, \nabla f(x)\rangle$, $x \in G$.

DEFINITION 5.1 (constrained controlled martingale problem (CCMP)). *For $\mu \in \mathcal{P}(G)$ a solution to the $(\mu, L, G, (D_i, F_i)_{i=1}^N)$ CCMP is a pair of $\{\mathcal{F}_t\}$ adapted processes $(Z(\cdot), \Phi(\cdot))$ on some filtered probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ such that the following*

hold. (i) $Z(\cdot)$ *is a* G *valued process with, a.s., continuous trajectories.* (ii) $Z(0)$ *has probability law* μ. (iii) $\Phi(\cdot)$ *is a* U *valued, measurable, and* $\{\mathcal{F}_t\}$ *adapted process.* (iv) *There is an* $\{\mathcal{F}_t\}$ *adapted,* N*-dimensional "boundary" process* $Y(\cdot) = (Y_1(\cdot), \ldots, Y_N(\cdot))$ *such that for each* $i \in \{1, 2, \ldots, N\}$, P*-a.s.,* $Y_i(0) = 0$, $Y_i(\cdot)$ *is continuous and nondecreasing, and for all* $t \in (0, \infty)$, $\int_0^t \mathcal{I}_{F_i}(Z(s))dY_i(s) = Y_i(t)$. (v) *For all* $f \in C_0^\infty(G)$, $f(Z(t)) - \int_0^t \int_S (Lf)(Z(s), \alpha)\Phi(s)(d\alpha)ds - \sum_{i=1}^N \int_0^t (D_i f)(Z(s))$ $dY_i(s)$ *is an* $\mathcal{F}_t$ *martingale.*

The proof of the following result is standard and thus is omitted (cf. Theorem 4.5.2 in [41]).

THEOREM 5.2. *Let* $(Z(\cdot), \Phi(\cdot))$ *be a solution of the* $(\mu, L, G, (D_i, F_i)_{i=1}^N)$ *CCMP on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$. *Then there exists an enlargement* $(\overline{\Omega}, \overline{\mathcal{F}}, \{\overline{\mathcal{F}}_t\}, \overline{P})$ *of the above space such that* (i) *there is a* $\overline{\mathcal{F}}_t$ *Wiener process* $\overline{W}(\cdot)$ *defined on the enlarged space,* (ii) *the processes* $(Z(\cdot), \Phi(\cdot))$ *are measurable and* $\overline{\mathcal{F}}_t$ *adapted, and* (iii) *for all* $t \geq 0$, *a.s.*

$$Z(t) = \Gamma\left(Z(0) + \int_0^t \int_S b(Z(s), \alpha)\Phi(s)(d\alpha)ds + \int_0^t \sigma(Z(s))d\overline{W}(s)\right). \tag{5.2}$$

Conversely, if there is a pair of processes $(Z(\cdot), \Phi(\cdot))$ *solving* (5.2) *on some filtered probability space* $(\overline{\Omega}, \overline{\mathcal{F}}, \{\overline{\mathcal{F}}_t\}, \overline{P})$ *satisfying* (i), (ii), *and* (iii) *above, then the pair is a solution of the* $(\mu, L, G, (D_i, F_i)_{i=1}^N)$ *CCMP where* μ *is the probability law of* $Z(0)$.

A solution to the CCMP is closely related to the following patchwork controlled martingale problem (PCMP) introduced in the context of uncontrolled constrained processes by Kurtz in [26].

DEFINITION 5.3. *For* $\mu \in \mathcal{P}(G)$ *a solution to the* $(\mu, L, G, (D_i, F_i)_{i=1}^N)$ *PCMP is an* $\{\mathcal{F}_t\}$ *adapted vector stochastic process* $(\xi(\cdot), \Lambda(\cdot), \lambda_0(\cdot), \ldots, \lambda_N(\cdot))$, *with values in* $G \times U \times \mathbb{R}_+^{N+1}$ *on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ *such that the following hold:* (i) $\xi(\cdot)$ *has continuous trajectories a.s.* (ii) $\xi(0)$ *has probability law* μ. (iii) $\Lambda(\cdot)$ *is a* U *valued, measurable,* $\{\mathcal{F}_t\}$ *adapted process.* (iv) *For all* $i \in \{0, 1, 2, \ldots, N\}$, P*-a.s.,* $\lambda_i(0) = 0$, $\lambda_i(\cdot)$ *is continuous and nondecreasing, and for all* $t \in [0, \infty)$, $\int_0^t \mathcal{I}_{F_i}(\xi(s))d\lambda_i(s) = \lambda_i(t)$, *where we define* $F_0 \doteq G$. (iv) *For all* $t \geq 0$, $\sum_{i=0}^m \lambda_i(t) = t$, *a.s.* (v) *For all* $f \in C_0^\infty(G)$, $f(\xi(t)) - \int_0^t \int_S (Lf)(\xi(s), \alpha)\Lambda(s)(d\alpha)d\lambda_0(s) - \sum_{i=1}^N \int_0^t (D_i f)(Z(s))d\lambda_i(s)$ *is a* $\mathcal{F}_t$ *martingale.*

The proof of the following result is similar to the proof of Lemma 3.1 of [12] except that instead of condition (S.a) and (S.b) of [12] we use Condition 2.2(c).

LEMMA 5.4. *Suppose that* $(\xi(\cdot), \Lambda(\cdot), \lambda_0(\cdot), \ldots, \lambda_N(\cdot))$ *is a solution of the* $(\mu, L, G,$ $(D_i, F_i)_{i=1}^N)$ *PCMP on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$. *Then, a.s.,* $\lambda_0(\cdot)$ *is a strictly increasing process such that* $\lambda_0(t) \to \infty$ *as* $t \to \infty$.

The following proposition establishes the connection between a solution of a CCMP and a solution of the PCMP. For the proof of the proposition we refer the reader to Theorem 3.4 of [12].

PROPOSITION 5.5. *Suppose that* $(\xi(\cdot), \Lambda(\cdot), \lambda_0(\cdot), \ldots, \lambda_N(\cdot))$ *is a solution of the* $(\mu, L, G, (D_i, F_i)_{i=1}^N)$ *PCMP on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$. *Then if for* $t \geq 0$ $\tau(t) \doteq \inf\{s \geq 0 : \lambda_0(s) \geq t\}$, $\mathcal{G}_t \doteq \mathcal{F}_{\tau(t)}$, $Z(t) \doteq \xi(\tau(t))$, $\Phi(t) \doteq \Lambda(\tau(t))$, *and for* $i = 1, \ldots, N$, $Y_i(t) \doteq \lambda_i(\tau(t))$, *then* $(Z(\cdot), \Phi(\cdot))$ *is the solution of the* $(\mu, L, G, (D_i, F_i)_{i=1}^N)$ *CCMP on* $(\Omega, \mathcal{F}, \{\mathcal{G}_t\}, P)$ *with the corresponding boundary processes* $\{Y_i(\cdot)\}_{i=1}^N$.

The following lemma is the first step in the characterization of the invariant measure for the family $\{P_x^v\}$ of Theorem 2.9.

For a measurable space $(\Omega, \mathcal{F})$ we denote by $\mathcal{M}_F(\Omega)$ the space of all finite, possibly identically zero, measures on $(\Omega, \mathcal{F})$. For a measurable map $v : G \to U$, $x \in G$, and $B \in \mathcal{B}(S)$ we will sometimes write $v(x)(B)$ as $v(x, B)$.

LEMMA 5.6. *Let $v : G \to U$ be a measurable map. Let η_v be as in Theorem 3.2. Then there exist measures $\mu_i \in \mathcal{M}_F(F_i)$ such that for all $f \in C_0^\infty(G)$*

$$\int_{G\times S} (Lf)(x,\alpha)\mu_0(dx, d\alpha) + \sum_{i=1}^N \int_{F_i} (D_i f)(x)\mu_i(dx) = 0, \tag{5.3}$$

where $\mu_0 \in \mathcal{P}(G\times S)$ is given as $\mu_0(A\times B) \doteq \int_A v(x, B)\eta_v(dx)$, $A \in \mathcal{B}(G)$, $B \in \mathcal{B}(S)$.

Proof. Let $X(\cdot)$ be a solution of (2.3) with $X(0) \sim \eta_v$ on some filtered probability space. Then $X(\cdot)$ is a stationary process. From Remark 2.7 there exist continuous increasing adapted processes $Y_i(\cdot)$, $i = 1, \ldots, N$, such that (2.2) holds with $u(\cdot)$ replaced by $v(X(\cdot))$. Let $g \in C_b^2(G)$ be as in Lemma 4.2. Then via an application of Ito's formula we have that

$$\begin{aligned} g(X(t)) = g(X(0)) &+ \int_0^t (Lg)(X(s), v(X(s)))ds + \sum_{i=1}^N \int_0^t (D_i g)(X(s))dY_i(s) \\ &+ \int_0^t \langle \nabla g(X(s)), \sigma(X(s))dW(s)\rangle. \end{aligned}$$

Taking expectations in the above equality, using the stationarity of $X(\cdot)$, and recalling the properties of the function $g(\cdot)$, we have that for all $t \geq 0$

$$\begin{aligned} \sum_{i=1}^N E(Y_i(t)) &\leq \sum_{i=1}^N E\left(\int_0^t (D_i g)(X(s))dY_i(s)\right) \\ &\leq \int_0^t E|Lg(X(s), v(X(s)))|ds \\ &\leq \overline{C}t, \end{aligned}$$

where

$$\overline{C} \doteq \sup_{x\in G, u\in U} |Lg(x, u)|. \tag{5.4}$$

Thus if we define for $A \in \mathcal{B}(F_i)$, $i = 1, \ldots, N$, $\mu_i(A) \doteq E(\int_0^1 \mathcal{I}_A(X(s))dY_i(s))$, then $\mu_i \in \mathcal{M}_F(F_i)$ since

$$E\left(\int_0^1 \mathcal{I}_{F_i}(X(s))dY_i(s)\right) = E(Y_i(1)) \leq \overline{C}. \tag{5.5}$$

Now let $f \in C_0^\infty(G)$ be arbitrary. Then another application of Ito's formula gives

$$\begin{aligned} f(X(1)) = f(X(0)) &+ \int_0^1 (Lf)(X(s), v(X(s)))ds + \sum_{i=1}^N \int_0^1 (D_i f)(X(s))dY_i(s) \\ &+ \int_0^1 \langle \nabla f(X(s)), \sigma(X(s))dW(s)\rangle. \end{aligned}$$

Taking expectations and using the stationarity of $X(\cdot)$ we have that

$$\int_G (Lf)(x, v(x))\eta_v(dx) + \sum_{i=1}^{N} \int_{F_i} (D_i f)(x)\mu_i(dx) = 0.$$

The proof now follows on recalling the definition of μ_0 and observing that for $(x, u) \in G \times U$, $(Lf)(x, u) = \int_S (Lf)(x, \alpha)u(d\alpha)$. □

The following extension of Echeverria–Weiss–Kurtz criterion (cf. [42, 27]) is an essential step in our proof of Theorem 3.4.

THEOREM 5.7. *Suppose that there exist measures $\mu_0 \in \mathcal{M}(G \times S)$, $\mu_i \in \mathcal{M}_F(F_i)$, $i = 1, \ldots, N$, such that for all $f \in C_0^\infty(G)$* (5.3) *holds. Decompose $\hat{\mu}_0$ as*

$$\hat{\mu}_0(dx, d\alpha) = v(x, d\alpha)\eta(dx), \tag{5.6}$$

where $\eta \in \mathcal{P}(G)$ is given as $\eta(A) = \hat{\mu}_0(A \times S)$, $A \in \mathcal{B}(G)$, and $v(x, d\alpha)$ is the appropriate regular conditional distribution. Then there exists a solution $(Z(\cdot), \Phi(\cdot))$ to the CCMP $(\eta, L, G, (D_i, F_i)_{i=1}^N)$ on some filtered probability space $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ such that (i) *$Z(\cdot)$ is a stationary process with the invariant measure η;* (ii) *$\Phi(s)(\cdot) = v(Z(s), \cdot)$ for all $s \in [0, \infty)$, a.s.;* (iii) *$Z(\cdot)$ is a positive recurrent, strongly Feller–Markov process with transition probability family $\{P_x^v\}_{x \in G}$ and $\eta = \eta_v$ is its unique invariant measure (cf. Theorem* 3.2*).*

Proof. Assume without loss of generality that $S \cap \{1, \ldots, N\} = \emptyset$. Define a new control set $\tilde{S} \doteq S \cup \{1, \ldots, N\}$. Let $\tilde{d}(\cdot, \cdot)$ be a distance on it defined as follows. For $x, y \in \tilde{S}$, $\tilde{d}(x, y) \doteq d(x, y)$ if $x \in S$ and $y \in S$; $\tilde{d}(x, x) = 0$ and we set $\tilde{d}(x, y) \doteq 1$ otherwise, where $d(\cdot, \cdot)$ is the given metric on S. Clearly $(\tilde{S}, \tilde{d}(\cdot, \cdot))$ is a compact metric space. For $n \in \mathbb{N}$ (where $\mathbb{N}$ is the set of all positive integers), define the linear operator $C_n : C_0^\infty(G) \to C_b(G \times \tilde{S})$ as follows. For $f \in C_0^\infty(G)$ and $(x, \tilde{\alpha}) \in G \times \tilde{S}$

$$\begin{aligned}(C_n f)(x, \tilde{\alpha}) &\doteq (Lf)(x, \tilde{\alpha}) \text{ if } \tilde{\alpha} \in S \\ &\doteq n(D_i f)(x) \text{ if } \tilde{\alpha} \in \{1, \ldots, N\}.\end{aligned}$$

Define $\tilde{\nu}_n \in \mathcal{P}(G \times \tilde{S})$ as follows. For $h \in C_b(G \times \tilde{S})$

$$\begin{aligned}&\int_{G \times \tilde{S}} h(x, \tilde{\alpha})\tilde{\nu}_n(dx, d\tilde{\alpha}) \\ &\quad \doteq \frac{1}{K_n}\left(\int_{G \times S} h(x, \alpha)\mu_0(dx, d\alpha) + \frac{1}{n}\sum_{i=1}^{N} \int_{F_i} h(x, i)\mu_i(dx)\right),\end{aligned} \tag{5.7}$$

where $K_n \doteq \mu_0(G \times S) + \frac{1}{n}\sum_{i=1}^{N} \mu_i(F_i)$.

From the assumption that (5.3) holds it follows now that for all $f \in C_0^\infty(G)$

$$\int_{G \times \tilde{S}} (C_n f)(x, \tilde{\alpha})\tilde{\nu}_n(dx, d\tilde{\alpha}) = 0. \tag{5.8}$$

Disintegrate $\tilde{\nu}_n$ as follows. For $A \in \mathcal{B}(G)$ and $B \in \mathcal{B}(\tilde{S})$,

$$\tilde{\nu}_n(A \times B) = \int_A \tilde{v}_n(x, B \cap S)\eta^n(dx) + \sum_{i=1}^{N} \int_A \tilde{v}_{i,n}(x)\delta_{\{i\}}(B)\eta^n(dx),$$

where for $B \in \mathcal{B}(S)$ the maps $\tilde{v}_n(\cdot, B)$ and $\tilde{v}_{i,n}(\cdot)$ are measurable; for all $x \in G$ $\tilde{v}_n(x,\cdot) \in \mathcal{M}_F(S)$, $\tilde{v}_{i,n}(x) \geq 0$, $i = 1, \ldots, N$; $\tilde{v}_n(x, S) + \sum_{i=1}^N \tilde{v}_{i,n}(x) = 1$ and $\eta^n \in \mathcal{P}(G)$ is given as follows. For $A \in \mathcal{B}(G)$

$$\eta^n(A) \doteq \frac{1}{K_n}\left(\mu_0(A \times S) + \frac{1}{n}\sum_{i=1}^N \mu_i(A \cap F_i)\right). \tag{5.9}$$

Also define $\tilde{\nu} \in \mathcal{P}(G \times S)$ as the normalization of μ_0, i.e., $\tilde{\nu} \doteq \hat{\mu}_0$. Recall that from (5.6), $\tilde{\nu}(dx, d\alpha) = v(x, d\alpha)\eta(dx)$. For fixed $x \in G$ define a probability measure $v_n(x, d\tilde{\alpha})$ on $\tilde{S}$ as follows. For $A \in \mathcal{B}(\tilde{S})$

$$\begin{aligned} v_n(x, A) &\doteq v(x, A \cap S) \text{ if } x \in G^0 \\ &\doteq \tilde{v}_n(x, A \cap S) + \sum_{i=1}^N \tilde{v}_{i,n}(x)\delta_{\{i\}}(A) \text{ otherwise.} \end{aligned} \tag{5.10}$$

It is easy to check that for all $h \in C_b(G \times \tilde{S})$

$$\int_{G\times\tilde{S}} h(x,\tilde{\alpha})\tilde{\nu}_n(dx, d\tilde{\alpha}) = \int_{G\times\tilde{S}} h(x,\tilde{\alpha}) v_n(x, d\tilde{\alpha})\eta^n(dx). \tag{5.11}$$

Using (5.8), (5.11), and Theorem 2.4 of [28] we now have that there exists a filtered probability space (for the sake of simplicity we suppress the dependence of the filtered probability space on n in our notation) $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$ on which is given an adapted G valued stationary process $X_n(\cdot)$ with continuous paths such that the probability law of $X_n(0)$ is η^n and for all $f \in C_0^\infty(G)$,

$$f(X_n(t)) - \int_0^t \left(\int_{\tilde{S}} (C_n f)(X_n(s), \tilde{\alpha}) v_n(X_n(s), d\tilde{\alpha})\right) ds \tag{5.12}$$

is an $\mathcal{F}_t$ martingale.

For $x \in G$ let $v_n^0(x, d\alpha) \in \mathcal{M}_F(S)$ be defined as follows. For $A \in \mathcal{B}(S)$

$$\begin{aligned} v_n^0(x, A) &\doteq v(x, A) \text{ if } x \in G^0 \\ &\doteq \tilde{v}_n(x, A) \text{ if } x \in \partial G. \end{aligned} \tag{5.13}$$

Also, define for $i \in \{1, \ldots, N\}$ $v_{i,n}^0 : G \to [0, 1]$ as

$$v_{i,n}^0(x) \doteq \tilde{v}_{i,n}(x)\mathcal{I}_{\partial G}(x). \tag{5.14}$$

Note that for all $x \in G$

$$\begin{aligned} v_n(x, A) &= v_n^0(x, A) \text{ if } A \in \mathcal{B}(S) \\ &= \sum_{i=1}^N v_{i,n}^0(x)\mathcal{I}_{\{i\}}(A) \text{ if } A \subset \{1, \ldots, N\}. \end{aligned} \tag{5.15}$$

Rewriting (5.12) using (5.15) we have that for all $f \in C_0^\infty(G)$

$$\begin{aligned} f(X_n(t)) - \int_0^t \left(\int_S (Lf)(X_n(s), \alpha) v_n^0(X_n(s), d\alpha)\right) ds \\ - \sum_{i=1}^N n \int_0^t (D_i f)(X_n(s)) v_{i,n}^0(X_n(s)) ds \end{aligned}$$

is an $\mathcal{F}_t$ martingale. Now define for $t \in [0,\infty)$, $i \in \{1,\dots,N\}$,

$$\lambda_0^n(t) \doteq \int_0^t v_n^0(X_n(s),S)ds,$$
$$\lambda_i^n(t) \doteq \int_0^t v_{i,n}^0(X_n(s))ds.$$

Also, for $x \in G$ define $\Lambda_n(x,\cdot) \in \mathcal{P}(S)$ as follows. For $A \in \mathcal{B}(S)$

$$\Lambda_n(x,A) \doteq \frac{v_n^0(x,A)}{v_n^0(x,S)} \text{ if } v_n^0(x,S) \neq 0 \tag{5.16}$$
$$\doteq \pi(A) \text{ otherwise,}$$

where π is an arbitrary probability measure on S. Then in this new notation we have that for all $f \in C_0^\infty(G)$

$$f(X_n(t)) - \int_0^t \left(\int_S (Lf)(X_n(s),\alpha)\Lambda_n(X_n(s),d\alpha) \right) d\lambda_0^n(s)$$
$$- \sum_{i=1}^N n \int_0^t (D_i f)(X_n(s))d\lambda_i^n(s)$$

is an $\mathcal{F}_t$ martingale. Clearly, for all $t \geq 0$, $\sum_{i=0}^N \lambda_i^n(t) = t$. Furthermore, for $i = 1,\dots,N$,

$$\lambda_i^n(t) = \int_0^t \mathcal{I}_{F_i}(X_n(s))d\lambda_i^n(s) \qquad \forall t \geq 0. \tag{5.17}$$

To prove (5.17) note that, it suffices to show that for all $t \geq 0$, $E(v_{i,n}^0(X_n(t))) = E(\mathcal{I}_{F_i}(X_n(t))v_{i,n}^0(X_n(t)))$. Also,

$$\begin{aligned} E(v_{i,n}^0(X_n(t))) &= \int_G v_{i,n}^0(x)\eta^n(dx) \\ &= \tilde{\nu}_n(G \times \{i\}) \\ &= \tilde{\nu}_n(F_i \times \{i\}) \\ &= E(\mathcal{I}_{F_i}(X_n(t))v_{i,n}^0(X_n(t))), \end{aligned}$$

where the next to last equality follows from (5.7). This proves (5.17). Thus it follows that $(X_n(\cdot),\Lambda_n(X_n(\cdot)),\lambda_0^n(\cdot),\dots,\lambda_N^n(\cdot))$ solves the $(\eta^n,L,G,(nD_i,F_i)_{i=1}^N)$ PCMP on $(\Omega,\mathcal{F},P,(\mathcal{F}_t))$. From Lemma 5.4 it follows that λ_0^n is a.s. strictly increasing. Now define $\tau_n : [0,\infty) \to [0,\infty)$ as $\tau_n(t) \doteq \inf\{s \geq 0 : \lambda_0^n(s) \geq t\}$, $t \in [0,\infty)$. Also for $t \geq 0$, let $\mathcal{G}_t^n \doteq \mathcal{F}_{\tau_n(t)}$, $Z_n(t) \doteq X_n(\tau_n(t))$, $\Phi_n(t) \doteq \Lambda_n(Z_n(t))$, and for $i = 1,\dots,N$ $Y_{i,n}(t) \doteq \lambda_{i,n}(\tau_n(t))$. Then from Proposition 5.5, $(Z_n(\cdot),\Phi_n(\cdot))$ solve the CCMP on $(\Omega,\mathcal{F},P,(\mathcal{G}_t^n))$ with the corresponding boundary processes $\{Y_{i,n}(\cdot)\}_{i=1}^N$. Next note that since $\lambda_0^n(0) = 0$ and for $0 \leq s \leq t < \infty$

$$\begin{aligned} |\lambda_0^n(t) - \lambda_0^n(s)| &= \left| \int_s^t v_n^0(X_n(r),S)dr \right| \\ &\leq |t-s|, \quad a.s., \end{aligned}$$

we have that the family $\{\lambda_0^n(\cdot)\}$ is tight in $C([0,\infty);[0,\infty))$. Next observe that from Theorem 5.2 there exists an enlargement $(\overline{\Omega},\overline{\mathcal{F}},\{\overline{\mathcal{F}}_t\},\overline{P})$ of the above space such that there is a $\overline{\mathcal{F}}_t$ Wiener process $\overline{W}(\cdot)$ defined on the enlarged space and

$$Z_n(t) = \Gamma\left(Z_n(0) + \int_0^\cdot \int_S b(Z_n(s),\alpha)\Phi_n(s)(d\alpha)ds + \int_0^\cdot \sigma(Z_n(s))d\overline{W}(s)\right)(t), \tag{5.18}$$

where the dependence of the Wiener process and the space on n is again suppressed in the notation. Since the probability law of $Z_n(0)$ is same as that of $X_n(0)$, i.e., η^n and from (5.9) $\eta^n(A) \to \eta(A)$ as $n \to \infty$ for all $A \in \mathcal{B}(G)$, we have that the family $\{Z_n(0)\}$ is tight. Furthermore, using the Lipschitz property of the Skorohod map we have that for $0 \le s \le t < \infty$

$$|Z_n(t) - Z_n(s)| \le Kr|t-s| + K\left|\int_s^t \sigma(Z_n(s))dW(s)\right|.$$

Recalling that $\sigma(\cdot)$ is bounded we have as a result of the above observations that the family $\{Z_n(\cdot)\}$ is tight in $C([0,\infty):G)$. Let $(Z(\cdot),\lambda_0(\cdot))$ be a weak limit point of the sequence $(Z_n(\cdot),\lambda_0^n(\cdot))$ and relabel the convergent subsequence as $(Z_n(\cdot),\lambda_0^n(\cdot))$. Observing that $\lambda_0^n(t) \le t$, a.s., for all $t \ge 0$ and $n \in \mathbb{N}$ and $E(\lambda_0^n(t)) = \frac{t}{K_n}\mu_0(G\times S) \to t$, as $n \to \infty$, we have that $\lambda_0(t) = t$ for all $t \ge 0$, a.s. Next observe that from the weak convergence of $Z_n(\cdot)$ and $\lambda_0^n(\cdot)$ we have that as $n \to \infty$, $X_n(\cdot) = Z_n(\lambda_0^n(\cdot))$ converges weakly to $Z(\lambda_0(\cdot)) \equiv Z(\cdot)$. Since for each $n \in \mathbb{N}$, $X_n(\cdot)$ is stationary, we must have that the limit $Z(\cdot)$ is a stationary process too. Also, since the law of $Z(0)$ is η we have that the stationary distribution is η. Next note that, from (5.13) and (5.16), for all $x \in G^0$, $\Lambda_n(x,d\alpha) = v(x,d\alpha)$. Also from Theorem 4.2.1 in [31] we have that for all $n \in \mathbb{N}$, $E\left(\int_0^\infty \mathcal{I}_{\partial G}(Z_n(s))ds\right) = 0$. From these two observations, (5.18), and the Lipschitz property of the Skorohod map, it follows that

$$Z_n(t) = \Gamma\left(Z_n(0) + \int_0^\cdot \int_S b(Z_n(s),\alpha)v(Z_n(s),d\alpha)ds + \int_0^\cdot \sigma(Z_n(s))d\overline{W}(s)\right)(t)$$

for all $t \ge 0$, a.s. The Feller property of the family $\{P_x^v\}$ (see Theorem 2.9) now gives that $Z_n(\cdot)$ converges weakly to the solution of

$$\tilde{Z}(t) = \Gamma\left(\tilde{Z}(0) + \int_0^\cdot \int_S b(\tilde{Z}(s),\alpha)v(\tilde{Z}(s),d\alpha)ds + \int_0^\cdot \sigma(\tilde{Z}(s))d\overline{W}(s)\right)(t).$$

Since $Z_n(\cdot)$ also converges weakly to $Z(\cdot)$ we must have that $Z(\cdot)$ and $\tilde{Z}(\cdot)$ have the same distribution, in particular $Z(\cdot)$ is a stationary Markov process with the stationary distribution η.

This proves (i) and (ii) of the theorem. Finally, part (iii) follows from Theorem 3.2. □

6. Stability properties of the constrained controlled diffusions. We will now like to obtain some stability properties of the class of processes obtained as a solution of an equation of the form (1.1). We begin with the following lemma, the proof of which is contained in the proof of Theorem 4.4 of [2]. For $x \in G$ let $X^x(\cdot)$ be the solution of (1.1) with $X^x(0) = x$ on some filtered probability space $(\Omega,\mathcal{F},\{\mathcal{F}_t\},P)$ on which is given an admissible pair $(u(\cdot),W(\cdot))$.

LEMMA 6.1 (cf. Theorem 4.4 of [2]). *There exists $\alpha, r_1, C_1, \Delta, \theta \in (0,\infty)$ such that for all $r_2 \in (0,\infty)$ and $t \in (0,\infty)$,*

$$\sup_{x\in G:|x|=r_2} \sup P(\tau_1(x) > t) \le \frac{e^{\alpha C_1 r_2}}{e^{(\alpha-\theta)\Delta}} e^{-\theta t},$$

where $\tau_1 \doteq \inf\{t > 0 : |X^x(t)| = r_1\}$ *and the inner supremum on the left side above is taken over all possible solutions* $X(\cdot)$ *of* (1.1) *with* $X(0) = x$ *given on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ *with some admissible pair* $(u(\cdot), W(\cdot))$.

Remark 6.2. Theorem 4.4 of [2] is stated for uncontrolled constrained diffusion processes; however, the result (and most of the proof) holds in the generality considered here. The only place where the proof in [2] needs to be modified is as follows. The proof of Theorem 4.4 of [2] relies on Lemma 4.3 of the same paper. However, the proof of Lemma 4.3, presented in [2], at one place uses the Markov property of $X^x(\cdot)$. Thus in the appendix of this work we provide an alternate proof of this lemma which does not appeal to the Markov property and holds for the class of processes $X^x(\cdot)$ considered here.

LEMMA 6.3. *Let* r_1 *be as in Lemma* 6.1 *and let* $r_2 \in (r_1, \infty)$ *be arbitrary. For* $x \in G$ *let* $X^{x,(u,W)}(\cdot)$ *denote the solution of* (1.1), *with* $X^{x,(u,W)}(0) = x$, *given on some filtered probability space* $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$ *and with an admissible pair* $(u(\cdot), W(\cdot))$. *Let*

$$\tau(x) \doteq \inf\{t \geq 0 : |X^{x,(u,W)}(t)| = r_1 \ \text{ and } \ |X^{x,(u,W)}(s)| = r_2 \ \text{ for some } \ \mathrm{s} \in [0, \mathrm{t}]\},$$

where we have suppressed the dependence of $\tau(x)$ *on* $(u(\cdot), W(\cdot))$ *in the notation.*

Then there exists a $\delta_0 \in (0, \infty)$ *such that*

$$\inf_{x \in G : |x| = r_1} \inf_{u(\cdot), W(\cdot)} E(\tau(x)) > \delta_0 \tag{6.1}$$

and there exist $\kappa_0, \theta_0 \in (0, \infty)$ *such that for all* $t \in [0, \infty)$

$$\sup_{x \in G : |x| = r_1} \sup_{u(\cdot), W(\cdot)} P(\tau(x) > t) < \kappa_0 e^{-\theta_0 t}. \tag{6.2}$$

Proof. For notational simplicity we denote $X^{x,(u,W)}(\cdot)$ by $X^x(\cdot)$. We first prove (6.2). Given $X^x(\cdot)$ as in the statement of the lemma, define $\tau_0(x) \doteq \inf\{t \geq 0 : |X^x(t)| = r_2\}$. In view of Lemma 6.1 and Lemma 4.4 it suffices to show that there exist $\kappa', \theta_0' \in (0, \infty)$ such that for all $t \geq 0$, $\sup_{x \in G : |x| = r_1} \sup_{u(\cdot), W(\cdot)} P(\tau_0(x) > t) < \kappa' e^{-\theta_0' t}$. This will follow, if we show that for all $k \in \mathbb{N}$

$$\sup_{u(\cdot), W(\cdot)} \sup_{x \in G : |x| = r_1} P(\tau_0(x) > k) < e^{-\theta_0' k}. \tag{6.3}$$

Noting that $P(\tau_0(x) > k) = E\left(E\left(\mathcal{I}_{[\tau_0(x) > k]} \mid \mathcal{F}_{k-1}\right) \mathcal{I}_{[\tau_0(x) > k-1]}\right)$, we have from Lemma 4.4 that in order to show (6.3) it suffices to show that there exists an $\epsilon_0 \in (0, 1)$ such that

$$\sup_{x \in G : |x| \leq r_2} \sup_{u(\cdot), W(\cdot)} P(\tau_0(x) > 1) < \epsilon_0. \tag{6.4}$$

We will prove this by the method of contradiction. Suppose that (6.4) does not hold for any $\epsilon_0 \in (0, 1)$. Then there exist $\{x^n, u^n(\cdot), W^n(\cdot), X^n(\cdot), Y^n(\cdot)\}_{n \geq 1}$ such that for each $n \in \mathbb{N}$, $x^n \in \{x \in G : |x| \leq r_2\}$, $(u^n(\cdot), W^n(\cdot))$ is an admissible pair on some filtered probability space, $X^n(\cdot)$ and $Y^n(\cdot) \doteq (Y_1^n(\cdot), \ldots, Y_N^n(\cdot))$ are obtained as a solution of (1.1) with $(u(\cdot), W(\cdot))$ replaced by $(u^n(\cdot), W^n(\cdot))$, $X^n(0) = x^n$, and $\lim_{n \to \infty} P(\tau_{0,n} > 1) = 1$, where $\tau_{0,n} \doteq \inf\{t \geq 0 : |X^n(t)| = r_2\}$.

Let $\{f_i\}_{i=1}^{\infty}$ be a countable dense set in the unit ball of $C(S)$. Define, for $t \geq 0$ and $j \geq 1$, $\beta_j^n(t) \doteq \int_S f_j(\alpha) u^n(t, d\alpha)$. Let B denote the closed unit ball of

$L_\infty[0,\infty)$ endowed with the metric $\overline{d}(\cdot,\cdot)$ defined as follows. For $x, y \in B$, $\overline{d}(x,y) \doteq \sum_{M=1}^{\infty}\sum_{j=1}^{\infty}\frac{\langle x-y, e_j^M\rangle_M}{2^M 2^j}$, where for each $M \in \mathbb{N}$, $\{e_j^M(\cdot)\}_{j=1}^{\infty}$ is a complete orthonormal system in $L^2[0,M]$ and $\langle\cdot,\cdot\rangle_M$ denotes the usual inner product in $L^2[0,M]$. Clearly $(B,\overline{d}(\cdot,\cdot))$ is a compact metric space. Let E denote the countable product of B endowed with the product topology. Then E is a compact Polish space and $\beta^n(\cdot) \doteq (\beta_1^n(\cdot),\ldots)$ is an E valued random variable.

Recalling that $X^n(0) = x^n$ and $|x^n| \le r_2$ we see that the family $X^n(0)$ is tight. Furthermore, using the Lipschitz property of the Skorohod map and Condition 2.4(ii) we see that there exists $\tilde{C} < \infty$ such that for all $0 \le s \le t < \infty$

$$|X^n(t) - X^n(s)| \le \tilde{C}\left[|t-s| + \left|\int_s^t \sigma(X^n(q))dW^n(q)\right|\right].$$

Using the boundedness of $\sigma(\cdot)$ we now have that $\{X^n(\cdot)\}$ is tight in $C([0,\infty):G)$. Next choosing $g \in C_b^2(G)$ as in Lemma 4.2 we see that for $0 \le s \le t < \infty$

$$\sum_{i=1}^{N}|Y_i^n(t) - Y_i^n(s)| \le \overline{C}|t-s| + \left|\int_s^t \langle \nabla g(X^n(q)), \sigma(X^n(q))dW^n(q)\rangle\right|,$$

where $\overline{C}$ is as defined in (5.4). Combining this with the fact that $Y^n(0) = 0$ we have that $\{Y^n(\cdot)\}$ is tight in $C([0,\infty):[0,\infty)^N)$. Thus $(\beta^n(\cdot), X^n(\cdot), Y^n(\cdot))$ is a tight family of random variables with values in $\overline{E} \doteq E \times C([0,\infty):G) \times C([0,\infty):[0,\infty)^N)$. Pick a weakly convergent subsequence of the above sequence and relabel it as the original sequence. By going to the Skorohod representation space $(\overline{\Omega}, \overline{\mathcal{F}}, P)$—however, keeping the same notation for random variables for convenience—we have that there exists an $\overline{E}$ valued random element $(\beta(\cdot), X(\cdot), Y(\cdot))$ such that $(\beta^n(\cdot), X^n(\cdot), Y^n(\cdot))$ converges a.s. to $(\beta(\cdot), X(\cdot), Y(\cdot))$ as $n \to \infty$.

Next note that for $f \in C_0^\infty(G)$ and $0 \le t_1 \le t_2 < \infty$

(6.5)

$$E\left(\left(f(X^n(t_2)) - f(X^n(t_1)) - \int_{t_1}^{t_2}\left(\int_S (Lf)(X^n(s),\alpha)u^n(s,d\alpha)\right)ds \right.\right.$$
$$\left.\left. - \sum_{i=1}^{N}\int_{t_1}^{t_2}(D_i f)(X^n(s))dY_i^n(s)\right)\psi(X^n(s_1), Y^n(s_1),\ldots,X^n(s_m),Y^n(s_m))\right) = 0,$$

where $m \in \mathbb{N}$, $0 \le s_1 \le \cdots \le s_m \le t_1$, and ψ is an arbitrary continuous and bounded function defined on the obvious domain. From Lemma 2.4 of [12] we have that $\int_{t_1}^{t_2}(D_i f)(X^n(s))dY_i^n(s) \to \int_{t_1}^{t_2}(D_i f)(X(s))dY_i(s)$ a.s. as $n \to \infty$. Also from the Lipschitz property of the coefficients $b(\cdot)$ and σ (cf. Condition 2.4(i), (iii)) and Lemma II.1.3 of [6] we have that

$$\int_{t_1}^{t_2}\left(\int_S (Lf)(X^n(s),\alpha)u^n(s,d\alpha)\right)ds \to \int_{t_1}^{t_2}\left(\int_S (Lf)(X(s),\alpha)u(s,d\alpha)\right)ds$$

a.s., as $n \to \infty$, where $u(\cdot)$ is a U valued measurable process satisfying $\int_S f_i(\alpha)u(t,d\alpha) = \alpha_i(t)$ for all $i \in \mathbb{N}$.

Thus taking limit as $n \to \infty$ in (6.5) we have that

$$E\left(\left(f(X(t_2)) - f(X(t_1)) - \int_{t_1}^{t_2}\left(\int_S (Lf)(X(s),\alpha)u(s,d\alpha)\right)ds \right.\right.$$
$$\left.\left. - \sum_{i=1}^{N}\int_{t_1}^{t_2}(D_i f)(X(s))dY_i(s)\right)\psi(X(s_1),Y(s_1),\ldots,X(s_m),Y(s_m))\right) = 0.$$

Furthermore, without loss of generality, we can take $u(\cdot)$ to be $\mathcal{F}_t^{X,Y}$ adapted. Also noting that for any $f \in C_b(G)$ such that $f = 0$ on F_i we have that $\int_0^\infty f(X^n(s))dY_i^n(s) = 0$, it follows that for such an f, $\int_0^\infty f(X(s))dY_i(s) = 0$. Thus for all $i \in \{1,\ldots,N\}$ and $t \geq 0$, $Y_i(t) = \int_0^t \mathcal{I}_{F_i}(X(s))dY_i(s)$, a.s. Thus $(X(\cdot),u(\cdot))$ solves the CCMP for $(\delta_{\{x\}}, L, G, (D_i,F_i)_{i=1}^N)$ on the filtered probability space $(\overline{\Omega},\overline{\mathcal{F}},\mathcal{F}_t^{X,Y})$. Finally, defining $\tau \doteq \inf\{t : |X(t)| = r_2\}$ we have that $\tau_{0,n} \to \tau$ a.s. and thus $P(\tau \geq 1) = 1$. But this is clearly impossible in view of Condition 2.5. Thus we have arrived at a contradiction. This proves (6.2). The proof of (6.1) follows via a similar argument via contradiction. This proves the lemma. □

As an immediate consequence of above lemmas we have the following result.

LEMMA 6.4. *For $\pi \in \mathcal{P}(G)$ with support contained in S_0 and admissible pair $(u(\cdot),W(\cdot))$ given on some filtered probability space $(\Omega,\mathcal{F},\{\mathcal{F}_t\},P)$, let $X^{\pi,(u,W)}(\cdot)$ denote the solution of* (1.1), *with $X^{\pi,(u,W)}(0)$ having the probability law π. Let*

$$\tau(\pi) \doteq \inf\{t \geq 0 : |X^{\pi,(u,W)}(t)| = r_1 \ \text{ and } \ |X^{\pi,(u,W)}(s)| = r_2 \ \text{ for some } \ s \in [0,t]\}.$$

Define $\eta^{\pi,(u,W)} \in \mathcal{P}(G)$ as follows. For $f \in C_b(G)$

$$\int_G f(y)\eta^{\pi,(u,W)}(dy) \doteq \frac{E\left(\int_0^{\tau(\pi)} f(X^{\pi,(u,W)}(t))dt\right)}{E(\tau(\pi))}.$$

Then the family $\{\eta^{\pi,(u,W)} : \pi \in \mathcal{P}(G);\ \mathrm{supp}(\pi) \subset S_0;\ (u(\cdot),W(\cdot))$ admissible$\}$ is tight.

Proof. Let $\epsilon > 0$ be arbitrary. Let $\theta_0,\kappa_0,\delta_0$ be as in Lemma 6.3. It follows from Lemma 4.5 of [2] that for all $M \in (0,\infty)$ the family $\{X^{x,(u,W)}(t), t \geq 0; |x| \leq M; (u(\cdot),W(\cdot))$ admissible$\}$ is tight. Using this observation and Lemma 4.4 we have that there exists a compact set K^ϵ in G such that

$$P(X^{\pi,(u,W)}(t) \notin K^\epsilon) \leq \frac{(\epsilon\theta_0\delta_0)^2}{4\kappa_0}$$

for all $t \in (0,\infty)$, $\pi \in \mathcal{P}(G)$, $\mathrm{supp}(\pi) \subset S_0$, and $(u(\cdot),W(\cdot))$ admissible. Hence

$$\begin{aligned}
\eta^{\pi,(u,W)}((K^\epsilon)^c) &= \frac{\int_0^\infty E\left(\mathcal{I}_{\{\tau(\pi)>t\}}\mathcal{I}_{\{X^{\pi,(u,W)}(t)\notin K^\epsilon\}}\right)dt}{E(\tau(\pi))} \\
&\leq \frac{\epsilon\theta_0\delta_0}{2\sqrt{\kappa_0}}\frac{\int_0^\infty \sqrt{P(\tau(\pi)>t)}dt}{E(\tau(\pi))} \\
&\leq \frac{\epsilon\theta_0}{2}\int_0^\infty e^{-\frac{\theta_0 t}{2}}dt \\
&\leq \epsilon,
\end{aligned}$$

where the next to last inequality follows from Lemmas 4.4 and 6.3. This proves the lemma. □

7. Proof of Theorem 3.4. Let $X^x(\cdot)$ solve (1.1) with $X^x(0) = x$ on some filtered probability space with an admissible pair $(u(\cdot), W(\cdot))$. Define stopping times τ_i, ξ_i, $i \in \mathbb{N}$, as follows:

$$\tau_1 \doteq \inf\{t \geq 0 : |X^x(t)| = r_1\}. \tag{7.1}$$

For $n \geq 1$

$$\xi_n \doteq \inf\{t \geq \tau_n : |X^x(t)| = r_2\} \tag{7.2}$$

and

$$\tau_{n+1} \doteq \inf\{t \geq \xi_n : |X^x(t)| = r_1\}. \tag{7.3}$$

From Lemma 6.1 and Lemma 6.3 it follows that for all $i \in \mathbb{N}$, $E(\xi_i) < \infty$ and $E(\tau_i) < \infty$.

Now suppose that there is a $v : G \to U$ such that for all $t \geq 0$, $v(X^x(t)) = u(t)$, a.s. From the strong Markov property of the solution of (2.3) it follows that $\{X^x(\tau_i)\}_{i\geq 1}$ is a $S_0 \doteq \{x \in G : |x| = r_1\}$ valued Markov chain. Furthermore, from Condition 2.5 it follows that for $i \in \mathbb{N}$ the probability law of $X(\tau_i)$ has a density, with respect to the surface measure on S_0, which is bounded away from 0. Using the above property of the Markov chain $\{X(\tau_i)\}_{i\geq 1}$, it follows along the lines of Lemma IV.4.1 of [25] that there exists a unique invariant measure, ρ, for this chain. Extend the measure ρ to $\tilde{\rho} \in \mathcal{P}(G)$ by setting $\tilde{\rho}(A) \doteq \tilde{\rho}(A \cap S_0)$ for $A \in \mathcal{B}(G)$. Let $X(\cdot)$ be given as a solution of (2.3) with $X(0)$ having the probability law $\tilde{\rho}$. Define $\eta \in \mathcal{P}(G)$ as follows: For $f \in C_b(G)$ $\int_G f(x)\eta(dx) \doteq \frac{E\left(\int_0^{\tau_2} f(X(t))dt\right)}{E(\tau_2)}$. Then it follows as in Theorem IV.4.1 of [25] that η is the unique invariant measure for the Markov process $X(\cdot)$, i.e., in the notation of Theorem 3.2, $\eta = \eta_v$.

The following compactness result is a crucial step in the proof.

LEMMA 7.1. *The family* $\{\eta_v | v : G \to U;\ \ v \ \text{is measurable}\}$ *is a compact set in* $\mathcal{P}(G)$.

Proof. We begin by observing that as an immediate consequence of the above representation of η_v and Lemma 6.4, we have that the above family is tight. Now let $\{v_n\}$ be a sequence of measurable maps from G to U. Suppose that η_{v_n} converges to $\eta \in \mathcal{P}(G)$. We will like to show that there exists a measurable $v : G \to U$ such that $\eta = \eta_v$. Define the sequence $\{\nu_n\}$ of elements of $\mathcal{P}(G \times S)$ as follows. For $A \in \mathcal{B}(G)$, $B \in \mathcal{B}(S)$ $\nu_n(A \times B) \doteq \int_A v_n(x, B)\eta_{v_n}(dx)$. From Lemma 5.6 there exist measures $\mu_i^n \in \mathcal{M}_F(F_i)$, $i = 1, \ldots, N$, $n \in \mathbb{N}$, such that for all $f \in C_0^\infty(G)$

$$\int_{G\times S} (Lf)(x, \alpha)\nu_n(dx, d\alpha) + \sum_{i=1}^{N} \int_{F_i} (D_i f)(x)\mu_i^n(dx) = 0. \tag{7.4}$$

From the compactness of S and Lemma 7.1 we have that $\{\nu_n\}_{n\geq 1}$ is a tight family. Denote by $\overline{F}_i$ the one point compactification of F_i. Extend, for each $i = 1, \ldots, N$, μ_i^n to an element of $\mathcal{M}_F(\overline{F}_i)$ in a natural way, denoting the extension as $\overline{\mu}_i^n$. Also note that from (5.5) we have that the measures μ_i^n can be chosen such that $\mu_i^n(F_i) = \overline{\mu}_i^n(\overline{F}_i) \leq \overline{C}$, where $\overline{C}$ is the constant defined in (5.4). Thus, by going to a subsequence if necessary, we have that there exist $\nu \in \mathcal{P}(G \times S)$ and $\overline{\mu}_i \in \mathcal{M}_F(\overline{F}_i)$ such that for all $h \in C_b(G \times S)$ and $h_i \in C_b(\overline{F}_i)$, $i = 1, \ldots, N$, $\int_{G\times S} h(x, \alpha)\nu_n(dxd\alpha)$ converges to

$\int_{G\times S} h(x,\alpha)\nu(dxd\alpha)$ and $\int_{\overline{F}_i} h_i(x)\overline{\mu}^i_n(dx)$ converges to $\int_{\overline{F}_i} h_i(x)\overline{\mu}^i(dx)$, as $n\to\infty$. Also note that $\nu(dx\times S)=\eta(dx)$. Let $v: G\to U$ be a measurable map such that $\nu(dxd\alpha)=v(x,d\alpha)\eta(dx)$. For $i=1,\dots,N$, let μ_i be the restriction of $\overline{\mu}_i$ to F_i. Then from (7.4) we have that $\int_G (Lf)(x,\alpha)\nu(dx,d\alpha)+\sum_{i=1}^N \int_{F_i}(D_if)(x)\mu_i(dx)=0$. From Theorem 5.7 it now follows that $\eta=\eta_v$. This proves the lemma. □

Let

$$\beta^* \doteq \inf_v \int_G k(x,v(x))\eta_v(dx), \tag{7.5}$$

where the infimum on the right side is taken over all Markov controls v. In rest of the section we will show that the infimum above is attained by some Markov control v and furthermore for any admissible pair $(u(\cdot),W(\cdot))$ given on some filtered probability space $\limsup_{T\to\infty}\frac{1}{T}\int_0^T k(X(s),u(s))ds\ge\beta^*$, a.s., where $X(\cdot)$ solves (1.1) with an arbitrary initial distribution. This fact along with Lemma 4.1 will prove Theorem 3.4.

PROPOSITION 7.2. *Let β^* be as defined in* (7.5). *Then, there exists a measurable map $v: G\to U$ such that $\int_G k(x,v(x))\eta_v(dx)=\beta^*$.*

Proof. Let $v_n: G\to U$ be a sequence of maps such that $\int_G k(x,v_n(x))\eta_{v_n}(dx)$ converges to β^*, as $n\to\infty$. For $n\in\mathbb{N}$, define $\nu_n\in\mathcal{P}(G\times S)$ as follows. For $f\in C_b(G\times S)$

$$\int_{G\times S} f(x,\alpha)\nu_n(dxd\alpha)\doteq\int_{G\times S} f(x,\alpha)v_n(x,d\alpha)\eta_{v_n}(dx).$$

From Lemma 7.1 we have that $\{\nu_n\}_{n\ge1}$ is a tight sequence of probability measures. By going to a subsequence if necessary, we have that there exists a $\nu\in\mathcal{P}(G\times S)$ and $\eta\in\mathcal{P}(G)$ such that $\nu_n\to\nu$ and $\eta_{v_n}\to\eta$ as $n\to\infty$. Thus recalling that $\int_G k(x,v_n(x))\eta_{v_n}(dx)=\int_{G\times S}\overline{k}(x,\alpha)\nu_n(dxd\alpha)$ we have that $\int_{G\times S}\overline{k}(x,\alpha)\nu(dxd\alpha)=\beta^*$. Clearly, $\eta(dx)=\nu(dx\times S)$. Furthermore, as in the proof of Lemma 7.1 we have via an application of Theorem 5.7 that if $v: G\to U$ is a measurable map such that $\nu(dxd\alpha)=v(x,d\alpha)\eta(dx)$, then $\eta=\eta_v$. Hence

$$\begin{aligned}\beta^* &= \int_{G\times S}\overline{k}(x,\alpha)\nu(dxd\alpha)\\ &= \int_G\left(\int_S \overline{k}(x,\alpha)v(x,d\alpha)\right)\eta_v(dx)\\ &= \int_G k(x,v(x))\eta_v(dx).\end{aligned}$$ □

PROPOSITION 7.3. *Let $X(\cdot)$ be the solution of* (1.1) *on some filtered probability space $(\Omega,\mathcal{F},\{\mathcal{F}_t\},P)$ on which is given an admissible pair $(u(\cdot),W(\cdot))$. Then $\limsup_{t\to\infty}\frac{1}{t}\int_0^t k(X(s),u(s))ds\ge\beta^*$, a.s., where β^* is as defined in* (7.5).

