We also consider the optimal investment problem with random and unobservable $a(\cdot)$. Following Lakner [23] and Rishel [28], we assume that $a(t)$ is a Gaussian process modelled by a system of linear Itô's equations. However, we consider a more general case when $(a(\cdot), r(\cdot))$ may depend on the realized returns (i.e., $b(\cdot) \neq 0$ in (2.4) below, and $r(\cdot)$ is correlated with $S(\cdot)$). We express the optimal strategy via solution of a Cauchy problem (4.3), (4.8) for a *linear* parabolic equation in $(n+1)$-dimensional vector space. Thus, we propose a simpler method than dynamic programming: the *nonlinear* parabolic Bellman equation is replaced for a linear parabolic equation. Note that the solution in Lakner [23] expresses the optimal strategy via a conditional expectation of a random claim that depends on $w(\cdot)$; the solution presented below is also based on the martingale method but is more constructive, provided we can solve the Cauchy problem (4.3), (4.8). Using the technique of backward stochastic partial differential equations, we prove existence and uniqueness of the solution for this Cauchy problem. Furthermore, the most restrictive condition in Lakner [23] was that the initial covariance of $a(0)$ is small enough (condition (3.5)). We replace it by another condition (4.9) that depends on U: it is less restrictive than (3.5) for some U's and more restrictive for others U's. For some problems, our condition (4.9) is automatically satisfied. In addition, we allow correlated $a(\cdot)$ and $w(\cdot)$.

2. The model and definitions. Consider a diffusion model of a market consisting of a locally risk free bank account or bond with price $B(t)$, $t \geq 0$, and n risky stocks with prices $S_i(t)$, $t \geq 0$, $i = 1, 2, \ldots, n$, where $n < +\infty$ is given. The prices of the stocks evolve according to the following equations:

$$dS_i(t) = S_i(t)\left(a_i(t)dt + \sum_{j=1}^{n} \sigma_{ij}(t)dw_j(t)\right), \quad t > 0, \tag{2.1}$$

where $w_i(t)$ are standard independent Wiener processes, $a_i(t)$ are appreciation rates, and $\sigma_{ij}(t)$ are volatility coefficients. The initial price $S_i(0) > 0$ is a given nonrandom constant. The price of the bond evolves according to the following equation:

$$B(t) = B(0) \exp\left(\int_0^t r(t) dt \right), \tag{2.2}$$

where $B(0)$ is a given constant which we take to be 1 without loss of generality, and $r(t)$ is the random process of the risk free interest rate.

We are given a probability space $(\Omega, \mathcal{F}, \mathbf{P})$, where Ω is a set of elementary events, $\mathcal{F}$ is a complete σ-algebra of events, and $\mathbf{P}$ is a probability measure.

We introduce the vector processes ($^\top$ denoted transpose)

$$w(t) = (w_1(t), \dots, w_n(t))^\top, \quad S(t) = (S_1(t), \dots, S_n(t))^\top, \quad a(t) = (a_1(t), \dots, a_n(t))^\top,$$

and the matrix process $\sigma(t) = \{\sigma_{ij}(t)\}_{i,j=1}^n$.

Let $\mathbf{1} \triangleq (1, \dots, 1)^\top \in \mathbf{R}^n$, and $\widetilde{a}(t) \triangleq a(t) - r(t)\mathbf{1}$.

We define the return to time t by $dR_i(t) = dS_i(t)/S_i(t)$, $R_i(0) = 0$, and introduce the vector of returns $R(t) = (R_1(t), \dots, R_n(t))^\top$ and of excess returns $\widetilde{R}_i(t) = R_i(t) - \int_0^t r(s)\, ds$.

Let $\{\mathcal{F}_t^{S,r}\}_{0 \le t \le T}$ be the filtration generated by the process $(r(t), S(t))$ completed with the null sets of $\mathcal{F}$.

Set $\widetilde{S}(t) \triangleq \exp\left(- \int_0^t r(s) ds \right) S(t)$.

We denote by $|x|$ the Euclidean norm of a vector $x \in \mathbf{R}^k$. For an Euclidean space E, we denote by $\mathrm{B}([0,T]; E)$ the set of bounded measurable functions $f(t) : [0,T] \to E$. We denote by I_n the identity matrix in $\mathbf{R}^{n \times n}$. As usual, we say that $A < B$ for symmetric matrices if the matrix $B - A$ is definitely positive. We denote $\phi^- \triangleq \max(0, -\phi)$, and we denote by $\mathbb{I}_{\{\cdot\}}$ the indicator function.

The model for r, σ, and a. To describe the distribution of $\widetilde{a}(t)$, we shall use the model introduced in Lakner [23, p. 84], generalized for our case of random r, nonconstant coefficients for the equation for $\widetilde{a}$, and correlated r, $\widetilde{a}$, and w. We assume that we are given measurable deterministic processes $\alpha(t)$, $\beta(t)$, $b(t)$, and $\delta(t)$ such that

$$d\widetilde{a}(t) = \alpha(t)[\delta(t) - \widetilde{a}(t)]dt + b(t) d\widetilde{R}(t) + \beta(t) dW(t), \tag{2.3}$$

where $\alpha(t) \in \mathbf{R}^{n \times n}$, $\beta(t) \in \mathbf{R}^{n \times n}$, $b(t) \in \mathbf{R}^{n \times n}$, $\delta(t) \in \mathbf{R}^n$, and where W is an n-dimensional Wiener process in $(\Omega, \mathcal{F}, P)$. We assume that $\alpha(t)$, $\beta(t)$, $b(t)$, and $\delta(t)$ are continuous in t and such that the matrix $\beta(t)$ is invertible and $|\beta(t)^{-1}| \le c$, where $c > 0$ is a constant. Further, we assume that $\widetilde{a}(0)$ follows an n-dimensional normal distribution with mean vector m_0 and covariance matrix γ_0. The vector m_0 and the matrix γ_0 are assumed to be known. We note that this setting covers the case when $\widetilde{a}$ is an n-dimensional Ornstein–Uhlenbeck process with mean-reverting drift.

Clearly, (2.3) can be rewritten as

$$d\widetilde{a}(t) = \Big(\alpha(t)\delta(t) + [b(t) - \alpha(t)]\widetilde{a}(t) \Big) dt + b(t)\sigma(t) dw(t) + \beta(t) dW(t). \tag{2.4}$$

In addition, it can be seen that $\widetilde{R}_i(t)$ evolves as

$$d\widetilde{R}_i(t) = \widetilde{a}_i(t) dt + \sum_{j=1}^n \sigma_{ij}(t) dw_j(t), \quad t > 0. \tag{2.5}$$

We assume that the process $\sigma(t)$ is continuous in t, nonrandom, and such that $\sigma(t)\sigma(t)^\top \geq c_\sigma I_n$, where $c_\sigma > 0$ is a constant.

Further, we assume that $r(\cdot) = \phi_r(\widetilde{R}(\cdot), \Theta)$, where Θ is a random element in a metric space $\mathcal{X}_r$, and where $\phi_r : C([0,T];\mathbf{R}^n) \times \mathcal{X}_r \to \mathrm{B}([0,T];\mathbf{R})$ is a measurable function, and Θ does not depend on $(w(\cdot), W(\cdot), \widetilde{a}(0))$. In addition, we assume that the process $r(t)$ is adapted to the filtration generated by $(\widetilde{R}(t), \Theta)$. Note that the closed system (2.4)–(2.5) for the pair $(\widetilde{a}(t), \widetilde{R}(t))$ does not include $r(\cdot)$, and $(\widetilde{a}(\cdot), \widetilde{R}(\cdot))$ does not depend on Θ. Therefore, the market model is well defined. The assumptions for measurability of r don't look very natural. However, they cover generic models when r is independent on $\widetilde{R}$ or nonrandom, and we can still consider some models with correlated r and $\widetilde{R}$.

Under these assumptions, the solution of (2.1) is well defined, but the market is incomplete.

Let $\widetilde{\phi}_m(t,s)$, $m = 0, 1$, be the solution of the matrix equation

$$\begin{cases} \frac{d\widetilde{\phi}_m}{dt}(t,s) = [m \cdot b(t) - \alpha(t)]\widetilde{\phi}_m(t,s), \\ \widetilde{\phi}_m(s,s) = I_n. \end{cases}$$

Let

$$\widetilde{K}_m(t) \triangleq \int_0^t \widetilde{\phi}_m(t,s) b(s)\sigma(s)\sigma(s)^\top b(s)^\top \widetilde{\phi}_m(t,s)^\top ds, \quad m = 0, 1. \tag{2.6}$$

We have that

$$\widetilde{a}(t) = \widetilde{\phi}_1(t,0)\widetilde{a}(0) + \int_0^t \widetilde{\phi}_1(t,s)[\alpha(s)\delta(s)ds + b(s)\sigma(s)dw(s) + \beta(s)dW(s)].$$

It follows that $\widetilde{K}_1(t)$ is the covariance matrix for $\widetilde{a}(t)$ calculated with $\beta(t) \equiv 0$ and $\widetilde{a}(0) = 0$. By the linearity of (2.4), it follows that $\widetilde{K}_1(t)$ is the conditional covariance for $\widetilde{a}(t)$ given $(W(\cdot)|_{[0,t]}, \widetilde{a}(0))$ or $(W(\cdot)|_{[0,T]}, \widetilde{a}(0))$.

Note that $\widetilde{K}_m(t)$ can be found as solutions of linear equations that one can easily derive from (2.4) and (4.1) (see, e.g., Arnold [1, Chapter 8]).

We assume that b is "small." More precisely, we assume that there exists $\varepsilon > 0$ such that

$$T\widetilde{K}_m(t) + \varepsilon I_n < \sigma(t)\sigma(t)^\top \quad \forall t \in [0,T], \quad m = 0, 1. \tag{2.7}$$

The risk neutral probability measure. Set $Q(t) \triangleq (\sigma(t)\sigma(t)^\top)^{-1}$, and set

$$\mathcal{Z} \triangleq \exp\left(\int_0^T [\sigma(t)^{-1}\widetilde{a}(t)]^\top dw(t) + \frac{1}{2}\int_0^T \widetilde{a}(t)^\top Q(t)\widetilde{a}(t)dt \right). \tag{2.8}$$

Proposition 2.1.

$$\mathbf{E}\Big\{ \exp \frac{1}{2}\int_0^T \widetilde{a}(t)^\top Q(t)\widetilde{a}(t)dt \,\Big|\, W(\cdot), \widetilde{a}(0) \Big\} < +\infty \qquad \textit{a.s.} \tag{2.9}$$

By this proposition, the Novikov's condition is satisfied conditionally, and $\mathbf{E}\{\mathcal{Z}^{-1} \,|\, W(\cdot), \widetilde{a}(0)\} = 1$, then $\mathbf{E}\mathcal{Z}^{-1} = 1$.

Define the (equivalent) probability measure $\mathbf{P}_*$ by $d\mathbf{P}_*/d\mathbf{P} = \mathcal{Z}^{-1}$. Let $\mathbf{E}_*$ be the corresponding expectation.

The wealth and strategies. Let $X_0 > 0$ be the initial wealth at time $t = 0$, and let $X(t)$ be the wealth at time $t > 0$, $X(0) = X_0$. We assume that

$$X(t) = \pi_0(t) + \sum_{i=1}^{n} \pi_i(t), \tag{2.10}$$

where the pair $(\pi_0(t), \pi(t))$ describes the portfolio at time t. The process $\pi_0(t)$ is the investment in the bond, $\pi_i(t)$ is the investment in the ith stock $\pi(t) = (\pi_1(t), \dots, \pi_n(t))^\top$, $t \geq 0$.

DEFINITION 2.2. *The process* $\widetilde{X}(t) \triangleq \exp\left(-\int_0^t r(s)ds\right) X(t)$ *is called the normalized (or discounted) wealth.*

Let $\mathbf{S}(t) \triangleq \operatorname{diag}(S_1(t), \dots, S_n(t))$ and $\widetilde{\mathbf{S}}(t) \triangleq \operatorname{diag}(\widetilde{S}_1(t), \dots, \widetilde{S}_n(t))$ be diagonal matrices with the corresponding diagonal elements. The portfolio is said to be self-financing if

$$dX(t) = \pi(t)^\top \mathbf{S}(t)^{-1} dS(t) + \pi_0(t) r(t) dt = \pi(t)^\top dR(t) + \pi_0(t) r(t) dt. \tag{2.11}$$

It follows from (2.10) that for such portfolios

$$\begin{aligned} dX(t) &= r(t)X(t)\,dt + \pi(t)^\top \left(\widetilde{a}(t)\,dt + \sigma(t)\,dw(t)\right), \\ d\widetilde{X}(t) &= B(t)^{-1}\pi(t)^\top d\widetilde{R}(t), \end{aligned} \tag{2.12}$$

so π alone suffices to specify the portfolio; the process π_0 is uniquely defined by π via (2.10), (2.12); π it is called a self-financing strategy.

DEFINITION 2.3. *Let* $\bar{\Sigma}$ *be the class of all* $\mathcal{F}_t^{S,r}$*-predictable processes* $\pi(\cdot)$ *such that*

- $\int_0^T \left(|\pi(t)^\top \widetilde{a}(t)|^2 + |\pi(t)^\top \sigma(t)|^2\right) dt < \infty$ *a.s.*
- *there exists a constant* q_π *such that* $\mathbf{P}\left(\widetilde{X}(t) - X_0 \geq q_\pi \ \forall t \in [0,T]\right) = 1$.

A process $\pi(\cdot) \in \bar{\Sigma}$ is said to be an *admissible* strategy with corresponding wealth $X(\cdot)$.

For an admissible strategy $\pi(\cdot)$, $X(t, \pi(\cdot))$ denotes the corresponding total wealth, and $\widetilde{X}(t, \pi(\cdot))$ the corresponding normalized total wealth. It follows that $\widetilde{X}(t, \pi(\cdot))$ is a $\mathbf{P}_*$-supermartingale with $\mathbf{E}_* \widetilde{X}(t, \pi(\cdot)) \leq X_0$ and $\mathbf{E}_* |\widetilde{X}(t, \pi(\cdot))| \leq |X_0| + 2|q_\pi|$.

Note that by definition, admissible strategies from $\bar{\Sigma}$ use observations of $r(t)$ and $S(t)$ only. For these strategies, the processes $X(t)$ and $\widetilde{X}(t)$ are $\mathcal{F}_t^{S,r}$-adapted.

The following definition is standard.

DEFINITION 2.4. *Let* ξ *be a given random variable. An admissible strategy* $\pi(\cdot)$ *is said to replicate the claim* ξ *if* $X(T, \pi(\cdot)) = \xi$ *a.s.*

3. Problem statement and preliminary results. Let $T > 0$, let $\widehat{D} \subset \mathbf{R}$ be convex and bounded below, and let $X_0 \in \widehat{D}$ be given. Let $U(\cdot) : \widehat{D} \to \mathbf{R} \cup \{-\infty\}$ be such that $U(X_0) > -\infty$.

We may state our general problem as follows: Find an admissible self-financing strategy $\pi(\cdot)$ which solves the following optimization problem:

$$\text{Maximize} \quad \mathbf{E}U(\widetilde{X}(T, \pi(\cdot))) \quad \text{over} \quad \pi(\cdot) \in \bar{\Sigma} \tag{3.1}$$

$$\text{subject to} \begin{cases} \widetilde{X}(0, \pi(\cdot)) = X_0, \\ \widetilde{X}(T, \pi(\cdot)) \in \widehat{D} \quad \text{a.s.} \end{cases} \tag{3.2}$$

The condition $\widetilde{X}(T,\pi(\cdot))\in\widehat{D}$ may represent a requirement for a minimal normalized terminal wealth if $\widehat{D}=[k,+\infty)$, $k>0$. This condition may also represent a requirement for the normalized terminal wealth in goal achieving problems if $\widehat{D}=[k_0,k_1]$, $k_0<k_1$.

We assume that U, X_0, and $\widehat{D}$ satisfy the following two conditions.

CONDITION 3.1. *There exists a measurable set $\Lambda\subseteq[0,\infty)$, and a measurable function $F(\cdot,\cdot):(0,\infty)\times\Lambda\to\widehat{D}$ such that for each $z>0$, $\widehat{x}=F(z,\lambda)$ is a solution of the optimization problem*

$$\text{Maximize}\quad zU(x)-\lambda x\quad\text{over } x\in\widehat{D}. \tag{3.3}$$

Note that the usual concavity hypotheses imply this condition, but more general utility functions are also covered. For example, this condition is satisfied for the goal achieving problem when $U(x)$ is a step function (see, e.g., Karatzas [16], Dokuchaev and Zhou [10]).

Let $\bar{\mathcal{Z}}\triangleq\mathbf{E}\{\mathcal{Z}|\mathcal{F}_T^{S,r}\}$. Since $(\widetilde{R}(\cdot),\widetilde{a}(\cdot))$ does not depend on Θ, we have that $\mathcal{Z}$ does not depend on Θ, and $\bar{\mathcal{Z}}=\mathbf{E}\{\mathcal{Z}|\widetilde{R}(\cdot)\}$. Let $F(\cdot)$ be as in Condition 3.1.

CONDITION 3.2. *There exists $\widehat{\lambda}\in\Lambda$ such that $\mathbf{E}_*|F(\bar{\mathcal{Z}},\widehat{\lambda})|<+\infty$ and $\mathbf{E}_*F(\bar{\mathcal{Z}},\widehat{\lambda})=X_0$.*

We solve our problem in two steps using the martingale approach. First we show that $\mathbf{E}U(F(\bar{\mathcal{Z}},\widehat{\lambda}))$ is an upper bound for the expected utility of normalized terminal wealth for $\pi(\cdot)\in\bar{\Sigma}$. Then we find a portfolio $\widehat{\pi}(\cdot)$ which replicates the claim $B(T)F(\bar{\mathcal{Z}},\widehat{\lambda})$. This establishes the optimality of $\widehat{\pi}(\cdot)$.

The optimal claim. The following theorem is a reformulation of Theorem 2.5 from Lakner [23] under slightly more general conditions that allow discontinuous functions F and U such as step functions.

THEOREM 3.1. *(Dokuchaev and Haussmann [8]). With $\widehat{\lambda}$ as in Condition 3.2, let $\widehat{\xi}\triangleq F(\bar{\mathcal{Z}},\widehat{\lambda})$. Then*

(i) $\mathbf{E}\,U^-(\widehat{\xi})<\infty$, $\widehat{\xi}\in\widehat{D}$ *a.s.;*

(ii) $\mathbf{E}U(\widehat{\xi})\geq\mathbf{E}U(\widetilde{X}(T,\pi(\cdot)))\ \forall\pi(\cdot)\in\bar{\Sigma}$*;*

(iii) *The claim $B(T)\widehat{\xi}$ is attainable in $\bar{\Sigma}$, and there exists a replicating strategy in $\bar{\Sigma}$. This strategy is optimal for problem* (3.1)–(3.2).

This theorem uses the duality approach for constrained optimization that goes back to Lagrange, and $\widehat{\lambda}$ as the corresponding Lagrange multiplier.

Remark 3.1. Theorem 2.5 from Lakner [23] was stated under some additional assumptions that can be formulated in our notations as

(i) $b(t)\equiv 0$, r is nonrandom, r, σ, α, β, δ are constant, and $\widehat{D}=(0,+\infty)$;

(ii) U is strictly concave and continuously differentiable on $(0,+\infty)$, and $\lim_{x\to+\infty}U'(x)=0$;

(iii) there exists a function $J(\cdot):\widehat{D}\to\mathbf{R}$ such that $J(\lambda/x)\equiv F(x,\lambda)$;

(iv) $\mathbf{E}_*J(\lambda/\bar{\mathcal{Z}})<+\infty$ for any $\lambda>0$.

Solution via conditional expectation. Let

$$\widehat{a}(t)\triangleq\mathbf{E}\big\{\widetilde{a}(t)\,\big|\,\mathcal{F}_t^{S,r}\big\}.$$

Set $\widetilde{\alpha}(t)\triangleq\alpha(t)-b(t)$ and $m_0\triangleq\mathbf{E}\widetilde{a}(0)$.

Let $\gamma(t) \in \mathbf{R}^{n\times n}$ be the unique solution (in the class of symmetric nonnegative definite matrices) of the deterministic Riccati's equation

$$\begin{cases} \frac{d\gamma}{dt}(t) = -[b(t)\sigma(t)^\top + \gamma(t)]Q(t)[b(t)\sigma(t)^\top + \gamma(t)]^\top \\ \qquad\qquad -\widetilde{\alpha}(t)\gamma(t) - \gamma(t)\widetilde{\alpha}(t)^\top + \beta(t)\beta(t)^\top, \\ \gamma(0) = \gamma_0. \end{cases} \tag{3.4}$$

Here $\gamma_0 \triangleq \mathbf{E}[\widetilde{a}(0)-m_0][\widetilde{a}(0)-m_0]^\top$. In fact, $\gamma(t) = \mathbf{E}\left\{[\widetilde{a}(t) - \widehat{a}(t)][\widetilde{a}(t) - \widehat{a}(t)]^\top \big| \mathcal{F}_t^{S,r}\right\}$.

Let $A(t) \triangleq -\widetilde{\alpha}(t) - \gamma(t)Q(t)$, and let $\phi(t)$ be the solution of the matrix equation

$$\begin{cases} \frac{d\phi}{dt}(t) = A(t)\phi(t), \\ \phi(0) = I_n, \end{cases}$$

where I_n is the unit matrix in $\mathbf{R}^{n\times n}$.

The following theorem is a reformulation of Theorem 4.3 from Lakner [23]. It gives the solution of the investment problem via conditional expectation of future values of some processes with known evolution.

THEOREM 3.2. *(Lakner [23]). Let conditions* (i)–(iv) *in Remark* 3.1 *hold, let* $U(x)$ *be twice differentiable on* $(0, +\infty)$*, and let*

$$\operatorname{tr}\gamma_0 + T\|\beta\|^2 < K_1, \quad K_1 = \frac{1}{360T\|\sigma^{-1}\|^2 K_0}, \quad K_0 = \max_{t\in[0,T]} \|e^{-\alpha t}\|^2, \tag{3.5}$$

where $\|\cdot\|$ *denotes the Frobenius matrix norm, i.e.,* $\|\sigma^{-1}\|^2 = \operatorname{tr}[\sigma^{-1}\sigma^{-1^\top}]$*. Further, let*

$$J(x) < K(1 + x^{-5}), \quad -J'(x) < K(1 - x^{-2}) \tag{3.6}$$

for some $K > 0$*. Then the optimal strategy is*

$$\pi(t)^\top = H(t)\bar{\mathcal{Z}}(t)\mathbf{E}\left\{J'(\widehat{\lambda}\bar{\mathcal{Z}})\bar{\mathcal{Z}}^{-2}\left[-\gamma(t)[\phi(t)^\top]^{-1}\int_t^T \phi(s)^\top[\sigma^\top]^{-1}d\widehat{w}(s) - \widehat{a}(t)\right]\Big| \mathcal{F}_t^{S,r}\right\},$$

where $H(t) \triangleq \widehat{\lambda}e^{r(t-T)}Q$ *and* $\widehat{w}(t) \triangleq w(t) - \int_0^t \sigma^{-1}\widehat{a}(s)ds$*.*

We propose below another solution such that the optimal strategy is presented via solution of a linear deterministic parabolic equation. We replace conditions (3.5) by condition (4.9) which can be less restrictive and is always satisfied if $\widehat{D}$ is bounded. In addition, we dropped condition (3.6) and the condition that (r, a) and w are independent: we allow $b(\cdot) \neq 0$ and $r = \phi_r(\widetilde{R}(\cdot), \Theta)$.

4. Main results: Solution via linear parabolic equation.

Let $y(t) = (y_1(t), \dots, y_{n+1}(t)) = (\widehat{a}(t), y_{n+1}(t))$ be a process in $\mathbf{R}^{n+1}$, where

$$\widehat{a}(t) = \mathbf{E}\{\widetilde{a}(t)|\mathcal{F}_t^{S,r}\},$$
$$y_{n+1}(t) = -\frac{1}{2}\int_0^t \widehat{a}(s)^\top Q(s)\widehat{a}(s)ds + \int_0^t \widehat{a}(s)^\top Q(s)\, d\widetilde{R}(s).$$

Let functions $f(\cdot) : \mathbf{R}^{n+1} \times [0,T] \to \mathbf{R}^{n+1}$ and $g(\cdot) : \mathbf{R}^{n+1} \times [0,T] \to \mathbf{R}^{(n+1)\times n}$ be such that

$$f(x,t) \triangleq \begin{pmatrix} [A(t) - b(t)\sigma(t)^\top Q(t)]\widehat{x} + \alpha(t)\delta(t) \\ -\frac{1}{2}\widehat{x}^\top Q(t)\widehat{x} \end{pmatrix},$$

$$g(x,t) \triangleq \begin{pmatrix} [b(t)\sigma(t)^\top + \gamma(t)]Q(t) \\ \widehat{x}^\top Q(t) \end{pmatrix}.$$

Here $A(t)$ and $\gamma(t)$ are matrices defined above, $\gamma(t)$ is the solution of (3.4), and

$$x=(x_1,\dots,x_{n+1})^\top=\begin{pmatrix}\widehat{x}\\ x_{n+1}\end{pmatrix},\qquad \widehat{x}=(x_1,\dots,x_n)^\top.$$

By Theorem 10.3 from Liptser and Shiryaev [24, p. 396], the equation for $\widehat{a}(t)$ is

$$\begin{cases} d\widehat{a}(t)=[A(t)\widehat{a}(t)-b(t)\sigma(t)^\top Q(t)\widehat{a}(t)+\alpha(t)\delta(t)]dt+[b(t)\sigma(t)^\top+\gamma(t)]Q(t)d\widetilde{R}(t),\\ \widehat{a}(0)=m_0.\end{cases}$$

(4.1)

By (4.1)–(4.6), it follows that $y(\cdot)$ is the solution of the Itô's equation

$$\begin{cases} dy(t)=f(y(t),t)dt+g(y(t),t)\,d\widetilde{R}(t),\\ y(0)=y_0,\end{cases}\tag{4.2}$$

with

$$y_0=\begin{pmatrix}m_0\\0\end{pmatrix}\in\mathbf{R}^{n+1},\qquad m_0=\mathbf{E}\widetilde{a}(0).$$

The function $f(y,t)$ here does not satisfy Lipschitz condition with respect to $y\in\mathbf{R}^{n+1}$. However, the solution of this equation is uniquely defined. (It is shown in the proof of Lemma 4.1 below that the solution of (4.2) can be presented as a part of the unique solution of some Itô's equation with coefficients that are affine with respect to the state variable.)

LEMMA 4.1. *Let a function $\Phi(\cdot):\mathbf{R}^{n+1}\to\mathbf{R}$ be such that*

(i) $\mathbf{E}_*\Phi(y(T))=X_0$;

(ii) $\Phi(x)$ *is continuously twice differentiable;*

(iii) $\mathbf{E}_*\Phi(y(T))^2<+\infty$.

Then there exists a unique classical solution $V:\mathbf{R}^{n+1}\times[0,T]\to\mathbf{R}$ of the boundary value problem

$$\frac{\partial V}{\partial t}(x,t)+\frac{\partial V}{\partial x}(x,t)f(x,t)+\frac{1}{2}\mathrm{tr}\left\{\frac{\partial^2 V}{\partial x^2}(x,t)\,g(x,t)\sigma(t)\sigma(t)^\top g(x,t)^\top\right\}=0,\tag{4.3}$$

$$V(x,T)=\Phi(x).\tag{4.4}$$

Further, the processes $\widetilde{X}(t,\pi(\cdot))\triangleq V(y(t),t)$ and $\pi(t)^\top\triangleq B(t)\frac{\partial V}{\partial x}(y(t),t)g(y(t),t)$, are uniquely defined as elements of the spaces $C([0,T],L_2(\Omega,\mathcal{F},P_*))$ and $L_2([0,T],L_2(\Omega,\mathcal{F},P_*))$, respectively, and there exists a constant $C>0$ such that

$$\sup_{t\in[0,T]}\mathbf{E}_*|\widetilde{X}(t,\pi(\cdot))|^2+\mathbf{E}_*\int_0^T B(t)^{-2}|\pi(t)|^2dt\le C\mathbf{E}_*|\Phi(y(T))|^2\tag{4.5}$$

for all these Φ. Further, the strategy $\pi(t)=(\pi_1(t),\dots,\pi_n(t))$ belongs to $\bar{\Sigma}$ and replicates the claim $B(T)\Phi(y(T))$ given the initial wealth X_0 with the normalized wealth $\widetilde{X}(t)=V(y(t),t)$.

Note that estimate (4.5) restates the Krylov–Ficera estimate (see Theorem 5.3.3 from Rozovskii [29]) or its modification from Dokuchaev [5]).

Further, we have that

$$d\bar{\mathcal{Z}}(t)=\widehat{a}(t)\bar{\mathcal{Z}}(t)d\widetilde{R}(t).\tag{4.6}$$

Formula (4.6) was derived in Theorem 3.1 from Lakner [23] for the case when σ is constant and $b = 0$. The proof for a nonconstant $\sigma(t)$ and $b \neq 0$ can be found in Dokuchaev and Haussmann [8] and in Chapter 9 from Dokuchaev [6]. It follows that

$$y_{n+1}(t) = \ln \bar{\mathcal{Z}}(t). \tag{4.7}$$

Introduce the function $e(\cdot) : \mathbf{R}^{n+1} \to \mathbf{R}$ such that $e(y) = \exp[y_{n+1}]$ for $y = (y_1, \dots, y_{n+1})^\top$. Note that $\bar{\mathcal{Z}} = e(y(T))$.

Let $V = V(x, t, \lambda) : \mathbf{R}^{n+1} \times [0, T] \times \Lambda \to \mathbf{R}$ be the solution of partial differential equation (4.3) with the condition

$$V(x, T, \lambda) = F(e(x), \lambda). \tag{4.8}$$

The following result is now immediate.

THEOREM 4.2. *Let $\widehat{\lambda}$ be such as in Condition* 3.2. *Assume that the function $F(\cdot, \widehat{\lambda}) : \mathbf{R} \to \mathbf{R}$ is such that conditions* (i)–(ii) *of Lemma* 4.1 *are satisfied with $\Phi(x) \triangleq F(e(x), \widehat{\lambda})$, and*

$$\mathbf{E}_* F(\bar{\mathcal{Z}}, \widehat{\lambda})^2 < +\infty. \tag{4.9}$$

Then there exists an unique classical solution V of problem (4.3)–(4.8) *for $\lambda = \widehat{\lambda}$, and there exists an admissible self-financing strategy $\pi(\cdot) \in \bar{\Sigma}$ which replicates the claim $B(T)F(\bar{\mathcal{Z}}, \widehat{\lambda})$. This strategy is an optimal solution of problem* (3.1)–(3.2) *and*

$$\widehat{\pi}(t)^\top = B(t) \frac{\partial V}{\partial x}(y(t), t, \widehat{\lambda}) b(y(t), t), \quad \widetilde{X}(t, \pi(\cdot)) = V(y(t), t, \widehat{\lambda}). \tag{4.10}$$

Note that it is possible that condition (4.9) is not satisfied but the optimal claim $F(\bar{\mathcal{Z}}, \widehat{\lambda})$ is still replicable in the class of strategies $\bar{\Sigma}$. For example, let $U(x) \equiv \log x$, $X_0 = 1$, and $(0, +\infty) \subseteq \widehat{D}$, then $\Lambda = (0, \infty)$, $F(z, \lambda) = z/\lambda$, $\widehat{\lambda} = 1$, and the strategy is $\pi(t)^\top = B(t)\widehat{a}(t)^\top \bar{\mathcal{Z}}(t) Q(t)$ is replicating (and optimal) even in the case when (4.9) is not satisfied.

5. Special cases. Note that conditions (3.5) were imposed in Lakner [23] with the only purpose to ensure that

$$\mathbf{E}_* \bar{\mathcal{Z}}^5 < +\infty, \qquad \mathbf{E}_* \bar{\mathcal{Z}}^{-4} < +\infty. \tag{5.1}$$

Our condition (4.9) for examples (i)–(iii) listed below is satisfied if $\mathbf{E}_* \bar{\mathcal{Z}}^\mu < +\infty$ for some $\mu \in \mathbf{R}$. For example (i), condition (4.9) is less restrictive than (5.1) if $l < 5/2$ and more restrictive if $l > 5/2$. For example (ii), condition (4.9) is less restrictive than (5.1) if $l < 2$ and more restrictive if $l > 2$. For example (iii), condition (4.9) is always less restrictive than (5.1). These examples are from Dokuchaev and Haussmann [7]:

(i) *Power utility.* Assume $\widehat{D} = [0, +\infty)$, $X_0 > 0$, $U(x) = d^{-1}x^d$, where either $d \in (0, 1)$ or $d < 0$. Then $\Lambda = (0, \infty)$, $F(z, \lambda) = (z/\lambda)^l$, and $\widehat{\lambda} = X_0^{-1/l}(\mathbf{E}_* \bar{\mathcal{Z}}^l)^{1/l}$, where $l = 1/(1 - d)$.

(ii) Assume $\widehat{D} = [0, +\infty)$, $U(x) = -x^d + x$, where $d = 1 + 1/l$, and $l > 0$ is an integer, $X_0 > d^{-l}$. Then $\Lambda = [0, \infty)$, $F(z, \lambda) = (1 + \lambda/z)^l d^{-l}$, $\widehat{\lambda}$ is a root of a polynomial of degree l.

(iii) *Mean-variance utility.* Assume $\widehat{D} = \mathbf{R}$, $U(x) = -kx^2 + cx$, where $k \in \mathbf{R}$ and $c \geq 0$, $X_0 > 0$, then $F(z, \lambda) = (c - \lambda/z)/(2k)$.

We present below some sufficient conditions that ensure $\mathbf{E}_*\bar{\mathcal{Z}}^\mu < +\infty$ and, therefore, can be useful for verifying (6.2).

Let $\widetilde{K}(t)$ be the covariance for $\widetilde{a}(t)$ under the probability measure $\mathbf{P}_*$, and let $\widehat{K}(t)$ be the covariance for $\widehat{a}(t)$ under $\mathbf{P}_*$.

LEMMA 5.1. *If $\mu \in [0,1]$, then $\mathbf{E}_*\bar{\mathcal{Z}}^\mu < +\infty$. Let $\mu < 0$ or $\mu > 1$. Then $\mathbf{E}_*\bar{\mathcal{Z}}^\mu < +\infty$ if there exist $\varepsilon > 0$ and $p > 1$ such that at least one of the following conditions holds:*

(i) *$\kappa(p)\widehat{K}(t) < \sigma(t)\sigma(t)^\top - \varepsilon I_n$ for $t \in [0,T]$, where $\kappa(p) \triangleq qT(\mu^2 p - \mu) > 0$ with $q \triangleq p(p-1)^{-1}$.*

(ii) *$\kappa(p)\widetilde{K}(t) < \sigma(t)\sigma(t)^\top - \varepsilon I_n$ for $t \in [0,T]$.*

It follows from Proposition 7.2 that $\widetilde{K}(t)$ and $\widehat{K}(t)$ are the covariances of the processes defined by (2.4) and (4.1), respectively, with $\widetilde{R}(\cdot)$ replaced by $\widetilde{R}_*(\cdot)$. Thus, these covariances can be found as solutions of linear deterministic equations that one can easily derive from (2.4) and (4.1) (see, e.g., Arnold [1, Chapter 8]).

6. Case of discontinuous F. To proceed further, we shall need a special weighted L_2-space with a weight defined via some parabolic equation. First, we introduce the operator

$$\mathcal{M}(t)p \triangleq -\sum_{i=1}^{n+1}\frac{\partial}{\partial x_i}\left(p(x)f_i(x,t)\right) + \frac{1}{2}\sum_{i,j=1}^{n+1}\frac{\partial^2}{\partial x_i \partial x_j}\left(p(x)\widehat{g}_{ij}(x,t)\right),$$

where $\widehat{g} \triangleq g\sigma\sigma^\top g^\top$.

Let $\rho_i \in L_2(\mathbf{R}^{n+1}) \cap C^2(\mathbf{R}^{n+1})$, $i = 0, 1$, be given such that $\rho_i(x) > 0$ for all $x \in \mathbf{R}^{n+1}$ and $\int_{\mathbf{R}^{n+1}} \rho_i(x)dx = 1$.

We consider the following parabolic equation:

$$\begin{cases} \frac{\partial p}{\partial t}(x,t) = \mathcal{M}(t)p(x,t) + \rho_1(x), \quad t \in [0,T], \\ p(x,0) = \rho_0(x). \end{cases} \tag{6.1}$$

This boundary value problem has the unique classical solution $p(x,t)$ that is continuous in $\mathbf{R}^{n+1} \times [0,T]$. Let

$$\rho(x) \triangleq \min_{t\in[0,T]} p(x,t).$$

We have that

$$p(\cdot,t) = \mathrm{G}(t,0)\rho_0 + \int_0^t \mathrm{G}(t,s)\rho_1 ds,$$

where $\mathrm{G}(t,s)$ is the semigroup operator generated by (6.1) (with $\rho_1 \equiv 0$) and such that $\mathrm{G}(s,s)\rho_i \equiv \rho_i$. We have that $(\mathrm{G}(t,s)\rho_i)(x) > 0$ for $t \in [s, s+\varepsilon)$ for some $\varepsilon = \varepsilon(x,s) > 0$. Hence $p(x,t) > 0$ for all x, t, and $\rho(x) > 0$ for all $x \in \mathbf{R}^{n+1}$. We shall use this ρ as a weight function.

We have that $\rho \in L_2(\mathbf{R}^{n+1}) \cap L_1(\mathbf{R}^{n+1})$, since $|\rho(x)| \le |\rho_0(x)|$. We introduce the weighted space $L_{2,\rho}(\mathbf{R}^{n+1})$ with the norm

$$\|u\|_{L_{2,\rho}(\mathbf{R}^{n+1})} \triangleq \left(\int_{\mathbf{R}^{n+1}} \rho(x)|u(x)|^2 dx\right)^{1/2}.$$

We introduce the space $\mathcal{Y}_k$ of functions $u = \{u_i(x,t)\}_{i=1}^k : \mathbf{R}^{n+1} \times [0,T] \to \mathbf{R}^k$ with the norm

$$\|u\|_{\mathcal{Y}_k} \triangleq \left(\sum_{i=1}^k \int_0^T \|u_i(\cdot,t)\|^2_{L_{2,\rho}(\mathbf{R}^{n+1})}\, dt \right)^{1/2}.$$

Further, we introduce the space $\mathcal{W}^1$ of functions $u = u(x,t) : \mathbf{R}^{n+1} \times [0,T] \to \mathbf{R}$ with the norm

$$\|u\|_{\mathcal{W}^1} \triangleq \|u\|_{\mathcal{Y}_1} + \left\| \frac{\partial u}{\partial x}\, g \right\|_{\mathcal{Y}_n}.$$

Finally, we introduce the space $\mathcal{W}^1_C$ consisting of all functions $u(\cdot) \in \mathcal{W}^1$ such that $u(\cdot) \in C([0,T]; L_{2,\rho}(\mathbf{R}^{n+1}))$ with the norm

$$\|u\|_{\mathcal{W}^1_C} \triangleq \sup_{t\in[0,T]} \|u(\cdot,t)\|_{L_{2,\rho}(\mathbf{R}^{n+1})} + \|u\|_{\mathcal{W}^1}.$$

The above space is a Banach space, since the weighted space $L_{2,\rho}(\mathbf{R}^{n+1})$ is a Hilbert space.

In fact, the spaces $\mathcal{Y}_k$, $\mathcal{W}^1$, and $\mathcal{W}^1_C$, are the completions in the corresponding norms of the set of smooth functions $u : \mathbf{R}^{n+1} \times [0,T] \to \mathbf{R}^k$ or $u : \mathbf{R}^{n+1} \times [0,T] \to \mathbf{R}$, respectively, that have finite support.

THEOREM 6.1. *Let p be the solution of* (6.1)*, and let $\mathcal{W}^1_C$ be the corresponding space defined via the weight $\rho(x) = \min_{t\in[0,T]} p(x,t)$. Let $\Phi(\cdot) : \mathbf{R}^{n+1} \to \mathbf{R}$ be a measurable function such that*

$$\int_{\mathbf{R}^{n+1}} p(x,T)\Phi(x)^2 dx < +\infty. \tag{6.2}$$

Then boundary value problem (4.3)–(4.4) *admits a unique solution $V \in \mathcal{W}^1_C$. Moreover, there exists a constant $C > 0$ independent on $\Phi(\cdot)$ and such that*

$$\|V\|^2_{\mathcal{W}^1_C} \le C \int_{\mathbf{R}^{n+1}} p(x,T)\Phi(x)^2 dx. \tag{6.3}$$

Note that condition (6.2) allows discontinuous Φ.

Remark 6.1. The definition of $\mathcal{W}^1_C$ ensures that problem (4.3)–(4.4) can be stated in $\mathcal{W}^1_C$. The functions V and $(\partial V/\partial x)g$ are measurable and $L_{2,\rho}$-integrable. The equality in (4.4) is the equality for elements of the space $L_{2,\rho}(\mathbf{R}^{n+1})$, it is meaningful since $V(\cdot,t)$ is continuous in t in $L_{2,\rho}(\mathbf{R}^{n+1})$. The equality in (4.3) is the equality for elements of the dual space $\mathcal{W}^{1*}$, since all components of $\frac{\partial^2 V}{\partial x^2}(x,t)\, g(x,t)\sigma(t)\sigma(t)^\top g(x,t)^\top$ belong to $\mathcal{W}^{1*}$.

It follows from the proof of Theorem 6.1 below that $\|p(\cdot,T)\|_{L_1(\mathbf{R}^{n+1})} = 2$. Hence (6.2) is satisfied for any bounded Φ. In addition, it can be shown that $\|p(\cdot,T)\|_{L_2(\mathbf{R}^{n+1})} \le C \sum_{i=1,2} \|\rho_i(\cdot)\|_{L_2(\mathbf{R}^{n+1})}$, where $C > 0$ is a constant that does not depend on ρ_i. Therefore, (6.2) is satisfied for any $\Phi \in L_4(\mathbf{R}^{n+1})$.

Theorem 6.1 gives the possibility to present the optimal investment strategy via the solution of (4.3)–(4.4) for the case of discontinuous F. An example is the goal-achieving problem, when $\widehat{D} = [0,\infty)$, $X_0 \in (0,\alpha)$, and $U(x) = 0$ if $0 \le x < \alpha$, $U(x) = 1$ if $x \ge \alpha$. Then $\Lambda = (0,\infty)$, $F(z,\lambda) = \alpha$ if $0 < \lambda \le z/\alpha$, $F(z,\lambda) = 0$ if $\lambda > z/\alpha$, and (6.2) holds for $\Phi(x) = F(e(x),\lambda)$ $(\forall\lambda)$.

7. Appendix: Proofs.

Proof of Proposition 2.1. By Jensen's inequality, it follows that

$$\begin{aligned}\mathbf{E}\Big\{\exp\tfrac{1}{2}\textstyle\int_0^T \widetilde{a}(t)^\top Q(t)\widetilde{a}(t)dt \,\Big|\, W(\cdot),\widetilde{a}(0)\Big\}&\\ = \mathbf{E}\Big\{\exp\tfrac{1}{T}\textstyle\int_0^T \tfrac{T}{2}\widetilde{a}(t)^\top Q(t)\widetilde{a}(t)dt \,\Big|\, W(\cdot),\widetilde{a}(0)\Big\}&\\ \le \tfrac{1}{T}\textstyle\int_0^T \mathbf{E}\Big\{\exp\tfrac{T}{2}\widetilde{a}(t)^\top Q(t)\widetilde{a}(t)dt \,\Big|\, W(\cdot),\widetilde{a}(0)\Big\}.&\end{aligned}$$

For definitely positive matrices we have that if $A > B > 0$, then $B^{-1} > A^{-1}$. By condition (2.7) with $m = 1$, it follows that

$$\begin{aligned}\widetilde{K}_0(t)^{-1} &> T[\sigma(t)\sigma(t)^\top - \varepsilon I_n]^{-1} = TQ(t)[I_n - \varepsilon Q(t)]^{-1}\\ &= TQ(t)\left[I_n + \textstyle\sum_{k=1}^{+\infty}\{\varepsilon Q(t)\}^k\right] > TQ(t) + T\varepsilon Q(t)^2 > TQ(t) + M,\end{aligned}\tag{7.1}$$

where $M = M(\varepsilon) > 0$ is a definitely positive constant matrix. Clearly, we can take $\varepsilon > 0$ small enough to ensure convergency of the series in (7.1).

To complete the proof, we shall use the following fact. Let ξ be a Gaussian n-dimensional vector, $K_\xi \triangleq \mathbf{E}(\xi - \mathbf{E}\xi)(\xi - \mathbf{E}\xi)^\top > 0$. It is known that the probability density function for ξ is $C\exp[-\frac{1}{2}(x-\mathbf{E}\xi)^\top K_\xi^{-1}(x-\mathbf{E}\xi)]$, where $C > 0$ is a constant. It follows that $\mathbf{E}\exp(\frac{1}{2}\xi^\top P\xi) < +\infty$ for any matrix $P \in \mathbf{R}^{n\times n}$ such that $0 < P < K_\xi^{-1}$. Then the proof follows from (7.1).

We introduce the process

$$\widetilde{R}_*(t) \triangleq \int_0^t \sigma(s)\, dw(s).$$

Let n-dimensional vector random process $\widetilde{a}_*(t)$ be defined as the solution of

$$d\widetilde{a}_*(t) = \Big(\alpha(t)\delta(t) - \alpha(t)\widetilde{a}_*(t)\Big)dt + b(t)d\widetilde{R}_*(t) + \beta(t)dW(t), \quad \widetilde{a}_*(0) = \widetilde{a}(0).$$

Set

$$\mathcal{Z}_* \triangleq \exp\left(\int_0^T [\sigma(t)^{-1}\widetilde{a}_*(t)]^\top dw(t) - \frac{1}{2}\int_0^T \widetilde{a}_*(t)^\top Q(t)\widetilde{a}_*(t)dt\right).\tag{7.2}$$

Proposition 7.1. *There exists a measurable function* $\psi : C([0,T];\mathbf{R}^n)\times \mathrm{B}([0,T];\mathbf{R}^n) \to \mathbf{R}$ *such that* $\mathcal{Z}_* = \psi(\widetilde{R}_*(\cdot),\widetilde{a}_*(\cdot))$ *and* $\mathcal{Z} = \psi(\widetilde{R}(\cdot),\widetilde{a}(\cdot))$.

Proof. Clearly, ψ is defined by

$$\log \mathcal{Z}_* = \int_0^T \widetilde{a}_*(t)^\top Q(t)\left(d\widetilde{R}_*(t) - \frac{1}{2}\widetilde{a}_*(t)dt\right).\tag{7.3}$$

Let $r_*(\cdot) \triangleq \phi_r(\widetilde{R}_*(\cdot),\Theta)$ and $B_*(t) \triangleq B(0)\exp\left(\int_0^t r_*(s)ds\right)$ (ϕ_r is defined in section 2). Let

$$\bar{\mathcal{Z}}_* \triangleq \mathbf{E}\{\mathcal{Z}_*|\widetilde{R}_*(\cdot), r_*(\cdot)\}.\tag{7.4}$$

Let $\mathcal{T} \triangleq C([0,T];\mathbf{R}^n)\times\mathbf{R}^n$. Clearly, there exists a measurable mapping $\mathcal{A} : [0,T]\times C([0,T];\mathbf{R}^n)\times\mathcal{T} \to C([0,T];\mathbf{R}^n)$ such that $\widetilde{a}_*(t) = \mathcal{A}(t,\widetilde{R}_*(\cdot),W(\cdot),\widetilde{a}(0))$ and $\widetilde{a}(t) = \mathcal{A}(t,\widetilde{R}(\cdot),W(\cdot),\widetilde{a}(0))$.

We have that $\bar{\mathcal{Z}}_* = \mathbf{E}\{\mathcal{Z}_*|\widetilde{R}_*(\cdot)\} = \bar{\psi}(\widetilde{R}_*(\cdot))$ and

$$\bar{\mathcal{Z}}_* = \mathbf{E}\{\psi([\widetilde{R}_*(\cdot), \widetilde{a}_*(\cdot))]|\widetilde{R}_*(\cdot)\} = \mathbf{E}\{\psi[\widetilde{R}_*(\cdot), \mathcal{A}\big(\cdot, \widetilde{R}_*(\cdot), W(\cdot), \widetilde{a}(0)\big)]|\widetilde{R}_*(\cdot)\}.$$

By Proposition 7.1, it follows that

$$\bar{\mathcal{Z}} = \mathbf{E}\{\psi[\widetilde{R}(\cdot), \widetilde{a}(\cdot)]|\widetilde{R}(\cdot)\} = \mathbf{E}\{\psi[\widetilde{R}(\cdot), \mathcal{A}\big(\cdot, \widetilde{R}(\cdot), W(\cdot), \widetilde{a}(0)\big)]|\widetilde{R}(\cdot)\}.$$

Hence there exists a measurable mapping $\bar{\psi}(\cdot) : C([0,T];\mathbf{R}^n) \to \mathbf{R}$ such that

$$\bar{\mathcal{Z}} = \bar{\psi}(\widetilde{R}(\cdot)), \quad \bar{\mathcal{Z}}_* = \bar{\psi}(\widetilde{R}_*(\cdot)). \tag{7.5}$$

PROPOSITION 7.2. *Let a function* $\phi : C([0,T];\mathbf{R}^n)\times \mathrm{B}([0,T];\mathbf{R}^n)\times \mathrm{B}([0,T];\mathbf{R}) \to \mathbf{R}$ *be such that* $\mathbf{E}\phi^-(\widetilde{R}(\cdot), \widetilde{a}(\cdot), r(\cdot)) < +\infty$. *Further, let a function* $\widehat{\phi} : C([0,T];\mathbf{R}^n) \times \mathrm{B}([0,T];\mathbf{R}) \to \mathbf{R}$ *be such that* $\mathbf{E}\widehat{\phi}^-(\widetilde{R}(\cdot), r(\cdot)) < +\infty$. *Then*

$$\mathbf{E}\phi(\widetilde{R}(\cdot), \widetilde{a}(\cdot), r(\cdot)) = \mathbf{E}\mathcal{Z}_*\phi(\widetilde{R}_*(\cdot), \widetilde{a}_*(\cdot), r_*(\cdot)), \tag{7.6}$$

$$\mathbf{E}\widehat{\phi}(\widetilde{R}(\cdot), r(\cdot)) = \mathbf{E}\bar{\mathcal{Z}}_*\widehat{\phi}(\widetilde{R}_*(\cdot), r_*(\cdot)), \tag{7.7}$$

$$\mathbf{E}_*\widehat{\phi}(\widetilde{R}(\cdot), r(\cdot)) = \mathbf{E}\widehat{\phi}(\widetilde{R}_*(\cdot), r_*(\cdot)). \tag{7.8}$$

Proof. By assumption $(\Theta, W(\cdot), \widetilde{a}(0))$ is independent of $w(\cdot)$. To prove (7.6) it suffices to prove

$$\mathbf{E}\left\{\phi(\widetilde{R}(\cdot), \widetilde{a}(\cdot), r(\cdot))\Big|\Theta, W(\cdot), \widetilde{a}(0)\right\} = \mathbf{E}\left\{\mathcal{Z}_*\phi(\widetilde{R}_*(\cdot), \widetilde{a}_*(\cdot), r_*(\cdot))\Big|\Theta, W(\cdot), \widetilde{a}(0)\right\} \quad \text{a.s.} \tag{7.9}$$

Thus, for the next paragraph, without loss of generality, we shall suppose that $(\Theta, W(\cdot), \widetilde{a}(0))$ is deterministic, since for each value of $(\Theta, W(\cdot), \widetilde{a}(0))$ we can construct $\widetilde{R}, \widetilde{R}_*, \widetilde{a}, \widetilde{a}_*$.

By the linearity of (2.4), it follows that $\widetilde{K}_0(t)$ defined by (2.6) is the conditional covariance for $\widetilde{a}_*(t)$ given $(W(\cdot), \widetilde{a}(0))$. Similar to the proof of Proposition 2.1, it can be shown that (2.7) with $m = 0$ ensures that $\mathbf{E}\{\mathcal{Z}_*|\Theta, W(\cdot), \widetilde{a}(0)\} = 1$ and $\mathbf{E}\mathcal{Z}_* = 1$. We define the probability measure $\bar{\mathbf{P}}$ by $d\bar{\mathbf{P}}/d\mathbf{P} = \mathcal{Z}_*$. (Each value of $(\Theta, W(\cdot), \widetilde{a}(0))$ generates its own $\bar{\mathbf{P}}$.) By Girsanov's theorem, the process

$$\bar{w}(t) \triangleq w(t) - \int_0^t \sigma(s)^{-1}\widetilde{a}_*(s)ds$$

is a Wiener process under $\bar{\mathbf{P}}$. From this we obtain

$$\begin{aligned} d\widetilde{R}(t) &= \mathcal{A}(t, \widetilde{R}(\cdot), W(\cdot), \widetilde{a}(0))dt + \sigma(t)dw(t), \\ d\widetilde{R}_*(t) &= \mathcal{A}(t, \widetilde{R}_*(\cdot), W(\cdot), \widetilde{a}(0))dt + \sigma(t)d\bar{w}(t). \end{aligned}$$

Then for each value of $(\Theta, W(\cdot), \widetilde{a}(0))$ the processes $(\widetilde{R}(\cdot), \widetilde{a}(\cdot), r(\cdot))$ and $(\widetilde{R}_*(\cdot), \widetilde{a}_*(\cdot), r_*(\cdot))$ have the same distribution on the probability spaces defined by $\mathbf{P}$ and $\bar{\mathbf{P}}$, respectively, and (7.9), hence (7.6) follows.

Further, (7.7) follows by taking conditional expectation in (7.6). Finally, using Proposition 7.1 and (7.6),

$$\begin{aligned} \mathbf{E}_*\widehat{\phi}(\widetilde{R}(\cdot), r(\cdot)) &= \mathbf{E}\mathcal{Z}^{-1}\widehat{\phi}(\widetilde{R}(\cdot), r(\cdot)) = \mathbf{E}\psi(\widetilde{R}(\cdot), \widetilde{a}(\cdot))^{-1}\widehat{\phi}(\widetilde{R}(\cdot), r(\cdot)) \\ &= \mathbf{E}\mathcal{Z}_*\psi(\widetilde{R}_*(\cdot), \widetilde{a}_*(\cdot))^{-1}\widehat{\phi}(\widetilde{R}_*(\cdot), r_*(\cdot)) = \mathbf{E}\widehat{\phi}(\widetilde{R}_*(\cdot), r_*(\cdot)). \end{aligned}$$

We turn now to Theorem 3.1. Define $\widehat{\xi}_* \triangleq F(\bar{\mathcal{Z}}_*, \widehat{\lambda})$. It follows from (7.5) that if we define $\widetilde{\phi}$ by $\widehat{\xi} = \widetilde{\phi}(\widetilde{R}(\cdot))$, then $\widehat{\xi}_* = \widetilde{\phi}(\widetilde{R}_*(\cdot))$.

Proof of Theorem 3.1. Let us show that $\mathbf{E}U^-(\widehat{\xi}) < \infty$ so that $\mathbf{E}U(\widehat{\xi})$ is well defined. For $k = 1, 2, \dots$, we introduce the random events

$$\Omega_*^{(k)} \triangleq \big\{-k \le U(\widehat{\xi}_*) \le 0\big\}, \quad \Omega^{(k)} \triangleq \big\{-k \le U(\widehat{\xi}) \le 0\big\},$$

along with their indicator functions, $\mathbb{I}_*^{(k)}$ and $\mathbb{I}^{(k)}$, respectively. The number $\widehat{\xi}_*$ provides the unique maximum of the function $\bar{\mathcal{Z}}_* U(\xi_*) - \widehat{\lambda}\xi_*$ over $\widehat{D}$, and $X_0 \in \widehat{D}$. By Proposition 7.2, we have for all $k = 1, 2, \dots,$

$$\begin{aligned}\mathbf{E}\mathbb{I}^{(k)}U(\widehat{\xi}) - \mathbf{E}\mathbb{I}_*^{(k)}\widehat{\lambda}\widehat{\xi}_* &= \mathbf{E}\mathbb{I}_*^{(k)}\left(\bar{\mathcal{Z}}_* U(\widehat{\xi}_*) - \widehat{\lambda}\widehat{\xi}_*\right) \ge \mathbf{E}\mathbb{I}_*^{(k)}\left(\bar{\mathcal{Z}}_* U(X_0) - \widehat{\lambda}X_0\right)\\ &= \mathbf{E}\mathbb{I}^{(k)}U(X_0) - \widehat{\lambda}X_0\mathbf{P}(\Omega_*^{(k)}) \ge -|U(X_0)| - |\widehat{\lambda}X_0| > -\infty.\end{aligned}$$

Further, we have that $\mathbf{E}|\widehat{\xi}_*| = \mathbf{E}_*|\widehat{\xi}| < +\infty$. Hence $\mathbf{E}U^-(\widehat{\xi}) < \infty$.

Now observe that for any $\pi \in \bar{\Sigma}$ we can apply (7.7) and (7.8) to $U(\widetilde{X}^\pi(T))$ (and use (7.5)) to obtain

$$\begin{aligned}\mathbf{E}U(\widetilde{X}^\pi(T)) = \mathbf{E}_*\{\bar{\mathcal{Z}}U(\widetilde{X}^\pi(T))\} \quad &\le \mathbf{E}_*\{\bar{\mathcal{Z}}U(\widetilde{X}^\pi(T)) - \widehat{\lambda}\widetilde{X}^\pi(T)\} + \widehat{\lambda}X_0\\ &\le \mathbf{E}_*\{\bar{\mathcal{Z}}U(\widehat{\xi}) - \widehat{\lambda}\widehat{\xi}\} + \widehat{\lambda}X_0 = \mathbf{E}_*\bar{\mathcal{Z}}U(\widehat{\xi}) = \mathbf{E}U(\widehat{\xi}).\end{aligned}$$

Thus (ii) is satisfied.

Let us show (iii). Since σ is nonrandom, hence w-adapted, then $\widehat{\xi}_* = \widehat{\phi}(w(\cdot))$, where $\widehat{\phi}(\cdot) : \mathrm{B}([0,T];\mathbf{R}^n) \to \mathbf{R}$ is a measurable functions. By the Martingale representation theorem,

$$\widehat{\xi}_* = \mathbf{E}\widehat{\xi}_* + \int_0^T f(t, w(\cdot)|_{[0,t]})^\top dw(t),$$

where $f(t,\cdot) : \mathrm{B}([0,t];\mathbf{R}^n) \to \mathbf{R}^n$ is a measurable function such that $\int_0^T |f(t, w(\cdot)|_{[0,t]})|^2 dt < +\infty$ a.s. There exists a unique measurable function $f_0(t,\cdot) : \mathrm{B}([0,t];\mathbf{R}^n) \to \mathbf{R}^n$ such that $f(t, w(\cdot)|_{[0,t]}) \equiv f_0(t, \widetilde{R}_*(\cdot)|_{[0,t]})$. Thus,

$$\widehat{\xi}_* = \mathbf{E}\widehat{\xi}_* + \int_0^T f_0(t, \widetilde{R}_*(\cdot)|_{[0,t]})^\top dw(t) = \mathbf{E}\widehat{\xi}_* + \int_0^T f_0(t, \widetilde{R}_*(\cdot)|_{[0,t]})^\top \sigma(t)^{-1} d\widetilde{R}_*(t).$$

Proposition 7.2 implies that $\mathbf{E}\widehat{\xi}_* = \mathbf{E}_*\widehat{\xi} = X_0$, and

$$\widehat{\xi} = X_0 + \int_0^T f_0(t, \widetilde{R}(\cdot)|_{[0,t]})^\top \sigma(t)^{-1} d\widetilde{R}(t).$$

Hence the strategy $\widehat{\pi}(t)^\top = B(t) f_0(t, \widetilde{R}(\cdot)|_{[0,t]})^\top \sigma(t)^{-1}$ replicates $B(T)\widehat{\xi}$. It belongs to $\bar{\Sigma}$; in particular, since w and $\widetilde{R}$ generate the same sigma-algebra and $\widehat{D}$ is convex, then $\widetilde{X}(t, \pi(\cdot)) = \mathbf{E}\left\{\widehat{\xi}\,|\,\widetilde{R}(\cdot)|_{[0,t]}\right\} \in \widehat{D}$, hence bounded below. This completes the proof of Theorem 3.1.

Proof of Lemma 4.1. Let $\mathcal{V} \triangleq \mathbf{R}^n \times \mathbf{R} \times \mathbf{R}^{\frac{n(n+1)}{2}}$. Clearly, $\mathcal{V}$ is an $\widetilde{n}$-dimensional linear vector space, where $\widetilde{n} \triangleq n + 1 + n(n+1)/2$. Let $\widetilde{y}(t) = (\widetilde{y}_1(t), \widetilde{y}_2(t), \widetilde{y}_3(t))$ be a process in $\mathcal{V}$ such that

$$\widetilde{y}(t) = (y(t), \widetilde{y}_3(t)) = (\widetilde{y}_1(t), \widetilde{y}_2(t), \widetilde{y}_3(t)) = \big(\widehat{a}(t), \ln \bar{\mathcal{Z}}(t), \widehat{a}(t)\widehat{a}(t)^\top\big).$$

The last equality is satisfied by (4.7). It can be seen that the equation for $\widetilde{y}(t)$ is linear:

$$\begin{aligned}
d\widetilde{y}_1(t) &= [\widehat{A}(t)\widetilde{y}_1(t) + v(t)]dt + E(t)\,d\widetilde{R}(t),\\
d\widetilde{y}_2(t) &= -\tfrac{1}{2}\mathrm{Tr}\{Q(t)\widetilde{y}_3(t)\}\,dt + \widetilde{y}_1(t)^\top Q(t)\,d\widetilde{R}(t),\\
d\widetilde{y}_3(t) &= [\widehat{A}(t)\widetilde{y}_3(t) + \widetilde{y}_3(t)^\top \widehat{A}(t)^\top + v(t)\widetilde{y}_2(t)^\top\\
&\qquad + \widetilde{y}_2(t)v(t)^\top + \tfrac{1}{2}\{E(t)\sigma(t)\sigma(t)^\top E(t)^\top\}]dt\\
&\qquad + E(t)\,d\widetilde{R}(t)\widetilde{y}_2(t)^\top + y_2(t)\,d\widetilde{R}(t)^\top E(t)^\top.
\end{aligned}$$

Here $\widehat{A}(t)$, $v(t)$, $E(t)$ are known deterministic functions in $\mathbf{R}^{n\times n}$, $\mathbf{R}^n$ and $\mathbf{R}^{n\times n}$, respectively. In particular, $\widehat{A}(t) = A(t) - b(t)\sigma(t)^\top Q(t)$. Thus, the equation for $\widehat{y}(t)$ can be rewritten as

$$\left\{\begin{array}{l} d\widetilde{y}(t) = \widetilde{f}(\widetilde{y}(t),t)dt + \sum_{i=1}^n \widetilde{g}_i(\widetilde{y}(t),t)\,d\widetilde{R}_i(t),\\ \widetilde{y}(0) = \widetilde{y}_0, \end{array}\right. \tag{7.10}$$

with $\widetilde{y}_0 = \big(m_0, 0, m_0 m_0^\top\big)$, and with some functions $\widetilde{f}(\widetilde{x},t) : \mathcal{V}\times[0,T]\to\mathcal{V}$ and $\widetilde{g}_i(\widetilde{x},t) : \mathcal{V}\times[0,T]\to\mathcal{V}$, $i = 1,\dots,n$, that are affine in $\widetilde{x}\in\mathcal{V}$ with continuous in t coefficients. In particular, $\partial\widetilde{f}(\widetilde{x},t)/\partial\widetilde{x}$ and $\partial\widetilde{g}_i(\widetilde{x},t)/\partial\widetilde{x}$ depend only on t, and they are uniformly bounded. Hence (7.10) has a unique solution. Therefore, (4.2) has the unique solution $y(t)$.

Let $\widetilde{V}(\widetilde{x},t) \triangleq \mathbf{E}_*\Phi(\bar{y}^{\widetilde{x},s}(T))$, where the process $\bar{y}^{\widetilde{x},s}(\cdot)$ takes values in $\mathbf{R}^{n+1}$ and is such that $\widetilde{y}^{\widetilde{x},s}(\cdot) = (\bar{y}^{\widetilde{x},s}(\cdot), \widetilde{y}_3^{\widetilde{x},s}(\cdot))$ is the solution of (7.10) given the initial condition $\widetilde{y}(s) = \widetilde{x}\in\mathcal{V}$. Then $\widetilde{V}(\widetilde{x},t)$ is the classical solution of the boundary value problem for the corresponding backward Kolmogorov's equation

$$\left\{\begin{array}{l} \frac{\partial\widetilde{V}}{\partial t}(\widetilde{x},t) + \mathcal{L}(t)\widetilde{V}(\widetilde{x},t) = 0, \quad t\in[0,T],\\ \widetilde{V}(\widetilde{x},T) = \Phi(\widetilde{x}_1,\widetilde{x}_2), \end{array}\right. \tag{7.11}$$

where $\widetilde{x} = (\widetilde{x}_1,\widetilde{x}_2,\widetilde{x}_3)\in\mathbf{R}^n\times\mathbf{R}\times\mathbf{R}^{\frac{n(n+1)}{2}}$, and where $\mathcal{L}(t)$ is the second order differential operator on functions $v : \mathcal{V}\to\mathbf{R}$ generated by the Markov process $\widetilde{y}(t)$.

Let $y^{x,s}(\cdot) = (y_1^{x,s}(\cdot),\dots,y_{n+1}^{x,s}(\cdot))$ be the solution of (4.2), and let $V(x,t) \triangleq \mathbf{E}_*\Phi(y^{x,t}(T))$. Clearly,

$$\widetilde{y}^{\widetilde{x},s}(t) \equiv (y^{x,s}(t), \widehat{y}^{x,s}(t)\widehat{y}^{x,s}(t)^\top) = \big(y_1^{x,s}(t),\dots,y_n^{x,s}(t), y_{n+1}^{x,s}(t),\, \widehat{y}^{x,s}(t)\widehat{y}^{x,s}(t)^\top\big)\,,$$

if

$$\begin{aligned}
&\widetilde{x} = (x,\widetilde{x}_3) = (\widehat{x}, x_{n+1}, \widehat{x}\widehat{x}^\top), \quad \widehat{x} = (x_1,\dots,x_n),\\
&x = (x_1,\dots,x_n,x_{n+1}) = (\widehat{x},x_{n+1})\in\mathbf{R}^{n+1},\\
&\widetilde{x}_3 = \widehat{x}\widehat{x}^\top\in\mathbf{R}^{n(n+1)/2}, \quad \widehat{y}^{x,s}(\cdot) = (y_1^{x,s}(\cdot),\dots,y_n^{x,s}(\cdot)).
\end{aligned}$$

In that case, $V(x,t)\equiv\widetilde{V}(x_1,\widehat{x}_2,\widehat{x}_2\widehat{x}_2^\top)$, where $x = (\widehat{x},x_{n+1})$, $\widehat{x}\in\mathbf{R}^n$. Therefore, $V(x,t)$ is the classical solution of problem (4.3)–(4.4).

Let $y_*(\cdot)$ denote the solution of (4.2) with $\widetilde{R}(\cdot)$ replaced by $\widetilde{R}_*(\cdot) = \int_0^\cdot \sigma(t)\,dw(t)$.

Set $\widetilde{X}_*(t) \triangleq V(y_*(t),t)$. From (4.3) and Itô's lemma, it follows that

$$\widetilde{X}_*(T) = \widetilde{X}_*(t) + \int_t^T B_*(s)^{-1}\pi_*(s)^\top d\widetilde{R}_*(s),$$

where $\pi_*(t)^\top \triangleq B_*(t)\frac{\partial V}{\partial x}(y_*(t),t)g(y_*(t),t)$. It follows that $\widetilde{X}_*(0) = V(y_*(0),0) = \mathbf{E}V(y_*(T),T) = X_0$ and

$$d\widetilde{X}_*(t) = B_*(t)^{-1}\pi_*(t)^\top d\widetilde{R}_*(t), \quad \widetilde{X}_*(T) = \Phi(y_*(T)). \tag{7.12}$$

Then $\widetilde{X}_*(t) = \widetilde{\psi}(t,\widetilde{R}_*)$ for some measurable $\widetilde{\psi}$, and the result follows if we observe that $\widetilde{X}(t) = \widetilde{\psi}(t,\widetilde{R})$ replicates the claim as desired for $\pi(t)^\top \triangleq B(t)\frac{\partial V}{\partial x}(y(t),t)g(y(t),t)$.

To continue, we require some a priori estimates. Let $\zeta_*(t) \triangleq B_*(t)^{-1}\sigma(t)^\top\pi_*(t)$.

We consider the conditional probability space given in $(\Theta, W(\cdot), \widetilde{a}(0))$. With respect to the conditional probability space, it follows from (7.12) that

$$\begin{cases} d\widetilde{X}_*(t) = \zeta_*(t)^\top dw(t), \\ \widetilde{X}_*(T) = \Phi(y_*(T)). \end{cases} \tag{7.13}$$

By Proposition 2.2 from El Karoui, Peng, and Quenez [12], the (unique) solution $(\zeta_*(t), \widetilde{X}_*(t))$ of linear stochastic backward equation (7.13) is a process in $L_2([0,T], L_2(\Omega,\mathcal{F},P)) \times C([0,T], L_2(\Omega,\mathcal{F},P))$, and there exists a constant c_0, independent of $(\Phi(\cdot), \Theta, W(\cdot), \widetilde{a}(0))$, and such that

$$\begin{aligned} \sup_{t\in[0,T]} \mathbf{E}\left\{|\widetilde{X}_*(t)|^2 \middle| \Theta, W(\cdot), \widetilde{a}(0)\right\} \quad &+\mathbf{E}\left\{\int_0^T |\zeta_*(t)|^2 dt \middle| \Theta, W(\cdot), \widetilde{a}(0)\right\} \\ &\le c_0 \mathbf{E}\left\{\Phi(y_*(T))^2 \middle| \Theta, W(\cdot), \widetilde{a}(0)\right\} \quad \text{a.s.} \end{aligned}$$

Hence

$$\sup_{t\in[0,T]} \mathbf{E}|\widetilde{X}_*(t)|^2 + \mathbf{E}\int_0^T B_*(t)^{-2}|\pi_*(t)|^2 dt \le c_1 \mathbf{E}\Phi(y_*(T))^2, \tag{7.14}$$

where $c_1 > 0$ is a constant that does not depend on $\Phi(\cdot)$. Then (4.5) follows. This completes the proof. □

Proof of Theorem 4.2. Clearly, the equation for $y(t)$ is

$$\begin{cases} d\widehat{a}(t) = [A(t)\widehat{y}(t) - b(t)\sigma(t)^\top Q(t) + \alpha(t)\delta(t)]dt + \gamma(t)Q(t)\,d\widetilde{R}(t), \\ dy_{n+1}(t) = \frac{1}{2}\widehat{a}(t)^\top Q(t)\widehat{a}(t)dt - \widehat{a}(t)^\top Q(t)\,d\widetilde{R}(t). \end{cases}$$

As in the proof above, it can be shown that $\widetilde{X}(t) = V(y(t),t,\widehat{\lambda})$ is the solution of (7.12), i.e., it is the normalized wealth. Then the proof follows.

Let $\mathcal{N}_2$ be the set of all Gaussian processes $\bar{a}(t) : [0,T]\times\Omega \to \mathbf{R}^n$ which are progressively measurable with respect to the filtration generated by $[a(0), w(t), W(t)]$ and such that $\mathbf{E}\int_0^T |\bar{a}(t)|^2 dt < +\infty$. For $\bar{a}(\cdot) \in \mathcal{N}_2$, let

$$Z(t,\bar{a}(\cdot)) \triangleq \exp\left[\int_0^t \bar{a}(s)^\top Q(s) d\widetilde{R}(s) - \frac{1}{2}\int_0^t \bar{a}(s)^\top Q(s)\bar{a}(s)ds\right].$$

Proposition 7.3. *Let $\bar{a}(\cdot) \in \mathcal{N}_2$, let $p \in (1,+\infty)$, and let $\mu \in \mathbf{R}$, $\mu < 0$ or $\mu > 1$. Let $\bar{K}(t)$ be the covariance matrix of $\bar{a}(t)$ under $\mathbf{P}_*$, and let $\kappa(p) \triangleq qT(\mu^2 p - \mu)$, where $q \triangleq p(p-1)^{-1}$. Let $\kappa(p)\bar{K}(t) < \sigma(t)\sigma(t)^\top - \varepsilon I_n$, where $\varepsilon > 0$ is a constant. Then $\mathbf{E}_* Z(t,\bar{a}(\cdot))^\mu < +\infty$.*

Proof of Proposition 7.3. If $\mu \in [0,1]$, then $\mathbf{E}_* Z(t,\bar{a}(\cdot))^\mu < +\infty$ (see Lakner [23, p. 93]). Therefore, we can assume without loss of generality that $\mu < 0$ or $\mu > 1$. Clearly,

$$Z(t,\bar{a}(\cdot))^\mu = \exp\left[\mu \int_0^t \bar{a}(s)^\top Q(s) d\widetilde{R}(s) - \tfrac{\mu}{2}\int_0^t \bar{a}(s)^\top Q(s)\bar{a}(s)ds\right] = \zeta(t)\zeta_0(t),$$

where

$$\zeta(t) \triangleq \exp\left[\mu \int_0^t \bar{a}(s)^\top Q(s) d\widetilde{R}(s) - \frac{\mu^2 p}{2}\int_0^t \bar{a}(s)^\top Q(s)\bar{a}(s)ds\right],$$

and

$$\zeta_0(t) \triangleq \exp\left[\frac{\mu^2 p - \mu}{2}\int_0^t \bar{a}(s)^\top Q(s)\bar{a}(s)ds\right].$$

By Hölder inequality, $\mathbf{E}_* \mathcal{Z}^\mu \le [\mathbf{E}_* \zeta(T)^p]^{1/p} [\mathbf{E}_* \zeta_0(T)^q]^{1/q}$.

Similar to the proof of Lemma A.1 from Lakner [23], we have that $\mathbf{E}_* \zeta(T)^p < +\infty$ because $\zeta(t)^p$ is a positive local martingale with respect to $\mathbf{P}_*$, thus by Fatou's lemma it is a supermartingale.

By Jensen's inequality,

$$\begin{aligned}\mathbf{E}_* \zeta_0(T)^q &= \mathbf{E}_* \exp\left[q\tfrac{\mu^2 p-\mu}{2}\int_0^T \bar{a}(s)^\top Q(s)\bar{a}(s)ds\right] \\ &= \mathbf{E}_* \exp\left[\tfrac{1}{2T}\kappa(p)\int_0^T \bar{a}(s)^\top Q(s)\bar{a}(s)ds\right] \le \tfrac{1}{T}\int_0^T \mathbf{E}_* \exp\left[\tfrac{1}{2}\kappa(p)\bar{a}(s)^\top Q(s)\bar{a}(s)\right] ds.\end{aligned} \tag{7.15}$$

Remember that $Q \triangleq (\sigma\sigma^\top)^{-1}$, and $\kappa(p) > 0$. Similar to (7.1), we obtain

$$\begin{aligned}\bar{K}(t)^{-1} &> \kappa(p)[\sigma(t)\sigma(t)^\top - \varepsilon I_n]^{-1} = \kappa(p)Q(t)[I_n - \varepsilon Q(t)]^{-1} \\ &= \kappa(p)Q(t)\left[I_n + \textstyle\sum_{k=1}^{+\infty}\{\varepsilon Q(t)\}^k\right] > \kappa(p)Q(t) + \kappa(p)\varepsilon Q(t)^2 \\ &> \kappa(p)Q(t) + M_1,\end{aligned} \tag{7.16}$$

where $M_1 = M_1(\varepsilon) > 0$ is a definitely positive constant matrix. (We can take $\varepsilon > 0$ small enough to ensure convergency.) Similar to the proof of Proposition 2.1, it follows from (7.15), (7.16) that $\mathbf{E}_* \zeta_0(T)^q < +\infty$ and $\mathbf{E}_* Z(t,\bar{a}(\cdot))^\mu < +\infty$. □

Proof of Lemma 5.1. If $\mu \in [0,1]$, then $\mathbf{E}_* \bar{\mathcal{Z}}^\mu < +\infty$ (see Lakner [23, p. 93]). Therefore, we can assume without loss of generality that $\mu < 0$ or $\mu > 1$. Note that $\widehat{a}(\cdot) \in \mathcal{N}_2$. By Proposition 7.3, if (i) is satisfied, then $\mathbf{E}_* \bar{\mathcal{Z}}^\mu < +\infty$.

Further, let (ii) be satisfied. Clearly, $\widetilde{a}(\cdot) \in \mathcal{N}_2$. By Proposition 7.3 again, $\mathbf{E}_* Z(T,\widetilde{a}(\cdot))^\mu < +\infty$. By (7.4), $\bar{\mathcal{Z}}_* = \mathbf{E}\{Z(T,\widetilde{a}_*(\cdot))|\widetilde{R}_*(\cdot), r_*(\cdot)\}$. Hence, by Jensen's inequality $\mathbf{E}_* \bar{\mathcal{Z}}^\mu \le \mathbf{E}_* Z(T,\widetilde{a}(\cdot))^\mu < +\infty$.

Proof of Theorem 6.1. Let τ be a random variable that takes values in $[0,T]$ and such that $\mathbf{P}(\tau = 0) = 1/2$ and $\mathbf{P}(\tau \in (t_1,t_2]) = (t_2 - t_1)/(2T)$ for $0 < t_1 < t_2 \le T$. Let $\eta_i \in L_2(\Omega,\mathcal{F},\mathbf{P},\mathbf{R}^{n+2})$ be random vectors such that they have the probability density functions $\rho_i(x)$, $i = 0,1$. We assume that $\tau, \eta_0, \eta_1, w, \Theta, W(\cdot), \widetilde{a}(0)$ are mutually independent.

Let $\eta \triangleq \eta_0 \mathbb{I}_{\{\tau=0\}} + \eta_1 \mathbb{I}_{\{\tau>0\}}$, and let $\eta_*(\cdot)$ be the solution of the Itô's equation

$$\begin{cases} d\eta_*(t) = f(\eta_*(t),t)dt + g(\eta_*(t),t)d\widetilde{R}_*(t), & t > \tau, \\ \eta_*(\tau) = \eta. \end{cases} \tag{7.17}$$

Equation (6.1) is the forward Kolmogorov's equation for the case when time of birth is distributed as τ, and the vector $\eta_*(t)$ has the conditional probability density function $p(x,t)/2$ in the sense that $\mathbf{P}(\eta_*(t)\in\Gamma,\ t\geq\tau)=1/2\int_\Gamma p(x,t)dx$ for any domain $\Gamma\subset\mathbf{R}^{n+1}$, where p is the solution of (6.1).

Note that we need random τ with the selected probability density on $(0,T]$ to generate the free term in parabolic equation (6.1).

Assume that $\Phi(\cdot)\in C^2(\mathbf{R}^{n+1})$ and it has finite support. Let $V(x,t)\triangleq\mathbf{E}_*\Phi(y^{x,t}(T))$, where $y^{x,s}(\cdot)$ is the solution of (4.2). Then $V(x,t)$ is the classical solution of problem (4.3)–(4.4). Set $\widetilde{Y}_*(t)\triangleq V(\eta_*(t),t)$. From (4.3) and Itô's lemma, it follows that

$$\widetilde{Y}_*(T)=\widetilde{Y}_*(t)+\int_t^T B_*(s)^{-1}\varrho_*(s)^\top d\widetilde{R}_*(s),\quad \tau\leq t\leq T,$$

where $\varrho_*(t)^\top\triangleq B_*(t)\frac{\partial V}{\partial x}(\eta_*(t),t)g(\eta_*(t),t)$. Hence

$$d\widetilde{Y}_*(t)=B_*(t)^{-1}\varrho_*(t)^\top d\widetilde{R}_*(t),\quad \widetilde{Y}_*(T)=\Phi(\eta_*(T)). \tag{7.18}$$

To continue, we require some estimates. Let $\widehat{\zeta}_*(t)\triangleq B_*(t)^{-1}\sigma(t)^\top\varrho_*(t)$.

Consider the conditional probability space given in $(\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0))$. With respect to the conditional probability space, it follows from (7.18) that

$$\begin{cases} d\widetilde{Y}_*(t)=\widehat{\zeta}_*(t)^\top dw(t),\\ \widetilde{Y}_*(T)=\Phi(\eta_*(T)).\end{cases} \tag{7.19}$$

By Proposition 2.2 from El Karoui, Peng, and Quenez [12] again, the (unique) solution $(\widehat{\zeta}_*(t),\widetilde{Y}_*(t))$ of stochastic backward equation (7.19) is a process in $L_2([\tau,T],L^2(\Omega,\mathcal{F},P))\times C([\tau,T],L^2(\Omega,\mathcal{F},P))$ given $(\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0))$, and there exists a constant C_0 that is independent of $(\Phi(\cdot),\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0))$, and such that

$$\begin{aligned}&\sup_{t\in[0,T]}\mathbf{E}\mathbb{I}_{\{t\geq\tau\}}\left\{|\widetilde{Y}_*(t)|^2\big|\,\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0)\right\}\\ &+\mathbf{E}\big\{\textstyle\int_0^T\mathbb{I}_{\{t\geq\tau\}}|\widehat{\zeta}_*(t)|^2dt\,\big|\,\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0)\big\}\\ &=\sup_{t\in[\tau,T]}\mathbf{E}\left\{|\widetilde{Y}_*(t)|^2\,\big|\,\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0)\right\}+\mathbf{E}\big\{\textstyle\int_\tau^T|\widehat{\zeta}_*(t)|^2dt\Big|\,\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0)\big\}\\ &\qquad\leq C_0\mathbf{E}\left\{\Phi(\eta_*(T))^2\,\big|\,\tau,\eta,\Theta,W(\cdot),\widetilde{a}(0)\right\}\quad\text{a.s.}\end{aligned}$$

Hence there exists a constant c_0, independent of $\Phi(\cdot)$ and such that

$$\sup_{t\in[0,T]}\mathbf{E}\mathbb{I}_{\{t\geq\tau\}}|\widetilde{Y}_*(t)|^2+\mathbf{E}\int_0^T\mathbb{I}_{\{t\geq\tau\}}B_*(t)^{-2}|\varrho_*(t)|^2dt\leq c_0\mathbf{E}\Phi(\eta_*(T))^2. \tag{7.20}$$

Let $\Phi(\cdot)$ be a general measurable function satisfying the conditions specified in the theorem. Then, there exists a sequence $\{\Phi^{(i)}(\cdot)\}$, where $\Phi^{(i)}(\cdot)\in C^2(\mathbf{R}^{n+1})$ are such that they all have finite support and

$$\mathbf{E}|\Phi^{(i)}(\eta_*(T))-\Phi(\eta_*(T))|^2=\textstyle\int_{\mathbf{R}^{n+2}}p(x,T)|\Phi^{(i)}(x)-\Phi(x)|^2dx\to0\quad\text{as}\quad i\to\infty. \tag{7.21}$$

Let $\widetilde{Y}_*^{(i)}(\cdot)$, $\varrho_*^{(i)}(\cdot)$, and $V^{(i)}(\cdot)$ be the corresponding processes and functions. Let

$$\Psi_{i,j}\triangleq\sup_{t\in[0,T]}\mathbf{E}\mathbb{I}_{\{t\geq\tau\}}|\widetilde{Y}_*^{(i)}(t)-\widetilde{Y}_*^{(j)}(t)|^2+\mathbf{E}\int_0^T\mathbb{I}_{\{t\geq\tau\}}B_*(t)^{-2}|\varrho_*^{(i)}(t)-\varrho_*^{(j)}(t)|^2dt.$$

By (7.20)–(7.21) and the linearity of (7.19), it follows that

$$\Psi_{i,j} \le c_0 \mathbf{E}|\Phi^{(i)}(\eta_*(T)) - \Phi^{(j)}(\eta_*(T))|^2 \to 0 \quad \text{as} \quad i,j \to \infty.$$

We have that $V^{(j)} \in \mathcal{W}_C^1$, since they are bounded together with their partial derivatives with respect to $x_1, \dots, x_{n+1}$. Remember that $0 < \rho(x) \le p(x,t)$ for all x, t. Further, we have that

$$\Psi_{i,j} = \sup_{t\in[0,T]} \int_{\mathbf{R}^{n+1}} p(x,t)|V^{(i)}(x,t) - V^{(j)}(x,t)|^2 dx + \int_s^T dt \int_{\mathbf{R}^{n+1}} p(x,t) \left| \left[\frac{\partial V^{(i)}}{\partial x}(x,t) - \frac{\partial V^{(j)}}{\partial x}(x,t) \right] g(x,t) \right|^2 dx.$$

Hence $\|V^{(i)} - V^{(j)}\|^2_{\mathcal{W}_C^1} \le \Psi_{i,j} \to 0$ as $i,j \to \infty$. Therefore, $V^{(i)}$ is a Cauchy sequence in $\mathcal{W}_C^1$, and it has the limit V in $\mathcal{W}_C^1$. This V is the desired solution, and (6.3) is satisfied. This completes the proof. □

Note that it follows from the proof above that the sequences $\{\widetilde{Y}_*^{(i)}(\cdot)\}_{i=1}^\infty$ and $\{\varrho_*^{(i)}(\cdot)\}_{i=1}^\infty$ are Cauchy sequences in the spaces $C([\tau,T]; L^2(\Omega, \mathcal{F}, \mathbf{P}\{\cdot \mid \tau\}))$ and $L_2([\tau,T]; L^2(\Omega, \mathcal{F}, \mathbf{P}\{\cdot \mid \tau\}))$, respectively. Hence the corresponding limits $\widetilde{Y}_*(\cdot)$, $\varrho_*(\cdot)$ exist and belong to these spaces given τ.

This paper presents the development of some results and ideas that grew from our collaboration with Ulrich Haussmann during the author's stay at Pacific Institute for the Mathematical Sciences, Vancouver (see, e.g., Dokuchaev and Haussmann [8]).

Acknowledgments. The author wishes to thank Prof. U. Haussmann for the support and useful discussion. The author also wishes to thank the anonymous referees for their insightful comments which greatly strengthened the paper.

HYBRID CONTROL SYSTEMS AND VISCOSITY SOLUTIONS*

SHEETAL DHARMATTI† AND MYTHILY RAMASWAMY‡

Abstract. We investigate a model of hybrid control system in which both discrete and continuous controls are involved. In this general model, discrete controls act on the system at a given set interface. The state of the system is changed discontinuously when the trajectory hits predefined sets, namely, an autonomous jump set A or a controlled jump set C where the controller can choose to jump or not. At each jump, the trajectory can move to a different Euclidean space. We prove the continuity of the associated value function V with respect to the initial point. Using the dynamic programming principle satisfied by V, we derive a quasi-variational inequality satisfied by V in the viscosity sense. We characterize the value function V as the unique viscosity solution of the quasi-variational inequality by the comparison principle method.

Key words. dynamic programming principle, viscosity solution, quasi-variational inequality, hybrid control

1. Introduction.

Many complicated control systems, like flight control and transportation, perform computer coded checks and issue logical as well as continuous control commands. The interaction of these different types of dynamics and information leads to hybrid control problems. Thus hybrid control systems are those having continuous and discrete dynamics and continuous and discrete controls. Many control systems, which involve both logical decision making and continuous evolution, are of this type. Typical examples of such systems are constrained robotic systems [1] and automated highway systems [8]. See [5], [6], and the references therein for more examples of such systems.

In [5], Branicky, Borkar, and Mitter presented a model for the most general hybrid control system in which continuous controls are present and, in addition, discrete controls act at a given set interface, which corresponds to the logical decision making process as in the above examples. The state of the system is changed discontinuously when the trajectory hits these predefined sets, namely, an autonomous jump set A or a controlled jump set C where the controller can choose to jump or not. They prove right continuity of the value function corresponding to this hybrid control problem. Using the dynamic programming principle they arrive at the partial differential equation satisfied by the value function, which turns out to be the quasi-variational inequality, referred hereafter as QVI.

In [4], Bensoussan and Menaldi study a similar system and prove that the value function u is close to a certain u_ε which they mention to be continuous indicating the use of the basic ordinary differential equation estimate for continuous trajectories and the continuity of the first hitting time (see [4, Theorem 2.5 and Remark 3.5]). They

prove its uniqueness as a viscosity solution of the QVI in a certain special case where the autonomous jump set is empty and the controlled jump set is the whole space.

In our work, we study this problem in a more general case in which the autonomous jump set is nonempty and the controlled jump set can be arbitrary. Our model is based on that of [5]. Our main aim is to prove uniqueness in the most general case when the sets A and C are nonempty and also to obtain precise estimates to improve the earlier continuity results. Our motivation comes from the fact that in all the real-life models mentioned above, logical decision making is always involved as well as the continuous control. This will correspond to a nonempty autonomous jump set A.

Here we prove the local Hölder continuity of the value function under a transversality condition, the same as the one assumed in [5] and [4] (see (2.36) in [4]). For this we need to follow the trajectories starting from two neighboring points, through their continuous evolution, and through their discrete jumps since the autonomous jump set is nonempty. This involves careful estimation of the distance between the trajectories in various time intervals and summing up these terms to show that the distance remains small for initial points sufficiently close enough. Although the basic estimates used are similar to those available in the literature (e.g., [3], [4]), the crucial point in our proof is the convergence of the above summation. This also allows us to get the precise Hölder exponent for the continuity of the value function.

As in [5] and [4], using the dynamic programming principle, we arrive at the QVI satisfied by the value function. Then we show that the value function is the unique viscosity solution of the QVI. Our proof is very different from [4]. Their approach using a fixed point method does not seem to be suitable, as it is for the general case of a nonempty autonomous jump set. Our approach is based on the comparison principle in the class of bounded continuous functions. It is inspired by earlier work on impulse and switching control and game theoretic problems in the literature, namely, [2], [7], [9], particularly the idea of defining a sequence of new auxiliary functions. But the presence of the autonomous and controlled jump sets leads to different equations on these sets, and hence some new ideas are needed to arrive at the conclusion.

2. Notation and assumptions. In a hybrid control system, as in [5], the state vector during continuous evolution is given by the solution of the following problem:

$$\dot{X}(t) = f(X(t), u(t)), \tag{2.1}$$

$$X(0) = x, \tag{2.2}$$

where $X(t) \in \Omega := \bigcup_i \Omega_i \times \{i\}$, with each Ω_i a closed connected subset of $\mathbb{R}^{d_i}$, i, $d_i \in Z_+$; $x \in \Omega$; and $f : \Omega \times \mathcal{U} \to \Omega$. Actually, $f = f_i$ with the understanding that $\dot{X}(t) = f_i(X(t), u(t))$ whenever $x \in \Omega_i$. $\mathcal{U}$ is the continuous control set

$$\mathcal{U} = \{u : [\,0, \infty) \to U \mid u \ \text{ measurable, } U \text{ compact metric space}\}\,.$$

The trajectory also undergoes discrete jumps when it hits predefined sets A, the autonomous jump set, and C, the controlled jump set. A predefined set D is the destination set for both autonomous jumps as well as controlled jumps:

$$\begin{aligned} A &= \bigcup_i A_i \times \{i\}, \quad A_i \subseteq \Omega_i \subseteq \mathbb{R}^{d_i}, \\ C &= \bigcup_i C_i \times \{i\}, \quad C_i \subseteq \Omega_i \subseteq \mathbb{R}^{d_i}, \\ D &= \bigcup_i D_i \times \{i\}, \quad D_i \subseteq \Omega_i \subseteq \mathbb{R}^{d_i}\ . \end{aligned}$$

The trajectory starting from $x \in \Omega_i$, on hitting A, that is the respective $A_i \subseteq \Omega_i$, jumps to the destination set D according to the given transition map g. g uses discrete controls from the discrete control set V_1 and can move the trajectory from A_i to $D_j \subseteq \Omega_j \subseteq \mathbb{R}^{d_j}$. The trajectory then will continue its evolution under f_j till it again hits A or C, in particular A_j or C_j. On hitting C the controller can choose either to jump or not to jump. If the controller chooses to jump, then the trajectory is moved to a new point in D. In this case the controller can also move from Ω_i to any of the Ω_j.

This gives rise to a sequence of hitting times of A, which we denote by σ_i, and a sequence of hitting times of C, where the controller chooses to make a jump which is denoted by ξ_i. Thus σ_i and ξ_i are the times when continuous and discrete dynamics interact. Hence the trajectory of this problem is composed of continuous evolution given by (2.1) between two hitting times and discrete jumps at the hitting times. We denote $(X(\sigma_i^-), u(\cdot))$ by x_i and $g(X(\sigma_i^-), v)$ by x_i' and the destination of $X(\xi_i^+, u(\cdot))$ by $X(\xi_i)'$. In general we take the trajectory to be left continuous so that $X_x(\sigma_i)$ means $X_x(\sigma_i^-)$ and $X_x(\xi_i)$ means $X_x(\xi_i^-)$, whereas $X_x(\sigma_i^+)$ will be denoted by x_i' and $X_x(\xi_i^+)$ will be denoted by $X_x(\xi_i)'$.

We give the inductive limit topology on Ω, namely,

$$(x_n, i_n) \in \Omega \text{ converges to } (x, i) \in \Omega \quad \text{if for some } N \text{ large and } \forall n \geq N,$$

$$i_n = i, \quad x, x_n \in \Omega_i, \quad \Omega_i \subseteq \mathbb{R}^{d_i} \quad \text{for some } i, \quad \text{and } \|x_n - x\|_{\mathbb{R}^{d_i}} < \varepsilon.$$

With the understanding of the above topology we suppress the second variable i from Ω. We follow the same for A, C, and D. We make the following basic assumptions on the sets A, C, D, and on functions f and g.

(A1): Each Ω_i is the closure of a connected, open subset of $\mathbb{R}^{d_i}$.

(A2): A_i, C_i, D_i are closed, ∂A_i,∂C_i are C^2. For all i and for all $x \in D_i$, $|x| < R$, and $\partial A_i \supseteq \partial \Omega_i$ for all i.

(A3): $g : A \times V_1 \to D$ is a bounded, uniformly Lipschitz continuous map, with Lipschitz constant G with the understanding that $g = \{g_i\}$ and $g_i : A_i \times V \to D_j$.

(A4): Vector field f is Lipschitz continuous with Lipschitz constant L in the state variable x and uniformly continuous in control variable u. Also,

$$|f(x, u)| \leq F \quad \forall x \in \Omega \quad \text{and} \quad \forall u \in U. \tag{2.3}$$

(A5): We assume ∂A_i is compact for all i, and for some $\xi_0 > 0$, following transversality condition holds

$$f(x_0, u) \cdot \eta(x_0) \leq -2\xi_0 \ \ \forall x_0 \ \in \ \partial A_i \ \ \forall u \in U, \tag{2.4}$$

where $\eta(x_0)$ is the unit outward normal to ∂A_i at x_0. We assume a similar transversality condition on ∂C_i.

(A6):

$$\inf_i d(A_i, C_i) \geq \beta \quad \text{and} \quad \inf_i \ d(A_i, D_i) \geq \beta > 0, \tag{2.5}$$

where d is the appropriate Euclidean distance. Note that the above rules out infinitely many jumps in finite time.

(A7): We assume the control sets U and V_1 to be compact metric spaces.

Now $(u(\cdot), v, \xi_i, X(\xi_i)')$ is the control, and the total discounted cost is given by

$$J(x, u(\cdot), v, \xi_i, X(\xi_i)') = \int_0^\infty K(X_x(t), u(t))e^{-\lambda t}dt + \sum_{i=0}^{\infty} C_a(X(\sigma_i), v)e^{-\lambda\sigma_i} + \sum C_c(X(\xi_i), X(\xi_i)')e^{-\lambda\xi_i}, \tag{2.6}$$

where λ is the discount factor, $K : \Omega \times \mathcal{U} \to \mathbb{R}_+$ is the running cost, $C_a : A \times V_1 \to \mathbb{R}_+$ is the autonomous jump cost, and $C_c : C \times D \to \mathbb{R}_+$ is the controlled jump cost. The value function V is then defined as

$$V(x) = \inf_{\theta \in (\mathcal{U} \times V_1 \times [0,\infty) \times D)} J(x, u(\cdot), v, \xi_i, X(\xi_i)'). \tag{2.7}$$

We assume the following conditions on the cost functionals.

(C1): K is Lipschitz continuous in the x variable with Lipschitz constant K_1 and is uniformly continuous in the u variable. Moreover, K is bounded by K_0.

(C2): C_a and C_c are uniformly continuous in both variables and bounded below by $C' > 0$. Moreover, C_a is Lipschitz continuous in the x variable with Lipschitz constant C_1 and is bounded above by C_0. Also we assume

$$C_c(x, y) < C_c(x, z) + C_c(z, y) \quad \forall x \in C_i, z \in D \cap C_j, y \in D.$$

We now give two simple examples of hybrid control systems. For more examples, see [5].

Example 2.1 (collisions). Consider the ball of mass m which is moving in vertical and horizontal directions in a room under gravity with gravitational constant g. The dynamics can be given as

$$\begin{aligned} \dot{x} &= v_x, \quad \dot{v_x} = 0, \\ \dot{y} &= v_y, \quad \dot{v_y} = -mg. \end{aligned}$$

On hitting the boundaries of the room $A_1 = \{(x, y)|y = 0, \text{ or } y = R_1\}$ we instantly set v_y to $-\rho v_y$ for some $\rho \in [0, 1]$, the coefficient of restitution. Similarly we reset v_x to $-\rho v_x$ on hitting the boundary $A_2\{(x, y)|x = 0 \text{ or } x = R_2\}$. Thus in this case the sets A_1 and A_2 are autonomous jump sets. We can generalize the above system by allowing dynamics to occur in different $\mathbb{R}^d$ after hitting.

The next example illustrates the importance of the transversality condition, in the absence of which the optimal trajectory and hence the optimal control may fail to exist.

Example 2.2. Consider the dynamical system in $\mathbb{R}^2$ given by

$$\begin{aligned} \dot{x_1}(t) &= 1, \quad x_1(0) = 0, \\ \dot{x_2}(t) &= u, \quad x_2(0) = 0, \end{aligned}$$

where $u \in [0, 1]$, and when the trajectory hits the set A given by $A = \{(x_1, x_2)|(x_1 - 1)^2 + (x_2 + 1)^2 = 1\}$ it jumps to $(10^{10}, 10^{10})$. The cost is given by $\int_0^\infty e^{-t} \min\{|x_1(t) + x_2(t)|, 210^{10}\}$.

Here the vector field $(u, 1)$ is not transversal to the boundary at $(1, 0)$ for $u = 0$. Hence optimal trajectory does not exist and, moreover, the value function is discontinuous at $(1, 0)$.

In the following sections we are interested in exploring the value function of the hybrid control problem defined in (2.7). In section 2 we show that the value function is bounded and locally Hölder continuous with respect to the initial point. In section 3, we use viscosity solution techniques and the dynamic programming principle to derive a partial differential equation satisfied by V in the viscosity sense, which turns out to be the Hamilton–Jacobi–Bellman QVI. Section 4 deals with uniqueness of the solution of the QVI. We give a comparison principle proof characterizing the value function as unique viscosity solution of the QVI.

3. Continuity of the value function. Let the trajectory given by the solution of (2.1) and starting from the point x be denoted by $X_x(t, u(\cdot))$. Since $x \in \Omega$, it belongs in particular to some Ω_i. Then we have from the theory of ordinary differential equations

$$|X_x(t, u(\cdot)) - X_z(t, u(\cdot))| \le e^{Lt}|x - z|, \tag{3.1}$$

$$|X_x(t, u(\cdot)) - X_x(\bar{t}, u(\cdot))| \le F|t - \bar{t}|, \tag{3.2}$$

where F and L are as in (A4).

Define the first hitting time of the trajectory as

$$T(x) = \inf_u \{t > 0 \mid X_x(t, u) \in A\}.$$

Notice that this $T(x)$ is in particular with respect to A_i as $x \in \Omega_i$. By assuming a suitable transversality condition on ∂A_i and ∂C_i we prove the continuity of T in the topology of $\mathbb{R}^{d_i}$. This is equivalent to proving the continuity of T on Ω with respect to the inductive limit topology on Ω. Hereafter by convention we assume the topology to be of that Ω_i, in which the respective points belong.

THEOREM 3.1. *Assume* (A1)–(A7). *Let $X(t)$ be the trajectory given by the solution of* (2.1)*. Let the first hitting time $T(x)$ be finite. Then it is locally Lipschitz continuous, i.e., there exists a $\delta_1 > 0$ depending on f, ξ_0, and the distance function from ∂A_i such that for all y, $\bar{y}$ in $B(x, \delta_1)$, a δ_1 neighborhood of x in Ω*

$$|T(y) - T(\bar{y})| < C|y - \bar{y}|, \quad \textit{where } C \textit{ depends on } \xi_0.$$

Proof. Step 1. *Estimates for points near ∂A.* First we show that there exist $\delta > 0$ and $C > 0$ such that

$$T(x) < C\, d(x) \quad \forall x \in B(A_i, \delta) \setminus \overset{\circ}{A},$$

where $B(A_i, \delta)$ is a δ neighborhood of A_i and $d(x)$ is a signed distance of x from ∂A_i given by

$$d(x) = \begin{cases} -\operatorname{dist}(x, \partial A_i) & \text{if } x \in \overset{\circ}{A}_i, \\ 0 & \text{if } x \in \partial A_i, \\ \operatorname{dist}(x, \partial A_i) & \text{if } x \in \bar{A}_i^c. \end{cases}$$

For simplicity of notation we drop the suffix i from now on, remembering that the distances are in $\mathbb{R}^{d_i}$. It is possible to choose $R > 0$ such that in a small neighborhood of ∂A, say $B(\partial A, R)$, the above signed distance function d is C^1, thanks to our assumption (A2).

Now for $x_0 \in \partial A$ choose u_0 in $\mathcal{U}$ such that $u_0(t) = u_0$ for all t and $r_0 < R$ such that

$$f(x, u_0) \cdot Dd(x) < -\xi_0 \quad \forall x \in B(x_0, r_0). \tag{3.3}$$

Observe that we can choose r_0 independent of x_0 by using compactness of ∂A. Now consider the trajectory starting from x, given by

$$\begin{aligned} \dot{X}(t) &= f(X(t), u_0), \\ X(0) &= x, \end{aligned}$$

where $x \in B(x_0, r_0)$. Then

$$\begin{aligned} d(X(s)) - d(x) = &\int_0^s Dd(x) \cdot f(x, u_0)\ d\tau + \int_0^s \big(Dd(X(\tau)) - Dd(x)\big) \cdot f(X(\tau), u_0)\ d\tau \\ &+ \int_0^s Dd(x) \cdot (f(X(\tau), u_0) - f(x, u_0))\ d\tau. \end{aligned}$$

By using (3.3) and (2.3),

$$\begin{aligned} d(X(s)) - d(x) \le &\int_0^s -\xi_0\ d\tau + F \int_0^s (Dd(X(\tau)) - Dd(x))\ d\tau \\ &+ \int_0^s Dd(x) \cdot (f(X(\tau), u_0) - f(x, u_0))\ d\tau. \end{aligned}$$

Let c be the bound on Dd on $B(\partial A, r_0)$. Restricting s to be small so that $X(\tau)$ is in the r_0 neighborhood of ∂A, we are assured that Dd is continuous. So is f. Thus

$$\begin{aligned} d(X(s)) - d(x) &\le -\xi_0 s + o(Fs)\ + o(cLs) \\ &< -\frac{1}{2}\xi_0 s \quad \text{for } \ 0 < s < \bar{s} \end{aligned}$$

for some $\bar{s}$ dependent only on modulus of continuity of f and Dd and independent of x. Choose $\delta = \min\{r_0, \frac{\bar{s}\xi_0}{2}\}$. If x is in the δ ball around x_0, then $d(x) < \frac{\bar{s}\xi_0}{2}$ and, choosing $s_x = 2\frac{d(x)}{\xi_0}$, will imply

$$s_x < \bar{s} \quad \text{and hence} \quad d\,(X(s_x)) < 0.$$

Thus by our definition of d, $X(s_x) \in \overset{\circ}{A}$, which implies

$$T(x) < s_x = 2\frac{d(x)}{\xi_0}.$$

Then for $C = \frac{2}{\xi_0}$ we have

$$T(x) < Cd(x) \quad \forall x \in B(x_0, \delta) \setminus \overset{\circ}{A}\,.$$

Step 2. *Estimate for any two points in* Ω. In this step we estimate $|T(x) - T(\bar{x})|$ for any $x, \bar{x} \in \Omega$. Define

$$t(\bar{x}, \bar{u}) = \inf\{t > 0 \mid X(t) \in A, \dot{X}(t) = f(X(t), \bar{u}), X(0) = \bar{x}\}.$$

For given $0 < \epsilon < 1$, and $\bar{x} \in \Omega$ by the definition of $T(\bar{x})$, we can choose $\bar{u} \in \mathcal{U}$ such that

$$\bar{t} = t(\bar{x}, \bar{u}) < T(\bar{x}) + \epsilon. \tag{3.4}$$

Using estimate (3.1),

$$|X_{\bar{x}}(\bar{t}, \bar{u}) - X_x(\bar{t}, \bar{u})| \leq |\bar{x} - x| e^{L\bar{t}} \leq |\bar{x} - x| e^{L(T(\bar{x})+\varepsilon)}. \tag{3.5}$$

Define $\delta_1 = \delta e^{-L(T(\bar{x})+1)}$, where δ is as in Step 1. Let us choose x such that $|x - \bar{x}| < \delta_1$. Then

$$|X_{\bar{x}}(\bar{t}, \bar{u}) - X_x(\bar{t}, \bar{u})| \leq |\bar{x} - x| e^{L\bar{t}} < |\bar{x} - x| e^{L(T(\bar{x})+1)} < \delta.$$

Also we have $X_{\bar{x}}(\bar{t}, \bar{u}) \in \partial A$. Hence, $X_x(\bar{t}, \bar{u}) \in B(\partial A, \delta) \setminus \overset{\circ}{A}$. Therefore, by Step 1,

$$T(X_x(\bar{t}, \bar{u})) < C d(X_x(\bar{t}, \bar{u})). \tag{3.6}$$

We claim that

$$T(x) \leq \bar{t} \ + T(X_x(\bar{t}, \bar{u})). \tag{3.7}$$

For given $\varepsilon_1 > 0$, choose $u_1 \in \mathcal{U}$ such that

$$T(X_x(\bar{t}, \bar{u})) \geq t(X_x(\bar{t}, \bar{u}), u_1) - \varepsilon_1.$$

Define a new control u_2 by

$$u_2(s) = \begin{cases} \bar{u}(s) & \text{if } s \leq \bar{t}, \\ u_1(s - \bar{t}) & \text{if } s > \bar{t}. \end{cases}$$

Then

$$T(x) \leq t(x, u_2) \leq \bar{t} + t\left(X_x(\bar{t}, \bar{u}), u_1\right) \leq \bar{t} + T\left(X_x(\bar{t}, \bar{u})\right) + \varepsilon_1.$$

Since ε_1 is arbitrary, this proves (3.7). Using (3.4) and (3.7) for $x \in B(\bar{x}, \delta_1)$ we get

$$\begin{aligned} T(x) &\leq T(\bar{x}) + T(X_x(\bar{t}, \bar{u})) + \epsilon \\ &\leq T(\bar{x}) + C\ d(X_x(\bar{t}, \bar{u})) + \epsilon \quad \text{by (3.6)}. \end{aligned}$$

Notice that $d(X_x(\bar{t}, \bar{u})) \leq |X_x(\bar{t}, \bar{u}) - X_{\bar{x}}(\bar{t}, \bar{u})|$. So by (3.5)

$$T(x) \leq T(\bar{x}) + C\ |x - \bar{x}|\ e^{L(T(\bar{x})\,+\,\varepsilon)} + \epsilon.$$

Interchanging the roles of x and $\bar{x}$ we get

$$|T(x) - T(\bar{x})| \leq C\ |x - \bar{x}|\ e^{L(T(\bar{x}) \vee T(x))} \tag{3.8}$$

as ϵ tends to 0, where $T(\bar{x}) \vee T(x) = \max\{T(\bar{x}),\ T(x)\}$. Also observe that

$$\begin{aligned} T(x) &\leq T(\bar{x}) + C\ |x - \bar{x}|\ e^{L(T(\bar{x})+\varepsilon)} + \epsilon \\ &\leq T(\bar{x}) + C\delta + \varepsilon \leq T(\bar{x}) + C\delta + 1 \\ &\leq T(\bar{x}) + 2. \end{aligned}$$

Hence for all x belonging to $B(\bar{x}, \delta_1)$, T is bounded. Let this bound be T_0. Then we have

$$|T(x) - T(\bar{x})| < C|x - \bar{x}|e^{LT_0}.$$

Hence we conclude that the first hitting time of trajectory is locally Lipschitz continuous with respect to the initial point. □

Now we take up the issue of continuity of the value function. For this proof we need some estimates on hitting times of trajectories starting from two nearby points. We prove these estimates in the following lemmas. We fix the controls $\bar{u}$ and $\bar{v}$ and suppress them in the following calculations.

LEMMA 3.2. *Let σ_1 and Σ_1 be the first hitting times of trajectories evolving with fixed controls $\bar{u}$ and $\bar{v}$ according to* (2.1) *starting from x and z, respectively. Let x_1 and z_1 be points where these trajectories hit A for the first time:*

$$x_1 = X_x(\sigma_1), \quad z_1 = X_z(\Sigma_1), \quad x_1, z_1 \in \partial A.$$

If $|x - z| < \delta_1$, where δ_1 is as in Theorem 3.1*, then*

$$|x_1 - z_1| \leq (1 + FC)e^{L(\Sigma_1 \vee \sigma_1)}|x - z|. \tag{3.9}$$

Proof. Note here that by Theorem 3.1 we have the estimate on $|\sigma_1 - \Sigma_1|$ given by (3.8),

$$|\sigma_1 - \Sigma_1| < Ce^{L(\Sigma_1 \vee \sigma_1)}\ |x - z|. \tag{3.10}$$

Using this we estimate $|x_1 - z_1|$. Without loss of generality we assume that $\Sigma_1 > \sigma_1$,

$$\begin{aligned} |x_1 - z_1| &= |X_x(\sigma_1) - X_z(\Sigma_1)| \\ &\leq |X_x(\sigma_1) - X_z(\sigma_1)| + |X_z(\sigma_1) - X_z(\Sigma_1)|. \end{aligned}$$

Using (3.1) we get

$$|X_x(\sigma_1) - X_z(\sigma_1)| < e^{L\sigma_1}|x - z|,$$

while (3.2) and (3.10) lead to

$$|X_z(\sigma_1) - X_z(\Sigma_1)| \leq F|\sigma_1 - \Sigma_1| \leq FCe^{L\Sigma_1}|x - z|.$$

Combining these estimates, we get

$$|x_1 - z_1| \leq e^{L\Sigma_1}|x - z|(1 + FC) \quad \text{for} \quad z \in B(x, \delta_1). \qquad \square$$

Observe that the destination points of x_1 and z_1, which are denoted by ${x_1}' = g(x_1, \bar{v})$ and ${z_1}' = g(z_1, \bar{v})$, may belong to $\Omega_j \subseteq \mathbb{R}^{d_j}$. Without loss of generality we assume that ${x_1}', {z_1}' \in \Omega_2 \subseteq \mathbb{R}^{d_2}$, and the evolution of trajectories takes place in Ω_2 till the next hitting time. Let σ_2 and Σ_2 be the next hitting times of the trajectories when they hit A once again. The next lemma deals with the estimate of $|\sigma_2 - \Sigma_2|$.

LEMMA 3.3. *Let the first hitting time of trajectories starting from x and z, and evolving with fixed control $\bar{u}$, be σ_1 and Σ_1, and the second hitting times are σ_2 and Σ_2. Then there exists δ_2 such that for $|x - z| < \delta_2$,*

$$|\sigma_2 - \Sigma_2| \leq Ce^{(\Sigma_2 \vee \sigma_2)}(FC + G(FC + 1))|x - z| \tag{3.11}$$

and if we denote

$$x_2 = X_{x_1'}(\sigma_2 - \sigma_1), \quad x_2' = g(x_2),$$
$$z_2 = X_{z_1'}(\Sigma_2 - \Sigma_1), \quad z_2' = g(z_2),$$

then

$$|x_2 - z_2| \le (FC+1)e^{L(\Sigma_2 \vee \sigma_2)}(FC + G(FC+1))|x - z|. \tag{3.12}$$

Proof. Without loss of generality let $\sigma_1 < \Sigma_1$. Observe that σ_2 and Σ_2 are the first hitting times of trajectories starting from points $X_{x_1'}(\Sigma_1 - \sigma_1)$ and z_1' at time $t = \Sigma_1$. Then

$$T(z_1') = (\Sigma_2 - \Sigma_1) \quad \text{and} \quad T(X_{x_1'}(\Sigma_1 - \sigma_1)) = \sigma_2 - \Sigma_1.$$

Hence by (3.8)

$$|\sigma_2 - \Sigma_2| \le Ce^{L(\Sigma_2 - \Sigma_1)}|X_{x_1'}(\Sigma_1 - \sigma_1) - z_1'|$$

whenever $|X_{x_1'}(\Sigma_1 - \sigma_1) - z_1'| \le \delta_1$. Now

$$|X_{x_1'}(\Sigma_1 - \sigma_1) - z_1'| \le |X_{x_1{}'}(\Sigma_1 - \sigma_1) - x_1'| + |x_1' - z_1'|.$$

Hence by using estimate (3.2) and (3.10) for the first term we have

$$|X_{x_1'}(\Sigma_1 - \sigma_1) - x_1'| \le F|\Sigma_1 - \sigma_1| \le FCe^{L\Sigma_1}|x - z|,$$

whereas using Lipschitz continuity of g and (3.9) for the second term we get

$$|x_1' - z_1'| \le G|x_1 - z_1| \le G(FC+1)e^{L\Sigma_1}|x - z| \quad \text{for} \quad z \in B(x, \delta_1).$$

Combining the above two estimates we have

$$|X_{x_1'}(\Sigma_1 - \sigma_1) - z_1'| \le e^{L\Sigma_1}(FC + G(FC+1))|x - z| \tag{3.13}$$

and by our choice of $\delta_2 = \min\{\delta_1, \frac{\delta_1 e^{-L\Sigma_1}}{FC+G(FC+1)}\}$, $|X_{x_1'}(\Sigma_1 - \sigma_1) - z_1'| < \delta_1$. Using (3.13) in the estimate of $|\sigma_2 - \Sigma_2|$ for $z \in B(x, \delta_2)$ we have

$$|\sigma_2 - \Sigma_2| \le Ce^{L\Sigma_2}(FC + G(FC+1))|x - z|. \tag{3.14}$$

Now we estimate $|x_2 - z_2|$:

$$\begin{aligned} |x_2 - z_2| &= |X_{x_1'}(\sigma_2 - \sigma_1) - X_{z_1'}(\Sigma_2 - \Sigma_1)| \\ &\le |X_{x_1'}(\sigma_2 - \sigma_1) - X_{z_1'}(\sigma_2 - \Sigma_1)| + |X_{z_1'}(\sigma_2 - \Sigma_1) - X_{z_1'}(\Sigma_2 - \Sigma_1)|. \end{aligned}$$

Observe that by the semigroup property

$$X_{x_1'}(\sigma_2 - \sigma_1) = X_{X_{x_1'}(\Sigma_1 - \sigma_1)}(\sigma_2 - \Sigma_1).$$

Hence

$$|X_{x_1'}(\sigma_2 - \sigma_1) - X_{z_1'}(\sigma_2 - \Sigma_1)| = |X_{X_{x_1'}(\Sigma_1 - \sigma_1)}(\sigma_2 - \Sigma_1) - X_{z_1'}(\sigma_2 - \Sigma_1)|$$

and by (3.1)

$$|X_{x_1'}(\sigma_2-\sigma_1)-X_{z_1'}(\sigma_2-\Sigma_1)| \le e^{L(\sigma_2-\Sigma_1)}|X_{x_1'}(\Sigma_1-\sigma_1)-z_1'|. \tag{3.15}$$

From (3.2) and (3.14) we get

$$\begin{aligned}|X_{z_1'}(\sigma_2-\Sigma_1)-X_{z_1'}(\Sigma_2-\Sigma_1)| &\le F|\sigma_2-\Sigma_1-(\Sigma_2-\Sigma_1)|\\ &\le FCe^{L\Sigma_2}(FC+G(FC+1))|x-z|.\end{aligned} \tag{3.16}$$

Together these estimates yield, for $z \in B(x,\delta_2)$,

$$|x_2-z_2| \le e^{L\Sigma_2}(FC+1)(FC+G(FC+1))|x-z|. \qquad \square$$

Let σ_i and Σ_i be the ith hitting times of trajectories starting from x and z, respectively. With the above notation we assume that $x_i', z_i' \in \Omega_{i+1} \subseteq \mathbb{R}^{d_{i+1}}$. We apply Theorem 3.1 and the above lemmas recursively to find estimates on successive hitting times and points where trajectories hit A. We generalize the above estimates for the ith hitting times of trajectories when they hit A. For simplicity of calculations we denote $FC+G(FC+1)$ by P hereafter.

REMARK 3.4. *Let the control $\bar{u}$ be fixed. Let σ_i and Σ_i be the ith consecutive hitting time of the trajectory starting from x and z, respectively, when they hit A, and let x_i, z_i be the points on ∂A where trajectories hit A. Then proceeding along lines similar to those of Lemmas* 3.2 *and* 3.3 *we get the estimates for $|\sigma_i-\Sigma_i|$ and $|x_i-z_i|$ which are given by*

$$\begin{aligned}|\sigma_i-\Sigma_i| &\le Ce^{L\Sigma_i}P^{i-1}|x-z|,\\ |x_i-z_i| &\le e^{L\Sigma_i}(FC+1)P^{i-1}|x-z|\end{aligned}$$

whenever $|x-z|<\delta_i$, where $\delta_i := \min\{\delta_1,\delta_2,\ldots,\frac{\delta_1 e^{-L\Sigma_i}}{P^{i-1}}\}$.

THEOREM 3.5 (continuity of the value function). *Under the assumptions of Theorem* 3.1*, value function V of hybrid control problem defined by* (2.7) *is bounded and locally Hölder continuous with respect to the initial point.*

Proof. First we show that the value function is bounded. For any $u \in \mathcal{U}$ and $v \in V_1$,

$$V(x) \le \int_0^\infty K(X_x(t),u(t))e^{-\lambda t}dt + \sum_{i=0}^{\infty} C_a(X(\sigma_i),v)e^{-\lambda\sigma_i}.$$

By our assumptions (C1) and (C2),

$$V(x) \le K_0\int_0^{+\infty} e^{-\lambda t}\,dt \;+\sum_{i=1}^{+\infty} C_0e^{\lambda\sigma_i} \le \frac{K_0}{\lambda} \;+C_0\sum_{i=1}^{+\infty} e^{-\lambda\sigma_i}.$$

From (A5), recalling that $\beta = \inf\ d(A_i,D_i)$,

$$\sigma_{i+1} \;\ge\; \sigma_i + \frac{\beta}{\sup|f(x,u)|} \;\ge\; \sigma_i+\beta/F. \tag{3.17}$$

Hence we get

$$\sum_{i=1}^{\infty} e^{-\lambda\sigma_i} \le e^{-\lambda\sigma_1}\sum_{i=1}^{\infty}\left(e^{-\lambda\beta/F}\right)^i \le e^{-\lambda\sigma_1}\frac{1}{1-e^{-\lambda\beta/F}}, \tag{3.18}$$

leading to

$$V(x) \le \frac{K}{\lambda} + C_0 e^{-\lambda\sigma_1} \frac{1}{1 - e^{-\lambda\beta/F}}.$$

This proves $V(x)$ is bounded.

We now show that V defined in (2.7) is locally Hölder continuous with respect to the initial point. Let $x, z \in \Omega$. Regarding $V(x)$ as in (2.7), we assume that the controller chooses not to make any controlled jumps. Note that the controller has this choice because in the interior of C he can always choose not to jump. On the boundary of C that is ∂C by the transversality condition, vector field is nonzero and hence he can continue the evolution without jumping. Thus in any case he can choose not to jump. Then given $\varepsilon > 0$, we can choose the controls $\overline{u}, \overline{v}$ depending on ε such that

$$V(z) \ge \int_0^\infty K(X_z(t), \overline{u}(t)) e^{-\lambda t} dt + \sum_{i=1}^\infty C_a(X_z(\Sigma_i), \overline{v}) e^{-\lambda\Sigma_i} - \varepsilon.$$

Also

$$V(x) \le \int_0^\infty K(X_x(t), \bar{u}(t)) e^{-\lambda t} dt + \sum_{i=1}^\infty C_a(X_x(\sigma_i), \bar{v}) e^{-\lambda\sigma_i}.$$

Hence

$$\begin{aligned} V(x) - V(z) \le & \int_0^\infty |K(X_x(t), \overline{u}(t)) - K(X_z(t), \overline{u}(t))| e^{-\lambda t} dt \\ & + \sum_{i=1}^\infty |C_a(X_x(\sigma_i), \overline{v}) - C_a\big(X_z(\Sigma_i), \overline{v}\big)| e^{-\lambda(\sigma_i \vee \Sigma_i)} + \varepsilon, \end{aligned}$$

where $\sigma_i \vee \Sigma_i = \max\{\sigma_i, \Sigma_i\}$. Now for T large to be chosen precisely later on we split the integral and summation as follows:

$$\begin{aligned} V(x) - V(z) \le & \int_0^T |K(X_x(t), \overline{u}(t)) - K(X_z(t), \overline{u}(t))| e^{-\lambda t} dt \\ & + \sum_{i=1}^N |C_a(X_x(\sigma_i), \overline{v}) - C_a(X_z(\Sigma_i), \overline{v})| e^{-\lambda(\sigma_i \vee \Sigma_i)} \\ & + \int_T^\infty |K(X_x(t), \overline{u}(t)) - K(X_z(t), \overline{u}(t))| e^{-\lambda t} dt \\ & + \sum_{i=N+1}^\infty |C_a(X_x(\sigma_i), \overline{v}) - C_a(X_z(\Sigma_i), \overline{v})| e^{-\lambda(\sigma_i \vee \Sigma_i)} + \varepsilon, \end{aligned} \tag{3.19}$$

where T will be chosen so that the tail end of the integral and summation become small and T is in between the Nth and $(N+1)$th hitting times of the trajectories. By using the bound K_0 on K given by (C1) we get

$$\int_T^\infty |K(X_x(t), \overline{u}(t)) - K(X_z(t), \overline{u}(t))| e^{-\lambda t} dt \le \frac{2K_0}{\lambda} e^{-\lambda T} \tag{3.20}$$

and by using bound C_0 on C_a given by (C2) and doing calculations along lines similar to those of (3.18) we get the estimate

(3.21)
$$\sum_{i=N+1}^{\infty} |C_a(X_x(\sigma_i),\overline{v}) - C_a(X_z(\Sigma_i),\overline{v})|e^{-\lambda(\sigma_i\vee\Sigma_i)} \le 2C_0\big(e^{-\lambda\beta/F}\big)^N \frac{1}{1-e^{-\lambda\beta/F}}.$$

Now we calculate $\int_0^T |K(X_x(t),\overline{u}(t)) - K(X_z(t),\overline{u}(t))|e^{-\lambda t}dt$. We will show that there exists $\bar{\delta} > 0$ such that if $|x-z| < \bar{\delta}$, then the sequence of σ_i and Σ_i can be, for example,

$$0 \le \sigma_1 \le \Sigma_1 \le \sigma_2 \le \Sigma_2 \le \cdots \le \sigma_n \le \Sigma_n \le T \tag{3.22}$$

$$\text{or} \quad 0 \le \Sigma_1 \le \sigma_1 \le \cdots \le \Sigma_n \le \sigma_n \le T.$$

That is, every A hitting time of trajectory starting from x is followed by A hitting time of trajectory starting from z.

Without loss of generality let us assume $\sigma_1 < \Sigma_1$. If $\Sigma_1 < \sigma_1$, the following calculations go through with appropriate changes and hence we split this integral, assuming (3.22) as follows:

$$\begin{aligned}\int_0^T Ie^{-\lambda t}dt \le{}& \int_0^{\sigma_1} Ie^{-\lambda t}dt + \int_{\sigma_1}^{\Sigma_1} Ie^{-\lambda t}dt + \int_{\Sigma_1}^{\sigma_2} Ie^{-\lambda t}dt + \cdots \\ &+ \int_{\sigma_n}^{\Sigma_n} Ie^{-\lambda t}dt + \int_{\Sigma_n}^{\sigma_{n+1}} Ie^{-\lambda t}dt,\end{aligned} \tag{3.23}$$

where $I = |K(X_x(t),\overline{u}(t)) - K(X_z(t),\overline{u}(t))|$. In this there are two types of integrals:

1. $\int_{\sigma_i}^{\Sigma_i} Ie^{-\lambda t}dt$;
2. $\int_{\Sigma_i}^{\sigma_{i+1}} Ie^{-\lambda t}dt$.

If $|x-z| < \delta_N$, where $\delta_N = \min\{\delta_1,\delta_2,\ldots,\frac{\delta_1 e^{-L\Sigma_N}}{P^{N-1}}\}$, we can estimate the above integrals using Lemmas 3.2 and 3.3 and Remark 3.4. We use the bound on K to evaluate the first integral.

$$\int_{\sigma_i}^{\Sigma_i} Ie^{-\lambda t}dt \le \frac{2K_0}{\lambda}\big(e^{-\lambda\sigma_i} - e^{-\lambda\Sigma_i}\big) \le \frac{2K_0}{\lambda}\,\lambda|\sigma_i - \Sigma_i|.$$

Using Remark 3.4,

$$\int_{\sigma_i}^{\Sigma_i} Ie^{-\lambda t}dt \le 2K_0CP^{i-1}e^{L\Sigma_i}. \tag{3.24}$$

To evaluate the second integral we use the Lipschitz continuity of K.

$$\begin{aligned}\int_{\Sigma_i}^{\sigma_{i+1}} Ie^{-\lambda t}dt &= \int_{\Sigma_i}^{\sigma_{i+1}} |K\big(X_{x_i'}(t-\sigma_i)\big) - K\big(X_{z_i'}(t-\Sigma_i)\big)|e^{-\lambda t}dt \\ &\le K_1\int_{\Sigma_i}^{\sigma_{i+1}} |X_{x_i'}(t-\sigma_i) - X_{z_i'}(t-\Sigma_i)|e^{-\lambda t}dt.\end{aligned} \tag{3.25}$$

By the semigroup property,

$$|X_{x_i'}(t-\sigma_i) - X_{z_i'}(t-\Sigma_i)| = |X_{X_{x_i'}(\Sigma_i-\sigma_i)}(t-\Sigma_i) - X_{z_i'}(t-\Sigma_i)|$$
$$\leq e^{L(t-\Sigma_i)}|X_{x_i'}(\Sigma_i-\sigma_i) - z_i'| \quad \text{by (3.1).}$$

Now by generalizing the estimate in (3.13) we get

$$|X_{x_i'}(\Sigma_i-\sigma_i) - z_i'| \leq P^i e^{L\Sigma_i}|x-z|. \tag{3.26}$$

Hence substituting the above estimates in (3.25), we get

$$\int_{\Sigma_i}^{\sigma_{i+1}} Ie^{-\lambda t}dt \leq K_1 e^{-L\Sigma_i}P^i e^{L\Sigma_i}|x-z| \int_{\Sigma_i}^{\sigma_{i+1}} e^{(L-\lambda)t}dt.$$

For $L \neq \lambda$,

$$\int_{\Sigma_i}^{\sigma_{i+1}} Ie^{-\lambda t}dt \leq K_1 P^i\ |x-z|\ \frac{e^{(L-\lambda)(\sigma_{i+1})} - e^{(L-\lambda)\Sigma_i}}{L-\lambda} \tag{3.27}$$
$$\leq K_1 P^i |x-z|\ \frac{e^{(L-\lambda)T}-1}{L-\lambda}$$

and for $L = \lambda$,

$$\int_{\Sigma_i}^{\sigma_{i+1}} Ie^{-\lambda t}dt \leq K_1 e^{-L\Sigma_i}P^i e^{L\Sigma_i}|x-z| \int_{\Sigma_i}^{\sigma_{i+1}} dt \tag{3.28}$$
$$\leq K_1 P^i |x-z|\ |\sigma_{i+1}-\Sigma_i|$$
$$\leq K_1 P^i\ |x-z|\ \ 2T.$$

For $L \neq \lambda$, by using (3.24), (3.27), $\int_0^T Ie^{-\lambda t}dt$ becomes

$$\int_0^T Ie^{-\lambda t}dt \leq \sum_{i=1}^N 2K_0 C P^{i-1}e^{LT}|x-z| + \sum_{i=1}^N \frac{K_1}{L-\lambda}P^i\big(e^{(L-\lambda)T}-1\big)|x-z|.$$

Hence

$$\left.\begin{aligned}\int_0^T Ie^{-\lambda t}dt \leq\ & 2K_0 C\left[\tfrac{P^N-1}{P-1}\right]|x-z| \\ & + K_1\left[\tfrac{P^N-1}{P-1}\right]\tfrac{e^{(L-\lambda)T}-1}{L-\lambda}|x-z|\end{aligned}\right\} \quad \text{for } L \neq \lambda \tag{3.29}$$

and for $L = \lambda$, using (3.24) and (3.28),

$$\int_0^T Ie^{-\lambda t}dt \leq \sum_{i=1}^N 2K_0|\sigma_i - \Sigma_i| + \sum_{i=1}^N K_1 T P^i |x-z|$$
$$\leq \sum_{i=1}^N 2K_0 C P^{i-1}|x-z| + \sum_{i=1}^N K_1 T P^i |x-z|.$$

Thus

$$\left.\begin{aligned}\int_0^T Ie^{-\lambda t}dt \leq\ & 2K_0 C\left(\tfrac{P^N-1}{P-1}\right)|x-z| \\ & + 2K_1 T\left(\tfrac{P^N-1}{P-1}\right)|x-z|\end{aligned}\right\} \quad \text{for } L = \lambda. \tag{3.30}$$

Furthermore, by using (C2) and Remark 3.4 we get

$$\sum_{i=1}^{N} |C_a(x_i,\overline{v}) - C_a(z_i,\overline{v})| e^{-\lambda(\sigma_i \vee \Sigma_i)} \leq \sum_{i=1}^{N} 2C_1 |x_i - z_i| e^{-\lambda(\sigma_i \vee \Sigma_i)} \leq 2C_1 \sum_{i=1}^{N} (FC+1) e^{LT} P^{i-1} |x-z|,$$

(3.31)
$$\sum_{i=1}^{N} |C_a(x_i,\overline{v}) - C_a(z_i,\overline{v})| e^{-\lambda(\sigma_i \vee \Sigma_i)} \leq 2C_1(FC+1) e^{LT} |x-z| \left(\frac{P^{N-1}-1}{P-1} \right).$$

Since P is a constant, without loss of generality we can assume

$$\frac{P^N}{P-1} < 2P^N. \tag{3.32}$$

Also observe that $\sigma_i - \sigma_{i+1} \geq \beta/F$ implies that $T \geq \sigma_{N+1} - \sigma_1 \geq N\beta/F$ and hence

$$N < TF/\beta. \tag{3.33}$$

Using (3.20), (3.21), (3.29), (3.31), (3.32), (3.33) in (3.19) for $L \neq \lambda$ we have

$$\begin{aligned} V(x) - V(z) \leq\ & 4K_0 C e^{LT} P^{TF/\beta}\ |x-z| + 2K_1 P^{TF/\beta}\ \frac{e^{(L-\lambda)T}-1}{L-\lambda} |x-z| \\ & + \frac{2K_0}{\lambda} e^{-\lambda T} + 2C_1 e^{LT} P^{TF/\beta}\ |x-z| \\ & + 2C_0 \left(e^{-\lambda\beta/F}\right)^{TF/\beta}\ \frac{1}{1-e^{-\lambda\beta/F}}. \end{aligned}$$

Now we further restrict $|x-z| < (\delta_1)^{\frac{1}{1-\theta}}$ for some θ such that $0 < \theta < 1$. Then choose T such that

$$P^{TF/\beta} e^{LT} = |x-z|^{-\theta}.$$

This gives

$$T = \frac{-\theta \log |x-z|}{\lambda + F \log P/\beta}. \tag{3.34}$$

This together with the choice of $|x-z|$ implies

$$\delta_N = \frac{\delta_1}{e^{L\Sigma_N} P^{N-1}} > \frac{\delta_1}{e^{LT} P^{TF/\beta}}\ =\ \delta_1 |x-z|^{\theta}\ >\ |x-z|. \tag{3.35}$$

Thus $|x-z| < \delta_N$ and hence the above estimate holds true for our choice of T. Then substituting the value of T in the above estimate, for $L \neq \lambda$, we get

$$\begin{aligned} V(x) - V(z) \leq\ & 4K_0 C |x-z|^{1-\theta} + \frac{K_1}{L-\lambda} |x-z|^{1-\theta} + C_1 |x-z|^{1-\theta} \\ & + \frac{2K_0}{\lambda} |x-z|^{\frac{\lambda\theta}{(F\log P/\beta)+L}}\ +\ 2C_0 |x-z|^{\frac{\lambda\theta}{(F\log P/\beta)+L}}. \end{aligned}$$

Here we have used the fact that $e^{(L-\lambda)T}-1<e^{LT}$. Thus we have proved that in the $\delta_1^{\frac{1}{1-\theta}}$ ball around x,

$$V(x)-V(z)<C_1|x-z|^{\theta_1} \quad \text{for some constant } C_1,$$

where

$$\theta_1=\min\left\{1-\theta,\ \frac{\lambda\ \theta}{(F\log P/\beta)+L}\right\} \quad \text{for } 0<\theta<1.$$

For $L=\lambda$, using (3.20), (3.21), (3.30), (3.31), (3.32), and (3.34) in (3.19), we have

$$\begin{aligned}V(x)-V(z)\le{}& 4K_0C|x-z|^{1-\theta}+2\frac{K_1}{(F\log P/\beta)+L}\log(|x-z|)|x-z|^{1-\theta}\\&+2C_1(FC+1)|x-z|^{1-\theta}+\frac{2K_0}{L}|x-z|^{\frac{L\theta}{(F\log P/\beta)+L}}\\&+2C_0|x-z|^{\frac{L\theta}{(F\log P/\beta)+L}}.\end{aligned}$$

Since $|x-z|^{1-\theta}$ goes to 0 faster than $\log(|x-z|)$ goes to $-\infty$ as $|x-z|\to 0$, all terms on the right-hand side (RHS) go to 0. The modulus of continuity of V is the same as that of $\log(r)r^{1-\theta}$. This suggests that in the $\delta_1^{\frac{1}{1-\theta}}$ ball around x,

$$V(x)-V(z)<C_1|x-z|^{\theta_1} \quad \text{for some constant } C_1$$

and for all θ_1 such that

$$\theta_1<\min\left\{1-\theta,\ \frac{L\theta}{(F\log P/\beta)+L}\right\} \quad \text{for } \ 0<\theta<1.$$

Thus in any case we have shown that (for θ_1 chosen depending on $L\neq\lambda$ or $L=\lambda$)

$$V(x)-V(z)\le C_1|x-z|^{\theta_1} \quad \text{for some constant } C_1.$$

Interchanging the roles of x and z we will get

$$V(z)-V(x)\le C_2|x-z|^{\theta_1} \quad \text{for some constant } C_2.$$

Together these will give

$$|V(x)-V(z)|\le C|x-z|^{\theta_1} \quad \text{for some constant } C.$$

This proves the Hölder continuity of V.

Now we want to justify our claim in (3.22), i.e., if $\sigma_1<\Sigma_1$, we can choose $|x-z|$ small enough such that (3.22) holds. If we restrict $|x-z|$ such that $|x-z|\le\min(\frac{\beta}{4FC}\ ,(\frac{\beta}{4CF})^{\frac{1}{1-\theta}})$, then by Remark 3.4,

$$|\Sigma_i-\sigma_i|\le Ce^{LT}(FC+G(FC+1))^{TF/\beta}|x-z|.$$

By our choice of T,

$$|\Sigma_i-\sigma_i|\le C|x-z|^{1-\theta}\le\frac{1}{4}\frac{\beta}{F}<\frac{1}{2}|\sigma_i-\sigma_{i+1}|$$

and this together with the assumption $\sigma_1<\Sigma_1$ implies $\sigma_i<\Sigma_i<\sigma_{i+1}$ for all i. So our claim is justified. □

4. Dynamic programming principle and the QVI. Under our assumptions (A1)–(A7), an optimal trajectory exists for any initial condition as shown in [5, Theorem 6.4]. The following dynamic programming principle and derivation of the QVI is also found in the literature [5], [4]. For the sake of completeness we prove it in detail here.

THEOREM 4.1 (dynamic programming principle). *Let V be the value function of the hybrid control problem as given in* (2.7). *If t_1 is the first hitting time of A, then*

$$V(x) = \inf_u \left\{ \int_0^{t_1} K(X(t), u(t)) e^{-\lambda t} dt + e^{-\lambda t} MV(X_x(t_1)) \right\}, \tag{DPPA}$$

where

$$M\phi(x) = \inf_{v \in \mathcal{V}} \{\phi(g(x,v)) + C_a(x,v)\}$$

and if t_1 is the first hitting time of C, then

$$V(x) = \inf_u \left\{ \int_0^{t_1} K(X(t), u(t)) e^{-\lambda t} dt + e^{-\lambda t} NV(X_x(t_1)) \right\}, \tag{DPPC}$$

where

$$N\phi(x) = \inf_{x' \in D} \{(\phi(x')) + C_c(x,x')\}.$$

For any $T > 0$,

$$\begin{aligned} V(x) = \inf_{u,v,\xi_i, X(\xi_i)'} \Bigg\{ & \int_0^T K(X_x(t), u(t)) e^{-\lambda t} dt + \sum_{\sigma_i < T} e^{-\lambda \sigma_i} C_a(X(\sigma_i), v) \\ & + \sum_{\xi_i < T} e^{-\lambda \xi_i} C_c\big(X(\xi_i), X(\xi_i)'\big) + e^{-\lambda T} V(X_x(T)) \Bigg\}. \end{aligned} \tag{DPP}$$

Proof. Let t_1 be the first hitting time of trajectory when it hits $A \cup C$. If t_1 is a first hitting time of A, we denote it by σ_1,

$$\begin{aligned} V(x) \leq & \int_0^{\sigma_1} K(X(t), u(t)) e^{-\lambda t} dt + C_a(X(\sigma_1), v) e^{-\lambda \sigma_1} \\ & + \Bigg[\int_{\sigma_1}^{\infty} K(X(t), u(t)) e^{-\lambda t} dt + \sum_{i=2}^{\infty} C_a(X(\sigma_i), v) e^{-\lambda \sigma_i} \\ & + \sum_{i=1}^{\infty} C_c\big(X(\xi_i), X(\xi_i)'\big) e^{-\lambda \xi_i} \Bigg]. \end{aligned}$$

We change the variable $t' = t - \sigma_1$ in the square bracket. Then taking the infimum in the square brackets over the control variables we get a value function of the trajectory starting from the point $g(X_x(\sigma_1), v)$. Hence,

$$\begin{aligned} V(x) \leq & \int_0^{\sigma_1} K(X(t), u(t)) e^{-\lambda t} dt + e^{-\lambda \sigma_1} C_a(X(\sigma_1), v) \\ & + e^{-\lambda \sigma_1} V(g(X_x(\sigma_1), v). \end{aligned}$$

Now taking the infimum over discrete controls v belonging to $\mathcal{V}$ in the last two terms we get

$$V(x) \le \int_0^{\sigma_1} K(X(t), u(t))e^{-\lambda t}dt + MV(X_x(\sigma_1)).$$

Further taking the infimum over continuous controls u in $\mathcal{U}$ we have the one-way inequality in (DPPA). For the reverse inequality, let $\varepsilon > 0$ be given. Choose the control $\theta_\varepsilon = (u_\varepsilon, v_\varepsilon, \xi_{i_\varepsilon}, X(\xi_i)'_\varepsilon)$ such that

$$\begin{aligned} V(x) + \varepsilon \ge & \int_0^{\sigma_1} K(X(t), u_\varepsilon(t))e^{-\lambda t}dt + C_a(X(\sigma_1), v_\varepsilon)e^{-\lambda\sigma_1} \\ & + e^{-\lambda\sigma_1}\left[\int_{\sigma_1}^{\infty} K(X(t), u_\varepsilon(t))e^{-\lambda t}dt + \sum_{i=2}^{\infty} C_a(X(\sigma_i), v_\varepsilon)e^{-\lambda\sigma_i}\right. \\ & \left. + \sum_{i=1}^{\infty} C_c\big(X(\xi_{i_\varepsilon}), X(\xi_i)'_\varepsilon\big)e^{-\lambda\xi_{i_\varepsilon}}\right] \end{aligned}$$

with calculations similar to those earlier, we can conclude that

$$\begin{aligned} V(x) + \varepsilon &\ge \int_0^{\sigma_1} K(X(t), u(t))e^{-\lambda t}dt + MV(X_x(\sigma_1)) \\ &\ge \inf_u \int_0^{\sigma_1} K(X(t), u(t))e^{-\lambda t}dt + MV(X_x(\sigma_1)). \end{aligned}$$

Hence as $\varepsilon \to 0$ we have other way inequality. Thus (DPPA) is proved. Now we proceed to prove (DPPC). Let t_1 be the first hitting time of C where the controller chooses to jump. In this case we write $t_1 = \xi_1$. Then

$$\begin{aligned} V(x) \le & \int_0^{\xi_1} K(X(t), u(t))e^{-\lambda t}dt + C_c\big(X(\xi_1), X(\xi_1)'\big)e^{-\lambda\xi_1} \\ & + \left[\int_{\xi_1}^{\infty} K(X(t), u(t))e^{-\lambda t}dt + \sum_{i=1}^{\infty} C_a(X(\sigma_i), v)e^{-\lambda\sigma_i}\right. \\ & \left. + \sum_{i=2}^{\infty} C_c\big(X(\xi_i), X(\xi_i)'\big)e^{-\lambda\xi_i}\right]. \end{aligned}$$

Doing the change of variables $t' = t - \xi_1$ in the square brackets and taking the infimum over the control variables, it is the value function of trajectory starting from $(X_x(\xi_1))'$. Hence,

$$V(x) \le \int_0^{\xi_1} K(X(t), u(t))e^{-\lambda t}dt + e^{-\lambda\xi_1}C_c(X(\xi_1), X(\xi_1)') + e^{-\lambda\xi_1}V(X_x(\xi_1)').$$

Now taking the infimum over $(X_x(\xi_1))' \in D$ in the last two terms we get

$$V(x) \le \int_0^{\xi_1} K(X(t), u(t))e^{-\lambda t}dt + NV(X_x(\xi_1)),$$

and taking the infimum over u in $\mathcal{U}$ on the RHS we will get the one-way inequality of (DPPC).

For the reverse inequality, given $\varepsilon > 0$ choose $\theta_\varepsilon = (u_\varepsilon, v_\varepsilon, \xi_{i_\varepsilon}, X(\xi_i)'_\varepsilon)$ such that

$$\begin{aligned} V(x) + \varepsilon &\geq \int_0^{\xi_{1_\varepsilon}} K(X(t), u_\varepsilon(t)) e^{-\lambda t} dt + NV(X_x(\xi_{1_\varepsilon})) \\ &\geq \inf_u \int_0^{\xi_{1_\varepsilon}} K(X(t), u(t)) e^{-\lambda t} dt + NV(X_x(\xi_{1_\varepsilon})). \end{aligned}$$

As $\varepsilon \to 0$ we will get

$$V(x) = \inf_u \left\{ \int_0^{\xi_1} K(X(t), u(t)) e^{-\lambda t} dt + NV(X_x(\xi_1)) \right\},$$

which proves (DPPC). The proof of (DPP) for any $T > 0$ follows similarly, which we skip here. □

THEOREM 4.2 (quasi-variational inequality). *Under the assumptions* (A1)–(A7) *and* (C1), (C2)*, the value function* V *described in* (2.7) *satisfies the following the QVI in the viscosity sense:*

$$\text{(QVI)} \qquad V(x) = \begin{cases} MV(x) & \forall x \in A, \\ \min\{NV(x), -H(x, DV(x))\} & \forall x \in C, \\ -H(x, DV(x)) & \forall x \in \Omega \setminus A \cup C, \end{cases}$$

where H *is the Hamiltonian given by*

$$H(x,p) = \sup_{u \in U} \left\{ \frac{-K(x,u) - f(x,u) \cdot p}{\lambda} \right\}.$$

Proof. Let $x \in A$. In this case we have to show that $V(x) = MV(x)$. Since $x \in A$, the first hitting time of trajectory is $\sigma_1 = 0$. Hence, by (DPPA) we get $V(x) = MV(x)$.

Now we consider the case $x \in \Omega \setminus A \cup C$. In this case we want to show that V satisfies the Hamilton–Jacobi–Bellman (HJB) equation in the viscosity sense. For we need to show the following: for all $\phi \in C^1(\Omega)$ and x local maximum of $V - \phi$

$$V(x) + H(x, D\phi(x)) \leq 0$$

and for all $\phi \in C^1(\Omega)$ and x local minimum of $V - \phi$

$$V(x) + H(x, D\phi(x)) \geq 0.$$

Let $r = \min\{\mathbf{d}(x, \partial A), \mathbf{d}(x, \partial C)\}$. Choose $R < r$. Then in the ball $B(x, R)$ no impulses are applied. Now V is continuous at x, and assume that $V - \phi$ has local maximum at x. Choose τ small enough such that $X_x(\tau) \in B(x, R)$. By our choice of R and τ, τ is less than the first hitting time. Then, since x is the local maximum of $V - \phi$,

$$\begin{aligned} \phi(x) - \phi(X_x(\tau)) &\leq V(x) - V(X_x(\tau)) \\ &\leq \int_0^\tau K(X_x(t), u(t)) e^{-\lambda t} dt + (e^{-\lambda\tau} - 1) V(X_x(\tau)), \end{aligned}$$

where the second inequality follows by (DPP), since $\tau < \sigma_1$ and $\tau < \xi_1$. Dividing by τ and taking the limit as $\tau \to 0$ we get

$$-D\phi(x) \cdot f(x) \leq K(x, u(0)) - \lambda V(x),$$

which implies

$$V(x) + \frac{-K(x, u(0) - D\phi(x) \cdot f(x)}{\lambda} \leq 0.$$

Taking the supremum over all $u \in \mathcal{U}$ we will get

$$V(x) + H(x, D\phi(x)) \leq 0.$$

Hence V is a viscosity subsolution of HJB equation.

To show that V is a viscosity supersolution, let $V - \phi$ have local minimum at x. Then for τ such that $X_x(\tau) \in B(x, R)$,

$$\begin{aligned}\phi(X_x(\tau)) - \phi(x) &\leq V(X_x(\tau)) - V(x) \\ &\leq (1 - e^{-\lambda\tau})V(X_x(\tau)) - \int_0^\tau K(X_x(t), u(t))e^{-\lambda t}dt \quad \text{by (DPP).}\end{aligned}$$

Dividing by τ and taking the limit as $\tau \to 0$ we get

$$\lambda V(x) - K(x, u(0)) - D\phi(x) \cdot f(x) \geq 0,$$

$$V(x) + \frac{-K(x, u(0)) - D\phi(x) \cdot f(x)}{\lambda} \geq 0.$$

Taking the supremum over all u we will get

$$V(x) + H(x, D\phi(x)) \geq 0.$$

Hence V is a viscosity supersolution of the HJB equation. Thus we have shown that in the case $x \in \Omega \setminus A \cup C$, V satisfies the HJB equation in the viscosity sense.

Now consider the case $x \in C$. We observe that if $x \in C$, and the controller chooses to jump, then by (DPPC), V should satisfy $NV(x)$. Whereas if the controller decides not to jump, then the system undergoes some continuous evolution and we can analyze as before to conclude that V satisfies the HJB equation in the viscosity sense. In this case we have to show that V satisfies the following equation in the viscosity sense:

$$\min\{V(x) - NV(x), V(x) + H(x, DV(x))\} = 0.$$

For this we need to show that, for all $\phi \in C^1(\Omega), x$ local minimum of $V - \phi$

$$\min\{V(x) - NV(x), V(x) + H(x, DV(x))\} \geq 0,$$

and for all $\phi \in C^1(\Omega), x$ local maximum of $V - \phi$,

$$\min\{V(x) - NV(x), V(x) + H(x, DV(x))\} \leq 0.$$

Now if $V(x) = NV(x)$, there is nothing to prove.

Suppose $V(x) < NV(x)$; then we need to show that V satisfies the HJB equation in the viscosity sense. We show that whenever $V(x) < NV(x)$ there exists $r > 0$ and a ball $B(x, r)$ around x such that it is not optimal to apply any impulses on $B(x, r)$. Then we can do the analysis in this ball to conclude as in the case of $x \in \Omega \setminus A \cup C$. For we claim that there exists $\varepsilon > 0$ such that

$$V(x) = \inf_{u, v, \xi_i, X(\xi_i)'} \left\{ \int_0^{t_1} K(X_x(t), u(t))e^{-\lambda t}dt + NV(X_x(t_1)) \mid t_1 > \varepsilon \right\}.$$

Suppose not; then $\varepsilon = 0$, which implies $\xi_1 = 0$, which by (DPPC) implies $V(x) = NV(x)$; this is a contradiction of our hypothesis $V(x) < NV(x)$. Hence $\varepsilon > 0$. Choose $r < \min\{d(x, X_x(\varepsilon)), d(A, C)\}$. Then in the ball $B(x, r)$, no impulses are applied. So we can do the analysis in this ball around x and conclude as in the earlier case. This proves the QVI for the case $x \in C$. ∎

5. Uniqueness. We take up the issue of uniqueness of the viscosity solutions of (QVI) in this section. Inspired by the earlier work on impulse control problem (see [2], [9]), we prove the comparison between any two solutions of the QVI.

THEOREM 5.1. *Assume* (A1)–(A7) *and* (C1), (C2). *Let* $u_1, u_2 \in BC(\Omega)$, *bounded continuous functions on* Ω, *be two viscosity solutions of the QVI given by* (QVI). *Then* $u_1 = u_2$.

Proof. The idea of the proof is to show that $u_1(x) \le u_2(x)$ for all $x \in \Omega$. We define the following auxiliary function Φ on $\bigcup_{i=1}^{\infty} (\Omega_i \times \Omega_i)$ that is Φ^i on each $\Omega_i \times \Omega_i$ by

$$\Phi^i(x, y) = u_1(x) - u_2(y) - \frac{1}{\epsilon}|x - y|^2 - \kappa\big(|x|^2 + |y|^2\big), \tag{5.1}$$

where ε and κ are small positive parameters to be chosen suitably later on. Observe that for each i, Φ^i attains its supremum over $\Omega_i \times \Omega_i$, thanks to the last two terms, which become large negative as $|x|, |y|$ goes to 0. We prove the theorem in two steps. In the first step of the proof we show that $\sup_i \sup_{\Omega_i \times \Omega_i} \Phi^i(x, y) \le 0$. In the next step we prove the uniqueness using Step 1.

Step 1. Let

$$\sup_i \sup_{\Omega_i \times \Omega_i} \Phi^i(x, y) = C > 0.$$

Fix $\kappa > 0$ such that $\kappa < \min\{\frac{C}{2}, \frac{C'}{2}\}$. If the above supremum is achieved at some (x_0, y_0), the following proof gets simplified. If not, corresponding to this κ we can choose (x_κ, y_κ) in some $\Omega_i \times \Omega_i$, say, $\Omega_1 \times \Omega_1$, such that

$$\Phi^1(x_\kappa, y_\kappa) > C - \kappa > \frac{C}{2}. \tag{5.2}$$

Let Φ^1 attain its supremum at some finite point, say, at (x_0, y_0) in $\Omega_1 \times \Omega_1$. Then

$$\sup_{\Omega_1 \times \Omega_1} \Phi^1(x, y) = \Phi^1(x_0, y_0) > C - \kappa > \frac{C}{2}. \tag{5.3}$$

Since x_0 and y_0 can lie in different sets in Ω_1, $u_1(x_0)$ and $u_2(y_0)$ will satisfy different equations from the QVI. We list below the different cases which arise:

1. $(x_0, y_0) \in A \times C$ or $C \times A$.
2. $(x_0, y_0) \in \Omega \setminus (A \cup C) \times \Omega \setminus (A \cup C)$.
3. $x_0, y_0 \notin A$ and one of x_0 or $y_0 \in C$. This takes care of $(x_0, y_0) \in C \times \Omega \setminus (A \cup C), (x_0, y_0) \in \Omega \setminus (A \cup C) \times C$, $(x_0, y_0) \in C \times C$.
4. $x_0, y_0 \notin C$ and one of the x_0 or $y_0 \in A$, i.e., $(x_0, y_0) \in A \times A$ or $(x_0, y_0) \in A \times \Omega \setminus (A \cup C)$, $(x_0, y_0) \in \Omega \setminus (A \cup C) \times A$.

Our idea is to show that in any of these cases, $u_1(x) - u_2(x)$ is arbitrarily small for ε and κ small. For this we will estimate $u_1(x_0) - u_2(y_0)$ at the maximum point (x_0, y_0) of Φ^1 or $u_1(x_n) - u_2(y_n)$ at the maximum point (x_n, y_n) of ψ_n, a suitably defined auxiliary function. The crucial point in our proof is that after at most finitely many

steps, say n_0, at the maximum point of ψ_{n_0} both u_1 and u_2 satisfy the HJB equation. Then we can use the usual comparison principle available in the literature. We first list some standard estimates needed later in the proof.

LEMMA 5.2. *Let Φ and (x_0, y_0) be as above. Then*

(i) $\frac{|x_0-y_0|^2}{\epsilon} \le C$ *for some C independent of κ and ε;*

(ii) $\sqrt{\kappa}|x_0|, \sqrt{\kappa}|y_0| \le \hat{C}$ *for some $\hat{C}$ independent of κ and ε;*

(iii) $\frac{|x_0-y_0|^2}{\epsilon} \le \omega_\kappa^1(\sqrt{C\epsilon})$, *where ω_κ^1 is the local modulus of continuity of both u_1 and u_2 in the ball of radius R, dependent on κ but independent of ε, $R = R(\kappa) = \hat{C}/\sqrt{\kappa}$ in Ω_1.*

Proof. By our assumption

$$2\Phi^1(x_0, y_0) \ge \Phi^1(x_0, x_0) + \Phi^1(y_0, y_0). \tag{5.4}$$

Hence

$$\frac{2}{\epsilon}|x_0 - y_0|^2 \le u_1(x_0) - u_1(y_0) + u_2(x_0) - u_2(y_0). \tag{5.5}$$

Since u_1 and u_2 are bounded,

$$\frac{|x_0 - y_0|^2}{\epsilon} \le C,$$

which proves (i). This also implies

$$|x_0 - y_0| \le \sqrt{C\epsilon}.$$

To prove (ii), fix some $z \in \Omega_1$ such that $|z| = 1$; then $\Phi^1(x_0, y_0) \ge \Phi^1(z, z)$, which implies

$$\begin{aligned}\kappa\big(|x_0|^2 + |y_0|^2\big) &\le u_1(x_0) - u_1(z) - u_2(y_0) + u_2(z) - \frac{1}{\epsilon}|x_0 - y_0|^2 + 2\kappa|z|^2 \\ &\le C + 2\kappa \le C + 2.\end{aligned}$$

Hence $\sqrt{\kappa}|x_0| \le \hat{C}$, where $\hat{C}$ is independent of κ and ε. Similarly, $\sqrt{\kappa}|y_0| \le \hat{C}$. This proves (ii). Hence x_0 and y_0 lie in some ball B_R of radius $R = R(\kappa)$.

Now using the estimate in (i) and the modulus of continuity of u_1 and u_2 in the compact set $\bar{B}_{R(\kappa)}$ in Ω_1, we get

$$\frac{|x_0 - y_0|^2}{\epsilon} \le \omega_\kappa^1(\sqrt{C\epsilon}).$$

This proves (iii). □

Now we consider the different cases listed earlier.

Case 1. $(x_0, y_0) \in A \times C$ or $C \times A$.

Claim. This case does not occur.

Without loss of generality let $(x_0, y_0) \in A \times C$. Since $d(A, C) > \beta$,

$$\Rightarrow |x_0 - y_0| > \beta.$$

On the other hand by Lemma 5.2(i),

$$|x_0 - y_0| < \sqrt{C\epsilon}.$$

So choosing ϵ such that $\sqrt{C\epsilon} < \frac{\beta}{2}$,

$$|x_0 - y_0| < \frac{\beta}{2},$$

which is a contradiction. Hence Case 1 does not occur, for small ε.

Case 2. $(x_0, y_0) \in \Omega \setminus (A \cup C) \times \Omega \setminus (A \cup C)$.

In this case at $(x_0, y_0) \in \Omega_1 \times \Omega_1$, u_1, u_2 both satisfy the HJB equation. Hence we do all the calculations in Ω_1. Let us define the test functions ϕ_1 and ϕ_2 on Ω_1 as follows:

$$\phi_1(x) = u_2(y_0) + \frac{1}{\epsilon}|x - y_0|^2 + \kappa\big(|x|^2 + |y_0|^2\big), \tag{5.6}$$

$$\phi_2(y) = u_1(x_0) - \frac{1}{\epsilon}|x_0 - y|^2 - \kappa\big(|x_0|^2 + |y|^2\big). \tag{5.7}$$

Then, since (x_0, y_0) is point of supremum for Φ^1, $u_1 - \phi_1$ attains its maximum at x_0 and $u_2 - \phi_2$ attains its minimum at y_0. Also observe

$$D\phi_1(x_0) = \frac{2}{\epsilon}(x_0 - y_0) + 2\kappa x_0, \tag{5.8}$$

$$D\phi_2(y_0) = \frac{2}{\epsilon}(x_0 - y_0) - 2\kappa y_0, \tag{5.9}$$

and by Lemma 5.2

$$|D\phi_2(y_0)| \le \frac{2}{\epsilon}|x_0 - y_0| + \sqrt{\kappa}\hat{C}. \tag{5.10}$$

Now by definition of the viscosity sub- and supersolutions, and using u_1 as the subsolution and u_2 as the supersolution,

$$\begin{aligned} &u_1(x_0) + H(x_0, D\phi_1(x_0)) \le 0 \le u_2(y_0) + H(y_0, D\phi_2(y_0)) \\ &\quad \Rightarrow u_1(x_0) - u_2(y_0) \le H(y_0, D\phi_2(y_0)) - H(x_0, D\phi_1(x_0)). \end{aligned}$$

By our assumptions (A1)–(A7) and the definition of Hamiltonian H, one can easily prove that H satisfies the structural condition

$$|H(x,p) - H(y,q)| \le F|p - q| + L|q||x - y| + K_1|x - y|, \tag{5.11}$$

where K_1 is the Lipschitz constant for the running cost k. Using (5.11) we get

$$\begin{aligned} u_1(x_0) - u_2(y_0) \le{}& L\,|D\phi_2(y_0)|\,|x_0 - y_0| + K_1|x_0 - y_0| \\ &+ F\,|D\phi_2(y_0) - D\phi_1(x_0)|. \end{aligned}$$

Substituting from (5.8), (5.9), and (5.10),

$$u_1(x_0) - u_2(y_0) \le \frac{2L}{\epsilon}|x_0 - y_0|^2 + \sqrt{\kappa}L\hat{C}|x_0 - y_0| + K_1|x_0 - y_0| + 2\kappa F|x_0 + y_0|.$$

By Lemma 5.2 we then get

$$u_1(x_0) - u_2(y_0) \le 2L\omega^1_\kappa(\sqrt{C\epsilon}) + L\hat{C}\sqrt{C\kappa\varepsilon} + K_1(\sqrt{C\epsilon}) + 4F\hat{C}\sqrt{\kappa}. \tag{5.12}$$

Also observe that by (5.2)

$$\begin{aligned}\frac{C}{2} < C - \kappa &< \Phi^1(x_\kappa, x_\kappa) \\ &\le \Phi^1(x_0, y_0) \\ &\le u_1(x_0) - u_2(y_0) \\ &\le 2L\omega_\kappa^1\big(\sqrt{C\epsilon}\big) + 2L\hat{C}\sqrt{C\kappa\varepsilon} + K_1\big(\sqrt{C\epsilon}\big) + 4F\hat{C}\sqrt{\kappa}.\end{aligned}$$

Now fixing κ and sending ε to 0 and then choosing κ such that $4F\hat{C}\sqrt{\kappa} < \frac{C}{4}$ we will have

$$\frac{C}{2} < \frac{C}{4}.$$

This is a contradiction. Hence,

$$\sup_i \sup_{\Omega_i \times \Omega_i} \Phi^i(x, y) \le 0.$$

Case 3. $x_0, y_0 \notin A$, and one of $x_0, y_0 \in C$. Without loss of generality let $y_0 \in C$. $x_0 \notin A$ and u_1 is a subsolution of the QVI implies

$$u_1(x_0) + H(x_0, Du_1(x_0)) \le 0,$$

$$y_0 \in C \Rightarrow \max\{u_2(y_0) + H(y_0, Du_2(y_0)), u_2(y_0) - Nu_2(y_0)\} = 0,$$

and u_2 is a solution of the QVI, in particular it is a supersolution. Hence either $u_2 + H \ge 0$ or $u_2 - Nu_2 \ge 0$ at y_0.

If $u_2(y_0) + H(y_0, Du_2(y_0)) \ge 0$, we can proceed as in Case 2 and get a contradiction. Otherwise assume $u_2(y_0) - Nu_2(y_0) \ge 0$. Since u_2 is also a subsolution

$$u_2(x) \le Nu_2(x) \quad \forall x \in C.$$

Therefore,

$$u_2(y_0) = Nu_2(y_0) = \inf_{y' \in D} u_2(y') + c_c(y_0, y') = \inf_i \inf_{D_i} u_2(y') + c_c(y_0, y').$$

As each D_i is compact, the infimum is attained on each D_i. If the infimum over i is not attained, then we can choose y_0' in, say, D_2 such that

$$u_2(y_0) = Nu_2(y_0) > u_2(y_0') + c_c(y_0, y_0') - \kappa, \quad y_0' \in D_2.$$

Also $y_0' \notin A$. We estimate the difference $\Phi^1(x_0, y_0)$ and $\Phi^2(y_0', y_0')$ in the following lemma, which we will use to define another auxiliary function ψ_1, and consider the maximum point (x_1, y_1) of ψ_1, in the same spirit as in the earlier work on the impulse control problem (see [2], [7], [9]). We will show that after at most a finite number of such auxiliary functions, we necessarily arrive at Case 2.

Recall that y_0' lies in D, hence by (A2), $|y_0'| < R$. We will also need that x_0 and y_0 are not too close to y_0' in case $y_0' \in \Omega_1$. The following lemma proves this fact. More generally we prove here that whenever $u(x) = Nu(x)$ or $u(x) = Mu(x)$ the destination point is at a certain positive distance away from the point of supremum.

LEMMA 5.3. *Let $u \in BC(\Omega)$ be a solution of* (QVI). *If x, x', and $g(x,v')$ belong to $D_1 \subseteq \Omega_1$ and if*

$$\begin{aligned} &u(x) = Nu(x) > u(x') + c_c(x,x') - \kappa \\ \text{or} \quad &u(x) = Mu(x) = u(g(x,v')) + c_a(x,v'), \end{aligned}$$

then there exists an $\alpha_1 > 0$ depending only on the uniform continuity of u on $D_1 \subseteq \Omega_1$ but independent of ε and κ such that

$$|x - x'| > \alpha_1 \tag{5.13}$$

$$\text{or} \quad |x - g(x,v')| > \alpha_1, \tag{5.14}$$

depending on which equation $u(x)$ satisfies.

Proof. We claim that there exists $\alpha_1 > 0$ such that $|x - x'| > \alpha_1$. Suppose the contrary. That is, there exists sequence $x_n,\ x_n' \in \Omega_1$ such that

$$u(x_n) > u\big(x_n'\big) + c_c\big(x_n, x_n'\big) - \kappa \ \text{ and } \ |x_n - x_n'| \to 0.$$

Then by continuity of u, $|u(x_n) - u(x_n')| \to 0$. But

$$|u(x_n) - u\big(x_n'\big)| = c_c\big(x_n, x_n'\big) - \kappa > C' - \kappa > \frac{C'}{2} > 0,$$

which is a contradiction. Hence given $\frac{C'}{4}$ choose the corresponding α_1 given by uniform continuity of u on $D_1 \subseteq \Omega_1$ such that $|y - z| < \alpha_1 \Rightarrow |u(y) - u(z)| < \frac{C'}{4}$. Then

$$|x - x'| > \alpha_1.$$

This proves (5.13).

To prove that $|x - g(x,v')| > \alpha_1$, we proceed with arguments similar to those above and choose α_1 corresponding to the $\frac{C'}{4}$ in the definition of uniform continuity of u on D_1. ∎

In the next lemma we estimate the difference $\Phi^1(x_0,y_0)$ and $\Phi^2(y_0',y_0')$, which we are going to use to define new auxiliary function ψ_1.

LEMMA 5.4. *Let Φ be as defined in* (5.1) *and let $(x_0,y_0) \in \Omega_1 \times \Omega_1$ be as in* (5.3), *the point where Φ^1 attains supremum. Let $y_0' \in D_2$ be such that*

$$u_2(y_0) = Nu_2(y_0) > u_2\big(y_0'\big) + c_c\big(y_0, y_0'\big) - \kappa. \tag{5.15}$$

Then

$$\Phi^1(x_0,y_0) - \Phi^2\big(y_0',y_0'\big) \le \kappa K$$

for some constant $K > 1$ depending only on the constants of the problem and independent of ϵ and κ.

Proof.

$$\begin{aligned} \Phi^1(x_0,y_0) - \Phi^2\big(y_0',y_0'\big) = u_1(x_0) - u_2(y_0) - \frac{1}{\epsilon}|x_0 - y_0|^2 - \kappa\big(|x_0|^2 + |y_0|^2\big) \\ - u_1\big(y_0'\big) + u_2\big(y_0'\big) + 2\kappa|y_0'|^2. \end{aligned}$$

Using (5.15) we get

$$\Phi^1(x_0,y_0)-\Phi^2\big(y_0',y_0'\big)<u_1(x_0)-c_c\big(y_0,y_0'\big)-\frac{1}{\epsilon}|x_0-y_0|^2-\kappa\big(|x_0|^2+|y_0|^2\big)\\ -u_1\big(y_0'\big)+2\kappa|y_0'|^2+\kappa.$$

Also $u_1(y_0)\le Nu_1(y_0)\le u_1(y_0')+c_c(y_0,y_0')$. Hence,

$$\begin{aligned}\Phi^1(x_0,y_0)-\Phi^2\big(y_0',y_0'\big)&\le u_1(x_0)-u_1(y_0)-\frac{1}{\epsilon}|x_0-y_0|^2-\kappa\big(|x_0|^2+|y_0|^2\big)+2\kappa|y_0'|^2\\ &\quad+\kappa\le u_1(x_0)-u_1(y_0)+2\kappa|y_0'|^2+\kappa\\ &\le u_1(x_0)-u_1(y_0)+2\kappa R^2+\kappa\\ &\le \omega_\kappa^1\big(\sqrt{C\epsilon}\big)+2\kappa R^2+\kappa.\end{aligned}$$

Using the modulus of continuity of u_1, on $\bar{B_R}$ in Ω_1 for a given $\kappa>0$ choose $\epsilon>0$ such that

$$\omega_\kappa^1\big(\sqrt{C\epsilon}\big)<\kappa\Rightarrow\Phi^1(x_0,y_0)-\Phi^2\big(y_0',y_0'\big)\le\kappa K.$$

This proves the lemma. □

We use the above difference to define another auxiliary function ψ_1. We further restrict α_2 given by Lemma 5.3, if necessary, so that $\alpha_2<\frac{\beta}{2}$. Define

$$\psi_1^2(x,y)=\Phi^2(x,y)+2\kappa K\,\zeta_1(x,y),$$

$$\psi_1^i(x,y)=\Phi^i(x,y)\quad\forall i\ne 2,$$

where, $\zeta_1(x,y)\in C_0^\infty(\Omega_2\times\Omega_2)$, such that

$$\zeta_1\big(y_0',y_0'\big)=1;\quad 0\le\zeta_1\le 1;\quad |D\zeta_1|\le\frac{2}{\alpha_2};$$

$$\zeta_1(x,y)<1\text{ if }(x,y)\ne\big(y_0',y_0'\big);$$

$$\text{and}\ \ \zeta_1(x,y)=0\quad\forall(x,y)\ \text{ such that }|x-y_0'|^2+|y-y_0'|^2>\alpha_1,$$

i.e., ζ_1 has support in the α_1 ball around $(y_0',y_0')\in\Omega_2\times\Omega_2$, having maximum at (y_0',y_0') and it vanishes on all $\Omega_i\times\Omega_i$ other than $i=2$.

Observe that by the definition of ψ_1^i,

$$\begin{aligned}\psi_1^2\big(y_0',y_0'\big)&=\Phi^2\big(y_0',y_0'\big)+2\kappa K\\ &\ge\Phi^1(x_0,y_0)-K\kappa+2\kappa K\\ &\ge\sup_i\sup_{\Omega_i\times\Omega_i}\Phi^i(x,y)+\kappa K-\kappa\\ &\ge\psi_1^2(x,y)-2\kappa K\,\zeta_1(x,y)+\kappa(K-1).\end{aligned}$$

As ζ_1 is 0 for all $(x,y)\in\Omega_i\times\Omega_i$, $i\ne 2$, and for (x,y) outside the α_1 ball around (y_0',y_0') in $\Omega_2\times\Omega_2$, we have for all such (x,y)

$$\psi_1^2\big(y_0',y_0'\big)>\psi_1^2(x,y).$$

Hence ψ_1^2 has the supremum over $\Omega_2 \times \Omega_2$ in the α_1 ball around (y_0', y_0'). Let (x_1, y_1) be such that

$$\sup_{\Omega_2 \times \Omega_2} \psi_1^2 = \psi_1^2(x_1, y_1).$$

Then

$$\psi_1^2(x_1, y_1) \geq \psi_1^1(x_0, y_0) = \Phi^1(x_0, y_0) > C - \kappa. \tag{5.16}$$

Since $\alpha_1 < \frac{\beta}{2}$, $x_1, y_1 \notin A$. We remark here that by using the technique of Lemma 5.2, we can prove that

$$\frac{|x_1 - y_1|^2}{\epsilon} \leq \omega_\kappa^2\big(\sqrt{C\epsilon}\big) + 2K\kappa \quad \text{and} \quad |x_1|, |y_1| < \hat{C}\sqrt{\kappa}.$$

Thus either $x_1, y_1 \notin C$ or one of them is in C. If $x_1, y_1 \notin C$, we are in Case 2 or Case 4. If we are in Case 2, we can get the comparison by working with ψ_1 instead of Φ as in Case 2. We will show in the next step of the proof how to handle Case 4. Now if one of $x_1, y_1 \in C$, we are again in Case 3. So without loss of generality let $y_1 \in C$ and y_1 be such that $u_2(y_1) - Nu_2(y_1) \geq 0$. Then, as earlier, the approximate infimum will be attained at some point, say, $y_1' \in D$, some D_i which we call D_3. That is

$$u_2(y_1) = Nu_2(y_1) > u_2\big(y_1'\big) + c_c\big(y_1, y_1'\big) - \kappa.$$

We define ψ_2 on $\bigcup \Omega_i \times \Omega_i$, that is, ψ_2^i on $\Omega_i \times \Omega_i$, by

$$\psi_2^i(x, y) = \Phi^i(x, y) + 2\kappa K \sum_{j=1}^{2} \zeta_j(x, y),$$

where $\zeta_2(y_1', y_1') = 1$ and ζ_2 has support in the α_3 ball around (y_1', y_1') in $\Omega_3 \times \Omega_3$ with the properties $\zeta_2 \in C_0^\infty(\Omega \times \Omega)$, $0 \leq \zeta_2 \leq 1$, $|D\zeta_2| \leq \frac{2}{\alpha_3}$, $\zeta_2(x, y) < 1$ if $(x, y) \neq (y_1', y_1')$. Hence as before we can show that the supremum of ψ_2 is attained in the α_3 ball around (y_1', y_1'). Also we can show that ψ_2^3 satisfies the inequality similar to (5.16), namely,

$$\psi_2^2(x_1, y_1) \geq \psi_1^2(x_1, y_1) = \Phi^1(x_0, y_0) > C - \kappa.$$

Thus we can proceed to define $\psi_3, \psi_4, \ldots, \psi_n$ and so on, in case $u_2(y_i) = Nu_2(y_i)$. We now claim that this process has to terminate in finitely many steps, which is the content of the following lemma.

LEMMA 5.5. *Suppose $(x_n, y_n) \in \Omega_{n+1} \times \Omega_{n+1}$, $y_n' \in D_{n+2}$ are sequences such that*

$$u_2(y_n) = Nu_2(y_n) > u_2(y_n') + c_c(y_n, y_n') - \kappa, \quad y_n \in B(y_{n-1}', \alpha_{n+1});$$
$$\psi_n(x, y) = \psi_{n-1}(x, y) + 2\kappa K\, \zeta_n(x, y); \quad \psi_n(x_n, y_n) = \sup_{\Omega_{n+1} \times \Omega_{n+1}} \psi_n(x, y);$$

where ζ_n is such that $\zeta_n \in C_0^\infty(\Omega \times \Omega)$; actually ζ_n has support in the α_{n+1} ball around $(y_n', y_n') \in \Omega_{n+2} \times \Omega_{n+2}$. $0 \leq \zeta_n \leq 1$; $|D\zeta_n| < \frac{2}{\alpha_{n+1}}$; $\zeta_n(y_{n-1}', y_{n-1}') = 1$, $n = 1, 2, \ldots$. Then $n < n_0 = [\frac{8\hat{C}}{C'}]$, where $\hat{C}$ is a bound on u_1 and u_2 and C' is the lower bound on c_c.

Proof. Observe that y_i', $y_{i+1} \in D_{i+2}$. By uniform continuity of u_2 on $D_{i+2} \subseteq \Omega_{i+2}$, for all i,

$$|y_{i+1} - y_i'| < \alpha_{i+1} \Rightarrow |u_2(y_{i+1}) - u_2(y_i')| < \frac{C'}{4}.$$

By assumption,

$$\begin{aligned} u_2(y_0) &> u_2(y_0') + c_c(y_0, y_0') - \kappa \\ &> u_2(y_0') + C' - \kappa\ ; \quad \text{because } c_c \geq C' > 0 \\ &> u_2(y_1) - \frac{C'}{4} + C' - \kappa = u_2(y_1) + \frac{3}{4}C' - \kappa \\ &> u_2(y_1') + c_c(y_1, y_1') + \frac{3}{4}C' - 2\kappa \ > \ u_2(y_1') + C' + \frac{3}{4}C' - 2\kappa \\ &> u_2(y_2) - \frac{C'}{4} + C' + \frac{3}{4}C' - 2\kappa = u_2(y_2) + \frac{6}{4}C' - 2\kappa. \end{aligned}$$

Therefore, at the nth stage we will get

$$\hat{C} \geq u_2(y_0) > u_2(y_n) + \frac{3}{4}nC' - n\kappa.$$

By using $\kappa < \frac{C'}{2}$, if $n > n_0 = [\frac{8\hat{C}}{C'}]$, then $u_2(y_0) > \hat{C}$, which is a contradiction, because $|u_2| < \hat{C}$. □

Thus we have only a finite sequence of $\{y_n\}$ such that $u_2(y_n) = Nu_2(y_n)$. So, for $n > n_0 = [\frac{8\hat{C}}{C'}]$ necessarily $u_2(y_n) < Nu_2(y_n)$ and hence

$$u_2(y_n) + H(y_n, Du_2(y_n)) \geq 0.$$

Hence both u_1 and u_2 satisfy the HJB at the supremum point of auxiliary function ψ_n. Now we proceed as in Case 2 taking care of the extra terms.

In this case we define test functions ϕ_1 and ϕ_2 by

$$\phi_1(x) = u_2(y_n) + \frac{1}{\epsilon}|x - y_n|^2 + \kappa\big(|x|^2 + |y_n|^2\big) - 2\kappa K \sum_{j=1}^{n} \zeta_j(x, y_n), \tag{5.17}$$

$$\phi_2(y) = u_1(x_n) - \frac{1}{\epsilon}|x_n - y|^2 - \kappa\big(|x_n|^2 + |y|^2\big) + 2\kappa K \sum_{j=1}^{n} \zeta_j(x_n, y). \tag{5.18}$$

Then by the definition of (x_n, y_n), $u_1 - \phi_1$ has maximum at x_n and $u_2 - \phi_2$ has minimum at y_n. Using u_1 as the viscosity subsolution and u_2 as the viscosity supersolution, we get

$$u_1(x_n) - u_2(y_n) \leq H(y_n, D\phi_2(y_n)) - H(x_n, D\phi_1(x_n)).$$

Let $\alpha = \min\{\alpha_1, \ldots, \alpha_{n+1}\}$. Also, whenever $(x_n, y_n) \in \Omega_{j+1} \times \Omega_{j+1}$ we can write

$$D\phi_1(x_n) = \frac{2}{\epsilon}(x_n - y_n) + 2\kappa x_n - 2K\kappa \sum_{j=1}^{n} D\zeta_j(x_n, y_n), \tag{5.19}$$

$$D\phi_2(y_n) = \frac{2}{\epsilon}(x_n - y_n) - 2\kappa y_n + 2K\kappa \sum_{j=1}^{n} D\zeta_i(x_n, y_n), \tag{5.20}$$

$$|D\phi_1(y_n)| \leq \frac{2}{\epsilon}(x_n - y_n) + 2\kappa|y_n| + \frac{4nK\kappa}{\alpha}. \tag{5.21}$$

Hence by structural condition on H given by (5.11),

(5.22)
$$u_1(x_n) - u_2(y_n) \le L|D\phi_2(y_n)|\,|x_n - y_n| + K_1|x_n - y_n| + F|D\phi_2(y_n) - D\phi_2(x_n)|.$$

By using (5.19), (5.20), (5.21) in the above we get

$$u_1(x_n) - u_2(y_n) \le \frac{2L}{\epsilon}|x_n - y_n|^2 + 2\kappa L|y_n|\,|x_n - y_n| + \left(\frac{4K\kappa n}{\alpha}\right)|x_n - y_n| + K_1|x_n - y_n| + 4F\kappa(|x_n| + |y_n|) + \frac{8\kappa K n}{\alpha}. \tag{5.23}$$

Now by using the technique of Lemma 5.2 for ψ_n, we can prove that

$$\begin{aligned} |x_n - y_n| &< \sqrt{C\epsilon}, \\ \frac{|x_n - y_n|^2}{\epsilon} &\le \omega_\kappa^n\big(\sqrt{C\epsilon}\big) + 2\kappa K, \\ |x_n|\,|y_n| &\le \sqrt{\kappa}\hat{C}, \end{aligned}$$

where $\hat{C}, K$, and C are independent of ε and κ. Using these estimates in (5.23) we will get

$$u_1(x_n) - u_2(y_n) \le 2L\omega_\kappa^n\big(\sqrt{C\epsilon}\big) + 4L\kappa K + 2L\hat{C}\sqrt{C\kappa\varepsilon} + \left(\frac{4K\kappa n}{\alpha}\right)\sqrt{C\epsilon} + K_1\big(\sqrt{C\epsilon}\big) + 8F\hat{C}\sqrt{\kappa} + \frac{8\kappa K n}{\alpha}. \tag{5.24}$$

Also observe that from (5.3),

$$\frac{C}{2} < C - \kappa < \Phi^1(x_0, y_0) \le \psi_n^{n+1}(x_n, y_n).$$

Hence

$$\begin{aligned} \frac{C}{2} < C - \kappa &\le u_1(x_n) - u_2(y_n) - \frac{|x_n - y_n|^2}{\varepsilon} - \big(|x_n|^2 + |y_n|^2\big) + 2\kappa K\sum_{j=1}^{n}\zeta_j(x^n, y^n) \\ &\le u_1(x_n) - u_2(x_n) + 2\kappa K n. \end{aligned}$$

By using (5.24) in the above, with $n \le n_0$ given by Lemma 5.5, we get

$$\frac{C}{2} \le 2L\omega_\kappa^n\big(\sqrt{C\epsilon}\big) + 4L\kappa K + 2L\hat{C}\sqrt{C\kappa\varepsilon} + \left(\frac{4K\kappa n_0}{\alpha}\right)\sqrt{C\epsilon} + K_1(\sqrt{C\epsilon}) + 8F\hat{C}\sqrt{\kappa} + \frac{8\kappa K n_0}{\alpha} + 2\kappa K n_0.$$

Now first fixing κ and sending ε to 0 we get

$$\frac{C}{2} \le 8F\hat{C}\sqrt{\kappa} + 4L\kappa K + \frac{8\kappa K n_0}{\alpha} + 2\kappa K n_0.$$

Now we can choose κ so that the RHS of the above expression is strictly less than $\frac{C}{4}$ and hence we will get $\frac{C}{2} \le \frac{C}{4}$. This is a contradiction; hence, $\sup_i \sup_{\Omega_i\times\Omega_i} \psi_n^i(x, y) \le 0$. This implies that

$$\sup_i \sup_{\Omega_i\times\Omega_i} \Phi^i(x, y) \le \sup_i \sup_{\Omega_i\times\Omega_i} \psi_n^i(x, y) \le 0.$$

Thus in this case also we have $\sup_i \sup_{\Omega_i \times \Omega_i} \Phi^i(x,y) \le 0$.

Case 4. Now consider the last case where one of the x_0 or y_0 is in A. Without loss of generality we assume that $y_0 \in A$.

LEMMA 5.6. *Let Φ be as defined by* (5.1) *and let (x_0, y_0) be as in* (5.24)*, that is, $\Phi^1(x_0,y_0) = \sup_{\Omega_1 \times \Omega_1} \Phi^1$. Moreover, let y_0 be such that $u_2(y_0) = Mu_2(y_0) = u_2(g(y_0,v_0)) + c_a(y_0,v_0)$, where $g(y_0,v_0) \in \Omega_2$. Then*

$$\Phi^1(x_0,y_0) - \Phi^2(g(y_0,v_0), g(y_0,v_0)) < \kappa K$$

for some constant $K > 1$ depending only on the constants of the problem and independent of ϵ and κ.

Proof.

$$\begin{aligned}\Phi^1(x_0,y_0) - \Phi^2(g(y_0,v_0),(g(y_0,v_0)) &= u_1(x_0) - u_2(y_0) - \frac{1}{\epsilon}|x_0 - y_0|^2 - \kappa(|x_0|^2 + |y_0|^2) \\ &\quad - u_1(g(y_0,v_0)) + u_2(g(y_0,v_0)) + 2\kappa|g(y_0,v_0)|^2 \\ &= u_1(x_0) - c_a(y_0,v_0) - \frac{1}{\epsilon}|x_0 - y_0|^2 \\ &\quad - \kappa(|x_0|^2 + |y_0|^2) - u_1(g(y_0,v_0)) + 2\kappa|g(y_0,v_0)|^2.\end{aligned}$$

We add and subtract $u_1(y_0)$ in the above, and observing that $u_1(y_0) \le Mu_1(y_0) \le u_1(g(y_0,v_0)) + c_a(y_0,v_0)$, we get

$$\begin{aligned}\Phi^1(x_0,y_0) - \Phi^2(g(y_0,v_0), g(y_0,v_0)) &\le u_1(x_0) - u_1(y_0) - c_a(y_0,v_0) \\ &\quad - u_1(g(y_0,v_0)) + u_1(y_0) + 2\kappa|g(y_0,v_0)|^2 \\ &\le u_1(x_0) - u_1(y_0) + 2\kappa|g(y_0,v_0)|^2 \\ &\le \omega_\kappa^1(|x_0 - y_0|) + 2\kappa R^2.\end{aligned}$$

We can choose ϵ such that $\omega_\kappa^1(\sqrt{C\epsilon}) < \kappa$. Then by the Lemma 5.2,

$$\begin{aligned}&\omega_\kappa^1(|x_0 - y_0|) \le \omega_\kappa^1\big(\sqrt{C\epsilon}\big) < \kappa \\ &\quad \Rightarrow \Phi^1(x_0,y_0) - \Phi^2(g(y_0,v_0), g(y_0,v_0)) \le K\kappa,\end{aligned}$$

where K depends on the modulus of continuity of u_1 and R. This proves the lemma. □

To proceed, if necessary, we restrict $\alpha_2 < \frac{\beta}{2}$, where α_2 is as in Lemma 5.3 and define a C_0^∞ function ζ_1 on $\Omega \times \Omega$ by

$$\zeta_1(g(y_0,v_0), g(y_0,v_0)) = 1; \quad 0 \le \zeta_1 \le 1; \quad |D\zeta_1| < \frac{2}{\alpha_2};$$

$$\zeta_1(x,y) < 1 \text{ if } (x,y) \ne (g(y_0,v_0), g(y_0,v_0));$$

$$\text{and} \quad \operatorname{supp} \zeta_1 \subseteq B((g(y_0,v_0), g(y_0,v_0)), \alpha_2).$$

Note that ζ_1 is nonzero only on $\Omega_2 \times \Omega_2$ and it vanishes on all other $\Omega_i \times \Omega_i$. Define a new auxiliary function ψ_1 on $\Omega \times \Omega$ denoted by ψ_1^i on $\Omega_i \times \Omega_i$ such that

$$\begin{aligned}\psi_1^2(x,y) &= \Phi^i(x,y) + 2K\kappa\zeta_1(x,y), \\ \psi_1^i(x,y) &= \Phi^i(x,y) \quad \text{for } i \ne 2.\end{aligned}$$

Then arguing as in Case 3 we can conclude that ψ_1^2 attains its maximum in the α_2 ball around $(g(y_0, v_0), g(y_0, v_0))$. Let (x_1, y_1) be such that $\psi_1^2(x_1, y_1) = \sup_{\Omega_2 \times \Omega_2} \psi_1^2$. Since $\alpha_2 < \frac{\beta}{2}$, $x_1, y_1 \notin A$. Using techniques similar to those of Lemma 5.2 we can prove that

$$\frac{|x_1 - y_1|^2}{\epsilon} \leq \omega_\kappa^2\big(\sqrt{C\epsilon}\big) + 2K\kappa,$$
$$|x_1|,\ |y_1| < \hat{C}\sqrt{\kappa}.$$

Now either $(x_1, y_1) \in \Omega \setminus (A \cup C) \times \Omega \setminus (A \cup C)$ or one of x_1 or $y_1 \in C$. In both cases, we are either in Case 2 or in Case 3. Thus in any case, after finitely many steps, we will arrive at Case 2 and get that $\sup_i \sup_{\Omega_i \times \Omega_i} \Phi^i(x, y) \leq 0$. This proves the claim in Step 1.

Step 2. In Step 2 we show the uniqueness. For any $x \in \Omega$,

$$u_1(x) - u_2(x) \leq \Phi(x, x) + 2\kappa|x|^2.$$

Sending κ to 0, we get

$$\begin{aligned} u_1(x) - u_2(x) &\leq \Phi(x, x) \\ &\leq \sup_i \sup_{\Omega_i \times \Omega_i} \Phi^i(x, y) \\ &\leq 0, \end{aligned}$$

where the last inequality follows by Step 1. Now interchanging the roles of u_1 and u_2, we get other way inequality, which proves that $u_1 = u_2$ for all $x \in \Omega$, and hence the uniqueness. □

Acknowledgments. The authors would like to thank Prof. M. K. Ghosh for introducing them to the problem and Prof. L. C. Evans for useful references and discussions on switching problems. The authors would also like to thank referees for suggesting useful corrections.

BOUNDED VARIATION SINGULAR STOCHASTIC CONTROL AND DYNKIN GAME*

FREDERIK BOETIUS†

Abstract. We consider a bounded variation singular stochastic control problem with value V in a general situation with control of a diffusion and nonlinear cost functional defined as solution to a backward stochastic differential equation (BSDE). Associated with this is a Dynkin game with value u. We establish the well-known relation $\frac{\partial}{\partial x}V = u$ for this general situation. A saddle point for the Dynkin game is given by the pair of first action times of an optimal control.

The methods are from stochastic analysis and include a priori estimates, pathwise construction, and comparison theorems for forward stochastic differential equations (FSDE) and BSDE.

Key words. backward stochastic differential equation, singular stochastic control, optimal stopping, Dynkin game, nonlinear cost functional, comparison theorem for SDE, pathwise construction

1. Introduction.

Recent years have seen a steeply increasing interest in mathematical finance. Among other theories, the theory of irreversible investment under uncertainty has benefited from this development and received treatment in both mathematical and economical journals (see the references below). Many examples for different kinds of real-life investment problems are collected in the monograph by Dixit and Pindyck [25]. Furthermore, the subject attracts attention because it is intimately related to the behavior and treatment of options. Whereas the option is typical for a single irreversible decision of a small investor, the irreversible investment problem is a large-scale analogue requiring continuous decision making. Both aspects, and the implications for economic equilibrium, are discussed at length by Baldursson and Karatzas [5]. The mathematical counterpart of this "duality" between irreversible investment and options is found in the relation between singular stochastic control and optimal stopping, which has been studied extensively for simple models and, recently, also in some complex situations.

One of the key elements in modern mathematical finance is the use of backward stochastic differential equations (BSDE) for pricing and hedging contingent claims, both in perfect and imperfect markets. With the help of BSDE these problems can be solved in the original probability spaces. Furthermore, they provide the means to overcome some shortcomings in the standard expected utility framework. An overview of the broad range of applications is given by El Karoui, Peng, and Quenez [31].

This paper tries to further extend the mathematical results on singular control and optimal stopping to more general situations. Allowing for partly reversible investment, the related stopping problem becomes a game of optimal stopping or Dynkin game. Cost functionals are defined as solutions to BSDE, so the optimization problem is posed in the context of g-semisolutions, in the terminology of Peng [61].

There are two major approaches to the problem based on analytical or on probabilistic tools. To arrive at our results we make use of results from stochastic analysis, in particular, comparison theorems and a priori estimates for SDE. Keeping in mind the analytical characterizations in optimal control and optimal stopping, the main theorem, Theorem 1.3 below, also deals with the old relationship of smooth fit in control and the smooth pasting condition in optimal stopping.

1.1. Problem formulation. Assume as given a probability space $(\Omega, \mathcal{F}, \boldsymbol{P})$, a time interval $\bar{\imath} := [0, T]$, and a filtration $\{\mathcal{F}_t\}_{t\in\bar{\imath}}$ satisfying the usual conditions, generated by a standard d-dimensional Brownian motion W_t. For a random starting point η with values in $\mathbb{R}^n$ and initial time $t_0 \in \bar{\imath}$ we consider the *controlled forward backward stochastic differential equations (FBSDE)* on $[t_0, T]$:

$$\begin{aligned} dX_u &= b(u, X_u)\,du - dC_u + \sigma(u, X_u)^\top\,dW_u, \\ dY_u &= -g(u, X_u, Y_u, Z_u)\,du - a_u^\top\,dC_u + Z_u^\top\,dW_u, \\ X_{t_0} &= \eta, \\ Y_T &= \xi = h(X_T). \end{aligned} \tag{1.1}$$

We use the notation $a^\top\,dC := {a^U}^\top\,dC^U - {a^L}^\top\,dC^L$. C is called the control, and a class of admissible controls will be introduced in Definition 2.1. Further assumptions on the data (b, σ, C, h, g, a) will be fixed in Definition 2.2 below, which states conditions for existence and uniqueness of solutions to (1.1) for an n-dimensional state process X. We will focus on $n = 1$ and $\eta = x \in \mathbb{R}$.

Control problem. The solution to (1.1) is denoted by $(X_t^{t_0,x,C}, Y_t^{t_0,x,C}, Z_t^{t_0,x,C})$. Then $X^{t_0,x,C}$ is called the state process, and $Y^{t_0,x,C}$ is the cost associated with control C. To justify terminology, write the backward state component $Y = Y_t^{t_0,x,C}$ in the standard representation

$$Y_t = E\left[h(X_T) + \int_t^T g(s, X_s, Y_s, Z_s)\,ds + \int_{[t,T)} a_s^U\,dC_s^U - \int_{[t,T)} a_s^L\,dC_s^L \middle| \mathcal{F}_t\right].$$

Viewing h, g, and a as the terminal, running, and control cost, the process Y can be seen as the dynamic version of some cost functional dependent on the state process X and the control C exercised. If g is linear in y, then Y_t is obtained by integrating over appropriately discounted costs after time t.

To ease notation we set $t_0 = 0$ and omit this index henceforth.

Definition 1.1. *The control problem comprises determining the value function V and finding an optimal control $C^\star \in \mathcal{A}$ with the property*

$$V(t_0, x) := V(x) := \operatorname*{ess\,inf}_{C\in\mathcal{A}} Y_0^{x,C} = Y_0^{x,C^\star} \qquad [\boldsymbol{P}]. \tag{1.2}$$

The problem is said to be well-posed if $|V(x)| < \infty$.

While $V(x) < \infty$ is obvious, we assume $-\infty < V(x) < \infty$ for all x.

Thus in the control problem one faces the problem of minimizing the cost functional Y, which is defined in an unusual way as solution to a BSDE. Taking a look at its representation above we see that its components are more or less standard in a control problem, namely, a terminal cost h dependent on the state X_T when reaching the time horizon, proportional cost a^U for decreasing X, and proportional recovery of cost a^L for increasing X, and a running cost g. The unusual fact is that the running

cost depends not only on the state of the system but also on the current cost level and the process Z from the martingale representation of Y. Observe that if the running cost is of the form $g(t,x,y,z) = g^1(t,x) + g^2(t)y$, then the effect of g^2 is discounting and Y_0 can be written as a standard expected value without reference to Y_t.

A similar situation in a control problem was considered by Peng [60]. Including Y in the running cost is a step toward using his g-expectation concept [61]. In economic terms, a nonlinear cost g corresponds to a nonadditive stochastic differential utility as introduced by Duffie and Epstein [26]. Its main feature is that, in contrast to standard additive utility, preferences with respect to timing differences need not be induced by discounting. As an example in applications one may consider a situation where the credit rating and therefore the financing cost of an investor depend on the prospects of his business, measured by the expected payoff Y. In financial applications Z has an interpretation as information process or hedging portfolio, whence its inclusion may turn out to be useful.

As the data need not be Markov, b, σ, a, g, h, and therefore V also may depend on ω in an $\mathcal{F}_{t_0}$-measurable way; we omit this dependence in the notation. One might wish to consider also the behavior of the value V as the system evolves, and we actually need to do so when we introduce the associated Dynkin game. Then one has to take the past of ω into account. Observe that an extension of (1.2) by using $\operatorname{ess\,inf}_{C\in\mathcal{A}} Y_t^{x,C}$ for $t>0$ leads to senseless results. To avoid a cumbersome definition we set $V_t(x) := Y_t^{x,C^*}$ for an optimal control C^*, as we will consider such V_t only in the case that there is a solution to the control problem.

Associated stochastic game of optimal stopping. Now we turn to a two-player stochastic game of optimal stopping or Dynkin game associated with the above control problem. It will turn out that its value is the derivative of the value in the control problem and that a pair of optimal stopping times is determined by the first action time of an optimal control.

So denote by $\mathcal{T}_t$ the class of $\mathcal{F}_s$-stopping times with values a.s. in $[t,T]$, and $\mathcal{T} := \mathcal{T}_0$. Assume for a while that b, h, and g are partially differentiable with respect to (x,y,z), σ is linear in x, and g is linear in z (hence Dg is independent of z). Γ^x denotes a deflator process (see (2.2)). For initial condition (t_0,x) (again, we omit t_0) and $\sigma,\tau\in\mathcal{T}_0$ define the payoff $R_t^{t_0,x}(\sigma,\tau) = R_t^x = R_t$, where (R,Q) is the solution of the BSDE

$$\begin{aligned} dR_u &= -\langle Dg(t,X_t^{x,0,0},V_t(x)),(\Gamma_t^x,R_t,Q_t)\rangle \boldsymbol{\chi}_{t\le\sigma\wedge\tau}\,dt + Q_t^\top\,dW_t,\\ R_T &= \Big(h_x(X_T^{x,0,0})\boldsymbol{\chi}_{\sigma\wedge\tau=T} + a_\tau^L \boldsymbol{\chi}_{\substack{\tau\le\sigma\\ \tau<T}} + a_\sigma^U \boldsymbol{\chi}_{\substack{\sigma\le\tau\\ \sigma<T}}\Big)\Gamma^x_{\sigma\wedge\tau\wedge T}. \end{aligned} \tag{1.3}$$

Interpretation. R^x defined through (1.3) has the integral representation

$$\begin{aligned} R_t(\sigma,\tau) = E\bigg[\int_t^{\sigma\wedge\tau} &\langle Dg(s,X_s^{x,0,0},V_s(x)),(\Gamma_s^x,R_s,Q_s)\rangle\,ds\\ &+ h_x(X_T^{x,0,0})\Gamma_T^x\boldsymbol{\chi}_{\sigma\wedge\tau=T} + a_\sigma^U\Gamma_\sigma^x\boldsymbol{\chi}_{\substack{\sigma\le\tau\\ \sigma<T}} + a_\tau^L\Gamma_\tau^x\boldsymbol{\chi}_{\substack{\tau\le\sigma\\ \tau<T}}\,\bigg|\,\mathcal{F}_t\bigg]. \end{aligned} \tag{1.4}$$

We interpret this as a game for two players MIN and MAX: MIN pays MAX at rate $\langle Dg,\cdot\rangle$ as long as the game continues and the amount $h_x\Gamma_T$ upon reaching the time horizon T. If one of the players chooses to terminate early at times σ or τ, MIN pays MAX $a_\sigma^U\Gamma_\sigma$ or $a_\tau^L\Gamma_\tau$, depending on whether MIN or MAX stopped the game.

So MIN seeks to minimize $R^x(\sigma,\tau)$ by choice of σ, whereas MAX wishes to maximize the payoff by choice of τ.

Formally we define the upper and lower values

$$u^+(x) := \operatorname*{ess\,inf}_{\sigma\in\mathcal{T}} \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} R_0^x(\sigma,\tau), \tag{1.5a}$$

$$u^-(x) := \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} \operatorname*{ess\,inf}_{\sigma\in\mathcal{T}} R_0^x(\sigma,\tau). \tag{1.5b}$$

We assume $-\infty < u^-(x)$. By the definition of u^+ and u^-, $u^- \le u^+$ holds $\boldsymbol{P}$-a.s.

A solution of the game consists of a pair of stopping times such that neither of the two players has an incentive to deviate from his strategy. The optimization of the opponent is anticipated, and the right of choosing one's strategy first gives no advantage, i.e., has no additional value, which is the meaning of the Isaac's equation (1.6) below.

DEFINITION 1.2. *The associated stochastic game of optimal stopping or Dynkin game consists of determining the upper and lower values u^+ and u^- and the value function u as solution to the Isaac's equation*

$$u(x) := u^+(x) = u^-(x), \tag{1.6}$$

and of finding a saddle point $(\sigma^\star,\tau^\star)\in\mathcal{T}\times\mathcal{T}$, i.e., stopping times such that

$$\begin{aligned} u(x) &= R_0^x(\sigma^\star,\tau^\star) \\ &= \operatorname*{ess\,inf}_{\sigma\in\mathcal{T}} R_0^x(\sigma,\tau^\star) = \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} R_0^x(\sigma^\star,\tau) \qquad [\boldsymbol{P}]. \end{aligned} \tag{1.7}$$

To obtain the relation between the two problems we will make some convexity (2.8) and smoothness (3.15) assumptions. These could be relaxed up to some point.

Our main result is the following theorem.

THEOREM 1.3. *Let the dimension of the state process be $n = 1$ and assume that* (2.8) *and* (3.15) *hold and that there exists an optimal control $C = (C^U, -C^L)$ for the control problem introduced in Definition* 1.1 *starting at x. Then the value function of the control problem V is partially differentiable at x with respect to the space variable. The associated Dynkin game introduced in Definition* 1.2 *has a solution, and its value is the partial derivative of the value of the control problem:*

$$\frac{\partial}{\partial x} V(x) = u(x). \tag{1.8}$$

Let $\sigma^0 := \inf\{t \ge 0 \,|\, C_t^U > C_0^U\}$ and $\tau^0 := \inf\{t \ge 0 \,|\, C_t^L > C_0^L\}$ denote the first action times of the controls C^U and C^L. They form a saddle point for the Dynkin game which has value

$$u(x) = R_0^x(\sigma^0,\tau^0). \tag{1.9}$$

1.2. Remarks and references. Singular stochastic control problems, their connection with a problem of optimal stopping, and the relation $\frac{\partial}{\partial x}V = u$ date back to an investigation of spaceship control by Bather and Chernoff [7]. The optimization problem received much interest after the work of Beneš, Shepp, and Witsenhausen [11], who were able to obtain some explicit solutions. The methods employed in their work and by several authors thereafter include characterizations of the value as a

solution to a Hamilton–Jacobi–Bellman PDE restricted to a bounded domain, with terminal condition and gradient constraints at the boundaries. If systems of this type are solved directly, additional information about the behavior of the value at the boundary is required. This usually takes the form of the *principle of smooth fit* stating that the value should be twice continuously differentiable across the boundary. Alternatively, one tries to derive the value from solutions to a related free boundary problem; thus in essence one establishes a relation with a stopping problem of the form $\frac{\partial}{\partial x}V = u$, where it is known as the *principle of smooth pasting* that the value u of the stopping problem is once continuously differentiable across the boundary. This was made rigorous by Karatzas [42].

In contrast to this analytical approach, probabilistic methods, namely, a pathwise construction, were introduced by Karatzas and Shreve [44] for the link between monotone follower and optimal stopping of Brownian motion. The rule for deriving an optimal stopping time as first action time of an optimal control is also due to [44]. These results were extended by the same authors in [45], [46] and also by Karatzas [43], Baldursson [4], El Karoui and Karatzas [29], [30], Baldursson and Karatzas [5], and Boetius and Kohlmann [18], among others. In the latter paper, instead of a monotone follower problem, the control of a diffusion is considered. Therefore exercise of control feeds back into the dynamics of the system, requiring the use of a comparison theorem.

The relation between singular stochastic control and Dynkin games was, to our knowledge, first noted by Taksar [67]. A result similar to ours for control of Brownian motion and very general cost data was obtained by Karatzas and Wang [49]. An extension to infinite time horizon and additional absolutely continuous control ("mixed control" and "mixed game" problems) is treated by Hamadene, Lepeltier, and Wu [39]. Theorem 1.3 focuses on the relation of the value functions and optimal strategies, respectively, saddle point, for the general case of bounded variation control of a diffusion with stochastic dynamics and cost structure and with a cost functional defined as solution to a nonlinear BSDE. Again, the basic ideas are those of Karatzas and Shreve [44], but the general formulation especially for the cost functional in the problem poses some technical difficulties and requires the frequent use of comparison theorems for BSDE.

It should be noted that the pathwise approach of [44] breaks down if control may be exercised in more than one dimension, as there is no extension of the powerful tool of comparison theorems in that case. This is due to the phenomenon of coalescing stochastic flows; see, e.g., Baxendale [8] and Darling [22]. Consequently, singular control problems in higher dimensions are inherently difficult. Results for that case, including existence of optimal controls, were obtained by Menaldi and Taksar [59], Soner and Shreve [66], and Kruk [52], [53], to mention but a few.

We should note that existence of an optimal control is an essential element in this paper. A simple example for nonexistence of an optimal control in a finite horizon problem by Lalley is presented in Karatzas and Shreve [44, p. 863], who also provide a nonconstructive general existence result for monotone control problems using weak-$*$ compactness arguments. Compactness arguments relying on strong growth assumptions for the data are used by Haussmann and Suo [40], and Ma and Yong [55] provide a proof for the case when cost data grow less than linearly. A general existence result for bounded variation control by Karatzas and Wang [49] makes use of a result of Komlós [51] on L^1-convergence of the Cesàro sequences of ϵ-optimal processes. Hamadene and Lepeltier [37], [36] obtain existence of a solution to both, the control problem and the Dynkin game, using BSDE if the Isaac's condition is satisfied.

Properties of optimal controls and state processes can be found in, e.g., Fleming and Soner [33, p. 360] and have been subject to a number of articles by several authors.

Besides the problems of irreversible or partially reversible investment mentioned already, applications extend from the original problem of spaceship control in [7] to queueing systems, control of storage or manufacturing systems, mathematical biology, optimal dividend distribution and risk control (in particular, in the insurance industry), optimal consumption and investment, portfolio optimization under transaction costs, and hedging and pricing under constraints. Some of the more recent articles in this context are those by Højgaard and Taksar [41], Cadenillas [19], Alvarez [2], Kushner [54], Benth, Karlsen, and Reikvam [13], and Schmock, Shreve, and Wystup [64], to mention but a few. We should point to Davis and Norman [24] for their treatment of a control problem in two dimensions. Further references are given, e.g., in [17].

The valuation of American contingent claims is one of the most prominent examples of optimal stopping problems in finance; the problem was first investigated in Samuelson [63] and McKean [58]. An account of this valuation problem is given, e.g., in Karatzas and Shreve [48], which we also cite for further references.

Further applications are given in the field of real options, where they usually exhibit the phenomenon of hysteresis or the "value of waiting to invest"; see, e.g., McDonald and Siegel [57] and especially Dixit and Pindyck [25] for an account of investment decisions where real options play an important role. Recent applications for technology adoption or credit default are given in, e.g., Alvarez [1] and Alvarez and Stenbacka [3].

Applications of Dynkin games in financial markets are considered in Ma and Yong [56] and Kifer [50]. Games and their applications in economics are widely discussed by Fudenberg and Tirole [35]. More recently it was discovered that the value of an optimal stopping problem or a Dynkin game can be represented as the solution to an appropriately reflected BSDE; see the articles by Cvitanić and Karatzas [21] and El Karoui, Kapoudjian, Pardoux, Peng, and Quenez [28]. Hamadene and Lepeltier [38] obtained the saddle point strategy for the mixed game problem when the Isaac's condition is satisfied.

There is a vast general literature on problems of optimal stopping, and one may refer to, e.g., Friedman [34, Chap. 16], Shiryaev [65], and Bensoussan and Lions [12] for an analytical approach and to Davis and Karatzas [23] for a probabilistic approach. The game of stopping under consideration was introduced by Dynkin [27] and studied further by Bismut [14], [15] and others. Further references are given in [17].

This paper is organized as follows. In section 1 we introduce the optimization problems, state the main result, and note some applications. Section 2 is devoted to notation and the basic tools from stochastic analysis. It also contains some consequences of the convex structure in the control problem. Section 3 contains the proof of Theorem 1.3. Here we perform the pathwise analysis and obtain the crucial estimates for the difference quotient of cost functionals. Finally, section 4 takes a look at several possible extensions.

2. Preliminaries. We now introduce in more detail terminology and basic assumptions (subsection 2.1), recall a priori estimates and comparison theorems (subsection 2.2) that are essential to many arguments, and discuss some consequences of the convex structure (subsection 2.3) that we will investigate.

2.1. Basic notation. We use the following notation as defined in Ma and Yong [56] for the different spaces of measurable random variables:

- For a σ-algebra, $\mathcal{G} \subset \mathcal{F}_T$ $L^p_{\mathcal{G}}(\Omega;\mathbb{R}^k)$ denotes the set of $\mathcal{G}$-measurable $\mathbb{R}^k$-valued random variables X such that $E\big[|X|^p\,dt\big] < \infty$.
- $L^p_{\mathcal{F}}(\Omega; L^p(0,T;\mathbb{R}^k))$ denotes the set of $\mathcal{F}_t$-progressively measurable $\mathbb{R}^k$-valued processes X_t such that $E\big[\int_0^T |X_t|^p\,dt\big] < \infty$; we write $L^p_{\mathcal{F}}(0,T;\mathbb{R}^k)$ if there is no danger of confusion.
- $L^p_{\mathcal{F}}(\Omega; C(\bar{\imath};\mathbb{R}^k))$ denotes the set of $\mathcal{F}_t$-progressively measurable continuous $\mathbb{R}^k$-valued processes X_t such that $E\big[\sup_{\bar{\imath}}|X_t|^p\big] < \infty$.
- $W^{1,\infty}(M,N)$ for Euclidean spaces M, N denotes the set of functions $f : M \to N$ that are Lipschitz continuous w.r.t. the metrices derived from the scalar products.
- $L^p_{\mathcal{F}}(0,T;W^{1,\infty}(M,N))$ for Euclidean spaces M, N denotes the set of functions $f : \bar{\imath} \times M \times \Omega \to N$ such that (a) for fixed $m \in M$, $(t,\omega) \mapsto f(t,m,\omega)$ is $\mathcal{F}_t$-progressively measurable, (b) $f(t,0,\omega) \in L^p_{\mathcal{F}}(0,T;N)$, and (c) there exists a constant $L \in \mathbb{R}_{>0}$ such that

$$\big|f(t,m,\omega) - f(t,m',\omega)\big| \le L|m-m'| \qquad \forall m,m' \in M,\ \text{a.e. } t \in \bar{\imath},\ \boldsymbol{P}\text{-a.s.}$$

- $L^p_{\mathcal{F}_T}(\Omega; W^{1,\infty}(M,N))$ for Euclidean spaces M, N denotes the set of functions $f : M \times \Omega \to N$ such that for any $m \in M$, $\omega \mapsto f(m,\omega)$ is $\mathcal{F}_T$-measurable, $m \mapsto f(m,\omega)$ is uniformly Lipschitz, and $f(0,\omega) \in L^p_{\mathcal{F}}(\Omega;N)$.

$\|\cdot\|_p$ denotes the usual p-norm in the spaces defined above.

For an $\mathbb{R}^k$-valued process $B = (B^j)^\top_{1\le j\le k}$ of bounded variation its absolute variation is denoted by $|B| := \sum_{j=1}^k |B^j|$; i.e., if $\mu_j = \mu_j^+ - \mu_j^-$ is the (ω-dependent) signed measure (with Hahn-decomposition (μ_j^+, μ_j^-)) defined by

$$\mu_j(A) := \int \boldsymbol{\chi}_A\,dB^j, \qquad \text{then} \qquad \int \boldsymbol{\chi}_A\,d|B| = \sum_{j=1}^k (\mu_j^+(A) + \mu_j^-(A)).$$

For an $\mathbb{R}^k$-valued progressively measurable process $a = (a^j)_{1\le j\le k}$ and an $\mathbb{R}^k$-valued bounded variation process $C = (C^j)_{1\le j\le k}$ we use—depending on whether we focus on a norm for a or C—the notation

$$\|a\|^2_{[C,\bar{\imath}]} := E\left[\sum_{j=1}^k \left(\int_{\bar{\imath}} |a^j_s|\,d|C^j|_s\right)^2\right] =: |C|^2_{[a,\bar{\imath}]}. \tag{2.1}$$

Using the Hölder inequality we obtain the estimates

$$E\left[\left(\int_{\bar{\imath}} a_s^\top\,dC_s\right)^2\right] \le k\|a\|^2_{[C,\bar{\imath}]} = k|C|^2_{[a,\bar{\imath}]} \le kE\left[\sum_{j=1}^k \left(|C^j|_T \int_{\bar{\imath}} |a^j(s)|^2\,d|C^j|_s\right)\right].$$

For a function $f : \mathbb{R} \to \mathbb{R}$ we define the Dini derivatives

$$\Delta^\pm f(x) := \limsup_{\delta \searrow 0} \frac{f(x\pm\delta) - f(x)}{\pm\delta}, \qquad \Delta_\pm f(x) := \liminf_{\delta \searrow 0} \frac{f(x\pm\delta) - f(x)}{\pm\delta}$$

and the one-sided differentials $D^+f := \Delta^+ f = \Delta_+ f$ and $D^-f := \Delta^- f = \Delta_- f$ if they exist. Note that D^+f and D^-f exist for convex functions f, are left continuous and right continuous, respectively, and satisfy $D^-f(x) \le D^+f(x) \le D^-f(y)$ for $x < y$ (cf. problem 3.6.19 of Karatzas and Shreve [47]).

DEFINITION 2.1. *Denote by $\mathcal{A}$ the class of admissible controls. It consists of all $\mathbb{R}$-valued, $\{\mathcal{F}_t\}$-adapted processes C with paths $\boldsymbol{P}$-a.s. left continuous with right-hand limits (LCRL) and of bounded variation satisfying $|C|^2_{[\mathbf{1},\bar{\imath}]} = E\big[|C|^2_T\big] < \infty$. We write C decomposed in $C = C^U - C^L$, where C^U, C^L are nonnegative, increasing, and LCRL, and the decomposition is minimal. We also use the notation $C = (C^U, -C^L)$.*

DEFINITION 2.2. *Data (b, σ, C) for the forward and (h, g, a, C) for the backward equation in (1.1) are called standard data if they satisfy*

- *$b \in L^2_{\mathcal{F}}(0, T; W^{1,\infty}(\mathbb{R}, \mathbb{R}))$ and $\sigma \in L^2_{\mathcal{F}}(0, T; W^{1,\infty}(\mathbb{R}, \mathbb{R}^d))$;*
- *$C \in \mathcal{A}$ and $a = (a^U, a^L) : \bar{\imath} \times \Omega \to \mathbb{R}^2$ progressively measurable such that $a^U \geq a^L$ and for all $\tilde{C} \in \mathcal{A}$ the process*

$$\int_{[0,t)} a_s^\top \, d\tilde{C}_s := \int_{[0,t)} a_s^U \, d\tilde{C}_s^U - \int_{[0,t)} a_s^L \, d\tilde{C}_s^L$$

  is in $L^2_{\mathcal{F}}(0, T; \mathbb{R})$ and has LCRL paths $\boldsymbol{P}$-a.s.;
- *$g \in L^2_{\mathcal{F}}(0, T; W^{1,\infty}(\mathbb{R} \times \mathbb{R} \times \mathbb{R}^d, \mathbb{R}))$ and $h \in L^2_{\mathcal{F}_T}(\Omega; W^{1,\infty}(\mathbb{R}, \mathbb{R}))$.*

So apart from sufficient measurability we require uniform Lipschitz continuity of the data (b, σ, g, h) and square integrability and we consider bounded variation control. The processes involved need not be Markov.

Note that (1.1) is well defined even for decompositions of C that are not minimal. At times, we will work with such decompositions as well. From the requirements on a it is clear that $Y^{x,C^U,C^L} \leq Y^{x,\bar{C}^U,\bar{C}^L}$ if (C^U, C^L) and $(\bar{C}^U, \bar{C}^L)$ are nonnegative, increasing, LCRL decompositions of the same process $C \in \mathcal{A}$ and (C^U, C^L) is minimal.

Using a transformation as in Peng [61], which shifts the control C from the equation into the data, it is easy to see that (1.1) has a unique solution $(X, Y, Z) \in L^2_{\mathcal{F}}(0, T; \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d)$. See also the construction in subsection 3.2, where this transformation is applied expressis verbis. Dependence on data and parameters η, b, σ, C, ξ, h, a, g may be expressed by a superscript, and we also refer to the components of C, in particular when using a certain decomposition. Results on existence and uniqueness of solutions to FSDE can be found in, e.g., Karatzas and Shreve [47]; for BSDE one may consider, e.g., El Karoui, Peng, and Quenez [31] or the monographs by Yong and Zhou [68, Chap. 7] or Ma and Yong [56].

Sometimes we consider the backward equation without reference to a particular forward process. We then omit dependence of g on x and write ξ for the terminal condition, with suitably adapted meaning of standard data.

We further introduce *deflator processes* to refer to some flow properties of solutions to the forward equation in (1.1), under the additional convexity assumptions in (2.8) below. In effect we will require σ to be affine and b to be convex in x; thus $\sigma_x(t)$ and $D_x^+ b$ are well defined. The biased deflator process Γ^{x,C^U,C^L} for a control $(C^U, -C^L) \in \mathcal{A}$ is given as solution to the FSDE

$$\begin{aligned} d\Gamma_t^{x,C^U,C^L} &= \Gamma_t^{x,C^U,C^L} \big(D_x b(t, X_t^{x,C^U,C^L}) \, dt + \sigma_x(t)^\top \, dW_t \big), \\ \Gamma_0^{x,C^U,C^L} &= 1. \end{aligned} \tag{2.2}$$

Its uncontrolled version is abbreviated as $\Gamma^x := \Gamma^{x,0,0}$, which serves as deflator for the payoff in the Dynkin game (1.3). Properties of the deflator processes are discussed in more detail in subsection 2.3.

2.2. Comparison theorems and a priori estimates. Comparison theorems lie at the heart of the pathwise approach taken in this paper, and in some instances

we need a priori estimates for BSDE to obtain convergence results. Due to the impact of controls they appear in a slightly different form from those known commonly in the literature.

LEMMA 2.3 (a priori estimates for FSDE). *For $i \in \{1,2\}$ let (b^i, σ^i, C^i) denote standard data, let $x^i \in \mathbb{R}$, and let X^i be the corresponding solutions of the FSDE. Define*

$$\begin{aligned} &\boldsymbol{\delta} X_t := X_t^1 - X_t^2, && \boldsymbol{\delta} x := x^1 - x^2, && \boldsymbol{\delta} C_t = C_t^1 - C_t^2, \\ &\boldsymbol{\delta} b_t := b^1(t, X_t^2) - b^2(t, X_t^2), && \boldsymbol{\delta}\sigma_t := \sigma^1(t, X_t^2) - \sigma^2(t, X_t^2). \end{aligned}$$

Then there is a constant K_4 depending only on T and L such that

$$E\big[\sup_{\bar\imath} |\boldsymbol{\delta} X_t|^2\big] \le K_4\big(|\boldsymbol{\delta} x|^2 + \|\boldsymbol{\delta} b\|_2^2 + \|\boldsymbol{\delta}\sigma\|_2^2 + E\big[|\boldsymbol{\delta} C|_T^2\big]\big). \tag{2.3}$$

LEMMA 2.4 (a priori estimates for BSDE). *Let, for $i \in \{1,2\}$, (Y^i, Z^i) be the solutions of the BSDE* (1.1) *corresponding to standard data (g^i, ξ^i, a^i, C^i), and define*

$$\begin{aligned} &\boldsymbol{\delta} Y_t := Y_t^1 - Y_t^2, && \boldsymbol{\delta} Z_t := Z_t^1 - Z_t^2, && \boldsymbol{\delta}\xi := \xi^1 - \xi^2, \\ &\boldsymbol{\delta} g_t := g^1(t, Y_t^2, Z_t^2) - g^2(t, Y_t^2, Z_t^2), && \boldsymbol{\delta} a_t := a_t^1 - a_t^2, && \boldsymbol{\delta} C_t := C_t^1 - C_t^2. \end{aligned}$$

There are constants depending only on L and T such that for all $t \le T$

$$E\left[\int_t^T |\boldsymbol{\delta} Z_s|^2\, ds\right] \le K_2\big(\|\boldsymbol{\delta}\xi\|_2^2 + \|\boldsymbol{\delta} g\|_2^2 + \|\boldsymbol{\delta} a\|_{[C^1,\bar\imath]}^2 + |\boldsymbol{\delta} C|_{[a^2,\bar\imath]}^2\big)\big(1 + e^{K_3(T-t)}\big) \tag{2.4}$$

and the running maximum of differences satisfies

$$E\big[\sup_{\bar\imath} |\boldsymbol{\delta} Y_t|^2\big] \le K_4\big(\|\boldsymbol{\delta}\xi\|_2^2 + \|\boldsymbol{\delta} g\|_2^2 + \|\boldsymbol{\delta} a\|_{[C^1,\bar\imath]}^2 + |\boldsymbol{\delta} C|_{[a^2,\bar\imath]}^2\big). \tag{2.5}$$

The proof for both lemmata is along the lines of El Karoui, Peng, and Quenez [31] or Peng [61], the main tools being the Itô formula, and the Burkholder–Davis–Gundy, Hölder, and Gronwall inequalities. It may be worthwhile noting that an application of the latter requires a.e. continuity of the functions involved. We do not encounter difficulties in using the Gronwall inequality as the maps $t \mapsto E\big[|\boldsymbol{\delta} X_t|^2\big]$ and $t \mapsto E\big[|C|_t\big]$ are continuous a.e. in $\bar\imath$. Details are given in [17]. An even stronger result on jumps of right continous with left-hand limits (RCLL) processes can be found in Proposition 1.2.26 of Karatzas and Shreve [47].

THEOREM 2.5 (comparison theorem for FSDE). *Consider, for $i \in \{1,2\}$, the solutions X^i of the FSDE corresponding to standard data (b^i, σ^i, C^i) and initial condition $x^i \in \mathbb{R}$. Assume further that*

$$\begin{aligned} &b^1(\omega,t,x) \ge b^2(\omega,t,x), && \sigma^1(\omega,t,x) = \sigma^2(\omega,t,x), \\ &-d(\boldsymbol{\delta} C_t) \ge 0 \quad \textit{(i.e., } \boldsymbol{\delta} C \textit{ decreasing)}, && \boldsymbol{\delta} x \ge 0. \end{aligned}$$

Then the difference $\boldsymbol{\delta} X_t$ is positive a.s.:

$$X_t^1 \ge X_t^2 \quad \forall t \in \bar\imath \quad [\boldsymbol{P}].$$

COROLLARY 2.6. *It is easy to see that instead of $b^1 \ge b^2$ it is actually sufficient if one of the conditions*

$$b^1(\omega,t,X_t^1) \ge b^2(\omega,t,X_t^1), \qquad b^1(\omega,t,X_t^2) \ge b^2(\omega,t,X_t^2) \tag{2.6}$$

holds. If, e.g., b^1 is independent of x, this reduces to $b^1(\omega,t) \ge b^2(\omega,t,X_t^1)$.

The comparison theorem for the backward equation in (1.1) is quite similar.

THEOREM 2.7 (comparison theorem for BSDE). *Let, for $i \in \{1,2\}$, (g^i, ξ^i, a^i, C^i) denote standard data and (Y^i, Z^i) denote the corresponding solutions of the BSDE. a^i may depend on Y. Assume further that $\boldsymbol{P}$-a.s.*

$$g^1(t,y,z) - g^2(t,y,z) \geq 0, \qquad \xi^1 - \xi^2 \geq 0, \tag{2.7a}$$

$$a^1(t)^\top d(C^1_t - C^2_t) \geq 0, \qquad (a^1(t) - a^2(t))^\top dC^2_t \geq 0. \tag{2.7b}$$

Then the difference $\boldsymbol{\delta} Y_t := Y^1_t - Y^2_t$ is nonnegative $\boldsymbol{P}$-a.s.

Both theorems can be proved using the linearization arguments of El Karoui, Peng, and Quenez [31] or El Karoui and Quenez [32], which only need to be adapted to include the control process C. Note that the equality $\sigma^1 = \sigma^2$ is vital for this argument in the forward case.

It follows from the arguments in [31], [32] that, instead of the first inequality in (2.7a), it is sufficient if one of the conditions

$$g^1(t, Y^1_t, Z^1_t) - g^2(t, Y^1_t, Z^1_t) \geq 0, \quad g^1(t, Y^2_t, Z^2_t) - g^2(t, Y^2_t, Z^2_t) \geq 0 \tag{2.7c}$$

holds. This will prove useful in situations where we make use of the convexity of the driver $g(t,x,y,z)$. In situations where, e.g., g^1 does not depend on (Y^1, Z^1), we conclude that $g^1_t \geq g^2(t, Y^1_t, Z^1_t)$ is also sufficient.

Instead of (2.7b) it is actually sufficient if we have

$$\int_{[0,t)} a^1(s)^\top dC^1_s - \int_{[0,t)} a^2(s)^\top dC^2_s \quad \text{is increasing in } t. \tag{2.7d}$$

Hence the theorem remains true if (2.7b) is replaced by (2.7d) or

$$a^2(t)^\top d(C^1_t - C^2_t) \geq 0, \qquad (a^1(t) - a^2(t))^\top dC^1_t \geq 0. \tag{2.7e}$$

Often we can use properties of Y^i when verifying (2.7a), e.g., $Y^i \geq 0$, because then we can restrict the estimate to $y \in \mathbb{R}_{\geq 0}$. On the contrary, we usually know very little about the processes Z^i. Hence, if one of the drivers is linear in z, (2.7a) in effect requires that the partial derivatives g^1_z, g^2_z agree. This will force us to assume that g_z is independent of x, y, z, as in the associated Dynkin game the driver takes the form $\langle (g_x, g_y, g_z), (\Gamma, R, Q) \rangle$.

Note that all of the above results still hold if we use $C^i = (C^{i,U}, C^{i,L})$ where the decomposition is not minimal.

2.3. Convex structure of the control problem. An important prerequisite for our proof of the relation $\frac{\partial}{\partial x} V = u$ is convexity of the value V, which will be discussed in Theorem 2.10 below. We also include some useful estimates and comparison results for controlled forward processes and biased deflators in section 2.4 below.

DEFINITION 2.8. *Let the dimension of the state space be $n = 1$. The control problem* (1.2) *has convex structure if the data satisfy*

$$b \text{ is convex in the space variable } x, \tag{2.8a}$$

$$\sigma \text{ is affine in the space variable } x, \tag{2.8b}$$

$$h \text{ is convex and increasing in the space variable } x, \tag{2.8c}$$

$$g \text{ is convex in the variables } (x,y,z) \text{ and increasing in } x. \tag{2.8d}$$

It should be noted that in the case of affine dynamics b, σ in the forward equation, monotonicity of h and g in x is not required. In fact, most arguments in the discussion below remain unchanged or could even be simplified in that case.

Let, for $i \in \{1,2\}$, (b,σ,C^i,g,h,a) denote standard data for the controlled forward-backward system (1.1), and let $x^i \in \mathbb{R}$ and $\lambda \in [0,1]$. Denote, for $j \in \{1,2,\lambda\}$,

$$x^\lambda = \lambda x^1 + (1-\lambda)x^2, \qquad C^\lambda = \lambda C^1 + (1-\lambda)C^2,$$
$$X^j = X^{x^j,b,C^j,\sigma}, \qquad (Y^j,Z^j) = (Y,Z)^{g,h(T,X_T^j),a,C^j}.$$

Thus X^λ starts at a convex combination of x^1, x^2 and is controlled by a convex combination of controls C^1, C^2.

PROPOSITION 2.9. *Assume* (2.8). *Then the following inequalities hold* $\boldsymbol{P}$*-a.s. for all* $t \in \bar{\imath}$*:*

$$\bar{X}_t^\lambda := \lambda X_t^1 + (1-\lambda)X_t^2 \geq X_t^\lambda, \tag{2.9a}$$
$$\bar{Y}_t^\lambda := \lambda Y_t^1 + (1-\lambda)Y_t^2 \geq Y_t^\lambda. \tag{2.9b}$$

The proof can be done for the forward and backward cases separately: Starting with the forward equation, let

$$\bar{b}_t^\lambda := \lambda b(t,X_t^1) + (1-\lambda)b(t,X_t^2)$$

denote the driver of $\bar{X}^\lambda$. Then $\bar{b}_t^\lambda \geq b(t,\bar{X}_t^\lambda)$ as b is convex, which suffices according to Corollary 2.6. Now observe that we just need to prove (2.9b) with Y^λ defined by the (not necessarily minimal) decomposition $\lambda(C^{1,U},C^{1,L}) + (1-\lambda)(C^{2,U},C^{2,L})$; here $\boldsymbol{\delta}C = 0$. Defining the driver $\bar{g}^\lambda$ for $\bar{Y}^\lambda$ analogously and using (2.9a), (2.8c), and (2.8d) we obtain (2.9b).

The linearity assumption on σ may not be dropped easily, as the following example shows. Let $b = C = 0$ and $\sigma(t,x) = |x|$. Then the FSDE has a unique strong solution for each initial value $x \in \mathbb{R}$. Define X^i by

$$X_t^1 = 1 + \int_0^t |X_s^1|\,dW_s, \qquad X_t^2 = -1 + \int_0^t |X_s^2|\,dW_s;$$

hence

$$X_t^1 = \exp(W_t - \tfrac{1}{2}t), \qquad X_t^2 = -\exp(-W_t - \tfrac{1}{2}t).$$

Let $\lambda = \frac{1}{2}$; then $X_t^\lambda = 0$ is the solution of $X_t^\lambda = \int_0^t |X_s^\lambda|\,dW_s$. But

$$2\bar{X}_t^\lambda = \exp\left(-\frac{1}{2}t\right)\big(\exp(W_t) - \exp(-W_t)\big),$$

so $\boldsymbol{P}\{\bar{X}_t^\lambda > X_t^\lambda\} = \boldsymbol{P}\{\bar{X}_t^\lambda < X_t^\lambda\} = \frac{1}{2}$.

We then have as an easy consequence of (2.9) the following theorem.

THEOREM 2.10 (convexity of the value). *Assume that* (2.8) *holds. Then* V *is convex with respect to the starting point; i.e., if* $x^1, x^2 \in \mathbb{R}$ *and* $\lambda \in [0,1]$*, then*

$$V(\lambda x^1 + (1-\lambda)x^2) \leq \lambda V(x^1) + (1-\lambda)V(x^2).$$

The proof is analogous to the arguments in Karatzas and Shreve [44].

2.4. Properties of controlled forward processes. In this section we use the comparison theorem to work out some properties of the state process under a convex structure. We analyze differences of state processes and recall a result from the theory of stochastic flows on differentiability with respect to the initial condition.

Recall that the biased deflator process Γ^{x,C^U,C^L} for control $(C^U,-C^L)$ (with the uncontrolled version abbreviated as $\Gamma^x := \Gamma^{x,0,0}$) of (2.2) is the solution to the FSDE

$$\begin{aligned} d\Gamma_t^{x,C^U,C^L} &= \Gamma_t^{x,C^U,C^L}\big(D_x^+ b(t,X_t^{x,C^U,C^L})\,dt + \sigma_x(t)^\top\,dW_t\big),\\ \Gamma_0^{x,C^U,C^L} &= 1. \end{aligned}$$

When there is no ambiguity we also write $\Gamma^{x,C} := \Gamma^{x,C^U,C^L}$, as we do for controlled processes $X^{x,C}$. We further define geometric Brownian motions Γ^{up} and Γ^{lo}:

$$d\Gamma_t^{up} = \Gamma_t^{up} L\,dt + \Gamma_t^{up}\sigma_x(t)^\top\,dW_t, \qquad \Gamma_0^{up} = 1, \tag{2.10}$$

$$d\Gamma_t^{lo} = -\Gamma_t^{lo} L\,dt + \Gamma_t^{lo}\sigma_x(t)^\top\,dW_t, \qquad \Gamma_0^{lo} = 1. \tag{2.11}$$

Here L is a Lipschitz constant for b. These processes form universal bounds for "difference quotients" and differentials of the forward process.

LEMMA 2.11. *Let (b,σ,C) denote standard data of the FSDE satisfying* (2.8a) *and* (2.8b). *Then the following estimates hold for all $t\in\bar{\imath}$ a.s.:*

$$X_t^{x+\delta,C^U,0} - X_t^{x,C^U,0} \le X_t^{x+\delta,0,0} - X_t^{x,0,0} \le X_t^{x+\delta,0,C^L} - X_t^{x,0,C^L}, \tag{2.12}$$

$$\delta\Gamma_t^{lo} \le \delta\Gamma_t^{x,C^U,C^L} \le X_t^{x+\delta,C^U,C^L} - X_t^{x,C^U,C^L} \le \delta\Gamma_t^{x+\delta,C^U,C^L} \le \delta\Gamma_t^{up}, \tag{2.13}$$

$X_t^{x+\delta,C^U,0} - X_t^{x,C^U,0} \ge 0$, *and* $\Gamma_t^{lo} > 0$. *Furthermore, we have*

$$\lim_{\delta\searrow 0}\frac{1}{\delta}\big(X_t^{x+\delta,C} - X_t^{x,C}\big) = \Gamma_t^{x,C}. \tag{2.14}$$

Proof. Nonnegativity of the first term in (2.12) follows from the comparison theorem, Theorem 2.5, as both processes have the same driver and controls.

For the first inequality in (2.12), define the stopping time

$$\rho := \inf\{t\in\bar{\imath}\,|\,X_t^{x+\delta,C^U,0} \le X_t^{x,0,0}\}$$

and observe that, due to the left continuity of both processes and the comparison theorem (Theorem 2.5), ρ separates the intervals where the difference of these processes is positive and negative, respectively:

$$\begin{aligned} X_t^{x+\delta,C^U,0} &\ge X_t^{x,0,0} \qquad \text{if } t\le\rho,\\ X_t^{x+\delta,C^U,0} &\le X_t^{x,0,0} \qquad \text{if } t>\rho. \end{aligned}$$

Now set $\hat{X}^1 := X^{x+\delta,0,0} - X^{x,0,0}$ and $\hat{X}^2 := X^{x+\delta,C^U,0} - X^{x,C^U,0}$. For $t\le\rho$ consider $\tilde{X}^1 := X^{x+\delta,0,0} - X^{x+\delta,C^U,0}$ and $\tilde{X}^2 := X^{x,0,0} - X^{x,C^U,0}$. As $\hat{X}^1 - \hat{X}^2 = \tilde{X}^1 - \tilde{X}^2$ it suffices to prove $\tilde{X}^1 \ge \tilde{X}^2$. Both processes are nonnegative and have the same starting point 0 and control process 0. Their diffusion matrices are $\sigma(s,\tilde{X}_s^1)$ and $\sigma(s,\tilde{X}_s^2)$. Their drivers $\tilde{b}^1$ and $\tilde{b}^2$ satisfy

$$\begin{aligned} \tilde{b}_s^1 &= b(s,X_s^{x+\delta,0,0}) - b(s,X_s^{x+\delta,C^U,0}) \ge D_x^+ b(s,X_s^{x+\delta,C^U,0})\tilde{X}_s^1,\\ \tilde{b}_s^2 &= b(s,X_s^{x,0,0}) - b(s,X_s^{x,C^U,0}) \le D_x^- b(s,X_s^{x,0,0})\tilde{X}_s^2, \end{aligned}$$

due to the convexity of b in the space variable. As $D_x^+ b(s, X_s^{x+\delta,C^U,0}) \geq D_x^- b(s, X_s^{x,0,0})$ for $s \leq \rho$, the first inequality in (2.12) for $t \leq \rho$ follows from the comparison theorem (Theorem 2.5) and Corollary 2.6.

For $t > \rho$ consider $\hat{X}^1$ and $\hat{X}^2$. They are nonnegative, satisfy $\hat{X}_\rho^1 - \hat{X}_\rho^2 \geq 0$ by the above argument, and have the same control process 0. Their diffusion matrices are $\sigma(s, \hat{X}_s^1)$ and $\sigma(s, \hat{X}_s^2)$. Their drivers $\hat{b}^1$ and $\hat{b}^2$ satisfy

$$\begin{aligned}
\hat{b}_s^1 &= b(s, X_s^{x+\delta,0,0}) - b(s, X_s^{x,0,0}) \geq D_x^+ b(s, X_s^{x,0,0}) \hat{X}_s^1, \\
\hat{b}_s^2 &= b(s, X_s^{x+\delta,C^U,0}) - b(s, X_s^{x,C^U,0}) \leq D_x^- b(s, X_s^{x+\delta,C^U,0}) \hat{X}_s^2,
\end{aligned}$$

due to the convexity of b in the space variable. Then $\hat{X}_t^1 \geq \hat{X}_t^2$ for $t > \rho$ follows from $D_x^+ b(s, X_s^{x,0,0}) \geq D_x^- b(s, X_s^{x+\delta,C^U,0})$ and Corollary 2.6. This completes the proof of the first inequality in (2.12). □

For the second inequality consider the stopping time

$$\varrho := \inf\{t \in \bar{\imath} \,|\, X_t^{x+\delta,0,0} \leq X_t^{x,0,C^L}\}$$

and define the processes $\bar{X}^1 := X^{x+\delta,0,C^L} - X^{x+\delta,0,0}$, $\bar{X}^2 := X^{x,0,C^L} - X^{x,0,0}$, $\check{X}^1 := X^{x+\delta,0,C^L} - X^{x,0,C^L}$, and $\check{X}^2 := X^{x+\delta,0,0} - X^{x,0,0}$. Analogous arguments as employed for the first inequality show that $\bar{X}^1 - \bar{X}^2 \geq 0$ for $t \leq \varrho$ and $\check{X}^1 - \check{X}^2 \geq 0$ for $t > \varrho$, which are equivalent to the second inequality in (2.12).

The proof of (2.13) rests on quite similar arguments. $\Gamma^{lo} > 0$ $\boldsymbol{P}$-a.s. is a standard property of geometric Brownian motion. The first and last inequalities follow from the Lipschitz property of b, linearity of σ, and the comparison theorem (Theorem 2.5). For the second and third inequalities, use convexity of b in x, which gives the estimate

$$\begin{aligned}
D_x^+ b(t, X_t^{x,C^U,C^L}) &\big(X_t^{x+\delta,C^U,C^L} - X_t^{x,C^U,C^L}\big) \\
&\leq b(t, X_t^{x+\delta,C^U,C^L}) - b(t, X_t^{x,C^U,C^L}) \\
&\leq D_x^+ b(t, X_t^{x+\delta,C^U,C^L}) \big(X_t^{x+\delta,C^U,C^L} - X_t^{x,C^U,C^L}\big),
\end{aligned}$$

and apply, again, the comparison theorem.

Equation (2.14) is a standard property of stochastic flows; see, e.g., section V.7 of Protter [62]. We give a short outline of the argument in our situation. In view of (2.13) it suffices to prove

$$\Gamma_t^{x+\delta,C} \quad \searrow \quad \Gamma_t^{x,C} \qquad \text{as } \delta \searrow 0. \tag{2.15}$$

It is obvious from Theorem 2.5 that $X_t^{x+\delta,C}$ and hence $\Gamma_t^{x+\delta,C}$ decrease as $\delta \searrow 0$. By the dominated convergence theorem, with

$$\|\boldsymbol{\delta} D_x^+ b\|_2^2 := E\left[\int_0^T (D_x^+ b(s, X_s^{x+\delta,C}) - D_x^+ b(s, X_s^{x,C}))^2 |\Gamma_s^{x,C}|^2 \, ds\right],$$

$\|\boldsymbol{\delta} D_x^+ b\|_2^2 \overset{\delta\searrow 0}{\longrightarrow} 0$. Hence $E\big[\sup_{0\leq s\leq T} \big|\Gamma_s^{x+\delta,C} - \Gamma_s^{x,C}\big|^2\big]$ converges to zero as the a priori estimates of Lemma 2.3 show. Hence $\Gamma_t^{x+\delta,C} - \Gamma_t^{x,C}$ also converges uniformly in t $\boldsymbol{P}$-a.s. to zero, so (2.14) follows. □

3. Bounded variation control and associated Dynkin game. The proof of Theorem 1.3 essentially rests on the four relations

$$u^-(x) \le u^+(x), \qquad \Delta_- V(x) \le \Delta^+ V(x),$$
$$\Delta^+ V(x) \le u^-(x), \qquad u^+(x) \le \Delta_- V(x).$$

Here $\Delta^+ V$ and $\Delta_- V$ denote the upper right and lower left Dini derivatives of the value function V. The first inequality follows from the definitions (1.5) and the second from Theorem 2.10. The third and fourth are the subject of this section and are proved in Lemmata 3.8 and 3.15.

For our investigation of the value function of the control problem we choose an optimal trajectory and a state process that tracks it from a nearby starting point, up to a pair of stopping times. The essentials of this construction are illustrated best in the context of monotone controls, and we therefore recommend consulting, e.g., [44], [5], or [18]. In what follows, properties of tracking processes in a monotone control problem for the left- and right-hand side Dini derivative, respectively, are combined, which makes the construction more intricate. The aim of this pathwise analysis is to construct controls such that the difference of costs, calculated for original and disturbed starting points, resembles the payoff of a stochastic game of optimal stopping. Thus we establish correspondence between "difference quotients" of the control cost process and the cost of stopping times.

The formulation of tracking and the analysis of cost behavior is carried out without reference to specific properties of the trajectory tracked, but to draw conclusions on the value process we will have to assume that an optimal policy exists. We start with a discussion of right-hand side difference quotients. The left-hand side difference quotient is almost parallel, and there is a brief outline in section 3.3 of the steps necessary. The section closes with the proof of the main theorem.

3.1. Upper right Dini derivative: Construction and properties of the tracking process. First we will introduce the construction of a tracking process and recall some properties of the state processes in this situation. Then we analyze characteristics of the control involved and of the cost functionals. To also have these results available when discussing the lower left Dini derivatives we restrict our assumptions for a while to

(3.1a) b is differentiable in x and either convex or concave;

(3.1b) σ is linear in the space variable x;

(3.1c) h is increasing in the space variable x;

(3.1d) g is increasing in the space variable x;

(3.1e) both components of a are nonnegative.

Making use of the convexity of the data and its consequences presented in Lemma 2.11, we then find estimates for the difference quotient of cost functionals and investigate its limit behavior. This enables us to find an estimate for the upper right Dini derivative of the value function V in terms of the value function of a Dynkin game.

Construction of the tracking process from above. We consider a controlled process $X^\star = X^{x,C^U,C^L}$ and a process X^δ starting in $x+\delta$ and tracking $X^\star$ from above.

Let $\sigma \in \mathcal{T}$ and define the crossing time

$$\tau^\delta := \inf\{t \geq 0 \,|\, X_t^{x+\delta,C^U,0} \leq X_t^{x,C^U,C^L}\}. \tag{3.2}$$

The tracking process X^δ for the starting point $x+\delta$ is given by

$$X_t^\delta := \begin{cases} X_t^{x+\delta,C^U,0}, & t \leq \sigma \wedge \tau^\delta, \\ X_t^{x,C^U,C^L}, & t > \sigma \wedge \tau^\delta. \end{cases} \tag{3.3}$$

Its upper control is parallel to that of the state traced, and it has no lower control until σ occurs or X^{x,C^U,C^L} crosses its trajectory.

We want to obtain X^δ as controlled process $X^{x+\delta,C^{\delta,U},C^{\delta,L}}$ to compare the costs associated with X^δ and $X^\star$. To achieve this, define

$$C_t^{\delta,U} := \begin{cases} C_t^U, & t \leq \sigma, \\ C_t^U + X_\sigma^{x+\delta,C^U,0} - X_\sigma^{x,C^U,C^L}, & t > \sigma, \sigma \leq \tau^\delta, \\ C_t^U, & t > \sigma, \sigma > \tau^\delta, \end{cases} \tag{3.4a}$$

$$C_t^{\delta,L} := \begin{cases} 0, & t \leq \sigma \wedge \tau^\delta, \\ C_t^L - C_\sigma^\lambda, & t > \sigma, \sigma \leq \tau^\delta, \\ C_t^L - C_{\tau^\delta}^L - (X_{\tau^\delta}^{x+\delta,C^U,0} - X_{\tau^\delta}^{x,C^U,C^L}), & t > \tau^\delta, \sigma > \tau^\delta. \end{cases} \tag{3.4b}$$

We have to check that $C^{\delta,L}$ is increasing at τ^δ: Consider $t > \tau^\delta$ on $\{\sigma > \tau^\delta\}$. Then by definition of τ^δ

$$\begin{aligned} 0 &\leq C_t^L - C_{\tau^\delta+}^L + X_{\tau^\delta+}^{x,C^U,C^L} - X_{\tau^\delta+}^{x+\delta,C^U,0} \\ &= C_t^L - C_{\tau^\delta+}^L + X_{\tau^\delta}^{x,C^U,C^L} - (C_{\tau^\delta+}^U - C_{\tau^\delta}^U) \\ &\quad + (C_{\tau^\delta+}^L - C_{\tau^\delta}^L) - \big(X_{\tau^\delta}^{x+\delta,C^U,0} - (C_{\tau^\delta+}^U - C_{\tau^\delta}^U)\big) \\ &= C_t^L - C_{\tau^\delta}^L - \big(X_{\tau^\delta}^{x+\delta,C^U,0} - X_{\tau^\delta}^{x,C^U,C^L}\big). \end{aligned} \tag{3.5}$$

Hence $C^\delta := (C^{\delta,U}, -C^{\delta,L})$ is in $\mathcal{A}$. The elements of this decomposition are nonnegative, increasing, and LCRL, but need not be minimal. We take up this question in Lemma 3.8.

The next lemma tells us that C^δ is really the control needed to obtain X^δ.

LEMMA 3.1. *Let $C^\delta \in \mathcal{A}$ as defined in* (3.4). *Then $X^{x+\delta,C^{\delta,U},C^{\delta,L}} = X^\delta$ and*

$$0 \leq X_t^{x+\delta,C^{\delta,U},C^{\delta,L}} - X_t^{x,C^U,C^L} \leq X_t^{x+\delta,C^U,0} - X_t^{x,C^U,0}. \tag{3.6}$$

Furthermore, $Y_t^{x+\delta,C^{\delta,U},C^{\delta,L}} = Y_t^{x,C^U,C^L}$ and $Z_t^{x+\delta,C^{\delta,U},C^{\delta,L}} = Z_t^{x,C^U,C^L}$ for $\sigma \wedge \tau^\delta < t \leq T$.

See Baras, Elliott, and Kohlmann [6] for a treatment of jumps between stochastic processes in the context of stochastic flows.

Proof. $X_t^\delta = X_t^{x+\delta,C^{\delta,U},C^{\delta,L}}$ for $t \leq \sigma \wedge \tau^\delta$ is obvious from the construction. Consider the right-hand side limit $X_{\sigma\wedge\tau^\delta+}^{x+\delta,C^{\delta,U},C^{\delta,L}}$, which equals $X_{\sigma\wedge\tau^\delta+}^{x,C^U,C^L}$ by definition of C^δ; hence $X_t^{x+\delta,C^{\delta,U},C^{\delta,L}} = X_t^\delta$ for $t > \sigma \wedge \tau^\delta$. The equalities for Y^{x,C^U,C^L} and Z^{x,C^U,C^L} on $(\sigma \wedge \tau^\delta, T]$ follow from the uniqueness of solutions to BSDE.

It remains to prove (3.6). The first inequality follows from (3.3) and the definition of τ^δ. Observe that $X^{x,C^U,C^L} \geq X^{x,C^U,0}$ from the comparison theorem (Theorem 2.5).

For $t \le \sigma \wedge \tau^\delta$ the second inequality then follows from the definition of C^δ. Furthermore, $X_t^{x+\delta,C^{\delta,U},C^{\delta,L}} = X_t^{x,C^U,C^L}$ for $t > \sigma \wedge \tau^\delta$; it follows from the comparison theorem (Theorem 2.5) that the right-hand side is nonnegative, which completes the proof. □

Thus we may introduce the notation

$$X_t^\star := X_t^{x,C^U,C^L}, \qquad Y_t^\star := Y_t^{x,C^U,C^L}, \qquad Z_t^\star := Z_t^{x,C^U,C^L},$$
$$Y_t^\delta := Y_t^{x+\delta,C^{\delta,U},C^{\delta,L}}, \qquad Z_t^\delta := Z_t^{x+\delta,C^{\delta,U},C^{\delta,L}}.$$

$\frac{1}{\delta}\big(Y^\delta - Y^\star\big)$ will be the difference quotient under observation later in this section.

We will also make use of the following estimate, which reformulates some results on controlled processes of Lemma 2.11 for our situation.

LEMMA 3.2. *Assume* (3.1b) *holds. Then for any $C \in \mathcal{A}$ and initial values $x, x+\delta$ the estimate*

$$0 < \delta\Gamma_t^{lo} \le X_t^{x+\delta,C^U,C^L} - X_t^{x,C^U,C^L} \le \delta\Gamma_t^{up} \tag{3.7}$$

holds, and $X_t^{x+\delta,C^U,C^L}$ decreases as δ decreases. Furthermore, X^δ decreases to $X^\star$.

These are consequences of the Lipschitz property of the data b and σ, linearity of σ, and the comparison theorem (Theorem 2.5).

Some characteristics of the tracking process. Next define the first action time τ^0 of C^L by

$$\tau^0 := \inf\{t \ge 0 \,|\, X_t^{x,C^U,0} < X_t^\star\} = \inf\{t \ge 0 \,|\, C_t^L > C_0^L\}. \tag{3.8}$$

Observe that $\tau^\delta \searrow \tau^0$ a.s. Due to their definition, this follows from the right-hand side in (3.7) and existence of right-hand limits for all processes involved.

We know further that $\boldsymbol{P}$-a.s. if $C^L_{\tau^0+}(\omega) > C^L_{\tau^0}(\omega)$, there is a $\delta_0(\omega)$ such that $\tau^\delta(\omega) = \tau^0(\omega)$ for all $\delta \le \delta_0$. This again follows from (3.7) if we set $\delta_0 := (C^L_{\tau^0+} - C^L_{\tau^0})/\Gamma^{up}_{\tau^0}$.

Next assume (2.8a) and (2.8b) hold. Then for $t \in \bar{\imath}$

$$\delta\Gamma_t^{x,C^U,0}\boldsymbol{\chi}_{t\le\sigma\wedge\tau^0} \le X_t^\delta - X_t^\star \le \delta\Gamma_t^{x+\delta,C^U,0}\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta} \qquad \boldsymbol{P}\text{-a.s.} \tag{3.9}$$

This follows from the convexity of b and definition of τ^0, τ^δ, and X^δ as in Lemma 2.11.

At the end of this section we will assume that (C^U, C^L) is in fact optimal for the control problem, but this is of no importance in the development of the next results.

Bounds for C^L. We wish to give an estimate for C_t^L if $t \le \tau^\delta$. We derive this from the definition of τ^δ in the following way: Let $\tilde{\Theta}_t(\omega) \in [X_t^{x,C^U,0}(\omega), X_t^\star(\omega)] \subset \mathbb{R}$ such that

$$b_x(t,\tilde{\Theta}_t)\big(X_t^\star - X_t^{x,C^U,0}\big) = b(t,X_t^\star) - b(t,X_t^{x,C^U,0}) \qquad \boldsymbol{P}\text{-a.s.}$$

Observe that b_x is either nondecreasing or nonincreasing in x, so $\tilde{\Theta}_t$ can be chosen in an $\mathcal{F}_t$-measurable, LCRL way. Thus $\tilde{\Theta}$ is progressively measurable, and we let $\Gamma_t^{\tilde{\Theta}}$ be the solution of the linear SDE

$$d\Gamma_t^{\tilde{\Theta}} = b_x(t,\tilde{\Theta}_t)\Gamma_t^{\tilde{\Theta}}\,dt + \sigma_x(t,\Gamma_t^{\tilde{\Theta}})^\top\,dW_t, \qquad \Gamma_0^{\tilde{\Theta}} = 1.$$

It is obvious from the comparison theorem (Theorem 2.5) and Lipschitz continuity of b that $\Gamma_t^{lo} \le \Gamma_t^{\tilde\Theta} \le \Gamma_t^{up}$ a.s. Hence $\Gamma_t^{\tilde\Theta} \in \mathbb{R}_{>0}$ for $t \le \tau^\delta$ a.s. Now consider $X^\star - X^{x,C^U,0}$: Apply the Itô formula to $\big(\Gamma_t^{\tilde\Theta}\big)^{-1}\big(X_t^\star - X_t^{x,C^U,0}\big)$ and recall that this equals zero for $t \le \tau^0$ to get the representation

$$X_t^\star - X_t^{x,C^U,0} = \int_0^t b_x(s,\tilde\Theta_s)\big(X_s^\star - X_s^{x,C^U,0}\big)\,ds + C_t^L + \int_0^t \sigma(s, X_s^\star - X_s^{x,C^U,0})^\top\,dW_s = \int_{\tau^0}^{\tau^0\vee t} \Gamma_t^{\tilde\Theta}\big(\Gamma_s^{\tilde\Theta}\big)^{-1}\,dC_s^L.$$

This leads to the following estimate for $\tau^0 < t \le \tau^\delta$:

$$\begin{aligned}\Big(\sup_{\tau^0<s\le t}\Gamma_s^{\tilde\Theta}\Big)^{-1}\Gamma_t^{\tilde\Theta}C_t^L &= \Big(\inf_{\tau^0<s\le t}\big(\Gamma_s^{\tilde\Theta}\big)^{-1}\Big)\Gamma_t^{\tilde\Theta}C_t^L\\ &\le \int_{\tau^0}^t \Gamma_t^{\tilde\Theta}\big(\Gamma_s^{\tilde\Theta}\big)^{-1}\,dC_s^L = X_t^\star - X_t^{x,C^U,0}\\ &\le X_t^{x+\delta,C^U,0} - X_t^{x,C^U,0} \le \delta\Gamma_t^{up}.\end{aligned}$$

Similarly we obtain a lower bound on C_t^L for t with $C_t^L > 0$, i.e., $t > \tau^0$. The results are summarized in the following lemma.

LEMMA 3.3. *Let τ^0 and τ^δ be as defined in* (3.8) *and* (3.2)*, and assume* (3.1) *holds. Then C_t^L has $\boldsymbol{P}$-a.s. upper and lower bounds for $\tau^0 < t \le \tau^\delta$:*

$$\big(X_t^\star - X_t^{x,C^U,0}\big)\frac{1}{\Gamma_t^{\tilde\Theta}}\Big(\inf_{\tau^0<s\le t}\Gamma_s^{\tilde\Theta}\Big) \le C_t^L \le \big(X_t^\star - X_t^{x,C^U,0}\big)\frac{1}{\Gamma_t^{\tilde\Theta}}\Big(\sup_{\tau^0<s\le t}\Gamma_s^{\tilde\Theta}\Big).$$

Thus C^L satisfies

$$C_t^L \le \delta\Gamma_t^{up}\big(\Gamma_t^{lo}\big)^{-1}\Big(\sup_{\tau^0\le s\le t}\Gamma_s^{up}\Big) =: \delta\cdot\overline{C_t^{L,\delta}} \qquad \text{for } t \le \tau^\delta \ \boldsymbol{P}\text{-a.s.}$$

Note that if (2.8) and (3.15) hold, it follows from convexity of b and the comparison theorem (Theorem 2.5) that for $t \le \tau^\delta$

$$\Gamma_t^{x,C^U,0} \le \Gamma_t^{\tilde\Theta} \le \Gamma_t^{x+\delta,C^U,0}. \tag{3.10}$$

Limit behavior of cost functionals. Our plan is to find bounds for the process $\frac{1}{\delta}\big(Y^\delta - Y^\star\big)$, which will result in a first connection with a Dynkin game. But before we can investigate this "difference quotient" we need more information about the processes Y^δ and their behavior as $\delta \searrow 0$. We start with the following lemma.

LEMMA 3.4. *Assume that* (3.1) *holds. Let, for $\delta, \delta' \in \mathbb{R}_{>0}$, the processes Y^δ, $Y^{\delta'}$ be the cost functionals associated with $x+\delta$, $x+\delta'$ according to the construction* (3.3)*. Then*

$$Y_t^\star \le Y_t^\delta \le Y_t^{\delta'} \qquad \text{for } \delta \le \delta' \text{ for all } t\ \boldsymbol{P}\text{-a.s.}$$

Proof. Let us look at the inequality $Y_t^\star \le Y_t^\delta$ first. For $t > \sigma \wedge \tau^\delta$ equality holds by definition of $(C^{\delta,U}, C^{\delta,L})$.

Now let $t \le \sigma \wedge \tau^\delta$. We wish to apply the comparison theorem, Theorem 2.7. From Lemma 3.1 and properties (3.1c) and (3.1d) of h, g it follows that

$$h(X_T^\delta) \ge h(X_T^\star), \qquad g(t, X_t^\delta, y, z) \ge g(t, X_t^\star, y, z).$$

Consider the difference of control processes $\boldsymbol{\delta}C := \big(C^{\delta,U} - C^U, -(C^{\delta,L} - C^L)\big)$. The components have the representation

$$\begin{aligned}
C^{\delta,U}_t - C^U_t &= \big(X^\delta_\sigma - X^\star_\sigma\big)\boldsymbol{\chi}_{\substack{t>\sigma\\ \sigma\le\tau^\delta}},\\
C^{\delta,L}_t - C^L_t &= -C^L_t\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta} - C^L_\sigma\boldsymbol{\chi}_{\substack{t>\sigma\wedge\tau^\delta\\ \sigma\le\tau^\delta}} - \big(C^L_{\tau^\delta} + (X^\delta_{\tau^\delta} - X^\star_{\tau^\delta})\big)\boldsymbol{\chi}_{\substack{t>\sigma\wedge\tau^\delta\\ \sigma>\tau^\delta}}.
\end{aligned}$$

Recall the argument in (3.5) to see that both components of $\boldsymbol{\delta}C$ are increasing and therefore $\int_{[0,t)} a_s^\top\, d(\boldsymbol{\delta}C_s)$ is increasing in t.

So the assumptions of the comparison theorem (Theorem 2.7) are satisfied, which completes the proof of the first inequality. □

For the second inequality observe that we are done if $t > \sigma\wedge\tau^\delta$, as then $Y^\delta_t = Y^\star_t$. For $t \le \sigma\wedge\tau^\delta$ the processes satisfy

$$\begin{aligned}
Y^{\delta'}_t - Y^\delta_t = Y^{\delta'}_{\sigma\wedge\tau^\delta} - Y^\delta_{\sigma\wedge\tau^\delta} &+ \int_t^{\sigma\wedge\tau^\delta} g(s,X^{\delta'}_s,Y^{\delta'}_s,Z^{\delta'}_s) - g(s,X^\delta_s,Y^\delta_s,Z^\delta_s)\,ds\\
&- \int_t^{\sigma\wedge\tau^\delta} Z^{\delta'}_s - Z^\delta_s\,dW_s.
\end{aligned}$$

Hence it suffices to prove $Y^{\delta'}_{\sigma\wedge\tau^\delta} \ge Y^\delta_{\sigma\wedge\tau^\delta}$, as $g(s,X^{\delta'}_s,y,z) \ge g(s,X^\delta_s,y,z)$ and an application of the comparison theorem (Theorem 2.7) will complete the argument.

To this end use a slightly different representation (cf. (3.11) below):

$$\begin{aligned}
Y^\delta_{\sigma\wedge\tau^\delta} - Y^\star_{\sigma\wedge\tau^\delta} &= \big(h(X^\delta_T) - h(X^\star_T)\big)\boldsymbol{\chi}_{\sigma\wedge\tau^\delta=T} + a^U_\sigma\big(X^\delta_\sigma - X^\star_\sigma\big)\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta\\ \sigma<T}}\\
&\quad + a^L_{\tau^\delta}\big(X^\delta_{\tau^\delta} - X^\star_{\tau^\delta}\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}}\\
&\le \big(h(X^{\delta'}_T) - h(X^\star_T)\big)\boldsymbol{\chi}_{\sigma\wedge\tau^\delta=T} + a^U_\sigma\big(X^{\delta'}_\sigma - X^\star_\sigma\big)\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta\\ \sigma<T}}\\
&\quad + a^L_{\tau^\delta}\big(C^L_{\tau^\delta+} - C^L_{\tau^\delta}\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}} + \big(Y^{\delta'}_{\sigma\wedge\tau^\delta+} - Y^\star_{\sigma\wedge\tau^\delta+}\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}}\\
&= Y^{\delta'}_{\sigma\wedge\tau^\delta} - Y^\star_{\sigma\wedge\tau^\delta},
\end{aligned}$$

where the inequality is due to the definition of $C^{\delta,L}$ and (3.5), $Y^{\delta'} \ge Y^\star$ and (3.1c), and (3.1e) and the monotonicity of X^δ in δ. The last equality follows from $\tau^\delta \le \tau^{\delta'}$. This completes the proof. □

Observe that we can interpret $Y^\delta - Y^\star$ as solution to a BSDE where the terminal value is $\mathcal{F}_{\sigma\wedge\tau^\delta}$-measurable. In this form it resembles the payoff of a stochastic game of optimal stopping:

$$\begin{aligned}
Y^\delta_t - Y^\star_t = E\Bigg[&\int_t^{\sigma\wedge\tau^\delta} g(s,X^\delta_s,Y^\delta_s,Z^\delta_s) - g(s,X^\star_s,Y^\star_s,Z^\star_s)\,ds\\
&+ \big(h(X^\delta_T) - h(X^\star_T)\big)\boldsymbol{\chi}_{\sigma\wedge\tau^\delta=T} + a^U_\sigma\big(X^\delta_\sigma - X^\star_\sigma\big)\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta\\ \sigma<T}}\\
&+ a^L_{\tau^\delta}\big(X^\delta_{\tau^\delta} - X^\star_{\tau^\delta}\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}} + \int_{[t,\sigma\wedge\tau^\delta)} a^L_s\,dC^L_s \,\Bigg|\, \mathcal{F}_t\Bigg].
\end{aligned} \tag{3.11}$$

We will use this representation in the discussion of limit behavior of $\frac{1}{\delta}\big(Y^\delta - Y^\star\big)$. As a first step we establish a result on the convergence of Y^δ to $Y^\star$.

LEMMA 3.5. *Assume that* (3.1) *holds. Then* Y_t^δ *converges to* $Y_t^\star$ $\boldsymbol{P}$*-a.s. uniformly in* t*, and further,*

$$\lim_{\delta \searrow 0} E\left[\sup_{t\le s\le T} \left|Y_s^\delta - Y_s^\star\right|^2\right] = 0, \tag{3.12}$$

$$\lim_{\delta \searrow 0} E\left[\int_t^T \left|Z_s^\delta - Z_s^\star\right|^2 ds\right] = 0. \tag{3.13}$$

The convergence in (3.12) *is monotone.*

Proof. We know from Lemma 3.4 that $\sup_{t\le s\le T}(Y_s^\delta - Y_s^\star)$ is nonnegative and decreases as δ decreases to zero. If we set $A := \{\omega \mid \lim_{\delta\searrow 0}(\sup_{t\le s\le T} Y_s^\delta - Y_s^\star) > 0\}$, then $\boldsymbol{P}(A) = 0$ follows from (3.12).

But (3.12) and (3.13) follow from Lemma 2.4 if we can show that—in the notation of that lemma—$\|\boldsymbol{\delta}\xi\|_2^2$, $\|\boldsymbol{\delta}g\|_2^2$, and $|\boldsymbol{\delta}C|_{[a,\bar{\imath}]}^2$ converge to zero. Hence it suffices to prove convergence of the data in the respective 2-norms.

We first consider the driver and write

$$\boldsymbol{\delta}g_s = g(s, X_s^\delta, Y_s^\star, Z_s^\star) - g(s, X_s^\star, Y_s^\star, Z_s^\star) \le L\cdot\delta\cdot\Gamma_s^{up},$$

where L denotes a Lipschitz constant of g. Hence $\|\boldsymbol{\delta}g_s\|_2^2 \le L^2\cdot\delta^2\cdot\|\Gamma_s^{up}\|_2^2$, which converges to zero as $\delta \searrow 0$. The same argument can be applied to $\boldsymbol{\delta}\xi = h(X_T^\delta) - h(X_T^\star)$.

From the definition of the processes X^δ, $X^\star$ we have

$$\begin{aligned}\left(X_{\tau^\delta}^\delta - X_{\tau^\delta}^\star\right) &= \left(X_{\tau^0}^\delta - X_{\tau^0}^\star\right) + \int_{\tau^0}^{\tau^\delta} \left(b(s, X_s^\delta) - b(s, X_s^\star)\right) ds \\ &\quad + \int_{\tau^0}^{\tau^\delta} \sigma\left(s, (X_s^\delta - X_s^\star)\right) dW_s - (C_{\tau^\delta}^L - C_{\tau^0}^L).\end{aligned} \tag{3.14}$$

Also recall that $C^{\delta,L}$ is constant on $[t, \tau^0]$. Therefore we can estimate the difference of controls in the following way:

$$\begin{aligned}|\boldsymbol{\delta}C|_{[a,\bar{\imath}]}^2 &= E\left[\left(\int_{\bar{\imath}} a_s^L\, d\left|C^{\delta,L} - C^L\right|_s\right)^2 + \left(\int_{\bar{\imath}} a_s^U\, d\left|C^{\delta,U} - C^U\right|_s\right)^2\right] \\ &= E\left[\left(\left(a_{\tau^\delta}^L(X_{\tau^\delta}^\delta - X_{\tau^\delta}^\star)\right)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}} + \int_{[t,\sigma\wedge\tau^\delta)} a_s^L\, dC_s^L\right)^2\right. \\ &\qquad \left. + \left(a_\sigma^U(X_\sigma^\delta - X_\sigma^\star)\right)^2\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta\\ \sigma<T}}\right] \\ &\le E\left[\left(\left(a_{\tau^\delta}^L(X_{\tau^\delta}^\delta - X_{\tau^\delta}^\star)\right) + \int_{[\tau^0,\tau^\delta)} a_s^L\, dC_s^L\right)^2\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}}\right. \\ &\qquad \left. + \left(a_\sigma^U(X_\sigma^\delta - X_\sigma^\star)\right)^2\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta\\ \sigma<T}}\right] \\ &\le \delta^2 E\left[3\left(\max_{\tau^0\le s\le\tau^\delta} a_s^L\right)^2\left(|\Gamma_{\tau^0}^{up}|^2 + \left(\int_{\tau^0}^{\tau^\delta} L\Gamma_s^{up}\, ds\right)^2\right.\right. \\ &\qquad \left.\left. + \int_{\tau^0}^{\tau^\delta} |\sigma(s, \Gamma_s^{up})|^2\, ds\right)\right] + \delta^2 E\left[\left(a_\sigma^U\Gamma_\sigma^{up}\right)^2\right].\end{aligned}$$

The second inequality is due to (3.14), where we have used (3.7), (3.6), Lipschitz continuity of b, and linearity of σ. The last term obviously converges to zero as $\delta \searrow 0$, which completes the proof. □

3.2. Upper right Dini derivative: Estimates for the difference quotient. From now on we assume smoothness of the data of the FBSDE (1.1):

(3.15a) b is differentiable in x;

(3.15b) h is differentiable in x;

(3.15c) g is partially differentiable in x, y, and z;

(3.15d) g_y is increasing in x;

(3.15e) g_z is independent of x, y, and z;

(3.15f) both components of a are nonnegative and continuous.

Under (3.15e) we may drop dependence on z in the notation for g_x, g_y, and g_z.

We now define processes $\tilde{R}^{up,\delta}$ and $\tilde{R}^{lo,\delta}$, which converge to the same limiting process $\tilde{R}$ as $\delta \searrow 0$ and serve as majorants and minorants to the difference quotient $\frac{1}{\delta}(Y^\delta - Y^\star)$. Thus they help us investigate its limit behavior. To facilitate the argument we use the translation to a control-free FBSDE as in Peng [61]; we define

$$\tilde{Y}_t^\delta := \frac{1}{\delta}\left((Y_t^\delta - Y_t^\star) + \int_{[0,\sigma\wedge\tau^\delta\wedge t)} a_s^L \, dC_s^L\right) \qquad \text{and} \qquad \tilde{Z}_t^\delta := \frac{1}{\delta}(Z_t^\delta - Z_t^\star).$$

Then $(\tilde{Y}^\delta, \tilde{Z}^\delta)$ is solution to a BSDE with data

$$\begin{aligned}
\xi^{\tilde{Y}} &:= \frac{1}{\delta}\big(h(X_T^\delta) - h(X_T^\star)\big)\boldsymbol{\chi}_{\sigma\wedge\tau^\delta = T} + a_\sigma^U \frac{1}{\delta}\big(X_\sigma^\delta - X_\sigma^\star\big)\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta \\ \sigma<T}} \\
&\quad + a_{\tau^\delta}^L \frac{1}{\delta}\big(X_{\tau^\delta}^\delta - X_{\tau^\delta}^\star\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma \\ \tau^\delta<T}} + \frac{1}{\delta}\int_{[0,\sigma\wedge\tau^\delta)} a_s^L \, dC_s^L, \\
g^{\tilde{Y}}(t,y,z) &:= \Bigg(\Delta_x\tilde{g}_t \frac{1}{\delta}(X_t^\delta - X_t^\star) + \Delta_y\tilde{g}_t\boldsymbol{\chi}_{y\ge 0}\cdot y \\
&\qquad - \Delta_y\tilde{g}_t \frac{1}{\delta}\int_{[0,t)} a_s^L \, dC_s^L\Bigg)\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta} + \Delta_z\tilde{g}_t \cdot z\boldsymbol{\chi}_{t\le\sigma}, \\
C_t^{\tilde{Y}} &:= (0,0).
\end{aligned}$$

Here $\Delta_x\tilde{g}_t$, $\Delta_y\tilde{g}_t$, and $\Delta_z\tilde{g}_t$ are defined as

$$\begin{aligned}
\Delta_x\tilde{g}_t &:= \big(g(t,X_t^\delta,Y_t^\star,Z_t^\star) - g(t,X_t^\star,Y_t^\star,Z_t^\star)\big)\frac{1}{X_t^\delta - X_t^\star}\boldsymbol{\chi}_{X_t^\delta\neq X_t^\star}, \\
\Delta_y\tilde{g}_t &:= \big(g(t,X_t^\delta,Y_t^\delta,Z_t^\star) - g(t,X_t^\delta,Y_t^\star,Z_t^\star)\big)\frac{1}{Y_t^\delta - Y_t^\star}\boldsymbol{\chi}_{Y_t^\delta\neq Y_t^\star}, \\
\Delta_z\tilde{g}_t &:= \big(g(t,X_t^\delta,Y_t^\delta,Z_t^\delta) - g(t,X_t^\delta,Y_t^\delta,Z_t^\star)\big)\frac{1}{Z_t^\delta - Z_t^\star}\boldsymbol{\chi}_{Z_t^\delta\neq Z_t^\star}.
\end{aligned}$$

Observe that $Y_t^\delta - Y_t^\star = 0$ for $t > \sigma\wedge\tau^\delta$; hence $Y_t^\delta - Y_t^\star$ is $\mathcal{F}_{\sigma\wedge\tau^\delta}$-measurable. Therefore $Z_t^\delta - Z_t^\star = 0$ for $t > \sigma\wedge\tau^\delta$ and we can in effect extend the $\Delta_z\tilde{g}$-component in the definition of $g^{\tilde{Y}}$ from $[0,\sigma\wedge\tau^\delta]$ to $[0,\sigma]$. Observe also that $\tilde{Y}^\delta \ge 0$ by (3.15f)

and Lemma 3.4, and that $\tilde{Y}^\delta_t = \frac{1}{\delta}(Y^\delta_t - Y^\star_t)$ for $t \le \sigma \wedge \tau^0$. The representation of $(\tilde{Y}^\delta, \tilde{Z}^\delta)$ as solution of a BSDE with the data $(\xi^{\tilde{Y}}, g^{\tilde{Y}}, C^{\tilde{Y}})$ can be verified directly.

From now on we will assume that (3.15) holds. Therefore we drop the z-variable in the notation of partial derivatives of g. Observe also that $\Delta_x\tilde{g}$, $\Delta_y\tilde{g}$, and $\Delta_z\tilde{g}$ do not depend on $Z^\star$ and Z^δ in this case.

Now assume g to be partially differentiable and define $(\tilde{R}^{up,\delta}, \tilde{Q}^{up,\delta})$ as solution to the BSDE with data

$$\begin{aligned}
\xi^{up,\delta} &:= h_x(X_T^{x+\delta,C^U,0})\Gamma_T^{x+\delta,C^U,0}\boldsymbol{\chi}_{\sigma\wedge\tau^\delta=T} + a^U_\sigma\Gamma_\sigma^{x+\delta,C^U,0}\boldsymbol{\chi}_{\substack{\sigma\le\tau^\delta\\ \sigma<T}} \\
&\quad + \big(\max_{\tau^0\le s\le\tau^\delta} a^L_s\big)\big(\sup_{\tau^0\le s\le\tau^\delta}\Gamma_s^{x+\delta,C^U,0}\big)^2\big(\inf_{\tau^0\le s\le\tau^\delta}\Gamma_s^{x,C^U,0}\big)^{-1}\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}}, \\
g^{up,\delta}(t,y,z) &:= \Big(g_x(t,X^\delta_t,Y^\star_t)\Gamma_t^{x+\delta,C^U,0} + g_y(t,X^\delta_t,Y^\delta_t)\boldsymbol{\chi}_{y\ge0}\boldsymbol{\chi}_{A^+_{g,\delta}}\cdot y \\
&\quad + L\big(\max_{\tau^0\le s\le\tau^\delta\wedge t} a^L_s\big)\overline{C^{L,\delta}_t}\Big)\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta} + g_z(t)\cdot z\boldsymbol{\chi}_{t\le\sigma}, \\
C^{up,\delta}_t &:= (0,0).
\end{aligned}$$

Similarly we let $(\tilde{R}^{lo,\delta}, \tilde{Q}^{lo,\delta})$ be the solution to the BSDE with data

$$\begin{aligned}
\xi^{lo,\delta} &:= h_x(X_T^{x,C^U,0})\Gamma_T^{x,C^U,0}\boldsymbol{\chi}_{\sigma\wedge\tau^0=T} + a^U_\sigma\Gamma_\sigma^{x,C^U,0}\boldsymbol{\chi}_{\substack{\sigma\le\tau^0\\ \sigma<T}} \\
&\quad + \big(\min_{\tau^0\le s\le\tau^\delta} a^L_s\big)\big(\inf_{\tau^0\le s\le\tau^\delta}\Gamma_s^{x,C^U,0}\big)^2\big(\sup_{\tau^0\le s\le\tau^\delta}\Gamma_s^{x+\delta,C^U,0}\big)^{-1}\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}}, \\
g^{lo,\delta}(t,y,z) &:= g_x(t,X^\star_t,Y^\star_t)\Gamma_t^{x,C^U,0}\boldsymbol{\chi}_{t\le\sigma\wedge\tau^0} + \Big(g_y(t,X^\star_t,Y^\star_t)\boldsymbol{\chi}_{y\ge0}\boldsymbol{\chi}_{A^-_{g,\delta}}\cdot y \\
&\quad - L\big(\max_{\tau^0\le s\le\tau^\delta\wedge t} a^L_s\big)\overline{C^{L,\delta}_t}\Big)\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta} + g_z(t)\cdot z\boldsymbol{\chi}_{t\le\sigma}, \\
C^{lo,\delta}_t &:= (0,0).
\end{aligned}$$

Recall the definition of $\overline{C^{L,\delta}_t}$ in Lemma 3.3. L again denotes a Lipschitz constant of g.

We need $A^+_{g,\delta}$ and $A^-_{g,\delta}$ to eliminate the negative and positive parts in the $g_y\cdot y$ -terms for $t > \sigma\wedge\tau^0$. The reason is that $\boldsymbol{\chi}_{t\le\tau^\delta}$ decreases to $\boldsymbol{\chi}_{t\le\tau^0}$ in δ, so we have to add a condition that ensures the required monotonicity of the data. More specifically, we define

$$\begin{aligned}
A^+_{g,\delta} &:= \{t \le \sigma\wedge\tau^0\} \cup \{g_y(t,X^\delta_t,Y^\delta_t) \ge 0\}, \\
A^-_{g,\delta} &:= \{t \le \sigma\wedge\tau^0\} \cup \{g_y(t,X^\star_t,Y^\star_t) \le 0\}.
\end{aligned}$$

We also use the nonstandard convention $\max_{\tau^0\le s\le\tau^\delta\wedge t} a^L_s = 0$ for $t < \tau^0$.

We are now in a position to formulate the estimate.

LEMMA 3.6. *Assume that* (2.8) *and* (3.15) *hold. Then* $\tilde{R}^{up,\delta}, \tilde{Y}^\delta, \tilde{R}^{lo,\delta}$ *satisfy*

$$\tilde{R}^{lo,\delta}_t \le \tilde{Y}^\delta_t \le \tilde{R}^{up,\delta}_t \qquad \forall t\in\bar{\imath}\ \boldsymbol{P}\text{-a.s.} \tag{3.16}$$

Further, $\tilde{R}^{up,\delta}$ *decreases and* $\tilde{R}^{lo,\delta}$ *increases as* $\delta \searrow 0$ *to the same limiting process* $\tilde{R}$ *defined below, in* $L^2_{\mathcal{F}}(0,T;\mathbb{R})$ *and for all* $t\in\bar{\imath}$ $\boldsymbol{P}$*-a.s.*

Proof. To apply the comparison theorem (Theorem 2.7) with supplementary condition (2.7c) to $\tilde{R}^{up,\delta}$, $\tilde{Y}^\delta$, $\tilde{R}^{lo,\delta}$, we have to estimate the drivers and terminal conditions of the three processes.

Consider the drivers first. Their components satisfy

$$\begin{aligned} g_x(t,X_t^\star,Y_t^\star)\Gamma_t^{x,C^U,0}\boldsymbol{\chi}_{t\le\sigma\wedge\tau^0} &\le \Delta_x\tilde g_t\frac{1}{\delta}\big(X_t^\delta - X_t^\star\big)\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta} \\ &\le g_x(t,X_t^\delta,Y_t^\star)\Gamma_t^{x+\delta,C^U,0}\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta}, \\ g_y(t,X_t^\star,Y_t^\star)\frac{1}{\delta}\big(Y_t^\delta - Y_t^\star\big)\boldsymbol{\chi}_{A^-_{g,\delta}} &\le \Delta_y\tilde g_t\frac{1}{\delta}\big(Y_t^\delta - Y_t^\star\big) \\ &\le g_y(t,X_t^\delta,Y_t^\delta)\frac{1}{\delta}\big(Y_t^\delta - Y_t^\star\big)\boldsymbol{\chi}_{A^+_{g,\delta}}, \end{aligned}$$

$$\begin{aligned} &g_y(t,X_t^\star,Y_t^\star)\frac{1}{\delta}\int_{[\tau^0,\tau^\delta\wedge t)} a_s^L\,dC_s^L - L\big(\max_{\tau^0\le s\le\tau^\delta\wedge t} a_s^L\big)\overline{C_t^{L,\delta}} \\ &\qquad\le \Delta_y\tilde g_t\frac{1}{\delta}\int_{[\tau^0,\tau^\delta\wedge t)} a_s^L\,dC_s^L - \Delta_y\tilde g_t\frac{1}{\delta}\int_{[\tau^0,\tau^\delta\wedge t)} a_s^L\,dC_s^L \\ &\text{(which equals zero)} \\ &\qquad\le g_y(t,X_t^\delta,Y_t^\delta)\frac{1}{\delta}\int_{[\tau^0,\tau^\delta\wedge t)} a_s^L\,dC_s^L + L\big(\max_{\tau^0\le s\le\tau^\delta\wedge t} a_s^L\big)\overline{C_t^{L,\delta}}, \\ &\qquad\qquad g_z(t)\frac{1}{\delta}\big(Z_t^\delta - Z_t^\star\big) = \Delta_z\tilde g_t\frac{1}{\delta}\big(Z_t^\delta - Z_t^\star\big). \end{aligned}$$

The estimates for $\Delta_x\tilde g$ follow from (3.15c), (2.8d), and (3.9). For the estimates of $\Delta_y\tilde g$ use (2.8d), (3.15c), Lemma 3.4, and the definition of $A^\pm_{g,\delta}$.

For the third line estimate of the La^L-term recall Lipschitz continuity of g and Lemma 3.3. As g_z is independent of (x,y,z) and $\tau^\delta\ge\tau^0$, we can summarize this as

$$g^{lo,\delta}(t,\tilde Y^\delta,\tilde Z^\delta) \le g^{\tilde Y}(t,\tilde Y^\delta,\tilde Z^\delta) \le g^{up,\delta}(t,\tilde Y^\delta,\tilde Z^\delta). \tag{3.17}$$

In a similar way we can estimate the terms in h_x, a^U, and h, respectively, in the definitions of $\xi^{lo,\delta}$, $\xi^{\tilde Y}$, and $\xi^{up,\delta}$ by (2.8c), (3.15b), and (3.9). For the terms in a^L observe that by Lemma 3.3, (2.13), and (3.10),

$$\begin{aligned} &a^L_{\tau^\delta}\frac{1}{\delta}\big(X^\delta_{\tau^\delta} - X^\star_{\tau^\delta}\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}} + \frac{1}{\delta}\int_{[\sigma\wedge\tau^0,\sigma\wedge\tau^\delta)} a_s^L\,dC_s^L \\ &\quad\le \frac{1}{\delta}\big(\max_{\tau^0\le s\le\tau^\delta} a_s^L\big)\Big(X^\delta_{\tau^\delta} - X^\star_{\tau^\delta} + \big(X^\star_{\tau^\delta} - X^{x,C^U,0}_{\tau^\delta}\big)(\Gamma^{\tilde\Theta}_{\tau^\delta})^{-1}\big(\sup_{\tau^0\le s\le\tau^\delta}\Gamma^{\tilde\Theta}_s\big)\Big)\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}} \\ &\qquad\le \big(\max_{\tau^0\le s\le\tau^\delta} a_s^L\big)\big(\sup_{\tau^0\le s\le\tau^\delta}\Gamma^{x+\delta,C^U,0}_s\big)^2\big(\inf_{\tau^0\le s\le\tau^\delta}\Gamma^{x,C^U,0}_s\big)^{-1}\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}}. \end{aligned}$$

Similarly we can estimate the a^L-term in $\xi^{lo,\delta}$:

$$\begin{aligned} &\big(\min_{\tau^0\le s\le\tau^\delta} a_s^L\big)\big(\inf_{\tau^0\le s\le\tau^\delta}\Gamma^{x,C^U,0}_s\big)^2\big(\sup_{\tau^0\le s\le\tau^\delta}\Gamma^{x+\delta,C^U,0}_s\big)^{-1}\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}} \\ &\qquad\le a^L_{\tau^\delta}\frac{1}{\delta}\big(X^\delta_{\tau^\delta} - X^\star_{\tau^\delta}\big)\boldsymbol{\chi}_{\substack{\tau^\delta<\sigma\\ \tau^\delta<T}} + \frac{1}{\delta}\int_{[\sigma\wedge\tau^0,\sigma\wedge\tau^\delta)} a_s^L\,dC_s^L. \end{aligned}$$

Hence $\xi^{lo,\delta}\le\xi^{\tilde Y^\delta}\le\xi^{up,\delta}$. An application of the comparison theorem (Theorem 2.7) and (2.7c) completes the proof of (3.16). □

Let us now prove monotony of $\tilde{R}^{lo,\delta}$ and $\tilde{R}^{up,\delta}$ in δ. We show that the data are monotone in δ so that we can again apply the comparison theorem (Theorem 2.7).

Consider the terminal values first. The summands in $\xi^{up,\delta}$ are nonnegative. The terms in h_x and a^U decrease with δ by (3.15b), (3.15f), (2.15), and $\tau^\delta \searrow \tau^0$. The third term decreases to $a^L_{\tau^0}\Gamma^{x,C^U,0}_{\tau^0}$, as a^L and Γ are continuous.

The terms in h_x and a^U of $\xi^{lo,\delta}$ are independent of δ. The a^L-term increases as $\delta \searrow 0$, as $\sup_{\tau^0\le s\le\tau^\delta}\Gamma^{x+\delta,C^U,C^L}_s$ decreases and $\boldsymbol{\chi}_{\tau^\delta<\sigma,\tau^\delta<T}$ increases. Hence $\xi^{up,\delta}$ and $\xi^{lo,\delta}$ decrease and increase, respectively, to $\tilde{\xi}$, where

$$\tilde{\xi} := h_x(X^{x,C^U,0}_T)\Gamma^{x,C^U,0}_T\boldsymbol{\chi}_{\sigma\wedge\tau^0=T} + a^U_\sigma\Gamma^{x,C^U,0}_\sigma\boldsymbol{\chi}_{\substack{\sigma\le\tau^0\\ \sigma<T}} + a^L_{\tau^0}\Gamma^{x,C^U,0}_{\tau^0}\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}}.$$

Next we show that the drivers $g^{up,\delta}$ and $g^{lo,\delta}$ decrease and increase, respectively, and for $t\neq\sigma\wedge\tau^0$ converge to $\tilde{g}$ defined by

$$\begin{aligned}\tilde{g}(t,y,z) := {}& \Big(g_x(t,X^\star_t,Y^\star_t)\Gamma^{x,C^U,0}_t + g_y(t,X^\star_t,Y^\star_t)\boldsymbol{\chi}_{y\ge0}\cdot y\Big)\boldsymbol{\chi}_{t\le\sigma\wedge\tau^0}\\ &+ g_z(t)\cdot z\boldsymbol{\chi}_{t\le\sigma}.\end{aligned}$$

Convergence and monotony of the g_x-term of $g^{up,\delta}$ is obvious; for $g^{lo,\delta}$ it is trivial. The terms in $\pm L(\max_{\tau^0\le s\le\tau^\delta\wedge t}a^L_s)$ equal zero for $t<\sigma\wedge\tau^0$; they are decreasing in absolute value. As $\boldsymbol{\chi}_{\tau^0\le t\le\sigma\wedge\tau^\delta}$ converges to zero, both terms decrease and increase, respectively, to zero for $t\neq\sigma\wedge\tau^0$.

For $t\le\sigma\wedge\tau^0$ the $g_y\cdot y$ -term in $g^{up,\delta}$ decreases by (3.15d), monotony of X^δ in δ and Lemma 3.4. For $t>\sigma\wedge\tau^0$ it decreases and is nonnegative thanks to the definition of $A^+_{g,\delta}$. As $\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta}$ decreases to zero, the full $g_y\cdot y$ -component also decreases to zero.

Convergence of the $g_y\cdot y$ -term in $g^{lo,\delta}$ for $t\le\sigma\wedge\tau^0$ is trivial. For $t>\sigma\wedge\tau^0$ we are restricted to the negative values by definition of $A^-_{g,\delta}$, and as $\boldsymbol{\chi}_{t\le\sigma\wedge\tau^\delta}$ decreases to zero, the $g_y\cdot y$ -term increases to zero.

The g_z-term remains unaffected by (3.15e). So $g^{lo,\delta}\nearrow\tilde{g}$ and $g^{up,\delta}\searrow\tilde{g}$ as $\delta\searrow0$ for $t\neq\sigma\wedge\tau^0$.

Let $(\tilde{R},\tilde{Q})$ be the solution to the BSDE with data $(\tilde{\xi},\tilde{g},0)$. $\tilde{R}$ will serve as limiting process for $\tilde{R}^{up,\delta}$ and $\tilde{R}^{lo,\delta}$. By the comparison theorem, left continuity of the processes involved, and the above discussion of the data $(\xi^{up,\delta},g^{up,\delta})$ and $(\xi^{lo,\delta},g^{lo,\delta})$, we have

$$\tilde{R}^{lo,\delta}_t\le\tilde{R}_t\le\tilde{R}^{up,\delta}_t\qquad\forall t\in\bar{\imath}\ \boldsymbol{P}\text{-a.s.},$$

and $\tilde{R}_t-\tilde{R}^{lo,\delta}_t$ and $\tilde{R}^{up,\delta}_t-\tilde{R}_t$ decrease as $\delta\searrow0$.

Furthermore, the differences of the data and hence the processes $\tilde{R}_t-\tilde{R}^{lo,\delta}_t$ and $\tilde{R}^{up,\delta}_t-\tilde{R}_t$ decrease to zero in $L^2_{\mathcal{F}}(0,T;\mathbb{R})$. To be precise, set

$$\begin{aligned}\|\boldsymbol{\delta}g^{up,\delta}\|^2_2 &:= E\left[\int_0^{\sigma\wedge\tau^\delta}\left|\tilde{g}(s,\tilde{R}_s,\tilde{Q}_s)-g^{up,\delta}(s,\tilde{R}_s,\tilde{Q}_s)\right|^2ds\right],\\ \|\boldsymbol{\delta}g^{lo,\delta}\|^2_2 &:= E\left[\int_0^{\sigma\wedge\tau^\delta}\left|\tilde{g}(s,\tilde{R}_s,\tilde{Q}_s)-g^{lo,\delta}(s,\tilde{R}_s,\tilde{Q}_s)\right|^2ds\right],\\ \|\boldsymbol{\delta}\xi^{up,\delta}\|^2_2 &:= E\big[\big|\tilde{\xi}-\xi^{up,\delta}\big|^2\big],\\ \|\boldsymbol{\delta}\xi^{lo,\delta}\|^2_2 &:= E\big[\big|\tilde{\xi}-\xi^{lo,\delta}\big|^2\big],\end{aligned}$$

which converge to zero as $\delta \searrow 0$ by the dominated convergence theorem. The a priori estimates in Lemma 2.4 show that

$$\lim_{\delta\searrow 0} E\Big[\sup_{0\le s\le T}\big|\tilde R^{up,\delta}_s - \tilde R_s\big|^2\Big] = \lim_{\delta\searrow 0} E\Big[\sup_{0\le s\le T}\big|\tilde R^{lo,\delta}_s - \tilde R_s\big|^2\Big] = 0.$$

By monotony of $\tilde R^{lo,\delta}$ and $\tilde R^{up,\delta}$, these converge also $\boldsymbol{P}$-a.s. to $\tilde R$ uniformly in t. As $T \in \mathbb{R}_{>0}$ is bounded, $\tilde R^{lo,\delta}$ and $\tilde R^{up,\delta}$ converge to $\tilde R$ in $L^2_{\mathcal{F}}(0,T;\mathbb{R})$. □

Recall the payoff R of the associated Dynkin game in Definition 1.2. Now define the data

$$\begin{aligned}\xi^R &:= \Big(h_x(X^{x,0,0}_T)\boldsymbol{\chi}_{\sigma\wedge\tau^0=T} + a^U_\sigma \boldsymbol{\chi}_{\substack{\sigma\le\tau^0\\ \sigma<T}} + a^L_{\tau^0}\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}}\Big)\Gamma^x_{\sigma\wedge\tau^0\wedge T},\\ g^R(t,y,z) &:= \Big(g_x(t,X^{x,0,0}_t, Y^\star_t)\Gamma^x_t + g_y(t,X^{x,0,0}_t,Y^\star_t)\cdot y\Big)\boldsymbol{\chi}_{t\le\sigma\wedge\tau^0}\\ &\quad + g_z(t)\cdot z\boldsymbol{\chi}_{t\le\sigma},\end{aligned}$$

and $C^R := 0$. Then the solution (R,Q) of the BSDE with data $(\xi^R, g^R, a, 0)$ is the payoff defined in (1.3) and has the representation

$$\begin{aligned}R^x_t(\sigma,\tau^0) = E\Bigg[&\int_t^{\sigma\wedge\tau^0}\langle Dg(s,X^{x,0,0}_s,Y^\star_s),(\Gamma^x_s,R_s,Q_s)\rangle\,ds\\ &+\ h_x(X^{x,0,0}_T)\Gamma^x_T\boldsymbol{\chi}_{\sigma\wedge\tau^0=T} + a^U_\sigma\Gamma^x_\sigma\boldsymbol{\chi}_{\substack{\sigma\le\tau^0\\ \sigma<T}} + a^L_{\tau^0}\Gamma^x_{\tau^0}\boldsymbol{\chi}_{\substack{\tau^0<\sigma\\ \tau^0<T}}\,\Big|\,\mathcal{F}_t\Bigg].\end{aligned} \tag{3.18}$$

Lemma 3.7. *Assume that* (2.8) *and* (3.15) *hold. Then*

$$\lim_{\delta\searrow 0}\frac{1}{\delta}\big(Y^\delta_t - Y^\star_t\big) \le R^x_t(\sigma,\tau^0) \tag{3.19}$$

holds $\boldsymbol{P}$*-a.s. for all* $t \le \sigma\wedge\tau^0$.

Proof. We use the notation of Lemma 3.6. From the construction of $\tilde Y^\delta$ we have $\tilde Y^\delta_t = \frac{1}{\delta}\big(Y^\delta_t - Y^\star_t\big)$ for $t \le \sigma\wedge\tau^0$. Hence by (3.16)

$$\tilde R^{lo,\delta}_t \le \frac{1}{\delta}\big(Y^\delta_t - Y^\star_t\big) \le \tilde R^{up,\delta}_t \qquad \text{for } t\le\sigma\wedge\tau^0 \ \boldsymbol{P}\text{-a.s.}$$

As $\tilde R^{lo,\delta}$ and $\tilde R^{up,\delta}$ converge to $\tilde R$, so does $\frac{1}{\delta}\big(Y^\delta - Y^\star\big)$. Hence the limit in (3.19) exists, and it suffices to prove

$$\tilde R_t \le R^x_t(\sigma,\tau^0) \qquad \text{for } t\le\sigma\wedge\tau^0 \ \boldsymbol{P}\text{-a.s.}$$

First observe that $\tilde R$ remains unchanged if we restrict the g_z-term in the definition of $\tilde g$ to $[0,\sigma\wedge\tau^0]$. This follows from the fact that $\tilde R_t$ is $\mathcal{F}_{\sigma\wedge\tau^0}$-measurable for $t > \sigma\wedge\tau^0$; hence $\tilde Q_t = 0$ on $(\sigma\wedge\tau^0, T]$.

Recall that $X^\star_t = X^{x,C^U,0}_t$ for $t \le \tau^0$ by definition and that $X^{x,C^U,0} \le X^{x,0,0}$ and $\Gamma^{x,C^U,0} \le \Gamma^{x,0,0}$ by (2.8a) and the comparison theorem (Theorem 2.5).

Hence $\tilde g(t,y,z) \le g^R(t,y,z)$ is a consequence of (2.8d), (3.15c). Using (2.8c), (3.15b), and (3.15f) we deduce $\tilde\xi \le \xi^R$. Hence the assumptions of the comparison theorem are satisfied, which completes the proof. □

Let us now consider the case where $C = (C^U, -C^L)$ is optimal for the problem starting in x; i.e., the value $V_t(x)$ is the state process of a controlled BSDE:

$$V_t(x) = Y_t^\star = Y_t^{x,C} \qquad \forall t \geq 0.$$

LEMMA 3.8. *Assume that* (2.8) *and* (3.15) *hold and that there exists an optimal control* (C^U, C^L) *for the control problem* 1.1 *in* x. *Let* $V(x)$ *be its value. Then the upper right Dini derivative of* V *with respect to the initial condition satisfies*

$$\Delta^+ V(x) \leq u^-(x).$$

Proof. By optimality of C in x and Lemma 3.7 we have

$$\limsup_{\delta \searrow 0} \frac{1}{\delta}\big(V(x+\delta) - V(x)\big) \leq \limsup_{\delta \searrow 0} \frac{1}{\delta}\big(Y_0^\delta - Y_0^\star\big) \leq R_0^x(\sigma, \tau^0).$$

This holds even if the decomposition (3.4) is not minimal. As $\sigma \in \mathcal{T}$ is arbitrary we obtain

$$\Delta^+ V(x) \leq \operatorname*{ess\,inf}_{\sigma \in \mathcal{T}} R_0(\sigma, \tau^0) \leq u^-(x). \tag{3.20}$$ □

3.3. Lower left Dini derivative. The construction of an estimate for the lower left Dini derivative of V is essentially the same as that in section 3.1. This is intuitively obvious if we consider $-X$ instead of X as the controlled forward process, and all proofs relying on the set of conditions in (3.1) translate one to one to the new situation. For example, C^U and C^L just change their roles. We therefore only outline the argument by listing the statements.

However, for our investigation of the difference quotient the transformation $X \mapsto -X$ cannot be applied as it does not preserve convexity of the data. So we give the definitions of upper and lower bounds and limiting process for the difference quotient in detail.

Construction of the tracking process from below. We construct a process $X^{-\delta}$ that tracks a given controlled process $X^\star = X^{x,C^U,C^L}$, starting at a distance δ below x and jumping on $X^\star$ some time afterwards.

Let $\tau \in \mathcal{T}$ arbitrary and set the crossing time

$$\sigma^\delta := \inf\{t \geq 0 \,|\, X_t^{x-\delta,0,C^L} \geq X_t^{x,C^U,C^L}\}. \tag{3.21}$$

The tracking process $X^{-\delta}$ for the starting point $x - \delta$ is defined as

$$X_t^{-\delta} := \begin{cases} X_t^{x-\delta,0,C^L}, & t \leq \sigma^\delta \wedge \tau, \\ X_t^{x,C^U,C^L}, & t > \sigma^\delta \wedge \tau. \end{cases} \tag{3.22}$$

It has parallel lower and no upper control as long as either τ occurs or $X^\star$ crosses its path.

To obtain $X^{-\delta}$ as a controlled process define $C^{-\delta} = (C^{-\delta,U}, -C^{-\delta,L})$ by

$$C_t^{-\delta,U} := \begin{cases} 0, & t \leq \sigma^\delta \wedge \tau, \\ C_t^U - C_{\sigma^\delta}^U - \big(X_{\sigma^\delta}^{x,C^U,C^L} - X_{\sigma^\delta}^{x-\delta,0,C^L}\big), & t > \sigma^\delta, \sigma^\delta \leq \tau, \\ C_t^U - C_\tau^U, & t > \tau, \sigma^\delta > \tau, \end{cases} \tag{3.23a}$$

$$C_t^{-\delta,L} := \begin{cases} C_t^L, & t \leq \tau, \\ C_t^L, & t > \tau, \sigma^\delta \leq \tau, \\ C_t^L + (X_\tau^{x,C^U,C^L} - X_\tau^{x-\delta,0,C^L}), & t > \tau, \sigma^\delta > \tau. \end{cases} \tag{3.23b}$$

From the definition of σ^δ we have for $t > \sigma^\delta$, $\sigma^\delta \le \tau$

$$\begin{aligned}0 \le C^U_t - C^U_{\sigma^\delta+} + X^{x-\delta,0,C^L}_{\sigma^\delta+} - X^{x,C^U,C^L}_{\sigma^\delta+}&\\ = C^U_t - C^U_{\sigma^\delta+} + X^{x-\delta,0,C^L}_{\sigma^\delta} + (C^L_{\sigma^\delta+} - C^L_{\sigma^\delta})&\\ - \big(X^{x,C^U,C^L}_{\sigma^\delta} - (C^U_{\sigma^\delta+} - C^U_{\sigma^\delta}) + (C^L_{\sigma^\delta+} - C^L_{\sigma^\delta})\big)&\\ = C^U_t - C^U_{\sigma^\delta} - \big(X^{x,C^U,C^L}_{\sigma^\delta} - X^{x-\delta,0,C^L}_{\sigma^\delta}\big)&\end{aligned}$$

so $C^{-\delta,U}$ is increasing; hence $C^{-\delta} \in \mathcal{A}$. Again, this decomposition need not be minimal. In addition to the notation of $X^\star$, $Y^\star$, and $Z^\star$ in section 3.1 we set

$$Y^{-\delta}_t := Y^{x-\delta,C^{-\delta,U},C^{-\delta,L}}_t, \qquad Z^{-\delta}_t := Z^{x-\delta,C^{-\delta,U},C^{-\delta,L}}_t.$$

The following statements and their proofs are parallel to Lemmata 3.1, 3.2, 3.3, 3.4, and 3.5. As noted above, instead of a line-by-line imitation we could use a transformation

$$\begin{aligned}\check b(t,x) &:= -b(t,-x), & \check\sigma(t,x) &:= \sigma(t,x),\\ \check h(x) &:= -h(-x), & \check g(t,x,y,z) &:= -g(t,-x,-y,-z)\end{aligned}$$

by which

$$\begin{aligned}(X^{x,C^U,C^L}, Y^{x,C^U,C^L}, Z^{x,C^U,C^L}) \mapsto &(\check X^{-x,C^L,C^U}, \check Y^{-x,C^L,C^U}, \check Z^{-x,C^L,C^U})\\ &= (-X^{x,C^U.C^L}, -Y^{x,C^U,C^L}, -Z^{x,C^U,C^L})\end{aligned}$$

and apply the results of section 3.1.

LEMMA 3.9. *Let $C^{-\delta}$ be as defined in* (3.23) *and assume* (3.1) *holds. Then we have $X^{x-\delta,C^{-\delta,U},C^{-\delta,L}} = X^{-\delta}$ and*

$$0 \le X^{x,C^U,C^L}_t - X^{x-\delta,C^{-\delta,U},C^{-\delta,L}}_t \le X^{x,0,C^L}_t - X^{x-\delta,0,C^L}_t. \tag{3.24}$$

Furthermore, $Y^{x-\delta,C^{-\delta,U},C^{-\delta,L}}_t = Y^{x,C^U,C^L}_t$ and $Z^{x-\delta,C^{-\delta,U},C^{-\delta,L}}_t = Z^{x,C^U,C^L}_t$ for $\sigma^\delta \wedge \tau < t \le T$. As δ decreases, $X^{x-\delta,C^U,C^L}_t$ increases and $X^{-\delta}$ increases to $X^\star$.

A bound for C^U. Define the first action time σ^0 of C^U by

$$\sigma^0 := \inf\{t \ge 0 \,|\, X^{x,0,C^L}_t > X^\star_t\} = \inf\{t \ge 0 \,|\, C^U_t > C^U_0\} \tag{3.25}$$

and observe that $\sigma^\delta \searrow \sigma^0$ $\boldsymbol{P}$-a.s. With $\hat\Theta$ defined suitably and $\Gamma^{\hat\Theta}$ the solution of the linear SDE

$$d\Gamma^{\hat\Theta}_t = b_x(t,\hat\Theta_t)\Gamma^{\hat\Theta}_t\,dt + \sigma_x(t,\Gamma^{\hat\Theta}_t)\,dW_t, \qquad \hat X_0 = 1,$$

the following representation leads to the analogue of Lemma 3.3:

$$\begin{aligned}X^{x,0,C^L}_t - X^\star_t = \int_0^t b_x(s,\hat\Theta_s)\big(X^{x,0,C^L}_s - X^\star_s\big)\,ds + C^U_t&\\ + \int_0^t \sigma(s, X^{x,0,C^L}_s - X^\star_s)\,dW_s = \int_{\sigma^0}^{\sigma^0\vee t} \Gamma^{\hat\Theta}_t\big(\Gamma^{\hat\Theta}_s\big)^{-1}\,dC^U_s.&\end{aligned}$$

LEMMA 3.10. *Let σ^0 and σ^δ be as defined in* (3.25) *and* (3.21)*, and assume* (3.1) *holds. Then C_t^U has $\boldsymbol{P}$-a.s. upper and lower bounds for $\sigma^0 < t \le \sigma^\delta$:*

$$\big(X_t^{x,0,C^L} - X_t^\star\big)\frac{1}{\Gamma_t^{\hat\Theta}}\Big(\inf_{\sigma^0<s\le t}\Gamma_s^{\hat\Theta}\Big) \le C_t^U \le \big(X_t^{x,0,C^L} - X_t^\star\big)\frac{1}{\Gamma_t^{\hat\Theta}}\Big(\sup_{\sigma^0<s\le t}\Gamma_s^{\hat\Theta}\Big).$$

Thus C^U satisfies

$$C_t^U \le \delta\Gamma_t^{up}\big(\Gamma_t^{lo}\big)^{-1}\Big(\sup_{\sigma^0\le s\le t}\Gamma_s^{up}\Big) =: \delta\cdot\overline{C_t^{U,-\delta}} \qquad \text{for } t\le\sigma^\delta \ \boldsymbol{P}\text{-a.s.}$$

Limit behavior of cost functionals. The difference of tracked and tracking cost functional has the representation

$$\begin{aligned} Y_t^\star - Y_t^{-\delta} = E\Big[&\int_t^{\sigma^\delta\wedge\tau} g(s,X_s^\star,Y_s^\star,Z_s^\star) - g(s,X_s^{-\delta},Y_s^{-\delta},Z_s^{-\delta})\,ds \\ &+ \big(h(X_T^\star) - h(X_T^{-\delta})\big)\boldsymbol{\chi}_{\sigma^\delta\wedge\tau=T} + a_\tau^L\big(X_\tau^\star - X_\tau^{-\delta}\big)\boldsymbol{\chi}_{\substack{\tau<\sigma^\delta\\ \tau<T}} \\ &+ a_{\sigma^\delta}^U\big(X_{\sigma^\delta}^\star - X_{\sigma^\delta}^{-\delta}\big)\boldsymbol{\chi}_{\substack{\sigma^\delta\le\tau\\ \sigma^\delta<T}} + \int_{[t,\sigma^\delta\wedge\tau)} a_s^U\,dC_s^U \,\Big|\, \mathcal{F}_t\Big]. \end{aligned} \tag{3.26}$$

Again the value is monotone in δ, and $(Y^{-\delta}, Z^{-\delta})$ converges to $(Y^\star, Z^\star)$.

LEMMA 3.11. *Assume that* (3.1) *holds. Let, for $\delta,\delta'\in\mathbb{R}_{>0}$, the processes $Y^{-\delta}, Y^{-\delta'}$ be as defined in Lemma* 3.9*. Then*

$$Y_t^{-\delta'} \le Y_t^{-\delta} \le Y_t^\star \qquad \text{for } \delta\le\delta' \ \forall\ t \ \boldsymbol{P}\text{-a.s.}$$

LEMMA 3.12. *Assume that* (3.1) *holds. Then $Y_t^{-\delta}$ converges to $Y_t^\star$ $\boldsymbol{P}$-a.s. uniformly in t, and further,*

$$\lim_{\delta\searrow 0} E\Big[\sup_{t\le s\le T}\big|Y_s^\star - Y_s^{-\delta}\big|^2\Big] = 0, \tag{3.27}$$

$$\lim_{\delta\searrow 0} E\bigg[\int_t^T \big|Z_s^\star - Z_s^{-\delta}\big|^2\,ds\bigg] = 0. \tag{3.28}$$

The convergence in (3.27) *is monotone.*

Estimates for the difference quotient $\frac{1}{\delta}\big(Y^\star - Y^{-\delta}\big)$. The structure of our approach is the same as in section 3.2, but we have to make slight modifications in the definitions of upper and lower bounds $\hat R^{up,-\delta}$ and $\hat R^{lo,-\delta}$ for the transformed process $\hat Y^{-\delta}$. Again, the bounds converge to a common limit $\hat R$ that gives an estimate for the payoff of the associated Dynkin game.

We rewrite $\frac{1}{\delta}\big(Y^\star - Y^{-\delta}\big)$ as an uncontrolled process similar to the construction in Lemma 3.6 and consider

$$\hat Y_t^{-\delta} := \frac{1}{\delta}\left(\big(Y_t^\star - Y_t^{-\delta}\big) + \int_{[0,\sigma^\delta\wedge\tau\wedge t)} a_s^U\,dC_s^U\right) \quad\text{and}\quad \hat Z_t^{-\delta} := \frac{1}{\delta}\big(Z_t^\star - Z_t^{-\delta}\big).$$

It can be verified directly that $(\hat{Y}^{-\delta}, \hat{Z}^{-\delta})$ is the solution of a BSDE with data

$$\begin{aligned}
\xi^{\hat{Y}} &:= \frac{1}{\delta}\big(h(X_T^\star) - h(X_T^{-\delta})\big)\boldsymbol{\chi}_{\sigma^\delta\wedge\tau=T} + a_\tau^L\frac{1}{\delta}\big(X_\tau^\star - X_\tau^{-\delta}\big)\boldsymbol{\chi}_{\substack{\tau<\sigma^\delta\\ \tau<T}}\\
&\quad + a_{\sigma^\delta}^U\frac{1}{\delta}\big(X_{\sigma^\delta}^\star - X_{\sigma^\delta}^{-\delta}\big)\boldsymbol{\chi}_{\substack{\sigma^\delta\le\tau\\ \sigma^\delta<T}} + \frac{1}{\delta}\int_{[0,\sigma^\delta\wedge\tau)} a_s^U\,dC_s^U,\\
g^{\hat{Y}}(t,y,z) &:= \Big(\Delta_x\hat{g}_t\frac{1}{\delta}(X_t^\star - X_t^{-\delta}) + \Delta_y\hat{g}_t\boldsymbol{\chi}_{y\ge0}\cdot y\\
&\quad - \Delta_y\hat{g}_t\frac{1}{\delta}\int_{[0,t)} a_s^U\,dC_s^U\Big)\boldsymbol{\chi}_{t\le\sigma^\delta\wedge\tau} + \Delta_z\hat{g}_t\cdot z\boldsymbol{\chi}_{t\le\tau},\\
C_t^{\hat{Y}} &:= (0,0).
\end{aligned}$$

Here $\Delta_x\hat{g}_t$, $\Delta_y\hat{g}_t$, and $\Delta_z\hat{g}_t$ are defined as

$$\begin{aligned}
\Delta_x\hat{g}_t &:= \big(g(t,X_t^\star,Y_t^\star,Z_t^\star) - g(t,X_t^{-\delta},Y_t^\star,Z_t^\star)\big)\frac{1}{X_t^\star - X_t^{-\delta}}\boldsymbol{\chi}_{X_t^{-\delta}\neq X_t^\star},\\
\Delta_y\hat{g}_t &:= \big(g(t,X_t^{-\delta},Y_t^\star,Z_t^\star) - g(t,X_t^{-\delta},Y_t^{-\delta},Z_t^\star)\big)\frac{1}{Y_t^\star - Y_t^{-\delta}}\boldsymbol{\chi}_{Y_t^{-\delta}\neq Y_t^\star},\\
\Delta_z\hat{g}_t &:= \big(g(t,X_t^{-\delta},Y_t^{-\delta},Z_t^\star) - g(t,X_t^{-\delta},Y_t^{-\delta},Z_t^{-\delta})\big)\frac{1}{Z_t^\star - Z_t^{-\delta}}\boldsymbol{\chi}_{Z_t^{-\delta}\neq Z_t^\star}.
\end{aligned}$$

Observe that $\hat{Y}^{-\delta}\ge 0$ by (3.15f) and Lemma 3.11, and that for $t\le\sigma^0\wedge\tau$, $\hat{Y}_t^{-\delta} = \frac{1}{\delta}(Y_t^\star - Y_t^{-\delta})$.

We will assume that (3.15) holds. Again we define processes $(\hat{R}^{up,-\delta},\hat{Q}^{up,-\delta})$ and $(\hat{R}^{lo,-\delta},\hat{Q}^{lo,-\delta})$ as solutions to the BSDE with data $(\xi^{up,-\delta},g^{up,-\delta},C^{up,-\delta})$ and $(\xi^{lo,-\delta},g^{lo,-\delta},C^{lo,-\delta})$, where

$$\begin{aligned}
\xi^{up,-\delta} &:= h_x(X_T^{x,0,C^L})\Gamma_T^{x,0,C^L}\boldsymbol{\chi}_{\sigma^\delta\wedge\tau=T} + a_\tau^L\Gamma_\tau^{x,0,C^L}\boldsymbol{\chi}_{\substack{\tau<\sigma^\delta\\ \tau<T}}\\
&\quad + \big(\max_{\sigma^0\le s\le\sigma^\delta} a_s^U\big)\big(\sup_{\sigma^0\le s\le\sigma^\delta}\Gamma_s^{x,0,C^L}\big)^2\big(\inf_{\sigma^0\le s\le\sigma^\delta}\Gamma_s^{x-\delta,0,C^L}\big)^{-1}\boldsymbol{\chi}_{\substack{\sigma^0\le\tau\\ \sigma^0<T}},\\
\xi^{lo,-\delta} &:= h_x(X_T^{x-\delta,0,C^L})\Gamma_T^{x-\delta,0,C^L}\boldsymbol{\chi}_{\sigma^0\wedge\tau=T} + a_\tau^L\Gamma_\tau^{x-\delta,0,C^L}\boldsymbol{\chi}_{\substack{\tau<\sigma^0\\ \tau<T}}\\
&\quad + \big(\min_{\sigma^0\le s\le\sigma^\delta} a_s^U\big)\big(\inf_{\sigma^0\le s\le\sigma^\delta}\Gamma_s^{x-\delta,0,C^L}\big)^2\big(\sup_{\sigma^0\le s\le\sigma^\delta}\Gamma_s^{x,0,C^L}\big)^{-1}\boldsymbol{\chi}_{\substack{\sigma^\delta\le\tau\\ \sigma^\delta<T}},\\
g^{up,-\delta}(t,y,z) &:= \Big(g_x(t,X_t^\star,Y_t^\star)\Gamma_t^{x,0,C^L} + g_y(t,X_t^\star,Y_t^\star)\boldsymbol{\chi}_{y\ge0}\boldsymbol{\chi}_{A^+_{g,-\delta}}\cdot y\\
&\quad + L\big(\max_{\sigma^0\le s\le\sigma^\delta\wedge t} a_s^U\big)\overline{C_t^{U,-\delta}}\Big)\boldsymbol{\chi}_{t\le\sigma^\delta\wedge\tau} + g_z(t)\cdot z\boldsymbol{\chi}_{t\le\tau},\\
g^{lo,-\delta}(t,y,z) &:= g_x(t,X_t^{-\delta},Y_t^\star)\Gamma_t^{x-\delta,0,C^L}\boldsymbol{\chi}_{t\le\sigma^0\wedge\tau}\\
&\quad + \Big(g_y(t,X_t^{-\delta},Y_t^{-\delta})\boldsymbol{\chi}_{y\ge0}\boldsymbol{\chi}_{A^-_{g,-\delta}}\cdot y\\
&\quad - L\big(\max_{\sigma^0\le s\le\sigma^\delta\wedge t} a_s^U\big)\overline{C_t^{U,-\delta}}\Big)\boldsymbol{\chi}_{t\le\sigma^\delta\wedge\tau} + g_z(t)\cdot z\boldsymbol{\chi}_{t\le\tau},\\
C_t^{up,-\delta} &:= C_t^{lo,-\delta} := (0,0).
\end{aligned}$$

Here $A^+_{g,-\delta}$ and $A^-_{g,-\delta}$ are defined as

$$A^+_{g,-\delta} := \{t \le \sigma^0 \wedge \tau\} \cup \{g_y(t, X^\star_t, Y^\star_t) \ge 0\},$$
$$A^-_{g,-\delta} := \{t \le \sigma^0 \wedge \tau\} \cup \{g_y(t, X^{-\delta}_t, Y^{-\delta}_t) \le 0\}.$$

We use the convention $\sup_{\sigma^0 \le s \le \sigma^\delta \wedge t} a^U_s = 0$ for $t < \sigma^0$. L denotes a Lipschitz constant for g.

The limiting process $\hat{R}$ is defined as the state process of a BSDE with data

$$\hat{\xi} := h_x(X^{x,0,C^L}_T)\Gamma^{x,0,C^L}_T \boldsymbol{\chi}_{\sigma^0 \wedge \tau = T} + a^L_\tau \Gamma^{x,0,C^L}_\tau \boldsymbol{\chi}_{\substack{\tau < \sigma^0 \\ \tau < T}} + a^U_{\sigma^0}\Gamma^{x,0,C^L}_{\sigma^0} \boldsymbol{\chi}_{\substack{\sigma^0 \le \tau \\ \sigma^0 < T}},$$

$$\hat{g}(t,y,z) := \Big(g_x(t, X^\star_t, Y^\star_t)\Gamma^{x,0,C^L}_t + g_y(t, X^\star_t, Y^\star_t)\boldsymbol{\chi}_{y \ge 0} \cdot y\Big)\boldsymbol{\chi}_{t \le \sigma^0 \wedge \tau} + g_z(t) \cdot z \boldsymbol{\chi}_{t \le \tau}$$

and control zero. Its property as limit of the difference quotient is the subject of the following lemma, which is the analogue to Lemma 3.6. The proof is straightforward.

LEMMA 3.13. *Assume that* (2.8) *and* (3.15) *hold. The processes* $\hat{R}^{up,-\delta}$, $\hat{Y}^{-\delta}$, $\hat{R}^{lo,-\delta}$ *satisfy*

$$\hat{R}^{lo,-\delta}_t \le \hat{Y}^{-\delta}_t \le \hat{R}^{up,-\delta}_t \qquad \forall t \in \bar{\imath}\ \boldsymbol{P}\text{-a.s.} \tag{3.29}$$

Further, $\hat{R}^{up,-\delta}_t$ *decreases and* $\hat{R}^{lo,-\delta}_t$ *increases as* $\delta \searrow 0$ *to the same limiting process* $\hat{R}$ *defined above, in* $L^2_{\mathcal{F}}(0,T;\mathbb{R})$ *and for all* $t \in \bar{\imath}$ $\boldsymbol{P}$*-a.s.*

We now can formulate the estimate in terms of the Dynkin game 1.2.

LEMMA 3.14. *Assume that* (2.8) *and* (3.15) *hold. Then*

$$\lim_{\delta \searrow 0} \frac{1}{\delta}\big(Y^\star_t - Y^{-\delta}_t\big) \ge R^x_t(\sigma^0, \tau) \tag{3.30}$$

holds $\boldsymbol{P}$*-a.s. for all* $t \le \sigma^0 \wedge \tau$.

Proof. By Lemma 3.13 it suffices to prove

$$\hat{R}_t \ge R^x_t(\sigma^0, \tau) \qquad \boldsymbol{P}\text{-a.s. for } t \le \sigma^0 \wedge \tau.$$

This follows from the comparison theorem (Theorem 2.7), if the data satisfy $\hat{g}(t,y,z) \ge g^R(t,y,z)$ and $\hat{\xi} \ge \xi^R$. But this is a consequence of the convexity assumptions. Especially observe that $\Gamma^{x,0,C^L} \ge \Gamma^{x,0,0}$ holds for the deflator processes, as b is convex and $X^{x,0,C^L} \ge X^{x,0,0}$. □

We now conclude this discussion with the following lemma.

LEMMA 3.15. *Assume that* (2.8) *and* (3.15) *hold and that there exists an optimal control* (C^U, C^L) *for the control problem* 1.1 *in* x. *Let* $V(x)$ *be its value. Then the lower left Dini derivative of* V *with respect to the initial condition satisfies*

$$\Delta_- V(x) \ge u^+(x).$$

Proof. By the optimality of $(C^U, -C^L)$ in x and Lemma 3.7 we have

$$\liminf_{\delta \searrow 0} \frac{1}{\delta}\big(V(x) - V(x-\delta)\big) \ge \liminf_{\delta \searrow 0} \frac{1}{\delta}\big(Y^\star_0 - Y^{-\delta}_0\big) \ge R^x_0(\sigma^0, \tau).$$

As $\tau \in \mathcal{T}$ is arbitrary this gives

$$\Delta_- V(x) \ge \operatorname*{ess\,sup}_{\tau \in \mathcal{T}} R^x_0(\sigma^0, \tau) \ge u^+(x) \qquad \boldsymbol{P}\text{-a.s} \tag{3.31}$$ □

3.4. Proof of Theorem 1.3. By Lemma 3.15, the definitions in (1.5), Lemma 3.8, and Theorem 2.10 we have the relations

$$\Delta^+ V(x) \le u^-(x) \le u^+(x) \le \Delta_- V(x) \le \Delta^+ V(x). \tag{3.32}$$

Consequently, equality holds in (3.32). So V is differentiable at x with partial derivative equal to the solution of the Isaac's equation $u^-(x) = u^+(x) = u(x)$.

Let us suppress dependence on x. By (3.20), (3.31), (3.32), and the Isaac's equation

$$\operatorname*{ess\,inf}_{\sigma\in\mathcal{T}} R_0(\sigma,\tau^0) = \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} \operatorname*{ess\,inf}_{\sigma\in\mathcal{T}} R_0(\sigma,\tau)$$
$$= u(x) = \operatorname*{ess\,inf}_{\sigma\in\mathcal{T}} \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} R_0(\sigma,\tau) = \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} R_0(\sigma^0,\tau).$$

Hence (σ^0,τ^0) is an optimal pair or saddle point for the associated Dynkin game.

4. Extensions. In this section we briefly discuss some variations, such as weaker assumptions on the data and certain subspaces of controls.

Relaxing requirements on the data. Although the results of Theorem 1.3 are presented in a fairly general situation, some of the conditions in (2.8) and (3.15) can be found to be very restrictive. So we note that the removal of global Lipschitz conditions on the cost data g, h w.r.t. the state X and extension to a stochastic, possibly infinite time horizon can be achieved through similar localization arguments as in Boetius and Kohlmann [18]. To ensure validity of comparison theorems and a priori estimates one may consult, e.g., El Karoui and Quenez [32].

Removing the monotonicity of the cost data in x will be possible in exchange for stronger assumptions on the forward equation, notably the requirement that b is affine, and integrability conditions to ensure existence of the cost functionals of the Dynkin game. In this way quadratic costs can be included in our considerations.

To lift the assumption of Lipschitz continuity for the running cost g w.r.t. y and z is less easy because then the BSDE may no longer have a solution; see Bender and Kohlmann [10] or Bender [9] for solvability of BSDE under weak conditions.

Relaxation of convexity assumptions without losing convexity of the value is considered by Alvarez [2].

Monotone control as limiting case. From Definitions 1.1 and 1.2 we obtain a monotone control problem and a problem of optimal stopping if we require $C^L = 0$ and $\tau = T$. Let V^m and u^m denote the respective values. The monotone control problem models an irreversible investment problem, so it is natural to ask whether this is obtainable as a limit in some sense of partially reversible investment problems. In fact, when we consider the control problem and Dynkin game under the convex structure (2.8) and choose $a^L \le 0$, we obtain

$$V^m(x) = V(x), \qquad u^m(x) = u(x).$$

For the control problem this becomes intuitively clear if we recall that the cost data are increasing in x; thus exercising control C^L leads to a worse cost situation in the running and terminal costs for any future time, and, in addition, we incur the cost $-a^L_t\, dC^L_t$. Thus, letting $a^L = 0$ will allow us to treat the monotone case as a limiting situation. This is even more obvious in the Dynkin game: if $a^L \le 0$, the player seeking to maximize the cost functional R will never terminate the game, because he would forego the chance of profiting from the running cost g_x and the terminal cost h_x.

Modifications on the space of controls. Monotone follower problems with finite fuel, a limitation on the amount of control to be exercised, form a particularly interesting class of control problems. In many situations it is possible to express the value of the control problem with finite fuel in terms of the value without such additional condition and the risk with zero control available; see e.g., Chow, Menaldi, and Robin [20], or Karatzas [43]. The most interesting element is that for the monotone follower there is no time value of control or additional hysteresis effect, so a control optimal under a finite fuel restriction does not save resources compared to optimal behavior without restriction. The reason for this is that the "displacement" caused by a certain amount of controlling activity is constant over time, and so is its influence on the cost functional.

This result carries over to the situation of Theorem 1.3 if one considers a generalized finite fuel condition defined as follows: Take the starting values from an interval $[a,b] \subset \mathbb{R}$ and call controls $C \in \mathcal{A}$ admissible, or elements of $\mathcal{A}_{[a,b]}$, if the controlled forward process $X^{0,x,C}$ stays in the moving interval $[X^{0,a,0}, X^{0,b,0}]$. Denoting the value by $V_{[a,b]}$ it is easy to see that Theorem 1.3 still holds.

The same is true if we consider subclasses of $\mathcal{A}$ or $\mathcal{A}_{[a,b]}$ whose elements have a finite *partition of monotone control* $\boldsymbol{P}$-a.s., which means that there exists a sequence of $\mathcal{F}_t$-stopping times $(\theta_n)_{\mathbb{N}}$ such that $\theta_0 = 0$,

$$\theta_n \xrightarrow{=} T, \qquad C_t \text{ is monotone in } [\theta_{n-1}, \theta_n).$$

Details can be found in [17] or Boetius and Kohlmann [18].

These modifications are useful when one tries to construct solutions to the partially irreversible investment problem from optimal strategies of small investors. The latter take the form of optimal stopping or "entry-exit" sequential stopping problems; see [16] or Baldursson and Karatzas [5]. In the case of monotone control one finds that the control problem and a family of stopping problems are equivalent. In the case of bounded variation control this leads to a representation of the Dynkin game in terms of two closely related entry-exit problems; see [17].

Acknowledgments. I am very much indebted to Michael Kohlmann for many helpful and constructive discussions and to two unknown referees for their useful and precise remarks and recommendations that made this paper more readable.

OPTIMAL CONSUMPTION-INVESTMENT PROBLEMS IN INCOMPLETE MARKETS WITH STOCHASTIC COEFFICIENTS*

NETZAHUALCÓYOTL CASTAÑEDA-LEYVA† AND DANIEL HERNÁNDEZ-HERNÁNDEZ‡

Abstract. The goal of this paper is to solve an optimal consumption-investment problem in the context of an incomplete financial market. The model is a generalization of the Black and Scholes diffusion model, where the coefficients of the diffusion modelling the stock's price depend on some stochastic economic factors. Based on the martingale approach, a basic methodology to get the optimal solution is presented. Combining this procedure with stochastic control techniques, explicit solutions for HARA and logarithmic utility functions are obtained.

Key words. optimal investment and consumption, incomplete markets, stochastic volatility, martingale method, optimal control, Black–Scholes model

DOI. 10.1137/S0363012904440885

1. Introduction.

Since the fundamental work of Black and Scholes to value European options, their model has become a cornerstone in the development and study of many problems in mathematical finance. In recent years, different generalizations of this classical model have been studied, trying to model more precisely the dynamics of the asset prices. In this sense, it is natural to consider a model with stochastic coefficients (interest rate, return rate, and volatility), depending on economic external factors. In fact, several contributions show empirical arguments justifying these kinds of models. For example, Fouque, Papanicolaou, and Sircar [FPS00] present a detailed analysis when the external factor is a mean reverting Ornstein–Uhlenbeck (O–U) process, which can be, for instance, a *leader* interest rate. On the other hand, recently, Barndorff–Nielsen and Shephard [BaSp02] propose a model for volatility based on the O–U process with background subordinator (nonnegative Levy process). They also give a detailed statistical analysis, identifying important volatility effects in the asset prices: heavy tailed of returns, volatility clustering, and right skewness in some cases.

The relevance of the diffusion models presented in this paper is not limited only to economical or empirical qualities, they also have proved to be tractable. For example, we can find explicit solutions of problems in the context of optimal investment (Zariphopoulou [Za01]), optimal consumption process (Fleming and Hernández-Hernández [FlHe02]), and valuation (Davis [Da00]). This feature contrasts with technical constraints or difficulties in the implementation of other affine approaches. For instance, in the model proposed by Barndorff–Nielsen and Shephard [BaSp02] their background subordinator induces a constraint for the trading portfolio proportion, which should belong to the interval $[0, 1]$. This fact was mentioned by Benth, Karlsen,

and Reikvam [BKR03] in their study of some investment problems.

The goal of this work is to solve the problem of maximizing the expected utility of terminal wealth and/or consumption in some finite time interval $[0, T]$, as well as to find an *optimal* trading strategy.

The investor's financial market is composed of a bank account, a risky asset, and an economic external correlated factor. The dynamics of the risky asset price and the external factor are diffusion processes where, as it was already mentioned, this last one affects the coefficients of the model. On the other hand, since the external factor is not traded, this problem drops into the family of incomplete markets. We deal with two particular utility functions: hyperbolic absolute risk aversion (HARA) and logarithmic. However, since the arguments are similar, most of the effort is concentrated in solving the optimization problem when the utility function is HARA, which is also the most complex.

We will use the martingale method to solve this problem, formulating the investor's problem as a convex optimization one, referred to as the *primal problem*. In this context, the primal problem has an associated *dual* problem, which turns out to be an stochastic optimal control problem, where the control processes belong to the set of equivalent local martingale measures.

The martingale method goes back to the fundamental contribution by Harrison and Pliska [HaPl81], and it has now become a popular approach to study optimal terminal wealth and/or consumption problems. This method is particularly powerful when the financial market is incomplete. For instance, in Karatzas and Shreve [KaSr98] and some references therein, a wide class of optimization problems for incomplete markets are studied using this approach. However, explicit optimal solutions are not presented in general, except for logarithmic utility or when the coefficients are deterministic. In Kramkov and Schachermayer [KrSc99] optimal investment problems for incomplete markets are analyzed when the stock prices are driven by semimartingales, for a wide class of utility functions. In both references, under suitable conditions, some characterizations of the optimization problem are presented. In particular, they show that there is no duality gap between the primal and dual problems.

We shall solve the investor's problem using a composition of the martingale method and stochastic control techniques. With this goal in mind, we pose the primal and dual problems and state the existence of their solutions, which shall imply the absence of duality gap. When the utility function is HARA, the solution to the dual problem relies on stochastic control techniques, while in the logarithmic case the solution is straightforward.

The paper is organized as follows. In section 2 the model and the investor's problem as well as its primal representation is established. Next, in section 3 we write down the associated dual problem. The martingale method is also explained, and a practical condition for absence of duality gap is given. Furthermore, a relevant relationship between optimal solutions of both problems is obtained. Also, we present the basic steps of the martingale method. Finally, in section 4 closed form solutions, when the utility function is HARA and logarithmic, are presented.

Throughout the paper all inequalities involving random variables are understood to be satisfied almost surely.

2. The model and primal problem. In this section the underlying model of the financial market is introduced, and a stochastic dynamic model for optimal consumption and investment on a finite horizon is considered.

Let $(\Omega, \mathcal{F}_T, P)$ be a complete probability space, where a two-dimensional standard

Brownian motion (BM) $\{(W_{1t}, W_{2t}), \mathcal{F}_t\}_{0\leq t\leq T}$ is defined, with $\{\mathcal{F}_t\}_{0\leq t\leq T}$ being the augmentation of the filtration $\left\{\mathcal{F}_t^{(W_{1t},W_{2t})}\right\}_{0\leq t\leq T}$. The securities market is modelled using this BM and involves a risky asset, a bond, and an external economic factor such that, for $0 \leq t \leq T$:

1. The bond price process is given by $S_t^0 \triangleq \exp\int_0^t r(Y_s)\,ds$, where the interest rate $r(\cdot)$ is a real function in $C_b^2(\mathbf{R})$, where $C_b^2(\mathbf{R})$ is the class of $C^2(\mathbf{R})$ functions which are bounded together with their first and second derivatives.
2. The asset price process S_t satisfies the stochastic differential equation (SDE)

$$dS_t = S_t\left[\mu(Y_t)\,dt + \sigma(Y_t)\,dW_{1t}\right], \quad \text{with} \quad S_0 = 1. \tag{2.1}$$

   It is assumed that the functions $\mu(\cdot)$ and $\sigma(\cdot)$ belong to $C_b^2(\mathbf{R})$, with $\sigma(\cdot) \geq \sigma_0$, for some constant $\sigma_0 > 0$.
3. The dynamics of the external factor Y_t is modelled as a diffusion process solving the SDE

$$dY_t = g(Y_t)\,dt + \beta\left(\rho dW_{1t} + \varepsilon dW_{2t}\right), \quad \text{with} \quad Y_0 = y \in \mathbf{R}, \tag{2.2}$$

   where $|\rho| \leq 1$, $\varepsilon \triangleq \sqrt{1-\rho^2}$, $\beta \neq 0$, and $g(\cdot)$ belongs to $C^1(\mathbf{R})$, with $g'(\cdot)$ bounded.

The parameter ρ is the correlation coefficient between the BM W_1 driving the asset price and the BM from the external factor $\breve{W} \triangleq \rho W_1 + \varepsilon W_2$. Except when $\rho = \pm 1$, the securities market is *incomplete*, since the external factor Y cannot be traded. Finally, without loss of generality, we fix $\beta = 1$.

Let π_t be the net amount of capital allocated in the risk asset, and c_t the rate at which capital is consumed at time t. Then, the investor's wealth process evolves as

$$dX_t = -c_t dt + \frac{X_t - \pi_t}{S_t^0} dS_t^0 + \frac{\pi_t}{S_t} dS_t,$$

with initial capital $X_0 = x > 0$. Formally, $\{\pi_t, \mathcal{F}_t\}_{0\leq t\leq T}$ is a trading **portfolio** process if it is progressively measurable and $\int_0^T \pi_u^2 du < \infty$, whereas $\{c_t, \mathcal{F}_t\}_{0\leq t\leq T}$ is a **consumption** process if it is nonnegative and progressively measurable with $\int_0^T c_t dt < \infty$. Their associated **wealth** process, denoted by $X^{\pi,c} \triangleq X^{x,y,\pi,c}$, is the solution to the integral equation

$$X_t^{\pi,c} + \int_0^t c_s ds \triangleq x + \int_0^t \left[r(Y_s)\,X_s^{\pi,c} + \left[\mu(Y_s) - r(Y_s)\right]\pi_s\right] ds + \int_0^t \pi_s \sigma(Y_s)\,dW_{1s}.$$

We say that a trading *strategy* (π, c) is **admissible** if $X^{\pi,c} \geq 0$; the set of such strategies is denoted as $\mathcal{A}(x, y)$.

The investor's problem consists of

$$\text{maximizing} \quad E\left\{U_1(X_T^{\pi,c}) + \int_0^T U_2(c_t)\,dt\right\}, \quad \text{over} \quad (\pi, c) \in \mathcal{A}(x, y), \tag{2.3}$$

as well as to find an *optimal* trading strategy $(\hat{\pi}, \hat{c})$. The utility functions U_1, $U_2 : \mathbf{R}_+ \to \mathbf{R}$ are differentiable, strictly increasing, and concave. In addition to these fundamental properties, it is assumed that $U_i'(\infty) \triangleq \lim_{b\to\infty} U_i'(b) = 0$ and $U_i'(0+) \triangleq \lim_{b\downarrow 0} U_i'(b) = \infty$, for $i = 1, 2$.

The solution of this optimization problem will be obtained using the martingale approach (see [HaPl81]), and the first step in this direction will be to characterize the family $\mathcal{A}(x,y)$ and get the *primal* representation of the investor's problem (2.3); see Lemma 2.2 and expression (P) below.

Define the function $\theta : \mathbf{R} \to \mathbf{R}$ as

$$\theta(y) \triangleq \frac{\mu(y) - r(y)}{\sigma(y)}, \quad y \in \mathbf{R}.$$

Now, denote by $\mathcal{M}$ the set of progressively measurable processes $\{\nu_t, \mathcal{F}_t\}_{t\in[0,T]}$ such that $E\int_0^T \nu_u^2 du < \infty$ and the local martingale, given by

$$Z_t^\nu \triangleq \exp\left(-\int_0^t \left[\theta(Y_u)\, dW_{1u} + \nu_u dW_{2u}\right] - \frac{1}{2}\int_0^t \left[\theta^2(Y_u) + \nu_u^2\right] du\right), \tag{2.4}$$

is a martingale for all $y \in \mathbf{R}$. Note that all bounded processes belong to $\mathcal{M}$, since $\theta(\cdot)$ is bounded. Then, for each $\nu \in \mathcal{M}$ we can define a probability measure P^ν on $(\Omega, \mathcal{F}_T)$ as

$$dP^\nu \triangleq Z_T^\nu dP. \tag{2.5}$$

Observe that $P \ll P^\nu \ll P$ and $Z_t^\nu \triangleq dP^\nu/dP|_{\mathcal{F}_t}$, for $t \in [0,T]$. Under the measure P^ν, the two-dimensional process $\{(W_{1t}^\nu, W_{2t}^\nu), \mathcal{F}_t\}_{0\le t\le T}$

$$W_{1t}^\nu \triangleq W_{1t} + \int_0^t \theta(Y_u)\, du \quad \text{and} \quad W_{2t}^\nu \triangleq W_{2t} + \int_0^t \nu_u du, \tag{2.6}$$

is a BM, and the dynamics of the processes Y_t and Z_t can be written as

$$dY_t = \left[g(Y_t) - \rho\theta(Y_t) - \varepsilon\nu_t\right] dt + \rho dW_{1t}^\nu + \varepsilon dW_{2t}^\nu, \tag{2.7}$$

$$dZ_t^\nu = Z_t^\nu\left(\left[\theta^2(Y_t) + \nu_t^2\right] dt - \theta(Y_t)\, dW_{1t}^\nu - \nu_t dW_{2t}^\nu\right). \tag{2.8}$$

Furthermore, the discounted price and wealth processes satisfy

$$d\left[\frac{S_t}{S_t^0}\right] = \frac{S_t}{S_t^0}\sigma(Y_t)\, dW_{1t}^\nu, \tag{2.9}$$

$$d\left[\frac{X_t^{\pi,c}}{S_t^0}\right] + \frac{c_t}{S_t^0}dt = \frac{\pi_t}{S_t^0}\sigma(Y_t)\, dW_{1t}^\nu, \quad (\pi, c) \in \mathcal{A}(x,y). \tag{2.10}$$

Remark 2.1. The above displayed equations imply the following:

(i) The process S_t/S_t^0 is a continuous P^ν-martingale, since $\sigma(\cdot)$ is bounded. Hence, $\mathcal{M} \subset \mathcal{P} \triangleq \{Q : P \ll Q \ll P$ and S/S^0 is a Q-local martingale for all $y \in \mathbf{R}\}$, in the sense that $P^\nu \in \mathcal{P}$ for each $\nu \in \mathcal{M}$.

(ii) The discounted process $X_t^{\pi,c}/S_t^0 + \int_0^t \left(c_s/S_s^0\right) ds$ is a nonnegative continuous P^ν-local martingale and, by Fatou's lemma, is also a P^ν-supermartingale.

The following lemma allows us to characterize the set of admissible trading strategies $\mathcal{A}(x,y)$, and it will be useful to write down the primal problem. It is analogous to Theorem 1 in [Cu97] and Theorem 5.6.2 in [KaSr98], and even though it is a known result its proof is crucial to put into firm ground the main contributions of this paper. Some parts of the proof are quoted from the above references. Condition (2.11) below is referred hereafter as the *budget constraint*.

LEMMA 2.2. *Let B be a nonnegative $\mathcal{F}_T$-measurable random variable and c_t a consumption rate process such that*

$$\sup_{\nu\in\mathcal{M}} E^{\nu}\left\{\frac{B}{S_T^0}+\int_0^T \frac{c_t}{S_t^0}dt\right\}\leq x. \tag{2.11}$$

Then, there exists a trading portfolio π such that $(\pi,c)\in\mathcal{A}(x,y)$ and $X_T^{\pi,c}\geq B$. Conversely, if $(\pi,c)\in\mathcal{A}(x,y)$, then $B\stackrel{\circ}{=}X_T^{\pi,c}$ satisfies the budget constraint (2.11).

Proof. The last part of the lemma is straightforward, since, from Remark 2.1, when $\pi\in\mathcal{A}(x,y)$ and $\nu\in\mathcal{M}$ the discounted process $X_t^{\pi,c}/S_t^0+\int_0^t\left(c_s/S_s^0\right)ds$ is a P^{ν}-supermartingale. Hence

$$E^{\nu}\left[\frac{X_T^{\pi,c}}{S_T^0}+\int_0^T\frac{c_t}{S_t^0}dt\right]\leq E^{\nu}X_0^{\pi,c}=x,$$

and, since ν was chosen arbitrarily, the budget constraint (2.11) follows.

Now, to establish the first part, we define the following discounted process:

$$\frac{\check{X}_t}{S_t^0}\stackrel{\circ}{=}\operatorname{ess\,sup}_{\nu\in\mathcal{M}}E^{\nu}\left[\frac{B}{S_T^0}+\int_t^T\frac{c_u}{S_u^0}du\mid\mathcal{F}_t\right],\quad t\in[0,T]\,. \tag{2.12}$$

Note that, by hypothesis,

$$\check{X}_0=\sup_{\nu\in\mathcal{M}}E^{\nu}\left\{\frac{B}{S_T^0}+\int_0^T\frac{c_t}{S_t^0}dt\right\}\leq x\quad\text{and}\quad\check{X}_T\equiv B. \tag{2.13}$$

It will be shown that the process $\check{X}$ induces an admissible trading strategy (π,c) such that $X_T^{\pi,c}\geq B$. First, it will be verified that $\check{X}$ satisfies the dynamic programming equation (DPE)

$$\frac{\check{X}_s}{S_s^0}=\operatorname{ess}\sup_{\nu\in\mathcal{M}}E^{\nu}\left[\frac{\check{X}_t}{S_t^0}+\int_s^t\frac{c_u}{S_u^0}du\mid\mathcal{F}_s\right],\quad 0\leq s\leq t\leq T. \tag{2.14}$$

From the definition of $\check{X}_t$ it follows that

$$E^{\nu}\left[\frac{B}{S_T^0}+\int_t^T\frac{c_u}{S_u^0}du\mid\mathcal{F}_s\right]=E^{\nu}\left[E^{\nu}\left(\frac{B}{S_T^0}+\int_t^T\frac{c_u}{S_u^0}du\mid\mathcal{F}_t\right)\mid\mathcal{F}_s\right]\leq E^{\nu}\left[\frac{\check{X}_t}{S_t^0}\mid\mathcal{F}_s\right],$$

and then

$$\begin{aligned}\frac{\check{X}_s}{S_s^0}&=\operatorname{ess}\sup_{\nu\in\mathcal{M}}E^{\nu}\left[\frac{B}{S_T^0}+\int_s^T\frac{c_u}{S_u^0}du\mid\mathcal{F}_s\right]\\&=\operatorname{ess}\sup_{\nu\in\mathcal{M}}E^{\nu}\left[\frac{B}{S_T^0}+\int_t^T\frac{c_u}{S_u^0}du+\int_s^t\frac{c_u}{S_u^0}du\mid\mathcal{F}_s\right]\\&\leq\operatorname{ess}\sup_{\nu\in\mathcal{M}}E^{\nu}\left[\frac{\check{X}_t}{S_t^0}+\int_s^t\frac{c_u}{S_u^0}du\mid\mathcal{F}_s\right].\end{aligned}$$

Next, the reverse inequality shall be verified, namely

$$\frac{\check{X}_s}{S^0_s} \geq E^\nu\left[\frac{\check{X}_t}{S^0_t} + \int_s^t \frac{c_u}{S^0_u} du \mid \mathcal{F}_s\right], \quad \text{for each } \nu \in \mathcal{M}. \tag{2.15}$$

Given $\nu \in \mathcal{M}$ and $t \in [0,T]$ fixed, define $\mathcal{M}^\nu(t) \triangleq \{\eta \in \mathcal{M} : \eta \equiv \nu \text{ in } [0,t]\}$ and

$$J^\eta_t \triangleq E^\eta\left[\frac{B}{S^0_T} + \int_t^T \frac{c_u}{S^0_u} du \mid \mathcal{F}_t\right] = E\left[\frac{Z^\eta_T}{Z^\eta_t}\left(\frac{B}{S^0_T} + \int_t^T \frac{c_u}{S^0_u} du\right) \mid \mathcal{F}_t\right], \quad \eta \in \mathcal{M}^\nu(t).$$

The second equality in the last expression is due to Bayes' formula for conditional expectations; see III.3.9 in [JaSh87] or Lemma 3.5.3 in [KaSr91]. On the other hand, note that Z^η_T/Z^η_t depends only on the values of ν in $[t,T]$. Then, $\check{X}_t/S^0_t = \sup_{\eta\in\mathcal{M}^\nu(t)} J^\eta_t$. In fact,

$$\frac{\check{X}_t}{S^0_t} = \lim_{n\to\infty} J^{\eta_n}_t, \tag{2.16}$$

for some increasing sequence $\{J^{\eta_n}_t\}_{n\geq 1}$, with $\eta_n \in \mathcal{M}^\nu(t)$. This is true since the set $\{J^\eta_t\}_{\eta\in\mathcal{M}^\nu(t)}$ is a closed family by pair maximization (see Theorem A.3 in [KaSr98]). From (2.16) and the conditional monotone convergence theorem, inequality (2.15) holds if for all $n \geq 1$

$$\frac{\check{X}_s}{S^0_s} \geq E^\nu\left[J^{\eta_n}_t + \int_s^t \frac{c_u}{S^0_u} du \mid \mathcal{F}_s\right].$$

This inequality is established observing that

$$\begin{aligned}
\frac{\check{X}_s}{S^0_s} &\geq E^{\eta_n}\left[\frac{B}{S^0_T} + \int_s^T \frac{c_u}{S^0_u} du \mid \mathcal{F}_s\right] = E^{\eta_n}\left[\frac{B}{S^0_T} + \int_s^t \frac{c_u}{S^0_u} du + \int_t^T \frac{c_u}{S^0_u} du \mid \mathcal{F}_s\right] \\
&= E^{\eta_n}\left[E^{\eta_n}\left(\frac{B}{S^0_T} + \int_t^T \frac{c_u}{S^0_u} du \mid \mathcal{F}_t\right) + \int_s^t \frac{c_u}{S^0_u} du \mid \mathcal{F}_s\right] \\
&= E^\nu\left[J^{\eta_n}_t + \int_s^t \frac{c_u}{S^0_u} du \mid \mathcal{F}_s\right].
\end{aligned}$$

Now, from the DPE (2.14), it follows that the process $\check{X}_\cdot/S^0_\cdot + \int_0^\cdot \left(c_t/S^0_t\right) dt$ is a P^ν-supermartingale with a right continuous with left limits (RCLL) modification, for each $\nu \in \mathcal{M}$. Using the Doob–Meyer supermartingale decomposition theorem and the local martingale representation theorem, this process can be written as

$$\frac{\check{X}_t}{S^0_t} + \int_0^t \frac{c_s}{S^0_s} ds =: \check{X}_0 + \int_0^t (\psi^\nu_{1s} dW^\nu_{1s} + \psi^\nu_{2s} dW^\nu_{2s}) - A^\nu_t, \tag{2.17}$$

where ψ^ν_1, ψ^ν_2, are progressively measurable processes with $\int_0^T ([\psi^\nu_{1s}]^2 + [\psi^\nu_{2s}]^2) ds < \infty$, and A^ν is a predictable integrable increasing process with $A^\nu_0 \equiv 0$; see Theorem 3.3.9 in [LiSh01] and Problem 3.4.16 in [KaSr91]. Thus, denoting by 0 the null process $\nu \equiv 0$, and using (2.17), the following identity holds:

$$\int_0^t (\psi^\nu_{1s} dW^\nu_{1s} + \psi^\nu_{2s} dW^\nu_{2s}) - A^\nu_t = \int_0^t \left(\psi^0_{1s} dW^0_{1s} + \psi^0_{2s} dW^0_{2s}\right) - A^0_t.$$

According to expression (2.6), we obtain that

$$0 = \int_0^t \left[\left(\psi_{1s}^{\nu} - \psi_{1s}^{0}\right) dW_{1s} + \left(\psi_{2s}^{\nu} - \psi_{2s}^{0}\right) dW_{2s}\right] + A_t^0 - A_t^{\nu} + \int_0^t \left[\left(\psi_{1s}^{\nu} - \psi_{1s}^{0}\right) \theta\left(Y_s\right) + \psi_{2s}^{\nu}\nu_s\right] ds.$$

This equation has the form $L + V + \phi \equiv 0$, where L is a continuous P-local martingale, V is a predictable finite variation process, and ϕ is a continuous process with zero quadratic variation, such that $L_0 = V_0 = \phi_0 = 0$. The above suggests that all those terms should be the zero process. In fact, from Proposition I.4.49.d in [JaSh87], the *covariation* $\langle L, V\rangle$ is identically zero. Thus, $0 = \langle \phi, \phi\rangle = \langle L + V, L + V\rangle = \langle L\rangle + \langle V\rangle + 2\langle L, V\rangle$. Hence $\langle L\rangle = \langle V\rangle = 0$, i.e.,

$$\psi_1^{\nu} \equiv \psi_1^0, \quad \psi_2^{\nu} \equiv \psi_2^0, \quad \text{and} \quad A_{\cdot}^{\nu} \equiv A_{\cdot}^0 + \int_0^{\cdot} \psi_{2s}^0 \nu_s ds \geq 0, \quad \nu \in \mathcal{M}.$$

This, together with the fact that $\left\{\int_0^t \psi_{2s}^0 ds < 0\right\} \cup \left\{\int_0^t \psi_{2s}^0 ds > 0\right\}$ is a null event, implies that $A_t^{\nu} = A_t^0$ for $t \in [0, T]$. Hence

$$\psi \stackrel{\circ}{=} \psi_1^0 \equiv \psi_1^{\nu}, \quad \psi_2^{\nu} \equiv 0, \quad \text{and} \quad A^{\nu} \equiv A^0, \quad \nu \in \mathcal{M}.$$

Thus, (2.17) can be written as

$$\frac{\check{X}_t}{S_t^0} + \int_0^t \frac{c_s}{S_s^0} ds = \check{X}_0 + \int_0^t \psi_s dW_{1s}^{\nu} - A_t^0, \quad \nu \in \mathcal{M}. \tag{2.18}$$

Now, assume for a moment that the budget constraint (2.11) holds with equality

$$\check{X}_0 = \sup_{\nu \in \mathcal{M}} E^{\nu}\left\{\frac{B}{S_T^0} + \int_0^T \frac{c_t}{S_t^0} dt\right\} = x. \tag{2.19}$$

Next, define the trading portfolio $\pi_t \stackrel{\circ}{=} S_t^0 \psi_t / \sigma\left(Y_t\right)$, for $t \in [0, T]$. Then, using (2.10), (2.18), and (2.19), it follows that $X^{x,y,\pi,c}$ satisfies

$$\begin{aligned} \frac{X_t^{x,y,\pi,c}}{S_t^0} &= x - \int_0^t \frac{c_s}{S_s^0} ds + \int_0^t \frac{\pi_s}{S_s^0} \sigma\left(Y_s\right) dW_{1s}^{\nu} = x - \int_0^t \frac{c_s}{S_s^0} ds + \int_0^t \psi_s dW_{1s}^{\nu} \\ &= \frac{\check{X}_t}{S_t^0} + A_t^0 \geq \frac{\check{X}_t}{S_t^0} \geq 0. \end{aligned}$$

In particular, $X_T^{x,y,\pi,c} \geq \check{X}_T \equiv B$. On the other hand, when $\check{X}_0 < x$, substituting $\check{X}_0$ by x and applying the above arguments to the trading strategy (π, c), but also investing in the bank account the exceeding initial capital $x - \check{X}_0$, we get

$$X^{x,y,\pi,c} \geq X^{\check{X}_0,y,\pi,c} \geq 0 \quad \text{and} \quad X_T^{x,y,\pi,c} \geq B. \qquad \square$$

Thanks to Lemma 2.2, the original investor's problem can be written as a convex optimization problem, referred to as *primal problem*, consisting of

$$\text{(P)} \qquad \text{maximizing} \quad E\left\{U_1\left(B\right) + \int_0^T U_2\left(c_t\right) dt\right\} \quad \text{over} \quad (B, c) \in \mathcal{B}\left(x, y\right),$$

where $\mathcal{B}(x,y)$ is the set of pairs (B,c) such that B is a nonnegative $\mathcal{F}_T$-measurable random variable and c is a consumption rate process satisfying the budget constraint (2.11).

The next theorem suggests the relationship between the trading portfolio π and the final wealth B. Its proof is based on arguments given in the proof of the previous lemma. This result is analogous to Theorem 5.8.9 in [KaSr98].

THEOREM 2.3. *Let c be a consumption rate process and $\check{\nu} \in \mathcal{M}$. Then, the following statements are equivalent:*
(i)

$$(B,c) \in \mathcal{B}(x,y) \quad \text{and} \quad E^{\check{\nu}}\left[\frac{B}{S_T^0} + \int_0^T \frac{c_t}{S_t^0} dt\right] = x,$$

(ii) $(\pi,c) \in \mathcal{A}(x,y)$, $X_T^{\pi,c} \equiv B$, *and* $X^{\pi,c}/S^0 + \int_0^{\cdot} \left(c_s/S_s^0\right) ds$ *is a* $P^{\check{\nu}}$*-martingale with representation*

$$\frac{X_t^{\pi,c}}{S_t^0} + \int_0^t \frac{c_s}{S_s^0} ds = x + \int_0^t \psi_s dW_{1s}^{\check{\nu}}, \quad t \in [0,T], \tag{2.20}$$

where ψ is a progressively measurable process with $\int_0^T \psi_u^2 du < \infty$.

Proof. (i) implies (ii): We shall verify that $X_t^{\pi,c} \equiv \check{X}_t$, where

$$\pi_t = \frac{S_t^0}{\sigma(Y_t)} \psi_t \tag{2.21}$$

is the trading portfolio and $\check{X}_t$ is defined in (2.12). From (2.13) and (i), we have

$$E^{\check{\nu}}\left[\frac{\check{X}_T}{S_T^0} + \int_0^T \frac{c_t}{S_t^0} dt\right] = E^{\check{\nu}}\left[\frac{B}{S_T^0} + \int_0^T \frac{c_t}{S_t^0} dt\right] = x = \sup_{\nu \in \mathcal{M}} E^{\nu}\left[\frac{B}{S_T^0} + \int_0^T \frac{c_t}{S_t^0} dt\right] = \check{X}_0.$$

Then $\check{X}_{\cdot}/S_{\cdot}^0 + \int_0^{\cdot} \left(c_s/S_s^0\right) ds$ is a $P^{\check{\nu}}$-martingale, since it is a $P^{\check{\nu}}$-supermartingale with constant mean. Thus, from (2.18), $A^0 \equiv 0$ and $X^{\pi,c} \equiv \check{X}$. The rest follows from the martingale representation theorem.

(ii) implies (i): From Remark 2.1, for each $\nu \in \mathcal{M}$ the discounted process $X_{\cdot}^{\pi,c}/S_{\cdot}^0 + \int_0^{\cdot} \left(c_s/S_s^0\right) ds$ is a P^{ν}-supermartingale; in particular, it is a $P^{\check{\nu}}$-martingale. Hence, $(B,c) \in \mathcal{B}(x,y)$ and $E^{\check{\nu}}\left[B/S_T^0 + \int_0^T \left(c_s/S_s^0\right) ds\right] = x$, where $B \equiv X_T^{\pi,c}$. ∎

Remark 2.4. The following identities will be used later; see [Cu97]. For any consumption process c, $\nu \in \mathcal{M}$ and $t \in [0,T]$,

$$E^{\nu}\left[\int_t^T \frac{c_u}{S_u^0} du \mid \mathcal{F}_t\right] = E\left[\int_t^T \frac{Z_u^{\nu}}{Z_t^{\nu}} \frac{c_u}{S_u^0} du \mid \mathcal{F}_t\right], \tag{2.22}$$

$$E^{\nu} \int_0^T \frac{c_u}{S_u^0} du = E \int_0^T \frac{Z_u^{\nu}}{S_u^0} c_u du. \tag{2.23}$$

3. Dual problem. In this section the dual problem is posed using techniques from convex optimization, and the relationship between the optimal values of the primal and dual problems is studied.

The Legendre–Frechel transform $\tilde{U}_i$ corresponding to the utility function U_i is defined as

$$\tilde{U}_i(z) \triangleq \max_{b\geq 0}\{U_i(b) - zb\}, \quad z > 0. \tag{3.1}$$

From the definition of $\tilde{U}_i(\cdot)$ and elementary calculus, it follows that, for $z > 0$,

$$\tilde{U}_i(z) =: U_i(I_i(z)) - zI_i(z), \tag{3.2}$$

where $I(\cdot)$ is the inverse function of $U_i'(\cdot)$. The associated *dual functional* to the primal problem (P) is defined, for $\nu \in \mathcal{M}$ and $\lambda \geq 0$, as follows:

$$\begin{aligned} L(\nu,\lambda) &\triangleq L(\nu,\lambda;x,y) \\ &\triangleq \sup_{B\geq 0, c\geq 0}\left\{E\left[U_1(B) + \int_0^T U_2(c_t)\,dt\right] - \lambda E^{\nu}\left[\frac{B}{S_T^0} + \int_0^T \frac{c_t}{S_t^0}dt\right]\right\} + \lambda x. \end{aligned}$$

Here the argument "$B \geq 0$, $c \geq 0$" means that B is a nonnegative $\mathcal{F}_T$-measurable random variable and c is a consumption rate process. We point out that the present definition is a variant of the classical dual functional given in (8.6.2) in [Lu69]. The *dual* problem consists of

$$\text{(D)} \qquad \text{minimizing} \quad L(\nu,\lambda), \quad \text{over} \quad \nu \in \mathcal{M} \ \text{ and } \ \lambda > 0.$$

It is not difficult to verify that the following inequality, relating the optimal values of the primal and dual problems, holds:

$$\sup_{(B,c)\in\mathcal{B}(x,y)} E\left\{U_1(B) + \int_0^T U_2(c_t)\,dt\right\} \leq \inf_{\nu\in\mathcal{M},\lambda>0} L(\nu,\lambda). \tag{3.3}$$

When equality holds in (3.3), we say that there is no duality *gap*. In the next section we will establish this property for HARA utility functions. On the other hand, note that using (2.23), (3.1), and (3.2) the dual functional can be written as

$$L(\nu,\lambda) = E\left[\tilde{U}_1\left(\lambda\frac{Z_T^{\nu}}{S_T^0}\right) + \int_0^T \tilde{U}_2\left(\lambda\frac{Z_t^{\nu}}{S_t^0}\right)dt\right] + \lambda x, \quad \nu \in \mathcal{M}, \quad \lambda > 0. \tag{3.4}$$

This representation of $L(\nu,\lambda)$ is inspired as a natural extension, from complete to incomplete markets, of the results presented in section 3.6 in [KaSr98].

The next proposition shows, under suitable conditions, the relationship between the optimal solutions of the primal (P) and dual (D) problems.

PROPOSITION 3.1. *Assume that for some* $(\hat{\nu},\hat{\lambda}) \in \mathcal{M}\times\mathbf{R}_+$ *the pair* $(\hat{B},\hat{c})$, *defined as*

$$\hat{B} \triangleq I_1\left(\hat{\lambda}\frac{Z_T^{\hat{\nu}}}{S_T^0}\right) \quad \textit{and} \quad \hat{c}_t \triangleq I_2\left(\hat{\lambda}\frac{Z_t^{\hat{\nu}}}{S_t^0}\right), \quad t \in [0,T], \tag{3.5}$$

belongs to $\mathcal{B}(x,y)$ *and*

$$E^{\hat{\nu}}\left[\frac{\hat{B}}{S_T^0}+\int_0^T\frac{\hat{c}_t}{S_t^0}dt\right]=x. \tag{3.6}$$

Then, $(\hat{B},\hat{c})$ *is the optimal solution to the primal problem* (P)*, whereas* $(\hat{\nu},\hat{\lambda})$ *is the optimal solution to the dual problem* (D)*. In particular, there is no duality gap.*

Proof. From (3.4) and (3.2), it follows that

$$\begin{aligned}
\inf_{\nu\in\mathcal{M},\lambda>0}L(\nu,\lambda)&=\inf_{\nu\in\mathcal{M},\lambda>0}E\left\{\tilde{U}_1\left(\lambda\frac{Z_T^\nu}{S_T^0}\right)+\int_0^T\tilde{U}_2\left(\lambda\frac{Z_t^\nu}{S_t^0}\right)dt+\lambda x\right\}\\
&\le E\left[\tilde{U}_1\left(\hat{\lambda}\frac{Z_T^{\hat{\nu}}}{S_T^0}\right)+\int_0^T\tilde{U}_2\left(\hat{\lambda}\frac{Z_t^{\hat{\nu}}}{S_t^0}\right)dt\right]+\hat{\lambda}x\\
&=E\left[U_1(\hat{B})+\int_0^T U_2(\hat{c}_t)\,dt\right]-\hat{\lambda}E\left[\frac{Z_T^{\hat{\nu}}}{S_T^0}\frac{\hat{B}}{S_T^0}+\int_0^T\frac{Z_t^{\hat{\nu}}}{S_t^0}\hat{c}_t dt\right]+\hat{\lambda}x\\
&=E\left[U_1(\hat{B})+\int_0^T U_2(\hat{c}_t)\,dt\right]-\hat{\lambda}E^{\hat{\nu}}\left[\frac{\hat{B}}{S_T^0}+\int_0^T\frac{\hat{c}_t}{S_t^0}dt\right]+\hat{\lambda}x\\
&=E\left[U_1(\hat{B})+\int_0^T U_2(\hat{c}_t)\,dt\right]\\
&\le\sup_{(B,c)\in\mathcal{B}(x,y)}E\left\{U_1(B)+\int_0^T U_2(c_t)\,dt\right\}.
\end{aligned}$$

Using (3.3), we conclude that there is no duality gap and, furthermore, $(\hat{B},\hat{c})$ is the optimal solution to the primal problem (P), whereas $(\hat{\nu},\hat{\lambda})$ is the optimal solution to the dual problem (D). □

Remark 3.2. The *optimal pair* $(\hat{B},\hat{c})$ given in (3.5) is similar to the one given in (6.3.16) and (6.3.17) in [KaSr98], with $\hat{\lambda}=\mathcal{Y}_{\hat{\nu}}(x)$ and $\mathcal{Y}_{\hat{\nu}}(\cdot)$ being the inverse function of $\mathcal{X}_{\hat{\nu}}(\cdot)$. An existence result and a characterization of the optimal solution to the dual problem (D) are also given in section 6.5 in [KaSr98]. However, except for deterministic coefficients (section 6.6) and logarithmic case (Example 6.7.2), the optimal process $\hat{\nu}$ is not obtained explicitly.

Remark 3.3. Based on the previous results, the following steps can be formulated to solve the investor's problem using the martingale method:

1. Given the utility function $U_1(\cdot)$ and $U_2(\cdot)$, write down the dual problem and obtain its optimal solution $(\hat{\nu},\hat{\lambda})\in\mathcal{M}\times\mathbf{R}_+$.
2. Verify that the pair $(\hat{B},\hat{c})$ given by (3.5) belongs to $\mathcal{B}(x,y)$ and satisfies (3.6), and then apply Proposition 3.1 and Theorem 2.3.
3. Finally, from (2.21) and (2.20), the optimal trading portfolio $\hat{\pi}$ is obtained.

These steps will be applied successfully for HARA and logarithmic utility functions in the next section.

4. Results for HARA utility function. In this section we solve explicitly the optimal consumption-investment problem for HARA utility functions $U_1(b)=U_2(b)=\frac{1}{\gamma}b^\gamma$ with parameter $\gamma\neq 0$ and $\gamma<1$.

The corresponding Legendre–Frechel transform $\tilde{U}_i:\mathbf{R}^+\to\mathbf{R}$ is given by $\tilde{U}(z)=U(I(z))-zI(z)=-z^\alpha/\alpha$, where $I(z)=z^{\alpha-1}$ and $\alpha\triangleq-\gamma/(1-\gamma)$. Notice that

$\alpha < 1$, $\alpha \neq 0$ and $\gamma = -\alpha/(1-\alpha)$. Hence, the dual functional (3.4) can be written as

$$L(\nu,\lambda) =: \lambda x - \frac{1}{\alpha}\lambda^{\alpha}\Lambda_{\nu}, \tag{4.1}$$

where $\Lambda_{\nu} \stackrel{\circ}{=} E\left(\left[Z_T^{\nu}/S_T^0\right]^{\alpha} + \int_0^T \left[Z_t^{\nu}/S_t^0\right]^{\alpha} dt\right)$. Fixing $\nu \in \mathcal{M}$, and using elementary calculus, the optimal value of the parameter λ can be derived and is given by

$$\hat{\lambda}(\nu) = (\Lambda_{\nu}/x)^{1/(1-\alpha)};$$

see definition of the dual problem (D). Substituting this value in (4.1), we obtain

$$L(\nu, \hat{\lambda}(\nu)) = \frac{1}{\gamma}x^{\gamma}\Lambda_{\nu}^{1-\gamma}, \qquad \nu \in \mathcal{M}.$$

Depending on the sign of the HARA parameter, $0 < \gamma < 1$ [$\gamma < 0$], the dual problem consisting of minimizing $L(\nu, \hat{\lambda}(\nu))$ over the set of processes ν in $\mathcal{M}$, is equivalent to

$$\text{minimize [maximize]} \quad J(T,y,\nu) \stackrel{\circ}{=} \Lambda_{\nu}, \quad \text{over} \quad \nu \in \mathcal{M}. \tag{4.2}$$

This is a stochastic control problem, referred to as the *auxiliary* problem, and will be solved using dynamic programming techniques as well as analytic arguments. Note that, in this case, the martingale method reduces the original investor's problem with two control variables to only one control process $\nu \in \mathcal{M}$.

On the other hand, observe that

$$\begin{aligned}[Z_t^{\nu}]^{\alpha} &= e^{-\alpha\int_0^t [\theta(Y_s)dW_{1s} + \nu_s dW_{2s}] - \frac{1}{2}\alpha^2\int_0^t \left[\theta^2(Y_s)+\nu_s^2\right]ds - \frac{1}{2}\alpha(1-\alpha)\int_0^t \left[\theta^2(Y_s)+\nu_s^2\right]ds} \\ &= Z_t^{\alpha,\nu} e^{-\frac{1}{2}\alpha(1-\alpha)\int_0^t \left[\theta^2(Y_s)+\nu_s^2\right]ds}, \quad t \in [0,T], \end{aligned} \tag{4.3}$$

with $Z^{\alpha,\nu}$ (see (2.4)) given by

$$Z_t^{\alpha,\nu} \stackrel{\circ}{=} \exp\left(-\alpha\int_0^t \left[\theta(Y_u)\,dW_{1u} + \nu_u dW_{2u}\right] - \frac{1}{2}\alpha^2\int_0^t \left[\theta^2(Y_u) + \nu_u^2\right]du\right).$$

Proceeding as in (2.5) and (2.6), we can define a new measure $P^{\alpha,\nu}$ in $\mathcal{F}_T$ and a BM $(W_1^{\alpha,\nu}, W_2^{\alpha,\nu})$, respectively. Under this measure, the dynamics of the external factor Y evolves as

$$dY_t = \left[g(Y_t) - \alpha\rho\theta(Y_t) - \alpha\varepsilon\nu_t\right]dt + \rho dW_{1t}^{\alpha,\nu} + \varepsilon dW_{2t}^{\alpha,\nu}, \quad \text{with} \quad Y_0 = y \in \mathbf{R}. \tag{4.4}$$

Now, from (4.3) and (2.23), we obtain the following representation for the functional $J(T,y,\nu)$:

$$\begin{aligned} J(T,y,\nu) &= E\left[\left(\frac{Z_T^{\nu}}{S_T^0}\right)^{\alpha} + \int_0^T \left(\frac{Z_t^{\nu}}{S_t^0}\right)^{\alpha} dt\right] \\ &= E^{\alpha,\nu}\left[e^{-\alpha\int_0^T \left[r(Y_t)+\frac{1}{2}(1-\alpha)\left(\theta^2(Y_t)+\nu_t^2\right)\right]dt}\right. \\ &\quad \left. + \int_0^T e^{-\alpha\int_0^t \left[r(Y_s)+\frac{1}{2}(1-\alpha)\left(\theta^2(Y_s)+\nu_s^2\right)\right]ds} dt\right] \\ &= E^{\alpha,\nu}\left[e^{\int_0^T q(Y_t,\nu_t)dt} + \int_0^T e^{\int_0^t q(Y_s,\nu_s)ds} dt\right], \quad (T,y,\nu) \in \mathbf{R}_+ \times \mathbf{R} \times \mathcal{M}, \end{aligned}$$

where $q(y,v) \triangleq -\alpha\left[r(y)+\frac{1}{2}(1-\alpha)\left(\theta^2(y)+v^2\right)\right]$, for $(y,v)\in\mathbf{R}^2$.

Case $\gamma<0$. The *value function* associated with the auxiliary problem (4.2) is defined as

$$W(T,y) \triangleq \sup_{\nu\in\mathcal{M}} J(T,y,\nu), \quad (T,y)\in\mathbf{R}_+\times\mathbf{R}, \tag{4.5}$$

with $W(0,y)=1$. Some basic properties of the value function will be established next, in order to solve this optimal control problem.

First, note that, denoting by $|\cdot|_\infty$ the supremum norm, the following estimates hold:

$$\begin{aligned} &E\left[e^{-\alpha\int_0^T\left(|r|_\infty+\frac{1}{2}(1-\alpha)\left(|\theta|_\infty^2+\nu_u^2\right)\right)du}+\int_0^T e^{-\alpha\int_0^t\left(|r|_\infty+\frac{1}{2}(1-\alpha)\left(|\theta|_\infty^2+\nu_u^2\right)\right)du}dt\right] \\ &\quad\le J(T,y,\nu)\le 1+T, \end{aligned} \tag{4.6}$$

and they imply that

$$0<K_1\le W(T,y)\le 1+T, \tag{4.7}$$

where

$$K_1 \triangleq (1+T)\,e^{-\alpha\left(|r|_\infty+\frac{1}{2}(1-\alpha)|\theta|_\infty^2\right)T}. \tag{4.8}$$

Note that the constant K_1 does not depend on the initial condition y.

Now, it will be verified that the function $W(T,\cdot)$ is Lipschitz. Using the fact that $q(y,v)$ is bounded above, the dominated convergence theorem can be applied to establish the y-differentiability of $J(T,y,\nu)$ (see Theorem 5.5.5 in [Fr75]). In fact,

$$\begin{aligned} J_y(T,y,\nu)=E^{\alpha,\nu}&\left[e^{\int_0^T q(Y_t,\nu_t)dt}\int_0^T q_y(Y_t,\nu_t)\frac{\partial}{\partial y}Y_t dt\right. \\ &\left.+\int_0^T e^{\int_0^t q(Y_s,\nu_s)ds}\int_0^t q_y(Y_s,\nu_s)\frac{\partial}{\partial y}Y_s ds dt\right], \end{aligned}$$

where $\frac{\partial}{\partial y}Y_s=\exp\left(\int_0^s\left[g'(Y_u)-\alpha\rho\theta'(Y_u)\right]du\right)$. Furthermore,

$$\left|\int_0^T q_y(Y_s,\nu_s)\frac{\partial}{\partial y}Y_s ds\right| \le K_2 \triangleq \alpha\left(|r'|_\infty+(1-\alpha)|\theta|_\infty|\theta'|_\infty\right)Te^{\left(|g'|_\infty+\alpha|\theta'|_\infty\right)T},$$

which implies that

$$|J_y(T,y,\nu)|\le K_2(1+T).$$

Observe that K_2 does not depend on ν and y, and hence $W(T,\cdot)$ is Lipschitz with constant $K_2(1+T)$. This estimate together with (4.7) yields that, when W_y is well defined,

$$\frac{|W_y(T,y)|}{W(T,y)}\le K \triangleq \frac{K_2}{K_1}(1+T). \tag{4.9}$$

The above estimate will be used later in this section.

It is convenient to restrict for a moment the set of control processes to those in $\mathcal{M}$ taking values in $[-M, M]$ for a fixed constant $M > 0$. This set will be denoted by $\mathcal{M}^M$, and the corresponding *constrained value function* by $W^M(T, y)$. This restriction will be removed later.

The verification theorem below states that

$$w(T, y) = W^M(T, y),$$

where $w(T, y)$ is the unique smooth function (see Theorem IV.4.3 and Remark IV.4.1 in [FlSo93]) in $C^{1,2}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right) \cap C_p\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right)$ satisfying the associated Hamilton–Jacobi–Bellman (HJB) equation:

$$\begin{aligned} w_T = 1 + \frac{1}{2} w_{yy} + (g - \alpha\rho\theta) w_y - \alpha \left[r + \frac{1}{2}(1-\alpha)\theta^2 \right] w \\ + \alpha \sup_{v \in [-M, M]} \left\{ -\varepsilon w_y v - \frac{1}{2}(1-\alpha) w v^2 \right\} \quad \text{with} \quad w(0, y) = 1. \end{aligned} \tag{4.10}$$

The supremum selector on the r.h.s. of the above equation induces a Markov *policy* defined, for $(t, y) \in [0, T] \times \mathbf{R}$, as follows:

$$\begin{aligned} \nu^*(t, y) &\triangleq \arg \max_{v \in [-M, M]} \left\{ -\varepsilon w_y(t, y) v - \frac{1}{2}(1-\alpha) w(t, y) v^2 \right\} \\ &= \begin{cases} -\dfrac{\varepsilon}{1-\alpha} \dfrac{w_y(t, y)}{w(t, y)}, & \text{if} \quad \dfrac{\varepsilon}{1-\alpha} \dfrac{|w_y(t, y)|}{w(t, y)} \le M \quad \text{and} \quad w(t, y) \neq 0 \\ -M \operatorname{sgn} w_y(t, y), & \text{otherwise.} \end{cases} \end{aligned} \tag{4.11}$$

THEOREM 4.1 (verification). *Given $T > 0$, let $w(T, y)$ be the unique solution to* (4.10). *Then,*

(i) $w(T, y) \ge J(T, y, \nu)$, *for* $(T, y) \in \bar{\mathbf{R}}_+ \times \mathbf{R}$ *and* $\nu \in \mathcal{M}^M$,

(ii) $w(T, y) = W^M(T, y) = J(T, y, \hat{\nu})$, *where* $\hat{\nu} \in \mathcal{M}^M$ *is the Markov policy given by*

$$\hat{\nu}_t \triangleq \nu^*(T - t, Y_t), \quad t \in [0, T]. \tag{4.12}$$

In particular, $\hat{\nu}$ is the optimal process for the constrained auxiliary problem associated with (4.5).

Proof. (i) Given $v \in [-M, M]$, define the functional $\mathcal{L}^v$ as

$$\mathcal{L}^v f \triangleq f_t + \frac{1}{2} f_{yy} + (g - \alpha\rho\theta - \alpha\varepsilon v) f_y, \quad \text{with} \quad f \in C^{1,2}([0, T] \times \mathbf{R}).$$

In particular, when $f(t, y) = w(T - t, y)$, we get

$$\begin{aligned} [\mathcal{L}^v + q(y, v)] w(T - t, y) = -w_t + \frac{1}{2} w_{yy} + (g - \alpha\rho\theta) w_y - \alpha \left[r + \frac{1}{2}(1-\alpha)\theta^2 \right] w \\ + \alpha \left[-\varepsilon w_y v - \frac{1}{2}(1-\alpha) w v^2 \right]. \end{aligned}$$

Hence, from (4.10), we have

$$[\mathcal{L}^{\nu_t} + q(Y_t, \nu_t)] w(T - t, Y_t) \le -1; \quad t \in [0, T] \quad \nu \in \mathcal{M}^M. \tag{4.13}$$

This inequality together with the Feynman-Kac formula imply, using a change of variable in the time parameter, that

$$
\begin{aligned}
w(T,y) &= E^{\alpha,\nu}\left[e^{\int_0^T q(Y_u,\nu_u)du} w\left(0,Y_T\right)\right. \\
&\qquad \left. - \int_0^T e^{\int_0^t q(Y_u,\nu_u)du}\left[\mathcal{L}^{\nu_t} + q(Y_t,\nu_t)\right] w(T-t,Y_t)dt\right] \\
&\geq E^{\alpha,\nu}\left[e^{\int_0^T q(Y_u,\nu_u)du} + \int_0^T e^{\int_0^t q(Y_u,\nu_u)du}dt\right] \qquad (4.14)\\
&= J\left(T,y,\nu\right).
\end{aligned}
$$

See, for instance, (D.13) in [FlSo93] and Corollary 4.4.5 in [KaSr91].

(ii) Since $w_y(t,y)$ is continuous, the Markov policy $\nu^*(t,y)$ defined in (4.11) is bounded, continuous, and y-locally Lipschitz. Hence, the Markov control process $\hat{\nu}$ defined in (4.12) belongs to $\mathcal{M}^M$ and, from the definition of $\nu^*(t,y)$, for $\nu \triangleq \hat{\nu}$ inequalities (4.13) and (4.14) become equalities. Therefore, $w(T,y) = W^M(T,y) = J(T,y,\hat{\nu})$. □

COROLLARY 4.2. *Let $w(T,y)$ be the unique solution to* (4.10), *with $M > \varepsilon K/(1-\alpha)$. Then,*

$$w(T,y) = W(T,y),$$

where $W(T,y)$ is the unconstrained value function defined in (4.5), *and*

$$\hat{\nu}_t \triangleq \nu^*(T-t,Y_t) = -\frac{\varepsilon}{1-\alpha}\frac{W_y(T-t,Y_t)}{W(T-t,Y_t)}, \quad t\in[0,T], \qquad (4.15)$$

is the optimal control process. Furthermore, $W(T,y) \in C^{1,2}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right) \cap C_b^{0,1}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right)$ and solves the following partial differential equation (PDE):

$$W_T = 1 + \frac{1}{2}W_{yy} + (g - \alpha\rho\theta)W_y - \alpha\left[r + \frac{1}{2}(1-\alpha)\theta^2\right]W - \frac{1}{2}\gamma\varepsilon^2\frac{W_y^2}{W}, \qquad (4.16)$$

with initial data $W(0,y) = 1$.

Proof. Using (4.9) it follows that, for $M > \varepsilon K/(1-\alpha)$, we have

$$\frac{\varepsilon}{1-\alpha}\frac{|W_y(T,y)|}{W(T,y)} < M,$$

and hence $w(T,y) = W^M(T,y) = W(T,y)$. Thus, using (4.12) and (4.11), the optimal process is given by (4.15). Finally, substituting the Markov policy (4.11) in the HJB equation (4.10), we obtain (4.16). □

Case $0 < \gamma < 1$. In this case the *value function* associated with the auxiliary problem (4.2) is defined as

$$W(T,y) \triangleq \inf_{\nu\in\mathcal{M}} J(T,y,\nu) = \inf_{\nu\in\mathcal{M}} E^{\alpha,\nu}\left\{e^{\int_0^T q(Y_t,\nu_t)dt} + \int_0^T e^{\int_0^t q(Y_s,\nu_s)ds}dt\right\}. \qquad (4.17)$$

As in the previous case, we expect similar conclusions if a suitable bound for the ratio $W_y(T,y)/W(T,y)$ can be obtained. However, in this case we cannot apply the dominated convergence theorem to find an estimate of $W_y(T,y)$ independent of M, because $q(y,v)$ is not bounded above. Instead, a more involved technique will be used, exploring qualitative properties of the corresponding HJB equation.

First, note that it is not difficult to prove that $W(T,y)$ is increasing with respect to T, and also that estimate (4.7) holds in the reverse sense, with K_1 given by (4.8), i.e.,

$$1+T \leq W(T,y) \leq K_1. \tag{4.18}$$

Now, let us restrict the control processes to the set $\mathcal{M}^M$, for some positive constant $M>0$. Hence, taking $[-M,M]$ as the control space, the following verification theorem holds. Its proof is based on the same arguments used in the case when γ is negative and will be omitted. In this case, it can also be guaranteed the existence and uniqueness of $w(T,y) \in C^{1,2}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right) \cap C_p\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right)$, satisfying the associated HJB equation (4.10), with $\alpha < 0$.

THEOREM 4.3 (verification). *Given $M>0$, let $w(T,y)$ be the unique solution to* (4.10). *Then,*

(i) $w(T,y) \leq J(T,y,\nu)$, *for* $(T,y) \in \mathbf{R}_+ \times \mathbf{R}$ *and* $\nu \in \mathcal{M}^M$,

(ii) $w(T,y) = W^M(T,y) = J(T,y,\hat{\nu})$, *where $\hat{\nu}$ is the Markov control process in $\mathcal{M}^M$ given by* (4.12), *with $\nu^*(t,y)$ as in* (4.11). *In particular, $\hat{\nu}$ is the optimal control process for the constrained auxiliary problem related with* (4.17).

The following is the main result of this paper.

THEOREM 4.4. *There exists a constant $\tilde{K}>0$ such that for $M > \varepsilon\tilde{K}/(1-\alpha)$,*

$$w(T,y) = W(T,y)$$

and $\hat{\nu}$, given by (4.15), *is an optimal control process, where $W(T,y)$ is the unconstrained value function* (4.17). *Furthermore, $W \in C^{1,2}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right) \cap C_b^{0,1}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right)$ and solves the PDE* (4.16), *with initial data $W(0,y)=1$.*

Proof. To estimate $W_y(T,y)$ we shall obtain first an upper bound for $W_T^M(T,y)$ and then extract qualitative properties of $W^M(T,y)$ from the HJB equation (4.10), where $w(T,y) = W^M(T,y)$. To get such an upper bound for $W_T^M(T,y)$, we extend, and denote by the same symbol, the optimal process $\hat{\nu}$ from the constrained problem in $[0,T]$ to the interval $[0,T+\Delta]$, in such a way that it vanishes in $(T,T+\Delta]$; see (4.12) and (4.11). This extended process belongs to $\mathcal{M}(T+\Delta)$, since $\theta(\cdot)$ is bounded.

Therefore,

$$\begin{aligned}
W^M(T+\Delta,y)-W^M(T,y) &\le J(T+\Delta,y,\hat{\nu})-J(T,y,\hat{\nu})\\
&= E^{\alpha,\hat{\nu}}_{T+\Delta}\left[e^{\int_0^{T+\Delta}q(Y_t,\hat{\nu}_t)dt}+\int_0^{T+\Delta}e^{\int_0^t q(Y_s,\hat{\nu}_s)ds}dt\right]\\
&\quad -E^{\alpha,\hat{\nu}}_{T}\left[e^{\int_0^{T}q(Y_t,\hat{\nu}_t)dt}+\int_0^{T}e^{\int_0^t q(Y_s,\hat{\nu}_s)ds}dt\right]\\
&= E^{\alpha,\hat{\nu}}_{T+\Delta}\left[e^{\int_0^{T}q(Y_t,\hat{\nu}_t)dt}\left(e^{\int_T^{T+\Delta}q(Y_t,0)dt}-1\right)\right.\\
&\quad \left.+e^{\int_0^{T}q(Y_t,\hat{\nu}_t)dt}\int_T^{T+\Delta}e^{\int_T^t q(Y_s,0)ds}dt\right]\\
&\le E^{\alpha,\hat{\nu}}_{T+\Delta}e^{\int_0^{T}q(Y_t,\hat{\nu}_t)dt}\left[e^{-\alpha\left(|r|_\infty+\frac{1}{2}(1-\alpha)|\theta|^2_\infty\right)\Delta}-1\right.\\
&\quad \left.+\int_T^{T+\Delta}e^{-\alpha\int_T^t\left(|r|_\infty+\frac{1}{2}(1-\alpha)|\theta|^2_\infty\right)ds}dt\right]\\
&= \left[e^{K_3\Delta}-1+\int_0^{\Delta}e^{K_3 t}dt\right]E^{\alpha,\hat{\nu}}_{T+\Delta}e^{\int_0^{T}q(Y_t,\hat{\nu}_t)dt}.
\end{aligned}$$

The last inequality is due to the fact that $q(y,0)\le K_3 \stackrel{\circ}{=} -\alpha\left[|r|_\infty+\frac{1}{2}(1-\alpha)|\theta|^2_\infty\right]$. Observe that K_3 does not depend on M and y. Then, from the dominated convergence theorem, we have

$$0\le W^M_T(T,y)\le (1+K_3)\,W^M(T,y). \tag{4.19}$$

The next step in the proof shall be to get upper and lower bounds for $W^M_y(T,y)$. This will be done only when y is positive; the same arguments can be adapted when y is negative. Define

$$\Phi(p)\stackrel{\circ}{=}\sup_{v\in[-M,M]}\left\{-\varepsilon pv-\frac{1}{2}(1-\alpha)v^2\right\},\quad p\in\mathbf{R}. \tag{4.20}$$

Then, the HJB equation (4.10) can be written as

$$W^M_T=1+\frac{1}{2}W^M_{yy}+(g-\alpha\rho\theta)W^M_y-\alpha\left[r+\frac{1}{2}(1-\alpha)\theta^2\right]W^M+\alpha W^M\Phi\left(\frac{W^M_y}{W^M}\right). \tag{4.21}$$

On the other hand, the mean value theorem and (4.18) enables us to find a sequence $\{y_n\}$, with $y_n\in[n,2n]$, such that

$$\left|W^M_y(T,y_n)\right|=\frac{1}{n}\left|W^M(T,2n)-W^M(T,n)\right|\le\frac{2}{n}K_1.$$

This inequality allows us to reduce the analysis of W^M_y to only the critical points of $W^M_y(T,\cdot)$, *i.e.,* the points $\tilde{y}>0$ where $W^M_{yy}(T,\tilde{y})=0$. We study three different cases, based on the coefficient of W^M_y in the PDE (4.21):

(a) $g(\tilde{y}) - \alpha\rho\theta(\tilde{y}) \leq -1$ and $W_y^M(T,\tilde{y}) > 0$ or $g(\tilde{y}) - \alpha\rho\theta(\tilde{y}) \geq 1$ and $W_y^M(T,\tilde{y}) < 0$,

(b) $g(\tilde{y}) - \alpha\rho\theta(\tilde{y}) \geq -1$ and $W_y^M(T,\tilde{y}) > 0$, and

(c) $g(\tilde{y}) - \alpha\rho\theta(\tilde{y}) \leq 1$ and $W_y^M(T,\tilde{y}) < 0$.

Case (a): Condition (a) is equivalent to $|g(\tilde{y}) - \alpha\rho\theta(\tilde{y})| \geq 1$ and $[g(\tilde{y}) - \alpha\rho\theta(\tilde{y})] W_y^M(T,\tilde{y}) < 0$. Thus, from (4.21), (4.19), and (4.18), we get

$$\begin{aligned} 0 &< -[g(\tilde{y}) - \alpha\rho\theta(\tilde{y})] W_y^M \\ &= -W_T^M + 1 - \alpha\left[r(\tilde{y}) + \frac{1}{2}(1-\alpha)\theta^2(\tilde{y})\right] W^M + \alpha W^M \Phi\left(\frac{W_y^M}{W^M}\right) \\ &\leq 1 - \alpha\left[r(\tilde{y}) + \frac{1}{2}(1-\alpha)\theta^2(\tilde{y})\right] W^M \\ &\leq 1 + K_1 K_3. \end{aligned}$$

That is, $\left|(g(\tilde{y}) - \alpha\rho\theta(\tilde{y})) W_y^M(T,\tilde{y})\right| \leq \tilde{K}_1 \doteq 1 + K_1 K_3$, where $\tilde{K}_1$ does not depend on $\tilde{y}$ and M. Hence

$$\left|W_y^M(T,\tilde{y})\right| \leq \tilde{K}_1. \tag{4.22}$$

To study cases (b) and (c) we use the logarithmic transformation $V(T,y) \doteq \log W^M(T,y)$. Noting that $W_T^M = W^M V_T$, $W_y^M = W^M V_y$, and $W_{yy}^M = W^M\left(V_y^2 + V_{yy}\right)$, the PDE (4.21) can be written in terms of V as

$$\frac{1}{2}V_y^2 + [g - \alpha\rho\theta] V_y + \frac{1}{2}V_{yy} = V_T - \frac{1}{W^M} + \alpha\left[r + \frac{1}{2}(1-\alpha)\theta^2\right] - \alpha\Phi(V_y). \tag{4.23}$$

Note that from (4.19) and (4.20),

$$V_T \leq 1 + K_3 \quad \text{and} \quad 0 \leq -\alpha\Phi(V_y) \leq \frac{1}{2}\gamma\varepsilon^2 V_y^2.$$

These estimates, together with (4.23), imply that

$$\frac{1}{2}\left(1 - \gamma\varepsilon^2\right) V_y^2 + [g - \alpha\rho\theta] V_y + \frac{1}{2}V_{yy} \leq (K_3 + 1) + \alpha\left[r + \frac{1}{2}(1-\alpha)\theta^2\right] \leq 1 + 2K_3.$$

Then, $V_y^2 + 2\tilde{g}V_y + \frac{1}{1-\gamma\varepsilon^2}V_{yy} \leq \tilde{\alpha}$, with $\tilde{\alpha} \doteq 2(1 + 2K_3)/\left(1 - \gamma\varepsilon^2\right) > 0$ and

$$\tilde{g}(y) \doteq (g(y) - \alpha\rho\theta(y))/\left(1 - \gamma\varepsilon^2\right).$$

If $\tilde{y} > 0$ is a critical point of $V_y(T,\cdot)$, it follows that

$$V_y^2(T,\tilde{y}) + 2\tilde{g}(\tilde{y}) V_y(T,\tilde{y}) \leq \tilde{\alpha},$$

which is equivalent to $[V_y(T,\tilde{y}) + \tilde{g}(\tilde{y})]^2 \leq \tilde{\alpha} + \tilde{g}^2(\tilde{y})$. Thus,

$$-\tilde{g}(\tilde{y}) - \sqrt{\tilde{\alpha} + \tilde{g}^2(\tilde{y})} \leq V_y(T,\tilde{y}) \leq -\tilde{g}(\tilde{y}) + \sqrt{\tilde{\alpha} + \tilde{g}^2(\tilde{y})}. \tag{4.24}$$

Case (b): When $\tilde{g}(\tilde{y}) \geq -1$ and $V_y(T,\tilde{y}) > 0$. Since the function $\tilde{h}(u) \doteq -u + \sqrt{\tilde{\alpha} + u^2}$ is bounded when $u \geq -1$, then the r.h.s. of (4.24) is bounded. Hence,

$$0 < V_y(T,\tilde{y}) \leq \tilde{K}_2 \doteq 1 + \sqrt{1 + \tilde{\alpha}}. \tag{4.25}$$

Note that the constant $\tilde{K}_2$ does not depend on $\tilde{y}$ and M.

Case (c): When $\tilde{g}(\tilde{y}) \leq 1$ and $V_y(T,\tilde{y}) < 0$. Similarly, since the function $\tilde{h}(u) \doteq -u - \sqrt{\tilde{\alpha} + u^2}$ is bounded when $u \leq 1$, then the l.h.s. of (4.24) is bounded, and hence

$$-\tilde{K}_2 \leq V_y(T,\tilde{y}) < 0. \tag{4.26}$$

Putting together (4.22), (4.25), and (4.26), we get

$$|V_y(T,\tilde{y})| \leq \tilde{K} \doteq \tilde{K}_1 \vee \tilde{K}_2, \tag{4.27}$$

for any positive critical point $\tilde{y}$ of $V_y(T,\cdot)$. Now, if $M > [\varepsilon/(1-\alpha)]\tilde{K}$, using (4.27) we conclude that

$$\frac{\varepsilon}{1-\alpha}\frac{\left|W_y^M\right|}{W^M} < M \quad \text{and} \quad w(T,y) = W^M(T,y) = W(T,y).$$

This implies, using (4.12) and (4.11), that the control process $\hat{\nu}$ defined in (4.15) is optimal. Finally, substituting the Markov policy (4.11) in the HJB equation (4.10) yields (4.16). □

Solution to the investor's problem. Now we shall obtain explicitly an optimal trading strategy for the investor's problem when the utility function is HARA. The main argument is based on a Dynkin's result, which turns out to be the key idea to go back from the dual optimization problem solved above to the investor's one; see Proposition 5.4.2 in [KaSr98].

The optimal process $\hat{\nu}$ for the associated dual problem is given by (4.15), with $W(T,y)$ being the smooth solution of the HJB equation (4.16). According to the steps described at the end of the last section, we consider as candidates for being the optimal final wealth and consumption process to

$$\hat{B} \doteq I\left(\hat{\lambda}\frac{Z_T^{\hat{\nu}}}{S_T^0}\right) = \frac{x}{\Lambda_{\hat{\nu}}}\left(\frac{Z_T^{\hat{\nu}}}{S_T^0}\right)^{\alpha-1} \quad \text{and} \quad \hat{c}_t \doteq I\left(\hat{\lambda}\frac{Z_t^{\hat{\nu}}}{S_t^0}\right) = \frac{x}{\Lambda_{\hat{\nu}}}\left(\frac{Z_t^{\hat{\nu}}}{S_t^0}\right)^{\alpha-1}, \quad t \in [0,T],$$

where

$$\hat{\lambda} = \left(\frac{\Lambda_{\hat{\nu}}}{x}\right)^{\frac{1}{1-\alpha}} \quad \text{and} \quad \Lambda_{\hat{\nu}} = E\left[\left(\frac{Z_T^{\hat{\nu}}}{S_T^0}\right)^{\alpha} + \int_0^T \left(\frac{Z_t^{\hat{\nu}}}{S_t^0}\right)^{\alpha} dt\right] = W(T,y).$$

To derive the expression of the optimal trading portfolio $\hat{\pi}$, we will prove first that the process defined as

$$M_t \doteq \left(\frac{Z_t^{\hat{\nu}}}{S_t^0}\right)^{\alpha} W(T-t, Y_t) + \int_0^t \left(\frac{Z_u^{\hat{\nu}}}{S_u^0}\right)^{\alpha} du, \quad t \in [0,T],$$

is a martingale, and then find its stochastic integral representation. Note first that the initial and terminal expectation of this process coincides, i.e., $EM_T = M_0$, since $M_0 = W(T,y) = \Lambda_{\hat{\nu}}$ and $M_T = \left(Z_T^{\hat{\nu}}/S_T^0\right)^{\alpha} + \int_0^T \left(Z_t^{\hat{\nu}}/S_t^0\right)^{\alpha} dt$. Under the original measure P, we write down the system of SDE in $[0,T]$,

$$\begin{aligned} dY_t &= g(Y_t)\,dt + \rho dW_{1t} + \varepsilon dW_{2t}, & Y_0 &= y, \\ d\left[\frac{Z_t^{\hat{\nu}}}{S_t^0}\right] &= -\frac{Z_t^{\hat{\nu}}}{S_t^0}\left[r(Y_t)\,dt + \theta(Y_t)\,dW_{1t} + \hat{\nu}_t dW_{2t}\right], & \frac{Z_0^{\hat{\nu}}}{S_0^0} &= z = 1. \end{aligned}$$

This system has associated a differential operator, defined as

$$\mathcal{L}f \triangleq f_t + gf_y - rzf_z - z\left(\rho\theta + \varepsilon\nu^*\right) f_{yz} + \frac{1}{2}f_{yy} + \frac{1}{2}z^2\left(\theta^2 + \nu^{*2}\right) f_{zz},$$

for $f \in C^{1,2,2}\left([0,T] \times \mathbf{R} \times \mathbf{R}_+\right)$. In particular, when $f\left(t,y,z\right) \triangleq W\left(T-t,y\right) z^\alpha$, and using (4.15) and (4.16), it is not difficult to verify that

$$\mathcal{L}f\left(t,y,z\right) = -z^\alpha.$$

Therefore,

$$M_t = f\left(t, Y_t, \frac{Z_t^{\hat{\nu}}}{S_t^0}\right) - \int_0^t \mathcal{L}f\left(s, Y_s, \frac{Z_s^{\hat{\nu}}}{S_s^0}\right) ds.$$

Thus, from Proposition 5.4.2 in [KaSr91], M is a nonnegative local martingale. Furthermore, it is also a martingale since it is a supermartingale with constant mean.

Now define the nonnegative process

$$\frac{\hat{X}_t}{S_t^0} \triangleq E^{\hat{\nu}}\left[\frac{\hat{B}}{S_T^0} + \int_t^T \frac{\hat{c}_u}{S_u^0} du \mid \mathcal{F}_t\right], \quad t \in [0,T].$$

From (2.4), we obtain

$$\begin{aligned}
\frac{\hat{X}_t}{S_t^0} &= E^{\hat{\nu}}\left[\frac{\hat{B}}{S_T^0} + \int_t^T \frac{\hat{c}_u}{S_u^0} du \mid \mathcal{F}_t\right] \\
&= \frac{x}{W\left(T,y\right) Z_t^{\hat{\nu}}} E\left[\left(\frac{Z_T^{\hat{\nu}}}{S_T^0}\right)^\alpha + \int_t^T \left(\frac{Z_u^{\hat{\nu}}}{S_u^0}\right)^\alpha du \mid \mathcal{F}_t\right] \\
&= \frac{x}{W\left(T,y\right) Z_t^{\hat{\nu}}} E\left[M_T - \int_0^t \left(\frac{Z_u^{\hat{\nu}}}{S_u^0}\right)^\alpha du \mid \mathcal{F}_t\right] \\
&= x\frac{\left[Z_t^{\hat{\nu}}\right]^{\alpha-1}}{\left[S_t^0\right]^\alpha} \frac{W\left(T-t,Y_t\right)}{W\left(T,y\right)}.
\end{aligned}$$

However, by Ito's formula

$$\begin{aligned}
d\left[Z^{\hat{\nu}}\right]^{\alpha-1} &= \left(1-\alpha\right)\left[Z^{\hat{\nu}}\right]^{\alpha-1}\left[\left(1-\frac{\alpha}{2}\right)\left(\theta^2+\hat{\nu}^2\right)dt + \theta dW_1 + \hat{\nu}dW_2\right], \\
dW &= \left(-W_t + \frac{1}{2}W_{yy} + gW_y\right)dt + W_y\left(\rho dW_1 + \varepsilon dW_2\right), \\
d\left[S^0\right]^{-\alpha} &= -\alpha r\left[S^0\right]^{-\alpha} dt.
\end{aligned}$$

Here W represents the process $W\left(T-t,Y_t\right)$, for $t \in [0,T]$. Then, using (4.15) and

(4.16), we get

$$
\begin{aligned}
&d\left(\frac{\left[Z^{\hat{\nu}}\right]^{\alpha-1}}{\left[S^0\right]^{\alpha}}\,W\right)\\
&\quad=\frac{\left[Z^{\hat{\nu}}\right]^{\alpha-1}}{\left[S^0\right]^{\alpha}}\left(-\alpha r W dt+(1-\alpha)\,W\left[\left(1-\frac{\alpha}{2}\right)\left(\theta^2+\hat{\nu}^2\right)dt+\theta dW_1+\hat{\nu}dW_2\right]\right.\\
&\qquad\left.+\left[-W_t+\frac{1}{2}W_{yy}+gW_y\right]dt\right.\\
&\qquad\left.+W_y\left(\rho dW_1+\varepsilon dW_2\right)+(1-\alpha)\left(\rho\theta+\varepsilon\hat{\nu}\right)W_y dt\right)\\
&\quad=\frac{\left[Z^{\hat{\nu}}\right]^{\alpha-1}}{\left[S^0\right]^{\alpha}}\left(-dt+W\left[(1-\alpha)\,\theta+\rho\frac{W_y}{W}\right]\left[\theta dt+dW_1\right]\right)\\
&\quad=\frac{\left[Z^{\hat{\nu}}\right]^{\alpha-1}}{\left[S^0\right]^{\alpha}}\left(-dt+W\left[(1-\alpha)\,\theta+\rho\frac{W_y}{W}\right]dW_1^{\hat{\nu}}\right).
\end{aligned}
$$

Thus,

$$
\begin{aligned}
d\frac{\hat{X}}{S^0}+\frac{\hat{c}}{S^0}dt&=\frac{x}{W(T,y)}d\left(\frac{\left[Z^{\hat{\nu}}\right]^{\alpha-1}}{\left[S^0\right]^{\alpha}}W\right)+\frac{x}{W(T,y)}\left(\frac{Z^{\hat{\nu}}}{S^0}\right)^{\alpha-1}\frac{1}{S^0}dt\\
&=\frac{x}{W(T,y)}\frac{\left[Z^{\hat{\nu}}\right]^{\alpha-1}}{\left[S^0\right]^{\alpha}}W\left[(1-\alpha)\,\theta+\rho\frac{W_y}{W}\right]dW_1^{\hat{\nu}}\\
&=:\frac{\hat{\pi}}{S^0}\sigma dW_1^{\hat{\nu}},
\end{aligned}
$$

where

$$
\hat{\pi}_t\doteq\frac{\hat{X}_t}{\sigma(Y_t)}\left[(1-\alpha)\,\theta(Y_t)+\rho\frac{W_y(T-t,Y_t)}{W(T-t,Y_t)}\right]=:\pi^*(T-t,\hat{X}_t,Y_t),
$$

with

$$
\pi^*(t,x,y)\doteq\frac{x}{\sigma(y)}\left[(1-\alpha)\,\theta(y)+\rho\frac{W_y(t,y)}{W(t,y)}\right],\quad(t,x,y)\in[0,T]\times\mathbf{R}_+\times\mathbf{R}.
$$

Moreover, the optimal consumption process $\hat{c}$ can be written in a feedback form as

$$
\begin{aligned}
\hat{c}_t&=\frac{x}{\Lambda_{\hat{\nu}}}\left(\frac{Z_t^{\hat{\nu}}}{S_t^0}\right)^{\alpha-1}=x\left(\frac{Z_t^{\hat{\nu}}}{S_t^0}\right)^{\alpha-1}\frac{W(T-t,Y_t)}{W(T,y)}\frac{1}{W(T-t,Y_t)}\\
&=:c^*\left(T-t,\hat{X}_t,Y_t\right),
\end{aligned}
$$

with

$$
c^*(t,x,y)\doteq\frac{x}{W(t,y)},\quad(t,x,y)\in[0,T]\times\mathbf{R}_+\times\mathbf{R}.
$$

From the formula of $\hat{X}$ together with (2.10), we conclude that $(\hat{\pi},\hat{c})\in\mathcal{A}(x,y)$ and $X^{\hat{\pi},\hat{c}}\equiv\hat{X}$. Moreover, $X_T^{\hat{\pi},\hat{c}}\equiv\hat{B}$ is the optimal terminal wealth.

The optimal investment and consumption policies obtained above depend on the solution of the PDE (4.16). Performing a power transformation, it is possible to

get a functional representation, which might be useful to approximate its solution through a fixed point algorithm. Suppose that $W(T,y) =: [h(T,y)]^{\delta}$, for some $\delta > 0$. Then, $W_T = \delta h^{\delta-1} h_T$, $W_y = \delta h^{\delta-1} h_y$, $W_y^2/W = \delta^2 h^{\delta-2} h_y^2$, and $W_{yy} = \delta h^{\delta-1} h_{yy} + \delta(\delta-1) h^{\delta-2} h_y^2$. Using (4.16), it follows that $h(T,y)$ solves the PDE

$$h_T = \frac{1}{\delta} h^{1-\delta} + \frac{1}{2} h_{yy} + (g - \alpha\rho\theta) h_y - \frac{\alpha}{\delta}\left[r + \frac{1}{2}(1-\alpha)\theta^2\right] h + \frac{1}{2}\left(\delta - 1 - \gamma\delta\varepsilon^2\right)\frac{h_y^2}{h},$$

with initial condition $h(0,y) = 1$. However, observe that when $\delta \stackrel{\circ}{=} 1/\left(1-\gamma\varepsilon^2\right)$ the last nonlinear term in the previous PDE vanishes. Hence, for this value of δ, the PDE (4.16) is equivalent to

(4.28)
$$h_T = \frac{1}{\delta} h^{1-\delta} + \frac{1}{2} h_{yy} + (g - \alpha\rho\theta) h_y - \frac{\alpha}{\delta}\left[r + \frac{1}{2}(1-\alpha)\theta^2\right] h, \quad \text{with} \quad h(0,y) = 1.$$

The previous power transformation was introduced by Zariphopoulou in [Za01] for an optimal investment problem.

On the other hand, since the function $h(T,y)$ belongs to the set of functions $C^{1,2}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right) \cap C_b^{0,1}\left(\bar{\mathbf{R}}_+ \times \mathbf{R}\right)$, the Feynman–Kac formula can be used to get the following representation:

$$h(T,y) = E\left(e^{-\frac{\alpha}{\delta}\int_0^T \left[r(\check{Y}_u) + \frac{1}{2}(1-\alpha)\theta^2(\check{Y}_u)\right] du}\right.$$
$$\left. + \quad \frac{1}{\delta}\int_0^T h^{1-\delta}\left(T-u, \check{Y}_u\right) e^{-\frac{\alpha}{\delta}\int_0^u \left[r(\check{Y}_s) + \frac{1}{2}(1-\alpha)\theta^2(\check{Y}_s)\right] ds} du\right), \tag{4.29}$$

for $(T,y) \in \bar{\mathbf{R}}_+ \times \mathbf{R}$. Here $\{\check{Y}_t\}_{t\in[0,T]}$ is the solution of the SDE

$$d\check{Y}_t = \left[g(\check{Y}_t) - \alpha\rho\theta(\check{Y}_t)\right] dt + d\check{W}_t, \tag{4.30}$$

with initial condition $\check{Y}_0 = y$ and $\check{W}_t$ being a Brownian motion; see Theorem 5.7.6 and Corollary 4.4.5 in [KaSr91].

Remark 4.5 (logarithmic utility). Analogous results can be derived when $U_1(b) = U_1(b) = \log b$. In this case, the dual optimization problem is equivalent to

$$\text{minimize} \quad E\left\{\int_0^T \nu_t^2 dt + \int_0^T \int_0^t \nu_s^2 ds dt\right\} \quad \text{over} \quad \nu \in \mathcal{M}.$$

The optimal solution can be easily obtained and is given by $(\hat{\nu}, \hat{\lambda}) \equiv (0, (1+T)/x)$. Further, the optimal trading strategy $(\hat{\pi}, \hat{c})$ is given by $\hat{\pi}_t = \pi^*(t, X_t^{\hat{\pi},\hat{c}}, Y_t)$ and $\hat{c}_t = c^*(t, X_t^{\hat{\pi},\hat{c}}, Y_t)$, where

$$\pi^*(t,x,y) \stackrel{\circ}{=} x\frac{\mu(y) - r(y)}{\sigma^2(y)} \quad \text{and} \quad c^*(t,x,y) \stackrel{\circ}{=} \frac{x}{1+T-t},$$

$$\text{for} \qquad (t,x,y) \in [0,T] \times \mathbf{R}_+ \times \mathbf{R}.$$

Remark 4.6 (investment or consumption). Modifying slightly the above arguments it is also possible to get explicit optimal solutions for optimal investment or consumption problems. The optimal investment problem is defined as the investor's problem (2.3) with $U_2(\cdot) = 0$, whereas when $U_1(\cdot) = 0$ it corresponds to the optimal consumption problem. These results are summarized below.

1. *Investment problem with logarithmic utility function.* The dual functional is

$$L(\nu, \lambda) = E \int_0^T r(Y_u)\, du - 1 + \lambda x - \log \lambda - E \log Z_T^{\nu},$$

whereas the optimal values for both the dual and primal problems are, respectively, $\hat{\lambda} = 1/x$, $\hat{\nu} = 0$,

$$X_t^{\hat{\pi}} = x \frac{S_t^0}{Z_t^0}, \quad \text{and} \quad \hat{\pi}_t = \frac{\mu(Y_t) - r(Y_t)}{\sigma^2(Y_t)} X_t^{\hat{\pi}}, \quad t \in [0, T].$$

2. *Investment problem with HARA utility function.* The dual functional is

$$L(\nu, \lambda) = \lambda x - \frac{1}{\alpha} \lambda^{\alpha} \Lambda_{\nu},$$

where $\Lambda_{\nu} \triangleq E\left(Z_T^{\nu}/S_T^0\right)^{\alpha}$; the optimal control process $\hat{\nu}$ is given by (4.15). Here the corresponding value function $W(T, y)$ is the solution of the PDE

$$W_T = \frac{1}{2} W_{yy} + (g - \alpha\rho\theta) W_y - \alpha \left[r + \frac{1}{2}(1 - \alpha)\theta^2 \right] W - \frac{1}{2} \gamma \varepsilon^2 \frac{W_y^2}{W},$$

with $W(0, y) = 1$. The optimal wealth and trading portfolio processes are

$$X_t^{\hat{\pi}} = x \left(\frac{S_t^0}{Z_t^0} \right)^{\alpha} \frac{W(T - t, Y_t)}{W(T, y)}, \quad \hat{\pi}_t = \pi^* \left(T - t, X_t^{\hat{\pi}}, Y_t \right), \quad t \in [0, T],$$

where $\pi^*(t, x, y) = (x/\sigma(y)) [(1 - \alpha)\theta(y) + \rho W_y(t, y)/W(t, y)]$; for details see [CaHe03].

3. *Consumption problem with logarithmic utility function.* The dual functional is

$$L(\nu, \lambda) = E \int_0^T \int_0^t r(Y_u)\, du dt + \lambda x - T(1 + \log \lambda) - E \int_0^T \log Z_t^{\nu} dt,$$

and the optimal values are $\hat{\lambda} = T/x$, $\hat{\nu} = 0$. Furthermore,

$$X_t^{\hat{\pi}, \hat{c}} = x \frac{T - t}{T} \frac{S_t^0}{Z_t^0}, \quad \hat{\pi}_t = \frac{\mu(Y_t) - r(Y_t)}{\sigma^2(Y_t)} X_t^{\hat{\pi}, \hat{c}}, \quad \text{and} \quad \hat{c}_t = \frac{1}{T - t} X_t^{\hat{\pi}, \hat{c}}, \quad t \in [0, T].$$

4. *Consumption problem with HARA utility function.* The dual functional is

$$L(\nu, \lambda) = \lambda x - \frac{1}{\alpha} \lambda^{\alpha} \Lambda_{\nu}, \quad \text{where} \quad \Lambda_{\nu} \triangleq E \int_0^T \left(\frac{Z_t^{\hat{\nu}}}{S_t^0} \right)^{\alpha} dt.$$

The optimal solution to the dual problem is the process $\hat{\nu}$ given by (4.15), where the corresponding value function $W(T,y)$ solves the PDE

$$W_T = 1 + \frac{1}{2}W_{yy} + (g - \alpha\rho\theta)\,W_y - \alpha\left[r + \frac{1}{2}(1-\alpha)\,\theta^2\right]W - \frac{1}{2}\gamma\varepsilon^2\frac{W_y^2}{W},$$

with $W(0,y) = 0$. The optimal processes are

$$X_t^{\hat{\pi},\hat{c}} = x\left(\frac{S_t^0}{Z_t^0}\right)^{\alpha}\frac{W(T-t,Y_t)}{W(T,y)}, \quad \hat{\pi}_t = \pi^*(T-t, X_t^{\hat{\pi},\hat{c}}, Y_t),$$

$$\text{and} \quad \hat{c}_t = c^*(T-t, X_t^{\hat{\pi},\hat{c}}, Y_t),$$

where $\pi^*(t,x,y) \triangleq (x/\sigma(y))\left[(1-\alpha)\,\theta(y) + \rho W_y(t,y)/W(t,y)\right]$ and $c^*(t,x,y) \triangleq x/W(t,y)$.

GENERALIZED SAMPLED-DATA STABILIZATION OF WELL-POSED LINEAR INFINITE-DIMENSIONAL SYSTEMS*

HARTMUT LOGEMANN†, RICHARD REBARBER‡, AND STUART TOWNLEY§

Abstract. We consider well-posed linear infinite-dimensional systems, the outputs of which are sampled in a generalized sense using a suitable weighting function. Under certain natural assumptions on the system, the weighting function, and the sampling period, we show that there exists a generalized hold function such that unity sampled-data feedback renders the closed-loop system exponentially stable (in the state-space sense) as well as L^2-stable (in the input-output sense). To illustrate our main result, we describe an application to a structurally damped Euler–Bernoulli beam.

Key words. generalized hold, generalized sampling, infinite-dimensional systems, sampled-data control, stabilization

1. Introduction.

The design of sampled-data controllers is important both for applications, because of digital implementation issues, and for theoretical development. Sampled-data control for infinite-dimensional systems has been considered in a number of papers; see [12, 13, 14, 15, 18, 19, 30]. In this paper we develop generalized sampled-data control for well-posed linear continuous-time infinite-dimensional systems. Generalized sampled-data control has been frequently studied for finite-dimensional systems (see, for instance, [2, 10]) and for infinite-dimensional systems in Tarn et al. [28] and Tarn, Zavgren, and Zeng [29]. A well-posed system Σ has generating operators (A, B, C), where A is the generator of a strongly continuous semigroup $\mathbf{T} = (\mathbf{T}_t)_{t\geq 0}$ governing the state evolution of the uncontrolled system, B is the control operator, and C is the observation operator; see, for example, [5, 23, 25, 27, 31]. Denote by u and y the input and output of Σ. For a given sampling period $\tau > 0$, a generalized sampled-data feedback control will have the form

$$u(t) = v(t) - H(t - k\tau)y_k, \qquad t \in [k\tau, (k+1)\tau), \quad k = 0, 1, 2, \dots . \tag{1.1}$$

In (1.1), $H(\cdot)$ represents a generalized hold element in the feedback, $v(\cdot)$ denotes an external input to the closed-loop sampled-data feedback system, and y_k is the kth sample of the output y. In the most general setting, y_k is obtained via generalized sampling (i.e., weighted averaging):

$$y_k := \int_0^{\tau-\delta} w(s)y((k-1)\tau + \delta + s)\, ds,$$

where $\delta \in (0, \tau)$ and w is a suitable scalar-valued weighting function defined on $[(k-1)\tau + \delta, k\tau]$. This kind of generalized sampling is natural for well-posed systems where the output typically is in L^2_{loc} but is not necessarily continuous. The feedback element $H(\cdot)$ in (1.1) is also referred to as a periodic gain, as in [28, 29] and Chammas and Leondes [2].

Control objective. Choose a generalized hold function H defined on $[0, \tau]$, such that the unity sampled-data feedback given by (1.1), when applied to the well-posed system Σ, yields an exponentially stable closed-loop system.

Our main result is Theorem 4.4. Loosely speaking, Theorem 4.4, part (1), states that for a given well-posed system Σ, we can choose H to meet the control objective if

(i) the unstable portion of the spectrum of A consists of at most finitely many eigenvalues with finite algebraic multiplicities,
(ii) the semigroup generated by the stable part of A is exponentially stable,
(iii) the unstable (finite-dimensional) part of the observed discrete-time system $(C, \mathbf{T}_\tau)$ is observable,
(iv) $\int_0^{\tau-\delta} w(s)e^{\lambda s}ds \neq 0$ for all unstable eigenvalues λ of A,
(v) the unstable subspace of Σ is contained in the closure of its reachable subspace.

In Proposition 4.6 we show that conditions (i)–(iv) above are in fact necessary, and in Remark 4.3 it is noted that condition (iv) is in fact satisfied "generically." Furthermore, if the semigroup generated by A is analytic, then (v) is also necessary. In [19] we showed, however, that in general (v) is not necessary for stabilization by idealized sampling and generalized hold sampled-data control. This necessity issue is also discussed in [18, 19, 30].

In Theorem 4.4, part (2), we show that the resulting closed-loop system with external input v is L^2-stable in an input-output sense. In part (3) we show that if the square-integrable input v is such that $\dot{v}$ is also square-integrable, and if the initial state satisfies a certain natural smoothness condition, then the output $y(t)$ of the sampled-data feedback system converges to 0 as $t \to \infty$.

Our main result extends, generalizes, and improves the basic result in [29] in a number of ways. First, the results in [29] are proved for systems with bounded operators B and C and then stated without proof for a class of systems with unbounded B and C satisfying the conditions of the set-up developed in [4]. The unboundedness in this class of systems is quite limited and allows only a few systems described by partial differential equations with boundary control and observation. The results in [29] were further developed in [28] to encompass a class of neutral systems. In our paper, we work in the context of the theory of well-posed systems, the largest class of infinite-dimensional systems for which there exists a well-developed state-space and frequency-domain theory; see, for example, [5, 22, 23, 25, 26, 27, 31, 32]. Well-posed systems allow for considerable unboundedness of the control and observation operators B and C, and they encompass many of the most commonly studied partial differential equations with boundary control and observation and all functional differential equations of retarded and neutral type with delays in the inputs and outputs. Second, in contrast to [28, 29], not only do we prove results on exponential stability but we also obtain results on input-output stability.

The paper is organized as follows: In section 2 we describe in detail various results relevant to the sampled-data control of well-posed systems. In section 3 we discuss issues relating to sampled-data feedback stabilization. In section 4 we present our

main result. In section 5 we illustrate our results by applying them to a structurally damped Euler–Bernoulli beam.

Notation. $\mathbb{N}$ denotes the set of positive integers; $\mathbb{N}_0 := \mathbb{N} \cup \{0\}$; $\mathbb{R}_+ := [0, \infty)$; for $\alpha \in \mathbb{R}$, set $\mathbb{C}_\alpha := \{s \in \mathbb{C} \mid \operatorname{Re} s > \alpha\}$; for a real or complex Banach space Z, $\alpha \in \mathbb{R}$ and $0 < p \leq \infty$, we define the exponentially weighted spaces $L^p_\alpha(\mathbb{R}_+, Z) := \{f \in L^p_{\mathrm{loc}}(\mathbb{R}_+, Z) : f(\cdot)\exp(-\alpha\,\cdot) \in L^p(\mathbb{R}_+, Z)\}$ and $W^{1,p}_\alpha(\mathbb{R}_+, Z) := \{f \in L^p_{\mathrm{loc}}(\mathbb{R}_+, Z) : f(\cdot)\exp(-\alpha\,\cdot) \in W^{1,p}(\mathbb{R}_+, Z)\}$; we endow $L^p_\alpha(\mathbb{R}_+, Z)$ with the norm $\|f\|_{L^p_\alpha} := \|e^{-\alpha\,\cdot} f(\cdot)\|_{L^p}$; $W^{1,p}_c([a, b], Z)$ denotes the subspace of all functions in $W^{1,p}([a, b], Z)$ with support contained in the open interval (a, b); $\mathcal{B}(Z_1, Z_2)$ denotes the space of bounded linear operators from a Banach space Z_1 to a Banach space Z_2; we write $\mathcal{B}(Z)$ for $\mathcal{B}(Z, Z)$; let $A : \operatorname{dom}(A) \subset Z \to Z$ be a linear operator, where $\operatorname{dom}(A)$ denotes the domain of A; the resolvent set of A and the spectrum of A are denoted by $\varrho(A)$and $\sigma(A)$, respectively; if $A \in \mathcal{B}(Z)$, then $r(A)$ denotes the spectral radius of A.

2. Preliminaries on well-posed systems. Before developing our main results for generalized sampled-data control of well-posed linear systems we first need to cover some basic background material on well-posed linear systems. We cover only those basic properties we need and some specific results relevant in a context of sampled-data control. There are a number of equivalent definitions of well-posed systems; see [5, 22, 23, 25, 26, 27, 31, 32]. We will be brief in the following and refer the reader to [22, 23] for the original definition of a well-posed system, to [31] for issues related especially to admissibility, and to [25] for a more comprehensive treatment. Throughout this section, we will consider a well-posed system Σ with state-space X, input space $\mathbb{R}^m$, and output space $\mathbb{R}^p$, generating operators (A, B, C), input-output operator G, and transfer function $\mathbf{G}$. Here X is a real Hilbert space with norm denoted by $\|\cdot\|$, A is the generator of a strongly continuous semigroup $\mathbf{T} = (\mathbf{T}_t)_{t\geq 0}$ on X, $B \in \mathcal{B}(\mathbb{R}^m, X_{-1})$, and $C \in \mathcal{B}(X_1, \mathbb{R}^p)$, where X_1 denotes the space $\operatorname{dom}(A)$ endowed with the norm $\|z\|_1 := \|(s_0 I - A)z\|$, while X_{-1} denotes the completion of X with respect to the norm $\|z\|_{-1} = \|(s_0 I - A)^{-1} z\|$, where $s_0 \in \varrho(A)$ (different choices of s_0 lead to equivalent norms). Clearly, the norm $\|\cdot\|_1$ is equivalent to the graph norm of A. Moreover, $X_1 \subset X \subset X_{-1}$ and the canonical injections are bounded and dense. The semigroup $\mathbf{T}$ restricts to a strongly continuous semigroup on X_1 and extends to a strongly continuous semigroup on X_{-1} with the exponential growth constant being the same on all three spaces; the generator of the restriction (extension) of $\mathbf{T}$ is a restriction (extension) of A; we shall use the same symbol $\mathbf{T}$ (respectively, A) for the original semigroup (respectively, generator) and the associated restrictions and extensions: with this convention, we may write $A \in \mathcal{B}(X, X_{-1})$ (considered as a generator on X_{-1}, the domain of A is X). The spectra of A and its extension coincide. For $s_0 \in \varrho(A)$, $s_0 I - A$, considered as an operator in $\mathcal{B}(X, X_{-1})$, provides an isometric isomorphism from X to X_{-1} (we refer the reader to [7] for more details on the extrapolation space X_{-1}). The operator B is an *admissible control operator* for $\mathbf{T}$; i.e., for each $t \in \mathbb{R}_+$ there exists $\beta_t \geq 0$ such that

$$\left\| \int_0^t \mathbf{T}_{t-s} B u(s)\, ds \right\| \leq \beta_t \|u\|_{L^2([0,t],\mathbb{R}^m)} \quad \forall\, u \in L^2([0, t], \mathbb{R}^m).$$

The operator C is an *admissible observation operator* for $\mathbf{T}$; i.e., for each $t \in \mathbb{R}_+$ there exists $\gamma_t \geq 0$ such that

$$\left(\int_0^t \|C\mathbf{T}_s z\|^2 ds \right)^{1/2} \leq \gamma_t \|z\| \quad \forall\, z \in X_1.$$

The control operator B is said to be *bounded* if it is so as a map from the input space $\mathbb{R}^m$ to the state space X; otherwise it is said to be *unbounded*. The observation operator C is said to be *bounded* if it can be extended continuously to X; otherwise C is said to be *unbounded*.

The so-called Λ-*extension* C_Λ of C is defined by

$$C_\Lambda z = \lim_{s\to\infty,\, s\in\mathbb{R}} Cs(sI-A)^{-1}z,$$

with $\operatorname{dom}(C_\Lambda)$ consisting of all $z \in X$ for which the above limit exists. For every $z \in X$, $\mathbf{T}_t z \in \operatorname{dom}(C_\Lambda)$ for almost all (a.a.) $t \in \mathbb{R}_+$, and if $\alpha > \omega(\mathbf{T})$, then $C_\Lambda \mathbf{T} z \in L^2_\alpha(\mathbb{R}_+, \mathbb{R}^p)$, where

$$\omega(\mathbf{T}) := \lim_{t\to\infty} \frac{1}{t} \ln \|\mathbf{T}_t\|$$

denotes the exponential growth constant of $\mathbf{T}$. The transfer function $\mathbf{G}$ satisfies

$$\frac{1}{s-s_0}\left(\mathbf{G}(s)-\mathbf{G}(s_0)\right) = -C(sI-A)^{-1}(s_0 I-A)^{-1}B \quad \forall\, s, s_0 \in \mathbb{C}_{\omega(\mathbf{T})},\ s \neq s_0, \tag{2.1}$$

and for every $\alpha > \omega(\mathbf{T})$, $\mathbf{G}$ is analytic and bounded on $\mathbb{C}_\alpha$. Moreover, the input-output operator $G : L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m) \to L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^p)$ is continuous and right-shift invariant; for every $\alpha > \omega(\mathbf{T})$, $G \in \mathcal{B}(L^2_\alpha(\mathbb{R}_+, \mathbb{R}^m), L^2_\alpha(\mathbb{R}_+, \mathbb{R}^p))$ and

$$(\mathfrak{L}(Gu))(s) = \mathbf{G}(s)(\mathfrak{L}(u))(s) \quad \forall\, s \in \mathbb{C}_\alpha,\ \forall\, u \in L^2_\alpha(\mathbb{R}_+, \mathbb{R}^m),$$

where $\mathfrak{L}$ denotes the Laplace transform. It follows from (2.1) that if two well-posed systems have the same generating operators, then the difference of their transfer functions is constant: roughly speaking, the generating operators determine the input-output behavior of a well-posed system up to a constant.

In the following, let $s_0 \in \mathbb{C}_{\omega(\mathbf{T})}$ be fixed but arbitrary. For $x^0 \in X$ and $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, let x and y denote the state and output functions of Σ, respectively, corresponding to the initial condition $x(0) = x^0 \in X$ and the input function u. Then $x(t) = \mathbf{T}_t x^0 + \int_0^t \mathbf{T}_{t-s} B u(s)\, ds$ for all $t \in \mathbb{R}_+$, and $y(t) = C_\Lambda \mathbf{T}_t x^0 + (Gu)(t)$ for a.a. $t \in \mathbb{R}$. Moreover, $x(t) - (s_0 I - A)^{-1} B u(t) \in \operatorname{dom}(C_\Lambda)$ for a.a. $t \in \mathbb{R}_+$ and

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x^0, \quad \text{for a.a. } t \in \mathbb{R}_+, \tag{2.2a}$$

$$y(t) = C_\Lambda\left(x(t) - (s_0 I - A)^{-1} B u(t)\right) + \mathbf{G}(s_0)u(t) \quad \text{for a.a. } t \geq 0. \tag{2.2b}$$

Of course, the differential equation (2.2a) has to be interpreted in X_{-1}. In the following, we identify Σ and (2.2) and refer to (2.2) as a well-posed system. We say that the well-posed system (2.2) is *exponentially stable* if $\omega(\mathbf{T}) < 0$. If the well-posed system (2.2) is *regular*, i.e., the limit

$$\lim_{s\to\infty,\, s\in\mathbb{R}} \mathbf{G}(s) = D$$

exists, then $x(t) \in \operatorname{dom}(C_\Lambda)$ for a.a. $t \in \mathbb{R}_+$ and the output equation (2.2b) simplifies to

$$y(t) = C_\Lambda x(t) + Du(t) \quad \text{for a.a. } t \geq 0.$$

Moreover, in the regular case, we have that $(sI - A)^{-1} B\mathbb{R}^m \subset \operatorname{dom}(C_\Lambda)$ for all $s \in \varrho(A)$ and

$$\mathbf{G}(s) = C_\Lambda (sI - A)^{-1} B + D \quad \forall\, s \in \mathbb{C}_{\omega(\mathbf{T})}.$$

The matrix $D \in \mathbb{R}^{p\times m}$ is called the *feedthrough matrix* of (2.2). We mention that if the control operator B or the observation operator C is bounded, then (2.2) is regular.

The following result relates to the asymptotic behavior of the output y of the well-posed system (2.2) under the assumption that x^0 and u satisfy certain "smoothness" conditions.

PROPOSITION 2.1. *Let $\alpha > \omega(\mathbf{T})$, $x^0 \in X$, and $u \in W^{1,2}_\alpha(\mathbb{R}_+, \mathbb{R}^m)$. If there exists $t_0 \in \mathbb{R}_+$ such that $\mathbf{T}_{t_0}(Ax^0 + Bu(0)) \in X$, then the output y of the well-posed system (2.2) is continuous on $[t_0, \infty)$ [1] and satisfies*

$$\lim_{t\to\infty} y(t)e^{-\alpha t} = 0.$$

Proof. Let $x^0 \in X$, $t_0 \in \mathbb{R}_+$, and $u \in W^{1,2}_\alpha(\mathbb{R}_+, \mathbb{R}^m)$ be such that $\mathbf{T}_{t_0}(Ax^0 + Bu(0)) \in X$. The output y of the well-posed system (2.2) is given by

$$y(t) = C_\Lambda \mathbf{T}_t x^0 + (Gu)(t) \quad \text{for a.a. } t \in \mathbb{R}_+. \tag{2.3}$$

Let us first assume that $\alpha = 0$. Then, by hypothesis, $0 = \alpha > \omega(\mathbf{T})$; that is, the well-posed system (2.2) is exponentially stable. Define a right-shift-invariant operator $F : L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m) \to L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^p)$ by setting

$$(Ff)(t) := \int_0^t ((Gf)(\zeta) - \mathbf{G}(0)f(\zeta))\, d\zeta \quad \forall\, f \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m),\ \forall\, t \in \mathbb{R}_+.$$

The transfer function $\mathbf{F}$ of F is given by $\mathbf{F}(s) = (\mathbf{G}(s) - \mathbf{G}(0))/s$. Clearly, $\mathbf{F}$ is analytic and bounded on $\mathbb{C}_0$ and so, $F \in \mathcal{B}(L^2(\mathbb{R}_+, \mathbb{R}^m), L^2(\mathbb{R}_+, \mathbb{R}^p))$. Using that G commutes with the integration operator (by right-shift invariance), a routine calculation gives

$$Gu = F\dot{u} + \mathbf{G}(0)u + G(u(0)\theta) - \mathbf{G}(0)u(0),$$

where θ denotes the unit-step function. Setting

$$y_1 := F\dot{u} + \mathbf{G}(0)u \qquad \text{and} \qquad y_2 := C_\Lambda \mathbf{T}x^0 + G(u(0)\theta) - \mathbf{G}(0)u(0),$$

it follows from (2.3) that

$$y(t) = y_1(t) + y_2(t) \quad \text{for a.a. } t \in \mathbb{R}_+. \tag{2.4}$$

It is clear that y_1 is continuous. Since $u, \dot{u} \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, we may conclude that $\lim_{t\to\infty} u(t) = 0$. Using again that $\dot{u} \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, it follows from the boundedness of F and G that $F\dot{u}$ and $(d/dt)(F\dot{u})$ are in $L^2(\mathbb{R}_+, \mathbb{R}^p)$, showing that $\lim_{t\to\infty}(F\dot{u})(t) = 0$. Thus, $\lim_{t\to\infty} y_1(t) = 0$. Taking the Laplace transform of y_2 gives

$$(\mathfrak{L}y_2)(s) = C(sI - A)^{-1}x^0 + \frac{1}{s}(\mathbf{G}(s) - \mathbf{G}(0))u(0) \quad \forall\, s \in \mathbb{C}_0.$$

Invoking (2.1) we obtain that for all $s \in \mathbb{C}_0$,

$$(\mathfrak{L}y_2)(s) = C(sI-A)^{-1}x^0 + C(sI-A)^{-1}A^{-1}Bu(0) = C(sI-A)^{-1}A^{-1}(Ax^0 + Bu(0)),$$

[1] The output y of the well-posed system (2.2) is an element in $L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, and so, strictly speaking, y is not a function but an equivalence class of functions coinciding almost everywhere in $\mathbb{R}_+$. We say that y is continuous on $[t_0, \infty)$ if there exists a representative in the equivalence class which is continuous on $[t_0, \infty)$.

implying that $y_2(t) = C_\Lambda \mathbf{T}_t A^{-1}(Ax^0 + Bu(0))$ for a.a. $t \in \mathbb{R}_+$. Hence, since $\mathbf{T}_{t_0}(Ax^0 + Bu(0)) \in X$,

$$y_2(t) = C\mathbf{T}_{t-t_0} A^{-1} \mathbf{T}_{t_0}(Ax^0 + Bu(0)) \quad \text{for a.a. } t \in [t_0, \infty). \tag{2.5}$$

Obviously, the right-hand side of (2.5) is continuous on $[t_0, \infty)$ and converges to 0 as $t \to \infty$. The claim now follows from (2.4).

Let us now assume that $\alpha \neq 0$. Define the operator $G_\alpha : L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m) \to L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^p)$ by setting $G_\alpha(u) := e^{-\alpha \cdot} G(e^{\alpha \cdot} u)$. It is trivial that there exists a well-posed system Σ_α with generating operators $(A - \alpha I, B, C)$ and input-output operator G_α (the exponentially weighted version of the well-posed system (2.2)). Since $\alpha > \omega(\mathbf{T})$, it is clear that Σ_α is exponentially stable. If y is the output of the well-posed system (2.2), then

$$y(t)e^{-\alpha t} = C_\Lambda \mathbf{T}_t e^{-\alpha t} x^0 + (G_\alpha(e^{-\alpha \cdot} u))(t) \quad \text{for a.a. } t \in \mathbb{R}_+. \tag{2.6}$$

The right-hand side of (2.6) is the output of the exponentially stable well-posed system Σ_α corresponding to the initial value x^0 and the control function $e^{-\alpha \cdot} u \in W^{1,2}(\mathbb{R}_+, \mathbb{R}^m)$. Moreover, since $\mathbf{T}_{t_0}(Ax^0 + Bu(0)) \in X$,

$$\mathbf{T}_{t_0} e^{-\alpha t_0}\big((A - \alpha I)x^0 + B(e^{-\alpha \cdot} u)(0)\big) = e^{-\alpha t_0} \mathbf{T}_{t_0}\big(Ax^0 + Bu(0) - \alpha x^0\big) \in X.$$

Thus, by what we have already proved, it follows that the right-hand side of (2.6), and hence the function $t \mapsto y(t)e^{-\alpha t}$, is continuous on $[t_0, \infty)$ and converges to 0 as $t \to \infty$. □

We close this section with a simple sufficient condition for a triple of operators (A, B, C) to be the generating operators of a well-posed system. Here $A : \mathrm{dom}(A) \subset X \to X$ generates a strongly continuous semigroup $\mathbf{T} = (\mathbf{T}_t)_{t \geq 0}$, and $B \in \mathcal{B}(\mathbb{R}^m, X_{-1})$ and $C \in \mathcal{B}(X_1, \mathbb{R}^p)$ are admissible control and observation operators for $\mathbf{T}$, respectively. Assume that the semigroup $\mathbf{T}$ is analytic; let $s_0 \in \varrho(A)$ and let $\alpha \geq 0$. Then the fractional powers $(s_0 I - A)^{-\alpha}$ and $(s_0 I - A)^\alpha$ are well-defined (where $(s_0 I - A)^0 := I$), $(s_0 I - A)^\alpha$ is closed, and $(s_0 I - A)^{-\alpha} \in \mathcal{B}(X)$. We endow the domain of $(s_0 I - A)^\alpha$ with the norm

$$\|z\|_\alpha := \|(s_0 I - A)^\alpha z\|$$

and denote the resulting Hilbert space by X_α. Let $X_{-\alpha}$ be the completion of X with respect to the norm

$$\|z\|_{-\alpha} := \|(s_0 I - A)^{-\alpha} z\|.$$

It is trivial that $X_0 = X$ and $(s_0 I - A)^{-\alpha} \in \mathcal{B}(X, X_\alpha)$. If $\alpha \in (0, 1)$, then X_α and $X_{-\alpha}$ can be interpreted as interpolation spaces: between X and X_1 in the case of the former and between X and X_{-1} in the case of the latter. The operator $(s_0 I - A)^\alpha$ extends to an operator in $\mathcal{B}(X, X_{-\alpha})$ and similarly, $(s_0 I - A)^{-\alpha}$ extends to an operator in $\mathcal{B}(X_{-\alpha}, X)$; we shall use the same symbol $(s_0 I - A)^\alpha$ (respectively, $(s_0 I - A)^{-\alpha}$) to denote the extensions.

PROPOSITION 2.2. *Assume that the semigroup $\mathbf{T}$ generated by A is analytic and that $B \in \mathcal{B}(\mathbb{R}^m, X_{-1})$ and $C \in \mathcal{B}(X_1, \mathbb{R}^p)$ are admissible control and observation operators for $\mathbf{T}$, respectively. If there exist $\alpha, \beta \in [0, 1]$ with $\alpha + \beta \leq 1$ and such that $B \in \mathcal{B}(\mathbb{R}^m, X_{-\alpha})$ and $C \in \mathcal{B}(X_\beta, \mathbb{R}^p)$, then there exists a regular well-posed system with generating operators (A, B, C).*

Proof. Fix $\lambda \in \varrho(A)$. It follows from the hypothesis that $\tilde{B} := (\lambda I - A)^{-\alpha} B \in \mathcal{B}(\mathbb{R}^m, X)$ and $\tilde{C} = C(\lambda I - A)^{-\beta} \in \mathcal{B}(X, \mathbb{R}^p)$. Since $\alpha + \beta \leq 1$, the operator $(\lambda I - A)^{\alpha+\beta}(sI - A)^{-1}$ is in $\mathcal{B}(X)$ for all $s \in \varrho(A)$. Consequently, the function $\mathbf{G}$ defined by

$$\mathbf{G}(s) := \tilde{C}(\lambda I - A)^{\alpha+\beta}(sI - A)^{-1}\tilde{B}$$

is analytic on $\varrho(A)$. Moreover,

$$\begin{aligned}(\lambda I - A)^{\alpha+\beta}(sI - A)^{-1} &= (\lambda I - A)^{\alpha+\beta-1}(\lambda I - A)(sI - A)^{-1} \\ &= (\lambda I - A)^{\alpha+\beta-1}[(\lambda + s)(sI - A)^{-1} + I] \ \forall\, s \in \varrho(A). \end{aligned} \tag{2.7}$$

Fix $\gamma > \omega(\mathbf{T})$. The fact that A generates an analytic semigroup guarantees the existence of a constant $M > 0$ such that $\|(sI - A)^{-1}\| \leq M/|s - \gamma|$ for all $s \in \mathbb{C}_\gamma$. Therefore we obtain from (2.7) that the $\mathcal{B}(X)$-valued function $s \mapsto (\lambda I - A)^{\alpha+\beta}(sI - A)^{-1}$ is bounded on $\mathbb{C}_\gamma$. Consequently, $\mathbf{G}$ is bounded on $\mathbb{C}_\gamma$. Moreover, since

$$(sI - A)^{-1}(\lambda I - A)^{\alpha} z = (\lambda I - A)^{\alpha}(sI - A)^{-1} z \in X \quad \forall\, z \in X,\ \forall\, s \in \varrho(A)$$

and

$$(\lambda I - A)^{\alpha}(\lambda I - A)^{\beta} z = (\lambda I - A)^{\alpha+\beta} z \in X \quad \forall\, z \in X_1,$$

an application of the resolvent identity yields for all $s, s_0 \in \varrho(A)$ with $s \neq s_0$

$$\begin{aligned}\frac{1}{s_0 - s}(\mathbf{G}(s) - \mathbf{G}(s_0)) &= \tilde{C}(\lambda I - A)^{\alpha+\beta}(sI - A)^{-1}(s_0 I - A)^{-1}\tilde{B} \\ &= C(sI - A)^{-1}(s_0 I - A)^{-1} B.\end{aligned}$$

Invoking a result in [5], we may now conclude that there exists a well-posed system with generating operators (A, B, C). To show that this system is regular, it suffices to prove that $(s_0 I - A)^{-1} B\mathbb{R}^m \subset \operatorname{dom} C_\Lambda$ for $s_0 \in \varrho(A)$; see [31]. But this follows trivially from the identity

$$C(sI - A)^{-1}(s_0 I - A)^{-1} B = \tilde{C}(\lambda I - A)^{\alpha+\beta}(s_0 I - A)^{-1}(sI - A)^{-1}\tilde{B}$$

and the facts that $\tilde{C} \in \mathcal{B}(X, \mathbb{R}^p)$, $(\lambda I - A)^{\alpha+\beta}(s_0 I - A)^{-1} \in \mathcal{B}(X)$, and $\tilde{B} \in \mathcal{B}(\mathbb{R}^m, X)$. ∎

3. The sampled-data system. Let $\tau > \delta > 0$, $H \in L^2([0, \delta], \mathbb{R}^{m\times p})$, $w \in L^2([0, \tau - \delta], \mathbb{R})$, and $v \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$. We apply the following sampled-data feedback control law to the well-posed system (2.2):

$$u(t) = \begin{cases} v(t) - H(t - k\tau)y_k, & t \in [k\tau, k\tau + \delta) \\ v(t), & t \in [k\tau + \delta, (k+1)\tau) \end{cases} \quad \forall\, k \in \mathbb{N}_0, \ \text{where} \tag{3.1a}$$

$$y_0 := 0 \qquad \text{and} \qquad y_k := \int_0^{\tau-\delta} w(s) y((k-1)\tau + \delta + s)\, ds \quad \forall\, k \in \mathbb{N}. \tag{3.1b}$$

The function v represents the input signal of the sampled-data feedback system and emphasises our input-output as well as state-space point of view.

Remark 3.1. Defining $H_\tau \in L^2([0, \tau], \mathbb{R}^{m\times p})$ by

$$H_\tau(t) := \begin{cases} H(t), & t \in [0, \delta], \\ 0, & t \in (\delta, \tau], \end{cases} \tag{3.2}$$

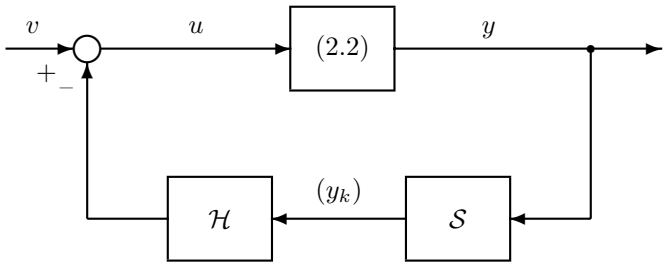

FIG. 1. *Feedback system with generalized sampling $\mathcal{S}$ and generalized hold $\mathcal{H}$.*

and setting

$$\big(\mathcal{H}((y_k))\big)(t) := H_\tau(t-k\tau)y_k \quad \forall\, t \in [k\tau,(k+1)\tau),\ \forall\, k \in \mathbb{N}_0,$$

(3.1a) can be written in the form $u = v - \mathcal{H}((y_k))$. The operator $\mathcal{H}$ represents a generalized hold operation with hold function H_τ (see, for example, [1]). Similarly, (3.1b) describes a generalized sampling operation (see [1]). The function w is called the weighting function of the sampler (3.1b). Note that instantaneous sampling of the form $y_k = y(k\tau)$ is in general not possible since typically the output y of a well-posed system (2.2) need not be continuous. Indeed, the state-space formula (2.2b) for the output does not hold for all $t \in \mathbb{R}_+$, but only for a.a. $t \in \mathbb{R}$: in particular, it might not hold at $t = k\tau$ for some $k \in \mathbb{N}_0$.

The sampled-data feedback system obtained by applying the control law (3.1) to the well-posed system (2.2) is illustrated in Figure 1, where $\mathcal{S}$ denotes the generalized sampling operation given by (3.1b).

It is clear that for given initial state $x^0 \in X$ and given input function $v \in L^2_{\mathrm{loc}}(\mathbb{R}_+,\mathbb{R}^m)$, the (unique) state trajectory $x(\cdot;x^0,v)$ of the sampled-data feedback system given by (2.2) and (3.1) can be obtained recursively from (2.2b), (3.1b), and

$$x(0;x^0,v) = x^0, \tag{3.3a}$$

$$x(k\tau+t;x^0,v) = \mathbf{T}_t x(k\tau;x^0,v) + \int_0^t \mathbf{T}_{t-s}B(v(k\tau+s) - H_\tau(s)y_k)\,ds$$

$$\forall\, t \in (0,\tau],\ \forall\, k \in \mathbb{N}_0. \tag{3.3b}$$

Note that $x(\cdot;x^0,v)$ is a continuous X-valued function defined on $\mathbb{R}_+$. For simplicity, in the following we shall occasionally use the abbreviation $x := x(\cdot;x^0,v)$. We define

$$x_k := x(k\tau), \quad x_{k,\delta} := x(k\tau+\delta) \qquad \forall\, k \in \mathbb{N}_0.$$

For $\sigma,\tau > 0$, we define the left-shift/truncation operator $\mathbf{L}^\tau_\sigma : L^2_{\mathrm{loc}}(\mathbb{R}_+,\mathbb{R}^m) \to L^2(\mathbb{R}_+,\mathbb{R}^m)$ by setting

$$(\mathbf{L}^\tau_\sigma f)(t) := \begin{cases} f(t+\sigma), & t \in [0,\tau], \\ 0, & t \in (\tau,\infty). \end{cases}$$

In the following lemma we establish the basic discrete-time equations (involving x_k, $x_{k,\delta}$, y_k, and $\mathbf{L}^\tau_{k\tau+\delta}v$) associated with the sampled-data feedback system given by (2.2) and (3.1).

LEMMA 3.2. *Let $\tau > \delta > 0$, $H \in L^2([0,\delta],\mathbb{R}^{m\times p})$, and $w \in L^2([0,\tau-\delta],\mathbb{R})$. We assume that*

$$\int_0^{\tau-\delta} w(s)\mathbf{T}_s z\,ds \in X_1 \quad \forall\, z \in X. \tag{3.4}$$

Then the following statements hold.

(1) *The operator*

$$L_w : X \to X_1,\ z \mapsto \int_0^{\tau-\delta} w(s)\mathbf{T}_s z\,ds \tag{3.5}$$

is in $\mathcal{B}(X, X_1)$.

(2) *The sequences (x_k), $(x_{k,\delta})$, and (y_k) satisfy, for all $k \in \mathbb{N}_0$,*

$$x_{k+1} = \mathbf{T}_{\tau-\delta}x_{k,\delta} + \int_0^{\tau-\delta} \mathbf{T}_{\tau-\delta-s}Bv(k\tau+\delta+s)\,ds, \tag{3.6}$$

$$y_{k+1} = CL_w x_{k,\delta} + M_w \mathbf{L}^\tau_{k\tau+\delta} v, \tag{3.7}$$

$$x_{k+1,\delta} = (\mathbf{T}_\tau + K_H C L_w)x_{k,\delta} + M_{H,w}\mathbf{L}^\tau_{k\tau+\delta} v, \tag{3.8}$$

where $K_H \in \mathcal{B}(\mathbb{R}^p, X)$, $M_w \in \mathcal{B}(L^2(\mathbb{R}_+,\mathbb{R}^m),\mathbb{R}^p)$, and $M_{H,w} \in \mathcal{B}(L^2(\mathbb{R}_+,\mathbb{R}^m), X)$ are defined by

$$K_H z = -\int_0^\delta \mathbf{T}_{\delta-s}BH(s)z\,ds \quad \forall\, z \in \mathbb{R}^p, \tag{3.9}$$

$$M_w f = \int_0^{\tau-\delta} w(s)(Gf)(s)\,ds \quad \forall\, f \in L^2(\mathbb{R}_+,\mathbb{R}^m), \tag{3.10}$$

$$M_{H,w} f = K_H M_w f + \int_0^\tau \mathbf{T}_{\tau-s}Bf(s)\,ds \quad \forall\, f \in L^2(\mathbb{R}_+,\mathbb{R}^m), \tag{3.11}$$

respectively.

Remark 3.3. It is easy to show, using integration by parts, that (3.4) holds for any $w \in L^2([0,\tau-\delta],\mathbb{R})$ for which there exist a partition $0 = t_0 < t_1 < \cdots < t_n = \tau-\delta$ and functions $w_j \in W^{1,1}([t_{j-1},t_j],\mathbb{R})$ such that $w(t) = w_j(t)$ for all $t \in (t_{j-1},t_j)$ and all $j = 1,2,\ldots,n$.

Proof of Lemma 3.2. Statement (1) follows from a routine application of the closed-graph theorem. To prove statement (2), note first that (3.6) follows immediately from the variation-of-parameters formula combined with the fact that the control u given by (3.1a) satisfies

$$u(t) = v(t) \quad \forall\, t \in [k\tau+\delta,(k+1)\tau). \tag{3.12}$$

To derive (3.7), we use (2.2b) and (3.12) to obtain

$$\begin{aligned} y(k\tau+\delta+s) = C_\Lambda\big(x(k\tau+\delta+s) - (s_0 I - A)^{-1}Bv(k\tau+\delta+s)\big) \\ + \mathbf{G}(s_0)v(k\tau+\delta+s) \quad \text{for a.a. } s \in [0,\tau-\delta]. \end{aligned} \tag{3.13}$$

It follows from the variation-of-parameters formula that the function $\tilde{x} : s \mapsto x(k\tau+\delta+s)$ is the state trajectory of (2.2) corresponding to the initial condition $\tilde{x}(0) = x(k\tau+\delta) = x_{k,\delta}$ and the control function $s \mapsto v(k\tau+\delta+s)$. By (3.13), the function $s \mapsto y(k\tau+\delta+s)$ is the corresponding output, and thus

$$y(k\tau+\delta+s) = C_\Lambda \mathbf{T}_s x_{k,\delta} + (G\mathbf{L}^\tau_{k\tau+\delta}v)(s) \quad \text{for a.a. } s \in [0,\tau-\delta].$$

Combining this with (3.1b) gives

$$y_{k+1} = \int_0^{\tau-\delta} w(s) \left(C_\Lambda \mathbf{T}_s x_{k,\delta} + (G\mathbf{L}^\tau_{k\tau+\delta} v)(s) \right) ds.$$

A standard argument involving the approximation of $x_{k,\delta}$ by elements in X_1, the admissibility of C and the boundedness of the operator L_w (see statement (1)) shows that

$$\int_0^{\tau-\delta} w(s) C_\Lambda \mathbf{T}_s x_{k,\delta}\, ds = C L_w x_{k,\delta}.$$

Hence, with M_w given by (3.10),

$$y_{k+1} = C L_w x_{k,\delta} + M_w \mathbf{L}^\tau_{k\tau+\delta} v,$$

which is (3.7). To prove (3.8), note that $k\tau + \delta + s \in [(k+1)\tau, (k+1)\tau + \delta]$ for all $s \in [\tau - \delta, \tau]$ and so, by (3.1a),

$$u(k\tau + \delta + s) = v(k\tau + \delta + s) - H(s + \delta - \tau) y_{k+1} \quad \forall\, s \in [\tau - \delta, \tau],\ \forall\, k \in \mathbb{N}_0.$$

Combining this with (3.12), we may conclude that

$$x_{k+1,\delta} = \mathbf{T}_\tau x_{k,\delta} + \int_0^\tau \mathbf{T}_{\tau-s} B v(k\tau + \delta + s)\, ds - \int_{\tau-\delta}^\tau \mathbf{T}_{\tau-s} B H(s + \delta - \tau) y_{k+1}\, ds.$$

Changing the integration variable s in the second integral to $\zeta = s + \delta - \tau$ gives

$$\begin{aligned} x_{k+1,\delta} &= \mathbf{T}_\tau x_{k,\delta} + \int_0^\tau \mathbf{T}_{\tau-s} B v(k\tau + \delta + s)\, ds - \int_0^\delta \mathbf{T}_{\delta-\zeta} B H(\zeta) y_{k+1}\, d\zeta \\ &= \mathbf{T}_\tau x_{k,\delta} + K_H y_{k+1} + \int_0^\tau \mathbf{T}_{\tau-s} B v(k\tau + \delta + s)\, ds \quad \forall\, k \in \mathbb{N}_0, \end{aligned}$$

where K_H is given by (3.9). Together with (3.7) and (3.11) this yields (3.8). □

The sampled-data feedback system given by (2.2) and (3.1) is called *exponentially bounded* if there exist constants $N \geq 1$ and $\nu \in \mathbb{R}$ such that

$$\|x(t; x^0, 0)\| \leq N e^{\nu t} \|x^0\| \quad \forall\, t \in \mathbb{R}_+,\ \forall\, x^0 \in X, \tag{3.14}$$

where $x(t; x^0, 0)$ is given by (3.3) (with $v = 0$). The number ν is called an *exponential bound* of the sampled-data feedback system. Obviously any bounded operator $\Delta \in \mathcal{B}(X)$ satisfies $\|\Delta^k\| \leq \|\Delta\|^k$; i.e., Δ is *power bounded*. If $q > 0$ is such that there exists $M \geq 1$ so that

$$\|\Delta^k\| \leq M q^k \quad \forall\, k \in \mathbb{N}_0, \tag{3.15}$$

then q is a *power bound* for Δ.

LEMMA 3.4. *Let $\tau > \delta > 0$, $H \in L^2([0, \delta], \mathbb{R}^{m \times p})$, and $w \in L^2([0, \tau - \delta], \mathbb{R})$. Let $L_w \in \mathcal{B}(X, X_1)$ and $K_H \in \mathcal{B}(\mathbb{R}^p, X)$ be given by* (3.5) *and* (3.9)*, respectively, and assume that* (3.4) *holds. Furthermore, let $\nu \in \mathbb{R}$. Then the following statements hold.*

(1) *If $e^{\nu\tau}$ is a power bound for the operator $\mathbf{T}_\tau + K_H C L_w$, then $\nu \in \mathbb{R}$ is an exponential bound for the sampled-data feedback system given by* (2.2) *and* (3.1).

(2) *Under the additional assumption that* $\mathbf{T}$ *is a group, the converse of statement* (1) *holds; that is, if* $\nu \in \mathbb{R}$ *is an exponential bound for the sampled-data feedback system given by* (2.2) *and* (3.1)*, then* $e^{\nu\tau}$ *is a power bound for* $\mathbf{T}_\tau + K_H C L_w$.

The lemma shows in particular that the sampled-data feedback system is exponentially bounded. We define the *exponential growth* $\omega_{\rm sd}$ of the sampled-data feedback system to be the infimum of all $\nu \in \mathbb{R}$ for which there exists $N \geq 1$ such that (3.14) holds. Note that $-\infty \leq \omega_{\rm sd} < \infty$. If $\omega_{\rm sd} < 0$, then we say that the sampled-data feedback system is *exponentially stable*. Similarly, the infimum of all $q > 0$ for which there exists $M \geq 1$ such that (3.15) holds is called the *power growth* of Δ. If the power growth is smaller than 1, we say that Δ is *power stable*. It follows from Gelfand's spectral radius formula

$$r(\Delta) = \lim_{k\to\infty} \|\Delta^k\|^{1/k}$$

that the power growth of Δ coincides with $r(\Delta)$. As a consequence, Lemma 3.4 has the following corollary.

COROLLARY 3.5. *Let* $\tau > \delta > 0$, $H \in L^2([0,\delta], \mathbb{R}^{m\times p})$, *and* $w \in L^2([0,\tau-\delta],\mathbb{R})$. *Let* $L_w \in \mathcal{B}(X, X_1)$ *and* $K_H \in \mathcal{B}(\mathbb{R}^p, X)$ *be given by* (3.5) *and* (3.9)*, respectively, and assume that* (3.4) *holds. Then* $r(\mathbf{T}_\tau + K_H C L_w) \geq e^{\omega_{\rm sd}\tau}$*; under the additional assumption that* $\mathbf{T}$ *is a group, we have* $r(\mathbf{T}_\tau + K_H C L_w) = e^{\omega_{\rm sd}\tau}$ (*we adopt the convention* $e^{-\infty\tau} := 0$).

Proof of Lemma 3.4. We define $\Delta \in \mathcal{B}(X)$ by setting

$$\Delta := \mathbf{T}_\tau + K_H C L_w.$$

To prove statement (1), let $\nu \in \mathbb{R}$ and assume that $e^{\nu\tau}$ is a power bound for Δ. By the variation-of-parameter formula we obtain for the state trajectory $x(\cdot; x^0, 0)$ of the sampled-data feedback system

$$x(k\tau + t; x^0, 0) = \mathbf{T}_t x_k - \int_0^t \mathbf{T}_{t-s} B H_\tau(s) y_k \, ds \quad \forall\, t \in [0,\tau),\ \forall\, k \in \mathbb{N}_0,$$

where H_τ is given by (3.2). Using (3.6) and (3.7), we obtain

$$x(k\tau+t; x^0, 0) = \mathbf{T}_{t+\tau-\delta} x_{k-1,\delta} - \int_0^t \mathbf{T}_{t-s} B H_\tau(s) C L_w x_{k-1,\delta}\, ds \quad \forall\, t \in [0,\tau),\ \forall\, k \in \mathbb{N}.$$

Invoking the admissibility of B, (3.8), and the hypothesis, we may conclude that there exist $N_1, N_2 \geq 0$ such that

$$\|x(k\tau + t; x^0, 0)\| \leq N_1 \|x_{k-1,\delta}\| \leq N_2 (e^{\nu\tau})^{k-1} \|x_{0,\delta}\| \quad \forall\, t \in [0,\tau),\ \forall\, k \in \mathbb{N}.$$

Noting that $x(t; x^0, 0) = \mathbf{T}_t x^0$ for all $t \in [0,\tau]$ and setting

$$N := \left(\max\{ \sup_{0\leq s\leq\tau} \|\mathbf{T}_s\|, N_2 \|\mathbf{T}_\delta\| e^{-\nu\tau} \} \right) \sup_{0\leq s\leq\tau} e^{-\nu s},$$

it follows that

$$\|x(k\tau + t; x^0, 0)\| \leq N e^{\nu(k\tau+t)} \|x^0\| \quad \forall\, t \in [0,\tau),\ \forall\, k \in \mathbb{N}_0.$$

This holds for all $x^0 \in X$, showing that ν is an exponential bound for the sampled-data feedback system.

To prove statement (2), assume that $\mathbf{T}$ is a group and let $\nu \in \mathbb{R}$ be an exponential bound for the sampled-data feedback system. Then there exists $N \geq 1$ such that (3.14) holds and therefore

$$\|x_{k,\delta}\| \leq Ne^{\nu(k\tau+\delta)}\|x^0\| = Ne^{\nu\delta}(e^{\nu\tau})^k\|x^0\| \quad \forall\, k \in \mathbb{N}_0.$$

Since $x_{0,\delta} = \mathbf{T}_\delta x^0$, it follows from (3.8) that $x_{k,\delta} = \Delta^k \mathbf{T}_\delta x^0$. Hence, using the group property of $\mathbf{T}$, we obtain

$$\|\Delta^k \mathbf{T}_\delta x^0\| \leq N\|\mathbf{T}_{-\delta}\|e^{\nu\delta}(e^{\nu\tau})^k\|\mathbf{T}_\delta x^0\| \quad \forall\, k \in \mathbb{N}_0.$$

Since this holds for all $x^0 \in X$, it follows that $e^{\nu\tau}$ is a power bound for Δ. ∎

4. Main result. We first state and prove a technical lemma.

LEMMA 4.1. *Let $S \in \mathbb{R}^{n\times n}$, $a > 0$, and $f \in L^1([0,a],\mathbb{R})$. The matrix $\int_0^a f(t)e^{St}\,dt$ is invertible if and only if $\int_0^a f(t)e^{\lambda t}\,dt \neq 0$ for all $\lambda \in \sigma(S)$.*

Proof. Using the Jordan form of S, it is easy to show that a complex number μ is an eigenvalue of the matrix $\int_0^a f(t)e^{St}dt$ if and only if $\mu = \int_0^a f(t)e^{\lambda t}\,dt$ for some $\lambda \in \sigma(S)$. ∎

In the following we shall impose a number of assumptions on the well-posed system (2.2), the weighting function w, and the sampling constants $\tau > \delta > 0$.

A1. There exists $\beta < 0$ such that $\sigma(A) \cap \overline{\mathbb{C}}_\beta$ consists of finitely many isolated eigenvalues of A with finite algebraic multiplicities.

If A1 holds, then there exists a simple closed curve Γ in the complex plane not intersecting $\sigma(A)$, enclosing $\sigma(A) \cap \overline{\mathbb{C}}_\beta$ in its interior and having $\sigma(A) \cap (\mathbb{C} \setminus \overline{\mathbb{C}}_\beta)$ in its exterior. The operator

$$\Pi := \frac{1}{2\pi i}\int_\Gamma (sI - A)^{-1}\,ds \tag{4.1}$$

is a projection operator, and we have

$$X = X^+ \oplus X^-, \qquad \text{where} \quad X^+ := \Pi X, \quad X^- := (I - \Pi)X. \tag{4.2}$$

It follows from a standard result (see, for example, Lemma 2.5.7 in [6]) that $\dim X^+ < \infty$, $X^+ \subset X_1$, X^+ and X^- are $\mathbf{T}_t$-invariant for all $t \geq 0$, and

$$\sigma(A|_{X^+}) = \sigma(A) \cap \overline{\mathbb{C}}_\beta, \qquad \sigma(A|_{X^-}) = \sigma(A) \cap (\mathbb{C} \setminus \overline{\mathbb{C}}_\beta).$$

It is useful to introduce the notation

$$A^+ := A|_{X^+}, \quad A^- := A|_{X_1 \cap X^-}, \qquad \mathbf{T}_t^+ := \mathbf{T}_t|_{X^+}, \quad \mathbf{T}_t^- := \mathbf{T}_t|_{X^-}. \tag{4.3}$$

Clearly, $\mathbf{T}_t^+$ is a semigroup on the finite-dimensional space X^+ with generator A^+, i.e., $\mathbf{T}_t^+ = e^{A^+ t}$, and $\mathbf{T}_t^-$ is a strongly continuous semigroup on X^- with generator A^-. Since the spectrum of A considered as an operator on X coincides with the spectrum of A considered as an operator on X_{-1}, the projection operator Π on X defined in (4.1) extends to a projection on X_{-1}. We will use the same symbol Π for the original projection and its associated extension. Obviously, the operator A^- extends to an operator in $\mathcal{B}(X^-, (X_{-1})^-)$, and the same symbol A^- will be used to denote this extension. The decomposition (4.2) induces decompositions of the control operator $B \in \mathcal{B}(\mathbb{R}^m, X_{-1})$ and the observation operator $C \in \mathcal{B}(X_1, \mathbb{R}^p)$:

$$B^+ := \Pi B, \quad B^- := (I - \Pi)B, \quad C^+ := C|_{X^+}, \quad C^- := C|_{X_1 \cap X^-}. \tag{4.4}$$

The following simple lemma will be useful in the proof of Theorem 4.4.

LEMMA 4.2. *Assume that* A1 *holds. There exists a well-posed system* Σ^- *with generating operators* (A^-, B^-, C^-) [2] *and input-output operator* $G^- := G - G^+$, *where* G^+ *denotes the input-output operator of the* (*finite-dimensional*) *system* (A^+, B^+, C^+), *that is,* $(G^+u)(t) = \int_0^t C^+ e^{A^+(t-s)} B^+ u(s)\, ds$ *for all* $t \in \mathbb{R}_+$ *and all* $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$. *Moreover, for any* $x^0 \in X$ *and* $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$, *the output* y *of the well-posed system* (2.2) *can be written in the form*

$$y(t) = (C^-)_\Lambda \mathbf{T}^-_t (I - \Pi) x^0 + (G^- u)(t) + C^+ \Pi x(t) \quad \text{for a.a. } t \in \mathbb{R}_+, \tag{4.5}$$

where $x(t) = \mathbf{T}_t x^0 + \int_0^t \mathbf{T}_{t-s} B u(s)\, ds$ *for all* $t \in \mathbb{R}_+$. *The* Λ*-extension of* C^- *satisfies*

$$(C^-)_\Lambda z = C_\Lambda z \quad \forall\, z \in \mathrm{dom}((C^-)_\Lambda) = \mathrm{dom}(C_\Lambda) \cap X^-. \tag{4.6}$$

Proof. It is trivial that the Λ-extension of C^- satisfies (4.6). The admissibility of B and C immediately implies that B^- and C^- are admissible control and observation operators for $\mathbf{T}^-$, respectively. Defining $\mathbf{G}^+(s) := C^+(sI - A^+)^{-1}B^+$, it follows from (2.1) that

$$\begin{aligned} &\frac{1}{s - s_0}(\mathbf{G}(s) - \mathbf{G}(s_0)) - \frac{1}{s - s_0}(\mathbf{G}^+(s) - \mathbf{G}^+(s_0)) = \\ &- C^-(sI - A^-)^{-1}(s_0 I - A^-)^{-1} B^- \quad \forall\, s, s_0 \in \mathbb{C}_{\omega(\mathbf{T})},\ s \neq s_0. \end{aligned}$$

Choosing $\alpha > \omega(\mathbf{T})$ and setting $\mathbf{G}^-(s) := \mathbf{G}(s) - \mathbf{G}^+(s)$ for all $s \in \mathbb{C}_\alpha$, it is clear that $\mathbf{G}^-$ is analytic and bounded on $\mathbb{C}_\alpha$ and $\mathbf{G}^-$ satisfies

$$\frac{1}{s - s_0}\big(\mathbf{G}^-(s) - \mathbf{G}^-(s_0)\big) = -C^-(sI - A^-)^{-1}(s_0 I - A^-)^{-1} B^- \ \ \forall\, s, s_0 \in \mathbb{C}_\alpha,\ s \neq s_0.$$

Invoking a result in [5], we may now conclude that there exists a well-posed system Σ^- with generating operators (A^-, B^-, C^-) and input-output operator G^- (or, equivalently, transfer function $\mathbf{G}^-$).[3] To prove (4.5), let $x^0 \in X$ and $u \in L^2_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{R}^m)$ and note that

$$\Pi \mathbf{T}_t x^0 \in X^+ \subset X_1 \subset \mathrm{dom}(C_\Lambda) \quad \forall\, t \in \mathbb{R}_+$$

and

$$(I - \Pi)\mathbf{T}_t x^0 = \mathbf{T}^-_t (I - \Pi) x^0 \in \mathrm{dom}(C_\Lambda) \cap X^- = \mathrm{dom}((C^-)_\Lambda) \quad \text{for a.a. } t \in \mathbb{R}_+.$$

Thus, by (4.6), we may write the output $y = C_\Lambda \mathbf{T} x^0 + Gu$ in the form

$$y = (C^-)_\Lambda \mathbf{T}^- (I - \Pi) x^0 + G^- u + C^+ \mathbf{T}^+ \Pi x^0 + G^+ u. \tag{4.7}$$

[2] For (A^-, B^-, C^-) to be the generating operators of a well-posed system it is of course necessary that B^- maps into $(X^-)_{-1} = ((I - \Pi)X)_{-1}$, the extrapolation space associated with A^-. Since, by definition, B^- maps into $(I - \Pi)X_{-1} =: (X_{-1})^-$, there seems to be a difficulty. However, it is clear that the spaces $(X^-)_{-1}$ and $(X_{-1})^-$ are both completions of X^- endowed with the norm $\|\cdot\|_{-1}$. Hence there exists an isometric isomorphism $(X^-)_{-1} \to (X_{-1})^-$ whose restriction to X^- is the identity, and so we can safely identify $(X^-)_{-1}$ and $(X_{-1})^-$.

[3] Alternatively, the claim that there exists a well-posed system Σ^- with generating operators (A^-, B^-, C^-) and input-output operator G^- can be proved by direct verification of the defining properties of a well-posed system as given in, for example, [25, 27, 31].

With x given by $x(t) = \mathbf{T}_t x^0 + \int_0^t \mathbf{T}_{t-s} B u(s)\, ds$, it is clear that Πx is the state trajectory of the finite-dimensional system given by (A^+, B^+, C^+) corresponding to the initial state Πx^0 and the input function u. Therefore, $C^+\mathbf{T}^+\Pi x^0 + G^+ u = C^+\Pi x$, and (4.5) follows from (4.7). □

We recall that the linear bounded map

$$R_{t_0} : L^2([0,t_0],\mathbb{R}^m) \to X, \;\; f \mapsto \int_0^{t_0} \mathbf{T}_{t_0-s} B f(s)\, ds \tag{4.8}$$

is called the reachability operator of the well-posed system (2.2) at time t_0.

We assume, in addition to A1, that the following conditions are satisfied. Let $t_0 > 0$ be fixed and assume that $\tau > \delta \geq t_0$.

A2. The semigroup $\mathbf{T}^-$ is exponentially stable; that is, $\omega(\mathbf{T}^-) < 0$.

A3. The pair $(C^+, \mathbf{T}^+_\tau)$ is observable.

A4. The constants τ and δ and the function $w \in L^2([0,\tau-\delta],\mathbb{R})$ are such that (3.4) holds and

$$\int_0^{\tau-\delta} w(s) e^{\lambda s}\, ds \neq 0 \quad \forall\, \lambda \in \sigma(A^+). \tag{4.9}$$

A5. $\overline{\operatorname{im}}\, R_{t_0} \supset X^+$.

Remark 4.3. Of course, A2 holds if the generator A^- satisfies the spectrum-determined-growth assumption. Trivially, for A5 to hold, it is sufficient that the well-posed system (2.2) is approximately controllable in time t_0. If the function w is a nonzero constant, then it is clear that (4.9) holds if and only if

$$(\tau-\delta)\lambda \neq 2\pi i k \quad \forall\, \lambda \in \sigma(A^+),\; \forall\, k \in \mathbb{Z}\setminus\{0\}.$$

The observability condition A3 is implied by observability of the pair (C^+, A^+) and the nonpathological sampling assumption

$$\tau(\lambda-\mu) \neq 2\pi i k \quad \forall\, \lambda,\mu \in \sigma(A^+),\; \forall\, k \in \mathbb{Z}\setminus\{0\}. \tag{4.10}$$

We do not want to focus here on the issue of pathological sampling and instead refer the reader to Proposition 6.2.11 in [24] for more on this. We note that conditions (4.10) and (4.9) are "generically" satisfied in the following sense: the set of all $\tau > t_0$ for which (4.10) holds is open and dense in (t_0,∞), and, for given $\tau > \delta \geq t_0$, the set of all $w \in L^2([0,\tau-\delta],\mathbb{R})$ for which (4.9) holds is open and dense in $L^2([0,\tau-\delta],\mathbb{R})$.

The control function u generated by the sampled-data control law (3.1) depends on the initial value $x^0 \in X$ and the input function $v \in L^2_{\mathrm{loc}}(\mathbb{R}_+,\mathbb{R}^m)$. We express this dependence by writing $u = u(\cdot; x^0, v)$. It is natural to define the output $y(\cdot; x^0, v)$ of the sampled-data feedback system given by (2.2) and (3.1) to be the output of (2.2) corresponding to the initial condition x^0 and the control $u(\cdot; x^0, v)$. We are now in the position to formulate the main result of this paper.

THEOREM 4.4. *Assume that* A1–A5 *are satisfied. For every* $\varepsilon \in (0, -\omega(\mathbf{T}^-))$ *there exists* $H \in L^2([0,\delta],\mathbb{R}^{m\times p})$ *such that the following statements hold.*

(1) *The sampled-data feedback system given by* (2.2) *and* (3.1) *is exponentially stable with exponential growth* $\omega_{\mathrm{sd}} < \omega(\mathbf{T}^-) + \varepsilon < 0$.

(2) *For every* $\alpha \in [\omega(\mathbf{T}^-)+\varepsilon, 0]$ *there exists* $N \geq 1$ *such that*

$$\|y(\cdot; x^0, v)\|_{L^2_\alpha} \leq N(\|x^0\| + \|v\|_{L^2_\alpha}) \quad \forall\, x^0 \in X,\;\; \forall\, v \in L^2_\alpha(\mathbb{R}_+,\mathbb{R}^m).$$

(3) *If* $\alpha \in [\omega(\mathbf{T}^-)+\varepsilon, 0]$, $x^0 \in X$, *and* $v \in W^{1,2}_\alpha(\mathbb{R}_+, \mathbb{R}^m)$ *and there exists* $t_1 \in \mathbb{R}_+$ *such that* $\mathbf{T}_{t_1}(Ax^0 + Bv(0)) \in X$, *then* $y(\cdot; x^0, v)$ *is continuous on* $[t_1, \infty)$ *and*

$$\lim_{t\to\infty} y(t; x^0, v)e^{-\alpha t} = 0.$$

Statement (2) shows in particular that there exists $H \in L^2([0,\delta], \mathbb{R}^{m\times p})$ such that the sampled-data feedback system given by (2.2) and (3.1) is L^2_α-input-output stable.

Proof of Theorem 4.4. We define $\Delta_H \in \mathcal{B}(X)$ by setting

$$\Delta_H := \mathbf{T}_\tau + K_H C L_w, \tag{4.11}$$

where the operators $L_w \in \mathcal{B}(X, X_1)$ and $K_H \in \mathcal{B}(\mathbb{R}^p, X)$ are given by (3.5) and (3.9), respectively. It is convenient to set $\omega^- := \omega(\mathbf{T}^-)$. Let $\varepsilon \in (0, -\omega^-)$.

(1) To prove that for a suitable hold function H, $\omega_{\mathrm{sd}} < \omega^- + \varepsilon$, we note that, by Corollary 3.5, it is sufficient to show the existence of a function $H \in L^2([0,\delta], \mathbb{R}^{m\times p})$ such that $r(\Delta_H) < e^{(\omega^-+\varepsilon)\tau}$. Defining the operators

$$K_H^+ := \Pi K_H, \quad K_H^- := (I-\Pi)K_H, \quad L_w^\pm := L_w|_{X^\pm} = \int_0^{\tau-\delta} w(s)\mathbf{T}_s^\pm \, ds, \tag{4.12}$$

we have $K_H^\pm \in \mathcal{B}(\mathbb{R}^p, X^\pm)$, $L_w^+ \in \mathcal{B}(X^+)$, and $L_w^- \in \mathcal{B}(X^-, X_1 \cap X^-)$, where $X_1 \cap X^-$ is endowed with the norm $\|\cdot\|_1$. The operator Δ_H can then be written in the form

$$\Delta_H = \begin{pmatrix} \mathbf{T}_\tau^+ + K_H^+ C^+ L_w^+ & K_H^+ C^- L_w^- \\ K_H^- C^+ L_w^+ & \mathbf{T}_\tau^- + K_H^- C^- L_w^- \end{pmatrix}. \tag{4.13}$$

By A4, $\int_0^{\tau-\delta} w(s)e^{\lambda s}\, ds \neq 0$ for all $\lambda \in \sigma(A^+)$ and hence an application of Lemma 4.1 shows that the matrix $L_w^+ = \int_0^{\tau-\delta} w(s)e^{A^+ s}\, ds$ is invertible. Since L_w^+ and $\mathbf{T}_\tau^+ = e^{A^+\tau}$ commute, we have that

$$(C^+L_w^+, (L_w^+)^{-1}\mathbf{T}_\tau^+ L_w^+) = (C^+L_w^+, \mathbf{T}_\tau^+). \tag{4.14}$$

Using A3, i.e., observability of the pair $(C^+, \mathbf{T}_\tau^+)$, it follows that the pair $(C^+L_w^+, \mathbf{T}_\tau^+)$ is observable. Hence, by the pole-placement theorem for finite-dimensional systems, there exists $Q \in \mathcal{B}(\mathbb{R}^p, X^+)$ such that

$$\sigma(\mathbf{T}_\tau^+ + QC^+L_w^+) = \{0\}. \tag{4.15}$$

Denoting the canonical basis of $\mathbb{R}^p$ by $(e_1, e_2, \dots, e_p)$, it follows from the fact that $\delta \geq t_0$ (see A4) combined with assumption A5 that for every $\eta > 0$, there exist $h_1, h_2, \dots, h_p \in L^2([0,\delta], \mathbb{R}^m)$ such that

$$\sum_{j=1}^p \|R_\delta h_j - Qe_j\|^2 \leq \eta^2. \tag{4.16}$$

Setting $H := -(h_1, h_2, \dots, h_p) \in L^2([0,\delta], \mathbb{R}^{m\times p})$, it follows that

$$R_\delta h_j = K_H e_j \quad \forall\, j \in \{1, 2, \dots, p\}.$$

Therefore, invoking (4.16), we obtain that for all $z = (z_1, z_2, \dots, z_p)^T \in \mathbb{R}^p$,

$$\|K_H z - Qz\| = \left\| \sum_{j=1}^{p} z_j (K_H e_j - Q e_j) \right\| \le \sum_{j=1}^{p} \|K_H e_j - Q e_j\| \, |z_j|$$
$$\le \left(\sum_{j=1}^{p} \|K_H e_j - Q e_j\|^2 \right)^{1/2} \|z\| \le \eta \|z\|.$$

Thus, $\|K_H - Q\| \le \eta$, and so, since Q maps into X^+,

$$\|K_H^+ - Q\| = \|\Pi(K_H - Q)\| \le \|\Pi\| \eta, \tag{4.17a}$$
$$\|K_H^-\| = \|(I - \Pi)(K_H - Q)\| \le \|I - \Pi\| \eta. \tag{4.17b}$$

Using (4.13), we may write

$$\Delta_H = \begin{pmatrix} \mathbf{T}_\tau^+ + QC^+L_w^+ & QC^-L_w^- \\ 0 & \mathbf{T}_\tau^- \end{pmatrix} + \begin{pmatrix} (K_H^+ - Q)C^+L_w^+ & (K_H^+ - Q)C^-L_w^- \\ K_H^- C^+ L_w^+ & K_H^- C^- L_w^- \end{pmatrix}. \tag{4.18}$$

We denote the first operator on the right-hand side of (4.18) by Δ and the second by P_H. Obviously, by (4.15), $r(\Delta) = e^{\omega^- \tau}$. By upper semicontinuity of the spectrum (see [11], pp. 208), there exists $\gamma > 0$ such that

$$r(\Delta_H) = r(\Delta + P_H) < e^{(\omega^- + \varepsilon)\tau}, \tag{4.19}$$

provided that $\|P_H\| \le \gamma$. It follows from (4.17) that the latter can be accomplished by choosing $\eta > 0$ sufficiently small.

(2) To prove statement (2) of the theorem, choose $H \in L^2([0, \delta], \mathbb{R}^{m \times p})$ such that (4.19) holds. Choose $\nu \in (\omega^-, \omega^- + \varepsilon)$ such that $e^{\nu\tau}$ is a power bound for Δ_H. Let $x^0 \in X$, $\alpha \in (\nu, 0]$, and $v \in L^2_\alpha(\mathbb{R}_+, \mathbb{R}^m)$. Recall that the feedback control produced by the sampled-data control law (3.1) is denoted by $u(\cdot; x^0, v)$. With H_τ defined by (3.2) we have

$$u(t; x^0, v)e^{-\alpha t} = e^{-\alpha t} v(t) - e^{-\alpha(t - k\tau)} H_\tau(t - k\tau) y_k e^{-\alpha k\tau} \quad \forall\, t \in [k\tau, (k+1)\tau),\ \forall\, k \in \mathbb{N}_0.$$

In the following, the numbers $N_i > 0$ are suitable constants, depending only on α but not on x^0 and v. It follows from the above identity that

$$\int_{k\tau}^{(k+1)\tau} \|u(t; x^0, v)e^{-\alpha t}\|^2 dt \le N_1 \left(\|y_k e^{-\alpha k\tau}\|^2 + \int_{k\tau}^{(k+1)\tau} \|v(t)e^{-\alpha t}\|^2 dt \right) \quad \forall\, k \in \mathbb{N}_0. \tag{4.20}$$

Using that $e^{\nu\tau}$ is a power bound for Δ_H and that $0 \ge \alpha > \nu$, we may conclude from (3.7), (3.8), and (4.11) that

$$\sum_{k=0}^{\infty} \|x_{k,\delta} e^{-\alpha k\tau}\|^2 \le N_2 \left(\|x_{0,\delta}\|^2 + \int_0^\infty \|v(t)e^{-\alpha t}\|^2 dt \right) \tag{4.21}$$

and

$$\sum_{k=0}^{\infty} \|y_k e^{-\alpha k\tau}\|^2 \le N_3 \left(\|x_{0,\delta}\|^2 + \int_0^{\infty} \|v(t)e^{-\alpha t}\|^2 dt \right). \tag{4.22}$$

Now $y_0 = 0$, and so $u(t) = v(t)$ for all $t \in [0, \tau)$. Hence,

$$x(t; x^0, v) = \mathbf{T}_t x^0 + \int_0^t \mathbf{T}_{t-s} B v(s)\, ds \quad \forall\, t \in [0, \tau), \tag{4.23}$$

showing that

$$\|x_{0,\delta}\| = \|x(\delta; x^0, v)\| \le N_4(\|x^0\| + \|v\|_{L^2}) \le N_4(\|x^0\| + \|v\|_{L^2_\alpha}). \tag{4.24}$$

Inserting this into (4.21) and (4.22) yields

$$\sum_{k=0}^{\infty} \|x_{k,\delta} e^{-\alpha k\tau}\|^2 \le N_5(\|x^0\|^2 + \|v\|^2_{L^2_\alpha}) \tag{4.25}$$

and

$$\sum_{k=0}^{\infty} \|y_k e^{-\alpha k\tau}\|^2 \le N_6(\|x^0\|^2 + \|v\|^2_{L^2_\alpha}). \tag{4.26}$$

It follows from (4.20) and (4.26) that

$$\|u(\cdot; x^0, v)\|_{L^2_\alpha} \le N_7(\|x^0\| + \|v\|_{L^2_\alpha}). \tag{4.27}$$

To derive a similar estimate for $x(\cdot; x^0, v)$, we note that by the variations-of-parameter formula we have, for $k \in \mathbb{N}$ and $t \in [0, \tau)$,

$$\begin{aligned} x(k\tau + t; x^0, v) = \mathbf{T}_{t+\tau-\delta} x_{k-1,\delta} &- \int_{k\tau}^{k\tau+t} \mathbf{T}_{k\tau+t-s} B H_\tau(s - k\tau) y_k\, ds \\ &+ \int_{(k-1)\tau+\delta}^{k\tau+t} \mathbf{T}_{k\tau+t-s} B v(s)\, ds, \end{aligned}$$

where H_τ is defined in (3.2). A change of variables leads to

$$x(k\tau + t; x^0, v) = \mathbf{T}_{t+\tau-\delta} x_{k-1,\delta} - \int_0^t \mathbf{T}_{t-s} B H_\tau(s) y_k\, ds + \int_{\delta-\tau}^t \mathbf{T}_{t-s} B v(k\tau + s)\, ds.$$

Hence,

$$\begin{aligned} \|x(k\tau + t; x^0, v) e^{-\alpha(k\tau+t)}\|^2 \le N_8 \Bigg(&\|x_{k-1,\delta} e^{-\alpha(k-1)\tau}\|^2 + \|y_k e^{-\alpha k\tau}\|^2 \\ &+ \int_{(k-1)\tau}^{(k+1)\tau} \|v(s)e^{-\alpha s}\|^2 ds \Bigg) \ \forall\, k \in \mathbb{N},\ \forall\, t \in [0, \tau), \end{aligned} \tag{4.28}$$

and so,

$$\int_{k\tau}^{(k+1)\tau} \|x(t;x^0,v)e^{-\alpha t}\|^2 dt \le N_9\Bigg(\|x_{k-1,\delta}e^{-\alpha(k-1)\tau}\|^2 + \|y_k e^{-\alpha k\tau}\|^2 + \int_{(k-1)\tau}^{(k+1)\tau} \|v(s)e^{-\alpha s}\|^2 ds\Bigg) \quad \forall\, k \in \mathbb{N}. \tag{4.29}$$

Combining this with (4.23), (4.25), and (4.26) shows that

$$\|x(\cdot;x^0,v)\|_{L^2_\alpha} \le N_{10}(\|x^0\| + \|v\|_{L^2_\alpha}). \tag{4.30}$$

Using that $\alpha > \nu > \omega^-$, we have that the weighted semigroup $t \mapsto \mathbf{T}^-_t e^{-\alpha t}$ is exponentially stable and $G^- \in \mathcal{B}(L^2_\alpha(\mathbb{R}_+,\mathbb{R}^m), L^2_\alpha(\mathbb{R}_+,\mathbb{R}^p))$. Combining this with (4.27) and (4.30), an application of (4.5) (with $u = u(\cdot;x^0,v)$, $x = x(\cdot;x^0,v)$, and $y = y(\cdot;x^0,v)$) yields the claim.

(3) Since the space of all $W^{1,2}_c([0,\delta],\mathbb{R}^{m\times p})$ is dense in $L^2([0,\delta],\mathbb{R}^{m\times p})$, an inspection of the proof of statement (1) shows that there exists $H \in W^{1,2}_c([0,\delta],\mathbb{R}^{m\times p})$ such that (4.19) holds. Choose $\nu \in (\omega^-, \omega^- + \varepsilon)$ such that $e^{\nu\tau}$ is a power bound for Δ_H. Fix $\alpha \in (\nu, 0]$. Let $x^0 \in X$ and $v \in W^{1,2}_\alpha(\mathbb{R}_+,\mathbb{R}^m)$ be such that $Ax^0 + Bv(0) \in X$. It follows from (3.1a) and (4.22) that $u(\cdot;x^0,v) \in W^{1,2}_\alpha(\mathbb{R}_+,\mathbb{R}^m)$. Denoting the output of the well-posed system Σ^- corresponding to the initial value $(I-\Pi)x^0$ and the control $u(\cdot;x^0,v)$ by y^-, we have that

$$y^- = (C^-)_\Lambda \mathbf{T}^-(I-\Pi)x^0 + G^- u(\cdot;x^0,v). \tag{4.31}$$

Since $u(0;x^0,v) = v(0)$, we may conclude that

$$\mathbf{T}^-_{t_1}\big(A^-(I-\Pi)x^0 + B^- u(0;x^0,v)\big) = (I-\Pi)\mathbf{T}_{t_1}\big(Ax^0 + Bv(0)\big) \in (I-\Pi)X = X^-.$$

An application of Proposition 2.1 to Σ^- now yields that y^- is continuous on $[t_1,\infty)$ and

$$\lim_{t\to\infty} \|y^-(t)e^{-\alpha t}\| = 0. \tag{4.32}$$

Since $v \in L^2_\alpha(\mathbb{R}_+,\mathbb{R}^m)$, it is clear that $\int_{(k-1)\tau}^{(k+1)\tau} \|v(s)e^{-\alpha s}\|^2 ds$ converges to 0 as $k\to\infty$. Furthermore, it follows from (4.25) and (4.26) that $x_{k,\delta}e^{-\alpha k\tau}$ and $y_k e^{-\alpha k\tau}$ converge to 0 as $k\to\infty$. Consequently, the right-hand side of (4.28) converges to 0 as $k\to\infty$ and therefore,

$$\lim_{t\to\infty} \|x(t)e^{-\alpha t}\| = 0. \tag{4.33}$$

Finally, by (4.31) and Lemma 4.2 (applied to the well-posed system (2.2) with control $u = u(\cdot;x^0,v)$),

$$y(\cdot;x^0,v) = y^-(t) + C^+\Pi x(\cdot;x^0,v).$$

Therefore, $y(\cdot;x^0,v)$ is continuous on $[t_1,\infty)$, and, furthermore, we may conclude from (4.32) and (4.33) that $\lim_{t\to\infty} y(t;x^0,v)e^{-\alpha t} = 0$. ∎

Remark 4.5. (1) If in Theorem 4.4 assumption A5 is replaced by the stronger assumption that $\operatorname{im} R_{t_0} \supset X^+$ (that is, every state in X^+ is reachable from 0 in time

t_0), then an inspection of the above proof shows that there exists $H \in L^2([0,\delta],\mathbb{R}^{m\times p})$ such that (i) $\omega_{\rm sd} \le \omega(\mathbf{T}^-)$ and (ii) the conclusions of statements (2) and (3) of Theorem 4.4 remain true for every $\alpha \in (\omega(\mathbf{T}^-),0]$.

(2) From a practical point of view, it is important that the "structure" of the stabilizing hold function H (the existence of which is guaranteed by Theorem 4.4) is as simple as possible. In this context, we define $S([0,\delta],\mathbb{R}^{m\times p})$ to be the space of $\mathbb{R}^{m\times p}$-valued step functions on $[0,\delta]$ and $CPL_c([0,\delta],\mathbb{R}^{m\times p})$ to be the space of $\mathbb{R}^{m\times p}$-valued continuous piecewise affine-linear functions with support contained in the open interval $(0,\delta)$. We recall that $S([0,\delta],\mathbb{R}^{m\times p})$ and $CPL_c([0,\delta],\mathbb{R}^{m\times p})$ are dense in $L^2([0,\delta],\mathbb{R}^{m\times p})$. Moreover, it is clear that $CPL_c([0,\delta],\mathbb{R}^{m\times p}) \subset W_c^{1,2}([0,\delta],\mathbb{R}^{m\times p})$. Therefore an inspection of the proof of Theorem 4.4 shows that, for every $\varepsilon \in (0,-\omega(\mathbf{T}^-)$, there exist

(i) $H \in S([0,\delta],\mathbb{R}^{m\times p})$ such that statements (1) and (2) of Theorem 4.4 hold;

(ii) $H \in CPL_c([0,\delta],\mathbb{R}^{m\times p})$ such that statements (1)–(3) of Theorem 4.4 hold.

It follows from [18, 30] that assumptions A1 and A2 are necessary conditions for the stabilization of (2.2) by any of the commonly used sampled-data feedback designs including the control law (3.1) (see [18, 30]). In this context the following proposition is of interest.

PROPOSITION 4.6. *Let $\tau > \delta > 0$, $H \in L^2([0,\delta],\mathbb{R}^{m\times p})$, and $w \in L^2([0,\tau-\delta],\mathbb{R})$. Assume that* (3.4) *holds. If the sampled-data feedback system given by* (2.2) *and* (3.1) *is exponentially stable, then conditions* A1–A4 *hold, and if the semigroup $\mathbf{T}$ is analytic, then* A5 *holds also.*

Proof. Assume that the sampled-data feedback system given by (2.2) and (3.1) is exponentially stable. It follows from [30] that A1 and A2 hold. We claim that the pair $(C^+L_w^+,\mathbf{T}_\tau^+)$ is observable. Suppose not; then we can find $z \in X^+$, $z \neq 0$, and $\zeta \in \mathbb{C}$ with $|\zeta| \ge 1$ so that

$$\mathbf{T}_\tau^+ z = \zeta z \qquad \text{and} \qquad C^+L_w^+ z = 0.$$

Now choose $z^0 \in X^+$ such that $z = \mathbf{T}_\delta^+ z^0$. We consider the state trajectory $x(\cdot;x^0,0)$ of the sampled-data feedback system corresponding to the initial state

$$x^0 := \begin{pmatrix} z^0 \\ 0 \end{pmatrix}$$

and the external input function $v = 0$. Then, using (4.13),

$$x(k\tau+\delta;x^0,0) = x_{k,\delta} = \Delta_H^k x_{0,\delta} = \Delta_H^k \mathbf{T}_\delta x^0 = \Delta_H^k \begin{pmatrix} \mathbf{T}_\delta^+ z^0 \\ 0 \end{pmatrix} = \Delta_H^k \begin{pmatrix} z \\ 0 \end{pmatrix} = \zeta^k \begin{pmatrix} z \\ 0 \end{pmatrix}.$$

Since $z \neq 0$, we may conclude that $x(k\tau+\delta;x^0,0)$ does not converge to 0 as $k \to \infty$, yielding a contradiction to the exponential stability of the sampled-data feedback system. Hence the pair $(C^+L_w^+,\mathbf{T}_\tau^+)$ is observable. To show that A3 and A4 hold, let $\mathcal{O}_L$ and $\mathcal{O}$ be the observability matrices for the pairs $(C^+L_w^+,\mathbf{T}_\tau^+)$ and $(C^+,\mathbf{T}_\tau^+)$, respectively. Since L_w^+ and $\mathbf{T}_\tau^+ = e^{A^+\tau}$ commute, it follows that

$$\mathcal{O}_L = \mathcal{O}\,L_w^+.$$

If (4.9) fails to hold, then, by Lemma 4.1, L_w^+ is singular, implying that $\mathcal{O}_L$ loses rank. If A3 fails to hold, then $(C^+,\mathbf{T}_\tau^+)$ is not observable and again $\mathcal{O}_L$ will lose rank. In both cases $(C^+L_w^+,\mathbf{T}_\tau^+)$ will not be observable, which is impossible. Therefore both A3 and A4 must hold.

To complete the proof we just need to show that A5 also holds if $\mathbf{T}$ is analytic. Define the operator $B_\tau^+ : \mathbb{R}^p \to X^+$ by

$$B_\tau^+ z = \int_0^\tau \mathbf{T}_{\tau-s}^+ B^+ H_\tau(s) z \, ds \quad \forall\, z \in \mathbb{R}^p,$$

where H_τ is defined in (3.2). It follows from [30] that the pair $(\mathbf{T}_\tau^+, B_\tau^+)$ is controllable. A routine argument based on the Hautus criterion for controllability then shows that the pair (A^+, B^+) is also controllable. Finally, an application of Proposition 1.2 in [19] yields that condition A5 is satisfied. □

5. Example. We will illustrate Theorem 4.4 with a standard model for an Euler–Bernoulli beam with structural damping (see Chen and Russell [3]). Let $z(\xi, t)$ be the lateral deflection of a beam, where $\xi \in [0, 1]$ and $t > 0$ denote space and time, respectively. We assume that the flexural rigidity EI and the mass density per unit length m are both constant. We normalize so that $EI/m = 1$. The Euler–Bernoulli beam with structural damping is described by the following fourth-order partial differential equation

$$z_{tt}(\xi, t) - 2\gamma z_{t\xi\xi}(\xi, t) + z_{\xi\xi\xi\xi}(\xi, t) = 0, \tag{5.1}$$

where $\gamma \in (0, 1)$ denotes the damping constant. We assume that the beam is hinged at $\xi = 0$ and has a freely sliding clamped end at $\xi = 1$, with shear (also known as lateral) force $u(t)$ at $\xi = 1$:

$$z(0, t) = 0, \qquad z_{\xi\xi}(0, t) = 0, \tag{5.2a}$$

$$z_\xi(1, t) = 0, - z_{\xi\xi\xi}(1, t) = u(t). \tag{5.2b}$$

For this system we consider a standard observation, the velocity at $\xi = 1$:

$$y(t) = z_t(1, t). \tag{5.3}$$

The applicability of our considerations below to other boundary conditions is briefly discussed in Remark 5.1 at the end of this section.

Our first aim is to represent the controlled and observed partial differential equation given by (5.1)–(5.3) as an abstract well-posed system of the form (2.2). We write $L^2(0, 1)$ and $W^{q,2}(0, 1)$, respectively, in place of the more cumbersome $L^2([0, 1], \mathbb{R})$ and $W^{q,2}([0, 1], \mathbb{R})$. Let $A_0 : \mathrm{dom}(A_0) \subset L^2(0, 1) \to L^2(0, 1)$ be given by

$$\begin{aligned} &A_0 f = d^4 f / d\xi^4, \\ &\mathrm{dom}(A_0) = \{f \in W^{4,2}(0, 1) : f(0) = 0,\ f''(0) = 0,\ f'(1) = 0,\ f'''(1) = 0\}. \end{aligned}$$

The operator A_0 is closed, bijective, self-adjoint, and coercive and has compact resolvent. The numbers $(-\pi/2 + \pi k)^4$, where $k \in \mathbb{N}$, are the eigenvalues of A_0 with associated eigenvectors e_k given by

$$e_k(\xi) = \sqrt{2} \sin((-\pi/2 + \pi k)\xi), \quad k \in \mathbb{N}.$$

The family $(e_k)_{k \in N}$ forms an orthonormal basis of $L^2(0, 1)$. Moreover,

$$A_0^{1/2} f = -f'', \quad \mathrm{dom}(A_0^{1/2}) = \{f \in W^{2,2}(0, 1) : f(0) = 0,\ f'(1) = 0\}.$$

Let $X := \mathrm{dom}(A_0^{1/2}) \times L^2(0,1)$. Endowed with the inner product

$$\langle (x_1, x_2)^T, (y_1, y_2)^T \rangle := \langle A_0^{1/2} x_1, A_0^{1/2} y_1 \rangle_{L^2} + \langle x_2, y_2 \rangle_{L^2},$$

X becomes a Hilbert space. Defining the operator

$$A = \begin{pmatrix} 0 & I \\ -A_0 & -2\gamma A_0^{1/2} \end{pmatrix}, \quad \mathrm{dom}(A) = \mathrm{dom}(A_0) \times \mathrm{dom}(A_0^{1/2}), \tag{5.4}$$

(5.1) and (5.2) (with $u = 0$) can be written in the form $\dot{x} = Ax$, where $x(t) = (z(\cdot, t), z_t(\cdot, t))^T$. The eigenvalues of A are given by

$$\lambda_{\pm k} = (-\gamma \pm i\sqrt{1-\gamma^2})(-\pi/2 + \pi k)^2, \quad k \in \mathbb{N}, \tag{5.5}$$

with associated eigenvectors

$$f_{\pm k} = \frac{\sqrt{2}}{1 - e^{\mp 2i\varphi}} \begin{pmatrix} e_k/\lambda_{\pm k} \\ e_k \end{pmatrix}, \quad k \in \mathbb{N},$$

where $\varphi := \arccos(-\gamma)$, so that $e^{i\varphi} = -\gamma + i\sqrt{1-\gamma^2}$. It is a routine exercise to check that $(f_{\pm k})_{k \in \mathbb{N}}$ is a Riesz basis for X. For $k \in \mathbb{N}$, the unit vectors

$$g_{\pm k} = \frac{1}{\sqrt{2}} \begin{pmatrix} -e_k/\lambda_{\mp k} \\ e_k \end{pmatrix} \in \mathrm{dom}(A^*)$$

are eigenvectors of A^* with associated eigenvalues $\bar{\lambda}_{\pm k} = \lambda_{\mp k}$. Furthermore, introducing the set $\mathbb{Z}^* := \mathbb{Z} \setminus \{0\}$, we have that

$$\langle f_j, g_l \rangle = \begin{cases} 0, & j \neq l, \\ 1, & j = l, \end{cases}$$

i.e., $(f_j)_{j \in \mathbb{Z}^*}$ and $(g_j)_{j \in \mathbb{Z}^*}$ are biorthogonal. Consequently, A is a Riesz spectral operator (as defined in [6]) and thus can be represented in the form

$$Ax = \sum_{j \in \mathbb{Z}^*} \lambda_j \langle x, g_j \rangle f_j \quad \forall\, x \in \mathrm{dom}(A) = \left\{ x \in X : \sum_{j \in \mathbb{Z}^*} |\lambda_j|^2 |\langle x, g_j \rangle|^2 < \infty \right\};$$

moreover, $\sigma(A) = \{\lambda_j : j \in \mathbb{Z}^*\}$ and A generates a strongly continuous semigroup $\mathbf{T}$ given by

$$\mathbf{T}_t x = \sum_{j \in \mathbb{Z}^*} e^{\lambda_j t} \langle x, g_j \rangle f_j \quad \forall\, x \in X;$$

see, e.g., Theorem 2.3.5 in [6]. It follows from the location of $\sigma(A)$ combined with a standard result in semigroup theory (see, e.g., Theorem 5.2 in [16, p. 61]) that the semigroup $\mathbf{T}$ is analytic.

To write the controlled partial differential equation given by (5.1) and (5.2) in the abstract form (2.2a), we need to determine the input operator B. Moreover, in order to prove admissibility of B, we need to expand B in terms of the functions f_j. To this end it is useful to recall that the inner product on X has a continuous extension to $X_{-1} \times \mathrm{dom}(A^*)$, where $\mathrm{dom}(A^*)$ is endowed with the graph norm of

A^*. More precisely, there exists a bounded nondegenerate sesquilinear form $[\cdot,\cdot]$ on $X_{-1}\times\mathrm{dom}(A^*)$ such that $[x_1,x_2]=\langle x_1,x_2\rangle$ for all $(x_1,x_2)\in X\times\mathrm{dom}(A^*)$. The space X_{-1} may be identified with the dual of $\mathrm{dom}(A^*)$. Following the procedure outlined in [8], we obtain that

$$B=(0,\delta_1)^T, \tag{5.6}$$

where δ_1 denotes the Dirac distribution (or unit mass) with support at $\xi=1$.[4] Consequently, the controlled partial differential equation given by (5.1) and (5.2) can be written in the form (2.2a) with $x(t)=(z(\cdot,t),z_t(\cdot,t))^T$ and the operators A and B given by (5.4) and (5.6), respectively.

In order to verify that B is admissible, we first note that $(f_j)_{j\in\mathbb{Z}^*}$ is a Schauder basis of X_{-1}. Indeed, for arbitrary $x\in X_{-1}$, we have that

$$x=AA^{-1}x=A\sum_{j\in\mathbb{Z}^*}\langle A^{-1}x,g_j\rangle f_j=\sum_{j\in\mathbb{Z}^*}\langle A^{-1}x,g_j\rangle\lambda_j f_j,$$

and it is clear that the coefficients $\langle A^{-1}x,g_j\rangle\lambda_j$ in the expansion on the right-hand side are unique. It is easy to see that $\langle A^{-1}x,g_j\rangle=[x,g_j]/\lambda_j$ for $x\in X_{-1}$ and $j\in\mathbb{Z}^*$. Thus, for arbitrary $x\in X_{-1}$,

$$x=\sum_{j\in\mathbb{Z}^*}[x,g_j]f_j.$$

Since $[B,g_j]=\sin(-\pi/2+\pi|j|)=(-1)^{|j|+1}$, we obtain the following expansion for B in X_{-1}:

$$B=\sum_{j\in\mathbb{Z}^*}(-1)^{|j|+1}f_j. \tag{5.7}$$

A standard application of the Carleson measure criterion (see [8, 33]) yields that B is an admissible control operator for the semigroup $\mathbf{T}$. Since the observation (5.3) is described by the operator $C:=B^*$, we conclude that C is an admissible observation operator. From (5.5) and (5.7), it is easy to see that for any $\varepsilon>0$, $B\in\mathcal{B}(\mathbb{R},X_{-(1/4+\varepsilon)})$ and $C\in\mathcal{B}(X_{1/4+\varepsilon},\mathbb{R})$. Hence we can apply Proposition 2.2 to conclude that (A,B,C) are the generating operators of a regular well-posed system.

The semigroup generated by A has exponential growth constant $-\gamma\pi^2/4$, the real part of the rightmost eigenvalue of A. Our aim is to construct a hold function H such that the sampled-data feedback control law (3.1) with weighting $w(s)\equiv 1$ achieves closed-loop exponential growth $\omega_{\mathrm{sd}}\le-9\gamma\pi^2/4$. To this end, fix $\beta\in(-9\gamma\pi^2/4,-\gamma\pi^2/4)$. Then assumption A1 holds, the subspace X^+ of X is spanned by $\{f_{-1},f_1\}$, and $\sigma(A^+)=\sigma(A)\cap\overline{\mathbb{C}}_\beta=\{\lambda_1,\overline{\lambda}_1\}$. It is clear that $\omega(\mathbf{T}^-)=-9\gamma\pi^2/4<0$, showing that A2 holds. It is straightforward to show that $(f_j)_{j\in\mathbb{Z}^*}$ is a Schauder basis of X_1, so that $(f_j)_{j\in\mathbb{Z}^*}$ is a Schauder basis of each of the three spaces X_1, X, and X_{-1}. With respect to this basis we have that

$$A=\mathrm{diag}_{j\in\mathbb{Z}^*}(\lambda_j),\quad \mathbf{T}_t=\mathrm{diag}_{j\in\mathbb{Z}^*}(e^{\lambda_j t}),\quad B=(((-1)^{|j|+1})_{j\in\mathbb{Z}^*})^T,\quad C=(c_j)_{j\in\mathbb{Z}^*},$$

where

$$c_k=2(-1)^{k+1}/(1-e^{-2i\varphi}),\quad c_{-k}=\overline{c}_k\qquad\forall\,k\in\mathbb{N}.$$

[4] Strictly speaking, B is the operator in $\mathcal{B}(\mathbb{R},X_{-1})$ given by $Bv=v(0,\delta_1)^T$, but it is convenient to identify B and $B1=(0,\delta_1)^T$.

Furthermore,

$$A^+ = \operatorname{diag}(\dots, 0, 0, \overline{\lambda}_1, \lambda_1, 0, 0, \dots), \quad \mathbf{T}_t^+ = \operatorname{diag}(\dots, 0, 0, e^{\overline{\lambda}_1 t}, e^{\lambda_1 t}, 0, 0, \dots),$$

$$B^+ = (\dots, 0, 0, 1, 1, 0, 0, \dots)^T, \quad C^+ = (\dots, 0, 0, \overline{c}_1, c_1, 0, 0, \dots).$$

It follows in particular that assumption A3 is satisfied. Furthermore, since

$$\sum_{j \in \mathbb{Z}^*} \frac{1}{|\operatorname{Re} \lambda_j|} = 2 \sum_{j=1}^{\infty} \frac{1}{\gamma(-\pi/2 + \pi j)^2} < \infty,$$

Theorem 4.1 in [20] implies that, for any $t > 0$, there exists a unique sequence $(p_j)_{j \in \mathbb{Z}^*}$ in $L^2([0,t], \mathbb{C})$ such that

$$\int_0^t e^{\lambda_j s}\, \overline{p}_l(s)\, ds = \begin{cases} 0, & j \neq l, \\ 1, & j = l; \end{cases} \tag{5.8}$$

that is, $(e^{\lambda_j \cdot})_{j \in \mathbb{Z}^*}$ and $(p_j)_{j \in \mathbb{Z}^*}$ are biorthogonal (note that $\overline{p}_j = p_{-j}$ for all $j \in \mathbb{Z}^*$). Consequently,

$$\operatorname{im} R_{t_0} \supset X^+ \quad \forall\, t_0 \in (0, \infty), \tag{5.9}$$

where R_{t_0} is the reachability operator given by (4.8). The inclusion (5.9) shows in particular that A5 holds for every $t_0 > 0$. Since $\sigma(A^+) = \{\lambda_1, \overline{\lambda}_1\}$, condition (4.10) is satisfied, provided that

$$\tau \neq \frac{4k}{\pi \sqrt{1 - \gamma^2}} \quad \forall\, k \in \mathbb{N}. \tag{5.10}$$

Furthermore, since $w(s) \equiv 1$ and $\operatorname{Re} \lambda_1 \neq 0$, (4.9) holds for all $\tau > \delta > 0$, and therefore, we may conclude that assumption A4 is satisfied.

Choose $\tau > 0$ such that (5.10) holds and fix $\delta \in (0, \tau)$. It follows from Theorem 4.4 (combined with Remark 4.5 and (5.9)) that there exists $H \in L^2([0,\delta], \mathbb{R})$ such that the sampled-data feedback control law (3.1) with weighting $w(s) \equiv 1$ achieves closed-loop exponential growth $\omega_{\mathrm{sd}} \leq -9\gamma\pi^2/4$. We now use the construction in the proof of Theorem 4.4 to compute such a hold function H. To this end, note that the operator L_w^+ defined in (4.12) can be represented as

$$L_w^+ = \operatorname{diag}(\dots, 0, 0, \overline{\lambda}, \lambda, 0, 0, \dots), \quad \text{where } \lambda := (e^{\lambda_1(\tau - \delta)} - 1)/\lambda_1.$$

We first find $Q \in \mathcal{B}(\mathbb{C}, X^+)$ such that (4.15) holds. Since Q is of the form

$$Q = (\dots, 0, 0, q_{-1}, q_1, 0, 0, \dots)^T,$$

we do this by computing $q_{-1}, q_1 \in \mathbb{C}$ with the property that the two eigenvalues of the matrix

$$\begin{pmatrix} e^{\overline{\lambda}_1 \tau} & 0 \\ 0 & e^{\lambda_1 \tau} \end{pmatrix} + \begin{pmatrix} q_{-1} \\ q_1 \end{pmatrix} (\overline{c}_1, c_1) \begin{pmatrix} \overline{\lambda} & 0 \\ 0 & \lambda \end{pmatrix} = \begin{pmatrix} e^{\overline{\lambda}_1 \tau} + q_{-1} \overline{c}_1 \overline{\lambda} & q_{-1} c_1 \lambda \\ q_1 \overline{c}_1 \overline{\lambda} & e^{\lambda_1 \tau} + q_1 c_1 \lambda \end{pmatrix}$$

are both equal to 0. A routine calculation leads to

$$q_1 = \frac{-e^{2\lambda_1 \tau}}{(e^{\lambda_1 \tau} - e^{\overline{\lambda}_1 \tau}) c_1 \lambda} = \frac{e^{2\lambda_1 \tau} \lambda_1}{c_1 (e^{\lambda_1 \tau} - e^{\overline{\lambda}_1 \tau})(1 - e^{\lambda_1(\tau - \delta)})}, \quad q_{-1} = \overline{q}_1. \tag{5.11}$$

We now compute $h \in L^2([0,\delta],\mathbb{R})$ such that $R_\delta h = Q$, in which case (4.16) holds for every $\eta > 0$. Using (5.8) to solve $R_\delta h = Q$ for h, we find that

$$h(t) = q_1\overline{p}_1(\delta - t) + \overline{q}_1 p_1(\delta - t) \quad \forall\, t \in [0,\delta].$$

The control law (3.1) with $H = -h$ (and with $w(s) \equiv 1$) achieves closed-loop exponential growth $\omega_{\rm sd} \leq -9\gamma\pi^2/4$. It is shown in [21, section 4] how to construct the functions p_j.

Remark 5.1. If we kept the same form for the boundary control in (5.2) but modified the remaining boundary conditions to other "natural" boundary conditions, identified in [9, 21], we could go through the same process to find a "stabilizing" generalized hold function H. The only difference being that the eigenvalues and eigenvectors would be given by asymptotic formulas—see, e.g., [17] for the formulas for such a beam with one end clamped and the other end free. On the other hand, if the control appears as a bending moment force (e.g., $z_{\xi\xi}(1,t) = u(t)$), then the resulting system will not be well-posed, and our theory does not apply.

EXISTENCE OF MINIMIZERS FOR POLYCONVEX AND NONPOLYCONVEX PROBLEMS*

GIOVANNI CUPINI† AND ELVIRA MASCOLO†

Abstract. We study the existence of Lipschitz minimizers of integral functionals

$$\mathcal{I}(u) = \int_\Omega \varphi(x, \det Du(x))\, dx,$$

where Ω is an open subset of $\mathbb{R}^N$ with Lipschitz boundary, $\varphi : \Omega \times (0, +\infty) \to [0, +\infty)$ is a continuous function, and $u \in W^{1,N}(\Omega, \mathbb{R}^N)$, $u(x) = x$ on $\partial\Omega$. We consider both the cases of φ convex and nonconvex with respect to the last variable. The attainment results are obtained passing through the minimization of an auxiliary functional and the solution of a prescribed Jacobian equation.

Key words. nonpolyconvex functional, existence of minimizers, Lipschitz regularity, prescribed Jacobian equation

1. Introduction.

In this paper we consider integral functionals

$$\mathcal{I}(u) = \int_\Omega \varphi(x, \det Du(x))\, dx, \tag{1.1}$$

where Ω is a bounded open subset of $\mathbb{R}^N$ with a Lipschitz boundary, $N \geq 2$, $\varphi : \Omega \times (0, +\infty) \to [0, +\infty)$ is a continuous function, and $u \in W^{1,N}(\Omega, \mathbb{R}^N)$.

We aim at proving the existence of Lipschitz solutions to the variational problem

$$\min \left\{ \mathcal{I}(u) \,:\, u \in W^{1,N}(\Omega, \mathbb{R}^N), \quad \det Du > 0 \text{ a.e.}, \quad u(x) = x \text{ on } \partial\Omega \right\}. \tag{1.2}$$

Notice that even if a growth condition from below of the type $t^p \leq \varphi(x, t)$ (which is common in the theory of calculus of variations) is assumed, no coercivity of $\mathcal{I}$ follows in any Sobolev space, preventing us from establishing the existence of minimizers via the direct method. Nevertheless many problems of this type have a solution, and the question of fixing which conditions on φ ensure the existence of solutions is worthy of interest, as is its applications in physics, mainly in elasticity theory and in the problem of the equilibrium of gases (see [17], [5], [6], and [12]). For instance, (1.2) is the variational problem corresponding to a nonhomogeneous elastic material with reference configuration Ω whose stored energy φ is a nonnegative, continuous function depending on the position x in the reference configuration and the size of the deformation of the volume element $\det Du(x) > 0$.

It is well known that an important role is played by the convexity of φ with respect to the last variable: when φ is convex, then $\mathcal{I}$ is said to be a polyconvex functional; if not, then $\mathcal{I}$ is nonpolyconvex. The polyconvex case $\varphi = \varphi(t)$ has been studied by Dacorogna [5] and the nonpolyconvex case by Mascolo and Schianchi [14] and Cellina and Zagatti [4].

In order to solve (1.2) our strategy is the following: The first step is to look for solutions to the following problem (from now on referred to as the *auxiliary* problem)

(1.3)
$$\min\left\{\mathcal{J}(v)=\int_\Omega \varphi(x,v(x))\,dx\,:\,v\in L^1(\Omega),\quad v>0 \text{ a.e.},\quad \int_\Omega v(x)\,dx=|\Omega|\right\},$$

where $|\Omega|$ stands for the N-dimensional Lebesgue measure of Ω. Then, if v is a solution to (1.3), the second step is to solve in $W^{1,N}(\Omega)$ the boundary value problem

$$\begin{cases}\det Du(x)=v(x) & \text{for a.e. } x \text{ in } \Omega,\\ u(x)=x & \text{on } \partial\Omega.\end{cases} \tag{1.4}$$

A solution u to (1.4) is a solution to (1.2), too. In fact, if $w\in W^{1,N}(\Omega)$, $w(x)=x$ on $\partial\Omega$, then $\det Dw\in L^1(\Omega)$ and $\int_\Omega \det Dw(x)\,dx=|\Omega|$; therefore, if $\det Dw>0$ a.e., then

$$\mathcal{I}(u)=\mathcal{J}(v)\le \mathcal{J}(\det Dw)=\mathcal{I}(w)\,.$$

Following the above scheme, Mascolo in [13] proves the existence of minimizers of (1.2) for smooth domains Ω and $\varphi\in C^2(\overline{\Omega}\times(0,+\infty))$ strictly convex in the last variable.

As far as problem (1.3) is concerned, Ekeland and Temam in [8] prove a relaxation result and Ball and Knowles in [1] obtain an attainment result with the tool of the Young measures; see also Friesecke [10] for related results. The boundary value problem (1.4) may have no solution unless v is sufficiently regular. For instance, the simple continuity of v is not a sufficient condition to get Lipschitz solutions; see the counterexamples independently given by Burago and Kleiner [2] and McMullen [15]. Thus, also the regularity properties of minimizers of the auxiliary problem have to be studied. The pioneering papers on (1.4) are due to Moser [16] and Dacorogna and Moser [7]. In particular, in [7] the authors prove that if v is in $C^{k,\alpha}(\overline{\Omega})$, $k\ge 0$, and $\partial\Omega\in C^{k+3,\alpha}$, then there exists a diffeomorphism of class $C^{k+1,\alpha}(\overline{\Omega})$ solution to (1.4). Later results are due to Rivière and Ye, who prove in [18, Theorem 4] the existence of a bi-Lipschitz homeomorphism u solution to (1.4) under less restrictive assumptions on Ω with v satisfying a Dini-type continuity property. In [19] Ye proves existence results in the framework of the Sobolev spaces.

The plan of the paper is the following. In section 2 we introduce a class of open sets, invariant under bi-Lipschitz homeomorphisms, which is slightly larger than that of open sets with Lipschitz boundaries; see Definition 2.1. In Theorem 2.4 we state the existence of Lipschitz solutions to (1.4) with Ω in this class of open sets and Hölder continuous datum v. It is a variant of the above-cited Theorem 4 in [18], and in the appendix we give the details of the proof. In section 3 we deal with polyconvex functionals. We consider the class of functions φ strictly convex in the last variable satisfying, as a substitute for the growth conditions,

$$\lim_{t\to 0^+} D_t\varphi(x,t)=\lambda_0 \text{ with } \lambda_0\in\mathbb{R}\cup\{-\infty\},\qquad \lim_{t\to+\infty} D_t\varphi(x,t)=+\infty, \tag{1.5}$$

uniformly with respect to x. In Proposition 3.1 we prove that a unique solution v to (1.3) exists and that v is in $L^\infty(\Omega)$. In Proposition 3.5, under more regularity assumptions on φ, we prove that v is Hölder continuous. Therefore, the Lipschitz solution u to (1.4), which exists by Theorem 2.4, is a minimizer of (1.2); see Theorem 3.6. In section 4 we deal with a function φ nonconvex with respect to t, satisfying (1.5).

Denoting φ^{**} the convex envelope of φ with respect to t, we assume that there exist $\alpha, \beta \in L^\infty(\Omega)$, $\beta(x) > \alpha(x)$, $\inf \alpha > 0$ such that for every $x \in \Omega$,

$$t \mapsto \varphi^{**}(x,t) \text{ is affine in } [\alpha(x), \beta(x)]$$

and

$$\varphi(x,\cdot) \equiv \varphi^{**}(x,\cdot) \text{ and } \varphi(x,\cdot) \text{ is strictly convex} \qquad \text{in } (0,\alpha(x)] \text{ and } [\beta(x), +\infty).$$

Under these assumptions in Theorem 4.1 we prove the existence of a bounded solution v to the auxiliary problem (1.3). In section 5 under regularity assumptions on φ we get that v is piecewise Hölder continuous; see Theorem 5.2. In section 6 first we prove that if in (1.4) the datum v is piecewise Hölder continuous, there exists a Lipschitz solution; see Proposition 6.2. Then, solving (1.4) with v the piecewise Hölder continuous solution to the auxiliary problem, in Theorems 6.3 and 6.4 we get a Lipschitz continuous minimizer of functional (1.1). In section 7 we consider special classes of nonpolyconvex functionals. First we consider the class of functionals with a nonconvex φ satisfying $\varphi(x,\alpha(x)) = \varphi(x,\beta(x)) = 0$. This class has been considered by Zagatti [20] (see also Celada and Perrotta [3] for the case $\varphi(x,u,t)$) with the assumption $\int_\Omega \alpha(x)\,dx < |\Omega| < \int_\Omega \beta(x)\,dx$. In [20] and [3] the attainment result is proved using different arguments: the Baire category method and the convex integration method, respectively. Theorems 7.1 and 7.2 are attainment results including the cases $\int_\Omega \alpha\,dx \geq |\Omega|$ and $\int_\Omega \beta(x)\,dx \leq |\Omega|$. Theorem 7.4 deals with a *perturbation* of these functionals; see problem (7.2). We conclude the section considering functionals with φ satisfying the structure condition $\varphi(x,t) = \tilde{\varphi}(|x|,t)$. In this case the existence of bounded radial solutions to (1.3) directly implies the existence of Lipschitz solutions to (1.4).

2. Notation and preliminary results. In the following if Ω is a measurable subset of $\mathbb{R}^N$, then $|\Omega|$ stands for its N-dimensional Lebesgue measure. We write Q in place of $(0,1)^N$ and $B_r(x)$ denotes the ball in $\mathbb{R}^N$ with center at x and radius r. If $\varphi : \Omega \times (0,+\infty) \to [0,+\infty)$, then φ^{**} is the convex envelope of φ with respect to the second variable, i.e., $t \mapsto \varphi^{**}(x,t)$ is the greatest convex function lower than $t \mapsto \varphi(x,t)$. For the sake of simplicity we write $\varphi(x,\cdot)$ instead of $t \mapsto \varphi(x,t)$,

$$D_t^- \varphi(x,s) := \lim_{t \to s^-} \frac{\varphi(x,t) - \varphi(x,s)}{t-s}, \qquad D_t^+ \varphi(x,s) := \lim_{t \to s^+} \frac{\varphi(x,t) - \varphi(x,s)}{t-s},$$

and $\partial\varphi(x,s) := \{d \in \mathbb{R} : \varphi(x,t) \geq \varphi(x,s) + d(t-s) \text{ for every } t \in (0,+\infty)\}$.

We define a class of bounded open subsets of $\mathbb{R}^N$.

DEFINITION 2.1. *We say that a bounded open set Ω of $\mathbb{R}^N$ is of class (L) if $\overline{\Omega}$ has a covering of finitely many open sets Ω_j such that for every j there exists a bi-Lipschitz homeomorphism $\psi_j : \overline{\Omega_j \cap \Omega} \to \overline{Q}$ satisfying*

(a) $\psi_j(\overline{\Omega}_j \cap \partial\Omega) = \{0\} \times [0,1]^{N-1}$, *whenever* $\overline{\Omega}_j \cap \partial\Omega$ *is not empty;*

(b) $\det D\psi_j$ *is Lipschitz continuous and there exists* $A \geq 1$ *such that* $\frac{1}{A} \leq \det D\psi_j \leq A$.

The above definition describes a larger class than that of open sets with Lipschitz boundary, i.e., with the boundary which locally is the graph of a Lipschitz function. This result can be proved in a way similar to that of Proposition A.1 in [7].

LEMMA 2.2. *If a bounded open set Ω of $\mathbb{R}^N$ has a Lipschitz boundary, then it is of class (L).*

An easy consequence of the chain rule for Lipschitz functions is that Definition 2.1 is invariant under bi-Lipschitz homeomorphisms.

LEMMA 2.3. *Let $u_0 : \mathbb{R}^N \to \mathbb{R}^N$ be a bi-Lipschitz homeomorphism, with* $\det Du_0$ *Lipschitz continuous,* $\frac{1}{A} \le \det Du_0 \le A$ *for some* A. *If* Ω *is of class* (L), *then* $u_0(\Omega)$ *is of class* (L), *too.*

On the contrary, there are examples of bounded open sets of $\mathbb{R}^N$ with Lipschitz boundary which are mapped by a bi-Lipschitz homeomorphism $u : \mathbb{R}^N \to \mathbb{R}^N$ onto sets with a not (Lipschitz) continuous boundary; see, e.g., [11, pp. 8–9]. Therefore, the converse of Lemma 2.2 is not true.

Now, we state an existence result of Lipschitz solutions to

$$\begin{cases} \det Du = f & \text{in } \Omega, \\ u(x) = x & \text{on } \partial\Omega \end{cases} \tag{2.1}$$

with f Hölder continuous.

THEOREM 2.4. *Let $\Omega \subset \mathbb{R}^N$ be a bounded connected open set of class (L). Let f be a Hölder continuous function,* $\inf f > 0$, $\int_\Omega f(x)\,dx = |\Omega|$. *Then there exists a bi-Lipschitz homeomorphism $u : \overline{\Omega} \to \overline{\Omega}$ solution to* (2.1).

A similar result is proved in [18, Theorem 4], with a weaker assumption on v, which is assumed to satisfy a Dini-type continuity property, and a regular domain Ω. In [18] the proof is given for cubes only. The proof of Theorem 2.4, based upon the application to open sets of class (L) of the partition method due to Moser [16], is in the appendix.

3. Polyconvex problems: An attainment result. In this section we consider the variational problem

$$\min\left\{\int_\Omega \psi(x, \det Du(x))\,dx \,:\, u \in W^{1,N}(\Omega, \mathbb{R}^N),\quad \det Du > 0 \text{ a.e.},\quad u(x) = x \text{ on } \partial\Omega\right\}, \tag{3.1}$$

where Ω is a bounded open subset of $\mathbb{R}^N$ with a Lipschitz boundary and $\psi : \Omega \times (0, +\infty) \to [0, +\infty)$ is a continuous function.

To get solutions to (3.1), we first consider the following variational problem:

$$\min\left\{\int_\Omega \psi(x, v(x))\,dx \,:\, v \in L^1(\Omega),\quad v > 0 \text{ a.e.},\quad \int_\Omega v(x)\,dx = a\right\},\quad a > 0. \tag{3.2}$$

As far as the problem (3.2) is concerned, the Lipschitz regularity of the boundary of Ω can be dropped.

We prove that there exists a (unique) bounded solution to (3.2) if

(H1) $t \mapsto \psi(x, t)$ is strictly convex for all $x \in \Omega$;

(H2) there exists $\lambda_0 \in \mathbb{R} \cup \{-\infty\}$ such that

$$\lim_{t \to 0^+} D_t^+ \psi(x, t) = \lambda_0, \quad \lim_{t \to +\infty} D_t^- \psi(x, t) = +\infty, \quad \text{uniformly in } x.$$

PROPOSITION 3.1. *Assume that $\psi : \Omega \times (0, +\infty) \to [0, +\infty)$ is a continuous function satisfying* (H1) *and* (H2). *Then for every $\lambda > \lambda_0$ there exists a unique $u_\lambda \in L^\infty(\Omega)$,* $\inf u_\lambda > 0$ *such that*

$$\lambda \in \partial\psi(x, u_\lambda(x)) \quad \forall\, x \in \Omega. \tag{3.3}$$

Moreover, there exists $\lambda_a > \lambda_0$ such that u_{λ_a} is the unique solution to (3.2).

Proof. We proceed as follows: At first we prove that for every $\lambda > \lambda_0$ there exists a function u_λ such that (3.3) holds. Then, we prove that u_λ is in $L^\infty(\Omega)$, $\inf u_\lambda > 0$, and there exists λ_a such that $\int_\Omega u_{\lambda_a}\,dx = a$. Thus, it turns out that u_{λ_a} is a solution to (3.2) and it is unique, because of the strict convexity of the functional.

Step 1. *The definition of u_λ.* Fixing $x \in \Omega$, we define the sets

$$C(x) := \left\{ s \in (0,+\infty) \,:\, D_t^-\psi(x,s) < D_t^+\psi(x,s) \right\}, \quad \Omega_C := \{ x \in \Omega \,:\, C(x) \neq \emptyset \}.$$

Notice that $\partial\psi(x,s) = [D_t^-\psi(x,s), D_t^+\psi(x,s)]$ for all $(x,s) \in \Omega \times (0,+\infty)$.

Suppose that $x \in \Omega \setminus \Omega_C$. From (H1) and the definition of Ω_C, the function $D_t\psi(x,\cdot) : (0,+\infty) \to (\lambda_0,+\infty)$ is well defined, continuous, and strictly increasing. Moreover, it is a surjective function because of (H2). Let $u(x,\cdot)$ be its inverse function, i.e., $u(x,\cdot) : (\lambda_0,+\infty) \to (0,+\infty)$ is such that $u(x,\lambda)$ (from now on denoted by $u_\lambda(x)$) is the unique positive number such that $\lambda = D_t\psi(x,u_\lambda(x))$. $u(x,\cdot)$ is a well defined, strictly increasing, and continuous function.

Now let us consider $x \in \Omega_C$. From (H1), $C(x)$ is (at most) a countable set, so that we denote $C(x) = \{t_n(x)\}_{n\in J(x)}$, where $J(x) \subseteq \mathbb{N}$. As in the above case, if $\lambda \notin \cup_{n\in J(x)}\partial\psi(x,t_n(x))$, we define $u_\lambda(x)$ as the unique positive number such that $D_t\psi(x,u_\lambda(x)) = \lambda$. If instead $\lambda \in \partial\psi(x,t_n(x))$ for some $n \in J(x)$, then we set $u_\lambda(x) = t_n(x)$. Notice that if $u_\lambda(x)$ is chosen greater (less) than $t_n(x)$, then $\lambda < D_t^-\psi(x,u_\lambda(x))$ ($\lambda > D_t^+\psi(x,u_\lambda(x))$). It is easy to prove that for each $x \in \Omega_C$ the function $u(x,\cdot) : (\lambda_0,+\infty) \to (0,+\infty)$ is well defined, increasing, and continuous.

Thus, $u_\lambda : \Omega \to (0,+\infty)$ is the unique function satisfying (3.3) and it is measurable, since

$$\{ x \in \Omega \,:\, u_\lambda(x) < t \} = \left\{ x \in \Omega \,:\, D_t^-\psi(x,t) > \lambda \right\}$$

and $D_t^-\psi(x,t) = \sup_{h<0}(\psi(x,t+h)-\psi(x,t))/h$. By the second limit in (H2) for every $\lambda > \lambda_0$ there exists $R > 0$ such that $D_t^-\psi(x,R) > \lambda$ for every $x \in \Omega$, which implies $u_\lambda(x) < R$ for every $x \in \Omega$. In fact, if $u_\lambda(x) \geq R$ for some x, then by the convexity of ψ with respect to the second variable it would be $D_t^-\psi(x,R) \leq D_t^-\psi(x,u_\lambda(x))$ and by (3.3) we would obtain $D_t^-\psi(x,R) \leq \lambda$, which is a contradiction. Thus, u_λ is in $L^\infty(\Omega)$. The first limit in (H2) implies that for each $\lambda > \lambda_0$ there exists $c(\lambda) > 0$ such that $\sup_{y\in\Omega} D_t^+\psi(y,t) < \lambda$ for every $t < c(\lambda)$. Therefore, it cannot be $u_\lambda(x) < c(\lambda)$, because $\lambda \leq D_t^+\psi(x,u_\lambda(x))$, so that $\inf u_\lambda > 0$.

Step 2. *The definition of λ_a.* Define $\Psi : (\lambda_0,+\infty) \to (0,+\infty)$, $\Psi(\lambda) := \int_\Omega u_\lambda(x)\,dx$, where $u_\lambda(x) = u(x,\lambda)$ is defined as in Step 1. By the monotonicity of u with respect to λ, Ψ is increasing. It holds true that $\lim_{\lambda\to\lambda_0^+} u_\lambda(x) = 0$. In fact, suppose that $\lim_{\lambda\to\lambda_0^+} u_\lambda(x) = \delta(x) > 0$. By (H1), the first limit in (H2), and (3.3), we get

$$\lambda_0 < D_t^-\psi(x,\delta(x)) \leq D_t^-\psi(x,u_\lambda(x)) \leq \lambda\,.$$

Therefore, letting λ go to λ_0^+ we get a contradiction. Analogously it can be proved that $\lim_{\lambda\to+\infty} u_\lambda(x) = +\infty$. Hence,

$$\lim_{\lambda\to\lambda_0^+} \Psi(\lambda) = 0, \quad \lim_{\lambda\to+\infty} \Psi(\lambda) = +\infty. \tag{3.4}$$

From the previous step $\lambda \mapsto u_\lambda(x)$ is continuous and increasing for all x and $u_\lambda \in L^\infty(\Omega)$ for all λ, and therefore Ψ is a continuous function. Thus, there exists $\lambda_a > \lambda_0$

such that $\Psi(\lambda_a) = a$. We claim that u_{λ_a} is a solution to (3.2). In fact, from (H1) and (3.3) for every $w \in L^1(\Omega)$ such that $w > 0$ and $\int_\Omega w(x)\,dx = a$, we have that

$$\psi(x, w(x)) \geq \psi(x, u_{\lambda_a}(x)) + \lambda_a\big(w(x) - u_{\lambda_a}(x)\big) \quad \forall\, x \in \Omega.$$

Thus,

$$\begin{aligned}\int_\Omega \psi(x, w(x))\,dx &\geq \int_\Omega \psi(x, u_{\lambda_a}(x))\,dx + \lambda_a \int_\Omega (w(x) - u_{\lambda_a}(x))\,dx \\ &= \int_\Omega \psi(x, u_{\lambda_a}(x))\,dx\,. \qquad \square\end{aligned}$$

REMARK 3.2. *The growth conditions*

$$\lim_{t\to 0^+} \inf_{y\in\Omega} \psi(y,t) = +\infty\,, \quad \lim_{t\to+\infty} \inf_{y\in\Omega} \frac{\psi(y,t)}{t} = +\infty$$

imply (H2). *If the first limit in* (H2) *is not uniform with respect to* x, *then maybe* $\inf u_\lambda = 0$. *Moreover, the proof of Proposition* 3.1 *works also if we replace* $\lim_{t\to+\infty} D_t^- \psi(x,t) = +\infty$ *with the more general*

$$\lim_{t\to+\infty} D_t^- \psi(x,t) = \lambda_\infty, \qquad \lambda_\infty \in \mathbb{R} \cup \{+\infty\}.$$

It is easy to prove the following refinement of Proposition 3.1.

PROPOSITION 3.3. *Let* $\psi : \Omega \times (0,+\infty) \to [0,+\infty)$ *be a continuous function, differentiable with respect to the last variable,* $D_t\psi \in C(\Omega \times (0,+\infty))$. *If* (H1) *and* (H2) *hold, then the functions* u_λ *in Proposition* 3.1 *are continuous for every* $\lambda > \lambda_0$.

Proof. For every $\lambda > \lambda_0$ let $u_\lambda \in L^\infty(\Omega)$ be as in Proposition 3.1. u_λ is lower semicontinuous. In fact, if

$$\liminf_{x\to x_0} u_\lambda(x) < \alpha < u_\lambda(x_0)\,, \tag{3.5}$$

then (H1) and (3.3) imply $D_t\psi(x_0,\alpha) < \lambda$. By continuity of $D_t\psi$ there exists $\delta > 0$ such that $D_t\psi(x,\alpha) < \lambda$ for every $x \in (x_0 - \delta, x_0 + \delta)$. Then, from (3.3) again we have that $D_t\psi(x,\alpha) < D_t\psi(x, u_\lambda(x))$ for every $x \in (x_0 - \delta, x_0 + \delta)$, which implies $\alpha < u_\lambda(x)$, in contradiction with (3.5). Analogously the upper semicontinuity of u_λ can be proved. $\square$

To get Hölder continuous solutions to (3.2) we require more regularity on ψ:

(H3) there exists $0 < \sigma \leq 1$ such that for every compact $K \subset (0,+\infty)$ and for every $t \in K$ the function $x \mapsto D_t\psi(x,t)$ is of class $C^{0,\sigma}(\Omega)$ with $[D_t\psi(\cdot,t)]_{0,\sigma} \leq k_K$;

(H4) for every $m > 0$ there exists $c_m > 0$ such that

$$\psi(x,t) \geq \psi(x,s) + D_t\psi(x,s)(t-s) + c_m|t-s|^{2+\varepsilon}$$

for every $t > s \geq m$, for every $x \in \Omega$, and for some $\varepsilon \geq 0$.

REMARK 3.4. *Assumption* (H4) *is equivalent to assuming that for every* $m > 0$ *there exists* $\tilde{c}_m > 0$ *such that*

$$D_t\psi(x,t) - D_t\psi(x,s) \geq \tilde{c}_m|t-s|^{1+\varepsilon} \quad \forall\, t > s \geq m \quad \forall\, x \in \Omega. \tag{3.6}$$

Roughly speaking, if $\psi \in C^2$ *satisfies* (H4), *then* $D_{tt}\psi$ *may vanish provided that a suitable growth near the zeros is satisfied; see* (3)(a) *below.*

Notice that if ψ_0 *satisfies* (H4) *and* $\psi_1 = \psi_1(x,t)$ *is such that* $\psi_1(x,\cdot)$ *is convex and* C^1, *then* $\psi = \psi_0 + \psi_1$ *satisfies* (H4), *too. Examples of functions* ψ_0 *satisfying* (H4) *are as follows.*

(1) $\psi_0(t) := (1+t^2)^{p/2}$, $p \geq 2$. *See* [9] *for details.*
(2) $\psi_0(x,t) := |t - a(x)|^p$ *with* $a : \Omega \to \mathbb{R}$ *and* $p \geq 2$.
(3) $\psi_0 : \overline{\Omega} \times (0,+\infty) \to [0,+\infty)$ *of class* C^2*, strictly convex with respect to* t *such that for every* x *there exist at most finitely many positive numbers* $\{s_i(x)\}$ *such that* $D_{tt}\psi_0(x, s_i(x)) = 0$ *and the following hold:*
   (a) *there exist* $\varepsilon, c > 0$ *such that* $D_{tt}\psi_0(x,t) \geq c|t - s_i(x)|^\varepsilon$ *for every* t *in a neighborhood of* $s_i(x)$*;*
   (b) *there exists* $M > 0$ *such that* $\inf\{D_{tt}\psi_0(x,t) : (x,t) \in \Omega \times [M,+\infty)\} > 0$.

PROPOSITION 3.5. *Let* $\psi : \Omega \times (0,+\infty) \to [0,+\infty)$ *be a continuous function, differentiable with respect to the last variable, satisfying* (H1)–(H4)*. Then for each* $\lambda > \lambda_0$*, the function* u_λ *in Proposition* 3.1 *is in* $C^{0,\sigma/(1+\varepsilon)}(\Omega)$*. In particular, for every* $a > 0$ *the unique solution* u_{λ_a} *to* (3.2) *is Hölder continuous.*

Proof. Fix λ and let u_λ, from now on referred to as u, be the correspondent function as described in Proposition 3.1. From the strict convexity of ψ with respect to the last variable and since $\lambda = D_t\psi(x, u(x))$ for every $x \in \Omega$ it is easy to check that u is γ-Hölder continuous with Hölder constant $[u]_\gamma$ if and only if

$$D_t\psi\big(y, u(x) + [u]_{0,\gamma}|x-y|^\gamma\big) - D_t\psi(x, u(x)) \geq 0 \quad \forall\, x, y \in \Omega. \tag{3.7}$$

Fix $x, y \in \Omega$. By (H4) and (3.6) there exist $\varepsilon \geq 0$ and $\tilde{c} > 0$ such that

$$D_t\psi(x,t) - D_t\psi(x,s) \geq \tilde{c}(t-s)^{1+\varepsilon} \quad \forall\, t > s \geq \inf u > 0 \quad \forall\, x \in \Omega. \tag{3.8}$$

Consider the compact interval $K = [\inf u, \|u\|_\infty]$ and let s and t be equal to $u(x)$ and $u(x) + (\frac{k}{\tilde{c}}|x-y|^\sigma)^{1/(1+\varepsilon)}$, respectively, with σ and k_K as in (H3). Using (3.8) and (H3) to estimate $D_t\psi(y,t) - D_t\psi(y,s)$ and $D_t\psi(y,s) - D_t\psi(x,s)$, respectively, we get

$$D_t\psi(y,t) - D_t\psi(x,s) = D_t\psi(y,t) - D_t\psi(y,s) + D_t\psi(y,s) - D_t\psi(x,s) \geq 0.$$

Then u is γ-Hölder continuous with $\gamma = \frac{\sigma}{1+\varepsilon}$.

Thus, for fixed $a > 0$, the solution u_{λ_a} to (3.2), which exists by Proposition 3.1, is Hölder continuous. ∎

Now we are ready to state an existence result of Lipschitz solutions to the polyconvex problem (3.1).

THEOREM 3.6. *Suppose that* Ω *is a bounded open subset of* $\mathbb{R}^N$ *with Lipschitz boundary and let* $\psi : \Omega \times (0,+\infty) \to [0,+\infty)$ *be a continuous function, differentiable with respect to the last variable, satisfying* (H1)–(H4)*. Then there exists a Lipschitz continuous solution to* (3.1)*.*

Proof. Set $a = |\Omega|$ and consider the variational problem (3.2). From Propositions 3.1 and 3.5 such a problem has a (unique) solution $u_{\lambda_a} \in C^{0,\gamma}(\Omega)$, $\gamma > 0$, and $\inf u_{\lambda_a} > 0$. Hence, from Theorem 2.4 there exists a bi-Lipschitz homeomorphism u solving

$$\begin{cases} \det Du = u_{\lambda_a} & \text{in } \Omega, \\ u(x) = x & \text{on } \partial\Omega, \end{cases}$$

and u is a solution to (3.1), too. ∎

4. Nonpolyconvex problems: Attainment result for the auxiliary problem. In this section we consider the variational problem

$$\min\left\{\int_\Omega \varphi(x, v(x))\,dx \,:\, v \in L^1(\Omega),\, v > 0 \text{ a.e.}, \quad \int_\Omega v(x)\,dx = a\right\}, \quad a > 0, \tag{4.1}$$

where Ω is a bounded open subset of $\mathbb{R}^N$, and $\varphi : \Omega \times (0,+\infty) \to [0,+\infty)$ is a continuous function, nonconvex with respect to the last variable t.

Let φ^{**} be the convex envelope of φ with respect to the second variable and define

$$\Omega_A := \{x \in \Omega : t \to \varphi(x,t) \text{ is not strictly convex}\}.$$

We assume that the following assumptions hold:

(K1) Ω_A is a (not empty) measurable set and there exist $\alpha, \beta \in L^\infty(\Omega_A)$, $\beta(x) > \alpha(x)$ for all x, $\inf \alpha > 0$, such that $\varphi(x,\cdot)$ and $\varphi^{**}(x,\cdot)$ both coincide and are strictly convex in $(0,\alpha(x)]$ and $[\beta(x),+\infty)$ for every $x \in \Omega_A$;

(K2) $\varphi^{**}(x,\cdot)$ is affine in $[\alpha(x),\beta(x)]$ for all $x \in \Omega_A$, i.e., for every $\alpha(x) \le t \le \beta(x)$,

$$\varphi^{**}(x,t) = h(x)t + q(x) \text{ with } \ h(x) = \frac{\varphi(x,\beta(x)) - \varphi(x,\alpha(x))}{\beta(x) - \alpha(x)};$$

(K3) there exists $\lambda_0 \in \mathbb{R} \cup \{-\infty\}$ such that

$$\lim_{t\to 0^+} D_t^+ \varphi(x,t) = \lambda_0, \quad \lim_{t\to+\infty} D_t^- \varphi(x,t) = +\infty, \quad \text{uniformly in } x.$$

THEOREM 4.1. *Assume* (K1), (K2), *and* (K3). *Then there exist* $\lambda_a > \lambda_0$ *and* $v_{\lambda_a} \in L^\infty(\Omega)$, $\inf v_{\lambda_a} > 0$ *such that*

(i) $v_{\lambda_a}(x) \notin (\alpha(x),\beta(x))$ *for every* $x \in \Omega_A$;

(ii) $\lambda_a \in \partial\varphi^{**}(x, v_{\lambda_a}(x))$ *for every* $x \in \Omega$;

(iii) $\int_\Omega v_{\lambda_a}(x)\,dx = a$.

In particular, v_{λ_a} *is a solution to* (4.1). *Moreover, if* $\Omega = B_1(0)$ *and* $\varphi(x,t) = \tilde\varphi(|x|,t)$, *then* v_{λ_a} *is a radial function.*

We postpone the proof of Theorem 4.1 to the following lemma.

LEMMA 4.2. *Let* O *be a bounded measurable subset of* $\mathbb{R}^N$. *Let* $\alpha, \beta \in L^1(O)$ *be such that* $\alpha(x) \le \beta(x)$ *for a.e.* x *and suppose*

$$\int_O \alpha(x)\,dx < \kappa < \int_O \beta(x)\,dx\,. \tag{4.2}$$

Then there exists $r > 0$ *such that* $\Theta : O \to \mathbb{R}$, $\Theta(x) := \alpha(x)$ *if* $x \in O \cap B_r(0)$ *and* $\Theta(x) := \beta(x)$ *else, satisfying* $\int_O \Theta(x)\,dx = \kappa$.

Proof. Let R be such that $O \subset B_R(0)$. Consider the functions $\theta_\rho : O \to \mathbb{R}$, $0 \le \rho \le R$, defined as follows: $\theta_0 := \beta$ and if $\rho \ne 0$, then $\theta_\rho(x) := \alpha(x)$, if $x \in O \cap B_r(0)$ and $\theta_\rho(x) := \beta(x)$ else. The continuity of $\rho \to \int_O \theta_\rho(x)\,dx$ and (4.2) imply that there exists $0 < r < R$ such that $\int_O \theta_r(x)\,dx = \kappa$. □

We are now ready to prove Theorem 4.1.

Proof of Theorem 4.1. We divide the proof into three steps. In Step 1 we define a family of functions $v_\lambda^- : \Omega \to (0,+\infty)$, $\lambda > \lambda_0$, such that

$$v_\lambda^-(x) \notin (\alpha(x),\beta(x)) \quad \forall x \in \Omega_A \quad \forall \lambda > \lambda_0 \tag{4.3}$$

and

$$\lambda \in \partial\varphi^{**}\big(x, v_\lambda^-(x)\big) \quad \forall x \in \Omega \quad \forall \lambda > \lambda_0. \tag{4.4}$$

In Step 2 we define a function v_{λ_a} satisfying (i), (ii), and (iii). Finally, in Step 3 we consider the case $\varphi(x,t) = \tilde\varphi(|x|,t)$.

Step 1. *The definition of* v_λ^-. Let us define the function $\psi : \Omega\times(0,+\infty) \to [0,+\infty)$ such that $\psi \equiv \varphi$ in $(\Omega \setminus \Omega_A) \times (0,+\infty)$ and

$$\psi(x,t) := \begin{cases} \varphi(x,t) & \text{if } x \in \Omega_A,\ 0 < t \le \alpha(x), \\ \varphi(x, t+\beta(x)-\alpha(x)), & \\ -\varphi(x,\beta(x)) + \varphi(x,\alpha(x)) & \text{if } x \in \Omega_A,\ t > \alpha(x). \end{cases} \tag{4.5}$$

(K1) and (K2) imply that for every $x \in \Omega_A$

$$D_t^-\varphi(x,\alpha(x)) \le h(x) = \frac{\varphi(x,\beta(x)) - \varphi(x,\alpha(x))}{\beta(x)-\alpha(x)} \le D_t^+\varphi(x,\beta(x)) \tag{4.6}$$

and that ψ satisfies (H1). Moreover, for every $x \notin \Omega_A$ and every $t > 0$ we have $\partial\psi(x,t) = \partial\varphi(x,t) = \partial\varphi^{**}(x,t)$. If instead $x \in \Omega_A$, then

$$\partial\psi(x,t) = \begin{cases} \partial\varphi(x,t) & \text{if } \ 0 < t < \alpha(x), \\ \partial\varphi^{**}(x,\alpha(x)) \cup \partial\varphi^{**}(x,\beta(x)) & \text{if } \ t = \alpha(x), \\ \partial\varphi(x, t+\beta(x)-\alpha(x)) & \text{if } \ t > \alpha(x). \end{cases} \tag{4.7}$$

We claim that (K3) implies that ψ satisfies (H2).

The first limit in (K3) and the assumption $\inf\alpha > 0$ imply $\lim_{t\to 0^+} D_t^+\psi(x,t) = \lambda_0$, uniformly. Let us prove that ψ satisfies the property on the second limit in (H2). Since $\alpha, \beta \in L^\infty(\Omega_A)$, then for every $x \in \Omega$ and $t > \|\alpha\|_{L^\infty(\Omega_A)}$,

$$\begin{aligned} \inf_{y\in\Omega} D_t^-\varphi(y,t) &\le \min\Big\{ \inf_{y\in\Omega_A} D_t^-\varphi(y, t+\beta(y)-\alpha(y)), \inf_{y\in\Omega\setminus\Omega_A} D_t^-\varphi(y,t)\Big\} \\ &= \inf_{y\in\Omega} D_t^-\psi(y,t) \le D_t^-\psi(x,t) \le D_t^-\varphi(x, t+\|\beta-\alpha\|_{L^\infty(\Omega_A)}) \end{aligned}$$

so that by (K3) as t goes to $+\infty$, we get

$$\lim_{t\to+\infty} \inf_{y\in\Omega} D_t^-\psi(y,t) = \lim_{t\to+\infty} D_t^-\psi(x,t) = +\infty \quad \forall x \in \Omega.$$

Since ψ satisfies the assumptions of Proposition 3.1, then for every $\lambda > \lambda_0$ there exists $u_\lambda \in L^\infty(\Omega)$, $\inf u_\lambda > 0$, satisfying (3.3). Moreover, for every $x \in \Omega_A$,

$$\begin{array}{ll} u_\lambda(x) < \alpha(x) & \text{if } \ \lambda < D_t^-\varphi(x,\alpha(x)), \\ u_\lambda(x) = \alpha(x) & \text{if } \ \lambda \in [D_t^-\varphi(x,\alpha(x)), D_t^+\varphi(x,\beta(x))], \\ u_\lambda(x) > \alpha(x) & \text{if } \ \lambda > D_t^+\varphi(x,\beta(x)). \end{array} \tag{4.8}$$

Let us define $v_\lambda^- : \Omega \to (0,+\infty)$,

$$v_\lambda^-(x) := u_\lambda(x) + (\beta(x)-\alpha(x))\chi_{\{y\in\Omega_A\,:\,h(y)<\lambda\}}(x).$$

Since $u_\lambda \in L^\infty(\Omega)$ and $\alpha, \beta \in L^\infty(\Omega_A)$, then $v_\lambda^- \in L^\infty(\Omega)$. From (3.3), (4.6), (4.7), and (4.8) if $x \in \Omega_A$, the following implications hold:

- if $\lambda < D_t^-\varphi(x,\alpha(x))$, then $v_\lambda^-(x) = u_\lambda(x) < \alpha(x)$ and $\lambda \in \partial\psi(x,u_\lambda(x)) = \partial\varphi(x,v_\lambda^-(x))$;
- if $\lambda \in [D_t^-\varphi(x,\alpha(x)), h(x)]$, then $v_\lambda^-(x) = u_\lambda(x) = \alpha(x)$ and $\lambda \in \partial\varphi^{**}(x,\alpha(x))$;
- if $\lambda \in (h(x), D_t^+\varphi(x,\beta(x))]$, then $v_\lambda^-(x) = \beta(x)$ and $\lambda \in \partial\varphi^{**}(x,\beta(x))$;
- if $\lambda > D_t^+\varphi(x,\beta(x))$, then $v_\lambda^-(x) = u_\lambda(x) + \beta(x) - \alpha(x) > \beta(x)$ and $\lambda \in \partial\psi(x,u_\lambda(x)) = \partial\varphi(x,v_\lambda^-(x))$.

Thus (4.3) holds and

$$\lambda \in \partial\varphi^{**}\big(x, v_\lambda^-(x)\big) \tag{4.9}$$

for every $x \in \Omega_A$ and $\lambda > \lambda_0$. When $x \notin \Omega_A$, the equality $v_\lambda^-(x) = u_\lambda(x)$ and (3.3) imply (4.9). Therefore, (4.4) holds true.

Step 2. *The definition of* λ_a *and* v_{λ_a}. Let us define $\Phi : (\lambda_0, +\infty) \to (0, +\infty)$,

$$\Phi(\lambda) := \int_\Omega v_\lambda^-(x)\,dx = \int_\Omega \Big(u_\lambda(x) + (\beta(x) - \alpha(x))\chi_{\{y\in\Omega_A\,:\,h(y)<\lambda\}}(x)\Big)\,dx.$$

As in the proof of (3.4) we have that $\lim_{\lambda\to\lambda_0^+}\Phi(\lambda) = 0$ and $\lim_{\lambda\to+\infty}\Phi(\lambda) = +\infty$.

For each $\lambda > \lambda_0$, define $v_\lambda^+ : \Omega \to (0, +\infty)$,

$$v_\lambda^+(x) := u_\lambda(x) + (\beta(x) - \alpha(x))\chi_{\{y\in\Omega_A\,:\,h(y)\le\lambda\}}(x).$$

For every $\mu > \lambda_0$,

$$\lim_{\lambda\to\mu^-}\Phi(\lambda) = \Phi(\mu), \quad \lim_{\lambda\to\mu^+}\Phi(\lambda) = \int_\Omega v_\mu^+(x)\,dx.$$

Thus, Φ is discontinuous at μ if and only if $|\{y \in \Omega_A\,:\,h(y) = \mu\}| > 0$.

Only one of the following cases is possible:

1. there exists $\lambda_a > \lambda_0$ such that $\Phi(\lambda_a) = a$;
2. there exists $\lambda_a > \lambda_0$ such that $\Phi(\lambda_a) < a = \lim_{\lambda\to\lambda_a^+}\Phi(\lambda)$;
3. there exists $\lambda_a > \lambda_0$ such that $\Phi(\lambda_a) < a < \lim_{\lambda\to\lambda_a^+}\Phi(\lambda)$.

Case 1. As proved in Step 1, $v_{\lambda_a}^-$ satisfies (i), (ii), and $\inf v_{\lambda_a}^- \ge \inf u_{\lambda_a} > 0$. Moreover, by definition of λ_a, (iii) holds. Thus, define $v_{\lambda_a} = v_{\lambda_a}^-$.

Case 2. As above, $v_{\lambda_a}^-$ satisfies (i), (ii), and $\inf v_{\lambda_a}^- \ge \inf u_{\lambda_a} > 0$. It is easy to check that a property analogous to (i) is satisfied by $v_{\lambda_a}^+$ and that $\inf v_{\lambda_a}^+ \ge \inf v_{\lambda_a}^- > 0$. By the very definition of $v_{\lambda_a}^+$ we have also $\int_\Omega v_{\lambda_a}^+\,dx = a$.

Let us prove that $\lambda_a \in \partial\varphi^{**}(x, v_{\lambda_a}^+(x))$ for every x. If $x \notin \Omega_A$ or if $x \in \Omega_A$ and $h(x) \ne \lambda_a$, then $v_{\lambda_a}^-(x) = v_{\lambda_a}^+(x)$ and the above inclusion follows. Suppose that $x \in \Omega_A$ and $h(x) = \lambda_a$. Then $v_{\lambda_a}^-(x) = \alpha(x) < \beta(x) = v_{\lambda_a}^+(x)$ and (K2) implies $\lambda_a \in \partial\varphi^{**}(x, \beta(x)) = \partial\varphi^{**}(x, v_{\lambda_a}^+(x))$.

We have so proved that $\lambda_a \in \partial\varphi^{**}(x, v_{\lambda_a}^+(x))$ for every $x \in \Omega$. Thus, define $v_{\lambda_a} := v_{\lambda_a}^+$.

Case 3. Define $O := \{x \in \Omega_A\,:\,\lambda_a = h(x)\}$ and $\kappa := a - \int_{\Omega\setminus O} v_{\lambda_a}^-(x)\,dx$. The assumption $\Phi(\lambda_a) < a < \lim_{\lambda\to\lambda_a^+}\Phi(\lambda)$ implies

$$\int_O \alpha(x)\,dx = \int_O v_{\lambda_a}^-(x)\,dx < \kappa < \int_\Omega v_{\lambda_a}^+(x)\,dx - \int_{\Omega\setminus O} v_{\lambda_a}^-(x)\,dx = \int_O \beta(x)\,dx.$$

From Lemma 4.2, there exists $\Theta : O \to \mathbb{R}$, $\Theta(x) \in \{\alpha(x), \beta(x)\}$ such that $\int_O \Theta(x)\,dx = \kappa$. Define $v_{\lambda_a} : \Omega \to \mathbb{R}$, $v_{\lambda_a}(x) = v_{\lambda_a}^-(x)$ if $x \notin O$ and $v_{\lambda_a}(x) = \Theta(x)$ else.

It is easy to prove that v_{λ_a} satisfies (i), (ii), (iii), and $\inf v_{\lambda_a} > 0$.

Since $\varphi \ge \varphi^{**}$, then for every $v \in L^1(\Omega)$ such that $v > 0$ a.e. and $\int_\Omega v\,dx = a$, we have that

$$\begin{aligned}\int_\Omega \varphi(x, v(x))\,dx &\ge \int_\Omega \varphi^{**}(x, v(x))\,dx \\ &\ge \int_\Omega \varphi^{**}(x, v_{\lambda_a}(x))\,dx + \lambda_a\int_\Omega (v(x) - v_{\lambda_a}(x))\,dx = \int_\Omega \varphi(x, v_{\lambda_a}(x))\,dx.\end{aligned} \tag{4.10}$$

Thus, v_{λ_a} is a solution to (4.1).

Step 3. *The case* $\varphi(x,t) = \tilde{\varphi}(|x|,t)$. Assume that Ω is the unit ball $B_1(0)$ and that φ has the radial structure $\varphi(x,t) = \tilde{\varphi}(|x|,t)$. It is easy to prove that $\varphi^{**}(x,t) = (\tilde{\varphi})^{**}(|x|,t)$ and that α, β, h are radial functions. Moreover, the sets Ω_A, $\{y \in \Omega_A : h(y) < \lambda\}$ and $\{y \in \Omega_A : h(y) = \lambda\}$ are symmetric sets with respect to the origin. If ψ is defined as in Step 1 above, then it immediately follows that $\psi(x,t) = \tilde{\psi}(|x|,t)$. Looking at the first step of the proof of Proposition 3.1, it turns out that u_λ, satisfying $\partial\psi(x, u_\lambda(x)) = \lambda$, is a radial function for all λ. All these facts allow us to conclude that whenever Cases 1 or 2 in Step 2 hold, i.e., $\Phi(\lambda_a) = a$ or $\Phi(\lambda_a) < a = \lim_{\lambda\to\lambda_a^+} \Phi(\lambda)$, respectively, then v_{λ_a} is a radial function. To prove that v_{λ_a} is radial in the third case it is sufficient to notice that the sets O, $O \cap B_r(0)$, and $O \setminus B_r(0)$ are symmetric with respect to the origin and consequently the function Θ is radial. ∎

5. Nonpolyconvex problems: Regularity result for the auxiliary problem. In this section we prove a regularity result for solutions to the nonconvex variational problem (4.1). Let Ω be a bounded open subset of $\mathbb{R}^N$ and let $\varphi : \Omega\times(0,+\infty) \to [0,+\infty)$ be a continuous function, differentiable with respect to the last variable, $D_t\varphi \in C^{0,\delta}(\Omega \times K)$, $0 < \delta \le 1$, for every compact K in $(0,+\infty)$ such that

(A1) there exist $\alpha, \beta \in C^{0,\delta}(\Omega)$, $\beta(x) > \alpha(x)$ for every x, $\inf \alpha > 0$ such that $\varphi(x,\cdot)$ and $\varphi^{**}(x,\cdot)$ both coincide and are strictly convex in $(0,\alpha(x)]$ and $[\beta(x),+\infty)$ for every $x \in \Omega$;

(A2) $t \to \varphi^{**}(x,t)$ is affine in $[\alpha(x),\beta(x)]$ for every $x \in \Omega$, i.e., for every $\alpha(x) \le t \le \beta(x)$,

$$\varphi^{**}(x,t) = h(x)t + q(x) \text{ with } \ h(x) = \frac{\varphi(x,\beta(x)) - \varphi(x,\alpha(x))}{\beta(x) - \alpha(x)}.$$

Moreover,

$$|\partial\{x : h(x) = \lambda\}| = 0 \quad \forall\, \lambda \in \mathbb{R};$$

(A3) there exists $\lambda_0 \in \mathbb{R} \cup \{-\infty\}$ such that

$$\lim_{t\to 0^+} D_t\varphi(x,t) = \lambda_0, \quad \lim_{t\to+\infty} D_t\varphi(x,t) = +\infty, \quad \text{uniformly in } x;$$

(A4) for every $m > 0$ there exists $c_m > 0$ such that

$$\varphi(x,t) \ge \varphi(x,s) + D_t\varphi(x,s)(t-s) + c_m|t-s|^{2+\varepsilon}$$

for every $s,t \ge m$ such that $s < t \le \alpha(x)$ or $\beta(x) \le s < t$ for every $x \in \Omega$ and some $\varepsilon \ge 0$.

The following result is in the same spirit of Lemma 4.2.

LEMMA 5.1. *Let O be an open set in $\mathbb{R}^N$. Let $\alpha, \beta \in L^1(O)$ be such that $\alpha(x) \le \beta(x)$ for a.e. x and suppose that*

$$\int_O \alpha(x)\,dx < \kappa < \int_O \beta(x)\,dx. \tag{5.1}$$

Then there exists a finite number of balls $B_{\rho_j}(y_j)$, $j = 1,\dots,m$, satisfying

(1) $\overline{B_{\rho_j}(y_j)} \subset\subset O$, $j = 1,\dots,m$;

(2) $\overline{B_{\rho_i}(y_i)} \cap \overline{B_{\rho_j}(y_j)} = \emptyset$ *for every* $i \ne j$;

(3) $\int_O \Theta(x)\,dx = \kappa$,

where $\Theta(x) := \alpha(x)$ *if* $x \in \cup_{1\le j\le m} B_{\rho_j}(y_j)$ *and* $\Theta(x) := \beta(x)$ *else.*

Proof. Since O is open, there exist (at most) countably many pairwise disjoint balls $\{B_{R_j}(y_j)\}_{j\in J}$ in O, and a negligible set $\mathcal{N}$ such that $O = \mathcal{N} \cup (\bigcup_{j\in J} B_{R_j}(y_j))$. Without loss of generality we assume $J = \{1, 2, \dots, m\}$ if $\operatorname{card} J = m \in \mathbb{N}$ and $J = \mathbb{N}$ if J is countable. For every $n \in J$, let us define the function $\theta_n : O \to \mathbb{R}$,

$$\theta_n(x) := \begin{cases} \alpha(x) & \text{if } x \in \displaystyle\bigcup_{1\le j\le n} B_{R_j}(y_j), \\ \beta(x) & \text{else.} \end{cases}$$

If J is finite, then (5.1) implies $\int_O \theta_m(x)\,dx < \kappa$. If $J = \mathbb{N}$, it is easy to check that $\lim_{n\to+\infty} \int_O \theta_n(x)\,dx < \kappa$; thus, there exists $m \in \mathbb{N}$ such that

$$\int_O \theta_m(x)\,dx = \int_{\cup_{1\le j\le m} B_{R_j}(y_j)} \alpha(x)\,dx + \int_{O\setminus\cup_{1\le j\le m} B_{R_j}(y_j)} \beta(x)\,dx < \kappa\,.$$

Aiming at (1) and (2), we slightly reduce the radius of the previously selected balls $\{B_{R_j}(y_j)\}_{1\le j\le m}$. This can easily be done by noticing that

$$\lim_{\varepsilon\to 0^+} \int_{\cup_{j=1}^m B_{R_j}(y_j)\setminus B_{R_j-\varepsilon}(y_j)} (\beta(x) - \alpha(x))\,dx = 0.$$

Thus, there exists $0 < \varepsilon < \min\{R_j \,:\, 1 \le j \le m\}$ such that

$$\int_{\cup_{1\le j\le m} B_{R_j-\varepsilon}(y_j)} \alpha(x)\,dx + \int_{O\setminus\cup_{1\le j\le m} B_{R_j-\varepsilon}(y_j)} \beta(x)\,dx < \kappa\,. \tag{5.2}$$

Set $R := \max\{R_j - \varepsilon \,:\, 1 \le j \le m\}$ and define $\theta : O \times [0, R] \to \mathbb{R}$, $\theta(x, 0) := \beta(x)$ and

$$\theta(x,\rho) := \begin{cases} \alpha(x) & \text{if } x \in \displaystyle\bigcup_{1\le j\le m} (B_{R_j-\varepsilon}(y_j) \cap B_\rho(y_j)), \\ \beta(x) & \text{else} \end{cases}$$

for every $\rho > 0$. From (5.2) we have that

$$\int_O \theta(x, R)\,dx < \kappa < \int_O \theta(x, 0)\,dx = \int_O \beta(x)\,dx.$$

Since $\rho \to \int_O \theta(x,\rho)\,dx$ is a continuous function, there exists $\overline{\rho}$ such that $\int_O \theta(x,\overline{\rho})\,dx = \kappa$. The claim of the theorem follows by defining $\Theta(x) := \theta(x,\overline{\rho})$ and $\rho_j := \min\{R_j - \varepsilon, \overline{\rho}\}$, $1 \le j \le m$. ∎

Let h be as in (A2). For every $\lambda > \lambda_0$ we define

$$\Omega_\lambda^+ := \{x \,:\, h(x) > \lambda\}, \quad \Omega_\lambda^- := \{x \,:\, h(x) < \lambda\}, \quad \Omega_\lambda^= := \{x \,:\, h(x) = \lambda\}. \tag{5.3}$$

Under (A1)–(A4) there exists a piecewise Hölder continuous solution to (4.1).

THEOREM 5.2. *Let* $\varphi : \Omega \times (0, +\infty) \to [0, +\infty)$ *be a continuous function, differentiable with respect to the last variable,* $D_t\varphi(x,t)$ *in* $C^{0,\delta}(\Omega \times K)$ *for every compact* $K \subset (0, +\infty)$. *Suppose that* (A1)–(A4) *hold. Then, with fixed* $a > 0$ *there exist* $\lambda_a > \lambda_0$ *and* $v_{\lambda_a} \in L^\infty(\Omega)$, $\inf v_{\lambda_a} > 0$, *satisfying the following properties:*

(i) $D_t\varphi^{**}(x, v_{\lambda_a}(x)) = \lambda_a$ *for every* $x \in \Omega$;

(ii) $\int_\Omega v_{\lambda_a}(x)\,dx = a$;
(iii) v_{λ_a} *is Hölder continuous in* $\Omega^+_{\lambda_a} \cup \Omega^-_{\lambda_a}$;
(iv) $v_{\lambda_a}(x) < \alpha(x)$ *for all* $x \in \Omega^+_{\lambda_a}$ *and* $v_{\lambda_a}(x) > \beta(x)$ *for all* $x \in \Omega^-_{\lambda_a}$;
(v) *in* $\Omega^=_{\lambda_a}$ *either* $v_{\lambda_a} \equiv \alpha$ *or* $v_{\lambda_a} \equiv \beta$ *or*

$$v_{\lambda_a}(x) = \begin{cases} \alpha(x) & \text{if } x \in \bigcup_{1\le j\le m} B_{\rho_j}(y_j), \\ \beta(x) & \text{if } x \in \Omega^=_{\lambda_a} \setminus \bigcup_{1\le j\le m} B_{\rho_j}(y_j) \end{cases} \tag{5.4}$$

with $B_{\rho_j}(y_j) \subset\subset \operatorname{int}\Omega^=_{\lambda_a}$, $j = 1,\dots,m$ *such that* $\overline{B_{\rho_i}(y_i)} \cap \overline{B_{\rho_j}(y_j)} = \emptyset$ *if* $i \neq j$.

Moreover, v_{λ_a} *is a solution to* (4.1).

Proof. Let $\psi : \Omega \times (0,+\infty) \to [0,+\infty)$ be defined as

$$\psi(x,t) := \begin{cases} \varphi(x,t) & \text{if } \ 0 < t \le \alpha(x)\,,\ x \in \Omega, \\ \varphi(x, t+\beta(x)-\alpha(x)), & \\ -\varphi(x,\beta(x)) + \varphi(x,\alpha(x)) & \text{if } \ t > \alpha(x)\,,\ x \in \Omega. \end{cases} \tag{5.5}$$

It holds true that ψ is a continuous function, differentiable with respect to the last variable, satisfying (H1)–(H4) in section 3, with possibly different constants. By Proposition 3.5 for every $\lambda > \lambda_0$, there exists u_λ such that $u_\lambda \in C^{0,\gamma}(\Omega)$ for some $0 < \gamma \le 1$, $\inf u_\lambda > 0$, and

$$D_t\psi(x, u_\lambda(x)) = \lambda \quad \forall\, x \in \Omega. \tag{5.6}$$

Moreover (see (4.6) and (4.8)),

$$u_\lambda < \alpha \text{ in } \Omega^+_\lambda, \quad u_\lambda = \alpha \text{ in } \Omega^=_\lambda, \quad u_\lambda > \alpha \text{ in } \Omega^-_\lambda. \tag{5.7}$$

Let $\Phi : (\lambda_0, +\infty) \to \mathbb{R}$ be the left-continuous function defined as

$$\Phi(\lambda) := \int_\Omega \Big(u_\lambda(x) + (\beta(x) - \alpha(x))\chi_{\Omega^-_\lambda}(x) \Big)\, dx, \quad \lambda > \lambda_0.$$

We have three different cases:

1. there exists $\lambda_a > \lambda_0$ such that $\Phi(\lambda_a) = a$;
2. there exists $\lambda_a > \lambda_0$ such that $\Phi(\lambda_a) < a = \lim_{\lambda\to\lambda_a^+} \Phi(\lambda)$;
3. there exists $\lambda_a > \lambda_0$ such that $\Phi(\lambda_a) < a < \lim_{\lambda\to\lambda_a^+} \Phi(\lambda)$.

Let us consider the first two cases: since (A1)–(A3) imply (K1)–(K3), then by proceeding as in Theorem 4.1 there exists $v_{\lambda_a} \in L^\infty(\Omega)$, $\inf v_{\lambda_a} > 0$, which satisfies (i) and (ii). Moreover, if case 1 holds, then $v_{\lambda_a} := u_{\lambda_a} + (\beta - \alpha)\chi_{\{h<\lambda_a\}}$, i.e.,

$$v_{\lambda_a} := u_{\lambda_a} \text{ in } \Omega^+_{\lambda_a}, \quad v_{\lambda_a} := \alpha \text{ in } \Omega^=_{\lambda_a}, \quad v_{\lambda_a} := u_{\lambda_a} + \beta - \alpha \text{ in } \Omega^-_{\lambda_a};$$

if instead case 2 holds, then $v_{\lambda_a} := u_{\lambda_a} + (\beta - \alpha)\chi_{\{h\le\lambda\}}$, i.e.,

$$v_{\lambda_a} := u_{\lambda_a} \text{ in } \Omega^+_{\lambda_a}, \quad v_{\lambda_a} := \beta \text{ in } \Omega^=_{\lambda_a}, \quad v_{\lambda_a} := u_{\lambda_a} + \beta - \alpha \text{ in } \Omega^-_{\lambda_a}.$$

Therefore, from the Hölder continuity of α and β, (5.6) and (5.7) it follows that v_{λ_a} satisfies (iii), (iv), and (v). Moreover, reasoning as in (4.10) we get that v_{λ_a} is a solution to (4.1).

Suppose the third case holds. We define v_{λ_a} as in the proof of Theorem 4.1, but using Lemma 5.1 instead of Lemma 4.2. Precisely, since

$$\int_{\Omega^=_{\lambda_a}} \alpha(x)\,dx < \kappa < \int_{\Omega^=_{\lambda_a}} \beta(x)\,dx$$

with

$$\kappa := a - \int_{\Omega\setminus\Omega^{=}_{\lambda_a}} \Big(u_{\lambda_a}(x) + (\beta(x)-\alpha(x))\chi_{\Omega^{-}_{\lambda_a}}(x)\Big)\,dx,$$

then from Lemma 5.1 there exist m balls $B_{\rho_j}(y_j) \subset\subset \operatorname{int}\Omega^{=}_{\lambda_a}$, $j=1,\dots,m$, $\overline{B_{\rho_i}(y_i)} \cap \overline{B_{\rho_j}(y_j)} = \emptyset$ for every $i \neq j$ such that $\Theta : \operatorname{int}\Omega^{=}_{\lambda_a} \to \mathbb{R}$,

$$\Theta := \alpha \quad \text{in } \textstyle\bigcup_{1\le j\le m} B_{\rho_j}(y_j), \qquad \Theta := \beta \quad \text{in } \operatorname{int}\Omega^{=}_{\lambda_a} \setminus \textstyle\bigcup_{1\le j\le m} B_{\rho_j}(y_j)$$

satisfies $\int_{\operatorname{int}\Omega^{=}_{\lambda_a}} \Theta(x)\,dx = \kappa$.

Define v_{λ_a} as follows:

$$v_{\lambda_a}(x) := \begin{cases} u_{\lambda_a}(x) & \text{if } x \in \Omega^{+}_{\lambda_a}, \\ \alpha(x) & \text{if } x \in \bigcup_{1\le j\le m} B_{\rho_j}(y_j), \\ \beta(x) & \text{if } x \in \Omega^{=}_{\lambda_a} \setminus \bigcup_{1\le j\le m} B_{\rho_j}(y_j), \\ u_{\lambda_a}(x) + \beta(x) - \alpha(x) & \text{if } x \in \Omega^{-}_{\lambda_a}. \end{cases}$$

We have that $v_{\lambda_a} \in L^\infty(\Omega)$, $\inf v_{\lambda_a} > 0$, and it satisfies (i)–(v). Moreover, v_{λ_a} is a solution to (4.1). ∎

6. Nonpolyconvex problems: Attainment result in a general setting. In this section we consider the variational problem

$$\min\left\{\int_\Omega \varphi(x, \det Du(x))\,dx \,:\, u \in W^{1,N}(\Omega,\mathbb{R}^N), \quad \det Du > 0 \text{ a.e., } u(x) = x \text{ on } \partial\Omega\right\}, \tag{6.1}$$

where Ω is a bounded open subset of $\mathbb{R}^N$ with Lipschitz boundary and $\varphi : \Omega \times (0,+\infty) \to [0,+\infty)$ is a nonconvex function with respect to the second variable.

Before stating an attainment result for (6.1), we need some preliminary results.

LEMMA 6.1. *Let Ω be a bounded open set with Lipschitz boundary and let $\overline{\Omega} = \cup_{i=1}^m \overline{\Omega}_i$ with $\{\Omega_i\}$ pairwise disjoint open connected sets with Lipschitz boundary.*

Consider $\alpha_i > 0$, $i = 1,\dots,m$, with $\sum_{i=1}^m \alpha_i = |\Omega|$. Then there exists a bi-Lipschitz homeomorphism $u_0 : \overline{\Omega} \to \overline{\Omega}$ such that $\det Du_0 \in C^\infty(\overline{\Omega})$, $\inf \det Du_0 > 0$, and

$$u_0(x) = x \quad \text{on } \partial\Omega, \quad |u_0(\Omega_i)| = \alpha_i, \quad i = 1,\dots,m. \tag{6.2}$$

Moreover, $u_0(\Omega_i)$ is an open set of class (L) for every i.

Proof. Fix $0 < \delta < \min\{\alpha_i/|\Omega_i| \,:\, i = 1,\dots,m\}$. For every $1 \le i \le m$ let $\eta_i \in C^\infty_c(\Omega_i)$ be such that $\int_{\Omega_i} \eta_i(x)\,dx = 1$. Define

$$f(x) = \delta + \sum_{i=1}^m (\alpha_i - \delta|\Omega_i|)\eta_i(x), \quad x \in \overline{\Omega}.$$

Hence, $f \in C^\infty(\overline{\Omega})$, $\inf f > 0$, $\int_{\Omega_i} f(x)\,dx = \alpha_i$ for every i, and $\int_\Omega f(x)\,dx = |\Omega|$. From Theorem 2.4 there exists a bi-Lipschitz homeomorphism $u_0 : \overline{\Omega} \to \overline{\Omega}$ such that

$$\det Du_0 = f \text{ in } \Omega, \qquad u_0(x) = x \text{ on } \partial\Omega.$$

Therefore,

$$|u_0(\Omega_i)| = \int_{\Omega_i} \det Du_0(x)\,dx = \int_{\Omega_i} f(x)\,dx = \alpha_i, \quad i = 1,\dots,m;$$

moreover, Lemma 2.3 implies that $u_0(\Omega_i)$ is an open set of class (L) for each i. ∎

PROPOSITION 6.2. *Let Ω and Ω_i, $i = 1, \dots, m$, be as in Lemma 6.1. Suppose that $g_i : \overline{\Omega_i} \to [c_0, +\infty)$, with $c_0 > 0$, $i = 1, \dots, m$, are Hölder continuous functions satisfying*

$$\sum_{i=1}^{m} \int_{\Omega_i} g_i(x)\, dx = |\Omega|.$$

Then there exists a Lipschitz continuous function $u : \overline{\Omega} \to \overline{\Omega}$ such that

$$u(x) = x \text{ on } \partial\Omega, \quad \det Du(x) = g_i(x) \quad \forall x \in \Omega_i \quad \forall i = 1, \dots, m. \tag{6.3}$$

Proof. By Lemma 6.1 there exists a bi-Lipschitz homeomorphism $u_0 : \overline{\Omega} \to \overline{\Omega}$ such that

$$u_0(x) = x \text{ on } \partial\Omega, \qquad |u_0(\Omega_i)| = \int_{\Omega_i} g_i(x)\, dx$$

and $u_0(\Omega_i)$ is of class (L) for each $i = 1, \dots, m$. Moreover, $f := \det Du_0$ is of class $C^\infty(\overline{\Omega})$ and $\inf f > 0$. Since $\frac{g_i}{f} \circ u_0^{-1}$ is Hölder continuous in $\overline{u_0(\Omega_i)}$ and it satisfies

$$\int_{u_0(\Omega_i)} \frac{g_i}{f} \circ u_0^{-1}(y)\, dy = \int_{\Omega_i} g_i(x)\, dx = |u_0(\Omega_i)|,$$

then from Theorem 2.4 there exists a bi-Lipschitz homeomorphism $z_i : \overline{u_0(\Omega_i)} \to \overline{u_0(\Omega_i)}$ such that

$$\begin{cases} \det Dz_i = \dfrac{g_i}{f} \circ u_0^{-1} & \text{in } u_0(\Omega_i), \\ z_i(y) = y & \text{on } \partial u_0(\Omega_i). \end{cases}$$

Thus, $u_i = z_i \circ u_0$ is a Lipschitz homeomorphism such that

$$\begin{cases} \det Du_i = g_i & \text{in } \Omega_i, \\ u_i = u_0 & \text{on } \partial\Omega_i. \end{cases}$$

Hence, the Lipschitz continuous function $u : \overline{\Omega} \to \overline{\Omega}$ such that $u(x) = u_i(x)$ for every $x \in \overline{\Omega}_i$, $i = 1, \dots, m$, satisfies (6.3). ∎

We are in position to state an existence result for the nonpolyconvex problem (6.1). The sets Ω_λ^+, Ω_λ^-, and $\Omega_\lambda^=$ are defined in (5.3).

THEOREM 6.3. *Let Ω be a bounded open subset of $\mathbb{R}^N$ with Lipschitz boundary and let $\varphi : \Omega \times (0, +\infty) \to [0, +\infty)$ be a continuous function, differentiable with respect to the last variable, $D_t\varphi \in C^{0,\delta}(\Omega \times K)$, $0 < \delta \le 1$, for every compact $K \subset (0, +\infty)$.*

Suppose that (A1)–(A4) *hold and assume that, for every $\lambda > \lambda_0$, Ω_λ^+, Ω_λ^-, and $\operatorname{int} \Omega_\lambda^=$ are either empty or connected open sets with Lipschitz boundary. Then the variational problem* (6.1) *has a Lipschitz continuous solution.*

Proof. From Theorem 5.2, applied with $a = |\Omega|$, there exist $\lambda_a > \lambda_0$ and a solution v_{λ_a} to (4.1) with $\inf v_{\lambda_a} > 0$. Throughout we write v instead of v_{λ_a}.