Proof. In view of Proposition 7.2 it suffices to show that for a.e. ω and for every sequence $t_k\to\infty$ (as $k\to\infty$), there exists a further subsequence (denoted again as the original sequence) such that

$$\lim_{k\to\infty}\frac{1}{t_k}\int_0^{t_k} k(X(s),u(s))ds=\int_G k(x,v(x))\eta_v(dx) \tag{7.6}$$

for some measurable $v: G\to U$, possibly depending on ω and the subsequence.

Define a family of probability measures $\{\nu_t\}_{t\geq 0}$ on $G \times S$ as follows. For $f \in C_b(G \times S)$,

$$\nu_t(f) \doteq \frac{1}{t}\int_0^t \int_S f(X(s),\alpha)u(s,d\alpha)ds. \tag{7.7}$$

We first claim that the family $\{\nu_{t_k}\}$ is a tight family for any sequence $t_k \to \infty$. Since S is compact, in order to prove the claim, it suffices to show that the family $\{\tilde{\nu}_{t_k}\}_{k\geq 1}$ of probability measures on G defined as

$$\tilde{\nu}_{t_k}(f) \doteq \frac{1}{t_k}\int_0^{t_k} f(X(s))ds, \qquad f \in C_b(G),$$

is tight. For $n \in \mathbb{N}$, let f_n be a nonnegative smooth map defined on G such that $f_n(x) = 0$ for $|x| < n$ and $f_n(x) = 1$ for $|x| > n+1$. Using estimates obtained in Lemmas 6.3 (cf. 6.1), 6.4, 4.4, we have as in [6, Chapter 6, pp. 153–154] that for all $\epsilon > 0$, there exists $N(\epsilon) \in \mathbb{N}$ such that for all $n \geq N(\epsilon)$, $\limsup_{t\to\infty} \frac{1}{t}\int_0^t f_n(X(s))ds \leq \epsilon$. This immediately implies the a.s. tightness of $\{\tilde{\nu}_{t_k}\}_{k\geq 1}$ and hence the claim. Now define measures $\mu_{i,k} \in \mathcal{M}_F(F_i)$ as

$$\mu_{i,k}(f) \doteq \frac{1}{t_k}\int_0^{t_k} f(X(s))dY_i(s), \qquad f \in C_b(F_i), \tag{7.8}$$

$i = 1,\dots,N$. Observe that if $g \in C_b^2(G)$ is defined as in the proof of Lemma 5.4, then

$$\begin{aligned}\mu_{i,k}(F_i) &= \frac{Y_i(t_k)}{t_k}\\ &\leq \overline{C} + \frac{1}{t_k}\left|\int_0^{t_k}\langle \nabla g(X(s)), \sigma(X(s))dW(s)\rangle\right| + o(1),\end{aligned}$$

where $\overline{C}$ is defined via (5.4). Noting that the second term on the right side of the above display converges to 0, a.s., as $k \to \infty$, we have that a.s. $\sup_k \mu_{i,k}(F_i) < \infty$, $i = 1,\dots$. Denote the extension of $\mu_{i,k}$ to $\overline{F}_i$, the one point compactification of F_i, by $\overline{\mu}_{i,k}$. Now fix an ω outside a suitable null set. Then, by going to a subsequence if necessary, we have that, for the given ω, there exist $\nu \in \mathcal{P}(G \times S)$, $\overline{\mu}_i \in \mathcal{M}_F(\overline{F}_i)$ such that for all $f \in C_b(G \times S)$ and $f_i \in C_b(\overline{F}_i)$, $i = 1,\dots,N$, $\int_{G\times S} f(x,\alpha)\nu_{t_k}(dxd\alpha)$ converges to $\int_{G\times S} f(x,\alpha)\nu(dxd\alpha)$ and $\int_{\overline{F}_i} f_i(x)\overline{\mu}_{i,k}(dx)$ converges to $\int_{\overline{F}_i} f_i(x)\overline{\mu}_i(dx)$, as $k \to \infty$. Let $f \in C_0^\infty(G)$. Applying Ito's formula to $f(X(t_k))$, dividing by t_k, and taking the limit as $k \to \infty$, we have that

$$\int_{G\times S}(Lf)(x,\alpha)\nu(dxd\alpha) + \sum_{i=1}^N \int_{F_i}(D_i f)(x)\mu_i(dx) = 0.$$

Hence from Theorem 5.7 we have that if $\eta(dx) \doteq \nu(dx \times S)$ and ν is disintegrated as $\nu(dxd\alpha) = v(x,d\alpha)\eta(dx)$, then $\eta = \eta_v$. This immediately yields that

$$\lim_{k\to\infty}\frac{1}{t_k}\int_0^{t_k} k(X(s),u(s))ds = \int_G \overline{k}(x,v)\eta_v(dx).$$

This proves the proposition. □

We are now ready to prove our main result.

Proof of Theorem 3.4. From Proposition 7.2 there exists a measurable map $\overline{v}: G \to U$ such that

$$\beta^* = \int_G k(x, \overline{v}(x))\eta_{\overline{v}}(dx). \tag{7.9}$$

Let $\overline{X}(\cdot)$ solve (2.3), with v replaced by $\overline{v}$ on some filtered probability space with probability law of $\overline{X}(0)$ equal to μ. Then, from Lemma 4.1

$$\limsup_{T\to\infty} \frac{1}{T}\int_0^T k(\overline{X}(s), \overline{v}(\overline{X}(s)))ds = \int_G k(x, \overline{v}(x))\eta_{\overline{v}}(dx), \tag{7.10}$$

a.s. Combining (7.9) and (7.10) we have that $\beta^* = \limsup_{T\to\infty} \frac{1}{T}\int_0^T k(\overline{X}(s), v(\overline{X}(s)))$ ds. The result now follows from Proposition 7.3. □

8. Characterizing the value via the HJB equation. One of the important goals in optimal control theory is to derive the HJB equation for the value function and characterize the value function as the unique solution (in an appropriate class) of the PDE. The detailed treatment of this aspect of the ergodic control problem studied in this paper will be undertaken elsewhere; however, we briefly outline below the key steps in such a program.

The classical approach to the HJB equation for the ergodic control is by the "vanishing discount method" (cf. [10, 8, 6, 3]). In this approach the first step is to characterize the value function $V_\alpha(x)$ of the discounted control problem,

$$V_\alpha(x) = \inf_u E\left(\int_0^\infty e^{-\alpha t}k(X^x(s), u(s))ds\right), \tag{8.1}$$

where $\alpha \in (0, \infty)$, the infimum is taken over all admissible controls u and $X^x(\cdot)$ is the solution of (1.1) with $X(0) \equiv x$. The natural HJB equation associated with the control problem (8.1) will be

$$\begin{aligned} \inf_{u\in U}(L\psi(x,u) + k(x,u) - \alpha\psi(x)) = 0, &\qquad x \in G, \\ \langle \nabla\psi(x), d_i\rangle = 0, &\qquad x \in \partial G,\ \ i \in In(x). \end{aligned} \tag{8.2}$$

Theory of classical solutions for such PDEs in domains with corners is not available; however, using the seminal ideas of Crandall and Lions [11, 33], Dupuis and Ishii [14] have proved the existence of a viscosity solution to (8.2). We remark that [14] considers the case of bounded domains; however, the key ideas there can be adapted to cover the current setting. By standard techniques (cf. Theorem III.2.1 in [6]) it can be shown that $V_\alpha(\cdot) \in C_b(G)$. Next, in order to establish that V_α is the unique viscosity solution of (8.2), we will need to adapt the proofs of Theorems I.1 and II.1 of [33] to oblique derivative problems in domains with corners.

The next key step in the program is to show that the family $\{V_\alpha(x) - V_\alpha(0); \alpha \in (0,1)\}$ is precompact in $C(G)$. The proof of this statement is currently the biggest obstacle since the classical derivation (see Theorem VI.3.1 of [6]) makes use of certain gradient estimates on $V_\alpha(x)$, uniform in α, which are currently unavailable. Another approach based on viscosity solutions, taken in [3], avoids this difficulty by making some strong stability assumptions on the model (a restoring force towards bounded sets that grows without bound as $|x| \to \infty$), which are not satisfied in the current setup because of the radially homogeneous nature of the problem.

Once the above compactness issue is resolved one can, by usual limiting arguments, as $\alpha \to 0$, (cf. [3]) and the stability properties of the viscosity solution (cf. Proposition I.3 [33]), exhibit a solution (V^*, ρ^*) for the HJB equation for the ergodic control problem:

$$\begin{aligned} \inf_{u\in U} (LV^*(x,u) + k(x,u) - \rho^*) = 0, \qquad & x \in G, \\ \langle \nabla\psi(x), d_i\rangle = 0, \qquad & x \in \partial G, \ \ i \in In(x). \end{aligned} \tag{8.3}$$

Finally one would like to establish that $\rho^* = \text{ess inf}_u \limsup_{T\to\infty} \frac{1}{T}\int_0^T k(X(s),u(s))ds$, where the infimum is taken over all admissible controls. The proof of this statement will proceed along the lines of Theorem 4.2 of [3].

Appendix.

Sketch of the proof for the near monotone case. We assume that all the conditions on the model imposed in the earlier sections, except Condition 3.1, hold. We will replace this "blanket stability" condition by the following assumption on the function k. Following [6], we will call a Markov control v a stable stationary Markov control if the corresponding solution to (2.3) is a positive recurrent Markov process and has a unique invariant measure, denoted as η_v. We denote the collection of all such controls by $\mathcal{F}^*$. The near monotone condition on the cost function k is as follows.

CONDITION 9.1. (a) $\beta \doteq \inf_{v\in\mathcal{F}^*} \int_G k(x,v(x))\eta_v(dx) < \infty$; (b) $\liminf_{|x|\to\infty} \inf_{u\in U} k(x,u) > \beta$.

Part (a) of the above condition is satisfied if, for example, there exist a $\delta, M \in (0,\infty)$, and some measurable map $v : G \to U$ such that $b(x,v(x)) \in \mathcal{C}(\delta)$ for all $x \in G$ such that $|x| > M$. The (b) part of the condition is obviously satisfied if $k(x,u) = \psi(|x|)$ for a monotone increasing map $\psi : \mathbb{R}_+ \to \mathbb{R}$.

The key steps in the proof of Theorem 3.4 for this setup are, once more, Propositions 7.2 and 7.3 (with β^* there replaced by β). Since in the near monotone case the proof of Proposition 7.2 is very similar to that of Proposition 7.3, we sketch only the proof of the latter case.

Sketch of Proposition 7.3 in the near monotone case. Let $\{\nu_t\}_{t\geq 0}$ be as defined in (7.7) and let $\overline{G}$ be the one point compactification of G and denote the point at ∞ by p_∞. Since S is compact, we have that $\{\nu_t\}_{t\geq 0}$ is a tight family of probability measures on $\overline{G}\times S$. Define $\mu_{i,k} \in \mathcal{M}_F(F_i)$, via (7.8). Then there exist $\mu \in \mathcal{P}(\overline{G}\times S)$, $\overline{\mu}_i \in \mathcal{M}_F(F_i)$, such that for all $f \in C_b(\overline{G}\times S)$ and $f_i \in C_b(\overline{F}_i)$, $i = 1,\dots,N$, $\int_{\overline{G}\times S} f(x,\alpha)\nu_{t_k}(dxd\alpha)$ converges to $\int_{\overline{G}\times S} f(x,\alpha)\nu(dxd\alpha)$ and $\int_{\overline{F}_i} f_i(x)\overline{\mu}_{i,k}(dx)$ converges to $\int_{\overline{F}_i} f_i(x)\overline{\mu}_i(dx)$, as $k\to\infty$. Let ν be decomposed as $\nu = (1-\rho)\nu_1 + \rho\nu_\infty$, where $\nu_1 \in \mathcal{P}(G\times S)$ and $\nu_\infty \in \mathcal{P}(\{p_\infty\}\times S)$. Now using the near monotonicity of k, one shows, exactly as in [6, pp. 146–147] that $\rho = 0$. Thus we have that $\nu = \nu_1 \in \mathcal{P}(G\times S)$. The rest of the proof is exactly the same as in the stable case.

Proof of Lemma 4.2. We begin by observing that the geometry of the space G implies that there exists $C \in (1,\infty)$ such that for all $x \in G$ and $\lambda \in \Lambda$, $d(x,F_\lambda) \leq C\max_{i\in\lambda}\langle x, n_i\rangle$. Next, from Condition 2.2(c), it follows that for all $\lambda \in \Lambda$, there exist positive constants $\{c_i^\lambda\}_{i\in\lambda}$ such that $\eta^\lambda \doteq \sum_{i\in\lambda} c_i^\lambda n_i$ satisfies $\langle \eta^\lambda, d_i\rangle > 0$ for all $i \in \lambda$. Define $\tilde{c} \doteq \inf_{i\in\lambda;\ \lambda\in\Lambda}\langle \eta^\lambda, d_i\rangle$. Furthermore as a convenient normalization we take $\sum_{i\in\lambda} c_i^\lambda = \frac{1}{2}$. Next define constants (γ_k, β_k), $k = 0,1,\dots,N$, inductively as follows:

$\gamma_N \doteq \frac{1}{2(C+1)}$, $\beta_N \doteq \tilde{c}\gamma_N$, and for $k = 1, \ldots, N$, $\gamma_{N-k} \doteq \frac{\beta_{N-k+1}}{C}$, $\beta_{N-k} \doteq \tilde{c}\gamma_{N-k}$. Let ϕ, ψ be maps from $\mathbb{R}_+$ to $\mathbb{R}_+$ defined as follows:

$$\begin{aligned}\phi(x) &\doteq x - 1, \qquad x \in \left[0, \frac{1}{2}\right] \\ &\doteq 0, \qquad x \geq 1\end{aligned}$$

and

$$\begin{aligned}\psi(x) &\doteq 0, \qquad x \in \left[0, \frac{1}{2}\right] \\ &\doteq 1, \qquad x \geq 1.\end{aligned}$$

Now define for $\lambda \in \Lambda$, $f_\lambda : G \to \mathbb{R}$ as follows:

$$f_\lambda(x) \doteq a_\lambda \phi\left(\frac{\langle \eta^\lambda, x\rangle}{\beta_{|\lambda|}}\right) \prod_{j \notin \lambda} \psi\left(\frac{\langle n_j, x\rangle}{\gamma_{|\lambda|}}\right),$$

where $|\lambda|$ denotes the cardinality of the set λ and a_λ are suitable positive chosen inductively as follows. For all λ with $|\lambda| = 1$ we choose a_λ so that $a_\lambda \langle \eta_\lambda, d_i\rangle \geq \beta_1$, $i \in \lambda$. Having chosen a_λ for all λ with $1 \leq |\lambda| < k$, we choose a_λ, for a $\lambda \in \Lambda$ with $|\lambda| = k$, such that $a_\lambda \langle \eta_\lambda, d_i\rangle \geq \beta_k(M_{k-1} + 1)$, $i \in \lambda$, where

$$M_{k-1} \doteq \sum_{j=1}^{k-1} \sum_{\lambda : |\lambda| = j} \left(- \inf_{x \in F_i ; i \in \lambda} \langle \nabla f_\lambda(x), d_i\rangle \right)^+.$$

Finally define $g : G \to \mathbb{R}$ as $g(x) \doteq \sum_{\lambda \in \Lambda} f_\lambda(x)$. It can be verified as in [12] that g defined as above satisfies (4.1). □

Alternate proof of Lemma 4.3 of [2]. We give a proof which, unlike the proof in [2], does not appeal to the Markov property of $X^x(\cdot)$. This lemma is needed for the proof of Theorem 4.4 of [2] and therefore the proof of Lemma 6.1 of the present paper.

LEMMA 9.2 (Lemma 4.3 of [2]). *For $x \in G$ and an admissible pair $(u(\cdot), W(\cdot))$ given on some filtered probability space, $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, P)$. Let $X^x(\cdot)$ denote the solution of (1.1) with $X^x(0) = x$. Let $\Delta > 0$ be fixed. For $n \in \mathbb{N}$ let ν_n be defined as follows:*

$$\nu_n \doteq \sup_{(n-1)\Delta \leq s \leq n\Delta} \left| \int_{(n-1)\Delta}^{s} \sigma(X^x(s)) dW(s) \right|.$$

Then for any $\rho \in (0, \infty)$ and $m, n \in \mathbb{N}$, $m \leq n$,

$$E\left(e^{\rho \sum_{i=m}^n \nu_i}\right) \leq \left(2\sqrt{2} e^{k^2 \rho^2 r^2 \Delta}\right)^{(n-m+1)}.$$

Proof. Let $\int_0^\cdot \sigma(X^x(s)) dW(s) \equiv (M_1(\cdot), \ldots, M_k(\cdot))$. Then for $i = 1, \ldots, k$, $M_i(\cdot)$ is a square integrable $\{\mathcal{F}_t\}$ martingale. An application of Cauchy–Schwarz inequality gives that

$$E\left(e^{\rho \sum_{i=m}^n \nu_i}\right) \leq \left(\prod_{j=1}^{k} E\left(e^{k\rho \sum_{i=m}^n M_j^i}\right)\right)^{\frac{1}{k}},$$

where for $j = 1, \dots, k$, $i = m, m+1, \dots, n$, $M_j^i \doteq \sup_{(i-1)\Delta \le s \le i\Delta} |M_j(s) - M_j((i-1)\Delta)|$. Now fix a $j \in \{1, \dots, k\}$. In view of Condition 2.5, $|\langle M_j \rangle(t)| \to \infty$, a.s. as $t \to \infty$. Thus from Theorem V.1.6 in [38], $M_j(\cdot)$ has the same probability law as $B(\tau(\cdot))$, where $\tau(\cdot) \doteq \langle M_j \rangle(\cdot)$, $B(t)$ is a $\mathcal{G}_t$ standard Brownian motion, $\mathcal{G}_t \doteq \mathcal{F}_{S(t)}$, and $S(t) \doteq \inf\{s \ge 0 : \langle M_j \rangle(s) > t\}$. Next observe that

$$\begin{aligned} E\left(e^{k\rho \sum_{i=m}^n M_j^i}\right) &= E\left(e^{k\rho \sum_{i=m}^n \sup_{0\le s\le\Delta} |B(\tau((i-1)\Delta+s)) - B(\tau((i-1)\Delta))|}\right) \\ &= E\left(H_{n-1} e^{k\rho \sup_{0\le s\le\Delta} |B(\tau((n-1)\Delta+s)) - B(\tau((n-1)\Delta))|}\right), \end{aligned}$$

where $H_{n-1} \doteq e^{k\rho \sum_{i=m}^{n-1} \sup_{0\le s\le\Delta} |B(\tau((i-1)\Delta+s)) - B(\tau((i-1)\Delta))|}$. Note that H_{n-1} is $\mathcal{G}_{\tau((n-1)\Delta)}$ measurable. Furthermore, from Condition 2.4(iv) we have that for $0 < s < t < \infty$, $|\tau(t) - \tau(s)| \le r^2 |t - s|$ and therefore

$$\begin{aligned} &\sup_{0\le s\le\Delta} |B(\tau((n-1)\Delta + s)) - B(\tau((n-1)\Delta))| \\ &\quad \le \sup_{0\le t\le r^2\Delta} |B(\tau((n-1)\Delta) + t) - B(\tau((n-1)\Delta))|. \end{aligned}$$

Finally note that

$$\begin{aligned} &E\left(H_{n-1} e^{k\rho \sup_{0\le s\le\Delta} |B(\tau((n-1)\Delta+s)) - B(\tau((n-1)\Delta))|}\right) \\ &\le E\left(H_{n-1} E\left(e^{k\rho \sup_{0\le t\le r^2\Delta} |B(\tau((n-1)\Delta)+t) - B(\tau((n-1)\Delta))|} \mid \mathcal{G}_{\tau((n-1)\Delta)}\right)\right) \\ &\le E\left(H_{n-1} 2\left(E(e^{2k\rho |B(r^2\Delta)|})\right)^{\frac{1}{2}}\right) \\ &\le 2\sqrt{2} e^{k^2\rho^2 r^2 \Delta} E\left(H_{n-1}\right), \end{aligned}$$

where the second inequality above follows from Doob's inequality for submartingales. Iterating the above inequalities we have the result. □

Acknowledgments. I would like to thank the referees and an associate editor for suggesting various improvements to the manuscript.

ON REFLECTING BOUNDARY PROBLEM FOR OPTIMAL CONTROL*

OANA-SILVIA SEREA†

Abstract. This paper deals with Mayer's problem for controlled systems with reflection on the boundary of a closed subset K. The main result is the characterization of the *possibly discontinuous* value function in terms of a unique solution *in a suitable sense* to a partial differential equation of Hamilton–Jacobi–Bellman type.

Key words. control of variational inequality, boundary reflection, viscosity solutions

1. Introduction.

We investigate the Mayer control problem:

$$\text{Minimize } g(x(T)) \tag{1}$$

for a given $T > 0$ over all absolutely continuous solutions of the following differential variational inequality:

$$\begin{cases} \text{(i) } x'(t) \in f(x(t), u(t)) - N_K(x(t)) \text{ for almost all } t \geq t_0, \\ \text{(ii) } x(t) \in K \text{ for all } t \geq t_0,\ x(t_0) = x_0, \text{ and} \\ u(\cdot) : [0, \infty) \to U \text{ is a measurable function,} \end{cases} \tag{2}$$

where $N_K(x)$ is the normal cone to K at $x \in K$ (see Definition 1).

Here K is a nonempty closed subset of $\mathbb{R}^N$, $g : K \to \mathbb{R}$ and f is a function from $K \times U$ into $\mathbb{R}^N$.

If $\mathcal{U}(t_0)$ is the set of measurable controls on $[t_0, \infty)$ with values in U, the value function corresponding to the optimal control problem (1), (2) is given by

$$V(t_0, x_0) = \inf_{u(\cdot) \in \mathcal{U}(t_0)} g(x(T; t_0, x_0, u(\cdot)) \text{ for all } (t_0, x_0) \in [0, T] \times K, \tag{3}$$

where $x(\cdot; t_0, x_0, u(\cdot))$ denotes the solution of (2) starting from (t_0, x_0).

By the very definition it is easy to see that the value function is finite on its domain $[0, T] \times K$, if and only if (2) has solutions. This explains the choice of the form of the right-hand side of the differential inclusion (2). We notice that $N_K(x) = \{0\}$ whenever $x \in \text{int}K$; f is modified only on the boundary of K, so (2) is a problem with reflection at the boundary. We shall show that this reflection allows us to obtain the existence of solutions to (2) (see section 1).

Our main purpose in this paper is to characterize the value function (3) by an equation of Hamilton–Jacobi type.

Of course, the characterization is based on a suitable definition for the notion of viscosity solutions of a Hamilton–Jacobi–Bellman inequality (HJBI) that we will introduce below.

†Laboratoire de Mathématiques, Unité CNRS, FRE-2218, Université de Bretagne Occidentale, 6 avenue Victor Le Gorgeu, BP 809, 29285 Brest cedex, France (Oana-Silvia.Serea@univ-brest.fr).

More precisely, we will prove that the value function V is the unique solution to

$$\text{(HJBI)} \qquad \begin{cases} \frac{\partial V}{\partial t}(t,x) + H(x, \frac{\partial V}{\partial x}(t,x)) - \left\langle \frac{\partial V}{\partial x}(t,x),\ N_K(x) \right\rangle \ni 0 \\ \qquad \text{if } (t,x) \in [0,T) \times K, \\ \text{with the condition } V(T,x) = g(x) \text{ if } x \in K, \end{cases}$$

where $H(x,p) := \min_{u \in U} \langle f(x,u), p \rangle$.

If the boundary of K, $\partial K \in C^1$, and K is the closure of an open set, we will show that V is a viscosity solution of the following Hamilton–Jacobi equation with Neumann-type boundary condition in the sense of [13]:

$$(4) \qquad \begin{cases} \frac{\partial V}{\partial t}(t,x) + H(x, \frac{\partial V}{\partial x}(t,x)) = 0 \text{ if } (t,x) \in [0,T) \times K, \\ \frac{\partial V}{\partial n}(t,x) = 0 \text{ if } (t,x) \in [0,T) \times \partial K, \\ \text{with the condition } V(T,x) = g(x),\ x \in K, \end{cases}$$

where $n(x)$ is the unit outward normal to K at $x \in \partial K$.

It is well known that the value function for the Skorokhod control problem (see [3], [13]) with a smooth K is a viscosity solution of (4). The Skorokhod problem for a smooth K has been considered and solved by Lions [13] and Lions and Snitzman [14]. Another study was made by Tanaka in [18] when K is convex with normal reflection. By a different approach, this problem was considered like a viability problem for a differential inclusion by Frankowska in [8]. Note that the notion of solutions of the Skorokhod problem is not the same as the notion of solutions to (2) that we use in this paper, but for the smooth case the two control problems lead to the same Hamilton–Jacobi equation (4).

Our second interest is to establish that the two following systems,

$$(5) \qquad \begin{cases} \text{(i) } x'(t) \in F(x(t)) - N_K(x(t)) \text{ for almost all } t \geq t_0, \\ \text{(ii) } x(t) \in K \text{ for all } t \in [t_0, \infty),\ t_0 \geq 0,\ x(t_0) = x_0 \in K \end{cases}$$

and

$$(6) \qquad \begin{cases} \text{(i) } x'(t) \in \Pi_{\overline{co} T_K(x(t))} F(x(t)) \text{ for almost all } t \geq t_0, \\ \text{(ii) } x(t) \in K \text{ for all } t \in [t_0, \infty),\ t_0 \geq 0,\ x(t_0) = x_0 \in K, \end{cases}$$

have the same set of solutions.

Here K is compact, $F : K \to \mathbb{R}^N$ is a set valued map and $\overline{co} A$ is the closed convex hull of a set A.

In general, the map $x \to N_K(x)$ has no easy continuity properties and so the right side of the differential inclusion is (2). For this reason the set of solutions to (5) or (6) may be empty. So it is necessary to find regularity hypotheses for K in order to provide existence and eventually uniqueness results for (5) or (6).

These kind of results for a general map F can be applied, in particular, when $F(\cdot) = f(\cdot, U)$, allowing us to obtain properties of the set of solutions to (2).

Our main contribution here is the fact that by introducing the projection on the closed convex hull of $T_K(x)$ in (6) we succeed in treating the case where the set K is only compact, improving the already known equivalence and existence results of [2] where K is supposed to be sleek.

Existence and equivalence results for (5) and (6) are established by Henry [11] for a convex set. The convexity assumption on the set K, has been relaxed by Cornet in [6], who merely required the tangential regularity. We also refer to Thibault [19] for

the case of a closed set K for an existence result of viable solution, but the reflection is made using the Clarke normal cone. Note that in [19] the set K may depend on t.

We note that the boundary reflection control problem was not yet well studied for nonsmooth K. We also succeed in generalizing some existence and equivalence results of [2] for the systems (5) and (6).

Let us explain how this paper is organized.

In the first section we introduce some preliminaries and we study the systems (5), (6).

In the second section we prove that the value function is a viscosity solution of (HJBI) in the sense of Definition 3, and a uniqueness result for the solutions of this partial differential inequality is also established.

In the third section we study the case of discontinuous and only bounded value functions for our control problem. Our main result says that V is the unique generalized solution to the corresponding (HJBI) for arbitrary discontinuous terminal cost g.

The fourth section concerns existence and uniqueness results of l.s.c. solutions to (HJBI) in the sense of Definition 16.

The last section is an appendix with technical proofs of our claims.

2. Preliminaries.

2.1. Definitions, assumptions, and notations. We assume that $f : K \times U \to \mathbb{R}$ is continuous and satisfies

$$(\mathrm{H}_f) \qquad \begin{cases} ||f(x,u)|| \le a(1+\|x\|), \\ ||f(x,u)-f(y,u)|| \le c_1 \|x-y\| \text{ for all } x,y \in K, u \in U, \\ \text{the set } f(x,U) \text{ is convex,} \end{cases}$$

where $c_1, a > 0$ are constants; U is a compact metric space.

We recall the notions of tangent and normal cones.

Definition 1. *For $x \in K$, we define by*

$$T_K(x) = \left\{ v \in \mathbb{R}^N | \lim_{h \to 0^+} \inf d_K(x+hv)/h = 0 \right\}$$

the tangent cone to K at x and by

$$N_K(x) = T_K(x)^- = \{ p \in \mathbb{R}^N | \langle p,\ v \rangle \le 0 \text{ for all } v \in T_K(x) \}$$

the normal cone to K at x.

Recall that $T_K(x)$ is a closed cone and $N_K(x)$ is a closed convex cone.

Let us describe some classes of sets which will be used in the following sections.

Definition 2. *A closed set $K \subset \mathbb{R}^N$ is called proximal retract if there exists a neighborhood I of K such that the projection $\Pi_K(\cdot)$ is single-valued in I, with $\Pi_K(x) := \{ z \in K \mid ||x-z|| = \inf_{y \in K} ||x-y|| \}$ for all $x \in \mathbb{R}$.*

We will describe some of the properties of such sets. This will be the key for the proof of the existence and uniqueness results concerning (5) and (HJBI). The class of proximal retracts includes closed, convex subsets of $\mathbb{R}^N$ and submanifolds of $\mathbb{R}^N$ of class $\mathrm{C}^{1,1}$. Another class of proximal retracts is the class of weakly convex sets (see [8] for the definition and the geometrical interpretation). A complete characterization of proximal retract sets is made in [17] (see Theorem 4.1, p. 5245). In particular, such sets have the property that there exists $\rho > 0$ such that every nonzero normal "can be

realized" by a ball with a radius equal to ρ. This characterization says, in particular, that only "exterior" corners are allowed.

So, if K is proximal retract, then from Theorem 4.1 in [17], Lemma 4.2 and Theorem 2.2 in [6] we have the following:

- There exist $r, c > 0$ such that the application $x \to N_K(x) \cap B(0,r) + cx$ is monotone[1] on K. This monotonicity property, which is equivalent to Definition 2, is very important because it allows us to establish the uniqueness of solutions to (2).

- The set K is sleek, i.e., the map $x \to T_K(x)$ is l.s.c.

- For all $x \in K$, $T_K(x) = C_K(x)$, where $C_K(x)$ denotes Clarke's tangent cone.[2] Note that the class of sleek sets is larger then the class of proximal retracts.

2.2. Viscosity solutions. To describe the value function as a unique solution to the corresponding HJBI, we introduce the following definition of solutions to (HJBI).

DEFINITION 3. *A viscosity supersolution of* (HJBI) *is an l.s.c. function* $\psi : (0,T) \times K \to \mathbb{R}$ *such that*

$$\begin{gathered}
\text{for any } \phi \in C^1 \text{ and } (t_0,x_0) \in \arg\min(\psi - \phi), \\
\text{if } x_0 \in \operatorname{int} K,\ \frac{\partial \phi}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial \phi}{\partial x}(t_0,x_0)\right) \le 0 \\
\text{and if } x_0 \in \partial K,\ \text{there exists } y_0 \in N_K(x_0) \text{ such that} \\
\frac{\partial \phi}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial \phi}{\partial x}(t_0,x_0)\right) - \left\langle y_0,\ \frac{\partial \phi}{\partial x}(t_0,x_0)\right\rangle \le 0
\end{gathered}$$

and a viscosity subsolution of (HJBI) *is a u.s.c. function* $\varphi : (0,T) \times K \to \mathbb{R}$ *such that*

$$\begin{gathered}
\text{for any } \phi \in C^1 \text{ and } (t_0,x_0) \in \arg\max(\varphi - \phi), \\
\text{if } x_0 \in \operatorname{int} K,\ \frac{\partial \phi}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial \phi}{\partial x}(t_0,x_0)\right) \ge 0 \\
\text{and if } x_0 \in \partial K,\ \text{there exists } z_0 \in N_K(x_0) \text{ such that} \\
\frac{\partial \phi}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial \phi}{\partial x}(t_0,x_0)\right) - \left\langle z_0,\ \frac{\partial \phi}{\partial x}(t_0,x_0)\right\rangle \ge 0.
\end{gathered}$$

A viscosity solution of (HJBI) *is a function which is both subsolution and supersolution.*

It is clear that a viscosity solution is a continuous function because it is simultaneously u.s.c. and l.s.c.

Remark 4. A motivation for our definition of (HJBI) is the fact that, when (t_0,x_0) is a differentiability point of V, we have in the usual sense

$$\frac{\partial V}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial V}{\partial x}(t_0,x_0)\right) - \left\langle N_K(x_0),\ \frac{\partial V}{\partial x}(t_0,x_0)\right\rangle \ni 0. \tag{7}$$

[1] Recall that a set valued map $G : K \to \mathbb{R}^N$ is monotone if $\langle y_1 - y_2, x_1 - x_2\rangle \ge 0$ for all $y_i \in G(x_i)$, $i \in \{1,2\}$.

[2] $C_K(x) = \{v \mid \lim_{h \to 0^+, K \ni x' \to x} d_K(x' + hv)/h = 0\}$. This tangent cone is always convex.

Indeed, there exists $\lambda \in [0,1]$ such that

$$0 = \lambda \left(\frac{\partial V}{\partial t}(t_0, x_0) + H\left(x_0, \frac{\partial V}{\partial x}(t_0, x_0)\right) - \left\langle y_0, \ \frac{\partial V}{\partial x}(t_0, x_0) \right\rangle \right) + (1-\lambda) \left(\frac{\partial V}{\partial t}(t_0, x_0) + H\left(x_0, \frac{\partial V}{\partial x}(t_0, x_0)\right) - \left\langle z_0, \ \frac{\partial V}{\partial x}(t_0, x_0) \right\rangle \right),$$

and because $N_K(x_0)$ is convex, (7) is verified.

It is quite natural to obtain an equation of the form (7), namely a partial differential inequality. The motivation lies in the fact that for a smooth set, the reflection is channeled in a fixed direction, given by the outward normal. For nonsmooth sets the outward normal will be replaced with the normal cone which, in general, contains many directions.

Note that this definition contains those given by Lions in [13], when the boundary of K, $\partial K \in C^1$.

2.3. Control systems with reflection on the boundary of a constraint set. In this section we study the differential inequalities (5) and (6) by explaining the method which we use in order to get a boundary reflection for closed sets K. This allows us to give some applications to the properties of solutions to the controlled system (2).

We consider a closed set K, a set valued map $F : K \to \mathbb{R}^N$, and the following differential inclusion:

$$\begin{cases} \text{(i) } x'(t) \in F(x(t)) \text{ for almost all } t \geq t_0, \\ \text{(ii) } x(t_0) = x_0 \in K, \ t_0 \geq 0. \end{cases} \tag{8}$$

The equation (6) appears naturally if we want a given closed set to become a viability[3] domain of a new system which is "as close as possible" to the original dynamic system (8).

Indeed, when the necessary and sufficient condition for the existence of viable solutions

$$F(x) \cap T_K(x) \neq \emptyset \text{ for all } x \in K$$

is not satisfied, the natural way to solve the above problem is to introduce the projected problem (6).

We note that $\Pi_{\overline{co}T_K(x)}F(x) = F(x)$ whenever $x \in \text{int}K$; F is modified only on the boundary of K, so (6) is a problem of reflection at the boundary. Moreover, the application $x \to \Pi_{\overline{co}T_K(x)}F(x)$ has no easy continuity properties, but, thanks to the properties of the projection on a convex cone, it is possible to prove that the solutions to (5) and (6) coincide. We do not make any assumption on the regularity of the set K, improving already known results of [2] where the set K is sleek.

It is easier to find sufficient conditions for the set K in order to obtain continuity properties of the right-hand side of (5). So, for the study of existence and uniqueness of solutions we consider (5). We have the following proposition.

PROPOSITION 5. (i) *Suppose that K is closed and F is a set valued map. Then the sets of absolutely continuous solutions to* (5) *and* (6) *are equal.*

[3]Recall that a solution $x(\cdot)$ to (8) is called viable in K if $x(t) \in K$ for all $t \geq 0$. The set K is a viability domain for (8) if for all $x_0 \in K$ there exists a solution to (8) which is viable in K.

Moreover if F is a Marchaud map[4] *and K is bounded and sleek, then*

(ii) *for every $(t_0, x_0) \in [0, \infty) \times K$ there exists a solution of* (5) *or equivalently of* (6).

(iii) *the restriction of the map $(t_0, x_0) \in [0, T] \times K \to S_F(t_0, x_0)$ to a compact set C is compact into $[0, \infty) \times K \times W^{1,1}(0, \infty\ ; K)e^{-bt}$ for all b with $b > a$. Here $S_F(t_0, x_0)$ denotes the set of solutions to* (5) *starting from (t_0, x_0).*

Before giving the proof, we note that the first part of the above proposition is a generalization of Theorem 10.1.1 in [2] where the set K is supposed to be sleek; here K is only bounded. The second part recalls well-known existence and compactness results (see [1] and [2]).

Proof. (i) Using Proposition 0.6.4 from [1] we deduce that

$$\Pi_{\overline{co}T_K(x)} F(x) \subset F(x) - N_K(x) \text{ for all } x \in K,$$

and, consequently, a solution to (6) is also a solution to (5).

Conversely, if $x(t) \in K$ for all $t \geq t_0$, we have

$$\lim_{h \to 0} \frac{x(t+h) - x(t)}{h} \in T_K(x(t)) \text{ and } \lim_{h \to 0} \frac{x(t) - x(t-h)}{h} \in -T_K(x(t)) \text{ for a.e. } t \geq t_0,$$

so $x'(t) \in T_K(x(t)) \cap -T_K(x(t)) \subset N_K(x(t))^{\perp}$ a.e. $t \geq t_0$.

Let $t \geq t_0$ be a derivability point of $x(\cdot)$, and let $x'(t) = f(t) - p(t)$ with $f(t) \in F(x(t))$ and $p(t) \in N_K(x(t))$.

The above arguments say that $\langle x'(t) - f(t), x'(t) \rangle = 0$.

Thus, $x'(t) \in \Pi_{\overline{co}T_K(x(t))} f(t) \subset \Pi_{\overline{co}T_K(x(t))} F(x(t))$ for a.e. $t \geq t_0$.

(ii) We prove now the existence of a solution to the differential inequality (5). If K is sleek, then the map $x \to N_K(x)$ has a closed graph.

For all $x \in K$, we set $H(x) = F(x) - a(1 + ||x||)B \cap N_K(x)$, where B denotes the unit ball of $\mathbb{R}^N$.

Because the map $x \to a(1 + ||x||)B \cap N_K(x)$ is Marchaud, H is also Marchaud. Hence by Theorem 2.1.3 in [1] the existence of solutions of (5) follows.

Let us prove that the closed subset K is a viability domain for the differential inclusion (5).

Indeed, using the equality $I - \Pi_{N_K(x)} = \Pi_{T_K(x)}$, we have that for any $x \in K$ and $f \in F(x)$, $f - \Pi_{N_K(x)} f \in (F(x) - N_K(x)) \cap T_K(x)$.

Using the estimation $||\Pi_{N_K(x)} f|| \leq ||f|| \leq a(1 + ||x||)$, we get that $\Pi_{N_K(x)} f \in a(1 + ||x||)B \cap N_K(x)$ and consequently $f - \Pi_{N_K(x)} f \in H(x) \cap T_K(x)$.

The above arguments say that H satisfies the hypotheses of viability theorem 4.2.1 of [1], and since $H(x) \subset F(x) - N_K(x)$, the second part ensues.

(iii) See Theorem 2.2.1 in [1]. □

Now, let us begin a short study of the optimal control problem with reflected trajectories. From now on, we consider that the set valued map F is given by the equality

$$F(x) = f(x, U) = \{f(x, u), u \in U\} \text{ for all } x \in K.$$

[4] A set valued map F from $\mathbb{R}^N$ onto $\mathbb{R}^N$ is called Marchaud map if F is u.s.c. with nonempty compact convex values and has a linear growth.

We denote by $S_f(t_0, x_0)$ the set of absolutely continuous solutions to

$$\begin{cases} \text{(i) } x'(t) \in f(x(t), u(t)) - N_K(x(t)) \text{ for almost all } t \geq t_0, \\ \text{(ii) } x(t) \in K \text{ for all } t \geq t_0,\ x(t_0) = x_0 \in K \text{ for all } u(\cdot) \in \mathcal{U}(t_0), \end{cases} \tag{9}$$

and by $S_F(t_0, x_0)$ the set of absolutely continuous solutions to

$$\begin{cases} \text{(i) } x'(t) \in F(x(t)) - N_K(x(t)) \text{ for almost all } t \geq t_0, \\ \text{(ii) } x(t) \in K \text{ for all } t \geq t_0,\ x(t_0) = x_0 \in K. \end{cases} \tag{10}$$

We will prove now that (9) and (10) are equivalent. In this paper, we will use one of these systems to simplify our proofs.

PROPOSITION 6. *Suppose that K is a compact sleek set and (H_f) holds.*

(i) *If $x(\cdot)$ is a solution to* (10) *starting from $(t_0, x_0) \in [0, T] \times K$, then there exists $u(\cdot) \in \mathcal{U}(t_0)$ such that $x(\cdot)$ is equal to $x(\cdot; t_0, x_0, u(\cdot))$, the solution of* (9).

(ii) *As a direct consequence of* (i),

$$S_F(t_0, x_0) = S_f(t_0, x_0) \text{ for all } (t_0, x_0) \in [0, \infty) \times K.$$

Proof. We essentially use the fact that K is sleek (which implies that the application $x \to N_K(x)$ has a closed graph) and Theorem 1.14.1 from [1]. Consider $\Phi(t) := \{v \in U |\ x'(t) \in f(x(t), v) - N_K(x(t))\}$ for a.e. $t \geq t_0$. We can prove that the multivalued function Φ has a measurable selection which gives our measurable control $u(\cdot) \in \mathcal{U}(t_0)$. □

Moreover, with an easy computation, using the fact that K is proximal retract and Gronwall's inequality, we obtain the following estimation.

LEMMA 7. *Assume that (H_f) holds true and K is a bounded proximal retract. Then for $x_0(\cdot) \in S_f(t_0, x_0)$, $x_1(\cdot) \in S_f(t_1, x_1)$ with fixed $u(\cdot) \in \mathcal{U}(t_0)$ and for $t \geq t_1 \geq t_0$, there exists $C > 0$, a constant depending on t, such that*

$$\|x_0(t; t_0, x_0, u(\cdot)) - x_1(t; t_1, x_1, u(\cdot))\| \leq C(\|x_0 - x_1\| + |t_0 - t_1|).$$

We omit the proof of Lemma 7 because it is an easy adaptation of Lemma 4.4, p. 143, proved in [6]. As a direct consequence of the above estimation we obtain the following.

COROLLARY 8. *Assume that (H_f) holds true and K is a bounded proximal retract. Then for fixed $u(\cdot) \in \mathcal{U}(t_0)$ there exists an unique solution of* (2).

2.4. The optimal control problem. First, we give some standard results concerning the regularity of V without proof. Later we shall prove the existence and the uniqueness of viscosity solutions of (HJBI).

LEMMA 9. *Suppose that (H_f) holds true and K is a compact proximal retract. Then we have the following:*

(i) *(Existence of an optimal control.) If g is l.s.c., then V is l.s.c. and there exists an optimal trajectory starting from each point $(t_0, x_0) \in [0, T] \times K$, i.e., there exists $\bar{x}(\cdot) \in S_F(t_0, x_0)$ such that*

$$V(t_0, x_0) = g(\bar{x}(T; t_0, x_0, \bar{u}(\cdot))) \text{ for all } (t_0, x_0) \in [0, T] \times K.$$

(ii) *If g is a Lipschitz function, then V is locally Lipschitz and bounded.*

Next we give the Bellman dynamic programming.

PROPOSITION 10 (dynamic programming principle). *Let $g : K \to \mathbb{R}$ be a bounded function, K a compact proximal retract, and suppose that (H_f) holds. Then, for all $(t_0, x_0) \in [0, T] \times K$ we have*

$$V(t_0, x_0) = \inf_{x \in S_F(t_0, x_0)} V(t_0 + h, x(t_0 + h)) \text{ with } h > 0 \text{ small enough.} \tag{11}$$

3. The Hamilton–Jacobi partial differential variational inequality.

3.1. Existence result. The aim of this section is to provide an existence and a comparison result for viscosity solutions to a partial differential inequality with a kind of boundary conditions for nonsmooth sets, which generalizes first order Hamilton–Jacobi equations with Neumann conditions for smooth sets.

Using the dynamic programming principle we prove that the value function for the control problem (1), (2) is the viscosity solution of (HJBI) in the sense of Definition 3.

PROPOSITION 11. *If K is a compact proximal retract, g a Lipschitz function, and (H_f) holds true, then V is a locally Lipschitz viscosity solution of* (HJBI) *with the final condition $V(T,x) = g(x)$ for all $x \in K$.*

This theorem can be considered as an existence result of solutions to (HJBI).

Proof. First we prove that V is a supersolution.

We consider $(t_0, x_0) \in \arg\min(V - \psi), \psi \in C^1$, with

$$V(t_0, x_0) = \psi(t_0, x_0) \text{ and } V(t, x) \geq \psi(t, x)$$

in a neighborhood of (t_0, x_0).

For all $h > 0$ small enough, there exists $x_h(\cdot) \in S_F(t_0, x_0)$ such that

$$\psi(t_0, x_0) + h^2 = V(t_0, x_0) + h^2 \geq V(t_0 + h, x_h(t_0 + h)) \geq \psi(t_0 + h, x_h(t_0 + h)).$$

For a subset A of $\mathbb{R}^N$ we denote by $B(A, \varepsilon) = \{x \in \mathbb{R}^N | \inf_{y \in A} ||y - x|| \leq \varepsilon\}$. $B(A, \varepsilon)$ denotes the neighborhood of the set A with a radius equal to $\varepsilon > 0$.

Let M be a bound of F on K. Using the Lipschitz property of $F(\cdot)$ and the upper semicontinuity of $N_K(\cdot) \cap B(0, M)$, we have that, for all $\varepsilon > 0$, there exists an $h > 0$ small enough such that the following inclusions hold:

$$\begin{aligned}
\frac{1}{h}(x_h(t_0 + h) - x_0) &\in \frac{1}{h}\int_{t_0}^{t_0+h} (F(x_h(s)) - N_K(x_h(s)) \cap B(0, M))ds \\
&\subset \frac{1}{h}\int_{t_0}^{t_0+h} (F(x_0))ds + B(0,1)\frac{1}{h}\int_{t_0}^{t_0+h} L||x_h(s) - x_0||ds \\
&\quad - \frac{1}{h}\int_{t_0}^{t_0+h} B(N_K(x_0) \cap B(0, M), \varepsilon)ds \\
&= F(x_0) + B(0,1)\frac{1}{h}\int_{t_0}^{t_0+h} L||x_h(s) - x_0||ds - B(N_K(x_0) \cap B(0, M), \varepsilon).
\end{aligned}$$

Hence for all $\varepsilon > 0$, there exists a sequence h_n such that $\lim_{n\to\infty} h_n = 0$ and

$$\lim_n \frac{1}{h_n}(x_{h_n}(t_0 + h_n) - x_0) \in F(x_0) - B(N_K(x_0) \cap B(0, M), \varepsilon).$$

Letting $\varepsilon \to 0$ we obtain that

$$\lim_n \frac{1}{h_n}(x_{h_n}(t_0 + h_n) - x_0) \in F(x_0) - N_K(x_0) \cap B(0, M). \tag{12}$$

Moreover,

$$\begin{aligned}
&\lim_n \left(\frac{1}{h_n}[\psi(t_0 + h_n, x_{h_n}(t_0 + h_n; t_0, x_0, u(\cdot))) - \psi(t_0, x_0)] - h_n\right) \\
&= \lim_n \left(\frac{1}{h_n}\left[\psi\left(t_0 + h_n, x_0 + h_n\left(\frac{1}{h_n}(x_{h_n}(t_0 + h_n) - x_0)\right) - \psi(t_0, x_0)\right] - h_n\right).
\end{aligned} \tag{13}$$

Using (12) and (13) we have the following.

First case ($x_0 \in \text{int}K$). Then $N_K(x_0) = \{0\}$ and there exists $u \in U$ such that

$$\frac{\partial \psi}{\partial t}(t_0, x_0) + \left\langle \frac{\partial \psi}{\partial x}(t_0, x_0),\ f(x_0, u) \right\rangle \leq 0,$$

and consequently

$$\frac{\partial \psi}{\partial t}(t_0, x_0) + \inf_{u \in U} \left\langle \frac{\partial \psi}{\partial x}(t_0, x_0), f(x_0, u) \right\rangle \leq 0.$$

Second case ($x_0 \in \partial K$). Then $\{0\} \subset N_K(x_0)$ and there exist $u \in U$, $y_u \in N_K(x_0)$ such that:

$$\frac{\partial \psi}{\partial t}(t_0, x_0) + \left\langle \frac{\partial \psi}{\partial x}(t_0, x_0),\ f(x_0, u) - y_u \right\rangle \leq 0.$$

So, there exists $w_0 = y_u \in N_K(x_0) \cap B(0, M)$ such that

$$\frac{\partial \psi}{\partial t}(t_0, x_0) + \inf_{u \in U} \left\langle \frac{\partial \psi}{\partial x}(t_0, x_0),\ f(x_0, u) \right\rangle - \left\langle w_0,\ \frac{\partial \psi}{\partial x}(t_0, x_0) \right\rangle \leq 0$$

and V is a supersolution.