From Theorem 5.2 v is Hölder continuous in $\Omega_{\lambda_a}^+ \cup \Omega_{\lambda_a}^-$. If $\operatorname{int} \Omega_{\lambda_a}^=$ is empty, we get the thesis applying Proposition 6.2 with $\Omega_1 = \Omega_{\lambda_a}^+$, $\Omega_2 = \Omega_{\lambda_a}^-$, and replacing g_1 and g_2 with the continuous extension of v to $\Omega_{\lambda_a}^+$ and to $\Omega_{\lambda_a}^-$, respectively.

If $\operatorname{int}\Omega^{=}_{\lambda_a}$ is not empty, correspondingly to (v) of Theorem 5.2 we have to consider three cases.

If $v = \alpha$ in $\Omega^{=}_{\lambda_a}$, the thesis follows by applying Proposition 6.2 with $m = 3$, choosing $\Omega_1 = \Omega^{+}_{\lambda_a}$, $\Omega_2 = \Omega^{-}_{\lambda_a}$, $\Omega_3 = \operatorname{int}\Omega^{=}_{\lambda_a}$, and replacing, as above, g_1 and g_2 with the continuous extension of v to $\Omega^{+}_{\lambda_a}$ and $\Omega^{-}_{\lambda_a}$, respectively, and g_3 with α. Analogously, we proceed if $v = \beta$ in $\Omega^{=}_{\lambda_a}$, but defining $g_3 = \beta$.

Now suppose that (5.4) holds. In this case the thesis follows by Proposition 6.2 choosing $\Omega_1 = \Omega^{+}_{\lambda_a}$, $\Omega_2 = \Omega^{-}_{\lambda_a}$, $\Omega_3 = \operatorname{int}\Omega^{=}_{\lambda_a} \setminus \cup_{1\le j\le n} B_{\rho_j}(y_j)$, $\Omega_{3+i} = B_{\rho_i}(y_i)$ for every $i = 1,\dots,n$ and $g_1 = v$, $g_2 = v$, $g_3 = \beta$, $g_{3+i} = \alpha$, for every $i = 1,\dots,n$. ∎

With obvious changes in the proof above, we get the following theorem.

THEOREM 6.4. *Let Ω and φ be as in Theorem* 6.3. *Suppose that* (A1)–(A4) *hold and assume that for every $\lambda > \lambda_0$,*

$$\overline{\Omega^{+}_{\lambda}} = \bigcup_{i=1}^{h} \overline{A_i}, \quad \overline{\Omega^{-}_{\lambda}} = \bigcup_{i=h+1}^{k} \overline{A_i}, \quad \operatorname{int}\Omega^{=}_{\lambda} = \bigcup_{i=k+1}^{l} A_i \tag{6.4}$$

with A_i either empty or pairwise disjoint open connected sets with Lipschitz boundary. Then the variational problem (6.1) *has a Lipschitz continuous solution.*

REMARK 6.5. *The following are examples of sets Ω and functions $h : \Omega \to \mathbb{R}$ such that for every $\lambda \in \mathbb{R}$* (6.4) *holds with either empty or disjoint open sets $\{A_i\}$ with Lipschitz boundary:*

(a) *Ω is a bounded and convex set and h is strictly convex in Ω and constant on $\partial\Omega$;*

(b) *$\Omega = B_1(0)$ and h is a radial function, $h(x) = \tilde{h}(|x|)$, with $\tilde{h}$ piecewise monotone, i.e., there exists $0 = s_0 < s_1 < \cdots < s_m = 1$ such that $\tilde{h}|_{[s_i,s_{i+1}]}$ is monotone for all i.*

7. Nonpolyconvex problems: Some special cases. In this section we consider particular classes of the variational problem (6.1), where Ω is a bounded open subset of $\mathbb{R}^N$ with Lipschitz boundary and $\varphi : \Omega \times (0,+\infty) \to [0,+\infty)$ is a continuous function satisfying (A1) and (A2). We begin considering the case of functions φ such that h in (A2) is a constant. See [20] and [3] for related results.

THEOREM 7.1. *Let $\varphi : \Omega\times(0,+\infty) \to [0,+\infty)$ be a continuous function satisfying* (A1) *and* (A2) *with h constant. If $\int_\Omega \alpha(x)\,dx \le |\Omega| \le \int_\Omega \beta(x)\,dx$, then* (6.1) *has a Lipschitz continuous solution.*

Proof. Consider the auxiliary problem (4.1) with $a = |\Omega|$. If $\int_\Omega \alpha(x)\,dx$ is equal to $|\Omega|$, then α solves (4.1). Then from Theorem 2.4 there exists a Lipschitz homeomorphism u solution to (2.1) with $f = \alpha$. Moreover, u is a solution of (6.1). The same argument works if $\int_\Omega \beta(x)\,dx$ is equal to $|\Omega|$. Of course in this case choose $f = \beta$.

Suppose $\int_\Omega \alpha(x)\,dx < |\Omega| < \int_\Omega \beta(x)\,dx$. Then using Lemma 5.1 with $O = \Omega$, we get that a Lipschitz continuous solution u to (4.1) exists with $u \equiv \alpha$ on pairwise disjoint balls $B_{\rho_j}(y_j) \subset\subset \Omega$, $j = 1,\dots,n$, and with $u \equiv \beta$ outside these balls. The thesis follows by Proposition 6.2 with $m = n+1$, $\Omega_j = B_{\rho_j}(y_j)$, and $g_j = \alpha$ if $j = 1,\dots,m-1$ and with $\Omega_m = \Omega \setminus \bigcup_{j=1}^{n} B_{\rho_j}(y_j)$, $g_m = \beta$. ∎

THEOREM 7.2. *Let $\varphi : \Omega \times (0,+\infty) \to [0,+\infty)$ be a continuous function, differentiable with respect to the last variable, $D_t\varphi \in C^{0,\delta}(\Omega \times K)$, $0 < \delta \le 1$, for every compact $K \subset (0,+\infty)$. Suppose that* (A1), (A2) *with h constant,* (A3), *and* (A4) *hold. If $\int_\Omega \alpha(x)\,dx > |\Omega|$ or $\int_\Omega \beta(x)\,dx < |\Omega|$, then* (6.1) *has a Lipschitz continuous solution.*

Proof. Let $a = |\Omega|$. From Theorem 5.2 there exist $\lambda_a > \lambda_0$ and $v_{\lambda_a} \in L^\infty(\Omega)$ satisfying

$$v_{\lambda_a}(x) \notin (\alpha(x), \beta(x)), \quad D_t\varphi^{**}(x, v_{\lambda_a}(x)) = \lambda_a, \quad \int_\Omega v_{\lambda_a}(x)\,dx = |\Omega|. \tag{7.1}$$

(A1), (A2), and (A3) imply $h = D_t\varphi(x, \alpha(x)) = D_t\varphi(x, \beta(x))$ and the definition of $\{v_\lambda\}$ (see the proofs of Theorems 4.1 and 5.2) gives that $\lambda < h$ if and only if $v_\lambda(x) < \alpha(x)$ for all x, $\lambda > h$ if and only if $v_\lambda(x) > \beta(x)$ for all x. Therefore, if $\int_\Omega \alpha(x)\,dx > |\Omega|$, then $\lambda_a < h$ and $v_{\lambda_a}(x) < \alpha(x)$. Thus, using the notation in (5.3), $\Omega^+_{\lambda_a} = \Omega$. Analogously, if $\int_\Omega \beta(x)\,dx < |\Omega|$, then $\lambda_a > h$ and $v_{\lambda_a}(x) > \beta(x)$, so that $\Omega^-_{\lambda_a} = \Omega$. Therefore, Theorem 5.2 implies that v_{λ_a} is Hölder continuous in Ω. A Lipschitz continuous solution u to

$$\begin{cases} \det Du = v_{\lambda_a} & \text{in } \Omega, \\ u(x) = x & \text{on } \partial\Omega, \end{cases}$$

solution also to (6.1), exists because of Theorem 2.4. ∎

In Propositions 7.3 and 7.4 we deal with a variant of functionals considered above, precisely

$$\min\left\{\int_\Omega \Phi(x, \det Du(x))\,dx : u \in W^{1,N}(\Omega, \mathbb{R}^N),\ \det Du > 0 \text{ a.e.}, \quad u(x) = x \text{ on } \partial\Omega\right\} \tag{7.2}$$

with $\Phi(x,t) = \varphi(x,t) + f(x)t$.

Proposition 7.3. *Let Ω be a bounded open convex set in $\mathbb{R}^N$ and let $\varphi : \Omega \times (0, +\infty) \to [0, +\infty)$ satisfy the assumptions of Theorem 7.2 with $\lambda_0 = -\infty$ in* (A3). *Suppose that $f : \Omega \to (0, +\infty)$ is a strictly convex function, constant on $\partial\Omega$. Then there exists a Lipschitz solution to* (7.2).

Proof. It is easy to see that Φ satisfies the assumptions of Theorem 6.3. Since $\Phi^{**}(x,t) = \varphi^{**}(x,t) + f(x)t$ for every $x \in \Omega$, then in $(0, \alpha(x)]$ and in $[\beta(x), +\infty)$ we have that $\Phi(x,\cdot) = \Phi^{**}(x,\cdot)$. Moreover, for every $t \in [\alpha(x), \beta(x)]$ it holds true that $\Phi^{**}(x,t) = H(x)t + q(x)$ with $H(x) := \mu + f(x)$ and the superlevel, sublevel, and level sets of H satisfy the assumptions in Theorem 6.3. (A3) implies that $D_t\Phi(x,t) = D_t\varphi(x,t) + f(x)$ goes to $-\infty$ as $t \to -\infty$ and goes to $+\infty$ as $t \to +\infty$, uniformly with respect to x. The thesis easily follows from Theorem 6.3. ∎

From now on, Ω is the unit ball B in $\mathbb{R}^N$ centered at the origin.

Proposition 7.4. *Let $\varphi : B \times (0, +\infty) \to [0, +\infty)$ satisfy the assumptions of Theorem 7.2 with $\lambda_0 = -\infty$ in* (A3). *Let $f \in C^{0,\gamma}([0,1])$, $0 < \gamma \le 1$, $f(s) > 0$ for every s, f piecewise monotone. Then there exists a Lipschitz continuous solution to* (7.2) *with $\Phi(x,t) = \varphi(x,t) + f(|x|)t$.*

Proof. Proceeding as in the proof of Proposition 7.3, the thesis easily follows from Remark 6.5(b) and from Theorem 6.4 applied to $\Phi(x,t) = \varphi(x,t) + f(|x|)t$. ∎

Now, we deal with one more class of nonpolyconvex functionals, characterized by an integrand φ with radial structure $\varphi(x,t) = \tilde\varphi(|x|, t)$. Precisely, we deal with the variational problem

$$\min\left\{\int_B \tilde\varphi(|x|, \det Du(x))\,dx \ :\ u \in W^{1,N}(B, \mathbb{R}^N),\ \det Du > 0 \text{ a.e.},\ u(x) = x \text{ on } \partial B\right\} \tag{7.3}$$

and $\tilde{\varphi} : [0,1) \times (0,+\infty) \to [0,+\infty)$ is a continuous function.

THEOREM 7.5. *Let $\tilde{\varphi} : [0,1) \times (0,+\infty) \to [0,+\infty)$ be a continuous function satisfying the following assumptions:*

(i) *there exist $a, b \in L^\infty(0,1)$, $b(s) > a(s) > 0$ for every s, $\inf a > 0$, such that $\tilde{\varphi}(s,\cdot)$ and $\tilde{\varphi}^{**}(s,\cdot)$ both coincide and are strictly convex in $(0,a(s)]$ and $[b(s),+\infty)$ for all $s \in [0,1)$;*

(ii) *$\tilde{\varphi}^{**}(x,\cdot)$ is affine in $[a(s),b(s)]$ for all $s \in [0,1)$;*

(iii) *there exists $\lambda_0 \in \mathbb{R} \cup \{-\infty\}$ such that*

$$\lim_{t\to 0^+} D_t^+ \tilde{\varphi}(s,t) = \lambda_0, \quad \lim_{t\to+\infty} D_t^- \tilde{\varphi}(s,t) = +\infty, \quad \text{uniformly in } s.$$

Then there exists a Lipschitz solution to (7.3).

Proof. Let us define $\varphi(x,t) := \tilde{\varphi}(|x|,t)$ for every $x \in B$. Notice that $\varphi^{**}(x,t) = \tilde{\varphi}^{**}(|x|,t)$ and that assumptions (K1), (K2), and (K3) of Theorem 4.1 holds with $\Omega = \Omega_A = B$, $\alpha(x) = a(|x|)$, and $\beta(x) = b(|x|)$. Let $v \in L^\infty(B)$, $\inf v > 0$, be the radial solution of (4.1). It is a known fact (see, e.g., [15]) that there exists a bi-Lipschitz solution u to (2.1) with $f = v$ and $\Omega = B$. Thus, u is a solution to (7.3), too. ∎

Appendix. Proof of Theorem 2.4. In the following we use the arguments of the proof of Lemma 1 in [16] and the fact, proved in [18], that if $\Omega = (0,1)^N$ and f is Hölder continuous, then there exists a bi-Lipschitz homeomorphism solution to (2.1). We divide the proof into steps.

Step 1. Let Ω be a bounded open connected subset of $\mathbb{R}^N$ of class (L). Thus, there exist m open sets Ω_j such that $\overline{\Omega} \subset \cup_j \Omega_j$ and m bi-Lipschitz homeomorphisms $\psi_j : \overline{\Sigma}_j \to \overline{Q}$, with $\Sigma_j = \Omega \cap \Omega_j$ and $Q = (0,1)^N$ such that $\det D\psi_j \in \mathrm{Lip}(\overline{\Sigma}_j)$ and $\frac{1}{A} < \det D\psi_j < A$ for some $A \geq 1$. Consider a partition of unity $\{\phi_j\}_{j=1}^m$ subordinate to such a covering of $\overline{\Omega}$: $\{\phi_j\}_{j=1}^m$ is a family of smooth and nonnegative functions, $\sum_j \phi_j(x) = 1$ for every $x \in \overline{\Omega}$ and

$$\operatorname{supp} \phi_j \subset\subset \Omega_j \quad \forall\, j = 1,\dots,m. \tag{7.4}$$

Since $\Omega = \cup_{j=1}^m \Sigma_j$ and Ω is connected, we can assume that for every $k = 2,\dots,m$ there exists $\rho(k) < k$ such that $\Sigma_k \cap \Sigma_{\rho(k)}$ is not empty. Define the matrix (α_{hk}), $1 \leq h \leq m$, $2 \leq k \leq m$,

$$\alpha_{hk} = \begin{cases} 1 & \text{if } h = k, \\ -1 & \text{if } h = \rho(k), \\ 0 & \text{else.} \end{cases}$$

Each of the $m-1$ columns contains exactly one pair $+1$, -1 so that $\sum_{k=2}^m \alpha_{hk} = 0$ for every h.

Define $\eta_k \in C_c^\infty(\Sigma_k \cap \Sigma_{\rho(k)})$ such that $\int_\Omega \eta_k(x)\,dx = 1$. Let $g \in C^{0,\alpha}(\overline{\Omega})$ be such that $\int_\Omega g(x)\,dx = 0$. Define the Hölder continuous functions $g_h : \overline{\Omega} \to \mathbb{R}$, $1 \leq h \leq m$,

$$g_h := g\phi_h|_{\overline{\Omega}} - \sum_{k=2}^m \lambda_k \alpha_{hk} \eta_k,$$

where $\lambda_2,\dots,\lambda_m$ are real numbers solutions of the following system of m equations

$$\sum_{k=2}^m \lambda_k \alpha_{hk} = \int_\Omega g\phi_h\,dx, \qquad h = 1,\dots,m. \tag{7.5}$$

Since the rank of (α_{hk}) is $m-1$ and both $\sum_{h=1}^m \sum_{k=2}^m \lambda_k \alpha_{hk}$ and $\sum_{h=1}^m \int_\Omega g\phi_h\,dx$ are equal to 0, then system (7.5) is uniquely solvable.

We claim that $\operatorname{supp} g_h \subseteq \overline{\Sigma}_h$. In fact $\operatorname{supp}\ \phi_h|_{\overline{\Omega}} \subseteq \overline{\Sigma}_h$ and, since $\alpha_{hk} \neq 0$ if and only if $h = k$ or $h = \rho(k)$,

$$\operatorname{supp} \lambda_k \alpha_{hk} \eta_k \subset \Sigma_k \cap \Sigma_{\rho(k)} \subseteq \Sigma_h$$

for every $k = 2, \dots, m$. Moreover, from (7.5) there exists $M > 0$ depending on Ω, $\{\phi_j\}_j$, and $\{\eta_j\}_j$ only such that $\sup |g_h| \leq M \sup |g|$.

Step 2. Let Ω, $\{\Sigma_j\}_j$, $\{\psi_j\}_j$, $\{\phi_j\}_j$, $\{\eta_j\}_j$, m, and M be as above. Let f in (2.1) be such that $\sup |f-1| < m^{-1}M^{-1}$. Define m Hölder continuous functions g_h reasoning as in the previous step with g replaced by $f-1$. For every $j = 1, \dots, m+1$ define $f_j : \overline{\Omega} \to (0, +\infty)$,

$$f_j(x) := \begin{cases} 1 & \text{if } j = 1, \\ 1 + \sum_{h=1}^{j-1} g_h(x) & \text{if } j > 1. \end{cases}$$

In particular $f_{m+1} = f$. Notice that each f_j is a Hölder continuous function, and since $\sup |f-1| < m^{-1}M^{-1}$, then $\inf f_j > 0$. Fixed $j = 1, \dots, m$, we have that

$$f_{j+1} - f_j = 0 \quad \text{in } \overline{\Omega} \setminus \overline{\Sigma}_j, \qquad \int_\Omega f_j(x)\,dx = |\Omega|, \qquad \int_{\Sigma_j} f_{j+1}(x)\,dx = \int_{\Sigma_j} f_j(x)\,dx. \tag{7.6}$$

Define $f_j^*, f_{j+1}^* : \overline{Q} \to (0, +\infty)$,

$$f_j^* := f_j\big(\psi_j^{-1}\big) \det D\psi_j^{-1}, \quad f_{j+1}^* := f_{j+1}\big(\psi_j^{-1}\big) \det D\psi_j^{-1},$$

so that $f_j^*, f_{j+1}^* \in C^{0,\alpha}(\overline{Q})$ and $\int_Q f_j^*\,dx = \int_Q f_{j+1}^*\,dx$.

As proved in [18] there exist two bi-Lipschitz homeomorphisms $v_j, w_j : \overline{Q} \to \overline{Q}$ solutions to

$$\begin{cases} \det Dv_j = \frac{f_j^*}{\int_Q f_j^*\,dx} & \text{in } Q, \\ v_j(y) = y & \text{on } \partial Q, \end{cases} \quad \text{and} \quad \begin{cases} \det Dw_j = \frac{f_{j+1}^*}{\int_Q f_j^*\,dx} & \text{in } Q, \\ w_j(y) = y & \text{on } \partial Q, \end{cases}$$

respectively. Let us consider $\varphi_j : \overline{Q} \to \overline{Q}$, $\varphi_j(y) := (v_j^{-1} \circ w_j)(y)$. Then

$$\det D\varphi_j(y) = \det Dv_j^{-1}(w_j(y)) \det Dw_j(y) = \frac{f_{j+1}^*(y)}{f_j^*(\varphi_j(y))} \quad \forall\, y \in \overline{Q}$$

so that

$$f_j\big((\psi_j^{-1} \circ \varphi_j)(y)\big) \det D\psi_j^{-1}(\varphi_j(y)) \det D\varphi_j(y) = f_{j+1}\big(\psi_j^{-1}(y)\big) \det D\psi_j^{-1}(y) \quad \forall y \in \overline{Q}.$$

Using the invertibility of ψ_j the equality above implies that

$$f_j(u_j(x)) \det Du_j(x) = f_{j+1}(x) \quad \forall\, x \in \overline{\Sigma}_j, \tag{7.7}$$

where $u_j : \overline{\Sigma}_j \to \overline{\Sigma}_j$ is the Lipschitz continuous function defined as $u_j(x) := (\psi_j^{-1} \circ \varphi_j \circ \psi_j)(x)$.

Since $\varphi_j(\psi_j(x)) = \psi_j(x)$ for all $x \in \partial\Sigma_j$, we have that $u_j(x) = x$ for every $x \in \partial\Sigma_j$. Then $\tilde{u}_j : \overline{\Omega} \to \mathbb{R}$, $j = 1, \dots, m$,

$$\tilde{u}_j(x) := \begin{cases} u_j(x) & \text{if } x \in \overline{\Sigma}_j, \\ x & \text{else} \end{cases}$$

is Lipschitz continuous and from (7.6) and (7.7)

$$f_j(\tilde{u}_j(x)) \det D\tilde{u}_j(x) = f_{j+1}(x) \quad \forall\, x \in \overline{\Omega}.$$

Iterating this argument on j and recalling that $f_1 = 1$ and $f_{m+1} = f$, we get that $\tilde{u}_1 \circ \cdots \circ \tilde{u}_m$ is a Lipschitz solution to (2.1).

Step 3. Now we suppose that f in (2.1) satisfies $\sup |f - 1| \geq m^{-1}M^{-1}$. There exists $c_1 > 0$ and $0 < t_1 < 1$ such that $\int_\Omega c_1 f^{t_1}(x)\, dx = |\Omega|$ and $\sup |c_1 f^{t_1} - 1| < m^{-1}M^{-1}$. Applying the same arguments described in Step 2 to $g := c_1 f^{t_1} - 1$, we obtain a Lipschitz function u_1 satisfying (2.1) with f replaced by $c_1 f^{t_1}$. Applying again this procedure to $g := c_2 f^{t_2} - c_1 f^{t_1}$, with a suitable choice of c_2 and t_2 in such a way that $t_1 < t_2 \leq 1$, $\int_\Omega c_2 f^{t_2}\, dx = |\Omega|$ and $\sup |c_2 f^{t_2} - c_1 f^{t_1}| < m^{-1}M^{-1}$, we get u_2 Lipschitz solution to

$$\begin{cases} c_1 f^{t_1}(u_2) \det Du_2 = c_2 f^{t_2} & \text{in } \Omega, \\ u_2(x) = x & \text{on } \partial\Omega. \end{cases}$$

Hence, $u_1 \circ u_2$ solves (2.1) with f replaced by $c_2 f^{t_2}$. It can be proved that the exponents $\{t_i\}$ can be chosen such that in finitely many steps, say n, we get $t_n = 1$. The existence of a Lipschitz continuous solution to (2.1) follows.

ε-OPTIMAL BIDDING IN AN ELECTRICITY MARKET WITH DISCONTINUOUS MARKET DISTRIBUTION FUNCTION*

EDWARD J. ANDERSON† AND HUIFU XU‡

Abstract. This paper investigates the optimal bidding strategy (supply function) for a generator offering power into a wholesale electricity market. The model has three characteristics: the uncertainties facing the generator are described by a single probability function, namely the market distribution function; the supply function to be chosen is nondecreasing but need not be smooth; the objective function is the expected profit which can be formulated as a Stieltjes integral along the generator's supply curve. In previous work the market distribution function has been assumed smooth, but in practice this assumption may not be satisfied. This paper focuses on the case that the market distribution function is not continuous, and hence an optimal supply function may not exist. We consider a modified optimization problem and show the existence of an optimal solution for this problem. Then we show constructively how such an optimum can be approximated with an ε-optimal supply function by undercutting when the generator does not hold a hedging contract (and possibly overcutting when the generator has a hedging contract). Our results substantially extend previous work on the market distribution model.

Key words. electricity markets, discontinuous market distribution function, R-semicontinuity, ε-optimal supply function

1. Introduction.

In recent years many countries have carried out substantial restructuring of their electricity industries. Though each country has adopted its own solution, the trend has been towards increased market mechanisms, particularly at the wholesale level. It is important to understand the operation of these electricity markets, and yet the special features that are characteristic of wholesale electricity markets make this a challenging task.

We begin by sketching the fundamentals of the way that a wholesale market for electricity works. Generators compete to supply electricity to users (primarily retailers providing electricity to consumers). The price paid fluctuates as demand (and supply) varies. The price is determined through a process that is a type of sealed bid auction. In each time period each generator submits a bid, which we refer to as a supply function $S(p)$, which gives the quantity of electricity that the generator is willing to supply for any price p (strictly, this is a price per megawatt hour and the quantity is measured in megawatts). The supply function is increasing (not necessarily strictly) and often has to satisfy other restrictions imposed by the market operator. The spot price is determined from the combined supply functions of all the generators, and is such that supply at the spot price is just sufficient to meet demand. In practice this has to take account of the location of both the generators and the demand within the network, but we will ignore location effects in this paper. A generator needs to decide on the supply function to offer into the market in order to maximize profits. The

demand at any time is uncertain and the offers of other generators are also unknown.

A number of authors have used equilibrium concepts to look at the operation of an electricity market. An important set of papers is that by Green and Newbery [8], Green [9], Newbery [12], and Green [7], in which they analyze the experience in the pool market of England and Wales using the concept of an equilibrium in supply functions (see Klemperer and Meyer [10]). The concept of supply function equilibria has also been applied in this context by Rudkevich [13, 14], Anderson and Philpott [1], and Baldick, Grant, and Kahn [5]. The equilibrium models usually assume the smoothness or piecewise linearity of generators' supply functions and consequently it becomes relatively easy to find the optimal choice of strategy by a single generator. However, this may not be the case when we allow general supply functions.

Some recent papers have looked in detail at the optimal strategy for a generator offering power in an electricity spot market. The conclusions depend largely on the models that are used to describe both the generator's objective and constraints, and the market mechanisms. Anderson and Philpott [2] study strategies for generators making offers into an electricity market when either or both of the demand and the offers of competing generators are stochastic. They introduce the *market distribution function* and use it to describe the residual demand for a generator. The market distribution function ψ is a function of price p and quantity q and the value $\psi(q,p)$ represents the probability that a generator is not fully dispatched if it offers a quantity q of electricity at price p. The advantage of this approach is that in many circumstances a single function $\psi(q,p)$ is enough to determine a generator's expected profit given any particular offer curve.

Anderson and Philpott [2] explore the problem of finding an offer curve that maximizes the expected value of the profit made by an individual generator. The offer curve is simply a monotonic continuous curve in the two-dimensional (quantity, price) space. This curve need not be smooth; indeed, in practice it will often take the form of a series of steps. Anderson and Philpott show that the problem of maximizing expected profit is, in some circumstances, equivalent to maximizing a line integral along the offer curve of the market distribution function and they derive necessary conditions for a supply offer curve to be optimal. Anderson and Xu [4] study the same model and extend the analysis to include necessary conditions of a higher order in the presence of horizontal and/or vertical sections in an offer curve. They also derive sufficient conditions for an offer curve to be locally optimal. Neame, Philpott, and Pritchard [11] use Anderson and Philpott's model to study a generator's optimal choice of supply offer curve under the assumption that the generator is a price taker.

All of this work has been carried out under the assumption that the market distribution function $\psi(q,p)$ is continuously differentiable in both price p and quantity q. In this paper we address the problem of finding optimal offer strategies when ψ may be discontinuous in price.

In many electricity wholesale markets, a generator's offer curve consists of a finite number of steps. For instance, in Australia generator bids are restricted to have no more than ten prices. We can model a generator's offer strategy as a step function of price. In this case the market clearing price will not have a continuous distribution; instead, the distribution of clearing price will be concentrated at certain prices. The consequence of this is that the market distribution function will be discontinuous at these prices. The probability of not being fully dispatched if an offer is made of a quantity q at a price p (i.e., the value of ψ) will increase discontinuously as the price moves from just below the offer of another generator to the same price as the other

generator, when the dispatch will be shared between the two generators. In fact this discontinuity happens in both directions of price movement, since as the price moves from being the same as the other generator to just above this level, there is another discontinuous jump in the probability of not being fully dispatched. Previous work in this area has generally made the assumption that the market has a large number of participants, with offer prices well diversified, and so the market distribution function for a generator is nearly continuous and can be approximated with a continuous function.

In this paper we look in more detail at what happens with a discontinuous market distribution function. In the most natural models for this, the existence of an optimal solution for a generator will not be guaranteed (and indeed will occur only rarely). The lack of an optimal solution just reflects the actual difficulty associated with undercutting that can occur in practice. Suppose we know that another generator is offering power at \$30 per MWh, and we have to choose our best offer curve. For example, we might suppose that the other generator is nonstrategic and always submits the same offer. Power we offer at any price up to \$30 will be used in preference to the other generator, power at \$30 will involve a sharing out of the demand between us and the other generator, and power offered at any price higher than \$30 will be dispatched only when the power from the other generator is insufficient to meet demand. This leads to a profit function that is discontinuous in price (in both directions) if we choose to offer power at a single price. A typical good solution to this problem involves offering some power at a price just below the \$30 mark. The closer to \$30 the better for us, but the price must remain below \$30 in order to avoid having to share dispatch. In other words, as we indicated, there is no optimal solution unless we take explicit account of the discretization that may be forced on us by market rules such as, for example, the restriction that we use whole numbers of cents as prices.

In theory at least, this type of undercutting behavior, when translated into the framework of a Nash equilibrium, with different generators all engaged in the same process, will lead to very competitive outcomes as generators repeatedly lower their offer prices towards their true marginal costs. This is essentially the same kind of argument that gives rise to low consumer prices in the Bertrand equilibrium of classical microeconomics. But it can be argued that this is misleading, since markets usually operate in the form of a sealed bid auction, with participants unaware of the bids of other generators. This leads to the possibility of less competitive outcomes through the use of strategies which randomize over the prices offered (see von der Fehr and Harbord [15]).

In this paper, however, we will not discuss equilibrium solutions. Instead we seek to characterize solutions which approach optimality in the undercutting case. In practice it is not unusual for a generator to know the prices at which one or more of the other generators will offer power. For example, there may be nonstrategic generators who offer some quantity of energy at fixed prices which do not vary from day to day. It may be surprising that this occurs, since it is clear that this policy will not in general be optimal for the nonstrategic generator. One explanation is that more complex randomized policies may offer only a limited improvement in profit. As a concrete example of this behavior, consider the Australian market, in which a single generation unit offers power at 10 different price points, set for a 24-hour period (with quantities offered at each price point set separately for each half-hour). These price points are not usually varied from one day to the next; moreover, complete information on all bids is freely available one day after the event (see the web site www.nemmco.com).

For example, power from the Bayswater (coal-fired) power station in New South Wales is offered at a number of price points, but these have included the price \$22.89 for many months on end.

In order to deal with the undercutting behavior, our approach is to alter the model to ensure that the limit of undercutting solutions is a solution with the limiting value. The fundamental idea is to suppose that the generator we are interested in has automatic priority of dispatch when there are other generators offering at the same price. This will ensure that the market distribution function has sufficient continuity properties to guarantee that there will be an optimal solution. Though the exact optimal value is unachievable, the generator can operate in a way that gets as close as it likes to this value. From a practical point of view, establishing the supremum value, and the limiting solution which achieves this, is useful since it enables the generator to find a good solution near the limit, and also bounds the opportunity cost of accepting a suboptimal outcome. In practice market rules imply further restrictions on bids offered, but knowledge of the best possible limit solution will help to guide the selection of a suitable bidding policy.

There is another complication we need to consider. In most cases a generator will have hedging contracts for a significant part of its output. As we shall see, this can have the effect of reversing some of the incentives for the generator. If the generator has contracted for a larger quantity than will actually be dispatched in a certain period, then the generator will benefit from lower prices. The consequence is that, in this case, it will usually be optimal to "overcut" another generator's offer. Hence, to use the same example as above, if another generator has offered some quantity at \$30 per MWh, then we could well decide to make an offer of some amount of power a little above this level (and the closer to \$30 the better). In the case that offers have to be made in whole numbers of cents this would lead to an offer at \$30.01.

We can summarize this paper as follows. We first demonstrate the existence of an optimal solution for a modified problem (section 2). The modified problem differs from the original problem through the method used to determine the sharing of dispatch when two generators offer power at the same price: essentially, the optimizing generator is given the ability to choose its best sharing rule. Care is needed in determining the precise form of the objective function in these circumstances (Theorem 2.9) and in establishing the appropriate form of continuity in order to show the existence result (Lemma 2.7). Then we explore the necessary conditions for an optimal solution to this modified problem (section 3). Next we show how to use an optimal solution for the modified problem to generate an ε-optimal solution for the original problem (section 4). Finally, we illustrate all this with an example (section 5).

2. Problem formulation and fundamentals. In this section we will introduce some notation and formulate the problem that we shall consider.

We consider the behavior of a single generator, which we call A, and we let $R(q, p)$ be the profit for generator A if it is dispatched q at a clearing price p. Usually $R(q, p)$ has three components. First there is the cost, $C(q)$, of generating a quantity q of electricity, which is often taken to be an increasing convex function. Second there is the money, pq, paid to the generator through the market clearing mechanism. Finally, we must also consider the hedging contracts entered into by the generator. These are financial instruments which do not involve the actual generation of electricity; the money paid under the contract is tied to the pool price. If the generator enters into a contract at a strike price f for a quantity Q, and the actual spot price is p, then the generator will pay an amount $Q(p - f)$ to the other party in the contract. The

contracts we consider are two-way contracts for differences, so if the spot price is lower than the contract strike price, then the generator will receive an amount $Q(f-p)$. Contracts of this sort are a common feature of electricity markets operating with a "pool" structure in which prices for all traded electricity are determined through a combined pricing and dispatch mechanism (such as the markets operating in Australia and New Zealand and the old pool arrangements in England and Wales). Note that this is a different environment than that of markets which are based on bilateral contracts, such as in the new trading arrangements in England and Wales.

Thus we arrive at the following expression for the profit to generator A as a function of spot price p and dispatched quantity q:

$$R(q,p) = pq - C(q) + Q(f-p). \tag{2.1}$$

We will not assume any particular functional form for the function R. However, throughout this paper we will assume that R has continuous bounded partial derivatives, R_q and R_p, and is strictly concave in q for fixed p. Thus we have $R_q(\cdot,p)$ strictly decreasing for each fixed p. In the case that (2.1) holds, this assumption will be satisfied provided that the marginal cost of generation is strictly increasing, since $R_q(q,p) = p - C'(q)$.

Next we consider the market dispatch mechanism. We will restrict attention to the case where there is a single node. We consider this from the point of view of generator A. We model the sequence of events in this way. First generator A submits a supply function $S_A(p)$, which gives the total amount of power that generator A is prepared to supply as a function of the price p. Then all the other generators submit their supply functions, which we collectively write as $S_B(p)$—this is the total amount of power that all the other generators are prepared to supply as a function of price. We take both S_A and S_B as right-continuous increasing functions (not necessarily strictly increasing). Where there is a discontinuity in S_A, a jump up occurs at a certain price p, and this corresponds to a certain quantity of power being offered at p and all available at that price. Hence right-continuity is a natural assumption here.

Finally, a demand occurs, where demand at this node is given by a function $D(p)$ of price. We suppose that from the point of view of generator A, both $S_B(p)$ and $D(p)$ are uncertain and must be modeled as stochastic. The market clears at the lowest price p for which $S_A(p) + S_B(p) \geq D(p)$.

In the model we are considering, which corresponds to the most common type of pool market, all generators are paid this clearing price for all the electricity that they are dispatched. This is a type of uniform price auction mechanism. There are other (discriminatory) auction price mechanisms that have been proposed.

Throughout this paper, we assume that a generator's supply function (or equivalently supply curve) is nondecreasing. It can be step-like or strictly increasing, or both. Rather than dealing with a supply function $S_A(\cdot)$ directly, it is convenient to model the offer using a continuous curve $\mathbf{s} = \{(\hat{q}(\tau), \hat{p}(\tau)), 0 \leq \tau \leq T\}$, in which the components $\hat{q}(\tau)$ and $\hat{p}(\tau)$ are continuous monotonic increasing function of τ, and $\hat{q}(\tau)$ and $\hat{p}(\tau)$ trace, respectively, the quantity and price components. Without loss of generality we may take $\hat{q}(0) = \hat{p}(0) = 0$ and $\hat{p}(T) \leq p_M$, where p_M is a bound on the price of any offer. It is quite common for electricity markets to have a cap on prices; for example, this is \$10,000 per MWh in Australia. We also assume that q_M is a bound on the generation capacity of generator A, and thus $\hat{q}(T) \leq q_M$.

In all markets there are restrictions on the form of offers made into the market; we have already mentioned the need for offers to consist of step functions in many

cases. But in this paper we will not include any constraints on the form of offers. Our perspective is that a generator which has a specific optimal offer curve will usually be able to approximate this within the rules of the market. Owners of generators will often be offering power from more than one generation set in a coordinated way, and this can also increase their flexibility.

We use a single market distribution function $\psi(q,p)$ to describe the uncertainty in the market. Following Anderson and Philpott [2], $\psi(q,p)$ is defined as the probability of generator A not being fully dispatched if it offers an amount of generation q at a price p. Different generators will have different market distribution functions, but we just write ψ rather than ψ_A for this function. It turns out that when $\psi(q,p)$ is continuous, knowledge of the single function ψ is enough to determine the expected profit for a generator. When ψ is continuous, Anderson and Philpott [2] have demonstrated that the expected profit if a generator offers in a supply curve $\mathbf{s}$ can be expressed as a Stieltjes integral along the line $\mathbf{s}$:

$$v(\mathbf{s}) = \int_{\mathbf{s}} R(q,p)\ d\psi(q,p). \tag{2.2}$$

The generator's aim is to choose an optimal supply curve $\mathbf{s}$ so that $v(\mathbf{s})$ is maximized. Note that the market distribution function ψ is assumed to be known. Anderson and Philpott [3] have proposed a Bayesian inference method to estimate ψ given data on the market behavior in previous days. Note that although the setting is a stochastic one, this formulation of the problem of maximizing expected profit has converted the objective function into a deterministic optimization problem.

When the function ψ is discontinuous we need a different form of the fundamental relationship (2.2), and this will be derived in Theorem 2.9 below.

2.1. Discontinuous ψ function. Previous work in this area has assumed that the market distribution function is continuous. In this paper, rather than requiring ψ to be continuous, we assume that ψ may be discontinuous at a finite number of prices. Since ψ is a type of probability distribution function, a discontinuity in its value corresponds to a single price at which there is a jump in the probability of being fully dispatched. For this to occur two things have to happen. First some other generator has to make an offer which contains a "step," a distinct tranche of energy at a given price, and second this price has to be determined in advance (in other words, it cannot be drawn from a continuous distribution). The first condition may be met because of market rules which only allow step function offers, but for a discontinuity in ψ it is also necessary to be able to predict the prices at which other generators make offers.

We illustrate this with an example.

Example 2.1. Suppose that just two generators A and B are offering power into the spot market. Generator B is nonstrategic: its offer does not vary and is known in advance from previous market data. Thus the only uncertainty is in relation to the level of demand. Suppose that the generator B offers 200 MW at a price of \$10 per MWh, 300 MW at a price of \$14, and 300 MW at a price of \$18. Thus generator B's supply function is

$$S_B(p) = \begin{cases} 0 & \text{for } 0 \le p < 10, \\ 200 & \text{for } 10 \le p < 14, \\ 500 & \text{for } 14 \le p < 18, \\ 800 & \text{for } p \ge 18. \end{cases}$$

Consider generator A offering 100 MW at price \$10 per MWh. We suppose that demand, which can be a function of price, is uncertain. If the market clears at price \$10 with a total demand of 300 MW, then all the power offered at this price is dispatched. However, if the demand is below 300 MW at price \$10, then market rules will impose some sharing of dispatch should the market clear at this price. Suppose that the market rules share dispatch proportionately to the quantity offered at that price, so that one third of demand is met from generator A and two thirds from generator B. Thus neither of the generators gets fully dispatched at price \$10. On the other hand, if generator A offers 100 MW at price $\$10 - \varepsilon$, where $\varepsilon > 0$ is small, then it is fully dispatched provided that the demand at price \$10 is greater than or equal to 100 MW. Therefore the probability of not being fully dispatched if generator A offers at price \$10 with a quantity of 100 MW is strictly greater than the probability of not being fully dispatched if A offers at price $\$10 - \varepsilon$ with a quantity of 100 MW; i.e.,

$$\lim_{\epsilon \downarrow 0} \psi(100, 10 - \varepsilon) < \psi(100, 10).$$

This example motivates us to consider discontinuities in the functions $S_B(p)$. We write $\mathcal{P}$ for the entire set of prices at which the other generators may make significant offers, and hence at which there may be discontinuities in $S_B(p)$. Let $\mathcal{P} \equiv \{p^1, \ldots, p^n\}$, where $0 < p^1 < \cdots p^n \leq p_M$. We assume that the prices in $\mathcal{P}$ are known in advance.

For clarity we write $\omega_1 \in \Omega_1$ for the realizations of the demand, and $\omega_2 \in \Omega_2$ for realizations of the other generator offers. More formally, we assume a probability space $(\Omega_1 \times \Omega_2, \mathcal{F}, \Pr)$. The demand need not be independent of other generator offers. We shall assume that for every realization ω_1, the demand, $D(p, \omega_1)$, is a continuously differentiable decreasing function of p. Moreover we assume that for every realization ω_2, the total of the other generator offers, $S_B(p, \omega_2)$, is a continuously differentiable increasing function of p except at points in $\mathcal{P}$. We will normally omit the explicit dependence on ω_1 and ω_2, and write $D(p)$ and $S_B(p)$.

Observe that in any realization (of demand and other generator offers) for which $D(p) < q + \lim_{\varepsilon \downarrow 0} S_B(p - \varepsilon)$, an offer of q at price p cannot be fully dispatched (since if it were fully dispatched, then the price is at least p and so the other generators would be dispatched at least $\lim_{\varepsilon \to 0} S_B(p - \varepsilon)$, giving a contradiction). Hence

$$\psi(q, p) \geq \Pr(D(p) < q + \lim_{\varepsilon \downarrow 0} S_B(p - \varepsilon)). \tag{2.3}$$

If $p \notin \mathcal{P}$, then for every realization of other generator offers $\lim_{\varepsilon \downarrow 0} S_B(p - \varepsilon) = S_B(p)$ and thus $\psi(q, p) \geq \Pr(D(p) < q + S_B(p))$.

On the other hand, in any realization for which an offer of q at price p is not fully dispatched we can show that $D(p) < q + \lim_{\varepsilon \downarrow 0} S_B(p + \varepsilon)$ (since in this case the clearing price is p or less, and so the maximum quantity dispatched from the other generators is $\lim_{\varepsilon \downarrow 0} S_B(p + \varepsilon)$). Thus

$$\psi(q, p) \leq \Pr(D(p) < q + \lim_{\varepsilon \downarrow 0} S_B(p + \varepsilon)) \tag{2.4}$$

and $\psi(q, p) \leq \Pr(D(p) < q + S_B(p))$ when $p \notin \mathcal{P}$. Hence, except at points of discontinuity in S_B,

$$\psi(q, p) = \Pr(D(p) < q + S_B(p)). \tag{2.5}$$

We may use this as a definition of $\psi(q,p)$ for $p \notin \mathcal{P}$, but for $p \in \mathcal{P}$ the value of ψ depends on the sharing rule.

Since in any realization of demand and other generator offers in which $D(p) < q + S_B(p)$ the same inequality holds for any higher value of p or q, we can deduce that $\psi(q,p)$ is increasing in both its arguments at prices $p \notin \mathcal{P}$. Moreover we can use (2.3) and (2.4) to show that $\psi(q,p)$ is also increasing in p at prices $p \in \mathcal{P}$.

Note that since ψ is monotonic increasing in p and bounded, the two limits $\lim_{\delta \downarrow 0} \psi(q, p^j + \delta)$ and $\lim_{\delta \downarrow 0} \psi(q, p^j - \delta)$ will both exist. For convenience, we will use the following notation: for $j = 1, \ldots, n$,

$$\psi_+(q,p^j) = \lim_{\delta \downarrow 0} \psi(q, p^j + \delta),$$

$$\psi_-(q,p^j) = \lim_{\delta \downarrow 0} \psi(q, p^j - \delta),$$

$$\Phi(q,p^j) \equiv \psi_+(q,p^j) - \psi_-(q,p^j). \tag{2.6}$$

Thus $\Phi(q,p^j)$ is the jump in the probability of dispatch that takes place if the generator offers an amount q at a price just below p^j in comparison with what happens if the price is increased to be just above p^j.

It is important to consider the expected return for a generator offering a curve $\mathbf{s}$ when the market distribution function is discontinuous: in the continuous case we have the expression (2.2). In general we would expect to have, in addition to an integral, a sum of discrete values $R(q,p)$ at points (q,p) on $\mathbf{s}$ at which there is a jump in the value of ψ. This is indeed what happens when the curve $\mathbf{s}$ is strictly increasing. We will show later that if we define $q^j(\mathbf{s})$ as the point at which the curve $\mathbf{s}$ crosses the discontinuity p^j, then

$$v(\mathbf{s}) = \int_{\mathbf{s}^C} R(q,p)\, d\psi(q,p) + \sum_{j=1}^{n} R(q^j(\mathbf{s}), p^j) \Phi(q^j(\mathbf{s}), p^j), \tag{2.7}$$

where $\mathbf{s}^C$ is the part of curve $\mathbf{s}$ excluding the points $(q^j(\mathbf{s}), p^j)$. However, when the curve $\mathbf{s}$ has a horizontal section at one of the prices p^j, things are more complex.

2.2. Sharing rules. If we suppose that the generator is offering power at the same price p^j as another generator, then we cannot calculate the expected profit without knowledge of the market rules concerning the sharing of dispatch between two generators offering at the same price. Moreover, the value of ψ at p^j gives just the probability of complete dispatch, whereas the sharing rules imply more information than this. Specifically the values of ψ might not be enough to determine a generator's expected profit. It may be that two different sharing rules give the same ψ values but different expected profit. To illustrate this we return to Example 2.1.

Example 2.2. Suppose as before that generator B offers 200 MW at price \$10 and 300 MW at \$14, while generator A offers 100 MW at \$10. Suppose that sharing of dispatch between two generators offering at the same price is proportional to the offers made at that price. Suppose now that generator A has costs of \$8 per MWh and demand is uniformly distributed between 0 MW and 500 MW. Thus with probability 0.4 demand is greater than 300 MW, the market clears at \$14, and the profit to generator A is \$600 per hour. On the other hand, with probability 0.6 the market will clear at \$10 and generator A will be only partially dispatched. It is not hard to see that the total expected profit per hour is given by

$$v = 0.6 \int_0^{100} 2\frac{x}{100} dx + 0.4 \times 600 = 300.$$

Consider now a sharing rule which gives priority to generator B. In this case with probability 0.4 the demand is less than 200 MW and generator A is not dispatched at all (while generator B is partially dispatched). We have the following expression for expected profit:

$$v = 0.2 \int_0^{100} 2\frac{x}{100} dx + 0.4 \times 600 = 260.$$

Notice that in this second case, too, generator A is not fully dispatched unless demand is greater than 300 MW. So both these sharing rules have the same value for $\psi(100, 10)$, which is the probability of generator A not being fully dispatched with this offer. Indeed the two rules will give the same value of $\psi(q, 10)$ for any value of q.

In order to make further progress we need to consider specific sharing rules. We will write $v(\mathbf{s},\mathcal{L})$ for the expected profit when an offer curve of $\mathbf{s}$ is used together with market sharing rules defined by $\mathcal{L}$. We will investigate the particular choice of sharing rule which is best for generator A.

Suppose that generator A uses the supply function $S_A(p)$ and the other generators use the supply function $S_B(p)$. We write $S_B(p_-)$ for the limit $\lim_{\varepsilon \downarrow 0} S_B(p - \varepsilon)$ and $S_A(p_-)$ for the limit $\lim_{\varepsilon \downarrow 0} S_A(p - \varepsilon)$.

We are interested in the sharing rule to be applied when the market clears at price p^j. The market clears at this price if and only if $D(p^j)$ satisfies

$$S_A(p^j_-) + S_B(p^j_-) \le D(p^j) \le S_A(p^j) + S_B(p^j). \tag{2.8}$$

A sharing rule $\mathcal{L}$ is any method for determining the dispatch quantity $\gamma_A(\mathcal{L})$ for generator A in this case. Though this is not made explicit in the notation, the sharing rule is applied at a particular price p^j; and in general we need to define a sharing rule for each price $p \in \mathcal{P}$. Notice that $\gamma_A(\mathcal{L})$ is a function of the demand, but we suppress this dependence in the notation.

A feasible sharing rule has to satisfy the following inequalities:

$$S_A(p^j_-) \le \gamma_A(\mathcal{L}) \le S_A(p^j), \tag{2.9}$$

$$S_B(p^j_-) \le D(p^j) - \gamma_A(\mathcal{L}) \le S_B(p^j). \tag{2.10}$$

The right-hand inequalities correspond to the restriction that no generator can be dispatched more than it offers at price p^j. The left-hand inequalities correspond to the restriction that any power offered at prices less than p^j must be completely dispatched.

More generally, we can make the following definition.

DEFINITION 2.3. *Let the market clear at price $p \in (0, p^M)$, and thus*

$$S_A(p_-) + S_B(p_-) \le D(p) \le S_A(p) + S_B(p).$$

Then $\mathcal{L}$ is a feasible sharing rule if it determines uniquely the respective dispatch quantities $\gamma_A \in [S_A(p_-), S_A(p)]$ for generator A, and $\gamma_B \in [S_B(p_-), S_B(p)]$ for the other generators, such that

$$\gamma_A + \gamma_B = D(p).$$

Notice that unless two generators both offer power at the price p there will only be one possible choice for γ_A and γ_B. Thus the only prices at which the sharing rule needs to be defined are p^j, $j = 1, 2, \ldots, n$.

We let $q^*(p^j)$ be the value of q at which $R(q,p^j)$ achieves its maximum over $[0,q_M]$. Our assumptions on R imply that this is unique. We have $q^*(p^j)=0$ if $R_q(0,p^j)<0$, $q^*(p^j)=q_M$ if $R_q(q_M,p^j)>0$, and $R_q(q^*(p^j),p^j)=0$ otherwise. Notice that $q^*(p^j)$ is not affected by any hedging contracts.

Now we define the sharing rule $\mathcal{L}^*$ as follows. Let

$$q^j=\begin{cases} S_A(p^j) & \text{if } S_A(p^j)<q^*(p^j),\\ q^*(p^j) & \text{if } S_A(p^j_-)\le q^*(p^j)\le S_A(p^j),\\ S_A(p^j_-) & \text{if } q^*(p^j)<S_A(p^j_-).\end{cases}$$

It is easy to see that q^j maximizes $R(q,p^j)$ subject to $S_A(p^j_-)\le q\le S_A(p^j)$. Since we also require that (2.10) be satisfied, we define the dispatch amount γ_A from generator A under $\mathcal{L}^*$ (when the price is p^j) as

$$\gamma_A(\mathcal{L}^*)=\begin{cases} (a) & D(p^j)-S_B(p^j_-) & \text{if } D(p^j)-S_B(p^j_-)<q^j,\\ (b) & D(p^j)-S_B(p^j) & \text{if } D(p^j)-S_B(p^j)>q^j,\\ (c) & q^j & \text{otherwise.}\end{cases}$$

The lemma below demonstrates that $\mathcal{L}^*$ is the *best* choice of sharing rule for generator A, in the sense that no other sharing rule will produce such a large profit for A.

LEMMA 2.4. *$\mathcal{L}^*$ is a feasible sharing rule, and $v(\mathbf{s},\mathcal{L}^*)\ge v(\mathbf{s},\mathcal{L})$ for every feasible sharing rule $\mathcal{L}$.*

Proof. We consider the profit when the clearing price is $p^j\in\mathcal{P}$, since if the clearing price is not in $\mathcal{P}$ no sharing rule will be needed. We write I_A for the interval $[S_A(p^j_-),S_A(p^j)]$ and I_B for the interval $[D(p^j)-S_B(p^j),D(p^j)-S_B(p^j_-)]$. The length of interval I_A is the offer from A at price p^j, while I_B is the range of possible residual demand for A at this price. Therefore a feasible sharing rule has γ_A in both I_A and I_B.

We wish to establish that γ_A is the unique optimal solution to

$$\max_{q\in I_A\cap I_B} R(q,p^j). \tag{2.11}$$

From (2.8) we observe that I_A and I_B will overlap, so the feasible set for the maximization problem is nonempty. Observe also that q^j is the unique optimal solution to the problem

$$\max_{q\in I_A} R(q,p^j),$$

which implies that, within interval I_A, $R(\cdot,p^j)$ is strictly increasing for $q\le q^j$ and strictly decreasing for $q>q^j$.

We consider the three cases in the definition of $\gamma_A(\mathcal{L}^*)$. In case (a) q^j falls to the right of the interval I_B, hence the right end point of I_B, $D(p^j)-S_B(p^j_-)$, is the optimal solution of (2.11). Similarly in case (b) q^j falls to the left of the interval I_B, and hence the left-hand end point of interval I_B, $D(p^j)-S_B(p^j)$, is the optimal solution of (2.11). In case (c) q^j is in I_B and is therefore the optimal solution of (2.11). This shows $\gamma_A(\mathcal{L}^*)$ is the optimal solution of (2.11). ∎

2.3. *R*-semicontinuous ψ function. We need to define a specific type of discontinuity behavior for the function ψ. In fact, at some points in the (q,p) plane we

need ψ to be continuous from above, and at other points to be continuous from below, depending on the characteristics of the function R.

DEFINITION 2.5. *Suppose that the market distribution function $\psi(q,p)$ is continuous at all prices $p \notin \mathcal{P}$. ψ is called R-semicontinuous if $\psi_-(q,p^j) = \psi(q,p^j)$ when $R_q(q,p^j) \geq 0$ and $\psi_+(q,p^j) = \psi(q,p^j)$ when $R_q(q,p^j) < 0$, $j = 1,\ldots,n$.*

With the form of profit function given in (2.1) we can see that an R-semicontinuous market distribution function will have the property of being continuous from below (in the (q,p) plane) when $p > C'(q)$, and will be continuous from above when the reverse inequality holds. We will show that ψ will be R-semicontinuous when the sharing rule $\mathcal{L}^*$ is applied.

Though we have assumed that both demand and other generator offers are well behaved in any given realization, we also need to have the realizations of demand and offers in some sense continuously distributed through the appropriate spaces.

Assumption 2.6 (continuity). The function $q \longmapsto \Pr(D(p) < q + S_B(p))$ is continuous on $[0, q^M]$, and the function $q \longmapsto \Pr(D(p) < q + S_B(p))$ is continuous on $[0, p^M] \backslash \mathcal{P}$.

This assumption implies, from (2.5), that $\psi(q,p)$ is continuous at all prices $p \notin \mathcal{P}$.

LEMMA 2.7. *Under Assumption* 2.6*, if the sharing rule $\mathcal{L}^*$ is used, then the market distribution function ψ is R-semicontinuous.*

Proof. We consider an offer of an amount q by generator A at a price p^j, where $\psi(q,\cdot)$ is discontinuous. We suppose that there is no other offer by generator A. Thus $S_A(p^j) = q$ and $S_A(p^j_-) = 0$.

Suppose first that $R_q(q,p^j) \geq 0$, so $q \leq q^*(p^j)$. From the definition of q^j, we have $q^j = q$, thus $\mathcal{L}^*$ will choose to dispatch an amount q, if this is possible when the constraints due to the demand realization are considered.

Recall that $\psi(q,p^j)$ is defined as the probability of not being fully dispatched when A makes an offer of q at p^j. Under $\mathcal{L}^*$, the probability of not being fully dispatched is the probability of either the market clearing at a price below p^j or clearing at price p^j but $D(p^j) - S_B(p^j_-) < q$, which means generator B's offer at p^j is not dispatched at all, and the residual demand for generator A falls below q. In this case A gets dispatched $D(p^j) - S_B(p^j_-)$. This is exactly the case (a) in the definition of $\gamma_A(\mathcal{L}^*)$.

Define the event

$$H = \{(\omega_1,\omega_2) : D(p^j,\omega_1) < q + S_B(p^j_-,\omega_2)\}.$$

Then

$$\psi(q,p^j) = \Pr(H).$$

In what follows, we show $\psi(q,\cdot)$ is continuous at $p = p^j$ from below. We write G_ε for the event that an offer of q at price $p^j - \varepsilon$ is not fully dispatched; i.e.,

$$G_\varepsilon = \{(\omega_1,\omega_2) : D(p^j - \varepsilon,\omega_1) < q + S_B(p^j - \varepsilon,\omega_2)\}.$$

Then the G_ε are monotonically increasing sets as ε decreases to zero, with, say, a limit G. D is a continuous function of p in each realization, and so if $(\omega_1,\omega_2) \in H$, then for some choice of $\varepsilon_0 > 0$, $D(p^j - \varepsilon,\omega_1) < q + S_B(p^j - \varepsilon,\omega_2)$ for $0 < \varepsilon < \varepsilon_0$. Therefore $H \subset G$. From the axioms of probability, $\Pr(G) = \lim_{\varepsilon\to 0} \Pr(G_\varepsilon)$. Thus $\psi(q,p^j) \leq \lim_{\varepsilon\to 0} \psi(q,p^j - \varepsilon)$. But since ψ is increasing in p, there must be equality here, i.e., $\psi_-(q,p^j) = \psi(q,p^j)$, as required.

Now consider the case that $R_q(q,p^j) < 0$ and we show $\psi(q,\cdot)$ is continuous at $p = p^j$ from above.

In this case $q > q^*(p^j)$. The probability of not being fully dispatched under $\mathcal{L}^*$ is the probability of either the market clearing at a price below p^j or of clearing at p^j with $D(p^j) - S_B(p^j) < q$. Thus $\psi(q, p^j) = \Pr(J)$ where

$$J = \{(\omega_1, \omega_2) : D(p^j, \omega_1) < q + S_B(p^j, \omega_2)\}.$$

We write F_ε for the event that an offer of q at price $p^j + \varepsilon$ is not fully dispatched. Then F_ε is monotonically decreasing as ε decreases to zero, with a limit F, say. So every realization in F is in every F_ε for $\varepsilon < \varepsilon_0$, where ε_0 depends on the realization; i.e., for every $(\omega_1, \omega_2) \in F$, $D(p^j + \varepsilon, \omega_1) < q + S_B(p^j + \varepsilon, \omega_2)$ for $\varepsilon > 0$. Thus from the continuity of D and S_B, $F \subset \{(\omega_1, \omega_2) : D(p^j, \omega_1) \le q + S_B(p^j, \omega_2)\}$. Thus from Assumption 2.6

$$\begin{aligned}\Pr(F) &\le \Pr((\omega_1, \omega_2) : D(p^j, \omega_1) \le q + S_B(p^j, \omega_2)) \\ &= \Pr((\omega_1, \omega_2) : D(p^j, \omega_1) < q + S_B(p^j, \omega_2)) = \psi(q, p^j).\end{aligned}$$

Now, since $\lim_{\varepsilon \to 0} \Pr(F_\varepsilon) = \Pr(F)$, we have established that $\psi_+(q, p^j) \le \psi(q, p^j)$, and the monotonicity of ψ shows that these are equal. □

The reverse implication does not hold: we can have an R-semicontinuous ψ without using the sharing rule $\mathcal{L}^*$.

2.4. Expected profit. We let $\Psi = \{(q, p) : 0 < \psi(q, p) < 1\}$. In line with Definition 2.5, we can divide Ψ into two regions Ψ_+ and Ψ_-, where

$$\Psi_+ = \{(q, p) \in \Psi : R_q(q, p) \ge 0\}, \qquad \Psi_- = \{(q, p) \in \Psi : R_q(q, p) < 0\}.$$

In the case that ψ is R-semicontinuous, to calculate the expected profit from a supply curve $\mathbf{s}$ when it has a segment on the horizontal line $\{(q, p^j) : q \in [0, q^M]\}$, we need to think of it as part of the region below that line in the set Ψ_+ and part of the region above that line in the set Ψ_-. This motivates the following definitions:

$$\begin{aligned}\Psi^j &= \{(q, p) \in \Psi : 0 \le q \le q_M,\ p^{j-1} < p < p^j\} \cup \{(q, p^j) \in \Psi_+\} \\ &\quad \cup \{(q, p^{j-1}) \in \Psi_-\}, \qquad j = 2, \dots, n, \\ \Psi^1 &= \{(q, p) \in \Psi : 0 \le q \le q_M,\ 0 \le p < p^1\} \cup \{(q, p^1) \in \Psi_+\}, \\ \Psi^{n+1} &= \{(q, p) \in \Psi : 0 \le q \le q_M,\ p^n < p \le p^M\} \cup \{(q, p^n) \in \Psi_-\}, \\ \mathbf{s}^j &= \mathbf{s} \cap \Psi^j.\end{aligned}$$

It is not hard to see that the values q^j which we introduced in relation to the sharing rule $\mathcal{L}^*$ also define the points at which an offer curve $\mathbf{s}$ moves from Ψ^j to Ψ^{j+1}. Thus, writing q^j as a function of $\mathbf{s}$,

$$q^j(\mathbf{s}) = \sup\{q : (q, p^j) \in \mathbf{s}^j\}$$

for $j = 1, \dots, n$. From the monotonicity of the offer curve $\mathbf{s}$, and because R_q is decreasing, we can also write

$$q^j(\mathbf{s}) = \inf\{q : (q, p^j) \in \mathbf{s}^{j+1}\}.$$

Under the assumptions of Lemma 2.7, we can take ψ as R-semicontinuous and made up from a number of different pieces ψ^j, where ψ^j is defined on the interval between p^{j-1} and p^j and is well behaved on that interval. Thus we let

$$\psi^j(q, p) = \begin{cases} \psi_+(q, p^{j-1}) & \text{for } p = p^{j-1}, \\ \psi(q, p) & \text{for } p^{j-1} < p < p^j, \\ \psi_-(q, p^j) & \text{for } p = p^j \end{cases}$$

for $j = 2, \ldots, n$, and

$$\psi^1(q,p) = \begin{cases} \psi(q,p) & \text{for } 0 \le p < p^1, \\ \psi_-(q,p^1) & \text{for } p = p^1, \end{cases}$$

$$\psi^{n+1}(q,p) = \begin{cases} \psi_+(q,p^n) & \text{for } p = p^n, \\ \psi(q,p) & \text{for } p^n < p \le p^M. \end{cases}$$

We need to make an assumption on the behavior of the function ψ.

Assumption 2.8 (continuous differentiability). $\psi(q,p)$ is continuously differentiable for $p \notin \mathcal{P}$ and each ψ^j can be extended to a continuously differentiable function on an open set W^j which contains the closure of the set Ψ^j.

THEOREM 2.9. *Suppose that a generator offers a curve* $\mathbf{s}$ *and Assumptions* 2.6 *and* 2.8 *are satisfied. If sharing rule* $\mathcal{L}^*$ *is used, then the expected profit for the generator is*

$$v(\mathbf{s}) = \sum_{j=1}^{n+1} \int_{\mathbf{s}^j} R(q,p)\ d\psi^j(q,p) + \sum_{j=1}^{n} R(q^j(\mathbf{s}),p^j)\Phi(q^j(\mathbf{s}),p^j), \tag{2.12}$$

where Φ *is defined in* (2.6).

Proof. To simplify our presentation we prove the theorem for $n = 1$ with just one price discontinuity at p^1. The case with $n > 1$ can be dealt with similarly. We suppose that generator A uses an offer curve $\mathbf{s}$ which we take as $\mathbf{s} = \{(x(\tau), y(\tau))\}$ in parameter form.

We write γ_A for the dispatch quantity from generator A given the offer curve $\mathbf{s}$. We start by showing that $\psi(x(\tau), y(\tau))$ is the probability that γ_A is less than $x(\tau)$. In the case that ψ is continuous in a neighborhood of $(x(\tau), y(\tau))$, this is straightforward and is implicitly established in [2]. But when $y(\tau) = p^1$ we need to be more careful. Observe that from the definition of $\mathcal{L}^*$, if $x(\tau) < q^1$, then

$$\Pr(\gamma_A < x(\tau)) = \Pr(D(p^1) - S_B(p^1_-) < x(\tau)).$$

But the probability of an offer of $x(\tau)$ at price p^1 is not fully dispatched under $\mathcal{L}^*$ with the same probability. Hence $\Pr(\gamma_A < x(\tau)) = \psi(x(\tau), y(\tau))$ as required. The case when $x(\tau) \ge q^1$ can be dealt with similarly.

We let τ^1 be such that $y(\tau^1) = p^1$ and $x(\tau^1) = q^1$. We consider the expected profit on a segment, $\mathbf{s}_\delta \equiv \{(x(\tau), y(\tau)) : \tau^1 - \delta < \tau \le \tau^1 + \delta\}$, of curve $\mathbf{s}$. From our observation on $\psi(x(\tau), y(\tau))$ we know that the probability that the market clears at a price p and quantity q on the offer curve in the segment $\mathbf{s}_\delta$ is given by $\psi(x(\tau^1 + \delta), y(\tau^1 + \delta)) - \psi(x(\tau^1 - \delta), y(\tau^1 - \delta))$.

The expected profit from the line segment $\mathbf{s}_\delta$ is bounded above (below) by this probability multiplied by the supremum (infimum) of R over the set $\mathbf{s}_\delta$. Since R is continuously differentiable, for δ small enough, the expected profit from segment $\mathbf{s}_\delta$ is

$$v(\mathbf{s}_\delta) = R(x(\tau^1), y(\tau^1))(\psi(x(\tau^1 + \delta), y(\tau^1 + \delta)) - \psi(x(\tau^1 - \delta), y(\tau^1 - \delta))) + o(\delta).$$

The total expected profit from the offer curve $\mathbf{s}$ can be written as $v(\mathbf{s}) = v(\mathbf{s}^1_\delta) + v(\mathbf{s}_\delta) + v(\mathbf{s}^2_\delta)$, where $\mathbf{s}^1_\delta$, $\mathbf{s}^2_\delta$ are the other components of $\mathbf{s}$ created when $\mathbf{s}_\delta$ is removed. So $\mathbf{s}^1_\delta = \{(x(\tau), y(\tau)) : \tau \le \tau^1 - \delta\}$ and $\mathbf{s}^2_\delta = \{(x(\tau), y(\tau)) : \tau \ge \tau^1 + \delta\}$. These components lie entirely within the regions where ψ is continuously differentiable (and

given by ψ^i), using Assumption 2.8. Using the result of Anderson and Philpott [2] we know that

$$v(\mathbf{s}^i_\delta) = \int_{\mathbf{s}^i_\delta} R(q,p)\ d\psi^i(q,p), \qquad i = 1,2.$$

By driving δ to zero, we have

$$\begin{aligned}\lim_{\delta\to 0} v(\mathbf{s}_\delta) &= R(x(\tau^1),y(\tau^1))(\psi^2(x(\tau^1),y(\tau^1)) - \psi^1(x(\tau^1),y(\tau^1)))\\ &= R(q^1,p^1)\Phi(q^1,p^1),\end{aligned}$$

and

$$\lim_{\delta\to 0}\int_{\mathbf{s}^i_\delta} R(q,p)\ d\psi^i(q,p) = \int_{\mathbf{s}^i} R(q,p)\ d\psi^i(q,p), \qquad i = 1,2.$$

This completes the proof. □

2.5. Existence of an optimal solution. Having established the objective function formula (2.12), our approach to showing that an optimal solution exists is to concentrate on the formal problem of maximizing (2.12) given an R-semicontinuous market distribution function ψ.

In order to discuss the optimality of a continuous offer curve, we need to compare the line integrals on two distinct curves. When ψ is continuous, Anderson and Philpott [2] use Green's theorem and observe that

$$\int\int_{\mathcal{S}} Z(q,p)\ dpdq = \int_{\mathcal{C}} R(q,p)\ d\psi(q,p),$$

where $\mathcal{S}$ is a region enclosed by a curve $\mathcal{C}$ and

$$Z(q,p) = \begin{cases} R_q\psi_p - R_p\psi_q, & (q,p)\in\Psi,\\ 0 & \text{otherwise.}\end{cases} \tag{2.13}$$

Clearly this result will not hold when the curve $\mathcal{C}$ crosses one of the lines of discontinuity at $p\in\mathcal{P}$.

Our approach will be to calculate the change in v that arises from a change in offer curve $\mathbf{s}$ by applying Green's theorem separately to each region Ψ^j together with a calculation of the change that arises across the lines of discontinuity. We need to start with a lemma that can be established using an integration by parts argument.

LEMMA 2.10. *Suppose $p^j\in\mathcal{P}$ and $0\le q_1<q_2\le q_M$. Then, under Assumption 2.8,*

$$\begin{aligned}&\int_{q_1}^{q_2} R(q,p^j)\ d\psi^j(q,p^j) - \int_{q_1}^{q_2} R(q,p^j)\ d\psi^{j+1}(q,p^j) + R(q_2,p^j)\Phi(q_2,p^j)\\ &\qquad -R(q_1,p^j)\Phi(q_1,p^j)\\ &= \int_{q_1}^{q_2}\Phi(q,p^j)R_q(q,p^j)\ dq.\end{aligned}$$

Proof. Let

$$v_1 = \int_{q_1}^{q_2} R(q,p^j)\ d\psi^j(q,p^j) + R(q_2,p^j)\Phi(q_2,p^j)$$

and

$$v_2 = \int_{q_1}^{q_2} R(q, p^j)\ d\psi^{j+1}(q, p^j) + R(q_1, p^j)\Phi(q_1, p^j).$$

From Assumption 2.8, both $\psi^j(\cdot, p^j)$ and $\psi^{j+1}(\cdot, p^j)$ are continuously differentiable, and we have already assumed that $R(\cdot, p^j)$ is continuously differentiable. Integrating both v_1 and v_2 by parts, we obtain

$$\begin{aligned} v_1 - v_2 &= R(q_2, p^j)\psi^j(q_2, p^j) - R(q_1, p^j)\psi^j(q_1, p^j) - \int_{q_1}^{q_2} \psi^j(q, p^j)R_q(q, p^j)\ dq \\ &\quad - R(q_2, p^j)\psi^{j+1}(q_2, p^j) + R(q_1, p^j)\psi^{j+1}(q_1, p^j) + \int_{q_1}^{q_2} \psi^{j+1}(q, p^j)R_q(q, p^j)\ dq \\ &\quad + R(q_2, p^j)\Phi(q_2, p^j) - R(q_1, p^j)\Phi(q_1, p^j) \\ &= \int_{q_1}^{q_2} \Phi(q, p^j)R_q(q, p^j)\ dq, \end{aligned}$$

as required. □

Note that v_1 is the expected return of the generator for offering $q_2 - q_1$ at price just under p^j, and v_2 is the expected return of the generator for offering $q_2 - q_1$ at price just above p^j. The lemma states that the difference between these two values can be expressed as the integral of $\Phi(q, p^j)R_q(q, p^j)$ with respect to q from q_1 to q_2. Since R_q is the marginal profit, $\Phi(q, p^j)R_q(q, p^j)$ represents the difference of the marginal profits between the offer of q at just above p^j and the offer of q at just below p^j.

Anderson and Philpott [2] and Anderson and Xu [4] treat $v(\mathbf{s})$ in (2.2) as an objective function and investigate the necessary and sufficient conditions for an offer curve $\mathbf{s}$ to be a local maximum. When ψ is continuously differentiable on Ψ, Anderson and Xu prove that there exists a maximum over the set of curves that are considered. However, the existence result is not straightforward when ψ is not continuous, and our first result is to confirm that a maximum does exist provided that ψ satisfies the conditions we have given.

A generator need not offer all its generation capacity into the market; the offer curve will start at some point $(0, \hat{p}(0))$ and finish at $(\hat{q}(T), \hat{p}(T))$. However, the clearing price is determined as though the offer curve began with a vertical segment from the origin to $(0, \hat{p}(0))$ and finished with a vertical segment from $(\hat{q}(T), \hat{p}(T))$ to $(\hat{q}(T), p_M)$. Hence we assume that Λ, the set of possible offer curves, has these characteristics. The following result has been established by Anderson and Xu [4].

LEMMA 2.11. *Let Λ be the set of monotonic continuous curves starting at the origin and ending on the closed line segment from $(0, p_M)$ to (q_M, p_M). Then Λ is compact under the Hausdorff metric:*

$$|\mathbf{s}_1 - \mathbf{s}_2|_H = \max_{(q_1,p_1)\in\mathbf{s}_1} \min_{(q_2,p_2)\in\mathbf{s}_2} \sqrt{(q_1 - q_2)^2 + (p_1 - p_2)^2}.$$

We need some sort of compactness result such as this to ensure the existence of an optimal solution; once compactness is established in some topology, then the existence result follows provided that we have a suitable continuity property in that topology. Our next result uses compactness to establish that the problem of finding a curve $\mathbf{s}$ which maximizes the expected profit $v(\mathbf{s})$ in (2.12) has an optimal solution. But before we prove this theorem we need to establish a preliminary lemma (which is required because $q^j(\mathbf{s})$ is not a continuous function of $\mathbf{s}$).

LEMMA 2.12. *If* $\mathbf{s}_k \to \mathbf{s}$ *in the Hausdorff metric and for some* j: $\lim_{k\to\infty} q^j(\mathbf{s}_k) = q_0$, *then*

$$\int_{q^j(\mathbf{s})}^{q_0} \Phi(q,p^j)R_q(q,p^j)\ dq \le 0. \tag{2.14}$$

Proof. Observe that if $q^j(\mathbf{s}) = q_0$ there is nothing to prove, so we suppose these two are unequal. Since $\mathbf{s}_k \to \mathbf{s}$ in the Hausdorff metric we can deduce that $\min_{(q,p)\in\mathbf{s}} \left((q_0-q)^2 + (p^j-p)^2\right)^{1/2} = 0$ and hence that $(q_0,p^j) \in \mathbf{s}$. Thus, from monotonicity, all of the line interval $(q^j(\mathbf{s}),p^j)$ to (q_0,p^j) is in $\mathbf{s}$. First we suppose that $q^j(\mathbf{s}) < q_0$. Then, from the definition of q^j, this line interval lies in Ψ^{j+1} and hence is part of Ψ_-, where $R_q < 0$. Since $\Phi(q,p^j) \ge 0$, the inequality (2.14) follows. On the other hand, if $q^j(\mathbf{s}) > q_0$, then the line interval (q_0,p^j) to $(q^j(\mathbf{s}),p^j)$ lies in Ψ^j and hence is part of Ψ_+, where $R_q \ge 0$. Again, we have shown the desired inequality (2.14) after noting that the limits of the integral are reversed. ∎

THEOREM 2.13 (existence). *Let* Λ *be defined as above and let* v *be the expected return function given in* (2.12). *Under Assumptions* 2.6 *and* 2.8, *if the market distribution function is* R*-semicontinuous, then* v *achieves its maximum on* Λ.

Proof. Let $v^* = \sup_{\mathbf{s}\in\Lambda} v(\mathbf{s})$, which exists since R is bounded and ψ lies between 0 and 1. For every $k > 0$, there exists a supply curve $\mathbf{s}_k \in \Lambda$ such that $v^* - v(\mathbf{s}_k) \le \frac{1}{k}$. Since Λ is a compact set, there exists $\mathbf{s}^* \in \Lambda$ such that $|\mathbf{s}_k - \mathbf{s}^*|_H \to 0$ (we can take a subsequence if necessary). In addition we shall arrange that for each j, $\lim_{k\to\infty} q^j(\mathbf{s}_k)$ exists. We want to prove that $v(\mathbf{s}^*) = v^*$. We will do this by showing that $v(\mathbf{s}_k) \to v(\mathbf{s}^*)$, using Green's theorem on each of the Ψ^j regions together with Lemma 2.10 for the crossovers from one Ψ^j to the next.

We define $\mathbf{s}^{*j} = \mathbf{s}^* \cap \Psi^j$ and $\mathbf{s}_k^j = \mathbf{s}_k \cap \Psi^j$. Thus

$$v(\mathbf{s}^*) = \sum_{j=1}^{n+1} \int_{\mathbf{s}^{*j}} R(q,p)\ d\psi^j(q,p) + \sum_{j=1}^{n} R(q^j(\mathbf{s}^*),p^j)\Phi(q^j(\mathbf{s}^*),p^j),$$

$$v(\mathbf{s}_k) = \sum_{j=1}^{n+1} \int_{\mathbf{s}_k^j} R(q,p)\ d\psi^j(q,p) + \sum_{j=1}^{n} R(q^j(\mathbf{s}_k),p^j)\Phi(q^j(\mathbf{s}_k),p^j).$$

Let $\operatorname{sign}(q,p)$ be a function such that $\operatorname{sign}(q,p) = 1$ if (q,p) is located below the curve $\mathbf{s}^*$; $\operatorname{sign}(q,p) = -1$ if (q,p) is located above the curve $\mathbf{s}^*$; and $\operatorname{sign}(q,p) = 0$ if (q,p) is located on the curve $\mathbf{s}^*$. Now, using Green's theorem

$$\begin{aligned}
&\int_{\mathbf{s}_k^j} R(q,p)\ d\psi^j(q,p) - \int_{\mathbf{s}^{*j}} R(q,p)\ d\psi^j(q,p) \\
&= \int\int_{A_k^j} \operatorname{sign}(q,p)Z(q,p)\ dq\ dp + \int_{q^j(\mathbf{s}^*)}^{q^j(\mathbf{s}_k)} R(q,p^j)\ d\psi^j(q,p^j) \\
&\quad - \int_{q^{j-1}(\mathbf{s}^*)}^{q^{j-1}(\mathbf{s}_k)} R(q,p^{j-1})\ d\psi^j(q,p^j),
\end{aligned}$$

where A_k^j is the area between $\mathbf{s}^{*j}$ and $\mathbf{s}_k^j$, and Z is given by (2.13). Let A_k be the entire area between $\mathbf{s}^*$ and $\mathbf{s}_k$. Then

$$v(\mathbf{s}_k) - v(\mathbf{s}^*) = \int\int_{A_k} \operatorname{sign}(q,p)Z(q,p)\ dq\ dp$$

$$+\sum_{j=1}^{n}\int_{q^j(\mathbf{s}^*)}^{q^j(\mathbf{s}_k)} R(q,p^j)\ d\psi^j(q,p^j) - \sum_{j=1}^{n}\int_{q^j(\mathbf{s}^*)}^{q^j(\mathbf{s}_k)} R(q,p^j)\ d\psi^{j+1}(q,p^j)$$
$$+\sum_{j=1}^{n} R(q^j(\mathbf{s}_k),p^j)\Phi(q^j(\mathbf{s}_k),p^j) - \sum_{j=1}^{n} R(q^j(\mathbf{s}^*),p^j)\Phi(q^j(\mathbf{s}^*),p^j)$$
$$= \int\int_{A_k} \operatorname{sign}(q,p)Z(q,p)\ dq\ dp + \sum_{j=1}^{n}\int_{q^j(\mathbf{s}^*)}^{q^j(\mathbf{s}_k)} \Phi(q,p^j)R_q(q,p^j)\ dq$$

using Lemma 2.10.

Since $|\mathbf{s}_k - \mathbf{s}^*|_H \to 0$ and Z is bounded from Assumption 2.6, the area integral approaches zero as $k \to \infty$. Also from Lemma 2.12, we know that

$$\lim_{k\to\infty}\int_{q^j(\mathbf{s}^*)}^{q^j(\mathbf{s}_k)} \Phi(q,p^j)R_q(q,p^j)\ dq \le 0.$$

Thus $v(\mathbf{s}^*) \ge \lim_{k\to\infty} v(\mathbf{s}_k) = v^*$, but from the definition of v^*, $v(\mathbf{s}^*) \le v^*$, and thus we have established the desired equality. □

Using this theorem and the results of Theorem 2.9 and Lemma 2.7, we have the immediate corollary.

COROLLARY 2.14. *Under Assumptions* 2.6 *and* 2.8*, if the sharing rule* $\mathcal{L}^*$ *is used, then there is an optimal supply curve.*

3. Necessary conditions for optimality. From Theorem 2.13, we know that the problem of maximizing profit using the sharing rule $\mathcal{L}^*$ is well defined. This is equivalent to the following maximization problem:

$$\max_{\mathbf{s}\in\Lambda}\ v(\mathbf{s}) \equiv \sum_{j=1}^{n+1}\int_{\mathbf{s}^j} R(q,p)\ d\psi^j(q,p) + \sum_{j=1}^{n} R(q^j(\mathbf{s}),p^j)\Phi(q^j(\mathbf{s}),p^j). \tag{3.1}$$

In this section, we discuss necessary conditions for an offer curve to be optimal for this problem.

When ψ is continuously differentiable, optimality conditions were derived by Anderson and Philpott [2] and extended by Anderson and Xu [4]. Let $\mathbf{s} = \{(\hat{q}(\tau),\hat{p}(\tau)) : 0 \le \tau \le T\}$ be the offer curve. The main tool that is used in investigating the optimality conditions of $\mathbf{s}$ is the line integral of Z along $\mathbf{s}$, which is defined by

$$w(\tau) = \int_0^\tau Z(\hat{q}(t),\hat{p}(t))(\hat{q}'(t) + \hat{p}'(t))\ dt.$$

When ψ is not continuously differentiable, we need to use a different approach.

We take ψ as R-semicontinuous and we define, for $(q,p) \in \Psi^j$, the function $Z^j(q,p) = R_q\psi_p^j - R_p\psi_q^j$. This will make Z^j match Z in the interior of Ψ^j and be defined by continuity for points in Ψ^j that lie on its boundary.

Given a monotonic continuous, piecewise smooth offer curve $\mathbf{s} = \{(\hat{q}(\tau),\hat{p}(\tau)), 0 \le \tau \le T\}$, for each τ we let $J(\tau)$ be the index of the region Ψ^j in which $(\hat{q}(\tau),\hat{p}(\tau))$ lies and we let τ^j be the parameter value at which the curve moves from Ψ^j to Ψ^{j+1}, and thus $\hat{q}(\tau^j) = q^j$. Then we define

$$w(\tau) = \int_0^\tau Z^{J(\tau)}(\hat{q}(t),\hat{p}(t))(\hat{q}'(t) + \hat{p}'(t))\ dt + \sum_{j=1}^{J(\tau)-1} \Phi(q^j,p^j)R_q(q^j,p^j).$$

THEOREM 3.1 (first order necessary conditions). *Suppose that* $\mathbf{s} = \{\hat{q}(\tau), \hat{p}(\tau), 0 \leq \tau \leq T\}$ *is an offer curve and Assumptions* 2.6 *and* 2.8 *are satisfied. Suppose that there exist* m *numbers* $0 \leq \tau_1 < \tau_2 < \cdots < \tau_m \leq T$ *with* $0 < \hat{q}(\tau) < q_M$ *and* $0 < \hat{p}(\tau) < p_M$ *for* $\tau_1 < \tau < \tau_m$. *Suppose further that on each section* (τ_{i-1}, τ_i), $i = 2, \ldots, m$, $\mathbf{s}$ *is either strictly increasing in both components, or horizontal, or vertical, with different characteristics in successive segments and with* $\tau_1(\tau_m)$ *the smallest (largest) parameter value such that* $(\hat{q}(\tau), \hat{p}(\tau)) \in \Psi$. *If* $\mathbf{s}$ *is optimal for* (3.1), *then* $w(\tau_1) = 0$ *and* $w(\tau_m) = w(T)$. *Moreover, for each interval* I *being one of* (τ_{i-1}, τ_i), $i = 2, \ldots, m$, *one of the following holds:*

(i) $\mathbf{s}$ *is strictly increasing in both components and* $w(\tau) = w(\tau_{i-1})$ *for* $\tau \in I$.

(ii) $\mathbf{s}$ *is horizontal on* I. *For* $\tau \in I$ *with* $(\hat{q}(\tau), \hat{p}(\tau)) \in \Psi_+$, *then* $w(\tau) \leq w(\tau_{i-1})$; *for* $\tau \in I$ *with* $(\hat{q}(\tau), \hat{p}(\tau)) \in \Psi_-$, *then* $w(\tau) \leq w(\tau_i)$. *Moreover, if* $\hat{p}(\tau_i) \notin \mathcal{P}$, *then* $w(\tau_{i-1}) = w(\tau_i)$.

(iii) $\mathbf{s}$ *is vertical on* I, $w(\tau_{i-1}) = w(\tau_i)$, *and* $w(\tau) \geq w(\tau_i)$ *for* $\tau \in I$.

Proof. We begin by looking at the w values at τ_1 and τ_m. First, we prove $w(\tau_1) = 0$ (the proof that $w(\tau_m) = w(T)$ is similar). By assumption, for any $\tau < \tau_1$, $(\hat{q}(\tau), \hat{p}(\tau))$ is located outside the Ψ region where Z and $w(\tau)$ are zero. Note that if $\hat{p}(\tau_1) \notin \mathcal{P}$, then w is continuous at τ_1 and $w(\tau_1) = 0$. Thus we only need to consider the case that $\hat{p}(\tau_1) = p^j \in \mathcal{P}$. This means that the lower boundary of Ψ contains a horizontal section $p = p^j$ and the point $(\hat{q}(\tau_1), \hat{p}(\tau_1))$ is located on the horizontal section. We consider three cases according to whether the point $(\hat{q}(\tau_1), \hat{p}(\tau_1))$ is located in Ψ_+, in Ψ_-, or on the line separating these regions. In the latter case $R_q(\hat{q}(\tau_1), \hat{p}(\tau_1)) = 0$, and hence $w(\tau_1) = 0$. If $(\hat{q}(\tau_1), \hat{p}(\tau_1))$ is in Ψ_+, then $J(\tau_1) = j - 1$ and $w(\tau_1) = 0$ by the definition of the w function. Thus we are left with the case when $(\hat{q}(\tau_1), \hat{p}(\tau_1))$ is in Ψ_-, when $J(\tau_1) = j$. By definition, since Z is zero outside Ψ,

$$w(\tau_1) = R_q(\hat{q}(\tau_1), p^j)\Phi(\hat{q}(\tau_1), p^j) \leq 0.$$

Suppose for a contradiction that $w(\tau_1) < 0$. Since $\Phi(q, p^j) = \psi(q, p^j_+)$ for all q with (q, p_j) at the boundary, this implies that $\psi(\hat{q}(\tau_1), p^j_+) > 0$. By Assumption 2.8, $\psi(q, p^j_+)$ is continuous in q, and so there exists $\delta > 0$ such that $\psi(\hat{q}(\tau_1) - \delta, p^j_+) > 0$. Consider another supply curve $\mathbf{r}$ which enters Ψ at a point $(\hat{q}(\tau_1) - \delta, p^j_+)$ and then goes horizontally until it reaches the point $(\hat{q}(\tau_1), p^j_+)$ and then joins $\mathbf{s}$ to the end. Using Lemma 2.10, it is easy to verify the difference between the expected profits of the two supply curves,

$$E(\mathbf{s}) - E(\mathbf{r}) = \int_{\hat{q}(\tau_1)-\delta}^{\hat{q}(\tau_1)} R_q(x, p^j)\Phi(x, p^j)dx = \delta w(\tau_1) + o(\delta) < 0,$$

for δ sufficiently small. This contradicts the optimality of $\mathbf{s}$ and establishes $w(\tau_1) = 0$.

Part (i). This part of the theorem amounts to the statement that if $\hat{q}(\tau)$ and $\hat{p}(\tau)$ are both increasing in an interval $\tau \in (\tau_A, \tau_B)$ and we choose a point $(\hat{q}, \hat{p}) = (\hat{q}(\tau^*), \hat{p}(\tau^*))$ in this interval, then $Z(\hat{q}, \hat{p}) = 0$ if $(\hat{q}, \hat{p})$ is in the interior of a Ψ^j, and $\Phi(\hat{q}, \hat{p})R_q(\hat{q}, \hat{p}) = 0$ if $\hat{p} \in \mathcal{P}$. The first statement is proved in Anderson and Philpott [2], but for convenience we will repeat their argument here. We begin by defining a small perturbation of $\mathbf{s}$ around the point $(\hat{q}(\tau^*), \hat{p}(\tau^*))$. Reparameterizing $\mathbf{s}$ if necessary, we can assume that $\hat{q}'(\tau^*) > 0$. Let

$$\mathbf{r}_\delta(\tau) = \begin{cases} (\hat{q}(2\tau - (\tau^* - \delta)), \hat{p}(\tau^* - \delta)), & \tau^* - \delta \leq \tau \leq \tau^*, \\ (\hat{q}(\tau^* + \delta), \hat{p}(2\tau - (\tau^* + \delta)), & \tau^* \leq \tau \leq \tau^* + \delta, \\ (\hat{q}(\tau), \hat{p}(\tau)), & \text{otherwise.} \end{cases}$$

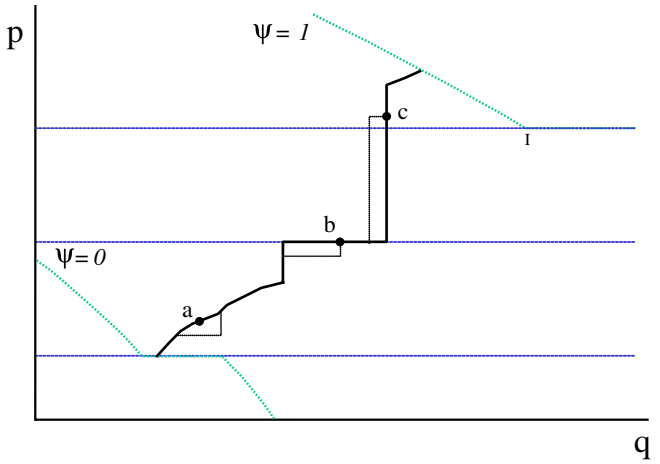

FIG. 1. *Perturbations for first order optimality.*

This perturbation is illustrated in Figure 1 at the point marked a.

In the case that $\hat{p}(\tau^*) \notin \mathcal{P}$ we can avoid any discontinuities within the perturbation by taking δ small enough. In this case

$$v(\mathbf{r}_\delta) - v(\mathbf{s}) = \int \int_{A(\delta)} Z(q,p)\ dqdp,$$

where $A(\delta)$ is the region between the two curves. Since $\mathbf{s}$ is optimal and Z is continuous in this region we obtain the conclusion that $Z(\hat{q}(\tau^*), \hat{p}(\tau^*)) \leq 0$, since otherwise we have $v(\mathbf{r}_\delta) > v(\mathbf{s})$ for δ small enough. If we reverse the direction of the perturbation (going above $(\hat{q}(\tau^*), \hat{p}(\tau^*))$ rather than below it) we can show that $Z(\hat{q}(\tau^*), \hat{p}(\tau^*)) \geq 0$. The two inequalities show that $Z = 0$ as required.

Now suppose that $\hat{p}(\tau^*) = p^j \in \mathcal{P}$. Using Lemma 2.10 and the usual Green's theorem argument we have

$$\begin{aligned} v(\mathbf{r}_\delta) - v(\mathbf{s}) = &\int \int_{A^j(\delta)} Z(q,p)\ dqdp + \int \int_{A^{j+1}(\delta)} Z(q,p)\ dqdp \\ &+ \int_{\hat{q}(\tau^*)}^{\hat{q}(\tau^*+\delta)} \Phi(q,p^j) R_q(q,p^j)\ dq, \end{aligned}$$

where $A^i(\delta) = A(\delta) \cap \Psi^i$. But we have just shown that $Z(q,p) = 0$ along the $\mathbf{s}$ curve (except where $\mathbf{s}$ crosses the p^j line). The continuity of Z implies that both the first two integrals are $o(\delta)$. Thus the continuity of Φ and R_q will imply that

$$v(\mathbf{r}_\delta) - v(\mathbf{s}) = (\hat{q}(\tau^* + \delta) - \hat{q}(\tau^*))\Phi(\hat{q}(\tau^*), p^j) R_q(\hat{q}(\tau^*), p^j) + o(\delta).$$

Since $\hat{q}'(\tau^*) > 0$, $\hat{q}(\tau^*+\delta) - \hat{q}(\tau^*)$ is $O(\delta)$, and thus $\Phi(\hat{q}(\tau^*), p^j) R_q(\hat{q}(\tau^*), p^j) \leq 0$ from the optimality of $\mathbf{s}$. Again reversing the perturbation shows $\Phi(\hat{q}(\tau^*), p^j) R_q(\hat{q}(\tau^*), p^j) \geq 0$, and thus

$$\Phi(\hat{q}(\tau^*), p^j) R_q(\hat{q}(\tau^*), p^j) = 0,$$

as required.

Part (ii). As before we consider a point with parameter $\tau^* \in (\tau_{i-1}, \tau_i)$, a horizontal section. We will need to use two different types of perturbation. Suppose first that $(\hat{q}(\tau_{i-1}), \hat{p}(\tau_{i-1})) \in \Psi_+$. There are two possibilities: $\mathbf{s}$ is vertical immediately before τ_{i-1} and $\mathbf{s}$ is strictly increasing immediately before τ_{i-1}. We only consider the first case in detail.

Let $\delta > 0$ be small and define $\tau_{i-1}(-\delta) = \hat{p}^{-1}(\hat{p}(\tau_{i-1}) - \delta)$ so that this is the parameter value at which $\mathbf{s}$ reaches a price level δ below $\hat{p}(\tau_{i-1})$. Let $\mathbf{r}_\delta$ be the perturbation of $\mathbf{s}$ which moves a horizontal section from $\hat{q}(\tau_{i-1})$ to $\hat{q}(\tau^*)$ down by an amount δ. Thus

$$\mathbf{r}_\delta(\tau) = \begin{cases} (\hat{q}(\tau), \hat{p}(\tau)), & 0 \le \tau < \tau_{i-1}(-\delta), \\ (\hat{q}(\tau_{i-1} - \tau_{i-1}(-\delta) + \tau), \hat{p}(\tau_{i-1}) - \delta), & \tau_{i-1}(-\delta) \le \tau < \tau^* - \tau_{i-1} + \tau_{i-1}(-\delta), \\ (\hat{q}(\tau^*), \hat{p}(\tau + \tau_{i-1} - \tau^*)), & \tau^* - \tau_{i-1} + \tau_{i-1}(-\delta) \le \tau < \tau^*, \\ (\hat{q}(\tau), \hat{p}(\tau)), & \tau^* \le \tau \le T. \end{cases}$$

This perturbation is illustrated in Figure 1, with $(\hat{q}(\tau^*), \hat{p}(\tau^*))$ shown as the point marked b. If $(\hat{q}(\tau^*), \hat{p}(\tau^*)) \in \Psi_+$, then this perturbation does not involve a discontinuity in Z, and thus

$$\begin{aligned} v(\mathbf{r}_\delta) - v(\mathbf{s}) &= \int_{\hat{p}(\tau_{i-1})-\delta}^{\hat{p}(\tau_{i-1})} \int_{\hat{q}(\tau_{i-1})}^{\hat{q}(\tau^*)} Z(q,p)\ dqdp \\ &= \delta \int_{\hat{q}(\tau_{i-1})}^{\hat{q}(\tau^*)} Z(q, \hat{p}(\tau_{i-1}))\ dq + o(\delta). \end{aligned}$$

Since $\mathbf{s}$ is optimal, we obtain the conclusion that $\int_{\hat{q}(\tau_{i-1})}^{\hat{q}(\tau^*)} Z(q, \hat{p}(\tau_{i-1}))dq \le 0$, since otherwise we have $v(\mathbf{r}_\delta) > v(\mathbf{s})$ for δ small enough. Thus $w(\tau^*) \le w(\tau_{i-1})$. In the case that $\mathbf{s}$ is strictly increasing immediately before τ_{i-1}, we need to make a slightly more complex definition for $\mathbf{r}_\delta(\tau)$ and the area over which Z is integrated is no longer rectangular, but the basic argument is the same.

Now if $(\hat{q}(\tau^*), \hat{p}(\tau^*)) \in \Psi_-$, then $(\hat{q}(\tau_i), \hat{p}(\tau_i)) \in \Psi_-$ and we choose a perturbation that moves a horizontal section of $\mathbf{s}$ from $\hat{q}(\tau^*)$ to $\hat{q}(\tau_i)$ upward by an amount δ. If $(\hat{q}(\tau^*), \hat{p}(\tau^*)) \in \Psi_-$, then the continuity of Z for this perturbation implies that $\int_{\hat{q}(\tau^*)}^{\hat{q}(\tau_i)} Z(q, \hat{p}(\tau_i))dq \ge 0$ and hence $w(\tau^*) \le w(\tau_i)$.

When $\hat{p}(\tau_i) \notin \mathcal{P}$ we have continuity for Z without having to restrict ourselves to $(\hat{q}(\tau^*), \hat{p}(\tau^*)) \in \Psi_+$ for a perturbation downwards at the beginning of the horizontal section, or $(\hat{q}(\tau^*), \hat{p}(\tau^*)) \in \Psi_-$ for a perturbation upwards at the end of the horizontal section. Hence we can take $\tau^* = \tau_i$ for the first argument and $\tau^* = \tau_{i-1}$ for the second argument to show that both the inequalities $w(\tau_i) \le w(\tau_{i-1})$ and $w(\tau_{i-1}) \le w(\tau_i)$ hold, and hence that there is equality.

Part (iii). Suppose $\mathbf{s}$ is vertical on the interval between τ_{i-1} and τ_i. We establish the result using perturbations of either end of the interval. We begin with a perturbation that moves the lower part of the interval to the left. There are two possibilities: $\mathbf{s}$ is horizontal immediately before τ_{i-1} or $\mathbf{s}$ is strictly increasing immediately before τ_{i-1}. The first case makes it slightly simpler to give an explicit perturbation, and we restrict ourselves to this.

Let $\delta > 0$ be small and define $\tau_{i-1}(-\delta) = \hat{q}^{-1}(\hat{q}(\tau_{i-1}) - \delta)$ so that this is the parameter value at which $\mathbf{s}$ reaches a quantity $\hat{q}(\tau_{i-1}) - \delta$. Let $\mathbf{r}_\delta$ be the perturbation of $\mathbf{s}$ which moves a vertical section from $\hat{p}(\tau_{i-1})$ to $\hat{p}(\tau^*)$ to the left by an amount δ;

thus:

$$\mathbf{r}_\delta(\tau) = \begin{cases} (\hat{q}(\tau), \hat{p}(\tau)), & 0 \le t < \tau_{i-1}(-\delta), \\ (\hat{q}(\tau_{i-1}) - \delta), \hat{p}(\tau_{i-1} - \tau_{i-1}(-\delta) + t), & \tau_{i-1}(-\delta) \le t < \tau^* - \tau_{i-1} + \tau_{i-1}(-\delta), \\ (\hat{q}(t + \tau_{i-1} - \tau^*), \hat{p}(\tau^*)), & \tau^* - \tau_{i-1} + \tau_{i-1}(-\delta) \le t < \tau^*, \\ (\hat{q}(\tau), \hat{p}(\tau)), & \tau^* \le t \le T. \end{cases}$$

This perturbation is illustrated in Figure 1, with $(\hat{q}(\tau^*), \hat{p}(\tau^*))$ shown as the point marked c. In general this perturbation may involve a number of different regions Ψ^j. Suppose that $(\hat{q}(\tau_{i-1}), \hat{p}(\tau_{i-1})) \in \Psi^f$ and $(\hat{q}(\tau^*), \hat{p}(\tau^*)) \in \Psi^g$. Write $A(\delta)$ for the region between the two curves, $\mathbf{s}$ and $\mathbf{r}_\delta$, and $A^j(\delta) = A(\delta) \cap \Psi^j$. Then

$$\begin{aligned} v(\mathbf{s}) - v(\mathbf{r}_\delta) &= \sum_{j=f}^{g} \int\int_{A^j(\delta)} Z(q,p)\ dqdp + \sum_{j=f}^{g-1} \int_{\hat{q}(\tau_{i-1})-\delta}^{\hat{q}(\tau_{i-1})} \Phi(q, p^j) R_q(q, p^j)\ dq \\ &= \delta \int_{\hat{p}(\tau_{i-1})}^{p^f} Z(\hat{q}(\tau_{i-1}), p)\ dp + \delta \sum_{j=f+1}^{g-1} \int_{p^{j-1}}^{p^j} Z(\hat{q}(\tau_{i-1}), p)\ dp \\ &\quad + \delta \int_{p^{g-1}}^{\hat{p}(\tau^*)} Z(\hat{q}(\tau_{i-1}), p)\ dp + \delta \sum_{j=f}^{g-1} \Phi(\hat{q}(\tau_{i-1}), p^j) R_q(\hat{q}(\tau_{i-1}), p^j) + o(\delta) \\ &= \delta(w(\tau^*) - w(\tau_{i-1})) + o(\delta). \end{aligned}$$

As $\mathbf{s}$ is optimal we obtain the conclusion that $w(\tau^*) \ge w(\tau_{i-1})$, since otherwise we have $v(\mathbf{r}_\delta) > v(\mathbf{s})$ for δ small enough.

The other perturbation to be considered involves a section of the vertical segment from τ^* to τ_i, which moves to the right. The argument in this case is exactly the same and we can show that $w(\tau^*) \ge w(\tau_i)$. Moreover, since these results also apply with $\tau^* = \tau_{i-1}$ and with $\tau^* = \tau_i$, we see that $w(\tau_i) = w(\tau_{i-1})$. □

In many cases there will only be a single solution which satisfies the necessary conditions, and hence the optimal solution can be identified without further computation. Later we will illustrate the application of these conditions on an example, but first it is helpful to give some more general discussion.

In practice, the nature of the optimal solution will be quite dependent on the form of the $Z = 0$ curve. If, as is usually the case, this is a monotonic increasing curve, then the optimal solution will typically follow it for much of its length, with some small variations introduced by the discontinuities. We see this behavior in the example we consider in the next section.

On a vertical section of the offer curve we must have w values greater than at the end points of the section. In the case when neither of the end points is on a horizontal price discontinuity, then this will imply that the beginning (bottom) of the vertical section is in a region where $Z > 0$ and the end of the section is in a region where $Z < 0$. If the bottom end point, say $(\hat{q}(\tau_{i-1}), \hat{p}(\tau_{i-1}))$, lies on a horizontal price discontinuity, say p^j, then we need to consider two cases. First suppose that $(\hat{q}(\tau_{i-1}), \hat{p}(\tau_{i-1})) \in \Psi_-$, which in turn implies $(\hat{q}(\tau_{i-1}), \hat{p}(\tau_{i-1})) \in \Psi^{j+1}$. Then $J(\tau_{i-1}) = j + 1$ and $w(\tau_{i-1})$ already incorporates the jump at this discontinuity; thus the vertical section must begin in a region where $Z > 0$ to avoid contradicting the necessary conditions. The other case occurs when $(\hat{q}(\tau_{i-1}), \hat{p}(\tau_{i-1})) \in \Psi_+$, in which case $R_q \ge 0$ and the jump in value is positive. In this case, we can draw no immediate conclusion on the sign of Z at the start of the vertical section. The same kind of argument shows that if the top end of a vertical section is at a price discontinuity, then when this point is in Ψ_+

we can conclude that the vertical section finishes in a region where $Z < 0$, and no conclusion can be drawn when the point is in Ψ_-.

Now consider a horizontal section that does not coincide with a price discontinuity. In this case the condition of the theorem simply says that $w(\tau)$ is less than the w values at both end points. So the left-hand end of the horizontal section must be in a region where $Z < 0$ and the right-hand end in a region where $Z > 0$.

When the horizontal section runs along a price discontinuity the situation is a little more complex. Suppose first that the left-hand end of the horizontal section is in Ψ_+. Then the necessary conditions for optimality imply that w is decreasing and hence that the beginning of the horizontal section is in a region where $Z \leq 0$. In the same way, if the right-hand end of the horizontal section is in Ψ_-, then we can deduce that this end point is in a region where $Z \geq 0$.

4. Construction of an approximate optimal supply function through undercutting and overcutting. We have found a form of sharing rule for which there will be an optimal solution. However, this form of sharing rule will not occur in practice. Our eventual aim is to have a way of generating ε-optimal solutions for problems with arbitrary sharing rules.

We suppose that we have found an optimal solution $\mathbf{s}^*$ for the modified problem with sharing rule $\mathcal{L}^*$. The next step is to create an ε-optimal solution for the problem using undercutting and overcutting. We define the solution $\mathbf{s}^*(\delta)$ for any $\delta > 0$ by following $\mathbf{s}^*$ except at the prices in $\mathcal{P}$. In essence, where $\mathbf{s}^* = p^j$ and lies in Ψ_+, we undercut the solution and set $\mathbf{s}^*(\delta) = \mathbf{s}^* - \delta$. Where $\mathbf{s}^* = p^j$ and lies in Ψ_-, we overcut the solution and set $\mathbf{s}^*(\delta) = \mathbf{s}^* + \delta$. To make this definition more precise involves some messy technical details, which we will give below. We shall assume that the equation $R_q(q,p) = 0$ defines a single monotonically increasing line which divides Ψ_+ and Ψ_-, and we write this in the form $p = \Gamma(q)$. In the case in which R is given by (2.1), Γ is just C'. If $\mathbf{s}^*$ moves from the region Ψ_+ to the region Ψ_- at a single value p^j, then $\mathbf{s}^*(\delta)$ follows the line $p = \Gamma(q)$ to join the undercutting section to the overcutting one.

We need to go back to the individual component functions $\hat{q}(\tau)$ and $\hat{p}(\tau)$, say, that define $\mathbf{s}^*$. We let $q_\delta(\tau) = \hat{q}(\tau)$ for every τ. We have the following definitions for $p_\delta(\tau)$:

$$p_\delta(\tau) = \begin{cases} p^j - \delta & \text{for } \{\tau : p^j - \delta \leq \hat{p}(\tau) \leq p^j, (\hat{q}(\tau), p^j - \delta) \in \Psi_+\}, \\ p^j + \delta & \text{for } \{\tau : p^j \leq \hat{p}(\tau) \leq p^j + \delta, (\hat{q}(\tau), p^j + \delta) \in \Psi_-\}, \\ \Gamma(\hat{q}(\tau)) & \text{for } \{\tau : p^j - \delta \leq \hat{p}(\tau) \leq p^j, (\hat{q}(\tau), p^j - \delta) \notin \Psi_+, (\hat{q}(\tau), p^j) \in \Psi_+\}, \\ \Gamma(\hat{q}(\tau)) & \text{for } \{\tau : p^j \leq \hat{p}(\tau) \leq p^j + \delta, (\hat{q}(\tau), p^j + \delta) \notin \Psi_-, (\hat{q}(\tau), p^j) \in \Psi_-\}, \\ \hat{p}(\tau) & \text{otherwise.} \end{cases}$$

As it stands this defines $p_\delta(\tau)$ in such a way that it may not be continuous. We need to make the definition of p_δ continuous by filling in these (vertical) gaps. Suppose that

$$\hat{p}(\tau_{0-}) = \lim_{\tau \uparrow \tau_0} \hat{p}(\tau) = \lim_{\tau \downarrow \tau_0} \hat{p}(\tau) - \eta$$

for some $\eta > 0$. Then we define

$$(\widetilde{p}_\delta(\tau), \widetilde{q}_\delta(\tau)) = \begin{cases} (p_\delta(\tau), q_\delta(\tau)) & \text{for } \tau < \tau_0, \\ (p_\delta(\tau_{0-}) + \tau - \tau_0, q_\delta(\tau_0)) & \text{for } \tau_0 \leq \tau \leq \tau_0 + \eta, \\ (p_\delta(\tau - \gamma), q_\delta(\tau - \gamma)) & \text{for } \tau > \tau_0 + \eta. \end{cases}$$

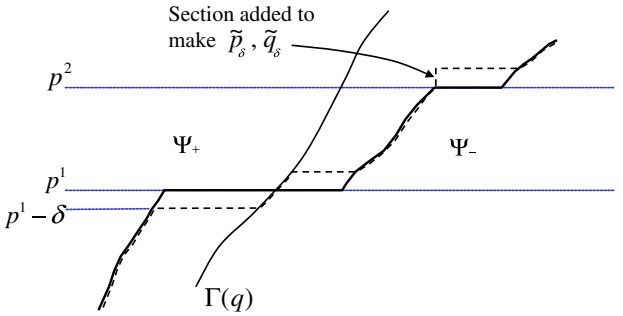

FIG. 2. *Construction of* $\mathbf{s}^*(\delta)$.

This removes one of the discontinuities, and we can continue in the same way to remove each of the other discontinuities (at most one of which is introduced at each p^j). Then $\mathbf{s}^*(\delta)$ is defined by $(\tilde{p}_\delta(\tau), \tilde{q}_\delta(\tau))$. Figure 2 illustrates this construction.

Our key result is that $\mathbf{s}^*(\delta)$ is ε-optimal for small enough δ. We are now in a position to prove this.

THEOREM 4.1. *Suppose that* $\mathbf{s}^*$ *maximizes the expected profits of the generator when the sharing rule* $\mathcal{L}^*$ *is used. Then*

$$\lim_{\delta \downarrow 0} u(\mathbf{s}^*(\delta)) = \sup_{\mathbf{s} \in \Lambda} u(\mathbf{s}),$$

where $u(\mathbf{r})$ *denotes the expected profits of the generator given a supply curve* $\mathbf{r}$ *with some other sharing rule* $\mathcal{L}$.

Proof. We write $v(\mathbf{r})$ for the expected profit of the generator given a supply curve $\mathbf{r}$ with the ideal sharing rule $\mathcal{L}^*$. From Lemma 2.4 we know that $v(\mathbf{s}) \geq u(\mathbf{s})$. Thus

$$v(\mathbf{s}^*) \geq \sup_{\mathbf{s} \in \Lambda} u(\mathbf{s}).$$

Moreover, as each $\mathbf{s}^*(\delta) \in \Lambda$, $\lim_{\delta \downarrow 0} u(\mathbf{s}^*(\delta)) \leq \sup_{\mathbf{s} \in \Lambda} u(\mathbf{s})$. So it is enough to show $\lim_{\delta \downarrow 0} u(\mathbf{s}^*(\delta)) = v(\mathbf{s}^*)$.

Now it is not hard to see that $q^j(\mathbf{s}^*(\delta)) = q^j(\mathbf{s}^*)$ for each j. This is a result of the construction we have used for $\mathbf{s}^*(\delta)$. Thus

$$v(\mathbf{s}^*) - v(\mathbf{s}^*(\delta)) = \sum_{j=1}^{n+1} \left(\int_{\mathbf{s}^{*j}} R(q,p)\ d\psi^j(q,p) - \int_{\mathbf{s}^*(\delta)^j} R(q,p)\ d\psi^j(q,p) \right).$$

Since the end points of the segments $\mathbf{s}^{*j}$ and $\mathbf{s}^*(\delta)^j$ coincide within each Ψ^j, we can use Green's theorem within this region to show that the difference between the integrals tends to zero as $\delta \to 0$. So $v(\mathbf{s}^*) = \lim_{\delta \to 0} v(\mathbf{s}^*(\delta))$. But as $\mathbf{s}^*(\delta)$ does not contain a tranche offered at any p^j the sharing rule used will not affect the expected profit, and hence $v(\mathbf{s}^*(\delta)) = u(\mathbf{s}^*(\delta))$ for each δ. □

5. An example. In order to illustrate the ideas we have discussed above we return to the example we considered before. We now suppose that the market demand is given by $D(p) + \epsilon$ where $D(p) = 800 - \frac{10}{3}p^2$, and the random shock ϵ ranges uniformly over $[0, 2300]$. We wish to find the optimal offer curve for generator A. For $p \neq 10, 14, 18$, we can derive the market distribution function for generator A:

$$\psi(q,p) = \frac{1}{2300}(q - D(p) + S_B(p))$$

and

$$\Psi = \left\{ (q,p) : 0 < \frac{1}{2300}(q - D(p) + S_B(p)) < 1 \right\}.$$

The values of ψ at $p = 10, 14, 18$ will depend on the market sharing rules, which we do not need to specify.

We need to specify a contract position and the cost of generation. We suppose that generator A has contracts for a total quantity of 800 MW at a strike price of \$15 per MWh (that is, $Q = 800$ MW), and we take the total capacity for the generators to offer into the market as 1100 MW. We also take the costs generator A incurs for generating an amount q MWh as nonlinear and given by $C(q) = 10q + 0.004q^2$. Thus the profit function (in \$ per hour) is

$$R(q,p) = qp - 10q - 0.004q^2 + 800(15 - p).$$

We wish to find an optimal supply curve for generator A so that its expected profit is maximized. However, since ψ here is discontinuous, an optimal supply curve may not exist.

Note that

$$R_q(q,p) = p - 10 - 0.008q.$$

Thus $q^*(p^j) = 125(p^j - 10)$, and

$$\Psi_+ = \{(q,p) \in \Psi : q \le 125(p - 10)\},$$
$$\Psi_- = \{(q,p) \in \Psi : q > 125(p - 10)\}.$$

The optimal sharing rule $\mathcal{L}^*$ is defined according to the rules set out earlier. Essentially, the aim of the sharing rule is to obtain a dispatch of $125(p^j - 10)$ for generator A at each of the prices $p^j = 10, 14, 18$ (or as close to this figure as possible).

In what follows, we derive the optimal supply curve, assuming the sharing rule $\mathcal{L}^*$, using Theorem 3.1. Note that for $p \neq 10, 14$, or 18,

$$Z(q,p) = R_q\psi_p - R_p\psi_q = \frac{1}{2300}\left[(p - 10 - 0.008q)\left(\frac{20}{3}p\right) - q + 800\right].$$

In Figure 3 we show the upper and lower boundaries of the region Ψ (i.e., where $\psi = 0$ and $\psi = 1$) together with the curve (in fact a parabola) where $Z = 0$ and the straight line $p = C'(q) = 10 + 0.008q$.

We will try to identify an optimal offer curve which satisfies the first order necessary conditions that are derived in Theorem 3.1. To do this we consider tracing a curve starting at the lower boundary $\psi = 0$ and finishing at $\psi = 1$. According to part (i) of Theorem 3.1, the optimal offer curve must follow the $Z = 0$ line at any point where it is neither horizontal nor vertical, and it is natural to start by considering a solution which follows this line. The argument given below shows that, for this example, there will be only one solution that satisfies the necessary optimality conditions. This is often the case for this type of problem (but not always). If there is more than one solution satisfying the optimality conditions, then the expected profits for the different offer curves need to be compared directly in order to find a global optimum.

Observe, though, that a solution which follows the line $Z = 0$ from the point $B = (507.2, 9.372)$ where it crosses $\psi = 0$ through the point D cannot be optimal.

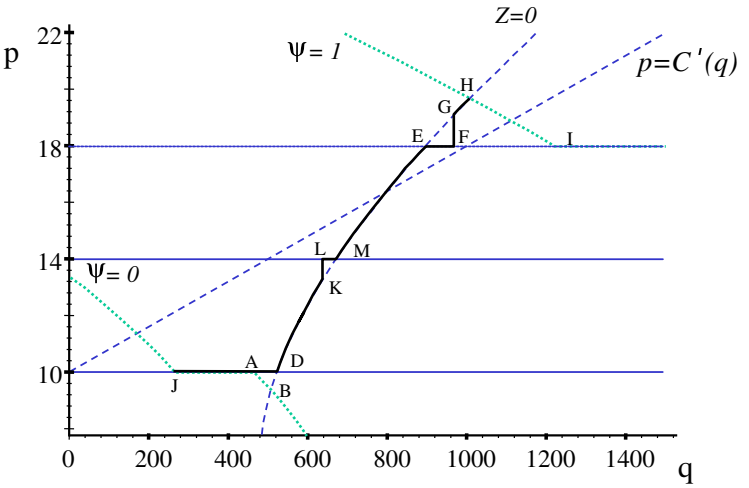

FIG. 3. *An optimal solution for the example.*

The line $Z = 0$ crosses $p = 10$ at $D = (521.7, 10)$, and at this point there is a discontinuity in w which would contradict the necessary condition (i) of the theorem. In fact, $\Phi(521.7, 10)R_q(521.7, 10) = -0.363$.

Thus we need to consider the possibility of a vertical segment finishing at the $p = 10$ line. In order to satisfy the conditions of the theorem, the integral of Z along the vertical section would have to exactly match the jump down that occurs at $p = 10$. For convenience we define

$$W_1(q, a, b) = \int_a^b Z(q, p)dp + \Phi(q, b)R_q(q, b)$$

to be the w integral over a vertical segment at q starting at $p = a$ and finishing at $p = b$ where there is supposed to be a discontinuity. Thus in this case we are interested in finding a starting point (q, a) for which $W_1(q, a, 10) = 0$. The possibilities here are to begin by following the line $Z = 0$ from the point B, but to start a vertical segment before reaching D, or to start from some point between A and B with a vertical section. However, it is not hard to check that in all cases $W_1(q, a, 10)$ will be negative.

Therefore we next consider a horizontal segment starting from some point in JA. This is in the region Ψ_-, and thus the necessary conditions will just imply that $w(\tau)$ is less than the w value at the next corner point. This condition will be satisfied since Z is positive in this region. However, this same condition will ensure that this horizontal section of the optimal offer curve does not go beyond D where Z changes sign. In fact, the necessary conditions imply that the horizontal segment starts at $J = (266.6, 10)$.

Now we consider the possibility of a vertical section which finishes on the horizontal line $p = 14$. Again, using the necessary conditions will imply that we should start this vertical segment at a point (q, a) where $W_1(q, a, 14) = 0$. This equation defines a curve which crosses the $Z = 0$ line at the point $K = (643.7, 13.4)$. Again we can establish that the horizontal section must run from $L = (643.7, 14)$ to the point $M = (671.8, 14)$ on the $Z = 0$ line and no further.

The solution then has to follow the $Z = 0$ line until the point $E = (898.0, 18)$. At this point it starts a horizontal segment. Since the solution is now in the Ψ_+ region,

the start of this horizontal section remains in the region "below the line" including $14 < p < 18$. For this reason there is no jump in the w value until the line leaves the horizontal, and there cannot be a solution with a vertical segment ending at the $p = 18$ line which satisfies the necessary conditions.

To make our discussion here easier we define

$$W_2(q, a, b) = \Phi(q, a)R_q(q, a) + \int_a^b Z(q, p)dp,$$

which is the w integral over a vertical segment starting at $(q, a) \in \Psi_+$ when a is a price discontinuity. In this case, we need to continue with a vertical segment starting at a point $(q, 18)$ and ending at a point (q, b), either on the $Z = 0$ line or on the upper boundary $\psi = 1$, with $W_2(q, 18, b) = 0$. Now the curve defined by $W_2(q, 18, b) = 0$ intersects the $Z = 0$ line at $G = (921.2, 18.36)$. The optimal solution then continues along the $Z = 0$ line until crossing the upper boundary at $H = (1009.6, 19.675)$. The complete optimal solution is shown in Figure 1.

Having found the optimal solution to the problem when $\mathcal{L}^*$ is used, it is straightforward to generate ε-optimal solutions for the case where we do not have the ideal sharing rule when prices coincide. We should follow the solution described above, but overcutting slightly for horizontal sections of the offer curve in Ψ_- and undercutting in Ψ_+. It will not matter what the offer looks like outside the region Ψ. If we choose to undercut and overcut by an amount of \$0.01, we end up with the following offer schedule:

(a) an amount of 266.6 MW at price \$0 (or any price below \$10),
(b) an amount of 521.7–266.6 = 255. 1 MW at price \$10.01,
(c) an amount of 643.7–521.7 = 122.0 MW in a smooth curve rising to a price of \$13.40,
(d) an amount of 671.8–643.7 = 28. 1 MW at a price of \$14.01,
(e) an amount of 898.0–671.8 = 226. 2 MW in a smooth curve rising to a price of \$17.99,
(f) an amount of 921.2–898.0 = 23.2 MW at a price of \$17.99,
(g) an amount of 1009.6–921.2 = 88.4 MW in a curve from a price of \$18.36 to \$19.67,
(h) an amount of 1100–1009.6 = 90.4 MW at \$50 (or any price above \$19.67).

The offer schedule above now needs to be altered in line with market rules. In the case that only step functions are allowed as offers, then the smooth curves of (c), (e), and (g) will need to be approximated with step functions. In the case that piecewise linear offers are required, then these curves would be approximated by one or more linear segments.

6. Discussion. Work on optimal offer policies and on Nash equilibria in an electricity market setting has often confronted the issue of undercutting (though our discussion of overcutting solutions is new). The essential problem is that the possibility of undercutting on price will in many models lead to highly competitive (Bertrand-type) equilibrium solutions, with no possibility of supporting an equilibrium in which generators offer at prices above their marginal costs. However, this idealized behavior is very far from that which is observed in actual markets around the world. Different authors have suggested a variety of methods to address the issue.

Using supply functions as a model for the offer procedure is one approach which avoids the difficulty of undercutting. In this framework we usually assume that there

is no single price at which a generator offers a significant quantity of power, and this allows us to formulate models in which Nash equilibria exist for supply functions.

An alternative approach which has been suggested by von der Fehr and Harbord [15], and which has been used by Wolfram [16] and Brunekreeft [6], is to assume that offers are made at one or a small number of prices but that these prices are not revealed in advance to the other players. This allows a type of mixed strategy to be played which chooses prices according to a continuous distribution. This clearly rules out the possibility of undercutting, since even though we know the strategy of the other player, we do not know a price which we can then undercut.

In this paper we do not try to establish equilibrium conditions; instead we concentrate on the question of evaluating the optimal (or ε-optimal) offer strategy. From a generator's viewpoint this is valuable if the generator wishes to achieve the maximum one period profit. The analysis we give can then point to the best possible policy which is likely to involve some part of the offer either just below or just above other players' prices. But the analysis is also valuable if the generator decides to adopt a less aggressive policy, since it indicates the degree of suboptimality involved in adopting any other (nonundercutting) solution. In practice generators will also need to build an offer according to specific market rules: again we can think of the optimal supply function strategy as setting a benchmark against which other policies can be compared. Sometimes, as in Australia and New Zealand, these market rules imply that a step function is used, in which case a step function approximation to the type of policy shown in Figure 3 should be constructed. Other markets allow an offer to be piecewise linear, which will enable a much closer approximation to be achieved.

It is natural to ask whether the type of analysis we give here could be extended to an equilibrium analysis. In fact it is not possible to construct an exact Nash equilibrium in offers with the type of undercutting behavior we have analyzed. However, an interesting area for further research is the existence of an ε-equilibrium, in which player i submits an offer S_i (being a step function satisfying the market rules) in such a way that the expected profit for player i, $v_i(S_i)$, is within ε of the best possible expected profit for player i given the offers of the other generators. Such a step function ε-equilibrium will not be unique, and so there will be the usual conceptual problems of coordination on nonunique equilibria, coupled here with additional difficulties in coordinating on an appropriate value of ε. Nevertheless, such ε-equilibrium might be arrived at in practice through repeated adjustment of generator offers in response to the other generators, but where generators prefer not to change their offer strategy unless this will lead to an increase in expected profit of at least ε.

APPROXIMATION OF SOLUTIONS OF RICCATI EQUATIONS*

PAVEL BUBÁK†, CORNELIS V. M. VAN DER MEE‡, AND ANDRÉ C. M. RAN§

Abstract. This paper deals with two interrelated issues. One is an invariant subspace approach to finding solutions for the algebraic Riccati equation for a class of infinite dimensional systems. The second is approximation of the solution of the algebraic Riccati equation by finite dimensional approximants. The theory of exponentially dichotomous operators and bisemigroups is instrumental in our approach.

Key words. Riccati equation, matrix approximation, exponential dichotomy

AMS subject classifications. 93C25, 49N10, 47D06

1. Introduction.

The goal of this paper is twofold. The first goal is to use the theory of exponentially dichotomous operators and bisemigroups to derive a result from the existence of solutions to an algebraic Riccati equation of the type occurring in LQ-optimal control. This approach allows one to mimic the finite dimensional approach to algebraic Riccati equations; that is, it allows one to use an invariant subspace argument to obtain the extremal solutions to the algebraic Riccati equation. This topic is dealt with in section 2. It is a continuation of earlier work in this direction presented in [18, 19].

The second goal is to use the results obtained in section 2 to discuss finite dimensional approximations of the solutions of the algebraic Riccati equation and of the corresponding closed loop semigroup. Our results in this direction are presented in section 3.

The work on which this paper reports is loosely based on the work done by the first author for his masters thesis, in combination with work on the perturbation of bisemigroup generators of the last two authors [19].

Finite dimensional approximations of solutions of algebraic Riccati equations and of the corresponding closed loop semigroups are the topic of several earlier contributions; see [2, 8, 14, 12, 13, 20]. In comparison with [14] we do not discuss the algebraic Riccati equation coming from H^∞-control theory, but rather confine ourselves to the one stemming from LQ-optimal control. The result we obtain is, in this special case, the same, under slightly different assumptions, but with a completely different, and in our view, more transparent proof. In [20] attention was also focused on the algebraic Riccati equation from LQ-optimal control. The assumptions there are seriously weaker than the ones imposed in previous works. In particular, instead of exponential stability (or exponential stabilizability) in [20] strong stabilizability is assumed. Instead, we consider exponentially dichotomous operators, which allows us to deal with Hamiltonian operators of linear systems that have no spectrum within a strip

about the imaginary axis and for which one of the off-diagonal operators is compact. However, we obtain stronger results on the closed loop approximants (compare our Theorem 3.4 with Theorem 4.2 in [20]) in return for our stronger assumptions. Again, our methods of proof are quite different from the ones in [20].

Our approach is part of a long tradition of studying stability results for solutions of Riccati equations by performing a stability analysis of certain invariant subspaces of the Hamiltonian operator, while also linking these to stable factorizations of a transfer function [3, 17]. Structural similarities between these interlocking problems and state space approaches to solve convolution equations [5] and stationary transport equations [10] have naturally led to the formal study of exponentially dichotomous operators [4], results on their perturbation [19], and its present stability analysis of Hamiltonian operators of autonomous linear systems.

In [19] we have linked the left and right canonical Wiener–Hopf factorizability of a transfer function built from the Hamiltonian operator

$$\begin{pmatrix} A_0 & -D \\ -Q & -A_1 \end{pmatrix} \tag{1.1}$$

of a linear system to the existence of the stable and anti-stable solution of a Riccati equation, under hardly more than the assumption that $-A_0$ and $-A_1$ generate exponentially decaying C_0-semigroups on a general Banach space. Even though not stated explicitly, stability results for these solutions of the Riccati equations are expected (and thus now conjectured) to hold if the transfer function has a left or right canonical Wiener–Hopf factorization. Using the well-known fact that this is true for positive selfadjoint transfer functions on a Hilbert space, we naturally arrive at the basic outline of the present paper. The stability analysis itself appears to be straightforward.

Our present approach may be viewed as a tool to derive stability results for Riccati equations starting from the Hamiltonian operator, where the derivation of the latter is standard system theory [7, 15]. Many of the existing results (but not all; see [20]) can thus be derived in a transparent way, but the present approach potentially leads to useful applications to delay systems where the underlying spaces are L^1 [11].

When dealing with Hamiltonian operators of the type (1.1) with $D = BR^{-1}B^*$, $Q = C^*C$, and $A_0 = A_1^* = A$, the infinitesimal generator of a C_0-semigroup on a separable Hilbert space $\mathcal{H}$, it is sufficient to require the exponential stabilizability of (A, B) or the exponential detectability of (C, A) to arrive at an exponentially dichotomous operator on $\mathcal{H}\dot{+}\mathcal{H}$ after a similarity implementing state feedback or output injection (e.g., see [7]). Thus for the purpose of this article it is sufficient to deal with Hamiltonian operators that are exponentially dichotomous.

Let us conclude the introduction with some notations and definitions. By $\mathcal{D}(A)$, $\operatorname{Ker} A$, and $\operatorname{Im} A$ we denote the domain, kernel, and range of a linear operator A, respectively, and by $I_{\mathcal{H}}$ the identity operator on a Hilbert space $\mathcal{H}$. By $\mathcal{H} \stackrel{\text{def}}{=} \mathcal{H}_1\dot{+}\mathcal{H}_2$ we denote the orthogonal direct sum of the Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ and by $A \stackrel{\text{def}}{=} A_1\dot{+}A_2$ the linear operator on $\mathcal{H}$ with domain $\{(x_1, x_2) : x_j \in \mathcal{D}(\mathcal{H}_j), j = 1, 2\}$ defined by $A(x_1, x_2) = (A_1x_1, A_2x_2)$.

2. Preliminaries. A closed and densely defined linear operator $-S$ on a Hilbert space $\mathcal{H}$ is called *exponentially dichotomous* [4] if for some bounded projection P commuting with S, the restrictions of S to $\operatorname{Im} P$ and of $-S$ to $\operatorname{Ker} P$ are the infinitesimal generators of exponentially decaying C_0-semigroups. We then define the *bisemigroup*

generated by $-S$ as

$$E(t;-S) = \begin{cases} e^{-tS}(I-P), & t > 0 \\ -e^{-tS}P, & t < 0. \end{cases}$$

Its *separating projection* P is given by $P = -E(0^-;-S) = I_{\mathcal{H}} - E(0^+;-S)$. One easily verifies [4] the existence of $\varepsilon > 0$ such that $\{\lambda \in \mathbb{C} : |\operatorname{Re}\lambda| \le \varepsilon\}$ is contained in the resolvent set $\rho(S)$ of S and for every $x \in \mathcal{H}$

$$(\lambda - S)^{-1}x = -\int_{-\infty}^{\infty} e^{\lambda t}E(t;-S)x\,dt, \qquad |\operatorname{Re}\lambda| \le \varepsilon. \tag{2.1}$$

As a result, $\|(\lambda - S)^{-1}x\| \to 0$ as $\lambda \to \infty$ in $\{\lambda \in \mathbb{C} : |\operatorname{Re}\lambda| \le \varepsilon'\}$ for some $\varepsilon' \in (0, \varepsilon]$.

We have the following perturbation result given also in [19]. We shall give its proof for selfcontainedness.

THEOREM 2.1. *Let $-S_0$ be exponentially dichotomous, Γ be a compact operator, and $-S = -S_0 + \Gamma$, where $\mathcal{D}(S) = \mathcal{D}(S_0)$. Suppose the imaginary axis is contained in the resolvent set of S. Then $-S$ is exponentially dichotomous. Moreover, $E(t;-S) - E(t;-S_0)$ is a compact operator, also in the limits as $t \to 0^{\pm}$.*

Proof. There exists $\varepsilon > 0$ such that

$$\int_{-\infty}^{\infty} e^{\varepsilon|t|}\|E(t;-S_0)\|\,dt < \infty. \tag{2.2}$$

Using the resolvent identity

$$(\lambda - S)^{-1} - (\lambda - S_0)^{-1} = -(\lambda - S_0)^{-1}\Gamma(\lambda - S)^{-1}, \qquad |\operatorname{Re}\lambda| \le \varepsilon,$$

for some $\varepsilon > 0$, we obtain the convolution integral equation

$$E(t;-S)x - \int_{-\infty}^{\infty} E(t-\tau;-S_0)\Gamma E(\tau;-S)x\,d\tau = E(t;-S_0)x, \tag{2.3}$$

where $x \in \mathcal{H}$ and $0 \ne t \in \mathbb{R}$. In (2.3), the convolution kernel $E(\cdot;-S_0)\Gamma$ is continuous in the norm except for a jump discontinuity in $t = 0$, as a result of the strong continuity (except for the jump) of $E(\cdot;-S_0)$ and the compactness of Γ. Further, (2.2) implies that $e^{\varepsilon|\cdot|}E(\cdot;-S_0)\Gamma$ is Bochner integrable.

The symbol of the convolution integral equation (2.3), which equals $I_{\mathcal{H}} + (\lambda - S_0)^{-1}\Gamma = (\lambda - S_0)^{-1}(\lambda - S)$, tends to $I_{\mathcal{H}}$ in the norm as $\lambda \to \infty$ in the strip $|\operatorname{Re}\lambda| \le \varepsilon$, since Γ is compact and $(\lambda - S_0)^{-1}$ tends to zero strongly. Moreover, it is a compact perturbation of the identity which, by definition, only takes invertible values on the imaginary axis. Thus there exists $\varepsilon_0 \in (0, \varepsilon]$ such that the symbol only takes invertible values on the strip $|\operatorname{Re}\lambda| \le \varepsilon_0$.

Before proceeding with the proof we now state the Bochner–Phillips theorem [6, 9]:

- Let $\mathcal{A}_0$ be a Banach algebra, $\mathcal{A}$ its natural extension to a Banach algebra with unit element, and $W_{\mathcal{A}_0}$ the Banach algebra of all ordered pairs (A_∞, A), where $A_\infty \in \mathcal{A}$ and A is a Bochner integrable function from $\mathbb{R}$ into $\mathcal{A}_0$, endowed with the norm

$$\|(A_\infty, A)\|_{W_{\mathcal{A}_0}} \stackrel{def}{=} \|A_\infty\|_{\mathcal{A}} + \int_{-\infty}^{\infty} \|A(t)\|_{\mathcal{A}_0}\,dt.$$

Then (A_∞, A) is invertible in $W_{\mathcal{A}_0}$ if and only if A_∞ and all of the Fourier transform values

$$A_\infty + \int_{-\infty}^{\infty} e^{i\lambda t} A(t)\, dt, \qquad \lambda \in \mathbb{R},$$

are invertible elements of $\mathcal{A}$. In that case the inverse (B_∞, B) is given by $B_\infty = (A_\infty)^{-1}$ and

$$B_\infty + \int_{-\infty}^{\infty} e^{i\lambda t} B(t)\, dt = \left[A_\infty + \int_{-\infty}^{\infty} e^{i\lambda t} A(t)\, dt \right]^{-1}, \qquad \lambda \in \mathbb{R}.$$

We now apply this result in two different situations: (i) $\mathcal{A} = \mathcal{A}_0 = L(\mathcal{H})$ is the Banach algebra of bounded linear operators on $\mathcal{H}$, and (ii) $\mathcal{A}_0 = K(\mathcal{H})$ is the Banach algebra of compact operators on $\mathcal{H}$ and $\mathcal{A} = \{\lambda I_{\mathcal{H}} + K : \lambda \in \mathbb{C}, K \in K(\mathcal{H})\}$. We then also use that an element $(A_\infty, A) \in W_{L(\mathcal{H})}$ induces a bounded linear operator on $BC(\mathbb{R}^-; \mathcal{H}) \oplus BC(\mathbb{R}^*; \mathcal{H})$, the bounded continuous functions from $\mathbb{R}$ into $\mathcal{H}$ with a jump discontinuity at $t = 0$, by convolution.

By the Bochner–Phillips theorem, the convolution equation (2.3) has a unique solution $u(\cdot; x) = E(\cdot; -S)x$ with the following properties:

1) $E(\cdot; -S)$ is strongly continuous, except for a jump discontinuity at $t = 0$,
2) $\int_{-\infty}^{\infty} e^{\varepsilon_0 |t|} \|E(t; -S)\|\, dt < \infty$; hence $E(\cdot; -S)$ is exponentially decaying,
3) $E(t; -S) - E(t; -S_0)$ is a compact operator, also in the limits as $t \to 0^{\pm}$, and
4) the identity (2.1) holds.

As result [4], $-S$ is exponentially dichotomous. □

The set $\theta = (A_0, Q, D; \mathcal{H})$ is called a *triple* if $\mathcal{H}$ is a complex Hilbert space, A_0 generates a strongly continuous semigroup on $\mathcal{H}$ of negative exponential type, and Q and D are bounded selfadjoint operators on $\mathcal{H}$. Then obviously $-S_0 = (-A_0) \dot{+} A_0^*$ is exponentially dichotomous on $\mathcal{H} \dot{+} \mathcal{H}$ and $P_0 = I_{\mathcal{H}} \dot{+} 0$ is the separating projection of the corresponding bisemigroup $E(\cdot; -S_0)$. The triple θ is called *semicompact* if D is a compact operator on $\mathcal{H}$, and *compact* if both D and Q are compact operators on $\mathcal{H}$. The triple θ is called *positive semidefinite* if Q and D are positive semidefinite selfadjoint, and *antipodal* if one of Q and D is positive semidefinite selfadjoint and the other is negative semidefinite selfadjoint.

Theorem 2.1 can be used to prove the following more specific result.

THEOREM 2.2. *Let $\theta = (A_0, Q, D; \mathcal{H})$ be a positive semidefinite and semicompact triple. Then the block matrix operator $-S$ defined on $\mathcal{H} \dot{+} \mathcal{H}$ by*

$$S = \begin{bmatrix} A_0 & -D \\ -Q & -A_0^* \end{bmatrix},$$

is exponentially dichotomous.

Proof. Suppose (2.2) is satisfied. Let us define the operator

$$S_Q = \begin{bmatrix} A_0 & 0 \\ -Q & -A_0^* \end{bmatrix}, \qquad \mathcal{D}(S_Q) = \mathcal{D}(S_0).$$

Consider the unique and positive semidefinite solution X of the Lyapunov equation (e.g., [7, (1.12)–(1.13)])

$$A_0^* X + X A_0 = -Q,$$

given by

$$Xx = \int_0^\infty e^{\tau A_0^*} Q e^{-\tau A_0} x \, d\tau, \qquad x \in \mathcal{H}.$$

Note that

$$\begin{bmatrix} I & 0 \\ -X & I \end{bmatrix} S_Q \begin{bmatrix} I & 0 \\ X & I \end{bmatrix} = S_0.$$

So S_Q and S_0 are similar. Hence $-S_Q$ is exponentially dichotomous, and we obtain

$$E(\cdot; -S_Q) = \begin{bmatrix} I & 0 \\ X & I \end{bmatrix} E(\cdot; -S_0) \begin{bmatrix} I & 0 \\ -X & I \end{bmatrix}.$$

We also see that the separating projection P_Q of $E(\cdot; -S_Q)$ is given by

$$P_Q = \begin{bmatrix} I & 0 \\ X & 0 \end{bmatrix}.$$

Next, we remark that $S - S_Q$ is a compact operator. Hence by Theorem 2.1, to prove that $-S$ is exponentially dichotomous, it suffices to prove that $-S$ does not have imaginary eigenvalues. Indeed, let λ be an imaginary eigenvalue of $-S$. Then there exist $x \in \mathcal{D}(A_0)$ and $y \in \mathcal{D}(A_0^*)$ such that

$$\begin{aligned} (\lambda + A_0)x - Dy &= 0, \\ -Qx + (\lambda - A_0^*)y &= 0. \end{aligned}$$

Then, since λ is purely imaginary, we have

$$\langle Qx, x\rangle + \langle Dy, y\rangle = \langle (\lambda - A_0^*)y, x\rangle + \langle (\lambda + A_0)x, y\rangle = 0,$$

which implies $Qx = Dy = 0$. But then $(\lambda - A_0)x = (\lambda + A_0^*)y = 0$ for some imaginary λ, and hence $x = y = 0$, as claimed. □

Let

$$P = -E(0^-; -S) = I_{\mathcal{H}\dot{+}\mathcal{H}} - E(0^+; -S)$$

denote the separating projection of $E(\cdot; -S)$. Consider the indefinite scalar product generated by

$$\mathcal{J}_1 = \begin{bmatrix} 0 & -I_{\mathcal{H}} \\ -I_{\mathcal{H}} & 0 \end{bmatrix}$$

on $\mathcal{H}\dot{+}\mathcal{H}$. Since $\mathcal{J}_1 S + S^* \mathcal{J}_1 = 2(Q\dot{+}D)$, the real part $\frac{1}{2}(S + \mathcal{J}_1^{-1} S^* \mathcal{J}_1)$ of S with respect to the indefinite scalar product generated by $\mathcal{J}_1$ is positive semidefinite selfadjoint whenever $\theta = (A_0, Q, D; \mathcal{H})$ is a positive semidefinite triple. Hence, in this case it is clear that $\operatorname{Im} P$ is a $\mathcal{J}_1$-nonpositive and $\operatorname{Ker} P$ is a $\mathcal{J}_1$-nonnegative S-invariant subspace of $\mathcal{H}\dot{+}\mathcal{H}$ (cf. [1, section 3.2]). Also [1], since iS is selfadjoint with respect to the indefinite scalar product generated by

$$\mathcal{J}_2 = \begin{bmatrix} 0 & iI_{\mathcal{H}} \\ -iI_{\mathcal{H}} & 0 \end{bmatrix},$$

it is clear that $\operatorname{Im} P$ and $\operatorname{Ker} P$ are $\mathcal{J}_2$-neutral S-invariant subspaces of $\mathcal{H}\dot{+}\mathcal{H}$ (i.e., on these subspaces the sesquilinear form $(x,y)\mapsto(\mathcal{J}_2x,y)$ is trivial).

Further, with X as above and $\theta=(A_0,Q,D;\mathcal{H})$ a positive semidefinite triple, we have

$$-S_X \stackrel{def}{=} \begin{bmatrix} I_{\mathcal{H}} & 0 \\ -X & I_{\mathcal{H}} \end{bmatrix} (-S) \begin{bmatrix} I_{\mathcal{H}} & 0 \\ X & I_{\mathcal{H}} \end{bmatrix} = -S_0 + \begin{bmatrix} I_{\mathcal{H}} \\ -X \end{bmatrix} D \begin{bmatrix} X & I_{\mathcal{H}} \end{bmatrix},$$

which implies that $(A_0-DX, XDX, -D;\mathcal{H})$ is an antipodal compact triple.

We need the following definitions. Suppose W is a continuous function from the extended imaginary axis $i(\mathbb{R}\cup\{\infty\})$ into $\mathcal{L}(\mathcal{H})$. Then by a *left canonical* (*Wiener–Hopf*) *factorization* of W we mean a representation of W of the form

$$W(\lambda)=W_+(\lambda)W_-(\lambda), \qquad \operatorname{Re}\lambda=0,$$

in which $W_\pm(\pm\lambda)$ is continuous on the closed right half-plane (the point at ∞ included), is analytic on the open right half-plane, and takes only invertible values for λ in the closed right half-plane (the point at infinity included). Obviously, such an operator function only takes invertible values on the extended imaginary axis. By a *right canonical* (*Wiener–Hopf*) *factorization* we mean a representation of W of the form

$$W(\lambda)=W_-(\lambda)W_+(\lambda), \qquad \operatorname{Re}\lambda=0,$$

where $W_\pm(\lambda)$ is as above.

THEOREM 2.3. *Let $\theta=(A_0,Q,D;\mathcal{H})$ be a positive semidefinite and semicompact triple. Then we have the following decompositions:*

$$Im\,P\dot{+}Ker\,P_0=\mathcal{H}\dot{+}\mathcal{H}, \tag{2.4}$$

$$Ker\,P\dot{+}Im\,P_0=\mathcal{H}\dot{+}\mathcal{H}. \tag{2.5}$$

Proof. Let us introduce the operators

$$V=P_0P+(I-P_0)(I-P), \tag{2.6}$$

$$V_Q=P_0P_Q+(I-P_0)(I-P_Q). \tag{2.7}$$

Then

$$V_Q=\begin{bmatrix} I_{\mathcal{H}} & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} I_{\mathcal{H}} & 0 \\ X & 0 \end{bmatrix}+\begin{bmatrix} 0 & 0 \\ 0 & I_{\mathcal{H}} \end{bmatrix}\begin{bmatrix} 0 & 0 \\ -X & I_{\mathcal{H}} \end{bmatrix}=\begin{bmatrix} I_{\mathcal{H}} & 0 \\ -X & I_{\mathcal{H}} \end{bmatrix},$$

so that V_Q is invertible. On the other hand, the identity

$$\begin{aligned} &E(t;-S)-\int_{-\infty}^{\infty}E(t-\tau;-S_Q)\begin{bmatrix} 0 & D \\ 0 & 0 \end{bmatrix}E(\tau;-S)\,d\tau \\ &=E(t;-S)-\int_{-\infty}^{\infty}E(t-\tau;-S_Q)\begin{bmatrix} 0 & D^{1/2} \\ 0 & 0 \end{bmatrix}\left(E(\tau;-S^*)\begin{bmatrix} 0 & 0 \\ D^{1/2} & 0 \end{bmatrix}\right)^* d\tau \\ &=E(t;-S_Q), \end{aligned}$$

which is analogous to (2.3) and where the integrand is norm continuous in τ, implies that

$$P-P_Q=-\int_{-\infty}^{\infty}E(-\tau;-S_Q)\begin{bmatrix} 0 & D \\ 0 & 0 \end{bmatrix}E(\tau;-S)\,d\tau,$$

is compact. Further,

$$V - V_Q = [P_0 - (I - P_0)]\,(P - P_Q)$$

implies that $V - V_Q$ is compact. As a result, V is a Fredholm operator of index zero.

Now the operator V satisfies the identities

$$\begin{aligned}\operatorname{Ker} V &= [\operatorname{Im} P \cap \operatorname{Ker} P_0] \dot{+} [\operatorname{Ker} P \cap \operatorname{Im} P_0],\\ \operatorname{Im} V &= [\operatorname{Im} P + \operatorname{Ker} P_0] \cap [\operatorname{Ker} P + \operatorname{Im} P_0].\end{aligned}$$

So, in order to establish (2.4) and (2.5) it suffices to prove that

$$\operatorname{Im} P \cap \operatorname{Ker} P_0 = \operatorname{Ker} P \cap \operatorname{Im} P_0 = \{0\}.$$

Indeed, the operator function

$$\begin{aligned}W(\lambda) &= I + \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2}\end{bmatrix} (\lambda - S_0)^{-1} \begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0\end{bmatrix}\\ &= I + \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2}\end{bmatrix} \begin{bmatrix} 0 & (\lambda + A_0^*)^{-1} \\ (\lambda - A_0)^{-1} & 0\end{bmatrix} \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2}\end{bmatrix}\end{aligned} \tag{2.8}$$

has the identity operator as its real part for imaginary λ and hence

$$\sup_{\operatorname{Re}\lambda = 0} \|I_{\mathcal{H}} - cW(\lambda)\| < 1$$

for some $c > 0$.

Also, W belongs to the Wiener algebra in the sense that there exists a norm measurable operator function $L(\cdot)$ for which W is equal to I plus the Fourier transform of L, and with L having only compact operators as its values such that

$$\int_{-\infty}^{\infty} e^{\varepsilon|t|} \|L(t)\|\, dt < \infty,$$

because of the norm continuity of $L(t)$ for $t \in \mathbb{R} \setminus \{0\}$ and the exponential decay of $\|L(t)\|$ as $t \to \pm\infty$. As a result [9], cW and hence W has left and right canonical factorizations

$$W(\lambda) = W_-^{(l)}(\lambda) W_+^{(l)}(\lambda) = W_+^{(r)}(\lambda) W_-^{(r)}(\lambda), \qquad |\operatorname{Re}\lambda| \le \varepsilon, \tag{2.9}$$

for some $\varepsilon > 0$, where $W_-^{(l)}(\lambda)$, $W_-^{(r)}(\lambda)$ and their inverses are analytic in the half-plane $\operatorname{Re}\lambda < \varepsilon$ and tend to the identity in the norm as $\lambda \to \infty$ in this half-plane and $W_+^{(l)}(\lambda)$, $W_+^{(r)}(\lambda)$ and their inverses are analytic in the half-plane $\operatorname{Re}\lambda > -\varepsilon$ and tend to the identity in the norm as $\lambda \to \infty$ in this half-plane. Using

$$S = S_0 - \begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0\end{bmatrix} \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2}\end{bmatrix}$$

and

$$W(\lambda)^{-1} = I - \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2}\end{bmatrix} (\lambda - S)^{-1} \begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0\end{bmatrix},$$

we obtain

$$W(\lambda)^{-1}\begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S_0)^{-1} = \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S)^{-1}. \tag{2.10}$$

Letting $x \in \operatorname{Ker} P_0 \cap \operatorname{Im} P$, we substitute the first of the factorizations (2.9) into (2.10), observe that the left- and right-hand sides of the resulting identity

$$W_-^{(l)}(\lambda)^{-1}\begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S_0)^{-1}x = W_+^{(l)}(\lambda)\begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S)^{-1}x$$

are analytic in λ for $\operatorname{Re}\lambda < \varepsilon$ and $\operatorname{Re}\lambda > -\varepsilon$, respectively, apply Liouville's theorem, and obtain

$$\begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S_0)^{-1}x = \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S)^{-1}x = 0.$$

Next, we employ the equality

$$\begin{aligned}(\lambda - S)^{-1}x - (\lambda - S_0)^{-1}x &= -(\lambda - S)^{-1}\begin{bmatrix} 0 & D \\ Q & 0 \end{bmatrix}(\lambda - S_0)^{-1}x \\ &= -(\lambda - S)^{-1}\begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0 \end{bmatrix}\cdot\begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}(\lambda - S_0)^{-1}x = 0\end{aligned}$$

to enable the application of Liouville's theorem to the analytic continuation of $(\lambda - S)^{-1}x = (\lambda - S_0)^{-1}x$ and conclude that $x = 0$. As a result, $\operatorname{Ker} P_0 \cap \operatorname{Im} P = \{0\}$, as claimed. In a similar way we prove that $\operatorname{Im} P_0 \cap \operatorname{Ker} P = \{0\}$. □

Theorem 2.3 implies that $(\lambda - S_0)^{-1}(\lambda - S)$ has left and right canonical factorizations (as in (2.9)). Letting

$$\Gamma = \begin{bmatrix} 0 & D \\ Q & 0 \end{bmatrix},$$

these factorizations have the following form ([3, Chapter 1])

$$(\lambda - S_0)^{-1}(\lambda - S) = \big[I + (\lambda - S_0)^{-1}(I - \mathcal{P})\Gamma\big]\big[I + \mathcal{P}(\lambda - S_0)^{-1}\Gamma\big],$$

where

$$\begin{aligned}(I + (\lambda - S_0)^{-1}(I - \mathcal{P})\Gamma)^{-1} &= I - (I - \mathcal{P})(\lambda - S)^{-1}\Gamma, \\ (I + \mathcal{P}(\lambda - S_0)^{-1}\Gamma)^{-1} &= I - (\lambda - S)^{-1}\mathcal{P}\Gamma.\end{aligned}$$

Here $\mathcal{P}$ is either the projection of $\mathcal{H}\dot{+}\mathcal{H}$ onto $\operatorname{Im} P$ along $\operatorname{Ker} P_0$ (for the right canonical factorization) or the projection of $\mathcal{H}\dot{+}\mathcal{H}$ onto $\operatorname{Ker} P$ along $\operatorname{Im} P_0$ (for the left canonical factorization).

The following result has been established in [18] for a positive semidefinite triple, without assuming the compactness of D. As a result, in [18] one does not get the compactness of Π_+, only its boundedness.

THEOREM 2.4. *Let $(A_0, Q, D; \mathcal{H})$ be a positive semidefinite and semicompact triple. Then there exist unique positive semidefinite selfadjoint operators $-\Pi_+$ and Π_- on $\mathcal{H}$, where Π_+ is compact and Π_- is bounded, such that*

(1) *the image and kernel of the separating projection P of $E(\cdot;-S)$ are graph subspaces in the sense that*

$$\mathrm{Im}\, P = \mathrm{Im} \begin{bmatrix} I_{\mathcal{H}} \\ \Pi_- \end{bmatrix}, \qquad \mathrm{Ker}\, P = \mathrm{Im} \begin{bmatrix} \Pi_+ \\ I_{\mathcal{H}} \end{bmatrix}, \tag{2.11}$$

(2) Π_- *maps $\mathcal{D}(A_0)$ into $\mathcal{D}(A_0^*)$ and Π_+ maps $\mathcal{D}(A_0^*)$ into $\mathcal{D}(A_0)$,*

(3) Π_- *is a solution of the operator Riccati equation*

$$\Pi A_0 x + A_0^* \Pi x + Qx - \Pi D \Pi x = 0, \qquad x \in \mathcal{D}(A_0), \tag{2.12}$$

and Π_+ is a solution of the operator Riccati equation

$$A_0 \Pi x + \Pi A_0^* x + \Pi Q \Pi x - Dx = 0, \qquad x \in \mathcal{D}(A_0^*), \tag{2.13}$$

(4) *and $A_0 - D\Pi_-$ and $A_0 + \Pi_+ Q$ are the infinitesimal generators of exponentially decaying C_0-semigroups on $\mathcal{H}$.*

Proof. According to Theorem 2.3, there exist bounded projections $\mathcal{P}^{(l)}$ and $\mathcal{P}^{(r)}$ on $\mathcal{H}\dot{+}\mathcal{H}$ such that $\mathcal{P}^{(l)}$ projects $\mathcal{H}\dot{+}\mathcal{H}$ onto $\mathrm{Ker}\, P$ along $\mathrm{Im}\, P_0$ and $\mathcal{P}^{(r)}$ projects $\mathcal{H}\dot{+}\mathcal{H}$ onto $\mathrm{Im}\, P$ along $\mathrm{Ker}\, P_0$. Hence there exist bounded linear operators Π_- and Π_+ on $\mathcal{H}$, so-called angular operators (cf. [3, Chapter 5]), such that

$$\mathcal{P}^{(l)} = \begin{bmatrix} I_{\mathcal{H}} & 0 \\ \Pi_- & 0 \end{bmatrix}, \qquad \mathcal{P}^{(r)} = \begin{bmatrix} 0 & \Pi_+ \\ 0 & I_{\mathcal{H}} \end{bmatrix}. \tag{2.14}$$

As a result, there exist bounded linear operators Π_- and Π_+ on $\mathcal{H}$ such that (2.11) is true.

One easily proves that

$$\mathcal{P}^{(l)} = V^{-1}(I_{\mathcal{H}} - P_0), \qquad \mathcal{P}^{(r)} = V^{-1} P_0,$$

where V is given by (2.6). Since the projections P_0 and $I - P_0$ commute with $(\lambda - S_0)^{-1}$ and P and $I - P$ commute with $(\lambda - S)^{-1}$ whenever $|\mathrm{Re}\, \lambda| \leq \varepsilon$ for some $\varepsilon > 0$, the invertible operator V maps $\mathcal{D}(S_0) = \mathcal{D}(S) = \mathcal{D}(A_0)\dot{+}\mathcal{D}(A_0^*)$ onto itself. Consequently, $\mathcal{P}^{(l)}$ and $\mathcal{P}^{(r)}$ map this domain into itself and hence Π_- maps $\mathcal{D}(A_0)$ into $\mathcal{D}(A_0^*)$ and Π_+ maps $\mathcal{D}(A_0^*)$ into $\mathcal{D}(A_0)$.

The Riccati equations (2.12) and (2.13) follow from the identities

$$S \begin{bmatrix} I_{\mathcal{H}} \\ \Pi_- \end{bmatrix} x = \begin{bmatrix} I_{\mathcal{H}} \\ \Pi_- \end{bmatrix} (A_0 - D\Pi_-)x, \qquad S \begin{bmatrix} \Pi_+ \\ I_{\mathcal{H}} \end{bmatrix} y = \begin{bmatrix} \Pi_+ \\ I_{\mathcal{H}} \end{bmatrix} (-A_0^* - Q\Pi_+)y, \tag{2.15}$$

where $x \in \mathcal{D}(A_0)$ and $y \in \mathcal{D}(A_0^*)$, in the standard way. Furthermore, since S is exponentially dichotomous with separating projection P and

$$\mathrm{Ker}\, P = \mathrm{Im} \begin{bmatrix} I_{\mathcal{H}} \\ \Pi_- \end{bmatrix}, \qquad \mathrm{Im}\, P = \mathrm{Im} \begin{bmatrix} \Pi_+ \\ I_{\mathcal{H}} \end{bmatrix},$$

we immediately have part (4) of Theorem 2.4.

Now remark that Π_- and Π_+ are selfadjoint (because of the $\mathcal{J}_2$-neutrality of $\mathrm{Im}\, P$ and $\mathrm{Ker}\, P$), while $-\Pi_+$ and Π_- are positive semidefinite (because of the $\mathcal{J}_1$-nonpositivity of $\mathrm{Im}\, P$ and the $\mathcal{J}_1$-nonnegativity of $\mathrm{Ker}\, P$).

Finally, from the compactness of $V - V_Q$ and hence from the compactness of

$$V^{-1} - V_Q^{-1} = \begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix} - \begin{bmatrix} I_{\mathcal{H}} & 0 \\ X & I_{\mathcal{H}} \end{bmatrix} = \begin{bmatrix} 0 & \Pi_+ \\ \Pi_- - X & 0 \end{bmatrix},$$

where V and V_Q are given by (2.6) and (2.7), it follows directly that Π_+ and $\Pi_- - X$ are compact operators. ∎

In [16] a closely related existence result was obtained under the assumption that the spectrum of the block matrix operator S only consists of algebraically and geometrically simple eigenvalues and does not have finite accumulation points.

3. Approximation. Letting $\mathcal{H}_n$ be a sequence of closed linear subspaces of $\mathcal{H}$, there exist unique operators $\pi_n : \mathcal{H} \to \mathcal{H}_n$ and $\imath_n : \mathcal{H}_n \to \mathcal{H}$ such that $\imath_n\pi_n$ is the orthogonal projection of $\mathcal{H}$ onto $\mathcal{H}_n$ and $\pi_n\imath_n$ is the identity operator on $\mathcal{H}_n$. We assume that $\imath_n\pi_n$ tends to $I_{\mathcal{H}}$ in the strong sense.

Starting from a given triple $\theta = (A_0, Q, D; \mathcal{H})$, we define $Q_n = \pi_n Q \imath_n$, $D_n = \pi_n D \imath_n$, which are selfadjoint on $\mathcal{H}_n$ and positive semidefinite whenever Q and D are positive semidefinite. Let A_{0n} be a generator of a strongly continuous semigroup on $\mathcal{H}_n$ of negative exponential type. Then a sequence of triples $\theta_n = (A_{0n}, Q_n, D_n; \mathcal{H}_n)$ is called an *approximant* to the triple θ if the following condition holds: for some $\varepsilon > 0$ we have the approximation

$$\lim_{n\to\infty} e^{\varepsilon|t|} \, \|\hat{\imath}_n E(t; -S_{0n})\hat{\pi}_n x - E(t; -S_0)x\|_{\mathcal{H}} = 0 \tag{3.1}$$

for every $x \in \mathcal{H}$, uniformly in $t \in \mathbb{R} \setminus \{0\}$. Here $\hat{\pi}_n = \pi_n \dot{+} \pi_n$, $\hat{\imath}_n = \imath_n \dot{+} \imath_n$ and $S_{0n} = A_{0n} \dot{+} (-A_{0n}^*)$ on $\mathcal{H}_n \dot{+} \mathcal{H}_n$. The sequence of triples θ_n is called a *finite dimensional approximant* to θ if it is an approximant to θ and the spaces $\mathcal{H}_n = \pi_n[\mathcal{H}]$ are finite dimensional.

We remark that it is easily seen that $\imath_n Q_n \pi_n$ converges to Q strongly, while $\imath_n D_n \pi_n$ converges to D in norm because of the compactness of D.

THEOREM 3.1. *Let $\theta_n = (A_{0n}, Q_n, D_n; \mathcal{H}_n)$ be a sequence of triples approximant to the positive semidefinite semicompact triple $\theta = (A_0, Q, D; \mathcal{H})$. Put*

$$S_n = \begin{bmatrix} A_{0n} & -D_n \\ -Q_n & -A_{0n}^* \end{bmatrix}.$$

Then

$$\lim_{n\to\infty} \|\hat{\imath}_n E(t; -S_n)\hat{\pi}_n x - E(t; -S)x\|_{\mathcal{H}} = 0 \tag{3.2}$$

for every $x \in \mathcal{H} \dot{+} \mathcal{H}$, uniformly in $t \in \mathbb{R} \setminus \{0\}$.

Proof. Consider the sequence of triples $\theta_n^Q = (A_{0n}, Q_n, 0; \mathcal{H}_n)$ approximant to the positive semidefinite triple $\theta = (A_0, Q, 0; \mathcal{H})$. Put

$$S_n^Q = \begin{bmatrix} A_{0n} & 0 \\ -Q_n & -A_{0n}^* \end{bmatrix}.$$

In analogy with (2.3) we obtain

$$E(t; -S_n^Q)x = E(t; -S_{0n})x + \int_{-\infty}^{\infty} E(t - \tau; -S_{0n})\Gamma_Q E(\tau; -S_n^Q)x \, d\tau.$$

Because of (3.1), we see that $\|E(t;-S_{0n})\|$ has a finite upper bound which is independent of $t \in \mathbb{R} \setminus \{0\}$ and $n \in \mathbb{N}$. Using dominated convergence, we take the limit under the integral sign and find that for some $\varepsilon > 0$

$$\lim_{n\to\infty} e^{\varepsilon|t|} \left\| \hat{\imath}_n E(t;-S_n^Q)\hat{\pi}_n x - E(t;-S^Q)x \right\|_{\mathcal{H}} = 0 \tag{3.3}$$

for every $x \in \mathcal{H}$, uniformly in $t \in \mathbb{R} \setminus \{0\}$.

Next, in analogy with (2.3) we have

$$E(t;-S_n) - \int_{-\infty}^{\infty} E(t-\tau;-S_n^Q)\Gamma_n^D E(\tau;-S_n)\,d\tau = E(t;-S_n^Q),$$

where $\Gamma_n^D = \begin{pmatrix} 0 & D_n \\ 0 & 0 \end{pmatrix}$. This integral equation implies that

$$\begin{aligned} \hat{\imath}_n E(t;-S_n)\hat{\pi}_n x - \int_{-\infty}^{\infty} \hat{\imath}_n E(t-\tau;-S_n^Q)\Gamma_n^D E(\tau;-S_n)\hat{\pi}_n x\,d\tau \\ = \hat{\imath}_n E(t;-S_n^Q)\hat{\pi}_n x, \end{aligned} \tag{3.4}$$

where $x \in \mathcal{H}\dot{+}\mathcal{H}$. Note that $\Gamma_n^D = \hat{\pi}_n \Gamma_D \hat{\imath}_n$, so that (3.4) can be written in the form

$$\begin{aligned} \hat{\imath}_n E(t;-S_n)\hat{\pi}_n x - \int_{-\infty}^{\infty} \hat{\imath}_n E(t-\tau;-S_n^Q)\hat{\pi}_n \Gamma_D \cdot \hat{\imath}_n E(\tau;-S_n)\hat{\pi}_n x\,d\tau \\ = \hat{\imath}_n E(t;-S_n^Q)\hat{\pi}_n x, \end{aligned}$$

where $x \in \mathcal{H}\dot{+}\mathcal{H}$. Equation (3.3) and the compactness of Γ_D imply that for some $\varepsilon > 0$

$$\lim_{n\to\infty} e^{\varepsilon|t|} \left\| \hat{\imath}_n E(t;-S_n^Q)\hat{\pi}_n \Gamma_D - E(t;-S^Q)\Gamma_D \right\|_{\mathcal{H}} = 0,$$

uniformly in $t \in \mathbb{R} \setminus \{0\}$. Because of the unique solvability of (3.4) on the complex Banach space of bounded continuous $\mathcal{H}_n$-valued functions on the real line with a possible jump discontinuity in $t = 0$, in combination with (3.3), we obtain (3.2) as claimed. □

Let

$$X_n = \int_0^{\infty} e^{\tau A_{0n}^*} Q_n e^{\tau A_{0n}}\,d\tau$$

be the unique solution of the Lyapunov equation

$$A_{0n}^* X_n + X_n A_{0n} = -Q_n.$$

Using dominated convergence one easily proves that, under the hypotheses of Theorem 3.1,

$$\lim_{n\to\infty} \|\imath_n X_n \pi_n x - Xx\| = 0, \qquad x \in \mathcal{H}. \tag{3.5}$$

Similarly, the unique solution

$$Y_n = \int_0^{\infty} e^{\tau A_{0n}} D_n e^{\tau A_{0n}^*}\,d\tau$$

of the Lyapunov equation

$$A_{0n}Y_n + Y_nA_{0n}^* = -D_n$$

has the property that

$$\lim_{n\to\infty} \|\imath_n Y_n \pi_n x - Yx\| = 0, \qquad x \in \mathcal{H},$$

where

$$Y = \int_0^\infty e^{\tau A_0} D\, e^{\tau A_0^*}\, d\tau$$

is the unique solution of the Lyapunov equation

$$A_0Y + YA_0^* = -D.$$

Let us now prove the strong stability of Π_- and the stability of Π_+ in the norm if a positive semidefinite and semicompact triple is approximated by a sequence of triples in the sense of the above definition. The obvious way to do so is to study the operator Wiener–Hopf equation

$$u(t;x) - \int_0^\infty E(t-\tau;-S_0)\Gamma u(\tau;x)\, d\tau = E(t;-S_0)x, \tag{3.6}$$

where $x \in \operatorname{Ker} P_0$ and $t > 0$, or the operator Wiener–Hopf equation

$$v(t;x) - \int_{-\infty}^0 E(t-\tau;-S_0)\Gamma v(\tau;x)\, d\tau = E(t;-S_0)x, \tag{3.7}$$

where $x \in \operatorname{Im} P$ and $t < 0$. Unfortunately, their integral kernel $E(\cdot;-S_0)\Gamma$ is, in general, not Bochner integrable. If it were, one would trivially obtain the solutions of (3.6) and (3.7) as follows:

$$u(t;x) = E(t;-S)\mathcal{P}^{(l)}x, \qquad v(t;x) = E(t;-S)\mathcal{P}^{(r)}x.$$

Let us therefore introduce the modified operator convolution kernel

$$\begin{aligned} K(t;-S_0) &= \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_0) \begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0 \end{bmatrix} \\ &= \begin{cases} \begin{bmatrix} 0 & -Q^{1/2}e^{-tA_0}D^{1/2} \\ 0 & 0 \end{bmatrix}, & t < 0, \\ \\ \begin{bmatrix} 0 & 0 \\ D^{1/2}e^{tA_0^*}Q^{1/2} & 0 \end{bmatrix}, & t > 0. \end{cases} \end{aligned}$$

Note that $K(t;-S_0)$ is compact and norm continuous in $t \neq 0$. This integral kernel satisfies

$$\begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_0)\Gamma = K(t;-S_0) \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix}$$

and leads to operator Wiener–Hopf equations with Bochner integrable convolution kernel and symbol $W(\lambda)$ defined by (2.8). Indeed, these equations are given by

$$w(t;x) - \int_0^\infty K(t-\tau;-S_0)w(\tau;x)\,d\tau = \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_0)x, \tag{3.8}$$

where $x \in \operatorname{Ker} P_0$ and $t > 0$, and by

$$z(t;x) - \int_{-\infty}^0 K(t-\tau;-S_0)z(\tau;x)\,d\tau = \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_0)x, \tag{3.9}$$

where $x \in \operatorname{Im} P$ and $t < 0$. Equations (3.8) and (3.9) are uniquely solvable, because their symbol $W(\lambda)$ has left and right canonical Wiener–Hopf factorizations. Once (3.8) and (3.9) have been solved, we have

$$u(t;x) = E(t;-S_0)x + \int_0^\infty E(t-\tau;-S_0)\begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0 \end{bmatrix} w(\tau;x)d\tau \tag{3.10}$$

for $x \in \operatorname{Ker} P_0$ and $t > 0$, and

$$v(t;x) = E(t;-S_0)x + \int_{-\infty}^0 E(t-\tau;-S_0)\begin{bmatrix} 0 & D^{1/2} \\ Q^{1/2} & 0 \end{bmatrix} z(\tau;x)d\tau \tag{3.11}$$

for $x \in \operatorname{Im} P_0$ and $t < 0$. We then finally obtain

$$\mathcal{P}^{(l)}x = u(0^+;x), \qquad \mathcal{P}^{(r)}x = -v(0^-;x),$$

and hence [cf. (2.14)]

$$\Pi_- x = \begin{bmatrix} 0 & I_{\mathcal{H}} \end{bmatrix} u(0^+;x), \quad \Pi_+ x = -\begin{bmatrix} I_{\mathcal{H}} & 0 \end{bmatrix} v(0^-;x). \tag{3.12}$$

THEOREM 3.2. *Let $\theta_n = (A_{0n}, Q_n, D_n; \mathcal{H}_n)$ be a sequence of triples approximant to the positive semidefinite semicompact triple $\theta = (A_0, Q, D; \mathcal{H})$. Then*

$$\lim_{n\to\infty} \|\imath_n \Pi_{-,n} \pi_n x - \Pi_- x\| = 0, \tag{3.13}$$

and

$$\lim_{n\to\infty} \|\imath_n \Pi_{+,n} \pi_n x - \Pi_+ x\| = 0 \tag{3.14}$$

for every $x \in \mathcal{H}$.

Proof. From (3.1), the strong convergence $\imath_n Q_n^{1/2} \pi_n \to Q^{1/2}$ and the compactness of $D^{1/2}$, we obtain for some $\varepsilon > 0$

$$\lim_{n\to\infty} e^{\varepsilon|t|}\, \|\hat{\imath}_n K(t;-S_{0n})\hat{\pi}_n - K(t)\| = 0,$$

uniformly in $t \in \mathbb{R} \setminus \{0\}$, and hence for some $\varepsilon > 0$

$$\lim_{n\to\infty} \int_{-\infty}^\infty e^{\varepsilon|t|}\, \|\hat{\imath}_n K(t;-S_{0n})\hat{\pi}_n - K(t)\|\, dt = 0.$$

Thus, using (3.1) and the unique solvability of (3.8), we get for some $\varepsilon > 0$

$$\lim_{n\to\infty} e^{\varepsilon|t|}\, \|\hat{\imath}_n w_n(t;\hat{\pi}_n x) - w(t;x)\| = 0$$

for every $x \in \mathcal{H}\dot{+}\mathcal{H}$, uniformly in $t \in \mathbb{R}^+$. Similarly, for some $\varepsilon > 0$ we have

$$\lim_{n\to\infty} e^{\varepsilon|t|} \|\hat{\imath}_n z_n(t;\hat{\pi}_n x) - z(t;x)\| = 0$$

for every $x \in \mathcal{H}\dot{+}\mathcal{H}$, uniformly in $t \in \mathbb{R}^-$. With the help of (3.1), (3.10), and (3.11), we find for some $\varepsilon > 0$

$$\lim_{n\to\infty} e^{\varepsilon|t|} \|\hat{\imath}_n u_n(t;\hat{\pi}_n x) - u(t;x)\| = 0$$

for every $x \in \mathcal{H}\dot{+}\mathcal{H}$, uniformly in $t \in \mathbb{R}^+$, as well as

$$\lim_{n\to\infty} e^{\varepsilon|t|} \|\hat{\imath}_n v_n(t;\hat{\pi}_n x) - v(t;x)\| = 0$$

for every $x \in \mathcal{H}\dot{+}\mathcal{H}$, uniformly in $t \in \mathbb{R}^-$. Using (3.12) we then easily obtain (3.13) and (3.14). □

The following result strengthens the convergence properties stated in Theorem 3.2.

THEOREM 3.3. *Let $\theta_n = (A_{0n}, Q_n, D_n; \mathcal{H}_n)$ be a sequence of triples approximant to the positive semidefinite semicompact triple $\theta = (A_0, Q, D; \mathcal{H})$. Then*

$$\lim_{n\to\infty} \|\imath_n(\Pi_{-,n} - X_n)\pi_n - (\Pi_- - X)\| = 0, \tag{3.15}$$

$$\lim_{n\to\infty} \|\imath_n \Pi_{+,n}\pi_n - \Pi_+\| = 0. \tag{3.16}$$

Proof. From (3.8) and $E(t;-S_0) = 0\dot{+}e^{tA_0^*}$ for $t > 0$ it is clear that for every $t > 0$ the right-hand side of (3.8) can be viewed as the result of applying a compact operator to a vector $x \in \mathcal{H}$. Since (3.1) and the compactness of $D^{1/2}$ imply that for some $\varepsilon > 0$

$$\lim_{n\to\infty} \left\| \imath_n D_n^{1/2} e^{tA_{0n}^*}(I - P_{0n})\pi_n - D^{1/2}e^{tA_0^*}(I - P_0) \right\| = 0, \qquad t > 0,$$

we have

$$\lim_{n\to\infty} \left\| \hat{\imath}_n \begin{bmatrix} Q_n^{1/2} & 0 \\ 0 & D_n^{1/2} \end{bmatrix} E(t;-S_{0n})\hat{\pi}_n - \begin{bmatrix} Q^{1/2} & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_0) \right\| = 0,$$

and this allows one to sharpen the derivation of (3.14) and to obtain (3.16) instead.

To prove (3.15), we replace (3.7), (3.9), and (3.11) by

$$v_Q(t;x) - \int_{-\infty}^{0} E(t-\tau;-S_Q)\Gamma_D v_Q(\tau;x)\, d\tau = E(t;-S_Q)x, \tag{3.17}$$

$$z_Q(t;x) - \int_{-\infty}^{0} K(t-\tau;-S_Q) z_Q(\tau;x)\, d\tau = \begin{bmatrix} 0 & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_Q)x, \tag{3.18}$$

$$v_Q(t;x) = E(t;-S_Q)x + \int_{-\infty}^{0} E(t-\tau;-S_Q) \begin{bmatrix} 0 & D^{1/2} \\ 0 & 0 \end{bmatrix} z_Q(\tau;x) d\tau\,, \tag{3.19}$$

respectively, where $x \in \mathcal{H}$, $\Gamma_D = \begin{pmatrix} 0 & D \\ 0 & 0 \end{pmatrix}$, and the convolution kernel $K(t;-S_Q)$ satisfies

$$K(t;-S_Q) \begin{bmatrix} 0 & 0 \\ 0 & D^{1/2} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & D^{1/2} \end{bmatrix} E(t;-S_Q).$$

Repeating the proof of (3.16) with the help of (3.17), (3.18), and (3.19) we obtain (3.15). □

It remains to consider the approximation of the C_0-semigroups generated by $A_0 - D\Pi_-$ and $A_0^* + Q\Pi_+$. Indeed, from (2.15) we easily derive the identity

$$S\begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix} = \begin{bmatrix} A_0 & -D \\ -Q & -A_0^* \end{bmatrix}\begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix} = \begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix}\begin{bmatrix} A_0 - D\Pi_- & 0 \\ 0 & -A_0^* - Q\Pi_+ \end{bmatrix},$$

where $A_0 - D\Pi_-$ and $A_0^* + Q\Pi_+$ both generate exponentially decaying C_0-semigroups on $\mathcal{H}$. Writing down the analogous identity for resolvent operators and applying the inverse Laplace transform, we get

$$\begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix}^{-1} E(t;-S)\begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix} = \begin{cases} e^{t(A_0 - D\Pi_-)} \dot{+} 0_{\mathcal{H}}, & t > 0, \\ 0_{\mathcal{H}} \dot{+} \left(-e^{-t(A_0^* + Q\Pi_+)}\right), & t < 0, \end{cases} \tag{3.20}$$

where $0_{\mathcal{H}}$ denotes the zero operator on $\mathcal{H}$.

THEOREM 3.4. *Let $\theta_n = (A_{0n}, Q_n, D_n; \mathcal{H}_n)$ be a sequence of triples approximant to the positive semidefinite semicompact triple $\theta = (A_0, Q, D; \mathcal{H})$. Then for $t > 0$ we have*

$$\lim_{n\to\infty} \left\| \imath_n e^{t(A_{0n} - D_n\Pi_{-,n})}\pi_n - e^{t(A_0 - D\Pi_-)} \right\| = 0, \tag{3.21}$$

$$\lim_{n\to\infty} \left\| \imath_n e^{t(A_{0n}^* + Q_n\Pi_{+,n})}\pi_n - e^{t(A_0^* - Q\Pi_+)} \right\| = 0, \tag{3.22}$$

uniformly in t on compact intervals of either $[0,\infty)$ or $(-\infty, 0]$.

Proof. Because of (3.2) and (3.20), it suffices to prove that for each $x \in \mathcal{H}$ we have

$$\lim_{n\to\infty} \|[\hat{\imath}_n M_n \hat{\pi}_n - M]\, x\| = 0, \tag{3.23}$$

$$\lim_{n\to\infty} \left\| \left[\hat{\imath}_n M_n^{-1} \hat{\pi}_n - M^{-1}\right] x \right\| = 0, \tag{3.24}$$

where

$$M = \begin{bmatrix} I_{\mathcal{H}} & \Pi_+ \\ \Pi_- & I_{\mathcal{H}} \end{bmatrix}, \qquad M_n = \begin{bmatrix} I_{\mathcal{H}_n} & \Pi_{+,n} \\ \Pi_{-,n} & I_{\mathcal{H}_n} \end{bmatrix}.$$

Indeed, (3.13), (3.16), and the compactness of the operator Π_+ imply that

$$\lim_{n\to\infty} \|\imath_n(I_{\mathcal{H}_n} - \Pi_{-,n}\Pi_{+,n})\pi_n - (I_{\mathcal{H}} - \Pi_-\Pi_+)\| = 0.$$

Now note that $I_{\mathcal{H}} - \Pi_-\Pi_+$ is invertible, as a result of the existence of the projection P [cf. (2.11)]. Thus

$$\lim_{n\to\infty} \left\|\imath_n(I_{\mathcal{H}_n} - \Pi_{-,n}\Pi_{+,n})^{-1}\pi_n - (I_{\mathcal{H}} - \Pi_-\Pi_+)^{-1}\right\| = 0,$$

and by taking the adjoint

$$\lim_{n\to\infty} \left\|\imath_n(I_{\mathcal{H}_n} - \Pi_{+,n}\Pi_{-,n})^{-1}\pi_n - (I_{\mathcal{H}} - \Pi_+\Pi_-)^{-1}\right\| = 0.$$

We now easily show that

$$M^{-1} = \begin{bmatrix} (I_{\mathcal{H}} - \Pi_+\Pi_-)^{-1} & -(I_{\mathcal{H}} - \Pi_+\Pi_-)^{-1}\Pi_+ \\ -(I_{\mathcal{H}} - \Pi_-\Pi_+)^{-1}\Pi_- & (I_{\mathcal{H}} - \Pi_-\Pi_+)^{-1} \end{bmatrix}. \tag{3.25}$$

Hence from (3.25) and the analogous expression for M_n^{-1}, we now easily derive (3.23) and (3.24). □

4. Conclusions and remarks. In this paper, exponentially dichotomous block matrix operators on $\mathcal{H}\dot{+}\mathcal{H}$ have been studied as additive perturbations of exponentially dichotomous operators of the type $A_0\dot{+}(-A_0^*)$. This allows a considerable range of LQ-optimal control theory applications; for instance, the example in [16] concerning the heat equation could be dealt with in this way. (We did not do so explicitly, because we expect no better results than the ones one can expect for a Hamiltonian that is a Riesz spectral operator, and taking as approximations for $\mathcal{H}_n$ the spaces spanned by the first n vectors in a properly constructed Riesz basis of eigenvectors of the Hamiltonian. The results would be no better than the ones already existing in the literature.)

Also we considered (possibly finite dimensional) approximations. In connection with the latter topic there are still many open questions. Questions that are natural from a numerical analysis point of view come to mind; for instance, how is the speed of convergence in the results described in section 3 tied to the speed of convergence in (3.1) and to the speed of convergence of $\imath_n D\pi_n$ to D? What about Lipschitz estimates and relative error bounds? All these points are open problems, although an analysis of our proofs may provide some answers.

Finally, delay systems defy application of the existing results. In order to be able to deal with applications to delay systems we would need criteria for exponential dichotomy, where the linear operator is not a perturbation of a naturally given exponentially dichotomous operator, and where a Banach space setting is adopted.

Acknowledgments. The authors would like to express their appreciation for the strenuous efforts of the referees to improve the contents and presentation of this paper. Cornelis V. M. van der Mee is greatly indebted to the Department of Mathematics of Vrije Universiteit, Amsterdam for its hospitality during visits in which the major part of his research was conducted.

ON EXISTENCE OF LIMIT OCCUPATIONAL MEASURES SET OF A CONTROLLED STOCHASTIC DIFFERENTIAL EQUATION*

VIVEK BORKAR† AND VLADIMIR GAITSGORY‡

Abstract. We establish that, under certain conditions, the set of occupational measures as well as the set of mathematical expectations of occupational measures generated by the admissible controls and the corresponding solutions of a controlled stochastic differential equation (CSDE) converge (with the time horizon tending to infinity) to a set called limit occupational measures set (LOMS) and we show that this limit set coincides with the set of stationary marginal distributions of the CSDE. We also demonstrate the applicability of our results for averaging of singularly perturbed CSDE.

Key words. singularly perturbed controlled stochastic differential equations, occupational measures, averaging method, limit occupational measures sets, approximation of slow motions

1. Introduction.

In this paper we establish that, under certain conditions, the set of occupational measures as well as the set of mathematical expectations of occupational measures generated by the admissible controls and the corresponding solutions of a controlled stochastic differential equation (CSDE) converge (with the time horizon tending to infinity) to a set called limit occupational measures set (LOMS) and we show that this limit set coincides with the set of stationary marginal distributions of the CSDE.

The motivation for our study is the applicability of results to averaging of singularly perturbed CSDE. We show that, given a singularly perturbed CSDE, the slow components of its state variables are approximated by the solutions of the averaged system in which the controls take values in the LOMS of the system describing the fast dynamics. In the deterministic control setting, a similar approach was used in [4], [5], [6], [7], [8], [26], [27], [28] (see also [18], [19], [24], [25], [30], [46], [51] for related results). The current paper is based on a combination of ideas developed in the deterministic setting and also on results of [11], [13], and [49] which describe the set of stationary marginal distributions of the CSDE.

Note that singularly perturbed problems of control and optimization have been considered in both deterministic and stochastic literature (see [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [12], [17], [18], [19], [20], [21], [22], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [35], [36], [37], [38], [39], [41], [42], [43], [44], [45], [46], [48], [50], [51], [53] and references therein). Singularly perturbed CSDE, in particular, have been studied in [2], [3], [12], [32], [33], and [38], where earlier references can also be found. In [2], [3], and [12] the Hamilton–Jacobi–Bellman (HJB) equations corresponding to

singularly perturbed CSDE were analyzed. In [2], in particular, it was shown that the optimal value function of the problem of optimal control of singularly perturbed CSDE with a fairly general structure (the only structural constraint was the periodicity in fast variables) converges to a viscosity solution of the HJB equation in which the fast variables are averaged out. In [12], results concerning asymptotic behavior of singularly perturbed CSDE with nongenerate diffusion were obtained. In [32] and [33], singularly perturbed CSDE linear in fast variables were studied and the limit behavior of the attainability sets was described. In [38], weak convergence methods were used to establish a number of important results concerning mainly the case when the fast dynamics are not controlled.

The results obtained in this paper can be used for an approximation of the slow dynamics of singularly perturbed CSDE having a general structure (that is, in particular, nonlinear and nonperiodic in fast variables, and having a controlled fast dynamics). It allows one to treat stochastic nondegenerate and degenerate diffusion cases (as well as a purely deterministic case) in a similar manner and also to deal with the situation when the classical approach, based on equating the singular perturbation parameter to zero, may not lead to a correct approximation of the slow dynamics.

The paper is organized as follows: In section 2 we introduce some notations and define the LOMS of the CSDE as the limit towards which converges the set of mathematical expectations of occupational measures generated by the controls and solutions of the CSDE. In section 3 we identify necessary and sufficient conditions for the LOMS to exist (Theorems 3.2 and 3.3) and also sufficient conditions for every element of the LOMS to be asymptotically approximated (in mean) by an occupational measure obtained with some admissible control (Theorem 3.4). In section 4 we establish that if the LOMS exists, it coincides with the set of marginal stationary distributions of the CSDE (Theorem 4.1) and show that every occupational measure converges to this set in mean (Theorem 4.2). The proofs for sections 3 and 4 are contained in sections 6 and 7.

In section 5 we demonstrate the applicability of above mentioned results to averaging of singularly perturbed CSDE (Theorem 5.1). The proofs for section 5 are contained in section 8.

2. Preliminaries. For a compact set U and m dimensional Euclidean space R^m, $\mathcal{P}(U\times R^m)$ and $\mathcal{P}(U\times\bar{R}^m)$ will stand for the spaces of probability measures defined on the σ- algebras of Borel subsets of $U\times R^m$ and $U\times\bar{R}^m$, respectively, with $\bar{R}^m$ being the one point compactification of R^m (see, e.g., [23, p. 126]). Note that any probability measure μ on $U\times R^m$ may be identified with the unique probability measure on $U\times\bar{R}^m$ that restricts to μ on $U\times R^m$ and perforce assigns zero probability to its complement. Conversely, any probability measure μ on $U\times\bar{R}^m$, assigning probability one to $U\times R^m$, defines a unique probability measure on $U\times R^m$. Thus, $\mathcal{P}(U\times R^m)$ can be considered as a subset of $\mathcal{P}(U\times\bar{R}^m)$ consisting of the probability measures μ on $U\times\bar{R}^m$ with $\mu(U\times R^m)=1$.

The set $\mathcal{P}(U\times\bar{R}^m)$ will be treated as a compact metric space with a metric $\rho(\cdot,\cdot)$ consistent with its weak convergence topology which is metrizable and compact. There are many ways of how $\rho(\cdot,\cdot)$ can be introduced. In this paper the following definition will be used (in most of the cases): for any $\mu',\mu''\in\mathcal{P}(U\times\bar{R}^m)$,

$$\rho(\mu',\mu'')\stackrel{def}{=}\sum_{i=1}^{\infty}2^{-i}\left|\int f_i(u,y)\mu'(du,dy)-\int f_i(u,y)\mu''(du,dy)\right|, \tag{2.1}$$

where $f_i(u,y), i=1,2,\dots$, is the sequence of Lipschitz continuous functions which is

dense in the unit ball of $C(U \times \bar{R}^m)$ (the space of continuous functions defined on $U \times \bar{R}^m$). Using the metric ρ, one can define the Hausdorff metric ρ_H on the set of subsets of $\mathcal{P}(\bar{R}^m \times U)$ as follows: $\forall \mathcal{M}_i \subset \mathcal{P}(U \times \bar{R}^m), i = 1, 2,$

$$\rho_H(\mathcal{M}_1, \mathcal{M}_2) \stackrel{def}{=} \max \left\{ \sup_{\mu \in \mathcal{M}_1} \rho(\mu, \mathcal{M}_2), \sup_{\mu \in \mathcal{M}_2} \rho(\mu, \mathcal{M}_1) \right\}, \tag{2.2}$$

where (here and in what follows)

$$\rho(\mu, \mathcal{M}_i) \stackrel{\text{def}}{=} \inf_{\mu' \in \mathcal{M}_i} \rho(\mu, \mu'). \tag{2.3}$$

Remark 1. Note that, if $\mathcal{M}_1$ and/or $\mathcal{M}_2$ are not closed, then from the fact that $\rho_H(\mathcal{M}_1, \mathcal{M}_2) = 0$ it does not follow that $\mathcal{M}_1 = \mathcal{M}_2$. That is, $\rho_H(\cdot, \cdot)$ is, in fact, a semimetric. By some abuse of terminology we still will refer to it as to a metric keeping in mind that its equality to zero is equivalent to the equality of the closures of the corresponding sets.

We will be dealing with a CSDE

$$dy(\tau) = a(u(\tau), y(\tau))d\tau + b(y(\tau))dW(\tau) \tag{2.4}$$

with the initial conditions

$$y(0) = y_0, \tag{2.5}$$

where:

- the functions $a(u, y) : U \times R^m \to R^m$ and $b(y) : R^m \to R^{m \times m}$ are continuous and satisfy Lipschitz conditions in y, with $a(u, y)$ satisfying it uniformly with respect to $u \in U$;
- U is a compact metric space;
- $W(\cdot)$ is an R^m-valued standard Brownian motion;
- y_0 is an R^m-valued random variable independent of $W(\cdot)$;
- *admissible controls* $u(\cdot)$ are $U-$valued random processes progressively measurable with respect to a right continuous and complete filtration $\{\mathcal{F}_\tau\} \subset \mathcal{F}$ of σ-fields (with $(\Omega, \mathcal{F}, \mathcal{P})$ being a given probability space) such that:
  - $\{y_0$ and $W(\theta); \theta \le \tau\}$ is measurable with respect to $\mathcal{F}_\tau$ for $\tau \ge 0$,
  - For $\tau' \ge \tau \ge 0$, $W(\tau') - W(\tau)$ is independent of $\mathcal{F}_\tau$.

Let $S > 0$, $u(\cdot)$ be an admissible control and $y(\cdot)$ be the corresponding solution of the CSDE (2.4) on the interval $[0, S]$. Define the occupational measure $\mu_S^{u(\cdot), y(\cdot)}$ generated by the pair $(u(\cdot), y(\cdot))$ on this interval by taking

$$\mu_S^{u(\cdot), y(\cdot)}(Q) \stackrel{def}{=} \frac{1}{S} meas\{\tau \ : \ (u(\tau), y(\tau)) \in Q\} \tag{2.6}$$

for any Borel subset Q of $U \times \bar{R}^m$, with *meas* standing for the Lebesgue measure on $[0, S]$. Note that $\mu_S^{u(\cdot), y(\cdot)}$ is uniquely defined by

$$\int f_i(u, y) \mu_S^{u(\cdot), y(\cdot)}(du, dy) = \frac{1}{S} \int_0^S f_i(u(\tau), y(\tau)) d\tau, \quad i = 1, 2, \ldots, \tag{2.7}$$

where $f_i(\cdot)$ are as in (2.1). From (2.7) it follows that, for any fixed $\mu \in \mathcal{P}(U \times \bar{R}^m)$, the value of the metric $\rho(\mu, \mu_S^{u(\cdot), y(\cdot)})$ is a random variable, which allows one to easily verify

that $\mu_S^{u(\cdot),y(\cdot)}$ is a $\mathcal{P}(U \times \bar{R}^m)$- valued random variable. Define also the mathematical expectation $E[\mu_S^{u(\cdot),y(\cdot)}]$ of $\mu_S^{u(\cdot),y(\cdot)}$ as the probability measure on $\bar{R}^m \times U$ such that

$$E[\mu_S^{u(\cdot),y(\cdot)}](Q) \stackrel{def}{=} \frac{1}{S} E[meas\{\tau \ : \ (y(\tau), u(\tau)) \in Q\}] \tag{2.8}$$

for any Borel subset Q of $U \times \bar{R}^m$. By (2.7) and (2.8),

$$\int f_i(u,y) E[\mu_S^{u(\cdot),y(\cdot)}](du,dy) = E\left[\int_0^S f_i(u,y)\mu_S^{u(\cdot),y(\cdot)}(du,dy)\right]$$

$$= E\left[\frac{1}{S}\int_0^S f_i(u(\tau),y(\tau))d\tau\right], \quad i = 1,2,\ldots, \tag{2.9}$$

with $E[\mu_S^{u(\cdot),y(\cdot)}]$ being uniquely defined by these equations.

Denote by $\mathcal{M}(S,y_0)$ and $E[\mathcal{M}(S,y_0)]$ the collections of the occupational measures and their mathematical expectations:

$$\mathcal{M}(S,y_0) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),\ y(\cdot))} \{\mu_S^{u(\cdot),y(\cdot)}\}, \quad E[\mathcal{M}(S,y_0)] \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),\ y(\cdot))} \{E[\mu_S^{u(\cdot),y(\cdot)}]\}, \tag{2.10}$$

where the unions are over all admissible controls and corresponding solutions of (2.4) with the initial condition (2.5).

By analogy with the deterministic setting (see [26], [27], and [28]), we introduce the following definition.

DEFINITION. *A convex and compact set $\mathcal{M} \subset \mathcal{P}(U \times R^m)$ will be called LOMS of the CSDE* (2.4) *with respect to the initial conditions having probability distributions from a given class $\mathcal{C}$ if, for any initial conditions with the distribution from this class,*

$$\rho_H(E[\mathcal{M}(S,y_0)],\mathcal{M}) \leq \ \nu^{\mathcal{C}}(S), \qquad \lim_{S\to\infty} \nu^{\mathcal{C}}(S) = 0. \tag{2.11}$$

The following assumption about the solutions of (2.4) will be used throughout the paper.

Assumption 1. There exists $\alpha > 0$ such that any solution of (2.4) obtained with an admissible control satisfies the inequality

$$\sup_{\tau,u(\cdot)} E[||y(\tau)||^\alpha] \leq c_1(E[||y_0||^\alpha] + 1), \ c_1 \ = \text{const}. \tag{2.12}$$

As an example let us consider the case when the CSDE (2.4) is linear. That is,

$$a(u,y) \stackrel{\text{def}}{=} A_1 y + A_2 u, \quad b(y) \stackrel{\text{def}}{=} A_3, \tag{2.13}$$

where U is a compact subset of R^s (for some natural s) and $A_i, i = 1,2,3$, are matrices of the corresponding dimensions. In this case the solution of (2.4) can be presented in the form

$$y(\tau) = e^{A_1\tau}y(0) + \int_0^\tau e^{A_1(\tau-\tau')}A_2u(\tau')d\tau' + \int_0^\tau e^{A_1(\tau-\tau')}A_3dW(\tau') \tag{2.14}$$

and it is easy to verify that Assumption 1 will be valid with $\alpha = 2$ if the eigenvalues of A_1 have negative real parts. Note that, for general nonlinear systems, sufficient conditions for Assumption 1 to be valid can be derived from the existence of the corresponding Liapunov functions (see, e.g., [11], [16], and [34] for classical results on the uncontrolled case).

3. Strong and weak h-approximation conditions. Let $h(u,y) : U \times \bar{R}^m \to R^j$ be defined by

$$h(u,y) \stackrel{\text{def}}{=} (f_1(u,y), f_2(u,y), \dots, f_j(u,y)), \tag{3.1}$$

where, as above, $f_i(\cdot)$ are as in the definition of the metric $\rho(\cdot,\cdot)$ (see (2.1)). In some instances (e.g., in the definitions below or in Lemma 3.1 and Theorems 3.2, 3.4(i)) we will consider j, and hence $h(\cdot)$, as being fixed. In other cases (e.g., in Theorems 3.3 and 3.4(ii)), the reference "*for every* $h(u,y)$ *as in* (3.1)" will be used in order to indicate that j can be any positive integer: $j = 1, 2, \dots$.

DEFINITION. *We shall say that the CSDE* (2.4) *satisfies* strong h-approximation condition (S-h-AC) *if, for any initial condition* y_0' *and admissible control* $u'(\cdot)$*, corresponding to any other initial condition* y_0'' *there exists an admissible control* $u''(\cdot)$ *such that the solutions* $y'(\cdot)$ *and* $y''(\cdot)$ *of the CSDE* (2.4) *(obtained with* y_0'*,* $u'(\cdot)$ *and* y_0''*,* $u''(\cdot)$*, respectively) satisfy the inequality*

$$E\left[\left\|\frac{1}{S}\int_0^S h(u'(\tau),y'(\tau))d\tau - \frac{1}{S}\int_0^S h(u''(\tau),y''(\tau))d\tau\right\|\right]$$

$$\le \nu_h(S)(1 + E[||y_0'||^\alpha] + E[||y_0''||^\alpha]) \tag{3.2}$$

for some monotone decreasing $\nu_h(\cdot) : [0,\infty) \to [0,\infty)$ *such that* $\lim_{S\to\infty} \nu_h(S) = 0$ *(*α *is the same as in Assumption* 1*).*

DEFINITION. *We shall say that the CSDE* (2.4) *satisfies* weak h-approximation condition (W-h-AC) *if*

$$\left\|E\left[\frac{1}{S}\int_0^S h(u'(\tau),y'(\tau))d\tau\right] - E\left[\frac{1}{S}\int_0^S h(u''(\tau),y''(\tau))d\tau\right]\right\|$$

$$\le \nu_h(S)(1 + E[||y_0'||^\alpha] + E[||y_0''||^\alpha]), \tag{3.3}$$

where y_0', y_0''*,* $u'(\cdot), u''(\cdot)$*,* $y'(\cdot), y''(\cdot)$*,* $\nu_h(\cdot)$ *and* α *are as above.*

Note that, in the linear case (2.13), one can take $u''(\cdot) = u'(\cdot)$ and obtain (see (2.14)) that

$$E[||y'(\tau) - y''(\tau)||] = E[||e^{A_1\tau}(y_0' - y_0'')||] \le ||e^{A_1\tau}||(E[||y_0'||] + E[||y_0''||]). \tag{3.4}$$

Since $h(\cdot)$ satisfies Lipschitz conditions, the validity of S-h-AC will follow from (3.4) (with $\nu_h(S) = O(\frac{1}{S})$ and $\alpha \ge 1$) if the eigenvalues of A_1 have negative real parts, in which case $||e^{A_1\tau}|| \le \beta_1 e^{-\beta_2\tau}$, with β_1, β_2 being positive constants. Note that A_3 in (2.13) can be degenerate or, in fact, it can be zero (the deterministic case). Note also that a Liapunov-type stability condition which leads to the validity of a similar estimate (and, thus, leads to the fulfillment of S-h-AC with $u''(\cdot) = u'(\cdot)$) for a nonlinear CSDE can be found in [11].

Remark 2. Note that W-h-AC is an auxiliary condition which is introduced in order to simplify our consideration. It is obvious that it is implied by S-h-AC, but we were unable to construct an example in which W-h-AC is satisfied while S-h-AC is not. We leave the question of whether it is possible to construct such an example (or whether W-h-AC and S-h-AC are equivalent) open. Note that, in case

of the uncontrolled dynamics (U consists only of one point; say, $U = \{\bar{u}\}$), S-h-AC is implied by W-h-AC and, hence, W-h-AC and S-h-AC are equivalent. In fact, as is noticed later (see Remark 4 on page 10), if W-h-AC is satisfied, then there exists a nonrandom vector $\tilde{h}$ such that

$$E\left[\left\|\frac{1}{S}\int_0^S h(\bar{u}, y(\tau))d\tau - \tilde{h}\right\|\right] \le \bar{\nu}^{(C,\alpha)}(S), \qquad \lim_{S\to\infty} \bar{\nu}^{(C,\alpha)}(S) = 0 \tag{3.5}$$

for any solution $y(\cdot)$ of (2.4) which has the initial condition satisfying the inequality $E[||y(0)||^\alpha] \le C = \text{const}$. It follows that, for any two solutions $y'(\cdot)$ and $y''(\cdot)$ of (2.4) with the initial conditions satisfying a similar inequality,

$$E\left[\left\|\frac{1}{S}\int_0^S h(\bar{u}, y'(\tau))d\tau - \frac{1}{S}\int_0^S h(\bar{u}, y''(\tau))d\tau\right\|\right] \le 2\bar{\nu}^{(C,\alpha)}(S).$$

Therefore, S-h-AC is satisfied.

For $h(u, y)$ as in (3.1), let $V_h(S, y_0)$ stand for the collection of random variables

$$V_h(S, y_0) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),\ y(\cdot))} \left\{\frac{1}{S}\int_0^S h(u(\tau), y(\tau))d\tau\right\} = \bigcup_{\mu\in\mathcal{M}(S,y_0)} \left\{\int h(u, y)\mu(du, dy)\right\} \tag{3.6}$$

and $E[V_h(S, y_0)]$ stand for the set of the corresponding mathematical expectations

$$\begin{aligned} E[V_h(S, y_0)] &\stackrel{\text{def}}{=} \bigcup_{(u(\cdot),\ y(\cdot))} \left\{E\left[\frac{1}{S}\int_0^S h(u(\tau), y(\tau))d\tau\right]\right\} \\ &= \bigcup_{\mu\in E[\mathcal{M}(S,y_0)]} \left\{\int h(u, y)\mu(du, dy)\right\}, \end{aligned} \tag{3.7}$$

where, in both (3.6) and (3.7), the first unions are over the admissible controls and corresponding solutions of (2.4) with the initial conditions (2.5).

Next, we introduce the Hausdorff metric $d_H^E(\cdot, \cdot)$ on collections of random variables as follows.

Definition. *Let V_1 and V_2 be two collections of integrable random variables defined on the same probability space and taking values in R^j. Then*

$$d_H^E(V_1, V_2) \stackrel{def}{=} \max\left\{\sup_{\zeta\in V_1} d^E(\zeta, V_2),\ \sup_{\zeta\in V_2} d^E(\zeta, V_1)\right\}, \tag{3.8}$$

with

$$d^E(\zeta, V_2) \stackrel{\text{def}}{=} \inf_{\zeta'\in V_2} E[||\zeta-\zeta'||]\ \ \forall\zeta\in V_1, \quad d^E(\zeta, V_1) \stackrel{\text{def}}{=} \inf_{\zeta'\in V_1} E[||\zeta-\zeta'||]\ \ \forall\zeta\in V_2, \tag{3.9}$$

where (here and in what follows) $||\cdot||$ is the Euclidean norm in R^j.

It is easy to see that d_H^E is nonnegative, symmetric, and satisfies the triangle inequality. For the constant valued collections of random variables, which can be viewed as just subsets of R^j, the definition above is reduced to the "standard" definition of the Hausdorff metric (semimetric) in R^j:

$$d_H(V_1, V_2) = \max\left\{\sup_{\zeta\in V_1} d(\zeta, V_2), \sup_{\zeta\in V_2} d(\zeta, V_1)\right\}, \qquad d(\zeta, V_i) = \inf_{\zeta'\in V_i} ||\zeta-\zeta'||,\ \ i = 1, 2. \tag{3.10}$$

Note that, as in the case with $\rho_H(\cdot,\cdot)$ (see Remark 1 on page 3), the equality $d_H(\cdot,\cdot) = 0$ is equivalent to the fact that the closures of the corresponding subsets of R^j are equal.

LEMMA 3.1. *S-h-AC is equivalent to the fulfillment of the inequality*

$$d_H^E(V_h(S,y_0'),V_h(S,y_0'')) \le \nu_h(S)(1+E[||y_0'||^\alpha]+E[||y_0''||^\alpha]), \tag{3.11}$$

and W-h-AC is equivalent to the fulfillment of the inequality

$$d_H(E[V_h(S,y_0')],E[V_h(S,y_0'')]) \le \nu_h(S)(1+E[||y_0'||^\alpha]+E[||y_0''||^\alpha]) \tag{3.12}$$

for any initial conditions y_0' and y_0''.

Proof. The proof is obvious. □

DEFINITION. *We shall say that the initial condition* (2.5) *has a probability distribution belonging to the class (C,α) if*

$$E[||y_0||^\alpha] \le C = \text{const}. \tag{3.13}$$

THEOREM 3.2. *Let Assumption* 1 *be valid. If the CSDE* (2.4) *satisfies W-h-AC, then there exists a convex and compact set $V_h \subset R^j$ such that, for any initial condition y_0 with the probability distribution from the class (C,α),*

$$d_H(E[V_h(S,y_0)],V_h) \le \ \nu_h^{C,\alpha}(S), \qquad \lim_{S\to\infty}\nu_h^{C,\alpha}(S)=0. \tag{3.14}$$

Conversely, if there exists V_h such that (3.14) *is valid for any initial condition y_0 with the probability distribution from the class (C,α), then W-h-AC is satisfied for any initial conditions y_0', y_0'' with the probability distributions from this class.*

Proof. The fact that the validity of (3.14) implies W-h-AC is obvious since from (3.14) it follows that

$$d_H(E[V_h(S,y_0')],E[V_h(S,y_0'')]) \le d_H(E[V_h(S,y_0')],V_h)+d_H(V_h,E[V_h(S,y_0'')])$$

$$\le 2\nu_h^{C,\alpha}(S),$$

which, by (3.12), leads to the fulfillment of W-h-AC. The proof of the fact that W-h-AC implies the existence of a convex and compact set V_h which satisfies (3.14) for any initial condition y_0 with the probability distribution from the class (C,α) is given in section 6. □

THEOREM 3.3. *Let Assumption* 1 *be valid. If the CSDE* (2.4) *satisfies W-h-AC for any vector function $h(u,y)$ as in* (3.1). *Then the LOMS $\mathcal{M}$ of the CSDE* (2.4) *with respect to the initial conditions having the probability distribution from the class (C,α) exists. That is, for any initial condition y_0 with the probability distribution from this class, the estimate is valid:*

$$\rho_H(E[\mathcal{M}(S,y_0)],\mathcal{M}) \le \ \nu^{C,\alpha}(S), \qquad \lim_{S\to\infty}\nu^{C,\alpha}(S)=0. \tag{3.15}$$

Also, the LOMS $\mathcal{M}$ allows the representation

$$\mathcal{M} \stackrel{\text{def}}{=} \{\mu\in\mathcal{P}(U\times R^m) \mid \int h(u,y)\mu(du,dy)\in V_h \ \ \forall h(u,y) \ \ \textit{as in} \ (3.1)\}, \tag{3.16}$$

where V_h are convex and compact sets the existence of which (for every $h(u,y)$ as in (3.1)*) is established by Theorem* 3.2.

Conversely, if there exists a convex and compact set $\mathcal{M} \subset \mathcal{P}(U \times R^m)$ *which satisfies* (3.15) *with any initial condition* y_0 *having the probability distribution from the class* (C, α)*, then W-h-AC is satisfied for any vector function* $h(\cdot)$ *as in* (3.1) *and any initial conditions* y_0', y_0'' *with the probability distributions from this class. Also, for any* $h(\cdot)$ *as in* (3.1)*, the estimate* (3.14) *is valid with*

$$V_h = \bigcup_{\mu \in \mathcal{M}} \left\{ \int h(u, y) \mu(du, dy) \right\}. \tag{3.17}$$

Proof of Theorem 3.3 is in the end of section 6.

THEOREM 3.4. *Let Assumption* 1 *be valid.* (i) *If the CSDE* (2.4) *satisfies S-h-AC, then, for any initial condition* y_0 *with the probability distribution from the class* (C, α)*,*

$$\sup_{\zeta \in V_h} d^E(\zeta, V_h(S, y_0)) \le \tilde{\nu}_h^{(C,\alpha)}(S), \qquad \lim_{S \to \infty} \tilde{\nu}_h^{(C,\alpha)}(S) = 0, \tag{3.18}$$

where V_h *is as in* (3.14) *and* $d^E(\cdot, \cdot)$ *is defined by* (3.9).

(ii) *If the CSDE* (2.4) *satisfies S-h-AC for any vector function* $h(\cdot)$ *as in* (3.1)*, then, for any initial condition* y_0 *with the probability distribution from the class* (C, α)*,*

$$\sup_{\mu \in \mathcal{M}} \rho^E(\mu, \mathcal{M}(S, y_0)) \le \tilde{\nu}^{(C,\alpha)}(S), \qquad \lim_{S \to \infty} \tilde{\nu}^{(C,\alpha)}(S) = 0, \tag{3.19}$$

where

$$\rho^E(\mu, \mathcal{M}(S, y_0)) \stackrel{\text{def}}{=} \inf_{\mu' \in \mathcal{M}(S, y_0)} E[\rho(\mu, \mu')]. \tag{3.20}$$

Proof of Theorem 3.4 is in section 6.

In conclusion of this section let us consider the following simple result which is used in the proof of Theorem 3.4.

PROPOSITION 3.5. *Let* V_i*,* $i = 1, \dots, k$ *be collections of random variables defined on the same probability space such that any element* $\zeta_i \in V_i$ *is independent from any element* $\zeta_j \in V_j$ *for* $i \ne j$*. Assume also that*

$$E[||\zeta_i||^2] \le \bar{c} = \text{const} \qquad \forall \zeta_i \in V_i, \qquad i = 1, 2 \dots k.$$

Then

$$d_H^E \left(\frac{1}{k} \sum_1^k V_i, \ \frac{1}{k} \sum_1^k E[V_i] \right) \le \sqrt{\frac{\bar{c}}{k}}, \tag{3.21}$$

where $E[V_i]$ *stands for the set of mathematical expectations of the elements of* V_i *and* $d_H^E(\cdot, \cdot)$ *is defined in* (3.8).

Proof. Take an arbitrary element $\zeta \in \frac{1}{k} \sum_1^k V_i$. By definition it is presented in the form $\zeta = \frac{1}{k} \sum_1^k \zeta_i$, where $\zeta_i \in V_i$. Consider

$$\bar{\zeta} \stackrel{\text{def}}{=} E[\zeta] = \frac{1}{k} \sum_1^k E[\zeta_i] \in \frac{1}{k} \sum_1^k E[V_i].$$

Due to the independence of ζ_i, $i = 1, \dots, k$,

$$E[||\zeta - \bar{\zeta}||] \le \sqrt{E[||\zeta - \bar{\zeta}||^2]} = \sqrt{\frac{1}{k^2}\sum_1^k E[||\zeta_i - E[\zeta_i]||^2]} \le \sqrt{\frac{\bar{c}}{k}}. \tag{3.22}$$

Now take an arbitrary $\bar{\zeta} \in \frac{1}{k}\sum_1^k E[V_i]$. By definition, there exist $\zeta_i \in V_i$ such that $\bar{\zeta} = \frac{1}{k}\sum_1^k E[\zeta_i]$. Define $\zeta \stackrel{\text{def}}{=} \frac{1}{k}\sum_1^k \zeta_i \in \frac{1}{k}\sum_1^k V_i$. Similarly to (3.22), one can establish that $E[||\zeta - \bar{\zeta}||] \le \sqrt{\frac{\bar{c}}{k}}$. This completes the proof of the proposition. ∎

4. Representation of the limit occupational measures set. Let $C_0^2(R^m)$ be the space of twice continuously differentiable functions $f(y) : R^m \to R^1$ which vanish at infinity along with their first and second derivatives and let $\mathcal{D}$ be a countable dense set in $C_0^2(R^m)$. Let $L : C_0^2(R^m) \to C_b(U \times R^m)$ be the operator defined as follows:

$$(Lf)(y,u) \;=\; \frac{1}{2} tr(b(y)b^T(y)\nabla^2 f(y)) + \langle \nabla f(y), a(u,y)\rangle \quad \forall f \in C_0^2(R^m). \tag{4.1}$$

Define the set of probability measures $D \subset \mathcal{P}(R^s \times A)$ by

$$D \;=\; \{\mu \in \mathcal{P}(U \times R^m) : \int (Lf)(u,y)\mu(du,dy) = 0 \;\; \forall f \in \mathcal{D}\}. \tag{4.2}$$

and introduce the following assumption.

Assumption 2. For some $\alpha > 0$,

$$\int ||y||^\alpha \mu(du,dy) \le c_2 = \text{const} \qquad \forall \mu \in D. \tag{4.3}$$

Note that the set D is convex and it is easy to verify that it is compact if Assumption 2 is satisfied. In fact, from this assumption it follows that D is tight and, hence, by Prohorov's theorem (see, e.g., Theorem 2.3.1, p. 25 in [15]), it is relatively compact in $\mathcal{P}(U \times R^m)$. Also, D is closed. This implied the compactness.

In [13] and [49] it was shown that, under some mild conditions, the set D represents the set of marginal distributions of stationary relaxed solutions of (2.4). In the following theorem it is established that, if W-h-AC is satisfied for any $h(u,y)$ as in (3.1)), then the LOMS of the CSDE (2.4) exists (the existence being implied by Theorem 3.3) and coincides with D.

THEOREM 4.1. *Let Assumptions* 1 *and* 2 *be satisfied with* $\alpha \ge 2$. *Then,*

(i) *The estimate*

$$\rho_H\left(\bigcup_{\{y_0\}\in(C,\alpha)} \{E[\mathcal{M}(S,y_0)]\},\; D\right) \le \bar{\nu}^{(C,\alpha)}(S), \qquad \lim_{S\to\infty} \bar{\nu}^{(C,\alpha)}(S) = 0, \tag{4.4}$$

is valid, where the union is over all initial conditions with the probability distribution from the class (C,α).

(ii) *If W-h-AC is satisfied for any* $h(u,y)$ *as in* (3.1), *then the LOMS* $\mathcal{M}$ *of the CSDE* (2.4) *with respect to the initial conditions having the probability distribution from the class* (C,α) *exists and is equal to* D*:*

$$\mathcal{M} = D. \tag{4.5}$$

Proof. The statement (i) of the theorem is proved in section 7 on the basis of Theorem 4.2 stated below. The validity of (ii) is proved on the basis of (i) as follows. By (3.15),

$$\rho_H\left(\bigcup_{\{y_0\}\in(C,\alpha)}\{E[\mathcal{M}(S,y_0)]\},\ \mathcal{M}\right)\le\nu^{C,\alpha}(S).$$

If now one assumes that (4.4) is valid, it will follow that

$$\rho_H(\mathcal{M},D)\le\nu^{C,\alpha}(S)+\bar\nu^{(C,\alpha)}(S)\quad\Rightarrow\quad\rho_H(\mathcal{M},D)=0.$$

The latter implies (4.5) since both $\mathcal{M}$ and D are compact. □

THEOREM 4.2. *Let Assumption* 1 *be satisfied with* $\alpha\ge 2$. *Then, for any initial condition* y_0 *with the probability distribution from the class* (C,α),

$$\sup_{\mu\in\mathcal{M}(S,y_0)}E[\rho(\mu,D)]\le\bar\nu^{(C,\alpha)}(S),\qquad\lim_{S\to\infty}\bar\nu^{(C,\alpha)}(S)=0,\tag{4.6}$$

where $\rho(\mu,D)$ *is defined as in* (2.3).

Proof of Theorem 4.2 is in section 7.

COROLLARY 4.3. *Let Assumptions* 1 *and* 2 *be valid with* $\alpha\ge 2$. *If the CSDE* (2.4) *satisfies W-h-AC for any vector function* $h(\cdot)$ *as in* (3.1), *then, for any initial condition* y_0 *with the probability distribution from the class* (C,α),

$$\rho_H(E[\mathcal{M}(S,y_0)],D)\le\ \nu^{C,\alpha}(S),\qquad\lim_{S\to\infty}\nu^{(C,\alpha)}(S)=0.\tag{4.7}$$

If the CSDE (2.4) *satisfies S-h-AC for any vector function* $h(\cdot)$ *as in* (3.1), *then, for any initial condition* y_0 *with the probability distribution from the class* (C,α),

$$\sup_{\mu\in D}\rho^E(\mu,\mathcal{M}(S,y_0))\le\tilde\nu^{(C,\alpha)}(S),\qquad\lim_{S\to\infty}\tilde\nu^{(C,\alpha)}(S)=0.\tag{4.8}$$

Proof. The proof follows immediately from Theorems 3.3, 3.4, and 4.1(ii). □

Remark 3. The estimate (4.8) is, in fact, equivalent to the validity of S-h-AC for any vector function $h(\cdot)$. Let us show that if (4.8) is satisfied, then, for any $y_0',u'(\cdot)$ and any y_0'', there exists $u''(\cdot)$ such that (3.2) is valid (with y_0',y_0'' being assumed to be from the class (C,α)). Let $\mu_S^{u'(\cdot)y'(\cdot)}$ be the occupational measure generated by the pair $(u'(\cdot),y'(\cdot))$ on the interval $[0,S]$. By (4.6), there exists $\mu_S'\in D$ such that $E[\rho(\mu_S^{u'(\cdot)y'(\cdot)},\mu_S')]\le\bar\nu^{(C,\alpha)}(S)$. From (4.8) it follows, in turn, that the estimate $E[\rho(\mu_S',\mu_S'')]\le\tilde\nu^{(C,\alpha)}(S)$ is valid for some $\mu_S''\in\mathcal{M}(S,y_0'')$. By definition, μ_S'' is an occupational measure generated on the interval $[0,S]$ by some admissible control $u''(\cdot)$ and the corresponding solution $y''(\cdot)$ of the CSDE (2.4) which satisfies the initial condition $y''(0)=y_0''$. That is, $\mu_S''=\mu_S^{u''(\cdot)y''(\cdot)}$ and $E[\rho(\mu_S^{u'(\cdot)y'(\cdot)},\mu_S^{u''(\cdot)y''(\cdot)})]\le\bar\nu^{(C,\alpha)}(S)+\tilde\nu^{(C,\alpha)}(S)$. The latter estimate implies the validity of S-h-AC for any $h(\cdot)$ as in (3.1).

Remark 4. Under Assumptions 1 and 2, one can show that, corresponding to any extreme point μ of D, there exists an admissible control $u_\mu(\cdot)$ and the corresponding solution $y_\mu(\cdot)$ of the CSDE (2.4) such that, for any $h(\cdot)$ as in (3.1), there almost surely exists the limit

$$\lim_{S\to\infty}\frac{1}{S}\int_0^S h(u_\mu(\tau),y_\mu(\tau))d\tau=\int h(u,y)\mu(du,dy).\tag{4.9}$$

We do not give the proof of this statement in the paper (it is based on results of [13], [49], and the ergodic theory). Let us note only that, for the uncontrolled case mentioned in Remark 2 on page 5, it follows that, if W-h-AC is satisfied, then the value of the integral on the right-hand side of (4.9) is the same for any extreme points μ of D and, hence, it is the same for all elements of D. Denoting this value as $\tilde{h}$ and using (4.6), one can easily verify the validity of (3.5).

Let $g(u,y) : U \times R^m \to R^n$ be continuous and satisfy Lipschitz conditions in y. Define the collection of R^n-valued random variables $V_g(S,y_0)$ similarly to (3.6) with the replacement of $h(\cdot)$ by $g(\cdot)$. That is,

$$V_g(S,y_0) \stackrel{\text{def}}{=} \bigcup_{(u(\cdot),y(\cdot))} \left\{ \frac{1}{S}\int_0^S g(u(\tau),y(\tau))d\tau \right\} = \bigcup_{\mu\in\mathcal{M}(S,y_0)} \left\{ \int g(u,y)\mu(du,dy) \right\}, \tag{4.10}$$

where, as in (3.6), the first union is over all admissible controls and corresponding solutions of the CSDE (2.4). Define also the set $V_g \subset R^n$ by

$$V_g \stackrel{\text{def}}{=} \bigcup_{\mu\in D} \left\{ \int g(u,y)\mu(du,dy) \right\}, \tag{4.11}$$

where the union is over elements of D. Note that from the convexity of D it follows that V_g is convex. Also, the following two corollaries used in averaging of singularly perturbed CSDE (see section 5 below) are valid.

Corollary 4.4. *Let Assumptions* 1 and 2 *be satisfied with* $\alpha \geq 2$. *Then the set* V_g *is compact and there exists a function* $\bar{\nu}_g^{(C,\alpha)}(S)$, *tending to zero as* S *tends to infinity, such that for any initial condition* y_0 *with the distribution from the class* (C,α),

$$\sup_{v\in V_g(S,y_0)} E[d(v,V_g)] \leq \bar{\nu}_g^{(C,\alpha)}(S). \tag{4.12}$$

Corollary 4.5. *Let Assumptions* 1 and 2 *be valid with* $\alpha \geq 2$ *and let the CSDE* (2.4) *satisfies S-h-AC for any vector function* $h(u,y)$ *as in* (3.1). *Then there exists a function* $\tilde{\nu}_g^{(C,\alpha)}(S)$, *tending to zero as* S *tends to infinity, such that for any initial condition* y_0 *with the probability distribution from the class* (C,α),

$$\sup_{v\in V_g} d^E(v, V_g(S,y_0)) \leq \tilde{\nu}_g^{(C,\alpha)}(S). \tag{4.13}$$

Proofs of Corollaries 4.4 *and* 4.5. The proofs follow from Theorems 4.1(ii), (4.2), and Theorems 4.1(ii), (3.4), respectively, if $g(\cdot) = h(\cdot)$ (with $h(\cdot)$ being as in (3.1)). In the general case, the corollaries are proved in section 7. □

5. Application in averaging of singularly perturbed controlled stochastic differential equations. Consider the following singularly perturbed CSDE:

$$dy^\epsilon(t) = \frac{1}{\epsilon}a(u(t),y^\epsilon(t))dt + \frac{1}{\sqrt{\epsilon}}b(y^\epsilon(t))dB_1(t). \tag{5.1}$$

$$dz^\epsilon(t) = g(u(t),y^\epsilon(t),z^\epsilon(t))dt + \sigma(z^\epsilon(t))dB_2(t), \tag{5.2}$$

with the initial conditions

$$y^\epsilon(0) = y_0, \qquad z^\epsilon(0) = z_0, \tag{5.3}$$

where:

- ϵ is a small positive parameter;
- the functions $b(\cdot) : R^m \to R^{m\times m}$ and $\sigma(\cdot) : R^n \to R^{n\times n}$ satisfy Lipschitz conditions; the functions $a(u,y) : U \times R^m \to R^m$ and $g(u,y,z) : U \times R^m \times R^n \to R^n$ are continuous and satisfy Lipschitz conditions, respectively, in y and (y,z) uniformly with respect to $u \in U$;
- U is a compact metric space;
- $B_1(\cdot)$ and $B_2(\cdot)$ are R^m- and R^n-valued independent standard Brownian motions;
- y_0 and z_0 are R^m- and R^n-valued random variables which have bounded fourth moments and are independent of $B_1(\cdot), B_2(\cdot)$;
- *admissible controls* $u(\cdot)$ are U-valued random processes progressively measurable with respect to a right continuous and complete filtration $\{\hat{\mathcal{F}}_t\}$ of σ-fields such that
  - $\{y_0, z_0 \ \& \ B_1(\theta), B_2(\theta); \theta \le t\}$ is measurable with respect to $\hat{\mathcal{F}}_t$ for $t \ge 0$,
  - For $t' \ge t \ge 0$, $B_1(t') - B_1(t)$ and $B_2(t') - B_2(t)$ are independent of $\hat{\mathcal{F}}_t$.

Let us set $\tau = \frac{t}{\epsilon}, y(\tau) = y^\epsilon(\epsilon\tau), u'(\tau) = u^\epsilon(\epsilon\tau), W(\tau) = \frac{1}{\sqrt{\epsilon}} B_1(\epsilon\tau)$ and $\{\mathcal{F}_\tau\} = \{\hat{\mathcal{F}}_{\epsilon\tau}\}$. The subsystem (5.1) takes then the form of the CSDE (2.4) and is called *the associated system*. Assuming that the associated system satisfies Assumptions 1 and 2, let us define the averaged CSDE by

$$dz(t) = \tilde{g}(\mu(t), z(t))dt + \sigma(z(t))dB_2(t), \tag{5.4}$$

where:

- $\tilde{g}(\mu, z) \stackrel{\text{def}}{=} \int_{R^m \times U} g(u,y,z)\mu(du,dy) : \mathcal{P}(R^m \times U) \times R^n \to R^n$;
- the Brownian motion $B_2(\cdot)$ and the initial condition $z(0) = z_0$ are the same as in (5.2);
- *admissible controls* $\mu(\cdot)$ are $\{\hat{\mathcal{F}}_t\}$-progressive D-valued random processes (D being defined in (4.2)).

Let $G(\cdot) : R^n \to R$ be Lipschitz continuous and $T > 0$. Consider the problem of optimal control

$$\inf_{u(\cdot), y^\epsilon(\cdot), z^\epsilon(\cdot)} E[G(z^\epsilon(T))] \stackrel{\text{def}}{=} G^*_\epsilon, \tag{5.5}$$

where inf is over the admissible controls and the corresponding solutions of the singularly perturbed CSDE (5.1) and (5.2). Consider also the problem

$$\inf_{\mu(\cdot), z(\cdot)} E[G(z(T))] \stackrel{\text{def}}{=} G^*_{av}, \tag{5.6}$$

where inf is over the admissible controls and the corresponding solutions of the averaged CSDE (5.4). Note that, if $\sigma(\cdot) \equiv 0$, then the averaged system (5.4) is purely deterministic and the minimization in (5.6) can be restricted to open loop controls (a similar phenomenon was dealt with in [1], where the fast dynamics were defined by a Markov decision process).

THEOREM 5.1. (i) *Let the associated system satisfy Assumptions* 1 *and* 2 *with* $\alpha = 4$. *Then, corresponding to any admissible solution* $(y^\epsilon(\cdot), z^\epsilon(\cdot))$ *of the singularly perturbed CSDE* (5.1) and (5.2), *there exists an admissible solution* $z(\cdot)$ *of the averaged CSDE* (5.4) *such that*

$$\max_{t\in[0,T]} E[||z^\epsilon(t) - z(t)||^2] \le \tilde{\nu}(\epsilon), \qquad \lim_{\epsilon\to 0} \tilde{\nu}(\epsilon) = 0 \tag{5.7}$$

and the following inequality is valid:

$$\liminf_{\epsilon\to 0} G^*_\epsilon \geq G^*_{av}. \tag{5.8}$$

(ii) *If, in addition, the associated system satisfies S-h-AC for any vector function* $h(\cdot)$ *as in* (3.1)*, then, corresponding to an arbitrary admissible solution* $z(\cdot)$ *of the averaged CSDE* (5.4)*, there exists an admissible solution* $(y^\epsilon(\cdot), z^\epsilon(\cdot))$ *of the singularly perturbed CSDE* (5.1) and (5.2) *such that* (5.7) *is valid and*

$$\lim_{\epsilon\to 0} G^*_\epsilon \;=\; G^*_{av}. \tag{5.9}$$

Proof. The proof's details are outlined in section 8. □

Remark 5. The approximation of the z-components of the state variables of the CSDE (5.1) and (5.2) by the solutions of the averaged system (5.4) stated in Theorem 5.1 has many similarities with the classical relaxed control setting (see [52]). In contrast to the latter, however, the approximation established in Theorem 5.1 is asymptotic (that is valid when the small parameter tends to zero) and also the controls used in (5.4) take values in the LOMS (and not in the space of all probability measures defined on the control set).

Remark 6. Note that the conditions of Theorem 5.1 can be relaxed. Namely, the theorem remains valid if Assumptions 1 and 2 are satisfied with $\alpha > 2$ and also if they are satisfied with $\alpha = 2$ (to prove the result in the latter case, one needs to impose some additional conditions; in particular, one needs to assume that there exists an integrable random variable η such that the solution of the associated system satisfy the inequality $||y(\tau)||^2 \leq \eta \ \forall \tau \geq 0$). Note also that a statement similar to Theorem 5.1 is valid for singularly perturbed CSDE in which the fast subsystem may depend on the slow state variables. The proof of such a statement is in many ways similar to one outlined in section 8 but it is more technically involved and we do not include it in the paper.

Let us consider a special case when $b(y) = 0$. That is, the associated system is deterministic and it can be written in the form

$$\frac{dy(\tau)}{d\tau} = a(u(\tau), y(\tau)). \tag{5.10}$$

Assume that there exist positive definite matrices F_1 and F_2 such that, for any y', y'' and any $u \in U$,

$$(a(u, y') - a(u, y''))^T F_1 (y' - y'') \leq -(y' - y'')^T F_2 (y' - y''), \tag{5.11}$$

Note that (5.11) is satisfied if $a(u, y) = A_1 y + A_2 u$ (as in (2.13)), with the eigenvalues of A_1 having negative real parts. Taking $y^T F_1 y$ as a Liapunov function, one can easily verify (see, e.g., [27]) that solutions $y'(\tau)$ and $y''(\tau)$ of (5.10) obtained with the same control and with initial conditions $y'(0) = y'_0,\ y''(0) = y''_0$, satisfy the inequality

$$||y'(\tau) - y''(\tau)|| \leq \beta_1 e^{-\beta_2 \tau} ||y'_0 - y''_0|| \quad \forall \tau \geq 0, \tag{5.12}$$

where β_1 and β_2 are some positive constants. This implies the validity of S-h-AC. From (5.12) it follows (see Theorem 3.1(ii) in [25]) that there exists a compact set $Y \subset R^m$ such that any solution $y(\cdot)$ of (5.10) satisfies the inequality

$$\min_{y\in Y} ||y(\tau) - y|| \leq \beta_1 e^{-\beta_2 \tau} \min_{y\in Y} ||y(0) - y|| \qquad \forall \tau \geq 0, \tag{5.13}$$

where β_1, β_2 are as in (5.12) (that is, Y is forward invariant with respect to the solutions of (5.10) and is a global attractor for these solutions). Using the inequality (5.13), it is straightforward to verify that Assumption 1 is satisfied with an arbitrary positive α. Also, using this inequality, one can establish that $\mu(U \times Y) = 1 \ \ \forall \mu \in \mathcal{M}$, where, as above, $\mathcal{M}$ is the limit occupational measures set. Hence, this set allows the representation (see (4.2) and Theorem 4.1(ii))

$$\mathcal{M} = D = \{\mu \in \mathcal{P}(U \times Y) : \int_{U \times Y} \langle \nabla f(y), a(u,y) \rangle \mu(du, dy) = 0 \ \forall \ f \in \mathcal{D}\}, \tag{5.14}$$

where $\mathcal{P}(U \times Y)$ is the space of probability measures defined on Borel subsets of $U \times Y$. Note that the representation of the LOMS in the form (5.14) is consistent with one obtained for the deterministic case in [26] and that Assumption 2 is satisfied automatically in this case.

As an example, let us consider the singularly perturbed CSDE (5.1) and (5.2), in which: $y = (y_1, y_2)$ (that is, $y \in R^2$); U is a square in R^2: $U = \{(u_1, u_2) : \ |u_i| \leq 1, \ i = 1, 2\}$;

$$b(y) = 0, \qquad a(u,y) = (-y_1 + u_1, \ -y_2 + u_2); \tag{5.15}$$

and the slow dynamics are one dimensional ($z \in R^1$) with $z_0 = 0$ (zero initial condition) and with

$$\sigma(z) = \sigma = \text{const}, \qquad g(u,y,z) = g(u,y) \stackrel{\text{def}}{=} y_2 u_1 - y_1 u_2. \tag{5.16}$$

Consider the optimal control problem (5.5) with $G(z) = z$. Using (5.15) and (5.16), it is easy to verify that, if the fast subsystem (5.1) is multiplied by ϵ and, then ϵ is formally equated to zero, the resulting slow dynamics become uncontrolled and the value of the objective function is equal to zero. The limit of the optimal value of (5.5) is, however, strictly less than zero: $\lim_{\epsilon \to 0} G^*_\epsilon < 0$. This is evidenced by the fact that, if the rapidly oscillating controls $u_1(t) = cos(\frac{t}{\epsilon})$, $u_2(t) = sin(\frac{t}{\epsilon})$ are used, then the value of the objective function can be verified to be equal to $-0.5T + O(\epsilon) < 0$. Thus, the classical approach based on the equating of the singular perturbation parameter to zero is not applicable in the given example. The averaged problem is equivalent in this case to the infinite dimensional linear program

$$\min_{\mu \in D} \int_{U \times Y} g(u,y) \mu(du, dy) \stackrel{\text{def}}{=} g^*, \tag{5.17}$$

with $G^*_{av} = g^* T$, where D is as in (5.14) and $g(u,y)$ is defined in (5.16). Note that the solution of the problem (5.17) has been found numerically by approximating the problem with finite dimensional linear programs (using the approach proposed in [29]). The optimal value g^* of (5.17), in particular, was found to be approximately equal to -0.7679. One may conclude, therefore (by (5.9)), that $\lim_{\epsilon \to 0} G^*_\epsilon \approx -0.7679T$.

In some cases the averaged system can be equivalent to the system obtained via equating of the singular parameter to zero. To illustrate that, let us assume that the associated system is linear (that is, (2.13) is true, with eigenvalues of A_1 having negative real parts). Let us assume also that the slow subsystem (5.2) is linear in y and u. That is,

$$g(u,y,z) \stackrel{\text{def}}{=} A_4(z) y + A_5(z) u, \tag{5.18}$$

with $A_4(z), A_5(z)$ being matrices functions of the corresponding dimensions, then the averaged system becomes equivalent to

$$dz(t) = A_4(z(t))\bar{y}(t) + A_5(z(t))\bar{u}(t) + \sigma(z(t))dB_2(t), \tag{5.19}$$

where

$$(\bar{u}(t), \bar{y}(t)) \in \Omega \stackrel{\text{def}}{=} \left\{ (\bar{u}, \bar{y}) \mid (\bar{u}, \bar{y}) = \int (u, y)\mu(du, dy),\ \mu \in D \right\}. \tag{5.20}$$

Under the assumption that U is convex, it can be shown (although, we do not do it in this paper) that the set Ω defined above can be represented in the form

$$\Omega = \{(\bar{u}, \bar{y}) \mid \bar{y} = -A_1^{-1}A_2\bar{u},\ \bar{u} \in U\}. \tag{5.21}$$

and that (5.19) is equivalent to the system

$$dz(t) = (-A_4(z(t))A_1^{-1}A_2 + A_5(z(t)))\bar{u}(t) + \sigma(z(t))dB_2(t), \quad \bar{u}(t) \in U. \tag{5.22}$$

Note that the system (5.22) can be obtained via multiplying (5.1) by ϵ, then formally equating ϵ to zero and expressing y as a function of u, and then substituting the result into (5.2).

6. Proofs for section 3. Proofs of Theorems 3.2 and 3.4 are based on a number of lemmas stated below.

LEMMA 6.1. *Let a function $\psi(S) : (0, \infty) \to R^1$ be such that, for some monotone decreasing function $\nu(S)$, $lim_{S\to\infty}\nu(S) = 0$, the following inequalities are valid:*

$$|\psi(S) - \psi(kS)| \le \nu(S), \quad k = 1, 2, \ldots. \tag{6.1}$$

Let also

$$|\psi(S') - \psi(S'')| \le \frac{\alpha|S'' - S'|}{\max\{S', S''\}} \quad \forall S', S'' > 0, \qquad \alpha = \text{const}. \tag{6.2}$$

Then there exists a limit

$$lim_{S\to\infty}\psi(S) \stackrel{\text{def}}{=} A \tag{6.3}$$

and the estimate

$$|\psi(S) - A| \le \nu(S) \quad \forall S > 0 \tag{6.4}$$

is valid.

Proof. To establish the existence of the limit it is sufficient to show that, corresponding to any $\delta > 0$, there exists $S_\delta > 0$ such that, for any $S'' \ge S' \ge S_\delta$,

$$|\psi(S'') - \psi(S')| \le \delta. \tag{6.5}$$

Note that from (6.1) it follows that, for any $k_2 \ge k_1 \ge 1$,

$$|\psi(S) - \psi\left(\frac{k_2}{k_1}S\right)| \le |\psi(S) - \psi(k_2S)| + |\psi(k_2S) - \psi\left(\frac{k_2}{k_1}S\right)| \le \nu(S) + \nu\left(\frac{k_2}{k_1}S\right) \le 2\nu(S).$$

Choose integer $k_2 \geq k_1 \geq 1$ in such a way that

$$0 \leq \frac{S''}{S'} - \frac{k_2}{k_1} \leq \frac{\delta}{2\alpha} \Rightarrow 0 \leq S'' - \frac{k_2}{k_1} S' \leq \frac{\delta}{2\alpha} S'.$$

Then, by (6.2),

$$|\psi(S'') - \psi(S')| \leq |\psi(S'') - \psi\left(\frac{k_2}{k_1} S'\right)| + |\psi\left(\frac{k_2}{k_1} S'\right) - \psi(S')| \leq \frac{\alpha |S'' - \frac{k_2}{k_1} S'|}{\frac{k_2}{k_1} S'} + 2\nu(S')$$

$$\leq \frac{\delta}{2} + 2\nu(S).$$

Choosing S_δ to be such that $\nu(S_\delta) = \frac{\delta}{2}$, one establishes (6.5). Thus the limit (6.3) exists. Passing to the limit as $k \to \infty$ in (6.1), one obtains the estimate (6.4). □

In the following lemmas, it is always supposed that Assumption 1 is satisfied.

LEMMA 6.2. *Let $h(\cdot)$ be as in* (3.1) *and the constant c_h be defined by*

$$c_h \stackrel{\text{def}}{=} \max_{(u,y) \in U \times \bar{R}^m} ||h(u,y)||. \tag{6.6}$$

Then the following estimates are valid:

$$\sup_{\zeta \in V_h(S,y_0)} E[||\zeta||] \leq c_h \qquad \Rightarrow \qquad \sup_{\zeta \in E[V_h(S,y_0)]} ||\zeta|| \leq c_h; \tag{6.7}$$

$$d_H^E(V_h(S',y_0), V_h(S'',y_0)) \leq \frac{2c_h |S'' - S'|}{\max\{S', S''\}}; \tag{6.8}$$

$$d_H(E[V_h(S',y_0)], E[V_h(S'',y_0)]) \leq \frac{2c_h |S'' - S'|}{\max\{S', S''\}}. \tag{6.9}$$

Proof. Note that (6.7) is obvious and that (6.9) follows from (6.8) since

$$d_H(E[V_1], E[V_2]) \leq d_H^E(V_1, V_2)$$

for any collections of random variables V_1 and V_2 such that $E[||\zeta||] < \infty \ \ \forall \zeta \in V_i, i = 1, 2$. Let us prove (6.8). Assume that $S'' \geq S'$. Then, by (6.7), for any admissible control $u(\cdot)$ and corresponding solution $y(\cdot)$ of the CSDE (2.4),

$$E\left[\left\| \frac{1}{S'} \int_0^{S'} h(u(\tau), y(\tau)) d\tau - \frac{1}{S''} \int_0^{S''} h(u(\tau), y(\tau)) d\tau \right\|\right]$$

$$\leq E\left[\left\| \left(\frac{1}{S'} - \frac{1}{S''}\right) \int_0^{S'} h(u(\tau), y(\tau)) d\tau \right\|\right] + E\left[\left\| \frac{1}{S''} \int_{S'}^{S''} h(u(\tau), y(\tau)) d\tau \right\|\right]$$

$$\leq \frac{2c_h (S'' - S')}{S''}.$$

This implies (6.8). □

LEMMA 6.3. *Let y_0 be fixed (nonrandom) and $\Psi(p, S, y_0)$ be the support function of the set $E[V_h(S, y_0)]$:*

$$\Psi_h(p, S, y_0) \stackrel{\text{def}}{=} \sup_{v \in E[V_h(S,y_0)]} \{p^T v\}.$$

If the CSDE (2.4) *satisfies W-h-AC, then there exists a convex, positively homogeneous and Lipschitz continuous function* $\Psi_h(p)$ *such that*

$$|\Psi_h(p,S,y_0)-\Psi_h(p)|\le c\nu_h(S)||p||(1+||y_0||^\alpha), \tag{6.10}$$

where $\nu_h(S)$ *is the function introduced in* (3.2) *and* $c=1+c_1$ (c_1 *is the constants from* (2.12)).

Proof. Note, first, that $\Psi_h(p,S,y_0)$ allows also the representation

$$\Psi_h(p,S,y_0)=\frac{1}{S}\sup_{(u(\cdot),y(\cdot))}\left\{E\left[\int_0^S p^T h(u(\tau),y(\tau))d\tau|y(0)=y_0\right]\right\},$$

where the sup is over all admissible controls and corresponding solutions of (2.4).

From (6.7) it follows that

$$|\Psi_h(p,S,y_0)|\le c_h||p||,\quad |\Psi_h(p',S,y_0)-\Psi_h(p'',S,y_0)|\le c_h||p'-p''|| \tag{6.11}$$

and from (6.9) it follows that

$$|\Psi_h(p,S',y_0)-\Psi_h(p,S'',y_0)|\le\frac{2c_h||p|||S''-S'|}{\max\{S',S''\}}. \tag{6.12}$$

Also, by (3.12),

$$|\Psi_h(p,S,y_0')-\Psi_h(p,S,y_0'')|\le\nu_h(S)||p||(1+||y_0'||^\alpha+||y_0''||^\alpha). \tag{6.13}$$

Note that if (6.10) is established, then the fact that $\Psi_h(p)$ is convex, positively homogeneous and Lipschitz continuous will follow from the fact that $\Psi_h(p,S,y_0)$ is convex, positively homogeneous and Lipschitz continuous in p (see (6.11)).

By Lemma 6.1, to establish (6.10), it is sufficient to verify the validity of the following estimates:

$$|\Psi(p,kS,y_0)-\Psi(p,S,y_0)|\le c\nu_h(S)||p||(1+||y_0||^\alpha), k=1,2,\dots. \tag{6.14}$$

For $k=1$ it is obvious. Assume that

$$|\Psi(p,(k-1)S,y_0)-\Psi(p,S,y_0)|\le c\nu_h(S)||p||(1+||y_0||^\alpha) \tag{6.15}$$

and show the validity of (6.14) using the induction. Define the collection of random variables $W_h(S,y_0)$ as follows:

$$W_h(S,y_0)\stackrel{\text{def}}{=}\bigcup_{(u(\cdot),y(\cdot))}\left\{\left(\frac{1}{S}\int_0^S h(u(\tau),y(\tau))d\tau,\ y(S)\right)\right\}, \tag{6.16}$$

where the union is over all admissible controls and corresponding solutions of the CSDE (2.4). Using dynamic programming, one can obtain

$$\Psi_h(p,kS,y_0)=\sup_{(\zeta,\eta)\in W_h((k-1)S,y_0)}\left\{\frac{k-1}{k}E[p^T\zeta]+\frac{1}{k}E[\Psi_h(p,S,\eta)]\right\}. \tag{6.17}$$

By (6.13) and (2.12), for any η such that $(\zeta,\eta)\in W_h((k-1)S,y_0)$,

$$|E[\Psi_h(p,S,\eta)]-\Psi_h(p,S,y_0)\ |\le E[|\Psi_h(p,S,\eta)-\Psi_h(p,S,y_0)|]$$

$$\leq \nu_h(S)||p||(1+E[||\eta||^\alpha]+||y_0||^\alpha) \leq \nu_h(S)||p||(1+c_1(1+||y_0||^\alpha)+||y_0||^\alpha)$$

$$= c\nu_h(S)||p||(1+||y_0||^\alpha),$$

with the constant c being as defined in the statement of the lemma. Hence, using (6.17), one can obtain

$$\left|\Psi_h(p,kS,y_0) - \left(\frac{k-1}{k}\Psi_h(p,(k-1)S,y_0)+\frac{1}{k}\Psi_h(p,S,y_0)\right)\right|$$

$$= \left|\Psi_h(p,kS,y_0) - \sup_{(\zeta,\eta)\in W_h((k-1)S,y_0)}\left\{\frac{k-1}{k}E[p^T\zeta]+\frac{1}{k}\Psi_h(p,S,y_0)\right\}\right|$$

$$\leq \frac{1}{k}\sup_{(\zeta,\eta)\in W_h((k-1)S,y_0)}\{|E[\Psi_h(p,S,\eta)]-\Psi_h(p,S,y_0)|\} \leq \left(\frac{1}{k}\right)c\nu_h(S)||p||(1+||y_0||^\alpha).$$

From (6.15) it follows, on the other hand, that

$$\left|\frac{k-1}{k}\Psi_h(p,(k-1)S,y_0) - \frac{k-1}{k}\Psi_h(p,S,y_0))\right| \leq \left(\frac{k-1}{k}\right)c\nu_h(S)||p||(1+||y_0||^\alpha)$$

$$\Rightarrow \qquad |\Psi_h(p,kS,y_0)-\Psi_h(p,S,y_0)|$$

$$\leq \left|\Psi_h(p,kS,y_0) - \left(\frac{k-1}{k}\Psi_h(p,(k-1)S,y_0\right)+\frac{1}{k}\Psi_h(p,S,y_0))\right|$$

$$+\left|\frac{k-1}{k}\Psi_h(p,(k-1)S,y_0) - \frac{k-1}{k}\Psi_h(p,S,y_0)\right| \leq \left(\frac{1}{k}+\frac{k-1}{k}\right)c\nu_h(S)||p||(1+||y_0||^\alpha).$$

The latter implies (6.14). □

LEMMA 6.4. *Let the CSDE* (2.4) *satisfy W-h-AC and let V_h be a convex and compact subset of R^j defined by*

$$V_h \stackrel{\text{def}}{=} \{v \mid p^T v \leq \Psi_h(p)\ \forall p \in R^j\}. \tag{6.18}$$

Then, for any y_0 with the probability distribution from the class (C,α),

$$d_H(coE[V_h(S,y_0)],V_h) \leq c(1+C)\nu_h(S), \tag{6.19}$$

where co stands for the convex hull of the corresponding set.

Comment. The notation (6.18) anticipates the fact that this set will coincide with the set V_h, the existence of which is claimed in Theorem 3.2.

Proof. Note that the fact that the set V_h is convex and compact follows from its definition in the form (6.18) and from the continuity of $\Psi_h(p)$.

Let y_0 be random. The support functions of both $E[V_h(S,y_0)]$ and $coE[V_h(S,y_0)]$ are equal to $E[\Psi_h(p,S,y_0)]$:

$$\sup_{v\in coE[V_h(S,y_0)]}\{p^Tv\} = \sup_{v\in E[V_h(S,y_0)]}\{p^Tv\} = E[\Psi_h(p,S,y_0)].$$

The support function for V_h is $\Psi_h(p)$ (see Corollary 13.2.1 in [47]). Hence (see, e.g., Lemma П2.9, p. 207 in [24]),

$$d_H(coE[V_h(S,y_0)],V_h) \le \sup_{||p||\le 1} |E[\Psi_h(p,S,y_0)] - \Psi_h(p)|. \tag{6.20}$$

By (6.10),

$$| E[\Psi_h(p,S,y_0)] - \Psi_h(p) | \le c\nu_h(S)||p||(1+E[||y_0||^\alpha]) \le c\nu_h(S)||p||(1+C) \tag{6.21}$$

for any y_0 with the probability distribution from the class (C,α). This and (6.20) imply (6.19). □

LEMMA 6.5. *For any $S>0$ and $k=1,2,\ldots$, there exists a collection of random variables $V'_h(kS,y_0)$ such that*

$$V'_h(kS,y_0) \subset V_h(kS,y_0) \qquad \Rightarrow \qquad E[V'_h(kS,y_0)] \subset E[V_h(kS,y_0)] \tag{6.22}$$

and such that: (i) *The estimate*

$$d_H(E[V'_h(kS,y_0)], coE[V_h(S,y_0)]) \le \frac{\bar c_h}{k} + c\nu_h(S)(1+E[||y_0||^\alpha]), \tag{6.23}$$

is valid if W-h-AC is satisfied; and (ii) *The estimate*

$$d^E_H(V'_h(kS,y_0), coE[V_h(S,y_0)] \le \frac{c_h}{\sqrt{k}} + \frac{\bar c_h}{k} + c\nu_h(S)(1+E[||y_0||^\alpha]), \tag{6.24}$$

is valid if S-h-AC is satisfied ($c_h, \bar c_h$ and c being constants).

Proof. The following three parts detail the proof.

Part I: *Construction of $V'_h(kS,y_0)$.* Consider the CSDE (2.4) on the interval $[0,kS]$ $(k=1,2,\ldots)$. Denote by $\{u(\cdot)\}^{0,kS}$ the family of admissible controls on the interval $[0,kS]$ such that the restriction of any control from this family to the interval $((i-1)S,iS]$ $(k\ge i\ge 1)$ is conditionally independent on $\mathcal{F}_{(i-1)S}$ conditioned on $y((i-1)S)$.

Define $V'(kS,y_0)$ as the collection of random variables

$$V'_h(kS,y_0) \stackrel{\text{def}}{=} \bigcup_{\{u(\cdot),y(\cdot)\}^{0,kS}} \left\{ \frac{1}{kS}\int_0^{kS} h(u(\tau),y(\tau))d\tau \right\} \tag{6.25}$$

and $E[V'(kS,y_0)]$ as the set of corresponding mathematical expectations

$$E[V'_h(kS,y_0)] \stackrel{\text{def}}{=} \bigcup_{\{u(\cdot),y(\cdot)\}^{0,kS}} \left\{ E\left[\frac{1}{kS}\int_0^{kS} h(u(\tau),y(\tau))d\tau \right] \right\}, \tag{6.26}$$

where, in both cases, the union is over the controls from $\{u(\cdot)\}^{0,kS}$ and the corresponding solutions of the CSDE (2.4) on the interval $[0,kS]$. Note that, by definition,

$$V'_h(S,y_0) = V_h(S,y_0), \qquad E[V'_h(S,y_0)] = E[V_h(S,y_0)] \tag{6.27}$$

and that the inclusions (6.22) are valid for $k=2,3,\ldots$.

Let $\{u(\cdot),y(\cdot)\}_\eta^{(i-1)S,iS}$ be the family of restrictions to the interval $((i-1)S,iS]$ of the controls $\{u(\cdot)\}^{0,kS}$ and the solutions of the CSDE (2.4) which are obtained with

these controls and satisfy the initial conditions $y((i-1)S) \stackrel{\text{def}}{=} \eta$. Define the collection of random variables $V'_h((i-1)S, iS, \eta)$ $(i = 1, \dots, k)$:

$$V_h((i-1)S,\ iS,\ \eta) \stackrel{\text{def}}{=} \bigcup_{\{u(\cdot),y(\cdot)\}_\eta^{(i-1)S,iS}} \left\{ \frac{1}{S} \int_{(i-1)S}^{iS} h(u(\tau), y(\tau)) d\tau \right\} \tag{6.28}$$

and the set of corresponding mathematical expectations $E[V_h((i-1)S, iS, \eta)]$:

$$E[V_h((i-1)S, iS, \eta)] \stackrel{\text{def}}{=} \bigcup_{\{u(\cdot),y(\cdot)\}_\eta^{(i-1)S,iS}} \left\{ E\left[\frac{1}{S} \int_{(i-1)S}^{iS} h(u(\tau), y(\tau)) d\tau \right] \right\}. \tag{6.29}$$

It is easy to verify that

$$V'_h(kS, y_0) = \bigcup_{(\zeta,\eta)\in W'_h((k-1)S,y_0)} \left\{ \frac{k-1}{k}\zeta + \frac{1}{k} V_h((k-1)S,\ kS,\ \eta) \right\} \tag{6.30}$$

$$\Rightarrow\ E[V'_h(kS, y_0)] = \bigcup_{(\zeta,\eta)\in W'_h((k-1)S,y_0)} \left\{ \frac{k-1}{k} E[\zeta] + \frac{1}{k} E[V_h((k-1)S,\ kS,\ \eta)] \right\}, \tag{6.31}$$

where

$$W'_h((k-1)S, y_0) \tag{6.32}$$

$$\stackrel{\text{def}}{=} \bigcup_{\{u(\cdot),y(\cdot)\}^{0,(k-1)S}} \left\{ \left(\frac{1}{(k-1)S} \int_0^{(k-1)S} h(u(\tau), y(\tau)) d\tau,\ y((k-1)S) \right) \right\},$$

the union being over the controls from the family of restrictions of the elements of $\{u(\cdot)\}^{0,kS}$ to the interval $[0, (k-1)S]$ and corresponding solutions of the CSDE (2.4).

Part II: *Proof of Lemma* 6.5(i). Using induction, let us show that

$$d_H(E[V'_h(kS, y_0)],\ \frac{1}{k}\sum_1^k E[V_h((i-1)S,\ iS,\ y_0)] \le c\nu_h(S)(1+E[||y_0||^\alpha]),\quad k = 1, 2, \dots. \tag{6.33}$$

For $k = 1$ it is immediate since, by definition, $E[V_h(S, y_0)] = E[V_h(0,\ S,\ y_0)]$. Assume that the estimate

$$d_H(E[V'_h((k-1)S,\ y_0)], \frac{1}{k-1}\sum_1^{k-1} E[V_h((i-1)S,\ iS,\ y_0)]) \le c\nu_h(S)(1+E[||y_0||^\alpha]) \tag{6.34}$$

is valid. From Assumption 1 and W-h-AC (see (3.12)) it follows that, for any η such that $(\zeta, \eta) \in W'_h((k-1)S, y_0)$,

$$d_H(E[V_h((k-1)S,\ kS,\ \eta)],\ E[V_h((k-1)S,\ kS,\ y_0)]) \le \nu_h(S)(1+E[||\eta||^\alpha]+E[||y_0||^\alpha])$$

$$\le \nu_h(S)(1 + c_1(1 + E[||y_0||^\alpha]) + E[||y_0||^\alpha]) = c\nu_h(S)(1 + E[||y_0||^\alpha]).$$

This and (6.31) lead to the estimate

$$d_H(E[V'(kS, y_0)],\ \frac{k-1}{k}E[V'((k-1)S,\ y_0)] + \frac{1}{k}E[V_h((k-1)S,\ kS,\ y_0)])$$

$$= d_H\left(E[V'(kS,y_0)],\ \bigcup_{(\zeta,\eta)\in W'_h((k-1)S,y_0)}\left\{\frac{k-1}{k}E[\zeta]+\frac{1}{k}E[V_h((k-1)S,\ kS,\ y_0)]\right\}\right)$$
$$\leq \left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha]).$$

Using the estimate above and (6.34), one can further obtain that

$$d_H(E[V'(kS,y_0)],\ \frac{1}{k}\sum_1^k E[V_h((i-1)S,\ iS,\ y_0)])$$
$$\leq d_H\left(\frac{k-1}{k}E[V'((k-1)S,\ y_0)]+\frac{1}{k}E[V_h((k-1)S,\ kS,\ y_0)]\right),$$
$$\frac{1}{k}\sum_1^k E[V_h((i-1)S,\ iS,\ y_0)]\ +\ \left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])$$
$$\leq\ d_H\left(\frac{k-1}{k}E[V'((k-1)S,\ y_0)],\frac{k-1}{k}\frac{1}{k-1}\sum_1^{k-1}E[V_h((i-1)S,\ iS,\ y_0)]\right)$$
$$+\left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])\leq\left(\frac{k-1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])+\left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])$$
$$= c\nu_h(S)(1+E[||y_0||^\alpha]).$$

Thus, (6.33) is established.

Since

$$E[V_h((i-1)S,\ iS,\ y_0)]=E[V_h(S,y_0)]\quad\forall i=1,\dots,k,$$

(6.33) is equivalent to

$$d_H(E[V'_h(kS,y_0)],\ \frac{1}{k}\sum_1^k E[V_h((S,y_0)])\leq c\nu_h(S)(1+E[||y_0||^\alpha]).$$

By Shapley–Folkman's theorem (see, e.g., [24, p. 204])

$$d_H\left(\frac{1}{k}\sum_1^k E[V_h(S,y_0)],\ coE[V_h(S,y_0)]\right)\leq\frac{2(j+1)c_h}{k},\tag{6.35}$$

where c_h is as in (6.6) and j is the dimension of the Euclidean space containing the subsets above. These imply (6.23) with $\bar{c}_h\stackrel{\text{def}}{=}2(j+1)c_h$.

Part III: *Proof of Lemma* 6.5(ii). Let $y_0^0\stackrel{\text{def}}{=}y_0$ and let y_0^i $i=1,\dots,k-1$ have the same probability distribution as y_0 and be independent of y_0 and among themselves (and also independent of $W(\cdot)$). Using induction, let us show that

$$d_H^E\left(V'_h(kS,y_0),\ \frac{1}{k}\sum_1^k V_h((i-1)S,\ iS,\ y_0^{i-1})\right)\leq c\nu_h(S)(1+E[||y_0||^\alpha]),\quad k=1,2,\dots.\tag{6.36}$$

For $k = 1$, the above expression is obviously true. Assume that

$$d_H^E\left(V_h'((k-1)S, y_0),\ \frac{1}{k-1}\sum_1^{k-1} V_h((i-1)S,\ iS,\ y_0^{i-1})\right) \le c\nu_h(S)(1+E[||y_0||^\alpha]). \tag{6.37}$$

From Assumption 1 and S-h-AC (see (3.11)) it follows that, for any η such that $(\zeta, \eta) \in W_h'((k-1)S, y_0)$,

$$d_H^E\left(V_h((k-1)S,\ kS,\ \eta),\ V_h((k-1)S,\ kS,\ y_0^{k-1})\right) \le \nu_h(S)(1+E[||\eta||^\alpha]+E[||y_0||^\alpha])$$

$$\le \nu_h(S)(1+c_1(1+E[||y_0||^\alpha])+E[||y_0||^\alpha]) = c\nu_h(S)(1+E[||y_0||^\alpha]).$$

Hence, by (6.30),

$$d_H^E\left(V'(kS, y_0),\ \frac{k-1}{k}V'((k-1)S,\ y_0)+\frac{1}{k}V_h((k-1)S,\ kS,\ y_0^{k-1})\right)$$

$$= d_H^E\left(V'(kS, y_0), \bigcup_{(\zeta,\eta)\in W_h'((k-1)S,y_0)}\left\{\frac{k-1}{k}\zeta+\frac{1}{k}V_h((k-1)S,\ kS,\ y_0^{k-1})\right\}\right)$$

$$\le \left(\frac{1}{k}\right)\sup_{(\zeta,\eta)\in W_h'((k-1)S,y_0)} d_H^E(V_h((k-1)S,\ kS,\ \eta),\ V_h((k-1)S,\ kS,\ y_0^{k-1}))$$

$$\le \left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha]).$$

Using this estimate and (6.37), one obtains

$$d_H^E\left(V'(kS, y_0),\ \frac{1}{k}\sum_1^k V_h((i-1)S,\ iS,\ y_0^{i-1})\right)$$

$$\le d_H^E\left(\frac{k-1}{k}V'((k-1)S,\ y_0)+\frac{1}{k}V_h((k-1)S,\ kS,\ y_0^{k-1}),\ \frac{1}{k}\sum_1^k V_h((i-1)S,\ iS,\ y_0^{i-1})\right)$$

$$+\left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])$$

$$\le d_H^E\left(\frac{k-1}{k}V'((k-1)S,\ y_0),\ \frac{k-1}{k}\frac{1}{k-1}\sum_1^{k-1} V_h((i-1)S,\ iS,\ y_0^{i-1})\right)$$

$$+\left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha]) \le \left(\frac{k-1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])+\left(\frac{1}{k}\right)c\nu_h(S)(1+E[||y_0||^\alpha])$$

$$= c\nu_h(S)(1+E[||y_0||^\alpha]).$$

This proves the validity of the estimate (6.36).

The elements of $V_h((i-1)S,\ iS,\ y_0^{i-1}), i = 1, 2, \ldots, k$, are mutually independent and, by (6.6),

$$E[||\zeta||^2] \le c_h^2 \qquad \forall\zeta \in V_h((i-1)S,\ iS,\ y_0^{i-1}), \quad i = 1, 2, \ldots, k.$$

Hence, one can use Proposition 3.5 and the fact that $E[V_h((i-1)S,\ iS,\ y_0^{i-1})] = E[V_h(S, y_0)]$ to obtain

$$d_H^E\left(\frac{1}{k}\sum_1^k V_h((i-1)S,\ iS,\ y_0^{i-1}),\ \frac{1}{k}\sum_1^k E[V_h((i-1)S,\ iS,\ y_0^{i-1})]\right)$$
$$= d_H^E\left(\frac{1}{k}\sum_1^k V_h((i-1)S,\ iS,\ y_0^{i-1}),\ \frac{1}{k}\sum_1^k E[V_h(S, y_0)]\right) \le \frac{c_h}{\sqrt{k}}.$$

The last estimate along with (6.35) and (6.33) imply (6.24). □

COROLLARY 6.6. *For any y_0 with the probability distribution from the class (C, α),*

$$d_H(E[V_h'(kS, y_0)], V_h) \le \frac{\bar{c}_h}{k} + 2c(1+C)\nu_h(S) \tag{6.38}$$

if W-h-AC is satisfied and

$$d_H^E(V_h'(kS, y_0), V_h) \le \frac{c_h}{\sqrt{k}} + \frac{\bar{c}_h}{k} + 2c(1+C)\nu_h(S) \tag{6.39}$$

if S-h-AC is satisfied.

Proof. The estimates follow from (6.19), (6.23) and (6.19), (6.24), respectively. □

LEMMA 6.7. *For any y_0 with the probability distribution from the class (C, α),*

$$\sup_{\zeta\in V_h} d(\zeta,\ E[V_h(S, y_0)]) \le \nu_h^1(S), \qquad \lim_{S\to\infty} \nu_h^1(S) = 0 \tag{6.40}$$

if W-h-AC is satisfied, and

$$\sup_{\zeta\in V_h} d^E(\zeta,\ V_h(S, y_0)) \le \nu_h^2(S), \qquad \lim_{S\to\infty} \nu_h^2(S) = 0 \tag{6.41}$$

if S-h-AC is satisfied.

Proof. Using (6.9) with $S'' = S$ and $S' = \lfloor S^{\frac{1}{2}}\rfloor S^{\frac{1}{2}}$, one can obtain

$$d_H(E[V_h(\lfloor S^{\frac{1}{2}}\rfloor S^{\frac{1}{2}}, y_0)],\ E[V_h(S, y_0)]) \le \frac{2c_h}{S^{\frac{1}{2}}}, \tag{6.42}$$

where $\lfloor S^{\frac{1}{2}}\rfloor$ stands for the integer part of $S^{\frac{1}{2}}$. Hence,

$$\sup_{\zeta\in V_h} d(\zeta,\ E[V_h(S, y_0)]) \le \sup_{\zeta\in V_h} d(\zeta,\ E[V_h(\lfloor S^{\frac{1}{2}}\rfloor S^{\frac{1}{2}}, y_0)]) + \frac{2c_h}{S^{\frac{1}{2}}}. \tag{6.43}$$

From (6.22) and (6.38) (with the replacement of S by $S^{\frac{1}{2}}$ and the replacement of k by $\lfloor S^{\frac{1}{2}}\rfloor$) it follows, on the other hand, that

$$\sup_{\zeta\in V_h} d(\zeta,\ E[V_h(\lfloor S^{\frac{1}{2}}\rfloor S^{\frac{1}{2}}, y_0)]) \le \sup_{\zeta\in V_h} d(\zeta,\ E[V_h'(\lfloor S^{\frac{1}{2}}\rfloor S^{\frac{1}{2}}, y_0)])$$
$$\le d_H(E[V_h'(\lfloor S^{\frac{1}{2}}\rfloor S^{\frac{1}{2}}, y_0)],\ V_h) \le \frac{\bar{c}_h}{\lfloor S^{\frac{1}{2}}\rfloor} + 2c(1+C)\nu_h(S^{\frac{1}{2}})$$

This and (6.43) imply (6.40) with $\nu_h^1(S) \stackrel{\text{def}}{=} \frac{2c_h}{S^{\frac{1}{2}}} + \frac{\bar{c}_h}{\lfloor S^{\frac{1}{2}}\rfloor} + 2c(1+C)\nu_h(S^{\frac{1}{2}})$.

To establish (6.41), one can use (6.8) and obtain, similarly to (6.42), that

$$d_H^E(V_h(\lfloor S^{\frac12}\rfloor S^{\frac12}, y_0),\ V_h(S, y_0)) \le \frac{2c_h}{S^{\frac12}},$$

$$\Rightarrow \quad \sup_{\zeta\in V_h} d^E(\zeta,\ V_h(S, y_0)) \le \sup_{\zeta\in V_h} d^E(\zeta,\ V_h(\lfloor S^{\frac12}\rfloor S^{\frac12}, y_0)]) + \frac{2c_h}{S^{\frac12}}. \tag{6.44}$$

By (6.22) and (6.39) (with S being replaced by $S^{\frac12}$ and k by $\lfloor S^{\frac12}\rfloor$ as above),

$$\sup_{\zeta\in V_h} d^E(\zeta,\ V_h(\lfloor S^{\frac12}\rfloor S^{\frac12}, y_0)) \le \sup_{\zeta\in V_h} d^E(\zeta,\ V_h'(\lfloor S^{\frac12}\rfloor S^{\frac12}, y_0))$$

$$\le d_H^E(V_h'(\lfloor S^{\frac12}\rfloor S^{\frac12}, y_0),\ V_h) \le \frac{c_h}{\sqrt{\lfloor S^{\frac12}\rfloor}} + \frac{\bar c_h}{\lfloor S^{\frac12}\rfloor} + 2c(1+C)\nu_h(S^{\frac12}).$$

This and (6.44) imply (6.41) with $\nu_h^2(S)$ being equal to the sum of $\frac{2c_h}{S^{\frac12}}$ and the right-hand side of the last inequality. □

Proof of Theorem 3.2. By (6.19),

$$sup_{\zeta\in E[V_h(S,y_0)]} d(\zeta, V_h) \le sup_{\zeta\in coE[V_h(S,y_0)]} d(\zeta, V_h) \le d_H(coE[V_h(S, y_0)], V_h)$$

$$\le c(1+C)\nu_h(S).$$

Comparing this estimate and (6.40), one obtains (3.14) with $\nu_h^{C,\alpha}(S) \stackrel{\text{def}}{=} \max\{c(1+C)\nu_h(S), \nu_h^1(S)\}$. □

Proof of Theorem 3.4. The statement (i) of the theorem is established by (6.41), with $\tilde\nu_h^{C,\alpha}(S) \stackrel{\text{def}}{=} \nu_h^2(S)$. Let us prove the statement (ii). Assume it is not true. Then there exists a number $\delta > 0$, and sequences $\mu_l \in \mathcal{M}$ and $S_l, l = 1, 2, \dots$, ($S_l \to \infty$ as $l \to \infty$) such that, for any $\mu' \in \mathcal{M}(S_l, y_0)$,

$$E[\rho(\mu_l, \mu')] = \sum_{i=1}^{\infty} 2^{-i} E\left[\left|\int f_i(u,y)\mu_l(du,dy) - \int f_i(u,y)\mu'(du,dy)\right|\right] \ge \delta \tag{6.45}$$

$$\Rightarrow \sum_{i=1}^{N} 2^{-i} E[|\int f_i(u,y)\mu_l(du,dy) - \int f_i(u,y)\mu'(du,dy)|] \ge \frac{\delta}{2} \quad \forall \mu' \in \mathcal{M}(S_l, y_0)$$

for N large enough. Hence, for any $\mu' \in \mathcal{M}(S_l, y_0)$,

$$E\left[\sqrt{\sum_{i=1}^{N}\left|\int f_i(u,y)\mu_l(du,dy) - \int f_i(u,y)\mu'(du,dy)\right|^2}\right] \ge \frac{c_N\delta}{2}, \quad c_N = \text{const.} \tag{6.46}$$

Let $h(u,y)$ be defined by (3.1) with $j = N$ and let $\zeta_l \stackrel{\text{def}}{=} \int h(u,y)\mu_l(du,dy)$; by (3.17), $\zeta_l \in V_h$. Also, by (3.6), $V_h(S_l, y_0)$ is the union of all $\zeta' \stackrel{\text{def}}{=} \int h(u,y)\mu'(du,dy)$ over $\mu' \in \mathcal{M}(S_l, y_0)$. The estimate (6.46) is equivalent, thus, to

$$E[||\zeta_l - \zeta'||] \ge \frac{c_N\delta}{2} \quad \forall \zeta' \in V_h(S_l, y_0) \qquad \Leftrightarrow \qquad d^E(\zeta_l, V_h(S_l, y_0)) \ge \frac{c_N\delta}{2}.$$

The latter contradicts (6.41). □

Proof of Theorem 3.3. Let Assumption 1 and W-h-AC be satisfied for any $h(\cdot)$ as in (3.1). Then, by Theorem 3.2, for any such $h(\cdot)$ and any initial condition y_0 with the probability distribution from the class (C,α), there exists a convex and compact set V_h such that (3.14) is satisfied. From Corollary 3.7 in [28] (see also Theorem 3.1(i) in [27] and more general results in [7]) it follows that

$$\rho_H(E[\mathcal{M}(S,y_0)],\bar{\mathcal{M}}) \le \ \nu^{C,\alpha}(S) \tag{6.47}$$

for some $\nu^{C,\alpha}(S)$ tending to zero as S tends to infinity, where

$$\bar{\mathcal{M}} \stackrel{\text{def}}{=} \{\mu \in \mathcal{P}(U\times \bar{R}^m) \mid \int h(u,y)\mu(du,dy) \in V_h \ \ \forall h(u,y) \ \ as\ in\ (3.1)\}.$$

It is easy to verify that the set $\bar{\mathcal{M}}$ is convex and compact. Hence, the estimate (3.15) will be established if one shows that $\mathcal{M}=\bar{\mathcal{M}}$. Since, by definition, $\mathcal{M}\subset\bar{\mathcal{M}}$, it is enough to show that $\bar{\mathcal{M}}\subset\mathcal{M}$.

For $N=1,2,\dots$, let $Y_N \stackrel{\text{def}}{=} \{y\in R^m \mid ||y||\le N\}$ and $Y_N^c \stackrel{\text{def}}{=} \{y\in R^m \mid ||y||>N\}$. By (2.8) and (2.10), for any $\mu\in E[\mathcal{M}(S,y_0)]$, there exists an admissible control $u(\cdot)$ and the corresponding solution $y(\cdot)$ of the CSDE (2.4) such that

$$\mu(U\times Y_N^c) = \frac{1}{S}\int_0^S E[\chi_{Y_N^c}(y(\tau))]d\tau \ \le \ \frac{1}{N^\alpha}\frac{1}{S}\int_0^S E[\chi_{Y_N^c}(y(\tau))\ ||y(\tau)||^\alpha]d\tau,$$

where $\chi_{Y_N^c}(y(\tau))$ is the indicator function of Y_N^c. Hence, using Assumption I and the fact that y_0 has the probability distribution from the class (C,α), one obtains that, for any $\mu\in E[\mathcal{M}(S,y_0)]$,

$$\mu(U\times Y_N^c) \le \frac{1}{N^\alpha}\frac{1}{S}\int_0^S E[||y(\tau)||^\alpha]d\tau \le \frac{1}{N^\alpha}c_1(C+1)$$
$$\Rightarrow \qquad \mu(U\times Y_N) \ge 1-\frac{1}{N^\alpha}c_1(C+1).$$

Take an arbitrary $\mu\in\bar{\mathcal{M}}$. By (6.47), there exists a sequence $\mu_i\in E[\mathcal{M}(S_i,y_0)]$ (S_i tends to infinity as i tends to infinity) such that

$$\lim_{i\to\infty}\rho(\mu_i,\mu)=0 \quad \Rightarrow \quad \mu(U\times Y_N)\ge \limsup_{i\to\infty}\mu_i(U\times Y_N)\ge 1-\frac{1}{N^\alpha}c_1(C+1)$$
$$\Rightarrow \qquad \mu(U\times R^m)=1.$$

The latter implies that $\mu\in\mathcal{M}$ and, hence, $\bar{\mathcal{M}}\subset\mathcal{M}$.

Using the second representation for $E[V_h(S,y_0)]$ in (3.7), it is straightforward to verify that the validity of (3.15) implies the validity of (3.14) with V_h as in (3.17) for any $h(\cdot)$ as in (3.1). The fact that W-h-AC is satisfied for any such $h(\cdot)$ follows now from Theorem 3.2. □

7. Proofs for sections 4. *Proof of Theorem* 4.2. Assume that (4.6) is not valid. Then there exist a number $\delta>0$ and initial conditions y_0 with the probability distribution from the class (C,α) such that, for some S_i, $\lim_{i\to\infty}S_i=\infty$, and some $\mu_i\in\mathcal{M}(S_i,y_0)$,

$$E[\inf_{\mu'\in D}\rho(\mu_i,\mu')]\ge\delta \quad i=1,2,\dots, \qquad \Rightarrow \qquad E[\inf_{\mu'\in D}\ \rho(\mu^*,\mu')]\ge\delta, \tag{7.1}$$

where it is assumed (without loss of generality) that $\mu_i \to \mu^*$ in law as $i \to \infty$. From the fact that $\mu_i \in \mathcal{M}(S_i, y_0)$ it follows that there exist an admissible control $u^i(\cdot)$ and the corresponding solution $y^i(\cdot)$ of the CSDE (2.4) (with the initial conditions $y^i(0) = y_0$) such that μ_i is the occupational measure of the pair $(u^i(\cdot), y^i(\cdot))$ on the interval $[0, S_i]$ (see (2.6)). Hence, for any $f \in \mathcal{D}$

$$\frac{1}{S_i}(f(y^i(S) - f(y(0))) = \int_{U\times\bar{R}^m} (Lf)(u,y)\mu_i(du,dy)$$

$$+\frac{1}{S_i}\int_0^{S_i} \langle \nabla f(y^i(\tau)), b(y^i(\tau))dW(\tau)\rangle,$$

where, in order for the integration in the first term of the right-hand side to be legitimate, the definition of $(Lf) : U\times R^m \to R^1$ (see (4.1) above) is formally extended to $(Lf) : U \times \bar{R}^m \to R^1$ by setting $(Lf)(\cdot,\infty) \stackrel{\text{def}}{=} 0$.

The left-hand side and the variance of the second term on the right-hand side of the above expression tend to zero as $S_i \to \infty$ (this can be easily derived from the fact that the probability distribution of y_0 belongs to the class (C, α) and from that Assumption 1 is satisfied with $\alpha \geq 2$). Hence, the first term on the right-hand side tends to zero in law.

By Skorohod's theorem (see, e.g., [15, p. 23]), there exist $\mathcal{P}(U \times \bar{R}^m)$-valued random variables $\tilde{\mu}_i$ and $\tilde{\mu}^*$ defined on a common probability space such that they agree in law with μ_i and μ^*, respectively, and such that

$$\lim_{i\to\infty} \rho(\tilde{\mu}_i, \tilde{\mu}^*) = 0 \quad a.s. \tag{7.2}$$

$$\Rightarrow \quad \lim_{i\to\infty} \int_{U\times\bar{R}^m} (Lf)(u,y)\tilde{\mu}_i(dxdu) = \int_{U\times\bar{R}^m} (Lf)(u,y)\tilde{\mu}^*(du,dy) \quad a.s.$$

$$\Rightarrow \quad \int_{U\times\bar{R}^m} (Lf)(u,y)\tilde{\mu}^*(du,dy) = 0 \ \ a.s. \quad \Rightarrow \quad \int_{U\times\bar{R}^m} (Lf)(u,y)\mu^*(du,dy) = 0 \ \ a.s.$$

Since $\mathcal{D}$ is countable, the last expression is valid for all $f \in \mathcal{D}$ outside a common zero probability set. Hence, if one establishes that $\mu^* \in \mathcal{P}(U \times R^m)$ a.s., it will follow that $\mu^* \in D$ a.s. and, thus, it will contradict (7.1).

To complete the proof of the theorem, one needs to show now that $\mu^* \in \mathcal{P}(U\times R^m)$ a.s. That is, one needs to show that

$$\mu^*(U \times R^m) = 1 \quad a.s. \tag{7.3}$$

From Assumption 1 it follows that, for any $\delta > 0$, there exists a compact set $Y_\delta \subset R^m$ such that

$$E[\tilde{\mu}_i(U \times Y_\delta)] = E[\mu_i(U \times Y_\delta)] \geq 1 - \delta,$$

where it is also taken into account that $\tilde{\mu}_i$ and μ_i agree in law. By (7.2),

$$\tilde{\mu}^*(U \times Y_\delta) \geq \limsup_{i\to\infty} \tilde{\mu}_i(U \times Y_\delta) \quad a.s.$$

$$\Rightarrow \quad E\left[\tilde{\mu}^*(U \times Y_\delta)\right] \geq E[\limsup_{i\to\infty} \tilde{\mu}_i(U \times Y_\delta)] \geq \limsup_{i\to\infty} E[\tilde{\mu}_i(U \times Y_\delta)] \geq 1 - \delta.$$

Since μ^* and $\tilde{\mu}^*$ agree in law,

$$E[\tilde{\mu}^*(U \times Y_\delta)] = E[\mu^*(U \times Y_\delta)] \quad \Rightarrow \quad E[\mu^*(U \times Y_\delta)] \geq 1 - \delta.$$

Since δ can be arbitrary small, the latter implies that $E[\mu^*(U \times R^m)] = 1$ which, in turn, implies the validity of (7.3). This completes the proof of the theorem. □

Proof of Theorem 4.1(i). It can be easily verified that $\rho(\mu, D)$ is a convex function of μ. Hence, by (4.6),

$$\rho(E[\mu], D) \leq E[\rho(\mu, D)] \leq \bar{\nu}^{(C,\alpha)}(S) \quad \forall \mu \in \mathcal{M}(S, y_0)$$

$$\Rightarrow \sup_{\mu \in E[\mathcal{M}(S,y_0)]} \rho(\mu, D) \leq \bar{\nu}^{(C,\alpha)}(S).$$

Since the above estimate is uniform with respect to the initial conditions y_0 which have the probability distribution from the class (C, α), it follows that

$$\sup_{\{y_0\} \in (C,\alpha)} \left\{ \sup_{\mu \in E[\mathcal{M}(S,y_0)]} \rho(\mu, D) \right\} \leq \bar{\nu}^{(C,\alpha)}(S).$$

In Lemma 7.1 below it is shown that

$$\sup_{\mu \in D} \rho \left(\mu, \bigcup_{\{y_0\} \in (C,\alpha)} E[\mathcal{M}(S, y_0)] \right) = 0. \tag{7.4}$$

These imply (4.4). □

LEMMA 7.1. *The equation* (7.4) *is valid if the conditions of Theorem* 4.1 *are satisfied.*

Proof. For any $h(\cdot)$ as in (3.1), define the set D_h by

$$D_h \stackrel{\text{def}}{=} \bigcup_{\mu \in D} \left\{ \int h(u, y) \mu(du, dy) \right\}. \tag{7.5}$$

As follows from Lemma 3.5 in [28], the validity of (7.4) will be established if one shows that

$$\sup_{v \in D_h} d \left(v, \bigcup_{\{y_0\} \in (C,\alpha)} \{E[V_h(S, y_0)]\} \right) = 0. \tag{7.6}$$

Take an arbitrary element $v \in D_h$. By definition, there exists $\mu \in D$ such that $v = \int h(u, y) \mu(du, dy)$. From results in [13] and [49] it follows that there exists m-dimensional standard Brownian motion $W'(\cdot)$ and a stationary $\mathcal{P}(U) \times R^m$ - valued random process $(\lambda'(\tau), y'(\tau))$ such that

$$dy'(\tau) = \tilde{a}(\lambda'(\tau), y'(\tau))dt + b(y'(\tau))dW'(\tau), \qquad \tilde{a}(\lambda, y) \stackrel{\text{def}}{=} \int a(u, y)\lambda(du), \tag{7.7}$$

and

$$E \left[\int h(u, y'(\tau))\lambda'(\tau)(du) \right] = \int h(u, y)\mu(du, dy) = v \quad \forall \tau \geq 0, \tag{7.8}$$

$$E[||y'(\tau)||^{\alpha}] = \int ||y||^{\alpha}\mu(du,dy) \le c_2 \quad \forall \tau \ge 0, \tag{7.9}$$

with $W'(\cdot)$ being independent of $y'(0)$ and $\lambda'(\cdot)$ being nonanticipative (i.e., for $\bar{\tau} > \tau, W'(\bar{\tau}) - W'(\tau)$ is independent of $\{y'(0)$ and $W'(\theta), \lambda'(\theta), \theta \le \tau\}$); ($c_2$ is the constant from Assumption 2). Using Filippov type chattering lemma for CSDE (see, e.g., [14, p. 15]), one can establish that there exists a sequence of admissible controls $u^i(\cdot)$ and the corresponding sequence of solutions $y^i(\cdot)$ of the CSDE (2.4) (considered with $W'(\cdot)$ instead of $W(\cdot)$) such that $y^i(0) = y'(0)$ and such that

$$\lim_{i\to\infty} E\left[\left\| \frac{1}{S}\int_0^S h(u^i(\tau), y^i(\tau))d\tau - \frac{1}{S}\int_0^S \int h(u, y'(\tau))\lambda'(\tau)(du)d\tau \right\|\right] = 0. \tag{7.10}$$

From (7.8) and (7.10) it follows that

$$\lim_{i\to\infty} \left\| E\left[\frac{1}{S}\int_0^S h(u^i(\tau), y^i(\tau))d\tau\right] - v \right\| = 0. \tag{7.11}$$

Since

$$E\left[\frac{1}{S}\int_0^S h(u^i(\tau), y^i(\tau))d\tau\right] \in E[V_h(S, y'(0))] \subset \bigcup_{\{y_0\}\in(C,\alpha)} \{E[V_h(S, y_0)]\}$$

(the last inclusion being due to the fact that, by (7.9), $y'(0)$ has the probability distribution from the class (C, α) with $C \ge c_2$), one can use (7.11) to obtain that

$$dist\left(v, \bigcup_{\{y_0\}\in(C,\alpha)} \{E[V_h(S, y_0)]\}\right) = 0.$$

As v is an arbitrary element of D_h, this implies (7.6). □

The proofs of Corollaries 4.4 and 4.5 are based on the following result.

LEMMA 7.2. *A sequence $\mu^k \in \mathcal{P}(U \times R^m), k = 1, 2, \ldots,$ converges to $\mu \in \mathcal{P}(U \times R^m)$ in the metric ρ defined in* (2.1) *(that is, $\lim_{k\to\infty} \rho(\mu^k, \mu) = 0$) if and only if*

$$\lim_{k\to\infty} \int f(u,y)\mu^k(du,dy) = \int f(u,y)\mu(du,dy)$$

for any bounded continuous function $f(u, y) : U \times R^m \to R^1$.

Proof. follows from Theorem 2.1.1 in [15]. □

Proof of Corollary 4.4. By Assumption 2 (see (4.3)), for any $\mu \in D$ and $N \ge 1$,

$$N^{\alpha-1}\int_{||y||\ge N} ||y||\mu(du,dy) \le \int_{||y||\ge N} ||y||^{\alpha}\mu(du,dy) \le \int ||y||^{\alpha}\mu(du,dy) \le c_2$$

$$\int_{||y||\ge N} ||y||\mu(du,dy) \le \frac{c_2}{N^{\alpha-1}} \qquad \forall \mu \in D. \tag{7.12}$$

Let $\xi_N(\theta) : [0,\infty) \to [0,1]$ be a continuous function such that $\xi_N(\theta) = 1$ for $\theta \in [0, N]$ and such that $\xi_N(\theta) = 0$ for $\theta \in [N+1, \infty)$. Let $g_N(u,y) \stackrel{\text{def}}{=} g(u,y)\xi_N(||y||)$. According to these definitions, $g_N(u,y) = g(u,y)$ for $||y|| \le N$ and also

$$||g_N(u,y)|| \le ||g(u,y)||, \quad ||g_N(u,y)|| \le \max_{u\in U, ||y||\le N} ||g(u,y)|| \qquad \forall (u,y) \in U \times Y.$$

Due to the Lipschitz continuity of $g(u,y)$,

$$||g(u,y)|| \le a_1 + a_2||y|| \quad \Rightarrow \quad ||g_N(u,y)|| \le a_1 + a_2||y|| \qquad \forall y \in R^m, \tag{7.13}$$

where $a_i = \text{const}, i = 1,2$. By (7.12), it is implied that

$$\left\| \int g(u,y)\mu(du,dy) - \int g_N(u,y)\mu(du,dy) \right\| \le \frac{a_3}{N^{\alpha-1}} \ \ \forall \mu \in D, \quad a_3 = \text{const}. \tag{7.14}$$

From (7.12) and (7.13) it follows that the set V_g is bounded. Let us prove that it is closed by showing that, if $\mu_k \in D$ and the limit $\lim_{k\to\infty} \int g(u,y)\mu_k(du,dy)$ exists, then this limit belongs to V_g. Assume the above limit does exist. Due to the fact that D is compact, one may also assume (without loss of generality) that $\lim_{k\to\infty} \rho(\mu_k,\mu) = 0$ for some $\mu \in D$. By virtue of Lemma 7.2 and since $g_N(u,y)$ is bounded, the latter leads to the equality $\lim_{k\to\infty} \int g_N(u,y)\mu_k(du,dy) = \int g_N(u,y)\mu(du,dy)$, which, in turn, implies that

$$\begin{aligned}
&\lim_{k\to\infty} \left\| \int g(u,y)\mu_k(du,dy) - \int g(u,y)\mu(du,dy) \right\| \\
&\le \limsup_{k\to\infty} \left\| \int g(u,y)\mu_k(du,dy) - \int g_N(u,y)\mu_k(du,dy) \right\| \\
&\quad + \lim_{k\to\infty} \left\| \int g_N(u,y)\mu_k(du,dy) - \int g_N(u,y)\mu(du,dy) \right\| \\
&\quad + \left\| \int g_N(u,y)\mu(du,dy) - \int g(u,y)\mu(du,dy) \right\| \\
&\le \frac{2a_3}{N^{\alpha-1}} \quad \Rightarrow \quad \lim_{k\to\infty} \int g(u,y)\mu_k(du,dy) = \int g(u,y)\mu(du,dy) \in V_g.
\end{aligned}$$

This proves that V_g is compact.