The proof of the fact that V is subsolution is similar and we omit it. □

3.2. Uniqueness result. This section concerns the uniqueness of the viscosity solutions of (HJBI). The importance of this result leads us to treat it separately. Moreover, the characterization of the value function as the unique solution of (HJBI) ensues.

THEOREM 12 (uniqueness result in the Lipschitz case). *Assume that* (H_f) *holds true. Let K be a compact proximal retract and g be a Lipschitz function. Then there exists at most one uniformly continuous viscosity solution of* (HJBI) *which satisfies the final condition $V(T, x) = g(x)$ for all $x \in K$.*

The proof can be adapted from Evans [7]. We only underline that the difference to Evans' proof is due to the monotonicity of the multivalued function $x \to N_K(x) \cap B(0, M) + cx$.

4. The discontinuous case. In this section we investigate the value function V when $g : K \to \mathbb{R}$ is supposed to be bounded. In this case the value is only a bounded function. A natural question is how to use the viscosity theory to describe V. Here we establish a relation between the value and the viscosity sub or supersolutions of (HJBI). This kind of problem has been studied for the Bolza problem in [15], [16].

The main point of this section is to prove the following.

THEOREM 13. *Suppose that K is a proximal retract and* (H_f) *holds.*

(i) *If g is bounded, then for every $(t, x) \in [0, T] \times K$*

$$V(t, x) = \inf\{\psi(t, x) |\ \psi \text{ l.s.c. supersolution of (HJBI)};\ \psi(T, \cdot) \geq g(\cdot)\} \text{ and}$$
$$V(t, x) = \sup\{\varphi(t, x) |\ \varphi \text{ u.s.c. subsolution of (HJBI)};\ \varphi(T, \cdot) \leq g(\cdot)\}.$$

(ii) *If g is l.s.c., then*

$$V = \min\{\psi \mid \psi \text{ l.s.c. supersolution of (HJBI)};\ \psi(T, \cdot) \geq g(\cdot)\}.$$

(iii) *If g is u.s.c., then*

$$V = \max\{\varphi \mid \varphi \text{ u.s.c. subsolution of (HJBI) } ;\ \varphi(T,\cdot) \le g(\cdot)\}.$$

Before giving the proof, we note that the above theorem allows us to get, in particular, a stronger uniqueness result. More precisely, if ψ is an l.s.c. supersolution and φ is a u.s.c. subsolution of (HJBI) satisfying $\psi(T,\cdot) \ge \varphi(T,\cdot)$ on K, then $\psi \ge \varphi$ on $[0,T] \times K$.

Proof. (i) Let ψ be an l.s.c. supersolution of (HJBI) with $\psi(T,\cdot) \ge g(\cdot)$. We want to prove that $V \le \psi$ on $[0,T] \times K$. To do this we use the following lemma proved in the appendix.

LEMMA 14. *Assume that (H_f) holds true, K is a compact proximal retract, and $\psi : (0,T) \times K \to \mathbb{R}$ is an l.s.c. viscosity supersolution of* (HJBI). *Then for every $(t_0,x_0) \in (0,T) \times K$ there exists a solution $x(\cdot;t_0,x_0,u(\cdot))$ of* (2) *such that*

$$\psi(t,x(t)) \le \psi(t_0,x_0) \text{ for all } t \in [t_0,T]. \tag{14}$$

So we obtain that there exists an $x(\cdot) \in S_F(t_0,x_0)$ satisfying (14). Hence we have $V(t_0,x_0) \le g(x(T)) \le \psi(T,x(T)) \le \psi(t_0,x_0)$.

Using the very definition of the value function, for all $\varepsilon > 0$ there exists $u_\varepsilon(\cdot) \in \mathcal{U}(t_0)$ such that $g\left(x\left(T;t_0,x_0,u_\varepsilon(\cdot)\right)\right) < V(t_0,x_0) + \varepsilon$.

For $M_1 > \sup_{x\in K} g(x)$ we define $l_\epsilon : \mathbb{R}^N \to \mathbb{R}$ by the following formula:

$$l_\epsilon(x) = \begin{cases} g\left(x\left(T;t_0,x_0,u_\varepsilon(\cdot)\right)\right) & \text{if } x = x\left(T;t_0,x_0,u_\varepsilon(\cdot)\right), \\ M_1, & \text{if } x \ne x\left(T;t_0,x_0,u_\varepsilon(\cdot)\right). \end{cases}$$

Obviously l_ε is l.s.c. so V_{l_ε}, the value function of the control problem with g replaced by l_ε, is a l.s.c. supersolution of (HJBI) and $V_{l_\epsilon}(T,\cdot) = l_\epsilon(\cdot) \ge g(\cdot)$.

We also have $V_{l_\epsilon}(t_0,x_0) = g\left(x\left(T;t_0,x_0,u_\varepsilon(\cdot)\right)\right) \le V(t_0,x_0) + \varepsilon$. By the definition of the infimum we obtain

$$V(t_0,x_0) = \inf\{\psi(t_0,x_0) \mid \psi \text{ l.s.c. supersolution of (HJBI); } \psi(T,\cdot) \ge g(\cdot)\}.$$

Now let us prove the second relation. Let $(t_0,x_0) \in (0,T) \times K$. We denote by $A(t_0,x_0) := \{x(T) |\ x(\cdot) \in S_F(t_0,x_0)\}$. By Proposition 5 $A(t_0,x_0)$ is a compact set. We define $h : \mathbb{R}^N \to \mathbb{R}$ by

$$h(y) = \begin{cases} V(t_0,x_0) \text{ if } y \in A(t_0,x_0), \\ m \text{ if } y \in \mathbb{R}^N \setminus A(t_0,x_0), \end{cases}$$

where $m = \inf_{x\in K} g(x)$. So, h is u.s.c. because $A(t_0,x_0)$ is closed.

Obviously we have that $V_h(t_0,x_0) = V(t_0,x_0)$ and $V_h(T,\cdot) \le h(\cdot) \le g(\cdot)$.

Moreover, V_h is (see Lemma 21 in the appendix) a u.s.c. subsolution for (HJBI).

Now, to complete the proof of (i) we use the definition of the supremum and the following lemma proved in the appendix.

LEMMA 15. *Assume that (H_f) holds true, K is a compact proximal retract, and $\varphi : (0,T) \times K \to \mathbb{R}$ is a u.s.c. viscosity subsolution of* (HJBI) *such that $\varphi(T,x) \le g(x)$ for all $x \in K$. Then $V(t,x) \ge \varphi(t,x)$ for every $(t,x) \in (0,T) \times K$.*

The proofs of (ii) and (iii) are direct consequences of Lemma 14, Lemma 15, and Lemma 21. ∎

5. On l.s.c. solutions of HJBI with reflection on smooth sets. If $g : \mathbb{R}^N \to \mathbb{R}$ is an l.s.c. function, then V is also l.s.c. In [5], [8] a modification of the concept of viscosity solutions for semicontinuous functions was proposed. This approach is based on a construction of "touching from one side" functions, which is usual for viscosity solutions theory.

We suppose that K is a $\mathrm{C}^{1,1}$ submanifold with boundary. If we denote by $n(x)$ the unit outward normal to K at $x \in \partial K$, the normal cone $N_K(x)$ is generated by $n(x)$, i.e., $N_K(x) = [0,\infty)n(x)$ for $x \in \partial K$ and $N_K(x) = \{0\}$ for $x \in \mathrm{int}K$.

We propose a definition for l.s.c. solutions to the HJBI of Barron–Jensen–Frankowska type.

DEFINITION 16. *A viscosity l.s.c. solution of* (HJBI) *is a function* $\psi : [0,T]\times K \to \mathbb{R}$ *such that*

$$\text{for any } \phi \in C^1 \text{ and } (t_0,x_0) \in \arg\min(\psi-\phi),$$

$$\text{if } (t_0,x_0) \in [0,T)\times \mathrm{int}K, \text{ we have } \frac{\partial\phi}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial\phi}{\partial x}(t_0,x_0)\right) \le 0;$$

$$\text{if } (t_0,x_0) \in (0,T]\times \mathrm{int}K, \text{ we have } \frac{\partial\phi}{\partial t}(t_0,x_0) + H\left(x_0, \frac{\partial\phi}{\partial x}(t_0,x_0)\right) \ge 0;$$

$$\text{if } (t_0,x_0) \in [0,T)\times \partial K, \text{ then there exists } u \in U \text{ such that}$$

$$\frac{\partial\phi}{\partial t}(t_0,x_0) + \left\langle (f(x_0,u) - \Pi_{N_K(x)} f(x_0,u)), \frac{\partial\phi}{\partial x}(t_0,x_0)\right\rangle \le 0;$$

$$\text{if } (t_0,x_0) \in (0,T]\times \partial K \text{ and } \min_{u\in U}\langle f(x_0,u), n(x_0)\rangle > 0, \text{ then for all } u \in U,$$

$$\frac{\partial\phi}{\partial t}(t_0,x_0) + \left\langle (f(x_0,u) - \Pi_{N_K(x)} f(x_0,u)), \frac{\partial\phi}{\partial x}(t_0,x_0)\right\rangle \ge 0.$$

Note that in $\mathrm{int}K$ the equation is satisfied in the Barron–Jensen–Frankowska sense (see [5], [8]).

We obtain the following uniqueness results.

PROPOSITION 17. *Suppose that K is a $C^{1,1}$ submanifold with boundary and for any $u \in U$ and for all $x_0 \in K$ we have $\langle f(x_0,u), n(x_0)\rangle < 0$. If g is l.s.c. and (H_f) holds true, then the value function V is the unique l.s.c. viscosity solution of* (HJBI) *which verifies the final condition $V(T,x) = g(x)$ for all $x \in K$, and for all $(t,x) \in (0,T]\times\partial K$ we have*

$$\lim \inf_{\substack{(t',x')\to(t,x)\\ x\in intK}} V(t',x') = V(t,x).$$

The proof is similar to the proof of Theorem 2.3 in [8].

PROPOSITION 18. *Suppose that K is a $C^{1,1}$ submanifold with boundary and for any $u \in U$ and for all $x_0 \in K$ we have $\langle f(x_0,u), n(x_0)\rangle > 0$. If g is l.s.c. and (H_f) holds true, then the value function V is the unique l.s.c. viscosity solution of* (HJBI) *which verifies the final condition $V(T,x) = g(x)$ for all $x \in K$, and for all $(t,x) \in (0,T]\times\partial K$ we have*

$$\lim \inf_{\substack{(t',x')\to(t,x)\\ x\in intK}} V(t',x') = V(t,x).$$

Proof. Step 1. V satisfies Definition 16. The proof of the first inequality is similar to the proof of the fact that V is an l.s.c. supersolution of (HJBI).

For proving the second inequality we observe that for all $x_0 \in \partial K$ and $u \in U$,

$$\Phi_u(x_0) := f(x_0,u) - \Pi_{N_K(x)} f(x_0,u) \in \Pi_{T_K(x)} f(x_0,u) = \Pi_{\partial T_K(x)} f(x_0,u).$$

Consequently, $-f(x_0,u) + \Pi_{N_K(x)} f(x_0,u) \in -\Pi_{\partial T_K(x)} f(x_0,u)$.

As K is a $C^{1,1}$ submanifold and for all $x_0 \in K$, $\min_{u\in U}\langle f(x_0,u), n(x_0)\rangle > 0$, $\Phi_u(\cdot)$ is a Lipschitz application on ∂K. Moreover, ∂K is locally invariant (see [2, viability theorem 3.2.4] by $\Phi_u(\cdot)$ and by $-\Phi_u(\cdot)$ (because $\partial T_K(x) = -\partial T_K(x)$).

Now let $(t_0,x_0) \in \arg\min (V-\phi)$, $\phi \in C^1$. We have two cases.

First case ($x_0 \in \partial K$). For a fixed constant control $u \in U$, we consider the solution of

$$\begin{cases} x'(t) = -f(x(t),u) + \Pi_{N_K(x(t))} f(x(t),u), \\ x(t_0) = x_0, \end{cases}$$

which stays in ∂K because of the invariance properties of $\Phi_u(\cdot)$. Using the dynamic programming principle we get $V(t_0,x_0) \geq V(t_0-h, x(t_0-h))$ with $h>0$ small enough. So, $\phi(t_0,x_0) \geq \phi(t_0-h,x(t_0-h))$ with $h>0$ small enough. Recall that $\phi \in C^1$ and consequently

$$\frac{\partial \phi}{\partial t}(t_0,x_0) + \left\langle (f(x_0,u) - \Pi_{N_K(x)} f(x_0,u)), \frac{\partial \phi}{\partial x}(t_0,x_0) \right\rangle \geq 0.$$

Second case ($x_0 \in \mathrm{int}K$). $N_K(x_0) = \{0\}$ and for all $u \in U$, because f is a Lipschitz application, there exists $B(x_0;r_u)$, $r_u > 0$, such that the solution to

$$\begin{cases} x'(t) = -f(x(t),u), \\ x(t_0) = x_0 \end{cases}$$

stays in $B(x_0;r_u)$. Using the dynamic programming principle, for $h>0$ small enough $V(t_0,x_0) \geq V(t_0-h,x(t_0-h))$ so $\phi(t_0,x_0) \geq \phi(t_0-h,x(t_0-h))$. Because $\phi \in C^1$ we obtain $\frac{\partial \phi}{\partial t}(t_0,x_0) + \langle (f(x_0,u), \frac{\partial \phi}{\partial x}(t_0,x_0)\rangle \geq 0$. This allows us to say that V is an l.s.c. solution of (HJBI).

Step 2 (uniqueness). Now let us prove that V is the unique l.s.c. solution of (HJBI). Let W be an l.s.c. solution of (HJBI) with $W(T,x) = g(x)$ for all $x \in K$. We have already proved (see Theorem 13) that $W \geq V$.

For the reverse inequality we consider $(t_0,x_0) \in (0,T) \times K$ and $x(\cdot) \in S_F(t_0,x_0)$. There exists $u(\cdot) \in \mathcal{U}(t_0)$ such that $x(\cdot) = x(\cdot;t_0,x_0,u(\cdot))$. We have two cases.

First case ($x(T) \in \mathrm{int}K$). For a fixed $u(\cdot) \in \mathcal{U}(t_0)$, ∂K is invariant by $\Phi_{u(.)}(\cdot)$ and $\Phi_{u(.)}(\cdot)$ is Lipschitz in the second variable, so we have that $x([t_0,T]) \subset \mathrm{int}K$.

By the measurable viability theorem (see Theorem 4.7 in [10], [2]) $Epi(W)$ is viable for the dynamics given by $(t,x,y) \to (-1, -f(x(t),u(t)), 0)$. For the solution starting from $(T,x(T),W(T,x(T)))$, we have for all $t \in [t_0,T]$, $W(T-t,x(T-t)) \leq W(T,x(T))$, so $W(t_0,x_0) \leq W(T,x(T)) = g(x(T))$.

Second case ($x(T) \in \partial K$). Denote by τ the first time with the property $x(\tau) \in \partial K$. Using invariance properties of $\Phi_{u(.)}(\cdot)$ and because $\Phi_{u(.)}(\cdot)$ is Lipschitz in the second variable, we obtain that $x([t_0,\tau)) \subset \mathrm{int}K$ and $x([\tau,T]) \subset \partial K$.

As in the above case, we apply the measurable viability theorem (see Theorem 4.7 in [10], [2]) to $Epi(W)$, on the one hand, to $[\tau,T]$ for the dynamics given by $(t,x,y) \to (-1, -f(x(t),u(t)) + \Pi_{N_K(x(t))} f(x(t),u(t)), 0)$ for the solution starting from $(T,x(T),W(T,x(T)))$ and, on the other hand, to $[t_0,\tau_n)$ for the dynamics given by

$(t,x,y) \to (-1, -f(x(t),u(t)), 0)$ for the solution starting from $(\tau, x(\tau), W(\tau, x(\tau)) = \lim_n (\tau_n, x_n, W(\tau, x(\tau)), x_n \in \text{int}K$.

We have $W(t_0,x_0) \le W(\tau, x(\tau))$ and $W(\tau, x(\tau)) \le W(T, x(T)) = g(x(T))$. Consequently, by definition of the value function $W(t_0,x_0) \le V(t_0,x_0)$. □

We note that here we can obtain uniqueness for l.s.c. solutions only in two (extremal) cases, where the vector field $f(x,u)$ is pointing only outside of the domain or only inside. For the intermediate situation it seems that we cannot obtain uniqueness (see the counterexample given below). The lack of uniqueness can be a consequence of the fact that in the intermediate situation we lose the Lipschitz regularity of $\Phi_u(\cdot)$ in ∂K and the idea of the above proof will fail.

Counterexample. Now we will show that a uniqueness result is not possible using our definition without imposing boundary properties on our dynamics as we did in the above propositions. We do this by giving a counterexample.

Let $K = [0,1] \subset \mathbb{R}$. For a dynamics given by $f = 0$ and $g = 1$ the value function is $V(t,x) = 1$ for all $(t,x) \in [0,1] \times [0,1]$. Moreover V is an l.s.c. solution of HJBI in the sense of our definition. Define

$$u(t,x) = \begin{cases} 1 \text{ if } (t,x) \in [0,1] \times (0,1], \\ 0 \text{ if (t,x)} \in [0,1] \times \{0\}. \end{cases}$$

It is easy to verify that u is also an l.s.c. solution for the HJBI and we do not have uniqueness because $\langle f(x_0), n(x_0) \rangle = 0$ for all $x_0 \in \partial K$.

For another definition of the discontinuous solution Ley [12] obtained a counterexample proving that there is no uniqueness to HJB with a notion of the solution in the Ishii–Barles–Perthame sense.

6. Appendix. Let us give the proof of Lemma 14 and Lemma 15. We shall use the following classical viability theorem and the fact that the definition of super and subsolutions to (HJBI) can be written equivalently in terms of subdifferentials. (See [15] to get formulations of viscosity solutions in terms of subdifferentials of the PDE associated to the Mayer control problem with $K = R^N$.)

THEOREM 19 (see [2, viability theorem 3.2.4]). *Assume that G is a Marchaud map and let $D \subset \mathbb{R}^N$ be closed. If for every $z \in D$ we have*

$$\text{for all } p \in N_D(z), \quad \min_{y \in G(z)} \langle y, p \rangle \le 0, \tag{15}$$

then for every $x_0 \in D$, $t_0 < T$, there exists a solution $x(\cdot)$ to the Cauchy problem $x'(s) \in G(x(s))$, $x(t_0) = x_0$ such that $x(t) \in D$ for all $t \in [t_0, T]$.

Now we give the proof of Lemma 14 and Lemma 15.

Proof of Lemma 14. Fix $t_0 \in (0,T)$. We set

$$D_\psi = \text{cl}(\{(t,x,r) \ : \ t \in (0,T], \ x \in K, \ r \ge \psi(t,x)\}) \cup [T, \infty) \times K \times \mathbb{R},$$

$$\tilde{F}(t,x,r) = \begin{cases} 0 \text{ if } t < 0, \\ \frac{t}{t_0}(1, F(x) - N_K(x) \cap B(0,M), 0) \text{ if } t \in [0, t_0], \\ (1, F(x) - N_K(x) \cap B(0,M), 0) \text{ if } t \in [t_0, T], \\ (1, F(x) - N_K(x) \cap B(0,M), 0) \text{ if } t > T, \end{cases}$$

where cl denote the closure and M is a bound of F on K. We show that (15) holds true for $\tilde{F}$ and D_ψ.

First case ($x_0 \in \text{int}K$). Let $z_0 = (s_0, x_0, r_0 := \psi(t_0,x_0)) \in D_\psi$. If $s_0 = 0$, then $\tilde{F} = 0$. Obviously (15) holds.

If $s_0 \geq T$ and $(p_s, p_x, p_r) \in N_{D_\psi}(s_0, x_0, r_0)$, then $p_s \leq 0$, $p_x = 0$, $p_r = 0$. Hence (15) holds.

It remains to consider the case $s_0 \in (0, T)$. We have $N_{D_\psi}(s_0, x_0, r_0) \subset N_{D_\psi}(s_0, x_0, \psi(s_0, x_0))$. Let $(p_s, p_x, p_r) \in N_{D_\psi}(s_0, x_0, \psi(s_0, x_0))$.

If $p_r < 0$, then $(p_s/-p_r,\, p_x/-p_r) \in \partial_- \psi(s_0, x_0)$ (see Proposition 4.1 in [9]).

Since ψ is a supersolution of (HJBI) there exists $y_0 \in N_K(x_0)$ such that

$$\frac{p_s}{-p_r} + \min_{z \in F(x_0)} \left\langle z,\ \frac{p_x}{-p_r} \right\rangle - \left\langle y_0,\ \frac{p_x}{-p_r} \right\rangle \leq 0 \quad \text{and}$$
$$\frac{p_s}{-p_r} + \min_{z \in \{F(x_0) - N_K(x_0) \cap B(0,M)\}} \left\langle z,\ \frac{p_x}{-p_r} \right\rangle \leq 0.$$

Hence $\min_{\tilde{y} \in \tilde{F}(s_0, x_0, r_0)} \langle \tilde{y}, (p_s, p_x, p_r) \rangle \leq 0$.

Now we consider the case $p_r = 0$. By a Rockafellar's lemma (see, for instance, Lemma 4.2 in [9]) there exists a sequence $s_n \to s_0$, $x_n \to x_0$, and $p_{s_n} \to p_s$, $p_{x_n} \to p_x$, $p_{r_n} \to 0$, $p_{r_n} < 0$ such that $(p_{s_n}, p_{x_n}, p_{r_n}) \in N_{D_\psi}(p_{s_n}, p_{x_n}, p_{r_n})$. Since $p_{r_n} < 0$ we obtain from the previous case that

$$\min_{\tilde{y}_n \in \tilde{F}(s_n, x_n, r_n)} \langle \tilde{y}, (p_{s_n}, p_{x_n}, p_{r_n}) \rangle \leq 0.$$

We get $\min_{\tilde{y} \in \tilde{F}(s_0, x_0, r_0)} \langle \tilde{y}, (p_s, p_x, p_r) \rangle \leq 0$, because $\tilde{F}$ is Marchaud.

Second case ($x_0 \in \partial K$). Let $z_0 = (s_0, x_0, r_0 := \psi(t_0, x_0)) \in D_\psi$. If $s_0 = 0$, then $\tilde{F} = 0$. Obviously (15) holds true.

If $s_0 \geq T$ and $(p_s, p_x, p_r) \in N_{D_\psi}(s_0, x_0, r_0)$, then $p_s \leq 0$, $p_x \in N_K(x_0)$, $p_r = 0$. Hence $[F(x_0) - N_K(x_0)] \cap T_K(x_0) \neq \emptyset$ and (15) holds.

It remains to consider $s_0 \in (0, T)$, which is similar to the first case.

Finally we obtain $\min_{\tilde{y} \in \tilde{F}(s_0, x_0, r_0)} \langle \tilde{y}, (p_s, p_x, p_r) \rangle \leq 0$.

In view of the above theorem we have a solution $z(\cdot)$ to the Cauchy problem $z'(s) \in \tilde{F}(z(s))$, $z(t_0) = z_0$. Let $z(s) = (t(s), x(s), r(s))$.

By the definition of $\tilde{F}$ we have $t(s) = s$, $r(s) = r_0 = \psi(t_0, x_0)$. Hence, (14) holds true and the proof is completed. □

Proof of Lemma 15. The proof is divided into several steps.

First step. We fix $t_0 \in (0, T)$, $u(\cdot) \in \mathcal{U}(t_0)$ such that $u(\cdot)$ is a continuous function. We set

$$D_\varphi = \mathrm{cl}(\{(t, x, r)\ :\ t \in (0, T],\ x \in K,\ r \leq \varphi(t, x)\}) \cup [T, \infty) \times K \times \mathbb{R},$$
$$G(t, x, r) = \begin{cases} 0 \text{ if } t < 0, \\ \frac{t}{t_0}(1, F(x, u(t)) - N_K(x) \cap B(0, M), 0) \text{ if } t \in [0, t_0], \\ (1, F(x, u(t)) - N_K(x) \cap B(0, M), 0) \text{ if } t \in [t_0, T], \\ (1, F(x, u(t)) - N_K(x) \cap B(0, M), 0) \text{ if } t > T, \end{cases}$$

and we want to prove that for every $(t_0, x_0, \varphi(t_0, x_0)) \in (0, T) \times K \times \mathbb{R}$ the solution $x(\cdot; t_0, x_0, u(\cdot))$ to (2) satisfies

$$\varphi(t, x(t)) \geq \varphi(t_0, x_0) \text{ for all } t \in [t_0, T]. \tag{16}$$

Since φ is a u.s.c. viscosity subsolution of (HJBI) we have

$$\text{for any } \phi \in C^1 \text{ and } (t_0, x_0) \in \arg\max(\varphi - \phi),$$
$$\text{there exists } z_0 \in N_K(x_0) \text{ such that}$$
$$\frac{\partial \phi}{\partial t}(t_0, x_0) + H\left(x_0, \frac{\partial \phi}{\partial x}(t_0, x_0)\right) - \left\langle z_0, \frac{\partial \phi}{\partial x}(t_0, x_0)\right\rangle \geq 0,$$
$$\text{so } -\frac{\partial \phi}{\partial t}(t_0, x_0) + \min_{y_0 \in N_K(x_0) \cap B(0,M)} \left\{ \left\langle (f(x_0, u(t_0)) - y_0), -\frac{\partial \phi}{\partial x}(t_0, x_0)\right\rangle \right\} \leq 0.$$

Using the same arguments as we used in the proof of the above lemma and because G is a Marchaud map, we obtain

$$\min_{y_0 \in N_K(x_0) \cap B(0,M)} \langle (f(x_0, u(t_0)) - y_0), (p_s, p_x, p_r)\rangle \leq 0.$$

So, for every $(p_t, p_x, p_r) \in N_{D_\varphi}(t_0, x_0, \varphi(t_0, x_0))$,

$$\min_{\tilde{y} \in G(t_0, x_0, \varphi(t_0, x_0))} \langle \tilde{y}, (p_s, p_x, p_r)\rangle \leq 0.$$

Using Theorem 19 we obtain that for every $(t_0, x_0, \varphi(t_0, x_0)) \in (0, T) \times K \times \mathbb{R}$ the solution $x(\cdot; t_0, x_0, u(\cdot))$ to (2) satisfies (16).

Second step. Fix $u(\cdot) \in \mathcal{U}(t_0)$. Then there exists a sequence $u_n(\cdot) \subset \mathcal{U}(t_0)$ of continuous functions such that $u_n(\cdot) \to u(\cdot)$ in $L^\infty(0, T; U)$.

For all $n \in \mathbb{N}$, $x_n(\cdot; t_0, x_0, u_n(\cdot))$ satisfies

$$x_n'(t) \in f(x_n(s), u_n(s))ds - \int_{t_0}^t N_K(x_n(s)) \cap B(0, M)ds, \text{ or equivalently}$$
$$x_n(t) \in x_0 + \int_{t_0}^t f(x_n(s), u_n(s))ds - \int_{t_0}^t N_K(x_n(s)) \cap B(0, M)ds. \tag{17}$$

As $B(0, M)$ is a compact set and the application $N_K(\cdot) \cap B(0, M)$ is u.s.c., there exists a measurable selection $y_n(\cdot) \in N_K(x_n(s)) \cap B(0, M)$. Moreover, for all $s \in [t_0, T]$ there exists

$$\lim_{n \to \infty} y_n(s) = y(s) \in N_K(x(s)) \cap B(0, M).$$

Hence, by the Lebesgue theorem we obtain that

$$\int_{t_0}^t y_n(s)ds \to \int_{t_0}^t y(s)ds \in \int_{t_0}^t N_K(x(s)) \cap B(0, M)ds \text{ a.e. } t \in [t_0, T].$$

Recall that the restriction of the application $(t_0, x_0) \in [0, T] \times K \to S_F(t_0, x_0)$ to a compact set C is compact into $[0, \infty) \times K \times W^{1,1}(0, \infty; K)e^{-bt}$ for all b with $b > a$. Since $x_n(\cdot; t_0, x_0, u_n(\cdot)) \in S_F(t_0, x_0)$ there exists $x(\cdot) \in S_F(t_0, x_0)$ such that $\lim_{n \to \infty} x_n(\cdot) = x(\cdot)$ in $W^{1,1}(0, T; K)$.

Passing to the limit in (17) we obtain that for almost all $t \in [t_0, T]$ $x(t) \in x_0 + \int_{t_0}^t f(x(s), u(s))ds - \int_{t_0}^t N_K(x(s)) \cap B(0, M))ds$ and consequently, $x(\cdot) = x(\cdot; t_0, x_0, u(\cdot))$.

Third step. Assume that $\bar{x}(\cdot; t_0, x_0, \bar{u}(\cdot))$ is an optimal trajectory for V, starting from $(t_0, x_0) \in [0, T] \times K$, i.e., $V(t_0, x_0) = g(\bar{x}(T; t_0, x_0, \bar{u}(\cdot))$.

Then there exists a sequence of continuous functions $u_n(\cdot)$, such that $u_n(\cdot) \to \bar{u}(\cdot)$ in $L^\infty(0, T; U)$ and consequently $x_n(\cdot; t_0, x_0, u_n(\cdot)) \to \bar{x}(\cdot; t_0, x_0, \bar{u}(\cdot))$ in $W^{1,1}(0, T; K)$.

Using the above arguments for every $n \in \mathbb{N}$, $\varphi(t, x_n(t; t_0, x_0, u_n(\cdot)) \geq \varphi(t_0, x_0)$ for all $t \in [t_0, T]$ and consequently, $\varphi(T, x_n(T; t_0, x_0, u_n(\cdot)) \geq \varphi(t_0, x_0)$.

As φ is u.s.c., we obtain by letting $n \to \infty$

$$\begin{aligned} V(t_0, x_0) = g(\bar{x}(T; t_0, x_0, \bar{u}(\cdot))) &\geq \varphi(T, (\bar{x}(T; t_0, x_0, \bar{u}(\cdot))) \\ &\geq \limsup_{n \to \infty} \varphi(T, x_n(T; t_0, x_0, u_n(\cdot)) \geq \varphi(t_0, x_0). \end{aligned}$$

Then $V \geq \varphi$ and the proof is complete. □

For the proof of Lemma 21 let us establish a stability result for (HJBI).

LEMMA 20. *Assume that $H : K \times \mathbb{R}^N \to \mathbb{R}$ is a continuous Hamiltonian and let K be a compact proximal retract. If $w_n : (0, T) \times K \to \mathbb{R}$ is an increasing (decreasing) sequence of uniformly locally bounded l.s.c. (u.s.c.) supersolutions (subsolutions) of* (HJBI) *and w is a pointwise limit of w_n, then w is an l.s.c. (u.s.c.) supersolution (subsolution) of* (HJBI).

The proof of this lemma is adapted from [3]. The main difficulties and changes with Barles's proof are given by the regularity of the application $N_K(\cdot)$.

LEMMA 21. *Assume that (H_f) holds. Let K be a compact proximal retract and g be a u.s.c. (respectively, l.s.c.) function. Then V is a u.s.c. subsolution (respectively, l.s.c. supersolution) of* (HJBI).

Proof. We define a sequence $g_n : K \to \mathbb{R}$ by

$$g_n(x) = \sup_{y \in K} (g(y) - n||x - y||).$$

The supconvolutions g_n are Lipschitz, $g_n(x) \geq g_{n+1}(x)$, and $\lim g_n(x) = g(x)$ for every $x \in K$. Using Proposition 11, V_{g_n} is a Lipschitz solution to (HJBI) with $V_{g_n}(T, \cdot) = g_n(\cdot)$ and $V_{g_n} \geq V$.

Denote $U(t, x) = \lim V_{g_n}(t, x)$. Then, using the above result, U is a u.s.c. subsolution of (HJBI) and $U(T, x) = g(x)$. Obviously $U \geq V$ and by Lemma 15 we have that $U = V$. So V is a u.s.c. subsolution for (HJBI).

The proof in the l.s.c. case is similar to the u.s.c. case. □

VARIATIONAL ANALYSIS APPLIED TO THE PROBLEM OF OPTICAL PHASE RETRIEVAL*

JAMES V. BURKE† AND D. RUSSELL LUKE‡

Abstract. We apply nonsmooth analysis to a well-known optical inverse problem, phase retrieval. The phase retrieval problem arises in many different modalities of electromagnetic imaging and has been studied in the optics literature for over forty years. The state of the art for this problem in two dimensions involves iterated projections for solving a nonconvex feasibility problem. Despite widespread use of these algorithms, current mathematical theory cannot explain their success. At the heart of projection algorithms is a nonconvex, nonsmooth optimization problem. We obtain some insight into these algorithms by applying techniques from nonsmooth analysis. In particular, we show that the weak closure of the set of directions toward the projection generate the subdifferential of the corresponding squared set distance function. Following a pattern of proof described in [F. H. Clarke, Yu. S. Ledyaev, R. J. Stern, and P. R. Wolenski, *Nonsmooth Analysis and Control Theory*, Springer-Verlag, New York, 1998], this result is generalized to provide conditions under which the subdifferential of an integral function equals the integral of the subdifferential.

1. Introduction.

The phase retrieval problem arises frequently in a number of different optical imaging modalities including diffraction imaging and interferometry. While the imaging models differ slightly, the feature common to these techniques is the problem of recovering the phase of a complex-valued function from measurements of the amplitude of that function, as well as other a priori constraints. There are many unsolved mathematical problems surrounding wavefront reconstruction and phase retrieval in general. Nevertheless, engineers and physicists have been solving this problem in some sense for over thirty years. The most famous application of phase retrieval came with NASA's Hubble Space Telescope (HST). Optical wavefront reconstruction played a central role in the effort to identify gross manufacturing errors in the HST and to design, in effect, a pair of glasses for the near-sighted telescope. We refer the reader to [16] for a review and tutorial of wavefront reconstruction. Here we present only the abstract setting.

The *forward imaging* model is formulated on the space $L^2[\mathbb{R}^2, \mathbb{R}^2]$ of square integrable functions mapping $\mathbb{R}^2$ to $\mathbb{R}^2$. The model input $u : \mathbb{R}^2 \to \mathbb{R}^2$ is an optical field generated by the object we are trying to observe. The optical device is characterized by a unitary bounded linear operator $\mathcal{F}_m : L^2[\mathbb{R}^2, \mathbb{R}^2] \to L^2[\mathbb{R}^2, \mathbb{R}^2]$. The subscript m indicates certain parameter settings in the optical device that constitute a particular known "tuning" such as focus. Let $\mathbb{R}_+$ denote the nonnegative orthant. The model output, or data, corresponding to the mth tuning of the device, $\psi_m : \mathbb{R}^2 \to \mathbb{R}_+$, is

amplitude measurements. The imaging model is given by

$$|\mathcal{F}_m(u(\cdot))| = \psi_m(\cdot), \qquad m = 0, 1, \ldots, M, \tag{1}$$

where the modulus $|\cdot|$ is the *pointwise Euclidean* magnitude. Our discussion switches frequently between the finite- and infinite-dimensional settings. Whenever there is chance for confusion, we indicate a mapping F on the function space explicitly as $F(u(\cdot))$.

Wavefront reconstruction is an *inverse problem*: given $\mathcal{F}_m$ and ψ_m, $m = 0, 1, \ldots, M$, determine u satisfying (1). For a more detailed review of the existence and uniqueness theory behind this problem we refer to [16] and references therein. For our purposes it suffices to note that there is no known closed-form solution to this inverse problem. Moreover, in the presence of noise it is likely that a solution does not exist, thus solution techniques involve minimizing a performance measure. Even though the performance measure that we consider is smooth, the modulus in (1) leads to a nonsmooth objective (see Theorem 3.1 in section 3). At first glance, it would seem that one could easily handle nonsmoothness by squaring both sides of (1). It turns out, however, that objectives based on the *modulus* function, or a nearby smooth approximation, perform better than objectives built upon the modulus squared [16]. Therefore, it can be advantageous to exploit nonsmoothness rather than to avoid it.

Since noise in the data is most often modeled as additive white noise, the least squares error metric is used to find the best fit to (1). For $m = 0, 1, \ldots, M$ and ψ_m not equal to zero a.e., define

$$\mathbb{Q}_m := \left\{ u \in L^2[\mathbb{R}^2, \mathbb{R}^2] \;\middle|\; |\mathcal{F}_m(u)| = \psi_m \text{ a.e.} \right\}. \tag{2}$$

The phase retrieval problem is given by

$$\begin{aligned} &\text{minimize } J(u) \\ &\quad \text{over} \quad u \in L^2[\mathbb{R}^2, \mathbb{R}^2], \end{aligned} \tag{3}$$

where

$$J(u) = \sum_{m=0}^{M} \frac{\beta_m}{2} \text{dist}^{\,2}(u; \mathbb{Q}_m) \tag{4}$$

is the weighted ($\beta_m > 0$ for $m = 0, \ldots, M$) squared set distance error for the phase retrieval problem and

$$\text{dist}\,(u; \mathbb{Q}_m) := \inf_{w \in \mathbb{Q}_m} \|u - w\|. \tag{5}$$

The error metric (4) has a long tradition in the optics literature [9, 10]. It has also been studied in the convex setting where each of the sets $\mathbb{Q}_m$ is assumed to be convex (e.g., see [2, 7]).

Problem (3) is often reformulated as a feasibility problem: the function u must lie in the intersection of the sets $\mathbb{Q}_0 \cap \mathbb{Q}_1 \cap \cdots \mathbb{Q}_m$, assuming that this intersection is nonempty. Projection algorithms are often used to find a point in the intersection of such a collection of sets. Independent of the mathematical literature on projections (and in some cases *before* these algorithms appeared in the mathematical literature) optical scientists developed image processing algorithms for recovering the phase from amplitude measurements known in the optics literature as *iterative transform methods*.

Here one adjusts the phase of the current estimate, $u^{(\nu)}$, at iteration ν by replacing the magnitude of the image $\mathcal{F}_m(u^{(\nu)}(\cdot))$ with the known pointwise magnitude $\psi_m(\cdot)$ and then inverse transforming the result, $\mathcal{F}_m^*(\psi_m(\cdot)\exp(\sqrt{-1}\ \arg(\mathcal{F}_m(u^{(\nu)}(\cdot)))))$. It is straightforward to show that this operation is a projection [16]. The Gerchberg–Saxton algorithm [10] is a classical example of this type of algorithm. When the sets $\mathbb{Q}_m$ are convex and the intersection is nonempty, then this approach is perfectly reasonable since cyclic projections onto such a finite collection of convex sets converges to the intersection (e.g., see [3] and the references therein). In the setting of phase retrieval, however, the sets $\mathbb{Q}_m$ are not even weakly closed, let alone convex [16, Property 4.1]. This poses serious challenges to any convergence theory for algorithms based on projections. Not surprisingly, many have noted that iterative transform algorithms often stagnate. There are some well-known strategies for dealing with these problems [9], but it has recently been observed that these too are applications of convex operator splitting strategies in nonconvex, nonlinear settings [4], so convergence is still problematic.

To overcome some of the problems inherent in treating the leading algorithms as nonconvex instances of projection algorithms, we approach the problem in its variational form (3) using the tools of nonsmooth analysis. We show that, for the squared set distance error metric (4), some projection algorithms can be viewed as *subgradient descent algorithms*. Thus, the critical object for our analysis is the *subdifferential*, or generalized derivative of the squared set distance error metric $J(u)$. In this analysis, the space to which the data $\{\psi_m : m = 0, 1, \dots M\}$ belongs is of critical importance. We require these functions to be nonnegative and finite-valued with their value tending to zero as their argument diverges to infinity in norm. Specifically, we assume that the data belongs to the set $\mathbb{U}$ where

(6)
$$\mathbb{U} = \left\{ v \in L^1 \cap L^2 \cap L^\infty[\mathbb{R}^2, \mathbb{R}] \text{ such that } v(x) \geq 0 \text{ a.e. and } |v(x)| \to 0 \text{ as } |x| \to \infty \right\}.$$

In section 2 we review the theory of projections applied to this problem. The most common projection algorithms, stated in general form in section 2.3, are central to current numerical techniques for this problem. In section 3, we look at the problem from the perspective of nonsmooth least squares, beginning first with finite-dimensional nonsmooth analysis in section 3.2 and building toward the infinite-dimensional analysis in section 3.5. We then apply these results to the problem of wavefront reconstruction in section 3.6. In the final section of the paper we present a result on the exchange of subdifferentiation and integration. Such results have a long history, beginning with Rockafellar's result [20] for convex normal integrands. Our result is in the spirit of [6, Theorem 3.5.18]. Indeed, our method of proof parallels that given by Clarke, Ledyaev, Stern, and Wolenski. The key difference between our result and [6, Theorem 3.5.18] is that our domain of integration is all of $\mathbb{R}^2$ as opposed to an interval in $\mathbb{R}$.

2. Geometric approaches.

2.1. Projections. In general, it may be difficult to prove that the projection of a given point onto a given set exists, much less to identify it with a formula. Much of the general theory of projections [24] does not apply since the sets in question are neither weakly closed nor convex [16, Property 4.1]. However, in the application to phase retrieval there is a very simple characterization in terms of pointwise, finite-dimensional projections.

Our focus is on sets of the form

$$\mathbb{Q}(b) := \left\{ u \in L^2[\mathbb{R}^2, \mathbb{R}^2] \;\middle|\; |u| = b \text{ a.e.} \right\}. \tag{7}$$

Here the set $\mathbb{Q}(b)$ is parameterized by the *function* $b : \mathbb{R}^2 \to \mathbb{R}_+$. Alternatively, one can think of this set as being parameterized *pointwise* by $x \in \mathbb{R}^2$, that is, at each point x, the set $\mathbb{Q}(b(x)) \subset \mathbb{R}^2$ is simply the sphere of radius $b(x)$, denoted $b(x)\mathbb{S}$, where $\mathbb{S}$ is the unit sphere in $\mathbb{R}^2$. For the closed set $\mathbb{Q}$ in the Hilbert space $\mathbb{X}$, we define the projection operator $\Pi_{\mathbb{Q}}(v)$ as the multivalued mapping, or multifunction, given as the set of all solutions to the minimum distance problem for the set $\mathbb{Q}$:

$$\Pi_{\mathbb{Q}}(v) := \arg\min_{u \in \mathbb{Q}} \|v - u\| = \{\bar{u} \in \mathbb{Q} : \|v - \bar{u}\| = \inf_{u \in \mathbb{Q}} \|v - u\|\}. \tag{8}$$

It is a simple matter to characterize the pointwise projection $\Pi_{b(x)\mathbb{S}} : \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$:

$$\Pi_{b(x)\mathbb{S}}(v) = b(x)\Pi_{\mathbb{S}}(v) = b(x) \times \begin{cases} \frac{v}{|v|} & \text{for } v \neq 0, \\ \mathbb{S} & \text{for } v = 0, \end{cases} \qquad v \in \mathbb{R}^2. \tag{9}$$

Note that the projection is multivalued at $v = 0$. In the following sections we construct the infinite-dimensional projection $\Pi_{\mathbb{Q}(b)} : L^2[\mathbb{R}^2, \mathbb{R}^2] \rightrightarrows L^2[\mathbb{R}^2, \mathbb{R}^2]$ onto $\mathbb{Q}(b)$ from the corresponding pointwise projection at the point x, $\Pi_{b(x)\mathbb{S}} : \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ onto $b(x)\mathbb{S}$.

2.2. Measurable multifunctions. We now review some of the properties of measurable multifunctions used in this study [1, 6, 11, 21]. In section 3.3 we extend this review to include the integration theory of measurable multivalued mappings. For more information on this and related topics, we refer the interested reader to [21, chapter 14].

Let $\Omega \neq \emptyset$ and let $\mathcal{A}$ be a σ-field of subsets of Ω, called the *measurable* subsets of Ω or the $\mathcal{A}$-*measurable* subsets. The corresponding measure space is denoted $(\Omega, \mathcal{A})$. Our discussion is limited to *complete nonatomic* measure spaces.

The multifunction $F : \Omega \rightrightarrows \mathbb{R}^n$ is said to be $\mathcal{A}$-measurable, or simply measurable, if for all open sets $\mathbb{V}$ the set $\{x \mid \mathbb{V} \cap F(x) \neq \emptyset\}$ is in $\mathcal{A}$. The multifunction F is said to be $\mathcal{A} \otimes \mathcal{B}^n$-*measurable* if $\text{gph}(F) = \{(x, v) \mid v \in F(x)\} \in \mathcal{A} \otimes \mathcal{B}^n$. Here $\mathcal{B}^n$ denotes the Borel σ-field on $\mathbb{R}^n$ and $\mathcal{A} \otimes \mathcal{B}^n$ is the σ-field on $\Omega \times \mathbb{R}^n$ generated by all sets $A \times D$ with $A \in \mathcal{A}$ and $D \in \mathcal{B}^n$. If $F(x)$ is closed for each x, then F is *closed*. Similarly, F is said to be *convex* if $F(x)$ is convex for each x. Finally, we note that the completeness of the measure space guarantees the measurability of subsets of Ω obtained as the projections of measurable subsets $\mathbb{G}$ of $\Omega \times \mathbb{R}^n$:

$$\mathbb{G} \in \mathcal{A} \otimes \mathcal{B}^n \quad \Longrightarrow \quad \{\omega \in \Omega \mid \exists\, x \in \mathbb{R}^n \text{ with } (\omega, x) \in \mathbb{G}\} \in \mathcal{A},$$

and thus F is $\mathcal{A}$-measurable if and only if F is $\mathcal{A} \otimes \mathcal{B}^n$-measurable [21, Theorem 14.8].

Let $F : \Omega \rightrightarrows \mathbb{R}^n$. Denote by $\mathcal{S}(F)$ the set of μ-measurable functions $f : \Omega \to \mathbb{R}^n$ that satisfy $f(x) \in F(x)$ a.e. in Ω $(x \in \Omega)$. We call $\mathcal{S}(F)$ the *set of measurable selections* of F.

THEOREM 2.1 (measurable selections [21, Corollary 14.6]). *A closed-valued measurable map $F : \Omega \rightrightarrows \mathbb{R}^n$ always admits a measurable selection.*

For a measurable function $f = (f_1, \ldots, f_n)$, $f_i : \Omega \to \mathbb{R}$, for $i = 1, \ldots, n$, the integral $\int f d\mu$ is defined to be the vector

$$\left(\int f_1, d\mu, \ldots, \int f_n d\mu \right).$$

The set

$$\left\{ \int f d\mu \mid f \in \mathcal{S}(F) \right\}$$

is the *integral* of the multivalued mapping $F : \Omega \rightrightarrows \mathbb{R}^n$ and is denoted by $\int F d\mu$ or $\int F$. We say that $F : \Omega \rightrightarrows \mathbb{R}^n$ is *integrably bounded*, or for emphasis μ-integrably bounded, if there is a μ-integrable $a : \Omega \to \mathbb{R}^n_+$ such that

$$(|v_1|, \ldots, |v_n|) \leq a(x)$$

for all pairs $(x, v) \in (\Omega, \mathbb{R}^n)$ satisfying $v \in F(x)$. Here and elsewhere we interpret vector inequalities as elementwise inequalities. If $a(x)$ in the above inequality is *square-integrable* with respect to the measure μ on the measure space $(\Omega, \mathcal{A}, \mu)$, then the multifunction F is said to be L^2-bounded. When $\Omega = \mathbb{R}^n$, we let $L^2_m(\mathbb{R}^n, \mathcal{A}, \mu)$ denote the Hilbert space of functions mapping $\mathbb{R}^n$ to $\mathbb{R}^m$ with inner product on the measure space $(\mathbb{R}^n, \mathcal{A}, \mu)$ given by

$$\langle f, g \rangle = \int_{\mathbb{R}^n} (f(x), g(x)) \mu(dx), \tag{10}$$

where $(\cdot, \cdot)$ denotes the usual finite-dimensional vector inner product.

The next property is a generalization of [6, Exercise 3.5.14].

PROPOSITION 2.2 (weak compactness of measurable selections). *Let the multifunction $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ be closed, convex-valued, and L^2-bounded on $L^2_m(\mathbb{R}^n, \mathcal{M}^n, \nu_n)$, where $\mathcal{M}^n$ is the Lebesgue field on $\mathbb{R}^n$ and ν_n is the n-dimensional Lebesgue measure. Then the set of measurable selections $\mathcal{S}(F)$ is a weakly compact, convex set in $L^2_m(\mathbb{R}^n, \mathcal{M}^n, \nu_n)$.*

Proof. This set is clearly convex since F is pointwise convex-valued. Thus, by [8, Theorem 1, p. 58] we need only show that $\mathcal{S}(F)$ is weakly sequentially compact. Consider any sequence $\{f_i\} \subset \mathcal{S}(F)$. We must show that $\{f_i\}$ has a weakly convergent subsequence with limit $f_* \in \mathcal{S}(F)$. Since the sequence is L^2-bounded, reflexivity, separability, and Alaoglu's theorem [23, Exercise 18(b), p. 269] imply that there exists a weakly convergent subsequence whose limit belongs to the weak closure of $\mathcal{S}(F)$. Since $\mathcal{S}(F)$ is convex, the strong and weak closures of $\mathcal{S}(F)$ coincide. Hence the result follows if $\mathcal{S}(F)$ is strongly closed. Since strong convergence implies the existence of a subsequence that is almost everywhere pointwise convergent [23, Theorem 3.12], and $F(x)$ is pointwise closed, we have that $\mathcal{S}(F)$ is strongly closed. □

2.3. Application to wavefront reconstruction: Projection algorithms. We now characterize the projections associated with the problem of phase retrieval in terms of the corresponding pointwise projections. This allows us to describe a general algorithmic framework that includes many of the currently used phase retrieval algorithms. Let $b \in L^2[\mathbb{R}^2, \mathbb{R}]$ with $b(x) \geq 0$ a.e., let the pointwise projection $b(x)\Pi_{\mathbb{S}}$ be defined by (9), and let $\mathbb{Q}(b)$ be defined by (7). For $u, v \in L^2[\mathbb{R}^2, \mathbb{R}^2]$, it is shown in [16, Theorem 4.2] that the projection $\Pi_{\mathbb{Q}(b)} : L^2[\mathbb{R}^2, \mathbb{R}^2] \rightrightarrows L^2[\mathbb{R}^2, \mathbb{R}^2]$ onto $\mathbb{Q}(b)$ is characterized as the collection of measurable selections from the pointwise projection mapping (9):

$$\Pi_{\mathbb{Q}(b)}(u) = \mathcal{S}\left(b(\cdot)\Pi_{\mathbb{S}}(u(\cdot))\right) \quad \text{and} \quad \operatorname{dist}(u; \mathbb{Q}(b)) = \| \, |u| - b \, \|. \tag{11}$$

One can characterize the projection onto the sets $\mathbb{Q}_m$ defined in (2) in a similar fashion. The $\mathcal{F}_m$-transform of $\Pi_{\mathbb{Q}(b)}(u)$ is the $\mathcal{F}_m$-transform of all $v \in \Pi_{\mathbb{Q}(b)}(u)$ and is

written $\mathcal{F}_m\left(\Pi_{\mathbb{Q}(b)}(u)\right)$. For each of the unitary operators $\mathcal{F}_m$ and all $u \in L^2[\mathbb{R}^2, \mathbb{R}^2]$, we know from [16, Corollary 4.3] that

$$\Pi_{\mathbb{Q}_m}(u) = \mathcal{F}_m^* \left(\Pi_{\mathbb{Q}(\psi_m)}(\mathcal{F}_m(u))\right) \quad \text{and} \quad \operatorname{dist}(u; \mathbb{Q}_m) = \| \, |\mathcal{F}_m(u)| - \psi_m \| \, . \tag{12}$$

A general framework for projection algorithms can be found in [3], which considers sequences of weighted relaxed projections of the form

$$u^{(\nu+1)} \in \left(\sum_{m=0}^{M} \gamma_m^{(\nu)} \left[(1 - \alpha_m^{(\nu)}) \mathcal{I} + \alpha_m^{(\nu)} \Pi_{\mathbb{Q}_m} \right] \right) (u^{(\nu)}). \tag{13}$$

Here $\mathcal{I}$ is the identity mapping, $\alpha_m^{(\nu)}$ is a relaxation parameter usually in the interval $[0, 2]$, and the weights $\gamma_m^{(\nu)}$ are nonnegative scalars summing to one. General results for these types of algorithms apply only to convex sets. In the convex setting the inclusion in (13) is an equality since projections onto convex sets are single-valued. In the nonconvex setting this is not the case.

It is shown in [16] that the Gerchberg–Saxton algorithm [10] and its variants can be viewed as an instance of (13). As in [16] we use the change of variables $\lambda^{(\nu)} \beta_m^{(\nu)} = \gamma_m^{(\nu)} \alpha_m^{(\nu)}$ to rewrite (13) as

$$u^{(\nu+1)} \in \left(\mathcal{I} - \lambda^{(\nu)} \mathcal{G}^{(\nu)} \right) \left(u^{(\nu)} \right), \tag{14}$$

where for all ν the operators $\mathcal{G}^{(\nu)} : L^2 \to L^2$ are given by

$$\mathcal{G}^{(\nu)} := \sum_{m=0}^{M} \mathcal{G}_m^{(\nu)} \qquad \text{with} \qquad \mathcal{G}_m^{(\nu)} := \beta_m^{(\nu)} \left(\mathcal{I} - \Pi_{\mathbb{Q}_m} \right). \tag{15}$$

In (14) the nonnegative weights $\beta_m^{(\nu)}$ do not necessarily sum to 1, and the parameters $\lambda^{(\nu)}$ are to be interpreted as *step lengths*. This formulation of the projection algorithm is shown in the next section to correspond to a steepest descent algorithm for a weighted squared distance function.

3. Nonsmooth analysis. Convergence results for projection methods applied to the phase retrieval problem are not possible in general due to the nonconvexity of the constraint sets. The nonconvexity of the constraint sets is associated with the nonsmoothness of the square of the set distance error $\operatorname{dist}(u; \mathbb{Q}_m)$ defined in (5). This is fundamentally different from the convex setting in a Hilbert space where the squared distance function is smooth.

3.1. Least squares. In general the optimal value of the weighted squared set distance error $J(u)$ defined by (4) is nonzero. Classical techniques for solving the problem numerically are based on satisfying a first-order necessary condition for optimality. For smooth functions this condition simply states that the gradient takes the value zero at any local solution to the optimization problem. However, the functions $\operatorname{dist}^2(u; \mathbb{Q}_m)$ are not differentiable. The easiest way to see this is to consider the one-dimensional function $a(x) = \, ||x| - b|^2$, where $b > 0$. This function is not differentiable at $x = 0$. (Indeed, it is not even subdifferentiably regular at $x = 0$—see (19)). It is precisely at these points that the finite-dimensional projection operator $\Pi_{b\mathbb{S}}$ is multivalued. Similarly, $\operatorname{dist}^2(u; \mathbb{Q}_m)$ is not differentiable at functions u for which there exists a set $\Omega \subset \operatorname{supp}(\psi_m)$ of positive measure on which u vanishes.

In the nonsmooth setting the usual first-order necessary condition for optimality is replaced by a first-order variational principle of the form $0 \in \partial J(u_*)$, where ∂ denotes a *subdifferential* operator such as those studied in [5, 6, 12, 13, 15, 18]. In this paper, the phrase *the subdifferential* refers to the nonconvex subdifferential introduced by Kruger and Mordukhovich [15]. This subdifferential is precisely described in Definition 3.12, and its calculus is extensively developed in [18]. The main result of this paper is the characterization of the subdifferential of the distance functions $\text{dist}^{\,2}(\cdot;\mathbb{Q}_m)$ and the objective function J (equation (4)). We do this by following the pattern of proof used by Clarke, Ledyaev, Stern, and Wolenski in [6, Theorem 3.5.18]. A consequence of this approach is that we also establish the subdifferential regularity of the functions $\text{dist}^{\,2}(\cdot;\mathbb{Q}_m)$ and J. This in turn implies that for these functions the Clarke subdifferential [5, 6] and the nonconvex subdifferential [15] are equivalent. The statement of the main result now follows.

THEOREM 3.1 (projections and subdifferentials). *Let $\psi_m : \mathbb{R}^2 \to \mathbb{R}_+$ belong to $\mathbb{U}$ where the set $\mathbb{U}$ is defined in* (6)*, and let $\Pi_{\mathbb{Q}_m} : L^2 \rightrightarrows \mathbb{Q}_m$ be defined by* (8)*. Then the functions $\text{dist}^{\,2}(\cdot;\mathbb{Q}_m)$ and J are everywhere subdifferentially regular and for $u \in L^2[\mathbb{R}^2,\mathbb{R}^2]$ we have*

$$\partial\left(\text{dist}^{\,2}(u;\mathbb{Q}_m)\right) = 2\text{cl}^*\left(\mathcal{I} - \Pi_{\mathbb{Q}_m}(u)\right) \tag{16}$$

and

$$\partial J(u) = \sum_{m=0}^{M} \text{cl}^*\left(\mathcal{G}_m(u)\right), \tag{17}$$

where $\mathcal{G}_m$ is defined by (15)*, J is defined in* (4)*, and $\text{cl}^*(\,\cdot\,)$ denotes the weak-star closure.*

Note that in a Hilbert-space setting $\text{cl}^*(\,\cdot\,) = w\text{–cl}(\,\cdot\,)$, where $w\text{–cl}(\,\cdot\,)$ denotes the weak closure. The proof is given at the end of this section. In passing, we note that in the convex case Theorem 3.1 is an elementary consequence of a much more general result for convex functions given in [19, Theorem 20]. For further results along these lines we refer the reader to [5, Proposition 2.5.4] and [21, Example 8.53].

3.2. Finite-dimensional nonsmooth analysis. In [16, Theorem 4.2] it is shown that the squared set distance error $\text{dist}^{\,2}(u;\mathbb{Q}(b))$ defined in (7) is given as the integral of the *pointwise* distance function defined by (11). In Theorem 3.1 we extend this correspondence to the subdifferentials of the associated infinite- and finite-dimensional functions. We begin this analysis by introducing the necessary tools from finite-dimensional variational analysis.

Recall that

$$\text{dist}^{\,2}(u;\mathbb{Q}(b)) \;=\; \int_{\mathbb{R}^2} r^2(u(x);b(x))dx \;=\; \|u\|^2 + \|b\|^2 + 2h(u;b),$$

where the pointwise residual $r : \mathbb{R}^2 \times \mathbb{R}_+ \to \mathbb{R}$ and the mapping $h : L^2[\mathbb{R}^2,\mathbb{R}^2] \to \mathbb{R}$ are given by

$$r(u(x);b(x)) = |u(x)| - b(x) \qquad \text{and} \qquad h(u;b) := \int_{\mathbb{R}^2} -|u(x)|\,b(x)dx, \tag{18}$$

respectively. While $\text{dist}^{\,2}(u;\mathbb{Q}(b))$ is not smooth, it is straightforward to show that it is Lipschitz continuous on bounded subsets of $L^2[\mathbb{R}^2,\mathbb{R}^2]$.

A function $f : \mathbb{X} \to \mathbb{R}$ is *locally Lipschitz near* x if there exists a constant $K \geq 0$ and a neighborhood $\mathbb{V}(x) \subset \mathbb{X}$ of x such that

$$|f(z) - f(y)| \leq K\|z - y\| \qquad \forall\, z, y \in \mathbb{V}(x).$$

For any set $\mathbb{V} \subset X$ over which f is finite-valued, f is said to be *locally Lipschitz on* $\mathbb{V}$ if it is locally Lipschitz at every $x \in \mathbb{V}$. The function is said to be *(globally) Lipschitz on* $\mathbb{V}$ if

$$|f(x) - f(y)| \leq K\|x - y\| \qquad \forall\, x, y \in \mathbb{V}.$$

PROPOSITION 3.2 (Lipschitz constants). *If* $b \in L^2[\mathbb{R}^2, \mathbb{R}]$ *with* $b(x) \geq 0$ *a.e., then the mapping* $\operatorname{dist}^2(\cdot; \mathbb{Q}(b)) : L^2[\mathbb{R}^2, \mathbb{R}^2] \to \mathbb{R}_+$ *is finite-valued and Lipschitz on any bounded subset* $\mathbb{V} \subset L^2[\mathbb{R}^2, \mathbb{R}^2]$ *with Lipschitz constant*

$$K = K_{\|\cdot\|^2} + K_{2h(\cdot;b)},$$

where $K_{\|\cdot\|^2} = 2\sup_{u \in \mathbb{V}} \|u\|$ *is a Lipschitz constant for* $\|u\|^2$ *on* $\mathbb{V}$ *and* $K_{2h(\cdot;b)} = 2\|b\|$ *is a Lipschitz constant for* $h(\cdot; b)$*, independent of* $\mathbb{V}$*.*

Proof. This follows from the proof of [16, Lemma B.2]. ∎

Lipschitz continuity of the squared set distance error J is a straightforward consequence of Proposition 3.2 and the fact the mappings $\mathcal{F}_m$ are unitary.

We now introduce some basic definitions from nonsmooth analysis. In our discussion we allow mappings to have infinite values; thus it is convenient to define the extended reals $\overline{\mathbb{R}}$, where $\overline{\mathbb{R}} = \mathbb{R} \cup \{+\infty\}$. The *effective domain* of $f : \mathbb{R}^n \to \overline{\mathbb{R}}$, denoted $\operatorname{dom} f \subset \mathbb{R}^n$, is the set on which f is finite. To avoid certain pathological mappings the discussion is restricted to *proper*, i.e., not everywhere infinite, *lower semicontinuous* (l.s.c.) functions.

DEFINITION 3.3 (subderivatives [21]). *For a Lipschitz function* $f : \mathbb{R}^m \to \overline{\mathbb{R}}$ *and a point* $u_* \in \mathbb{R}^m$ *with* $f(u_*)$ *finite,*

(i) *the* subderivative *function* $df(u_*) : \mathbb{R}^m \to \overline{\mathbb{R}}$ *is defined by*

$$df(u_*)(w) := \liminf_{\tau \searrow 0} \frac{f(u_* + \tau w) - f(u_*)}{\tau};$$

(ii) *the* regular subderivative *function (or the Clarke generalized directional derivative when* f *is Lipschitz)* $\widehat{d}f(u_*) : \mathbb{R}^m \to \overline{\mathbb{R}}$ *is defined by*

$$\widehat{d}f(u_*)(w) := \limsup_{u \to u_*,\, \tau \searrow 0} \frac{f(u + \tau w) - f(u)}{\tau}.$$

DEFINITION 3.4 (subgradients: finite-dimensions [21]). *Consider a function* $f : \mathbb{R}^m \to \overline{\mathbb{R}}$*, a point* $v \in \mathbb{R}^m$*, and a point* $u_* \in \mathbb{R}^m$ *with* $f(u_*)$ *finite.*

(i) v *is a* regular subgradient *of* f *at* u_* *if*

$$\liminf_{\substack{u \to u_* \\ u \neq u_*}} \frac{f(u) - f(u_*) - \langle v,\ u - u_* \rangle}{|u - u_*|} \geq 0.$$

We call the set of regular subgradients v *the* regular subdifferential *of* f *at* u_* *and denote this set by* $\widehat{\partial} f(u_*)$*.*

(ii) *v is a* (general) subgradient *of f at u_* if there are sequences $u^{(\nu)} \to u_*$ and $v^{(\nu)} \in \widehat{\partial} f(u^{(\nu)})$ with $f(u^{(\nu)}) \to f(u_*)$ and $v^{(\nu)} \to v$. We call the set of (general) subgradients v the* (general) subdifferential *of f at u_* and denote this set by $\partial f(u_*)$.*

(iii) *v is a* Clarke subgradient *of f at u_* if f is l.s.c. on a neighborhood of u_* and v satisfies*

$$\langle v,\ w\rangle \leq \widehat{d} f(u_*)(w)\ \forall w \in \mathbb{R}^m.$$

We call the set of Clarke subgradients v the Clarke subdifferential *of f at u_* and denote this set by $\overline{\partial} f(u_*)$.*

(iv) *A Lipschitz function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ is said to be* (subdifferentially) regular *at $u_* \in \operatorname{dom} f$ with $\partial f(u_*) \neq \emptyset$ if*

$$\partial f(u_*) = \widehat{\partial} f(u_*). \tag{19}$$

Remark 3.5 (subdifferentials with closed graphs). From the definitions it can be shown that if $f : \mathbb{R}^n \to \mathbb{R}$ is continuous, then the subgradients ∂f and $\widehat{\partial} f$ are closed with $\widehat{\partial} f$ convex and $\widehat{\partial} f \subset \partial f$. Moreover, the mapping ∂f is outer semicontinuous [21, Definition 5.4]. Therefore, by [21, Theorem 5.7] the graph of ∂f is closed.

Remark 3.6 (subdifferentials of compositions). If $g : \mathbb{X} \to \overline{\mathbb{R}}$ is given as the composition of two functions $f : \mathbb{Y} \to \overline{\mathbb{R}}$ and $h : \mathbb{X} \to \mathbb{Y}$, i.e., $g(x) = (f \circ h)(x) = f(h(x))$, then we write $\partial g(x) = \partial(f \circ h)(x)$. On the other hand, we write $\partial f(h(x))$ to denote the subdifferential of f evaluated at $h(x)$.

The subdifferential definitions are illustrated with the following important example.

Example 3.7 (subdifferential of the modulus). Let $b \in (0, \infty)$. Since the function $b|u|$ is convex it is subdifferentially regular for all u, and

$$\partial\left(b|u|\right) = b\partial\left(|u|\right) = \begin{cases} b\frac{u}{|u|} & \text{if } u \neq 0, \\ b\mathbb{B} & \text{if } u = 0, \end{cases}$$

where $b\mathbb{B}$ is the ball of radius b: $\mathbb{B} = \{u : |u| \leq 1\}$.

In contrast, the function $-b|u|$ for $b \in (0, \infty)$ is not regular at 0. Nevertheless for all u

$$\partial\left(-b|u|\right) = b\partial\left(-|u|\right) = \begin{cases} -b\frac{u}{|u|} & \text{if } u \neq 0, \\ b\mathbb{S} & \text{if } u = 0, \end{cases}$$

where $b\mathbb{S}$ is the sphere of radius b: $\mathbb{S} = \{u : |u| = 1\}$. The Clarke subdifferential of $-b|u|$ is the convex hull, denoted $\operatorname{conv}(\cdot)$, of the generalized subdifferential:

$$\overline{\partial}\left(-b|u|\right) \ = \ \operatorname{conv} \partial\left(-b|u|\right) \ = \ -\partial(b|u|\,).$$

Proof. The first part of the statement is a trivial modification of [21, Exercise 8.27]. The last statement follows from [21, Theorem 8.49]. ∎

This example yields the following correspondence between finite-dimensional projections $\Pi_{b\mathbb{S}}$ and the subdifferential $\partial(-b|u|\,)$.

Proposition 3.8 (pointwise projections and subdifferentials). *Let $\Pi_{b\mathbb{S}}(u)$ be the projection defined in* (9)*. For $u \in \mathbb{R}^2$, $b \in \mathbb{R}_+$, and $r^2 : \mathbb{R}^2 \to \mathbb{R}_+$ defined in* (18) *we have*

$$\partial(-b|u|\,) = -\Pi_{b\mathbb{S}}(u), \quad \overline{\partial}(-b|u|\,) = -\operatorname{conv}\left(\Pi_{b\mathbb{S}}(u)\right), \quad \textit{and} \quad \partial r^2(u; b) = 2(I - \Pi_{b\mathbb{S}}(u)),$$

where I is the finite-dimensional identity operator. Moreover,

$$\overline{\partial} r^2(u;b) = \operatorname{conv}\,[2(I - \Pi_{b\mathbb{S}}(u))].$$

As with the finite-dimensional projection $\Pi_{b\mathbb{S}}$ and the infinite-dimensional projection $\Pi_{\mathbb{Q}(b)} : L^2[\mathbb{R}^2, \mathbb{R}^2] \rightrightarrows L^2[\mathbb{R}^2, \mathbb{R}^2]$ defined in (11), there is a relationship between the finite-dimensional Clarke subdifferential $\overline{\partial} r^2(u(x); b(x))$ (x fixed) and the "subdifferential" of the square distance function, $\partial(\text{dist}^{\,2}(u; \mathbb{Q}(b)))$. In infinite-dimensional spaces there are several possible definitions for the subdifferential depending on the underlying geometry and topology of the space. Fortunately, in the separable Hilbert-space setting of phase retrieval many of these definitions coincide [18, Theorem 9.2]. Thus we can choose the characterization that is most convenient. The following development parallels that of Clarke, Ledyaev, Stern, and Wolenski in [6, chapter 3, section 5]. We begin by recalling the definitions and theorems necessary for the analysis.

3.3. Integrals of multivalued functions. We now develop some properties of integrals of multivalued mappings. The next theorem, due to Hildenbrand [11], is a restatement of Theorems 3 and 4 of Aumann [1] for multifunctions on the nonatomic measure space $(\Omega, \mathcal{A}, \mu)$. These results are central to the theory of integrals of multivalued functions.

THEOREM 3.9 (integrals of multifunctions [11, Theorem 4 and Proposition 7]). *The following properties hold for integrably bounded multifunctions $F : \Omega \rightrightarrows \mathbb{R}^n$ on nonatomic measure spaces $(\Omega, \mathcal{A}, \mu)$:*

(i) *if F is $\mathcal{A} \otimes \mathcal{B}^n$-measurable, then $\int F = \int \operatorname{conv} F$;*

(ii) *if F is closed (not necessarily $\mathcal{A} \otimes \mathcal{B}^n$-measurable), then $\int F$ is compact.*

The following result is instrumental in the proof of our main result. It is a generalization of [6, Exercise 3.5.17].

PROPOSITION 3.10 (weak closure of nonconvex multivalued integrands). *Let v be chosen from the set of selections $\mathcal{S}(\operatorname{conv} F)$, where $F : \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ is a nonempty, closed, $\mathcal{M}^2 \otimes \mathcal{B}^2$-measurable, L^2-bounded multifunction on $L_2^2(\mathbb{R}^2, \mathcal{M}^2, P)$ for the probability measure $P(dx) = b(x)dx$ defined by the density $b : \mathbb{R}^2 \to \mathbb{R}_+$. Then there exists a sequence $\{f_i\}$ of measurable selections of F which converges weakly to v. Consequently,*

$$\mathcal{S}(\operatorname{conv} F) \subset \operatorname{cl}^*(\mathcal{S}(F)). \tag{20}$$

Proof. Consider the box $\mathbb{I}_n = [-n, n] \times [-n, n]$ for $n = 1, 2, 3, \ldots$. Suppose each box $\mathbb{I}_n$ is partitioned into $(2n^2)^2$ pixels of width $1/n$. Set

$$t_k^n = \frac{k}{n} - n \quad \text{for } k = 0, 1, \ldots, 2n^2,$$

and for each $t \in [-n, n]$ define

$$\underline{(t)}_n = \max\{t_k^n : t_k^n \le t, k = 0, \ldots, 2n^2\} \quad \text{and} \quad \overline{(t)}_n = \min\{t_k^n : t_k^n \ge t, k = 0, \ldots, 2n^2\}.$$

Note that $0 < \max\{t - \underline{(t)}_n, \overline{(t)}_n - t\} \le 1/n$ whenever $t \in [-n, n]$. By Theorem 3.9 there exists a selection $f_n \in F$ on $(\mathbb{R}^2, \mathcal{M}^2, P)$ corresponding to the partition of the box $\mathbb{I}_n$ such that

$$\int_{\mathbb{R}^2} f_n(x) b(x) dx = \int_{\mathbb{R}^2} v(x) b(x) dx$$

with

$$\int_{t_j^n}^{t_{j+1}^n}\int_{t_k^n}^{t_{k+1}^n} f_n(x)b(x)dx = \int_{t_j^n}^{t_{j+1}^n}\int_{t_k^n}^{t_{k+1}^n} v(x)b(x)dx, \quad n = 1,2,3,\ldots,\ j,k = 0,\ldots,2n^2.$$

We show that the sequence f_n converges weakly to v. Let $g \in C^\infty[\mathbb{R}^2,\mathbb{R}^2]$ and $\mathcal{X}_{\mathbb{M}}$ be the indicator of the box $\mathbb{M} = [\alpha,\beta]\times[\gamma,\eta]$. Given $\epsilon > 0$ we will show that there exists n' such that $|\langle g\mathcal{X}_{\mathbb{M}},\ f_n - v\rangle| \le \epsilon$ for all $n \ge n'$, i.e., $\langle g\mathcal{X}_{\mathbb{M}},\ f_n - v\rangle \to 0$.

Let n_1 be such that $\mathbb{M} \subset \mathbb{I}_{n_1}$ for all $n \ge n_1$. Choose $n \ge n_1$. Integration by parts yields

$$\langle g\mathcal{X}_{\mathbb{M}},\ f_n - v\rangle = \left(g(\beta,\eta),\ \int_\gamma^\eta\int_\alpha^\beta [f_n(s,t)-v(s,t)]b(s,t)ds\,dt\right) \tag{21}$$

$$-\int_\gamma^\eta \left(g_y(\beta,y),\ \int_\gamma^y\int_\alpha^\beta [f_n(s,t)-v(s,t)]b(s,t)ds\,dt\right)dy \tag{22}$$

$$-\int_\alpha^\beta \left(g_x(x,\eta),\ \int_\gamma^\eta\int_\alpha^x [f_n(s,t)-v(s,t)]b(s,t)ds\,dt\right)dx \tag{23}$$

$$+\int_\gamma^\eta\int_\alpha^\beta \left(g_{xy}(x,y),\int_\gamma^y\int_\alpha^x [f_n(s,t)-v(s,t)]b(s,t)ds\,dt\right)dx\,dy. \tag{24}$$

Note that each of these terms contains an expression of the form

$$\begin{aligned}\int_{\hat\gamma}^{\hat\eta}\int_{\hat\alpha}^{\hat\beta}(f_n(s,t)-v(s,t))b(s,t)ds\,dt &= \int_{\underline{(\hat\eta)}_n}^{\hat\eta}\int_{\hat\alpha}^{\hat\beta}(f_n(s,t)-v(s,t))b(s,t)ds\,dt\\ &+\int_{\hat\gamma}^{\overline{(\hat\gamma)}_n}\int_{\hat\alpha}^{\hat\beta}(f_n(s,t)-v(s,t))b(s,t)ds\,dt\\ &+\int_{\overline{(\hat\gamma)}_n}^{\underline{(\hat\eta)}_n}\int_{\hat\alpha}^{\overline{(\hat\alpha)}_n}(f_n(s,t)-v(s,t))b(s,t)ds\,dt\\ &+\int_{\overline{(\hat\gamma)}_n}^{\underline{(\hat\eta)}_n}\int_{\underline{(\hat\beta)}_n}^{\hat\beta}(f_n(s,t)-v(s,t))b(s,t)ds\,dt,\end{aligned} \tag{25}$$

where $[\hat\gamma,\hat\eta]\times[\hat\alpha,\hat\beta] \subset [\gamma,\eta]\times[\alpha,\beta] \subset [-n,n]\times[-n,n]$. Let $a \in L_2^2(\mathbb{R}^2,\mathcal{M}^2,P)$ be an L^2-bound for conv F. For any box of the form $[\alpha',\beta']\times[\gamma',\eta']$, we have the bound

$$\begin{aligned}\left|\int_{\gamma'}^{\eta'}\int_{\alpha'}^{\beta'}(f_n(s,t)-v(s,t))b(s,t)ds\,dt\right| &\le \int_{\gamma'}^{\eta'}\int_{\alpha'}^{\beta'}|f_n(s,t)-v(s,t)|b(s,t)ds\,dt\\ &\le \int_{\gamma'}^{\eta'}\int_{\alpha'}^{\beta'}2|a(s,t)|b(s,t)ds\,dt\\ &= 2\int_{\mathbb{R}^2}|a(x)|\mathcal{X}_{[\alpha',\beta']\times[\gamma',\eta']}(x)b(x)dx\\ &\le 2\|a\|\int_{\mathbb{R}^2}\mathcal{X}_{[\alpha',\beta']\times[\gamma',\eta']}(x)b(x)dx\\ &= 2\|a\|\int_{[\alpha',\beta']\times[\gamma',\eta']}b(x)dx.\end{aligned}$$

Next note that the Lebesgue measure of each of the sets $[\underline{(\hat{\eta})}_n, \hat{\eta}] \times [\hat{\alpha}, \hat{\beta}]$, $[\hat{\gamma}, \overline{(\hat{\gamma})}_n] \times [\hat{\alpha}, \hat{\beta}]$, $[\overline{(\hat{\gamma})}_n, \hat{\eta}] \times [\hat{\alpha}, \overline{(\hat{\alpha})}_n]$, and $[\overline{(\hat{\gamma})}_n, \underline{(\hat{\eta})}_n] \times [\underline{(\hat{\beta})}_n, \hat{\beta}]$ appearing in (25) is bounded by

$$\frac{1}{n} \max\{(\eta - \gamma), (\beta - \alpha)\},$$

which can be made arbitrarily small. By [23, Exercise 12, p. 33], for every $\bar{\epsilon} > 0$ there is an $\delta(\bar{\epsilon}) > 0$ such that

$$\int_{\mathbb{E}} b(x)dx \leq \bar{\epsilon} \quad \text{whenever } \mathcal{M}(\mathbb{E}) \leq \delta(\bar{\epsilon}),$$

where $\mathcal{M}(\mathbb{E})$ is the Lebesgue measure of the set $\mathbb{E}$. Therefore, given $\bar{\epsilon} > 0$, we can choose n so that $\frac{1}{n} \max\{(\eta - \gamma), (\beta - \alpha)\} < \delta(\bar{\epsilon})$. By combining this with (25), we obtain the bound

$$\left| \int_{\hat{\gamma}}^{\hat{\eta}} \int_{\hat{\alpha}}^{\hat{\beta}} (f_n(s,t) - v(s,t)) b(s,t) ds\, dt \right| \leq 8\|a\|\bar{\epsilon}. \tag{26}$$

If we set

$$\Gamma = \max\left\{ |g(s,t)|,\ |g_y(s,t)|,\ |g_x(s,t)|,\ |g_{xy}(s,t)| \ :\ (s,t) \in [\alpha, \beta] \times [\gamma, \eta] \right\},$$

the bound (26) yields the following bound for the sum of the four integrands (21)–(24):

$$|\langle g\mathcal{X}_{\mathbb{M}},\ f_n - v \rangle| \leq \Gamma[1 + (\eta - \gamma) + (\beta - \alpha) + (\eta - \gamma)(\beta - \alpha)]\,[8\|a\|\bar{\epsilon}]\,.$$

Given any $\epsilon > 0$ there exists an $\bar{\epsilon} > 0$ such that the left-hand side, and so also the right-hand side, of this inequality is less than ϵ; moreover, for this $\bar{\epsilon}$ there is an n' such that

$$\frac{1}{n} \max\{(\eta - \gamma), (\beta - \alpha)\} < \delta(\bar{\epsilon}) \qquad \forall\, n \geq n'.$$

Therefore, for all $n \geq n'$ we have $|\langle g\mathcal{X}_{\mathbb{M}},\ f_n - v \rangle| \leq \epsilon$, which is what we set out to show. Since functions of the form $g\mathcal{X}_{\mathbb{M}}$, where $g \in C^\infty[\mathbb{R}^2, \mathbb{R}^2]$ and $\mathbb{M} \subset \mathbb{R}^2$ is a box, are dense in $L_2^2(\mathbb{R}^2, \mathcal{M}^2, P)$ we have that the sequence f_n converges weakly to v. ∎

3.4. Application to wavefront reconstruction. We now apply the above results to the weighted negative modulus mapping $-b(\cdot)|u(\cdot)|$.

PROPOSITION 3.11 (integrals of projections and subgradients). *Let $b \in \mathbb{U}$ be a density function for the probability measure $P(dx) = b(x)dx$ on $(\mathbb{R}^2, \mathcal{M}^2)$ and let $u \in L^2[\mathbb{R}^2, \mathbb{R}^2]$. The negative modulus function $-|u(x)|$ has the following properties:*

(i) *$\mathcal{S}\left(b(\cdot)\overline{\partial}(-|u(\cdot)|)\right)$ is a weakly compact, convex set in $L_2^2(\mathbb{R}^2, \mathcal{M}^2, \nu_2)$;*

(ii) *$\int \partial(-|u(x)|)b(x)dx = \int -\operatorname{conv}\left(\Pi_{\mathbb{S}}(u(x))\right) b(x)dx$, and $\int \partial(-|u(x)|)b(x)dx$ is a compact subset of $\mathbb{R}^2$;*

(iii) *$\mathcal{S}\left(b(\cdot)\overline{\partial}(-|u(\cdot)|)\right) \subset -\mathrm{cl}^*\left(\Pi_{\mathbb{Q}(b)}(u)\right)$ for all $u \in L^2[\mathbb{R}^2, \mathbb{R}^2]$, where $\mathbb{Q}(b)$ is defined by (7) and $\Pi_{\mathbb{Q}(b)}(u)$ by (8).*

Proof. (i) At each x, $b(x)\overline{\partial}(-|u(x)|)$ is closed and convex-valued. In addition, by Example 3.7 every element of the set $\overline{\partial}(-|u(x)|)$ has magnitude less than or equal to 1 and so the multifunction $b(\cdot)\overline{\partial}(-|u(\cdot)|)$ is L^2-bounded in $(\mathbb{R}^2, \mathcal{M}^2, \nu_2)$. Hence, by Proposition 2.2, the multifunction $\mathcal{S}\left(b(x)\overline{\partial}(-|u(x)|)\right)$ is weakly compact in $L_2^2(\mathbb{R}^2, \mathcal{M}^2, \nu_2)$.

(ii) We wish to apply Theorem 3.9, so we must show that the multifunction F written as the composition of a multifunction with a measurable function

$$F(x) = [\partial(-|\cdot|) \circ u](x) = \partial(-|u(x)|)$$

is P-integrably bounded and $\mathcal{M}^2 \otimes \mathcal{B}^2$-measurable. By Example 3.7, the multifunction $F : \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ is P-integrably bounded with bound equal to 1. By Remark 3.5 $\partial(-|\cdot|) : \mathbb{R}^2 \rightrightarrows \mathbb{R}^2$ has closed graph and is therefore $\mathcal{M}^2 \otimes \mathcal{B}^2$-measurable. By hypothesis, the function u is a Lebesgue measurable mapping from $(\mathbb{R}^2, \mathcal{M}^2)$ into $(\mathbb{R}^2, \mathcal{M}^2)$. Thus, by [11, Proposition 1.b, p. 59] the composite multifunction F defined above is $\mathcal{M}^2 \otimes \mathcal{B}^2$-measurable. Therefore Theorem 3.9 applies to give the result.

(iii) By Proposition 3.10 every $v(\cdot) \in \mathcal{S}\left(b(\cdot)\overline{\partial}(-|u(\cdot)|)\right)$ is the weak limit of a sequence of functions in $\mathcal{S}\left(b(\cdot)\partial(-|u(\cdot)|)\right)$, since $\operatorname{conv}\left(\partial(-|u(\cdot)|)\right) = \overline{\partial}(-|u(\cdot)|)$ (see Example 3.7). If $v \in \mathcal{S}\left(b(\cdot)\partial(-|u(\cdot)|)\right)$, then by [16, Theorem 4.2] and Proposition 3.8 $-v \in \mathcal{S}(b(\cdot)\Pi_{\mathbb{S}}(u(\cdot)))$. Hence, by (11),

$$\mathcal{S}\left(b(\cdot)\partial(-|u(\cdot)|)\right) \subset -\Pi_{\mathbb{Q}(b)}(u),$$

from which the result follows. □

3.5. Infinite-dimensional nonsmooth analysis. The next step is to relate the subdifferential of the integral to the integral of the subdifferential. We begin with a brief review of infinite-dimensional nonsmooth analysis. For a complete discussion see [5, 6, 12, 13, 14, 15, 17, 18] and the references therein. To begin with, let $df(u)$ and $\widehat{d}f(u)$ be defined in exactly the same way that they were defined in the finite-dimensional setting in Definition 3.3.

DEFINITION 3.12 (subgradients: infinite-dimensions). *Let $\mathbb{X}$ be a separable Hilbert space, let $f : \mathbb{X} \to \overline{\mathbb{R}}$ be locally Lipschitz continuous, and let $u_* \in \operatorname{dom} f$.*

(i) *A vector $v \in \mathbb{X}^*$ is a* Dini ϵ-subgradient *of f at u_* if*

$$\langle v, w\rangle \le df(u_*)(w) + \epsilon\|w\| \qquad \forall\, w \in \mathbb{X},$$

where $df(u_*)(w)$ is the infinite-dimensional version of the subderivative defined in Definition 3.3(i). *We call the set of Dini ϵ-subgradients v the* Dini ϵ-subdifferential *of f at u_* and denote this set by $\partial_\epsilon^- f(u_*)$. When $\epsilon = 0$, we write $\partial^- f(u_*)$ instead of $\partial_0^- f(u_*)$. By the definition of the subderivative function Definition* 3.3(i) *and the regular subgradient Definition* 3.4(i) *it can be shown that for Lipschitz f the Dini 0-subdifferential is simply the infinite-dimensional version of the regular subgradient, $\partial^- f(u_*) = \widehat{\partial} f(u_*)$.*

(ii) *A vector $v \in \mathbb{X}^*$ is a* subgradient *of f at u_* if there are sequences $\epsilon^{(\nu)} \searrow 0$, $u^{(\nu)} \to u_*$, and $v^{(\nu)} \in \partial_\epsilon^- f(u^{(\nu)})$ with $v^{(\nu)} \overset{w^*}{\to} v$, where $\overset{w^*}{\to}$ denotes weak-star convergence. We call the set of subgradients v the* subdifferential *of f at u_* and denote this set by $\partial f(u_*)$.*

(iii) *We define the Clarke generalized subdifferential, $\overline{\partial} f(u_*)$ of f at u_*, as in the finite-dimensional case, Definition* 3.4(iii).

(iv) *The function f is said to be* subdifferentially regular *at u_* if $\partial f(u_*) \neq \emptyset$ and*

$$\partial f(u_*) = \widehat{\partial} f(u_*).$$

Remark 3.13. This construction of the subdifferential comes from [14] where it is used the to construct the A-subdifferential, or approximate subdifferential. However,

due to the equivalence theorem of Mordukhovich and Shao [18, Theorem 9.2] it can also be used in the separable Hilbert space setting to define the subdifferential given in [15]. From Mordukhovich and Shao [18, Theorem 8.11], we also obtain the relation

$$\overline{\partial} f(u_*) = \mathrm{cl}^*\,(\mathrm{conv}\ \partial f(u_*)). \tag{27}$$

In particular, this implies that f is subdifferentiably regular at u_* if and only if

$$\overline{\partial} f(u_*) = \partial f(u_*).$$

In addition, when f is strictly differentiable, then $\partial f(u)$ coincides with the Fréchet derivative. Finally, we note that the sets $\partial f(u)$ are weakly closed.

Until now we have been concerned with the issue of when a subset of $\mathbb{R}^n$ depends measurably on the parameter $x \in \Omega$. It is equally important for us to consider the properties of measurable real-valued functions on $\mathbb{R}^n$. For this we make use of *normal* integrands as defined in [21, Definition 14.27]. A function $f : \Omega \times \mathbb{R}^n \to \overline{\mathbb{R}}$ is called a normal integrand if its epigraphical mapping $\mathrm{epi}\, f(x, \cdot\,)$, $x \in \Omega$, is closed-valued and measurable. Any autonomous, Lipschitz continuous mapping, i.e., $f(x, u) := g(u)$, where $g : \mathbb{R}^n \to \mathbb{R}$ is Lipschitz, is a normal integrand [21, Example 14.30]. For example, the mapping $|u|$ is a normal integrand. We use normal integrands to prove the measurability of the following important mappings.

Lemma 3.14 (measurability of exposed faces). *Consider a closed-valued Lebesgue measurable multifunction $F : \mathbb{R}^m \rightrightarrows \mathbb{R}^n$. For $x \in \mathbb{R}^m$ and $w \in \mathbb{R}^n$ define $F_* : \mathbb{R}^m \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ by*

$$F_*(x, w) = \mathrm{argmax}\,\{\langle v\,,\, w\rangle \mid v \in F(x)\}\,.$$

Then F_* is closed-valued and Lebesgue measurable.

Remark 3.15. Whenever the set $F_*(x, w)$ is nonempty it is called an exposed face of the convex set $F(x)$ [22, section 18]. It is easily shown that these sets are indeed *faces* of $F(x)$ in the sense of [22, section 18]. Here we have focused on Lebesgue measure, but other σ-finite complete measures are possible.

Proof. Since F is closed-valued and measurable, [21, Example 14.32] implies that the function $f : (\mathbb{R}^m \times \mathbb{R}^n) \times \mathbb{R}^n \to \overline{\mathbb{R}}$ given by

$$f(x, w, v) = \langle v\,,\, -w\rangle + \delta_{F(x)}(v)$$

is a normal integrand. Hence the result follows from [21, Theorem 14.37] since

$$F_*(x, w) = \mathrm{argmin}\, f(x, w, v). \qquad \square$$

We remark that if, in addition, F is compact-valued, then so is F_*.

Lemma 3.16 (subgradients of normal integrands [21, Theorem 14.56]). *Let $(\Omega, \mathcal{A}, \mu)$ be a complete measure space. For the proper normal integrand $f : \Omega \times \mathbb{R}^n \to \mathbb{R}$, and any $u(x) \in \mathrm{dom}\, f(x, \cdot\,)$ depending measurably on $x \in \Omega$, the subderivative functions*

$$(x, w) \mapsto \widehat{d} f(x, u(x))(w), \qquad (x, w) \mapsto df(x, u(x))(w)$$

are normal integrands and the subdifferential mappings

$$x \mapsto \widehat{\partial} f(x, u(x)), \qquad x \mapsto \partial f(x, u(x))$$

are closed-valued and measurable.

In the remainder of this section, whenever we speak of measure we will be referring to Lebesgue measure.

LEMMA 3.17 (measurable selections for the regular subderivative). *Let $f : \mathbb{R}^n \to \mathbb{R}$ be locally Lipschitz and let $u : \mathbb{R}^m \to \mathbb{R}^n$ and $w : \mathbb{R}^m \to \mathbb{R}^n$ be measurable mappings. Then the subdifferential mapping $\overline{\partial} f(u(\cdot))$ is measurable and possesses a measurable selection $v : \mathbb{R}^m \to \mathbb{R}^n$ such that*

$$\langle v(x)\,,\, w(x)\rangle = \widehat{d}f(u(x))(w(x)) \qquad \text{a.e. } x \in \mathbb{R}^m. \tag{28}$$

Proof. By [21, Theorem 14.56] the mapping ∂f is measurable. Since $\overline{\partial} f(u)$ is simply the convex hull of $\partial f(u)$ for all $u \in \mathbb{R}^n$, [21, Exercise 14.12] implies that $\overline{\partial} f$ is compact convex-valued and measurable. Hence, by [21, Theorem 14.13], the mapping $\overline{\partial} f(u(\cdot))$ is also compact convex-valued and measurable. It remains to establish the existence of a measurable selection satisfying (28).

By [21, Theorem 8.49], we have $\widehat{d}f(u)(w) = \sup\langle \overline{\partial} f(u)\,,\, w\rangle$ for all $w \in \mathbb{R}^n$, and we have shown that the mapping $\overline{\partial} f$ is compact convex-valued and measurable. Therefore, by Lemma 3.14, the mapping

$$F_*(u, w) = \operatorname{argmax}\left\{\langle v\,,\, w\rangle \;\middle|\; v \in \overline{\partial} f(u)\right\}$$

is also compact convex-valued and measurable with

$$\operatorname{dom}(F_*) = \{(u, w) \mid F_*(u, w) \neq \emptyset\} = \mathbb{R}^n \times \mathbb{R}^n.$$

Again, by [21, Theorem 14.13], the mapping $F_*(u(\cdot), w(\cdot))$ is also compact convex-valued and measurable. The measurable selection theorem Theorem 2.1 now implies the existence of a measurable function $v(\cdot)$ such that $v(x) \in F_*(u(x), w(x))$ a.e., which proves the lemma. ∎

We now have our first general result on the interchange of integration and subdifferentiation.

LEMMA 3.18 (interchange of subdifferentiation and integration. I). *Let $\mathcal{H} = L^2_m(\mathbb{R}^n, \mathcal{M}^n, \nu_n)$ be the Hilbert space of square integrable functions mapping from $\mathbb{R}^n$ to $\mathbb{R}^m$ defined in section 2.2, where $\mathcal{M}^n$ is the σ-field of Lebesgue measurable sets on $\mathbb{R}^n$ and ν_n is Lebesgue measure. For simplicity, we write $dx = \nu_n(dx)$. Let $f : \mathbb{R}^m \to \mathbb{R}$ be globally Lipschitz continuous with Lipschitz constant K, and suppose there exists $\hat{u} \in \mathcal{H}$ such that $f \circ \hat{u}$ is an L^2-bounded function on the space $(\mathbb{R}^n, \mathcal{M}^n, \mu)$ where $\mu = b\nu_n$, where $b : \mathbb{R}^n \to \mathbb{R}_+$ with $b \in L^1 \cap L^2 \cap L^\infty[\mathbb{R}^n, \mathbb{R}]$. Define the integral functional $J : \mathcal{H} \to \overline{\mathbb{R}}$ by*

$$J(u) = \int f(u(x))b(x)dx.$$

Then J is globally Lipschitz with Lipschitz constant $K\|b\|_2$, and for every $u \in \mathcal{H}$ the mapping $f \circ u$ is L^2-bounded and

$$\overline{\partial} J(u) \subset \mathcal{S}(b(\cdot)\overline{\partial} f(u(\cdot))). \tag{29}$$

Proof. Let $u \in \mathcal{H}$. The fact that $f \circ u$ is L^2-bounded follows immediately from the inequality

$$|f(u(x))| \leq |f(\hat{u}(x))| + K|u(x) - \hat{u}(x)|.$$

The global Lipschitz continuity of J is a consequence of the following derivation:

$$\begin{aligned}|J(u) - J(v)| &\leq \int K|u(x) - v(x)|b(x)dx \\ &= K\langle |u - v|,\, b\rangle \\ &\leq K\|b\|_2\|u - v\|_2.\end{aligned}$$

Remark 3.13 tells us that $\overline{\partial}J(u)$ is a weakly compact convex subset of $\mathcal{H}$ for all $u \in \mathcal{H}$. We also have from Proposition 2.2 that the set $\mathcal{S}(b(\cdot)\overline{\partial}f(u(\cdot)))$ is also a weakly compact convex subset of $\mathcal{H}$ for all $u \in \mathcal{H}$. Hence the inclusion (29) follows if it can be shown that

$$\sup\left\{\langle v\,,\, w\rangle \;\middle|\; v \in \mathcal{S}(b(\cdot)\overline{\partial}f(u(\cdot)))\right\} \geq \widehat{d}J(u)(w)$$

for all $w \in \mathcal{H}$.

Let $w \in \mathcal{H}$ and let $\{u_i\} \subset \mathcal{H}$ and $\{\tau_i\} \subset \mathbb{R}_+$ be such that $\{u_i\}$ strongly converges to u and $\tau_i \downarrow 0$ with

$$\widehat{d}J(u)(w) = \lim_{i\to\infty} \frac{J(u_i + \tau_i w) - J(u_i)}{\tau_i}.$$

Then, by Fatou's lemma,

$$\begin{aligned}\widehat{d}J(u)(w) &= \lim_{i\to\infty} \int \frac{f(u_i(x) + \tau_i w(x)) - f(u_i(x))}{\tau_i} b(x)dx \\ &\leq \int \limsup_{i\to\infty} \frac{f(u_i(x) + \tau_i w(x)) - f(u_i(x))}{\tau_i} b(x)dx \\ &\leq \int \widehat{d}f(u(x))(w(x))b(x)dx.\end{aligned} \tag{30}$$

By Lemma 3.17, the multifunction $\overline{\partial}f(u(\cdot))$ possesses a measurable selection v such that $\widehat{d}f(u(x))(w(x)) = \langle v(x)\,,\, w(x)\rangle$ a.e. on $\mathbb{R}^n$. Therefore, by (30) we have

$$\begin{aligned}\widehat{d}J(u)(w) &\leq \int \langle v(x)\,,\, w(x)\rangle\, b(x)dx \\ &\leq \sup\left\{\langle v\,,\, w\rangle \;\middle|\; v \in \mathcal{S}(b(\cdot)\overline{\partial}f(u(\cdot)))\right\},\end{aligned}$$

proving the result. □

3.6. Application to wavefront reconstruction. In the next proposition we establish the connection between the projection $\Pi_{\mathbb{Q}(b)}$ defined by (8) and the subdifferential of $h : L^2[\mathbb{R}^2, \mathbb{R}^2] \to \mathbb{R}$ defined by (18), where $b \in \mathbb{U}$ with $\mathbb{U}$ defined in (6). Proposition 3.19 is a special case of a more general result to be proved in the final section (Theorem 4.2). However, here we provide a separate and fundamentally different proof which provides the motivation for the perturbation methods studied in [16].

PROPOSITION 3.19 (projection-subdifferential equivalence). *Let $b \in \mathbb{U}$ and let $\Pi_{\mathbb{Q}(b)} : L^2 \rightrightarrows \mathbb{Q}(b)$ be as defined in* (8) *with $\mathbb{Q}(b)$ defined by* (7)*, and $h : L^2[\mathbb{R}^2, \mathbb{R}^2] \to \overline{\mathbb{R}}$ be as defined by* (18)*. Then for all $u \in L^2[\mathbb{R}^2, \mathbb{R}^2]$*

$$\overline{\partial}\left(h(u; b)\right) = \mathcal{S}\left(b(\cdot)\overline{\partial}\left(-|u(\cdot)|\right)\right) = \mathrm{cl}^*\left(-\Pi_{\mathbb{Q}(b)}(u)\right) = \partial\left(h(u; b)\right). \tag{31}$$

Thus, in particular, $h(\cdot; b)$ is everywhere subdifferentiably regular.

Proof. Note that the equivalences in (31) are scale invariant in the sense that if they are shown to be true for a given function b, then they must be true with b replaced by αb for any choice of $\alpha > 0$ since

$$\alpha\partial(h(u;b)) = \partial(h(u;\alpha b)), \qquad \alpha\mathcal{S}(b(\cdot)\bar{\partial}(-|u(\cdot)|)) = \mathcal{S}(\alpha b(\cdot)\bar{\partial}(-|u(\cdot)|)),$$

and

$$\alpha \operatorname{cl}^*(-\Pi_{Q(b)}(u)) = \operatorname{cl}^*(-\Pi_{Q(\alpha b)}(u)).$$

Since b is nonnegative and integrable, we may therefore assume with no loss in generality that b is a probability density function for some probability measure $P(dx) = b(x)dx$.