Let $V_{g_N}(S,y_0)$ and V_{g_N} be defined by (4.10) and (4.11) with the replacement of $g(\cdot)$ by $g_N(\cdot)$. By (7.14),

$$d_H(V_{g_N}, V_g) \le \frac{a_3}{N^{\alpha-1}}. \tag{7.15}$$

Similarly to (7.12), from Assumption 1 it follows that, for any y_0 having a probability distribution from the class (C,α),

$$E\left[\int_{||y||\ge N} ||y||\mu(du,dy) \right] \le \frac{a_4}{N^{\alpha-1}} \qquad \forall \mu \in \mathcal{M}(S,y_0) \tag{7.16}$$

$$\Rightarrow \ E\left[\left\| \int g(u,y)\mu(du,dy) - \int g_N(u,y)\mu(du,dy) \right\| \right] \le \frac{a_5}{N^{\alpha-1}} \ \ \forall \mu \in \mathcal{M}(S,y_0) \tag{7.17}$$

$$\Rightarrow \qquad d_H^E(V_{g_N}(S,y_0), V_g(S,y_0)) \le \frac{a_5}{N^{\alpha-1}}, \tag{7.18}$$

where a_4, a_5 are positive constants. From (7.15) and (7.18) it follows that, to prove (4.12), it is enough to prove that

$$\sup_{v\in V_{g_N}(S,y_0)} E[d(v,V_{g_N})] \le \nu_{g_N}(S), \qquad \lim_{S\to\infty} \nu_{g_N}(S) = 0. \tag{7.19}$$

Assume it is not true. Then there exists $\delta > 0$ and sequences $S_i, \lim_{i\to\infty} S_i = 0$, and $\mu_i \in \mathcal{M}(S_i, y_0$ such that

$$E\left[d\left(\int g_N(u,y)\mu_i(du,dy), V_{g_N}\right)\right] \geq \delta, \tag{7.20}$$

with $\mu_i \to \mu^*$ in law as $i \to \infty$. Like in the proof of Theorem 4.2, let $\tilde{\mu}_i$ and $\tilde{\mu}^*$ be $\mathcal{P}(U \times R^m)$-valued random variables defined on a common probability space such that they agree in law with μ_i and μ^*, respectively, and such that (7.2) is satisfied. From (7.2) and Lemma 7.2 it follows that

$$\lim_{i\to\infty} \int g_N(u,y)\tilde{\mu}_i(du,dy) = \int g_N(u,y)\tilde{\mu}^*(du,dy) \in V_{g_N} \quad a.s.,$$

the last inclusion being implied by the fact that $\tilde{\mu}^* \in D$ (which is established similarly to the proof of Theorem 4.2). Hence, $E[d(\int g_N(u,y)\tilde{\mu}^*(du,dy), V_{g_N})] = 0$. This contradicts the following inequalities resulting from (7.20) and the fact that $\tilde{\mu}_i$ and μ_i agree in law:

$$E\left[d\left(\int g_N(u,y)\tilde{\mu}^*(du,dy),\ V_{g_N}\right)\right] = \lim_{i\to\infty} E\left[d\left(\int g_N(u,y)\tilde{\mu}_i(du,dy), V_{g_N}\right)\right] \geq \delta$$

Thus Corollary 4.4 is proved. □

Proof of Corollary 4.5. By (7.15) and (7.18), to prove (4.12), it is sufficient to prove that

$$\sup_{v\in V_{g_N}} d^E(v, V_{g_N}(S, y_0)) \leq \ \nu_{g_N}(S), \qquad \lim_{S\to\infty} \nu_{g_N}(S) = 0. \tag{7.21}$$

Assume it is not true. Then there exist a number $\delta > 0$ and sequences $\mu_i \in D$ and $S_i, i = 1, 2, \ldots, (S_i \to \infty$ as $i \to \infty)$ such that

$$E\left[\left\|\int g_N(u,y)\mu_i(du,dy) - \int g_N(u,y)\mu(du,dy)\right\|\right] \geq \delta \qquad \forall \mu \in \mathcal{M}(S_i, y_0). \tag{7.22}$$

From Theorem 3.4(ii) (see (3.19)) it follows that there exists $\mu^{S_i} \in \mathcal{M}(S_i, y_0)$, such that

$$E[\rho(\mu_i, \mu^{S_i})] \leq 2\tilde{\nu}^{(C,\alpha)}(S_i), \qquad \lim_{i\to\infty} \tilde{\nu}^{(C,\alpha)}(S_i) = 0. \tag{7.23}$$

Without loss of generality, one may assume that $\mu_i \to \mu^*$ and $\mu^{S_i} \to \mu^{**}$ in law. Also, using Skorohod's theorem, one can verify (similar to the way it is done in the proof of Theorem 4.2) that there exist $\mathcal{P}(U \times R^m)$-valued random variables $\tilde{\mu}_i, \tilde{\tilde{\mu}}_i, \tilde{\mu}^*$ and $\tilde{\tilde{\mu}}^{**}$ defined on a common probability space such that they agree in law with μ_i, μ^{S_i}, μ^* and μ^{**} and such that, almost sure, $\tilde{\mu}_i \to \tilde{\mu}^*$, $\tilde{\tilde{\mu}}_i \to \tilde{\tilde{\mu}}^{**}$. Note that $E[\rho(\tilde{\mu}_i, \tilde{\tilde{\mu}}_i)] = E[\rho(\mu_i, \mu^{S_i})]$ and, hence, by (7.23),

$$E[\rho(\tilde{\mu}^*, \tilde{\tilde{\mu}}^{**})] \leq \lim_{i\to\infty} E[\rho(\tilde{\mu}^*, \tilde{\mu}_i)] + \limsup_{i\to\infty} E[\rho(\tilde{\mu}_i, \tilde{\tilde{\mu}}_i)] + \lim_{i\to\infty} E[\rho(\tilde{\tilde{\mu}}_i, \tilde{\tilde{\mu}}^{**})]$$

$$\leq \lim_{i\to\infty} 2\tilde{\nu}^{(C,\alpha)}(S_i) = 0 \qquad \Rightarrow \qquad E[\rho(\tilde{\mu}^*, \tilde{\tilde{\mu}}^{**})] = 0 \qquad \Rightarrow \qquad \tilde{\mu}^* = \tilde{\tilde{\mu}}^{**} \ \ a.s.$$

The latter implies (by virtue of Lemma 7.2) that

$$\lim_{i\to\infty}\int g_N(u,y)\tilde{\mu}_i(du,dy)=\lim_{i\to\infty}\int g_N(u,y)\tilde{\tilde{\mu}}_i(du,dy)=\int g_N(u,y)\tilde{\mu}^*(du,dy)\quad a.s.$$
$$\Rightarrow\quad 0=\lim_{i\to\infty}E\left[\left\|\int g_N(u,y)\tilde{\mu}_i(du,dy)-\int g_N(u,y)\tilde{\tilde{\mu}}_i(du,dy)\right\|\right]$$
$$=\lim_{i\to\infty}E\left[\left\|\int g_N(u,y)\mu_i(du,dy)-\int g_N(u,y)\mu^{S_i}(du,dy)\right\|\right].$$

These equalities contradict (7.22) and, thus, prove the corollary. □

8. Proofs for section 5.

LEMMA 8.1. *Let the assumptions of Theorem* 5.1 *be satisfied. Then any admissible solution* $(y^\epsilon(\cdot),z^\epsilon(\cdot))$ *of the singularly perturbed CSDE* (5.1) *and* (5.2) *and any admissible solution* $z(\cdot)$ *of the averaged CSDE* (5.4) *satisfy the inequalities*

$$E[||y^\epsilon(t)||^4]\le L\qquad E[||z^\epsilon(t)||^4]\le L\qquad E[||z(t)||^4]\le L\quad\forall t\in[0,T];\tag{8.1}$$

$$E[||z^\epsilon(t)-z^\epsilon(\theta)||^2]\le L|t-\theta|\qquad E[||z(t)-z(\theta)||^2]\le L|t-\theta|\quad\forall t,\theta\in[0,T],\tag{8.2}$$

where L *is a positive constant.*

Proof. The proof follows a standard argument based on Lemma 4.12 in [40, p. 125] and an application of the Gronwall–Bellman lemma. □

Proof of Theorem 5.1(i). Let $u^\epsilon(t)$ be an admissible control and $(y^\epsilon(t),z^\epsilon(t))$ be the solution of the singularly perturbed CSDE (5.1) and (5.2) obtained with this control. Divide the interval $[0,T]$ by the points $t_l\overset{def}{=}l\Delta(\epsilon)$, $l=0,1,\dots,N_\epsilon$, where $\Delta(\epsilon)$ is a function of ϵ such that

$$\lim_{\epsilon\to0}\Delta(\epsilon)=0,\qquad\lim_{\epsilon\to0}\frac{\Delta(\epsilon)}{\epsilon}=\infty\tag{8.3}$$

and N_ϵ is the integer part of $\frac{T}{\Delta(\epsilon)}$. For $l=1,\dots,N_\epsilon$, define a $\mathcal{P}(U\times\bar{R}^m)$-valued random variable $\bar{\mu}_l$ by

$$\int f_i(u,y)\bar{\mu}_l(du,dy)=\frac{1}{\Delta(\epsilon)}\int_{t_{l-1}}^{t_l}f_i(u^\epsilon(t),y^\epsilon(t))dt\ =\frac{1}{S_\epsilon}\int_0^{S_\epsilon}f_i(\bar{u}(\tau),\bar{y}(\tau))d\tau,\tag{8.4}$$

where $f_i(u,y)$, $i=1,2,\dots$, are as in (2.7) and

$$(\bar{u}(\tau),\bar{y}(\tau))\overset{\text{def}}{=}(u(t_{l-1}+\epsilon\tau),y(t_{l-1}+\epsilon\tau)),\qquad S_\epsilon\overset{\text{def}}{=}\frac{\Delta(\epsilon)}{\epsilon}.$$

The equations in (8.4) imply that $\bar{\mu}_l$ is the occupational measure generated on the interval $[0,S_\epsilon]$ by the control $\bar{u}(\tau)$ and the corresponding solution $\bar{y}(\tau)$ of the associated system (2.4). Hence, by Theorem 4.2,

$$E[\rho(\bar{\mu}_l,D)]\le\bar{\nu}^{(C,\alpha)}(S_\epsilon)\overset{\text{def}}{=}\nu(\epsilon),\qquad\lim_{\epsilon\to0}\nu(\epsilon)=0.\tag{8.5}$$

For any $\mu',\mu''\in\mathcal{P}(U\times\bar{R}^m)$, let

$$\hat{\rho}(\mu',\mu'')\overset{\text{def}}{=}\rho(\mu',\mu'')+\left(\sum_{i=1}^{\infty}2^{-2i}\left|\int f_i(u,y)\mu'(du,dy)-\int f_i(u,y)\mu''(du,dy)\right|^2\right)^{\frac{1}{2}}\tag{8.6}$$

It is easy to see that $\hat{\rho}(\cdot,\cdot)$ is a metric on $\mathcal{P}(U \times \bar{R}^m)$ and that

$$\rho(\mu',\mu'') \le \hat{\rho}(\mu',\mu'') \le 2\rho(\mu',\mu'') \qquad \forall \mu',\mu'' \in \mathcal{P}(U \times \bar{R}^m). \tag{8.7}$$

The advantage of using $\hat{\rho}(\cdot,\cdot)$ instead of $\rho(\cdot,\cdot)$ is that, for any μ, the solution of the problem $\min_{\mu' \in D} \hat{\rho}(\mu,\mu')$, called the projection of μ onto D, is unique (this being easily verifiable on the basis of the inequality $\hat{\rho}(\mu,(1-\lambda)\mu'+\lambda\mu'') < (1-\lambda)\hat{\rho}(\mu,\mu') + \lambda\hat{\rho}(\mu,\mu'')$ $\forall \lambda \in (0,1)$).

Let μ_l stand for the projection of $\bar{\mu}_l$ onto D. By (8.5) and (8.7),

$$E[\hat{\rho}(\bar{\mu}_l,\mu_l)] = E[\hat{\rho}(\bar{\mu}_l,D)] \le 2\nu(\epsilon) \tag{8.8}$$

Using (8.8) and slightly extending arguments in the proof of Corollary 4.5 (to take into account the dependence on z), one can verify that, for any $N > 0$,

$$E[||\tilde{g}(\bar{\mu}_l,z) - \tilde{g}(\mu_l,z)||] \le \nu_N(\epsilon) \quad \forall\, z : ||z|| \le N, \qquad \lim_{\epsilon \to 0} \nu_N(\epsilon) = 0. \tag{8.9}$$

Also, it can be verified that the estimates (8.1) and Assumption 2 (with $\alpha = 4$) imply that

$$E[||\tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||^4] \le L_1, \quad E[||\tilde{g}(\mu_l,z^\epsilon(t_l))||^4] \le L_1, \quad L_1 = \text{const.} \tag{8.10}$$

as well as that

$$E[||\tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||\chi_N] \le \kappa(N), \quad E[||\tilde{g}(\mu_l,z^\epsilon(t_l))||\chi_N] \le \kappa(N), \quad \lim_{N \to \infty} \kappa(N) = 0, \tag{8.11}$$

where χ_N is the indicator function of the event: $||z^\epsilon(t_l)|| > N$ ($\bar{\chi}_N$ below will stand for the indicator function of $||z^\epsilon(t_l)|| \le N$). From (8.9) and (8.11) it follows that

$$E[||\tilde{g}(\bar{\mu}_l,z^\epsilon(t_l)) - \tilde{g}(\mu_l,z^\epsilon(t_l))||] \le E[||\tilde{g}(\bar{\mu}_l,z^\epsilon(t_l)) - \tilde{g}(\mu_l,z^\epsilon(t_l))||\bar{\chi}_N]$$

$$+ E[||\tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||\chi_N] + E[||\tilde{g}(\mu_l,z^\epsilon(t_l))||\chi_N] \;\le\; \nu_N(\epsilon) + 2\kappa(N),$$

which implies that there exists $\hat{\nu}(\epsilon)$, $\lim_{\epsilon \to 0} \hat{\nu}(\epsilon) = 0$, such that

$$E[||\tilde{g}(\bar{\mu}_l,z^\epsilon(t_l)) - \tilde{g}(\mu_l,z^\epsilon(t_l))||] \le \hat{\nu}(\epsilon). \tag{8.12}$$

This estimate and (8.10) imply, in turn, that

$$E[||\tilde{g}(\mu_l,z^\epsilon(t_l)) - \tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||^2]$$

$$\le \sqrt{E[||\tilde{g}(\mu_l,z^\epsilon(t_l)) - \tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||]}\sqrt{E[||\tilde{g}(\mu_l,z^\epsilon(t_l)) - \tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||^3]}$$

$$\le L_2\sqrt{\hat{\nu}(\epsilon)}, \qquad L_2 = \text{const.}$$

Thus, denoting $\bar{\nu}(\epsilon) \stackrel{\text{def}}{=} L_2\sqrt{\hat{\nu}(\epsilon)}$, one obtains

$$E[||\tilde{g}(\mu_l,z^\epsilon(t_l)) - \tilde{g}(\bar{\mu}_l,z^\epsilon(t_l))||^2] \le \bar{\nu}(\epsilon), \qquad \lim_{\epsilon \to 0} \bar{\nu}(\epsilon) = 0. \tag{8.13}$$

Now define the admissible control $\mu(t)$ of the averaged system as follows. On the intervals $[t_0,t_1)$ and $[t_{N_\epsilon},T]$, take $\mu(t) = \mu$ (an arbitrary element of D). On any other

interval $[t_l, t_{l+1}), l = 1, 2, \dots, N_\epsilon - 1$, take $\mu(t) = \mu_l$. Let $z(t)$ be the solution of the averaged system (5.4) obtained with the control $\mu(t)$. By definition, it satisfies

$$z(t) = z_0 + \int_0^t \tilde{g}(\mu(t'), z(t'))dt' + \int_0^t \sigma(z(t'))dB_2(t').$$

Subtracting this from

$$z^\epsilon(t) = z_0 + \int_0^t g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t'))dt' + \int_0^t \sigma(z^\epsilon(t'))dB_2(t'),$$

one can obtain that

(8.14)

$$E[||z^\epsilon(t) - z(t)||^2] \le K\left\{E\left[\left\|\int_0^t g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t'))dt' - \int_0^t \tilde{g}(\mu(t'), z(t'))dt'\right\|^2\right] + \int_0^t E[||z^\epsilon(t') - z(t')||]^2 dt'\right\},$$

where K is a positive constant. Let us evaluate the first term on the right-hand side of (8.14). Let k_t stand for the integer part of $\frac{t}{\Delta(\epsilon)} (k_t\Delta(\epsilon) \le t \le T)$. Then

$$\begin{aligned}
&E\left[\left\|\int_0^t g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t'))dt' - \int_0^t \tilde{g}(\mu(t'), z(t'))dt'\right\|^2\right] \\
&\le K_1\Bigg\{ E\Bigg[\Bigg\|\sum_{l=1}^{k_t}\int_{t_{l-1}}^{t_l}(g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t')) - g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t_l)))dt' \\
&+\sum_{l=1}^{k_t}(\tilde{g}(\bar{\mu}_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z^\epsilon(t_l)))\Delta(\epsilon) + \sum_{l=1}^{k_t-1}(\tilde{g}(\mu_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z(t_l)))\Delta(\epsilon) \\
&+\sum_{l=1}^{k_t-1}\int_{t_l}^{t_{l+1}}(\tilde{g}(\mu(t'), z(t_l)) - \tilde{g}(\mu(t'), z(t')))dt'\Bigg\|^2\Bigg] + \Delta(\epsilon)\Bigg\} \\
&\le K_2\Bigg\{E\Bigg[\Bigg\|\sum_{l=1}^{k_t}\int_{t_{l-1}}^{t_l}(g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t')) - g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t_l)))dt'\Bigg\|^2\Bigg] \\
&+E\Bigg[\Bigg\|\sum_{l=1}^{k_t}(\tilde{g}(\bar{\mu}_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z^\epsilon(t_l)))\Bigg\|^2 + \Bigg\|\sum_{l=1}^{k_t-1}(\tilde{g}(\mu_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z(t_l)))\Bigg\|^2\Bigg]\Delta^2(\epsilon) \\
&+E\Bigg[\Bigg\|\sum_{l=1}^{k_t-1}\int_{t_l}^{t_{l+1}}(\tilde{g}(\mu(t'), z(t_l)) - \tilde{g}(\mu(t'), z(t')))dt'\Bigg\|^2\Bigg] + \Delta(\epsilon)\Bigg\}, \quad K_1, K_2 = \text{const.}
\end{aligned}$$

(8.15)

Using Cauchy–Schwarz inequality (two times), one can obtain that

$$E\left[\left\|\sum_{l=1}^{k_t}\int_{t_{l-1}}^{t_l}(g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t')) - g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t_l)))dt'\right\|^2\right]$$

$$\leq\ k_t \sum_{l=1}^{k_t} E\left[\left\| \int_{t_{l-1}}^{t_l} (g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t')) - g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t_l)))dt' \right\|^2\right]$$

$$\leq\ k_t \Delta(\epsilon) \sum_{l=1}^{k_t} \int_{t_{l-1}}^{t_l} E\left[\| g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t')) - g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t_l))\|^2\right] dt'$$

$$\leq K_3 \Delta(\epsilon), \qquad K_3 = \text{const}, \tag{8.16}$$

where, to obtain the last inequality, it has been taken into account that $g(u, y, z)$ satisfies Lipschitz conditions in z and also that, by (8.2), $E[||z^\epsilon(t') - z^\epsilon(t_l)||^2] \leq L\Delta(\epsilon)\ \forall t' \in [t_{l-1}, t_l]$. Similarly, using Cauchy–Schwarz inequality and the fact that $\tilde{g}(\mu, z)$ satisfies Lipschitz conditions in z as well as that $E[||z(t') - z(t_l)||^2] \leq L\Delta(\epsilon)\ \forall t' \in [t_l, t_{l+1}]$, one can obtain that

$$E\left[\left\| \sum_{l=1}^{k_t - 1} \int_{t_l}^{t_{l+1}} (\tilde{g}(\mu(t'), z(t_l)) - \tilde{g}(\mu(t'), z(t')))dt' \right\|^2\right] \leq\ K_4 \Delta(\epsilon),\ \ K_4 = \text{const}. \tag{8.17}$$

Also, by (8.13),

$$E\left[\left\| \sum_{l=1}^{k_t} (\tilde{g}(\bar{\mu}_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z^\epsilon(t_l))) \right\|^2\right] \Delta^2(\epsilon)$$

$$\leq k_t \sum_{l=1}^{k_t} E[||\tilde{g}(\bar{\mu}_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z^\epsilon(t_l))||^2] \Delta^2(\epsilon)\ \leq\ K_5 \bar{\nu}(\epsilon), \quad K_5 = \text{const}, \tag{8.18}$$

and, by (8.1) and (8.2),

$$E\left[\left\| \sum_{l=1}^{k_t - 1} (\tilde{g}(\mu_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z(t_l))) \right\|^2\right] \Delta^2(\epsilon)$$

$$\leq k_t \sum_{l=1}^{k_t - 1} E\left[\|\tilde{g}(\mu_l, z^\epsilon(t_l)) - \tilde{g}(\mu_l, z(t_l))\|^2\right] \Delta^2(\epsilon) \leq K_6 \sum_{l=1}^{k_t - 1} E[||z^\epsilon(t_l) - z(t_l)||^2] \Delta(\epsilon)$$

$$\leq K_7 \left(\int_0^t E[||z^\epsilon(t') - z(t')||^2] dt' + \Delta^{\frac{1}{2}}(\epsilon) \right), \qquad K_6, K_7 = \text{const}. \tag{8.19}$$

Substitution of (8.16)–(8.19) into (8.15) leads to

$$E\left[\left\| \int_0^t g(u^\epsilon(t'), y^\epsilon(t'), z^\epsilon(t'))dt' - \int_0^t \tilde{g}(\mu(t'), z(t'))dt' \right\|^2\right]$$

$$\leq\ K_8 \left(\int_0^t E[||z^\epsilon(t') - z(t')||^2] dt' + \bar{\nu}(\epsilon) + \Delta^{\frac{1}{2}}(\epsilon) \right), \qquad K_8 = \text{const}. \tag{8.20}$$

The latter, in turn, being substituted into (8.14) implies (with the help of a Gronwall–Bellman lemma) the validity of (5.7) with $\tilde{\nu}(\epsilon) = K_9(\bar{\nu}(\epsilon) + \Delta^{\frac{1}{2}}(\epsilon)), K_9 = \text{const}$. The validity of (5.8) follows from the Lipschitz continuity of $G(z)$. □

Proof of Theorem 5.1(ii) *(Outline).* Let $S_\epsilon = \frac{\Delta(\epsilon)}{\epsilon}$ (as in the proof of Theorem 5.1(i)) and let

$$\nu(\epsilon) \stackrel{\text{def}}{=} \tilde{\nu}^{(C,\alpha)}(S_\epsilon), \tag{8.21}$$

where $\tilde{\nu}^{(C,\alpha)}(\cdot)$ is the function from the estimate (4.8). Note that $\lim_{\epsilon\to 0}\nu(\epsilon) = 0$. Let J^ϵ be the integer part of $\nu^{-\frac{1}{2}}(\epsilon)$, which implies, in particular, that

$$\lim_{\epsilon\to 0} J^\epsilon = \infty, \qquad \lim_{\epsilon\to 0}(\nu(\epsilon)J^\epsilon) = 0. \tag{8.22}$$

Using the fact that D is compact, one can show that, for any $\epsilon > 0$, there exists a finite subset $D^\epsilon \stackrel{\text{def}}{=} \{\Upsilon^\epsilon_1, \dots, \Upsilon^\epsilon_{J^\epsilon}\}$ of D such that $\rho_H(D^\epsilon, D) \le \delta(\epsilon)$, where $\delta(\epsilon)$ is some function tending to zero as ϵ tends to zero.

It can be verified (by standard applications of a Gronwall–Bellman lemma) that, given a solution $z'(t)$ of the averaged system (5.4) obtained with an arbitrary admissible control $\mu'(t)$, there exists a piecewise constant admissible control $\mu(t)$:

$$\mu(t) = \mu_l \in D^\epsilon \quad \forall t \in [t_{l-1}, t_l), \qquad l = 1, \dots, N_\epsilon \tag{8.23}$$

such that the solution $z(t)$ of the averaged system (5.4), obtained with the use of this control, satisfies the inequality

$$\max_{t\in[0,T]} E[||z'(t) - z(t)||^2] \le \kappa(\epsilon), \qquad \lim_{\epsilon\to 0}\kappa(\epsilon) = 0.$$

Let us show that corresponding to any solution $z(t)$ of the averaged system (5.4) obtained with a control (8.23), there exists an admissible control $u^\epsilon(t)$ the use of which in the singularly perturbed CSDE (5.1) and (5.2) leads to the solution $(y^\epsilon(t), z^\epsilon(t))$ satisfying (5.7).

Take $u^\epsilon(t) = u$ (an arbitrary element of U) on the intervals $[0, t_1)$ and $[t_{N_\epsilon}, T]$ and denote by $(y^\epsilon(t), z^\epsilon(t))$ the solution of (5.1) and (5.2) on the interval $[0, t_1]$ obtained with this control.

From Corollary 4.3 (see (4.8) and the notation (8.21)) it follows that there exist random variables $\bar{\Upsilon}^\epsilon_j \in \mathcal{M}(S_\epsilon, y^\epsilon(t_1))$ such that

$$\frac{E[\rho^2(\bar{\Upsilon}^\epsilon_j, \Upsilon^\epsilon_j)]}{2} \le E[\rho(\bar{\Upsilon}^\epsilon_j, \Upsilon^\epsilon_j)] \le \nu(\epsilon), \quad j = 1, \dots, J^\epsilon, \tag{8.24}$$

where the left inequality is obtained by taking into account that $\frac{\rho(\cdot,\cdot)}{2} \le 1$ (see (2.1)) and, hence, $\frac{\rho^2(\cdot,\cdot)}{2} \le \rho(\cdot,\cdot)$. Define $\bar{\mu}_1$ by

$$\bar{\mu}_1 \stackrel{\text{def}}{=} \sum_{j=1}^{J^\epsilon} \bar{\Upsilon}^\epsilon_j \chi(\mu_1 = \Upsilon^\epsilon_j), \tag{8.25}$$

where $\chi(A)$ is the indicator function of the "event A." By (8.24),

$$E[\rho(\bar{\mu}_1, \mu_1)] = \sum_{j=1}^{J^\epsilon} E[\rho(\bar{\Upsilon}^\epsilon_j, \Upsilon^\epsilon_j)\chi(\mu_1 = \Upsilon^\epsilon_j)]$$

$$\le \sum_{j=1}^{J^\epsilon} \sqrt{E[\rho^2(\bar{\Upsilon}^\epsilon_j, \Upsilon^\epsilon_j)]}\sqrt{E[\chi(\mu_1 = \Upsilon^\epsilon_j)]} \le \sqrt{2\nu(\epsilon)}\sum_{j=1}^{J^\epsilon}\sqrt{E[\chi(\mu_1 = \Upsilon^\epsilon_j)]}$$

$$\leq \sqrt{2\nu(\epsilon)}\sqrt{J^\epsilon}\sqrt{\sum_{j=1}^{J^\epsilon} E[\chi(\mu_1 = \Upsilon_j^\epsilon)]} = \sqrt{2\nu(\epsilon)}\sqrt{J^\epsilon} \stackrel{\text{def}}{=} \nu^*(\epsilon). \tag{8.26}$$

Note that, as follows from (8.22), $\lim_{\epsilon\to 0}\nu^*(\epsilon) = 0$.

The fact that $\bar\Upsilon_j^\epsilon$ is an element of $\mathcal{M}(S_\epsilon, y^\epsilon(t_1))$ implies that there exists an admissible control $\bar u_j^\epsilon(\tau)$ and the corresponding solution $\bar y_j^\epsilon(\tau)$ of the associated system with $\bar y_j^\epsilon(0) = y^\epsilon(t_1)$ such that the occupational measure generated by this pair on the interval $[0, S_\epsilon]$ coincides with $\bar\Upsilon_j$. That is,

$$\frac{1}{S_\epsilon}\int_0^{S_\epsilon} f_i(\bar u_j^\epsilon(\tau), \bar y_j^\epsilon(\tau))d\tau = \int f_i(u,y)\bar\Upsilon_j(du,dy) \quad \forall i = 1,2,\dots. \tag{8.27}$$

Now take

$$u^\epsilon(t) \stackrel{\text{def}}{=} \sum_{j=1}^{J^\epsilon} \bar u_j^\epsilon\left(\frac{t-t_1}{\epsilon}\right)\chi(\mu_1 = \Upsilon_j^\epsilon) \quad \forall t \in [t_1, t_2)$$

and, using this control, extend the solution $(y^\epsilon(t), z^\epsilon(t))$ of the CSDE (5.1) and (5.2) to the interval $[t_1, t_2]$. By construction, $y^\epsilon(t) = \sum_{j=1}^{J^\epsilon}\bar y_j^\epsilon(\frac{t-t_1}{\epsilon})\chi(\mu_1 = \Upsilon_j^\epsilon)$ and also (see (8.25) and (8.27))

$$\frac{1}{\Delta(\epsilon)}\int_{t_1}^{t_2} f_i(u^\epsilon(t), y^\epsilon(t))dt = \sum_{j=1}^{J^\epsilon}\left(\frac{1}{S_\epsilon}\int_0^{S_\epsilon} f_i(\bar u_j^\epsilon(\tau), \bar y_j^\epsilon(\tau))d\tau\right)\chi(\mu_1 = \Upsilon_j^\epsilon)$$

$$= \sum_{j=1}^{J^\epsilon}\left(\int f_i(u,y)\bar\Upsilon_j^\epsilon(du,dy)\right)\chi(\mu_1 = \Upsilon_j^\epsilon) = \int f_i(u,y)\bar\mu_1(du,dy)\ \forall i = 1,2,\dots.$$

Continuing in a similar fashion, one can define an admissible control $u^\epsilon(t)$ and the corresponding solution $(y^\epsilon(t), z^\epsilon(t))$ of the CSDE (5.1) and (5.2) such that, on any interval $[t_l, t_{l+1}), l = 1, \dots, N_\epsilon - 1$,

$$\frac{1}{\Delta(\epsilon)}\int_{t_l}^{t_{l+1}} f_i(u^\epsilon(t), y^\epsilon(t))dt = \int f_i(u,y)\bar\mu_l(du,dy) \quad \forall i = 1,2,\dots, \tag{8.28}$$

where $\bar\mu_l$ satisfy the inequalities

$$E[\rho(\bar\mu_l, \mu_l)] \leq \nu^*(\epsilon) \qquad \forall l = 1, \dots, N_\epsilon - 1, \tag{8.29}$$

with $\nu^*(\epsilon)$ being as in (8.26).

Using arguments similar to the proof of Corollary 4.5, one can verify that (8.29) implies the validity of (8.9) which, in turn, implies the validity of (8.12) and (8.13). The latter leads to the estimate similar to (8.20), which, being substituted into (8.14), leads to (5.7). Due to the Lipschitz continuity of $G(z)$, one can easily derive now that $\limsup_{\epsilon\to 0} G_\epsilon^* \leq G_{av}^*$, which, along with (5.8), implies (5.9). □

Acknowledgment. The authors express their gratitude to Prof. H. Kushner for useful discussions at early stages of this work.

STRUCTURED NONCOMMUTATIVE MULTIDIMENSIONAL LINEAR SYSTEMS*

JOSEPH A. BALL†, GILBERT GROENEWALD‡, AND TANIT MALAKORN§

Abstract. We introduce a class of multidimensional linear systems with evolution along a free semigroup. The transfer function for such a system is a formal power series in noncommuting indeterminates. Standard system-theoretic properties (the operations of cascade/parallel connection and inversion, controllability, observability, Kalman decomposition, state-space similarity theorem, minimal state-space realizations, Hankel operators, realization theory) are developed for this class of systems. We also draw out the connections with the much earlier studied theory of rational and recognizable formal power series. Applications include linear-fractional models for classical discrete-time systems with structured, time-varying uncertainty, dimensionless formulas in robust control, multiscale systems and automata theory, and the theory of formal languages.

Key words. multidimensional linear systems, free semigroup, controllability, observability, minimality, realization, formal power series, noncommuting indeterminates

1. Introduction.

This paper considers extensions of standard system-theoretic ideas for classical, discrete-time, input/state/output linear systems to the case of certain types of generalized i/s/o systems having evolution along a free semigroup (in place of evolution along the nonnegative integers, as in the classical case). One can introduce formal frequency-domain techniques and arrive at a transfer function for such a system which is a formal power series in noncommuting variables; such objects have occurred in the context of the theory of formal languages and automata theory as well as in connection with realization theory for bilinear systems in the work of Schützenberger and Fliess (see [37, 38, 39, 20, 21, 22, 23] and the book [15] for a good survey).

We first review those aspects of the classical theory which we here generalize to the setting of systems evolving on a free semigroup; this material can be found in many books on linear system and control theory (see, e.g., [32, 16]). By a classical, discrete-time, i/s/o linear system (referred to here simply as a *linear system* for short) we mean a system Σ of linear equations of the form

$$\begin{aligned} x(n+1) &= Ax(n) + Bu(n), \\ y(n) &= Cx(n) + Du(n) \end{aligned} \tag{1.1}$$

(where n takes values in the integers $\mathbb{Z}$), with $x(n)$ taking values in the *state-space* $\mathcal{H}$, $u(n)$ taking values in the *input-space* $\mathcal{U}$, and $y(n)$ taking values in the *output-space* $\mathcal{Y}$, where here we assume that $\mathcal{H}$, $\mathcal{U}$, and $\mathcal{Y}$ are *finite-dimensional* linear spaces over the field of complex numbers $\mathbb{C}$. It is convenient to identify the operator

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} : \begin{bmatrix} \mathcal{H} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \mathcal{H} \\ \mathcal{Y} \end{bmatrix}$$

as the *connection matrix* or *colligation* of the system Σ. Given such a system Σ, if one initializes the state $x(0)$ at time 0 and feeds in an input string $\{u(n)\}_{n\in\mathbb{Z}_+}$, one can use the system equations (1.1) to uniquely determine the state $x(n)$ for all future times $n > 0$ and the output $y(n)$ for the present and all future times $n \geq 0$; the result is

$$\begin{aligned} x(n) &= A^n x(0) + \sum_{k=0}^{n-1} A^{n-1-k} B u(k), \\ y(n) &= CA^n x(0) + \sum_{k=0}^{n-1} CA^{n-1-k} B u(k) + Du(n). \end{aligned} \tag{1.2}$$

Application of the *Z-transform*

$$\{x(n)\}_{n\in\mathbb{Z}_+} \mapsto \sum_{n=0}^{\infty} x(n) z^n$$

to the system equations (1.1) converts the expressions (1.2) to the so-called frequency-domain formulas

$$\begin{aligned} \widehat{x}(z) &= (I - zA)^{-1} x(0) + z(I - zA)^{-1} B \widehat{u}(z), \\ \widehat{y}(z) &= C(I - zA)^{-1} x(0) + T_\Sigma(z) \widehat{u}(z), \end{aligned} \tag{1.3}$$

where

$$T_\Sigma(z) = D + zC(I - zA)^{-1} B \tag{1.4}$$

is a rational $\mathcal{L}(\mathcal{U}, \mathcal{Y})$-valued function analytic at the origin called the *transfer function* of the system Σ. Standard system-theoretic ideas in this context are *controllability* and *observability*. The system is said to be *controllable* if for every h in the state-space $\mathcal{H}$ there is an $N < 0$ and an input string $\{u(n)\}_{n=N,N+1,\ldots,-1}$ so that h is achievable as $h = x(0)$ if the system is run with initialization $x(N) = 0$ and input string $\{u(n)\}_{n=N,N+1,\ldots,-1}$. It works out that the system Σ is controllable if and only if the *controllability operator*

$$\mathcal{C} = \begin{bmatrix} B & AB & A^2B & \cdots \end{bmatrix} : \ell_{\text{fin}}(\mathbb{Z}_-, \mathcal{U}) \to \mathcal{H}$$

has full rank (equal to $\dim \mathcal{H}$).[1] Here $\ell_{\text{fin}}(\mathbb{Z}_-, \mathcal{U})$ denotes the linear space of all $\mathcal{U}$-valued summable sequences on $\mathbb{Z}_-$ with finite support. Similarly, the system is said to be *observable* if the state-vector $h \in \mathcal{H}$ can be uniquely recovered from the output string $\{y(n)\}_{n\geq 0}$ generated by running the system with initial condition $x(0) = h$ and

[1] By the Cayley–Hamilton theorem, it suffices to consider only the finite matrix $\mathcal{C}_n = \begin{bmatrix} B & AB & \cdots & A^{n-1}B \end{bmatrix}$, where $n = \dim \mathcal{H}$ in place of $\mathcal{C}$.

zero input string $u(n) = 0$ for $n \geq 0$; this in turn is equivalent to the *observability operator*

$$\mathcal{O} = \mathrm{col}_{n\geq 0}[CA^n] \colon \mathcal{H} \to \ell(\mathbb{Z}_+, \mathcal{Y})$$

being injective.[2] Here and in what follows, we often use the following notation. If $\mathcal{H}_i$, $\widetilde{\mathcal{H}}_j$, $\mathcal{U}$, and $\mathcal{Y}$ are finite-dimensional linear spaces (for each index i in an index set S and index j in an index set $\widetilde{S}$), and if we are given linear operators $B_j \colon \mathcal{U} \to \widetilde{\mathcal{H}}_j$ and $C_i \colon \mathcal{H}_i \to \mathcal{Y}$, then $\mathrm{col}_{j\in\widetilde{S}}\, B_j$ denotes the block-operator *column* matrix representing a linear operator from $\mathcal{U}$ into $\oplus_{j\in\widetilde{S}}\widetilde{\mathcal{H}}_j$ given by

$$\mathrm{col}_{j\in\widetilde{S}}\, B_j \colon u \to \oplus_{j\in\widetilde{S}} B_j u, \tag{1.5}$$

while $\mathrm{row}_{i\in S}\, C_i$ denotes the block-operator *row* matrix representing a linear operator from $\oplus_{i\in S}\mathcal{H}_i$ into $\mathcal{Y}$ given by

$$\mathrm{row}_{i\in S}\, C_i \colon \oplus_{i\in S}\, h_i \mapsto \sum_{i\in S} C_i h_i. \tag{1.6}$$

We say that the system $\Sigma = (U \colon (\mathcal{H}\oplus\mathcal{U}) \to (\mathcal{H}\oplus\mathcal{Y}))$ is a *realization* of the $\mathcal{L}(\mathcal{U},\mathcal{Y})$-valued function $T(z)$ if $T(z) = T_\Sigma(z)$. There is a theory of *minimality* of a realization Σ of a given matrix-valued function $T(z)$: we say that the realization $\Sigma = (U \colon (\mathcal{H}\oplus\mathcal{U}) \to (\mathcal{H}\oplus\mathcal{Y}))$ of $T(z)$ is a *minimal realization* if, whenever $\Sigma' = (U' \colon (\mathcal{H}'\oplus\mathcal{U}) \to (\mathcal{H}'\oplus\mathcal{Y}))$ is another realization of $T(z)$, it is the case that $\dim\mathcal{H} \leq \dim\mathcal{H}'$. It is well known that Σ is a minimal realization of $T_\Sigma(z)$ if and only if Σ is both controllable and observable; moreover, given a realization $\Sigma' = (U' \colon (\mathcal{H}' \oplus \mathcal{U}) \to (\mathcal{H}' \oplus \mathcal{Y}))$ of $T(z)$ which is not controllable and/or not observable, the *Kalman decomposition* of the system leads to a procedure for cutting down the system to a controllable and observable (and therefore minimal) realization $\Sigma'_{c/o} = (U_{c/o} \colon \mathcal{H}'_{c/o} \oplus \mathcal{U} \to \mathcal{H}'_{c/o} \oplus \mathcal{Y})$ for $T(z)$ ($T_{\Sigma'_{c/o}}(z) = T_\Sigma(z) = T(z)$). Moreover, the *Hankel operator* $\mathbb{H} = \mathcal{O}\cdot\mathcal{C} \colon \ell_{\mathrm{fin}}(\mathbb{Z}_-,\mathcal{U}) \to \ell(\mathbb{Z}_+,\mathcal{Y})$, the map of a past input signal to the future output signal generated by the system (under the assumption that the state is initialized to be zero sufficiently far in the past and if the input string is taken to be zero on the present and future), plays a prominent role in realization theory, since $\mathbb{H} = \mathbb{H}^T$ is also completely determined by the Taylor coefficients of the transfer function $T(z)$ of Σ. Indeed, a given $\mathcal{L}(\mathcal{U},\mathcal{Y})$-valued function $T(z)$ analytic at the origin can be realized as the transfer function $T(z) = T_\Sigma(z)$ for some finite-dimensional system Σ (1.1) if and only if the Hankel operator $\mathbb{H}^T$ constructed from $T(z)$ has finite rank; in this case there is a canonical construction (the *shift realization*) of a minimal realization $\Sigma_{\mathbb{H}^T} = (U_{\mathbb{H}^T} \colon \mathcal{H}_{\mathbb{H}^T} \oplus \mathcal{U} \to \mathcal{H}_{\mathbb{H}^T} \oplus \mathcal{Y})$ for $T(z)$ with $\dim\mathcal{H}_{\mathbb{H}^T} = \mathrm{rank}\,\mathbb{H}^T$.

The purpose of this paper is to extend these ideas to various classes of systems with evolution along a free semigroup rather than along $\mathbb{Z}_+$ or $\mathbb{Z}$. We consider three main classes of such systems, which we refer to as (1) *noncommutative Fornasini–Marchesini systems*, (2) *noncommutative Givone–Roesser systems*, and (3) *noncommutative full-structured systems*. In all these examples, application of a formal Z-transform to the system equations, under the assumption that the state-vector is initialized to be zero, gives rise to the input-output map for the system being given by

[2] Again by the Cayley–Hamilton theorem, for the present classical case one can replace $\mathcal{O}$ by the finite matrix $\mathcal{O}_n = \mathrm{col}_{j=0,1,\ldots,n-1}[CA^j]$, where n is the dimension of the state-space $\mathcal{H}$.

multiplication by a formal power series in noncommuting indeterminates (the *transfer function* of the system) of the form

$$T_\Sigma(z) = D + C(I - Z(z)A)^{-1}Z(z)B, \tag{1.7}$$

where $Z(z)$ is a linear pencil in noncommuting indeterminates $z = (z_1, \dots, z_d)$. The particular form of the linear pencil $Z(z)$ is determined by the particular form of the state equations. For the reader's convenience, section 2 states the main results in explicit, concrete form for these particular classes of examples. In section 3 the added formalism is introduced to describe a general structured noncommutative multidimensional linear system (SNMLS; see Definition 3.7 below). In section 4 we show that such standard system-theoretic operations as cascade connection, parallel connection, and system inversion can be carried out in this context. With the formalism from section 3 in hand, unified proofs are given of the results on controllability, observability, Kalman decomposition, state-space similarity, minimality of realizations, Hankel operators, and construction of minimal realizations in sections 5, 6, 7, 8, 9, 10, and 11, respectively. The final section 12 makes connections of our framework with the theory of recognizable formal power series presented in [15], developed in the work of Schützenberger [37, 38, 39] and Fliess [20, 21].

In applications it is sometimes convenient to view the indeterminates as noncommuting variables, and a formal power series $T(z) = \sum_{w \in \mathcal{F}_d} T_w z^w$ (where $\mathcal{F}_d$ is the set of all words in the d letters $1, 2, \dots, d$ and where $z^w = z_{i_N} \cdots z_{i_1}$ if $w = i_N \cdots i_1$) as a function $\delta \mapsto T(\delta) = \sum_{w \in \mathcal{F}_d} T_w \otimes \delta^w$ defined on some domain of noncommuting operator-tuples $\delta = (\delta_1, \dots, \delta_d)$ (where $\delta^w = \delta_{i_N} \cdots \delta_{i_1}$, multiplication here given by operator composition); this calculus of operator-substitution is important for several of the applications listed below.

Now we mention several areas for applications of the results of this paper.

1. *Robust control theory.* Formal power series and their realizations appear prominently in the theory of robust control of classical 1-D (one-dimensional) systems subject to structured possibly time-varying uncertainty (see [33, 13, 12, 10, 11]). A commonly used model for structured uncertainty in a classical linear, finite-dimensional, feedback-control system is a so-called linear-fractional model, whereby the uncertainty is assumed to have a certain block structure which then enters the nominal plant through a feedback loop. In the case where one considers time-varying uncertainty, the time-varying input-output operator for the disturbed plant can be identified with the evaluation of the transfer function $T_\Sigma(z)$ at $z = \delta$, where $\delta = (\delta_1, \dots, \delta_d)$ is a d-tuple of time-varying operators on ℓ^2 parametrizing the time-varying structured uncertainty. Questions concerning minimality, realizability, and reduction which we explore here have direct relevance for this application. In a companion paper [5], we impose an energy balance law on an SNMLS to define the notion of a *conservative* SNMLS and obtain a realization theorem for this class of noncommutative systems; such conservative (or more generally dissipative) SNMLSs are directly relevant to the robust H^∞-control problems discussed in [33]. In the followup paper [6], we make more explicit the connections of this paper and [5] with linear-fractional models for structured uncertainty and μ-analysis in the presence of structured time-varying uncertainty. Conservative SNMLSs of noncommutative Fornasini–Marchesini type appear also in [7] and [8] in connection with other kinds of problems from multivariable operator theory. Recent closely related work of Alpay and Kalyuzhnyĭ-Verbovetzkiĭ [1] uses the state-space similarity theorem for noncommutative Givone–Roesser systems to develop a realization theory for noncommutative rational J-unitary formal

power series, including connections with noncommutative formal reproducing kernel Pontryagin spaces.

2. *Dimensionless linear matrix inequalities.* As pointed out in [28, 30], many formulas occurring in engineering involving matrix quantities have the same form independent of the size of the matrices. This motivates the study of rational functions in noncommuting variables and the study of noncommutative positivity domains associated with such rational expressions. Realizations such as (1.7) are exactly what is needed to convert (numerically unmanageable) rational matrix inequalities into (highly manageable) linear matrix inequalities (see [30]). Here one substitutes d-tuples of symmetric matrices of variable common size for the indeterminates in the noncommutative rational expression.

3. *Wavelet analysis/multiscale systems.* There have been some attempts in the literature (see [14, 2]) to attach a system evolution to multiresolution structure and multiscale modeling. We expect the setting and results of this paper to have some connections with the work in [14, 2], but details remain to be worked out.

4. *Automata and the theory of formal languages.* It has been known for some time (see [15] and the references there) that formal power series in noncommuting variables, particularly, recognizable and rational formal power series (see section 12 below), arise naturally in connection with the theory of automata and formal languages. In this context, the coefficients of the formal power series may come from a semiring (a ring without subtraction such as the nonnegative integers or the nonnegative rational numbers) rather than operators between two Hilbert spaces, and the free semigroup may be only a monoid. Roughly, a formal power series is said to be recognizable if the support set of its coefficients is recognizable. A subset of a free semigroup (or, more generally, of a monoid) is said to be *recognizable*, in turn, if it can be identified with the set of successful paths (from an initial state to a final state) generated by a finite automaton. Recognizability of a formal power series turns out to be equivalent to existence of a certain type of realization (see section 12 below). Many of the familiar results (e.g., realization through a Hankel-matrix construction, equivalence of minimality of realization with simultaneous controllability and observability, and a state-space similarity theorem) have been worked out in this automaton context. Further details can be found in [15, 19, 32]. Our results give a broader perspective in which to view recognizable formal power series.

5. *Commutative multidimensional system theory.* We view the "noncommutative Fornasini–Marchesini systems" introduced here as noncommutative analogues of the (commutative) Fornasini–Marchesini systems introduced by Fornasini and Marchesini [24] in the multidimensional system theory literature, while the "noncommutative Givone–Roesser systems" are noncommutative analogues of the (commutative) multidimensional Givone–Roesser systems appearing in [26, 27, 36]. In what we call the *commutative case* (evolution along an integer lattice rather than along a free semigroup), the theory of controllability, observability, state-space similarity, and reduction to and construction of a minimal realization of a transfer function is problematic (see, e.g., [31, 25]). By the results here, however, the situation in the noncommutative case is much more like the classical 1-D case. A possible direction for future work is the application of the noncommutative theory as a vehicle for deeper understanding of the commutative case; indeed, the realization theorem in [24] for commutative Fornasini–Marchesini systems is based on the noncommutative realization theorem from [20].

In other directions the commutative theory is ahead of the noncommutative theory. We mention the recent work of Ambrozie and Timotin [3] and of the first author

and Bolotnikov [4], which studies classes of functions with a realization similar to the type of realizations discussed here (see (3.19)) in a commutative (and conservative) setting but with resolvent containing a certain polynomial in the frequency variables rather than just a linear term. In particular, [4] contains a realization result which generalizes the commutative analogue of the main result of [5]. A nonlinear analogue of the realization results of [4] would probably demand a nonlinear version of the Taylor functional calculus (see [41] for a start in this direction). Results on minimality, controllability, and observability obtained in the present paper for this case of higher-degree polynomial in the resolvent of the realization could be obtained by first finding an equivalent system representation having a linear resolvent (or first-order system equations), or, more directly, by developing a more coordinate-free behavioral framework for noncommutative system theory (see [35] for the commutative case).

2. Three classes of examples of structured noncommutative multidimensional linear systems. In this section we introduce and state the main results for the three main examples of SNMLSs. Here the reader can understand the examples and statements of all the main results without having to confront the added formalism of the general definition involving an "admissible graph" (see Definition 3.7 below).

2.1. Noncommutative Fornasini–Marchesini systems. For d a positive integer, let $\mathcal{F}_d$ be the free semigroup generated by the set of d letters $\{1, 2, \dots, d\}$. Elements of $\mathcal{F}_d$ are words w of the form $w = i_N i_{N-1} \cdots i_1$, where $i_k \in \{1, 2, \dots, d\}$ for each $k = 1, \dots, N$. We include the empty word $\emptyset$ as an element of $\mathcal{F}_d$. The semigroup operation is concatenation: $w \cdot w' = i_N i_{N-1} \cdots i_1 i'_{N'} i'_{N'-1} \cdots i'_1$ if $w = i_N i_{N-1} \cdots i_1$ and $w' = i'_{N'} i'_{N'-1} \cdots i'_1$; the empty word $\emptyset$ serves as the identity element of the semigroup $\mathcal{F}_d$. A Fornasini–Marchesini connection matrix U^{FM} is a matrix of the form

$$U^{FM} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A_1 & B_1 \\ \vdots & \vdots \\ A_d & B_d \\ C & D \end{bmatrix} : \begin{bmatrix} \mathcal{H} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{i=1}^{d} \mathcal{H} \\ \mathcal{Y} \end{bmatrix}.$$

The associated system equations are

$$\Sigma^{FM}: \begin{cases} x(1w) = A_1 x(w) + B_1 u(w), \\ \qquad \vdots \\ x(dw) = A_d x(w) + B_d u(w), \\ y(w) \quad = Cx(w) + Du(w) \quad \text{for } w \in \mathcal{F}_d, \end{cases} \tag{2.1}$$

where the state $x(w)$ takes values in the state-space $\mathcal{H}$ and consists of only one component, $u(w)$ takes values in the input-space $\mathcal{U}$, and $y(w)$ takes values in the output-space $\mathcal{Y}$. We consider this type of system as a noncommutative analogue of the (commutative) multidimensional linear systems studied by Fornasini and Marchesini (see, e.g., [24]). We let $z = (z_1, \dots, z_d)$ be a collection of d formal noncommuting variables and consider the formal noncommutative multivariable Z-transform

$$\{x(w)\}_{w \in \mathcal{F}_d} \mapsto \widehat{x}(z) := \sum_{w \in \mathcal{F}_d} x(w) z^w, \tag{2.2}$$

where $z^w = z_{i_N} z_{i_{N-1}} \cdots z_{i_1}$ if $w = i_N i_{N-1} \cdots i_1$. Then, as will be seen in more generality in section 3 (see Example 3.8 and formula (3.20) below), application of the formal Z-transform to the system (2.1) on $\mathcal{T}_{\text{future}}$ leads to the representation

$$\widehat{x}(z) = (I - (Z_{\text{row}}(z) \otimes I_{\mathcal{H}})A)^{-1} x(\emptyset) + (I - (Z_{\text{row}}(z) \otimes I_{\mathcal{H}})A)^{-1} (Z_{\text{row}}(z) \otimes I_{\mathcal{H}}) \cdot B\widehat{u}(z),$$
$$\widehat{y}(z) = C(I - (Z_{\text{row}}(z) \otimes I_{\mathcal{H}})A)^{-1} x(\emptyset) + T_{\Sigma^{FM}}(z)\widehat{u}(z), \tag{2.3}$$

where the formal power series $T_{\Sigma}^{FM}(z)$ (the *transfer function* of the noncommutative Fornasini–Marchesini system Σ^{FM}) is given by

$$\begin{aligned} T_{\Sigma^{FM}}(z) &= D + C(I - (Z_{\text{row}}(z) \otimes I_{\mathcal{H}})A)^{-1}(Z_{\text{row}}(z) \otimes I_{\mathcal{H}})B \\ &= D + C(I - z_1 A_1 - \cdots - z_d A_d)^{-1}(z_1 B_1 + \cdots + z_d B_d) \\ &= D + \sum_{v \in \mathcal{F}_d} \sum_{j=1}^{d} C A^v B_j z^v z_j, \end{aligned} \tag{2.4}$$

where we have used the conventions

$$\begin{aligned} Z_{\text{row}}(z) \otimes I_{\mathcal{H}} &= \begin{bmatrix} z_1 I_{\mathcal{H}} & \cdots & z_d I_{\mathcal{H}} \end{bmatrix}, \\ A^v &= A_{i_N} A_{i_{N-1}} \cdots A_{i_1} \text{ if } v = i_N i_{N-1} \cdots i_1. \end{aligned}$$

We now also consider the associated backward system equations

$$\Sigma_{\text{past}}^{FM}\colon \begin{cases} x(w) = \sum_{i=1}^{d} A_i x(wi) + \sum_{i=1}^{d} B_i u(wi), \\ y(w) = Cx(w) + Du(w) \quad \text{for } w \in \mathcal{F}_d. \end{cases} \tag{2.5}$$

We view the system as running on both the present and future $\mathcal{T}_{\text{future}} := \mathcal{F}_d$ and on the past $\mathcal{T}_{\text{past}} := \mathcal{F}_d \setminus \emptyset$ (where we think of the two appearances of $\mathcal{F}_d$ here as two distinct copies of $\mathcal{F}_d$). The forward equations (2.1) apply for $w \in \mathcal{T}_{future}$, while the backward equations (2.5) apply for $wi \in \mathcal{T}_{past}$. The noncommutative Fornasini–Marchesini system Σ^{FM} is said to be *FM-controllable* if any state-vector $h \in \mathcal{H}$ can be achieved as $h = x(\emptyset)$ by running the system on the past $\mathcal{T}_{\text{past}}$ with state-initialization equal to zero on all locations $w \in \mathcal{T}_{\text{past}}$ of sufficiently long length with some input string $\{u(w)\}_{w \in \mathcal{T}_{\text{past}}}$ having finite support on the past; this condition turns out to be equivalent to the *Fornasini–Marchesini controllability matrix* $\mathcal{C}^{FM}$ given by

$$\mathcal{C}^{FM} = \text{row}_{N=1,2,\ldots} \, \text{row}_{i_1, i_2, \ldots, i_N \in \{1,\ldots,d\}} [A_{i_N} A_{i_{N-1}} \cdots A_{i_2} B_{i_1}] \tag{2.6}$$

having full rank, i.e., having $\operatorname{im} \mathcal{C}^{FM} = \mathcal{H}$. This fact amounts to the specialization of the analysis in section 5 to Example 3.8; a direct analysis can be found in [34].

Dually, we say that the noncommutative Fornasini–Marchesini system Σ^{FM} is *FM-observable* if the state-vector $h \in \mathcal{H}$ can be uniquely recovered from the present and future output string $\{y_i(w)\}_{w \in \mathcal{T}_{\text{future}}}$ generated by running the forward system equations (2.1) of Σ^{FM} with the state initialized by $x(\emptyset) = h$ and with zero input string on the future ($u(w) = 0$ for $w \in \mathcal{T}_{\text{future}} = \mathcal{F}_d$). In terms of the system operators, FM-observability of Σ^{FM} is equivalent to the *Fornasini–Marchesini observability operator* $\mathcal{O}^{FM}$ being injective, where

$$\mathcal{O}^{FM} = \text{col}_{N=0,1,2,\ldots} \, \text{col}_{i_1, i_2, \ldots, i_N \in \{1,\ldots,d\}} [C A_{i_N} A_{i_{N-1}} \cdots A_{i_1}]. \tag{2.7}$$

(Here and elsewhere we interpret $A_{i_N}A_{i_{N-1}}\cdots A_{i_1}$ to be equal to the identity operator $I_{\mathcal{H}}$ in case $N = 0$.) This fact follows from specializing the results of section 6 to Example 3.8 below; again a direct discussion can be found in [34].

The Hankel operator $\mathbb{H}^{FM}$ of the noncommutative Fornasini–Marchesini system Σ^{FM} is the composition $\mathbb{H}^{FM} = \mathcal{O}^{FM}\mathcal{C}^{FM} : \ell_{\text{fin}}(\mathcal{T}_{\text{past}}, \mathcal{U}) \to \ell(\mathcal{T}_{\text{future}}, \mathcal{Y})$; the Hankel operator has the same physical interpretation as in the classical case; $\mathbb{H}^{FM}$ maps a past input to the corresponding future output of a given system trajectory, under the assumption that the state has been initialized to zero in the distant past. Matrix entries of $\mathbb{H}^{FM}$ are given by

$$\mathbb{H}^{FM}_{i_N i_{N-1}\cdots i_1; i'_{N'} i'_{N'-1}\cdots i'_1} = CA_{i_N}A_{i_{N-1}}\cdots A_{i_1}A_{i'_{N'}}A_{i'_{N'-1}}\cdots A_{i'_2}B_{i'_1}, \tag{2.8}$$

where $N = 0, 1, 2, \ldots$, $N' = 1, 2, \ldots$, and $i_k, i'_{k'} \in \{1, \ldots, d\}$ for all k, k'. From the factorization $\mathbb{H}^{FM} = \mathcal{O}^{FM}\mathcal{C}^{FM}$ we see that $\mathbb{H}^{FM}$ has finite rank for any (finite-dimensional) noncommutative Fornasini–Marchesini system. The matrix entries of $\mathbb{H}^{FM}$ can also be expressed directly in terms of the Taylor coefficients (sometimes also called Markov parameters) of the transfer function $T_{\Sigma^{FM}}(z) = \sum_{w\in\mathcal{F}_d} T_w z^w$:

$$\mathbb{H}^{FM}_{v,w} = T_{vw}. \tag{2.9}$$

This type of Hankel operator is obtained by specializing the Hankel operator discussed in section 10 to Example 3.8 below; an explicit discussion of this (Fornasini–Marchesini) case is given in [34].

Given a formal power series $T(z) = \sum_{w\in\mathcal{F}_d} T_w z^w$ in d noncommuting variables $z = (z_1, \ldots, z_d)$ (where $z^w = z_{i_N}\cdots z_{i_1}$ if $w = i_N\cdots i_1$ and where $z^\emptyset = 1$) with operator-valued coefficients $T_w \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$, we say that the noncommutative Fornasini–Marchesini system Σ^{FM} is a (noncommutative Fornasini–Marchesini) realization of $T(z)$ if $T(z) = T_{\Sigma^{FM}}(z)$. A given (noncommutative Fornasini–Marchesini) realization Σ^{FM} of $T(z)$ with state-space $\mathcal{H}$ is said to be *FM-minimal* if, whenever $\Sigma^{FM\prime}$ is another noncommutative Fornasini–Marchesini realization of $T(z)$ with state-space $\mathcal{H}'$, then $\dim\mathcal{H} \le \dim\mathcal{H}'$. Two noncommutative Fornasini–Marchesini systems Σ^{FM} and $\Sigma^{FM\prime}$ with the same input- and output-spaces and connection matrices

$$U^{FM} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A_1 & B_1 \\ \vdots & \vdots \\ A_d & B_d \\ C & D \end{bmatrix} : \begin{bmatrix} \mathcal{H} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{i=1}^d \mathcal{H} \\ \mathcal{Y} \end{bmatrix},$$

$$U^{FM\prime} = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} = \begin{bmatrix} A'_1 & B'_1 \\ \vdots & \vdots \\ A'_d & B'_d \\ C' & D' \end{bmatrix} : \begin{bmatrix} \mathcal{H}' \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{i=1}^d \mathcal{H}' \\ \mathcal{Y} \end{bmatrix}$$

are said to be *FM-similar* if there is a bijective linear operator $\Gamma : \mathcal{H} \to \mathcal{H}'$ such that

$$\begin{bmatrix} \Gamma & & & \\ & \ddots & & \\ & & \Gamma & \\ & & & I_{\mathcal{Y}} \end{bmatrix} \begin{bmatrix} A_1 & B_1 \\ \vdots & \vdots \\ A_d & B_d \\ C & D \end{bmatrix} = \begin{bmatrix} A'_1 & B'_1 \\ \vdots & \vdots \\ A'_d & B'_d \\ C' & D' \end{bmatrix} \begin{bmatrix} \Gamma & 0 \\ 0 & I_{\mathcal{U}} \end{bmatrix}.$$

The following theorem summarizes the results of Theorems 8.2, 9.1, and 11.1 when specialized to the case of noncommutative Fornasini–Marchesini systems (Example 3.8).

THEOREM 2.1.

(1) *Suppose that* Σ^{FM} *and* $\Sigma^{FM\prime}$ *are two noncommutative Fornasini–Marchesini systems which are both FM-controllable and FM-observable. Then* Σ^{FM} *and* $\Sigma^{FM\prime}$ *are FM-similar if and only if they realize the same transfer function:*

$$T_{\Sigma^{FM}}(z) = T_{\Sigma^{FM\prime}}(z).$$

(2) *The noncommutative Fornasini–Marchesini system* Σ^{FM} *is an FM-minimal realization of its transfer function* $T_{\Sigma^{FM}}(z)$ *if and only if* Σ^{FM} *is both FM-controllable and FM-observable.*

(3) *Suppose that* $T(z) = \sum_{w\in\mathcal{F}_d} T_w z^w$ *is a formal power series in* d *noncommuting variables* $z = (z_1, \dots, z_d)$ *with matrix coefficients* $T_w \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$. *Then* $T(z)$ *can be realized as the transfer function* $T(z) = T_{\Sigma^{FM}}(z)$ *of a finite-dimensional noncommutative Fornasini–Marchesini system* Σ^{FM} *if and only if the associated Hankel matrix*

$$\mathbb{H}^T = [T_{vw}]_{v\in\mathcal{F}_d, w\in\mathcal{F}_d\setminus\{\emptyset\}}$$

has finite rank. In this case there is a canonical construction (shift realization) of a minimal realization with state-space $\mathcal{H}$ *having* $\dim\mathcal{H} = \operatorname{rank}\mathbb{H}^T$.

2.2. Noncommutative Givone–Roesser systems. Just as was done above for the case of noncommutative Fornasini–Marchesini systems, the domain evolution for a *noncommutative Givone–Roesser system* which we discuss now is the free semigroup $\mathcal{F}_d$ on the set of d letters $\{1, 2, \dots, d\}$ (for d a positive integer). We take the associated Givone–Roesser connection matrix U^{GR}, however, to have the form

$$U^{GR} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A_{11} & \dots & A_{1d} & B_1 \\ \vdots & & \vdots & \vdots \\ A_{d1} & \dots & A_{dd} & B_d \\ C_1 & \dots & C_d & D \end{bmatrix} : \begin{bmatrix} \mathcal{H}_1 \\ \vdots \\ \mathcal{H}_d \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \mathcal{H}_1 \\ \vdots \\ \mathcal{H}_d \\ \mathcal{Y} \end{bmatrix}$$

for *auxiliary state-spaces* $\mathcal{H}_1, \dots, \mathcal{H}_d$, an input-space $\mathcal{U}$, and an output-space $\mathcal{Y}$ (all finite-dimensional linear spaces for our discussion here). The associated system equations then are

$$\Sigma^{GR}: \begin{cases} x_1(1w) = A_{11}x_1(w) + \cdots + A_{1d}x_d(w) + B_1u(w), \\ \qquad\vdots \\ x_d(dw) = A_{d1}x_1(w) + \cdots + A_{dd}x_d(w) + B_du(w), \\ y(w) \quad = C_1x_1(w) + \cdots + C_dx_d(w) + Du(w), \end{cases} \text{for } w \in \mathcal{F}_d, \tag{2.10}$$

where the state $x(w) = \operatorname{col}_{j=1,\dots,d} x_j(w)$ at position $w \in \mathcal{F}_d$ consists of d components $x_1(w), \dots, x_d(w)$ with $x_j(w)$ taking values in the auxiliary state-space $\mathcal{H}_j$ for $j = 1, \dots, d$; $u(w)$ takes values in the input-space $\mathcal{U}$; and $y(w)$ takes values in the output-space $\mathcal{Y}$. In case $i, j \in \{1, \dots, d\}$ with $i \neq j$ we set $x_i(jw) = 0$. We consider this type of system as a noncommutative analogue of the (commutative) multidimensional linear systems introduced by Givone and Roesser (see, e.g., [26, 27, 36]). If we apply

the noncommutative formal Z-transform (2.2) to the system equations (2.10) and solve, we get

$$\begin{aligned}\widehat{x}(z) &= (I - (Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}})A)^{-1}x(\emptyset) + (I - (Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}})A)^{-1}(Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}}) \\ &\qquad \cdot B\widehat{u}(z), \\ \widehat{y}(z) &= C(I - (Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}})A)^{-1}x(\emptyset) + T_{\Sigma^{GR}}(z)\widehat{u}(z),\end{aligned} \tag{2.11}$$

where the formal power series $T_{\Sigma^{GR}}(z)$ (the *transfer function* of the noncommutative Givone–Roesser system Σ^{GR}) is given by

$$\begin{aligned}T_{\Sigma^{GR}}(z) &= D + C(I - (Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}})A)^{-1}(Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}})B \\ &= D + \begin{bmatrix} C_1 & \cdots & C_d \end{bmatrix} \left(\begin{bmatrix} I_{\mathcal{H}_1} & & \\ & \ddots & \\ & & I_{\mathcal{H}_d} \end{bmatrix} - \begin{bmatrix} z_1A_{11} & \cdots & z_1A_{1d} \\ \vdots & & \vdots \\ z_dA_{d1} & \cdots & z_dA_{dd} \end{bmatrix} \right)^{-1} \begin{bmatrix} z_1B_1 \\ \vdots \\ z_dB_d \end{bmatrix} \\ &= D + \sum_{N=1}^{\infty} \sum_{i_1,\ldots,i_N \in \{1,\ldots,d\}} C_{i_N} A_{i_N,i_{N-1}} A_{i_{N-1},i_{N-2}} \cdots A_{i_2,i_1} B_{i_1} z_{i_N} z_{i_{N-1}} \cdots z_{i_2} z_{i_1},\end{aligned} \tag{2.12}$$

where we have used the convention

$$Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}} = \begin{bmatrix} z_1 I_{\mathcal{H}_1} & & \\ & \ddots & \\ & & z_d I_{\mathcal{H}_d} \end{bmatrix}.$$

We now also consider the associated backward system equations

$$\Sigma^{GR}_{\mathrm{past}} : \begin{cases} x_1(w) = \sum_{i=1}^d A_{1i}x_i(w1) + B_1u(w1), \\ \qquad \vdots \\ x_d(w) = \sum_{i=1}^d A_{di}x_i(wd) + B_du(wd), \\ y(w) \;\; = \sum_{i=1}^d C_ix(w) + Du(w) \quad \text{for } w \in \mathcal{F}_d. \end{cases} \tag{2.13}$$

We follow the same convention as explained above for noncommutative Fornasini–Marchesini systems and view the system Σ^{GR} as running on both the present and future $\mathcal{T}_{\mathrm{future}} := \mathcal{F}_d$ and on the past $\mathcal{T}_{\mathrm{past}} := \mathcal{F}_d \setminus \emptyset$, with the forward equations (2.10) applying for $w \in \mathcal{T}_{future}$ and the backward equations (2.13) applying for $wi \in \mathcal{T}_{past}$. The noncommutative Givone–Roesser system Σ^{GR} is said to be *GR-controllable* if, for each $i \in \{1, \ldots, d\}$, any state-vector $h_i \in \mathcal{H}_i$ can be achieved as the ith component $h_i = x_i(\emptyset)$ of the state-vector $x(\emptyset)$ at the empty-set location by running the system on the past $\mathcal{T}_{\mathrm{past}}$ with state-initialization equal to zero on all locations $w \in \mathcal{T}_{\mathrm{past}}$ of sufficiently long length with some input string $\{u(w)\}_{w \in \mathcal{T}_{\mathrm{past}}}$ having finite support on the past; this condition turns out to be equivalent to the ith *Givone–Roesser controllability matrix* $\mathcal{C}_i^{GR}$ given by

$$\mathcal{C}_i^{GR} = \mathrm{row}_{N=0,1,\ldots} \, \mathrm{row}_{i_1,i_2,\ldots,i_N \in \{1,\ldots,d\}} [A_{i,i_N} A_{i_N,i_{N-1}} \cdots A_{i_2,i_1} B_{i_1}] \tag{2.14}$$

(where the $N = 0$ term is to be interpreted as simply B_i) having full rank, i.e., having $\mathrm{im}\, \mathcal{C}_i^{GR} = \mathcal{H}_i$ for each $i = 1, \ldots, d$. This fact follows by specializing the analysis in section 5 to Example 3.9 below; a direct discussion is in [34].

Dually, we say that the noncommutative Givone–Roesser system Σ^{GR} is *GR-observable* if, for each $i = 1, \dots, d$, the state-vector $h_i \in \mathcal{H}_i$ can be uniquely recovered from the present and future output string $\{y(w)\}_{w \in \mathcal{T}_{\text{future}}}$ generated by running the forward system equations (2.10) of Σ^{GR} with the state initialized by $x_i(\emptyset) = h_i$ and $x_{i'}(\emptyset) = 0$ for $i' \neq i$, and with zero input string on the future ($u(w) = 0$ for $w \in \mathcal{T}_{\text{future}} = \mathcal{F}_d$). In terms of the system operators, GR-observability of Σ^{GR} is equivalent to the ith *Givone–Roesser observability operator* $\mathcal{O}_i^{GR}$ being injective for each $i = 1, \dots, d$, where

$$\mathcal{O}_i^{GR} = \operatorname{col}_{N=0,1,2,\dots} \operatorname{col}_{i_1,i_2,\dots,i_N \in \{1,\dots,d\}} [C_{i_N} A_{i_N,i_{N-1}} A_{i_{N-1},i_{N-2}} \cdots A_{i_1,i}]. \tag{2.15}$$

Here the $N = 0$ term is to be interpreted as simply C_i. All these matters follow upon specialization of the analysis in section 6 to Example 3.9 below; again, a direct discussion is in [34].

There are d Hankel operators $\mathbb{H}^{GR,1}, \dots, \mathbb{H}^{GR,d}$ for a noncommutative Givone–Roesser system Σ^{GR}; namely, for each $i = 1, \dots, d$,

$$\mathbb{H}^{GR,i} = \mathcal{O}_i^{GR} \mathcal{C}_i^{GR} \colon \ell_{\text{fin}}(\mathcal{T}_{\text{past}}, \mathcal{U}) \to \ell(\mathcal{T}_{\text{future}}, \mathcal{Y}).$$

Each Hankel operator $\mathbb{H}^{GR,i}$ again has a physical interpretation as mapping a past input to the corresponding future output of a given system trajectory under the assumption that the state has been initialized to zero in the distant past, but where the observations are taken only with respect to the ith component $x_i(\emptyset)$ of the state at position $\emptyset$. Matrix entries of $\mathbb{H}^{GR,i}$ are given by

$$\begin{aligned} &\mathbb{H}^{GR,i}_{i_N i_{N-1} \cdots i_1;\, i'_{N'} i'_{N'-1} \cdots i'_1} \\ &\qquad = C_{i_N} A_{i_N,i_{N-1}} A_{i_{N-1},i_{N-2}} \cdots A_{i_1,i} A_{i,i'_{N'}} A_{i'_{N'},i'_{N'-1}} \cdots A_{i'_2,i'_1} B_{i'_1}, \end{aligned} \tag{2.16}$$

where $N' = 0, 1, 2, \dots$, $N = 0, 1, 2, \dots$, and $i_k, i'_{k'} \in \{1, \dots, d\}$ for all k, k'. Some small values of N and N' in formula (2.16) require special interpretation; for example, for case $N = 0$ and $N' = 0$ we interpret (2.16) as giving

$$\mathbb{H}^{GR,i}_{\emptyset;\emptyset} = C_i B_i.$$

From the factorization $\mathbb{H}^{GR,i} = \mathcal{O}_i^{GR} \mathcal{C}_i^{GR}$ we see that $\mathbb{H}^{GR,i}$ has finite rank for each $i = 1, \dots, d$ for any (finite-dimensional) noncommutative Givone–Roesser system. The matrix entries of $\mathbb{H}^{GR,i}$ can also be expressed directly in terms of the Taylor coefficients (sometimes also called Markov parameters) of the transfer function $T_{\Sigma^{GR}}(z) = \sum_{w \in \mathcal{F}_d} T_w z^w$: indeed,

$$\mathbb{H}^{GR,i}_{v,w} = T_{viw} \quad \text{for } v, w \in \mathcal{F}_d,\ i \in \{1, \dots, d\}. \tag{2.17}$$

These details amount to the specialization of section 10 to Example 3.9 below, and also can be found (in explicit form) in [34].

Given a formal power series $T(z) = \sum_{w \in \mathcal{F}_d} T_w z^w$ in d noncommuting variables $z = (z_1, \dots, z_d)$ (where $z^w = z_{i_N} \cdots z_{i_1}$ if $w = i_N \cdots i_1$ and where $z^\emptyset = 1$) with operator-valued coefficients $T_w \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$, we say that the noncommutative Givone–Roesser system Σ^{GR} is a (noncommutative Givone–Roesser) realization of $T(z)$ if $T(z) = T_{\Sigma^{GR}}(z)$. A given (noncommutative Givone–Roesser) realization Σ^{GR} of $T(z)$ with auxiliary state-spaces $\mathcal{H}_1, \dots, \mathcal{H}_d$ is said to be *GR-minimal* if, whenever $\Sigma^{GR\prime}$

is another noncommutative Givone–Roesser realization of $T(z)$ with auxiliary state-spaces $\mathcal{H}'_1, \dots, \mathcal{H}'_d$, then $\dim \mathcal{H}_i \le \dim \mathcal{H}'_i$ for each $i = 1, \dots, d$. Two noncommutative Givone–Roesser systems Σ^{GR} and $\Sigma^{GR\prime}$ with the same input- and output-spaces and connection matrices

$$U^{GR} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A_{11} & \dots & A_{1d} & B_1 \\ \vdots & & \vdots & \vdots \\ A_{d1} & \dots & A_{dd} & B_d \\ C_1 & \dots & C_d & D \end{bmatrix} : \begin{bmatrix} \mathcal{H}_1 \\ \vdots \\ \mathcal{H}_d \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \mathcal{H}_1 \\ \vdots \\ \mathcal{H}_d \\ \mathcal{Y} \end{bmatrix},$$

$$U^{GR\prime} = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} = \begin{bmatrix} A'_{11} & \dots & A'_{1d} & B'_1 \\ \vdots & & \vdots & \vdots \\ A'_{d1} & \dots & A'_{dd} & B'_d \\ C'_1 & \dots & C'_d & D' \end{bmatrix} : \begin{bmatrix} \mathcal{H}'_1 \\ \vdots \\ \mathcal{H}'_d \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \mathcal{H}'_1 \\ \vdots \\ \mathcal{H}'_d \\ \mathcal{Y} \end{bmatrix}$$

are said to be *GR-similar* if, for each $i = 1, \dots, d$, there is a bijective linear operator $\Gamma_i \colon \mathcal{H}_i \to \mathcal{H}'_i$ such that

$$\begin{bmatrix} \Gamma_1 & & & \\ & \ddots & & \\ & & \Gamma_d & \\ & & & I_{\mathcal{Y}} \end{bmatrix} \begin{bmatrix} A_{11} & \cdots A_{1d} & B_1 \\ \vdots & \vdots & \vdots \\ A_{d1} & \cdots A_{dd} & B_d \\ C_1 & \cdots C_d & D \end{bmatrix} = \begin{bmatrix} A'_{11} & \cdots & A'_{1d} & B'_1 \\ \vdots & & \vdots & \vdots \\ A'_{d1} & \cdots & A'_{dd} & B'_d \\ C'_1 & \cdots & C'_d & D' \end{bmatrix} \begin{bmatrix} \Gamma_1 & & & \\ & \ddots & & \\ & & \Gamma_d & \\ & & & I_{\mathcal{U}} \end{bmatrix}.$$

The following theorem summarizes the results of Theorems 8.2, 9.1, and 11.1 when specialized to the case of noncommutative Givone–Roesser systems (Example 3.9).

THEOREM 2.2.

(1) *Suppose that Σ^{GR} and $\Sigma^{GR\prime}$ are two noncommutative Givone–Roesser systems which are both GR-controllable and GR-observable. Then Σ^{GR} and $\Sigma^{GR\prime}$ are GR-similar if and only if they realize the same transfer function:*

$$T_{\Sigma^{GR}}(z) = T_{\Sigma^{GR\prime}}(z).$$

(2) *The noncommutative Givone–Roesser system Σ^{GR} is a GR-minimal realization of its transfer function $T_{\Sigma^{GR}}(z)$ if and only if Σ^{GR} is both GR-controllable and GR-observable.*

(3) *Suppose that $T(z) = \sum_{w \in \mathcal{F}_d} T_w z^w$ is a formal power series in d noncommuting variables $z = (z_1, \dots, z_d)$ with matrix coefficients $T_w \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$. Then $T(z)$ can be realized as the transfer function $T(z) = T_{\Sigma^{GR}}(z)$ of a finite-dimensional noncommutative Givone–Roesser system Σ^{GR} if and only if the associated Hankel matrices*

$$\mathbb{H}^{T,i} = [T_{viw}]_{v \in \mathcal{F}_d, w \in \mathcal{F}_d}$$

have finite rank for $i = 1, \dots, d$. In this case there is a canonical construction (shift realization) of a minimal realization with auxiliary state-space $\mathcal{H}_i$ having $\dim \mathcal{H}_i = \operatorname{rank} \mathbb{H}^{T,i}$ for $i = 1, \dots, d$.

In fact, it can be shown that a formal power series $T(z) = \sum_{w \in \mathcal{F}_d} T_w z^w$ in d noncommuting variables $z = (z_1, \ldots, z_d)$ has an FM-realization if and only if it has a GR-realization if and only if it is *rational* in the sense of Schützenberger (see [15]). One of the points of part (3) in Theorems 2.1 and 2.2 is that they identify the precise Hankel matrices with rank(s) equal to the state-space dimension(s) in a minimal realization of Fornasini–Marchesini or Givone–Roesser type. We discuss these connections between various types of noncommutative realizations in section 12.

2.3. Noncommutative full-structured systems. Our last concrete example of a structured noncommutative system is what we call a "full-structured" system. For this case it is convenient to assume that the evolution of the system takes place on the free semigroup generated by a certain Cartesian product set. Denote by $\mathcal{F}_{n,m}$ the free semigroup generated by the set $E = \{1, \ldots, n\} \times \{1, \ldots, m\}$. Thus elements of $\mathcal{F}_{n,m}$ are words w of the form $(i_N, j_N)(i_{N-1}, j_{N-1}) \cdots (i_1, j_1)$, where $i_k \in \{1, \ldots, n\}$ and $j_k \in \{1, \ldots, m\}$ for all $k = 1, \ldots, N$. Again we let $\emptyset$ denote the empty word which serves as the identity for the semigroup $\mathcal{F}_{n,m}$. By a *full-structured connection matrix* U^{full} we mean a block-operator matrix of the form

$$U^{\text{full}} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A_{11} & \cdots & A_{1n} & B_1 \\ \vdots & & \vdots & \vdots \\ A_{m1} & \cdots & A_{mn} & B_m \\ C_1 & \cdots & C_n & D \end{bmatrix} : \begin{bmatrix} \oplus_{i=1}^n \mathcal{H} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{j=1}^m \mathcal{H} \\ \mathcal{Y} \end{bmatrix},$$

where $\mathcal{H}$ (the *state-space*), $\mathcal{U}$ (the *input-space*), and $\mathcal{Y}$ (the *output-space*) are finite-dimensional linear spaces. The associated system equations are

(2.18)
$$\Sigma^{\text{full}}: \begin{cases} x_1((1,j)\cdot w) = A_{j1}x_1(w) + \cdots + A_{jn}x_n(w) + B_j u(w) & \text{for } j = 1, \ldots, m, \\ \qquad\qquad \vdots \\ x_n((n,j)\cdot w) = A_{j1}x_1(w) + \cdots + A_{jn}x_n(w) + B_j u(w) & \text{for } j = 1, \ldots, m, \\ x_i((i',j)\cdot w) = 0 \quad \text{if } i \neq i', \\ y(w) = C_1 x_1(w) + \cdots + C_n x_n(w) + Du(w). \end{cases}$$

Here the state-vector $x(w) = \text{col}_{i=1,\ldots,n}\, x_i(w) \in \oplus_{i=1}^n \mathcal{H}$ consists of n components $x_i(w)$ for $i = 1, \ldots, n$ with each $x_i(w)$ in the auxiliary state-space $\mathcal{H}$, while $u(w)$ assumes values in the input-space $\mathcal{U}$ and $y(w)$ assumes values in the output-space $\mathcal{Y}$. Note that the state trajectory $\{x(w)\}_{w \in \mathcal{F}_{n,m}}$ incorporates some redundancy; namely, *if* $\{x(w)\}_{w \in \mathcal{F}_{n,m}} = \{\text{col}_{i=1,\ldots,n}[x_i(w)]\}_{w \in \mathcal{F}_{n,m}}$ *is the state trajectory satisfying the state-update equation in* (2.18) *for some choice of input signal* $\{u(w)\}_{w \in \mathcal{F}_{n,m}}$*, then, for each fixed* $j \in \{1, \ldots, m\}$ *and* $w \in \mathcal{F}_{n,m}$,

(2.19) $$x_i((i,j)\cdot w) \text{ is independent of } i \in \{1, \ldots, n\}.$$

We shall work with the redundant form (2.18) of the system equations rather than rewriting them in a more economical form.

We let $z = (z_{11}, \ldots, z_{1m}; z_{21}, \ldots, z_{2m}; \ldots; z_{n1}, \ldots, z_{nm})$ be a collection of nm noncommuting variables indexed by $\{1, \ldots, n\} \times \{1, \ldots, m\}$. Application of the noncommutative Z-transform (2.2) (with respect to $\mathcal{F}_{n,m}$ rather than with respect to $\mathcal{F}_d$)

converts the system equations to

$$\widehat{x}(z) = (I - (Z_{\text{full}}(z) \otimes I_{\mathcal{H}})A)^{-1}x(\emptyset) + (I - (Z_{\text{full}}(z) \otimes I_{\mathcal{H}})A)^{-1}(Z_{\text{full}}(z) \otimes I_{\mathcal{H}}) \cdot B\widehat{u}(z),$$
$$\widehat{y}(z) = C(I - (Z_{\text{full}}(z) \otimes I_{\mathcal{H}})A)^{-1}x(\emptyset) + T_{\Sigma^{\text{full}}}(z)\widehat{u}(z), \tag{2.20}$$

where $T_{\Sigma^{\text{full}}}(z)$ (the *transfer function* of the noncommutative full-structured system Σ^{full}) is given by

$$\begin{aligned}
T_{\Sigma^{\text{full}}}(z) &= D + C(I - (Z_{\text{full}}(z) \otimes I_{\mathcal{H}})A)^{-1}(Z_{\text{full}}(z) \otimes I_{\mathcal{H}})B \\
&= D + \begin{bmatrix} C_1 & \cdots & C_n \end{bmatrix} \\
&\cdot \left(\begin{bmatrix} I_{\mathcal{H}} & & \\ & \ddots & \\ & & I_{\mathcal{H}} \end{bmatrix} - \begin{bmatrix} \sum_{j=1}^m z_{1j}A_{j1} & \cdots & \sum_{j=1}^m z_{1j}A_{jn} \\ \vdots & & \vdots \\ \sum_{j=1}^m z_{nj}A_{j1} & \cdots & \sum_{j=1}^m z_{nj}A_{jn} \end{bmatrix} \right)^{-1} \begin{bmatrix} \sum_{j=1}^m z_{1j}B_j \\ \vdots \\ \sum_{j=1}^m z_{nj}B_j \end{bmatrix} \\
&= D + \sum_{N=1}^{\infty} \sum_{i_1,\ldots,i_N \in \{1,\ldots,n\}} \sum_{j_1,\ldots,j_N \in \{1,\ldots,m\}} C_{i_N}A_{j_N,i_{N-1}}A_{j_{N-1},i_{N-2}} \cdots A_{j_2,i_1}B_{j_1} \\
&\qquad \cdot z_{i_N,j_N}z_{i_{N-1},j_{N-1}} \cdots z_{i_2,j_2}z_{i_1,j_1},
\end{aligned} \tag{2.21}$$

and where $Z_{\text{full}}(z) \otimes I_{\mathcal{H}}$ is given by

$$Z_{\text{full}}(z) \otimes I_{\mathcal{H}} = \begin{bmatrix} z_{1,1}I_{\mathcal{H}} & \cdots & z_{1,m}I_{\mathcal{H}} \\ \vdots & & \vdots \\ z_{n,1}I_{\mathcal{H}} & \cdots & z_{n,m}I_{\mathcal{H}} \end{bmatrix}.$$

The backward full-structured system equations have the form

$$\Sigma^{\text{full}}_{past}\colon \begin{cases} x_1(w) = \sum_{j=1}^m \sum_{i'=1}^n A_{j,i'}x_{i'}(w \cdot (1,j)) + \sum_{j=1}^m B_j u(w \cdot (1,j)), \\ \qquad \vdots \\ x_n(w) = \sum_{j=1}^m \sum_{i'=1}^n A_{j,i'}x_{i'}(w \cdot (n,j)) + \sum_{j=1}^m B_j u(w \cdot (n,j)), \\ y(w) \quad = \sum_{i=1}^n C_i x_i(w) + Du(w), \end{cases} \tag{2.22}$$

and are to be interpreted as the evolution of the system on the past $\mathcal{T}_{\text{past}} = \mathcal{F}_{n,m} \setminus \{\emptyset\}$. The noncommutative full-structured system Σ^{full} is said to be *full-controllable* if, for each $i \in \{1,\ldots,n\}$, any state-vector $h \in \mathcal{H}$ can be achieved as the ith component $h_i = x_i(\emptyset)$ (for some, or equivalently for any $i \in \{1,\ldots,n\}$) of the state-vector $x(\emptyset)$ at the empty-set location by running the system on the past $\mathcal{T}_{\text{past}}$ with state-initialization equal to zero on all locations $w \in \mathcal{T}_{\text{past}}$ of sufficiently long length with some input string $\{u(w)\}_{w \in \mathcal{T}_{\text{past}}}$ having finite support on the past; this condition turns out to be equivalent to the *full-structured controllability matrix* $\mathcal{C}_1^{\text{full}}$ given by

$$\begin{aligned}
\mathcal{C}_1^{\text{full}} = \text{row}_{N=1,2,\ldots} \text{row}_{(1,j_N)(i_{N-1},j_{N-1})\cdots(i_1,j_1)\colon\, i_1,i_2,\ldots,i_{N-1} \in \{1,\ldots,n\};j_1,\ldots,j_N \in \{1,\ldots,m\}} \\
[A_{j_N,i_{N-1}}A_{j_{N-1},i_{N-2}} \cdots A_{j_2,i_1}B_{j_1}]
\end{aligned} \tag{2.23}$$

having full rank, i.e., having $\text{im}\,\mathcal{C}_1^{\text{full}} = \mathcal{H}$. These facts amount to the specialization of the results of section 5 to Example 3.10 below.

Dually, we say that the noncommutative full-structured system $\Sigma^{\rm full}$ is *full-observable* if the state-vector $h \in \mathcal{H}$ can be uniquely recovered from the n-tuple of present and future output strings $\{y_i(w)\}_{i=1,\dots,n;w\in\mathcal{T}_{\rm future}}$ (with $\mathcal{T}_{\rm future} = \mathcal{F}_{n,m}$). Here, for each $i = 1,\dots,n$, the ith output string $\{y_i(w)\}_{w\in\mathcal{F}_{n,m}}$ is generated by running the forward system equations (2.18) of $\Sigma^{\rm full}$ with the state initialized by $x_i(\emptyset) = h_i$ and $x_{i'}(\emptyset) = 0$ for $i' \neq i$ and with zero input string on the future ($u(w) = 0$ for $w \in \mathcal{T}_{\rm future} = \mathcal{F}_{n,m}$). In terms of the system operators, full-observability of $\Sigma^{\rm full}$ is equivalent to the *full observability operator* $\mathcal{O}^{\rm full}\colon \mathcal{H} \to \oplus_{i=1}^n \ell(\mathcal{F}_{n,m},\mathcal{Y})$ being injective, where

$$\begin{aligned}\mathcal{O}^{\rm full} &= \operatorname{col}_{i=1,\dots,n} \operatorname{col}_{N=0,1,2,\dots} \operatorname{col}_{(i_N,j_N)\cdots(i_1,j_1)\colon\, i_1,\dots,i_N\in\{1,\dots,n\};j_1,\dots,j_N\in\{1,\dots,m\}} \\ &\qquad [C_{i_N} A_{j_N,i_{N-1}} A_{j_{N-1},i_{N-2}} \cdots A_{j_1,i}]. \end{aligned} \tag{2.24}$$

Here the $N = 0$ term is to be interpreted as simply C_i. These matters amount to specialization of the results of section 6 to Example 3.10 below.

We define the Hankel operator $\mathbb{H}^{\rm full}$ for a noncommutative full-structured system $\Sigma^{\rm full}$ as the composition $\mathbb{H}^{\rm full} = \mathcal{O}^{\rm full}\mathcal{C}_1^{\rm full}\colon \ell_{\rm fin}(\mathcal{T}_{\rm past}^1,\mathcal{U}) \to \oplus_{i=1}^n \ell(\mathcal{T}_{\rm future},\mathcal{Y})$; here $\mathcal{T}_{\rm past}^1$ denotes a certain subset of the past $\mathcal{T}_{\rm past}$, namely, the set of all nonempty words $(i_1,j_1)\cdot(i_2,j_2)\cdots(i_N,j_N)$ for which the leading letter (i_1,j_1) has first component i_1 equal to 1. Again the Hankel operator $\mathbb{H}^{\rm full}$ has a physical interpretation as mapping a past input to the corresponding future output of a given system trajectory (in this case an n-tuple of future outputs) under the assumption that the state has been initialized to zero in the distant past. Matrix entries of $\mathbb{H}^{\rm full}$ are given by

$$\begin{aligned}&\mathbb{H}^{\rm full}_{i,(i_N,j_N)\cdots(i_1,j_1);(i'_{N'},j'_{N'}),(i'_{N'-1},j'_{N'-1})\cdots(i'_1,j'_1)} \\ &\qquad = C_{i_N} A_{j_N,i_{N-1}} A_{j_{N-1},i_{N-2}} \cdots A_{j_1,i} A_{j'_{N'},i'_{N'-1}} \cdots A_{j'_2,i'_1} B_{j'_1}, \end{aligned} \tag{2.25}$$

where $N = 0,1,2,\dots$, $N' = 1,2,\dots$, and $i_k, i'_{k'} \in \{1,\dots,n\}$ and $j_k, j'_{k'} \in \{1,\dots,m\}$ for all k and k'; some small values of N and N' in formula (2.25) require special interpretation; for example, for case $N = 0$ and $N' = 1$ we interpret (2.25) as giving

$$\mathbb{H}^{\rm full}_{i,\emptyset;(1,j)} = C_i B_j.$$

From the factorization $\mathbb{H}^{\rm full} = \mathcal{O}^{\rm full}\mathcal{C}_1^{\rm full}$ we see that $\mathbb{H}^{\rm full}$ has finite rank equal to the dimension of the state-space in a minimal realization for any (finite-dimensional) noncommutative full-structured system. The matrix entries of $\mathbb{H}^{\rm full}$ can also be expressed directly in terms of the Taylor coefficients of the transfer function $T_{\Sigma^{\rm full}}(z) = \sum_{w\in\mathcal{F}_{n,m}} T_w z^w$: indeed

$$\mathbb{H}^{\rm full}_{i,v;(1,j_N)w'} = T_{v\cdot(i,j_N)\cdot w'} \quad \text{for } v,w' \in \mathcal{F}_{n,m},\ i \in \{1,\dots,n\}. \tag{2.26}$$

These results all fall out of specializing the results of section 10 to Example 3.10 below.

Given a formal power series $T(z) = \sum_{w\in\mathcal{F}_{n,m}} T_w z^w$ in $n\cdot m$ noncommuting variables $z = (z_{11},\dots,z_{1m};\cdots;z_{n1},\cdots,z_{nm})$ (where $z^w = z_{i_N,j_N}\cdots z_{i_1,j_1}$ if $w = (i_N,j_N)\cdots(i_1,j_1)$ and where $z^\emptyset = 1$) with $\mathcal{L}(\mathcal{U},\mathcal{Y})$-valued coefficients T_w, we say that the noncommutative full-structured system $\Sigma^{\rm full}$ is a (noncommutative full) realization of $T(z)$ if $T(z) = T_{\Sigma^{\rm full}}(z)$. A given (noncommutative full) realization $\Sigma^{\rm full}$ of $T(z)$ with auxiliary state-space $\mathcal{H}$ is said to be *full-minimal* if, whenever $\Sigma^{\rm full\,\prime}$ is another noncommutative full realization of $T(z)$ with auxiliary state-space $\mathcal{H}$, then

$\dim \mathcal{H} \le \dim \mathcal{H}'$. Two noncommutative full-structured systems Σ^{full} and $\Sigma^{\text{full}\prime}$ with the same input- and output-spaces and connection matrices

$$U^{\text{full}} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A_{11} & \cdots & A_{1n} & B_1 \\ \vdots & & \vdots & \vdots \\ A_{m1} & \cdots & A_{mn} & B_m \\ C_1 & \cdots & C_n & D \end{bmatrix} : \begin{bmatrix} \oplus_{i=1}^n \mathcal{H} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{j=1}^m \mathcal{H} \\ \mathcal{Y} \end{bmatrix},$$

$$U^{\text{full}\prime} = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} = \begin{bmatrix} A'_{11} & \cdots & A'_{1n} & B'_1 \\ \vdots & & \vdots & \vdots \\ A'_{m1} & \cdots & A'_{mn} & B'_m \\ C'_1 & \cdots & C'_n & D' \end{bmatrix} : \begin{bmatrix} \oplus_{i=1}^n \mathcal{H}' \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{j=1}^m \mathcal{H}' \\ \mathcal{Y} \end{bmatrix}$$

are said to be *full-similar* if there is a bijective linear operator $\Gamma : \mathcal{H} \to \mathcal{H}'$ such that

$$\begin{bmatrix} \Gamma & & & \\ & \ddots & & \\ & & \Gamma & \\ & & & I_{\mathcal{Y}} \end{bmatrix} \begin{bmatrix} A_{11} & \cdots A_{1n} & B_1 \\ \vdots & \vdots & \vdots \\ A_{m1} & \cdots A_{mn} & B_m \\ C_1 & \cdots C_n & D \end{bmatrix} = \begin{bmatrix} A'_{11} & \cdots & A'_{1n} & B'_1 \\ \vdots & & \vdots & \vdots \\ A'_{m1} & \cdots & A'_{mn} & B'_m \\ C'_1 & \cdots & C'_n & D' \end{bmatrix} \begin{bmatrix} \Gamma & & & \\ & \ddots & & \\ & & \Gamma & \\ & & & I_{\mathcal{U}} \end{bmatrix}.$$

The following theorem summarizes the results of Theorems 8.2, 9.1, and 11.1 when specialized to the case of noncommutative full-structured systems (Example 3.10).

THEOREM 2.3.

(1) *Suppose that Σ^{full} and $\Sigma^{full\prime}$ are two noncommutative full-structured systems which are both full-controllable and full-observable. Then Σ^{full} and $\Sigma^{full\prime}$ are full-similar if and only if they realize the same transfer function:*

$$T_{\Sigma^{full}}(z) = T_{\Sigma^{full\prime}}(z).$$

(2) *The noncommutative full-structured system Σ^{full} is a full-minimal realization of its transfer function $T_{\Sigma^{full}}(z)$ if and only if Σ^{full} is both full-controllable and full-observable.*

(3) *Suppose that $T(z) = \sum_{w \in \mathcal{F}_{n,m}} T_w z^w$ is a formal power series in $n \cdot m$ noncommuting variables $z = (z_{11}, \ldots, z_{1m}; \ldots; z_{n1}, \ldots, z_{nm})$ with matrix coefficients $T_w \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$. Then $T(z)$ can be realized as the transfer function $T(z) = T_{\Sigma^{full}}(z)$ of a finite-dimensional noncommutative full-structured system Σ^{full} if and only if the associated Hankel matrix*

$$\mathbb{H}^T = [T_{v \cdot (i,i_N) \cdot w}]_{i \in \{1,\ldots,n\}, v \in \mathcal{F}_{n,m}; (1,j_N) \cdot w \in \mathcal{F}_{n,m} \setminus \{\emptyset\}}$$

has finite rank for $i = 1, \ldots, n$. In this case there is a canonical construction (shift realization) of a minimal realization with state-space $\mathcal{H}$ having $\dim \mathcal{H} = \operatorname{rank} \mathbb{H}^T$.

3. Structured noncommutative multidimensional linear systems: Definition and basic properties. Our general notion of structured noncommutative

multidimensional linear system (SNMLS) will be associated with a graph G. As is standard, a graph G consists of a set of vertices V together with a set of edges E. Each edge $e \in E$ connects a source vertex $\mathbf{s}(e)$ (where $\mathbf{s}\colon E \to V$ is the *source map*) to a range vertex $\mathbf{r}(e)$ (where $\mathbf{r}\colon E \to V$ is the *range map*). We assume throughout that V and E are *finite* sets. For our application to SNMLSs, we require a few additional properties, encoded in the following definition of an *admissible graph*.

DEFINITION 3.1. *We say that the graph $G = (V, E, \mathbf{s}\colon E \to V, \mathbf{r}\colon E \to V)$ is an admissible graph if*

(1) *the set of vertices V of G has a disjoint partitioning $V = S \dot\cup R$ into two subsets S and R such that each edge e of G has source vertex $\mathbf{s}(e) \in S$ and range vertex $\mathbf{r}(e) \in R$;*
(2) *for a given $s \in S$ and $r \in R$ there is at most one edge $e \in E$ connecting s to r (i.e., at most one edge e with $\mathbf{s}(e) = s$ and $\mathbf{r}(e) = r$);*
(3) *each pathwise-connected component G_k of G is a nondegenerate complete bipartite graph; i.e., the vertices of G_k have a partitioning $V(G_k) = S_k \dot\cup R_k$ (with $S_k \subset S$, $R_k \subset R$ and both $S_k \neq \emptyset$ and $R_k \neq \emptyset$) such that for each pair (s, r) with $s \in S_k$ and $r \in R_k$ there is exactly one edge $e \in E$ with $\mathbf{s}(e) = s$ and $\mathbf{r}(e) = r$.*

In other words, conditions (1) and (2) say that G is a *bipartite* graph. Thus admissible graphs amount to bipartite graphs having connected path components which are complete bipartite subgraphs. Thus the set of edges E can be identified with a subset of the Cartesian product $S \times R$, where S and R are called the source vertices and range vertices, respectively.

Admissible graphs G have the following intrinsic characterization.

THEOREM 3.2. *Suppose that we are given finite disjoint sets S, R, and E together with mappings $\mathbf{s}\colon E \to S$ and $\mathbf{r}\colon E \to R$. Associated with these data is a graph G defined as follows: the vertex set of G is $V := S \cup R$, and there exists an edge connecting v to v' if and only if there is an $e \in E$ either with $v = \mathbf{s}(e), v' = \mathbf{r}(e)$ or with $v' = \mathbf{s}(e), v = \mathbf{r}(e)$. Then G is admissible in the sense of Definition* 3.1 *if and only if the following conditions hold:*

(1) *$\mathbf{s}\colon E \to S$ is surjective.*
(2) *$\mathbf{r}\colon E \to R$ is surjective.*
(3) *The map $\mathbf{s} \times \mathbf{r}\colon E \to S \times R$ given by*

$$\mathbf{s} \times \mathbf{r}\colon e \mapsto (\mathbf{s}(e), \mathbf{r}(e))$$

is injective.
(4) *Whenever e_1, e_2, and e_3 are elements of E with $\mathbf{r}(e_1) = \mathbf{r}(e_2)$ and $\mathbf{s}(e_1) = \mathbf{s}(e_3)$, then there is an edge e_4 in E, with $\mathbf{s}(e_4) = \mathbf{s}(e_2)$, and $\mathbf{r}(e_4) = \mathbf{r}(e_3)$.*

Proof. Let G be an admissible graph with pathwise-connected components equal to the subgraphs $G_1, \dots, G_K$. Since each G_k is a complete bipartite graph by assumption, we have that the vertex set $V(G_k)$ has a disjoint partitioning $V(G_k) = S_k \dot\cup R_k$ for nonempty subsets $S_k \subset S$ and $R_k \subset R$, and the edge set $E(G_k)$ of G_k can be identified with the Cartesian product $S_k \times R_k$ (with $\mathbf{s}(s, r) = s$ and $\mathbf{r}(s, r) = r$ for $s \in S_k$ and $r \in R_k$). As $\mathbf{s}$ maps $E(G_k)$ onto S_k and $\mathbf{r}$ maps $E(G_k)$ onto R_k for each $k = 1, \dots, K$, we see that $\mathbf{s}$ maps E onto S and $\mathbf{r}$ maps E onto R. Condition (2) in Definition 3.1 says that $\mathbf{s} \times \mathbf{r}$ is injective on E. Finally, suppose that $e_1, e_2, e_3 \in E$ as in condition (4). Then $\mathbf{r}(e_1) = \mathbf{r}(e_2) = r$ implies that $\mathbf{s}(e_1)$ and $\mathbf{s}(e_2)$ are in the same pathwise-connected component S_i of G. On the other hand, $\mathbf{s}(e_1) = \mathbf{s}(e_3)$ implies that $\mathbf{s}(e_3)$ is also in S_i and $\mathbf{r}(e_3) \in R_i$. The assumption that the pathwise-connected

component G_i is a complete bipartite graph implies that there is an edge e_4 connecting $\mathbf{s}(e_2)$ to $\mathbf{r}(e_3)$.

Conversely, suppose that G arises from source vertex function $\mathbf{s}\colon E \to S$ and range vertex function $\mathbf{r}\colon E \to R$ satisfying conditions (1)–(4) as in the statement of the theorem. By definition, the vertex set V is partitioned into two disjoint subsets S and R such that each edge of G connects an element of S with an element of R or vice versa; i.e., Definition 3.1(1) holds. Condition (3) in Theorem 3.2 gives Definition 3.1(2). Suppose that $s \in S$ and $r \in R$ are in the same pathwise-connected component of the graph G. By the bipartite structure of G, this means that there is a path $e_1 e_2 \cdots e_{2N-1}$ (necessarily of odd length) connecting s to r:

$$\mathbf{s}(e_1) = s,\ \mathbf{r}(e_1) = \mathbf{s}(e_2),\ \mathbf{r}(e_2) = \mathbf{s}(e_3),\ \ldots,\ \mathbf{r}(e_{2N-2}) = \mathbf{s}(e_{2N-1}),\ \mathbf{r}(e_{2N-1}) = r.$$

Without loss of generality we may suppose that we have chosen the shortest such path. If $N > 1$, we may use condition (4) to produce a shorter path connecting s to r. Hence it must be the case that $N = 1$ and the path consists of a single edge $e \in E$ connecting s to r and hence (s, r). Thus if $s \in S$ and $r \in R$ are connected by a path of G, then they are connected by a path of length 1. Condition (1) in the theorem implies that every $s \in S$ is connected to some $r \in R$. We conclude that each pathwise-connected component of G is a complete bipartite graph; i.e., Definition 3.1(3) is satisfied, and the theorem follows. □

If e is an edge in the admissible graph G, then we have the notation $\mathbf{s}(e)$ for the source vertex of e, and $\mathbf{r}(e)$ for the range vertex of e. Conversely, given an $s \in S$ and a $r \in R$, there is an edge e connecting s to r (i.e., $e \in E$ with $\mathbf{s}(e) = s$ and $\mathbf{r}(e) = r$); exactly one s and r are in the same path-connected component p of G. For v any vertex of G (either a source vertex or a range vertex) we shall let $[v]$ denote the path-connected component containing v. Thus s and r are in the same path-connected component exactly when $[s] = [r]$. When this is the case, by the admissibility axioms the edge e connecting s to r is unique. We shall denote this edge by $e_{s,r}$:

$$e_{s,r} \text{ determined by } \mathbf{s}(e_{s,r}) = s \text{ and } \mathbf{r}(e_{s,r}) = r. \tag{3.1}$$

Note that $e_{s,r}$ is defined for $s \in S$ and $r \in R$ exactly when $[s] = [r]$.

We associate with each admissible graph G a linear form in noncommuting indeterminates $z = (z_e : e \in E)$ indexed by the edge set E of G, as follows. For each $e \in E$, define a matrix $I_{G,e} = [I_{G,e;s,r}]_{s\in S, r\in R}$ (with rows indexed by S and columns indexed by R) with matrix entries given by

$$I_{G,e;s,r} = \begin{cases} 1 & \text{if } (s,r) = (\mathbf{s}(e), \mathbf{r}(e)), \\ 0 & \text{otherwise.} \end{cases} \tag{3.2}$$

We then define the *structure matrix* $Z_G(z)$ associated with each admissible graph G to be the linear form in the noncommuting indeterminates $z = (z_e : e \in E)$ given by

$$Z_G(z) = \sum_{e\in E} I_{G,e} z_e.$$

We are now ready to give examples of admissible graphs with their associated structure matrices in connection with certain well-known noncommutative multidimensional linear models. We refer to [34] for further details on the motivation and construction of these models.

Example 3.3 (noncommutative Fornasini–Marchesini structure matrix). In this case, we take the admissible graph G^{FM} to be a complete bipartite graph having only one source vertex. Thus we take $S^{FM} = \{1\}$, and $R^{FM} = E^{FM} = \{1, \dots, d\}$ with $\mathbf{s}^{FM}(i) = 1$, $\mathbf{r}^{FM}(i) = i$, i.e., $n = 1, m = d$. Thus we have

$$I_{G^{FM},i} = \begin{bmatrix} 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \end{bmatrix},$$

where 1 is located in the ith slot. Thus, the structure matrix for the noncommutative Fornasini–Marchesini case is simply given by

$$Z_{G^{FM}}(z) = \sum_{i=1}^{d} I_{G^{FM},i} z_i = \begin{bmatrix} z_1 & \cdots & z_d \end{bmatrix} =: Z_{\mathrm{row}}(z).$$

Example 3.4 (noncommutative Givone–Roesser structure matrix). In this case, we take the admissible graph G^{GR} to have d path-connected components, with each path-connected component containing only one source and one range vertex. Thus, we take $S^{GR} = R^{GR} = E^{GR} = \{1, \dots, d\}$ with $\mathbf{s}^{GR}(i) = i$, $\mathbf{r}^{GR}(i) = i$, and thus $n = d = m$. We then have

$$I_{G^{GR},i} = \begin{bmatrix} 0 & \cdots & 0 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 1 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 0 & \cdots & 0 \end{bmatrix},$$

where 1 is located at the (i, i)th entry. Therefore, the structure matrix for the noncommutative Givone–Roesser case has the diagonal form

$$Z_{G^{GR}}(z) = \sum_{i=1}^{d} z_i I_{G^{GR},i} = \begin{bmatrix} z_1 & & \\ & \ddots & \\ & & z_d \end{bmatrix} := Z_{\mathrm{diag}}(z).$$

Example 3.5 (full matrix block structure matrix). In this case, we take G^{full} to be a general finite, complete bipartite graph. Thus we take $S = \{1, \dots, n\}$, $R = \{1, \dots, m\}$, and $E = \{(i, j) : i \in S, j \in R\}$ with $\mathbf{s}^{\mathrm{full}}(i, j) = i$, $\mathbf{r}^{\mathrm{full}}(i, j) = j$, where $d = nm$. Then we have

$$I_{G^{\mathrm{full}},(i,j)} = \begin{bmatrix} 0 & \cdots & 0 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 1 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 0 & \cdots & 0 \end{bmatrix},$$

where 1 is located at the (i, j)th entry. Thus the structure matrix for this case has the full-block structure

$$Z_{G^{\mathrm{full}}}(z) = \begin{bmatrix} z_{1,1} & \cdots & z_{1,m} \\ \vdots & & \vdots \\ z_{n,1} & \cdots & z_{n,m} \end{bmatrix} =: Z_{\mathrm{full}}(z).$$

Note that Example 3.3 amounts to the special case of this example where $n = 1$.

Example 3.6 (the general structure matrix). Suppose that the admissible graph G has path-connected components G_k with source vertices $S_k = \{(k,1),\dots,(k,n_k)\}$, range vertices $R_k = \{(k,1),\dots,(k,m_k)\}$, and edge sets $E_k = \{(k,i,j) : 1 \le i \le n_k, 1 \le j \le m_k\}$ for $k = 1,\dots,K$. Define a graph G to have source vertex set

$$S = \cup_{k=1}^{K} S_k = \{(k,i) : 1 \le k \le K, 1 \le i \le n_k\},$$

range vertex set

$$R = \cup_{k=1}^{K} R_k = \{(k,j) : 1 \le k \le K, 1 \le j \le m_k\},$$

and edge set

$$E = \cup_{k=1}^{K} E_k = \{(k,i,j) : 1 \le k \le K, 1 \le i \le n_k, 1 \le j \le m_k\},$$

with $\mathbf{s}(k,i,j) = (k,i)$, $\mathbf{r}(k,i,j) = (k,j)$ for $(k,i,j) \in E$. Then the associated structure matrix $Z_G(z)$ is given by

$$Z_G(z) = \begin{bmatrix} Z_{\text{full},1}(z^1) & & \\ & \ddots & \\ & & Z_{\text{full},K}(z^K) \end{bmatrix},$$

where we let z^k denote the $(n_k \cdot m_k)$-tuple of variables $z^k = (z_{k,i,j} : 1 \le i \le n_k; 1 \le j \le m_k)$ and where

$$Z_{\text{full},k}(z^k) = \begin{bmatrix} z_{k,1,1} & \cdots & z_{k,1,m_k} \\ \vdots & & \vdots \\ z_{k,n_k,1} & \cdots & z_{k,n_k,m_k} \end{bmatrix}$$

is as in Example 3.5 for $k = 1,\dots,K$. By the definition of an admissible graph as a graph with path-connected components equal to complete bipartite graphs, we see that this example amounts to the general case.

To define an SNMLS, in addition to an admissible graph we require a collection of finite-dimensional linear spaces $\mathcal{H}_p$ indexed by each path-connected component p of G. We often abbreviate the whole collection simply by

$$\mathcal{H} = \{\mathcal{H}_p : p \in P(G)\},$$

where $P(G)$ denotes the set of path-connected components of G. In general, for $v \in V$ we use the notation $[v]$ to denote the path-connected component of G containing v (whether v be in S or in R). Thus, for each $s \in S$ and $r \in R$ we have associated finite-dimensional linear spaces $\mathcal{H}_{[s]}$ and $\mathcal{H}_{[r]}$, which are distinct only for s and r in distinct path-connected components of G. In addition, we need a *connection matrix* or *colligation*

(3.3)
$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} [A_{r,s}]_{r\in R, s\in S} & \operatorname{col}_{r\in R}[B_r] \\ \operatorname{row}_{s\in S}[C_s] & D \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S}\mathcal{H}_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R}\mathcal{H}_{[r]} \\ \mathcal{Y} \end{bmatrix},$$

where $\mathcal{U}$ and $\mathcal{Y}$ are linear spaces, here taken also to be finite-dimensional, called the input-space and output-space, respectively.

We now introduce our notion SNMLS.

DEFINITION 3.7. *By an* SNMLS*, we mean a collection of objects*

$$\Sigma = (G,\ \mathcal{H},\ U), \tag{3.4}$$

where

(1) *G is an admissible graph (called the* structure graph *of Σ),*
(2) *$\mathcal{H} = \{\mathcal{H}_p : p \in P(G)\}$ is a collection of finite-dimensional spaces $\mathcal{H}_p$ (called the* auxiliary state-spaces *of Σ), and*
(3) *U is a matrix of the form* (3.3) *(called the* connection matrix *or* colligation *of Σ).*

With any SNMLS we associate an i/s/o linear system with evolution along a free semigroup as follows. We denote by $\mathcal{F}_E$ the free semigroup generated by the edge set E. An element of $\mathcal{F}_E$ is then a word w of the form $w = e_N \cdots e_1$, where each e_r is an edge of G for $r = 1, \dots, N$. We denote the empty word (consisting of no letters) by $\emptyset$. The semigroup operation is concatenation: if $w = e_N \cdots e_1$ and $w' = e'_{N'} \cdots e'_1$, then ww' is defined to be

$$ww' = e_N \cdots e_1 e'_{N'} \cdots e'_1.$$

Note that the empty word $\emptyset$ acts as the identity element for this semigroup. Equivalently, we may view $\mathcal{F}_E$ as a homogeneous tree of degree $\#E + 1$ (where $\#E$ is the number of edges of G) with root $\emptyset$; this point of view appears in the "multiscale system theory" in [14].

If $\Sigma = (G,\ \mathcal{H},\ U)$ is an SNMLS, we associate the system equations (with evolution along $\mathcal{F}_E$)

$$\Sigma\colon \begin{cases} x_{\mathbf{s}(e)}(ew) &= \Sigma_{s\in S} A_{\mathbf{r}(e),s} x_s(w) + B_{\mathbf{r}(e)} u(w), \\ x_{s'}(ew) &= 0 \quad \text{if } s' \neq \mathbf{s}(e), \\ y(w) &= \Sigma_{s\in S} C_s x_s(w) + Du(w). \end{cases} \tag{3.5}$$

Here the *state-vector* $x(w)$ at position w (for $w \in \mathcal{F}_E$) has the form of a column vector

$$x(w) = \operatorname{col}_{s\in S}\, x_s(w),$$

with column entries indexed by the source vertices $s \in S$ and with column entry $x_s(w) \in \mathcal{H}_{[s]}$ (thus $x(w) \in \oplus_{s\in S}\mathcal{H}_{[s]}$), while $u(w) \in \mathcal{U}$ denotes the *input* at position w and $y(w) \in \mathcal{Y}$ denotes the *output* at position w. Just as in the classical case, if we specify an initial condition $x(\emptyset) \in \oplus_{s\in S}\mathcal{H}_{[s]}$ and feed in an input string $\{u(w)\}_{w\in\mathcal{F}_E}$, then (3.5) enables us to recursively compute $x(w)$ for all $w \in \mathcal{F}_E \setminus \{\emptyset\}$ and $y(w)$ for all $w \in \mathcal{F}_E$.

As these systems include the full-structured case discussed in section 2.3 as a special case (see Example 3.10 below) where some redundancy occurs in the state-vector of a system trajectory (see (2.18)), in general some redundancy in the state-vector occurs for trajectories of a general SNMLS Σ as well. Indeed, the analogue of (2.19) for this more general setting is the following: *if $\{x(w)\}_{w\in\mathcal{F}_E} = \{\operatorname{col}_{s\in S}[x_s(w)]\}_{w\in\mathcal{F}_E}$ is the state trajectory solving the state-update equation in* (3.5) *for some choice of input signal $\{u(w)\}_{w\in\mathcal{F}_E}$, then necessarily, for each fixed $r \in R$ and $w \in \mathcal{F}_E$,*

$$x_s(e_{s,r}w) \text{ is independent of } s \text{ for all } s \text{ with } [s] = [r]. \tag{3.6}$$

It will be convenient for purposes of the matrix manipulations to come that we maintain the form (3.5) of the system equations rather than rewriting them in a more economical form.

The solution of these recursions can be made more explicit as follows. Note first of all that a consequence of the system equations is that

$$x(ew) \in \mathcal{H}_{\mathbf{s}(e)} := \mathrm{col}_{s\in S}[\boldsymbol{\delta}_{s,\mathbf{s}(e)}\mathcal{H}_{[\mathbf{s}(e)]}] \quad \text{for all } e \in E \text{ and } w \in \mathcal{F}_E$$

(where $\boldsymbol{\delta}_{s,s'}$ is the Kronecker delta function). Given $x(\emptyset)$ and $\{u(w)\}_{w\in\mathcal{F}_E}$, we can solve the system equations (3.5) or (3.10) uniquely for $\{x(w)\}_{w\in\mathcal{F}_E\setminus\{\emptyset\}}$ and $\{y(w)\}_{w\in\mathcal{F}_E}$ as follows:

$$\begin{aligned} x_{\mathbf{s}(e_N)}(e_N\cdots e_1) &= \sum_{s\in S} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})}\cdots A_{\mathbf{r}(e_1),s}x_s(\emptyset) \\ &\quad + \sum_{r=1}^{N} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}\cdots A_{\mathbf{r}(e_{r+1}),\mathbf{s}(e_r)}B_{\mathbf{r}(e_r)}u(e_{r-1}\cdots e_1), \end{aligned} \tag{3.7}$$

where we interpret $u(e_{r-1}\cdots e_1)$ to be $u(\emptyset)$ when $r = 1$, and where we set

$$x_s(e_Ne_{N-1}\cdots e_1) = 0 \quad \text{if } s \neq \mathbf{s}(e_N).$$

Also,

$$\begin{aligned} y(e_N\cdots e_1) &= \sum_{s\in S} C_{\mathbf{s}(e_N)}A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})}\cdots A_{\mathbf{r}(e_1),s}x_s(\emptyset) \\ &\quad + \sum_{r=1}^{N} C_{\mathbf{s}(e_N)}A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}\cdots A_{\mathbf{r}(e_{r+1}),\mathbf{s}(e_r)}B_{\mathbf{r}(e_r)}u(e_{r-1}\cdots e_1) + Du(e_N\cdots e_1). \end{aligned} \tag{3.8}$$

This formula must be interpreted appropriately for special cases. As examples, for the particular cases $r = 1$ and $r = N$ we have the interpretations

$$\begin{aligned} &A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}\cdots A_{\mathbf{r}(e_{r+1}),\mathbf{s}(e_r)}B_{\mathbf{r}(e_r)}u(e_{r-1}\cdots e_1)|_{r=1} \\ &\quad = A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}\cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)}B_{\mathbf{r}(e_1)}u(\emptyset), \\ &A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}\cdots A_{\mathbf{r}(e_{r+1}),\mathbf{s}(e_r)}B_{\mathbf{r}(e_r)}u(e_{r-1}\cdots e_1)|_{r=N} = B_{\mathbf{r}(e_N)}u(e_{N-1}\cdots e_1). \end{aligned}$$

If we set

$$\Delta_e = i_{\mathbf{s}(e)}A_{\mathbf{r}(e),\cdot}\colon \oplus_{s\in S}\mathcal{H}_{[s]} \to \oplus_{s\in S}\mathcal{H}_{[s]},$$

where i_s denotes the natural injection $h \mapsto \mathrm{col}_{s'\in S}[\delta_{s',s}h]$ of $\mathcal{H}_{[s]}$ into $\oplus_{s'\in S}\mathcal{H}_{[s']}$, and if we use our assumption that $x_{s'}(ew) = 0$ if $s' \neq \mathbf{s}(e)$, then (3.7) and (3.8) can be rewritten as

$$\begin{aligned} x(w) &= \Delta^w x(\emptyset) + \sum_{w',w''\in\mathcal{F}_E,e\in E:\ w'ew''=w} \Delta^{w'}i_{\mathbf{s}(e)}B_{\mathbf{r}(e)}u(w''), \\ y(w) &= C\Delta^w x(\emptyset) + \sum_{w',w''\in\mathcal{F}_E,e\in E:\ w'ew''=w} C\Delta^{w'}i_{\mathbf{s}(e)}B_{\mathbf{r}(e)}u(w'') + Du(w), \end{aligned} \tag{3.9}$$

where we use the noncommutative functional calculus

$$\Delta^v = \Delta_{e_N}\Delta_{e_{N-1}}\cdots\Delta_{e_1} \quad \text{if } v = e_N e_{N-1}\cdots e_1 \in \mathcal{F}_E, \qquad \Delta^{\emptyset} = I_{\mathcal{H}}.$$

The system equations (3.5) can also be written more compactly in operator-theoretic form as

$$\Sigma\colon \begin{cases} x(ew) &= I_{\Sigma,e}Ax(w) + I_{\Sigma,e}Bu(w), \\ y(w) &= Cx(w) + Du(w), \end{cases} \tag{3.10}$$

where $I_{\Sigma;e}$ is a higher-multiplicity version of the coefficient matrices $I_{G,e}$ appearing in (3.2):

$$I_{\Sigma;e}\colon \oplus_{r\in R}\mathcal{H}_{[r]} \to \oplus_{s\in S}\mathcal{H}_{[s]}$$

with matrix entries $[I_{\Sigma;e}]_{s\in S, r\in R}$ given by

$$[I_{\Sigma;e}]_{s,r} = \begin{cases} I_{\mathcal{H}_{[\mathbf{s}(e)]}} = I_{\mathcal{H}_{[\mathbf{r}(e)]}} & \text{if } s = \mathbf{s}(e) \text{and } r = \mathbf{r}(e), \\ 0 & \text{otherwise.} \end{cases} \tag{3.11}$$

Also, just as in the classical case, it is convenient to introduce "frequency-domain" notation for explicit representation of system trajectories. For any linear space $\mathcal{H}$, we define the formal noncommutative Z-transform of a sequence of $\mathcal{H}$-valued functions as a formal power series in several noncommuting indeterminates $z = (z_e : e \in E)$ as follows:

$$\{h(w)\}_{w\in\mathcal{F}_E} \mapsto \widehat{h}(z) = \sum_{w\in\mathcal{F}_E} h(w)z^w, \tag{3.12}$$

where $z^{\emptyset} = 1$, $z^w = z_{e_N}z_{e_{N-1}}\cdots z_{e_1}$ if $w = e_N e_{N-1}\cdots e_1$. Then, applying the Z-transform to (3.10) gives

$$\sum_{w\in\mathcal{F}_E} x(ew)z^w = I_{\Sigma,e}A\widehat{x}(z) + I_{\Sigma,e}B\widehat{u}(z). \tag{3.13}$$

Multiply (3.13) on the left by z_e to get

$$\sum_{w\in\mathcal{F}_E} x(ew)z^{ew} = z_e I_{\Sigma,e}A\widehat{x}(z) + z_e I_{\Sigma,e}B\widehat{u}(z). \tag{3.14}$$

Summing (3.14) over all edges $e \in E$, we get

$$\sum_{e\in E}\sum_{w\in\mathcal{F}_E} x(ew)z^{ew} = Z_\Sigma(z)A\widehat{x}(z) + Z_\Sigma(z)B\widehat{u}(z), \tag{3.15}$$

where we have set

$$Z_\Sigma(z) = \sum_{e\in E} z_e I_{\Sigma,e}. \tag{3.16}$$

Note that the definition of the formal Z-transform yields

$$\sum_{e\in E}\sum_{w\in\mathcal{F}_E} x(ew)z^{ew} = \widehat{x}(z) - x(\emptyset).$$

Thus (3.15) becomes

$$\widehat{x}(z) = x(\emptyset) + Z_\Sigma(z)A\widehat{x}(z) + Z_\Sigma(z)B\widehat{u}(z). \tag{3.17}$$

Solving (3.17) for $\widehat{x}(z)$, we obtain

$$\widehat{x}(z) = (I - Z_\Sigma(z)A)^{-1}\, x(\emptyset) + (I - Z_\Sigma(z)A)^{-1}\, Z_\Sigma(z)B\widehat{u}(z). \tag{3.18}$$

Substitution of (3.17) into the formal Z-transform of the output equation of (3.10) then gives

$$\begin{aligned} \widehat{y}(z) &= C\widehat{x}(z) + D\widehat{u}(z) \\ &= C\,(I - Z_\Sigma(z)A)^{-1}\, x(\emptyset) + T_\Sigma(z)\widehat{u}(z), \end{aligned} \tag{3.19}$$

where we have set

$$T_\Sigma(z) = D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B \tag{3.20}$$

equal to the *transfer function* of the SNMLS Σ, where the inverse is taken in the algebra $\mathcal{L}(\oplus_{s\in S}\mathcal{H}_{[s]})\langle\langle z\rangle\rangle$ of formal power series with operator coefficients in the noncommuting variables $z = (z_e : e \in E)$. We can write $T_\Sigma(z)$ explicitly as a formal power series in the form

$$\begin{aligned} T_\Sigma(z) = T_\emptyset + \sum_{N=1}^{\infty} \sum_{e_1,\dots,e_N\in E} & C_{\mathbf{s}(e_N)} \\ & \cdot A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} z_{e_N} z_{e_{N-1}} \cdots z_{e_2} z_{e_1}. \end{aligned} \tag{3.21}$$

Example 3.8 (noncommutative Fornasini–Marchesini system). Here we continue Example 3.3. As the structure graph G is connected in this case, we assume that we are given a single finite-dimensional linear space $\mathcal{H}$ together with an input-space $\mathcal{U}$ and an output-space $\mathcal{Y}$. Then the structure matrix (3.16) $Z_{FM}(z)$ is the row matrix

$$Z_{\Sigma^{FM}}(z) = \sum_{j=1}^{d} z_j I_{\Sigma^{FM},j} = \begin{bmatrix} z_1 I_\mathcal{H} & \cdots & z_d I_\mathcal{H} \end{bmatrix} =: Z_{\mathrm{row}}(z) \otimes I_\mathcal{H},$$

where

$$I_{\Sigma^{FM},j} = \begin{bmatrix} 0 & \cdots & 0 & I_\mathcal{H} & 0 & \cdots & 0 \end{bmatrix}$$

(with nonzero entry in the jth column), and the connection matrix U^{FM} has the form

$$U^{FM} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} \mathrm{col}_{j=1,\dots,d}[A_j] & \mathrm{col}_{j=1,\dots,d}[B_j] \\ C & D \end{bmatrix} : \begin{bmatrix} \mathcal{H} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{j=1}^d \mathcal{H} \\ \mathcal{Y} \end{bmatrix}. \tag{3.22}$$

Thus, $I_{\Sigma^{FM},j}A = A_j$, $I_{\Sigma^{FM},j}B = B_j$, and therefore the associated noncommutative Fornasini–Marchesini system is given by

$$\Sigma^{FM}: \begin{cases} x(1w) = A_1 x(w) + B_1 u(w), \\ \qquad\vdots \\ x(dw) = A_d x(w) + B_d u(w), \\ y(w) \;\; = Cx(w) + Du(w), \end{cases} \tag{3.23}$$

i.e., we are in the setting of the noncommutative Fornasini–Marchesini systems discussed in section 2.1. Since in this case $Z_{\Sigma^{FM}}(z)A = \sum_{i=1}^{d} z_i A_i$ and similarly $Z_{\Sigma^{FM}}(z)B = \sum_{i=1}^{d} z_i B_i$, the transfer function $T_{\Sigma^{FM}}(z)$ in (3.20) for the noncommutative Fornasini–Marchesini system has the form given in (2.4).

We remark that any SNMLS can be embedded into a noncommutative Fornasini–Marchesini system having a certain special form as follows. Given a general SNMLS $\Sigma = (G, \mathcal{H}, U)$, we associate a Fornasini–Marchesini system

$$\Sigma^{FM} = (G^{FM}, \mathcal{H}^{FM}, U^{FM})$$

as follows. We let G^{FM} be the unique Fornasini–Marchesini graph having the same edge set as G: $E^{FM} = E$. Thus we take the source-vertex set S^{FM} to be $S^{FM} = \{1\}$, and the range-vertex set R^{FM} to be $R^{FM} = E$, with associated source and range vertex maps $\mathbf{s}^{FM}$ and $\mathbf{r}^{FM}$ given by $\mathbf{s}^{FM}(e) = 1$ and $\mathbf{r}^{FM}(e) = e$ for $e \in E$. We let $\mathcal{H}^{FM} = \oplus_{s \in S} \mathcal{H}$, and we define the connection matrix $U^{FM} = \left[\begin{smallmatrix} A^{FM} & B^{FM} \\ C^{FM} & D^{FM} \end{smallmatrix}\right]$ by

$$\begin{bmatrix} A^{FM} & B^{FM} \\ C^{FM} & D^{FM} \end{bmatrix} = \begin{bmatrix} \mathrm{col}_{e \in E}[A_e^{FM}] & \mathrm{col}_{e \in E}[B_e^{FM}] \\ C & D \end{bmatrix} : \begin{bmatrix} \mathcal{H}^{FM} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{e \in E} \mathcal{H}^{FM} \\ \mathcal{Y} \end{bmatrix}$$

and by

$$\begin{aligned} A_e^{FM} &= i_{\mathbf{s}(e)} A_{\mathbf{r}(e),\cdot} \colon \mathcal{H}^{FM} \to \mathcal{H}^{FM}, \\ B_e^{FM} &= i_{\mathbf{s}(e)} B_{\mathbf{r}(e)} \colon \mathcal{U} \to \mathcal{H}^{FM}, \\ C^{FM} &= C \colon \mathcal{H}^{FM} \to \mathcal{Y}, \\ D^{FM} &= D \colon \mathcal{U} \to \mathcal{Y}, \end{aligned}$$

where $i_{\mathbf{s}(e)} \colon \mathcal{H}_{[s]} \to \mathrm{col}_{s' \in S} \mathcal{H}_{[s']}$ is the natural injection $h \mapsto \mathrm{col}_{s' \in S} \delta_{s',s} h$. A consequence of formula (3.9) is that Σ *and* Σ^{FM} *associated in this way have the same system trajectories.*

Example 3.9 (noncommutative Givone–Roesser system). Here we continue Example 3.4. In this case the structure graph G has d connected components, so we assume that we give d auxiliary state-spaces $\mathcal{H}_1, \dots, \mathcal{H}_d$. The structure matrix (3.16) then has the diagonal form

$$Z_{\Sigma^{GR}}(z) = \sum_{j=1}^{d} I_{\Sigma^{GR},j} z_j = \begin{bmatrix} z_1 I_{\mathcal{H}_1} & & \\ & \ddots & \\ & & z_d I_{\mathcal{H}_d} \end{bmatrix} =: Z_{\mathrm{diag}}(z) \otimes I_{\mathcal{H}},$$

where $I_{\Sigma^{GR},j}$ is a $d \times d$ matrix with zero entries except at the (j,j)th entry, where $[I_{\Sigma^{GR},j}]_{j,j} = I_{\mathcal{H}_j}$, and the connecting matrix U^{GR} is of the form

(3.24)
$$U^{GR} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} [A_{j,i}]_{j,i=1,\dots,d} & \mathrm{col}_{j=1,\dots,d}[B_j] \\ \mathrm{row}_{i=1,\dots,d}[C_i] & D \end{bmatrix} : \begin{bmatrix} \oplus_{i=1}^{d} \mathcal{H}_i \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{j=1}^{d} \mathcal{H}_j \\ \mathcal{Y} \end{bmatrix}.$$

Thus,

(3.25)
$$I_{\Sigma^{GR},i} A = \begin{bmatrix} 0 & \cdots & 0 \\ \vdots & & \vdots \\ A_{i,1} & \cdots & A_{i,d} \\ \vdots & & \vdots \\ 0 & \cdots & 0 \end{bmatrix} \quad \text{and} \quad I_{\Sigma^{GR},i} B = \begin{bmatrix} 0 \\ \vdots \\ B_i \\ \vdots \\ 0 \end{bmatrix}$$

(where the nonzero row is row i in both expressions), and therefore the noncommutative Givone–Roesser system is given by

$$\Sigma^{GR}\colon \begin{cases} x_i(iw) &= \sum_{i'\in S} A_{i,i'}x_{i'}(w) + B_i u(w) \quad \text{for } e\in E,\\ x_{i''}(iw) &= 0 \quad \text{if } i''\neq i,\\ y(w) &= \sum_{i'=1}^{d} C_{i'}x_{i'}(w) + Du(w), \end{cases} \tag{3.26}$$

as stated in section 2.2. Here $x_i(iw)\in\mathcal{H}_i$ for $i=1,\dots,d$. The transfer function $T_{\Sigma^{GR}}(z)$ for the noncommutative Givone–Roesser system then has the form as given in (2.12).

Example 3.10 (noncommutative full-structured system). Here we continue Example 3.5. We assume that the structure matrix G has the form G^{full}, as in Example 3.5. As the structure graph G^{full} has only one connected component, we need specify only one auxiliary state-space $\mathcal{H}$ for an SNMLS $\Sigma=(G^{\text{full}},\mathcal{H},U)$ with structure graph G^{full}. The structure matrix (3.16) is the full-block operator matrix with each matrix entry containing one of the variables

$$Z_{\Sigma^{\text{full}}}(z)=\sum_{i=1}^{n}\sum_{j=1}^{m} I_{\Sigma^{\text{full}},(i,j)}z_{i,j}=\begin{bmatrix} z_{1,1}I_{\mathcal{H}} & \cdots & z_{1,m}I_{\mathcal{H}}\\ \vdots & & \vdots\\ z_{n,1}I_{\mathcal{H}} & \cdots & z_{n,m}I_{\mathcal{H}}\end{bmatrix} =: Z_{\text{full}}(z)\otimes I_{\mathcal{H}},$$

where $I_{\Sigma^{\text{full}},(i,j)}$ is an $n\times m$ matrix with zero entries except at the (i,j)th entry, where $[I_{\Sigma^{\text{full}},(i,j)}]_{i,j}=I_{\mathcal{H}}$. The connecting operator U^{full} in this case is given by

$$U^{\text{full}}=\begin{bmatrix} A & B\\ C & D\end{bmatrix}:\begin{bmatrix}\oplus_1^n\mathcal{H}\\ \mathcal{U}\end{bmatrix}\to\begin{bmatrix}\oplus_1^m\mathcal{H}\\ \mathcal{Y}\end{bmatrix},$$

where

$$A=\begin{bmatrix} A_{1,1} & \cdots & A_{1,n}\\ \vdots & & \vdots\\ A_{m,1} & \cdots & A_{m,n}\end{bmatrix},\quad B=\begin{bmatrix}B_1\\ \vdots\\ B_m\end{bmatrix},\quad C=\begin{bmatrix}C_1 & \cdots & C_n\end{bmatrix},$$

and the system equations (3.5) assume the form

$$\Sigma^{\text{full}}\colon \begin{cases} x_i((i,j)\cdot w) &= \sum_{i'=1}^{n} A_{j,i'}x_{i'}(w) + B_j u(w),\\ x_{i''}((i,j)\cdot w) &= 0 \quad \text{if } i''\neq i,\\ y(w) &= \sum_{i'=1}^{n} C_{i'}x_{i'}(w) + Du(w), \end{cases} \tag{3.27}$$

and we are in the setting of the noncommutative full-structured systems discussed in section 2.3. The transfer function $T_{\Sigma^{\text{full}}}(z)$ for the full-block operator matrix case then has the form as in (2.21).

Example 3.11 (the general SNMLS system). Here we continue Example 3.6. Suppose that the admissible graph G is the union of complete bipartite graphs G_k with source-vertex set $S_k=\{(k,i)\colon 1\le i\le n_k\}$, range-vertex set $R_k=\{(k,j)\colon 1\le j\le m_k\}$, and edge set $E_k=\{(k,i,j)\colon 1\le i\le n_k; 1\le j\le m_k\}$ for $k=1,\dots,K$. Note that $k=1,\dots,K$ labels the set P of path-connected components of G. Let $\mathcal{H}=\{\mathcal{H}_k\colon k=1,\dots,K\}$ denote a specification of a finite-dimensional linear space for each path-connected component $k=1,\dots,K$, and suppose that $\Sigma=(G,\mathcal{H},U)$ is an SNMLS with structure graph G. Then the connection matrix U has the form

$$U=\begin{bmatrix}[A_{k',k}] & [B_{k'}]\\ [C_k] & D\end{bmatrix}:\begin{bmatrix}\oplus_{k=1}^{K}[\oplus_{i=1}^{n_k}\mathcal{H}_k]\\ \mathcal{U}\end{bmatrix}\to\begin{bmatrix}\oplus_{k'=1}^{K}[\oplus_{j=1}^{m_{k'}}\mathcal{H}_{k'}]\\ \mathcal{Y}\end{bmatrix},$$

where each $A_{k',k}$, $B_{k'}$, and C_k in turn has the form

$$\begin{aligned}
&A_{k',k} = [A_{k',k;j,i}]_{j=1,\dots,m_{k'};i=1,\dots,n_k}, \quad \text{where } A_{k',k;j,i}\colon \mathcal{H}_k \to \mathcal{H}_{k'},\\
&B_{k'} = \operatorname{col}_{j=1,\dots,m_{k'}}[B_{k',j}], \quad \text{where } B_{k',j}\colon \mathcal{U} \to \mathcal{H}_{k'},\\
&C_k = \operatorname{row}_{i=1,\dots,n_k}[C_{k,i}], \quad \text{where } C_{k,i}\colon \mathcal{H}_k \to \mathcal{Y}.
\end{aligned}$$

The structure matrix $Z_\Sigma(z)$ has the block-diagonal form

$$Z_\Sigma(z) = \begin{bmatrix} Z_{\text{full},1}(z^1)\otimes I_{\mathcal{H}_1} & & \\ & \ddots & \\ & & Z_{\text{full},K}(z^K)\otimes I_{\mathcal{H}_K} \end{bmatrix},$$

where z^k is the collection of variables $z^k = \{z_{k,i,j} : i = 1,\dots,n_k; j = 1,\dots,m_k\}$ and each $Z_{\text{full},k}(z^k)\otimes I_{\mathcal{H}_k}$ is a full-block structure matrix (of block size $n_k \times m_k$), as in Example 3.10. While the structure matrix splits as the direct sum, the system trajectories for the whole system Σ in general can be quite complicated since there is no corresponding splitting for the A matrix generating the system dynamics.

If one substitutes general noncommuting operators $\delta = (\delta_{k,i,j}\colon k = 1,\dots,K; i = 1,\dots,n_k; j = 1,\dots,m_k)$ for the noncommuting formal variables $z_{k,i,j}$, then $Z_\Sigma(\delta)$ is the most general structure matrix coming up in μ-synthesis analysis (see [33]). Part of the advantage of the notion of SNMLS introduced here is the setting thereby given for proving results in the theory of μ-synthesis in a unified way for a general structure. We refer to [6] for further details.

4. System operations: Cascade/parallel connection and inversion. Suppose that we are given two SNMLSs

$$\Sigma'' = (G, \mathcal{H}'', U''), \qquad \Sigma' = (G, \mathcal{H}', U')$$

with the same structure graph G and with connection matrices

$$\begin{aligned}
U'' &= \begin{bmatrix} A'' & B'' \\ C'' & D'' \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S}\mathcal{H}''_{[s]} \\ \mathcal{U}'' \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R}\mathcal{H}''_{[r]} \\ \mathcal{Y}'' \end{bmatrix},\\
U' &= \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S}\mathcal{H}'_{[s]} \\ \mathcal{U}' \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R}\mathcal{H}'_{[r]} \\ \mathcal{Y}' \end{bmatrix},
\end{aligned}$$

with the property that the output-space for U' coincides with the input-space for U'':

$$\mathcal{Y}' = \mathcal{U}''.$$

We then define the *cascade connection* $\Sigma = \Sigma''\circ\Sigma'$ of Σ'' with Σ' to be the SNMLS $\Sigma = (G, \mathcal{H}, U)$ with auxiliary state-spaces $\mathcal{H}_p$ given by $\mathcal{H}_p = \begin{bmatrix} \mathcal{H}''_p \\ \mathcal{H}'_p \end{bmatrix}$ and with colligation U given by

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} := \begin{bmatrix} A'' & B''C' & B''D' \\ 0 & A' & B' \\ C'' & D''C' & D''D' \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S}\mathcal{H}''_{[s]} \\ \operatorname{col}_{s\in S}\mathcal{H}'_{[s]} \\ \mathcal{U}' \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R}\mathcal{H}''_{[r]} \\ \operatorname{col}_{r\in R}\mathcal{H}'_{[r]} \\ \mathcal{Y}'' \end{bmatrix}.$$

Here we have identified the space $\operatorname{col}_{s\in S}\begin{bmatrix} \mathcal{H}''_{[s]} \\ \mathcal{H}'_{[s]} \end{bmatrix}$ with $\begin{bmatrix} \operatorname{col}_{s\in S}\mathcal{H}''_{[s]} \\ \operatorname{col}_{s\in S}\mathcal{H}'_{[s]} \end{bmatrix}$ as well as $\operatorname{col}_{r\in R}\begin{bmatrix} \mathcal{H}''_{[r]} \\ \mathcal{H}'_{[r]} \end{bmatrix}$ with $\begin{bmatrix} \operatorname{col}_{r\in R}\mathcal{H}''_{[r]} \\ \operatorname{col}_{r\in R}\mathcal{H}'_{[r]} \end{bmatrix}$ in the natural way. In more detail, the colligation coefficients A, B,

C, D are given by

$$A_{r,s} = \begin{bmatrix} A''_{r,s} & B''_r C'_s \\ 0 & A'_{r,s} \end{bmatrix} : \begin{bmatrix} \mathcal{H}''_{[s]} \\ \mathcal{H}'_{[s]} \end{bmatrix} \to \begin{bmatrix} \mathcal{H}''_{[r]} \\ \mathcal{H}'_{[r]} \end{bmatrix}, \qquad B_r = \begin{bmatrix} B''_r D' \\ B'_r \end{bmatrix} : \mathcal{U}' \to \begin{bmatrix} \mathcal{H}''_{[r]} \\ \mathcal{H}'_{[r]} \end{bmatrix},$$

$$C_s = \begin{bmatrix} C''_s & D''C'_s \end{bmatrix} : \begin{bmatrix} \mathcal{H}''_{[s]} \\ \mathcal{H}'_{[s]} \end{bmatrix} \to \mathcal{Y}'', \qquad D = D''D' : \mathcal{U}' \to \mathcal{Y}''.$$

We note that the cascade connection $\Sigma = \Sigma'' \circ \Sigma'$ has the following interpretation. Suppose that we are given an initial condition $x'(\emptyset) = x'_0$ and an input string $\{u'(w)\}_{w \in \mathcal{F}_E}$ to generate a trajectory $\{u'(w), x'(w), y'(w)\}_{w \in \mathcal{F}_E}$ of Σ' via the system equations

$$\Sigma' : \begin{cases} x'_{\mathbf{s}(e)}(ew) &= \Sigma_{s \in S} A'_{\mathbf{r}(e),s} x'_s(w) + B'_{\mathbf{r}(e)} u'(w), \\ x'_{s'}(ew) &= 0 \quad \text{if } s' \neq \mathbf{s}(e), \\ y'(w) &= \Sigma_{s \in S} C'_s x'_s(w) + D' u'(w). \end{cases} \tag{4.1}$$

We then let $x''(\emptyset) = x''_0 \in \mathcal{H}''$ be arbitrary and set $u''(w) = y'(w)$ to generate a system trajectory $\{u''(w), x''(w), y''(w)\}_{w \in \mathcal{F}_E}$ of Σ'', via the system equations

$$\Sigma'' : \begin{cases} x''_{\mathbf{s}(e)}(ew) &= \Sigma_{s \in S} A''_{\mathbf{r}(e),s} x''_s(w) + B''_{\mathbf{r}(e)} u''(w), \\ x''_{s'}(ew) &= 0 \quad \text{if } s' \neq \mathbf{s}(e), \\ y''(w) &= \Sigma_{s \in S} C''_s x''_s(w) + D'' u''(w). \end{cases} \tag{4.2}$$

The resulting triple $\left\{u'(w), \left[\begin{smallmatrix} x''(w) \\ x'(w) \end{smallmatrix}\right], y''(w)\right\}_{w \in \mathcal{F}_E}$ then is a system trajectory of $\Sigma = \Sigma'' \circ \Sigma'$, and every system trajectory of $\Sigma'' \circ \Sigma'$ arises in this way.

The main result concerning cascade connection is that this is the state-space operation corresponding to multiplication of the corresponding transfer functions.

THEOREM 4.1. *Let Σ'' and Σ' be SNMLSs for which the cascade connection $\Sigma := \Sigma'' \circ \Sigma'$ is defined as above. Then the transfer function $T_\Sigma(z)$ for Σ is the product of the transfer functions $T_{\Sigma''}(z)$ and $T_{\Sigma'}(z)$ for Σ'' and Σ':*

$$T_{\Sigma'' \circ \Sigma'}(z) = T_{\Sigma''}(z) \cdot T_{\Sigma'}(z). \tag{4.3}$$

Proof. We have seen (see (3.19)) that the transfer function $T_\Sigma(z)$ is characterized by the property that

$$\widehat{y}(z) = T_\Sigma(z) \widehat{u}(z)$$

whenever $\{u(w), x(w), y(w)\}_{w \in \mathcal{F}_E}$ is a trajectory of Σ with $x(\emptyset) = 0$. By the interpretation for the cascade connection $\Sigma'' \circ \Sigma'$ given in the preceding paragraph, we know that $\{u(w), x(w), y(w)\}_{w \in \mathcal{F}_E}$ has the form $\left\{u'(w), \left[\begin{smallmatrix} x''(w) \\ x'(w) \end{smallmatrix}\right], y''(w)\right\}_{w \in \mathcal{F}_E}$, where

$$\{u'(w), x'(w), y'(w)\}_{w \in \mathcal{F}_E}$$

is a trajectory of Σ' with $x'(\emptyset) = 0$, where $\{u''(w), x''(w), y''(w)\}_{w \in \mathcal{F}_E}$ is a trajectory of Σ'' with $x''(\emptyset) = 0$, and where we impose the interconnection law $y'(w) = u''(w)$. It therefore follows that

$$\begin{aligned} \widehat{y}(z) = \widehat{y''}(z) &= T_{\Sigma''}(z) \widehat{y'}(z) \\ &= T_{\Sigma''}(z) \left(T_{\Sigma'}(z) \widehat{u'}(z) \right) \\ &= \left(T_{\Sigma''}(z) T_{\Sigma'}(z) \right) \widehat{u}(z), \end{aligned}$$

and we conclude that it must be the case that $T_\Sigma(z) = T_{\Sigma''}(z)T_{\Sigma'}(z)$, as asserted. Of course the result can also be verified by direct computation using the formula (3.20) for the transfer function in terms of A, B, C, D. ∎

We next define the *parallel connection* of two SNMLSs as follows. We suppose that we are given two SNMLSs

$$\Sigma'' = (G, \mathcal{H}'', U''), \qquad \Sigma' = (G, \mathcal{H}', U')$$

with the same structure graph G and with the same input-space $\mathcal{U}$ and the same output-space $\mathcal{Y}$:

$$U'' = \begin{bmatrix} A'' & B'' \\ C'' & D'' \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S} \mathcal{H}''_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R} \mathcal{H}''_{[r]} \\ \mathcal{Y} \end{bmatrix},$$
$$U' = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S} \mathcal{H}'_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R} \mathcal{H}'_{[r]} \\ \mathcal{Y} \end{bmatrix}.$$

We then define the *parallel sum* $\Sigma = \Sigma''[+]\Sigma'$ of Σ'' and Σ' to be $\Sigma = (G, \mathcal{H}, U)$ with auxiliary state-spaces $\mathcal{H}_p$ again equal to the direct sums $\mathcal{H}_p = \begin{bmatrix} \mathcal{H}''_p \\ \mathcal{H}'_p \end{bmatrix}$ and with connection matrix U given by

$$U = \begin{bmatrix} A'' & 0 & B'' \\ 0 & A' & B' \\ C'' & C' & D'' + D' \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S} \mathcal{H}''_{[s]} \\ \operatorname{col}_{s\in S} \mathcal{H}'_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R} \mathcal{H}''_{[r]} \\ \operatorname{col}_{r\in R} \mathcal{H}'_{[r]} \\ \mathcal{Y} \end{bmatrix}.$$

Here again we identify $\operatorname{col}_{s\in S} \begin{bmatrix} \mathcal{H}''_{[s]} \\ \mathcal{H}'_{[s]} \end{bmatrix}$ with $\begin{bmatrix} \operatorname{col}_{s\in S} \mathcal{H}''_{[s]} \\ \operatorname{col}_{s\in S} \mathcal{H}'_{[s]} \end{bmatrix}$ and $\operatorname{col}_{r\in R} \begin{bmatrix} \mathcal{H}''_{[r]} \\ \mathcal{H}'_{[r]} \end{bmatrix}$ with $\begin{bmatrix} \operatorname{col}_{r\in R} \mathcal{H}''_{[r]} \\ \operatorname{col}_{r\in R} \mathcal{H}'_{[r]} \end{bmatrix}$ in the natural way. In this case the physical interpretation is that we feed an initial state $x'(\emptyset) = x'_0 \in \operatorname{col}_{s\in S} \mathcal{H}'_{[s]}$ and an input string $\{u(w)\}_{w\in\mathcal{F}_E}$ into Σ' to generate a trajectory $\{u(w), x'(w), y'(w)\}_{w\in\mathcal{F}_E}$ of Σ' along with an initial state $x''(\emptyset) = x''_0 \in \operatorname{col}_{s\in S} \mathcal{H}''_{[s]}$ and the same input string $(u(w))_{w\in\mathcal{F}_E}$ to generate a trajectory $\{u(w), x''(w), y''(w)\}$ of Σ''. We then set $y(w) = y'(w) + y''(w)$. Then $\left\{u(w), \begin{bmatrix} x''(w) \\ x'(w) \end{bmatrix}, y(w)\right\}_{w\in\mathcal{F}_E}$ is a system trajectory of $\Sigma = \Sigma''[+]\Sigma'$, and every trajectory of $\Sigma''[+]\Sigma'$ is of this form. With this system interpretation, the following result follows easily along the same lines as the proof of Theorem 4.1.

THEOREM 4.2. *Suppose that Σ'' and Σ' are two SNMLSs for which the parallel sum $\Sigma := \Sigma''[+]\Sigma'$ is defined as above. Then the transfer function $T_\Sigma(z)$ for Σ is the sum of the transfer functions $T_{\Sigma''}(z)$ and $T_{\Sigma'}(z)$ for Σ'' and Σ':*

$$T_{\Sigma''[+]\Sigma'}(z) = T_{\Sigma''}(z) + T_{\Sigma'}(z). \tag{4.4}$$

Our final system operation is inversion. We suppose that we are given an SNMLS $\Sigma = (G, \mathcal{H}, U)$ for which the colligation

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} : \begin{bmatrix} \operatorname{col}_{s\in S} \mathcal{H}_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \operatorname{col}_{r\in R} \mathcal{H}_{[r]} \\ \mathcal{Y} \end{bmatrix}$$

is such that the feedthrough operator $D : \mathcal{U} \to \mathcal{Y}$ is invertible. We then define the inverse colligation

$$\Sigma^\times = (G, \mathcal{H}, U^\times)$$

with the same structure graph G and auxiliary state-spaces $\mathcal{H} = \{\mathcal{H}_p : p \in P(G)\}$ but with colligation $U^\times$ given by

$$U^\times = \begin{bmatrix} A^\times & B^\times \\ C^\times & D^\times \end{bmatrix} = \begin{bmatrix} A - BD^{-1}C & BD^{-1} \\ -D^{-1}C & D^{-1} \end{bmatrix} : \begin{bmatrix} \mathrm{col}_{s\in S}\, \mathcal{H}_{[s]} \\ \mathcal{Y} \end{bmatrix} \to \begin{bmatrix} \mathrm{col}_{r\in R}\, \mathcal{H}_{[r]} \\ \mathcal{U} \end{bmatrix}.$$

The point here is that $\{y(w), x(w), u(w)\}_{w\in\mathcal{F}_E}$ is a system trajectory of $U^\times$ if and only if $\{u(w), x(w), y(w)\}_{w\in\mathcal{F}_E}$ is a system trajectory of U; i.e., system-inversion amounts to interchange of inputs and outputs. If we then work with system trajectories having $x(\emptyset) = 0$, we see that $\widehat{y}(z) = T_\Sigma(z)\widehat{u}(z)$ is equivalent to $\widehat{u}(z) = T_{\Sigma^\times}(z)\widehat{y}(z)$. Of course it is also possible to verify the formal power series identities

$$T_{\Sigma^\times}(z) \cdot T_\Sigma(z) = I_\mathcal{U}, \qquad T_\Sigma(z) \cdot T_{\Sigma^\times}(z) = I_\mathcal{Y}$$

directly by use of the explicit formula (3.20) for the transfer function. In any case, we record this observation in the following theorem.

THEOREM 4.3. *Suppose that $\Sigma = (G, \mathcal{H}, U)$ is an SNMLS with colligation*

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} : \begin{bmatrix} \mathrm{col}_{s\in S}\, \mathcal{H}_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \mathrm{col}_{r\in R}\, \mathcal{H}_{[r]} \\ \mathcal{Y} \end{bmatrix}$$

having invertible feedthrough operator $D : \mathcal{U} \to \mathcal{Y}$. Then

$$T_\Sigma(z) = D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B$$

is invertible in the space $\mathcal{L}(\mathcal{U}, \mathcal{Y})\langle\langle z\rangle\rangle$ (formal power series in the noncommuting variables $z = (z_e)_{e\in E}$ with coefficients in the space $\mathcal{L}(\mathcal{U}, \mathcal{Y})$ of operators from $\mathcal{U}$ to $\mathcal{Y}$), with inverse $T_\Sigma^{-1}(z) \in \mathcal{L}(\mathcal{Y}, \mathcal{U})\langle\langle z\rangle\rangle$ given by

$$T_\Sigma^{-1}(z) = T_{\Sigma^\times}(z) := D^{-1} - D^{-1}C(I - Z_\Sigma(z)[A - BD^{-1}C])^{-1}Z_\Sigma(z)BD^{-1}. \tag{4.5}$$

Remark 4.4. For the classical case, there exists a converse to Theorem 4.1; i.e., given Σ, it is possible to describe geometrically all possible nontrivial decompositions of Σ as $\Sigma = \Sigma'' \circ \Sigma'$ (see, e.g., [9]). These results can also be extended to more general linear-fractional decompositions (see [29] and [18]). Presumably such results can also be worked out for SNMLSs, but we leave this project to another occasion.

5. Reachability and controllability. The building blocks for reachability and controllability operators are certain operators $\Psi_w : \mathcal{U} \to \mathcal{H}_s$ associated with any word w,

$$\Psi_w = A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} \quad \text{if } w = e_N \cdots e_1. \tag{5.1}$$

Note that the word $w = e_N e_{N-1} \cdots e_2 e_1$ can be written, for each $r = 1, 2, \ldots, N$, as the concatenation

$$w = w'_r w''_{r-1},$$

where we have set

$$w'_r = e_N e_{N-1} \cdots e_r \text{ for } r = 1, \ldots, N, \quad w''_{r-1} = e_{r-1} \cdots e_1 \text{ for } r = 2, \ldots, N, \quad w''_0 = \emptyset.$$

From formula (3.7), we see that the $\mathbf{s}(e_N)$th component of the state trajectory at location $w = e_N \cdots e_1$ for Σ generated by input string $\{u(v)\}_{v \in \mathcal{F}_E}$ with zero initial condition $x(\emptyset) = 0$ is given by

$$\begin{aligned} x_{\mathbf{s}(e_N)}(w) &= \sum_{r=1}^{N} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} \cdots A_{\mathbf{r}(e_{r+1}),\mathbf{s}(e_r)} B_{\mathbf{r}(e_r)} u(w''_{r-1}) \\ &= \sum_{r=1}^{N} \Psi_{w'_r} u(w''_{r-1}). \end{aligned}$$

Just as in the classical case, the indexing is a little more natural if we consider controllability operators instead. Up to this point we have been considering the system evolution only on the "future time" $\mathcal{T}_{\text{future}} := \mathcal{F}_E$. We now define the "past time" $\mathcal{T}_{\text{past}}$ to be a second copy of $\mathcal{F}_E$ but with the empty word deleted: $\mathcal{T}_{\text{past}} := \mathcal{F}_E \setminus \{\emptyset\}$. We emphasize that $\mathcal{T}_{\text{future}}$ and $\mathcal{T}_{\text{past}}$ are considered to be disjoint sets; given a nonempty word w in $\mathcal{F}_E$, we will specify in the particular context whether it is to be considered as an element of $\mathcal{T}_{\text{future}}$ or of $\mathcal{T}_{\text{past}}$.

Let us now introduce the system evolution on the past, which is given by

$$\Sigma_{\text{past}}\colon \begin{cases} x_s(w) = \sum_{e\colon \mathbf{s}(e)=s} \sum_{s' \in S} A_{\mathbf{r}(e),s'} x_{s'}(we) + \sum_{e\colon \mathbf{s}(e)=s} B_{\mathbf{r}(e)} u(we), \\ y(w) \;\; = \sum_{s \in S} C_s x_s(w) + Du(w), \end{cases} \tag{5.2}$$

or, in aggregate form,

$$\Sigma_{\text{past}}\colon \begin{cases} x(w) = \sum_{e \in E} I_{\Sigma,e} A x(we) + \sum_{e \in E} I_{\Sigma,e} B u(we), \\ y(w) = Cx(w) + Du(w). \end{cases} \tag{5.3}$$

This evolution can actually be derived from the forward evolution by doing the change of "time" variable $w''_{r-1} \mapsto w'_r$ along each finite path w (where the initial segment w''_{r-1} is viewed as a point in the future $\mathcal{T}_{\text{future}}$, while the corresponding final segment w'_r is viewed as a position in the past $\mathcal{T}_{\text{past}}$), and then taking a span over paths as was done above. In this way, the span of all vectors generated at some finite position in the future from zero initial condition on the state at $\emptyset$ over all possible input strings on $\mathcal{T}_{\text{future}}$ is transformed into the set of all possible states achieved at time $\emptyset$ (the final point for the past) over all possible finitely supported input strings on the past with zero state initialization in the distant past.

More precisely, fix a finite word $w = e_N \cdots e_1$, and assume that we run the system in the past $\mathcal{T}_{\text{past}}$ using the system equations (5.2) or (5.3) under the assumption that $x(v) = 0$ for all $v \in \mathcal{T}_{\text{past}}$ with $|v| \geq N$, where N is an arbitrary length, and that $u(v) = 0$ for all $v \in \mathcal{T}_{\text{past}}$ except for those of the form $v = w'_r = e_N \cdots e_r$ for some r with $1 \leq r \leq N$. Then the $\mathbf{s}(e_N)$th component of the resulting state trajectory $x(\cdot)$ at the location $\emptyset$ is

$$\begin{aligned} x_{\mathbf{s}(e_N)}(\emptyset) &= \sum_{r=1}^{N} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} \cdots A_{\mathbf{r}(e_{r+1}),\mathbf{s}(e_r)} B_{\mathbf{r}(e_r)} u(w'_r) \\ &= \sum_{r=1}^{N} \Psi_{w'_r} u(w'_r). \end{aligned}$$

Then the linear space $\boldsymbol{\mathcal{C}}_w$ consisting of all vectors $x_s \in \mathcal{H}_s$ achievable as $x_s(\emptyset)$ when the system is run with state set equal to zero in the distant past and with input taken to be equal to zero except along some left segment of the word w is characterized as

$$\boldsymbol{\mathcal{C}}_w = \operatorname{im} \mathcal{C}_w,$$

where the *controllability operator* associated with the word w is given by

$$\mathcal{C}_w = \operatorname*{row}_{r=1,\dots,N} \Psi_{w'_r} : \ell_{\mathrm{fin}}(\mathcal{T}^w_{\mathrm{past}}, \mathcal{U}) \to \mathcal{H}_{[s]}, \tag{5.4}$$

where $\mathcal{T}^w_{\mathrm{past}} = \{w'_r : r = 1, \dots, N\} \subset \mathcal{T}_{\mathrm{past}}$.

More generally, we denote by $\mathcal{F}_E^{\infty_R}$ the set of all nonempty words which have a beginning on the left but are infinite to the right:

$$\mathcal{F}_E^{\infty_R} = \{e_1 e_2 \cdots e_N \cdots : e_j \in E \text{ for } j = 1, 2, 3, \dots\}.$$

Fix an infinite word $w = e_1 e_2 \cdots e_N \cdots \in \mathcal{F}_E^{\infty_R}$. Set $w^N = e_1 e_2 \cdots e_N$ equal to the finite word obtained as the truncation of w after N letters, and define

$$\mathcal{C}_w = \operatorname{row}_{N=1,2,3,\dots} \Psi_{w^N} : \ell_{\mathrm{fin}}(\mathcal{T}^w_{\mathrm{past}}, \mathcal{U}) \to \mathcal{H}_{[\mathbf{s}(LL[w])]},$$

where $LL[w]$ (for w a finite or infinite word) denotes the *leading letter* of w,

$$LL[e_1 e_2 \cdots e_N \cdots] = e_1,$$

and where $\mathcal{T}^w_{\mathrm{past}} = \cup\{w^N : N = 1, 2, 3, \dots\}$. Then the image of $\mathcal{C}_w$ (as an operator on $\ell_{\mathrm{fin}}(\mathcal{T}^w_{\mathrm{past}}, \mathcal{U})$) is the linear space of all possible states $x_{\mathbf{s}(e_1)} \in \mathcal{H}_{[\mathbf{s}(e_1)]}$ ($e_1 = LL[w]$) arising in the form $x_{\mathbf{s}(e_1)}(\emptyset)$ from a system trajectory (5.2) under the assumptions that $x(w) = 0$ for all words $w \in \mathcal{T}_{\mathrm{past}}$ of sufficiently large length and that the input string $\{u(w)\}_{w \in \mathcal{T}_{\mathrm{past}}}$ is supported on $w^1, \dots, w^N$ for some finite N.

It is natural to initialize the state to be zero in the far past but to allow input strings of arbitrary finite support. Given $s \in S$, we define the controllability operator $\mathcal{C}_s$ as the block row matrix

$$\mathcal{C}_s = \operatorname*{row}_{w \in \mathcal{T}_{\mathrm{past}} \text{ with } \mathbf{s}(LL[w]) = s} \Psi_w : \ell_{\mathrm{fin}}(\mathcal{T}^s_{\mathrm{past}}, \mathcal{U}) \to \mathcal{H}_{[s]}. \tag{5.5}$$

Here we set

$$\mathcal{T}^s_{\mathrm{past}} = \bigcup_{w \in \mathcal{T}_{\mathrm{past}} \text{ with } s = \mathbf{s}(LL[w])} \mathcal{T}^w_{\mathrm{past}}. \tag{5.6}$$

If we define $\boldsymbol{\mathcal{C}}_s$ to be the linear space of all vectors $x_s \in \mathcal{H}_s$ achievable as $x_s = x_s(\emptyset)$ when we run the system on $\mathcal{T}_{\mathrm{past}}$ with an input string of finite support and with state initialization set equal to zero at all positions $v \in \mathcal{T}_{\mathrm{past}}$ with $|v|$ sufficiently large, then we have

$$\boldsymbol{\mathcal{C}}_s = \operatorname{im} \mathcal{C}_s.$$

Remark 5.1. More generally, we may define an apparently more general controllability operator as follows. For $p \in P$ (the set of path-connected components of the structure graph G associated with the SNMLS Σ (see Definition 3.7)), set

$\mathcal{T}^p_{\rm past} = \bigcup_{s:[s]=p} \mathcal{T}^s_{\rm past}$. We define the controllability operator $\mathcal{C}_p$ as the block row matrix

$$\mathcal{C}_p = \operatorname*{row}_{s:[s]=p} \mathcal{C}_s \colon \ell_{\rm fin}(\mathcal{T}^p_{\rm past}, \mathcal{U}) \to \mathcal{H}_p. \tag{5.7}$$

Then the image of $\mathcal{C}_p$ consists of the linear span of all vectors $x_p \in \mathcal{H}_p$ expressible as $x_s(\emptyset)$ (for some s with $[s] = p$) when the system Σ is run over the past $\mathcal{T}^p_{\rm past}$ with some input string on $\mathcal{T}^p_{\rm past}$ of finite support and with state-vector initialized to be zero at all positions v sufficiently far in the past.

Note, however, from the formula (5.1) for Ψ_w that Ψ_w is independent of the value of $\mathbf{s}(LL[w])$; i.e., if $w = e_N e_{N-1} \cdots e_2 e_1$ and $w' = e'_N e_{N-1} \cdots e_2 e_1$, then $\Psi_{w'} = \Psi_w$, as long as $\mathbf{r}(e'_N) = \mathbf{r}(e_N)$. Thus $\operatorname{im} \mathcal{C}_s = \operatorname{im} \mathcal{C}_p$ for any $s \in S$ with $[s] = p$.

It will be convenient to make this invariance property more explicit. We define a bijection $w \mapsto w^{\wedge s}$ from $\mathcal{T}^{s'}_{\rm past}$ to $\mathcal{T}^s_{\rm past}$ by

$$w^{\wedge s} = e_{s,\mathbf{r}(e_N)} e_{N-1} \cdots e_1 \quad \text{if } w = e_N e_{N-1} \cdots e_1. \tag{5.8}$$

Note that $e_{s,\mathbf{r}(e_N)}$ is well defined as (3.1) whenever it is the case that $[s] = [\mathbf{s}(e_N)] (= [\mathbf{r}(e_N)])$. As observed in the previous paragraph, the controllability-operator building blocks Ψ_w given by (5.1) are invariant under this transformation:

$$\text{for } s, s' \in S \text{ with } [s] = [s'], \quad \Psi_w = \Psi_{w^{\wedge s'}} \text{ for } w \in \mathcal{T}^s_{\rm past}. \tag{5.9}$$

For each of the three choices of controllability operator $\mathcal{C}_w$, $\mathcal{C}_s$, and $\mathcal{C}_p$ (where $\mathcal{C}_p$ is as in Remark 5.1), we have a corresponding notion of controllability, namely, the system Σ is X-controllable (where $X = \mathcal{F}_E^{\infty_R}$ (the set of words which are infinite to the right), $X = S$ or $X = P$) if the operator $\mathcal{C}_x$ is surjective for all $x \in X$. A consequence of Remark 5.1, however, is that S-controllability and P-controllability are equivalent. The notion of controllability most convenient for our purposes here is the weakest of these, namely P-controllability (or equivalently, S-controllability). We therefore make the following definition.

DEFINITION 5.2. *We say that the SNMLS Σ is* structured-controllable *or simply* controllable *if the operator*

$$\mathcal{C}_p \colon \ell_{fin}(\mathcal{T}^p_{past}, \mathcal{U}) \to \mathcal{H}_p$$

given by (5.7) *is surjective for each path-connected component p of the admissible graph G associated with Σ, or equivalently (by Remark* 5.1*), if the operator*

$$\mathcal{C}_s \colon \ell_{fin}(\mathcal{T}^s_{past}, \mathcal{U}) \to \mathcal{H}_{[s]}$$

given by (5.5) *is surjective for each $s \in S$ (or equivalently, for some s with $[s] = p$ for each $p \in P$).*

6. Observability. Analogously, we have a dual array of observability operators, but with one additional parameter (roughly due to the fact that $\mathcal{T}_{\rm future}$ includes the empty word $\emptyset$, while $\mathcal{T}_{\rm past}$ does not), namely $\mathcal{O}_{s,w}$ for each $s \in S$ and infinite word $w = e_1 e_2 \cdots e_N \cdots \in \mathcal{F}_E^{\infty_R}$, $\mathcal{O}_s$ for each $s \in S$, and $\mathcal{O}_p$ for each $p \in P$. For $w = e_1 e_2 \cdots e_N \cdots \in \mathcal{F}_E^{\infty_R}$ and $s \in S$, we define $\mathcal{O}_{s,w}$ as the block-operator column matrix

$$\mathcal{O}_{s,w} = \operatorname*{col}_{N=0,1,2,\ldots} [C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} \cdots A_{\mathbf{r}(e_1),s}] \colon \mathcal{H}_{[s]} \to \ell(\mathcal{T}^w_{\rm future}, \mathcal{Y}), \tag{6.1}$$

where we interpret the formula for the case $N = 0$ to mean

$$[\mathcal{O}_{s,w}]_0 = C_s \tag{6.2}$$

and where we put $\mathcal{T}^w_{\text{future}} = \{(w^N)^\top = e_N e_{N-1} \cdots e_1 \colon N = 0, 1, 2, \dots\} \subset \mathcal{T}_{\text{future}}$. For any $s \in S$, we define an associated observability operator $\mathcal{O}_s$ as the column matrix

$$\mathcal{O}_s = \operatorname*{col}_{v = e_N e_{N-1} \cdots e_1 \in \mathcal{T}_{\text{future}}} [C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N), \mathbf{s}(e_{N-1})} \cdots A_{\mathbf{r}(e_1), s}] \colon \mathcal{H}_{[s]} \to \ell(\mathcal{T}_{\text{future}}, \mathcal{Y}), \tag{6.3}$$

with again the interpretation (6.2) for the case $v = \emptyset$ column entry. Finally, for path-connected component $p \in P$ we define an associated observability operator $\mathcal{O}_p$ by

$$\mathcal{O}_p = \operatorname*{col}_{s \in S \colon [s] = p} \mathcal{O}_s \colon \mathcal{H}_p \to \operatorname*{col}_{s \in S \colon [s] = p} \ell(\mathcal{T}_{\text{future}}, \mathcal{Y}). \tag{6.4}$$

Clearly, for each infinite word $w \in \mathcal{F}_E^{\infty_R}$, index $s \in S$, and path-connected component $p \in P$ with $[s] = p$, we have the subspace inclusions

$$\ker \mathcal{O}_p \subset \ker \mathcal{O}_s \subset \ker \mathcal{O}_{s,w}. \tag{6.5}$$

For each of the cases $X = S \times \mathcal{F}_E^{\infty_R}$, $X = S$, and $X = P$, we have a notion of X-observability: Σ is X-observable if the operator $\mathcal{O}_x$ is injective for all $x \in X$. By the set of inclusions (6.5) we see that we have the chain of implications: $S \times \mathcal{F}_E^{\infty_R}$-observability implies S-observability, which in turn implies P-observability. Note that each of these observability notions has a system-theoretic interpretation, as follows:

1. $S \times \mathcal{F}_E^{\infty_R}$-observability means that, for each fixed infinite word $w \in \mathcal{F}_E^{\infty_R}$, an initial state $x_s \in \mathcal{H}_{[s]}$ is uniquely determined from the observations $y((w^N)^\top)$ (for $N = 0, 1, 2, \dots$) obtained by letting the system drift with initial condition $x_s(\emptyset) = x_s$ and $x_{s'}(\emptyset) = 0$ for $s' \neq s$ and with zero input string $u(w) = 0$ for all $w \in \mathcal{F}_E$.

2. S-observability means again that, for each $s \in S$, one can detect an initial state $x_s \in \mathcal{H}_{[s]}$ by the same experiment, but with additional observations, namely $y(v)$ for all $v \in \mathcal{F}_E$.

3. P-observability means again that one can detect an initial state $x_p \in \mathcal{H}_p$ but one must do the experiment described above for S-observability with initial condition $x_s(\emptyset) = x_p$ and $x_{s'}(\emptyset) = 0$ for $s' \neq s$ for each $s \in S$ with $[s] = p$.

For our notion of observability here, we take the weakest of these notions and make the following definition.

DEFINITION 6.1. *We say that the SNMLS* $\Sigma = (G, \mathcal{H}, U)$ *is* structured-observable *(or simply* observable*) if the operator* $\mathcal{O}_p \colon \mathcal{H}_p \to col_{s \in S \colon [s] = p} \ell(\mathcal{T}_{future}, \mathcal{Y})$ *given by* (6.4) *is injective for each* $p \in P$.

7. Kalman decomposition. In this section we obtain a Kalman-type decomposition for SNMLSs; for a good summary of these results for the classical case, we refer to [16].

Let $\Sigma = (G, \mathcal{H}, U)$ be an SNMLS as in Definition 3.7. For each $p \in P$ (the set of path-connected components of the admissible graph G), we let $\mathcal{C}_p$ be the controllability operator defined by (5.7) and $\mathcal{O}_p$ be the observability operator defined by (6.4).[3] From

[3] As it is only the images $\operatorname{im} \mathcal{C}_p$ of the controllability operators $\mathcal{C}_p$ which enter in here, by Remark 5.1 without loss of generality one can in all the discussion below replace $\mathcal{C}_p$ with $\mathcal{C}_{s_p}$ for any fixed choice of $s_p \in S$ with $[s_p] = p$.

the definitions we see that

$$A_{r,s}\colon \operatorname{im}\mathcal{C}_{[s]} \to \operatorname{im}\mathcal{C}_{[r]}, \tag{7.1}$$

$$A_{r,s}\colon \ker\mathcal{O}_{[s]} \to \ker\mathcal{O}_{[r]}, \tag{7.2}$$

$$\ker\mathcal{O}_{[s]} \subset \ker C_s, \tag{7.3}$$

$$\operatorname{im} B_r \subset \operatorname{im}\mathcal{C}_{[r]} \tag{7.4}$$

for all $r \in R$ and $s \in S$. We introduce a direct-sum decomposition

$$\mathcal{H}_p = \mathcal{H}_{p,c/o} \oplus \mathcal{H}_{p,c/no} \oplus \mathcal{H}_{p,nc/o} \oplus \mathcal{H}_{p,nc/no} \tag{7.5}$$

according to the following recipe:

1. Set $\mathcal{H}_{p,c/no} = \operatorname{im}\mathcal{C}_p \cap \ker\mathcal{O}_p$.
2. Choose $\mathcal{H}_{p,c/o}$ so that $\mathcal{H}_{p,c/no} \oplus \mathcal{H}_{p,c/o} = \operatorname{im}\mathcal{C}_p$.
3. Choose $\mathcal{H}_{p,nc/no}$ such that $\mathcal{H}_{p,c/no} \oplus \mathcal{H}_{p,nc/no} = \ker\mathcal{O}_p$.
4. Choose $\mathcal{H}_{p,nc/o}$ such that $\mathcal{H}_p = \mathcal{H}_{p,c/o} \oplus \mathcal{H}_{p,c/no} \oplus \mathcal{H}_{p,nc/o} \oplus \mathcal{H}_{p,nc/no}$.

Fix an $r \in R$ and an $s \in S$. Note that $A_{r,s}\colon \mathcal{H}_{[s]} \to \mathcal{H}_{[r]}$, $B_r\colon \mathcal{U} \to \mathcal{H}_{[r]}$, and $C_s\colon \mathcal{H}_{[s]} \to \mathcal{Y}$, while $\mathcal{H}_{[s]}$, and $\mathcal{H}_{[r]}$ have the direct-sum decompositions

$$\begin{aligned}\mathcal{H}_{[s]} &= \mathcal{H}_{[s],c/o} \oplus \mathcal{H}_{[s],c/no} \oplus \mathcal{H}_{[s],nc/o} \oplus \mathcal{H}_{[s],nc/no},\\ \mathcal{H}_{[r]} &= \mathcal{H}_{[r],c/o} \oplus \mathcal{H}_{[r],c/no} \oplus \mathcal{H}_{[r],nc/o} \oplus \mathcal{H}_{[r],nc/no}.\end{aligned}$$

We may therefore represent $A_{r,s}$, B_r, and C_s as matrices with respect to these direct-sum decompositions of $\mathcal{H}_{[s]}$ and $\mathcal{H}_{[r]}$:

$$A_{r,s} = \begin{bmatrix} A_{r,s;c/o,c/o} & A_{r,s;c/o,c/no} & A_{r,s;c/o,nc/o} & A_{r,s;c/o,nc/no} \\ A_{r,s;c/no,c/o} & A_{r,s;c/no,c/no} & A_{r,s;c/no,nc/o} & A_{r,s;c/no,nc/no} \\ A_{r,s;nc/o,c/o} & A_{r,s;nc/o,c/no} & A_{r,s;nc/o,nc/o} & A_{r,s;nc/o,nc/no} \\ A_{r,s;nc/no,c/o} & A_{r,s;nc/no,c/no} & A_{r,s;nc/no,nc/o} & A_{r,s;nc/no,nc/no} \end{bmatrix},$$

$$B_r = \begin{bmatrix} B_{r,c/o} \\ B_{r,c/no} \\ B_{r,nc/o} \\ B_{r,nc/no} \end{bmatrix}, \qquad C_s = \begin{bmatrix} C_{s,c/o} & C_{s,c/no} & C_{s,nc/o} & C_{s,nc/no} \end{bmatrix}.$$

From (7.1) we see that

$$A_{r,s;nc/o,c/o} = 0, \quad A_{r,s;nc/o,c/no} = 0, \quad A_{r,s;nc/no,c/o} = 0, \quad A_{r,s;nc/no,c/no} = 0.$$

From (7.2) we see that

$$A_{r,s;c/o,c/no} = 0, \quad A_{r,s;c/o,nc/no} = 0, \quad A_{r,s;nc/o,c/no} = 0, \quad A_{r,s;nc/o,nc/no} = 0.$$

From (7.4) we see that

$$B_{r,nc/o} = 0, \qquad B_{r,nc/no} = 0.$$

From (7.3) we see that

$$C_{s,c/no} = 0, \qquad C_{s,nc/no} = 0.$$

We are therefore left with

$$A_{r,s} = \begin{bmatrix} A_{r,s;c/o,c/o} & 0 & A_{r,s;c/o,nc/o} & 0 \\ A_{r,s;c/no,c/o} & A_{r,s;c/no,c/no} & A_{r,s;c/no,nc/o} & A_{r,s;c/no,nc/no} \\ 0 & 0 & A_{r,s;nc/o,nc/o} & 0 \\ 0 & 0 & A_{r,s;nc/no,nc/o} & A_{r,s;nc/no,nc/no} \end{bmatrix},$$

$$B_r = \begin{bmatrix} B_{r,c/o} \\ B_{r,c/no} \\ 0 \\ 0 \end{bmatrix}, \qquad C_s = \begin{bmatrix} C_{s,c/o} & 0 & C_{s,nc/o} & 0 \end{bmatrix}. \tag{7.6}$$

This analysis leads us to the following result.

THEOREM 7.1. *Let $\Sigma = (G, \mathcal{H}, U)$ be an SNMLS. Decompose each $\mathcal{H}_p$ as in* (7.5) *with resulting decompositions* (7.6) *for the system matrices $A_{r,s}$, B_r, and C_s.*

(1) *Define a reduced SNMLS $\Sigma_{c/o} = (G, \mathcal{H}_{c/o}, U_{c/o})$ with auxiliary state-spaces $(\mathcal{H}_{c/o})_p = \mathcal{H}_{p,c/o}$ as in* (7.5) *and with connection matrix*

$$U_{c/o} = \begin{bmatrix} A_{c/o} & B_{c/o} \\ C_{c/o} & D_{c/o} \end{bmatrix} : \begin{bmatrix} \oplus_{s\in S}\mathcal{H}_{[s],c/o} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r\in R}\mathcal{H}_{[r],c/o} \\ \mathcal{Y} \end{bmatrix}$$

given by

$$[A_{c/o}]_{r,s} = A_{r,s;c/o,c/o}, \quad [B_{c/o}]_r = B_{r,c/o}, \quad [C_{c/o}]_s = C_{s,c/o}, \quad D_{c/o} = D$$

determined as in (7.6). *Then the SNMLS $\Sigma_{c/o}$ is structured-controllable and structured-observable and has the same transfer function as Σ:*

$$D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B = D_{c/o} + C_{c/o}(I - Z_{\Sigma_{c/o}}(z)A_{c/o})^{-1}Z_{\Sigma_{c/o}}(z)B_{c/o}.$$

(2) *Define a reduced system $\Sigma_c = (G, \mathcal{H}_c, U_c)$ with auxiliary state-spaces*

$$(\mathcal{H}_c)_p = \mathcal{H}_{p,c/o} \oplus \mathcal{H}_{p,c/no}$$

with components determined as in (7.5) *and with connection matrix*

$$U_c = \begin{bmatrix} A_c & B_c \\ C_c & D_c \end{bmatrix} : \begin{bmatrix} \oplus_{s\in S}\mathcal{H}_{[s],c} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r\in R}\mathcal{H}_{[r],c} \\ \mathcal{Y} \end{bmatrix}$$

given by

$$[A_c]_{r,s} = \begin{bmatrix} A_{r,s;c/o,c/o} & 0 \\ A_{r,s;c/no,c/o} & A_{r,s;c/no,c/no} \end{bmatrix}, \qquad [B_c]_r = \begin{bmatrix} B_{r,c/o} \\ B_{r,c/no} \end{bmatrix},$$
$$[C_c]_s = \begin{bmatrix} C_{s,c/o} & 0 \end{bmatrix}, \qquad D_c = D,$$

with matrix entries determined as in (7.6). *Then the SNMLS Σ_c is structured-controllable and has the same transfer function as Σ:*

$$D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B = D_c + C_c(I - Z_{\Sigma_c}(z)A_c)^{-1}Z_{\Sigma_c}(z)B_c.$$

(3) *Define a reduced system $\Sigma_o = (G, \mathcal{H}_o, U_o)$ with auxiliary state-spaces $(\mathcal{H}_o)_p = \mathcal{H}_{p,c/o} \oplus \mathcal{H}_{p,nc/o}$ with components determined as in* (7.5) *and with connection matrix*

$$U_o = \begin{bmatrix} A_o & B_o \\ C_o & D_o \end{bmatrix} : \begin{bmatrix} \oplus_{s\in S}\mathcal{H}_{[s],o} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r\in R}\mathcal{H}_{[r],o} \\ \mathcal{Y} \end{bmatrix}$$

given by

$$[A_o]_{r,s} = \begin{bmatrix} A_{r,s;c/o,c/o} & A_{r,s;c/o,nc/o} \\ 0 & A_{r,s;nc/o,nc/o} \end{bmatrix}, \qquad [B_o]_r = \begin{bmatrix} B_{r,c/o} \\ 0 \end{bmatrix},$$
$$[C_o]_s = \begin{bmatrix} C_{s,c/o} & C_{s,nc/o} \end{bmatrix}, \qquad D_o = D,$$

with matrix entries determined as in (7.6). *Then the SNMLS* Σ_o *is structured-observable and has the same transfer function as* Σ*:*

$$D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B = D_o + C_o(I - Z_{\Sigma_o}(z)A_o)^{-1}Z_{\Sigma_o}(z)B_o.$$

8. State-space similarity theorem. We begin with a definition.

DEFINITION 8.1. *Given two SNMLSs* $\Sigma = (G, \mathcal{H}, U)$ *and* $\Sigma' = (G, \mathcal{H}', U')$ *with a common structure graph* G *and with common input- and output-spaces, so that*

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} : \begin{bmatrix} \oplus_{s\in S}\mathcal{H}_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r\in R}\mathcal{H}_{[r]} \\ \mathcal{Y} \end{bmatrix},$$
$$U' = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} : \begin{bmatrix} \oplus_{s\in S}\mathcal{H}'_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r\in R}\mathcal{H}'_{[r]} \\ \mathcal{Y} \end{bmatrix},$$

we say that Σ *and* Σ' *are* similar *(via a state-space similarity) if there is a collection* $\Gamma = \{\Gamma_p : p \in P\}$ *of bijective linear operators* $\Gamma_p : \mathcal{H}_p \to \mathcal{H}'_p$ *(for each path-connected component* p *of* G*) such that*

$$\begin{bmatrix} (\oplus_{r\in R}\Gamma_{[r]}) & 0 \\ 0 & I_{\mathcal{Y}} \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} A' & B' \\ C' & D' \end{bmatrix} \begin{bmatrix} (\oplus_{s\in S}\Gamma_{[s]}) & 0 \\ 0 & I_{\mathcal{U}} \end{bmatrix}. \tag{8.1}$$

It is an easy computation to see that two systems Σ and Σ' have the same transfer functions if they are similar. On the other hand, Theorem 7.1 is not true in general, since an SNMLS Σ which is not already structured-controllable and structured-observable cannot be similar to its structured-controllable/structured-observable part, as in this case necessarily $\dim \mathcal{H}_{p,c/o} < \dim \mathcal{H}_p$ for some p. The next theorem gives the converse under a controllability/observability hypothesis.

THEOREM 8.2. *Suppose that* $\Sigma = (G, \mathcal{H}, U)$ *and* $\Sigma' = (G, \mathcal{H}', U')$ *are two SNMLSs with a common structure graph* G *and common input- and output-spaces* $\mathcal{U}$ *and* $\mathcal{Y}$*. Assume that both* Σ *and* Σ' *are structured-controllable and structured-observable. Then* Σ *and* Σ' *are similar; i.e., there are bijective linear maps* $\Gamma_p : \mathcal{H}_p \to \mathcal{H}'_p$ *for each path-connected component* p *of* G *such that* (8.1) *holds if and only if* Σ *and* Σ' *have the same transfer function*

$$T_\Sigma(z) = T_{\Sigma'}(z).$$

Moreover, in this situation the collection of state-space similarity operators

$$\Gamma_p : \mathcal{H}_{[p]} \to \mathcal{H}'_{[p]}$$

implementing the similarity between Σ *and* Σ' *is unique.*

Proof. We have already observed that in general two systems which are similar have the same transfer function. It remains to show the following: *under the assumption that* Σ *and* Σ' *are structured-controllable and structured-observable, if*

$T_\Sigma(z) = T_{\Sigma'}(z)$, then Σ and Σ' are similar. From the expression (3.21) for the transfer function, we see that the hypothesis that $T_\Sigma(z) = T_{\Sigma'}(z)$ amounts to the assertion that

$$\begin{aligned} &C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} \\ &\quad = C'_{\mathbf{s}(e_N)} A'_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A'_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A'_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B'_{\mathbf{r}(e_1)} \end{aligned} \tag{8.2}$$

for all nonempty words $w = e_N e_{N-1} \cdots e_1 \in \mathcal{F}_E$, with the interpretation

$$C_{\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} = C'_{\mathbf{s}(e_1)} B'_{\mathbf{r}(e_1)} \tag{8.3}$$

in case $w = e_1$ has length 1 together with

$$D = D' \tag{8.4}$$

corresponding to the case $w = \emptyset$. Recalling the definitions (6.3) and (5.1), we see immediately from (8.2) and (8.3) that

$$[\mathcal{O}_s]_v \mathcal{C}_w = [\mathcal{O}'_s]_v \mathcal{C}'_w \tag{8.5}$$

whenever $s \in S$, $v \in \mathcal{T}_{\text{future}}$, and $w \in \mathcal{T}^s_{\text{past}}$. By the same type of argument as that appearing in Remark 5.1, in fact (8.5) holds for each $s \in S$, $v \in \mathcal{T}_{\text{future}}$, and $w \in \mathcal{T}^{s'}_{\text{past}}$ for any $s' \in S$ in the same path-connected component as s (i.e., with $[s'] = [s]$); indeed, if $w = ew' \in \mathcal{T}^s_{\text{past}}$, there is a unique adjustment $e' \in E$ of e so that $w' = e'w' \in \mathcal{T}^{s'}_{\text{past}}$, $\mathcal{C}_{w'} = \mathcal{C}_w$, and also $\mathcal{C}'_{w'} = \mathcal{C}'_w$. Hence the equality (8.5) with $w \in \mathcal{T}^s_{\text{past}}$ implies the equality (8.5) with $w \in \mathcal{T}^{s'}_{\text{past}}$ for any s' with $[s'] = [s]$ as well.

We attempt to define $\Gamma_p \colon \mathcal{H}_p \to \mathcal{H}'_p$ by

$$\Gamma_p \colon \Psi_w u \mapsto \Psi'_w u \quad \text{for } u \in \mathcal{U} \text{ and } w \in \mathcal{F}_E \text{ with } [\mathbf{r}(LL[w])] = s_p, \tag{8.6}$$

where Ψ_w and Ψ'_w are given by (5.1) and where $s_p \in S$ is any choice of source vertex with $[s_p] = p$. Note that a consequence of Remark 5.1 is that we can always adjust $LL[w]$ to achieve $\mathbf{s}(LL[w]) = s_p$ (for any fixed choice of $s_p \in S$ with $[s_p] = p$) without affecting $\operatorname{im} \Psi_w$ and $\operatorname{im} \Psi'_w$. Explicitly, we have

$$\begin{aligned} \Gamma_p \colon\ & A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} u \\ &\mapsto A'_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A'_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A'_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B'_{\mathbf{r}(e_1)} u, \end{aligned} \tag{8.7}$$

where $w = e_N e_{N-1} \cdots e_1 \in \mathcal{F}_E$ and where e_N is normalized so that $\mathbf{s}(e_N) = s_p$ with the interpretation

$$\Gamma_p \colon B_{\mathbf{r}(e_1)} u \mapsto B'_{\mathbf{r}(e_1)} u \tag{8.8}$$

in case $w = e_1$ (with $\mathbf{s}(e_1) = s_p$) has length 1. We then extend Γ_p to

$$\mathcal{D}_{s_p} = \operatorname{span}\{\Psi_w u \colon w \in \mathcal{T}^{s_p}_{\text{future}} \text{ with } \mathbf{s}(LL[w]) = s_p,\ u \in \mathcal{U}\} \tag{8.9}$$

by linearity, where we set

$$\mathcal{T}^{s_p}_{\text{future}} = \{w \in \mathcal{F}_E \setminus \{\emptyset\} \colon \mathbf{s}(LL[w]) = s_p\}.$$

We first wish to check that Γ_p is well defined. We must therefore show the following: *given a map $w \mapsto u_w$ from $\mathcal{T}^{s_p}_{future}$ to $\mathcal{U}$ with finite support (so $u_w = 0$ for*

all but finitely many words $w \in \mathcal{T}_{\text{future}}^{s_p}$) *such that* $\sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi_w u_w = 0$, *it follows that* $\sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi'_w u_w = 0$. Since $\sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi_w u_w = 0$, we then also have

$$\mathcal{O}_p \cdot \sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi_w u_w = 0. \tag{8.10}$$

From the definition of $\mathcal{O}_p$, equation (8.10) in turn means that

$$\mathcal{O}_s \cdot \sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi_w u_w = 0 \quad \text{for each } s \in S \text{ with } [s] = p. \tag{8.11}$$

From the extended domain of validity of (8.5) explained above, (8.11) immediately implies

$$\mathcal{O}'_s \cdot \sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi'_w u_w = \quad \text{for each } s \in S \text{ with } [s] = p. \tag{8.12}$$

By the assumption that Σ' is structured-observable, we know that $\mathcal{O}'_p$ is injective. Hence we see from (8.12) that

$$\sum_{w\in\mathcal{T}_{\text{future}}^{s_p}} \Psi'_w u_w = 0.$$

We conclude that Γ_p is well-defined on its domain $\mathcal{D}_{s_p}$ (see (8.9)), as wanted.

Since Σ by hypothesis is structured-controllable, we see that in fact $\mathcal{D}_{s_p} = \mathcal{H}_p$, and hence Γ_p is defined on all of $\mathcal{H}_p$. Similarly, since Σ' is structured-controllable, we see that $\Gamma_p(\mathcal{H}_p)$ is equal to all of $\mathcal{H}'_p$, i.e., that Γ_p is surjective.

It remains to see that Γ_p is injective; i.e., *given a map* $w \mapsto u_w$ *from* $\mathcal{T}_{future}^{s_p}$ *to* $\mathcal{U}$ *with finite support such that* $\sum_{w\in\mathcal{T}_{future}^{s_p}} \Psi'_w u_w = 0$, *it follows that* $\sum_{w\in\mathcal{T}_{future}^{s_p}} \Psi_w u_w = 0$. This follows by the same argument as in the proof that Γ_p is well defined, with the roles of Σ and Σ' interchanged. We conclude that (8.6) extends by linearity to define a bijective linear transformation from $\mathcal{H}_p$ onto $\mathcal{H}'_p$.

It remains now only to check that $\Gamma = \{\Gamma_p \colon p \in P\}$ satisfies (8.1). This amounts to verifying

$$\Gamma_{[r]} A_{r,s} = A'_{r,s} \Gamma_{[s]}, \tag{8.13}$$

$$\Gamma_{[r]} B_r = B'_r, \tag{8.14}$$

$$C_s = C'_s \Gamma_{[s]}, \tag{8.15}$$

$$D = D'. \tag{8.16}$$

Note that (8.16) follows immediately from (8.4), while (8.14) follows from (8.8). By the structured-controllability hypothesis on Σ, to show (8.13) and (8.15) it suffices to show

$$\begin{aligned} &\Gamma_{[r]} A_{r,s} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} \\ &\quad = A'_{r,s} \Gamma_{[s]} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)}, \end{aligned} \tag{8.17}$$

$$\begin{aligned} &C_s A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} \\ &\quad = C'_s \Gamma_{[s]} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} B_{\mathbf{r}(e_1)} \quad \text{if } [s] = [\mathbf{r}(e_N)] \end{aligned} \tag{8.18}$$

for all words $w = e_N e_{N-1} \cdots e_1 \in \mathcal{T}^{s_p}_{\text{future}}$ (with proper interpretation for $N = 1$) for each $p \in P$. Note that (8.17) is an immediate consequence of the definition (8.6) of Γ_p together with the completeness of the path-connected components of G, while (8.18) follows from the definition (8.6) combined with the completeness of the path-connected components of G and the equality of moments (8.2) and (8.3).

As for the last statement in Theorem 8.2, suppose that $\Gamma'_p \colon \mathcal{H}_p \to \mathcal{H}'_p$ is any other linear isomorphism between $\mathcal{H}_p$ and $\mathcal{H}'_p$ so that (8.1) is satisfied. Then a consequence of (8.1) is that necessarily Γ'_p must also satisfy (8.6) (with Γ'_p in place of Γ_p). By the first part of the proof, $\Gamma'_p = \Gamma_p$ for all $p \in P$, and the uniqueness assertion in Theorem 8.2 follows as well. This completes the proof of Theorem 8.2. ∎

9. Minimal state-space realizations. Suppose that we are given an admissible graph G together with a formal power series

$$T(z) = \sum_{w \in \mathcal{F}_E} T_w z^w$$

in the noncommuting variables $z = \{z_e \colon e \in E\}$ (where E is the edge set of G) with coefficients T_w in the space $\mathcal{L}(\mathcal{U}, \mathcal{Y})$ of linear operators between the (finite-dimensional) linear spaces $\mathcal{U}$ and $\mathcal{Y}$. We say that the SNMLS $\Sigma = (G, \mathcal{H}, U)$ (with structure graph equal to G) is a *G-structured realization* for $T(z)$ if $T(z)$ is equal to the transfer function of Σ, i.e., if

$$T_\emptyset = D, \qquad T_{e_N e_{N-1} \cdots e_1} = C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N), \mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}), \mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2), \mathbf{s}(e_1)} B_{\mathbf{r}(e_1)},$$

where the connection matrix U for Σ has the form

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} [A_{r,s}] & [B_r] \\ [C_s] & D \end{bmatrix} : \begin{bmatrix} \oplus_{s \in S} \mathcal{H}_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r \in R} \mathcal{H}_{[r]} \\ \mathcal{Y} \end{bmatrix}.$$

We say that the SNMLS Σ is a *structured-minimal realization* for $T(z)$ if $\dim \mathcal{H}'_p \geq \dim \mathcal{H}_p$ for each path-connected component p of G whenever $\Sigma' = (G, \mathcal{H}', U')$ is another G-structured realization for $T(z)$. The following theorem establishes the equivalence of structured-minimality with simultaneous structured-controllability and structured-observability for G-structured realizations of a given formal power series $T(z)$.

THEOREM 9.1. *Suppose that $\Sigma = (G, \mathcal{H}, U)$ is a G-structured realization for the formal power series $T(z) = \sum_{w \in \mathcal{F}_E} T_w z^w$. Then Σ is a G-structured minimal realization for $T(z)$ if and only if Σ is both structured-controllable and structured-observable (with structure graph G).*

Proof. Suppose first that $\Sigma = (G, \mathcal{H}, U)$ is a structured-controllable and structured-observable realization of $T(z)$ and that $\Sigma' = (G, \mathcal{H}', U')$ is another structured realization of $T(z)$ (with the same structure graph G). By part (1) of Theorem 7.1, we may cut the realization Σ' down to a structured-controllable and structured-observable realization $\Sigma'_{c/o} = (G, \mathcal{H}'_{c/o}, U'_{c/o})$ for $T(z)$; as part of the construction we have $\dim \mathcal{H}'_p \geq \dim \mathcal{H}'_{p,c/o}$ for each $p \in P$. We now have that $\Sigma = (G, \mathcal{H}, U)$ and $\Sigma'_{c/o} = (G, \mathcal{H}'_{c/o}, U'_{c/o})$ are both structured-controllable and structured-observable realizations of the same formal power series $T(z)$. By the state-space-similarity theorem (Theorem 8.2), it follows that Σ and $\Sigma'_{c/o}$ are similarvia a state-space similarity

$\Gamma = \{\Gamma_p \colon \mathcal{H}_p \to \mathcal{H}'_{p,c/o} \colon p \in P\}$. In particular,

$$\dim \mathcal{H}_p = \dim \mathcal{H}'_{p,c/o} \le \dim \mathcal{H}'_p.$$

As Σ' was any other G-structured realization of $T(z)$, it follows that Σ is a G-structured minimal realization, as wanted.

Conversely, suppose that Σ is G-structured minimal. By part (1) of Theorem 7.1, we may cut Σ down to a structured-controllable and structured-observable realization $\Sigma_{c/o} = (G, \mathcal{H}_{c/o}, U_{c/o})$ of the same formal power series $T(z)$. By the construction in Theorem 7.1, $\mathcal{H}_{p,c/o} \subset \mathcal{H}_p$. On the other hand, by the assumption that Σ is G-structured minimal, we must also have $\dim \mathcal{H}_p \le \dim \mathcal{H}_{p,c/o}$, and hence we must have the equality $\mathcal{H}_p = \mathcal{H}_{p,c/o}$ for each $p \in P$. From the construction in Theorem 7.1, this means that the realization Σ is itself structured-controllable and structured-observable. This completes the proof of Theorem 9.1. ∎

10. Hankel operators. The notion of a Hankel operator $\mathbb{H}$ for a classical (1-D) linear system is the map which maps a past input sequence to the future output sequence, under the assumptions that the state has been initialized to be zero at $-\infty$ (roughly speaking) and that the future input string is set equal to zero. Since the controllability operator $\mathcal{C}$ maps the past history to the state at time zero, also under the assumption that the state has been initialized to be zero at $-\infty$, while the observability operator $\mathcal{O}$ maps a given state at time 0 into the future output sequence (under the assumption that the future input string is set equal to zero), we see immediately from the definitions that the Hankel operator $\mathbb{H}$ has the factorization $\mathbb{H} = \mathcal{O} \cdot \mathcal{C}$. For the case of SNMLSs, we have three notions ($\mathcal{C}_w$ for $w \in \mathcal{F}_E^{\infty_R}$, $\mathcal{C}_s$ for $s \in S$, and $\mathcal{C}_p$ for $p \in P$) of controllability operators which map some version of the past ($\mathcal{T}^w_{\text{past}}$, $\mathcal{T}^s_{\text{past}}$, or $\mathcal{T}^p_{\text{past}}$) to a state at the "present" position $\emptyset$, and three notions of observability operator ($\mathcal{O}_{s,w}$, $\mathcal{O}_s$, and $\mathcal{O}_p$ for $(s,w) \in S \times \mathcal{F}_E^{\infty_R}$, $s \in S$, and $p \in P$) mapping some state at the present position $\emptyset$ to outputs supported on some version of the future ($\mathcal{T}^w_{\text{future}}$, $\mathcal{T}_{\text{future}}$, or $\cup_{s\colon [s]=p} \mathcal{T}_{\text{future}}$. Thus a priori we have nine distinct possible notions of a Hankel operator. However, for purposes of the realization theory to be presented in section 11 below, only some of these are of interest for our purposes here, so we focus on them.

Let $\Sigma = (G, \mathcal{H}, U)$ be an SNMLS as in Definition 3.7. In this section we shall fix a cross section $p \mapsto s_p \in S$ of the map $[\cdot]\colon S \to P$ mapping a source vertex s to its associated path-connected component $[s] \in P$; i.e., for each $p \in P$, we let s_p be a fixed choice of element of S such that $[s_p] = p$. Consider any past input string $\{u(v)\}_{v \in \mathcal{T}^{s_p}_{\text{past}}}$. Run the system with this input string $u(w)$ for $w \in \mathcal{T}^{s_p}_{\text{past}}$ and with the state initialized to be zero in the distant past to generate a state $x(\emptyset)$ with s_pth component x_{s_p} equal to, say, $x_p \in \mathcal{H}_p$. For each $s \in S$ with $[s] = p$, we next run the system with zero inputs $u(w)$ for $w \in \mathcal{T}_{\text{future}}$ and with initial condition $x_s(\emptyset) = x_p$, $x_{s'}(\emptyset) = 0$ for $s' \ne s$. The result is an output sequence $\{y_s(w)\}_{w \in \mathcal{T}_{\text{future}}}$. The resulting composite map defined as taking the input string $\{u(v)\}_{v \in \mathcal{T}^{s_p}_{\text{past}}}$ to the output string $\{y_s(w)\}_{s\colon [s]=p; w \in \mathcal{T}_{\text{future}}}$ we define to be the Hankel operator $\mathbb{H}^p$:

$$\mathbb{H}^p = \mathcal{O}_p \mathcal{C}_{s_p} \colon \ell_{\text{fin}}(\mathcal{T}^{s_p}_{\text{past}}, \mathcal{U}) \to \oplus_{s\colon [s]=p} \ell(\mathcal{T}_{\text{future}}, \mathcal{Y}). \tag{10.1}$$

Explicitly, $\mathbb{H}^p$ is given as a bi-infinite matrix $[\mathbb{H}^p_{(s,w),v}]$ with rows indexed by pairs (s,w) with $s \in S$ with $[s] = p$ and with $w \in \mathcal{T}_{\text{future}}$, and with columns indexed by words $v \in \mathcal{T}^{s_p}_{\text{past}}$. In terms of the connecting operator U for Σ, the matrix entries are

given explicitly as

$$\begin{aligned}\mathbb{H}^p_{(s,w),w'} &= C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} \\ &\qquad \cdot A_{\mathbf{r}(e_1),s} A_{\mathbf{r}(e'_{N'}),\mathbf{s}(e'_{N'-1})} A_{\mathbf{r}(e'_{N'-1}),\mathbf{s}(e'_{N'-2})} \cdots A_{\mathbf{r}(e'_2),\mathbf{s}(e'_1)} B_{\mathbf{s}(e'_1)} \\ &= C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} A_{\mathbf{r}(e_1),s} \Psi_{w'} \qquad (10.2)\end{aligned}$$

if $w = e_N e_{N-1} \cdots e_2 e_1$ and $w' = e'_{N'} e'_{N'-1} \cdots e'_2 e'_1$, where $e'_{N'}$ is constrained to satisfy $\mathbf{s}(e'_{N'}) = s_p$ and where we use (5.1) to define $\Psi_{w'}$. (We leave it to the reader to give the appropriate interpretations for these formulas in case $N = 1$ and/or $N' = 0$.) As explained in the context of Remark 5.1, if we replace w' by w'' of the form

$$w'' = e_{s,\mathbf{r}(e'_{N'})} e'_{N'-1} \cdots e'_2 e'_1$$

for any s with $[s] = [\mathbf{s}(e'_{N'})] = [\mathbf{r}(e'_{N'})]$, then $\Psi_{w''} = \Psi_{w'}$. Since $v \in \mathcal{T}^{s_p}_{\text{past}}$, where $[s_p] = p$, we may therefore rewrite the Hankel matrix entry as a moment of the transfer function $T_\Sigma(z) = \sum_{w \in \mathcal{F}_E} T_w z^w$, namely,

$$\begin{aligned}\mathbb{H}^p_{(s,w),v} &= C_{\mathbf{s}(e_N)} A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})} A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})} \cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)} \\ &\qquad \cdot A_{\mathbf{r}(e_1),\mathbf{s}(e_{s,\mathbf{r}(e'_{N'})})} A_{\mathbf{r}(e_{s,\mathbf{r}(e'_{N'})}),\mathbf{s}(e'_{N'-1})} A_{\mathbf{r}(e'_{N'-1}),\mathbf{s}(e'_{N'-2})} \cdots A_{\mathbf{r}(e'_2),\mathbf{s}(e'_1)} B_{\mathbf{s}(e'_1)} \\ &= T_{e_N e_{N-1} \cdots e_1 e_{s,\mathbf{r}(e'_{N'})} e'_{N'-1} \cdots e'_2 e'_1}, \qquad (10.3)\end{aligned}$$

or, more compactly,

$$\mathbb{H}^p_{(s,w),ev'} = T_{w e_{s,\mathbf{r}(e)} v'} \qquad (10.4)$$

for $s \in S$, $w \in \mathcal{T}_{\text{future}}$, and ev' (with $e \in E$ with $\mathbf{s}(e) = s_p$ and $v' \in \mathcal{F}_E$) the generic form of an element in $\mathcal{T}^{s_p}_{\text{past}}$.

From the factorization (10.1) and the definitions, it is easy to see the following result; we shall obtain a converse in section 11 below.

THEOREM 10.1. *Suppose that the SNMLS Σ (see Definition 3.7) is structured-controllable and structured-observable. Then the dimension of the auxiliary state-space $\mathcal{H}_p$ (for a given path-connected component $p \in P$ of the structure graph) is given by*

$$\dim \mathcal{H}_p = \operatorname{rank} \mathbb{H}^p.$$

Proof. By definition, $\mathcal{C}_{s_p}$ is a surjective map to $\mathcal{H}_p$ if Σ is structured-controllable, and $\mathcal{O}_p$ is an injective map if Σ is structured-observable. Hence the result is immediate from the factorization (10.1). ∎

COROLLARY 10.2. *If $T(z)$ is the transfer function of an SNMLS Σ having structure graph G, then, for each path-connected component $p \in P$, the Hankel operator $\mathbb{H}^p$ formed from G and $T(z)$ according to the formula* (10.4) *has finite rank.*

We shall obtain a converse of Corollary 10.2 in section 11 below.

11. Realization theory for structured noncommutative linear systems. Suppose that we are given an admissible graph G together with a formal power series $T(z) = \sum_{v \in \mathcal{F}_E} T_v z^v$ in noncommuting variables $z = (z_e : e \in E)$ indexed by the edge set E of G and with coefficients T_v equal to linear operators between the finite-dimensional linear spaces $\mathcal{U}$ and $\mathcal{Y}$. The realization problem associated with the data set $\mathbb{D} := (G, T(z))$ then is the following: *construct a finite-dimensional SNMLS $\Sigma = (G, \mathcal{H}, U)$ having G as its structure graph and $T(z)$ as its transfer function.*

A necessary condition for the problem to have a solution was formulated in Corollary 10.2. The content of the following theorem is the converse. We shall need the following conventions. Let G be an admissible graph. As in section 10, we assume that we have specified a cross section $p \mapsto s_p$ of the map $[\cdot]\colon S \to P$, so $s_p \in S$ with $[s_p] = p$ for each $p \in P$. For $v \in \mathcal{T}^s_{\rm past}$ (where $\mathcal{T}^s_{\rm past}$ is defined as in (5.6)), we let δ_v be the Kronecker delta function on $\mathcal{T}^s_{\rm past}$:

$$\delta_v(v') = \begin{cases} 1 & \text{if } v' = v, \\ 0 & \text{if } v' \neq v, \end{cases} \qquad \text{for } v' \in \mathcal{T}^s_{\rm past}.$$

Then $\{\delta_v u\colon v \in \mathcal{T}^s_{\rm past},\, u \in \mathcal{U}\}$ is a spanning set for the linear space $\ell_{\rm fin}(\mathcal{T}^s_{\rm past}, \mathcal{U})$. Recall the notation $e_{s,r}$ as in (3.1) for the unique edge connecting $s \in S$ to $r \in R$, defined whenever $[s] = [r]$, and the notation $w^{\wedge s}$ introduced in (5.8).

THEOREM 11.1. *Suppose that we are given the data set $\mathbb{D} = (G, T(z))$ for a realization problem as above. For each path-connected component $p \in P$ of G, associate the Hankel matrix $\mathbb{H}^p$ as in* (10.4). *Then the realization problem for the data set $\mathbb{D}$ is solvable if and only if*

$$\operatorname{rank} \mathbb{H}^p < \infty \quad \textit{for each } p \in P. \tag{11.1}$$

When the condition (11.1) *holds, a structured-minimal realization of $T(z)$ can be constructed as follows.*

For each $p \in P$, let $\mathcal{H}_p$ be the linear space

$$\mathcal{H}_p = \ell_{fin}(\mathcal{T}^{s_p}_{past}, \mathcal{U}) / \ker \mathbb{H}^p, \tag{11.2}$$

and set $\mathcal{H}$ equal to the collection

$$\mathcal{H} = \{\mathcal{H}_p\colon p \in P\}.$$

For each source vertex $s \in S$ and range vertex $r \in R$ of G, define linear operators $A_{r,s}\colon \mathcal{H}_{[s]} \to \mathcal{H}_{[r]}$, $B\colon \mathcal{U} \to \mathcal{H}_{[r]}$, $C_s\colon \mathcal{H}_{[s]} \to \mathcal{Y}$, and $D\colon \mathcal{U} \to \mathcal{Y}$ by

$$A_{r,s}\colon \left[\{u(v)\}_{v \in \mathcal{T}^{s_{[s]}}_{past}}\right]_{\mathcal{H}_{[s]}} \mapsto \left[\{u'(v)\}_{v \in \mathcal{T}^{s_{[r]}}_{past}}\right]_{\mathcal{H}_{[r]}}, \ \textit{where}$$

$$u'(v) = \begin{cases} u((v')^{\wedge s_{[s]}}) & \textit{if } v \textit{ has the form } v = e_{s_{[r]},r} v' \textit{ with } v' \in \mathcal{T}^s_{past}, \\ 0 & \textit{otherwise,} \end{cases}$$

$$B_r\colon u \mapsto [\delta_{e_{s_{[r]},r}} u]_{\mathcal{H}_{[r]}},$$

$$C_s\colon \left[\{u(v)\}_{v \in \mathcal{T}^{s_{[s]}}_{past}}\right]_{\mathcal{H}_{[s]}} \mapsto \mathbb{H}^{[s]}_{(s,\emptyset),\cdot}\left(\{u(v)\}_{v \in \mathcal{T}^{s_{[s]}}_{past}}\right)$$

$$= \sum_{v \in \mathcal{T}^{s_{[s]}}_{past}} T_{v^{\wedge s}} u(v),$$

$$D = T_\emptyset. \tag{11.3}$$

Use (11.3) *to define a connection matrix U by*

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} [A_{r,s}] & [B_r] \\ [C_s] & D \end{bmatrix} : \begin{bmatrix} \oplus_{s \in S} \mathcal{H}_{[s]} \\ \mathcal{U} \end{bmatrix} \to \begin{bmatrix} \oplus_{r \in R} \mathcal{H}_{[r]} \\ \mathcal{Y} \end{bmatrix}.$$

Then the collection $\Sigma = (G, \mathcal{H}, U)$ is a structured-minimal SNMLS with structure graph G having $T(z)$ as its transfer function.

Proof. We have already observed in Corollary 10.2 the necessity of the condition (11.1) for the realization problem to have a solution. It remains to prove the sufficiency. This follows if we can verify that the formulas (11.2) and (11.3) provide a structured-minimal realization of $T(z)$ (with structure matrix G).

As a preliminary step, we note that the formula for $A_{r,s}$ in (11.3) when specialized to elements of $\mathcal{H}_{[s]}$ of the form $[\delta_v u]_{\mathcal{H}_{[s]}}$ (where $v \in \mathcal{T}_{\text{past}}^{s_{[s]}}$) assumes the form

$$A_{r,s}\colon [\delta_v u]_{\mathcal{H}_{[s]}} \mapsto [\delta_{e_{s_{[r]},r}(v^{\wedge s})}]_{\mathcal{H}_{[r]}}. \tag{11.4}$$

Note also that the set $\{[\delta_v u]_{\mathcal{H}_{[s]}}\colon v \in \mathcal{T}_{\text{past}}^{s_{[s]}},\ u \in \mathcal{U}\}$ is a spanning set for $\mathcal{H}_{s_{[s]}}$ since $\{\delta_v u\colon v \in \mathcal{T}_{\text{past}}^{s_{[s]}},\ u \in \mathcal{U}\}$ is a spanning set for $\ell_{\text{fin}}(\mathcal{T}_{\text{past}}^{s_{[s]}}, \mathcal{U})$. Similarly, the action of C_s in (11.3) on delta functions can be written as

$$C_s\colon [\delta_v u]_{\mathcal{H}_{[s]}} \mapsto T_{v^{\wedge s}} u \quad \text{for } v \in \mathcal{T}_{\text{past}}^{s_{[s]}}. \tag{11.5}$$

The verification proceeds via a number of steps.

Step 1: *Verification that $A_{r,s}$ is well defined.* Suppose that $\{u(v)\}_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}}$ represents the zero element of $\mathcal{H}_{[s]}$; thus $\mathbb{H}^{[s]}(\{u(v)\}_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}}) = 0$. Explicitly, this means

$$\sum_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}} T_{wv^{\wedge s'}} u(v) = 0 \quad \text{for all } w \in \mathcal{F}_E \text{ and } s' \in S \text{ with } [s'] = [s]. \tag{11.6}$$

View $\{u(v)\}_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}}$ as equal to $\sum_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}} \delta_v u(v)$, and use the formula (11.4) combined with linearity: the result is

$$A_{r,s}\colon \sum_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}} \delta_v u(v) \mapsto \sum_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}} \delta_{e_{s_{[r]},r} v^{\wedge s}} u(v) \in \ell(\mathcal{T}_{\text{past}}^{s_{[r]}}, \mathcal{U}).$$

For the right-hand side of this formula to represent the zero element of $\mathcal{H}_{[r]}$ we need to have $\mathbb{H}^{[r]}(\sum_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}} \delta_{e_{s_{[r]},r} v^{\wedge s}} u(v)) = 0$, which is to say

$$\sum_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}} T_{w'(e_{s_{[r]},r} v^{\wedge s})^{\wedge s''}} u(v) = 0 \quad \text{for all } w' \in \mathcal{F}_E, s'' \in S \text{ with } [s''] = [r]. \tag{11.7}$$

However, it is easily verified that

$$(e_{s_{[r]},r} v^{\wedge s})^{\wedge s''} = e_{s'',r} v^{\wedge s}.$$

Hence the condition (11.7) amounts to the known condition (11.6) for the special case $w = w' e_{s'',r}$ and $s' = s$. We conclude that the formula for $A_{r,s}$ in (11.3), or equivalently the formula (11.4) for $A_{r,s}$ on a spanning subset of $\mathcal{H}_{[r]}$, is well defined.

Step 2: *Verification that C_s is well defined.* We again suppose that $\{u(v)\}_{v \in \mathcal{T}_{\text{past}}^{s_{[s]}}}$ represents the zero element of $\mathcal{H}_{[s]}$, i.e., that (11.6) holds. Then $C_s(\{u(v)\}_{v \in \mathcal{T}_{\text{past}}^{[s]}})$ by definition is the left-hand side of (11.6) for the special case $w = \emptyset$ and $s' = s$. Hence C_s is well defined, as wanted.

Step 3: *Verification that* $T_\Sigma(z) = T(z)$. Let $e \in E$ be an edge of G. Use the formula for B_r in (11.3) and the formula (11.5) for the action of C_s on delta functions to compute

$$\begin{aligned} C_{\mathbf{s}(e)}B_{\mathbf{r}(e)}u &= C_{\mathbf{s}(e)}\left(\left[\delta_{e_{s_{[\mathbf{r}(e)]},\mathbf{r}(e)}}u\right]_{\mathcal{H}_{[\mathbf{r}(e)]}}\right) = T_{(e_{s_{[\mathbf{r}(e)]},\mathbf{r}(e)})^{\wedge\mathbf{s}(e)}u} \\ &= T_e u, \end{aligned} \tag{11.8}$$

where the equality $(e_{s_{[\mathbf{r}(e)]},\mathbf{r}(e)})^{\wedge\mathbf{s}(e)} = e_{\mathbf{s}(e),\mathbf{r}(e)} = e$ follows from the uniqueness condition (3) in the admissibility conditions (see Definition 3.1) for the graph G. Similarly, by using the formula for B_r in (11.3) combined with (11.4), a straightforward induction argument gives that, for any word $w = e_N e_{N-1}\cdots e_2 e_1$ of length at least 2,

$$A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})}\cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)}B_{\mathbf{r}(e_1)}u = \left[\delta_{w^{\wedge s_{[\mathbf{r}(e_N)]}}}u\right]_{\mathcal{H}_{[\mathbf{r}(e_N)]}}. \tag{11.9}$$

From the uniqueness axiom in Definition 3.1 we have

$$(w^{\wedge[\mathbf{r}(e_N)]})^{\wedge\mathbf{s}(e_N)} = w \quad \text{if } e_N = LL[w]. \tag{11.10}$$

Applying the formula (11.5) to (11.9) and using (11.10), we get

$$\begin{aligned} &C_{\mathbf{s}(e_N)}A_{\mathbf{r}(e_N),\mathbf{s}(e_{N-1})}A_{\mathbf{r}(e_{N-1}),\mathbf{s}(e_{N-2})}\cdots A_{\mathbf{r}(e_2),\mathbf{s}(e_1)}B_{\mathbf{r}(e_1)}u = T_{(w^{\wedge[\mathbf{r}(e_N)]})^{\wedge\mathbf{s}(e_N)}u} \\ &= T_w u \text{ for } w = e_N e_{N-1}\cdots e_2 e_1. \end{aligned} \tag{11.11}$$

Combining (11.8) and (11) with the definition $D = T_\emptyset$ in (11.3), we see that $T_\Sigma(z) = T(z)$, as wanted.

Step 4: *Verification that* Σ *is structured-controllable.* By formula (11.9) we have

$$\Psi_w u = [\delta_w u]_{\mathcal{H}_p} \quad \text{for } w \in \mathcal{T}_{\text{past}}^{s_p} \text{ and } u \in \mathcal{U}.$$

As the set $\{[\delta_w u]_{\mathcal{H}_p} : w \in \mathcal{T}_{\text{past}}^{s_p} \text{ and } u \in \mathcal{U}\}$ is spanning for the space

$$\mathcal{H}_p = \ell_{\text{fin}}(\mathcal{T}_{\text{past}}^{s_p}, \mathcal{U})/\ker \mathbb{H}^p,$$

we conclude that Σ is structured-controllable, as wanted.

Step 5: *Verification that* Σ *is structured-observable.* From the various definitions it is easy to verify that

$$\mathcal{O}_s\left(\left[\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_{[s]}}}\right]_{\mathcal{H}_{[s]}}\right) = \mathbb{H}^{[s]}_{(s,\cdot),\cdot}\left(\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_{[s]}}}\right) \in \ell(\mathcal{T}_{\text{future}}, \mathcal{Y})$$

for each source vertex $s \in S$. Since, by definition, $\mathcal{O}_p = \text{col}_{s:\,[s]=p}\,\mathcal{O}_s$ for each $p \in P$, we can then make the identification

$$\mathcal{O}_p\left(\left[\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_p}}\right]_{\mathcal{H}_p}\right) = \mathbb{H}^p\left(\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_p}}\right) \in \oplus_{s:\,[s]=p}\ell(\mathcal{T}_{\text{future}}, \mathcal{Y}).$$

In this way we see that $[\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_p}}]_{\mathcal{H}_p} \in \ker \mathcal{O}_p$ if and only if $\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_p}} \in \ker \mathbb{H}^p$, i.e., if and only if $[\{u(v)\}_{v\in\mathcal{T}_{\text{past}}^{s_p}}]_{\mathcal{H}_p}$ is the zero equivalence class in $\mathcal{H}_p$. We conclude that Σ is structured-observable as wanted, and the proof of Theorem 11.1 is now complete. ∎

We now consider the situation where the formal power series $T(z) = \sum_{v \in \mathcal{F}_d} T_v z^v$ is given but the admissible graph G is not specified. By comparing the various Hankel operators involved, we have the following result.

THEOREM 11.2. *Suppose that we are given the formal power series in the d noncommuting variables $z = (z_1, \dots, z_d)$, and let G and G' be two admissible graphs with edge sets E and E' of the same cardinality. Then $T(z)$ has a G-structured realization $\Sigma = \{G, \mathcal{H}, U\}$ if and only if $T(z)$ has a G'-structured realization $\Sigma' = \{G', \mathcal{H}', U'\}$.*

Proof. Let G be any admissible graph with edge set E labeled as $E = \{1, \dots, d\}$, and let G^{FM} be the Fornasini–Marchesini admissible graph with source-vertex set $S = \{1\}$, range-vertex set $R = \{1, \dots, d\}$, and edge set $E = \{1, \dots, d\}$, with $\mathbf{s}(j) = 1$ and $\mathbf{r}(j) = j$ for $j = 1, \dots, d$. We show that $T(z)$ has a G-structured realization $\Sigma = (G, \mathcal{H}, U)$ if and only if $T(z)$ has a G^{FM}-structured realization $\Sigma^{FM} = (G^{FM}, \mathcal{H}^{FM}, U^{FM})$. For s in S define the Hankel operator $\mathbb{H}^s \colon \ell_{\mathrm{fin}}(\mathcal{T}^s_{\mathrm{past}}, \mathcal{U}) \to \ell(\mathcal{T}_{\mathrm{future}}, \mathcal{Y})$ by

$$\mathbb{H}^s \colon \{u(v)\}_{v \in \mathcal{T}^s_{\mathrm{past}}} \mapsto \mathbb{H}^{[s]}_{(s,\cdot),\cdot} \left(\{u(v^{\wedge s})\}_{v \in \mathcal{T}^{s_{[s]}}_{\mathrm{past}}} \right).$$

As the map $v \mapsto v^{s_{[s]}}$ is a bijection between $\mathcal{T}^s_{\mathrm{past}}$ and $\mathcal{T}^{s_{[s]}}_{\mathrm{past}}$, we see that $\mathbb{H}^s$ is similar to $\mathbb{H}^{[s]}_{(s,\cdot),\cdot}$. By definition,

$$\mathbb{H}^p = \mathrm{col}_{s \colon [s]=p} \left[\mathbb{H}^p_{(s,\cdot),\cdot} \right]$$

from which we get the estimates

$$\max_{s \colon [s]=p} \operatorname{rank} \mathbb{H}^p_{(s,\cdot),\cdot} \le \operatorname{rank} \mathbb{H}^p \le \sum_{s \colon [s]=p} \operatorname{rank} \mathbb{H}^p_{(s,\cdot),\cdot}. \tag{11.12}$$

As we observed above that $\mathbb{H}^s$ and $\mathbb{H}^{[s]}_{(s,\cdot),\cdot}$ have the same rank, we can rewrite (11.12) as

$$\max_{s \colon [s]=p} \operatorname{rank} \mathbb{H}^s \le \operatorname{rank} \mathbb{H}^p \le \sum_{s \colon [s]=p} \operatorname{rank} \mathbb{H}^s. \tag{11.13}$$

From the characterization (10.4) of $\mathbb{H}^p$ we see that

$$\mathbb{H}^{FM} = \mathrm{col}_{p \in P} \, \mathrm{col}_{s \colon [s]=p} [\mathbb{H}^s] = \mathrm{col}_{s \in S} [\mathbb{H}^s]. \tag{11.14}$$

By combining (10.4) with the estimates (11.13), we see that $\mathbb{H}^{FM}$ has finite rank if and only if $\mathbb{H}^p$ has finite rank for each $p \in P$.

Now suppose that G and G' are two admissible graphs with the same edge set E and that $T(z)$ is a given formal power series in the noncommuting variables $z = (z_e \colon e \in E)$. By the first part of the proof, realizability of $T(z)$ as the transfer function of an SNMLS with structure graph G and realizability of $T(z)$ as the transfer function of an SNMLS with structure graph G' are each equivalent to realizability of $T(z)$ as the transfer function of a noncommutative Fornasini–Marchesini system with structure graph G^{FM} having edge set E. Hence G-realizability and G'-realizability are equivalent to each other. This completes the proof of Theorem 11.2. ∎

12. Recognizable and rational formal power series. Formal power series in noncommuting variables of the form arising here have come up in the theory of formal languages as studied in computer science [15]. For the sake of concreteness we index the noncommuting variables simply by $\{1,\dots,d\}$ and work with the semigroup $\mathcal{F}_d$ generated by the concrete set of letters $\{1,\dots,d\}$, as was done in sections 2.1 and 2.2 in the setting of noncommutative Fornasini–Marchesini and Givone–Roesser systems. We specialize the discussion in [15] to the setting here, where we take the scalars to be the field $\mathbb{C}$ of complex numbers rather than a general semiring, i.e., a "ring without subtraction." A formal power series $\sum_{v\in\mathcal{F}_d} T_v z^v$ (with coefficients T_v equal to linear operators acting between the finite-dimensional linear spaces $\mathcal{U}$ and $\mathcal{Y}$) is said to be *recognizable* if there are finite-dimensional linear space $\mathcal{H}$ and operators $A_1,\dots,A_d\colon \mathcal{H}\to\mathcal{H}$, $B\colon \mathcal{U}\to\mathcal{H}$, and $C\colon \mathcal{H}\to\mathcal{Y}$ such that

$$T_v = CA^vB \quad \text{for } v\in\mathcal{F}_d.$$

In terms of the linear systems discussed here, one can view a recognizable series $T(z)=\sum_{v\in\mathcal{F}_d}(CA^vB)z^v$ as the transfer function of a noncommutative Fornasini–Marchesini system

$$\Sigma^{FM}\colon \begin{cases} x(jw) &= A_jx(w)+B_ju(w) \quad \text{for } j=1,\dots,d,\\ y(w) &= Cx(w)+Du(w), \end{cases}$$

with the special structure that

$$B_j =: B \text{ is independent of } j \text{ and } D=CB.$$

More economical is to consider the recognizable series as the transfer function of a system of the form

$$\Sigma^{\mathrm{rec}}\colon \begin{cases} x(1w) &= A_1x(w)+Bu(1w),\\ &\vdots\\ x(dw) &= A_dx(w)+Bu(dw),\\ y(w) &= Cx(w). \end{cases} \tag{12.1}$$

One can check that application of the formal noncommutative Z-transform (2.2) to the system equations Σ^{rec} yields the frequency-domain formulas

$$\begin{aligned} \widehat{x}(z) &= (I-Z_{\mathrm{row}}(z)A)^{-1}(x(\emptyset)-Bu(\emptyset))+(I-Z_{\mathrm{row}}(z)A)^{-1}B\widehat{u}(z),\\ \widehat{y}(z) &= C(I-Z_{\mathrm{row}}(z)A)^{-1}(x(\emptyset)-Bu(\emptyset))+T_{\Sigma^{\mathrm{rec}}}(z)\cdot\widehat{u}(z), \end{aligned} \tag{12.2}$$

where the *transfer function* $T_{\Sigma^{\mathrm{rec}}}(z)$ for the recognizable system Σ^{rec} given by

$$T_{\Sigma^{\mathrm{rec}}}(z)=\sum_{v\in\mathcal{F}_d} CA^vBz^v \tag{12.3}$$

has the form of a recognizable formal series. In particular, if the initial condition is given by the input-injection $x(\emptyset)=Bu(\emptyset)$, then multiplication by the transfer function $T_{\Sigma^{\mathrm{rec}}}(z)$ provides the input-output map in the frequency domain $\widehat{y}(z)=T_{\Sigma^{\mathrm{rec}}}(z)\widehat{u}(z)$.

All the results in sections 5, 6, 8, and 11 (notions of controllability and observability, equivalence of controllability and observability with minimality, state-space similarity theorem, realization theorem) have parallels for the case of recognizable

systems in place of general SNMLSs; in fact, as surveyed nicely in Chapters 1 and 2 of [15], all these results, with the exception of the identification of a recognizable series $T(z) = \sum_{v \in \mathcal{F}_d} (CA^v B) z^v$ as the transfer function of a noncommutative linear system of the form (12.1), already appear in the literature—even in the more general setting where the scalars are taken to be a general semiring rather than the field $\mathbb{C}$ of complex numbers as is done here (see [37, 38, 17, 39, 20, 21, 22, 23]). We now survey these results from our system-theoretic perspective.

To obtain a physical interpretation for the recognizable controllability operator $\mathcal{C}^{\mathrm{rec}}$ introduced below, it is natural to define the backward system equations giving the evolution on the past $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}} = \mathcal{F}_d$ to be

$$\Sigma^{\mathrm{rec}}_{\mathrm{backward}}\colon \begin{cases} x(w) &= \sum_{i=1}^{d} A_i x(wi) + Bu(w), \\ y(w) &= Cx(w). \end{cases} \tag{12.4}$$

If we run the backward system equations on the past and present $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}} := \mathcal{F}_d$ with the state initialized to be zero sufficiently far in the past and with an input string $\{u(w)\}_{w \in \mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}}$ with finite support on $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}$ to compute the state $x(\emptyset)$ at location $\emptyset$, the result is

$$x(\emptyset) = \mathcal{C}^{\mathrm{rec}}(\{u(w)\}_{w \in \mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}}),$$

where the *recognizable controllability operator* $\mathcal{C}^{\mathrm{rec}}$ is given by

$$\mathcal{C}^{\mathrm{rec}} = \mathrm{row}_{w \in \mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}} A^w B, \tag{12.5}$$

where we set $A^w = A_{i_N} A_{i_{N-1}} \cdots A_{i_1}$ if $w = i_N i_{N-1} \cdots i_1 \in \mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}$ (with $A^{\emptyset} = I_{\mathcal{H}}$). Note that this controllability operator has close to the same form as the Fornasini–Marchesini controllability operator $\mathcal{C}^{FM}$ (2.6); the difference is that a recognizable system has only one input operator B and that the columns of $\mathcal{C}^{\mathrm{rec}}$ are indexed by $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}$ which includes the empty word, with $[\mathcal{C}^{\mathrm{rec}}]_{\emptyset} = B$.

We say that the system Σ^{rec} is *recognizable-controllable* if the image $\operatorname{im} \mathcal{C}^{\mathrm{rec}}$ of the recognizable-controllability operator $\mathcal{C}^{\mathrm{rec}}$ is the whole state-space $\mathcal{H}$.

The observability operator $\mathcal{O}^{\mathrm{rec}}\colon \mathcal{H} \to \ell(\mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}, \mathcal{Y})$ produces the future output $\{y(v)\}_{v \in \mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}}$ generated by the system for a given prescribed initial condition $x(\emptyset) \in \mathcal{H}$ under the assumption that the zero input string $\{u(v)\}_{v \in \mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}}$ is fed into the system; explicitly, we have[4]

$$\mathcal{O}^{\mathrm{rec}} = \operatorname*{row}_{v \in \mathcal{F}_d} CA^v. \tag{12.6}$$

Note that $\mathcal{O}^{\mathrm{rec}}$ has exactly the same form as the Fornasini–Marchesini observability operator $\mathcal{O}^{FM}$ from (2.7). We say that the system Σ^{rec} is *recognizable-observable* if the recognizable-observability operator $\mathcal{O}^{\mathrm{rec}}$ is injective on $\mathcal{H}$.

We can now obtain a *recognizable Kalman decomposition* of the state-space $\mathcal{H}$,

$$\mathcal{H} = \mathcal{H}_{c/o} \oplus \mathcal{H}_{c/no} \oplus \mathcal{H}_{nc/o} \oplus \mathcal{H}_{nc/no},$$

[4]Here $\mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}$ is taken to be $\mathcal{F}_d$; the location $\emptyset$ in $\mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}$ is identified with the location $\emptyset$ in $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}$ (i.e., both $\mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}$ and $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}$ contain the "present"), but a given nonempty word w as an element of the future $\mathcal{T}^{\mathrm{rec}}_{\mathrm{future}}$ is to be considered distinct from the same word w considered as an element of the past $\mathcal{T}^{\mathrm{rec}}_{\mathrm{past}}$.

by the same recipe used in section 7 (by using $\mathcal{C}^{\rm rec}$ in place of $\mathcal{C}_{s_p}$ and $\mathcal{O}^{\rm rec}$ in place of $\mathcal{O}_p$). We then obtain the decompositions

$$A_j = \begin{bmatrix} A_{j;c/o,c/o} & 0 & A_{j;c/o,nc/o} & 0 \\ A_{j;c/no,c/o} & A_{j;c/no,c/no} & A_{j;c/no,nc/o} & A_{j;c/no,nc/no} \\ 0 & 0 & A_{j;nc/o,nc/o} & 0 \\ 0 & 0 & A_{j;nc/no,nc/o} & A_{j;nc/no,nc/no} \end{bmatrix},$$

$$B = \begin{bmatrix} B_{c/o} \\ B_{c/no} \\ 0 \\ 0 \end{bmatrix}, \qquad C = \begin{bmatrix} C_{c/o} & 0 & C_{nc/o} & 0 \end{bmatrix} \tag{12.7}$$

for the system matrices $A_1, \dots, A_d, B, C$ of $\Sigma^{\rm rec}$. It is then easily verified that the reduced recognizable system $\Sigma^{\rm rec}_{c/o}$ with system matrices

$$A_{1;c/o,c/o}, \dots, A_{d;c/o,c/o}, B_{c/o}, C_{c/o}$$

is both recognizable-controllable and recognizable-observable and produces the same transfer function: $T_{\Sigma^{\rm rec}}(z) = T_{\Sigma^{\rm rec}_{c/o}}(z)$. Given two recognizable systems $\Sigma^{\rm rec}$ with system matrices $A_1, \dots, A_d, B, C$ and $\Sigma^{\rm rec\prime}$ with system matrices $A'_1, \dots, A'_d, B', C'$, let us say that $\Sigma^{\rm rec}$ and $\Sigma^{\rm rec\prime}$ are *recognizable-similar* if there is a bijective linear map $\Gamma\colon \mathcal{H} \to \mathcal{H}'$ so that $\Gamma A_j = A'_j \Gamma$ for $j = 1, \dots, d$, $\Gamma B = B'$, and $C' = C\Gamma$. Following the same argument as in section 8, we have the *state-space similarity theorem for recognizable systems*: *given two recognizable systems* $\Sigma^{rec} = (A_1 \dots, A_d, B, C)$ *and* $\Sigma^{rec\prime} = (A'_1, \dots, A'_d, B', C')$ *with the same input-space* $\mathcal{U}$ *and output-space* $\mathcal{Y}$*, which are both recognizable-controllable and recognizable-observable, then* Σ^{rec} *and* $\Sigma^{rec\prime}$ *have the same transfer function*

$$T_{\Sigma^{rec}}(z) = T_{\Sigma^{rec\prime}}(z)$$

if and only if Σ^{rec} *and* $\Sigma^{rec\prime}$ *are recognizable-similar.* Furthermore, one can say that the recognizable system $\Sigma^{\rm rec}$ with state-space $\mathcal{H}$ is a *recognizable-minimal realization* for its transfer function $T(z) = T_{\Sigma^{\rm rec}}(z)$ if, whenever $\Sigma^{\rm rec\prime}$ with state-space $\mathcal{H}'$ is any other recognizable realization for the same $T(z)$, then $\dim \mathcal{H} \le \dim \mathcal{H}'$. Following the same line of argument as in section 9, one can show the following: *the recognizable system* Σ^{rec} *is a recognizable-minimal realization of its transfer function* $T_{\Sigma^{rec}}(z)$ *if and only if* Σ^{rec} *is recognizable-controllable and recognizable-observable.*

We next define the *recognizable Hankel operator* by

$$\mathbb{H}^{\rm rec} = \mathcal{O}^{\rm rec} \cdot \mathcal{C}^{\rm rec}\colon \ell_{\rm fin}(\mathcal{T}^{\rm rec}_{\rm past}, \mathcal{U}) \to \ell(\mathcal{T}^{\rm rec}_{\rm future}, \mathcal{Y}). \tag{12.8}$$

The matrix entries of $\mathbb{H}^{\rm rec}$ are then given by

$$\mathbb{H}^{\rm rec}_{w,v} = CA^{wv}B \quad \text{for } w, v \in \mathcal{F}_d \tag{12.9}$$

or directly in terms of the Taylor coefficients of the transfer function $T_{\Sigma^{\rm rec}}(z) = \sum_{v \in \mathcal{F}_d} T_v z^v$ as

$$\mathbb{H}^{\rm rec}_{w,v} = T_{wv} \quad \text{for } w, v \in \mathcal{F}_d. \tag{12.10}$$

In the case that $\Sigma^{\rm rec}$ is both recognizable-controllable and recognizable-observable, we see from the factorization (12.8) that

$$\operatorname{rank} \mathbb{H}^{\rm rec} = \dim \mathcal{H}.$$

In particular, $\operatorname{rank}\mathbb{H}^{\mathrm{rec}} < \infty$, where we now use (12.10) to define $\mathbb{H}^{\mathrm{rec}}$ directly in terms of the formal power series $T(z) = \sum_{v\in\mathcal{F}_d} T_v z^v$, which is a necessary condition for $T(z)$ to have a recognizable realization $T(z) = \sum_{v\in\mathcal{F}_d}(CA^vB)z^v$. For the converse, we have the following realization theorem.

THEOREM 12.1. *Let the formal power series $T(z) = \sum_{v\in\mathcal{F}_d} T_v z^v$ in d noncommuting indeterminates $z = (z_1, \dots, z_d)$, with coefficients T_v equal to linear operators between the linear spaces $\mathcal{U}$ and $\mathcal{Y}$, be given. Then a necessary and sufficient condition for $T(z)$ to be recognizable, i.e., for the existence of a linear space $\mathcal{H}$ and operators $A_1, \dots, A_d$ on $\mathcal{H}$, $B\colon \mathcal{U} \to \mathcal{H}$, and $C\colon \mathcal{H} \to \mathcal{Y}$ with $T_v = CA^vB$ for $v \in \mathcal{F}_d$, is that*

$$\operatorname{rank}\mathbb{H}^{rec} < \infty. \tag{12.11}$$

When this holds, a recognizable-minimal realization $(A_1, \dots, A_d, B, C)$ can be constructed as follows: set

$$\mathcal{H} = \ell_{fin}(\mathcal{T}^{rec}_{past}, \mathcal{U})/\ker\mathbb{H}^{rec} \tag{12.12}$$

and define operators $A_j\colon \mathcal{H} \to \mathcal{H}$ (for $j = 1, \dots, d$), $B\colon \mathcal{U} \to \mathcal{H}$, and $C\colon \mathcal{H} \to \mathcal{Y}$:

$$A_j\colon [\delta_v]_{\mathcal{H}} \mapsto [\delta_{jv}]_{\mathcal{H}} \quad \text{for } v \in \mathcal{T}^{rec}_{past},$$

$$B\colon u \mapsto [\delta_\emptyset]_{\mathcal{H}}, \tag{12.13}$$

$$C\colon [\{u(v)\}_{v\in\mathcal{T}^{rec}_{past}}]_{\mathcal{H}} \mapsto \sum_{v\in\mathcal{T}^{rec}_{past}} T_v u(v). \tag{12.14}$$

Proof. The proof parallels the ideas in the proof of Theorem 11.1, so we omit the details. The result is also essentially contained in Theorem 1.5 of [15] (without any system-theoretic interpretation using the system equations (12.1) and (12.4)), where it is attributed to [17] and [20]. □

Note that the recognizable Hankel $\mathbb{H}^{\mathrm{rec}}$ is almost the same as the Fornasini–Marchesini Hankel $\mathbb{H}^{\mathrm{FM}}$; namely, we have

$$\mathbb{H}^{\mathrm{rec}} = \begin{bmatrix}\operatorname{col}_{v\in\mathcal{F}_d}[T_v] & \mathbb{H}^{FM}\end{bmatrix}. \tag{12.15}$$

In particular, we see that

$$\operatorname{rank}\mathbb{H}^{FM} \le \operatorname{rank}\mathbb{H}^{\mathrm{rec}} \le \dim\mathcal{U} + \operatorname{rank}\mathbb{H}^{FM},$$

and hence $\mathbb{H}^{\mathrm{FM}}$ has finite rank if and only if $\mathbb{H}^{\mathrm{rec}}$ has finite rank. Combining this observation with Theorems 12.1, 11.1, and 11.2, we arrive at the following result.

COROLLARY 12.2. *Let a formal power series $T(z) = \sum_{v\in\mathcal{F}_d} T_v z^v$ in d noncommuting variables $z = (z_1, \dots, z_d)$ and an admissible graph G with edge set E labeled as $E = \{1, \dots, d\}$ be given. Then T has a realization of the form $T(z) = D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B$ for an SNMLS $\Sigma = (G, \mathcal{H}, U)$ if and only if $T(z) = C(I - z_1A_1 - \cdots - z_dA_d)^{-1}B$ is recognizable.*

A related notion arising in the theory of formal languages, particularly in the work of Schützenberger, is that of rationality. We say that a formal power series $T(z) = \sum_{v\in\mathcal{F}_d} T_v z^v \in \mathbb{C}\langle\langle z\rangle\rangle$ in noncommuting variables $z = (z_1, \dots, z_d)$ with scalar coefficients $T_v \in \mathbb{C}$ is *rational* if it is in the smallest subalgebra of $\mathbb{C}\langle\langle z\rangle\rangle$ which contains the polynomials and is invariant under the operator $R(z) \mapsto R^*(z) = \sum_{n=0}^{\infty}(R(z))^n$ defined on proper formal power series $R(z) = \sum_{v\in\mathcal{F}_d\setminus\{\emptyset\}} R_v z^v$. The demand here that the constant term $R_\emptyset$ vanish guarantees that, for each word w, the w-coefficient

of $R(z)^n$ vanishes for all $n \geq N_w$ for some $N_w < \infty$, and hence that the infinite series expression for $R^*(z)$ is convergent in the topology of coefficientwise convergence. The $*$-operation also makes sense in the setting where the scalars are taken from a general semiring K; in case K is a field (as we assume), the $*$-operation $R(z) \mapsto R^*(z)$ can be identified as $R^*(z) = (I - R(z))^{-1}$. In case that $T(z) = \sum_{v \in \mathcal{F}_d} T_v z^v \in \mathcal{L}(\mathcal{U}, \mathcal{Y})\langle\langle z \rangle\rangle$ has coefficients T_v equal to operators between finite-dimensional linear spaces $\mathcal{U}$ and $\mathcal{Y}$, we say that $T(z)$ is rational if each of its matrix entries (with respect to some bases for $\mathcal{U}$ and $\mathcal{Y}$) is rational. In case $\mathcal{U} = \mathcal{Y}$ and $T_\emptyset = 0$, we can define

$$T^*(z) := \sum_{n=0}^{\infty} (T(z))^n = (I - T(z))^{-1} \tag{12.16}$$

just as in the scalar case. The following lemma assures us that $T^*(z)$ is again rational if $T(z)$ is rational. This result is actually a special case of Lemma I.6.3 in [15], but we include a proof for the sake of completeness.

LEMMA 12.3. *Suppose that $T(z) = [T_{ij}(z)]_{i,j=1}^N \in \mathcal{L}(\mathbb{C}^N)\langle\langle z \rangle\rangle$ is a formal power series in the noncommuting variables $z = (z_1, \ldots, z_d)$ with matrix entries $T_{ij}(z) \in \mathbb{C}\langle\langle z \rangle\rangle$ all rational such that $T_\emptyset = [T_{\emptyset,ij}]_{i,j=1}^N = 0$. Then all matrix entries of the formal power series $T^*(z)$ given by* (12.16) *are also rational.*

Proof. If $N = 1$, the result is clear. By induction we assume that the result is true for all $N < N_0$ and seek to prove the result for $N = N_0$. Given $T(z) \in \mathcal{L}(\mathbb{C}^{N_0})\langle\langle z \rangle\rangle$ with $T_\emptyset = 0$, consider a block decomposition of $T(z)$,

$$T(z) = \begin{bmatrix} a(z) & b(z) \\ c(z) & d(z) \end{bmatrix},$$

and a corresponding block decomposition of $T^*(z) = (I_{N_0} - T(z))^{-1}$,

$$(I_{N_0} - T(z))^{-1} = \begin{bmatrix} \alpha(z) & \beta(z) \\ \gamma(z) & \delta(z) \end{bmatrix},$$

where $a(z)$ and $\alpha(z)$ are both of size $K \times K$ for some K with $1 \leq K < N_0$. From the identity

$$(I_{N_0} - T(z))^{-1} = I_{N_0} + T(z)(I_{N_0} - T(z))^{-1}$$

we get the collection of identities

$$\begin{aligned} \alpha(z) &= I_K + a(z)\alpha(z) + b(z)\gamma(z), \\ \beta(z) &= a(z)\beta(z) + b(z)\delta(z), \\ \gamma(z) &= c(z)\alpha(z) + d(z)\gamma(z), \\ \delta(z) &= I_{N_0-K} + c(z)\beta(z) + d(z)\delta(z). \end{aligned} \tag{12.17}$$

We may then solve the second and third equations in (12.17) for $\beta(z)$ and $\gamma(z)$, respectively, to get

$$\beta(z) = (I_K - a(z))^{-1} b(z)\delta(z), \tag{12.18}$$

$$\gamma(z) = (I_{N_0-K} - d(z))^{-1} c(z)\alpha(z). \tag{12.19}$$

By the induction assumption we see immediately from (12.18) and (12.19) that $\beta(z)$ and $\gamma(z)$ are rational. Plugging back into the first and fourth identities in (12.17)

then gives

$$\alpha(z) = I_K + a(z)\alpha(z) + b(z)(I_{N_0-K} - d(z))^{-1}c(z)\alpha(z),$$
$$\delta(z) = I_{N_0-K} + c(z)(I_K - a(z))^{-1}b(z)\delta(z) + d(z)\delta(z).$$

We may then solve these equations for $\alpha(z)$ and $\delta(z)$ to get

$$\alpha(z) = \big(I_K - [a(z) + b(z)(I_{N_0-K} - d(z))^{-1}c(z)]\big)^{-1}, \tag{12.20}$$

$$\delta(z) = \big(I_{N_0-K} - [c(z)(I_K - a(z))^{-1}b(z) + d(z)]\big)^{-1}. \tag{12.21}$$

Again as a consequence of the induction assumption, (12.20) and (12.21) imply that $\alpha(z)$ and $\delta(z)$ are rational as well, and the lemma follows. □

The following characterization of rational formal power series can be seen as a corollary of the results of this paper.

COROLLARY 12.4. *Let a formal power series $T(z) = \sum_{v\in\mathcal{F}_d} T_v z^v$ in d noncommuting variables $z = (z_1, \dots, z_d)$ and an admissible graph G with edge set $E = \{1, \dots, d\}$ be given. Then the following are equivalent:*

1. *$T(z)$ is rational.*
2. *For each path-connected component p of G, the Hankel operator $\mathbb{H}^p$ given by (10.4) has finite rank.*
3. *$T(z)$ has a realization $T(z) = D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B$ for an SNMLS $\Sigma = (G, \mathcal{H}, U)$ having structure graph G.*

Proof. We first show that (1) $\Longrightarrow$ (3). Note first that any scalar constant D (considered as a formal power series in noncommuting variables $z = (z_1, \dots, z_d)$) is realizable (with zero auxiliary state-spaces $\mathcal{H}_p$).

We next note that any monomial z_e is realizable for each edge $e = 1, \dots, d$. Indeed, set $\mathcal{H}_{[\mathbf{s}(e)]} = \mathbb{C}$ and $\mathcal{H}_p = \{0\}$ for $p \neq [\mathbf{s}(e)]$ and set

$$A = [A_{r,s}]_{r\in R, s\in S} \quad \text{with } A_{r,s} = 0,$$
$$B = \mathrm{col}_{r\in R}[B_r] \quad \text{with } B_r = \begin{cases} 1 & \text{if } r = \mathbf{r}(e), \\ 0 & \text{otherwise,} \end{cases}$$
$$C = \mathrm{row}_{s\in S}[C_s] \quad \text{with } C_s = \begin{cases} 1 & \text{if } s = \mathbf{s}(e), \\ 0 & \text{otherwise,} \end{cases}$$
$$D = 0.$$

Then the associated transfer function is given by

$$\begin{aligned} T_\Sigma(z) &= D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B \\ &= 0 + CZ_\Sigma(z)B \\ &= \sum_{s\in S}\sum_{r\in R} C_s[Z_\Sigma(z)]_{s,r}B_r \\ &= \sum_{s\in S}\sum_{r\in R}\sum_{e'\in E} C_s I_{\Sigma,e';s,r}B_r z_{e'} \\ &= \sum_{e'\in E} C_{\mathbf{s}(e')}B_{\mathbf{r}(e')}z_{e'} \\ &= z_e. \end{aligned}$$

We conclude that each monomial z_e has a realization as asserted.

By Theorems 4.1, 4.2, and 4.3, products, sums, and inverses of invertible formal power series which are realizable (as the transfer function of an SNMLS Σ with structure graph G) are again realizable. By the inductive definition of rational formal power series given above, we may now conclude that any scalar rational formal power series $T(z)$ has the form of a transfer function $T(z) = T_\Sigma(z)$ for an SNMLS Σ with given admissible graph G as structure graph.

If each scalar entry $[T(z)]_{i,j}$ of a matrix of formal power series is realizable, it is easy to construct a realization (not necessarily minimal) for the formal power series $T(z)$ with matrix coefficients. This concludes the proof of (1) $\Longrightarrow$ (3).

We next verify (3) $\Longrightarrow$ (1). Assume that the formal power series $T(z)$ has a realization of the form $T(z) = D + C(I - Z_\Sigma(z)A)^{-1}Z_\Sigma(z)B$ for a finite-dimensional SNMLS $\Sigma = (G, \mathcal{H}, \left[\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right])$. By Lemma 12.3 it follows that $(I - Z_\Sigma(z)A)^{-1}$ is rational. As products and sums of rational matrix functions are rational, it then follows that $T(z)$ is rational, as wanted.

The equivalence of (2) and (3) is just a restatement of Theorem 11.1. ∎

Remark 12.5. We note that the equivalence (1) $\Longleftrightarrow$ (2) between rationality and finiteness of the rank of an associated Hankel operator is known as Kronecker's theorem in the classical case.

Remark 12.6. Combining (1) $\Longleftrightarrow$ (3) in Corollary 12.4 with Corollary 12.2, we see that a formal power series is recognizable if and only if it is rational; this result goes back to Schützenberger (see Theorem I.6.1 in [15]).

Remark 12.7. In [22] Fliess gives an alternative system interpretation of a recognizable formal power series in terms of a homogeneous bilinear system with evolution along the nonnegative integers $\mathbb{Z}_+$ but with state-update equation of the form

$$x(n+1) = \left[\sum_{j=0}^{d} u_j(n)A_j\right] x(n),$$

with $A_0, \ldots, A_d$ linear operators on the state-space $\mathcal{H}$ and with $u_0(n), \ldots, u_d(n)$ equal to $d+1$ scalar-valued controls. The input-output operator for the system is obtained as

$$(x_0, (u_0(n), \ldots, u_d(n))_{n\in\mathbb{Z}_+}) \mapsto T_\Sigma(u)x_0,$$

where $T_\Sigma(z)$ is the recognizable formal power series $T_\Sigma(z) = C(I - z_0A_0 - z_1A_1 - \cdots - z_dA_d)^{-1}$ and where $T_\Sigma(u)$ is defined via the substitution

$$z_{i_N} z_{i_{N-1}} \ldots z_{i_0} \mapsto u_{i_N}(N)u_{i_{N-1}}(N-1)\cdots u_{i_0}(0).$$

Multidimensional versions of such bilinear systems, including connections with formal power series in this more general setting, are given in [23]. Sontag [40] used a variation of Fliess's Hankel-matrix construction to solve the following related moment problem connected with an alternative formulation of a bilinear system realization problem: *given operators $T_w \in \mathcal{L}(\mathcal{U}, \mathcal{Y})$ for $w \in \mathcal{F}_E$ ($E = \{1, \ldots, d\}$), find operators $C_1, \ldots, C_d\colon \mathcal{H} \to \mathcal{Y}$, $A_1, \ldots, A_d\colon \mathcal{H} \to \mathcal{H}$, and $B_1, \ldots, B_d\colon \mathcal{U} \to \mathcal{H}$ so that $T_{i_N i_{N-1}\cdots i_2 i_1} = C_{i_N}A_{i_{N-1}}\cdots A_{i_1}B_{i_1}$.*

Our discussion here gives a linear (rather than bilinear) system interpretation for a formal power series, but with evolution along a free semigroup rather than along $\mathbb{Z}_+$ and with a somewhat contrived input-injection for the initial condition on the

state required to recover the precise form of a recognizable series. The awkwardness of these various system interpretations for a recognizable formal power series gives some explanation as to why system operations work out well for transfer functions of SNMLSs (see section 4) but not so well for recognizable series—a point discussed in [30].

Acknowledgments. We thank the referees for useful suggestions which led to improvements in the paper; in particular, the material of section 4 appears as a result of a suggestion of one of the referees.

OPTIMAL CONTROL UNDER A DYNAMIC FUEL CONSTRAINT*

PETER BANK†

Abstract. We present a new approach to solve optimal control problems of the monotone follower type. The key feature of our approach is that it allows us to include an arbitrary dynamic fuel constraint. Instead of dynamic programming, we use the convexity of our cost functional to derive a first order characterization of optimal policies based on the Snell envelope of the objective functional's gradient at the optimum. The optimal control policy is constructed explicitly in terms of the solution to a representation theorem for stochastic processes obtained in Bank and El Karoui (2004), *Ann. Probab.*, 32, pp. 1030–1067. As an illustration, we show how our methodology allows us to extend the scope of the explicit solutions obtained for the classical monotone follower problem and for an irreversible investment problem arising in economics.

Key words. monotone follower, Snell envelope, dynamic fuel constraint

DOI. 10.1137/040616966

Introduction. Many optimization problems involve so-called finite fuel constraints on the allowable control policies, i.e., upper bounds on the resources a control policy can use. The usual methodology to address these optimization problems is to specify a Markovian framework and to compute the problem's value function either by PDE methods based on the problem's Hamilton–Jacobi–Bellman equation or by probabilistic methods and the variational method of switching paths. In some special cases this leads to a more or less explicit solution to the optimization problem.

In any case, the constraint has so far only been specified by a *constant* upper bound for the overall amount of "fuel" a control policy is allowed to use. *Dynamic* upper bounds, by contrast, are difficult to take into account as their introduction increases the dimensionality of the problem, making it typically impossible to solve the Hamilton–Jacobi–Bellman equation explicitly. On the other hand, it is well known that in some problems the optimal policy for a (constant) finite fuel constraint can be derived from the optimal policy obtained when disregarding the fuel constraint completely: one just has to follow the unconstraint policy up to the moment when all fuel has been spent; see, e.g., Chow, Menaldi, and Robin (1985), Karatzas (1985), and Fleming and Soner (1993). It is thus natural to conjecture that a suitable variant of this principle should hold true for situations where a dynamic finite fuel constraint is specified by an increasing adapted process. The corroboration of this conjecture and the description of a general framework where it holds true constitute the main results of the present paper.

We consider a convex minimization problem in which a policy θ incurs the costs

$$C(\theta) = \mathbb{E}\int_0^\infty c(t,\theta_t)\,\mu(dt) + \mathbb{E}\int_0^\infty k_t\,d\theta_t \quad (\theta \in \mathscr{A})\,,$$

where $c(t,.)$ describes the (convex) running costs and k_t the control costs at time $t \geq 0$. Our approach is based on a characterization of optimal policies in terms of first order conditions. More specifically, Theorem 2.2 shows that an optimal control policy will exercise control whenever its impact is maximal as measured by the Snell envelope of the cost functional's subgradient at the optimum; it also shows that, actually, all available fuel should be spent whenever this Snell envelope tends to decrease. The occurrence of Snell envelopes in this characterization highlights the intimate relationship between singular control and optimal stopping problems which has already been observed in Karatzas and Shreve (1984, 1985) and El Karoui and Karatzas (1988, 1991).

The construction of an optimal policy is achieved in Theorem 3.1, which relates the dynamic finite fuel problem with a stochastic representation theorem obtained in Bank and El Karoui (2004). This representation theorem has found a number of other applications ranging from utility maximization to optimal stopping; we refer the reader to Bank and Föllmer (2003) for an overview. Here it provides us with a lower bound which the optimal control policy has to respect if enough fuel is available to do so. This lower bound turns out to be independent of the fuel constraint, thus providing a universal signal process which allows one to construct optimal policies for a whole class of finite fuel problem at the same time.

As an application we provide an explicit solution to the monotone follower problem for Lévy processes with quadratic cost functional in the spirit of Beneš, Shepp, and Witsenhausen (1980/81). We also illustrate how explicit solutions obtained for singular control problems without any fuel constraint, as obtained, e.g., in Kobila (1993), can actually be used to describe optimal policies for problems with a dynamic fuel constraint.

Notation and conventions. All (in)equalities between random variables are meant to hold true in the $\mathbb{P}$–a.s. sense. We shall let $\mathscr{T}$ denote the set of all stopping times, and we use $\mathscr{T}(I)$ to denote the class of stopping times almost surely taking values in a given random set I, such as, e.g., $I = [S, +\infty]$ with $S \in \mathscr{T}$. A supremum over an empty set is defined to be $\sup \varnothing \stackrel{\Delta}{=} -\infty$. Intervals $[a,b]$ with $b < a$ are interpreted as the empty set. We also put $x^+ \stackrel{\Delta}{=} x \vee 0 = \max\{x, 0\}$ and $x^- \stackrel{\Delta}{=} (-x)^+$.

1. The general control problem. A well-known problem in stochastic optimization is the problem of controlling the motion of a particle so as to keep it as close to the origin as possible over some period of time. In the formulation as a monotone follower problem suggested and analyzed by Karatzas and Shreve (1984), one considers a model where the dynamics of the uncontrolled particle is given by a standard Brownian motion W on the real line and where the control θ is an increasing adapted process θ which specifies the downward displacement of the particle caused by the control. Hence, in this case, the controlled particle would follow the dynamics $W_t - \theta_t$ $(t \geq 0)$. The cost incurred by a control policy θ can, for instance, be described as

$$C(\theta) = \mathbb{E} \int_0^\infty \delta e^{-\delta t} \frac{1}{2} \left(W_t - \theta_t\right)^2 \, dt,$$

and one could start studying the optimization problem to minimize C subject to, e.g., a finite fuel constraint on the control θ.

More generally, let $(\Omega, \mathscr{F}_\infty, (\mathscr{F}_t)_{t\geq 0}, \mathbb{P})$ be a filtered probability space satisfying the usual conditions of right-continuity and completeness. Controls θ are given by increasing, left-continuous adapted processes starting at $\theta_0 = \underline{\vartheta} \in \mathbb{R}$. We shall impose

a dynamic finite fuel constraint, specified by an increasing adapted process $\overline{\vartheta}$ with left-continuous paths and values in $[\underline{\vartheta}, +\infty]$. The class of admissible controls is therefore

$$\mathscr{A} \triangleq \{\theta \text{ incr., left-cont., adapted with } \underline{\vartheta} = \theta_0 \leq \theta_t \leq \overline{\vartheta}_t \text{ for all } t \geq 0 \ \mathbb{P}\text{–a.s.}\}\,.$$

REMARK 1.1. *Note that the lower bound $\underline{\vartheta}$ is assumed to be a real constant, not a process. Assuming a dynamic lower bound would mean that a minimum amount of control must have been exercised up to each point in time, a natural, yet much more demanding, extension which is beyond the scope of the present paper.*

The costs incurred by a control policy will be composed of running costs and control costs. The running costs are described by a measurable random field

$$c : \Omega \times [0, \infty) \times \mathbb{R} \to \mathbb{R}$$

and a positive optional random measure $\mu = \mu(\omega, dt)$ on the time axis satisfying the following convexity and regularity assumption.

ASSUMPTION 1.

(i) *The measure μ is atomless and has full support* $\operatorname{supp}\mu = [0, +\infty)$ *almost surely.*

(ii) *For any $(\omega, t) \in \Omega \times [0, +\infty)$, the mapping $\vartheta \mapsto c(\omega, t, \vartheta)$ is strictly convex with continuous derivative $c'(\omega, t, \vartheta) = \frac{\partial}{\partial \vartheta} c(\omega, t, \vartheta)$ increasing from $c'(\omega, t, -\infty) = -\infty$ to $c'(\omega, t, +\infty) = +\infty$.*

(iii) *For $\vartheta \in \mathbb{R}$ fixed, $(\omega, t) \mapsto c(\omega, t, \vartheta)$ is progressively measurable and $\mathbb{P} \otimes \mu$-integrable.*

(iv) *The process $(\omega, t) \mapsto \inf_{\vartheta \in [\underline{\vartheta}, \overline{\vartheta}_t(\omega)]} c(\omega, t, \vartheta)$ is $\mathbb{P} \otimes \mu$-integrable.*

The control costs are described by a stochastic process k with the following properties.

ASSUMPTION 2. *The process k is optional, of class (D), and continuous in expectation with $k_\infty = 0$. Moreover, the family of random variables $(\int_0^\infty k_t^-\, d\theta_t,\ \theta \in \mathscr{A})$ is bounded in $L^1(\mathbb{P})$.*

REMARK 1.2. *Recall that an optional process $k = (k_t)_{t \geq 0}$ is of class (D) if the family of random variables $(k_T,\ T \in \mathscr{T})$ is uniformly integrable. Such a process is continuous in expectation provided $\lim_n \mathbb{E}[k_{T_n}] = \mathbb{E}[k_T]$ for any monotone sequence of stopping times (T_n) with limit $T = \lim_n T_n$.*

These assumptions allow us to consider the cost functional

$$C(\theta) = \mathbb{E} \int_0^\infty c(t, \theta_t)\, \mu(dt) + \mathbb{E} \int_0^\infty k_t\, d\theta_t \quad (\theta \in \mathscr{A})\,.$$

The general optimization problem we shall be concerned with in this paper can now be stated as follows:

$$\text{Minimize } C(\theta) \text{ over } \theta \in \mathscr{A}\,. \tag{1}$$

REMARK 1.3.

(i) *Full support of μ ensures that strict convexity transfers from the random field c to our cost functional C. Our assumptions on the derivative of c will be used when applying a representation theorem obtained in Bank and El Karoui* (2004)*; see section* 3. *Integrability of $c(., \vartheta)$ for $\vartheta \in \mathbb{R}$ means that the decision not to intervene at all will not cause infinite costs. Integrability of $\inf_{\vartheta \in [\underline{\vartheta}, \overline{\vartheta}_\cdot]} c(., \vartheta)$ is assumed to ensure that our minimization problem* (1) *has a finite value. For the same reason we assume L^1-boundedness of*

($\int_0^\infty k_t^-\, d\theta_t,\ \theta \in \mathscr{A}$), *which amounts to requiring that the negative (!) "costs" of exercising control must not be "too large."*

(ii) *Observe that our introductory example would be accommodated in this setting by choosing*

$$c(\omega, t, \vartheta) \triangleq \frac{1}{2}\left(W_t(\omega) - \vartheta\right)^2, \quad \mu(dt) = \delta e^{-\delta t}\, dt \quad \textit{and} \quad k \equiv 0\,.$$

Observe furthermore that this setting can also accommodate the monotone follower problems studied in Chow, Menaldi, and Robin (1985)*, Karatzas* (1985)*, Karatzas and Shreve* (1984)*, as well as the irreversible investment problems solved in Kobila* (1993) *(see Criterion* (3.2) *and Condition* (5.1)*), Scheinkman and Zariphopoulou* (2001) *(see section* 4.2*), and Baldursson and Karatzas* (1997)*. Settings* not *covered by our framework include Chiarolla* (1997) *and Jacka* (1999, 2002) *since their cost functional is specified in terms of the controlled system instead of the cumulatively exercised control. We also do* not *cover the "cheap monotone follower" of Chiarolla and Haussmann* (1994) *as they allow for two-dimensional controls. Also uncovered remains the finite fuel problem of Beneš, Shepp, and Witsenhausen* (1980/81) *and Karatzas and Shreve* (1985)*, where two-sided controls are considered.*

2. First order conditions for optimality. In this section, we are going to provide a first order characterization of optimal control policies for problem (1). While the main avenue of approach to achieve this characterization is classical, we need to be a little bit careful to ensure that our Assumptions 1 and 2 suffice to deduce all the integrability requirements we need along the way.

Our first step is to note that the convex functional C is supported by the subgradients

$$\nabla C(\theta)_S \triangleq \mathbb{E}\left[\int_S^\infty c'(t, \theta_t)\, \mu(dt) \,\middle|\, \mathscr{F}_S\right] + k_S \quad (S \in \mathscr{T}) \tag{2}$$

in the following sense.

LEMMA 2.1. *For any $\theta \in \mathscr{A}$, the optional process $\nabla C(\theta)$ of* (2) *is well defined and $\nabla C(\theta)^-$ is $\mathbb{P}\otimes d\theta$-integrable. If also $\nabla C(\theta)^+$ is $\mathbb{P}\otimes d\theta$-integrable, then $C(\theta) < \infty$ and $\nabla C(\theta)$ satisfies the subgradient property*

$$C(\theta') - C(\theta) \geq \mathbb{E}\int_0^\infty \nabla C(\theta)_s\, d(\theta'_s - \theta_s) \quad \textit{for any} \quad \theta' \in \mathscr{A} \textit{ with } C(\theta') < +\infty\,.$$

Proof.

(i) As $c'(t, \theta_t) \geq c'(t, \underline{\vartheta}) \in L^1(\mathbb{P}\otimes\mu)$ by convexity and $\mathbb{P}\otimes\mu$-integrability of $c(t, \vartheta)$ for $\vartheta \in \mathbb{R}$, the conditional expectation appearing in (2) is well defined as a random variable taking values in $(-\infty, +\infty]$. As for $\mathbb{P}\otimes d\theta$-integrability of $\nabla C(\theta)^-$, we note that

$$c'(t, \theta_t)^-(\theta_t - \underline{\vartheta}) \leq c(t, \underline{\vartheta}) - \inf_{\vartheta \in [\underline{\vartheta}, \overline{\vartheta}_t]} c(t, \vartheta) \in L^1(\mathbb{P}\otimes\mu)$$

by Assumption 1(iii) and (iv), and this yields

$$\mathbb{E}\int_0^\infty \int_s^\infty c'(t, \theta_t)^-\, \mu(dt)\, d\theta_s = \mathbb{E}\int_0^\infty c'(t, \theta_t)^-(\theta_t - \underline{\vartheta})\, \mu(dt) < +\infty$$

by Fubini's theorem. By Assumption 2,

$$\mathbb{E}\int_0^\infty k_s^-\, d\theta_s < +\infty\,,$$

and it follows that

$$\nabla C(\theta)_s^- \le \mathbb{E}\left[\int_s^\infty c'(t,\theta_t)^-\,\mu(dt)\,\middle|\,\mathscr{F}_s\right] + k_s^-$$

is $\mathbb{P}\otimes d\theta_s$-integrable.

(ii) Let us now assume $\mathbb{P}\otimes d\theta$-integrability of $\nabla C(\theta)^+$ and show that both $\int_\cdot^\infty c'(t,\theta_t)^+\,\mu(dt)$ and k^+ inherit this integrability property. In addition, we shall see that $C(\theta)<\infty$.
To wit, note that in (i) we actually obtained $\int_\cdot^\infty c'(t,\theta)^-\,\mu(dt)\in L^1(\mathbb{P}\otimes d\theta)$ and that $k^-\in L^1(\mathbb{P}\otimes d\theta)$ by Assumption 2. So we can write

$$\mathbb{E}\left[\int_s^\infty c'(t,\theta_t)^+\,\mu(dt)\,\middle|\,\mathscr{F}_s\right] + k_s^+ = \nabla C(\theta)_s + \mathbb{E}\left[\int_s^\infty c'(t,\theta_t)^-\,\mu(dt)\,\middle|\,\mathscr{F}_s\right] + k_s^-$$

to deduce that also both summands on the left side are $\mathbb{P}\otimes d\theta$-integrable if, as we assume, $\nabla C(\theta)$ is.
To obtain $C(\theta)<\infty$, note that by convexity of $c(t,.)$ we have

$$c(t,\theta_t) \le c(t,\underline{\vartheta}) + c'(t,\theta_t)(\theta_t-\underline{\vartheta})\,.$$

By Assumption 1 the $c(t,\underline{\vartheta})$-term on the right side of the above estimate is $\mathbb{P}\otimes\mu$-integrable. Moreover, the $\mathbb{P}\otimes d\theta$-integrability of $\int_\cdot^\infty c'(t,\theta_t)^\pm\,\mu(dt)$ established before entails that also $c'(t,\theta_t)(\theta_t-\vartheta)$ is $\mathbb{P}\otimes\mu$-integrable by Fubini's theorem. Hence $c(t,\theta_t)^+\in L^1(\mathbb{P}\otimes\mu)$, which in conjunction with $k\in L^1(\mathbb{P}\otimes d\theta)$ yields $C(\theta)<\mathbb{R}$.

(iii) We finally can prove our subgradient estimate for θ' with $C(\theta')<+\infty$, assuming as in (ii) that $\nabla C(\theta)^+$ (and thus $\nabla C(\theta)$) is $\mathbb{P}\otimes d\theta$-integrable.
We start from the convexity estimate

$$(3)\quad c(t,\theta_t') - c(t,\theta_t) \ge c'(t,\theta_t)(\theta_t'-\theta_t) = c'(t,\theta_t)(\theta_t'-\underline{\vartheta}) - c'(t,\theta_t)(\theta_t-\underline{\vartheta})\,.$$

Since $C(\theta'), C(\theta)<\infty$, the cost process k is both $\mathbb{P}\otimes d\theta'$- and $\mathbb{P}\otimes d\theta$-integrable and the left side of (3) is $\mathbb{P}\otimes\mu$-integrable. In (ii) we have shown that also the last term in (3), $c'(t,\theta_t)(\theta_t-\underline{\vartheta})$, is $\mathbb{P}\otimes\mu$-integrable. It thus follows that the positive part of the remaining $c'(t,\theta_t)(\theta_t'-\underline{\vartheta})$-term on the right side of (3) is $\mathbb{P}\otimes\mu$-integrable or, equivalently by Fubini's theorem, that $\int_\cdot^\infty c'(t,\theta_t)^+\,\mu(dt)$ is $\mathbb{P}\otimes d\theta'$-integrable. As a consequence, the expectation

$$\mathbb{E}\int_0^\infty\left\{\int_s^\infty c'(t,\theta_t)\,\mu(dt)+k_s\right\}d(\theta_s'-\theta_s) = \mathbb{E}\int_0^\infty \nabla C(\theta)_s\,d(\theta_s'-\theta_s)\in[-\infty,+\infty)$$

is well defined and indeed not larger than $C(\theta')-C(\theta)$. □

Let us denote by $\mathbb{S}(\theta)$ the lower Snell envelope of $\nabla C(\theta)$ as follows:

$$\mathbb{S}(\theta)_S = \operatorname*{ess\,inf}_{T\in\mathscr{T}([S,\infty])} \mathbb{E}\left[\nabla C(\theta)_T \,|\, \mathscr{F}_S\right] \quad (S\in\mathscr{T}).$$

We refer the reader to El Karoui (1981) for a comprehensive account on Snell envelopes. Let us just note here that $S(\theta)$ is a submartingale taking values in $(-\infty, 0]$. Indeed, we can choose $T=\infty$ to see that $\mathbb{S}(\theta)_S \le \mathbb{E}\left[\nabla C(\theta)_\infty \,|\, \mathscr{F}_S\right] = 0$ by definition of $\nabla C(\theta)$ and our assumption that $k_\infty = 0$. Moreover, using that $c'(t,\underline{\vartheta}) \ge c(t,\underline{\vartheta}-1) - c(t,\underline{\vartheta}) \in L^1(\mathbb{P}\otimes\mu)$ by Assumption 1 and that k is of class (D) by Assumption 2, we obtain

$$\inf_{T\in\mathscr{T}} \mathbb{E}\nabla C(\theta)_T \ge \mathbb{E}\int_0^\infty c'(t,\underline{\vartheta})\wedge 0\,\mu(dt) + \inf_{T\in\mathscr{T}} \mathbb{E}k_T > -\infty\,.$$

This entails that almost surely $\mathbb{S}(\theta)$ does not take the value $-\infty$.

We shall use $M(\theta)$ and $A(\theta)$ to denote the martingale and predictable increasing part in the Doob–Meyer decomposition

$$\mathbb{S}(\theta) = M(\theta) + A(\theta)$$

of the submartingale $\mathbb{S}(\theta)$.

After these preliminaries, we can now give the following characterization of optimal policies in terms of first order conditions.

THEOREM 2.2. *Under Assumptions* 1 *and* 2, *a control policy* $\theta^*\in\mathscr{A}$ *is optimal for problem* (1) *if*

(i) θ^* *is flat off* $\{\nabla C(\theta^*) = \mathbb{S}(\theta^*)\}$ *and*
(ii) $A(\theta^*)$ *is flat off* $\{\theta^* = \overline{\vartheta}\}$.

REMARK 2.3.

(i) *An increasing process* θ *is said to be flat off a set* $A\in\mathscr{F}_\infty\otimes\mathscr{B}([0,\infty))$ *if the induced measure* $d\theta$ *almost surely does not charge the set* A: $\mathbb{E}\int_0^\infty 1_A\,d\theta = 0$.
(ii) *Condition* (i) *requires that control should be exercised only when its marginal impact on future costs is maximal. Condition* (ii) *reveals that all fuel should be spent at moments when the maximal expected marginal impact tends to decrease.*
(iii) *In fact, conditions* (i) *and* (ii) *are also* necessary *for optimality of* $\theta^*\in\mathscr{A}$. *This result could be derived using arguments from the calculus of variations. It is much easier, however, to deduce this observation directly from our construction of the unique optimal policy in section* 3.

The proof of this theorem uses the following two lemmata and will be given at the end of this section.

LEMMA 2.4. *A plan* $\theta^*\in\mathscr{A}$ *is optimal for problem* (1) *if for any* $\theta\in\mathscr{A}$ *the process* $\nabla C(\theta^*)^-$ *is* $\mathbb{P}\otimes d\theta$*-integrable and we have*

$$\mathbb{E}\int_0^\infty \nabla C(\theta^*)_s\,d\theta^*_s \le \mathbb{E}\int_0^\infty \nabla C(\theta^*)_s\,d\theta_s\,. \tag{4}$$

Proof. For $\theta\equiv\underline{\vartheta}$ the right side in (4) vanishes and therefore $\nabla C(\theta^*)^+$ must be $\mathbb{P}\otimes d\theta^*$-integrable. This allows us to use the subgradient estimate of Lemma 2.1 to obtain

$$C(\theta) - C(\theta^*) \ge \mathbb{E}\int_0^\infty \nabla C(\theta^*)_s\,d(\theta-\theta^*)_s$$

for any $\theta \in \mathscr{A}$ with $C(\theta) < \infty$. By (4), the right side in this estimate is nonnegative and therefore θ^* attains the minimum of $C(.)$ over $\mathscr{A}$ as claimed. □

The preceding lemma suggests that an optimal policy for our convex optimization problem (1) should also be a solution to some linear minimization problem. Solutions to this kind of linear minimization problem are characterized by the following result.

LEMMA 2.5. *Let $\phi \leq 0$ be an optional process of class (D) which is continuous in expectation with $\phi_\infty = 0$. Let ψ denote its lower Snell envelope*

$$\psi_S = \operatorname*{ess\,inf}_{T \in \mathscr{T}([S,\infty])} \mathbb{E}\,[\,\phi_T \,|\, \mathscr{F}_S\,] \quad (S \in \mathscr{T}),$$

and consider the corresponding Doob–Meyer decomposition $\psi = M + A$ into a uniformly integrable martingale M and an increasing, predictable process A with $A_0 = 0$.

Then θ^* solves the linear optimization problem

$$\textit{Minimize } \mathbb{E}\int_0^\infty \phi_s\, d\theta_s \textit{ subject to } \theta \in \mathscr{A}$$

if it satisfies

(i) *θ^* is flat off $\{\phi = \psi\}$ and*

(ii) *A is flat off $\{\theta^* = \overline{\vartheta}\}$.*

If the value of the above minimization problem is finite, these two conditions are also necessary for optimality of $\theta^* \in \mathscr{A}$.

Proof. As ϕ is of class (D) and continuous in expectation, so is its Snell envelope ψ. In particular, ψ is a right-continuous process with left limits and its predictable compensator A has continuous paths almost surely increasing to $A_\infty \in L^1(\mathbb{P})$. Moreover, $0 = \psi_\infty = M_\infty + A_\infty$ implies that $\psi_S = \mathbb{E}\,[\,A_T - A_\infty \,|\, \mathscr{F}_T\,]$ for $T \in \mathscr{T}$. For any control policy $\theta \in \mathscr{A}$, this allows us to derive the following estimate:

$$\begin{aligned}(5)\qquad \mathbb{E}\int_0^\infty \phi_t\, d\theta_t &\geq \mathbb{E}\int_0^\infty \psi_t\, d\theta_t = \mathbb{E}\int_0^\infty (A_t - A_\infty)\, d\theta_t = -\mathbb{E}\int_0^\infty (\theta_t - \underline{\vartheta})\, dA_t \\ &\geq -\mathbb{E}\int_0^\infty (\overline{\vartheta}_t - \underline{\vartheta})\, dA_t\,.\end{aligned}$$

Indeed, the first estimate is due to $\phi \geq \psi$, the second equality follows by partial integration, and the last estimate holds true because $dA \geq 0$ and $\theta \leq \overline{\vartheta}$ by admissibility of θ.

It is now easy to see that any θ^* satisfying (i) and (ii) will yield equality everywhere in (5). On the other hand, these two conditions are also necessary for a plan θ^* to minimize $\mathbb{E}\int_0^\infty \phi_s\, d\theta_s$ over $\theta \in \mathscr{A}$, provided the value of our linear minimization problem is finite. This follows readily from (5) in conjunction with the identity

$$(6)\qquad \inf_{\theta \in \mathscr{A}} \mathbb{E}\int_0^\infty \phi_s\, d\theta_s = -\mathbb{E}\int_0^\infty (\overline{\vartheta}_t - \underline{\vartheta})\, dA_t\,.$$

To prove this identity, we introduce for $n = 1, 2, \ldots$ the sequence of stopping times

$$\begin{aligned}T_0^n &\triangleq \inf\{t \geq 0 \mid \phi_t = \psi_t\},\\ T_j^n &\triangleq \inf\{t \geq T_{j-1}^n \mid \phi_t = \psi_t,\ \overline{\vartheta}_t > \overline{\vartheta}_{T_{j-1}^n} + 1/n\} \quad (j = 1, 2, \ldots)\end{aligned}$$

and consider the admissible control policy

$$\theta_t^n \triangleq \sum_{j=0}^\infty \overline{\vartheta}_{T_j^n + 1}(T_j^n, T_{j+1}^n](t) \quad (t \geq 0)\,.$$

For $\theta = \theta^n$ we have equality in the first part of estimate (5), and so we obtain

$$\mathbb{E}\int_0^\infty \phi_s \, d\theta_s^n = -\mathbb{E}\int_0^\infty (\theta_t^n - \underline{\vartheta}) \, dA_t \, .$$

It follows from general results on optimal stopping that dA is supported by the set $\{t \geq 0 \mid \phi_t = \psi_t\}$ almost surely. By definition of the stopping times T_j^n $(j = 0, 1, \ldots)$ this entails that almost surely $\overline{\vartheta}_t \leq \theta_t^n + 1/n$ for dA-a.e. t. We can thus conclude that

$$\mathbb{E}\int_0^\infty \phi_s \, d\theta_s^n = -\mathbb{E}\int_0^\infty (\theta_t^n - \underline{\vartheta}) \, dA_t \leq -\mathbb{E}\int_0^\infty (\overline{\vartheta}_t - \underline{\vartheta}) \, dA_t + \frac{1}{n}\mathbb{E}A_\infty \, .$$

For $n \uparrow \infty$ this establishes the desired identity (6), accomplishing our proof. □

It is now easy to give the following proof.

Proof of Theorem 2.2. Let $\theta^* \in \mathscr{A}$ be a policy such that θ^* is flat off $\{\nabla C(\theta^*) = \psi(\theta^*)\}$ and $A(\theta^*)$ is flat off $\{\theta^* = \overline{\vartheta}\}$. Since $k_\infty = 0$ entails $\nabla C(\theta^*)_\infty = 0$, the process $\psi \triangleq \psi(\theta^*) \leq 0$ is actually the Snell envelope of both $\nabla C(\theta^*)$ and $\phi \triangleq \nabla C(\theta^*) \wedge 0$, an optional process of class (D) which is continuous in expectation due to our assumptions on c, k, and μ. As a consequence, the above flat off conditions entail that θ^* actually satisfies both optimality conditions of Lemma 2.5 for this choice of $\phi \leq 0$. It follows that

$$\mathbb{E}\int_0^\infty \nabla C(\theta^*) \, d\theta^* = \mathbb{E}\int_0^\infty \phi \, d\theta^* \leq \mathbb{E}\int_0^\infty \phi \, d\theta = \mathbb{E}\int_0^\infty \nabla C(\theta^*) \wedge 0 \, d\theta$$

for all $\theta \in \mathscr{A}$. Lemma 2.1 yields in particular that the left side of this estimate is finite and it thus follows that $\nabla C(\theta^*)^-$ is $\mathbb{P} \otimes d\theta$-integrable for all $\theta \in \mathscr{A}$. In addition, the above estimate entails that θ^* satisfies the first order condition (4), and so we can use Lemma 2.4 to conclude that θ^* is an optimal policy for problem (1). □

REMARK 2.6. *For problems without fuel constraint ($\overline{\vartheta} \equiv +\infty$), the integrability assertion in Lemma* 2.4 *implies in particular that for an optimal policy $\theta^* \in \mathscr{A}$ the gradient $\nabla C(\theta^*)$ has to be nonnegative, i.e.,*

$$k_S \geq -\mathbb{E}\left[\int_S^{+\infty} c'(t, \theta_t) \, \mu(dt) \,\middle|\, \mathscr{F}_S\right] .$$

Moreover, condition (i) *in Theorem* 2.2 *implies that equality must hold true in the above relation whenever S is a time of intervention. This is in accordance with the first order characterizations obtained for such problems in Bertola* (1998) *and Bank and Riedel* (2001).

3. Construction of an optimal policy. In this section, we shall show how to use the first order characterization of the optimal policy provided by Theorem 2.2 in order to construct the solution to the finite fuel problem (1). The construction will be given in terms of a progressively measurable random process κ specifying a lower bound which the optimal control should respect granted enough fuel is left to do so. This lower bound is characterized as the optional solution κ to the representation problem

$$k_S = -\mathbb{E}\left[\int_S^\infty c'(t, \sup_{s \in [S,t)} \kappa_s) \, \mu(dt) \,\middle|\, \mathscr{F}_S\right] \quad \text{for any} \quad S \in \mathscr{T} \, . \tag{7}$$

Assumptions 1 and 2 ensure existence of a solution to this problem; see Theorem 3 in Bank and El Karoui (2004).

THEOREM 3.1. *Under Assumptions* 1 *and* 2*, the unique minimizer for problem* (1) *is given by*

$$\theta_t^* \triangleq \sup_{s\in[0,t)} \{\kappa_s \wedge \overline{\vartheta}_s\} \vee \underline{\vartheta} \quad (t \geq 0)\,,$$

where κ *is the optional process solving the representation problem* (7).

REMARK 3.2. *Note that the process* κ *does not depend on the bounds* $\underline{\vartheta}, \overline{\vartheta}$ *describing the set of admissible policies. It thus can be viewed as a universal signal process which yields optimal policies for a whole class of finite fuel problems.*

Proof. Let us verify that the policy $\theta^* \in \mathscr{A}$ satisfies the first order conditions derived in Theorem 2.2.

We first compute the lower Snell envelope $\mathbb{S}(\theta^*)$ of $\nabla C(\theta^*)$. To this end, consider $S, T \in \mathscr{T}$ with $S \leq T$ and note that by definition of θ^* and (7) we have

$$\begin{aligned}
&\mathbb{E}\left[\nabla C(\theta^*)_T \,|\, \mathscr{F}_S\right] \\
&\quad = \mathbb{E}\left[\int_T^\infty \left\{c'\left(t,\ \sup_{s\in[0,t)} \{\kappa_s \wedge \overline{\vartheta}_s\} \vee \underline{\vartheta}\right) - c'\left(t,\ \sup_{s\in[T,t)} \kappa_s\right)\right\} \mu(dt) \,\middle|\, \mathscr{F}_S\right] \\
&\quad \geq \mathbb{E}\left[\int_T^\infty \left\{c'\left(t,\ \sup_{s\in[0,t)} \{\kappa_s \wedge \overline{\vartheta}_s\}\right) - c'\left(t,\ \sup_{s\in[T,t)} \kappa_s\right)\right\} \mu(dt) \,\middle|\, \mathscr{F}_S\right] \\
&\quad \geq \mathbb{E}\left[\int_T^\infty \left\{c'\left(t,\ \sup_{s\in[0,t)} \{\kappa_s \wedge \overline{\vartheta}_s\}\right) - c'\left(t,\ \sup_{s\in[S,t)} \kappa_s\right)\right\} \mu(dt) \,\middle|\, \mathscr{F}_S\right] \\
&\quad \geq \mathbb{E}\left[\int_S^\infty \left\{c'\left(t,\ \sup_{s\in[0,t)} \{\kappa_s \wedge \overline{\vartheta}_s\}\right) - c'\left(t,\ \sup_{s\in[S,t)} \kappa_s\right)\right\} \wedge 0\, \mu(dt) \,\middle|\, \mathscr{F}_S\right].
\end{aligned}$$

Note that the last expression no longer depends on $T \geq S$, thus providing a lower bound for the Snell envelope $\mathbb{S}(\theta^*)$. In fact, it coincides with this envelope since we have equality in any of the above estimates for $T = T_S \triangleq \inf\{t \geq S \mid \kappa_t > \overline{\vartheta}_{t+}\}$. This is easy to see for the first of these estimates since, by definition of T_S, $\sup_{s\in[0,T_S]}\{\kappa_s \wedge \overline{\vartheta}_s\} \geq \overline{\vartheta}_{T_S+} \geq \underline{\vartheta}$, whence $\sup_{s\in[0,t)}\{\kappa_s \wedge \overline{\vartheta}_s\} \geq \underline{\vartheta}$ for $t > T_S$. Equality for the second estimate can be deduced from the observation that T_S is a point of increase for $\sup_{s\in[S,t)} \kappa_s$ which yields $\sup_{s\in[S,t)} \kappa_s = \sup_{s\in[T_S,t)} \kappa_s$ for $t \in (T_S, \infty]$. Finally, equality for the third estimate holds true since

$$c'\left(t,\ \sup_{s\in[0,t)} \{\kappa_s \wedge \overline{\vartheta}_s\}\right) - c'\left(t,\ \sup_{s\in[S,t)} \kappa_s\right) \quad \text{is} \quad \begin{cases} \geq 0 & \text{for } t \in (S, T_S]\,, \\ \leq 0 & \text{for } t \in (T_S, +\infty]\,, \end{cases}$$

again by definition of T_S. For later use, let us also note here that the stopping time T_S is actually the largest stopping time which attains

$$\mathbb{S}(\theta^*)_S = \operatorname*{ess\,inf}_{T\in\mathscr{T}([S,\infty])} \mathbb{E}\left[\nabla C(\theta^*)_T \,|\, \mathscr{F}_S\right],$$

since the above difference is always nonpositive and actually strictly negative on some nontrivial time interval starting at T_S whenever $T_S < +\infty$.

Let us now verify the flat off conditions characterizing optimal plans as described in Theorem 2.2. If S is a point of increase for θ^*, we have $\kappa_S \geq \theta^*_{S+} = \sup_{s\in[0,T_S]}\{\kappa_s \wedge$

$\overline{\vartheta}_s\} \geq \underline{\vartheta}$, and so $\sup_{s\in[S,t)} \kappa_s \geq \sup_{s\in[0,t)}\{\kappa_s \wedge \overline{\vartheta}_s\} \geq \underline{\vartheta}$ for $t \in (S,\infty]$. This allows us to conclude that

$$\begin{aligned}\mathbb{S}(\theta^*)_S &= \mathbb{E}\left[\int_S^\infty \left\{c'\left(t,\ \sup_{s\in[0,t)}\{\kappa_s\wedge\overline{\vartheta}_s\}\right) - c'\left(t,\ \sup_{s\in[S,t)}\kappa_s\right)\right\}\wedge 0\,\mu(dt)\,\middle|\,\mathscr{F}_S\right]\\ &= \mathbb{E}\left[\int_S^\infty \left\{c'\left(t,\ \sup_{s\in[0,t)}\{\kappa_s\wedge\overline{\vartheta}_s\}\right) - c'\left(t,\ \sup_{s\in[S,t)}\kappa_s\right)\right\}\mu(dt)\,\middle|\,\mathscr{F}_S\right]\\ &= \mathbb{E}\left[\int_S^\infty c'\left(t,\ \sup_{s\in[0,t)}\{\kappa_s\wedge\overline{\vartheta}_s\}\vee\underline{\vartheta}\right)\mu(dt)\,\middle|\,\mathscr{F}_S\right] + k_S = \nabla C(\theta^*)_S\,.\end{aligned}$$

So, θ^* is indeed flat off $\{\mathbb{S}(\theta^*) = \nabla C(\theta^*)\}$.

If, on the other hand, S is a point of increase for the predictable compensator $A(\theta^*)$ of $\mathbb{S}(\theta^*)$, then, by classical results on optimal stopping, the only stopping time in $\mathscr{T}([S,+\infty])$ attaining $\mathbb{S}(\theta^*)_S$ is S itself. In particular, the maximal stopping time T_S determined above coincides with S: $T_S = S$, i.e., $S = \inf\{t \geq S \mid \kappa_t > \overline{\vartheta}_{t+}\}$ almost surely. This implies $\kappa_S \geq \overline{\vartheta}_{S+}$ and so $\theta^*_{S+} \geq \overline{\vartheta}_{S+}$ $\mathbb{P}$-a.s. We deduce that almost surely $\theta^*_t = \overline{\vartheta}_t$ for any joint point of continuity t for both θ^* and $\overline{\vartheta}$, i.e., for all but at most countably many points t.

Hence, in order to deduce the desired flat off condition $\theta^*_t = \overline{\vartheta}_t$ for $dA(\theta^*)$-a.e. t, it now suffices to note that $A(\theta^*)$ has continuous sample paths. This, however, holds true because $\nabla C(\theta^*)^-$ and thus also $\mathbb{S}(\theta^*)$ are continuous in expectation. □

4. Applications. As an immediate consequence of Theorem 3.1 we obtain an extension of a result in Karatzas (1985) from the Brownian case to our larger class of finite fuel problems.

COROLLARY 4.1. *The optimal control policy in problem* (1) *with finite fuel (*$\overline{\vartheta} \equiv$ const*) is just the optimal control policy with infinite fuel (*$\overline{\vartheta} \equiv +\infty$*) until all fuel has been exhausted.* □

To obtain a more general result, let us note the following version of the dynamic programming principle.