If (31) holds, then the subdifferential regularity of $h(\cdot;b)$ follows immediately from Proposition 3.11(i) and (27). By Lemma 3.18 and part (iii) of Proposition 3.11,

$$\overline{\partial}h(u;b) \subset \mathcal{S}\left(b(\cdot)\overline{\partial}(-|u(\cdot)|)\right) \subset \operatorname{cl}^*\left(-\Pi_{\mathbb{Q}(b)}(u)\right).$$

Since $\partial h(u;b) \subset \overline{\partial}h(u;b)$, the result follows once it is shown that

$$\operatorname{cl}^*\left(-\Pi_{\mathbb{Q}(b)}(u)\right) \subset \partial h(u;b). \tag{32}$$

By Proposition 3.2 the mapping h is globally Lipschitz continuous with Lipschitz constant $K = \|b\|$, and by Remark 3.13 $\partial h(u;b)$ is weakly closed. Therefore, if $-\Pi_{\mathbb{Q}(b)}(u) \subset \partial h(u;b)$, then $\operatorname{cl}^*\left(-\Pi_{\mathbb{Q}(b)}(u)\right) \subset \partial h(u;b)$. We now show that $-\Pi_{\mathbb{Q}(b)}(u) \subset \partial h(u;b)$.

Let $v \in -\Pi_{\mathbb{Q}(b)}(u)$ and for all $\epsilon > 0$ define $\tilde{u}_\epsilon := u\mathcal{X}_{\operatorname{supp}(u)} + \epsilon v(1 - \mathcal{X}_{\operatorname{supp}(u)})$. Then, by [16, Theorem 4.1],

$$\|u - \tilde{u}_\epsilon\| = \epsilon\|v(1 - \mathcal{X}_{\operatorname{supp}(u)})\| \leq \epsilon\|b\|,$$

and $|\cdot|$ is differentiable at $\tilde{u}_\epsilon(x)$ for every $x \in \operatorname{supp}(b)$ with

$$v(x) = -\nabla|\tilde{u}_\epsilon(x)|b(x) \qquad \forall\, \epsilon > 0.$$

For every $w \in L^2[\mathbb{R}^2, \mathbb{R}^2]$ and $x \in \operatorname{supp}(b)$, we have

$$\frac{|\tilde{u}_\epsilon(x) + tw(x)| - |\tilde{u}_\epsilon(x)|}{t} \to (\nabla|\tilde{u}_\epsilon(x)|, w(x)),$$

and, since $|\cdot|$ is Lipschitz with Lipschitz constant 1,

$$\left|\frac{|\tilde{u}_\epsilon(x) + tw(x)| - |\tilde{u}_\epsilon(x)|}{t}\right| \leq |w(x)| \qquad \forall\, x \in \operatorname{supp}(b).$$

Therefore, by the Lebesgue dominated convergence theorem, the function $h(\cdot;b)$ is Gâteaux differentiable at $\tilde{u}_\epsilon$ with Gâteaux derivative $-\nabla|\tilde{u}_\epsilon|b = v$. Hence, since $|\cdot|$ is Lipschitz continuous the lim inf in Definition 3.3(ii) is attained as a limit yielding $dh(\tilde{u}_\epsilon;b)(w) = \langle v, w\rangle$. Consequently

$$v \in \partial^- h(\tilde{u}_\epsilon;b) \qquad \forall\, \epsilon > 0.$$

Taking the limit as $\epsilon \downarrow 0$, we find that $v \in \partial h(u;b)$. Therefore, $-\Pi_{\mathbb{Q}(b)}(u) \subset \partial h(u;b)$. ∎

The proof of Theorem 3.1 now follows easily from the calculus of subdifferentials.

Proof of Theorem 3.1. [16, Corollary 4.3] gives the representation

$$\begin{aligned}\operatorname{dist}^2(u, \mathbb{Q}_m) &= \operatorname{dist}^2(\mathcal{F}_m(u), \mathbb{Q}(\psi_m)) \\ &= \|\mathcal{F}_m(u)\|^2 + \|\psi_m\|^2 + 2h[\mathcal{F}_m(u); \psi_m].\end{aligned}$$

By applying [18, Theorem 6.7] together with Proposition 3.19 and [16, Corollary 4.3], we obtain

$$\begin{aligned}\partial \operatorname{dist}^2(\mathcal{F}_m(u), \mathbb{Q}(\psi_m)) &= 2\partial\left(\left(\frac{1}{2}\|\cdot\|^2 + h(\cdot; \psi_m)\right) \circ \mathcal{F}_m\right)(u) \\ &= 2\mathcal{F}_m^*\left[\mathcal{F}_m(u) + \operatorname{cl}^*\left(-\Pi_{\mathbb{Q}_m}(\mathcal{F}_m(u))\right)\right] \\ &= 2\operatorname{cl}^*\left(\mathcal{I} - \Pi_{\mathbb{Q}_m}(u)\right).\end{aligned}$$

Hence the subdifferential regularity of all the functions involved in conjunction with [18, Theorem 4.1] yields the result. ∎

4. Concluding remarks. We conclude with a generalization of Theorem 3.19. Theorem 4.2 establishes the equivalence of the infinite-dimensional subdifferential objects in the setting relevant to phase retrieval and establishes their relation to the finite-dimensional Clarke subdifferential. The result, and its proof, closely parallels that given in [6, Theorem 3.5.18].

LEMMA 4.1 (interchange of subdifferentiation and integration. II). *Let the hypotheses of Lemma* 3.18 *hold. Then*

$$\mathcal{S}(b(\cdot)\partial f(u(\cdot))) \subset \partial J(u). \tag{33}$$

Proof. Let $z \in \mathcal{S}(b(\cdot)\partial f(u(\cdot)))$. Since $\partial f(u(\cdot))$ is closed-valued and measurable, there exists $v \in \mathcal{S}(\partial f(u(\cdot)))$ for which $z = bv$. We show that $z \in \partial J(u)$. For this purpose, let C be a countably dense subset of $\operatorname{gph} \widehat{\partial} f$. Observe that

$$\partial f(u) = \left\{ \lim_{j\to\infty} v^j \;\middle|\; \{(u^j, v^j)\} \subset C,\, u^j \to u \right\}.$$

Let $\{(u^k, v^k)\}$ be an enumeration of C. Then for each $x \in \mathbb{R}^n$ and each integer $i \in \{1, 2, \dots\}$, define $k_i(x)$ be the first integer k for which

$$|u^k - u(x)| \le \frac{1}{i} \quad \text{and} \quad |v^k - v(x)| \le \frac{1}{i}.$$

For each $i = 1, 2, \dots$, define $u^i : \mathbb{R}^n \to \mathbb{R}^m$ and $v^i : \mathbb{R}^n \to \mathbb{R}^m$ by

$$u^i(x) = u^{k_i(x)} \quad \text{and} \quad v^i(x) = v^{k_i(x)}.$$

We claim that the functions u^i and v^i are measurable with

$$v^i(x) \in \widehat{\partial} f(u^i(x)) \text{ a.e.} \tag{34}$$

for $i = 1, 2, \dots$. Indeed, the range of both u^i and v^i is contained in the set C and so is countable. Moreover, for a given integer k,

$$\begin{aligned}&\left\{x \;\middle|\; (u^i(x), v^i(x)) = (u^k, v^k)\right\} \\ &= \left[\bigcap_{j=1}^{k-1} \left\{x \;\middle|\; \max\{|u^j - u(x)|, |v^j - v(x)|\} > \frac{1}{i}\right\}\right] \\ &\quad \cap \left\{x \;\middle|\; \max\{|u^k - u(x)|, |v^k - v(x)|\} \le \frac{1}{i}\right\},\end{aligned}$$

where each of the sets on the left-hand side is measurable.

Next observe that for all $w \in \mathcal{H}$, we have from Fatou's lemma that

$$dJ(u^i)(w) = \liminf_{\tau \searrow 0} \frac{J(u^i + \tau w) - J(u^i)}{\tau} \geq \int_{\mathbb{R}^2} df(u^i(x))(w(x))b(x)dx \geq \left\langle bv^i \, , \, w \right\rangle,$$

where the last inequality follows from (34). Hence $bv^i \in \widehat{\partial} J(u^i)$ for $i = 1, 2, \ldots$. Finally, since $u^i \to u$ and $v^i \to v$ by construction, we have $bv \in \partial J(u)$. ∎

THEOREM 4.2 (interchange of subdifferentiation and integration). *Let the hypotheses of Lemma* 3.18 *hold with* $n = m = 2$. *Then, for all* $u \in \mathcal{H} = L^2[\mathbb{R}^2, \mathbb{R}^2]$,

$$\partial J(u) = \mathrm{cl}^* \mathcal{S}(b(\cdot)\partial f(\cdot)) = \mathcal{S}(b(\cdot)\overline{\partial} f(\cdot)) = \overline{\partial} J(u).$$

In particular, this implies that J *is everywhere subdifferentially regular.*

Proof. By Proposition 3.10 we have

$$\mathcal{S}(b(\cdot)\overline{\partial} f(u(\cdot))) \subset \mathrm{cl}^* \, \mathcal{S}(b(\cdot)\partial f(u(\cdot))).$$

Since the set $\partial J(u)$ is weakly closed, Lemma 4.1 implies that

$$\mathrm{cl}^* \, \mathcal{S}(b(\cdot)\partial f(u(\cdot))) \subset \partial J(u).$$

Combining these facts with Lemma 3.18 yields

$$\begin{aligned} \overline{\partial} J(u) &\subset \mathcal{S}(b(\cdot)\overline{\partial} f(u(\cdot))) \\ &\subset \mathrm{cl}^* \, \mathcal{S}(b(\cdot)\partial f(u(\cdot))) \\ &\subset \partial J(u) \\ &\subset \overline{\partial} J(u), \end{aligned}$$

which proves the result. ∎

The restriction in Theorem 4.2 to the case $n = m = 2$ follows from the use of this hypothesis in Proposition 3.10. However, we believe that it is possible to extend this proposition to the general case, which would allow us to remove the restriction $n = m = 2$ from Theorem 4.2.

BREGMAN MONOTONE OPTIMIZATION ALGORITHMS*

HEINZ H. BAUSCHKE†, JONATHAN M. BORWEIN‡, AND PATRICK L. COMBETTES§

Abstract. A broad class of optimization algorithms based on Bregman distances in Banach spaces is unified around the notion of Bregman monotonicity. A systematic investigation of this notion leads to a simplified analysis of numerous algorithms and to the development of a new class of parallel block-iterative surrogate Bregman projection schemes. Another key contribution is the introduction of a class of operators that is shown to be intrinsically tied to the notion of Bregman monotonicity and to include the operators commonly found in Bregman optimization methods. Special emphasis is placed on the viability of the algorithms and the importance of Legendre functions in this regard. Various applications are discussed.

Key words. Banach space, block-iterative method, Bregman distance, Bregman monotone, Bregman projection, $\mathfrak{B}$-class operator, convex feasibility problem, essentially smooth function, essentially strict convex function, Fejér monotone, Legendre function, monotone operator, proximal mapping, proximal point algorithm, resolvent, subgradient projection

1. Introduction.

A sequence $(x_n)_{n\in\mathbb{N}}$ in a Banach space $\mathcal{X}$ is *Fejér monotone* with respect to a set $S \subset \mathcal{X}$ if

$$(\forall x \in S)(\forall n \in \mathbb{N}) \quad \|x_{n+1} - x\| \leq \|x_n - x\|. \tag{1.1}$$

In Hilbert spaces, this notion has proven to be remarkably useful and successful in attempts to unify and harmonize the convergence proofs of a large number of optimization algorithms; see, e.g., [5, 6, 9, 40, 41, 49, 60]. A classical example is the method of cyclic projections for finding a point in the intersection $S \neq \emptyset$ of a finite family of closed convex sets $(S_i)_{1\leq i\leq m}$. In 1965, Bregman [14, Thm. 1] showed that for every initial point $x_0 \in \mathcal{X}$ the sequence $(x_n)_{n\in\mathbb{N}}$ generated by the cyclic projections algorithm

$$(\forall n \in \mathbb{N}) \quad x_{n+1} = P_{n \,(\mathrm{mod}\, m)+1} x_n, \tag{1.2}$$

where P_i denotes the metric projector onto S_i and where the mod m function takes values in $\{0, \ldots, m-1\}$, is Fejér monotone with respect to S and converges weakly to a point in that set. Two years later [15], the same author investigated the convergence of this method in a general topological vector space $\mathcal{X}$. To this end, he introduced a distance-like function $D\colon E \times E \to \mathbb{R}$, where E is a convex subset of $\mathcal{X}$ such that $S = E \cap \bigcap_{i=1}^m S_i \neq \emptyset$. The conditions defining D require, in particular, that for

§Laboratoire Jacques-Louis Lions, Université Pierre et Marie Curie – Paris 6, 75005 Paris, France (plc@math.jussieu.fr).

every $i \in \{1, \dots, m\}$ and every $y \in E$, there exists a point $P_i y \in E \cap S_i$ such that $D(P_i y, y) = \min D(E \cap S_i, y)$. In this broader context, Bregman showed that for every initial point $x_0 \in E$ the cyclic projections algorithm (1.2) produces a sequence that satisfies the monotonicity property

$$(\forall x \in S)(\forall n \in \mathbb{N}) \quad D(x, x_{n+1}) \leq D(x, x_n) \tag{1.3}$$

and whose cluster points are in S [15, eq. (1.2) and Thm. 1]. If $\mathcal{X}$ is a Hilbert space, an example of a D-function satisfying the required conditions relative to the weak topology is $D\colon \mathcal{X}^2 \to \mathbb{R}\colon (x, y) \mapsto \|x - y\|^2/2$. In this case, we recover the previous convergence result [15, Example 1] and observe that (1.3) reduces to (1.1). If $\mathcal{X}$ is the Euclidean space $\mathbb{R}^N$, another example of a suitable D-function is

$$D\colon E \times E \to \mathbb{R}\colon (x, y) \mapsto f(x) - f(y) - \langle x - y, \nabla f(y) \rangle, \tag{1.4}$$

where $f\colon E \subset \mathbb{R}^N \to \mathbb{R}$ is a convex function which is differentiable on E and satisfies a set of auxiliary properties [15, Example 2]. Due to its importance in applications, this particular type of D-function was further studied in [30] and has since been known as a *Bregman distance* (see [33] for an historical account). In $\mathbb{R}^N$, various investigations have focused on the use of Bregman distances in projection, proximal point, and fixed point algorithms; see [7, 31, 32, 33, 46, 47, 83]. (See also [58, 59], where extensions of (1.4) to nondifferentiable functions were studied.) Extensions to Hilbert [18, 20, 61] and Banach [1, 8, 21, 23, 24, 25, 26, 27, 55, 56, 75] spaces have also been considered more recently. In the present paper, we adopt the following definition for Bregman distances.

DEFINITION 1.1. *Let $\mathcal{X}$ be a real Banach space and let $f\colon \mathcal{X} \to]-\infty, +\infty]$ be a lower semicontinuous convex function which is Gâteaux-differentiable on* $\operatorname{int}\operatorname{dom} f \neq \emptyset$. *The* Bregman distance *(for brevity D-*distance*) associated with f is the function*

$$\begin{aligned} &D\colon \mathcal{X} \times \mathcal{X} \to [0, +\infty], \\ &(x, y) \mapsto \begin{cases} f(x) - f(y) - \langle x - y, \nabla f(y) \rangle & \text{if } y \in \operatorname{int}\operatorname{dom} f, \\ +\infty & \text{otherwise.} \end{cases} \end{aligned} \tag{1.5}$$

In addition, the Bregman distance to a set $C \subset \mathcal{X}$ is the function

$$\begin{aligned} D_C\colon \mathcal{X} &\to [0, +\infty], \\ y &\mapsto \inf D(C, y). \end{aligned} \tag{1.6}$$

In Hilbert spaces, one recovers $D\colon (x, y) \mapsto \|x - y\|^2/2$ by setting $f = \|\cdot\|^2/2$. This observation suggests that the following natural variant of the notion of Fejér monotonicity suits the environment described in Definition 1.1.

DEFINITION 1.2. *A sequence $(x_n)_{n\in\mathbb{N}}$ in $\mathcal{X}$ is* Bregman monotone *(for brevity D-*monotone*) with respect to a set $S \subset \mathcal{X}$ if the following conditions hold:*

(i) $S \cap \operatorname{dom} f \neq \emptyset$.
(ii) $(x_n)_{n\in\mathbb{N}}$ *lies in* $\operatorname{int}\operatorname{dom} f$.
(iii) $(\forall x \in S \cap \operatorname{dom} f)(\forall n \in \mathbb{N})$ $D(x, x_{n+1}) \leq D(x, x_n)$.

Let us note that item (ii) is stated only for the sake of clarity and that it could be replaced by $x_0 \in \operatorname{int}\operatorname{dom} f$ since, in view of (1.5), (iii) then forces the whole sequence $(x_n)_{n\in\mathbb{N}}$ to lie in $\operatorname{int}\operatorname{dom} f$.

The importance of the notion of Bregman monotonicity is implicit in [15]. In the Euclidean space setting of [32] (see also [33, page 55]), Bregman monotone sequences were called "D_f Fejér monotone" by analogy with (1.1).

The goal of this paper is to provide a broad framework for the design and the analysis of algorithms based on Bregman distances around the notion of D-monotonicity. This framework not only will lead to a unified convergence analysis for existing algorithms, but also will serve as a basis for the development of a new class of parallel, block-iterative, surrogate Bregman projection methods for solving convex feasibility problems involving variational inequalities, convex inequalities, equilibrium constraints, and fixed point constraints. The tools developed in this paper also provide the main building blocks for the algorithms proposed in [10] to find best Bregman approximations from intersections of closed convex sets in reflexive Banach spaces.

Guide to the paper. We proceed towards our goal of constructing a broad framework for Bregman distance-based algorithms in several steps.

We collect assumptions, notation, and basic results in section 2. The standing assumptions on the underlying space $\mathcal{X}$ and the function f that generates the Bregman distance are stated in section 2.1. In sections 2.2–2.6, we introduce basic notation and terminology, including D-viable operators and Legendre functions. Useful identities for the Bregman distance are provided in section 2.7.

A general and powerful class of operators based on Bregman distances is introduced and analyzed in section 3. This so-called $\mathfrak{B}$-class includes types of operators fundamental in Bregman optimization such as D-firm operators, D-resolvents, D-prox operators, and (subgradient) D-projections, which correspond to their classical counterparts when $\mathcal{X}$ is a Hilbert space and $f = \|\cdot\|^2/2$. For example, it is shown that if $\mathcal{X}$ is reflexive and f is Legendre, then D-prox operators belong to $\mathfrak{B}$ (Corollary 3.25). This result underscores the importance of Legendreness. Moreover, $\mathfrak{B}$-class operators are stable under a certain type of parallel combination, which will be crucial in the formulation of a new block-iterative algorithmic framework in section 5.

Section 4 is devoted to D-monotonicity. This is a central notion in the analysis of Bregman optimization methods because it describes the behavior of a wide class of algorithms based on Bregman distances. Assumptions are given under which simple characterizations can be established for the weak and strong convergence of D-monotone sequences. In conjunction with the results of section 3, D-monotonicity provides a global framework for the development and analysis of algorithms. Indeed, we show that D-monotone sequences can be generated systematically via the iterative scheme

$$x_0 \in \operatorname{int}\operatorname{dom} f \;\text{ and }\; (\forall n \in \mathbb{N})\;\; x_{n+1} \in T_n x_n, \;\text{ where }\; T_n \in \mathfrak{B}. \tag{1.7}$$

A detailed convergence analysis of this unifying model is carried out which, in turn, covers and extends known convergence results.

Finally, in section 5, we are in a position to construct a new block-iterative algorithmic framework. Results obtained in sections 3 and 4 are combined to construct and investigate new classes of parallel, block-iterative methods for solving convex feasibility problems. The main result, Theorem 5.7, provides conditions sufficient for the weak and strong convergence of sequences generated by the new algorithm. Section 5.4 presents several scenarios in which these sufficient conditions are satisfied, including the frequently encountered situation when f is a separable Legendre function on $\mathbb{R}^N$ such that $\operatorname{dom} f^*$ is open (Example 5.14). The concluding sections, sections 5.5 and 5.6, discuss how the main result can be applied to specific optimization problems such as solving convex inequalities, finding common zeros of maximal monotone operators, finding common minimizers of convex function, and finding common fixed points of D-firm operators.

2. Notation, assumptions, and basic facts.

2.1. Standing assumptions. We assume throughout the paper that $\mathcal{X}$ is a real Banach space and that $f\colon \mathcal{X} \to]-\infty,+\infty]$ is a lower semicontinuous convex function which is Gâteaux-differentiable on $\operatorname{int}\operatorname{dom} f \neq \emptyset$.

2.2. Basic notation. Throughout, $\mathbb{N}$ is the set of nonnegative integers. The norm of $\mathcal{X}$ and that of its topological dual $\mathcal{X}^*$ is denoted by $\|\cdot\|$, the associated metric distance by d, and the canonical bilinear form on $\mathcal{X} \times \mathcal{X}^*$ by $\langle\cdot,\cdot\rangle$. (If $\mathcal{X}$ is a Hilbert space, $\langle\cdot,\cdot\rangle$ denotes also its scalar (or inner) product.) The metric distance function to a set $C \subset \mathcal{X}$ is $d_C\colon \mathcal{X} \to [0,+\infty] : y \mapsto \inf_{x\in C} \|x-y\|$ where, by convention, $\inf \emptyset = +\infty$. For every $y \in \operatorname{int}\operatorname{dom} f$, we set $f_y = f - \nabla f(y)$. The symbols $\rightharpoonup$, $\overset{*}{\rightharpoonup}$, and $\to$ denote, respectively, weak, weak$*$, and strong convergence. $\mathfrak{S}(x_n)_{n\in\mathbb{N}}$ and $\mathfrak{W}(x_n)_{n\in\mathbb{N}}$ are, respectively, the sets of strong and weak cluster points of a sequence $(x_n)_{n\in\mathbb{N}}$ in $\mathcal{X}$. $\operatorname{bdry} C$ denotes the boundary of a set $C \subset \mathcal{X}$, $\operatorname{int} C$ its interior, and $\overline{C}$ its closure. The closed ball of center x and radius ρ is denoted by $B(x;\rho)$. The normalized duality mapping J of $\mathcal{X}$ is defined by

$$(\forall x \in \mathcal{X}) \quad J(x) = \big\{x^* \in \mathcal{X}^* \mid \|x\|^2 = \langle x, x^*\rangle = \|x^*\|^2\big\}. \tag{2.1}$$

$\mathbb{R}^N$ is the standard N-dimensional Euclidean space.

2.3. Set-valued operators. Let $\mathcal{Y}$ be a Banach space and $2^{\mathcal{Y}}$ the family of all subsets of $\mathcal{Y}$. A set-valued operator from $\mathcal{X}$ to $\mathcal{Y}$ is an operator $A\colon \mathcal{X} \to 2^{\mathcal{Y}}$. It is characterized by its graph $\operatorname{gr} A = \{(x,u) \in \mathcal{X} \times \mathcal{Y} \mid u \in Ax\}$; its domain is $\operatorname{dom} A = \{x \in \mathcal{X} \mid Ax \neq \emptyset\}$ (with closure $\overline{\operatorname{dom}} A$); its range is $\operatorname{ran} A = \bigcup_{x\in\mathcal{X}} Ax$ (with closure $\overline{\operatorname{ran}} A$); and, if $\mathcal{Y} = \mathcal{X}$, its fixed point set is $\operatorname{Fix} A = \{x \in \mathcal{X} \mid x \in Ax\}$ (with closure $\overline{\operatorname{Fix}} A$). The graph of the inverse A^{-1} of A is $\{(u,x) \in \mathcal{Y} \times \mathcal{X} \mid (x,u) \in \operatorname{gr} A\}$. If $B\colon \mathcal{X} \to 2^{\mathcal{Y}}$ and $\alpha \in \mathbb{R}$, then $\operatorname{gr}(\alpha A + B) = \{(x, \alpha u + v) \in \mathcal{X} \times \mathcal{Y} \mid (x,u) \in \operatorname{gr} A, (x,v) \in \operatorname{gr} B\}$. As is customary, if $x \in \operatorname{dom} A$ and A is single-valued on $\operatorname{dom} A$, we shall denote the unique element in Ax by Ax. Finally, A is locally bounded at $x \in \mathcal{X}$ if there exists $\rho \in]0,+\infty[$ such that $A\big(B(x;\rho)\big)$ is bounded. (We adopt the same definition as in [79, section 17]; it differs slightly from Phelps' definition [71, Chap. 2] which requires $x \in \operatorname{dom} A$.)

2.4. Orbits and suborbits of algorithms. In section 4 and subsequent sections, we shall discuss various algorithms. Sequences generated by algorithms are called orbits, and their subsequences are referred to as suborbits.

2.5. Functions. The domain of a function $g\colon \mathcal{X} \to]-\infty,+\infty]$ is $\operatorname{dom} g = \{x \in \mathcal{X} \mid g(x) < +\infty\}$ (with closure $\overline{\operatorname{dom}} g$), and g is proper if $\operatorname{dom} g \neq \emptyset$. Moreover, g is subdifferentiable at $x \in \operatorname{dom} g$ if its subdifferential at this point,

$$\partial g(x) = \big\{x^* \in \mathcal{X}^* \mid (\forall y \in \mathcal{X}) \ \ \langle y - x, x^*\rangle + g(x) \leq g(y)\big\}, \tag{2.2}$$

is not empty; a subgradient of g at x is an element of $\partial g(x)$. The domain of continuity of g is

$$\operatorname{cont} g = \big\{x \in \mathcal{X} \mid \ |g(x)| < +\infty \ \text{ and } g \text{ is continuous at } x\big\}, \tag{2.3}$$

and its lower level set at height $\eta \in \mathbb{R}$ is $\operatorname{lev}_{\leq\eta} g = \{x \in \mathcal{X} \mid g(x) \leq \eta\}$. Recall that the value of g^*, the conjugate of g, at point $x^* \in \mathcal{X}^*$ is defined by

$$g^*(x^*) = \sup_{x\in\mathcal{X}} \langle x, x^*\rangle - g(x); \tag{2.4}$$

g is cofinite if $\operatorname{dom} g^* = \mathcal{X}^*$. Furthermore, g is coercive if $\lim_{\|x\|\to+\infty} g(x) = +\infty$, supercoercive if $\lim_{\|x\|\to+\infty} g(x)/\|x\| = +\infty$, (weak) lower semicontinuous if its lower level sets $\big(\operatorname{lev}_{\leq\eta} g\big)_{\eta\in\mathbb{R}}$ are (weakly) closed, and (weak) inf-compact if they are (weakly) compact. If $\mathcal{X}$ is reflexive, the notions of weak inf-compactness and coercivity coincide for weak lower semicontinuous functions. The set of minimizing sequences of g is denoted by

$$\mathcal{M}(g) = \big\{(x_n)_{n\in\mathbb{N}} \text{ in } \operatorname{dom} g \mid g(x_n) \to \inf g(\mathcal{X})\big\} \tag{2.5}$$

and the set of global minimizers of g by $\operatorname{Argmin} g$. (If it is a singleton, its unique element is denoted by $\operatorname{argmin} g$.) The inf-convolution of two functions $g_1, g_2 \colon \mathcal{X} \to]-\infty,+\infty]$ is $g_1 \,\square\, g_2 \colon \mathcal{X} \to [-\infty,+\infty] : x \mapsto \inf_{y\in\mathcal{X}} g_1(y) + g_2(x-y)$.

The indicator function of a set $C \subset \mathcal{X}$ is the function $\iota_C \colon \mathcal{X} \to \{0,+\infty\}$ that takes value 0 on C and $+\infty$ on its complement, and its normal cone is

$$N_C = \partial\iota_C \colon \mathcal{X} \to 2^{\mathcal{X}^*} : x \mapsto \begin{cases} \big\{x^* \in \mathcal{X}^* \mid (\forall y \in C) \;\; \langle y-x, x^*\rangle \leq 0\big\} & \text{if } x \in C,\\ \varnothing & \text{otherwise.}\end{cases} \tag{2.6}$$

2.6. *D*-viability and Legendre functions. Operators based on Bregman distances are not defined outside of $\operatorname{int}\operatorname{dom} f$. Thus, using the terminology of [3], for an algorithm such as (1.7) to be viable in the sense that its iterates remain in $\operatorname{int}\operatorname{dom} f$, the operators involved must satisfy the following viability condition.

DEFINITION 2.1. *An operator $T \colon \mathcal{X} \to 2^{\mathcal{X}}$ is* D-viable *if* $\operatorname{ran} T \subset \operatorname{dom} T = \operatorname{int}\operatorname{dom} f$.

It was shown in [7] that a sufficient condition for Bregman projection operators onto closed convex sets in Euclidean spaces to be D-viable is that f be a Legendre function. (In this context, "D-viability" was called "zone consistency" after [30].) The classical finite-dimensional definition of a Legendre function, as introduced by Rockafellar in [77, section 26], is of limited use in general Banach spaces since the resulting class of functions loses some of its remarkable finite-dimensional properties. In the context of Banach spaces, we introduced in [8] the following notion a Legendre function. It not only generalizes Rockafellar's classical definition but also preserves its salient properties in reflexive spaces. (For results on Legendre functions in nonreflexive spaces, see [13].)

DEFINITION 2.2 ([8, Def. 5.2]). *The function f is*

(i) essentially smooth *if ∂f is both locally bounded and single-valued on its domain;*

(ii) essentially strictly convex *if $(\partial f)^{-1}$ is locally bounded on its domain and f is strictly convex on every convex subset of* $\operatorname{dom}\partial f$*;*

(iii) Legendre *if it is both essentially smooth and essentially strictly convex.*

Such functions will be of prime importance in our analysis as they will be shown to provide a simple and convenient sufficient condition for the D-viability of the operators commonly encountered in Bregman optimization methods in Banach spaces.

2.7. Basic properties of Bregman distances. The following properties follow directly from (1.5).

PROPOSITION 2.3. *Let $\{x,y\} \subset \mathcal{X}$ and $\{u,v\} \subset \operatorname{int}\operatorname{dom} f$. Then*

(i) $D(u,v) + D(v,u) = \langle u-v, \nabla f(u) - \nabla f(v)\rangle$;

(ii) $D(x,u) = D(x,v) + D(v,u) + \langle x-v, \nabla f(v) - \nabla f(u)\rangle$;

(iii) $D(x,v) + D(y,u) = D(x,u) + D(y,v) + \langle x-y, \nabla f(u) - \nabla f(v)\rangle$.

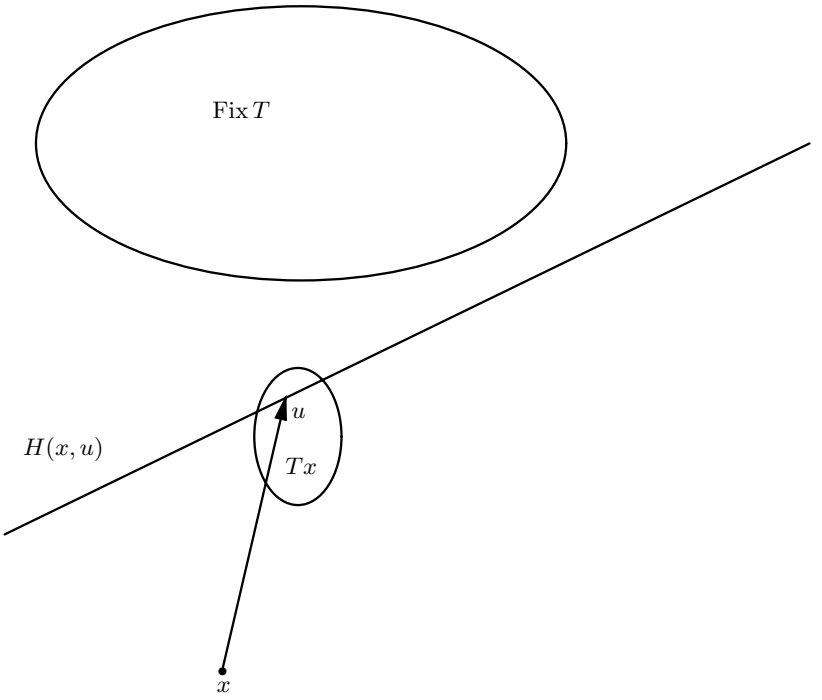

FIG. 1. *If $T \in \mathfrak{B}$, $x \in \operatorname{int}\operatorname{dom} f$, and $u \in Tx$, the half-space $H(x,u)$ contains* $\operatorname{Fix} T$.

3. Operators associated with Bregman distances. In Hilbert spaces, various nonlinear operators are involved in the design of algorithms, including projection operators, proximal operators, resolvents, subgradient projection operators, firmly nonexpansive operators, and combinations of these. Such operators arise in convex feasibility problems, in equilibrium theory, in systems of convex inequalities, in variational inequalities, as well as in numerous fixed point problems [5, 6, 9, 17, 35, 40, 41, 60, 72, 78]. Intrinsically tied to the very definition of these operators is the use of the standard notion of metric distance to measure the proximity between two points. In the context of Bregman distances, it is therefore natural to attempt to define variants of these operators. This effort has been undertaken by several authors at various levels of generality. In this section, we systematically study nonlinear operators associated with Bregman distances in order to bring together and extend a collection of results disseminated in the literature. Specifically, we investigate when D-firm operators, D-resolvents, D-prox operators, D-projectors, and subgradient D-projectors belong to class $\mathfrak{B}$. (For relationships among these operators in the classical case, i.e., when $\mathcal{X}$ is a Hilbert space and $f = \|\cdot\|^2/2$, see [9, Prop. 2.3].) Moreover, the class $\mathfrak{B}$ is shown to be closed under a certain type of relaxed parallel combination. The discussion is not limited to convex problems as nonconvex extensions of standard algorithms have been found to be quite useful in a number of applications; see [12, 28, 43, 52, 62].

3.1. The class $\mathfrak{B}$. Ultimately, our goal is to define a class of operators for which (1.7) systematically generates D-monotone sequences. In this perspective, the operators employed in (1.7) must be D-viable (see Definition 2.1) and induce a certain monotonicity property (see Definition 1.2). These requirements lead to the following class of operators (see Figure 1).

DEFINITION 3.1. *For every x and u in $\operatorname{int}\operatorname{dom} f$, set*

$$H(x,u) = \big\{y \in \mathcal{X} \mid \langle y-u, \nabla f(x) - \nabla f(u)\rangle \leq 0\big\}. \tag{3.1}$$

Then

$$\mathfrak{B} = \big\{T\colon \mathcal{X} \to 2^{\mathcal{X}} \mid \operatorname{ran} T \subset \operatorname{dom} T = \operatorname{int}\operatorname{dom} f,\ (\forall (x,u) \in \operatorname{gr} T)\ \operatorname{Fix} T \subset H(x,u)\big\}.$$

If $\mathcal{X}$ is Hilbertian, $f = \|\cdot\|^2/2$, and only single-valued operators are considered, then $\mathfrak{B}$ reverts to the class $\mathfrak{T}$ of operators introduced in [9] and further investigated in this context in [41, 42]. In these studies, $\mathfrak{T}$ was shown to play a central role in the analysis of Fejér monotone algorithms. Because of Proposition 3.3(i) below, there is some overlap between the "paracontractions" introduced in [31, 75] (see also [24, 26]) and operators in $\mathfrak{B}$. Furthermore, if f satisfies certain conditions and $T \in \mathfrak{B}$ is single-valued with $\operatorname{Fix} T \neq \emptyset$, then T is "totally nonexpansive" in the sense of [24].

LEMMA 3.2. *Let C_1 and C_2 be two convex subsets of $\mathcal{X}$ such that C_1 is closed and $C_1 \cap \operatorname{int} C_2 \neq \emptyset$. Then $\overline{C_1 \cap \operatorname{int} C_2} = C_1 \cap \overline{C_2}$.*

Proof. Since C_2 is convex with nonempty interior, $\overline{C_1 \cap \operatorname{int} C_2} \subset \overline{C_1} \cap \overline{\operatorname{int} C_2} = C_1 \cap \overline{C_2}$. To show the reverse inclusion, fix $x_0 \in C_1 \cap \operatorname{int} C_2$ and $x_1 \in C_1 \cap \overline{C_2}$. By convexity, $[x_0, x_1] \subset C_1$ and $[x_0, x_1[\subset \operatorname{int} C_2$. Therefore, $(\forall \alpha \in [0,1[)\ x_\alpha = (1-\alpha)x_0 + \alpha x_1 \in C_1 \cap \operatorname{int} C_2$. Consequently $x_1 = \lim_{\alpha \uparrow 1^-} x_\alpha \in \overline{C_1 \cap \operatorname{int} C_2}$, and we conclude $C_1 \cap \overline{C_2} \subset \overline{C_1 \cap \operatorname{int} C_2}$. ∎

PROPOSITION 3.3. *Let T be an operator in $\mathfrak{B}$ and let $F = \bigcap_{(x,u)\in \operatorname{gr} T} H(x,u)$. Then*

(i) $(\forall (x,u) \in \operatorname{gr} T)(\forall y \in \operatorname{Fix} T)\ \ D(y,u) \leq D(y,x) - D(u,x)$;
(ii) $(\forall (x,u) \in \operatorname{gr} T)\ \ D(u,x) \leq D_{\operatorname{Fix} T}(x)$;
(iii) $(\forall (x,u) \in \operatorname{gr} T)(\forall y \in \overline{\operatorname{Fix}} T)\ \ D(x,u) + D(u,x) \leq \langle y - x, \nabla f(u) - \nabla f(x)\rangle$.

Now suppose that $f|_{\operatorname{int}\operatorname{dom} f}$ is strictly convex; then

(iv) $\operatorname{Fix} T = F \cap \operatorname{int}\operatorname{dom} f$;
(v) $\operatorname{Fix} T$ *is convex;*
(vi) T *is single-valued on* $\operatorname{Fix} T$.

If, in addition, $\operatorname{Fix} T \neq \emptyset$, then

(vii) $\overline{\operatorname{Fix}} T = F \cap \overline{\operatorname{dom}} f$;
(viii) $(\forall (x,u) \in \operatorname{gr} T)(\forall y \in \overline{\operatorname{Fix}} T)\ \ D(y,u) \leq D(y,x) - D(u,x)$.

Proof. (i) Take $(x,u) \in \operatorname{gr} T$ and $y \in \operatorname{Fix} T$. Then Proposition 2.3(ii) and the inclusion $y \in H(x,u)$ yield $D(y,u) = D(y,x) - D(u,x) + \langle y-u, \nabla f(x) - \nabla f(u)\rangle \leq D(y,x) - D(u,x)$. (ii) By (i), $(\forall (x,u) \in \operatorname{gr} T)(\forall y \in \operatorname{Fix} T)\ D(u,x) \leq D(y,x)$. (iii) Take $(x,u) \in \operatorname{gr} T$ and $y \in \overline{\operatorname{Fix}} T$, and suppose $y_n \to y$ for some sequence $(y_n)_{n\in\mathbb{N}}$ in $\operatorname{Fix} T$. Then it follows from Proposition 2.3(i) that

$$\begin{aligned}(\forall n \in \mathbb{N})\ \ D(x,u) + D(u,x) &= \langle x-u, \nabla f(x) - \nabla f(u)\rangle \\ &= \langle x - y_n, \nabla f(x) - \nabla f(u)\rangle + \langle y_n - u, \nabla f(x) - \nabla f(u)\rangle \\ &\leq \langle x - y_n, \nabla f(x) - \nabla f(u)\rangle\,. \end{aligned} \tag{3.2}$$

Since $\langle x - y_n, \nabla f(x) - \nabla f(u)\rangle \to \langle x - y, \nabla f(x) - \nabla f(u)\rangle$, the proof is complete. (iv) Take $y \in F \cap \operatorname{int}\operatorname{dom} f$. Then $y \in \bigcap_{u\in Ty} H(y,u)$ and, in turn,

$$(\forall u \in Ty)\ \ \langle y-u, \nabla f(y) - \nabla f(u)\rangle \leq 0. \tag{3.3}$$

However, $\{y\} \cup Ty \subset \operatorname{int}\operatorname{dom} f$ and, since $f|_{\operatorname{int}\operatorname{dom} f}$ is strictly convex, ∇f is strictly monotone on $\operatorname{int}\operatorname{dom} f$. Therefore $Ty = \{y\}$ and $y \in \operatorname{Fix} T$. Thus, $F \cap \operatorname{int}\operatorname{dom} f \subset$

$\operatorname{Fix} T$. Since $T \in \mathfrak{B}$, the reverse inclusion is clear. (iv) $\Rightarrow$ (v) Since the sets $\big(H(x,u)\big)_{(x,u)\in \operatorname{gr} T}$ and $\operatorname{int}\operatorname{dom} f$ are convex, so is their intersection $\operatorname{Fix} T$. (vi) was proved in the proof of (iv). (iv) $\Rightarrow$ (vii) Observe that F is closed and apply Lemma 3.2. (viii) Take $(x,u) \in \operatorname{gr} T$, $y_0 \in \operatorname{Fix} T$, and $y \in \overline{\operatorname{Fix}} T$. By (iv) and (vii), $\operatorname{Fix} T = F \cap \operatorname{int}\operatorname{dom} f$ and $\overline{\operatorname{Fix}} T = F \cap \overline{\operatorname{dom}} f$. Since F and $\operatorname{dom} f$ are convex, $[y_0, y] \subset F$ and $[y_0, y[\subset \operatorname{int}\operatorname{dom} f$. Therefore,

$$(\forall \alpha \in [0,1[)\ \ y_\alpha = (1-\alpha)y_0 + \alpha y \in \operatorname{Fix} T. \tag{3.4}$$

Invoking the lower semicontinuity and convexity of f, we get

$$f(y) \leq \underline{\lim}_{\alpha\uparrow 1^-} f(y_\alpha) \leq \overline{\lim}_{\alpha\uparrow 1^-} f(y_\alpha) \leq \overline{\lim}_{\alpha\uparrow 1^-} (1-\alpha)f(y_0) + \alpha f(y) = f(y). \tag{3.5}$$

Hence $\lim_{\alpha\uparrow 1^-} f(y_\alpha) = f(y)$ and, in turn,

$$(\forall z \in \operatorname{int}\operatorname{dom} f)\ \ \lim_{\alpha\uparrow 1^-} D(y_\alpha, z) = D(y,z). \tag{3.6}$$

On the other hand, since $u \in Tx$ and $T \in \mathfrak{B}$, (3.4) and (i) yield

$$(\forall \alpha \in [0,1[)\ \ D(y_\alpha, u) \leq D(y_\alpha, x) - D(u,x). \tag{3.7}$$

Consequently, $D(y,u) \leq D(y,x) - D(u,x)$. □

3.2. *D*-firm operators. An operator $T\colon \mathcal{X} \to \mathcal{X}$ is said to be firmly nonexpansive if for all x and y in $\operatorname{dom} T$ one has [51]

$$(\forall \alpha \in]0,+\infty[)\ \ \|Tx - Ty\| \leq \|\alpha(x-y) + (1-\alpha)(Tx - Ty)\|. \tag{3.8}$$

For the sake of notational simplicity, let us now suppose that $\mathcal{X}$ is smooth. Then its normalized duality map J is single-valued and, upon invoking the equivalence $(\forall \alpha \in]0,+\infty[)\ \|u\| \leq \|u + \alpha v\| \Leftrightarrow 0 \leq \langle v, Ju\rangle$ [51], we observe that (3.8) is equivalent to

$$\langle Tx - Ty, J(Tx - Ty)\rangle \leq \langle x - y, J(Tx - Ty)\rangle. \tag{3.9}$$

If $\mathcal{X}$ is not a Hilbert space, then J is not linear and this type of inequality may be difficult to manipulate. In Hilbert spaces, $J = \operatorname{Id} = \nabla f$ for $f = \|\cdot\|^2/2$, and (3.9) can therefore be written

$$\langle Tx - Ty, \nabla f(Tx) - \nabla f(Ty)\rangle \leq \langle Tx - Ty, \nabla f(x) - \nabla f(y)\rangle. \tag{3.10}$$

In the framework of Bregman distances, this inequality suggests the following definition.

DEFINITION 3.4. *An operator* $T\colon \mathcal{X} \to 2^{\mathcal{X}}$ *with* $\operatorname{dom} T \cup \operatorname{ran} T \subset \operatorname{int}\operatorname{dom} f$ *is* D-firm *if*

$$(\forall (x,u) \in \operatorname{gr} T)(\forall (y,v) \in \operatorname{gr} T)\ \ \langle u - v, \nabla f(u) - \nabla f(v)\rangle \leq \langle u - v, \nabla f(x) - \nabla f(y)\rangle. \tag{3.11}$$

PROPOSITION 3.5. *Let* $T\colon \mathcal{X} \to 2^{\mathcal{X}}$ *be a D-firm operator. Then*

(i) $(\forall (x,u) \in \operatorname{gr} T)\ \ \operatorname{Fix} T \subset H(x,u)$;

(ii) $T \in \mathfrak{B}$ *if* $\operatorname{int}\operatorname{dom} f = \operatorname{dom} T$;

(iii) T *is single-valued on its domain if* $f|_{\operatorname{int}\operatorname{dom} f}$ *is strictly convex;*

(iv) $(\forall (x,u) \in \operatorname{gr} T)(\forall (y,v) \in \operatorname{gr} T) \quad D(u,v) + D(v,u) \leq D(u,y) + D(v,x) - D(u,x) - D(v,y)$.

Proof. (i) Suppose $y \in Ty$. Then (3.11) implies that

$$(\forall (x,u) \in \operatorname{gr} T) \quad \langle y - u, \nabla f(x) - \nabla f(u) \rangle \leq 0. \tag{3.12}$$

(i) $\Rightarrow$ (ii) is clear. (iii) Fix $x \in \operatorname{dom} T$ and $\{u,v\} \subset Tx$. Then (3.11) implies that

$$\langle u - v, \nabla f(u) - \nabla f(v) \rangle \leq 0. \tag{3.13}$$

Since ∇f is strictly monotone on $\operatorname{int}\operatorname{dom} f \supset \{u,v\}$, we obtain $u = v$. (iv) follows from Proposition 2.3(i), (3.11), and Proposition 2.3(iii). □

Remark 3.6. For single-valued operators in Hilbert spaces and f strongly convex (i.e., $f - \beta\|\cdot\|^2/2$ is convex for some $\beta \in]0,+\infty[$), item (iv) above was used to define D-firmness in [18].

3.3. *D*-resolvents. The resolvent of an operator $A\colon \mathcal{X} \to 2^{\mathcal{X}}$ is $(\operatorname{Id} + A)^{-1}$. It is known that an operator $T\colon \mathcal{X} \to \mathcal{X}$ is firmly nonexpansive if and only if it is the resolvent of an accretive operator $A\colon \mathcal{X} \to 2^{\mathcal{X}}$ [19].

Now let $A\colon \mathcal{X} \to 2^{\mathcal{X}^*}$ be a nontrivial operator, i.e., $\operatorname{gr} A \neq \emptyset$. Then, in the context of Bregman distances, it is reasonable to introduce the following variant of the notion of a resolvent to obtain an operator from $\mathcal{X}$ to $\mathcal{X}$ (this definition appears to have first been proposed in $\mathbb{R}^N$ in [46]).

DEFINITION 3.7. *The* D-resolvent *associated with* $A\colon \mathcal{X} \to 2^{\mathcal{X}^*}$ *is the operator*

$$R_A = (\nabla f + A)^{-1} \circ \nabla f\colon \mathcal{X} \to 2^{\mathcal{X}}. \tag{3.14}$$

An a posteriori motivation for (3.14) is that it preserves the usual fixed point characterization of the zeros of A, namely,

$$(\forall x \in \mathcal{X})(\forall \gamma \in]0,+\infty[) \quad 0 \in Ax \quad \Leftrightarrow \quad x \in \operatorname{Fix} R_{\gamma A}, \tag{3.15}$$

as $0 \in Ax \Leftrightarrow \nabla f(x) \in \nabla f(x) + \gamma A(x) = (\nabla f + \gamma A)(x) \Leftrightarrow x \in (\nabla f + \gamma A)^{-1}\big(\nabla f(x)\big)$. It is also consistent with previous attempts to define resolvents for monotone operators:

- Let $\mathcal{X}$ be smooth and set $f = \|\cdot\|^2/2$. Then $\nabla f = J$ and $R_A = (J + A)^{-1} \circ J$. This type of resolvent was used in [57].
- If $\mathcal{X}$ is Hilbertian and $f\colon x \mapsto \|\Pi x\|^2/2$, where Π is the metric projector onto a closed vector subspace of $\mathcal{X}$, then $\nabla f = \Pi$ and $R_A = (\Pi + A)^{-1} \circ \Pi$. This generalized resolvent was used in [54].

PROPOSITION 3.8. *R_A satisfies the following properties:*

(i) $\operatorname{dom} R_A \subset \operatorname{int}\operatorname{dom} f$.
(ii) $\operatorname{ran} R_A \subset \operatorname{int}\operatorname{dom} f$.
(iii) $\operatorname{Fix} R_A = (\operatorname{int}\operatorname{dom} f) \cap A^{-1}0$.
(iv) *Suppose A is monotone. Then the following conditions hold:*
  (a) *R_A is D-firm.*
  (b) *R_A is single-valued on its domain if $f|_{\operatorname{int}\operatorname{dom} f}$ is strictly convex.*
  (c) *Suppose* $\operatorname{ran}\nabla f \subset \operatorname{ran}(\nabla f + A)$. *Then* $R_A \in \mathfrak{B}$. *If, in addition, $f|_{\operatorname{int}\operatorname{dom} f}$ is strictly convex, then* $\operatorname{Fix} R_A$ *is convex.*

Proof. (i) is clear. (ii) We have

$$\begin{aligned} \operatorname{ran} R_A \subset \operatorname{ran}(\nabla f + A)^{-1} &= \operatorname{dom}(\nabla f + A) = \operatorname{dom}\nabla f \cap \operatorname{dom} A \subset \operatorname{dom}\nabla f \\ &= \operatorname{int}\operatorname{dom} f. \end{aligned} \tag{3.16}$$

(iii) $\operatorname{Fix} R_A \subset \operatorname{int}\operatorname{dom} f$ by (i) and $(\forall x \in \operatorname{int}\operatorname{dom} f)\ 0 \in Ax \Leftrightarrow x \in R_A x$ by (3.15). Hence, $A^{-1}0 \cap \operatorname{int}\operatorname{dom} f = \operatorname{Fix} R_A \cap \operatorname{int}\operatorname{dom} f = \operatorname{Fix} R_A$. (iv) Suppose that A is monotone. (a) In view of (i) and (ii), let us show that (3.11) is satisfied. Fix (x,u) and (y,v) in $\operatorname{gr} R_A$. Then $\nabla f(x) - \nabla f(u) \in Au$ and $\nabla f(y) - \nabla f(v) \in Av$. Consequently, since A is monotone, we get $\langle u-v, \nabla f(x) - \nabla f(u) - (\nabla f(y) - \nabla f(v))\rangle \geq 0$. (b) follows from (a) and Proposition 3.5(iii). (c) $\operatorname{ran}\nabla f \subset \operatorname{ran}(\nabla f + A) \Leftrightarrow \operatorname{ran}\nabla f \subset \operatorname{dom}(\nabla f + A)^{-1} \Leftrightarrow \operatorname{dom} R_A = \operatorname{dom}\nabla f = \operatorname{int}\operatorname{dom} f$. In view of (a) and Proposition 3.5(ii), $R_A \in \mathfrak{B}$. Proposition 3.3(v) implies the convexity of $\operatorname{Fix} R_A$. □

DEFINITION 3.9 (see [86, sections 32.14 and 32.21]). *A is*

(i) weakly coercive *if* $\lim_{\|x\|\to+\infty} \inf \|Ax\| = +\infty$;

(ii) strongly coercive *if*

$$(\forall x \in \operatorname{dom} A) \quad \lim_{\|y\|\to+\infty} \inf \frac{\langle y - x, Ax\rangle}{\|y\|} = +\infty;$$

(iii) 3-monotone *if*

$$\big(\forall\big((x,x^*),(y,y^*),(z,z^*)\big) \in (\operatorname{gr} A)^3\big)\ \ \langle x-y, x^*\rangle + \langle y-z, y^*\rangle + \langle z-x, z^*\rangle \geq 0;$$

(iv) 3^*-monotone *if it is monotone and*

$$(\forall (x,x^*) \in \operatorname{dom} A \times \operatorname{ran} A)\ \ \sup\big\{\langle x-y, y^*-x^*\rangle \mid (y,y^*) \in \operatorname{gr} A\big\} < +\infty.$$

LEMMA 3.10 (see [86, section 32.21], [16]). *Suppose that $\mathcal{X}$ is reflexive and that A is monotone and satisfies one of the following properties:*

(i) *A is 3-monotone.*

(ii) *A is strongly coercive.*

(iii) *$\operatorname{ran} A$ is bounded.*

(iv) *$A = \partial\varphi$, where $\varphi\colon \mathcal{X} \to]-\infty, +\infty]$ is a proper function.*

Then A is 3^*-monotone.

The following lemma is Reich's extension to a reflexive Banach space setting of the Brézis–Haraux theorem [16] on the range of the sum of two monotone operators.

LEMMA 3.11 (see [74, Thm. 2.2]). *Suppose that $\mathcal{X}$ is reflexive and let $A_1, A_2\colon \mathcal{X} \to 2^{\mathcal{X}^*}$ be two monotone operators such that $A_1 + A_2$ is maximal monotone and A_1 is 3^*-monotone. In addition, suppose that $\operatorname{dom} A_2 \subset \operatorname{dom} A_1$ or A_2 is 3^*-monotone. Then $\operatorname{int}\operatorname{ran}(A_1 + A_2) = \operatorname{int}(\operatorname{ran} A_1 + \operatorname{ran} A_2)$ and $\overline{\operatorname{ran}}\,(A_1 + A_2) = \overline{\operatorname{ran} A_1 + \operatorname{ran} A_2}$.*

PROPOSITION 3.12. *Let $\gamma \in]0, +\infty[$. Suppose that $\mathcal{X}$ is reflexive and that A is maximal monotone with $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A = \operatorname{dom}\partial f \cap \operatorname{dom} A \neq \emptyset$. Then $\nabla f + \gamma A$ is maximal monotone. Moreover, the inclusions*

$$\begin{cases} \operatorname{int}(\operatorname{ran}\nabla f + \gamma \operatorname{ran} A) \subset \operatorname{ran}(\nabla f + \gamma A) \\ \operatorname{ran}\nabla f + \gamma \operatorname{ran} A \subset \overline{\operatorname{ran}}\,(\nabla f + \gamma A) \end{cases} \tag{3.17}$$

are satisfied if one of the following conditions holds:

(i) *$\operatorname{dom} A \subset \operatorname{int}\operatorname{dom} f$.*

(ii) *A is 3^*-monotone.*

Proof. Since f is proper, lower semicontinuous, and convex, ∂f is maximal monotone [79, Thm. 30.3] and $\operatorname{int}\operatorname{dom} f = \operatorname{cont} f \subset \operatorname{dom}\partial f \subset \operatorname{dom} f$ [48, Chap. I]. Since $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A = \operatorname{dom}\partial f \cap \operatorname{dom} A \neq \emptyset$, we have $(\operatorname{int}\operatorname{dom}\partial f) \cap \operatorname{dom}\gamma A = (\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A \neq \emptyset$, and it follows from Rockafellar's sum theorem [79, section 23] that $\partial f + \gamma A$ is maximal monotone. However, the above assumption implies

that $\operatorname{dom}(\nabla f + \gamma A) = \operatorname{dom}(\partial f + \gamma A)$ and, in turn, that $\nabla f + \gamma A = \partial f + \gamma A$ since $\{\nabla f\} = \partial f|_{\operatorname{int}\operatorname{dom} f}$. Thus, $\nabla f + \gamma A$ is maximal monotone. The second assertion is an application of Lemma 3.11 with $A_1 = \nabla f$ and $A_2 = \gamma A$. Indeed, $\operatorname{dom}\nabla f = \operatorname{int}\operatorname{dom} f$ and, by Lemma 3.10(iv), ∂f is 3^*-monotone and so is, therefore, ∇f since $\operatorname{gr}\nabla f \subset \operatorname{gr}\partial f$. ∎

THEOREM 3.13. *Let $\gamma \in]0,+\infty[$. Suppose that $\mathcal{X}$ is reflexive, that A is maximal monotone with $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A = \operatorname{dom}\partial f \cap \operatorname{dom} A \neq \varnothing$, and that one of the following conditions holds:*

(i) *$\mathcal{X}$ is smooth and $f = \|\cdot\|^2/2$.*
(ii) *$(\nabla f + \gamma A)^{-1}$ is locally bounded at every point in $\mathcal{X}^*$.*
(iii) *$\nabla f + \gamma A$ is weakly coercive.*
(iv) *$\operatorname{dom} A \subset \operatorname{int}\operatorname{dom} f$ or A is 3^*-monotone, and one of the following conditions holds:*
  (a) *$\operatorname{ran}\nabla f + \gamma \operatorname{ran} A = \mathcal{X}^*$.*
  (b) *f is Legendre and cofinite.*
  (c) *$\operatorname{ran}(\nabla f + \gamma A)$ is closed and $0 \in \operatorname{ran} A$.*
  (d) *$\operatorname{ran}\nabla f$ is open and $0 \in \operatorname{ran} A$.*

Then $R_{\gamma A} \in \mathfrak{B}$.

Proof. In view of Proposition 3.8(iv)(c), it suffices to show that $\operatorname{ran}\nabla f \subset \operatorname{ran}(\nabla f + \gamma A)$. (i) Since $\mathcal{X}$ is smooth, $\nabla f = J$ [34, Corollary I.4.5] and Rockafellar's surjectivity theorem [79, Thm. 10.7] yields $\operatorname{ran}(\nabla f + \gamma A) = \mathcal{X}^*$. (ii) Proposition 3.12 asserts that $\nabla f + \gamma A$ is maximal monotone. It therefore follows from the Brézis–Browder surjectivity theorem (see [34, Thm. V.3.8] or [86, Thm. 32.G]) that $\operatorname{ran}(\nabla f + \gamma A) = \mathcal{X}^*$. (iii) $\Rightarrow$ (ii) follows from [86, Cor. 32.35] since $\nabla f + \gamma A$ is maximal monotone. (iv) By Proposition 3.12, (3.17) holds. (a) By (3.17), $\mathcal{X}^* = \operatorname{int}(\operatorname{ran}\nabla f + \gamma \operatorname{ran} A) \subset \operatorname{ran}(\nabla f + \gamma A)$. (b) $\Rightarrow$ (a) By [8, Thm. 5.10], Legendreness guarantees $\operatorname{ran}\nabla f = \operatorname{int}\operatorname{dom} f^*$ while cofiniteness gives $\operatorname{int}\operatorname{dom} f^* = \mathcal{X}^*$. Consequently, $\operatorname{ran}\nabla f + \gamma \operatorname{ran} A = \mathcal{X}^*$. (c) By (3.17), $\operatorname{ran}\nabla f = \operatorname{ran}\nabla f + \{0\} \subset \operatorname{ran}\nabla f + \gamma \operatorname{ran} A \subset \overline{\operatorname{ran}}\,(\nabla f + \gamma A) = \operatorname{ran}(\nabla f + \gamma A)$. (d) By (3.17), $\operatorname{ran}\nabla f = \operatorname{int}(\operatorname{ran}\nabla f + \{0\}) \subset \operatorname{int}(\operatorname{ran}\nabla f + \gamma \operatorname{ran} A) \subset \operatorname{ran}(\nabla f + \gamma A)$. ∎

In connection with the problem of finding zeros of maximal monotone operators, the following corollary is particularly useful.

COROLLARY 3.14. *Let $\gamma \in]0,+\infty[$. Suppose that $\mathcal{X}$ is reflexive, that A is maximal monotone with $0 \in \operatorname{ran} A$, and that one of the following conditions holds:*

(i) *$\operatorname{ran}\nabla f$ is open and $\operatorname{dom} A \subset \operatorname{int}\operatorname{dom} f$.*
(ii) *f is Legendre and $\operatorname{dom} A \subset \operatorname{int}\operatorname{dom} f$.*
(iii) *f is Legendre, A is 3^*-monotone, and $\operatorname{dom} A \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$.*

Then $R_{\gamma A} \in \mathfrak{B}$.

Proof. The assertions follow from Theorem 3.13(iv)(d). Indeed, in (i), $\operatorname{dom} A \subset \operatorname{int}\operatorname{dom} f = \operatorname{cont} f \subset \operatorname{dom}\partial f \Rightarrow (\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A = \operatorname{dom}\partial f \cap \operatorname{dom} A = \operatorname{dom} A \neq \varnothing$. On the other hand, in (ii) and (iii), $\operatorname{ran}\nabla f$ is open since Legendreness yields $\operatorname{ran}\nabla f = \operatorname{int}\operatorname{dom} f^*$ [8, Thm. 5.10]. Consequently, if $\operatorname{dom} A \subset \operatorname{int}\operatorname{dom} f$, then (ii) is a consequence of (i). Otherwise, if A is 3^*-monotone and $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A \neq \varnothing$, then it suffices to note that essential smoothness yields $\operatorname{dom}\partial f = \operatorname{int}\operatorname{dom} f$ [8, Thm. 5.6], whence $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom} A = \operatorname{dom}\partial f \cap \operatorname{dom} A \neq \varnothing$. ∎

Remark 3.15. In $\mathbb{R}^N$, Corollary 3.14(i) corresponds to [46, Thm. 4].

3.4. *D*-prox operators. The classical notion of a proximal operator was introduced by Moreau [64, 65, 67] in Hilbert spaces. The proximal operator associated with a function $\varphi\colon \mathcal{X} \to]-\infty,+\infty]$ is $\operatorname{prox}^{\varphi}\colon y \mapsto \operatorname{argmin}\varphi + \|\cdot - y\|^2/2$. Outside of

Hilbert spaces, this notion is of less interest since Fermat's rule for the minimization of $\varphi + \|\cdot - y\|^2/2$ becomes a nonseparable inclusion, namely, $0 \in \partial\varphi(x) + J(x-y)$.

In $\mathbb{R}^N$, the idea of defining proximal operators based on D-distance—rather than quadratic—penalizations was introduced in [32]. In our setting, they will be defined as follows.

DEFINITION 3.16. *Let* $\varphi\colon \mathcal{X} \to]-\infty,+\infty]$. *The* D-prox operator *of index* $\gamma \in]0,+\infty[$ *associated with* φ *is the operator*

$$\operatorname{prox}_\gamma^\varphi\colon \mathcal{X} \to 2^{\mathcal{X}},$$
$$y \mapsto \left\{ x \in \operatorname{dom} f \cap \operatorname{dom}\varphi \mid \varphi(x) + \frac{1}{\gamma}D(x,y) = \min\left(\varphi + \frac{1}{\gamma}D(\cdot,y)\right)(\mathcal{X}) < +\infty \right\}.$$

It follows from this definition that

$$\operatorname{dom}\operatorname{prox}_\gamma^\varphi \subset \operatorname{int}\operatorname{dom} f \quad \text{and} \quad \operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset \operatorname{dom} f \cap \operatorname{dom}\varphi. \tag{3.18}$$

Recall (see section 2.5) that a function is weak inf-compact if all its lower level sets are weakly compact.

LEMMA 3.17. *Suppose that* $g_1\colon \mathcal{X} \to]-\infty,+\infty]$ *is weak lower semicontinuous and bounded from below and that* $g_2\colon \mathcal{X} \to]-\infty,+\infty]$ *is weak inf-compact. Then* $g_1 + g_2$ *is weak inf-compact.*

Proof. Set $\beta = \inf g_1(\mathcal{X})$ and let $\eta \in \mathbb{R}$. Since g_1 and g_2 are weak lower semicontinuous, so is their sum, and therefore $\operatorname{lev}_{\le\eta}(g_1+g_2)$ is weakly closed. On the other hand, $\operatorname{lev}_{\le\eta}(g_1+g_2)$ is contained in the weakly compact set $\operatorname{lev}_{\le\eta-\beta} g_2$. We conclude that $\operatorname{lev}_{\le\eta}(g_1+g_2)$ is weakly compact. ∎

The following result concerns the domain requirement for the D-viability of D-prox operators. Recall (see sections 2.5 and 2.2) that $\mathcal{M}$ denotes the set of minimizing sequences of a function and that $\mathfrak{W}$ is the set of weak cluster points of a sequence.

THEOREM 3.18. *Let* $\gamma \in]0,+\infty[$, *let* $\varphi\colon \mathcal{X} \to]-\infty,+\infty]$ *be such that* $\operatorname{dom} f \cap \operatorname{dom}\varphi \neq \emptyset$, *and assume that one of the following conditions holds:*

(i) $(\forall y \in \operatorname{int}\operatorname{dom} f)(\exists\,(x_n)_{n\in\mathbb{N}} \in \mathcal{M}(f_y + \gamma\varphi))(\exists\, x \in \mathfrak{W}(x_n)_{n\in\mathbb{N}})$ $f + \gamma\varphi$ *is weak lower semicontinuous at* x.

(ii) $(\forall y \in \operatorname{int}\operatorname{dom} f)$ $f_y + \gamma\varphi$ *is weak inf-compact.*

(iii) φ *is weak lower semicontinuous and bounded from below, and, for every* $y \in \operatorname{int}\operatorname{dom} f$, f_y *is weak inf-compact.*

(iv) φ *is weak inf-compact.*

Then $\operatorname{dom}\operatorname{prox}_\gamma^\varphi = \operatorname{int}\operatorname{dom} f$.

Proof. Fix $y \in \operatorname{int}\operatorname{dom} f$ and set $g = f_y + \gamma\varphi$. (i) Pick $(x_n)_{n\in\mathbb{N}} \in \mathcal{M}(g)$ such that $x_{k_n} \rightharpoonup x$ and g is weak lower semicontinuous at x. It follows that $g(x) \le \underline{\lim}\, g(x_{k_n}) = \inf g(\mathcal{X})$ and hence $g(x) = \inf g(\mathcal{X})$. Therefore, g achieves its infimum and the result holds since $\operatorname{prox}_\gamma^\varphi y = \operatorname{Argmin}(f_y+\gamma\varphi) = \operatorname{Argmin}(g)$. (ii) ⇒ (i) Take $(x_n)_{n\in\mathbb{N}} \in \mathcal{M}(g)$. Then it follows from weak inf-compactness of g that $(x_n)_{n\in\mathbb{N}}$ lies in a weakly compact set and therefore that $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \neq \emptyset$. On the other hand, as g is weak inf-compact, it is weak lower semicontinuous and so is $f + \gamma\varphi = f_y + \gamma\varphi + \nabla f(y) = g + \nabla f(y)$. (iii) ⇒ (ii) follows from Lemma 3.17. (iv) ⇒ (ii) It is clear that f_y is weak lower semicontinuous. On the other hand, it follows from the convexity of f that, for every $x \in \mathcal{X}$, $\langle x - y, \nabla f(y)\rangle + f(y) \le f(x)$ and, therefore, $f_y(x) \ge f_y(y)$. Hence $\inf f_y(\mathcal{X}) \ge f_y(y) > -\infty$ and, by Lemma 3.17, g is weak inf-compact. ∎

The following fundamental result is due to Moreau [66] and Rockafellar [76].

LEMMA 3.19. *Let* $y^* \in \mathcal{X}^*$. *Then* $f - y^*$ *is coercive if and only if* $y^* \in \operatorname{int}\operatorname{dom} f^*$.

LEMMA 3.20. *Let* $g_1, g_2\colon \mathcal{X} \to]-\infty,+\infty]$ *be two convex functions. Then*

(i) *if* g_1 *and* g_2 *are lower semicontinuous and* $0 \in \operatorname{int}\big(\operatorname{dom} g_1 - \operatorname{dom} g_2\big)$, *then* $(g_1 + g_2)^* = g_1^* \,\square\, g_2^*$ [2];
(ii) *if* $\operatorname{cont} g_1 \cap \operatorname{dom} g_2 \neq \varnothing$, *then* $\partial(g_1 + g_2) = \partial g_1 + \partial g_2$ [79, Thm. 28.2].

PROPOSITION 3.21. *Let* $\varphi\colon \mathcal{X} \to \left]-\infty, +\infty\right]$ *be a lower semicontinuous convex function such that* $\operatorname{dom} f \cap \operatorname{dom} \varphi \neq \varnothing$ *and let* $\gamma \in \left]0, +\infty\right[$. *Suppose that* $\mathcal{X}$ *is reflexive and that one of the following conditions holds:*

(i) $(\forall y \in \operatorname{int}\operatorname{dom} f)(\exists\, (x_n)_{n\in\mathbb{N}} \in \mathcal{M}(f_y + \gamma\varphi))\ \ \sup_{n\in\mathbb{N}} \|x_n\| < +\infty$.
(ii) $(\forall y \in \operatorname{int}\operatorname{dom} f)\ \ f_y + \gamma\varphi$ *is coercive.*
(iii) $\operatorname{ran} \nabla f \subset \operatorname{int}\operatorname{dom} (f + \gamma\varphi)^*$.
(iv) $f + \gamma\varphi$ *is cofinite.*
(v) $0 \in \operatorname{int}(\operatorname{dom} f - \operatorname{dom}\varphi)$ *and* $\operatorname{dom} f^* + \gamma \operatorname{dom}\varphi^* = \mathcal{X}^*$.
(vi) φ *is bounded from below and* f *is essentially strictly convex.*
(vii) $f + \gamma\varphi$ *is supercoercive.*
(viii) φ *is bounded from below and* f *is supercoercive.*
(ix) φ *is coercive.*

Then $\operatorname{dom} \operatorname{prox}_\gamma^\varphi = \operatorname{int}\operatorname{dom} f$.

Proof. Let y be an arbitrary point in $\operatorname{int}\operatorname{dom} f$. Note that, since φ is weak lower semicontinuous, so are $f + \gamma\varphi$ and $f_y + \gamma\varphi$ and that, since $\mathcal{X}$ is reflexive, coercive weak lower semicontinuous functions are weak inf-compact. (i) is a consequence of Theorem 3.18(i). Indeed, take a bounded sequence $(x_n)_{n\in\mathbb{N}} \in \mathcal{M}(f_y + \gamma\varphi)$. Then it follows from the reflexivity of $\mathcal{X}$ that $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \neq \varnothing$. (ii) follows at once from Theorem 3.18(ii). (iii) $\Leftrightarrow$ (ii) $\nabla f(y) \in \operatorname{int}\operatorname{dom} (f+\gamma\varphi)^* \Leftrightarrow f+\gamma\varphi-\nabla f(y)$ is coercive by Lemma 3.19. (iv) $\Rightarrow$ (iii) is clear. (v) $\Rightarrow$ (iv) Lemma 3.20(i) yields

$$\begin{aligned} \operatorname{dom} f^* + \gamma \operatorname{dom}\varphi^* &= \operatorname{dom} f^* + \operatorname{dom}\gamma\varphi^*(\cdot/\gamma) = \operatorname{dom} f^* + \operatorname{dom}(\gamma\varphi)^* \\ &= \operatorname{dom}\big(f^* \,\square\, (\gamma\varphi)^*\big) \end{aligned} \tag{3.19}$$

and

$$0 \in \operatorname{int}(\operatorname{dom} f - \operatorname{dom}\varphi) \ \ \Rightarrow \ \ f^* \,\square\, (\gamma\varphi)^* = (f + \gamma\varphi)^*. \tag{3.20}$$

Hence $\operatorname{dom} f^* + \gamma \operatorname{dom}\varphi^* = \mathcal{X}^* \Rightarrow \operatorname{dom}(f + \gamma\varphi)^* = \mathcal{X}^*$. (vi) is a consequence of Theorem 3.18(iii): indeed, by [8, Thm. 5.9(ii)], $\nabla f(y) \in \operatorname{int}\operatorname{dom} f^*$ and f_y is therefore coercive by Lemma 3.19. (vii) $\Rightarrow$ (iv) See [8, Thm. 3.4]. (viii) $\Rightarrow$ (vii) is clear. (ix) is a consequence of Theorem 3.18(iv). $\square$

The next result gathers some facts concerning D-prox operators for convex functions.

PROPOSITION 3.22. *Let* $\varphi\colon \mathcal{X} \to \left]-\infty, +\infty\right]$ *be convex and let* $\gamma \in \left]0, +\infty\right[$. *Then the following hold:*

(i) $\operatorname{prox}_\gamma^\varphi = \big(\partial(f + \gamma\varphi)\big)^{-1} \circ \nabla f$.
(ii) *If, in addition,* $\operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset \operatorname{int}\operatorname{dom} f$, *then*
  (a) $\operatorname{prox}_\gamma^\varphi = R_{\gamma\partial\varphi}$;
  (b) $\operatorname{Fix}\operatorname{prox}_\gamma^\varphi = (\operatorname{int}\operatorname{dom} f) \cap \operatorname{Argmin}\,\varphi$;
  (c) $\operatorname{prox}_\gamma^\varphi$ *is D-firm;*
  (d) $\operatorname{prox}_\gamma^\varphi$ *is single-valued on its domain if* $f|_{\operatorname{int}\operatorname{dom} f}$ *is strictly convex.*

Proof. Fix $y \in \operatorname{int}\operatorname{dom} f$. (i) By (3.18), $\operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset \operatorname{dom} f \cap \operatorname{dom}\varphi$. If $\operatorname{dom} f \cap \operatorname{dom}\varphi = \varnothing$, both sides of the desired identity reduce to the trivial operator $z \mapsto \varnothing$. If not, take $x \in \operatorname{dom} f \cap \operatorname{dom}\varphi$. Since $\operatorname{cont}\nabla f(y) = \mathcal{X}$, Lemma 3.20(ii) yields

$\partial(f_y + \gamma\varphi)(x) = \partial(f + \gamma\varphi)(x) - \nabla f(y)$. Consequently,

$$\begin{aligned} x \in \operatorname{prox}_\gamma^\varphi y &\Leftrightarrow 0 \in \partial(f_y + \gamma\varphi)(x) \\ &\Leftrightarrow \nabla f(y) \in \partial(f + \gamma\varphi)(x) \\ &\Leftrightarrow x \in \big(\partial(f + \gamma\varphi)\big)^{-1}\big(\nabla f(y)\big). \end{aligned} \tag{3.21}$$

(ii) Suppose $\operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset \operatorname{int}\operatorname{dom} f$. (a) On the one hand, it follows from (3.18) that $\operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset (\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom}\varphi$. On the other hand, $\operatorname{ran} R_{\gamma\partial\varphi} \subset \operatorname{dom}(\nabla f + \gamma\partial\varphi) \subset (\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom}\varphi$. Therefore, if $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom}\varphi = \varnothing$, both sides of the desired identity reduce to the trivial operator $z \mapsto \varnothing$. If not, take $x \in (\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom}\varphi = \operatorname{cont} f \cap \operatorname{dom}\varphi$. Lemma 3.20(ii) now yields $\partial(f+\gamma\varphi)(x) = \nabla f(x) + \gamma\partial\varphi(x)$ and (3.21) becomes

$$x \in \operatorname{prox}_\gamma^\varphi y \Leftrightarrow \nabla f(y) \in \nabla f(x) + \gamma\partial\varphi(x) \Leftrightarrow x \in R_{\gamma\partial\varphi} y. \tag{3.22}$$

(a) $\Rightarrow$ (b) follows from Proposition 3.8(iii). (a) $\Rightarrow$ (c) Since $\partial\varphi$ is monotone, $R_{\gamma\partial\varphi}$ is D-firm by Proposition 3.8(iv)(a). (a) $\Rightarrow$ (d) follows from Proposition 3.8(iv)(b). ∎

We now turn our attention to the range requirement for the D-viability of D-prox operators.

PROPOSITION 3.23. *Let $\varphi\colon \mathcal{X} \to]-\infty, +\infty]$ be convex such that $\operatorname{dom} f \cap \operatorname{dom}\varphi \neq \varnothing$, and let $\gamma \in]0, +\infty[$. Assume that one of the following conditions holds:*

(i) $\operatorname{dom}\partial(f + \gamma\varphi) \subset \operatorname{int}\operatorname{dom} f$.
(ii) $\operatorname{dom} f \cap \operatorname{dom}\varphi \subset \operatorname{int}\operatorname{dom} f$.
(iii) $\operatorname{dom} f$ *is open.*
(iv) $\operatorname{dom}\varphi \subset \operatorname{int}\operatorname{dom} f$.
(v) $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom}\varphi \neq \varnothing$ *and one of the following conditions holds:*
  (a) $\operatorname{dom}\partial f \cap \operatorname{dom}\partial\varphi \subset \operatorname{int}\operatorname{dom} f$.
  (b) f *is essentially smooth.*
  (c) $\operatorname{dom}\partial\varphi \subset \operatorname{int}\operatorname{dom} f$.

Then $\operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset \operatorname{int}\operatorname{dom} f$.

Proof. (i) By Proposition 3.22(i),

$$\operatorname{ran}\operatorname{prox}_\gamma^\varphi \subset \operatorname{ran}\big(\partial(f + \gamma\varphi)\big)^{-1} = \operatorname{dom}\partial(f + \gamma\varphi) \subset \operatorname{int}\operatorname{dom} f. \tag{3.23}$$

(ii) $\Rightarrow$ (i) $\operatorname{dom}\partial(f + \gamma\varphi) \subset \operatorname{dom}(f + \gamma\varphi) = \operatorname{dom} f \cap \operatorname{dom}\varphi \subset \operatorname{int}\operatorname{dom} f$. (iii) $\Rightarrow$ (ii) and (iv) $\Rightarrow$ (ii) are clear. (v) $\Rightarrow$ (i) It results from Lemma 3.20(ii) that $\partial(f + \gamma\varphi) = \partial f + \gamma\partial\varphi$. Whence, (a) $\Rightarrow$ (i). (b) $\Rightarrow$ (a) Essential smoothness $\Rightarrow \operatorname{dom}\partial f = \operatorname{int}\operatorname{dom} f$ [8, Thm. 5.6(iii)]. (c) $\Rightarrow$ (a) is clear. ∎

Upon combining Propositions 3.23, 3.22(ii)(c), 3.21, and 3.5(ii), we obtain the following theorem.

THEOREM 3.24. *Let $\varphi\colon \mathcal{X} \to]-\infty, +\infty]$ be a lower semicontinuous convex function such that $\operatorname{dom} f \cap \operatorname{dom}\varphi \neq \varnothing$, and let $\gamma \in]0, +\infty[$. Suppose that $\mathcal{X}$ is reflexive and that one of conditions* (i)–(ix) *in Proposition* 3.21 *holds together with one of conditions* (i)–(v) *in Proposition* 3.23. *Then* $\operatorname{prox}_\gamma^\varphi \in \mathfrak{B}$.

The following special case underscores the importance of the notion of Legendreness.

COROLLARY 3.25. *Let $\varphi\colon \mathcal{X} \to]-\infty, +\infty]$ be a lower semicontinuous convex function such that $(\operatorname{int}\operatorname{dom} f) \cap \operatorname{dom}\varphi \neq \varnothing$, and let $\gamma \in]0, +\infty[$. Suppose that $\mathcal{X}$ is reflexive, that f is Legendre, and that φ is bounded below. Then*

(i) $\operatorname{prox}_\gamma^\varphi$ *is single-valued on its domain and* $\operatorname{prox}_\gamma^\varphi \in \mathfrak{B}$;

(ii) *for every* x *and* y *in* $\operatorname{int}\operatorname{dom} f$,

$$x = \operatorname{prox}_\gamma^\varphi y \;\Leftrightarrow\; (\forall z \in \operatorname{dom}\varphi)\;\; \langle z - x, \nabla f(y) - \nabla f(x)\rangle / \gamma + \varphi(x) \le \varphi(z).$$

Proof. (i) Combine Propositions 3.23(v)(b), 3.22(ii)(c) and (d), 3.21(vi), and 3.5(ii). (ii) By (3.22), $x = \operatorname{prox}_\gamma^\varphi y \Leftrightarrow \nabla f(y) - \nabla f(x) \in \gamma\partial\varphi(x)$. ∎

Remark 3.26. A special case of Theorem 3.18(iii) in $\mathbb{R}^N$ can be found in [32, Prop. 3.1]. In $\mathbb{R}^N$, assertions (iv) and (v)(b) of Proposition 3.23 appear in [58, Lemma 3.3]. In the case when $\mathcal{X}$ is Hilbertian and $f = \|\cdot\|^2/2$, the characterization supplied by Corollary 3.25(ii) is well known; see, e.g., [48, section II.2].

3.5. *D*-projections. The following concept goes back to Bregman's original paper [15].

DEFINITION 3.27. *The* D-projector *onto a set* $C \subset \mathcal{X}$ *is the operator*

$$\begin{aligned} P_C\colon \mathcal{X} &\to 2^{\mathcal{X}},\\ y &\mapsto \big\{x \in C \cap \operatorname{dom} f \mid D(x,y) = D_C(y) < +\infty\big\}. \end{aligned} \tag{3.24}$$

It is clear that, for any $\gamma \in\,]0,+\infty[$, $P_C = \operatorname{prox}_\gamma^{\iota_C}$. Hence, the results of section 3.4 will automatically yield results on D-projections when specialized to $\varphi = \iota_C$. Before we proceed in this direction, let us introduce a couple of definitions, which are natural adaptations of standard ones in metric approximation theory [81].

DEFINITION 3.28. *A set* $C \subset \mathcal{X}$ *is* D-proximinal *if* $\operatorname{dom} P_C = \operatorname{int}\operatorname{dom} f$ *and* D-semi-Chebyshev *if* P_C *is single-valued on its domain.* C *is* D-Chebyshev *if it is* D*-proximinal and* D*-semi-Chebyshev.*

DEFINITION 3.29. *A set* $C \subset \mathcal{X}$ *is* D-approximately weakly compact *if*

$$(\forall y \in \operatorname{int}\operatorname{dom} f)(\forall (x_n)_{n\in\mathbb{N}} \text{ in } C \cap \operatorname{dom} f)\;\; D(x_n, y) \to D_C(y) \;\Rightarrow\; \mathfrak{W}(x_n)_{n\in\mathbb{N}} \cap C \neq \varnothing.$$

THEOREM 3.30. *Let* C *be a subset of* $\mathcal{X}$ *such that* $C \cap \operatorname{dom} f \neq \varnothing$ *and assume that one of the following conditions holds:*

(i) C *is* D*-approximately weakly compact.*
(ii) $(\forall y \in \operatorname{int}\operatorname{dom} f)(\exists\, \eta \in \mathbb{R})\;\; C \cap \operatorname{lev}_{\le\eta} f_y$ *is nonempty and weakly compact.*
(iii) C *is weakly closed and, for every* $y \in \operatorname{int}\operatorname{dom} f$, f_y *is weak inf-compact.*
(iv) C *is weakly compact.*

Then C *is* D*-proximinal.*

Proof. (i) Since f is weak lower semicontinuous, $f + \iota_C$ is weak lower semicontinuous at every point in C. Now fix $y \in \operatorname{int}\operatorname{dom} f$ and $(x_n)_{n\in\mathbb{N}} \in \mathcal{M}(f_y + \iota_C)$. Then $D(x_n, y) \to D_C(y)$ and Definition 3.29 yields $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \cap C \neq \varnothing$. Now take $x \in \mathfrak{W}(x_n)_{n\in\mathbb{N}} \cap C$. Since $f + \iota_C$ is weak lower semicontinuous at x, the claims follow from Theorem 3.18(i) with $\varphi = \iota_C$. (ii) Fix $y \in \operatorname{int}\operatorname{dom} f$. As minimizing $D(\cdot, y)$ over C is equivalent to minimizing the weak lower semicontinuous function f_y over the weakly compact set $C \cap \operatorname{lev}_{\le\eta} f_y$, the result follows. Assertions (iii) and (iv) follow, respectively, from assertions (iii) and (iv) in Theorem 3.18 with $\varphi = \iota_C$. ∎

Upon setting $\varphi = \iota_C$, Proposition 3.21 becomes the following.

PROPOSITION 3.31. *Let* C *be a closed and convex subset of* $\mathcal{X}$ *such that* $C \cap \operatorname{dom} f \neq \varnothing$. *Suppose that* $\mathcal{X}$ *is reflexive and that one of the following conditions holds:*

(i) $(\forall y \in \operatorname{int}\operatorname{dom} f)(\forall (x_n)_{n\in\mathbb{N}} \in \mathcal{M}(f_y + \iota_C))\;\; \sup_{n\in\mathbb{N}} \|x_n\| < +\infty$.
(ii) $(\forall y \in \operatorname{int}\operatorname{dom} f)\;\; f_y + \iota_C$ *is coercive.*
(iii) $\operatorname{ran}\nabla f \subset \operatorname{int}\operatorname{dom}(f + \iota_C)^*$.

(iv) $f + \iota_C$ *is cofinite.*
(v) $0 \in \operatorname{int}(\operatorname{dom} f - C)$ *and* $\operatorname{dom} f^* + \operatorname{dom} \iota_C^* = \mathcal{X}^*$.
(vi) f *is essentially strictly convex.*
(vii) $f + \iota_C$ *is supercoercive.*
(viii) f *is supercoercive.*
(ix) C *is bounded.*

Then C *is* D*-proximinal.*

Likewise, Proposition 3.22 with $\varphi = \iota_C$ yields the following.

PROPOSITION 3.32. *Let* C *be a convex subset of* $\mathcal{X}$. *Then the following hold:*
(i) $P_C = \big(\partial(f + \iota_C)\big)^{-1} \circ \nabla f$.
(ii) *If, in addition,* $\operatorname{ran} P_C \subset \operatorname{int} \operatorname{dom} f$, *then*
  (a) $P_C = R_{N_C}$.
  (b) $\operatorname{Fix} P_C = C \cap \operatorname{int} \operatorname{dom} f$.
  (c) P_C *is* D*-firm.*
  (d) C *is* D*-semi-Chebyshev if* $f|_{\operatorname{int} \operatorname{dom} f}$ *is strictly convex.*

The D-viability requirements for the range of P_C are obtained by setting $\varphi = \iota_C$ in Proposition 3.23.

PROPOSITION 3.33. *Let* $C \subset \mathcal{X}$ *be convex such that* $C \cap \operatorname{dom} f \neq \emptyset$. *Assume that one of the following conditions holds:*
(i) $\operatorname{dom} \partial(f + \iota_C) \subset \operatorname{int} \operatorname{dom} f$.
(ii) $C \cap \operatorname{dom} f \subset \operatorname{int} \operatorname{dom} f$.
(iii) $\operatorname{dom} f$ *is open.*
(iv) $C \subset \operatorname{int} \operatorname{dom} f$.
(v) $C \cap \operatorname{int} \operatorname{dom} f \neq \emptyset$ *and one of the following conditions holds:*
  (a) $C \cap \operatorname{dom} \partial f \subset \operatorname{int} \operatorname{dom} f$;
  (b) f *is essentially smooth.*

Then $\operatorname{ran} P_C \subset \operatorname{int} \operatorname{dom} f$.

THEOREM 3.34. *Let* $C \subset \mathcal{X}$ *be a closed convex set such that* $C \cap \operatorname{dom} f \neq \emptyset$. *Suppose that* $\mathcal{X}$ *is reflexive and that one of conditions* (i)–(ix) *in Proposition* 3.31 *holds together with one of conditions* (i)–(v) *in Proposition* 3.33. *Then* $P_C \in \mathfrak{B}$.

Proof. Since Proposition 3.31 parallels Proposition 3.21 and Proposition 3.33 parallels Proposition 3.23, it suffices to set $\varphi = \iota_C$ in Theorem 3.24. □

We conclude this section with the following result.

COROLLARY 3.35. *Suppose that* $\mathcal{X}$ *is reflexive, that* f *is Legendre, and that* C *is a closed convex subset of* $\mathcal{X}$ *such that* $C \cap \operatorname{int} \operatorname{dom} f \neq \emptyset$. *Then*
(i) C *is* D*-Chebyshev and* $P_C \in \mathfrak{B}$;
(ii) *for every* x *and* y *in* $\operatorname{int} \operatorname{dom} f$,

$$x = P_C y \quad \Leftrightarrow \quad \begin{cases} x \in C, \\ C \subset H(y, x). \end{cases} \tag{3.25}$$

Proof. Take $\varphi = \iota_C$ in Corollary 3.25. □

Remark 3.36. Proposition 3.31(vii)–(ix) can be found in [1, Prop. 2.1]. Corollary 3.35(i) covers [8, Cor. 7.9] (see also [7, section 3] in the special case of Euclidean spaces), which was obtained via different arguments. If $\mathcal{X}$ is Hilbertian and $f = \|\cdot\|^2/2$, Corollary 3.35(ii) reduces to the classical characterization of metric projections onto closed convex sets.

3.6. Subgradient *D*-projections. The D-projection onto a closed convex set may be hard to compute. If the set is specified as a lower level set, it can be approximated by the D-projection onto a separating hyperplane, which is much easier

to compute. In the traditional case when $\mathcal{X}$ is Hilbertian and $f = \|\cdot\|^2/2$, this is a standard approach which goes back to [73] (see also [6, 37, 60]). In the context of Bregman distances, we shall define subgradient D-projections as follows (see also [27, 59] for special instances).

DEFINITION 3.37. *Suppose that*

$$\begin{cases} \mathcal{X} \text{ is reflexive and } f \text{ is Legendre,} \\ g\colon \mathcal{X} \to \left]-\infty,+\infty\right] \text{ is lower semicontinuous and convex,} \\ \operatorname{lev}_{\leq 0} g \cap \operatorname{int}\operatorname{dom} f \neq \varnothing \;\text{ and }\; \operatorname{dom} f \subset \operatorname{dom} g. \end{cases} \tag{3.26}$$

For every $x \in \operatorname{int}\operatorname{dom} f$ *and* $x^* \in \partial g(x)$, *set*

$$G(x,x^*) = \big\{y \in \mathcal{X} \mid \langle x-y, x^*\rangle \geq g(x)\big\}. \tag{3.27}$$

The operator

$$Q_g\colon \operatorname{int}\operatorname{dom} f \to \mathcal{X}\colon x \mapsto \big\{P_{G(x,x^*)}x \mid x^* \in \partial g(x)\big\} \tag{3.28}$$

is the subgradient D-projector *onto* $\operatorname{lev}_{\leq 0} g$.

Note that $G(x,x^*)$ is a proper closed half-space if $x^* \neq 0$ and the whole space $\mathcal{X}$ otherwise; the latter may occur only when $x \in \operatorname{Argmin} g$.

PROPOSITION 3.38. *Suppose that* (3.26) *is in force and let* Q_g *be the subgradient* D*-projector onto* $\operatorname{lev}_{\leq 0} g$. *Then*

(i) $\operatorname{Fix} Q_g = \operatorname{lev}_{\leq 0} g \cap \operatorname{int}\operatorname{dom} f$;

(ii) $Q_g \in \mathfrak{B}$.

Proof. Fix $x \in \operatorname{int}\operatorname{dom} f$ and $x^* \in \partial g(x)$. Since $\operatorname{int}\operatorname{dom} f \subset \operatorname{int}\operatorname{dom}\, g \subset \operatorname{dom}\partial g$, $\partial g(x) \neq \varnothing$ and the closed convex set $G(x,x^*)$ is well defined. Moreover, (2.2) yields

$$(\forall y \in \operatorname{lev}_{\leq 0}\, g)\;\; \langle y-x, x^*\rangle \leq g(y) - g(x) \leq -g(x). \tag{3.29}$$

Therefore, $\operatorname{lev}_{\leq 0}\, g \subset G(x,x^*)$ and, in turn, $G(x,x^*) \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$. Hence, Corollary 3.35(i) asserts that $P_{G(x,x^*)}$ is single-valued with $\operatorname{ran} P_{G(x,x^*)} \subset \operatorname{int}\operatorname{dom} f = \operatorname{dom} P_{G(x,x^*)}$, whence $\operatorname{ran} Q_g \subset \operatorname{int}\operatorname{dom} f = \operatorname{dom} Q_g$. (i) Take $y \in \mathcal{X}$. Then it follows from Proposition 3.32(ii)(b) that

$$\begin{aligned} y \in \operatorname{Fix} Q_g &\Leftrightarrow (\exists\, y^* \in \partial g(y))\;\; y = P_{G(y,y^*)}y \\ &\Leftrightarrow (\exists\, y^* \in \partial g(y))\;\; y \in G(y,y^*) \cap \operatorname{int}\operatorname{dom} f \\ &\Leftrightarrow (\exists\, y^* \in \partial g(y))\;\; 0 = \langle y-y, y^*\rangle \geq g(y) \;\text{ and }\; y \in \operatorname{int}\operatorname{dom} f \\ &\Leftrightarrow y \in \operatorname{lev}_{\leq 0}\, g \cap \operatorname{int}\operatorname{dom} f. \end{aligned}$$

Thus, $\operatorname{Fix} Q_g = \operatorname{lev}_{\leq 0}\, g \cap \operatorname{int}\operatorname{dom} f$. (ii) To show that $Q_g \in \mathfrak{B}$ observe that Corollary 3.35(ii) implies that $G(x,x^*) \subset H(x, P_{G(x,x^*)}x)$. Consequently, $\operatorname{Fix} Q_g \subset \operatorname{lev}_{\leq 0} g \subset G(x,x^*) \subset H(x, P_{G(x,x^*)}x)$, where $(x, P_{G(x,x^*)}x)$ is an arbitrary point in $\operatorname{gr} Q_g$. Altogether, $Q_g \in \mathfrak{B}$. ∎

3.7. Relaxed parallel combination of $\mathfrak{B}$-class operators. The following proposition describes a scheme to aggregate $\mathfrak{B}$-class operators in order to create a new $\mathfrak{B}$-class operator.

PROPOSITION 3.39. *Suppose that* $\mathcal{X}$ *is reflexive and that* f *is Legendre. Let* $(T_i)_{i\in I}$ *be a finite family of operators in* $\mathfrak{B}$ *such that* $\bigcap_{i\in I} \operatorname{Fix} T_i \neq \varnothing$, *let* $(\omega_i)_{i\in I}$ *be*

weights in $]0,1]$ *such that* $\sum_{i\in I}\omega_i = 1$, *and let* λ *be a relaxation parameter in* $]0,1]$. *For every* $x \in \operatorname{int}\operatorname{dom} f$, *select* $(u_i)_{i\in I} \in \bigtimes_{i\in I} T_i x$, *put*

$$H(x) = \big\{y \in \mathcal{X} \mid \langle y, x^*\rangle \leq \eta(x)\big\}, \tag{3.30}$$

where

$$\begin{cases} x^* = \nabla f(x) - \sum_{i\in I}\omega_i \nabla f(u_i), \\ \eta(x) = \sum_{i\in I}\omega_i \left\langle x + \lambda(u_i - x), \nabla f(x) - \nabla f(u_i)\right\rangle, \end{cases} \tag{3.31}$$

and define $T\colon \operatorname{int}\operatorname{dom} f \to \mathcal{X}\colon x \mapsto P_{H(x)}x$. *Then the following hold:*

(i) T *is single-valued on* $\operatorname{dom} T = \operatorname{int}\operatorname{dom} f \supset \operatorname{ran} T$.
(ii) *For every* $x \in \operatorname{int}\operatorname{dom} f$, *the following statements are equivalent:*
  (a) $x \in \bigcap_{i\in I}\operatorname{Fix} T_i$.
  (b) $x^* = 0$.
  (c) $H(x) = \mathcal{X}$.
  (d) $x \in H(x)$.
  (e) $x \in \operatorname{Fix} T$.
(iii) $\operatorname{Fix} T = \bigcap_{i\in I}\operatorname{Fix} T_i$.
(iv) $\overline{\operatorname{Fix}}\, T = \bigcap_{i\in I}\overline{\operatorname{Fix}}\, T_i$.
(v) $(\forall x \in \operatorname{int}\operatorname{dom} f)\ H(x) = H(x, Tx)$.
(vi) $T \in \mathfrak{B}$.

Proof. Fix $x \in \operatorname{int}\operatorname{dom} f$. (i) We first observe that the operator T is well defined. Indeed, since $(T_i)_{i\in I}$ lies in $\mathfrak{B}$, x^* and $\eta(x)$ are well defined and we have

$$\begin{aligned} \emptyset \neq \bigcap_{i\in I}\operatorname{Fix} T_i &\subset (\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} H(x, u_i) \\ &\subset (\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} \big\{y \in \mathcal{X} \mid \langle y - u_i, \nabla f(x) - \nabla f(u_i)\rangle \\ &\qquad\qquad \leq (1-\lambda)\langle x - u_i, \nabla f(x) - \nabla f(u_i)\rangle\big\} \\ &\subset (\operatorname{int}\operatorname{dom} f) \cap \Big\{y \in \mathcal{X} \mid \sum_{i\in I}\omega_i \langle y - u_i, \nabla f(x) - \nabla f(u_i)\rangle \\ &\qquad\qquad \leq (1-\lambda)\sum_{i\in I}\omega_i\langle x - u_i, \nabla f(x) - \nabla f(u_i)\rangle\Big\} \\ &= (\operatorname{int}\operatorname{dom} f) \cap H(x), \end{aligned} \tag{3.32}$$

where the second inclusion follows from the inequality $\lambda \leq 1$ and the monotonicity of ∇f. Whence, $(\operatorname{int}\operatorname{dom} f) \cap H(x) \neq \emptyset$, and it follows from Corollary 3.35(i) that $P_{H(x)}x$ is a well-defined point in $\operatorname{int}\operatorname{dom} f$. (ii) Since f is essentially strictly convex, it is strictly convex on $\operatorname{int}\operatorname{dom} f$ and it follows from Proposition 3.3(vi) that (a) $\Rightarrow$ $(\forall i \in I)\ u_i = x \Rightarrow$ (b). (b) $\Rightarrow$ (c) Suppose $x^* = 0$ and fix $y \in \bigcap_{i\in I}\operatorname{Fix} T_i$. Then,

since $(T_i)_{i\in I}$ lies in $\mathfrak{B}$,

$$\begin{aligned}0 &\leq \sum_{i\in I}\omega_i\,\langle u_i - y, \nabla f(x) - \nabla f(u_i)\rangle\\ &= \eta(x) - \langle y, x^*\rangle - (1-\lambda)\sum_{i\in I}\omega_i\,\langle x - u_i, \nabla f(x) - \nabla f(u_i)\rangle\\ &\leq \eta(x). \qquad (3.33)\end{aligned}$$

Accordingly, $H(x) = \mathcal{X}$. The implications (c) $\Rightarrow$ (d) $\Rightarrow$ $x = P_{H(x)}x$ $\Rightarrow$ (e) are clear in view of Proposition 3.32(ii)(b). (e) $\Rightarrow$ (a) We have

$$\begin{aligned}x \in \operatorname{Fix} T &\Leftrightarrow x = P_{H(x)}x\\ &\Leftrightarrow x \in H(x)\\ &\Leftrightarrow \langle x, x^*\rangle \leq \eta(x)\\ &\Leftrightarrow \lambda\sum_{i\in I}\omega_i\,\langle x - u_i, \nabla f(x) - \nabla f(u_i)\rangle \leq 0\\ &\Leftrightarrow (\forall i \in I)\ \ x = u_i \in T_i x\\ &\Leftrightarrow x \in \bigcap_{i\in I}\operatorname{Fix} T_i,\end{aligned}$$

where the next to last equivalence follows from the strict monotonicity of ∇f on $\operatorname{int}\operatorname{dom} f$ (f is strictly convex on $\operatorname{int}\operatorname{dom} f$) and the inequalities $\lambda > 0$ and $\min_{i\in I}\omega_i > 0$. (iii) (i) and (ii) yield $\operatorname{Fix} T = (\operatorname{int}\operatorname{dom} f) \cap \operatorname{Fix} T = \bigcap_{i\in I}(\operatorname{Fix} T_i \cap \operatorname{int}\operatorname{dom} f) = \bigcap_{i\in I}\operatorname{Fix} T_i$. (iv) Set $(\forall i \in I)\ F_i = \bigcap_{(x,u)\in \operatorname{gr} T_i} H(x,u)$. Then (iii) and Proposition 3.3(iv) yield $\operatorname{Fix} T = (\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} F_i$. Therefore, by Lemma 3.2 and Proposition 3.3(vii),

$$\overline{\operatorname{Fix}}\, T = \overline{\operatorname{dom}}\, f \cap \bigcap_{i\in I} F_i = \bigcap_{i\in I}(F_i \cap \overline{\operatorname{dom}}\, f) = \bigcap_{i\in I}\overline{\operatorname{Fix}}\, T_i. \qquad (3.34)$$

(v) By Corollary 3.35(ii), we always have $H(x) \subset H(x, P_{H(x)}x) = H(x, Tx)$. Now suppose $x \in H(x)$. Then (ii) yields $H(x) = \mathcal{X} = H(x,x) = H(x, P_{H(x)}x) = H(x, Tx)$. Next, suppose $x \notin H(x)$. Then (ii) yields $x^* \neq 0$ and $H(x)$ is therefore a proper closed half-space in $\mathcal{X}$. On the other hand, $x \neq P_{H(x)}x = Tx$ and, since ∇f is injective [8, Thm. 5.10], $\nabla f(x) \neq \nabla f(Tx)$. Consequently, $H(x, Tx)$ is also a proper closed half-space in $\mathcal{X}$. Since $Tx \in H(x) \cap \operatorname{bdry} H(x, Tx)$ and $H(x) \subset H(x, Tx)$, we conclude $H(x) = H(x, Tx)$. (vi) It follows successively from (iii), (3.32), and (v) that $\operatorname{Fix} T = \bigcap_{i\in I}\operatorname{Fix} T_i \subset H(x) = H(x, Tx)$. In view of (i), the proof is complete. ∎

4. Bregman monotonicity.

4.1. Properties. *D*-monotonicity was introduced in Definition 1.2. We first collect some elementary properties.

PROPOSITION 4.1. *Let $(x_n)_{n\in\mathbb{N}}$ be a sequence in $\mathcal{X}$ which is D-monotone with respect to a set $S \subset \mathcal{X}$. Then the following hold:*

(i) $(\forall x \in S \cap \operatorname{dom} f)\ \big(D(x, x_n)\big)_{n\in\mathbb{N}}$ *converges.*

(ii) $(\forall n \in \mathbb{N})\ \ D_S(x_{n+1}) \leq D_S(x_n)$.