COROLLARY 4.2. *For each stopping time* $S \in \mathscr{T}$*, the process*

$$\theta^S_t \triangleq \sup_{s\in[S,t)}\{\kappa_s\wedge\overline{\vartheta}_s\}\vee\underline{\vartheta}$$

attains

$$\operatorname*{ess\,inf}_{\theta\in\mathscr{A},\,\theta_S=\underline{\vartheta}} \mathbb{E}\left[\int_S^\infty c(t,\theta_t)\,\mu(dt) + \int_S^\infty k_t\,d\theta_t\,\middle|\,\mathscr{F}_S\right]. \tag{8}$$

In particular, $\theta^S_{S+} = \underline{\vartheta}\vee\limsup_{t\searrow S}\kappa_t\wedge\overline{\vartheta}_{S+}$ *describes the initial policy decision one has to take when starting to minimize costs at time* S*.*

Proof. Define $\overline{\vartheta}^S_t \triangleq \underline{\vartheta}$ for $t \leq S$ and $\overline{\vartheta}^S_t \triangleq \overline{\vartheta}_t$ for $t > S$, and note that by Theorem 3.1 θ^S is the optimal policy in the set of admissible policies $\mathscr{A}^S$ corresponding to $\overline{\vartheta}^S$ instead of $\overline{\vartheta}$. It thus attains $\inf_{\theta\in\mathscr{A}^S} C(\theta)$ and also

$$\inf_{\theta\in\mathscr{A},\,\theta_S=\underline{\vartheta}} \mathbb{E}\left[\int_S^\infty c(t,\theta_t)\,\mu(dt) + \int_S^\infty k_t\,d\theta_t\right] = \mathbb{E}\left[\int_S^\infty c(t,\theta^S_t)\,\mu(dt) + \int_S^\infty k_t\,d\theta^S_t\right].$$

It is easy to see that this infimum is actually the expectation of ess inf in (8). This, however, allows us to conclude our assertion, since this essential infimum is always less than $\mathbb{E}\left[\int_S^\infty c(t,\theta^S_t)\,\mu(dt) + \int_S^\infty k_t\,d\theta^S_t \,\middle|\, \mathscr{F}_S\right]$ almost surely. □

The preceding corollary can be used in two ways. On the one hand, it shows that the process κ of (7) can be used to describe optimal solutions not only when starting at time 0, but actually for any arbitrary initial time $S \in \mathscr{T}$. On the other hand, it allows us to deduce κ (at least partially) from the policies attaining (8). This observation yields the following corollary.

COROLLARY 4.3. *Let K be an optional process such that, for $S \in \mathscr{T}$, $K_S = \theta^S_{S+}$ is the initial value of the optimal policy for problem* (8) *when working under the fuel constraint $\theta^S_t \in [\underline{\vartheta}, \overline{\vartheta}_t]$ $(t \geq S)$. Then the optimal policy for problem* (1) *with fuel constraint $\overline{\vartheta}' \leq \overline{\vartheta}$ is given by*

$$\theta'_t \triangleq \sup_{s\in[0,t)} \{K_s \wedge \overline{\vartheta}'_s\} \vee \underline{\vartheta}\,.$$

In particular, the solutions to the problem without fuel constraint ($\overline{\vartheta} \equiv +\infty$) suffice to determine the optimal policies for the problem with an arbitrary dynamic fuel constraint.

4.1. Monotone follower problems. Let us now come back to the special case of a monotone follower problem studied by Karatzas and Shreve (1984) which we used to motivate the formulation of our general finite fuel problem (1) in section 1. We wish to determine a control policy $\theta \in \mathscr{A}$ which minimizes

$$C(\theta) \triangleq \mathbb{E} \int_0^\infty \delta e^{-\delta t} \frac{1}{2} (W_t - \theta_t)^2 \, dt\,,$$

where W is a standard Brownian motion. It follows from Theorem 3.1 that we can solve this problem explicitly for an arbitrary $\overline{\vartheta}$ by providing a solution to the representation problem (7). In our present setting, this amounts to finding a progressively measurable κ such that

$$\mathbb{E}\left[\int_S^\infty \delta e^{-\delta t} \sup_{s\in[S,t)} \kappa_s \, dt \,\middle|\, \mathscr{F}_S \right] = e^{-\delta S} W_S \quad \text{for all} \quad S \in \mathscr{T}. \tag{9}$$

It is intuitively clear (and has been established formally in Karatzas (1985)) that the optimal policy consists in reflecting the controlled Brownian motion at a certain threshold c. This suggests that we consider the ansatz $\kappa_s \triangleq W_s - c$ for some constant $c \in \mathbb{R}$. Plugging this into (9) and using the independence and time-homogeneity of the increments of W, it is easy to see that (9) will be satisfied if we choose

$$c \triangleq \mathbb{E} \int_0^\infty \delta e^{-\delta t} \sup_{s\in[0,t)} W_s \, dt\,.$$

In fact, looking back, we see that the above reasoning will apply not only to Brownian motion but actually to any Lévy process satisfying suitable integrability properties.

COROLLARY 4.4. *Let X be a Lévy process such that $\mathbb{E}\int_0^\infty \delta e^{-\delta t} X_t^2 \, dt < +\infty$. Then the optimal policy for the monotone follower problem*

$$\textit{Minimize } C(\theta) \triangleq \mathbb{E} \int_0^\infty \delta e^{-\delta t} \frac{1}{2} (X_t - \theta_t)^2 \, dt \textit{ over } \theta \in \mathscr{A}$$

is given by

$$\theta^*_t = \sup_{s\in[0,t)} \{(X_s - c) \wedge \overline{\vartheta}_s\} \vee \underline{\vartheta},$$

where $c \triangleq \mathbb{E}\int_0^\infty \delta e^{-\delta t} \sup_{s\in[0,t)} X_s \, dt < +\infty$.

Proof. We merely have to note that $c < +\infty$ follows from the square-integrability condition on X and Doob's maximal inequality for the martingale $(X_t - t\mathbb{E}X_1)_{t\geq 0}$. □

REMARK 4.5. *While Beneš, Shepp, and Witsenhausen* (1980/81) *study a practically identical cost functional, they allow for downward* and *upward displacement of the particle: controls merely have to be of bounded variation. As they show, in this situation the amount of fuel left becomes crucial for the optimal control decision so that there is no longer a universal process like* κ *describing the optimal policy. Indeed, one will accept larger distances of the controlled processes from the origin with little fuel left than with a lot.*

More generally, the above approach will allow us to explicitly describe optimal control policies whenever the representation problem (9) can be solved explicitly for a given process W, not necessarily Brownian motion. This is indeed possible for a large class of diffusions, as shown in Bank and Föllmer (2003).

If, on the other hand, one wishes to consider a nonquadratic cost functional under a dynamic finite fuel constraint, we can use Corollary 4.2 to reduce the construction of an optimal policy to the unconstraint case with infinite fuel and make use of the results of Chow, Menaldi, and Robin (1985) or Karatzas (1985).

4.2. Irreversible investments. Let us finally illustrate how Corollary 4.4 can be used to extend the closed form solutions obtained for certain irreversible investment problems in Kobila (1993) and Scheinkman and Zariphopoulou (2001) to incorporate a dynamic finite fuel constraint.

Kobila (1993) studies the problem of maximizing a reward functional of (essentially) the type

$$R(\theta) \triangleq \mathbb{E}\int_0^\infty e^{-\delta t}\Pi(X_t, \theta_t)\, dt,$$

where X is a geometric Brownian motion and $\Pi = \Pi(x, \vartheta) : (0, +\infty)\times\mathbb{R} \to \mathbb{R}$ describes the reward function. Apart from a number of technical conditions, Π is assumed to be strictly concave in ϑ; see Condition (5.1) in Kobila (1993). All increasing, left-continuous processes θ with $\theta \geq \underline{\vartheta} = \theta_0$ are considered admissible controls, i.e., $\overline{\vartheta} \equiv +\infty$.

Taking a dynamic programming approach, the authors set up and explicitly solve the Hamilton–Jacobi–Bellman equation for this problem. It turns out that the optimal policy consists in keeping the problem's state process (X, θ) away from a "forbidden" region $\mathscr{R}$ of the form

$$\mathscr{R} = \{(x, \vartheta) \in (0, +\infty) \times \mathbb{R} \mid \phi(x) > \vartheta\}$$

for an explicitly given continuous function ϕ. In particular, when starting at time $S \in \mathscr{T}$ in $\theta_S^S = \underline{\vartheta} \in \mathbb{R}$ the optimal policy requires an initial jump to $K_S = \underline{\vartheta} \vee \phi(X_S)$, i.e., to the minimal $\vartheta \geq \underline{\vartheta}$ such that $(X_S, \vartheta) \notin \mathscr{R}$.

It now follows from Corollary 4.4 that the region $\mathscr{R}$ computed in Kobila (1993) can actually be used to solve the same problem with an arbitrary dynamic fuel constraint $\overline{\vartheta} \not\equiv +\infty$: the optimal policy still consists in keeping the state process away from the region $\mathscr{R}$, at least as long as enough fuel is left to do so. If this is not the case, one has to wait until further supply of fuel becomes available (i.e., until $\overline{\vartheta}$ increases) and then use this fuel to move the state process as close as possible to the complement of $\mathscr{R}$.

The problem studied in Scheinkman and Zariphopoulou (2001) can be viewed as the problem in Kobila (1993) with an additional finite fuel constraint: $\underline{\vartheta} = 0$ and $\overline{\vartheta} = 1$. Given our previous observation, this gives a probabilistic explanation for the similarity of the explicit solution computed in Scheinkman and Zariphopoulou (2001) to the results of Kobila (1993).

Acknowledgments. The author is greatly indebted to Thaleia Zariphopoulou for suggesting this problem. He also wishes to express his gratitude to two anonymous referees for their extremely helpful comments, suggestions, and corrections.

COORDINATION AND GEOMETRIC OPTIMIZATION VIA DISTRIBUTED DYNAMICAL SYSTEMS*

JORGE CORTÉS† AND FRANCESCO BULLO‡

Abstract. This paper discusses dynamical systems for disk-covering and sphere-packing problems. We present facility location functions from geometric optimization and characterize their differentiable properties. We design and analyze a collection of distributed control laws that are related to nonsmooth gradient systems. The resulting dynamical systems promise to be of use in coordination problems for networked robots; in this setting the distributed control laws correspond to local interactions between the robots. The technical approach relies on concepts from computational geometry, nonsmooth analysis, and the dynamical system approach to algorithms.

Key words. distributed dynamical systems, coordination and cooperative control, geometric optimization, disk-covering problem, sphere-packing problem, nonsmooth analysis, Voronoi partitions

1. Introduction.

Consider n sites $(p_1, \ldots, p_n)$ evolving within a convex polygon Q according to one of the following interaction laws: (i) each site moves away from the closest other site or polygon boundary, (ii) each site moves toward the furthest vertex of its own Voronoi polygon, or (iii) each site moves toward a geometric center (circumcenter, incenter, centroid, etc.) of its own Voronoi polygon. Recall that the Voronoi polygon of the ith site is the closed set of points $q \in Q$ closer to p_i than to any other p_j.

These and related interaction laws give rise to strikingly simple dynamical systems whose behavior remains largely unknown. What are the critical points of such dynamical systems? What is their asymptotic behavior? Are these systems optimizing any aggregate function? In what way do these local interactions give rise to distributed systems? Does any biological ensemble evolve according to these behaviors and are they of any engineering use in coordination problems? These are the questions that motivate this paper.

Coordination in robotics, control, and biology. Coordination problems are becoming increasingly important in numerous engineering disciplines. The deployment of large groups of autonomous vehicles is rapidly becoming possible because of technological advances in computing, networking, and miniaturization of electromechanical systems. These future multiple-vehicle networks will coordinate their actions to perform challenging spatially distributed tasks (e.g., search and recovery

operations, exploration, surveillance, and environmental monitoring for pollution detection and estimation). This future scenario motivates the study of algorithms for autonomy, adaptation, and coordination of multiple-vehicle networks. It is also important to take into careful consideration all constraints on the behavior of the multiple-vehicle network. Coordination algorithms need to be adaptive and distributed in order for the resulting closed-loop network to be scalable, to comply with bandwidth limitations, to tolerate failures, and to adapt to changing environments, topologies, and sensing tasks. The interaction laws introduced above have these properties and, remarkably, they optimize network-wide performance measures for meaningful spatially distributed tasks.

Coordinated group motions are also a widespread phenomenon in biological systems. Some species of fish spend their lives in schools as a defense mechanism against predators. Others travel as swarms in order to protect an area that they have claimed as their own. Flocks of birds are able to travel in large groups and act as one unit. Other animals exhibit remarkable collective behaviors when foraging and selecting food. Certain foraging behaviors include individual animals partitioning their environment in nonoverlapping individual zones whereas other species develop overlapping team areas. These biological network systems possess extraordinary dynamic capabilities without apparently following a group leader. Yet these complex coordinated behaviors emerge while each individual has no global knowledge of the network state and can only plan its motion according to the observation of its closest neighbors.

Facility location, nonsmooth stability analysis, and cooperative control. To analyze the interaction laws introduced above we rely on concepts and methods from various disciplines. Facility location problems play a prominent role in the field of geometric optimization [1, 5]. Facility location pervades a broad spectrum of scientific and technological areas, including resource allocation (where to place mailboxes in a city or cache servers on the internet), quantization and information theory, mesh and grid optimization methods, clustering analysis, data compression, and statistical pattern recognition. Smooth multicenter functions for so-called centroidal Voronoi configurations and smooth distributed dynamical systems are presented in [11, 14]. Multicenter functions are studied in resource allocation problems [13, 29] and in quantization theory [16, 20]. The role of Voronoi tessellations and computational geometry in facility location is discussed in [23, 26].

The notion and computational properties of the generalized gradient are thoroughly studied in nonsmooth analysis [9]. In particular, tools for establishing stability and convergence properties of nonsmooth dynamical systems are presented in [3, 15, 27]. Finally, we refer to [17] for guidelines on how to design dynamical systems for optimization purposes, and to [4] for gradient descent flows in distributed computation in settings with fixed-communication topologies.

Recent years have witnessed a large research effort focused on motion planning and formation control problems for multiple-vehicle systems [18, 22, 19, 24, 30, 31]. Within the literature on behavior-based robotics, heuristic approaches to the design of interaction rules and emerging behaviors have been investigated (see [2] and references therein). Along this specific line of research, no formal results guaranteeing the correctness of the proposed algorithms or their optimality with respect to an aggregate objective are currently available. The aim of this work is to design distributed coordination algorithms for dynamic networks as well as to provide formal verifications of their asymptotic correctness. A key aspect of our treatment is the inherent complexity of studying networks whose communication topology changes along the

system evolution, as opposed to networks with fixed communication topologies. This key aspect is present in the analysis of distributed control laws in [18, 30, 31] and of agreement protocols in [24].

Statement of contributions. We consider two facility location functions from geometric optimization that characterize coverage performance criteria. A collection of sites provides optimal service to a domain of interest if (i) it minimizes the largest distance from any point in the domain to one of the sites, or (ii) it maximizes the minimum distance between any two sites. In other words, if $P = (p_1, \ldots, p_n)$ are n sites evolving within a convex polygon Q, we extremize the *multicenter functions*

$$\max_{q \in Q} \left\{ \min_{i \in \{1,\ldots,n\}} d(q, p_i) \right\}, \qquad \min_{i \neq j \in \{1,\ldots,n\}} \left\{ \tfrac{1}{2} d(p_i, p_j), d(p_i, \partial Q) \right\},$$

where $d(p, q)$ and $d(p, \partial Q)$ are the distances between p and q, and between p and the boundary of Q, respectively. (The role of the $\frac{1}{2}$ factor will become clear later.) We study the differentiable properties of these functions via nonsmooth analysis. We show the functions are globally Lipschitz and regular, we compute their generalized gradients, and we characterize their critical points. Under certain technical conditions, we show that the local minima of the first multicenter function are so-called circumcenter Voronoi configurations, and that these critical points correspond to the solutions of disk-covering problems. Similarly, under analogous technical conditions, we show that the local maxima of the second multicenter function are so-called incenter Voronoi configurations, and that these critical points correspond to the solutions of sphere-packing problems.

Next, we aim to design distributed algorithms that extremize the multicenter functions. Roughly speaking, by distributed we mean that the evolution of each site depends at most on the location of its own Voronoi neighbors. We study the generalized gradient flows induced by the multicenter functions using nonsmooth stability analysis. Although these dynamical systems possess some convergence properties, they are not amenable to distributed implementations. Next, drawing connections with quantization theory, we consider two dynamical systems associated to each multicenter function. First, we consider a novel strategy based on the generalized gradient of the 1-center functions of each site, and second, we consider a geometric centering strategy similar to the well-known Lloyd algorithm [16, 20].

Remarkably, these strategies arising from the nonsmooth gradient information have natural geometric interpretations and are indeed the local interaction rule described earlier. For the first (respectively, second) multicenter function, the first strategy corresponds to the interaction law "move toward the furthest vertex of own Voronoi polygon" (respectively, "move away from the closest other site or polygon boundary"), and the second strategy corresponds to the interaction law "move toward circumcenter of own Voronoi polygon" (respectively, "move toward incenter of own Voronoi polygon"). We prove the uniqueness of the solutions of the resulting distributed dynamical systems and we analyze their asymptotic behavior using nonsmooth stability analysis, showing that the active sites will approach the corresponding centers of their own Voronoi cells.

Two of our results are related to well-known conjectures in the locational optimization literature [13, 29]: (i) that the first multicenter problem is equivalent to a disk-covering problem (how to cover a region with possibly overlapping disks of equal minimum radius), and (ii) that the generalized Lloyd strategy "move toward

circumcenter of own Voronoi polygon" converges to the set of circumcenter Voronoi configurations.

Organization. The paper is organized as follows. Section 2 provides the preliminary concepts on Voronoi partitions, nonsmooth analysis, stability analysis, and gradient flows, and introduces the multicenter problems. Section 3 presents a complete treatment on the functions analysis and algorithm design for the 1-center problems. Section 4 discusses the differentiable properties and the critical points of the multicenter functions. Section 5 introduces a number of dynamical systems (smooth and nonsmooth, distributed and nondistributed) and analyzes their asymptotic correctness.

2. Preliminaries and problem setup. Let $N \in \mathbb{N}$. We denote by $\|\cdot\|$ the Euclidean distance function on $\mathbb{R}^N$ and by $v \cdot w$ the scalar product of the vectors $v, w \in \mathbb{R}^N$. Let $\mathrm{vrs}(v)$ denote the unit vector in the direction of $0 \neq v \in \mathbb{R}^N$, i.e., $\mathrm{vrs}(v) = v/\|v\|$. Given a set S in $\mathbb{R}^N$, we denote its convex hull by $\mathrm{co}(S)$ and its interior set by $\mathrm{int}(S)$. If S is a convex set in $\mathbb{R}^N$, let $\mathrm{proj}_S : \mathbb{R}^N \to S$ denote the orthogonal projection onto S and let $\mathrm{D}_S : \mathbb{R}^N \to \mathbb{R}$ denote the distance function to S. For $R > 0$, let $\overline{B}_N(p, R) = \{q \in \mathbb{R}^N \mid \|p - q\| \leq R\}$ and $B_N(p, R) = \mathrm{int}(\overline{B}_N(p, R))$. A set $\{v_1, \ldots, v_M\}$ of vectors in $\mathbb{R}^N$ *positively spans* $\mathbb{R}^N$ if any $w \in \mathbb{R}^N$ can be written as $w = \sum_{l=1}^{M} a_l v_l$, with $a_l \geq 0$, $l \in \{1, \ldots, M\}$. The following simple lemma, e.g., see [8], characterizes this situation.

LEMMA 2.1. *Given a set $\{v_1, \ldots, v_M\}$ of $M > N$ arbitrary vectors in $\mathbb{R}^N$, the following statements are equivalent:*

(i) *$\{v_1, \ldots, v_M\}$ positively spans $\mathbb{R}^N$;*
(ii) *$0 \in \mathrm{int}(\mathrm{co}\{v_1, \ldots, v_M\})$;*
(iii) *for each $w \in \mathbb{R}^N$, there exists v_i such that $w \cdot v_i > 0$.*

Let Q be a convex simple polygon in $\mathbb{R}^2$. We denote by $\mathrm{Ed}(Q) = \{e_1, \ldots, e_L\}$ and $\mathrm{Ve}(Q) = \{v_1, \ldots, v_L\}$ the set of edges and vertexes of Q, respectively. Let $P = (p_1, \ldots, p_n) \in Q^n \subset (\mathbb{R}^2)^n$ denote the location of n points (which we will call generators) in the space Q. Let $\pi_i : Q^n \to Q$ be the canonical projection onto the ith factor, $\pi_i(p_1, \ldots, p_n) = p_i$. Note that this mapping is surjective, continuous, and open (the latter meaning that open sets of Q^n are mapped onto open sets of Q).

2.1. Voronoi partitions. We present here some relevant concepts on Voronoi diagrams and refer the reader to [12, 23] for comprehensive treatments. A *partition* of Q is a collection of n polygons $\mathcal{W} = \{W_1, \ldots, W_n\}$ with disjoint interiors whose union is Q. Of course, more general types of partitions could be considered (as, for instance, continuous deformations of the previous ones), but these will be sufficient for our purposes. The *Voronoi partition* $\mathcal{V}(P) = (V_1(P), \ldots, V_n(P))$ of Q generated by the points $(p_1, \ldots, p_n)$ is defined by

$$V_i(P) = \{q \in Q \mid \|q - p_i\| \leq \|q - p_j\| \ \forall j \neq i\}.$$

For simplicity, we shall refer to $V_i(P)$ as V_i. Since Q is a convex polygon, the boundary of each V_i is the union of a finite number of segments. If V_i and V_j share an edge, i.e., $V_i \cap V_j$ is neither empty nor a singleton, then p_i is called a *(Voronoi) neighbor* of p_j (and vice versa). All Voronoi neighboring relations are encoded in the mapping $\mathcal{N} : Q^n \times \{1, \ldots, n\} \to 2^{\{1, \ldots, n\}}$, where $\mathcal{N}(P, i)$ is the set of indexes of the Voronoi neighbors of p_i. Of course, $j \in \mathcal{N}(P, i)$ if and only if $i \in \mathcal{N}(P, j)$. We will often omit P and instead write $\mathcal{N}(i)$.

For $P \in Q^n$, the vertexes of the Voronoi partition $\mathcal{V}(P)$ are classified as follows: the vertex v is

- *of type* (a) if it is the center of the circle passing through three generators (say, p_i, p_j, and p_k),
- *of type* (b) if it is the intersection between an edge of Q and the bisector determined by two generators (say, e, p_i, and p_j), and
- *of type* (c) if it is a vertex of Q, i.e., it is determined by two edges of Q and by the generator of a cell containing it (say, e, f, and p_i).

Correspondingly, we shall write $v(i,j,k)$, $v(e,i,j)$, and $v(e,f,i)$, respectively, whenever we are interested in making explicit the elements defining the vertex v. The vertex $v \in \mathrm{Ve}(V_i(P))$ is said to be *nondegenerate* if it is determined by exactly three elements (e.g., as described above, three generators, or an edge and two generators, or two edges and one generator), otherwise it is said to be *degenerate*. Further, the configuration P is said to be *nondegenerate at the ith generator* if all vertexes $v \in \mathrm{Ve}(V_i(P))$ are nondegenerate, otherwise P is *degenerate at the ith generator*. Finally, a configuration P is said to be *nondegenerate* if all its vertexes are nondegenerate, otherwise it is said to be *degenerate*. These concepts are illustrated in Figure 2.1.

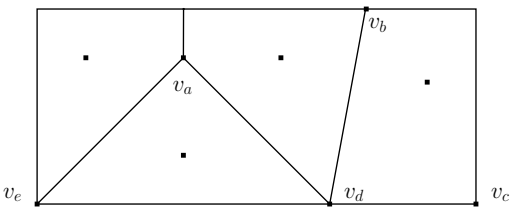

FIG. 2.1. *A Voronoi partition with degenerate and nondegenerate vertexes. Vertexes v_a, v_b, and v_c are nondegenerate vertexes of type* (a), (b), *and* (c), *respectively. Vertexes v_d and v_e are degenerate.*

For $P \in Q^n$, the edges of the Voronoi partition $\mathcal{V}(P)$ are classified as follows: the edge e is

- *of type* (a) if it is a segment of the bisector determined by two generators (say, p_i, p_j), and
- *of type* (b) if it is contained in the boundary of Q, i.e., it is a subset of an edge of Q and it belongs to a single cell (say, the cell of the generator p_i).

Correspondingly, we shall write $e(i,j)$ and $e(i)$, respectively, whenever we are interested in making explicit the elements defining the edge e. Further, when considering an edge of type (a), we let $n_{e(i,j)}$ denote the unit normal to $e(i,j)$ pointing toward $\mathrm{int}(V_i(P))$. When considering an edge of type (b), we let $n_{e(i)}$ denote the unit normal to $e(i)$ pointing toward $\mathrm{int}(Q)$.

2.2. The disk-covering and the sphere-packing problems. We are interested in the following locational optimization problems:

$$\min_{p_1,\dots,p_n} \left\{ \max_{q \in Q} \left\{ \min_{i \in \{1,\dots,n\}} \|q - p_i\| \right\} \right\}, \tag{2.1}$$

$$\max_{p_1,\dots,p_n} \left\{ \min_{\substack{i,j \in \{1,\dots,n\} \\ i \neq j,\ e \in \mathrm{Ed}(Q)}} \left\{ \tfrac{1}{2}\|p_i - p_j\|, \mathrm{D}_e(p_i) \right\} \right\}. \tag{2.2}$$

The optimization problem (2.1) is referred to as the p-center problem in [13, 29]. Throughout the paper, we will refer to it as the multicircumcenter problem. In the context of coverage control of mobile sensor networks [11], the multicircumcenter problem corresponds to considering the worst case scenario, in which no information is available on the distribution of the events taking place in the environment Q. The network therefore tries to minimize the largest possible distance of any point in Q to one of the generators' locations given by $p_1, \dots, p_n$, i.e., to minimize the function

$$\mathcal{H}_{\mathrm{DC}}(P) = \max_{q \in Q} \left\{ \min_{i \in \{1,\dots,n\}} \|q - p_i\| \right\} = \max_{i \in \{1,\dots,n\}} \left\{ \max_{q \in V_i} \|q - p_i\| \right\}.$$

It is conjectured in [29] that this problem can be restated as a disk-covering problem: how to cover a region with (possibly overlapping) disks of minimum radius. The disk-covering problem then reads

$$\min\{R \mid \cup_{i \in \{1,\dots,n\}} \overline{B}_2(p_i, R) \supseteq Q\}.$$

We shall present a proof of this statement in Theorem 4.7 below. Given a polytope W in $\mathbb{R}^N$, its circumcenter, denoted by $\mathrm{CC}(W)$, is the center of the minimum-radius sphere that contains W. The circumradius of W, denoted by $\mathrm{CR}(W)$, is the radius of this sphere. We will say that P is a *circumcenter Voronoi configuration* if $p_i = \mathrm{CC}(V_i(P))$, for all $i \in \{1, \dots, n\}$. We denote by $\mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$ the set of vertexes of the Voronoi partition where the value $\mathcal{H}_{\mathrm{DC}}(P)$ is attained, i.e., $v \in \mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$ if there exists i such that $v \in V_i(P)$ and $\|v - p_i\| = \mathcal{H}_{\mathrm{DC}}(P)$. In such cases, we will often refer to both the vertex v and the generator p_i as *active*.

We will refer to the optimization problem (2.2) as the multi-incenter problem. In the context of applications, this problem corresponds to the situation where we are interested in maximizing the coverage of the area Q in such a way that the sensing radius of the generators do not overlap (in order not to interfere with each other) or leave the environment. We therefore consider the maximization of the function

$$\mathcal{H}_{\mathrm{SP}}(P) = \min_{\substack{i,j \in \{1,\dots,n\} \\ i \neq j,\, e \in \mathrm{Ed}(Q)}} \left\{ \tfrac{1}{2}\|p_i - p_j\|, \mathrm{D}_e(p_i) \right\} = \min_{i \in \{1,\dots,n\}} \left\{ \min_{q \notin \mathrm{int}(V_i)} \|q - p_i\| \right\}.$$

A similar conjecture to the one presented above is that the multi-incenter problem can be restated as a sphere-packing problem: how to maximize the coverage of a region with nonoverlapping disks (contained in the region) of maximum radius. The problem reads

$$\max\{R \mid \cup_{i \in \{1,\dots,n\}} \overline{B}_2(p_i, R) \subseteq Q\,,\ B_2(p_i, R) \cap B_2(p_j, R) = \emptyset\}.$$

In Theorem 4.8 we provide a positive answer to this question. Given a polytope W in $\mathbb{R}^N$, its incenter set (or Chebyshev center set; see [6]), denoted by $\mathrm{IC}(W)$, is the set of the centers of maximum-radius spheres contained in W. The inradius of W, denoted by $\mathrm{IR}(W)$, is the common radius of these spheres. We will say that $P \in Q^n$ is an *incenter Voronoi configuration* if $p_i \in \mathrm{IC}(V_i(P))$, for all $i \in \{1, \dots, n\}$. If P is an incenter Voronoi configuration and each Voronoi region $V_i(P)$ has a unique incenter, $\mathrm{IC}(V_i(P)) = \{p_i\}$, then we will say that P is a *generic incenter Voronoi configuration*. We denote by $\mathrm{Ed}_{\mathrm{SP}}(\mathcal{V}(P))$ the set of edges of the Voronoi partition where the value $\mathcal{H}_{\mathrm{SP}}(P)$ is attained; i.e., $e \in \mathrm{Ed}_{\mathrm{SP}}(\mathcal{V}(P))$ if there exists i such that $e \in \mathrm{Ed}(V_i(P))$ and $\mathrm{D}_e(p_i) = \mathcal{H}_{\mathrm{SP}}(P)$. In such cases, we will often refer to both the edge e and the generator p_i as *active*.

2.3. Nonsmooth analysis. The following facts on nonsmooth analysis [9] will be most helpful in analyzing the properties of the locational optimization functions for the disk-covering and the sphere-packing problems, as well as the convergence of the distributed algorithms we will propose to extremize them.

We begin by recalling some basic notions. A function $f : \mathbb{R}^N \to \mathbb{R}$ is said to be *locally Lipschitz at* $x \in \mathbb{R}^N$ if there exist positive constants L_x and ϵ such that $|f(y) - f(y')| \leq L_x \|y - y'\|$ for all $y, y' \in B_N(x, \epsilon)$. The function f is said to be *locally Lipschitz on* $S \subset \mathbb{R}^N$ *if it is locally Lipschitz at* x*, for all* $x \in S$. Note that continuously differentiable functions at x are locally Lipschitz at x. On the other hand, a function $f : \mathbb{R}^N \to \mathbb{R}$ is said to be *regular at* $x \in \mathbb{R}^N$ if for all $v \in \mathbb{R}^N$ the right directional derivative of f at x in the direction of v, denoted by $f'(x; v)$, exists and coincides with the generalized directional derivative of f at x in the direction of v, denoted by $f^o(x; v)$. The interested reader is referred to [9] for the precise definition of these directional derivatives. Again, a continuously differentiable function at x is regular at x. Also, a locally Lipschitz function at x which is convex is regular (cf. Proposition 2.3.6 in [9]).

From Rademacher's theorem [9], we know that locally Lipschitz functions are differentiable almost everywhere (in the sense of Lebesgue measure). If Ω_f denotes the set of points in $\mathbb{R}^N$ at which f fails to be differentiable and S denotes any other set of measure zero, the *generalized gradient* of f is defined by

$$\partial f(x) = \operatorname{co}\left\{ \lim_{i \to +\infty} df(x_i) \mid x_i \to x\,,\ x_i \notin S \cup \Omega_f \right\}.$$

Note that this definition coincides with $df(x)$ if f is continuously differentiable at x. A point $x \in \mathbb{R}^N$ which verifies that $0 \in \partial f(x)$ is called a *critical point of* f. The following result corresponds to Proposition 2.3.12 in [9].

PROPOSITION 2.2. *Let* $f_k : \mathbb{R}^N \to \mathbb{R}$, $k \in \{1, \ldots, m\}$ *be locally Lipschitz functions at* $x \in \mathbb{R}^N$ *and let* $f(x') = \max\{f_k(x') \mid k \in \{1, \ldots, m\}\}$. *Then,*

(i) *f is locally Lipschitz at x,*

(ii) *if $I(x')$ denotes the set of indexes k for which $f_k(x') = f(x')$, we have*

$$\partial f(x) \subset \operatorname{co}\{\partial f_i(x) \mid i \in I(x)\}\,, \tag{2.3}$$

and if f_i, $i \in I(x)$, is regular at x, then equality holds and f is regular at x.

The extrema of Lipschitz functions are characterized by the following result.

PROPOSITION 2.3. *Let f be a locally Lipschitz function at $x \in \mathbb{R}^N$. If f attains a local minimum or maximum at x, then $0 \in \partial f(x)$, i.e., x is a critical point.*

Let $\operatorname{Ln} : 2^{\mathbb{R}^N} \to 2^{\mathbb{R}^N}$ be the set-valued mapping that associates to each subset S of $\mathbb{R}^N$ the set of its least-norm elements $\operatorname{Ln}(S)$. If the set S is convex, then the set $\operatorname{Ln}(S)$ reduces to a singleton and we note the equivalence $\operatorname{Ln}(S) = \operatorname{proj}_S(0)$. In this paper, we shall only apply this function to convex sets. For a locally Lipschitz function f, we consider the *generalized gradient vector field* $\operatorname{Ln}(\partial f) : \mathbb{R}^N \to \mathbb{R}^N$ given by $x \mapsto \operatorname{Ln}(\partial f)(x) = \operatorname{Ln}(\partial f(x))$. The following theorem (cf. [9]) establishes an important feature of this vector field.

THEOREM 2.4. *Let f be a locally Lipschitz function at x. Assume $0 \notin \partial f(x)$. Then, there exists $T > 0$ such that*

$$f(x - t \operatorname{Ln}(\partial f)(x)) \leq f(x) - \frac{t}{2} \|\operatorname{Ln}(\partial f)(x)\|^2\,, \quad 0 < t < T\,.$$

The vector $-\operatorname{Ln}(\partial f)(x)$ is called a direction of descent.

2.4. Stability analysis via nonsmooth Lyapunov functions. Throughout the paper, we will define the solutions of differential equations with discontinuous right-hand sides in terms of differential inclusions [15]. Let $F : \mathbb{R}^N \to 2^{\mathbb{R}^N}$ be a set-valued map. Consider the differential inclusion

$$\dot{x} \in F(x)\,. \tag{2.4}$$

A solution to this equation on an interval $[t_0, t_1] \subset \mathbb{R}$ is defined as an absolutely continuous function $x : [t_0, t_1] \to \mathbb{R}^N$ such that $\dot{x}(t) \in F(x(t))$ for almost all $t \in [t_0, t_1]$. Given $x_0 \in \mathbb{R}^N$, the existence of at least a solution with initial condition x_0 is guaranteed by the following lemma.

LEMMA 2.5. *Let the mapping F be upper semicontinuous with nonempty, compact, and convex values. Then, given $x_0 \in \mathbb{R}^N$, there exists a local solution of* (2.4) *with initial condition x_0.*

Now, consider the differential equation

$$\dot{x}(t) = X(x(t))\,, \tag{2.5}$$

where $X : \mathbb{R}^N \to \mathbb{R}^N$ is measurable and essentially locally bounded. There are various notions of solutions to discontinuous differential equations (see [7, Chapter 1] for a comparative discussion between them). Here, we will understand the solution of this equation in the Filippov sense, which we define in the following. For each $x \in \mathbb{R}^N$, consider the set

$$K[X](x) = \bigcap_{\delta>0} \bigcap_{\mu(S)=0} \mathrm{co}\{X(B_N(x,\delta) \setminus S)\}\,,$$

where μ denotes the usual Lebesgue measure in $\mathbb{R}^N$. Alternatively, one can show [25] that there exists a set S_X of measure zero such that

$$K[X](x) = \mathrm{co}\left\{ \lim_{i\to+\infty} X(x_i) \mid x_i \to x\,,\ x_i \notin S \cup S_X \right\}\,,$$

where S is any set of measure zero. A Filippov solution of (2.5) on an interval $[t_0, t_1] \subset \mathbb{R}$ is defined as a solution of the differential inclusion $\dot{x} \in K[X](x)$. Since the multivalued mapping $K[X] : \mathbb{R}^N \to 2^{\mathbb{R}^N}$ is upper semicontinuous with nonempty, compact, convex values and locally bounded (cf. [15]), the existence of Filippov solutions of (2.5) is guaranteed by Lemma 2.5.

A set M is *weakly invariant* (respectively, *strongly invariant*) for (2.5) if for each $x_0 \in M$, M contains a maximal solution (respectively, all maximal solutions) of (2.5). Given a locally Lipschitz function $f : \mathbb{R}^N \to \mathbb{R}$, the *set-valued Lie derivative of f with respect to X* at x is defined as

$$\widetilde{\mathcal{L}}_X f(x) = \{a \in \mathbb{R} \mid \exists v \in K[X](x) \text{ such that } \zeta \cdot v = a \ \ \forall \zeta \in \partial f(x)\}\,.$$

For each $x \in \mathbb{R}^N$, $\widetilde{\mathcal{L}}_X f(x)$ is a closed and bounded interval in $\mathbb{R}$, possibly empty. If f is continuously differentiable at x, then $\widetilde{\mathcal{L}}_X f(x) = \{df \cdot v \mid v \in K[X](x)\}$. If, in addition, X is continuous at x, then $\widetilde{\mathcal{L}}_X f(x)$ corresponds to the singleton $\{\mathcal{L}_X f(x)\}$, the usual Lie derivative of f in the direction of X at x. The importance of the set-valued Lie derivative stems from the next result [3].

THEOREM 2.6. *Let $x : [t_0, t_1] \to \mathbb{R}^N$ be a Filippov solution of (2.5). Let f be a locally Lipschitz and regular function. Then $\frac{d}{dt}(f(x(t)))$ exists a.e. and $\frac{d}{dt}(f(x(t))) \in \widetilde{\mathcal{L}}_X f(x(t))$ a.e.*

The following result is a generalization of the LaSalle principle for differential equations of the form (2.5) with nonsmooth Lyapunov functions. The formulation is taken from [3] and slightly generalizes the one presented in [27].

THEOREM 2.7 (LaSalle principle). *Let $f : \mathbb{R}^N \to \mathbb{R}$ be a locally Lipschitz and regular function. Let $x_0 \in \mathbb{R}^N$ and let $f^{-1}(\leq f(x_0), x_0)$ be the connected component of $\{x \in \mathbb{R}^N \mid f(x) \leq f(x_0)\}$ containing x_0. Assume the set $f^{-1}(\leq f(x_0), x_0)$ is bounded and assume either $\max \widetilde{\mathcal{L}}_X f(x) \leq 0$ or $\widetilde{\mathcal{L}}_X f(x) = \emptyset$ for all $x \in f^{-1}(\leq f(x_0), x_0)$. Then $f^{-1}(\leq f(x_0), x_0)$ is strongly invariant for (2.5). Let*

$$Z_{X,f} = \{x \in \mathbb{R}^N \mid 0 \in \widetilde{\mathcal{L}}_X f(x)\}.$$

Then, any solution $x : [t_0, +\infty) \to \mathbb{R}^N$ of (2.5) starting from x_0 converges to the largest weakly invariant set M contained in $\overline{Z}_{X,f} \cap f^{-1}(\leq f(x_0), x_0)$. Furthermore, if the set M is a finite collection of points, then the limit of all solutions starting at x_0 exists and equals one of those points.

The proof of the last fact in the theorem statement is the same as in the smooth case, since it only relies on the continuity of the trajectory. The next statement is based on Theorem 2 of [25].

PROPOSITION 2.8. *Under the same assumptions of Theorem 2.7, if $\max \widetilde{\mathcal{L}}_X f(x) < -\epsilon < 0$ a.e. on $\mathbb{R}^N \setminus Z_{X,f}$, then $Z_{X,f}$ is attained in finite time.*

Proof. Let $x : [t_0, +\infty) \to \mathbb{R}^N$ be a Filippov solution starting from x_0. We argue that there must exist T such that $x(T) \in Z_{X,f}$. Otherwise, we have

$$f(x(t)) = f(x(t_0)) + \int_{t_0}^{t} \frac{d}{ds} f(x(s)) ds < f(x(t_0)) - \epsilon(t - t_0) \overset{t \to +\infty}{\longrightarrow} -\infty,$$

contradicting the fact that $f^{-1}(\leq f(x_0), x_0)$ is strongly invariant and bounded. ∎

2.5. Nonsmooth gradient flows. Finally, we are in a position to present the nonsmooth analogue of well-known results on gradient flows. Given a locally Lipschitz and regular function f, consider the following generalized gradient flow:

$$\dot{x}(t) = -\operatorname{Ln}(\partial f)(x(t)). \tag{2.6}$$

Theorem 2.4 guarantees that unless the flow is at a critical point, $-\operatorname{Ln}(\partial f)(x)$ is always a direction of descent at x. In general, the vector field $\operatorname{Ln}(\partial f)$ in (2.6) is discontinuous. We understand its solution in the Filippov sense. Note that since f is locally Lipschitz, $\operatorname{Ln}(\partial f) = df$ almost everywhere. An important observation in this setting is that $K[df](x) = \partial f(x)$ (cf. [25]). The following result, which is a generalization of the discussion in [3], guarantees the convergence of this flow to the set of critical points of f.

PROPOSITION 2.9. *Let $x_0 \in \mathbb{R}^N$ and assume $f^{-1}(\leq f(x_0), x_0)$ is bounded. Then, any solution $x : [t_0, +\infty) \to \mathbb{R}^N$ of (2.6) starting from x_0 converges asymptotically to the set of critical points of f contained in $f^{-1}(\leq f(x_0), x_0)$.*

Proof. Let $a \in \widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial f)} f(x)$. By definition, there exists $w \in K[-\operatorname{Ln}(\partial f)](x) = -\partial f(x)$ such that $a = w \cdot \zeta$ for all $\zeta \in \partial f(x)$. In particular, for $\zeta = -w \in \partial f(x)$, we have $a = -\|w\|^2 \leq 0$. Therefore, $\max \widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial f)} f(x) \leq 0$ or $\widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial f)} f(x) = \emptyset$. Now, resorting to the LaSalle principle (Theorem 2.7), we deduce that any solution

$x : [t_0, +\infty) \to \mathbb{R}^N$ starting from x_0 converges to the largest weakly invariant set contained in $\overline{Z}_{-\operatorname{Ln}(\partial f),f} \cap f^{-1}(\leq f(x_0), x_0)$. Let us see that $Z_{-\operatorname{Ln}(\partial f),f}$ is equal to $L_0 = \{x \in Q^n \mid 0 \in \partial f(x)\}$. Obviously, $L_0 \subset Z_{-\operatorname{Ln}(\partial f),f}$. Conversely, assume $x \in Z_{-\operatorname{Ln}(\partial f),f}$. Then, $0 \in \widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial f)} f(x)$; i.e., there exists $v \in -\partial f(x)$ such that $\zeta \cdot v = 0$ for all $\zeta \in \partial f(x)$. In particular, for $\zeta = -v$, we get $\|v\|^2 = 0$, that is, $v = 0 \in \partial f(x)$, as desired. Note that $Z_{-\operatorname{Ln}(\partial f),f} = L_0$ is the equilibrium set of (2.6) and therefore is weakly invariant. Finally, we prove that it is also closed. Let $x \in \overline{Z}_{-\operatorname{Ln}(\partial f),f}$ and consider a sequence $\{x_k \in \mathbb{R}^N \mid k \in \mathbb{N}\} \subset Z_{-\operatorname{Ln}(\partial f),f}$ such that $x_k \to x$. Then, using the fact that the multivalued mapping $K[-v]$ is upper semicontinuous, for any $\epsilon > 0$ there exists k_0 such that for $k \geq k_0$, $\partial f(x_k) \subset \partial f(x) + B_N(0, \epsilon)$. Since $x_k \in Z_{-\operatorname{Ln}(\partial f),f}$, then $0 \in \partial f(x) + B_N(0, \epsilon)$ for all $\epsilon > 0$, and this implies that $0 \in \partial f(x)$, i.e., $x \in Z_{-\operatorname{Ln}(\partial f),f}$. Hence the largest weakly invariant set contained in $\overline{Z}_{-\operatorname{Ln}(\partial f),f} \cap f^{-1}(\leq f(x_0), x_0)$ is $Z_{-\operatorname{Ln}(\partial f),f} \cap f^{-1}(\leq f(x_0), x_0) = \{x \in f^{-1}(\leq f(x_0), x_0) \mid 0 \in \partial f(x)\}$. □

3. The 1-center problems. In this section we consider the disk-covering and the sphere-packing problems with a single generator, i.e., $n = 1$. This treatment will give us the necessary insight to tackle later the more involved multicenter version of both problems. When $n = 1$, the minimization of $\mathcal{H}_{\mathrm{DC}}$ simply consists of finding the center of the minimum-radius sphere enclosing the polygon Q. On the other hand, the maximization of $\mathcal{H}_{\mathrm{SP}}$ corresponds to determining the center of the maximum-radius sphere contained in Q. Let us therefore define the functions

$$\begin{aligned} \operatorname{lg}_Q(p) &= \max\{\|q - p\| \mid q \in Q\} = \max\{\|v - p\| \mid v \in \operatorname{Ve}(Q)\}, \\ \operatorname{sm}_Q(p) &= \min\{\|q - p\| \mid q \notin \operatorname{int}(Q)\} = \min\{\operatorname{D}_e(p) \mid e \in \operatorname{Ed}(Q)\}. \end{aligned} \tag{3.1}$$

When $n = 1$, we then have that $\mathcal{H}_{\mathrm{DC}} = \operatorname{lg}_Q : Q \to \mathbb{R}$ and $\mathcal{H}_{\mathrm{SP}} = \operatorname{sm}_Q : Q \to \mathbb{R}$.

3.1. Smoothness and critical points. We here discuss the smoothness properties and the critical points of the 1-center functions. Since the function lg_Q is the maximum of a (finite) set of convex functions in p, it is also a convex function [6]. Therefore, any local minimum of lg_Q is also global.

LEMMA 3.1. *The function* lg_Q *has a unique global minimum, which is the circumcenter of the polygon* Q.

Proof. Let $F : \mathbb{R} \to \mathbb{R}$ be any continuous nondecreasing function. Then

$$F(\operatorname{lg}_Q(p)) = \max\{F(\|v - p\|) \mid v \in \operatorname{Ve}(Q)\}.$$

If we take $F(x) = x^2$, each function $\|v - p\|^2$ is strictly convex, and hence $F(\operatorname{lg}_Q(p))$ is also strictly convex. Therefore, this latter function has a single minimum on Q. Since any global minimum of lg_Q is also a global minimum of $F(\operatorname{lg}_Q(p))$, we conclude the result. □

The function sm_Q is the minimum of a (finite) set of affine (hence, concave) functions defined on the half-planes determined by the edges of Q, and hence it is also a concave function [6] on the intersection of their domains, which is precisely Q. Therefore, any local maximum of sm_Q is also global. However, this maximum is not unique in general.

LEMMA 3.2. *The incenter set of the polygon* Q *is the set of maxima of the function* sm_Q *and it is a segment.*

Proof. It is clear that the set of maxima of sm_Q is $\operatorname{IC}(Q)$. As a consequence of the concavity of sm_Q over the convex domain Q, one deduces that $\operatorname{IC}(Q)$ is a convex

set. Now, assume there are three points p_1, p_2, p_3 in $\mathrm{IC}(Q)$ which are not aligned. Since $B_2(q, \mathrm{IR}(Q)) \subset Q$ for all $q \in \mathrm{co}(p_1, p_2, p_3) \subset \mathrm{IC}(Q)$, and $\mathrm{co}(p_1, p_2, p_3)$ has a nonempty interior, there exist $q_0 \in Q$ and $r > \mathrm{IR}(Q)$ such that $B_2(q_0, r) \subset Q$, which is a contradiction. □

Note that the circumcenter of a polygon can be computed via the finite-step algorithm described in [28]. The incenter set of a polygon can be computed via the following linear program in q and r: maximize the radius r of the sphere centered at q subject to the constraints that the distance between q and each of the polygon edges is greater than or equal to r. Formally, the problem can be expressed as follows. For each $e \in \mathrm{Ed}(Q)$, select a point $q_e \in Q$ belonging to e. Then, we set

$$\begin{aligned} &\text{maximize } r\,, \\ &\text{subject to } (q - q_e) \cdot n_e \geq r \quad \forall\, e \in \mathrm{Ed}(Q)\,. \end{aligned}$$

In what follows, let us examine dynamical systems that compute these geometric centers.

PROPOSITION 3.3. *The functions* $\mathrm{lg}_Q(p)$, $-\mathrm{sm}_Q(p)$ *are locally Lipschitz and regular, and their generalized gradients are given by*

$$\partial \mathrm{lg}_Q(p) = \mathrm{co}\{\mathrm{vrs}(p - v) \mid v \in \mathrm{Ve}(Q)\,,\ \mathrm{lg}_Q(p) = \|p - v\|\}\,, \tag{3.2}$$

$$\partial \mathrm{sm}_Q(p) = \mathrm{co}\{n_e \mid e \in \mathrm{Ed}(Q)\,,\ \mathrm{sm}_Q(p) = \mathrm{D}_e(p)\}\,. \tag{3.3}$$

Moreover,

$$0 \in \partial \mathrm{lg}_Q(p) \Longleftrightarrow p = \mathrm{CC}(Q)\,, \quad 0 \in \partial \mathrm{sm}_Q(p) \Longleftrightarrow p \in \mathrm{IC}(Q)\,, \tag{3.4}$$

and, if $0 \in \mathrm{int}(\partial \mathrm{sm}_Q(p))$, *then* $\mathrm{IC}(Q) = \{p\}$.

Proof. Given the expressions in (3.1) and Proposition 2.2, we deduce that lg_Q and $-\mathrm{sm}_Q$ are locally Lipschitz and regular, and that their generalized gradients are given by (3.2) and (3.3), respectively. Concerning (3.4), the implications from right to left in (3.4) readily follow from Proposition 2.3. As for the other ones, note that it is sufficient to prove that p is a local minimum (respectively, that p is a local maximum). We prove the result for the function lg_Q. The proof for sm_Q is analogous. Assume that $0 \in \partial \mathrm{lg}_Q(p)$. Then there exist vertexes $v_{i_1}, \ldots, v_{i_K}$ of Q with $\mathrm{lg}_Q(p) = \|v_{i_l} - p\|$, $l \in \{1, \ldots, K\}$ such that $0 = \sum_{l \in \{1,\ldots,K\}} \lambda_l \,\mathrm{vrs}(p - v_{i_l})$, where $\sum_{l \in \{1,\ldots,K\}} \lambda_l = 1$, $\lambda_l \geq 0$, $l \in \{1, \ldots, K\}$. Let U be a neighborhood of p and take $q \in U$. One can show that there must exist l^* such that $(p - v_{i_{l^*}}) \cdot (q - p) \geq 0$, since otherwise $0 = 0 \cdot (q - p) = (\sum_{l \in \{1,\ldots,K\}} \lambda_l \,\mathrm{vrs}(p - v_{i_l})) \cdot (q - p) < 0$, which is a contradiction. Then

$$\|q - v_{i_{l^*}}\|^2 = \|q - p\|^2 + \|p - v_{i_{l^*}}\|^2 - 2(q - p) \cdot (v_{i_{l^*}} - p) \geq \|p - v_{i_{l^*}}\|^2\,.$$

Therefore, $\mathrm{lg}_Q(q) \geq \|p - v_{i_{l^*}}\| = \mathrm{lg}_Q(p)$, which shows that p is a local minimum. Finally, if $0 \in \mathrm{int}(\partial \mathrm{sm}_Q(p))$, then one can see that p is a strict local maximum. Furthermore, there cannot be any other local (hence global) maximum of sm_Q, as we now show. Assume $\bar{p} \in \mathrm{IC}(Q)$. By hypothesis, the sphere $B_2(\bar{p}, \mathrm{sm}_Q(p))$ centered at $\bar{p}$ of radius $\mathrm{sm}_Q(p)$ is contained in Q. Consider the vector $\bar{p} - p$. By Lemma 2.1, there exists $e \in \mathrm{Ed}(Q)$ with $\mathrm{D}_e(p) = \mathrm{sm}_Q(p)$ such that $(\bar{p} - p) \cdot n_e > 0$. Therefore, there are points of $B_2(\bar{p}, \mathrm{sm}_Q(p))$ which necessarily belong to the half-plane defined by e where Q is not contained, which is a contradiction. □

3.2. Convergence properties for nonsmooth gradient flows. Here we study the generalized gradient flows arising from the two 1-center functions. An immediate consequence of Propositions 2.9 and 3.3 is the following result.

COROLLARY 3.4. *The gradient flows of the functions* $\lg_Q$ *and* sm_Q*,*

$$\dot{x}(t) = -\operatorname{Ln}(\partial \lg_Q)(x(t))\,, \tag{3.5}$$

$$\dot{x}(t) = \operatorname{Ln}(\partial \mathrm{sm}_Q)(x(t))\,, \tag{3.6}$$

converge asymptotically to the circumcenter $\mathrm{CC}(Q)$ *and the incenter set* $\mathrm{IC}(Q)$*, respectively.*

The following two propositions discuss the convergence properties of the gradient descents.

PROPOSITION 3.5. *If* $0 \in \operatorname{int}(\partial \lg_Q(\mathrm{CC}(Q)))$*, then the flow* (3.5) *reaches* $\mathrm{CC}(Q)$ *in finite time.*

Proof. Let us prove that there exists $\epsilon > 0$ such that $\max \widetilde{\mathcal{L}}_{-\operatorname{Ln}[\lg_Q]} \lg_Q < -\epsilon$ a.e. on $Q \setminus \{\mathrm{CC}(Q)\}$. Take $p \neq \mathrm{CC}(Q)$. We know that each element $a \in \widetilde{\mathcal{L}}_{-\operatorname{Ln}[\lg_Q]} \lg_Q(p)$ can be expressed as $a = -\|w\|^2$, with $-w \in \partial \lg_Q(p)$. Therefore, we have

$$\max \widetilde{\mathcal{L}}_{-\operatorname{Ln}[\lg_Q]} \lg_Q(p) = -\|\operatorname{Ln}[\lg_Q](p)\|^2\,.$$

If there is a single vertex of Q involved in $\partial \lg_Q(p)$, then moving along the direction $-\operatorname{Ln}[\lg_Q](p)$ obviously decreases the distance to that vertex while maintaining constant the norm of the least-norm element, which is 1. If there are two or more vertexes involved, then the generalized gradient at p (cf. (3.2)) can be alternatively described as a polygonal region of the form

$$\{x \in \mathbb{R}^N \mid g_1(x) \leq 0, \ldots, g_s(x) \leq 0\},$$

where each g_r is a linear function whose annihilation corresponds to a set of the form $\mathrm{co}\{\mathrm{vrs}(p - v_{r,1}), \mathrm{vrs}(p - v_{r,2})\}$ for certain vertexes $v_{r,1}$, $v_{r,2}$ of Q. Now, the computation of the least-norm element in $\partial \lg_Q(p)$ can be formulated as the convex problem

$$\begin{aligned} &\text{minimize } \|x\|^2 \\ &\text{subject to } g_1(x) \leq 0, \ldots, g_s(x) \leq 0\,. \end{aligned}$$

Let $x^* = \operatorname{Ln}[\lg_Q](p)$. Let R denote the set of indexes r for which $g_r(x^*) = 0$. Then x^* is a regular point [21], meaning that $dg_r(x^*)$, $r \in R$ are linearly independent vectors. This is because the cardinality of R is at most 2 (since the intersection of two lines already determines a point), and the gradients of the functions g_r are independent when considered pairwise. We apply then the Kuhn–Tucker first-order necessary conditions for optimality [21] to conclude that there must exist $r^* \in R$ such that $g_{r^*}(x^*) = 0$. It is easy to see that r^* must be unique, since otherwise x^* does not have minimum norm. Therefore, we have that $\operatorname{Ln}[\lg_Q](p)$ is determined as the least-norm element in $\mathrm{co}\{\mathrm{vrs}(p - v_{r^*,1}), \mathrm{vrs}(p - v_{r^*,2})\}$. As a consequence, moving along the direction $-\operatorname{Ln}[\lg_Q](p)$ decreases the distance to the vertexes $v_{r^*,1}$, $v_{r^*,2}$, and hence the norm of the least-norm element decreases. If, along the flow (3.5), a new vertex of Q enters in the computation of $\partial \lg_Q(p(t))$, then there can be a jump in the norm of $\operatorname{Ln}[\lg_Q](p(t))$, which by definition will always be decreasing. Finally, note that if $v_{r^*,1}$, $v_{r^*,2}$ are active at the circumcenter, then they cannot be opposite with respect to $\mathrm{CC}(Q)$. If this was the case, then the assumption that 0 lies in $\operatorname{int}(\partial \lg_Q(\mathrm{CC}(Q)))$

would imply that there exists another vertex v of Q, which is active at the circumcenter and lies in the half-plane defined by the line from $v_{r^*,1}$ to $v_{r^*,2}$ which does not contain the point $p(t)$. Therefore, the vertex v would be further away from $p(t)$ than $v_{r^*,1}$ and $v_{r^*,2}$, which is a contradiction. Consequently, we conclude

$$\|\operatorname{Ln}[\lg_Q](p)\| \geq \epsilon = \min\big\{1, \{\|\operatorname{Ln}(\operatorname{co}\{\operatorname{vrs}(\operatorname{CC}(Q)-v), \operatorname{vrs}(\operatorname{CC}(Q)-w)\})\| \mid v, w \in I(\operatorname{CC}(Q)), \operatorname{CC}(Q)-v \neq -(\operatorname{CC}(Q)-w)\}\big\} > 0 \quad \forall p \neq \operatorname{CC}(Q).$$

Resorting now to Proposition 2.8, we deduce that the circumcenter $\operatorname{CC}(Q)$ is attained in finite time. ∎

Remark 3.6. Note that if $0 \in \partial \lg_Q(\operatorname{CC}(Q)) \setminus \operatorname{int}(\partial \lg_Q(\operatorname{CC}(Q)))$, then generically convergence is achieved over an infinite time horizon.

PROPOSITION 3.7. *The flow* (3.6) *reaches the set* $\operatorname{IC}(Q)$ *in finite time.*

Proof. Let $p \notin \operatorname{IC}(Q)$. We know $\min \widetilde{\mathcal{L}}_{\operatorname{Ln}[\operatorname{sm}_Q]} \operatorname{sm}_Q(p) = \|\operatorname{Ln}[\operatorname{sm}_Q](p)\|^2$. Moreover, for all $p \notin \operatorname{IC}(Q)$, we have

$$\|\operatorname{Ln}[\operatorname{sm}_Q](p)\| \geq \epsilon = \min\big\{1, \{\|\operatorname{Ln}(\operatorname{co}\{n_e, n_f\})\| \mid e, f \in \operatorname{Ed}(Q), n_e \neq -n_f\}\big\} > 0.$$

Resorting to Proposition 2.8, we deduce the desired result. ∎

Figure 3.1 shows an example of the implementation of the gradient descent (3.5) and (3.6). Note that if the circumcenter $\operatorname{CC}(Q)$ (respectively, the incenter set $\operatorname{IC}(Q)$) is first computed offline, then the strategy of directly going toward it would converge in a less "erratic" way. Note also that the move-toward-the-center strategy is exponentially fast.

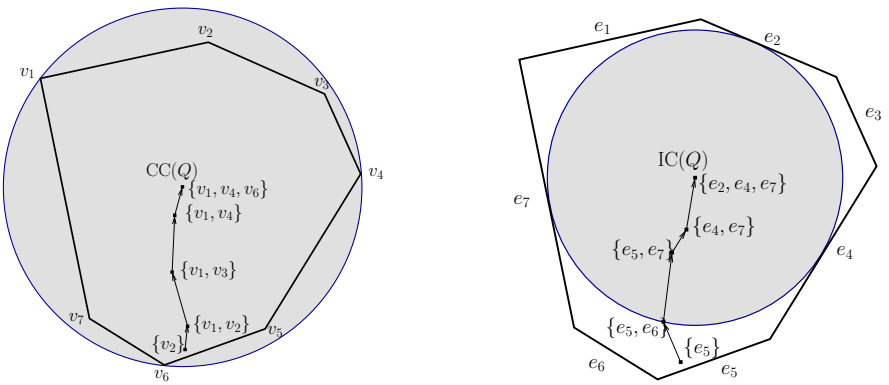

FIG. 3.1. *Illustration of the gradient descent of* $\lg_Q$ *and* sm_Q. *The points where the curve* $t \mapsto p(t)$ *fails to be differentiable correspond to points where there is a new vertex* v *of* Q *such that* $\|p(t) - v\| = \lg_Q(p(t))$ *(respectively, a new edge* e *of* Q *such that* $\operatorname{D}_e(p(t)) = \operatorname{sm}_Q(p(t))$*). The circumcenter and the incenter are attained in finite time according to Propositions* 3.5 *and* 3.7.

Finally, we conclude this section with four results useful for later developments.

LEMMA 3.8. *Let* $q \in Q$, *let* $v(q)$ *be one of the vertexes of* Q *which is furthest away from* q, *and let* $e(q)$ *be one of the edges of* Q *which is nearest to* q. *Then*

(i) $\operatorname{Ln}[\lg_Q](q) \cdot (q - v(q)) \geq 0$, *and the inequality is strict if* $q \neq \operatorname{CC}(Q)$,
(ii) $(q - \operatorname{CC}(Q)) \cdot (q - v(q)) \geq \|q - \operatorname{CC}(Q)\|^2/2$,
(iii) $\operatorname{Ln}[\operatorname{sm}_Q](q) \cdot n_e \geq 0$, *and the inequality is strict if* $q \notin \operatorname{IC}(Q)$, *and*
(iv) $(x - q) \cdot n_e \geq \operatorname{IR}(Q) - \operatorname{D}_e(q) \geq 0$ *for any* $x \in \operatorname{IC}(Q)$, *and the second inequality is strict if* $q \notin \operatorname{IC}(Q)$.

Proof. Let q be a point in Q. If $q = \mathrm{CC}(Q)$, claims (i) and (ii) are obviously satisfied since $\mathrm{Ln}[\mathrm{lg}_Q](q) = 0$. Assume then that $q \neq \mathrm{CC}(Q)$.

Let us prove (i) first. By Proposition 3.3, $0 \notin \partial\, \mathrm{lg}_Q(q)$, and hence $\mathrm{Ln}[\mathrm{lg}_Q](q) \neq 0$. Let us prove $\mathrm{Ln}[\mathrm{lg}_Q](q) \cdot (q - v(q)) > 0$ reasoning by contradiction. If $\mathrm{Ln}[\mathrm{lg}_Q](q) \cdot (q - v(q)) \leq 0$, then $d/dt \left(\| q - t\, \mathrm{Ln}[\mathrm{lg}_Q](q) - v \| \right)_{t=0} = \mathrm{vrs}(q - v) \cdot (-\mathrm{Ln}[\mathrm{lg}_Q](q)) \geq 0$, which implies that $\| q - t\, \mathrm{Ln}[\mathrm{lg}_Q](q) - v \| \geq \| q - v \| = \mathrm{lg}_Q(q)$ for $t > 0$ small enough. On the other hand, invoking Theorem 2.4 we have that $\mathrm{lg}_Q(q) - t \| \mathrm{Ln}[\mathrm{lg}_Q](q) \|^2 / 2 \geq \mathrm{lg}_Q(q - t\, \mathrm{Ln}[\mathrm{lg}_Q](q)) \geq \| q - t\, \mathrm{Ln}[\mathrm{lg}_Q](q) - v \|$. Gathering both facts, we conclude $-t \| \mathrm{Ln}[\mathrm{lg}_Q](q) \|^2 / 2 \geq 0$, which is a contradiction.

Let us now prove (ii). Since $q \neq \mathrm{CC}(Q)$, we have $\| q - v(q) \| > \mathrm{CR}(Q)$. Consider then a ball $\overline{B}_2(v(q), \| q - v(q) \|)$ centered at the vertex $v(q)$ with radius $\| q - v(q) \|$. By definition of the circumcenter, $\mathrm{CC}(Q)$ must lie in the interior of $\overline{B}_2(v(q), \| q - v(q) \|)$. Consequently, $\| \mathrm{CC}(Q) - v(q) \| < \| q - v(q) \|$. Then, from $\| \mathrm{CC}(Q) - v(q) \|^2 = \| \mathrm{CC}(Q) - q \|^2 + \| q - v(q) \|^2 - 2(q - \mathrm{CC}(Q)) \cdot (q - v(q))$, we deduce

$$2(q - \mathrm{CC}(Q)) \cdot (q - v(q)) - \| \mathrm{CC}(Q) - q \|^2 = \| q - v(q) \|^2 - \| \mathrm{CC}(Q) - v(q) \|^2 > 0\,,$$

which implies the desired result.

Let us now prove (iii). If $q \in \mathrm{IC}(Q)$, the claim is obviously satisfied since $\mathrm{Ln}[\mathrm{sm}_Q](q) = 0$. Assume then that $q \notin \mathrm{IC}(Q)$. By Proposition 3.3, $0 \notin \partial\, \mathrm{sm}_Q(q)$, and hence $\mathrm{Ln}[\mathrm{sm}_Q](q) \neq 0$. Let us prove $\mathrm{Ln}[\mathrm{sm}_Q](q) \cdot n_e > 0$ reasoning by contradiction. If $\mathrm{Ln}[\mathrm{sm}_Q](q) \cdot n_e \leq 0$, then $d/dt \left(\mathrm{D}_e(q + t\, \mathrm{Ln}[\mathrm{sm}_Q](q)) \right)_{t=0} = n_e \cdot \mathrm{Ln}[\mathrm{sm}_Q](q) \leq 0$, which implies that $\mathrm{D}_e(q + t\, \mathrm{Ln}[\mathrm{sm}_Q](q)) \leq \mathrm{D}_e(q) = \mathrm{sm}_Q(q)$ for $t > 0$ small enough. On the other hand, invoking Theorem 2.4 for the function $-\mathrm{sm}_Q$, we have that $\mathrm{sm}_Q(q) + t \| \mathrm{Ln}[\mathrm{sm}_Q](q) \|^2 / 2 \leq \mathrm{sm}_Q(q + t\, \mathrm{Ln}[\mathrm{sm}_Q](q)) \leq \mathrm{D}_e(q + t\, \mathrm{Ln}[\mathrm{sm}_Q](q))$. Gathering both facts, we conclude $t \| \mathrm{Ln}[\mathrm{sm}_Q](q) \|^2 / 2 \leq 0$, which is a contradiction.

Let us now prove (iv). By definition, $\mathrm{D}_e(q) \leq \mathrm{IR}(Q)$. This inequality is strict if $q \notin \mathrm{IC}(Q)$. Let $x \in \mathrm{IC}(Q)$. If we take a point O in the edge e, then the function D_e can be expressed as $\mathrm{D}_e(p) = (p - O) \cdot n_e$. Then, we have

$$\mathrm{D}_e(x) = (x - O) \cdot n_e = (x - q) \cdot n_e + (q - O) \cdot n_e = (x - q) \cdot n_e + \mathrm{D}_e(q)\,.$$

Since $\mathrm{D}_e(x) \geq \mathrm{sm}_Q(x) = \mathrm{IR}(Q)$, we conclude that $(x - q) \cdot n_e \geq \mathrm{IR}(Q) - \mathrm{D}_e(q) \geq 0$, and that the second inequality is strict if $q \notin \mathrm{IC}(Q)$. ∎

4. Analysis of the multicenter functions. Here we study the locational optimization functions $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$ for the disk-covering and sphere-packing problems. We characterize their smoothness properties, generalized gradients, and critical points for arbitrary numbers of generators.

4.1. Smoothness and generalized gradients. We start by providing some alternative expressions and useful quantities. We write

$$\mathcal{H}_{\mathrm{DC}}(P) = \max_{i \in \{1,\dots,n\}} G_i(P)\,, \quad \mathcal{H}_{\mathrm{SP}}(P) = \min_{i \in \{1,\dots,n\}} F_i(P)\,,$$

where

$$G_i(P) = \max_{q \in V_i(P)} \| q - p_i \|\,, \quad F_i(P) = \min_{q \notin \mathrm{int}(V_i(P))} \| q - p_i \|\,.$$

Note that $G_i(P) = \mathrm{lg}_{V_i(P)}(p_i)$ and $F_i(P) = \mathrm{sm}_{V_i(P)}(p_i)$, where, for $i \in \{1, \dots, n\}$,

$$\mathrm{lg}_{V_i} : V_i \to \mathbb{R}\,, \quad \mathrm{sm}_{V_i} : V_i \to \mathbb{R}\,.$$

Proposition 3.3 provides an explicit expression for the generalized gradients of lg_{V_i} and sm_{V_i} when the Voronoi cell V_i is held fixed. Despite the slight abuse of notation, it is convenient to let $\partial \lg_{V_i(P)}(p_i)$ denote $\partial \lg_V(p_i)_{|V=V_i(P)}$ and let $\partial \mathrm{sm}_{V_i(P)}(p_i)$ denote $\partial \mathrm{sm}_V(p_i)_{|V=V_i(P)}$.

In contrast to this analysis at fixed Voronoi partition, the properties of the functions G_i and F_i are strongly affected by the dependence on the Voronoi partition $\mathcal{V}(P)$. We endeavor to characterize these properties in order to study $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$.

PROPOSITION 4.1. *The functions $G_i, -F_i : Q^n \to \mathbb{R}$ are locally Lipschitz and regular. As a consequence, the locational optimization functions $\mathcal{H}_{DC}, -\mathcal{H}_{SP} : Q^n \to \mathbb{R}$ are locally Lipschitz and regular.*

Proof. (a) *G_i is locally Lipschitz and regular.* The definition of the function G_i admits the following alternative expression:

$$G_i(P) = \max_{v \in \mathrm{Ve}(V_i)} \|p_i - v\| . \tag{4.1}$$

Let P_0 be nondegenerate at the ith generator. Then there exists a neighborhood U of P_0 where the set $\mathcal{N}(i)$ does not change. Let $\{v_1, \ldots, v_{M_1}\}$, $\{w_1, \ldots, w_{M_2}\}$, $\{z_1, \ldots, z_{M_3}\}$ be the vertexes of V_i of types (a), (b), and (c), respectively. Then G_i can be locally written as

$$G_i(P) = \max \left\{ \max_{\ell \in \{1,\ldots,M_1\}} \|v_\ell - p_i\|, \max_{\ell \in \{1,\ldots,M_2\}} \|w_\ell - p_i\|, \max_{\ell \in \{1,\ldots,M_3\}} \|z_\ell - p_i\| \right\}$$

for all $P \in U$. Therefore, G_i restricted to U coincides with the function $\mathcal{G}_{\mathcal{N}(i)} : Q^n \to \mathbb{R}$ defined by

$$\mathcal{G}_{\mathcal{N}(i)}(P) = \max \left\{ \max_{\ell \in \{1,\ldots,M_1\}} \|v_\ell - p_i\|, \max_{\ell \in \{1,\ldots,M_2\}} \|w_\ell - p_i\|, \max_{\ell \in \{1,\ldots,M_3\}} \|z_\ell - p_i\| \right\}. \tag{4.2}$$

The function $\mathcal{G}_{\mathcal{N}(i)}$ is the maximum of a fixed finite set of locally Lipschitz and regular functions and, consequently, locally Lipschitz and regular by Proposition 2.2. We conclude that G_i is both locally Lipschitz and regular at P_0.

Let P_0 be degenerate at the ith generator. Then in any neighborhood U of P_0 there are different sets of neighbors of the ith generator. Indeed, because the number of generators, edges of the boundary Q, and vertexes of Q is finite, there is only a finite number of different sets of neighbors of the ith generator over U, say $\mathcal{N}^1(i), \ldots, \mathcal{N}^L(i)$. This implies that G_i admits the alternative expression $G_i(P) = \min\left\{\mathcal{G}_{\mathcal{N}^1(i)}(P), \ldots, \mathcal{G}_{\mathcal{N}^L(i)}(P)\right\}$ over U. From this expression, one can conclude that G_i is both locally Lipschitz and regular at P_0.

(b) *$-F_i$ is locally Lipschitz and regular.* From the definition of F_i, it is clear that its value at a configuration P is attained at the boundary of the Voronoi region V_i. Therefore, one only minimizes among the edges associated with the Voronoi neighbors $\mathcal{N}(i)$ and the edges of Q with nonempty intersection with V_i. Moreover, one can also see that the minimum must be attained at a point of the form $\mathrm{proj}_e(p_i)$, for some edge e of V_i. Now, consider the function $\mathcal{F}_i : Q^n \to \mathbb{R}$ defined by

$$\mathcal{F}_i(P) = \min \left\{ \min_{j \in \{1,\ldots,n\}} \|p_i - \frac{p_i + p_j}{2}\| , \min_{e \in \mathrm{Ed}(Q)} \mathrm{D}_e(p_i) \right\}. \tag{4.3}$$

We shall prove that $\mathcal{F}_i$ coincides with F_i. Clearly, $\mathcal{F}_i(P) \leq F_i(P)$. If $k \notin \mathcal{N}(i)$, then $(p_i + p_k)/2 \notin V_i$. Since $Q \setminus V_i$ is open, there exists a neighborhood of $(p_i + p_k)/2$ such

that $U \subset Q/V_i$. Therefore,

$$\|p_i - \frac{p_i + p_k}{2}\| > \min_{q \in U} \|p_i - q\| \geq \min_{q \notin \text{int}(V_i)} \|p_i - q\| = F_i(P)\,.$$

If an edge e of Q does not intersect V_i, then $\text{proj}_e(p_i) \notin V_i$. Using again the fact that $Q \backslash V_i$ is open, there exists a neighborhood U of $\text{proj}_e(p_i)$ in $\mathbb{R}^2$ such that $U \cap Q \subset Q \backslash V_i$. Then

$$\text{D}_e(p_i) = \|p_i - \text{proj}_e(p_i)\| > \min_{q \in U \cap Q} \|p_i - q\| \geq F_i(P)\,.$$

As a consequence of the previous inequalities, F_i equals $\mathcal{F}_{\mathcal{N}(i)}$. Resorting now to Proposition 2.2, we conclude that $-F_i$ is locally Lipschitz and regular. □

Next, one can actually prove the following stronger result.

PROPOSITION 4.2. *The locational optimization functions $\mathcal{H}_{DC}, \mathcal{H}_{SP} : Q^n \to \mathbb{R}$ are globally Lipschitz, with Lipschitz constant equal to* 1.

Proof. (a) *$\mathcal{H}_{DC}$ is globally Lipschitz.* Let P, P' be two configurations of the n generators. Without loss of generality, assume that $\mathcal{H}_{\text{DC}}(P) \leq \mathcal{H}_{\text{DC}}(P')$. Let i, j and q_0, $q_0' \in Q$ be such that $\mathcal{H}_{\text{DC}}(P) = G_i(P) = \|q_0 - p_i\|$ and $\mathcal{H}_{\text{DC}}(P') = G_j(P') = \|q_0' - p_j'\|$. Now consider the set $B_2(q_0', G_i(P))$. Then there exists a k such that $p_k \in \overline{B}_2(q_0', G_i(P))$ (otherwise, $\|q_0' - p_l\| > G_i(P)$, which contradicts the definition of the function $\mathcal{H}_{\text{DC}}$). On the other hand, we necessarily have that $p_k' \notin B_2(q_0', G_j(P'))$, since otherwise $\|q_0' - p_k'\| < \|q_0' - p_j'\|$, which implies that $q_0' \notin V_j'$, a contradiction. Finally, we apply the triangle inequality to obtain $\|q_0' - p_k'\| \leq \|q_0' - p_k\| + \|p_k - p_k'\|$. Gathering the previous facts, we have

$$\begin{aligned} |\mathcal{H}_{\text{DC}}(P') - \mathcal{H}_{\text{DC}}(P)| &= G_j(P') - G_i(P) \\ &\leq \|q_0' - p_k'\| - \|q_0' - p_k\| \leq \|p_k - p_k'\| \leq \|P - P'\|\,. \end{aligned}$$

(b) *$\mathcal{H}_{SP}$ is globally Lipschitz.* Let P, P' be two configurations of the n generators. Without loss of generality, assume that $\mathcal{H}_{\text{SP}}(P) \leq \mathcal{H}_{\text{SP}}(P')$. Let i, j and q_0, $q_0' \in Q$ be such that $\mathcal{H}_{\text{SP}}(P) = F_i(P) = \|q_0 - p_i\|$ and $\mathcal{H}_{\text{SP}}(P') = F_j(P') = \|q_0' - p_j'\|$. We treat separately the following two cases: (i) q_0 does not belong to the boundary of Q, and (ii) q_0 belongs to the boundary of Q. In case (i), it necessarily exists $k \in \mathcal{N}(i)$ such that $\|q_0 - p_i\| = \|q_0 - p_k\|$. If $\|q_0 - p_i'\| \geq F_j(P')$, then

$$\begin{aligned} |\mathcal{H}_{\text{SP}}(P') - \mathcal{H}_{\text{SP}}(P)| = F_j(P') - F_i(P) &\leq \|q_0 - p_i'\| - \|q_0 - p_i\| \\ &\leq \|p_i - p_i'\| \leq \|P - P'\|\,. \end{aligned} \tag{4.4}$$

If, on the contrary, $\|q_0 - p_i'\| < F_j(P')$, then $q_0 \in \text{int}(V_i')$. Therefore, $\|q_0 - p_k'\| \geq F_k(P') \geq F_j(P')$. Now we perform the same computation as in (4.4) to conclude $|\mathcal{H}_{\text{SP}}(P') - \mathcal{H}_{\text{SP}}(P)| \leq \|P - P'\|$.

In case (ii), we prove that $\|q_0 - p_i'\| \geq F_j(P')$. Suppose this is not true, i.e., $\|q_0 - p_i'\| < F_j(P')$. Let $m = q_0 + \epsilon(q_0 - p_i')$, with sufficiently small $\epsilon > 0$ such that $\|m - p_i'\| < F_j(P')$. Clearly $m \notin Q$. On the other hand, by definition $B_2(p_i', F_i(P')) \subset V_i'$. Now we have

$$B_2(p_i', F_j(P')) \subset B_2(p_i', F_i(P')) \subset V_i' \subset Q\,.$$

But since $\|m - p_i'\| < F_j(P')$, then $m \in B_2(p_i', F_j(P')) \subset Q$, which is a contradiction. Therefore, $\|q_0 - p_i'\| \geq F_j(P')$, and now the same argument as in (4.4) guarantees that $|\mathcal{H}_{\text{SP}}(P') - \mathcal{H}_{\text{SP}}(P)| \leq \|P - P'\|$. □

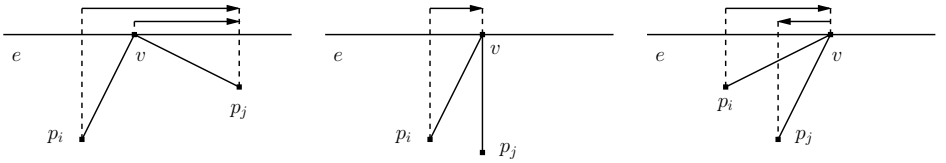

FIG. 4.1. *To illustrate* (4.5) *we draw the vectors* $\mathrm{proj}_e(p_j - v(e,i,j))$ *and* $\mathrm{proj}_e(p_j - p_i)$ *for various locations of* p_i, p_j, *and* e. *The left, center, and right figures correspond to* $\lambda(e,i,j) > 0$, $\lambda(e,i,j) = 0$, $\lambda(e,i,j) < 0$, *respectively.*

We now introduce some quantities that are useful in characterizing the generalized gradient of the functions G_i. Given a vertex of type (b), $v = v(e,i,j)$, determined by the edge e and two generators p_i and p_j, we consider the scalar function $\lambda(e,i,j)$ defined by

$$\mathrm{proj}_e(p_j - v(e,i,j)) = \lambda(e,i,j)\ \mathrm{proj}_e(p_j - p_i)\,, \tag{4.5}$$

where recall that proj_e denotes the orthogonal projection onto the edge e; see Figure 4.1. One can see that $\lambda(e,i,j) + \lambda(e,j,i) = 1$. If e is a segment in the line $ax + by + c = 0$, $(\Delta x_{ij}, \Delta y_{ij}) = p_j - p_i$, $(x_m, y_m) = (p_i + p_j)/2$, then one can show

$$\lambda(e,i,j) = \frac{1}{2} - \frac{(a\Delta x_{ij} + b\Delta y_{ij})(ax_m + by_m + c)}{(a\Delta y_{ij} - b\Delta x_{ij})^2}\,. \tag{4.6}$$

Given a vertex of type (a), $v = v(i,j,k)$, determined by the three generators p_i, p_j, and p_k, we consider the scalar function $\mu(i,j,k)$ defined by

$$\mathrm{proj}_{e_{jk}}(p_\ell - v(i,j,k)) = \mu(i,j,k)\ \mathrm{proj}_{e_{jk}}(p_\ell - p_i)\,, \tag{4.7}$$

where e_{jk} is the bisector of p_j and p_k and where $p_\ell = p_j$ if p_j belongs to the half-plane defined by e_{jk} containing p_i, and $p_\ell = p_k$ otherwise. One can see that $\mu(i,j,k) = \mu(i,k,j)$ and that $\mu(i,j,k) + \mu(j,k,i) + \mu(k,i,j) = 1$. From the expression for λ, one can obtain

$$\mu(i,j,k) = \frac{1}{2} + \frac{(\Delta x_{ij}\Delta x_{jk} + \Delta y_{ij}\Delta y_{jk})(\Delta x_{ik}\Delta x_{jk} + \Delta y_{ik}\Delta y_{jk})}{2(x_k\Delta y_{ij} - x_j\Delta y_{ik} + x_i\Delta y_{jk})^2}. \tag{4.8}$$

Note that, in general, λ and μ are not positive functions. Now we are ready to describe in detail the structure of the generalized gradient of the functions G_i, F_i.

PROPOSITION 4.3. *The generalized gradient of* $G_i : Q^n \to \mathbb{R}$ *at* $P \in Q^n$ *is*

$$\partial G_i(P) = \mathrm{co}\{\partial_v G_i(P) \in (\mathbb{R}^2)^n \mid v \in \mathrm{Ve}(V_i(P)) \text{ such that } G_i(P) = \|p_i - v\|\},$$

where we consider separately the following cases. If $v = v(i,j,k)$ *is a nondegenerate vertex of type* (a), *then*

$$\begin{aligned}&\partial_{v(i,j,k)} G_i(P) = \partial_{v(k,i,j)} G_k(P) = \partial_{v(j,k,i)} G_j(P)\\ &= (0,\dots,\underbrace{\mu(i,j,k)\,\mathrm{vrs}(p_i - v)}_{i\text{th place}},\dots,\underbrace{\mu(j,k,i)\,\mathrm{vrs}(p_j - v)}_{j\text{th place}},\dots,\underbrace{\mu(k,i,j)\,\mathrm{vrs}(p_k - v)}_{k\text{th place}},\dots,0),\end{aligned}$$

where, without loss of generality, we let $i < j < k$. If $v = v(e,i,j)$ is a nondegenerate vertex of type (b)*, then*

$$\partial_{v(e,i,j)} G_i(P) = \partial_{v(e,j,i)} G_j(P) \\ = (0, \dots, \underbrace{\lambda(e,i,j)\operatorname{vrs}(p_i - v)}_{ith\ place}, \dots, \underbrace{\lambda(e,j,i)\operatorname{vrs}(p_j - v)}_{jth\ place}, \dots, 0),$$

where, without loss of generality, we let $i < j$. If $v = v(e,f,i)$ is a nondegenerate vertex of type (c), then

$$\partial_{v(e,f,i)} G_i(P) = (0, \dots, 0, \underbrace{\operatorname{vrs}(p_i - v)}_{ith\ place}, 0, \dots, 0).$$

Finally, if the vertex v is degenerate, i.e., if v is determined by $d > 3$ elements (generators or edges), then there are $\binom{d-1}{2}$ pairs of elements which determine the vertex v together with the generator p_i. In this case, $\partial_v G_i(P)$ is the convex hull of $\partial_{v(\alpha,\beta,\gamma)} G_i(P)$ for all $\binom{d-1}{2}$ such triplets (α,β,γ).

Note that, at all nondegenerate configurations P, the quantity $\partial_v G_i(P)$ is the generalized gradient of the function $(p_1, \dots, p_n) \mapsto \|p_i - v(i,j,k)\|$; however, this interpretation cannot be given when P is degenerate.

Proof. We present the proof for the expression for $\partial G_i(P)$. Let us consider first the case when P is a nondegenerate configuration for the ith generator. According to the proof of Proposition 4.1, G_i coincides with the function $\mathcal{G}_{\mathcal{N}(i)}$ over a neighborhood U of P. Hence, $\partial G_i(P) = \partial \mathcal{G}_{\mathcal{N}(i)}(P)$ which, according to (4.2) and Proposition 2.2, takes the form

$$\operatorname{co}\left\{ \frac{\partial}{\partial P} \|v - p_i\| \mid v \in \operatorname{Ve}(V_i(P)) \text{ such that } \|v - p_i\| = G_i(P) \right\}.$$

If $v = v(i,j,k)$ is a nondegenerate vertex of type (a), then one can compute

$$\frac{\partial}{\partial p_i} \|p_i - v(i,j,k)\| = \operatorname{vrs}(p_i - v)\left(I_2 - \frac{\partial v}{\partial p_i}\right) = \mu(i,j,k)\operatorname{vrs}(p_i - v),$$
$$\frac{\partial}{\partial p_j} \|p_i - v(i,j,k)\| = -\operatorname{vrs}(p_i - v)\left(\frac{\partial v}{\partial p_j}\right) = \mu(j,k,i)\operatorname{vrs}(p_j - v),$$
$$\frac{\partial}{\partial p_\ell} \|p_i - v(i,j,k)\| = 0, \qquad \ell \neq i,j,k,$$

where in the first and second chain of equalities we have used the expression of μ given in (4.8). If $v = v(e,i,j)$ is a nondegenerate vertex of type (b), then one can compute

$$\frac{\partial}{\partial p_i} \|p_i - v(e,i,j)\| = \operatorname{vrs}(p_i - v)\left(I_2 - \frac{\partial v}{\partial p_i}\right) = \lambda(e,i,j)\operatorname{vrs}(p_i - v),$$
$$\frac{\partial}{\partial p_j} \|p_i - v(e,i,j)\| = -\operatorname{vrs}(p_i - v)\left(\frac{\partial v}{\partial p_j}\right) = \lambda(e,j,i)\operatorname{vrs}(p_j - v),$$
$$\frac{\partial}{\partial p_\ell} \|p_i - v(e,i,j)\| = 0, \qquad \ell \neq i,j,$$

where in the first and second chain of equalities we have used the expression of λ given in (4.6). If $v = v(e, f, i)$ is a nondegenerate vertex of type (c), then

$$\frac{\partial}{\partial p_i}\|p_i - v(e,f,i)\| = \mathrm{vrs}(p_i - v)\,,$$
$$\frac{\partial}{\partial p_\ell}\|p_i - v(e,f,i)\| = 0\,, \qquad \ell \neq i\,.$$

If P is a degenerate configuration at the ith generator, then, following the proof of Proposition 4.1, the generalized gradient of G_i can be expressed as the convex hull of the generalized gradients of each of the functions $\mathcal{G}_{\mathcal{N}^1(i)}, \ldots, \mathcal{G}_{\mathcal{N}^L(i)}$. The claim now follows by reproducing the previous discussion for the generalized gradients of each of the functions $\mathcal{G}_{\mathcal{N}^\ell(i)}$, $\ell \in \{1, \ldots, L\}$. □

The expression for $\partial F_i(P)$ can be deduced in an analogous (and simpler) way, since according to the proof of Proposition 4.1, it is not necessary to establish any distinction between the degenerate and the nondegenerate configurations. Accordingly, we state the following result without proof.

PROPOSITION 4.4. *The generalized gradient of $F_i : Q^n \to \mathbb{R}$ at $P \in Q^n$ is*

$$\partial F_i(P) = \mathrm{co}\{\partial_e F_i(P) \in (\mathbb{R}^2)^n \mid e \in \mathrm{Ed}(V_i(P)) \text{ such that } F_i(P) = \mathrm{D}_e(p_i)\}$$

where, if $e = e(i,j)$ is an edge of type (a)*, then*

$$\partial_{e(i,j)} F_i(P) = \partial_{e(j,i)} F_j(P) = \frac{1}{2}(0, \ldots, \underbrace{n_{e(i,j)}}_{i\text{th place}}, \ldots, \underbrace{-n_{e(i,j)}}_{j\text{th place}}, \ldots, 0),$$

and if $e = e(i)$ is an edge of type (b)*, then*

$$\partial_{e(i)} F_i(P) = (0, \ldots, \underbrace{n_{e(i)}}_{i\text{th place}}, \ldots, 0).$$

Next, we give conditions under which the functions λ and μ take positive values.

LEMMA 4.5. *Let $P \in Q^n$ and let $v \in \mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$. Then*

(i) *if v belongs to an edge e of Q, then there exist generators p_i and p_j such that $\lambda(e,i,j)$ and $\lambda(e,j,i)$ are positive, and*

(ii) *if v belongs to $\mathrm{int}(Q)$, then there exist generators p_i, p_j, and p_k such that $\mu(i,j,k)$, $\mu(j,k,i)$, and $\mu(k,i,j)$ are positive.*

Proof. Consider first the case when v is nondegenerate. If v is in the edge e of Q (i.e., v is of type (b)), let p_i and p_j be the two generators determining it. From the definition of λ, one sees that the values $\lambda(e,i,j) = 0$ and $\lambda(e,j,i) = 0$ correspond to, respectively, p_j and p_i lying on the orthogonal line to e passing through $v(e,i,j)$. If $\lambda(e,i,j) \leq 0$, then there exists $w \in e \cap V_j$ such that $\|p_j - w\| > \|p_j - v\| = \mathcal{H}_{\mathrm{DC}}(P)$, which is a contradiction. Therefore, $\lambda(e,i,j) > 0$. The same argument guarantees $\lambda(e,j,i) > 0$. If v is of type (a) and p_i, p_j, and p_k are the elements determining it, a similar argument leads to the conclusion that $\mu(i,j,k)$, $\mu(j,k,i)$, and $\mu(k,i,j)$ are positive.

Consider the case when v is degenerate. Let $\{i_1, \ldots, i_m\}$ be such that $v \in V_{i_\ell}$, $\ell \in \{1, \ldots, m\}$. Assume v is in an edge e of Q. Let l denote the orthogonal line to the edge e passing through v. We claim that there must exist generators i, j in $\{i_1, \ldots, i_m\}$ on both sides of l (and, therefore, the values of the corresponding

$\lambda(e,i,j)$ and $\lambda(e,j,i)$ are positive; cf. Figure 4.1). Assume this is not the case, i.e., $\{p_{i_1},\dots,p_{i_m}\}$ are contained in one of the closed half-planes defined by l, say l_-. Take $w \in l_+ \cap e$ arbitrarily close to v. Since $\{p_{i_1},\dots,p_{i_m}\} \subset l_-$, we have $\|p_{i_\ell} - w\| > \|p_{i_\ell} - v\|$ for all $\ell \in \{1,\dots,m\}$. On the other hand, since no generator outside the set $\{p_{i_1},\dots,p_{i_m}\}$ is involved in the definition of v, there must exist ℓ^* such that $w \in V_{i_{\ell^*}}$. Therefore, $G_{i_{\ell^*}}(P) \geq \|p_{i_{\ell^*}} - w\| > \|p_{i_{\ell^*}} - v\| = \mathcal{H}_{\mathrm{DC}}(P)$, which is a contradiction. Assume now that $v \in \mathrm{int}(Q)$. Our claim is that for any line l passing through v, there must exist generators on both sides of l (by (4.7), this would imply (ii)). If this is not the case, i.e., $\{p_{i_1},\dots,p_{i_m}\} \subset l_-$, then take $w \in B_2(v,\epsilon) \cap l_+ \cap o$, where o denotes the orthogonal line to l passing through v. As before, $w \in V_{i_{\ell^*}}$ for some ℓ^* and $\|p_{i_{\ell^*}} - w\| > \|p_{i_{\ell^*}} - v\|$, which yields a contradiction. □

This completes our analysis of the generalized gradients of G_i and F_i and, with these results, we return to studying the generalized gradients of $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$. An immediate consequence of Propositions 2.2 and 4.1 is that

$$\begin{aligned} \partial\mathcal{H}_{\mathrm{DC}}(P) &= \mathrm{co}\{\partial G_i(P) \mid i \in I(P)\}, \\ \partial\mathcal{H}_{\mathrm{SP}}(P) &= \mathrm{co}\{\partial F_i(P) \mid i \in I(P)\}. \end{aligned} \tag{4.9}$$

Furthermore, we can provide the following more detailed characterization.

PROPOSITION 4.6. *Let $P \in Q^n$. For each $i \in \{1,\dots,n\}$, the image by π_i of the generalized gradients of $\mathcal{H}_{DC}$ and $\mathcal{H}_{SP}$ at P is given by*

$$\pi_i(\partial\mathcal{H}_{DC}(P)) = \begin{cases} \pi_i(\partial G_i(P)) & \text{if } i \in I(P),\ \mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P)) \subset \mathrm{Ve}(V_i(P)), \\ \mathrm{co}\{\pi_i(\partial G_i(P)), 0\} & \text{if } i \in I(P),\ \mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P)) \not\subset \mathrm{Ve}(V_i(P)), \\ 0 & \text{if } i \notin I(P); \end{cases}$$

$$\pi_i(\partial\mathcal{H}_{SP}(P)) = \begin{cases} \pi_i(\partial F_i(P)) & \text{if } i \in I(P),\ \mathrm{Ed}_{\mathrm{SP}}(\mathcal{V}(P)) \subset \mathrm{Ed}(V_i(P)), \\ \mathrm{co}\{\pi_i(\partial F_i(P)), 0\} & \text{if } i \in I(P),\ \mathrm{Ed}_{\mathrm{SP}}(\mathcal{V}(P)) \not\subset \mathrm{Ed}(V_i(P)), \\ 0 & \text{if } i \notin I(P). \end{cases}$$

Proof. From (4.9), if $i \notin I(P)$, then $\pi_i(\partial\mathcal{H}_{\mathrm{DC}}(P)) = 0$, $\pi_i(\partial\mathcal{H}_{\mathrm{SP}}(P)) = 0$. If $i \in I(P)$, then using Proposition 4.3 we deduce that the generators p_j such that ∂G_j has a nonzero entry in the ith place (and hence contributes to the projection by π_i of $\partial\mathcal{H}_{\mathrm{DC}}$) must share a vertex with the ith generator. Analogously, if $i \in I(P)$, then using Proposition 4.4 we deduce that the generators p_j such that ∂F_j has a nonzero entry in the ith place (and hence contributes to the projection by π_i of $\partial\mathcal{H}_{\mathrm{SP}}$) must satisfy $j \in \mathcal{N}(i)$. For the disk-covering function, if v is a common vertex of V_i and V_j, determined by i, j, and a third element α, then $\partial_{v(\alpha,j,i)}G_j = \partial_{v(\alpha,i,j)}G_i$, and the expression for $\pi_i(\partial\mathcal{H}_{\mathrm{DC}}(P))$ then follows. The argument for the expression of $\pi_i(\partial\mathcal{H}_{\mathrm{SP}}(P))$ is analogous. □

4.2. Critical points. Having characterized the generalized gradients of $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$, we now turn to studying their critical points.

THEOREM 4.7 (Minima of $\mathcal{H}_{\mathrm{DC}}$). *Let $P \in Q^n$ be a nondegenerate configuration and $0 \in \mathrm{int}(\partial\mathcal{H}_{DC}(P))$. Then P is a strict local minimum of $\mathcal{H}_{DC}$, all generators are active, and P is a circumcenter Voronoi configuration.*

Proof. Since P is nondegenerate, note from Proposition 4.3 that $\partial_v G_i$ is a singleton for each $v \in \mathrm{Ve}(V_i(P))$, $i \in \{1,\dots,n\}$. Let $w \in (\mathbb{R}^2)^n$. We claim that moving the configuration of the generators from P in the direction w can only increase the cost. The hypothesis $0 \in \mathrm{int}(\partial\mathcal{H}_{\mathrm{DC}}(P))$ implies by Lemma 2.1 that there exists i

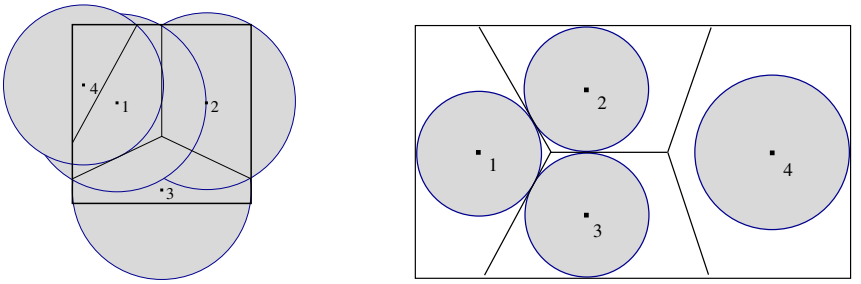

FIG. 4.2. *Local extrema of the disk-covering and the sphere-packing functions in a convex polygonal environment. The configuration on the left corresponds to a local minimum of* $\mathcal{H}_{DC}$ *with* $0 \in \partial\mathcal{H}_{DC}(P)$ *and* $\operatorname{int}(\partial\mathcal{H}_{DC}(P)) = \emptyset$. *The configuration on the right corresponds to a local maximum of* $\mathcal{H}_{SP}$ *with* $0 \in \partial\mathcal{H}_{SP}(P)$ *and* $\operatorname{int}(\partial\mathcal{H}_{SP}(P)) = \emptyset$. *In both configurations, the 4th generator is inactive and noncentered.*

and $v \in \operatorname{Ve}(V_i(P)) \cap \operatorname{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$ such that $w \cdot \partial_v G_i(P) > 0$. Since P is nondegenerate, v will still belong to $V_i(P + \epsilon w)$ for sufficiently small $\epsilon > 0$, and consequently $\mathcal{H}_{\mathrm{DC}}(P + \epsilon w) \geq G_i(P + \epsilon w) > G_i(P) = \mathcal{H}_{\mathrm{DC}}(P)$. Therefore, P is a strict local minimum.

Since π_i is an open map, the set $\pi_i(\operatorname{int}(\partial\mathcal{H}_{\mathrm{DC}}(P)))$ is open for each $i \in \{1, \ldots, n\}$. Therefore, $\pi_i(\operatorname{int}(\partial\mathcal{H}_{\mathrm{DC}}(P))) \neq 0$, and hence all generators are active, i.e., $I(P) = \{1, \ldots, n\}$. Let us see that all generators must also be centered. Assume P is nondegenerate and consider the ith generator. Take $w \in \mathbb{R}^2$ and let $\overline{w} \in (\mathbb{R}^2)^n$ be the vector which has w in the ith place and 0 otherwise. By Lemma 2.1, there exist j and $v \in \operatorname{Ve}(V_j(P)) \cap \operatorname{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$ such that $\overline{w} \cdot \partial_v G_j > 0$. Since $\overline{w} \cdot \partial_v G_j = w \cdot \pi_i(\partial_v G_j) > 0$, then necessarily $\pi_i(\partial_v G_j) \neq 0$, and therefore $v \in V_i(P)$ and $\pi_i(\partial_v G_j) = \pi_i(\partial_v G_i)$. The vertex v is determined by p_i, p_j and a third element, say α. Depending on whether α corresponds to an edge or to another generator, we have that $\pi_i(\partial_v G_i)$ is equal to $\lambda(\alpha, i, j) \operatorname{vrs}(p_i - v)$ or $\mu(\alpha, i, j) \operatorname{vrs}(p_i - v)$. In any case, from Lemma 4.5, we deduce that $\lambda(\alpha, i, j)$ (respectively, $\mu(\alpha, i, j)$) belongs to the interval $(0, 1)$. Therefore, $w \cdot \pi_i(\partial_v G_i) > 0$ implies $w \cdot \operatorname{vrs}(p_i - v) > 0$. Since $\operatorname{vrs}(p_i - v) \in \partial \lg_{V_i(P)}(p_i) = \partial \lg_V(p_i)_{|V=V_i(P)}$ (cf. (3.2)), we conclude from Lemma 2.1 that $0 \in \operatorname{int}(\partial \lg_{V_i(P)}(p_i))$. By Proposition 3.3, this implies that $p_i = \mathrm{CC}(V_i)$. Hence, P is a circumcenter Voronoi configuration. □

THEOREM 4.8 (Maxima of $\mathcal{H}_{\mathrm{SP}}$). *Let* $P \in Q^n$ *and* $0 \in \operatorname{int}(\partial\mathcal{H}_{SP}(P))$. *Then* P *is a strict local maximum of* $\mathcal{H}_{SP}$, *all generators are active, and* P *is a generic incenter Voronoi configuration.*

Proof. The proof of this result is analogous to the proof of Theorem 4.7. Note that $0 \in \operatorname{int}(\partial \operatorname{sm}_{V_i(P)}(p_i))$ implies, by Proposition 3.3, that $\mathrm{IC}(V_i(P)) = \{p_i\}$, and hence P is a generic incenter Voronoi configuration. □

Remark 4.9. Theorems 4.7 and 4.8 precisely provide the interpretation of the multicenter problems that we gave in section 2.2: since all generators are active, they share the same radius. If one drops the hypothesis that 0 belongs to the generalized gradient of the locational optimization function, then one can think of simple examples where P is a local minimum of $\mathcal{H}_{\mathrm{DC}}$ (respectively, local maximum of $\mathcal{H}_{\mathrm{SP}}$), and there are generators which are inactive and noncentered; see Figure 4.2.

5. Dynamical systems for the multicenter problems. In this section, we describe three algorithms that (locally) extremize the multicenter functions for the disk-covering and the sphere-packing problems. We first examine the gradient flow

descent associated with the locational optimization functions $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$. This flow is guaranteed to find a local critical point, but it has the drawback of being centralized, as we describe later. Then we propose two decentralized flows for each problem. One roughly consists of a distributed implementation of the gradient descent. As we show, it is very much in the spirit of behavior-based robotics. The other one follows the logical strategy given the results in Theorems 4.7 and 4.8: each generator moves toward the circumcenter (alternatively, incenter set) of its own Voronoi polygon. We call them Lloyd flows, since they resemble the original Lloyd algorithm for vector quantization problems, where each quantizer moves toward the centroid or center of mass of its own Voronoi region, see [14, 16, 20]. We present continuous-time versions of the algorithms and discuss their convergence properties. In our setting, the generators' location obeys a first-order dynamical behavior described by

$$\dot{p}_i = u_i(p_1, \dots, p_n)\,, \quad i \in \{1, \dots, n\}\,. \tag{5.1}$$

The dynamical system (5.1) is said to be (strongly) *centralized* if there exists at least an $i \in \{1, \dots, n\}$ such that $u_i(p_1, \dots, p_n)$ cannot be written as a function of the form $u_i(p_i, p_{i_1}, \dots, p_{i_m})$, with $m < n-1$. The dynamical system (5.1) is said to be *Voronoi-distributed* if each $u_i(p_1, \dots, p_n)$ can be written as a function of the form $u_i(p_i, p_{i_1}, \dots, p_{i_m})$, with $i_k \in \mathcal{N}(P, i)$, $k \in \{1, \dots, m\}$. Finally, the dynamical system (5.1) is said to be *nearest-neighbor-distributed* if each $u_i(p_1, \dots, p_n)$ can be written as a function of the form $u_i(p_i, p_{i_1}, \dots, p_{i_m})$, with $\|p_i - p_{i_k}\| \leq \|p_i - p_j\|$ for all $j \in \{1, \dots, n\}$ and $k \in \{1, \dots, m\}$. A nearest-neighbor-distributed dynamical system is also Voronoi-distributed.

It is well known that there are at most $3n-6$ neighborhood relationships in a planar Voronoi diagram [23, section 2.3]. Therefore, the number of Voronoi neighbors of each site is on average less than or equal to 6. (Recall that sites are Voronoi-neighbors if they share an edge, not just a vertex.) We refer to [11] for more details on the distributed character of Voronoi neighborhood relationships.

Note that the set of indexes $\{i_1, \dots, i_m\}$ for a specific generator p_i of a Voronoi-distributed or a nearest-neighbor-distributed dynamical system is not the same for all possible configurations P. In other words, the identity of both the Voronoi neighbors and the nearest neighbors might change along the evolution; i.e., the topology of the dynamical system is *dynamic*.

5.1. Nonsmooth gradient dynamical systems. Consider the (signed) generalized gradient descent flow (2.6) for the locational optimization functions $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$,

$$\dot{P} = -\operatorname{Ln}(\partial \mathcal{H}_{\mathrm{DC}})(P)\,, \quad \dot{P} = \operatorname{Ln}(\partial \mathcal{H}_{\mathrm{SP}})(P)\,.$$

Alternatively, we may write the following for each $i \in \{1, \dots, n\}$:

$$\dot{p}_i = -\pi_i(\operatorname{Ln}(\partial \mathcal{H}_{\mathrm{DC}})(p_1, \dots, p_n))\,, \tag{5.2}$$

$$\dot{p}_i = \pi_i(\operatorname{Ln}(\partial \mathcal{H}_{\mathrm{SP}})(p_1, \dots, p_n))\,. \tag{5.3}$$

As noted in section 2.4, these vector fields are discontinuous, and therefore we understand their solution in the Filippov sense. Equation (4.9) and Propositions 4.3 and 4.4 provide an expression of the generalized gradients at P, $\partial \mathcal{H}_{\mathrm{DC}}(P)$ and $\partial \mathcal{H}_{\mathrm{SP}}(P)$. One needs to first compute the generalized gradient, then compute the least-norm element, and finally project it to each of the n components; therefore, the expressions

in Proposition 4.6 are not helpful. Note that the least-norm element of convex sets can be computed efficiently, see [6], however closed-form expressions are not available in general.

One can see that the compact set Q^n is strongly invariant for both vector fields $-\operatorname{Ln}(\partial\mathcal{H}_{\mathrm{DC}})$ and $\operatorname{Ln}(\partial\mathcal{H}_{\mathrm{SP}})$. Indeed, the components for each generator of both vector fields point always toward Q. Regarding $-\operatorname{Ln}(\partial\mathcal{H}_{\mathrm{DC}})$, this is a consequence of Proposition 4.3 and of Lemma 4.5. Regarding $\operatorname{Ln}(\partial\mathcal{H}_{\mathrm{SP}})$, this is a consequence of Proposition 4.4.

PROPOSITION 5.1. *For the dynamical system* (5.2) *(respectively,* (5.3)*), the generators' location* $P = (p_1, \ldots, p_n)$ *converges asymptotically to the set of critical points of* $\mathcal{H}_{DC}$ *(respectively, of* $\mathcal{H}_{SP}$*).*

Proof. From Propositions 4.1 and 4.2, $\mathcal{H}_{\mathrm{DC}}$ and $-\mathcal{H}_{\mathrm{SP}}$ are globally Lipschitz and regular over Q^n. The result follows from Proposition 2.9 considering the dynamical system restricted to the strongly invariant and compact domain Q^n. □

Remark 5.2. The gradient dynamical systems enjoy convergence guarantees, but their implementation is centralized for two reasons. First, all functions $G_i(P)$ (respectively, $F_i(P)$) need to be compared in order to determine which generator is active. Second, the least-norm element of the generalized gradients depends on the relative position of the active generators with respect to each other and to the environment.

Remark 5.3. As illustrated in Figure 5.1 the evolution of the gradient dynamical systems may not leave fixed the generators that are already centers (circumcenters or incenters).

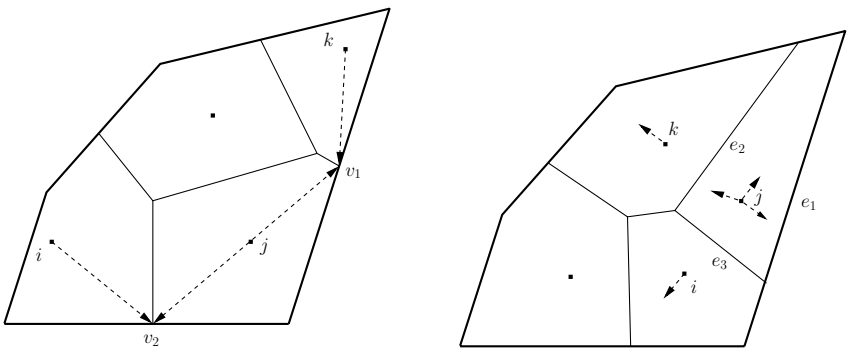

FIG. 5.1. *Illustration of the gradient descent. In the left figure, the only active vertexes at the given configuration are* v_1 *and* v_2*. Although the* j*th generator is in the circumcenter of its own Voronoi region, the control law* (5.2) *will drive it toward the vertex* v*. In the right figure, the only active edges at the given configuration are* e_1*,* e_2*, and* e_3*. Although the* j*th generator is in the incenter of its own Voronoi region, the control law* (5.3) *will drive it away from the edge* e_1*.*

5.2. Nonsmooth dynamical systems based on distributed gradients. In this section, we propose a distributed implementation of the previous gradient dynamical systems and explore its relation with behavior-based rules in multiple-vehicle coordination. Consider the following modifications of the gradient dynamical systems (5.2)–(5.3):

$$\dot{p}_i = -\operatorname{Ln}(\partial \lg_{V_i(P)})(P)\,, \tag{5.4}$$

$$\dot{p}_i = \operatorname{Ln}(\partial \operatorname{sm}_{V_i(P)})(P)\,, \tag{5.5}$$

for $i \in \{1,\dots,n\}$. Note that the system (5.4) is Voronoi-distributed, since $\mathrm{Ln}(\partial \lg_{V_i(P)})(P)$ is determined only by the position of p_i and of its Voronoi neighbors $\mathcal{N}(P,i)$. On the other hand, the system (5.5) is nearest-neighbor-distributed, since $\mathrm{Ln}(\partial \mathrm{sm}_{V_i(P)})(P)$ is determined only by the position of p_i and its nearest neighbors.

For future reference, let $\mathrm{Ln}(\partial \lg_{\mathcal{V}})(P) = (\mathrm{Ln}(\partial \lg_{V_1(P)})(P),\dots,\mathrm{Ln}(\partial \lg_{V_n(P)})(P))$, $\mathrm{Ln}(\partial \mathrm{sm}_{\mathcal{V}})(P) = (\mathrm{Ln}(\partial \mathrm{sm}_{V_1(P)})(P),\dots,\mathrm{Ln}(\partial \mathrm{sm}_{V_n(P)})(P))$, and write

$$\dot{P} = -\mathrm{Ln}(\partial \lg_{\mathcal{V}})(P)\,, \quad \dot{P} = \mathrm{Ln}(\partial \mathrm{sm}_{\mathcal{V}})(P)\,.$$

As for the previous dynamical systems, note that these vector fields are discontinuous, and therefore we understand their solutions in the Filippov sense. One can see that the compact set Q^n is strongly invariant for both vector fields $-\mathrm{Ln}(\partial \lg_{\mathcal{V}})$ and $\mathrm{Ln}(\partial \mathrm{sm}_{\mathcal{V}})$. This fact is a consequence of the expressions for the generalized gradients of lg and sm in Proposition 3.3. Note that in the 1-center case, (5.2) (respectively, (5.3)) coincides with (5.4) (respectively, with (5.5)).

PROPOSITION 5.4. *Let $P \in Q^n$. Then the solutions of the dynamical systems* (5.4) *and* (5.5) *starting at P are unique.*

Proof. (a) *Uniqueness of solution for* (5.4). Let $D_{\lg}$ be the set of $P \in Q^n$ such that P is nondegenerate and $\lg_{V_i(P)}(p_i)$ is attained at a single vertex for all i. Note that $Q^n \setminus D_{\lg}$ has measure zero, and that the vector field $-\mathrm{Ln}(\partial \lg_{\mathcal{V}})$ is differentiable (and hence locally Lipschitz) when restricted to any connected component of $D_{\lg}$. Let P, P' belong to different connected components of $D_{\lg}$, and let $\|P - P'\| \le \epsilon$. Consider all the indexes i at which the values of $\lg_{V_i(P)}(p_i)$ and $\lg_{V_i(P')}(p_i')$ are attained at different vertexes. For these indexes,

$$-\mathrm{Ln}(\partial \lg_{V_i(P)})(p_i) + \mathrm{Ln}(\partial \lg_{V_i(P')})(p_i') = \mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i')$$

for certain vertexes v and w'. Note that for ϵ small enough, the vertex w' in the Voronoi configuration P' corresponds to a vertex w in the Voronoi configuration P. By construction, p_i and p_i' belong to an $O(\epsilon)$ neighborhood of the bisector b_{vw} determined by v and w, and $n_{vw} \cdot (p_i - p_i') < 0$. In addition, the component of $\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i')$ along b_{vw} is $O(\epsilon)$ whereas $n_{vw} \cdot \mathrm{vrs}(v - p_i) > 0$ and $n_{vw} \cdot \mathrm{vrs}(w' - p_i') = n_{vw} \cdot \mathrm{vrs}(w - p_i) + O(\epsilon)$, with $n_{vw} \cdot \mathrm{vrs}(w - p_i) < 0$. Then

$$\begin{aligned}
&\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i') \\
&\quad = \mathrm{proj}_{n_{vw}}(\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i')) + \mathrm{proj}_{b_{vw}}(\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i')) \\
&\qquad\qquad = \mathrm{proj}_{n_{vw}}(\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i')) + O(\epsilon)\,,
\end{aligned}$$

and, in turn, for sufficiently small ϵ,

$$\begin{aligned}
&(p_i - p_i') \cdot (\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i')) \\
&\qquad = (n_{vw} \cdot (p_i - p_i'))(n_{vw} \cdot (\mathrm{vrs}(v - p_i) - \mathrm{vrs}(w' - p_i'))) + O(\epsilon^2) < 0\,.
\end{aligned}$$

The result now follows from Theorem 1 on page 106 in [15].

(b) *Uniqueness of solution for* (5.5). Let D_{sm} be the set of $P \in Q^n$ such that $\mathrm{sm}_{V_i(P)}(p_i)$ is attained at a single edge for all i. Note that $Q^n \setminus D_{\mathrm{sm}}$ has measure zero, and that the vector field $\mathrm{Ln}(\partial \mathrm{sm}_{\mathcal{V}})$ is differentiable(and hence locally Lipschitz) when restricted to any connected component of D_{sm}. Let P, P' belong to different connected components of D_{sm}, and let $\|P - P'\| \le \epsilon$. Consider all the indexes i at which the values of $\mathrm{sm}_{V_i(P)}(p_i)$ and $\mathrm{sm}_{V_i(P')}(p_i')$ are attained at different edges.

Assume these edges are of type (a) (the type (b) case can be treated analogously). For these indexes,

$$\mathrm{Ln}(\partial \,\mathrm{sm}_{V_i(P)})(p_i) - \mathrm{Ln}(\partial \,\mathrm{sm}_{V_i(P')})(p_i') = \mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i' - p_k')\,,$$

for some uniquely determined p_j and p_k', with $j \neq k$. By construction, p_i and p_i' belong to an $O(\epsilon)$ neighborhood of the bisector b_{jk} determined by p_j and p_k, and $n_{kj} \cdot (p_i - p_i') < 0$. In addition, the component of $\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i' - p_k')$ along b_{jk} is $O(\epsilon)$ whereas $n_{kj} \cdot \mathrm{vrs}(p_i - p_j) > 0$ and $n_{kj} \cdot \mathrm{vrs}(p_i' - p_k') = n_{kj} \cdot \mathrm{vrs}(p_i - p_k) + O(\epsilon)$, with $n_{kj} \cdot \mathrm{vrs}(p_i - p_k) < 0$. Then

$$\begin{aligned}
&\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i' - p_k') \\
&\quad = \mathrm{proj}_{n_{kj}}(\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i' - p_k')) + \mathrm{proj}_{b_{jk}}(\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i' - p_k')) \\
&\qquad\qquad = \mathrm{proj}_{n_{kj}}(\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i - p_k)) + O(\epsilon)\,,
\end{aligned}$$

and, in turn, for sufficiently small ϵ,

$$\begin{aligned}
&(p_i - p_i') \cdot (\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i' - p_k')) \\
&\qquad = (n_{kj} \cdot (p_i - p_i'))(n_{kj} \cdot (\mathrm{vrs}(p_i - p_j) - \mathrm{vrs}(p_i - p_k))) + O(\epsilon^2) < 0\,.
\end{aligned}$$

The result now follows from Theorem 1 on page 106 in [15]. □

Remark 5.5 (relation with behavior-based robotics: move toward the furthest-away vertex). The distributed gradient control law in the disk-covering setting (5.4) has an interesting interpretation in the context of behavior-based robotics. Consider the ith generator. If the maximum of $\mathrm{lg}_{V_i(P)}$ is attained at a single vertex v of its Voronoi cell V_i, then $\mathrm{lg}_{V_i(P)}$ is differentiable at that configuration and its derivative corresponds to $\mathrm{vrs}(p_i - v)$. Therefore, the control law (5.4) corresponds to the behavior "move toward the furthest vertex in own Voronoi cell." If there are two or more vertexes of V_i where the value $\mathrm{lg}_{V_i(P)}(p_i)$ is attained, then (5.4) provides an average behavior by computing the least-norm element in the convex hull of all $\mathrm{vrs}(p_i - v)$ such that $\|p_i - v\| = \mathrm{lg}_{V_i(P)}(p_i)$.

Remark 5.6 (relation with behavior-based robotics: move away from the nearest neighbor). The distributed gradient control law in the sphere-packing setting (5.5) also has an interesting interpretation. For the ith generator, if the minimum of $\mathrm{sm}_{V_i(P)}$ is attained at a single edge e, then $\mathrm{sm}_{V_i(P)}$ is differentiable at that configuration, and its derivative is n_e. The control law (5.5) corresponds to the behavior "move away from the nearest neighbor" (where a neighbor can also be the boundary of the environment). If there are two or more edges where the value $\mathrm{sm}_{V_i(P)}(p_i)$ is attained, then (5.5) provides an average behavior in an analogous manner as before.

PROPOSITION 5.7. *For the dynamical system* (5.4)*, the generators' location* $P = (p_1, \ldots, p_n)$ *converges asymptotically to the largest weakly invariant set contained in the closure of* $A_{\mathrm{DC}}(Q) = \{P \in Q^n \mid i \in I(P) \implies p_i = \mathrm{CC}(V_i)\}$.

Proof. Let $a \in \widetilde{\mathcal{L}}_{-\mathrm{Ln}(\partial \mathrm{lg}_{\mathcal{V}})}\mathcal{H}_{\mathrm{DC}}(P)$. By definition, $a = -\mathrm{Ln}(\partial \,\mathrm{lg}_{\mathcal{V}})(P) \cdot \zeta$, for all $\zeta \in \partial\mathcal{H}_{\mathrm{DC}}(P)$. Let $v \in \mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$. From Proposition 4.3 and Lemma 4.5, we know that, independently of the degenerate/nondegenerate character of the Voronoi partition at v, there always exist either an edge e of Q and generators p_i and p_j, or generators p_i, p_j, and p_k, such that $\lambda(e, i, j)$, $\lambda(e, j, i) > 0$ (respectively, $\mu(i, j, k)$,

$\mu(j,k,i)$, $\mu(k,i,j) > 0$). If v is a vertex of type (b), then

$$
\begin{aligned}
a &= -\operatorname{Ln}(\partial \lg_{\mathcal{V}})(P) \cdot \partial_v G_i \\
&= -\operatorname{Ln}(\partial \lg_{V_i(P)})(P) \cdot \lambda(e,i,j) \operatorname{vrs}(p_i - v) - \operatorname{Ln}(\partial \lg_{V_j(P)})(P) \cdot \lambda(e,j,i) \operatorname{vrs}(p_j - v).
\end{aligned} \tag{5.6}
$$

From Lemma 3.8(i) we conclude that $a \leq 0$, and the inequality is strict if either $p_i \neq \mathrm{CC}(V_i)$ or $p_j \neq \mathrm{CC}(V_j)$. The same conclusion can be derived if v is a vertex of type (a). Therefore, $\max \widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}})} \mathcal{H}_{\mathrm{DC}}(P) \leq 0$ or $\widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}})} \mathcal{H}_{\mathrm{DC}}(P) = \emptyset$. Now, resorting to the LaSalle principle (Theorem 2.7), we deduce that the solution $P : [0, +\infty) \to Q^n$ starting from P_0 converges to the largest weakly invariant set contained in $\overline{Z}_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}}), \mathcal{H}_{\mathrm{DC}}} \cap \mathcal{H}_{\mathrm{DC}}^{-1}(\leq \mathcal{H}_{\mathrm{DC}}(P_0), P_0) \cap Q^n$.

Let us see that $Z_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}}), \mathcal{H}_{\mathrm{DC}}} \cap Q^n$ is equal to $A_{\mathrm{DC}}(Q)$. Take a configuration $P \in A_{\mathrm{DC}}(Q)$. Then $\operatorname{Ln}(\partial \lg_{V_i(P)})(P) = 0$ if $i \in I(P)$, and $\pi_i(\zeta) = 0$ if $i \notin I(P)$, for any $\zeta \in \partial \mathcal{H}_{\mathrm{DC}}(P)$ (cf. Proposition 4.6). Consequently, $0 = -\operatorname{Ln}(\partial \lg_{\mathcal{V}})(P) \cdot \zeta$, for all $\zeta \in \partial \mathcal{H}_{\mathrm{DC}}(P)$, and so $0 \in \widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}})} \mathcal{H}_{\mathrm{DC}}(P)$. Therefore, $A_{\mathrm{DC}}(Q) \subset Z_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}}), \mathcal{H}_{\mathrm{DC}}}$. Now, consider $P \in Z_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}}), \mathcal{H}_{\mathrm{DC}}}$. Then $0 \in \widetilde{\mathcal{L}}_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}})} \mathcal{H}_{\mathrm{DC}}(P)$, that is, $0 = -\operatorname{Ln}(\partial \lg_{\mathcal{V}})(P) \cdot \zeta$, for all $\zeta \in \partial \mathcal{H}_{\mathrm{DC}}(P)$. If P is nondegenerate, we deduce from (5.6) and Lemma 3.8 that all the active generators are centered, i.e., $P \in A_{\mathrm{DC}}(Q)$. If P is degenerate, consider a degenerate vertex v where the value of $\mathcal{H}_{\mathrm{DC}}(P)$ is attained. For simplicity, we deal with the case where v is contained in an edge e of Q (the case $v \in \operatorname{int}(Q)$ is treated analogously). From Lemma 4.5 we know that there exist generators p_i, p_j determining v on opposite sides of l, the orthogonal line to the edge e passing through v. From (5.6) and Lemma 3.8 we deduce that both p_i and p_j are centered. Now, for each generator p_k with $v \in V_k$ in the same side of l as p_i (respectively, p_j), we consider the triplet (e,j,k) (respectively, (e,i,k)). Again resorting to (5.6) and Lemma 3.8, we conclude that p_k is also centered. Finally, if a generator p_k with $v \in V_k$ is such that $p_k \in l$, any of the triplets (e,j,k) or (e,i,k) can be invoked in a similar argument to ensure that p_k is centered. Therefore, $P \in A_{\mathrm{DC}}(Q)$, and hence $(Z_{-\operatorname{Ln}(\partial \lg_{\mathcal{V}}), \mathcal{H}_{\mathrm{DC}}} \cap Q^n) \subset A_{\mathrm{DC}}(Q)$. □

PROPOSITION 5.8. *For the dynamical system* (5.5)*, the generators' location* $P = (p_1, \ldots, p_n)$ *converges asymptotically to the largest weakly invariant set contained in the closure of* $A_{\mathrm{SP}}(Q) = \{P \in Q^n \mid i \in I(P) \implies p_i \in \mathrm{IC}(V_i)\}$.

Proof. Let $a \in \widetilde{\mathcal{L}}_{\operatorname{Ln}(\partial \operatorname{sm}_{\mathcal{V}})} \mathcal{H}_{\mathrm{SP}}(P)$. By definition, $a = \operatorname{Ln}[\operatorname{sm}_{\mathcal{V}}](P) \cdot \zeta$, for all $\zeta \in \partial \mathcal{H}_{\mathrm{SP}}(P)$. Let $e \in \mathrm{Ed}_{\mathrm{SP}}(\mathcal{V}(P))$. If e is an edge of type (a), i.e., a segment of the bisector determined by p_i and p_j, we compute (cf. Proposition 4.4)

$$
\begin{aligned}
a &= \operatorname{Ln}(\partial \operatorname{sm}_{\mathcal{V}})(P) \cdot \partial_e F_i \\
&= \operatorname{Ln}(\partial \operatorname{sm}_{V_i(P)})(P) \cdot \pi_i(\partial_e F_i) + \operatorname{Ln}(\partial \operatorname{sm}_{V_j(P)})(P) \cdot \pi_j(\partial_e F_i)\,.
\end{aligned} \tag{5.7}
$$

From Lemma 3.8(iii) we conclude that $a \geq 0$, and the inequality is strict if either $p_i \notin \mathrm{IC}(V_i)$ or $p_j \notin \mathrm{IC}(V_j)$. The same conclusion can be derived if e is a vertex of type (b). Therefore, $\min \widetilde{\mathcal{L}}_{\operatorname{Ln}(\partial \operatorname{sm}_{\mathcal{V}})} \mathcal{H}_{\mathrm{SP}}(P) \geq 0$ or $\widetilde{\mathcal{L}}_{\operatorname{Ln}(\partial \operatorname{sm}_{\mathcal{V}})} \mathcal{H}_{\mathrm{SP}}(P) = \emptyset$. Now, applying the LaSalle principle (Theorem 2.7) with the function $-\mathcal{H}_{\mathrm{SP}}$, we deduce that the solution $P : [0, +\infty) \to Q^n$ starting from P_0 converges to the largest weakly invariant set contained in $\overline{Z}_{\operatorname{Ln}(\partial \operatorname{sm}_{\mathcal{V}}), \mathcal{H}_{\mathrm{SP}}} \cap \mathcal{H}_{\mathrm{SP}}^{-1}(\leq \mathcal{H}_{\mathrm{SP}}(P_0), P_0) \cap Q^n$. From (5.7), and resorting to Proposition 4.6 and Lemma 3.8, one can also show that $Z_{\operatorname{Ln}(\partial \operatorname{sm}_{\mathcal{V}}), \mathcal{H}_{\mathrm{SP}}} \cap Q^n$ is equal to $A_{\mathrm{SP}}(Q)$. □

Remark 5.9. The sets $A_{\mathrm{DC}}(Q)$ and $A_{\mathrm{SP}}(Q)$ are not closed in general. If $\dim Q = 1$, then it can be seen that they indeed are. In higher dimensions one can find sequences

$\{P_k \in Q^n \mid k \in \mathbb{N}\}$ in these sets which converge to configurations P where not all active generators are centered.

5.3. Distributed dynamical systems based on geometric centering. Here, we propose alternative distributed dynamical systems for the multicenter functions. Our design is directly inspired by the results in Theorems 4.7 and 4.8 on the critical points of the multicenter functions $\mathcal{H}_{\mathrm{DC}}$ and $\mathcal{H}_{\mathrm{SP}}$. For $i \in \{1, \dots, n\}$, consider the dynamical systems

$$\dot{p}_i = \mathrm{CC}(V_i) - p_i\,, \tag{5.8}$$

$$\dot{p}_i \in \mathrm{IC}(V_i) - p_i\,. \tag{5.9}$$

Alternatively, we may write $\dot{P} = \mathrm{CC}(\mathcal{V}(P)) - P$ and $\dot{P} \in \mathrm{IC}(\mathcal{V}(P)) - P$. Note that both systems are Voronoi-distributed. Also, note that the vector field (5.8) is continuous, since the circumcenter of a polygon depends continuously on the location of its vertexes, and the location of the vertexes of the Voronoi partition depends continuously on the location of the generators; see [23]. However, (5.9) is a differential inclusion, since the incenter sets may not be singletons. By Lemma 2.5, the existence of solutions to (5.9) is guaranteed by the following result.

PROPOSITION 5.10. *Consider the set-valued map* $\mathrm{IC}(\mathcal{V}) - \mathrm{Id} : Q^n \to 2^{(\mathbb{R}^2)^n}$ *given by* $P \mapsto \mathrm{IC}(\mathcal{V}(P)) - P$. *Then* $\mathrm{IC}(\mathcal{V}) - \mathrm{Id}$ *is upper semicontinuous with nonempty, compact, and convex values.*

Proof. Clearly, the map $\mathrm{IC}(\mathcal{V}) - \mathrm{Id}$ takes nonempty and compact values. From Lemma 3.2, we also know that it takes convex values. Furthermore, since the identity map is continuous, it suffices to check that $P \mapsto \mathrm{IC}(\mathcal{V}(P))$ is upper semicontinuous. We then have to verify that, given $P_0 \in Q^n$, for each $\epsilon > 0$ there exists $\delta > 0$ such that

$$\mathrm{IC}(\mathcal{V}(P)) \subset \mathrm{IC}(\mathcal{V}(P_0)) + B_{2n}(0, \epsilon) \quad \text{if } \|P - P_0\| \leq \delta\,. \tag{5.10}$$

Now, for each i, if $\mathrm{IC}(V_i(P_0))$ is not a singleton, then it is a segment (cf. Lemma 3.2) whose extremal points $q_{i1}(P_0)$, $q_{i2}(P_0)$ are the intersection points of some bisectors of the edges of the Voronoi cell. It is clear that $q_{i\alpha}(P) \to q_{i\alpha}(P_0)$ when $P \to P_0$ for $\alpha = 1, 2$. Therefore, given $\epsilon > 0$, one can choose $\delta_i > 0$ such that if $\|P - P_0\| \leq \delta_i$, then $\|q_{i\alpha}(P) - q_{i\alpha}(P_0)\| \leq \epsilon/n$. Since $\mathrm{IC}(V_i(P))$ is contained in the segment joining $q_{i1}(P)$ and $q_{i2}(P)$, we deduce $\mathrm{IC}(V_i(P)) \subset \mathrm{IC}(V_i(P_0)) + B_2(0, \epsilon/n)$. On the other hand, if $\mathrm{IC}(V_i(P_0))$ is a singleton, then it coincides with the intersection points $q_{i1}(P_0), \dots, q_{im}(P_0)$ of some bisectors of the edges of the Voronoi cell. The above reasoning also guarantees that there exits $\delta_i > 0$ such that $q_{i\alpha}(P) \in \mathrm{IC}(V_i(P_0)) + B_2(0, \epsilon/n)$, $\alpha = 1, \dots, m$, if $\|P - P_0\| \leq \delta_i$. Since $\mathrm{IC}(V_i(P))$ is contained in one of the segments joining the points $q_{i1}(P), \dots, q_{im}(P)$, we again deduce $\mathrm{IC}(V_i(P)) \subset \mathrm{IC}(V_i(P_0)) + B_2(0, \epsilon/n)$. The statement in (5.10) follows by taking the minimum of $\delta_1, \dots, \delta_n$. □

Having established the existence of solutions, one can also see that the compact set Q^n is strongly invariant for the vector field $\mathrm{CC}(\mathcal{V}) - \mathrm{Id}$ and for the differential inclusion $\mathrm{IC}(\mathcal{V}) - \mathrm{Id}$. Next, we characterize the asymptotic convergence of the dynamical systems under study.

PROPOSITION 5.11. *For the dynamical system* (5.8) *(respectively,* (5.9)*), the generators' location* $P = (p_1, \dots, p_n)$ *converges asymptotically to the largest weakly invariant set contained in the closure of* $A_{\mathrm{DC}}(Q)$ *(respectively, in the closure of* $A_{\mathrm{SP}}(Q)$*).*

Proof. The proof of this result is parallel to the proofs of Propositions 5.7 and 5.8. The sequence of steps is the same as before, though now one resorts to Lemma 3.8(ii) and Lemma 3.8(iv). The only additional observation is that when computing the set-valued Lie derivative for (5.9), one has that $a \in \widetilde{\mathcal{L}}_{\mathrm{IC}(\mathcal{V})-\mathrm{Id}}\mathcal{H}_{\mathrm{SP}}(P)$ if and only if there exists $x \in \mathrm{IC}(\mathcal{V}(P))$ such that $a = (x - P) \cdot \zeta$, for any $\zeta \in \partial\mathcal{H}_{\mathrm{SP}}(P)$. The application of Lemma 3.8 guarantees that $a \geq 0$ and that the inequality is strict if any of the active generators is not in its corresponding incenter set. ∎

5.4. Simulations. To illustrate the performance of the distributed coordination algorithms, we include some simulation results. The algorithms are implemented in `Mathematica` as a single centralized program. We compute the bounded Voronoi diagram of a collection of points using the `Mathematica` package `ComputationalGeometry`. We compute the circumcenter of a polygon via the algorithm in [28] and the incenter set via the `LinearProgramming` solver in `Mathematica`. Measuring displacements in meters, we consider the domain determined by the vertexes

$$\{(0,0),(2.5,0),(3.45,1.5),(3.5,1.6),(3.45,1.7),(2.7,2.1),(1.,2.4),(.2,1.2)\}.$$

In Figures 5.2 and 5.3, we illustrate the performance of the dynamical systems (5.4) and (5.8), respectively, minimizing the multicircumcenter function $\mathcal{H}_{\mathrm{DC}}$. In Figures 5.4 and 5.5, we illustrate the performance of the dynamical systems (5.5) and (5.9), respectively, maximizing the multi-incenter function $\mathcal{H}_{\mathrm{SP}}$. Observing the final configurations in the four figures, one can verify, visually and numerically, that the active generators are asymptotically centered as forecast by our analysis.

The left (respectively, right) figure illustrates the initial (respectively, final) locations and Voronoi partition. The central figure illustrates the network evolution. After* 20 *seconds, the multicenter function is approximately* .2498 *meters.*

6. Conclusions. We have introduced two multicenter functions that provide quality-of-service measures for mobile networks. We have shown that both functions are globally Lipschitz, and we have computed their generalized gradients. Furthermore, under certain technical conditions, we have characterized via nonsmooth analysis their critical points as center Voronoi configurations and as solutions of disk-covering and sphere-packing problems. We have also considered various algorithms that extremize the multicenter functions. First, we considered the nonsmooth gradient flows induced by their respective generalized gradients. Second, we devised a novel strategy based on the generalized gradients of the 1-center functions of each generator. Third, we introduced and characterized a geometric centering strategy with resemblances to the classical Lloyd algorithm. We have unveiled the remarkable geometric interpretations of these algorithms, discussed their distributed character and analyzed their asymptotic behavior using nonsmooth stability analysis.

Future directions of research include the following: (i) sharpening the asymptotic convergence results for the proposed dynamical systems (e.g., proving that all generators will asymptotically be centered), (ii) considering the setting of convex polytopes in $\mathbb{R}^N$, for $N > 2$, (iii) understanding in what sense the proposed multicircumcenter and the multi-incenter problems can be shown to be dual, and (iv) analyzing other meaningful geometric optimization problems and their relations with cooperative behaviors.

Symbol	: **Description and page(s) when applicable**
$A_{\mathrm{DC}}(Q)$	: Set of configurations $P \in Q^n$ where all active generators are in the circumcenter of its own Voronoi region, 1567
$A_{\mathrm{SP}}(Q)$	: Set of configurations $P \in Q^n$ where all active generators are in the incenter set of its own Voronoi region, 1568
$\mathrm{CC}(Q)$	: Circumcenter of polytope Q, 1548
$\mathrm{CR}(Q)$	: Circumradius of polytope Q, 1548
D_S	: Distance function to the convex set S, 1546
$\mathrm{Ed}(Q)$	: Edges of polygon Q, 1546
$\mathrm{Ed}_{\mathrm{SP}}(\mathcal{V}(P))$	: Edges where the value of $\mathcal{H}_{\mathrm{SP}}(P)$ is attained, 1546
$e(i)$	: Edge of $\mathcal{V}(P)$ belonging to V_i and to the boundary of Q, 1547
$e(i,j)$	: Edge of $\mathcal{V}(P)$ determined by p_i and p_j, 1547
$F_i(P)$	: Smallest distance from p_i to the boundary of $V_i(P)$, 1556
$G_i(P)$	: Largest distance from p_i to the boundary of $V_i(P)$, 1556

$\mathrm{IC}(Q)$	: Incenter set of polytope Q, 1548
$\mathrm{IR}(Q)$	: Inradius of polytope Q, 1548
$K[X]$	: Filippov mapping associated with a measurable and essentially locally bounded mapping $X : \mathbb{R}^N \to \mathbb{R}^N$, 1550
$\lambda(e,i,j)$	: Scalar function associated with the vertex $v(e,i,j)$, 1559
$\mathrm{Ln}(S)$	: Least-norm element of the convex set S, 1549
$\mathrm{lg}_Q(p)$	: Largest distance from p to the boundary of Q, 1552
$\mu(i,j,k)$	: Scalar function associated with the vertex $v(i,j,k)$, 1559
$\mathcal{N}(P,i)$, $\mathcal{N}(i)$	: Set of neighbors of the ith generator at configuration P, 1546
$n_{e(i,j)}$	: Unit normal to $e(i,j)$ pointing toward $\mathrm{int}(V_i(P))$, 1547
$n_{e(i)}$	: Unit normal to $e(i)$ pointing toward $\mathrm{int}(Q)$, 1547
proj_S	: Orthogonal projection onto the convex set S, 1546
π_i	: Canonical projection from Q^n onto the ith factor, 1546
$\widetilde{\mathcal{L}}_X f$	: Set-valued Lie derivative of f with respect to X, 1550
$\mathrm{sm}_Q(p)$	: Smallest distance from p to the boundary of Q, 1552
$v(i,j,k)$	: Vertex of $\mathcal{V}(P)$ determined by p_i, p_j, and p_k, 1547
$v(e,i,j)$	: Vertex of $\mathcal{V}(P)$ determined by $e \in \mathrm{Ed}(Q)$ and p_i, p_j, 1547
$v(e,f,i)$	: Vertex of $\mathcal{V}(P)$ determined by $e, f \in \mathrm{Ed}(Q)$, and p_i, 1547
$\mathrm{Ve}_{\mathrm{DC}}(\mathcal{V}(P))$	: Vertexes of $\mathcal{V}(P)$ where the value of $\mathcal{H}_{\mathrm{DC}}(P)$ is attained, 1548
$\mathrm{vrs}(v)$	: Unit vector in the direction of $0 \neq v \in \mathbb{R}^N$, 1546
$\mathrm{Ve}(Q)$	: Vertexes of polygon Q, 1546
$\mathcal{V}(P)$	: Voronoi partition of Q generated by $P = (p_1, \ldots, p_n)$, 1546
$Z_{X,f}$	: Set formed by points $x \in \mathbb{R}^N$ such that 0 belongs to $\widetilde{\mathcal{L}}_X f(x)$, 1551

EXPONENTIAL STABILIZATION OF LAMINATED BEAMS WITH STRUCTURAL DAMPING AND BOUNDARY FEEDBACK CONTROLS*

JUN-MIN WANG†, GEN-QI XU‡, AND SIU-PANG YUNG§

Abstract. We study the boundary stabilization of laminated beams with structural damping which describes the slip occurring at the interface of two-layered objects. By using an invertible matrix function with an eigenvalue parameter and an asymptotic technique for the first order matrix differential equation, we find out an explicit asymptotic formula for the matrix fundamental solutions and then carry out the asymptotic analyses for the eigenpairs. Furthermore, we prove that there is a sequence of generalized eigenfunctions that forms a Riesz basis in the state Hilbert space, and hence the spectrum determined growth condition holds. Furthermore, exponential stability of the closed-loop system can be deduced from the eigenvalue expressions. In particular, the semigroup generated by the system operator is a C_0-group due to the fact that the three asymptotes of the spectrum are parallel to the imaginary axis.

Key words. Riesz basis, laminated beams, exponential stability

1. Introduction.

The vibration suppression of the laminated beams due to the demand for advanced performance has been one of the main research topics in smart materials and structures. These composite laminates usually have superior structural properties such as adaptability, and the design of their piezoelectric materials can be used as both actuators and sensors. The detailed physical background can be found in [10] and the references therein. In [4], Hansen and Spies derived three mathematical models for two-layered beams with structural damping due to the interfacial slip. Our interest in this paper is to study the first model in [4] which is closely related to the Timoshenko beam theory. The equations for this beam model are

$$\begin{cases} mw_{tt} + (G(\psi - w_x))_x = 0, & 0 < x < 1,\ t \geq 0, \\ I_m(3s_{tt} - \psi_{tt}) - G(\psi - w_x) - (D(3s_x - \psi_x))_x = 0, & 0 < x < 1,\ t \geq 0, \\ I_m s_{tt} + G(\psi - w_x) + \frac{4}{3}\gamma s + \frac{4}{3}\beta I_m s_t - (Ds_x)_x = 0, & 0 < x < 1,\ t \geq 0, \end{cases} \tag{1.1}$$

where $w(x,t)$ denotes the transverse displacement, $\psi(x,t)$ represents the rotation angle and $s(x,t)$ is proportional to the amount of slip along the interface at time t and longitudinal spatial variable x, respectively, and $m > 0$ is the density of the beams, $G, I_m, D, \gamma > 0$ are the shear stiffness, mass moment of inertia, flexural rigidity, and adhesive stiffness of the beams together with $\beta > 0$ as the adhesive damping parameter. Moreover, $\sqrt{G/m}$ and $\sqrt{D/I_m}$ are two wave speeds and we always assume

that they are different in the present paper (see [7]). We refer to [4] for the detailed derivation of the mathematical model and its physical parameters. It is easy to find that if the slip s is assumed to be identically zero, then the first two equations of system (1.1) can be reduced exactly to the Timoshenko beam system. The third equation in (1.1) describes the dynamics of the slip. For convenience, if we introduce another variable ξ of the effective rotation angle by

$$\xi = 3s - \psi, \tag{1.2}$$

then (1.1) changes to

$$\begin{cases} mw_{tt} + (G(3s - \xi - w_x))_x = 0, & 0 < x < 1,\ t \geq 0, \\ I_m\xi_{tt} - G(3s - \xi - w_x) - (D\xi_x)_x = 0, & 0 < x < 1,\ t \geq 0, \\ I_m s_{tt} + G(3s - \xi - w_x) + \frac{4}{3}\gamma s + \frac{4}{3}\beta I_m s_t - (Ds_x)_x = 0, & 0 < x < 1,\ t \geq 0. \end{cases} \tag{1.3}$$

For system (1.3), we impose the cantilever boundary conditions, which can be easily obtained from the principle of virtual work (see [4]),

$$\begin{cases} w(0,t) = 0, \quad \xi(0,t) = 0, \quad s(0,t) = 0, \\ \xi_x(1,t) = u_2(t), \quad s_x(1,t) = 0, \quad 3s(1,t) - \xi(1,t) - w_x(1,t) = u_1(t), \end{cases} \tag{1.4}$$

where $u_1(t)$ and $u_2(t)$ are boundary control forces, and the initial conditions (for $0 < x < 1$)

$$(w, \xi, s)\Big|_{t=0} = (w_0, \xi_0, s_0) \quad \text{and} \quad (w_t, \xi_t, s_t)\Big|_{t=0} = (w_1, \xi_1, s_1). \tag{1.5}$$

We point out that due to the action of the slip s, the uncontrolled system (1.3) with boundary conditions (1.4) ($u_1 = u_2 \equiv 0$) in [4] can achieve the asymptotic stability but it does not reach the exponential stability (see Corollary 2.3 and Note 2.1).

In this paper, the following boundary feedback controls are proposed to exponentially stabilize systems (1.3) and (1.4):

$$u_2(t) = -k_2\xi_t(1,t), \quad u_1(t) = k_1 w_t(1,t), \tag{1.6}$$

where k_1 and k_2 are positive constant feedback gains. Then the boundary conditions become

$$\begin{cases} w(0,t) = 0, \quad \xi(0,t) = 0, \quad s(0,t) = 0, \\ \xi_x(1,t) = -k_2\xi_t(1,t), \quad s_x(1,t) = 0, \quad 3s(1,t) - \xi(1,t) - w_x(1,t) = k_1 w_t(1,t), \end{cases} \tag{1.7}$$

and the closed-loop system has both internal damping and boundary controls.

Our goal is to show that the closed-loop system (1.3) with (1.7) is exponentially stable in the state Hilbert space. This will follow from proving the following three aspects: (i) the closed-loop system is dissipative in the state space and the system operator has compact resolvents; (ii) there exist three asymptotes of frequencies for the system which are parallel to the imaginary axis from the left side; (iii) the generalized eigenfunctions of the system form a Riesz basis in the state space and hence the spectrum determined growth condition, and the exponential stability holds for the system. Among these, (i) is easy to verify while (ii) and (iii) are very difficult to solve. Our interests in this paper are mainly concentrated on the asymptotically spectral analysis and the proof of Riesz basis for the system.

Now let us briefly outline the contents of this paper. In the next section, the well-poseness of the system will be established. Asymptotic estimates of the eigenvalues for the system will be given in section 3. This is the foundation that we shall use to investigate the exponential stability and basis property for the system. Section 4 is devoted to the asymptotic expansion of the corresponding eigenfunctions. Finally, in the last section, we obtain a more profound result, namely, the existence of a sequence of the generalized eigenfunctions of the system that forms a Riesz basis in the state Hilbert space. Consequently, the spectrum determined growth condition and the exponential stability are concluded. Furthermore, the semigroup generated by the system operator is actually a C_0-group based on the spectrum distribution of the system.

2. Well-posedness of the system. We start our investigation by formulating the problem on the state Hilbert space. Let

$$\mathcal{H} := \big(H_E^1(0,1) \times L^2(0,1)\big)^3 \tag{2.1}$$

with

$$H_E^i(0,1) := \{f \in H^i(0,1) \mid f(0) = 0\} \quad \text{for } i = 1,2, \tag{2.2}$$

where $H^i(0,1)$ $(i = 1,2)$ denote the usual Sobolev spaces. The inner product in $\mathcal{H}$ is defined by

$$\begin{aligned}\langle Y_1, Y_2\rangle_{\mathcal{H}} :&= m\langle z_1, z_2\rangle_{L^2} + G\langle 3s_1 - \xi_1 - w_1', 3s_2 - \xi_2 - w_2'\rangle_{L^2} + I_m\langle \varphi_1, \varphi_2\rangle_{L^2} \\ &\quad + D\langle \xi_1', \xi_2'\rangle_{L^2} + 3I_m\langle h_1, h_2\rangle_{L^2} + 3D\langle s_1', s_2'\rangle_{L^2} + 4\gamma\langle s_1, s_2\rangle_{L^2},\end{aligned} \tag{2.3}$$

where $Y_i := [w_i, z_i, \xi_i, \varphi_i, s_i, h_i]^\top \in \mathcal{H}$ with $i = 1,2$, in which the superscript $\top$ denotes the transpose of a vector or a matrix, $\langle\cdot,\cdot\rangle_{L^2}$ is the inner product on $L^2(0,1)$, and the prime represents the differentiation with respect to x. In view of system (1.3) and (1.7), we define a linear operator $\mathcal{A} : \mathcal{D}(\mathcal{A}) \subset \mathcal{H} \to \mathcal{H}$ in Hilbert space $\mathcal{H}$ by

$$\mathcal{A}\begin{bmatrix} w \\ z \\ \xi \\ \varphi \\ s \\ h \end{bmatrix} := \begin{bmatrix} z \\ \frac{G}{m}(\xi' + w'' - 3s') \\ \varphi \\ \frac{G}{I_m}(3s - \xi - w') + \frac{D}{I_m}\xi'' \\ h \\ \frac{G}{I_m}(\xi + w' - 3s) - \frac{4}{3}\frac{\gamma}{I_m}s - \frac{4}{3}\beta h + \frac{D}{I_m}s'' \end{bmatrix} \tag{2.4}$$

with

$$\mathcal{D}(\mathcal{A}) := \left\{ [w,z,\xi,\varphi,s,h]^\top \in \mathcal{H} \;\middle|\; \begin{array}{l} w \in H_E^2(0,1),\ \xi \in H_E^2(0,1),\ s \in H_E^2(0,1), \\ z \in H_E^1(0,1),\ \varphi \in H_E^1(0,1),\ h \in H_E^1(0,1), \\ \xi'(1) = -k_2\varphi(1),\ s'(1) = 0, \\ 3s(1) - \xi(1) - w'(1) = k_1 z(1) \end{array} \right\}. \tag{2.5}$$

If we set $Y := [w, w_t, \xi, \xi_t, s, s_t]^\top$, then the closed-loop system (1.3), (1.5), and (1.7) can be formulated into an abstract evolution equation in $\mathcal{H}$:

$$\begin{cases} \dfrac{d}{dt}Y(t) = \mathcal{A}Y(t), \quad t > 0, \\ Y(0) := [w_0,\ w_1,\ \xi_0,\ \xi_1,\ s_0,\ s_1]^\top. \end{cases} \tag{2.6}$$

THEOREM 2.1. *Let $\mathcal{A}$ be defined by* (2.4) *and* (2.5). *Then $\mathcal{A}$ is dissipative in $\mathcal{H}$. In addition, $\mathcal{A}^{-1}$ exists and is compact on $\mathcal{H}$. Therefore, $\mathcal{A}$ generates a C_0-semigroup $e^{\mathcal{A}t}$ of contractions on $\mathcal{H}$ and the spectrum $\sigma(\mathcal{A})$ consists of isolated eigenvalues only.*

Proof. Since for any $[w, z, \xi, \varphi, s, h]^\top \in \mathcal{D}(\mathcal{A})$,

$$\begin{aligned}
&\big\langle \mathcal{A}[w,z,\xi,\varphi,s,h]^\top,\ [w,z,\xi,\varphi,s,h]^\top \big\rangle_{\mathcal{H}} \\
&= \Big\langle \Big[z,\ \frac{G}{m}(\xi' + w'' - 3s'),\ \varphi,\ \frac{G}{I_m}(3s - \xi - w') + \frac{D}{I_m}\xi'',\ h, \\
&\frac{G}{I_m}(\xi + w' - 3s) - \frac{4}{3}\frac{\gamma}{I_m}s - \frac{4}{3}\beta h + \frac{D}{I_m}s''\Big]^\top,\ [w,z,\xi,\varphi,s,h]^\top \Big\rangle_{\mathcal{H}} \\
&= G\langle \xi' + w'' - 3s',\ z\rangle_{L^2} + G\langle 3h - \varphi - z',\ 3s - \xi - w'\rangle_{L^2} \\
&+ \langle G(3s - \xi - w') + D\xi'',\ \varphi\rangle_{L^2} + D\langle \varphi', \xi'\rangle_{L^2} + 3D\langle h', s'\rangle_{L^2} + 4\gamma\langle h, s\rangle_{L^2} \\
&+ \langle G(\xi + w' - 3s) - \frac{4}{3}\gamma s - \frac{4}{3}I_m\beta h + Ds'',\ 3h\rangle_{L^2} \\
&= G\big[\xi(x) + w'(x) - 3s(x)\big]\overline{z(x)}\Big|_0^1 + D\xi'(x)\overline{\varphi(x)}\Big|_0^1 + 3Ds'(x)\overline{h(x)}\Big|_0^1 \\
&- G\langle 3s - \xi - w',\ 3h - \varphi - z'\rangle_{L^2} + G\langle 3h - \varphi - z',\ 3s - \xi - w'\rangle_{L^2} \\
&- D\langle \xi',\ \varphi'\rangle_{L^2} + D\langle \varphi', \xi'\rangle_{L^2} + 3D\langle h', s'\rangle_{L^2} + 4\gamma\langle h, s\rangle_{L^2} \\
&- 3D\langle s',\ h'\rangle_{L^2} - 4\gamma\langle s, h\rangle_{L^2} - 4\beta I_m\langle h, h\rangle_{L^2} \\
&= -k_1 G|z(1)|^2 - k_2 D|\varphi(1)|^2 - G\langle 3s - \xi - w',\ 3h - \varphi - z'\rangle_{L^2} \\
&+ G\langle 3h - \varphi - z',\ 3s - \xi - w'\rangle_{L^2} - D\langle \xi',\ \varphi'\rangle_{L^2} + D\langle \varphi', \xi'\rangle_{L^2} + 3D\langle h', s'\rangle_{L^2} \\
&+ 4\gamma\langle h, s\rangle_{L^2} - 3D\langle s',\ h'\rangle_{L^2} - 4\gamma\langle s, h\rangle_{L^2} - 4\beta I_m\langle h, h\rangle_{L^2},
\end{aligned}$$

it follows that

$$\operatorname{Re}\big\langle \mathcal{A}[w,z,\xi,\varphi,s,h]^\top, [w,z,\xi,\varphi,s,h]^\top \big\rangle_{\mathcal{H}} = -k_1 G|z(1)|^2 - k_2 D|\varphi(1)|^2 - 4\beta I_m\|h\|_{L^2}^2 \le 0.$$

Hence, $\mathcal{A}$ is dissipative in $\mathcal{H}$. We accomplish the proof by showing that $0 \in \rho(\mathcal{A})$ because from Theorem 4.6 of [6], if $\mathcal{A}^{-1}$ exists, $\mathcal{A}$ must be densely defined in $\mathcal{H}$. Therefore, the Lumer–Phillips theorem can be applied to conclude that $\mathcal{A}$ generates a C_0-semigroup $e^{\mathcal{A}t}$ of contractions on $\mathcal{H}$.

To do so, for each $F := [u_1, u_2, \eta_1, \eta_2, v_1, v_2]^\top \in \mathcal{H}$, we seek $Y := [w, z, \xi, \varphi, s, h]^\top \in \mathcal{D}(\mathcal{A})$ such that

$$\mathcal{A}Y = F$$

which yields

$$\begin{cases} z = u_1, \quad G(\xi' + w'' - 3s') = mu_2, \\ \varphi = \eta_1, \quad G(3s - \xi - w') + D\xi'' = I_m\eta_2, \\ h = v_1, \quad 3G(\xi + w' - 3s) - 4\gamma s - 4\beta I_m h + 3Ds'' = 3I_m v_2, \\ \xi'(1) = -k_2\varphi(1), \quad s'(1) = 0, \\ 3s(1) - \xi(1) - w'(1) = k_1 z(1), \quad w(0) = \xi(0) = s(0) = 0. \end{cases} \tag{2.7}$$

From the first equation of (2.7), we have

$$G\big(\xi(x) + w'(x) - 3s(x)\big) = Gw'(0) + m\int_0^x u_2(r)dr. \tag{2.8}$$

By eliminating the term $G\big(\xi(x) + w'(x) - 3s(x)\big)$ from the second and the third equations of (2.7), it follows that

$$D\xi''(x) = I_m\eta_2(x) + Gw'(0) + m\int_0^x u_2(r)dr \tag{2.9}$$

and

$$3Ds''(x) - 4\gamma s(x) = 3I_m v_2(x) + 4\beta I_m v_1(x) - 3\left[Gw'(0) + m\int_0^x u_2(r)dr\right]. \tag{2.10}$$

A simple computation of (2.9), yields

$$\xi(x) = -k_2\eta_1(1)x - \frac{G}{D}w'(0)\left(x - \frac{x^2}{2}\right) - \widehat{\xi}(x), \tag{2.11}$$

where

$$\widehat{\xi}(x) := \frac{I_m}{D}\int_0^1 K_1(x,r)\eta_2(r)dr + \frac{m}{D}\int_0^1 K_2(x,r)u_2(r)dr \tag{2.12}$$

and

$$K_1(x,r) := \begin{cases} r, & 0 \le r < x, \\ x, & x \le r \le 1, \end{cases} \qquad K_2(x,r) := \begin{cases} x - \dfrac{x^2}{2} - \dfrac{r^2}{2}, & 0 \le r \le x, \\ x(1-r), & x \le r \le 1. \end{cases}$$

Similarly, it follows from (2.10) that

$$s(x) = a\sinh(bx) + \frac{G}{D}w'(0)\frac{1-\cosh(bx)}{b^2} + \frac{4\beta I_m}{3Db}\int_0^x \sinh(b(x-r))v_1(r)dr + \widehat{s}(x), \tag{2.13}$$

where a will be given later in (2.18), and

$$b := \sqrt{\frac{4\gamma}{3D}}, \quad \widehat{s}(x) := \frac{1}{b}\int_0^x \sinh(b(x-r))\left[\frac{I_m}{D}v_2(r) - \frac{m}{D}\int_0^r u_2(t)dt\right]dr. \tag{2.14}$$

Substitute (2.11) and (2.13) into (2.8), and integrate from 0 to x respect to x, to obtain

$$\begin{aligned} w(x) = {} & 3a\int_0^x \sinh(br)dr + w'(0)\left[\frac{3G}{Db^2}\int_0^x (1-\cosh(br))dr + \frac{G}{D}\left(\frac{x^2}{2} - \frac{x^3}{6}\right) + x\right] \\ & + \frac{4\beta I_m}{bD}\int_0^x (x-r)\sinh(b(x-r))v_1(r)dr - \frac{1}{2}\xi'(1)x^2 + \widehat{w}(x), \end{aligned} \tag{2.15}$$

where $\widehat{w}(x)$ is given by

$$\widehat{w}(x) := 3\int_0^x \widehat{s}(r)dr - \int_0^x \widehat{\xi}(r)dr + \frac{m}{G}\int_0^x (x-r)u_2(r)dr. \tag{2.16}$$

Using the boundary conditions $s'(1)=0$ in (2.13) and $3s(1)-\xi(1)-w'(1)=k_1u_1(1)$ in (2.8), respectively, we obtain that

$$\begin{cases} ab\cosh b - \dfrac{G}{D}w'(0)\dfrac{\sinh b}{b} + \dfrac{4\beta I_m}{3D}\displaystyle\int_0^1 \cosh(b(1-r))v_1(r)dr + \widehat{s}'(1) = 0, \\ Gw'(0) + m\displaystyle\int_0^1 u_2(r)dr = -k_1Gu_1(1). \end{cases} \tag{2.17}$$

Thus, a and $w'(0)$ in (2.13) and (2.15), respectively, can be obtained as follows:

$$\begin{cases} a = \dfrac{G}{D}w'(0)\dfrac{\sinh b}{b^2\cosh b} - \dfrac{4\beta I_m}{3Db\cosh b}\displaystyle\int_0^1 \cosh(b(1-r))v_1(r)dr - \dfrac{\widehat{s}'(1)}{b\cosh b}, \\ w'(0) = -\dfrac{m}{G}\displaystyle\int_0^1 u_2(r)dr - k_1u_1(1). \end{cases} \tag{2.18}$$

Hence, there is a solution $Y=[w,z,\xi,\varphi,s,h]^\top \in \mathcal{D}(\mathcal{A})$ so that $\mathcal{A}Y=F$, which in turn implies that $\mathcal{A}^{-1}$ exists. Finally, by the Sobolev embedding theorem, we can claim that $\mathcal{A}^{-1}$ is compact on $\mathcal{H}$ and thus the spectrum $\sigma(\mathcal{A})$ consists of isolated eigenvalues only (see [5]). The proof is complete. □

As a consequence of Theorem 2.1, we have the following corollary.

COROLLARY 2.2. *Let $\mathcal{A}$ be defined by* (2.4) *and* (2.5)*, and let $T(t)$ be a C_0-semigroup on $\mathcal{H}$ generated by $\mathcal{A}$. Then $T(t)$ is asymptotically stable in $\mathcal{H}$, i.e.,*

$$\lim_{t\to\infty}\|T(t)Y\| = 0 \quad \forall\, Y\in\mathcal{H}.$$

Proof. Since $T(t)$ is a C_0-semigroup of contractions on $\mathcal{H}$, the proof will be accomplished by showing that there is no eigenvalue on the imaginary axis (see [3, p. 130]). Assume that $\lambda=i\tau,\ \tau\in\mathbb{R}$ is an eigenvalue of $\mathcal{A}$ and $Y:=[w,z,\xi,\varphi,s,h]^\top \in \mathcal{D}(\mathcal{A})$ is an eigenfunction associated with λ. Then we have

$$z = i\tau w, \quad \varphi = i\tau\xi, \quad h = i\tau s,$$

and

$$\mathrm{Re}\langle \mathcal{A}Y,\ Y\rangle_{\mathcal{H}} = -k_1G|z(1)|^2 - k_2D|\varphi(1)|^2 - 4\beta I_m\|h\|_{L^2} \equiv 0.$$

Thus, it follows that

$$h(x) = i\tau s(x) \equiv 0, \quad z(1) = i\tau w(1) \equiv 0, \quad \varphi(1) = i\tau\xi(1) \equiv 0$$

and functions w and ξ satisfy the following equations:

$$\begin{cases} m\tau^2 w(x) + G\big(\xi'(x) + w''(x)\big) = 0, \quad 0<x<1, \\ I_m\tau^2\xi(x) - G\big(\xi(x) + w'(x)\big) + D\xi''(x) = 0, \quad 0<x<1, \\ \xi(x) + w'(x) = 0, \quad 0<x<1, \\ w(0) = \xi(0) = w(1) = \xi(1) = 0, \quad \xi'(1) = -k_2\varphi(1) = 0,\ w'(1) = -\xi(1) - k_1z(1) = 0. \end{cases} \tag{2.19}$$

By a direct computation, we obtain that (2.19) has a unique trivial solution only. Thus $w(x) = \xi(x) \equiv 0$ and hence $Y \equiv 0$, which contradicts that Y is an eigenfunction. Therefore, no eigenvalue exists on the imaginary axis. The proof is complete. □

COROLLARY 2.3. *If $k_1 = k_2 \equiv 0$ in* (1.6)*, that is, there is no control imposed on system* (1.3)*, then there is no eigenvalue on the imaginary axis. So the uncontrolled system* (1.3) *with its boundary conditions* (1.4) *is also asymptotically stable.*

Proof. Similar to the proof of Corollary 2.2, if $k_1 = k_2 \equiv 0$ and assume that $\lambda = i\tau,\ \tau \in \mathbb{R}$ is an eigenvalue with $Y := [w, z, \xi, \varphi, s, h]^\top$ being an eigenfunction, then it follows that $s \equiv 0$ and the functions w and ξ satisfy the following equations:

$$\begin{cases} m\tau^2 w(x) = 0, \quad 0 < x < 1, \\ I_m \tau^2 \xi(x) + D\xi''(x) = 0, \quad 0 < x < 1, \\ w(0) = \xi(0) = \xi'(1) = 0, \quad w'(1) = -\xi(1). \end{cases} \tag{2.20}$$

Therefore, one has $w = \xi \equiv 0$ and hence $Y \equiv 0$. The proof is complete. □

Note 2.1. We should note here that if $k_1 = k_2 \equiv 0$ in (1.6), then system (1.3) with its boundary conditions (1.4) cannot achieve the exponential stability. This is because of the fact that from the asymptotes of the system given later in (3.28), if $k_1 = k_2 \equiv 0$, then the eigenvalues of the first and second branches are very close to the imaginary axis as their moduli go to the infinity.

Let us now formulate the eigenvalue problem for the operator $\mathcal{A}$. If $\lambda \in \sigma(\mathcal{A})$ and $Y_\lambda := [w, z, \xi, \varphi, s, h]^\top \in \mathcal{D}(\mathcal{A})$ is a corresponding eigenfunction, then it is routine to verify that $\mathcal{A}Y_\lambda = \lambda Y_\lambda$ implies that $z = \lambda w,\ \varphi = \lambda\xi,\ h = \lambda s$ with w, ξ as well as s satisfying the following characteristic equations, for $0 < x < 1$:

$$\begin{cases} m\lambda^2 w(x) + G(3s' - \xi' - w'')(x) = 0, \\ I_m\lambda^2 \xi(x) - G(3s - \xi - w')(x) - D\xi''(x) = 0, \\ I_m\lambda^2 s(x) + G(3s - \xi - w')(x) + \frac{4}{3}\gamma s(x) + \frac{4}{3}\beta\lambda I_m s(x) - Ds''(x) = 0, \\ w(0) = 0, \quad \xi(0) = 0, \quad s(0) = 0, \\ \xi'(1) = -\lambda k_2 \xi(1), \quad s'(1) = 0, \quad 3s(1) - \xi(1) - w'(1) = \lambda k_1 w(1). \end{cases} \tag{2.21}$$

For brevity in notation, from now on, we define

$$r_1 := \sqrt{\frac{m}{G}}, \quad r_2 := \sqrt{\frac{I_m}{D}}, \quad d_1 := \frac{G}{D}, \quad d_2 := \frac{\gamma}{D}, \quad d_3 := 3d_1 + \frac{4}{3}d_2. \tag{2.22}$$

(2.21) then becomes

$$\begin{cases} r_1^2\lambda^2 w(x) + 3s'(x) - \xi'(x) - w''(x) = 0, \\ r_2^2\lambda^2 \xi(x) - 3d_1 s(x) + d_1\xi(x) + d_1 w'(x) - \xi''(x) = 0, \\ r_2^2\lambda^2 s(x) + d_3 s(x) - d_1\xi(x) - d_1 w'(x) + \frac{4}{3}\beta r_2^2\lambda s(x) - s''(x) = 0, \\ w(0) = 0, \quad \xi(0) = 0, \quad s(0) = 0, \\ \xi'(1) = -\lambda k_2\xi(1), \quad s'(1) = 0, \quad 3s(1) - \xi(1) - w'(1) = \lambda k_1 w(1). \end{cases} \tag{2.23}$$

Clearly, (2.23) is a coupled system of ordinary differential equations. In order to solve these equations, we shall use the matrix operator pencil method (see [8]). Let

$$w_1 := w, \quad w_2 := w', \quad \xi_1 := \xi, \quad \xi_2 := \xi', \quad s_1 := s, \quad s_2 := s' \tag{2.24}$$

and

$$\Phi := [w_1,\ w_2,\ \xi_1,\ \xi_2,\ s_1,\ s_2]^\top. \tag{2.25}$$

Then (2.23) becomes

$$\begin{cases} T^D(x,\lambda)\Phi(x) := \Phi'(x) + M(\lambda)\Phi(x) = 0, \\ T^R(x,\lambda)\Phi(x) := W^0(\lambda)\Phi(0) + W^1(\lambda)\Phi(1) = 0, \end{cases} \tag{2.26}$$

where

(2.27)

$$W^0(\lambda) := \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ & & O_{3\times 6} & & & \end{bmatrix}, \quad W^1(\lambda) := \begin{bmatrix} & & O_{3\times 6} & & & \\ 0 & 0 & \lambda k_2 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ \lambda k_1 & 1 & 1 & 0 & -3 & 0 \end{bmatrix},$$

and

$$M(\lambda) := D_0 - \lambda D_1 - \lambda^2 D_2 \tag{2.28}$$

with D_0, D_1, and D_2 being three matrices defined by

$$D_0 := \begin{bmatrix} 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & -3 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & -d_1 & -d_1 & 0 & 3d_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & d_1 & d_1 & 0 & -d_3 & 0 \end{bmatrix}, \quad D_1 := \begin{bmatrix} O_{4\times 4} & O_{4\times 2} \\ O_{2\times 4} & D_{11} \end{bmatrix}, \tag{2.29}$$

$$D_2 := \begin{bmatrix} r_1^2 D_{21} & O_{2\times 2} & O_{2\times 2} \\ O_{2\times 2} & r_2^2 D_{21} & O_{2\times 2} \\ O_{2\times 2} & O_{2\times 2} & r_2^2 D_{21} \end{bmatrix}, \quad D_{11} := \begin{bmatrix} 0 & 0 \\ \frac{4}{3}\beta r_2^2 & 0 \end{bmatrix}, \quad D_{21} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}. \tag{2.30}$$

THEOREM 2.4. *The characteristic equation* (2.21) *is equivalent to the first order linear system* (2.26). *Also* $\lambda \in \sigma(\mathcal{A})$ *if and only if* (2.26) *has a nontrivial solution.*

3. Asymptotic behavior of eigenfrequencies. In this section, we are looking for the asymptotic expressions for the eigenvalues of $\mathcal{A}$. It will be accomplished by expanding the characteristic determinant $\Delta(\lambda)$ of (2.26) via an asymptotic expression of the fundamental matrix solution, which can be obtained by modifying a standard technique of Birkhoff–Langer (see [1]) and later of Tretter (see [8] or [9]) for tackling the matrix operator pencils. A key step is an invertible matrix transformation which is very powerful and universal in the sense that it can be applied to a lot of other coupled problems.

To begin, we shall diagonalize the leading term $\lambda^2 D_2$ in (2.28). For each $0 \neq \lambda \in \mathbb{C}$, define an invertible matrix in λ by

$$P(\lambda) := \begin{bmatrix} P_1(\lambda) & & \\ & P_2(\lambda) & \\ & & P_2(\lambda) \end{bmatrix}, \quad P_1(\lambda) := \begin{bmatrix} r_1\lambda & r_1\lambda \\ r_1^2\lambda^2 & -r_1^2\lambda^2 \end{bmatrix}, \tag{3.1}$$

$$P_2(\lambda) := \begin{bmatrix} r_2\lambda & r_2\lambda \\ r_2^2\lambda^2 & -r_2^2\lambda^2 \end{bmatrix}.$$

For any $\lambda \neq 0$, a simple computation shows that

$$P^{-1}(\lambda) := \begin{bmatrix} P_1^{-1}(\lambda) & & \\ & P_2^{-1}(\lambda) & \\ & & P_2^{-1}(\lambda) \end{bmatrix} \tag{3.2}$$

with

$$P_1^{-1}(\lambda) := \begin{bmatrix} \frac{1}{2r_1\lambda} & \frac{1}{2r_1^2\lambda^2} \\ \frac{1}{2r_1\lambda} & \frac{-1}{2r_1^2\lambda^2} \end{bmatrix}, \quad P_2^{-1}(\lambda) := \begin{bmatrix} \frac{1}{2r_2\lambda} & \frac{1}{2r_2^2\lambda^2} \\ \frac{1}{2r_2\lambda} & \frac{-1}{2r_2^2\lambda^2} \end{bmatrix}.$$

So matrix $P(\lambda)$ is a polynomial of degree 2 in λ. Define

$$\Psi(x) := P^{-1}(\lambda)\Phi(x), \quad \widehat{T}^D(x,\lambda) := P(\lambda)^{-1}T^D(x,\lambda)P(\lambda). \tag{3.3}$$

Then we have

$$\widehat{T}^D(x,\lambda)\Psi(x) = \Psi'(x) - \widehat{M}(\lambda)\Psi(x) = 0, \tag{3.4}$$

where

$$\begin{aligned}
\widehat{M}(\lambda) &= -P(\lambda)^{-1}M(\lambda)P(\lambda) \\
&= -P(\lambda)^{-1}\begin{bmatrix} 0 & -1 & 0 & 0 & 0 & 0 \\ -r_1^2\lambda^2 & 0 & 0 & 1 & 0 & -3 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & -d_1 & -d_1 - r_2^2\lambda^2 & 0 & 3d_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & d_1 & d_1 & 0 & -d_3 - r_2^2(\frac{4}{3}\beta\lambda + \lambda^2) & 0 \end{bmatrix} P(\lambda) \\
&= -\begin{bmatrix} -\frac{1}{2} & \frac{-1}{2r_1\lambda} & 0 & \frac{1}{2r_1^2\lambda^2} & 0 & \frac{-3}{2r_1^2\lambda^2} \\ \frac{1}{2} & \frac{-1}{2r_1\lambda} & 0 & \frac{-1}{2r_1^2\lambda^2} & 0 & \frac{3}{2r_1^2\lambda^2} \\ 0 & \frac{-d_1}{2r_2^2\lambda^2} & \frac{-d_1}{2r_2^2\lambda^2} - \frac{1}{2} & \frac{-1}{2r_2\lambda} & \frac{3d_1}{2r_2^2\lambda^2} & 0 \\ 0 & \frac{d_1}{2r_2^2\lambda^2} & \frac{d_1}{2r_2^2\lambda^2} + \frac{1}{2} & \frac{-1}{2r_2\lambda} & \frac{-3d_1}{2r_2^2\lambda_2^2} & 0 \\ 0 & \frac{d_1}{2r_2^2\lambda^2} & \frac{d_1}{2r_2^2\lambda^2} & 0 & -\frac{1}{2} - \frac{2}{3}\frac{\beta}{\lambda} - \frac{d_3}{2r_2^2\lambda^2} & \frac{-1}{2r_2\lambda} \\ 0 & \frac{-d_1}{2r_2^2\lambda^2} & \frac{-d_1}{2r_2^2\lambda^2} & 0 & \frac{1}{2} + \frac{2}{3}\frac{\beta}{\lambda} + \frac{d_3}{2r_2^2\lambda^2} & \frac{-1}{2r_2\lambda} \end{bmatrix} P(\lambda) \\
&= -\begin{bmatrix} -r_1\lambda & 0 & \frac{1}{2}d_4 & -\frac{1}{2}d_4 & -\frac{3}{2}d_4 & \frac{3}{2}d_4 \\ 0 & r_1\lambda & -\frac{1}{2}d_4 & \frac{1}{2}d_4 & \frac{3}{2}d_4 & -\frac{3}{2}d_4 \\ -\frac{1}{2}d_6 & \frac{1}{2}d_6 & -r_2\lambda - \frac{d_7}{2\lambda} & -\frac{d_7}{2\lambda} & \frac{3d_7}{2\lambda} & \frac{3d_7}{2\lambda} \\ \frac{1}{2}d_6 & -\frac{1}{2}d_6 & \frac{d_7}{2\lambda} & r_2\lambda + \frac{d_7}{2\lambda} & -\frac{3d_7}{2\lambda} & -\frac{3d_7}{2\lambda} \\ \frac{1}{2}d_6 & -\frac{1}{2}d_6 & \frac{d_7}{2\lambda} & \frac{d_7}{2\lambda} & -r_2\lambda - \frac{2}{3}\beta r_2 - \frac{d_8}{2\lambda} & -\frac{2}{3}\beta r_2 - \frac{d_8}{2\lambda} \\ -\frac{1}{2}d_6 & \frac{1}{2}d_6 & -\frac{d_7}{2\lambda} & -\frac{d_7}{2\lambda} & \frac{2}{3}\beta r_2 + \frac{d_8}{2\lambda} & r_2\lambda + \frac{2}{3}\beta r_2 + \frac{d_8}{2\lambda} \end{bmatrix}
\end{aligned}$$

with

$$d_4 := \frac{r_2^2}{r_1^2}, \quad d_5 := \frac{r_1^2}{r_2^2}, \quad d_6 := d_1 d_5, \quad d_7 := \frac{d_1}{r_2}, \quad d_8 := \frac{d_3}{r_2}. \tag{3.5}$$

It is seen from the above that $\widehat{M}(\lambda)$ can be written as

$$\widehat{M}(\lambda) := \lambda\widehat{M}_1 + \widehat{M}_0 + \lambda^{-1}\widehat{M}_{-1}, \tag{3.6}$$

where

$$\widehat{M}_1 := \operatorname{diag}[r_1, -r_1, r_2, -r_2, r_2, -r_2] \tag{3.7}$$

and

$$\widehat{M}_0 := \begin{bmatrix} O_{2\times 2} & \frac{1}{2}d_4\widehat{M}_{01} & -\frac{3}{2}d_4\widehat{M}_{01} \\ -\frac{1}{2}d_6\widehat{M}_{01} & O_{2\times 2} & O_{2\times 2} \\ \frac{1}{2}d_6\widehat{M}_{01} & O_{2\times 2} & \frac{2}{3}\beta r_2\widehat{M}_{02} \end{bmatrix}, \quad \widehat{M}_{-1} := \begin{bmatrix} O_{2\times 2} & O_{2\times 4} \\ O_{4\times 2} & \widehat{M}_{-11} \end{bmatrix} \tag{3.8}$$

with

$$\widehat{M}_{01} := \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix}, \quad \widehat{M}_{02} := \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix}, \quad \widehat{M}_{-11} := \begin{bmatrix} \frac{1}{2}d_7\widehat{M}_{02} & -\frac{3}{2}d_7\widehat{M}_{02} \\ -\frac{1}{2}d_7\widehat{M}_{02} & \frac{1}{2}d_8\widehat{M}_{02} \end{bmatrix}.$$

On the basis of these transformations, we are now in a position to find an asymptotic expression for the fundamental matrix solution of system (3.4).

THEOREM 3.1. *Let $0 \neq \lambda \in \mathbb{C}$, and let $\widehat{M}(\lambda)$ be given by* (3.6) *and assume that $r_1 \neq r_2$. For $x \in [0,1]$, set*

$$E(x,\lambda) := \operatorname{diag}\left[e^{r_1\lambda x},\ e^{-r_1\lambda x},\ e^{r_2\lambda x},\ e^{-r_2\lambda x},\ e^{r_2\lambda x},\ e^{-r_2\lambda x}\right]. \tag{3.9}$$

Then there exists a fundamental matrix solution $\widehat{\Psi}(x,\lambda)$ for system (3.4)*, which satisfies*

$$\Psi'(x) = \widehat{M}(\lambda)\Psi(x) \tag{3.10}$$

such that for large enough $|\lambda|$,

$$\widehat{\Psi}(x,\lambda) = \left(\widehat{\Psi}_0(x) + \frac{\widetilde{\Theta}(x,\lambda)}{\lambda}\right) E(x,\lambda), \tag{3.11}$$

where

$$\widehat{\Psi}_0(x) := \operatorname{diag}[1,\ 1,\ 1,\ 1,\ e_1(x),\ e_2(x)] \tag{3.12}$$

and

$$\widetilde{\Theta}(x,\lambda) := \widehat{\Psi}_1(x) + \lambda^{-1}\widehat{\Psi}_2(x) + \cdots \tag{3.13}$$

with all entries uniformly bounded in $[0,1]$. Here,

$$e_1(x) := e^{\frac{2}{3}\beta r_2 x} \quad \text{and} \quad e_2(x) := e^{-\frac{2}{3}\beta r_2 x}. \tag{3.14}$$

Proof. Since $\widehat{M}_1$ given by (3.7) is a diagonal matrix, it follows that $E(x,\lambda)$ given by (3.9) is a fundamental matrix solution to (3.10) which involves only the leading order terms, that is, to say

$$E'(x,\lambda) = \lambda\widehat{M}_1 E(x,\lambda).$$

Now we look for a fundamental matrix solution of (3.10) in the form of

$$\widehat{\Psi}(x,\lambda)=\left(\widehat{\Psi}_0(x)+\lambda^{-1}\widehat{\Psi}_1(x)+\cdots+\lambda^{-n}\widehat{\Psi}_n(x)+\cdots\right)E(x,\lambda).$$

The left-hand side of (3.10) is

$$\begin{aligned}\widehat{\Psi}'(x,\lambda)=&\left(\widehat{\Psi}_0'(x)+\lambda^{-1}\widehat{\Psi}_1'(x)+\cdots+\lambda^{-n}\widehat{\Psi}_n'(x)+\cdots\right)E(x,\lambda)\\&+\lambda\left(\widehat{\Psi}_0(x)+\lambda^{-1}\widehat{\Psi}_1(x)+\cdots+\lambda^{-n}\widehat{\Psi}_n(x)+\cdots\right)\widehat{M}_1E(x,\lambda).\end{aligned}$$

Compare it with the right-hand side of (3.10),

$$\big(\lambda\widehat{M}_1+\widehat{M}_0+\lambda^{-1}\widehat{M}_{-1}\big)\big(\widehat{\Psi}_0(x)+\lambda^{-1}\widehat{\Psi}_1(x)+\cdots+\lambda^{-n}\widehat{\Psi}_n(x)+\cdots\big)E(x,\lambda),$$

to give, according to the coefficients of $\lambda^1,\lambda^0,\lambda^{-1},\ldots,\lambda^{-n},\ldots$, that

$$\begin{gathered}\widehat{\Psi}_0(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_0(x)=0,\\ \widehat{\Psi}_0'(x)-\widehat{M}_0\widehat{\Psi}_0(x)+\widehat{\Psi}_1(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_1(x)=0,\\ \widehat{\Psi}_1'(x)-\widehat{M}_0\widehat{\Psi}_1(x)-\widehat{M}_{-1}\widehat{\Psi}_0(x)+\widehat{\Psi}_2(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_2(x)=0,\\ \vdots\\ \widehat{\Psi}_n'(x)-\widehat{M}_0\widehat{\Psi}_n(x)-\widehat{M}_{-1}\widehat{\Psi}_{n-1}(x)+\widehat{\Psi}_{n+1}(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_{n+1}(x)=0,\\ \vdots\end{gathered}$$

Using the arguments in [8, p. 135] (or [1]), we conclude that there is an asymptotic fundamental matrix solution $\widehat{\Psi}(x,\lambda)$ for system (3.10). It remains to show that the leading order term $\widehat{\Psi}_0(x)$ is given by (3.12). Indeed, since $\widehat{\Psi}_0(x)$ can be determined by the matrix equations

$$\widehat{\Psi}_0(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_0(x)=0 \tag{3.15}$$

and

$$\widehat{\Psi}_0'(x)-\widehat{M}_0\widehat{\Psi}_0(x)+\widehat{\Psi}_1(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_1(x)=0, \tag{3.16}$$

where $\widehat{M}_1$ and $\widehat{M}_0$ are given in (3.7), (3.8), respectively, it follows that if $\widehat{\Psi}_0$ is known, then one can deduce the leading order term $\widehat{\Psi}_1$ of $\widetilde{\Theta}(x,\rho)$ in (3.13) from (3.16) and

$$\widehat{\Psi}_1'(x)-\widehat{M}_0\widehat{\Psi}_1(x)-\widehat{M}_{-1}\widehat{\Psi}_0(x)+\widehat{\Psi}_2(x)\widehat{M}_1-\widehat{M}_1\widehat{\Psi}_2(x)=0$$

with $\widehat{M}_{-1}$ being given in (3.8). Similarly, we obtain all the terms $\widehat{\Psi}_1,\widehat{\Psi}_2,\ldots,\widehat{\Psi}_n,\ldots$ of $\widetilde{\Theta}(x,\lambda)$ in (3.13). So, the proof will be accomplished if we would find the leading order term $\widehat{\Psi}_0$ in (3.11).

Let us denote by $c_{ij}(x)$ the (i,j)-entry of the matrix $\widehat{\Psi}_0(x)$ with $i,j=1,2,\ldots,6$. Since $\widehat{M}_1$ is diagonal, it follows from (3.15) and $r_1\neq r_2$ that the entries $c_{ij}(x)$ of $\widehat{\Psi}_0$ satisfy

$$\begin{cases}c_{ij}(x)=0 & \text{if}\quad 1\le i\le 2,\ 1\le j\le 6,\ i\neq j,\\ c_{ij}(x)=0 & \text{if}\quad 3\le i\le 4,\ 1\le j\le 6,\ i\neq j,\ j\neq i+2,\\ c_{ij}(x)=0 & \text{if}\quad 5\le i\le 6,\ 1\le j\le 6,\ i\neq j,\ j\neq i-2,\end{cases}$$

and the entries $c_{ii}(x)$ $(i = 1, 2, \ldots, 6)$, $c_{35}(x)$, $c_{53}(x)$, $c_{46}(x)$, and $c_{64}(x)$ can be found by substituting them into (3.16) to obtain

$$\begin{cases} c'_{ii}(x) = 0 \quad \text{for } \ i = 1, 2, 3, 4, \\ c'_{55}(x) = \frac{2}{3}\beta r_2 c_{55}(x), \quad c'_{66}(x) = -\frac{2}{3}\beta r_2 c_{66}(x), \\ c'_{35}(x) = 0, \quad c'_{53}(x) = \frac{2}{3}\beta r_2 c_{53}(x), \\ c'_{46}(x) = 0, \quad c'_{64}(x) = -\frac{2}{3}\beta r_2 c_{64}(x). \end{cases} \tag{3.17}$$

(3.12) then follows from $\widehat{\Psi}_0(0) = I$. The proof is complete. □

By virtue of transformation for $\widehat{\Psi}(x, \lambda)$ in (3.3), we have immediately the following corollary, which shows the relationship between (2.26) and (3.4).

COROLLARY 3.2. *Let $0 \neq \lambda \in \mathbb{C}$, let $r_1 \neq r_2$, and let $\widehat{\Psi}(x, \lambda)$ given by* (3.11) *be a fundamental matrix solution of system* (3.4). *Then*

$$\widehat{\Phi}(x, \lambda) := P(\lambda)\widehat{\Psi}(x, \lambda) \tag{3.18}$$

is a fundamental matrix solution for the first order linear system (2.26).

We are now ready to estimate the asymptotic eigenfrequencies of the system. Note that the eigenvalues of the first order linear system in (2.26) are given by the zeros of the characteristic determinant

$$\Delta(\lambda) := \det\left(T^R \widehat{\Phi}(x, \lambda)\right), \quad \lambda \in \mathbb{C}, \tag{3.19}$$

where operator T^R is given in (2.26) and $\widehat{\Phi}(x, \lambda)$ is any fundamental matrix of $T^D(x, \lambda)\Phi(x) = 0$ (see [8]). We shall derive the asymptotic expansion of eigenfrequencies by substituting (3.11) and (3.18) into (3.19), together with the boundary conditions in (2.26). In fact, since

$$T^R \widehat{\Phi}(x, \lambda) = W^0(\lambda)P(\lambda)\widehat{\Psi}(0, \lambda) + W^1(\lambda)P(\lambda)\widehat{\Psi}(1, \lambda), \tag{3.20}$$

using (2.27) and (3.1), a simple computation gives

$$W^0(\lambda)P(\lambda) = \begin{bmatrix} r_1\lambda & r_1\lambda & 0 & 0 & 0 & 0 \\ 0 & 0 & r_2\lambda & r_2\lambda & 0 & 0 \\ 0 & 0 & 0 & 0 & r_2\lambda & r_2\lambda \\ & & & O_{3\times 6} & & \end{bmatrix}$$

and

$$W^1(\lambda)P(\lambda) = \begin{bmatrix} & & & O_{3\times 6} & & \\ 0 & 0 & r_2 r_3\lambda^2 & r_2 r_4\lambda^2 & 0 & 0 \\ 0 & 0 & 0 & 0 & r_2^2\lambda^2 & -r_2^2\lambda^2 \\ r_1 r_5\lambda^2 & r_1 r_6\lambda^2 & r_2\lambda & r_2\lambda & -3r_2\lambda & -3r_2\lambda \end{bmatrix},$$

where

$$r_3 := k_2 + r_2, \quad r_4 := k_2 - r_2, \quad r_5 := k_1 + r_1, \quad r_6 := k_1 - r_1. \tag{3.21}$$

Once again for notational simplicity, set

$$[a]_1 := a + \mathcal{O}(\lambda^{-1}).$$

Since $\widehat{\Psi}_0(0) = I$ and $E(0,\lambda) = I$, a direct computation yields

$$W^0(\lambda)P(\lambda)\widehat{\Psi}(0,\lambda) = \begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 & 0 & 0 & 0 & 0 \\ 0 & 0 & \lambda[r_2]_1 & \lambda[r_2]_1 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda[r_2]_1 & \lambda[r_2]_1 \\ & & O_{3\times 6} & & & \end{bmatrix}$$

and

$$W^1(\lambda)P(\lambda)\widehat{\Psi}(1,\lambda) = \begin{bmatrix} & & O_{3\times 6} & & & \\ 0 & 0 & \lambda^2 E_3[r_2r_3]_1 & \lambda^2 E_4[r_2r_4]_1 & 0 & 0 \\ 0 & 0 & 0 & 0 & [r_2^2]_1\lambda^2 E_3E_5 & -[r_2^2]_1\lambda^2 E_4E_6 \\ \lambda^2 E_1[r_1r_5]_1 & \lambda^2 E_2[r_1r_6]_1 & \lambda E_3[r_2]_1 & \lambda E_4[r_2]_1 & -3\lambda E_3E_5[r_2]_1 & -3\lambda E_4E_6[r_2]_1 \end{bmatrix},$$

where

$$\begin{cases} E_1 := e^{r_1\lambda}, \quad E_2 := e^{-r_1\lambda}, \quad E_3 := e^{r_2\lambda}, \quad E_4 := e^{-r_2\lambda}, \\ E_5 := e_1(1) = e^{\frac{2}{3}\beta r_2}, \quad E_6 := e_2(1) = e^{-\frac{2}{3}\beta r_2}. \end{cases} \tag{3.22}$$

Hence,

$$T^R\widehat{\Phi}(x,\lambda) = \begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 & 0 & 0 & 0 & 0 \\ 0 & 0 & \lambda[r_2]_1 & \lambda[r_2]_1 & 0 & 0 \\ 0 & 0 & 0 & 0 & \lambda[r_2]_1 & \lambda[r_2]_1 \\ 0 & 0 & \lambda^2 E_3[r_2r_3]_1 & \lambda^2 E_4[r_2r_4]_1 & 0 & 0 \\ 0 & 0 & 0 & 0 & [r_2^2]_1\lambda^2 E_3E_5 & -[r_2^2]_1\lambda^2 E_4E_6 \\ \lambda^2 E_1[r_1r_5]_1 & \lambda^2 E_2[r_1r_6]_1 & \lambda E_3[r_2]_1 & \lambda E_4[r_2]_1 & -3\lambda E_3E_5[r_2]_1 & -3\lambda E_4E_6[r_2]_1 \end{bmatrix}.$$

Therefore,

$$\begin{aligned} \Delta(\lambda) = \det(T^R\widehat{\Phi}(x,\lambda)) &= \lambda^9 r_1^2 r_2^5 \times \det\begin{bmatrix} [1]_1 & [1]_1 \\ [r_5]_1E_1 & [r_6]_1E_2 \end{bmatrix} \\ &\quad \times \det\begin{bmatrix} [1]_1 & [1]_1 \\ [r_3]_1E_3 & [r_4]_1E_4 \end{bmatrix} \times \det\begin{bmatrix} [1]_1 & [1]_1 \\ -E_3E_5[1]_1 & E_4E_6[1]_1 \end{bmatrix} \\ &= r_1^2 r_2^5 \lambda^9 \Delta_1(\lambda)\Delta_2(\lambda)\Delta_3(\lambda), \end{aligned}$$

where

$$\begin{cases} \Delta_1(\lambda) := r_6E_2 - r_5E_1 + \mathcal{O}(\lambda^{-1}), \\ \Delta_2(\lambda) := r_4E_4 - r_3E_3 + \mathcal{O}(\lambda^{-1}), \\ \Delta_2(\lambda) := E_4E_6 + E_3E_5 + \mathcal{O}(\lambda^{-1}) \end{cases} \tag{3.23}$$

with r_i $(i = 3,4,5,6)$ being given in (3.21) and E_i $(i = 1,2,\dots,6)$ in (3.22), respectively. With all these preparations, we come to the proof of the asymptotic behavior of the eigenvalues.

THEOREM 3.3. *Let $r_1 \neq r_2$ and let $\Delta(\lambda)$ be the characteristic determinant of system (2.26). Then the following asymptotic expansion for $\Delta(\lambda)$ holds:*

$$\Delta(\lambda) = r_1^2 r_2^5 \lambda^9 \Delta_1(\lambda)\Delta_2(\lambda)\Delta_3(\lambda) \tag{3.24}$$

with $\Delta_i(\lambda)$ being given in (3.23). If $k_i \neq r_i$ $(i = 1, 2)$, then there are three branches of asymptotic eigenvalues given by (as $|n| \to \infty$ and $n \in \mathbb{Z}$)

$$\begin{cases} \lambda_{jn} = \mu_j + r_j^{-1} n\pi i + \mathcal{O}(n^{-1}) & \text{for } j = 1, 2, \\ \lambda_{3n} = \mu_3 + r_2^{-1}(n + \frac{1}{2})\pi i + \mathcal{O}(n^{-1}), \end{cases} \tag{3.25}$$

where

$$\mu_j := \begin{cases} \frac{1}{2r_j} \ln \frac{k_j - r_j}{k_j + r_j}, & k_j > r_j \\ \frac{1}{2r_j} \left(\ln \frac{r_j - k_j}{k_j + r_j} + \pi i \right), & k_j < r_j \end{cases} \qquad \text{for } j = 1, 2 \tag{3.26}$$

and

$$\mu_3 := -\frac{2}{3}\beta. \tag{3.27}$$

Moreover, we have, as $|n| \to \infty$,

$$\mathrm{Re}\lambda_{jn} \to \frac{1}{2r_j} \ln \left| \frac{k_j - r_j}{k_j + r_j} \right| < 0 \ \text{ for } j = 1, 2 \quad \text{and} \quad \mathrm{Re}\lambda_{3n} \to \mu_3 < 0. \tag{3.28}$$

Furthermore, if k_1 and k_2 satisfy the conditions

$$k_1 \neq \begin{cases} \dfrac{\alpha_1 + 1}{1 - \alpha_1} r_1 & \text{for } k_1 > r_1, \\ \dfrac{1 - \alpha_1}{\alpha_1 + 1} r_1 & \text{for } k_1 < r_1, \end{cases} \qquad \alpha_1 := \left| \frac{k_2 - r_2}{k_2 + r_2} \right|^{r_1/r_2}, \quad 0 < \alpha_1 < 1, \tag{3.29}$$

and

$$k_1 \neq \begin{cases} \dfrac{\alpha_2 + 1}{1 - \alpha_2} r_1 & \text{for } k_1 > r_1, \\ \dfrac{1 - \alpha_2}{\alpha_2 + 1} r_1 & \text{for } k_1 < r_1, \end{cases} \qquad \alpha_2 := e^{-\frac{4}{3}\beta r_1}, \quad 0 < \alpha_2 < 1, \tag{3.30}$$

then the zeros of $\Delta(\lambda)$ are simple when their moduli are sufficiently large.

Proof. By $\Delta(\lambda) = 0$ and (3.24), it follows that

$$\Delta_1(\lambda)\Delta_2(\lambda)\Delta_3(\lambda) = 0 \tag{3.31}$$

and

$$\Delta_i(\lambda) = 0 \quad \text{for } i = 1, 2, 3.$$

Let $\Delta_1(\lambda) = 0$. Then we obtain

$$r_6 E_2 - r_5 E_1 + \mathcal{O}(\lambda^{-1}) = 0, \tag{3.32}$$

which is equivalent to (from (3.21) and (3.23))

$$(k_1 - r_1)e^{-r_1\lambda} - (k_1 + r_1)e^{r_1\lambda} + \mathcal{O}(\lambda^{-1}) = 0. \tag{3.33}$$

Since the solutions of the equation

$$(k_1 - r_1)e^{-r_1\lambda} - (k_1 + r_1)e^{r_1\lambda} = 0$$

are given by

$$\tilde{\lambda}_{1n} = \mu_1 + r_1^{-1} n\pi i, \quad n \in \mathbb{Z},$$

it follows from Rouché's theorem that the solutions to (3.33) are in the form

$$\lambda_{1n} = \tilde{\lambda}_{1n} + \mathcal{O}(n^{-1}) = \mu_1 + r_1^{-1} n\pi i + \mathcal{O}(n^{-1}), \quad n \in \mathbb{Z} \text{ and } |n| \to \infty. \tag{3.34}$$

Similarly, let $\Delta_2(\lambda) = 0$. Then the equation

$$(k_2 - r_2)e^{-r_2\lambda} - (k_2 + r_2)e^{r_2\lambda} + \mathcal{O}(\lambda^{-1}) = 0 \tag{3.35}$$

has the solutions

$$\lambda_{2n} = \mu_2 + r_2^{-1} n\pi i + \mathcal{O}(n^{-1}), \quad n \in \mathbb{Z} \text{ and } |n| \to \infty. \tag{3.36}$$

Also, let $\Delta_3(\lambda) = 0$. The equation

$$e_2(1)e^{-r_2\lambda} + e_1(1)e^{r_2\lambda} + \mathcal{O}(\lambda^{-1}) = 0 \tag{3.37}$$

has the solutions

$$\lambda_{3n} = \mu_3 + r_2^{-1}\Big(n + \frac{1}{2}\Big)\pi i + \mathcal{O}(n^{-1}), \quad n \in \mathbb{Z} \text{ and } |n| \to \infty. \tag{3.38}$$

Finally, by a direct computation, it follows from (3.29) and (3.30) that k_1 and k_2 satisfy the following conditions:

$$\frac{1}{r_1}\ln\left|\frac{k_1 - r_1}{k_1 + r_1}\right| \neq \frac{1}{r_2}\ln\left|\frac{k_2 - r_2}{k_2 + r_2}\right|, \quad \frac{1}{2r_1}\ln\left|\frac{k_1 - r_1}{k_1 + r_1}\right| \neq -\frac{2}{3}\beta.$$

Thus $\mu_1 \neq \mu_2$ and $\mu_1 \neq \mu_3$. The last assertion is then concluded. The proof is complete. □

THEOREM 3.4. *Suppose $r_1 \neq r_2$ and $k_i \neq r_i$ $(i = 1, 2)$. Let $\mathcal{A}$ be defined by* (2.4) *and* (2.5). *Then all eigenvalues of $\mathcal{A}$ have the asymptotic expressions given by* (3.25). *Moreover, if k_1 and k_2 satisfy conditions* (3.29) *and* (3.30), *then all eigenvalues of the system with sufficiently large moduli are simple.*

4. Asymptotic behavior of eigenfunctions. In this section, we shall consider the asymptotic behavior for eigenfunctions of $\mathcal{A}$. It will be used in the proof of the Riesz basis in the last section.

THEOREM 4.1. *Suppose $r_1 \neq r_2$ and $k_i \neq r_i$ $(i = 1, 2)$. Let $\sigma(\mathcal{A}) := \{\lambda_{1n}, \lambda_{2n}, \lambda_{3n}, n \in \mathbb{Z}\}$ be the eigenvalues of $\mathcal{A}$ with λ_{jn} $(j = 1, 2, 3)$ being given in* (3.25). *Then the corresponding eigenfunctions*

$$\Big\{[w_{jn}, \lambda_{jn}w_{jn}, \xi_{jn}, \lambda_{jn}\xi_{jn}, s_{jn}, \lambda_{jn}s_{jn}]^\top, \quad j = 1, 2, 3,\ n \in \mathbb{Z}\Big\}$$

have the following asymptotic expressions for $|n| \to \infty,\ n \in \mathbb{Z}$*:*

(4.1)
$$\begin{cases} w'_{1n}(x) = \frac{1}{2}(e^{-r_1\lambda_{1n}x} + e^{r_1\lambda_{1n}x}) + \mathcal{O}(n^{-1}), \quad w'_{jn}(x) = \mathcal{O}(n^{-1}) \ \text{for}\ j = 2,3, \\ \lambda_{1n}w_{1n}(x) = \frac{1}{2}r_1^{-1}(e^{r_1\lambda_{1n}x} - e^{-r_1\lambda_{1n}x}) + \mathcal{O}(n^{-1}), \ \lambda_{jn}w_{jn}(x) = \mathcal{O}(n^{-1}) \ \text{for}\ j = 2,3, \\ \xi'_{2n}(x) = \frac{1}{2}(e^{-r_2\lambda_{2n}x} + e^{r_2\lambda_{2n}x}) + \mathcal{O}(n^{-1}), \quad \xi'_{jn}(x) = \mathcal{O}(n^{-1}) \ \text{for}\ j = 1,3, \\ \lambda_{2n}\xi_{2n}(x) = \frac{1}{2}r_2^{-1}(e^{r_2\lambda_{2n}x} - e^{-r_2\lambda_{2n}x}) + \mathcal{O}(n^{-1}), \quad \lambda_{jn}\xi_{jn}(x) = \mathcal{O}(n^{-1}) \ \text{for}\ j = 1,3, \\ s'_{3n}(x) = \frac{1}{2}(e_2(x)e^{-r_2\lambda_{3n}x} + e_1(x)e^{r_2\lambda_{3n}x}) + \mathcal{O}(n^{-1}), \ s'_{jn}(x) = \mathcal{O}(n^{-1}) \ \text{for}\ j = 1,2, \\ \lambda_{3n}s_{3n}(x) = \frac{1}{2}r_2^{-1}(e_1(x)e^{r_2\lambda_{3n}x} - e_2(x)e^{-r_2\lambda_{3n}x}) + \mathcal{O}(n^{-1}), \\ \lambda_{jn}s_{jn}(x) = \mathcal{O}(n^{-1}) \quad \text{for}\ j = 1,2, \end{cases}$$

where r_1, r_2 *are given in* (2.22) *and* $e_1(x), e_2(x)$ *are given in* (3.14)*, respectively. Moreover,* $\{[w_{jn}, \lambda_{jn}w_{jn}, \xi_{jn}, \lambda_{jn}\xi_{jn}, s_{jn}, \lambda_{jn}s_{jn}]^\top (j = 1,2,3,\ n \in \mathbb{Z})\}$ *are approximately normalized in* $\mathcal{H}$ *in the sense that there exist positive constants* c_1 *and* c_2 *independent of* n *such that* $(j = 1,2,3)$

$$c_1 \le \|w'_{jn}\|_{L^2}, \|\lambda_{jn}w_{jn}\|_{L^2}, \|\xi'_{jn}\|_{L^2}, \|\lambda_{jn}\xi_{jn}\|_{L^2}, \|s'_{jn}\|_{L^2}, \|\lambda_{jn}s_{jn}\|_{L^2} \le c_2 \tag{4.2}$$

for all integers n*.*

Proof. Note that the jth component of $\Phi(x) = [w_1(x), w_2(x), \xi_1(x), \xi_2(x), s_1(x), s_2(x)]^\top$ in (2.25) with respect to the eigenvalue λ can be obtained by taking the determinant of the matrices which are replaced one of the rows of $T^R\widehat{\Phi}$ in (3.20) by $e_j^\top(\widehat{\Phi}(x,\lambda))$ so that their determinants are not zero, where e_j is the jth column of the identity matrix. Indeed, we have from (3.18) that $\widehat{\Phi}(x,\lambda) = P(\lambda)\widehat{\Psi}(x,\lambda)$ and hence

$$\widehat{\Phi}(x,\lambda) = \begin{bmatrix} \widehat{\Phi}_{11}(x,\lambda) & O_{2\times 2} & O_{2\times 2} \\ O_{2\times 2} & \widehat{\Phi}_{22}(x,\lambda) & O_{2\times 2} \\ O_{2\times 2} & O_{2\times 2} & \widehat{\Phi}_{33}(x,\lambda) \end{bmatrix}, \tag{4.3}$$

where

$$\widehat{\Phi}_{ii}(x,\lambda) := \begin{bmatrix} r_i\lambda e^{r_i\lambda x}[1 + \mathcal{O}(\lambda^{-1})] & r_i\lambda e^{-r_i\lambda x}[1 + \mathcal{O}(\lambda^{-1})] \\ r_i^2\lambda^2 e^{r_i\lambda x}[1 + \mathcal{O}(\lambda^{-1})] & -r_i^2\lambda^2 e^{-r_i\lambda x}[1 + \mathcal{O}(\lambda^{-1})] \end{bmatrix} \quad \text{for}\ \ i = 1,2 \tag{4.4}$$

and

$$\widehat{\Phi}_{33}(x,\lambda) := \begin{bmatrix} r_2\lambda e^{r_2\lambda x}e_1(x)[1 + \mathcal{O}(\lambda^{-1})] & r_2\lambda e^{-r_2\lambda x}e_2(x)[1 + \mathcal{O}(\lambda^{-1})] \\ r_2^2\lambda^2 e^{r_2\lambda x}e_1(x)[1 + \mathcal{O}(\lambda^{-1})] & -r_2^2\lambda^2 e^{-r_2\lambda x}e_2(x)[1 + \mathcal{O}(\lambda^{-1})] \end{bmatrix} \tag{4.5}$$

with $e_i(x)$ $(i = 1,2)$ being given in (3.14).

Thus, the first component of $\Phi(x)$ is given by

$$\begin{aligned} w_1(x,\lambda) &= r_1^{-2} r_2^{-5} \lambda^{-8} \det \begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 \\ \lambda e^{r_1\lambda x}[r_1]_1 & \lambda e^{-r_1\lambda x}[r_1]_1 \end{bmatrix} \\ &\quad \times \det \begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda^2 E_3[r_2 r_3]_1 & \lambda^2 E_4[r_2 r_4]_1 \end{bmatrix} \times \det \begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ -\lambda^2 E_3 E_5[r_2^2]_1 & \lambda^2 E_4 E_6[r_2^2]_1 \end{bmatrix} \\ &= \left(e^{-r_1\lambda x} - e^{r_1\lambda x} + \mathcal{O}(\lambda^{-1})\right) \left(r_4 e^{-r_2\lambda} - r_3 e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \\ &\quad \times \left(e_2(1) e^{-r_2\lambda} + e_1(1) e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right). \end{aligned}$$

By (3.23), (3.25), and (3.31), we conclude that

$$w_1(x,\lambda) = \begin{cases} r_7(\lambda)\left(e^{-r_1\lambda x} - e^{r_1\lambda x} + \mathcal{O}(\lambda^{-1})\right) & \text{if } \lambda = \lambda_{1n}, \\ \mathcal{O}(\lambda^{-1}) & \text{if } \lambda = \lambda_{2n} \text{ or } \lambda_{3n}, \end{cases} \tag{4.6}$$

where $r_7(\lambda)$ is bounded in λ and has the form

$$r_7(\lambda) := \left(r_4 e^{-r_2\lambda} - r_3 e^{r_2\lambda}\right)\left(e_2(1) e^{-r_2\lambda} + e_1(1) e^{r_2\lambda}\right). \tag{4.7}$$

Similarly, we have

$$\begin{aligned} w_2(x,\lambda) &= r_1^{-2} r_2^{-5} \lambda^{-8} \det \begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 \\ \lambda^2 e^{r_1\lambda x}[r_1^2]_1 & -\lambda^2 e^{-r_1\lambda x}[r_1^2]_1 \end{bmatrix} \\ &\quad \times \det \begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda^2 E_3[r_2 r_3]_1 & \lambda^2 E_4[r_2 r_4]_1 \end{bmatrix} \times \det \begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ -\lambda^2 E_3 E_5[r_2^2]_1 & \lambda^2 E_4 E_6[r_2^2]_1 \end{bmatrix} \\ &= -r_1\lambda \left(e^{-r_1\lambda x} + e^{r_1\lambda x} + \mathcal{O}(\lambda^{-1})\right) \left(r_4 e^{-r_2\lambda} - r_3 e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \\ &\quad \times \left(e_2(1) e^{-r_2\lambda} + e_1(1) e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \end{aligned}$$

and

$$w_2(x,\lambda) = \begin{cases} -\lambda r_1 r_7(\lambda)\left(e^{-r_1\lambda x} + e^{r_1\lambda x} + \mathcal{O}(\lambda^{-1})\right) & \text{if } \lambda = \lambda_{1n}, \\ r_1\lambda[\mathcal{O}(\lambda^{-1})] & \text{if } \lambda = \lambda_{2n} \text{ or } \lambda_{3n}. \end{cases} \tag{4.8}$$

Also, along the same line,

$$\begin{aligned} w_3(x,\lambda) &= r_1^{-2} r_2^{-5} \lambda^{-8} \det \begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 \\ \lambda^2 E_1[r_1 r_5]_1 & \lambda^2 E_2[r_1 r_6]_1 \end{bmatrix} \\ &\quad \times \det \begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda e^{r_2\lambda x}[r_2]_1 & \lambda e^{-r_2\lambda x}[r_2]_1 \end{bmatrix} \times \det \begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ -\lambda^2 E_3 E_5[r_2^2]_1 & \lambda^2 E_4 E_6[r_2^2]_1 \end{bmatrix} \\ &= \left(r_6 e^{-r_1\lambda} - r_5 e^{r_1\lambda} + \mathcal{O}(\lambda^{-1})\right) \left(e^{-r_2\lambda x} - e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right) \\ &\quad \times \left(e_2(1) e^{-r_2\lambda} + e_1(1) e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \end{aligned}$$

and from (3.23), (3.25), and (3.31), we obtain that

$$w_3(x,\lambda) = \begin{cases} r_8(\lambda)\left(e^{-r_2\lambda x} - e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right) & \text{if } \lambda = \lambda_{2n}, \\ \mathcal{O}(\lambda^{-1}) & \text{if } \lambda = \lambda_{1n} \text{ or } \lambda_{3n} \end{cases} \tag{4.9}$$

with

$$r_8(\lambda) := \left(r_6 e^{-r_1\lambda} - r_5 e^{r_1\lambda}\right)\left(e_2(1)e^{-r_2\lambda} + e_1(1)e^{r_2\lambda}\right). \tag{4.10}$$

Furthermore,

$$\begin{aligned} w_4(x,\lambda) &= r_1^{-2} r_2^{-5}\lambda^{-8} \det\begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 \\ \lambda^2 E_1[r_1 r_5]_1 & \lambda^2 E_2[r_1 r_6]_1 \end{bmatrix} \\ &\quad \times \det\begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda^2 e^{r_2\lambda x}[r_2^2]_1 & -\lambda^2 e^{-r_2\lambda x}[r_2^2]_1 \end{bmatrix} \times \det\begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ -\lambda^2 E_3 E_5[r_2^2]_1 & \lambda^2 E_4 E_6[r_2^2]_1 \end{bmatrix} \\ &= -r_2\lambda\left(r_6 e^{-r_1\lambda} - r_5 e^{r_1\lambda} + \mathcal{O}(\lambda^{-1})\right)\left(e^{-r_2\lambda x} + e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right) \\ &\quad \times \left(e_2(1)e^{-r_2\lambda} + e_1(1)e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \end{aligned}$$

and

$$w_4(x,\lambda) = \begin{cases} -\lambda r_2 r_8(\lambda)\left(e^{-r_2\lambda x} + e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right) & \text{if } \lambda = \lambda_{2n}, \\ r_2\lambda[\mathcal{O}(\lambda^{-1})] & \text{if } \lambda = \lambda_{1n} \text{ or } \lambda_{3n}. \end{cases} \tag{4.11}$$

Also, the fifth component of $\Phi(x)$ can be given by

$$\begin{aligned} w_5(x,\lambda) &= -r_1^{-2} r_2^{-4}\lambda^{-8} \det\begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 \\ \lambda^2 E_1[r_1 r_5]_1 & \lambda^2 E_2[r_1 r_6]_1 \end{bmatrix} \\ &\quad \times \det\begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda^2 E_3[r_2 r_3]_1 & \lambda^2 E_4[r_2 r_4]_1 \end{bmatrix} \times \det\begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda e^{r_2\lambda x} e_1(x)[r_2]_1 & \lambda e^{-r_2\lambda x} e_2(x)[r_2]_1 \end{bmatrix} \\ &= -\left(r_6 e^{-r_1\lambda} - r_5 e^{r_1\lambda} + \mathcal{O}(\lambda^{-1})\right)\left(r_4 e^{-r_2\lambda} - r_3 e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \\ &\quad \times \left(e_2(x)e^{-r_2\lambda x} - e_1(x)e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right), \end{aligned}$$

and we conclude from (3.23), (3.25), and (3.31) that

$$w_5(x,\lambda) = \begin{cases} r_9(\lambda)\left(e_2(x)e^{-r_2\lambda x} - e_1(x)e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right) & \text{if } \lambda = \lambda_{3n}, \\ \mathcal{O}(\lambda^{-1}) & \text{if } \lambda = \lambda_{1n} \text{ or } \lambda_{2n} \end{cases} \tag{4.12}$$

with

$$r_9(\lambda) := -\left(r_6 e^{-r_1\lambda} - r_5 e^{r_1\lambda} + \mathcal{O}(\lambda^{-1})\right)\left(r_4 e^{-r_2\lambda} - r_3 e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right). \tag{4.13}$$

For the last component of $\Phi(x)$, one has

$$\begin{aligned} w_6(x,\lambda) &= r_1^{-2} r_2^{-4}\lambda^{-8} \det\begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ -\lambda^2 e^{r_2\lambda x} e_1(x)[r_2^2]_1 & \lambda^2 e^{-r_2\lambda x} e_2(x)[r_2^2]_1 \end{bmatrix} \\ &\quad \times \det\begin{bmatrix} \lambda[r_2]_1 & \lambda[r_2]_1 \\ \lambda^2 E_3[r_2 r_3]_1 & \lambda^2 E_4[r_2 r_4]_1 \end{bmatrix} \times \det\begin{bmatrix} \lambda[r_1]_1 & \lambda[r_1]_1 \\ \lambda^2 E_1[r_1 r_5]_1 & \lambda^2 E_2[r_1 r_6]_1 \end{bmatrix} \\ &= r_2\lambda\left(r_6 e^{-r_1\lambda} - r_5 e^{r_1\lambda} + \mathcal{O}(\lambda^{-1})\right)\left(r_4 e^{-r_2\lambda} - r_3 e^{r_2\lambda} + \mathcal{O}(\lambda^{-1})\right) \\ &\quad \times \left(e_2(x)e^{-r_2\lambda x} + e_1(x)e^{r_2\lambda x} + \mathcal{O}(\lambda^{-1})\right) \end{aligned}$$

and

(4.14)
$$w_6(x,\lambda)=\begin{cases}-\lambda r_2 r_9(\lambda)\left(e_2(x)e^{-r_2\lambda x}+e_1(x)e^{r_2\lambda x}+\mathcal{O}(\lambda^{-1})\right) & \text{if } \lambda=\lambda_{3n},\\ r_2\lambda[\mathcal{O}(\lambda^{-1})] & \text{if } \lambda=\lambda_{1n} \text{ or } \lambda_{2n}.\end{cases}$$

On the basis of above computations, (4.1) can then be deduced from (4.6)–(4.14) by setting

$$w_n(x)=-\frac{w_1(x,\lambda)}{2r_1\lambda r_7(\lambda)},\quad \xi_n(x)=-\frac{w_3(x,\lambda)}{2r_2\lambda r_8(\lambda)},\quad s_n(x)=-\frac{w_5(x,\lambda)}{2r_2\lambda r_9(\lambda)} \tag{4.15}$$

in (4.6)–(4.14), respectively. Finally, it follows from (3.25) that

$$\begin{cases}\|e^{-r_j\lambda_{jn}x}\|_{L^2}=\dfrac{1-e^{-2r_j\mu_j}}{2r_j\mu_j}+\mathcal{O}(n^{-1}) \quad \text{for } j=1,2,\\ \|e^{r_j\lambda_{jn}x}\|_{L^2}=\dfrac{e^{2r_j\mu_j}-1}{2r_j\mu_j}+\mathcal{O}(n^{-1}) \quad \text{for } j=1,2,\\ \|e^{-r_2\lambda_{3n}x}\|_{L^2}=\dfrac{1-e^{-2r_2\mu_3}}{2r_2\mu_3}+\mathcal{O}(n^{-1}),\\ \|e^{r_2\lambda_{3n}x}\|_{L^2}=\dfrac{e^{2r_2\mu_3}-1}{2r_2\mu_3}+\mathcal{O}(n^{-1}),\end{cases} \tag{4.16}$$

where μ_j $(j=1,2,3)$ are given in (3.26) and (3.27). These together with (4.1) yield (4.2). The proof is complete. □

5. The Riesz basis property and exponential stability of the system. In the previous sections, we have obtained the asymptotic expressions of eigenpairs of $\mathcal{A}$ and concluded that there are three asymptotes for the spectrum $\sigma(\mathcal{A})$ with their asymptotic expressions in (3.25). In this section, we shall prove that there exists a sequence of generalized eigenfunctions of $\mathcal{A}$ which forms a Riesz basis for $\mathcal{H}$. Furthermore, the exponential stability of the system can be determined by its spectrum distribution.

For these purposes, we introduce another equivalent inner product on $\mathcal{H}$. Let $Y_j:=[w_j,z_j,\xi_j,\varphi_j,s_j,h_j]^\top\in\mathcal{H}$ $(j=1,2)$ define a new inner product in $\mathcal{H}$ by

(5.1)
$$[Y_1,\ Y_2]_H:=\langle w_1',w_2'\rangle_{L^2}+\langle z_1,z_2\rangle_{L^2}+\langle\xi_1',\xi_2'\rangle_{L^2}+\langle\varphi_1,\varphi_2\rangle_{L^2}+\langle s_1',s_2'\rangle_{L^2}+\langle h_1,h_2\rangle_{L^2},$$

and write its induced norm of (5.1) by $\|\cdot\|_H$. One can easily check that $\mathcal{H}$ is a Hilbert space under this new inner product. From now on, we shall consider our problem in $\mathcal{H}$ associated with this new inner product of (5.1). For convenience, define another Hilbert space

$$\mathcal{L}:=\left(L^2(0,1)\right)^6 \tag{5.2}$$

with an inner product (for any $X_j:=[w_j,z_j,\xi_j,\varphi_j,s_j,h_j]^\top\in\mathcal{L},\ j=1,2$)

$$\langle X_1,\ X_2\rangle_{\mathcal{L}}:=\langle w_1,w_2\rangle_{L^2}+\langle z_1,z_2\rangle_{L^2}+\langle\xi_1,\xi_2\rangle_{L^2}+\langle\varphi_1,\varphi_2\rangle_{L^2}+\langle s_1,s_2\rangle_{L^2}+\langle h_1,h_2\rangle_{L^2}$$

and define the subspaces of $\mathcal{H}$ and $\mathcal{L}$, respectively, by

(5.3)
$$\begin{cases} \mathcal{H}_1 := \{Y \in \mathcal{H} \mid Y = [w, z, 0, 0, 0, 0]^\top\}, \\ \mathcal{H}_2 := \{Y \in \mathcal{H} \mid Y = [0, 0, \xi, \varphi, 0, 0]^\top\}, \\ \mathcal{H}_3 := \{Y \in \mathcal{H} \mid Y = [0, 0, 0, 0, s, h]^\top\}, \end{cases} \quad \begin{cases} \mathcal{L}_1 := \{X \in \mathcal{L} \mid X = [w, z, 0, 0, 0, 0]^\top\}, \\ \mathcal{L}_2 := \{X \in \mathcal{L} \mid X = [0, 0, \xi, \varphi, 0, 0]^\top\}, \\ \mathcal{L}_3 := \{X \in \mathcal{L} \mid X = [0, 0, 0, 0, s, h]^\top\}. \end{cases}$$

Obviously, we have

$$\mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2 \oplus \mathcal{H}_3 \quad \text{and} \quad \mathcal{L} = \mathcal{L}_1 \oplus \mathcal{L}_2 \oplus \mathcal{L}_3, \tag{5.4}$$

where the sign $\oplus$ denotes the direct sum in the sense of orthogonality with respect to the inner products $[\cdot, \cdot]_H$ and $\langle \cdot, \cdot \rangle_{\mathcal{L}}$ in $\mathcal{H}$ and $\mathcal{L}$, respectively.

Before continuing, let us recall some forms of notation. For a closed operator $\mathbf{A}$ in a Hilbert space $\mathbf{H}$, a nonzero element $\phi \in \mathbf{H}$ is called a generalized eigenvector of $\mathbf{A}$, corresponding to an eigenvalue λ of $\mathbf{A}$, if there is an integer $\nu \geq 1$ such that $(\lambda I - \mathbf{A})^\nu \phi = 0$. If $\nu = 1$, then ϕ is an eigenvector. A sequence $\{\phi_n\}_{n=1}^\infty$ in $\mathbf{H}$ is called a Riesz basis for $\mathbf{H}$ if there exists an orthonormal basis $\{e_n\}_{n=1}^\infty$ in $\mathbf{H}$ and a linear bounded invertible operator T such that

$$T\phi_n = e_n, \quad n = 1, 2, \dots .$$

Let $\{\lambda_n\}_{n=1}^\infty = \sigma(\mathbf{A})$ be the spectrum of $\mathbf{A}$. Suppose each λ_n has finite algebraic multiplicity m_n, and let $\{\psi_{n_i}\}_1^{m_n}$ be the set of generalized eigenvectors of $\mathbf{A}$ corresponding to λ_n. If $\{\psi_{n_i} \mid 1 \leq i \leq m_n,\ n = 1, 2, \dots\}$ form a Riesz basis for $\mathbf{H}$, then the C_0-semigroup generated by $\mathbf{A}$ can be represented as

$$e^{\mathbf{A}t} x = \sum_{n=1}^{\infty} e^{\lambda_n t} \sum_{j=1}^{m_n} a_{nj} f_{nj}(t) \psi_{nj} \quad \forall\, x = \sum_{n=1}^{\infty} \sum_{j=1}^{m_n} a_{nj} \psi_{nj} \in \mathbf{H}, \tag{5.5}$$

where $f_{nj}(t)$ are the polynomials of t with order not greater than m_n. In particular, if m_n has a uniform upper bound and $\{\psi_{n_i}\}_1^{m_n}$ is the eigenvector (not generalized eigenvector) set of $\mathcal{A}$ with respect to λ_n for all sufficiently large n, then the spectrum determined growth condition holds, i.e., $\omega(\mathbf{A}) = s(\mathbf{A})$, where $\omega(\mathbf{A})$ is the growth bound of $e^{\mathbf{A}t}$, and $s(\mathbf{A})$ is the spectral bound of $\mathbf{A}$ (see [2]).

To establish the Riesz basis property for the root space of the operator $\mathcal{A}$, we recall a result of Bari's theorem in [11].

THEOREM 5.1. *Let $\mathbf{H}$ be a separable Hilbert space and let $\{e_n;\ n \in \mathbb{Z}\}$ be an orthonormal basis for $\mathbf{H}$. If $\{f_n;\ n \in \mathbb{Z}\}$ is an ω-independent sequence that is quadratically close to $\{e_n;\ n \in \mathbb{Z}\}$, then $\{f_n;\ n \in \mathbb{Z}\}$ is a Riesz basis for $\mathbf{H}$.*

LEMMA 5.2. *Let $\{\phi_n(x);\ n \in \mathbb{N}\}$ and $\{1, \psi_n(x);\ n \in \mathbb{N}\}$ be two subsets in $L^2(0,1)$ defined by, respectively,*

$$\phi_n(x) := \sin n\pi x \quad \text{and} \quad \psi_n(x) := \cos n\pi x \quad \forall\, x \in (0,1),\ n \in \mathbb{N}.$$

Then $\{\phi_n(x);\ n \in \mathbb{N}\}$ and $\{1, \psi_n(x);\ n \in \mathbb{N}\}$ are two orthogonal bases in $L^2(0,1)$. Moreover, for any scalars $\alpha, \beta \neq 0 \in \mathbb{C}$ the vector family $\{\Psi_n := [\cosh(\alpha + in\pi)x, \beta \sinh(\alpha + in\pi)x]^\top, n \in \mathbb{Z}\}$ forms a Riesz basis on the Hilbert space $L^2(0,1) \times L^2(0,1)$.

Proof. The first assertion is a direct result in [11] and it is easily verified that

$$\left\{ \begin{bmatrix} 0 \\ \sin n\pi x \end{bmatrix}, \quad \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad \begin{bmatrix} \cos n\pi x \\ 0 \end{bmatrix} \right\}_{n \in \mathbb{N}}$$

constitutes a Riesz basis on $L^2(0,1)\times L^2(0,1)$. So the sequence

$$\left\{\begin{bmatrix}\cos n\pi x\\ \sin n\pi x\end{bmatrix},\quad \begin{bmatrix}1\\0\end{bmatrix},\quad \begin{bmatrix}\cos n\pi x\\ -\sin n\pi\end{bmatrix}\right\}_{n\in\mathbb{N}}$$

also forms a Riesz basis on $L^2(0,1)\times L^2(0,1)$. Let T be an invertible matrix function in $(0,1)$ given by

$$T:=\begin{bmatrix}\cosh\alpha x & i\sinh\alpha x\\ \beta\sinh\alpha x & i\beta\cosh\alpha x\end{bmatrix}\quad \text{with } |T|=i\beta \text{ for each } x\in(0,1).$$

Then we obtain, for $n\in\mathbb{N}$,

$$\begin{bmatrix}\cosh(\alpha+in\pi)x\\ \beta\sinh(\alpha+in\pi)x\end{bmatrix}=T\begin{bmatrix}\cos n\pi x\\ \sin n\pi x\end{bmatrix},\quad \begin{bmatrix}\cosh(\alpha-in\pi)x\\ \beta\sinh(\alpha-in\pi)x\end{bmatrix}=T\begin{bmatrix}\cos n\pi x\\ -\sin n\pi x\end{bmatrix},$$

and

$$\begin{bmatrix}\cosh\alpha x\\ \beta\sinh\alpha x\end{bmatrix}=T\begin{bmatrix}1\\0\end{bmatrix}.$$

Thus, the sequence $\{\Psi_n:=[\cosh(\alpha+in\pi)x,\ \beta\sinh(\alpha+in\pi)x]^\top, n\in\mathbb{Z}\}$ also forms a Riesz basis on the Hilbert space $L^2(0,1)\times L^2(0,1)$. The second assertion is concluded. □

THEOREM 5.3. *Suppose $r_1\neq r_2$ and $k_i\neq r_i$ $(i=1,2)$. Let $\mathcal{A}$ be defined by* (2.4) *and* (2.5)*, and let*

$$\Psi_{jn}:=[w'_{jn},\ \lambda_{jn}w_{jn},\ \xi'_{jn},\ \lambda_{jn}\xi_{jn},\ s'_{jn},\ \lambda_{jn}s_{jn}]^\top,\quad (j=1,2,3,\ n\in\mathbb{Z}), \tag{5.6}$$

where the entries are given as (4.1) *corresponding to the eigenvalues λ_{jn}. Then $\{\Psi_{1n},\Psi_{2n},\Psi_{3n};\ n\in\mathbb{Z}\}$ forms a Riesz basis in Hilbert space $\mathcal{L}$ provided that $\{\Psi_{jn},\ j=1,2,3,\ n\in\mathbb{Z}\}$ is ω-linearly independent in $\mathcal{L}$.*

Proof. Let three vector families be given by

$$\begin{aligned}
\Phi_{1n}&:=\big[\cosh(r_1\mu_1+in\pi)x,\ r_1^{-1}\sinh(r_1\mu_1+in\pi)x,0,0,0,0\big]^\top,\\
\Phi_{2n}&:=\big[0,0,\cosh(r_2\mu_2+in\pi)x,\ r_2^{-1}\sinh(r_2\mu_2+in\pi)x,0,0\big]^\top,\\
\Phi_{3n}&:=\Big[0,0,0,0,\cosh i\Big(n+\frac{1}{2}\Big)\pi x,\ r_3^{-1}\sinh i\Big(n+\frac{1}{2}\Big)\pi x\Big]^\top.
\end{aligned}$$

Then one concludes from Lemma 5.2 that the families $\{\Phi_{jn},\ n\in\mathbb{Z}\}$ $(j=1,2,3)$ are the Riesz bases for $\mathcal{L}_j$, respectively. Also, by using the asymptotic expressions of both eigenvalues (3.25) and their eigenfunctions (4.1), it follows that

$$\begin{cases}
\|w'_{1n}-\cosh(r_1\mu_1+in\pi)x\|_{L^2}=\mathcal{O}(n^{-1}),\\
\|r_1\lambda_{1n}w_{1n}-\sinh(r_1\mu_1+in\pi)x\|_{L^2}=\mathcal{O}(n^{-1}),\\
\|\xi'_{2n}-\cosh(r_2\mu_2+in\pi)x\|_{L^2}=\mathcal{O}(n^{-1}),\\
\|r_2\lambda_{2n}\xi_{1n}-\sinh(r_2\mu_2+in\pi)x\|_{L^2}=\mathcal{O}(n^{-1}),\\
\|s'_{3n}-\cosh i(n+\frac{1}{2})\pi x\|_{L^2}=\mathcal{O}(n^{-1}),\\
\|r_3\lambda_{3n}s_{3n}-\sinh i(n+\frac{1}{2})\pi x\|_{L^2}=\mathcal{O}(n^{-1}).
\end{cases} \tag{5.7}$$

Hence, we obtain

$$\begin{aligned} &\|\Psi_{1n} - \Phi_{1n}\|_{\mathcal{L}_1} = \mathcal{O}(n^{-1}),\\ &\|\Psi_{2n} - \Phi_{2n}\|_{\mathcal{L}_2} = \mathcal{O}(n^{-1}),\\ &\|\Psi_{3n} - \Phi_{3n}\|_{\mathcal{L}_3} = \mathcal{O}(n^{-1}). \end{aligned} \tag{5.8}$$

Therefore, by Theorem 5.1 (Bari's theorem), $\{\Psi_{1n}, \Psi_{2n}, \Psi_{3n}; n \in \mathbb{Z}\}$ forms a Riesz basis for $\mathcal{L}$ provided that $\{\Psi_{jn};\ j = 1, 2, 3, n \in \mathbb{Z}\}$ is ω-linearly independent in $\mathcal{L}$. □

As a consequence of this theorem, we obtain the main results of the paper.

THEOREM 5.4. *Suppose $r_1 \neq r_2$ and $k_i \neq r_i$ $(i = 1, 2)$. Let $\mathcal{A}$ be defined by* (2.4) *and* (2.5). *Then there exists a sequence of generalized eigenfunctions of $\mathcal{A}$ which forms a Riesz basis for $\mathcal{H}$.*

Proof. In Theorem 4.1, we have obtained the asymptotic expressions of the eigenfunctions of $\mathcal{A}$ corresponding to the eigenvalues with large moduli. Without loss of generality, we may assume that

$$Y_{jn} := [w_{jn}, \lambda_{jn} w_{jn}, \xi_{jn}, \lambda_{jn}\xi_{jn}, s_{jn}, \lambda_{jn} s_{jn}]^\top \quad \text{for } j = 1, 2, 3 \text{ and } n \in \mathbb{Z}$$

is an eigenfunction corresponding to the eigenvalue λ_{jn} in which the entries have the asymptotic expansions given in (4.1). Then $\{Y_{jn};\ j = 1, 2, 3, n \in \mathbb{Z}\}$ is ω-linearly independent in $\mathcal{H}$. The proof will be completed via an isomorphic mapping between two Hilbert spaces $\mathcal{H}$ and $\mathcal{L}$ that maps Y_{jn} to Ψ_{jn}, where $\{\Psi_{jn};\ j = 1, 2, 3, n \in \mathbb{Z}\}$ is a sequence given by (5.6).

To do this, for any $F := [f_1, f_2, g_1, g_2, u_1, u_2]^\top \in \mathcal{H}$, we define a linear bounded operator $\mathcal{T} : \mathcal{H} \to \mathcal{L}$ by

$$\mathcal{T}F := [f_1', f_2, g_1', g_2, u_1', u_2]^\top := \widehat{F}.$$

Since $[F,\ Y_{jn}]_H = \langle \widehat{F},\ \Psi_{jn} \rangle_{\mathcal{L}}$, it is easy to prove that $\mathcal{T}$ is isomorphic and satisfies

$$\|\mathcal{T}F\|_{\mathcal{L}} = \|\widehat{F}\|_{\mathcal{L}} = \|F\|_H. \tag{5.9}$$

In particular, for $j = 1, 2, 3$ and $n \in \mathbb{Z}$,

$$\mathcal{T}Y_{jn} = \Psi_{jn} \quad \text{and} \quad \|Y_{jn}\|_H = \|\Psi_{jn}\|_{\mathcal{L}}.$$

Moreover, $\{Y_{jn};\ j = 1, 2, 3, n \in \mathbb{Z}\}$ is ω-linearly independent in $\mathcal{H}$, so is $\{\Psi_{jn};\ j = 1, 2, 3, n \in \mathbb{Z}\}$ in $\mathcal{L}$. Therefore, by Theorem 5.3, $\{\Psi_{jn};\ j = 1, 2, 3, n \in \mathbb{Z}\}$ forms a Riesz basis in $\mathcal{L}$. Hence, $\{Y_{jn}; j = 1, 2, 3,\ n \in \mathbb{Z}\}$ forms a Riesz basis for $\mathcal{H}$. The proof is complete. □

THEOREM 5.5. *Suppose $r_1 \neq r_2$ and $k_i \neq r_i$ $(i = 1, 2)$. Let $\mathcal{A}$ be defined by* (2.4) *and* (2.5), *and let $T(t)$ be a C_0-semigroup generated by $\mathcal{A}$ in $\mathcal{H}$. Then $T(t)$ is exponentially stable, and in fact it is a C_0-group in $\mathcal{H}$.*

Proof. As a direct consequence of Theorems 3.4 and 5.4, the spectrum determined growth condition $\omega(\mathbf{A}) = s(\mathbf{A})$ for $T(t)$ holds. Furthermore, Corollary 2.2 implies that there is no eigenvalue on the imaginary axis. This, together with (3.25) and the spectrum determined growth condition, shows that $T(t)$ is an exponentially stable semigroup on $\mathcal{H}$. Moreover, $T(t)$ is also a C_0-group in $\mathcal{H}$. This is because of the fact that the spectrum of $\mathcal{A}$ distributes in a vertical strip due to Theorems 3.3 and 3.4. □

Acknowledgment. The authors would like to thank the referees for their very valuable suggestions and comments.

THE REGULARITY OF THE WAVE EQUATION WITH PARTIAL DIRICHLET CONTROL AND COLOCATED OBSERVATION*

BAO-ZHU GUO† AND XU ZHANG‡

Abstract. In this paper we analyze a multidimensional controlled wave equation on a bounded domain, subject to partial Dirichlet control and colocated observation. By means of a partial Fourier transform, it is shown that the system is well-posed and regular in the sense of D. Salamon and G. Weiss. The corresponding feedthrough operator is found to be the identity operator on the input space.

Key words. wave equation, transfer function, well-posed and regular system, partial Dirichlet control and colocated observation, partial Fourier transform

1. Introduction.

A very general class of linear infinite-dimensional systems for which there is a well established theory parallel to that for finite-dimensional systems is the class of *well-posed and regular linear systems* (see [5]). This generic framework covers many systems governed by partial differential equations with actuators and sensors supported on isolated points, on a subdomain, or on a part of the boundary of the spatial region. There are many papers in this field (e.g., [7], [13], [14], [15], [16], [20], [21], [24], [25], [26], [27], [34], [35], [36], [38], and the references therein). Recently, the regular linear system theory has been generalized to the time-varying case in [22]. We refer to [5] for a nice earlier summary of well-posed system theory.

Well-posedness and regularity are two new crucial concepts introduced in linear infinite-dimensional systems theory under the above-mentioned framework. It is notable that these two concepts are completely different from those one usually uses in partial differential equations. For the reader's convenience, we shall recall their definitions and other related notions in section 2. As remarked in [4], very little is known about the well-posedness or the regularity of controlled infinite-dimensional systems. In [2], the well-posedness of the wave equation with Dirichlet input and colocated output in a two-dimensional (2-D) disk was proved by a direct method. The well-posedness of the same equation on a bounded open domain of $\mathbb{R}^n (n \geq 2)$ with a smooth boundary was proved in [1] using microlocal analysis. The well-posedness and regularity of the multidimensional heat equation with both Dirichlet- and Neumann-type boundary control has been established in [3]. To the best of our knowledge, [3] is the first article dealing with the regularity of a multidimensional partial differential equation system, although well-posedness and regularity have been well-established

for many one-dimensional systems (see [11]). The regularity of the wave equation in a 2-D disk with Dirichlet control and colocated observation was first obtained in [12]. However, the same problem for a general bounded domain in $\mathbb{R}^n$ has remained open.

The aim of this paper is to give a positive solution to the above-mentioned problem. More precisely, we consider the following multidimensional wave equation with partial Dirichlet control and colocated observation:

$$\begin{cases} w_{tt}(x,t) - \Delta w(x,t) = 0, & x \in \Omega,\ t > 0, \\ w(x,t) = 0, & x \in \Gamma_1,\ t > 0, \\ w(x,t) = u(x,t), & x \in \Gamma_0,\ t > 0, \\ y(x,t) = -\dfrac{\partial(-\Delta)^{-1} w_t(x,t)}{\partial \nu}, & x \in \Gamma_0,\ t > 0. \end{cases} \tag{1.1}$$

Here, $\Omega \subset \mathbb{R}^n$ $(n \geq 2)$ is a bounded domain with the smooth boundary $\partial\Omega = \overline{\Gamma_0} \cup \overline{\Gamma_1}$, both Γ_0 and Γ_1 are disjoint parts of the boundary relatively open in $\partial\Omega$ with $\mathrm{int}(\Gamma_0) \neq \emptyset$, and ν is the unit normal vector of Γ_0 pointing towards the exterior of Ω. In system (1.1), u is the *input function* (or *control*) and y is the *output function* (or *output*). Put $\mathcal{H} = L^2(\Omega) \times H^{-1}(\Omega)$ and $U = L^2(\Gamma_0)$. The following result comes from Proposition 2.2 of [1] and Theorem 4.2 of [19, p. 46] (see also [17]).

THEOREM 1.1. *Let $T > 0$, $(w_0, w_1) \in \mathcal{H}$, and $u \in L^2(0,T;U)$. Then there exists a unique solution $(w, w_t) \in C([0,T];\mathcal{H})$ to (1.1) satisfying $w(\cdot,0) = w_0$ and $w_t(\cdot,0) = w_1$. Moreover, there exists a constant $C > 0$, independent of (w_0, w_1, u), such that*

$$\|(w(\cdot,T), w_t(\cdot,T))\|_{\mathcal{H}}^2 + \|y\|_{L^2(0,T;U)}^2 \leq C \left[\|(w_0,w_1)\|_{\mathcal{H}}^2 + \|u\|_{L^2(0,T;U)}^2 \right].$$

Theorem 1.1 implies that the system described by (1.1) is well-posed with state space $\mathcal{H}$, input space U, and output space U (the precise definition of these concepts will be given in the next section). We mention that Proposition 2.2 of [1] says that there exists a $C^* > 0$ independent of u such that

$$\|y\|_{L^2(0,T;U)}^2 \leq C^* \|u\|_{L^2(0,T;U)}^2 \ \text{ when } (w_0,w_1) = 0.$$

However, as was indicated in [2] and [37], Theorem 1.1 can be derived from here with relative ease.

The main goal of this paper is to show that the system described by (1.1) is regular as well. Our result reads as follows.

THEOREM 1.2. *System (1.1) is regular. More precisely, if $w(\cdot,0) = w_t(\cdot,0) = 0$ and $u(x,t) \equiv u(x)$ is a step input with some $u \in U$, then the corresponding output y satisfies*

$$\lim_{\sigma \to 0} \int_{\Gamma_0} \left| \frac{1}{\sigma} \int_0^\sigma y(x,t)dt - u(x) \right|^2 dx = 0.$$

This result allows us to study dynamic stabilization, optimal control, or other problems for system (1.1) using a theory that is parallel in many ways to the finite-dimensional theory; see, e.g., [6]. Also, as we shall explain in section 2, Theorem 1.2 states that system (1.1) has feedthrough operator $\mathbb{D} = I$, where I is the identity operator on U.

This paper is organized as follows: In the next section, we introduce the background and the necessary preliminaries about well-posed and regular systems. The proof of Theorem 1.2 is given in section 3.

2. Preliminaries. In this section, we shall briefly recall some background about infinite-dimensional well-posed and regular systems (see [5], [27], [30], [31], [32], [33], [34]).

Let X, U, and Y be three Hilbert spaces. Denote by $\|\cdot\|$ the norm of X (induced by its inner product). In what follows, we choose X, U, and Y to be the state, input, and output spaces, respectively, of an infinite-dimensional linear system. This system is described by the equations

$$\begin{cases} \dot{x}(t) = \mathbb{A}x(t) + \mathbb{B}u(t), \quad x(0) = x_0 \in X, \\ y(t) = \mathbb{C}_e x(t) + \mathbb{D}_e u(t), \end{cases} \tag{2.1}$$

where the (usually unbounded) operator $\mathbb{A}$ generates a C_0-semigroup $\mathbb{T}(\cdot)$ on X, $\mathbb{B}$ is a control operator from U to X, $\mathbb{C}_e$ is an observation operator from X to Y, and $\mathbb{D}_e$ is a bounded operator from U to Y. In (2.1), $u(t) \in U$, $x(t) \in X$, and $y(t) \in Y$ are called the input, the state, and the output, respectively. The input function $u(\cdot)$ is assumed to be in the space $L^2_{loc}(0, \infty; U)$, but the representation (2.1) is valid only if $u \in H^1_{loc}(0, \infty; U)$ and $\mathbb{A}x(0) + \mathbb{B}u(0) \in X$ (see [28] for details). For the case that both $\mathbb{B}$ and $\mathbb{C}_e$ are bounded, a nice theory for system (2.1) has been summarized in the book [9]. The framework of well-posed system theory is, however, mainly concerned with the case where neither $\mathbb{B}$ nor $\mathbb{C}_e$ is bounded.

Let us recall some basic notation. The Hilbert space X_{-1} is defined as the completion of X with respect to the norm

$$\|x\|_{-1} = \|(\beta - \mathbb{A})^{-1}x\| \qquad \forall\, x \in X,$$

and the space X_1 is the space $D(\mathbb{A})$ with the norm

$$\|x\|_1 = \|(\beta - \mathbb{A})x\| \qquad \forall\, x \in D(\mathbb{A}),$$

where $\beta \in \rho(\mathbb{A})$, the resolvent set of $\mathbb{A}$. It is easy to verify that both X_{-1} and X_1 are independent of the choice of β. It was shown in [30] that $X_{-1} = D(\mathbb{A}^*)'$, the dual space of $D(\mathbb{A}^*)$ with respect to the pivot X. Identifying X with its dual space, we have the following continuous, dense inclusions:

$$X_1 \hookrightarrow X \hookrightarrow X_{-1}.$$

DEFINITION 2.1. *System* (2.1) *is said to be well-posed if the following hold:*

(a) $\mathbb{A}$ *generates a* C_0*-semigroup* $\mathbb{T}(\cdot)$ *on* X.

(b) $\mathbb{B} \in \mathcal{L}(U, X_{-1})$ *is an admissible control operator for* $\mathbb{T}(\cdot)$*, i.e., for some (and hence for any)* $t > 0$ *there exists* $C_t > 0$ *such that*

$$\left\| \int_0^t \mathbb{T}(t-\tau)\mathbb{B}u(\tau)d\tau \right\|^2 \le C_t \int_0^t \|u(t)\|_U^2 dt \qquad \forall\, u \in L^2(0, t; U).$$

(c) *The domain* $D(\mathbb{C}_e) \supset D(\mathbb{A})$*. If we denote by* $\mathbb{C}$ *the restriction of* $\mathbb{C}_e$ *to* $D(\mathbb{A})$*, then* $\mathbb{C} \in \mathcal{L}(X_1, Y)$ *is an admissible observation operator for* $\mathbb{T}(\cdot)$*, which means that for some (and hence for any)* $t > 0$*, there exists* $C_t' > 0$ *such that*

$$\int_0^t \|\mathbb{C}\mathbb{T}(\cdot)x\|_Y^2 dt \le C_t' \|x\|^2 \qquad \forall\, x \in D(\mathbb{A}).$$

(d) *The input-output map is bounded; i.e., for some (and hence for any)* $t > 0$, *there exists* $C_t'' > 0$ *such that*

$$\int_0^t \|y(t)\|_Y^2 dt \le C_t'' \int_0^t \|u(t)\|_U^2 dt \qquad \forall\, u \in L^2(0,t;U) \text{ when } x_0 = 0.$$

It should be noted that the definition above is not the standard one given by [5] or [8], but it is equivalent to Weiss's definition (see [16], [23], [27]). From [31], $\mathbb{B}$ is admissible for $\mathbb{T}(\cdot)$ if and only if the adjoint operator $\mathbb{B}^*$ is admissible for $\mathbb{T}^*(\cdot)$, the adjoint C_0-semigroup of $\mathbb{T}(t)$.

Roughly speaking, a well-posed system is a system for which both the state and output depend continuously on the initial state and input function of the system.

If system (2.1) is well-posed, then the weak solution of (2.1) can be represented as (see [5], [28])

$$\begin{cases} x(t) = \mathbb{T}(t)x_0 + \displaystyle\int_0^t \mathbb{T}(t-\tau)\mathbb{B}u(\tau)d\tau \in C([0,\infty);X) \\ \qquad \forall\, x_0 \in X, u \in L^2_{loc}(0,\infty;U), \\ y(t) = \mathbb{C}_\Lambda\left[x(t) - (\lambda - \mathbb{A})^{-1}\mathbb{B}u(t)\right] + \mathbb{H}(\lambda)u(t) \in L^2_{loc}(0,\infty;Y) \\ \qquad \forall\, u \in L^2_{loc}(0,\infty;U), \end{cases} \tag{2.2}$$

where $\mathbb{C}_\Lambda x = \lim_{\lambda\to+\infty} \mathbb{C}\lambda(\lambda - \mathbb{A})^{-1}x$ for all $x \in D(\mathbb{C}_\Lambda)$ is by definition the Λ-extension of $\mathbb{C}$, where $D(\mathbb{C}_\Lambda)$ is the subspace of X for which the associated limit exists (see [5]). $\mathbb{H}(\lambda)$ is called the transfer function which is defined in some right-half planes and is an analytic $\mathcal{L}(U,Y)$-valued function. It can be shown that if $\hat{u}(\lambda)$ exists, then

$$\hat{y}(\lambda) = \mathbb{H}(\lambda)\hat{u}(\lambda) \quad \text{ when } x_0 = 0, \tag{2.3}$$

where $\hat{}$ denotes the Laplace transform. In terms of the operators from (2.1), we have (see [28])

$$\mathbb{H}(\lambda) = \mathbb{C}_e(\lambda - \mathbb{A})^{-1}\mathbb{B} + \mathbb{D}_e.$$

The transfer function $\mathbb{H}(\lambda)$ can be determined by the triple of operators $(\mathbb{A}, \mathbb{B}, \mathbb{C})$ up to an additive constant bounded operator in the following way (see [8]):

$$\frac{\mathbb{H}(\lambda) - \mathbb{H}(\beta)}{\lambda - \beta} = -\mathbb{C}(\lambda - \mathbb{A})^{-1}(\beta - \mathbb{A})^{-1}\mathbb{B} \qquad \forall\, \lambda, \beta \in \mathcal{C}_\rho^+,\ \lambda \ne \beta, \tag{2.4}$$

where $\mathcal{C}_\rho^+ = \{\lambda \in \mathcal{C} |\ \mathrm{Re}\lambda > \rho\}$ for some $\rho > 0$ and $\mathcal{C}$ stands for the complex plane. Using the transfer function, the boundedness of the input-output map described in condition (d) of Definition 2.1 can be expressed as the boundedness of the transfer function on an open right complex half plane (see [8], [11], [16])

$$\sup_{\mathrm{Re}\lambda \ge \alpha > \rho} \|\mathbb{H}(\lambda)\|_{\mathcal{L}(U,Y)} < \infty \tag{2.5}$$

for some $\alpha \in \mathbb{R}$.

The paper [32] introduced an important subclass of well-posed systems, the so-called *regular systems*, for which the representation (2.2) becomes much simpler.

DEFINITION 2.2. *System* (2.1) *is said to be regular if it is well-posed and there exists an operator* $\mathbb{D} \in \mathcal{L}(U,Y)$ *such that, for* $x_0 = 0$ *and* $u(t) \equiv u \in U$*, the output* y *of* (2.1) *satisfies*

$$\lim_{t\to 0} \frac{1}{t} \int_0^t y(\tau)d\tau = \mathbb{D}u \tag{2.6}$$

in the strong topology of Y*. The above* $\mathbb{D}$ *and property* (2.6) *are called the feedthrough operator and the* regularity *of system* (2.1)*, respectively.*

It was shown in [34] that, in the frequency domain, (2.6) is equivalent to

$$\lim_{\lambda\in\mathbb{R},\, \lambda\to+\infty} \mathbb{H}(\lambda)u = \mathbb{D}u \qquad \forall\, u \in U. \tag{2.7}$$

If a well-posed system is regular, then (2.2) can be written as

$$\begin{cases} x(t) = \mathbb{T}(t)x_0 + \displaystyle\int_0^t \mathbb{T}(t-\tau)\mathbb{B}u(\tau)d\tau \in C([0,\infty);X), \\ \qquad x_0 \in X,\ u \in L^2_{loc}(0,\infty;U), \\ y(t) = \mathbb{C}_\Lambda x(t) + \mathbb{D}u(t) \in L^2_{loc}(0,\infty;Y),\ u \in L^2_{loc}(0,\infty;U). \end{cases} \tag{2.8}$$

In this case, the transfer function is uniquely determined by the quadruple of operators $(\mathbb{A},\mathbb{B},\mathbb{C},\mathbb{D})$ and can be represented as

$$\mathbb{H}(\lambda) = \mathbb{D} + \mathbb{C}_\Lambda(\lambda - \mathbb{A})^{-1}\mathbb{B}. \tag{2.9}$$

It is seen that the representations (2.8) and (2.9) resemble that for finite-dimensional systems.

Roughly speaking, a *well-posed regular* system is like a linear finite-dimensional system among the infinite-dimensional systems but with the feature of allowing both control and observation operators to be unbounded in some sense. Unlike stability, controllability, observability, etc., which have finite-dimensional counterparts, regularity is an important but new concept in linear infinite-dimensional systems under the elegant framework of well-posed linear systems theory.

Now let us introduce a special class of well-posed systems: the colocated second-order linear systems. It is well known that "passivity," which was introduced in connection with circuit theory in the 1950s (see [10]), is a very important concept in control system design. It means that the increase of energy stored in the system does not exceed the energy that enters from the external world. For such a system, the transfer function is positive real, and negative output feedback produces a dissipative system, which is stable in the sense of Lyapunov. For a long time, it has been known by engineers that a partial differential equation describing a mechanical system, like a flexible structure in which the power flow into the system is the scalar product $\langle u, y\rangle$ (e.g., when u is force and y is velocity), leads to a positive-real system (2.1) in which $U = Y$ and $\mathbb{A}^* + \mathbb{A} \le 0, \mathbb{C} = \mathbb{B}^*$ if actuators and sensors are designed in a "colocated" fashion. The particular case $\mathbb{A} + \mathbb{A}^* = 0$ corresponds to energy preserving systems. This means that the measurement and control action are made dual in some sense. In [11] and [35], an abstract setting of a second-order passive system of the following type was studied. The state space is $X = D(\mathbb{A}_0^{1/2}) \times H$, and the input and output spaces are the same $U = Y$ (see also [2], [37]):

$$\begin{cases} \ddot{x}(t) + \mathbb{A}_0 x(t) = \mathbb{B}_0 u(t), \\ y(t) = \mathbb{B}_0^* \dot{x}(t), \end{cases} \tag{2.10}$$

where

(i) $\mathbb{A}_0 : D(\mathbb{A}_0)(\subset H) \to H$ is an unbounded positive self-adjoint operator in the Hilbert space H;

(ii) $\mathbb{B}_0 \in \mathcal{L}(U, (D(\mathbb{A}_0^{1/2}))')$;

(iii) $\mathbb{B}_0^* \in \mathcal{L}(D(\mathbb{A}_0^{1/2}), U)$ is defined as

$$(\mathbb{B}_0^* x, u)_U = \langle x, \mathbb{B}_0 u \rangle_{D(\mathbb{A}_0^{1/2}) \times (D(\mathbb{A}_0^{1/2}))'} \qquad \forall\, x \in D(\mathbb{A}_0^{1/2});$$

(iv) an extension $\tilde{\mathbb{A}}_0 \in \mathcal{L}(D(\mathbb{A}_0^{1/2}), (D(\mathbb{A}_0^{1/2}))')$ of $\mathbb{A}_0$ is defined by

$$\langle \tilde{\mathbb{A}}_0 x, z \rangle_{(D(\mathbb{A}_0^{1/2}))' \times D(\mathbb{A}_0^{1/2})} = (\mathbb{A}_0^{1/2} x, \mathbb{A}_0^{1/2} z)_H \qquad \forall\, x, z \in D(\mathbb{A}_0^{1/2}).$$

It was found in [11] that if system (2.10) is well-posed, its transfer function is uniquely determined by the pair $(\mathbb{A}_0, \mathbb{B}_0)$:

$$H(\lambda) = \lambda \mathbb{B}_0^* (\lambda^2 + \tilde{\mathbb{A}}_0)^{-1} \mathbb{B}_0. \tag{2.11}$$

Actually, it was indicated in [2] and [37] that, for this system, the boundedness of the transfer function on some open right half complex plane implies automatically the admissibility of $\left[\begin{smallmatrix} 0 \\ \mathbb{B}_0 \end{smallmatrix}\right]$ for the associated semigroup generated by $\mathbb{A} = \left[\begin{smallmatrix} 0 & I \\ -\mathbb{A}_0 & 0 \end{smallmatrix}\right]$. This system is closely related (via feedback) to the example in [29].

To end this section, we return to our wave equation (1.1) with control $u \in L^2_{loc}(0, \infty; U), U = L^2(\Gamma_0)$. We formulate our problem in the framework of (2.10), although it is already available in the literature (see, e.g., [1]).

Let $H = H^{-1}(\Omega)$ be the dual space of the usual Sobolev space $H_0^1(\Omega)$ (with respect to the pivot space $L^2(\Omega)$). Let A_0 be the positive self-adjoint operator in H induced by the bilinear form $a(\cdot, \cdot)$ defined by

$$\langle A_0 f, g \rangle_{H^{-1}(\Omega) \times H_0^1(\Omega)} = a(f, g) = \int_\Omega \nabla f(x) \overline{\nabla g(x)} dx \qquad \forall\, f, g \in H_0^1(\Omega). \tag{2.12}$$

By means of the Lax–Milgram theorem, A_0 is a canonical isomorphism from $D(A_0) = H_0^1(\Omega)$ to H. If we introduce the Laplacian $-\Delta : H^2(\Omega) \cap H_0^1(\Omega) \to L^2(\Omega)$, then it is easy to show that $A_0 f = -\Delta f$ for $f \in H^2(\Omega) \cap H_0^1(\Omega)$ and that $A_0^{-1} g = (-\Delta)^{-1} g$ for any $g \in L^2(\Omega)$. Hence, A_0 is an extension of usual Laplacian to the space $H_0^1(\Omega)$.

It is well known that $D(A_0^{1/2}) = L^2(\Omega)$. Define the Dirichlet map

$$\Upsilon \in \mathcal{L}(L^2(\Gamma_0), L^2(\Omega)),$$

i.e., $\Upsilon u = v$ by

$$\begin{cases} \Delta v = 0 & \text{in } \Omega, \\ v|_{\Gamma_1} = 0, \quad v|_{\Gamma_0} = u. \end{cases} \tag{2.13}$$

Using the Dirichlet map, we can rewrite the first three equations in (1.1) as

$$\ddot{w} + A_0(w - \Upsilon u) = 0. \tag{2.14}$$

We identify H with its dual H'. Then the following relations hold:

$$D(A_0^{1/2}) \hookrightarrow H \hookrightarrow (D(A_0^{1/2}))'.$$

An extension $\tilde{A}_0 \in \mathcal{L}(D(A_0^{1/2}), (D(A_0^{1/2}))')$ of A_0 is defined by

$$\langle \tilde{A}_0 f, g\rangle_{(D(A_0^{1/2}))'\times D(A_0^{1/2})} = (A_0^{1/2} f, A_0^{1/2} g)_H \qquad \forall\ f, g \in D(A_0^{1/2}). \tag{2.15}$$

Hence, (2.14) can be rewritten in $\mathcal{H}_{-1}$ as

$$\ddot{w} + \tilde{A}_0 w = B_0 u, \tag{2.16}$$

where $B_0 \subset \mathcal{L}(U, (D(A_0^{1/2}))')$ is given by

$$B_0 u = \tilde{A}_0 \Upsilon u \qquad \forall\ u \in U. \tag{2.17}$$

Define $B_0^* \in \mathcal{L}(D(A_0^{1/2}), U)$ by

$$(B_0^* f, u)_U = \langle f, B_0 u\rangle_{D(A_0^{1/2})\times (D(A_0^{1/2}))'} \qquad \forall\ f \in D(A_0^{1/2}).$$

Then for any $f \in D(A_0^{1/2})$ and $u \in C_0^\infty(\Gamma_0)$, we have

$$\begin{aligned}
&\langle f, B_0 u\rangle_{D(A_0^{1/2})\times (D(A_0^{1/2}))'} = \langle \tilde{A}_0 f, \tilde{A}_0^{-1} B_0 u\rangle_{D(A_0^{1/2})\times (D(A_0^{1/2}))'} \\
&= (A_0^{1/2} f, A_0^{1/2} \tilde{A}_0^{-1} B_0 u)_H = (A_0^{-1} A_0^{1/2} f, A_0^{-1} A_0^{1/2} \tilde{A}_0^{-1} B_0 u)_{H_0^1(\Omega)} \\
&= (A_0^{-1/2} f, A_0^{-1/2} \Upsilon u)_{H_0^1(\Omega)} = (f, \Upsilon u)_{L^2(\Omega)} \\
&= (A_0 A_0^{-1} f, \Upsilon u)_{L^2(\Omega)} = -\left(\frac{\partial (-\Delta)^{-1} f}{\partial \nu}, u\right)_U.
\end{aligned}$$

In the last step, we used the fact that

$$\int_\Omega \nabla v \nabla \phi = 0 \qquad \forall\ \phi \in H_0^1(\Omega)$$

holds for any classical solution v of (2.13). Since $C_0^\infty(\Gamma_0)$ is dense in $L^2(\Gamma_0)$, we obtain

$$B_0^* = -\frac{\partial (-\Delta)^{-1}}{\partial \nu}\bigg|_{\Gamma_0}. \tag{2.18}$$

Now, we have formulated system (1.1) into an abstract form of the second-order system (2.10) in the state space $\mathcal{H}$:

$$\begin{cases} \ddot{w}(t) + \tilde{A}_0 w(t) = B_0 u(t), \\ y(t) = B_0^* \dot{w}, \end{cases} \tag{2.19}$$

where B_0 and B_0^* are defined by (2.17) and (2.18), respectively.

The main contribution of this paper is to show that system (2.19) is regular with feedthrough operator $\mathbb{D} = I$.

3. Proof of Theorem 1.2. From (2.19), we see that system (1.1) is in the framework of form (2.10) discussed in section 2. Since system (1.1) is well-posed, it follows from (2.11) that the transfer function of system (1.1) is

$$H(\lambda) = \lambda B_0^* (\lambda^2 + \tilde{A}_0)^{-1} B_0, \tag{3.1}$$

where $\tilde{A}_0$, B_0, and B_0^* are given by (2.15), (2.17), and (2.18), respectively. Moreover, from the well-posedness and (2.5), it follows that there exists a positive number $\alpha > 0$ such that

$$\sup_{\mathrm{Re}\lambda \geq \alpha} \|H(\lambda)\|_{\mathcal{L}(U)} = M < \infty. \tag{3.2}$$

To begin, we show the following proposition.

PROPOSITION 3.1. *Theorem* 1.2 *is valid if for any* $u \in C_0^\infty(\Gamma_0)$ *the solution* u_ε *to the equation*

$$\begin{cases} u_\varepsilon(x) - \varepsilon^2 \Delta u_\varepsilon(x) = 0, & x \in \Omega, \\ u_\varepsilon(x) = 0, & x \in \Gamma_1, \\ u_\varepsilon(x) = u(x), & x \in \Gamma_0 \end{cases} \tag{3.3}$$

satisfies

$$\lim_{\varepsilon \to 0} \int_{\Gamma_0} \left| \varepsilon \frac{\partial u_\varepsilon(x)}{\partial \nu} - u(x) \right|^2 dx = 0, \tag{3.4}$$

where ε *are real and positive numbers.*

Proof. In light of the equivalence between (2.6) and (2.7), in order to prove Theorem 1.2 we need only to show that

$$\lim_{\lambda \in \mathbb{R},\, \lambda \to +\infty} H(\lambda) u = u \tag{3.5}$$

for any $u \in L^2(\Gamma_0) = U$ in the strong topology of U, where $H(\lambda)$ is given by (3.1). We claim that in order to show (3.5), it suffices to show that (3.5) is satisfied for all $u \in C_0^\infty(\Gamma_0)$. Indeed, for any $u \in U$ and any given $\delta > 0$, since $C_0^\infty(\Gamma_0)$ is dense in $L^2(\Gamma_0)$, if (3.5) is valid for $u \in C_0^\infty(\Gamma_0)$, then one can find $u_0 \in C_0^\infty(\Gamma_0)$ and the real number $\beta > \alpha$ such that

$$\|u_0 - u\|_U < \min\left\{ \frac{\delta}{3M}, \frac{\delta}{3} \right\}, \qquad \sup_{\lambda \in \mathbb{R},\, \lambda > \beta} \|H(\lambda) u_0 - u_0\|_U < \frac{\delta}{3},$$

where M and α are given in (3.2). Therefore,

$$\sup_{\lambda \in \mathbb{R},\, \lambda > \beta} \|H(\lambda) u - u\|_U = \sup_{\lambda \in \mathbb{R},\, \lambda > \beta} \|H(\lambda) u_0 - u_0 + H(\lambda)(u - u_0) - u + u_0\|_U < \delta.$$

This shows that (3.5) is valid for any $u \in U$.

Now assume that $u \in C_0^\infty(\Gamma_0)$, and put

$$w_\lambda(x) = ((\lambda^2 + \tilde{A}_0)^{-1} B_0 u)(x).$$

Then w_λ satisfies

$$\begin{cases} \lambda^2 w_\lambda(x) - \Delta w_\lambda(x) = 0, & x \in \Omega, \\ w_\lambda(x) = 0, & x \in \Gamma_1, \\ w_\lambda(x) = u(x), & x \in \Gamma_0, \end{cases} \tag{3.6}$$

and

$$(H(\lambda) u)(x) = -\lambda \frac{\partial((-\Delta)^{-1} w_\lambda)(x)}{\partial \nu} \qquad \forall\, x \in \Gamma_0. \tag{3.7}$$

Since $u \in C_0^\infty(\Gamma_0)$, there exists a unique classical solution to (3.6). Take a function $v \in H^2(\Omega)$ such that

$$\begin{cases} \Delta v(x) = 0, & x \in \Omega, \\ v(x) = 0, & x \in \Gamma_1, \\ v(x) = u(x), & x \in \Gamma_0. \end{cases} \tag{3.8}$$

Then (3.6) can be written as

$$\begin{cases} \lambda^2 w_\lambda(x) - \Delta(w_\lambda(x) - v(x)) = 0, \quad x \in \Omega, \\ (w_\lambda - v)\big|_{\partial\Omega} = 0, \end{cases} \tag{3.9}$$

or equivalently

$$-\lambda^2((-\Delta)^{-1} w_\lambda)(x) = w_\lambda(x) - v(x).$$

Hence (3.7) becomes

$$(H(\lambda)u)(x) = \frac{1}{\lambda}\frac{\partial w_\lambda(x)}{\partial \nu} - \frac{1}{\lambda}\frac{\partial v(x)}{\partial \nu}. \tag{3.10}$$

Letting $u_\varepsilon(x) = w_\lambda(x)$ with $\varepsilon = \lambda^{-1}$ and noting that $\frac{\partial v(x)}{\partial \nu}$ is independent of λ, we conclude the required result. □

The rest of this section is devoted to proving that the solution u_ε of (3.3) with $u \in C_0^\infty(\Gamma_0)$ satisfies (3.4). We shall go a little bit further. Indeed, we will show that there exists a constant $C > 0$ such that for all $\varepsilon \in (0, 1)$, any solution $u_\varepsilon \in H^2(\Omega)$ of

$$\left(\varepsilon^2 \Delta - 1\right) u_\varepsilon(x) = 0, \quad x \in \Omega,$$

satisfies the following inequality:

$$\left\| \varepsilon \frac{\partial u_\varepsilon}{\partial \nu} - u_\varepsilon \right\|^2_{L^2(\partial\Omega)} \leq C\varepsilon \left\| u_\varepsilon \right\|^2_{H^{3/2}(\partial\Omega)}.$$

This will be performed by estimating the Dirichlet–Neumann map by means of easy Fourier analysis tools after applying a diffeomorphism to reduce locally our geometry to the half-space. Notice that the Dirichlet–Neumann map for the Laplacian in a manifold was more precisely computed in [18] by using symbolic calculus of pseudodifferential operators.

Proof of Theorem 1.2. By Proposition 3.1, we need only to show that the solution u_ε of (3.3) with $u \in C_0^\infty(\Gamma_0)$ satisfies (3.4) . We assume $0 < \varepsilon < 1$ throughout the proof.

For any $x_0 \in \partial\Omega$, suppose without loss of generality that in an open neighborhood $V_{x_0} \subset \mathbb{R}^n$ of x_0,

$$V_{x_0} \cap \Omega = \{(x', x_n) = (x_1, x_2, \dots, x_{n-1}, x_n) \in V_{x_0},\ x_n - \phi(x') > 0\}$$

for some $\phi \in C^3(\mathbb{R}^{n-1})$. Then the unit outward normal vector to $V_{x_0} \cap \partial\Omega$ at $(x', \phi(x'))$ is defined by

$$\nu(x') = \frac{\left(\partial_{x_1}\phi(x'), \dots, \partial_{x_{n-1}}\phi(x'), -1\right)}{\sqrt{1 + |\nabla\phi(x')|^2}}.$$

Let us use the geodesic normal coordinates as follows. Let

$$(h,s)=(h_1,h_2,\dots,h_{n-1},s)\in\mathbb{R}^n.$$

We introduce a diffeomorphism by

$$\Psi(h,s)=(h,\phi(h))-s\nu(h)$$

such that

(i) $\Psi^{-1}(\Omega_{x_0})=B_r=\{(h,s)\in\mathbb{R}^n,|(h,s)|<r\}$;
(ii) $\Psi^{-1}(\Omega_{x_0}\cap\Omega)=B_r^+=\{(h,s)\in B_r,s>0\}$;
(iii) $\Psi^{-1}(\Omega_{x_0}\cap\partial\Omega)=\{(h,s)\in B_r,s=0\}=\{|h|<r\}\times\{0\}$

for some $r>0$ and an open neighborhood $\Omega_{x_0}(\subset V_{x_0})$ of x_0, where $|\cdot|$ denotes the Euclidean norm. Using the diffeomorphism $\Psi:B_r\to\Omega_{x_0}$, the normal derivative on the boundary becomes

$$\frac{\partial}{\partial\nu}=-\partial_s,$$

and the operator in the first equation of (3.3) can be written in the form

$$\Delta-\frac{1}{\varepsilon^2}=\partial_s^2+P\,(h,s,-i\partial_h)+\ell(h,s)\partial_s-\frac{1}{\varepsilon^2},$$

where $\partial_h=(\partial_{h_1},\dots,\partial_{h_{n-1}})$, ℓ is a continuous function, and P is a second-order elliptic differential operator in the h variables only.

The proof is now divided into three steps.

Step 1. *Flattening and localization.* We first flatten the local domain $\Omega_{x_0}\cap\Omega$ with the above diffeomorphism Ψ and set

$$\tilde{u}_\varepsilon(h,s)=u_\varepsilon(\Psi(h,s)),\qquad \tilde{u}(h)=u_\varepsilon(\Psi(h,0)). \tag{3.11}$$

Then $\tilde{u}_\varepsilon$ satisfies

$$\begin{cases}\partial_s^2\tilde{u}_\varepsilon(h,s)+\displaystyle\sum_{i,j=1}^{n-1}a_{ij}(h,s)\partial_{h_i}\partial_{h_j}\tilde{u}_\varepsilon(h,s)+Q\tilde{u}_\varepsilon(h,s)-\frac{1}{\varepsilon^2}\tilde{u}_\varepsilon(h,s)=0,\\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad (h,s)\in B_r^+,\\ \tilde{u}_\varepsilon(h,0)=\tilde{u}(h),\qquad |h|<r,\end{cases} \tag{3.12}$$

where Q is a linear differential operator of order 1 with continuous coefficients in B_r and $(a_{ij})_{1\le i,j\le n-1}$ is a strictly positive definite symmetric matrix of continuous functions of (h,s) in B_r. Assume that $\lambda_0>0$ is a constant such that

$$\sum_{i,j=1}^{n-1}a_{ij}(h,s)\xi_i\xi_j\ge\lambda_0|\xi|^2\quad\forall\,\xi=(\xi_1,\xi_2,\dots,\xi_{n-1})\in\mathbb{R}^{n-1},\quad(h,s)\in B_r. \tag{3.13}$$

Let $\mu_0>0$ be such that $\mu_0<\frac{\lambda_0}{(n-1)^2}$. Since a_{ij} is continuous in B_r, one can find a scalar $\rho\in(0,r)$ such that

$$|a_{ij}(h,s)-a_{ij}(0,0)|\le\mu_0\qquad\forall\,i,j=1,2,\dots,n-1,\quad(h,s)\in B_\rho^+. \tag{3.14}$$

Second, we introduce a cutoff function $\varphi = \varphi(h,s) \in C_0^\infty(B_\rho)$ such that $0 \le \varphi \le 1$ and $\varphi = 1$ in $B_{\rho/2}$. Set, for all $(h,s) \in \mathbb{R}^{n-1} \times \mathbb{R}^+$,

$$\chi_\varepsilon(h,s) = \varphi(h,s)\tilde{u}_\varepsilon(h,s), \qquad f(h) = \varphi(h,0)\tilde{u}(h). \tag{3.15}$$

Then one can check that $\chi_\varepsilon \in H^2(\mathbb{R}^{n-1} \times \mathbb{R}^+)$ and $\chi_\varepsilon(h,s) = 0$ in $\mathbb{R}^{n-1} \times \{s \ge \rho\}$. By (3.12), χ_ε satisfies

$$\begin{cases} \partial_s^2 \chi_\varepsilon(h,s) + \displaystyle\sum_{i,j=1}^{n-1} a_{ij}(0,0)\partial_{h_i}\partial_{h_j}\chi_\varepsilon(h,s) - \frac{1}{\varepsilon^2}\chi_\varepsilon(h,s) \\ \qquad = G\chi_\varepsilon(h,s) + L\tilde{u}_\varepsilon(h,s), \qquad (h,s) \in \mathbb{R}^{n-1} \times \mathbb{R}^+, \\ \chi_\varepsilon(h,0) = f(h), \qquad h \in \mathbb{R}^{n-1}, \end{cases} \tag{3.16}$$

where

$$\begin{cases} G\chi_\varepsilon(h,s) &= \displaystyle\sum_{i,j=1}^{n-1} [a_{ij}(0,0) - a_{ij}(h,s)]\partial_{h_i}\partial_{h_j}\chi_\varepsilon(h,s), \\ L\tilde{u}_\varepsilon(h,s) &= -\varphi(h,s)Q\tilde{u}_\varepsilon(h,s) + [\partial_s^2, \varphi]\tilde{u}_\varepsilon(h,s) \\ &\quad + \displaystyle\sum_{i,j=1}^{n-1} a_{ij}(h,s)[\partial_{h_i}\partial_{h_j}, \varphi]\tilde{u}_\varepsilon(h,s) \end{cases} \tag{3.17}$$

with

$$[\partial_s^2, \varphi]\tilde{u}_\varepsilon = 2\partial_s\varphi\partial_s\tilde{u}_\varepsilon + \partial_s^2\varphi\tilde{u}_\varepsilon, \;\; [\partial_{h_i}\partial_{h_j}, \varphi]\tilde{u}_\varepsilon = \partial_{h_i}\varphi\partial_{h_j}\tilde{u}_\varepsilon + \partial_{h_j}\varphi\partial_{h_i}\tilde{u}_\varepsilon + \partial_{h_i}\partial_{h_j}\varphi\tilde{u}_\varepsilon.$$

Clearly, G and L are two linear differential operators of order 2 and order 1, respectively.

Step 2. *Partial Fourier transform.* Fix s, for any $\chi(\cdot,s) \in L^2(\mathbb{R}^{n-1})$. From now on, we denote by $\widehat{\chi}(\xi,s)$ the partial Fourier transform of $\chi(h,s)$ with respect to h, i.e.,

$$\widehat{\chi}(\xi,s) = \int_{\mathbb{R}^{n-1}} \chi(h,s)e^{-i\langle h,\xi\rangle}dh.$$

Applying the above partial Fourier transform to system (3.16), it becomes

$$\begin{cases} \partial_s^2\widehat{\chi_\varepsilon}(\xi,s) - \dfrac{1}{\varepsilon^2}(\varepsilon^2\xi^\top A\xi + 1)\widehat{\chi_\varepsilon}(\xi,s) = \widehat{G\chi_\varepsilon}(\xi,s) + \widehat{L\tilde{u}_\varepsilon}(\xi,s), \\ \qquad (\xi,s) \in \mathbb{R}^{n-1} \times \mathbb{R}^+, \\ \widehat{\chi_\varepsilon}(\xi,0) = \widehat{f}(\xi), \qquad \xi \in \mathbb{R}^{n-1}, \end{cases} \tag{3.18}$$

where $A = \{a_{ij}(0,0)\}_{1\le i,j\le n-1}$ is a positive definite symmetric matrix. Notice that

$$\widehat{\chi_\varepsilon}(\xi,s) = 0 \qquad \forall (\xi,s) \in \mathbb{R}^{n-1} \times [\rho, +\infty)\,. \tag{3.19}$$

To analyze the solution of (3.18) satisfying (3.19), we decompose $\widehat{\chi_\varepsilon}(\xi,s)$ as follows. Let

$$\widehat{\chi_\varepsilon}(\xi,s) = w_\varepsilon(\xi,s) + v_\varepsilon(\xi,s), \qquad (\xi,s) \in \mathbb{R}^{n-1} \times \mathbb{R}^+, \tag{3.20}$$

where w_ε satisfies

$$\begin{cases} \partial_s^2 w_\varepsilon(\xi,s) - \dfrac{1}{\varepsilon^2}(\varepsilon^2 \xi^\top A\xi + 1) w_\varepsilon(\xi,s) = 0, \qquad (\xi,s) \in \mathbb{R}^{n-1} \times \mathbb{R}^+, \\ w_\varepsilon(\xi,0) = \widehat{f}(\xi), \qquad \xi \in \mathbb{R}^{n-1}, \\ \lim\limits_{s\to+\infty} w_\varepsilon(\xi,s) = 0, \qquad \xi \in \mathbb{R}^{n-1}, \end{cases} \tag{3.21}$$

and v_ε satisfies

$$\begin{cases} \partial_s^2 v_\varepsilon(\xi,s) - \dfrac{1}{\varepsilon^2}(\varepsilon^2 \xi^\top A\xi + 1) v_\varepsilon(\xi,s) = \widehat{G\chi_\varepsilon}(\xi,s) + \widehat{L\widetilde{u}_\varepsilon}(\xi,s), \\ \qquad (\xi,s) \in \mathbb{R}^{n-1} \times \mathbb{R}^+, \\ v_\varepsilon(\xi,0) = 0, \qquad \xi \in \mathbb{R}^{n-1}, \\ v_\varepsilon(\xi,s) = -\widehat{f}(\xi) e^{-s\frac{\sqrt{\varepsilon^2\xi^\top A\xi+1}}{\varepsilon}}, \qquad (\xi,s) \in \mathbb{R}^{n-1} \times [\rho,+\infty)\,. \end{cases} \tag{3.22}$$

The validity of the last equality comes from (3.19) and the following explicit expression of the solution of (3.21):

$$w_\varepsilon(\xi,s) = \widehat{f}(\xi) e^{-s\frac{\sqrt{\varepsilon^2\xi^\top A\xi+1}}{\varepsilon}}. \tag{3.23}$$

We claim that there exists a constant $C > 0$ such that for all $\varepsilon \in (0,1)$

$$\int_{\mathbb{R}^{n-1}} |\varepsilon \partial_s w_\varepsilon(\xi,0) + w_\varepsilon(\xi,0)|^2 d\xi \le C\varepsilon^2 \|u_\varepsilon\|^2_{H^1(\partial\Omega)}. \tag{3.24}$$

Indeed, by (3.23), we get

$$\int_{\mathbb{R}^{n-1}} |\varepsilon \partial_s w_\varepsilon(\xi,0) + w_\varepsilon(\xi,0)|^2 d\xi = \int_{\mathbb{R}^{n-1}} \left(\frac{\varepsilon^2 \xi^\top A\xi}{\sqrt{\varepsilon^2\xi^\top A\xi + 1} + 1} \right)^2 |\widehat{f}(\xi)|^2 d\xi$$

$$\le \int_{\mathbb{R}^{n-1}} \varepsilon^2 \xi^\top A\xi |\widehat{f}(\xi)|^2 d\xi,$$

and (3.24) follows easily.

Now we need to bound the quantity $\int_{\mathbb{R}^{n-1}} |\varepsilon \partial_s v_\varepsilon(\xi,0) + v_\varepsilon(\xi,0)|^2 d\xi$ uniformly with respect to ε. This will be done in the next step.

Step 3. *Estimate of* $\varepsilon\partial_s v_\varepsilon(\cdot,0) + v_\varepsilon(\cdot,0)$. We will estimate $\partial_s v_\varepsilon(\cdot,0)$ by means of a classical trace theorem. This requires the computation of $\partial_s^2 v_\varepsilon$ and $\partial_s v_\varepsilon$. To do it, we estimate $\widehat{L\widetilde{u}_\varepsilon}$ and $\widehat{G\chi_\varepsilon}$ first. Throughout the proof, C denotes several positive constants independent of ε.

(a) *Estimate of* $\widehat{L\widetilde{u}_\varepsilon}$ *and* $\widehat{G\chi_\varepsilon}$. Clearly, we have

$$\left\| \widehat{L\widetilde{u}_\varepsilon} \right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le C \left\| u_\varepsilon \right\|_{H^1(\Omega)}. \tag{3.25}$$

By (3.14) and the Plancherel formula, it follows that

$$\begin{aligned} \|\widehat{G\chi_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} &= (2\pi)^{\frac{n-1}{2}} \|G\chi_\varepsilon\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \\ &\le (2\pi)^{\frac{n-1}{2}} \mu_0 \sum_{i,j=1}^{n-1} \|\partial_{h_i}\partial_{h_j}\chi_\varepsilon\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \\ &\le \mu_0 (n-1)^2 \||\xi|^2 \widehat{\chi_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}. \end{aligned} \tag{3.26}$$

From (3.26) and noting (3.20), we find

$$\|\widehat{G\chi_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le \mu_0(n-1)^2 \left\||\xi|^2 w_\varepsilon\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \mu_0(n-1)^2 \left\||\xi|^2 v_\varepsilon\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}. \tag{3.27}$$

On the other hand, multiplying (3.22) by $-|\xi|^2\overline{v_\varepsilon}$ and then integrating by parts over $\mathbb{R}^{n-1}\times\mathbb{R}^+$, taking (3.13) and the last equality of (3.22) into account, we have

$$\lambda_0 \left\||\xi|^2 v_\varepsilon\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le \|\widehat{G\chi_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \|\widehat{L\tilde{u}_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}. \tag{3.28}$$

Substituting (3.28) into (3.27), we get

$$\begin{aligned} &\left(1-\tfrac{\mu_0(n-1)^2}{\lambda_0}\right)\left\|\widehat{G\chi_\varepsilon}\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \\ &\le \mu_0(n-1)^2\left\||\xi|^2 w_\varepsilon\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \tfrac{\mu_0(n-1)^2}{\lambda_0}\left\|\widehat{L\tilde{u}_\varepsilon}\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}. \end{aligned} \tag{3.29}$$

Moreover, from (3.23) and (3.13), we have

$$\begin{aligned} \left\||\xi|^2 w_\varepsilon\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} &= \left(\int_{\mathbb{R}^{n-1}} \left||\xi|^2\,\widehat{f}(\xi)\right|^2 \left(\int_0^{+\infty} e^{-2s\frac{\sqrt{\varepsilon^2\xi^\top A\xi+1}}{\varepsilon}} ds\right) d\xi\right)^{1/2} \\ &= \left\|\sqrt{\frac{\varepsilon}{2\sqrt{\varepsilon^2\xi^\top A\xi+1}}}\,|\xi|^2\,\widehat{f}\right\|_{L^2(\mathbb{R}^{n-1})} \\ &\le \sqrt{\tfrac{1}{2\sqrt{\lambda_0}}}\left\||\xi|^{3/2}\,\widehat{f}\right\|_{L^2(\mathbb{R}^{n-1})} \le C\,\|u_\varepsilon\|_{H^{3/2}(\partial\Omega)}. \end{aligned} \tag{3.30}$$

Finally, it follows from (3.29), (3.30), and (3.25) that

$$\left\|\widehat{G\chi_\varepsilon}\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le C\left(\|u_\varepsilon\|_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|_{H^1(\Omega)}\right). \tag{3.31}$$

(b) *Estimate of* $\partial_s^2 v_\varepsilon$. Multiplying (3.22) by $\overline{\partial_s^2 v_\varepsilon}$ and then integrating by parts over $\mathbb{R}^{n-1}\times\mathbb{R}^+$, we obtain, noticing the last equality of (3.22),

$$\|\partial_s^2 v_\varepsilon\|^2_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le \left(\|\widehat{G\chi_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \|\widehat{L\tilde{u}_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}\right)\|\partial_s^2 v_\varepsilon\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}.$$

This together with (3.25) and (3.31) gives

$$\|\partial_s^2 v_\varepsilon\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le C[\|u_\varepsilon\|_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|_{H^1(\Omega)}]. \tag{3.32}$$

(c) *Estimate of* $\partial_s v_\varepsilon$. Noticing the last equality of (3.22), multiplying (3.22) by $-\overline{v_\varepsilon}$, and integrating by parts over $\mathbb{R}^{n-1}\times\mathbb{R}^+$, we also have

$$\begin{aligned} &\|\partial_s v_\varepsilon\|^2_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \frac{1}{\varepsilon^2}\|v_\varepsilon\|^2_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \\ &\le \|\varepsilon(\widehat{G\chi_\varepsilon} + \widehat{L\tilde{u}_\varepsilon})\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}\left\|\frac{v_\varepsilon}{\varepsilon}\right\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}. \end{aligned}$$

Thus,

$$\|\partial_s v_\varepsilon\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le \varepsilon\left(\|\widehat{G\chi_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \|\widehat{L\tilde{u}_\varepsilon}\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}\right).$$

This together with (3.25) and (3.31) gives

$$\|\partial_s v_\varepsilon\|_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} \le C[\|u_\varepsilon\|_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|_{H^1(\Omega)}]. \tag{3.33}$$

(d) *Estimate of* $\partial_s v_\varepsilon(\cdot,0)$. We use the following standard inequality:

$$\begin{aligned}\int_{\mathbb{R}^{n-1}} |\partial_s v_\varepsilon(\xi,0)|^2\, d\xi &= -2\int_{\mathbb{R}^{n-1}}\int_0^{+\infty} \mathrm{Re}\left(\partial_s v_\varepsilon(\xi,s)\overline{\partial_s^2 v_\varepsilon}(\xi,s)\right) ds d\xi \\ &\le \|\partial_s v_\varepsilon\|^2_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)} + \left\|\partial_s^2 v_\varepsilon\right\|^2_{L^2(\mathbb{R}^{n-1}\times\mathbb{R}^+)}.\end{aligned} \tag{3.34}$$

This together with (3.32) and (3.33) gives the desired estimate for v_ε:

$$\int_{\mathbb{R}^{n-1}} |\varepsilon\partial_s v_\varepsilon(\xi,0) + v_\varepsilon(\xi,0)|^2 d\xi \le C\varepsilon^2[\|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|^2_{H^1(\Omega)}]. \tag{3.35}$$

Here we used the fact that $v_\varepsilon(\cdot,0)=0$ given by the second equation of (3.22).

Combining (3.20), the estimates (3.24) and (3.35) imply

$$\int_{\mathbb{R}^{n-1}} |\varepsilon\partial_s \widehat{\chi_\varepsilon}(\xi,0) + \widehat{\chi_\varepsilon}(\xi,0)|^2 d\xi \le C\varepsilon^2[\|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|^2_{H^1(\Omega)}], \tag{3.36}$$

and hence by the Parseval formula, we obtain

$$\int_{\mathbb{R}^{n-1}} |\varepsilon\partial_s \chi_\varepsilon(s,0) + \chi_\varepsilon(s,0)|^2 ds \le C\varepsilon^2[\|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|^2_{H^1(\Omega)}]. \tag{3.37}$$

By (3.15), we deduce from (3.37) that

$$\int_{|s|<\rho/2} |\varepsilon\partial_s \tilde{u}_\varepsilon(s,0) + \tilde{u}_\varepsilon(s,0)|^2 ds \le C\varepsilon^2[\|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|^2_{H^1(\Omega)}], \tag{3.38}$$

which implies by the change of coordinates involving Ψ that

$$\int_{\tilde{\Omega}_{x_0}\cap\partial\Omega} \left|\varepsilon\frac{\partial u_\varepsilon(x)}{\partial\nu} - u_\varepsilon(x)\right|^2 dx \le C\varepsilon^2[\|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|^2_{H^1(\Omega)}], \tag{3.39}$$

where $\tilde{\Omega}_{x_0}\subset\Omega_{x_0}$ is an open neighborhood of $x_0\in\partial\Omega$. Since x_0 is arbitrarily chosen, one easily deduces from (3.39) that

$$\left\|\varepsilon\frac{\partial u_\varepsilon}{\partial\nu} - u_\varepsilon\right\|^2_{L^2(\partial\Omega)} \le C\varepsilon^2[\|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)} + \|u_\varepsilon\|^2_{H^1(\Omega)}]. \tag{3.40}$$

Now, multiplying (3.3) by u_ε and integrating by parts, we find

$$\|\varepsilon\nabla u_\varepsilon\|^2_{L^2(\Omega)} + \|u_\varepsilon\|^2_{L^2(\Omega)} = \varepsilon^2\int_{\partial\Omega}\frac{\partial u_\varepsilon(x)}{\partial\nu}u_\varepsilon(x)dx.$$

Hence, using the Cauchy–Schwarz inequality, we get

$$\begin{aligned}\varepsilon^2\|u_\varepsilon\|^2_{H^1(\Omega)} &\le \varepsilon\left(\left\|\varepsilon\frac{\partial u_\varepsilon}{\partial\nu} - u_\varepsilon\right\|_{L^2(\partial\Omega)} + \|u_\varepsilon\|_{L^2(\partial\Omega)}\right)\|u_\varepsilon\|_{L^2(\partial\Omega)} \\ &\le \frac{\varepsilon}{2C}\left\|\varepsilon\frac{\partial u_\varepsilon}{\partial\nu} - u_\varepsilon\right\|^2_{L^2(\partial\Omega)} + \left(1+\frac{C}{2}\right)\varepsilon\|u_\varepsilon\|^2_{L^2(\partial\Omega)}.\end{aligned}$$

Substituting the above formula into (3.40), we have finally proved that there exists a constant $C > 0$ such that for all $\varepsilon \in (0, 1)$ any solution $u_\varepsilon \in H^2(\Omega)$ of

$$\left(\varepsilon^2 \Delta - 1\right) u_\varepsilon(x) = 0, \qquad x \in \Omega,$$

satisfies

$$\left\| \varepsilon \frac{\partial u_\varepsilon}{\partial \nu} - u_\varepsilon \right\|^2_{L^2(\partial\Omega)} \leq C\varepsilon \|u_\varepsilon\|^2_{H^{3/2}(\partial\Omega)}. \tag{3.41}$$

Therefore,

$$\lim_{\varepsilon \to 0} \left\| \varepsilon \frac{\partial u_\varepsilon}{\partial \nu} - u \right\|_{L^2(\Gamma_0)} = 0.$$

This completes the proof of Theorem 1.2. □

Acknowledgments. The special case of Theorem 1.2 in a 2-D disk was first proved in [12] when Bao-Zhu Guo was visiting INRIA in Metz, France in 2002. The authors would like to thank the anonymous referees for their careful reading, helpful suggestions, and many corrections of the manuscript.

REGULARITY OF THE FREE BOUNDARY IN AN OPTIMIZATION PROBLEM RELATED TO THE BEST SOBOLEV TRACE CONSTANT*

JULIÁN FERNÁNDEZ BONDER†, JULIO D. ROSSI‡, AND NOEMI WOLANSKI†

Abstract. In this paper we study the regularity properties of a free boundary problem arising in the optimization of the best Sobolev trace constant in the immersion $H^1(\Omega) \hookrightarrow L^q(\partial\Omega)$ for functions that vanish in a subset of Ω. This problem is also related to a minimization problem for Steklov eigenvalues.

Key words. Sobolev trace constant, free boundaries, eigenvalue optimization problems

1. Introduction.

The study of Sobolev inequalities and of optimal constants is a subject of interest in the analysis of PDEs and related topics. It has been widely studied in the past by many authors and is still an area of intensive research. See, for instance, the book [1] and, for recent developments in this field, see the articles [6, 11, 9, 17] and the survey [7] among others.

The optimal Sobolev constant and its corresponding extremals (if they exist) are related to eigenvalue problems. In the case of the best Sobolev trace embedding $H^1(\Omega) \to L^q(\partial\Omega)$, where Ω is a bounded smooth domain in $\mathbb{R}^N$, the best constant and the extremal (that exists for $1 \le q < 2_* = 2(N-1)/(N-2)$ since the immersion is compact) give rise to the following elliptic problem with nonlinear boundary conditions:

$$\begin{cases} -\Delta u + u = 0 & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = \lambda u^{q-1} & \text{on } \partial\Omega. \end{cases}$$

The constant λ depends on the normalization of the extremal u. For instance, if u is chosen so that $\|u\|_{L^q(\partial\Omega)} = 1$, then $\lambda = S$, the best Sobolev trace constant. In the linear case, $q = 2$, this problem becomes an eigenvalue problem that is known as the *Steklov eigenvalue problem* [19].

In this paper we are interested in the best Sobolev trace constant among functions that vanish in a subset of Ω. We try to optimize this best constant when varying the subset in the class of measurable sets with prescribed positive measure α. In a previous article [10], we proved that there exists an optimal set. In this paper we focus our attention on regularity properties of these optimal sets.

More precisely, in [10] we studied the following problem. Let

$$\mathcal{J}(v) = \int_\Omega |\nabla v|^2 + v^2\, dx,$$
$$\mathcal{A}_\alpha = \{v \in H^1(\Omega) \ / \ \|v\|_{L^q(\partial\Omega)} = 1 \text{ and } |\{v > 0\}| = \alpha\}.$$

Then the problem is as follows:

$$(P_\alpha) \qquad \text{Find } \phi_0 \in \mathcal{A}_\alpha \text{ such that } S(\alpha) := \inf_{v\in\mathcal{A}_\alpha} \mathcal{J}(v) = \mathcal{J}(\phi_0).$$

In [10] we proved that there exists a solution ϕ_0 to (P_α), but the approach in [10] does not give any regularity properties of ϕ_0 or of the *hole* $\{\phi_0 = 0\}$.

In this paper we consider a different approach. Instead of minimizing $\mathcal{J}(v)$ over $\mathcal{A}_\alpha$ we penalize the functional and minimize without the measure restriction. This approach has been used with great success by many authors starting with the work [2] (see also, for instance, [3, 15, 16, 20]). Thus, let

$$\mathcal{J}_\varepsilon(v) = \int_\Omega |\nabla v|^2 + v^2\, dx + F_\varepsilon(|\{v > 0\}|), \tag{1.1}$$

where

$$F_\varepsilon(s) = \begin{cases} \dfrac{1}{\varepsilon}(s-\alpha) & \text{if } s \geq \alpha, \\ \varepsilon(s-\alpha) & \text{if } s < \alpha. \end{cases}$$

The penalized problem is to minimize $\mathcal{J}_\varepsilon$ over the class

$$\mathcal{K}_1 = \{v \in H^1(\Omega) \,/\, \|v\|_{L^q(\partial\Omega)} = 1\}.$$

For technical reasons, it is better to minimize in the class

$$\mathcal{K} = \{v \in H^1(\Omega) \,/\, \|v\|_{L^q(\Gamma_N)} = 1,\ v = \varphi_0 \text{ on } \Gamma_D\},$$

where $\emptyset \neq \Gamma_N \subset \partial\Omega$, $\Gamma_D = \partial\Omega \setminus \Gamma_N$ is the closure of a relatively open set of the boundary and $\varphi_0 \in H^1(\Omega)$, $\varphi_0 \geq c_0 > 0$ on Γ_D. We will only need to assume that $\Gamma_D \neq \emptyset$ at the end of our arguments. See section 4, Lemma 4.3.

So the penalized problem is as follows:

$$(P_\varepsilon) \qquad \text{Find } u_\varepsilon \in \mathcal{K} \text{ such that } \mathcal{J}_\varepsilon(u_\varepsilon) = \inf_{v\in\mathcal{K}} \mathcal{J}_\varepsilon(v).$$

Observe that minimizing $\mathcal{J}_\varepsilon$ over $\mathcal{K}$ gives a problem with mixed boundary conditions. We believe that this problem has independent interest.

The main idea is to prove that for ε small any minimizer u_ε of $\mathcal{J}_\varepsilon$ in $\mathcal{K}$ satisfies $|\{u_\varepsilon > 0\}| = \alpha$; therefore, the penalization term F_ε vanishes, and hence we have a minimizer of our original problem. This allows us to avoid the passage to the limit (as $\varepsilon \to 0$) where uniform bounds are needed. Proving regularity of the minimizers of $\mathcal{J}_\varepsilon$ and their free boundaries, $\partial\{u_\varepsilon > 0\}$, is easier than the original problem, thanks to the results of [4].

The main theorem in this article is the following.

THEOREM 1.1. *For every $\varepsilon > 0$ there exists a solution $u_\varepsilon \in \mathcal{K}$ to (P_ε). Moreover, any such solution is a locally Lipschitz continuous function and the free boundary*

$\partial\{u_\varepsilon > 0\}$ is locally a $C^{1,\beta}$ surface up to a set of zero $\mathcal{H}^{N-1}$ measure. In the case $N = 2$ the free boundary is locally a $C^{1,\beta}$ surface. Moreover, if $\Gamma_D \neq \emptyset$, for ε small we have $|\{u_\varepsilon > 0\}| = \alpha$.

Outline of the paper. In section 2 we begin our analysis of problem (P_ε) for fixed ε. First we prove the existence of a minimizer, local Lipschitz regularity, and nondegeneracy near the free boundary (Theorem 2.1). Then we prove that a minimizer u_ε of (P_ε) is a weak solution to the free boundary problem

$$\begin{cases} -\Delta u + u = 0 & \text{in } \{u > 0\} \cap \Omega, \\ \dfrac{\partial u}{\partial \nu} = \lambda_\varepsilon & \text{on } \partial\{u > 0\} \cap \Omega, \end{cases}$$

where λ_ε is a positive constant (Theorem 2.6).

In section 3, again for fixed ε, we analyze the regularity of the free boundary and show that, up to a set of zero $\mathcal{H}^{N-1}$ measure, $\partial\{u_\varepsilon > 0\}$ is locally a $C^{1,\beta}$ surface and, in the case $N = 2$, the free boundary has no exceptional points (Theorem 3.1). The proof of this result follows almost exactly the lines in [4], so we note only the significant differences and refer the reader to [4] for further details.

In section 4 we analyze the behavior of the solutions to (P_ε) for small ε. We prove that if $\Gamma_D \neq \emptyset$, the positivity set of the minimizer u_ε has measure α (Theorem 4.1).

Finally, in section 5, we go back to our original problem and show, under some mild assumptions on the solutions ϕ_0 to (P_α), that they are also solutions to (P_ε) for small ε, so they inherit the properties of the solutions to (P_ε) (Theorem 5.1). These extra assumptions are satisfied, for instance, if Ω is a ball (Corollary 5.1). In the general case, without the assumption that $\Gamma_D \neq \emptyset$, we prove that the set of α's for which there is a solution to (P_α) with smooth free boundary is dense in $(0, |\Omega|)$ (Theorem 5.2). Then, we show that the minimizers of (P_ε) converge (up to a subsequence) to a solution to (P_α) (Theorem 5.3). We believe that this last result might be of interest in numerical approximations.

2. The penalized problem. In this section, we consider the penalized problem (P_ε) stated in the introduction and prove the existence of a minimizer and some regularity properties.

THEOREM 2.1. *There exists a solution to the problem (P_ε). Moreover, any such solution u_ε has the following properties:*

(1) *u_ε is locally Lipschitz continuous in Ω.*

(2) *For every $D \subset\subset \Omega$, there exist constants $C, c > 0$ such that for every $x \in D \cap \{u_\varepsilon > 0\}$,*

$$c\,\mathrm{dist}(x, \partial\{u_\varepsilon > 0\}) \leq u_\varepsilon(x) \leq C\,\mathrm{dist}(x, \partial\{u_\varepsilon > 0\}).$$

(3) *For every $D \subset\subset \Omega$, there exists a constant $c > 0$ such that for $x \in \partial\{u > 0\}$ and $B_r(x) \subset D$,*

$$c \leq \frac{|B_r(x) \cap \{u_\varepsilon > 0\}|}{|B_r(x)|} \leq 1 - c.$$

The constants may depend on ε.

The proof will be divided into a series of steps for the reader's convenience.

Proof of existence. Let $(u_n) \subset \mathcal{K}$ be a minimizing sequence for $\mathcal{J}_\varepsilon$. Then $\mathcal{J}_\varepsilon(u_n)$ is bounded and so $\|u_n\|_{H^1(\Omega)} \leq C$. Therefore there exists a subsequence (that we still

call u_n) and a function $u_\varepsilon \in H^1(\Omega)$ such that

$$\begin{aligned} u_n &\rightharpoonup u_\varepsilon \quad \text{weakly in } H^1(\Omega),\\ u_n &\to u_\varepsilon \quad \text{strongly in } L^q(\partial\Omega),\\ u_n &\to u_\varepsilon \quad \text{a.e. } \Omega. \end{aligned}$$

Thus,

$$\begin{aligned} &\|u_\varepsilon\|_{L^q(\Gamma_N)} = 1,\\ &u_\varepsilon = \varphi_0 \quad \text{on} \quad \Gamma_D,\\ &|\{u_\varepsilon > 0\}| \le \liminf_{n\to\infty} |\{u_n > 0\}|, \quad \text{and}\\ &\|u_\varepsilon\|_{H^1(\Omega)} \le \liminf_{n\to\infty} \|u_n\|_{H^1(\Omega)}. \end{aligned}$$

Hence $u_\varepsilon \in \mathcal{K}$ and

$$\mathcal{J}_\varepsilon(u_\varepsilon) \le \liminf_{n\to\infty} \mathcal{J}_\varepsilon(u_n) = \inf_{v\in\mathcal{K}} \mathcal{J}_\varepsilon(v);$$

therefore u_ε is a minimizer of $\mathcal{J}_\varepsilon$ in $\mathcal{K}$. □

Remark 1. Any minimizer u_ε of $\mathcal{J}_\varepsilon$ satisfies the inequality

$$\Delta u - u \ge 0 \quad \text{in } \Omega. \tag{2.1}$$

In fact, this can be seen by performing one-side perturbations. Namely, we let $v = u_\varepsilon - t\varphi$ with $t > 0$ and $\varphi \in C_0^\infty(\Omega)$, $\varphi \ge 0$, to get

$$\int_\Omega \nabla u_\varepsilon \nabla\varphi + u_\varepsilon\varphi \le 0.$$

In the remainder of the section we will remove the subscript ε from the solution of (P_ε).

For the proof of properties (1)–(3), we apply the ideas developed in [4]. To this end, we need a series of lemmas.

LEMMA 2.1. *Let $u \in \mathcal{K}$ be a solution to (P_ε). There exists a constant $C = C(N,\Omega,\varepsilon)$ such that for every ball $B_r \subset\subset \Omega$*

$$\frac{1}{r} \fint_{\partial B_r} u \ge C \quad \textit{implies} \quad u > 0 \quad \textit{in} \quad B_r.$$

Proof. The idea is similar to that of Lemma 3.2 in [4]. Let v be the solution to

$$\begin{cases} v = u & \text{in } \overline{\Omega \setminus B_r},\\ \Delta v = v & \text{in } B_r. \end{cases} \tag{2.2}$$

Then $v \in \mathcal{K}$, $v > 0$ in B_r. We claim that

$$\|u - v\|^2_{H^1(\Omega)} = \|u\|^2_{H^1(\Omega)} - \|v\|^2_{H^1(\Omega)}. \tag{2.3}$$

In fact,

$$\int_{B_r} \nabla v \nabla(v-u) + v(v-u)\,dx = 0$$

since $v - u \in H_0^1(B_r)$. This implies

$$\int_{B_r} \nabla u \nabla v + uv \, dx = \int_{B_r} |\nabla v|^2 + v^2 \, dx. \tag{2.4}$$

This equality implies the claim since $u = v$ in $\Omega \setminus B_r$.

By (2.1), $u \le v$ in B_r. Now, by (2.3), since u is a minimizer and $u = v$ in $\Omega \setminus B_r$, we have

$$\begin{aligned} \int_\Omega |\nabla(u-v)|^2 + (u-v)^2 \, dx &\le -F_\varepsilon(|\{u>0\}|) + F_\varepsilon(|\{v>0\}|) \\ &\le C_\varepsilon \, |\{u=0\} \cap B_r|. \end{aligned} \tag{2.5}$$

Now, as in [4], the idea is to control $|\{u=0\} \cap B_r|$ from above by the left-hand side of (2.5). By replacing $u(x)$ by $u(x_0 + rx)/r$ we can assume that $B_r = B_1(0)$. For $|z| \le \frac{1}{2}$ we consider the change of variables from B_1 into itself such that z becomes the new origin. We call $u_z(x) = u\big((1-|x|)z+x\big)$, $v_z(x) = v\big((1-|x|)z+x\big)$ and define

$$r_\xi = \inf \left\{ r \text{ such that } \frac{1}{8} \le r \le 1 \quad \text{and} \quad u_z(r\xi) = 0 \right\}$$

if this set is nonempty. Observe that this change of variables leaves the boundary fixed.

Now, for almost every $\xi \in \partial B_1$ we have

$$v_z(r_\xi \xi) = \int_{r_\xi}^1 \frac{d}{dr}(u_z - v_z)(r\xi) \, dr \le \sqrt{1 - r_\xi} \left(\int_{r_\xi}^1 |\nabla(u_z - v_z)(r\xi)|^2 \, dr \right)^{1/2}. \tag{2.6}$$

Let us see that

$$v_z(r_\xi \xi) \ge C(N,\Omega)(1 - r_\xi) \fint_{\partial B_1} u. \tag{2.7}$$

In fact, $v_z(r_\xi \xi) = v\big((1-r_\xi)z + r_\xi \xi\big)$, and if $|(1-r_\xi)z + r_\xi \xi| \le \frac{3}{4}$, by the Harnack inequality applied to a solution to $\Delta v - r^2 v = 0$ in B_1 with $r \le 1$,

$$v_z(r_\xi \xi) \ge C_N v(0).$$

Clearly (2.7) follows from

$$v(0) \ge \alpha(N) \fint_{\partial B_1} v = \alpha(N) \fint_{\partial B_1} u. \tag{2.8}$$

But (2.8) is a consequence of the mean value property of solutions to the Schrödinger equation $\Delta v - r^2 v = 0$, namely,

$$v(0) = \frac{1}{J(r)} \fint_{\partial B_1(0)} v,$$

where $J(r) = \Gamma(N/2)(\frac{r}{2})^{1-\frac{N}{2}} I_{\frac{N-2}{2}}(r)$ and $I_{\frac{N-2}{2}}$ is the Bessel function. In particular,

$$J(0) = 1.$$

See Theorem 9.9 in [18] for this result.

Now, if $|(1-r_\xi)z + r_\xi\xi| \geq \frac{3}{4}$, we prove by a comparison argument that inequality (2.7) also holds. In fact, first observe that we can assume that $⨍_{\partial B_1} v = ⨍_{\partial B_1} u = 1$. Then, by (2.8), $v \geq C_N\alpha$ in $B_{3/4}$. Let $w(x) = e^{-\lambda|x|^2} - e^{-\lambda}$. There exists $\lambda = \lambda(N,\alpha)$ such that

$$\begin{cases} \Delta w \geq w & \text{in } B_1 \setminus B_{3/4}, \\ w \leq C_N\alpha & \text{in } \partial B_{3/4}, \\ w = 0 & \text{in } \partial B_1, \end{cases}$$

so that, since $\Delta v \leq v$, there holds that $v \geq w \geq C(1-|x|)$ in $B_1 \setminus B_{3/4}$. Therefore,

$$v_z(r_\xi\xi) \geq C\Big(1 - |(1-r_\xi)z + r_\xi\xi|\Big) ⨍_{\partial B_1} u \geq C(1-r_\xi) ⨍_{\partial B_1} u$$

since $|z| \leq \frac{1}{2}$. Thus (2.7) holds for every $r_\xi \geq \frac{1}{8}$.

By (2.6) and (2.7) we have

$$c\sqrt{1-r_\xi} ⨍_{\partial B_1} u \leq \left(\int_{r_\xi}^1 |\nabla(u_z - v_z)|^2(r\xi)\, dr \right)^{1/2}.$$

Hence

$$\begin{aligned} c^2 \int_{\partial B_1} (1-r_\xi)\, dS_\xi \left(⨍_{\partial B_1} u \right)^2 &\leq \int_{\partial B_1} \int_{r_\xi}^1 |\nabla(u_z - v_z)|^2(r\xi)\, dr\, dS_\xi \\ &\leq C \int_{B_1} |\nabla(u_z - v_z)|^2\, dx. \end{aligned}$$

Since

$$\int_{\partial B_1} (1-r_\xi)\, dS_\xi \geq \int_{B_1 \setminus B_{1/4}(z)} \chi_{\{u=0\}}\, dx,$$

we have

$$\begin{aligned} c^2 |\{x \in B_1 \setminus B_{1/4}(z) \,/\, u(x) = 0\}| \left(⨍_{\partial B_1} u \right)^2 &\leq C \int_{B_1} |\nabla(u_z - v_z)|^2\, dx \\ &\leq K \int_{B_1} |\nabla(u-v)|^2\, dx. \end{aligned}$$

Finally, we integrate over $z \in B_{1/2}(0)$ and use (2.5) to obtain

$$\begin{aligned} |B_1 \cap \{u=0\}| \left(⨍_{\partial B_1} u \right)^2 &\leq K \int_{B_1} |\nabla(u-v)|^2\, dx \\ &\leq K C_\varepsilon |B_1 \cap \{u=0\}|. \end{aligned} \tag{2.9}$$

Therefore we either have $u > 0$ a.e. in B_1 or else $⨍_{\partial B_1} u \leq \sqrt{KC_\varepsilon}$.

Hence we deduce that if

$$⨍_{\partial B_1} u \geq \sqrt{KC_\varepsilon} = C(N, \Omega, \varepsilon),$$

then $|B_1 \cap \{u = 0\}| = 0$. Thus by (2.5) $u = v > 0$ in B_1. □

Now we can prove the Lipschitz continuity of the minimizer u.

Proof of Theorem 2.1(1). The proof follows as in [4, Lemma 3.3]. In fact, let $D \subset\subset D' \subset\subset \Omega$ and $x \in D$. Let $r > 0$ be the largest number such that $B_r(x) \subset \{u > 0\} \cap D'$. As in [4] we prove by using Lemma 2.1 that $\{u > 0\}$ is open and

$$\frac{1}{r} \fint_{\partial B_r(x)} u \leq C$$

with C independent of either u or x. Since $u > 0$ in $B_r(x)$, it is a solution to

$$\Delta u = u \quad \text{in } B_r(x).$$

In fact, let v be the solution to $\Delta v = v$ in $B_r(x)$, $v = u$ on $\Omega \setminus B_r(x)$. Then,

$$0 \leq \|u - v\|^2_{H^1(\Omega)} = \|u\|^2_{H^1(\Omega)} - \|v\|^2_{H^1(\Omega)} = \mathcal{J}_\varepsilon(u) - \mathcal{J}_\varepsilon(v) \leq 0.$$

Thus, $u = v$ in $B_r(x)$.

Hence, there is a universal constant such that

$$|\nabla u(x)| \leq C \left\{ r\|u\|_{L^\infty(B_r(x))} + \frac{1}{r} \fint_{\partial B_r(x)} u \right\}.$$

Now, since u is subharmonic in Ω and $D' \subset\subset \Omega$, there holds that u is bounded in D' by a constant that depends on the H^1 norm of u in Ω, which is bounded by a constant that depends only on Ω and ε. Therefore,

$$|\nabla u(x)| \leq C$$

with C depending only on N, Ω, ε, D, and D'. □

In order to prove the nondegeneracy of u we need the following lemma (see [4, Lemma 3.4]).

LEMMA 2.2. *Let $u \in \mathcal{K}$ be a solution to (P_ε). For $0 < \kappa < 1$ there exists a constant $c = c(\kappa, N, \Omega, \varepsilon)$ such that for every ball $B_r(x_0) \subset\subset \Omega$,*

$$\frac{1}{r} \fint_{\partial B_r} u \leq c \quad \textit{implies that} \quad u = 0 \quad \textit{in} \quad B_{\kappa r}.$$

Proof. As in [4, Lemma 3.4], we consider the function

$$\phi_s^N(x) = \begin{cases} \dfrac{s}{N-2} \left(\left(\dfrac{s}{|x|} \right)^{N-2} - 1 \right) & \text{for} \quad N \geq 3, \\ s \log \dfrac{s}{|x|} & \text{for} \quad N = 2, \\ s - |x| & \text{for} \quad N = 1. \end{cases} \tag{2.10}$$

For simplicity let us take $\bar{u}(x) = \dfrac{1}{r} u(x_0 + rx)$,

$$\bar{F}_\varepsilon(s) = \begin{cases} \dfrac{1}{\varepsilon} \left(s - \dfrac{\alpha}{r^N} \right) & \text{if } s > \dfrac{\alpha}{r^N}, \\ \varepsilon \left(s - \dfrac{\alpha}{r^N} \right) & \text{if } s \leq \dfrac{\alpha}{r^N}, \end{cases}$$

and

$$\bar{\mathcal{J}}_\varepsilon(w) = \int_{\Omega^r} |\nabla w|^2 + r^2 w^2 + \bar{F}_\varepsilon(|\{w > 0\}|),$$

where $\Omega^r = \frac{1}{r}(\Omega - x_0)$. Thus, $\mathcal{J}_\varepsilon(u) = r^N \bar{\mathcal{J}}_\varepsilon(\bar{u})$.

Now, let $v(x) = \frac{\gamma\sqrt{\kappa}}{-\phi_\kappa^N(\sqrt{\kappa})} \max(-\phi_\kappa^N(x), 0)$, where, since $\bar{u}$ is subharmonic,

$$\gamma := \frac{1}{\sqrt{\kappa}} \sup_{B_{\sqrt{\kappa}}} \bar{u} \le C_1(N,\kappa) \fint_{\partial B_1} \bar{u} = C_1(N,\kappa) \frac{1}{r} \fint_{\partial B_r(x_0)} u.$$

Hence, $v \ge \bar{u}$ on $\partial B_{\sqrt{\kappa}}$, and therefore if

$$w = \begin{cases} \min(\bar{u}, v) & \text{in} \quad B_{\sqrt{\kappa}}, \\ \bar{u} & \text{in} \quad \Omega^r \setminus B_{\sqrt{\kappa}}, \end{cases}$$

there holds that

$$\begin{aligned}
&\int_{B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \, dx + |B_\kappa \cap \{\bar{u} > 0\}| \\
&\quad = \bar{\mathcal{J}}_\varepsilon(\bar{u}) - \int_{\Omega^r \setminus B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \, dx + |B_\kappa \cap \{\bar{u} > 0\}| - \bar{F}_\varepsilon(|\{\bar{u} > 0\}|) \\
&\quad \le \bar{\mathcal{J}}_\varepsilon(w) - \int_{\Omega^r \setminus B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \, dx + |B_\kappa \cap \{\bar{u} > 0\}| - \bar{F}_\varepsilon(|\{\bar{u} > 0\}|) \\
&\quad = \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla w|^2 + r^2 w^2 \, dx - \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \, dx + |B_\kappa \cap \{\bar{u} > 0\}| \\
&\qquad\qquad + \bar{F}_\varepsilon(|\{w > 0\}|) - \bar{F}_\varepsilon(|\{\bar{u} > 0\}|) \\
&\quad \le \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla w|^2 + r^2 w^2 \, dx - \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \, dx + (1 - \varepsilon) \, |B_\kappa \cap \{\bar{u} > 0\}|,
\end{aligned}$$

since $w = 0$ in B_κ, $w = \bar{u}$ in $\Omega^r \setminus B_{\sqrt{\kappa}}$. We have also used that $\bar{F}_\varepsilon(A) - \bar{F}_\varepsilon(B) \ge \varepsilon(A - B)$ if $A \ge B$ and $\{w > 0\} \subset \{\bar{u} > 0\}$. This inclusion follows from the fact that $w \le \bar{u}$. Thus,

$$\begin{aligned}
&\int_{B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \, dx + \varepsilon |B_\kappa \cap \{\bar{u} > 0\}| \\
&\quad \le \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla w|^2 + r^2 w^2 \, dx - \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla \bar{u}|^2 + r^2 \bar{u}^2 \\
&\quad = \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} |\nabla \bar{u} - \nabla(\bar{u} - v)^+|^2 - |\nabla \bar{u}|^2 \, dx + r^2 \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} \left(\bar{u} - (\bar{u} - v)^+\right)^2 - \bar{u}^2 \, dx \\
&\quad = -\int_{B_{\sqrt{\kappa}} \setminus B_\kappa} \nabla(\bar{u} - v)^+ \nabla(\bar{u} + v) \, dx - r^2 \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} (\bar{u} - v)^+ (\bar{u} + v) \, dx \\
&\quad = -\int_{B_{\sqrt{\kappa}} \setminus B_\kappa} \nabla(\bar{u} - v)^+ \nabla \bar{u} \, dx - r^2 \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} (\bar{u} - v)^+ \bar{u} \, dx \\
&\qquad\quad - \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} \nabla(\bar{u} - v)^+ \nabla v \, dx - r^2 \int_{B_{\sqrt{\kappa}} \setminus B_\kappa} (\bar{u} - v)^+ v \, dx
\end{aligned}$$

$$\leq -2\int_{B_{\sqrt{\kappa}}\setminus B_\kappa} \nabla(\bar{u}-v)^+\nabla v\,dx - 2r^2\int_{B_{\sqrt{\kappa}}\setminus B_\kappa}(\bar{u}-v)^+ v\,dx$$
$$\leq 2\int_{\partial B_\kappa}\bar{u}\nabla v\,\eta\,dS \leq C_2(N,\kappa)\,\gamma\int_{\partial B_\kappa}\bar{u}.$$

Therefore,

$$\int_{B_\kappa}|\nabla\bar{u}|^2 + r^2\bar{u}^2\,dx + \varepsilon|B_\kappa\cap\{\bar{u}>0\}| \leq C_2(N,\kappa)\,\gamma\int_{\partial B_\kappa}\bar{u}. \tag{2.11}$$

Here we have used that $\min(\bar{u},v) = \bar{u}-(\bar{u}-v)^+$, $\Delta v = 0$ in $B_{\sqrt{\kappa}}\setminus B_\kappa$, $v=0$ on ∂B_κ, and $(\bar{u}-v)^+ = 0$ on $\partial B_{\sqrt{\kappa}}$.

Recall that γ is controlled by $\frac{1}{r}⨍_{\partial B_r(x_0)}u$; thus γ will be small if $\frac{1}{r}⨍_{\partial B_r(x_0)}u$ is small.

On the other hand, by standard estimates,

$$\begin{aligned}\int_{\partial B_\kappa}\bar{u} &\leq C_3(N,\kappa)\int_{B_\kappa}|\nabla\bar{u}|+\bar{u}\,dx\\ &\leq C_3(N,\kappa)\Big\{\frac{1}{2}\int_{B_\kappa}|\nabla\bar{u}|^2\,dx + \frac{1}{2}|B_\kappa\cap\{\bar{u}>0\}| + \gamma|B_\kappa\cap\{\bar{u}>0\}|\Big\}\\ &\leq C_3(N,\kappa)\Big\{\int_{B_\kappa}|\nabla\bar{u}|^2 + r^2\bar{u}^2\,dx + |B_\kappa\cap\{\bar{u}>0\}|\Big\}\end{aligned}$$

if $\gamma \leq 1/2$.

Thus, by (2.11), if γ is small enough ($\gamma \leq 1/2$ and $C_2(N,\kappa)C_3(N,\kappa)\gamma < 1$), we deduce that $|B_\kappa\cap\{\bar{u}>0\}| = 0$. That is, $u=0$ in $B_{r\kappa}(x_0)$ and the lemma is proved. □

We can now prove the nondegeneracy of u.

Proof of Theorem 2.1(2). Let $x\in\{u>0\}$ and $r = \operatorname{dist}(x,\{u=0\})$. As we proved in (2.8), since $\Delta u = u$ in $B_r(x)$, there holds that

$$u(x) \geq \alpha(N)⨍_{\partial B_r(x)}u.$$

Since $u(x)>0$,

$$\frac{1}{r}⨍_{\partial B_r(x)}u \geq c,$$

where c is the constant in Lemma 2.2 for $\kappa = 1/2$. Thus,

$$u(x) \geq c\alpha\, r.$$

The upper bound clearly follows from the Lipschitz continuity of u. Hence (2) is proved. □

Proof of Theorem 2.1(3). In order to prove the uniform positive density of $\{u>0\}$ and $\{u=0\}$ at every free boundary point we proceed as in [4, Lemma 3.7]. The only difference is that the function v that we have to take is the one in (2.2).

This ends the proof of Theorem 2.1. □

COROLLARY 2.1. *Let $u \in \mathcal{K}$ be a solution to (P_ε). Let $D \subset\subset \Omega$. There exist constants $c, C > 0$ depending only on N, Ω, D, and ε such that for $B_r(x) \subset D$ and $x \in \partial\{u > 0\}$,*

$$c \leq \frac{1}{r} \fint_{\partial B_r(x)} u \leq C. \tag{2.12}$$

Proof. The proof follows easily from Lemmas 2.1 and 2.2. ∎

LEMMA 2.3. *Let $u \in \mathcal{K}$ be a solution to (P_ε). Then u satisfies, for every $\varphi \in C_0^\infty(\Omega)$ such that $\operatorname{supp}\varphi \subset \{u > 0\}$,*

$$\int_\Omega \nabla u \nabla \varphi + u\varphi \, dx = 0. \tag{2.13}$$

Moreover, the application

$$\lambda(\varphi) := -\int_\Omega \nabla u \nabla \varphi + u\varphi \, dx$$

from $C_0^\infty(\Omega)$ into $\mathbb{R}$ defines a nonnegative Radon measure with support on $\Omega \cap \partial\{u > 0\}$.

Proof. The proof follows exactly as in [4, Lemma 4.2]. ∎

THEOREM 2.2. *Let $u \in \mathcal{K}$ be a solution to (P_ε). Let $D \subset\subset \Omega$. Then there exist constants $C, c > 0$ such that for $B_r(x) \subset D$ and $x \in \partial\{u > 0\}$,*

$$c\, r^{N-1} \leq \int_{B_r(x)} d\lambda \leq C\, r^{N-1}.$$

Proof. For n large enough, let $u_n = u * \rho_n$, where ρ_n are the standard mollifiers. Then

$$\begin{aligned}\int_{B_r(x)} \lambda * \rho_n \, dx &= \int_{B_r(x)} \Delta u_n - u_n \, dx = \int_{\partial B_r(x)} \nabla u_n \cdot \nu \, dS - \int_{B_r(x)} u_n \\ &\leq \omega_{N-1} \sup_{\partial B_r(x)} |\nabla u_n| \, r^{N-1} \leq C\, r^{N-1}\end{aligned}$$

since $|\nabla u_n| \leq |\nabla u| \leq C$ for a certain constant C depending on D. By taking the limit for $n \to \infty$ we get

$$\int_{B_r(x)} d\lambda \leq C\, r^{N-1}.$$

The other inequality follows as in the proof of Theorem 4.3 in [4] by taking as $G_y(z)$ the (positive) Green function of $-\Delta + Id$ with homogeneous Dirichlet boundary conditions in the ball $B_r(x)$. Then for $0 < \kappa < 1/2$ and $y \in B_{\kappa r}(x)$ one uses the inequality

$$v(y) \geq Cv(x) \geq C\alpha \fint_{\partial B_r(x)} u$$

for v the solution to $\Delta v - v = 0$ in $B_r(x)$, $v = u$ on $\partial B_r(x)$, which follows from the Harnack inequality and (2.8). ∎

THEOREM 2.3 (representation theorem). *Let $u \in \mathcal{K}$ be a solution to (P_ε). Then*

(1) $\mathcal{H}^{N-1}(D \cap \partial\{u > 0\}) < \infty$ *for every* $D \subset\subset \Omega$.
(2) *There exists a Borel function* q_u *such that*

$$\Delta u - u = q_u \, \mathcal{H}^{N-1} \lfloor \partial\{u > 0\}.$$

(3) *For* $D \subset\subset \Omega$ *there are constants* $0 < c \le C < \infty$ *depending on* N, Ω, D, *and the constants in* (2.12) *such that for* $B_r(x) \subset D$ *and* $x \in \partial\{u > 0\}$,

$$c \le q_u(x) \le C, \quad c\, r^{N-1} \le \mathcal{H}^{N-1}(B_r(x) \cap \partial\{u > 0\}) \le C\, r^{N-1}.$$

Proof. The proof follows exactly as in Theorem 4.5 in [4]. □

Remark 2. Let $u \in \mathcal{K}$ be a solution to (P_ε) and let $D \subset\subset \Omega$. Then $D \cap \partial\{u > 0\}$ has finite perimeter. Thus, the reduced boundary $\partial_{\mathrm{red}}\{u > 0\}$ is defined as well as the measure theoretic normal $\nu(x)$ for $x \in \partial_{\mathrm{red}}\{u > 0\}$. See [8].

If the free boundary $\partial\{u > 0\}$ is a regular surface, then $q_u = -\partial_\nu u$. In Theorem 2.4 it is shown that this is true for almost all points in the reduced boundary.

PROPOSITION 2.1. *Let* $u \in \mathcal{K}$ *be a solution to* (P_ε) *and let* $B_{\rho_k}(x_k) \subset \Omega$ *be a sequence of balls with* $\rho_k \to 0$, $x_k \to x_0 \in \Omega$, *and* $u(x_k) = 0$. *Let*

$$u_k(x) := \frac{1}{\rho_k} u(x_k + \rho_k x).$$

We call u_k *a blow-up sequence with respect to* $B_{\rho_k}(x_k)$. *Since* u *is locally Lipschitz continuous, there exists a blow-up limit* $u_0 : \mathbb{R}^N \to \mathbb{R}$ *satisfying* (2.12) *with the same constants, when* $x_k \in \partial\{u > 0\}$ *and such that for a subsequence,*

$$\begin{aligned}
&u_k \to u_0 \quad \text{in} \quad C^\alpha_{\mathrm{loc}}(\mathbb{R}^N) \quad \text{for every} \quad 0 < \alpha < 1,\\
&\nabla u_k \to \nabla u_0 \quad \text{weakly}\star \text{ in} \quad L^\infty_{\mathrm{loc}}(\mathbb{R}^N),\\
&\partial\{u_k > 0\} \to \partial\{u_0 > 0\} \quad \text{locally in Hausdorff distance},\\
&\chi_{\{u_k > 0\}} \to \chi_{\{u_0 > 0\}} \quad \text{in} \quad L^1_{\mathrm{loc}}(\mathbb{R}^N),\\
&\Delta u_0 = 0 \quad \text{in} \quad \{u_0 > 0\}.
\end{aligned}$$

Moreover, if $x_k \in \partial\{u > 0\}$, *then* $0 \in \partial\{u_0 > 0\}$.

Proof. The proof follows as in [4, section 4.7], observing that $\Delta u_k - \rho_k^2 u_k = 0$ in $\{u_k > 0\}$. □

THEOREM 2.4 (identification of q_u). *Let* $u \in \mathcal{K}$ *be a solution to* (P_ε). *Then, for almost every* $x_0 \in \partial_{\mathrm{red}}\{u > 0\}$,

$$u(x_0 + x) = q_u(x_0) \langle x, \nu(x_0) \rangle^- + o(|x|) \quad \text{for} \quad x \to 0$$

with $\nu(x_0)$ *the outward unit normal de* $\partial\{u > 0\}$ *in the measure theoretic sense.*

Proof. The proof follows exactly as in Theorem 4.8 and Remark 4.9 in [4]. □

Remark 3. Observe that by Theorem 2.1(3)

$$\mathcal{H}^{N-1}(\partial\{u > 0\} \setminus \partial_{\mathrm{red}}\{u > 0\}) = 0.$$

See [8].

Now we get a more precise identification of q_u.

THEOREM 2.5. *Let* $u \in \mathcal{K}$ *be a solution to* (P_ε) *and let* q_u *be the function in Theorem* 2.4. *Then there exists a constant* λ_u *such that*

$$\limsup_{\substack{x \to x_0 \\ u(x) > 0}} |\nabla u(x)| = \lambda_u \qquad \text{for every } x_0 \in \Omega \cap \partial\{u > 0\}, \tag{2.14}$$

$$q_u(x_0) = \lambda_u, \qquad \mathcal{H}^{N-1} \text{ a.e. } x_0 \in \Omega \cap \partial\{u > 0\}. \tag{2.15}$$

Moreover, if B is a ball contained in $\{u = 0\}$ touching the boundary $\partial\{u > 0\}$ at x_0, then

$$\limsup_{\substack{x \to x_0 \\ u(x)>0}} \frac{u(x)}{\operatorname{dist}(x, B)} = \lambda_u. \tag{2.16}$$

Proof. We follow the ideas of [2, Theorem 3] and [16, Theorem 5.1 and Lemma 5.2].

Let $x_0, x_1 \in \partial\{u > 0\}$ and $\rho_k \to 0^+$. For $i = 0, 1$, let $x_{i,k} \to x_i$ with $u(x_{i,k}) = 0$ such that $B_{\rho_k}(x_{i,k}) \subset \Omega$ and such that the blow-up sequence

$$u_{i,k}(x) = \frac{1}{\rho_k} u(x_{i,k} + \rho_k x)$$

has a limit $u_i(x) = \lambda_i \langle x, \nu_i \rangle^-$, with $0 < \lambda_i < \infty$ and ν_i a unit vector. We will prove that $\lambda_0 = \lambda_1$. From this, the theorem will follow as in [16].

Assume that $\lambda_1 < \lambda_0$. Then we will perturb the minimizer u near x_0 and x_1 and get an admissible function with less energy, which is a contradiction. We perform a perturbation that increases the measure of the positivity set in a neighborhood of $x_{0,k}$ and decreases its measure in a neighborhood of $x_{1,k}$. We perform this perturbation in such a way that we change the measure of the positivity set in an amount of essentially order $o(\rho_k^N)$.

To this end, we take a nonnegative C_0^∞ symmetric function Φ supported in the unit interval and for $t > 0$ small, we define

$$\tau_k(x) = \begin{cases} x + t\rho_k \Phi\Big(\dfrac{|x - x_{0,k}|}{\rho_k}\Big)\nu_0 & \text{for } x \in B_{\rho_k}(x_{0,k}), \\ x - t\rho_k \Phi\Big(\dfrac{|x - x_{1,k}|}{\rho_k}\Big)\nu_1 & \text{for } x \in B_{\rho_k}(x_{1,k}), \\ x & \text{elsewhere,} \end{cases}$$

which is a diffeomorphism if t is small enough. Now, let

$$v_k(x) = u(\tau_k^{-1}(x)),$$

which are admissible functions. Moreover, since $\|D\tau_k^{-1}\| \le C$ independent of k for t small enough, there holds that

$$\|\nabla v_k\|_{L^\infty} \le C$$

independent of k.

Also, we have

$$F_\varepsilon(|\{v_k > 0\}|) - F_\varepsilon(|\{u > 0\}|) = o(t)\, \rho_k^N + o(\rho_k^N). \tag{2.17}$$

In fact, $v_k = u$ in $\Omega \setminus (B_{\rho_k}(x_{0,k}) \cup B_{\rho_k}(x_{1,k}))$ and

$$|\{v_k > 0\} \cap B_{\rho_k}(x_{i,k})| - |\{u > 0\} \cap B_{\rho_k}(x_{i,k})| = \\ = (-1)^i\, \rho_k^N \Big(t \int_{B_1 \cap \{y_1 = 0\}} \Phi(|y|)\, d\mathcal{H}_y^{N-1} + o_i(t) \Big) + o(\rho_k^N),$$

since $\Phi(|y|)$ is radially symmetric and $\chi_{\{u_{i,k}>0\}} \to \chi_{\{\langle x,\nu_i\rangle<0\}}$ in $L^1_{\rm loc}(\mathbb{R}^N)$.

Similar computations that also involve the development of ∇v_k in terms of ∇u and $D\tau_k$ give

$$\begin{aligned}\int_\Omega |\nabla v_k|^2\,dx - \int_\Omega |\nabla u|^2\,dx \\ = \rho_k^N\Big((\lambda_1^2-\lambda_0^2)\,t\int_{B_1(0)\cap\{y_1=0\}}\Phi(|y|)\,d\mathcal{H}_y^{N-1}+o(t)\Big)+o(\rho_k^N).\end{aligned} \tag{2.18}$$

See [2] or [16] for detailed computations.

It remains to estimate the difference of the L^2 norms. Since $u(x_{i,k})=0$ there holds that

$$u(x)\le C\rho_k^N \quad \text{in } B_{\rho_k}(x_{i,k}).$$

On the other hand,

$$0=u(x_{i,k})=v_k(\tau_k(x_{i,k}))=v_k(x_{i,k}+(-1)^i\,t\rho_k\Phi(0)\nu_i).$$

Thus,

$$v_k(z)\le C\big|z-x_{i,k}-(-1)^i\,t\rho_k\Phi(0)\nu_i\big|\le K\rho_k \quad \text{if } z\in B_{\rho_k}(x_{i,k}).$$

Therefore,

$$\int_\Omega v_k^2\,dx-\int_\Omega u^2\,dx=o(\rho_k^N). \tag{2.19}$$

Thus, we get from (2.17), (2.18), and (2.19), for t small enough and k large enough, that

$$\mathcal{J}_\varepsilon(v_k)<\mathcal{J}_\varepsilon(u),$$

a contradiction. □

Summing up, we have the following theorem,

THEOREM 2.6. *Let $u\in\mathcal{K}$ be a solution to (P_ε). Then u is a weak solution to the free boundary problem*

$$\begin{aligned}-\Delta u+u&=0 && \text{in } \{u>0\}\cap\Omega,\\ \frac{\partial u}{\partial\nu}&=\lambda_u && \text{on } \partial\{u>0\}\cap\Omega,\end{aligned}$$

where λ_u is the constant in Theorem 2.5. More precisely, $\mathcal{H}^{N-1}$ a.e. point $x_0\in\partial\{u>0\}$ belongs to $\partial_{red}\{u>0\}$ and

$$u(x_0+x)=\lambda_u\langle x,\nu(x_0)\rangle^-+o(|x|) \quad \text{for } x\to 0.$$

Finally, we get an estimate of the gradient of u that will be needed in order to get the regularity of the free boundary.

THEOREM 2.7. *Let $u\in\mathcal{K}$ be a solution to (P_ε). Given $D\subset\subset\Omega$, there exist constants $C=C(N,\varepsilon,D)$, $r_0=r_0(N,D)>0$, and $\gamma=\gamma(N,\varepsilon,D)>0$ such that if $x_0\in D\cap\partial\{u>0\}$ and $r<r_0$, then*

$$\sup_{B_r(x_0)}|\nabla u|\le\lambda_u(1+Cr^\gamma).$$

Proof. The proof follows the lines of the proof of Theorem 4.1 in [5].

Let $U_k = \left(|\nabla u| - \lambda_u - \frac{1}{k}\right)^+$ and $U_0 = \left(|\nabla u| - \lambda_u\right)^+$. By (2.14) we know that U_k vanishes in a neighborhood of the free boundary. Also, the support of U_k is contained in $\{u > 0\}$. Therefore U_k satisfies

$$\Delta U_k \geq U_k \quad \text{in } \Omega \cap \{u > 0\}$$

and vanishes in a neighborhood of the free boundary. We extend U_k by zero into $\{u = 0\}$ and set

$$h_k(r) = \sup_{B_r(x_0)} U_k, \qquad h_0(r) = \sup_{B_r(x_0)} U_0$$

for any $r < r_0 = \operatorname{dist}(D, \partial\Omega)$ and $x_0 \in D \cap \partial\{u > 0\}$.

Then, $h_k(r) - U_k$ is a supersolution of $\Delta v = v$ in the ball $B_r(x_0)$ and

$$\begin{aligned} h_k(r) - U_k &\geq 0 && \text{in } B_r(x_0) \\ &= h_k(r) && \text{in } B_r(x_0) \cap \{u = 0\}. \end{aligned}$$

Applying the weak Harnack inequality (see [12, p. 246]) with $1 \leq p < N/(N-2)$, we get

$$\inf_{B_{r/2}(x_0)} \left(h_k(r) - U_k\right) \geq cr^{-N/p} \|h_k(r) - U_k\|_{L^p(B_r(x_0))} \geq c h_k(r),$$

since, by Theorem 2.1(3), $|B_r(x_0) \cap \{u = 0\}| \geq cr^N$. Taking now $k \to \infty$ we obtain

$$\inf_{B_{r/2}(x_0)} \left(h_0(r) - U_0\right) \geq c h_0(r)$$

for some $0 < c < 1$, which is the same as

$$\sup_{B_{r/2}(x_0)} U_0 \leq (1 - c) h_0(r).$$

Therefore

$$h_0\left(\frac{r}{2}\right) \leq (1 - c) h_0(r),$$

from which it follows that $h_0(r) \leq Cr^\gamma$ for some $C > 0$, $0 < \gamma < 1$, and now the conclusion of the theorem follows. □

3. Regularity of the free boundary. At this point we have that our minimizer u_ε meets the conditions of the regularity theory developed in [4], the only difference being the equation satisfied by u_ε in $\{u_\varepsilon > 0\}$.

We recall some definitions and point out the only significant difference with [4]. The rest of the proof of the regularity then follows as sections 7 and 8 of [4] with only minor modifications.

Throughout this section we remove the subscript ε.

DEFINITION 3.1 (flat free boundary points). *Let $0 < \sigma_+, \sigma_- \leq 1$ and $\tau > 0$. We say that u is of class*

$$F(\sigma_+, \sigma_-; \tau) \quad \textit{in} \quad B_\rho = B_\rho(0)$$

if

(1) $0 \in \partial\{u > 0\}$ *and*

$$\begin{aligned} u &= 0 && \text{for} \quad x_N \geq \sigma_+\rho, \\ u(x) &\geq -\lambda(x_N + \sigma_-\rho) && \text{for} \quad x_N \leq -\sigma_-\rho; \end{aligned}$$

(2) $|\nabla u| \leq \lambda(1+\tau)$ *in* B_ρ.

If the origin is replaced by x_0 *and the direction* e_N *by the unit vector* ν, *we say that* u *is of class* $F(\sigma_+, \sigma_-; \tau)$ *in* $B_\rho(x_0)$ *in direction* ν.

Observe that the results in section 2 imply that the minimizer u of $\mathcal{J}_\varepsilon$ is in the class $F(\sigma, 1; \sigma)$ in $B_\rho(x_0)$ in direction $\nu_u(x_0)$ for every $x_0 \in \partial_{red}\{u > 0\}$ with $\sigma = \sigma(\rho) \to 0$ as $\rho \to 0$.

The following lemma (Lemma 7.2 in [4]) is the only one that requires a nonobvious modification.

LEMMA 3.1. *There is a constant* $C = C(N)$ *such that* $u \in F(\sigma, 1; \sigma)$ *in* $B_\rho(x_0)$ *in direction* ν *implies* $u \in F(2\sigma, C\sigma; \sigma)$ *in* $B_{\rho/2}(x_0)$ *in direction* ν.

Proof. Clearly, by a change of variables, we may assume that $x_0 = 0$ and $\nu = e_N$. Let $\bar{u}(x) = u(\rho x)/\lambda\rho$; then $|\nabla \bar{u}| \leq 1 + \sigma$ and $\bar{u} \in F(\sigma, 1; \sigma)$ in B_1. That is, $\bar{u} = 0$ if $x_N > \sigma$. Define

$$\eta(x') = \begin{cases} \exp\left(-\dfrac{9|x'|^2}{1 - 9|x'|^2}\right) & \text{for } |x'| < \frac{1}{3}, \\ 0 & \text{otherwise} \end{cases}$$

and choose $s \geq 0$ maximal with the property that $\bar{u} = 0$ in $x_N > \sigma - s\eta(x')$.

Now, the proof follows as in Lemma 7.2 of [4] with the only difference being that the comparison function v must be the solution to $\Delta v = \rho^2 \bar{u}$ in $D = B_1 \cap \{x_N < \sigma - s\eta(x')\}$ instead of a harmonic function. The estimate

$$\partial_{-\nu} v \leq 1 + C\sigma$$

follows from

$$|\nabla(v + x_N)| \leq C\Big[\sup_D (v + x_N) + \rho^2\Big] \leq C\sigma$$

in $D \cap B_{1/2}$ if $\rho^2 \leq C\sigma$, since

$$\Delta(v + x_N) = \rho^2 \bar{u} \qquad \text{in } D,$$

$v + x_N \leq C\sigma$ in D, and $|\bar{u}(x)| \leq 2$. □

Once this lemma is established the following regularity result follows.

THEOREM 3.1. *Let* $u \in \mathcal{K}$ *be a solution to* (P_ε). *Then* $\partial_{red}\{u > 0\}$ *is a* $C^{1,\beta}$ *surface locally in* Ω, *and the remainder of the free boundary has zero* $\mathcal{H}^{N-1}$ *measure. Moreover, if* $N = 2$, *then the whole free boundary is a* $C^{1,\beta}$ *surface.*

4. Behavior of the minimizer for small ε. To complete the analysis of the problem, we now show that if ε is small enough, then

$$|\{u_\varepsilon > 0\}| = \alpha.$$

To this end, we need to prove that the constant $\lambda_\varepsilon := \lambda_{u_\varepsilon}$ is bounded from above and below by positive constants independent of ε. We perform this task in a series of lemmas.

LEMMA 4.1. *Let $u_\varepsilon \in \mathcal{K}$ be a solution to (P_ε). Then there exist constants $C, c > 0$ independent of ε such that*

$$c \le |\{u_\varepsilon > 0\}| \le \alpha + C\varepsilon. \tag{4.1}$$

Proof. As $\mathcal{J}_\varepsilon(u_\varepsilon)$ is bounded from above uniformly in ε we obtain

$$F_\varepsilon(|\{u_\varepsilon > 0\}|) \le C.$$

Hence

$$|\{u_\varepsilon > 0\}| \le \alpha + C\varepsilon.$$

For the lower bound, we proceed as follows: by the Sobolev trace embedding, for some $1 < p < 2$ such that $p(N-1)/(N-p) > q$,

$$1 \le \|u_\varepsilon\|_{L^q(\partial\Omega)} \le C\|u_\varepsilon\|_{W^{1,p}(\Omega)} \le C\|u_\varepsilon\|_{H^1(\Omega)}|\{u_\varepsilon > 0\}|^\theta$$

for some exponent θ that depends only on p. Since $\|u_\varepsilon\|_{H^1(\Omega)}$ is uniformly bounded, the lower bound follows. ∎

LEMMA 4.2. *Let $u_\varepsilon \in \mathcal{K}$ be a solution to (P_ε). Then there exists a constant $C > 0$ independent of ε such that*

$$\lambda_\varepsilon := \lambda_{u_\varepsilon} \le C.$$

Proof. Let $D \subset\subset \Omega$ smooth, such that $\omega = |D| > \alpha$ and $|\Omega \setminus D| < c$, where c is the constant in Lemma 4.1. Then,

$$|D \cap \{u_\varepsilon > 0\}| \le \alpha + C\varepsilon < \omega$$

for ε small enough. On the other hand,

$$|D \cap \{u_\varepsilon > 0\}| \ge |\{u_\varepsilon > 0\}| - |\Omega \setminus D| \ge c - |\Omega \setminus D| > 0.$$

Therefore by the relative isoperimetric inequality, we have

$$\mathcal{H}^{N-1}(D \cap \partial\{u_\varepsilon > 0\}) \ge c_0 \min\{|D \cap \{u_\varepsilon > 0\}|, |D \cap \{u_\varepsilon = 0\}|\}^{\frac{N-1}{N}} \ge c_1 > 0.$$

Now take $\varphi \in C_0^\infty(\Omega)$ as a test function in Lemma 2.3 such that $0 \le \varphi \le 1$, $\varphi \equiv 1$ in D, and $\|\nabla\varphi\|_\infty \le C = C(\operatorname{dist}(D, \partial\Omega))$ to get, since $\|u_\varepsilon\|_{H^1(\Omega)}$ is bounded independently of ε,

$$C \ge \int_\Omega \nabla u^\varepsilon \nabla\varphi \, dx + \int_\Omega u_\varepsilon \varphi \, dx = \lambda_\varepsilon(\varphi) \ge \lambda_\varepsilon \mathcal{H}^{N-1}(D \cap \partial_{\mathrm{red}}\{u_\varepsilon > 0\}).$$

This completes the proof of the lemma. ∎

The proof of the uniform lower bound follows similarly to Lemma 6 in [2]. We only make a sketch of the proof for the reader's convenience. It is at this point where we need the hypothesis that $\Gamma_D \ne \emptyset$.

LEMMA 4.3. *Let $\Gamma_D \ne \emptyset$ be the closure of a relatively open subset of $\partial\Omega$. Let $\varphi_0 \in H^1(\Omega)$ with $\varphi_0 \ge c_0 > 0$ in Γ_D. Let $u_\varepsilon \in \mathcal{K}$ be a solution to (P_ε). Then*

(1) *u_ε is positive in a neighborhood of Γ_D (depending on ε);*

(2) *there exists a constant* $c > 0$ *independent of* ε *such that*

$$c < \lambda_\varepsilon := \lambda_{u_\varepsilon}.$$

Proof. Let us first prove (1). In fact, arguing as in (2.9), given $y_0 \in \Gamma_D$ there exists a constant $K > 0$ independent of ε such that

$$|\Omega_r \cap \{u = 0\}| \left(\frac{1}{r} \fint_{\partial\Omega_r} u \right)^2 \leq K \int_{\Omega_r} |\nabla(u - v)|^2 \, dx,$$

where $\Omega_r = \Omega \cap B_r(y_0)$ and v is the solution of

$$\begin{cases} \Delta v = v & \text{in } \Omega_r, \\ v = u & \text{on } \partial\Omega_r. \end{cases}$$

Therefore,

$$\left(\frac{c_0}{r} \right)^2 |\Omega_r \cap \{u = 0\}| \leq K(\|u\|^2_{H^1(\Omega_r)} - \|v\|^2_{H^1(\Omega_r)}) \leq \frac{C}{\varepsilon} |\Omega_r \cap \{u = 0\}|.$$

Thus, $u > 0$ in Ω_r for small r depending on ε.

In order to see (2) we proceed as in [2, Lemma 6]. Let $y_0 \in \Gamma_D$ and let D_t with $0 \leq t \leq 1$ be a family of open sets with smooth boundary and uniformly (in ε and t) bounded curvatures such that D_0 is an exterior tangent ball at y_0, D_1 contains a free boundary point, $D_t \cap \partial\Omega \subset \Gamma_D$, and $D_0 \subset\subset D_t$ for $t > 0$.

Let $t \in (0, 1)$ be the first time that D_t touches the free boundary and let $x_0 \in \partial D_t \cap \partial\{u_\varepsilon > 0\} \cap \Omega$. Now, take w as the solution to $\Delta w = w$ in $D_t \setminus \overline{D}_0$ with $w = c_0$ on ∂D_0 and $w = 0$ on ∂D_t. Thus $w \leq u_\varepsilon$ in $D_t \cap \Omega$ and $\partial_{-\nu} w(x_0) \geq c\, c_0$ with c independent of ε; therefore, for r small enough,

$$\frac{1}{r} \fint_{\partial B_r(x_0)} u_\varepsilon \geq \frac{1}{r} \fint_{\partial B_r(x_0)} w \geq \bar{c}\, c_0$$

with $\bar{c}$ independent of ε.

If v_0 is the solution to

$$\begin{cases} \Delta v = v & \text{in } B_r(x_0), \\ v = u & \text{on } \partial B_r(x_0), \end{cases}$$

then, by (2.9), we have

$$\begin{aligned} c|B_r(x_0) \cap \{u_\varepsilon = 0\}| &\leq |B_r(x_0) \cap \{u_\varepsilon = 0\}| \left(\frac{1}{r} \fint_{\partial B_r(x_0)} u_\varepsilon \right)^2 \\ &\leq K \int_{B_r(x_0)} |\nabla(u_\varepsilon - v_0)|^2 \, dx \\ &\leq K(\|u_\varepsilon\|^2_{H^1(B_r(x_0))} - \|v_0\|^2_{H^1(B_r(x_0))}). \end{aligned}$$

Now let $\delta_r = |B_r(x_0) \cap \{u_\varepsilon = 0\}|$ and let $x_1 \in \partial\{u_\varepsilon > 0\}$ be such that the free boundary is smooth in a neighborhood of x_1. We perturb $\{u_\varepsilon > 0\}$ in a neighborhood of x_1 so that the measure of the perturbed set is increased by an amount δ_r (cf. Theorem 2.5).

Let Φ be a smooth nonnegative function supported in $B_\kappa(x_1)$ with $\kappa > 0$ small. For $x \in B_\kappa(x_1)$ we write $x = \sigma + s\nu(\sigma)$ with $\sigma \in \partial\{u_\varepsilon > 0\}$ and $s \in \mathbb{R}$, where $\nu(\sigma)$ is the outer unit normal to the free boundary at σ. We define the change of variables $y = x - \Phi(\sigma)\tau\nu(\sigma)$ with $\tau > 0$ small and the deformed set $\mathcal{D}_{\delta_r}$ such that $\mathcal{D}_{\delta_r} \cap B_\kappa(x_1) = \{y \,/\, x \in \{u_\varepsilon > 0\} \cap B_\kappa(x_1)\}$. Observe that if r is small we can perform this perturbation in such a way that it decreases the measure of $\{u_\varepsilon > 0\}$ by exactly δ_r. Also, observe that $\delta_r \to 0$ as $r \to 0$.

Now let v_r be the solution of

$$\begin{cases} \Delta v = v & \text{in } \mathcal{D}_{\delta_r}, \\ v = 0 & \text{on } \partial\mathcal{D}_{\delta_r} \cap B_\kappa(x_1), \\ v = u_\varepsilon & \text{on } \partial B_\kappa(x_1) \cap \overline{\mathcal{D}}_r. \end{cases} \tag{4.2}$$

Then v_r verifies

$$\frac{\partial v_r}{\partial \nu} = -\lambda_\varepsilon + o(\delta_r).$$

On the other hand,

$$u_\varepsilon = \lambda_\varepsilon \delta_r + o_\varepsilon(\delta_r) \qquad \text{on } \partial\{v_r > 0\} \cap B_\kappa(x_1).$$

Thus

$$\begin{aligned} \int_{B_\kappa(x_1)} |\nabla v_r|^2 + v_r^2 \, dx - \int_{B_\kappa(x_1)} |\nabla u_\varepsilon|^2 + (u_\varepsilon)^2 \, dx \\ &= \int_{B_\kappa(x_1)} |\nabla(u_\varepsilon - v_r)|^2 + (u_\varepsilon - v_r)^2 \, dx \\ &= -\int_{\partial\{v_r > 0\} \cap B_\kappa(x_1)} \frac{\partial v_r}{\partial \nu} u_\varepsilon \, dS \\ &= \lambda_\varepsilon^2 \delta_r + o_\varepsilon(\delta_r). \end{aligned}$$

Now we extend v_r by zero to $B_\kappa(x_1) \setminus \mathcal{D}_{\delta_r}$ and define

$$w_r = \begin{cases} v_r & \text{in } B_\kappa(x_1), \\ v_0 & \text{in } B_r(x_0), \\ u & \text{elsewhere.} \end{cases}$$

Then $|\{w_r > 0\}| = |\{u_\varepsilon > 0\}|$ and $w_r = u_\varepsilon$ on $\partial\Omega$; thus

$$\begin{aligned} 0 \le \mathcal{J}_\varepsilon(w_r) - \mathcal{J}_\varepsilon(u_\varepsilon) &= \int_\Omega |\nabla w_r|^2 + w_r^2 \, dx - \int_\Omega |\nabla u_\varepsilon|^2 + (u_\varepsilon)^2 \, dx \\ &= \int_{B_r(x_0)} |\nabla v_0|^2 + v_0^2 \, dx - \int_{B_\kappa(x_0)} |\nabla u_\varepsilon|^2 + (u_\varepsilon)^2 \, dx \\ &\quad + \int_{B_\kappa(x_1)} |\nabla v_r|^2 + v_r^2 \, dx - \int_{B_\kappa(x_1)} |\nabla u_\varepsilon|^2 + (u_\varepsilon)^2 \, dx \\ &\le -c\delta_r + \lambda_\varepsilon^2 \delta_r + o_\varepsilon(\delta_r) \end{aligned}$$

for every $r > 0$ small. Therefore, $\lambda_\varepsilon^2 \ge c/2$. ∎

Now we are in a position to prove the main result of this section, namely, that for ε small the measure of the positivity set is exactly α.

THEOREM 4.1. *Let $\Gamma_D \neq \emptyset$ be the closure of a relatively open subset of $\partial\Omega$. Let $\varphi_0 \in H^1(\Omega)$ with $\varphi_0 \geq c_0 > 0$ in Γ_D. Let $u_\varepsilon \in \mathcal{K}$ be a solution to (P_ε). Then, for ε small*

$$|\{u_\varepsilon > 0\}| = \alpha. \tag{4.3}$$

Proof. Arguing by contradiction, assume first that $|\{u_\varepsilon > 0\}| > \alpha$. Let $x_1 \in \partial\{u_\varepsilon > 0\} \cap \Omega$ be a regular point. We will proceed as in the proof of the previous lemma. Given $\delta > 0$, we perturb the domain $\{u_\varepsilon > 0\}$ in a neighborhood of x_1, $B_\kappa(x_1)$, decreasing its measure by δ. We choose δ small so that the measure of the perturbed set is still larger than α. Then we let v be the solution to (4.2) extended by zero to the rest of $B_\kappa(x_1)$ and equal to u in the rest of Ω. We have

$$\begin{aligned} 0 \leq \mathcal{J}_\varepsilon(v) - \mathcal{J}_\varepsilon(u_\varepsilon) &= \int_\Omega |\nabla v|^2 + v^2 - \int_\Omega |\nabla u_\varepsilon|^2 + (u_\varepsilon)^2 + F_\varepsilon(|\{v > 0\}|) \\ &\qquad - F_\varepsilon(|\{u_\varepsilon > 0\}|) \\ &\leq \lambda_\varepsilon^2 \delta + o_\varepsilon(\delta) - \frac{1}{\varepsilon}\delta \leq \left(C^2 - \frac{1}{\varepsilon}\right)\delta + o_\varepsilon(\delta) < 0 \end{aligned}$$

if $\varepsilon < \varepsilon_0$, and then $\delta < \delta_0(\varepsilon)$, a contradiction.

Now assume that $|\{u_\varepsilon > 0\}| < \alpha$. We proceed as in the previous case but this time we perturb in a neighborhood of x_1 the set $\{u_\varepsilon > 0\}$, increasing the measure by δ. Then we construct the function v as before, and if δ is small enough, $|\{v > 0\}| < \alpha$. Then

$$\begin{aligned} 0 \leq \mathcal{J}_\varepsilon(v) - \mathcal{J}_\varepsilon(u_\varepsilon) &= \int_\Omega |\nabla v|^2 + v^2 - \int_\Omega |\nabla u_\varepsilon|^2 + (u_\varepsilon)^2 + F_\varepsilon(|\{v > 0\}|) \\ &\qquad - F_\varepsilon(|\{u_\varepsilon > 0\}|) \\ &\leq -\lambda_\varepsilon^2 \delta + o_\varepsilon(\delta) + \varepsilon\delta \leq (-c^2 + \varepsilon)\delta + o_\varepsilon(\delta) < 0 \end{aligned}$$

if $\varepsilon < \varepsilon_1$, and then $\delta < \delta_0(\varepsilon)$. Again, a contradiction that ends the proof. ∎

As a consequence of the previous theorem, we get the following corollary.

COROLLARY 4.1. *Let $\Gamma_D \neq \emptyset$ be the closure of a relatively open subset of $\partial\Omega$. Let $\varphi_0 \in H^1(\Omega)$ with $\varphi_0 \geq c_0 > 0$ in Γ_D. Then there exists a minimizer u of $\mathcal{J}(v)$ in the set*

$$\mathcal{K}_\alpha = \{v \in H^1(\Omega) \,/\, \|v\|_{L^q(\Gamma_N)} = 1,\ v = \varphi_0 \text{ on } \Gamma_D,\ |\{v > 0\}| = \alpha\}.$$

This minimizer can be chosen in such a way that it is locally Lipschitz continuous in Ω and the free boundary $\partial\{u > 0\} \cap \Omega$ is locally a $C^{1,\beta}$ surface up to a set of zero $\mathcal{H}^{N-1}$ measure. In the case $N = 2$ the free boundary is locally a $C^{1,\beta}$ surface.

Proof. From our previous results we have (4.3) for every ε small enough. Therefore we can take $u = u_\varepsilon$ and the desired regularity of u and its free boundary follows from the results of sections 2 and 3. ∎

5. Main results. In this section we go back to our original minimization problem related to the best Sobolev trace constant. Here we prove that any extremal is a locally Lipschitz continuous function and the boundary of the hole $\partial\{u > 0\} \cap \Omega$ is locally $C^{1,\beta}$ up to a set of zero $\mathcal{H}^{N-1}$ measure.

We begin with the following theorem.

THEOREM 5.1. *Let ϕ_0 be a minimizer for (P_α). Assume that there exists a positive constant c such that $\phi_0 > c$ in a ball $B_0' \subset \Omega$ (resp., on $B_0' \cap \partial\Omega$, where B_0' is a ball centered at $\partial\Omega$). Then ϕ_0 is a minimizer of $\mathcal{J}_\varepsilon$ in*

$$\mathcal{K}_2 = \{v \in H^1(\Omega) \,/\, \|v\|_{L^q(\partial\Omega)} = 1,\ v = \phi_0 \text{ in } B_0\}$$

(resp., ϕ_0/k is a minimizer of $\mathcal{J}_\varepsilon$ in $\mathcal{K} = \{v \in H^1(\Omega) \,/\, \|v\|_{L^q(\Gamma_N)} = 1,\ v = \phi_0/k \text{ on } \Gamma_D\}$ with $\Gamma_D = \partial\Omega \cap B_0$, $\Gamma_N = \partial\Omega \setminus \Gamma_D$). Here, B_0 is a ball compactly contained in B_0' and $k = \|\phi_0\|_{L^q(\Gamma_N)}$.

In particular, ϕ_0 is locally Lipschitz continuous in Ω and the free boundary $\partial\{\phi_0 > 0\} \cap \Omega$ is locally a $C^{1,\beta}$ surface up to a set of zero $\mathcal{H}^{N-1}$ measure. In the case $N = 2$ the free boundary is locally a $C^{1,\beta}$ surface.

Proof. We will make the proof for the first case; the second one follows in the same way.

Let ε be small enough so that any minimizer u_ε of $\mathcal{J}_\varepsilon$ in $\mathcal{K}_2$ verifies that $|\{u_\varepsilon > 0\}| = \alpha$. Then it follows that ϕ_0 is one such minimizer and thus the conclusions of the theorem follow. In fact, as ϕ_0 minimizes (P_α) we have

$$\mathcal{J}_\varepsilon(\phi_0) = \int_\Omega |\nabla\phi_0|^2 + |\phi_0|^2\,dx \le \int_\Omega |\nabla v|^2 + |v|^2\,dx \tag{5.1}$$

for any $v \in H^1(\Omega)$ such that $\|v\|_{L^q(\partial\Omega)} = 1$ and $|\{v > 0\}| = \alpha$. In particular (5.1) holds for $v = u_\varepsilon$. Thus

$$\mathcal{J}_\varepsilon(\phi_0) \le \mathcal{J}_\varepsilon(u_\varepsilon) = \inf_{v\in\mathcal{K}_2} \mathcal{J}_\varepsilon(v).$$

This ends the proof. ∎

In particular, by the symmetry results for minimizers of (P_α) in balls of [10] we have the following corollary.

COROLLARY 5.1. *Let $\Omega = B(x_0, r)$ be a ball and let ϕ_0 be a minimizer of (P_α). Then ϕ_0 is locally Lipschitz continuous in $B(x_0, r)$ and the free boundary $\partial\{\phi_0 > 0\} \cap B(x_0, r)$ is locally a $C^{1,\beta}$ surface up to a set of zero $\mathcal{H}^{N-1}$ measure. In the case $N = 2$ the free boundary is locally a $C^{1,\beta}$ surface.*

Proof. In [10] it was proved that any minimizer ϕ_0 of (P_α) in the case that Ω is a ball $B_r(x_0)$ satisfies that, for any $c_0 > 0$, $\{\phi_0 \ge c_0\} \cap \partial B_r(x_0)$ is a spherical cap. Since $\|\phi_0\|_{L^q(\partial\Omega)} = 1$, there exists $c_0 > 0$ such that $\{\phi_0 \ge c_0\} \cap \partial B_r(x_0) \ne \emptyset$. Hence the conditions of Theorem 5.1 are satisfied. ∎

In the general case, for the problem (P_α) we can prove that the set of α's for which there exist minimizers with smooth free boundary is dense in $(0, |\Omega|)$. More precisely, we have the following theorem.

THEOREM 5.2. *For any $0 < \alpha < |\Omega|$ there exists $\alpha_\varepsilon \to \alpha$ as $\varepsilon \to 0$ such that there exists a solution ϕ_ε of (P_{α_ε}) which is locally Lipschitz continuous in Ω and has locally a $C^{1,\beta}$ free boundary up to a set of zero $\mathcal{H}^{N-1}$ measure. In the case $N = 2$ the free boundary is locally a $C^{1,\beta}$ surface.*

Proof. Let u_ε be a minimizer of $\mathcal{J}_\varepsilon$. We already know that $\alpha_\varepsilon := |\{u_\varepsilon > 0\}| \le \alpha + C\varepsilon$ (see (4.1)). Let us see that $\alpha_\varepsilon \to \alpha$ as $\varepsilon \to 0$. If not, there exists a sequence $\varepsilon_j \to 0$ such that $\alpha_{\varepsilon_j} = |\{u_{\varepsilon_j} > 0\}| \le \theta < \alpha$. Let ϕ_0 be a minimizer of (P_α). By the strict monotonicity of $S(\alpha)$ (see [10, Remark 2.2]) we have

$$\begin{aligned}\mathcal{J}(\phi_0) = S(\alpha) < S(\theta) \le \mathcal{J}(u_{\varepsilon_j}) &= \mathcal{J}_{\varepsilon_j}(u_{\varepsilon_j}) - F_{\varepsilon_j}(\alpha_{\varepsilon_j}) \\ &\le \mathcal{J}_{\varepsilon_j}(\phi_0) - F_{\varepsilon_j}(\alpha_{\varepsilon_j}) = \mathcal{J}(\phi_0) - F_{\varepsilon_j}(\alpha_{\varepsilon_j}) \le \mathcal{J}(\phi_0) + C\varepsilon_j,\end{aligned}$$

a contradiction.

Now, taking $\phi_\varepsilon = u_\varepsilon$ we see that ϕ_ε is a minimizer of (P_{α_ε}). In fact, let v be an admissible function for (P_{α_ε}); then

$$\mathcal{J}(v) + F_\varepsilon(\alpha_\varepsilon) = \mathcal{J}_\varepsilon(v) \geq \mathcal{J}_\varepsilon(\phi_\varepsilon) = \mathcal{J}(\phi_\varepsilon) + F_\varepsilon(\alpha_\varepsilon)$$

and therefore

$$\mathcal{J}(v) \geq \mathcal{J}(\phi_\varepsilon).$$

The theorem is proved. □

Finally, we have the following result.

THEOREM 5.3. *Let u_ε be a minimizer of $\mathcal{J}_\varepsilon$ in $\mathcal{K}_1$. Then there exists $\phi_0 \in H^1(\Omega)$, a solution to (P_α) such that, up to a subsequence, $u_\varepsilon \to \phi_0$ in $H^1(\Omega)$.*

Proof. In the proof of Theorem 5.2 we showed that $|\{u_\varepsilon > 0\}| \to \alpha$ as $\varepsilon \to 0$.

It is easy to see that $\mathcal{J}_\varepsilon(u_\varepsilon)$ is bounded uniformly in ε and so u_ε is uniformly bounded in $H^1(\Omega)$. Therefore, passing to a subsequence if necessary, there exists $u_0 \in H^1(\Omega)$ such that

$$\begin{aligned} &u_\varepsilon \rightharpoonup u_0 \quad \text{weakly in } H^1(\Omega),\\ &u_\varepsilon \to u_0 \quad \text{strongly in } L^q(\partial\Omega),\\ &u_\varepsilon \to u_0 \quad \text{a.e. } \Omega. \end{aligned}$$

Thus,

$$\begin{aligned} &\|u_0\|_{L^q(\partial\Omega)} = 1,\\ &|\{u_0 > 0\}| \leq \alpha = \lim_{\varepsilon\to 0} |\{u_\varepsilon > 0\}|, \quad \text{and}\\ &\|u_0\|_{H^1(\Omega)} \leq \liminf_{\varepsilon\to 0} \|u_\varepsilon\|_{H^1(\Omega)}. \end{aligned}$$

Let us call $\phi_0 = u_0$ and let us see that ϕ_0 is a solution to (P_α). In fact, let $v \in H^1(\Omega)$ be such that $|\{v > 0\}| = \alpha$ and $\|v\|_{L^q(\partial\Omega)} = 1$. Then

$$\mathcal{J}(v) = \mathcal{J}_\varepsilon(v) \geq \mathcal{J}_\varepsilon(u_\varepsilon).$$

Now, since $\liminf_{\varepsilon\to 0} F_\varepsilon(|\{u_\varepsilon > 0\}|) \geq 0$, there holds that

$$\mathcal{J}(v) \geq \liminf_{\varepsilon\to 0} \mathcal{J}_\varepsilon(u_\varepsilon) \geq \liminf_{\varepsilon\to 0} \mathcal{J}(u_\varepsilon) \geq \mathcal{J}(\phi_0). \tag{5.2}$$

It remains to see that $|\{\phi_0 > 0\}| = \alpha$. Assume not; then $\alpha_1 := |\{\phi_0 > 0\}| < \alpha$. Thus, by the strict monotonicity of $S(\cdot)$, there holds that $S(\alpha) < S(\alpha_1)$, but

$$S(\alpha) = \inf_v \mathcal{J}(v) \geq \mathcal{J}(\phi_0) \geq S(\alpha_1),$$

a contradiction.

Now taking $v = \phi_0$ in (5.2),

$$\mathcal{J}(\phi_0) \leq \liminf_{\varepsilon\to 0} \mathcal{J}(u_\varepsilon) \leq \liminf_{\varepsilon\to 0} \mathcal{J}_\varepsilon(u_\varepsilon) \leq \mathcal{J}(\phi_0).$$

Hence, $\|\phi_0\|_{H^1(\Omega)} = \liminf_{\varepsilon\to 0} \|u_\varepsilon\|_{H^1(\Omega)}$ and thus, by taking a further subsequence if necessary, the convergence is actually strong. □

Remark 4. We believe that, as in the previous cases, the minimizers u_ε of $\mathcal{J}_\varepsilon$ in $\mathcal{K}_1$ will already be solutions to (P_α) for ε small. Nevertheless, despite the fact that the result of Theorem 5.3 does not give regularity of the minimizer ϕ_0, we believe that it could be of interest in numerical approximations of the solution to (P_α).

Acknowledgment. We wish to thank Prof. Luis Caffarelli for suggesting this approach to our optimization problem and for providing us with useful references.

L^∞-ESTIMATES FOR APPROXIMATED OPTIMAL CONTROL PROBLEMS*

C. MEYER† AND A. RÖSCH‡

Abstract. An optimal control problem for a two-dimensional elliptic equation is investigated with pointwise control constraints. This paper is concerned with discretization of the control by piecewise linear functions. The state and the adjoint state are discretized by linear finite elements. Approximation of order h in the L^∞-norm is proved in the main result.

Key words. linear-quadratic optimal control problems, error estimates, elliptic equations, numerical approximation, control constraints

DOI. 10.1137/040614621

1. Introduction.

This paper is concerned with the discretization of the two-dimensional elliptic optimal control problem

$$J(u) = F(y,u) = \frac{1}{2}\|y - y_d\|^2_{L^2(\Omega)} + \frac{\nu}{2}\|u\|^2_{L^2(\Omega)} \tag{1.1}$$

subject to the state equations

$$\begin{aligned} Ay + a_0 y &= u && \text{in } \Omega, \\ y &= 0 && \text{on } \Gamma \end{aligned} \tag{1.2}$$

and subject to the control constraints

$$a \le u(t,x) \le b \qquad \text{for a.a. } x \in \Omega, \tag{1.3}$$

where Ω is a bounded domain with boundary Γ; A denotes a second-order elliptic operator of the form

$$Ay(x) = -\sum_{i,j=1}^{2} D_i(a_{ij}(x) D_j y(x)),$$

where D_i denotes the partial derivative with respect to x_i, and a and b are real numbers. Moreover, $\nu > 0$ is a fixed positive number. We denote the set of admissible controls by U_{ad}:

$$U_{ad} = \{u \in L^2(\Omega) : \ a \le u \le b \ \text{ a.e. in } \Omega\}.$$

We discuss here the full discretization of the control and the state equations by a finite-element method. The asymptotic behavior of the discretized problem is studied.

The approximation of the discretization for semilinear elliptic optimal control problems is discussed in Arada, Casas, and Tröltzsch [1]. The optimal control problem (1.1)–(1.3) is a linear-quadratic counterpart of such a semilinear problem.

The discretization of optimal control problems by piecewise constant functions is well investigated; we refer to Falk [7] and Geveci [8]. Piecewise constant and piecewise linear discretization in space are discussed for a parabolic problem in Malanowski [12]. Theory and numerical results for elliptic boundary control problems are contained in Casas and Tröltzsch [6] and Casas, Mateos, and Tröltzsch [5]. All of these papers are mainly focused on L^2-estimates. However, in Arada, Casas, and Tröltzsch [1] and Casas, Mateos, and Tröltzsch [5] we find also L^∞-estimates of order h for piecewise constant functions.

Piecewise linear control discretizations for elliptic optimal control problems were studied by Casas and Tröltzsch [6] and Casas [4]. In an abstract optimization problem, piecewise linear approximations were investigated in Rösch [15]. In these papers, the convergence was mainly discussed in the L^2-norm.

Error estimates in the L^∞-norm can also be obtained by other discretization concepts; see Hinze [10] and Meyer and Rösch [13].

The interest for L^∞-estimates is motivated by the following circumstances. The L^∞-space plays an important role in the theory of semilinear optimal control problems. Usually, sufficient second-order optimality conditions hold in an L^∞-neighborhood of the optimal solution. These optimality conditions are the main ingredients for the convergence theory of the SQP method. For numerical computations the linear-quadratic subproblems have to be solved with a sufficient accuracy in the L^∞-norm.

In this paper, we will show that also for piecewise linear controls the approximation order h can be obtained in the L^∞-norm. A result of this type cannot be obtained with one of the above mentioned methods. The L^∞-estimate is obtained in two main steps. We prove in the first step that the discretized solutions violate a pointwise projection formula only in an order h. The L^∞-estimates for grid points and later for arbitrary points are derived in the second step.

The paper is organized as follows: In section 2 the discretizations are introduced and the main results are stated. Section 3 contains auxiliary results. The proofs of the approximation result is placed in section 4. The paper ends with numerical experiments shown in section 5.

2. Discretization and main result. Throughout this paper, Ω denotes a convex bounded open subset in $\mathbb{R}^2$ of class $C^{1,1}$. The coefficients a_{ij} of operator A belong to $C^{0,1}(\bar{\Omega})$ and satisfy the ellipticity condition

$$m_0|\xi|^2 \le \sum_{i,j=1}^{2} a_{ij}(x)\xi_i\xi_j \qquad \text{for all } (\xi, x) \in \mathbb{R}^2 \times \bar{\Omega}, \quad m_0 > 0.$$

Moreover, we require $y_d \in L^p(\Omega)$ for some $p > 2$. For the function $a_0 \in L^\infty(\Omega)$, we assume $a_0 \ge 0$. Next, we recall a result of Grisvard [9, Theorem 2.4.2.5].

LEMMA 2.1 (see [9]). *For every $p > 2$ and every function $g \in L^p(\Omega)$, the solution y of*

$$Ay + a_0 y = g \qquad \text{in } \Omega, \quad y|_\Gamma = 0,$$

belongs to $H_0^1(\Omega) \cap W^{2,p}(\Omega)$. Moreover, there exists a positive constant c, independent of a_0, such that

$$\|y\|_{W^{2,p}(\Omega)} \le c\|g\|_{L^p(\Omega)}.$$

We introduce the adjoint equation

$$\begin{aligned} A^*p + a_0 p &= y - y_d && \text{in } \Omega, \\ p &= 0 && \text{on } \Gamma, \end{aligned} \tag{2.1}$$

where A^* denotes the formally adjoint operator. Due to Lemma 2.1, the state equation and the adjoint equation admit unique solutions in $H_0^1(\Omega) \cap W^{2,p}(\Omega)$ if $y_d \in L^p(\Omega)$ for $p > 2$. This space is embedded in $C^{0,1}(\bar{\Omega})$.

We call the solution y of (1.2) for a control u associated state to u and write $y(u)$. In the same way, we call the solution p of (2.1) corresponding to $y(u)$ associated adjoint state to u and write $p(u)$.

Introducing the projection

$$\Pi_{[a,b]}(f(x)) = \max(a, \min(b, f(x))),$$

we can formulate the necessary and sufficient first-order optimality condition for (1.1)–(1.3).

LEMMA 2.2. *A necessary and sufficient condition for the optimality of a control $\bar{u}$ with the corresponding state $\bar{y} = y(\bar{u})$ and adjoint state $\bar{p} = p(\bar{u})$, respectively, is that the equation*

$$\bar{u}(x) = \Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{p}(x)\Big) \tag{2.2}$$

holds.

Since the optimal control problem is strictly convex, we obtain the existence of a unique optimal solution. The optimality condition can be formulated as the variational inequality

$$(\nu\bar{u} + \bar{p}, u - \bar{u})_U \geq 0 \qquad \text{for all } u \in U_{ad},$$

where $(\cdot,\cdot)_U$ denotes the natural inner product in $U = L^2(\Omega)$. A standard pointwise a.e. discussion of this variational inequality leads to the above formulated projection formula; see [12]. Clearly, the Lipschitz continuity of $\bar{p}$ implies that also $\bar{u}$ is Lipschitz continuous.

We are now able to introduce the discretized problem. We define a finite-element–based approximation of the optimal control problem (1.1)–(1.3). To this aim, we consider a family of triangulations $(T_h)_{h>0}$ of $\bar{\Omega}$. With each element $T \in T_h$, we associate two parameters $\rho(T)$ and $\sigma(T)$, where $\rho(T)$ denotes the diameter of the set T, and $\sigma(T)$ is the diameter of the largest ball contained in T. The mesh size of the grid is defined by $h = \max_{T\in T_h} \rho(T)$. We suppose that the following regularity assumptions are satisfied.

(A1) There exist two positive constants ρ and σ such that

$$\frac{\rho(T)}{\sigma(T)} \leq \sigma, \qquad \frac{h}{\rho(T)} \leq \rho$$

hold for all $T \in T_h$ and all $h > 0$.

(A2) Let us define $\bar{\Omega}_h = \bigcup_{T\in T_h} T$, and let Ω_h and Γ_h denote its interior and its boundary, respectively. We assume that $\bar{\Omega}_h$ is convex and that the vertices of T_h placed on the boundary of Γ_h are points of Γ. From [14, estimate (5.2.19)], it is known that

$$|\Omega \setminus \Omega_h| \leq Ch^2,$$

where $|.|$ denotes the measure of the set.

Next, to every boundary triangle T of T_h we associate another triangle $\hat{T}$ with the curved boundary as follows: the edge between the two boundary nodes of T is substituted by the corresponding curved part of Γ. We denote by $\hat{T}_h$ the union of these curved boundary triangles with the interior triangles to Ω of T_h such that $\bar{\Omega} = \bigcup_{\hat{T}\in\hat{T}_h} \hat{T}$. Moreover, we set

$$V_h = \{y_h \in C(\bar{\Omega}) : \ y_h \in \mathcal{P}_1 \text{ for all } T \in T_h, \text{ and } y_h = 0 \text{ on } \bar{\Omega} \setminus \Omega_h\},$$

$$U_h = \{u_h \in C(\bar{\Omega}) : u_h \in \mathcal{P}_1 \text{ for all } T \in T_h, \text{ and } u_h = \Pi_{[a,b]}(0) \text{ on } \bar{\Omega} \setminus \Omega_h\},$$
$$U_h^{ad} = U_h \cap U_{ad},$$

where $\mathcal{P}_1$ is the space of polynomials of degree less than or equal to 1. The definition of the set U_h is motivated by the projection formula (2.2) and the homogeneous boundary condition (2.1) of the adjoint equation.

For each $u_h \in U_h$, we denote by $y_h(u_h)$ the unique element of V_h that satisfies

$$a(y_h(u_h), v_h) = \int_\Omega u_h v_h \, dx \qquad \text{for all } v_h \in V_h, \tag{2.3}$$

where $a : V_h \times V_h \to \mathbb{R}$ is the bilinear form defined by

$$a(y_h, v_h) = \int_\Omega \left(a_0(x) y_h(x) v_h(x) + \sum_{i,j=1}^{2} a_{ij}(x) D_i y_h(x) D_j v_h(x) \right) dx.$$

In other words, $y_h(u_h)$ is the approximated state associated with u_h. Because of $y_h = v_h = 0$ on $\bar{\Omega} \setminus \Omega_h$ the integrals over Ω can be replaced by integrals over Ω_h. The finite-dimensional approximation of the optimal control problem is defined by

$$\inf J(u_h) = \frac{1}{2}\|y_h(u_h) - y_d\|^2_{L^2(\Omega)} + \frac{\nu}{2}\|u_h\|^2_{L^2(\Omega)}, \qquad u_h \in U_h^{ad}. \tag{2.4}$$

The adjoint equation is discretized in the same way:

$$a^*(p_h(u_h), v_h) = \int_\Omega (y_h(u_h) - y_d) v_h \, dx \qquad \text{for all } v_h \in V_h \tag{2.5}$$

with

$$a^*(p_h(u_h), v_h) = \int_\Omega \left(a_0(x) y_h(x) v_h(x) + \sum_{i,j=1}^{2} a_{ji}(x) D_i y_h(x) D_j v_h(x) \right) dx.$$

Now, we are able to state the main result.

THEOREM 2.3. *Let $\bar{u}$ and u_h be the optimal solution of* (1.1) *and* (2.4)*, respectively. Then, there exists a positive constant C independent of h with*

$$\|\bar{u} - u_h\|_{L^\infty(\Omega)} \le Ch. \tag{2.6}$$

The proof of Theorem 2.3 is contained in section 4. Moreover, the constant C is specified in that section.

3. Auxiliary results. We start with an L^2-estimate corresponding to Theorem 2.3.

LEMMA 3.1. *Let $\bar{u}$ and u_h be the optimal solution of* (1.1) *and* (2.4)*, respectively. Then, the estimate*

$$\|\bar{u} - u_h\|_{L^2(\Omega)} \le C_2 h \tag{3.1}$$

holds true with a positive constant C_2.

This statement can be easily proved by the arguments of Casas and Tröltzsch [6]. It is a special case of a new general result of Casas [4].

This and the Sobolev imbeddings imply easily the following L^∞-estimate:

$$\|\bar{p} - p(u_h)\|_{L^\infty(\Omega)} \le c\|\bar{p} - p(u_h)\|_{H^2(\Omega)} \le ch. \tag{3.2}$$

LEMMA 3.2. *The inequality*

$$\|\bar{p} - p_h(u_h)\|_{L^\infty(\Omega)} \le \kappa h \tag{3.3}$$

is valid with a positive constant κ.

Proof. First, we recall an L^∞-estimate for the finite-element solution

$$\|p(u_h) - p_h(u_h)\|_{L^\infty(\Omega)} \le ch; \tag{3.4}$$

see Braess [3]. Using (3.2), we find

$$\|\bar{p} - p_h\|_{L^\infty(\Omega)} \le \|\bar{p} - p(u_h)\|_{L^\infty(\Omega)} + \|p(u_h) - p_h\|_{L^\infty(\Omega)} \le \kappa h. \qquad \square$$

Next, we introduce a new notation for the piecewise linear functions. Let E_i be an arbitrary vertex of the triangulation T_h. Then, we define a basis function $e_i \in U_h$ by

$$e_i(E_j) = \delta_{ij},$$

where δ_{ij} is the Kronecker symbol. Therefore, we can represent the functions u_h and $p_h(u_h)$ by

$$u_h(x) = \sum_{E_i} u_i e_i(x),$$
$$(p_h(u_h))(x) = \sum_{E_i} p_i e_i(x)$$

with $u_i = u_h(E_i)$ and $p_i = (p_h(u_h))(E_i)$.

We denote the set of neighboring vertices of E_i, i.e., $(e_i, e_j)_U \ne 0$ and $i \ne j$, by $N(E_i)$.

LEMMA 3.3. *For every j with $E_j \in N(E_i)$, we have*

$$\frac{1}{\nu}|p_i - p_j| \le Dh \tag{3.5}$$

with

$$D = \frac{L + 2\kappa}{\nu}, \tag{3.6}$$

where L denotes the Lipschitz constant of $\bar{p}$.

Proof. Because of Lemma 2.1, $\bar{p}$ belongs to $W^{2,p}(\Omega)$ for a certain $p > 2$. Therefore, $\bar{p}$ is Lipschitz, and we have

$$|\bar{p}(E_i) - \bar{p}(E_j)| \le Lh.$$

Combining this inequality with (3.3), we obtain

$$\begin{aligned} |p_i - p_j| &\le |p_i - \bar{p}(E_i)| + |\bar{p}(E_i) - \bar{p}(E_j)| + |\bar{p}(E_j) - p_j| \\ &\le \kappa h + Lh + \kappa h. \qquad \square \end{aligned}$$

Next, we recall a property concerning the mass matrix.

LEMMA 3.4. *For every basis function e_i*

$$(e_i, e_i)_U \ge \sum_{E_j \in N(E_i)} (e_i, e_j)_U \tag{3.7}$$

is valid.

Proof. The element mass matrix of the reference element T_r is given by

$$M_r = \frac{1}{24} \begin{pmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 2 \end{pmatrix},$$

which has the desired property with equality. For an arbitrary triangle T_s we find

$$M_s = \frac{|T_s|}{|T_r|} M_r.$$

Consequently, every element mass matrix has this property. This holds also for the summation over all triangles. The inequality sign is obtained if the support of e_i contains at least one boundary point. $\square$

Next, we want to investigate the following quantity:

$$M := \max_i \left| u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu} p_i \Big) \right|. \tag{3.8}$$

Our main goal will be the proof of the inequality

$$M \le D \cdot h.$$

Of course for $M = 0$ such an inequality is automatically fulfilled. Therefore, we will now assume $M > 0$. In all what follows, the index i denotes a fixed vertex where this maximum is attained.

Equation (3.8) means that one of the following cases (A) and (B) occurs:

(A) $\quad M = u_i - \Pi_{[a,b]}(-\frac{1}{\nu} p_i)$,

(B) $\quad M = -(u_i - \Pi_{[a,b]}(-\frac{1}{\nu} p_i))$.

LEMMA 3.5. *Let $M > 0$ and i be an index where this maximum in* (3.8) *is attained. Then, we have*

$$\begin{aligned} M &\le u_i + \frac{1}{\nu} p_i \qquad \text{in case (A)}, \\ M &\le -\left(u_i + \frac{1}{\nu} p_i \right) \quad \text{in case (B)}. \end{aligned} \tag{3.9}$$

Moreover, there exists a constant $\varepsilon > 0$ such that $v_h = u_h - \varepsilon e_i$ is admissible in case (A) *and $v_h = u_h + \varepsilon e_i$ is admissible in case* (B).

Proof. We discuss here only case (A). Case (B) can be investigated in the same way.

Since M is positive and $\Pi_{[a,b]}(-\frac{1}{\nu}p_i) \in [a,b]$ by definition, we have

$$u_i > a.$$

Moreover, $u_i \le b$ and $M > 0$ imply $\Pi_{[a,b]}(-\frac{1}{\nu}p_i) < b$. Therefore, we have

$$\Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big) \ge -\frac{1}{\nu}p_i$$

and

$$M = u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big) \le u_i + \frac{1}{\nu}p_i.$$

Because of $u_i > a$, there exists an $\varepsilon > 0$ such that

$$u_i - \varepsilon > a.$$

This means that the control $v_h = u_h - \varepsilon e_i$ is admissible. ∎

LEMMA 3.6. *Let $M > 0$, and let i be an index, where the maximum in* (3.8) *is attained. Then, we have*

$$u_i + \frac{1}{\nu}p_i \le \max_{E_j \in N(E_i)} -\Big(u_j + \frac{1}{\nu}p_j\Big) \quad \text{in case (A)}, \tag{3.10}$$

$$-(u_i + \frac{1}{\nu}p_i) \le \max_{E_j \in N(E_i)} \Big(u_j + \frac{1}{\nu}p_j\Big) \quad \text{in case (B)}. \tag{3.11}$$

Moreover, if equality holds in (3.10) *or* (3.11), *then we have*

$$u_i + \frac{1}{\nu}p_i = -\Big(u_j + \frac{1}{\nu}p_j\Big) \quad \text{for all } j \text{ with } E_j \in N(E_i).$$

Proof. Without loss of generality, we discuss only case (A). We start with the optimality condition for u_h:

$$(\nu u_h + p_h(u_h), v_h - u_h)_U \ge 0 \qquad \text{for all } v_h \in U_h^{ad}.$$

We test this inequality with $v_h = u_h - \varepsilon e_i$:

$$(\nu u_h + p_h(u_h), -\varepsilon e_i)_U \ge 0.$$

From this, we obtain

$$(\nu u_i + p_i)(e_i, e_i)_U \le \sum_{E_j \in N(E_i)} -(\nu u_j + p_j)(e_i, e_j)_U.$$

Using (3.7), we find

$$\begin{aligned}(\nu u_i + p_i)(e_i, e_i)_U &\le \max_{E_j \in N(E_i)} -\Big(u_j + \frac{1}{\nu}p_j\Big) \sum_{E_j \in N(E_i)} (e_i, e_j)_U \\ &\le \max_{E_j \in N(E_i)} -\Big(u_j + \frac{1}{\nu}p_j\Big)(e_i, e_i)_U.\end{aligned}$$

Division by $(e_i, e_i)_U$ yields (3.10). Since the scalar products $(e_i, e_j)_U$ are positive for all j with $E_j \in N(E_i)$, equality can only occur if

$$u_i + \frac{1}{\nu} p_i = -\Big(u_j + \frac{1}{\nu} p_j\Big) \qquad \text{for all } j \text{ with } E_j \in N(E_i). \qquad \square$$

Next, we denote an index where the maximum is attained in (3.10) for case (A) by k:

$$-\Big(u_k + \frac{1}{\nu} p_k\Big) = \max_{E_j \in N(E_i)} -\Big(u_j + \frac{1}{\nu} p_j\Big). \tag{3.12}$$

In case (B), an index k is defined by

$$u_k + \frac{1}{\nu} p_k = \max_{E_j \in N(E_i)} \Big(u_j + \frac{1}{\nu} p_j\Big). \tag{3.13}$$

LEMMA 3.7. *Assume $M > 0$. It holds that*

$$-\Big(u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu} p_k\Big)\Big) \le M \le u_i + \frac{1}{\nu} p_i \le -\Big(u_k + \frac{1}{\nu} p_k\Big) \tag{3.14}$$

in case (A) *and that*

$$u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu} p_k\Big) \le M \le -\Big(u_i + \frac{1}{\nu} p_i\Big) \le u_k + \frac{1}{\nu} p_k \tag{3.15}$$

in case (B).

Proof. Again, we discuss only case (A): combining (3.9), (3.10), and (3.12), we find

$$M \le u_i + \frac{1}{\nu} p_i \le -\Big(u_k + \frac{1}{\nu} p_k\Big). \tag{3.16}$$

Moreover, we have by definition of M

$$M \ge \Big|u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu} p_k\Big)\Big|. \tag{3.17}$$

Due to (3.12) and $M > 0$, $u_k + \frac{1}{\nu} p_k$ is negative. Hence, the expression $u_k - \Pi_{[a,b]}(-\frac{1}{\nu} p_k)$ is nonpositive: in the case $-\frac{1}{\nu} p_k \le b$, we get

$$\Pi_{[a,b]}\Big(-\frac{1}{\nu} p_k\Big) \ge -\frac{1}{\nu} p_k.$$

Consequently, we find

$$0 > u_k - \Big(-\frac{1}{\nu} p_k\Big) \ge u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu} p_k\Big).$$

In the other case, $-\frac{1}{\nu} p_k > b$, we have $\Pi_{[a,b]}(-\frac{1}{\nu} p_k) = b$, and now

$$0 \ge u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu} p_k\Big) \tag{3.18}$$

follows from $u_k \le b$.

Combining (3.17) and (3.18), we have

$$M \geq -\Big(u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big)\Big). \tag{3.19}$$

This yields together with (3.16)

$$-\Big(u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big)\Big) \leq M \leq u_i + \frac{1}{\nu}p_i \leq -\Big(u_k + \frac{1}{\nu}p_k\Big),$$

i.e., inequality (3.14). ∎

LEMMA 3.8. *Assume $M > 0$. Then, there exists an index i with*

$$M = \Big|u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big)\Big|$$

and a corresponding index k, $E_k \in N(E_i)$ with

$$\Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big) \neq -\frac{1}{\nu}p_k. \tag{3.20}$$

Proof. Again, we discuss only case (A): first, we investigate the case where in inequality (3.14) at least one strong inequality occurs. Then, we have

$$-\Big(u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big)\Big) < -\Big(u_k + \frac{1}{\nu}p_k\Big).$$

This implies directly

$$\Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big) < -\frac{1}{\nu}p_k, \tag{3.21}$$

and the assertion is proved for this case.

In the other case, we discuss as follows. Here, we know

$$M = -\Big(u_k - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big)\Big).$$

This means that the maximum M is also attained in the vertex E_k. Consequently, we have case (B) for the vertex E_k, and hence (3.15) holds with $i = k$ and a corresponding index m instead of k. For the case where at least one strong inequality occurs in (3.15), i.e.,

$$u_m - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_m\Big) < u_m + \frac{1}{\nu}p_m \qquad \text{with } m \in N(E_k),$$

we can proceed as in the first part of the proof. Hence, we have only to show that the equality case cannot occur for the index k, too: First, there exists at least one common neighboring vertex ($E_l \in N(E_i)$ and $E_l \in N(E_k)$). Next, we can apply Lemma 3.6 for the indices i and k. Therefore, we obtain the equations

$$\begin{aligned} u_i + \frac{1}{\nu}p_i &= -\Big(u_k + \frac{1}{\nu}p_k\Big), \\ u_i + \frac{1}{\nu}p_i &= -\Big(u_l + \frac{1}{\nu}p_l\Big), \\ u_k + \frac{1}{\nu}p_k &= -\Big(u_l + \frac{1}{\nu}p_l\Big), \end{aligned}$$

implying $u_i + \frac{1}{\nu}p_i = 0$. This is a contradiction to (3.9) and $M > 0$. Therefore, the equality case cannot occur for the index k, too. Consequently, the assertion is true. □

LEMMA 3.9. *Assume that*

$$Dh < b - a$$

is valid. Then, the estimate

$$M = \max_i \Big| u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big)\Big| < Dh \tag{3.22}$$

holds true.

Proof. If $M = 0$, then (3.22) is automatically true. Therefore, we have only to discuss the case $M > 0$. Let us assume that the statement of Lemma 3.8 is true for an index i with case (A) and a corresponding index k. Case (B) can be discussed in the same way.

Inequality (3.21) implies directly

$$b = \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_k\Big) < -\frac{1}{\nu}p_k. \tag{3.23}$$

From this and (3.5), we obtain

$$-\frac{1}{\nu}p_i > b - Dh.$$

By assumption, the value $b - Dh$ is greater than a. From (A),

$$u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big) = M > 0,$$

and $u \le b$, we obtain

$$-\frac{1}{\nu}p_i \le b.$$

Consequently, we find

$$-\frac{1}{\nu}p_i = \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big),$$

which implies

$$u_i + \frac{1}{\nu}p_i = u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big) = M.$$

Using $u_i \le b$ and $\frac{1}{\nu}p_i < -(b - Dh)$, we find

$$u_i + \frac{1}{\nu}p_i < b - (b - Dh) = Dh.$$

Combining the last two inequalities, the assertion is proved. □

Let us briefly comment on the assumption $Dh < b - a$. First, this assumption is fulfilled for sufficiently small h. Second, in the cases $b - a \le Dh$ Theorem 2.3 holds trivially with $C = D$.

4. Proof of the main result. The proof of Theorem 2.3 is divided into two parts. In the next lemma we derive a corresponding estimate for the grid points. The estimate for arbitrary points is obtained in a second step.

LEMMA 4.1. *The estimate*

$$\max_i |u_h(E_i) - \bar{u}(E_i)| \le \Big(D + \frac{\kappa}{\nu}\Big)h$$

is valid.

Proof. For $b - a \le Dh$ the assertion is trivially fulfilled. Therefore, we have only to discuss the case $Dh < b - a$. From Lemma 3.9, we know

$$\max_i \Big|u_i - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_i\Big)\Big| \le Dh$$

or in other notation

$$\max_i \Big|u_h(E_i) - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_h(E_i)\Big)\Big| \le Dh.$$

From (3.3),

$$\|\bar{p} - p_h\|_{L^\infty(\Omega)} \le \kappa h,$$

and the Lipschitz continuity of the projection operator we deduce

$$\Big\|\Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{p}(E_i)\Big) - \Pi_{[a,b]}\Big(-\frac{1}{\nu}p_h(E_i)\Big)\Big\|_{L^\infty(\Omega)} \le \frac{\kappa}{\nu}h.$$

Using

$$\bar{u}(E_i) = \Pi_{[a,b]}\Big(-\frac{1}{\nu}\bar{p}(E_i)\Big)$$

and the triangle inequality, we end up with

$$\max_i |u_h(E_i) - \bar{u}(E_i)| \le \Big(D + \frac{\kappa}{\nu}\Big)h. \qquad \square$$

Now, we are able to prove Theorem 2.3.

Proof. A nongrid point $x \in T_i$ can be expressed by a convex linear combination of the vertices E_j of the corresponding triangle

$$x = \sum_{E_j \in T_i} \lambda_j E_j, \quad \sum_{E_j \in T_i} \lambda_j = 1.$$

Since u_h is linear on T_i, we get

$$\begin{aligned}
|u_h(x) - \bar{u}(x)| &= \Big|\sum_{E_j \in T_i} \lambda_j u_h(E_j) - \bar{u}(x)\Big| \\
&\le \sum_{E_j \in T_i} \lambda_j |u_h(E_j) - \bar{u}(E_j)| + \sum_{E_j \in T_i} \lambda_j |\bar{u}(x) - \bar{u}(E_j)| \\
&\le \Big(D + \frac{\kappa}{\nu}\Big)h + \sum_{E_j \in T_i} \lambda_j |\bar{u}(x) - \bar{u}(E_j)| \\
&\le \Big(D + \frac{\kappa}{\nu}\Big)h + \frac{L}{\nu}h.
\end{aligned}$$

In the final inequality we used the Lipschitz continuity of $\bar{u}$. Summarizing all results, we obtain

$$\|\bar{u} - u_h\|_{L^\infty(\Omega_h)} \le \Big(D + \frac{\kappa + L}{\nu}\Big)h.$$

Therefore, the assertion is true for every point $x \in T_i$ with

$$C = D + \frac{\kappa + L}{\nu}.$$

It remains to investigate the part $\Omega \setminus \Omega_h$. By definition, we have $u_h = \Pi_{[a,b]}(0)$ on this part. From (2.2), we obtain easily $\bar{u} = \Pi_{[a,b]}(0)$ on Γ. Let $x \in \Omega \setminus \Omega_h$ be an arbitrary point. From [14], we know that

$$\min_{x_\Gamma \in \Gamma} |x - x_\Gamma| \le c_\Gamma h^2$$

holds with a certain constant $c_\Gamma > 0$ independent of h. Therefore, we find for $x \in \Omega \setminus \Omega_h$

$$|u_h(x) - \bar{u}(x)| = |\Pi_{[a,b]}(0) - \bar{u}(x)| = |\bar{u}(x_\Gamma) - \bar{u}(x)| \le \frac{c_\Gamma L}{\nu} h^2. \qquad \square$$

5. Numerical example. We have tested the convergence theory by the following example:

$$\begin{aligned} -\Delta y &= u && \text{in } \Omega, \\ y &= 0 && \text{on } \Gamma \end{aligned} \tag{5.1}$$

with $\Omega = (0,1)\times(0,1)$. One can easily verify that this problem fulfills the assumptions mentioned in the beginning of section 2 except the boundary regularity. Although Γ is not of class $C^{1,1}$, the $W^{2,p}$-regularity of $\bar{p}$ (see Lemma 2.1) is obtained by a result of Grisvard [9] for convex polygonal domains.

In [13], we derived an exact solution to (5.1), which is also used here. For the reader's convenience, we recall this example.

The optimal state is defined by

$$\bar{y} = y_a - y_g$$

with an analytical part $y_a = \sin(\pi x_1)\sin(\pi x_2)$ and a less smooth function y_g. The function y_g represents the solution of

$$\begin{aligned} -\Delta y_g &= g && \text{in } \Omega, \\ y_g &= 0 && \text{on } \Gamma. \end{aligned}$$

Here, g is given by

$$g(x_1,x_2) = \begin{cases} \hat{u}(x_1,x_2) - a & \text{if } \hat{u}(x_1,x_2) < a, \\ 0 & \text{if } \hat{u}(x_1,x_2) \in [a,b], \\ \hat{u}(x_1,x_2) - b & \text{if } \hat{u}(x_1,x_2) > b \end{cases}$$

with $\hat{u}(x_1,x_2) = 2\pi^2 \sin(\pi x_1)\sin(\pi x_2)$. Due to the state equation (5.1), we obtain for the exact optimal control $\bar{u}$

$$\bar{u}(x_1,x_2) = \begin{cases} a & \text{if } \hat{u}(x_1,x_2) < a, \\ \hat{u}(x_1,x_2) & \text{if } \hat{u}(x_1,x_2) \in [a,b], \\ b & \text{if } \hat{u}(x_1,x_2) > b. \end{cases}$$

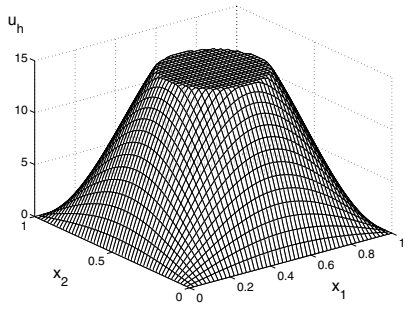

FIG. 5.1. *Optimal control* u_h.

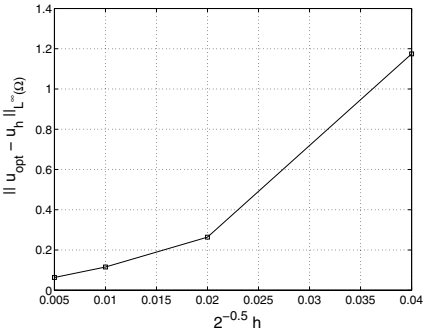

FIG. 5.2. $\|\bar{u} - u_h\|_{L^\infty(\Omega)}$.

TABLE 5.1

$h/\sqrt{2}$	0.04	0.02	0.01	0.005
$\|\bar{u} - u_h\|_{L^\infty(\Omega)}$	1.17450	0.26396	0.11536	0.06328

For the optimal adjoint state $\bar{p}$, we find

$$\bar{p}(x_1, x_2) = -2\,\pi^2\,\nu\,\sin(\pi x_1)\,\sin(\pi x_2).$$

To fulfill the necessary and sufficient first-order optimality conditions, the desired state y_d is defined by

$$y_d(x_1, x_2) = \bar{y} + \Delta\bar{p} = y_a - y_g + 4\,\pi^4\,\nu\,\sin(\pi x_1)\,\sin(\pi x_2).$$

The optimization problem was solved numerically by a primal-dual active set strategy; see [2], [11]. As mentioned in section 2, the state equation and the adjoint equation were discretized with linear finite elements. Here, uniform meshes were used. The resulting linear system of equations was solved with the conjugate gradient method.

To approximate the L^∞-norm $\|\bar{u} - u_h\|_{L^\infty(\Omega)}$, we evaluated $|\bar{u}(x) - u_h(x)|$ in the grid points, in the barycenters of the elements, and in the midpoints of the edges of the triangulation.

In a first test we chose $a = -15$ and $b = 15$. Here, we have $0 \in (a, b)$. Consequently the control is inactive near the boundary Γ.

Figure 5.1 shows the numerically calculated optimal control u_h for the mesh size $h/\sqrt{2} = 0.02$.

Figure 5.2 and Table 5.1 illustrate the convergence behavior for the first test. As one can see, the theoretical predictions are fulfilled, and one obtains linear approximation order for $\|\bar{u} - u_h\|_{L^\infty(\Omega)}$ (except on the coarsest grid).

In the second test we chose $a = 3$ and $b = 15$. Consequently, $0 \notin [a, b]$, i.e., the control is active near the boundary Γ.

Figure 5.3 shows again the numerically calculated optimal control u_h, for the mesh size $h/\sqrt{2} = 0.02$. Figure 5.4 and Table 5.2 illustrate the convergence behavior for the second test. The convergence behavior is similar to the first test and one again obtains linear convergence for $\|\bar{u} - u_h\|_{L^\infty(\Omega)}$.

OPTIMALITY OF AN (s, S) POLICY WITH COMPOUND POISSON AND DIFFUSION DEMANDS: A QUASI-VARIATIONAL INEQUALITIES APPROACH*

ALAIN BENSOUSSAN†, R. H. LIU‡, AND SURESH P. SETHI†

Abstract. We prove that an (s, S) policy is optimal in a continuous-review stochastic inventory model with a fixed ordering cost when the demand is a mixture of (i) a diffusion process and a compound Poisson process with exponentially distributed jump sizes, and (ii) a constant demand and a compound Poisson process. The proof uses the theory of impulse control. The Bellman equation of dynamic programming for such a problem reduces to a set of quasi-variational inequalities (QVI). An analytical study of the QVI leads to showing the existence of an optimal policy as well as the optimality of an (s, S) policy. Finally, the combination of a diffusion and a general compound Poisson demand is not completely solved. We explain the difficulties and what remains open. We also provide a numerical example for the general case.

Key words. stochastic inventory model, economic order quantity model, impulse control, quasi-variational inequalities, (s, S) policy, diffusion process, compound Poisson process

DOI. 10.1137/S0363012904443737

1. Introduction.

It is well known that the optimal ordering policies are of (s, S) type for a broad class of stochastic inventory models involving a fixed ordering cost, where s denotes the ordering point and $S \geq s$ is the order-up-to level. In other words, when the inventory level at time t is s or below, an order is issued at time t to bring the inventory level up to the level S. Ample literature exists. We review it briefly, while referring the readers to Presman and Sethi (2004) for a detailed review and a list of references on this subject.

One class of models that has been extensively studied in the literature is the continuous-review stochastic inventory models with a compound Poisson demand and fixed ordering cost. In this scenario, the demands arrive at random epochs governed by a Poisson process. At any epoch, the demand size is an independently and identically distributed (i.i.d.) random variable. Studies of (s, S) policies for this model are conducted by Richards (1975), Thompstone and Silver (1975), Archibald and Silver (1978), Feldman (1978), and Federgruen and Schechner (1983). Additionally, Tijms (1972), Sahin (1979, 1983), and Federgruen and Schechner (1983) consider the compound renewal demands in which the jump epochs are assumed to follow a renewal process. Zipkin (1986) uses a compound counting process to model demands. Some of these papers show that an (s, S) policy is optimal and others study the behavior of (s, S) policies without showing their optimality.

Another studied class of models is the so-called world-dependent demands or Markovian demands; see Beyer, Cheng, and Sethi (2006). Song and Zipkin (1993) consider a continuous-review model with world-dependent Poisson demands. They

use a continuous-time Markov chain to model the "state of the world." To solve the problem, they invoke the standard uniformization procedure (Keilson (1979) and Van Dijk (1990)) to convert the continuous-time problem to a discrete-time problem and then use the discrete-time dynamic programming to obtain a state-dependent (s, S) policy. A verification theorem, usually required to prove optimality in such problems, is given in Beyer, Sethi, and Taksar (1998) for problems with Markovian demands and a fairly general surplus cost function. We should mention that in a continuous-review model with Poisson or compound Poisson demands, since demands arrive only at discrete epochs, the optimal ordering decisions can be restricted to these epochs without loss of optimality. This is the key observation that makes the uniformization procedure applicable.

In contrast with Poisson process models, the classical economic order quantity (EOQ) problem is a "purely continuous" inventory model in the sense that the demands arrive continuously at a fixed constant rate. A natural and interesting model to study is the one that combines the constant continuous demand and the compound Poisson demand. However, this work had not been done until a very recent paper by Presman and Sethi (2004). A major reason, as mentioned in their paper, is that the presence of a constant demand means that the optimal ordering decisions may not be restricted only at the jump epochs of the compound Poisson demands. As a result, the standard uniformization procedure does not work in this case; see Presman and Sethi (2004) for other difficulties arising in the analysis of such a model.

Presman and Sethi (2004) consider the demand process to be the sum of a constant demand rate and a compound Poisson process. They develop a new approach to prove the optimality of an (s, S) policy in the presence of a fixed ordering cost. This is also a unified approach in the sense that it deals with both the long-run average cost and the discounted-cost criteria. Their approach can be outlined as follows: it starts with an (s, S) policy and then finds the corresponding discounted-cost formula and a closely related modified cost function. By minimizing the modified cost function, a candidate optimal (s, S) policy is obtained. Using this candidate and the formula for the discounted cost, a potential function is constructed, which is shown to satisfy the dynamic programming equation associated with the problem.

The next step in the generalization of the model is to add a Wiener process to the demand process and to prove the optimality of an (s, S) policy. This is the subject of this paper. We study an inventory model with a fixed ordering cost and a general demand process that consists of a compound Poisson demand and a diffusion process. Here the drift of the diffusion process represents the constant part of the demand. This is a problem of impulse control, the theory of which has been developed by Bensoussan and Lions (1984). The general idea is briefly as follows. Under the framework of impulse control, the Bellman equation of dynamic programming for the inventory problem under consideration reduces to a quasi-variational inequality (QVI). Using the QVI approach, i.e., by solving the QVI and analyzing the properties of its solution, it is possible to prove the existence of an optimal impulse control, and hence of an optimal inventory policy.

Bensoussan and Tapiero (1982) formulate a stochastic demand model consisting of a diffusion process and a pure Poisson process. They consider a finite horizon problem and derive the associated QVI. While they give conditions for an (s, S) policy to be optimal, they do not solve the problem.

Constantinides and Richard (1978) treat an infinite horizon discounted-cost inventory problem with a diffusion demand. They prove the existence and the optimality of an (s, S) policy. Sulem (1986) provides an explicit solution for this problem as well

as for its average-cost version. Some related models are Bather (1966), Whitt (1973), Puterman (1975), and Beyer (1994). But they do not go as far, for our purposes, as Sulem (1986) does.

A model presented by Browne and Zipkin (1991) also involves a diffusion term in the demand but treats it in a different way. While our model directly includes the diffusion as a part of the demand, they assume that the demand process is state-dependent and the underlying "state of the world" is modeled either by a continuous-time Markov chain or by a diffusion process. They consider an (s, S) policy, which typically is not optimal for their model.

Our primary goal is to prove that an (s, S) policy solves the QVI for the general stochastic demand model under consideration. We achieve it in two important cases: when the demand is (i) a mixture of a diffusion process and a compound Poisson process with exponentially distributed jump sizes, and (ii) a mixture of a constant demand and a compound Poisson process. However, the combination of a diffusion process and a general compound Poisson process is not completely solved. We explain the difficulties that arise and what remains open.

The specific steps taken in our approach are as follows. (i) We solve the QVI (4.2) by postulating that the first inequality is an equation (4.4) to the right of a number s (to be determined), and the second one is an equation (4.5) to the left of s. The value of s is fixed by imposing that the solution of the QVI is C^1 on the real line. (ii) We analytically solve (4.4) and (4.5) together with the boundary conditions (4.6) and (4.7) and the smoothness condition (4.8). This is done in three steps: (a) We solve (4.4) with condition (4.6) and obtain a C^1 solution G_s for any given s. (b) Then we show that a minimum $S(s)$ of the function G_s exists and that condition (4.7) is satisfied. (c) We use (4.5) to determine a unique optimal s. (iii) We check that the function constructed in this way satisfies the original QVI (4.2) of the inventory problem. This method leads to a unique function, which is C^1, and a unique pair (s, S). It is also the value function over the class of all (s, S) policies.

We emphasize that our approach is different from the one used in Presman and Sethi (2004) even though both involve QVIs. Presman and Sethi (2004) start with an arbitrary (s, S) policy and consider the cost function obtained using that policy. They derive a specific function of s and S, which is closely related to the cost function. They minimize this function to obtain an optimal pair (s, S) within the class of all (s, S) policies. They prove that the cost function associated with such an optimal (s, S) pair satisfies the QVI for the inventory problem and, therefore, is the minimum cost with respect to all feasible ordering decisions. We, on the other hand, begin with the QVI associated with the inventory control problem. We solve the QVI, as indicated above, to obtain the value function. In summary, our method is analytical in nature, whereas Presman and Sethi (2004) use a probabilistic approach. Moreover, we extend the result on the optimality of an (s, S) policy to include a diffusion demand.

Specifically, our paper makes the following main contributions.

1. We formulate a fairly general stochastic inventory model and consider the appropriate QVI.

2. Our work generalizes the stochastic demand considered in Presman and Sethi (2004) by allowing a Brownian motion term in the demand process. However, we must note that our generalization comes at the expense of requiring the compound Poisson process to have exponentially distributed jump sizes.

3. We solve the QVI analytically to obtain a closed-form solution.

4. We prove that an (s, S) policy solves the QVI for two important special cases,

mentioned earlier and in the abstract.

5. We reveal an interesting relation between the optimal values of S and s; see (5.5) and Remark 5.5.

6. We explain the difficulties with the general model having a combined demand process involving both diffusion and compound Poisson demands.

The rest of the paper is organized as follows. In section 2, we provide a precise formulation of the stochastic inventory problem under consideration. We also present the QVI that must be satisfied by the value function of the problem. In section 3, we briefly review the general theory of impulse control and QVI. In section 4, we derive a set of equations for a given s and solve them to obtain a closed-form solution. Section 5 presents some properties of the solution that are important to the optimal (s, S) policy. The existence of the corresponding S for each given s is proved. In section 6, we study the optimal (s, S) policy using the solution and an additional condition that must be satisfied by the solution if an (s, S) policy is to be optimal, including its existence. In section 7, we deal with a special case in which the random jump size in the compound Poisson process is assumed to be exponentially distributed. Section 8 treats the nondiffusion case using a different approach for the optimality proof. In section 9, we provide some explanations for the difficulties with the general case. A numerical example is presented. Section 10 concludes the paper.

2. Problem formulation. In this section, we provide a precise formulation of the stochastic inventory problem under consideration. We present the QVI associated with the problem that is satisfied by the value function.

We first define the demand process. Let $(\Omega, \mathcal{F}, \mathcal{P})$ be the underlying probability space. The cumulative demand $y(t)$ in the interval $[0, t]$ is a stochastic process given by

$$y(t) = Dt + \sigma W(t) + N(t), \tag{2.1}$$

where $D \geq 0$ is the constant demand per unit time, $W(t)$ denotes the standard Brownian motion with $W(0) = 0$, and $\sigma \geq 0$. The process $Dt + \sigma W(t)$ is referred to as a diffusion process with drift D and volatility σ. $N(t)$ is a compound Poisson process defined next. Let $n(t)$ be a right-continuous Poisson process with $n(0) = 0$ and the intensity $\lambda \geq 0$. Let $\xi_i \geq 0, i = 1, 2, \ldots,$ be a sequence of i.i.d. nonnegative random variables having distribution density $\mu(\cdot)$. Then,

$$N(t) = \sum_{i \leq n(t)} \xi_i, \quad t \geq 0.$$

We note that the process $n(t)$ produces a sequence of jump times and that ξ_i denotes the size (random) of the demand at the ith jump. We shall sometimes simply use ξ for the jump size for convenience in exposition.

Assumption 2.1. The Wiener process $W(t)$, the Poisson process $n(t)$, and the jump sequence $\{\xi_i\}$ are all independent.

Next we define the class of admissible ordering policies. Let $\mathcal{F}_t, t > 0$, be the sigma algebra generated by $\{N(s), W(s), 0 < s \leq t\}$ and $\mathcal{F}_0 = \{\emptyset, \Omega\}$. Let $\theta_i \geq 0, i = 1, 2, \ldots,$ be a strictly increasing sequence of stopping times with respect to the filtration $\{\mathcal{F}_{t+0}\}$, and let $u_i > 0$ be a positive random variable adapted to $\mathcal{F}_{\theta_i}$. An admissible ordering policy is defined by

$$U = (\theta_1, u_1, \theta_2, u_2, \ldots).$$

Here θ_i denotes the time of the ith order, and u_i denotes the amount ordered. We use $\mathcal{U}$ to denote the set of all admissible ordering policies.

The cumulative amount of orders from time 0 up to but not including t is then given by

$$M(t) = \sum_{\{i:\theta_i<t\}} u_i.$$

We assume the orders are delivered instantaneously. Then the surplus level $x^U(t)$ at time t under a policy $U \in \mathcal{U}$ is given by the equation

$$x^U(t) = x - Dt - \sigma W(t) - N(t) + M(t), \tag{2.2}$$

where $x^U(0) = x$ (a constant) is the initial surplus level at $t = 0$. Note the surplus $x^U(t)$ when positive means inventory and when negative means backlog.

Next we introduce the surplus and ordering costs. Let the surplus cost $f(x)$ be a nonnegative and piecewise continuously differentiable function with $f(0) = 0$. It gives the cost of holding inventory for $x > 0$ and the backlog cost for $x < 0$. As in Beyer, Sethi, and Taksar (1998), we make the following assumption on f.

Assumption 2.2. $f(x)$ has a polynomial growth rate.

Some additional properties of $f(x)$ will be specified later.

The cost $c(u)$ of ordering an amount u is given by

$$c(u) = \begin{cases} K + cu, & u > 0, \\ 0, & u = 0, \end{cases} \tag{2.3}$$

where $K > 0$ is the fixed set up cost of ordering, and c denotes the unit cost of each item ordered.

We consider in this paper a discounted cost objective function. Let $\rho > 0$ be the specified discount rate. For a given initial inventory level x and an ordering policy $U \in \mathcal{U}$, we define the discounted cost as

$$F(x, U) = E\left\{ \int_0^\infty f(x^U(t)) e^{-\rho t} dt + \sum_{i=1}^{\infty} c(u_i) e^{-\rho \theta_i} \right\}. \tag{2.4}$$

Define the value function associated with (2.4) as

$$F(x) = \inf_{U \in \mathcal{U}} F(x, U). \tag{2.5}$$

Our goal is to find a policy $U^* \in \mathcal{U}$ such that $F(x, U^*) = F(x)$.

Now we recall the notion of an (s, S) policy of ordering. For $-\infty < s < S < +\infty$, let $U^{s,S}$ denote the (s, S) policy given by the following function:

$$U^{s,S}(x) = \begin{cases} 0 & \text{if } x > s, \\ S - x & \text{if } x \le s, \end{cases}$$

where s is called the ordering level, and S is called the order-up-to level. Clearly $U^{s,S} \in \mathcal{U}$. Let $\mathcal{U}^{s,S}$ denote the subset of $\mathcal{U}$ containing all (s, S) policies.

Next we present the QVI associated with (2.2)–(2.5). To this end, we introduce the following operators. For function ϕ, let

$$\begin{cases} (A\phi)(x) = -\dfrac{\sigma^2}{2}\phi''(x) + D\phi'(x), \\ (B\phi)(x) = \lambda \displaystyle\int_0^\infty (\phi(x-\xi) - \phi(x))\mu(\xi)\, d\xi, \\ (M\phi)(x) = K + \inf\limits_{u\geq 0}(cu + \phi(x+u)). \end{cases}$$

The Bellman equation for the value function reduces to a set of inequalities:

$$\begin{cases} AV - BV + \rho V \leq f, \\ V \leq MV, \\ (AV - BV + \rho V - f)(V - MV) = 0. \end{cases} \tag{2.6}$$

These relations make sense a.e. x for any function $V(x)$ that is continuously differentiable. Our purpose therefore is to look for a C^1 solution of (2.6) with polynomial growth.

We make the following assumption on the random variable ξ.

Assumption 2.3. There is a $\bar{\pi} < 0$ such that

$$\int_0^\infty e^{-\pi\xi}\mu(\xi)d\xi < \infty \quad \text{for all } \pi > \bar{\pi}.$$

It should be noted that this assumption is stronger than that of a finite mean for the jump size ξ.

3. A brief review of the impulse control theory. The QVI (2.6) is a special case of the general QVI theory studied in Bensoussan and Lions (1984). They present results on the existence of solution and the probabilistic interpretation in the context of inventory control. In this section, we provide a brief review of related formulations and results from the general theory of QVIs for impulse control.

Let $\beta_\alpha(x) = \exp(-\alpha(1+x^2)^{\frac{1}{2}})$, $\alpha > 0$. Consider the Hilbert spaces L^2_α and H^1_α defined as follows:

$$L^2_\alpha = \left\{ v \,\middle|\, \int_{-\infty}^{+\infty} v^2\beta_\alpha^2\, dx < \infty \right\}, \quad H^1_\alpha = \{v | v \in L^2_\alpha, v' \in L^2_\alpha\}$$

with $(v,w)_\alpha = \int_{-\infty}^{+\infty} vw\beta_\alpha^2\, dx$, $v, w \in L^2_\alpha$. Define the bilinear form on H^1_α by

$$\begin{aligned} a_\alpha(v,w) = {} & \frac{\sigma^2}{2}\int_{-\infty}^{+\infty} v'w'\beta_\alpha^2\, dx + \int_{-\infty}^{+\infty} v'w\left(D - \frac{\alpha\sigma^2 x}{(1+x^2)^{\frac{1}{2}}}\right)\beta_\alpha^2\, dx \\ & + \rho\int_{-\infty}^{+\infty} vw\beta_\alpha^2\, dx - \int_{-\infty}^{+\infty}(Bv)w\beta_\alpha^2\, dx, \quad v, w \in H^1_\alpha. \end{aligned}$$

We first note some properties of Bv. These are

$$|Bv|_\alpha \leq \lambda(1 + C_\alpha)|v|_\alpha, \quad (Bv, v)_\alpha \leq \lambda(C_\alpha - 1)|v|^2_\alpha$$

with

$$C_\alpha = \left(\int_0^\infty \exp(2\alpha\xi)\mu(\xi)\, d\xi\right)^{\frac{1}{2}}, \quad 2\alpha < -\bar{\pi}.$$

These follow from

$$\int_{-\infty}^{+\infty} \beta_\alpha^2(x) \left(\int_0^{+\infty} v(x-\xi)\mu(\xi)\, d\xi \right)^2 dx \le \int_{-\infty}^{+\infty} \beta_\alpha^2(x) \left(\int_0^{+\infty} v^2(x-\xi)\mu(\xi)\, d\xi \right) dx$$

and

$$\beta_\alpha^2(x) \le \beta_\alpha^2(x-\xi)\exp(2\alpha\xi).$$

We also have

$$(Bv, v^+)_\alpha \le (Bv^+, v^+)_\alpha \text{ and } (Bv, v^-)_\alpha \ge -(Bv^-, v^-)_\alpha,$$

where $v^+ = \max(v, 0)$ and $v^- = \max(-v, 0)$. Set $\rho_\alpha = \alpha D + \alpha^2\sigma^2 + \lambda(C_\alpha - 1)$. Then we have

$$a_\alpha(v, v) \ge \frac{\sigma^2}{2} \int_{-\infty}^{+\infty} v'^2 \beta_\alpha^2\, dx + (\rho - \rho_\alpha) \int_{-\infty}^{+\infty} v^2 \beta_\alpha^2\, dx.$$

Note that for a sufficiently small α, we have $\rho_\alpha < \rho$.

We define the following variational inequality using the above notions:

$$\begin{cases} a_\alpha(v, w - v) \ge (f, w - v)_\alpha \\ \text{for any } w \in H_\alpha^1 \text{ such that } w \le Mv,\ v \le Mv, \text{ and } v \in H_\alpha^1. \end{cases} \tag{3.1}$$

Now let v^0 be defined as

$$v^0(x) = V_0 \exp(\alpha(1 + x^2)^{\frac{1}{2}}) = V_0 \beta_{-\alpha}(x),$$

where $V_0 > 0$ is a constant. We wish to find a V_0 such that

$$a_\alpha(v^0, w) \ge (f, w)_\alpha \quad \text{for any } w \ge 0. \tag{3.2}$$

Noting the fact that

$$|Bv^0(x)| \le \lambda v^0(x)\alpha e^\alpha \int_0^\infty \xi e^{\alpha\xi} \mu(\xi)\, d\xi,$$

we have

$$a_\alpha(v^0, w) \ge (\rho - \rho'_\alpha)(v^0, w)_\alpha,$$

where

$$\rho'_\alpha = D\alpha + \frac{1}{2}\sigma^2\alpha^2 + \frac{1}{2}\sigma^2\alpha + \lambda\alpha e^\alpha \int_0^\infty \xi e^{\alpha\xi} \mu(\xi)\, d\xi.$$

Therefore, it is sufficient for (3.2) to achieve

$$(\rho - \rho'_\alpha) V_0 \exp(\alpha(1 + x^2)^{\frac{1}{2}}) \ge f(x), \quad x \in (-\infty, +\infty).$$

Since f has a polynomial growth rate by Assumption 2.2, i.e., there exist positive constants f_0 and γ such that

$$f(x) \le f_0(1 + |x|^\gamma), \quad x \in (-\infty, +\infty),$$

and since

$$(\rho - \rho'_\alpha)V_0 \exp(\alpha(1+x^2)^{\frac{1}{2}}) \geq (\rho - \rho'_\alpha)V_0 \exp(\alpha|x|),$$

it is sufficient to pick a V_0 such that

$$\frac{V_0(\rho - \rho'_\alpha)}{f_0} \geq \max_{x>0}(1+x^\gamma)\exp(-\alpha x).$$

From the general result (Theorem 4.1, Chapter 4 in Bensoussan and Lions (1984)), it follows that the set of solutions of (3.1) satisfying $0 \leq v \leq v^0$ is nonempty, and it has a minimum solution $\underline{v}$ and a maximum solution $\bar{v}$. Moreover, one has the following probabilistic interpretation of the minimum solution $\underline{v}$ in the context of impulse control (Theorem 3.4, Chapter 6 in Bensoussan and Lions (1984)):

$$\underline{v}(x) = F(x) = \min_{U \in \mathcal{U}} F(x, U),$$

i.e., there exists an admissible control U such that the value function $F(x)$ is attained using this control, and $F(x)$ is indeed equal to the minimum solution $\underline{v}(x)$.

The C^1 solution of (2.6) we are aiming at will be a solution of (3.1). To check that it is the value function and the minimum solution of (3.1), one relies on the fact that such a solution satisfies

$$V(x) \leq F(x, U) \quad \text{for all } U \in \mathcal{U}.$$

These two statements are standard in the literature. For a proof of these in the pure diffusion case see section 1.4 in Chapter 6 of Bensoussan and Lions (1984).

For our purpose, it is sufficient to find a solution $V(x)$ of the QVI (2.6), which leads to an (s, S) policy. Then we can attach to this (s, S) policy an impulse control such that

$$V(x) = F(x, U^{s,S}).$$

This implies that the solution $V(x)$ obtained in this way is unique and is equal to $F(x)$.

Thus, the problem boils down to finding a solution $V(x)$ of (2.6), which is C^1 and of polynomial growth, and which corresponds to an (s, S) policy. Finding such a solution is, therefore, the main objective in the rest of the paper.

4. An (s, S) policy and QVI. Let F be a solution of (3.1), which is C^1 and of polynomial growth. Let $G(x) = F(x) + cx$ and

$$g(x) = f(x) + c\rho x. \tag{4.1}$$

Then G satisfies

$$\begin{cases} AG - BG + \rho G \leq g + cD + c\lambda\bar{\xi}, \\ G(x) \leq K + \inf_{u \geq 0} G(x+u), \\ (AG - BG + \rho G - g - cD - c\lambda\bar{\xi})(G(x) - K - \inf_{u \geq 0} G(x+u)) = 0, \end{cases} \tag{4.2}$$

where $\bar{\xi} = \int_0^\infty \xi\mu(\xi)\,d\xi$ is the mean of ξ.

Remark 4.1. If $\sigma = 0$ and $\lambda = 0$, then our model reduces to the classical EOQ model. In this case, the QVI (4.2) takes the special form

$$\begin{cases} DG' + \rho G \le g + cD, \\ G(x) \le K + \inf\limits_{u \ge 0} G(x+u), \\ (DG' + \rho G - g - cD)(G(x) - K - \inf\limits_{u \ge 0} G(x+u)) = 0. \end{cases} \tag{4.3}$$

Beyer and Sethi (1998) give a rigorous proof of the optimality of the well-known EOQ formula by using the QVI approach. It is easy to check that (4.3) is equivalent to the QVI (1) in their paper.

We make the following assumptions on the function g.

Assumption 4.2. There exists a number a such that g is increasing on (a, ∞) and decreasing and convex on $(-\infty, a)$. Furthermore, there exist a $c_0 > 0$ and an $x_1 \ge a$ such that $g'(x) \ge c_0$ for $x \ge x_1$.

Remark 4.3. Presman and Sethi (2004) do not require g to be convex on $(-\infty, a)$ in their study of the inventory model with demand consisting of only a constant term and a compound Poisson process.

Since we are interested in an (s, S) policy, we seek a solution of the QVI (4.2), which implies ordering up to S on the interval $(-\infty, s]$ and not ordering on the interval $(s, +\infty)$. This means that we are interested in finding an s such that G satisfies the following two equations:

$$AG - BG + \rho G = g + cD + c\lambda\bar{\xi} \quad \text{for } x \ge s, \tag{4.4}$$

$$G(x) = K + G(S) \quad \text{for } x \le s \tag{4.5}$$

with two boundary conditions

$$G'(s) = 0, \tag{4.6}$$

$$G'(S) = 0. \tag{4.7}$$

It follows from (4.4) to (4.7) that G is smooth, i.e.,

$$G \in C^1. \tag{4.8}$$

It will also have a polynomial growth rate. So our problem is reduced to finding a triple $\{s, S, G(x)\}$ which satisfies (4.4)–(4.7).

We will solve (4.4)–(4.7) in three steps. For s given, the first step finds a function $G = G_s$ which satisfies (4.4) and (4.6), which is constant on the left-hand side of s, and which is C^1. The function G_s will be obtained in Theorem 4.8 in this section. The second step is devoted to determining $S(s)$ satisfying (4.7); see Theorem 5.3 in section 5. The solution $\{s, S(s), G_s\}$ of (4.4), (4.6), and (4.7) will be unique by the analytic treatment pursued below. The third step will be to obtain s and to solve (4.5). This is accomplished in Theorem 6.1.

To proceed, it is convenient to introduce $H_s(x) = G_s'(x)$, which is the solution of

$$\begin{cases} -\dfrac{\sigma^2}{2} H_s''(x) + DH_s'(x) + (\rho + \lambda) H_s(x) - \lambda \displaystyle\int_0^{x-s} H_s(x-\xi)\mu(\xi)\, d\xi = g'(x), \\ H_s(s) = 0, \quad H_s \text{ has a polynomial growth, } x > s. \end{cases} \tag{4.9}$$

Note that $H_s(x) = 0$ for $x < s$. Set $Z_s(x) = H_s(x + s)$ and $g_s(x) = g(x + s)$, $x > 0$. It follows that

$$\begin{cases} -\dfrac{\sigma^2}{2} Z_s''(x) + DZ_s'(x) + (\rho + \lambda) Z_s(x) - \lambda \displaystyle\int_0^x Z_s(x - \xi)\mu(\xi)\, d\xi = g_s'(x), \\ Z_s(0) = 0, \quad Z_s \text{ has a polynomial growth, } x > 0. \end{cases} \tag{4.10}$$

Now we solve (4.10) by the transformation

$$Z_s(x) = \int_0^x \Gamma(x - \theta) Q_s(\theta)\, d\theta,$$

where $\Gamma(\theta)$ is a solution of

$$\begin{cases} -\dfrac{\sigma^2}{2} \Gamma''(\theta) + D\Gamma'(\theta) + (\rho + \lambda)\Gamma(\theta) - \lambda \displaystyle\int_0^\theta \Gamma(\theta - \xi)\mu(\xi)\, d\xi = 0, \\ \Gamma(0) = 1, \quad \Gamma(+\infty) = 0, \end{cases} \tag{4.11}$$

and $Q_s(x)$ is a solution of

$$-\frac{\sigma^2}{2} Q_s'(x) + \left(D - \frac{\sigma^2}{2} \Gamma'(0) \right) Q_s(x) = g_s'(x), \quad Q_s(+\infty) = 0. \tag{4.12}$$

Let us denote

$$\hat{\mu}(\pi) = \int_0^\infty e^{-\pi\xi} \mu(\xi)\, d\xi, \tag{4.13}$$

which by Assumption 2.3 is well defined for $\pi > \bar{\pi}$. We have the following results.

PROPOSITION 4.4. *There exists a unique solution $\Gamma(\theta) \geq 0$ of (4.11), whose Laplace transform $\hat{\Gamma}(\pi) = \int_0^\infty e^{-\pi\theta} \Gamma(\theta)\, d\theta$ is well defined for $\pi > \beta_1$, with $\bar{\pi} < \beta_1 < 0$, and it is given by*

$$\hat{\Gamma}(\pi) = \frac{\hat{\varphi}(\pi)}{\pi - \beta_1}, \tag{4.14}$$

where $\hat{\varphi}(\pi) > 0$ (to be defined next) for any $\pi > \bar{\pi}$.

Proof. By (4.11), the Laplace transform $\hat{\Gamma}(\pi)$ is given by

$$\hat{\Gamma}(\pi) = \frac{D - \frac{\sigma^2}{2}\pi - \frac{\sigma^2}{2}\Gamma'(0)}{\chi(\pi)} \tag{4.15}$$

with

$$\chi(\pi) = -\frac{\sigma^2}{2}\pi^2 + D\pi + \rho + \lambda - \lambda\hat{\mu}(\pi). \tag{4.16}$$

We have

$$\begin{aligned} &\chi(\bar{\pi}) = \chi(+\infty) = -\infty, \\ &\chi'(\pi) = -\sigma^2\pi + D + \lambda \int_0^\infty \xi e^{-\pi\xi} \mu(\xi)\, d\xi, \\ &\chi''(\pi) = -\sigma^2 - \lambda \int_0^\infty \xi^2 e^{-\pi\xi} \mu(\xi)\, d\xi < 0, \\ &\chi'(\bar{\pi}) = +\infty, \quad \chi'(+\infty) = -\infty, \quad \chi'(0) > 0. \end{aligned}$$

Hence, there exists a unique $\pi_0 > 0$ such that $\chi'(\pi_0) = 0$. Therefore, $\chi(\pi)$ has a unique maximum at π_0. Note that $\chi(0) = \rho > 0$. Then χ has two zeros β_1, β_2 with $\bar{\pi} < \beta_1 < 0 < \pi_0 < \beta_2$. We may then write (4.16) as

$$\chi(\pi) = -\frac{\frac{\sigma^2}{2}(\pi - \beta_1)(\pi - \beta_2)}{\hat{\varphi}(\pi)}, \quad \hat{\varphi}(\pi) > 0 \text{ for any } \pi > \bar{\pi}. \tag{4.17}$$

Then (4.15) becomes

$$\hat{\Gamma}(\pi) = -\frac{\left(D - \frac{\sigma^2}{2}\pi - \frac{\sigma^2}{2}\Gamma'(0)\right)\hat{\varphi}(\pi)}{\frac{\sigma^2}{2}(\pi - \beta_1)(\pi - \beta_2)}. \tag{4.18}$$

Since $\hat{\Gamma}(\pi)$ is well defined for any $\pi > 0$, we must get rid of $(\pi - \beta_2)$ in the denominator of (4.18). This implies that the numerator has a zero at β_2. As a result, we must have

$$\Gamma'(0) = \frac{2D}{\sigma^2} - \beta_2, \tag{4.19}$$

and accordingly, $\hat{\Gamma}(\pi)$ has the form (4.14). Additionally, since $\hat{\varphi}(0) = -\frac{\sigma^2\beta_1\beta_2}{2\rho} > 0$,

$$\Gamma(+\infty) = \lim_{\pi \to 0} \pi\hat{\Gamma}(\pi) = 0.$$

We now show that

$$\Gamma(\theta) \geq 0, \quad \theta \geq 0. \tag{4.20}$$

In fact, if (4.20) were not true, then Γ would have a negative minimum at $\theta_0 > 0$ such that $\Gamma(\theta_0) < 0$, $\Gamma'(\theta_0) = 0$, and $\Gamma''(\theta_0) > 0$. It follows that

$$\Gamma(\theta_0) - \int_0^{\theta_0} \Gamma(\theta_0 - \xi)\mu(\xi)\, d\xi \leq \Gamma(\theta_0)\left(1 - \int_0^{\theta_0} \mu(\xi)\, d\xi\right) < 0,$$

which is a contradiction with (4.11). This completes the proof. □

In addition to the proof, we have the following remark.

Remark 4.5. Since $\chi'(D/\sigma^2) > 0$, we know that $D/\sigma^2 < \pi_0 < \beta_2$. Hence, $\beta_2 > 2D/\sigma^2 - \beta_2$. Moreover,

$$\begin{aligned}\chi\left(\frac{2D}{\sigma^2} - \beta_2\right) &= -\frac{\sigma^2}{2}\beta_2^2 + D\beta_2 + \rho + \lambda - \lambda\hat{\mu}\left(\frac{2D}{\sigma^2} - \beta_2\right) \\ &= \lambda\hat{\mu}(\beta_2) - \lambda\hat{\mu}\left(\frac{2D}{\sigma^2} - \beta_2\right) < 0.\end{aligned}$$

Therefore, we have

$$\frac{2D}{\sigma^2} - \beta_2 < \beta_1 \text{ and } \Gamma'(0) < \beta_1.$$

PROPOSITION 4.6. *The solution* $\Gamma(\theta)$ *of* (4.11) *satisfies*

$$\exp(\beta_0\theta) \leq \Gamma(\theta) \leq \exp(\beta_1\theta), \quad \theta \geq 0, \tag{4.21}$$

where β_0 is the negative solution of the equation

$$-\frac{\sigma^2}{2}\beta_0^2 + D\beta_0 + \rho + \lambda = 0.$$

Proof. First we let $\Sigma(\theta) = \exp(\beta_1\theta)$. Then,

$$\begin{aligned}
&-\frac{\sigma^2}{2}\Sigma''(\theta) + D\Sigma'(\theta) + (\rho+\lambda)\Sigma(\theta) - \lambda\int_0^\theta \Sigma(\theta-\xi)\mu(\xi)\,d\xi \\
&= \exp(\beta_1\theta)\left(-\frac{\sigma^2}{2}\beta_1^2 + D\beta_1 + \rho + \lambda - \lambda\int_0^\theta \exp(-\beta_1\xi)\mu(\xi)\,d\xi\right) \\
&\geq \exp(\beta_1\theta)\left(-\frac{\sigma^2}{2}\beta_1^2 + D\beta_1 + \rho + \lambda - \lambda\int_0^\infty \exp(-\beta_1\xi)\mu(\xi)\,d\xi\right) = 0,
\end{aligned}$$

$\Sigma(0) = 1$, and $\Sigma(+\infty) = 0$. It follows that $\Gamma(\theta) \leq \exp(\beta_1\theta)$. Next, in terms of (4.11), we get $-\frac{\sigma^2}{2}\Gamma'' + D\Gamma' + (\rho+\lambda)\Gamma \geq 0$, which implies the first inequality of (4.21). This completes the proof. □

Using (4.19), the unique solution of (4.12) is given by

$$Q_s(x) = \frac{2}{\sigma^2}\int_x^\infty \exp(\beta_2(x-y))g_s'(y)dy.$$

Finally, we get the formula

$$H_s(x) = \int_s^x \Gamma(x-y)Q(y)dy, \tag{4.22}$$

where Q is given by

$$Q(x) = \frac{2}{\sigma^2}\int_x^\infty \exp(-\beta_2(y-x))g'(y)dy. \tag{4.23}$$

We have proved the following result.

PROPOSITION 4.7. *Let Assumptions* 2.1, 2.2, *and* 2.3 *hold. Then the function $H_s(x)$ defined in* (4.22) *is a solution of* (4.9).

We now obtain G_s using H_s. For a specified ordering level s, we set

$$G_s(x) = G_s(s) + \int_s^x H_s(y)\,dy. \tag{4.24}$$

Integrating (4.9) from s to $x > s$, we get

$$\begin{aligned}
&-\frac{\sigma^2}{2}(H_s'(x) - H_s'(s)) + DH_s(x) + (\rho+\lambda)\int_s^x H_s(y)\,dy \\
&\qquad - \lambda\int_s^x dy\int_0^{y-s} H_s(y-\xi)\mu(\xi)\,d\xi = g(x) - g(s).
\end{aligned}$$

Note that $H_s'(s) = Q(s)$. Hence,

$$\begin{aligned}
&-\frac{\sigma^2}{2}G_s''(x) + \frac{\sigma^2}{2}Q(s) + DG_s'(x) + (\rho+\lambda)(G_s(x) - G_s(s)) \\
&\qquad - \lambda\int_s^x dy\int_0^{y-s} H_s(y-\xi)\mu(\xi)\,d\xi = g(x) - g(s)
\end{aligned}$$

and

$$\int_s^x dy \int_0^{y-s} H_s(y-\xi)\mu(\xi)\,d\xi = \int_0^{x-s} G_s(x-\xi)\mu(\xi)\,d\xi - G_s(s) + G_s(s)\int_{x-s}^{\infty}\mu(\xi)\,d\xi.$$

Using these results and comparing with the right-hand side of (4.4), we obtain

$$G_s(s) = \frac{g(s) + \frac{\sigma^2}{2}Q(s) + cD + c\lambda\bar{\xi}}{\rho}. \tag{4.25}$$

We have proved the following theorem.

THEOREM 4.8. *Under Assumptions* 2.1, 2.2, *and* 2.3, *the function* $G_s(x)$ *defined by* (4.24) *and* (4.25) *is a solution of* (4.4) *and* (4.6).

5. Properties of the solution and finding S for any given s. This section further discusses the solution obtained above and derives some properties. These properties are important to finding an optimal (s, S) pair and completing the solution of (4.4)–(4.7). They are also important to proving the optimality of an (s, S) policy for our inventory model.

PROPOSITION 5.1. *There exists a unique number* $a_0 < a$ *such that* $Q(a_0) = 0$, $Q(x) < 0$ *if* $x < a_0$, *and* $Q(x) > 0$ *if* $x > a_0$. *Moreover,* $Q'(x) > 0$ *for* $x \le a$ *and* $Q(x) \ge 2c_0/\sigma^2\beta_2$ *for* $x \ge x_1$, *where* a, x_1, c_0 *are introduced in Assumption* 4.2.

Proof. In terms of (4.12), (4.19), and the relation $Q_s(x) = Q(x+s)$, we have

$$Q'(x) = \beta_2 Q(x) - \frac{2g'(x)}{\sigma^2}. \tag{5.1}$$

For $x < a$, from (4.23), and the convexity of g, we have

$$\begin{aligned} Q(x) &\ge \frac{2}{\sigma^2}\int_x^a \exp(-\beta_2(y-x))g'(y)\,dy \\ &\ge \frac{2}{\sigma^2}g'(x)\int_x^a \exp(-\beta_2(y-x))\,dy \\ &= \frac{2}{\sigma^2}g'(x)\frac{1-\exp(-\beta_2(a-x))}{\beta_2}, \end{aligned}$$

which gives

$$\beta_2 Q(x) - \frac{2g'(x)}{\sigma^2} \ge -\frac{2}{\sigma^2}g'(x)\exp(-\beta_2(a-x)) > 0.$$

Hence, $Q'(x) > 0$.

By (4.23), for $x < x_0 < a$, we have

$$Q(x) \le \frac{2}{\sigma^2}\int_x^{x_0} \exp(-\beta_2(y-x))g'(y)\,dy + \frac{2}{\sigma^2}\exp(-\beta_2(a-x))\int_a^{\infty}\exp(-\beta_2(y-a))g'(y)\,dy,$$

and again from the convexity of g, we have

$$Q(x) \le \frac{2}{\sigma^2}\frac{g'(x_0)}{\beta_2}(1-\exp(-\beta_2(x_0-x))) + \frac{2}{\sigma^2}\exp(-\beta_2(a-x))\int_a^{\infty}\exp(-\beta_2(y-a))g'(y)\,dy.$$

It can be seen that there exists an $x_0' < x_0$ such that

$$Q(x) < \frac{1}{\sigma^2\beta_2}g'(x_0) < 0 \quad \text{for } x < x_0'.$$

Since $Q(a) > 0$, it follows that there exists a unique $a_0 < a$ such that $Q(a_0) = 0$ and $Q(x) < 0$ if $x < a_0$, and $Q(x) > 0$ if $x > a_0$.

Finally, from Assumption 4.2, $g'(x) \geq c_0$ for $x \geq x_1 \geq a$, and thus, for $x > x_1$,

$$Q(x) \geq \frac{2c_0}{\sigma^2} \int_x^\infty \exp(-\beta_2(y-x))\, dy = \frac{2c_0}{\sigma^2\beta_2}.$$

This completes the proof. □

Remark 5.2. If g is convex on $(-\infty, \infty)$, then $Q'(x) \geq 0$ for any $x \in (-\infty, \infty)$. Indeed we have in this case,

$$Q(x) \geq \frac{2}{\sigma^2} g'(x) \int_x^\infty \exp(-\beta_2(y-x))\, dy = \frac{2}{\sigma^2} \frac{g'(x)}{\beta_2}.$$

Hence from (5.1), $Q'(x) \geq 0$.

Next we study the existence of an order-up-to level S. From Proposition 5.1, for $s > a_0$ and $y > s$, we see that $Q(y) > 0$. Hence, for $x > s > a_0$, we have $H_s(x) > 0$. Therefore, in particular,

$$G_s(x) > G_s(s) \quad \text{for } x > s > a_0. \tag{5.2}$$

For $s < x < a_0$, $H_s(x) < 0$. Hence, $G_s(x)$ decreases on $[s, a_0]$. Moreover, we know that for $x \geq x_1 \geq a$, we have $Q(x) \geq 2c_0/\sigma^2\beta_2$. Using (4.21), we have

$$\begin{aligned} H_s(x) &\geq \int_s^{a_0} \Gamma(x-\theta) Q(\theta)\, d\theta + \frac{2c_0}{\sigma^2\beta_2} \int_{x_1}^x \Gamma(x-\theta)\, d\theta \\ &\geq \int_s^{a_0} \exp(\beta_1(x-\theta)) Q(\theta)\, d\theta + \frac{2c_0}{\sigma^2\beta_2} \int_{x_1}^x \exp(\beta_0(x-\theta))\, d\theta \\ &= \exp(\beta_1(x-a_0)) \int_s^{a_0} \exp(\beta_1(a_0-\theta)) Q(\theta)\, d\theta - \frac{2c_0}{\sigma^2\beta_2\beta_0}(1 - \exp(\beta_0(x-x_0))). \end{aligned}$$

For x sufficiently large, we see that

$$H_s(x) \geq -\frac{c_0}{\sigma^2\beta_2\beta_0} > 0.$$

This implies that $G_s(x) \to \infty$ as $x \to \infty$.

Therefore, for $s < a_0$, $G_s(x)$ reaches its minimum on $[s, \infty)$. We denote by $S(s)$ the smallest minimum point. It is necessary to have $S(s) > a_0$, since $G_s(x)$ decreases on $[s, a_0]$. Furthermore,

$$H_s(S(s)) = 0.$$

For $s > a_0$, in view of (5.2), it is convenient to define $S(s) = s$. In summary, we have

$$G_s(S(s)) = \min_{x \geq s} G_s(x) \quad \text{for any } s. \tag{5.3}$$

Let us summarize the result we have just proved.

THEOREM 5.3. *Let Assumptions* 2.1, 2.2, 2.3, *and* 4.2 *hold. Then for any* s, *there exists an* $S(s)$ *such that* (5.3) *is satisfied. This, in turn, implies* (4.7).

Next we discuss some important properties of $S(s)$. For $s < a_0$, since $S(s)$ minimizes $G_s(x)$, we have $G_s''(S(s)) = H_s'(S(s)) > 0$, which implies that

$$Q(S(s)) + \int_s^{S(s)} \Gamma'(S(s) - \theta)Q(\theta)\, d\theta > 0, \quad s < a_0.$$

Note that for any s, $H_s(S(s)) = 0$, which gives

$$\int_s^{S(s)} \Gamma(S(s) - \theta)Q(\theta)\, d\theta = 0.$$

Therefore, $S(s)$ is differentiable and

$$S'(s)\left(Q(S(s)) + \int_s^{S(s)} \Gamma'(S(s) - \theta)Q(\theta)\, d\theta\right) - \Gamma(S(s) - s)Q(s) = 0. \tag{5.4}$$

It follows that

$$\begin{cases} S'(s) < 0 & \text{for } s < a_0, \\ S'(s) = 1 & \text{for } s > a_0. \end{cases} \tag{5.5}$$

Remark 5.4. Note that for $s < a_0$ and s close to a_0, we have $Q(s) \approx (s - a_0)Q'(a_0) = -\frac{2}{\sigma^2} g'(a_0)(s - a_0)$. Thus,

$$\int_s^{a_0} \Gamma(S(s) - \theta)(\theta - a_0)Q'(a_0)\, d\theta + \int_{a_0}^{S(s)} \Gamma(S(s) - \theta)(\theta - a_0)Q'(a_0)\, d\theta \approx 0,$$

and hence,

$$S(s) - a_0 \approx a_0 - s.$$

But we may also write (5.4) as

$$S'(s)\left(\Gamma(S(s) - s)Q(s) + \int_s^{S(s)} \Gamma(S(s) - \theta)Q'(\theta)\, d\theta\right) = \Gamma(S(s) - s)Q(s).$$

Hence, for $s < a_0$ and s close to a_0, we get

$$S'(s)\left(\Gamma(S(s) - s)Q(s) + \Gamma(S(s) - s)\int_s^{S(s)} Q'(\theta)\, d\theta\right) \approx \Gamma(S(s) - s)Q(s),$$

which implies that

$$S'(s) \approx \frac{Q(s)}{Q(S(s))} \approx \frac{s - a_0}{S(s) - a_0} \to -1 \quad \text{as } s \to a_0. \tag{5.6}$$

Remark 5.5. Relations (5.5) and (5.6) reveal the behavior of $S'(s)$ as s approaches the point a_0. An interesting question then arises: What is the behavior of $S'(s)$ and $S(s)$ as s decreases from a_0? The answer to this question would give us a deeper understanding of the optimal (s, S) policy. The answer may also enable us to deal with our model when no backlogging is allowed.

6. Optimal (s, S) policy as the solution of QVI. In this section we complete the solution of (4.4)–(4.7) by finding the value of s. In view of Theorems 4.8 and 5.3, the only remaining equation to be satisfied is (4.5). Moreover, it is enough to satisfy it at $x = s$, and this condition gives us the value of s. We then verify that the solution satisfies the QVI (4.2).

Consider the function $\gamma(s) = \int_s^{S(s)} H_s(x)\,dx$. Then,

$$\gamma'(s) = \int_s^{S(s)} \frac{\partial H_s}{\partial s}(x)\,dx = -Q(s)\int_s^{S(s)} \Gamma(x-s)\,dx.$$

We have

$$\begin{cases} \gamma'(s) > 0 & \text{for } s < a_0, \\ \gamma'(s) = 0 & \text{for } s \geq a_0. \end{cases}$$

Moreover, for $s < a_0$, we have by (4.21)

$$\begin{aligned} \gamma'(s) &\geq -Q(s)\int_s^{S(s)} \exp(\beta_0(x-s))\,dx \\ &= \frac{Q(s)}{\beta_0}(1 - \exp(\beta_0(S(s)-s))) \\ &\geq \frac{Q(s)}{\beta_0}(1 - \exp(\beta_0(a_0-s))). \end{aligned}$$

From Proposition 5.1, for $s < a_0$, we have $Q'(x) > 0$. Therefore, for $s < s_1 < a_0$, we have $Q(s) < Q(s_1) < 0$, and

$$\gamma'(s) \geq \frac{Q(s_1)}{\beta_0}(1 - \exp(\beta_0(a_0-s))).$$

Integrating the inequality from s to s_1, we get

$$\begin{aligned} \gamma(s_1) - \gamma(s) &\geq \frac{Q(s_1)}{\beta_0}\left(s_1 - s + \frac{1}{\beta_0}\exp(\beta_0(a_0-s_1)) - \frac{1}{\beta_0}\exp(\beta_0(a_0-s))\right) \\ &\geq \frac{Q(s_1)}{\beta_0}\left(s_1 - s + \frac{1}{\beta_0}\exp(\beta_0(a_0-s_1))\right). \end{aligned}$$

It follows that $\gamma(s) \to -\infty$ as $s \to -\infty$. As a result, we have shown that $\gamma(s)$ increases strictly from $-\infty$ to 0 as s goes from $-\infty$ to a_0. Therefore, there exists a unique $s < a_0$ such that $\gamma(s) = -K$, where K is the fixed component of the ordering cost function (2.3). This is the optimal s we have been looking for. Thus, we have the following result.

THEOREM 6.1. *Under the assumptions of Theorem* 5.3*, there exists one and only one s that satisfies the relation*

$$G_s(s) = K + G_s(S(s)). \tag{6.1}$$

Additionally, since $G_s(x)$ satisfies (4.4), we have

$$\begin{aligned} -\frac{\sigma^2}{2}G_s''(S(s)) + (\rho+\lambda)G_s(S(s)) - \lambda\int_0^{S(s)-s} G(S(s)-\xi)\mu(\xi)\,d\xi \\ - \lambda G_s(s)\int_{S(s)-s}^{\infty} \mu(\xi)\,d\xi = g(S(s)) + cD + c\lambda\bar{\xi}, \end{aligned}$$

which gives

$$(\rho+\lambda)G_s(S(s)) \geq \lambda G_s(S(s)) + g(S(s)) + cD + c\lambda\bar{\xi}.$$

Then,

$$\rho G_s(S(s)) \geq g(S(s)) + cD + c\lambda\bar{\xi}.$$

We also have from (4.25),

$$\rho G_s(s) = g(s) + \frac{\sigma^2}{2}Q(s) + cD + c\lambda\bar{\xi}. \tag{6.2}$$

Therefore, we get

$$-\rho K \geq g(S(s)) - g(s) - \frac{\sigma^2}{2}Q(s). \tag{6.3}$$

Remark 6.2. Presman and Sethi (2004) have shown that the ordering level s is unique when the demand consists of a compound Poisson process and a constant demand rate. Here we have proved the uniqueness of s, when the demand also includes a Wiener process.

We have completely solved (4.4)–(4.7). To finish, it remains to verify the QVI relations (4.2). The first relation in (4.2) is satisfied for $x \geq s$. For $x < s$, since $G_s(x) = G_s(s)$, we need to show that

$$\rho G_s(s) \leq g(x) + cD + c\lambda\bar{\xi}, \quad x < s.$$

This is done from (6.2), noting that $g(x)$ decreases for $x < s$ and $Q(s) < 0$.

The key issue is the second relation in (4.2), i.e., to verify the inequality

$$G_s(x) \leq K + \inf_{y \geq x} G_s(y). \tag{6.4}$$

It clearly holds for $x < s$, since $G_s(x) = G_s(s) = K + G_s(S(s))$. For $s < x < a_0$, we know that $H_s(x) < 0$. Then we have $G_s(x) \leq G_s(s)$, and (6.4) is satisfied.

There remains the case $x > a_0$, which turns out to be the most difficult one. First we prove the following result under a special condition. Then we treat two special cases in sections 7 and 8.

LEMMA 6.3. *If $S\,(:= S(s))$ is the unique zero of $H_s(x)$ on (s,∞), then (6.4) is satisfied for $x > a_0$.*

Proof. From the previous discussion on H_s, we have

$$\begin{cases} H_s(x) < 0 & \text{for } s < x < S, \\ H_s(x) > 0 & \text{for } x > S. \end{cases}$$

Therefore, $G_s(x)$ is decreasing on the interval (s,S) and increasing on (S,∞). Then,

$$G_s(S) < G_s(x) < G_s(s) \quad \text{for any } s < x < S$$

and

$$G_s(x) < G_s(y) \quad \text{for any } S < x < y.$$

It follows that for $s < x < S$,

$$G_s(x) < G_s(s) = K + G_s(S) < K + G_s(y) \qquad \text{for any } y \geq x,$$

and for $x > S$, $G_s(x) \leq G_s(y)$ for any $y \geq x$. Therefore (6.4) is satisfied. This completes the proof. □

With Lemma 6.3 in hand, we can state the main result of this section.

THEOREM 6.4. *Let Assumptions* 2.1, 2.2, 2.3*, and* 4.2 *hold. Let* $S(s)$ *be the unique zero of* $H_s(x)$ *on* (s, ∞)*. Then the triple* $\{s, S(s), G_s\}$ *defined by* (4.24), (4.25), (5.3)*, and* (6.1) *is a solution of the QVI* (4.2)*.*

In the next section, we give a special case where we can show that the condition of Lemma 6.3 holds, and thus by Theorem 6.4, we have a solution of the QVI (4.2). In section 8, we will see that in the nondiffusion case, we can obtain directly the result without relying on Lemma 6.3. This will be done by a different method, which fails when $\sigma > 0$.

7. Exponentially distributed jump size. We present a special case in which the random jump size in the compound Poisson process is assumed to be exponentially distributed. Additionally, we assume that the function g is convex on $(-\infty, \infty)$. Under these conditions, we prove the condition of Lemma 6.3, namely, the zero uniqueness of H_s. Thus by Theorem 6.4, we have obtained a solution of the QVI (4.2), which corresponds to an (s, S) policy. While the exponential assumption makes the analysis simpler, it is nevertheless an important case from the inventory modeling perspective.

Let $\mu(\xi) = e^{-\xi}$. Hence, $\bar{\pi} = -1$. Using (4.13) in (4.16), we have

$$\begin{aligned}\chi(\pi) &= -\frac{\sigma^2}{2}\pi^2 + D\pi + \rho + \lambda - \frac{\lambda}{\pi + 1} \\ &= \frac{-\frac{\sigma^2}{2}\pi^3 + (D - \frac{\sigma^2}{2})\pi^2 + (D + \rho + \lambda)\pi + \rho}{\pi + 1} = \frac{\zeta(\pi)}{\pi + 1},\end{aligned}$$

where

$$\zeta(\pi) = -\frac{\sigma^2}{2}\pi^3 + \left(D - \frac{\sigma^2}{2}\right)\pi^2 + (D + \rho + \lambda)\pi + \rho.$$

Since

$$\zeta(-\infty) = +\infty, \quad \zeta(-1) = -\lambda < 0, \quad \zeta(0) = \rho > 0, \text{ and } \zeta(+\infty) = -\infty,$$

ζ has three distinct zeros β_1, β_2, and β_3 with $\beta_3 < -1 < \beta_1 < 0 < \beta_2$. Therefore,

$$\chi(\pi) = \frac{-\frac{\sigma^2}{2}(\pi - \beta_3)(\pi - \beta_1)(\pi - \beta_2)}{\pi + 1}.$$

From (4.17), we get

$$\hat{\varphi}(\pi) = \frac{\pi + 1}{\pi - \beta_3},$$

and from (4.14), we have

$$\hat{\Gamma}(\pi) = \frac{\pi + 1}{(\pi - \beta_3)(\pi - \beta_1)} = \frac{1}{\beta_1 - \beta_3}\left(\frac{1 + \beta_1}{\pi - \beta_1} - \frac{1 + \beta_3}{\pi - \beta_3}\right).$$

It follows that

$$\Gamma(\theta) = \frac{1}{\beta_1 - \beta_3}((1+\beta_1)\exp(\beta_1\theta) - (1+\beta_3)\exp(\beta_3\theta)).$$

In terms of (4.22), we have

$$\begin{aligned} H_s(x) &= \frac{1}{\beta_1 - \beta_3}\int_s^x ((1+\beta_1)\exp(\beta_1(x-y)) - (1+\beta_3)\exp(\beta_3(x-y)))Q(y)\,dy \\ &= \frac{\exp(\beta_3 x)}{\beta_1 - \beta_3}\psi_s(x), \end{aligned}$$

where

$$\psi_s(x) = (1+\beta_1)\exp((\beta_1-\beta_3)x)\int_s^x \exp(-\beta_1 y)Q(y)\,dy - (1+\beta_3)\int_s^x \exp(-\beta_3 y)Q(y)\,dy.$$

Note that $\psi_s(a_0) < 0$, since $s < a_0$, and $Q(x) < 0$ for $x < a_0$. Additionally,

$$\begin{aligned} \psi_s'(x) &= (1+\beta_1)(\beta_1-\beta_3)\exp((\beta_1-\beta_3)x)\int_s^x \exp(-\beta_1 y)Q(y)\,dy \\ &\quad + (1+\beta_1)\exp((\beta_1-\beta_3)x)\exp(-\beta_1 x)Q(x) - (1+\beta_3)\exp(-\beta_3 x)Q(x) \\ &= (\beta_1-\beta_3)\exp((\beta_1-\beta_3)x)\left((1+\beta_1)\int_s^x \exp(-\beta_1 y)Q(y)\,dy + \exp(-\beta_1 x)Q(x)\right). \end{aligned}$$

Let

$$\vartheta(x) = (1+\beta_1)\int_s^x \exp(-\beta_1 y)Q(y)\,dy + \exp(-\beta_1 x)Q(x).$$

Then,

$$\vartheta'(x) = \exp(-\beta_1 x)(Q(x) + Q'(x)).$$

Recall Remark 5.2. Since g is convex on $(-\infty, \infty)$, we have $Q'(x) \geq 0$. Then $\vartheta'(x) > 0$ for $x > a_0$. Therefore,

$$\frac{\psi_s'(x)\exp(-(\beta_1-\beta_3)x)}{\beta_1-\beta_3}$$

increases strictly from $\vartheta(a_0) = (1+\beta_1)\int_s^{a_0}\exp(-\beta_1 y)Q(y)\,dy < 0$ to $+\infty$. Hence, there is a unique $S_0 > a_0$ such that $\psi_s'(S_0) = 0$ and $\psi_s'(S_0) < 0$ for $a_0 < x < S_0$, and $\psi_s'(S_0) > 0$ for $x > S_0$. Consequently, $\psi_s(x)$ decreases strictly on (a_0, S_0) and increases strictly on (S_0, ∞). Since $\psi_s(a_0) < 0$ and $\psi_s(+\infty) = +\infty$, it follows that there exists a unique $S(s)$ such that $\psi_s(S(s)) = 0$ on (a_0, ∞), and hence a unique $S := S(s)$ such that $H_s(S) = 0$ on (a_0, ∞).

Remark 7.1. If $\lambda = 0$ (pure diffusion), then it is not necessary to assume that g is convex everywhere. Indeed, in that particular case, $\chi(\pi)$ has only two zeros β_1, β_2 and $\beta_1 = \beta_0$, where β_0 is introduced in Proposition 4.6. Therefore, $H_s(S) = 0$ implies that

$$\int_s^S \exp(-\beta_0 y)Q(y)\,dy = 0$$

and so

$$-\int_s^{a_0}\exp(-\beta_0 y)Q(y)\,dy = \int_{a_0}^S \exp(-\beta_0 y)Q(y)\,dy.$$

It then follows that S is unique.

8. The nondiffusion case ($\sigma = 0$). In this section we drop the Wiener process from our demand, but we keep the general jump size distribution of the compound Poisson process. Thus the demand process we will consider is $y(t)$ given in (2.1) with $\sigma = 0$. We will not try to prove the zero uniqueness of H_s as we did in section 7 for the special exponential case. Instead, we develop a different analysis to ascertain the optimality of the obtained (s, S) policy. Recall that this model was treated by Presman and Sethi (2004) using a probabilistic method, and with a somewhat more general surplus cost function $f(x)$.

We state the following result.

THEOREM 8.1. *Under the assumptions of Theorem* 5.3 *and* $\sigma = 0$, *the triple* $\{s, S(s), G_s\}$ *defined by* (4.24), (4.25), (5.3), *and* (6.1) *is a solution of the QVI* (4.2).

Proof. From (4.15) and (4.16), we obtain

$$\hat{\Gamma}(\pi) = \frac{D}{D\pi + \rho + \lambda - \lambda\hat{\mu}(\pi)},$$

and from (4.11), Γ is the solution of

$$D\Gamma'(\theta) + (\rho + \lambda)\Gamma(\theta) - \lambda \int_0^\theta \Gamma(\theta - \xi)\mu(\xi)\, d\xi = 0, \quad \Gamma(0) = 1.$$

Hence, $\Gamma'(0) = -\frac{\rho+\lambda}{D}$. Therefore, from (4.19) we see that $\frac{\beta_2\sigma^2}{2} \to D$ as $\sigma \to 0$. Note that from (4.23), we get

$$\begin{aligned} Q(x) &= \frac{1}{D}\int_0^\infty \exp\left(-\frac{\beta_2\sigma^2}{2D}\theta\right) g'\left(x + \frac{\sigma^2\theta}{2D}\right) d\theta \\ &= \frac{1}{D}\int_0^\infty e^{-\theta} g'(x)\, d\theta = \frac{g'(x)}{D}. \end{aligned} \tag{8.1}$$

From the definition of a_0 in Proposition 5.1, we see that $a_0 = a$. Additionally, (4.25) becomes

$$G_s(s) = \frac{g(s) + cD + c\lambda\bar{\xi}}{\rho},$$

and (6.3) gives

$$-\rho K \geq g(S(s)) - g(s). \tag{8.2}$$

Now we let $L_s(x) = G_s(x) - G_s(s) = \int_s^x H_s(y)\, dy$. In terms of (4.22) and (8.1), we have

$$L_s(x) = \frac{1}{D}\int_s^x dy \int_s^y \Gamma(y - \theta)g'(\theta)\, dy = \frac{1}{D}\int_s^x \Gamma(x - \theta)(g(\theta) - g(s))\, d\theta.$$

Since g is decreasing on $(-\infty, a)$ and increasing on (a, ∞), we have $L_s(x) \leq 0$ for $s \leq x < a$. For $a < x < S$, we have

$$\begin{aligned} L_s(x) &= \frac{1}{D}\int_s^a \Gamma(x - \theta)(g(\theta) - g(s))\, d\theta + \frac{1}{D}\int_a^x \Gamma(x - \theta)(g(\theta) - g(s))\, d\theta \\ &\leq \frac{1}{D}\int_a^x \Gamma(x - \theta)(g(\theta) - g(s))\, d\theta \\ &\leq \frac{1}{D}(g(S) - g(s))\int_a^x \Gamma(x - \theta)\, d\theta \leq 0, \end{aligned}$$

where the last inequality holds because of (8.2). Moreover, $L_s(x)$ is the solution of

$$DL_s'(x) + (\rho+\lambda)L_s(x) - \lambda\int_0^{x-s} L_s(x-\xi)\mu(\xi)\,d\xi = g(x) - g(s),\ L_s(s) = 0. \tag{8.3}$$

Next, let $x_0 > S$ be the first value such that $L_s(x_0) = 0$ (note that $L_s(x) \to +\infty$ as $x \to +\infty$, so such an x_0 exists). We recall that $L_s(x) = 0$ for $x \le s$. Let $u \ge 0$. We can rewrite (8.3) as follows (even if $x_0 - u \le s$):

$$\begin{aligned} &DL_s'(x) + (\rho+\lambda)L_s(x) - \lambda\int_{x_0-u}^{x} L_s(\eta)\mu(x-\eta)\,d\eta \\ &\quad = (g(x)-g(s))\mathbb{1}_{x>s} + \lambda\int_s^{x_0-u} L_s(\eta)\mu(x-\eta)\,d\eta, \end{aligned} \tag{8.4}$$

which implies

$$DL_s'(x) + (\rho+\lambda)L_s(x) - \lambda\int_{x_0-u}^{x} L_s(\eta)\mu(x-\eta)\,d\eta \le (g(x)-g(s))\mathbb{1}_{x>s}. \tag{8.5}$$

Note that (8.4) and (8.5) hold for any x, and particularly for $x > x_0 - u$. Moreover, we have

$$L_s(x_0-u) \le 0. \tag{8.6}$$

Now we set

$$M_s(x) = L_s(x+u) + K. \tag{8.7}$$

It follows that

$$M_s(x_0-u) = K. \tag{8.8}$$

We rewrite (8.4) with x changed to $x+u > x_0$. Then,

$$DM_s'(x) + (\rho+\lambda)M_s(x) - (\rho+\lambda)K - \lambda\int_s^{x+u} L_s(\eta)\mu(x+u-\eta)\,d\eta = g(x+u) - g(s).$$

Since

$$\begin{aligned} \int_s^{x+u} L_s(\eta)\mu(x+u-\eta)\,d\eta &= \int_s^{x_0} L_s(\eta)\mu(x+u-\eta)\,d\eta + \int_{x_0}^{x+u} L_s(\eta)\mu(x+u-\eta)\,d\eta \\ &= \int_s^{x_0} L_s(\eta)\mu(x+u-\eta)\,d\eta + \int_{x_0-u}^{x} M_s(\eta)\mu(x-\eta)\,d\eta \\ &\quad -K\int_{x_0}^{x+u} \mu(x+u-\eta)\,d\eta, \end{aligned}$$

we have

$$
\begin{aligned}
DM_s'(x) + (\rho+\lambda)M_s(x) - \lambda \int_{x_0-u}^{x} M_s(\eta)\mu(x-\eta)\,d\eta \\
&= g(x+u) - g(s) + \rho K + \lambda K + \lambda \int_s^{x_0} L_s(\eta)\mu(x+u-\eta)\,d\eta \\
&\quad - \lambda K \int_{x_0}^{x+u} \mu(x+u-\eta)\,d\eta \\
&= g(x+u) - g(s) + \rho K + \lambda K + \lambda \int_s^{x_0} (L_s(\eta)+K)\mu(x+u-\eta)\,d\eta \\
&\quad - \lambda K \int_{s}^{x+u} \mu(x+u-\eta)\,d\eta \\
&\geq g(x+u) - g(s) + \rho K + \lambda K - \lambda K \int_s^{x+u} \mu(x+u-\eta)\,d\eta \\
&\geq g(x+u) - g(s) + \rho K.
\end{aligned} \tag{8.9}
$$

To proceed, we claim that the following relation holds:

$$
g(x+u) - g(s) + \rho K - (g(x) - g(s))\mathbb{1}_{x>s} \geq 0, \quad x > x_0 - u. \tag{8.10}
$$

In fact, we first note that $g(x_0) - g(s) > 0$, which follows from (8.5) written for $x = x_0$. Hence,

$$
g(x+u) - g(s) \geq g(x_0) - g(s) > 0.
$$

Now, if $x < s$, then (8.10) is obviously satisfied. If $x > s$, we have

$$
g(x+u) - g(s) + \rho K - (g(x) - g(s)) = g(x+u) - g(x) + \rho K.
$$

If $x > a$, we have $g(x+u) - g(x) > 0$, and if $s < x < a$, we have $g(x) < g(s)$ and $g(x+u) \geq g(x_0)$. Hence,

$$
g(x+u) - g(x) + \rho K \geq g(x_0) - g(s) + \rho K \geq 0.
$$

So in both cases we get (8.10).

Now setting $Y_s(x) = M_s(x) - L_s(x)$, $x \geq x_0 - u$, and combining (8.5)–(8.10), we get

$$
\begin{cases}
DY_s'(x) + (\rho+\lambda)Y_s(x) - \lambda \displaystyle\int_{x_0-u}^{x} Y_s(\eta)\mu(x-\eta)\,d\eta \geq 0, \\
Y_s(x_0-u) \geq 0.
\end{cases}
$$

Therefore, $Y_s(x) \geq 0$ for $x \geq x_0 - u$, and particularly $Y_s(x) \geq 0$ for $x \geq x_0$. It follows that

$$
L_s(x) \leq K + L_s(x+u), \quad x \geq x_0,\ u \geq 0,
$$

and then

$$
G_s(x) \leq K + G_s(x+u), \quad x \geq x_0,\ u \geq 0,
$$

i.e.,

$$
G_s(x) \leq K + \inf_{y \geq x} G_s(y), \quad x \geq x_0.
$$

For $s \le x \le x_0$, since $L_s(x) \le 0$, we have

$$G_s(x) \le G_s(s) = K + G_s(S) \le K + \inf_{y \ge x} G_s(y).$$

We have just completed the verification of the key relation (6.4) for $x > s$ and, therefore, have shown that the triple $\{s, S(s), G_s\}$ satisfies the QVI (4.2). This completes the proof. □

9. Remarks on the general case and numerical demonstration. We have pointed out in section 6 that the key issue in the analysis of the optimal (s, S) policy is (6.4). Whether it holds or not remains an open question for the general case, in which both diffusion and random jumps are present in the demand. In this section, we first remark the difficulty in trying to verify (6.4). Then we present a more complicated example to gain some insights into the general model.

Let, in general,

$$L_s(x) = G_s(x) - G_s(s) = \int_s^x H_s(y)\,dy = \int_s^x dy \int_s^y \Gamma(y-\theta)Q(\theta)\,d\theta.$$

Set $\zeta(x) = \frac{2}{\beta_2\sigma^2}(g(x) + \frac{\sigma^2}{2}Q(x))$. By (5.1), we have

$$\zeta'(x) = Q(x) \begin{cases} < 0 & \text{for } x < a_0, \\ > 0 & \text{for } x > a_0. \end{cases}$$

Hence,

$$L_s(x) = \int_s^x dy \int_s^y \Gamma(y-\theta)\zeta'(\theta)\,d\theta = \int_s^x \Gamma(x-y)(\zeta(y) - \zeta(s))\,dy.$$

We have shown that $L_s(x) \le 0$ for $s \le x \le a_0$. Then for $a_0 < x < S$, we have

$$\begin{aligned} L_s(x) &= \int_s^{a_0} \Gamma(x-y)(\zeta(y) - \zeta(s))\,dy + \int_{a_0}^x \Gamma(x-y)(\zeta(y) - \zeta(s))\,dy \\ &\le \int_{a_0}^x \Gamma(x-y)(\zeta(y) - \zeta(s))\,dy \\ &\le (\zeta(S) - \zeta(s)) \int_{a_0}^x \Gamma(x-y)\,dy. \end{aligned}$$

Remark 9.1. Here the difficulty is that we do not know if $\zeta(S) - \zeta(s) \le 0$ or not.

On the other hand, if we go back to see how we got (6.3), we can actually assert that

$$\begin{aligned} -\rho K &\ge \frac{\sigma^2}{2}H_s'(S) + g(S) - g(s) - \frac{\sigma^2}{2}Q(s) \\ &\ge \frac{\sigma^2}{2}(H_s'(S) - Q(S)) + g(S) - g(s). \end{aligned}$$

Remark 9.2. The difficulty here is that we do not know how $H_s'(S)$ compares with $Q(S)$.

In the rest of this section, we study a more general demand than that in section 7 and try to get some insights into this case. Let

$$\mu(\xi) = a_1 e^{-\alpha_1 \xi} + a_2 e^{-\alpha_2 \xi}$$

with $0 < \alpha_1 < \alpha_2$, $a_1 > 0$, $a_2 > 0$, $a_1\alpha_2 + a_2\alpha_1 = \alpha_1\alpha_2$. For $\pi > -\alpha_1 = \bar{\pi}$, we get

$$\hat{\mu}(\pi) = \frac{a_1}{\pi + \alpha_1} + \frac{a_2}{\pi + \alpha_2}$$

and

$$\chi(\pi) = -\frac{\sigma^2}{2}\pi^2 + D\pi + \rho + \lambda - \frac{\lambda a_1}{\pi + \alpha_1} - \frac{\lambda a_2}{\pi + \alpha_2} = \frac{\zeta(\pi)}{(\pi + \alpha_1)(\pi + \alpha_2)}.$$

Note that

$$\begin{aligned}
&\zeta(-\infty) = \zeta(\infty) = -\infty,\\
&\zeta(-\alpha_2) = \lambda a_2(\alpha_2 - \alpha_1) > 0,\\
&\zeta(-\alpha_1) = -\lambda a_1(\alpha_2 - \alpha_1) < 0,\\
&\zeta(0) = \rho\alpha_1\alpha_2 > 0.
\end{aligned}$$

Hence, ζ has four distinct zeros β_1, β_2, β_3, and β_4 with $\beta_4 < -\alpha_2 < \beta_3 < -\alpha_1 < \beta_1 < 0 < \beta_2$, and

$$\zeta(\pi) = -\frac{\sigma^2}{2}(\pi - \beta_4)(\pi - \beta_3)(\pi - \beta_1)(\pi - \beta_2).$$

It follows that

$$\hat{\Gamma}(\pi) = \frac{(\pi + \alpha_1)(\pi + \alpha_2)}{(\pi - \beta_1)(\pi - \beta_3)(\pi - \beta_4)} = \frac{A}{\pi - \beta_1} + \frac{B}{\pi - \beta_3} + \frac{C}{\pi - \beta_4},$$

where

$$A = \frac{(\beta_1 + \alpha_1)(\beta_1 + \alpha_2)}{(\beta_1 - \beta_3)(\beta_1 - \beta_4)}, \quad B = \frac{(\beta_3 + \alpha_1)(\beta_3 + \alpha_2)}{(\beta_3 - \beta_1)(\beta_3 - \beta_4)}, \quad C = \frac{(\beta_4 + \alpha_1)(\beta_4 + \alpha_2)}{(\beta_4 - \beta_1)(\beta_4 - \beta_3)},$$

and $A > 0$, $B > 0$, $C > 0$. Thus,

$$\Gamma(\theta) = A\exp(\beta_1\theta) + B\exp(\beta_3\theta) + C\exp(\beta_4\theta)$$

and

$$H_s(x) = \int_s^x (A\exp(\beta_1(x - \theta)) + B\exp(\beta_3(x - \theta)) + C\exp(\beta_4(x - \theta)))Q(\theta)\,dy.$$

We choose a surplus cost function $f(x)$ often used in the literature, i.e.,

$$f(x) = \begin{cases} hx & \text{for } x \geq 0,\\ -px & \text{for } x < 0, \end{cases}$$

where $h > 0$ is the unit holding cost per unit time, and $p > 0$ is the unit shortage cost per unit time. Then in terms of (4.1),

$$g(x) = \begin{cases} (h + c\rho)x & \text{for } x \geq 0,\\ -(p - c\rho)x & \text{for } x < 0. \end{cases}$$

Additionally, we assume $p > c\rho$ to avoid the trivial case in which the optimal s would be $-\infty$; see Presman and Sethi (2004).

Since $a = 0$ for the considered g function, we have

$$Q(x) = \begin{cases} \dfrac{2}{\sigma^2\beta_2}\left((p+h)e^{\beta_2 x} - (p-c\rho)\right) & \text{if } x < 0, \\ \dfrac{2}{\sigma^2\beta_2}(h+c\rho) & \text{if } x \geq 0. \end{cases}$$

Moreover,

$$a_0 = \frac{1}{\beta_2}\ln\left(\frac{p-c\rho}{p+h}\right) < 0.$$

Using the result for $Q(x)$, we can find the explicit expression for $H_s(x)$. Let

$$\begin{aligned} H_s^0(x) = & -(p-c\rho)\left(\frac{A}{\beta_1}e^{\beta_1(x-s)} + \frac{B}{\beta_3}e^{\beta_3(x-s)} + \frac{C}{\beta_4}e^{\beta_4(x-s)}\right) \\ & -(p+h)\left(\frac{A}{\beta_2-\beta_1}e^{\beta_1 x}e^{(\beta_2-\beta_1)s} + \frac{B}{\beta_2-\beta_3}e^{\beta_3 x}e^{(\beta_2-\beta_3)s}\right. \\ & \left. + \frac{C}{\beta_2-\beta_4}e^{\beta_4 x}e^{(\beta_2-\beta_4)s}\right). \end{aligned}$$

Then we have for $x < 0$,

$$\begin{aligned} H_s(x) = & \frac{2}{\sigma^2\beta_2}\left(H_s^0(x) + (p-c\rho)\left(\frac{A}{\beta_1} + \frac{B}{\beta_3} + \frac{C}{\beta_4}\right)\right. \\ & \left. + (p+h)\left(\frac{A}{\beta_2-\beta_1} + \frac{B}{\beta_2-\beta_3} + \frac{C}{\beta_2-\beta_4}\right)e^{\beta_2 x}\right), \end{aligned}$$

and for $x \geq 0$,

$$\begin{aligned} H_s(x) = & \frac{2}{\sigma^2\beta_2}\left(H_s^0(x) - (h+c\rho)\left(\frac{A}{\beta_1} + \frac{B}{\beta_3} + \frac{C}{\beta_4}\right)\right. \\ & \left. + (p+h)\beta_2\left(\frac{A}{\beta_1(\beta_2-\beta_1)}e^{\beta_1 x} + \frac{B}{\beta_3(\beta_2-\beta_3)}e^{\beta_3 x} + \frac{C}{\beta_4(\beta_2-\beta_4)}e^{\beta_4 x}\right)\right). \end{aligned}$$

We numerically test the zero of function $H_s(x)$. Set

$$\alpha_1 = 1, \quad \alpha_2 = 2, \quad a_1 = \frac{1}{2}, \quad a_2 = 2,$$

and choose

$$D = 0.1, \quad \lambda = 0.1, \quad \sigma = 0.2, \quad \rho = 0.05.$$

Using the Newton–Raphson procedure, the four zeros of ζ are calculated as

$$\beta_4 = -2.5136, \quad \beta_3 = -1.3112, \quad \beta_1 = -0.2497, \quad \beta_2 = 6.0746.$$

Set $p = 1$, $h = 1$, and $c = 5$. Then we obtain that $a_0 = -0.1615$.

From section 6 we know that the optimal value of s must satisfy the condition $s < a_0$. Therefore, we pick a number of values for s on the left of a_0 and numerically investigate the corresponding function $H_s(x)$. Figure 9.1 shows the graphs of $H_s(x)$ for seven different values of s, which are $s = -3$, -2, -1.5, -1, -0.75, -0.5, and -0.3. These graphs suggest that $H_s(x)$ has a unique zero S on (s, ∞).

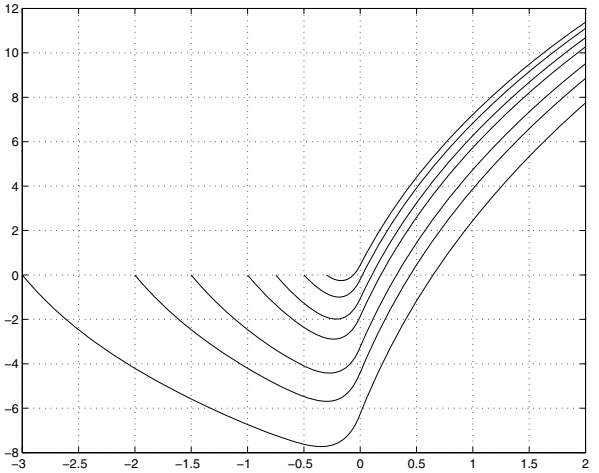

FIG. 9.1. *Graph of $H_s(x)$ for various values of s.*

10. Conclusions. We consider a continuous-review stochastic inventory model with a demand consisting of a compound Poisson process and a diffusion process. We formulate the inventory problem as an impulse control problem, which allows us to use the QVI approach to study it.

We prove the optimality of an (s, S) policy in two cases. (i) When the demand is a mixture of a diffusion process and a compound Poisson process with exponentially distributed jump sizes, and (ii) when the demand is a mixture of a constant demand and a compound Poisson process. However, the combination of a diffusion process and a general compound Poisson demand is not completely solved. We explain the difficulties that arise in the course of trying to prove the optimality (Remarks 9.1 and 9.2). We also present a condition in Lemma 6.3 that might be the key if the optimal decision is indeed of (s, S) type, which we believe to be the case. Although we have verified this condition for the special case of exponentially distributed jump demand and our numerical results in section 9 suggest that it holds for a more complicated example, the optimality of the general model remains an open and interesting problem for further study.

More generally, it would be of interest to extend the analysis of this paper to problems including Lévy processes having nonfinite Lévy measures. This extension is potentially important for problems in finance, where stock prices are often modeled by Lévy processes and there are fixed transaction costs incurred in buying and selling of stocks.

Further generalizations include inventory models with the Markovian demand as discussed in Beyer, Cheng, and Sethi (2006) in the discrete-time framework and with information delays as discussed in Bensoussan, Cakanyildirim, and Sethi (2005) also in the discrete-time framework. Extensions of our results to inventory models with lead times, lost sales case (Remark 5.5), nonstationary problems, and inventory problems with multiple products could also be considered. One could also investigate the use of the vanishing discount approach to obtain a proof of the optimality of an (s, S) policy in the average-cost case.

To conclude, we should mention that there is a large amount of literature treating the various proposed problems in the discrete-time framework. To ascertain the optimality of (s, S) policies in these cases when time is continuous and demand is more

general than a compound Poisson process is a challenging research agenda for future research on optimal control models of inventory problems.

Acknowledgment. We thank the reviewers whose comments have improved the exposition of this paper.

APPLICATIONS OF LEFSCHETZ NUMBERS IN CONTROL THEORY*

PETER SAVELIEV†

Abstract. We develop some applications of techniques of the Lefschetz coincidence theory in control theory. The topics are existence of equilibria and their robustness, and controllability and its robustness.

Key words. control system, equilibrium, controllability, robustness, fixed point theory, Lefschetz number, coincidence point, homology theory, algebraic topology

1. Introduction.

The goal of this paper is to provide examples of what Lefschetz coincidence theory can contribute to control theory. We discuss existence of equilibria and their robustness, and controllability and its robustness.

We develop some topological techniques, already available in dynamics, in the control theoretic setting. A (discrete) dynamical system on a manifold M is simply a map $f : M \to M$. Then $x \in M$ and $f(x)$ are the current and next states of the system, respectively. An equilibrium of the system is a fixed point of f. The problem of detecting equilibria can be treated via the more general coincidence problem [2, sect. VI.14], [4], [35, Ch. 7], [15]: "Given two maps $f, g : N \to M$ between two n-dimensional manifolds, what can be said about the coincidence set C of all x such that $f(x) = g(x)$?" Indeed, the equilibrium set $C = \{x \in M : f(x) = x\}$ is the coincidence set of f and the identity map $g : M \to M$. The famous Lefschetz coincidence theorem states that if the Lefschetz number λ_{fg} is not equal to zero, then there is at least one coincidence, i.e., $C \neq \varnothing$. Using this and other invariants, one can find out whether a dynamical system has an equilibrium or a periodic point.

In the case of a *controlled* dynamical system, the next state $f(x, u)$ depends not only on the current state, $x \in M$, but also on the *input*, $u \in U$. A discrete time control system is given by the space of inputs U, the space of states M, the "state-input" space $N = M \times U$, a map $f : N = M \times U \to M$, and the projection $g : N = M \times U \to M$ (in general, N is a fiber bundle and $g : N \to M$ is the bundle projection). Then, just as above, the equilibrium set $C = \{x \in M : f(x, u) = x \text{ for some } u \in U\}$ of the system is the coincidence set of the pair (f, g). However, since the dimensions of N and M are no longer equal, the Lefschetz *number* is replaced with the Lefschetz *homomorphism* [31], which does a better job of detecting coincidences.

Another application of the coincidence theory approach is controllability. A system is called controllable if any state can be reached from any other state; i.e., for each pair of states $x, y \in M$ there are inputs $u_0, \dots, u_r \in U$ such that $x_1 = f(u_0, x), x_2 = f(u_1, x_1), \dots, y = x_{r+1} = f(u_r, x_r)$. Therefore controllability is equivalent to surjectivity of the composition of several iterations of f. On the other hand, a map is surjective if it has a coincidence with any constant map.

The state space M is often a manifold, as opposed to a Euclidean space, when it appears in robotics. For example, $M = \mathbf{T}^n = (\mathbf{S}^1)^n$, the n-dimensional torus, is the space of all possible states of a robotic arm with n revolving joints [27, p. 1]; or $M = \mathbf{R}^3 \times SO(3)$ is the space of positions of a rigid body [25, Ch. 2]. Typically, we have $N = M \times U$. However, nontrivial bundles are also common. For example, consider a spherical pendulum with a gas jet control which is always directed in the tangent space. Then its state space is $M = \mathbf{S}^2$, the 2-sphere, while the state-input space N is the tangent bundle $T\mathbf{S}^2$ of $\mathbf{S}^2$, which is an $\mathbf{R}^2$-bundle over M not isomorphic to $M \times \mathbf{R}^2$ [27, p. 17]. In spite of the abundance of such examples [6], [25], [27], topological techniques have not thus far found broad applications in control theory. The only recent examples known to the author are [18], [19], [20], [21], [22].

The topological approach provides the following advantages. Consider a control system as a triple (M, N, f) of topological spaces M, N and a continuous map f as described above. Since our knowledge of the model is inevitably imprecise, we have to deal with perturbations of the system. As perturbations may be understood as variations of unknown parameters of the system, their effect on the behavior of the system is also unknown. However, if the system depends continuously on these parameters, the change of M, N, and f is also continuous. This means that we are to consider spaces homeomorphic to M, N and maps homotopic to f. An appropriate tool to deal with this degree of generality is homology theory. Indeed, the homology groups $H_*(M), H_*(N)$ of M, N and the homology homomorphism $f_* : H_*(N) \to H_*(M)$ of f remain constant under homeomorphisms of M, N and homotopies of f. They can also be rigorously and effectively computed [26], [19].

Further, the perturbations of f are normally assumed "small" (in particular, this is the basis of the notion of structural stability). However, unless actual estimates are available, we do not know how "small" the perturbations of the real system are. Therefore, in order to take into account the "worst possible scenario," we consider large, but still continuous, perturbations of the system. As an example, a constant external force, such as gravitation, in any of the above robotic systems may be treated as such a perturbation. Thus the use of homology theory provides answers with a new, for control theory, degree of robustness. Providing results of this nature is the first objective of this paper. We apply Lefschetz coincidence theory to prove existence of equilibria (Theorem 6.1) and controllability (Theorem 7.2) for systems determined by maps homotopic to f.

The second objective of this paper is to study robustness of these properties under arbitrarily small perturbations because sometimes they produce a dramatic change in the properties of the system. This change may be the loss of an equilibrium (Theorem 6.4) or the loss of controllability (Theorem 7.3).

The paper is organized as follows. Some preliminaries from algebraic topology are outlined in section 2. In section 3 we review the classical theory of Lefschetz numbers and show its inadequacy for control theory. In section 4 we consider the necessary generalization, the Lefschetz homomorphism, of the Lefschetz number and state several relevant results about existence of coincidences. In section 5 we state some results about removability of coincidences. In section 6 we provide sufficient conditions of existence of equilibria of a discrete system and their robustness. In section 7 we provide sufficient conditions of controllability of a discrete system and its robustness. In section 8 we discuss how our coincidence results can be applied to existence of equilibria and controllability of continuous time control systems. Notions of control theory are defined as needed; for details see [27], [29], [34].

2. Preliminaries from algebraic topology. The terminology we use is standard [2]. Suppose N is a topological space and $A \subset N$ is a subspace. The singular *homology group* $H_k(N, A)$ of N relative to A over $\mathbf{Q}$ or any other field is defined as follows. If Δ_k is the standard k-simplex, $k = 0, 1, 2, \dots$, any map $\sigma : \Delta_k \to N$ is called a singular k-simplex in N. We let $C_k(N, A)$ be the vector space over $\mathbf{Q}$ generated by all singular k-simplices of N whose images are not completely in A. Then the boundary operator $\partial_k : C_k(N, A) \to C_{k-1}(N, A)$ is defined in the natural way, and we let $H_k(N, A) = \ker \partial_k / \operatorname{Im} \partial_k$. Further, let $C^k(N, A)$ be the dual of $C_k(N, A)$, i.e., the vector space of all linear functions from $C_k(N, A)$ to $\mathbf{Q}$. Then ∂_k generates the coboundary operator $\partial^k : C^k(N, A) \to C^{k+1}(N, A)$, and we let $H^k(N, A) = \ker \partial^k / \operatorname{Im} \partial^k$ be the *cohomology group* of N relative to A. Also $H_k(N) = H_k(N, \varnothing)$, $H^k(N) = H^k(N, \varnothing)$. If (N, A) is a simplicial complex, its simplicial homology and cohomology are defined in the same way starting with $C_k(N, A)$ generated by all simplices of (N, A). The homology and cohomology groups $H_k(N, A; G)$, $H^k(N, A; G)$ over any group G can be defined in a similar fashion.

Homology and cohomology groups $\{H_k(N, A) : k = 0, 1, 2, \dots\}$, $\{H^k(N, A) : k = 0, 1, 2, \dots\}$ over fields are (graded) vector spaces with the following properties. The Betti numbers, $b_k = \dim H_k(N)$, for $k = 0, 1, 2$, are the numbers of path components, "tunnels," and "voids" of N, respectively. In the case of a path connected N, the identities of $H_0(N) = H^0(N) = \mathbf{Q}$ are denoted by 1. If N is contractible, it is *acyclic*; i.e., $H_k(N) = H^k(N) = 0$ for $k > 0$. If N is an n-dimensional simplicial complex, $H_k(N) = 0$ for all $k > n$. If M is a compact connected orientable n-dimensional manifold with boundary ∂M, then $H_n(M, \partial M) = H^n(M, \partial M) = \mathbf{Q}$. The identities of these two groups are the *fundamental classes* O_M and $\overline{O}_M$ of M, respectively. Further, there is the *Poincaré duality* isomorphism $D_M : H^k(M, \partial M) \to H_{n-k}(M)$ given by the cap product with the fundamental class O_M. The *cap product* is the homomorphism $\frown : H^k(N, A) \otimes H_m(N, A) \to H_{m-k}(N)$ given by $x \frown a = (1 \times x)\Delta a$, where Δ is a diagonal approximation. Then $a \in H_k(N, A)$ and $x \in H^k(N, A)$ are called *dual* if $x \frown a = \langle x, a \rangle = x(a) = 1$. In particular, O_M and $\overline{O}_M$ are dual. By the Künneth theorem, $H_k(M \times U) = \sum_{i+j=k} H_i(M) \otimes H_j(U)$, $k = 0, 1, 2, \dots$.

Suppose B is a subspace of the topological space M and $f : N \to M$ is a map; then $f : (N, A) \to (M, B)$ is a *map of pairs* if $f(A) \subset B$. In this case, f generates the natural homomorphism from $C_k(N, A)$ to $C_k(M, B)$. This homomorphism generates $f_* : H_k(N, A) \to H_k(M, B)$, the *homology homomorphism* of f, and $f^* : H^k(M, B) \to H^k(N, A)$, the *cohomology homomorphism* of f. Two maps $f, g : (N, A) \to (M, B)$ are called *homotopic* if f can be continuously "deformed" into g; i.e., there is a map $F : [0, 1] \times (N, A) \to (M, B)$ such that $F(0, \cdot) = f$ and $F(1, \cdot) = g$. If f and g are homotopic, then $f_* = g_*$. In particular, if f is homotopic to a constant map, then f_* is trivial; i.e., $f_* : H_k(N, A) \to H_k(M, B)$ is zero for $k = 1, 2, \dots$, or simply $f_* = 0$. In the case of n-manifolds, the homomorphism $f_* : H_n(N, \partial N) \to H_n(M, \partial M)$ is the multiplication by $\deg f$, the degree of f. The kth homotopy group $\pi_k(N)$ of N is the group of homotopy classes of maps of k-spheres to N.

3. Review of Lefschetz theory. In this section, M and N are orientable compact connected manifolds with boundaries $\partial M, \partial N$, and $\dim M = \dim N = n$.

Consider the fixed point problem: "If $f : M \to M$ is a map, what can be said about the set of points $x \in M$ such that $f(x) = x$?" Applications of fixed point theorems (Kakutani, Banach, etc.) to control problems are abundant [1], [7], [8], [16], [23], [28]. However, the methods we suggest in this paper go far beyond those.

One may associate with f an integer λ_f called the Lefschetz number [3]:

$$\lambda_f = \sum_k (-1)^k \mathrm{Trace}(f_{*k}),$$

where $f_{*k} : H_k(M) \to H_k(M)$ is induced by f. The *Lefschetz fixed point theorem* states that if $\lambda_f \neq 0$, then f has a fixed point.

The coincidence problem is concerned with a similar question about two maps $f, g : N \to M$ and their coincidences $x \in N, f(x) = g(x)$. One of the main tools is the Lefschetz coincidence number λ_{fg} defined similarly to λ_f as the alternating sum of traces of a certain endomorphism on the homology group of M. Algebraically, if $h : E_* \to E_*$ is a (degree 0) endomorphism of a finitely generated graded vector space $E_* = \{E_k\}$, given by $h_k : E_k \to E_k$, then its Lefschetz number is $L(h) = \sum_k (-1)^k \mathrm{Trace}(h_k)$. To apply this formula in the topological setting we let $E_* = H_*(M)$; then the Lefschetz number is defined as $\lambda_{fg} = L(g_* D_N f^* D_M^{-1})$, where $D_M : H^k(M, \partial M) \to H_{n-k}(M)$, $D_N : H^k(N, \partial N) \to H_{n-k}(N)$ are the Poincaré duality isomorphisms. Observe that for $f^* : H^k(M, \partial M) \to H^k(N, \partial N)$ to be well defined, the map f has to be boundary preserving, $f : (N, \partial N) \to (M, \partial M)$.

A *Lefschetz-type coincidence theorem* states that if $\lambda_{fg} \neq 0$, then the pair (f, g) (and any pair homotopic to them) has a coincidence. The converse is false in general. When $\lambda_{fg} = 0$, the maps f, g may have coincidences, but under certain circumstances they can be removed by homotopies of f, g [5].

Until the 1990's, such theorems have been mostly considered in the following two settings. First [2, sect. VI.14], [35, Ch. 7], $f : N \to M$ is a map between two n-manifolds as above. This way the Lefschetz theorem can be applied to detect equilibria of a dynamical system, but it does not apply to an even simplest control system because the dimensions of $N = M \times U$ and M have to be equal. Second [15], $f : X \to M$ is a map from an arbitrary topological space X to an open subset of $\mathbf{R}^n$, and all fibers $f^{-1}(y)$ are acyclic. Here the dimensions are also equal in the sense that $H_*(X) = H_*(M)$ (Vietoris theorem). Thus neither case is broad enough to cover control systems, the input spaces U of which have nonzero dimension.

As an example from dynamics, consider the problem of existence of closed orbits of a flow. The flow is given by a map $f : M \times [0, \infty) \to M$ so that the initial position is $f(0, x) = x$ and $f(t, x)$ is the position at time t. Closed orbits correspond to coincidences of f and the projection $p : M \times [0, \infty) \to M$. More generally, one considers $f : M \times X \to M$, where X is a topological space. This situation was studied in [24], [12], [13], [11] under the name "parametrized fixed point theory." These results can be applied to detect equilibria (section 6), but the setting is not general enough to study controllability (section 7). The author [30], [31] extended some of the results of [13] to the general case of two arbitrary maps $f, g : N \to M$ from an arbitrary topological space to a manifold. The content of these papers is briefly outlined in the next section.

4. Detecting coincidences. In this section, N is an arbitrary topological space, $A \subset N$, M is an orientable compact connected manifold with boundary ∂M, $\dim M = n$, and $f : (N, A) \to (M, \partial M)$, $g : N \to M$ are maps.

The generalization of the Lefschetz number is based on the fact that since the finitely generated graded vector space $E = H_*(M)$ is equipped with the cap product $\frown : E^* \otimes E_* \to E_*$, one can define the Lefschetz class $L(h) \in E_*$ of a graded endomorphism h given by $h_k : E_k \to E_{k+m}$ of any degree m, not just of degree 0 as in the classical case.

DEFINITION 4.1 (see [31, Proposition 2.2]). *If $h : H_k(M) \to H_{k+m}(M)$, $k = 0, 1, 2, \dots$, is a graded homomorphism of degree m, then the Lefschetz class $L(h) \in H_m(M)$ is defined as*

$$L(h) = \sum_k (-1)^{k(k+m)} \sum_j x_j^k \frown h(a_j^k),$$

where $\{a_1^k, \dots, a_{m_k}^k\}$ is a basis for $H_k(M)$ and $\{x_1^k, \dots, x_{m_k}^k\}$ the corresponding dual basis for $H^k(M)$.

It is easy to see that if the degree m of h is zero, $L(h) = \sum_k (-1)^k \mathrm{Trace}(h_k)$.

For a given $z \in H_s(N, A)$, suppose the homomorphism h_{fg}^z is defined as the composition

$$H_i(M) \xrightarrow{D_M^{-1}} H^{n-i}(M, \partial M) \xrightarrow{f^*} H^{n-i}(N, A) \xrightarrow{\frown z} H_{s-n+i}(N) \xrightarrow{g_*} H_{s-n+i}(M),$$

i.e.,

$$h_{fg}^z(x) = g_*((f^* D_M^{-1}(x)) \frown z).$$

Its degree is $m = s - n$.

DEFINITION 4.2. *The Lefschetz homomorphism $\Lambda_{fg} : H_s(N, A) \to H_{s-n}(M)$, $k = 0, 1, \dots$, of the pair (f, g) is defined by*

$$\Lambda_{fg}(z) = L(h_{fg}^z).$$

The degree of the homomorphism h_{fg}^z is zero if $z \in H_n(N, A)$. If, moreover, N is an orientable compact connected manifold of dimension n, we have $H_n(N, \partial N) = \mathbf{Q}$. Its identity is the fundamental class $O_N \in H_n(N, \partial N)$ of N. Since $D_N(x) = x \frown O_N$, we recover the classical *Lefschetz number*, $\lambda_{fg} = \Lambda_{fg}(O_N)$.

THEOREM 4.3 (see [31, Theorem 6.1]) (existence of coincidences). *If $\Lambda_{fg} \neq 0$, then any pair of maps f', g' homotopic to f, g has a coincidence.*

Especially important for the control theory applications are the following two corollaries. They are applied to existence of equilibria (section 6) and controllability (section 7), respectively. Observe that the second corollary is about a map of pairs and the first is not.

COROLLARY 4.4 (existence of fixed points) (cf. [13]). *Let $g : M \times U \to M$ be a map. Given $v \in H_s(U)$, suppose the homomorphism $g_v : H_i(M) \to H_{i+s}(M)$, $i = 0, 1, \dots$, of degree s is defined by*

$$g_v(x) = (-1)^{(n-i)s} g_*(x \otimes v),$$

$x \in H_i(M)$. Then, if

$$L(g_v) \neq 0 \text{ for some } v \in H_s(U),$$

then any map $g' : M \times U \to M$ homotopic to g has a fixed point x, $g'(x, u) = x$ for some u.

Proof. Let $(N, A) = (M, \partial M) \times U$, and apply Theorem 4.3 to the pair p, g, where $p : (M, \partial M) \times U \to (M, \partial M)$ is the projection. Also, according to Corollary 5.7 in [31], $\Lambda_{pg}(O_M \otimes v) = L(g_v)$. ∎

COROLLARY 4.5 (sufficient condition of surjectivity). *If*

$$f_* : H_n(N, A) \to H_n(M, \partial M) = \mathbf{Q} \text{ is nonzero,}$$

then any map $f' : (N, A) \to (M, \partial M)$ homotopic to f is onto.

Proof. Apply Theorem 4.3 to the pair f, c, where c is any constant map (as in section 5 in [30] and Proposition 6.8 in [31]). □

In the case of manifolds of equal dimensions, the condition of this corollary is equivalent to the nonvanishing of the degree $\deg f$ [2, p. 186] of f.

5. Removing coincidences. In this section, M is a compact orientable connected manifold with boundary ∂M, $\dim M = n$, N is a manifold, and $f, g : N \to M$ are maps.

When $\dim N = \dim M = n > 2$, the vanishing of the Lefschetz number λ_{fg} implies that the coincidence set can be removed by homotopies of f, g [5]. If $\dim N = n + m, m > 0$, this is no longer true even if λ_{fg} is replaced with Λ_{fg}. Some progress has been made for $m = 1$. In this case the secondary obstruction to the removability of a coincidence set was considered in [10], [9], [17]. These results can be used to study removability of equilibria when the dimension of the input space is 1. However, the conditions on f and g are hard to verify. Necessary conditions of the global removability for arbitrary m were considered in [14, section 5] with N a torus and M a nilmanifold. For some $m > 1$, a partial converse of Theorem 4.3 is provided by the author [32]. A version of this theorem is given below.

Suppose F is an isolated subset of the coincidence set of f, g and $f(F) = g(F) = \{x\}$, $x \in M \backslash \partial M$. Let D be a open neighborhood of x such that $D \cap \partial M = \varnothing$. Choose a neighborhood W of F in N with no coincidences such that $f(W) \subset D$ and $g(W) \subset D$. Suppose $V \subset \overline{V} \subset W$ is another neighborhood of F; then there is an open neighborhood $B \subset \overline{B} \subset D$ of x such that $f(W \backslash V) \subset D \backslash B$. Therefore $f : (W, W \backslash V) \to (D, D \backslash B)$ is a map of pairs.

THEOREM 5.1 (local removability of coincidences). *Suppose the following property is satisfied:*

$$(*)\ H^{k+1}(W, W \backslash V; \pi_k(\mathbf{S}^{n-1})) = 0 \text{ for } k \geq n+1.$$

Suppose also that

$$f_* : H_n(W, W \backslash V) \to H_n(D, D \backslash B) = \mathbf{Q} \text{ is zero.}$$

Then there is a homotopy of f constant on the complement of V to a map f' such that the new pair has no coincidences in V.

Since D is arbitrary we can say that the homotopy can be chosen *arbitrarily small.*

Proof. According to the proof of Theorem 2 in [32] the coincidence subset F can be removed by a homotopy of f constant on $N \backslash V$, provided the local cohomology index $I^W_{fg}(\tau)$ vanishes. This index is defined as follows. Since $F \subset V$ is the set of all coincidences in W, the map $(f, g) : (W, W \backslash V) \to D^\times = (D \times D, D \times D \backslash d(D))$, where $d(D)$ is the diagonal of $D \times D$, is well defined. Therefore the homomorphisms $(f, g)_* : H_k(W, W \backslash V) \to H_k(D^\times)$ and $(f, g)^* : H^k(D^\times) \to H^k(W, W \backslash V)$ are also well defined. Now let I_{fg} be the homology coincidence homomorphism defined by $I_{fg} = (f, g)_* : H_k(W, W \backslash V) \to H_k(D^\times)$. Let $I^W_{fg}(\tau) = (f, g)^*(\tau) \in H^n(W, W \backslash V)$ be the cohomology coincidence index [32, section 2], where τ is the identity of $H^n(D^\times) = \mathbf{Q}$. By Theorem 6.1 in [31], $\Lambda_{fg}(z) = \pi_*(\tau \frown I_{fg}(z))$, where $\pi : D \times D \to D$ is the projection on the first factor. Then, for any $z \in H_n(W, W \backslash V)$,

$$\begin{aligned} \Lambda_{fg}(z) &= \pi_*(\tau \frown (f, g)_*(z)) = \pi_*(f, g)_*((f, g)^*(\tau) \frown z) \\ &= \langle (f, g)^*(\tau), z \rangle = \left\langle I^W_{fg}(\tau), z \right\rangle. \end{aligned}$$

Therefore $I^W_{fg}(\tau) = 0$ if and only if $\Lambda_{fg}(z) = 0$ for all $z \in H_n(W, W \backslash V)$. Finally, observe that $g|_W$ is homotopic to a constant map. Therefore $f_* = 0$ if and only if $\Lambda_{fg}(z) = 0$ for all $z \in H_n(N, A)$ (section 5 in [30]). □

Condition (*) ensures that only the primary obstruction to removability, i.e., the Lefschetz number, can be nonzero. Further investigation of necessary conditions of removability of coincidences will require computing higher order obstructions. The case when $f(F)$ is not a single point is best addressed in the context of Nielsen theory via Wecken-type theorems [33]. In general, the homotopy of f cannot be always chosen arbitrarily small.

Especially important for the control theory applications are the following corollaries. They are applied to the disappearance under perturbations of equilibria (section 6) and controllability (section 7), respectively.

COROLLARY 5.2 (removability of fixed points). *Suppose the conditions of Theorem* 5.1 *are satisfied for $N = M \times U$, where U is a manifold, $x \in M \backslash \partial M$ is an isolated fixed point of $f : M \times U \to M$ (i.e., $f(x,u) = x$ for some $u \in U$), and $F = \{x\} \times \{u \in U : g(x,u) = x\}$. Then there is a homotopy of f to a map f' such that f' has no fixed points in a neighborhood of F. The homotopy can be chosen arbitrarily small and constant on the complement of a neighborhood of F.*

Proof. If $g : M \times U \to M$ is the projection, then F is the coincidence set of f, g. □

COROLLARY 5.3 (necessary condition of surjectivity). *Suppose the conditions of Theorem* 5.1 *are satisfied for $F = f^{-1}(x)$ of $f : N \to M$. Then there is a homotopy of f to a map f' which is not onto; specifically, $x \notin f'(N)$. The homotopy can be chosen arbitrarily small and constant on the complement of a neighborhood of F.*

Proof. If g is the constant map, then F is the coincidence set of f, g. □

These two corollaries are partial converses of Corollaries 4.4 and 4.5, respectively.

A submanifold F of N satisfies condition (*) if one of the following three conditions holds [32, section 4]:

- (a1) *M is a surface, i.e., $n = 2$; or*
- (a2) *F is acyclic, i.e., $H_k(F) = 0$ for $k = 1, 2, \ldots$; or*
- (a3) *every component of F is a homology m-sphere, i.e., $H_k(F) = 0$ for $k \neq 0, m$, for the following values of m and n:*
  (1) *$m = 4$ and $n \geq 6$;*
  (2) *$m = 5$ and $n \geq 7$;*
  (3) *$m = 12$ and $n = 7, 8, 9$, or $n \geq 14$.*

6. Existence of equilibria. In this section, M is a compact orientable connected manifold with boundary ∂M, $\dim M = n$, and U is a topological space.

A *discrete time control system* D_g is given by a map $g : M \times U \to M$, with U the *space of inputs* and M the *space of states* of the system.

We say that $D_{g'}$ is a *perturbation* of D_g if g' homotopic to g. To justify this definition, recall that a system $D_{g'}$ is normally called a perturbation of D_g if g' is "close enough" to g in terms of the distance between $g(z)$ and $g'(z)$. However, if g' is a simplicial approximation of g [2, p. 251], then g and g' are homotopic. Thus we permit large but continuous perturbations of the system. Properties preserved under such perturbations may be called *strongly robust*.

As before, suppose $\{a_1^k, \ldots, a_{m_k}^k\}$ is a basis for $H_k(M)$ and $\{x_1^k, \ldots, x_{m_k}^k\}$ the corresponding dual basis for $H^k(M)$.

THEOREM 6.1 (existence of equilibria). *If*

$$L(g_v) = (-1)^{ns} \sum_k (-1)^k \sum_j x_j^k \frown g_*(a_j^k \otimes v) \neq 0 \text{ for some } v \in H_s(U),$$

then every perturbation of the discrete time system D_g has an equilibrium.

Proof. In light of Corollary 4.4 we need only to show that the above formula for the Lefschetz class $L(g_v)$ of $g_v(x) = (-1)^{(n-i)s} g_*(x \otimes v)$, $x \in H_i(M)$, is true. Since the degree of g_v is s and $a_j^k \in H_k(M)$, we substitute $m = s$ and $i = k$ in Definition 4.1:

$$\begin{aligned} L(g_v) &= \sum_k (-1)^{k(k+s)} \sum_j x_j^k \frown (-1)^{(n-k)s} g_*(a_j^k \otimes v) \\ &= \sum_k (-1)^{k^2+ns} \sum_j x_j^k \frown g_*(a_j^k \otimes v), \end{aligned}$$

and the formula follows. □

The following is a generalization of a well-known theorem about dynamical systems.

COROLLARY 6.2. *Suppose D_g is a perturbation of the constant system D_p; i.e., $p(x,u) = x$ for all u. If the Euler characteristic of M is nonzero, $\chi(M) \neq 0$, then D_g has an equilibrium.*

Proof. Since $p_*(a_j^k \otimes v) = a_j^k$ if $v = 1$ and 0 otherwise, we have

$$\begin{aligned} L(g_v) &= \sum_k (-1)^k \sum_j x_j^k \frown p_*(a_j^k \otimes v) \\ &= \sum_k (-1)^k \sum_j 1 \\ &= \sum_k (-1)^k m_k \\ &= \chi(M). \end{aligned}$$ □

COROLLARY 6.3. *Suppose $M = \mathbf{S}^n$, and suppose one of the following conditions is satisfied:*

(1) *$g_*(d \otimes 1) \neq (-1)^{n+1} d$, where d is the identity of $H_n(\mathbf{S}^n)$; or*

(2) *$g_*(1 \otimes v) \neq 0$ for some $v \in H_n(U)$.*

Then every perturbation of the discrete time system D_g, $g : \mathbf{S}^n \times U \to \mathbf{S}^n$, has an equilibrium.

Proof. Let us compute $L(g_v)$ for an arbitrary $v \in H_s(U)$. As $a_j^k \in H_k(M)$, we have $a_j^k \otimes v \in H_{k+s}(M \times U)$ and $g_*(a_j^k \otimes v) \in H_{k+s}(M)$. Since $H_i(M) = H_i(\mathbf{S}^n) = 0$ for all $i \neq 0, n$, we have $g_*(a_j^k \otimes v) = 0$, except for the following two cases. (1) Choose $v = 1 \in H_0(U), s = 0$; then either $k = 0, a_j^0 = 1, x_j^0 = 1$, or $k = n, a_j^n = d, x_j^n = \overline{d}$. (2) Choose $v \in H_n(U), s = n$; then $k = 0, a_j^0 = 1, x_j^0 = 1$. Here $\overline{d}$ is the dual of d, $\overline{d} \frown d = 1$. Thus we have

$$\begin{aligned} (1)\ L(g_1) &= (-1)^{n0}(1 \frown g_*(1 \otimes 1) + (-1)^n \overline{d} \frown g_*(d \otimes 1)) \\ &= 1 + (-1)^n \overline{d} \frown g_*(d \otimes 1); \\ (2)\ L(g_v) &= (-1)^{nn}(1 \frown g_*(1 \otimes v)) \\ &= (-1)^n g_*(1 \otimes v). \end{aligned}$$

Now, if either $L(g_1)$ or $L(g_v)$ is nonzero, then D_g has an equilibrium by Theorem 6.1. □

Condition (1) means that the degree of $\overline{g}(\cdot) = g(\cdot, u_0) : \mathbf{S}^n \to \mathbf{S}^n$ is not equal to $(-1)^{n+1}$.

If $U = M$ is a compact Lie group and $g : M \times M \to M$ is the multiplication, then D_g has a equilibrium [13, Ex. 2.3]. For more examples, see [13], [30], [31].

In the control setting, Corollary 5.2 reads as follows.

THEOREM 6.4 (removability of equilibria). *Suppose U is a manifold, and suppose $x \in M\backslash\partial M$ is an isolated equilibrium of D_g. Suppose condition $(*)$ is satisfied for $F = \{x\} \times \{u \in U : g(x,u) = x\}$ and*

$$f_* : H_n(W, W\backslash V) \to H_n(D, D\backslash B) = \mathbf{Q} \text{ is zero,}$$

where $V \subset \overline{V} \subset W$ and $B \subset \overline{B} \subset D \subset M\backslash\partial M$ are neighborhoods of F and x, respectively. Then this equilibrium can be removed by an arbitrarily small perturbation restricted to a neighborhood of F.

7. Controllability. In this section, M is a compact orientable connected manifold with boundary ∂M, $\dim M = n$, and U is a topological space.

Suppose a discrete system D_f is given by $f : M \times U \to M$. The system D_f is called *controllable* [34] if any state can be reached from any other state by means of f; i.e., for each pair of states $x, y \in M$ there are inputs $u_0, \dots, u_r \in U$ such that $x_1 = f(u_0, x), x_2 = f(u_1, x_1), \dots, y = x_{r+1} = f(u_r, x_r)$, notation $x \rightsquigarrow_f y$.

Below, this notion is generalized in three nontypical, but topologically appropriate, ways. First, we consider the possibility of an arbitrary state reached not from any given state but from a state in a particular subset L of M. Second, as before, we permit arbitrary, not necessarily small, perturbations of f. Third, instead of looking into controllability of a new, perturbed system D_g, where g is homotopic to f, we allow for consecutive applications of possibly different maps each homotopic to f.

DEFINITION 7.1. *Given $L \subset M$, let $f' : L \times U \to M$ be the restriction of f. Then the system is called* strongly robustly controllable from L *if for any map f_0 homotopic to f', any maps $f_1, \dots, f_r$ homotopic to f, and for each $y \in M$ there is $x \in L$ and inputs $u_0, \dots, u_r \in U$ such that*

$$x_1 = f_0(x, u_0), x_2 = f_1(x_1, u_1), \dots, y = x_{r+1} = f_r(x_r, u_r).$$

Then the system is controllable if it is controllable from any point.

It is clear that controllability is equivalent to surjectivity of several iterations of f. To deal with surjectivity we apply Corollary 4.5, which requires f to be a map of pairs. For this purpose, in this section we make the following assumption about D_f. If the initial state lies at the boundary ∂M of M, then the next state, regardless of the input, lies within a certain neighborhood of ∂M. For simplicity we make a topologically equivalent assumption,

$$f(\partial M \times U) \subset \partial M.$$

Next, let U' be the set of controls that take any given state to the boundary of M, i.e.,

$$U' = \{u \in U : f(x,u) \in \partial M \text{ for all } x \in M\}.$$

Then $f(M \times U') \subset \partial M$. Combining this with the above assumption we conclude that f is a map of pairs, $f : (M, \partial M) \times (U, U') \to (M, \partial M)$. Let $L' = L \cap \partial M$; then $f' : (L, L') \times (U, U') \to (M, \partial M)$ is also a map of pairs.

The following theorem translates the above "reachability" condition into the language of homology: any element of $H_n(M, \partial M) = \mathbf{Q}$ can be reached from some $a_0 \in H_*(L, L')$ by means of f_*.

THEOREM 7.2 (sufficient condition of robust controllability). *Suppose that there are* $a_0 \in H_p(L, L')$, $v_0 \in H_{s_0}(U, U'), \dots, v_r \in H_{s_r}(U, U')$ *such that*

$$a_1 = f'_*(a_0 \otimes v_0), a_2 = f_*(a_1 \otimes v_1), \dots, a_{r+1} = f_*(a_r \otimes v_r) \in H_n(M, \partial M) \backslash \{0\}.$$

Then the discrete time system D_f *is strongly robustly controllable from* L.

Here, if $a_i \in H_{n_i}(M, \partial M)$, $i = 0, 1, 2, \dots, r$, then $n_0 = p, n_1 = p + s_0, n_2 = n_1 + s_1, \dots, n_{r+1} = n_r + s_r = n$. Thus we have a sequence of homology classes $a_0, \dots, a_r$ of $(M, \partial M)$ "climbing" dimensions from p to n.

Proof. The result of consecutive applications of f is defined as a map $F : (L, L') \times (U, U')^{r+1} \to (M, \partial M)$ given by

$$F(x, u_0, \dots, u_r) = f(\dots f(f'(x, u_0), u_1), \dots, u_r);$$

i.e., it is given by the composition

$$\begin{aligned} F : (L, L') \times (U, U') \times \dots \times (U, U') &\xrightarrow{f' \times Id} \\ (M, \partial M) \times (U, U') \times \dots \times (U, U') &\xrightarrow{f \times Id} \dots. \end{aligned}$$

Then $x \rightsquigarrow_f F(x, u_0, \dots, u_r)$. Suppose a map f_0 is homotopic to f' and maps $f_1, \dots, f_r$ are homotopic to f. The result of consecutive applications of $f_0, \dots, f_r$ is defined as a map $G : (L, L') \times (U, U')^{r+1} \to (M, \partial M)$ given by

$$G(x, u_0, \dots, u_r) = f_r(\dots f_1(f_0(x, u_0), u_1), \dots, u_r).$$

Therefore strong robust controllability from L means that $G : L \times U^{r+1} \to M$ is onto. By Corollary 4.5, if

$$F_* : H_n((L, L') \times (U, U') \times \dots \times (U, U')) \to H_n(M, \partial M) = \mathbf{Q}$$

is nonzero, then every map homotopic to F is onto. Since G is clearly homotopic to F, all we need to prove is that F_* is nonzero. By the Künneth theorem, F_* is given by the composition

$$\begin{aligned} F_* : H_*(L, L') \otimes H_*(U, U') \otimes \dots \otimes H_*(U, U') &\xrightarrow{f'_* \otimes Id} \\ H_*(M, \partial M) \otimes H_*(U, U') \otimes \dots \otimes H_*(U, U') &\xrightarrow{f_* \otimes Id} \dots. \end{aligned}$$

Now the condition of Theorem 7.2 implies that $f_*(\dots f_*(f'_*(a_0 \otimes v_0) \otimes v_2) \otimes \dots \otimes v_r) \neq 0$ for some $a_0 \in H_p(L, L')$ and some $v_0 \in H_{s_1}(U, U'), \dots, v_r \in H_{s_r}(U, U')$ such that $p + s_1 + \dots + s_r = n$. Therefore $F_*(a_0 \otimes v_0 \otimes v_2 \otimes \dots \otimes v_r) \neq 0$. □

Moreover, it is clear that what we have is the "finite time reachability"; i.e., every state can be reached in a finite number, $r + 1$, of steps, and that number is common for all states.

Theorem 7.2 involves multiple iterations of f_*, while it is preferable to have a condition involving only f_* itself. Let us consider a case when this is possible.

Consider first a simple example, where $U = \mathbf{S}^1$, $U' = \varnothing$, $M = \mathbf{T}^n = (\mathbf{S}^1)^n$, and $f : \mathbf{S}^1 \times \mathbf{T}^n \to \mathbf{T}^n$ is given by $f(u, x_1, \dots, x_n) = (u, x_1, \dots, x_{n-1})$. This may serve as a model for a robotic arm with n joints where only the first joint can be controlled directly and the next state of a joint is "read" from the current state of the previous joint. The system is obviously controllable. Indeed, after n iterations with inputs $u_1, \dots, u_n$ the system's state is $(u_n, \dots, u_1)$. Whether the system is robustly

controllable is not as obvious. The affirmative answer is provided by Theorem 7.2 as follows. Let L be a point, $p = 0$. Now, with d the identity of $H_1(\mathbf{S}^1)$ we choose

$$\begin{aligned} &v_0 = v_1 = \cdots = v_n = d \in H_1(\mathbf{S}^1), \text{ and} \\ &a_0 = 1 \in H_0(\mathbf{T}^n), \\ &a_1 = d \in H_1(\mathbf{T}^n), \\ &a_2 = d \otimes d \in H_2(\mathbf{T}^n), \\ &\quad \cdots \\ &a_n = d \otimes \cdots \otimes d \in H_n(\mathbf{T}^n). \end{aligned}$$

More generally, suppose the state space M has the product structure, $M = K_1 \times \cdots \times K_s$, where K_i are manifolds of dimensions k_i. Suppose $f = (h_1, \dots, h_s)$, where $h_i : U \times M \to K_i$. For $i = 1, \dots, s$, define maps $h_i^a : K_{i-1} \to K_i$, where $K_0 = U$, by $h_i^a(x_{i-1}) = h_i(a_0, \dots, a_{i-2}, x_{i-1}, a_i, \dots, a_s)$. If all h_i^a are onto, then the system is controllable. According to Corollary 4.5 it suffices to require that all $h_{i*}^a : H_{k_i}(K_{i-1}) \to H_{k_i}(K_i)$ are nonzero, $i = 1, \dots, s$.

Theorem 7.2 can be informally understood as follows. If there are some submanifolds $M_1, \dots, M_r$, $\dim M_i = n_i$, of M such that $M_0 = L, M_1 = f(M_0 \times U)$, $M_2 = f(M_1 \times U), \dots, M = f(M_r \times U)$, then the system is controllable. It means that the restrictions $f_0 : L \times U \to M_1, f_1 : M_1 \times U \to M_2, \dots, f_r : M_r \times U \to M$ of f are surjective. This holds, provided $f_{i*}(O_{M_i} \otimes O_U) = q_i O_{M_{i+1}}$, where $O_{M_i} \in H_{n_i}(M_i)$ is the fundamental class of M_i, for some $q_i \in \mathbf{Q}$. Since each O_{M_i} corresponds to $a_i = J_{i*}(O_{M_i}) \in H_{n_i}(M)$, where $J_i : M_i \to M$ is the inclusion, we arrive at the requirement of Theorem 7.2. The robustness of each of these surjectivity conditions can be tested by means of Corollary 5.3. As a special case we have the following.

THEOREM 7.3 (necessary condition of robust controllability). *Suppose U is a manifold and there is a fiber $F = f^{-1}(x), x \in M$, of f satisfying condition $(*)$ and*

$$f_* : H_n(W, W \backslash V) \to H_n(D, D \backslash B) = \mathbf{Q} \text{ is zero,}$$

where $V \subset \overline{V} \subset W$ and $B \subset \overline{B} \subset D \subset M \backslash \partial M$ are neighborhoods of F and x, respectively. Then there is an arbitrarily small perturbation restricted to a neighborhood of F of the system D_f which is not controllable from M; specifically, x is unreachable from any point.

Proof. Corollary 5.3 implies that there is g homotopic to f such that $x \notin g(M \times U)$. □

8. Continuous systems. In this section we outline, in fewer details than above, the possibilities of applying Lefschetz numbers to continuous systems.

In this section, M is a compact orientable connected smooth manifold with boundary ∂M, and $\dim M = n$. Let TM be the tangent bundle of M; then $\dim TM = 2n$.

A *continuous time control system* C_h [27, p. 16] is defined as a commutative diagram

$$\begin{array}{ccc} Q & \xrightarrow{h} & TM, \\ \downarrow p & \swarrow \pi_M & \\ M & & \end{array}$$

where $p : Q \to M$ is a fiber bundle over M and π_M is the projection. Thus C_h is a parametrized vector field on M.

We say that $x \in M$ is an *equilibrium* of this system if there is $y \in Q$ such that $h(y) = (x, 0) \in TM, x = p(y) \in M$. Detecting an equilibrium can be restated as a coincidence problem. Suppose $i : M \to TM$ is the inclusion and $p_1 : Q \times M \to Q$, $p_2 : Q \times M \to M$ are the projections. Define the maps $f, g : Q \times M \to TM$ by $f = hp_1, g = ip_2$. Then a coincidence of the pair f, g is an equilibrium of the system C_h. Therefore equilibria can be detected by means of the coincidence results in section 4, and their robustness can be studied by means of the results of section 5.

We have a simpler coincidence problem when M is parallelizable; i.e., TM is isomorphic to $M \times \mathbf{R}^n$. For example, $\mathbf{S}^1$, $\mathbf{S}^3$, $\mathbf{S}^7$ are parallelizable. Let $q : TM \simeq M \times \mathbf{R}^n \to M$ be the projection. Then a coincidence of the pair qh, p is an equilibrium of the system C_h, and we can use Theorem 4.3 to detect equilibria and Theorem 5.1 to study their robustness. In fact, D_{qh} is a discrete control system associated with the continuous system C_h. In particular, when $Q = M \times U$, the results of sections 6 and 7 can be applied to study equilibria and controllability of C_h.

For a general M a discrete system D_f associated with the continuous system C_h may be constructed as follows.

Let $\mathcal{A}$ be the topological space of *admissible controls* associated with C_h, i.e., a set of functions $z : [0, d] \to Q$, for all $d \in \mathbf{R}$. A map $c_z : [0, d] \to M$ is called a *trajectory* of the control system if there exists a control $z \in \mathcal{A}$ satisfying $pz = c_z$ and $\frac{d}{dt} c_z = hz$.

We assume that $Q = M \times U$, where U is the topological space of all possible inputs, and $p : Q = M \times U \to M$ is the projection. Then $\mathcal{A}$ is the set of pairs (c, p), where $c : [0, d] \to M$ is a trajectory and $p : [0, d] \to U$ is a function representing the input. To simplify things even further we consider only constant inputs. First, we assume that the system C_h satisfies the following existence and uniqueness property: for every $x \in M$ and any *constant* input $p(t) = u \in U$ there is a unique trajectory c such that $c(0) = x$ and $(c, p) \in \mathcal{A}$. Then the following end point map, $f_d : M \times U \to M$, is well defined. We let $f_d(x, u) = c(d)$, where $c : [0, d] \to M$ is the above trajectory. Assume also that the map $f = f_d$ is continuous. Then for each $d \geq 0$ we have a discrete time control system D_f.

Next, the system C_h is called *controllable* if any state can be reached from any other state; i.e., for each pair of states $x, y \in M$ there is a trajectory $c : [0, d] \to M$ such that $x = c(0), y = c(d)$.

We make the same assumption about D_f as in section 7: if the initial state lies at the boundary ∂M of M, then the next state, regardless of the input, lies within a certain neighborhood W of ∂M, or, alternatively, $f(\partial M \times U) \subset \partial M$. In particular, this condition is satisfied if $h(x, u)$ is tangent to ∂M for all $x \in \partial M$. Let U' be the set of controls that take any given state to the boundary ∂M, i.e.,

$$U' = \{u \in U : f(x, u) \in \partial M \text{ for all } x \in M\}.$$

Then f is a map of pairs, $f : (M, \partial M) \times (U, U') \to (M, \partial M)$. Given a subset L of M, let $L' = L \cap \partial M$, and let $f' : (L, L') \times (U, U') \to (M, \partial M)$ be the restriction of f.

THEOREM 8.1 (sufficient condition of controllability). *Suppose that there are* $a_0 \in H_p(L, L')$, $v_0 \in H_{s_0}(U, U'), \dots, v_r \in H_{s_r}(U, U')$ *such that*

$$a_1 = f'_*(a_0 \otimes v_0), a_2 = f_*(a_1 \otimes v_1), \dots, a_{r+1} = f_*(a_r \otimes v_r) \neq 0.$$

Then the continuous time system C_h *is controllable from* L *by means of piecewise constant controls.*

Proof. The discrete system D_f is controllable from L by Theorem 7.2. ∎

It follows also that if for a small enough $\varepsilon > 0$ a map $k : Q \to TM$ satisfies $d(k(z), h(z)) < \varepsilon$ for all $z \in Q$, where d is the distance on TM, and the system C_k satisfies all of the above assumptions, then C_k is also controllable. We can say then that C_h is *robustly controllable*.

Consider the applicability of Theorem 8.1 to local controllability or controllability in a Euclidean space. In either case, M is the n-ball. Then $H_i(M, \partial M)$ is nontrivial only in dimension n. As a result the above "chain" of homology classes $a_1, a_2, \dots, a_{r+1}$ has to have only one "link," $a_1 = f'_*(a_0 \otimes v_0) \in H_n(M, \partial M) \backslash \{0\}$. Thus Theorem 8.1 reduces to the claim of one-step controllability, provided f'_{*n} is nonzero. As a result the similarity between the homology reachability condition of Theorem 8.1 and the Lie bracket condition [27, section 3.1] does not materialize. The author believes, however, that a generalization of Theorem 7.2 will provide a necessary connection.

Observe also that if $\partial M = \varnothing$, then $f = f_d$ is homotopic to the constant map f_0 under the homotopy $H(t, x, u) = f_t(x, u)$, and hence $f_* = 0$. Therefore the condition of Theorem 8.1 is never satisfied.

Here is another approach to controllability. Let $\mathcal{A}'$ be the set of controls whose trajectories have one of the end points at the boundary of M, i.e.,

$$\mathcal{A}' = \{z : [0, d] \to Q, z \in \mathcal{A}, c_z(0) \in \partial M \text{ or } c_z(d) \in \partial M\}.$$

Define $G(u) = (c_z(0), c_z(d))$, the end points of the trajectory $c_z = pz : [0, d] \to M$ corresponding to z. Then $G : (\mathcal{A}, \mathcal{A}') \to (M \times M, \partial(M \times M))$ is a well-defined map of pairs.

THEOREM 8.2 (sufficient condition of controllability). *If*

$$G_* : H_{2n}(\mathcal{A}, \mathcal{A}') \to H_{2n}(M \times M, \partial(M \times M)) = \mathbf{Q} \text{ is nonzero,}$$

then the continuous time system C_h is controllable.

Proof. By Corollary 4.5, G is onto. □

A similar condition is found in [28], where a boundary operator $l : AC([0, 1], \mathbf{R}^n) \times L^\infty([0, 1], \mathbf{R}^n) \to \mathbf{R}^p$ is considered instead of G. One of the conditions of controllability is $\deg l_0 \neq 0$, where l_0 is the restriction of l to some p-dimensional subspace and $\deg l_0$ its topological degree.

Acknowledgment. The author thanks the referees for their comments that have helped significantly improve this paper.

INTRINSIC OBSERVER-BASED STABILIZATION FOR SIMPLE MECHANICAL SYSTEMS ON LIE GROUPS*

D. H. S. MAITHRIPALA†, W. P. DAYAWANSA‡, AND J. M. BERG†

Abstract. This paper presents a dynamic observer for a class of simple mechanical systems on Lie groups. This observer provides velocity estimates based on configuration measurements. The observer is *intrinsic*, so its performance does not depend on the choice of coordinates, and it is *coordinate free*, in the sense that the equations may be written explicitly without specifying coordinates for the configuration space. Our main result is obtained by specializing a previous result of Aghannan and Rouchon concerning velocity estimation of simple mechanical systems on Riemannian manifolds to such systems on Lie groups. This specialization is nonobvious and extremely powerful. Further we extend the original result to include velocity-dependent external forces. This estimator, combined with a coordinate-free formulation of passivity-based state-feedback control, allows the construction of a coordinate-free, intrinsic dynamic output feedback compensator. This is, to our knowledge, the first time such a result has been reported. Explicit expressions are computed for the Lie groups $SO(3)$ and $SE(3)$, allowing easy specialization to practical problems of rigid body motion. The theory is illustrated via application to the axisymmetric top and to a six-degrees-of-freedom microelectromechanical system.

1. Introduction.

The traditional approach to nonlinear control has been to extend the extremely successful concepts developed for linear systems. This tactic has led to notable success, but it is inherently limited by the great variety of nonlinear phenomena. An alternative is to exploit the structural properties of specific classes of nonlinear systems. In particular, the systematic geometric study of *mechanical control systems* has received much attention. Formally, a holonomic simple mechanical system consists of (i) a smooth manifold corresponding to the configuration space of the system, (ii) a smooth Lagrangian corresponding to kinetic energy minus potential energy, and (iii) a set of external forces or one-forms [1]. When some of these forces may be used for control, we refer to a simple mechanical *control* system [6, 24]. The study of mechanical systems from a modern geometric point of view can be found, for example, in the excellent texts of Abraham and Marsden [1], Arnold [5], Bloch et al. [12], Bullo and Lewis [15], and Marsden and Ratiu [29]. Certain important nonlinear optimal control problems naturally lead to the consideration of such systems. The relationship between optimal control and mechanics is explored in essays by Bloch and Crouch [8] and Jurdjevic [22]. Work by Bloch, Leonard, and Marsden [9], Bloch and Leonard [11], Bloch [12], and the references therein, develops the notion of controlled Lagrangian systems, in which Lagrangian systems are stabilized by symmetry-preserving kinetic energy shaping and damping injection in such a way

that the closed-loop system retains a Lagrangian structure [7, 9, 11]. These results have been extended to the case where the uncontrolled mechanical system has no underlying symmetry [10]. A parallel development for controller synthesis in Hamiltonian systems is the port controlled Hamiltonian approach [17, 33, 34, 40]. Both the Lagrangian and Hamiltonian methods make extensive use of structural features such as the Riemannian metric or the Poisson structure of the system. Symmetry-preserving tracking controls have been developed recently for general control systems admitting symmetry by Martin, Rouchon, and Rudolph [30] using the geometric notion of Cartan's moving frame method. The underlying Riemannian structure is exploited by Bullo and Murray [14] to derive intrinsic tracking controls for fully actuated simple mechanical systems on a general Riemannian manifold. The tools of passivity-based control have also been extended, through a generalization of LaSalle's invariance theorem, to a class of simple mechanical systems on Riemannian manifolds [32]. In a recent paper [2], Aghannan and Rouchon present an intrinsic observer that, given measurements of the configuration variables of a simple mechanical system on a Riemannian manifold, provides estimates of the states (both configurations and velocities). This is accomplished with a reformulation of the Luenberger observer, where the observation error is defined intrinsically by the geodesic distance between the actual and estimated configuration variables. These powerful results concerning the dynamics and control of systems on manifolds are intrinsic, implying that the performance will not depend on the choice of coordinates. However, on a general Riemannian manifold, their explicit expression requires coordinates. On a Lie group, however, due to the natural identification of tangent spaces and neighborhoods of a point by left-translation, coordinate-free explicit expressions may be feasible.

Simple mechanical control systems on Lie groups provide a rich source of control problems. Some examples include underwater vehicles, satellites, surface vessels, airships, hovercraft, and robots [3, 4, 11, 13, 41, 42]. Simple mechanical systems on Lie groups are also interesting as *subsets* of more complex interconnected systems. An example is a model of an electrostatically actuated microelectromechanical system (MEMS) with a mechanical subsystem represented as a simple mechanical system on the Lie group $SE(3)$, and an electrical subsystem without such an additional structure [25]. Systems on Lie groups exhibiting symmetry can be further exploited. When the Lagrangian of the system is invariant under the left action of the group on itself, and the external forces acting on the system are left invariant, a reduction of dynamics to the Lie algebra of the Lie group is immediate [11, 13, 29]. In this case no coordinates need to be introduced on the Lie group to express the system and control strategies. Open-loop, coordinate-free, motion planning algorithms using small amplitude forcing have been developed for underactuated systems with such symmetry [13]. One of the main contributions of the present work is to show how, with left-invariant kinetic energy but without additional symmetry constraints, explicit formulas for intrinsic, dynamic output feedback controllers may be obtained without introducing coordinates on the Lie group. For example, there is a wide class of mechanical systems on Lie groups for which the forces are dissipative or nonleft invariant. Examples include MEMS, robot manipulators, land vehicles, and general three-dimensional motion in a gravitational field with or without damping.

Specifically we specialize to Lie groups two intrinsic results for control [32] and estimation [2] of simple mechanical systems on general Riemannian manifolds. We give coordinate-free explicit expressions of these results valid on any simple mechanical system on a Lie group with left-invariant kinetic energy. For a given Lie group the key computations required are the Levi-Civita connection, the Riemannian curvature,

and an approximation to the associated distance function and parallel transport. The computation of these quantities require only a choice of coordinates for the Lie algebra of the Lie group. Once these quantities are computed they can be used for any simple mechanical system with left-invariant kinetic energy, merely by specifying the particular kinetic energy tensor and external forces. Unless the external forces are left invariant, the expression of the force terms may require coordinates on the Lie group.

In section 2 below we briefly review the necessary mathematical background. In section 3 we first employ the results of [32] to derive passivity-based full state-feedback control for uncoupled simple mechanical systems on Lie groups. We then derive similar results for simple mechanical systems on Lie groups that are coupled to a system on a general manifold by generalizing the results of [16].

Often in applications, configuration and velocity are not both easily measured. In some cases the velocities are available [4, 31, 36], while in others, it is the configuration [3, 37, 39]. In section 4 we consider the latter case, where the configuration variables are measured and the velocities must be estimated. Section 4 presents a coordinate-free explicit expression of the results of [2]. We apply feedback passivation followed by damping injection. Since the original result in [2] assumes all forces to be only configuration dependent, we require an extension of that result to accommodate velocity- and configuration-dependent forces. The extension is presented in the appendix.

Section 4 concludes with a statement of a separation principle for the dynamic output feedback law resulting from the combination of this estimator with the uncoupled passivity-based controller of section 3.

In section 5 we specifically compute and apply the dynamic output feedback controller to representative systems on two Lie groups of special interest, namely, the rotation group $SO(3)$ and the Euclidean motion group $SE(3)$. The expressions given in this section may be applied to many problems of practical significance arising from rigid body motion by specializing only the inertia tensor and the external force terms. The classical axisymmetric top problem is used to demonstrate the construction and performance of the observer on $SO(3)$. An example on $SE(3)$ models setpoint control in the presence of a saddle-node bifurcation for a MEMS. Simulation results show excellent performance.

2. Mathematical background. This section briefly describes the notation and several geometric notions that will be used in the rest of the paper. For additional details the reader is referred to the texts of [1, 15, 12, 18, 20, 21, 29, 35]. Let G be a connected Lie group and let $\mathcal{G} \simeq T_eG$ be its Lie algebra. The left-translation of $\zeta \in \mathcal{G}$ to T_gG will be denoted $g \cdot \zeta = DL_g\,\zeta$. The Lie bracket on $\mathcal{G}$ for any two $\zeta, \eta \in \mathcal{G}$ will be denoted $[\zeta, \eta] = ad_\zeta\,\eta$, and the dual of the ad operator will be denoted ad^*. Any smooth vector field $X(g)$ on G has the form $g \cdot \zeta(g)$ for some smooth $\zeta : G \mapsto \mathcal{G}$. Let $\{e_i\}$ be any basis for the Lie algebra $\mathcal{G}$ and let $\{E_i(g) = g \cdot e_i\}$ be the associated left-invariant basis vector field on G. Now $[e_i, e_j] = C_{ij}^k e_k$, where C_{ij}^k are the structure constants of the Lie algebra $\mathcal{G}$ ($C_{ij}^k = -C_{ji}^k$), and $[E_i, E_j] = C_{ij}^k E_k$.

2.1. The Riemannian structure. Consider a left-invariant metric $\langle\langle \cdot, \cdot \rangle\rangle$ on G. Such a metric induces a unique inner product $\langle\langle \cdot\,, \cdot \rangle\rangle_{\mathcal{G}}$ on $\mathcal{G}$ by the restriction of $\langle\langle \cdot\,, \cdot \rangle\rangle$ to T_eG. Define the isomorphism $I : \mathcal{G} \mapsto \mathcal{G}^*$ by the relation $\langle I\zeta\,,\, \eta \rangle = \langle\langle \zeta\,,\, \eta \rangle\rangle_{\mathcal{G}}$. Here $\langle \cdot, \cdot \rangle$ denotes the usual pairing between a vector and a covector. Let the matrix I be defined by $I_{ij} = \langle\langle e_i\,,\, e_j \rangle\rangle_{\mathcal{G}}$ and let I^{ij} be its inverse. I is symmetric and positive definite. In similar fashion such an I induces a unique left-invariant metric on G by the relation $\langle\langle g \cdot \zeta\,,\, g \cdot \eta \rangle\rangle = \langle I\zeta\,,\, \eta \rangle$.

The presentation that follows is based on the texts of [20, 21, 35]. Associated with any metric is a unique connection that is torsion free and metric called the Levi-Civita connection. For a vector field $X = X^k E_k$ and a vector $v = v^k E_k$ the Levi-Civita connection is given by

$$\nabla_v X = (dX^k(v) + \omega_{ij}^k(g) v^i X^j) E_k \,, \tag{2.1}$$

where $\omega_{ij}^k(g)$ are the connection coefficients in the frame $\{E_k\}$. If the metric is left invariant, then the connection coefficients are constant, given by

$$\omega_{ij}^k = \frac{1}{2}\left(C_{ij}^k - I^{ks}(I_{ir}C_{js}^r + I_{jr}C_{is}^r)\right). \tag{2.2}$$

Note that since in general E_k are not coordinate vector fields, ω_{ij}^k are not the Christoffel symbols. In the case of a left-invariant metric, the coefficients of the Riemannian curvature two-forms R_{jab}^k are also constant and can be shown to be [26]

$$R_{jab}^k = (-\omega_{rj}^k C_{ab}^r + 2\omega_{ar}^k \omega_{bj}^r). \tag{2.3}$$

We remark that they are in general different from the usual curvature coefficients that one would obtain in a coordinate frame field. The Riemannian curvature is then

$$R(\zeta\,,\,\eta)\xi = \{R_{jab}^k \xi^j (\zeta^a\,\eta^b - \zeta^b\,\eta^a) - \omega_{ij}^k C_{ab}^i \zeta^a\,\eta^b\,\xi^j\} e_k. \tag{2.4}$$

These derivations are based on Cartan's structural equations as presented in sections 9.3b–9.3e of [20].

2.1.1. The local distance function on a Lie group. Given any two points g and $\tilde{g}$ on a Riemannian manifold $(G, \langle\langle\cdot,\cdot\rangle\rangle)$, define the set of curves,

$$\Lambda(g,\tilde{g}) := \{\gamma : [0\ 1] \mapsto G \mid \gamma \text{ is piecewise smooth and } \gamma(0) = g, \gamma(1) = \tilde{g}\}. \tag{2.5}$$

Then the distance between g and $\tilde{g}$ is defined as

$$d(g,\tilde{g}) := \inf\{l(\gamma) : \gamma \in \Lambda(g,\tilde{g})\} \tag{2.6}$$

and defines a metric on the Riemannian manifold $(G, \langle\langle\cdot,\cdot\rangle\rangle)$ [21, 35]. If a C^1 curve $\gamma \in \Lambda(g,\tilde{g})$ exists such that $d(g,\tilde{g}) = l(\gamma)$, then it is referred to as a *segment*. It is known that segments are always geodesics and that any two sufficiently close points can be connected by a unique segment. In fact, since Lie groups are geodesically complete from the Hopf–Rinow theorem [21, 35] it follows that any two points on a Lie group can be joined by a geodesic.

For g and $\tilde{g}$ sufficiently close there exists a unique $\zeta_e \in \mathcal{G}$ such that

$$e := g^{-1}\tilde{g} = \exp \zeta_e. \tag{2.7}$$

Recall that $\exp s\zeta_e = e(s)$ is the one-parameter subgroup generated by ζ_e with respect to left-translation with $e(0) = id$ and $e(1) = e$. The inverse of this exponential map (2.7) defines local coordinates around g, commonly referred to as logarithmic coordinates [18]. For a fixed $g \in G$, define the function

$$f(\tilde{g}) := ||\zeta_e||_{\mathcal{G}}. \tag{2.8}$$

Since $e(s) = \exp s\zeta_e$ is a one-parameter subgroup, $f(\tilde{g})$ is the length of this curve and hence for g fixed $d(g, \tilde{g}) \leq f(\tilde{g})$. Equality holds if the metric is bi-invariant. In logarithmic coordinates, $f(\tilde{g}) = \sqrt{\zeta_e^T I \zeta_e}$ and up to order-two terms in ζ_e, $d(g, \tilde{g}) = \sqrt{\zeta_e^T I \zeta_e}$. Thus up to order-two terms, the geodesic distance between g and $\tilde{g}$ is explicitly given by the function (2.8) and is referred to as a local distance function.

The function $F(\tilde{g}) := \frac{1}{2} d^2(g, \tilde{g})$ plays a crucial role in the observer to be presented in section 4. From the above discussion it follows that up to third order $F(\tilde{g}) = \frac{1}{2} f^2(\tilde{g})$. Thus in logarithmic coordinates, up to second order, it follows that grad $F(\tilde{g}) = \tilde{g} \cdot \zeta_e$. The approximation arguments are intrinsic since smooth coordinate changes will not reduce the order of the neglected higher-order terms.

2.2. Simple mechanical control systems on Lie groups. A simple mechanical control system evolving on a Lie group G, equipped with a left-invariant metric $\langle\langle \cdot\,, \cdot \rangle\rangle$, is defined as a system with kinetic energy $E(\dot{g}) = \frac{1}{2}\langle\langle \dot{g}\,, \dot{g} \rangle\rangle$, and Lagrangian $L(g, \dot{g}) = E(\dot{g}) - U(g)$ for some smooth function $U(g)$ on G [15, 32]. A function with all nondegenerate critical points is referred to as a Morse function. For convenience in this paper we assume that $U(g)$ is a globally defined Morse function. Let $I : \mathcal{G} \mapsto \mathcal{G}^*$ be the isomorphism associated with the kinetic energy metric. Then the Euler–Lagrange equations of motion are given by

$$\dot{g} = g \cdot \zeta, \tag{2.9}$$

$$\nabla_{\dot{g}}\, \dot{g} = g \cdot I^{-1} \left(f^c(g) + f^d(g, \zeta) + \sum_i^m u_i f^i(g) \right) = g \cdot S(g, \zeta), \tag{2.10}$$

where $f^c(g)$, $f^d(g, \zeta)$, $f^i(g) \in \mathcal{G}^*$, and $u_i \in \mathcal{R}$. The conservative force $f^c(g)$ and damping force $f^d(g, \zeta)$ satisfy the conditions $\langle dU, g \cdot \xi \rangle = -\langle f^c(g), \xi \rangle$ and $\langle f^d(g, \xi), \xi \rangle \leq 0$ for any $\xi \in \mathcal{G}$. Here the $f^i(g)$ denote the control directions and are assumed to be linearly independent. The u_i are the magnitude of the forces and are the controls of the system. If $m < \dim(G)$, then the system is said to be *underactuated*, and if $m = \dim(G)$, the system is said to be *fully actuated*.

Equation (2.9) is the kinematic equation and (2.10) is the Euler–Lagrange equation of the system. These equations can also be expressed as

$$\dot{g} = g \cdot \zeta\,, \tag{2.11}$$

$$\dot{\zeta} = I^{-1} \left(ad^*_\zeta\, I\zeta + f^c(g) + f^d(g, \zeta) + \sum_i^m u_i f^i(g) \right), \tag{2.12}$$

where now (2.11)–(2.12) define a dynamical system on $G \times \mathcal{G}$, the left trivialization of TG. This formulation does not require coordinates on the Lie group G. In the case where the forcing terms do not depend on the configuration variable g, (2.12) represents a complete reduction of dynamics to $\mathcal{G}$ and is referred to as the Euler–Poincare equation. The kinematic equation (2.11) can be integrated to recover the configuration once the velocities have been solved for and hence is referred to as the reconstruction equation.

3. Passivity-based control for simple mechanical systems.

3.1. Uncoupled simple mechanical systems. The uncontrolled equilibrium points of the system are of the form $(\bar{g}, 0)$, where $\bar{g}$ is a critical point of $U(g)$. Assume that $\bar{g}$ is a local minimum. Since $U(g)$ is assumed to be a Morse function, $\bar{g}$ is in fact an

isolated local minimum. This implies that the equilibrium $(\bar{g}, 0)$ of the uncontrolled system is stable. If any of these criteria are not satisfied by the natural potential energy, for example if the desired equilibrium is not a local minima of $U(g)$, the methods of [10, 32] may be used to shape the potential energy. If the damping forces satisfy $\langle f^d(g,\zeta),\zeta\rangle < 0$, then the equilibrium $(\bar{g}, 0)$ is locally asymptotically stable. If this inequality is not strict, then the equilibrium is guaranteed only to be stable. Here we wish to enforce convergence to the equilibrium via "damping injection" control. Similarly, if the natural damping is insufficient, we may use this strategy to augment it.

For convenience assume that the damping force $f^d(g,\zeta)$ is of Rayleigh type. That is, $f^d(g,\zeta) = -R(g)\zeta$, where $R(g) : \mathcal{G} \mapsto \mathcal{G}^*$ is a map smooth in g so that the relation $\langle R(g)\zeta,\eta\rangle = \langle\langle\zeta,\eta\rangle\rangle_D$ defines a degenerate inner product on $\mathcal{G}$. This means that in a matrix representation $R(g)$ is symmetric and positive semidefinite. Let $\mathrm{Im}(B(g)) := span\{f^1(g),\dots,f^m(g)\}$.

To be *passive* a system must have a storage function satisfying the dissipation inequality with supply rate $y^T u$, where y is the system output [40]. For simple mechanical control systems the output that is compatible with passivity is completely determined and is given intrinsically by $y_i = \langle f^i(g)\,,\,\zeta\rangle$ or in a matrix representation by $y = B(g)^T\zeta$. Consider the storage function

$$H(g,\zeta) = \frac{1}{2}\langle\langle\zeta\,,\,\zeta\rangle\rangle_{\mathcal{G}} + U(g), \tag{3.1}$$

$$\dot{H} = -\langle R(g)\zeta,\zeta\rangle + \sum_i^m u_i\langle f^i(g)\,,\,\zeta\rangle \le \sum_i^m u_i\langle f^i(g)\,,\,\zeta\rangle = y^T u. \tag{3.2}$$

Thus (2.11)–(2.12) are passive with storage function H. Now consider the *damping injection* control

$$u_i = -y_i = -\langle f^i(g)\,,\,\zeta\rangle. \tag{3.3}$$

In matrix representations, (3.3) can also be written as $u = -B(g)^T\zeta$ and (3.2) as $\dot{H} = -\zeta^T R(g)\zeta - \zeta^T B(g)B(g)^T\zeta$.

Recall that Lie groups are complete metric spaces [35]. Thus, using this control, the generalized LaSalle invariance theorem of [32] guarantees that the trajectories of (2.11)–(2.12) converge to the largest invariant set of (2.11)–(2.12) contained in $\mathcal{S} := \{(g,\zeta) \mid \dot{H} = 0\}$. Let $\mathcal{N}(R(g))$ be the null space of the degenerate inner product $\langle\langle\cdot,\cdot\rangle\rangle_D$ and define $[\mathrm{Im}(B(g))]^\perp := \{\zeta \in \mathcal{G} \mid \langle f^i(g),\zeta\rangle = 0 \quad \text{for} \quad i = 1,\dots,m\}$. If at every $g \in G$, $\mathcal{N}(R(g)) \cap [\mathrm{Im}(B(g))]^\perp = \{0\}$, then $\mathcal{S} = \{(g,\zeta) \mid \zeta = 0\}$ and the largest invariant set contained in $\mathcal{S}$ consists of only the equilibrium points of the system. The equilibrium points of the system are given by the critical points of the potential energy function $U(g)$, and by assumption $(\bar{g}, 0)$ is a local nondegenerate minimum. Thus the damping control (3.3) locally asymptotically stabilizes $(\bar{g}, 0)$. In terms of a matrix representation the condition $\mathcal{N}(R(g)) \cap [\mathrm{Im}(B(g))]^\perp = \{0\}$ implies that the symmetric matrix $R(g) + B(g)B^T(g)$ is positive definite. From this point on we will assume this condition is satisfied. This is trivially the case for fully actuated systems.

We say an equilibrium is almost globally asymptotically stable if its region of attraction is an open and dense set. In particular the stabilization results are almost global if the potential energy function $U(g)$ is a globally defined smooth proper Morse function with a unique minimum at the desired equilibrium configuration $\bar{g}$ [23]. We return to this point in section 4 when we consider almost global performance of the dynamic output feedback compensator.

3.2. Coupled simple mechanical systems. Consider the product space $\mathcal{M} = \mathcal{Q} \times TG$ for some smooth manifold Q, and the class of systems on $\mathcal{M}$ of the form

$$\dot{q} = s^0(q, g, \zeta) + \sum_{i=1}^{m} s^i(q, g, \zeta) u_i, \tag{3.4}$$

$$\dot{g} = g \cdot \zeta \ , \tag{3.5}$$

$$\dot{\zeta} = I^{-1} \left(ad^*_\zeta I\zeta + f^c(g) + f^d(g, \zeta) + \sum_{i=m}^{m} f^i(g, \zeta, y) y_i \right), \tag{3.6}$$

$$y_i = h_i(q) \quad \text{for} \quad i = 1, 2, \dots, m, \tag{3.7}$$

where $q \in \mathcal{Q}$ and $s^i : \mathcal{M} \mapsto T\mathcal{Q}$ are smooth maps such that $\pi_Q \circ s^i = \pi_M$, where $\pi_Q : T\mathcal{Q} \mapsto \mathcal{Q}$ is the projection of $T\mathcal{Q}$ onto $\mathcal{Q}$, and $\pi_M : \mathcal{M} \mapsto \mathcal{Q}$ is the projection of $\mathcal{M}$ on to $\mathcal{Q}$. Furthermore let $y := [y_1\ y_2\ \cdots\ y_m]^T = [h_1\ h_2\ \cdots\ h_m]^T := h \in \mathcal{R}^m$ and $s := [s^1\ s^2\ \cdots\ s^m]$ be such that $D\,h$ is onto at every $q \in \mathcal{Q}$ and $\dim(span\{s^i\}_{i=1}^m) = m$ uniformly. If the matrix $L_s\, h := (L_{s^i} h_j)$ for $i, j = 1, 2, 3 \dots, m$ is nonsingular for all $q \in \mathcal{Q}, g \in G, \zeta \in \mathcal{G}$, then the interconnected system (3.4)–(3.7) has uniform relative degree $\{1, 1, \dots 1\}$ with respect to the outputs y_i. The uniform relative degree of the system implies that the feedback law

$$u = -[L_s\, h]^{-1} (L_{s^0}\, h - \nu) \tag{3.8}$$

is globally smooth. Thus the state feedback (3.8) input-output linearizes the system. Since $D\,h$ is full rank at each $q \in \mathcal{Q}$, the set $h^{-1}(y) \subset \mathcal{Q}$ is a smooth embedded submanifold of $\mathcal{Q}$ for each $y \in \mathcal{R}^m$. Introducing local coordinates (y, z) on $\mathcal{Q}$, the system (3.4)–(3.7) together with the control (3.8) can be expressed as

$$\dot{y} = \nu, \tag{3.9}$$

$$\dot{g} = g \cdot \zeta \ , \tag{3.10}$$

$$\dot{\zeta} = I^{-1} \left(ad^*_\zeta I\zeta + f^c(g) + f^d(g, \zeta) + \sum_{i=m}^{m} f^i(g, \zeta, y) y_i \right), \tag{3.11}$$

$$\dot{z} = N(z, g, \zeta, \nu, y). \tag{3.12}$$

The zero dynamics of the system are given by

$$\dot{g} = g \cdot \zeta \ , \tag{3.13}$$

$$\dot{\zeta} = I^{-1} \left(ad^*_\zeta I\zeta + f^c(g) + f^d(g, \zeta) \right), \tag{3.14}$$

$$\dot{z} = N(z, g, \zeta, 0, 0). \tag{3.15}$$

Consider the following candidate storage function for the input-output linearized system (3.9)–(3.11):

$$V(y, g, \zeta) = \frac{1}{2} \langle \langle \zeta, \zeta \rangle \rangle_{\mathcal{G}} + U(g) + \frac{1}{2} \sum_{i=1}^{m} {y_i}^2, \tag{3.16}$$

where the potential energy of the mechanical system is $U(g)$ and $U(g) \geq 0$ is Morse. Then specializing the results of [16, 38, 40] on passivity of interconnected subsystems, it can be shown that the control $\nu_i = -\langle f^i(g, \zeta, y)\ ,\ \zeta \rangle + w_i$ renders the input-output linearized system (3.9)–(3.11) passive with respect to the input-output pair (w, y)

and storage function V. Thus if $\bar{g}$ is a nondegenerate local minimum of $U(g)$ and $\langle f^d(g,\zeta)\ ,\ \zeta\rangle < 0$ for all $\zeta \in \mathcal{G}$, the control $w = -y$ locally asymptotically stabilizes the equilibrium $(0,\bar{g},0)$ of the input-output linearized system (3.9)–(3.11). Explicitly this control is given by

$$\nu_i = -\langle f^i(g,\zeta,y)\ ,\ \zeta\rangle - y_i. \tag{3.17}$$

Furthermore if the equilibrium of (3.15) is locally asymptotically stable with $g \equiv \bar{g}$ and $\zeta = 0$, then the equilibrium $(0,\bar{g},0)$ of the whole system (3.4)–(3.6) is locally asymptotically stable. The stability result of the composite system (3.4)–(3.6) is almost global if additionally $U(g)$ is a smooth proper Morse function with a unique minimum at the equilibrium configuration $\bar{g}$ and N is vacuous or satisfies some additional requirements given by Theorem 4.7 of [38]. Observe that if $\dim(\mathcal{Q}) = m$, then N is vacuous.

4. Intrinsic observer for velocity estimation. The controls (3.3) and (3.17) involve the feedback of both the configuration g and the velocity ζ. In the case where the configuration is available for measurement, but the velocity is not, we propose an intrinsic observer to estimate the velocity variable. This is based on the work reported in [2]. There a velocity estimate based on a configuration measurement is presented for a general Riemannian manifold and expressed in coordinates. We specialize that result to a Lie group equipped with a left-invariant metric. Our reformulation avoids the need to introduce coordinates on the Lie group and includes a proof that the external forcing can exhibit velocity dependence in addition to configuration dependence.

Consider the system given by (2.9)–(2.10). Let $(\tilde{g},\tilde{\zeta})$ be the estimated value of (g,ζ) and let $\alpha,\beta > 0$ be constant. Then it is shown in [2] that the following observer converges locally exponentially if the initial observer configuration error is sufficiently small:

$$\dot{\tilde{g}} = \tilde{g}\cdot\tilde{\zeta} - 2\alpha \operatorname{grad} F(\tilde{g}), \tag{4.1}$$

$$\nabla_{\dot{\tilde{g}}}\ \tilde{g}\cdot\tilde{\zeta} = \tilde{g}\cdot\Gamma(S) - \tilde{g}\cdot R(\tilde{\zeta},\tilde{g}^{-1}\operatorname{grad} F(\tilde{g}))\tilde{\zeta} - \beta \operatorname{grad} F(\tilde{g}), \tag{4.2}$$

where $F(\tilde{g}) = \frac{1}{2}d(g,\tilde{g})^2$ and $\Gamma(S)$ is the parallel transport of the resultant external force S at g to $\tilde{g}$ along the geodesic joining the two points. In [2] it is pointed out that replacing $\Gamma(S)$ and grad F by their respective first-order approximations will not affect the local convergence properties of the observer.

Although convergence is proved in [2] assuming that $S = S(g)$, the same basic argument holds when $S = S(g,\zeta)$, where we now use $\tilde{\zeta}$ instead of ζ in the parallel transport term $\Gamma(S(g,\tilde{\zeta}))$. In [2], the first variation of the observer dynamics is constructed, then contraction analysis is used to prove local exponential convergence of the observer. In the appendix we show that the first variation of the observer dynamics does not change when S is allowed to depend on the velocity ζ. Thus the contraction argument of [2] applies without modification and the local exponential convergence of the observer (4.1)–(4.2) follows even when $S = S(g,\zeta)$.

It was shown in section 2.1.1 that up to second order grad $F = \tilde{g}\zeta_e$. Therefore the first-order approximation of the observer (4.1)–(4.2) can be expressed as

$$\dot{\tilde{g}} = \tilde{g}\cdot(\tilde{\zeta} - 2\alpha\zeta_e), \tag{4.3}$$

$$\nabla_{\dot{\tilde{g}}}\ \tilde{g}\cdot\tilde{\zeta} = \tilde{g}\cdot\Gamma(S) - \tilde{g}\cdot R(\tilde{\zeta},\zeta_e)\tilde{\zeta} - \beta\ \tilde{g}\cdot\zeta_e. \tag{4.4}$$

Expanding (4.4), the first-order approximation of the observer is explicitly given by

$$\dot{\tilde{g}} = \tilde{g} \cdot (\tilde{\zeta} - 2\alpha\zeta_e), \tag{4.5}$$

$$\dot{\tilde{\zeta}} = I^{-1}\Big(ad^*_{\tilde{\zeta}} I\tilde{\zeta} - \alpha(ad^*_{\zeta_e} I\tilde{\zeta} + ad^*_{\tilde{\zeta}} I\zeta_e)\Big) + \alpha[\zeta_e, \tilde{\zeta}]_{\mathcal{G}} + \Gamma(S) - R(\tilde{\zeta}, \zeta_e)\tilde{\zeta} - \beta\zeta_e, \tag{4.6}$$

where up to order-two terms,

$$\Gamma(S) = \Big(S^k(g, \tilde{\zeta}) - \omega^k_{ij} S^i(g, \tilde{\zeta})\zeta^j_e\Big)\ e_k. \tag{4.7}$$

This coordinate-free formulation of the observer clearly shows its structure. For instance, the terms in (4.6) involving the gain α are the corrections to the inertial forces of the observer that are needed to compensate for curvature effects, $\Gamma(S)$ is the intrinsic model of the external forces of the observed system, and $R(\tilde{\zeta}, \zeta_e)\tilde{\zeta}$ is the curvature term that is needed to correct for the effects of possible divergence of nearby geodesics. The $2\alpha\zeta_e$ and $\beta\zeta_e$ terms are the error feedback that ensure convergence. The coordinate-free formulation also shows the versatility of the expressions (4.5)–(4.6). Specifically it is readily applicable to any simple mechanical system on the Lie group G. Depending on the specific problem all the control designer needs to do is specify the kinetic energy tensor I and the external forces S.

Using the observer (4.5)–(4.6), the control (3.3) can be implemented with velocity estimates replacing velocity measurements as

$$u_i = -\langle f^i(g)\ ,\ \tilde{\zeta}\rangle. \tag{4.8}$$

It is natural to ask whether the dynamic output feedback control (4.8) preserves the stability properties of the state-feedback control (3.3)—that is, whether a separation principle holds. In the appendix we show, using results of [28], that it does. In particular, if (3.3) is almost globally stabilizing (resp., asymptotically stabilizing), then so is (4.8).

5. Examples. In this section we demonstrate the preceding constructions for two cases of practical significance in which the configuration space of the simple mechanical systems are Lie groups—first $SO(3)$, and then $SE(3)$. Since these groups arise in many practical problems involving rigid body motions we include here explicit expressions for the Riemannian connection, Riemannian curvature, and the approximate local distance functions. To implement the observer in a specific application, now only the inertia tensor I and the external force S need to be changed. The effectiveness of the observer is demonstrated in $SO(3)$ for the axisymmetric top and in $SE(3)$ for a model of an electrostatically actuated MEMS.

5.1. The rotation group $SO(3)$. The rotation group, $SO(3)$, is the group of matrices $R \in GL(3, \mathcal{R})$ that satisfy the conditions $R\,R^T = R^T\,R = I$ and $\det(R) = 1$. Euler's theorem states that any given $R \in SO(3)$ is a rotation about some axis n by an angle ψ, that is, $R = \exp(\psi\hat{n})$, where

$$\psi\hat{n} = \frac{\psi}{2\sin\psi}(R - R^T), \tag{5.1}$$

and $\cos\psi = (\mathrm{tr}(R) - 1)/2$ for $|\psi| < \pi$.

The Lie algebra $so(3)$ of $SO(3)$ is the set of traceless skew symmetric 3×3 matrices. The Lie algebra $so(3)$ is identified with $\mathcal{R}^3$ by the isomorphism

$$\xi \in \mathcal{R}^3 \mapsto \hat{\xi} = \begin{bmatrix} 0 & -\xi^3 & \xi^2 \\ \xi^3 & 0 & -\xi^1 \\ -\xi^2 & \xi^1 & 0 \end{bmatrix} \in so(3), \tag{5.2}$$

where $\xi = [\xi^1\ \xi^2\ \xi^3]^T$. We will use both ξ and $\hat{\xi}$ to mean the same element of $so(3)$.

The isomorphism $I : so(3) \simeq \mathcal{R}^3 \mapsto so(3)^* \simeq \mathcal{R}^3$ defined by the positive definite matrix I induces a left-invariant metric on $SO(3)$ by the relation $\langle\langle R\cdot\xi\,,\, R\cdot\psi\rangle\rangle = \langle\langle \xi\,,\,\psi\rangle\rangle_{so(3)} = I\xi\cdot\psi$ for any two elements $R\cdot\xi, R\cdot\psi\ \in T_RSO(3)$. The Lie bracket on $so(3)$ is $[\xi\,,\,\psi]_{so(3)} = ad_\xi\,\psi = \xi\times\psi$ and the dual of the ad operator is given by $ad^*_\xi\,\Pi = \Pi\times\xi$, where $\Pi\in so(3)^*\simeq\mathcal{R}^3$.

From (2.11)–(2.12), a simple mechanical control system on $SO(3)$ takes the form

$$\dot{R} = R\hat{\zeta}, \tag{5.3}$$

$$\dot{\zeta} = I^{-1}\Big(I\zeta\ \times\ \zeta + \tilde{S}(R,\zeta)\Big), \tag{5.4}$$

where $\tilde{S}(R,\zeta) = f^c(R) + f^d(R,\zeta) + \sum_i^m u_i f^i(R)$. The passivity-based damping injection (3.3) takes the form

$$u_i = -\langle f^i(R)\,,\,\zeta\rangle. \tag{5.5}$$

The intrinsic observer (4.5)–(4.6) takes the form

$$\dot{\tilde{R}} = \tilde{R}(\hat{\tilde{\zeta}} - 2\alpha\hat{\zeta_e}), \tag{5.6}$$

$$\dot{\tilde{\zeta}} = I^{-1}\Big(I\tilde{\zeta}\times\tilde{\zeta} - \alpha\,(I\tilde{\zeta}\times\zeta_e + I\zeta_e\times\tilde{\zeta})\Big) + \alpha\zeta_e\times\tilde{\zeta} + \Gamma(S) - R_c(\tilde{\zeta},\zeta_e)\tilde{\zeta} - \beta\zeta_e, \tag{5.7}$$

where ζ_e satisfies $\exp(\zeta_e) = R^T\tilde{R}$ and is given by (5.1) as

$$\zeta_e = \frac{\psi}{2\sin\psi}(R^T\tilde{R} - \tilde{R}^TR), \tag{5.8}$$

where $\cos\psi = (\mathrm{tr}(R^T\tilde{R}) - 1)/2$ for $|\psi| < \pi$. The parallel transport term $\Gamma(S)$ is calculated from (4.7), where $S(R,\zeta) = I^{-1}\tilde{S}(R,\zeta)$, and the curvature term $R_c(\tilde{\zeta},\zeta_e)\tilde{\zeta}$ is calculated from (2.4).

If the potential energy $U(R)$ of the mechanical system is a globally defined smooth Morse function with a unique minimum at the equilibrium configuration $\bar{R}$, then the control (5.5) almost globally stabilizes the equilibrium $(\bar{R},0)$. Furthermore since $SO(3)$ is compact, from Corollary A.2 in the appendix it also follows that (5.5) implemented with the velocity observer also almost globally stabilizes the equilibrium $(\bar{R},0)$ if the initial observer configuration error is sufficiently small.

In the canonical basis the nonzero structure constants C^k_{ij} on $so(3)\simeq\mathcal{R}^3$ are

$$C^3_{12} = 1, \quad C^2_{13} = -1, \quad C^1_{23} = 1.$$

In the special case of axisymmetric rigid bodies, $I = \mathrm{diag}(I_x, I_y, I_z)$. For such examples using (2.2) the nonzero connection coefficients ω^k_{ij} are calculated to be

$$\omega^1_{23} = \frac{I_x - I_y + I_z}{2I_x}, \quad \omega^1_{32} = \frac{-I_x - I_y + I_z}{2I_x}, \quad \omega^2_{13} = \frac{I_x - I_y - I_z}{2I_y},$$

$$\omega^2_{31} = \frac{I_x + I_y - I_z}{2I_y}, \quad \omega^3_{12} = \frac{-I_x + I_y + I_z}{2I_z}, \quad \omega^3_{21} = \frac{-I_x + I_y - I_z}{2I_z}.$$

The nonzero curvature coefficients are too numerous to be listed here.

5.1.1. Angular velocity estimation for the axisymmetric top. In this section we demonstrate the effectiveness of the observer (5.6)–(5.7) by means of simulation. Consider the classical problem of an axisymmetric top in a gravitational field. Let $P = \{P_1, P_2, P_3\}$ be an inertial frame fixed at the fixed point of the top and let $e = \{e_1, e_2, e_3\}$ be a body-fixed orthonormal frame with the origin coinciding with that of P. At $t = 0$, the two frames coincide. Then let the coordinates of a point p in the inertial frame P be given by x and in the body frame, e, let the coordinates of the point p be given by X. They are related by $x(t) = R(t)X$, where $R(t) \in SO(3)$. Let $-P_3$ be the direction of gravity and let I be the inertia matrix of the axisymmetric top about the fixed point. The kinetic energy of the top is $K = I\zeta \cdot \zeta/2$, where ζ is the body angular velocity and the potential energy is $U(R) = mgl\, Re_3 \cdot P_3$. Here m is the mass of the top, g is the gravitational constant, and l is the distance along the e_3 axis to the center of mass. For simplicity we assume the top to be symmetric about the e_3 axis. The generalized potential forces $f^c(R)$ in the body frame will be given by the relation $\langle f^c(R), \zeta\rangle = -\langle dU, R \cdot \zeta\rangle = -mgl\, R\hat{\zeta}e_3 \cdot P_3$ for any $\zeta \in so(3)$, which yields that $f^c(R) = mgl\ R^T P_3 \times e_3$. The metric induced on $SO(3)$ by the kinetic energy is left invariant, and the system is a simple mechanical system on $SO(3)$. Thus the equations of motion on $SO(3) \times so(3)$ are given by (5.3)–(5.4), where $\tilde{S}(R) = mgl\ R^T P_3 \times e_3$. Since it is assumed that the top is symmetric about the e_3 axis, the inertia matrix is diagonal with $I_1 = I_2$, that is, $I = \mathrm{diag}(I_1, I_1, I_3)$.

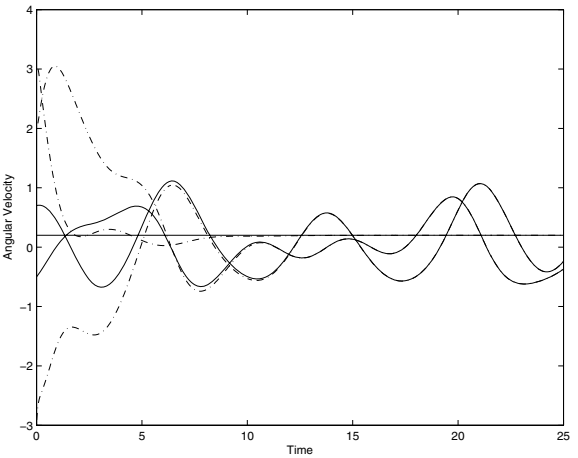

FIG. 5.1. *Angular velocity estimates versus true values in axisymmetric top simulation. The true values are the solid lines while the dotted lines are the estimated values.*

Substituting $I = \mathrm{diag}(1, 1, 2)$ and $S = I^{-1}(R^T P_3 \times e_3)$ in the observer (5.6)–(5.7) with $\alpha = \beta = 10$, we estimate the angular velocities of the axisymmetric top. The simulation results are shown in Figure 5.1. The initial body angular velocities of the axisymmetric top are $[.7\ \ -.5\ \ .2]$, the initial observer angular velocity is $[-3\ \ 2\ \ 3]$, while the initial observer configuration error corresponds to a $\pi/10$ radian rotation about the $P_2 = [0\ \ 1\ \ 0]^T$ axis.

5.2. The special Euclidean motion group $SE(3)$. The special Euclidean motion group $SE(3)$ is the semidirect product $SO(3) \times_s \mathcal{R}^3$. As a matrix group, an

element $A \in SE(3)$ and its inverse A^{-1} can be represented by

$$A = \begin{bmatrix} R & b \\ 0 & 1 \end{bmatrix}, \qquad A^{-1} = \begin{bmatrix} R^T & -R^T b \\ 0 & 1 \end{bmatrix},$$

where $R \in SO(3)$ and $b \in \mathcal{R}^3$.

The Lie algebra of $SE(3)$, denoted by $se(3)$, is the set of matrices

$$\zeta = \begin{bmatrix} \hat{\xi} & v \\ 0 & 0 \end{bmatrix},$$

where $\hat{\xi} \in so(3)$ and $v \in \mathcal{R}^3$. Then $se(3) \simeq \mathcal{R}^3 \times \mathcal{R}^3$ by identifying $\zeta \in se(3)$ with $(\xi\,,\, v) \in \mathcal{R}^3 \times \mathcal{R}^3$.

Let the inner product between the two elements $(\xi, v), (\psi, u) \in se(3)$ on $se(3)$, $\langle\langle \cdot\,,\, \cdot \rangle\rangle_{se(3)}$ be defined as $\langle\langle (\xi, v), (\psi, u) \rangle\rangle_{se(3)} = I_b \xi \cdot \psi + M v \cdot u$, where I_b is a positive definite matrix. This inner product on $se(3)$ defines a left-invariant metric on $SE(3)$ in the usual way. The Lie bracket on $se(3)$ is given by

$$[(\xi\,,\, v), (\psi\,,\, u)]_{se(3)} = ad_{(\xi\,,\, v)}(\psi\,,\, u) = (\xi \times \psi\,,\, \xi \times u - \psi \times v), \tag{5.9}$$

and the dual of the ad operator is given by

$$ad^*_{(\xi\,,\, v)} \begin{bmatrix} \Pi \\ \mu \end{bmatrix} = \begin{bmatrix} \Pi \times \xi + \mu \times v \\ \mu \times \xi \end{bmatrix}, \tag{5.10}$$

where $(\Pi, \mu) \in se(3)^* \simeq \mathcal{R}^3 \times \mathcal{R}^3$.

From (2.11)–(2.12), a simple mechanical control system on $SE(3)$ takes the form

$$\begin{bmatrix} \dot{R} & \dot{b} \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} R & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \hat{\xi} & v \\ 0 & 0 \end{bmatrix} \tag{5.11}$$

$$\begin{bmatrix} \dot{\xi} \\ \dot{v} \end{bmatrix} = I^{-1} \left(\begin{bmatrix} I_b \xi \times \xi \\ M v \times \xi \end{bmatrix} + \tilde{S}(R, b, \xi, v) \right), \tag{5.12}$$

where $\tilde{S}(R, b, \xi, v) = f^c(R, b) + f^d(R, b, \xi, v) + \sum_i^m u_i f^i(R, b)$.

The passivating control (3.3) takes the form

$$u_i = -\langle f^i(R, b)\,,\, (\xi, v) \rangle. \tag{5.13}$$

The intrinsic observer (4.5)–(4.6) takes the form

$$\begin{bmatrix} \dot{\tilde{R}} & \dot{\tilde{b}} \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} \tilde{R} & \tilde{b} \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \hat{\tilde{\xi}} - 2\alpha\, \hat{\xi}_e & \tilde{v} - 2\alpha\, v_e \\ 0 & 0 \end{bmatrix} \tag{5.14}$$

$$\begin{bmatrix} \dot{\tilde{\xi}} \\ \dot{\tilde{v}} \end{bmatrix} = \begin{bmatrix} I_b^{-1} \left(I_b \tilde{\xi} \times \tilde{\xi} - \alpha (I_b \tilde{\xi} \times \xi_e + I_b \xi_e \times \tilde{\xi}) \right) + \alpha\, \xi_e \times \tilde{\xi} \\ \tilde{v} \times \tilde{\xi} - 2\alpha\, \tilde{v} \times \xi_e \end{bmatrix}$$

$$+ \Gamma(S) - R_c(\tilde{\zeta}, \zeta_e)\tilde{\zeta} - \beta \zeta_e, \tag{5.15}$$

where $\zeta_e = (\Omega_e, V_e)$ satisfies $\exp(\zeta_e) = A^{-1}\tilde{A}$ and is explicitly given by

$$\Omega_e = \frac{\psi}{2\sin\psi}(R^T\tilde{R} - \tilde{R}^T R), \tag{5.16}$$

$$V_e = W^{-1}(R^T\tilde{b} - \tilde{R}^T b), \tag{5.17}$$

where $\cos\psi = (\mathrm{tr}(R^T\tilde{R}) - 1)/2$ for $|\psi| < \pi$ [29] and

$$W = I_{3\times 3} + \frac{(1-\cos\psi)}{\psi^2}\Omega_e + \frac{(\psi - \sin\psi)}{\psi^3}\Omega_e^2.$$

The parallel transport term $\Gamma(S)$ is calculated from (4.7), where $S(R, b, \xi, v) = I^{-1}\tilde{S}(R, b, \xi, v)$, and the curvature term $R_c(\tilde{\zeta}, \zeta_e)\tilde{\zeta}$ is calculated from (2.4). In the canonical basis the nonzero structure constants C_{ij}^k on $se(3) \simeq \mathcal{R}^6$ are

$$\begin{aligned} &C_{12}^3 = 1, \quad C_{13}^2 = -1, \quad C_{15}^6 = 1, \quad C_{16}^5 = -1, \quad C_{23}^1 = 1, \\ &C_{24}^6 = -1, \quad C_{26}^4 = 1, \quad C_{34}^5 = 1, \quad C_{35}^4 = -1. \end{aligned}$$

In the case where $I_b = \mathrm{diag}(I_x, I_y, I_z)$ and M is a positive scalar, using (2.2) the nonzero connection coefficients ω_{ij}^k are shown to be

$$\begin{aligned} &\omega_{23}^1 = \frac{I_x - I_y + I_z}{2I_x}, \quad \omega_{32}^1 = \frac{-I_x - I_y + I_z}{2I_x}, \quad \omega_{13}^2 = \frac{I_x - I_y - I_z}{2I_y}, \\ &\omega_{31}^2 = \frac{I_x + I_y - I_z}{2I_y}, \quad \omega_{12}^3 = \frac{-I_x + I_y + I_z}{2I_z}, \quad \omega_{21}^3 = \frac{-I_x + I_y - I_z}{2I_z}, \\ &\omega_{15}^6 = \omega_{26}^4 = \omega_{34}^5 = 1, \quad \omega_{16}^5 = \omega_{24}^6 = \omega_{35}^4 = -1. \end{aligned}$$

The coefficients of the curvature tensor R_{jab}^k can be calculated using (2.3).

5.2.1. Stabilization of an electrostatically actuated six-degrees-of-freedom micromirror. In this section, our observer-based stabilization approach is applied to an electrostatically actuated MEMS. An intrinsic and geometric model of a six-degrees-of-freedom, electrostatically actuated micromirror is developed in [25]. Such devices may be used as steerable micromirrors, for example, to guide an optical beam into one of a number of output fiberoptics or to simultaneously correct the phase and amplitude of an optical signal. For further physical motivation and applications the reader is referred to [25, 27] and the references therein. The device consists of a fixed bottom plate and a rigid top plate. The top plate is free to rotate and translate, subject to the constraint that each side is connected to a support structure through flexible cantilevers. The bottom plate is segmented into four drive electrodes. The system is actuated by a voltage difference between each electrode and the grounded top plate. Figure 5.2 is a schematic of the movable top plate. The points q_i denote the locations at which the external spring and damping forces act on the system.