(iii) $\big(D_S(x_n)\big)_{n\in\mathbb{N}}$ *converges.*

(iv) $(\forall (x, x') \in (S \cap \operatorname{dom} f)^2)\ \big(\langle x - x', \nabla f(x_n)\rangle\big)_{n\in\mathbb{N}}$ *converges.*

(v) $(x_n)_{n\in\mathbb{N}}$ *is bounded if, for some* $z \in S \cap \operatorname{dom} f$, *the set* $\operatorname{lev}_{\leq D(z,x_0)} D(z,\cdot)$ *is bounded. This is true in particular if* $S \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$, $\mathcal{X}$ *is reflexive, and one of the following properties is satisfied:*
  (a) f *is supercoercive;*
  (b) $\dim \mathcal{X} < +\infty$ *and* $\operatorname{dom} f^*$ *is open.*

Proof. (i) and (ii) are immediate consequences of Definition 1.2, and (iii) follows from (ii). (iv) Take x and x' in $S \cap \operatorname{dom} f$. By (i), the sequences $\big(f(x_n) + \langle x - x_n, \nabla f(x_n)\rangle\big)_{n\in\mathbb{N}}$ and $\big(f(x_n)+\langle x' - x_n, \nabla f(x_n)\rangle\big)_{n\in\mathbb{N}}$ converge and so does their difference $\big(\langle x - x', \nabla f(x_n)\rangle\big)_{n\in\mathbb{N}}$. (v) By definition, for every $x \in S\cap\operatorname{dom} f$, $(x_n)_{n\in\mathbb{N}}$ lies in $\operatorname{lev}_{\leq D(z,x_0)} D(z,\cdot)$. The second assertion follows from [8, Lemma 7.3(viii) and (ix)], which asserts that $D(z,\cdot)$ is coercive under the stated assumptions if $z \in \operatorname{int}\operatorname{dom} f$. ∎

The following example shows that the conclusion of Proposition 4.1(v) may hold even though the properties (a) and (b) are not satisfied.

EXAMPLE 4.2. *Let* $\mathcal{X} = \ell_2(\mathbb{N})$ *and define*

(4.1)
$$f\colon \mathcal{X} \to \left]-\infty,+\infty\right] : x = (\xi_k)_{k\in\mathbb{N}} \mapsto \begin{cases} \sum_{k\in\mathbb{N}} \xi_k - \ln(1+\xi_k) & \text{if } (\forall k \in \mathbb{N})\ \ \xi_k > -1, \\ +\infty & \text{otherwise.} \end{cases}$$

Then f *is Legendre and* $\operatorname{dom} f$ *is open. Moreover,* $\operatorname{lev}_{\leq \eta} D(0,\cdot)$ *is bounded for* $\eta > 0$ *sufficiently small.*

Proof. We only sketch the arguments, as the example is not utilized elsewhere. Observe that f is separable: $(\forall x \in \mathcal{X})\ f(x) = \sum_{k\in\mathbb{N}} h(\xi_k)$, where

$$(\forall \xi \in \mathbb{R})\ \ h(\xi) = \begin{cases} \xi - \ln(1+\xi) & \text{if } \xi > -1, \\ +\infty & \text{otherwise.} \end{cases} \tag{4.2}$$

Using calculus, one verifies that $\operatorname{dom} f = \big\{x \in \mathcal{X} \mid (\forall k \in \mathbb{N})\ \ \xi_k > -1\big\}$, which is open. Also, f is Gâteaux-differentiable on its domain with $\nabla f(x) = \big(\xi_k/(1+\xi_k)\big)_{k\in\mathbb{N}}$. Hence f is essentially smooth. Now $(\forall x \in \mathcal{X})\ f^*(x) = f(-x)$. Thus f^* is essentially smooth as well. By [8, Thm. 5.4], f is essentially strictly convex. Altogether, f is Legendre. Let $\alpha = \ln(2) - 1/2$. A careful analysis of the Bregman distance D_h associated with h reveals that $D_h(0,\xi) < \alpha \Rightarrow |\xi| < 1 \Rightarrow D_h(0,\xi) \geq \alpha|\xi|^2$. (In passing, we point out that $D_h(0,\cdot)$ is convex precisely on $]-1,+1[$.) Fix $\eta \in [0,\alpha[$ and $x \in \mathcal{X}$ such that $D(0,x) \leq \eta$. Then $(\forall k \in \mathbb{N})\ D_h(0,\xi_k) \geq \alpha|\xi_k|^2$. Summing yields $\eta \geq D(0,x) \geq \alpha\|x\|^2$, whence $x \in B(0;\sqrt{\eta/\alpha})$. ∎

The next two assumptions will be quite helpful in the analysis of the convergence of D-monotone sequences.

CONDITION 4.3. *Given* $S \subset \mathcal{X}$, *for every bounded sequence* $(x_n)_{n\in\mathbb{N}}$ *in* $\operatorname{int}\operatorname{dom} f$, *one has*

$$\begin{cases} x \in \mathfrak{W}(x_n)_{n\in\mathbb{N}} \cap S, \\ x' \in \mathfrak{W}(x_n)_{n\in\mathbb{N}} \cap S, \\ (x_n)_{n\in\mathbb{N}} \text{ is } D\text{-monotone with respect to } S \end{cases} \quad \Rightarrow \quad x = x'. \tag{4.3}$$

CONDITION 4.4. *For all bounded sequences* $(x_n)_{n\in\mathbb{N}}$ *and* $(y_n)_{n\in\mathbb{N}}$ *in* $\operatorname{int}\operatorname{dom} f$, *one has*

$$D(x_n, y_n) \to 0 \quad \Rightarrow \quad x_n - y_n \to 0. \tag{4.4}$$

These two assumptions cover familiar situations, as the following examples show.

EXAMPLE 4.5. *Suppose that S is a subset of $\mathcal{X}$ such that $S \cap \overline{\operatorname{dom}} f$ is a singleton. Then Condition 4.3 is satisfied.*

Proof. Take $(x_n)_{n\in\mathbb{N}}$ in $\operatorname{int}\operatorname{dom} f$. Then $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \subset \overline{\operatorname{dom}} f$ and, therefore, $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \cap S$ is at most a singleton. ∎

EXAMPLE 4.6. *Suppose that $S \subset \operatorname{int}\operatorname{dom} f$ is convex, $f|_S$ is strictly convex, and ∇f is sequentially weak-to-weak$*$ continuous at every point in S. Then Condition 4.3 is satisfied.*

Proof. Let $(x_n)_{n\in\mathbb{N}}$ be a bounded sequence which is D-monotone with respect to S. Then $x_{k_n} \rightharpoonup x \in S$ and $x_{l_n} \rightharpoonup x' \in S$ imply $\nabla f(x_{k_n}) \xrightarrow{*} \nabla f(x)$ and $\nabla f(x_{l_n}) \xrightarrow{*} \nabla f(x')$. Proposition 4.1(iv) therefore forces $\langle x - x', \nabla f(x)\rangle = \langle x - x', \nabla f(x')\rangle$; hence $\langle x - x', \nabla f(x) - \nabla f(x')\rangle = 0$. Since ∇f is strictly monotone on S, we get $x = x'$. ∎

Our next example requires the following lemma.

LEMMA 4.7. *Suppose that $\varepsilon \in \left]0, +\infty\right[$, $x \in \operatorname{dom} f$, and $y \in \operatorname{int}\operatorname{dom} f$. Then there exists $z \in \operatorname{int}\operatorname{dom} f$ such that $\|x - z\| \leq \varepsilon$ and $|D(x, y) - D(z, y)| \leq \varepsilon$.*

Proof. Put $(\forall \alpha \in [0,1[)\ x_\alpha = (1-\alpha)y + \alpha x$. Then $(x_\alpha)_{\alpha\in[0,1[}$ lies in $\operatorname{int}\operatorname{dom} f$, $\lim_{\alpha\uparrow 1^-} x_\alpha = x$ and, by (3.6), $\lim_{\alpha\uparrow 1^-} D(x_\alpha, y) = D(x, y)$. Thus, for α sufficiently close to 1, we can take $z = x_\alpha$. ∎

We now recall the notion of a Bregman/Legendre function in $\mathbb{R}^N$, which covers numerous functions of importance in convex optimization [7]. This notion will allow us to describe a finite-dimensional setting in which Condition 4.3 holds.

DEFINITION 4.8. *Suppose that $\mathcal{X} = \mathbb{R}^N$ and f is Legendre. Then f is* Bregman/Legendre*, if each of the following conditions is satisfied:*

(i) $\operatorname{dom} f^*$ *is open.*

(ii) $(\forall x \in \operatorname{dom} f \smallsetminus \operatorname{int}\operatorname{dom} f)$ $D(x, \cdot)$ *is coercive.*

(iii)
$$\begin{cases} x \in \operatorname{dom} f \smallsetminus \operatorname{int}\operatorname{dom} f, \\ (y_n)_{n\in\mathbb{N}} \text{ in } \operatorname{int}\operatorname{dom} f, \\ y_n \to y \in \operatorname{bdry}\operatorname{dom} f, \\ \big(D(x, y_n)\big)_{n\in\mathbb{N}} \text{ bounded} \end{cases} \quad \Rightarrow \quad D(y, y_n) \to 0.$$

(iv)
$$\begin{cases} (x_n)_{n\in\mathbb{N}} \text{ in } \operatorname{int}\operatorname{dom} f, \\ (y_n)_{n\in\mathbb{N}} \text{ in } \operatorname{int}\operatorname{dom} f, \\ x_n \to x \in \operatorname{dom} f \smallsetminus \operatorname{int}\operatorname{dom} f, \\ y_n \to y \in \operatorname{dom} f \smallsetminus \operatorname{int}\operatorname{dom} f, \\ D(x_n, y_n) \to 0 \end{cases} \quad \Rightarrow \quad x = y.$$

EXAMPLE 4.9. *Suppose that $\mathcal{X} = \mathbb{R}^N$, f is Bregman/Legendre, and S is a subset of $\mathcal{X}$ such that $S \cap \operatorname{dom} f \neq \varnothing$. Then Condition 4.3 is satisfied.*

Proof. Let us start with two useful facts, namely

$$\text{(4.5)} \qquad \begin{cases} x \in \operatorname{dom} f, \\ (y_n)_{n\in\mathbb{N}} \text{ in } \operatorname{int}\operatorname{dom} f, \\ y_n \to y, \\ \big(D(x, y_n)\big)_{n\in\mathbb{N}} \text{ bounded} \end{cases} \quad \Rightarrow \quad \begin{cases} D(y, y_n) \to 0, \\ y \in \operatorname{dom} f \end{cases}$$

and

$$\begin{cases} x \in \operatorname{dom} f, \\ (y_n)_{n\in\mathbb{N}} \text{ in } \operatorname{int}\operatorname{dom} f, \\ y_n \to y \in \operatorname{dom} f, \\ D(x, y_n) \to 0 \end{cases} \quad \Rightarrow \quad x = y. \tag{4.6}$$

If $x \in \operatorname{int}\operatorname{dom} f$, (4.5) follows from [7, Thm. 3.8(ii)]. On the other hand, if $x \in \operatorname{dom} f \smallsetminus \operatorname{int}\operatorname{dom} f$, (4.5) follows from [7, Prop. 3.3] if $y \in \operatorname{int}\operatorname{dom} f$ and from [7, Def. 5.2.BL2] if $y \in \operatorname{bdry}\operatorname{dom} f$. We now turn to (4.6). If x or y belongs to $\operatorname{int}\operatorname{dom} f$, it suffices to apply [7, Thm. 3.9(iii)]. Otherwise, $\{x, y\} \subset \operatorname{dom} f \smallsetminus \operatorname{int}\operatorname{dom} f$ and Lemma 4.7 ensures that, for every $n \geq 1$, we can find a point $x_n \in \operatorname{int}\operatorname{dom} f$ such that $\|x - x_n\| \leq 1/n$ and $|D(x, y_n) - D(x_n, y_n)| \leq 1/n$. Therefore, $x_n \to x$ and, since $D(x, y_n) \to 0$ by assumption, $D(x_n, y_n) \to 0$. It then follows from [7, Def. 5.2.BL3] that $x = y$. Now let $(x_n)_{n\in\mathbb{N}}$ be a bounded sequence which is D-monotone with respect to S and let $z \in S \cap \operatorname{dom} f$. Suppose $x_{k_n} \to x \in S$ and $x_{l_n} \to x' \in S$. Since by D-monotonicity the sequences $\big(D(z, x_{k_n})\big)_{n\in\mathbb{N}}$ and $\big(D(z, x_{l_n})\big)_{n\in\mathbb{N}}$ are bounded, (4.5) yields $D(x, x_{k_n}) \to 0$, $D(x', x_{l_n}) \to 0$, and $\{x, x'\} \subset S \cap \operatorname{dom} f$. However, it follows from Proposition 4.1(i) that $D(x, x_{k_n}) \to 0 \Rightarrow D(x, x_n) \to 0 \Rightarrow D(x, x_{l_n}) \to 0$. In view of (4.6), we conclude $x = x'$, as required. □

Following [25], we say that f is uniformly convex on bounded sets if, for every bounded set $B \subset \mathcal{X}$, one has

$$(\forall t \in]0, +\infty[) \quad \inf \mu\big(B \cap \operatorname{dom} f, t\big) > 0, \tag{4.7}$$

where

$$\mu\colon \operatorname{dom} f \times [0, +\infty[\to [0, +\infty] : (x, t) \mapsto \inf_{\substack{\|x-y\|=t \\ y\in\operatorname{dom} f}} \frac{f(x) + f(y)}{2} - f\left(\frac{x+y}{2}\right). \tag{4.8}$$

Examples of such functions are given in [84].

The next result gives sufficient conditions for Condition 4.4 to hold. (See also [22] and [82] for item (ii).)

EXAMPLE 4.10. *Condition* 4.4 *is satisfied whenever one of the following is true:*

(i) *f is uniformly convex on bounded sets.*

(ii) *$\mathcal{X} = \mathbb{R}^N$, $\operatorname{dom} f$ is closed, and $f|_{\operatorname{dom} f}$ is strictly convex and continuous.*

(iii) *$\mathcal{X} = \mathbb{R}$ and $f|_{\operatorname{dom} f}$ is strictly convex.*

Proof. (i) is a direct consequence of [25, Prop. 4.2]. (ii) and (iii) are special cases of (i) by [85, Prop. 3.6.6(i)]. □

In passing, we note that it follows from [85, Thm. 3.5.13] that item (i) of Example 4.10 forces the underlying space $\mathcal{X}$ to be reflexive.

The above assumptions lead to remarkably simple weak and strong convergence criteria for D-monotone sequences. In the case when $\mathcal{X}$ is Hilbertian and $f = \|\cdot\|^2/2$, Conditions 4.3 and 4.4 are satisfied and these criteria can essentially be found in [53] (see also [6] and [40]). Recall (see section 2) that $\mathfrak{S}$ denotes the set of strong cluster points of a sequence.

THEOREM 4.11. *Let $(x_n)_{n\in\mathbb{N}}$ be a bounded sequence in $\mathcal{X}$ which is D-monotone with respect to a set $S \subset \mathcal{X}$. Suppose that $\mathcal{X}$ is reflexive and Condition* 4.3 *is satisfied. Then*

(i) *$(x_n)_{n\in\mathbb{N}}$ converges weakly to a point in $S \cap \overline{\operatorname{dom}} f$ if and only if $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \subset S$;*

(ii) *supposing that* $x_n \rightharpoonup x \in S \cap \operatorname{int}\operatorname{dom} f$ *and Condition* 4.4 *is satisfied, then* $x_n \to x$ *if and only if* $\mathfrak{S}(x_n)_{n\in\mathbb{N}} \neq \varnothing$.

Proof. (i) Necessity is clear. To prove sufficiency, suppose that $\mathfrak{W}(x_n)_{n\in\mathbb{N}} \subset S$ and take x and x' in $\mathfrak{W}(x_n)_{n\in\mathbb{N}}$, say $x_{k_n} \rightharpoonup x$ and $x_{l_n} \rightharpoonup x'$. Then x and x' lie in S and (4.3) forces $x = x'$. Since $\mathcal{X}$ is reflexive and $(x_n)_{n\in\mathbb{N}}$ is bounded, we conclude $x_n \rightharpoonup x$. Furthermore, since $\overline{\operatorname{dom}} f \ni x_n \rightharpoonup x$ and $\overline{\operatorname{dom}} f$ is weakly closed, $x \in \overline{\operatorname{dom}} f$. (ii) Necessity is clear. To prove sufficiency, suppose that Condition 4.4 is satisfied, $x \in S \cap \operatorname{int}\operatorname{dom} f$, and $\mathfrak{S}(x_n)_{n\in\mathbb{N}} \neq \varnothing$, i.e., some subsequence $(x_{k_n})_{n\in\mathbb{N}}$ converges strongly. Since $x_n \rightharpoonup x$, we must have $x_{k_n} \to x$. In turn, [8, Lemma 7.3(x)] yields $D(x, x_{k_n}) \to 0$ and it follows from Proposition 4.1(i) that $D(x, x_n) \to 0$. In view of (4.4), we conclude $x_n \to x$. ∎

4.2. Construction.

ALGORITHM 4.12. *Starting with* $x_0 \in \operatorname{int}\operatorname{dom} f$, *at every iteration* $n \in \mathbb{N}$, *select first* $T_n \in \mathfrak{B}$ *and then* $x_{n+1} \in T_n x_n$.

PROPOSITION 4.13. *Let* $(x_n)_{n\in\mathbb{N}}$ *be an arbitrary orbit of Algorithm* 4.12. *Suppose that*

$$\bigcap_{n\in\mathbb{N}} \operatorname{Fix} T_n \neq \varnothing, \quad S \subset \bigcap_{n\in\mathbb{N}} \overline{\operatorname{Fix}}\, T_n, \quad \text{and} \quad S \cap \operatorname{dom} f \neq \varnothing. \tag{4.9}$$

Then

(i) *if* $f|_{\operatorname{int}\operatorname{dom} f}$ *is strictly convex,* $(x_n)_{n\in\mathbb{N}}$ *is* D*-monotone with respect to* S;

(ii) $\sum_{n\in\mathbb{N}} D(x_{n+1}, x_n) < +\infty$.

Proof. (i) Proposition 3.3(viii) yields $(\forall n \in \mathbb{N})(\forall y \in \overline{\operatorname{Fix}}\, T_n)\ D(y, x_{n+1}) \leq D(y, x_n)$. (ii) Fix $y \in \bigcap_{n\in\mathbb{N}} \operatorname{Fix} T_n$. Then Proposition 3.3(i) yields the stronger statement

$$(\forall n \in \mathbb{N})\ \ D(y, x_{n+1}) \leq D(y, x_n) - D(x_{n+1}, x_n). \tag{4.10}$$

Therefore $\sum_{n\in\mathbb{N}} D(x_{n+1}, x_n) \leq D(y, x_0)$. ∎

THEOREM 4.14. *Let* $(x_n)_{n\in\mathbb{N}}$ *be an arbitrary bounded orbit of Algorithm* 4.12. *Suppose that* $\mathcal{X}$ *is reflexive, that* $f|_{\operatorname{int}\operatorname{dom} f}$ *is strictly convex, and that* (4.9) *is satisfied. Suppose in addition that Condition* 4.3 *is satisfied and that*

$$\sum_{n\in\mathbb{N}} D(x_{n+1}, x_n) < +\infty \quad \Rightarrow \quad \mathfrak{W}(x_n)_{n\in\mathbb{N}} \subset S. \tag{4.11}$$

Then

(i) $(x_n)_{n\in\mathbb{N}}$ *converges weakly to a point* $x \in S$;

(ii) *the convergence is strong in* (i) *if* $x \in \operatorname{int}\operatorname{dom} f$, *Condition* 4.4 *is satisfied, and*

$$\sum_{n\in\mathbb{N}} D(x_{n+1}, x_n) < +\infty \quad \Rightarrow \quad \mathfrak{S}(x_n)_{n\in\mathbb{N}} \neq \varnothing. \tag{4.12}$$

Proof. Combine Theorem 4.11 and Proposition 4.13. ∎

5. Parallel block-iterative *D*-monotone algorithm.

5.1. Objective. For the remainder of this paper, we assume that

$$\begin{cases} \mathcal{X} \text{ is reflexive and } f \text{ is Legendre,} \\ (S_i)_{i\in I} \text{ is a countable family of closed convex subsets of } \mathcal{X}, \\ (\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} S_i \neq \varnothing, \\ S = \overline{\operatorname{dom}} f \cap \bigcap_{i\in I} S_i. \end{cases} \tag{5.1}$$

The purpose of this section is to develop a relaxed, parallel, block-iterative algorithm to solve the convex feasibility problem

$$\text{Find } x \in S. \tag{5.2}$$

5.2. Algorithm.

ALGORITHM 5.1. *Starting with $x_0 \in \operatorname{int}\operatorname{dom} f$, take at every iteration n*

① *a nonempty finite index set $I_n \subset I$,*

② *operators $(T_{i,n})_{i\in I_n}$ in $\mathfrak{B}$ such that $(\forall i \in I_n)\ S_i \cap \operatorname{int}\operatorname{dom} f \subset \operatorname{Fix} T_{i,n}$,*

③ *points $(u_{i,n})_{i\in I_n} \in \bigtimes_{i\in I_n} T_{i,n}x_n$,*

④ *weights $(\omega_{i,n})_{i\in I_n}$ in $[0,1]$ such that $\sum_{i\in I_n}\omega_{i,n} = 1$,*

⑤ *a relaxation parameter $\lambda_n \in\,]0,1]$*

and put

⑥ $x_n^* = \nabla f(x_n) - \sum_{i\in I_n}\omega_{i,n}\nabla f(u_{i,n})$,

⑦

$$\eta_n = \left\langle x_n, \nabla f(x_n) - \sum_{i\in I_n}\omega_{i,n}\nabla f(u_{i,n})\right\rangle - \lambda_n \sum_{i\in I_n}\omega_{i,n}\left\langle u_{i,n} - x_n, \nabla f(u_{i,n}) - \nabla f(x_n)\right\rangle,$$

⑧ $H_n = \big\{y \in \mathcal{X} \mid \langle y, x_n^*\rangle \le \eta_n\big\}$.

Then set $x_{n+1} = P_{H_n}x_n$.

We now motivate this algorithm geometrically. At iteration n, x_n is given and a finite block of indices I_n is retained. Set $I_n^+ = \big\{i \in I_n \mid \omega_{i,n} > 0\big\}$. Then, using Lemma 3.2 for the first and last equality, step ② for the third inclusion, and (3.32) for the fourth inclusion,

$$\begin{aligned} S &= \overline{(\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} S_i} \subset \overline{(\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I_n} S_i} \subset \overline{(\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I_n^+} S_i} \\ &\subset \overline{\bigcap_{i\in I_n^+} \operatorname{Fix} T_{i,n}} \subset \overline{(\operatorname{int}\operatorname{dom} f) \cap H_n} = \overline{\operatorname{dom}}\, f \cap H_n \subset H_n. \end{aligned} \tag{5.3}$$

Thus, H_n acts as an outer approximation to the intersection of the block of constraint sets $(\overline{\operatorname{dom}}\, f \cap S_i)_{i\in I_n}$ and, therefore, to S. More precisely, the block constraint $y \in \overline{\operatorname{dom}}\, f \cap \bigcap_{i\in I_n} S_i$ is replaced by the surrogate affine constraint $\langle y, x_n^*\rangle \le \eta_n$. The update x_{n+1} is then the D-projection of x_n onto H_n, i.e., the D-closest point to x_n which satisfies the surrogate constraint. (x_{n+1} is well defined by virtue of (5.1) and Corollary 3.35(i).) Naturally, such a point is considerably simpler to find than a point in $\overline{\operatorname{dom}}\, f \cap \bigcap_{i\in I_n} S_i$. In spirit, this type of surrogate constraint construction can be found—explicitly or implicitly—in several places in the literature, although not in the context of Bregman distances. (See, for instance, [39, 60] and the references therein.)

The parallel nature of the algorithm stems from the fact that the points $(u_{i,n})_{i\in I_n}$ at step ③ can be computed independently on concurrent processors. In addition, the algorithm has the ability to process variable blocks of constraints, which makes it possible to match closely the computational load of each iteration to the parallel processing architecture at hand. A discussion on the importance of block-processing for task scheduling on parallel architectures can be found in [33].

To shed more light on Algorithm 5.1, we first consider the case when $\mathcal{X}$ is Hilbertian and $f = \|\cdot\|^2/2$. Then, steps ⑥ and ⑦ become

$$\begin{cases} x_n^* = x_n - \sum_{i\in I_n}\omega_{i,n}u_{i,n}, \\ \eta_n = \big\langle x_n, x_n - \sum_{i\in I_n}\omega_{i,n}u_{i,n}\big\rangle - \lambda_n \sum_{i\in I_n}\omega_{i,n}\|u_{i,n} - x_n\|^2. \end{cases} \tag{5.4}$$

Furthermore, the updating step is explicitly given as

$$x_{n+1} = P_{H_n} x_n = x_n + \frac{\eta_n - \langle x_n, x_n^* \rangle}{\|x_n^*\|^2} x_n^* = x_n + \lambda_n L_n \left(\sum_{i \in I_n} \omega_{i,n} (u_{i,n} - x_n) \right), \tag{5.5}$$

where

$$L_n = \begin{cases} \dfrac{\sum_{i \in I_n} \omega_{i,n} \|u_{i,n} - x_n\|^2}{\| \sum_{i \in I_n} \omega_{i,n} (u_{i,n} - x_n)\|^2} & \text{if } x_n \notin \bigcap_{i \in I_n} S_i, \\ 1 & \text{otherwise.} \end{cases} \tag{5.6}$$

This is essentially the algorithm proposed in [41, section 6] (in this setting, the range of λ_n can be extended to $]0, 2[$), which itself contains those of [5, 6, 35, 37, 38, 60, 69] as special cases. In particular, if I is finite, $I_n \equiv I$, $\omega_{i,n} = \omega_i$, and $u_{i,n} = P_i x_n$, where P_i is the metric projector onto S_i, then (5.5)–(5.6) reduces to Pierra's classic extrapolated parallel projection method [72], which in turn can be traced back to Merzlyakov's method [63] for solving systems of linear inequalities in $\mathbb{R}^N$. Since $L_n \geq 1$ in (5.6), large extrapolations are possible in this algorithm by selecting $\lambda_n \approx 1$. It is known that these extrapolations yield significantly accelerated convergence in numerical experiments [36, 37, 50, 72] in comparison with purely averaged iterations, i.e.,

$$x_{n+1} = \sum_{i \in I_n} \omega_{i,n} u_{i,n}, \tag{5.7}$$

which can be derived from (5.5) by setting $\lambda_n = 1/L_n$.

Returning to the standing assumptions, let us now consider the parallel block-iterative update rule

$$\nabla f(x_{n+1}) = \sum_{i \in I_n} \omega_{i,n} \nabla f(u_{i,n}). \tag{5.8}$$

This alternative method for solving (5.2) was recently proposed by Censor and Herman in [29] (see also [31]) for the special case when $\mathcal{X} = \mathbb{R}^N$, I is finite, and $u_{i,n}$ is the D-projection of x_n onto S_i. If we assume that $\mathcal{X}$ is a Hilbert space and $f = \| \cdot \|^2/2$, then (5.8) reduces to (5.7) which, as noted above, is itself a special case of (5.5)–(5.6), hence of Algorithm 5.1. In general, however, we do not know whether (5.8) is always a particularization of Algorithm 5.1.

We now turn to Butnariu and Iusem's algorithmic framework [24] for solving (5.2). (In fact, they study the so-called stochastic convex feasibility problem, which is similar to (5.2) but allows for an uncountable index set I. Their framework requires measure theory for a precise formulation and their assumptions on the underlying function f are different from the ones made here. The reader is referred to [24] for further details.) Let $(R_i)_{i \in I}$ be a family of totally nonexpansive operators in the sense of [24]. (See also the paragraph following Definition 3.1.) Specialized to the case when I is finite, the update step in this algorithm is

$$x_{n+1} = \sum_{i \in I} \omega_i R_i x_n. \tag{5.9}$$

This resembles (5.8), except for notably absent gradients on both sides of the equation and for weights that do not depend on n. (If the R_i's are D-projectors, then

(5.9) can also be interpreted as a sequential algorithm in the product space X^I; see [11].) Note that if $\mathcal{X}$ is a Hilbert space and $f = \|\cdot\|^2/2$, then (5.9) once again corresponds to a parallel Cimmino-type algorithm, which is genuinely more restrictive than Algorithm 5.1 for this set-up.

While a detailed numerical and theoretical comparison of these algorithms lies beyond the scope of this paper, we remark that preliminary experiments suggest that Algorithm 5.1 is more flexible and faster than the one given by (5.8) and that Algorithm 5.1 is genuinely different from the method given by (5.9).

5.3. Convergence. The following notions were introduced in [6, Def. 3.7] and [41, Def. 6.5], respectively, to study the asymptotic behavior of Fejér monotone algorithms in Hilbert spaces. The former can be interpreted as an extension of the notion of demiclosedness at 0 [68] and the latter as an extension of the notion of demicompactness at 0 [70].

DEFINITION 5.2. *Algorithm* 5.1 *is*

- focusing *if for every bounded suborbit* $(x_{k_n})_{n\in\mathbb{N}}$ *it generates and every index* $i \in I$,

$$\begin{cases} i \in \bigcap_{n\in\mathbb{N}} I_{k_n}, \\ x_{k_n} \rightharpoonup x, \\ u_{i,k_n} - x_{k_n} \to 0 \end{cases} \quad \Rightarrow \quad x \in S_i; \tag{5.10}$$

- demicompactly regular *if there exists* $i \in I$, *called an* index of demicompact regularity, *such that for every bounded suborbit* $(x_{k_n})_{n\in\mathbb{N}}$ *it generates,*

$$\begin{cases} i \in \bigcap_{n\in\mathbb{N}} I_{k_n}, \\ u_{i,k_n} - x_{k_n} \to 0 \end{cases} \quad \Rightarrow \quad \mathfrak{S}(x_{k_n})_{n\in\mathbb{N}} \neq \emptyset. \tag{5.11}$$

We now describe the context in which the convergence of Algorithm 5.1 will be investigated.

CONDITION 5.3.

(i) *For some* $z \in \operatorname{dom} f \cap \bigcap_{i\in I} S_i$, $C = \operatorname{lev}_{\leq D(z,x_0)} D(z,\cdot)$ *is bounded.*

(ii) *For all sequences* $(u_n)_{n\in\mathbb{N}}$ *and* $(v_n)_{n\in\mathbb{N}}$ *in* C *such that* $(\forall n \in \mathbb{N})\ u_n \neq v_n$, *one has*

$$\frac{\langle u_n - v_n, \nabla f(u_n) - \nabla f(v_n)\rangle}{\|\nabla f(u_n) - \nabla f(v_n)\|} \to 0 \quad \Rightarrow \quad \nabla f(u_n) - \nabla f(v_n) \to 0. \tag{5.12}$$

CONDITION 5.4.

(i) $(\exists\, \delta_1 \in]0,1[)(\forall n \in \mathbb{N})(\exists\, j \in I_n)$

$$\|\nabla f(u_{j,n}) - \nabla f(x_n)\| = \max_{i\in I_n} \|\nabla f(u_{i,n}) - \nabla f(x_n)\| \ \text{ and } \ \omega_{j,n} \geq \delta_1.$$

(ii) $(\exists\, \delta_2 \in]0,1[)(\forall n \in \mathbb{N})\ \ \lambda_n \geq \delta_2$.

(iii) $(\forall i \in I)(\exists\, M_i \in \mathbb{N} \smallsetminus \{0\})(\forall n \in \mathbb{N})\ \ i \in \bigcup_{k=n}^{n+M_i-1} I_k$.

As will be seen subsequently, the above set of assumptions defines a broad framework which covers numerous practical situations. Note that, by virtue of (5.1), the quotient in (5.12) is well defined since ∇f is injective on $\operatorname{int}\operatorname{dom} f$ [8, Thm. 5.10]. Situations in which Condition 5.3(ii) is satisfied are detailed below. Note also that Condition 5.4(iii) imposes that every index i be activated at least once within any M_i consecutive iterations. This control rule, which has already been used in metric

projection algorithms in Hilbert spaces [35, 37, 38, 60], provides great flexibility in the management of the constraints and the implementation of the algorithm. Condition 5.4(i) provides added flexibility by offering the possibility of setting $\omega_{i,n} = 0$ if the corresponding step size $\|\nabla f(u_{i,n}) - \nabla f(x_n)\|$ is not maximal. It is thereby possible to meet the control condition Condition 5.4(iii) without actually using the ith constraint in the construction of x_{n+1}.

Recall that an operator T from a Banach space $\mathcal{Y}$ to its dual $\mathcal{Y}^*$ is said to be uniformly monotone on $U \subset \operatorname{dom} T$ with modulus c if [86, section 25.3]

$$(\forall x \in U)(\forall y \in U) \quad \langle x - y, Tx - Ty\rangle \geq \|x - y\| \cdot c(\|x - y\|), \tag{5.13}$$

where $c\colon [0, +\infty[\to [0, +\infty[$ is a strictly increasing function such that $c(0) = 0$. In particular, T is said to be strongly monotone on U with constant $\alpha \in]0, +\infty[$ if it is uniformly monotone on U with modulus $c\colon t \mapsto \alpha t$.

PROPOSITION 5.5. *Let z and C be as in Condition* 5.3(i). *Then Condition* 5.3(ii) *is satisfied in each of the following cases:*

(i) *∇f^* is uniformly monotone on $\nabla f(C)$.*
(ii) *∇f is Lipschitz-continuous on $\operatorname{dom} f = \mathcal{X}$.*
(iii) *$\mathcal{X} = \mathbb{R}^N$ and $\overline{C} \subset \operatorname{int}\operatorname{dom} f$.*
(iv) *$\mathcal{X} = \mathbb{R}^N$ and $z \in \operatorname{int}\operatorname{dom} f$.*

Proof. Let $(u_n)_{n\in\mathbb{N}}$ and $(v_n)_{n\in\mathbb{N}}$ be two sequences in C such that $(\forall n \in \mathbb{N})$ $u_n \neq v_n$. (i) Let c be the modulus of uniform monotonicity of ∇f^* on $\nabla f(C)$. Since ∇f is a bijection from $\operatorname{int}\operatorname{dom} f$ to $\operatorname{int}\operatorname{dom} f^*$ with inverse ∇f^* [8, Thm. 5.10] and since $C \subset \operatorname{int}\operatorname{dom} f$, we have $(\forall u \in C)(\forall v \in C)$ $\langle u - v, \nabla f(u) - \nabla f(v)\rangle \geq \|\nabla f(u) - \nabla f(v)\| \cdot c\,(\|\nabla f(u) - \nabla f(v)\|)$. Hence, since c is strictly increasing and $c(0) = 0$,

$$\begin{aligned} \frac{\langle u_n - v_n, \nabla f(u_n) - \nabla f(v_n)\rangle}{\|\nabla f(u_n) - \nabla f(v_n)\|} \to 0 \;&\Rightarrow\; c\big(\|\nabla f(u_n) - \nabla f(v_n)\|\big) \to 0 \\ &\Rightarrow\; \nabla f(u_n) - \nabla f(v_n) \to 0. \end{aligned} \tag{5.14}$$

(ii) $\Rightarrow$ (i) If ∇f is κ-Lipschitz-continuous on $\mathcal{X}$, then it follows from the Baillon–Haddad theorem [4, Cor. 10] that $(\forall x \in \mathcal{X})(\forall y \in \mathcal{X})$ $\langle x - y, \nabla f(x) - \nabla f(y)\rangle \geq \|\nabla f(x) - \nabla f(y)\|^2/\kappa$, i.e., ∇f^* is strongly monotone with constant $1/\kappa$. Consequently, ∇f^* is uniformly monotone on $\nabla f(C)$. (iii) Suppose

$$\frac{\langle u_n - v_n, \nabla f(u_n) - \nabla f(v_n)\rangle}{\|\nabla f(u_n) - \nabla f(v_n)\|} \to 0 \quad \text{and} \quad \nabla f(u_n) - \nabla f(v_n) \not\to 0. \tag{5.15}$$

Then there exists a strictly increasing sequence $(k_n)_{n\in\mathbb{N}}$ in $\mathbb{N}$ and $\varepsilon \in]0, +\infty[$ such that $\inf_{n\in\mathbb{N}} \|\nabla f(u_{k_n}) - \nabla f(v_{k_n})\| \geq \varepsilon$. Since $(u_{k_n})_{n\in\mathbb{N}}$ lies in C, it is bounded and therefore possesses a convergent subsequence, say $u_{k_{l_n}} \to u$. As $(v_{k_{l_n}})_{n\in\mathbb{N}}$ is also bounded, we can assume (passing to a subsequence if necessary) that it converges, say $v_{k_{l_n}} \to v$. Since $\{u, v\} \subset \overline{C} \subset \operatorname{int}\operatorname{dom} f$ and ∇f is continuous at every point in $\operatorname{int}\operatorname{dom} f$ by [77, Thm. 25.5], taking the limit yields $\|\nabla f(u) - \nabla f(v)\| \geq \varepsilon$ and, by injectivity of ∇f on $\operatorname{int}\operatorname{dom} f$ [8, Thm. 5.10], $u \neq v$. On the other hand, (5.15) yields

$$\frac{\big\langle u_{k_{l_n}} - v_{k_{l_n}}, \nabla f(u_{k_{l_n}}) - \nabla f(v_{k_{l_n}})\big\rangle}{\|\nabla f(u_{k_{l_n}}) - \nabla f(v_{k_{l_n}})\|} \to 0, \tag{5.16}$$

and, since $\|\nabla f(u) - \nabla f(v)\| \neq 0$, taking the limit yields $\langle u - v, \nabla f(u) - \nabla f(v)\rangle = 0$. However, $f|_{\operatorname{int}\operatorname{dom} f}$ is strictly convex and therefore ∇f is strictly monotone on $\operatorname{int}\operatorname{dom} f \supset \{u, v\}$. This forces $u = v$ and we reach a contradiction. (iv) In view of (iii), it is enough to show that $\overline{C} \subset \operatorname{int}\operatorname{dom} f$. If the inclusion does not hold, then we can find $y \in \operatorname{bdry}\operatorname{dom} f$ and $(y_n)_{n\in\mathbb{N}}$ in C such that $y_n \to y$. Thus $\sup_{n\in\mathbb{N}} D(z, y_n) \leq D(z, x_0) < +\infty$, and, at the same time, since f is essentially smooth, [7, Thm. 3.8(i)] yields $D(z, y_n) \to +\infty$, which is absurd. □

Remark 5.6. A careful analysis of [85, Corollary 3.4.4"(iii)⇔(iv)"], [85, Proposition 3.5.1], and [85, Proposition 3.6.2] shows that Proposition 5.5(i) holds as soon as ∇f is Lipschitz on bounded sets. In turn, this condition is satisfied in L_p spaces for $f = \|\cdot\|_p^s$, where $\{p, s\} \subset [2, +\infty[$. (The proof relies on the case when $s = 2$; see also Example 5.11 below.)

Examples of Legendre functions f which satisfy Conditions 4.3, 4.4, and 5.3(i)–(ii) will be supplied in section 5.4. Our main convergence result can now be stated and proved.

THEOREM 5.7. *Suppose that Conditions* 4.3, 4.4, 5.3, *and* 5.4 *are satisfied, and let* $(x_n)_{n\in\mathbb{N}}$ *be an arbitrary orbit of Algorithm* 5.1. *Then, for every* $n \in \mathbb{N}$, x_n *and* $(u_{i,n})_{i\in I_n}$ *lie in the bounded set* C. *If, in addition, Algorithm* 5.1 *is focusing, then the following statements hold true:*

(i) $(x_n)_{n\in\mathbb{N}}$ *converges weakly to a point* $x \in S$.

(ii) *If the weak limit* x *from* (i) *belongs to* $\operatorname{int}\operatorname{dom} f$ *and the algorithm is demicompactly regular, then* $(x_n)_{n\in\mathbb{N}}$ *converges strongly.*

Proof. For every $n \in \mathbb{N}$, set $T_n = P_{H_n}$ and $I_n^+ = \big\{i \in I_n \mid \omega_{i,n} > 0\big\}$. Since $x_0 \in \operatorname{int}\operatorname{dom} f$ and, by Proposition 3.39(vi), $T_n \in \mathfrak{B}$, we recognize that

(5.17) Algorithm 5.1 is a special case of Algorithm 4.12.

Our goal is to apply Theorem 4.14 and we must start by verifying (4.9). First, considering (5.1), Algorithm 5.1②, and Proposition 3.39(iii), we obtain

(5.18)
$$(\forall n \in \mathbb{N})\ \ \varnothing \neq (\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} S_i \subset \bigcap_{i\in I_n^+} (S_i \cap \operatorname{int}\operatorname{dom} f) \subset \bigcap_{i\in I_n^+} \operatorname{Fix} T_{i,n} = \operatorname{Fix} T_n.$$

Hence $\bigcap_{n\in\mathbb{N}} \operatorname{Fix} T_n \neq \varnothing$. In addition, (5.1), Lemma 3.2, and (5.18) yield

$$(\forall n \in \mathbb{N})\ \ S = \overline{\operatorname{dom}}\, f \cap \bigcap_{i\in I} S_i \subset \overline{\operatorname{Fix}}\, T_n. \tag{5.19}$$

Consequently, $S \subset \bigcap_{n\in\mathbb{N}} \overline{\operatorname{Fix}}\, T_n$. Next, we derive from (5.1) that

$$\varnothing \neq (\operatorname{int}\operatorname{dom} f) \cap \bigcap_{i\in I} S_i \subset \operatorname{dom} f \cap \overline{\operatorname{dom}}\, f \cap \bigcap_{i\in I} S_i = \operatorname{dom} f \cap S. \tag{5.20}$$

Thus, (4.9) holds. Now, let z and C be as in Condition 5.3(i). It follows from (5.17) and Proposition 4.13(i) that the sequences $(x_n)_{n\in\mathbb{N}}$ and $(T_n x_n)_{n\in\mathbb{N}}$ are contained in C, which is bounded. In order to verify (4.11), some key facts must be established. Let us

temporarily fix $n \in \mathbb{N}$. The first fact is supplied by the inclusion $x_{n+1} = P_{H_n} x_n \in H_n$, which yields

$$\|x_{n+1} - x_n\| \geq d_{H_n}(x_n). \tag{5.21}$$

Next, it follows from Condition 5.3(i), (5.1), Lemma 3.2, and Algorithm 5.1② that

$$(\forall i \in I_n) \;\; z \in S_i \cap \overline{\operatorname{dom}} f = \overline{S_i \cap \operatorname{int} \operatorname{dom} f} \subset \overline{\operatorname{Fix}} T_{i,n}. \tag{5.22}$$

Hence, for every $i \in I_n$, Algorithm 5.1③ and Proposition 3.3(viii) yield $D(z, u_{i,n}) \leq D(z, x_n) - D(u_{i,n}, x_n) \leq D(z, x_n)$. Therefore,

$$(\forall i \in I_n) \;\; u_{i,n} \in C. \tag{5.23}$$

Now, per Condition 5.4(ii), pick $j_n \in I_n$ such that

$$\|\nabla f(u_{j_n,n}) - \nabla f(x_n)\| = \max_{i \in I_n} \|\nabla f(u_{i,n}) - \nabla f(x_n)\| \quad \text{and} \quad \omega_{j_n,n} \geq \delta_1. \tag{5.24}$$

We claim that

(5.25)

$$\begin{cases} x_n \in \bigcap_{i \in I_n^+} \operatorname{Fix} T_{i,n} & \Leftrightarrow \quad u_{j_n,n} = x_n \quad \Leftrightarrow \quad \|\nabla f(u_{j_n,n}) - \nabla f(x_n)\| = 0, \\ x_n \notin \bigcap_{i \in I_n^+} \operatorname{Fix} T_{i,n} & \Rightarrow \quad d_{H_n}(x_n) \geq \delta_1 \delta_2 \dfrac{\langle u_{j_n,n} - x_n, \nabla f(u_{j_n,n}) - \nabla f(x_n) \rangle}{\|\nabla f(u_{j_n,n}) - \nabla f(x_n)\|}. \end{cases}$$

On the one hand, using Proposition 3.3(vi) and the injectivity of ∇f on $\operatorname{int} \operatorname{dom} f$ [8, Thm. 5.10], since (5.24) forces $j_n \in I_n^+$, we get $x_n \in \bigcap_{i \in I_n^+} \operatorname{Fix} T_{i,n} \Leftrightarrow (\forall i \in I_n^+)$ $u_{i,n} = x_n \Rightarrow u_{j_n,n} = x_n \Rightarrow \|\nabla f(u_{j_n,n}) - \nabla f(x_n)\| = 0 \Rightarrow (\forall i \in I_n)$ $\|\nabla f(u_{i,n}) - \nabla f(x_n)\| = 0 \Leftrightarrow (\forall i \in I_n)$ $u_{i,n} = x_n \Rightarrow (\forall i \in I_n^+)$ $u_{i,n} = x_n$. On the other hand, if $x_n \notin \bigcap_{i \in I_n^+} \operatorname{Fix} T_{i,n}$, then Proposition 3.39(ii) asserts that $x_n \notin H_n$ and $x_n^* \neq 0$, so that

$$\begin{aligned} d_{H_n}(x_n) &= \frac{\langle x_n, x_n^* \rangle - \eta_n}{\|x_n^*\|} \\ &= \lambda_n \frac{\sum_{i \in I_n} \omega_{i,n} \langle u_{i,n} - x_n, \nabla f(u_{i,n}) - \nabla f(x_n) \rangle}{\| \sum_{i \in I_n} \omega_{i,n} \big(\nabla f(u_{i,n}) - \nabla f(x_n) \big) \|} \qquad (5.26) \\ &\geq \delta_2 \frac{\sum_{i \in I_n} \omega_{i,n} \langle u_{i,n} - x_n, \nabla f(u_{i,n}) - \nabla f(x_n) \rangle}{\sum_{i \in I_n} \omega_{i,n} \|\nabla f(u_{i,n}) - \nabla f(x_n)\|} \qquad (5.27) \\ &\geq \delta_1 \delta_2 \frac{\langle u_{j_n,n} - x_n, \nabla f(u_{j_n,n}) - \nabla f(x_n) \rangle}{\|\nabla f(u_{j_n,n}) - \nabla f(x_n)\|}, \qquad (5.28) \end{aligned}$$

where (5.26) follows from [80, Lemma I.1.2] and (5.27) from Condition 5.4(ii). Altogether, (5.25) is verified. The third key fact is derived from (5.23) and Proposition 2.3(i) as follows:

$$\begin{aligned} (\forall i \in I_n) \;\; \operatorname{diam}(C) \|\nabla f(u_{i,n}) - \nabla f(x_n)\| &\geq \langle u_{i,n} - x_n, \nabla f(u_{i,n}) - \nabla f(x_n) \rangle \\ &= D(u_{i,n}, x_n) + D(x_n, u_{i,n}) \\ &\geq D(u_{i,n}, x_n). \end{aligned} \tag{5.29}$$

Let us now verify (4.11). To this end, let us fix $i \in I$ and $x \in \mathfrak{W}(x_n)_{n\in\mathbb{N}}$, say $x_{k_n} \rightharpoonup x$. Because $x \in \overline{\operatorname{dom} f}$, it is sufficient to show

$$D(x_{n+1}, x_n) \to 0 \quad \Rightarrow \quad x \in S_i. \tag{5.30}$$

Let M_i be as in Condition 5.4(iii). After passing to a subsequence of $(x_{k_n})_{n\in\mathbb{N}}$ if necessary, we assume that, for every $n \in \mathbb{N}$, $k_{n+1} \geq k_n + M_i$. This guarantees the existence of a sequence $(p_n)_{n\in\mathbb{N}}$ in $\mathbb{N}$ such that

$$(\forall n \in \mathbb{N}) \;\; k_n \leq p_n \leq k_n + M_i - 1 < k_{n+1} \leq p_{n+1} \quad \text{and} \quad i \in I_{p_n}. \tag{5.31}$$

Now consider the subsequence $(x_{p_n})_{n\in\mathbb{N}}$ of $(x_n)_{n\in\mathbb{N}}$. The triangle inequality yields

$$(\forall n \in \mathbb{N}) \;\; \|x_{p_n} - x_{k_n}\| \leq \sum_{l=k_n}^{k_n+M_i-2} \|x_{l+1} - x_l\| \leq (M_i - 1) \max_{k_n \leq l \leq k_n+M_i-2} \|x_{l+1} - x_l\|. \tag{5.32}$$

Now suppose $D(x_{n+1}, x_n) \to 0$. Then (4.4) yields

$$x_{n+1} - x_n \to 0 \tag{5.33}$$

and it follows from (5.21) that $d_{H_n}(x_n) \to 0$. Consequently, we derive from (5.25), (5.23), and Condition 5.3(ii) that $\max_{j\in I_n} \|\nabla f(u_{j,n}) - \nabla f(x_n)\| \to 0$. In turn, (5.29) implies that $D(u_{i,p_n}, x_{p_n}) \to 0$ and, invoking (4.4) again, we obtain

$$u_{i,p_n} - x_{p_n} \to 0. \tag{5.34}$$

We also derive from (5.32) and (5.33) that $x_{p_n} - x_{k_n} \to 0$, whence $x_{p_n} \rightharpoonup x$. However, since the algorithm is focusing, (5.10) yields $x \in S_i$. Thus (5.30) holds and, consequently, the following conclusions can be drawn:

(i) Theorem 4.14(i) asserts that $(x_n)_{n\in\mathbb{N}}$ converges weakly to $x \in S$.