The device is modeled as a mechanical subsystem coupled to an electrical subsystem via the electrostatic actuation forces. The configuration space of the mechanical system is the group of three-dimensional Euclidean motions represented by $SE(3)$. Let $e = (e_1, e_2, e_3)$ be a body-fixed orthonormal coordinate frame centered at the center of mass of the top plate, and let $P = (P_1, P_2, P_3)$ be an inertially fixed orthonormal coordinate frame coinciding with e when the system is in equilibrium with no actuation. At a given time t the orientation of the top plate with respect to the inertial frame is given by $R(t)$, while the displacement of the center of mass of the top

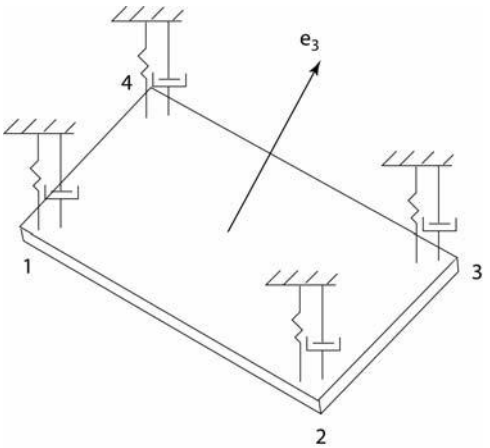

FIG. 5.2. *Schematic diagram of a rigid three-dimensional microactuator.*

plate with respect to the inertial frame is given by $b(t)$. The body angular velocity of the top plate is denoted by $\xi(t)$. The velocity of the center of mass of the top plate in the inertial coordinates is denoted by $\dot{b} = R(t)v(t)$, where $v(t)$ is the velocity of the center of mass in the body frame. The nonactuated equilibrium gap between the center of mass of the top plate and the bottom plate is d. The resistance in the pth capacitor circuit is r_p. The permittivity of the dielectric medium between the electrodes is ϵ. The electrode areas are each assumed to be equal, and denoted A. The charge stored in the pth capacitor is Q_p. The voltage control supplied to the pth capacitor is u_p. The position vector in the body-fixed coordinates of the ith point is q_i. The inertia matrix of the top plate is denoted by I. The total mass of the top plate is m.

The spring forces exerted by the cantilever beams are assumed to be linear in the absolute displacement. This assumption implies that the spring forces $F_p^C(R, b)$ are given by

$$\begin{bmatrix} F_i^C(R,b) \\ 0 \end{bmatrix} = - \begin{bmatrix} K_i & 0 \\ 0 & 0 \end{bmatrix} \left(\begin{bmatrix} R & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} q_i \\ 1 \end{bmatrix} - \begin{bmatrix} q_i \\ 1 \end{bmatrix} \right).$$

The structural dissipative forces $F_i^D(R, b, \xi, v)$ of the system are assumed to be of Rayleigh type and are given by

$$\begin{bmatrix} F_i^D(R,b,\xi,v) \\ 0 \end{bmatrix} = - \begin{bmatrix} C_i & 0 \\ 0 & 0 \end{bmatrix} \left(\begin{bmatrix} R & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \hat{\xi} & v \\ 0 & 0 \end{bmatrix} \begin{bmatrix} q_i \\ 1 \end{bmatrix} \right).$$

The 3×3 matrices K_i and C_i are positive semidefinite. Computing the torques about the center of mass of the movable electrode in the body coordinates, the generalized body forces due to the stiffness and structural damping of the cantilever are expressed by

$$f_i^c = \begin{bmatrix} \hat{q}_i R^T F_i^c \\ R^T F_i^C \end{bmatrix}, \quad f_i^d = \begin{bmatrix} \hat{q}_i R^T F_i^D \\ R^T F_i^D \end{bmatrix}.$$

Neglecting parasitics, allowing fringing, but assuming that the electrostatic field generated by each individual electrode does not interact with the others (these are standard

assumptions in the modeling of multielectrode electrostatic devices [19]), the generalized body electrostatic forces are given by $BW(Q)$, where $Q = [Q_1 \;\; Q_2 \;\; Q_3 \;\; Q_4]^T$,

$$W(Q) = \begin{bmatrix} w_1 \\ w_2 \\ w_3 \end{bmatrix} = \frac{1}{4\epsilon A} \begin{bmatrix} 1 & -1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ -1 & -1 & -1 & -1 \end{bmatrix} \begin{bmatrix} Q_1^2 \\ Q_2^2 \\ Q_3^2 \\ Q_4^2 \end{bmatrix},$$

$$B = \begin{bmatrix} -l_y\, e_1 & -l_x\, e_2 & 0 \\ 0 & 0 & 2e_3 \end{bmatrix}.$$

Using these generalized forces, in [25] the governing equation of the MEMS is shown to be

$$\dot{Q}_p = -\frac{1}{r_p}\left(V_{d_p} - u_p\right) \quad \text{for } p = 1, 2, 3, 4, \tag{5.18}$$

$$\begin{bmatrix} \dot{R} & \dot{b} \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} R & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \hat{\xi} & v \\ 0 & 0 \end{bmatrix} \tag{5.19}$$

$$\begin{bmatrix} \dot{\xi} \\ \dot{v} \end{bmatrix} = I^{-1}\left(\begin{bmatrix} I_b\xi \times \xi \\ Mv \times \xi \end{bmatrix} + \sum_{i=1}^{4} f_i^c(R, b) + \sum_{i=1}^{4} f_i^d(R, b, \xi, v) + B\; w(Q) \right), \tag{5.20}$$

$$y_{m_p} = V_{d_p} \quad \text{for } p = 1, 2, 3, 4, \tag{5.21}$$

$$y_p = Q_p \quad \text{for } p = 1, 2, 3, 4, \tag{5.22}$$

where g, y_{m_p}, and y_p are the measured outputs. The system has relative degree $\{1, 1, 1, 1\}$ with respect to the output $y = Q$, and stable zero dynamics.

For a given $\bar{Q}$, the corresponding equilibrium points of (5.19)–(5.20) are given by $\bar{\xi} = 0$, $\bar{v} = 0$, and

$$0 = \sum_{i=1}^{4} f_i^c(\bar{R}, \bar{b}) + Bw(\bar{Q}). \tag{5.23}$$

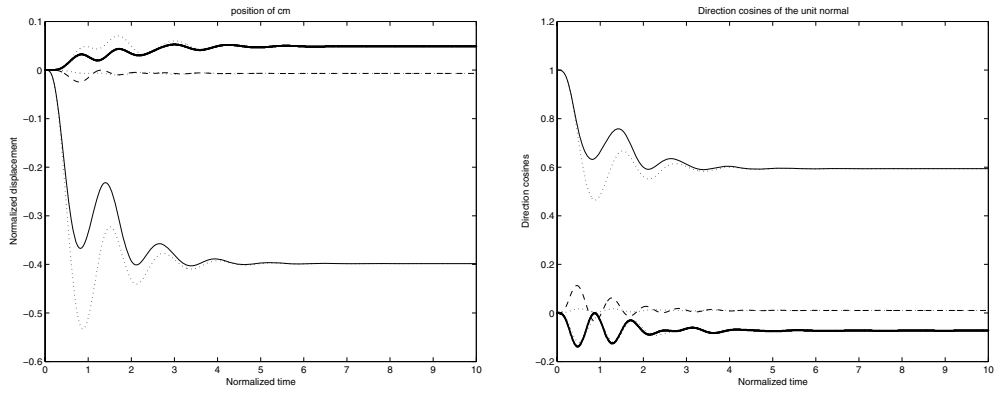
Using the results of section 3.2 it can be shown that the feedback law

$$u = \begin{bmatrix} V_{d_1} \\ V_{d_2} \\ V_{d_3} \\ V_{d_4} \end{bmatrix} + \begin{bmatrix} r_1(l_y\xi_1 - l_x\xi_2 + 2v_3)(Q_1 + \bar{Q}_1)/4\epsilon A \\ r_2(-l_y\xi_1 - l_x\xi_2 + 2v_3)(Q_2 + \bar{Q}_2)/4\epsilon A \\ r_3(-l_y\xi_1 + l_x\xi_2 + 2v_3)(Q_3 + \bar{Q}_3)/4\epsilon A \\ r_4(l_y\xi_1 + l_x\xi_2 + 2v_3)(Q_4 + \bar{Q}_4)/4\epsilon A \end{bmatrix} - \alpha \begin{bmatrix} r_1(Q_1 - \bar{Q}_1) \\ r_2(Q_2 - \bar{Q}_2) \\ r_4(Q_3 - \bar{Q}_3) \\ r_4(Q_4 - \bar{Q}_4) \end{bmatrix} \tag{5.24}$$

with $\alpha > 0$ locally asymptotically stabilizes the corresponding given equilibrium $(0, \bar{Q}, \bar{R}, \bar{b}, 0, 0)$.

The control (5.24) involves angular and linear velocity measurements. Making these measurements in situ on the MEMS is infeasible. Thus assuming that the configuration variables (R, b) are available for measurement (see [25] for a discussion of how to do this), we estimate the angular and linear velocities of the mirror in the body frame using the intrinsic observer of section 5.2, where now $S(R, b, \xi, v) = I^{-1}(\sum_{i=1}^{4} f_i^c(R, b) + \sum_{i=1}^{4} f_i^d(R, b, \xi, v) + B\; w(Q))$. MATLAB simulation results are shown in Figure 5.3. For comparison purposes the performance of both the full state-feedback controller and the dynamic output feedback controller are plotted on the

same figures for identical initial conditions of the MEMS. In the case of the dynamic output feedback control the initial observer configuration error corresponds to a $\pi/10$ rotation about the [1 1 0] axis and a translation of [3 3 3]. The initial body angular velocity error is [9 12 -9] and the initial velocity error of the center of mass in the body coordinates is [6 9 -3].



(a) Center of Mass (b) Direction Cosines

FIG. 5.3. *The position of the center of mass and the direction cosines of the unit normals of the movable electrode versus time. In the case of dynamic output feedback the thin solid curve corresponds to the P_3 direction, the thick solid curve corresponds to the P_1 direction, and the dashed curve corresponds to the P_2 direction. The dotted curves correspond to full state feedback.*

6. Conclusion. We present an intrinsic observer-based approach to the stabilization of a class of simple mechanical control systems on a Lie group. Specifically, we consider systems with left-invariant kinetic energy and a measured configuration variable. The result is obtained by specializing two general formulations on arbitrary Riemannian manifolds, namely, passivity-based control and intrinsic velocity estimation. This specialization is noteworthy because it results in drastically simplified explicit expressions for the controller that can be readily applied once the kinetic energy tensor and the external forces are specified. The observer is explicitly computed for two special cases of particular importance, namely, the rotation group $SO(3)$ and the Euclidean motion group $SE(3)$. The expressions given in those sections may be applied to the many problems of practical significance arising from rigid body motion by specializing only the inertia tensor and the external forces. Here the results are applied to estimation of the velocities of the axisymmetric top and to the stabilization of an electrostatically actuated MEMS model. Simulations show excellent performance.

Appendix.

A.1. First variation equations of the observer. If a separation principle is to hold in the presence of velocity-dependent control, then the observer must converge even when velocity terms are allowed in the external forces. Following [2] we first construct the first variation of the observer and then use contraction analysis to prove local exponential convergence of the observer. In what follows we show that including such velocity terms in S does not change the first variation equations obtained in [2]. Thus the contraction analysis of [2] holds without modification, and the observer converges when $S = S(q, v)$.

Consider the simple mechanical system on a Riemannian manifold $(M, \langle\langle \cdot, \cdot \rangle\rangle)$ given by

$$\dot{q} = v, \tag{A.1}$$

$$\nabla_{\dot{q}}\, v = S(q, v), \tag{A.2}$$

and the observer

$$\dot{\tilde{q}} = X(\tilde{q}, \tilde{v}) \;=\; \tilde{v} - \alpha \operatorname{grad} F(\tilde{q}), \tag{A.3}$$

$$\nabla_{\dot{\tilde{q}}}\, \tilde{v} = Y(\tilde{q}, \tilde{v}) \;=\; \Gamma(S(q, \tilde{v})) - R(\tilde{v}, \operatorname{grad} F(\tilde{q}))\tilde{v} - \beta \operatorname{grad} F(\tilde{q}), \tag{A.4}$$

where $R(\cdot, \cdot)\cdot$ is the curvature and $\Gamma(S(q, \tilde{v}))$ is the parallel transport of the external forces $S(q, \tilde{v})$ to $\tilde{q}$ along the unique geodesic joining q to $\tilde{q}$ (for q and $\tilde{q}$ sufficiently close). Observe that in the parallel transport term of $\Gamma(S(q, \tilde{v}))$ we use $\tilde{v}$ instead of v.

Let $(q(t), v(t))$ be a solution of (A.3)–(A.4) with initial condition (q_0, v_0) and $(\tilde{q}(t), \tilde{v}(t))$ be a solution of (A.3)–(A.4) with initial conditions $(\tilde{q}(0), \tilde{v}(0)) \neq (q_0, v_0)$. Let $s \mapsto \gamma(s) \in M$ be a smooth curve on M such that $\gamma(0) = q_0$ and $\gamma(1) = \tilde{q}_0$ and let $s \mapsto \tau(s) \in T_{\gamma(s)}M$ be a smooth vector field defined along $\gamma(s)$ such that $\tau(0) = v_0$ and $\tau(1) = \tilde{v}_0$. Let $(\tilde{q}(s, t), \tilde{v}(s, t))$ be a solution of (A.3)–(A.4) with initial conditions $(\gamma(s), \tau(s))$. Define

$$\frac{\partial \tilde{q}}{\partial s}(s, t) = J_q(s, t) \in T_{\tilde{q}(s,t)}M, \tag{A.5}$$

$$\frac{\partial \tilde{v}}{\partial s}(s, t) = \nabla_{J_q} \tilde{v} = J_v(s, t) \in T_{\tilde{q}(s,t)}M. \tag{A.6}$$

In coordinates these equations correspond exactly to those given by (6) in [2]. By construction it follows that $[J_q, \dot{\tilde{q}}] = 0$ and thus the first variation of (A.3)–(A.4) can be intrinsically computed as follows:

$$\frac{\partial \dot{\tilde{q}}}{\partial s} = \nabla_{J_q} \dot{\tilde{q}} = \nabla_{\dot{\tilde{q}}} J_q = \nabla_{J_q} X, \tag{A.7}$$

$$\frac{\partial \nabla_{\dot{\tilde{q}}}\, \tilde{v}}{\partial s} = \nabla_{J_q} \nabla_{\dot{\tilde{q}}}\, \tilde{v} = \nabla_{\dot{\tilde{q}}} \nabla_{J_q}\, \tilde{v} + R(J_q, \dot{\tilde{q}})\tilde{v} = \nabla_{J_q} Y, \tag{A.8}$$

where the second equality in (A.7) follows from $[J_q, \dot{\tilde{q}}] = 0$ and the second equality in (A.8) follows from

$$\nabla_{J_q} \nabla_{\dot{\tilde{q}}}\, \tilde{v} - \nabla_{\dot{\tilde{q}}} \nabla_{J_q}\, \tilde{v} = R(J_q, \dot{\tilde{q}})\tilde{v}.$$

Thus from (A.6), (A.7), and (A.8) we have the first variation equations of (A.3)–(A.4) as

$$\nabla_{\dot{\tilde{q}}} J_q = \nabla_{J_q} X, \tag{A.9}$$

$$\nabla_{\dot{\tilde{q}}} J_v = -R(J_q, \dot{\tilde{q}})\tilde{v} + \nabla_{J_q} Y. \tag{A.10}$$

When $X(\tilde{q}, \tilde{v}) = \tilde{v}$ and $Y(\tilde{q}, \tilde{v}) = 0$ we recover Jacobi's equation of geodesic variation $\nabla^2_{\dot{\tilde{q}}} J_q = -R(J_q, \tilde{v})\tilde{v}$.

Substituting for X and Y from (A.3)–(A.4) in (A.9) and (A.10) we have

$$\nabla_{\dot{\tilde{q}}} J_q = J_v - \alpha \nabla_{J_q} \text{grad}\, F, \tag{A.11}$$

$$\nabla_{\dot{\tilde{q}}} J_v = -R(J_q, \dot{\tilde{q}})\tilde{v} + \nabla_{J_q}\Gamma - \beta \nabla_{J_q} \text{grad}\, F - \nabla_{J_q} R(\tilde{v}, \text{grad}\, F(\tilde{q}))\tilde{v}. \tag{A.12}$$

From [35]

$$\begin{aligned}\nabla_{J_q} R(\tilde{v}, \text{grad}\, F(\tilde{q}))\tilde{v} = (\nabla_{J_q} R)\left((\tilde{v}, \text{grad}\, F(\tilde{q}))\tilde{v}\right) + R(\nabla_{J_q}\tilde{v}, \text{grad}\, F(\tilde{q}))\tilde{v} \\ + R(\tilde{v}, \nabla_{J_q} \text{grad}\, F(\tilde{q}))\tilde{v} + R(\tilde{v}, \text{grad}\, F(\tilde{q}))\nabla_{J_q}\tilde{v}.\end{aligned}$$

Then the first variation equations of the observer (A.3)–(A.4) are

$$\nabla_{\dot{\tilde{q}}} J_q = J_v - \alpha \nabla_{J_q} \text{grad}\, F, \tag{A.13}$$

$$\begin{aligned}\nabla_{\dot{\tilde{q}}} J_v = &-R(J_q, \dot{\tilde{q}})\tilde{v} + \nabla_{J_q}\Gamma - \beta \nabla_{J_q} \text{grad}\, F \\ &-(\nabla_{J_q} R)\left((\tilde{v}, \text{grad}\, F(\tilde{q}))\tilde{v}\right) - R(\nabla_{J_q}\tilde{v}, \text{grad}\, F(\tilde{q}))\tilde{v} \\ &-R(\tilde{v}, \nabla_{J_q} \text{grad}\, F(\tilde{q}))\tilde{v} - R(\tilde{v}, \text{grad}\, F(\tilde{q}))\nabla_{J_q}\tilde{v}.\end{aligned} \tag{A.14}$$

These equations correspond exactly with (9) of [2]. Note our curvature convention follows [20, 21, 35] which results in a sign difference from [2].

When $\tilde{q}$ and q are sufficiently close (i.e., up to second order)

$$\text{grad}\, F = 0, \quad \nabla_{J_q} \text{grad}\, F = J_q, \quad \nabla_{J_q}\Gamma(S(q, \tilde{v})) = 0.$$

Thus for sufficiently close $\tilde{q}$ and q the first variation equations reduce to

$$\nabla_{\dot{\tilde{q}}} J_q = J_v - \alpha J_q, \tag{A.15}$$

$$\nabla_{\dot{\tilde{q}}} J_v = -\beta J_q. \tag{A.16}$$

These equations correspond exactly with equation (10) of [2].

A.2. Separation principle. The following lemma proved in [28] provides the basis for a separation principle when the Lie group G is compact. Consider the system

$$\dot{g} = g \cdot \zeta, \tag{A.17}$$

$$\dot{\zeta} = I^{-1}\left(ad^*_\zeta \tilde{I}\zeta + f(g, \zeta)\right) + \psi(g, \zeta, q), \tag{A.18}$$

with $(g, \zeta) \in G \times \mathcal{G}$ and $q \in \mathcal{R}^n$ and $V = U(g) + \frac{1}{2}\langle\langle \zeta, \zeta \rangle\rangle_{\mathcal{G}}$, where $U(g)$ is a smooth globally defined Morse function and is the potential energy of the system. Also consider the following assumptions.

Assumption A.1. *The point* $(\bar{g}, 0)$ *is an almost globally stable equilibrium of* (A.17)–(A.18) *with* $\psi \equiv 0$ *and furthermore* $\langle\langle g^{-1}\text{grad}\, U, \zeta\rangle\rangle_{\mathcal{G}} + \langle\langle I^{-1} f, \zeta\rangle\rangle_{\mathcal{G}} \leq 0$.

The condition $\langle\langle g^{-1}\text{grad}\, U, \zeta\rangle\rangle_{\mathcal{G}} + \langle\langle I^{-1} f, \zeta\rangle\rangle_{\mathcal{G}} \leq 0$ is satisfied by any simple mechanical system with potential energy $U(g)$ and Rayleigh-type dissipation. The equilibrium $(\bar{g}, 0)$ is an almost globally stable equilibrium if $\bar{g}$ is a unique minimum of $U(g)$.

Assumption A.2. *The function* $q(t) \in \mathcal{R}^n$ *satisfies*

$$||q(t)|| \leq c||q(0)||e^{-\lambda t} \tag{A.19}$$

for some $c > 0, \lambda > 0$, *and all* $t > 0$.

ASSUMPTION A.3. *The interconnection term satisfies* $\psi(g,\zeta,0)\equiv 0$ *and the linear growth conditions*

$$||\psi|| \le \gamma_1(||q||)||\zeta|| + \gamma_2(||q||) \tag{A.20}$$

for two class $\mathcal{K}_\infty$ *functions* $\gamma_1(\cdot),\gamma_2(\cdot)$.

LEMMA A.1. *If the Lie group* G *is compact and if Assumptions* A.1–A.3 *are satisfied, then the equilibrium* $(\bar{g},0)$ *of the system* (A.17)–(A.18) *is almost globally stable. Convergence is asymptotic if the inequality in Assumption* A.1 *is strict.*

COROLLARY A.2. *For a compact Lie group* G *if the state-feedback control* (3.3) *almost globally stabilizes* $(\bar{g},0)$*, then the dynamic output feedback control* (4.8) *almost globally stabilizes* $(\bar{g},0)$*. Convergence is asymptotic if the control* (3.3) *ensures asymptotic convergence.*

Proof of Corollary A.2. Define the observation error of the velocities by $\zeta_{oe} := \tilde{\zeta} - \zeta$. From Theorem 1 of [2] we have that for sufficiently small initial observer configuration error,

$$(d(g(t),\tilde{g}(t)) + ||\zeta_{oe}(t)||_{\mathcal{G}}) < (d(g(0),\tilde{g}(0)) + ||\zeta_{oe}(0)||_{\mathcal{G}})\, e^{-\lambda t} \tag{A.21}$$

for some $\lambda > 0$. From (A.21) it follows that for nonzero initial velocity error,

$$||\zeta_{oe}(t)||_{\mathcal{G}} < c\,||\zeta_{oe}(0)||_{\mathcal{G}}\; e^{-\lambda t} \tag{A.22}$$

for some $c > 0$.

Substituting $\tilde{\zeta} = \zeta + \zeta_{oe}$ in the controls (4.8) we obtain a simple mechanical system in the form of (A.17)–(A.18), where the interconnection term $\psi(g,\zeta,\zeta_{oe}) = B(g)B(g)^T\zeta_{oe}$ with $B(g) = [f^1(g)\, f^2(g)\, \cdots\, f^m(g)]$. If the potential energy $U(g)$ of the system is a globally defined smooth Morse function with a unique minimum at $\bar{g}$ and the damping injection $u = -B^T\zeta$ almost globally stabilizes the equilibrium $(\bar{g},0)$, then it can be verified that Assumption A.1 is satisfied. From (A.22) Assumption A.2 is satisfied. Since $\psi(g,\zeta,\zeta_{oe}) = B(g)B(g)^T\zeta_{oe}$, if G is compact, it can be easily verified that Assumption A.3 is satisfied. Thus from Lemma A.1 the dynamic feedback control (4.8) almost globally stabilizes the equilibrium $(\bar{g},0)$ provided that the initial observer configuration error is sufficiently small. Convergence is asymptotic if the inequality in Assumption A.1 is strict. This is guaranteed if (3.3) ensures asymptotic convergence.

EXPONENTIAL STABILITY OF NONLINEAR SINGULARLY PERTURBED DIFFERENTIAL EQUATIONS*

G. GRAMMEL†

Abstract. Nonlinear singularly perturbed differential equations with two natural time scales are under consideration. It is shown that the exponential stability of both the boundary layer systems and the reduced system imply the exponential stability of the fully coupled system for small perturbation parameters. The asymptotic behavior of gain and decay rates is investigated. Moreover, it turns out that the achieved exponential stability is robust with respect to multivalued regular perturbations and small delays. The method of proof does not rely on (converse) Lyapunov theorems but on an appropriate version of Tychonov's theorem and manages without the smoothness of the vector fields involved.

Key words. exponential stability, singular perturbations, nonlinear differential equations with delays

AMS subject classifications. 34E15, 34D15, 34A60, 34K20

DOI. 10.1137/040614591

1. Introduction.

On $\mathbb{R}^n \times \mathbb{R}^m$, we consider the singularly perturbed differential equation

$$\begin{aligned} \dot{x}_\epsilon(t) &= f(x_\epsilon(t), y_\epsilon(t)), \quad x_\epsilon(0) = x^0, \\ \epsilon\, \dot{y}_\epsilon(t) &= g(x_\epsilon(t), y_\epsilon(t)), \quad y_\epsilon(0) = y^0, t \geq 0, \end{aligned} \tag{1}$$

where $\epsilon > 0$ is a small perturbation parameter reflecting the presence of two natural time scales. An important aim in singular perturbation theory is the decomposition of the coupled system into two unperturbed subsystems and to draw conclusions from certain properties of the unperturbed subsystems. In connection with exponential stability properties, this decomposition method works very well. The following fact on finite-dimensional smooth systems is well known; see [10, section 7, Corollary 2.3]. If both the unperturbed fast (boundary layer) systems and the unperturbed slow (reduced) system are exponentially stable with uniform gain and decay rates, then the singularly perturbed system is exponentially stable as well, at least for sufficiently small perturbation parameters. Suitable upper bounds for the perturbation parameter are obtained in [14]. In [4] the asymptotic behavior of the decay rates is investigated. All these works mentioned rely on a sophisticated Lyapunov theory, involving appropriate (converse) Lyapunov theorems. Consequently, the results are presented in a smooth, finite-dimensional ODE framework.

A different approach using the approximating properties of an averaged slow limit system has been presented in [2], where under mild regularity conditions the (near) asymptotic stability of the slow subsystem is investigated. In [7, 8] a similar method has been applied in order to characterize the exponential stability of (multivalued) differential equations with a fast time variable. Here, the method of proof is based on a suitable time discretization along with a computation of the distance between the

†Center for Mathematics, M6, Technical University Munich, Boltzmann St. 3, 85747 Garching, Germany (grammel@ma.tum.de).

perturbed and the unperturbed trajectories. The present paper aims at an adaption of this method to the coupled singularly perturbed system (1). The method provides several features listed below.

- The regularity of the vector fields involved is reduced to Lipschitz continuity.
- Estimates for both gain and decay rates are obtained.
- The results can be extended to differential equations in Banach spaces.
- Multivalued regular perturbations are taken into account.
- Small delays are considered.

The paper is organized as follows. In section 2 we present the setting and the main result, Theorem 2.5. This result is compared to the present literature on related problems. A version of Tychonov's theorem (see [15] or [3]) on the approximation of singularly perturbed differential equations along with important tools for the proof of Theorem 2.5 are provided in section 3. The proof of Theorem 2.5 is carried out in section 4. In section 5 an application to small delays is worked out in detail.

2. Setting and main result.

Assumption 2.1 (regularity). The mappings $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ and $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^m$ are Lipschitz continuous with constant $L \geq 0$. Moreover, the origin $(0,0) \in \mathbb{R}^n \times \mathbb{R}^m$ is an equilibrium point of (f,g), i.e., $f(0,0) = 0$ and $g(0,0) = 0$.

The decomposition of the singularly perturbed differential equation (1) into two unperturbed subsystems works as follows. Introducing the new time variable $s := \epsilon t$, the dynamic equations of (1) become

$$\begin{aligned} \dot{x}_\epsilon(s) &= \epsilon\, f(x_\epsilon(s), y_\epsilon(s)), \\ \dot{y}_\epsilon(s) &= g(x_\epsilon(s), y_\epsilon(s)), \quad s \geq 0. \end{aligned} \tag{2}$$

Setting $\epsilon = 0$ yields the so-called boundary layer systems, where the slow state $x \in \mathbb{R}^n$ is fixed.

Assumption 2.2 (exponential stability of the boundary layer systems). The boundary layer systems

$$\dot{y}_x(s) = g(x, y_x(s)), \quad y_x(0) = y^0, \quad s \geq 0,$$

are exponentially stable. In particular, there are constants $D \geq 1$, $\beta > 0$ such that for any $x \in \mathbb{R}^n$ there is a $\phi(x) \in \mathbb{R}^m$ with

$$\|y_x(s) - \phi(x)\| \leq De^{-\beta s}\|y^0 - \phi(x)\|$$

for all $s \geq 0$ and $y^0 \in \mathbb{R}^m$.

The graph of the mapping $\phi : \mathbb{R}^n \to \mathbb{R}^m$ defines the so-called equilibrium manifold in $\mathbb{R}^n \times \mathbb{R}^m$, whose regularity is investigated in the next section. Plugging for each $x \in \mathbb{R}^n$ the corresponding equilibrium $\phi(x) \in \mathbb{R}^m$ into the dynamic equations for the slow variable in (1) yields the so-called reduced system, which defines an approximating limit system for the x-trajectories, as $\epsilon \to 0$; see Theorem 3.5.

Assumption 2.3 (exponential stability of the reduced system). The reduced system

$$\dot{x}_0(t) = f(x_0(t), \phi(x_0(t))), \quad x_0(0) = x^0, \quad t \geq 0,$$

is exponentially stable. In particular, there are constants $C \geq 1$, $\alpha > 0$ such that

$$\|x_0(t)\| \leq Ce^{-\alpha t}\|x^0\|$$

for all $t \geq 0$ and $x^0 \in \mathbb{R}^n$.

These assumptions guarantee the exponential stability not only of the singularly perturbed differential equation (1) but also of a particular multivalued inflation of (1).

DEFINITION 2.4 (multivalued perturbation). *For a nondecreasing continuous function $\kappa : [0, \infty) \to [0, \infty)$ with $\kappa(0) = 0$ we define the multivalued perturbed vector fields*

$$F(x, y, \epsilon) := f(x, y) + \kappa(\epsilon)(\|x\| + \|y - \phi(x)\|)\mathbf{B}_{\mathbb{R}^n},$$

$$G(x, y, \epsilon) := g(x, y) + \kappa(\epsilon)(\|x\| + \|y - \phi(x)\|)\mathbf{B}_{\mathbb{R}^m},$$

where $\mathbf{B}_{\mathbb{R}^n}$ (respectively, $\mathbf{B}_{\mathbb{R}^m}$) denotes the closed unit ball of $\mathbb{R}^n$ (respectively, $\mathbb{R}^m$).

The multivalued perturbed vector fields produce a singularly perturbed differential inclusion

$$\begin{aligned} \dot{x}_\epsilon(t) &\in F(x_\epsilon(t), y_\epsilon(t), \epsilon), \quad x_\epsilon(0) = x^0, \\ \epsilon\, \dot{y}_\epsilon(t) &\in G(x_\epsilon(t), y_\epsilon(t), \epsilon), \qquad y_\epsilon(0) = y^0, \quad t \geq 0, \end{aligned} \tag{3}$$

which can be considered as a multivalued inflation of (1). We are now in a position to formulate the main result on the uniform exponential stability of nonlinear singularly perturbed systems.

THEOREM 2.5. *Let Assumptions 2.1, 2.2, and 2.3 be effective. There is a constant $E > 0$ such that for any $\delta > 0$ there is an $\epsilon_\delta > 0$ such that for any solution to (3) we can estimate*

$$\begin{aligned} \|x_\epsilon(t)\| &\leq (C + \delta)e^{-(\alpha-\delta)t}\|x^0\| + \epsilon E e^{-(\alpha-\delta)t}\|y^0 - \phi(x^0)\|, \\ \|y_\epsilon(t) - \phi(x_\epsilon(t))\| &\leq (D + \delta)e^{-(\beta-\delta)\frac{t}{\epsilon}}\|y^0 - \phi(x^0)\| + \epsilon E e^{-(\alpha-\delta)t}\|x^0\| \\ &\quad + \epsilon^2 E e^{-(\alpha-\delta)t}\|y^0 - \phi(x^0)\| \end{aligned}$$

for all initial values $x^0 \in \mathbb{R}^n$, $y^0 \in \mathbb{R}^m$, all times $t \geq 0$, and all perturbation parameters $\epsilon \in (0, \epsilon_\delta]$.

Note that the gain and decay of the leading terms in the estimations above approximate the exponential characteristics of the reduced system and the boundary layer systems. Surprisingly, the higher order terms are linear and quadratic, despite the fact that the order of the multivalued regular perturbation, determined by $\kappa(\epsilon)$, might be arbitrary.

What follows is a short discussion on related results. First, it is mentionable that in the pioneering work of Tychonov on the approximation of singularly perturbed differential equations (see [15] or also the survey [16] and the references therein) only (uniform) asymptotic stability properties of the fast subsystem are used. Moreover, as elaborated in [13] using Lyapunov's matrix function method, under certain conditions the additional asymptotic stability of the reduced system forces the asymptotical stability of the whole system for sufficiently small perturbation parameters. Related results can be found in [12]. The interest in exponential stability properties, as investigated in [14, 10, 4], seems to originate from the possibility of verifying it via linearization. In the present paper, we focus on additional multivalued perturbations. Hence it is essential to concentrate on exponential stability, since it is well known that mere asymptotic stability is not preserved even under small linearly bounded regular perturbations.

Second, we emphasize that the particular structure of the singularly perturbed differential inclusion (3) is essential in order to prove Theorem 2.5. The main tool, Tychonov's theorem, is valid for multivalued differential equations only under additional suppositions on the fast subsystems that are natural for single-valued differential equations but quite restrictive for multivalued differential equations. The point is that, in general, the reduced system does not produce all slow limit trajectories, as the perturbation parameter tends to zero. In other words, it is difficult to achieve upper semicontinuity at $\epsilon = 0$ of the solution mapping assigning to $\epsilon > 0$ the (slow) solution set to a singularly perturbed differential inclusion and to $\epsilon = 0$ the solution set to the reduced system. In [5] this problem is solved via a restriction to Lipschitz continuous solutions that excludes oscillations of the fast trajectories. Another approach is attempted in [17, 18]. Here, forward invariance and attractivity of a set of fast equilibrium states is assumed in order to achieve upper semicontinuity of the solution mapping. Recently, this idea has been enhanced in [19], where problems on an infinite time horizon are under investigation. However, for singularly perturbed differential inclusions not possessing a particular structure of the fast subinclusion, the use of averaging techniques (see [1] and also [6] for singularly perturbed nonlinear control systems) is indispensable in order to construct a sufficiently rich limit system.

3. Approximation. In this section we prove a version of Tychonov's theorem on the approximating properties of the reduced system, Theorem 3.5. This theorem applies to system (3) on a time interval $t \in [0, T]$, where $T > 0$ can be considered as a discretization step of the slow variable.

We proceed as follows. First, we show the Lipschitz continuity of the equilibrium manifold in order to obtain unique trajectories for the reduced system. Then we present a simple lemma on perturbed linear recursions which is used to obtain estimations for the slow variables on time intervals $[kT, (k+1)T]$ for $k \in \mathbb{N}$.

In what follows we consider the singularly perturbed system (3) in the natural time scale of the fast subsystem on the time interval $s \in \left[0, \frac{T}{\epsilon}\right]$. We introduce a step size of the fast variable, $H > 0$, and show boundedness of the trajectories for $s \in [0, H]$ uniformly in $\epsilon > 0$. An iteration of this result gives bounds for the trajectories on the whole time interval $s \in \left[0, \frac{T}{\epsilon}\right]$. Again, for the iteration the lemma on perturbed linear recursions is needed to show the exponential decay of the fast variables on time intervals $[kH, (k+1)H]$ for $k \in \mathbb{N}$.

3.1. Lipschitz continuity of the equilibrium manifold. The exponential stability of the boundary layer systems forces the Lipschitz continuity of the equilibrium manifold.

LEMMA 3.1. *Let Assumptions* 2.1 *and* 2.2 *be effective. The mapping* $\phi : \mathbb{R}^n \to \mathbb{R}^m$, $x \mapsto \phi(x)$ *is Lipschitz continuous with Lipschitz constant* $K = 2LSe^{LS}$, *where* $S = \log(2D)/\beta$.

Proof. For $x \in \mathbb{R}^n$, we define a mapping $A_x : \mathbb{R}^m \to \mathbb{R}^m$ by $A_x(y^0) = y_x(S)$ (in which $y_x(\cdot)$ is the solution to the corresponding boundary layer system with $y_x(0) = y^0$), where $S \geq 0$ is chosen such that

$$De^{-\beta S} = \frac{1}{2}.$$

For $x_1, x_2 \in \mathbb{R}^n$, using Assumption 2.2, we conclude that

$$\begin{aligned}\|\phi(x_1) - \phi(x_2)\| &= \|A_{x_1}(\phi(x_1)) - A_{x_2}(\phi(x_2))\| \\ &\leq \|A_{x_1}(\phi(x_1)) - A_{x_1}(\phi(x_2))\| + \|A_{x_1}(\phi(x_2)) - A_{x_2}(\phi(x_2))\| \\ &\leq De^{-\beta S}\|\phi(x_1) - \phi(x_2)\| + \|x_1 - x_2\| LSe^{LS}.\end{aligned}$$

We obtain

$$\|\phi(x_1) - \phi(x_2)\| \leq 2\|x_1 - x_2\| LSe^{LS},$$

and the proof is finished. ∎

3.2. Perturbed linear recursions. For two matrices $M, N \in \mathbb{R}^{2\times 2}$ we write $M \leq N$ if $M_{ij} \leq N_{ij}$ for all $1 \leq i, j \leq 2$.

LEMMA 3.2. *Let $a, b, c > 0$ be real constants with $a \neq b$ and $M_\epsilon \in \mathbb{R}^{2\times 2}$ defined by*

$$M_\epsilon := \begin{pmatrix} a + \epsilon c & \epsilon c \\ \epsilon c & b + \epsilon c \end{pmatrix}$$

for any $\epsilon \geq 0$. Then there is an $\epsilon_0 > 0$ such that we can estimate

$$0 \leq M_\epsilon^k \leq \begin{pmatrix} (a+\epsilon 2c)^k + \epsilon^2 (2d)^2 (b+\epsilon 2c)^k & \epsilon 2d(a+\epsilon 2c)^k + \epsilon 2d(b+\epsilon 2c)^k \\ \epsilon 2d(a+\epsilon 2c)^k + \epsilon 2d(b+\epsilon 2c)^k & (b+\epsilon 2c)^k + \epsilon^2 (2d)^2 (a+\epsilon 2c)^k \end{pmatrix}$$

for $k = 0, 1, 2, \ldots$, $\epsilon \in (0, \epsilon_0]$, where $d = \frac{c}{|a-b|}$.

Proof. The first inequality is obvious; we concentrate on the second one. The unperturbed matrix M_0 is diagonal with eigenvalues $\lambda_1(0) = a$, $\lambda_2(0) = b$ and eigenvectors $v_1(0) = (1, 0)^T$, $v_2(0) = (0, 1)^T$. Hence, for $\epsilon > 0$ sufficiently small, the characteristic polynomial of the perturbed matrix M_ϵ has two different zeros as well. A straightforward calculation yields

$$\left|\frac{\mathrm{d}\lambda_1}{\mathrm{d}\epsilon}(0)\right| = c, \qquad \left|\frac{\mathrm{d}\lambda_2}{\mathrm{d}\epsilon}(0)\right| = c.$$

Hence, for $\epsilon > 0$, we obtain the estimations $|\lambda_1(\epsilon) - a| \leq 2c\epsilon$, $|\lambda_2(\epsilon) - b| \leq 2c\epsilon$ for the eigenvalues of M_ϵ. For $\epsilon > 0$ we are looking for eigenvectors of the form $v_1(\epsilon) = (1, w(\epsilon))$, $v_2(\epsilon) = (u(\epsilon), 1)$. Straightforward computations yield

$$\left|\frac{\mathrm{d}w}{\mathrm{d}\epsilon}(0)\right| = \frac{c}{|a-b|}, \qquad \left|\frac{\mathrm{d}u}{\mathrm{d}\epsilon}(0)\right| = \frac{c}{|a-b|},$$

which allows us to estimate $|w(\epsilon)| \leq \frac{2c}{|a-b|}$, $|u(\epsilon)| \leq \frac{2c}{|a-b|}$ for sufficiently small $\epsilon > 0$. We conclude that

$$M_\epsilon^k \leq \begin{pmatrix} 1 & \epsilon\frac{2c}{|a-b|} \\ \epsilon\frac{2c}{|a-b|} & 1 \end{pmatrix} \begin{pmatrix} a+\epsilon 2c & 0 \\ 0 & b+\epsilon 2c \end{pmatrix}^k \begin{pmatrix} 1 & \epsilon\frac{2c}{|a-b|} \\ \epsilon\frac{2c}{|a-b|} & 1 \end{pmatrix}$$

for $\epsilon > 0$ sufficiently small, and the claim easily follows. ∎

3.3. Boundedness of the trajectories. In what follows, we consider the singularly perturbed differential inclusion (3) in the natural time scale of the fast subsystem, $s = \epsilon t$. Then the system becomes

$$\begin{aligned} \dot{x}_\epsilon(s) &\in \epsilon\, F(x_\epsilon(s), y_\epsilon(s), \epsilon), \quad x_\epsilon(0) = x^0, \\ \dot{y}_\epsilon(s) &\in G(x_\epsilon(s), y_\epsilon(s), \epsilon), \quad y_\epsilon(0) = y^0, \quad s \geq 0. \end{aligned} \tag{4}$$

Tychonov's theorem on the approximation applies to a time horizon that is bounded in the natural time scale of the slow subsystem. Hence, for a fixed $T \geq 0$,

we are interested in the system above for times $s \in [0, \frac{T}{\epsilon}]$. To this end, we consider the system above first on a time horizon $s \in [0, H]$, where $0 < H \leq \frac{T}{\epsilon}$. Since the estimations obtained are linear in the initial values, we can iterate the procedure $\left[\frac{T}{H\epsilon}\right]$ times (here, we set $[x] := \max\{k \in \mathbb{N} : \ k \leq x\}$ for real numbers $x \in \mathbb{R}$) and obtain estimations on the whole interval $s \in [0, \frac{T}{\epsilon}]$.

For an arbitrary $H > 0$ and $\epsilon > 0$ we set

$$P_H^\epsilon := \max_{(x_\epsilon, y_\epsilon)} \max_{s \in [0,H]} \|F(x_\epsilon(s), y_\epsilon(s), \epsilon)\|,$$

where the first maximum is taken over all trajectories (x_ϵ, y_ϵ) of (4).

LEMMA 3.3. *Let Assumptions* 2.1 *and* 2.2 *be effective. For any $H > 0$ there is an $\epsilon_H > 0$ such that*

$$P_H^\epsilon \leq 2(L + LK + 2)\|x^0\| + 4LD\|y^0 - \phi(x^0)\|$$

for all $\epsilon \in (0, \epsilon_H]$.

Proof. We set $M_s := \max_{0 \leq s' \leq s} \|y_\epsilon(s') - \phi(x_\epsilon(s'))\|$ and $N_s := \max_{0 \leq s' \leq s} \|x_\epsilon(s')\|$. Using the Gronwall lemma, for $s \in [0, H]$, we calculate

$$\begin{aligned}
&\|y_\epsilon(s) - \phi(x_\epsilon(s))\| \\
&\leq \|y_\epsilon(s) - y_{x^0}(s, y^0)\| + \|y_{x^0}(s, y^0) - \phi(x^0)\| + \|\phi(x^0) - \phi(x_\epsilon(s))\| \\
&\leq Lse^{Ls}\left(s\epsilon P_H^\epsilon + \kappa(\epsilon)N_s + \kappa(\epsilon)M_s\right) + De^{-\beta s}\|y^0 - \phi(x^0)\| + Ks\epsilon P_H^\epsilon \\
&\leq (Lse^{Ls}s\epsilon + Ks\epsilon)P_H^\epsilon + Lse^{Ls}\kappa(\epsilon)N_s + Lse^{Ls}\kappa(\epsilon)M_s + De^{-\beta s}\|y^0 - \phi(x^0)\|. \qquad (5)
\end{aligned}$$

We fix an arbitrary $\eta \in (0, \frac{1}{2}]$. Then, for $\epsilon_H > 0$ fulfilling

$$LHe^{LH}\kappa(\epsilon_H) \leq \eta \qquad (6)$$

and $\epsilon \in (0, \epsilon_H]$ we obtain

$$M_H \leq 2(LHe^{LH}H\epsilon + KH\epsilon)P_H^\epsilon + N_H + 2D\|y^0 - \phi(x^0)\|.$$

For $\epsilon_H > 0$ fulfilling (6) and

$$\kappa(\epsilon_H) \leq 1 \qquad (7)$$

we calculate

$$\begin{aligned}
P_H^\epsilon &\leq LN_H + L\max_{0 \leq s \leq H}\|y_\epsilon(s)\| + \kappa(\epsilon)N_H + \kappa(\epsilon)M_H \\
&\leq (L+1)N_H + L\max_{0 \leq s \leq H}\|\phi(x_\epsilon(s))\| + (L+1)M_H \\
&\leq (L + LK + 1)N_H + (L+1)M_H \\
&\leq (L + LK + 2)(\|x^0\| + \epsilon H P_H^\epsilon) + 2(L+1)(LHe^{LH}H\epsilon + KH\epsilon)P_H^\epsilon \\
&\quad + 2LD\|y^0 - \phi(x^0)\|
\end{aligned}$$

for all $\epsilon \in (0, \epsilon_H]$. Hence, for $\epsilon_H > 0$ fulfilling (6), (7), and

$$(L + LK + 2)\epsilon_H H + 2(L+1)(LHe^{LH}H\epsilon_H + KH\epsilon_H) \leq \frac{1}{2} \qquad (8)$$

we obtain the required estimation. ∎

LEMMA 3.4 (boundedness of the trajectories). *Let Assumptions* 2.1 *and* 2.2 *be effective. For any* $\delta \in (0,\beta)$ *there is an* $\epsilon_0 > 0$ *such that for any* $T > 0$ *there is a constant* $C_T \geq 0$ *with*

$$\begin{aligned}\|x_\epsilon(s)\| &\leq C_T\|x^0\| + \epsilon C_T\|y^0 - \phi(x^0)\|,\\ \|y_\epsilon(s) - \phi(x_\epsilon(s))\| &\leq \epsilon C_T\|x^0\| + (D+\delta)e^{-(\beta-\delta)s}\|y^0 - \phi(x^0)\| + \epsilon^2 C_T\|y^0 - \phi(x^0)\|\end{aligned}$$

for $\epsilon \in (0,\epsilon_0]$, $s \in \left[0, \frac{T}{\epsilon}\right]$. *Moreover, for* $\epsilon \in (0,\epsilon_0]$ *and* $s = \frac{T}{\epsilon}$, *the improved estimation*

$$\left\| y_\epsilon\left(\frac{T}{\epsilon}\right) - \phi\left(x_\epsilon\left(\frac{T}{\epsilon}\right)\right)\right\| \leq \epsilon C_T\|x^0\| + e^{-(\beta-\delta)\frac{T}{\epsilon}}\|y^0 - \phi(x^0)\| + \epsilon^2 C_T\|y^0 - \phi(x^0)\|$$

is valid.

Proof. Let $\delta \in (0,\beta)$. We choose $H \geq 1$ such that

$$e^{-\delta H} \leq \frac{1}{2D} \quad \text{and} \quad e^{-(\beta-\delta)H} \leq \frac{1}{2},$$

and then $\eta \in (0, \frac{1}{2}]$ and $\epsilon_0 \in (0, \epsilon_H]$, where $\epsilon_H > 0$ is given by (6), (7), and (8) such that

$$\frac{\epsilon_0 2D}{\epsilon_H L} + 4LD\epsilon_0 H + \eta 2D \leq \min\left\{\frac{e^{-(\beta-\delta)H}}{2}, \delta e^{-(\beta-\delta)H}\right\}.$$

From Lemma 3.3 and (5) we obtain

$$\begin{aligned}&\|y_\epsilon(s) - \phi(x_\epsilon(s))\|\\ &\leq \frac{\epsilon P_H^\epsilon}{\epsilon_H 4L} + \eta N_s + \eta M_s + De^{-\beta s}\|y^0 - \phi(x^0)\|\\ &\leq \frac{\epsilon P_H^\epsilon}{\epsilon_H 4L} + \eta N_H + \eta\left(\frac{\epsilon P_H^\epsilon}{\epsilon_H 2L} + N_H + 2D\|y^0 - \phi(x^0)\|\right) + De^{-\beta s}\|y^0 - \phi(x^0)\|\\ &\leq \frac{\epsilon P_H^\epsilon}{\epsilon_H 4L} + 2\eta\epsilon H P_H^\epsilon + \eta\left(\frac{\epsilon P_H^\epsilon}{\epsilon_H 2L} + 2D\|y^0 - \phi(x^0)\|\right) + De^{-\beta s}\|y^0 - \phi(x^0)\|\\ &\leq \left(2(L + LK + 2)\|x^0\| + 4LD\|y^0 - \phi(x^0)\|\right)\left(\frac{\epsilon}{\epsilon_H 4L} + 2\eta\epsilon H + \frac{\eta\epsilon}{\epsilon_H 2L}\right)\\ &\quad + \eta 2D\|y^0 - \phi(x^0)\| + De^{-\beta s}\|y^0 - \phi(x^0)\|. \qquad (9)\end{aligned}$$

Furthermore, we have

$$\|x_\epsilon(s)\| \leq \|x^0\| + \epsilon H\left(2(L + LK + 2)\|x^0\| + 4LD\|y^0 - \phi(x^0)\|\right)$$

for all $s \in [0, H]$, where $\epsilon_H > 0$ is given by (6) and (8). In particular, for $s = H$, we obtain

$$\begin{aligned}\|y_\epsilon(H) - \phi(x_\epsilon(H))\| &\leq (L + LK + 2)\left(\frac{\epsilon}{\epsilon_H L} + \epsilon 2H\right)\|x^0\|\\ &\quad + \left(\frac{\epsilon 2D}{\epsilon_H L} + 4LD\epsilon H + \eta 2D + De^{-\beta H}\right)\|y^0 - \phi(x^0)\|\\ &\leq (L + LK + 2)\left(\frac{\epsilon}{\epsilon_H L} + \epsilon 2H\right)\|x^0\|\\ &\quad + e^{-(\beta-\delta)H}\|y^0 - \phi(x^0)\|\end{aligned}$$

and

$$\|x_\epsilon(H)\| \le (1 + \epsilon H 2(L + LK + 2))\,\|x^0\| + \epsilon H 2LD\|y^0 - \phi(x^0)\|.$$

For $k = 0, 1, \dots, k_H := \left[\frac{T}{\epsilon H}\right]$ we set

$$X_k := \|x_\epsilon(kH)\|, \qquad Y_k := \|y_\epsilon(kH) - \phi(x_\epsilon(kH))\|.$$

Then we obtain the linear recursive relation

$$\begin{aligned} X_{k+1} &\le (1 + \epsilon C_H)X_k + \epsilon C_H Y_k, \\ Y_{k+1} &\le \epsilon C_H X_k + e^{-(\beta-\delta)H} Y_k, \end{aligned}$$

where

$$C_H := \max\left\{(L + LK + 2)\left(\frac{1}{\epsilon_H L} + 2H\right), 2H(L + LK + 2), 2HLD\right\}.$$

The corresponding matrix is

$$M_\epsilon := \begin{pmatrix} 1 + \epsilon C_H & \epsilon C_H \\ \epsilon C_H & e^{-(\beta-\delta)H} \end{pmatrix}.$$

According to Lemma 3.2 we can estimate

$$0 \le M_\epsilon^k \le \begin{pmatrix} (1 + \epsilon 2C_H)^k + \epsilon^2(2d)^2 & \epsilon 2d(1 + \epsilon 2C_H)^k + \epsilon 2d \\ \epsilon 2d(1 + \epsilon 2C_H)^k + \epsilon 2d & e^{-(\beta-\delta)kH} + \epsilon^2(2d)^2(1 + \epsilon 2C_H)^k \end{pmatrix}$$

with $d = 2C_H$. Since

$$(1 + \epsilon 2C_H)^k \le (1 + \epsilon 2C_H)^{\frac{T}{\epsilon H}} \le e^{\frac{2C_H T}{H}} \le e^{2C_H T}$$

for $k = 0, 1, \dots, k_H$, the estimation for the slow variable follows easily. As for the fast variable we have

$$\|y_\epsilon(kH) - \phi(x_\epsilon(kH))\| \le \epsilon C_T\|x^0\| + e^{-(\beta-\delta)kH}\|y^0 - \phi(x^0)\| + \epsilon^2 C_T\|y^0 - \phi(x^0)\|$$

for any $k = 0, 1, \dots, k_H$. For times $s \in [kH, (k+1)H]$, the required estimation follows from (9) and from the choice of η and ϵ_0. □

3.4. A version of Tychonov's theorem. Now we are in a position to prove an appropriate version of Tychonov's theorem on the uniform approximation of the slow trajectories. The interesting aspect of this version is the linearity of the estimations with respect to the initial conditions. The theorem is formulated and proven in the natural time scale of the fast subsystem $s = \epsilon t$; hence $x_\epsilon(\cdot)$ denotes the solution to the singularly perturbed system (4), whereas $x_0(\cdot)$ is the solution to the reduced system

$$\dot{x}_0(s) = \epsilon\, f(x_0(s), \phi(x_0(s))), \quad x_0(0) = x^0, \quad s \in \left[0, \frac{T}{\epsilon}\right].$$

Note that this version of Tychonov's theorem does not use Assumption 2.3, and hence gives information on the approximation of the slow variable on a time horizon that is bounded in the natural time scale of the slow variable. Under exponential stability

suppositions on the reduced system, the result can be extended to an infinite time interval; see [9].

THEOREM 3.5 (Tychonov). *Let Assumptions* 2.1 *and* 2.2 *be effective. There is an* $\epsilon_0 > 0$ *such that for any* $T > 0$ *there is a* $B_T \geq 0$ *such that we can estimate*

$$\max_{0 \leq s \leq \frac{T}{\epsilon}} \|x_\epsilon(s) - x_0(s)\| \leq (\epsilon + \kappa(\epsilon)) B_T \|x^0\| + \epsilon B_T \|y^0 - \phi(x^0)\|$$

for all initial values $x^0 \in \mathbb{R}^n$, $y^0 \in \mathbb{R}^m$ *and all perturbation parameters* $\epsilon \in (0, \epsilon_0]$.

Proof. We fix an arbitrary $\delta \in (0, \beta)$. Let $\epsilon_0 > 0$ be the corresponding upper bound for the perturbation parameter given by Lemma 3.4. Using Lemma 3.4, we calculate, for $s \in \left[0, \frac{T}{\epsilon}\right]$,

$$\begin{aligned}
&\|x_\epsilon(s) - x_0(s)\| \\
&\leq \int_0^s \epsilon \|f(x_\epsilon(s'), y_\epsilon(s')) - f(x_0(s'), \phi(x_0(s')))\| ds' \\
&\quad + \int_0^s \epsilon\kappa(\epsilon) \left(\|x_\epsilon(s')\| + \|y_\epsilon(s') - \phi(x_\epsilon(s'))\|\right) ds' \\
&\leq \int_0^s \epsilon L \left(\|x_\epsilon(s') - x_0(s')\| + \|y_\epsilon(s') - \phi(x_0(s'))\|\right) ds' \\
&\quad + \int_0^s \epsilon\kappa(\epsilon) \left(\|x_\epsilon(s')\| + \|y_\epsilon(s') - \phi(x_\epsilon(s'))\|\right) ds' \\
&\leq \int_0^s \epsilon L \left(\|x_\epsilon(s') - x_0(s')\| + \|y_\epsilon(s') - \phi(x_\epsilon(s'))\| + \|\phi(x_\epsilon(s')) - \phi(x_0(s'))\|\right) ds' \\
&\quad + \int_0^s \epsilon\kappa(\epsilon) \left(\|x_\epsilon(s')\| + \|y_\epsilon(s') - \phi(x_\epsilon(s'))\|\right) ds' \\
&\leq \int_0^s \epsilon L(1+K) \|x_\epsilon(s') - x_0(s')\| + \epsilon(L + \kappa(\epsilon)) \|y_\epsilon(s') - \phi(x_\epsilon(s'))\| + \epsilon\kappa(\epsilon) \|x_\epsilon(s')\| ds' \\
&\leq \int_0^s \epsilon L(1+K) \|x_\epsilon(s') - x_0(s')\| ds' \\
&\quad + \int_0^s \epsilon(L + \kappa(\epsilon)) \left(\epsilon C_T \|x^0\| + (D + \delta) e^{-(\beta - \delta)s'} \|y^0 - \phi(x^0)\|\right) ds' \\
&\quad + \int_0^s \epsilon(L + \kappa(\epsilon)) \epsilon^2 C_T \|y^0 - \phi(x^0)\| ds' \\
&\quad + \int_0^s \epsilon\kappa(\epsilon) \left(C_T \|x^0\| + \epsilon C_T \|y^0 - \phi(x^0)\|\right) ds'
\end{aligned}$$

for all $\epsilon \in (0, \epsilon_0]$. Hence, the Gronwall lemma yields the required estimate. ∎

4. Proof of Theorem 2.5. We fix a $\delta \in (0, \min\{\alpha, \beta\})$ and choose $T > 0$ such that

$$e^{-\delta T} \leq \frac{1}{2C}.$$

Let $\epsilon_0 > 0$ be the corresponding upper bound for the perturbation parameter given by Lemma 3.4. Then we choose $\epsilon_\delta \in (0, \epsilon_0]$ such that

$$(\epsilon_\delta + \kappa(\epsilon_\delta)) B_T \leq \min\left\{ \frac{e^{-(\alpha - \delta)T}}{2}, \delta e^{-(\alpha - \delta)T} \right\}.$$

For $s \in \left[0, \frac{T}{\epsilon}\right]$ we calculate

$$\begin{aligned} \|x_\epsilon(s)\| &\le \|x_\epsilon(s) - x_0(s)\| + \|x_0(s)\| \\ &\le (\epsilon + \kappa(\epsilon)) B_T \|x^0\| + \epsilon B_T \|y^0 - \phi(x^0)\| + C e^{-\alpha\epsilon s} \|x^0\|. \end{aligned} \tag{10}$$

In particular, for $s = \frac{T}{\epsilon}$, we obtain

$$\left\| x_\epsilon\left(\frac{T}{\epsilon}\right) \right\| \le e^{-(\alpha-\delta)T} \|x^0\| + \epsilon B_T \|y^0 - \phi(x^0)\|.$$

Moreover, by Lemma 3.4 we have

$$\left\| y_\epsilon\left(\frac{T}{\epsilon}\right) - \phi\left(x_\epsilon\left(\frac{T}{\epsilon}\right)\right) \right\| \le \epsilon C_T \|x^0\| + e^{-(\beta-\delta)\frac{T}{\epsilon}} \|y^0 - \phi(x^0)\| + \epsilon^2 C_T \|y^0 - \phi(x^0)\|.$$

For $k = 0, 1, 2, \ldots$, we set

$$X_k := \left\| x_\epsilon\left(\frac{kT}{\epsilon}\right) \right\|, \qquad Y_k := \left\| y_\epsilon\left(\frac{kT}{\epsilon}\right) - \phi\left(x_\epsilon\left(\frac{kT}{\epsilon}\right)\right) \right\|.$$

Then we obtain the linear recursive relation

$$\begin{aligned} X_{k+1} &\le e^{-(\alpha-\delta)T} X_k + \epsilon C' Y_k, \\ Y_{k+1} &\le \epsilon C' X_k + e^{-(\beta-\delta)\frac{T}{\epsilon}} Y_k + \epsilon C' Y_k, \end{aligned}$$

where

$$C' := \max\{B_T, C_T\}.$$

The corresponding matrix becomes

$$M_\epsilon := \begin{pmatrix} e^{-(\alpha-\delta)T} & \epsilon C' \\ \epsilon C' & e^{-(\beta-\delta)\frac{T}{\epsilon}} + \epsilon C' \end{pmatrix}.$$

As for the fast variables, the claim follows directly from Lemmas 3.2 and 3.4. For the slow variables we have

$$\left\| x_\epsilon\left(\frac{kT}{\epsilon}\right) \right\| \le e^{-(\alpha-\delta)kT} \|x^0\| + \epsilon E e^{-(\alpha-\delta)kT} \|y^0 - \phi(x^0)\|$$

for $k \in \mathbb{N}$. For times $s \in [\frac{kT}{\epsilon}, \frac{(k+1)T}{\epsilon}]$ the required estimation follows from (10) and from the choice of ϵ_δ. □

Remark 4.1. The proof of Theorem 2.5 is based on Gronwall-type estimations only; in particular no compactness arguments are used. Hence, the result is valid for systems in arbitrary real Banach spaces, and the proofs remain unchanged.

Remark 4.2. An inspection of the proof of Theorem 2.5 shows that the condition $\kappa(0) = 0$ in Definition 2.4 is only needed in order to achieve that the gain and exponential decay rates of the singularly perturbed multivalued differential equation (3) approximate the corresponding values of the reduced system and the boundary layer systems. If we are merely interested in the exponential stability of the singularly perturbed multivalued differential equation (3) for small perturbation parameters, then we need only that $\kappa(0) \ge 0$ is sufficiently small.

5. An application to small delays. An important application of decomposition results such as Theorem 2.5 is the construction of feedback controls. Assumptions 2.2 and 2.3 along with Theorem 2.5 allow a significant simplification of this problem, since the decoupled stabilization takes place in lower dimensional spaces. According to Theorem 2.5, one has to construct the feedback in a way that the boundary layer systems and the reduced system are exponentially stable. This construction is described in detail in [10] via Lyapunov functions.

Still the question arises to what extent this feedback is robust with respect to delays. In other words, for what kind of mappings $h : [0,\infty) \to [0,\infty)$ is the system with delays

$$\begin{aligned} \dot{x}_\epsilon(t) &= \tilde{f}(x_\epsilon(t), y_\epsilon(t), x_\epsilon(t-h(\epsilon)), y_\epsilon(t-h(\epsilon))), \quad t>0,\\ \epsilon\,\dot{y}_\epsilon(t) &= \tilde{g}(x_\epsilon(t), y_\epsilon(t), x_\epsilon(t-h(\epsilon)), y_\epsilon(t-h(\epsilon))), \quad t>0,\\ x_\epsilon(t) &= x^0, \quad t\in[-h(\epsilon),0],\\ y_\epsilon(t) &= y^0, \quad t\in[-h(\epsilon),0], \end{aligned} \tag{11}$$

exponentially stable for $\epsilon > 0$ sufficiently small? Since Theorem 2.5 applies to multivalued perturbations as given by (3), we can answer this question. To this end we formulate the delay as a regular perturbation, which is automatically contained in the differential inclusion (3). A similar idea has been used in [11] in order to show that exponentially stabilizing feedback controls are robust with respect to small delays.

THEOREM 5.1. *Let the mappings $\tilde{f} : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$, $\tilde{g} : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^m$ be Lipschitz continuous with Lipschitz constant $L \geq 0$. Let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$, $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^m$ given by*

$$f(x,y) := \tilde{f}(x,y,x,y), \quad g(x,y) := \tilde{g}(x,y,x,y)$$

satisfy Assumptions 2.1, 2.2, *and* 2.3. *Let $h : [0,\infty) \to [0,\infty)$ satisfy*

$$\frac{h(\epsilon)}{\epsilon} \to 0, \quad \text{as} \quad \epsilon \to 0.$$

Then there is a constant $E > 0$ such that for any $\delta > 0$ there is an $\epsilon_\delta > 0$ such that for any solution to the delayed feedback system (11) *we can estimate*

$$\begin{aligned} \|x_\epsilon(t)\| &\leq (C+\delta)e^{-(\alpha-\delta)t}\|x^0\| + \epsilon E e^{-(\alpha-\delta)t}\|y^0 - \phi(x^0)\|,\\ \|y_\epsilon(t) - \phi(x_\epsilon(t))\| &\leq (D+\delta)e^{-(\beta-\delta)t/\epsilon}\|y^0 - \phi(x^0)\| + \epsilon E e^{-(\alpha-\delta)t}\|x^0\|\\ &\quad + \epsilon^2 E e^{-(\alpha-\delta)t}\|y^0 - \phi(x^0)\| \end{aligned}$$

for all initial values $x^0 \in \mathbb{R}^n$, $y^0 \in \mathbb{R}^m$, all times $t \geq 0$, and all perturbation parameters $\epsilon \in (0, \epsilon_\delta]$.

Proof. Let (x_ϵ, y_ϵ) be a solution to (11). Without loss of generality we can assume that $0 < \epsilon \leq 1$. Then the right-hand side of the differential equation for x_ϵ is of order $\frac{1}{\epsilon}$ as well, and the x_ϵ trajectory can be treated as the y_ϵ trajectory. For short we write $z_\epsilon := (x_\epsilon, y_\epsilon)$ and use the norm $\|z_\epsilon(t)\| = \|x_\epsilon(t)\| + \|y_\epsilon(t)\|$. We claim that

$$\max_{t-h(\epsilon)\leq s\leq t} \|z_\epsilon(s)\| \leq 2\|z_\epsilon(t)\| \tag{12}$$

for all $t \geq 0$ and all sufficiently small perturbation parameters $\epsilon > 0$. We prove (12) by induction. First, let $t \in [0, h(\epsilon)]$ and $t^* \in [0,t]$ with

$$\|z_\epsilon(t^*)\| = \max_{t-h(\epsilon)\leq s\leq t} \|z_\epsilon(s)\|.$$

Then we can estimate

$$\begin{aligned}\|z_\epsilon(t)\| &\geq \|z_\epsilon(t^*)\| - L\frac{h(\epsilon)}{\epsilon}\max_{t-h(\epsilon)\leq s\leq t}\|z_\epsilon(s)\| - L\frac{h(\epsilon)}{\epsilon}\|z^0\| \\ &\geq \left(1 - 2L\frac{h(\epsilon)}{\epsilon}\right)\max_{t-h(\epsilon)\leq s\leq t}\|z_\epsilon(s)\|,\end{aligned}$$

which yields the estimation (12) for sufficiently small $\epsilon > 0$. In the next step we let $T \geq h(\epsilon)$ and assume that the estimation (12) is valid for $t = T - h(\epsilon)$. Let $T^* \in [T - h(\epsilon), T]$ such that

$$\|z_\epsilon(T^*)\| = \max_{T-h(\epsilon)\leq s\leq T}\|z_\epsilon(s)\|.$$

Then we can write

$$\begin{aligned}\|z_\epsilon(T)\| &\geq \|z_\epsilon(T^*)\| - L\frac{h(\epsilon)}{\epsilon}\max_{T-h(\epsilon)\leq s\leq T}\|z_\epsilon(s)\| - L\frac{h(\epsilon)}{\epsilon}\max_{T-2h(\epsilon)\leq s\leq T-h(\epsilon)}\|z_\epsilon(s)\| \\ &\geq \max_{T-h(\epsilon)\leq s\leq T}\|z_\epsilon(s)\| - L\frac{h(\epsilon)}{\epsilon}\max_{T-h(\epsilon)\leq s\leq T}\|z_\epsilon(s)\| - L\frac{h(\epsilon)}{\epsilon}2\|z_\epsilon(T-h(\epsilon))\| \\ &\geq \left(1 - L\frac{h(\epsilon)}{\epsilon} - 2L\frac{h(\epsilon)}{\epsilon}\right)\max_{T-h(\epsilon)\leq s\leq T}\|z_\epsilon(s)\|,\end{aligned}$$

which yields the estimation (12) for $t = T$ and sufficiently small $\epsilon > 0$.

In what follows we make use of the estimate

$$\max_{t-2h(\epsilon)\leq s\leq t}\|z_\epsilon(s)\| \leq 4\|z_\epsilon(t)\|, \tag{13}$$

which is valid for all $t \geq h(\epsilon)$ and sufficiently small $\epsilon > 0$. With Assumption 2.1 and (13) we can estimate

$$\|x_\epsilon(t) - x_\epsilon(t-h(\epsilon))\| \leq 4h(\epsilon)L(\|x_\epsilon(t)\| + \|y_\epsilon(t)\|)$$

and

$$\|y_\epsilon(t) - y_\epsilon(t-h(\epsilon))\| \leq 4\frac{h(\epsilon)}{\epsilon}L(\|x_\epsilon(t)\| + \|y_\epsilon(t)\|).$$

We are in a position to formulate the delay in (11) as a regular perturbation. To this end we write

$$\begin{aligned}&\left\|f(x_\epsilon(t), y_\epsilon(t)) - \tilde{f}(x_\epsilon(t), y_\epsilon(t), x_\epsilon(t-h(\epsilon)), y_\epsilon(t-h(\epsilon)))\right\| \\ &\quad\leq 8\frac{h(\epsilon)}{\epsilon}L^2(\|x_\epsilon(t)\| + \|y_\epsilon(t)\|) \\ &\quad\leq 8\frac{h(\epsilon)}{\epsilon}L^2(\|x_\epsilon(t)\| + \|y_\epsilon(t) - \phi(y_\epsilon(t))\| + \|\phi(y_\epsilon(t))\|) \\ &\quad\leq 8\frac{h(\epsilon)}{\epsilon}L^2(1+K)(\|x_\epsilon(t)\| + \|y_\epsilon(t) - \phi(y_\epsilon(t))\|)\end{aligned}$$

and compute in the same way

$$\begin{aligned}&\|g(x_\epsilon(t), y_\epsilon(t)) - \tilde{g}(x_\epsilon(t), y_\epsilon(t), x_\epsilon(t-h(\epsilon)), y_\epsilon(t-h(\epsilon)))\| \\ &\quad\leq 8\frac{h(\epsilon)}{\epsilon}L^2(1+K)(\|x_\epsilon(t)\| + \|y_\epsilon(t) - \phi(y_\epsilon(t))\|).\end{aligned}$$

Hence, the system (11) is included in the differential inclusion (3) with

$$\kappa(\epsilon) = 8\frac{h(\epsilon)}{\epsilon}L^2(1+K),$$

and the proof is finished. □

A BEHAVIORAL APPROACH TO TIME-VARYING LINEAR SYSTEMS. PART 1: GENERAL THEORY*

ACHIM ILCHMANN† AND VOLKER MEHRMANN‡

Abstract. We develop a behavioral approach to linear, time-varying, differential-algebraic systems. The analysis is "almost everywhere" in the sense that the statements hold on $\mathbb{R} \setminus \mathbb{T}$, where $\mathbb{T}$ is a discrete set. Controllability, observability, and autonomy are introduced and related to the behavior of the system. Classical results on the behavior of time-invariant systems are studied in the context of time-varying systems.

Key words. time-varying linear systems, behavioral approach, controllability, observability, autonomous system, adjoint system, latent variables

1. Introduction.

1.1. An algebraic approach and solution spaces. The aim of the present paper is to develop a behavioral approach to linear time-varying systems described by differential-algebraic equations of the form

$$R(\tfrac{\mathrm{d}}{\mathrm{d}t})w = 0, \tag{1.1}$$

where $R(D)$ is a $g\times q$ polynomial matrix in the indeterminate D with real meromorphic coefficient matrices belonging to $\mathcal{M}^{g\times q}$; we use the notation $R(D)\in\mathcal{M}^{g\times q}[D]$.

Instead of considering real meromorphic coefficients of $R(D)$ on the whole time axis $\mathbb{R}$, we also could develop the theory on some open interval $\mathbb{I}\subset\mathbb{R}$; this is omitted.

The ring $\mathcal{M}[D]$ is endowed with the multiplication rule

$$Df = fD + \dot{f}. \tag{1.2}$$

This is a consequence of assuming the associative rule $(Df)g = D(fg)$ for all differentiable functions f, g which yields $(Df)(g) = \frac{\mathrm{d}}{\mathrm{d}t}f\cdot g + f\cdot\frac{\mathrm{d}}{\mathrm{d}t}g = (\frac{\mathrm{d}}{\mathrm{d}t}f + fD)(g)$. The noncommutativity of $\mathcal{M}[D]$, in contrast to the commutative ring $\mathbb{R}[D]$ in the time-invariant case, is crucial in the following.

Note that we distinguish between the algebraic indeterminate D and the differential operator $\frac{\mathrm{d}}{\mathrm{d}t}$; for

$$R(D) = \sum_{i=0}^{n} R_i D^i \in \mathcal{M}[D]^{g\times q} \cong \mathcal{M}^{g\times q}[D],$$

equality in (1.1) means

$$\sum_{i=0}^{n} R_i(t)w^{(i)}(t) = 0 \qquad \text{for almost all } t\in\mathbb{R}.$$

Skew polynomial rings are, for example, treated in the monograph [6]; the ring $\mathcal{M}[D]$ was introduced in [14] to study linear time-varying systems. We are interested in the behavior introduced by all solutions of (1.1). Since the coefficients of $R(D)$ are meromorphic functions, we can only expect solutions which are defined "almost globally" (see subsection 1.3). To be more precise, we allow for the solution space

$$\mathcal{C}^\infty_{\mathrm{pw}}(\mathbb{R}^q) = \big\{w\in\mathcal{C}^\infty(\mathbb{R}\setminus\mathbb{T},\mathbb{R}^q)\;\big|\;\mathbb{T}\subset\mathbb{R}\text{ discrete}\big\}$$

of piecewise $\mathcal{C}^\infty$-functions (see the notation) defined almost everywhere on $\mathbb{R}$, and the set

$$\mathcal{C}^\infty_t(\mathbb{R}^q) = \big\{w\in\mathcal{C}^\infty(\mathbb{I},\mathbb{R}^q)\;\big|\;\mathbb{I}\subset\mathbb{R}\text{ an open interval with } t\in\mathbb{I}\big\},\qquad t\in\mathbb{R},$$

of $\mathcal{C}^\infty$-solution pieces on some open interval including t.

For $R(D)\in\mathcal{M}[D]^{g\times q}$, we study the *almost global behavior* given by the kernel representation

$$\ker R = \{w\in\mathcal{C}^\infty_{\mathrm{pw}}(\mathbb{R}^q)\,|\,R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = 0 \text{ for almost all } \tau\in\mathbb{R}\}$$

and the *local behavior*

$$\ker_t R = \{w\in\mathcal{C}^\infty_t(\mathbb{R}^q)\,|\,R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = 0 \text{ for all } \tau\in\operatorname{dom} w\},\qquad t\in\mathbb{R}.$$

1.2. Examples of system classes. Our approach generalizes results on the following subclasses of systems:

(a) Time-varying state space systems of the form

$$\begin{aligned} \tfrac{\mathrm{d}}{\mathrm{d}t}x(t) &= A(t)x(t) + B(t)u(t), \\ y(t) &= C(t)x(t) + F(t)u(t), \end{aligned} \tag{1.3}$$

with real analytic matrices $A \in \mathcal{A}^{n\times n}$, $B \in \mathcal{A}^{n\times m}$, $C \in \mathcal{A}^{p\times n}$, and $F \in \mathcal{A}^{p\times m}$, are well studied; see, for example, the standard monograph [30].

(b) Time-varying descriptor systems of the form

$$\begin{aligned} E(t)\,\tfrac{\mathrm{d}}{\mathrm{d}t}x(t) &= A(t)x(t) + B(t)u(t), \\ y(t) &= C(t)x(t) + F(t)u(t), \end{aligned} \tag{1.4}$$

with $A \in \mathcal{A}^{\ell\times n}$, $B \in \mathcal{A}^{\ell\times m}$, $C \in \mathcal{A}^{p\times n}$, $F \in \mathcal{A}^{p\times m}$, where $E \in \mathcal{A}^{\ell\times n}$ is allowed to be singular in the sense that $\operatorname{rk} E(t) < \min\{\ell, n\}$ for some $t \in \mathbb{R}$, have been studied by different authors. In [5] controllability and observability were studied in terms of derivative arrays. In [2] a first behavior-like approach to systems (1.4) with analytic coefficients was discussed. A more general approach that allows for larger classes of coefficients and that can be implemented also numerically was introduced in [20] and generalized partially to the nonlinear case in [18]. A completely different approach results from the study of differential-algebraic equations introduced in [1, 9, 19]. A general solvability theory for nonsquare linear time-varying systems was first given in [16] and analyzed for control problems in a behavioral context in [2, 20, 26]; see also [18] for the general nonlinear case.

(c) In [14] time-varying polynomial systems of the form

$$\begin{aligned} P(\tfrac{\mathrm{d}}{\mathrm{d}t})z(t) &= Q(\tfrac{\mathrm{d}}{\mathrm{d}t})u(t), \\ y(t) &= V(\tfrac{\mathrm{d}}{\mathrm{d}t})z(t) + W(\tfrac{\mathrm{d}}{\mathrm{d}t})u(t), \end{aligned} \tag{1.5}$$

where $P(D)$, $Q(D)$, $V(D)$, and $W(D)$ are matrices of size $r \times r$, $r \times m$, $p \times r$, and $p \times m$, respectively, over $\mathcal{M}[D]$ are studied under the following assumptions:

- $P(D)$ represents a so-called *full* operator, i.e., if z is a real analytic solution of $P(\frac{\mathrm{d}}{\mathrm{d}t})z = 0$ on some interval $\mathbb{I} \subset \mathbb{R}$, then this solution can be analytically extended to the whole of $\mathbb{R}$.
- For every $u \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ with bounded support to the left, there exist some $z \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^r)$ and $y \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^p)$ so that (1.5) is satisfied.

Time-invariant polynomial (so-called Rosenbrock) systems of the form (1.5)—i.e., $P(D)$, $Q(D)$, $V(D)$, and $W(D)$ are matrices over $\mathbb{R}[D]$ and $\det P(\cdot) \neq 0$—were introduced in [27] and are well studied; see, for example, [11, 39].

(d) Time-invariant polynomial systems in the so-called kernel representation

$$R(\tfrac{\mathrm{d}}{\mathrm{d}t})w(t) = 0, \qquad R(D) \in \mathbb{R}[D]^{g\times q} \tag{1.6}$$

were introduced by Willems in [35]; see also [36, 37, 38] and the monograph [24].

It is easy to see that time-varying descriptor systems (1.4) or, if $E = I_n$ and $n = \ell$, state space systems (1.3) are special cases of time-varying Rosenbrock systems

(1.5). Furthermore, time-varying Rosenbrock systems of the form (1.5) are a special case of systems in kernel representation (1.1): set $w = [z^T, u^T, y^T]^T$ and

$$R(D) = [R_1(D), R_2(D)], \quad R_1(D) = \begin{bmatrix} P(D) \\ V(D) \end{bmatrix}, \quad R_2(D) = \begin{bmatrix} -Q(D), & 0 \\ W(D), & -I_p \end{bmatrix}. \tag{1.7}$$

1.3. Examples of time-varying scalar differential equations. In the following, we present some prototypical scalar differential equations which illustrate how time-varying coefficients may affect the solutions in very different ways. Set, for $r(D) \in \mathcal{M}[D]$ and $\mathcal{W}$ a suitable solution space to be specified,

$$\ker_{\mathcal{W}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) := \{w \in \mathcal{W} \mid r(\tfrac{\mathrm{d}}{\mathrm{d}t})w = 0\}.$$

(i) Let $r(D) = tD + 1$. Then the function $t \mapsto w(t) = t^{-1}$ is a meromorphic solution of $r(\frac{\mathrm{d}}{\mathrm{d}t})w = t\frac{\mathrm{d}}{\mathrm{d}t}w + w = 0$.
The point 0 is the only zero of the leading coefficient $t \mapsto t$ of $r(D)$, and 0 is also a pole of $t \mapsto w(t)$. Therefore,

$$\ker_{\mathcal{A}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = \ker_{\mathcal{C}^\infty(\mathbb{R},\mathbb{R})} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = \{0\},$$

but, for every interval $\mathbb{I} \subset \mathbb{R}$ with $0 \notin \mathbb{I}$,

$$\dim \ker_{\mathcal{M}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = \dim \ker_{\mathcal{A}_{|_{\mathbb{I}}}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = 1 = \deg r(D).$$

In this example, in the meromorphic case the dimension of the solution space equals the degree of $r(D)$. This is not true in general, as illustrated by the following example.

(ii) Let $r(D) = t^2D + 1$. Then the function $t \mapsto w(t) = e^{1/t}$ solves $r(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$. The point 0 is again the only zero of the leading coefficient $t \mapsto t^2$ of $r(D)$, and 0 is also a pole of $t \mapsto w(t)$. But w is not meromorphic and the singularity at $t = 0$ differs from (i) as follows: no matter whether the solution w in (i) approaches 0 from the left or right, the limit at $t = 0$ does not exist; whereas, for the solution w in the present example, we have $\lim_{t\to 0-} w(t) = 0$ and $\lim_{t\to 0+} w(t) = \infty$. Hence,

$$\ker_{\mathcal{M}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = \{0\}.$$

For every interval $\mathbb{I} \subset \mathbb{R}$ with $0 \notin \mathbb{I}$ we have

$$\dim \ker_{\mathcal{M}_{|_{\mathbb{I}}}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = 1 = \deg r(D).$$

(iii) Let $r(D) = tD - 1$. Then the function $t \mapsto w(t) = t$ solves $r(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ and

$$\dim \ker_{\mathcal{A}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = 1 = \deg r(D).$$

Note that again the point $t = 0$ is the only zero of the leading coefficient $t \mapsto t$ of $r(D)$, but this time the zero does not produce a pole of the solution, the solution w is even a real analytic function on $\mathbb{R}$. However, the solution is not as arbitrary as for time-invariant systems, since $w(0) = 0$ is the only value at $t = 0$.

(iv) Let $r(D) = 2tD - 1$. Then the functions $t \mapsto w_+(t) = \sqrt{t}$ and $t \mapsto w_-(t) = \sqrt{-t}$ solve $r(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ on $(0, \infty)$ and $(-\infty, 0)$, respectively. For every interval $\mathbb{I} \subset \mathbb{R}$ with $0 \notin \mathbb{I}$, we have

$$\dim \ker_{\mathcal{A}_{|\mathbb{I}}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = 1 = \deg r(D).$$

However,

$$\ker_{\mathcal{M}} r(\tfrac{\mathrm{d}}{\mathrm{d}t}) = \{0\}.$$

The real analytic solution w_+ on $(0, \infty)$ cannot be continued to $(-\varepsilon, \infty)$ for any $\varepsilon > 0$.

This also proves that the attempt to connect real analytic solutions between critical points by cutting the neighborhood and going into the complex sphere, as suggested by Ilchmann et al. [13], does not work.[1]

(v) Let $r(D) = (1 - t^2)^2 D + 2t$. Then the function

$$t \mapsto w(t) = \begin{cases} \exp\left\{-(1-t^2)^{-1}\right\}, & t \in (-1, 1), \\ 0, & t \in \mathbb{R} \setminus (-1, 1), \end{cases}$$

satisfies $w \in \ker_{\mathcal{C}^\infty} r(\frac{\mathrm{d}}{\mathrm{d}t})$, is not real analytic, and has compact support. This is impossible for time-invariant scalar differential equations.

1.4. An example of a mobile manipulator. Systems of differential-algebraic equations play an important role in modeling multibody systems, electric circuits, or coupled systems of partial differential equations; see [1, 10]. We present an application which first shows that modeling does not necessarily lead to a state space system; second, it illustrates a simple system where the notion of input, output, and state is not a priori clear; and third, the example serves to illustrate the concepts introduced in the following sections. Consider a simplified, linearized model of a two-dimensional, three-link constrained mobile manipulator [12] as depicted in Figure 1.

The Lagrangian equations of motion take the form

$$\begin{aligned} M(\theta)\,\ddot{\theta} + D(\theta, \dot{\theta})\,\dot{\theta} + K(\theta) &= u + F^T(\theta)\mu, \\ \psi(\theta) &= 0, \end{aligned} \tag{1.8}$$

where $\theta = [\theta_1, \theta_2, \theta_3]^T$ is the vector of joint displacements, $u \in \mathbb{R}^3$ is the vector of control torques applied at the joints, and the maps $M : \mathbb{R}^3 \to \mathbb{R}^{3\times 3}$, $D : \mathbb{R}^3 \times \mathbb{R}^3 \to \mathbb{R}^{3\times 3}$, and $K : \mathbb{R}^3 \to \mathbb{R}^3$ model the mass, centrifugal and Coriolis forces, gravity, respectively. $l_1, l_2, l_3, l > 0$ are the lengths of the robot arms. The nonlinear constraint function is $\psi : \mathbb{R}^3 \to \mathbb{R}^2$, $F = \frac{\partial \psi}{\partial \theta}$, and $\mu \in \mathbb{R}^2$ represents the Lagrange multipliers and $F^T(\theta)\mu$ is the generalized constraint force. We are interested in the behavior, i.e., local solutions $t \mapsto [\theta(t)^T, u(t)^T]$ of (1.8). It can be shown that $u(\cdot)$ is a latent variable; for its definition, see [24, sect. 6.2]. Under suitable smoothness assumptions of the involved functions, it can be shown (see, for example, [25, p. 62]) that there exists a local (possibly global) solution $\theta(\cdot)$ of (1.8) on some open interval $\mathbb{I}$. Linearizing along this trajectory [4] and rewriting the system in Cartesian coordinates yields a model of the form

$$\begin{aligned} M_0(t)\,\ddot{z}(t) + D_0(t)\,\dot{z}(t) + K_0(t)\,z(t) &= S_0\,u(t) + F_0^T(t)\,\mu, \\ F_0(t)\,z(t) &= 0, \end{aligned}$$

[1] We are indebted to the anonymous referee of an earlier version of the present paper for pointing out this example to us.

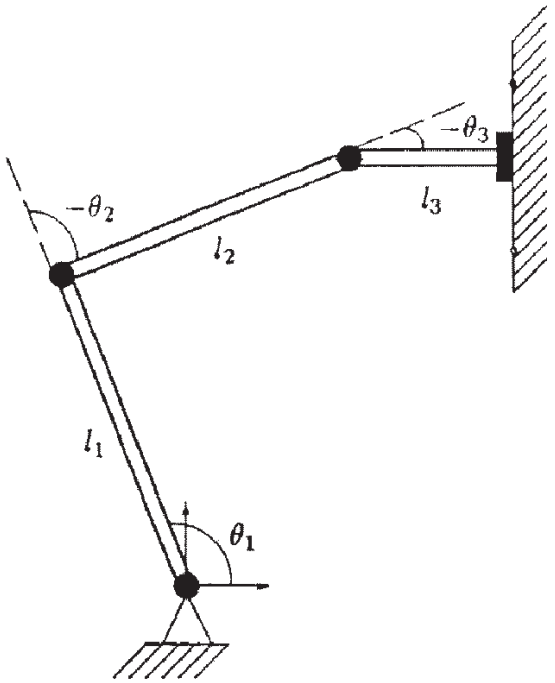

FIG. 1. *Three-link constrained mobile manipulator.*

where $M_0, D_0, K_0 \in \mathcal{C}^\omega(\mathbb{I}, \mathbb{R}^{3\times 3})$ and $S_0 \in \mathbb{R}^{3\times 3}$, $F_0^T \in \mathbb{R}^{3\times 2}$ with S_0 having full row rank. Introducing the eight-dimensional variable $x(t) = [z(t)^T, \dot{z}(t)^T, \mu(t)^T]^T$ results in the equivalent descriptor system description of the form

$$\begin{aligned} E(t)\,\tfrac{\mathrm{d}}{\mathrm{d}t}x(t) &= A(t)x(t) + B(t)u(t), \\ y(t) &= C(t)x(t), \end{aligned} \tag{1.9}$$

where

$$E(t) := \begin{bmatrix} I_3 & 0 & 0 \\ 0 & M_0(t) & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad A(t) := \begin{bmatrix} 0 & I_3 & 0 \\ -K_0(t) & -D_0(t) & F_0^T(t) \\ F_0(t) & 0 & 0 \end{bmatrix}, \quad B(t) := \begin{bmatrix} 0 \\ S_0 \\ 0 \end{bmatrix},$$

and $C(\cdot)$ denotes a matrix with appropriate format; see [12] for explicit data. Actually, in this example F_0 does not depend on t.

1.5. Literature survey. The crucial difference between time-varying and time-invariant ordinary, linear differential equations is that the solutions behave qualitatively considerably different. Whereas any local solution of a time-invariant system is always extendable to a global analytic solution, solutions of time-varying systems may have finite escape times. Simple examples have been presented in subsection 1.3. All algebraic contributions to time-varying systems struggle with this difficulty.

Early algebraic contributions to time-varying systems in polynomial descriptions are given in [15, 40, 41]; however, the assumptions on the system classes are rather restrictive.

In [7], matrices over the ring of linear differential operators $k[D]$ are considered, where k is a differential field. Linear dynamics are finitely generated left $k[D]$-modules. This contribution is rather on the algebraic side; the solution space is not specified. In [29] contributions to duality of systems in the setup of [7] for systems in generalized state space representation are given; however, the solution space is not specified either.

An important contribution by Fröhler and Oberst [8] has the following background: Consider the simple examples given in subsection 1.3. It can be shown that the local solution $(t \mapsto 1/t) \in \ker(t\frac{\mathrm{d}}{\mathrm{d}t} + 1)$ can be extended to a distribution belonging to $\mathcal{D}'(\mathbb{R}, \mathbb{R})$; however, $(t \mapsto \exp(1/2t^2)) \in \ker(t^3\frac{\mathrm{d}}{\mathrm{d}t} + 1)$ cannot be extended to a distribution belonging to $\mathcal{D}'(\mathbb{R}, \mathbb{R})$. Hence enlarging the solution space to allow for distributions on $\mathbb{R}$ does not necessarily resolve the problem, even in the simple case when the coefficients of the time-varying systems are polynomials. However, if the solution space is enlarged even further to allow for Sato's hyperfunctions, i.e., generalized distributions introduced in [31, 32], then [8] considers systems of the form (1.1), respectively, behavior in the kernel representation $\ker R$, where the coefficient matrices of the polynomial $R(D)$ are defined over rational analytic functions

$$\frac{f(\cdot)}{g(\cdot)} \quad \text{for } f, g \in \mathbb{C}[t] \quad \text{with} \quad g(t) \neq 0 \text{ for all } t \in \mathbb{I}.$$

Note that by multiplication with a least common multiple of all denominators of the coefficients, the coefficients of $R(D)$ are polynomials. Based on the seminal paper [22], where an algebraic analytic approach is developed to show a categorical duality between the solution spaces of linear partial differential equations with constant coefficients and certain polynomial modules associated to them, a generalization to time-varying but ordinary differential equations is achieved in [8].

The skew polynomial ring $\mathcal{M}[D]$ was first exploited by [14] to describe time-varying linear systems. This ring is nice in the sense that it is simple (i.e., the only two-sided ideals are the trivial ones) and admits right- and left-Euclidean division. Hence matrices over the ring can be transformed into the Teichmüller–Nakayama normal form; see section 2. The latter is the essential tool in [14] to study time-varying Rosenbrock systems of the form (1.5). The solution space is the set of $\mathcal{C}^\infty$-functions on the whole time axis; this is ensured by the assumption that $\operatorname{im} Q(\frac{\mathrm{d}}{\mathrm{d}t}) \subset \operatorname{im} P(\frac{\mathrm{d}}{\mathrm{d}t})$ and, most importantly, that $P(D)$ is a "full" operator, i.e., every local analytic solution of $P(\frac{\mathrm{d}}{\mathrm{d}t})z = 0$ is extendable to a global analytic solution on the whole of $\mathbb{R}$. The latter is a rather restrictive assumption. To overcome this assumption, in [13] a first approach in the spirit of the present paper was presented for scalar systems. A behavioral approach to a certain class of time-varying systems was presented in [3].

A completely different approach results from the study of differential-algebraic equations introduced in [1, 9]. A general solvability theory for nonsquare linear time-varying systems was first given in [16] and analyzed for control problems in a behavioral context in [2, 20, 26]; see also [18] for the general nonlinear case, and a latest monograph [19].

This paper is organized as follows. In section 2, the algebraic tools, such as the Teichmüller–Nakayama normal form, and some facts on the behavior are collected. In section 3, we introduce and characterize algebraically the concept of controllable behavior for the kernel and image representation. The relationship between behavior, controllable, and autonomous behavior is investigated in section 4. In section 5, observability is defined, it is related via the adjoint of the kernel representation to the controllable behavior, and it is characterized algebraically. Finally, in section 6 we

investigate the elimination of latent variables.

2. Behavior. In this section we present the Teichmüller–Nakayama normal form for matrices over $\mathcal{M}[D]$. This will be the main tool for analyzing $\ker_t R$. To this end we recall some results on matrices over the skew polynomial ring $\mathcal{M}[D]$; a standard reference for this is [6]. $\mathcal{M}[D]$ is *simple*, i.e., the only ideals which are right and left ideals at the same time are the trivial ones; the rank of a matrix over $\mathcal{M}[D]$ is unambiguous, since column rank and row rank coincide; the Teichmüller–Nakayama normal form is the analogue of the Smith normal form for matrices over the commutative ring $\mathbb{R}[D]$; it is simpler for matrices over $\mathcal{M}[D]$, since the class of transformations is larger. $W(D) \in \mathcal{M}[D]^{n\times n}$ is called *unimodular* if and only if there exists some $W(D)^{-1} \in \mathcal{M}[D]^{n\times n}$ such that $W(D)\,W(D)^{-1} = I_n$; two elements $q_1, q_2 \in \mathcal{M}[D]$ are *similar* if and only if $q_1 a = b q_2$ for some $a, b \in \mathcal{M}[D]$ for which q_1 and b (q_2 and a) are left (right) coprime. For example, $a(D) = D$ and $b(D) = D - 1/t$ are similar: $[D + (t^2-1)/t]a(D) = b(D)\,[D+t]$ and $D + (t^2-1)/t$, $b(D)$ are right coprime, $a(D)$, $D + t$ are left coprime. Moreover, this example shows that a unique factorization of the ring elements cannot be expected. However, Ore [23] has shown that the degree of similar polynomials coincide. The latter property is crucial for determining dimensions of solution spaces.

A proof and an interesting historical description of the following normal form can be found in [6, Chap. 8]. The proof is constructive, using elementary matrices and Euclidean division. So if the coefficients consist of real polynomials $\mathbb{R}[t]$, then it is possible to calculate a normal form by means of computer algebra.

THEOREM 2.1 (Teichmüller–Nakayama normal form). *Any $R(D) \in \mathcal{M}[D]^{g\times q}$ with $\mathrm{rk}_{\mathcal{M}[D]} R(D) = \ell$ can be factorized into*

$$R(D) = U(D)^{-1} \begin{bmatrix} I_{\ell-1} & 0 & 0 \\ 0 & r(D) & 0 \\ 0 & 0 & 0_{(g-\ell)\times(q-\ell)} \end{bmatrix} V(D)^{-1}, \tag{2.1}$$

where $U(D)$ and $V(D)$ are $\mathcal{M}[D]$-unimodular matrices of sizes g and q, respectively, and $r(D) \in \mathcal{M}[D]$ is nonzero, unique up to similarity, and of unique degree.

Remark 1. Let $R(D) \in \mathcal{M}[D]^{g\times q}$ and consider the factorization (2.1).

(i) Then we have, for almost all $t \in \mathbb{R}$,

$$\text{for all } w \in \mathcal{C}_t^\infty(\mathbb{R}^q): \left[w \in \ker_t R \iff w \in \ker_t \left(\left[\begin{array}{ccc|c} I_{\ell-1} & & & \\ & r & & 0_{\ell\times q} \end{array} \right] V^{-1} \right) \right].$$

Hence we may assume, without restriction of generality, that $R(D)$ has full row rank.

(ii) The set $\ker_t R$ becomes a *real vector space* if endowed, for $w_1, w_2 \in \ker_t R$, with addition

$$(w_1 + w_2)(\tau) := w_1(\tau) + w_2(\tau) \qquad \text{for all } \tau \in \operatorname{dom} w_1 \cap \operatorname{dom} w_2$$

and obvious scalar multiplication. The dimension of this vector space is defined as

$$\dim \ker_t R := \sup\left\{ k \in \mathbb{N} \;\middle|\; \exists\, w_1, \dots, w_k \in \ker_t R \text{ linearly independent on } \bigcap_{i=1}^{k} \operatorname{dom} w_i \right\}.$$

Furthermore,

$$\dim \ker_t R = \begin{cases} \deg r(D) & \text{for almost all } t \in \mathbb{R} \quad \text{if } \operatorname{rk} R(D) = q, \\ \infty & \text{for all } t \in \mathbb{R} \quad \text{if } \operatorname{rk} R(D) < q. \end{cases}$$

The latter is a simple consequence of (2.1) and the fact that the set of t where $r(\frac{\mathrm{d}}{\mathrm{d}t})\varphi(t) = 0$ does not have a solution is a subset of $\{t \in \mathbb{R} \mid r_N(t) = 0\}$, where $r(D) = \sum_{i=0}^{N} r_i(t) D^i$, $r_N \not\equiv 0$. To see this, use the canonical transformation to a vector-valued differential equation of first order; see, for example, [34, Chap. IV].

(iii) Let $\mathbb{T} = \mathbb{T}(R, U, V, r)$ denote the union of all zeros and poles of the meromorphic coefficients in all nonzero entries of $U(D)$, $U(D)^{-1}$, $V(D)$, $V(D)^{-1}$, and $r(D)$. Certainly, $\mathbb{T}$ is a discrete set which depends on the factorization and hence is not unique. $\mathbb{T}$ encompasses all possible critical points where a finite escape may occur (see the examples in subsection 1.3); however, $\mathbb{T}$ might be much larger. We gain system theoretic information from the normal form but may also hide information: consider, for example, a state space system of the form (1.3). Then this system does not have any critical points; however, taking it into a normal form may introduce a possibly nonempty set $\mathbb{T}$. It is an open problem to determine an algorithm for the transformation into the Teichmüller–Nakayama normal form which produces a "minimal" set $\mathbb{T}$.
However, there are situations where it is possible to determine a set including all critical points without invoking algebraic transformations, as in the Teichmüller–Nakayama normal form: For general linear and nonlinear descriptor systems, it has been shown in [16, 17, 18, 20] that for sufficiently often differentiable coefficient functions there exist invariants (corresponding to ranks of submatrices) which are independent of the choice of transformation matrices, and the set of points where these quantities jump includes all critical points.

(iv) If $R(D)$ is not left invertible, then the set of points where the local behavior is nontrivial, i.e., $\{t \in \mathbb{R} \mid \ker_t R \neq \{0\}\}$, is discrete.

Remark 2. Suppose that $R(D)$ has constant coefficients, i.e., $R(D) \in \mathbb{R}[D]^{g \times q}$.

(i) If the class of unimodular transformations for the computation of the normal form (2.1) is restricted to $\mathbb{R}[D]$-unimodular matrices, then we arrive at the Smith normal form

$$R(D) = U(D)^{-1} \begin{bmatrix} \operatorname{diag}\{r_1(D), \dots, r_l(D)\} & 0_{\ell \times (q-\ell)} \\ 0_{(g-\ell)\times \ell} & 0_{(g-\ell)\times(q-\ell)} \end{bmatrix} V(D)^{-1}, \tag{2.2}$$

where $U(D)$ and $V(D)$ are $\mathbb{R}[D]$-unimodular matrices of sizes g and q, respectively, and $r_i(D) \in \mathbb{R}[D]$ are nonzero monic polynomials with $r_i | r_{i+1}$, $i = 1, \dots, \ell - 1$, where $\ell = \operatorname{rk}_{\mathbb{R}[D]} R(D)$ and $r_i(D) = \psi_i(D)/\psi_{i-1}(D)$, $\psi_0(\cdot) \equiv 1$, and $\psi_i(D)$ is the greatest common divisor of minors of order i of $R(D)$; see, for example, [28, pp. 91–93].
Note that due to the smaller class of transformations, the Smith normal form is less simple than the Teichmüller–Nakayama normal form.

(ii) Suppose in addition that $\mathrm{rk}_{\mathbb{R}[D]} R(D) = q$. Then every local solution $w \in \mathcal{C}_t^N(\mathbb{R}^q)$ of $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$, where N is sufficiently large depending on $\deg R(D)$ and the degrees of the transformation matrices, can be continued to a global solution on $\mathbb{R}$ and is even real analytic. This follows immediately from the Smith normal form (2.2) and the theory of linear time-invariant differential equations. Therefore, we may identify $\ker_t R = \ker R$ for any $t \in \mathbb{R}$, and it follows that $\dim \ker_t R = \sum_{i=1}^{\ell} \deg r_i(D)$ for all $t \in \mathbb{R}$.

Remark 3. Suppose that $R(D) \in \mathcal{M}[D]^{g\times q}$ has full rank and $g \le q$. Let $R(D)$ be factorized as in (2.1) and differently into

$$R(D) = \bar{U}(D)^{-1} \left[\begin{array}{cc|c} I_{g-1} & & \\ & \bar{r}(D) & 0_{g\times(q-g)} \end{array}\right] \bar{V}(D)^{-1}. \tag{2.3}$$

Then a simple algebraic manipulation shows that

$$\bar{V}(D)^{-1} V(D) = \begin{bmatrix} W_1(D) & 0 \\ W_3(D) & W_4(D) \end{bmatrix}, \tag{2.4}$$

where $W_1(D) \in \mathcal{M}[D]^{g\times g}$ and $W_4(D) \in \mathcal{M}[D]^{(q-g)\times(q-g)}$ are unimodular, and where $W_3(D) \in \mathcal{M}[D]^{(q-g)\times g}$.

3. Controllability. In this section we introduce, study, and characterize the concept of controllability of systems (1.1). This is a generalization of the behavioral concept introduced by Willems [35]; see also [24].

DEFINITION 3.1. *Let $R(D) \in \mathcal{M}[D]^{g\times q}$ and $t \in \mathbb{R}$. A* local subbehavior $\mathfrak{B}_t$ *of* $\ker_t R$*, i.e., a subset $\mathfrak{B}_t \subset \ker_t R$, is called* locally controllable at $t \in \mathbb{R}$ *if and only if for every $w^1, w^2 \in \mathfrak{B}_t$ and every $t_0 \in (-\infty, t) \cap \mathrm{dom}\, w^1$ there exist $t_1 \in \mathrm{dom}\, w^2 \cap (t, \infty)$ and $w \in \mathfrak{B}_t$ such that*

$$w(t) = \begin{cases} w^1(t), & t \in (-\infty, t_0] \cap \mathrm{dom}\, w^1, \\ w^2(t), & t \in [t_1, \infty) \cap \mathrm{dom}\, w^2. \end{cases}$$

A behavior $\mathfrak{B} = \bigcup_{t\in\mathbb{R}} \mathfrak{B}_t$, $\mathfrak{B}_t \subset \ker_t R$, is called controllable almost everywhere *if and only if $\mathfrak{B}_t$ is locally controllable for almost all $t \in \mathbb{R}$. Since $\ker_t R$ is a real vector space by Remark* 1(ii)*, the family of its linear subspaces may be partially ordered by inclusion, and thus constitutes a lattice with respect to $+$ and $\cap$. Hence $\ker_t^{\mathrm{contr}} R \subset \ker_t R$ as* largest controllable local behavior *of $\ker_t R$ is well defined. The set $\ker^{\mathrm{contr}} R = \bigcup_{t\in\mathbb{R}} \ker_t^{\mathrm{contr}} R$ is called the* largest controllable behavior *of $\ker R$.*

This concept is illustrated in Figure 2.

Remark 4.

(i) Loosely speaking, controllability means that any two trajectories $w^1, w^2 \in \ker_t R$ can be connected by another trajectory $w \in \ker_t R$ so that in finite time w^1 moves via w into w^2. A similar notion of controllability via trajectories was introduced in [11] for time-invariant Rosenbrock systems of the form (1.5). For time-invariant state space systems of the form (1.3), the concept of controllability coincides with the one introduced in [24, sect. 5.2].

(ii) Since $\ker_t R$ is a linear subspace, the trajectory w^2 in Definition 3.1 may be replaced, without restriction of generality, by $w^2 = 0$.

We are now in position to prove the main theorem of this section, which characterizes controllability in algebraic terms. Recall that $R(D)$ is called *right invertible* if and only if there exists some $R^{\#}(D) \in \mathcal{M}[D]^{q\times g}$ such that $R(D)R^{\#}(D) = I_g$. In view of Remark 1(i) we assume that $R(D)$ has full row rank.

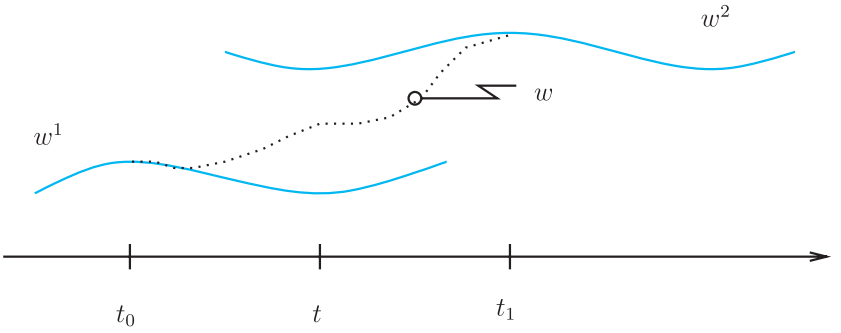

FIG. 2. *Local controllability at t.*

THEOREM 3.2. *Let $R(D) \in \mathcal{M}[D]^{g\times q}$ have full row rank. Then the behavior $\ker R$ is controllable almost everywhere if and only if $R(D)$ is right invertible.*

Proof. Suppose that $R(D)$ is factorized as in (2.1) and let $\mathbb{T} = \mathbb{T}(R, U, V, r)$ denote the discrete set given in Remark 1(iii). Then it remains to show that $\ker_t R$ is locally controllable at $t \in \mathbb{R} \setminus \mathbb{T}$ if and only if $r(D)$ is a nonzero meromorphic function.

"$\Rightarrow$": Suppose that $\deg r(D) \geq 1$ and $t \in \mathbb{R} \setminus \mathbb{T}$. By [34, Chap. IV] there exists an open interval $\mathbb{I} \subset \mathbb{R} \setminus \mathbb{T}$ with $t \in \mathbb{I}$ and some nonzero real analytic solution $\varphi : \mathbb{I} \to \mathbb{R}$ which solves $r(\frac{\mathrm{d}}{\mathrm{d}t})\varphi = 0$. By the construction of $\mathbb{T}$ and letting e_g denote the gth canonical basis vector in $\mathbb{R}^q$, it follows that

$$\hat{w}^1 := V(\tfrac{\mathrm{d}}{\mathrm{d}t})\, \varphi\, e_g \in \mathcal{C}^\omega(\mathbb{I}, \mathbb{R}^q)$$

and solves $R(\frac{\mathrm{d}}{\mathrm{d}t})\hat{w}^1 = 0$.

Seeking a contradiction, suppose that $\ker_t R$ were locally controllable at $t \in \mathbb{R}$. Let $t_0 \in (-\infty, t) \cap \mathbb{I}$. Then there exist $t_1 \in (t, \infty)$ and $w \in \ker_t R$ such that

$$w(t) = \begin{cases} w^1(t), & t \in (-\infty, t_0] \cap \operatorname{dom} w^1, \\ 0, & t \in [t_1, \infty). \end{cases} \tag{3.1}$$

Therefore,

$$\operatorname{diag}\big\{1, \ldots, 1, r(\tfrac{\mathrm{d}}{\mathrm{d}t}), 0, \ldots, 0\big\} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0 \qquad \text{for all } t \in \operatorname{dom} w,$$

which yields

$$V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w =: [0, \ldots, 0, \varphi_g, \ldots, \varphi_q]^T \in \mathcal{C}^\omega(\operatorname{dom} w, \mathbb{R}^q)$$

and $r(\frac{\mathrm{d}}{\mathrm{d}t})\varphi_g(t) = 0$ for all $t \in \operatorname{dom} w$. By (3.1) we have $\varphi_g(t) = 0$ for all $t \in [t_1, \infty)$, and since φ_g is real analytic, the identity property of real analytic functions gives $\varphi \equiv \varphi_g \equiv 0$, which is a contradiction.

"$\Leftarrow$": Let $t \in \mathbb{R} \setminus \mathbb{T}$, let $r(D)$ be meromorphic and nonzero, and let $w^1 \in \ker_t R$. Then there exists some open interval $\mathbb{I} := (\tau_0, \tau_1) \subset (\mathbb{R} \setminus \mathbb{T}) \cap \operatorname{dom} w^1$ with $t \in \mathbb{I}$ such that

$$w^1 =: V(\tfrac{\mathrm{d}}{\mathrm{d}t})\, [0, \ldots, 0, \varphi_{g+1}, \ldots, \varphi_q]^T \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^q).$$

Choose $\delta \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$ such that

$$\delta(t) = \begin{cases} 1, & t \leq \tau_0, \\ 0, & t \geq \tau_1. \end{cases}$$

Then

$$w := V(\tfrac{\mathrm{d}}{\mathrm{d}t})\,\delta\,[0,\dots,0,\varphi_{g+1},\dots,\varphi_q]^T \in \mathcal{C}^\infty(\mathbb{I},\mathbb{R}^q)$$

satisfies $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ and

$$w(t) = \begin{cases} w^1(t), & t \le \tau_0, \\ 0, & t \ge \tau_1. \end{cases}$$

This completes the proof. □

For time-invariant systems (1.1), Theorem 3.2 is derived differently in [24, Thm. 5.2.10].

Remark 5. For time-varying systems (1.3) or (1.5), it is well known that controllability of the system yields that it can be controlled in arbitrary short time. The proof of Theorem 3.2, in particular the choice of (τ_0,τ_1) and δ, shows that this is also valid for the behavior $\ker_t R$: If $\ker_t R$ is controllable, then $t_0 < t$ and $t_1 > t$ in Definition 3.1 can be replaced by any $t_0' < t < t_1'$ arbitrary close to t.

In the following remark we recall the classical concept of controllability for time-varying state space systems and clarify the set of admissible input functions.

Remark 6. Controllability for state space systems (1.3) means (see, for example, [33, Def. 3.1.6]) that for any $x^0, x^1 \in \mathbb{R}^n$ and $t_0 \in \mathbb{R}$, there exist $t_1 > t_0$ and a continuous function $u : [t_0,t_1] \to \mathbb{R}^m$ such that

$$x(t) = (Lu)(t) := \Phi(t,t_0)x^0 + \int_{t_0}^{t} \Phi(t,\tau)B(\tau)u(\tau)d\tau, \qquad t \in [t_0,t_1],$$

satisfies $x(t_1) = x^1$. Here Φ denotes the transition matrix of the homogeneous system $\dot{x} = Ax$.

Using the fact that the set of $\mathcal{C}^\infty$-functions with support in $[t_0,t_1]$ lies dense, with respect to the $\mathcal{L}^1$-norm, in the set of piecewise continuous functions with support included in $[t_0,t_1]$, it follows from a straightforward modification of the proof of Lemma A2 in [14] that, for all $t \in (t_0,t_1)$,

$$\begin{aligned}&\big\{(Lu)(t) \;\big|\; u \in \mathcal{C}^\infty((t_0,t_1),\mathbb{R}^m)\big\} \\ &\quad = \big\{(Lu)(t) \;\big|\; u : [t_0,t_1] \to \mathbb{R}^m \text{ piecewise continuous with } \operatorname{supp} u \subset [t_0,t_1]\big\}.\end{aligned}$$

Therefore, although in the original definition u is required to be continuous, we may choose, without any restriction of generality, $u \in \mathcal{C}^\infty(\mathbb{R},\mathbb{R}^m)$ with $\operatorname{supp} u \subset [t_0,t_1]$.

In the following proposition, it is shown how controllability encompasses other well-established controllability concepts.

PROPOSITION 3.3. *Consider a time-varying Rosenbrock system of the form* (1.5) *with corresponding* $R(D)$ *as defined in* (1.7)*, and suppose that* $R(D)$ *has full row rank. Then the following conditions are equivalent:*

(i) $\ker R$ *is controllable almost everywhere.*
(ii) $[P(D), -Q(D)]$ *is right invertible.*
(iii) $\ker[P,Q]$ *is controllable almost everywhere.*
(iv) (1.5) *is controllable in the sense defined in* [14].
(v) *If* $R(D)$ *represents a time-invariant Rosenbrock system* (1.5)*, then* (1.5) *is controllable in the sense defined in* [11].

(vi) *If $R(D)$ represents a state space system* (1.3) *with corresponding $R(D)$ as defined in* (1.7)*, then* (1.3) *is controllable in the classical sense as, for example, given in* [33, *Def.* 3.1.6].

Proof. The equivalences "(i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (iii)" follow from Theorem 3.2 and simple algebraic manipulations; "(ii) $\Leftrightarrow$ (iv)" follows from [14, Thm. 6.4]. "(ii) $\Leftrightarrow$ (v)" follows from [11, Cor. 7.3]. It remains to prove that the classical concept of controllability as given in Remark 6 is encompassed in the behavioral setup. It is easy to see that (iii) implies (vi), and we omit the proof. To prove the converse, suppose that (vi) holds. Then for given

$$(x^i, u^i) \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^n) \times \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m) \quad \text{such that } \tfrac{\mathrm{d}}{\mathrm{d}t}x^i(t) = A(t)x^i(t) + B(t)u^i(t), \quad i = 1, 2,$$

and given $t_0 \in \mathbb{R}$, we need to find

$$(x, u) \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^n) \times \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m), \quad \text{so that } \tfrac{\mathrm{d}}{\mathrm{d}t}x(t) = A(t)x(t) + B(t)u(t),$$

and $t_1 > t_0$ such that

$$(x(t), u(t)) = \begin{cases} \big(x^1(t), u^1(t)\big) & \text{for all } t \le t_0, \\ \big(x^2(t), u^2(t)\big) & \text{for all } t \ge t_1. \end{cases} \tag{3.2}$$

Let $\bar{x}^1 = x^1(t_0)$ and, for arbitrary but fixed $t_1 > t_0$, let $\bar{x}^2 = x^2(t_1)$. Then by (vi) we may choose $\widehat{u} \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ with $\operatorname{supp} \widehat{u} \subset [t_0, t_1]$ such that

$$x(t) = \Phi(t, t_0)\bar{x}_1 + \int_{t_0}^{t} \Phi(t, \tau)B(\tau)\widehat{u}(\tau)d\tau \qquad \text{satisfies} \quad x(t_2) = \bar{x}^2.$$

Define, for all $t \in \mathbb{R}$,

$$u(t) = \begin{cases} u^1(t) & \text{for all } t \le t_0, \\ \widehat{u}(t) & \text{for all } t \in (t_0, t_1), \\ u^2(t) & \text{for all } t \ge t_1 \end{cases} \quad \text{and} \quad x(t) = \Phi(t, t_0)\bar{x}_1 + \int_{t_0}^{t} \Phi(t, \tau)B(\tau)u(\tau)d\tau.$$

Then (x, u) satisfies $\dot{x} = Ax + Bu$ and (3.2). The function u is in general not infinitely many times differentiable at t_0 or at t_1, but applying Remark 6, one may replace $\widehat{u}$ so that $u \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$. This completes the proof. ∎

Next we study, for $R(D) \in \mathcal{M}[D]^{g\times q}$, the relationship between the local kernel representation $\ker_t R$ and the *local image representation* at $t \in \mathbb{R}$, i.e., for some $M(D) \in \mathcal{M}[D]^{q\times m}$, the real vector space

$$\operatorname{im}_t M := \{w \in \mathcal{C}_t^\infty(\mathbb{R}^q) \mid \exists\, l \in \mathcal{C}_t^\infty(\mathbb{R}^m) \text{ for all } \tau \in \operatorname{dom} w \cap \operatorname{dom} l : w(\tau) = M(\tfrac{\mathrm{d}}{\mathrm{d}t})\, l(\tau)\}.$$

PROPOSITION 3.4. *Let $R(D) \in \mathcal{M}[D]^{g\times q}$ have full row rank.* $\ker R$ *is controllable almost everywhere if and only if there exist $m \in \mathbb{N}$ and $M(D) \in \mathcal{M}[D]^{q\times m}$ such that* $\ker_t R = \operatorname{im}_t M$ *for almost all $t \in \mathbb{R}$.*

Proof. Suppose $R(D)$ is factorized as in (2.1) and let $\mathbb{T}$ denote the discrete set given in Remark 1. By Theorem 3.2 it remains to show that $r(D)$ is a nonzero meromorphic function if and only if $\ker_t R = \operatorname{im}_t M$ for all $t \in \mathbb{R} \setminus \mathbb{T}$.

"⇒": Set

$$M(D) := V(D) \begin{bmatrix} 0_{g\times(q-g)} \\ I_{q-g} \end{bmatrix}.$$

Then $\operatorname{im}_t M \subset \ker_t R$ for all $t \in \mathbb{R} \setminus \mathbb{T}$ is immediate. If $w \in \ker_t R$ for $t \in \mathbb{R} \setminus \mathbb{T}$, then $r(D)$ being nonzero and meromorphic yields

$$\left[I_g \;\middle|\; 0_{g\times(q-g)}\right] V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w(t) = 0 \qquad \text{for all } t \in \operatorname{dom} w \cap (\mathbb{R} \setminus \mathbb{T}),$$

and so there exists $l \in \mathcal{C}^\infty_t(\mathbb{R}^m)$ such that

$$V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = \begin{bmatrix} 0_{g\times(q-g)} \\ I_{(q-g)} \end{bmatrix} l.$$

"$\Leftarrow$": Let $t \in \mathbb{R} \setminus \mathbb{T}$ and choose an open interval $\mathbb{I} \subset (\mathbb{R} \setminus \mathbb{T})$ with $t \in \mathbb{I}$. Seeking a contradiction, by Theorem 3.2 one may assume that $\deg r(D) \geq 1$. Comparing the gth components of the identical vector spaces

$$\left\{ w \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^q) \;\middle|\; \left[\begin{array}{cc|c} I_{g-1} & & \\ & r(\frac{\mathrm{d}}{\mathrm{d}t}) & 0_{g\times(q-g)} \end{array}\right] V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0 \right\}$$

and $\{w \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^q) \mid \exists\, l \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^m) : w = M(\frac{\mathrm{d}}{\mathrm{d}t}) l\}$ yields that

$$\begin{aligned} \dim\{(V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w(t))_g \mid w \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^q) \wedge r(\tfrac{\mathrm{d}}{\mathrm{d}t})(V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w(t))_g = 0\} \\ = \dim\{(V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} M(\tfrac{\mathrm{d}}{\mathrm{d}t}) l(t))_g \mid l \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^m)\}. \end{aligned}$$

However, the former has finite dimension $\deg r(D) \geq 1$, while the latter is zero-dimensional or has infinite dimension. This is a contradiction, and hence the proof of the proposition is complete. □

Proposition 3.4 is known for time-invariant systems; see [24, Thm. 6.6.1]. However, the different proof presented here might also be of interest in the time-invariant case.

In the following proposition we show how to present the largest controllable behavior in terms of the nonunique factorization (2.1).

PROPOSITION 3.5. *If $R(D) \in \mathcal{M}[D]^{g\times q}$ is factorized as in* (2.1)*, then we have*

$$\ker_t^{\mathrm{contr}} R = \{w \in \ker_t R \,|\, [I_g, 0_{g\times(q-g)}] V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0\} \quad \textit{for almost all } t \in \mathbb{R}.$$

Proof. Since $[I_g, 0_{g\times(q-g)}]\, V(D)^{-1}$ is right invertible, it follows from Theorem 3.2 that

$$\ker_t^{\mathrm{c}} R := \{w \in \ker_t R \,|\, [I_g, 0] V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0\}$$

is a controllable behavior almost everywhere. Therefore, we have to show that $\ker_t^{\mathrm{contr}} R \subset \ker_t^{\mathrm{c}} R$ almost everywhere. Let $\mathbb{T}$ denote the union of all zeros and poles of the meromorphic coefficients in all entries of $U(D)$, $U(D)^{-1}$, $V(D)$, $V(D)^{-1}$, $r(D)$, $\bar{U}(D)$, $\bar{U}(D)^{-1}$, $\bar{V}(D)$, $\bar{V}(D)^{-1}$, and $\bar{r}(D)$. Then $\mathbb{T}$ is a discrete set. Let $w \in \ker_t^{\mathrm{contr}} R$ for $t \in \mathbb{R} \setminus \mathbb{T}$. Choose an open interval $\mathbb{I} \subset \mathbb{T}$ with $t \in \mathbb{I}$. Then

$$V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w =: [0, \ldots, 0, \varphi_g, \ldots, \varphi_q]^T \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R}^q) \quad \text{and} \quad r(\tfrac{\mathrm{d}}{\mathrm{d}t})\varphi_g = 0.$$

The function φ_g, as a solution of a linear ordinary differential equation with real analytic coefficients on $\mathbb{I}$, is real analytic on $\mathbb{I}$ itself. Therefore, the normal form (2.1) and the identity property of analytic function yields $\varphi_g \equiv 0$. This proves $w(t) = V(\frac{\mathrm{d}}{\mathrm{d}t})\,[0, \ldots, 0, \varphi_{g+1}, \ldots, \varphi_q]^T \in \ker_t^c R$.

If $R(D)$ is factorized as in (2.3), then by Remark 3 one concludes that

$$[I_g, 0]\,\bar{V}(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1}w = [I_g, 0]\begin{bmatrix} W_1(\frac{\mathrm{d}}{\mathrm{d}t}) & 0 \\ W_3(\frac{\mathrm{d}}{\mathrm{d}t}) & W_4(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1}w = [W_1(\tfrac{\mathrm{d}}{\mathrm{d}t}), 0]V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1}w,$$

and the result follows, since $W_1(D)$ is unimodular. This completes the proof. □

Example 1. Revisiting example (1.9), we now can show that this system is locally controllable almost everywhere.

Without loss of generality, we may assume that the coordinate system for the Lagrange multipliers is such that $F_0 = [F_1\, 0]$ with nonsingular $F_1 \in \mathbb{R}^{2\times 2}$, and we partition

$$-K_0 = \begin{bmatrix} K_{11}(t) & K_{12}(t) \\ K_{21}(t) & K_{22}(t) \end{bmatrix}, \quad M_0 = \begin{bmatrix} M_{11}(t) & M_{12}(t) \\ M_{21}(t) & M_{22}(t) \end{bmatrix}, \quad -D_0 = \begin{bmatrix} D_{11}(t) & D_{12}(t) \\ D_{21}(t) & D_{22}(t) \end{bmatrix},$$

and

$$S_0 = \begin{bmatrix} S_1 \\ S_2 \end{bmatrix},$$

with $K_{11}(t), M_{11}(t), D_{11}(t), \in \mathbb{R}^{2\times 2}$, $S_1 \in \mathbb{R}^{2\times 3}$, and all other formats accordingly. Then the system (1.9), for $t \in \mathbb{I}$, may be written as

$$\begin{bmatrix} I_2 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & M_{11}(t) & M_{12}(t) & 0 \\ 0 & 0 & M_{21}(t) & M_{22}(t) & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \\ \dot{x}_5 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & 0 & I_2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ K_{11}(t) & K_{12}(t) & D_{11}(t) & D_{12}(t) & F_1^T \\ K_{21}(t) & K_{22}(t) & D_{21}(t) & D_{22}(t) & 0 \\ F_1 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ S_1 \\ S_2 \\ 0 \end{bmatrix} u.$$

Since F_1 is nonsingular and S_1, S_2 are constant matrices of full row rank, it follows that $x_1 = 0$ and $\dot{x}_1 = 0$, whence $x_3 = 0$. Therefore, (1.9) is equivalent to

$$\begin{bmatrix} D & -1 & 0_{2\times 1} & 0 \\ -K_{12}(t) & M_{12}(t) & -F_1 & S_1 \\ -K_{22}(t) & M_{22}(t) & 0 & S_2 \end{bmatrix} \begin{bmatrix} x_2 \\ x_4 \\ x_5 \\ u \end{bmatrix} = 0,$$

with corresponding right invertible matrix $R(D)$. By Theorem 3.2, the system (1.9) is locally controllable almost everywhere on $\mathbb{I}$.

4. Autonomous behavior. In this section we show that the local behavior (in the sense almost everywhere) can be decomposed into the direct sum of the controllability subspace and an autonomous subspace.

DEFINITION 4.1. *Let $R(D) \in \mathcal{M}[D]^{g\times q}$ and $t \in \mathbb{R}$. A local subbehavior $\mathfrak{B}_t \subset \ker_t R$ is called* autonomous *if and only if for any $w^1, w^2 \in \mathfrak{B}_t$ with $w^1 \equiv w^2$ on some open interval $\mathbb{I} \subset \operatorname{dom} w^1 \cap \operatorname{dom} w^2$ with $t \in \mathbb{I}$ it follows that $w^1 \equiv w^2$ on $\operatorname{dom} w^1 \cap \operatorname{dom} w^2$.*

A behavior $\mathfrak{B} = \bigcup_{t\in\mathbb{R}} \mathfrak{B}_t \subset \ker_t R$ *is called* autonomous *if and only if* $\mathfrak{B}_t$ *is autonomous for almost all* $t \in \mathbb{R}$.

The above definition is a generalization of autonomous subbehavior of time-invariant systems as, for example, defined in [24, p. 67].

PROPOSITION 4.2. *Consider* $R(D) \in \mathcal{M}[D]^{g\times q}$ *with factorization* (2.1) *and* $\operatorname{rk} R(D) = g$. *Then for any autonomous behavior* $\ker^{\mathrm{aut}} R$, *the following properties hold:*

(i) $\ker_t^{\mathrm{aut}} R \cap \ker_t^{\mathrm{contr}} R = \{0\}$ *for almost all* $t \in \mathbb{R}$.

(ii) *If* $w \in \ker_t^{\mathrm{aut}} R$, *then*

$$\begin{bmatrix} I_{g-1} & \\ & r(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0.$$

(iii)

$$\left\{ w \in \mathcal{C}_t^\infty(\mathbb{R}^q) \;\middle|\; \begin{bmatrix} I_{g-1} & \\ & r(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0 \right\}$$

is an autonomous behavior for almost all $t \in \mathbb{R}$.

(iv) *The behavior* $\ker R$ *is autonomous if and only if* $R(D)$ *has full column rank.*

Proof. (i) If $w \in \ker^{\mathrm{aut}} R$ and $w \not\equiv 0$, then it cannot belong to the controllable behavior; otherwise Definition 4.1 would be violated.

(ii) By (i) and Proposition 3.5, any $w \in \ker_t^{\mathrm{aut}} R$ satisfies $[0_{(q-g)\times g}, I_{q-g}] V(\frac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0$. Hence (ii) follows from (2.1).

(iii) Let $\mathbb{T}$ denote the discrete set given in Remark 1 and let $t \in \mathbb{R}\setminus\mathbb{T}$. If $w \in \ker_t R$ and satisfies

$$\begin{bmatrix} I_{g-1} & \\ & r(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0,$$

then (2.1) yields that w is of the form

$$w = V(\tfrac{\mathrm{d}}{\mathrm{d}t})\, [0, \ldots, 0, \varphi_g, 0, \ldots, 0]^T$$

for some $\varphi_g \in \mathcal{C}_t^\infty(\mathbb{R})$ with $r(\frac{\mathrm{d}}{\mathrm{d}t})\varphi_g = 0$. Since r has real analytic coefficients, the solution is real analytic, too, and the identity property of real analytic functions ensures local uniqueness of w as in Definition 4.1. This completes the proof.

(iv) This statement follows immediately from the definition and from Theorem 2.1. ∎

Note that the representation of the autonomous behavior in Proposition 4.2(iii) is not uniquely defined; it depends on the factorization (2.1). This holds true already for time-invariant systems; see [24, Rem. 5.2.15]. However, the dimension of this autonomous behavior is unique; this follows from the fact that $r(D)$ is unique up to similarity, and the latter preserves the degree; see Theorem 2.1. For time-invariant systems (1.1), the results of Proposition 4.2 can be found in [24, sect. 5.2]. More importantly, the sum of an autonomous behavior and the controllable behavior is indeed uniquely defined. In the following we generalize this result to time-varying systems.

THEOREM 4.3. *Consider the system* $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ *with* $R(D) \in \mathcal{M}[D]^{g\times q}$ *and* $\operatorname{rk} R(D) = g$, *factorizations* (2.1), (2.3), *and define, for all* $t \in \mathbb{R}$,

$$\ker_t^{\mathrm{contr}} R = \{w \in \ker_t R \mid \begin{bmatrix} I_g, & 0_{g\times(q-g)} \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0\},$$

$$\ker_t^{\mathrm{aut}} R = \left\{ w \in \ker_t R \;\middle|\; \begin{bmatrix} I_{g-1} & \\ & r(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0 \right\},$$

$$\overline{\ker}_t^{\mathrm{aut}} R = \left\{ w \in \ker_t R \;\middle|\; \begin{bmatrix} I_{g-1} & \\ & \bar{r}(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} \bar{V}(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0 \right\},$$

where the latter is defined with respect to (2.3). *Then*

$$\ker_t R = \ker_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R = \overline{\ker}_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R \quad \textit{for almost all } t \in \mathbb{R}. \tag{4.1}$$

Proof. Let $\mathbb{T}$ denote the union of all zeros and poles of the meromorphic coefficients in all entries of $U(D)$, $U(D)^{-1}$, $V(D)$, $V(D)^{-1}$, $r(D)$ and $\bar{U}(D)$, $\bar{U}(D)^{-1}$, $\bar{V}(D)$, $\bar{V}(D)^{-1}$, $\bar{r}(D)$. $\mathbb{T}$ is a discrete set. In the following we consider $t \in \mathbb{R} \setminus \mathbb{T}$ and an open interval $\mathbb{I} \subset \mathbb{T}$ with $t \in \mathbb{I}$. We proceed in several steps.

Step 1. By Proposition 4.2(i) the sums in (4.1) are direct sums.

Step 2. The inclusion

$$\ker_t R \supset \ker_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R$$

follows from the definition of $\ker_t^{\mathrm{aut}} R$ and $\ker_t^{\mathrm{contr}} R$.

Step 3. We show

$$\ker_t R \subset \ker_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R. \tag{4.2}$$

Let $w \in \ker_t R$ and set

$$[\varphi_1, \dots, \varphi_q]^T := V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w \in \mathcal{C}^\infty(\mathbb{I}; \mathbb{R}^q).$$

Then

$$\begin{bmatrix} I_{g-1} & \\ & r(\frac{\mathrm{d}}{\mathrm{d}t}) \end{bmatrix} V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = 0,$$

and hence

$$[\varphi_1, \dots, \varphi_q]^T = [0, \dots, 0, \varphi_g, 0, \dots, 0]^T \quad \text{with } r(\tfrac{\mathrm{d}}{\mathrm{d}t})\varphi_g = 0.$$

Finally

$$w_1 := V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} [0, \dots, 0, \varphi_g, 0, \dots, 0]^T \in \ker_t^{\mathrm{aut}} R,$$
$$w_2 := V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} [0, \dots, 0, \varphi_{g+1}, \dots, \varphi_q]^T \in \ker_t^{\mathrm{contr}} R$$

yields $w_1 + w_2 = w$, whence (4.2).

Step 4. We show

$$\ker_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R \subset \overline{\ker}_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R.$$

Let $w_1 \in \ker_t^{\mathrm{aut}} R$ and $w_2 \in \ker_t^{\mathrm{contr}} R$. Then

$$[0, \dots, 0, \varphi_g, 0, \dots, 0]^T := V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w_1 \in \mathcal{C}^\infty(\mathbb{I}; \mathbb{R}^q) \quad \text{with } r(\tfrac{\mathrm{d}}{\mathrm{d}t})\varphi_g = 0,$$
$$[0, \dots, 0, \varphi_{g+1}, \dots, \varphi_q]^T := V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w_2 \in \mathcal{C}^\infty(\mathbb{I}; \mathbb{R}^q).$$

Since $w := w_1 + w_2 \in \ker_t R$, it follows from (2.3) that

$$\bar{V}(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} w = [0, \dots, 0, \bar{\varphi}_g, \dots, \bar{\varphi}_q]^T \in \mathcal{C}^\infty(\mathbb{I}; \mathbb{R}^q) \quad \text{with } r(\tfrac{\mathrm{d}}{\mathrm{d}t})\bar{\varphi}_g = 0.$$

Finally, setting

$$\bar{w}_1 := \bar{V}(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} [0, \dots, 0, \bar{\varphi}_g, 0, \dots, 0]^T \in \overline{\ker}^{\mathrm{aut}} R,$$
$$\bar{w}_2 := \bar{V}(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} [0, \dots, 0, \bar{\varphi}_{g+1}, \dots, \bar{\varphi}_q]^T \in \overline{\mathfrak{B}}_R^{\mathrm{contr}}$$

shows $w = \bar{w}_1 + \bar{w}_2 \in \overline{\ker}_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R$.

Step 5. The inclusion

$$\ker_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R \supset \overline{\ker}_t^{\mathrm{aut}} R \oplus \ker_t^{\mathrm{contr}} R$$

follows by symmetry as in Step 4. This completes the proof of the theorem. ∎

5. Observability. In this section, we study how one behavior can be observed from another. Essential for this are the concepts of adjoints of matrices over $\mathcal{M}[D]$ and the adjoint of a kernel representation $\ker R$.

Definition 5.1. *The* adjoint *for matrices over $\mathcal{M}[D]$ is defined as*

$$.^{\mathrm{ad}} : \mathcal{M}^{n\times m}[D] \to \mathcal{M}^{m\times n}[D], \qquad \sum_{i=0}^{k} P_i D^i \mapsto \left(\sum_{i=0}^{k} P_i D^i\right)^{\mathrm{ad}} := \sum_{i=0}^{k} (-1)^i D^i P_i^T.$$

Proposition 5.2. *The adjoint is an anti-isomorphism; i.e., it is surjective, injective, and satisfies, for arbitrary matrices $P(D), Q(D)$ over $\mathcal{M}[D]$ with appropriate formats,*

$$[P(D) + Q(D)]^{\mathrm{ad}} = P(D)^{\mathrm{ad}} + Q(D)^{\mathrm{ad}}, \tag{5.1}$$
$$[P(D) \cdot Q(D)]^{\mathrm{ad}} = Q(D)^{\mathrm{ad}} \cdot P(D)^{\mathrm{ad}}. \tag{5.2}$$

Proof. Surjectivity, injectivity, and addition are straightforward. It remains to prove the antimultiplication rule (5.2). This is well known in the scalar case; see, for example, [21, p. 25]. To prove the matrix case, denote the entries of $P(D) \in \mathcal{M}^{n\times m}[D]$, $Q(D) \in \mathcal{M}^{m\times l}[D]$ by $p_{ij}(D)$, $q_{ij}(D)$, respectively. Then

$$P(D)^{\mathrm{ad}} = \big(p_{ji}(D)^{\mathrm{ad}}\big)_{1\le i\le n,\, 1\le j\le m}, \qquad Q(D)^{\mathrm{ad}} = \big(q_{ji}(D)^{\mathrm{ad}}\big)_{1\le i\le m,\, 1\le j\le l}$$

and applying this to

$$\big(P(D)\cdot Q(D)\big)_{ij} = \sum_{\lambda=1}^{k} p_{i\lambda}(D) q_{\lambda j}(D)$$

and using the antimultiplication rule (5.2) for scalar polynomials yield the result. This completes the proof. ∎

Definition 5.3. *Let $R(D) \in \mathcal{M}[D]^{g\times q}$ and let $t \in \mathbb{R}$. The* local adjoint *of the kernel representation $\ker_t R$ is the image representation $\mathrm{im}_t R^{\mathrm{ad}}$, i.e., $(\ker_t R)^{\mathrm{ad}} = \mathrm{im}_t R^{\mathrm{ad}}$.*

Certainly, the projection onto the first q components of the kernel representation

$$\left\{ (\tilde{w}, l) \in \mathcal{C}_t^\infty(\mathbb{R}^q) \times \mathcal{C}_t^\infty(\mathbb{R}^g) \;\middle|\; \text{for all } \tau \in \mathrm{dom}\,\tilde{w} \cap \mathrm{dom}\, l : \left[I_q, R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})^{\mathrm{ad}} \right] \begin{bmatrix} \tilde{w}(\tau) \\ l(\tau) \end{bmatrix} = 0 \right\}$$

yields the image representation $\operatorname{im}_t R^{\mathrm{ad}}$.

The following definition is a straightforward generalization of observability for time-invariant systems in the behavioral setup; see [24, Def. 5.3.2].

DEFINITION 5.4. *Let* $[R_1(D), R_2(D)] \in \mathcal{M}[D]^{g\times(q_1+q_2)}$ *and let* $t \in \mathbb{R}$. *Then* $w_2 \in \mathcal{C}_t^\infty(\mathbb{R}^{q_2})$ *is called* locally observable at $t \in \mathbb{R}$ from $w_1 \in \mathcal{C}_t^\infty(\mathbb{R}^{q_1})$ *for* $t \in \mathbb{R}$ *if and only if*

$$\begin{bmatrix} w_1 \\ w_2 \end{bmatrix}, \begin{bmatrix} w_1 \\ \tilde{w}_2 \end{bmatrix} \in \ker_t [R_1, R_2]$$

implies that

$$\text{for all } \tau \in \operatorname{dom} w_2 \cap \operatorname{dom} \tilde{w}_2 : w_2(\tau) = \tilde{w}_2(\tau).$$

An algebraic characterization of observability is given in the following theorem.

THEOREM 5.5. *Let* $[R_1(D), R_2(D)] \in \mathcal{M}[D]^{g\times(q_1+q_2)}$. *Then* w_2 *is locally observable almost everywhere from* w_1 *if and only if* $R_2(D)$ *is left invertible.*

Proof. First note that in view of the linearity of the system, it remains to show that for almost all $t \in \mathbb{R}$ we have

$$\big[w_2 \in \ker_t R_2 \implies w_2 = 0\big] \iff R_2(D) \text{ is left invertible.}$$

"$\Leftarrow$" is immediate.

"$\Rightarrow$": Let $\mathbb{T}$ denote the discrete set of the union of all zeros and poles of the meromorphic coefficients in all entries of $U_2(D), U_2(D)^{-1}, V_2(D), V_2(D)^{-1}, r_2(D)$ which take $R_2(D)$ into a normal form (2.1).

Seeking a contradiction, suppose $R_2(D)$ is not left invertible and let $t \in \mathbb{T}$. Now either $\operatorname{rk}_{\mathcal{M}[D]} R_2(D) < q_2$ (in which case the normal form (2.1) applied to $R_2(D)$ yields the existence of some $w_2 \in \ker_t R_2$ with $w_2 \neq 0$) or, again by Theorem 2.1, there exist $r_2(D) \in \mathcal{M}[D]$ with $\deg r_2(D) \geq 1$ and unimodular $U_2(D) \in \mathcal{M}[D]^{g\times g}$, $V_2(D) \in \mathcal{M}[D]^{q_2\times q_2}$ such that

$$U_2(D)^{-1} R_2(D) V_2(D)^{-1} = \begin{bmatrix} I_{q_2-1} & 0_{(q_2-1)\times 1} \\ 0_{1\times(q_2-1)} & r_2(D) \\ 0_{(g-q_2)\times(q_2-1)} & 0 \end{bmatrix}. \tag{5.3}$$

By $\deg r_2(D) \geq 1$ there exists $\varphi \in \mathcal{C}_t^\infty(\mathbb{R})\backslash\{0\}$ such that $r_2(\frac{\mathrm{d}}{\mathrm{d}t})\varphi = 0$. Therefore $w_2 := (0, \ldots, 0, \varphi)^T \in \ker_t R_2$, which is a contradiction. This completes the proof. ∎

The following theorem relates the concepts of controllability and observability.

THEOREM 5.6. *For* $R(D) \in \mathcal{M}[D]^{g\times q}$ *the following two statements are equivalent:*

(i) *The behavior* $\ker R$ *is locally controllable almost everywhere.*

(ii) *The variable* l *is locally observable almost everywhere from* w *with respect to the behavior induced by*

$$\big[I_q, R^{\mathrm{ad}}\big] \begin{pmatrix} w \\ l \end{pmatrix} = 0.$$

Proof. By Theorem 3.2, statement (i) is equivalent to $R(D)$ being right invertible, which, by Proposition 5.2, is equivalent to $R(D)^{\mathrm{ad}}$ being left invertible. The latter is, by invoking Proposition 5.5, equivalent to assertion (ii). This completes the proof of the theorem. ∎

In order to relate the classical concepts of observability known in the literature to observability as introduced above, we have to permute the columns in the presentation (1.5), (1.7) in the following proposition.

PROPOSITION 5.7. *For a time-varying Rosenbrock system of the form* (1.5) *represented in the form*

$$R(D) = [R_1(D), R_2(D)], \quad R_1(D) = \begin{bmatrix} -Q(D), & 0 \\ W(D), & -I_p \end{bmatrix}, \quad R_2(D) = \begin{bmatrix} P(D) \\ V(D) \end{bmatrix},$$

the following conditions are equivalent:

(i) *w_2 is locally observable from w_1 almost everywhere with respect to the behavior induced by*

$$\left[R_1(\tfrac{\mathrm{d}}{\mathrm{d}t}), R_2(\tfrac{\mathrm{d}}{\mathrm{d}t})\right] \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = 0.$$

(ii) *$R_2(D)$ is left invertible.*

(iii) *$[R_1(D), R_2(D)]$ is observable in the sense defined in* [14].

(iv) *If $R(D)$ represents a time-invariant Rosenbrock system, then it is observable in the sense defined in* [11].

(v) *If $R(D)$ represents a state space system* (1.3) *in the form*

$$R_1(D) = \begin{bmatrix} -B & 0 \\ -F & I_p \end{bmatrix}, \qquad R_2(D) = \begin{bmatrix} DI_n - A \\ -C \end{bmatrix},$$

then it is observable in the classical sense; see, for example, [30].

Proof. The equivalence "(i) $\Leftrightarrow$ (ii)" follows from Theorem 5.5. The equivalences "(ii) $\Leftrightarrow$ (iii)" and "(ii) $\Leftrightarrow$ (iv)" follow from [14, Thm. 6.5] and [11, Cor. 7.6], respectively. They all can be shown directly, but only for state space systems we prove "(i) $\Leftrightarrow$ (v)" directly; it shows how observability in the classical sense and in the behavioral setup are related. Note that in the case of time-varying state space systems and time-invariant Rosenbrock systems the set of critical points $\mathbb{T}$ is empty, and the system is defined on the whole time axis.

Complete observability for time-varying state space systems of the form (1.3) means (see [30, Def. 9.7]) that for any open interval $\mathbb{I} \subset \mathbb{R}$ we have

$$\begin{bmatrix} \frac{\mathrm{d}}{\mathrm{d}t} I_n - A(t) \\ -C(t) \end{bmatrix} z(t) = 0 \quad \text{for all } t \in \mathbb{I} \qquad \Longrightarrow \qquad z(t) = 0 \quad \text{for all } t \in \mathbb{I}. \tag{5.4}$$

(5.4) is equivalent to $R_2(D)$ being left invertible, and hence "(i) $\Leftrightarrow$ (v)" follows from Theorem 5.5. This completes the proof of the theorem. ∎

Example 2. Revisiting Example 1, see also (1.9), with

$$C = \begin{bmatrix} 0 & 0 & I_2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix} \tag{5.5}$$

corresponding to measuring the positions, we see that the resulting matrix

$$\begin{bmatrix} E(t)D - A(t) \\ C \end{bmatrix}$$

is left invertible if and only if the matrix

$$\begin{bmatrix} D & -1 & 0 \\ -K_{12}(t) & M_{12}(t)D & -F_1 \\ -K_{22}(t) & M_{22}(t)D & 0 \end{bmatrix}$$

is left invertible over the ring $\mathcal{M}[D]$, which holds if and only if $K_{22}(t)$ is nonzero. The latter is typically the case in practice, since the stiffness matrix $K_0(t)$ is symmetric and positive definite. An application of Theorem 5.5 yields the following: x is locally observable from (u, y) at t with respect to the system (1.9), (5.5) if and only if $K_{22}(t)$ is nonzero.

6. Latent variables and elimination. In [24, sect. 6.2], full and manifest behavior is considered for time-invariant systems. We do not repeat these definitions for time-varying systems but show a time-varying version of the crucial Theorem 6.2.6 in [24].

THEOREM 6.1. *Let* $[R(D), S(D)] \in \mathcal{M}[D]^{g\times(q+s)}$. *Then there exists* $R'(D) \in \mathcal{M}[D]^{g'\times q}$ *such that, for almost all* $t \in \mathbb{R}$,

$$\ker_t R' = \{w \in \mathcal{C}^\infty_t(\mathbb{R}^q) \mid \exists\, l \in \mathcal{C}^\infty_t(\mathbb{R}^q) \text{ for all } \tau \in \operatorname{dom} w \cap \operatorname{dom} l : R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = S(\tfrac{\mathrm{d}}{\mathrm{d}\tau})l(\tau)\}. \tag{6.1}$$

Proof. By Theorem 2.1, there exists some unimodular $U(D) \in \mathcal{M}[D]^{g\times g}$ such that

$$U(D)R(D) = \begin{bmatrix} R'(D) \\ R''(D) \end{bmatrix}, \qquad U(D)S(D) = \begin{bmatrix} 0 \\ S''(D) \end{bmatrix},$$

where $R'(D) \in \mathcal{M}[D]^{g'\times q}$, $R''(D) \in \mathcal{M}[D]^{g''\times q}$, $S''(D) \in \mathcal{M}[D]^{g''\times s}$, and $\operatorname{rk}_{\mathcal{M}[D]} S''(D) = g''$.

Applying Theorem 2.1 again, there exist $\mathcal{M}[D]$-unimodular matrices $U(D)$ and $V(D)$ of sizes g'' and s, and $r(d) \in \mathcal{M}[D]$ such that

$$S''(D) = U(D)^{-1} \left[\begin{array}{cc|c} I_{g''-1} & 0 & \\ 0 & r(D) & 0_{g''\times(q-g'')} \end{array}\right] V(D)^{-1}.$$

Choose $\mathbb{T}$ as the discrete set of the union of all zeros and poles of the meromorphic coefficients in all entries of $U(D), V(D), U(D)^{-1}, V(D)^{-1}, r(D)$. Let $\mathbb{I}$ be an open interval with $\mathbb{I} \subset \mathbb{R} \setminus \mathbb{T}$ and $t \in \mathbb{I}$.

Then, for all $\tau \in \mathbb{I}$,

$$R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = S(\tfrac{\mathrm{d}}{\mathrm{d}\tau})l(\tau) \iff \begin{bmatrix} R'(\frac{\mathrm{d}}{\mathrm{d}\tau}) & 0 \\ R''(\frac{\mathrm{d}}{\mathrm{d}\tau}) & S''(\frac{\mathrm{d}}{\mathrm{d}\tau}) \end{bmatrix} \begin{bmatrix} w(\tau) \\ l(\tau) \end{bmatrix}.$$

Hence the inclusion "$\supset$" in (6.1) is obvious. To show "$\subset$" in (6.1), let $w \in \ker_t R'$ for $t \in \mathbb{I}$. Let $\tilde{l}_{g''} \in \mathcal{C}^\infty(\mathbb{I}, \mathbb{R})$ denote the solution of

$$r\big(\tfrac{\mathrm{d}}{\mathrm{d}\tau}\big)\tilde{l}_{g''}(\tau) = \big(U\big(\tfrac{\mathrm{d}}{\mathrm{d}\tau}\big)S''\big(\tfrac{\mathrm{d}}{\mathrm{d}\tau}\big)w(\tau)\big)_{g''} \qquad \text{on } \mathbb{I}.$$

This solution exists; see, for example, [34, Chap. IV]. Setting

$$l := V[0, \ldots, 0, \tilde{l}_{g''}]^T$$

yields

$$U(\tfrac{\mathrm{d}}{\mathrm{d}\tau})R''(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tfrac{\mathrm{d}}{\mathrm{d}\tau}) = \left[\begin{array}{cc|c} I_{g''-1} & 0 & \\ 0 & r(D) & 0_{g''\times(q-g'')} \end{array}\right] V(\tfrac{\mathrm{d}}{\mathrm{d}t})^{-1} l(\tau),$$

which is equivalent to $R(\frac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = S(\frac{\mathrm{d}}{\mathrm{d}\tau})l(\tau)$. This completes the proof of the theorem. ∎

As an "inverse" to Proposition 3.4, we show that any image representation of a behavior may be written as a kernel representation.

COROLLARY 6.2. *Let $M(D) \in \mathcal{M}[D]^{q\times m}$. Then there exist $g \in \mathbb{N}$ and $R'(D) \in \mathcal{M}[D]^{g\times q}$ such that*

$$\mathrm{im}_t\, M = \ker_t R' \qquad \textit{for almost all} \quad t \in \mathbb{R}.$$

Proof. Apply Theorem 6.1 to $[R(D), S(D)] = [I_q, M(D)]$. ∎

Acknowledgment. We are indebted to Jan C. Willems and anonymous referees for their constructive criticisms of an earlier version of this paper.

While the results of the present paper were reviewed, Eve Zerz [42] wrote, based on our findings, a much more elegant algebraic approach where she partially achieves the present results with shorter proofs and also characterizes behaviors included in each other.

A BEHAVIORAL APPROACH TO TIME-VARYING LINEAR SYSTEMS. PART 2: DESCRIPTOR SYSTEMS*

ACHIM ILCHMANN† AND VOLKER MEHRMANN‡

Abstract. In the sequel to [A. Ilchmann and V. Mehrmann, *SIAM J. Control Optim.*, 44 (2005), pp. 1725–1747], we discuss a behavioral approach for linear, time-varying, differential algebraic (descriptor) systems with real analytic coefficients. The analysis is "almost global" in the sense that the analysis is not restricted to an interval $\mathbb{I} \subset \mathbb{R}$ but is allowed for the "time axis" $\mathbb{R}\setminus\mathbb{T}$, where $\mathbb{T}$ is a discrete set of critical points, at which the solution may exhibit a finite escape time. Controllable, observable, and autonomous behavior for linear time-varying descriptor systems is characterized.

Key words. time-varying linear systems, descriptor systems, behavioral approach, controllability, observability, autonomous system

1. Introduction. In [12], a behavioral approach was developed for linear time-varying systems with real analytic coefficients. In this paper, this approach will be studied for the specific case of linear time-varying descriptor systems described by differential-algebraic equations of the form

$$\begin{array}{rcl} E(t)\,\dot{x}(t) &=& A(t)x(t) \;+\; B(t)u(t), \\ y(t) &=& C(t)x(t) \;+\; F(t)u(t), \end{array} \tag{1.1}$$

with real analytic matrices $A \in \mathcal{A}^{l\times n}$, $B \in \mathcal{A}^{l\times m}$, $C \in \mathcal{A}^{p\times n}$, $F \in \mathcal{A}^{p\times m}$, where $E \in \mathcal{A}^{l\times n}$ is allowed to be singular in the sense that rk $E(t) < \min\{l, n\}$ for some $t \in \mathbb{R}$. Throughout this paper, the nomenclature as introduced and listed in [12] will be used.

As in [12], we make use of the skew-polynomial rings $\mathcal{A}[D]$ and $\mathcal{M}[D]$ (see [6, 13]) of differential polynomials with coefficients in $\mathcal{A}$, $\mathcal{M}$, respectively, and indeterminate D representing the differential operator $\frac{\mathrm{d}}{\mathrm{d}t}$, and the multiplication rule $Df = fD + \dot{f}$. The algebraic object

$$R(D) = \sum_{i=0}^{n} R_i D^i \in \mathcal{M}[D]^{g\times q} \cong \mathcal{M}^{g\times q}[D]$$

acts on $\mathcal{C}^\infty$-functions w via

$$R(\tfrac{\mathrm{d}}{\mathrm{d}t})w(t) = \sum_{i=0}^{n} R_i(t) w^{(i)}(t)\,.$$

In this notation, time-varying descriptor systems (1.1) may be rewritten as

$$R(\tfrac{\mathrm{d}}{\mathrm{d}t})w = 0, \tag{1.2}$$

where

$$R(D) = \begin{bmatrix} ED - A & -B & 0 \\ -C & -F & I_p \end{bmatrix}, \quad \text{and} \quad w = \left[x^T, u^T, y^T\right]^T.$$

Systems of differential algebraic equations (often called descriptor systems) play an important role in modelling and control of multibody systems, electric circuits, or coupled systems of partial differential equations; see [1, 9].

The analysis of the behavior of (1.1) has to cope with three essential difficulties. First, the solutions of time-varying systems may exhibit critical points, i.e., a finite escape time. Second, descriptor systems behave quite differently from classical state space systems (i.e., $E = I_n$ in (1.1)). For state space systems, the function $u(\cdot)$ can be considered as an input function free to choose, and initial conditions can be arbitrary. This is in general not true for descriptor systems (1.1), since descriptor systems may contain algebraic constraints, which restrict the solutions, the set of possible inputs, and also the initial values to some manifold. Third, some of the constraints that arise (the hidden constraints) are not explicit and thus it is not clear how to choose the underlying spaces for the descriptor variables x, u, y. Finally, the analytic property of the solution or behavior is local, which is in contrast to the global algebraic properties of $R(D)$. These difficulties are illustrated by the following example.

Example 1.

(i) The scalar differential equations $t\dot{x} = -x$, $t^2\dot{x} = -x$, $t\dot{x} = x$, have local solutions $t \mapsto t^{-1}, e^{1/t}, t$, respectively. Hence at $t = 0$ the solution might be rational with a pole, not even analytic, or does not have any pole, respectively.

(ii) The variables $x_1, \ldots, x_4, u_1, u_2$ of the descriptor system (1.1) with

$$E = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \; A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \; B = \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix},$$
$$C = \begin{bmatrix} 0 & 0 & 0 & 1 \end{bmatrix}, \; F = 0_{1\times 2}$$

satisfy the equivalent description

$$u_2 = 0, \; \dot{x}_2 = x_1, \; y = x_4, \; \dot{x}_3 = x_2 + u_1.$$

Thus, u_2 is constrained to be 0 and cannot be freely chosen, as it could in the case of state space systems. The variables x_1 and x_4 can be viewed as input or state variables; the system description does not determine this.

Note also that if we choose the input u_1 as a step function, then either x_3 is chosen as input as well to compensate the delta distribution in u_1 (since $x_1 = \dot{x}_2 = \ddot{x}_3 - \dot{u}_1$), or we may have to enlarge the solution space to allow that x_1 is a delta distribution. But even if we do so, then we have the problem that x_1 is not observable from the output y, which means that internally the system has impulsive parts of the solution, which are not observed. For many types of practical systems, such as, for example, mechanical systems, this would be a disaster: impulses in the solution cannot be tolerated. □

Example 1 indicates that the behavioral viewpoint, where state-, output-, and input-variables are not distinguished, seems the appropriate concept for the analysis of descriptor systems. The behavioral approach has been introduced by Willems [25, 26, 27, 28]; see also the textbook [21] and [12] for a general presentation.

Motivated by Example 1 and as introduced in [12], we study, for $R(D) \in \mathcal{M}[D]^{g\times q}$, *local solutions* of $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ belonging to

$$\mathcal{C}_t^\infty(\mathbb{R}^q) \;:=\; \left\{w \in \mathcal{C}^\infty(\mathbb{I},\mathbb{R}^q)\,\middle|\, \mathbb{I} \subset \mathbb{R} \text{ an open interval with } t \in \mathbb{I}\right\}, \quad t \in \mathbb{R},$$

as the *almost global behavior* given by the kernel representation

$$\ker R \;=\; \left\{w \in \mathcal{C}_{\mathrm{pw}}^\infty(\mathbb{R}^q)\,\middle|\, R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = 0 \text{ for almost all } \tau \in \mathbb{R}\right\}.$$

The *local behavior*

$$\ker_t R \;=\; \left\{w \in \mathcal{C}_t^\infty(\mathbb{R}^q)\,\middle|\, R(\tfrac{\mathrm{d}}{\mathrm{d}\tau})w(\tau) = 0 \text{ for all } \tau \in \text{ dom } w\right\}, \qquad t \in \mathbb{R},$$

becomes a *real vector space* if endowed, for $w_1, w_2 \in \ker_t R$, with addition

$$(w_1 + w_2)(\tau) \;:=\; w_1(\tau) + w_2(\tau) \qquad \forall \tau \in \operatorname{dom} w_1 \cap \operatorname{dom} w_2\,,$$

and obvious scalar multiplication.

We also have to consider those points of the real axis, where the local solution is no longer extendable.

Definition 1.1. *Consider the descriptor system* (1.2). *The set of* critical points, *where the solution is not defined, is given by*

$$\mathbb{T}_R^{\mathrm{crit}} := \left\{ t' \in \mathbb{R} \;\middle|\; \begin{array}{l} \text{there exists, for some } \varepsilon > 0, \text{ a } \mathcal{C}^\infty \text{ function} \\ w : (t'-\varepsilon, t') \to \mathbb{R}^q \text{ or } w : (t', t'+\varepsilon) \to \mathbb{R}^q \\ \text{which solves (1.2) and cannot be extended to} \\ (t'-\varepsilon, t'] \text{ or } [t', t'+\varepsilon)\,, \text{ respectively.} \end{array} \right\} \tag{1.3}$$

Note that for the three differential equations in Example 1(i), the sets of critical points are $\{0\}$, $\{0\}$, $\emptyset$, respectively.

Since E in (1.1) is real analytic, it follows that for almost all $\hat{t} \in \mathbb{R}$, the rank of the matrix $E(\hat{t}) \in \mathbb{R}^{l\times m}$ is equal to $\mathrm{rk}_{\mathcal{A}} E$, and the set of critical points is a discrete set. It is an open problem to characterize the set of critical points. However, we will determine discrete sets which include all critical points.

We define the appropriate behavior, i.e., the solution space, of (1.2) on the time-axis $\mathbb{R}\backslash\mathbb{T}$, where $\mathbb{T}$ is discrete and includes the set of critical points of (1.2). Controllability and observability are defined in terms of trajectories (descriptor variables), which is a conceptual generalization of controllability and observability for state space systems. For these systems in [5] controllability and observability have been studied in terms of derivative arrays. In [4] a first behavior-like approach for analytic coefficients has been discussed. A more general approach that allows for larger classes of coefficients and that can also be implemented numerically has been introduced in [16]. In [11] a first approach in the spirit of the present paper was presented for scalar systems. A completely different approach results from the study of differential-algebraic equations; see [1, 8, 17]. A general solvability theory for nonsquare linear time-varying systems was first given in [15] and analyzed for control problems in a behavioral context in [4, 18, 22]; see also [16] for the general nonlinear case. In these papers, however, mainly the concept of regularization has been discussed, i.e., the problem of finding appropriate feedback that makes the system regular and also decreases the index. Here we consider controllability and observability in the behavioral context.

This paper is organized as follows. In section 2, we define critical points and follow the concepts of [15, 22] by deriving condensed forms for time-varying descriptor systems (1.2) to determine sets covering the critical points. In section 3, controllability is defined, algebraically characterized, and related to the well-known concepts of controllability. In section 4, we apply results from [12] and briefly discuss autonomous behavior and observability for descriptor systems.

2. Condensed forms. In this section, condensed forms with respect to state and input transformations are studied for time-varying descriptor systems (1.2). The condensed form allows us to classify the solution sets and to identify the constraint manifolds for the variables. These forms are akin to the forms derived in [4, 17, 18].

The construction of the condensed forms is based on the computation of analytic singular value decompositions that were introduced in [2] for analytic matrices and that are also valid for real analytic matrices. This result states that for a matrix function $A \in \mathcal{A}^{l\times n}$ there exist real orthogonal matrix functions $U \in \mathcal{A}^{l\times l}, V \in \mathcal{A}^{n\times n}$ and a diagonal matrix $\Sigma \in \mathcal{A}^{r\times r}$, where $r = \mathrm{rk}A$, such that

$$U^T A V \;=\; \begin{bmatrix} \Sigma & 0 \\ 0 & 0 \end{bmatrix}.$$

It should be noted, though, that, in contrast to the usual singular value decomposition for matrices, the diagonal elements of $\Sigma(t)$, in general, cannot be chosen positive or in descending order. In this way, however, the analytic singular value decomposition is not uniquely defined. Essentially, there is freedom to perform orthogonal transformations in the spaces associated with multiple singular values. This freedom can be removed by choosing minimal variation curves or by always choosing the analytic singular value decomposition to be closest to a reference point [3, 20].

THEOREM 2.1. *Consider a time-varying descriptor system of the form* (1.2) *with*

$$R(D) = \begin{bmatrix} ED - A & -B & 0 \\ -C & -F & I_p \end{bmatrix} \in \mathcal{A}[D]^{(l+p)\times(n+m+p)}.$$

(i) *There exist orthogonal matrices $U_1 \in \mathcal{A}^{l\times l}, V_1 \in \mathcal{A}^{n\times n}$ so that*

$$\begin{bmatrix} U_1 & 0 \\ 0 & I_p \end{bmatrix} R(D) \begin{bmatrix} V_1 & 0 \\ 0 & I_{m+p} \end{bmatrix} \tag{2.1}$$

corresponds to the descriptor system

$$\begin{array}{rcl} \Sigma_d \dot{x}_1 &=& A_{11} x_1 + A_{12} x_2 + A_{13} x_3 + B_1 u, \\ 0 &=& A_{21} x_1 + \Sigma_a x_2 + B_2 u, \\ 0 &=& A_{31} x_1 + B_3 u, \\ 0 &=& A_{41} x_1, \\ 0 &=& 0_{l-\nu}, \\ y &=& C_1 x_1 + C_2 x_2 + C_3 x_3 + F u, \end{array} \tag{2.2}$$

where $\Sigma_d \in \mathcal{A}^{d\times d}, \Sigma_a \in \mathcal{A}^{a\times a}$ are diagonal and invertible over $\mathcal{M}$ with $d = \mathrm{rk}\, E$, and $B_3 \in \mathcal{A}^{\gamma\times m}$, $A_{41} \in \mathcal{A}^{f\times d}$ with full row rank; i.e., $\gamma = \mathrm{rk}\, B_3$, $f = \mathrm{rk}\, A_{41}$, and $\nu = d + a + \gamma + f$. All matrices are real analytic and of conforming formats.

(ii) *There exist orthogonal matrices* $U_2 \in \mathcal{A}^{l\times l}, V_2 \in \mathcal{A}^{n\times n}, W \in \mathcal{A}^{p\times p}, Z \in \mathcal{A}^{m\times m}$ *so that*

$$\begin{bmatrix} U_2 & 0 \\ 0 & W \end{bmatrix} R(D) \begin{bmatrix} V_2 & 0 & 0 \\ 0 & Z & 0 \\ 0 & 0 & I_p \end{bmatrix} \tag{2.3}$$

corresponds to the following descriptor system in condensed form:

$$\begin{aligned}
\Sigma_d \dot{x}_1 &= A_{11}x_1 + A_{12}x_2 + A_{13}x_3 + A_{14}x_4 + A_{15}x_5 + B_{11}u_1 + B_{12}u_2,\\
0 &= A_{21}x_1 + \Sigma_a x_2 + \qquad\qquad\quad B_{21}u_1 + B_{22}u_2,\\
0 &= A_{31}x_1 + \qquad\qquad\qquad\quad \Sigma_\gamma u_1,\\
0 &= \qquad\qquad\quad \Sigma_f x_5,\\
0 &= 0_{l-\nu},\\
y_1 &= C_{11}x_1 + C_{12}x_2 + \Sigma_\omega x_3 + \qquad C_{15}x_5 + F_{11}u_1 + F_{12}u_2,\\
y_2 &= C_{21}x_1 + C_{22}x_2 + \qquad\qquad C_{25}x_5 + F_{21}u_1 + F_{22}u_2,
\end{aligned} \tag{2.4}$$

where $\Sigma_d, \Sigma_a, \Sigma_\gamma, \Sigma_f, \Sigma_\omega$ *are diagonal matrices that are invertible over* $\mathcal{M}$ *and have sizes* d, a, γ, f, ω*, respectively. Furthermore,* $\nu = d + a + \gamma + f$ *and all matrices are real analytic and of conforming formats.*

(iii) *There exist matrices* $U \in \mathcal{A}^{(l-p)\times(l-p)}$, $V \in \mathcal{M}^{n\times n}$ *invertible over* $\mathcal{M}$, $X \in \mathcal{M}^{p\times(l-p)}$, $W \in \mathcal{A}^{p\times p}$ *orthogonal,* $Z \in \mathcal{A}^{m\times m}$ *orthogonal, a scalar function* $\sigma \in \mathcal{A}$*, and a permutation matrix* $P \in \mathcal{A}^{(n+m)\times(n+m)}$ *so that*

$$\tilde{R}(D) := \begin{bmatrix} U & 0 \\ X & W \end{bmatrix} R(D) \begin{bmatrix} P & 0 \\ 0 & I_p \end{bmatrix} \tag{2.5}$$

$$= \left[\begin{array}{c|ccc|ccc|cc}
\sigma D I_d - \tilde{A}_{11} & -\tilde{A}_{13} & -\tilde{A}_{14} & -\tilde{B}_{12} & 0 & 0 & 0 & 0 & 0 \\ \hline
0 & 0 & 0 & \Sigma_a^{-1}\tilde{B}_{22} & I_a & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & I_f & 0 & 0 & 0 \\
\Sigma_\gamma^{-1}\tilde{A}_{31} & 0 & 0 & 0 & 0 & 0 & I_\gamma & 0 & 0 \\ \hline
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \hline
0 & -\Sigma_\omega & 0 & -\sigma^{-1}\tilde{F}_{12} & 0 & 0 & 0 & I_\omega & 0 \\
-\sigma^{-1}\tilde{C}_{21} & 0 & 0 & -\sigma^{-1}\tilde{F}_{22} & 0 & 0 & 0 & 0 & I_p
\end{array}\right]$$

corresponds to the meromorphic descriptor system in standard condensed

form

$$
\begin{aligned}
\sigma I_d \dot{x}_1 &= \tilde{A}_{11} x_1 + [\tilde{A}_{13},\ \tilde{A}_{14},\ \tilde{B}_{12}] \begin{bmatrix} x_3 \\ x_4 \\ u_2 \end{bmatrix}, \\
\begin{bmatrix} x_2 \\ x_5 \\ u_1 \end{bmatrix} &= \begin{bmatrix} 0 & 0 & 0 & -\Sigma_a^{-1}\tilde{B}_{22} \\ 0 & 0 & 0 & 0 \\ -\Sigma_\gamma^{-1}\tilde{A}_{31} & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_3 \\ x_4 \\ u_2 \end{bmatrix}, \qquad (2.6) \\
\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ \sigma^{-1}\tilde{C}_{21} \end{bmatrix} x_1 + \begin{bmatrix} \Sigma_\omega & 0 & \sigma^{-1}\tilde{F}_{12} \\ 0 & 0 & \sigma^{-1}\tilde{F}_{22} \end{bmatrix} \begin{bmatrix} x_3 \\ x_4 \\ u_2 \end{bmatrix},
\end{aligned}
$$

where

$$
\sigma(t) := \det \Sigma_d(t)\, \det \Sigma_a(t)\, \det \Sigma_\gamma(t)\, \det \Sigma_f(t) \quad \text{for all } t \in \mathbb{R}\,, \qquad (2.7)
$$

and all matrices are real analytic and of conforming formats. The integers d, a, γ, ω, f *are invariants of* (1.2).

Proof. The proof is constructive using a sequence of real analytic singular value decompositions. When multiplying with D, we will always use the product rule without saying so.

(i) Consider the first equation of (1.1) and choose orthogonal matrices $\tilde{U} \in \mathcal{A}^{l\times l}$, $\tilde{V} \in \mathcal{A}^{n\times n}$ so that

$$
[\tilde{R}(D), -\tilde{B}] = \tilde{U}[ED - A, -B] \begin{bmatrix} \tilde{V} & 0 \\ 0 & I_m \end{bmatrix} = \left[\begin{bmatrix} \Sigma_d & 0 \\ 0 & 0 \end{bmatrix} D - \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} \\ \tilde{A}_{21} & \tilde{A}_{22} \end{bmatrix}, \begin{bmatrix} \tilde{B}_1 \\ \tilde{B}_2 \end{bmatrix} \right],
$$

where $\Sigma_d \in \mathcal{A}^{d\times d}$ with $d = \mathrm{rk} E$ is diagonal.

Next, choose orthogonal matrices $\bar{U} \in \mathcal{A}^{(l-d)\times(l-d)}$, $\bar{V} \in \mathcal{A}^{(n-d)\times(n-d)}$ so that

$$
\begin{aligned}
[\bar{R}(D),\ -\bar{B}] &= \begin{bmatrix} I_d & 0 \\ 0 & \bar{U} \end{bmatrix} [\tilde{R}(D), -\tilde{B}] \begin{bmatrix} I_d & 0 & 0 \\ 0 & \bar{V} & 0 \\ 0 & 0 & I_m \end{bmatrix} \\
&= \left[\begin{bmatrix} \Sigma_d & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} D - \begin{bmatrix} \bar{A}_{11} & \bar{A}_{12} & \bar{A}_{13} \\ \bar{A}_{21} & \Sigma_a & 0 \\ \bar{A}_{31} & 0 & 0 \end{bmatrix}, \begin{bmatrix} \bar{B}_1 \\ \bar{B}_2 \\ \bar{B}_3 \end{bmatrix} \right],
\end{aligned}
$$

where $\Sigma_a \in \mathcal{A}^{a\times a}$ is diagonal and invertible over $\mathcal{M}$. Finally, choose an orthogonal $\hat{U} \in \mathcal{A}^{(l-d-a)\times(l-d-a)}$, so that $\left[\begin{smallmatrix} I_{d+a} & 0 \\ 0 & \hat{U} \end{smallmatrix}\right][\bar{R}(D), -\bar{B}]$ has the form (2.2) with $B_3 \in \mathcal{A}^{\gamma\times m}$, $\gamma = \mathrm{rk}\, B_3 = \mathrm{rk}\, \bar{B}_3$, and $A_{41} \in \mathcal{A}^{f\times d}$, $f = \mathrm{rk}\, A_{41}$. Performing all the transformations also on C and partitioning analogously shows (2.2).

(ii) We apply the so-called *index reduction process* as introduced in [18] to (2.4): Fix f variables of x_1, corresponding to some f linearly independent columns of A_{41}, i.e., choose a unitary matrix $Q \in \mathcal{A}^{d\times d}$ such that $A_{41}Q = [A_{41}^\alpha, A_{41}^\beta]$ with $A_{41}^\alpha \in \mathcal{A}^{f\times f}$ is invertible over $\mathcal{M}$. Then

$$
0 = A_{41}x_1 = A_{41}^\alpha x_1^\alpha + A_{41}^\beta x_1^\beta, \quad \begin{bmatrix} x_1^\alpha \\ x_1^\beta \end{bmatrix} := Q x_1,
$$

and so

$$\dot{x}_1^\alpha = -(A_{41}^\alpha)^{-1} A_{41}^\beta \dot{x}_1^\beta - \frac{d}{dt}\left((A_{41}^\alpha)^{-1} A_{41}^\beta\right) x_1^\beta.$$

Inserting $\dot{x}_1^\alpha$ into the differential equation of (2.2) leaves $d-f$ differential equations. Note that we may have introduced meromorphic functions by the inverse of A_{41}^α and its derivative. A multiplication from the left with a real analytic function yields a description in the form (1.1); however, the d differential equations have been reduced to $d-f$ differential equations and we may apply part (i) again. This index reduction process stops after finitely many iterations, and we arrive at the following condensed form:

$$\begin{array}{rcccccccccc}
\Sigma_d \dot{x}_1 & = & \hat{A}_{11}x_1 & + & \hat{A}_{12}x_2 & + & \hat{A}_{13}x_3 & + & \hat{A}_{14}x_4 & + & \hat{B}_1 u, \\
0 & = & \hat{A}_{21}x_1 & + & \Sigma_a x_2 & & & & & + & \hat{B}_2 u, \\
0 & = & \hat{A}_{31}x_1 & & & & & & & + & \hat{B}_3 u, \\
0 & = & & & & & & + & \Sigma_f x_4, & & \\
0 & = & 0_{l-\nu}, & & & & & & & & \\
y & = & \hat{C}_1 x_1 & + & \hat{C}_2 x_2 & + & \hat{C}_3 x_3 & + & \hat{C}_4 x_4 & + & F u,
\end{array} \tag{2.8}$$

where $\Sigma_d, \Sigma_a, \Sigma_f$ are diagonal matrices, invertible over $\mathcal{M}$, and of sizes d, a, f, respectively, and $\hat{B}_3 \in \mathcal{A}^{\gamma\times m}$ has full row rank over $\mathcal{A}$.

As a final step we perform an analytic singular value decomposition of $\hat{C}_3, \hat{B}_3$, respectively, and derive (2.4).

(iii) Using the fact that the fourth equation in (2.4) implies that $x_5 \equiv 0$, which can be extended even at points where Σ_f is singular, we can eliminate all terms invoking x_5 from all the other equations. This corresponds to multiplying (2.4) from the left first by

$$\begin{bmatrix}
I_d & -A_{12}\Sigma_a^{-1} & -[B_{11} - A_{12}\Sigma_a^{-1}B_{21}]\Sigma_\gamma^{-1} & 0 & 0 & 0 & 0 \\
0 & I_a & -B_{21}\Sigma_\gamma^{-1} & 0 & 0 & 0 & 0 \\
0 & 0 & I_\gamma & -A_{15}\Sigma_f^{-1} & 0 & 0 & 0 \\
0 & 0 & 0 & I_f & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & I_{l-\nu} & 0 & 0 \\
0 & -C_{12}\Sigma_a^{-1} & -F_{11}\Sigma_\gamma^{-1} & 0 & 0 & I_\omega & 0 \\
0 & -C_{22}\Sigma_a^{-1} & -F_{21}\Sigma_\gamma^{-1} & 0 & 0 & 0 & I_{p-\omega}
\end{bmatrix}$$

and then by

$$\begin{bmatrix} \sigma\Sigma_d^{-1} & 0 \\ 0 & I_{l-d+p} \end{bmatrix}$$

and from the right by

$$\begin{bmatrix}
I_d & 0 & 0 & 0 \\
-[A_{21} - B_{21}\Sigma_\gamma^{-1}A_{31}]\Sigma_a^{-1} & I_a & 0 & 0 \\
-C_{11}\Sigma_\omega^{-1} & 0 & I_\gamma & 0 \\
0 & 0 & 0 & I_{(n-\nu+f+m+p)\times(n-\nu+f+m+p)}
\end{bmatrix},$$

yielding the transformed system

$$
\begin{aligned}
\sigma\,\dot{x}_1 &= \tilde{A}_{11}x_1 + \quad \tilde{A}_{13}x_3 + \tilde{A}_{14}x_4 + \quad \tilde{B}_{12}u_2,\\
0 &= \quad \Sigma_a x_2 + \quad \sigma^{-1}\tilde{B}_{22}u_2,\\
0 &= \tilde{A}_{31}x_1 + \quad \Sigma_\gamma u_1,\\
0 &= \quad \Sigma_f x_5,\\
0 &= 0_{l-v},\\
y_1 &= \quad \Sigma_\omega x_3 + \quad \sigma^{-1}\tilde{F}_{12}u_2,\\
y_2 &= \sigma^{-1}\tilde{C}_{21}x_1 + \quad \sigma^{-1}\tilde{F}_{22}u_2,
\end{aligned}
\tag{2.9}
$$

where all matrices are real analytic. This proves (2.6). □

Remark 1.

(i) If the descriptor system (1.2) is time-invariant, then all transformations in Theorem 2.1 may be chosen as constant matrices and $\sigma = 1$. In this case, the condensed forms in Theorem 2.1 are well known; see, for example [3].

(ii) To derive (2.2), only an orthogonal transformation on the variables x in (2.1) has been applied. To derive (2.4), the transformations on the variables x and u have not been mixed.
To derive (2.6), we have used nonsingular transformations on x and orthogonal transformations on u. If we allow further linear combinations (which for classical systems where y, x, and u are fixed a priori as outputs, states, and controls, respectively, correspond to state feedback or output feedback), then we can simplify (2.6) further by removing blocks such as $\tilde{A}_{31}$ or by introducing almost everywhere invertible diagonal blocks in diagonal positions of the transformed matrices E or A. Note that the transformation of derivative feedback is not an equivalence transformation, because under derivative feedback the characteristic quantities d, a, γ, f, w are not invariants and hence the properties of the system may be altered by this transformation completely; see [18].

(iii) The description (2.6) is not quite of the form (1.1), since the coefficients of x_1 and u_2 in y_1 and y_2 may have poles at the zeros of σ.

(iv) An immediate consequence of (2.6) is that the variables in x_1 represent couplings between algebraic equations and differential equations that are not influenced by u_1. Systems where such couplings between differential equations and algebraic equations occur are typically called *high index systems*. For a detailed discussion of different index concepts see [1, 8, 17]

(v) The transformation leading to (2.6) does not invoke any differentiation of u. Hence, if the variables denoted by u are classified as inputs a priori, then no extra differentiability conditions for these variables arise; see [4, 18].

(vi) The condensed forms (2.1), (2.4), and (2.6) allow us to detect candidates for critical points, given by

$$
\mathbb{T}_R^{\mathrm{crit}} \subset \mathbb{T}_R := \{t' \in \mathbb{R} \,|\sigma(t') = 0\}\,. \tag{2.10}
$$

As can be seen from the first system considered in Example 1(i), the set $\mathbb{T}_R^{\mathrm{crit}} = \emptyset$ can be a strict subset of $\mathbb{T}_R = \{0\}$.

(vii) The reader may wonder why we display equations of the form $0 = 0$ in the condensed form. These arise typically when automatic modelling systems are used and describe redundant equations in the system. □

To characterize controllability we will need the following staircase form which generalizes the staircase form of Van Dooren [24] to systems with analytic coefficient matrices.

LEMMA 2.2. *For real analytic matrices $A \in \mathcal{A}^{n\times n}, B \in \mathcal{A}^{n\times m}$ there exist orthogonal matrices $P \in \mathcal{A}^{n\times n}$ and $Q \in \mathcal{A}^{m\times m}$ so that*

$$P \left[\ D I_n - A, -B\ \right] \begin{bmatrix} P^T & 0 \\ 0 & Q \end{bmatrix} \tag{2.11}$$

$$= \left[\begin{array}{cccc|cc} DI_{n_1} - A_{11} & -A_{12} & \cdots & -A_{1,s-1} & -A_{1,s} & -B_1 \quad 0 \\ -[\hat{A}_{21}, 0] & \ddots & & \vdots & \vdots & 0 \quad 0 \\ & \ddots & \ddots & -A_{s-2,s-1} & \vdots & \vdots \quad \vdots \\ & & -[\hat{A}_{s-1,s-2}, 0] & DI_{n_{s-1}} - A_{s-1,s-1} & -A_{s-1,s} & 0 \quad 0 \\ \hline 0 & \cdots & 0 & 0 & DI_{n_s} - A_{s,s} & 0 \quad 0 \end{array}\right],$$

where $n_1 \geq n_2 \geq \cdots \geq n_{s-1} \geq n_s \geq 0$, $n_{s-1} > 0$, and $B_1 \in \mathcal{A}^{n_1\times n_1}$ and $\hat{A}_{i,i-1} \in \mathcal{A}^{n_i\times n_i}$ are invertible over $\mathcal{M}$ for $i = 1, \ldots, s-1$.

Proof. A constructive proof is given by the following generalization of the so-called *Staircase Algorithm* to systems with real analytic coefficients. Whenever we use Σ in the following, it denotes a diagonal matrix.

Step 0. Choose orthogonal $U_B \in \mathcal{A}^{n\times n}$, $V_B \in \mathcal{A}^{m\times m}$ so that

$$B = U_B^T \begin{bmatrix} \Sigma_B & 0 \\ 0 & 0 \end{bmatrix} V_B \in \mathcal{A}^{n\times m} \quad \text{with invertible } \Sigma_B \in \mathcal{A}^{n_1\times n_1},$$

and set

$$\begin{aligned} A_0 &:= U_B A U_B^T + \dot{U}_B U_B^T = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \quad \text{with } A_{21} \in \mathcal{A}^{(n-n_1)\times n_1}, \\ B_0 &:= U_B B V_B = \begin{bmatrix} \Sigma_B & 0 \\ 0 & 0 \end{bmatrix}. \end{aligned}$$

Then, using the product rule, we have

$$U_B \left[\ D I_n - A, -B\ \right] \begin{bmatrix} U_B^T & 0 \\ 0 & V \end{bmatrix} = \left[\ D I_n - A_0, -B_0\ \right].$$

Step 1. If $n_1 < n$ and $A_{21} \neq 0$, then choose orthogonal $U_{21} \in \mathcal{A}^{(n-n_1)\times(n-n_1)}$, $V_{21} \in \mathcal{A}^{n_1\times n_1}$ so that

$$A_{21} = U_{21} \begin{bmatrix} \Sigma_{21} & 0 \\ 0 & 0 \end{bmatrix} V_{21}^T \in \mathcal{A}^{(n-n_1)\times n_1} \quad \text{with invertible } \Sigma_{21} \in \mathcal{A}^{n_2\times n_2},$$

and set

$$\begin{aligned} P_1 &:= \begin{bmatrix} V_{21}^T & 0 \\ 0 & U_{21}^T \end{bmatrix}, \\ A_1 &:= P_1 A_0 P_1^T + \dot{P}_1 P_1^T = \left[\begin{array}{cc|c} * & * & * \\ \Sigma_{21} & 0 & * \\ 0 & 0 & * \end{array}\right] + \left[\begin{array}{c|c} \dot{V}_{21}^T V_{21} & 0 \\ \hline 0 & \dot{U}_{21}^T U_{21} \end{array}\right], \\ B_1 &:= V_{21}^T \Sigma_B, \\ \widetilde{B}_1 &:= \begin{bmatrix} B_1 & 0 \\ 0 & 0 \end{bmatrix} \in \mathcal{A}^{n\times n}. \end{aligned}$$

Using the product rule, for some $\tilde{A}_{32} \in \mathcal{A}^{(n-n_1-n_2)\times n_2}$ this gives

$$P_1 \left[\ DI_n - A_0, -B_0\ \right] \begin{bmatrix} P_1^T & 0 \\ 0 & I_m \end{bmatrix} = \left[\ DI_n - A_1, -\widetilde{B}_1\ \right]$$

$$= \left[\begin{array}{c|cc} DI_n - \left[\begin{array}{c|cc} * & * & * \\ \hline [\Sigma_{21}, 0] & * & * \\ 0 & \tilde{A}_{32} & * \end{array}\right], & - \left[\begin{array}{c|c} B_1 & 0 \\ \hline 0 & 0 \\ 0 & 0 \end{array}\right] \end{array}\right].$$

Step 2. If $n_1 + n_2 < n$ and $\tilde{A}_{32} \neq 0$, then choose orthogonal matrices $U_{32} \in \mathcal{A}^{(n-n_1-n_2)\times(n-n_1-n_2)}$, $V_{32}^T \in \mathcal{A}^{n_2\times n_2}$ so that

$$\tilde{A}_{32} = U_{32} \begin{bmatrix} \Sigma_{32} & 0 \\ 0 & 0 \end{bmatrix} V_{32}^T \in \mathcal{A}^{(n-n_1-n_2)\times n_2} \quad \text{with invertible } \Sigma_{32} \in \mathcal{A}^{n_3\times n_3},$$

and set

$$\begin{aligned} P_2 &:= \operatorname{diag}\left\{I_{n_1}, V_{32}^T, U_{32}^T\right\}, \\ \hat{A}_{21} &:= V_{32}^T \Sigma_{21}, \\ A_2 &:= P_2 A_1 P_2^T + \dot{P}_2 P_2^T \\ &= \left[\begin{array}{c|cc} * & * & * \\ \hline V_{32}^T[\Sigma_{21}, 0] & * & * \\ 0 & U_{32}^T \tilde{A}_{32} V_{32} & * \end{array}\right] + \left[\begin{array}{c|cc} 0 & 0 & 0 \\ \hline 0 & \dot{V}_{32}^T V_{32} & 0 \\ 0 & 0 & \dot{U}_{32}^T U_{32} \end{array}\right] \\ &= \left[\begin{array}{cc|cc|c} * & * & * & * & * \\ \hline \hat{A}_{21} & 0 & * & * & * \\ \hline 0 & 0 & \Sigma_{32} & 0 & * \\ 0 & 0 & 0 & 0 & * \end{array}\right]. \end{aligned}$$

Then, for some $\tilde{A}_{43} \in \mathcal{A}^{(n-n_1-n_2-n_3)\times n_3}$,

$$\begin{aligned} P_2 P_1 &\left[\ DI_n - A_0, -B_0\ \right] \begin{bmatrix} P_1^T P_2^T & 0 \\ 0 & I_m \end{bmatrix} \\ &= \left[\ DI_n - A_2, -\widetilde{B}_1\ \right] \\ &= \left[\begin{array}{c|cc} DI_n - \left[\begin{array}{cc|cc|cc} * & * & * & * & * & * \\ \hline \hat{A}_{21} & 0 & * & * & * & * \\ \hline 0 & 0 & \Sigma_{32} & 0 & * & * \\ 0 & 0 & 0 & 0 & \tilde{A}_{43} & * \end{array}\right], & - \left[\begin{array}{c|c} B_1 & 0 \\ \hline 0 & 0 \\ \hline 0 & 0 \\ 0 & 0 \end{array}\right] \end{array}\right]. \end{aligned}$$

Step 3. In the remainder of the proof we proceed analogously as in Step 2 and terminate after finitely many steps with the form (2.11). This completes the proof. □

Example 2. As an example consider the model of a two-dimensional, three-link constrained mobile manipulator studied in [10]; see also [12]. This model leads, after linearization along a trajectory, to a system of the form

$$\begin{aligned} M_0(t)\,\ddot{z}(t) + D_0(t)\,\dot{z}(t) + K_0(t)\,z(t) &= S_0\,u(t) + F_0^T\,\mu(t), \\ F_0\,z(t) &= 0\,, \end{aligned} \tag{2.12}$$

where $M_0, D_0, K_0 \in \mathcal{C}^\omega(\mathbb{I}, \mathbb{R}^{3\times 3})$ and $S_0, F_0^T \in \mathbb{R}^{3\times 2}$ with S_0 having full rank. Introducing the eight-dimensional variable $x(t) = [z(t)^T, \dot{z}(t)^T, \mu(t)^T]^T$ results in the equivalent descriptor system description (1.1) with $F \equiv 0$,

$$E(t) = \begin{bmatrix} I_3 & 0 & 0 \\ 0 & M_0(t) & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad A(t) = \begin{bmatrix} 0 & I_3 & 0 \\ -K_0(t) & -D_0(t) & F_0^T \\ F_0 & 0 & 0 \end{bmatrix}, \quad B \equiv \begin{bmatrix} 0 \\ S_0 \\ 0 \end{bmatrix}, \tag{2.13}$$

and the specification of C is left open for the time being.

The critical points of (2.13) include those values of t where the mass matrix $M_0(t)$ changes rank. This happens, for example, when two arms of the manipulator are in one straight line.

Without loss of generality (by using an appropriate permutation of the basis), we may assume that the coordinate system for the Lagrange multipliers is such that $F_0 = [F_1\ 0]$ with nonsingular $F_1 \in \mathbb{R}^{2\times 2}$ and if we partition

$$\begin{aligned} -K_0 &= \begin{bmatrix} K_{11}(t) & K_{12}(t) \\ K_{21}(t) & K_{22}(t) \end{bmatrix}, \ M_0 = \begin{bmatrix} M_{11}(t) & M_{12}(t) \\ M_{21}(t) & M_{22}(t) \end{bmatrix}, \\ -D_0 &= \begin{bmatrix} D_{11}(t) & D_{12}(t) \\ D_{21}(t) & D_{22}(t) \end{bmatrix}, \ S_0 = \begin{bmatrix} S_1 \\ S_2 \end{bmatrix}, \end{aligned}$$

with $K_{11}(t), M_{11}(t), D_{11}(t), S_1 \in \mathbb{R}^{2\times 2}$ and all other formats accordingly, then system (2.13) may be written as

$$\begin{bmatrix} I_2 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & M_{11}(t) & M_{12}(t) & 0 \\ 0 & 0 & M_{21}(t) & M_{22}(t) & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \\ \dot{x}_5 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & 0 & I_2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ K_{11}(t) & K_{12}(t) & D_{11}(t) & D_{12}(t) & F_1^T \\ K_{21}(t) & K_{22}(t) & D_{21}(t) & D_{22}(t) & 0 \\ F_1 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ S_1 \\ S_2 \\ 0 \end{bmatrix} u.$$

Since F_1 is constant and nonsingular, we obtain $x_1 = 0$ and $\dot{x}_1 = 0$. Inserting this

and changing the order of equations and blocks leads to

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & M_{11}(t) & M_{12}(t) & 0 & 0 \\ 0 & M_{21}(t) & M_{22}(t) & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \\ \dot{x}_5 \\ \dot{x}_1 \end{bmatrix}$$
$$= \begin{bmatrix} 0 & 0 & 1 & 0 & 0 \\ K_{12}(t) & D_{11}(t) & D_{12}(t) & F_1^T & 0 \\ K_{22}(t) & D_{21}(t) & D_{22}(t) & 0 & 0 \\ 0 & 0 & 0 & 0 & F_1 \\ 0 & I_2 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_1 \end{bmatrix} + \begin{bmatrix} 0 \\ S_1 \\ S_2 \\ 0 \\ 0 \end{bmatrix} u.$$

We can repeat the reduction process once more by using that $x_3 = 0$, and hence $\dot{x}_3 = 0$, which gives a system

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & M_{22}(t) & 0 & 0 & 0 \\ 0 & M_{12}(t) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_2 \\ \dot{x}_4 \\ \dot{x}_3 \\ \dot{x}_5 \\ \dot{x}_1 \end{bmatrix}$$
$$= \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ K_{22}(t) & D_{22}(t) & 0 & 0 & 0 \\ K_{12}(t) & D_{12}(t) & 0 & F_1^T & 0 \\ 0 & 0 & 0 & 0 & F_1 \\ 0 & 0 & I_2 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_2 \\ x_4 \\ x_3 \\ x_5 \\ x_1 \end{bmatrix} + \begin{bmatrix} 0 \\ S_2 \\ S_1 \\ 0 \\ 0 \end{bmatrix} u.$$

Since the mass matrix M_0 is positive definite almost everywhere, we can eliminate the block M_{12} and obtain the system

$$\left[\begin{array}{cc|ccc} 1 & 0 & 0 & 0 & 0 \\ 0 & M_{22}(t) & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right] \left[\begin{array}{c} \dot{x}_2 \\ \dot{x}_4 \\ \hline \dot{x}_3 \\ \dot{x}_5 \\ \dot{x}_1 \end{array}\right]$$
$$= \left[\begin{array}{cc|ccc} 0 & 1 & 0 & 0 & 0 \\ K_{22}(t) & D_{22}(t) & 0 & 0 & 0 \\ \hline \tilde{K}_{12}(t) & \tilde{D}_{12}(t) & 0 & F_1^T & 0 \\ 0 & 0 & 0 & 0 & F_1 \\ 0 & 0 & I_2 & 0 & 0 \end{array}\right] \left[\begin{array}{c} x_2 \\ x_4 \\ \hline x_3 \\ x_5 \\ x_1 \end{array}\right] + \left[\begin{array}{c} 0 \\ S_2 \\ \hline \tilde{S}_1 \\ 0 \\ 0 \end{array}\right] u. \tag{2.14}$$

This system is essentially (apart from diagonal matrices Σ) in the condensed form (2.2), with

$$\Sigma_d = \begin{bmatrix} 1 & 0 \\ 0 & M_{22}(t) \end{bmatrix}, \quad \Sigma_a = \begin{bmatrix} 0 & F_1^T & 0 \\ 0 & 0 & F_1 \\ I_2 & 0 & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} \tilde{S}_1 \\ 0 \\ 0 \end{bmatrix}.$$

It is then obvious how the more refined forms (2.4) and (2.6) can be determined. ∎

3. Controllability. In this section we discuss the concept of controllability for descriptor systems of the form (1.2). Recall that (local) controllability for general systems of the form $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$, where $R(D) \in \mathcal{M}[D]^{g\times q}$, is introduced in [12, Def. 3.1] and discussed in [12, Rem. 3.2].

Remark 2. For descriptor systems with constant coefficients, several different controllability concepts have been introduced; see [3, 7, 19].

(i) System (1.1) with constant coefficients is called

R-controllable	iff	$\operatorname{rk}[\lambda E - A, B]$ is full for all $\lambda \in \mathbb{C}$,
I-controllable	iff	$\operatorname{rk}[E, AS_\infty, B]$ is full, where S_∞ spans the kernel of E,
strongly controllable	iff	the system is R-controllable and I-controllable.

We stress that these algebraic characterizations are sometimes misleading in the literature, since it is sometimes assumed that the rank of $[E, B]$ is full and sometimes not.

It follows that if system (1.1) is square and time-invariant (thus, in particular, $l = n$), then system (1.1) is *I-controllable* if and only if $n-(d+a+\gamma+f) = 0$. The constants a, d, f, γ are defined in Theorem 2.1(ii). I-controllability is related to regularization and index reduction; i.e., in particular it is needed to avoid impulsive solutions in the case of nondifferentiable input functions. In our framework this concept is not relevant.

(ii) If the descriptor system (1.2) is time-varying, then [12, Def. 3.1] is new; see [5, 22, 18] for a discussion of different controllability concepts for time-varying descriptor systems.

(iii) For time-invariant state-space systems, i.e. (1.1) with $E = I_n$, the algebraic conditions can be checked numerically via the Staircase Algorithm of [24]. In a similar fashion Lemma 2.2 may be used to check controllability for time-varying systems.

(iv) For time-invariant systems (1.2), [12, Def. 3.1] corresponds to the concept of R-controllability. This follows from Theorem 3.1 below. □

Theorem 2.1 and Lemma 2.2 put us in a position to characterize controllability of time-varying descriptor systems (1.2).

THEOREM 3.1. *Consider a time-varying descriptor system* (1.2) *and assume that* $R(D)$ *has full row rank over* $\mathcal{M}[D]$. *Consider the condensed form* (2.6) *and* σ *as defined in* (2.7). *Set, for notational convenience,*

$$G(t) := \tilde{A}_{11}(t), \quad S(t) := [\tilde{A}_{13}(t),\ \tilde{A}_{14}(t),\ \tilde{B}_{12}(t)], \quad v(t) := [x_3(t)^T,\ x_4(t)^T,\ u_2(t)^T]^T.$$

Then the following conditions are equivalent:

(i) (1.2) *is locally controllable almost everywhere.*
(ii) $R(D)$ *is right invertible over* $\mathcal{M}[D]$.
(iii) (2.3), *respectively* (2.4), *is locally controllable almost everywhere.*
(iv) $\hat{R}(D) := [\sigma DI_d - G,\ S]$ *is right invertible over* $\mathcal{M}[D]$.
(v) *In the staircase form* (2.11) *of the pair* $[DI_d - G,\ S]$, *the lower block is not present; i.e.,* $n_s = 0$.
(vi) *There exists a discrete set* $\mathbb{T} \subset \mathbb{R}$ *such that for every*

$$\begin{bmatrix} x_1^0 \\ v^0 \end{bmatrix}, \begin{bmatrix} x_1^1 \\ v^1 \end{bmatrix} \in \ ker_t \hat{R}$$

and for every open interval $\mathbb{I} \subset \mathbb{R}\setminus\mathbb{T}$ *and all* $t_0 \in \mathbb{I}$, *there exists* $t_1 > t_0,\ t_1 \in \mathbb{I}$, *and* $[x_1^T, v^T]^T \in \ ker_t\, \hat{R}$, *such that*

$$\begin{bmatrix} x_1(t) \\ v(t) \end{bmatrix} = \begin{cases} \begin{bmatrix} x_1^0(t) \\ v^0(t) \end{bmatrix} & \text{if } t \in (-\infty, t_0] \cap \mathbb{R} \setminus \mathbb{T}, \\ \begin{bmatrix} x_1^1(t) \\ v^1(t) \end{bmatrix} & \text{if } t \in [t_1, \infty) \cap \mathbb{R} \setminus \mathbb{T}. \end{cases}$$

Proof.

(i) $\Leftrightarrow$ (ii): This is proved in [12, Prop. 3.6].

(ii) $\Leftrightarrow$ (iii): The equivalence of local controllability almost everywhere of (1.2) and (2.4), respectively (1.1) and (2.6), follows from (2.3) by invoking orthogonality of U_2, V_2, W, Z.

(ii) $\Leftrightarrow$ (iv): By (2.5), there exist invertible matrices $\tilde{U} \in \mathcal{M}^{(l+p)\times(l+p)}$, $\tilde{V} \in \mathcal{M}^{(n+m+p)\times(n+m+p)}$ so that (1.1) is related to (2.6) in the form (1.2) by the transformation

$$\tilde{U} \begin{bmatrix} E & D-A & -B & 0 \\ & -C & -F & I_p \end{bmatrix} \tilde{V}$$

$$= \begin{bmatrix} \sigma DI_d - \tilde{A}_{11} & 0 & -\tilde{A}_{13} & -\tilde{A}_{14} & 0 & 0 & -\tilde{B}_{12} & 0 & 0 \\ 0 & -\Sigma_a & 0 & 0 & 0 & 0 & -\tilde{B}_{22} & 0 & 0 \\ -\tilde{A}_{31} & 0 & 0 & 0 & 0 & -\Sigma_\gamma & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -\Sigma_f & 0 & 0 & 0 & 0 \\ 0_{(l-\nu)\times d} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\sigma\Sigma_\omega & 0 & 0 & 0 & -\tilde{F}_{12} & \sigma I_\omega & 0 \\ -\tilde{C}_{21} & 0 & 0 & 0 & 0 & 0 & -\tilde{F}_{22} & 0 & \sigma I_{p-\omega} \end{bmatrix}. \tag{3.1}$$

The right-hand side is right invertible if and only if $l - \nu = l - d - a - \gamma - f = 0$ (which is a consequence of the full row rank assumption) and $[\sigma DI_d - G,\, S]$ is right invertible over $\mathcal{M}[D]$.

(iv) $\Leftrightarrow$ (v): By Lemma 2.2 there exist orthogonal matrices P and Q so that $P[\sigma DI_d - G, S]\left[\begin{smallmatrix} P^T & 0 \\ 0 & Q \end{smallmatrix}\right]$ is of the staircase form (2.11). Note that σ does not affect the staircase form. Now the equivalence (iv) $\Leftrightarrow$ (v) follows immediately since B_1 and $\hat{A}_{i,i-1}$ are invertible over $\mathcal{M}$ for $i = 1, \ldots, s-1$.

(ii) $\Leftrightarrow$ (vi): This equivalence follows readily from [12, Def. 3.1] and from (3.1), since the set of zeros and poles of the coefficients of $\tilde{U}$ and $\tilde{V}$ is a discrete set. ∎

Note that the assumption that (1.2) has full row rank over $\mathcal{M}[D]$ is equivalent to $l - d - a - \gamma - f = 0$ in (2.6).

Note further that the characterization in Theorem 3.1(ii) does not require a reinterpretation of variables as is done in [4]. Moreover, in contrast to the case of controllability of state space systems, here $u_1(\cdot)$ in (1.1) is not a "free input" variable.

For standard time-invariant state space systems (i.e., $E = I_n$), the right invertibility of $R(D)$ in Theorem 3.1 is derived differently in [21, Thm. 5.2.10].

Remark 3. For time-varying systems (1.1) with $E = I_n$, i.e., state space systems, it is well known that controllability of the system yields that it can be controlled in an arbitrary short time. The interval $\mathbb{I}$ in [12, Def. 3.1] can be replaced by any arbitrary short open interval $\widehat{\mathbb{I}} \subset \mathbb{I}$. This also holds true for descriptor systems (1.2), since $\hat{R}(D)$ in Theorem 3.1(iv) can be viewed locally as a state space system, namely, at those $t \in \mathbb{R}$ where $\sigma(t) \neq 0$; note that the zeros of σ are a discrete set. An alternative and constructive proof is given in [12, Thm. 3.3] for general systems of the form $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$. ∎

Example 3.

(i) $R(D) = [t^2D + 1, 1]$ has right inverse $[0, 1]^T$, and hence, by Theorem 3.1, $R(\frac{\mathrm{d}}{\mathrm{d}t})w = 0$ is controllable.

(ii) Revisit the linearized model (2.13) of the three-link constrained mobile manipulator. In Example 2 it is shown that (2.13) is equivalent to (2.11). Rewriting (2.11) in the form (1.2) and invoking that M_{22} is invertible over $\mathcal{M}$ and F_1 is nonsingular, it is easy to see that the corresponding $R(D)$ is right invertible. Therefore, by Theorem 3.1, the linearized model (2.13) is controllable. ∎

4. Observability and autonomous behavior. In [12, sect. 4], the concept of autonomous behavior $\ker_t^{\mathrm{aut}} R$ also has been introduced, and it has been shown that the behavior of a system (1.2) (and hence also of (1.1)) can be decomposed into the direct sum of a controllable and an autonomous behavior. It also immediately follows from the results in [12] that an autonomous behavior $\ker_t^{\mathrm{aut}} R$ of the system (1.2) is invariant under all transformations (2.1), (2.2), (2.4), (2.10). Loosely speaking, an autonomous behavior consists of those solutions which are uniquely determined if they are known on an arbitrarily small open interval. For systems (1.2) we have to cope with the problem of finite escape time.

Example 4. Consider a time-varying state space system (1.2) with $E = I_n$. By [14] there exists $T \in \mathcal{A}^{n\times n}$ invertible over $\mathcal{A}$ so that the coordinate transformation $z := T^{-1}x$ converts (1.1) into

$$\begin{array}{rcl} \frac{\mathrm{d}}{\mathrm{d}t}z_1(t) &=& A_{11}(t)z_1(t) + A_{12}(t)z_2(t) + B_1(t)u(t), \\ \frac{\mathrm{d}}{\mathrm{d}t}z_2(t) &=& A_{22}(t)z_2(t), \\ y(t) &=& C_1(t)z_1(t) + C_2(t)z_2(t) + F(t)u(t), \end{array} \tag{4.1}$$

with all matrices real analytic of conforming formats, and controllable subsystem $\frac{\mathrm{d}}{\mathrm{d}t}z_1(t) = A_{11}(t)z_1(t) + B_1(t)u(t)$. Since (4.1) is a state space system, finite escape time does not occur and the controllable and autonomous subspaces can be described globally. Set

$$\hat{R}(D) := \begin{bmatrix} DI - A_{11} & -A_{12} & -B_1 & 0 \\ 0 & DI - A_{22} & 0 & 0 \\ -C_1 & -C_2 & -F & -I_p \end{bmatrix}.$$

Then, for all $t \in \mathbb{R}$,

$$\ker_t^{\mathrm{contr}} \hat{R} = \left\{ w = [z_1^T, z_2^T, u^T, y^T]^T \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^{(n+m+p)}) \;\middle|\; \hat{R}(\tfrac{\mathrm{d}}{\mathrm{d}t})w = 0 \ \wedge \ z_2 = 0 \right\}$$

and

$$\ker_t^{\mathrm{aut}} \hat{R} = \left\{ w = [z_1^T, z_2^T, u^T, y^T]^T \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^{(n+m+p)}) \;\middle|\; \begin{array}{l} \hat{R}(\frac{\mathrm{d}}{\mathrm{d}t})w = 0,\ z_1 = 0, \\ u = 0,\ \dot{z}_2 = A_{22}\, z_2 \end{array} \right\}$$

is an autonomous behavior, and, hence, in the original coordinates, we have

$$\ker_t^{\mathrm{contr}} R = \begin{bmatrix} T(t) & 0 \\ 0 & I_{m+p} \end{bmatrix} \ker_t^{\mathrm{aut}} R \oplus \begin{bmatrix} T(t) & 0 \\ 0 & I_{m+p} \end{bmatrix} \ker_t^{\mathrm{contr}} \hat{R} \qquad \forall\, t \in \mathbb{R}.$$

Remark 4. Consider a time-varying descriptor system (1.1) in the condensed form (2.6). If (2.6) were controllable, then $\ker^{\mathrm{aut}} R = \{0\}$ would be the only autonomous

behavior of (2.6). To see this, note that x_3, x_4, u_2 are free to choose and hence cannot be a nonzero component of an autonomous behavior. Furthermore, since $[\sigma DI_d - G, S]$ is controllable by Theorem 3.1(iii), it follows that x_1 is uniquely (modulo initial condition) determined by x_3, x_4, u_2, and hence also not a nontrivial component of an autonomous behavior. Finally, (2.6) yields that the remaining components x_2, x_5, u_1, y_1, y_2 are uniquely determined by x_3, x_4, u_2, x_1. This shows $\ker^{\mathrm{aut}} R = \{0\}$.

If (2.6) is not controllable but has a nontrivial uncontrollable subspace, then there exists $\ker^{\mathrm{aut}} R \neq \{0\}$ which is determined by the uncontrollable subspace as for state space systems; see Example 4. □

In [12] it has also been discussed how one behavior can be observed from another. We refer to this paper for the definition of adjoints and observable behavior which generalize well-known concepts of observability, such as for time-varying state space systems (see, for example, [23]) and time-varying Rosenbrock systems (see [13]). It has also been shown that local observability and local controllability are dual concepts.

An application of [12, Thms. 5.5 and 5.6] to descriptor systems (1.2) yields the following result.

THEOREM 4.1. *Consider a descriptor system* (1.2) *with* $R(D) = [R_1(D), R_2(D)]$ *partitioned as*

$$R_1(D) = \begin{bmatrix} E\,D - A \\ -C \end{bmatrix}, \qquad R_2(D) = \begin{bmatrix} -B & 0 \\ -F & I_p \end{bmatrix}.$$

Then the following are equivalent:

(i) *The trajectory x is locally observable from (u, y) almost everywhere.*
(ii) *$R_1(D)$ is left invertible over $\mathcal{M}[D]$.*
(iii) *The matrix*

$$\begin{bmatrix} \sigma\, DI_d - \tilde{A}_{11} & -\tilde{A}_{13} & -\tilde{A}_{14} \\ -\tilde{A}_{31} & 0 & 0 \\ 0 & -\Sigma_\omega & 0 \\ -\sigma^{-1}\tilde{C}_{21} & 0 & 0 \end{bmatrix} \tag{4.2}$$

is left invertible over $\mathcal{M}[D]$, where the matrices in (4.2) *are from the condensed form* (2.4).

Proof. The equivalence (i)↔ (ii) follows from [12, Thms. 5.5 and 5.6]. To see (ii)↔ (iii), note that left invertibility of $R_2(D)$ is equivalent to

$$\begin{bmatrix} U & 0 \\ X & W \end{bmatrix} R_2(D)V = \begin{bmatrix} \sigma\, DI_d - \tilde{A}_{11} & 0 & -\tilde{A}_{13} & -\tilde{A}_{14} & 0 \\ 0 & -\Sigma_a & 0 & 0 & 0 \\ -\tilde{A}_{31} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -\Sigma_f \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -\Sigma_\omega & 0 & 0 \\ -\sigma^{-1}\tilde{C}_{21} & 0 & 0 & 0 & 0 \end{bmatrix}$$

being left invertible, where U, X, V, W are specified in Theorem 2.1(iii). Since $\left[\begin{smallmatrix} U & 0 \\ X & W \end{smallmatrix}\right]$ and V are invertible over $\mathcal{M}$, the latter holds true if and only if (4.2) is left invertible. This completes the proof. □

Example 5. Consider again the linearized model (2.13) of the three-link constrained mobile manipulator. Suppose that the positions can be measured, corre-

sponding to the additional equation

$$y = \begin{bmatrix} 0 & 0 & I_2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix}. \tag{4.3}$$

In Example 2 we have shown that $x_1 = 0$ and $x_3 = 0$ and thus $\dot{x}_1 = 0$ and $\dot{x}_3 = 0$, and permuting the variables accordingly to (2.14), we obtain

$$y = \left[\begin{array}{cc|ccc} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{array}\right] \begin{bmatrix} x_2 \\ x_4 \\ \hline x_3 \\ x_5 \\ x_1 \end{bmatrix}. \tag{4.4}$$

Hence by Theorem 4.1, x is observable from (u, y) with respect to the system (2.13), (4.3) or, equivalently, system (2.11), (4.4) if and only if

$$\left[\begin{array}{cc|ccc} D-1 & 0 & 0 & 0 & 0 \\ -K_{22} & M_{22}D - D_{22} & 0 & 0 & 0 \\ \hline -\tilde{K}_{12} & -\tilde{D}_{12} & 0 & -F_1^T & 0 \\ 0 & 0 & 0 & 0 & F_1 \\ 0 & 0 & -I_2 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right] \tag{4.5}$$

is left invertible over $\mathcal{M}[D]$. Since F_1 is invertible over $\mathcal{M}$, (4.5) is left invertible if and only if $\left[\begin{smallmatrix} D-1 & 0 \\ -K_{22} & M_{22}D - D_{22} \end{smallmatrix}\right]$ is invertible over $\mathcal{M}[D]$. Summarizing, x is observable from (u, v) almost everywhere if and only if K_{22} is invertible over $\mathcal{M}$. ∎

5. Conclusion. We have introduced a general behavioral approach to linear descriptor systems with real analytic coefficients. We have characterized autonomous, controllable, and observable behavior and have generalized results on time-varying ordinary differential equations and on time-invariant linear algebraic-differential equations. The results have been illustrated by several examples, which demonstrates that the approach also helps in understanding practical problems such as constrained multibody systems.

INTERIOR POINT METHODS IN FUNCTION SPACE*

MARTIN WEISER†

Abstract. A primal-dual interior point method for optimal control problems is considered. The algorithm is directly applied to the infinite-dimensional problem. Existence and convergence of the central path are analyzed, and linear convergence of a short-step path-following method is established.

Key words. interior point methods in function space, optimal control, complementarity functions

1. Introduction.

Numerical methods for solving optimal control problems governed by ODEs fall into two categories, the indirect methods [2, 3, 4, 6, 14, 15, 31] relying on Pontryagin's maximum principle, and the direct methods [7, 17, 21, 30, 37] based on the Karush–Kuhn–Tucker necessary conditions. Direct methods can be characterized by several features. Among them are the following:

(i) Position of discretization: Discretize-then-optimize approaches use an a priori parameterization of the control and possibly the state variables to reduce the optimal control problem to a finite-dimensional nonlinear program. These large nonlinear programs can then be solved by standard NLP solvers. Adaptive mesh refinement can be performed after the finite-dimensional optimum has been reached. On the other hand, optimize-then-discretize approaches formulate the optimization algorithms directly in the infinite-dimensional function space, employing discretization only for solving linear operator equations. Adaptive mesh refinement is used to meet the accuracy requirements imposed on the solution of the linear equations by the optimization algorithm.
Somewhere in between are function space sequential quadratic programming (SQP) methods where linear-quadratic programs are discretized.

(ii) Type of optimization algorithm: Among the most popular algorithms employed for solving the optimization problems arising in optimal control are SQP and interior point methods. A recent alternative are semismooth Newton methods [5, 34].

Discretize-then-optimize methods are covered by a vast amount of published literature using almost any available algorithm for solving the finite-dimensional NLPs. Solutions on consecutive mesh refinement levels or in consecutive SQP steps often exhibit pronounced similarities. This redundancy can be directly exploited by active set–type methods. In contrast, interior point methods are considered to benefit less from this redundancy [20, 40]. Nevertheless, interior point methods are reported to be very efficient for solving optimal control problems—a fact that is not well explained by straightforward application of finite-dimensional interior point convergence theory to

*Received by the editors November 5, 2003; accepted for publication (in revised form) April 14, 2005; published electronically November 23, 2005. This work was supported by the DFG Research Center MATHEON in Berlin. A preprint of this paper appeared as ZIB Report 03-35.

the discretized problems. The best currently known convergence rates of $1-\text{const}/\sqrt{n}$ would instead predict a pronounced mesh dependence of the convergence.

Among the optimize-then-discretize approaches, the SQP methods dominate the published material [1, 17, 22, 23, 27, 32, 33]. Here, Robinson's theory of generalized equations [29] can be used to analyze the function space methods, which leaves, however, the question of how to solve the infinite-dimensional linear-quadratic programs. This is implicitly addressed by infinite-dimensional interior point methods, which have nevertheless attracted less attention [35, 36, 24].

The present paper presents an infinite-dimensional interior point method directly applied to optimal control problems in function space in section 2. Existence and convergence of the central path are analyzed in section 3. Finally, linear convergence of a theoretical short-step path-following algorithm with classical predictor is shown in section 4. In particular, the rate of convergence does not depend on the size of any discretization.

Notation. The Lebesgue spaces and Sobolev spaces of functions with values in $\mathbb{R}^n$ are denoted by L_p^n and $(W_p^m)^n$, respectively. $S(x,\rho)$ is the open ball around x with radius ρ.

Some variables and operators are constructed such that they have a natural block partitioning corresponding to the components u and y of x. The individual blocks are denoted by the corresponding component as a superscript, e.g.,

$$g(x) = \begin{bmatrix} g^u(u) \\ g^y(y) \end{bmatrix} \quad \text{and} \quad \Psi(g(x),\eta) = \begin{bmatrix} \Psi^u(g^u(u),\eta^u) \\ \Psi^y(g^y(y),\eta^y) \end{bmatrix}.$$

2. Problem setting. On the time interval $\Omega = [0,1]$ we consider the optimal control problem

$$\min J(x) \quad \text{subject to} \quad \begin{aligned} c(x) &= 0 \quad \text{a.e.}, \\ r(x) &= 0, \\ g(x) &\geq 0 \quad \text{a.e.} \end{aligned} \tag{2.1}$$

with a partitioning of the variable $x = (u,y) \in X = L_\infty^{n_u}(\Omega) \times (W_\infty^1)^{n_y}(\Omega)$ into controls and states, a Lagrange-type cost functional

$$J(x) = \int_0^1 \tilde{f}(u(t),y(t))\,dt,$$

ordinary differential equations with boundary conditions

$$c(x) = \begin{bmatrix} \bar{c}(x) \\ y(0) - y_0 \end{bmatrix}, \quad \bar{c}(x)(t) = \tilde{c}(x(t)) - \dot{y}(t), \tag{2.2}$$

$$r(x) = \tilde{r}(y(1)) \tag{2.3}$$

as equality constraints, and pointwise state and control constraints

$$g(x)(t) = \begin{bmatrix} \tilde{g}^u(u(t)) \\ \tilde{g}^y(y(t)) \end{bmatrix}.$$

For the whole paper, we will restrict the discussion to the fixed time interval Ω and, hence, simplify the notation by omitting it from the function spaces. We assume all the functions $\tilde{f} : \mathbb{R}^{n_u} \times \mathbb{R}^{n_y} \to \mathbb{R}$, $\tilde{c} : \mathbb{R}^{n_u} \times \mathbb{R}^{n_y} \to \mathbb{R}^{n_y}$, $\tilde{r} : \mathbb{R}^{n_y} \to \mathbb{R}^{n_r}$, $\tilde{g}^u : \mathbb{R}^{n_u} \to \mathbb{R}^{n_{\eta_u}}$, and $\tilde{g}^y : \mathbb{R}^{n_y} \to \mathbb{R}^{n_{\eta_y}}$ to be twice Lipschitz-continuously differentiable.

For convenience, we give here a theorem on Nemyckii operators in L_∞, the straightforward proof of which can be found in [38].

THEOREM 2.1. *If $f : \mathbb{R}^n \to \mathbb{R}^m$ is k times differentiable and its kth derivative satisfies the Lipschitz condition*

$$|f^{(k)}(x) - f^{(k)}(y)| \le \kappa |x - y|, \tag{2.4}$$

the corresponding Nemyckii operator $\mathbf{f}$ defined by $\mathbf{f}(u)(t) = f(u(t))$ maps L^n_∞ into L^m_∞ and is k times Fréchet differentiable. For $1 \le p \le \infty$ its kth derivative can be continuously extended to an operator $\mathbf{f}^{(k)}(u) : (\prod_{j=1}^k L^n_{pk}) \to L^m_p$ that inherits boundedness and Lipschitz continuity from $f^{(k)}$:

$$\left\|\mathbf{f}^{(k)}(u)\right\|_{(\prod_{j=1}^k L^n_{pk}) \to L^m_p} \le \sup_{|x| \le \|u\|_{L^n_\infty}} |f^{(k)}(x)|, \tag{2.5}$$

$$\left\|\mathbf{f}^{(k)}(u+\delta u) - \mathbf{f}^{(k)}(u)\right\|_{(\prod_{j=1}^k L^n_{pk}) \to L^m_p} \le \kappa \left\|\delta u\right\|_{L^n_\infty}. \tag{2.6}$$

If in addition f is $k+1$ times differentiable and its $k+1$st derivative satisfies the Lipschitz condition

$$|f^{(k+1)}(x) - f^{(k+1)}(y)| \le \kappa |x - y|,$$

then $\mathbf{f}$ maps $(W^1_\infty)^n$ into $(W^1_\infty)^m$ and is k times differentiable. For $p \ge 1$ its kth derivative can be continuously extended to an operator $\mathbf{f}^{(k)}(u) : (\prod_{j=1}^k (W^1_{pk})^n) \to (W^1_p)^m$ that inherits boundedness and Lipschitz continuity from $f^{(k)}$ and $f^{(k+1)}$:

$$\begin{aligned} \left\|\mathbf{f}^{(k)}(u)\right\|_{(\prod_{j=1}^k (W^1_{pk})^n) \to (W^1_p)^m} &\le \sup_{|x| \le \|u\|_{L^n_\infty}} (k+1)|f^{(k)}(x)| + |f^{(k+1)}(x)|, \\ \left\|\mathbf{f}^{(k)}(u+\delta u) - \mathbf{f}^{(k)}(u)\right\|_{(\prod_{j=1}^k (W^1_{pk})^n) \to (W^1_p)^m} &\le (k+2)\kappa \left\|\delta u\right\|_{(W^1_\infty)^n}. \end{aligned} \tag{2.7}$$

If the derivatives of $f : \mathbb{R}^n \to \mathbb{R}^n$ and $g : \mathbb{R}^n \to \mathbb{R}^n$ commute, then so do the derivatives of the corresponding Nemyckii operators $\mathbf{f}'$ and $\mathbf{g}'$.

With Theorem 2.1 earlier, we conclude that

$$\begin{aligned} J &: L^{n_u}_\infty \times (W^1_\infty)^{n_y} \to \mathbb{R}, \\ c &: L^{n_u}_\infty \times (W^1_\infty)^{n_y} \to L^{n_y}_\infty, \quad \text{and} \\ g &: L^{n_u}_\infty \times (W^1_\infty)^{n_y} \to L^{n_{\eta u}}_\infty \times L^{n_{\eta y}}_\infty \end{aligned}$$

are twice Lipschitz-continuously differentiable operators.

The aim of the interior point method discussed here is to approximate Kuhn–Tucker points x_*. These are feasible points characterized by the existence of Lagrange multipliers $\lambda_c \in \mathbb{R}^{n_y} \times (L^{n_y}_\infty)^*$, $\lambda_r \in \mathbb{R}^{n_r}$, and $\eta \in (L^{n_{\eta u}}_\infty)^* \times ((W^1_\infty)^{n_{\eta y}})^*$ such that the following conditions are satisfied:

$$\begin{gathered} J'(x_*) - c'(x_*)^*\lambda_c - r'(x_*)^*\lambda_r - g'(x_*)^*\eta = 0, \\ c(x_*) = 0, \quad r(x_*) = 0, \\ g(x_*) \ge 0, \quad \eta \ge 0, \quad \langle \eta, g(x_*) \rangle = 0. \end{gathered} \tag{2.8}$$

Under certain assumptions (see, e.g., [26, 28]) these conditions are necessary for x_* to be a local solution of (2.1). Thus, Kuhn–Tucker points are promising candidates for solutions.

Unfortunately, the unwieldy complementarity condition (2.8) is difficult to handle numerically. The idea of primal-dual interior point methods is to relax the complementarity condition by

$$\eta \cdot g(x) = \mu, \quad \eta \geq 0, \quad g(x) \geq 0 \tag{2.9}$$

and to consider the homotopy $\mu \to 0$. Alternatively, complementarity functions $\psi(a, b; \mu) : \mathbb{R}^2 \times \mathbb{R} \to \mathbb{R}$ can be used to construct Nemyckii operators Ψ such that

$$\Psi(g(x), \eta; \mu) = 0$$

is more or less equivalent to the classical interior point relaxation (2.9).

These relaxations, however, are only well defined if $\eta \in L_1$, and are continuously differentiable only in case $\eta \in L_\infty$. Note that this is required to hold only during the homotopy for $\mu > 0$, not at the Kuhn–Tucker point itself. We will prove in Theorem 3.4 that the homotopy can indeed be performed in the more regular setting of $\eta \in L_\infty^{n_{\eta u}} \times L_\infty^{n_{\eta y}} \subset (L_\infty^{n_{\eta u}})^* \times ((W_\infty^1)^{n_{\eta y}})^*$ for $\mu > 0$.

Define the Lagrangian

$$L(x, \lambda_c, \lambda_r, \eta) = J(x) - \langle \lambda_c, c(x) \rangle - \langle \lambda_r, r(x) \rangle - \langle \eta, g(x) \rangle.$$

Let

$$F(x, \lambda_c, \lambda_r, \eta; \mu) = \begin{bmatrix} \partial_x L(x, \lambda_c, \lambda_r, \eta) \\ -c(x) \\ -r(x) \\ \Psi(\eta, g(x); \mu) \end{bmatrix}. \tag{2.10}$$

As will be shown in Theorem 3.2 later, F maps

$$V \times \mathbb{R}_+ = (L_\infty^{n_u} \times (W_\infty^1)^{n_y}) \times (\mathbb{R}^{n_y} \times L_\infty^{n_y}) \times \mathbb{R}^{n_r} \times (L_\infty^{n_{\eta u}} \times L_\infty^{n_{\eta y}}) \times \mathbb{R}_+ \tag{2.11}$$

into

$$Z = (L_\infty^{n_u} \times (W_1^1)^{n_y *}) \times (\mathbb{R}^{n_y} \times L_\infty^{n_y}) \times \mathbb{R}^{n_r} \times (L_\infty^{n_{\eta u}} \times L_\infty^{n_{\eta y}}).$$

3. The central path. The main object of analytical interest is the *central path* defined by the homotopy (2.9) in μ. First we consider its actual existence in the regular setting given by (2.11) before discussing convergence.

Throughout the paper, we will use the Fischer–Burmeister function [18]

$$\psi(a, b; \mu) = a + b - \sqrt{a^2 + b^2 + 2\mu} \tag{3.1}$$

as an example from a large class of different complementarity functions (see [11, 12, 13, 25]).

3.1. Existence. We begin with establishing some bounds on derivatives of the complementarity function and their inverses.

LEMMA 3.1. *The complementarity function* Ψ *defined via* (3.1) *maps* $L^n_\infty \times L^n_\infty \times \mathbb{R}$ *continuously into* L^n_∞. *Its derivative* $\partial_g \Psi(g,\eta;\mu)$ *is symmetric positive semidefinite, bounded by*

$$\|\partial_g \Psi\|_{L_\infty \to L_\infty} \le 2, \tag{3.2}$$

$$\left\|(\partial_g \Psi)^{-1}\right\|_{L_\infty \to L_\infty} \le \max\left(3, \frac{2}{\mu}\|g\|^2_{L_\infty}\right), \tag{3.3}$$

and Lipschitz continuous with a Lipschitz constant of $\mu^{-1/2}$. *The corresponding holds for* $\partial_\eta \Psi(g,\eta;\mu)$. *Furthermore, the derivatives commute.*

Proof. The claimed properties of the Nemyckii operator Ψ are directly inherited from ψ due to Theorem 2.1. From $(1+\phi)^{-1/2} \le \max(1-\phi/4, 2/3)$ for $\phi > 0$ we infer

$$\begin{aligned}
\min\left(\frac{\mu}{2a^2}, \frac{1}{3}\right) &= 1 - \max\left(1 - \frac{\mu}{2a^2}, \frac{2}{3}\right) \le 1 - \frac{1}{\sqrt{1+\frac{2\mu}{a^2}}} \\
&\le 1 - \frac{1}{\sqrt{1+\frac{b^2}{a^2}+\frac{2\mu}{a^2}}} = 1 - \frac{|a|}{\sqrt{a^2+b^2+2\mu}} \\
&\le \partial_a \psi(a,b;\mu) \\
&\le 1 + \frac{|a|}{\sqrt{a^2+b^2+2\mu}} \le 2.
\end{aligned} \tag{3.4}$$

Thus, $\partial_a \psi$ is uniformly positive definite. Due to Theorem 2.1, the derivative $\partial_g \Psi(g,\eta;\mu)$ of the Nemyckii operator Ψ is bounded by (3.2) and has an inverse that is bounded by (3.3).

As for the Lipschitz continuity, we estimate

$$|\partial_a^2 \psi| = \left| \frac{\sqrt{a^2+b^2+2\mu} - \frac{a^2}{\sqrt{a^2+b^2+2\mu}}}{a^2+b^2+2\mu} \right| \le \frac{1 - \frac{a^2}{a^2+b^2+2\mu}}{\sqrt{a^2+b^2+2\mu}} \le \frac{1}{\sqrt{2\mu}}$$

and

$$|\partial_{ab} \psi| = \left| \frac{ab}{(a^2+b^2+2\mu)^{3/2}} \right| \le \frac{|ab|}{(2|ab|+2\mu)^{3/2}} \le \frac{2}{3\sqrt{6\mu}}$$

such that $\|\psi''\| \le \mu^{-1/2}$. This Lipschitz constant for $\partial_a \psi$ is inherited by $\partial_g \Psi$. Because of symmetry, the same holds for $\partial_\eta \Psi$, which commutes with $\partial_g \Psi$. ∎

THEOREM 3.2. *The complementarity formulation* (2.10) *is a continuously differentiable mapping from* $V \times \mathbb{R}_+$ *to* Z. *Moreover, for any bounded set* $D \subset V$ *there is a constant* $c(D)$ *such that the derivative* $\partial_v F$ *satisfies the Lipschitz condition*

$$\|\partial_v F(v+\delta v;\mu) - \partial_v F(v;\mu)\|_{V \to Z} \le c(1+\mu^{-1/2})\,\|\delta v\|_V \tag{3.5}$$

on D.

Proof. The image spaces and differentiability of the second to fourth component of F have already been established in section 2 and Lemma 3.1. Only the adjoint expression

$$J'(x) - c'(x)^* \lambda_c - r'(x)^* \lambda_r - g'(x)^* \eta$$

remains to be discussed. We consider the terms separately.

First we write $J(x) = \langle \mathbf{1}, \tilde{\mathbf{f}}(x) \rangle$ with $\tilde{\mathbf{f}}'(x) \in \mathcal{L}(L_1^{n_u} \times (W_1^1)^{n_y}, L_1)$ due to Theorem 2.1 and thus obtain

$$J'(x) = \tilde{\mathbf{f}}'(x)^* \mathbf{1} \in \left(L_1^{n_u} \times (W_1^1)^{n_y}\right)^*. \tag{3.6}$$

With δ_0 denoting the point evaluation of the y component at $t = 0$, we have

$$c'(x) = \begin{bmatrix} \tilde{\mathbf{c}}'(x) - \partial_t \\ \delta_0 \end{bmatrix} \in \mathcal{L}\left(L_1^{n_u} \times (W_1^1)^{n_y} \to L_1^{n_y} \times \mathbb{R}^{n_r}\right)$$

again by Theorem 2.1 such that

$$c'(x)^* \lambda_c \in \left(L_1^{n_u} \times (W_1^1)^{n_y}\right)^*. \tag{3.7}$$

Similarly, we obtain

$$r'(x)^* \lambda_r \in \left(L_1^{n_u} \times (W_1^1)^{n_y}\right)^* \quad \text{and} \quad g'(x)^* \eta \in \left(L_1^{n_u} \times (W_1^1)^{n_y}\right)^*. \tag{3.8}$$

Collecting (3.6)–(3.8), $F(v; \mu) \in Z$ is verified. Continuous differentiability is inherited from J, c, g, and ψ.

As for the Lipschitz continuity of the derivative, we have to estimate the differences of

$$\partial_v F(v; \mu) = \begin{bmatrix} \partial_x^2 L(v) & -c'(x)^* & -r'(x)^* & -g'(x)^* \\ -c'(x) & & & \\ -r'(x) & & & \\ \partial_g \Psi(g(x), \eta; \mu) g'(x) & & & \partial_\eta \Psi(g(x), \eta; \mu) \end{bmatrix}$$

for arguments v_1 and v_2. We cover the blocks separately. First we see that

$$c'(x_1) - c'(x_2) = \tilde{\mathbf{c}}'(x_1) - \tilde{\mathbf{c}}'(x_2).$$

Since x_1 and x_2 are bounded in terms of D, the derivative of the Nemyckii operator $\tilde{\mathbf{c}}$ inherits the Lipschitz constant $\kappa_c(D)$ of $\tilde{c}'$ due to (2.6) of Theorem 2.1 with $p = \infty$. Thus, we conclude

$$\|c'(x_1) - c'(x_2)\|_{X \to L_\infty^{n_y} \times \mathbb{R}^{n_y}} \le \kappa_c(D) \|x_1 - x_2\|_X.$$

Analogously, we obtain

$$\|g'(x_1) - g'(x_2)\|_{X \to L_\infty^{n_\eta}} \le \kappa_g(D) \|x_1 - x_2\|_X.$$

Concerning the dual operators $c'(x)^*$ and $g'(x)^*$, we apply Theorem 2.1 with $p = 1$ in (2.6) and obtain

$$\|c'(x_1)^* - c'(x_2)^*\|_{L_\infty^{n_y} \times \mathbb{R}^{n_y} \to L_\infty^{n_u} \times ((W_1^1)^{n_y})^*} \le \kappa_c(D) \|x_1 - x_2\|_X$$

and

$$\|g'(x_1)^* - g'(x_2)^*\|_{L_\infty^{n_\eta} \to L_\infty^{n_u} \times ((W_1^1)^{n_y})^*} \le \kappa_g(D) \|x_1 - x_2\|_X.$$

Similar estimates for $r'(x)$ and $r'(x)^*$ are straightforward. As for $\partial_x^2 L(v)$, we estimate

$$\begin{aligned} \|J''(x_1) - J''(x_2)\|_{X \to L_\infty^{n_u} \times ((W_1^1)^{n_y})^*} &\le \kappa_f(D) \|x_1 - x_2\|_X, \\ \|c''(x_1)^* - c''(x_2)^*\|_{X \times L_\infty^{n_y} \times \mathbb{R}^{n_y} \to L_\infty^{n_u} \times ((W_1^1)^{n_y})^*} &\le \kappa_c(D) \|x_1 - x_2\|_X, \\ \|g''(x_1)^* - g''(x_2)^*\|_{X \times L_\infty^{n_\eta} \to L_\infty^{n_u} \times ((W_1^1)^{n_y})^*} &\le \kappa_g(D) \|x_1 - x_2\|_X \end{aligned}$$

as before. In view of

$$c''(x_1)^*\lambda_{c1} - c''(x_2)^*\lambda_{c2} = c''(x_1)^*(\lambda_{c1} - \lambda_{c2}) + (c''(x_1)^* - c''(x_2)^*)\lambda_{c2}$$

and the boundedness of $c''(x_1)^*$ due to (2.5) of Theorem 2.1, we derive a constant $\kappa(D)$ for

$$\|c''(x_1)^*\lambda_{c1} - c''(x_2)^*\lambda_{c2}\|_{X\to L_\infty^{n_u}\times((W_1^1)^{n_y})^*} \le \bar\kappa_c(D)\|v_1 - v_2\|_X.$$

Treating $r''(x)^*\lambda_r$ and $g''(x)^*\eta$ similarly, we obtain the desired estimate

$$\|\partial_x^2 L(v_1) - \partial_x^2 L(v_2)\|_{X\to L_\infty^{n_u}\times((W_1^1)^{n_y})^*} \le \kappa_L(D)\|v_1 - v_2\|_X.$$

Up to now, the Lipschitz constants have been completely independent of μ. For the blocks $\partial_g\Psi(v)g'(x)$ and $\partial_\eta\Psi(v)$ we obtain a Lipschitz constant of $\kappa_\Psi \le \text{const}(1 + \mu^{-1/2})$. Combining the Lipschitz constants of the individual blocks finally verifies (3.5). ∎

In order to prove the existence of the central path via an implicit function theorem, we first have to establish bounds on the inverse of $\partial_v F$.

THEOREM 3.3. *Suppose there exist an open bounded set $D \subset V$ and constants $\beta > 0$ and $\alpha > 0$ such that the following conditions hold uniformly for all $v \in D$ and $\mu > 0$:*

1. *The state equation satisfies the following inf-sup condition:*

$$\inf_{\xi\in\mathbb{R}^{n_r}} \sup_{\delta u\in L_2^{n_u}} \frac{\xi^T\partial_y r(x)\partial_y c(x)^{-1}\partial_u c(x)\delta u}{|\xi|\,\|\delta u\|_{L_2^{n_u}}} \ge \beta.$$

(*The linearized state equation is controllable.*)

2. *A strengthened Legendre–Clebsch-type condition holds:*

$$\xi^T M_u(t)\xi \ge \alpha|\xi|^2$$

for all $\xi \in \mathbb{R}^{n_u}$ and almost all $t \in \Omega$. Here,

$$\begin{aligned} M_u(t) := {}& \partial_u^2\tilde f(x(t)) - \partial_u^2\tilde c(x(t))^T\lambda_c(t) - (\tilde g^u)''(u(t))^T\eta^u(t) \\ & + (\tilde g^u)'(u(t))^T\partial_\eta\psi(\tilde g^u(u(t)),\eta^u(t);\mu)^{-1}\partial_g\psi(\tilde g^u(u(t)),\eta^u(t);\mu)(\tilde g^u)'(u(t)). \end{aligned}$$

3. *The augmented second derivative of the Lagrangian is uniformly positive definite on the nullspace of the state equation:*

$$\langle\xi, (\partial_x^2 L(v) + g'(x)^*\partial_\eta\Psi(g(x),\eta)^{-1}\partial_g\Psi(g(x),\eta)g'(x))\xi\rangle \ge \alpha\|\xi\|^2_{L_2^{n_u}\times(W_2^1)^{n_y}}$$

for all $\xi \in \ker c'(x)$.

Then $\partial_v F(v;\mu)$ has an inverse which is bounded by

$$\left\|\partial_v F(v;\mu)^{-1}\right\|_{Z\to V} \le \text{const}(1 + \mu^{-3}) \tag{3.9}$$

uniformly for $v \in D$.

Proof. We show that there is a unique solution of $\partial_v F(v;\mu)\Delta v = z$ with $\|\Delta v\|_V \le \text{const}(1 + \mu^{-3})\,\|z\|_Z$.

In order to simplify the notation, let $C = -c'(x)$, $C_u = -\partial_u c(x)$, $C_y = -\partial_y c(x)$, and analogously G, G_u, G_y, R, and R_y. Define $\Psi_\eta = \partial_\eta\Psi(g(x),\eta)$, $\Psi_g = \partial_g\Psi(g(x),\eta)$,

$\Psi^u_\eta = \partial_{\eta^u}\Psi^u(g^u(u),\eta^u)$, $\Psi^u_g = \partial_{g^u}\Psi^u(g^u(u),\eta^u)$, and analogously Ψ^y_η and Ψ^y_g. Moreover, let $M_u = \partial^2_u L(v) + G^*_u(\Psi^u_\eta)^{-1}\Psi^u_g G_u$, and analogously M_y. Finally, let $M_{uy} = \partial_{uy}L(v)$ and $M_{yu} = \partial_{yu}L(v)$.

The state derivative C_y represents the linearization of the initial value problem (2.2) and has a bounded solution for any right-hand side. Thus, C_y has a bounded inverse. More precisely, for any $p \geq 1$,

$$C_y^{-1} : L_p^{n_y} \to (W_p^1)^{n_y} \text{ is bounded uniformly for } v \in D. \tag{3.10}$$

Therefore, we can define the solution operator $S = C_y^{-1}C_u$.

In the following, we will refrain from writing the number of components of the function spaces, which should be clear from context.

In a first step, we reduce the system

$$\partial_v F(v;\mu)(\Delta x, \Delta\lambda_c, \Delta\lambda_r, \Delta\eta)^{\mathrm{T}} = [z_a, z_c, z_r, z_p]^{\mathrm{T}}$$

to a simple saddle point problem. Elimination of the inequality constraints' multipliers $\Delta\eta = \Psi_\eta^{-1}(z_p - \Psi_g G\Delta x)$ by Lemma 3.1 yields the equivalent system

$$\begin{bmatrix} M_u & M_{uy} & C_u^* & \\ M_{yu} & M_y & C_y^* & R_y^* \\ C_u & C_y & & \\ & R_y & & \end{bmatrix} \begin{bmatrix} \Delta u \\ \Delta y \\ \Delta\lambda_c \\ \Delta\lambda_r \end{bmatrix} = \begin{bmatrix} \bar z_a^u \\ \bar z_a^y \\ z_c \\ z_r \end{bmatrix},$$

where $(\bar z_a^u, \bar z_a^y)^{\mathrm{T}} = \bar z_a = z_a - G^*\Psi_\eta^{-1}z_p$. Then, $\Delta y = C_y^{-1}z_c - S\Delta u$ and $\Delta\lambda_c = C_y^{-*}(\bar z_a^y - M_y C_y^{-1}z_c - (M_{yu} - M_y S)\Delta u - R_y^*\Delta\lambda_r)$ can be eliminated, which yields

$$\begin{bmatrix} M_u + S^*M_yS - (M_{uy}S + S^*M_{yu}) & -S^*R_y^* \\ -R_yS & \end{bmatrix} \begin{bmatrix} \Delta u \\ \Delta\lambda_r \end{bmatrix} = \begin{bmatrix} \hat z_a^u \\ \hat z_r \end{bmatrix}. \tag{3.11}$$

Here we set $\hat z_a^u = \bar z_a^u - M_{uy}C_y^{-1}z_c - S^*(\bar z_a^y - M_y C_y^{-1}z_c)$ and $\hat z_r = z_r - R_y C_y^{-1}z_c$.

In the second step, we establish the existence of a bounded solution of (3.11), first in $L_2^{n_u}\times\mathbb{R}^{n_r}$ and then in $L_\infty^{n_u}\times\mathbb{R}^{n_r}$. Due to Theorem 2.1 and the observation (3.10), M_u, S^*M_yS, $M_{uy}S$, and S^*M_{yu} can all be continuously extended to L_2. Then, $M_u + S^*M_yS - (M_{uy}S + S^*M_{yu}) : L_2^{n_u} \to L_2^{n_u}$ is positive definite due to assumption 3. Moreover, R_yS satisfies the inf-sup-condition of assumption 1. Therefore, Brezzi's splitting theorem [10, 8] guarantees the existence of a solution $(\Delta u, \Delta\lambda_r) \in L_2^{n_u}\times\mathbb{R}^{n_r}$ of (3.11) with

$$\begin{aligned} \|\Delta u\|_{L_2} &\leq \text{const}\left(\|\hat z_a^u\|_{L_2} + \kappa|\hat z_r|\right) \quad \text{and} \\ |\Delta\lambda_r| &\leq \text{const}\left(\kappa\|\hat z_a^u\|_{L_2} + \kappa^2|\hat z_r|\right), \end{aligned} \tag{3.12}$$

where

$$\kappa = 1 + \|M_u + S^*M_yS - (M_{uy}S + S^*M_{yu})\|_{L_2\to L_2},$$

and the constants depend on α and β. Using Lemma 3.1 and, again, the extension of Nemyckii operators to L_2 provided by Theorem 2.1, we obtain the following dependencies on μ:

$$\begin{aligned} \|M_u\|_{L_2\to L_2} &= \|\partial_u^2 L\|_{L_2\to L_2} + \|G_u^*\left(\Psi_\eta^u\right)^{-1}\Psi_g^u G_u\|_{L_2\to L_2} \\ &\leq \text{const} + \|G_u^*\|_{L_2\to L_2}\|\left(\Psi_\eta^u\right)^{-1}\Psi_g^u\|_{L_2\to L_2}\|G_u\|_{L_2\to L_2} \\ &\leq \text{const}(1 + \|\left(\left(\Psi_\eta^u\right)^{-1}\Psi_g^u\|_{L_2\to L_2}\right) \\ &\leq \text{const}(1+\mu^{-1}), \end{aligned}$$

$$\begin{aligned}\|M_y\|_{W_2^1\to(W_2^1)^*} &= \|\partial_y^2 L\|_{W_2^1\to(W_2^1)^*} + \|G_y^*\big(\Psi_\eta^y\big)^{-1}\Psi_g^y G_y\|_{W_2^1\to(W_2^1)^*}\\ &\le \text{const} + \|G_y^*\|_{L_2\to(W_2^1)^*}\|\Psi\tbinom{y}{\eta}^{-1}\Psi_g^y\|_{L_2\to L_2}\|G_y\|_{W_2^1\to L_2}\\ &\le \text{const}\left(1+\|\big(\Psi_\eta^y\big)^{-1}\Psi_g^y\|_{L_2\to L_2}\right)\\ &\le \text{const}(1+\mu^{-1}), \qquad (3.13)\end{aligned}$$

$$\begin{aligned}\kappa &\le 1 + \|M_u\|_{L_2\to L_2} + \text{const}\,\|M_y\|_{W_2^1\to(W_2^1)^*} + \text{const}\\ &\le \text{const}(1+\mu^{-1}).\end{aligned}$$

As for Δu and $\Delta\lambda_r$, we first observe

$$\|\tilde z_a^u\|_{L_2} \le \|z_a\|_{L_2} + \|G_u^*\big(\Psi_\eta^u\big)^{-1} z_p^u\|_{L_2} \le \text{const}(1+\mu^{-1})\|z\|_Z,$$

$$\begin{aligned}\|S^*M_y C_y^{-1} z_c\|_{L_2} &\le \|S^*\|_{(W_2^1)^*\to L_2}\|M_y\|_{W_2^1\to(W_2^1)^*}\|C_y^{-1}z_c\|_{W_2^1}\\ &\le \text{const}(1+\mu^{-1})\|z_c\|_{L_2} \le \text{const}(1+\mu^{-1})\|z\|_Z,\end{aligned}$$

and hence

$$\|\hat z_a^u\|_{L_2} \le \text{const}(1+\mu^{-1})\|z\|_Z. \qquad (3.14)$$

From this we conclude that

$$\|\Delta u\|_{L_2} \le \text{const}(1+\mu^{-1})\|z\|_Z \quad\text{and}\quad |\Delta\lambda_r| \le \text{const}(1+\mu^{-2}).$$

Moreover, $|\hat z_r| \le \text{const}\,\|z\|_Z$ is evident from (3.10). Observing that $S : L_2^{n_u} \to (W_2^1)^{n_y}$ and $S^* : (W_1^1)^{n_y *} \to L_\infty^{n_u}$ due to (3.10), and additionally $R_y^* : \mathbb{R}^{n_r} \to (W_1^1)^{n_y *}$, we infer

$$(S^*M_yS - M_{uy}S - S^*M_{yu}) : L_2^{n_u} \to L_\infty^{n_u} \quad\text{and}\quad S^*R_y^* : \mathbb{R}^{n_r} \to L_\infty^{n_u}$$

such that (3.11) implies

$$M_u\Delta u = \hat z_a^u - (S^*M_yS - M_{uy}S - S^*M_{yu})\Delta u + S^*R_y^*\Delta\lambda_r \in L_\infty^{n_u}.$$

Using assumption 2, the desired regularity $\Delta u \in L_\infty^{n_u}$ is readily established

$$\|\Delta u\|_{L_\infty} \le \text{const}\,\|\hat z_a^u - (S^*M_yS - M_{uy}S - S^*M_{yu})\Delta u + S^*R_y^*\Delta\lambda_r\|_{L_\infty}. \qquad (3.15)$$

In order to estimate the right-hand side of (3.15), we first note that since $\dot y$ appears linearly in c, M_y is a Nemyckii operator. We thus infer

$$\begin{aligned}\|M_y\|_{L_\infty\to L_\infty} &\le \|\partial_y^2 L\|_{L_\infty\to L_\infty} + \|G_y^*\|_{L_\infty\to L_\infty}\|(\Psi_\eta^y)^{-1}\Psi_g^y\|_{L_\infty\to L_\infty}\|G_y\|_{L_\infty\to L_\infty}\\ &\le \text{const}(1+\mu^{-1}),\end{aligned}$$

where we used Theorem 2.1 to obtain $G_y \in \mathcal{L}(L_1, L_1)$, which implies $G_y^* \in \mathcal{L}(L_\infty, L_\infty)$. Then we derive upper bounds for the individual terms in (3.15) as follows:

$$\begin{aligned}&\|S^*M_yS - M_{uy}S - S^*M_{yu}\|_{L_2\to L_\infty}\|\Delta u\|_{L_2}\\ &\quad\le \|S^*\|_{L_\infty\to L_\infty}\|M_y\|_{L_\infty\to L_\infty}\|S\|_{L_2\to L_\infty}\,\text{const}(1+\mu^{-1})\|z\|_Z\\ &\quad\le \text{const}(1+\mu^{-2})\|z\|_Z,\end{aligned}$$

$$\|S^*R_y^*\|_{\mathbb{R}^{n_r}\to L_\infty}|\Delta\lambda_r| \le \text{const}(1+\mu^{-2})\|z\|,$$

and $\|\hat{z}_a^u\|_{L_\infty} \le \text{const}(1+\mu^{-1})$ analogously to (3.14). Thus, we conclude

$$\|\Delta u\|_{L_\infty} \le \text{const}(1+\mu^{-2})\|z\|_Z. \tag{3.16}$$

In the final step of the proof, we will now trace back the elimination chain from the beginning. First we get

(3.17)

$$\begin{aligned}
\|\Delta\lambda_c\|_{\mathbb{R}^{n_r}\times L_\infty} &= \|C_y^{-*}\Big(\bar{z}_a^y - M_y C_y^{-1} z_c - (M_{yu} - M_y S)\Delta u - R_y^*\Delta\lambda_r\Big)\|_{\mathbb{R}^{n_r}\times L_\infty} \\
&\le \text{const}\,\|\bar{z}_a^y - M_y C_y^{-1} z_c - (M_{yu} - M_y S)\Delta u - R_y^*\Delta\lambda_r\|_{(W_1^1)^*} \\
&\le \text{const}\,\Big(\|\bar{z}_a^y\|_{(W_1^1)^*} + \|M_y\|_{L_\infty\to L_\infty}\|C_y^{-1}z_c\|_{W_1^1} \\
&\qquad + \|M_{yu} - M_y S\|_{L_\infty\to L_\infty}\|\Delta u\|_{L_\infty} \\
&\qquad + \|R_y^*\|_{\mathbb{R}^{n_r}\to(W_1^1)^*}|\Delta\lambda_r|\Big) \\
&\le \text{const}\,\Big(\|z_a^y - G_y^*(\Psi_\eta^y)^{-1}\big(z_p^y - \Psi_w^y z_s^y\big)\|_{(W_1^1)^*} + (1+\mu^{-1})\|z\|_Z \\
&\qquad + (1+\mu^{-1})\|\Delta u\|_{L_\infty} + |\Delta\lambda_r|\Big) \\
&\le \text{const}\,\Big(\|z\|_Z + \|G_y^*\|_{L_\infty\to(W_1^1)^*}\|\big(\Psi_\eta^y\big)^{-1}\|_{L_\infty\to L_\infty}\|z_p^y - \Psi_w^y z_s^y\|_{L_\infty} \\
&\qquad + (1+\mu^{-3})\|z\|_Z\Big) \\
&\le \text{const}(1+\mu^{-3})\|z\|_Z.
\end{aligned}$$

The state Δy is bounded by

$$\|\Delta y\|_{W_\infty^1} \le \|C_y^{-1}z_c\|_{W_\infty^1} + \|S\|_{L_\infty\to W_\infty^1}\|\Delta u\|_{L_\infty} \le \text{const}(1+\mu^{-2})\|z\|_Z. \tag{3.18}$$

Finally, we obtain for the Lagrange multiplier $\Delta\eta$ the estimate

$$\begin{aligned}
\|\Delta\eta\|_{L_\infty} &\le \|\Psi_\eta^{-1}\|_{L_\infty\to L_\infty}\big(\|z_p\|_{L_\infty} + \|\Psi_g G\Delta x\|_{L_\infty}\big) \\
&\le \text{const}(1+\mu^{-3})\|z\|_Z.
\end{aligned} \tag{3.19}$$

Collecting (3.12) and (3.16)–(3.19) we obtain the claim (3.9). ∎

Now we are ready to prove that the central path exists locally, and that it can be continued up to $\mu = 0$ unless it leaves its bounded set of definition.

COROLLARY 3.4. *Suppose the assumptions of Theorem* 3.3 *are satisfied. If there are $v_0 \in D$ and $\mu_0 > 0$ with $F(v_0;\mu_0) = 0$, then there exists a maximal open interval $I_\mu \subset R_+$ around μ_0 and a continuously differentiable central path $v : I_\mu \to D$ with the following properties:*

1. *$v(\mu_0) = v_0$.*
2. *$F(v(\mu);\mu) = 0$ for all $\mu \in I_\mu$.*
3. *Either $\text{dist}(v(I_\mu), \partial D) = 0$ or $\inf I_\mu = 0$ holds.*

Proof. Due to Theorems 3.2 and 3.3 there is an open neighborhood of (v_0,μ_0) on which F and $\partial_v F$ are continuous and $\partial_v F$ is bijective. The implicit function theorem (cf. [41, Thm. 4.B]) guarantees the existence of a continuously differentiable central path $v(\mu)$ with $F(v(\mu),\mu) = 0$ on an open interval around μ_0. A closer inspection of the proof of the implicit function theorem and using the bounds derived in Theorems 3.2 and 3.3 shows that there is a constant $\epsilon = \epsilon(\text{dist}(v_0, D))$ independent of μ such that $v(\mu)$ exists on the open interval $]\mu_0 - \epsilon\mu^{-4}, \mu_0 + \epsilon\mu^{-4}[$.

Let $I_\mu \subset \mathbb{R}_+$ be a maximal open interval around μ_0, such that property 2 holds. Now assume that property 3 does not hold, i.e., $\operatorname{dist}(v(I_\mu), \partial D) \geq \varepsilon > 0$ and $\delta = \inf I_\mu > 0$. We consider $\mu = \delta + \epsilon\delta^{-4}/2$ with $\epsilon = \epsilon(\varepsilon)$. Again, due to the implicit function theorem, there is an open interval $J_\mu =]\mu - \epsilon\mu^{-4}, \mu + \epsilon\mu^{-4}[$ such that property 2 holds on J_μ and hence on $J_\mu \cup I_\mu$. Since $\mu - \epsilon\mu^{-4} < \delta$, this consequence contradicts the maximality of I_μ, and property 3 must be true. ∎

3.2. Convergence. Corollary 3.4 does not guarantee the existence of the central path for all $\mu > 0$, since the path may reach the boundary of D for some $\mu_{\lim} > 0$. Moreover, the upper bound for $\|\partial_v F(v;\mu)^{-1}\|$ which has been established in Theorem 3.3 is useless for proving convergence of the path towards a Kuhn–Tucker limit point. The two reasons are the possible occurrence of Dirac parts in the state constraints' multipliers at the beginning or end of constrained arcs, and the naive block elimination of the multipliers $\Delta\eta$ in the proof of Corollary 3.4.

Under more restrictive assumptions, in particular, the restriction to purely control constrained problems, a splitting into nearly active and nearly inactive constraints can be used to show both boundedness of the central path and independence of $\|\partial_v F(v;\mu)^{-1}\|$ with respect to μ.

DEFINITION 3.5. *For some $\rho > 0$ and functions $u \in L_\infty^{n_u}$ and $\eta \in L_\infty^{n_\eta^u}(\Omega)$, define the characteristic function $\chi^A = \chi^A(t;u,\eta,\mu)$ of the nearly active set vector Ω^A componentwise as*

$$\chi_i^A(t) = \begin{cases} 1, & \tilde{g}_i^u(u_i(t)) \leq \rho\eta_i^u(t), \\ 0 & \text{otherwise.} \end{cases}$$

The corresponding characteristic function χ^I of the nearly inactive set vector Ω^I is defined as $\mathbf{1} - \chi^A$, where $\mathbf{1} \in L_\infty^{n_\eta^u}$ is the constant function with value 1.

Note that pointwise multiplication with χ^A defines an orthogonal projector onto the corresponding L_∞ space over the nearly active set vector Ω^A.

First we address the issue of the central path leaving a bounded domain of definition. Assuming a suitable constraint qualification for nearly active constraints of points on the central path, we establish a priori bounds for the central path.

THEOREM 3.6. *Suppose $n_\eta^y = 0$; i.e., there are no state constraints. Assume that the following conditions are satisfied:*

(i) *The feasible region $D_u := \{u \in L_\infty^{n_u} : g(u) \geq 0\}$ is bounded.*

(ii) *The state contribution function in the state equation is linearly bounded:*

$$|\tilde{c}(u,y)| \leq \text{const}(1 + |y|) \quad \text{for all } y \in \mathbb{R}^{n_y} \text{ and } u \in D_u.$$

Then there is a bounded set $D_y \subset (W_\infty^1)^{n_y}$ such that for all $\mu > 0$ every solution v of $F(v;\mu) = 0$ satisfies $u \in D_u$ and $y \in D_y$.

If, in addition, there is a constant $\beta > 0$ such that the equality constraints and nearly active control constraints satisfy the inf-sup condition

$$\inf_{h \in \mathbb{R}^{n_r}, \xi \in L_\infty^{n_\eta^u}} \sup_{\delta u \in L_1^{n_u}} \frac{h^T \partial_y r(x) \partial_y c(x)^{-1} \partial_u c(x) \delta u + \langle \chi^A \xi, g'(u)\delta u \rangle}{(|h| + \|\chi^A \xi\|_{L_\infty^{n_\eta^u}}) \, \|\delta u\|_{L_1^{n_u}}} \geq \beta \tag{3.20}$$

uniformly for central path solutions v with $x \in D_u \times D_y$, then there is a bounded set $D_0 \subset V$ such that $v \in D_0$.

Proof. Suppose $v = (u, y, \lambda_c, \lambda_r, \eta)$ is a central path solution of $F(v;\mu) = 0$ for some $\mu > 0$. Since $\Psi(g(u), \eta) = 0$ implies $g(u) \geq 0$, we have $u \in D_u$ by assumption (i).

Assumption (ii) then guarantees the existence of a constant $\gamma_y < \infty$ such that $y \in S(0, \gamma_y) =: D_y$.

Now consider the state part of the adjoint equation

$$\partial_y J(x) - \partial_y c(x)^* \lambda_c - \partial_y r(y)^* \lambda_r = 0.$$

Due to the formulation of c as initial value problem, the inverse of $\partial_y c(x) : (W_1^1) \to L_1 \times \mathbb{R}^{n_y}$ is uniformly bounded on $D_u \times D_y$. Thus, we can conclude that

$$\begin{aligned}\|\lambda_c\|_{L_\infty \times \mathbb{R}^{n_y}} &\le \|\partial_y c(x)^{-*}\|_{(W_\infty^1)^* \to L_\infty \times \mathbb{R}^{n_y}} \|\partial_y J(x) - \partial_y r(y)^* \lambda_r\|_{(W_\infty^1)^*} \\ &\le \text{const}\, \|\partial_y J(x) - \partial_y r(y)^* \lambda_r\|_{(W_\infty^1)^*}.\end{aligned}$$

Since $\partial_y \tilde{f}(x)$ is uniformly bounded in $L_\infty^{n_y}$ for $x \in D_u \times D_y$, so is $\|\partial_y J(x)\|_{(W_\infty^1)^*}$, and we obtain

$$\|\lambda_c\|_{L_\infty \times \mathbb{R}^{n_y}} \le \text{const}(1 + |\lambda_r|). \tag{3.21}$$

Inserting $\lambda_c = \partial_y c(x)^{-*}(\partial_y J(x) - \partial_y r(y)^* \lambda_r)$ into the control part of the adjoint equation

$$\partial_u J(x) - \partial_u c(x)^* \lambda_c - g'(u)^* \eta = 0,$$

and splitting the Lagrange multiplier η into nearly active and nearly inactive parts yields

$$\begin{aligned}&\partial_u J(x) - \partial_u c(x)^* \partial_y c(x)^{-*} \partial_y J(x) - g'(u)^* \chi^I \eta \\ &\quad = (\partial_y r(y) \partial_y c(x)^{-1} \partial_u c(x))^* \lambda_r + g'(u)^* \chi^A \eta.\end{aligned}$$

Then the inf-sup condition of assumption (3.20) provides the estimate

$$\begin{aligned}\beta(|\lambda_r| + \|\chi^A \eta\|_{L_\infty}) &\le \sup_{u \in L_1} \frac{\langle (\partial_y r(x) \partial_y c(x)^{-1} \partial_u c(x))^* \lambda_r + g'(u)^* \chi^A \eta, u \rangle}{\|u\|_{L_1}} \\ &\le \|(\partial_y r(x) \partial_y c(x)^{-1} \partial_u c(x))^* \lambda_r + g'(u)^* \chi^A \eta\|_{L_\infty} \\ &= \|\partial_u J(x) - \partial_u c(x)^* \partial_y c(x)^{-*} \partial_y J(x) + g'(u) \chi^I \eta\|_{L_\infty}.\end{aligned}$$

Note that $\|\chi^I \eta\|_{L_\infty}$ is bounded by $\rho^{-1} \|g(u)\|_{L_\infty}$ and $\|\partial_y c(x)^{-*} \partial_y J(x)\|_{L_\infty \times \mathbb{R}^{n_y}}$ is bounded as shown earlier. Similarly, $\|\partial_u J(x)\|_{L_\infty}$ is bounded. $\|g'(u)\|_{L_\infty \to L_\infty}$ and $\|\partial_u c(x)\|_{L_1 \to L_1 \times \mathbb{R}^{n_y}}$ are bounded by Theorem 2.1. Thus, we conclude that

$$|\lambda_r| + \|\chi^A \eta\|_{L_\infty} \le \text{const}\, \beta^{-1}.$$

Combining this with $x \in D_u \times D_y$ verifies the boundedness of v. ∎

The splitting of the domain into nearly active and inactive regions leads also to improved estimates for the dependency of the complementarity function on the homotopy parameter μ.

The reason for the dependence of $\|\partial_v F(v; \mu)^{-1}\|$ on μ in Theorem 3.3 is the increase of $\|\partial_\eta \Psi^{-1}\|$ as $\mu \to 0$. This can be overcome by more sophisticated elimination of variables in the proof. As a preparation, we first prove a refinement of Lemma 3.1.

LEMMA 3.7. *The Fischer–Burmeister complementarity function satisfies the following estimates:*

$$\|\chi^A \partial_g \Psi(g(u), \eta)^{-1}\|_{L_\infty \to L_\infty} \le \left(1 - \frac{\rho}{\sqrt{1 + \rho^2}}\right)^{-1}, \tag{3.22}$$

$$\|\chi^I \partial_\eta \Psi(g(u), \eta)^{-1}\|_{L_\infty \to L_\infty} \le \left(1 - \frac{1}{\sqrt{1 + \rho^2}}\right)^{-1}. \tag{3.23}$$

In particular, both bounds are independent of μ.

Proof. In the relevant inequality (3.4) we now assume that $a \le \rho b$. This leads to

$$\partial_a \psi(a,b;\mu) \ge 1 - \frac{1}{\sqrt{1+\frac{b^2}{a^2}+\frac{2\mu}{a^2}}} \ge 1 - \frac{1}{\sqrt{1+\frac{1}{\rho^2}+\frac{2\mu}{a^2}}} \ge 1 - \frac{1}{\sqrt{1+\frac{1}{\rho^2}}}.$$

On the nearly active region, this assumption holds, such that due to the projection onto the nearly active region the estimate transfers to $\chi^A \partial_g \Psi(g(u),\eta)^{-1}$. Thus, (3.22) is verified. By symmetry, (3.23) is verified using the complementary assumption $a > \rho b$. ∎

THEOREM 3.8. *Assume* $n_\eta^y = 0$*; i.e., only control constraints are present. Suppose there exist a bounded set* $D \subset V$ *and constants* $\beta > 0$ *and* $\alpha > 0$ *such that the following conditions hold uniformly for all central path solutions* $v = v(\mu) \in D$ *with* $F(v(\mu);\mu) = 0$ *and* $\mu > 0$.

1. *State equation and nearly inactive control constraints satisfy the inf-sup condition*

$$\inf_{h\in\mathbb{R}^{n_r},\xi\in L_p^{n_\eta^u}} \sup_{\delta u\in L_q^{n_u}} \frac{h^T \partial_y r(x) \partial_y c(x)^{-1} \partial_u c(x) \delta u + \langle \chi^A \xi, g'(u)\delta u\rangle}{(|h| + \|\chi^A \xi\|_{L_p^{n_\eta^u}})\, \|\delta u\|_{L_q^{n_u}}} \ge \beta$$

for both $(p,q) = (\infty,1)$ *and* $(p,q) = (2,2)$.

2. *The augmented second derivative of the Lagrangian*

$$M = \partial_x^2 L(v) + g'(x)^* \partial_\eta \Psi(g(x),\eta)^{-1} \chi^I \partial_g \Psi(g(x),\eta) g'(x)$$

is positive semidefinite on the nullspace of the linearized state equation:

$$\langle \xi, M\xi\rangle \ge 0 \qquad \text{for } \xi \in \ker c'(x), \tag{3.24}$$

$$\langle \xi, M\xi\rangle \ge \alpha \|\xi\|^2_{L_2^{n_u}\times (W_2^1)^{n_y}} \qquad \text{for } \xi \in \ker c'(x) \cap \ker \chi^A g'(u). \tag{3.25}$$

Then $\partial_v F(v;\mu)$ *has an inverse which is bounded uniformly for* $(v,\mu) \in D \times \mathbb{R}_+$.

Before delving into the proof, let us briefly discuss the assumptions of Theorem 3.8. Mostly, they have counterparts in well-known optimality conditions, but they need to be extended a priori to a neighborhood of the central path in order to be able to show convergence.

Assumption 1 is a direct generalization of the linear independence constraint qualification (LICQ; see, e.g., [19, Def. 2.9]) from nonlinear programming to the infinite-dimensional setting. It is also a reinterpretation of regular points (cf. [28, (2.1)]) in the setting of interior points. It provides uniqueness of the Lagrange multipliers and is therefore necessary for proving invertibility of $\partial_v F$.

Convexity of the Lagrangian on the nullspace of the linearized state equation is generally required for sufficient second order optimality conditions. In particular, requirement (3.25) can be interpreted as an adaptation of the convexity condition given by Maurer [28, Thm. 3.5], whereas (3.24) is only technically necessary for invoking a certain saddle point lemma in the proof. In the control constrained setting, the Legendre–Clebsch condition that has been assumed explicitly in Theorem 3.3 is implied by the earlier convexity assumption.

LEMMA 3.9. *Assumption 2 of Theorem 3.8 implies a strengthened Legendre–Clebsch-type condition for almost all* $t \in \Omega$*:*

$$\begin{aligned} M_u(t) := {} & \partial_u^2 \tilde f(x(t)) - \partial_u^2 \tilde c(x(t))^T \lambda_c(t) - \tilde g''(u(t))^T \eta(t) \\ & + \tilde g'(u(t))^T \partial_\eta \psi(\tilde g(u(t)),\eta(t);\mu)^{-1} \chi^I \partial_g \psi(\tilde g(u(t)),\eta(t);\mu) \tilde g'(u(t)) \end{aligned}$$

satisfies

$$\xi^T M_u(t)\xi \geq 0 \qquad \text{for } \xi \in \mathbb{R}^{n_u}, \tag{3.26}$$

$$\xi^T M_u(t)\xi \geq \alpha|\xi|^2 \qquad \text{for } \xi \in \ker \chi^A(t)\tilde{g}'(u(t)). \tag{3.27}$$

Proof. Let $\xi \in \mathbb{R}^{n_u}$ be arbitrary and define $\delta u = \xi\chi_{[t-\epsilon,t+\epsilon]}$ for arbitrary $t \in \operatorname{int}(\Omega)$ and sufficiently small $\epsilon > 0$. Defining M_{yu}, M_{uy}, and S as in Theorem 3.3, we introduce $\delta y = S\delta u$ such that $(\delta u, \delta y) \in \ker c'(x)$. From standard ODE theory we know that $\|\delta y\|_{L_\infty} \leq \operatorname{const}\|\delta u\|_{L_1} \leq \operatorname{const}\epsilon$. Let $M_u = \partial_u^2 L(v) + g'(u)^*\chi^I\Psi_\eta(g(u),\eta)^{-1}\Psi_g(g(u),\eta)g'(u)$, $M_y = \partial_y^2 L(v)$, and

$$M = \begin{bmatrix} M_u & M_{uy} \\ M_{yu} & M_y \end{bmatrix}.$$

Since M_y, M_{yu}, and M_{uy} are uniformly bounded Nemyckii operators, we have by (3.24)

$$\begin{aligned}\langle \delta u, M_u \delta u\rangle &= \langle(\delta u,\delta y), M(\delta u,\delta y)\rangle - \langle \delta y, M_y\delta y\rangle - \langle \delta y, M_{uy}\delta u\rangle - \langle \delta u, M_{yu}\delta y\rangle \\ &\geq 0 - \operatorname{const}\|\delta y\|_{L_\infty}^2 - 2\operatorname{const}\|\delta y\|_{L_\infty}\|\delta u\|_{L_1} \\ &\geq -\operatorname{const}\epsilon^2\end{aligned}$$

for all t and $\epsilon > 0$, and hence $\xi^T M_u(t)\xi \geq 0$ for all ξ and almost all $t \in \Omega$, which verifies (3.26). Restricting ξ to $\ker\chi^A(t)\tilde{g}'(u(t))$ and using (3.25) instead of (3.24) finally proves (3.27). ∎

Proof of Theorem 3.8. The structure and line of argument is similar to the proof of Theorem 3.3. We, therefore, concentrate on the differences and extensions. Define $C, C_u, C_y, R, R_y, M_{uy}, M_{yu}$, and S as before. Let $G = -g'(u)$. Define $\Psi_g = \partial_g\Psi(g(u),\eta)$ and analogously Ψ_η. Finally, define M_u and M_y as in Lemma 3.9.

As before, the first step consists of eliminating the Lagrange multiplier, but here only the nearly inactive part $\chi^I\eta = \chi^I\Psi_\eta^{-1}(z_p - \Psi_g G\Delta u)$. In order to symmetrize the remaining system, the nearly active part of the complementarity equation is multiplied by Ψ_g^{-1}:

$$\begin{bmatrix} M_u & M_{uy} & C_u^* & & G^*\chi^A \\ M_{yu} & M_y & C_y^* & R_y^* & \\ C_u & C_y & & & \\ & R_y & & & \\ \chi^A G & & & & -\chi^A\Psi_g^{-1}\Psi_\eta \end{bmatrix} \begin{bmatrix} \Delta u \\ \Delta y \\ \Delta\lambda_c \\ \Delta\lambda_r \\ \chi^A\Delta\eta \end{bmatrix} = \begin{bmatrix} \bar{z}_a^u \\ z_a^y \\ z_c \\ z_r \\ \chi^A\Psi_g^{-1}z_p \end{bmatrix}$$

with $\bar{z}_a^u = z_a^u - G^*\chi^I\Psi_\eta^{-1}z_p$. Note that χ^A, Ψ_g^{-1}, and Ψ_η commute. Continuing with the elimination of Δy and λ_c as in the proof of Theorem 3.3, we end up with

$$\begin{bmatrix} T & -(R_yS)^* & G^*\chi^A \\ -R_yS & & \\ \chi^A G & & -\chi^A\Psi_g^{-1}\Psi_\eta \end{bmatrix} \begin{bmatrix} \Delta u \\ \Delta\lambda_r \\ \chi^A\Delta\eta \end{bmatrix} = \begin{bmatrix} \hat{z}_a^u \\ \hat{z}_r \\ \chi^A\Psi_g^{-1}z_p \end{bmatrix},$$

where $T = M_u + S^*M_yS - (M_{uy}S + S^*M_{yu})$, $\hat{z}_a^u = \bar{z}_a^u - M_{uy}C_y^{-1}z_c - S^*(\bar{z}_a^y - M_yC_y^{-1}z_c)$, and $\hat{z}_r = z_r - R_yC_y^{-1}z_c$. Due to assumption 2, T is positive definite on the nullspace of $\chi^A G$ and positive semidefinite on the whole space. Assumption 1 provides the inf-sup condition for the combined operator

$$\begin{bmatrix} -R_yS \\ \chi^A G \end{bmatrix},$$

and $\chi^A\Psi_g^{-1}\Psi_\eta$ is positive semidefinite. In this situation, the application of Brezzi's splitting theorem is substituted by a theorem of Braess and Blömer [9] on saddle point problems with penalty term. This guarantees the existence of a solution $(\Delta u, \Delta\lambda_r, \chi^A\Delta\eta) \in L_2^{n_u} \times \mathbb{R}^{n_r} \times L_2(\Omega^A)$ with

$$\|\Delta u\|_{L_2} + |\Delta\lambda_r| + \|\Delta\eta^A\|_{L_2} \le \text{const}\,\kappa(\|\hat{z}_a^u\|_{L_2} + |\hat{z}_r| + \|\chi^A\Psi_g^{-1}z_p\|_{L_2}),$$

where $\kappa = \|T\|+\|R_yS\|+\|G_A\|+\|\chi^A\Psi_g^{-1}\Psi_\eta\|+\alpha+\beta$. Note that due to Lemma 3.7 the operators $\chi^A\Psi_g^{-1}\Psi_\eta$ and $\chi^I\Psi_\eta^{-1}\Psi_g$ are bounded independently of μ. This property is inherited by κ and $\|\chi^A\Psi_g^{-1}z_p\|$, such that $\|\Delta u\|_{L_2}$, $|\Delta\lambda_r|$, and $\|\chi^A\Delta\eta\|_{L_2}$ are bounded independently of μ.

Subsequently, the L_∞-regularity of Δu and $\chi^A\Delta\eta$ is established. As in the proof of Theorem 3.3, we have

$$(S^*M_yS - M_{uy}S - S^*M_{yu})\Delta u + S^*R_y^*\Delta\lambda_r \in L_\infty^{n_u}$$

such that for almost all $t \in \Omega$ the finite-dimensional linear equation system

$$\begin{bmatrix} M_u(t) & \tilde{g}'(u(t))^T\chi^A(t) \\ \chi^A(t)\tilde{g}'(u(t)) & -B \end{bmatrix} \begin{bmatrix} \Delta u(t) \\ \chi^A\Delta\eta(t) \end{bmatrix} = \begin{bmatrix} a \\ \chi^A(t)b \end{bmatrix} \tag{3.28}$$

holds, with $B = \chi^A(t)\partial_g\psi(g(u(t)),\eta(t))^{-1}\partial_\eta\psi(g(u(t)),\eta(t))$. Here, a and b denote generic right-hand side vectors the norm of which is bounded by a constant independent of μ. By Lemma 3.9, $M_u(t)$ is positive definite on the nullspace of $\tilde{g}'(u(t))$, such that we can again apply the lemma by Braess and Blömer, now for the finite-dimensional equation (3.28). This yields

$$|\Delta u(t)| + |\chi^A\Delta\eta(t)| \le \text{const}(\|M_u(t)\| + \|\tilde{g}'(u(t))\| + \|B\| + \alpha + \beta)(|a| + |b|) \tag{3.29}$$

for almost all $t \in \Omega$, and hence

$$\|\Delta u\|_{L_\infty} \le \text{const}, \tag{3.30}$$

$$\|\chi^A\Delta\eta^A\|_{L_\infty} \le \text{const} \tag{3.31}$$

independently of μ. Finally, tracing back the elimination stack as in Theorem 3.3 verifies the claim. ∎

As in Corollary 3.4, local existence of the central path can be shown. Moreover, the a priori bound of the solution given by Theorem 3.6 eliminates the possibility of premature termination of the path. Finally, the fact that the inverse of $\partial_v F$ can be bounded independently of μ limits the length of the path and thus ensures convergence.

THEOREM 3.10. *Assume Theorem* 3.6 *holds, providing a bounded set* $D_0 \subset V$ *containing the central path. Define* $D = \bigcup_{v\in D_0} S(v,\epsilon)$ *for some* $\epsilon > 0$. *Suppose the assumptions of Theorem* 3.8 *hold on* D.

If there are $v_0 \in D_0$ *and* $\mu_0 > 0$ *with* $F(v_0;\mu_0) = 0$, *then the central path* $v(\mu)$ *exists for all* $0 < \mu \le \mu_0$ *and converges to a Kuhn–Tucker point* $v(0)$:

$$\|v(\mu) - v(0)\|_V \le \text{const}\,\sqrt{\mu}.$$

Proof. First we notice that due to Theorem 3.2, there is some $\epsilon > 0$ such that $\partial_v F(v;\mu)^{-1}$ is uniformly bounded on the neighborhood

$$U = \bigcup_{(v;\mu) \text{ with } F(v;\mu)=0} S((v,\mu),\epsilon)$$

of the central path solutions $v(\mu)$. As in the proof of Theorem 3.4, the central path exists on a maximal interval I_μ containing μ_0. Since due to Theorem 3.6 this central path is bounded away from ∂D, we have $\inf I_\mu = 0$. Thus, the central path exists for all $0 < \mu \le \mu_0$.

Next we estimate $\partial_\mu F(v(\mu);\mu)$. Since only the complementarity function Ψ depends on μ, this is given by $\partial_\mu \Psi(g(u),\eta;\mu) = -(g(u)^2+\eta^2+2\mu)^{-1/2}$. On the central path, we have $g(u)\cdot\eta = \mu$ a.e. and thus

$$\|\partial_\mu \Psi(g(u),\eta;\mu)\|_{L_\infty} \le (4\mu)^{-1/2}.$$

Now the derivative of the central path is given by

$$v'(\mu) = \partial_v F(v(\mu);\mu)^{-1}\partial_\mu F(v(\mu);\mu).$$

Theorem 3.8 yields

$$\|v'(\mu)\|_V \le \|\partial_v F(v(\mu);\mu)^{-1}\|_{Z\to V}\|\partial_\mu F(v(\mu);\mu)\|_Z \le \text{const}\,\mu^{-1/2}. \tag{3.32}$$

Therefore, the central path is uniformly continuous and converges to some limit point $v(0) \in D$ at a rate of

$$\|v(\mu)-v(0)\|_V \le \int_0^\mu \|v'(s)\|_V\,ds \le \text{const}\int_0^\mu s^{-1/2}\,ds = \text{const}\,\sqrt{\mu}.$$

The continuity of F on $D\times[0,\infty[$ implies that $F(v(0);0)=0$, such that $v(0)$ satisfies the first order necessary conditions (2.8). □

In the remainder of the section, we will apply the preceding theorems to a class of prototypical optimal control problems. We consider

$$\begin{aligned} \min \int_0^1 \left(\tilde f^y(y(t)) + \frac{\alpha}{2}|u(t)|^2\right) dt \\ \text{subject to} \quad \dot y(t) = Ay(t) + Bu(t), \\ y(0) = y_0, \\ a \le u(t) \le b. \end{aligned}$$

THEOREM 3.11. *Suppose that $\tilde f^y$ is convex and twice Lipschitz-continuously differentiable, $\alpha > 0$, $a < b$, $A \in \mathbb{R}^{n_y\times n_y}$, and $B \in \mathbb{R}^{n_y\times n_u}$. Assume there are v_0 and $\mu_0 > 0$ such that $F(v_0;\mu_0) = 0$. Then the central path $v(\mu)$ converges to a Kuhn–Tucker point $v(0) \in D$ at a rate of*

$$\|v(\mu)-v(0)\| \le \text{const}\,\sqrt{\mu}.$$

Proof. We restrict the discussion to a scalar control, i.e., $n_u = 1$. The extension to vector valued controls is straightforward but notationally more involved. We start with Theorem 3.6, choosing

$$\rho < \frac{1}{\mu_0}\left(\frac{b-a}{2}\right)^2 \tag{3.33}$$

for separating nearly active and nearly inactive constraints. Due to the box constraints and the linearity of the state equation, conditions (i) and (ii) are satisfied. Since no terminal boundary conditions are given, the inf-sup condition (3.20) simplifies to

$$\inf_{\xi\in L_p^2}\sup_{\delta u\in L_q^1}\frac{\langle \chi^A\xi, g'(u)\delta u\rangle}{\|\chi^A\xi\|_{L_p^2}\|\delta u\|_{L_q^1}} \ge \beta \quad \text{with } g'(u) = \begin{pmatrix} I \\ -I\end{pmatrix}.$$

Assume that for a central path solution (v, μ) with $\mu \le \mu_0$, the lower constraint $u \ge a$ is nearly active at t, i.e., $\rho\eta^a(t) \ge u(t) - a$. For simplicity, we will omit the argument t in the following. Together with (3.33) and the interior point condition $\eta^a(u-a) = \mu = \eta^b(b-u)$ holding for all central path solutions, this implies

$$\begin{aligned} b - u = b - a - (u - a) &\ge b - a - \sqrt{\rho\eta^a(u-a)} = b - a - \sqrt{\rho\mu} \\ &\ge b - a - \frac{b-a}{2} = \frac{b-a}{2} > \sqrt{\rho\mu} = \sqrt{\rho\eta^b(b-u)}. \end{aligned}$$

Squaring and dividing by $b-u$ finally yields $b-u > \rho\eta^b$, which implies that the upper constraint $u \le b$ is nearly inactive whenever the lower constraint is nearly active. Analogously, the converse can be shown, such that at most one of the two constraints is active. Since in $\chi^A\xi$ at least one component vanishes, we see that

$$\inf_{\xi\in L_p^2} \sup_{\delta u\in L_q^1} \frac{\langle \chi^A\xi, g'(u)\delta u\rangle}{\|\chi^A\xi\|_{L_p^2}\|\delta u\|_{L_q^1}} \ge \inf_{\xi\in L_p^1} \sup_{\delta u\in L_q^1} \frac{\langle \xi, \delta u\rangle}{\|\xi\|_{L_p^1}\|\delta u\|_{L_q^1}} \ge 1 \tag{3.34}$$

for both $(p, q) = (\infty, 1)$ and $(p, q) = (2, 2)$, which confirms the inf-sup condition.

Now we verify the assumptions of Theorem 3.8 on the whole space $D = V$. Assumption 1 is again the inf-sup condition (3.34). The Legendre–Clebsch condition 2 is satisfied due to $\alpha > 0$ and the linearity of the constraints, as is the positive definiteness condition 3 for $\partial_x^2 L(v)$. Since Theorem 3.8 thus holds on V, we can apply Theorem 3.10, which yields the claim. ∎

Remark 3.12. The main conditions to verify are the inf-sup constraint qualification and the convexity. While the latter has been explicitly assumed, the former is a direct consequence of the box constraints. More complex optimization problems require more work to verify the assumptions of Theorem 3.10. Nonlinearity of the state equation needs to be compensated by convexity and an a priori bound on λ as given by Theorem 3.6 in order to obtain convexity of the Lagrangian with respect to x. The inf-sup constraint qualification can be shown for more general constraints, e.g., pointwise convex polyhedric admissible sets for the control. It needs to be verified that at most n_u constraints are nearly active.

Numerical results for a specific problem of this class are given in [39].

4. A short-step path-following method. With the refined estimates from section 3.2, we can show linear convergence of a short-step path-following method. Note that this is a purely theoretical algorithm, since it relies on the exact solution of operator equations in function space and on knowledge of global Lipschitz constants. For an implementable approximation via inexact Newton corrector and inexact tangential predictor, we refer to [39].

We consider the following simple algorithm.

ALGORITHM 4.1.

1 initialize v_0, μ_0 such that $F(v_0; \mu_0) = 0$
2 choose $\sigma < 1$ sufficiently large
3 while $\mu_k > 0$
4 advance $\mu_{k+1} \leftarrow \sigma\mu_k$
5 compute one corrector step $\partial_v F(v_k; \mu_{k+1})\delta v_k = -\partial_\mu F(v_k; \mu_{k+1})$
6 advance $v_{k+1} \leftarrow v_k + \delta v_k$, $k \leftarrow k + 1$

The sequence v_k of iterates converges to the Kuhn–Tucker point $v(0)$.

First, we recall the essentials of an affine covariant Newton–Mysovskikh theorem from [16].

THEOREM 4.2. *Assume $F : X \to Y$ is a differentiable mapping with $F(x^*) = 0$. Assume the derivative $F'(x)$ is invertible on $D = S(x^*, \delta)$ and satisfies*

$$\|F'(x)^{-1}(F'(y) - F'(x))\| \le \omega\|y - x\| \tag{4.1}$$

for $x, y \in D$. Let the ordinary Newton sequence x^k starting at $x^0 \in D$ be defined by $x^{k+1} = x^k - F'(x^k)^{-1}F(x^k)$. Then x^k converges to x^* at a rate of

$$\|x^{k+1} - x^*\| \le \frac{\omega}{2}\|x^k - x^*\|^2.$$

THEOREM 4.3. *Suppose that F satisfies the assumptions of Theorem* 3.10*, providing a bounded set D. Let $v_0 \in D$ and $\mu_0 > 0$ be given such that $F(v_0; \mu_0) = 0$. Then there is a constant $\sigma < 1$ such that the sequence v_k of iterates generated by Algorithm* 4.1 *converges linearly to the limit point $v(0)$ of the central path.*

Proof. To begin with, we verify the assumptions of Theorem 4.2. By Theorems 3.2 and 3.8 there are constants γ_1 and γ_2 independent of $\mu \le \mu_0$, such that $\|\partial_v F(v; \mu) - \partial_v F(v(\mu); \mu)\|_{V\to Z} \le \gamma_1\mu^{-1/2}$ and $\|\partial_v F(v(\mu); \mu)^{-1}\|_{Z\to V} \le \gamma_2$. Omitting the argument μ from F, we use the Banach perturbation lemma to derive

$$\begin{aligned}
&\|\partial_v F(v)^{-1}\|_{Z\to V} \\
&\quad \le \|\partial_v F(v(\mu))^{-1}\|_{Z\to V}\|(I - (\partial_v F(v(\mu)) - \partial_v F(v))\partial_v F(v(\mu))^{-1})^{-1}\|_{Z\to Z} \\
&\quad \le \frac{\gamma_2}{1 - \gamma_1\mu^{-1/2}\|v - v(\mu)\|_V\gamma_2} \le 2\gamma_2
\end{aligned}$$

for $v \in D = S\big(v(\mu), \sqrt{\mu}/(2\gamma_2\gamma_1)\big)$. For $v_1, v_2 \in D$ we thus obtain

$$\begin{aligned}
&\|\partial_v F(v_1)^{-1}(\partial_v F(v_2) - \partial_v F(v_2))\|_{V\to V} \\
&\quad \le \|\partial_v F(v_1)^{-1}\|_{Z\to V}\|(\partial_v F(v_2) - \partial_v F(v_1))\|_{V\to Z} \\
&\quad \le 2\gamma_2\gamma_1\mu^{-1/2}\|v_2 - v_1\|_V,
\end{aligned}$$

which establishes the Lipschitz condition (4.1) with

$$\omega(\mu) \le \frac{2\gamma_2\gamma_1}{\sqrt{\mu}}.$$

As in (3.32) in the proof of Theorem 3.10, we obtain a bound on the derivative of the central path in the form of

$$\|v'(\mu)\|_V \le \frac{\beta}{\sqrt{\mu}}$$

with $\beta < \infty$ independent of μ. Define

$$\delta = (2\gamma_2\gamma_1)^{-1} \quad \text{and} \quad \sigma \ge \left(1 - \frac{\delta}{2(\delta + \beta)}\right)^2. \tag{4.2}$$

Let us assume by induction that $\|v_k - v(\mu_k)\|_V \le \delta\sqrt{\mu_k}/2$. Then we have

$$\begin{aligned}
\|v_k - v(\sigma\mu_k)\|_V &\le \|v_k - v(\mu_k)\|_V + (1 - \sigma)\mu_k \sup_{\mu\in[\sigma\mu_k, \mu_k]} \|v'(\mu)\|_V \\
&\le \frac{\delta\sqrt{\mu_k}}{2} + (1 - \sigma)\mu_k\beta(\sigma\mu_k)^{-1/2} \\
&= \sqrt{\mu_k}\left(\frac{\delta}{2} + \frac{\beta}{\sqrt{\sigma}} + \beta\sqrt{\sigma}\right).
\end{aligned}$$

With σ given by (4.2), some tedious calculation verifies

$$\frac{\delta}{2} + \frac{\beta}{\sqrt{\sigma}} + \beta\sqrt{\sigma} \le \delta\sqrt{\sigma}$$

and hence

$$\|v_k - v(\sigma\mu_k)\|_V \le \delta\sqrt{\mu_k\sigma}.$$

Now the corrector step, which is a Newton step for the problem $F(v;\sigma\mu_k) = 0$, leads to

$$\begin{aligned}\|v_{k+1} - v(\mu_{k+1})\|_V &\le \frac{\omega(\mu)}{2}\|v_k - v(\mu_{k+1})\|_V^2 \le \frac{\omega(\mu)}{2}\delta^2\mu_{k+1} \\ &\le \frac{\delta}{2}\sqrt{\mu_{k+1}},\end{aligned}$$

which completes the induction. As for the convergence of the iterates, we observe that by Theorem 3.10

$$\begin{aligned}\|v_k - v(0)\|_V &\le \|v_k - v(\mu_k)\|_V + \|v(\mu_k) - v(0)\|_V \\ &\le \frac{\delta}{2}\sqrt{\mu_k} + \text{const}\,\sqrt{\mu_k} \\ &\le \text{const}\,\sigma^{k/2}\sqrt{\mu_0},\end{aligned}$$

which proves linear convergence of $v_k \to v(0)$. ∎

A SEARCH ALGORITHM FOR A CLASS OF OPTIMAL FINITE-PRECISION CONTROLLER REALIZATION PROBLEMS WITH SADDLE POINTS*

JUN WU†, SHENG CHEN‡, GANG LI§, AND JIAN CHU†

Abstract. With game theory, we review the optimal digital controller realization problems that maximize a finite word length (FWL) closed-loop stability measure. For a large class of these optimal FWL controller realization problems which have saddle points, a minimax-based search algorithm is derived for finding a global optimal solution. The algorithm consists of two stages. In the first stage, the closed form of a transformation set is constructed which contains global optimal solutions. In the second stage, a subgradient approach searches this transformation set to obtain a global optimal solution. This algorithm does not suffer from the usual drawbacks associated with using direct numerical optimization methods to tackle these FWL realization problems. Furthermore, for a small class of optimal FWL controller realization problems which have no saddle point, the proposed algorithm also provides useful information to help solve them.

Key words. closed-loop stability, digital controller, finite word length, game theory, optimization, saddle points

1. Introduction.

There has been a growing awareness that finite-precision controller implementation can have a serious influence on the actual performance of a digital closed-loop control system [1], [2], [3]. Due to the finite word length (FWL) errors, a casual controller implementation may degrade the designed closed-loop performance, or even destabilize the designed stable closed-loop system, if the controller implementation structure is not carefully chosen. The FWL effect has become more critical with the growing popularity of robust controller design methods which focus only on dealing with large plant uncertainty and result in controllers of much higher order and complexity than traditional classical control [2]. There are generally two types of FWL errors in the digital controller implementation. The first one is the rounding errors that occur in arithmetic operations [4], [5], and the second one is the controller parameter representation errors which have critical influence on closed-loop stability [6], [7], [8], [9], [10], [11], [12]. Typically, these two types of errors are investigated separately for the reason of mathematical tractability.

In general, there exist two different strategies, called the direct and indirect strategies, for constructing digital controllers that can tolerate FWL implementation errors. For the indirect strategy, the transfer function of the digital controller has been de-

signed by some controller synthesis methods. It is well known that a transfer function can be fulfilled with different realizations, and different realizations possess different degrees of robustness to FWL errors. This property can be utilized to select "optimal" realizations that optimize some FWL performance measures. Various FWL performance measures have been investigated, and these include the averaged roundoff noise gain [5], the complex stability radius measure [6], the transfer function sensitivity measure [7], the l_1-based stability measure [8], the Frobenius-norm pole sensitivity measure [9], and the 1-norm pole sensitivity measure [10], [11]. In the direct strategy, controller design involves explicitly the considerations of FWL implementation. By extending the standard H_∞ control design to include FWL controller parameter perturbations, the work of [12] developed a Riccati inequality approach, which directly obtains optimal controller realizations satisfying both the H_∞ robustness and FWL closed-loop stability requirements. Similarly, by extending the standard linear quadratic Gaussian (LQG) control design to include the effects of FWL roundoff noise, the work of [4] developed a FWL-LQG controller design method. The direct strategy appears to be better than the indirect strategy, since the former does not make specific assumptions on the controller, and in theory it should be a preferred approach. However, except for a few methods, such as H_∞ and LQG, it is very difficult to extend various controller design methods to this direct strategy. But this difficulty does not exist in the indirect strategy, where controller synthesis and controller realization are two separate steps. Various existing controller design methods can be used to attain a transfer function or an initial realization of the controller, which can then be optimized to satisfy FWL implementation requirements.

This paper adopts the indirect strategy with the Frobenius-norm pole sensitivity measure proposed in [9]. Our motivation is as follows. The Frobenius-norm pole sensitivity measure was derived in [9], and the optimal controller realization problem was defined as the maximization of this measure over all the possible controller realizations. An analytical solution to this class of optimal realization problems was attempted in [9]. However, it was pointed out that the conditions presented in [9] are not sufficient to provide an optimal realization [13]. Consequently, the solution expression presented in [9] is in general a suboptimal solution, and numerical optimization methods have to be adopted [14] to find optimal solutions. Since these optimal FWL realization problems are highly complicated nonlinear and nonconvex optimization problems, especially when the order of the controller is large, a direct numerical optimization is computationally very expensive. Moreover, chances of search being trapped at some bad local solutions increase for large-scale problems, and it is impossible to tell whether or not a solution obtained is a global optimum. In this paper, these optimal FWL controller realization problems are reviewed with game theory [15], [16]. They are consequently divided into two types: optimization problems which have saddle points and optimization problems which do not have a saddle point.

For the class of optimal FWL realization problems with saddle points, this paper derives a minimax-based search algorithm for finding global optimal solutions. Our search algorithm is computationally much more efficient than usual numerical optimization for tackling this class of complicated optimization problems. Moreover, when this algorithm attains a solution, it is guaranteed to be a global optimal realization. Comments are made regarding why in practice the class of these optimization problems with saddle points is much larger than the class having no saddle point. It is shown that our proposed search algorithm is also useful in helping to solve the small class of these optimal FWL realization problems which have no saddle point. The

remainder of the paper is organized as follows. Section 2 defines the optimal FWL controller realization problem considered in this study and introduces some necessary mathematical preliminaries. In section 3, the proposed two-stage search algorithm is derived. Section 4 discusses the practical value of this algorithm. Section 5 presents several design examples, and the paper concludes with section 6.

2. Problem definition and preliminaries. For a complex-valued matrix $\mathbf{M} = [m_{ij}]$, $\mathbf{M}^T$ is the transposed matrix of $\mathbf{M}$, $\mathbf{M}^H$ is the Hermitian adjoint matrix of $\mathbf{M}$, $\mathbf{M}^*$ is conjugate to $\mathbf{M}$,

$$\|\mathbf{M}\|_{\max} \triangleq \max_{i,j} |m_{ij}|, \tag{1}$$

and the Frobenius norm is defined as

$$\|\mathbf{M}\|_F \triangleq \left(\sum_{i,j} |m_{ij}|^2 \right)^{1/2}. \tag{2}$$

Let $\mathrm{Vec}(\cdot)$ be the column stacking operator such that $\mathrm{Vec}(\mathbf{M})$ is a vector. For a real-valued positive semidefinite matrix $\mathbf{D} \geq 0$, the matrix $\mathbf{D}^{1/2}$ satisfies $\mathbf{D}^{1/2}(\mathbf{D}^{1/2})^T = \mathbf{D}$. For two real-valued matrices $\mathbf{M} = [m_{ij}]$ and $\mathbf{N} = [n_{ij}]$ of the same dimension, denote

$$\langle \mathbf{M}, \mathbf{N} \rangle = \sum_{i,j} m_{ij} n_{ij}. \tag{3}$$

2.1. Problem definition. Consider the discrete-time closed-loop control system, consisting of a linear time-invariant plant $P(z)$ and a digital controller $C(z)$. The plant model $P(z)$ is assumed to be strictly proper with a state-space description

$$\begin{cases} \mathbf{x}_P(t+1) = \mathbf{A}_P \mathbf{x}_P(t) + \mathbf{B}_P \mathbf{u}(t), \\ \mathbf{z}(t) = \mathbf{C}_P \mathbf{x}_P(t), \end{cases} \tag{4}$$

where $\mathbf{A}_P \in \mathcal{R}^{m \times m}$, $\mathbf{B}_P \in \mathcal{R}^{m \times l}$, and $\mathbf{C}_P \in \mathcal{R}^{q \times m}$. The digital controller $C(z)$ is described by

$$\begin{cases} \mathbf{x}_C(t+1) = \mathbf{A}_C \mathbf{x}_C(t) + \mathbf{B}_C \mathbf{z}(t), \\ \mathbf{u}(t) = \mathbf{C}_C \mathbf{x}_C(t) + \mathbf{D}_C \mathbf{z}(t), \end{cases} \tag{5}$$

with $\mathbf{A}_C \in \mathcal{R}^{n \times n}$, $\mathbf{B}_C \in \mathcal{R}^{n \times q}$, $\mathbf{C}_C \in \mathcal{R}^{l \times n}$, and $\mathbf{D}_C \in \mathcal{R}^{l \times q}$. Denote the *realization* of $C(z)$ as

$$\mathbf{X} \triangleq \begin{bmatrix} \mathbf{D}_C & \mathbf{C}_C \\ \mathbf{B}_C & \mathbf{A}_C \end{bmatrix}. \tag{6}$$

Assume that an initial realization of $C(z)$,

$$\mathbf{X}_0 \triangleq \begin{bmatrix} \mathbf{D}_C^0 & \mathbf{C}_C^0 \\ \mathbf{B}_C^0 & \mathbf{A}_C^0 \end{bmatrix}, \tag{7}$$

has been given by some controller synthesis method. Then all the realizations of $C(z)$ form a set

$$\mathcal{S}_C \triangleq \left\{ \mathbf{X} : \mathbf{X} = \mathbf{X}(\mathbf{T}) = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^{-1} \end{bmatrix} \mathbf{X}_0 \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T} \end{bmatrix} \right\}, \tag{8}$$

where the transformation $\mathbf{T} \in \mathcal{R}^{n\times n}$ is an arbitrary nonsingular matrix, and $\mathbf{0}$ and $\mathbf{I}$ denote the zero and identity matrices of appropriate dimensions, respectively. $\mathcal{S}_C$ is not a convex set, as

$$\lambda \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}_1^{-1} \end{bmatrix} \mathbf{X}_0 \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}_1 \end{bmatrix} + (1-\lambda) \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}_2^{-1} \end{bmatrix} \mathbf{X}_0 \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}_2 \end{bmatrix} \tag{9}$$

may not belong to $\mathcal{S}_C$ for any nonsingular $\mathbf{T}_1, \mathbf{T}_2 \in \mathcal{R}^{n\times n}$ and $0 < \lambda < 1$. The stability of the closed-loop control system depends on the eigenvalues of the closed-loop transition matrix

$$\begin{aligned} \overline{\mathbf{A}}(\mathbf{X}) &= \begin{bmatrix} \mathbf{A}_P + \mathbf{B}_P\mathbf{D}_C\mathbf{C}_P & \mathbf{B}_P\mathbf{C}_C \\ \mathbf{B}_C\mathbf{C}_P & \mathbf{A}_C \end{bmatrix} \\ &= \begin{bmatrix} \mathbf{A}_P & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} + \begin{bmatrix} \mathbf{B}_P & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \mathbf{X} \begin{bmatrix} \mathbf{C}_P & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \triangleq \mathbf{M}_0 + \mathbf{M}_1\mathbf{X}\mathbf{M}_2. \end{aligned} \tag{10}$$

All the different realizations $\mathbf{X}$ in $\mathcal{S}_C$ have exactly the same set of closed-loop poles if they are implemented with infinite precision. Since the closed-loop system has been designed to be stable, all the eigenvalues $\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))$, $1 \le k \le m+n$, of $\overline{\mathbf{A}}(\mathbf{X})$ are within the unit disk.

When $\mathbf{X}$ is implemented with an FWL digital processor of fixed-point format, it is perturbed to $\mathbf{X} + \Delta\mathbf{X}$. Each element of $\Delta\mathbf{X}$ is bounded by $\pm\varepsilon$; that is, $\|\Delta\mathbf{X}\|_{\max} \le \varepsilon$, where ε is the maximum representation error of the digital processor. With the perturbation $\Delta\mathbf{X}$, $\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))$ is moved to $\lambda_k(\overline{\mathbf{A}}(\mathbf{X}+\Delta\mathbf{X}))$. If an eigenvalue of $\overline{\mathbf{A}}(\mathbf{X}+\Delta\mathbf{X})$ is outside the open unit disk, the closed-loop system, designed to be stable, becomes unstable with the finite-precision implemented $\mathbf{X}$. It is therefore critical to know when the FWL error will cause closed-loop instability. This means that we would like to know the largest open "hypercube" in the perturbation space within which the closed-loop system remains stable. The size of this perturbation hypercube quantifies the FWL characteristics of $\mathbf{X}$ and is therefore a true FWL closed-loop stability measure for $\mathbf{X}$ [17].

Computing the size of this largest stable perturbation hypercube, however, is an unsolved open problem. An approximation to this true FWL closed-loop stability measure is the following Frobenius-norm pole sensitivity measure defined in [9]:

$$f(\mathbf{X}) \triangleq \min_{k\in\{1,\ldots,m+n\}} \frac{1 - |\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))|}{\sqrt{(l+n)(q+n)}\left\|\frac{\partial\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial\mathbf{X}}\right\|_F}. \tag{11}$$

Rigorous discussions regarding the rationality of $f(\mathbf{X})$ as an FWL closed-loop stability measure can be found in [9], [11]. Basically, under some mild assumptions and using a first-order approximation, it can be shown that the closed-loop system remains stable if $\|\Delta\mathbf{X}\|_{\max} < f(\mathbf{X})$. It has been argued in [18] that estimates obtained from first-order perturbation theory are often more realistic than rigorous bounds obtained by other means. Thus, the larger $f(\mathbf{X})$ is, the larger an FWL error $\Delta\mathbf{X}$ that the closed-loop system can tolerate. Moreover, $f(\mathbf{X})$ is computationally tractable, as is summarized in the following lemma given by [19].

LEMMA 1. *Let* $\overline{\mathbf{A}}(\mathbf{X}) = \mathbf{M}_0 + \mathbf{M}_1\mathbf{X}\mathbf{M}_2$ *given in* (10) *be diagonalizable. Denote* $\mathbf{p}_k$ *a right eigenvector of* $\overline{\mathbf{A}}(\mathbf{X})$ *corresponding to the eigenvalue* $\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))$. *The*

reciprocal left eigenvector $\mathbf{y}_k$ *related to* $\mathbf{p}_k$ *is obtained from* $[\mathbf{y}_1, \mathbf{y}_2, \ldots, \mathbf{y}_{m+n}] = [\mathbf{p}_1, \mathbf{p}_2, \ldots, \mathbf{p}_{m+n}]^{-H}$. *Then*

$$\frac{\partial \lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial \mathbf{X}} = \mathbf{M}_1^T \mathbf{y}_k^* \mathbf{p}_k^T \mathbf{M}_2^T \quad \forall k \in \{1, \ldots, m+n\}. \tag{12}$$

As different controller realizations $\mathbf{X}$ result in different values of $f(\mathbf{X})$, it is natural to search for "optimal" controller realizations that maximize the measure defined in (11). This leads to the following optimal FWL realization problem [9]:

$$\upsilon \triangleq \max_{\mathbf{X} \in \mathcal{S}_C} f(\mathbf{X}). \tag{13}$$

Numerical optimization methods have been used to attain solutions of this optimal realization problem (e.g., [14]). In general, the optimization problem (13) is highly nonlinear and nonconvex. Thus, numerical optimization methods do not guarantee attaining a global optimal solution and suffer from high costs, particularly for large-scale systems.

Now, let us define

$$g(\mathbf{X}, k) \triangleq \frac{1 - |\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))|}{\sqrt{(l+n)(q+n)} \left\| \frac{\partial \lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial \mathbf{X}} \right\|_F}. \tag{14}$$

Obviously, the optimal FWL realization problem (13) can be viewed as

$$\upsilon = \max_{\mathbf{X} \in \mathcal{S}_C} \min_{k \in \{1, \ldots, m+n\}} g(\mathbf{X}, k). \tag{15}$$

2.2. Saddle points and minimax theorem. This subsection introduces without proofs some properties of saddle points and the minimax theorem, which are useful in solving the optimization problem (15). The detailed discussion of this topic can be found in the standard game theory textbooks, such as [15], [16].

DEFINITION 1. $(\mathbf{X}', k') \in \mathcal{S}_C \times \{1, \ldots, m+n\}$ *is said to be a saddle point of* $g(\mathbf{X}, k)$ *if*

$$g(\mathbf{X}, k') \le g(\mathbf{X}', k') \le g(\mathbf{X}', k) \quad \forall \mathbf{X} \in \mathcal{S}_C, \ \forall k \in \{1, \ldots, m+n\}. \tag{16}$$

THEOREM 1. *If both* $(\mathbf{X}', k')$ *and* $(\mathbf{X}'', k'')$ *are saddle points of* $g(\mathbf{X}, k)$, *then*

$$g(\mathbf{X}', k') = g(\mathbf{X}'', k''). \tag{17}$$

The following theorem is the well-known minimax theorem in game theory.

THEOREM 2. *If and only if there exists at least a saddle point* $(\mathbf{X}', k')$ *of* $g(\mathbf{X}, k)$, *then*

$$\max_{\mathbf{X} \in \mathcal{S}_C} \min_{k \in \{1, \ldots, m+n\}} g(\mathbf{X}, k) = \min_{k \in \{1, \ldots, m+n\}} \max_{\mathbf{X} \in \mathcal{S}_C} g(\mathbf{X}, k) = g(\mathbf{X}', k'). \tag{18}$$

A direct corollary of Theorem 2 is stated as follows.

COROLLARY 1. *If* $g(\mathbf{X}, k)$ *has no saddle point, then*

$$\max_{\mathbf{X} \in \mathcal{S}_C} \min_{k \in \{1, \ldots, m+n\}} g(\mathbf{X}, k) < \min_{k \in \{1, \ldots, m+n\}} \max_{\mathbf{X} \in \mathcal{S}_C} g(\mathbf{X}, k). \tag{19}$$

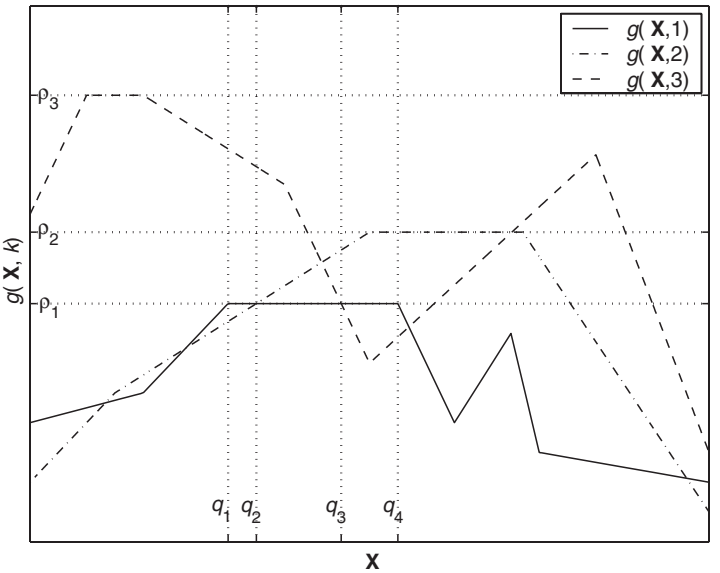

FIG. 1. *A simple illustration of ρ_k, $\mathcal{X}$, and saddle points.*

Theorems 1 and 2 show that for the optimal FWL realization problem (15) which has saddle points, any saddle point of $g(\mathbf{X}, k)$ is a global optimal solution of (15). Define

$$\rho_k \stackrel{\triangle}{=} \max_{\mathbf{X} \in \mathcal{S}_C} g(\mathbf{X}, k) \tag{20}$$

for $k \in \{1, \ldots, m+n\}$ and the index

$$k' = \arg \min_{k \in \{1,\ldots,m+n\}} \rho_k. \tag{21}$$

There exist an infinite number of $\mathbf{X} \in \mathcal{S}_C$ such that $g(\mathbf{X}, k') = \rho_{k'}$. Define

$$\mathcal{X} \stackrel{\triangle}{=} \{\mathbf{X} : g(\mathbf{X}, k') = \rho_{k'}, \mathbf{X} \in \mathcal{S}_C\}. \tag{22}$$

Figure 1 depicts a simple illustration for a case of ρ_k with $k \in \{1, 2, 3\}$. It is easily seen that in this case $\mathcal{X}$ is the segment between q_1 and q_4 on the $\mathbf{X}$-axis. It can also be observed in Figure 1 that the points between q_2 and q_3 (a subset of $\mathcal{X}$) are the realizations corresponding to saddle points. This observation accords with the following theorem, which provides a method for finding a saddle point.

THEOREM 3. *If and only if $\mathbf{X}' \in \mathcal{X}$ satisfies*

$$g(\mathbf{X}', k) \geq \rho_{k'} \quad \forall k \in \{1, \ldots, m+n\} \setminus \{k'\}, \tag{23}$$

then $(\mathbf{X}', k')$ is a saddle point of $g(\mathbf{X}, k)$.

3. Search algorithm. A main objective of this paper is how to find a global optimal solution to the optimal FWL realization problem (15) which has saddle points. In other words, we assume that there exist saddle points for $g(\mathbf{X}, k)$ in the problem (15). What happens if the problem has no saddle point and how to deal with it will be

discussed in section 4. Based on Theorem 3, a two-stage algorithm is developed to find a saddle point of the optimal FWL controller realization problem (15). The first stage focuses the attention on solving the optimization problem (20) for $k \in \{1, \ldots, m+n\}$, and the index k' and the closed-form expression of $\mathcal{X}$ are obtained in this stage. The second stage searches $\mathcal{X}$ for a controller realization $\mathbf{X}_{\text{opt}}$ that meets the condition $g(\mathbf{X}_{\text{opt}}, k) \geq \rho_{k'}\ \forall k \in \{1, \ldots, m+n\} \setminus \{k'\}$. Such an $\mathbf{X}_{\text{opt}}$ is a global optimal solution to the optimal FWL controller realization problem (13). We now discuss this two-stage algorithm in detail.

3.1. Stage 1 of the algorithm. It is known easily from (8) and (10) that

$$\overline{\mathbf{A}}(\mathbf{X}) = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^{-1} \end{bmatrix} \overline{\mathbf{A}}(\mathbf{X}_0) \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T} \end{bmatrix}. \tag{24}$$

This means that $\forall \mathbf{X} \in \mathcal{S}_C$, $\lambda_k(\overline{\mathbf{A}}(\mathbf{X})) = \lambda_k(\overline{\mathbf{A}}(\mathbf{X}_0))$. Thus, from (14), solving the maximization problem (20) is equivalent to solving the following minimization problem:

$$\eta_k \stackrel{\triangle}{=} \min_{\mathbf{X} \in \mathcal{S}_C} \left\| \frac{\partial \lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial \mathbf{X}} \right\|_F. \tag{25}$$

Combining Lemma 1 with the definition of $\|\cdot\|_F$, one has

$$\left\| \frac{\partial \lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial \mathbf{X}} \right\|_F = \|\mathbf{M}_1^T \mathbf{y}_k\|_F \, \|\mathbf{M}_2 \mathbf{p}_k\|_F \,. \tag{26}$$

Let $\mathbf{p}_k$ and $\mathbf{y}_k$ be partitioned into

$$\mathbf{p}_k = \begin{bmatrix} \mathbf{p}_k(1) \\ \mathbf{p}_k(2) \end{bmatrix}, \quad \mathbf{y}_k = \begin{bmatrix} \mathbf{y}_k(1) \\ \mathbf{y}_k(2) \end{bmatrix}, \quad \mathbf{p}_k(1), \mathbf{y}_k(1) \in \mathcal{C}^m, \quad \mathbf{p}_k(2), \mathbf{y}_k(2) \in \mathcal{C}^n. \tag{27}$$

Then it follows from (24) that

$$\begin{bmatrix} \mathbf{p}_k(1) \\ \mathbf{p}_k(2) \end{bmatrix} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^{-1} \end{bmatrix} \begin{bmatrix} \mathbf{p}_{0k}(1) \\ \mathbf{p}_{0k}(2) \end{bmatrix}, \quad \begin{bmatrix} \mathbf{y}_k(1) \\ \mathbf{y}_k(2) \end{bmatrix} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^T \end{bmatrix} \begin{bmatrix} \mathbf{y}_{0k}(1) \\ \mathbf{y}_{0k}(2) \end{bmatrix}, \tag{28}$$

where $\left[\mathbf{p}_{0k}^T(1)\ \mathbf{p}_{0k}^T(2)\right]^T$ and $\left[\mathbf{y}_{0k}^T(1)\ \mathbf{y}_{0k}^T(2)\right]^T$ are the right and reciprocal left eigenvectors of $\overline{\mathbf{A}}(\mathbf{X}_0)$ corresponding to $\lambda_k(\overline{\mathbf{A}}(\mathbf{X}_0))$, respectively. Combining (10) and (26)–(28), we have

$$\begin{aligned} \left\| \frac{\partial \lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial \mathbf{X}} \right\|_F^2 &= \|\mathbf{T}^{-1}\mathbf{p}_{0k}(2)\|_F^2 \|\mathbf{T}^T\mathbf{y}_{0k}(2)\|_F^2 \\ &\quad + \alpha_k^2 \|\mathbf{T}^T\mathbf{y}_{0k}(2)\|_F^2 + \beta_k^2 \|\mathbf{T}^{-1}\mathbf{p}_{0k}(2)\|_F^2 + \alpha_k^2\beta_k^2, \end{aligned} \tag{29}$$

where the constants $\alpha_k = \|\mathbf{C}_P \mathbf{p}_{0k}(1)\|_F$ and $\beta_k = \|\mathbf{B}_P^T \mathbf{y}_{0k}(1)\|_F$. It is easy to see that, in order to attain ρ_k, we need to minimize the function

$$\xi(\mathbf{T}, \alpha, \beta, \mathbf{p}, \mathbf{y}) \stackrel{\triangle}{=} \|\mathbf{T}^{-1}\mathbf{p}\|_F^2 \|\mathbf{T}^T\mathbf{y}\|_F^2 + \alpha^2 \|\mathbf{T}^T\mathbf{y}\|_F^2 + \beta^2 \|\mathbf{T}^{-1}\mathbf{p}\|_F^2 + \alpha^2\beta^2. \tag{30}$$

There are three different cases on minimizing $\xi(\mathbf{T}, \alpha, \beta, \mathbf{p}, \mathbf{y})$, depending on whether $\mathbf{p}$ and $\mathbf{y}$ are real-valued or complex-valued.

Case 1. $\mathbf{p}, \mathbf{y} \in \mathcal{R}^n$ and $\mathbf{y}^T\mathbf{p} \neq 0$.

Case 2. $\mathbf{p}, \mathbf{y} \in \mathcal{C}^n$ and $\det((\Upsilon(\mathbf{y}))^T\Upsilon(\mathbf{p})) > 0$, where

$$\Upsilon(\mathbf{y}) \triangleq [\mathrm{Re}(\mathbf{y})\ \mathrm{Im}(\mathbf{y})] \tag{31}$$

with $\mathrm{Re}(\mathbf{y})$ and $\mathrm{Im}(\mathbf{y})$ denoting the real and imaginary parts of $\mathbf{y}$, respectively.

Case 3. $\mathbf{p}, \mathbf{y} \in \mathcal{C}^n$ and $\det((\Upsilon(\mathbf{y}))^T\Upsilon(\mathbf{p})) < 0$.

Let $\mathbf{e}_i$ denote the ith coordinate vector, and define

$$\mathbf{r} \triangleq \begin{cases} \mathbf{y} & \text{for Case 2,} \\ \mathbf{y}^* & \text{for Case 3.} \end{cases} \tag{32}$$

The following theorem gives the results on minimizing $\xi(\mathbf{T}, \alpha, \beta, \mathbf{p}, \mathbf{y})$ for Cases 2 and 3. Case 1 is much simpler than Cases 2 and 3, and the result for Case 1 can easily be obtained in a similar way.

THEOREM 4. *Given positive* $\alpha, \beta \in \mathcal{R}$, $\mathbf{p}$ *and* $\mathbf{y}$ *being of Case* 2 *or* 3, *we have*

$$\min_{\substack{\mathbf{T}\in\mathcal{R}^{n\times n} \\ \det \mathbf{T}\neq 0}} \xi(\mathbf{T}, \alpha, \beta, \mathbf{p}, \mathbf{y}) = (|\mathbf{r}^H\mathbf{p}| + \alpha\beta)^2, \tag{33}$$

and $\xi(\mathbf{T}, \alpha, \beta, \mathbf{p}, \mathbf{y})$ *achieves the minimum if and only if*

$$\mathbf{T} = \mathbf{Q}\begin{bmatrix} \mathbf{H}^{1/2} & \mathbf{0} \\ \mathbf{F}(\mathbf{H}^{1/2})^{-T} & \mathbf{\Omega} \end{bmatrix}\mathbf{V}, \tag{34}$$

where $\mathbf{V} \in \mathcal{R}^{n\times n}$ *is an arbitrary orthogonal matrix, and* $\mathbf{\Omega} \in \mathcal{R}^{(n-2)\times(n-2)}$ *is an arbitrary nonsingular matrix; the orthogonal matrix* $\mathbf{Q}$ *can be obtained from the QR factorization of* $\Upsilon(\mathbf{r})$, *that is,*

$$\Upsilon(\mathbf{r}) = \mathbf{Q}\begin{bmatrix} \gamma_{11} & 0 & 0 & \cdots & 0 \\ \gamma_{12} & \gamma_{22} & 0 & \cdots & 0 \end{bmatrix}^T; \tag{35}$$

and the matrices $\mathbf{H}$ *and* $\mathbf{F}$ *are determined by*

$$\mathbf{H} = \frac{\beta}{\alpha}\begin{bmatrix} \gamma_{11} & \gamma_{12} \\ 0 & \gamma_{22} \end{bmatrix}^{-T}(\Upsilon(\mathbf{r}))^T\Upsilon(\mathbf{p})\begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} \gamma_{11} & \gamma_{12} \\ 0 & \gamma_{22} \end{bmatrix}^{-1} \tag{36}$$

and

$$\mathbf{F} = \frac{\beta}{\alpha}\begin{bmatrix} \mathbf{e}_3^T \\ \vdots \\ \mathbf{e}_n^T \end{bmatrix}\mathbf{Q}^T\Upsilon(\mathbf{p})\begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}\begin{bmatrix} \gamma_{11} & \gamma_{12} \\ 0 & \gamma_{22} \end{bmatrix}^{-1} \tag{37}$$

with $\theta \in [0, 2\pi)$ *which is solved from*

$$\begin{cases} \tan\theta = \frac{a_{21}-a_{12}}{a_{11}+a_{22}}, \\ a_{11}\cos\theta - a_{12}\sin\theta > 0 \end{cases} \tag{38}$$

and

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \triangleq (\Upsilon(\mathbf{r}))^T\Upsilon(\mathbf{p}). \tag{39}$$

Proof. See the appendix. ∎

Using Theorem 4, the single-pole peak ρ_k for $k \in \{1, \ldots, m+n\}$ can be computed. For example, when $\mathbf{p}_{0k}(2), \mathbf{y}_{0k}(2) \in \mathcal{C}^n$, and $\det((\Upsilon(\mathbf{y}_{0k}(2)))^T \Upsilon(\mathbf{p}_{0k}(2))) > 0$, we have

$$\rho_k = \frac{1 - |\lambda_k(\overline{\mathbf{A}}(\mathbf{X}_0))|}{\sqrt{(l+n)(q+n)}(|\mathbf{y}_{0k}^H(2)\mathbf{p}_{0k}(2)| + \|\mathbf{C}_P\mathbf{p}_{0k}(1)\|_F \|\mathbf{B}_P^T\mathbf{y}_{0k}(1)\|_F)}. \tag{40}$$

Thus, the index k' is readily given from $\rho_{k'} = \min_{k\in\{1,\ldots,m+n\}} \rho_k$. In addition, Theorem 4 with (34)–(39) provides the closed-form transformation set

$$\mathcal{T} \stackrel{\triangle}{=} \left\{\mathbf{T} : g(\mathbf{X}(\mathbf{T}), k') = \rho_{k'}, \mathbf{T} \in \mathcal{R}^{n\times n}, \det \mathbf{T} \neq 0\right\}. \tag{41}$$

Since $\mathbf{X}$ depends on $\mathbf{T}$ as is defined in (8), the realization set $\mathcal{X}$ given in (22) is defined on the transformation set $\mathcal{T}$ as

$$\mathcal{X} = \left\{\mathbf{X} : \mathbf{X} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^{-1} \end{bmatrix} \mathbf{X}_0 \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T} \end{bmatrix}, \mathbf{T} \in \mathcal{T}\right\}. \tag{42}$$

3.2. Stage 2 of the algorithm. This stage searches in $\mathcal{T}$ for an optimal transformation $\mathbf{T}_{\text{opt}}$ that satisfies $g(\mathbf{X}(\mathbf{T}_{\text{opt}}), k) \geq \rho_{k'}\ \forall k \in \{1, \ldots, m+n\}\backslash\{k'\}$. According to Theorem 3, the corresponding realization $\mathbf{X}_{\text{opt}} = \mathbf{X}(\mathbf{T}_{\text{opt}})$ is a global optimal solution for the optimal realization problem (13). Without any loss of generality, we will assume that $\mathbf{p}_{k'}$ and $\mathbf{y}_{k'}$ is of Case 2. From Theorem 4, the transformation set (41) is specified by

$$\mathcal{T} = \left\{\mathbf{T} : \mathbf{T} = \mathbf{Q} \begin{bmatrix} \mathbf{H}^{1/2} & \mathbf{0} \\ \mathbf{F}(\mathbf{H}^{1/2})^{-T} & \mathbf{\Omega} \end{bmatrix} \mathbf{V}\right\}, \tag{43}$$

where $\mathbf{Q}$, $\mathbf{H}$, and $\mathbf{F}$ are determined in Theorem 4 by setting $\alpha = \|\mathbf{C}_P\mathbf{p}_{0k'}(1)\|_F$, $\beta = \|\mathbf{B}_P^T\mathbf{y}_{0k'}(1)\|_F$, $\mathbf{p} = \mathbf{p}_{0k'}(2)$, and $\mathbf{r} = \mathbf{y} = \mathbf{y}_{0k'}(2)$, $\mathbf{\Omega} \in \mathcal{R}^{(n-2)\times(n-2)}$ is an arbitrary nonsingular matrix, and $\mathbf{V} \in \mathcal{R}^{n\times n}$ is an arbitrary orthogonal matrix. From (14), (29), and the definition of $\|\cdot\|_F$, it can be seen that $g(\mathbf{X}(\mathbf{T}), k) = g(\mathbf{X}(\mathbf{TV}), k)$ for any orthogonal $\mathbf{V} \in \mathcal{R}^{n\times n}$ and nonsingular $\mathbf{T} \in \mathcal{R}^{n\times n}$. This means that $\mathbf{V}$ plays no role in computing the value of $g(\mathbf{X}, k)$, and hence we simply set $\mathbf{V} = \mathbf{I}$. Thus we explore only those

$$\mathbf{T} = \mathbf{T}(\mathbf{\Omega}) = \mathbf{Q} \begin{bmatrix} \mathbf{H}^{1/2} & \mathbf{0} \\ \mathbf{F}(\mathbf{H}^{1/2})^{-T} & \mathbf{\Omega} \end{bmatrix}, \tag{44}$$

and the objective becomes to search for a nonsingular $\mathbf{\Omega}_{\text{opt}} \in \mathcal{R}^{(n-2)\times(n-2)}$ such that $g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega}_{\text{opt}})), k) \geq \rho_{k'}\ \forall k \in \{1, \ldots, m+n\} \setminus \{k'\}$. The detailed search procedure is as follows.

Initialization: Arbitrarily select a nonsingular $\mathbf{\Omega} \in \mathcal{R}^{(n-2)\times(n-2)}$ to obtain an initial point $\mathbf{X}(\mathbf{T}(\mathbf{\Omega}))$, let N be a large enough integer and τ a small positive number, and set $N_t = 1$.

Step 1: Find out

$$e = \arg \min_{k\in\{1,\ldots,m+n\}} g(\mathbf{X}, k).$$

If $g(\mathbf{X}, e) = \rho_{k'}$, which means that (23) holds, then $\mathbf{\Omega}_{\text{opt}} = \mathbf{\Omega}$ and terminate the routine. If $g(\mathbf{X}, e) > \rho_{k'}$ but $N_t \geq N$, which means that no saddle point is found after a large number of iterations, then the routine is also terminated for practical consideration.

Step 2: $\mathbf{\Omega} = \mathbf{\Omega} + \tau \frac{\partial g(\mathbf{X},e)}{\partial \mathbf{\Omega}} \| \frac{\partial g(\mathbf{X},e)}{\partial \mathbf{\Omega}} \|_F^{-1}$, $N_t = N_t + 1$, and go to *Step* 1.

For calculating $\frac{\partial g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),e)}{\partial \mathbf{\Omega}}$, let $\mathbf{e}_i$ denote the ith coordinate vector. The following well-known fact is useful: given any element y_{ij} in a nonsingular $\mathbf{Y} \in \mathcal{R}^{n\times n}$ with $i \in \{1,\ldots,n\}$ and $j \in \{1,\ldots,n\}$,

$$\frac{\partial \mathbf{Y}}{\partial y_{ij}} = \mathbf{e}_i \mathbf{e}_j^T \quad \text{and} \quad \frac{\partial \mathbf{Y}^{-1}}{\partial y_{ij}} = -\mathbf{Y}^{-1}\mathbf{e}_i \mathbf{e}_j^T \mathbf{Y}^{-1}. \tag{45}$$

From (10), (14), (28), and Lemma 1, we know that

$$g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),e) = \frac{(1-|\lambda_e|)/\sqrt{(l+n)(q+n)}}{\left\| \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^T(\mathbf{\Omega}) \end{bmatrix} \mathbf{M}_1^T \mathbf{y}_{0e}^* \mathbf{p}_{0e}^T \mathbf{M}_2^T \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^{-T}(\mathbf{\Omega}) \end{bmatrix} \right\|_F}. \tag{46}$$

From (44), we have

$$\left\| \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^T(\mathbf{\Omega}) \end{bmatrix} \mathbf{M}_1^T \mathbf{y}_{0e}^* \mathbf{p}_{0e}^T \mathbf{M}_2^T \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{T}^{-T}(\mathbf{\Omega}) \end{bmatrix} \right\|_F = \left\| \mathbf{U}_1^T \mathbf{\Phi}_e \mathbf{U}_2^{-T} \right\|_F, \tag{47}$$

where $\mathbf{U}_1$, $\mathbf{U}_2$, and $\mathbf{\Phi}_e$ are given, respectively, by ($\mathbf{I}$ in $\mathbf{U}_1$ and $\mathbf{U}_2$ have different dimensions)

$$\mathbf{U}_1 = \left[\begin{array}{c|cc} \mathbf{I} & \multicolumn{2}{c}{\mathbf{0}} \\ \hline \mathbf{0} & \mathbf{H}^{1/2} & \mathbf{0} \\ & \mathbf{F}(\mathbf{H}^{1/2})^{-T} & \mathbf{\Omega} \end{array} \right], \tag{48}$$

$$\mathbf{U}_2 = \left[\begin{array}{c|cc} \mathbf{I} & \multicolumn{2}{c}{\mathbf{0}} \\ \hline \mathbf{0} & \mathbf{H}^{1/2} & \mathbf{0} \\ & \mathbf{F}(\mathbf{H}^{1/2})^{-T} & \mathbf{\Omega} \end{array} \right], \tag{49}$$

$$\mathbf{\Phi}_e = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}^T \end{bmatrix} \mathbf{M}_1^T \mathbf{y}_{0e}^* \mathbf{p}_{0e}^T \mathbf{M}_2^T \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}^{-T} \end{bmatrix}. \tag{50}$$

For any element ψ_{ts} in $\mathbf{\Psi}_e = \mathbf{U}_1^T \mathbf{\Phi}_e \mathbf{U}_2^{-T}$, where $t \in \{1,\ldots,l+n\}$ and $s \in \{1,\ldots,q+n\}$, and any ω_{ij} in $\mathbf{\Omega}$, where $i \in \{1,\ldots,n-2\}$ and $j \in \{1,\ldots,n-2\}$,

$$\begin{aligned} \frac{\partial \psi_{ts}}{\partial \omega_{ij}} &= \mathbf{e}_t^T \frac{\partial \mathbf{U}_1^T}{\partial \omega_{ij}} \mathbf{\Phi}_e \mathbf{U}_2^{-T} \mathbf{e}_s + \mathbf{e}_t^T \mathbf{U}_1^T \mathbf{\Phi}_e \frac{\partial \mathbf{U}_2^{-T}}{\partial \omega_{ij}} \mathbf{e}_s \\ &= \mathbf{e}_t^T \mathbf{e}_{l+2+j} \mathbf{e}_{l+2+i}^T \mathbf{\Phi}_e \mathbf{U}_2^{-T} \mathbf{e}_s - \mathbf{e}_t^T \mathbf{U}_1^T \mathbf{\Phi}_e \mathbf{U}_2^{-T} \mathbf{e}_{q+2+j} \mathbf{e}_{q+2+i}^T \mathbf{U}_2^{-T} \mathbf{e}_s \\ &= \mathbf{e}_t^T \mathbf{e}_{l+2+j} \mathbf{e}_{l+2+i}^T \mathbf{\Phi}_e \mathbf{U}_2^{-T} \mathbf{e}_s - \mathbf{e}_t^T \mathbf{\Psi}_e \mathbf{e}_{q+2+j} \mathbf{e}_{q+2+i}^T \mathbf{U}_2^{-T} \mathbf{e}_s. \end{aligned} \tag{51}$$

That is,

$$\begin{aligned} \frac{\partial \psi_{ts}}{\partial \mathbf{\Omega}} = &\begin{bmatrix} \mathbf{e}_t^T & & \\ & \ddots & \\ & & \mathbf{e}_t^T \end{bmatrix} \left(\begin{bmatrix} \mathbf{e}_{l+3}\mathbf{e}_{l+3}^T \mathbf{\Phi}_e & \cdots & \mathbf{e}_{l+n}\mathbf{e}_{l+3}^T \mathbf{\Phi}_e \\ \vdots & \cdots & \vdots \\ \mathbf{e}_{l+3}\mathbf{e}_{l+n}^T \mathbf{\Phi}_e & \cdots & \mathbf{e}_{l+n}\mathbf{e}_{l+n}^T \mathbf{\Phi}_e \end{bmatrix} \right. \\ &\left. - \begin{bmatrix} \mathbf{\Psi}_e \mathbf{e}_{q+3}\mathbf{e}_{q+3}^T & \cdots & \mathbf{\Psi}_e \mathbf{e}_{q+n}\mathbf{e}_{q+3}^T \\ \vdots & \cdots & \vdots \\ \mathbf{\Psi}_e \mathbf{e}_{q+3}\mathbf{e}_{q+n}^T & \cdots & \mathbf{\Psi}_e \mathbf{e}_{q+n}\mathbf{e}_{q+n}^T \end{bmatrix} \right) \begin{bmatrix} \mathbf{U}_2^{-T}\mathbf{e}_s & & \\ & \ddots & \\ & & \mathbf{U}_2^{-T}\mathbf{e}_s \end{bmatrix}. \end{aligned} \tag{52}$$

Since

$$g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),e)=\frac{(1-|\lambda_e|)/\sqrt{(l+n)(q+n)}}{\sqrt{\sum_{t=1}^{l+n}\sum_{s=1}^{q+n}\psi_{ts}^{*}\psi_{ts}}}, \tag{53}$$

we can readily calculate

$$\frac{\partial g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),e)}{\partial \mathbf{\Omega}}=-\frac{1-|\lambda_e|}{\sqrt{(l+n)(q+n)}\,\|\mathbf{\Psi}_e\|_F^3}\mathrm{Re}\left[\sum_{t=1}^{l+n}\sum_{s=1}^{q+n}\psi_{ts}^{*}\frac{\partial \psi_{ts}}{\partial \mathbf{\Omega}}\right]. \tag{54}$$

Comment 1. In a way, the above search procedure solves

$$\min_{\mathbf{\Omega}\in\mathcal{R}^{(n-2)\times(n-2)}}\ \max_{k\in\{1,\ldots,m+n\}}\left(-g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),k)\right). \tag{55}$$

The function $h(\mathbf{\Omega})=\max_{k\in\{1,\ldots,m+n\}}\left(-g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),k)\right)$ to be minimized has corners where differentiability fails, although $g(\mathbf{X}(\mathbf{T}(\mathbf{\Omega})),k)$ is differentiable for any $k\in\{1,\ldots,m+n\}$. In fact, the problem (55) is a classical optimization problem which requires nondifferentiable optimization approaches, such as subgradient methods [22]. Subdifferentiation of h at $\mathbf{\Omega}$ is defined as

$$\aleph h(\mathbf{\Omega})=Conv\left\{\mathbf{J}\in\mathcal{R}^{(n-2)\times(n-2)}\ \middle|\ \begin{array}{c}\mathbf{J}=\lim\frac{\partial h(\mathbf{\Omega}_i)}{\partial \mathbf{\Omega}_i},\mathbf{\Omega}_i\to\mathbf{\Omega},\\ \frac{\partial h(\mathbf{\Omega}_i)}{\partial \mathbf{\Omega}_i}\ \text{exists},\frac{\partial h(\mathbf{\Omega}_i)}{\partial \mathbf{\Omega}_i}\ \text{converges}\end{array}\right\}, \tag{56}$$

where *Conv* denotes the convex hull. The elements of $\aleph h(\mathbf{\Omega})$ are called subgradients. Denote the directional derivative

$$h^{\circ}(\mathbf{\Omega},\mathbf{\Gamma})=\lim_{\substack{t\to 0\\ t>0}}\frac{h(\mathbf{\Omega}+t\mathbf{\Gamma})-h(\mathbf{\Omega})}{t} \tag{57}$$

in every direction $\mathbf{\Gamma}\in\mathcal{R}^{(n-2)\times(n-2)}$. A relationship between subgradients and the directional derivative is given in [22], which is restated in the following lemma.

LEMMA 2. $h^{\circ}(\mathbf{\Omega},\mathbf{\Gamma})=\max_{\mathbf{J}\in\aleph h(\mathbf{\Omega})}\langle\mathbf{J},\mathbf{\Gamma}\rangle$.

It is seen that $-\frac{\partial g(\mathbf{X},e)}{\partial \mathbf{\Omega}}$ is a subgradient of $h(\mathbf{\Omega})$ and our method is a subgradient algorithm. Since $h(\mathbf{\Omega})$ is differentiable almost everywhere when $\mathbf{\Omega}$ is not a local optimal point, there exists a neighborhood $\mathcal{B}_r=\left\{\mathbf{\Theta}\in\mathcal{R}^{(n-2)\times(n-2)}\ |\ \|\mathbf{\Theta}-\mathbf{\Omega}\|_F<r\right\}$ such that

$$h^{\circ}(\mathbf{\Omega},\mathbf{\Xi}-\mathbf{\Omega})<0 \tag{58}$$

and

$$\mathbf{\Xi}=\min_{\mathbf{\Theta}\in\mathcal{B}_r}h(\mathbf{\Omega}). \tag{59}$$

Then we have the following theorem.

THEOREM 5. *There exists* $\tau_m>0$ *such that for Step* 2 *of the above search algorithm*

$$\left\|\mathbf{\Omega}+\tau\frac{\partial g(\mathbf{X},e)}{\partial \mathbf{\Omega}}\left\|\frac{\partial g(\mathbf{X},e)}{\partial \mathbf{\Omega}}\right\|_F^{-1}-\mathbf{\Xi}\right\|_F<\|\mathbf{\Omega}-\mathbf{\Xi}\|_F \tag{60}$$

$\forall\tau\in(0,\tau_m)$.

Proof. By the definition of Frobenius norm,

$$\begin{aligned}&\left\|\boldsymbol{\Xi}-\boldsymbol{\Omega}-\tau\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\left\|\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\right\|_F^{-1}\right\|_F^2\\&=\|\boldsymbol{\Xi}-\boldsymbol{\Omega}\|_F^2+2\tau\left\langle-\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\left\|\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\right\|_F^{-1},\boldsymbol{\Xi}-\boldsymbol{\Omega}\right\rangle+\tau^2.\end{aligned}\tag{61}$$

Since $-\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}$ is a subgradient, from Lemma 2 and (58), one has

$$\left\langle-\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\left\|\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\right\|_F^{-1},\boldsymbol{\Xi}-\boldsymbol{\Omega}\right\rangle\le h^\circ(\boldsymbol{\Omega},\boldsymbol{\Xi}-\boldsymbol{\Omega})\left\|\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\right\|_F^{-1}<0.\tag{62}$$

Thus, for $0<\tau<\tau_m=2\big\langle\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\big\|\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\big\|_F^{-1},\ \boldsymbol{\Xi}-\boldsymbol{\Omega}\big\rangle$,

$$2\tau\left\langle-\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\left\|\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}\right\|_F^{-1},\boldsymbol{\Xi}-\ \boldsymbol{\Omega}\right\rangle+\tau^2<0.\tag{63}$$

This together with (61) proves the assertion. ∎

The above result shows that, for sufficiently small $\tau>0$, $\frac{\partial g(\mathbf{X},e)}{\partial\boldsymbol{\Omega}}$ is a good direction along which to update $\boldsymbol{\Omega}$ so that it becomes closer to $\boldsymbol{\Xi}$, although occasionally the updated $h(\boldsymbol{\Omega})$ may be worse. Therefore, $h(\boldsymbol{\Omega})$ will be improved significantly after some iterations. Our numerical examples listed in section 5 show that this simplest subgradient optimization algorithm behaves satisfactorily in practice, provided that τ is chosen appropriately. Of course, if this simplest subgradient algorithm fails in some cases, various enhanced subgradient algorithms [22], [23], [24] can be adopted to tackle the problem.

Comment 2. The termination at $N_t\ge N$ does not mean that the problem (55) has no saddle point. As $h(\boldsymbol{\Omega})$ may be nonconvex, our subgradient search sequence may possibly oscillate around a local optimum which is worse than $\rho_{k'}$. Regardless of whether or not the problem (55) has saddle points, when the routine does not find a saddle point, we can further increase the value of $\min_{k\in\{1,\ldots,m+n\}}g(\mathbf{X},k)$ by a direct numerical optimization. This is further discussed in the next section.

4. Discussions. The function $g(\mathbf{X},k)$ having saddle points is the main assumption in this paper. Here we explain heuristically that for many practical control systems this assumption is valid. First, from section 3.1, it is known that k', $\rho_{k'}$, and $\mathcal{X}$ exist regardless of whether or not $g(\mathbf{X},k)$ has saddle points. Second, Theorem 3 shows that if and only if there exist $\mathbf{T}\in\mathcal{T}$ satisfying

$$g(\mathbf{X}(\mathbf{T}),k)\ge\rho_{k'}\quad\forall k\in\{1,\ldots,m+n\}\setminus\{k'\},\tag{64}$$

the saddle points of $g(\mathbf{X},k)$ exist. From the definition of $g(\mathbf{X},k)$ in (14), $g(\mathbf{X},k)$ is proportional to the single-pole stability margin $1-|\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))|$, which is a fixed value, and inverse proportional to its eigenvalue sensitivity, which depends on $\mathbf{X}$. For practical digital closed-loop control systems, there exist usually only a few dominant poles which are near the unit circle and/or have relatively high eigenvalue sensitivities,

compared with all the other nondominant poles. For this reason, the index k' defined in (21) is usually the index of a dominant pole, and the values of $g(\mathbf{X}, k)$ for those nondominant poles at $\mathbf{X}(\mathbf{T})$ are larger than $\rho_{k'}$ for most $\mathbf{T} \in \mathcal{T}$. Therefore, to satisfy condition (64), one needs only to consider the few dominant poles whose indices are not k'. It should be observed that $\mathbf{T}$ in $\mathcal{T}$ has a fairly large degree of freedom. Specifically, the free parameter $\mathbf{\Omega}$ in (44) can be any nonsingular matrix in $\mathcal{R}^{(n-2)\times(n-2)}$. This large degree of freedom, together with the fact that there are typically just a few dominant poles to consider, means that most likely there exist $\mathbf{T} \in \mathcal{T}$ satisfying (64). Thus $g(\mathbf{X}, k)$ has saddle points for many practical problems. We conjecture without a rigorous proof that the class of optimal FWL controller realization problems (15) which have saddle points is much larger than the class having no saddle point. Empirically, we have tested a total of six FWL controller design examples that we found in the FWL controller design literature. Only one example, which is given in [14], was shown to possibly have no saddle point.

The routine presented in section 3.2 is computationally much more attractive than a direct numerical optimization of (13). Actually, all that is needed is to find a $\mathbf{T} \in \mathcal{T}$ such that $g(\mathbf{X}(\mathbf{T}), k) \geq \rho_{k'}$ for $k \in \{1, \ldots, m+n\} \setminus \{k'\}$, rather than to directly maximize $f(\mathbf{X}(\mathbf{T}))$ over $\mathcal{R}^{n\times n}$ (and, of course, $\det \mathbf{T} \neq 0$). The former objective can be attained often easily even for large-scale problems. In addition, the number of saddle points is infinite when $g(\mathbf{X}, k)$ has saddle points. Hence our algorithm can find global optimal solutions for most practical problems which have saddle points even though we do not strictly prove the convergence of the subgradient routine. An additional advantage of the algorithm presented, which is particularly important in practical applications, is that when the algorithm attains a solution the user knows for sure that it is a global optimal solution to the optimal realization problem (13). This should be compared with direct numerical optimization of (13) where even when it converges to a solution, there is no way to tell whether or not the solution is a global optimal one.

It should be pointed out that our algorithm, presented for the problems having saddle points, is also useful in helping to solve those optimal FWL realization problems which do not have a saddle point. Actually, the algorithm given in section 3 can be executed even for the problems which do not have a saddle point. Using the results of section 3.1, k' and $\rho_{k'}$ can be computed, and $\mathcal{X}$ is obtained in closed form. Corollary 1 tells us that $\rho_{k'}$ is an upper bound of the optimal value of the realization problem having no saddle point. After executing N iterations of the routine given in section 3.2, the resulting realization $\mathbf{X}_t$ obviously does not satisfy (64). But through these N iterations, $\min_{k\in\{1,\ldots,m+n\}} g(\mathbf{X}, k)$ has been increased to as close to $\rho_{k'}$ as possible under $\mathbf{X} \in \mathcal{X}$. Therefore, the value of $f(\mathbf{X}_t)$ is not much less than $\rho_{k'}$. This provides a small region $[f(\mathbf{X}_t), \rho_{k'}]$ within which the optimal value of the FWL controller realization problem lies. Of course, this also provides an excellent guess from which a direct numerical optimization approach can be used to find a (local) optimal solution for those optimization problems having no saddle point.

Obviously, the same idea is equally applicable to the problems whose saddle points are not found after N iterations of the search routine. In fact, when the subgradient routine is terminated after N iterations but the condition (64) is not met, one cannot answer the question of whether or not the problem (55) has any saddle point. However, one knows the small region within which the global optimal value lies, and the solution obtained after N iterations provides an excellent initial guess for a direct numerical optimization.

5. Design examples. Six examples are used to illustrate the effectiveness of the proposed design algorithm.

Example 1. The example in [25] is discretized with a sampling frequency of 5 Hz to obtain the discrete-time plant model

$$\mathbf{A}_P = \begin{bmatrix} 3.2439e-1 & -4.5451e+0 & -4.0535e+0 & -2.7003e-3 & 0 \\ 1.4518e-1 & 4.9477e-1 & -4.6945e-1 & -3.1274e-4 & 0 \\ 1.6814e-2 & 1.6491e-1 & 9.6681e-1 & -2.2114e-5 & 0 \\ 1.1889e-3 & 1.8209e-2 & 1.9829e-1 & 1.0000e+0 & 0 \\ 6.1301e-5 & 1.2609e-3 & 1.9930e-2 & 2.0000e-1 & 1.0000e+0 \end{bmatrix},$$

$$\mathbf{B}_P = [\,1.4518e-1 \quad 1.6814e-2 \quad 1.1889e-3 \quad 6.1301e-5 \quad 2.4979e-6\,]^T,$$

$$\mathbf{C}_P = [\,0 \quad 0 \quad 1.6188e+0 \quad -1.5750e-1 \quad -4.3943e+1\,]$$

and the initially designed digital controller

$$\mathbf{A}_C^0 = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & -4.7086e-1 \\ 1 & 0 & 0 & 0 & 0 & 2.6885e+0 \\ 0 & 1 & 0 & 0 & 0 & -6.6649e+0 \\ 0 & 0 & 1 & 0 & 0 & 9.4410e+0 \\ 0 & 0 & 0 & 1 & 0 & -8.2537e+0 \\ 0 & 0 & 0 & 0 & 1 & 4.2600e+0 \end{bmatrix}, \quad \mathbf{B}_C^0 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad \mathbf{D}_C^0 = [4.6000e-2],$$

$$\mathbf{C}_C^0 = [\,2.1187e-1 \quad 9.4498e-2 \quad 1.0887e-2 \quad -4.4171e-2 \quad -7.6000e-2 \quad -8.8562e-2\,].$$

The corresponding closed-loop transition matrix $\overline{\mathbf{A}}(\mathbf{X}_0)$ is then formed using (10), from which the eigenvalues and the eigenvectors of the ideal closed-loop system are computed. These 11 eigenvalues and their absolute values are

$$\begin{bmatrix} \lambda_{1,2} \\ \lambda_{3,4} \\ \lambda_{5,6} \\ \lambda_{7,8} \\ \lambda_{9,10} \\ \lambda_{11} \end{bmatrix} = \begin{bmatrix} 4.8368e-1 \pm j8.5569e-1 \\ 4.8135e-1 \pm j8.5363e-1 \\ 9.9993e-1 \pm j3.7887e-4 \\ 8.3967e-1 \pm j1.6514e-1 \\ 8.0884e-1 \pm j1.2026e-1 \\ 8.1905e-1 \end{bmatrix}, \quad \begin{bmatrix} |\lambda_{1,2}| \\ |\lambda_{3,4}| \\ |\lambda_{5,6}| \\ |\lambda_{7,8}| \\ |\lambda_{9,10}| \\ |\lambda_{11}| \end{bmatrix} \begin{bmatrix} 9.8293e-1 \\ 9.7999e-1 \\ 9.9993e-1 \\ 8.5575e-1 \\ 8.1774e-1 \\ 8.1905e-1 \end{bmatrix}.$$

This closed-loop system has five pairs of conjugate complex-valued eigenvalues and one real-valued eigenvalue. Using the method developed in section 3.1, the single-pole peak for each eigenvalue is computed, and they are

$$\begin{bmatrix} \rho_{1,2} \\ \rho_{3,4} \\ \rho_{5,6} \\ \rho_{7,8} \\ \rho_{9,10} \\ \rho_{11} \end{bmatrix} = \begin{bmatrix} 2.5072e-3 \\ 2.1295e-3 \\ 6.7344e-6 \\ 2.8586e-3 \\ 3.0832e-3 \\ 4.3181e-3 \end{bmatrix}.$$

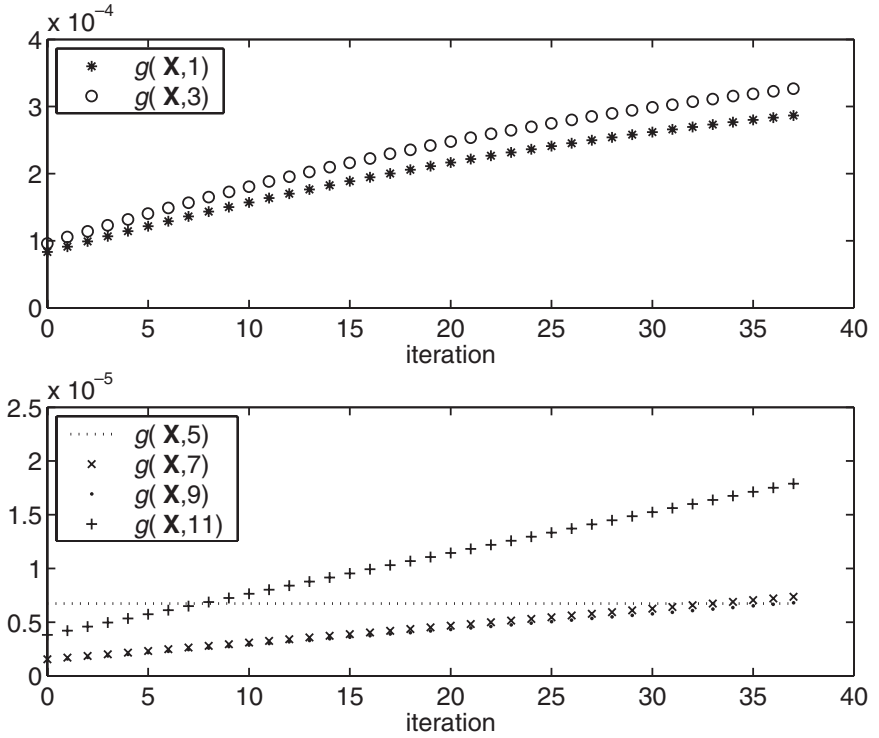

FIG. 2. *The values of* $g(\mathbf{X}, k)$ *in each iteration of the algorithm for Example* 1.

Obviously, the minimum value of all the ρ_k's is ρ_5 (or ρ_6). Therefore, $k' = 5$ and the corresponding matrices $\mathbf{Q}$, $\mathbf{H}$, and $\mathbf{F}$ in the set (44) are given by

$$\mathbf{Q} = \begin{bmatrix} -6.6011e-2 & -8.4915e-2 & -4.3670e-1 \\ -3.7006e-1 & -4.3518e-1 & -4.9156e-1 \\ -5.0566e-1 & -3.8025e-1 & 7.1063e-1 \\ -5.2127e-1 & -8.6900e-2 & -2.2452e-1 \\ -4.5786e-1 & 3.1775e-1 & -1.0190e-1 \\ -3.4878e-1 & 7.4183e-1 & 4.3249e-2 \end{bmatrix}$$

$$\begin{bmatrix} -5.1206e-1 & -5.2972e-1 & -5.0490e-1 \\ -2.2314e-1 & 1.7033e-1 & 5.9434e-1 \\ -2.5387e-1 & -1.6560e-1 & -5.3367e-2 \\ 7.4814e-1 & -2.4759e-1 & -2.2204e-1 \\ -2.0850e-1 & 6.8322e-1 & -4.1079e-1 \\ -1.4270e-1 & -3.6725e-1 & 4.1345e-1 \end{bmatrix},$$

$$\mathbf{H} = \begin{bmatrix} 2.6322e+0 & -3.9258e+2 \\ -3.9258e+2 & 6.9856e+6 \end{bmatrix}, \quad \mathbf{F} = \begin{bmatrix} 4.8432e+4 & -8.8104e+8 \\ -5.2079e+4 & 9.4682e+8 \\ 2.4998e+4 & -4.5374e+8 \\ -2.4644e+4 & 4.4816e+8 \end{bmatrix}.$$

Set $\tau = 0.1$ and the initial $\mathbf{\Omega} = \mathbf{I}$. Figure 2 illustrates the changes of $g(\mathbf{X}, k)$ in each iteration. From Figure 2, it can be seen that at the 37th iteration, the optimal

controller realization is found, since at this iteration the conditions of Theorem 3 are met and the algorithm terminates. The resulting matrix $\mathbf{\Omega}_{\text{opt}}$ is

$$\mathbf{\Omega}_{\text{opt}} = \begin{bmatrix} 2.3184e+0 & -1.6411e+0 & 5.5681e-1 & -7.6953e-1 \\ -1.6411e+0 & 2.4047e+0 & -8.2094e-1 & 7.0079e-1 \\ 5.5680e-1 & -8.2095e-1 & 1.2097e+0 & -3.7643e-1 \\ -7.6954e-1 & 7.0078e-1 & -3.7643e-1 & 1.3454e+0 \end{bmatrix}$$

and the corresponding global optimal transformation matrix is

$$\mathbf{T}_{\text{opt}} = \begin{bmatrix} -6.9470e+1 & -3.2765e+4 & -7.8507e-2 & & \\ 3.0977e+2 & 1.5431e+5 & -1.1360e+0 & & \\ -6.0267e+2 & -3.0945e+5 & 2.0130e+0 & & \\ 6.5537e+2 & 3.4747e+5 & -1.7153e+0 & & \\ -4.1530e+2 & -2.2683e+5 & 8.0247e-1 & & \\ 1.1931e+2 & 6.9580e+4 & -1.8821e-1 & & \end{bmatrix}$$
$$\begin{bmatrix} -4.3363e-1 & -2.7354e-1 & -5.0267e-1 \\ 5.4680e-1 & -1.0820e-1 & 9.5739e-1 \\ -1.6781e+0 & 4.2386e-1 & -7.3423e-1 \\ 2.2151e+0 & -9.5513e-1 & 4.9153e-1 \\ -1.1829e+0 & 1.0956e+0 & -8.7755e-1 \\ 1.7712e-1 & -4.5868e-1 & 5.6121e-1 \end{bmatrix}.$$

Example 2. The second example is taken from [14]. In this example, $m = 4$, $n = 10$, $l = 2$, and $q = 2$, and hence it is a closed-loop system of order 14. The initial controller realization $\mathbf{X}_0$ of $C(z)$ has been given [20]. The corresponding closed-loop transition matrix $\overline{\mathbf{A}}(\mathbf{X}_0)$ is formed using (10), from which the eigenvalues and the eigenvectors of the ideal closed-loop system are computed. This closed-loop system has six pairs of conjugate complex-valued eigenvalues and two real-valued eigenvalues given by

$$\begin{bmatrix} \lambda_{1,2} \\ \lambda_{3,4} \\ \lambda_5 \\ \lambda_{6,7} \\ \lambda_{8,9} \\ \lambda_{10,11} \\ \lambda_{12} \\ \lambda_{13,14} \end{bmatrix} = \begin{bmatrix} -8.4482e-1 \pm j7.8204e-2 \\ -3.7557e-1 \pm j3.3602e-1 \\ 2.1624e-1 \\ 7.1567e-1 \pm j9.6631e-3 \\ 9.2895e-1 \pm j1.2923e-1 \\ 9.8506e-1 \pm j7.5831e-2 \\ 8.3133e-1 \\ 8.8267e-1 \pm j3.7235e-2 \end{bmatrix}.$$

Using the method developed in section 3.1, the single-pole peaks for every eigenvalues are computed, and they are

$$\begin{bmatrix} \rho_{1,2} \\ \rho_{3,4} \\ \rho_5 \\ \rho_{6,7} \\ \rho_{8,9} \\ \rho_{10,11} \\ \rho_{12} \\ \rho_{13,14} \end{bmatrix} = \begin{bmatrix} 8.3118e-3 \\ 4.0562e-2 \\ 6.2954e-2 \\ 8.0984e-3 \\ 3.7768e-3 \\ 5.4246e-3 \\ 5.8442e-3 \\ 8.0773e-3 \end{bmatrix}.$$

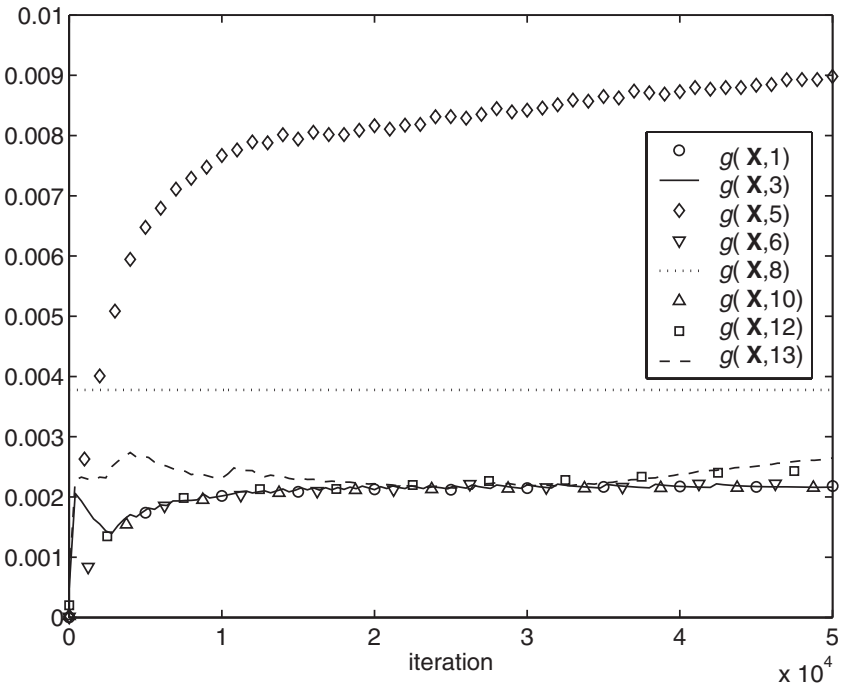

FIG. 3. *The values of* $g(\mathbf{X}, k)$ *in each iteration of the algorithm for Example* 2.

Obviously, the minimum value of all the ρ_k's is ρ_8 (or ρ_9). Therefore, $k' = 8$ and the corresponding matrices $\mathbf{Q}$, $\mathbf{H}$, and $\mathbf{F}$ in (44) are computed according to Theorem 4. With $\mathbf{T}$ in (44), the second stage of our algorithm can be executed. Figure 3 illustrates the changes of $g(\mathbf{X}, k)$ in each iteration of the second stage. From Figure 3, it can be seen that after the $N = 50000$ iteration, we still cannot find a realization satisfying (64). This suggests that this example most likely has no saddle point (although one cannot be sure). So we terminate the algorithm at the 50000 iteration and obtain a realization $\mathbf{X}_t$. Although this $\mathbf{X}_t$ is not an optimal realization, it is much better than $\mathbf{X}_0$, since $f(\mathbf{X}_t) = 2.1539e{-}3$ while $f(\mathbf{X}_0) = 1.1734e{-}4$. In particular, we notice that $\mathbf{X}_t$ is also better than the "optimal" realization given in [14], which was found by a direct numerical optimization search using the simulated annealing algorithm and has a FWL measure value of $1.5844e - 3$ [14]. At this stage, we are sure that the optimal solution given in [14] is not a global optimal one at all. Using the realization $\mathbf{X}_t$ obtained by our search algorithm as the initial point, we then use a direct numerical optimization method to solve for the optimization problem (13) and obtain a new optimal realization whose FWL measure value is $3.1929e - 3$. This optimal value is more than double the one given in [14]. Obviously, we cannot tell whether or not this new optimal realization is a global optimal one. However, we know that the optimal value of the FWL realization problem for this example lies in the range of $[3.1929e - 3,\ 3.7768e - 3]$. For this example, no other design has found a controller realization whose FWL closed-loop stability measure $f(\mathbf{X})$ is larger than $3e - 3$. Our algorithm is the first one to achieve a $f(\mathbf{X}) > 3e - 3$.

The saddle points (or the global optimal solutions) of the following four examples are found successfully by our proposed method.

Example 3. This example is a fluid power speed controller given in [8], where $m = 4$, $n = 4$, $l = 1$, and $q = 1$.

Example 4. This example is a discretized version of an H_∞ robust controller given in [26] with a sampling frequency of 250 Hz, where $m = 2$, $n = 3$, $l = 1$, and $q = 1$.

Example 5. This example is taken from [6], where $m = 3$, $n = 2$, $l = 1$, and $q = 1$.

Example 6. This example is a steel rolling mill proportional-integral-derivative controller given in [8], where $m = 3$, $n = 2$, $l = 1$, and $q = 1$.

As mentioned previously, the realizations of $C(z)$ are not unique. For instance, in Example 1, the initially designed controller $(\mathbf{A}_C^0, \mathbf{B}_C^0, \mathbf{C}_C^0, \mathbf{D}_C^0)$ is the controllable companion-form realization for

$$C(z) = \frac{0.046z^6 + 0.0159z^5 - 0.4284z^4 + 0.9227z^3 - 1.0043z^2 + 0.5983z - 0.1503}{z^6 - 4.26z^5 + 8.2537z^4 - 9.441z^3 + 6.6649z^2 - 2.6885z + 0.4709}.$$

Apart from the controllable companion form, denoted as $\mathbf{X}_c$, a controller is also often implemented in the parallel or series form in practice. Denote these two realizations of $C(z)$ as

$$\mathbf{X}_p = \begin{bmatrix} \mathbf{D}_C^p & \mathbf{C}_C^p \\ \mathbf{B}_C^p & \mathbf{A}_C^p \end{bmatrix} \tag{65}$$

and

$$\mathbf{X}_s = \begin{bmatrix} \mathbf{D}_C^s & \mathbf{C}_C^s \\ \mathbf{B}_C^s & \mathbf{A}_C^s \end{bmatrix}, \tag{66}$$

respectively. The parallel-form realization of $C(z)$ for Example 1 is given by

$$C(z) = 0.046 + \frac{1.8921e-7}{z-1} + \frac{-0.0024z + 0.0013}{z^2 - 0.9670z + 0.9589} + \frac{0.1056z - 0.1487}{z^2 - 1.6016z + 0.7103} + \frac{0.1087}{z - 0.6913}$$

with

$$\mathbf{A}_C^p = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & -9.5886e-1 & 9.6700e-1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -7.1030e-1 & 1.6016e0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 6.9134e-1 \end{bmatrix},$$

$$\mathbf{B}_C^p = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}^T, \quad \mathbf{D}_C^p = \begin{bmatrix} 4.6000e-2 \end{bmatrix},$$

$$\mathbf{C}_C^p = \begin{bmatrix} 1.8921e-7 & 1.2816e-3 & -2.3654e-3 & -1.4868e-1 & 1.0555e-1 \\ 1.0869e-1 \end{bmatrix},$$

while the series-form realization is

$$C(z) = 0.046\left(\frac{0.1812}{z-1}+1\right)\left(\frac{0.6344z+0.2556}{z^2-1.6016z+0.7103}+1\right) \times \left(\frac{4.8231}{z-0.6913}+1\right)\left(\frac{-1.0329z+0.0410}{z^2-0.9670z+0.9589}+1\right)$$

with

$$\mathbf{A}_C^s = \begin{bmatrix} 1 & 0 & 1.8120e-1 & 1.8120e-1 & 0 & 1.8120e-1 \\ 0 & 0 & -7.1030e-1 & 2.5562e-1 & 0 & 2.5562e-1 \\ 0 & 1 & 1.6016e0 & 6.3442e-1 & 0 & 6.3442e-1 \\ 0 & 0 & 0 & 6.9134e-1 & 0 & 4.8231e0 \\ 0 & 0 & 0 & 0 & 0 & -9.5886e-1 \\ 0 & 0 & 0 & 0 & 1 & 9.6700e-1 \end{bmatrix},$$

$$\mathbf{B}_C^s = \begin{bmatrix} 1.8120e-1 & 2.5562e-1 & 6.3442e-1 & 4.8231e0 & 4.1007e-2 \\ -1.0329e0 \end{bmatrix}^T,$$

$$\mathbf{C}_C^s = \begin{bmatrix} 4.6000e-2 & 0 & 4.6000e-2 & 4.6000e-2 & 0 & 4.6000e-2 \end{bmatrix},$$

$$\mathbf{D}_C^s = \begin{bmatrix} 4.6000e-2 \end{bmatrix}.$$

The above three realizations, $\mathbf{X}_c$, $\mathbf{X}_p$, and $\mathbf{X}_s$, are sparse because they contain many trivial parameters (0, 1, or -1). For Example 1, $\mathbf{X}_0$ has 13 nontrivial parameters, while $\mathbf{X}_p$ and $\mathbf{X}_s$ have only 12 nontrivial parameters (the repeated values, such as $1.8120e-1$ in $\mathbf{X}_s$, are counted as one nontrivial parameter). Clearly, a trivial parameter requires no arithmetic operation in a fixed-point implementation and does not cause any computational error. A sparse controller realization has computational advantages in practical implementations. An FWL closed-loop stability measure, which is similar to the one defined in (11) but takes into account the sparsity of controller realization, is defined in [9] as

$$f_{sp}(\mathbf{X}) \triangleq \min_{k\in\{1,\ldots,m+n\}} \frac{1-|\lambda_k(\overline{\mathbf{A}}(\mathbf{X}))|}{\sqrt{N_s \sum_{i,j} \delta(x_{ij}) \left|\frac{\partial \lambda_k(\overline{\mathbf{A}}(\mathbf{X}))}{\partial x_{ij}}\right|^2}}, \tag{67}$$

where

$$\delta(x_{ij}) = \begin{cases} 1, & x_{ij} \text{ is nontrivial,} \\ 0, & x_{ij} \text{ is trivial,} \end{cases} \tag{68}$$

and N_s is the number of nontrivial parameters in $\mathbf{X}$. Comparing the definitions of $f_{sp}(\mathbf{X})$ and $f(\mathbf{X})$, it follows that

$$f_{sp}(\mathbf{X}) \geq f(\mathbf{X}). \tag{69}$$

Table 1 lists the values of $f(\mathbf{X})$, $f_{sp}(\mathbf{X})$, and N_s for $\mathbf{X}_{\text{opt}}$, $\mathbf{X}_p$, $\mathbf{X}_s$, and $\mathbf{X}_c$ of every example except for Example 2. Example 2 is a multiple-input multiple-output system for which no parallel-form or series-form realization is defined. It can be seen that the optimal realization $\mathbf{X}_{\text{opt}}$ found by the proposed method has the best FWL

	N_s	5	4	4	9

closed-loop stability robustness as measured by either $f(\mathbf{X})$ or $f_{sp}(\mathbf{X})$, compared with the other three realizations. It can also be seen that the optimal realization obtained by the proposed search algorithm is a fully parameterized nonsparse one. The other three sparse realizations have similar numbers of nontrivial parameters, and thus have the same lighter computational load than that of the optimal one given here. However, it is worth pointing out that $\mathbf{X}_{\text{opt}}$ is not unique since $\mathbf{V}$ in (43) is an arbitrary orthogonal matrix. By choosing $\mathbf{V}$ in an appropriate way, one can obtain a sparse optimal realization $\mathbf{X}_{\text{opt}}$. The topic of how to make $\mathbf{X}_{\text{opt}}$ sparse is beyond the scope of this paper, and interested readers are referred to the work [1] for details.

6. Conclusions. We have developed an efficient search algorithm for solving the class of optimal FWL controller realization problems based on the Frobenius-norm pole sensitivity measure, which have saddle points. Our approach first constructs the closed form of a transformation matrix set which contains global optimal solutions and then searches this set with a subgradient routine to find a global optimal solution. The proposed algorithm has considerable advantages over using direct numerical optimization methods to tackle this class of optimal FWL realization problems. In particular, when the subgradient routine converges to a solution, it is guaranteed to be a global optimal solution. It has been conjectured with some empirical support that for many practical control systems the assumption of having saddle points is a valid one and the cases of optimal FWL controller realization problems which do not have saddle points are less common. It has been demonstrated that for this smaller class of optimal FWL realization problems without saddle points our algorithm also provides useful information to help solve them.

Appendix. Proof of Theorem 4. We present the proof for Case 2. The proof for Case 3 is similar and hence is omitted.

LEMMA 3 (see [21]). *Let real-valued matrices* $\mathbf{M}_{22}$, $\mathbf{M}_{21}$, *and* $\mathbf{M}_{11} > 0$ *be given with appropriate dimensions. Then*

$$\begin{bmatrix} \mathbf{M}_{11} & \mathbf{M}_{21}^T \\ \mathbf{M}_{21} & \mathbf{M}_{22} \end{bmatrix} > 0 \tag{70}$$

if and only if $\mathbf{M}_{22} - \mathbf{M}_{21}\mathbf{M}_{11}^{-1}\mathbf{M}_{21}^T > 0$.

LEMMA 4. *Given positive* $\alpha, \beta \in \mathcal{R}$, $\mathbf{p}, \mathbf{y} \in \mathcal{C}^n$, *and for any nonsingular* $\mathbf{T} \in \mathcal{R}^{n\times n}$, *we have*

$$\xi(\mathbf{T}, \alpha, \beta, \mathbf{p}, \mathbf{y}) \geq (|\mathbf{y}^H \mathbf{p}| + \alpha\beta)^2. \tag{71}$$

The equality occurs if and only if there exist $\mathbf{W} \in \mathcal{R}^{n\times n}$, $\mathbf{W} > 0$, *and* $\theta \in [0, 2\pi)$ *satisfying*

$$\mathbf{W}\Upsilon(\mathbf{y}) = \frac{\beta}{\alpha}\Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}. \tag{72}$$

When (72) *has solutions, the equality in* (71) *occurs only at the transformation matrix* $\mathbf{T} = \mathbf{W}^{1/2}\mathbf{V}$, *where* $\mathbf{V} \in \mathcal{R}^{n\times n}$ *is an arbitrary orthogonal matrix.*

Proof. First,

$$\begin{aligned} &\|\mathbf{T}^{-1}\mathbf{p}\|_F^2 \|\mathbf{T}^T\mathbf{y}\|_F^2 + \alpha^2 \|\mathbf{T}^T\mathbf{y}\|_F^2 + \beta^2 \|\mathbf{T}^{-1}\mathbf{p}\|_F^2 + \alpha^2\beta^2 \\ &\geq (\|\mathbf{T}^{-1}\mathbf{p}\|_F \|\mathbf{T}^T\mathbf{y}\|_F + \alpha\beta)^2. \end{aligned} \tag{73}$$

The equality holds if and only if

$$\alpha\|\mathbf{T}^T\mathbf{y}\|_F = \beta\|\mathbf{T}^{-1}\mathbf{p}\|_F. \tag{74}$$

Using the Cauchy–Schwarz inequality, we have

$$(\|\mathbf{T}^{-1}\mathbf{p}\|_F \|\mathbf{T}^T\mathbf{y}\|_F + \alpha\beta)^2 \geq (\|(\mathbf{T}^T\mathbf{y})^H \mathbf{T}^{-1}\mathbf{p}\|_F + \alpha\beta)^2 \geq (|\mathbf{y}^H\mathbf{p}| + \alpha\beta)^2. \tag{75}$$

The equality holds if and only if

$$\mathbf{T}^T\mathbf{y} = c\mathbf{T}^{-1}\mathbf{p} \tag{76}$$

for some complex number c.

To achieve (73) and (75) with equality, one needs to satisfy both of the conditions (74) and (76). This implies that $c = (\cos\theta + j\sin\theta)\frac{\beta}{\alpha}$ and $\theta \in [0, 2\pi)$. Thus,

$$\mathbf{T}^T\mathbf{y} = (\cos\theta + j\sin\theta)\frac{\beta}{\alpha}\mathbf{T}^{-1}\mathbf{p}. \tag{77}$$

As $\mathbf{T}$ is nonsingular, equality (77) is equivalent to

$$\mathbf{W}\mathbf{y} = (\cos\theta + j\sin\theta)\frac{\beta}{\alpha}\mathbf{p} \tag{78}$$

with $\mathbf{W} > 0$ and $\mathbf{T} = \mathbf{W}^{1/2}\mathbf{V}$. Noticing the map Υ defined in (31), condition (78) can be viewed as

$$\mathbf{W}\Upsilon(\mathbf{y}) = \frac{\beta}{\alpha}\Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}. \tag{79}$$

This completes the proof. □

LEMMA 5. *Given positive* $\alpha, \beta \in \mathcal{R}$, $\mathbf{p}, \mathbf{y} \in \mathcal{C}^n$, *and* $\operatorname{rank}(\Upsilon(\mathbf{y})) = 2$, (79) *has solutions if and only if* $\det((\Upsilon(\mathbf{y}))^T\Upsilon(\mathbf{p})) > 0$. *Moreover, any solution to* (79) *can be expressed as*

$$\left.\begin{aligned} &\tan\theta = \frac{a_{21} - a_{12}}{a_{11} + a_{22}} \\ &a_{11}\cos\theta - a_{12}\sin\theta > 0 \\ &\mathbf{W} = \mathbf{Q}\begin{bmatrix} \mathbf{H} & \mathbf{F}^T \\ \mathbf{F} & \mathbf{G} \end{bmatrix}\mathbf{Q}^T \end{aligned}\right\}, \tag{80}$$

where

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = (\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p}); \tag{81}$$

the orthogonal matrix $\mathbf{Q}$ *can be obtained from the QR factorization of* $\Upsilon(\mathbf{y})$*, that is,*

$$\Upsilon(\mathbf{y}) = \mathbf{Q} \begin{bmatrix} \gamma_{11} & 0 & 0 & \cdots & 0 \\ \gamma_{12} & \gamma_{22} & 0 & \cdots & 0 \end{bmatrix}^T; \tag{82}$$

$\mathbf{H}$ *and* $\mathbf{F}$ *are determined by*

$$\mathbf{H} = \frac{\beta}{\alpha} \begin{bmatrix} \gamma_{11} & \gamma_{12} \\ 0 & \gamma_{22} \end{bmatrix}^{-T} (\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} \gamma_{11} & \gamma_{12} \\ 0 & \gamma_{22} \end{bmatrix}^{-1}, \tag{83}$$

$$\mathbf{F} = \frac{\beta}{\alpha} \begin{bmatrix} \mathbf{e}_3^T \\ \vdots \\ \mathbf{e}_n^T \end{bmatrix} \mathbf{Q}^T \Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} \gamma_{11} & \gamma_{12} \\ 0 & \gamma_{22} \end{bmatrix}^{-1}; \tag{84}$$

and $\mathbf{G}$ *is given as*

$$\mathbf{G} = \mathbf{F}\mathbf{H}^{-1}\mathbf{F}^T + \mathbf{U} \tag{85}$$

with $\mathbf{U} \in \mathcal{R}^{(n-2)\times(n-2)}$ *being an arbitrary positive definite matrix.*

Proof. If $\det((\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p})) > 0$, it is easy to verify that $\mathbf{W}$ and θ given by (80)–(85) are a solution to (79). If, on the other hand, (79) has a solution $\mathbf{W}$ and θ, it can be seen that

$$(\Upsilon(\mathbf{y}))^T \mathbf{W} \Upsilon(\mathbf{y}) = \frac{\beta}{\alpha} (\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}. \tag{86}$$

On account of $(\Upsilon(\mathbf{y}))^T \mathbf{W} \Upsilon(\mathbf{y}) > 0$, we have

$$(\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} > 0. \tag{87}$$

A necessary condition to satisfy (87) is that

$$\det\left((\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p}) \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \right) > 0. \tag{88}$$

Since the left side of the above inequality is equal to $\det((\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p}))$, the condition (88) becomes $\det((\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p})) > 0$. This completes the proof of the first part of Lemma 5.

Now, when (81) is given, (87) holds if and only if all of the following three conditions are satisfied:

$$\left.\begin{array}{l} a_{21}\cos\theta - a_{22}\sin\theta = a_{11}\sin\theta + a_{12}\cos\theta \\ a_{11}\cos\theta - a_{12}\sin\theta > 0 \\ \det((\Upsilon(\mathbf{y}))^T \Upsilon(\mathbf{p})) > 0 \end{array}\right\}. \tag{89}$$

From the first line of (89), we directly obtain $\tan\theta = \frac{a_{21}-a_{12}}{a_{11}+a_{22}}$. Denote

$$\mathbf{S} = \mathbf{Q}^T \mathbf{W} \mathbf{Q}. \tag{90}$$

Then, from (79), (82), and (90), one has

$$\begin{aligned}\mathbf{S}\,[\,\mathbf{e}_1 \quad \mathbf{e}_2\,]\begin{bmatrix}\gamma_{11} & \gamma_{12}\\ 0 & \gamma_{22}\end{bmatrix} &= \mathbf{S}\begin{bmatrix}\gamma_{11} & 0 & 0 & \cdots & 0\\ \gamma_{12} & \gamma_{22} & 0 & \cdots & 0\end{bmatrix}^T\\ &= \frac{\beta}{\alpha}\mathbf{Q}^T\Upsilon(\mathbf{p})\begin{bmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{bmatrix}.\end{aligned} \tag{91}$$

Partition $\mathbf{S}$ into

$$\mathbf{S} = \begin{bmatrix}\mathbf{H} & \mathbf{F}^T\\ \mathbf{F} & \mathbf{G}\end{bmatrix}, \tag{92}$$

where $\mathbf{H} \in \mathcal{R}^{2\times 2}$, $\mathbf{F} \in \mathcal{R}^{(n-2)\times 2}$, and $\mathbf{G} \in \mathcal{R}^{(n-2)\times(n-2)}$. Then from (91) and noticing

$$(\Upsilon(\mathbf{y}))^T = \begin{bmatrix}\gamma_{11} & \gamma_{12}\\ 0 & \gamma_{22}\end{bmatrix}^T [\,\mathbf{e}_1 \quad \mathbf{e}_2\,]^T\,\mathbf{Q}^T, \tag{93}$$

we have

$$\begin{aligned}\mathbf{H} &= \begin{bmatrix}\mathbf{e}_1^T\\ \mathbf{e}_2^T\end{bmatrix}\mathbf{S}\,[\,\mathbf{e}_1 \quad \mathbf{e}_2\,]\\ &= \frac{\beta}{\alpha}\begin{bmatrix}\gamma_{11} & \gamma_{12}\\ 0 & \gamma_{22}\end{bmatrix}^{-T}(\Upsilon(\mathbf{y}))^T\Upsilon(\mathbf{p})\begin{bmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{bmatrix}\begin{bmatrix}\gamma_{11} & \gamma_{12}\\ 0 & \gamma_{22}\end{bmatrix}^{-1},\end{aligned} \tag{94}$$

$$\mathbf{F} = \begin{bmatrix}\mathbf{e}_3^T\\ \vdots\\ \mathbf{e}_n^T\end{bmatrix}\mathbf{S}\,[\,\mathbf{e}_1 \quad \mathbf{e}_2\,] = \frac{\beta}{\alpha}\begin{bmatrix}\mathbf{e}_3^T\\ \vdots\\ \mathbf{e}_n^T\end{bmatrix}\mathbf{Q}^T\Upsilon(\mathbf{p})\begin{bmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{bmatrix}\begin{bmatrix}\gamma_{11} & \gamma_{12}\\ 0 & \gamma_{22}\end{bmatrix}^{-1}. \tag{95}$$

From Lemma 3 and $\mathbf{S} > 0$, it is known that $\mathbf{G} = \mathbf{F}\mathbf{H}^{-1}\mathbf{F}^T + \mathbf{U}$, where $\mathbf{U} \in \mathcal{R}^{(n-2)\times(n-2)}$ is an arbitrary positive definite matrix. □

Combining Lemmas 4 and 5 leads to Theorem 4 for Case 2.

RISK SENSITIVE PORTFOLIO MANAGEMENT WITH COX–INGERSOLL–ROSS INTEREST RATES: THE HJB EQUATION*

TOMASZ R. BIELECKI†, STANLEY R. PLISKA‡, AND SHUENN-JYI SHEU§

Abstract. This paper presents an application of risk sensitive control theory in financial decision making. The investor has an infinite horizon objective that can be interpreted as maximizing the portfolio's risk adjusted exponential growth rate. There are two assets, a stock and a bank account, and two underlying Brownian motions, so this model is incomplete. The novel feature here is that the interest rate for the bank account is governed by Cox–Ingersoll–Ross dynamics. This is significant for risk sensitive portfolio management because the factor process, unlike in the Gaussian and all other cases treated in the literature, cannot be negative (under appropriate parameterization).

Key words. risk sensitive control, optimal portfolios, Cox–Ingersoll–Ross interest rates, incomplete model

AMS subject classifications. 60J20, 90A09, 90C40, 93E20

DOI. 10.1137/S0363012903437952

1. Introduction.

Beginning with the pioneering work by Merton [22], [23], [24] and continuing through the recent books by Karatzas and Shreve [18] and Korn [20], some very sophisticated stochastic control methods have been developed for portfolio management. Virtually all of these studies make use of an expected utility criterion. But recently a new criterion has emerged from the control theory literature. Called the *risk sensitive* criterion, this was originally used (see, for example, Whittle [27]) for a decision maker seeking to maximize some (random) cash reward (or minimize some cash payment) while simultaneously being concerned about the risk or uncertainty in the size of the reward. Essentially, this criterion equals the expected value of the reward minus a penalty term that is proportional to the variance of the reward. The constant of proportionality is a parameter whose value can be chosen to achieve for the decision maker an appropriate trade-off between the expectation of the reward and its variance.

Recognizing its relevance to portfolio management, Bielecki and Pliska [5] applied the risk sensitive idea to a version of Merton's [23] intertemporal capital asset pricing model. The result was an infinite horizon criterion that they called the *risk adjusted growth rate* and viewed as being analogous to the classical Markowitz single-period approach except that instead of trading off single-period criteria the investor is trading off the portfolio's long run growth rate versus its average volatility (see Bielecki and Pliska [9] for a detailed study of various economic and mathematical properties of this criterion). Bielecki and Pliska also showed in [5] and subsequent work (see [2], [3], [4], [6], [7], [8], and [10]) that the resulting models usually have the virtue of being more

tractable than corresponding models which use traditional expected utility criteria. Other studies of the risk sensitive criterion for portfolio management include Bagchi and Kumar [1], Fleming and Sheu [14], [15], [16], Kuroda and Nagai [21], Nagai [25], and Nagai and Peng [26]. Kaise and Sheu [17] discuss the solution of a general equation (in R^n) that is related to the Hamilton–Jacobi–Bellman (HJB) equation in this paper.

Throughout all this work on risk sensitive portfolio management the underlying factor process, if any, was taken to be Gaussian or, at least (see Nagai [25]), a process whose domain is all of some Euclidean space. The aim of this paper is to provide some initial results on risk sensitive portfolio management for a case where this kind of condition does not hold. Since interest rate processes are commonly taken as factor processes and since the so-called Cox–Ingersoll–Ross [12] interest rate process (a popular one in the finance literature) cannot be negative, this model of the factor process was chosen for our object of study.

The result is a risk sensitive portfolio optimization model having a factor process whose domain is the nonnegative portion of the real line. Since this is a model of interest rates, it is more realistic than, say, Gaussian models, but it comes with a price: the resulting analysis is exceptionally lengthy, complex, and technical. This is true even though our model is rather simple, having just this scalar-valued factor process, two assets (the usual bank account and a risky stock), and two underlying Brownian motions. Consequently, this paper will study only the associated HJB equation, saving the verification of optimality and related issues for a future, separate paper.

After formulation of our model in section 2, the main results are presented in section 3. Chief among these is Theorem 3.1, which asserts the HJB equation has a unique solution. Needed for its proof and of separate interest are some results pertaining to a related, "truncated" problem: for some fixed number M the investor is required to keep all of his or her money in the bank account whenever the interest rate exceeds M. Existence of a unique solution to the HJB equation for this truncated problem is established by Theorem 3.2. Intuitively, one should expect the solution of the truncated HJB equation to converge to the solution of the original one as $M \to \infty$; this is indeed the case, as stated in Theorem 3.3. The rest of the paper is devoted to the proofs of these three theorems. Theorem 3.2 is proved in section 4, while the other two are proved in section 5. Various technical results are relegated to an appendix.

2. Formulation of the optimal risk sensitive asset management problem. In this section we formulate an optimal dynamic asset management problem featuring a risk sensitive optimality criterion. Let $(\Omega, \{\mathcal{F}_t\}_{t\geq 0}, \mathcal{F}, \mathbf{P})$ be the underlying probability space. The securities market involves a single factor, namely, an interest rate r that is subject to the so-called Cox–Ingersoll–Ross [12] dynamics

$$dr_t = -c(r_t - \bar{r})dt + \lambda\sqrt{r_t}dW_t, \tag{1}$$

where $c, \bar{r}$, and λ are three specified positive scalar parameters. In order to ensure that the interest rate process is always strictly positive (not only is absorption at zero unrealistic, but with the interest rate fixed at zero our investment problem becomes trivial: continuously rebalance to some fixed proportion), we make the following assumption (see Feller [13]).

Assumption 2.1. $2c\bar{r} > \lambda^2$.

There are two assets. One is the customary bank account:

$$\frac{dS_0(t)}{S_0(t)} = r_t dt; \tag{2}$$

here $S_0(t)$ represents the time-t amount of money in the bank account assuming none is added or withdrawn after time 0. The other asset is a stock (or stock index) whose price process satisfies

$$\frac{dS_1(t)}{S_1(t)} = \mu(r_t)dt + \sigma dW_t + \rho d\bar{W}_t. \tag{3}$$

Here W_t and $\bar{W}_t$ are two independent Brownian motions, σ and ρ are two specified scalar parameters, and

$$\mu(r) := \mu_1 + \mu_2 r, \tag{4}$$

where μ_1 and μ_2 are two specified scalar parameters. Note that with $\mu_2 \neq 0$ we can allow the level of interest rates to affect the return properties of the stock, and with $\sigma \neq 0$ the residuals of the interest rate process will be correlated with the residuals of the stock's return process. For instance, with suitable values of σ and ρ this correlation is negative.

Trading strategies will be adapted real-valued stochastic processes that are denoted h. We shall interpret h_t as the proportion of the investor's time-t wealth that is invested in the stock. In general, for each time t we allow h_t to be any real number; that is, we do not impose any constraints on h_t, such as short selling restrictions.

Remark 2.1. For a well posed optimization problem one needs additional assumptions about admissible trading strategies to the effect that the SDE (5) below admits a unique, strong solution. In particular, we need to require that for any admissible strategy the measure transformations used throughout the paper are well defined. It follows from the results of Bielecki, Pliska, and Yong [11] that a strategy that is a feedback strategy in the state variable r_t and grows linearly in r_t satisfies the above requirements of admissibility under appropriate parameterization. Other choices are also possible. Since the main concern of this paper is analysis of the HJB equation, and since derivation of the equation is done by a formal argument, then the choice of a class of admissible trading strategies is not an issue here. Of course, when one turns to studying the optimality of a strategy, the choice of the class of admissible trading strategies will be an important and, frequently, a quite delicate issue. This issue will be addressed in a future work.

The investor's time-t wealth will be denoted V_t. Under the trading strategy h, the corresponding wealth process V will satisfy

$$\frac{dV_t}{V_t} = [(1-h_t)r_t + h_t\mu(r_t)]dt + h_t(\sigma dW_t + \rho d\bar{W}_t). \tag{5}$$

By standard results, there exists a unique, strong, and almost surely positive solution to this equation; it is given by

$$V_t = V_0 exp\left(\int_0^t h_t\sigma dW_t + \int_0^t h_t\rho d\bar{W}_t + \int_0^t \left[-\frac{1}{2}(\sigma^2+\rho^2)h_t^2 + (1-h_t)r_t + h_t\mu(r_t)\right]dt\right). \tag{6}$$

In this paper we consider the following family of risk sensitized optimal investment problems, labeled as $\mathcal{P}_\theta$:

$$\begin{gathered} \textit{for } \theta \in (0,\infty), \textit{ maximize the risk sensitized expected growth rate} \\ J_\theta(v,r;h) := \liminf_{t\to\infty}(-2/\theta)t^{-1} ln\ \mathbf{E}^h\ [e^{-(\theta/2)lnV_t}|V_0 = v, r_0 = r] \\ \textit{over the class of all admissible investment processes } h, \end{gathered} \tag{7}$$

where $\mathbf{E}^h$ is the expectation with respect to $\mathbf{P}$. The notation $\mathbf{E}^h$ emphasizes that the expectation is evaluated for the wealth process V corresponding to the investment strategy h.

The parameter θ here is interpreted as the measure of the investor's attitude toward risk; the bigger the value of θ, the more risk averse the investor. This is because the criterion can be interpreted, at least approximately, as the portfolio's exponential growth rate minus a penalty term which equals $\theta/4$ times the portfolio's asymptotic variance. A comprehensive interpretation of this risk sensitive objective for portfolio management can be found in Bielecki and Pliska [9].

We note that the techniques used in this paper can also be used to study problems $\mathcal{P}_\theta$ for negative values of θ, corresponding to risk seeking investors. The risk null case, for $\theta = 0$, can be studied independently or as the limit of the risk averse situation when the risk sensitivity parameter θ goes to zero. However, in this paper we shall not consider cases where $\theta \leq 0$.

For much of what follows we find it convenient to introduce the scalar parameter

$$\gamma := -\theta/2. \tag{8}$$

Since θ is always strictly positive, the parameter γ should always be regarded as strictly negative. Moreover, the reader should keep in mind that corresponding to any appearance of the parameter γ is $\theta = -2\gamma$.

3. Analysis of the Hamilton–Jacobi–Bellman equation. In this section we formulate our model and present our main results concerning the HJB equation corresponding to the investor's portfolio optimization problem $\mathcal{P}_\theta$. We not only establish existence and uniqueness of a solution, but also establish some important properties of this solution. This analysis is rather involved, and so the balance of this paper is devoted to the proof of the results in this section.

In view of our risk sensitive objective, we are interested in computing the expectation of quantities like V_t^γ for some $\gamma < 0$. Since by (6)

$$V_t^\gamma = V_0^\gamma exp\Bigg(\gamma \int_0^t h_t \sigma dW_t + \gamma \int_0^t h_t \rho d\bar{W}_t + \int_0^t \gamma \Bigg[-\frac{1}{2}(\sigma^2 + \rho^2) h_t^2 + (1 - h_t) r_t + h_t \mu(r_t) \Bigg] dt \Bigg), \tag{9}$$

we recognize that it is convenient to make a Girsanov-type change of probability measure. In particular, it is straightforward to show for each trading strategy h and $T > 0$ that

$$E[V_T^\gamma] = \tilde{E}\left[V_0^\gamma exp\left(\gamma \int_0^T L(r_t, h_t) dt \right) \right], \tag{10}$$

where we have introduced the notation $\tilde{E}$ for expectation under the new probability measure and the additional functions

$$L(r, u) := -\frac{1}{2}(1 - \gamma)(\sigma^2 + \rho^2) u^2 + \bar{\mu}(r) u + r, \tag{11}$$

and

$$\bar{\mu}(r) := \mu(r) - r. \tag{12}$$

Moreover, under this new probability measure the dynamics for the interest rate process r are given by

$$dr_t = (-c(r_t - \bar{r}) + \gamma\sigma\lambda\sqrt{r_t}h_t)dt + \lambda\sqrt{r_t}d\tilde{W}_t, \tag{13}$$

where $\tilde{W}$ denotes a (scalar-valued) Brownian motion under this new probability measure.

Using standard methods of risk sensitive control theory (see, for example, [8], [15], and [21]), it is now straightforward to specify the HJB dynamic programming equation:

$$\begin{aligned}\Lambda = {} & \frac{1}{2}\lambda^2 r\frac{d^2\Phi}{dr^2} - c(r-\bar{r})\frac{d\Phi}{dr} + \frac{1}{2}\lambda^2 r\left(\frac{d\Phi}{dr}\right)^2 \\ & + \inf_{\{u\in\mathbf{R}\}}\left[\gamma\sigma\lambda\sqrt{r}u\frac{d\Phi}{dr} + \gamma L(r,u)\right], \quad r > 0.\end{aligned} \tag{14}$$

We seek a solution in terms of the scalar Λ and the *bias function* Φ such that Λ is the optimal risk adjusted growth rate in problem $\mathcal{P}_\theta$ and such that the minimal selector identifies an optimal (or, at least, an ϵ-optimal) trading strategy.

It is convenient to transform this equation into a simpler form. Since the stock proportion h_t is unrestricted, we see that the minimizing value of u in the HJB equation must satisfy the first order condition $\gamma\sigma\lambda\sqrt{r}\Phi' + \gamma[-(1-\gamma)(\sigma^2+\rho^2)u + \bar{\mu}(r)] = 0$. In other words, our candidate h^* for the optimal trading strategy will satisfy the expression $h_t^* = u^*(r_t)$, where

$$u^*(r) := \frac{1}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\left(\bar{\mu}(r) + \sigma\lambda\sqrt{r}\frac{d\Phi}{dr}\right). \tag{15}$$

Remark 3.1. In view of Theorem 3.1 below, the candidate optimal strategy has a linear growth in the state variable r_t. Thus it is an admissible strategy (cf. Remark 2.1).

Substituting the preceding expression for u in the HJB equation, introducing the function

$$g := \frac{d\Phi}{dr},$$

and doing a little algebra enables one to see that the original HJB equation is equivalent to

$$\Lambda = \frac{1}{2}\lambda^2 r\frac{dg}{dr} + \frac{1}{2}\lambda^2 r\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)g^2 + b(r)g + d(r), \quad r > 0, \tag{16}$$

where we have introduced for convenience the functions

$$b(r) := -c(r-\bar{r}) + \frac{\gamma}{1-\gamma}\frac{\sigma\lambda}{\sigma^2+\rho^2}\sqrt{r}\bar{\mu}(r) \tag{17}$$

and

$$d(r) := \frac{1}{2}\frac{\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}[\bar{\mu}(r)]^2 + \gamma r. \tag{18}$$

The following theorem is our main result about the HJB equation.

THEOREM 3.1. *The HJB equation* (16) *has a unique solution* (Λ^*, g^*) *satisfying the following two properties:*

$$\lim_{r\to 0} g^*(r) = \frac{1}{c\bar{r}}\left[\Lambda^* - \frac{1}{2}\frac{\gamma}{1-\gamma}\frac{\mu_1^2}{\sigma^2+\rho^2}\right] \tag{19}$$

and either

$$\lim_{r\to\infty} \frac{g^*(r)}{\sqrt{r}} = -\left(1+\frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)^{-1}\left[\frac{|\mu_2-1|}{\lambda}\sqrt{\frac{-\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}} + \frac{\gamma}{1-\gamma}\frac{\sigma}{\sigma^2+\rho^2}\frac{\mu_2-1}{\lambda}\right] \tag{20}$$

for $\mu_2 \neq 1$ *or*

$$\lim_{r\to\infty} g^*(r) = -\left(1+\frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)^{-1}\left(\frac{c}{\lambda^2} - \left(\frac{c^2}{\lambda^4} - 2\frac{\gamma}{\lambda^2}\left(1+\frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\right)^{\frac{1}{2}}\right) \tag{21}$$

for $\mu_2 = 1$. *Moreover,* Λ^* *is characterized as the smallest* Λ *such that the HJB equation has a solution defined for all* r.

In order to study problem $\mathcal{P}_\theta$, as well as to investigate a related problem of separate interest, consider exactly the same problem except that now, for some arbitrary positive number M, we impose the trading strategy constraint that $h_t = 0$ if $r_t > M$. Analogous to the unconstrained problem, the dynamic programming equation for this constrained, truncated problem is

$$\Lambda_M = \frac{1}{2}\lambda^2 r\frac{dg}{dr} + \frac{1}{2}\lambda^2 r\left(1+\frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)g^2 + b(r)g + d(r), \quad 0 < r \leq M, \tag{22}$$

$$\Lambda_M = \frac{1}{2}\lambda^2 r\frac{dg}{dr} + \frac{1}{2}\lambda^2 r g^2 - c(r-\bar{r})g + \gamma r, \quad r > M. \tag{23}$$

In addition, our candidate for the optimal trading strategy is now given by

$$u_M^*(r) := \frac{1}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\Big(\bar{\mu}(r) + \sigma\lambda\sqrt{r}g(r)\Big), \qquad r \leq M, \tag{24}$$

$$u_M^*(r) := 0, \qquad r > M.$$

Moreover, for this constrained problem we have the following important result.

THEOREM 3.2. *The HJB equation* (22), (23) *for the constrained problem has a unique solution* (Λ_M^*, g_M^*) *satisfying the following two properties:*

$$\lim_{r\to 0} g_M^*(r) = \frac{1}{c\bar{r}}\left[\Lambda_M^* - \frac{1}{2}\frac{\gamma}{1-\gamma}\frac{\mu_1^2}{\sigma^2+\rho^2}\right] \tag{25}$$

and

$$\lim_{r\to\infty} g_M^*(r) = \frac{c}{\lambda^2} - \sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}}. \tag{26}$$

As our next main result indicates, the solutions of the two kinds of investment problems are related in an intuitive manner.

THEOREM 3.3. *The following hold:*

$$\lim_{M\to\infty} g_M^*(r) = g^*(r) \quad \forall r > 0 \tag{27}$$

and

$$\lim_{M\to\infty} \Lambda_M^* = \Lambda^*. \tag{28}$$

Remark 3.2. For (16), there is a smallest Λ such that (16) has a smooth solution g. This follows from the argument in [17]. We can show that Λ^* in Theorem 3.1 is this smallest value of Λ; see Theorem 5.1. The argument in [17] is applicable to equations in multidimensional spaces, and therefore it can be applied to a model with several assets and multiple factor processes. However, it is difficult to fully understand and analyze the solutions in such multidimensional cases.

These three theorems are proved in the following two sections. We now conclude this section by suggesting a procedure for computing the solution (Λ^*, g^*) of (16). Suppose that for a given number Λ we can solve our equation (16) for a function g satisfying (19). Since Λ^* is characterized as the smallest Λ such that this solution g is finite for all $r > 0$, if some value Λ gives a finite solution, then $\Lambda^* \le \Lambda$. On the other hand, if some value Λ does not correspond to a finite g, then $\Lambda < \Lambda^*$. Hence a suitable iterative procedure should converge to (Λ^*, g^*). To be more precise, we first choose $\Lambda_1 \le \Lambda^* \le \Lambda_2$ by some rough estimate and follow this procedure:

1. $\Lambda = (\Lambda_1 + \Lambda_2)/2$ and solve (16) and (19). If the solution g exists for all $r > 0$, go to step 2. Otherwise, go to step 3.
2. Save the solution (Λ, g), redefine $\Lambda_1 := \Lambda_1,\ \Lambda_2 := \Lambda$, and go to step 1.
3. Redefine $\Lambda_1 := \Lambda,\ \Lambda_2 := \Lambda_2$, and go to step 1.

The solution (Λ, g) in step 2 will give a good approximation of (Λ^*, g^*) after a sufficient number of iterations.

4. Proof of Theorem 3.2. We begin by transforming the constrained HJB equation (22) to a version that will be more convenient for some proofs. Denoting

$$A := 1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2},$$

$$\bar{\Lambda} := A\Lambda,$$

$$\bar{d}(r) := Ad(r),$$

and

$$\bar{g} := Ag, \tag{29}$$

we see by simple substitution that (22) is equivalent to

$$\bar{\Lambda} = \frac{1}{2}\lambda^2 r\frac{d\bar{g}}{dr} + \frac{1}{2}\lambda^2 r\bar{g}^2 + b(r)\bar{g} + \bar{d}(r), \quad 0 < r \le M. \tag{30}$$

We would like to know that this equation has a (possibly unique) solution $\bar{g}$ for an arbitrary $\bar{\Lambda}$, but establishing this is not so easy because the second term on the right-hand side is nonlinear and the coefficient of the first derivative term is degenerate at

$r = 0$ (so one cannot proceed with the analysis by considering the solution for all $r \geq 0$ and specifying the value of $\bar{g}(0)$). Our approach will be to address these issues by studying the function

$$\tilde{g}(r) := \bar{g}(r)e(r),$$

where

$$e(r) := r^{\frac{2c\bar{r}}{\lambda^2}} \exp\left(-\frac{2c}{\lambda^2}r + \frac{2\gamma\sigma}{(1-\gamma)\lambda(\sigma^2+\rho^2)}\int_0^r \frac{\bar{\mu}(s)}{\sqrt{s}}ds\right).$$

This is because $\bar{g}$ satisfies (30) if and only if $\tilde{g}$ satisfies

$$\frac{d\tilde{g}}{dr} + \frac{1}{e(r)}\tilde{g}^2 = \frac{2}{\lambda^2 r}e(r)[\bar{\Lambda} - \bar{d}(r)], \tag{31}$$

and this latter differential equation will be easier to analyze. Also, note for future arguments that (1) $e(r) > 0$ for all $r > 0$ and (2) equation (31) is equivalent to

$$\tilde{g}(r) = -\int_0^r \frac{1}{e(s)}\tilde{g}^2(s)ds + \int_0^r \frac{2}{\lambda^2 s}e(s)[\bar{\Lambda} - \bar{d}(s)]ds. \tag{32}$$

Using the preceding transformations we can prove (see Appendix A) the following initial key result in the proof of Theorem 3.2.

PROPOSITION 4.1. *If (Λ_M, g) is a solution of (22) defined on $(0, r_0]$ for some $r_0 > 0$, then either g satisfies (25), with g_M^* replaced with g, or*

$$\lim_{r\to 0} rg(r) = \frac{1}{A}\left(-\frac{2c\bar{r}}{\lambda^2} + 1\right). \tag{33}$$

Note that there is a trading strategy given by (15) associated with each solution g, where $g = d\Phi/dr$. Moreover, note that the asymptotic behavior stated in (33) implies that a solution satisfying (33) might not be compatible with our portfolio optimization problem. So from now on we shall focus on solutions of (22) that satisfy (25) rather than (33). The reason will become apparent below. In particular, see Corollary 4.1, which gives special properties of the solution satisfying (25).

Our next key result shows that there exists a unique solution g of (22) satisfying (25), at least a solution in some neighborhood of $r = 0$.

PROPOSITION 4.2. *Fix $\Lambda = \Lambda_M$. For small enough $r_0 > 0$ there exists a unique g satisfying (22) and (25) for all $r \in (0, r_0]$. It also satisfies*

$$|g(r)e(r)| \leq c_1 r^{\frac{2c\bar{r}}{\lambda^2}}, \qquad r \leq r_0, \tag{34}$$

for some positive number c_1. In addition, we have

$$g(r)e(r) \leq \int_0^r \frac{2}{\lambda^2 s}e(s)[\Lambda - d(s)]ds, \qquad r \leq r_0. \tag{35}$$

Proof. Since there is a correspondence between solutions of (22) and solutions of (32), it suffices to focus on the latter. For some suitable positive numbers r_0 and c_1 (to be decided later), consider the operator T defined for $f \in \mathbf{F}_{c_1}$, where

$$Tf(r) := -\int_0^r f^2(s)\frac{1}{e(s)}ds + \int_0^r \frac{2}{\lambda^2 s}e(s)[\bar{\Lambda} - \bar{d}(s)]ds$$

and

$$\mathbf{F}_{c_1} := \{f : |f(r)| \le c_1 r^{\frac{2c\bar{r}}{\lambda^2}}, 0 \le r \le r_0\}.$$

In order to show that $Tf \in \mathbf{F}_{c_1}$ we need to estimate $|Tf(r)|$. The first term in the definition of T is bounded by

$$c_1^2 \bar{c}_2 \int_0^r s^{\bar{g}} ds = c_1^2 c_2 r^{\delta+1},$$

where $\delta := \frac{2c\bar{r}}{\lambda^2}$ and $1/e(s) \le \bar{c}_2 s^{-\delta}$, $c_2 = \bar{c}_2/(1+\delta)$. The second term is bounded by

$$c_1(\bar{\Lambda})\bar{c}_3 \int_0^r s^{\delta-1} ds = c_1(\bar{\Lambda}) c_3 r^{\delta},$$

where $c_3 = \bar{c}_3/\delta$ and $e(r) \le \bar{c}_3 r^{\delta}$ for r small, and where

$$c_1(\bar{\Lambda}) := \max_{0<r\le 1} \left| \frac{2}{\lambda^2}[\bar{\Lambda} - \bar{d}(r)] \right|.$$

Therefore

$$|Tf(r)| \le [c_1^2 c_2 r + c_1(\bar{\Lambda})c_3] r^{\delta} \le [c_1^2 c_2 r_0 + c_1(\bar{\Lambda})c_3] r^{\delta}$$

if $r \le r_0$. It now follows by taking $c_1 = 2c_1(\bar{\Lambda})c_3$ and $r_0 = 1/[4c_2 c_3 c_1(\bar{\Lambda})]$ that

$$|Tf(r)| \le c_1 r^{\frac{2c\bar{r}}{\lambda^2}},$$

and so $T : \mathbf{F}_{c_1} \to \mathbf{F}_{c_1}$.

On the other hand, for $r \le r_0$

$$|Tf_1(r) - Tf_2(r)| \le \int_0^r |f_1(s) + f_2(s)||f_1(s) - f_2(s)| \frac{1}{e(s)} ds$$
$$\le ||f_1 - f_2|| 2c_1 \int_0^{r_0} s^{\frac{2c\bar{r}}{\lambda^2}} \frac{1}{e(s)} ds \le 2c_1 \bar{c}_2 r_0 ||f_1 - f_2||, \quad r \le r_0,$$

where $||\cdot||$ denotes the supnorm on $[0, r_0]$ and

$$\bar{c}_2 := \max_{r\le 1} \frac{1}{e(r)} r^{\frac{2c\bar{r}}{\lambda^2}}.$$

Hence by taking r_0 small enough so that $2c_1\bar{c}_2 r_0 < 1$, we see that T will be a contraction mapping from $\mathbf{F}_{c_1}$ into $\mathbf{F}_{c_1}$. Hence T has a unique fixed point, say $\tilde{g}$, which means that $\tilde{g}$ satisfies (32).

If we define $g(r) = \tilde{g}(r)/(Ae(r))$, then g is a solution of (22) defined on $(0, r_0]$. Therefore, in view of Proposition 4.1, either one of (33) or (25) holds. Since $\tilde{g}$ is in $\mathbf{F}_{c_1}$, it follows that we have (34). Then (33) cannot be true. Finally, (35) is a consequence of (32). This completes the proof of the proposition. □

The next main step is to show that one can choose Λ so that the value of r_0 in Proposition 4.2 can be taken to be M, that is, so that a solution of (22) will exist on all of $(0, M]$. The following result will be used in this step.

LEMMA 4.1. *Let g_1 and g_2 be the two solutions of* (22) *and* (25) *corresponding to values of Λ_M equal to Λ_1 and Λ_2, respectively. If $\Lambda_1 < \Lambda_2$, then $g_1 < g_2$.*

Proof. Because of the correspondence between solutions of (22) and solutions of (31), it suffices to study the latter. Since $\tilde{g}_1$ and $\tilde{g}_2$ both satisfy (31) (with their respective values of $\bar{\Lambda}$) we can subtract one equation from the other to obtain

$$\frac{d}{dr}(\tilde{g}_1 - \tilde{g}_2) + \frac{1}{e(r)}[\tilde{g}_1 + \tilde{g}_2][\tilde{g}_1 - \tilde{g}_2] = \frac{2}{\lambda^2 r} e(r)[\bar{\Lambda}_1 - \bar{\Lambda}_2].$$

We thus have

$$\tilde{g}_1(r) - \tilde{g}_2(r) = \int_0^r \frac{2e(s)}{\lambda^2 s}[\bar{\Lambda}_1 - \bar{\Lambda}_2] \exp\left(-\int_s^r \frac{\tilde{g}_1(u) + \tilde{g}_2(u)}{e(u)} du\right) ds.$$

This is strictly negative if $\bar{\Lambda}_1 < \bar{\Lambda}_2$, so Lemma 4.1 is established. □

COROLLARY 4.1. *For fixed Λ, suppose g defined on $(0, r_0]$ is the solution of (22) satisfying (25). Let $y < g(r_0)$, and suppose g_0 is a solution of (22) such that $g_0(r_0) = y$. Then $g_0(r)$ exists for $r \in (0, r_0]$ and g_0 satisfies (33).*

Remark 4.1. We omit a proof of this corollary since the argument is very similar to what was used for the proof of Lemma 4.1. While this corollary does not play a crucial role in the proof of Theorem 3.2, it sheds some light on why we are concerned with the boundary condition (33).

We note that if $g(r_0)$ is finite, then g is well defined for $r > r_0$, up to a (possibly infinite) point denoted $r(\bar{\Lambda})$, where $\lim_{r \to r(\bar{\Lambda})} g(r) = -\infty$ (if g explodes, then by (35) it explodes in the negative direction). For each $M > 0$ we now define

$$\bar{\Lambda}_*(M) := \inf\{\Lambda : \text{the corresponding solution } g \text{ of (22) satisfying (25) is finite for all } r \le M\}.$$

We then have the following proposition.

PROPOSITION 4.3. *Fix arbitrary $0 < M < \infty$. Then $\bar{\Lambda}_*(M) < \infty$ and, for each $\Lambda \ge \bar{\Lambda}_*(M)$, the corresponding solution g of (22) and (25) is finite for all $r \le M$. Moreover, $g(M) \to \infty$ as $\Lambda \to \infty$, and $g(M) \to -\infty$ as $\Lambda \to -\infty$.*

Remark 4.2. Note that in Lemma 5.2 below we prove that $\bar{\Lambda}_*(M) > -\infty$.

Proof. We prove $\bar{\Lambda}_*(M) < \infty$. The rest is a consequence of either Lemma 4.1 or a similar argument.

We first take an r_0 small enough and a finite $\bar{\Lambda}_0$, and

$$\tilde{g}_0(r) = \int_0^r \frac{2}{\lambda^2 s} e(s)(\bar{\Lambda}_0 - \bar{d}(s)) ds - \int_0^r \frac{1}{e(s)} \tilde{g}_0^2(s) ds, \quad r \le r_0.$$

We know that $\tilde{g}_0(r)$ is finite for $r \in [0, r_0]$. Now for $\theta > 0$ we consider

$$\tilde{g}_\theta(r) = \int_0^r \frac{2}{\lambda^2 s} e(s)(\bar{\Lambda}_0 + \theta - \bar{d}(s)) ds - \int_0^r \frac{1}{e(s)} \tilde{g}_\theta^2(s) ds, \quad r \le r_0.$$

This has solution $\tilde{g}_\theta(\cdot)$ in a neighborhood of 0 as given in Lemma 4.2 with $\bar{\Lambda} = \bar{\Lambda}_0 + \theta$. We know that $\tilde{g}_\theta(r)$ is finite for $r \in [0, r_0]$ and that

$$\tilde{g}_\theta(r) \ge \tilde{g}_0(r), \quad r \le r_0.$$

Let us fix $0 < r_1 < r_0$, a large $K > 0, K > \|\tilde{g}_0\|_{[r_1, r_0]}$, where $\|\tilde{g}_0\|_{[r_1, r_0]}$ is the maximum of $|\tilde{g}_0(r)|, r \in [r_1, r_0]$. There is a θ_0 such that for $\theta > \theta_0$, $\tilde{g}_\theta(\cdot)$ is increasing

for $r_1 \le r \le r_0$ if $|\tilde{g}_\theta(r)| \le K$. This is due to the following calculation:

$$\frac{d}{dr}\tilde{g}_\theta(r) = \frac{2}{\lambda^2 r}e(r)(\bar{\Lambda}_0 + \theta - \bar{d}(r)) - \frac{1}{e(r)}\tilde{g}_\theta^2(r)$$
$$\ge \frac{2}{\lambda^2 r_0}\inf_{[r_1,r_0]}\{e(r)(\bar{\Lambda}_0 + \theta_0 - \|\bar{d}\|_{[r_1,r_0]})\} - \left\|\frac{1}{e(\cdot)}\right\|_{[r_1,r_0]} K^2 > 0,$$

where the last inequality holds if θ_0 is large enough.

From this, for a fixed K, we must have $\tilde{g}_\theta(r_0) > K$ if θ is large enough. Suppose not. Then using the fact that $\tilde{g}_\theta(r) > \tilde{g}_0(r),\ r_1 \le r \le r_0$, and the above monotonicity result, we can conclude that

$$|\tilde{g}_\theta(r)| < K, \quad r_1 \le r \le r_0.$$

Thus

$$\frac{d}{dr}\tilde{g}_\theta(r) \ge \left(\frac{2}{\lambda^2 r_0}\inf_{[r_1,r_0]}\{e(r)(\bar{\Lambda}_0 + \theta - \|\bar{d}\|_{[r_1,r_0]})\} - \left\|\frac{1}{e(r)}\right\|_{[r_1,r_0]} K^2\right)$$

is larger than a given number (say L) for $r_1 \le r \le r_0$ if θ is large enough. For such θ,

$$\tilde{g}_\theta(r_0) = \tilde{g}_\theta(r_1) + \int_{r_1}^{r_0}\frac{d}{dr}\tilde{g}_\theta(r)dr \ge \tilde{g}_0(r_1) + L(r_0 - r_1),$$

and this is larger than K if L is large enough. This gives a contradiction.

Next, for a fixed $K > 0$, if θ is large enough, then $\tilde{g}_\theta(r_0) > K$ implies $\tilde{g}_\theta(r) > K,\ r_0 \le r \le M$. This follows by using the properties that

$$\inf_{r_0 \le r \le M}\frac{1}{r}e(r) > 0, \qquad \sup_{r_0 \le r \le M}\frac{1}{e(r)} < \infty$$

and the estimate

$$\frac{d}{dr}\tilde{g}_\theta(r) \ge \frac{2}{\lambda^2}\inf_{r_0 \le r \le M}\left\{\frac{1}{r}e(r)(\bar{\Lambda}_0 + \theta_0 - \|\bar{d}\|_{[r_0,M]})\right\} - \left\|\frac{1}{e(r)}\right\|_{[r_0,M]} K^2 > 0$$

for an $r_0 \le r \le M$ satisfying $\tilde{g}_\theta(r) = K$ if θ is large enough.

We conclude from the above analysis that for a $K > \|\tilde{g}_0\|_{[r_1,r_0]}$, there is a θ sufficiently large such that $\tilde{g}_\theta(M) > K$. This implies $\bar{\Lambda}_*(M) \le \bar{\Lambda}_0 + \theta < \infty$. As a consequence of this argument, we also have that $\tilde{g}_\theta(M)$ tends to ∞ as θ tends to ∞. This ends the proof of this proposition. □

We now know there exists a solution of (22) and (25) on all of $(0, M]$, so we turn to the study of the solution of the constrained dynamic programming equation for $r > M$, that is, (23). But the solution of this differential equation must satisfy the boundary condition at $r = M$ that has $g(M)$ taking the value that comes from the solution of (22) and (25) for $r \le M$. Hence the solution of (23) is well defined for $r > M$, at least in some neighborhood of M.

LEMMA 4.2. *Given a specified value of $g(M)$, (23) has a unique solution g on $[M, r_1)$, where $r_1 := \sup\{r > M : g(r) > -\infty\}$. Also, there exists some $K < \infty$, which does not depend on r_1 (but may depend on $g(M)$), such that $g(r) \le K$ on $[M, r_1)$.*

Proof. It is sufficient to prove the existence of K. The existence of r_1 follows from the theory of ordinary differential equations.

First note that (23) can be rewritten as

$$\frac{dg}{dr} - \frac{2c}{\lambda^2}\left[1 - \frac{\bar{r}}{r}\right] g + g^2 = \frac{2}{\lambda^2 r}[\Lambda_M - \gamma r], \quad r \geq M. \tag{36}$$

It suffices to show that if a solution is such that $g(r_0) < c_2$, then $g(r) < c_2$ for all $r > r_0$, where r_0 and c_2 here are large. Suppose, on the contrary, that there is some $r_1 > r_0$ such that $g(r) < c_2$ for $r_0 \leq r < r_1$ and $g(r_1) = c_2$. Then by differential equation (36) we must have $\frac{dg}{dr}(r_1) < 0$. But this is a contradiction, so Lemma 4.2 is established. □

For fixed M and any $\Lambda > \bar{\Lambda}_*(M)$ we know by Proposition 4.3 that (22) with $\Lambda_M = \Lambda$ has a solution g on $(0, M]$ with $g(M)$ finite. So corresponding to each such Λ we can, as in the following lemma, consider the solution g of (23) on $[M, r_1)$ that takes this corresponding value of $g(M)$ at $r = M$. In other words, for each $\Lambda > \bar{\Lambda}_*(M)$ we have a solution of (22) and (23) that is continuous on $(0, r_1)$ for some $r_1 > M$.

LEMMA 4.3. *Fix M and let g_1 and g_2 be two solutions of* (22), (23), *and* (25) *corresponding to values of Λ_M equal to Λ_1 and Λ_2, respectively, where $\Lambda_1, \Lambda_2 > \bar{\Lambda}_*(M)$. Then $\Lambda_1 < \Lambda_2$ implies $g_1(r) < g_2(r)$ if g_1 is defined at r.*

Proof. First consider two differential equations (36), one satisfied by $(g_1, \Lambda_M = \Lambda_1)$ and the other by $(g_2, \Lambda_M = \Lambda_2)$. Subtracting one from the other gives

$$\frac{d}{dr}(g_2 - g_1) + \left[-\frac{2c}{\lambda^2}(1 - \bar{r}/r) + g_2 + g_1\right](g_2 - g_1) = \frac{2}{\lambda^2 r}[\Lambda_2 - \Lambda_1],$$

in which case

$$g_2(r) - g_1(r) = \exp\left(-\int_M^r \left(-\frac{2c}{\lambda^2}(1 - \bar{r}/s) + g_1(s) + g_2(s)\right) ds\right)[g_2(M) - g_1(M)]$$

$$+ \int_M^r \frac{2}{\lambda^2 s}(\Lambda_2 - \Lambda_1) \exp\left(-\int_s^r \left(-\frac{2c}{\lambda^2}(1 - \bar{r}/u) + g_1(u) + g_2(u)\right) du\right) ds.$$

Since $g_2(M) - g_1(M) > 0$ by Lemma 4.1, Lemma 4.3 follows from this. □

For each $M > 0$ we now define

$$\Lambda_M^* := \inf\{\Lambda_M : \text{the corresponding solution } g \text{ of (22), (23) satisfying (25) is finite for all } r > 0\},$$

and we observe that $\Lambda_M^* \geq \bar{\Lambda}_*(M)$. We now have the following key result.

PROPOSITION 4.4. *For each fixed number $M < \infty$ we have $\Lambda_M^* < \infty$.*

Proof. We need to prove the existence of a Λ_M such that $g(r)$ is finite for all $r > 0$, where g is the solution for (22), (23), and (25). By (36), if $g(M) > 0$ and $\Lambda_M > 0$, then $g(r) > 0$ for all $r > M$. We can show by the argument in the proof of Lemma 4.3 that $g(M) > 0$ if Λ_M is sufficiently large. This completes the proof. □

By Lemma 4.3 we know for $\Lambda_M \geq \Lambda_M^*$ that there exists a solution of (22), (23), and (25) on all of $(0, \infty)$. In order to identify the "correct" solution we now investigate the limiting behavior of these solutions g as $r \to \infty$.

PROPOSITION 4.5. *Fix $M < \infty$ and arbitrary $\Lambda_M \geq \Lambda_M^*$, and consider the solution g of (22), (23) satisfying (25). Then exactly one of the following two conditions will hold; that is, either*

$$\lim_{r\to\infty} g(r) = \frac{c}{\lambda^2} - \sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} \tag{37}$$

or

$$\lim_{r\to\infty} g(r) = \frac{c}{\lambda^2} + \sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}}. \tag{38}$$

Proof. Denote

$$\alpha := \frac{c}{\lambda^2} - \sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}},$$

and note that α is negative and satisfies

$$\alpha^2 - \frac{2c}{\lambda^2}\alpha + \frac{2\gamma}{\lambda^2} = 0.$$

Next, define

$$\hat{g}(r) = g(r) - \alpha,$$

and note that, in view of (23), we must have

$$\frac{d\hat{g}}{dr} + \left(-2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{r}\right)\hat{g} + \hat{g}^2 = \left(\frac{2\Lambda_M}{\lambda^2} - \frac{2c\bar{r}}{\lambda^2}\alpha\right)\frac{1}{r}, \quad r > M. \tag{39}$$

We now claim there is c_1 large enough such that

$$\hat{g}(r) > -c_1/r, \quad r \geq M. \tag{40}$$

Denote $f(r) = \hat{g}(r) + c_1/r$. Then (40) is equivalent to

$$f(r) > 0, \quad r \geq M.$$

To prove this, we have the following observation. By (39), we easily see that

$$\frac{df(r)}{dr} < 0$$

if $f(r) = 0$. This implies that if $f(r_0) \leq 0$ for some $r_0 > 0$, then

$$f(r) < 0, \quad r > r_0.$$

We shall show that this cannot be true. Otherwise, using (39), we have

$$\frac{d\hat{g}}{dr} + \frac{1}{2}\hat{g}^2 < 0, \quad r \geq r_0.$$

This, in turn, implies

$$-\frac{1}{\hat{g}(r)} + \frac{1}{\hat{g}(r_0)} + \frac{1}{2}(r - r_0) < 0, \quad r \geq r_0.$$

But this cannot be true for all $r \geq r_0$, a contradiction that implies (40).

We now consider two cases, depending upon whether or not

$$\frac{2\Lambda_M}{\lambda^2} - \frac{2c\bar{r}}{\lambda^2}\alpha > 0. \tag{41}$$

If (41) is true and $\hat{g}(r_0) > 0$ for some $r_0 > M$, then $\hat{g}(r) > 0$ for all $r \geq r_0$. From this, we conclude that one of the following two possibilities holds: either there is $r_0 > M$ such that

$$\hat{g}(r) > 0, \quad r \geq r_0, \tag{42}$$

or there is $r_0 > M$ such that

$$\hat{g}(r) < 0, \quad r \geq r_0. \tag{43}$$

We have the same conclusion if the opposite of (41) holds, so it suffices to consider (42) and (43) separately. First we assume (43). This together with (40) implies

$$\lim_{r\to\infty} \hat{g}(r) = 0.$$

In other words,

$$\lim_{r\to\infty} g(r) = \alpha, \tag{44}$$

which is equivalent to (37) in this case.

For the rest of this proof we shall assume (42). We consider (41) only (the analysis for other case is similar). We rewrite (39) as follows:

$$\frac{d\hat{g}}{dr} = \left(\left(2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} - \frac{2c\bar{r}}{\lambda^2}\frac{1}{r}\right) - \hat{g}\right)\hat{g} + \left(\frac{2\Lambda_M}{\lambda^2} - \frac{2c\bar{r}}{\lambda^2}\alpha\right)\frac{1}{r}, \quad r > M. \tag{45}$$

Denote

$$\bar{f}(r) = \hat{g}(r) + \left(-2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{r}\right).$$

Assuming (42), by using (45) it is easy to see that

$$\frac{d\bar{f}(r)}{dr} > 0$$

if $r \geq r_0$ and $\bar{f}(r) < 0$. Moreover, if $\bar{f}(r) < 0$, then

$$\frac{d\hat{g}(r)}{dr} > \left(\frac{2\Lambda_M}{\lambda^2} - \frac{2c\bar{r}}{\lambda^2}\alpha\right)\frac{1}{r}.$$

These two observations imply that we cannot have $\bar{f}(r) < 0$ for all $r \geq r_0$, so there must exist some $r_1 > r_0$ such that

$$\hat{g}(r) + \left(-2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{r}\right) > 0, \quad r \geq r_1. \tag{46}$$

Using the same argument applied to

$$\hat{g}(r) + \left(-2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{r} \right) - \frac{c_2}{r}$$

for a large c_2, we can prove the existence of $r_2 > r_1$ such that

$$\hat{g}(r) + \left(-2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{r} \right) - \frac{c_2}{r} < 0, \quad r \geq r_2. \tag{47}$$

From (46) and (47), we have

$$\lim_{r\to\infty} \hat{g}(r) = 2\sqrt{\frac{c^2}{\lambda^4} - \frac{2\gamma}{\lambda^2}}.$$

This is equivalent to (38). This together with (44) completes the proof of Proposition 4.5. □

Remark 4.3. We shall pay special attention to the limiting behavior (37); (38) will now be ignored. There are reasons for doing this. It will be shown below that the solution satisfying (37) is unique and that it characterizes the solution associated with Λ_M^*. These interesting properties may also be considered as evidence that the minimality of Λ_M^* will play some special role for the portfolio optimization problem. A general study of multidimensional problems related to this observation can be found in [17].

We are now interested in the smallest Λ_M such that (22), (23), and (25) have a solution for all r. The following lemma states that there is at most one value of Λ_M giving a solution of (22), (23), and (25) that also satisfies (37).

LEMMA 4.4. *Suppose g_1 and g_2 are two solutions of* (22), (23), *and* (25) *corresponding to $\Lambda_M = \Lambda_1, \Lambda_2$, respectively. If both g_1 and g_2 satisfy* (37), *then $g_1 = g_2$ and $\Lambda_1 = \Lambda_2$.*

Proof. Subtracting the equation for g_2 from the equation for g_1 gives

$$\frac{d}{dr}(g_2 - g_1) + \left(-\frac{2c}{\lambda^2} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{r} + g_1 + g_2 \right)(g_2 - g_1) = \frac{2}{\lambda^2 r}(\Lambda_2 - \Lambda_1).$$

By (37) we then have

$$-(g_2 - g_1)(r)\bar{e}(r) = \int_r^\infty \frac{2}{\lambda^2 s}(\Lambda_2 - \Lambda_1)\bar{e}(s)ds, \tag{48}$$

where we have introduced the function

$$\bar{e}(r) := \exp\left\{ \int_{r_0}^r \left(-\frac{2c}{\lambda^2} + \frac{2c\bar{r}}{\lambda^2}\frac{1}{s} + g_1(s) + g_2(s) \right) ds \right\}.$$

Here $r_0 > M$ is fixed. The integral on the right-hand side of (48) is finite by (37). Moreover, (48) implies $g_2 - g_1 > 0$ if $\Lambda_2 - \Lambda_1 < 0$. But we also have $g_2 - g_1 < 0$ if $\Lambda_2 - \Lambda_1 < 0$. Therefore $\Lambda_1 = \Lambda_2$ and $g_1 = g_2$; that is, the proof of Lemma 4.4 is completed. □

It remains to prove the solution g^* corresponding to $\Lambda_M = \Lambda_M^*$ satisfies (37). In other words, with Lemma 4.4 establishing uniqueness, it remains to establish existence. This is a consequence of the following lemma, because if for $\Lambda_M = \bar{\Lambda}$ the

corresponding limit is (38), then for all $\Lambda_M < \bar{\Lambda}$ in some neighborhood of $\bar{\Lambda}$ the corresponding limits also satisfy (38). Hence if there exists a solution for $\Lambda_M = \Lambda_M^*$ (the infimum of Λ_M for which there exists a solution; Λ_M^* is finite by Proposition 4.3 above and Lemma 5.2 below, and the infimum is attained by the same kind of argument used below in the proof of Theorem 5.1), this solution must satisfy the other limit, namely, (37).

LEMMA 4.5. *If $\Lambda_M = \hat{\Lambda}$ is such that the corresponding solution of* (22), (23) *satisfies* (25) *and* (38), *then there exists some $\delta > 0$ such that for any $\Lambda_M > \hat{\Lambda} - \delta$ the solution of* (22), (23) *exists for all r.*

Proof. Let $\hat{g}$ be the solution corresponding to $\hat{\Lambda}$; thus

$$\frac{d\hat{g}}{dr} - \frac{2c}{\lambda^2}\left(1 - \frac{\bar{r}}{r}\right)\hat{g} + \hat{g}^2 = \frac{2}{\lambda^2 r}(\hat{\Lambda} - \gamma r), \quad r > M.$$

With g being the solution of (22) and (23) corresponding to Λ, write

$$\bar{g} := g - \hat{g},$$

and so

$$\frac{d\bar{g}}{dr} + \frac{d\hat{g}}{dr} - \frac{2c}{\lambda^2}\left(1 - \frac{\bar{r}}{r}\right)(\bar{g} + \hat{g}) + (\bar{g} + \hat{g})^2 = \frac{2}{\lambda^2 r}(\Lambda - \gamma r).$$

This implies

$$\frac{d\bar{g}}{dr} + \left(\frac{2c}{\lambda^2}\left(1 - \frac{\bar{r}}{r}\right) + 2\hat{g}\right)\bar{g} + \bar{g}^2 = \frac{2}{\lambda^2 r}(\Lambda - \hat{\Lambda}). \tag{49}$$

We now seek the solution of (49) such that $||\bar{g}|| \le \delta_1$, where

$$||\bar{g}|| := \sup_{r \ge M} |\bar{g}(r)|.$$

Here δ_1 will be chosen later in a manner which depends on δ, where $|\Lambda - \hat{\Lambda}| < \delta$. Note that (49) can be rewritten as

$$\bar{g}(r) = \bar{g}(M)\frac{1}{\bar{e}(r)} - \int_M^r \frac{\bar{e}(s)}{\bar{e}(r)}\bar{g}^2(s)ds + \frac{2}{\lambda^2}(\Lambda - \hat{\Lambda})\int_M^r \frac{\bar{e}(s)}{\bar{e}(r)}\frac{1}{s}ds,$$

where we introduce the function

$$\bar{e}(r) := \exp\left\{\int_M^r \left(-\frac{2c}{\lambda^2}(1 - \bar{r}/s) + 2\hat{g}(s)\right)ds\right\}.$$

We use again the fixed-point argument to get a solution g. Denote

$$\mathbf{F} := \{f : [M, \infty) \to \mathbf{R}, ||f|| \le \delta_1, f(M) = \bar{g}(M)\},$$

where $\bar{g}(M) = g(M) - \hat{g}(M)$, and where g is the solution of (22) corresponding to $\Lambda_M = \Lambda$. We denote for $f \in \mathbf{F}$

$$Tf(r) := \bar{g}(M)\frac{1}{\bar{e}(r)} - \int_M^r \frac{\bar{e}(s)}{\bar{e}(r)}f^2(s)ds + \frac{2}{\lambda^2}(\Lambda - \hat{\Lambda})\int_M^r \frac{\bar{e}(s)}{\bar{e}(r)}\frac{1}{s}ds.$$

We know $\bar{g}(M) \to 0$ if $\Lambda \to \hat{\Lambda}$. We consider

$$|\Lambda - \hat{\Lambda}| < \delta, \quad \bar{\delta} = |\bar{g}(M)| \max_{r \le M} \frac{1}{\bar{e}(r)},$$

where δ is small. Then take $\delta_1 > 0$ satisfying

$$\delta_1^2 \sup_{r \ge M} \int_M^r \frac{\bar{e}(s)}{\bar{e}(r)} ds + \bar{\delta} + \frac{2\delta}{\lambda^2} \sup_{r \ge M} \left\{ \int_M^r \frac{\bar{e}(s)}{\bar{e}(r)} \frac{1}{s} ds \right\} < \delta_1.$$

Note that for δ small enough we can take

$$\delta_1 = 2 \left(\bar{\delta} + \frac{2\delta}{\lambda^2} \sup_{r \ge M} \left\{ \int_M^r \frac{\bar{e}(s)}{\bar{e}(r)} \frac{1}{s} ds \right\} \right).$$

Then it is not difficult to show that the operator $T : \mathbf{F} \to \mathbf{F}$. Moreover, for arbitrary $f_1, f_2 \in \mathbf{F}$ we have

$$||Tf_1 - Tf_2|| \le 2\delta_1 \sup_{r \ge M} \frac{1}{\bar{e}(r)} \int_M^r \bar{e}(s) ds ||f_1 - f_2|| = K||f_1 - f_2||.$$

By taking δ_1 small enough one has the number $K < 1$. Then T is a contraction with a unique fixed point in $\mathbf{F}$, which is the unique solution of (23). This completes the proof of Lemma 4.5. □

5. Proofs of Theorems 3.1 and 3.3. The proofs of Theorems 3.1 and 3.3 are accomplished by the three propositions in this section. The first of these shows that the solutions of Theorem 3.2 converge as $M \to \infty$ to a solution of the HJB equation (16) that also satisfies conditions (19) and either (20) (if $\mu_2 \ne 1$) or (21) (if $\mu_2 = 1$). Later in this section we will show uniqueness, thereby completing the proofs of both Theorems 3.1 and 3.3.

PROPOSITION 5.1. *Let Λ_M^* and $g_M^*(r)$ be as in Theorem* 3.2. *Then $\Lambda_M^* \to \Lambda$ and $g_M^*(r) \to g(r)$ as $M \to \infty$, where Λ and $g(r)$ satisfy* (16) *and $g(r)$ also satisfies* (19) *and either* (20) *(in the case $\mu_2 \ne 1$) or* (21) *(in the case $\mu_2 = 1$).*

To prove Proposition 5.1 we need the following four lemmas. The first two of these are based upon the following equation:

$$(50)\quad \Lambda = \frac{1}{2}\lambda^2 r \frac{dg}{dr} + \frac{1}{2}\lambda^2 r \left(1 + \frac{\gamma}{1-\gamma} \frac{\sigma^2}{\sigma^2 + \rho^2}\right) g^2 + b(r)g + d(r), \quad r \le R_0 + 1.$$

Here $R_0 > 0$ is a specified constant, and it is noteworthy that this equation is essentially the same as (22), which is part of the dynamic programming equation in Theorem 3.2.

LEMMA 5.1. *Let $r_0 < R_0$ be arbitrary. Then there is $K > 0$, depending on r_0, R_0, and Λ, such that if* (50) *has a solution g, then*

$$|g(r)| \le K, \quad r_0 \le r \le R_0.$$

Moreover, K can be chosen to be increasing in Λ. Therefore, for r_0, R_0, Λ fixed, the set $\{|g(r)| : r_0 \le r \le R_0; g$ satisfies (50)$\}$ *is bounded.*

Remark 5.1. If the value of the ODE solution g is specified at $r_0 < R_0$, say, then the values of g for all r will be determined. The most interesting part of this lemma is the conclusion that regardless of the initial value we choose for g at r_0, if $g(r)$ is

finite in $(0, R_0+1]$, then $|g(r)| \le K$ for all $r_0 \le r \le R_0$, where K is independent of g, although it may depend on R_0. Consequently, in order to have a solution of (50) we cannot arbitrarily assign a value of g at r_0 (that is, $g(r_0)$ needs to satisfy $|g(r_0)| \le K$). Regarding the dependence of K on Λ, an expression for K is provided at the end of the proof that follows. This dependence will be used in the proof of Proposition 5.1.

Proof. Let g satisfy (50). Take $\phi : [0,\infty) \to [0,1]$ smooth such that

$$\begin{aligned} \phi(r) &= 1, \quad r_0 \le r \le R_0, \\ &= 0, \quad 0 \le r \le \tfrac{r_0}{2},\ R_0+1 < r. \end{aligned} \tag{51}$$

Without loss of generality, we can take ϕ such that it satisfies the following property:

$$\left| \frac{1}{\sqrt{\phi(r)}} \frac{d\phi(r)}{dr} \right| \le K_1.$$

Here K_1 is some number that may depend on r_0 and R_0. To see this, we denote $h(r)$ by

$$h(r) := \frac{1}{\sqrt{\phi(r)}} \frac{d\phi(r)}{dr}, \quad r \ge R_0,$$

and so

$$\sqrt{\phi(r)} = 1 + 2\int_{R_0}^{r} h(u)du, \quad r > R_0.$$

We then choose $h(\cdot)$ such that $h(\cdot)$ is bounded and

$$2\int_{R_0}^{R_0+1} h(u)du = -1.$$

Moreover, we choose $h(r) = 0, r \ge R_0+1$. The derivatives of h of any order at R_0 and R_0+1 are 0. Thus ϕ satisfies the required property on $[R_0,\infty)$. We can apply a similar argument for $r \in (0, r_0]$.

Consider

$$f(r) = \frac{1}{2}\phi(r)g^2(r).$$

Then $f(r)$ takes a maximum at some r_1 satisfying $r_0/2 \le r_1 \le R_0+1$. Denote

$$X^2 = 2f(r_1) = 2\max f(r).$$

Then

$$\frac{df}{dr}(r_1) = 0;$$

that is,

$$\phi(r_1)g(r_1)\frac{dg}{dr}(r_1) = -\frac{1}{2}g^2(r_1)\frac{d\phi}{dr}(r_1). \tag{52}$$

We multiply (50) at $r = r_1$ by $\phi(r_1)g(r_1)$ and use (52) to get

$$\begin{aligned} \Lambda\phi(r_1)g(r_1) = &-\frac{1}{4}\lambda^2 r_1 g^2(r_1)\frac{d\phi}{dr}(r_1) + \frac{1}{2}\lambda^2 r_1\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\phi(r_1)g^3(r_1) \\ &+ b(r_1)\phi(r_1)g^2(r_1) + d(r_1)\phi(r_1)g(r_1). \end{aligned}$$

Assume $g(r_1) \neq 0$. Then divide the above relation by $g(r_1)$ to obtain

$$\Lambda\phi(r_1) = -\frac{1}{4}\lambda^2 r_1 g(r_1)\frac{d\phi}{dr}(r_1) + \frac{1}{2}\lambda^2 r_1\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\phi(r_1)g^2(r_1) + b(r_1)\phi(r_1)g(r_1) + d(r_1)\phi(r_1).$$

Then

$$X^2 + 2\alpha X = \beta, \tag{53}$$

where

$$\alpha = \alpha(r_1) = \frac{1}{\lambda^2 r_1(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2})}\left(b(r_1)\sqrt{\phi(r_1)} - \frac{1}{4}\lambda^2 r_1 \frac{1}{\sqrt{\phi(r_1)}}\frac{d\phi}{dr}(r_1)\right),$$

$$\beta = \beta(r_1) = \frac{2}{\lambda^2 r_1(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2})}(-d(r_1)\phi(r_1) + \Lambda\phi(r_1)).$$

From (53),

$$X = -\alpha \pm \sqrt{\alpha^2 + \beta},$$

in which case

$$|X| \leq |\alpha| + \sqrt{\alpha^2 + \beta}.$$

We see $|X| \leq K$, where

$$K = \max\left\{|\alpha(r)| + \sqrt{\alpha(r)^2 + \beta(r)}, \frac{r_0}{2} \leq r \leq R_0 + 1\right\}$$

so that K depends on r_0, R_0, and Λ. Since

$$\max_{r_0 \leq r \leq R_0} |g(r)|^2 \leq X^2,$$

the result follows. □

The next lemma says that the set of all Λ such that (50) has a solution is bounded below.

LEMMA 5.2. *For a fixed R_0, there is a $\Lambda(R_0)$ such that if* (50) *has a solution g, then $\Lambda \geq \Lambda(R_0)$.*

Proof. We take $0 < r_0 < R_0$ and a smooth function ϕ as in (51). We can define $\hat{b}(r)$ for all $r > 0$ such that

$$\hat{b}(r) = b(r), \quad r \leq R_0$$

and such that the diffusion process defined by

$$d\hat{r}(t) = \hat{b}(\hat{r}(t))dt + \lambda\sqrt{\hat{r}(t)}dB(t)$$

has an invariant density that we denote by $\hat{p}(r)$. See [19].

Denote

$$\Phi(r) = \exp\left(\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right) W(r)\right),$$

where

$$W(r) = \int_{r_0}^{r} g(u)du.$$

Then

$$\hat{L}\Phi(r) = \hat{\Lambda}\Phi(r) - \hat{d}(r)\Phi(r), \quad r \le R_0,$$

where

$$\hat{\Lambda} = \left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\Lambda,$$

$$\hat{d}(r) = \left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right) d(r),$$

$$\hat{L}f(r) = \frac{1}{2}\lambda^2 r\frac{d^2 f}{dr^2}(r) + \hat{b}(r)\frac{df}{dr}(r).$$

We have

$$\int \hat{L}\Phi(r)\phi(r)\hat{p}(r)dr = \int \hat{\Lambda}\Phi(r)\phi(r)\hat{p}(r)dr - \int \hat{d}(r)\Phi(r)\phi(r)\hat{p}(r)dr.$$

The equation for the invariant density $\hat{p}$ is

$$\frac{1}{2}\frac{d^2}{dr^2}(\lambda^2 r\hat{p}(r)) - \frac{d}{dr}(\hat{b}(r)\hat{p}(r)) = 0.$$

In one dimension, we have

$$\frac{1}{2}\frac{d}{dr}(\lambda^2 r\hat{p}(r)) - \hat{b}(r)\hat{p}(r) = 0.$$

From this and the integration by parts formula we then have

$$\int \hat{L}\Phi(r)\phi(r)\hat{p}(r)dr = -\frac{1}{2}\int \lambda^2 r\frac{d\Phi}{dr}(r)\frac{d\phi}{dr}(r)\hat{p}(r)dr.$$

Consequently,

$$\hat{\Lambda}\int \Phi(r)\phi(r)\hat{p}(r)dr = \int \hat{d}(r)\Phi(r)\phi(r)\hat{p}(r)dr - \frac{1}{2}\int \lambda^2 r\frac{d\Phi}{dr}(r)\frac{d\phi}{dr}(r)\hat{p}(r)dr. \tag{54}$$

By Lemma 5.1 there is some number K, which depends on Λ, such that

$$\frac{1}{K} \le \Phi(r) \le K,$$

$$\left|\frac{d\Phi}{dr}(r)\right| \le K$$

for $r_0 \le r \le R_0$. From this and (54) we have

$$|\hat{\Lambda}| \int \Phi(r)\phi(r)\hat{p}(r)dr \le K\left(\|\hat{d}\| + \lambda^2 R_0 \left\|\frac{d\phi}{dr}\right\|\right).$$

The left-hand side is larger than

$$|\hat{\Lambda}|\frac{1}{K}\int \phi(r)\hat{p}(r)dr.$$

From these inequalities, $|\hat{\Lambda}|$ has an upper bound depending only on R_0. This completes the proof. □

For the following lemma and subsequent use we shall make use of a quantity that was defined in section 4, namely,

$$\Lambda_M^* := \inf\{\Lambda_M : \quad (22) \text{ and } (23) \text{ has a solution satisfying } (25)\}.$$

LEMMA 5.3. *For each $M_0 > 0$, the set $\{\Lambda_M^*; M \ge M_0\}$ is bounded above.*

Proof. It is enough to show that there is Λ such that (22)–(23) has a solution $g = g_M$ satisfying (25) such that $g(r) > 0$ for all r, for $\Lambda_M = \Lambda$ with $M \ge M_0$, since this will imply $\Lambda_M^* \le \Lambda$ by the definition of Λ_M^*.

We take Λ large enough such that (22) has a solution g satisfying

$$\lim_{r\to 0} g(r) = \frac{1}{c\bar{r}}\left(\Lambda - \frac{\gamma}{2(1-\gamma)}\frac{\mu_1^2}{\sigma^2+\rho^2}\right) > 0.$$

By (22), it is easy to see that $g(r) > 0$ for $0 < r \le M$, since in $0 < r \le M$, g is increasing at the zeros of g. This argument also applies to $M \le r$. That is, $g(r)$ cannot be $-\infty$ for finite r. Therefore, we get a unique solution of (22)–(23) satisfying (25). □

LEMMA 5.4. *Let $g = g_M$ be the solution of* (22) *and* (23) *satisfying* (25) *with $\Lambda = \Lambda_M^*$. Then there is some $M_0 > 0$ such that for $M \ge M_0$,*

$$g(r) < 0, \ r > M_0.$$

Proof. By (37), $g(r)$ will be negative if r is large enough. From (23) and the fact that Λ is bounded below (see Lemma 5.2), it is easy to see that $g(r) < 0$ for $r > M$ if M is large enough, since $g(r)$ for $r > M$ is increasing at zeros of g. This argument also applies to $M_0 \le r \le M$. Therefore, $g(r) < 0$ for $r > M_0$ if M is large enough. This completes the proof. □

Armed with these lemmas, we can now prove Proposition 5.1.

Proof of Proposition 5.1. By Lemmas 5.2 and 5.3, for a fixed $M_0 > 0$, $\{\Lambda_M^*, M \ge M_0\}$ is bounded above and below. We can take a sequence $M_n \to \infty$ as $n \to \infty$ such that $\Lambda_{M_n}^*$ converges to some Λ. Boundedness of $\{\Lambda_{M_n}^*\}$ also implies the uniform boundedness of $\{|g_{M_n}^*(r)|\}$ on compact sets by Lemma 5.1. This further implies the uniform boundedness of $\{|\frac{dg_{M_n}^*}{dr}(r)|\}$ on compact sets, by using (22) and (23). Therefore, we can take a subsequence of $\{M_n\}$ (still denoted by $\{M_n\}$), such that $g_{M_n}^*(r)$ converges to $g(r)$ uniformly on compact sets.

We know Λ, g satisfy (16) and g satisfies (19). In fact, we need only rule out the possibility that g satisfies (33). But since the $g_{M_n}^*(r)$ satisfy (34) for c_1 and r_0 independent of n (see the proof of Proposition 4.2), it follows that (33) cannot hold for g.

It remains to prove that (20) or (21) (depending on the case) holds for g, because then $(\Lambda^*, g^*) = (\Lambda, g)$ satisfies the properties in Theorem 3.1 (see also Theorem 5.1 below). From this it follows that the limit of (Λ_M^*, g_M^*) as $M \to \infty$ is unique, and so Proposition 5.1 will be proved.

We now prove that (20) holds for g when $\mu_2 \neq 1$. By Lemma 5.4, there is M_0 such that

$$g(r) < 0, \ r \geq M_0. \tag{55}$$

We need to know the behaviors of the solutions of (16) as $r \to \infty$. This will be given in Proposition 5.2 below. Now g given above is a solution of (16). Define $\bar{g} = Ag$, $A = 1 + \gamma\sigma^2/(1-\gamma)(\sigma^2+\rho^2)$. According to this theorem, either (56) or (57) holds. From (61), we can conclude the following. If (56) holds, then $g(r) < 0$ for r large. If (57) holds, then $g(r) > 0$ for r large. Since (55) holds, we must have (56). This in turn implies (20) by a simple calculation. The case $\mu_2 = 1$ is treated in a similar manner. This completes the proof. □

PROPOSITION 5.2. *Let (Λ, g) be a solution of* (16) *for $0 < r < \infty$. Then exactly one of the following relations holds:*
either

$$\lim_{r\to\infty} r(\bar{g}(r) - \bar{g}_0(r)) = -\frac{1}{8}\left(1 - \frac{\lambda}{|\lambda|}\left(\frac{-\gamma}{1-\gamma}\right)^{\frac{1}{2}} \frac{\sigma}{\sqrt{\sigma^2+\rho^2}}\right) \tag{56}$$

or

$$\lim_{r\to\infty} \frac{1}{\sqrt{r}}(\bar{g}(r) - \bar{g}_0(r)) = 2\left(-\frac{\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\right)^{\frac{1}{2}} \frac{|\mu_2 - 1|}{|\lambda|}, \quad \mu_2 \neq 1, \tag{57}$$

$$\lim_{r\to\infty} (\bar{g}(r) - \bar{g}_0(r)) = 2\left(\frac{c^2}{\lambda^4} - 2\frac{\gamma}{\lambda^2}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\right)^{\frac{1}{2}}, \quad \mu_2 = 1. \tag{58}$$

Here

$$\bar{g}_0(r) := -\frac{b(r)}{\lambda^2 r} - \left(-\frac{2\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)d(r)}{\lambda^2 r} + \frac{b(r)^2}{\lambda^4 r^2}\right)^{\frac{1}{2}},$$

while $b(\cdot), d(\cdot)$, and $\bar{g}(\cdot)$ are defined by (17), (18), *and* (29), *respectively.*

In order to prove Proposition 5.2 we need three more lemmas. For these we consider a function $g(r)$ that is finite for all r and satisfies (16) and (19). Using this and $\bar{g}_0(r)$ as specified in Proposition 5.2, we then define

$$\hat{g} := \bar{g} - \bar{g}_0.$$

Since $\bar{g}_0$ satisfies

$$\frac{1}{2}\lambda^2 r\bar{g}_0(r)^2 + b(r)\bar{g}_0(r) + \bar{d}(r) = 0,$$

it follows that

$$\frac{1}{2}\lambda^2 r\frac{d}{dr}\hat{g}(r) + \frac{1}{2}\lambda^2 r\hat{g}(r)^2 + \tilde{b}(r)\hat{g}(r) = L(r),$$

where

$$L(r) := \Lambda - \frac{1}{2}\lambda^2 r \frac{d}{dr}\bar{g}_0(r)$$

and

$$\tilde{b}(r) := b(r) + \lambda^2 r \bar{g}_0(r) = -\lambda^2 r \left(-\frac{2\bar{d}(r)}{\lambda^2 r} + \frac{b(r)^2}{\lambda^4 r^2} \right)^{\frac{1}{2}} = -\big(-2\lambda^2 r \bar{d}(r) + b(r)^2 \big)^{\frac{1}{2}}.$$

Notice this equation can be rewritten as

$$\frac{d\hat{g}}{dr} + \hat{g}^2 + \frac{2\tilde{b}(r)}{\lambda^2 r}\hat{g} = \frac{2L(r)}{\lambda^2 r}. \tag{59}$$

In order to investigate the asymptotic properties of (59) we calculate

$$-\frac{2\bar{d}(r)}{\lambda^2 r} + \frac{b(r)^2}{\lambda^4 r^2} = -\frac{2\gamma}{\lambda^2 r}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\left(\frac{1}{2}\frac{1}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\bar{\mu}(r)^2 + r\right)$$

$$+ \frac{1}{\lambda^4 r^2}\left(-c(r-\bar{r}) + \frac{\gamma}{1-\gamma}\frac{\sigma\lambda}{\sigma^2+\rho^2}\sqrt{r}\bar{\mu}(r)\right)^2$$

$$= \bar{\mu}(r)^2\left(-\frac{\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\frac{1}{\lambda^2 r} + \left(\frac{\gamma}{1-\gamma}\right)^2 \frac{\sigma^2}{(\sigma^2+\rho^2)^2}\frac{1}{\lambda^2 r}\right)$$

$$-2\frac{c\sigma\lambda}{\lambda^4}\frac{1}{\sigma^2+\rho^2}\frac{r-\bar{r}}{r}\frac{1}{\sqrt{r}}\bar{\mu}(r) + \frac{c^2}{\lambda^4}\frac{(r-\bar{r})^2}{r^2} - 2\frac{\gamma}{\lambda^2}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)$$

$$= -\frac{\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\frac{1}{\lambda^2 r}\bar{\mu}(r)^2 - 2\frac{c\sigma\lambda}{\lambda^4}\frac{1}{\sigma^2+\rho^2}\frac{r-\bar{r}}{r}\frac{1}{\sqrt{r}}\bar{\mu}(r) + \frac{c^2}{\lambda^4}\frac{(r-\bar{r})^2}{r^2}$$
$$- 2\frac{\gamma}{\lambda^2}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right).$$

Since

$$\frac{2\tilde{b}(r)}{\lambda^2 r} = -2\left(-\frac{2\bar{d}(r)}{\lambda^2 r} + \frac{b(r)^2}{\lambda^4 r^2}\right)^{\frac{1}{2}},$$

it follows when $\mu_2 \neq 1$ that

$$\frac{2\tilde{b}(r)}{\lambda^2 r} \cong -2\left(-\frac{\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\right)^{\frac{1}{2}} \frac{|\mu_2 - 1|}{|\lambda|}\sqrt{r} + O(1) \quad \text{as} \quad r \to \infty. \tag{60}$$

Moreover,

$$\bar{g}_0(r) \cong -\frac{1}{\lambda}\frac{\gamma}{1-\gamma}\frac{\sigma}{\sigma^2+\rho^2}(\mu_2 - 1)\sqrt{r} - \left(\frac{-\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\frac{1}{\lambda^2}\right)^{\frac{1}{2}}|\mu_2 - 1|\sqrt{r} + O(1) \text{ as } \quad r \to \infty. \tag{61}$$

On the other hand, if $\mu_2 = 1$, then

$$\frac{2\tilde{b}(r)}{\lambda^2 r} \cong -2\left(\frac{c^2}{\lambda^4} - 2\frac{\gamma}{\lambda^2}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\right)^{\frac{1}{2}} + O\left(\frac{1}{\sqrt{r}}\right) \quad \text{as} \quad r \to \infty \tag{62}$$

and

$$\bar{g}_0(r) \cong \frac{c}{\lambda^2} - \left(\frac{c^2}{\lambda^4} - 2\frac{\gamma}{\lambda^2}\left(1 + \frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\right)^{\frac{1}{2}} + O\left(\frac{1}{\sqrt{r}}\right) \quad \text{as} \quad r \to \infty.$$

From this we see that if $\mu_2 \neq 1$, then

$$L(r) \cong \frac{|\lambda|}{4}\left(\left(\frac{-\gamma}{1-\gamma}\frac{1}{\sigma^2+\rho^2}\right)^{\frac{1}{2}} + \frac{\lambda}{|\lambda|}\frac{\gamma}{1-\gamma}\frac{\sigma}{\sigma^2+\rho^2}\right)|\mu_2 - 1|\sqrt{r} + O\left(\frac{1}{\sqrt{r}}\right) \quad \text{as} \quad r \to \infty, \tag{63}$$

whereas if $\mu_2 = 1$, then

$$L(r) \cong \Lambda + O\left(\frac{1}{\sqrt{r}}\right) \quad \text{as} \quad r \to \infty.$$

We are now ready for the first of the three lemmas that will be used in the proof of Proposition 5.2.

LEMMA 5.5. *There exist positive numbers c_1 and r_1 such that*

$$\hat{g}(r) > -\frac{c_1}{r} \qquad \forall r \geq r_1. \tag{64}$$

Proof. This proof is by contradiction. Suppose it is false. Then for any $c_1 > 0$ and $r_2 > 0$ there exists some $r_0 > r_2$ such that

$$\hat{g}(r_0) \leq -c_1/r_0.$$

From this we shall prove that

$$\hat{g}(r) \leq -\frac{c_1}{r} \qquad \forall r \geq r_0. \tag{65}$$

But if this is not true, then without loss of generality there is some $r_1 > r_0$ such that $\hat{g}(r_1) = -c_1/r_1$ and

$$\hat{g}(r) < -c_1/r, \quad r_0 < r < r_1.$$

Denoting $f(r) := \hat{g}(r) + c_1/r$, we then see that

$$\frac{df(r_1)}{dr} = -\hat{g}(r_1)^2 + \frac{L(r_1)}{\lambda^2 r_1} - \frac{2\tilde{b}(r_1)}{\lambda^2 r_1}\hat{g}(r_1) - c_1\frac{1}{r_1^2} < 0$$

if we take c_1 large enough. This is a contradiction; (65) must be true if this lemma is false.

By (65) and (59), we have

$$\frac{d\hat{g}}{dr} + \hat{g}^2 < 0.$$

Then

$$\frac{\frac{d\hat{g}}{dr}}{\hat{g}^2} + 1 < 0,$$

which implies

$$\frac{1}{\hat{g}(r_0)} - \frac{1}{\hat{g}(r)} + (r - r_0) < 0$$

for all $r > r_0$. This cannot be true for all $r \geq r_0$, so (65) leads to a contradiction. The proof is complete. □

LEMMA 5.6. *Suppose for some large $r_0 > 0$ that with $r = r_0$ we have*

$$\frac{c_2}{r} < \hat{g}(r) < -\frac{2\tilde{b}(r)}{\lambda^2 r} + \frac{c_2}{r}. \tag{66}$$

If c_2 is large enough, then this inequality also holds for all $r \geq r_0$.

Proof. Suppose $\mu_2 \neq 1$. By (59) and (63), $\hat{g} - c_2/r$ is increasing at $r \geq r_0$ such that $\hat{g} - c_2/r = 0$. Therefore,

$$\frac{c_2}{r} < \hat{g}(r), \quad r \geq r_0.$$

Denote

$$r_1 := \inf\left\{ r > r_0 : \hat{g}(r) \geq -\frac{2\tilde{b}(r)}{\lambda^2 r} + \frac{c_2}{r} \right\}.$$

We have shown $\hat{g}(r) > c_2/r$ for $r_0 < r < r_1$, so it suffices to show we have $r_1 = \infty$.

Assume not. Then $\hat{g}(r_1) = -2\tilde{b}(r_1)/(\lambda^2 r_1) + c_2/r_1$ and

$$\hat{g}(r) < -\frac{2\tilde{b}(r)}{\lambda^2 r} + \frac{c_2}{r}, \quad r_0 \leq r < r_1.$$

We now consider

$$f(r) := \hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} - \frac{c_2}{r}$$

and show that $\frac{d}{dr} f(r_1) < 0$, which leads to a contradiction. We have

$$\begin{aligned} \frac{d}{dr} f(r_1) = & \frac{d}{dr}\hat{g}(r_1) + \frac{d}{dr}\left(\frac{2\tilde{b}(r)}{\lambda^2 r}\right)(r_1) + \frac{c_2}{r_1^2} \\ = & \frac{2L(r_1)}{\lambda^2 r_1} - \frac{c_2}{r_1}\left(-\frac{2\tilde{b}(r)}{\lambda^2 r} + \frac{c_2}{r_1}\right) + \frac{d}{dr}\left(\frac{2\tilde{b}(r)}{\lambda^2 r}\right)(r_1) + \frac{c_2}{r_1^2}. \end{aligned}$$

From this, (60), and (63) we can show $\frac{d}{dr} f(r_1) < 0$, thereby completing the proof for the case $\mu_2 \neq 1$. The case $\mu_2 = 1$ is handled in a similar manner. □

LEMMA 5.7. *With r_0 and c_2 as in the preceding lemma such that c_2 is large enough and* (66) *holds, for small $c_1 > 0$ there exists some $r_1 > r_0$ such that*

$$\hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} \geq -c_1$$

for all $r \geq r_1$.

Proof. We first show that there is some $r_1 > r_0$ satisfying

$$\hat{g}(r_1) + \frac{2\tilde{b}(r_1)}{\lambda^2 r_1} \geq -c_1. \tag{67}$$

Otherwise,

$$\hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} < -c_1 \qquad \forall r > r_0. \tag{68}$$

By (59), we have

$$\frac{d\hat{g}}{dr} \geq c_1 \hat{g} + \frac{2L(r)}{\lambda^2 r} \geq c_1 \hat{g} - \bar{c}\frac{1}{r} \geq \frac{c_1}{2}\hat{g}$$

if c_2 is large enough. Then

$$\hat{g}(r) \geq \exp\left\{\frac{c_1}{2}(r - r_0)\right\} \hat{g}(r_0).$$

But this contradicts (68), so (67) must be true.

Denote

$$f(r) := \hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r}.$$

Using (59), (60), and (63), we can easily see that

$$\frac{df(r)}{dr} > 0$$

if $f(r) = -c_1$ and c_1 small. From this and (67), $f(r) > -c_1$ for $r > r_1$. This completes the proof.

We are now ready for the proof of Proposition 5.2. Recall that $\hat{g} := \bar{g} - \bar{g}_0$ satisfies (59).

Proof of Proposition 5.2. By Lemmas 5.5–5.7, for positive numbers r_0 and c_1, c_2 (c_1 small, c_2 large) either

$$-\frac{c_2}{r} < -\hat{g}(r) < \frac{c_2}{r}, \quad r \geq r_0 \tag{69}$$

or

$$-c_1 < \hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} < \frac{c_2}{r}, \quad r \geq r_0. \tag{70}$$

We first suppose that (69) holds. Denote

$$e(r) := \exp\left(\int_{r_0}^{r} \frac{2\tilde{b}(s)}{\lambda^2 s} ds\right),$$

so that we have for $r \geq r_0$

$$\hat{g}(r) = -\int_r^\infty \frac{L(s)}{\lambda^2 s}\frac{e(s)}{e(r)} ds + \int_r^\infty \hat{g}(s)^2 \frac{e(s)}{e(r)} ds.$$

By (60) and l'Hôpital's rule we then have

$$\lim_{r\to\infty}\frac{r}{e(r)}\int_r^\infty \frac{L(s)}{\lambda^2 s}e(s)ds = \frac{1}{8}\left(1-\frac{\lambda\sigma}{|\lambda|}\left(\frac{-\gamma}{1-\gamma}\right)^{\frac{1}{2}}\left(\frac{1}{\sigma^2+\rho^2}\right)^{\frac{1}{2}}\right)$$

and

$$\lim_{r\to\infty}\frac{r}{e(r)}\int_r^\infty \hat{g}(s)^2 e(s)ds = 0.$$

This implies (56).

On the other hand, suppose (70) holds. Our next step is to show that

$$-c_2\frac{1}{r} < \hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} < \frac{c_2}{r}, \quad r \geq r_0. \tag{71}$$

We do this by first showing that there is some number $r_1 > r_0$ satisfying (71) for $r = r_1$. This is true, for if not, then

$$-c_1 \leq \hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} \leq -c_2\frac{1}{r}, \quad r \geq r_0,$$

where c_1 is given in (70). Then (59) implies

$$\frac{d\hat{g}}{dr} \geq c_2\frac{1}{r}\hat{g} + \frac{2L(r)}{\lambda^2 r} \geq \frac{c_2}{2}\frac{1}{r}\hat{g}.$$

Integrating this we obtain

$$\hat{g}(r) \geq \hat{g}(r_0)\exp\left(\frac{c_2}{2}\ln\left(\frac{r}{r_0}\right)\right) = \hat{g}(r_0)\left(\frac{r}{r_0}\right)^{c_2/2}.$$

But this contradicts the assertion that $\hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} < -\frac{c_2}{r}$ for all $r \geq r_0$, so we know (71) holds for some $r_1 > r_0$.

We now consider $f(r) : \hat{g}(r) + \frac{2\tilde{b}(r)}{\lambda^2 r} + \frac{c_2}{r}$ and use (59) to show that $f(r)$ is increasing at $f(r) = 0$. Therefore, $f(r_1) > 0$ implies $f(r) > 0$ for all $r \geq r_1$. Finally, (57) follows directly from (71), so this proof is completed. □

We now have fully established Proposition 5.1. Thus to complete the proofs of Theorems 3.1 and 3.3 it remains only to establish uniqueness of the solution of the HJB equation. This is accomplished by the following proposition.

PROPOSITION 5.3. *Let g_1 and g_2 be solutions of* (16) *satisfying* (19) *corresponding to Λ_1 and Λ_2, respectively. Let $\hat{g}_1 = \bar{g}_1 - \bar{g}_0$ and $\hat{g}_2 = \bar{g}_2 - \bar{g}_0$ with $\bar{g}_0$ defined as in Proposition* 5.2, *and suppose $\hat{g}_1$ and $\hat{g}_2$ both satisfy limit* (56). *Then $g_1 = g_2$ and $\Lambda_1 = \Lambda_2$.*

Proof. Denote

$$\bar{\Lambda}_1 = \left(1+\frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\Lambda_1, \ \bar{\Lambda}_2 = \left(1+\frac{\gamma}{1-\gamma}\frac{\sigma^2}{\sigma^2+\rho^2}\right)\Lambda_2.$$

We subtract the equation for $\hat{g}_2$ from the equation for $\hat{g}_1$, thereby obtaining

$$\frac{d}{dr}(\hat{g}_2-\hat{g}_1) + \left(\frac{2\tilde{b}(r)}{\lambda^2 r} + \hat{g}_1 + \hat{g}_2\right)(\hat{g}_2-\hat{g}_1) = \frac{\bar{\Lambda}_2 - \bar{\Lambda}_1}{\lambda^2 r}.$$

Denote

$$\tilde{e}(r) := \exp\left(\int_{r_0}^{r}\left(\frac{2\tilde{b}(s)}{\lambda^2 s} + \hat{g}_1(s) + \hat{g}_2(s)\right)ds\right).$$

Then

$$\frac{d}{dr}\Big(\big(\hat{g}_2(r) - \hat{g}_1(r)\big)\tilde{e}(r)\Big) = \frac{\bar{\Lambda}_2 - \bar{\Lambda}_1}{\lambda^2 r}\tilde{e}(r),$$

and so

$$\big(\hat{g}_2(r) - \hat{g}_1(r)\big)\tilde{e}(r) = -\int_r^\infty \frac{\bar{\Lambda}_2 - \bar{\Lambda}_1}{\lambda^2 s}\tilde{e}(s)ds.$$

Without loss of generality, suppose $\Lambda_2 - \Lambda_1 \geq 0$, in which case $\hat{g}_2(r) - \hat{g}_1(r) \leq 0$. But Lemma 4.1 implies $\hat{g}_2(r) - \hat{g}_1(r) \geq 0$. Therefore, $\hat{g}_2(r) = \hat{g}_1(r)$, $\Lambda_2 = \Lambda_1$, and this proof is completed. □

Remark 5.2. The following result, not crucial for the proofs of Theorems 3.1 or 3.3, says that Λ^* is the smallest number such that (16) has a solution defined on $[0, \infty)$. For $\Lambda = \Lambda^*$, (16) has a unique solution. A more general result of this kind is given in the paper by Kaise and Sheu [17].

THEOREM 5.1. *Let* Λ^* *be given in Theorem* 3.1. *Then there is only one solution for* (16) *on* $[0, \infty)$ *with* $\Lambda = \Lambda^*$. *Moreover, if* (16) *has a solution on* $[0, \infty)$ *for some* Λ, *then* $\Lambda \geq \Lambda^*$.

Proof. We consider only the case $\mu_2 \neq 1$ since the argument for the case $\mu_2 = 1$ is similar. Assume $\Lambda = \Lambda^*$ and g is a solution of (16) on $[0, \infty)$. Suppose $g \neq g^*$ with g^* as given in Theorem 3.1. Then (33) holds for g. Since g^* satisfies (25), a simple comparison argument for an ODE shows that $g(r) < g^*(r)$ for all r. But g satisfies either one of (56) or (57). Since g^* satisfies (56), therefore $g < g^*$ implies that g also satisfies (56). Now by Proposition 5.3, we conclude $g = g^*$, a contradiction.

We now consider Λ such that (16) has a solution g_0 defined on $[0, \infty)$. Then (16) must have a solution g defined on $[0, \infty)$ satisfying (25). If g_0 also satisfies (25), then $g = g_0$. See Corollary 4.1. If g_0 satisfies (33), then we have $g(r) > g_0(r)$ for small $r > 0$, and hence for all r. This implies that g is also defined for all $r > 0$. Now if $\Lambda < \Lambda^*$, then $g(r) < g^*(r)$ for all r by Lemma 4.1. By Proposition 5.2, g either satisfies (56) or (57). We know g^* satisfies (56). Together with $g < g^*$, we conclude that g satisfies (56). By Proposition 5.3, we have $g = g^*, \Lambda = \Lambda^*$, a contradiction to our assumption that $\Lambda < \Lambda^*$. This completes the proof. □

Appendix A. Proof of Proposition 4.1. In view of the equivalence between differential equations (22) and (30) it suffices to show that any solution $\bar{g}$ of (30) on $(0, r_0]$ satisfies either

$$\lim_{r\to 0} r\bar{g}(r) = -\frac{2c\bar{r}}{\lambda^2} + 1 \tag{72}$$

or

$$\lim_{r\to 0} \bar{g}(r) = \frac{1}{c\bar{r}}\left(\bar{\Lambda} - \frac{1}{2}A\frac{\gamma}{1-\gamma}\frac{\mu_1^2}{\sigma^2 + \rho^2}\right). \tag{73}$$

To do this we study the solution $\tilde{g}$ of the (equivalent) differential equation (31), from which we have

$$\frac{d\tilde{g}}{dr} \leq \frac{2}{\lambda^2 r}e(r)[\bar{\Lambda} - \bar{d}(r)].$$

So by Lemma A.1 (see the end of this appendix) we have

$$\tilde{g}(r) \leq \int_0^r \frac{2}{\lambda^2 s} e(s)[\bar{\Lambda} - \bar{d}(s)]ds.$$

Substituting for $e(s)$ and so forth, it is apparent that this implies for some number $c_1 > 0$ that

$$\tilde{g}(r) \leq c_1 r^{\frac{2c\bar{r}}{\lambda^2}}, \quad 0 < r < r_0. \tag{74}$$

Take a large c_2 and consider

$$f(r) = \tilde{g}(r) + c_2 r^{\frac{2c\bar{r}}{\lambda^2}-1}.$$

Using (31), it is easily seen that

$$\frac{df(r)}{dr} < 0 \text{ if } f(r) = 0.$$

Therefore, if we take c_2 such that $f(r_0) > 0$, then $f(r) > 0$ for $0 < r \leq r_0$. That is, we have proved

$$\tilde{g}(r) > -c_2 r^{\frac{2c\bar{r}}{\lambda^2}-1}, \quad 0 < r < r_0. \tag{75}$$

By a simple calculation, we have the following two cases:

$$\bar{\Lambda} - \bar{d}(r) > 0 \text{ for } r \text{ in some neighborhood of } 0, \tag{76}$$

or

$$\bar{\Lambda} - \bar{d}(r) < 0 \text{ for } r \text{ in some neighborhood of } 0. \tag{77}$$

First we suppose inequality (76) is true. By (31), $\tilde{g}(r)$ is increasing when r is small and $\tilde{g}(r) = 0$. Using the similar argument for (75), we have the following two possibilities: there is $r_1 > 0$ such that $\tilde{g}(r) < 0,\ r \leq r_1$, or $\tilde{g}(r) > 0,\ r \leq r_1$.

We consider the first possibility. That is, there is r_1 such that $\tilde{g}(r) < 0,\ r \leq r_1$. Conditions (76) and (31) imply

$$\frac{\frac{d\tilde{g}}{dr}}{\tilde{g}^2} \geq -\frac{1}{e(r)},$$

in which case

$$\frac{1}{\tilde{g}(r)} - \frac{1}{\tilde{g}(r_1)} \geq -\int_r^{r_1} \frac{1}{e(s)} ds,$$

that is,

$$-\frac{1}{\tilde{g}(r)} \leq -\frac{1}{\tilde{g}(r_1)} + \int_r^{r_1} \frac{1}{e(s)} ds.$$

It follows that for some constants $c_1, \bar{c}_1$, we have

$$-\tilde{g}(r) > \bar{c}_1 r^{\frac{2c\bar{r}}{\lambda^2}-1}, \tag{78}$$

since

$$\int_r^{r_1} \frac{1}{e(s)} ds \le c_1 r^{-\frac{2c\bar{r}}{\lambda^2}+1}.$$

By (31) again we have

$$\frac{1}{\tilde{g}(r)} - \frac{1}{\tilde{g}(r_1)} = -\int_r^{r_1} \frac{1}{e(s)} ds + \int_r^{r_1} \frac{2}{\lambda^2 s} e(s)[\bar{\Lambda} - \bar{d}(s)] \frac{1}{\tilde{g}^2(s)} ds. \tag{79}$$

We use this to study the limiting behavior of $\tilde{g}(r)$. For the first term on the right-hand side we have by l'Hôpital's rule

$$\lim_{r\to 0} r^{\frac{2c\bar{r}}{\lambda^2}-1} \int_r^{r_0} \frac{1}{e(s)} ds = \frac{1}{\frac{2c\bar{r}}{\lambda^2} - 1}.$$

For the second term on the right-hand side of (79) we have

$$\int_r^{r_0} \frac{2}{\lambda^2 s} e(s)[\bar{\Lambda} - \bar{d}(s)] \frac{1}{\tilde{g}^2(s)} ds \le c \int_r^{r_0} s^{-1+\frac{2c\bar{r}}{\lambda^2}-2\frac{2c\bar{r}}{\lambda^2}+2} ds \le c r^{-\frac{2c\bar{r}}{\lambda^2}+2}.$$

Here we use (78). Thus by (79) we have

$$\lim_{r\to 0} \frac{\tilde{g}(r)}{r^{\frac{2c\bar{r}}{\lambda^2}-1}} = -\frac{2c\bar{r}}{\lambda^2} + 1. \tag{80}$$

Hence for the first possibility (i.e, $\tilde{g}(r_1) < 0$ for some small $r_1 > 0$) and when (76) holds, we have proved (72).

Now we consider the second possibility: there is $r_1 > 0$ such that $\tilde{g}(r) > 0$ for all $r \le r_1$. In view of (32) it follows by l'Hôpital's rule and (74) that

$$\lim_{r\to 0} \frac{\tilde{g}(r)}{r^{\frac{2c\bar{r}}{\lambda^2}}} = \frac{1}{c\bar{r}} \left(\bar{\Lambda} - \frac{1}{2} A \frac{\gamma}{1-\gamma} \frac{\mu_1^2}{\sigma^2 + \rho^2} \right). \tag{81}$$

This, with the relation $\tilde{g}(r) = \bar{g}(r)e(r)$ and the definition of $e(\cdot)$, implies (73).

We summarize what we have shown. Assuming condition (76), we have (80) or (81). They are equivalent to (72) and (73), respectively.

For the remainder of this proof we consider the case that inequality (77) holds. Using the similar argument for (75), we consider

$$\tilde{g}(r) + r^{\frac{2c\bar{r}}{\lambda^2}-\alpha},$$

$1 > \alpha > 1/2$, and deduce there is $r_1 > 0$ such that

$$-\tilde{g}(r) < r^{\frac{2c\bar{r}}{\lambda^2}-\alpha}, \quad r \le r_1, \tag{82}$$

or

$$-\tilde{g}(r) > r^{\frac{2c\bar{r}}{\lambda^2}-\alpha}, \quad r \le r_1. \tag{83}$$

Let $0 < \delta < 1/2$ and $r_1 > 0$ be small, and consider two situations, depending upon whether

$$-\tilde{g}(r) > r^{\frac{2c\bar{r}}{\lambda^2}+\delta-1}, \quad 0 < r \le r_1. \tag{84}$$

For the first situation, assume (84) does not hold. Then by (82), (83) with $\alpha = 1-\delta$, we have

$$-\tilde{g}(r) \le r^{\frac{2c\bar{r}}{\lambda^2}+\delta-1}, \quad r \le r_1.$$

Note that we have already established the property $\tilde{g}(r) < 0$ for r small. From this, together with the property of $e(r)$ defined in section 4 and (31), we have

$$\tilde{g}(r) = -\int_0^r \frac{\tilde{g}^2(s)}{e(s)}ds + \int_0^r \frac{2e(s)}{\lambda^2 s}[\bar{\Lambda} - \bar{d}(s)]ds \ge -c_1 r^{\frac{2c\bar{r}}{\lambda^2}-1+2\delta} - c_2 r^{\frac{2c\bar{r}}{\lambda^2}} \ge -cr^{\frac{2c\bar{r}}{\lambda^2}-1+2\delta},$$

since $\delta < 1/2$. That is,

$$-\tilde{g}(r) \le cr^{\frac{2c\bar{r}}{\lambda^2}-1+2\delta}.$$

Continuing in an iterative fashion one obtains

$$-\tilde{g}(r) \le c_1 r^{\frac{2c\bar{r}}{\lambda^2}-1+2^m\delta}$$

if m is such that $2^m\delta < 1$, where c_1 may depend on m and δ. In particular, this holds for $m = m_0$, $2^{m_0}\delta < 1 \le 2^{m_0+1}\delta$. Apply this same procedure once more to obtain

$$\tilde{g}(r) \ge -c_1 r^{\frac{2c\bar{r}}{\lambda^2}-1+2\bar{\delta}} - c_2 r^{\frac{2c\bar{r}}{\lambda^2}} \ge -cr^{\frac{2c\bar{r}}{\lambda^2}}, \tag{85}$$

where $\bar{\delta} = 2^{m_0}\delta$. The last step is due to $2\bar{\delta} > 1$. We shall now show (81) by the following calculation. In view of (74) and (75) we have

$$\lim_{r\to 0} r^{-\frac{2c\bar{r}}{\lambda^2}} \int_0^r \frac{2e(s)}{\lambda^2 s}[\bar{\Lambda} - \bar{d}(s)]ds = \frac{1}{c\bar{r}}\left(\bar{\Lambda} - \frac{1}{2}A\frac{\gamma}{1-\gamma}\frac{\mu_1^2}{\sigma^2+\rho^2}\right). \tag{86}$$

In addition, by (74) and (85) we have

$$\lim_{r\to 0} r^{-\frac{2c\bar{r}}{\lambda^2}} \int_0^r \frac{1}{e(s)}\tilde{g}(s)^2 ds = 0.$$

This with (86) and (32) implies (81), which is equivalent to (73).

Now we consider the opposite situation, namely, there is $0 < \delta < 1/2$ such that (84) does hold for some r_1. Then

$$\frac{1}{\tilde{g}(r)} - \frac{1}{\tilde{g}(r_1)} = -\int_r^{r_1} \frac{1}{e(s)}ds + \int_r^{r_1} \frac{2}{\lambda^2 s}e(s)[\bar{\Lambda} - \bar{d}(s)]\frac{1}{\tilde{g}^2(s)}ds.$$

Corresponding to the two terms on the right-hand side we have

$$\lim_{r\to 0} r^{\frac{2c\bar{r}}{\lambda^2}-1} \int_r^{r_1} \frac{1}{e(s)}ds = \frac{1}{\frac{2c\bar{r}}{\lambda^2}-1}$$

and

$$\lim_{r\to 0} r^{\frac{2c\bar{r}}{\lambda^2}-1} \int_r^{r_1} \frac{2}{\lambda^2 s}e(s)[\bar{\Lambda} - \bar{d}(s)]\frac{1}{\tilde{g}^2(s)}ds = 0.$$

Hence

$$\lim_{r\to 0} \frac{\tilde{g}(r)}{r^{\frac{2c\bar{r}}{\lambda^2}-1}} = -\frac{2c\bar{r}}{\lambda^s} + 1; \tag{87}$$

thus by the definition of $e(\cdot)$ and the relationship between $\bar{g}$ and $\tilde{g}$ we see that (72) holds. This completes the proof of Proposition 4.1. □

The lemma that was used in the preceding proof follows.

LEMMA A.1. *If the differential equation* (31) *has a solution* $\tilde{g}$ *on* $(0, r_0]$ *for some* $r_0 > 0$, *then* $\tilde{g}(r) \to 0$ *as* $r \to 0$.

Proof. We first prove that for any $c_1 > 0$ there are $r_n, n = 1, 2, \ldots$, which tend to 0 as n tends to infinity and which satisfy $\tilde{g}(r_n) > -c_1$. If not, there is $r_1 > 0$ such that $\tilde{g}(r) \leq -c_1$ for all $0 < r \leq r_1$. Since

$$\frac{\frac{d\tilde{g}}{dr}}{\tilde{g}^2} + \frac{1}{e(r)} = \frac{2}{\lambda^2 r} e(r)[\bar{\Lambda} - \bar{d}(r)] \frac{1}{\tilde{g}^2(r)},$$

we have

$$\frac{1}{\tilde{g}(r)} - \frac{1}{\tilde{g}(r_1)} = -\int_r^{r_1} \frac{1}{e(s)} ds + \int_r^{r_1} \frac{2}{\lambda^2 s} e(s)[\bar{\Lambda} - \bar{d}(s)] \frac{1}{\tilde{g}^2(s)} ds. \tag{88}$$

For small $r > 0$, the first term on the right-hand side is bounded above by $-c_2 r^{-\frac{2c\bar{r}}{\lambda^2}+1}$ for some $c_2 > 0$, and the second term is bounded above by c_3/c_1^2 for some $c_3 > 0$. From this, the right-hand side converges to $-\infty$ as $r \to 0$, in which case $\tilde{g}(r) \to 0$ as $r \to 0$, a contradiction.

By this result we can take a sufficiently small $r_1 > 0$ such that $\tilde{g}(r_1) > -c_1$. Next we show that

$$\tilde{g}(r) > -c_1, \quad r \leq r_1. \tag{89}$$

To see this, suppose this is not true. Then there is some $r_2 < r_1$ such that $\tilde{g}(r_2) = -c_1$ and

$$\tilde{g}(r) > -c_1, \quad r_2 < r < r_1.$$

By (31)

$$\frac{d\tilde{g}}{dr}(r_2) = -\frac{1}{e(r_2)} c_1^2 + \frac{2}{\lambda^2 r_2} e(r_2)[\bar{\Lambda} - \bar{d}(r_2)] < 0.$$

This contradicts the specified property of c_1.

Finally, it suffices to show that for any $c_1 > 0$ there is some $r_3 > 0$ such that

$$\tilde{g}(r) \leq c_1, \quad r \leq r_3, \tag{90}$$

because it is easy to see that our lemma would then follow from (89) and (90). To prove (90), suppose there is $r_4 > 0$ such that $\tilde{g}(r_4) > c_1$. Then

$$\frac{d\tilde{g}}{dr}(r_4) \leq -\frac{1}{e(r_4)} c_1^2 + \frac{2}{\lambda^2 r_4} e(r_4)[\bar{\Lambda} - \bar{d}(r_4)] < 0.$$

Therefore, $\tilde{g}(r)$ is decreasing at r_4. This argument also shows that $\tilde{g}$ is decreasing on the set $\{\tilde{g}(r) > c_1\}$. Then we must have $\tilde{g} > c_1$ on $(0, r_4]$. This leads to a contradiction since using (88) with $r_1 = r_4$ and small r we have the right-hand side tending to $-\infty$ while the left-hand side is bounded. This completes the proof of Lemma A.1. □

A PRIORI ERROR ESTIMATES FOR THE FINITE ELEMENT DISCRETIZATION OF ELLIPTIC PARAMETER IDENTIFICATION PROBLEMS WITH POINTWISE MEASUREMENTS*

R. RANNACHER† AND B. VEXLER‡

Abstract. We develop an a priori error analysis for the finite element Galerkin discretization of parameter identification problems. The state equation is given by an elliptic partial differential equation of second order with a finite number of unknown parameters, which are estimated using pointwise measurements of the state variable.

Key words. parameter identification, finite elements, pointwise measurements, L^∞-error estimates

1. Introduction.

We consider parameter identification problems governed by an elliptic partial differential equation of second order. The finitely many unknown parameters are estimated using the measurements of point values of the *state variable*. Let $\Omega \subset \mathbb{R}^2$ be a convex polygonal domain; $L^2(\Omega)$ the corresponding Lebesgue space with inner product and norm denoted by $(\cdot,\cdot)$ and $\|\cdot\|_2$, respectively; and $H^m(\Omega)$ the Sobolev space of order $m \in \mathbb{N}$. With this notation, we set

$$V := \{v \in H^1(\Omega) \cap C(\overline{\Omega}) \,|\, v = 0 \text{ on } \partial\Omega\}.$$

The state variable $u \in V$ is determined by an elliptic partial differential equation (the *state equation*)

$$\begin{aligned} -\nabla \cdot (A(q)\nabla u) &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

for given Hölder continuous $f \in C^\alpha(\overline{\Omega})$, $\alpha \in (0,1)$. Here, $Q \subset \mathbb{R}^{n_p}$ denotes the open admissible set of parameters $q \in \mathbb{R}^{n_p}$, for which $A(q) = (A_{ij}(q))$ is a symmetric and positive definite 2×2 matrix with twice continuously differentiable entries $A_{ij} : Q \to C^{1+\alpha}(\overline{\Omega})$. The above conditions guarantee that, for any admissible value of the parameter q, the corresponding solution u of the state equation (1.1) is in $H^2(\Omega)$ (see, e.g., Grisvard [12]). At the corner points of $\partial\Omega$, the second derivatives of the solution may become singular. However, u has Hölder continuous second derivatives, $u \in C^{2+\alpha}(\overline{\Omega}_d)$, for each subdomain $\Omega_d \subset \Omega$ with distance $d > 0$ to the corner points.

The usual weak formulation of (1.1) is

$$a(q)(u,\phi) = (f,\phi) \quad \forall \phi \in V, \tag{1.2}$$

where the bilinear form $a(q)(\cdot,\cdot)$ is defined by

$$a(q)(u,\phi) := (A(q)\nabla u, \nabla\phi). \tag{1.3}$$

Further, the observation operator $C(\cdot)$ describing the mapping of the state variable u to the space of measurements $Z = \mathbb{R}^{n_m}$ is given by

$$C_i(v) = v(\xi_i), \quad i = 1, 2, \dots, n_m, \tag{1.4}$$

where $\{\xi_i\} \subset \Omega$ is a finite set of measurement points. We assume that $n_m \geq n_p$. The Euclidean product and norm on Q and Z are denoted by $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$, respectively, and the same notation is also used for the corresponding natural norms of matrices.

The values of the parameters are estimated from a given set of measurements $\hat{C} \in Z$ using a least squares approach such that we obtain a constrained optimization problem with the cost functional $J : V \to \mathbb{R}$:

$$\text{Minimize} \quad J(u) := \frac{1}{2}\|C(u) - \hat{C}\|^2 \tag{1.5}$$

under the constraint (1.2). Throughout, we assume the existence of a solution $(u, q) \in V \times Q$ of the problem (1.2), (1.5). For an analysis of the existence of solutions for parameter identification problems, see, e.g., Banks and Kunisch [2], Kravaris and Seinfeld [16], and Litvinov [17].

The state equation is discretized by a conforming finite element Galerkin method defined on a family $\{\mathcal{T}_h\}_{h>0}$ of shape regular quasi-uniform meshes $\mathcal{T}_h = \{K\}$ consisting of closed *cells* K which are either triangles or quadrilaterals. The straight parts which make up the boundary ∂K of a cell K are called *faces*. The mesh parameter h is defined as a cellwise constant function by setting $h_{|K} = h_K$, and h_K is the diameter of K. Usually we use the symbol h also for the maximal cell size, i.e.,

$$h = \max_{K\in\mathcal{T}_h} h_K. \tag{1.6}$$

For convenience, we assume that $0 < h < 1$. On the mesh $\mathcal{T}_h$ we define finite element spaces $V_h \subset V$ consisting of linear or bilinear shape functions; see, e.g., Brenner and Scott [5] or Johnson [14]. The corresponding discrete state $u_h \in V_h$ and parameter $q_h \in Q$ are determined by

$$\text{Minimize} \quad J(u_h), \tag{1.7}$$

under the constraint

$$a(q_h)(u_h, \phi_h) = (f, \phi_h) \quad \forall\phi_h \in V_h. \tag{1.8}$$

Since Q is finite dimensional, the parameter q_h is determined in the same space Q.

The main purpose of this paper is to analyze the behavior of the error in parameters $\|q - q_h\|$ for h tending to zero. There are a number of publications in which a priori error estimates are derived for optimal control problems governed by partial differential equations; see, e.g., Falk [8], Arada, Casas, and Tröltzsch [1], Deckelnic and Hinze [6], and Gunzburger and Hou [13]. However, there are only few published results on this topic in the context of parameter identification problems; see Falk [9], Neittaanmäki and Tai [18], and Kärkkäinen [15].

In Vexler [26], an a priori error analysis for the case of V-stable observation operators $C_i(\cdot)$ is developed and optimal-order convergence is shown,

$$\|q - q_h\| = \mathcal{O}(h^2), \tag{1.9}$$

essentially under the assumption that $|C_i(u) - C_i(u_h)| \leq ch^2\|u\|_{H^2}$. However, the generalization of this result to pointwise observations is not straightforward. For this case, we prove in this paper that, under certain regularity conditions,

$$\|q - q_h\| = \mathcal{O}(h^2|\log(h)|^2). \tag{1.10}$$

The proof uses the technique for estimating discrete Green functions developed in Frehse and Rannacher [10]. A complementary result of a posteriori error analysis for parameter identification problems is given in Becker and Vexler [4].

To the authors' knowledge, this is the first a priori error analysis for parameter identification problems with pointwise observations. The consideration of pointwise observations in determining discrete parameters seems very natural in view of practical measurement techniques; see [3] for applications in reactive flow analysis.

The paper is organized as follows. In the next section, we describe an algorithm for solving problem (1.7), (1.8). In section 3, we present a paradigm for a priori error analysis for discretization of a class of optimization problems. Thereafter, in section 4, we derive the announced error estimate using an L^∞-stability result, which is proven in section 5. In section 6, we present a numerical example confirming the asymptotic sharpness of our error estimate. Possible extensions are addressed in the last section.

2. Optimization algorithm. In this section, we reformulate the problem under consideration as an unconstrained optimization problem and describe a solution algorithm for it. Since the coefficient matrix $A(q)$ is assumed to be positive definite for parameters $q \in Q \subset \mathbb{R}^{n_p}$, the relation

$$a(q)(S(q), \phi) = (f, \phi) \quad \forall \phi \in H_0^1(\Omega) \tag{2.1}$$

defines an operator $S : Q \to H_0^1(\Omega)$. By the assumptions on the data of the problem and the Sobolev embedding theorem,

$$S : Q \to H_0^1(\Omega) \cap H^2(\Omega) \subset V. \tag{2.2}$$

The solution operator S can be shown to possess first and second derivatives which are continuous with respect to the norm of V; see Theorem 2.1 below. We recall that the existence of a solution $q \in Q$ of problem (1.5) is assumed. Let $Q_0 \subset Q$ be an open bounded set containing the optimal parameter q on which the coefficient matrix $A(q)$ is uniformly positive definite; i.e., there exists $\gamma \in \mathbb{R}_+$ such that

$$p^* A(q)p \geq \gamma\|p\|^2 \quad \forall p \in Q, \quad \forall q \in Q_0, \tag{2.3}$$

uniformly with respect to $x \in \overline{\Omega}$. We introduce the *reduced observation operator* $c : Q_0 \to Z$ by

$$c(q) := C(S(q)). \tag{2.4}$$

This allows us to reformulate the problem under consideration as an unconstrained optimization problem with the reduced cost functional $j : Q_0 \to \mathbb{R}$:

$$\text{Minimize} \quad j(q) := \frac{1}{2}\|c(q) - \hat{C}\|^2, \quad q \in Q_0. \tag{2.5}$$

Denoting by $G = c'(q) \in \mathbb{R}^{n_p \times n_m}$ the Jacobian matrix of the reduced observation operator $c(\cdot)$, the first-order necessary optimality condition $j'(q) = 0$ for (2.5) reads

$$G^*(c(q) - \hat{C}) = 0, \tag{2.6}$$

where G^* denotes the transpose of G. The positive semidefiniteness of the Hessian matrix $H := \nabla^2 j(q)$ is the second-order necessary optimality condition. A solution q of problem (2.5) is called *stable* if the sufficient optimality condition holds, i.e., if the Hessian H is positive definite. Throughout, we will assume the solution q to be stable. The stability of the solution is given, for instance, if the value of the cost functional $\|C(u) - \hat{C}\|$ is small enough and the matrix G has full rank n_p; see, e.g., [26] for details.

Since by assumption the matrix coefficient $A(\cdot)$ is twice continuously differentiable, there holds

$$\sup_{\xi\in Q_0} |||A(\xi)|||_{1,\infty} + \sup_{\xi\in Q_0} |||A'_{q_j}(\xi)|||_{1,\infty} + \sup_{\xi\in Q_0} |||A''_{q_j q_k}(\xi)|||_{1,\infty} < \infty, \tag{2.7}$$

where $|||B|||_{1,\infty} := \max_{i,j=1,2} \|B_{ij}\|_{1,\infty}$ for a matrix function $B = (B_{ij}) \in C^1(\overline{\Omega})^{2\times 2}$.

In the following propositions, we give representations of the Jacobian G of $c(\cdot)$, the Hessian H of $j(\cdot)$, and the Hessian of $c_i(\cdot)$.

THEOREM 2.1. *Let the reduced observation operator $c(\cdot)$ and the reduced functional $j(\cdot)$ be defined as in* (2.4) *and* (2.5)*, respectively.*

(i) *The elements of the Jacobian of $c(\cdot)$ at some $q \in Q_0$ are given by*

$$G_{ij} = \frac{\partial c_i}{\partial q_j}(q) = C_i(w_j), \quad i = 1, \dots, n_m,\ j = 1, \dots, n_p, \tag{2.8}$$

where $w_j \in V$ are the solutions of the problems

$$a(q)(w_j, \phi) = -(A'_{q_j}(q)\nabla u, \nabla\phi) \quad \forall \phi \in V, \tag{2.9}$$

with $u = S(q)$. The functions $w_j \in V$ depend continuously on $q \in Q$.

(ii) *The Hessian of $j(\cdot)$ can be expressed by*

$$H = G^*\, G + M, \tag{2.10}$$

where the matrix $M \in \mathbb{R}^{n_p \times n_p}$ is given by

$$M = \sum_{i=1}^{n_m} c_i''(q)(c_i(q) - \hat{C}_i). \tag{2.11}$$

The Hessian of $c_i(q)$ is given by

$$\frac{\partial^2}{\partial q_j\, \partial q_k} c_i(q) = C_i(v_{jk}), \tag{2.12}$$

where the $v_{jk} \in V$ are the solutions of the problems

$$\begin{aligned} a(q)(v_{jk}, \phi) = &-(A'_{q_j}(q)\nabla w_k, \nabla\phi) - (A'_{q_k}(q)\nabla w_j, \nabla\phi) \\ &- (A''_{q_j q_k}(q)\nabla u, \nabla\phi) \quad \forall \phi \in V, \end{aligned} \tag{2.13}$$

with w_j as defined in (2.9)*. The functions $v_{jk} \in V$ depend continuously on $q \in Q$.*

Proof. The derivation of the derivatives of $c(\cdot)$ uses the chain rule,

$$\frac{\partial c_i}{\partial q_j}(q) = \frac{\partial}{\partial q_j} C_i(S(q)) = S'_{q_j}(q)(\xi_i) =: w_j(\xi_i),$$

for $i = 1, \dots, n_m$, $j = 1, \dots, n_p$, where the functions w_j are determined by the relations (2.9). This is seen by considering the limit of difference quotients

$$\begin{aligned} 0 &= \lim_{t \to 0} \frac{1}{t} (a(q + tq_j)(S(q + tq_j), \phi) - (f, \phi) - a(q)(S(q), \phi) + (f, \phi)) \\ &= a(q)(S'_{q_j}(q), \phi) + a'_{q_j}(q)(S(q), \phi) = a(q)(w_j, \phi) + a'_{q_j}(q)(u, \phi). \end{aligned}$$

Analogously, we obtain

$$\frac{\partial^2 c_i}{\partial q_j \partial q_k}(q) = \frac{\partial^2}{\partial q_j \partial q_k} C_i(S(q)) = S''_{q_j q_k}(q)(\xi_i) =: v_{jk}(\xi_i),$$

where the functions v_{jk} are determined by the relations (2.13). To see this, we consider the limit of the difference quotient

$$\begin{aligned} 0 = \lim_{t \to 0} \frac{1}{t} &(a(q + tq_k)(S'_{q_j}(q + tq_k), \phi) + a'_{q_j}(q + tq_k)(S(q + tq_k), \phi) \\ &- a(q)(S'_{q_j}(q), \phi) - a'_{q_j}(q)(S(q), \phi)) \\ = a(q)(S''_{q_j q_k}(q), \phi) &+ a'_{q_k}(q)(S'_{q_j}(q), \phi) + a'_{q_j}(q)(S'_{q_k}(q), \phi) + a''_{q_k q_j}(q)(S(q), \phi). \end{aligned}$$

In Lemma 2.2 below, we will show that all the functions u, w_j, v_{jk} are in $V \cap H^2(\Omega)$. This is due to the fact that they are determined by second-order elliptic boundary value problems on a convex domain, with smooth coefficients and right-hand sides in $L^2(\Omega)$ which depend continuously on the parameter $q \in Q$. This implies that also their solutions depend continuously on $q \in Q$ with respect to the norm of the solution space $H_0^1(\Omega) \cap H^2(\Omega) \subset V$. Hence, the solution operator $S : Q \to V$ is twice continuously differentiable. This completes the proof. ∎

In practice the Hessian H of $j(\cdot)$ is computed using the representation

$$M_{jk} = -(A'_{q_j}(q)\nabla w_k, \nabla z) - (A'_{q_k}(q)\nabla w_j, \nabla z) - (A''_{q_j q_k}(q)\nabla u, \nabla z), \tag{2.14}$$

with the function z determined by the dual equation

$$(A(q)\nabla\phi, \nabla z) = \langle C(u) - \bar{C}, C(\phi)\rangle. \tag{2.15}$$

For later purposes, we provide some a priori bounds for the solutions of the boundary value problems introduced in Theorem 2.1, which follow by standard results of elliptic regularity theory.

LEMMA 2.2. *For the solutions of the elliptic boundary value problems* (2.9) *and* (2.13) *there hold the global* L^2 *a priori estimates*

$$\|u\|_{2,2} + \|w_j\|_{2,2} + \|v_{jk}\|_{2,2} \le c, \tag{2.16}$$

where c *is a generic constant depending only on the data of the problem. Further, for each subdomain* $\Omega_d \subset \Omega$ *with distance* $d > 0$ *to the corner points, there hold the* L^∞ *a priori estimates*

$$\|u\|_{C^{2+\alpha}(\overline{\Omega}_d)} + \|w_j\|_{C^{2+\alpha}(\overline{\Omega}_d)} + \|v_{jk}\|_{C^{2+\alpha}(\overline{\Omega}_d)} \le c_d \tag{2.17}$$

with a generic constant $c_d \approx d^{-1}$.

Proof. The variational equations defining u as well as w_j and v_{jk} can be rewritten in such a form that they represent second-order elliptic boundary value problems with

smooth coefficients and right-hand sides which are bounded functionals on $L^2(\Omega)$ and $C^\alpha_{\mathrm{loc}}(\Omega)$, respectively, as follows:

$$a(q)(u,\phi) = (f,\phi) \quad \forall \phi \in V, \tag{2.18}$$

$$a(q)(w_j,\phi) = (\nabla \cdot A'_{q_j}(q)\nabla u,\phi) \quad \forall \phi \in V, \tag{2.19}$$

$$\begin{aligned} a(q)(v_{jk},\phi) = {} & (\nabla \cdot A'_{q_j}(q)\nabla w_k,\phi) + (\nabla \cdot A'_{q_k}(q)\nabla w_j,\phi) \\ & + (\nabla \cdot A''_{q_j q_k}(q)\nabla u,\phi) \quad \forall \phi \in V. \end{aligned} \tag{2.20}$$

By assumption the coefficient functions $A'_{q_j}(q)$ and $A''_{q_j q_k}(q)$ are smooth. In view of the convexity of the polygonal domain Ω, the H^2-regularity estimates then follow by results from Grisvard [12]. A reference for the corresponding $C^{2+\alpha}$-estimates is Gilbarg and Trudinger [11]. In the first step, from (2.18), we get

$$\begin{aligned} \|u\|_{2,2} &\le c\|f\|_2 \le c, \\ \|u\|_{C^{2+\alpha}(\overline{\Omega}_d)} &\le c_d\big\{\|f\|_{C^\alpha(\overline{\Omega}_{d/2})} + \|u\|_{2,2}\big\} \le c_d. \end{aligned}$$

Then, using this in (2.19), we conclude that

$$\begin{aligned} \|w_j\|_{2,2} &\le c\|u\|_{2,2} \le c, \\ \|w_j\|_{C^{2+\alpha}(\overline{\Omega}_d)} &\le c_d\big\{\|u\|_{C^{2+\alpha}(\overline{\Omega}_{d/2})} + \|u\|_{2,2}\big\} \le c_d. \end{aligned}$$

Finally, this is used in (2.20) and allows us to conclude that

$$\begin{aligned} \|v_{jk}\|_{2,2} &\le c\max\big\{\|w_j\|_{2,2}, \|w_k\|_{2,2}\big\} + c\|u\|_{2,2} \le c, \\ \|v_{jk}\|_{C^{2+\alpha}(\overline{\Omega}_d)} &\le c_d\big\{\|w_j\|_{C^{2+\alpha}(\overline{\Omega}_{d/2})} + \|u\|_{C^{2+\alpha}(\overline{\Omega}_{d/2})} + \|w_j\|_{2,2}\big\} \le c_d. \end{aligned}$$

This completes the proof. □

Similar to the continuous case, we introduce a discrete solution operator S_h: $Q_0 \to V_h$ by the equation

$$a(q_h)(S_h(q_h),\phi_h) = (f,\phi_h) \quad \forall \phi_h \in V_h,\ q_h \in Q_0. \tag{2.21}$$

As before, we turn the discrete problem (1.7), (1.8) into an unconstrained minimization problem,

$$\text{Minimize} \quad j_h(q_h) := \frac{1}{2}\|c_h(q_h) - \hat{C}\|^2, \quad q_h \in Q_0, \tag{2.22}$$

where the discrete reduced observation operator c_h is defined by

$$c_h(q_h) = C(S_h(q)). \tag{2.23}$$

Denoting the corresponding Jacobian by $G_h = c'_h(q_h)$, the necessary optimality condition $j'_h(q_h) = 0$ reads

$$G_h^*(c_h(q_h) - \hat{C}) = 0. \tag{2.24}$$

The derivatives of the discrete observation operator c_h can be computed in a way analogous to that in Theorem 2.1.

Problem (2.22) is solved iteratively starting with an initial guess q_h^0 and using the recursive setting $q_h^{k+1} = q_h^k + \delta q_h$. The update δq_h is obtained as the solution of the system of linear equations

$$H_k\,\delta q_h = G_h^*(\hat{C} - c_h(q_h^k)), \tag{2.25}$$

where $G_h = c_h'(q_h^k)$, and H_k is an appropriate symmetric approximation of the Hessian $\nabla^2 j_h(q_h^k)$. The most widely used choice of the matrix $H_k = G_h^* G_h$ leads us to the Gauß–Newton algorithm; see, e.g., Nocedal and Wright [21].

For one step of the Gauß–Newton algorithm the state equation and n_p tangent problems (2.9) have to be solved, which involves the same linear operator but with different right-hand sides. Due to the small dimension n_p of the parameter space Q, the solution of (2.25) is uncritical. For discussing other Newton-type methods and trust-region techniques for globalization of the convergence in this context, see [26].

3. A paradigm for a priori error analysis. In this section we present a general approach to the error analysis of a class of optimization problems such as are considered in this paper. The main result is stated in the following theorem. It is a variant of well-known perturbation theorems for differentiable mappings, which is particularly tailored to the present situation. However, it seems easier to include the elementary proof than to search for the precise reference.

THEOREM 3.1. *Let $F, F_h : \mathbb{R}^n \to \mathbb{R}^n$, for a discretization parameter $h \in \mathbb{R}_+$, be continuously differentiable operators, and $x \in \mathbb{R}^n$ be a solution of $F(x) = 0$. Let the following conditions be fulfilled:*

(i) *The derivative $F'(x)$ is positive definite; i.e., there is a constant $\gamma > 0$ such that*

$$p^* F'(x) p \geq \gamma \|p\|^2, \quad p \in \mathbb{R}^n. \tag{3.1}$$

(ii) *There is a neighborhood U of x and a positive number $L(h) \in \mathbb{R}_+$ such that*

$$\|F_h'(\xi) - F_h'(\eta)\| \leq L(h)\|\xi - \eta\| \quad \forall \xi, \eta \in U. \tag{3.2}$$

(iii) *With the h-dependent constant $L(h)$, there holds*

$$\lim_{h \to 0} L(h)\|F(x) - F_h(x)\| = 0. \tag{3.3}$$

(iv) *There holds*

$$\lim_{h \to 0} \|F'(x) - F_h'(x)\| = 0. \tag{3.4}$$

Then, for h small enough, there exists $x_h \in U$ such that $F_h(x_h) = 0$, and $F_h'(x_h)$ is positive definite uniformly in h. Further, there holds the a priori error estimate

$$\|x - x_h\| \leq \frac{2}{\gamma}\|F(x) - F_h(x)\|. \tag{3.5}$$

Proof. Due to condition (iv), we can choose a positive number $h_1 \in \mathbb{R}_+$ such that for $h \leq h_1$ there holds

$$\|F'(x) - F_h'(x)\| \leq \frac{1}{4}\gamma. \tag{3.6}$$

Moreover, for $\rho = \rho(h) = \frac{\gamma}{kL(h)}$, with some $k \geq 4$ sufficiently large, there holds

$$B_\rho(x) = \{\xi \in \mathbb{R}^n,\ \|x - \xi\| \leq \rho\} \subset U. \tag{3.7}$$

For this choice, we obtain that, for $h \leq h_1$, $F_h'(\cdot)$ is positive definite on $B_\rho(x)$:

$$\begin{aligned} p^* F_h'(\xi) p &= p^* F'(x) p + p^*(F_h'(x) - F'(x))p + p^*(F_h'(\xi) - F_h'(x))p \\ &\geq \gamma\|p\|^2 - \|F_h'(x) - F'(x)\|\,\|p\|^2 - \|F_h'(\xi) - F_h'(x)\|\,\|p\|^2 \\ &\geq \left(\gamma - \frac{1}{4}\gamma - L(h)\rho\right)\|p\|^2 \geq \frac{1}{2}\gamma\|p\|^2. \end{aligned}$$

In a similar way, we conclude that, for $h \le h_1$, $F_h'(\cdot)$ is also bounded on $B_\rho(x)$:

$$\|F_h'(\xi)\| \le \beta := \|F'(x)\| + \frac{1}{2}\gamma.$$

Next, we prove that there exists a unique $x_h \in B_\rho(x)$ with $F_h(x_h) = 0$. To this end, we define an operator $D_s : \mathbb{R}^n \to \mathbb{R}^n$, for $s \in \mathbb{R}_+$, by

$$D_s(\xi) = \xi - sF_h(\xi).$$

For a certain choice of s, we show that D_s is a contraction on $B_\rho(x)$, and we use the Banach fixed point theorem. For $\xi \in B_\rho(x)$, $h \le h_1$, and an arbitrary $p \in \mathbb{R}^n$, there holds

$$\begin{aligned}\|D_s'(\xi)p\|^2 &= \|p - sF_h'(\xi)p\|^2 = \|p\|^2 - 2sp^*F_h'(\xi)p + s^2\|F_h'(\xi)p\|^2 \\ &\le (1 - s\gamma + s^2\beta^2)\|p\|^2.\end{aligned}$$

For the choice $s = \gamma(2\beta^2)^{-1}$, we obtain

$$\|D_s'(\xi)p\|^2 \le \Big(1 - \frac{\gamma^2}{4\beta^2}\Big)\|p\|^2,$$

and consequently,

$$\|D_s'(\xi)\| \le \Big(1 - \frac{\gamma^2}{4\beta^2}\Big)^{1/2} < 1.$$

Moreover, for arbitrary $\xi \in B_\rho(x)$, there holds

$$\begin{aligned}\|x - D_s(\xi)\| &= \|D_s(x) - D_s(\xi) + sF_h(x)\| \\ &\le \|D_s(x) - D_s(\xi)\| + s\|F_h(x) - F(x)\| \\ &\le \|D_s'(\eta)\|\,\|x - \xi\| + s\|F_h(x) - F(x)\|\end{aligned}$$

for a certain $\eta \in B_\rho$. Hence, the above estimate implies

$$\begin{aligned}\|x - D_s(\xi)\| &\le \Big(1 - \frac{\gamma^2}{4\beta^2}\Big)^{1/2}\rho + s\,\|F_h(x) - F(x)\| \\ &= \rho\left\{\Big(1 - \frac{\gamma^2}{4\beta^2}\Big)^{1/2} + s\frac{k}{\gamma}L(h)\|F_h(x) - F(x)\|\right\}.\end{aligned}$$

Due to condition (iii), there is a number $h_2 \in \mathbb{R}_+$ such that, for $h \le h_2$, there holds

$$L(h)\|F_h(x) - F(x)\| \le \frac{\gamma}{ks}\left\{1 - \Big(1 - \frac{\gamma^2}{4\beta^2}\Big)^{1/2}\right\}.$$

Hence, for $h < h_0 := \min\{h_1, h_2\}$,

$$\|x - D_s(\xi)\| \le \rho,$$

and consequently $D_s(\xi) \in B_\rho(x)$. For $h \le h_0$, by the Banach fixed point theorem, we obtain the existence of $x_h \in B_\rho(x)$ with $F_h(x_h) = 0$. By construction of $B_\rho(x)$, the derivative $F_h'(x_h)$ is positive definite with the h-independent constant $\frac{1}{2}\gamma$. This implies that, for a certain $\xi \in B_\rho(x)$,

$$(x - x_h)^*(F_h(x) - F_h(x_h)) = (x - x_h)^*F_h'(\xi)(x - x_h) \ge \frac{\gamma}{2}\|x - x_h\|^2.$$

Hence, using $F(x) = F_h(x_h) = 0$,

$$\|x - x_h\|^2 \le \frac{2}{\gamma}(x - x_h)^*(F_h(x) - F_h(x_h)) = \frac{2}{\gamma}(x - x_h)^*(F_h(x) - F(x))$$
$$\le \frac{2}{\gamma}\|F_h(x) - F(x)\|\,\|x - x_h\|.$$

This completes the proof. ∎

4. A priori error estimation. In this section we apply the paradigm presented in section 3 to the problem under consideration. We prove the following theorem.

THEOREM 4.1. *Let $q \in Q$ be a stable solution of (2.5). Then, for h small enough, there exists a stable solution $q_h \in Q$ of (2.22), and there holds the following a priori error estimate:*

$$\|q - q_h\| = \mathcal{O}(h^2|\log(h)|^2). \tag{4.1}$$

On the basis of the estimate (4.1), we can also derive optimal-order estimates for the error $u - u_h$ in the corresponding states. However, since this would be a simple exercise using the arguments developed below, and since the optimal states are of only minor practical interest in parameter estimation problems, we do not state these estimates.

The proof of Theorem 4.1 is given by checking the conditions from Theorem 3.1 for the operators

$$F(\xi) := \nabla j(\xi), \quad F_h(\xi) := \nabla j_h(\xi).$$

The constant in (4.1) turns out to depend in a reciprocal way on the distance

$$\delta := \min_{i=1,\dots,n_m} \operatorname{dist}(\xi_i, \Sigma)$$

of the set of measurement points ξ_i to the set Σ of corner points of $\partial\Omega$. Therefore, we will use generic constants c and c_δ, where c depends only on the domain Ω, the force f, and the characteristics of the mesh family $\{\mathcal{T}_h\}_h$, while c_δ may additionally depend on the distance δ like $c_\delta \approx \delta^{-1}$. Further, by $L^p(\Omega)$ and $W^{m,p}(\Omega)$, for $m \in \mathbb{N}$ and $1 \le p \le \infty$, we denote the standard Lebesgue and Sobolev spaces, respectively, and by $\|\cdot\|_p$ and $\|\cdot\|_{m,p}$ the corresponding norms. The restriction of such a norm to a subset $\Omega' \subset \Omega$ is indicated by $\|\cdot\|_{m,p;\Omega'}$.

By $i_h : C(\overline{\Omega}) \to V_h$ we denote the usual (linear) operator of nodal interpolation for which the following cellwise estimate is well known (see Brenner and Scott [5]):

$$h_K^{-2}\|v - i_h v\|_{p;K} + h_K^{-1}\|\nabla(v - i_h v)\|_{p;K} + \|\nabla^2 i_h v\|_{p;K} \le c\|\nabla^2 v\|_{p;K}, \tag{4.2}$$

for $1 \le p \le \infty$, with constants c independent of h.

An important ingredient of the proof of Theorem 4.1 is the following L^∞-stability theorem. For $d > 0$, we define the subset $\Omega_d \subset \Omega$ by

$$\Omega_d := \{x \in \Omega,\ \operatorname{dist}(x, \Sigma) > d\}.$$

THEOREM 4.2 (stability theorem). *Let $q \in Q_0$, $\psi \in H_0^1(\Omega) \cap C(\bar{\Omega})$, and a matrix $B = B(x) \in W^{1,\infty}(\Omega)^{2\times 2}$ be given. Moreover, let $v_h \in V_h$ be a solution of*

$$a(q)(v_h, \phi_h) = (B\nabla\psi, \nabla\phi_h) \quad \forall \phi_h \in V_h. \tag{4.3}$$

Then, there hold the L^2-stability estimate

$$\|v_h\|_2 + h\|\nabla v_h\|_2 \le c\,|||B|||_{1,\infty}\big\{\|\psi\|_2 + h\|\nabla\psi\|_2\big\} \tag{4.4}$$

and the local L^∞-stability estimate

$$\|v_h\|_{\infty;\Omega_d} \le c_d\,|||B|||_{1,\infty}\big\{|\log(h)|\,\|\psi\|_{\infty;\Omega_{d/2}} + \|\psi\|_2 + h\|\nabla\psi\|_2\big\}, \tag{4.5}$$

with a constant $c_d \approx d^{-1}$.

The L^2 estimate (4.4) is a standard result from finite element analysis, while the L^∞ estimate (4.5) can be concluded by estimates of discrete Green functions such as these developed in Frehse and Rannacher [10] and Rannacher and Scott [24] (see also Brenner and Scott [5, Chapter 7]). The proof for this is given in section 5 below. A similar L^∞-stability result has been proven in Rannacher [22] in the time-dependent parabolic case. For the solution q of problem (2.5), we introduce $\bar u_h \in V_h$ determined by

$$a(q)(\bar u_h, \phi_h) = (f, \phi_h) \quad \forall \phi_h \in V_h. \tag{4.6}$$

Further, we define $w_{j,h} \in V_h$ and $v_{jk,h} \in V_h$, for $j,k = 1, 2, \dots, n_p$, as the solutions of the problems

$$a(q)(w_{j,h}, \phi_h) = -(A'_{q_j}(q)\nabla\bar u_h, \nabla\phi_h) \quad \forall \phi_h \in V_h \tag{4.7}$$

and

$$\begin{aligned} a(q)(v_{jk,h}, \phi_h) = &-(A'_{q_j}(q)\nabla w_{k,h}, \nabla\phi_h) - (A'_{q_k}(q)\nabla w_{j,h}, \nabla\phi_h) \\ &- (A''_{q_j q_k}(q)\nabla\bar u_h, \nabla\phi_h) \quad \forall \phi_h \in V_h, \end{aligned} \tag{4.8}$$

respectively. The next lemma provides necessary estimates for the errors $u - \bar u_h$, $w_j - w_{j,h}$, and $v_{jk} - v_{jk,h}$. We recall the notation $\delta := \min_{i=1,\dots,n_m} \operatorname{dist}(\xi_i, \Sigma)$.

LEMMA 4.3. *Under the above assumptions the following estimates hold:*

$$\|C(u - \bar u_h)\| \le c_\delta h^2 |\log(h)|, \tag{4.9}$$

$$\|C(w_j - w_{j,h})\| \le c_\delta h^2 |\log(h)|^2, \quad j = 1, 2, \dots, n_p, \tag{4.10}$$

$$\|C(v_{jk} - v_{jk,h})\| \le c_\delta h^2 |\log(h)|^3, \quad j,k = 1, 2, \dots, n_p. \tag{4.11}$$

Proof. The proof uses the a priori bounds (2.16) and (2.17) provided in Lemma 2.2 for u, and the auxiliary functions w_j, v_{jk}, $j,k = 1, \dots, n_p$, corresponding to arbitrary $q \in Q_0$.

(i) By definition, $\bar u_h$ is the Ritz projection of u corresponding to the energy form $a(q)(\cdot,\cdot)$, i.e.,

$$a(q)(\bar u_h, \phi_h) = a(q)(u, \phi_h) \quad \forall \phi_h \in V_h.$$

By the standard L^2-error estimate for finite elements, there holds

$$\|u - \bar u_h\|_2 + h\|\nabla(u - \bar u_h)\|_2 \le ch^2. \tag{4.12}$$

Further, applying the L^∞-stability estimate (4.5) of Theorem 4.2 for the equation

$$a(q)(i_h u - \bar u_h, \phi_h) = a(q)(i_h u - u, \phi_h) \quad \forall \phi_h \in V_h,$$

with the nodal interpolant $i_h u \in V_h$ of u, yields the estimate

$$\|i_h u - \bar{u}_h\|_{\infty;\Omega_\delta} \le c_\delta \big\{ |\log(h)|\, \|i_h u - u\|_{\infty;\Omega_{\delta/2}} + \|i_h u - u\|_2 + h\|\nabla(i_h u - u)\|_2 \big\}.$$

From this, using the approximation properties (4.2) of i_h, we conclude the error estimate

$$\|u - \bar{u}_h\|_{\infty;\Omega_\delta} \le \|u - i_h u\|_{\infty;\Omega_\delta} + \|i_h u - \bar{u}_h\|_{\infty;\Omega_\delta} \le c_\delta h^2 |\log(h)|. \tag{4.13}$$

Here, the constant c_δ depends on the global H^2 norm and the local $W^{2,\infty}$ norm of the solution, which are both known to be bounded in view of the a priori bounds (2.16) and (2.17). Since $\xi_i \in \overline{\Omega}_\delta$, we obtain the estimate (4.9).

(ii) For proving (4.10), we introduce an additional discrete variable $\bar{w}_{j,h}$ determined by the equation

$$a(q)(\bar{w}_{j,h}, \phi_h) = -(A'_{q_j}(q)\nabla u, \nabla\phi_h) \quad \forall \phi_h \in V_h.$$

The error $e = w_j - w_{j,h}$ is split like $e = e_1 + e_2$, with $e_1 = w_j - \bar{w}_{j,h}$ and $e_2 = \bar{w}_{j,h} - w_{j,h}$. For the Ritz-projection error e_1, as before, there holds the L^2-error estimate

$$\|e_1\|_2 + h\|\nabla e_1\|_2 \le ch^2 \|w_j\|_{2,2} \le ch^2$$

and the pointwise error estimate

$$\|e_1\|_{\infty;\Omega_\delta} \le c_\delta h^2 \big\{ |\log(h)|\, \|\nabla^2 w_j\|_{\infty;\Omega_{\delta/2}} + \|w_j\|_{2,2} \big\} \le c_\delta h^2 |\log(h)|.$$

For $e_2 \in V_h$, we have

$$a(q)(e_2, \phi_h) = -(A'_{q_j}(q)\nabla(u - \bar{u}_h), \nabla\phi_h) \quad \forall \phi_h \in V_h.$$

Hence, the L^2-stability estimate (4.4) of Theorem 4.2 and the estimate (4.12) imply

$$\|e_2\|_2 + h\|\nabla e_2\|_2 \le c\big\{ \|u - \bar{u}_h\|_2 + h\|\nabla(u - \bar{u}_h)\|_2 \big\} \le ch^2.$$

This shows that, for $j = 1, \dots, n_p$,

$$\|w_j - w_{j,h}\|_2 + h\|\nabla(w_j - w_{j,h})\|_2 \le ch^2. \tag{4.14}$$

Further, the L^∞-stability estimate (4.5) of Theorem 4.2 yields

$$\|e_2\|_{\infty;\Omega_\delta} \le c_\delta \big\{ |\log(h)|\, \|u - \bar{u}_h\|_{\infty;\Omega_{\delta/2}} + \|u - \bar{u}_h\|_2 + h\|\nabla(u - \bar{u}_h)\|_2 \big\},$$

which, by (4.12) and (4.13), implies $\|e_2\|_{\infty;\Omega_\delta} \le c_\delta |\log(h)|^2 h^2$. We obtain

$$\|w_j - w_{j,h}\|_{\infty;\Omega_\delta} \le c_\delta |\log(h)|^2 h^2, \quad j = 1, \dots, n_p, \tag{4.15}$$

which implies the desired estimate (4.10).

(iii) The proof of (4.11) uses the same line of argument as before. Using the additional discrete variable $\bar{v}_{jk,h}$ determined by the equation

$$\begin{aligned} a(q)(\bar{v}_{jk,h}, \phi_h) = &-(A'_{q_j}(q)\nabla w_k, \nabla\phi_h) - (A'_{q_k}(q)\nabla w_j, \nabla\phi_h) \\ &- (A''_{q_j q_k}(q)\nabla u, \nabla\phi_h) \quad \forall \phi_h \in V_h, \end{aligned}$$

the error $e = v_{jk} - v_{jk,h}$ is split like $e = e_1 + e_2$, with $e_1 = v_{jk} - \bar{v}_{jk,h}$ and $e_2 = \bar{v}_{jk,h} - v_{jk,h}$. For the Ritz-projection error e_1, as before, we conclude the pointwise error estimate

$$\|e_1\|_{\infty;\Omega_\delta} \le c_\delta h^2 \big\{ |\log(h)|\, \|\nabla^2 v_{jk}\|_{\infty;\Omega_{\delta/2}} + \|v_{jk}\|_{2,2} \big\} \le c_\delta h^2 |\log(h)|.$$

For $e_2 \in V_h$, we have

$$\begin{aligned} a(q)(e_2,\phi_h) = &-(A'_{q_j}(q)\nabla(w_k - w_{k,h}), \nabla\phi_h) - (A'_{q_k}(q)\nabla(w_j - w_{j,h}), \nabla\phi_h) \\ &-(A''_{q_j q_k}(q)\nabla(u - \bar{u}_h), \nabla\phi_h) \quad \forall \phi_h \in V_h, \end{aligned}$$

and therefore, again by the L^∞-stability estimate (4.5) of Theorem 4.2,

$$\begin{aligned} \|e_2\|_{\infty;\Omega_\delta} \le c_\delta |\log(h)| \Big\{ &\max_{j=1,\dots,n_p} \|w_j - w_{j,h}\|_{\infty;\Omega_{\delta/2}} + \|u - \bar{u}_h\|_{\infty;\Omega_{\delta/2}} \Big\} \\ &+ c \max_{j=1,\dots,n_p} \big\{ \|w_j - w_{j,h}\|_2 + h\|\nabla(w_j - w_{j,h})\|_2 \big\} \\ &+ c\big\{ \|u - \bar{u}_h\|_2 + h\|\nabla(u - \bar{u}_h)\|_2 \big\}. \end{aligned}$$

Then, by the foregoing error estimates, we obtain $\|e_2\|_{\infty;\Omega_\delta} \le c_\delta h^2 |\log(h)|^3$, and consequently,

$$\|v_{jk} - v_{jk,h}\|_{\infty;\Omega_\delta} \le c_\delta |\log(h)|^3 h^2, \quad j,k = 1,\dots,n_p. \tag{4.16}$$

This eventually yields the desired estimated (4.11). □

A direct application of Lemma 4.3 leads to the following result.

LEMMA 4.4. *Under the above assumptions, there holds*

$$\Big| \frac{\partial}{\partial q_j}(j - j_h)(q) \Big| \le c_\delta h^2 |\log(h)|^2, \quad j = 1,2,\dots,n_p, \tag{4.17}$$

$$\Big| \frac{\partial^2}{\partial q_j \partial q_k}(j - j_h)(q) \Big| \le c_\delta h^2 |\log(h)|^3, \quad j,k = 1,2,\dots,n_p. \tag{4.18}$$

Proof. We have the representation

$$\begin{aligned} \frac{\partial}{\partial q_j}(j - j_h)(q) &= \langle C(u) - \hat{C}, C(w_j)\rangle - \langle C(\bar{u}_h) - \hat{C}, C(w_{j,h})\rangle \\ &= \langle C(u) - \hat{C}, C(w_j - w_{j,h})\rangle + \langle C(u - \bar{u}_h), C(w_{j,h})\rangle, \end{aligned}$$

from which we obtain

$$\Big| \frac{\partial}{\partial q_j}(j - j_h)(q) \Big| \le \|C(u) - \hat{C}\|\, \|C(w_j - w_{j,h})\| + \|C(u - \bar{u}_h)\|\, \|C(w_{j,h})\|.$$

By the a priori bounds (2.16) and (2.17) and the Sobolev embedding theorem, we see that

$$\|C(u)\| + \|C(w_j)\| + \|C(v_{jk})\| \le c. \tag{4.19}$$

Combining this with the error estimate (4.10) implies $\|C(w_{j,h})\| \le c$. Then, we can conclude the first estimate (4.17) from the error estimates of Lemma 4.3. To prove (4.18), we write

$$\begin{aligned}\frac{\partial^2}{\partial q_j q_k}(j-j_h)(q) &= \langle C(w_j), C(w_k)\rangle + \langle C(u)-\hat{C}, C(v_{jk})\rangle \\ &\quad - \langle C(w_{j,h}), C(w_{k,h})\rangle - \langle C(\bar{u}_h)-\hat{C}, C(v_{jk,h})\rangle \\ &= \langle C(w_j - w_{j,h}), C(w_k)\rangle + \langle C(w_{j,h}), C(w_k - w_{k,h})\rangle \\ &\quad + \langle C(u-\bar{u}_h), C(v_{jk})\rangle + \langle C(\bar{u}_h)-\hat{C}, C(v_{jk}-v_{jk,h})\rangle.\end{aligned}$$

Using as before the bounds (4.19) and the error estimates of Lemma 4.3 completes the proof. ∎

For the application of Theorem 3.1 it remains to check the Lipschitz condition (3.2). For two arbitrary parameter sets $\xi, \eta \in Q_0$, we set $u_\xi = S_h(\xi)$ and $u_\eta = S_h(\eta)$. Correspondingly, we define $w_{j,\xi}, w_{j,\eta} \in V_h$ and $v_{jk,\xi}, v_{jk,\eta} \in V_h$ similarly to $w_{j,h}$ and $v_{j,h}$ for $q = \xi$ and $q = \eta$, respectively.

LEMMA 4.5. *For $\xi, \eta \in Q_0$, there hold*

$$\|C(u_\xi - u_\eta)\| \le c_\delta |\log(h)|\, \|\xi - \eta\|, \tag{4.20}$$

$$\|C(w_{j,\xi} - w_{j,\eta})\| \le c_\delta |\log(h)|^2\, \|\xi - \eta\|, \tag{4.21}$$

$$\|C(v_{jk,\xi} - v_{jk,\eta})\| \le c_\delta |\log(h)|^3\, \|\xi - \eta\|. \tag{4.22}$$

Proof. Due to the definition of u_ξ and u_η, we have

$$(A(\xi)\nabla(u_\xi - u_\eta), \nabla\phi_h) = -((A(\xi) - A(\eta))\nabla u_\eta, \nabla\phi_h) \quad \forall \phi_h \in V_h.$$

Using Theorem 4.2, with $d = \delta$, we obtain

$$\|C(u_\xi - u_\eta)\| \le c\, |||(A(\xi) - A(\eta))|||_{1,\infty} \left\{ |\log(h)|\, \|u_\eta\|_{\infty;\Omega_{\delta/2}} + \|u_\eta\|_2 + h\|\nabla u_\eta\|_2 \right\}.$$

Since u_η is the Ritz projection of an H^2 function, all its norms occurring on the right-hand side are bounded independent of h and $\eta \in Q_0$ by standard estimates from finite element analysis. This implies (4.20) since

$$|||A(\xi) - A(\eta)|||_{1,\infty} \le c\|\xi - \eta\|.$$

The estimates (4.21) and (4.22) are obtained in a similar way. ∎

LEMMA 4.6. *For $\xi, \eta \in Q_0$, there holds*

$$\left| \frac{\partial^2}{\partial q_j q_k} j_h(\xi) - \frac{\partial^2}{\partial q_j q_k} j_h(\eta) \right| \le L(h)\|\xi - \eta\|, \tag{4.23}$$

where $L(h) = c_\delta |\log(h)|^3$.

Proof. We have

$$\begin{aligned}\frac{\partial^2}{\partial q_j q_k} j_h(\xi) - \frac{\partial^2}{\partial q_j q_k} j_h(\eta) &= \langle C(w_{j,\xi}), C(w_{k,\xi})\rangle + \langle C(u_\xi) - \hat{C}, C(v_{jk,\xi})\rangle \\ &\quad - \langle C(w_{j,\eta}), C(w_{k,\eta})\rangle - \langle C(u_\eta) - \hat{C}, C(v_{jk,\eta})\rangle \\ &= \langle C(w_{j,\xi} - w_{j,\eta}), C(w_{k,\xi})\rangle + \langle C(w_{j,\eta}), C(w_{k,\xi} - w_{k,\eta})\rangle \\ &\quad + \langle C(u_\xi - u_\eta), C(v_{jk,\xi})\rangle + \langle C(u_\eta) - \hat{C}, C(v_{jk,\xi} - v_{jk,\eta})\rangle,\end{aligned}$$

and, consequently,

$$\begin{aligned}\Big|\frac{\partial^2}{\partial q_j q_k} j_h(\xi) - \frac{\partial^2}{\partial q_j q_k} j_h(\eta)\Big| &\le \|C(w_{j,\xi} - w_{j,\eta})\|\,\|C(w_{k,\xi})\| \\ &\quad + \|C(w_{j,\eta})\|\,\|C(w_{k,\xi} - w_{k,\eta})\| + \|C(u_\xi - u_\eta)\|\,\|C(v_{jk,\xi})\| \\ &\quad + \|C(u_\eta) - \hat{C}\|\,\|C(v_{jk,\xi} - v_{jk,\eta})\|.\end{aligned}$$

Now, the assertion follows by the estimates of Lemma 4.5 if we can bound the terms $C(u_\eta)$, $C(w_{j,\eta})$, and $C(v_{jk,\xi})$. This is achieved by using the bounds for $C(u)$, $C(w_j)$, and $C(v_{jk})$ in (4.19) together with the error estimates of Lemma 4.3. ∎

To complete the proof of Theorem 4.1 we check the conditions of Theorem 3.1. Condition (3.1) is fulfilled due to the stability of the solution q of the problem (2.5). Condition (3.2) is shown in Lemma 4.6. Condition (3.3) is obtained by Lemma 4.4 and Lemma 4.6 using $\lim_{h\to 0} h^2|\log(h)|^5 = 0$. Finally, condition (3.4) holds due to Lemma 4.4. Hence, the estimate (3.5) of Theorem 3.1 completes the proof.

5. Proof of Theorem 4.2. (i) We begin with the L^2-stability estimate. Taking $\phi_h := v_h$ in (4.3), we obtain

$$\|\nabla v_h\|_2 \le c|||B|||_{1,\infty}\|\nabla\psi\|_2. \tag{5.1}$$

To estimate $\|v_h\|_2$, we use the solution $z \in V \cap H^2(\Omega)$ of the auxiliary equation

$$a(q)(\phi, z) = (\phi, v_h)\|v_h\|_2^{-1} \quad \forall \phi \in V.$$

Taking $\phi := v_h$ as test function and integrating by parts, we have

$$\begin{aligned}\|v_h\|_2 &= a(q)(v_h, z) = a(q)(v_h, z - i_h z) + a(q)(v_h, i_h z) \\ &= a(q)(v_h, z - i_h z) + (B\nabla\psi, \nabla i_h z) \\ &= a(q)(v_h, z - i_h z) + (B\nabla\psi, \nabla(i_h z - z)) - (\psi, \nabla\cdot B^T\nabla z).\end{aligned}$$

Then, using the approximation properties (4.2) of the interpolant $i_h z \in V_h$, we conclude that

$$\begin{aligned}\|v_h\|_2 &\le c\|\nabla v_h\|_2\|\nabla(z - i_h z)\|_2 + |||B|||_{1,\infty}\|\nabla\psi\|_2\|\nabla(z - i_h z)\|_2 \\ &\quad + |||B|||_{1,\infty}\|\psi\|_2\|z\|_{2,2} \\ &\le c\big\{h\|\nabla v_h\| + |||B|||_{1,\infty}h\|\nabla\psi\|_2 + |||B|||_{1,\infty}\|\psi\|_2\big\}\,\|z\|_{2,2}.\end{aligned}$$

Hence, observing (5.1) and the bound $\|z\|_{2,2} \le c$, we obtain

$$\|v_h\|_2 \le c|||B|||_{1,\infty}\big\{\|\psi\|_2 + h\|\nabla\psi\|_2\big\}. \tag{5.2}$$

(ii) Next, we prove the L^∞-stability estimate. Let $a \in \Omega_\delta$ be an arbitrary point lying in a cell K. For any fixed h, there exists a cellwise polynomial function δ_h with $\mathrm{supp}(\delta_h) \subset K$ such that

$$(\phi_h, \delta_h) = \phi_h(a) \quad \forall \phi_h \in V_h.$$

The function δ_h plays the role of an approximate Dirac function. Correspondingly, we introduce a regularized Green function $g \in V \cap H^2(\Omega)$ by

$$(A(q)\nabla\phi, \nabla g) = (\delta_h, \phi) \quad \forall \phi \in V,$$

and the corresponding Ritz projection $g_h \in V_h$ by

$$(A(q)\nabla\phi_h, \nabla g_h) = (\delta_h, \phi_h) \quad \forall \phi_h \in V_h.$$

For functions which are only cellwise defined, we will use the "broken" norm $\|v\|'_p := \sum_{K\in\mathcal{T}_h} \|v\|_{p;T}$. The following three lemmas provide the key estimates for the proof of the theorem.

LEMMA 5.1. *The following global L^2 estimates hold:*

$$\|g\|_2 + |\log(h)|^{-1/2}\|\nabla g\|_2 + h\|\nabla^2 g\|_2 \le c, \tag{5.3}$$

$$h^{-1}\|g - g_h\|_2 + \|\nabla(g - g_h)\|_2 + h\|\nabla^2 g_h\|'_2 \le c. \tag{5.4}$$

Proof. The assertion follows by standard L^2 a priori and error estimates for g and $g - g_h$, respectively. We skip the details and refer to [10]. Note that $\|\nabla^2 g_h\|'_2$ vanishes for linear finite elements. In the case of bilinear elements, we estimate using the interpolant $i_h g$ as follows:

$$\|\nabla^2 g_h\|'_2 \le \|\nabla^2(g_h - i_h g)\|'_2 + \|\nabla^2(g - i_h g)\|'_2 + \|\nabla^2 g\|_2.$$

For the first term, we obtain, using an inverse inequality,

$$\begin{aligned}\|\nabla^2(g_h - i_h g)\|'_2 &\le ch^{-1}\|\nabla(g_h - i_h g)\|_2 \\ &\le ch^{-1}\big\{\|\nabla(g - i_h g)\|_2 + \|\nabla(g - g_h)\|_2\big\}\end{aligned}$$

and obtain by the interpolation estimate (4.2), with $p = 2$, and by the other estimates derived before,

$$\|\nabla^2 g_h\|'_2 \le c\big\{h^{-1}\|\nabla(g - g_h)\|_2 + \|\nabla^2 g\|_2\big\} \le ch^{-1}.$$

This completes the proof. ∎

LEMMA 5.2. *For sufficiently small $h \ll \delta$, the following local L^2 estimate holds:*

$$\|\nabla(g - g_h)\|_{2;\Omega\setminus\Omega_{\delta/2}} + h\|\nabla^2 g\|_{2;\Omega\setminus\Omega_{\delta/2}} \le c_\delta h, \tag{5.5}$$

with a constant $c_\delta \approx \delta^{-1}$ but independent of h.

Proof. The assertion follows by standard local elliptic a priori estimates and by arguments from the local L^2 error analysis for finite elements, as provided in Nitsche and Schatz [20]:

$$\begin{aligned}\|\nabla^2 g\|_{2;\Omega\setminus\Omega_{\delta/2}} &\le c\|\Delta g\|_{2;\Omega\setminus\Omega_{3\delta/4}} + c_\delta\|g\|_2, \\ \|\nabla(g - g_h)\|_{2;\Omega\setminus\Omega_{\delta/2}} &\le c\|\nabla(g - i_h g)\|_{2;\Omega\setminus\Omega_{3\delta/4}} + c_\delta\|g - g_h\|_2,\end{aligned}$$

with constants $c_\delta \approx \delta^{-1}$. Now, the assertion follows by the interpolation estimate (4.2) and the other estimates already proven. ∎

LEMMA 5.3. *The following L^1 a priori and error estimates hold:*

$$\|\nabla g\|_1 + \|\nabla^2 g\|'_1 \le c|\log(h)|, \tag{5.6}$$

$$\|\nabla(g - g_h)\|_1 + h\|\nabla^2(g - g_h)\|'_1 \le ch|\log(h)|, \tag{5.7}$$

with a constant c independent of h and δ.

Proof. The proof can be found in [10]. ∎

For the point $a \in \Omega_d$, there holds

$$v_h(a) = (v_h, \delta_h) = (A(q)\nabla v_h, \nabla g_h) = (B\nabla\psi, \nabla g_h).$$

We employ a standard localization argument. Let $\omega \in C_0^\infty(\Omega)$ be a smooth function with the properties

$$0 \le \omega \le 1, \quad \omega_{|\Omega_{\delta/2}} \equiv 1, \quad \omega_{|\Omega\setminus\Omega_{\delta/4}} \equiv 0.$$

With this notation, we have

$$(B\nabla\psi, \nabla g_h) = (B\nabla(\omega\psi), \nabla g_h) + (B\nabla((1-\omega)\psi), \nabla g_h) =: \Sigma_1 + \Sigma_2.$$

First, we estimate the term Σ_1. By integration by parts and observing that $\psi_{|\partial\Omega} = 0$, we obtain

$$(B\nabla(\omega\psi), \nabla g_h) = \sum_{K\in\mathcal{T}_h} \big\{(\omega\psi, -\nabla\cdot(B\nabla g_h))_T + (\omega\psi, n\cdot B\nabla g_h)_{\partial K\setminus\partial\Omega}\big\},$$

where n is the outward unit normal vector to ∂K. Let $[\nabla g_h]$ denote the jump of the gradient across the interior faces $\Gamma \subset \partial K$. Using this notation, we obtain

$$\Sigma_1 \le \|\psi\|_{\infty;\Omega_{\delta/2}} \sum_{K\in\mathcal{T}_h} \left\{\|\nabla\cdot(B\nabla g_h)\|_{1;K} + \frac{1}{2}\|n\cdot[B\nabla g_h]\|_{1;\partial K\setminus\partial\Omega}\right\}.$$

First, the estimates of Lemma 5.3 yield

$$\sum_{K\in\mathcal{T}_h} \|\nabla\cdot(B\nabla g_h)\|_{1;K} \le c\,|||B|||_{1,\infty}\big\{\|\nabla g_h\|_1 + \|\nabla^2 g_h\|_1'\big\} \le c\,|||B|||_{1,\infty}\,|\log(h)|.$$

Next, observing that $g \in H^2(\Omega)$ and therefore $[B\nabla g] = 0$, we obtain by a trace theorem

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} \|n\cdot[B\nabla g_h]\|_{1;K\setminus\partial\Omega} &= \sum_{K\in\mathcal{T}_h} \|n\cdot[B\nabla(g_h - g)]\|_{1;\partial K\setminus\partial\Omega}\\ &\le c\,|||B|||_{1,\infty} \sum_{K\in\mathcal{T}_h} \big\{h^{-1}\|\nabla(g-g_h)\|_{1;K} + \|\nabla^2(g-g_h)\|_{1;K}'\big\}.\end{aligned}$$

Hence, collecting the foregoing estimates,

$$\Sigma_1 \le c\,|||B|||_{1,\infty}\,\|\psi\|_{\infty;\Omega_{\delta/2}}\big\{|\log(h)| + h^{-1}\|\nabla(g-g_h)\|_1 + \|\nabla^2(g-g_h)\|_1'\big\}.$$

Again using the estimates of Lemma 5.3, we obtain

$$\Sigma_1 \le c\,|||B|||_{1,\infty}\,\|\psi\|_{\infty;\Omega_{\delta/2}}|\log(h)|. \tag{5.8}$$

For the term Σ_2, we estimate as follows:

$$\begin{aligned}\Sigma_2 &= (B\nabla((1-\omega)\psi), \nabla(g_h - g)) + (B\nabla((1-\omega)\psi), \nabla g)\\ &\le |||B|||_{1,\infty}\big\{\|\nabla\psi\|_2\,\|\nabla(g_h-g)\|_{2;\Omega\setminus\Omega_{\delta/2}} + c_\delta\|\psi\|_2\,\|\nabla(g_h-g)\|_2\big\}\\ &\quad + c\,|||B|||_{1,\infty}\|\psi\|_2\,\big\{\|\nabla^2 g\|_{2;\Omega\setminus\Omega_{\delta/2}} + \|\nabla g\|_{2;\Omega\setminus\Omega_{\delta/2}}\big\}.\end{aligned}$$

Then, by the L^2 estimates of Lemmas 5.1 and 5.2, it follows that

$$\Sigma_2 \le c_\delta |||B|||_{1,\infty} \big\{ \|\psi\|_2 + h\|\nabla\psi\|_2 \big\}. \tag{5.9}$$

This completes the proof of the theorem.

6. Numerical results. In this section, we discuss a sample problem confirming the a priori error estimate of Theorem 4.1. The state equation is given by

$$\begin{aligned} -\nabla\cdot(A(q)\nabla u) &= 2 \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{6.1}$$

where Ω is the unit square. The matrix $A(q)$ is a function of the parameter $q = (q_1, q_2) \in Q = \mathbb{R}^2$, given by

$$A(q) = \begin{pmatrix} q_1^2 & q_1 q_2 \\ q_1 q_2 & \exp(q_2) \end{pmatrix}.$$

In this case the admissible set of parameters is $Q_0 = \{(q_1, q_2) \in Q : q_1 \neq 0, e^{q_2} > q_2^2\}$. The parameters are estimated from the measurements of the state variable at nine different points $\xi_i \in \Omega$; see Figure 6.1.

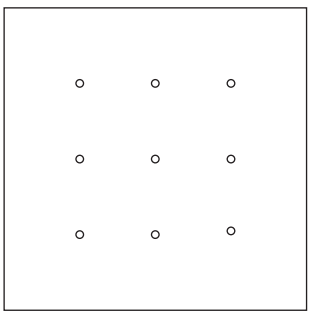

FIG. 6.1. *The computational domain with measurement points marked by circles.*

The vector of measurements $\hat{C}$ is given by

$$\hat{C}_i = C_i(S(\hat{q}))(1 + \varepsilon_i), \quad i = 1, \dots, 9,$$

where the reference parameter is $\hat{q} = (5, 6)$ and $\varepsilon = (\varepsilon_i)$ describes the data perturbation. We consider two cases:

(a) $\varepsilon \approx 0$, (b) $\varepsilon \approx (0.12, -0.26, 0.29, -0.37, -0.49, 0.13, -0.04, -0.45, 0.20)$.

Since the values of $C_i(S(\hat{q}))$ are not available analytically, they are computed approximately by solving state equation (6.1) on a very fine mesh with about 10^6 degrees of freedom. For case (a) the solution $q^{(a)}$ of the parameter identification problem matches the reference parameter $\hat{q}$, and hence the cost functional $J(u)$ almost vanishes in $q^{(a)}$. Case (b) is more realistic because of the "measurement errors" modeled by a randomly chosen ε. Moreover, in this case in contrast to case (a), the solution $q^{(b)}$ of the corresponding parameter identification problem and the reference parameter $\hat{q}$ differ.

The parameter identification problem is discretized using bilinear finite elements on uniformly refined meshes. The results are listed in Tables 6.1 and 6.2. For both cases the theoretically predicted orders of convergence are achieved.

7. Conclusions and extensions. In this paper we have derived an a priori error estimate for the finite element discretization of an elliptic discrete parameter identification problem with pointwise measurements. The crucial point in our argument is the stability estimate of Theorem 4.2. The result of Theorem 4.1 can be extended to situations in which such a stability estimate is available. We list some possible directions of generalization.

1. *More general meshes.* For simplicity, we have assumed a quasi-uniform mesh family $\{\mathcal{T}_h\}_h$. The analysis can be extended to locally refined meshes, provided that the ratio of $h_{\min}$ and $h = h_{\max}$ is polynomial, $h_{\min} \approx h^p$, with some $p \geq 1$. For such meshes the stability result of Theorem 4.2 holds true with $|\log(h_{\min})| \approx p|\log(h)|$. This will be shown in the forthcoming paper [23]. Related results for L^∞-error estimates can be extracted (with some work) from Schatz and Wahlbin [25].

2. *More general domains.* Our argument uses that the solution operator $S(\cdot)$ maps Q into $H_0^1(\Omega) \cap H^2(\Omega)$, which is guaranteed on smoothly bounded or convex domains. In the case of a domain with reentrant corners or edges this regularity property is lost. This lack of regularity of the solution can be compensated by an appropriate refinement of the mesh near the critical corner points or edges. The stability estimate of Theorem 4.2 also holds in this situation, in two as well as in three dimensions. This will be shown in a forthcoming paper.

3. *Higher-order approximation.* The result of Theorem 4.1 can be also extended to the case of higher-order finite elements, similar to the analysis of Nitsche [19]. In this case the logarithmic factor $|\log(h)|$ can be dropped in the stability Theorem 4.2.

4. *More general equations.* Theorem 4.1 can also be extended to more general elliptic equations or systems of the form

$$-\nabla \cdot (A(q)\nabla u + b_1(q)u) + b_2(q)u = f,$$

with parameter-dependent coefficients $A(q)$, $b_1(q)$, $b_2(q)$. Corresponding L^∞-error estimates for very general (nonlinear) elliptic systems have been derived in Dobrowolski and Rannacher [7].

DIRAC STRUCTURES AND BOUNDARY CONTROL SYSTEMS ASSOCIATED WITH SKEW-SYMMETRIC DIFFERENTIAL OPERATORS*

Y. LE GORREC†, H. ZWART‡, AND B. MASCHKE†

Abstract. Associated with a skew-symmetric linear operator on the spatial domain $[a, b]$ we define a Dirac structure which includes the port variables on the boundary of this spatial domain. This Dirac structure is a subspace of a Hilbert space. Naturally, associated with this Dirac structure is an infinite-dimensional system. We parameterize the boundary port variables for which the C_0-semigroup associated with this system is contractive or unitary. Furthermore, this parameterization is used to split the boundary port variables into inputs and outputs. Similarly, we define a linear port controlled Hamiltonian system associated with the previously defined Dirac structure and a symmetric positive operator defining the energy of the system. We illustrate this theory on the example of the Timoshenko beam.

Key words. port Hamiltonian systems, strongly continuous semigroup, boundary control systems, Dirac structures

1. Introduction.

Port Hamiltonian systems have been introduced in the finite-dimensional case as an analytical frame for the modeling and control of open physical systems [12, 14, 18, 28]. The key concepts are the definition of pairs of power conjugated variables and the geometric structure defined on them. This geometric structure is called the Dirac structure [2, 5]. These Dirac structures also define the internal geometric structure of the physical system as the structure of their interaction with the environment [12, 29]. It reflects the (discrete) topology and the geometry of the physical system under consideration such as the port connection graph, constraints, or interdomain coupling [4, 15, 18]. Furthermore, it is the geometric structure which allows us to define *implicit* Hamiltonian systems and Hamiltonian systems with *port variables* [4, 27, 28]. Port Hamiltonian systems have been used for the design of stabilizing control laws; see, e.g., [13, 21, 22].

Recently, an extension of port Hamiltonian systems to infinite-dimensional systems has been proposed for distributed parameter systems with energy flow at their boundary; see [16, 30]. The state space is a vector space of differential forms defined on the spatial domain and the port variables are defined on the boundary of the spatial domain. The port Hamiltonian system is defined with respect to a so-called *Stokes–Dirac structure*, which in turn is uniquely defined by the exterior derivatives and the order of the differential forms. The Stokes–Dirac structure represents the canonical

interdomain coupling in physical systems [19]. Finally, the Stokes–Dirac structures have been extended in order to encompass fluid dynamics and beam models [30].

Associated with linear skew-symmetric differential operators, we define Dirac structures and port Hamiltonian systems. Our definition extends the definition of Stokes–Dirac structures in which the operator needed to have differential degree one. We use an alternative definition of a Dirac structure on Hilbert spaces as proposed in [23] and [7]. In [7] Dirac structures on Hilbert spaces have also been used for the study of their composition (interconnection) and the definition of scattering representations. In this paper, we are restricting ourselves to one-dimensional spatial domains.

A major motivation of this work is to provide a theoretic formulation of open Hamiltonian systems, i.e., systems which are subject to some energy flow at their boundary. This formulation is *acausal*, i.e., a priori there is no distinction between inputs and outputs. The acausal formulation is obtained by first introducing boundary port variables. Second, these boundary port variables together with the (formal) skew-symmetric operator lead to the Dirac structure associated with the system.

The second motivation of this paper is to study the existence of solutions for our class of systems. This immediately implies some causality conditions among the port variables. Namely, for a (more or less) free choice of inputs there should exist a solution and the outputs should follow from it. In order to show existence of solutions, we relate our system to the class of boundary control systems. We remark that there are other general system classes which we could have chosen, e.g., system nodes [26]. We have chosen the class of boundary control systems, since this fits most naturally to our class of PDEs with their control at the boundary. As a result, we derive a parameterizing of the port variables such that the semigroup associated with the boundary control system is a contraction semigroup.

This paper is organized as follows. In section 2 we recall the definition of Dirac structures on Hilbert spaces. In section 3 we define Dirac structures associated with skew-symmetric linear differential operators and its conjugated port variables on the boundary of the spatial domain. In section 4 we associate with our Dirac structure a family of boundary control systems. The input of this boundary control system is chosen to lie in a subspace of the boundary port variables. The semigroup associated with this system is a contraction semigroup. By choosing the output to lie in the complementary of the "input subspace" we get a power balance system. The above construction gives the parameterization of all systems for which the associated semigroup is contractive and/or unitary. In section 5 we define a port Hamiltonian system associated with a skew-symmetric differential operator and with a Hamiltonian function. This Hamiltonian is a function defined by a symmetric and coercive linear operator and represents the energy in the system.

2. Dirac structures defined on Hilbert spaces. In this section, we recall the definition of Dirac structures defined on Hilbert spaces proposed by Parsian and Shafei Deh Abad in [23] and by Golo and coauthors in [7, 8]. We shall follow the definitions and notation of [7, 8] for the purpose of analyzing and treating the composition of Dirac structures in the frame of port-based modeling and control. This notation is borrowed partially from the bond graph language, which has been a major source of inspiration for the model definition of port Hamiltonian systems [7, 19, 18].

Let us first define the space of *bond variables* which is constituted of pairs of conjugated variables endowed with a pairing. For models of physical systems this corresponds to an associated instantaneous power; see [1, 11]. Let the *space of flow variables,* denoted by $\mathcal{F}$, and the *space of effort variables,* denoted by $\mathcal{E}$, be real Hilbert

spaces endowed with the inner products $\langle .\,,\,. \rangle_{\mathcal{F}}$ and $\langle .\,,\,. \rangle_{\mathcal{E}}$, respectively. Assume moreover that $\mathcal{F}$ and $\mathcal{E}$ are isometrically isomorphic, that is, there exists an isometry: $r_{\mathcal{F},\mathcal{E}} : F \longrightarrow \mathcal{E}$. Denote furthermore its inverse by $r_{\mathcal{E},\mathcal{F}}$. Define now the *space of bond variables* as the Hilbert space $\mathcal{B} = \mathcal{F} \times \mathcal{E}$ endowed with the natural inner product

$$\langle b^1, b^2 \rangle = \langle f^1, f^2 \rangle_{\mathcal{F}} + \langle e^1, e^2 \rangle_{\mathcal{E}}, \quad b^1 = (f^1, e^1), b^2 = (f^2, e^2) \in \mathcal{B}.$$

In order to define a Dirac structure, let us endow the bond space $\mathcal{B}$ with a *canonical symmetrical pairing*, i.e., a bilinear form defined as follows:

$$\langle b^1, b^2 \rangle_+ = \langle f^1, r_{\mathcal{E},\mathcal{F}} e^2 \rangle_{\mathcal{F}} + \langle e^1, r_{\mathcal{F},\mathcal{E}} f^2 \rangle_{\mathcal{E}}, \quad b^1 = (f^1, e^1), b^2 = (f^2, e^2) \in \mathcal{B}. \tag{2.1}$$

We define a Dirac structure on the bond space $\mathcal{B}$ using this canonical pairing. Denote by $\mathcal{D}^\perp$ the orthogonal subspace to $\mathcal{D}$ with respect to the symmetrical pairing (2.1):

$$\mathcal{D}^\perp = \{ b \in \mathcal{B} | \langle b, b' \rangle_+ = 0 \ \text{ for all } \ b' \in \mathcal{D} \}. \tag{2.2}$$

Definition 2.1. *A Dirac structure $\mathcal{D}$ on the bond space $\mathcal{B} = \mathcal{F} \times \mathcal{E}$ is a subspace of $\mathcal{B}$ which is maximally isotropic with respect to the canonical symmetrical pairing* (2.1)*, i.e.,*

$$\mathcal{D}^\perp = \mathcal{D}. \tag{2.3}$$

One may find different examples of such Dirac structures as well as some properties concerning their representations and their composition in [7, Chapter 5]. We shall now give a canonical example of a Dirac structure in the context of the port-based modeling of physical systems. Therefore, we consider the example of a lossless vibrating string. First, we recall the port-based model structure [19, 30] which gives rise to the definition of a Stokes–Dirac structure on Hilbert spaces of functions with a one-dimensional domain [7]. Second, we recall the formulation of the evolution equation as a port Hamiltonian system.

Example 2.2. Consider an elastic string defined on the one-dimensional spatial domain $Z = [a, b] \subset \mathbb{R}$ and subject to boundary conditions which allow some energy flow. Let us denote by $u(t, z)$ the displacement of the string at time t and position z. Let us first recall the port Hamiltonian formulation of its dynamics. This differs from the classical formulation based on the displacement $u(t, z)$ by the choice of the state variables [17, 30]. In this frame, the state variables are called *energy variables* and are chosen in such a way that the total energy of the string does not depend on their derivatives. The elastic potential energy is a function of the *strain*, and the energy variable is defined by

$$\epsilon(t, z) = \frac{\partial u}{\partial z}(t, z). \tag{2.4}$$

The associated coenergy variable is the *stress* given by

$$\sigma(t, z) = T(z)\, \epsilon(t, z) \tag{2.5}$$

with T denoting the elasticity modulus. Hence the potential energy is the quadratic function of the strain:

$$U(\epsilon(t, \cdot)) = \frac{1}{2} \int_a^b T(z)\, \epsilon(t, z)^2\, dz. \tag{2.6}$$

The kinetic energy K is a function of the kinetic *momentum*, $p(t,z)$, and it is defined by the quadratic function

$$K(p(t,\cdot)) = \frac{1}{2}\int_a^b \frac{p^2(t,z)}{\mu(z)}\,dz. \tag{2.7}$$

The associated coenergy variable is the *velocity* given by

$$v(t,z) = \frac{1}{\mu(z)}p(t,z), \tag{2.8}$$

where μ denotes the mass density.

The dynamical model of the vibrating string is obtained by coupling the elastic energy domain and the kinetic domain through the following relations. Consider the time variation of the energy variables, called flow variables,

$$\frac{\partial}{\partial t}\begin{pmatrix} p \\ \epsilon \end{pmatrix} = \begin{pmatrix} f_K \\ f_U \end{pmatrix}. \tag{2.9}$$

The canonical interdomain coupling between the elastic-potential energy and the kinetic energy relates the flow variables with the coenergy variables. This interdomain coupling is given by the differential operator [19]

$$\begin{pmatrix} f_K \\ f_U \end{pmatrix} = \begin{pmatrix} 0 & \frac{\partial}{\partial z} \\ \frac{\partial}{\partial z} & 0 \end{pmatrix}\begin{pmatrix} v \\ \sigma \end{pmatrix}. \tag{2.10}$$

Finally, the interaction of the vibrating string through its boundary is expressed by the definition of the boundary port variables, i.e., the velocity and stress at the boundaries of the string

$$\begin{pmatrix} w_K \\ w_U \end{pmatrix} = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} v|_{a,b} \\ \sigma|_{a,b} \end{pmatrix}. \tag{2.11}$$

The canonical interdomain coupling equation (2.10) and the boundary coupling equation (2.11) actually define a Dirac structure [7, Chapter 5] called the *Stokes–Dirac structure*. Let us explain this in more detail. Consider the Hilbert spaces of the flow variables $\mathcal{F} = L^2([a,b],\mathbb{R}) \times L^2([a,b],\mathbb{R}) \times \mathbb{R}^2 \ni (f_K, f_U, w_K)$ and of the effort variables $\mathcal{E} = L^2([a,b],\mathbb{R}) \times L^2([a,b],\mathbb{R}) \times \mathbb{R}^2 \ni (v,\sigma,w_U)$. Furthermore, endow the bond space $\mathcal{B} = \mathcal{F}\times\mathcal{E}$ with the following pairing:

$$\begin{aligned}
&\left\langle \left(f_K^1, f_U^1, w_K^1, v^1, \sigma^1, w_U^1\right),\ \left(f_K^2, f_U^2, w_K^2, v^2, \sigma^2, w_U^2\right)\right\rangle_+ \\
&\quad = \int_a^b f_K^1\, v^2\, dz + \int_a^b f_K^2\, v^1\, dz \\
&\qquad + \int_a^b f_U^1\, \sigma^2\, dz + \int_a^b f_U^2\, \sigma^1\, dz + {w_K^1}^T\, \Lambda w_U^2 + {w_K^2}^T\, \Lambda w_U^1,
\end{aligned}$$

where $\Lambda = \left(\begin{smallmatrix} I & 0 \\ 0 & -I \end{smallmatrix}\right)$.

This pairing on the bond space corresponds to the general definition given in (2.1) where both the flow and the effort vector space is a product space given by $\mathcal{F} = \mathcal{F}_{(a,b)} \times \mathcal{F}_\partial$ and $\mathcal{E} = \mathcal{E}_{(a,b)} \times \mathcal{E}_\partial$, respectively. The subspace of flow variables defined on the domain $[a,b]$ is $\mathcal{F}_{(a,b)} = L^2([a,b],\mathbb{R}) \times L^2([a,b],\mathbb{R}) \ni (f_K, f_U)$ and

the conjugated subspace of variables is $\mathcal{E}_{(a,b)} = L^2([a,b],\mathbb{R}) \times L^2([a,b],\mathbb{R}) \ni (v,\sigma)$. These Hilbert spaces are equal and hence the isometry $r_{\mathcal{F}_{(a,b)},\mathcal{E}_{(a,b)}}$ is the identity. On the contrary, for the pairing on the boundary port variables, the matrix Λ actually corresponds to the definition of an isometry $r_{\mathcal{F}_\partial,\mathcal{E}_\partial}$ between the boundary port spaces $\mathcal{F}_\partial = \mathbb{R}^2 \ni w_K$ and $\mathcal{E}_\partial = \mathbb{R}^2 \ni w_U$ endowed with the canonical Euclidean metric.

It has been shown in [7, 8] that (2.10) and (2.11) define a Dirac structure, namely, the Stokes–Dirac structure on $\mathcal{B}$ associated with the differential operator given in (2.10). We shall denote this Dirac structure by $\mathcal{D}_1$.

The system of two conservation laws (2.10), with the closure equations (2.5), (2.8), and (2.9), may be rewritten as the following Hamiltonian system [20]:

$$\frac{\partial}{\partial t}\begin{pmatrix} p \\ \epsilon \end{pmatrix} = \begin{pmatrix} 0 & \frac{\partial}{\partial z} \\ \frac{\partial}{\partial z} & 0 \end{pmatrix}\begin{pmatrix} \delta_p \mathcal{H} \\ \delta_\epsilon \mathcal{H} \end{pmatrix}, \tag{2.12}$$

where $\mathcal{H} = U + K$ denotes the Hamiltonian function corresponding to the total energy of the system and $\delta_p \mathcal{H}(x) = v$, $\delta_\epsilon \mathcal{H}(x) = \sigma$ denote the *variational derivatives* [20] of $\mathcal{H}$ with respect to the momentum p and the strain ϵ, respectively. This system is indeed a Hamiltonian system [20] if the differential operator in (2.12) is skew-symmetric, i.e., if the boundary variables are such that there is *no energy flow at the boundary* of the system:

$$w_K^{1\,T}\,\Lambda w_U^2 + w_K^{2\,T}\,\Lambda w_U^1 = 0. \tag{2.13}$$

In order to account for some energy flow at the boundary, the evolution equation (2.12) may be completed using the *port boundary variables* defined in (2.11), i.e., the velocity and the strain at the boundary

$$\begin{pmatrix} w_K \\ w_U \end{pmatrix} = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}\begin{pmatrix} \delta_p \mathcal{H}\,|_{a,b} \\ \delta_\epsilon \mathcal{H}\,|_{a,b} \end{pmatrix}. \tag{2.14}$$

The system composed of (2.12) and (2.14) defines a port Hamiltonian system with respect to the Stokes–Dirac structure. This port Hamiltonian system is generated by the Hamiltonian $\mathcal{H}$ [7, 8, 30] and it may be written in the following implicit way:

$$\left(\frac{\partial p}{\partial t}, \frac{\partial \epsilon}{\partial t}, w_K, \delta_p \mathcal{H}, \delta_\epsilon \mathcal{H}, w_U\right) \in \mathcal{D}_1. \tag{2.15}$$

Let us briefly compare the port Hamiltonian formulation with the formulation as a PDE. The evolution equations (2.12), with the closure equations (2.9), (2.5), may also be written in the form of the wave equations (in terms of the displacement of the string):

$$\mu \frac{\partial^2 u}{\partial t^2} = \frac{\partial}{\partial z}\left(T \frac{\partial u}{\partial z}\right). \tag{2.16}$$

The relation between the boundary conditions of this PDE and the port variables is given by

$$\begin{pmatrix} w_K \\ w_U \end{pmatrix} = \begin{pmatrix} v|_{a,b} \\ \sigma|_{a,b} \end{pmatrix} = \begin{pmatrix} \frac{\partial}{\partial t} u|_{a,b} \\ T(z)\,\frac{\partial u}{\partial z}|_{a,b} \end{pmatrix}. \tag{2.17}$$

This shows clearly that the PDE (2.16) does not reflect the physical structure of the system in the sense that it is not written as a system of conservation laws and

that the total energy appears clearly. Relation (2.17) shows the difference between port variables and boundary control systems in terms of physical elementary interface variables. One may not express the static equilibrium $\sigma_{|a,b}$(stress) in terms of $\frac{\partial u}{\partial z}$ without knowing $T(z)$.

Finally, we compare very briefly the port Hamiltonian formulation with a classical symplectic Hamiltonian formulation (see also [17]). Using the displacement $u(z,t)$ and the velocity $v(z,t) = \frac{\partial u}{\partial t}$ as state variables, one obtains the following infinite-dimensional Hamiltonian system (with energy flows being zero at the boundary):

$$\frac{\partial x}{\partial t} = \begin{pmatrix} 0 & \frac{1}{\mu} \\ -\frac{1}{\mu} & 0 \end{pmatrix} \begin{pmatrix} \frac{\delta H}{\delta u} \\ \frac{\delta H}{\delta v} \end{pmatrix} = \begin{pmatrix} 0 & \frac{1}{\mu} \\ -\frac{1}{\mu} & 0 \end{pmatrix} \begin{pmatrix} -\frac{\partial}{\partial z}\left(T\ \frac{\partial u}{\partial z}\right) \\ \mu v \end{pmatrix}, \tag{2.18}$$

where the Hamiltonian function is

$$H(u,v) = \int_a^b \left(\frac{1}{2}\ T\ \left(\frac{\partial u}{\partial z}\right)^2 + \frac{1}{2}\ \mu v^2 \right) dz. \tag{2.19}$$

Contrary to the port Hamiltonian formulation, this formulation does not make the physical structure of conservation laws appear. One may furthermore note that the Hamiltonian system is defined with respect to a *symplectic* Poisson bracket. This bracket is not canonical (it depends on the mass distribution of the string) and cannot be extended in a canonical way to a Dirac structure including boundary variables.

This example has shown that the Stokes–Dirac structure $\mathcal{D}_1$, associated with the canonical interdomain coupling, is derived from a skew-symmetric differential operator of order one. In section 3, we consider a generalization of this differential operator by considering skew-symmetric operators of any order and we derive Dirac structures on Hilbert spaces from them. In Example 2.2, we have also seen how the dynamics can be defined by using the canonical Dirac structure and the Hamiltonian; namely, the dynamics lives on the Dirac structure $\mathcal{D}_1$ and the total energy is defined by a Hamiltonian function. In section 4, we consider energy functions which are equal to the norm of the Hilbert space. Hence there the coenergy variables and the state variables are identical. We show how to parameterize the contractive semigroups associated with the Dirac structures defined in section 3. In section 5, finally, we distinguish between the state and the coenergy variables by introducing more general Hamiltonian functions and define port Hamiltonian systems associated with skew-symmetric differential operators of any order.

3. Dirac structure associated with a skew-symmetric operator. In this section, we extend the definition of Stokes–Dirac structures to skew-symmetric differential operators of any order. Therefore, we first recall how one may extend the Stokes theorem to such operators and how the Stokes theorem induces a symmetric pairing on the boundary variables. Second, we define boundary port variables as a linear combination of the boundary variables associated with the differential operator. Using these boundary port variables, we define a bond space and a Dirac structure associated with the differential operator.

Consider the differential operator $\mathcal{J}$ of order N

$$\mathcal{J}e = \sum_{i=0}^{N} P(i) \frac{d^i e}{dz^i}(z), \quad z \in [a,b], \tag{3.1}$$

where $e \in C^\infty((a,b);\mathbb{R}^n)$ and $P(i)$, $i = 0,\dots,N$, is an $n \times n$ real matrix. The formal adjoint $\mathcal{J}^*$ of $\mathcal{J}$ is given by

$$\mathcal{J}^* e = \sum_{i=0}^{N} P(i)^T (-1)^i \frac{d^i e}{dz^i}(z), \quad z \in [a,b].$$

Now assume that $\mathcal{J}$ is skew-symmetric, i.e., $\mathcal{J} = -\mathcal{J}^*$. From the above expression of $\mathcal{J}^*$ we see that this is equivalent to

$$P(i) = P(i)^T (-1)^{i+1}. \tag{3.2}$$

Using this property, we show that the bilinear symmetric pairing of e and $\mathcal{J}e$ depends only on the boundary values. Thus if the boundary values are zero, then $\langle e_1, \mathcal{J}e_2\rangle + \langle e_2, \mathcal{J}e_1\rangle = 0$, which corresponds to the fact that $\mathcal{J}$ is (formally) skew-symmetric.

THEOREM 3.1. *Let $\mathcal{J}$ be a skew-symmetric operator defined by* (3.1)*, and let $H^N((a,b);\mathbb{R}^n)$ denote the Sobolev space of N times differentiable functions on the interval (a,b). Then for any two functions $e_i \in H^N((a,b);\mathbb{R}^n)$, $i \in \{1,2\}$, we have that*

$$\begin{aligned} &\int_a^b e_1^T(z)(\mathcal{J}e_2)(z) + e_2^T(z)(\mathcal{J}e_1)(z)dz \\ &\quad = \left[\left(e_1^T(z), \dots, \frac{d^{N-1}e_1^T}{dz^{N-1}}(z) \right) Q \begin{pmatrix} e_2(z) \\ \vdots \\ \frac{d^{N-1}e_2}{dz^{N-1}}(z) \end{pmatrix} \right]_a^b, \end{aligned} \tag{3.3}$$

where

$$Q = (Q_{ij}), \qquad i,j = 1,\dots,N,$$

with

$$Q_{ij} = \begin{cases} 0, & i+j > N+1, \\ P(k)(-1)^{i-1}, & i+j-1 = k. \end{cases} \tag{3.4}$$

Furthermore, Q is a symmetric matrix.

Proof. The result can easily be derived from iterative integration by parts; see [10] for details. □

The above theorem shows that any skew-symmetric differential operator $\mathcal{J}$ gives rise to a symmetric bilinear product on the space of boundary conditions $e(a),\dots,\frac{d^{N-1}e}{dz^{N-1}}(a)$, $e(b),\dots,\frac{d^{N-1}e}{dz^{N-1}}(b)$. The coefficients of this symmetric product, captured in the matrix Q, are uniquely defined by the coefficients of the skew-symmetric differential operator $\mathcal{J}$. In what follows, we shall define port boundary variables and a bond space in such a way that the Stokes theorem applied to the differential operator may be expressed using the canonical symmetric pairing defined in (2.1). Therefore, let us focus, in a first step, on the properties of Q and define the matrix R_{ext} which is used for defining the port variables. First of all, note that Q has the following form:

$$Q = \begin{pmatrix} P(1) & P(2) & P(3) & \cdots & P(N-1) & P(N) \\ -P(2) & -P(3) & -P(4) & \cdots & -P(N) & 0 \\ P(3) & P(4) & \iddots & \iddots & 0 & 0 \\ -P(4) & \iddots & \iddots & \iddots & & \vdots \\ \vdots & \iddots & & & & \vdots \\ (-1)^{N-1}P(N) & 0 & \cdots & \cdots & \cdots & 0 \end{pmatrix}. \tag{3.5}$$

From the form of Q, the proof of the following lemma is immediate.

LEMMA 3.2. *The matrix Q introduced in Theorem* 3.1 *is symmetric and*

$$\ker Q = \{0\}$$

if and only if $\ker P(N) = \{0\}$.

From now on we assume that Q is nonsingular.

DEFINITION 3.3. *The matrix Q_{ext} in $\mathbb{R}^{2nN\times 2nN}$ associated with the differential operator $\mathcal{J}$ is defined by*

$$Q_{\text{ext}} = \begin{pmatrix} Q & 0 \\ 0 & -Q \end{pmatrix}. \tag{3.6}$$

Looking at (3.1), one can easily see that it is necessary to proceed to an appropriate change of variables to make this relation equivalent to the desired canonical symmetrical pairing defined in (2.1). This change of variables is done using the matrix R_{ext} detailed in Lemma 3.4.

LEMMA 3.4. *The matrix R_{ext} defined as*

$$R_{\text{ext}} = \frac{1}{\sqrt{2}} \begin{pmatrix} Q & -Q \\ I & I \end{pmatrix} \tag{3.7}$$

is invertible and satisfies

$$\begin{pmatrix} Q & 0 \\ 0 & -Q \end{pmatrix} = R_{\text{ext}}^T \Sigma R_{\text{ext}}, \tag{3.8}$$

where

$$\Sigma = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}. \tag{3.9}$$

All possible matrices R which satisfy (3.8) *are given by the formula*

$$R = U R_{\text{ext}}$$

with U satisfying $U^T \Sigma U = \Sigma$.

Proof. We have that

$$\frac{1}{\sqrt{2}} \begin{pmatrix} Q & I \\ -Q & I \end{pmatrix} \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix} \begin{pmatrix} Q & -Q \\ I & I \end{pmatrix} \frac{1}{\sqrt{2}} = \begin{pmatrix} Q & 0 \\ 0 & -Q \end{pmatrix}.$$

Thus using the fact that Q is symmetric $R_{\text{ext}} := \frac{1}{\sqrt{2}} \left(\begin{smallmatrix} Q & -Q \\ I & I \end{smallmatrix}\right)$ satisfies (3.8). Since Q is invertible, the invertibility of R_{ext} follows from (3.8).

Let W be another solution of (3.8). Hence

$$W^T \Sigma W = \begin{pmatrix} Q & 0 \\ 0 & -Q \end{pmatrix} = R_{\text{ext}}^T \Sigma R_{\text{ext}}.$$

This can be written in the equivalent form

$$R_{\text{ext}}^{-T} W^T \Sigma W R_{\text{ext}}^{-1} = \Sigma.$$

Calling $W R_{\text{ext}}^{-1} = U$, we have that $U^T \Sigma U = \Sigma$ and $W = U R_{\text{ext}}$, which proves the assertion. ∎

The crucial step in defining the Dirac structure associated with the operator $\mathcal{J}$ is to define the boundary port variables. These are the following linear combinations of the boundary conditions.

DEFINITION 3.5. *The boundary port variables associated with the differential operator $\mathcal{J}$ are the vectors $e_\partial, f_\partial \in \mathbb{R}^{nN}$ defined by*

$$\begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = R_{\text{ext}} \begin{pmatrix} e(b) \\ \vdots \\ \frac{d^{N-1}e}{dz^{N-1}}(b) \\ e(a) \\ \vdots \\ \frac{d^{N-1}e}{dz^{N-1}}(a) \end{pmatrix}, \tag{3.10}$$

where R_{ext} is defined by (3.7).

Consider the effort and flow spaces $\mathcal{E} = \mathcal{F} = L^2((a,b);\mathbb{R}^n) \times \mathbb{R}^{nN}$ with their natural inner product. We define the bond space $\mathcal{B}$ as $\mathcal{F} \times \mathcal{E}$ with the canonical symmetrical pairing

$$\begin{aligned} &\left\langle \left(f^1, f^1_\partial, e^1, e^1_\partial\right), \left(f^2, f^2_\partial, e^2, e^2_\partial\right) \right\rangle_+ \\ &\quad = \langle e^1, f^2 \rangle_{L^2} + \langle e^2, f^1 \rangle_{L^2} - \langle e^1_\partial, f^2_\partial \rangle - \langle e^2_\partial, f^1_\partial \rangle, \end{aligned} \tag{3.11}$$

where

$$(f^i, f^i_\partial, e^i, e^i_\partial) \in \mathcal{B}, \qquad i = \{1, 2\}.$$

Let us emphasize that this pairing on the bond space corresponds to the general definition given in (2.1), where the pairing on the bond space is defined modulo an isometry $r_{\mathcal{F},\mathcal{E}}$. The space of flow variables is the product space $\mathcal{F} = L^2((a,b);\mathbb{R}^n) \times \mathbb{R}^N$. Thus every flow element is a pair with the top element a function, and the bottom element is a part of the (boundary) port variable. The same description holds for the space of effort variables. The spaces $\mathcal{F}$ and $\mathcal{E}$ are equal and the natural isometry would be the identity. However, we choose

$$r_{\mathcal{F},\mathcal{E}} = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.$$

It is easy to see that this is an isometry, which is equal to its own inverse. Furthermore, with this choice (2.1) equals (3.11).

On the bond space $\mathcal{B}$ with the symmetrical pairing (3.11) we define the Dirac structure, $\mathcal{D}_\mathcal{J}$, associated with the linear skew symmetric operator $\mathcal{J}$.

This Dirac structure is nothing else but the expression of the Stokes theorem (recalled in Theorem 3.1) with respect to the port variables defined in Definition 3.5.

THEOREM 3.6. *Let $H^N((a,b);\mathbb{R}^n)$ denote the Sobolev space of N times differentiable functions on the interval (a,b). The subspace $\mathcal{D}_\mathcal{J}$ of $\mathcal{B}$ defined as*

$$\mathcal{D}_\mathcal{J} = \left\{ \begin{pmatrix} f \\ f_\partial \\ e \\ e_\partial \end{pmatrix} \;\middle|\; e \in H^N((a,b);\mathbb{R}^n), \mathcal{J}e = f, \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} = R_{\text{ext}} \begin{pmatrix} e(b) \\ \vdots \\ \frac{d^{N-1}e}{dz^{N-1}}(b) \\ e(a) \\ \vdots \\ \frac{d^{N-1}e}{dz^{N-1}}(a) \end{pmatrix} \right\} \tag{3.12}$$

is a Dirac structure.

Proof. The Dirac structure is defined by the fact that $\mathcal{D}_{\mathcal{J}} = \mathcal{D}_{\mathcal{J}}^{\perp}$.

Step 1. Recall that $\mathcal{D}_{\mathcal{J}} \subset \mathcal{D}_{\mathcal{J}}^{\perp}$ is equivalent to the canonical product $\langle b, b\rangle_+$ being zero for all $b \in \mathcal{D}_{\mathcal{J}}$. From (3.11) we have that

$$\begin{aligned}
&\langle (f, f_\partial, e, e_\partial,), (f, f_\partial, e, e_\partial)\rangle_+ \\
&\quad = \langle e, \mathcal{J}e\rangle_{L^2} + \langle e, \mathcal{J}e\rangle_{L^2} - e_\partial^T f_\partial - e_\partial^T f_\partial \\
&\quad = \left[\left(e^T(z), \dots, \frac{d^{N-1}e^T}{dz^{N-1}}(z) \right) Q \begin{pmatrix} e(z) \\ \vdots \\ \frac{d^{N-1}e}{dz^{N-1}}(z) \end{pmatrix} \right]_a^b - 2e_\partial^T f_\partial \\
&\quad = \left(e^T(b), \dots, \frac{d^{N-1}e^T}{dz^{N-1}}(a) \right) \begin{pmatrix} Q & 0 \\ 0 & -Q \end{pmatrix} \begin{pmatrix} e(b) \\ \vdots \\ \frac{d^{N-1}e}{dz^{N-1}}(a) \end{pmatrix} - 2e_\partial^T f_\partial \\
&\quad = \left(f_\partial^T, e_\partial^T \right) \Sigma \begin{pmatrix} f_\partial \\ e_\partial \end{pmatrix} - 2e_\partial^T f_\partial = 0,
\end{aligned}$$

where we have used Theorem 3.1 and (3.8).

Step 2. Let $(\phi, \phi_\partial, \varepsilon, \varepsilon_\partial) \in \mathcal{D}_{\mathcal{J}}^{\perp}$. Choose $e \in H^N((a,b); \mathbb{R}^n)$ with compact support strictly included in (a,b). Thus $\frac{d^k e}{dz^k}$, $k \in \{0, \dots, N-1\}$, are zero in a and b. Then it is easy to see that $(\mathcal{J}e, 0, e, 0) \in \mathcal{D}_{\mathcal{J}}$. Using (3.11) we have

$$0 = \langle e, \phi\rangle + \langle \varepsilon, f\rangle = \langle e, \phi\rangle + \langle \varepsilon, \mathcal{J}e\rangle$$

for all such e. This implies that $\varepsilon \in H^N((a,b); \mathbb{R}^n)$ and $\mathcal{J}\varepsilon = \phi$.

Step 3. Let $(\phi, \phi_\partial, \varepsilon, \varepsilon_\partial) \in \mathcal{D}_{\mathcal{J}}^{\perp}$ and let $(f, f_\partial, e, e_\partial) \in \mathcal{D}_{\mathcal{J}}$. From Step 2 and (3.11) we obtain

$$\begin{aligned}
0 &= \langle e, \mathcal{J}\varepsilon\rangle + \langle \varepsilon, \mathcal{J}e\rangle - e_\partial^T \phi_\partial - \varepsilon_\partial^T f_\partial \\
&= \left[\left(e^T(z), \dots, \frac{d^{N-1}e^T(z)}{dz^{N-1}}(z) \right) Q \begin{pmatrix} \varepsilon(z) \\ \vdots \\ \frac{d^{N-1}\varepsilon(z)}{dz^{N-1}}(z) \end{pmatrix} \right]_a^b - e_\partial^T \phi_\partial - \varepsilon_\partial^T f_\partial \\
&= \left(f_\partial^T, e_\partial^T \right) \Sigma R_{\text{ext}} \begin{pmatrix} \varepsilon(b) \\ \vdots \\ \frac{d^{N-1}\varepsilon}{dz^{N-1}}(a) \end{pmatrix} - e_\partial^T \phi_\partial - \varepsilon_\partial^T f_\partial \\
&= \left(e_\partial^T, f_\partial^T \right) \left[R_{\text{ext}} \begin{pmatrix} \varepsilon(b) \\ \vdots \\ \frac{d^{N-1}\varepsilon}{dz^{N-1}}(a) \end{pmatrix} - \begin{pmatrix} \phi_\partial \\ \varepsilon_\partial \end{pmatrix} \right].
\end{aligned}$$

By a proper choice of e, we can let the vectors e_∂ and f_∂ have arbitrary values. Thus the above equality has to hold for all $e_\partial \in \mathbb{R}^{nN}$ and $f_\partial \in \mathbb{R}^{nN}$. Consequently, we have that

$$R_{\text{ext}} \begin{pmatrix} \varepsilon(b) \\ \vdots \\ \frac{d^{N-1}\varepsilon}{dz^{N-1}}(a) \end{pmatrix} = \begin{pmatrix} \phi_\partial \\ \varepsilon_\partial \end{pmatrix}.$$

In conclusion, we have that $\mathcal{D}_{\mathcal{J}} = \mathcal{D}_{\mathcal{J}}^{\perp}$, and so $\mathcal{D}_{\mathcal{J}}$ is a Dirac structure. ∎