(ii) Suppose that $x \in \operatorname{int}\operatorname{dom} f$, $i \in I$ is an index of demicompact regularity, and $D(x_{n+1}, x_n) \to 0$. Then it results from (5.34) and (5.11) that (4.12) holds. In view of Condition 4.4, the strong convergence claim therefore follows from Theorem 4.14(ii). □

5.4. When all the assumptions hold. In this subsection, we describe scenarios in which all the assumptions required in Theorem 5.7 on f and on the constraint sets $(S_i)_{i\in I}$ are satisfied.

As a preamble to our first example, recall that if $\mathcal{X}$ is a Hilbert space, the Moreau–Yosida regularization of a proper lower semicontinuous convex function $\varphi\colon \mathcal{X} \to]-\infty, +\infty]$ with parameter $\gamma \in]0, +\infty[$ is the finite continuous convex function ${}_\gamma\varphi = \varphi \,\square\, \big(\|\cdot\|^2/(2\gamma)\big)$. Moreover, Moreau's classic proximal operator associated with φ and γ is given by Definition 3.16 for $f = \|\cdot\|^2/2$ and will be denoted by $\operatorname{Prox}_\gamma^\varphi$. It follows from Proposition 3.21(v) that $\operatorname{Prox}_\gamma^\varphi$ is defined everywhere and, from Proposition 3.22(ii)(d) and (c), that it is single-valued and firmly nonexpansive. Moreover [67, Prop. 7.d],

$$\nabla\, {}_\gamma\varphi = \frac{\operatorname{Id} - \operatorname{Prox}_\gamma^\varphi}{\gamma}. \tag{5.35}$$

EXAMPLE 5.8 (Moreau–Yosida regularization). *Let $\mathcal{X}$ be a Hilbert space, set $w = \|\cdot\|^2/2$, and define $f\colon \mathcal{X} \to \mathbb{R}$ by*

$$f = (1+\gamma)w - {}_1\varphi, \tag{5.36}$$

where $\varphi\colon \mathcal{X} \to]-\infty,+\infty]$ is a proper lower semicontinuous convex function and $\gamma \in]0,+\infty[$. Then

$$\begin{aligned} D\colon (x,y) \mapsto{}& \gamma w(x-y) + w(x-\operatorname{Prox}_1^{\varphi} y) + \varphi(\operatorname{Prox}_1^{\varphi} y) \\ &- \big(w(x-\operatorname{Prox}_1^{\varphi} x) + \varphi(\operatorname{Prox}_1^{\varphi} x)\big) \end{aligned} \tag{5.37}$$

and Conditions 4.4 and 5.3 are satisfied. If $\operatorname{Prox}^{\varphi}_{\frac{\gamma}{1+\gamma}}$ is affine or S is a singleton, then Condition 4.3 is also satisfied.

Proof. The expression (5.37) is derived from (1.5) by simple algebra. Now set $\psi = w - {}_1\varphi$. Then

$$\psi = w - \inf_{x\in\operatorname{dom}\varphi} \varphi(x) + w(\cdot - x) = \sup_{x\in\operatorname{dom}\varphi} \langle x,\cdot\rangle - \varphi(x) - w(x) = (\varphi + w)^*. \tag{5.38}$$

Hence, ψ is a proper lower semicontinuous convex function as the conjugate of one such function. Since ψ is convex, $f = \psi + \gamma w$ is strongly (hence uniformly) convex and, in view of Example 4.10(i), Condition 4.4 is therefore satisfied. On the other hand, (5.35) yields $\operatorname{dom}\nabla f = \mathcal{X}$ and $\nabla f = \operatorname{Prox}_1^{\varphi} + \gamma\operatorname{Id}$. Hence f is essentially smooth by [8, Thm. 5.6]. Furthermore, since $\operatorname{Prox}_1^{\varphi}$ is firmly nonexpansive, it is 1-Lipschitz and therefore ∇f is $(1+\gamma)$-Lipschitz. Accordingly, Proposition 5.5(ii) asserts that Condition 5.3(ii) is satisfied. Next, using standard Hilbertian convex calculus, we obtain

$$\begin{aligned} f^* &= \big(\psi + \gamma w\big)^* = \psi^* \,\square\, (w/\gamma) = (\varphi + w) \,\square\, (w/\gamma) = {}_{\gamma}\big(\varphi + w\big) \\ &= \big({}_{\gamma/(1+\gamma)}\varphi\big)\big(\,\cdot\,/(1+\gamma)\big) + w/(1+\gamma). \end{aligned} \tag{5.39}$$

It therefore follows from (5.35) that

$$\operatorname{dom}\nabla f^* = \mathcal{X} \quad\text{and}\quad \nabla f^* = \frac{\operatorname{Id} - \operatorname{Prox}^{\varphi}_{\gamma/(1+\gamma)}\big(\,\cdot\,/(1+\gamma)\big)}{\gamma}. \tag{5.40}$$

Consequently, f^* is also essentially smooth and it follows from [8, Thm. 5.4] that f is Legendre. Moreover, since $\mathcal{X}$ is a Hilbert space, it is reflexive. We also derive from (5.40) that, since $\operatorname{Id} - \operatorname{Prox}^{\varphi}_{\gamma/(1+\gamma)}$ is (firmly) nonexpansive, ∇f^* is $1/\gamma$-Lipschitz and, thereby, maps bounded sets to bounded sets. It then follows from [8, Thm. 3.3] that f is supercoercive, and Proposition 4.1(v)(a) asserts that Condition 5.3(i) is satisfied. Finally, since ∇f is continuous, it will be weakly continuous when it is affine, i.e., when $\operatorname{Prox}^{\varphi}_{\gamma/(1+\gamma)}$ is. In turn, Example 4.6 implies that Condition 4.3 is satisfied. On the other hand, if S is a singleton, the claim follows from Example 4.5. ∎

If we let φ be the indicator function of a nonempty closed convex set in (5.36), then we obtain the Legendre function studied in [8, Example 7.2]. Specializing even further, we obtain the following examples.

EXAMPLE 5.9 (distance). *In the previous example, set $\varphi = \iota_M$, where M is a closed affine subspace of $\mathcal{X}$, and let P_M be the metric projector onto M. Then Conditions 4.3, 4.4, and 5.3 are satisfied, $f = (1+\gamma)w - d_M^2/2$, and $D\colon (x,y) \mapsto \gamma w(x-y) + w(x - P_M y) - w(x - P_M x)$.*

EXAMPLE 5.10 (energy). *In the previous example, set* $M = \{0\}$ *and* $\gamma = 1$. *Then* $f = \|\cdot\|^2/2$, $\nabla f = \mathrm{Id}$, $D\colon (x,y) \mapsto \|x-y\|^2/2$, *and we recover the usual Fejér monotonicity framework.*

The next example shows that the function $f = \|\cdot\|^2/2$ can also be used outside Hilbert spaces.

EXAMPLE 5.11 (L_p spaces). *Let* $(\Omega, \mathcal{F}, \mu)$ *be a positive measure space and let* $p \in [2, +\infty[$. *Let* $\mathcal{X} = L_p(\Omega, \mathcal{F}, \mu)$, *equipped with its canonical norm, and set* $f = \|\cdot\|^2/2$. *Then Conditions* 4.4 *and* 5.3 *are satisfied. If* S *is a singleton, then Condition* 4.3 *is also satisfied.*

Proof. By [8, Example 6.5], f is Legendre and uniformly convex on closed balls. Hence Condition 4.4 holds by Example 4.10(i). Since f is supercoercive, Condition 5.3(i) follows from [8, Lemma 7.3(viii)]. We now establish Condition 5.3(ii). As $p \in [2, +\infty[$, [45, Corollary V.1.2] implies that $\rho_{\|\cdot\|}$, the modulus of smoothness of $\mathcal{X}$, is of power type 2. We thus obtain $\kappa \in]0, +\infty[$ so that (see [45, section IV.4])

$$(\forall t \in [0, +\infty[) \quad \rho_{\|\cdot\|}(t) \leq \kappa t^2. \tag{5.41}$$

Recall that $\nabla f = J$ and define $j(x) = J(x)/\|x\| = \nabla\|x\|$ for all nonzero $x \in \mathcal{X}$. Now (5.41) and [45, Lemma IV.5.1] yield

$$(\forall u \in S_{\mathcal{X}})(\forall v \in S_{\mathcal{X}}) \quad \|j(u) - j(v)\| \leq \kappa\|u - v\|. \tag{5.42}$$

Fix two nonzero points x and y in $\mathcal{X}$ and assume, without loss of generality, that $\|x\| \geq \|y\|$. Then, using the triangle inequality,

$$\left\| \frac{x}{\|x\|} - \frac{y}{\|y\|} \right\| = \left\| \left(\frac{x}{\|x\|} - \frac{y}{\|x\|} \right) + \frac{\|y\| \cdot y - \|x\| \cdot y}{\|x\| \cdot \|y\|} \right\| \leq \frac{2}{\|x\|}\|x - y\|. \tag{5.43}$$

Thus

$$\|j(x) - j(y)\| = \left\| j\left(\frac{x}{\|x\|}\right) - j\left(\frac{y}{\|y\|}\right) \right\| \leq \kappa \cdot \left\| \frac{x}{\|x\|} - \frac{y}{\|y\|} \right\| \leq \frac{2\kappa}{\|x\|}\|x - y\|, \tag{5.44}$$

where we have used the definition of j for the equality, (5.42) for the first inequality, and (5.43) for the second. Furthermore,

$$\begin{aligned} \|J(x) - J(y)\| &= \big\|\|x\| \cdot j(x) - \|y\| \cdot j(y)\big\| \\ &= \big\|\big(\|x\| \cdot j(x) - \|x\| \cdot j(y)\big) + \big(\|x\| \cdot j(y) - \|y\| \cdot j(y)\big)\big\| \\ &\leq \|x\| \cdot \|j(x) - j(y)\| + \|j(y)\| \cdot \big|\|x\| - \|y\|\big| \\ &\leq (2\kappa + 1) \cdot \|x - y\|, \end{aligned} \tag{5.45}$$

where the last inequality follows from (5.44) and the fact that $\|j(y)\| = 1$. Now (5.45) implies that $J = \nabla f$ is Lipschitz-continuous on $\operatorname{dom} f = \mathcal{X}$, with constant $2\kappa + 1$ (for $x = 0$ or $y = 0$, argue directly). We apply Proposition 5.5(ii) and conclude that Condition 5.3(ii) is satisfied. Finally, if S is a singleton, we employ Example 4.5. ∎

Guaranteeing Condition 4.3 requires some care.

Remark 5.12. As already discussed in Remark 5.6, Proposition 5.5(i) holds as soon as ∇f is Lipschitz on bounded sets. Thus, the assertions of Example 5.11 remain true for $f = \|\cdot\|^s/s$, where $s \in [2, +\infty[$. The case when $s = p$ is particularly interesting because then ∇f becomes J_φ, the duality mapping corresponding to the weight $\varphi\colon t \mapsto t^{p-1}$ (see [34]). If we specialize this further to the space $\ell_p(\mathbb{N})$, then

J_φ is known to be sequentially weakly continuous (see [34, Prop. II.4.14]) and thus Example 4.6 is applicable. To sum up,

> let $\mathcal{X} = \ell_p(\mathbb{N})$ and $f = \|\cdot\|^p/p$, for $p \in [2, +\infty[$;
> then Conditions 4.3, 4.4, and 5.3 are satisfied.

Additional examples can be generated in suitable product spaces such as $\ell_{p_1}(\mathbb{N}) \times \ell_{p_2}(\mathbb{N})$, equipped with the Euclidean product norm and with $\{p_1, p_2\} \subset [2, +\infty[$, or in certain spaces of power type 2. (See [45] for further information about such spaces.)

EXAMPLE 5.13 (closed domain Bregman/Legendre functions). *Let $\mathcal{X} = \mathbb{R}^N$ and let f be a Bregman/Legendre function with closed domain. Then Conditions* 4.3, 4.4, *and* 5.3 *are satisfied.*

Proof. Example 4.9 implies that Condition 4.3 holds. Condition 4.4 follows from [7, Def. 5.2.BL3 and Thm. 3.9(iii)]. It remains to check items (i) and (ii) in Condition 5.3: since $D(z, \cdot)$ is coercive for every $z \in \operatorname{dom} f$ [7, Remark 5.3], (i) holds, whereas (ii) follows from Proposition 5.5(iv). ☐

The class of Bregman/Legendre functions (see Definition 4.8) is large enough to contain many functions important in convex optimization and it is related to the Bregman functions of [30, 33], which require closed domains. We refer the reader to [7] for further information. The following example gives conditions that are easy to verify in practice.

EXAMPLE 5.14 (separable Bregman/Legendre functions). *Let $(\varphi_k)_{1\leq k\leq N} \colon \mathbb{R} \to]-\infty, +\infty]$ be a family of Legendre functions such that $(\operatorname{dom}\varphi_k^*)_{1\leq k\leq N}$ are open. Let $\mathcal{X} = \mathbb{R}^N$, and let $f \colon (\xi_k)_{1\leq k\leq N} \mapsto \sum_{k=1}^N \varphi_k(\xi_k)$. Then Conditions* 4.3, 4.4, *and* 5.3 *are satisfied.*

Proof. By [7, Corollary 5.13], f is Bregman/Legendre. Mimicking the proof of the previous example, we note that it remains to check Condition 4.4. For every $k \in \{1, \ldots, m\}$, since $\varphi_k|_{\operatorname{int}\operatorname{dom}\varphi_k}$ is strictly convex by Legendreness and $\varphi_k|_{\operatorname{dom}\varphi_k}$ is continuous by (3.5), $\varphi_k|_{\operatorname{dom}\varphi_k}$ is strictly convex. Hence, it follows from Example 4.10(iii) that the Bregman distance D_k induced by φ_k on $\mathbb{R}$ satisfies Condition 4.4 and, in turn, so does $D \colon \big((\xi_k)_{1\leq k\leq N}, (\chi_k)_{1\leq k\leq N}\big) \mapsto \sum_{k=1}^N D_k(\xi_k, \chi_k)$. ☐

Unlike the previous examples, the following example does not require that $\mathcal{X}$ be finite-dimensional or that f have full domain.

EXAMPLE 5.15. *Let $\mathcal{X}$ be the Hilbert space $\ell_2(\mathbb{N}) \times \mathbb{R}$ and define*

$$f \colon \mathcal{X} \to]-\infty, +\infty] : (x, \xi) \mapsto \begin{cases} \tfrac{1}{2}\|x\|^2 + \xi\ln(\xi) - \xi & \text{if } \xi > 0, \\ \tfrac{1}{2}\|x\|^2 & \text{if } \xi = 0, \\ +\infty & \text{if } \xi < 0. \end{cases} \tag{5.46}$$

Let $(\forall i \in I)$ $S_i = S = \ell_2(\mathbb{N}) \times [1, +\infty[$. Fix $(z, \zeta) \in S$, $\eta > 0$, and set $C = \operatorname{lev}_{\leq\eta} D\big((z, \zeta), \cdot\big)$. Then Conditions 4.3, 4.4, *and* 5.3 *are satisfied.*

Proof. Let $g = f(\cdot, 0)$ and $h = f(0, \cdot)$. Hence, $(\forall (x, \xi) \in \mathcal{X})$ $f(x, \xi) = g(x) + h(\xi)$. Note that g and h are Legendre, and so is f, with $\operatorname{dom} f = \ell_2(\mathbb{N}) \times [0, +\infty[$. Now, let D_g and D_h be the Bregman distances induced by g on $\ell_2(\mathbb{N})$ and h on $\mathbb{R}$, respectively. Take $(y, \chi) \in \mathcal{X}$ with $D\big((z, \zeta), (y, \chi)\big) = D_g(z, y) + D_h(\zeta, \chi) \leq \eta$. In particular, $D_g(z, y) \leq \eta$ and $D_h(\zeta, \chi) \leq \eta$. Since $D_g(z, \cdot)$ and $D_h(\zeta, \cdot)$ are coercive by Proposition 4.1(v)(a) and (b), C is bounded. Condition 4.3 is a consequence of Example 4.6. Since $D \colon (x, \xi) \mapsto D_g(x) + D_h(\xi)$, Condition 4.4 is immediate by Examples 5.10 and 5.13. Applying [7, Thm. 3.8.(i)] to h and $\zeta \in \operatorname{int}\operatorname{dom} h$, we obtain $\varepsilon \in]0, +\infty[$ such that $(\forall (y, \chi) \in C)$ $\chi \geq \varepsilon$. A straightforward computation shows

that ∇f^* is strongly monotone with constant $\min\{1,\varepsilon\}$. Therefore, using Proposition 5.5(iv), Condition 5.3(ii) holds as well and the proof is complete. ∎

5.5. Applications. A broad class of problems in convex optimization and nonlinear analysis are captured by the mixed convex feasibility problem

$$\text{Find } x \in \overline{\operatorname{dom}} f \text{ such that } \begin{cases} (\forall i \in I^{(1)}) & g_i(x) \le 0, \\ (\forall i \in I^{(2)}) & 0 \in A_i x, \\ (\forall i \in I^{(3)}) & \varphi_i(x) = \inf \varphi_i(\mathcal{X}), \\ (\forall i \in I^{(4)}) & T_i x = x, \end{cases} \tag{5.47}$$

where $(g_i)_{i\in I^{(1)}}$ and $(\varphi_i)_{i\in I^{(3)}}$ are families of proper lower semicontinuous convex functions from $\mathcal{X}$ into $]-\infty,+\infty]$, $(A_i)_{i\in I^{(2)}}$ is a family of maximal monotone operators from $\mathcal{X}$ into $2^{\mathcal{X}^*}$, and $(T_i)_{i\in I^{(4)}}$ is a family of D-firm operators from $\mathcal{X}$ into $\mathcal{X}$. Here, $I^{(1)}$, $I^{(2)}$, $I^{(3)}$, and $I^{(4)}$ are pairwise disjoint, possibly empty, countable index sets such that $I = \bigcup_{k=1}^{4} I^{(k)} \neq \emptyset$. Now let us define

$$(\forall i \in I)\ \ S_i = \begin{cases} \operatorname{lev}_{\le 0} g_i & \text{if } i \in I^{(1)}, \\ A_i^{-1}0 & \text{if } i \in I^{(2)}, \\ \operatorname{Argmin} \varphi_i & \text{if } i \in I^{(3)}, \\ \overline{\operatorname{Fix}} T_i & \text{if } i \in I^{(4)}. \end{cases} \tag{5.48}$$

Throughout this section, the following set of assumptions will be made.

CONDITION 5.16.

(i) *Conditions* 4.3, 4.4, 5.3, *and* 5.4 *are satisfied.*

(ii) *For every* $i \in I^{(1)}$, $\partial g_i(C)$ *is bounded and* $\operatorname{dom} f \subset \operatorname{dom} g_i$.

(iii) *For every* $i \in I^{(2)}$, *one of the following conditions holds:*

(a) $\operatorname{dom} A_i \subset \operatorname{int}\operatorname{dom} f$,

(b) A_i *is* 3^**-monotone.*

(iv) *For every* $i \in I^{(4)}$, $\operatorname{dom} T_i = \operatorname{int}\operatorname{dom} f$ *and* $T_i - \mathrm{Id}$ *is demiclosed at* 0 *in the sense that for every sequence* $(y_n)_{n\in\mathbb{N}}$ *in* $\operatorname{dom} T_i$

$$\begin{cases} y_n \rightharpoonup y, \\ (\forall n \in \mathbb{N})\ \ u_n \in T_i y_n, \\ u_n - y_n \to 0 \end{cases} \quad \Rightarrow \quad y \in \overline{\operatorname{Fix}} T_i. \tag{5.49}$$

Let us observe that the sets $(S_i)_{i\in I}$ are closed and convex. For $i \in I^{(1)} \cup I^{(2)} \cup I^{(3)}$, this follows from well-known facts; for $i \in I^{(4)}$, this follows from Condition 5.16(iv), Propositions 3.5(ii), the essential strict convexity of f, and Proposition 3.3(v). Accordingly, (5.47) is a special case of the convex feasibility problem (5.2) and it can therefore be solved by Algorithm 5.1.

ALGORITHM 5.17 (specific implementation of Algorithm 5.1). *Fix* $(\varepsilon_i)_{i\in I^{(2)}}$ *and* $(\varepsilon_i)_{i\in I^{(3)}}$ *in* $]0,+\infty[$. *Implement Algorithm* 5.1② *by choosing for every* $i \in I_n$

$$T_{i,n} = \begin{cases} Q_{g_i} & \text{if } i \in I^{(1)} \text{ (see Definition 3.37)}, \\ R_{\gamma_{i,n}A_i}, \text{ where } \gamma_{i,n} \in [\varepsilon_i, +\infty[& \text{if } i \in I^{(2)} \text{ (see Definition 3.7)}, \\ \operatorname{prox}^{\varphi_i}_{\gamma_{i,n}}, \text{ where } \gamma_{i,n} \in [\varepsilon_i, +\infty[& \text{if } i \in I^{(3)} \text{ (see Definition 3.16)}, \\ T_i & \text{if } i \in I^{(4)} \text{ (see Definition 3.4)}. \end{cases} \tag{5.50}$$

Thanks to Condition 5.16, (5.50) meets the requirements of Algorithm 5.1② since in each case we have the following:

- $T_{i,n} \in \mathfrak{B}$. This follows from Proposition 3.38(ii) if $i \in I^{(1)}$, from Corollary 3.14(ii) and (iii) if $i \in I^{(2)}$ (since $A_i^{-1}0 \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$, $\operatorname{dom} A_i \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$), from Corollary 3.25(i) if $i \in I^{(3)}$ (since φ_i is proper and $\operatorname{Argmin}\varphi_i \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$, φ_i is bounded below and $\operatorname{dom}\varphi_i \cap \operatorname{int}\operatorname{dom} f \neq \varnothing$), and from Proposition 3.5(ii) if $i \in I^{(4)}$.
- $S_i \cap \operatorname{int}\operatorname{dom} f \subset \operatorname{Fix} T_{i,n}$. (See Proposition 3.38(i), Proposition 3.8(iii), Proposition 3.22(ii)(b), and Proposition 3.3(iv) and (vii), respectively.)

THEOREM 5.18. *Suppose that Condition* 5.16 *is in force and let* $(x_n)_{n\in\mathbb{N}}$ *be an arbitrary orbit of Algorithm* 5.17. *Then* $(x_n)_{n\in\mathbb{N}}$ *converges weakly to a point* $x \in S$. *The convergence is strong if* $x \in \operatorname{int}\operatorname{dom} f$ *and any of the following assumptions is added:*

(i) *For some* $i \in I^{(1)}$ *and some* $\eta \in \left]0, +\infty\right[$, $C \cap \operatorname{lev}_{\leq\eta} g_i$ *is relatively compact.*
(ii) *For some* $i \in I^{(2)}$, $C \cap \operatorname{dom} A_i$ *is relatively compact.*
(iii) *For some* $i \in I^{(3)}$, $C \cap \operatorname{dom} \partial\varphi_i$ *is relatively compact.*
(iv) *For some* $i \in I^{(4)}$, T_i *is demicompact at* 0 *in the sense that for every sequence* $(y_n)_{n\in\mathbb{N}}$ *in* $\operatorname{dom} T_i$

$$\begin{cases} (y_n)_{n\in\mathbb{N}} \text{ bounded}, \\ (\forall n \in \mathbb{N})\ \ u_n \in T_i y_n, \\ u_n - y_n \to 0 \end{cases} \quad \Rightarrow \quad \mathfrak{S}(y_n)_{n\in\mathbb{N}} \neq \varnothing. \tag{5.51}$$

Proof. As seen above, (5.47) is a special case of (5.2), whereas Algorithm 5.17 is a special case of Algorithm 5.1. Invoking Theorem 5.7, we shall prove that Algorithm 5.17 is focusing to establish the weak convergence claim and then that it is demicompactly regular to establish the strong convergence claim. It is recalled that Theorem 5.7 asserts that $(x_n)_{n\in\mathbb{N}}$ and $\big((u_{i,n})_{i\in I_n}\big)_{n\in\mathbb{N}}$ lie in the bounded set C.

To show that Algorithm 5.17 is focusing, let us fix $i \in I$ and a suborbit $(x_{k_n})_{n\in\mathbb{N}}$ such that $i \in \bigcap_{n\in\mathbb{N}} I_{k_n}$, $x_{k_n} \rightharpoonup x$, and $u_{i,k_n} - x_{k_n} \to 0$. According to (5.10), we must show $x \in S_i$. Four cases will be considered:

(1) $i \in I^{(1)}$. We must show $g_i(x) \leq 0$. In view of (5.50), for every $n \in \mathbb{N}$, u_{i,k_n} is the D-projection of x_n onto $G_i(x_{k_n}, x_n^*) = \big\{y \in \mathcal{X} \mid \langle x_{k_n} - y, x_n^*\rangle \geq g_i(x_{k_n})\big\}$ for some $x_n^* \in \partial g_i(x_{k_n})$. Since $u_{i,k_n} \in G_i(x_{k_n}, x_n^*)$, we have

$$\|u_{i,k_n} - x_{k_n}\| \geq d_{G_i(x_{k_n},x_n^*)}(x_{k_n}) = \begin{cases} g_i^+(x_{k_n})/\|x_n^*\| & \text{if } x_n^* \neq 0, \\ 0 & \text{otherwise}, \end{cases} \tag{5.52}$$

where $g_i^+ = \max\{0, g_i\}$ and the last equality follows from [80, Lemma I.1.2]. Since $(x_{k_n})_{n\in\mathbb{N}}$ lies in C, $(x_n^*)_{n\in\mathbb{N}}$ is bounded by Condition 5.16(ii). Therefore, $u_{i,k_n} - x_{k_n} \to 0$ implies $g_i^+(x_{k_n}) \to 0$. However, as g_i^+ is convex and lower semicontinuous, it is weak lower semicontinuous and thus $g_i^+(x) \leq \varliminf g_i^+(x_{k_n}) = 0$. We conclude $g_i(x) \leq 0$.

(2) $i \in I^{(2)}$. We must show $(x, 0) \in \operatorname{gr} A_i$. For every $n \in \mathbb{N}$, (5.50) yields $u_{i,k_n} \in (\nabla f + \gamma_{i,k_n} A_i)^{-1}\big(\nabla f(x_{k_n})\big)$ and we define

$$u_n^* = \frac{\nabla f(x_{k_n}) - \nabla f(u_{i,k_n})}{\gamma_{i,k_n}}. \tag{5.53}$$

Therefore $\big((u_{i,k_n}, u_n^*)\big)_{n\in\mathbb{N}}$ lies in $\operatorname{gr} A_i$ and $u_{i,k_n} - x_{k_n} \to 0 \Rightarrow u_{i,k_n} \rightharpoonup x$. If for all n sufficiently large we have $x_{k_n} = u_{i,k_n}$, then by Proposition 3.8(iii) the

tail of $(x_{k_n})_{n\in\mathbb{N}}$ is in the weakly closed set $A_i^{-1}0$ and therefore $(x,0)\in \operatorname{gr} A_i$. Otherwise, we can extract a subsequence $(x_{k_{l_n}})_{n\in\mathbb{N}}$ such that, for all $n\in\mathbb{N}$, $x_{k_{l_n}}\neq u_{i,k_{l_n}}$. Since, on the one hand, $(x_{k_{l_n}})_{n\in\mathbb{N}}$ and $(u_{i,k_{l_n}})_{n\in\mathbb{N}}$ lie in C and, on the other hand,

$$(5.54)\quad (\forall n\in\mathbb{N})\ \ \|u_{i,k_{l_n}}-x_{k_{l_n}}\|\geq \frac{\langle u_{i,k_{l_n}}-x_{k_{l_n}},\nabla f(u_{i,k_{l_n}})-\nabla f(x_{k_{l_n}})\rangle}{\|\nabla f(u_{i,k_{l_n}})-\nabla f(x_{k_{l_n}})\|},$$

it follows from Condition 5.3(ii), (5.53), and the inequality $\inf_{n\in\mathbb{N}}\gamma_{i,k_{l_n}}\geq\varepsilon_i$ that $u_{i,k_{l_n}}-x_{k_{l_n}}\to 0\Rightarrow \nabla f(u_{i,k_{l_n}})-\nabla f(x_{k_{l_n}})\to 0\Rightarrow u^*_{l_n}\to 0$. Finally, since A_i is maximal monotone, $\operatorname{gr} A_i$ is sequentially closed in the weak $\times$ strong topology of $\mathcal{X}\times\mathcal{X}^*$ and we conclude that $(x,0)\in\operatorname{gr} A_i$, as required.

(3) $i\in I^{(3)}$. We must show $\varphi_i(x)=\inf\varphi_i(\mathcal{X})$, i.e., $(x,0)\in\operatorname{gr}\partial\varphi_i$. Since φ is a proper lower semicontinuous convex function, $A_i=\partial\varphi_i$ is maximal monotone [79, section 29] and 3*-monotone by Lemma 3.10(iv), and, in view of Propositions 3.22(ii)(a) and 3.23(v)(b), the claim follows from case (2).

(4) $i\in I^{(4)}$. We must show $x\in\overline{\operatorname{Fix}}\,T_i$. This follows at once from (5.49).

It remains to show that in each instance (i)–(iv), i is an index of demicompact regularity. Henceforth, $(x_{k_n})_{n\in\mathbb{N}}$ is a suborbit such that $i\in\bigcap_{n\in\mathbb{N}}I_{k_n}$ and $u_{i,k_n}-x_{k_n}\to 0$. By (5.11), we must show $\mathfrak{S}(x_{k_n})_{n\in\mathbb{N}}\neq\varnothing$. (i) Arguing as in case (1), we obtain $\varlimsup g_i(x_{k_n})\leq 0$. Therefore, the tail of $(x_{k_n})_{n\in\mathbb{N}}$ lies in the compact set $\overline{C\cap\operatorname{lev}_{\leq\eta}g_i}$, whence $\mathfrak{S}(x_{k_n})_{n\in\mathbb{N}}\neq\varnothing$. (ii) It follows from (3.16) that for every $n\in\mathbb{N}$

$$\begin{cases} u_{i,k_n}\in C\subset\operatorname{int}\operatorname{dom} f,\\ u_{i,k_n}\in\operatorname{ran}(\nabla f+\gamma_{i,k_n}A_i)^{-1}\circ\nabla f\subset\operatorname{dom}\nabla f\cap\operatorname{dom} A_i=\operatorname{int}\operatorname{dom} f\cap\operatorname{dom} A_i.\end{cases}$$

Therefore, $(u_{i,k_n})_{n\in\mathbb{N}}$ lies in the compact set $\overline{C\cap\operatorname{dom} A_i}$, whence $\mathfrak{S}(u_{i,k_n})_{n\in\mathbb{N}}\neq\varnothing$. Since $u_{i,k_n}-x_{k_n}\to 0$, we conclude $\mathfrak{S}(x_{k_n})_{n\in\mathbb{N}}\neq\varnothing$. (iii) As in case (3), this is a special case of (ii). (iv) This is clear from (5.51). ∎

Theorem 5.18 produces convergence results for various new block-iterative parallel schemes for solving problems, including solving convex inequalities ($I^{(2)}=I^{(3)}=I^{(4)}=\varnothing$), finding common zeros ($I^{(1)}=I^{(3)}=I^{(4)}=\varnothing$), solving systems of variational inequalities ($I^{(1)}=I^{(2)}=I^{(4)}=\varnothing$), finding common fixed points ($I^{(1)}=I^{(2)}=I^{(3)}=\varnothing$), and combinations of these. Note that D-projection methods are also captured by Theorem 5.18 since, in view of Proposition 3.32(ii)(c), one can take, for instance, T_i to be the D-projector onto S_i if $i\in I^{(4)}$ in (5.50).

Naturally, our framework also encompasses relaxed sequential algorithms, which are obtained by taking $(I_n)_{n\in\mathbb{N}}$ to be a sequence of singletons, as in the following example.

EXAMPLE 5.19. *Suppose $\mathcal{X}=\mathbb{R}^N$, $(S_i)_{1\leq i\leq m}$ is a (finite) family of half-spaces with D-projectors $(P_i)_{1\leq i\leq m}$, and, for every $n\in\mathbb{N}$, $I_n=\{n\ (\operatorname{mod} m)+1\}$ and $T_{i,n}=P_i$. Then Algorithm* 5.1 *reduces to the relaxed D-projection method of* [44].

In the case of unrelaxed sequential algorithms, our working assumptions can be loosened. This is discussed next.

5.6. Unrelaxed sequential algorithms. Algorithm 5.1 can be specialized to an unrelaxed sequential algorithm for solving the convex feasibility problem (5.2). Indeed, suppose that at each iteration n only one index, say $\mathrm{i}(n)$, is retained and $\lambda_n=1$. Then Algorithm 5.1⑧ becomes

$$(5.55)\qquad H_n=\big\{y\in\mathcal{X}\mid\langle y-u_n,\nabla f(x_n)-\nabla f(u_n)\rangle\leq 0\big\},$$

where $u_n \in T_n x_n$ for some $T_n \in \mathfrak{B}$ such that $S_{\mathrm{i}(n)} \cap \operatorname{int}\operatorname{dom} f \subset \operatorname{Fix} T_n$. Consequently, since by Corollary 3.35(ii) $P_{H_n} x_n = u_n$, Algorithm 5.1 can be rewritten as follows.

ALGORITHM 5.20. *Starting with $x_0 \in \operatorname{int}\operatorname{dom} f$, take at every iteration n*

① *an index $\mathrm{i}(n) \in I$,*

② *an operator T_n in $\mathfrak{B}$ such that $S_{\mathrm{i}(n)} \cap \operatorname{int}\operatorname{dom} f \subset \operatorname{Fix} T_n$.*

Then select $x_{n+1} \in T_n x_n$.

In this context, Definition 5.2 takes the following form.

DEFINITION 5.21. *Algorithm* 5.20 *is*

- focusing *if for every bounded suborbit $(x_{k_n})_{n\in\mathbb{N}}$ it generates and every index $i \in I$,*

$$\begin{cases} (\forall n \in \mathbb{N}) \;\; i = \mathrm{i}(k_n), \\ x_{k_n} \rightharpoonup x, \\ x_{k_n+1} - x_{k_n} \to 0 \end{cases} \quad \Rightarrow \quad x \in S_i; \tag{5.56}$$

- demicompactly regular *if there exists $i \in I$, called an* index of demicompact regularity*, such that for every bounded suborbit $(x_{k_n})_{n\in\mathbb{N}}$ it generates,*

$$\begin{cases} (\forall n \in \mathbb{N}) \;\; i = \mathrm{i}(k_n), \\ x_{k_n+1} - x_{k_n} \to 0 \end{cases} \quad \Rightarrow \quad \mathfrak{S}(x_{k_n})_{n\in\mathbb{N}} \neq \varnothing. \tag{5.57}$$

Removing item (ii) from Condition 5.3 yields the following set of assumptions for the unrelaxed sequential case.

CONDITION 5.22. *For some $z \in \operatorname{dom} f \cap \bigcap_{i\in I} S_i$, $C = \operatorname{lev}_{\leq D(z,x_0)} D(z,\cdot)$ is bounded.*

CONDITION 5.23. $(\forall i \in I)(\exists\, M_i \in \mathbb{N} \smallsetminus \{0\})(\forall n \in \mathbb{N}) \;\; i \in \big\{\mathrm{i}(n), \ldots, \mathrm{i}(n+M_i-1)\big\}$.

We now show that Algorithm 5.20 converges under this reduced set of assumptions.

THEOREM 5.24. *Suppose that Conditions* 4.3*,* 4.4*,* 5.22*, and* 5.23 *are satisfied and that Algorithm* 5.20 *is focusing. Then the following statements hold true for every orbit $(x_n)_{n\in\mathbb{N}}$ generated by Algorithm* 5.20*:*

(i) *$(x_n)_{n\in\mathbb{N}}$ converges weakly to a point $x \in S$.*

(ii) *If the weak limit x from* (i) *belongs to* $\operatorname{int}\operatorname{dom} f$ *and the algorithm is demicompactly regular, then $(x_n)_{n\in\mathbb{N}}$ converges strongly.*

Proof. In the proof of Theorem 5.7, note that Condition 5.3(ii) is used only to obtain (5.34), i.e., in the present context, $x_{p_n+1} - x_{p_n} \to 0$. However, this property follows directly from(5.33). □

As an example, we revisit Bregman's original cyclic projection method (1.2). (See [1, Thm. 3.1] for a special case.)

COROLLARY 5.25. *Suppose that Conditions* 4.3 *and* 4.4 *are satisfied, that $I = \{1, \ldots, m\}$, and that $C = \operatorname{lev}_{\leq D(z,x_0)} D(z,\cdot)$ is bounded for some $z \in \operatorname{dom} f \cap \bigcap_{1\leq i\leq m} S_i$. Let $(P_i)_{1\leq i\leq m}$ be the D-projectors of $(S_i)_{1\leq i\leq m}$. Then the following statements hold true for every orbit $(x_n)_{n\in\mathbb{N}}$ generated by* (1.2)*:*

(i) *$(x_n)_{n\in\mathbb{N}}$ converges weakly to a point $x \in \overline{\operatorname{dom}} f \cap \bigcap_{1\leq i\leq m} S_i$.*

(ii) *If the weak limit x from* (i) *belongs to* $\operatorname{int}\operatorname{dom} f$ *and $C \cap S_i$ is relatively compact (e.g., S_i is boundedly compact) for some $i \in \{1, \ldots, m\}$, then $(x_n)_{n\in\mathbb{N}}$ converges strongly.*

Proof. In view of Corollary 3.35(i), (1.2) is a special realization of Algorithm 5.20 with $(\forall n \in \mathbb{N})$ $T_n = P_{n \,(\mathrm{mod}\, m)+1}$ (single-valued) and $\lambda_n = 1$. In addition, the index

control rule $i\colon n \mapsto n \,(\mathrm{mod}\, m) + 1$ complies with Condition 5.23. On the other hand, algorithm (1.2) is focusing, as a direct consequence of the weak closedness of the sets $(S_j)_{1\leq j\leq m}$. Finally, i is an index of demicompact regularity since $(x_{nm+i})_{n\in\mathbb{N}}$ lies in $C \cap S_i$. The announced results therefore follow from Theorem 5.24. □

Remark 5.26. Throughout section 5, Legendreness has been imposed on f. This property has been shown to provide a rich and convenient framework in which our results could be derived in a unified manner. Further results can nonetheless be obtained from the analysis of sections 3 and 4 for functions which are not Legendre at the expense of more technical assumptions.

Acknowledgments. We wish to thank Dan Butnariu and Yair Censor for sending us [22, 25, 26, 29], Constantin Zălinescu for sending us [85], and especially Jon Vanderwerff for his help in the derivation of Example 5.11. Two anonymous referees made several helpful comments and suggestions, which led to improvements over the originally submitted version.

OPTIMAL COORDINATED MOTIONS OF MULTIPLE AGENTS MOVING ON A PLANE*

JIANGHAI HU†, MARIA PRANDINI‡, AND SHANKAR SASTRY†

Abstract. We address the problem of optimal coordinated motions of multiple agents moving in the same planar region. The agents' motions must satisfy a separation constraint throughout the encounter to be conflict-free. The objective is to determine the conflict-free maneuvers (motions) with the least combined energy, while taking into account the fact that agents may have different priorities. A formal classification of conflict-free maneuvers into homotopy types is introduced by using their braid representation. Various local and global optimality conditions are derived through variational analysis in the presence of the separation constraint. In the case of two agents, these optimality conditions allow us to construct the optimal maneuvers geometrically. For the general multi-agent case, a convex optimization algorithm is proposed to compute within each homotopy type a solution to the optimization problem restricted to the class of multilegged maneuvers. Since the number of types grows explosively with the number of agents, a stochastic algorithm is suggested as the "type chooser," thus leading to a randomized optimization algorithm.

1. Introduction.

In this paper, the problem of designing coordinated maneuvers for multiple agents moving on a plane is studied. The joint maneuver has to be chosen so as to guide each agent from its starting position to its target position, while avoiding *conflicts*, that is, situations where the Euclidean distance between any two agents is smaller than some fixed threshold $R > 0$. Among all the conflict-free joint maneuvers, we aim to determine the one with the least overall cost. Here the cost of a single agent's maneuver is its energy, and the overall cost is a weighted sum of the maneuver energies of all individual agents, with the weights representing the priorities of the agents. A precise formulation of the problem is given in section 3.

This problem is of great interest since it is actually encountered in many different practical areas. For example, in the air traffic control (ATC) context, aircraft flying at the same altitude must maintain a minimal horizontal separation R of at least 3 nautical miles (nmi) inside the terminal radar approach control facilities and 5 nmi in the en-route airspace [35]. In this case, the energy is closely related to practical aspects such as travel distance, fuel consumption, passenger comfort, etc. Numerous approaches have been proposed in the literature on aircraft conflict resolution, including optimal control theory [5], semidefinite programming [10], sequential quadratic programming [29], game theory [39, 40], parallel coordinates representation

[19], and genetic algorithms [28], to name a few. Readers are referred to [15, 23] for a survey on aircraft conflict resolution. Similar problems have been studied in other transportation systems as well, such as [30].

The problem of optimal multi-agent coordinated motions also finds applications in robotics. For example, for multiple cooperating mobile robots moving in a common workspace, the requirement that there be no collision among them can be reformulated as that their joint maneuver be conflict-free, with R being twice the robot radius. The literature on the general problem of robot motion planning with static or dynamic obstacles is vast (see, e.g., [4, 9, 11, 24, 38] and the survey [18]), and it is impossible to survey them in this paper. Here we limit our review to those contributions more relevant to our work. A large portion of the treatments focus on the feasibility and the algorithmic complexity aspects of the problem. Some of them indeed deal with the multiple robots case using certain optimality criteria. To name a few, [5] studies the problem of time-optimal cooperative motions of multiple Dubin vehicles moving at constant speed with bounded curvature, while in [25] each robot minimizes its own independent cost function by using techniques from multi-objective optimization and game theory. [7] addresses the problem of optimal motion planning for multiple nonholonomic manipulators transporting a grasped object.

The distinguishing feature of our approach to coordinated motion planning consists in the interpretation of maneuvers as braids. Besides giving a complete homotopic classification of conflict-free maneuvers, this also provides us insights on the derivation of optimality conditions. Although the space-time representation of motions is not new in the literature (see, e.g., [9, 37]), to our knowledge, however, it has never been used to such an extent in the optimality analysis of coordinated motions.

Due to the many different interpretations of conflict-free maneuvers (not only as braids, but also as, e.g., solutions to mechanical systems or geodesics in a manifold with boundary), many of the results in this paper can be derived in more than one way. For example, some of the local optimality conditions in section 3 can be derived by using the symmetry reduction method in [3, 26]. In most cases, we choose our approaches with an emphasis on their geometric appealing and their relevancy to the braid point of view. As a result, they may not always be the most elegant and efficient ones. In addition, although we focus exclusively on the case when the state space is $\mathbb{R}^2$, extensions to general state spaces are possible [16]. These possible extensions, as well as the remaining open issues, will be pointed out in the paper wherever possible.

This paper is organized as follows. In section 2, we introduce a formal classification of conflict-free maneuvers into homotopy types by using the notion of pure braids group. Inspired by the braid representation of conflict-free maneuvers, we define various transformations of joint maneuvers that preserve the minimum separation condition. Such transformations are used in the variational analysis in section 3 to derive local and global necessary conditions on optimal conflict-free maneuvers. In particular, the optimal conflict-free maneuvers for the 2-agent case are derived in section 3.3. Two mechanical interpretations of the problem are given in section 3.8.

As the number of agents increases, it is difficult in practice to derive analytically the optimal conflict-free maneuvers. By focusing on those maneuvers specified by a set of waypoints, we are able to use convex optimization techniques to obtain multilegged approximated solutions to the constrained optimization problem within each homotopy type (section 4). A stochastic algorithm is proposed in section 4.4 to address the problem of selecting the homotopy type, thus leading to a randomized convex optimization algorithm.

The paper is concluded in section 5 with some general remarks and the outline of some possible extensions of this research.

2. Classification of conflict-free maneuvers. In this section, we introduce a qualitative classification of conflict-free maneuvers involving multiple agents. Roughly speaking, two conflict-free maneuvers are classified as of the same "type" if there exists a continuous conflict-free deformation of one to the other. Hence switching between different types cannot be done smoothly without causing a conflict.

Consider n agents (numbered from 1 to n) moving in $\mathbb{R}^2$, where each agent, say agent i, starts at position $a_i \in \mathbb{R}^2$ at time t_0 and ends in position $b_i \in \mathbb{R}^2$ at time t_f. Let $T \triangleq [t_0, t_f]$ be the time interval of the encounter. Denote by $\mathbf{P}_i \triangleq \{\alpha_i \in C(T, \mathbb{R}^2) : \alpha_i(t_0) = a_i,\ \alpha_i(t_f) = b_i\}$ the set of maneuvers for agent i consisting of all the continuous maps from T to $\mathbb{R}^2$ that take the values a_i and b_i at times t_0 and t_f, respectively. Set $\mathbf{P}(\mathbf{a}, \mathbf{b}) \triangleq \prod_{i=1}^{n} \mathbf{P}_i$, where $\mathbf{a} = (a_1, \ldots, a_n)$ and $\mathbf{b} = (b_1, \ldots, b_n)$. Each element $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbf{P}(\mathbf{a}, \mathbf{b})$ is called a *joint maneuver* (n-maneuver or simply maneuver when there is no ambiguity) for the n-agent system. The *minimum separation over encounter* (MSE) for a joint maneuver α is defined to be the minimum Euclidean distance between any pair of agents during the whole time interval T, i.e.,

$$\Delta(\alpha) \triangleq \min_{1 \le i < j \le n} \inf_{t \in T} \|\alpha_i(t) - \alpha_j(t)\|.$$

The set of *conflict-free maneuvers* is then defined as

$$\mathbf{P}(R, \mathbf{a}, \mathbf{b}) \triangleq \{\alpha \in \mathbf{P}(\mathbf{a}, \mathbf{b}) : \Delta(\alpha) > R\},$$

where R is a positive number representing, for example, the radius of the protection zone surrounding an aircraft or twice the radius of a circular robot. We assume that the minimum distance between any pair of starting positions in the n-tuple $\langle a_i \rangle_{i=1}^{n}$ and any pair of ending positions in the n-tuple $\langle b_i \rangle_{i=1}^{n}$ is strictly greater than R, so that $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ is nonempty.

We distinguish different maneuvers in $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ according to the following equivalence relation.

DEFINITION 2.1 (R-homotopy). *Two conflict-free maneuvers in* $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ *are* R-homotopic *if there exists a continuous deformation of one to the other in* $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$*, or, equivalently, if there exists a continuous deformation of one to the other in* $\mathbf{P}(\mathbf{a}, \mathbf{b})$ *such that the joint maneuvers obtained throughout the deformation are conflict-free.*

The objective of this section is to characterize the structure of the equivalence classes of $\mathbf{P}(R, \mathbf{a}, \mathbf{b})$ induced by the R-homotopy relation. With this purpose in mind, we now recall the concept of braids [6, 32].

DEFINITION 2.2 (braids). *A* braid *joining* $\mathbf{a} = (a_1, \ldots, a_n)$ *to* $\mathbf{b} = (b_1, \ldots, b_n)$ *is an* n*-tuple* $\langle \gamma_i \rangle_{i=1}^{n}$ *of continuous curves in* $\mathbb{R}^2 \times T \subset \mathbb{R}^3$ *satisfying the following conditions:*

- *Each point* (a_i, t_0), $i = 1, \ldots, n$, *is joined by exactly one curve in* $\langle \gamma_i \rangle_{i=1}^{n}$ *to one of the points* (b_j, t_f), $1 \le j \le n$.
- *The plane* $t = \tau$ *intersects each curve at exactly one point for all* $\tau \in T$.
- $\gamma_i \cap \gamma_j = \emptyset$ *whenever* $i \neq j$.
